What is Disguise?

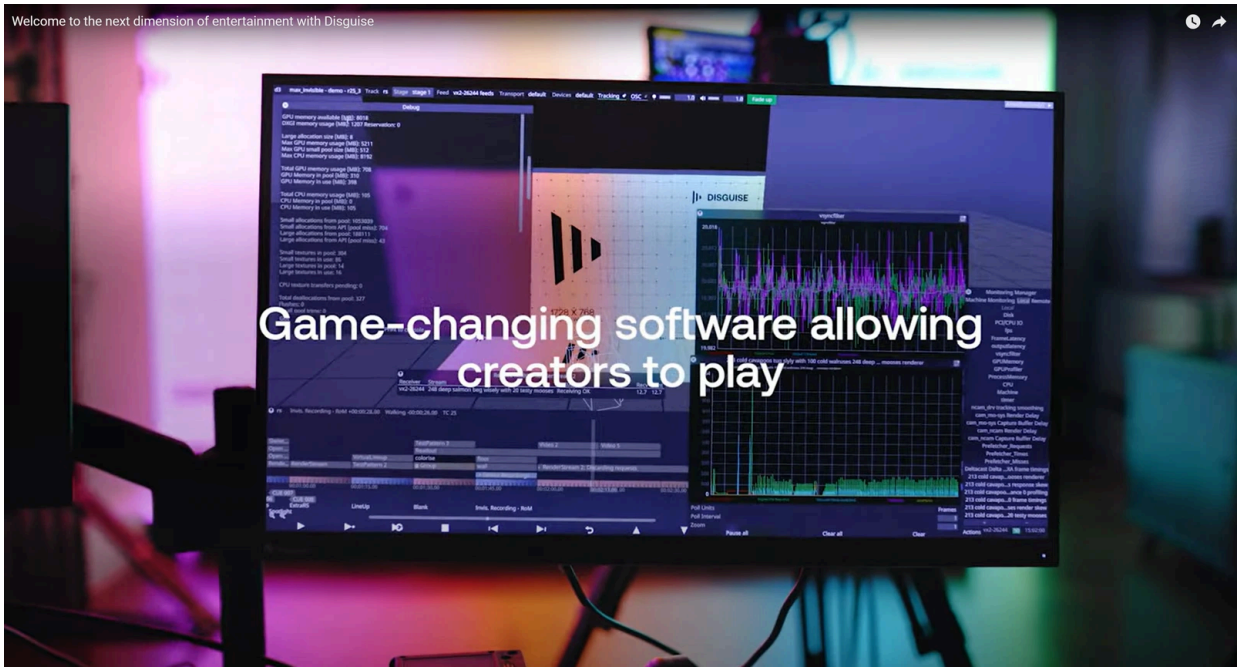
Disguise is the industry-leading platform at the heart of the new era of visual experiences. One powerful integrated system of software, hardware and cloud tools to power real-time or pre-rendered video content playback at scale.

We partner with the biggest entertainment brands and companies in the world to deliver the A-list of live music events, live TV broadcasts, location-based immersive experiences, installations, theatre, film and TV production, corporate keynotes and brand product launches.

We work hand-in-hand with our partners and offer a 24/7 global support system that ranges from essential technical service and online learning to innovative creative consultancy. From Disney to Snapchat, from Netflix to ESPN, from the Las Vegas Sphere to the Burj Khalifa, and from U2 to Beyonce, Disguise is the number one partner for the next dimension of entertainment.

For more information about our products, solutions, and services, please visit https://disguise.one.

Disguise 2024 Showcase



Watch on YouTube

Welcome to the new Help site!

Why change platform?

The user guide has been in action since 2017. While it has supported our users and internal teams for those 7 years, we are aware that some content has been inconsistent, inaccurate, out of date, or missing. With our legacy platform, the size of the team working on our publicly accessible technical documentation is small, and collaboration tools are limited.

At Disguise, we innovate rapidly and we need our documentation to reflect those changes and support our users.

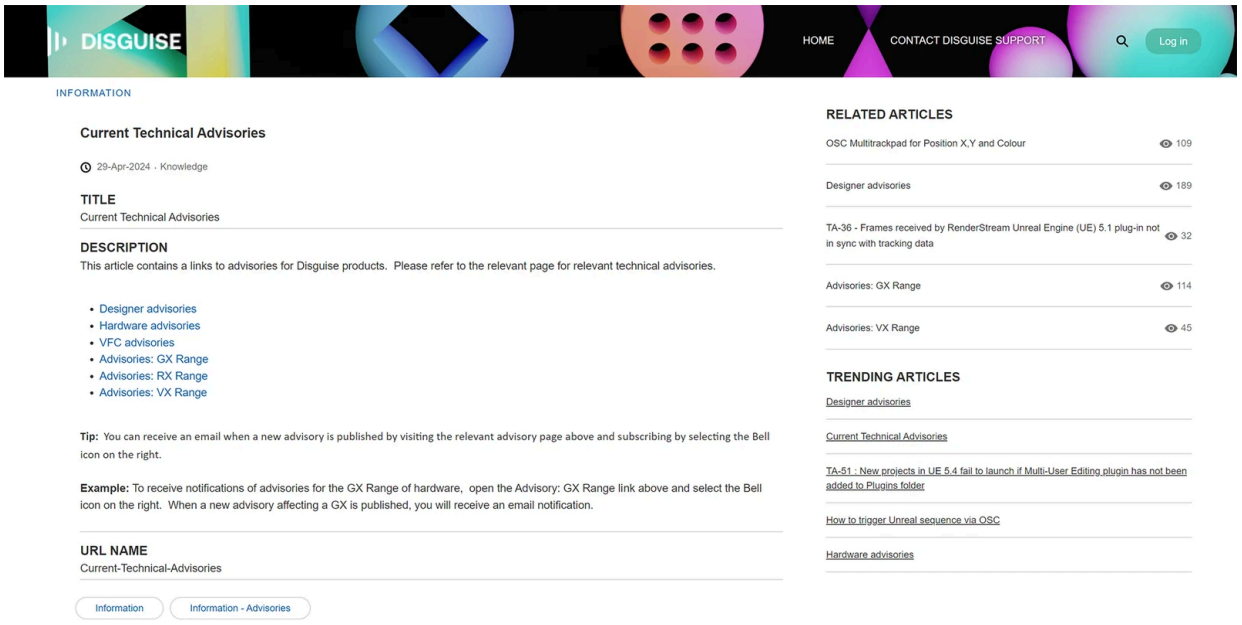
What's different?

The new site has been built using an open-source framework called Starlight and is source controlled in GitHub. Starlight is a documentation website framework for Astro which is a framework for generating web applications that can be extended with popular UI frameworks.

Our internal teams can all submit changes by adding a new branch, and then creating a pull request in GitHub. Pull requests require reviewers to approve changes before being merged into the main branch of the repository. Automatic deployment is triggered when new content is pushed to, or merged with, the main production branch. Once the production branch is built, all content is published to the live site.

The new process is faster and allows us to empower our experts across Disguise to collaborate on documentation by either writing, reviewing, or approving new content.

Technical Advisories Overview



Technical Advisories can now be found in the **Support portal** where you will be able to filter the advisories by category and be notified when a new advisory is added to a specific category such as a server range, or Designer version. To receive notifications, log in and select the Bell icon on the right.

Cloud Dashboard

Cloud Dashboard is a centralised management tool that enables users to launch Drive, Previz, and Mapping Matter on the Cloud platform. With Cloud Dashboard, you can manage your organisation and administer your team. You can also access your account to update your profile and customise your preferences.

Subscriptions

Cloud subscriptions

The following Cloud software are available for subscription:

- Starter
- Pro
- Studio

Learn more about Cloud subscriptions **here**.

Designer Pro subscriptions

Designer is available through Cloud where you can:

- Subscribe to Designer Pro - Select whether you want monthly or licenses. You can also adjust the quantity of licenses required.
- Manage your Designer Pro subscription.
- View the Designer release notes and download the Full installer.

Learn more about Designer Pro here.

Software Downloads

Designer Starter downloads

Designer is available through Cloud where you can:

- View the Designer release notes and download the Designer Starter installer.
- Log in to Disguise Cloud to authenticate your license using d3Manager.
- Upgrade to a Designer Pro subscription.
- Download previous versions of Designer.

Getting Started

Create a Disguise Cloud account

To sign up for Disguise cloud, you can create an account on the **Disguise cloud website**. It is free to sign up, no credit card is required. Please note that we recommend using a Chrome Browser to access Disguise Cloud.

Sign up with Google

1. Go to the Disguise Cloud account creation page, **https://disguise.cloud/signup**.

2. Click on the **Sign in with Google** button.
3. Confirm your Google email credentials.

Join with email

1. Go to the Disguise Cloud account creation page, **https://disguise.cloud/signup**.
2. Click on the **Join with email button**.
3. Confirm your email credentials.

Sign in

1. Go to the Disguise Cloud website, **https://disguise.cloud**.
2. Confirm your Google email credentials.

Sign out

1. Click on your profile avatar image.
2. Click **Sign Out**.

Edit your account details

1. To find your account details, select your Disguise Cloud avatar photo.
2. From the pop-up menu, click on your email address.
3. On the **Your Account** page, on the **General** tab, you can update your name, avatar photo, and light or dark mode application preference.
4. Click **Update**, edit the field that you wish to change, and then click **Save**.

Follow the links to learn more about Organisations and Domain Capture.

Cloud Troubleshooting

Disguise Cloud has some known issues that we are working hard to fix.

The sign in button has stopped working when the browser was closed during sign-up.

If this happens:

1. Restart your computer. Going offline and restarting will cause Designer to sign out of the cloud.
2. Sign back in once the computer has restarted and is connected to the internet.

”Get your D3 licence” message on D3 manager

This will be updated to “Get your Designer licence” in the next update. Designer and d3 have been used interchangeably by the Disguise Community. Designer is the formal name for our product.

Disguise Cloud avatar is cropped

This will be fixed in the next update.

Cloud login on Designer is not yet localised

Localisation is a key feature planned for a later release.

Create a support ticket from the Cloud Dashboard

1. To create a support ticket, click on your avatar photo.
2. From the pop-up menu, click on **Contact Support**.
3. Type your feedback into the input box and click on **Submit Feedback**.

If you are unable to log in or raise a ticket from Cloud Dashboard, please contact Cloud Support.

Domain Capture

Domain Capture lets users with the same email domain join your Disguise Cloud organisations. This feature allows users to join existing organisations rather than adding duplicate organisations for the same teams.

If your organisation has access to Drive, Previz and Mapping Matter, any users will also have access to these apps, along with the content files in Drive. This also includes Studio plan access to any shared groups in Mapping Matter, providing the same access to shared files and scenes.

Enabling Domain Capture

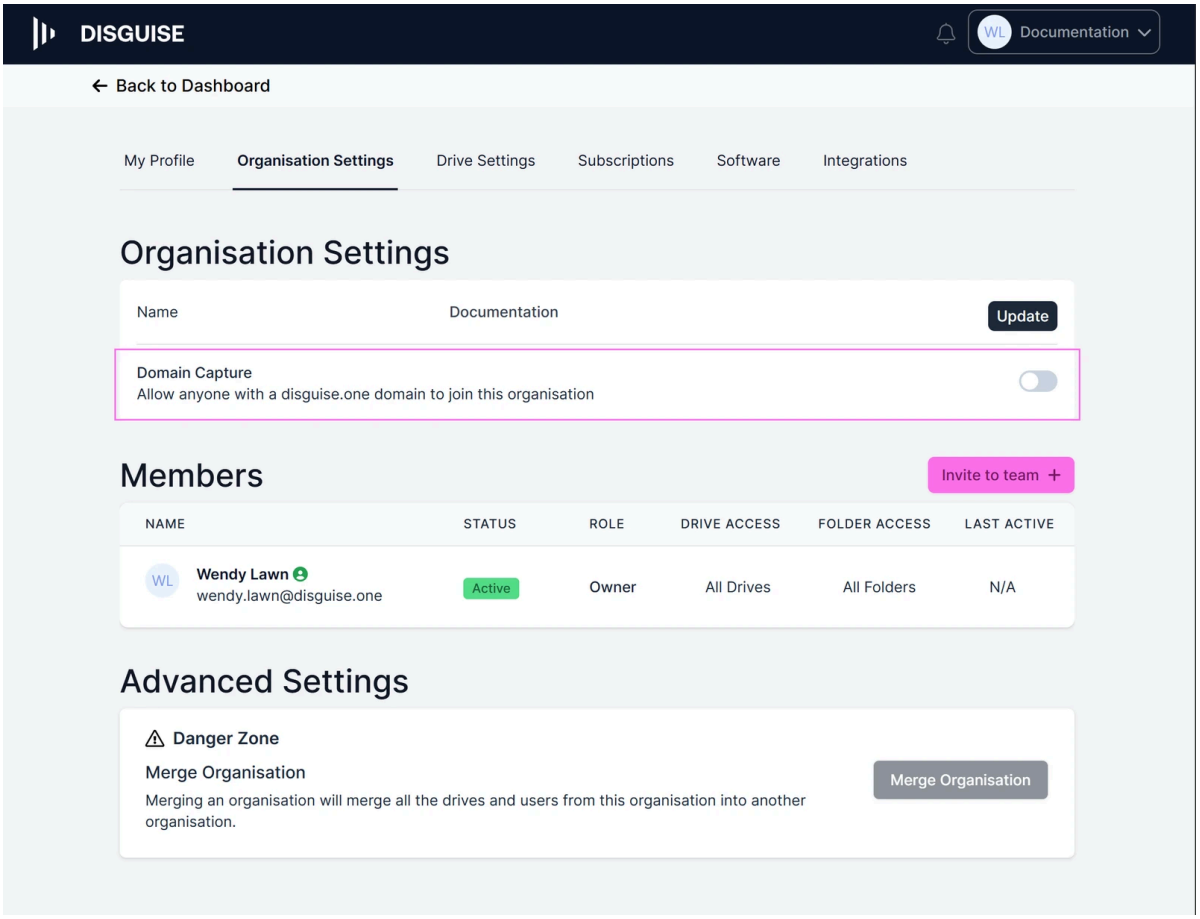
To enable Domain Capture, users must have an Admin or Owner role in an organisation and share the same email address domain. Please note that we are unable to support more widely shared email domain hosts such as Gmail, Outlook, and Hotmail. See **this link** for a list of commonly shared email domains that we are unable to support with Domain Capture.

If users do not share the same email domains, Admins will need to invite the member to join the organisation. See the Member Management page for more information.

When you create a new organisation, you have the option to **Allow anyone with @domain to join this Organisation**. Ensure toggle is enabled if you wish to allow users to join the organisation.

To enable Domain Capture in an existing organisation

1. Navigate to your **Profile Menu** (on the top right) > **Organisation Settings** and click to enable the toggle for **Domain Capture**.



2. Any members that have requested to join the organisation are listed in the Members section of Organisation Settings. The status for these members appears **Entitled**.
3. When an Admin enables Domain Capture, users with a matching email domain can request to join by navigating to **My Profile > Invitations**.
4. Admin/Owners can manually reject the user's request to join your organisation by clicking **Cancel**.

> **Note**
>
> The role that users are assigned is dependent on the type of Cloud plan subscribed to by the Admin of the Organisation.

Disabling Domain Capture

To disable Domain Capture, navigate to **Organisation Settings** and turn off the Domain Capture toggle. This will remove the list of eligible users. However, users who have already joined the organisation will remain members.

Join an existing organisation

Navigate to **My Profile > Invitations**.

Guest Accounts

The Guest Accounts feature in **Disguise Cloud** is designed to enable collaboration with a broader team within a structured and secure workspace. It provides sharing and interaction while maintaining control over access. Currently, guests using this feature do not have access to Previz or Mapping Matter.

When you send an invitation to a guest, it grants them access to a specific designated folder, inclusive of all its sub-folders, on a single Drive.

The Guest Accounts feature is a useful tool for inviting external team members to collaborate within a controlled workspace, ensuring that they can access the necessary content while keeping sensitive materials secure.

To invite a guest to collaborate

1. Navigate to **Organisation Settings** and click **Invite to Team.**
2. **Provide Guest Email:** Enter the email of the guest you wish to invite.
3. **Select Guest Role:** In the **Guest Role** section and choose the appropriate role for the guest based on the permissions they will need:
   - *Reviewer*: Reviewers can leave comments and view assets but cannot modify them.
   - *Collaborator*: Collaborators can upload new content and edit existing assets within their designated folder but cannot leave comments.
4. **Select Drive Folder:** Click **Select Drive Folder** to specify the Drive and folder that the guest will access.
5. **Confirm and Invite:** Click **Confirm** once you have entered the invitation details. Then, click **Invite** to send the invitation to the guest.
6. **Email Notification:** The guest will receive an email notification containing a link to the designated Drive folder, allowing them to access and collaborate within that folder.

For further role information, see Roles in an Organisation detailing permissions and limitations for guests, and other roles.

Roles in an Organisation

Organisation owners can assign roles to individuals and teams giving them different sets of permissions in the organisation.

The following roles exist in Disguise Cloud:

Admin

An Admin is the person who has administrator privileges in the Organisation or Drive. This means full drive access, and they can invite new users and manage content. They also have the power to manage user roles.

Owner

An Owner is the person who creates the Organisation or Drive. Owners are also able to manage Billing settings. Owners are Admins by default.

Member

A Member is part of an Organisation or Drive. A Member has access to Drive, and can upload and manage content.A

Billing

A Billing user is assigned to a user to enable them to manage billing, but have no other permissions. A Billing role does not count towards the seat count of a plan.

Reviewer (Guest)

A Reviewer role can be assigned by Admins when creating Guest Accounts. Learn more about Guest Accounts here.

Collaborators (Guest)

A Reviewer role can be assigned by Admins when creating Guest Accounts. Learn more about Guest Accounts here.

The permissions table below lists common actions and tasks performed in Disguise Cloud. The symbols indicate whether a person with that permission can (✔) or cannot (✘) perform the task.

Action/Role	Admin/Owner	Member	Billing	Reviewer (Guest)	Collaborator (Guest)
Create Organisations	✔	✘	✔	✘	✘
Invite people to join an Organisation	✔	✘	✔	✘	✘

Action/Role	Admin/Owner	Member	Billing	Reviewer (Guest)	Collaborator (Guest)

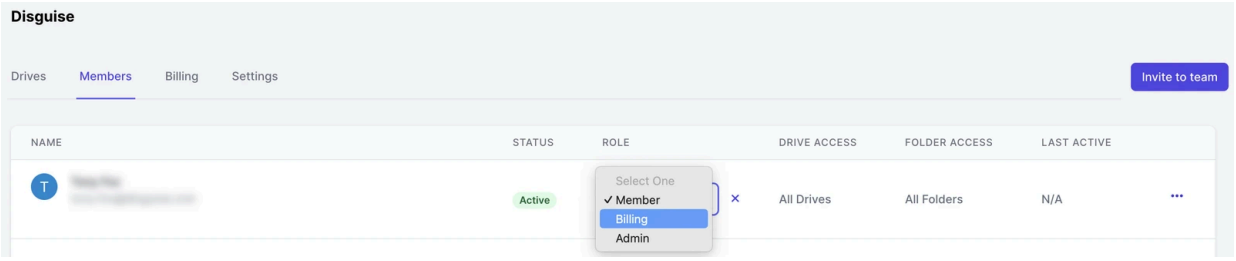
Admins can edit a member's role within the Organisation's settings under the Members section. This enables them to change a user's assigned role to either Member, Admin or Billing.



Organisation Settings

About Organisations

Disguise Cloud organisations bring together your company's users by having multiple accounts join the same organisation. This allows you to work together across multiple files and assets on collaborative projects. As an organisation Admin or Owner, you manage the Cloud accounts of your employees and the files that belong to your organisation.

You can invite others to join your organisation and assign them different roles, each providing varying levels of access and permissions. For more details, refer to Roles in an Organisation.

For more information on pricing please contact **Cloud Support**.

Create a new organisation

1. To create an organisation, navigate to the **Profile menu > Organisation Settings**.
2. Under **My Organisations**, click **Create an Organisation +**.
3. Under **Organisation Setup**, add the name of the organisation, toggle **Allow anyone at [*email domain*] to join**.
4. Select your Oganisation size and region.
5. Click **Create Organisation +**.

Invite a new member to an organisation

1. To access organisation management from the Dashboard, click on the **Management** button.
2. Click on the **Members** tab.
3. Click on the **Invite to Team** button.
4. Input the email address of the team member you want to add.
5. Select a Team Role for the new member by clicking on **Member** or **Administrator**.
6. Click on the Invite button.

> ⚠ **Caution**
>
> Cloud organisations cannot be deleted. However, they can be merged.

Merge organisations

> **Note**
>
> It is only possible to merge organisations if you have admin access to both organisations.
>
> Also, it is important to verify that the organisation you are merging into can support the changes. For example, if you're on Starter, you only get one drive, so you can't merge with another organisation.

1. Navigate to the **Profile menu > Organisaton Settings**.
2. Under **Advanced Settings**, Click on **Merge Organisation**.

Purchase a Cloud subscription

1. To purchase a Cloud subscription, left-click on your profile photo in the top right of the dashboard.
2. Select **Subscriptions**.
3. Select either Cloud Pro or Cloud Studio and click **Start 14 day trial**.
4. Add your payment details and click **Subscribe**.

You can view your active subscriptions on the **Subscriptions** page.

Purchase a Designer Pro subscription

To purchase a Designer Pro subscription, view this page.

Cancel a subscription

1. To cancel any subscription, ensure you are currently using the organisation associated with the subscription.
2. Navigate to **Subscriptions** in the profile menu in Cloud Dashboard.
3. Click **View**.
4. Click **Cancel**.

When you cancel a subscription, you will have a grace period until the next payment would normally be due. During this time, you are able to resume the subscription by clicking **Resume**.

Manage billing

1. To manage billing, navigate to the **Subscriptions** page in the profile menu.
2. Select the product you are subscribed to.
3. Click **Manage Billing**.

On this page you can:

- Click update your subscription to change your license quantity or billing plan.
- Use the edit icon to edit your payment method, or update your email and billing address.
- View your Invoice history. Your invoice will also be sent to the Admin/Owner's email address.

Order a Physical Dongle

The physical dongle is USB-based and can also host other supported licenses obtained from third parties such as Notch and TouchDesigner, as well as Designer. The USB Dongle can be purchased through the **Disguise Store**.

Using a dongle may be preferable if the license is to be shared in the same physical location.

Disguise USB Dongle

Follow the links to read more about Guest Accounts, Domain Capture, and Cloud Troubleshooting.

Cloud Overview

The Disguise Cloud platform is a collection of apps that are designed to empower and improve users' daily workflows with the Disguise platform. The focus of Disguise Cloud is to provide online-based interactions and experiences, with some additional offline features. Disguise Cloud is available for desktop and mobile.

Cloud Dashboard

Cloud Dashboard is a centralised management tool that enables users to launch Drive, Previz, and Mapping Matter on the Cloud platform. With Cloud Dashboard, you can manage your organisation and administer your team. You can also access your account to update your profile and customize your preferences.

Disguise Drive

Content teams involved in media and entertainment projects typically operate across various storage platforms. These solutions are not built specifically for complex, high-resolution projects and they don't acknowledge the modern way that studios and creatives are producing content. Disguise Drive allows users to upload and consolidate all of their project content in one simple online interface. A Drive is a place to collect and store content. Feel free to use it however best suits your setup. A Drive could be used for a project, a branch of your company or a location.

Previz

Previz empowers creative teams to publish and share 3D experiences and streamline the content review process. Users can preview 3D models from various perspectives with speed and ease. Designer users can share their creations to Previz, enabling collaboration and enhancing project efficiency. Sharing projects on Previz is straightforward, granting teams easy access to 3D visualisations for collaborative review. Previz supports 3D animations, cameras, and lighting, ensuring that your creative vision is accurately represented.

Collaboration is at the heart of Previz. Previz streamlines approval workflows for both internal teams and external clients, making the decision-making process more efficient and transparent. Discover how Previz can transform your creative projects here.

Mapping Matter

Mapping Matter is a simulation tool designed for audio visual professionals who need to create Video Projection Specs and recommendations for Large Scale Projects. It serves as a

comprehensive solution for confirming budget estimates, assessing luminance, pixel densities, and refining projector placements.

With the integration of Mapping Matter, Disguise Cloud is the only platform that offers interactive previsualisation and projection mapping tools directly in one web browser-based platform. Create large scale video projections in a simple 3D environment to plan everything you need before showtime. Learn more **here**.

Cloud APIs

Cloud APIs are documented on the Developer Portal. The Cloud API documentation walk you through the process of using the Cloud API to interact with your account, including your organisation, drives, and content.

These new APIs open up the possibilities to integrate applications that are part of your workflows with the Disguise Cloud ecosystem.

What can you do with the Content APIs?

- Manage Organisations and Drives:
  - Update your organisation properties.
  - Create, archive, and restore drives.
- Handle Assets and Folders:
  - View folder structure and download assets.
  - Upload assets and create folders.
  - Update, delete, and manage asset versions.

The APIs are divided into two categories:

- **Management API: Focused on managing organisations and drives.
- **Drive API**: Designed to handle assets and folders.

To learn more about our APIs and Integrations, go to **https://developer.disguise.one/cloud/**.

Creating a Previz

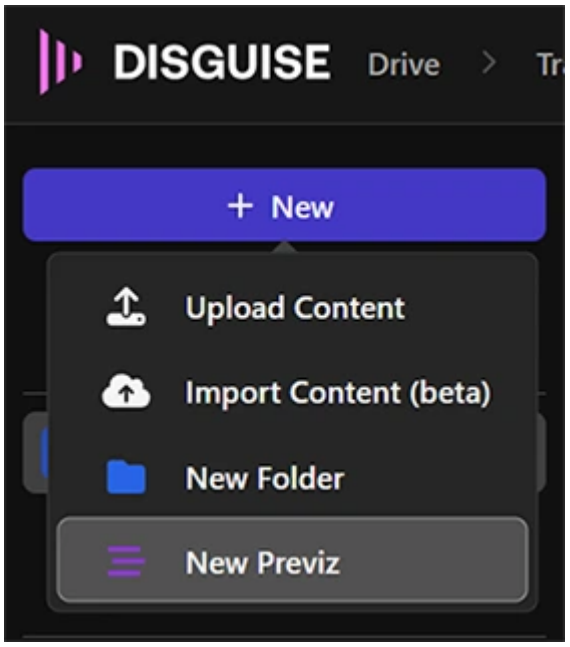
With Previz you can plan and preview your content in a real-time 3D environment.

Sequences in Previz can contain a range of different media including images, videos, 3d and scenes.

Create a new Previz

To create a new Previz:

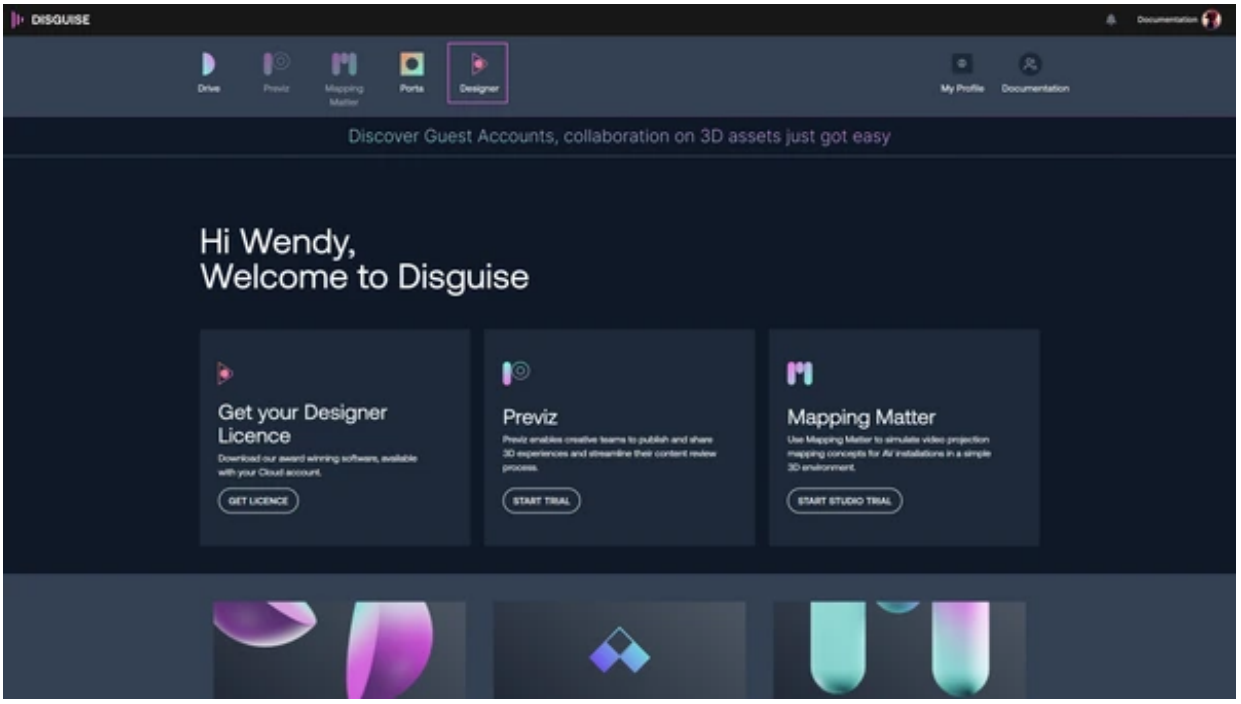
1. Select **New** from Drive.
2. Then select **New Previz** next to the team name in the team sidebar.
3. Enter the name for your new Previz.



Create a Previz

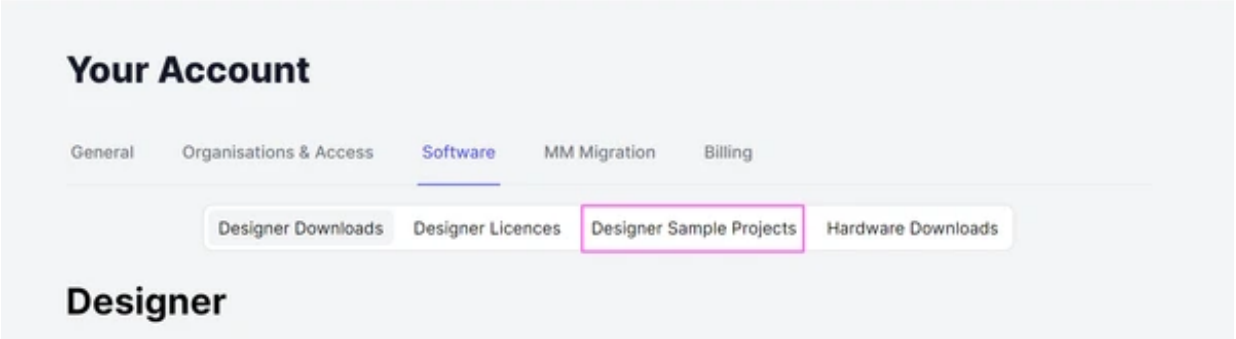
Designer Sample Projects

Designer Sample Projects are demo scenes created by Disguise ready for users to get started with Designer workflows. Covering each of the 7 industries Disguise operates in, these projects are available to download from Disguise Cloud.

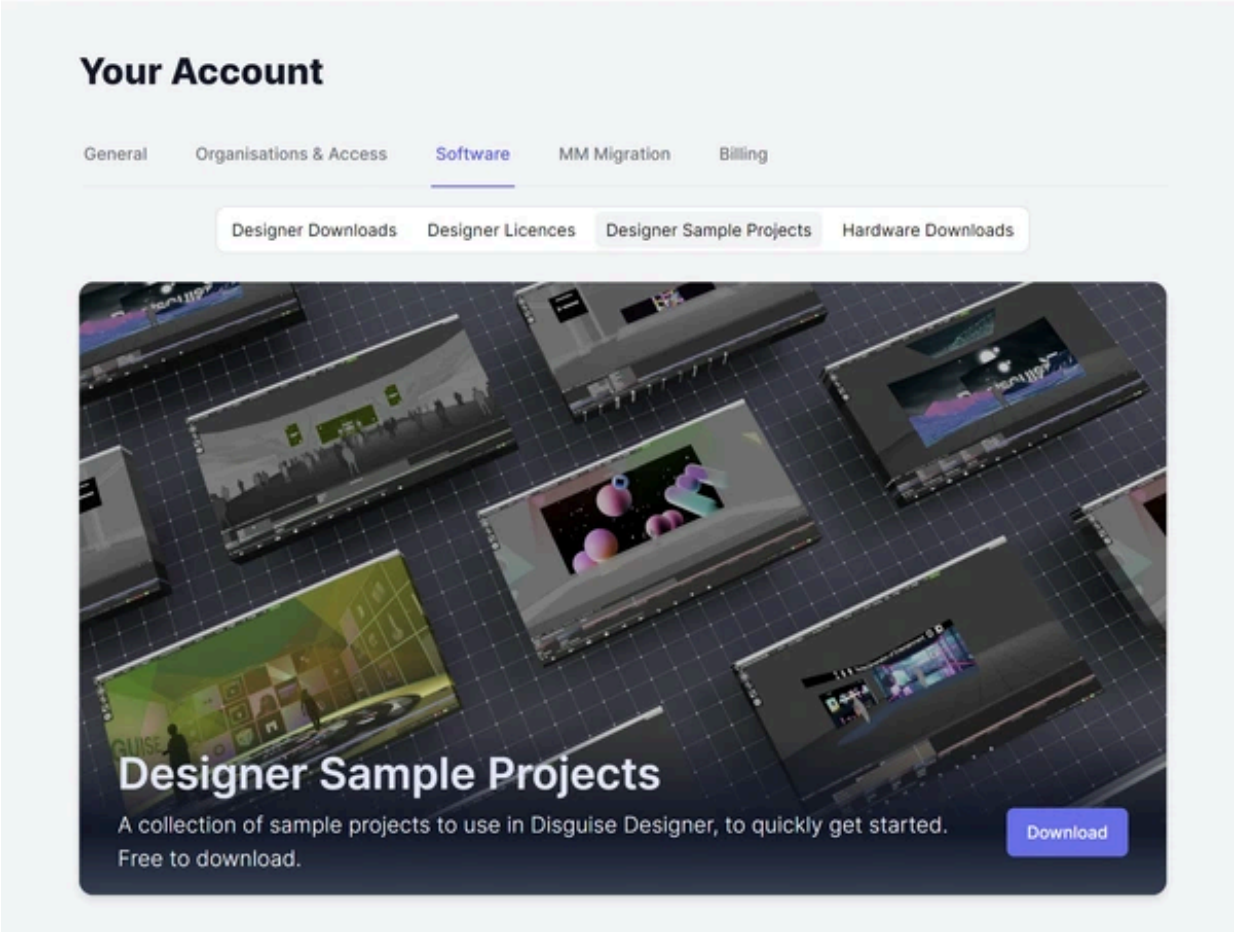


Downloading the Designer Sample Projects

1. Log in to your Disguise Cloud account.
2. In the Dashboard, click on **Designer**.
3. From the menu, select the **Designer Sample Projects** tab.
4. Click **View Content** to continue.
5. Click on the name or zip icon tile of a project.
6. Click on the **Download** button.



Select Designer Sample Projects

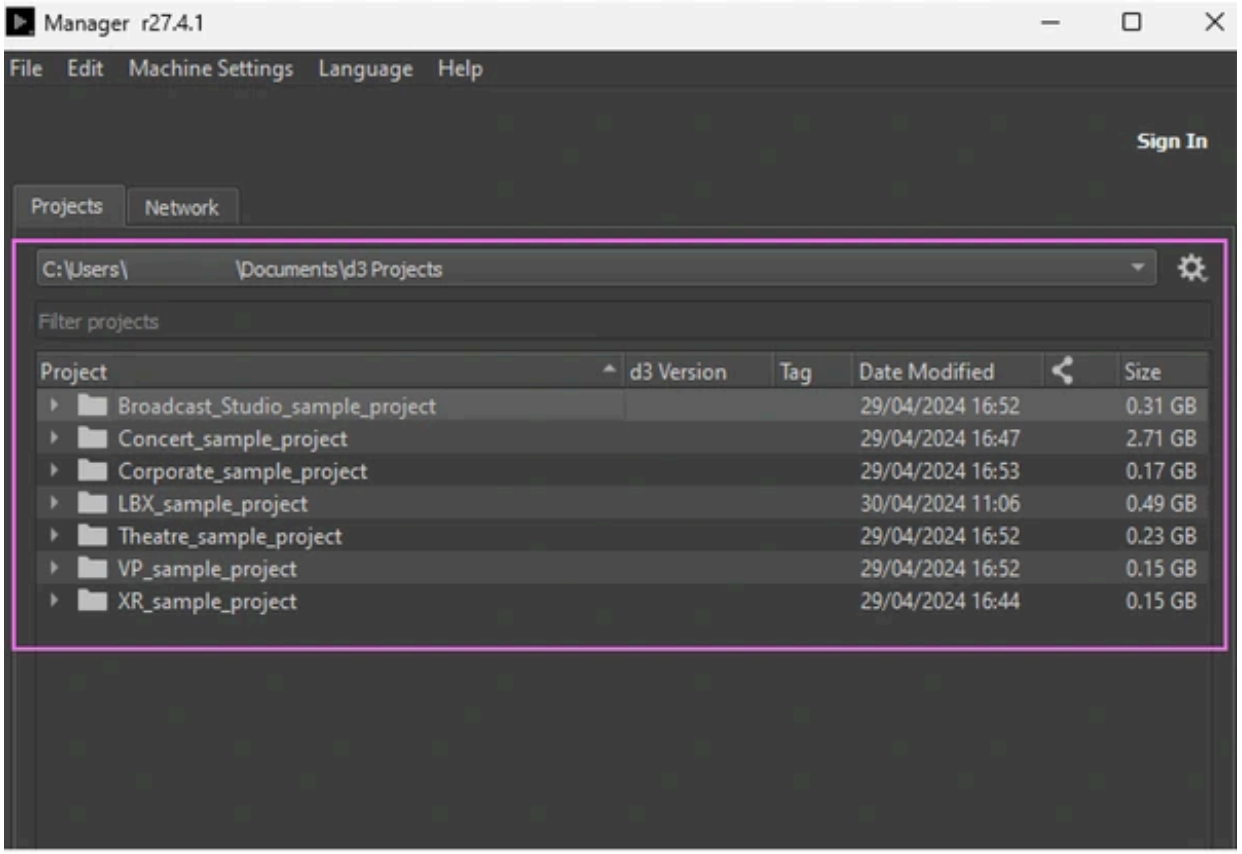


Download Sample projects

Installing the Designer Sample Projects

1. Once downloaded, extract each Designer Sample Project on your computer.

2. Add each of the Designer Sample Project folders to your d3 Projects folder. When you install Designer, the d3 Projects folder is automatically created in the default location: `C:\Users\[_username_]\Documents\d3 Projects`
3. Open **Manager** to view all the Designer Sample Projects.
4. Open the Sample Project in Designer by double-clicking on the project name.



Manager - sample projects

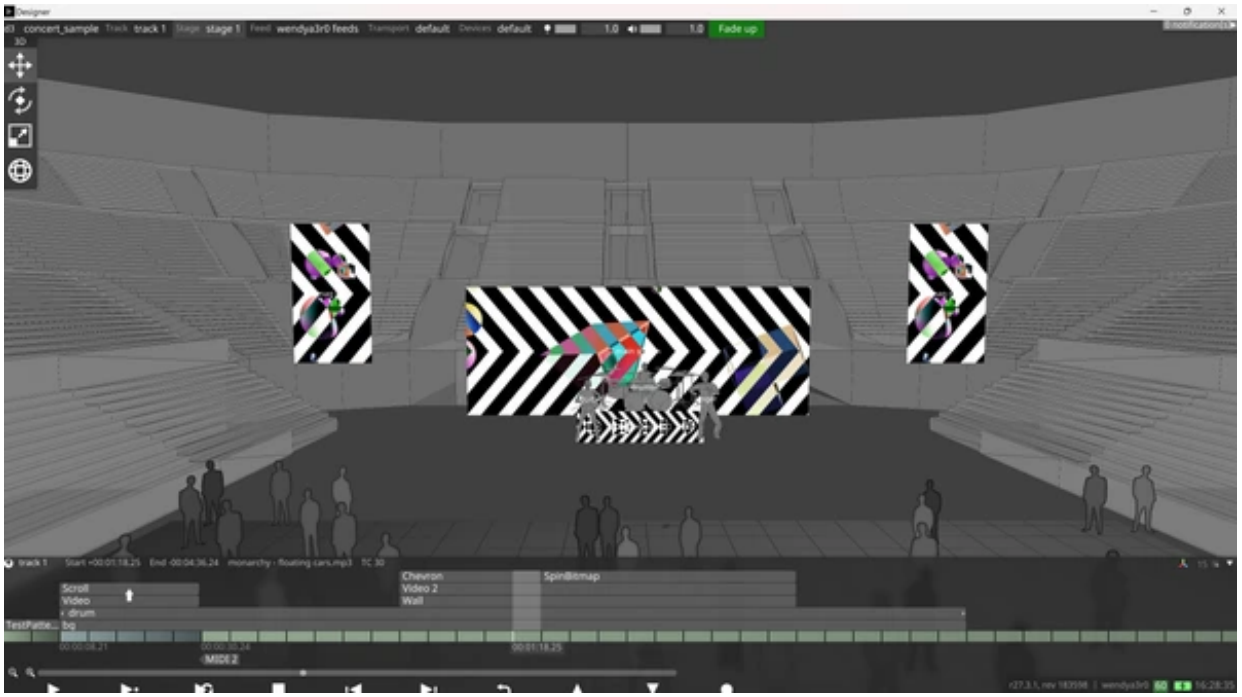
Live Concert Sample Project

Description

A concert venue with three screens placed behind a stage.

Demonstrates IMAG, live inputs, content slides in various aspect ratios, parallel mapping, Audio Quantizer, and matrix & MIDI device setup.

Concert_sample_project.zip Download link



Concert - sample project

Specs:

- Main screen: 2208 x 828px
- Drum riser: 736 x 184px
- Left and Right IMAG screens: 465 x 828px

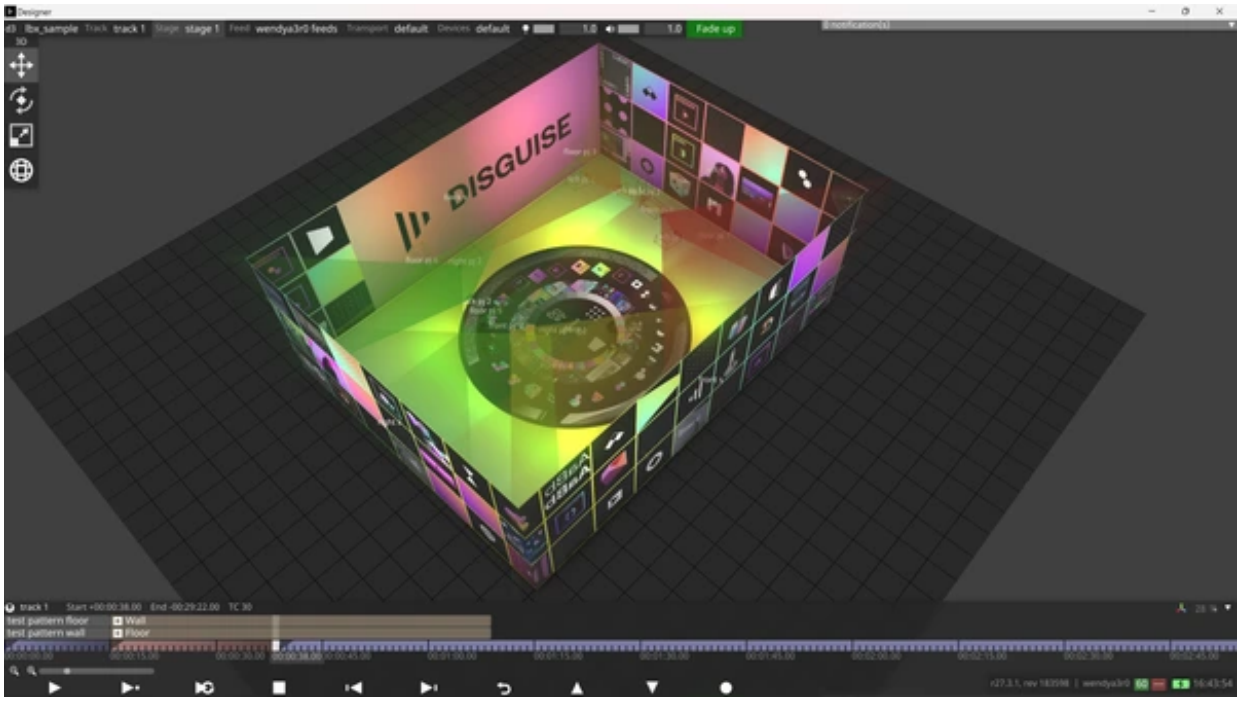
LBX Sample Project

Description

A 360° Immersive Room with projection surfaces on the walls and floor.

Demonstrates projection mapping, visualizer renderer in LUX mode, Omnical plan previsualization, dynamic blend, pixel-to-pixel mapping, and audio output patching.

LBX_sample_project.zip Download link



LBX - sample project

Specs:

- Left wall & Right wall: 2300px x 1024px
- Front wall & back wall: 2922px x 1024px
- Floor: 2922px x 2300px

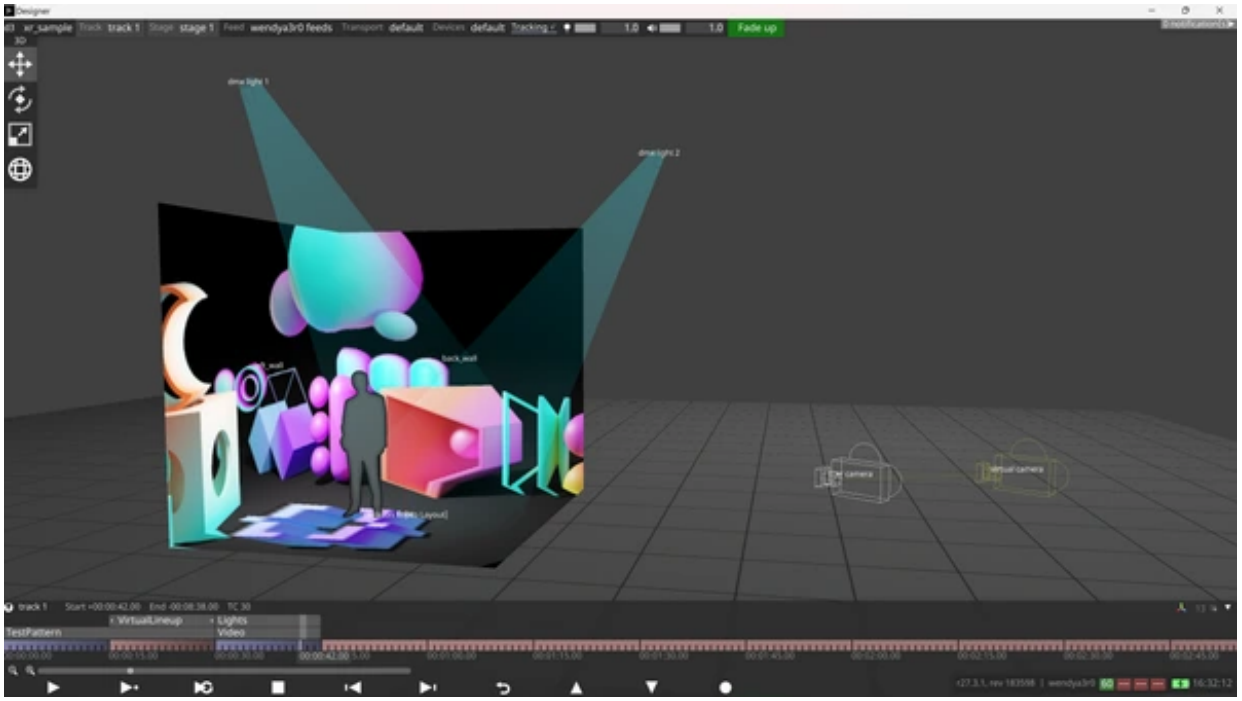
XR Cube Sample Project

Description

An extended reality volume, with three LED screens forming an “L” wall and floor stage.

Demonstrates a camera paired with a virtual camera. Includes provisions for camera tracking, matrix switching, and DMX lights control.

XR_sample_project.zip Download link



XR - sample project

Specs:

- Left wall: 1232 x 1232px
- Back wall: 1232 x 1232px
- Floor: 768 x 768px

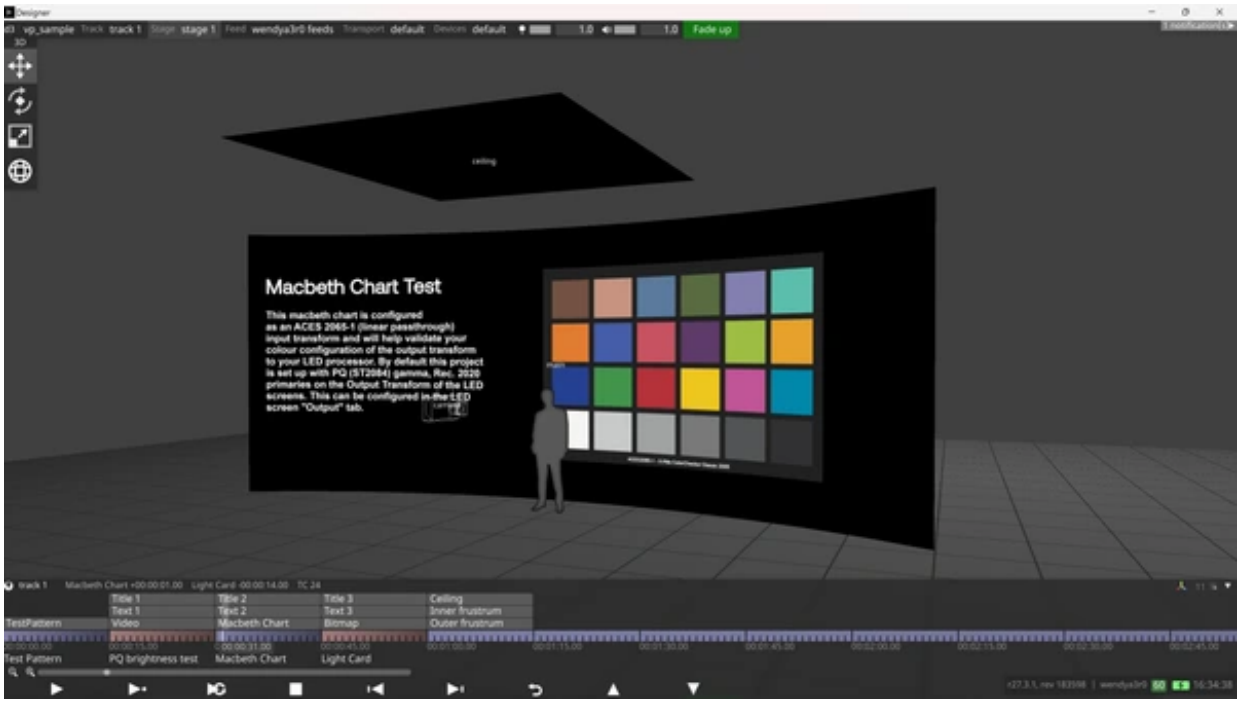
Virtual Production Sample Project

Description

A Virtual Production stage consisting of a curved LED screen and flat ceiling.

Demonstrates ACES colour profile, brightness test, Macbeth chart usage, Bitmap layer light cards for LED ceiling, camera frustum and out-of-frustum display, and shot recorder device.

VP_sample_project.zip Download link



VP - sample project

Specs:

- Main screen: 3840 x 1536px
- Ceiling: 1024 x 1024px

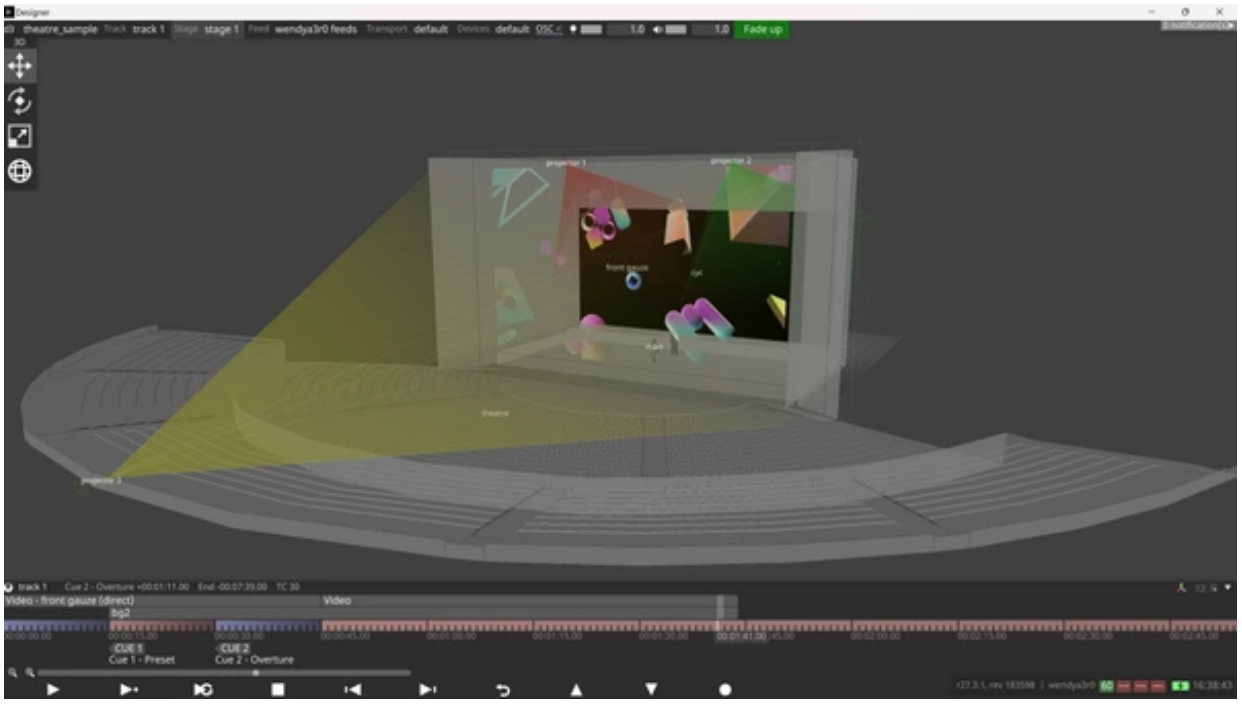
Theatre Sample Project

Description

A theatre stage with one projector for the front gauze and two for the rear screen.

Demonstrates projection mapping, matrices setup, OSC control, automation receiver, and simulation of gauze screen effects.

Theatre_sample_project.zip Download link



Theatre - sample project

Specs:

- Front Gauze: 1920 x 1080px
- Rear screen: 2400 x 1080px

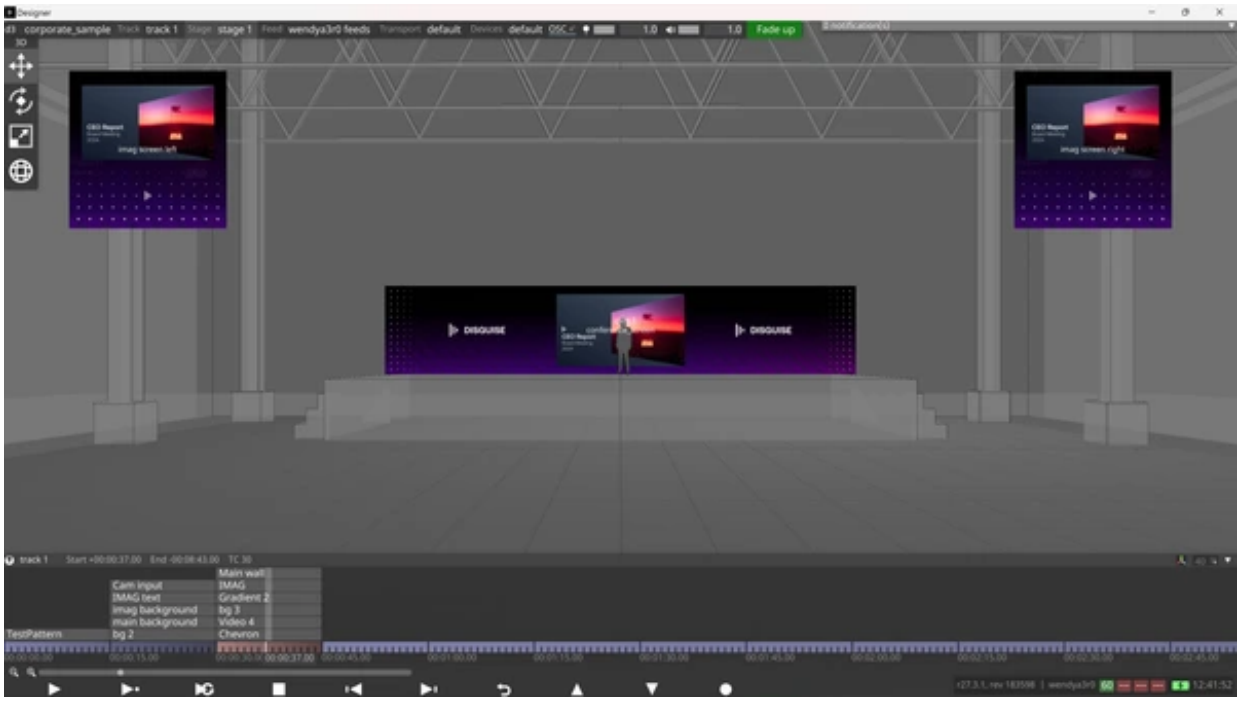
Corporate Sample Project

Description

A stage for a corporate event, consisting of one main LED screen and two side screens.

Demonstrates LED content mapping, live video input, redundant failover with matrix and d3Net, and internally generated text and effects.

Corporate_sample_project.zip Download link



Corporate - sample project

Specs:

- Main screen: 5632 x 1056px
- Side screens: 1056 x 1056px

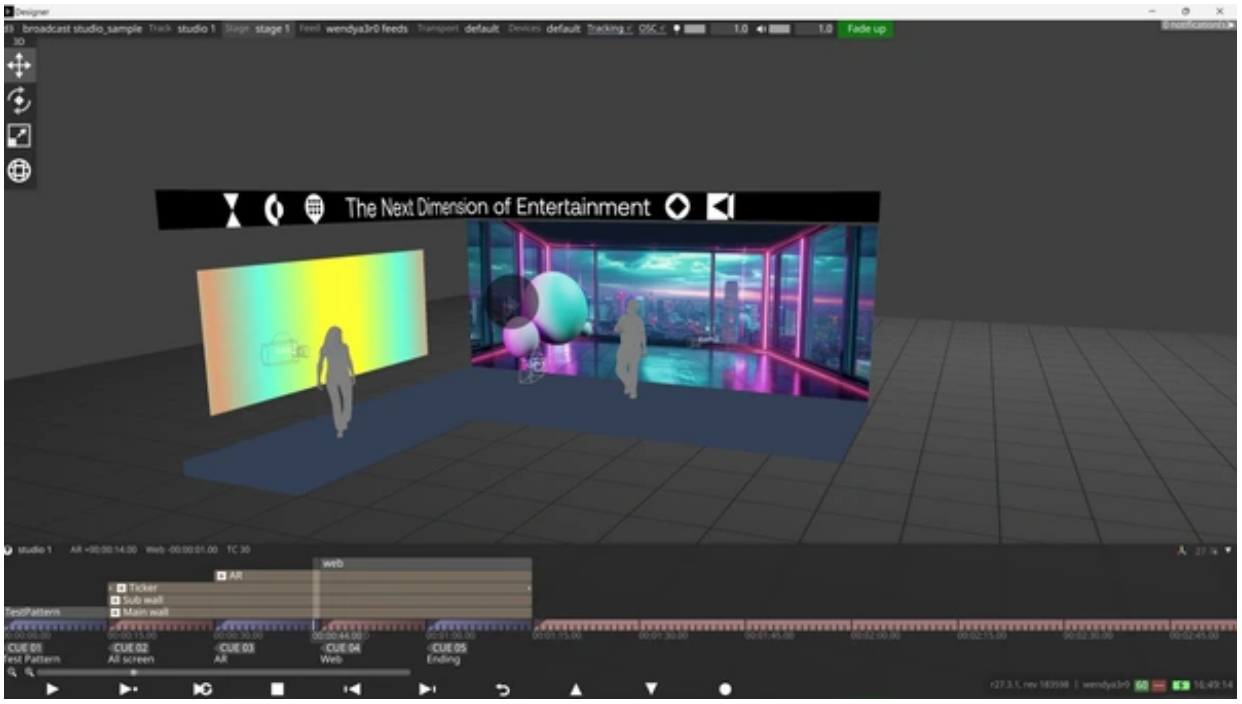
Broadcast Studio Sample Project

Description

A broadcast studio with a large video wall, a sub screen for breaking news or weather and a long ticker screen.

Demonstrates LED pixel mask, MR set, stage render layer front plate (AR), ticker scrolling, a web layer, timeline tags & cue list ready for Porta control, and layer patch to OSC.

Broadcast_Studio_sample_project.zip Download link



Broadcast studio - sample project

Specs:

- Main wall screen: 3072px x 1152px
- Sub wall screen: 1920px x 768px
- Ticker screen: 3072px x 192px

Disguise Drive Supported File Formats

Disguise Drive supports the following file formats:

Automatic Transcoding

Previz automatically transcodes your media for optimal performance in the viewer.

We can also accept a range of common video formats.

Video Formats

- MP4
- WebM
- MXF
- MPEG-2 TS container
- MPG
- fmp4
- FLV

Supported Video Codecs

- H.264
- VP9
- VP8
- MPEG-2

Not Supported

- HAP
- HAP-Q
- DXV

Audio Codecs

- AAC
- MP3

Recommended Video Specifications

- No larger than 8192 x 8192px
- h264 in a mp4 or quicktime container for the video
- aac or mp3 for audio

Transparency

Transparency in videos is not supported.

We are limited by the technologies implemented by the web browser vendors. WebM (the open video format pushed by the Mozilla Foundation in Firefox and Google in Chrome) allows video with transparency, but it is not supported by Safari nor IE / Edge. There is no good cross browser technology available to us at the moment.

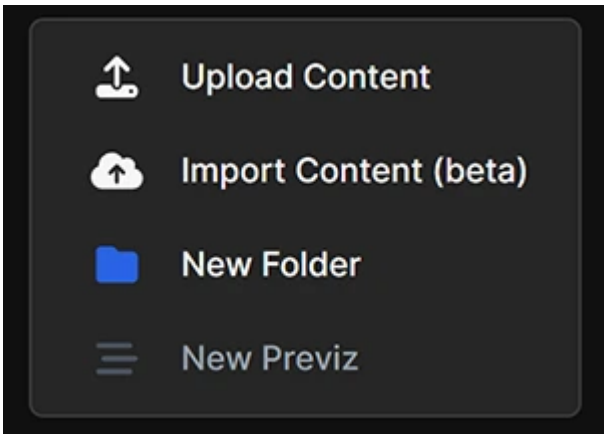
If you upload a video with a transparency layer, the transparent pixels will be rendered solid black in Previz.

Import Content from Third Party Services

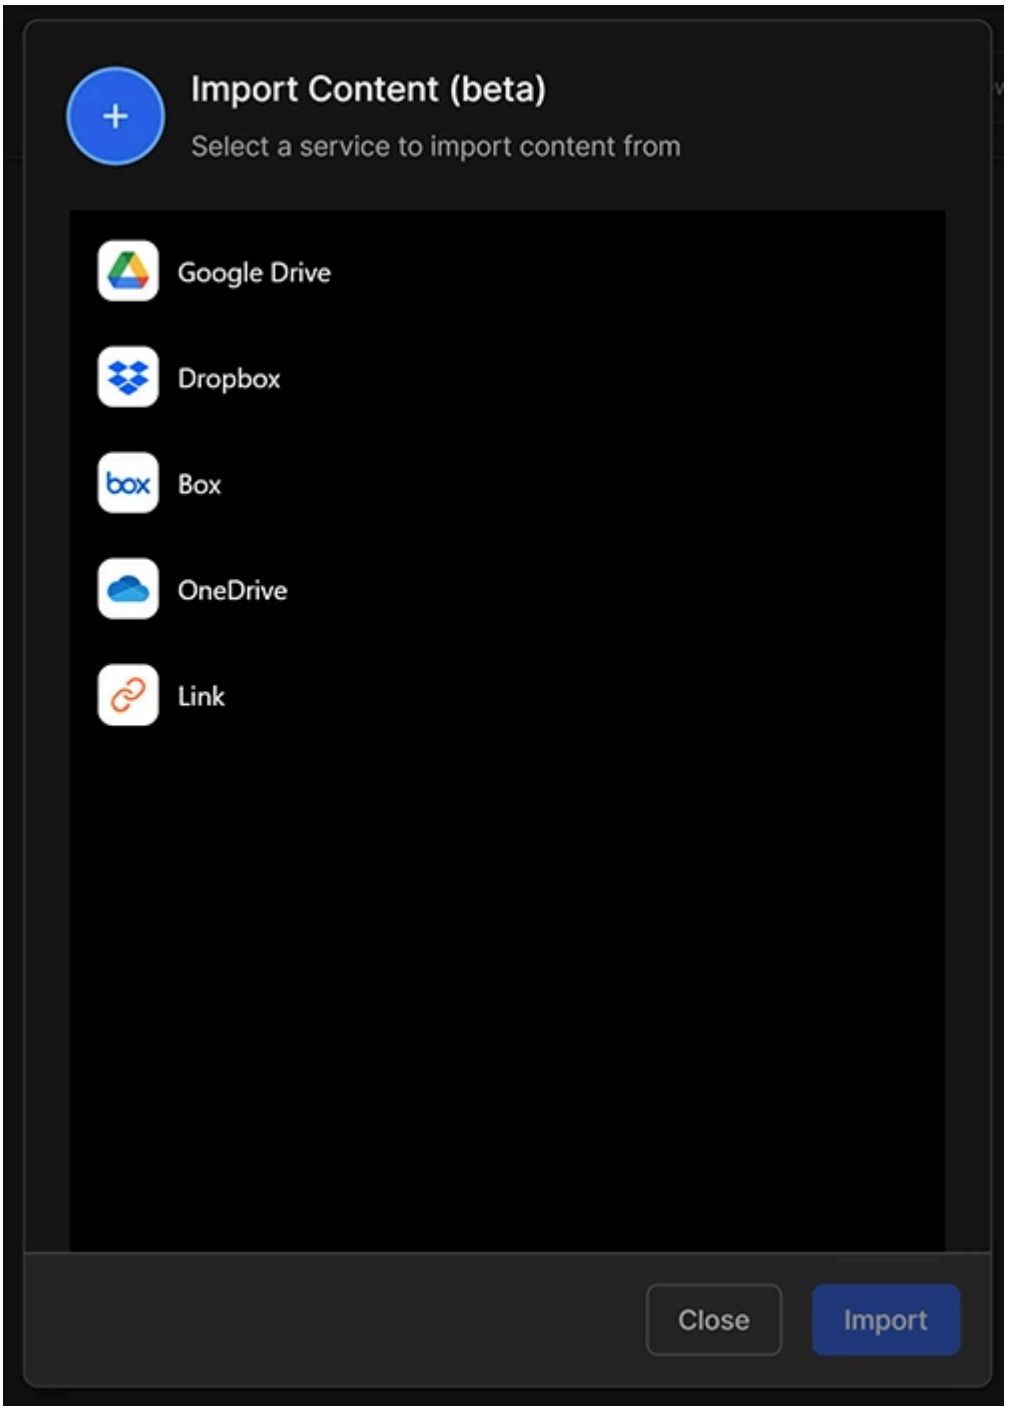
Cloud users can import content from third party storage services such as Google Drive, DropBox, Box, and via a link to an online storage service.

This feature is available for all Disguise Cloud users.

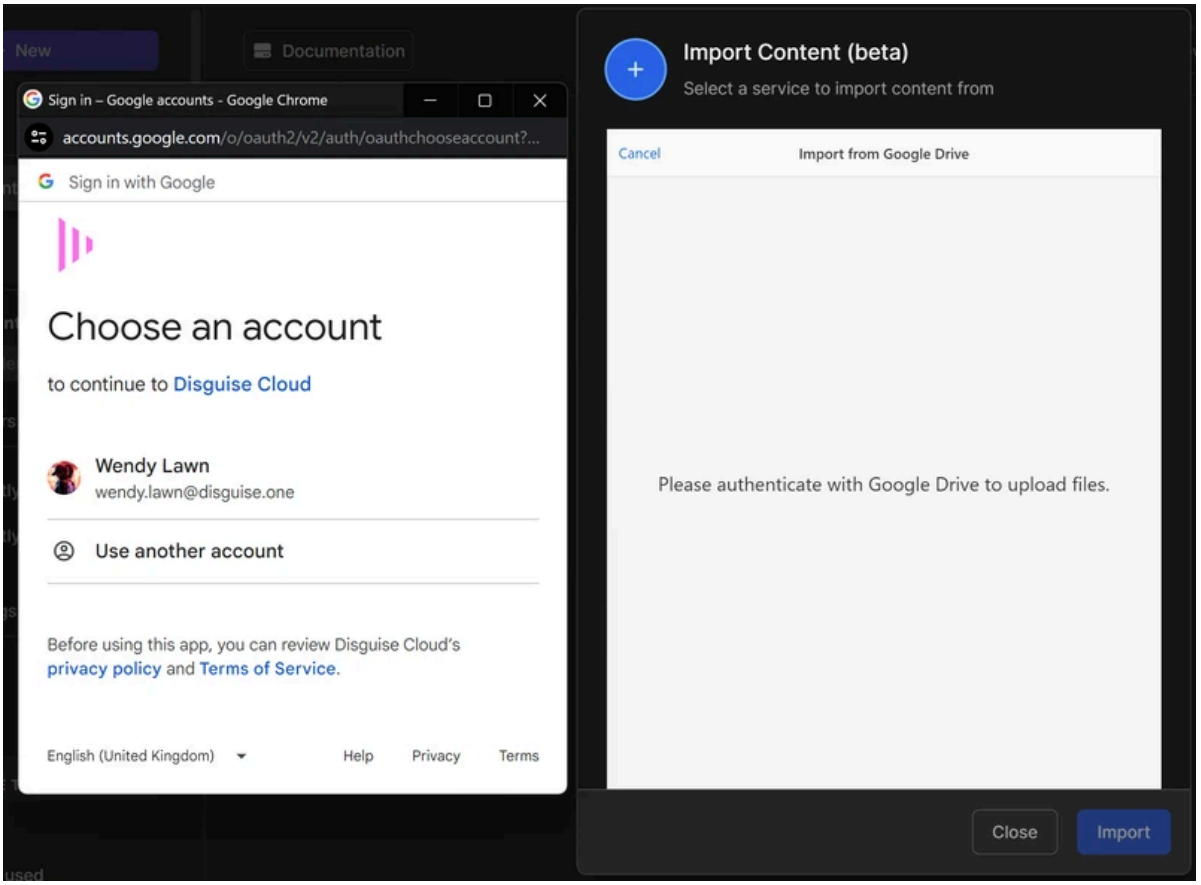
1. Log in to **Disguise Cloud**.
2. Right-click anywhere in Drive. Or, click **New**.
3. Select Import Content.



4. Select the third party service you wish to import content from. Options include **Google Drive**, **Dropbox**, **Box**, **OneDrive**, or via a link.



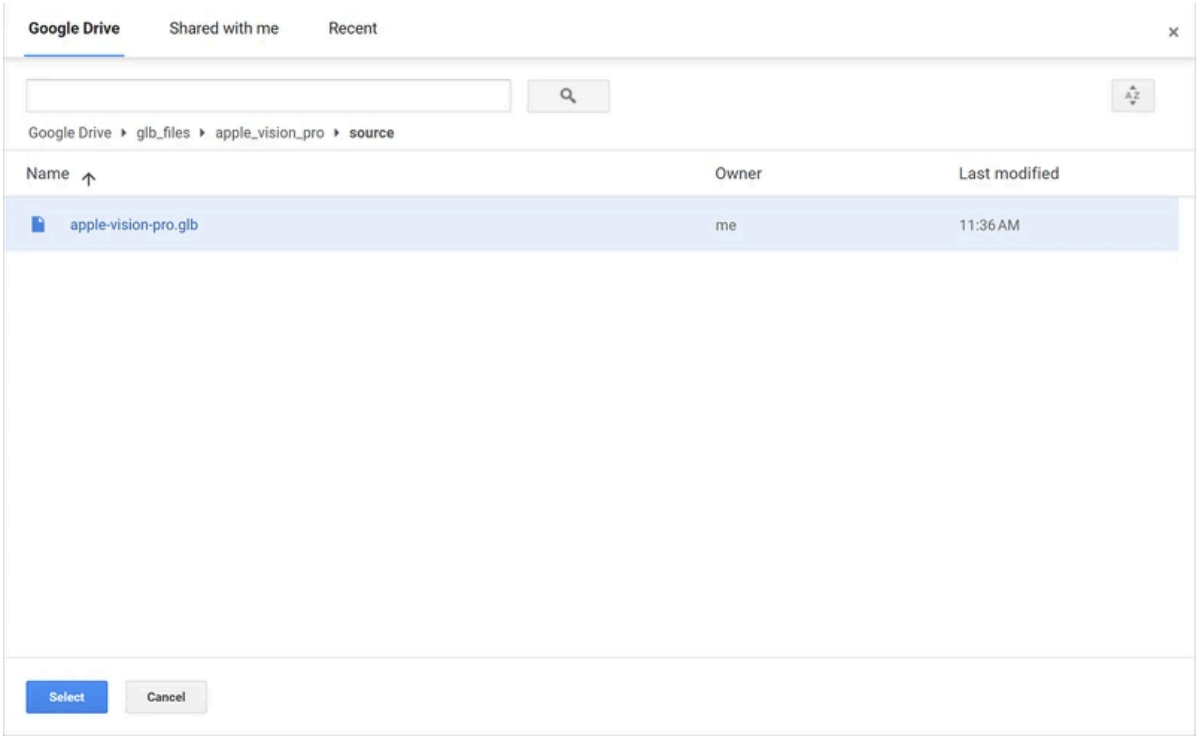
5. Sign-in to the service to access the content.



In this example, we use Google Drive

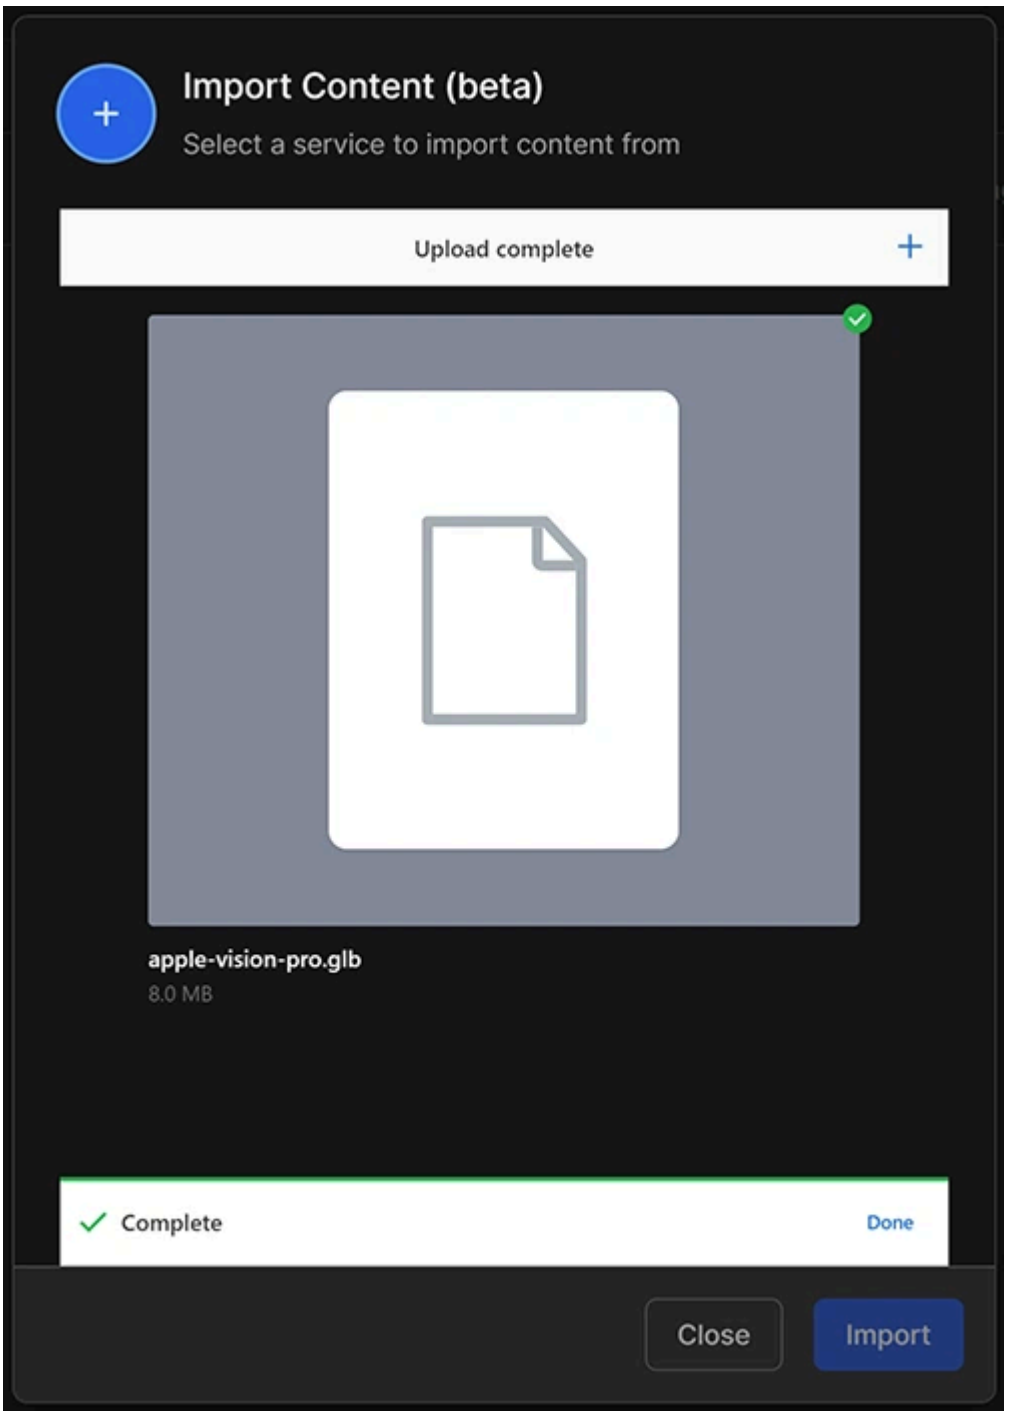
6. Confirm you are happy to use your Google account and click **Continue**.

7. Select the content files or folders you want to add to your Cloud Drive and click **Select**.

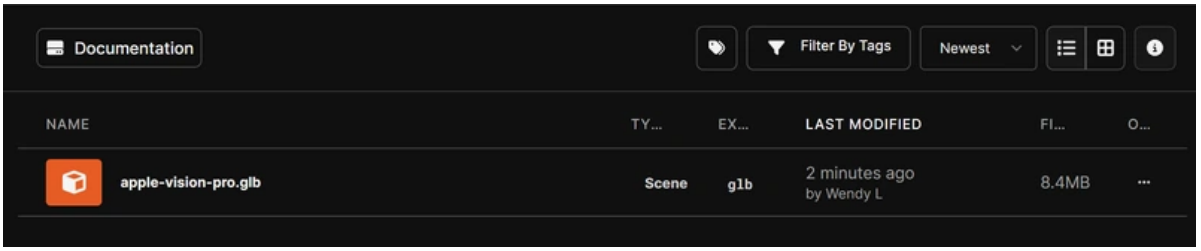


8. Next, click **Import**.

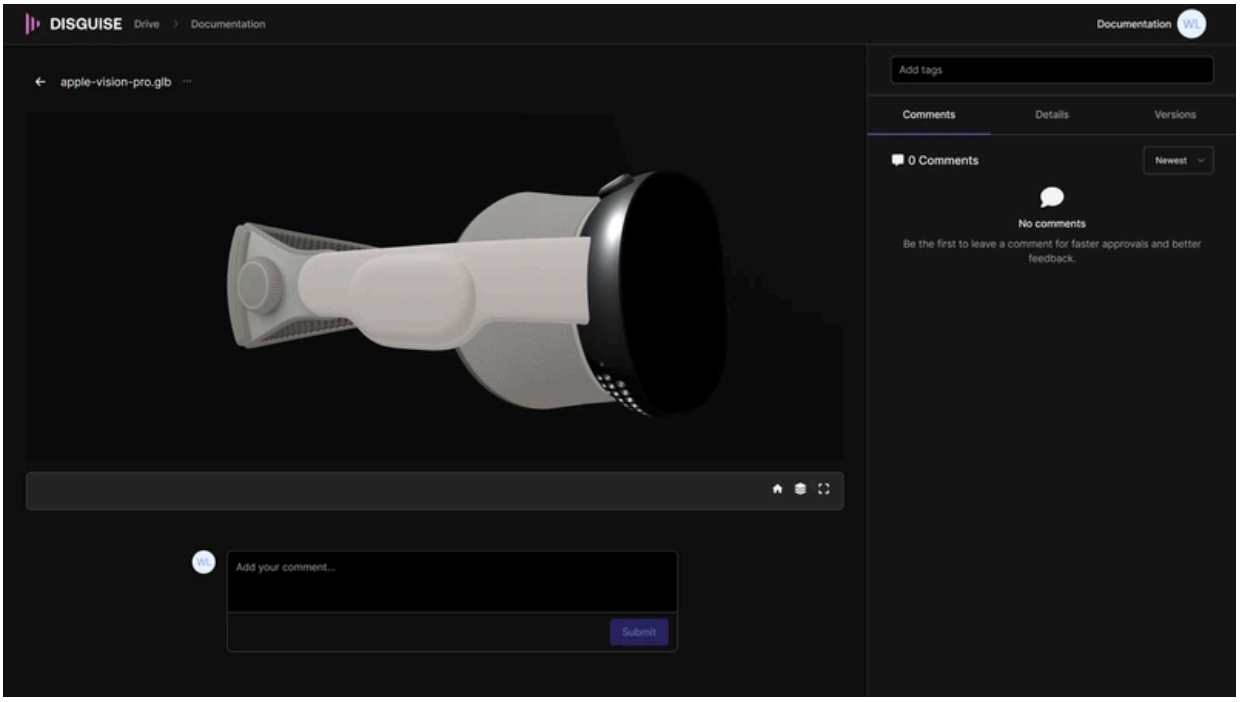
9. When the import has completed click **Close**.



10. Once imported, the content will appear in your drive.



11. You can preview 3D models with file formats such as .glb by clicking on the file name.



Uploading Content

Viewable file types

- Images
- Video
- Audio
- 3d Scenes (.gltf/.glb format)
- PDFs
- Folders containing the above file types

You are able to upload any type of file to your Drive, including ones not listed above, but only the above file types will be processed and viewable in the Drive application. The maximum file size for a single file is 20GB.

> **Note**: The amount of storage available is dependent on your subscription level.

There are two ways to add content to your previz:

1. Adding the files in the Drive application.
2. Dragging and dropping the files you want to upload to the Drive sidebar in your Previz.

Adding files in the Drive application

There are different ways to upload files to your Drive:

Method 1: Using the New Button

1. Navigate to the folder you want to upload the file to.
2. Click the **New** button at the top left of the Drive application.
3. Select **Upload Content**.
4. Browse for and select the file or files you wish to upload.

Method 2: Drag and Drop

1. Navigate to the folder you want to upload the file to.
2. Drag the file or files you wish to upload into the Drive application.

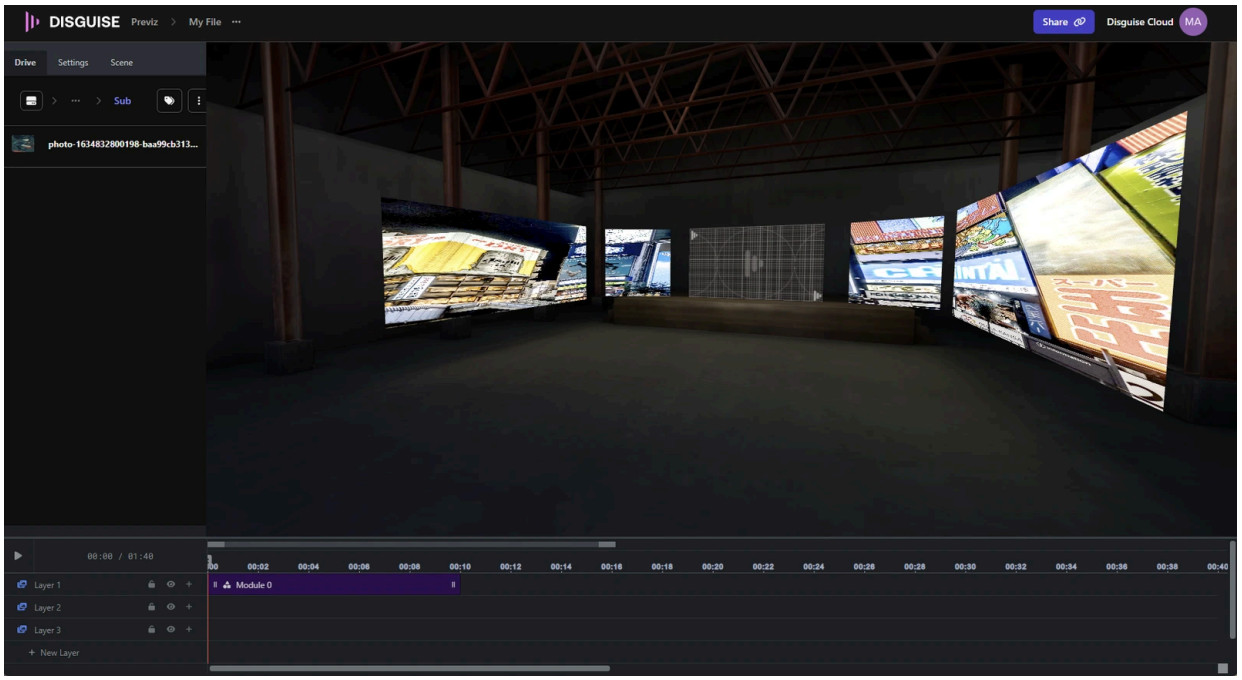
Method 3: Right-click

1. Navigate to the folder you want to upload the file to.
2. Right-click in the empty space in the folder content area.

3. Select **Upload Content**.
4. Browse for and select the file or files you wish to upload.

Drag files into Previz

1. In your Previz project, click on the Drive tab on the left sidebar.
2. Navigate to the folder where you want to upload the files.
3. Drag the files you want to upload into the Drive sidebar or use the right-click method.



Previz's Drive Sidebar

Using Drive

Set up a Drive

When you create an organisation, a primary Drive is automatically created for you with the name of your organisation. Primary Drives are indicated as such by a star icon in the Drive table in the Management area.

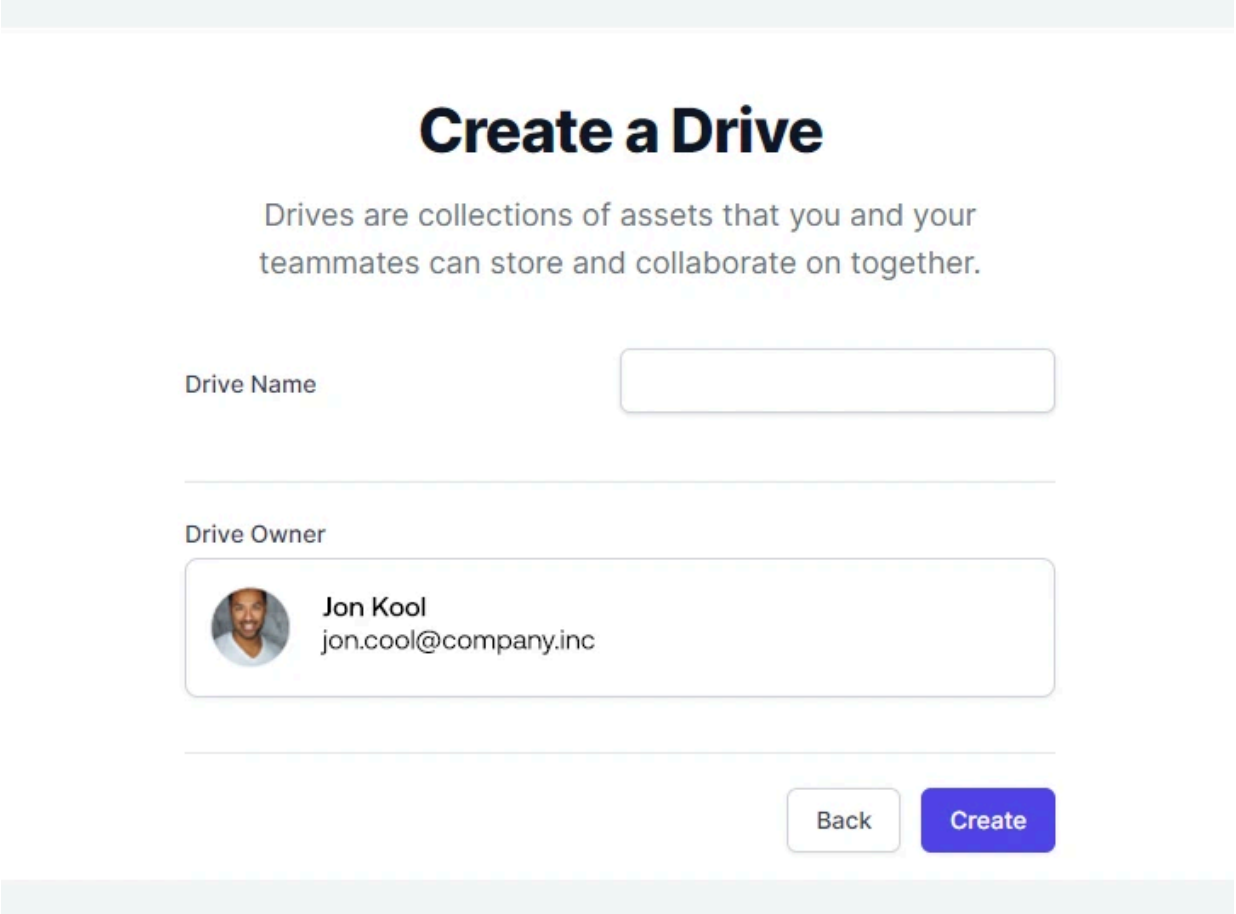
To add another Drive you will need to be on a paid plan.

If you want to add more Drives:

1. On your **Drive** page, click on the **+ New** icon and name the Drive.

Alternatively, here is a second method to create a Drive:

1. Click on the **Drives** tab if it is not the current tab.
2. Click on the **Create a Drive** button.
3. Type the Drive name in the **Drive Name** field.
4. Click on the **Create** button.
5. To configure your Drive, click on the **Update** button. Or if you'd rather do this at a later stage, click on **Not Now**.



Rename a Drive

1. To rename a Drive, click on **Settings** in Drive Settings.
2. To change the title, click on **Update**, type the new name, and then click **Save**.

Create a folder

1. To create a folder in your Drive, click on the plus icon **+** next to **Folders** below your Drive name.
2. Type the name for your new folder in the **Folder Name** text field and click **Create**.

Rename a folder

1. To rename a folder, click on the "..." symbol below OPTIONS in the Drive details view.
2. Click **Rename**.
3. Type the new name for your new folder in the **Rename Asset** field and click the **Rename Asset** button.

Delete a folder

1. To delete a folder, click on the "..." symbol below OPTIONS in the Drive details view.
2. Click **Delete**.
3. Click on the **Delete Asset** button to confirm you want to delete the folder.

Working with content

Supported file formats

The file formats currently supported in Disguise Drive are:

- Image: png, .jpg, .bmp, .webp, .gif
- Video: mp4, .mov, .ts,.avi, .y4m, .mkv
- Audio: .mp3, .wav
- 3D: .glb, .obj, .glTF, .fbx

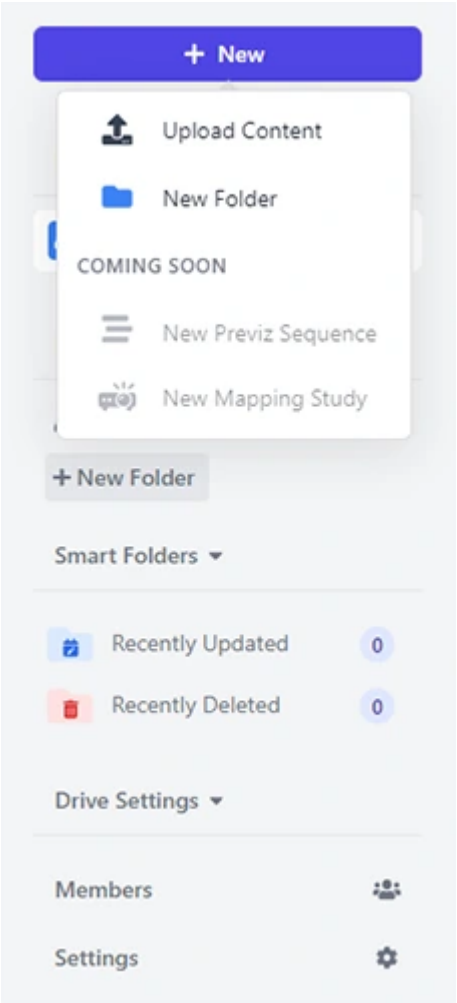
Upload content

1. From your **Drive** page, select the drive you want to use from the dropdown menu.
2. Click on the **+ New** icon and select **Upload Content**. This will allow you to browse your local files.
3. Select the item you want to upload and click **Open**.

The item will upload and appear listed in your drive.

Alternatively, you can drag and drop a file or asset or several files from your computer into the main drive content area to upload to the current directory you are in.

You can also upload a folder that will upload all files within that folder along with any nested folders.



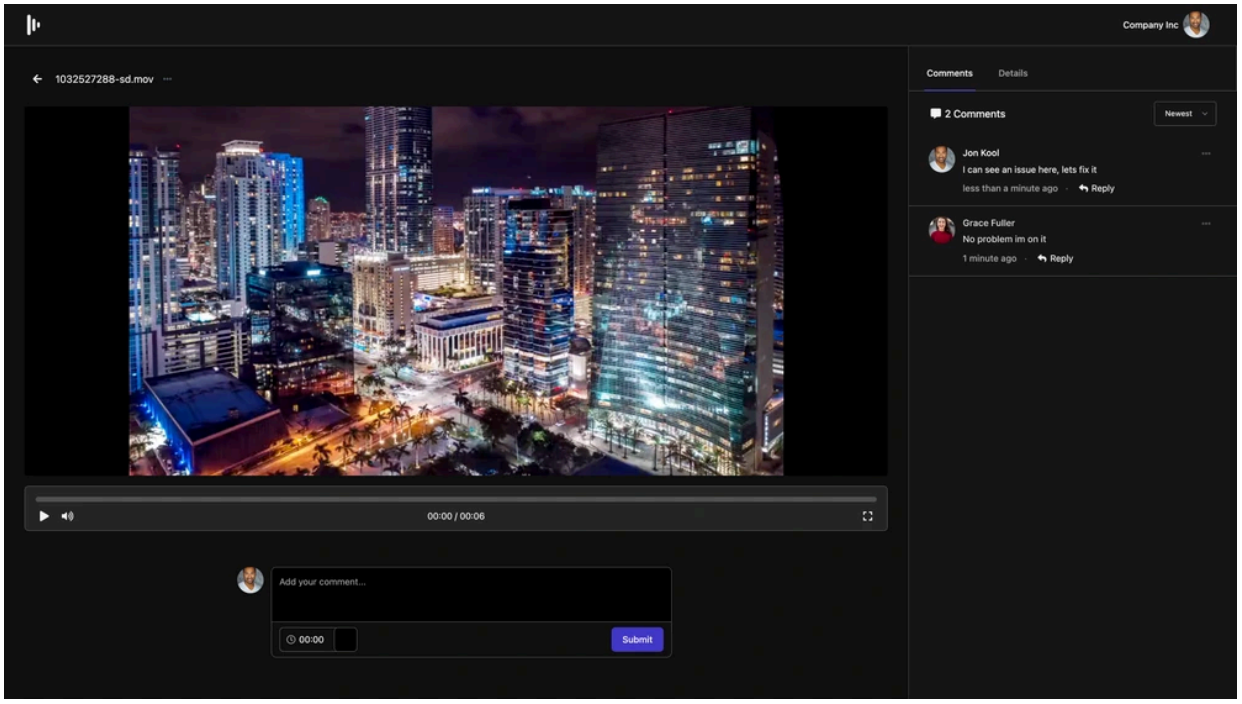
Preview content

To preview content, click on the item in drive view.

This will open a view of the item. Here, you can see any comments and details.

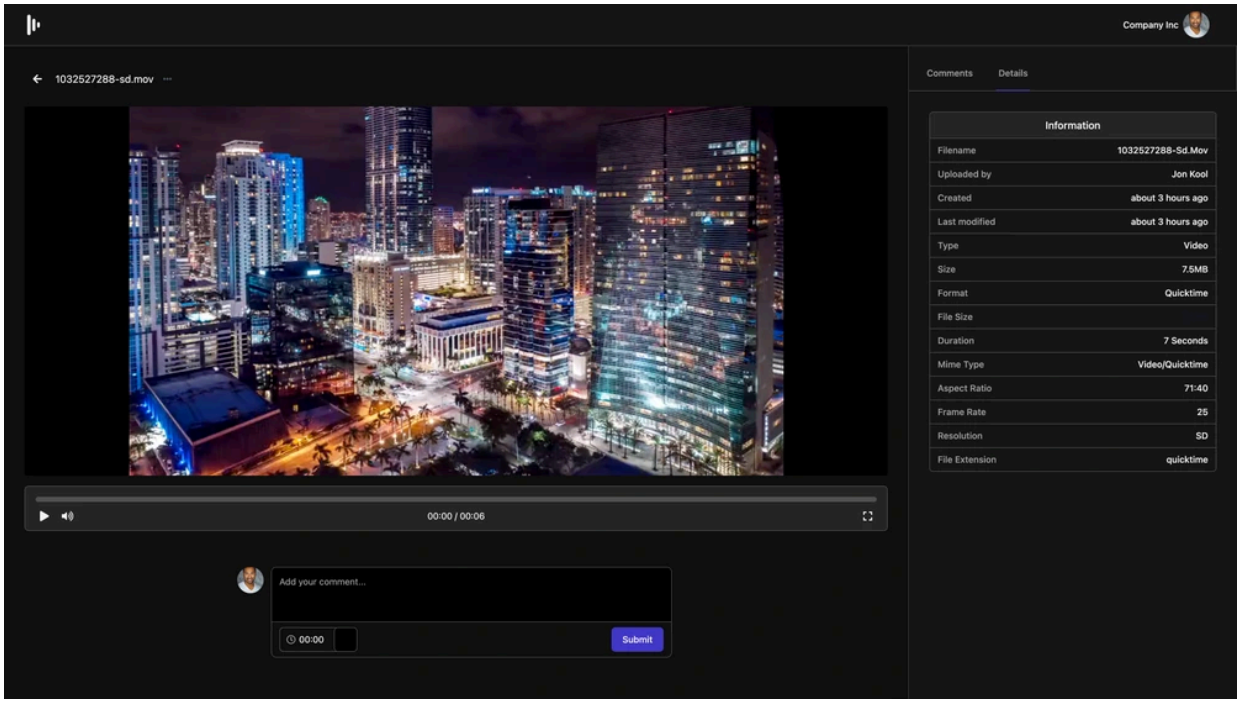
Leave a comment on an asset

1. To leave a comment on an asset, click on the item name to view it.
2. Then type on in the box below the item.
3. Click **Submit**.



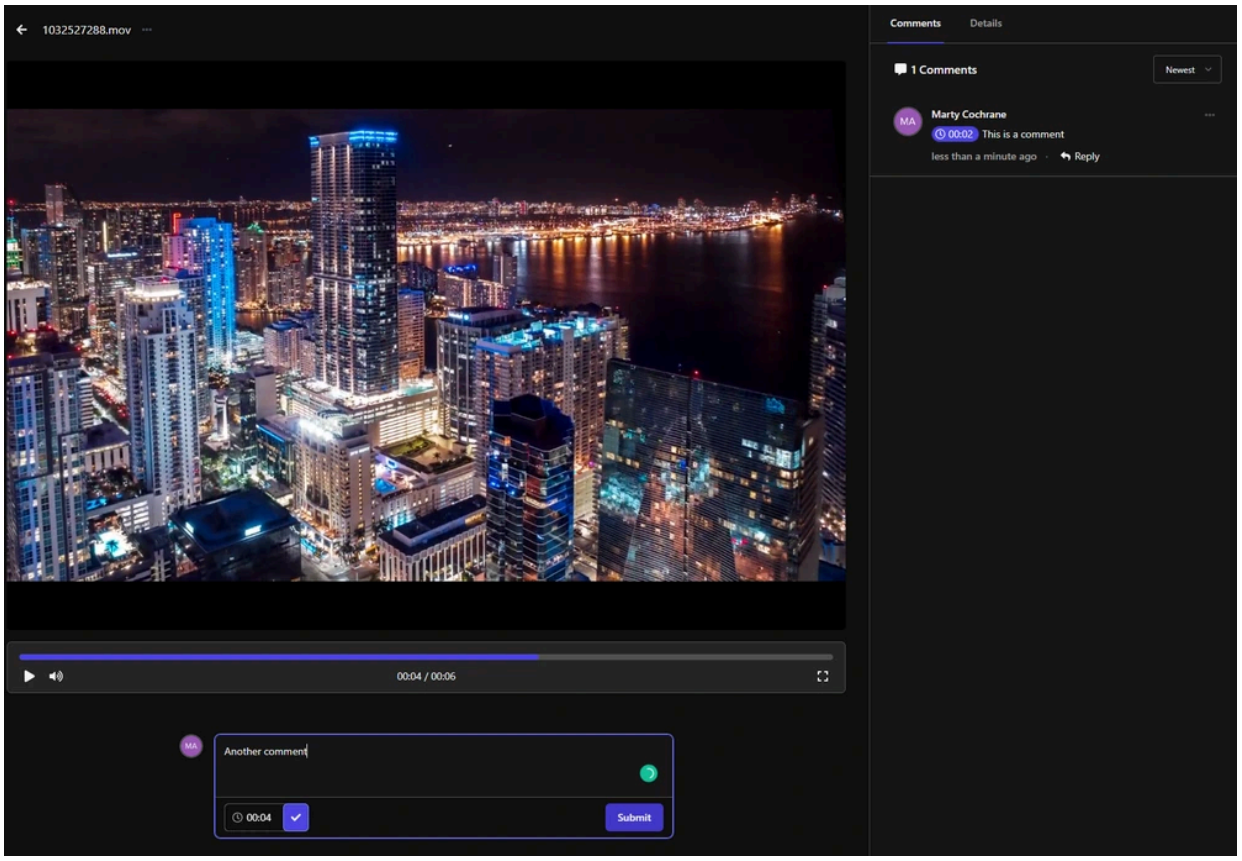
View the Metadata of an asset

1. To view an asset's Metadata, click on the item to preview it.
2. Click on the **details** tab.

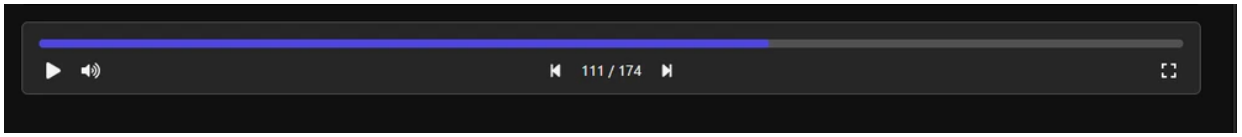


Add timestamped comments on a video

In the comment box, you can change the timestamp by clicking on it and adjusting the time and frames.



Clicking on a timestamp will jump you to the point in the video where the comment was left so you can review the frame it relates to.



Download an asset

1. From your drive's file list, click on the "..." below OPTIONS.
2. Click **Download**.

Delete an asset

1. From your drive's file list, click on the "..." below OPTIONS.
2. Click **Delete**.

Access recently deleted files

From your drive's file list view, click on the **Recently Deleted** SMART FOLDER.

This will list all of the recently deleted files and folders.

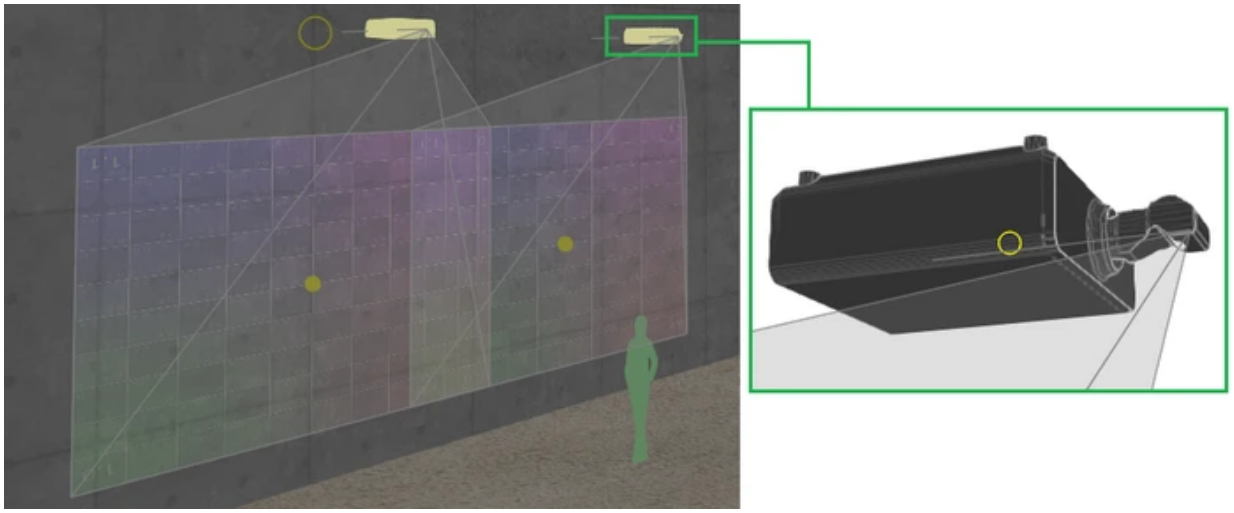
FAQs (legacy)

> **Note**
>
> This page documents the **legacy** edition of Mapping Matter, kept for users who have not yet migrated. The current Mapping Matter docs begin at Introduction.

Keystone

There's no Keystone tool in Mapping Matter. To quickly set perfectly mapped previews of your Content projected on any surface, you can use the Reverse Mapping Mode There will be no distortion / loss of image quality.

Ultra Short Throw



Here you'll learn how to simulate odd lens configurations (often used for Ultra Short Throw), such as *Reverse Mirror* or *Snorkel*.

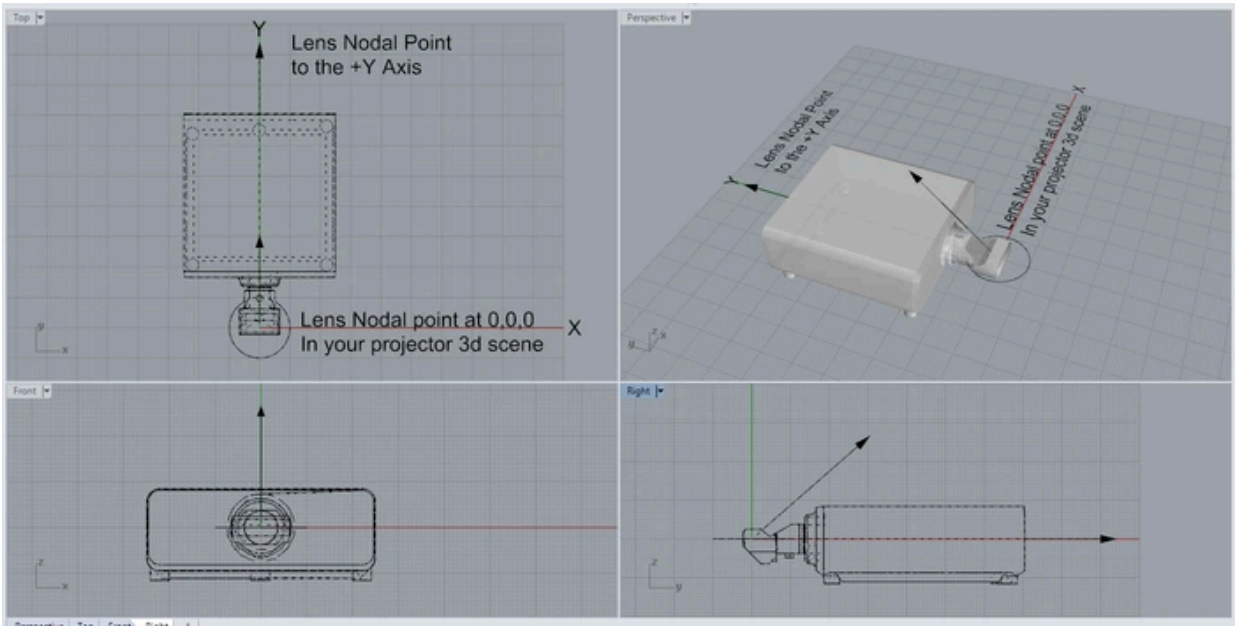
The Reverse Mirror type

> **Warning**
>
> You can design your Projector's mesh in another CAD software, and import it. Or you can directly create a basic custom box in Mapping Matter.

Create a single “joint” .OBJ body mesh in any CAD software, following all requirements below.

- Must have the axis Z-up. (Some softwares have Y-up.)
- It MUST be set in millimeters.
- Nodal Point must be at the Center (0, 0, 0) of your .OBJ file.

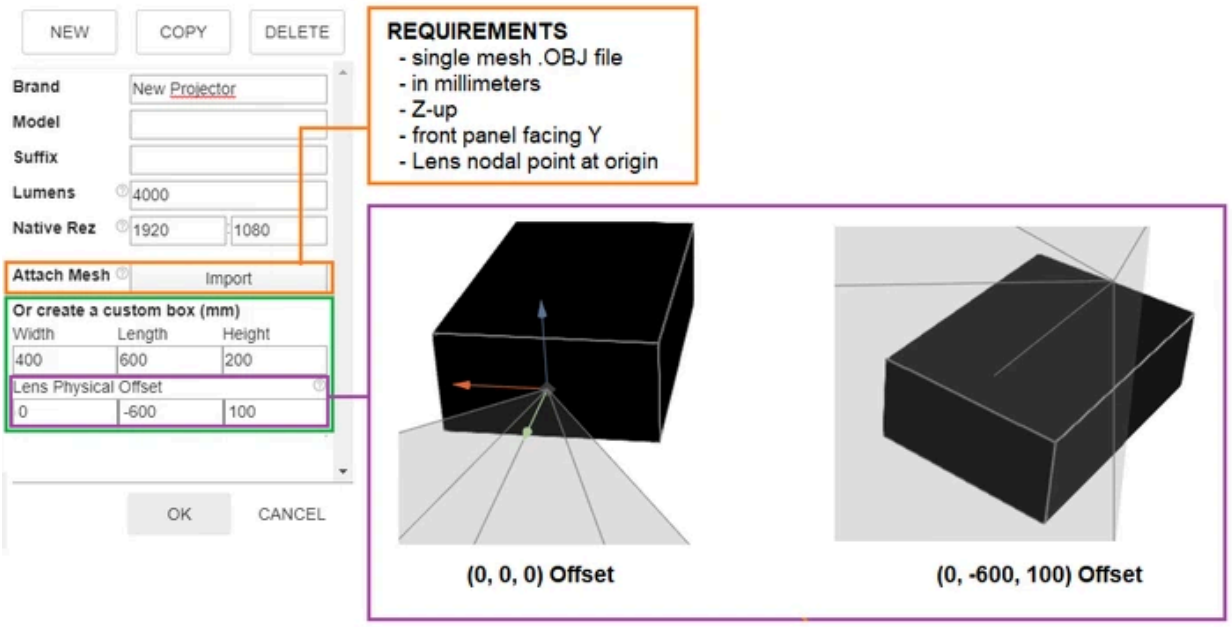
The Projector’s front panel should point towards the +Y axis. Note that the its body may be oriented however you like, it will simply be attached to the Light Beam in Mapping Matter.



Create a Projector in Mapping Matter.

> **Tip**
>
> Click here to learn how to manage your Projector Library.

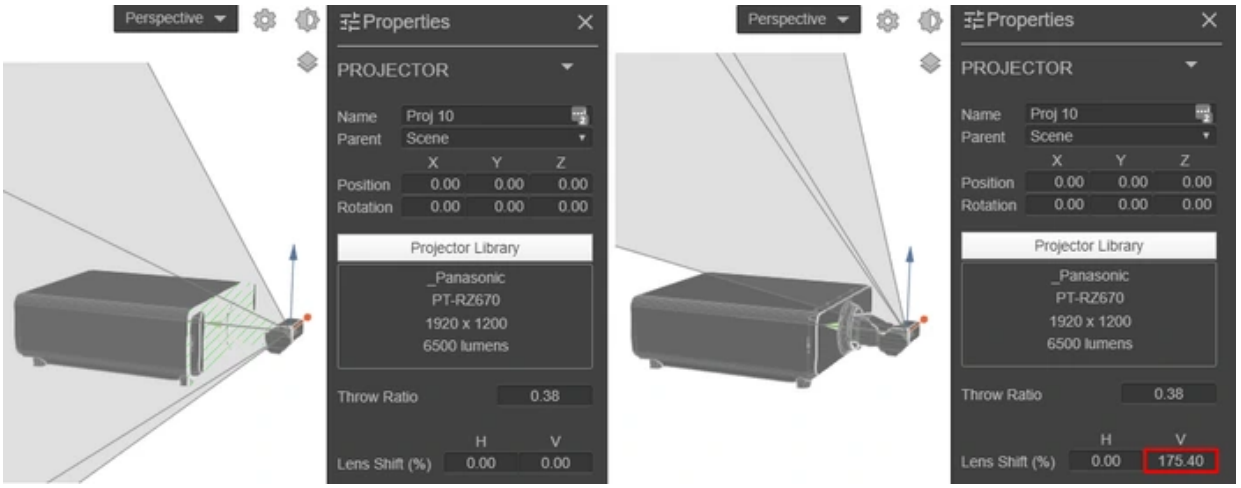
TOP MENU > Projectors > Projector



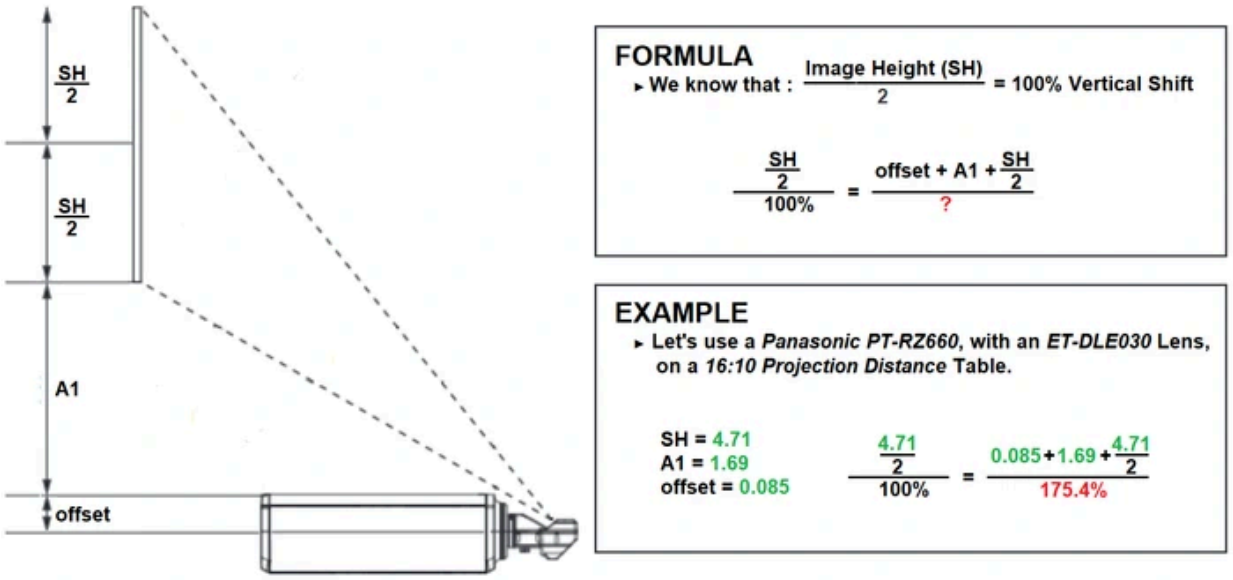
If you have any issue with your imported mesh, first make sure you followed the requirements above. Otherwise, you may have to Optimize your mesh pre-import.

You'll need to refresh your Browser for all updates to appear in your Scene and the Projector Library.

- Set the Throw Ratio according to the Manufacturer's specs.
- Adjust the Vertical Lens Shift. (Go to the **Properties** panel.)



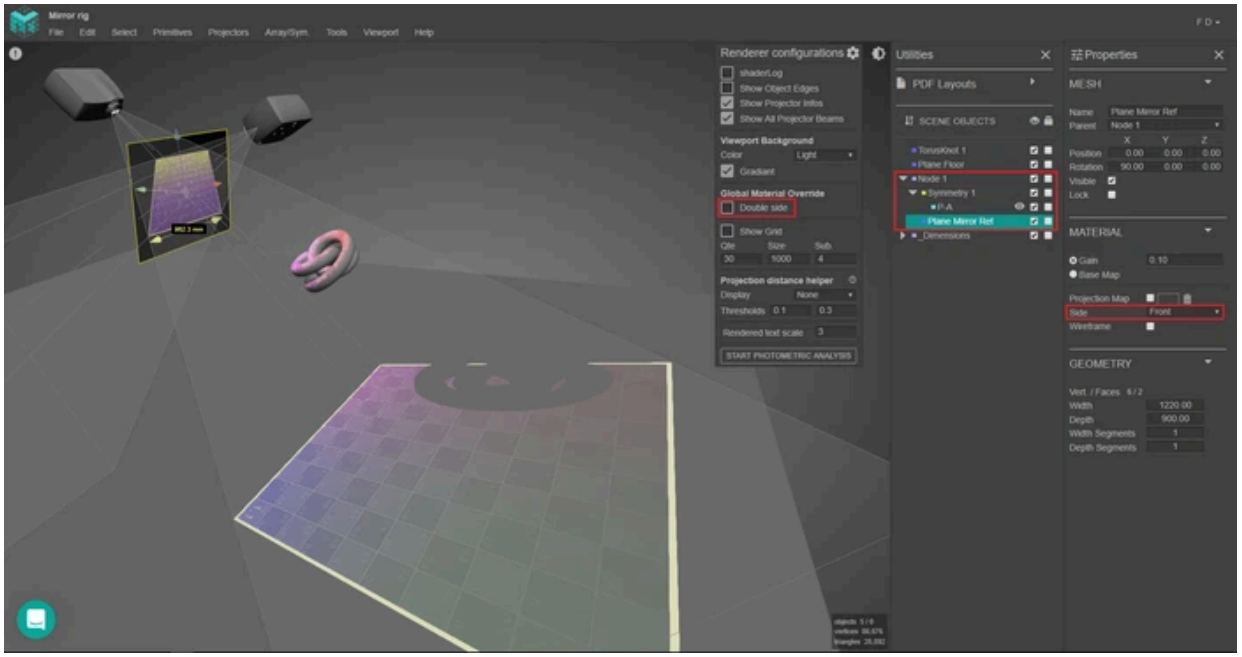
You can calculate the default (or "native") Vertical Lens Shift, using information that you will find in the Manufacturer's specs.



> **Tip**
>
> Learn how to use the Dimension Tool for your measurements.

Fake Mirror (Mirror Bounce)

There's no Mirror feature in Mapping Matter. But there's an easy workaround to achieve an identical result.



Make sure Global Material Override is disabled in the Viewport Settings panel.

Create a **Node** Primitive.

This will top the *Hierarchy* for all Objects of the Mirror setup, allowing you to move / rotate it all easily.

- Create a Symmetry, as a **Child of the Node**.
- Create a **Plane Primitive**, to simulate the Mirror itself. Make is a **Child of the Node**. And set its Side (MATERIAL) parameter to **Front**.
- Create a Projector. Make it a *Child* of the *Symmetry*. Adjust its Position / Orientation so it hits the Mirror from its Front side.

Pixel Resolution for Pixel

This may help you obtain your Full Projection's Resolution.

> **Warning**
>
> This method won't be as accurate as if calculated in a software like Autocad.

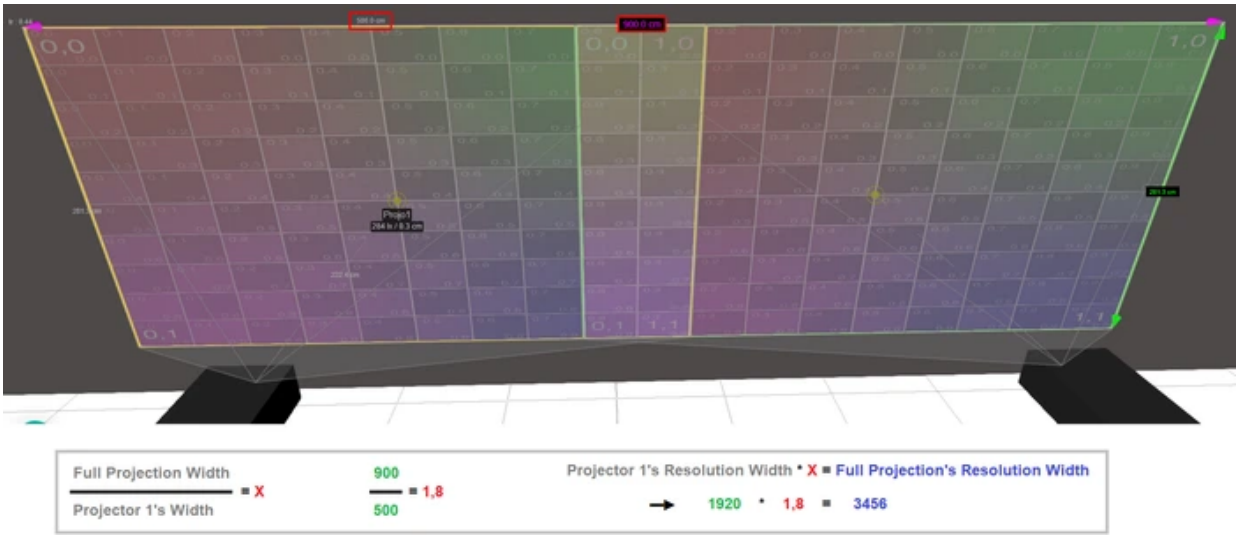
1. Use the Dimension Tool to measure the full area of Projection (Height & Width).

> **Tip**
>
> In the **Snap** toolbox, uncheck both **Bounding Box** and **Vertex** to get the Red Dot, which appears at any intersection between a Surface and your Cursor.

2. Check your Projector's Resolution, and solve the following equation.

Let's illustrate that with two 1920x1080 Projectors, on a 20% blending.

We'll find a Full Projection Resolution of 3456*1080 pixels.



Space Mouse

We don't support Space Mouses.

Shortcuts

Press **?** to display the full list of shortcuts.

?	Show / hide this help menu
space	Videos - Play/Pause
h	Videos - Restart
f	Videos - Forward 10 sec.
b	Videos - Backward 10 sec.

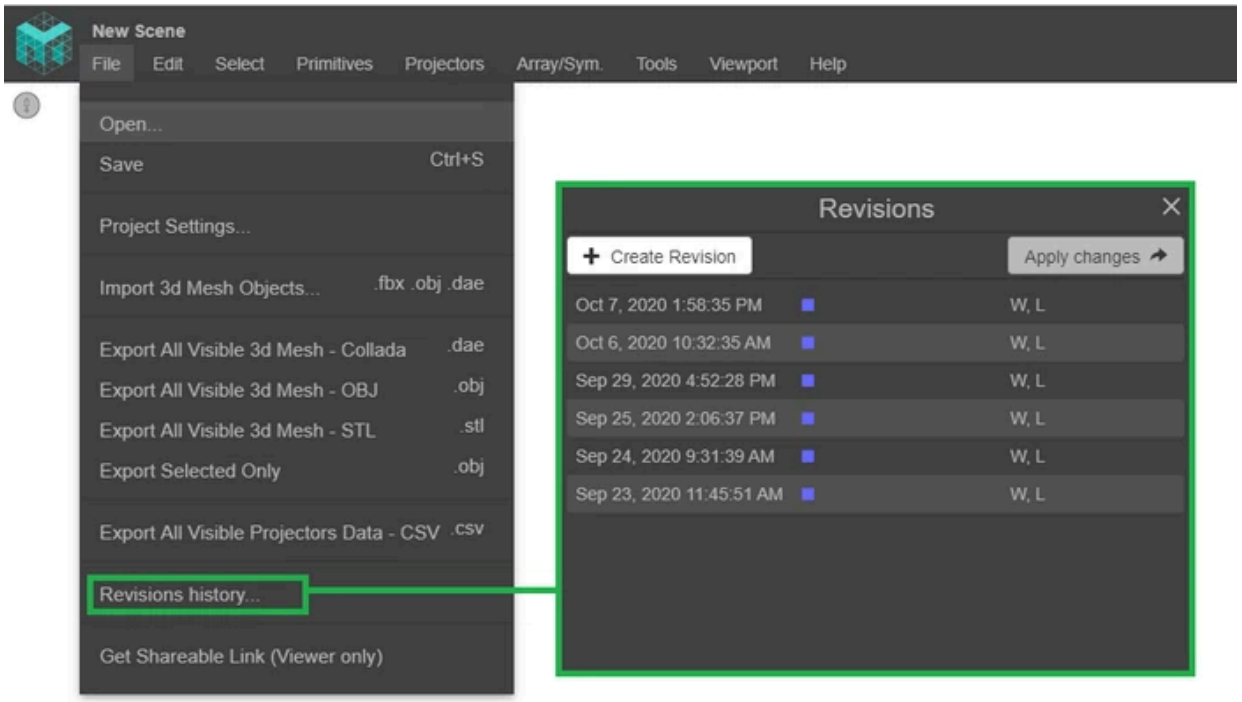
c 5	Camera - Perspective

Undo and Revisions History

You can Undo (**ctrl+Z**) or Redo (**ctrl+shift+Z)** any action by going to TOP MENU > Edit.

You can also use **Revisions History** to access the 10 last times you opened or refreshed your Scene.

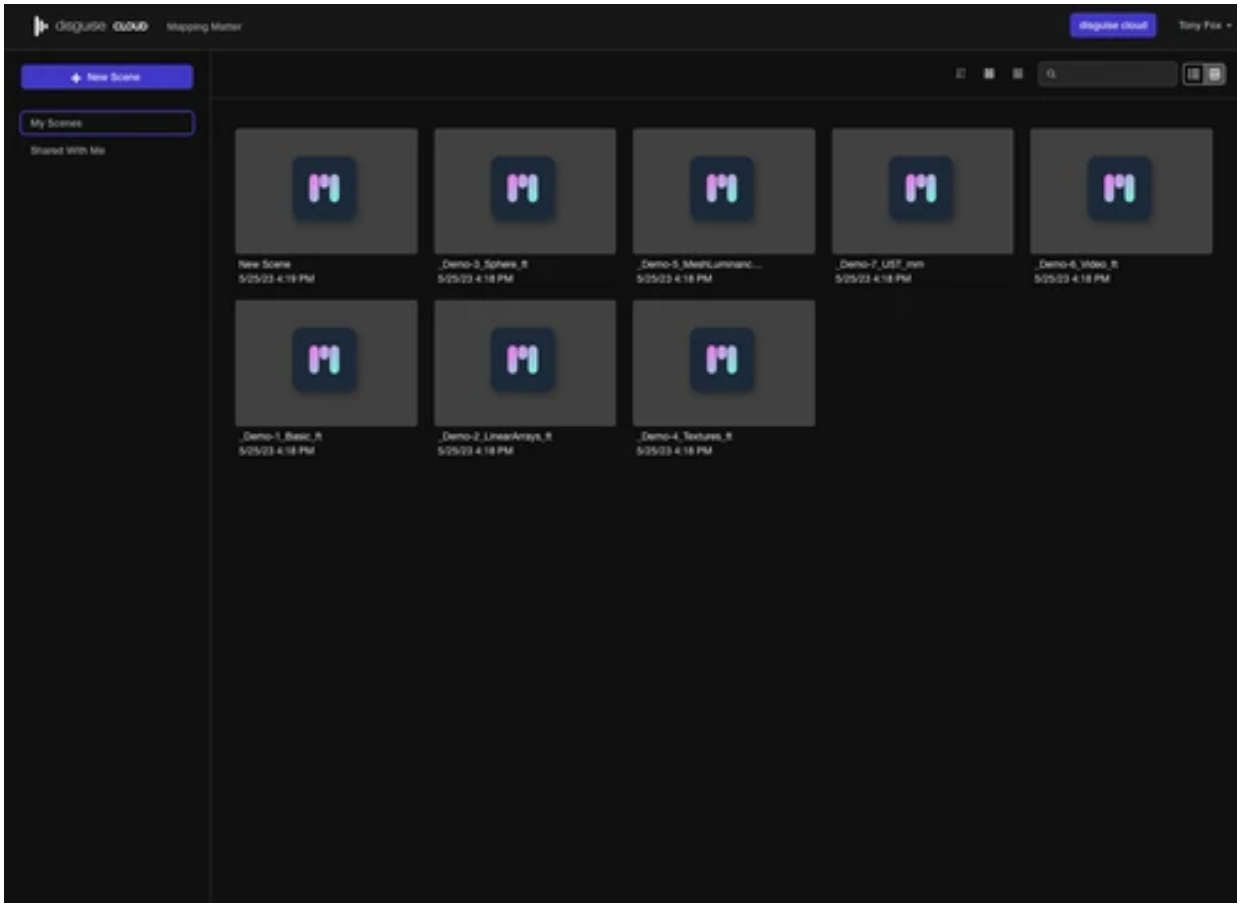


Getting Started (legacy)

> **Note**
>
> This page documents the **legacy** edition of Mapping Matter, kept for users who have not yet migrated. The current Mapping Matter docs begin at Introduction.

Home Page

- Here you can create / open / rename / duplicate / delete any Scene.
- You can change the display of all Scenes from Grid to List.
- You can sort them alphabetically / most recently used / by creation date.

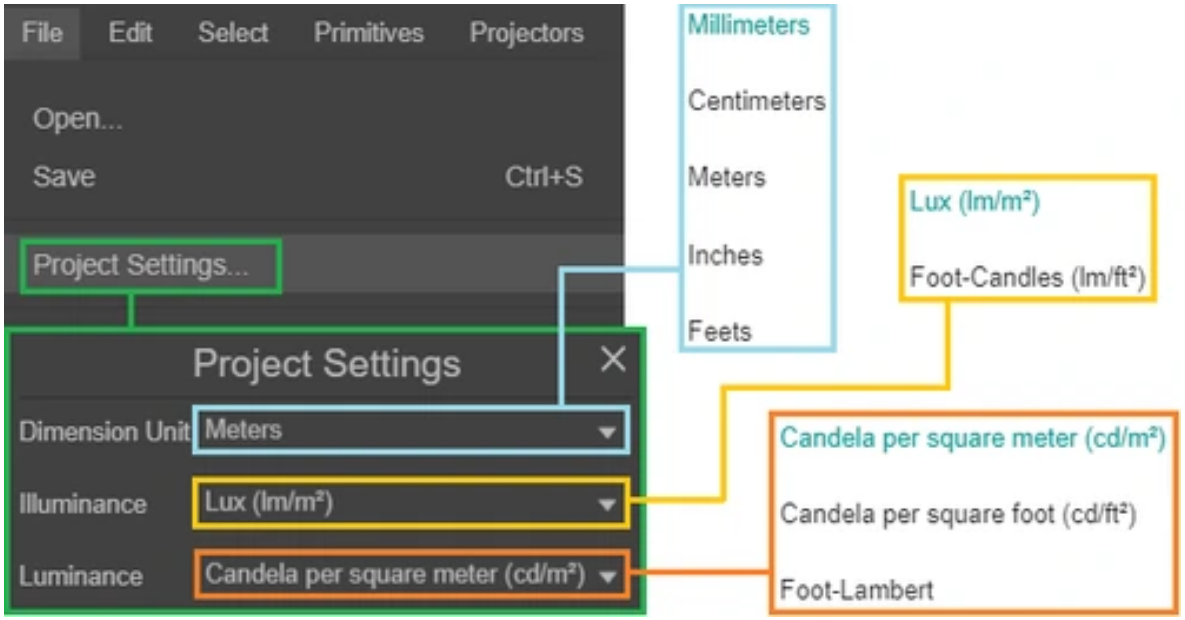


Mapping Matter

Base Units of Measurement

You first need to open a Scene. And then just navigate to :

TOP MENU > File > Project Settings...



Base units

Import a 3D Asset

We support .FBX(binary) very well, while .OBJ and .DAE work just fine. The maximum asset size is 100MB; you can load bigger assets but only locally.

> ⚠ **Warning**
>
> Mapping Matter is not primarily designed for performance. If you work with very heavy / complex 3D Assets, we strongly recommend to optimize your files before import. Otherwise, the Browser may crash (especially for computers with a small GPU).

Here's an article about pre-import 3D Asset Optimization.

Import a 3D Asset into your Scene

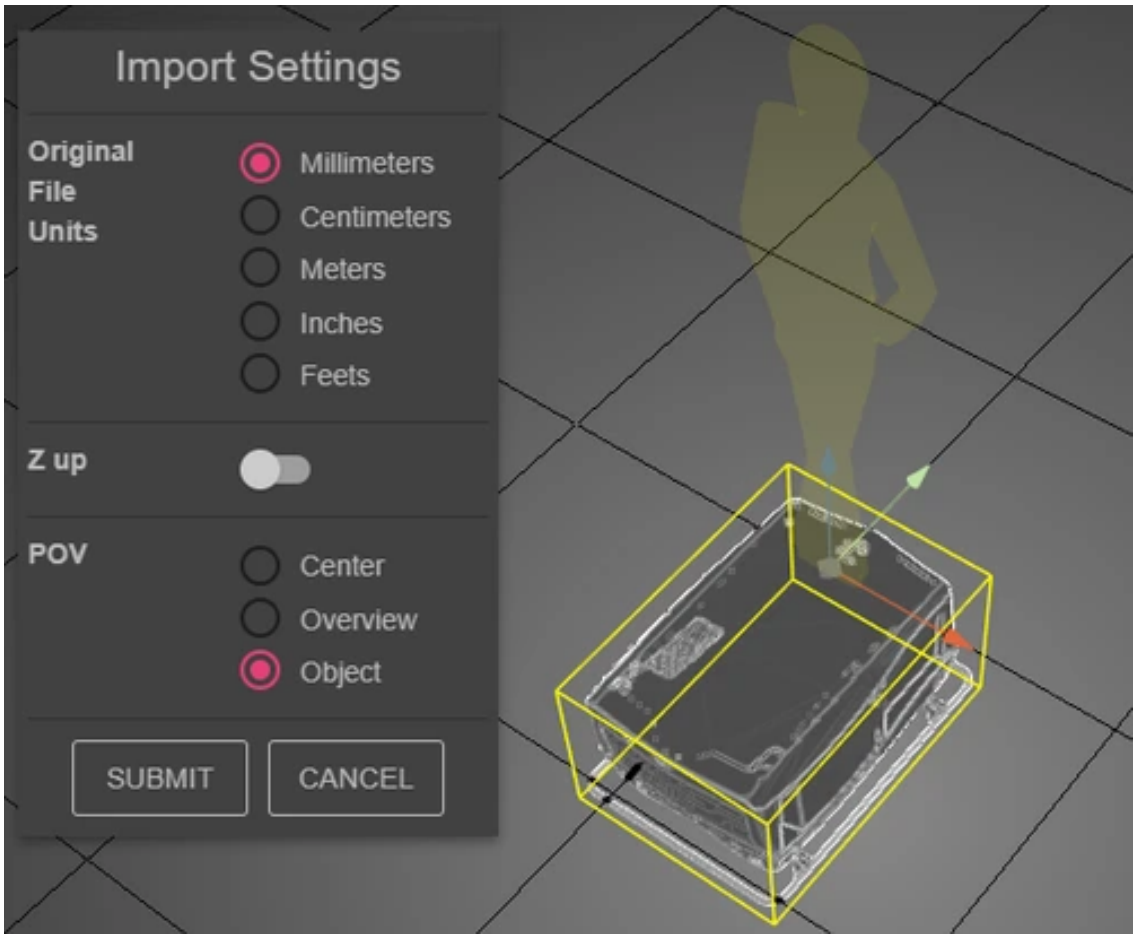
TOP MENU : File > Import 3D mesh Objects

This will give you access to the 3D Assets Library.

Double-click on any file to import it in your Scene.

The first time you import an asset into you Scene, the **Import Settings** window will pop-up.

> **Warning**
>
> For all updates to be effective in your Scene, you'll need to refresh your Browser.



Import 3D yellow shadow

Original File Units = the unit of measurement your 3D mesh was exported in.

Z up = map the imported asset's Y axis to the Scene's Z axis. This basically rotate your asset 90° on the X axis. This option is available because some 3D softwares export meshes with the Y up.

POV = Point Of View = change the camera perspective.

> **Tip**
>
> Do you see the humanoid yellow shadow? It has a 180 cm (5.91 feet) height. This will help get a sense of the Scale in your Scene.

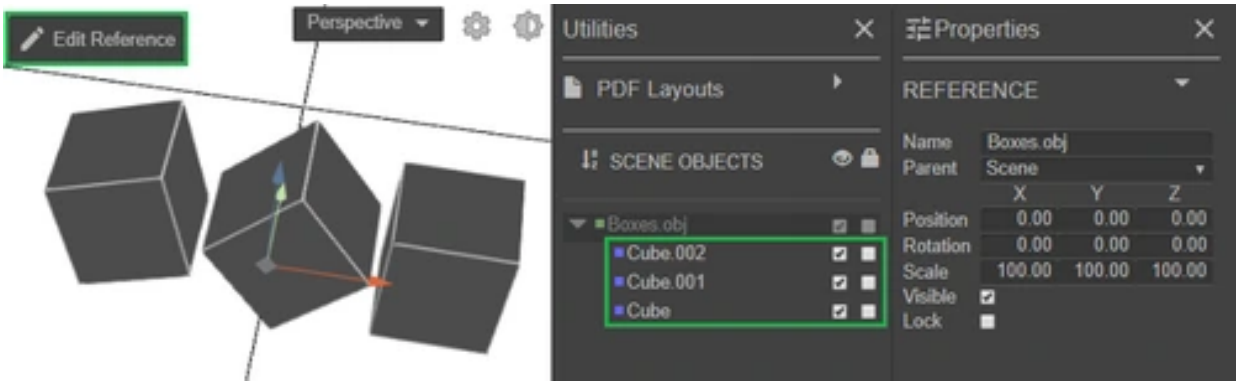
> **Warning**
>
> If you don't see your mesh despite setting the correct original file units, test with bigger units. Sometimes, files are read as if they were smaller.
>
> You can also import it first, and then multiply its scale through its Properties. (See the following section.)

Edit the Properties of an imported 3D mesh Object

The editing parameters available will depend on how the the asset was exported (format, software, etc).

1. Select your Object, go to its **Properties**.

2. Next, navigate to the **Reference** panel.
3. If you have a 3D asset built with different sub-Object meshes, you can edit each of them individually by enabling the **Edit Reference** mode.



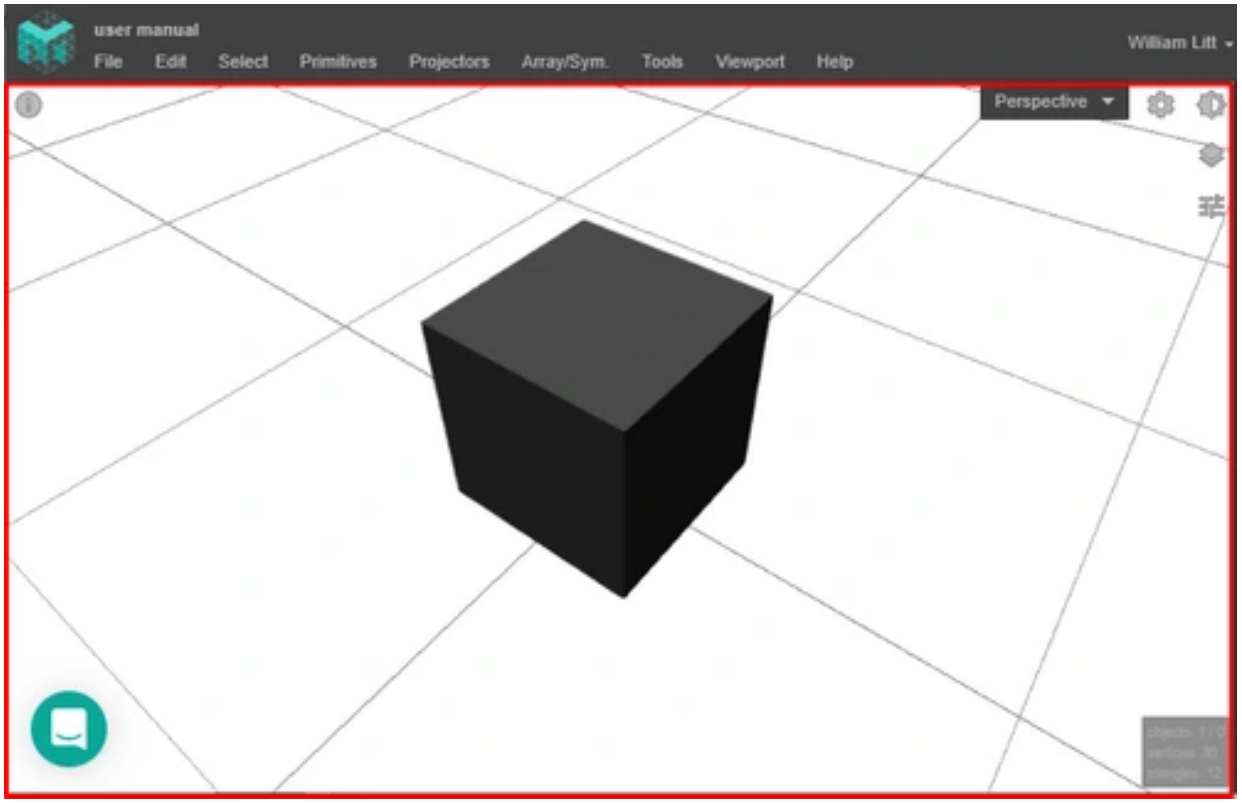
You cannot move / rotate / delete any sub-Object mesh individually, you'll have to import them already all set.

However, you can rename / hide them, and also edit their individual material.

If your mesh had UVs set pre-import, you can re-apply its Texture as a *Base Map*.

Move around the Viewport

The Viewport represents the whole visible area in which your Scene is displayed.



Viewport Overview

Pan

Hold left-click and drag to slide.

[Animated GIF: Pan]

Pan

Orbit

Hold right-click and drag to orbit your cursor. (On Mac: use two fingers while pressing on your touchpad.)

[Animated GIF: Orbit]

Orbit

Zoom-in & out

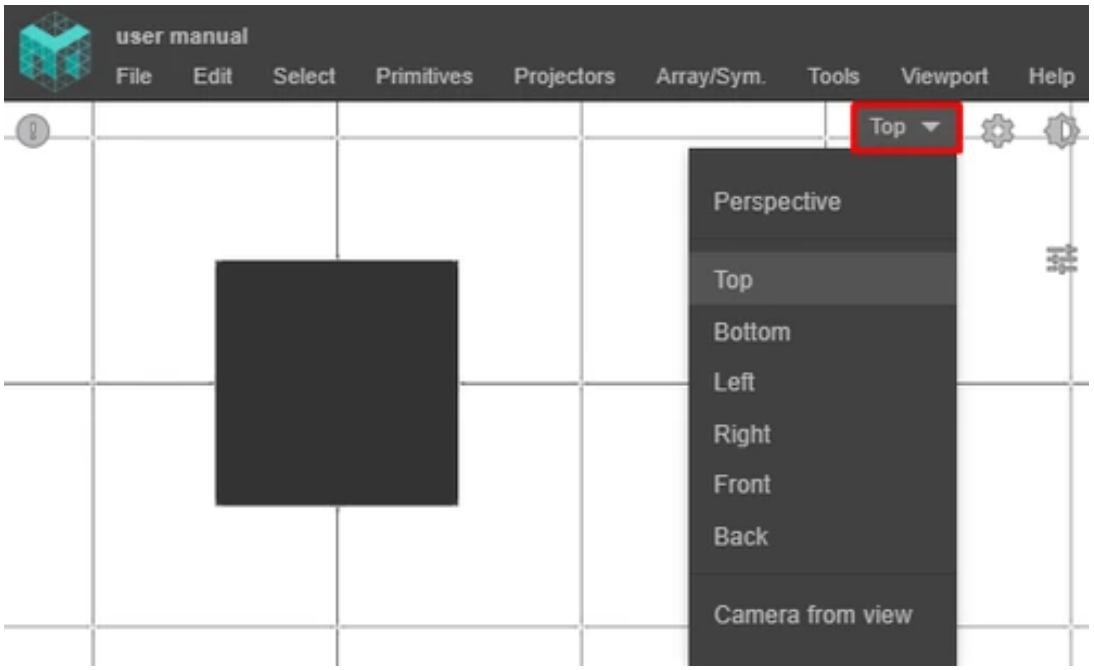
- Using your scroll wheel.
- Using two fingers on your touchpad.

- Zoom-extend by...
  - Double-clicking on the Object's body in the Viewport itself.
  - Or double-clicking on the Object's name in the Scene Objects list.

- Or select your Object, and go to TOP MENU > Viewport > Object Focus

Switch to another Point Of View (POV)

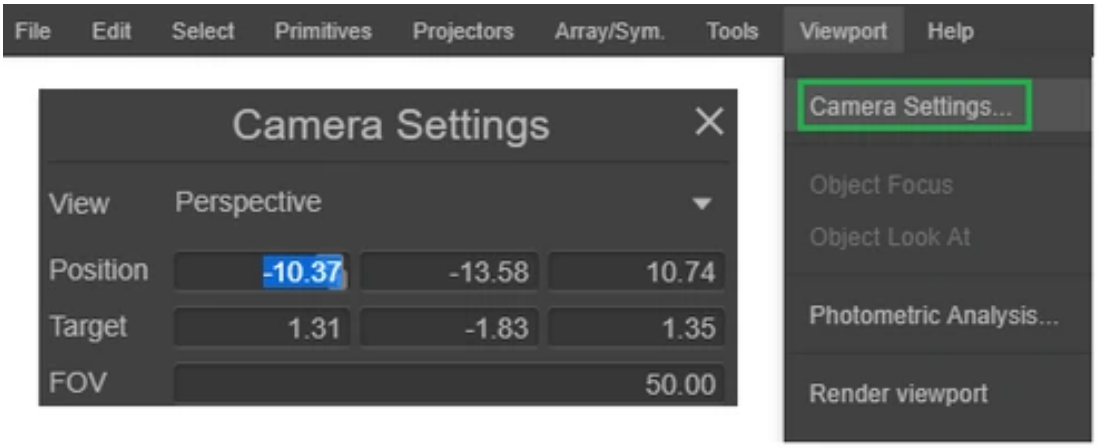
The **Perspective** dropdown menu allows to quickly look through our list of POVs.



Move viewport perspective overview

Camera from view = create a Camera from your current POV. This may come in handy as you may save a specific POV to come back to it later. All new Cameras will appear in the **Scene Objects** panel.

If needed, you can adjust very precisely the Position (and Target Point) of your Perspective POV (or any Orthographic Camera). Just go to **Camera Settings**.



Viewport camera settings

FOV = Zoom-in / out perfectly along the Target axis.

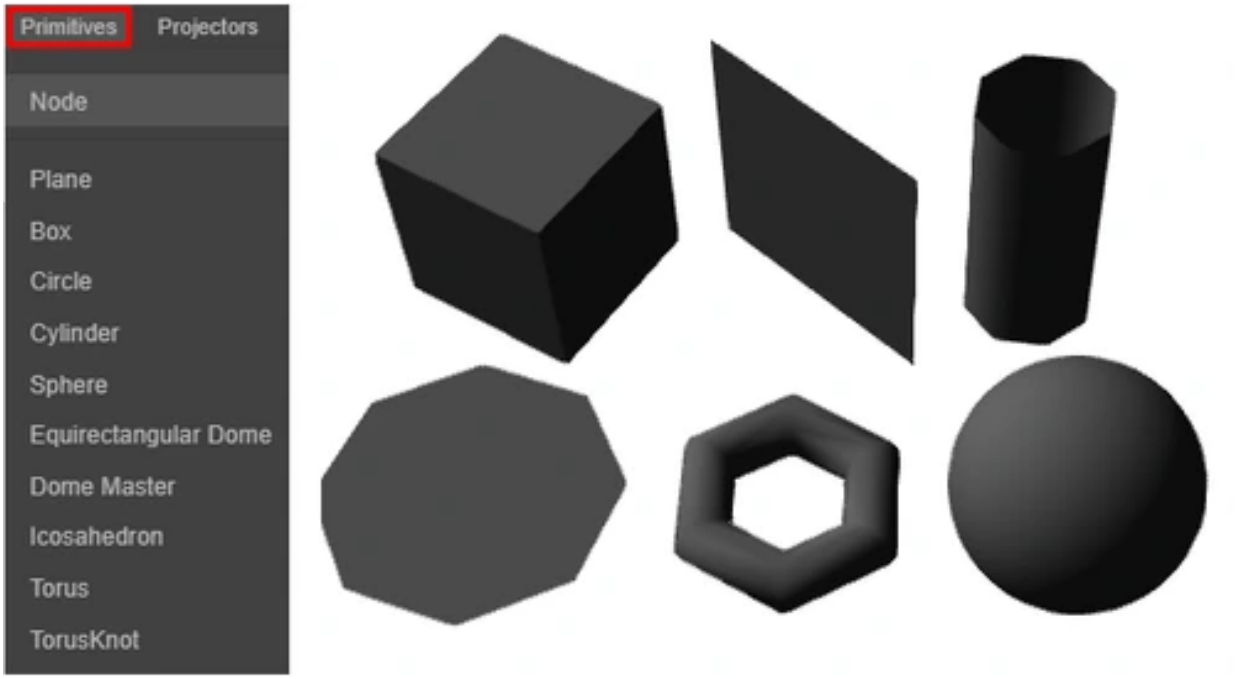
Primitives

Mapping Matter offers a quick & easy way to customize Parametric Objects. No need for advanced 3D skills.

Create a Primitive

Each type of **Primitive** has its own parameters to play with (Width, Height, Depth, Radius, Segments, etc).

TOP MENU > Primitives



Primitives overview

Customize a Primitive

Select it. Go to its **Properties**, and into the **GEOMETRY** section.

EXAMPLE 1: Build a Circular Wall with a Cylinder Primitive

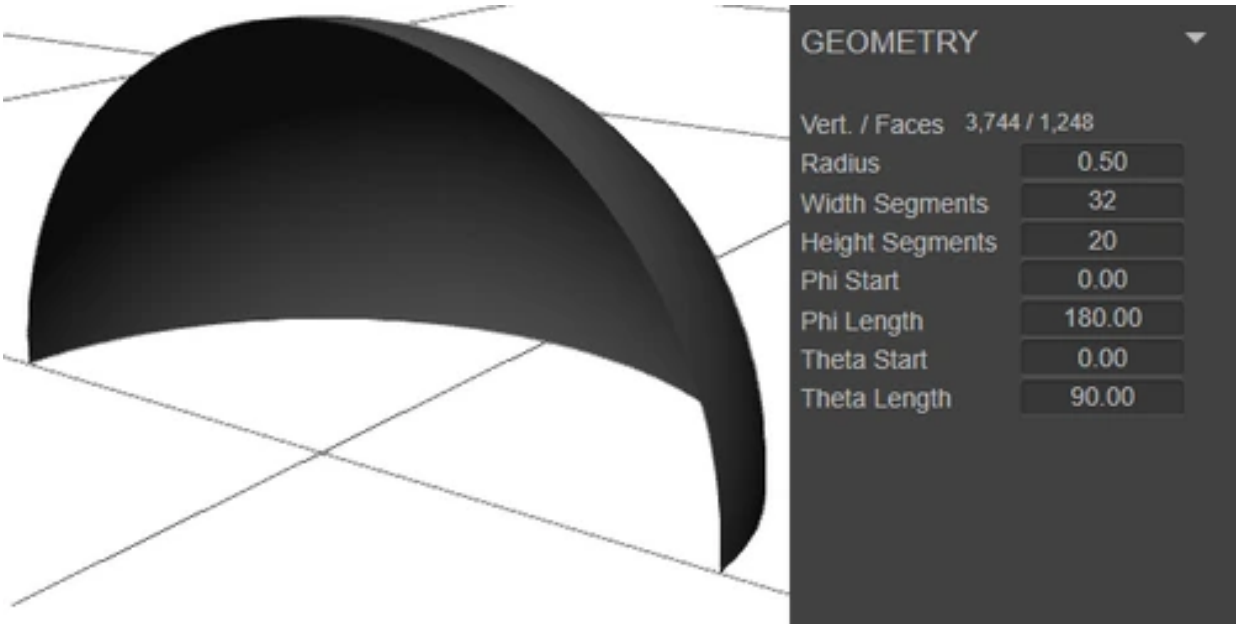
[Animated GIF: Primitive cyclinder circular wall]

Primitive cyclinder circular wall

Segments = higher values increase the resolution of the Primitive.

Theta = the angle of definition.

EXAMPLE 2: Build a semi-Dome with a Sphere Primitive



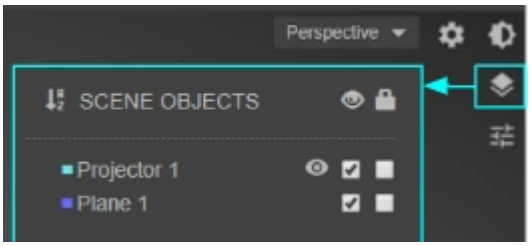
Primitive spheric half dome

Phi & Theta = the angles of definition for a Sphere.

Select / Sort / Rename / Delete / Hide / Lock an Object

Select

When you create an Object in your Scene, it will be listed in the **Scene Objects** panel.



Scene objects list

You can select an Object by clicking on its body in the Viewport, or through the Scene Objects list. Hold **Ctrl** to select many Objects.

> **Tip**
>
> If you have too many Objects in your Scene, try placing a group of Objects as Children of a Primitive Node. Learn about Parent / Child Hierarchy **here**.

Rename an Object

Select your Object in the **Scene Objects** panel.

Open the **Properties** panel, and edit its name in the textbox.

Tip

By default, all Objects will be sorted from A to Z. Click on the Scene Objects headline to sort them from Z to A. Using numbers like 1.1 / 1.2 / etc may come in handy if you have lots of Objects.

Scene objects headline

Delete an Object

Select it. And delete it...

by pressing Delete (PC) or Fn+Delete (Mac) on your keyboard,

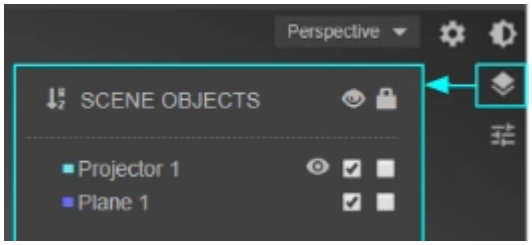
or through TOP MENU > Edit > Delete

Imported 3D Asset's sub-Objects cannot be deleted. However, you can hide them.

Hide / Show any Object of your Scene

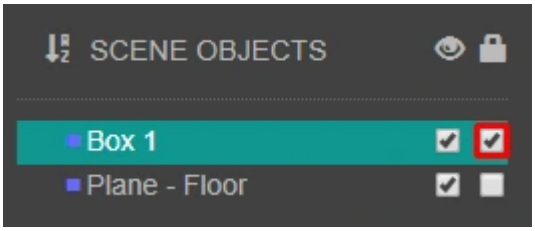
You will find this option in the **Scene Objects** panel.

Tick the box to make it visible.



Lock the properties of any Object in your Scene

Tick the box to lock it.

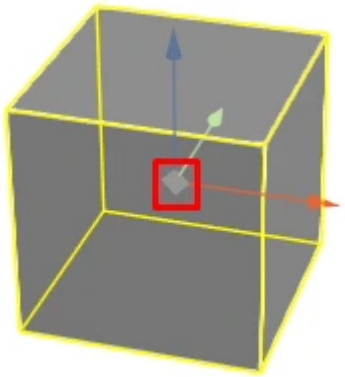


Scene object locked

> **Tip**
>
> Comes in pretty handy when you want to avoid selecting particular Objects while clicking around in the Viewport!

Move (or Duplicate) an Object

An Object's Position will be calculated from its Center Point, which appears as a diamond-shaped indicator.



Centre point

> **Tip**
>
> Hold **Ctrl** while clicking on different Objects to have them selected together. A new common Center Point will be calculated for the whole selection.

If you simply want to duplicate an Object, one way is to copy-paste it.

Select it.

Use Ctrl+C & Ctrl+V to have duplicated in any position.

Or go to TOP MENU > Edit > Clone to have it duplicated in the exact same position.

Using the Movement Gizmo in the Viewport

> **Definition**
>
> **Movement Gizmo** = visual 3D tool allowing you to move an Object in function of 3 axes (X, Y, Z).
>
> Three arrows point out of the Object's Center Point. By default, Red is for the X axis. Green for the Y axis. And Blue for the Z axis.

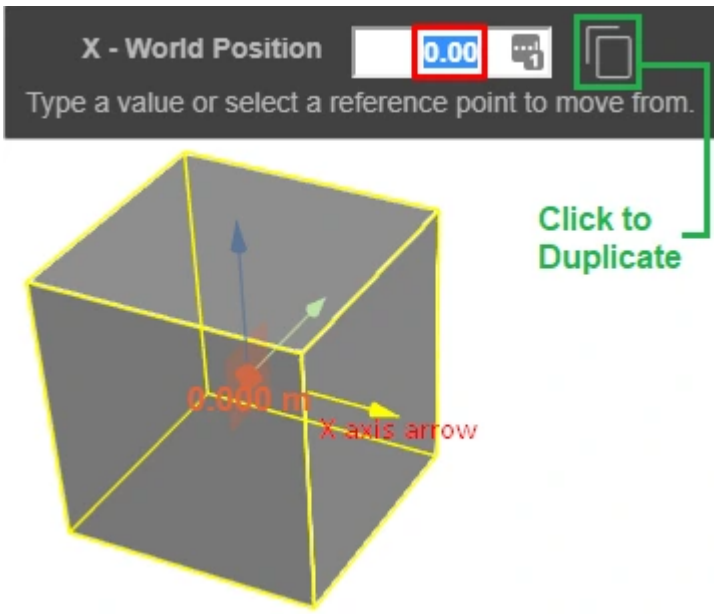
Hold-click on any axis vector and drag your cursor.

[Animated GIF: Move dup object axis]

Move dup object axis

> **Tip**
>
> You can also duplicate your Object by holding **Ctrl** while moving it.

Or click once on any axis vector, type a **World Position** value in the input box, and press **Enter**.



Move duplicate axis value

> **Tip**
>
> You can also move it away from its current position by inputting +X (positively) or +-X (negatively). E.g. to move it by -6 units on a given axis, set +-6 and press **Enter**.

Using coordinates in the properties panel

Hold-click on the input box of any coordinate and drag your cursor.

[Animated GIF: Move duplicate axis drag input box]

Move duplicate axis drag input box

Or type-in a specific value and press **Enter**

Using two reference points

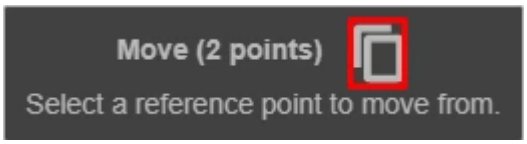
One to move from + one to move to.

[Animated GIF: Move from to - select object]

Move from to - select object

Select an Object, and click on its Center Point.

If you want to duplicate it, just click here.



Move duplicate ref duplicate

Click on a reference point to move from, and then another to move to.

Use the SNAP Tool to select a reference point more accurately in your Scene. This window will pop up automatically.

When neither Bounding Box or Vertex are enabled, the Red dot will appear at any intersection between the surface and your cursor.

[Animated GIF: Scene object locked]

*Scene object locked_*

> **Tip**
>
> You can add a constraint of movement on any given axis. Your Object will move (or be duplicated), but only along the chosen axis.
>
> Select your Object. Click on its Center Point. Click on the axis of constraint. Select a Point to move from, and another to move to.
>
> *[Animated GIF: Move duplicate axis constraint]*
>
> *Move duplicate axis constraint*

Move an Object A in orbit of an Object B

Here's a tutorial on how to set up a Pivot Point.

Rotate an Object

Select an Object. (Or many, holding **Ctrl**)

Press **R** on your keyboard to see the Rotation Gizmo.

Hold-click on any axis curve, and drag your cursor to adjust.

[Animated GIF: Rotate basic]

Rotate basic

Or click once on any axis curve, and type in a specific angle rotation value.

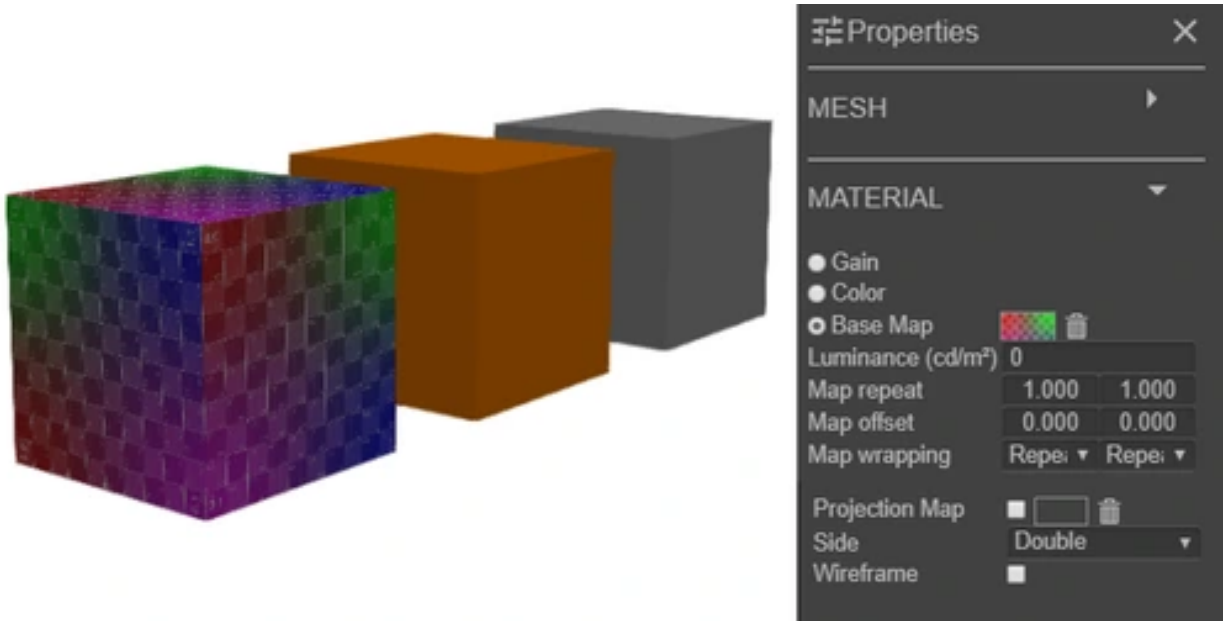
Rotate box"

Press **M** to get back to the Movement Gizmo.

> ⚠ **Warning**
>
> You have to be aware of a potential Gimbal Lock issue.
>
> *[Animated GIF: Rotation gimbal lockt]*
>
> Here is a definition of a Gimbal Lock issue: “When the pitch (green) and yaw (magenta) gimbals become aligned, changes to roll (blue) and yaw apply the same rotation to the airplane.” (Credits)

Material

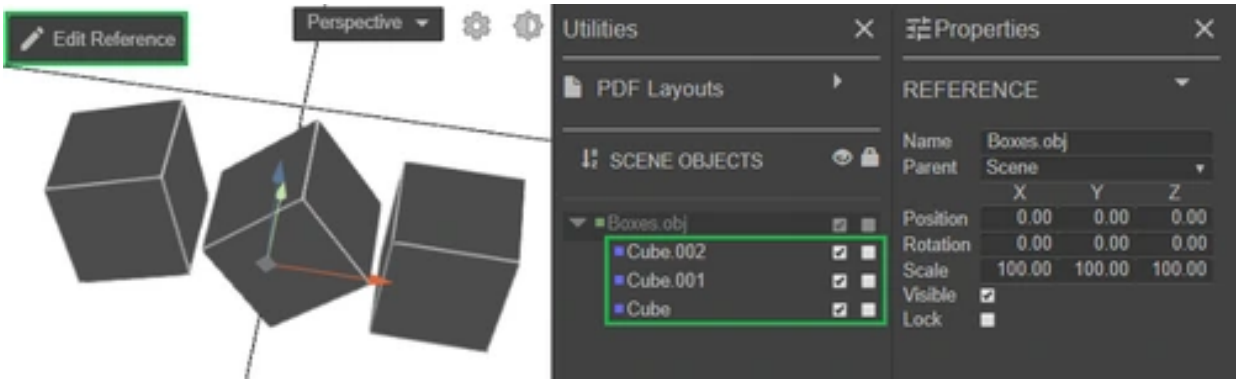
The **Material** of an Object refers to the characteristics of its surface. This has an impact on its appearance, reflectivity, and texture mapping.



Material overview

Select your Object.

You can also select an individual (sub-Object) mesh from an Imported 3D Asset. Just select your Asset, click on **Edit Reference**, and select any mesh in the **Scene Objects** list.



Go to its **Properties**, in the **MATERIAL** section.

Apply Gain

Gain = The gain ratio represents how much light is reflected by any given surface, compared to the light reflected from a standard white (magnesium oxide) board. A ratio of 1.0 will reflect the same amount of light as that of white board. Whereas a gray board with a 0.5 rating would reflect only 50% of the Light falling on.

This has an incidence in the Photometric Analysis mode, on the **Luminance** values

Apply Color

The brighter the selected color, the higher its reflectivity.

This has an incidence in the Photometric Analysis mode, on the **Luminance** values.

> **Tip**
>
> You can also manually adjust the Luminance setting below, to enhance its intrinsic brightness.
>
> Usually best to keep it at 0, unless you want to simulate a Screen / LED wall.
>
> >

Apply Base Map

The **Base Map** tool allows you to map (or “wrap”) an Image (or Video) onto the surface of a 3D mesh Object.

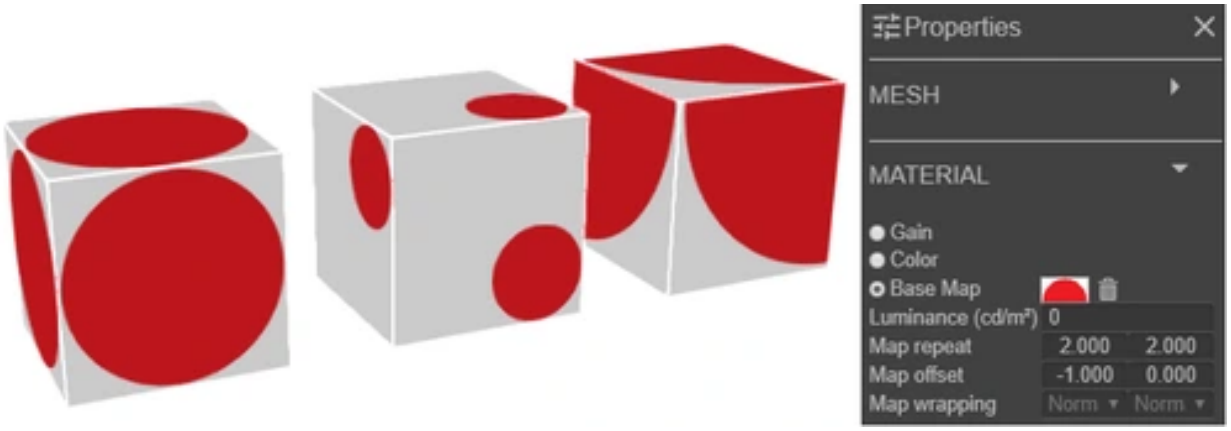
> **Warning**
>
> This will only work with **Primitives**, and imported 3D mesh Objects which already had their UVs set. You can set UVs in any good CAD software (e.g. Blender). To learn more, search for tutorials about “UV unwrapping”.

Go to **Base Map** and click in the framebox to open the **Texture Library**.

Material base map open texture

To learn how to use the Texture Library, click here.

Adjust the placement of your Texture with the **Map repeat** and **Map offset** ratios.



Material repeat offset

After you’ve selected an Image, you can remove it by clicking on the Trash icon.

> **Tip**
>
> You can also manually adjust the **Luminance** setting below, to enhance its intrinsic brightness.
>
> Usually best to keep it at 0, unless you want to simulate a Screen / LED wall.

*Material luminance_*

Apply a Projection Map (Projection Texture)

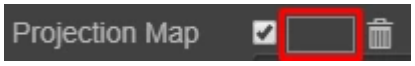
The Projection Map tool allows you to map (or “wrap”) an Image (or Video) onto the surface of a 3D mesh Object.

> ⚠ **Warning**
>
> This will only work with **Primitives**, and imported 3D mesh Objects which already had their UVs set. You can set UVs in any good CAD software (e.g. Blender). To learn more, search for tutorials about “UV unwrapping”.

The **Base Map** represents the intrinsic appearance of an Object.

Whereas the **Projection Map** represents a projected Texture onto the surface of an Object. By default, it won’t be visible in the Viewport. It will have to be “revealed”. Either by a Projector in Reverse Mapping mode, or using the Projection Texture tool.

Go to **Projection Map** and click in the framebox to open the **Texture Library**.



Projection map framebox

To learn how to use the Texture Library, click here

After you’ve selected an Image, you can remove it by clicking on the Trash icon.

Use Side to make it transparent

Warning

First, make sure **Global Material Override** is disabled.

Go to **Viewport Settings**, and tick off the **Double Side** option.

Also note that it will only work with 1-face meshes (e.g. it won’t work with a double wall).

Select an Object. Go to its **Properties**, and to the **MATERIAL** section.

[Animated GIF: Use Side to make it transparent]

*Use Side to make it transparent_*

Back = opacity prevents us to see through the surface.

Front = we can see through the surface.

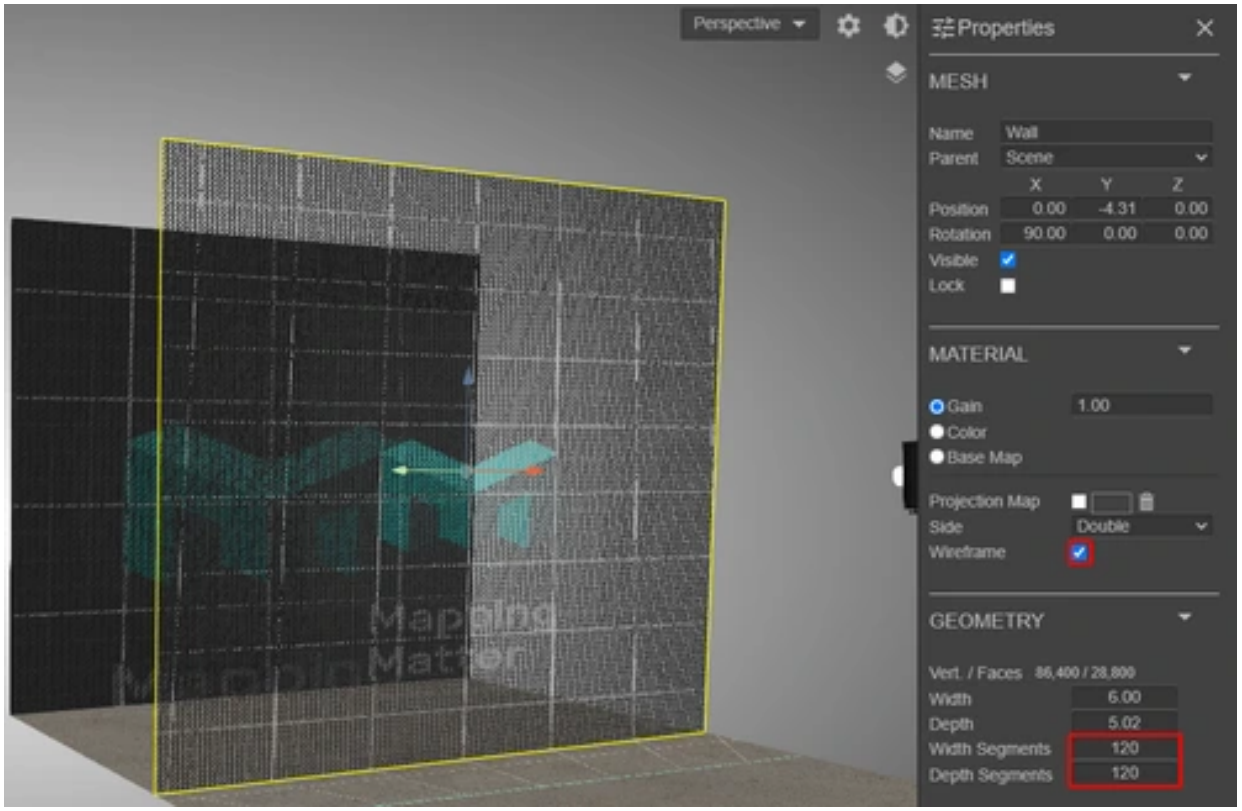
Double = what appears on one side also appears on the other

Use Wireframe to make it transparent

Wireframe =visual representation of a Mesh Object, only showing its vertices

> **Tip**
>
> Use a ***Circle Primitive** as a reference to measure any angle in your Scene, setting **360 Segments** and playing with its **Theta**. You can use the **Snap tool** to easily pin it where needed.
>
> *[Animated GIF: Material wireframe angle]*
>
> *Material wireframe angle*

> **Tip**
>
> You can also use **Wireframe** to create a “Transparent” Gauze / Scrim Material.



Material gauze

Parent Child Hierarchy

[Animated GIF: Parent - child]

Parent - child

The **Position** of an Object is calculated in function of the Center Point of its **Parent** Object.

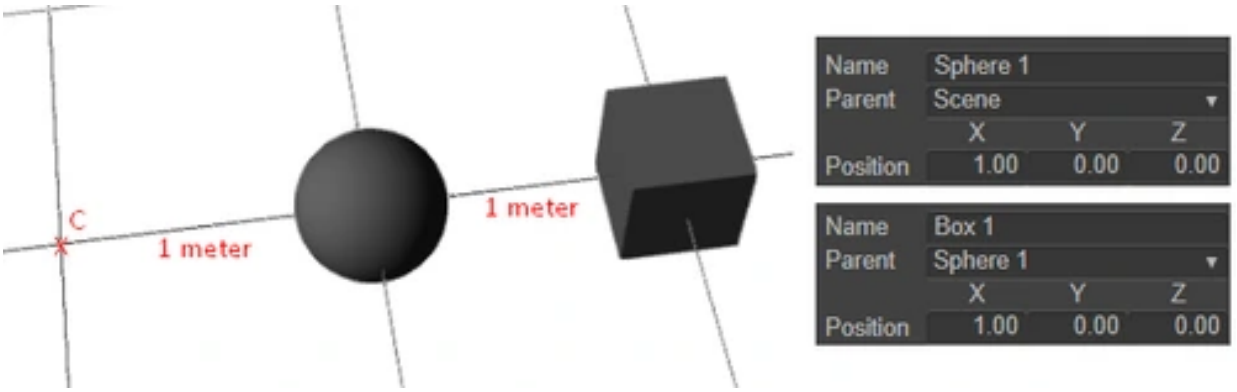
By default, each new Object is the **Child** of the Scene itself.

> **Tip**
>
> Here's how to offset the Center Point of the whole Scene. This may be useful when you're working on an imported Geometry which isn't centered already.

To change the Hierarchy between Objects :

Select your Object, go to its **Properties**, and to the **Parent** dropdown menu.

Illustration



Here both Sphere 1 and Box 1 have the coordinates (X=1, Y=0, Z=0). But Sphere 1 is positioned in function of its **Parent** the Scene (C), 1 meter away on the X axis. And Box 1 is 1 meter away from its Parent Sphere 1.

Arrays and Symmetries

These tools offer an easy, quick, and accurate way of creating large Object / Projector layouts in your Scene.

Definitions

Array = an immaterial Object which duplicates its Children into dummy Clones, either following a linear or a polar sequence.

Symmetry = an immaterial Object which duplicates its Children into dummy Clones, following a symmetric sequence.

Dummy = fake, visual only, not listed in Scene Objects, with no individual Propertie

Create a Linear Array

[Animated GIF: Parent - child hierarchy]

Parent - child hierarchy

TOP MENU : Array/Sym. > Array

The Array will appear as an Object, Child of your Scene, at (0, 0, 0).

Select the Object you want to lay out.

In the **Properties** panel, make the Object a **Child of the Array**.

Customize the Linear Array parameters.

Number = the total amount of Objects in the Array = original + dummies

Separation = the distance between each Object in the Linear Array

Create a Polar Array

[Animated GIF: Parent - child hierarchy]

Parent - child hierarchy

TOP MENU : Array/Sym. > Array Polar

The Array will appear as an Object, Child of your Scene, at (0, 0, 0).

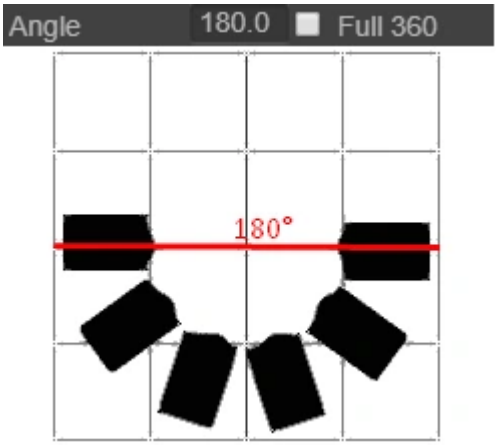
Select the Object you want to lay out.

In the **Properties** panel, make the Object a **Child of the Array**.

Customize the Polar Array parameters.

Number = the total amount of Objects in the Array = original + dummies

Angle = the angle of distribution for all Objects in a Polar Array.



Array polar angle

By default, a Full 360° angle distributes all Objects on a whole circle. But with a 180° input value, the distribution is limited on a 180° angle (half a circle). All Objects are automatically set equidistant to each other.

> **Tip**
>
> Use the Side tool to “see through” any Object in your Scene

Create a Symmetry

[Animated GIF: Array symmetry]

Array symmetry

TOP MENU : Array/Sym. > Symmetry

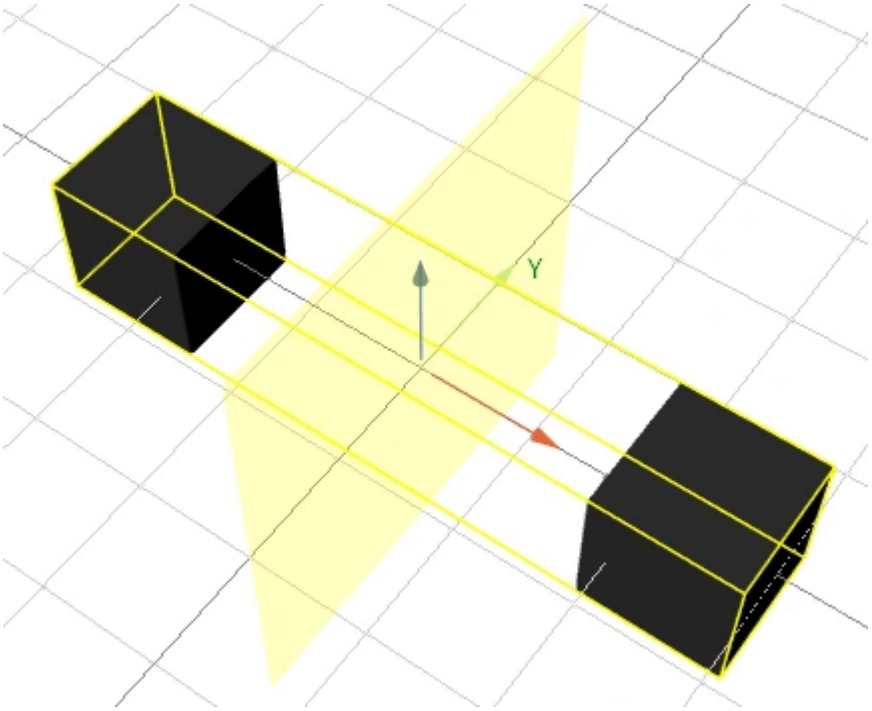
The Symmetry will appear as an Object, Child of your Scene, at (0, 0, 0).

Select the Object you want to lay out.

In the **Properties** panel, make the Object a **Child of the Symmetry**.

Now our Object has a symmetric dummy along the X axis of our Symmetry.

The axis of symmetry is the Y axis. This is illustrated by a transparent yellow plane, which appears when the Symmetry Object is selected.



Array symmetry plane reference

All modifications to our Object will be replicated immediately to its dummy.

> **Tip**
>
> You can also make an Array the Child of a Symmetry, etc.

Convert your dummy Objects into regular Objects

This will allow you to make individual modifications to your ex-dummy Objects.

You'll find each of them in the **Scene Objects** panel.

Select your original Object.

Go to the Properties panel.

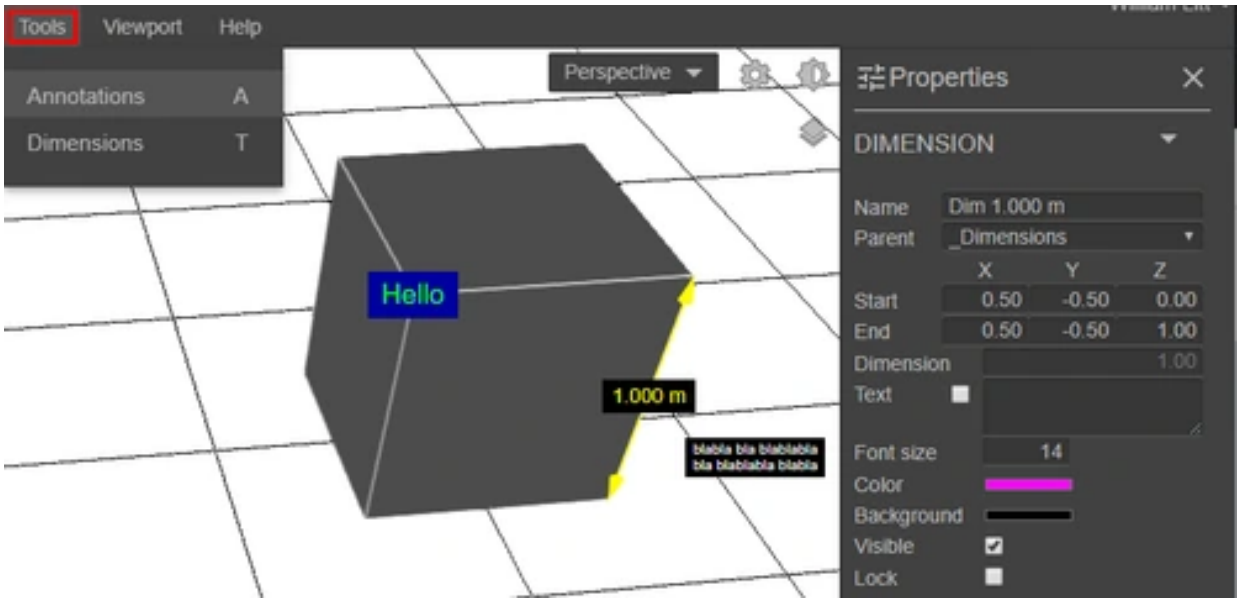
In the **Array (or Symmetry)** section, hit the **Bake** command.

Array symmetry bake

Annotations and Dimensions

The **Annotations** tool allows you to create a bodyless Object holding Text.

While **Dimensions** allows you to create a bodyless Object measuring the distance between two given points the Scene.



Create an Annotation or Dimension Object in your Scene

TOP MENU > Tools

> **Tip**
>
> You can also use the keyboards shortcuts **A** (Annotation) and **T** (Dimension). Press **?** for all keyboard shortcuts.

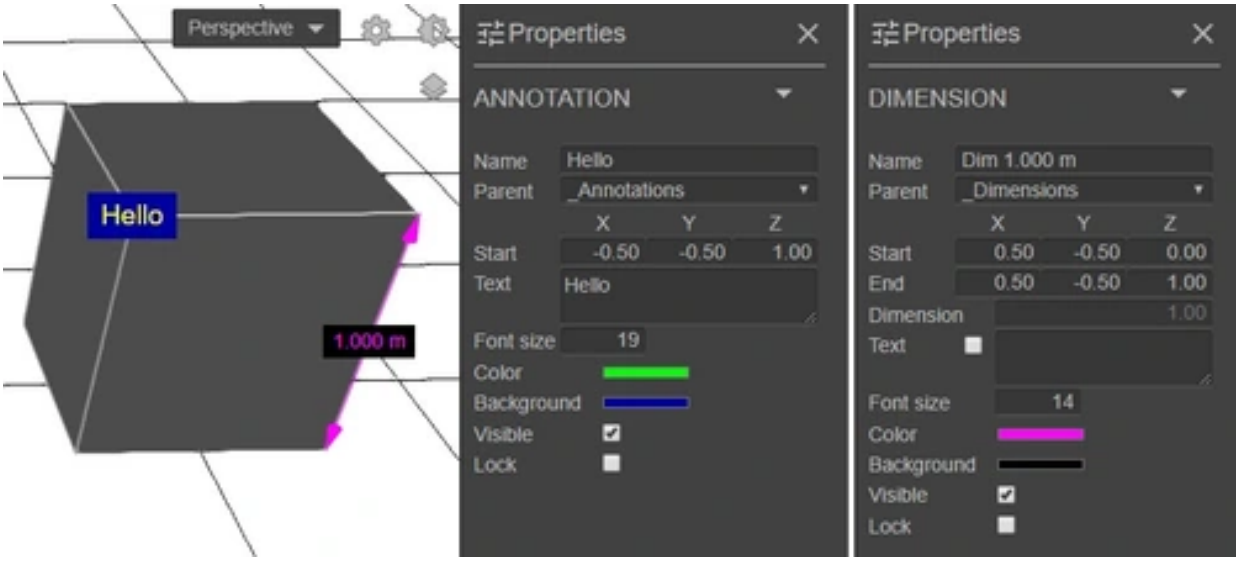
Select 1 or 2 Point(s) in your Scene.

1 Point only for Annotations. And 2 Points, from Start to End, for Dimensions.

> **Tip**
>
> Use the SNAP Tool to select a reference point more accurately in your Scene. This window will pop up automatically.
>
> When neither Bounding Box or Vertex are enabled, the Red dot will appear at any intersection between the surface and your cursor.
>
> *[Animated GIF: Snap tool]*

Edit an Annotation or Dimension

- Select the Object, from the Scene or the **Scene Objects** panel.
- Open the Object's **Properties** panel.

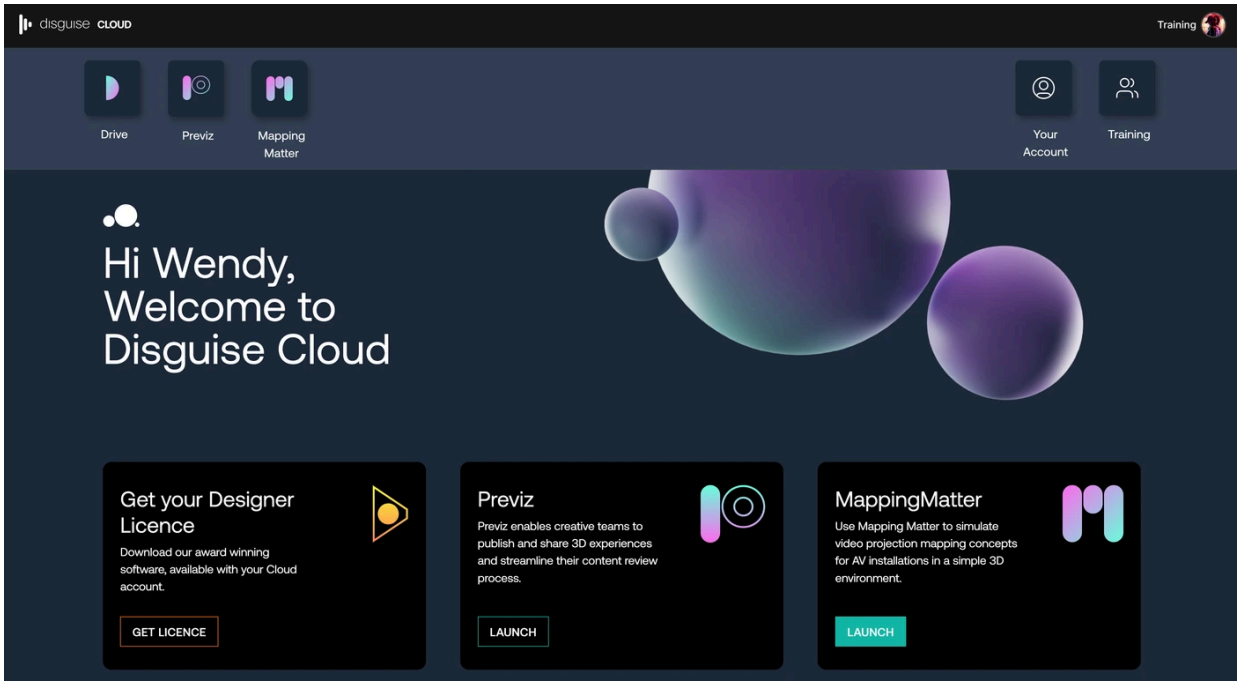


Annotations & dimensions properties

Introduction (legacy)

> **Note**
>
> This page documents the **legacy** edition of Mapping Matter, kept for users who have not yet migrated. The current Mapping Matter docs begin at Introduction.

Introduction



How it works

Data

This platform is web-based. Nothing to install / download / update / store. All of our Data is stored on the Amazon Web Services Cloud.

Supported Browser

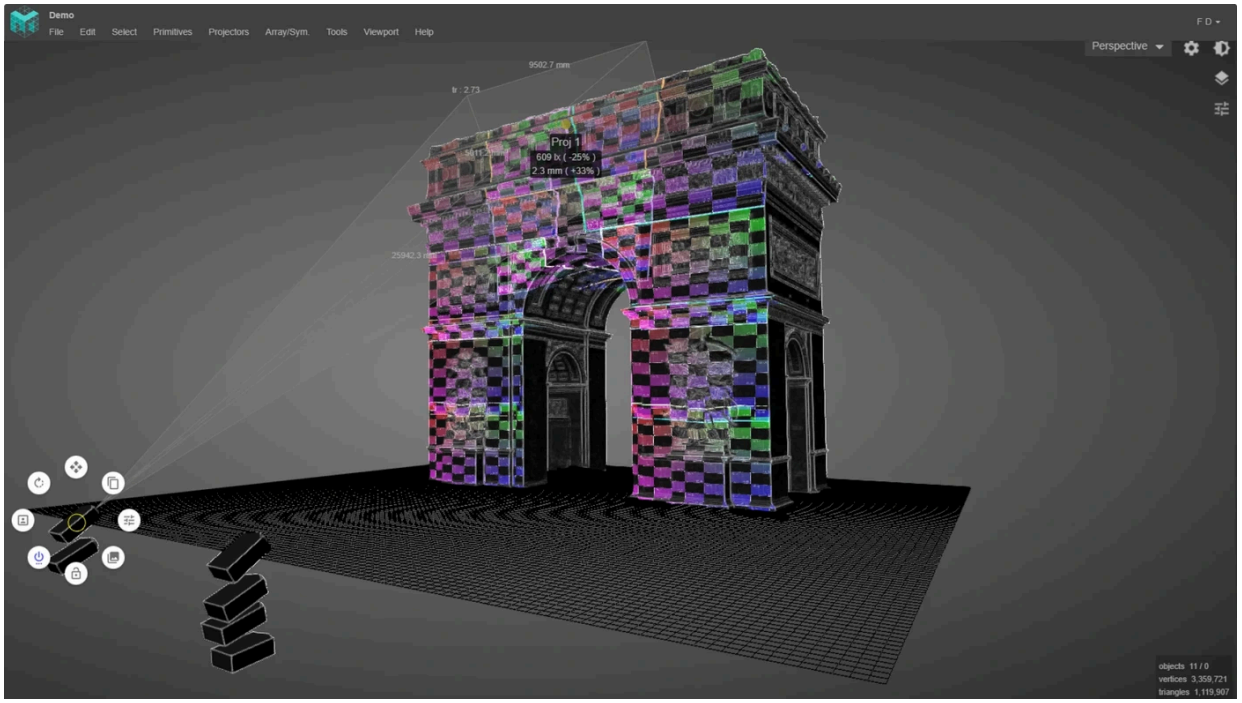
We only support Google Chrome.

OS

The platform works on both Mac and PC.

API

We use WebGL.



Who is Mapping Matter for/not for?

Who is it for?

Mapping Matter is a simulation tool designed for audio visual professionals such as Projectionnists, Technical Designers, Set Designers, Content Creators, Sales Team Members.

It will help them creating Projection Specs and Recommendations for large-scale projects (Shows, Permanent Installations, Building Projection Mapping, etc).

Mapping Matter provides fast, easy, enjoyable and highly comprehensible solutions to:

- Confirm budget estimates,
- Iterate on complex Projector placements,
- Work out Contrast Ratios (Photometric Analysis),
- Preview still Images and small Video clips on 3D Objects,
- See Projection Shadows on the Set,
- Measure Pixel Density (down to a single pixel),
- Share Client / Team Presentations,
- Define Media Server Output needs (with Convergence Simulation).

Who is it not for?

Mapping Matter is not intended for Content Creation and/or Video Playback. However it is possible to preview still Images and small .mp4 Clips on 3D Objects.

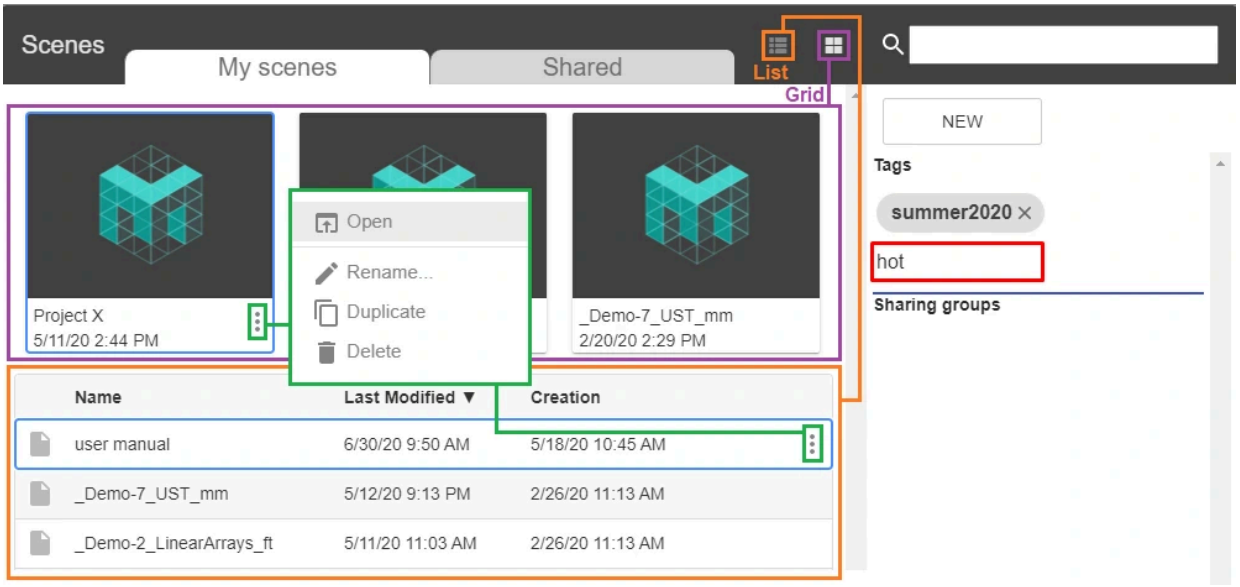
Libraries (legacy)

> **Note**
>
> This page documents the **legacy** edition of Mapping Matter, kept for users who have not yet migrated. The current Mapping Matter docs begin at Introduction.

Scene Library

This is where you'll manage all your Scenes. You need to be already inside any Scene to access it:

TOP MENU > File > Open



Here you can create / open / rename / duplicate / delete any Scene.

You can change the display of all Scenes from Grid to List.

You can sort them alphabetically / most recently used / by creation date.

Here's how to Share a Scene.

Click once only on any Scene to select it. Write any Tag and press Enter to save it.

Use Tags not Folders

There are no sub-folders. But you can use Tags to easily organize your Scenes and later find them using the integrated Search engine.

3D Asset Library

This is where you'll manage all the 3D Assets to import into your Scene.

TOP MENU > File > Import 3D mesh Objects

> ⚠ **Warning**
>
> For all updates to be effective in your Scene, you'll need to refresh your Browser.

Select and Import a 3D Asset

To find an asset in the Library, use the Scroll bar or the Search engine.

To import a new file, click on IMPORT NEW.

Supported Formats = the best is .FBX(binary), .OBJ and .DAE work fine.

Meshes = a single asset may contain many meshes. They will be accessible as sub-Objects in the Scene Objects panel.

Max individual asset size = 100MB. You can load a bigger asset but only locally : it won't be saved online, and will need to be re-imported each time you open your Scene. To do so, hold Alt while clicking on Import 3D Mesh Objects.

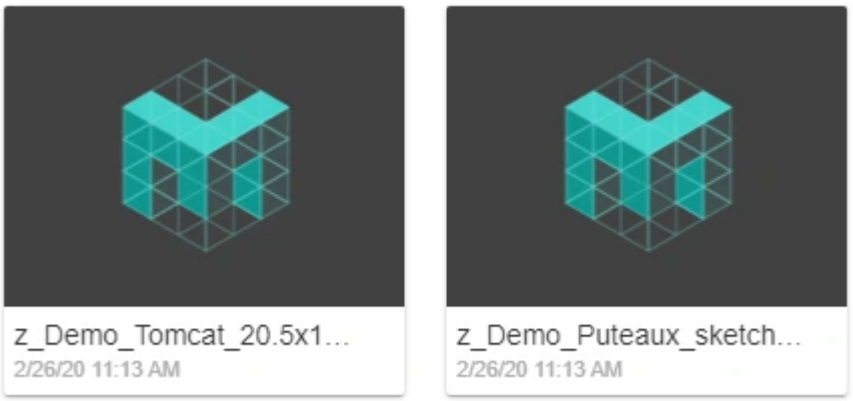
Storage = all imported files will be stored in the My Assets Library.

> 🚀 **Tip**
>
> Learn how to share a 3D Asset here.

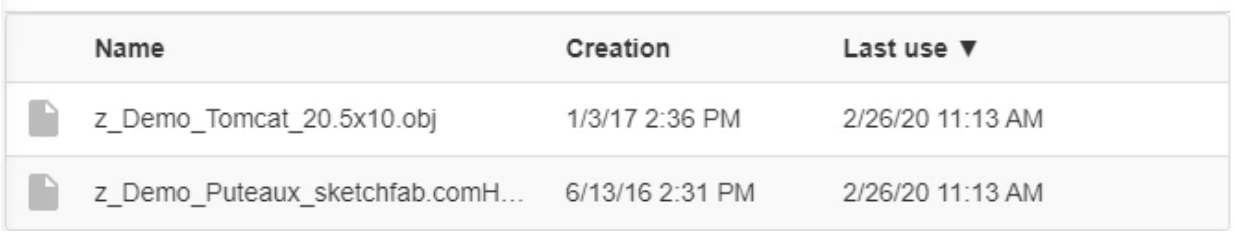
Organize your 3D Assets

Display Modes: try switching it from Grid to List by clicking there.

Here's what the **Grid Mode** looks :



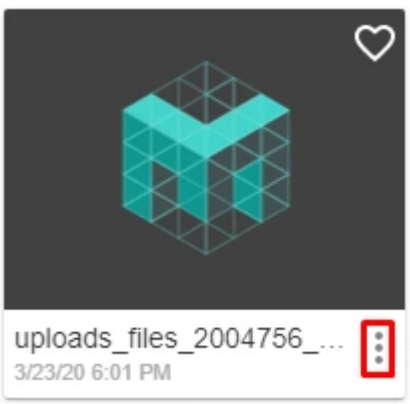
And here's what the **List Mode** looks like :



Name	Creation	Last use ▼
z_Demo_Tomcat_20.5x10.obj	1/3/17 2:36 PM	2/26/20 11:13 AM
z_Demo_Puteaux_sketchfab.comH...	6/13/16 2:31 PM	2/26/20 11:13 AM

Rename / Delete any asset by clicking here.

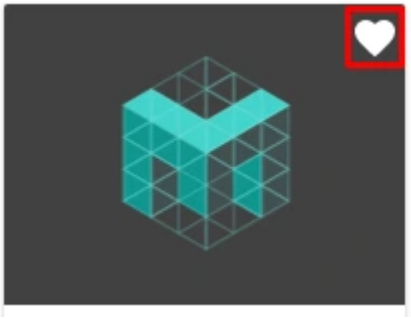
In the **Grid Mode** :



Or in the **List Mode** :

Favorites: click on an asset's Heart symbol to tag it as **Favorite**.

In the **Grid Mode** :



Or in the **List Mode** :

And activate **Favorite Only** to show all tagged assets:

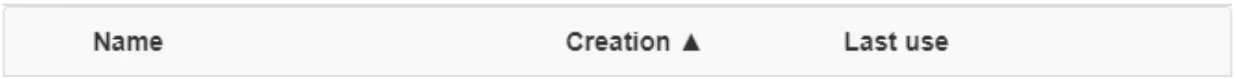
Sort your files.

In the **Grid Mode**, by most recently used, or alphabetical order.

Click on the Filter icon.

In the **List Mode** : by date of creation, last used, or alphabetically.

Click on the category title.



3D Asset Optimization

Mapping Matter is not primarily designed for performance. If you work with heavy / complex 3D Assets, we strongly recommend to optimize your files before import. Otherwise, the Browser may crash (especially for computers with small GPU).

Here are a few tips. We'll use Blender, but this is easily transposable to any advanced 3D modeling software.

Delete all unnecessary meshes

In Blender, switch to **Edit Mode** to delete.

Delete all unnecessary vertices

In Blender, go to Edit Mode > Mesh > Clean Up > Delete Loose. Or select & delete them manually.

Merge some (or all) your meshes

Select them, holding Shift. Press Ctrl + J to get them joint.

Export in .FBX(binary) from your 3D software to Mapping Matter

.FBX(binary) will load much faster in Mapping Matter, and often be lighter. .OBJ / .DAE will also work fine.

File Size : max 100mb. Learn here how to upload bigger files (locally only).

Projector Library

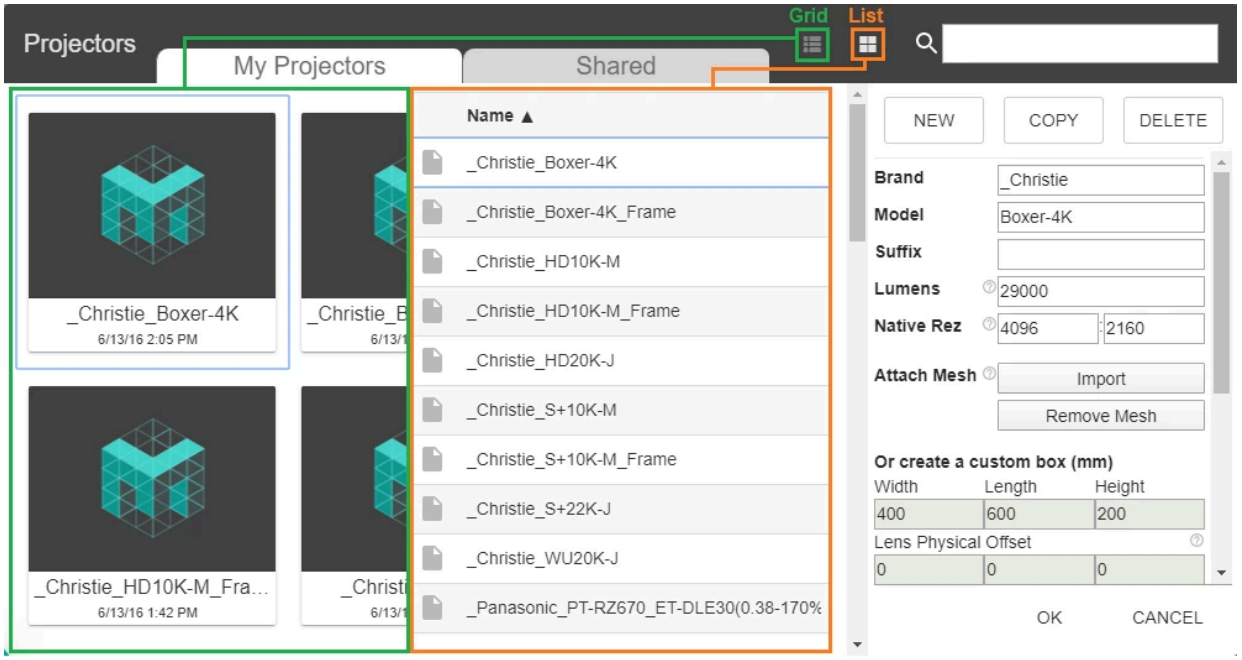
Mapping Matter is not a Projector Database. However, we provide you with a few demo Projectors.

Here you'll learn how to create and manage your own Projector Library.

> ⚠ **Warning**
>
> Refresh your Browser to see Projector Library updates applied in your Scene.

Manage all pre-existing Projectors

TOP MENU : Projectors > Projector



Info

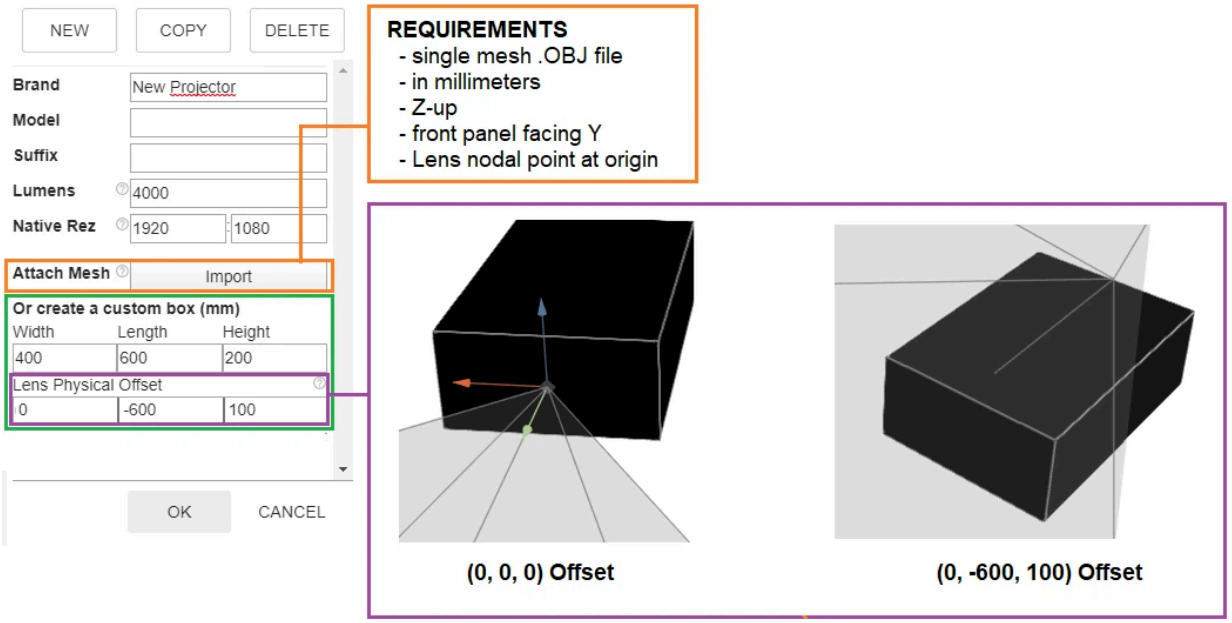
- You can display all Projectors in two modes: **Grid** or **List**.
- Sort them by Name or Creation Date, only in the **List** Display mode.
- Use the Search engine to find Projectors quicker.
- Use Tags to find them quicker in the Search engine.

Add a custom Projector to your Library

TOP MENU : Projectors > Projector

Click on **New**. And define its Specs in the section below.

For the Projector's body, you can either Attach Mesh or Create a custom box.



> **Warning**
>
> If you still don't see your mesh despite exporting it in millimeters, you may have to multiply its scale (before exporting it from your C4D software). Sometimes, the file may be read as way tinier than it is. Try multiplying its scale by 100x or 1000x.

After importing your file, try refreshing your browser and/or clearing your cache.

> **Tip**
>
> For odd Lens configurations (Ultra Short Throw / Mirror), check this article.

Finally, click on OK to create your Projector in the Scene.

Your new Projector and its Specs will be saved in your Projector Library.

Texture Library

The Texture Library contains your collection of Image and Video files.

This will be used to map an Object's *Material*, define a *Projector Image*, or do *Projective Texturing*.

> **Warning**
>
> For all updates to be effective in your Scene, you'll need to refresh your Browser.

Select and Import an Image / Video

To find a file in the Library, use the Scroll bar or the Search engine.

To import a new file, click on **Import New**

Supported Formats = JPEG / WEBP / GIF / PNG / BMP / ICO / MP4 / WEBM / OGG

Maximum file size = 50MB

All imported files will be stored in your Texture Library.

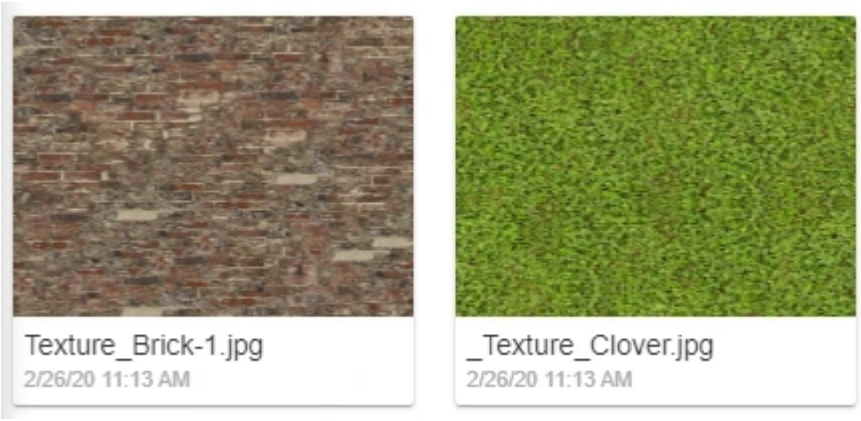
> **Tip**
>
> Learn how to share a Texture here.

Organize your Texture Library

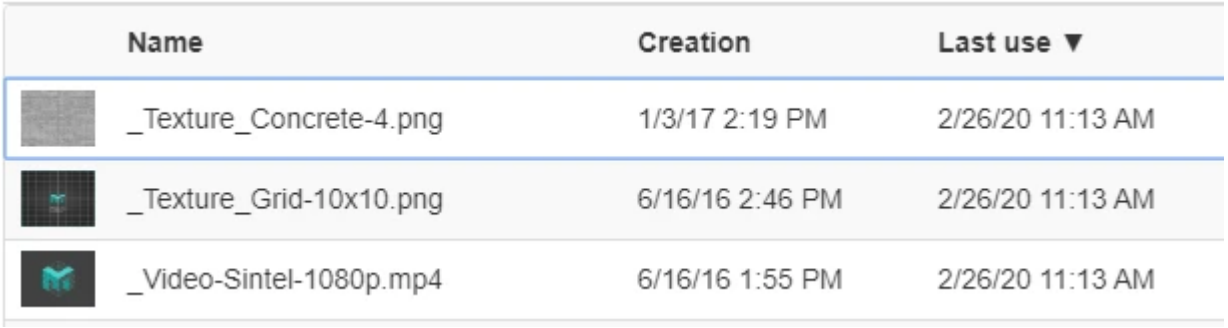
You can use different tools to organize your Texture Library.

Display Modes: try switching it from **Grid** to **List** by clicking on the corresponding icons.

Here's what the **Grid Mode** looks :

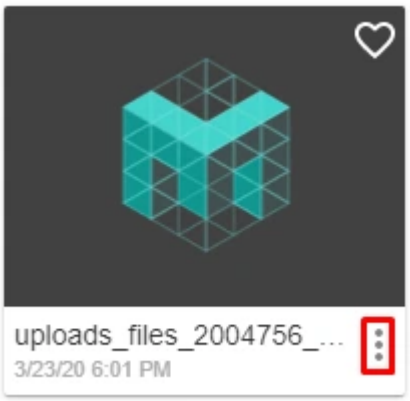


And here's what the **List Mode** looks like :



Rename / Delete

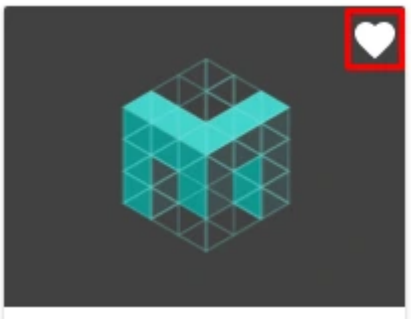
In the **Grid Mode**:



Or in the **List Mode** :

Favorites

In the **Grid Mode**:



Or in the **List Mode** :

	Name	Creation	Last use ▼
	_Texture_Concrete-4.png	1/3/17 2:19 PM	2/26/20 11:13 AM
	_Texture_Grid-10x10.png	6/16/16 2:46 PM	2/26/20 11:13 AM
	_Video-Sintel-1080p.mp4	6/16/16 1:55 PM	2/26/20 11:13 AM

And activate **Favorite Only** to show all tagged files :

Sort your files.

In the **Grid Mode**, by most recently used, or alphabetical order.

Click on the **Filter** icon.

In the **List Mode** : by date of creation, last used, or alphabetically.

Click on the category title.

Name	Creation ▲	Last use

My Account (legacy)

> **Note**

If you want to get (or modify) a Subscription, or obtain any information (e.g. expiry date), please reach out to support@disguise.one.

Print and Export (legacy)

> **Note**
>
> This page documents the **legacy** edition of Mapping Matter, kept for users who have not yet migrated. The current Mapping Matter docs begin at Introduction.

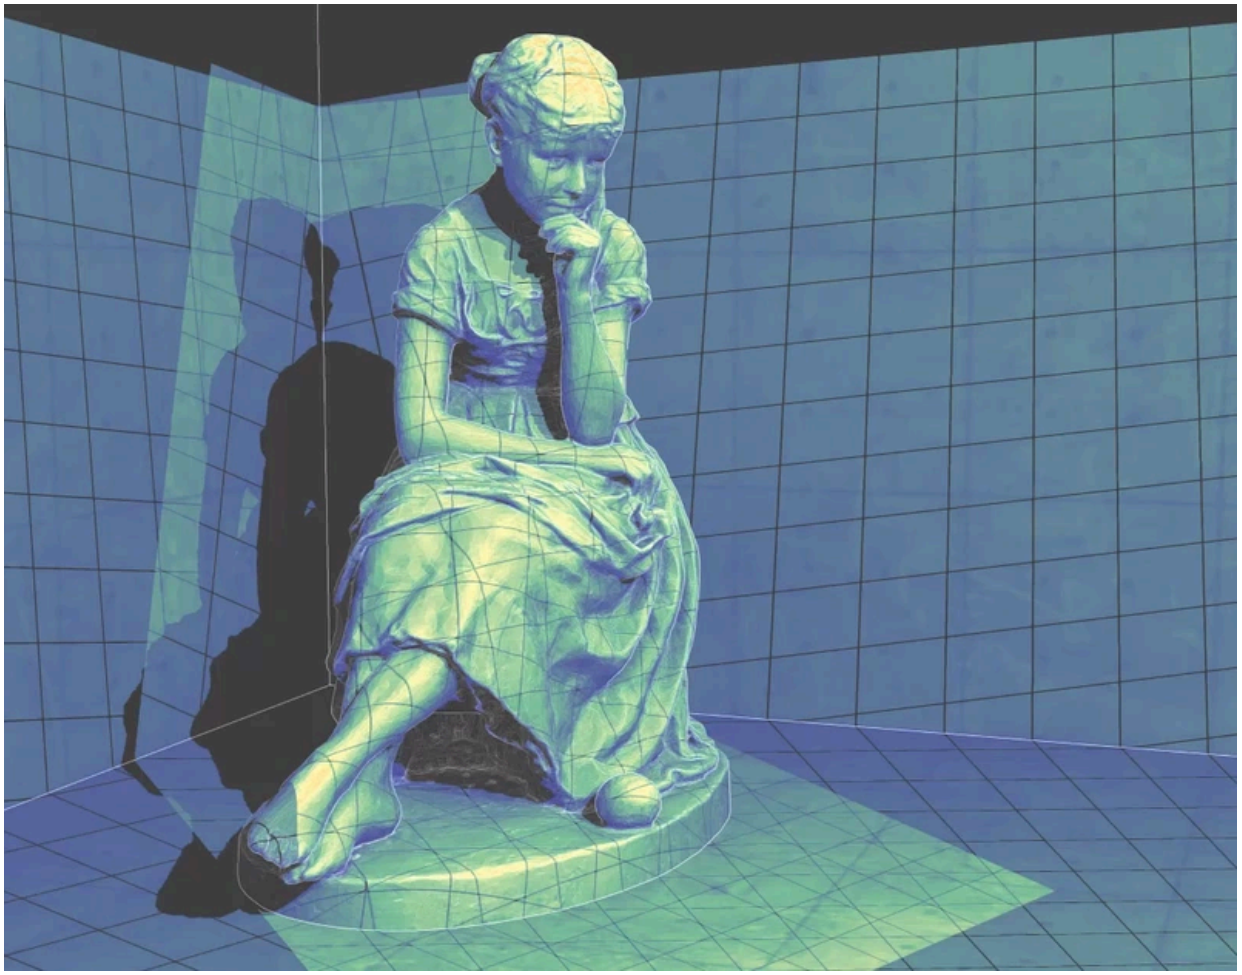
Snapshots / PDF Layouts

Save a Snapshot from your Scene

Adjust your Perspective in the Viewport.

TOP MENU > Viewport > Render Viewport

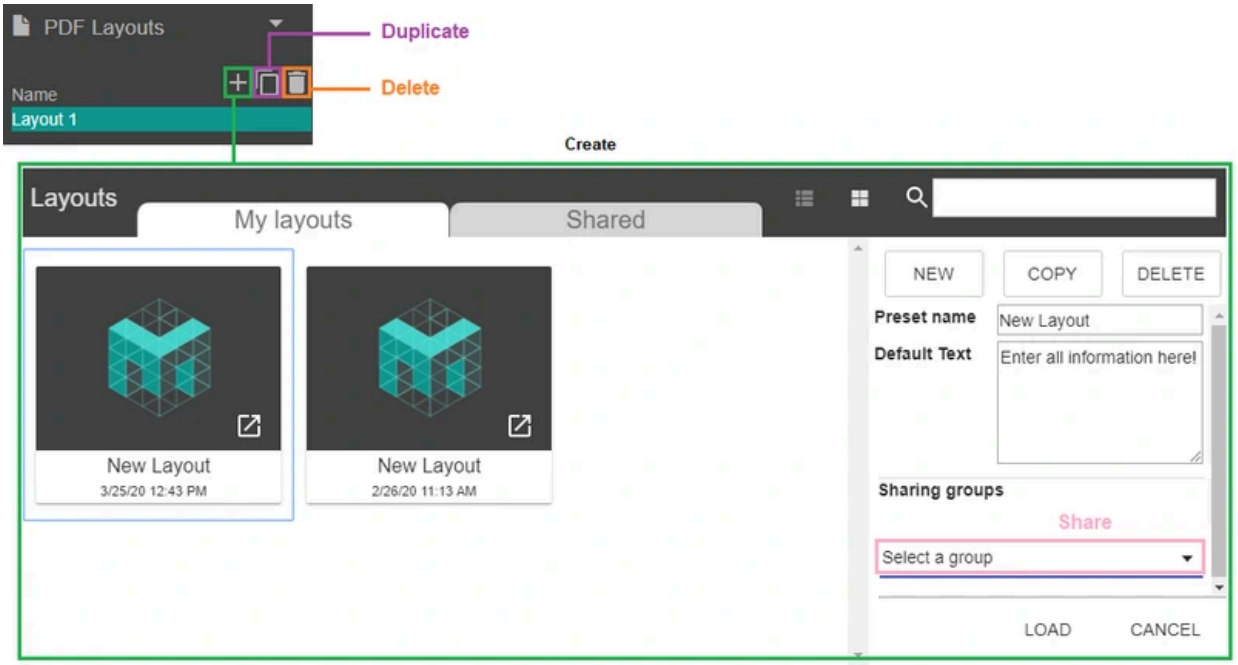
This will save a high resolution .PNG Image of your current *Viewport Perspective*.



Create a PDF Layout (and a Projectors' List)

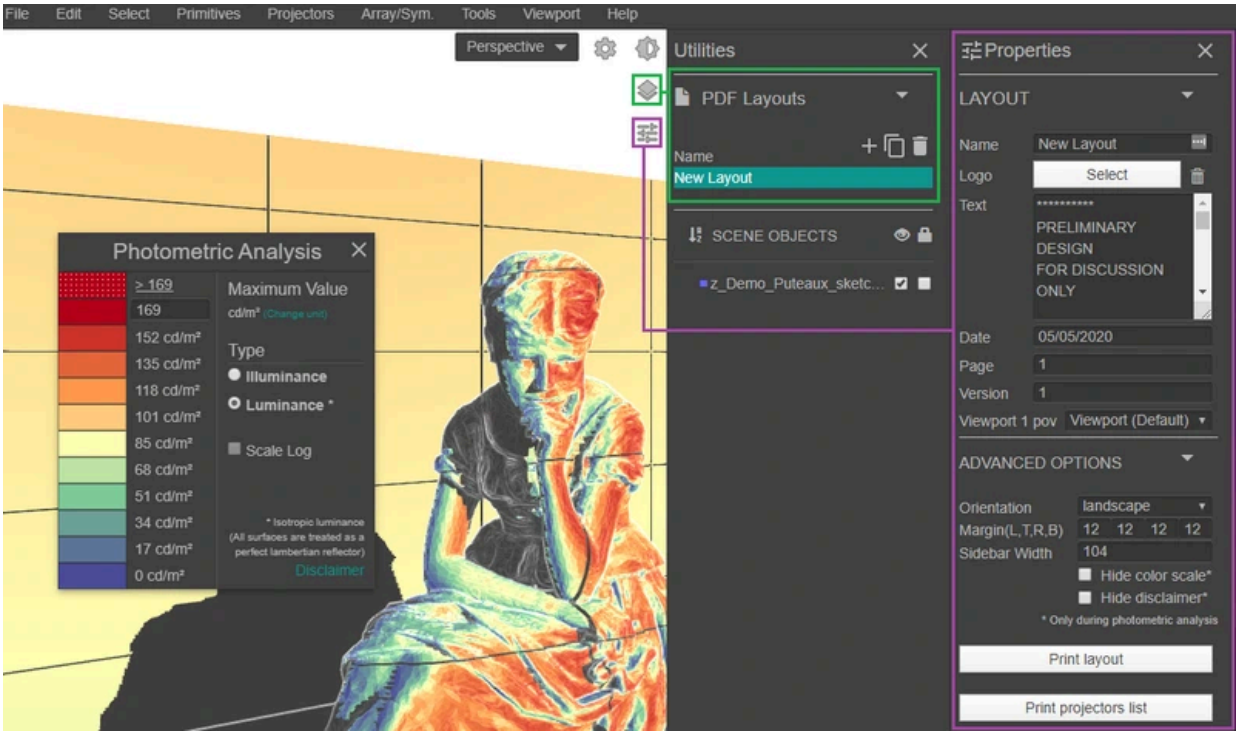
Go to **Scene Objects**, in the **PDF layout** section.

Select a Layout Template, or create a new Template.



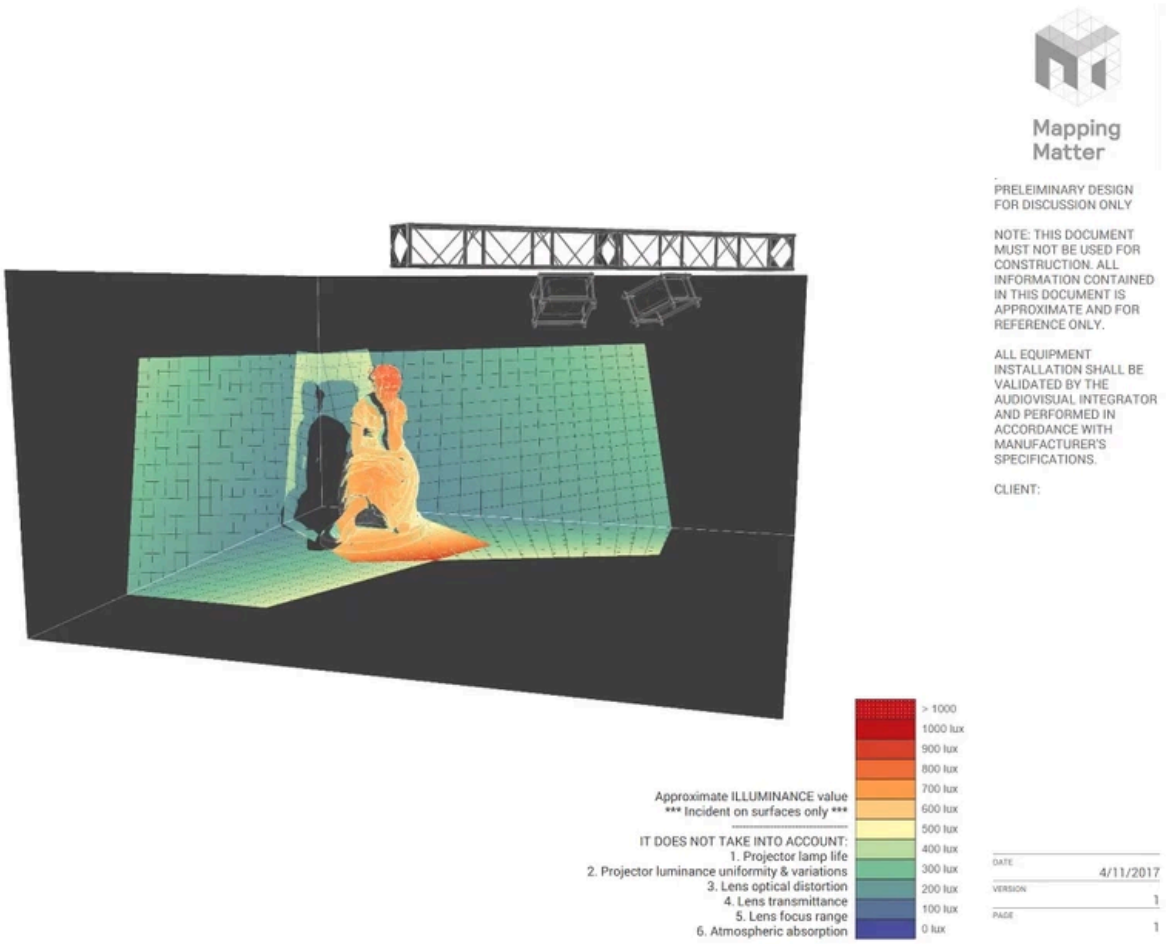
You'll have your own Template Library. You can **Share** any template, or use one from **Shared With Me**.

Go to its **Properties** panel.



By default, the Illustration Image will be taken from the Perspective POV. You can also select a Camera's POV in the **Viewport 1 pov** section.

Click on **Print layout**.



Click on **Print projectors list**.

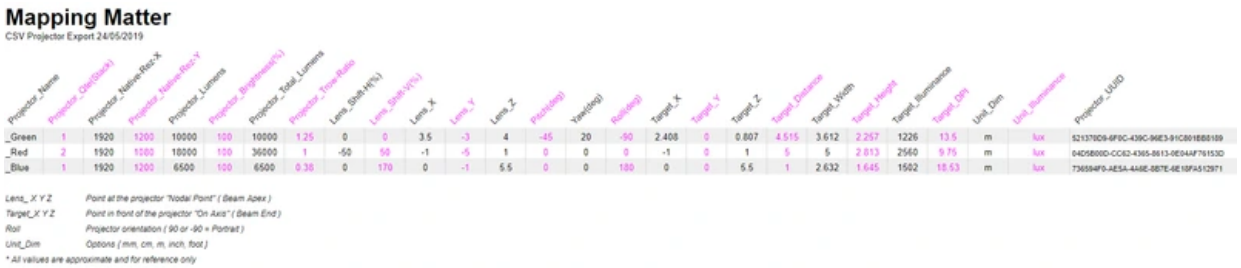
This will include information about all your Projectors in the Scene (Specs & in-Scene adjustments).

Name	Qte (Stack)	Brand	Model	Native Rez.	Lumens	Throw Ratio	Lens shift H	Lens shift V	Position(m) X	Position(m) Y	Position(m) Z	Rotation X	Rotation Y	Rotation Z
Proj A	1	Christie	S+10K-M Frame	1400 x 1050	10500	1.13	0%	0%	-1.93	-2.94	4.53	-25.00°	0.00°	-22.70°
Proj B	1	Christie	S+10K-M Frame	1400 x 1050	10500	1.13	0%	0%	-2.93	-2.01	4.53	-25.00°	0.00°	-67.00°

Export All Projectors Data (.CSV file)

TOP MENU > File > Export All Visible Projectors Data - CSV

This creates a .CSV file that you can transpose into all advanced professional media servers which support a 3D environment.



Mapping Matter

CSV Projector Export 24/05/2019

Projector_Name	Projector_Qty(Stack)	Projector_Native Res X	Projector_Native Res Y	Projector_Lumens	Projector_Brightness(%)	Projector_Total_Lumens	Projector_Throw Ratio	Lens_Shift-H(%)	Lens_Shift-V(%)	Lens_X	Lens_Y	Lens_Z	Pitch(deg)	Yaw(deg)	Roll(deg)	Target_X	Target_Y	Target_Z	Target_Distance	Target_Width	Target_Height	Target_Illuminance	Target_DPI	Unit_Dim	Unit_Illuminance	Projector_UUID

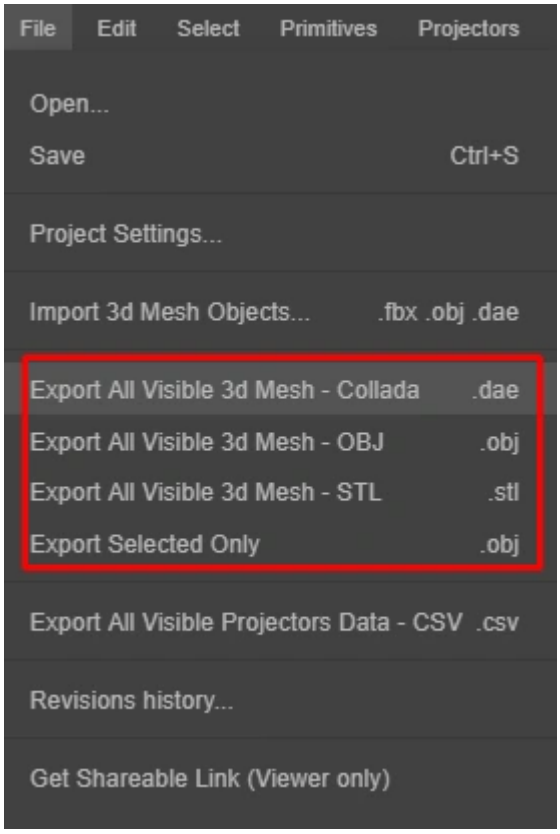
* All values are approximate and for reference only

> **Tip**
>
> Here's how the Mapping Matter integration works in Disguise.

Export 3D meshes

You can export All Visible (or only Selected) 3D meshes in a single file.



> **Warning**
>
> If you want your Projectors' Beams to be included in your export, first make sure **Show All Projector Beams** is enabled in the **Viewport Settings** panel.

Projectors and Cameras (legacy)

> **Note**
>
> This page documents the **legacy** edition of Mapping Matter, kept for users who have not yet migrated. The current Mapping Matter docs begin at Introduction.

Projectors/Cameras

Create (or Swap) a Projector

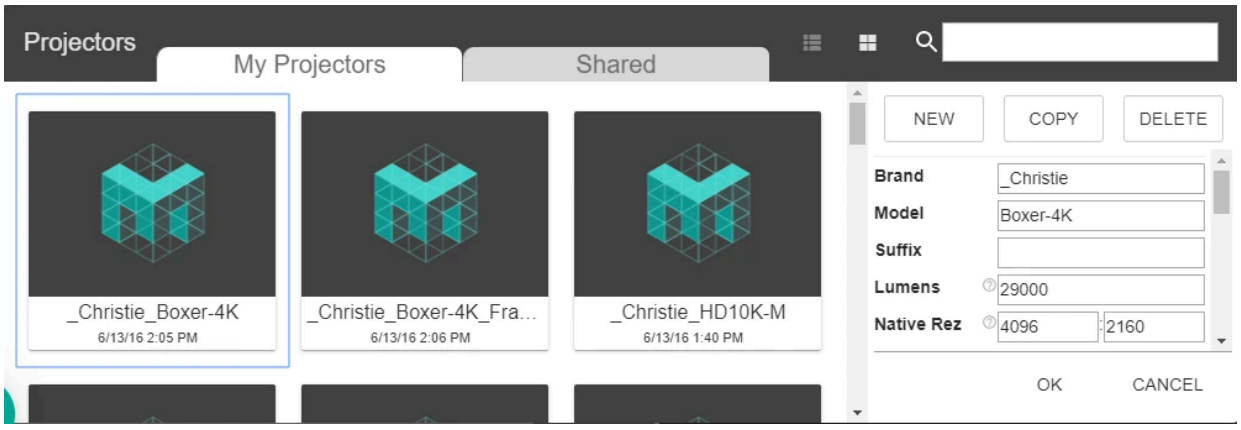
> **Warning**
>
> For all Projector modifications to be updated in your Scene, you'll need to refresh your Browser.

Create a Project in your Scene

TOP MENU : Projectors > Projector

Click to display Specs. Double-click to create it in your Scene.

To learn how to manage your Library and add new Projectors, click here.

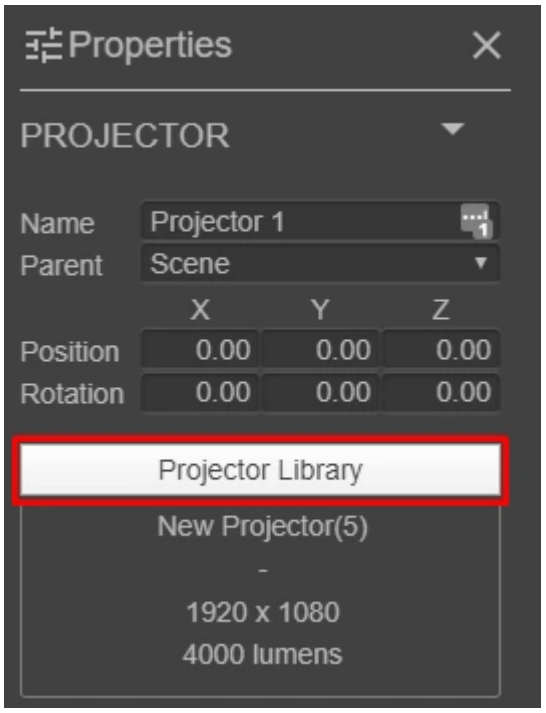


Swap a Projector from your Scene

You can test different Projectors, while the Scene Projector's settings (position, rotation, etc) remain unchanged.

Select a Projector. Go to its **Properties** and click on **Projector Library**.

> **Tip**
>
> You can also select many Projectors at once, holding **Ctrl**.



Projector Orientation

Use Rotation

[Animated GIF: Projector Orientation Basics]

The Orientation of a Projector is determined by the axis between its Lens and its *Target Point* (the Yellow Dot).

- With your keyboard's Arrows.

Press once on any Arrow for a 0.1° increment.

Hold **Shift** while pressing on any Arrow for a 1° increment.

- Through the Properties panel, with the Rotation input boxes.

Type-in a value.

Or left-click on any value, and drag to adjust. (Hold Shift to drag faster.)

- With the Rotation Gizmo. Press **R** on your keyboard to show the Rotation Gizmo.

Then hold-click on any curve to drag and adjust.

Or click once on any curve, and type-in a value.

User the Target Point

[Animated GIF: Projector Orientation]

- By dragging around the *Target Point* (the Yellow Dot) of the Projector.

Hold click on the **Target Point** of the Projector, and drag it around with your cursor.

- By aiming towards a Pin Point anywhere in the Scene.

Click on the Projector's **Target Point**. Then on the **Pin Point** icon. And anywhere in the Viewport.

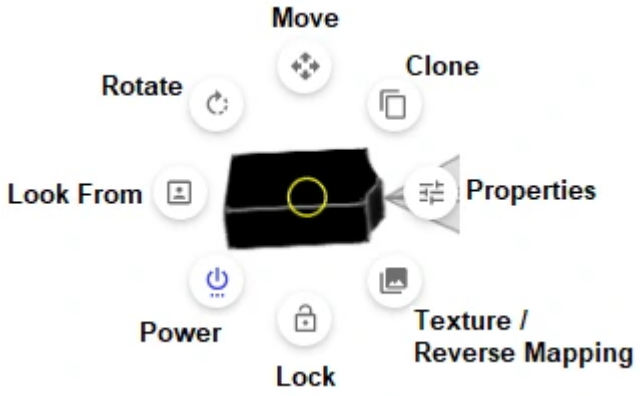
- Locking the Target Point

Select your Projector's **Target Point** and position it. Click on the **Target Point**, and enable the **Lock** icon. Now play with the **Position** and **Rotation** of your Projector.

Projector Beam

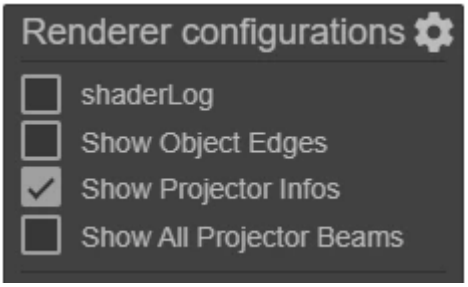
Here you'll learn how to adjust the *Throw Ratio / Throw Distance*, calculate the *Illuminance* and *Pixel Size* at the Target Point, and also adjust the *Brightness Factor*.

> **Tip**
>
> You can turn On / Off the Power an individual Beam through its Projector's Shortcut Wheel (in the Viewport). Or in its **Properties**.



Adjust the Width / Height / Throw Ratio

First, go to **Viewport Settings**, and make sure that **Show Projector Infos** is enabled.



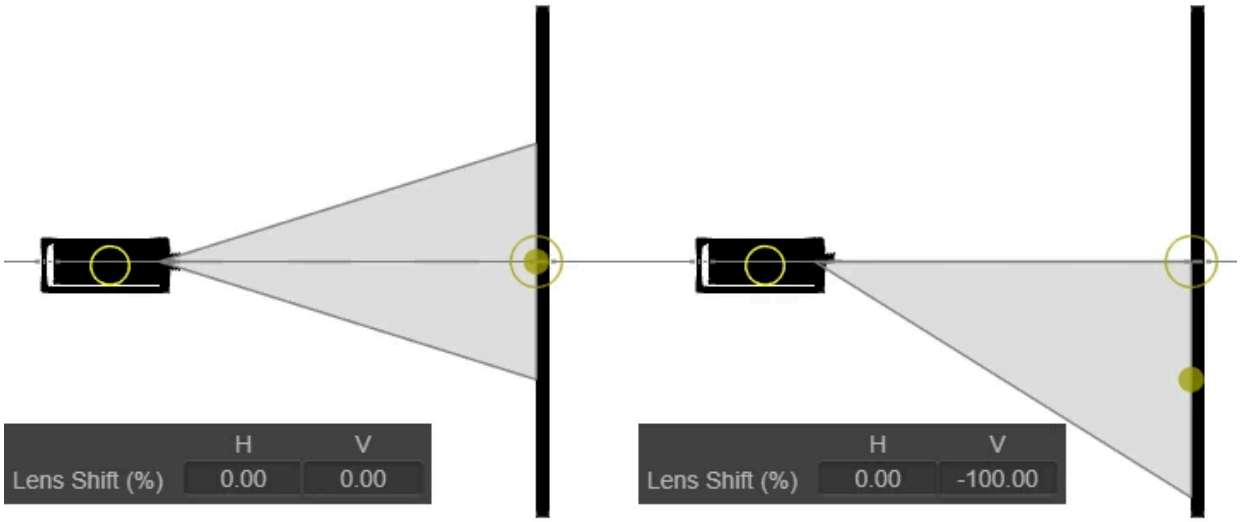
Adjust the Width / Height / Throw Ratio directly in the Viewport.

[Animated GIF: Projector Beam]

You can also adjust the **Throw Ratio** in the **Properties** panel. Just type-in a value, or hold-click on the input box and drag your cursor to adjust.

Lens Shift

Lens Shift allows to deviate the optical axis of the Beam. Select your Projector. Go to its **Properties**, and to **Lens Shift**. **H** = Horizontal, **V** = Vertical.



> **Warning**
>
> Our measurement reference is that 100% Shift represents 50% of the Image Height (or Width). This method is used by Barco and Christie. Other manufacturers may use another method (e.g. 100% Shift representing 100% of the Image Height).

Throw Distance, Illuminance & Pixel Size

[Animated GIF: Projector beam throw distance]

If the Beam's Depth axis hits no surface, Illuminance & Pixel Size will be calculated at its default Target Point.

But if it hits a surface, a new Target Point will be set at the intersection between the Beam's Depth axis and the given surface. Illuminance & Pixel Size will be automatically re-calculated.

Illuminance = value in Lux at Target Point.

Pixel Size = unit^2 at Target Point. Learn how to measure individual pixels using a Checkerboard, here.

Illuminance (**Stretch**) = the angle will make it x% dimmer (on matt surfaces).

Pixel Size (**Stretch**) = the angle will make it x% bigger (Keystone effect).

> **Tip**
>
> You can override the automatic Target Point reset by manually typing-in any specific value for the Beam's Depth. (See the GIF above.) The minimum is 1m on manual, but it may be shorter on automatic.

Adjust the Brightness Factor

This ratio is adjusting the total Lumens Output of the Projector.

> **Tip**
>
> A Projector's Lamp Life has a direct impact on the Brightness. The Brightness Factor is here to help you to integrate this reality.

Go to its Properties, and to the PROJECTOR menu.

Projector Image

The Projector Image refers to the visual content projected through the Beam.

Here you'll learn how to customize it with Images / Videos / Borders / Grid / Checkerboard.

[Animated GIF: Projector beam throw distance]

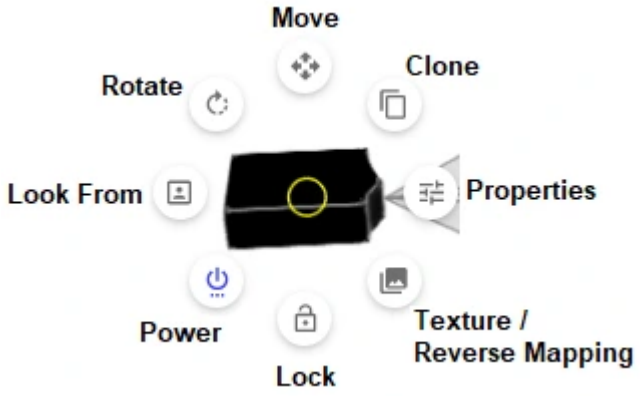
Select your Projector. Go to Properties > Projector > Projector Image

Use / Remove an Image (or Video)

Change the color of the Beam's borders

Add a parametric Grid

> **Tip**
>
> You can Look From any Projector. Using the Shortcut Wheel, or holding**Shift** while double-clicking on your Projector, or by clicking on the **Eye** icon from the **Scene Objects** panel.



Use / Remove an Image (or Video)

Click on the **Projector Image** button. You will have access to the Texture Library. It contains a collection of files that you may use for your Projector Image. You can also import your own files from your computer. Check how to use the Texture Library[here](#).

To remove a Projector Image, select your Projector and click on the Trash icon command.

> **Tip**
>
> You can preview a video in the Viewport. Just hit the space bar to start / stop it.

There will be no sound.

Use / Remove an Image (or Video)

Tick the **Border** box.

Click on the Color Bar and select a color.

To adjust the borders' thickness, type a value in the % input box.

> **Tip**
>
> A 5% border is a great way to represent Lens Tolerance.

Add a parametric Grid

Tick the appropriate box : **Grid** or **Checkerboard**.

Adjust the input values for the desired amount of (Left) vertical and (Right) horizontal blocks.

Use the Checkerboard to measure down to 1 pixel.

Projector Stack

[Animated GIF: Projector stack]

Select your Projector. Go to Properties > Projector > Projector Stack

Add any amount of dummy Projectors in the input box.

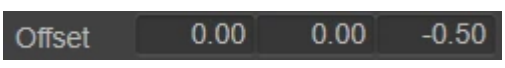
This will only create a dummy mesh and multiply the brightness.

Tick the “Automatic Lumens Multiplication” box (if you want to activate / de-activate the stacking effect on your Projector’s Beam).

If activated, the Lumens output of your Beam will be automatically multiplied.

The Total Stack Lumens value will be displayed in the Properties panel.

You may change the position sequencing of all additional dummy Projector by changing the Offset values in the input boxes below.



Reverse Mapping

Reverse Mapping allows you to reveal the projected Texture onto an Object’s surface.

The projected Texture may be applied as an Object's MATERIAL (Projection Map), or it may come from a **Camera Projector**.

Reverse Mapping is a powerful tool to quickly set perfectly mapped previews.

[Animated GIF: Projector reverse mapping]

In this example, a projected Texture was applied on the wall and revealed by the Projector in *Reverse Mapping* mode.

Activate Reverse Mapping on a Projector

Create or select a Projector.

Access its Shortcut Display in the Viewport.

Place your cursor on the Texture icon, and click on **Reverse Mapping**.

Now the Projector Beam will only reveal all projected Textures on the surfaces it hits.

Use the Projection Texture tool

The Projection Texture tool allows you to simultaneously reveal all projected Textures from the whole Scene. No need for any Projector Beam.

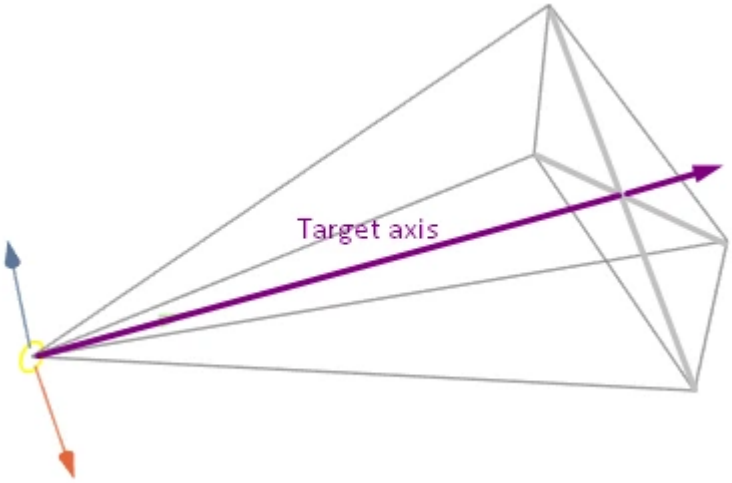
Go to **Brightness Settings** and ajust the value (in lux).

> **Tip**
>
> This may help removing the brighter overlap between Beams.

[Animated GIF: Projector reverse mapping projection texture blending]

Cameras

A Camera is a bodyless Object, no meshes attached.



Create a Camera

There are 2 methods to set a new Camera's position and orientation.

By default, creating it at the Center Point of your Scene.

TOP MENU > Projectors > Camera

It will be oriented towards the Scene's Y axis. Because its Target Point's position is by default (X=0, Y=2, Z=0).

Or from your current POV.

Go to

(in the top-right corner of your screen).

Select **Camera from View** in the dropdown menu.

Set the Target Point of your Camera

A Camera's Target axis will always be automatically re-oriented towards its Target Point, regardless of your Camera's position in the Scene.

You can position the Target Point by typing-in its coordinates.

Select your Camera. Go to **Properties**, and to **Camera**.

Type-in the Target Point's (X, Y, Z) coordinates.

Rotate your Camera's Field Of Vision (FOV)

The rotation will occur on the Target axis.

Type-in an angle value in the Roll input box, available in your Camera's **Properties**.

Example

Type-in 90 to have a 90° rotation, and get a portrait FOV.

Adjust your Camera's FOV dimensions (Focal Length, Resolution)

The *Focal Length* simulates a standard camera's Lens Focal Length (in millimeters). The longer the focal length, the narrower the FOV values.

Adjust your Camera's Focal Length in its **Properties**.

The Resolution may also be customized in your Camera's Focal Length in its **Properties**.

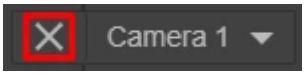
The Horizontal (H) and the Vertical (V) will be proportional to your Camera's FOV, for its Width and Height respectively.

Look from any existing Camera

You can switch your own POV to any of your Cameras' anytime.

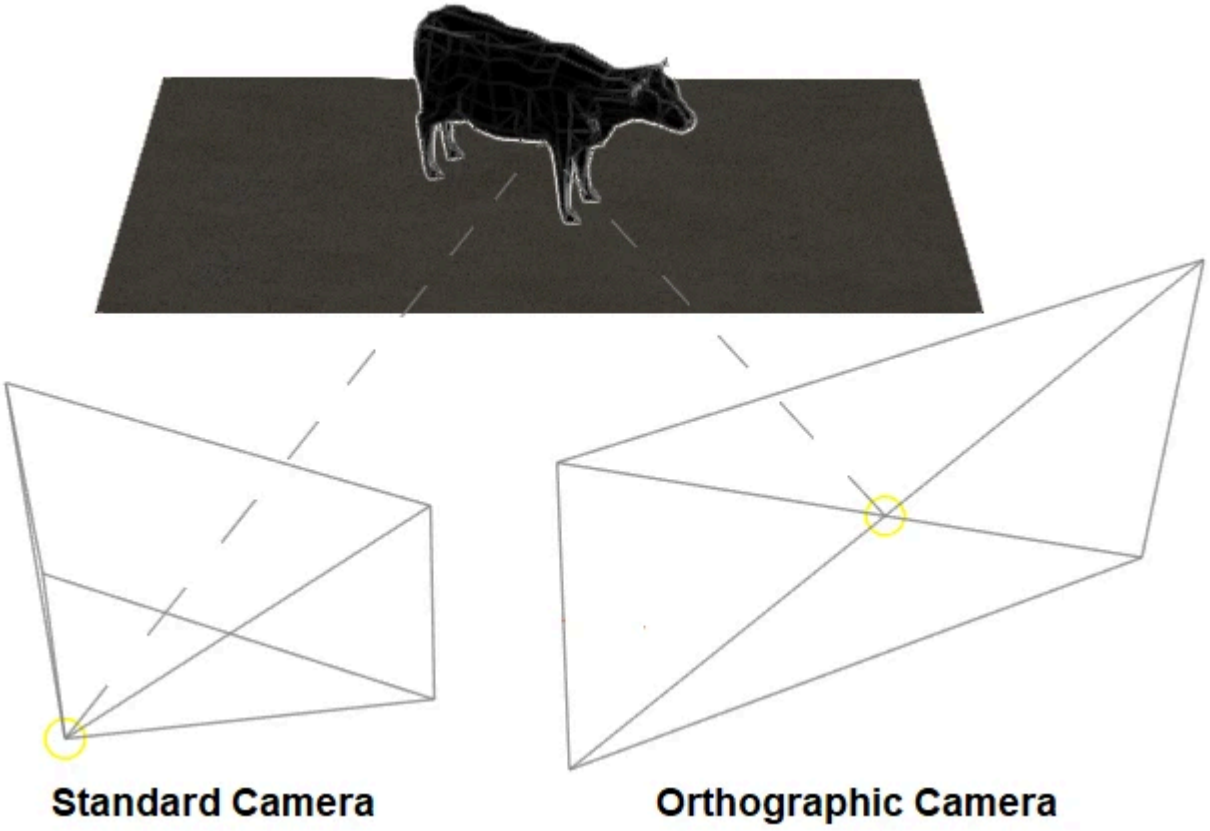
Just go to **Scene Objects** and click on the **Look From** icon.

To exit the Camera's POV, click on **Exit view**.



Use an Orthographic Camera

Orthographic translates into a flat FOV cone.

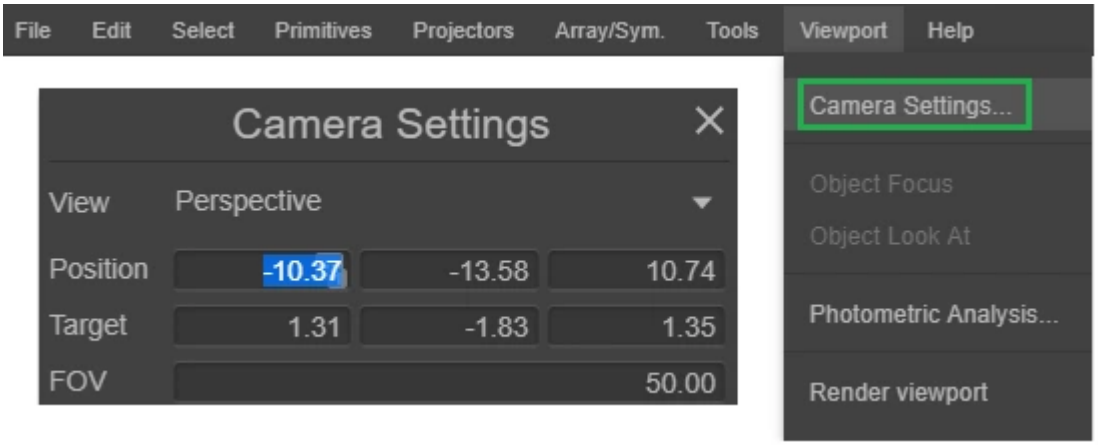


Go to

(in the top-right corner of your screen).

Select among Top / Bottom / Left / Right / Front / Back

Go to TOP MENU > Viewport > Camera Settings to adjust its Position/ Target / FOV.

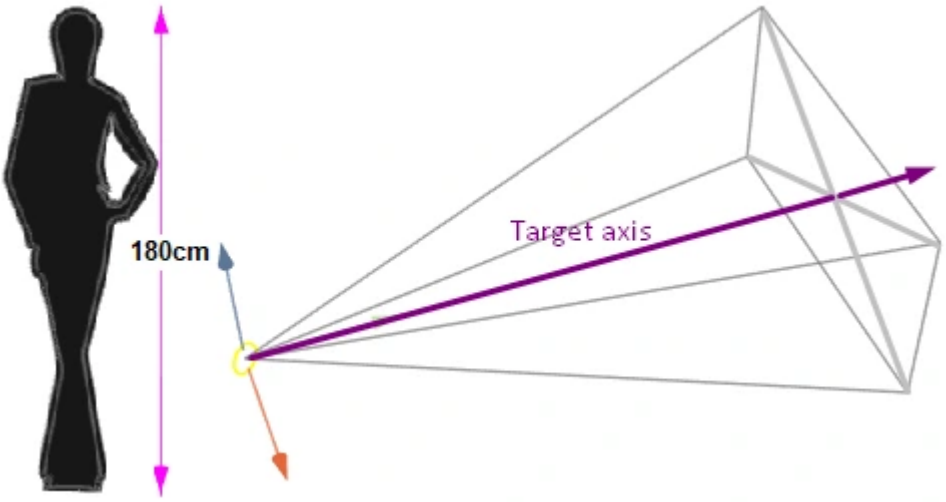


Camera Projectors

A Camera Projector is an hybrid Object, it shares some features of both a Camera and a Projector.

It is also represented in the Scene by a *human silhouette* 3D mesh (Height= 180cm).

The FOV is represented by a pyramidal cone. The Field Of Vision's dimensions are defined by the Camera Projector's Focal Length and Resolution.



Create a Camera Projector

You can only create it at the Center Point of your Scene.

TOP MENU > Projectors > Camera Projector

It will be oriented towards the Scene's Y axis. Because its Target Point's position is by default (X=0, Y=2, Z=0).

Adjust your Camera's FOV dimensions (Focal Length, Resolution)

The Focal Length simulates a standard camera's Lens Focal Length (in millimeters). The longer the focal length, the narrower the FOV. And vice-versa.

Adjust your Camera Projector's Focal Length in its Properties.

The Resolution may also be customized in your Camera Projector's **Properties**.

The Horizontal (**H**) and the Vertical (**V**) will be proportional to your Camera's FOV, for its Width and Height respectively

Project a Texture from your Camera Projector (Projective Texturing)

Projective Texturing allows you to see how your Objects' surfaces need to be mapped, in order to produce a certain Image from a given perspective.

This is particularly useful when you don't have any UVs on your 3D Objects.

[Animated GIF: Camera projector texture]

By default, the projected Texture won't be visible in the Viewport. It will have to be "revealed". Either by a Projector in **Reverse Mapping** mode, or using the Projection Texture tool.

Select your Camera Projector.

Go to its **Properties**, and click on Projector Image. (Or use the **Texture** shortcut icon, as displayed in the GIF.)

You will have access to the **Texture Library**. It contains a collection of files that you may use for your Camera Projector's Texture. You can also import your own files from your computer. Check how to use the Texture Library here.

Share (legacy)

> **Note**
>
> This page documents the **legacy** edition of Mapping Matter, kept for users who have not yet migrated. The current Mapping Matter docs begin at Introduction.

> **Warning**
>
> To share a Scene / an Individual Asset, you must first be in the same organisation as the people you wish to share it with. Ensure that both you and your teammates are part of the same organisation. If you need to manage members or add new teammates, please follow the steps outlined on this page. Note that after being added to a new organisation, your teammates may need to log in to Mapping Matter again.

For us to create one, please reach out at **support@disguise.one**

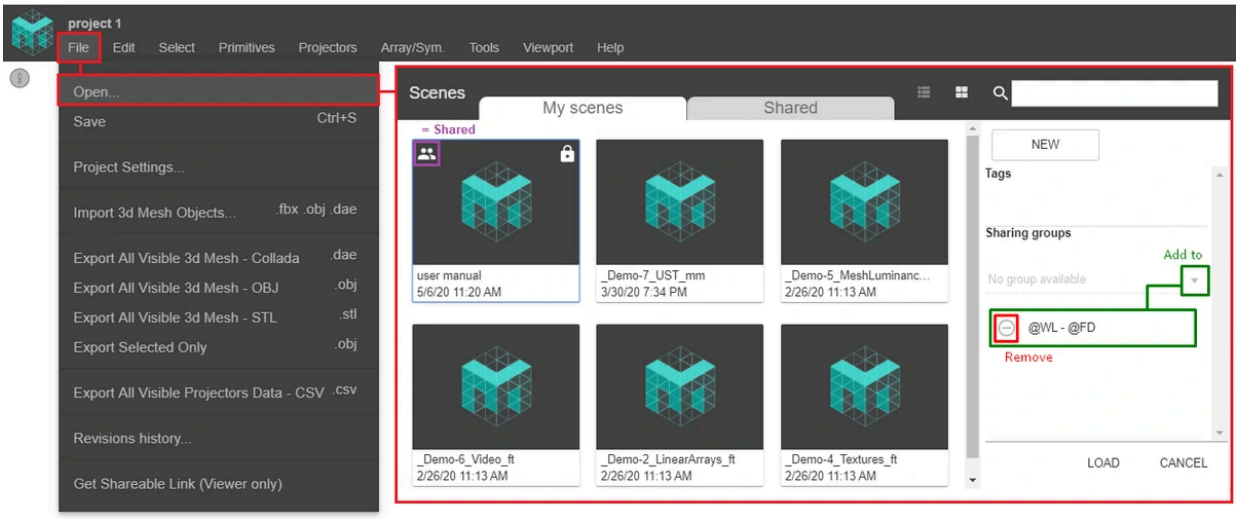
Your teammates may need to refresh their Browser to receive the copies.

Share a Scene

When you share a Scene file, it will also copy all of its assets (Projectors, Textures, 3D Objects, etc...).

> **Warning**
>
> You'll need to be the creator of the Scene. If it was shared with you, only a duplicate version of it can be shared. This option won't be accessible from the Home Page. You can do it through the Scene Library.

Access the Scene Library : TOP MENU > File > Open...

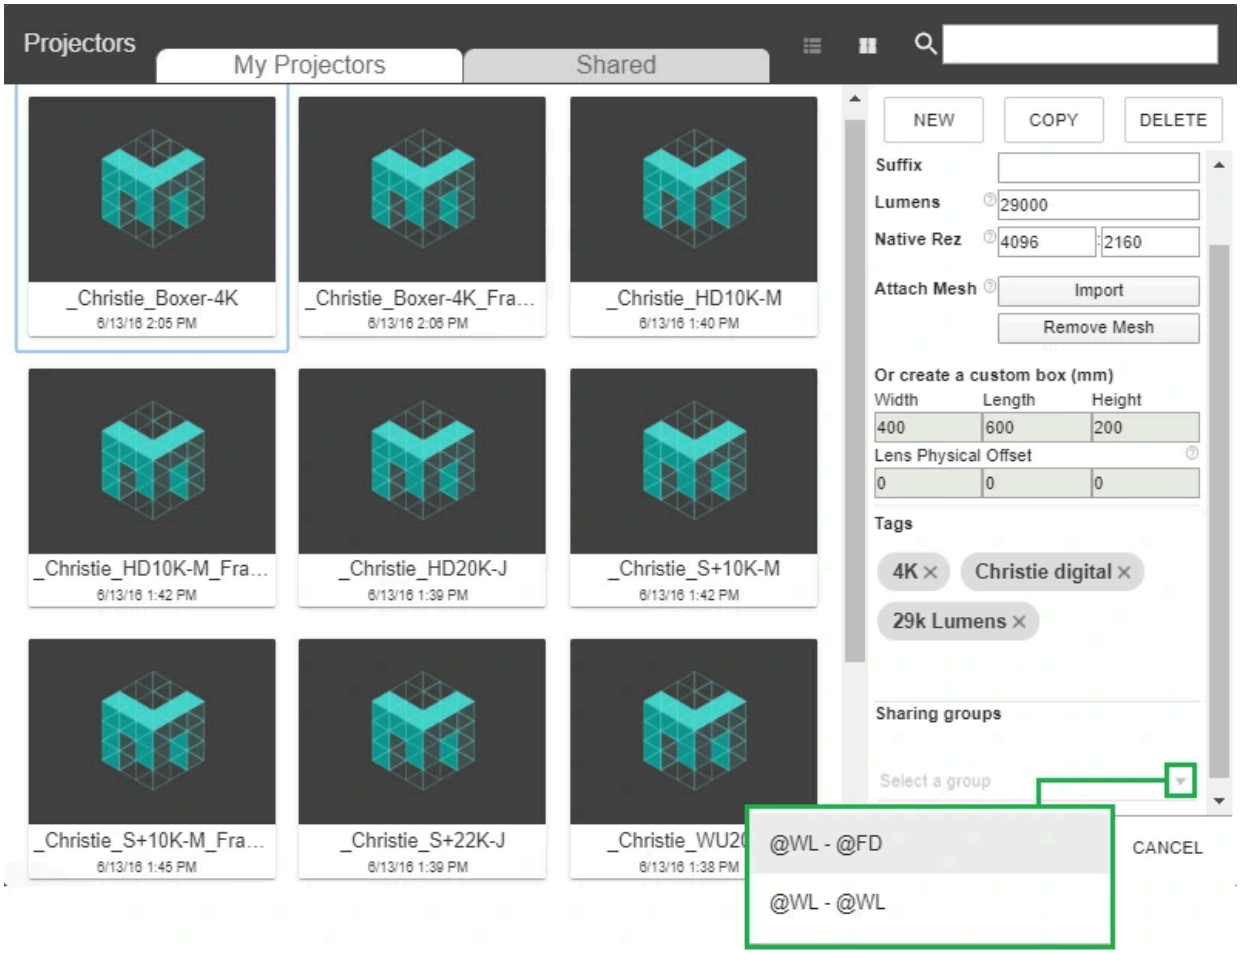


Share an Asset

Share a Projector

TOP MENU > Projectors > Projector

Select a Projector > Add it to any Group Sharing Folder



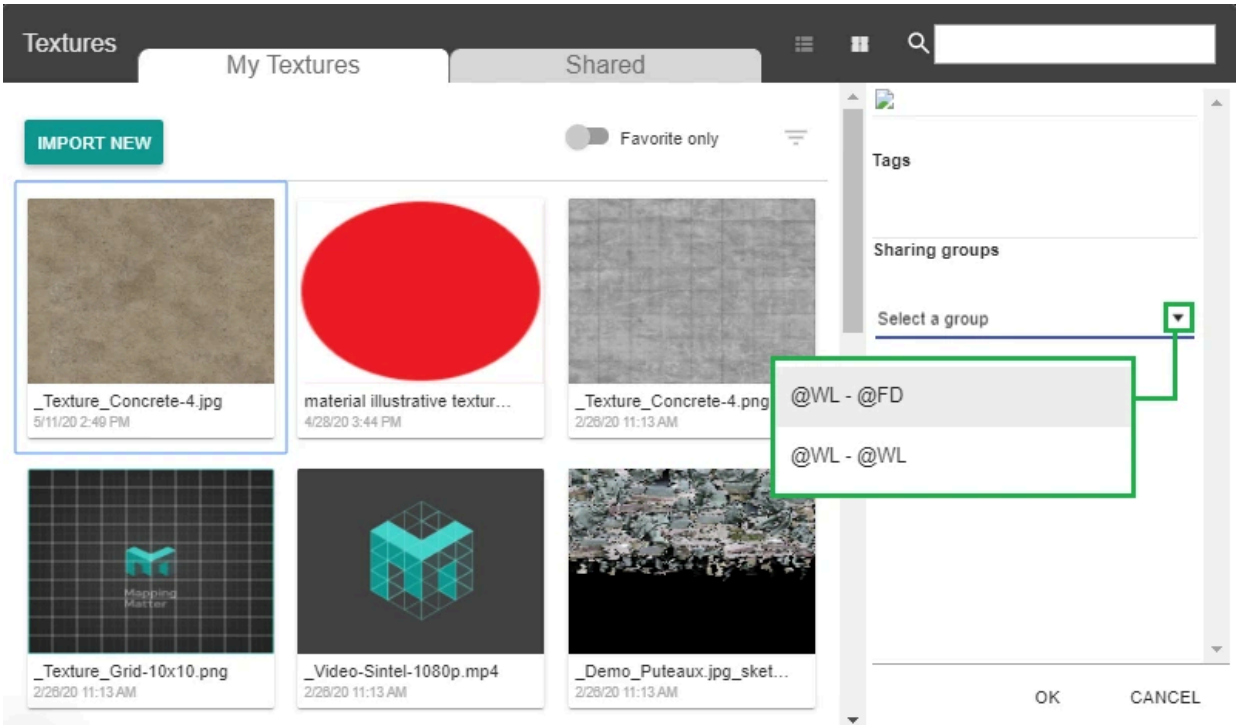
Share a Texture

You'll have access to the [Texture Library] through different paths.

Select a Projector > Properties > Projector Image

Select a Primitive > Properties > Base Map (or Projection Map).

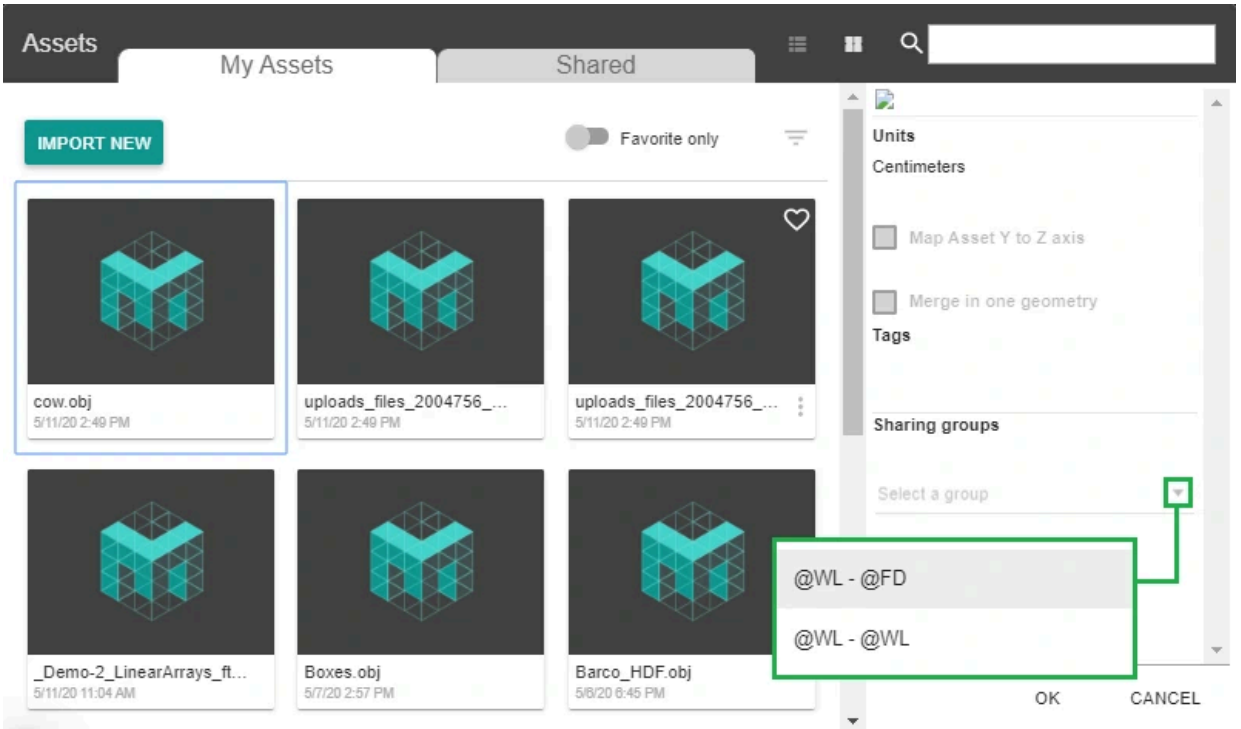
Select a Texture, and add it to any **Group Sharing Folder**.



Share a 3D mesh

TOP MENU > File > Import 3D Mesh Objects

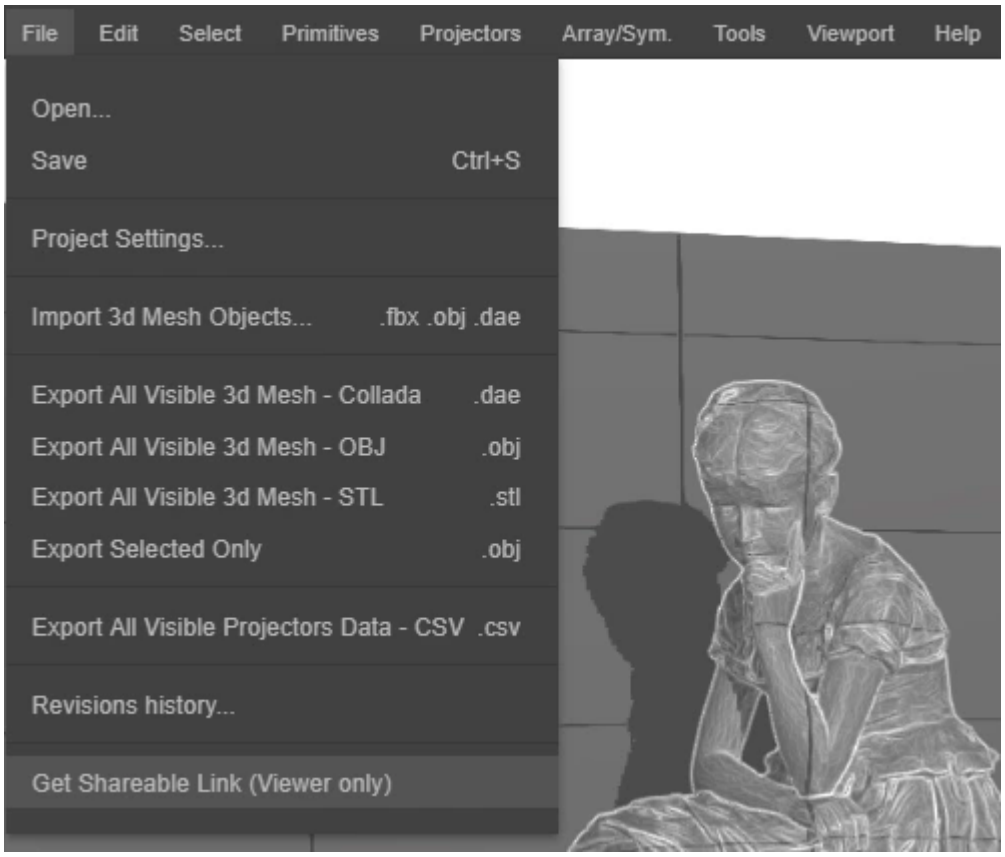
Select an Asset, and add it to any **Group Sharing Folder**.



Share a Viewer Only link

For anyone with the Link and Password to view your Scene and possibly previewing their own Content there.

How to generate a Viewer Only link



TOP MENU > File > Get Shareable Link

Tick the **Enabled Box**, and type-in a password.

How to operate on the Viewer's Landing Page

All people with the Link can preview their own Content on Reversed-Mapped Objects.

Imported Content will only apply on Objects which already had Content (Image / Video) as *Projection Map*.

The *Projection Map* has to be revealed in your Scene, either by a Projector in *Reverse Mapping* mode, or with the *Projection Texture* Tool.

Viewport Brightness (legacy)

> **Note**
>
> This page documents the **legacy** edition of Mapping Matter, kept for users who have not yet migrated. The current Mapping Matter docs begin at Introduction.

Viewport Settings

This helps you customize the visual information in your Scene.

Go to **Viewport Settings** (in the top-right corner of your screen).

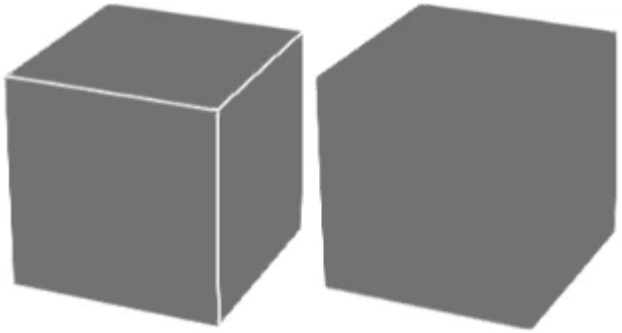
shaderlog

Enable / disable shaderlog.

This replicates *Luminance* as perceived by the human eye. It gives more detail in lower intensity, and less detail in higher intensity

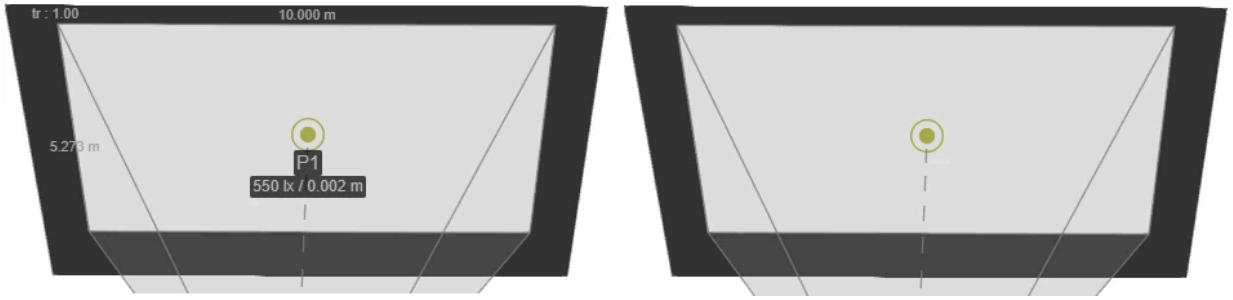
Show Object Edges

Tick the box to enable / disable it.



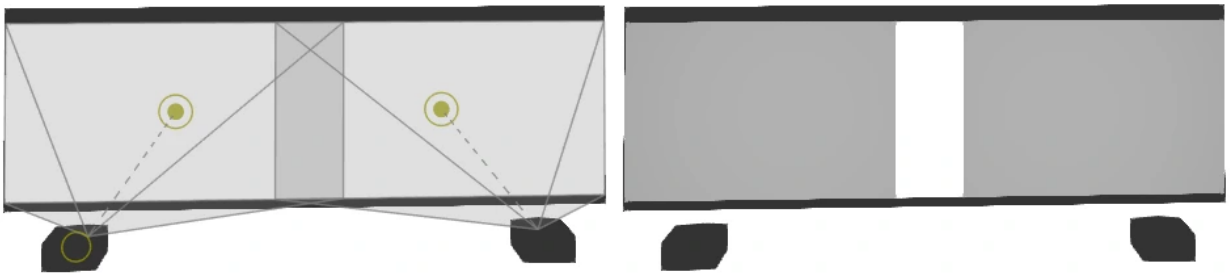
Show Projector Infos

Tick the box to enable / disable it.

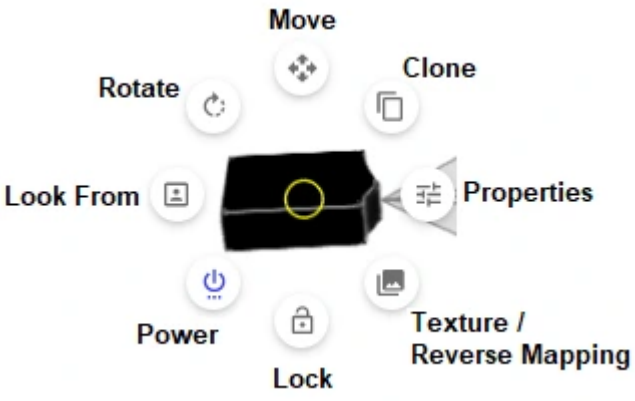


Show All Projector Beams

Tick the box to enable / disable it.



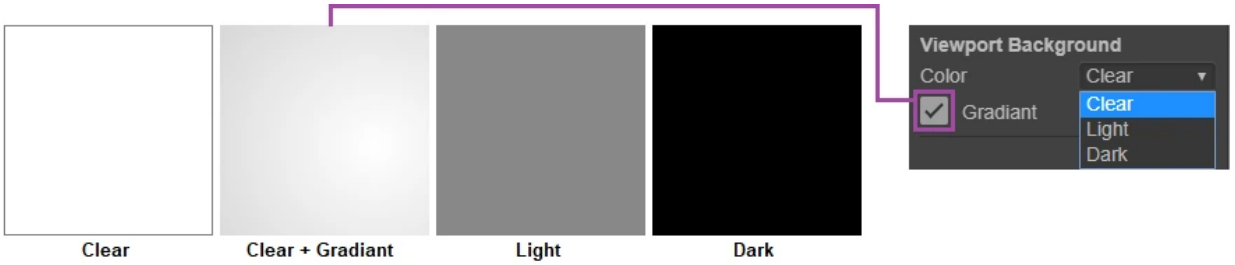
> **Tip**
>
> You can also turn On / Off the Power an individual Beam through its Projector's Shortcuts. Or in its **Properties**.



Viewport Background

You can change the **Viewport Background** for both ergonomic or aesthetic purposes.

Gradiant adds a soft esthetic glow to your Background.



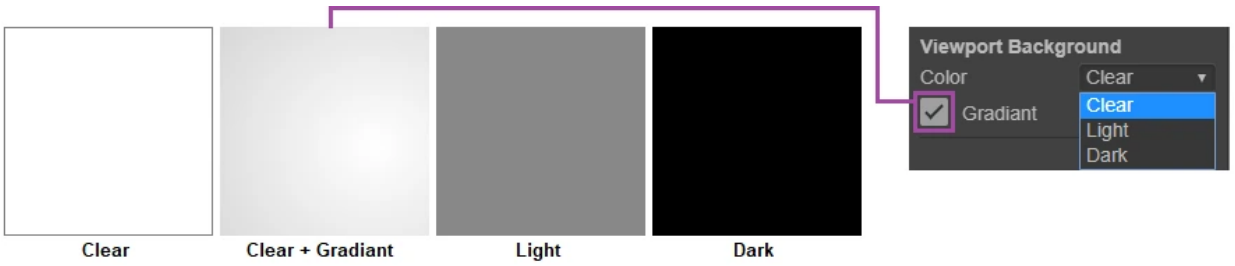
Global Material Override

Some Objects may have a Material Override option enabled. This means you can “see through” them in the Viewport.

Learn about the Side Tool for Material Override here.

This is a global effect. When enabled (with Double Side box ticked), all Material Overrides are suspended.

Show Grid



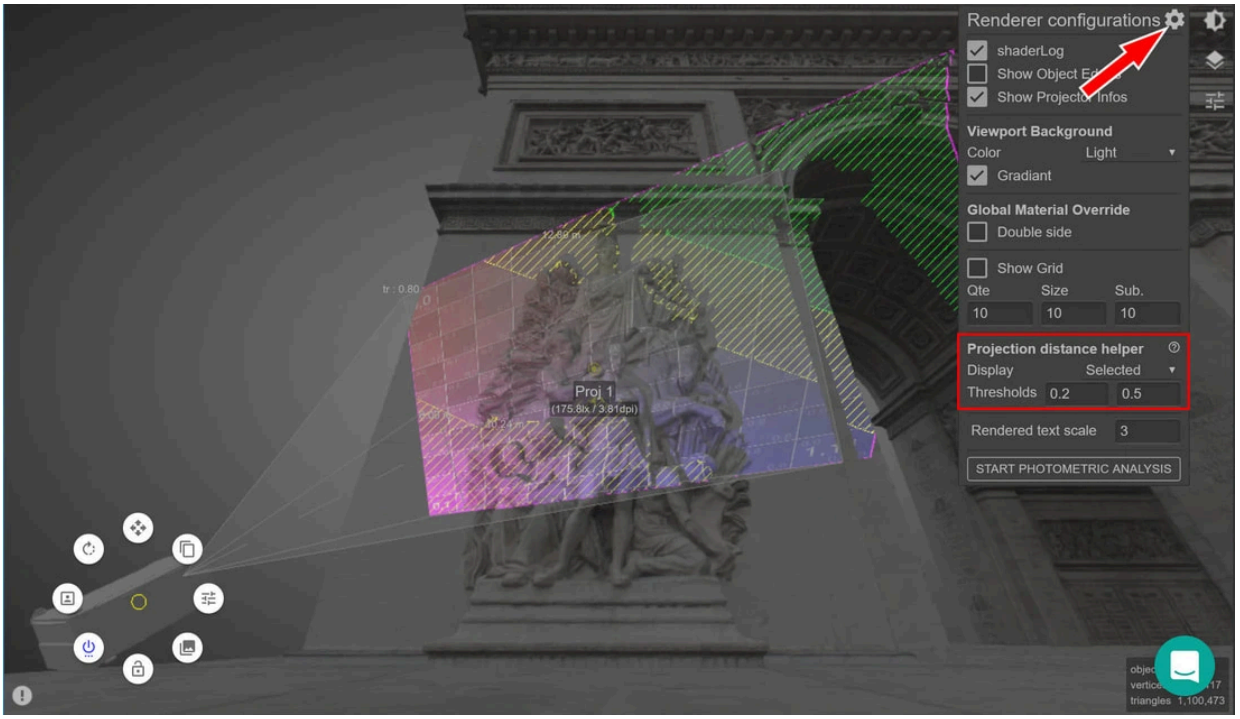
Qte = Quantity of Squares both Horizontal and Vertical.

Size = Unit Size of 1 Square.

Sub = Subdivisions of each Square.

Projection Distance Helper

This tool helps you visualizing the distance variations between a Projector’s Lens and the surfaces hit by its Beam. It will give you a better understanding of potential focus issues.



This is a global effect. When enabled, all Projectors apply it.

Go to Viewport Settings (in the top-right corner of your screen).

To disable it, go to the Display dropdown menu, and select **None**.

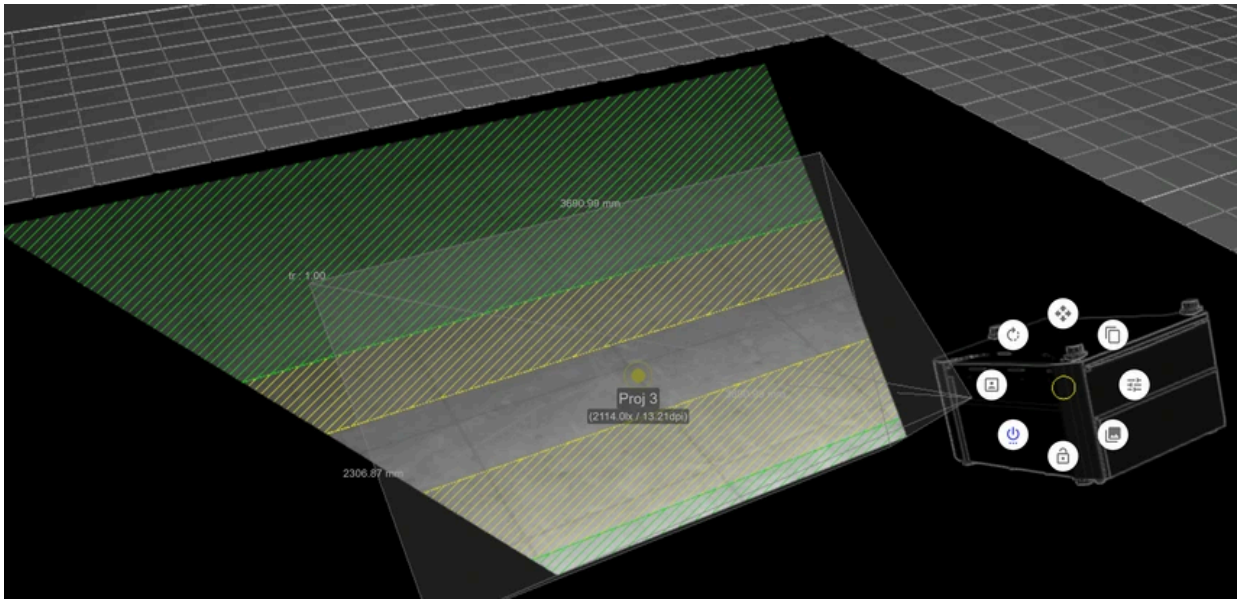
The two Thresholds parameters represent a fixed % value of the distance between any Projector and its Target Point.

Example

We have a Beam with a 10m projection distance.

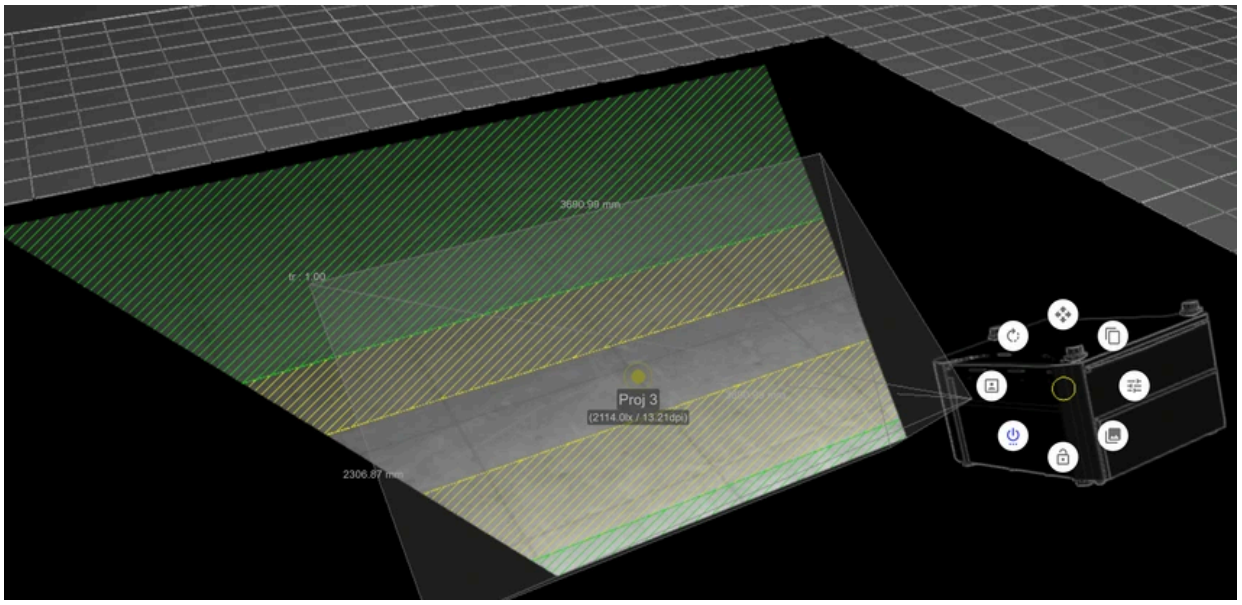
Both thresholds are set to 0.1 and 0.3.

Consequently, the areas between 1m and 3m away from the Target Point will be hatched in Yellow. And when 3m away or more, it will be all Green.



> **WARNING**
>
> This tool does not represent the real projection depth of field, or the minimum and maximum projection focus plane. But it's a simple and great way to flag potential focus issues.

Photometric Analysis



This tool allows you to evaluate both the *Illuminance* and *Luminance* on given surfaces in your Scene.

You can use this information to have an estimate of the Contrast Ratio on any surface. This will help you evaluate your needs in terms of Projection Light output.

Contrast Ratio = Projection Light / Ambient Light.

> **Tip**
>
> A 5 to 1 ratio is an indicative minimum for decent projection results. A 10 to 1 ratio is often pretty good.
>
> In reality, this will variate in function of numerous factors such as the surfaces' characteristics. Therefore, conducting on-site tests will be essential.

> **Warning**
>
> Photometric Analysis will exclude Ambient & Directional Light from its computation. You'll have to take that into account when estimating your Projection Light Output needs.

Start the **Photometric Analysis** mode either from the Viewport menu, or through the **Viewport Settings** panel.

Evaluate Illuminance and Luminance

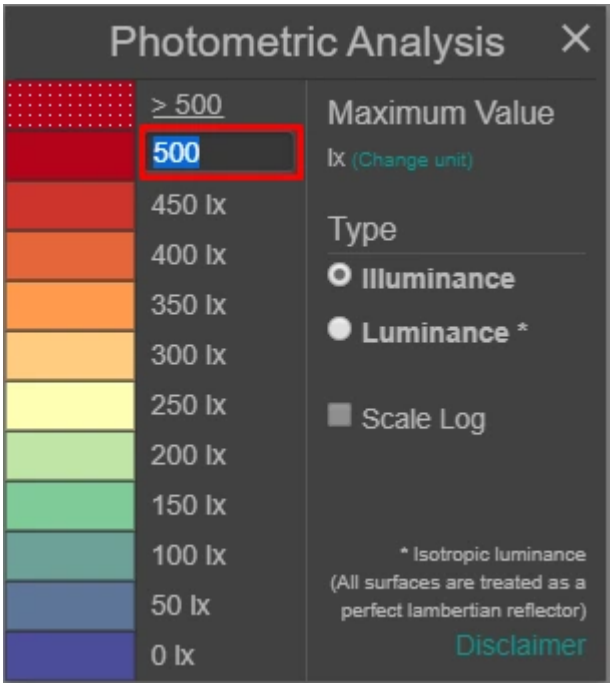
Illuminance = the amount of Light falling on a surface, per unit area.

The Object's Material and surface angle have no incidence on it.

Luminance = the amount of Light reflected from a surface, per unit area. Aka the Light Falloff.

The Object's Material (Gain / Color / Base Map) does have an incidence on it. The darker the surface, the lower the brightness.

The angle in which the Light Ray hits the surface also has an incidence. The wider the angle, the lower the brightness.



Scale Max is simply a reference value for all superior values in your Scene to show in a white-dotted Red.

You can also tick the **Scale Log** box to change the color distribution, as perceived by a human eye. It will give more details in the lower values, and less details in the higher ones.

> **Tip**
>
> Set Scale Max slightly above the Illuminance / Luminance value calculated at the Target Point. This info appears when Show Projector Infos (in Viewport Settings) is enabled.

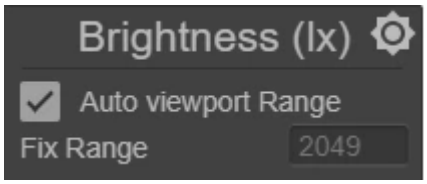
> **Warning**
>
> Changing the Color distribution with Scale Max / Scale Log does not affect the Brightness in your Scene. It simply presents you the same information on a different scale, allowing you to visualize variations as you please.

Brightness Settings

To adjust global Brightness parameters in your Scene:

Go to **Brightness Settings** (in the top-right corner of your screen).

Auto Viewport Range



This will define a value range for both *Projection Texture and Ambient / Directional Light*.

When enabled, the range is set automatically. The max brightness (100% white) will be adjusted in function of the selected Projector's Illuminance value on its Target Point.

When disabled, the range has to be set manually.

Example

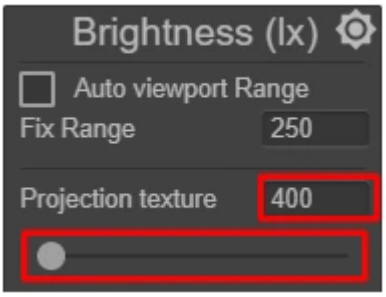
If we manually set 250 Lux, it will take 250 Lux to make any Object (which has a 1.0 Gain) 100% white. If it has a 0.5 Gain, 250 Lux will make it 50% white, etc. Same logic for Colors / Maps, the brighter the whiter.

Projection Texture

The Projection Texture tool is global effect. It allows you to simultaneously reveal all projected Textures from the Scene. No need for any Projector Beam.

The projected Textures may be applied as a Material Projection Map, or emitted from a Camera Projector.

Adjust the value in lux.

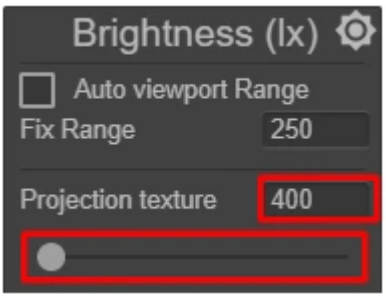


Ambient / Directional Light

Ambient & Directional Light are global effects. applying on all Objects of the Scene.

Ambient Light = the Light is equally emitted from all directions.

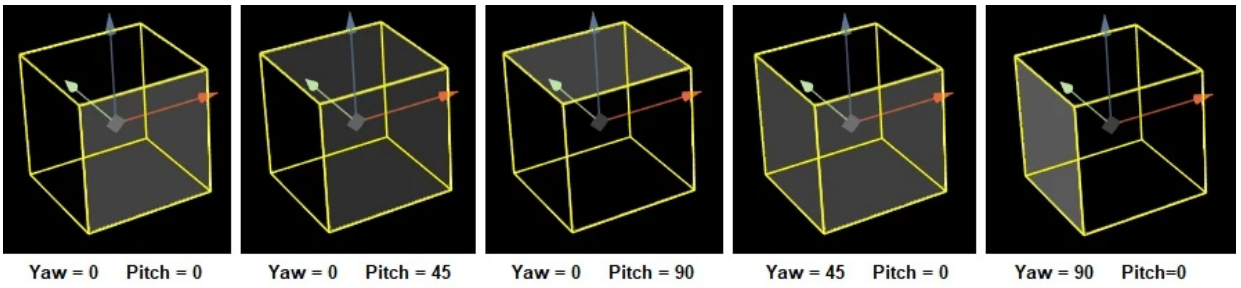
Directional Light = the Light is emitted from 1 source only.



Set a value (type-in or drag to adjust).

Yaw = the direction angle of the Light source, orbitting around the Blue Z axis. 180° shifts it to the opposite direction.

Pitch = the direction angle of the Light source, orbitting around the Red X (or Green Y) axis.



Cameras and POV

Mapping Matter has three viewpoint primitives:

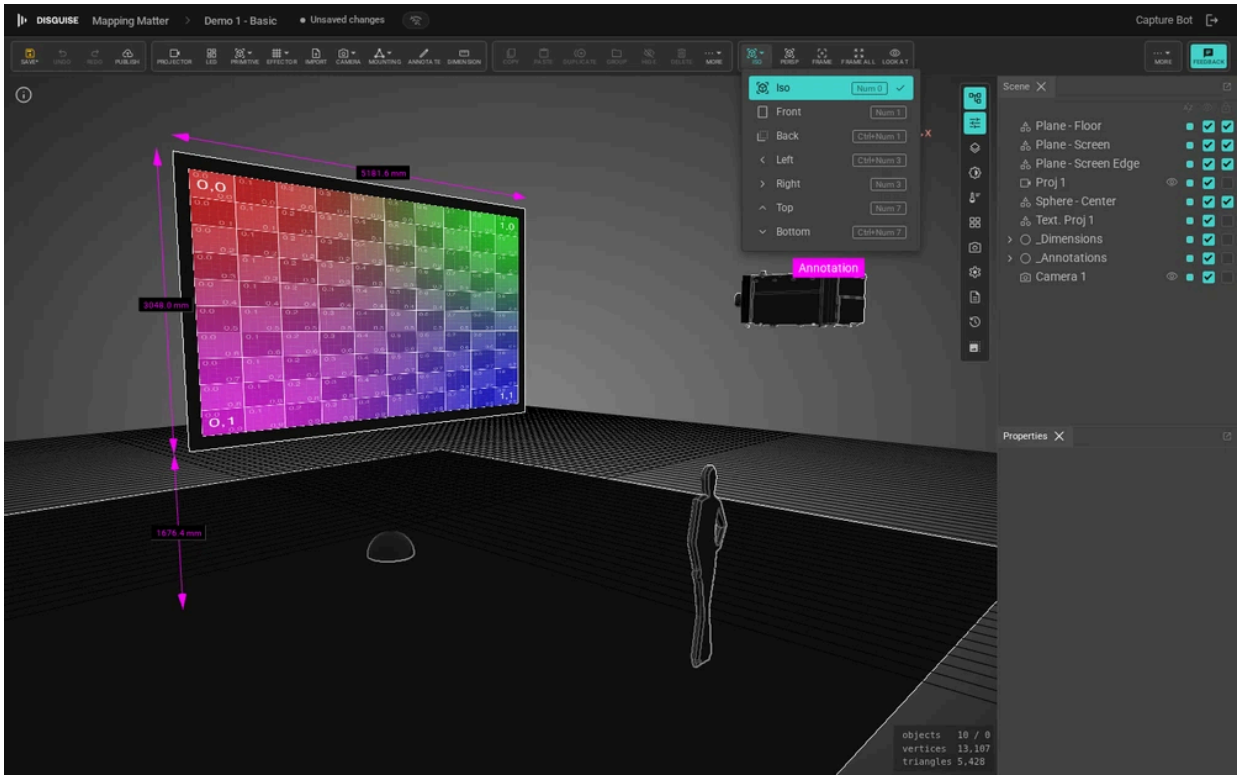
- **Saved views**: toolbar-driven snapshots of the Perspective camera that you can jump between.
- **POV camera**: a perspective scene object with an aim point, useful as a stand-in for a fixed observation location or a documented render position.
- **Observer**: a person object that places the camera at eye level, supports WASD walkthroughs, and unlocks the human acuity analysis.

Saved viewpoints

Click the **View** dropdown on the right of the toolbar to jump between **Perspective**, **Orthographic**, and the six axis views (Front, Back, Left, Right, Top, Bottom). The label updates to show the active view (`View: Perspective`, `View: Orthographic`, `View: Top`, etc.).

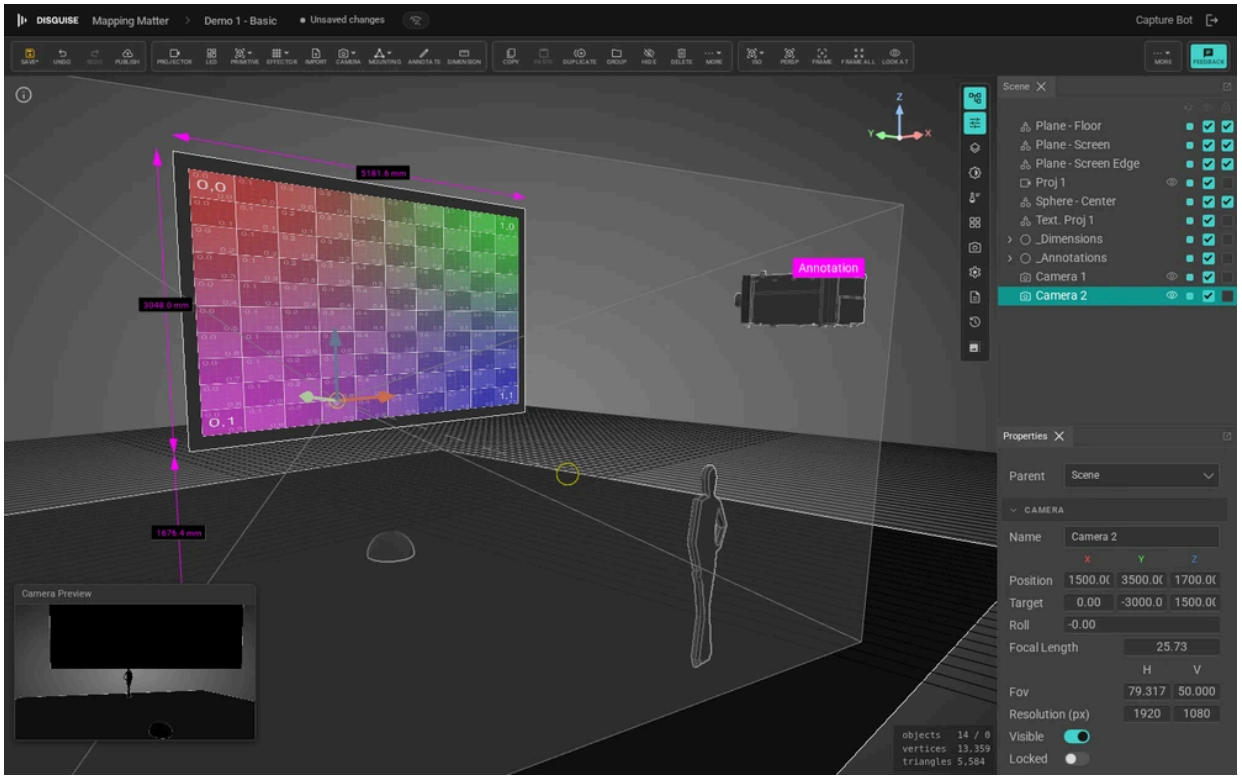
- **Perspective** and **Orthographic** are both free-orbit views. You choose which projection you want and keep your current viewing angle. Switching between them with `Num 5` flips the active projection in place.
- The six axis views snap to a clean axis-aligned orthographic view (and don't free-rotate by right-drag). Switching to one of them auto-frames the scene.

You can also reach the same views with the numpad: `Num 1/3/7` for Front/Right/Top (hold `Ctrl` for the opposite), `Num 0` for Perspective, `Num 5` to toggle ortho/perspective in place, and `Num 2/4/6/8` to orbit a perspective view in 15° steps. The **top-row digits** trigger the same actions, so laptops without a numpad work too. See Keyboard shortcuts for the full scheme.



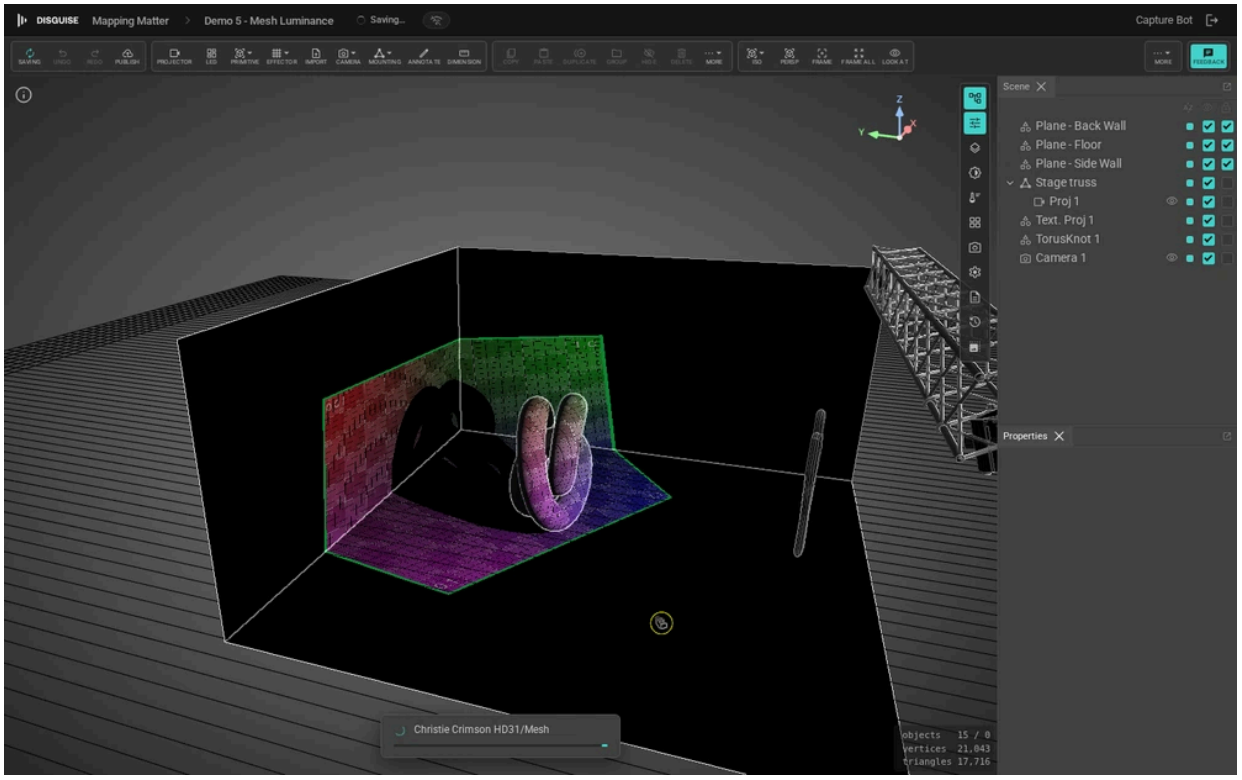
POV camera

A POV camera is a perspective camera with an aim point, closest to a traditional 3D-software camera object. Add one from the toolbar's **Camera** popover and pick **POV camera**. The camera body appears in the scene and an inset preview of what the camera sees opens in the viewport while the camera is selected.



In the POV camera's Properties panel:

- **Type**: Perspective or Orthographic.
- **FOV / focal length**: in degrees and millimetres.
- **Resolution**: H × V pixels for any rendered or exported still.
- **Sensor size**: derives focal-length-equivalent values.

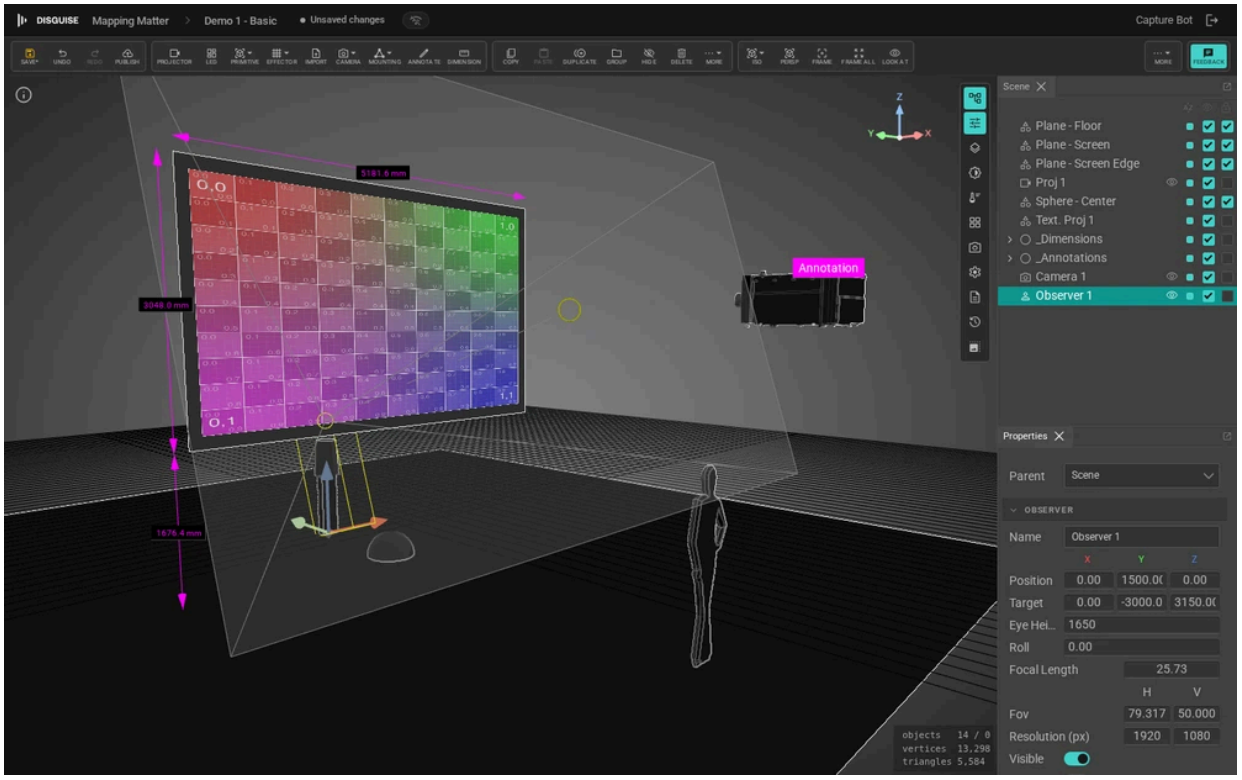


Observer

An **Observer** is a person object with the camera mounted at eye level. Use it to walk through the scene from a real human viewpoint, validate sightlines, and run human acuity analysis.

Add one from the toolbar's **Camera** popover and pick **Observer**. A simple person figure appears in the scene with a head, torso and a forward sight line emerging from the eye position.

When you aim the Observer up or down, the body stays standing upright and only the head pivots toward the target, so the figure looks where the camera is looking without leaning over.



Observer properties

- **Position**: XYZ of the figure's feet.
- **Target**: XYZ of the aim point the observer is looking at.
- **Eye Height**: height above the floor in the active scene unit. Defaults to **1650 mm** (95th-percentile standing adult).
- **Roll**: head roll.
- **Focal Length** / **Zoom**: perspective focal length, or zoom factor for an orthographic observer.
- **Resolution (px)**: H × V pixels for rendered output.

Look from the observer's eyes

Select an Observer and click **Look from** in the saved views strip (or use the eye-icon button on the Observer row in the Scene panel). The viewport jumps to the observer's eye position, hides the figure's body mesh, and locks the camera to the observer.

While looking from an Observer:

- `WASD`: walk forward / left / back / right at floor level.
- **Mouse look**: click the toolbar's **Mouse look** button to capture the cursor for free look-around. Click again or press `Escape` to release.
- **Lock projector view**: pins the Observer view so accidental viewport clicks don't move it.
- **Exit**: leave look-from mode and return to the previous Perspective view.

Human acuity analysis

When looking from an Observer, the toolbar exposes the **Acuity** button. Click it to colour-code every projected pixel and every LED pixel by how its apparent angular size compares to human visual acuity (1 arcminute, the 20/20 threshold). LED tiles and projected surfaces are tinted together so you can compare resolutions in a mixed rig. See Viewport & analysis: Human acuity for the colour key and what each band means.

Collaboration

Mapping Matter scenes are collaborative documents. A scene lives inside a **Production**, a shared unit that you decide who can open. Once people are on the Production, anyone with read access can open the scene, anyone with write access can edit it live, and edits stream to other clients within a second.

Productions and access

Each scene lives in a Production. A Production has a **visibility** (who can see it) and a list of **shares** (specific people and teams who have access).

- **Private (only me)**: the default for new Productions. Only the people listed in the share dialog can see it.
- **Organisation**: every member of the owning organisation can open and edit the Production as an Editor. Admins still control sharing, scope changes, and deletion.

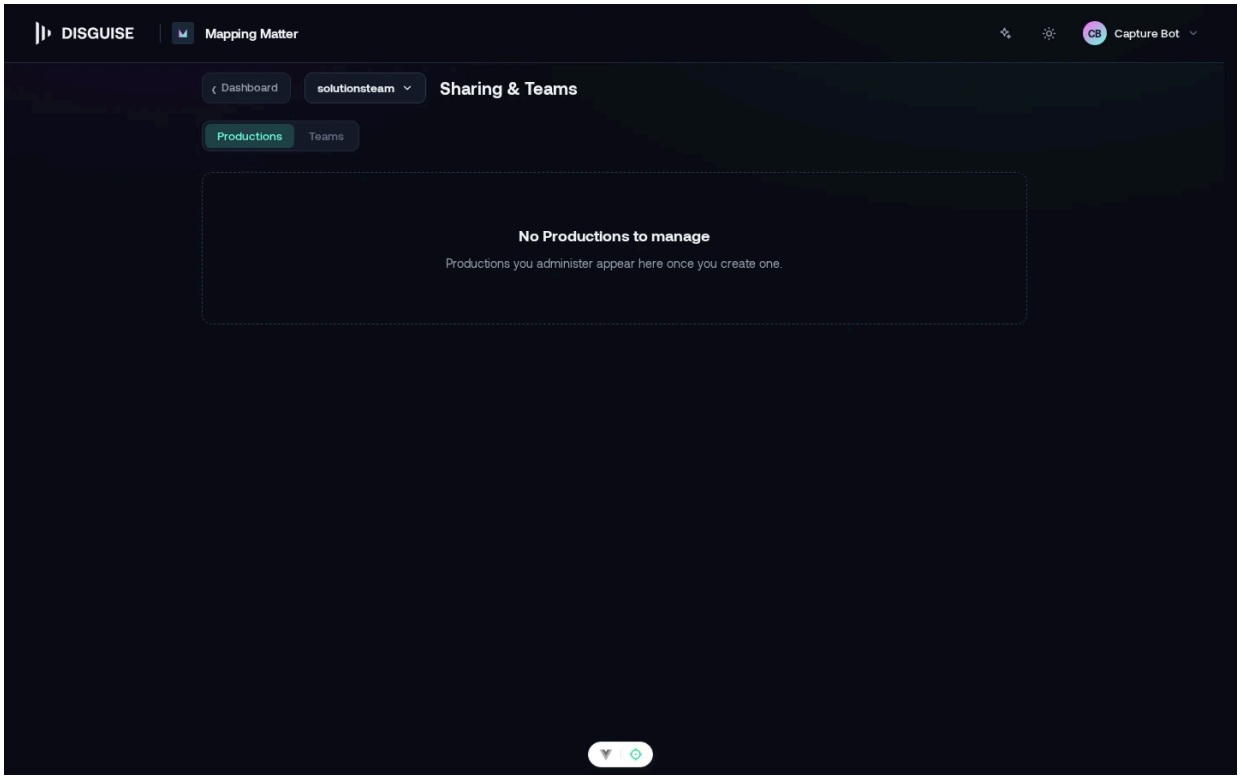
A user's role on a Production is the highest of:

1. Their explicit role on the Production (Admin / Editor / Viewer).
2. The org scope (Contributor / Editor if visibility is **Organisation** and they're in the owning org).
3. Membership of a Team that is shared onto the Production.

You can change visibility at any time. Flipping a Production from Private to Organisation grants every org member Editor access; flipping back removes that access immediately. Both directions prompt for confirmation.

Inviting people

Open **Publish & Share** in the editor and switch to the **Collaborate** tab to invite users to the current Production. You can also manage Productions from the launcher's **Sharing & Teams** dashboard (header menu).



- **By email**: type an email address. If the address belongs to a Disguise Cloud user, they're added immediately as the chosen role. If not, they receive a branded invitation email with a sign-in link, valid for 14 days; once they sign in with that email, they're auto-added to the Production.
- **Editor or Viewer**: pick the role at invite time. Editors can change scene content; Viewers can open the scene but can't edit. The role on an existing member can be changed inline.
- **Cross-organisation**: you can invite someone in another organisation. Cross-org invites land as Editor or Viewer (never as Admin); they can be revoked at any time.

Pending invitations and accepted members are listed together. Revoke an invite to invalidate the link, or remove a member to drop their access immediately. The owning org's Admins can manage the share list; Editors and Viewers cannot.

Teams

When the same group of people needs access to multiple Productions, set up a **Team** in the Sharing & Teams dashboard. A Team is a named group of users that you share onto a Production in one step rather than adding the same five people to ten Productions. Teams support external (cross-org) members the same way Productions do: invite by email, and the email-verified invitee joins on first sign-in.

A Team share grants Editor or Viewer (never Admin). To remove a Team's access from a Production, delete the Team share; to remove a person from every Production they're sharing into, take them out of the Team.

Real-time editing

Once two or more people are on a scene, edits stream live and presence shows up in the editor header.

The header shows an avatar for every user currently in the same scene. Hover an avatar to see the user's name. Each collaborator's view focus appears as a coloured cursor in the viewport, fading after a few seconds of inactivity.

To prevent conflicting edits, Mapping Matter takes a short-lived lock on the scene whenever a user is actively editing. If you try to edit while another user holds the lock, the toolbar shows a notice and your input is queued briefly. If a true conflict is detected (two users dragging the same object), Mapping Matter resolves by accepting the last write and surfacing a conflict toast with a quick undo to the affected user.

View-only and entitlements

Mapping Matter is free to read: any signed-in user can browse demo Productions and any Production they've been shared into. Creating and editing scenes requires an active Mapping Matter entitlement on the user's organisation.

If you open a scene without an editing entitlement (for example, you're an Editor on a shared Production but your own org doesn't have Mapping Matter), Mapping Matter shows a **View-only** notice once per session, and the editor hard-blocks every write action. People who only ever had Viewer access don't see the notice; they just open the scene read-only as expected.

Every mutation entry point is disabled and greyed in view-only mode: Properties sidebar inputs, toolbar copy / paste / duplicate / delete, transform gizmos, scene-tree drag-drop, layer add / remove, and every keyboard shortcut that would edit the scene. There are no controls that appear active but silently fail on write.

Sharing outside the editor

Productions are for ongoing collaboration. To share a frozen view with a client or external reviewer, without granting them access to live editing or scene history, publish a snapshot and create a link or user share.

See also

- Publish & share: snapshots, link shares, and user shares
- Snapshots & revisions
- Plan entitlements

Effectors

Effectors wrap a selected object (or group of objects) into a live container that produces copies. Edit the source and every copy follows; the originals stay editable in the scene tree, copies stay non-pickable until you bake. The toolbar **Effector** button in the add cluster opens a popover with four modes.

You can also create an effector with **no** selection: the effector's gizmo is added at the scene root and you populate it later by dragging objects into it in the Scene tree. Use this when you want to place the array/symmetry plane first and decide what to mirror or duplicate afterwards.

All four modes share the same lifecycle:

- The source object stays as a child of the effector, so edits propagate to every copy.
- Copies are non-pickable in the viewport and don't show in PDF / CSV exports unless the effector is baked.
- **Bake** (in the effector's Properties panel) converts the effector into independent objects, after which copies behave like any other scene object.

Symmetry

Mirrors the source across the array's X axis. Symmetry always produces exactly one copy. Move or rotate the source and the mirror tracks instantly, useful for stacked stage-left / stage-right rigs and any layout where the audience is centred on the venue's axis.

For projectors specifically, horizontal lens shift is inverted on the copy so the projected images converge symmetrically.

Linear Array

Duplicates along an axis. Set:

- **Number**: total instance count, including the original (1 = no copies, 2 = original + 1 copy, etc.).
- **Spacing** (X / Y / Z): inter-copy offset in the active scene unit. Most rigs use a single axis; setting two or three creates a diagonal stride.

The first copy sits one **Spacing** offset from the source; copies continue in the same direction.

Polar Array

Duplicates around the array's local origin. Copies share the source's distance from the array origin; only their angle around it changes.

- **Number**: total copy count including the source.
- **Angle Max**: spread in degrees (1–360). The first copy is at 0°, the last at Angle Max.
- **Full 360°**: when ticked, the spread wraps a complete circle and the last copy is placed at `Angle Max × (Number-1) / Number` so spacing is even.

To move the rotation centre, move the **Polar Array** object itself; the copies follow because they're its children.

Fan

Fans copies around a rotational axis. Unlike Polar Array, Fan keeps copies at fixed offsets from the source; only their *rotation* steps, not their position. Use Fan for things like lighting trusses tilted in chord progressions, or projector arrays where each unit toes inward.

- **Number**: total copy count including the source.
- **Spacing**: per-step position offset between copies. Independent of fan angle.
- **Fan Angle**: total angular spread in degrees.
- **Axis**: which Euler axis the fan rotates around: Yaw, Pitch or Roll.
- **Direction**: which side of the source the copies extend to (forward / backward).
- **Array Origin**: whether the source sits at one end of the spread or at its centre.

Mounting an effector on a truss

Mounting an effector onto a truss carries every copy with it: set the source projector's clamp position and all the copies inherit a chord-relative pose. The whole array slides as a unit along the chord.

See also

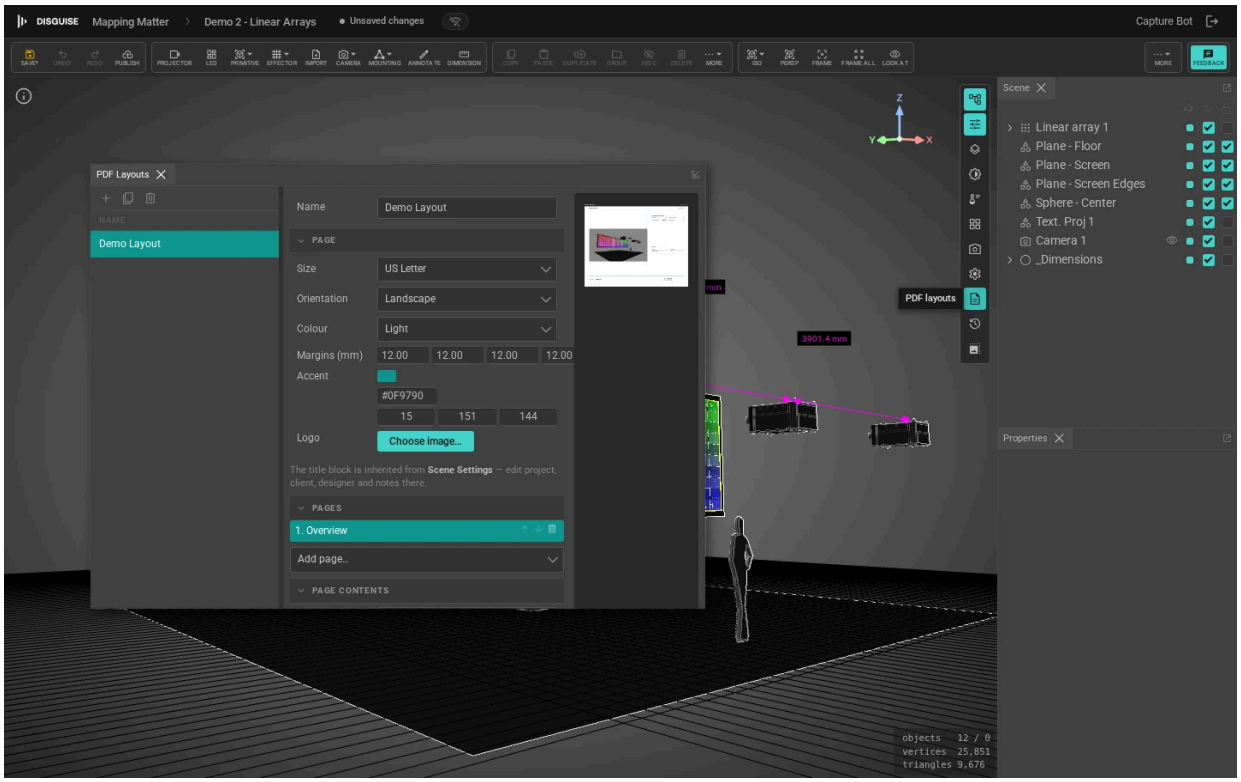
- Getting started: where the Effector button lives on the toolbar
- Trusses & mounting: clamping an effector to a truss
- Projectors and LED screens: the most common sources for effectors

Export and PDF Layouts

Mapping Matter produces field-ready documentation directly from your scene: fully customisable projection-study PDFs, projector spec CSVs, and 3D mesh exports for handoff to other tools.

Projection-study PDFs

A **projection study** is a bound PDF report you can shape page-by-page from a set of prebuilt templates. Open **PDF layouts** from the bottom Panels strip.



The panel has three areas:

- **Global page settings**: page size (**ISO A4** → **A0**, or **US Letter**), orientation, and margins. Every page in the layout uses these.
- **Title block**: logo image, free-text title, date, version, and page-number style. Applied to every page in the layout.
- **Pages list**: the list of pages that will be printed, in order. Add, remove, reorder, or swap the template. Each page's per-slot controls appear in the Properties panel when it's selected.

Templates

Every page picks from a set of prebuilt templates. Each template exposes typed **slots** that you fill:

- **Cover**: title block + hero render at any viewpoint.
- **Scene overview**: top-down or perspective render with a projector-count summary.
- **Per-projector detail** (repeats, one page per projector): projector's own viewpoint, spec table, throw and lens data.
- **Per-LED-screen detail** (repeats, one page per LED wall): spec table, tile-layout diagram, and 3D mesh view.
- **Per-observer detail** (repeats, one page per Observer): POV render and human-acuity page.
- **Photometric report**: illuminance (lux) and luminance renders on a chosen viewpoint.

Repeat pages materialise to one page per matching object when the PDF is generated, so a scene with eight projectors and one observer produces a single **Per-projector detail** entry in the list but eight pages in the output.

Render slots and visualisation modes

Any render slot on any page can be set to display one of several **visualisation modes**, picked per slot:

- **Projection output**: the beams-on-geometry view.
- **Pixel density**: pixels per unit length on the surface.
- **Pixel stretch**: the anisotropy of a projector's pixels on the surface.
- **Illuminance (lux)**: photometric heatmap.
- **Luminance**: the reflected-light view.
- **Visual acuity**: from an Observer's eye position.

The colour bar and legend follow the scene's active units and the panel's scale settings, so a lux page in a scene set to lumens per square metre reads the same as it does in the viewport.

Live preview + generate

The panel shows a **live preview** of the assembled document: swap templates or edit a slot and the preview updates in place. Click **Generate PDF** to render the final vector PDF using the scene's real render pipeline (via a headless HTML→PDF service). If no render service is configured the editor falls back to a browser print preview using the same layout, so you can still produce the deliverable locally.

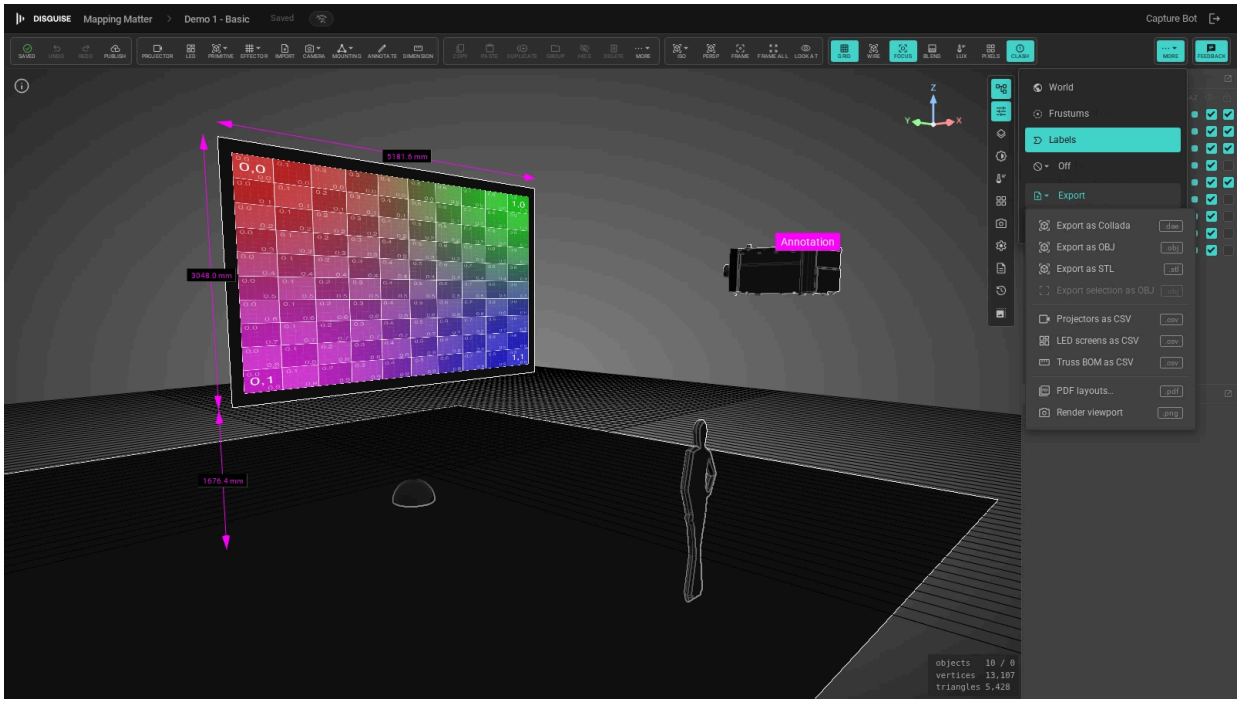
Generating a PDF never dirties the scene or flickers a mode to collaborators; the export uses an isolated render config that autosave and realtime broadcast ignore.

Reusing layouts across scenes

Save a study to the layout library from the panel's overflow menu. The whole page list, templates, slot settings, and title block are stored together, so you can drop the same study configuration onto a new project and just re-generate.

Export menu

Click **Export** on the right side of the toolbar to open the export dropdown:



CSV export

The **Projectors as CSV** and **LED screens as CSV** actions in the Export dropdown produce row-per-object specification tables. Useful for handoff to media servers (Designer, Notch, others) that import scene metadata.

Projector and LED CSV files are written without a UTF-8 byte-order mark so the Designer importer can parse them directly. **Truss BOM as CSV** still includes the BOM so Excel renders the multiplication sign in dimension columns correctly.

The **Truss BOM as CSV** action emits a rigging bill of materials: one row per truss (type, profile, dimensions, mass), one row per base, plus per-truss attachee rollups walked through any Symmetry copies so projector and LED counts reflect what's actually rigged. See Trusses & mounting.

3D mesh export

The Export dropdown's **Export as OBJ / Collada / STL** actions emit a scene mesh containing the selected geometry (or all visible geometry if nothing is selected). Use **Export selection as OBJ** to limit the output to the current selection. Multi-object selections (including imported References and projector bodies) emit non-empty geometry, and the units and axis convention match the whole-scene exports (metres, Y-up).

Snapshot export

A published snapshot can also be exported as a single self-contained `.zip` containing the scene JSON, all referenced textures, meshes, and the title block, used for offline archives and contractual handoff.

FAQs

Answers to the common questions when working in Mapping Matter: keystone correction, ultra-short-throw lenses, mirrors, pixel-resolution maths, navigation hardware, and sharing. If your question isn't here, send it through the **feedback form**.

How do I do keystone correction?

Mapping Matter does not have an explicit keystone tool because projection mapping itself solves the geometric correction problem: you align the projector to the surface and the geometry is correct. To visualise the projected texture *on the surface* without the physical beam visible, enable **Projection Map** in the receiving material's Properties panel and assign the same texture you assigned to the projector. This is useful for client review.

Can I model an ultra-short-throw projector?

Yes. UST lenses are first-class. Pick a UST projector from the **projector library** and Mapping Matter will:

- apply the lens's **fixed optical offset** (the large baked-in beam-up offset that defines a UST head) on top of any motorised shift,
- detect that you're on a UST lens and surface a **UST lens: add a fold mirror?** banner in the sidebar with an **Add suggested mirror** button that drops in a 45° fold plate aimed at the projector's target,
- show the beam footprint on the mirror plate so you can size it against the cone.

If the exact model isn't in the catalogue, click **+ Create custom** in the library overlay. The form covers everything the optics model needs (throw range, fixed optical offset with V/H plus convention, adjustable shift envelope and mode, mount slug), and the AI ghost-fill will populate them from the manufacturer + model name. See **Projectors: Custom projectors**.

Do I still need the "fake mirror" trick?

No. The **mirror feature** replaces the old workaround of parenting a Symmetry under an Empty Node. Use a real mirror plate for bounce, snorkel, and folded-beam configurations.

How do I calculate pixel resolution across multiple projectors?

The photometric analysis panel reports per-surface coverage and pixel density. For manual back-of-envelope:

```
effective_horizontal_pixels = N × image_width_px × (1 − blend_percent)
```

For example, two 1920 × 1080 projectors blended at 20%: `2 × 1920 × 0.8 = 3072` effective pixels.

Do you support SpaceMouse?

Not yet. The viewport supports keyboard + mouse navigation and the saved views strip; see Cameras & POV.

Where are the keyboard shortcuts?

Press `F1` anywhere in the editor, or open the Keyboard shortcuts page for the full list.

Where does the revision history live?

Every edit creates a revision automatically. Click **Revisions** in the bottom Panels strip to browse or restore. See Snapshots & revisions for the full model. The legacy “last 10 opens” snapshot system has been replaced by full history.

Which browsers are supported?

Recent desktop Chrome, Edge, Safari and Firefox on macOS and Windows. WebGL 2 is required. Mobile browsers are not supported.

How do I share with someone outside my organisation?

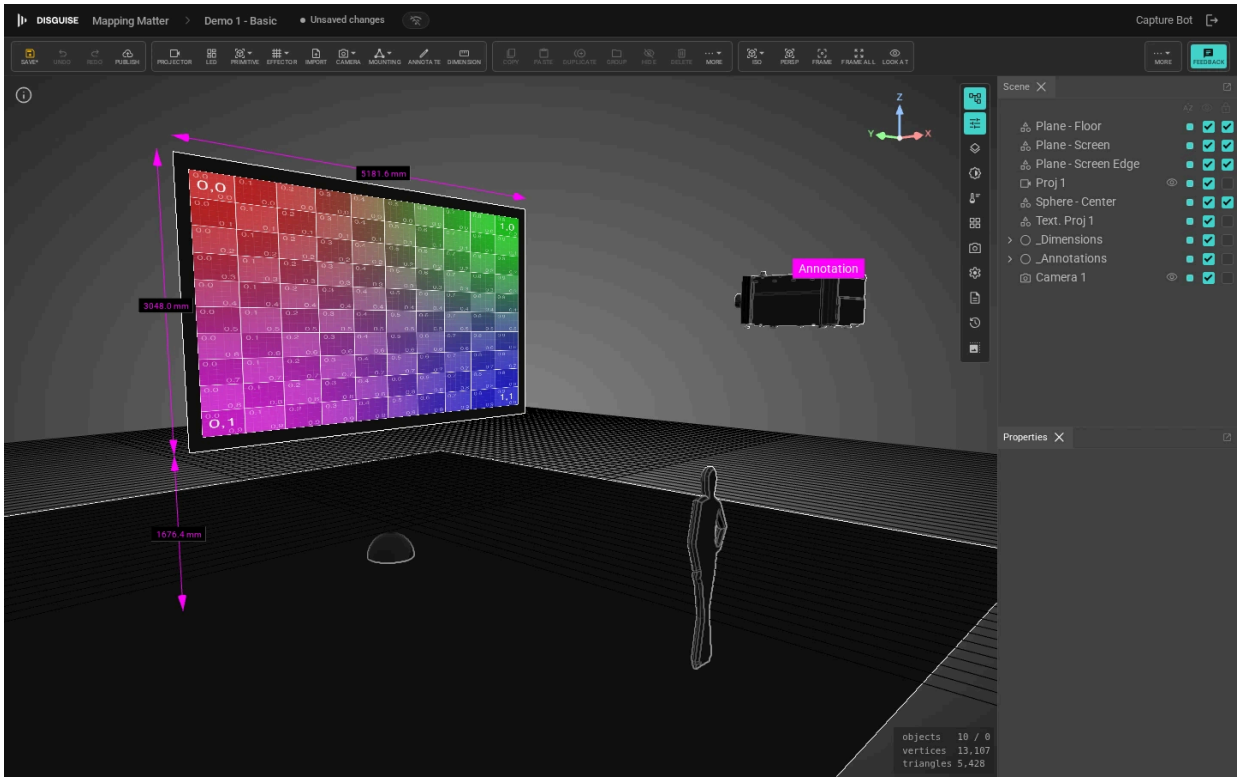
Publish a snapshot and add a link or user share (see Publish & share). Link shares can be password-protected and revoked at any time.

I get a “scene is locked by another user” notice. What now?

Another collaborator is actively editing. Mapping Matter queues your input for a few seconds; if the lock persists, ask them to pause. See **Collaboration**.

Feedback

Mapping Matter is under active development and we read every report. The fastest route to the team is the **Feedback** button pinned to the far right of the viewport toolbar.

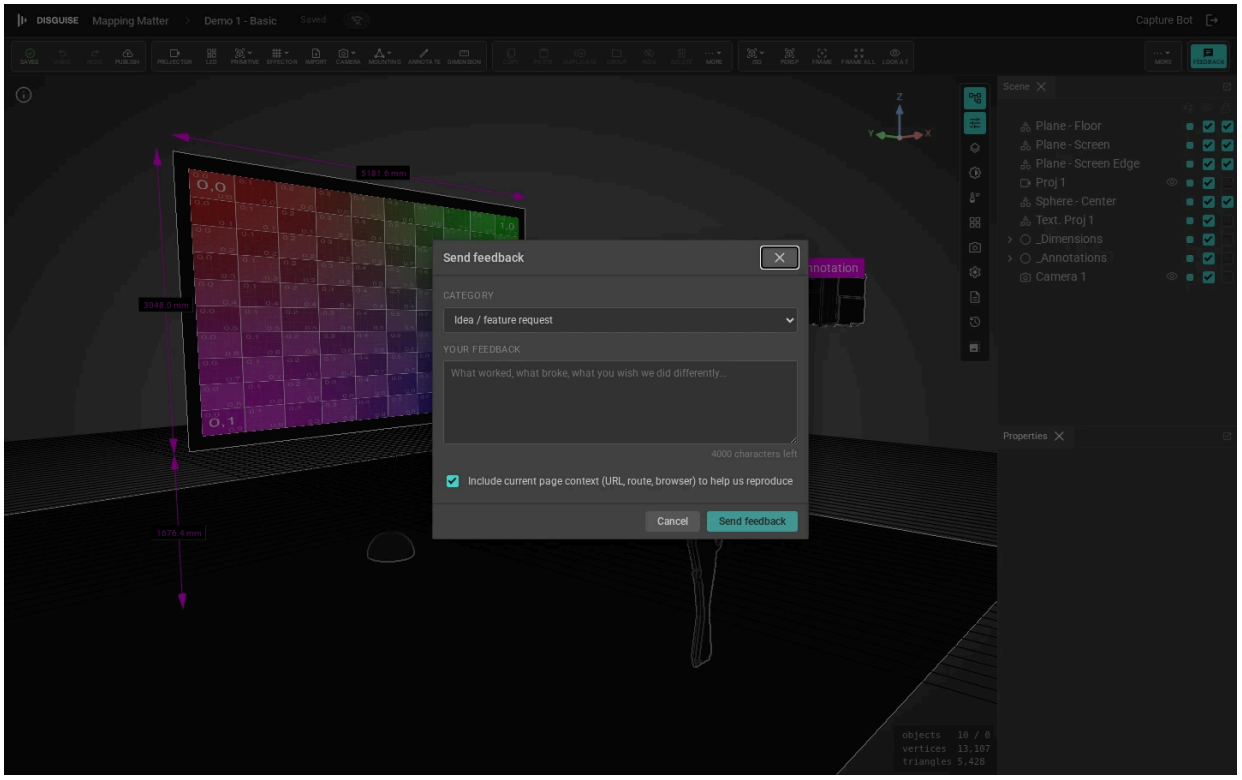


Submit a report

Click **Feedback** to open the feedback form. Choose a category, write a description, and submit.

Category	When to use it
Bug	Something didn't work as expected.
Idea	Feature suggestion or enhancement.
Usability	Something works but is hard to find, slow, or confusing.

Category	When to use it
Praise	Tell us what's working; this is the category we read most carefully.



Report a problem with a library entry

If a catalogue projector has the wrong throw ratio, lumens or lens options (or you spot a similar issue on an LED tile or truss), open the library overlay and click the small flag icon on the offending card. A short dialog pre-fills the entry's details so the report reaches the same triage queue with the right context. Use this rather than the general Feedback button whenever the problem is data on a specific catalogue item, so we can patch the model directly.

What is sent

Each submission includes:

- The text you wrote and the category you chose.
- Your Disguise Cloud user ID and the name of the project / scene you were in.
- The current URL, browser user-agent string, and Mapping Matter version.
- For library reports, the catalogue ID and the row's current spec values.
- No scene content or screenshots. If a bug needs visual context, attach a screenshot in the form's optional attachment field.

What happens next

Submissions land in the Disguise internal triage queue. A team member reviews each item, files a tracking ticket if it's actionable, and may follow up by email, so use a valid Disguise Cloud account when reporting.

You don't get an in-app reply. Status updates on individual reports are not currently exposed in Mapping Matter; product-wide changes are summarised in the release notes.

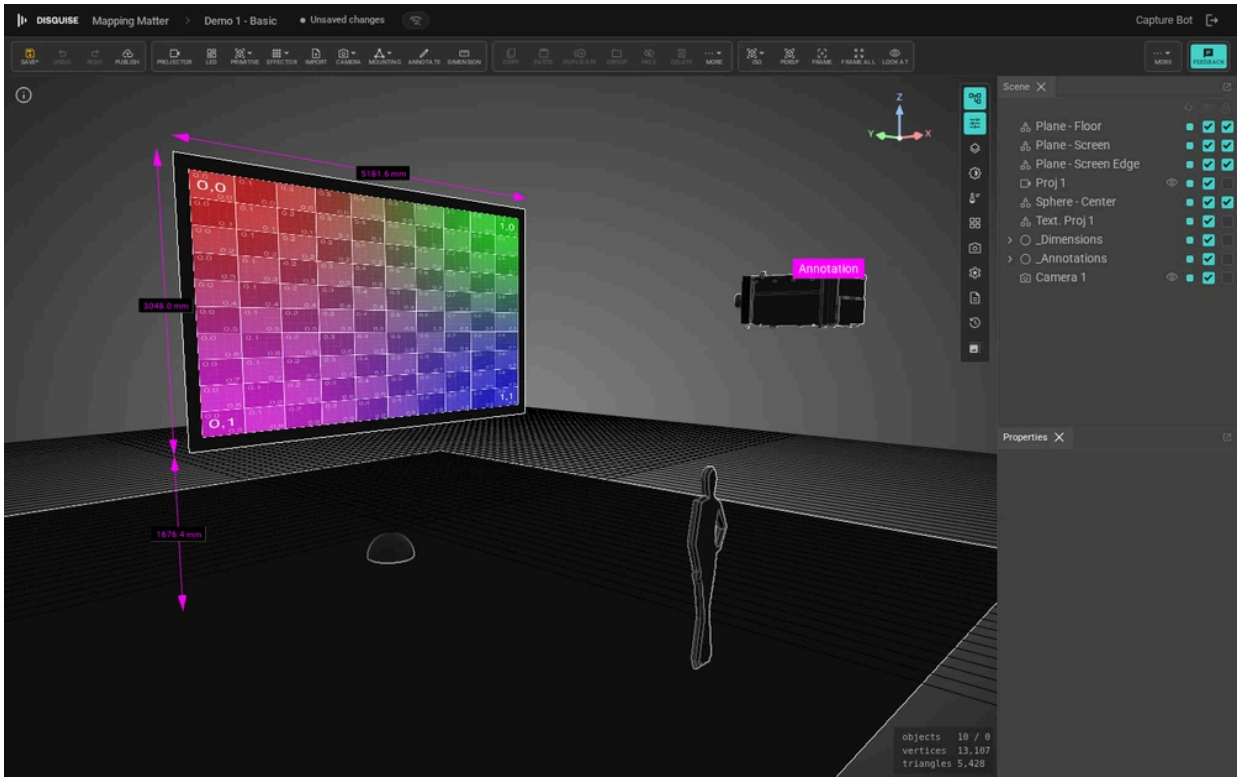
Getting Started

This page walks you through opening your first scene, the layout of the editor, and the basic operations you need to start designing.

Open or create a scene

You open Mapping Matter from the Disguise Cloud launcher dashboard. The launcher has up to three tabs:

- **My Projects**: your organisation's projects. Each project tile shows the plugins available on that project; clicking the Mapping Matter tile on a project opens its scene in the editor (if the project has no scene yet, Mapping Matter creates one).
- **Demos**: read-only demo scenes provided by Disguise. `Demo 1 - Basic` through `Demo 7 - UST` cover progressively richer setups (basic projection, linear arrays, sphere mapping, textures, mesh luminance, video playback, ultra-short-throw). Click a demo tile to open it in the editor.
- **Migratable**: only shown if you have scenes in **legacy Mapping Matter**. Each tile is a one-click handoff into the modern editor: the legacy scene is rebuilt as a new project with its meshes, textures and projectors carried over. The original is left untouched unless you opt in to marking it as migrated.

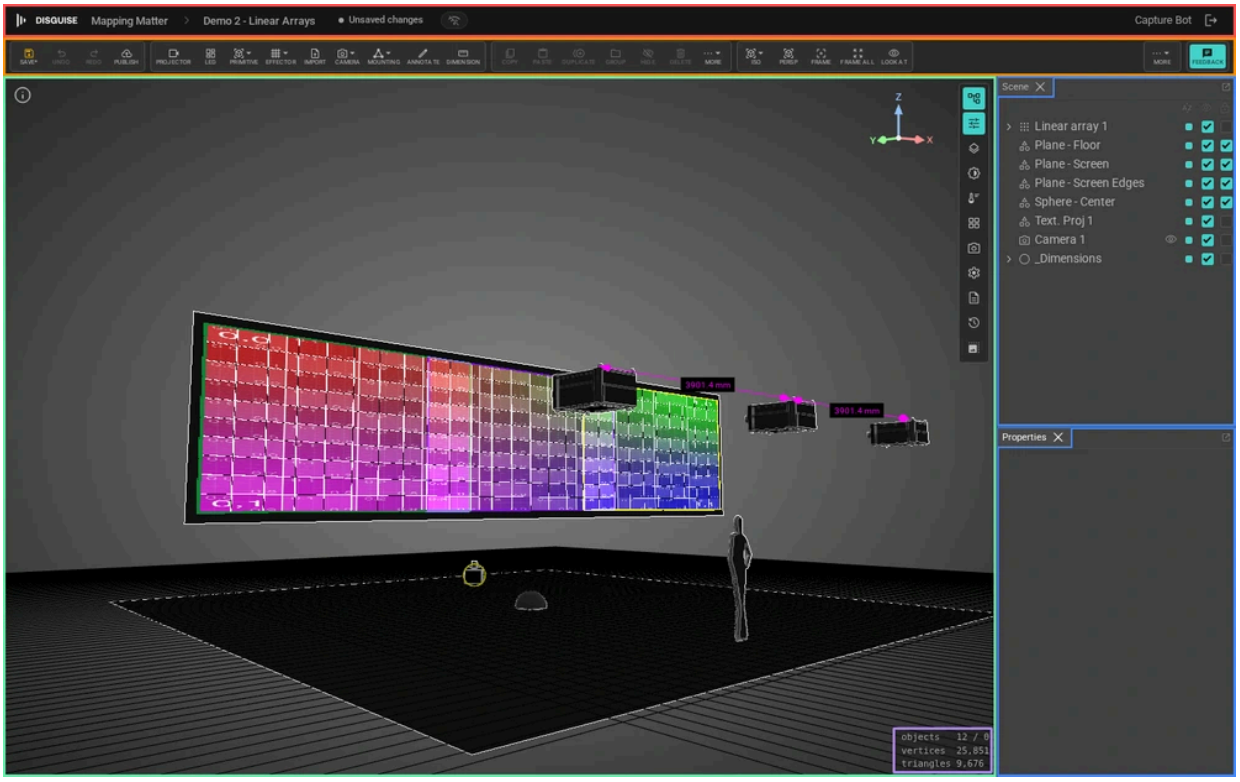


Project-to-scene is one-to-one: each project has exactly one Mapping Matter scene. To work on a different scene, switch projects in the launcher rather than looking for a scene picker inside Mapping Matter.

The launcher header shows a **sparkle icon**; open it any time to read the latest **What's New** announcement from the Disguise team. An unread dot appears when a new announcement is published; the dot clears once you open the panel. Fresh sign-ins to the dashboard always pick up the latest content.

The launcher remembers your **sort order** (Last edited ↔ Name), **scope filter** (All / Private / Org / Shared), and grid/list view per browser, so the dashboard opens the same way each time. The projector and LED library overlays in the editor persist their brand filter, origin filter, and sort the same way.

Editor layout



Region	Purpose
Header (top)	Disguise Cloud breadcrumb, scene name, network status, account menu.
Viewport toolbar (below the header)	Clustered buttons grouped left to right: file (Save / Undo / Redo / Publish), add objects, edit selection, view presets, display toggles, transform space, Export, Help. **Feedback** is pinned to the far right.
Viewport (centre)	The 3D scene. Pan with left-click drag on empty space, zoom with middle-click drag or scroll wheel, orbit with right-click drag.

Region	Purpose
🟦 Scene tree and Properties panels (right)	The Scene panel lists the scene graph; the Properties panel shows fields for the current selection. Both are dockable: open or close them from the bottom-edge **Panels** strip.
🟫 Panels strip (bottom edge)	Icon buttons for every dockable panel (Scene, Properties, Layers, Brightness, Pixel density, Camera settings, Viewport settings, PDF layouts, Revisions, Scene settings). Click any to open or close that panel.
🟪 Viewport info (bottom right)	Object / vertex / triangle counts.

If Mapping Matter deploys a new build while you're mid-session, a **Reload** banner appears in the top-right corner. It's non-blocking; click it when you're at a good stopping point. It never reloads on its own, so unsaved work stays safe. Focus a green **number field** in the Properties panel and the mouse wheel starts editing that field instead of scrolling the panel; focus off, and the panel scrolls again.

The toolbar adapts to viewport width. Below 1440 px the clusters collapse to icon-only buttons, and anything still wider than the editor pulls into a right-anchored **More** ▾ dropdown so the ribbon never overflows.

Panels

Click any icon button in the bottom-edge **Panels** strip to open or close that panel:

- **Scene**: scene graph tree with visibility and lock toggles per row.
- **Properties**: context-switched panel for the current selection (projector lens, LED tile count, material, etc.).
- **Layers**: bulk layer visibility and locking.
- **Brightness**: lux heatmap controls (see **Viewport & analysis**).
- **Accuracy**, **Camera settings**, **Viewport settings**: viewport tuning.
- **PDF layouts**: page templates (see **Export & PDF layouts**).
- **Revisions**: scene revision history.
- **Scene settings**: units, title block, auto-save.

Objects in the Scene panel are grouped into **layers**. Toggle a layer to hide everything beneath it, or include only specific layers when publishing a **snapshot**.

Reparenting in the Scene panel

Drag a row in the Scene panel onto another row to reparent it:

- Drop **onto** a node to set that node as the new parent.
- Drop **above or below** a sibling to reparent under the sibling's parent in that position.
- Drag a multi-selection to move the whole top-level selection at once.

The same restrictions as the Properties **Parent** dropdown apply: you can't reparent into a `Reference`, `Pov`, `Measure` or `Annotation`, into a locked subtree, or into the dragged object's own descendants.

Rearranging panels

Every panel is dockable. Grab the panel's header tab and drag it to:

- An edge of the editor: the panel snaps to a new vertical or horizontal rail.
- An existing panel's tab strip: the dragged panel becomes a tab alongside the target.
- The viewport area: the panel floats free as a movable window.

Your layout persists per scene, so the workspace you set up for a projector-heavy rig is different from the one for an LED-only scene.

Navigate the viewport

Action	Mouse
Pan	Left-click drag on empty space
Zoom	Middle-click drag, or scroll wheel
Orbit	Right-click drag
Frame selection	`F` (or the **Frame** button in the toolbar's view cluster)
Frame all	`Home`, or the **Frame all** button in the toolbar's view cluster. With nothing framable, Home recentres the camera on its default pose so pan/zoom speed feels normal again.

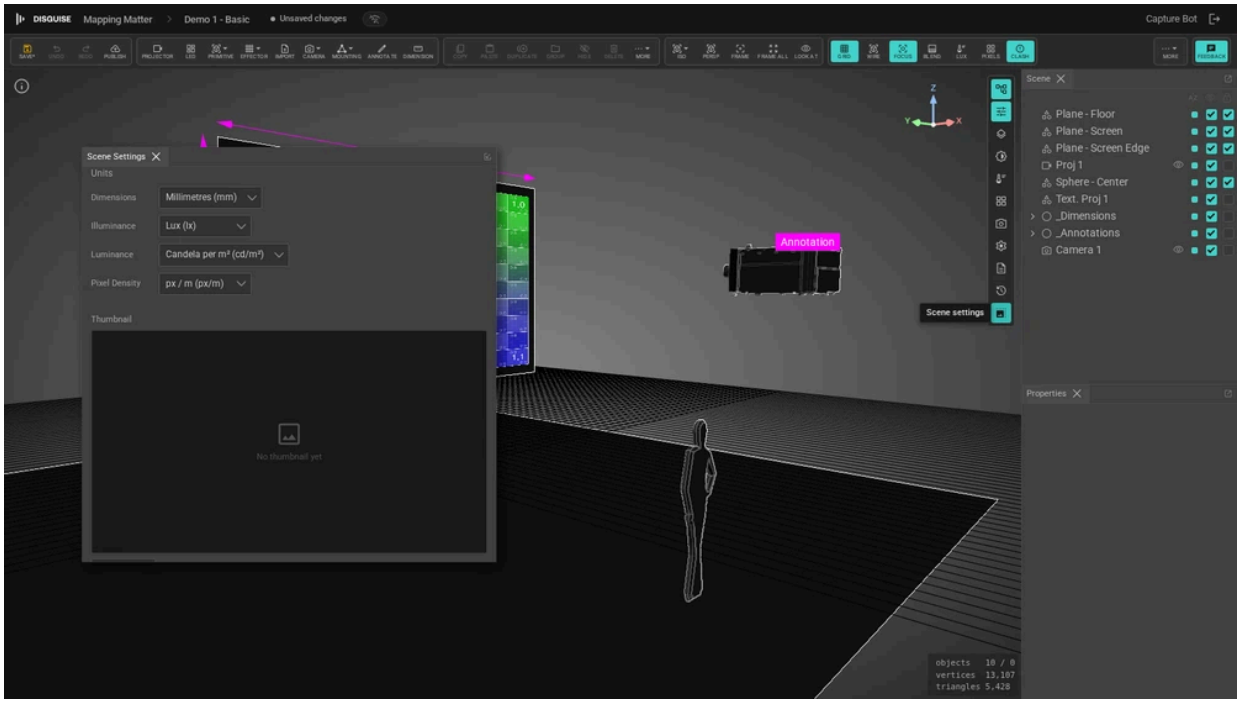
Action	Mouse
Look at selection	The **Look at** button (rotates the camera toward the current selection)

All keyboard shortcuts are listed in the **Keyboard shortcuts** page; press `F1` at any time to open the in-app reference.

If you prefer Blender / Maya's mouse convention, open **Scene settings** and turn on **Swap orbit / pan mouse buttons**. Left-drag then orbits, right-drag pans. Middle-click zoom is unchanged. The preference is per-browser and takes effect immediately across every open scene.

Scene units and settings

Click **Scene settings** in the bottom Panels strip to open the Scene Settings dialog. Set the working unit (mm, cm, m, ft, in), background colour and gradient, fog, and the title block that travels with every published snapshot.



Add objects

The viewport toolbar's add buttons are direct, with no "Add" submenu. Each button is in the second cluster from the left:

- **Projector**: opens the **projector library**.
- **LED**: opens the **LED library**.
- **Primitive**: popover with Plane, Box, Room, Circle, Cylinder, Sphere, Icosahedron, Torus, Torus Knot, Equirectangular Dome, Dome Master, and Empty Node.
- **Effector**: popover with Symmetry, Linear Array, Polar Array, and Fan effectors that duplicate or distribute the current selection.
- **Import**: opens the asset browser to bring in an `.obj`, `.fbx`, `.dae`, `.stl` or `.gltf` mesh. Imported meshes up to 100 MB are saved to your project library; larger meshes can still be loaded locally for the current session.
- **Camera**: popover with POV camera and Observer.
- **Mounting**: popover with truss types (Tower, Horizontal Span, Goal Post, A-Frame, Ladder, Arc, Ring), bases (Base Plate, GB Block, Sled, Outrigger), and a **Truss library...** entry for the full catalogue. See **Trusses & mounting**.
- **Annotate** (`A`): start the freehand annotation tool.
- **Dimension** (`T`): start the dimension measure tool.

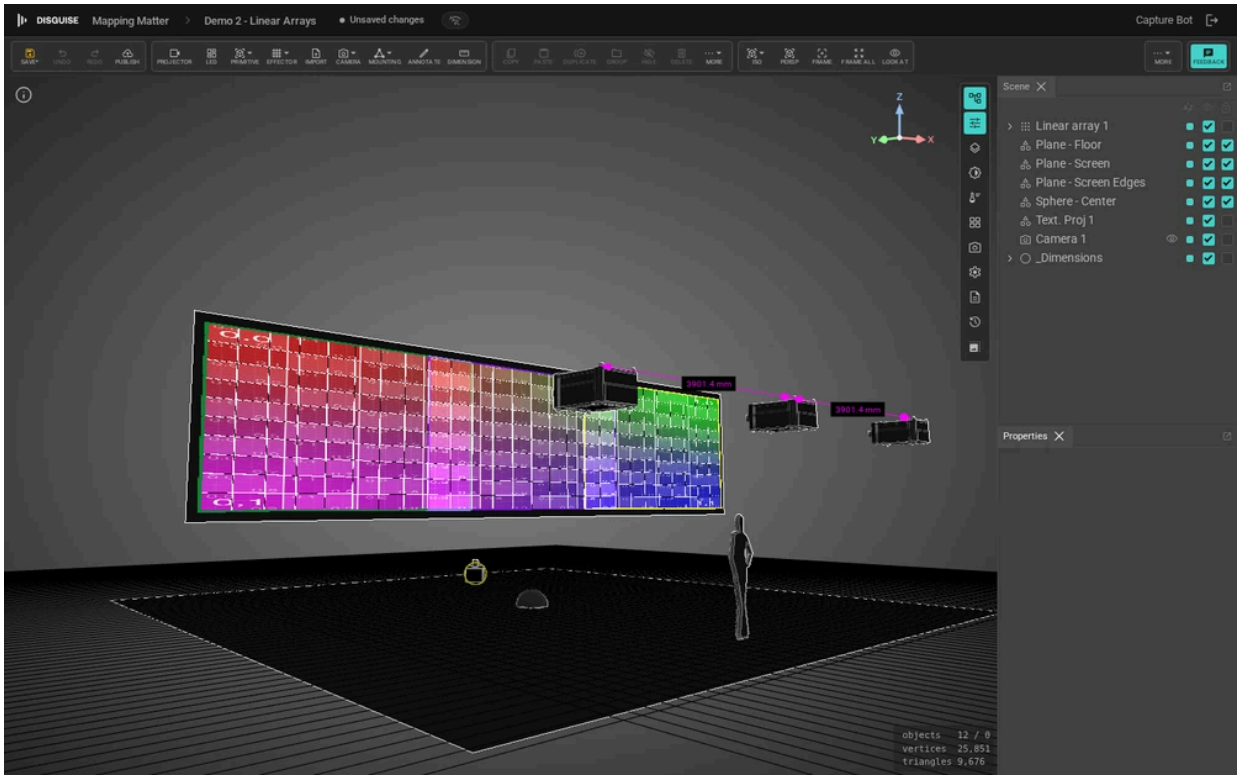
To add a mirror to a projector, select the projector and open the **Mirror** collapsible in its Properties panel; see **Mirror**.

Move, rotate, scale

Select any object and use the transform gizmo. Numerical position, rotation and scale are available in the Properties panel for the selection. The **World** / **Local** toggle in the toolbar switches the gizmo space. Changes auto-save and are added to the revision history.

Effectors: arrays and symmetries

Use the toolbar **Effector** button to wrap the current selection in an effector. Four modes are available (**Symmetry**, **Linear Array**, **Polar Array**, **Fan**), each with its own parameters and behaviour. See **Effectors** for the full reference and per-mode animations.



Materials and textures

Select any mesh and open its **Material** panel to set base map, projection map, colour, metallic, roughness, and emissive. Textures come from the **Library**; the same texture can be reused across multiple objects.

Saving, revisions and snapshots

You don't need to save manually; Mapping Matter auto-saves as you work. To return to an earlier state, click **Revisions** in the bottom Panels strip.

- **Revisions** are the per-edit history of your current scene. Restoring a revision overwrites the current scene.
- **Snapshots** are named, locked publishes of the scene at a point in time. Snapshots are how you share the design; see **Publish & share**.

See **Snapshots & revisions** for the full model.

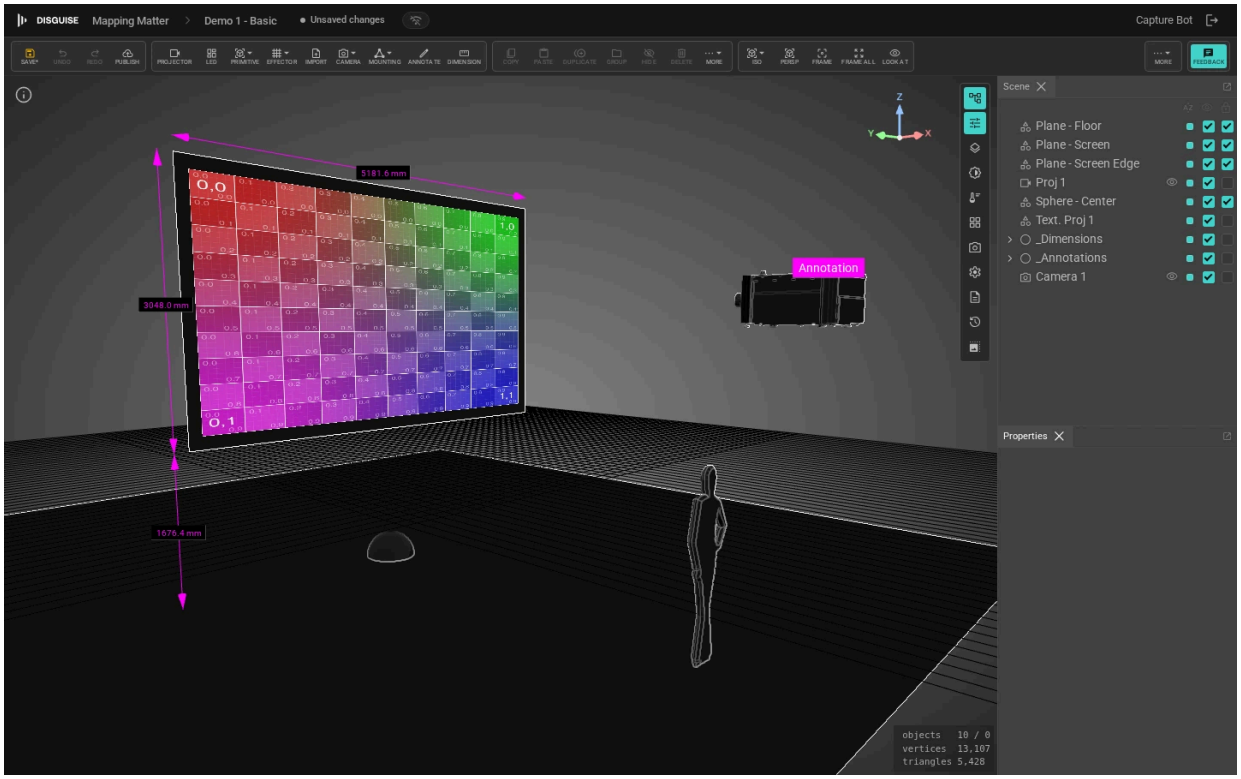
What's next

- Add projectors and aim them: see **Projectors**.
- Add an LED wall: see **LED screens**.
- Run a photometric or brightness check: see **Viewport & analysis**.

- Publish your work for a client: see **Publish & share**.

Introduction

Mapping Matter is a Disguise Cloud plugin for projection and LED design. In a scene you place projectors, LED tiles, cameras and observers; preview content on 3D geometry; run photometric, accuracy and brightness analyses; and publish snapshots for review.



How it works

Platform

Mapping Matter runs in desktop browsers (Chrome, Edge, Safari, Firefox) on macOS and Windows, and requires WebGL 2. Scenes, revisions and assets are stored in your Disguise Cloud project. There is no local install or backup.

Architecture

- **Scenes** are 3D documents tied to a Disguise Cloud project. They auto-save and keep a full revision history.
- **Snapshots** are named, locked publishes of a scene: read-only copies shared by anonymous link (with optional password) or by emailing specific users.

- **Collaboration** is real-time. You see other editors' cursors, and scene locks prevent conflicting edits.
- **Libraries** are split between your project (private assets, layouts, custom projectors) and a platform-wide demo library that signed-in users can browse.

Who uses it

Projection-mapping professionals: technical designers, projectionists, content creators, set designers, and sales engineers preparing budgets and proposals.

Typical use cases:

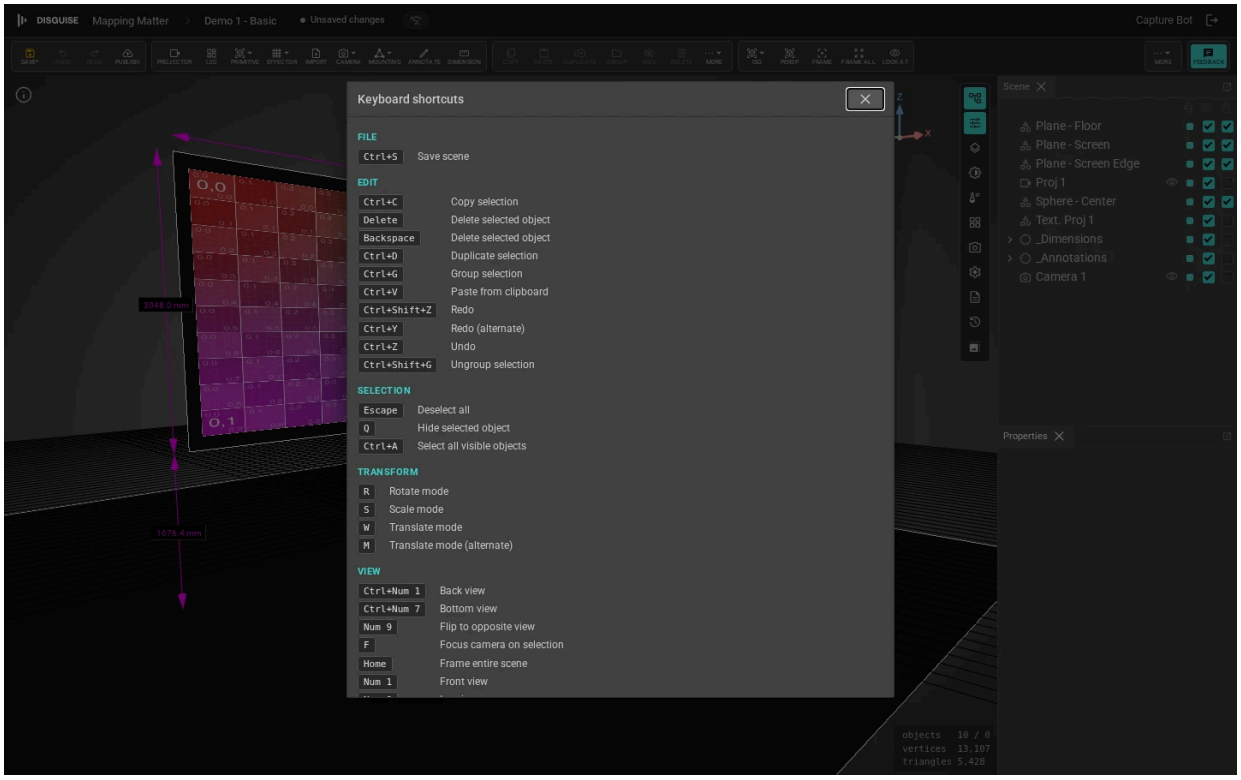
- Iterate on projector placement, lens choice, and stack count.
- Check contrast and coverage with the photometric and brightness viewports.
- Preview stills and short clips on 3D geometry, including LED tiles.
- Measure pixel density and overlap per surface.
- Produce PDF layouts and CSV exports for media servers.
- Share design intent with clients via published snapshots that can be password-protected and revoked.

What it isn't

Mapping Matter is not a content authoring or playback tool. It previews stills and short clips on geometry; use Designer for show authoring and playback.

Keyboard Shortcuts

Press `F1` at any time inside the editor to open the in-app shortcut reference. This page mirrors that reference for offline browsing; the in-app dialog is generated from the same registry that drives the handlers, so it can never drift.



File

Shortcut	Action
Ctrl+S	Save scene (auto-save also runs continuously)

Edit

Shortcut	Action
Ctrl+Z	Undo
Ctrl+Shift+Z	Redo
Ctrl+Y	Redo (alternate)

Shortcut	Action
Ctrl+C	Copy selection
Ctrl+V	Paste from clipboard
Ctrl+D	Duplicate selection
Ctrl+G	Group selection
Ctrl+Shift+G	Ungroup selection
Delete / Backspace	Delete selected object

Selection

Shortcut	Action
Ctrl+A	Select all visible objects
Q	Hide selected object
Escape	Deselect all

Transform

Shortcut	Action
W (or M)	Translate mode
R	Rotate mode
S	Scale mode

View

Shortcut	Action
F	Focus camera on selection
Home	Frame all (or reset camera to its home pose if nothing is framable)
G	Toggle scene grid

The numpad keys follow the Blender convention. Each ortho view auto-frames the scene after switching. All numpad shortcuts also fire from the **top-row digits** (`0` – `9`), so laptops without a numpad can drive them too. The in-app reference still shows the “Num …” labels for consistency.

Shortcut	Action
Num 0	Perspective view
Num 1	Front view
Ctrl+Num 1	Back view
Num 3	Right view
Ctrl+Num 3	Left view
Num 7	Top view
Ctrl+Num 7	Bottom view
Num 2 / Num 8	Orbit view down / up (15°, perspective only)
Num 4 / Num 6	Orbit view left / right (15°, perspective only)
Num 5	Toggle ortho / perspective (remembers the last ortho view)
Num 9	Flip to the opposite ortho view (Front ↔ Back, etc.)

The toolbar **View** dropdown applies the same auto-frame behaviour when you pick an ortho view from it.

Tools

Shortcut	Action
A	Open annotations tool
T	Open dimensions tool

Help

Shortcut	Action
F1	Show this shortcut reference

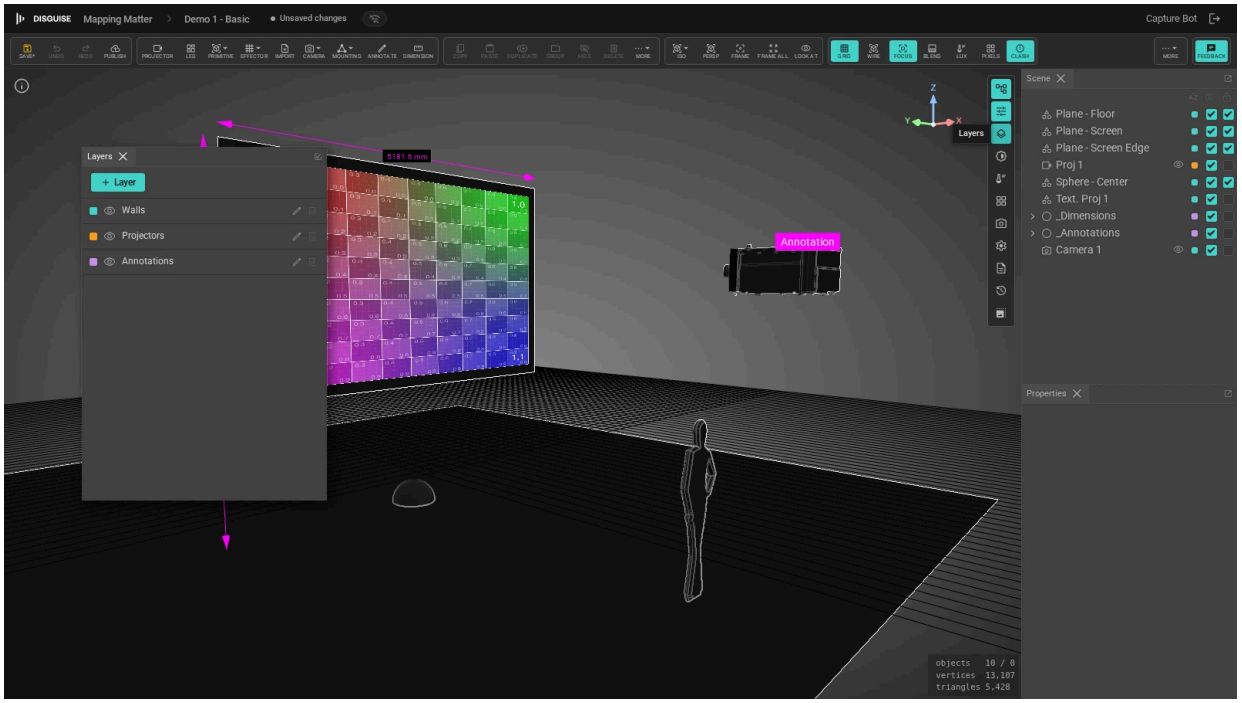
Shortcuts are fixed: they aren't user-remappable today. If a binding gets in your way, send us feedback and we'll consider remapping support.

Layers

Layers are a lightweight way to organise the objects in a Mapping Matter scene. Every scene starts with a single **Base** layer; you can add more layers, assign objects to them, and toggle whole groups of objects on and off at once. Layer membership also drives selective publishing: a snapshot can include only the layers you tick.

The Layers panel

Open the Layers panel from the **Layers** button in the bottom Panels strip. The panel lists every layer in the scene in order, with these per-row controls:



- A small colour swatch for the layer.
- A **visibility** toggle (eye icon) that shows or hides every object on the layer.
- The layer name.
- A **Rename** icon to change the name.
- A **Delete** icon to remove the layer. The **Base** layer cannot be deleted; deleting any other layer moves the objects assigned to it back to **Base**.

To add a layer, click the **+ Layer** button at the top of the panel and enter a name.

Layer changes are saved with the scene and broadcast to collaborators in real time, the same way that any other scene edit is.

Assigning objects to layers

Objects are assigned to layers from the **Scene** panel, not from the per-object Properties panel. Each row in the Scene panel shows a small layer chip; click the chip to open a layer popover and pick a layer:

- If the row is part of the current selection, the chosen layer is applied to **every** selected object.
- Otherwise, the chosen layer is applied to just that one row.

Objects without an explicit layer belong to the **Base** layer by default. When you delete a layer, its members fall back to **Base** automatically.

Visibility

Toggling a layer's eye icon hides or shows every object on that layer in the viewport. Per-object visibility (the eye toggle on individual rows in the Scene panel) is preserved across layer toggles: an object you hid manually stays hidden when the layer is shown again, and an object that the layer hid is restored when the layer comes back.

Locking is a **per-object** action, set from the lock toggle on each row in the Scene panel; there is no bulk lock toggle on the Layers panel itself. Locking blocks the gizmo and prevents the object from being edited or reparented; collaborators see the same lock state.

Layers in snapshots

When you publish a snapshot from **Publish & Share**, the **Publish** tab includes a **Layers to include** list. Tick the layers whose objects should appear in the published snapshot; by default, the currently-visible layers are pre-ticked.

This is how you produce a snapshot that highlights one part of a rig (for example, just the projector layer for a lighting brief), without rearranging or hiding objects in the working scene.

See Publish & share for the rest of the publish flow.

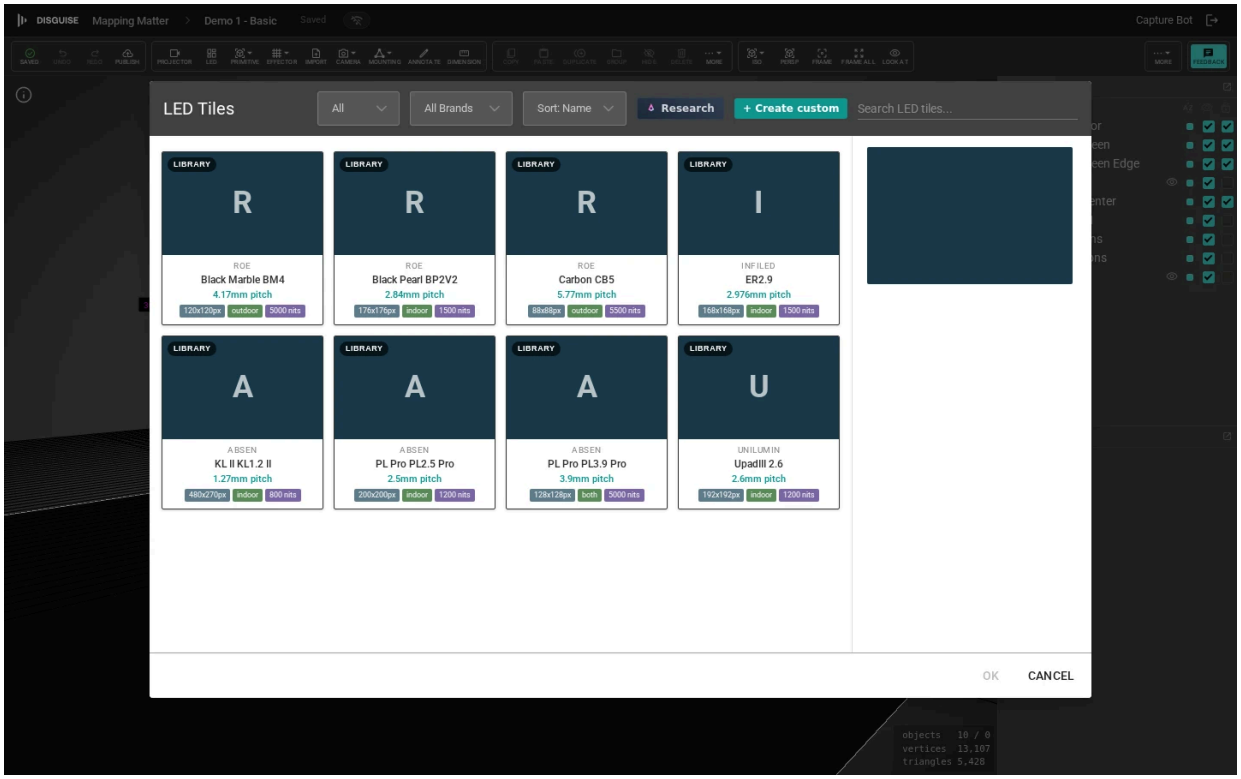
- Getting Started: overview of the editor and the Scene panel.
- Snapshots and Revisions: how snapshots fit alongside the revision history.
- Publish and Share: the full publish flow, including the **Layers to include** picker.

LED Screens

LED screens are first-class objects alongside projectors. You compose a wall from tiles, set physical pixel pitch, optionally curve the wall, and preview content directly on its surface. The same brightness and photometric viewports that analyse projection coverage also work on LED.

Add an LED screen

Click **LED** in the viewport toolbar's add cluster to open the LED library overlay. Choose a tile from the catalogue and set the wall layout.



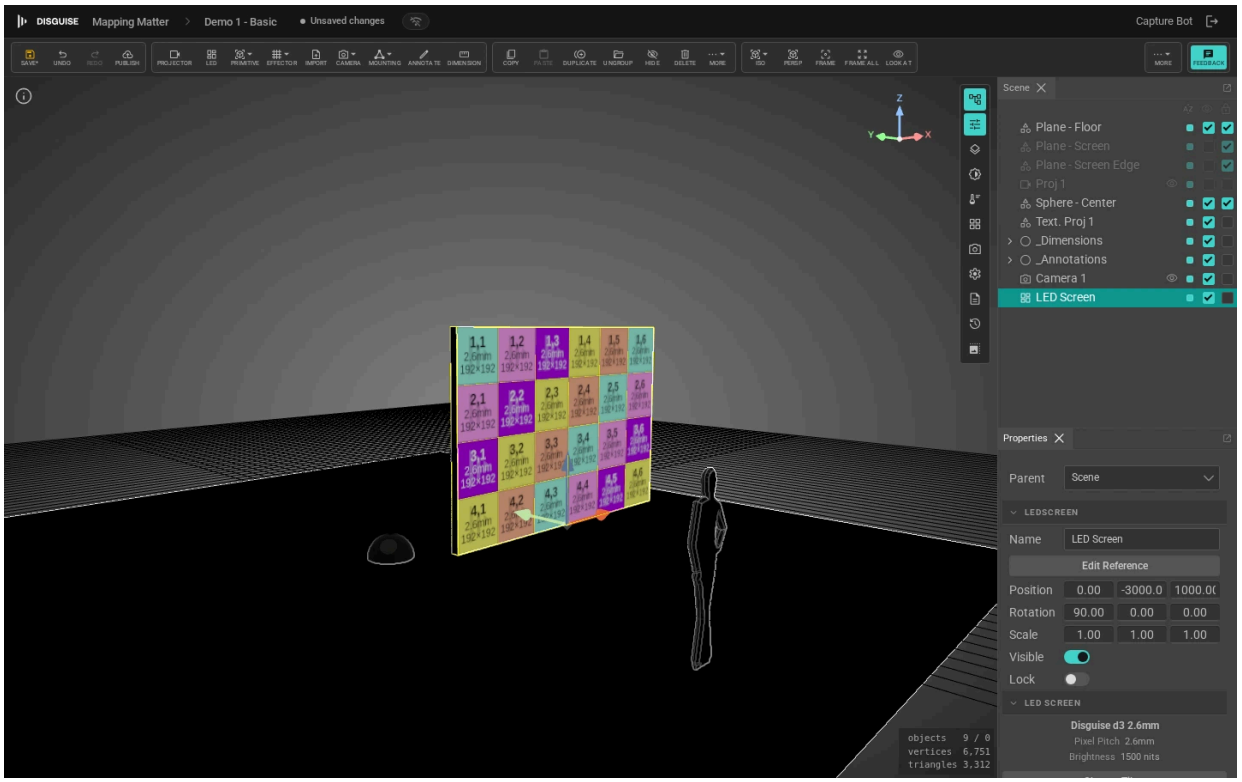
Configure the wall

The LED screen Properties panel covers:

- **Tile**: the active tile model (read-only label). Click **Change Tile...** to swap.
- **Pixel Pitch**: read-only, from the tile catalogue.
- **Tiles H** / **Tiles V**: horizontal and vertical tile counts (1–100 each).

- **Brightness (%)**: output factor from 1% to 200%, matching the projector control. The tile spec's rated peak brightness is shown read-only next to the field so you can see what the panel is rated at and how hard you're driving it. Combine **Brightness %** and the spec's nits to compare a flagship wall at 50% with a budget wall at 100%. When you multi-select LED screens and projectors together, the same **Brightness %** field writes to both.
- **Mounting**: Wall, Ground Stack, or Hung; affects how rigging is drawn.

The **Content** collapsible sets the **Texture** displayed on the wall and a fallback **Color** for when no texture is assigned.



The **Information** collapsible shows computed values: total **Resolution** (H × V pixels), physical **Dimensions**, aggregate **Weight** and **Power** draw across all tiles.

Curve the wall

To curve an LED wall, open the **Curve** collapsible in its Properties panel and toggle **Enable Curve**. The remaining fields appear:

- **Axis**: Horizontal or Vertical, the direction of curvature.
- **Direction**: Concave (curving toward the viewer) or Convex (curving away).
- **Tile Angle**: the angle each tile rotates relative to its neighbour, 0.1° to 45°.

The panel then displays the derived geometry:

- **Radius**: the absolute curve radius.

- **Total Curvature**: aggregate angle across all tiles.
- **Chord**: straight-line distance between the wall's outer tiles.
- **Depth**: maximum depth from the chord to the curved surface.

Every tile rotates by **Tile Angle** relative to the previous one; there is no per-tile override.

Position and rotate

LED walls follow the same transform rules as any other object: move, rotate, scale, and parent under groups or effectors. To duplicate a wall around a centre point or fan out a series of walls, use the toolbar **Effector** button with **Polar Array** or **Fan**.

Mount on a truss

LED tiles can be clamped to a truss the same way projectors are. The **Mounting** collapsible in the Properties panel surfaces clamp position, hang direction, height offset and the Ground tower / Flown truss / Existing truss quick-attach buttons. See Trusses & mounting.

Light, brightness and photometric analysis

LED screens cast forward-only emission into the scene: the panel's nits drive the lighting at the front of the wall, without spill behind the tiles. Curved walls emit along the curve (with adaptive sampling so wide arcs still light correctly), and LED contribution feeds the renderer's auto-exposure so a bright wall darkens the rest of the scene the way the eye expects.

LED screens contribute to the brightness viewport heatmap and to surface coverage statistics. Their photometric readout uses the **panel's native brightness** (rated nits × Brightness %) so the lux numbers match what you'd measure rather than depending on the displayed content. See Viewport & analysis.

Libraries and Assets

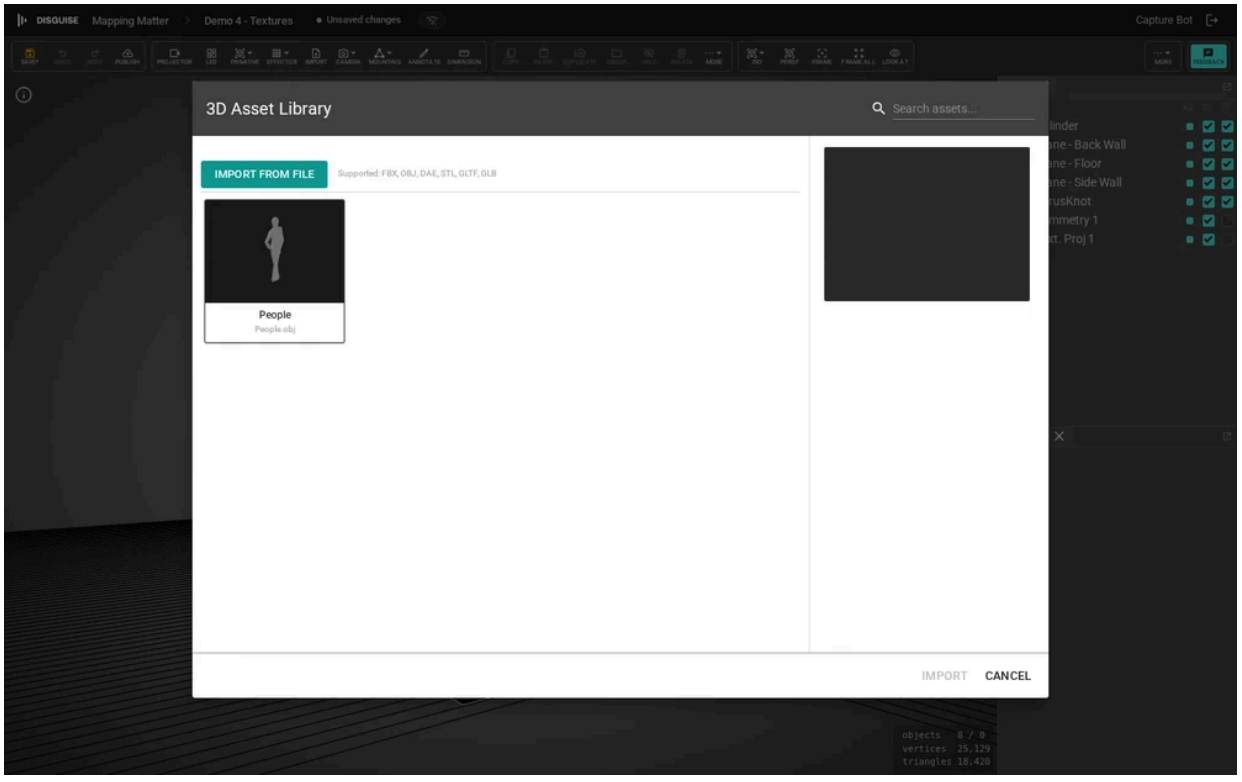
Mapping Matter splits content into per-project libraries (private to your project) and a platform demo library (read-only, available to everyone). Meshes, textures, projectors and layouts all share the same browser overlay pattern, with grid/list display and search.

Scenes are managed from the Disguise Cloud launcher, not from inside Mapping Matter; see Open or create a scene.

3D asset library

The 3D asset library holds imported meshes. Click **Import** in the toolbar add cluster to open the library overlay.

Supported formats: `.fbx` (binary), `.obj`, `.dae`, `.stl`, `.gltf`/`.glb`. Maximum saved size is 100 MB; larger files can still be loaded locally for the current session.



Import Settings

When you pick a file the **Import Settings** overlay opens. Set the file unit, the scale, and the rotation before confirming. The Bounds block shows two rows so you can sanity-check both the scene scaling and the picker:

- **Bounds**: the mesh extent expressed in the scene's current dimension unit. Switch the scene's dimension unit and this row's magnitude rescales.
- **In Source**: the raw bounding-box value in the unit you picked under **Original File Units**. Switch the picker and this row's unit label changes but the numbers stay the same.

A **Scale Reference** dropdown drops a translucent fixed-size helper next to the mesh while the overlay is open so you can eyeball its size before committing:

- **Yellow Human**: a 1.8 m figure (default).
- **1 m³ Cube**: a one-metre wireframe cube.
- **None**: no helper.

The helper renders at 50% opacity (so scene geometry remains visible through it) and sits a sensible distance from the import: small mm-scale imports get a 500 mm gap so the figure isn't on top of the origin, larger imports scale proportionally. The helper disappears on confirm or cancel.

Editing an imported mesh's colour

When a mesh has a single default material (no named material groups from the source file), the Properties panel shows its material controls inline, right below the **Edit Reference** button, so you can recolour, retexture or tweak opacity without switching modes. As soon as an imported mesh has named material groups, the inline panel disappears and the material controls move back inside Edit Reference, where you can pick which group to affect.

Delete an asset

The details pane of a user-imported mesh has a **Delete asset** action. Deleting removes the mesh from the library and stops it appearing in future scenes; instances already placed in your scenes keep their geometry until Disguise's background sweep runs (currently a 90-day retention window), so a mistaken delete is recoverable inside that period. The platform demo library is read-only, so Delete is only exposed for meshes your organisation owns.

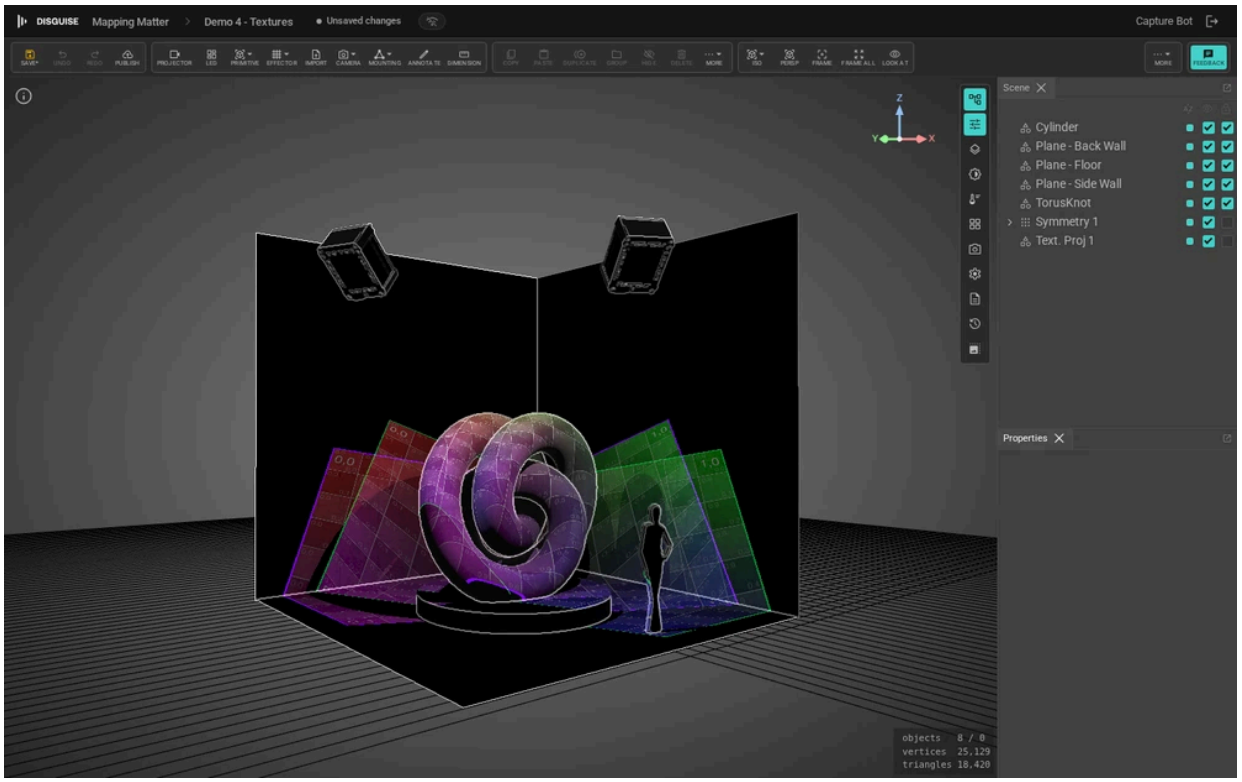
Optimisation tips

For best performance:

- Reduce unused geometry: delete loose vertices and hidden meshes.
- Merge meshes by material where possible.
- Export as `.fbx` binary or `.glb` (compact, fast to load).
- Avoid embedded textures over 4096 × 4096; assign textures separately from the texture library.

Texture library

Textures cover stills (`.jpg`, `.png`, `.webp`, `.gif`, `.bmp`) and short clips (`.mp4`, `.webm`, `.ogg`). Maximum size 50 MB.



Textures are assigned to projectors (as the projector image) or to meshes (as base map or projection map) via the Properties panel.

Projector library

The projector library lives in the same overlay pattern. Catalogue models are read-only; your project can also contain custom projectors that appear alongside catalogue entries.

Each card has a small flag icon; click it to report wrong specifications (incorrect throw ratio, missing lens, wrong lumens). The pre-filled dialog routes to the Disguise team via the same pipeline as the toolbar Feedback button.

Ownership scope

Every custom projector has an **ownership scope** that determines who sees it:

- **Project**: private to the current Production. Only members of the Production see the projector.

- **Organisation**: shared with every Production in your organisation. Anyone in the org sees the projector in the library, whether or not they're on the current Production.
- **Global**: the read-only platform catalogue. New custom projectors can't be added here.

When you create a new custom projector the ownership scope defaults to **Project**. Use the scope selector in the projector's edit dialog to promote it to **Organisation** so the rest of your team can pull it into any of their scenes without re-creating it. The launcher's Sharing & Teams area exposes the whole org projector library as its own section, where organisation admins can rename, delete, or scope-move entries from one place.

Legacy Mapping Matter customers can also import their existing custom projectors directly into the org library from the launcher, without having to open a scene.

LED library

The LED library opens from the toolbar **LED** button. It uses the same overlay pattern as projectors: filter by brand, sort by name or pixel pitch, switch between catalogue tiles and your project's own entries. If a tile model isn't in the catalogue, use **+ Create custom** to add it to the project.

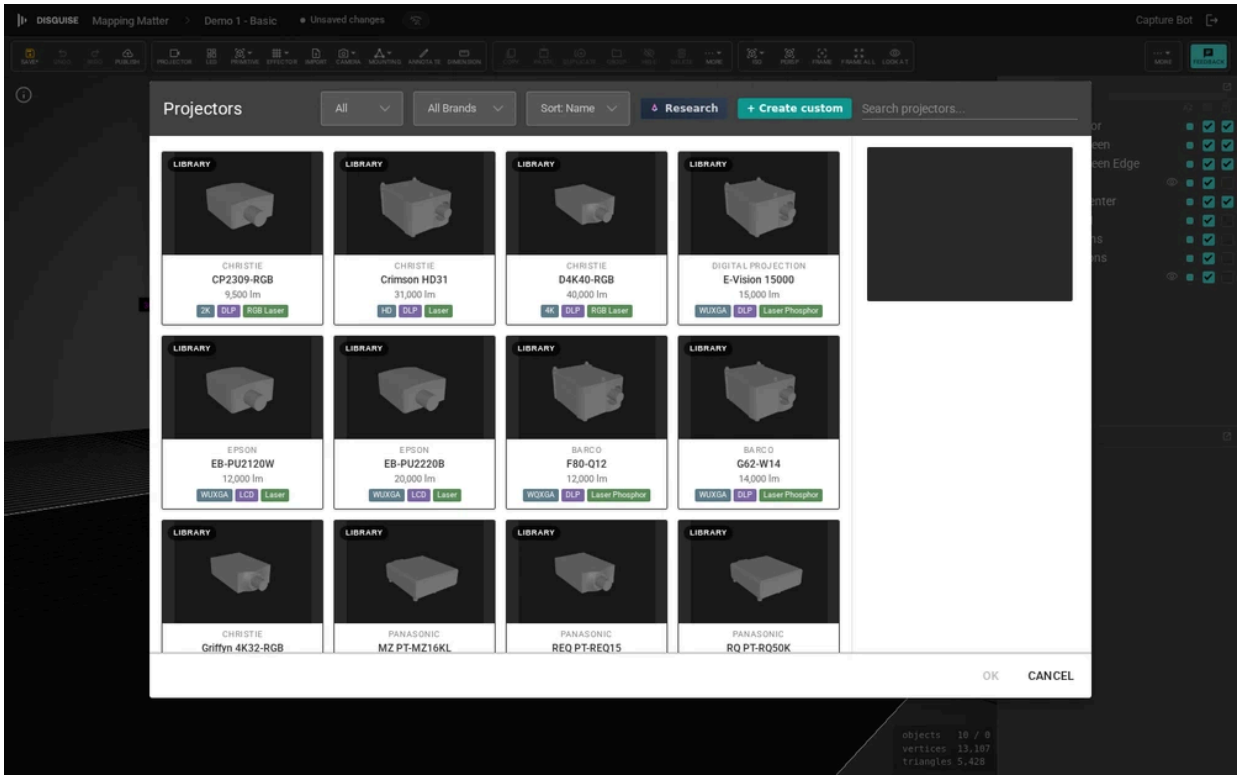
Truss library

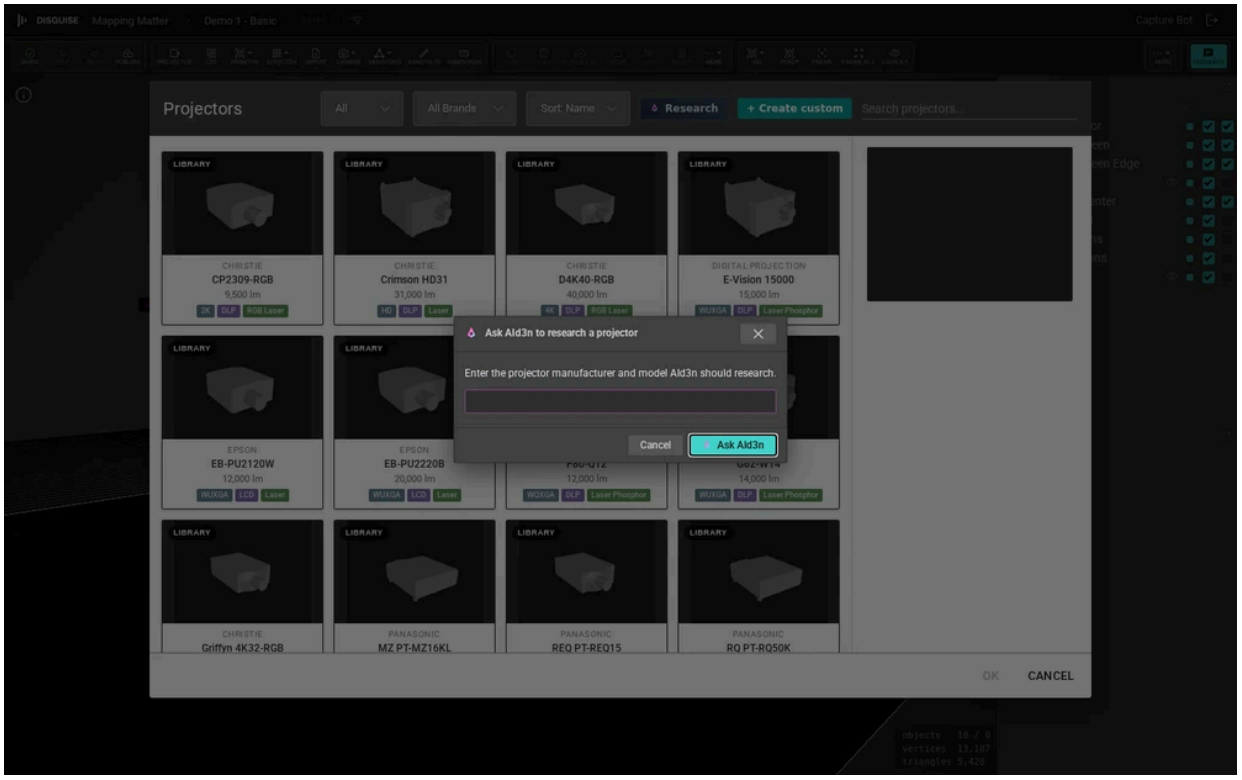
The truss library opens from the toolbar **Mounting** popover's **Truss library...** entry, and covers both truss profiles and mounting bases. Filter by cross-section or by the TRUSS / BASE toggle, then double-click an entry to add it to the scene. Custom trusses and bases are project-scoped and appear alongside the catalogue.

AId3n in the libraries

The Mapping Matter libraries are wired into **AId3n**, the Disguise AI assistant, so you can ask it to research a piece of kit and produce a custom entry rather than typing every field by hand.

- Each library overlay has an **Ask AId3n to research** call-to-action and a persistent **Research** button in the projector and LED library toolbars.





- Give AId3n a model name or paste a datasheet; it'll suggest spec values, propose a mesh, and surface them as an "AId3n suggests" banner you can accept, tweak, or discard.
- For meshes, a phase indicator shows progress (research → mesh search → preview).

- AId3n suggestions never overwrite catalogue entries; they create or update custom entries in your project, so the platform-wide catalogue stays trustworthy.

AId3n usage is metered against your organisation's credits; see your Disguise Cloud dashboard for the running total.

Layouts

A **layout** is a reusable PDF template with a title block, table of projector specs, page size, and viewport pose. Save the current PDF layout from the toolbar **Export** dropdown to add it to the layout library, then reuse it on other scenes.

See Export & PDF layouts.

Measurements and Annotations

Mapping Matter has two markup tools, both reached from direct buttons in the viewport toolbar's add cluster: **Dimension** (numeric measurement labels) and **Annotate** (freehand drawing). Both create real scene objects that persist across save and load, and both can be included in published snapshots and PDF layouts.

Dimensions

Click **Dimension** (or press `T`) on the toolbar, then click two points in the viewport to place a distance label. For an angle, click three points.

Vertex snap works across objects: pick the first point on one mesh and the second on a different mesh, and the tool will still snap to the nearest vertex on whatever's under the cursor. You can also orbit and pan while placing points; small drags (under about four pixels) are treated as a click, larger drags are treated as camera moves and don't drop a stray point when you release the mouse.

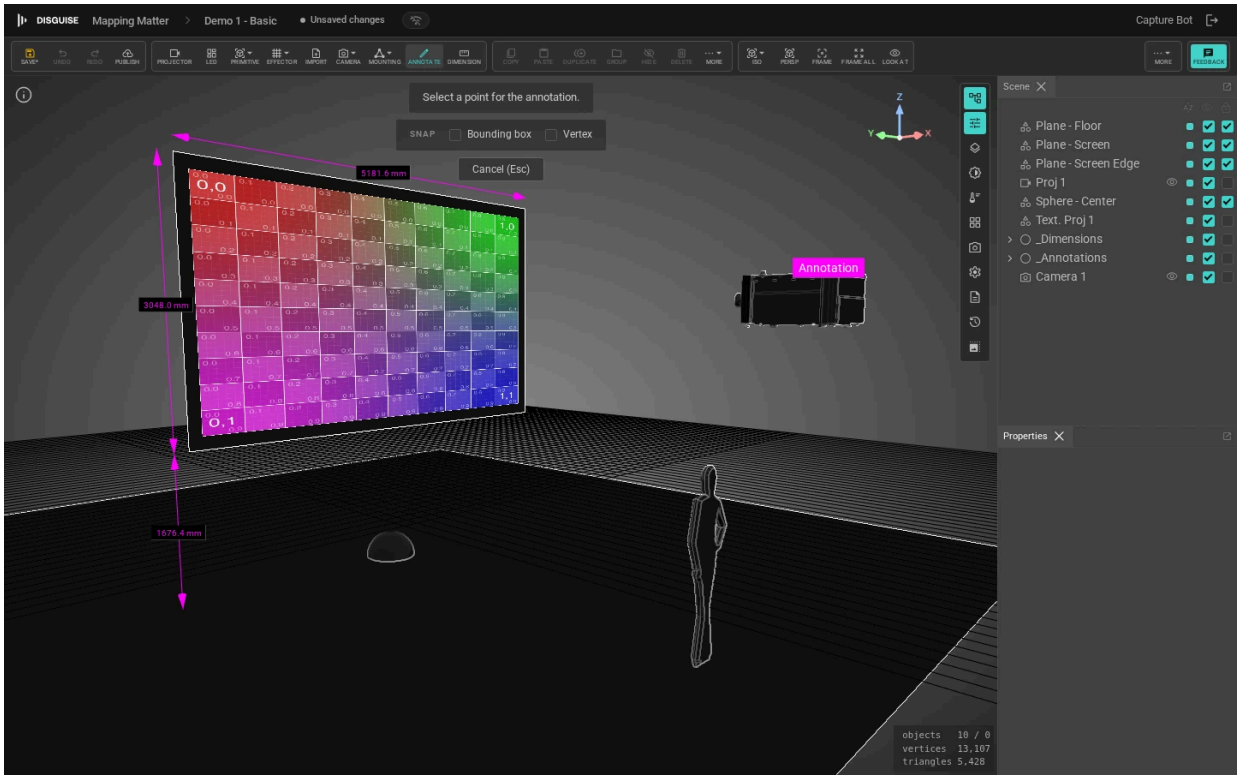
Each dimension carries:

- **Value**: the live numeric reading in the scene unit (mm, cm, m, ft, in).
- **Label**: optional free text.
- **Style**: leader colour, font size, decimal places.
- **Visibility**: toggle from the dimension's properties or hide via the Scene panel.

Dimensions are attached to scene geometry by default, so moving the underlying object moves the dimension with it.

Annotations

Click **Annotate** (or press `A`) on the toolbar to start a freehand annotation. Draw on screen; release to commit.



Annotations live on a layer in the Scene panel and can be hidden or excluded from snapshots like any other layer.

Mirror

A mirror folds a projector's beam. This is useful for short-throw rigs, snorkel-style installations, and any case where the physical projector body can't sit on the optical axis. The mirror is a property of the projector, not a separate scene object: Mapping Matter models the reflection geometry, shows the folded beam path, and warns when the projector overshoots the mirror.

Enable the mirror

1. Select the projector you want to fold.
2. In the projector's **Properties** panel, expand the **Mirror** collapsible.
3. Toggle **Mirror** on. A mirror plate appears attached to the projector, sized to the beam by default.
4. Drag the mirror plate in the viewport to position it between the projector and the surface; drag the projector's target point to aim the folded beam.

Suggested mirror for UST lenses

If the active lens has a large fixed optical offset (typical of ultra-short-throw lenses, where the image projects steeply off-axis), the projector sidebar shows a **UST lens: add a fold mirror?** hint banner with an **Add suggested mirror** button. Click it and Mapping Matter picks a fold-mirror placement (offset, 45° starter pitch, plate size) that bends the chief ray onto the projector's current target. From there you can fine-tune position, rotation and dimensions like any other mirror. The banner only appears while no mirror is enabled; once you add one, manually or via the button, it goes away.

When the mirror is selected, the gizmo target rotates the mirror itself rather than the projector, which lets you tilt the mirror without changing the projector's pose.

Beam footprint on the plate

While the mirror is enabled, Mapping Matter draws the projector's beam footprint as an amber quad on the plate itself, exactly where the rays land (visible on the plate in the clip above). This makes it easy to size and position the plate against the optical surface without leaving the viewport. The amber tint stays visible even when the plate flips red for overshoot, so you can read both signals at once.

The mirror sidebar's **Scale mirror to fit** button resizes the plate to the smallest dimensions that contain every frustum corner, useful when the default plate size is too generous or has been shrunk past the beam. Dimensions round up to the next 10 mm so a numerical residual doesn't leave the overshoot tint flickering on the edge.

Beam overshoot warning

If the projector beam falls outside the mirror plate boundary, Mapping Matter tints the overshooting beam red and the mirror plate edges that are clipped. Resize the mirror in its Properties (or use **Scale mirror to fit**) or reposition the projector to clear the warning.

Mirror properties

In the projector's Properties panel, under the **Mirror** section:

- **Product**: pick a manufacturer mirror from the catalogue (loads body mesh and dimensions), or use a generic flat plate.
- **Width** / **Height**: physical dimensions of the mirror plate.
- **Offset**: X / Y / Z offset from the projector body.
- **Rotation**: pitch / yaw / roll relative to the projector.

Changes update the folded beam path in real time.

Limitations

- Mapping Matter simulates a single, perfectly flat, 100% reflective mirror. Brightness loss from real mirrors should be accounted for separately when reading the photometric outputs.
- Mirror assemblies in the catalogue are reference geometry; confirm dimensions and mounting with the manufacturer before relying on them on-site.

- FAQs: ultra-short-throw and fake mirror techniques (now superseded by the mirror feature for most cases)

Plan Entitlements

Mapping Matter is delivered as a Disguise Cloud plugin. **Reading is public; creating and editing require an entitlement.**

What's free for any signed-in user

- Open and explore **demo scenes** (read-only).
- Open any **Production** you've been shared into (as Editor or Viewer) and view its scene without an entitlement of your own.
- Use the snapshot viewer for published shares.

What requires an entitlement

Creating or editing requires an active Mapping Matter entitlement on the user's organisation:

- Create a new Production.
- Edit a scene's geometry, projectors, LED screens, materials, or layers.
- Publish snapshots from a scene.

If you open a scene you've been shared as an Editor but your own org doesn't have Mapping Matter, the editor opens in **View-only** mode: every write affordance is blocked and a one-per-session notice tells you why.

Snapshot viewers

Recipients of a snapshot share, whether via anonymous link or user invite, do not need an entitled plan, and they never count against your seat allowance.

Upgrading

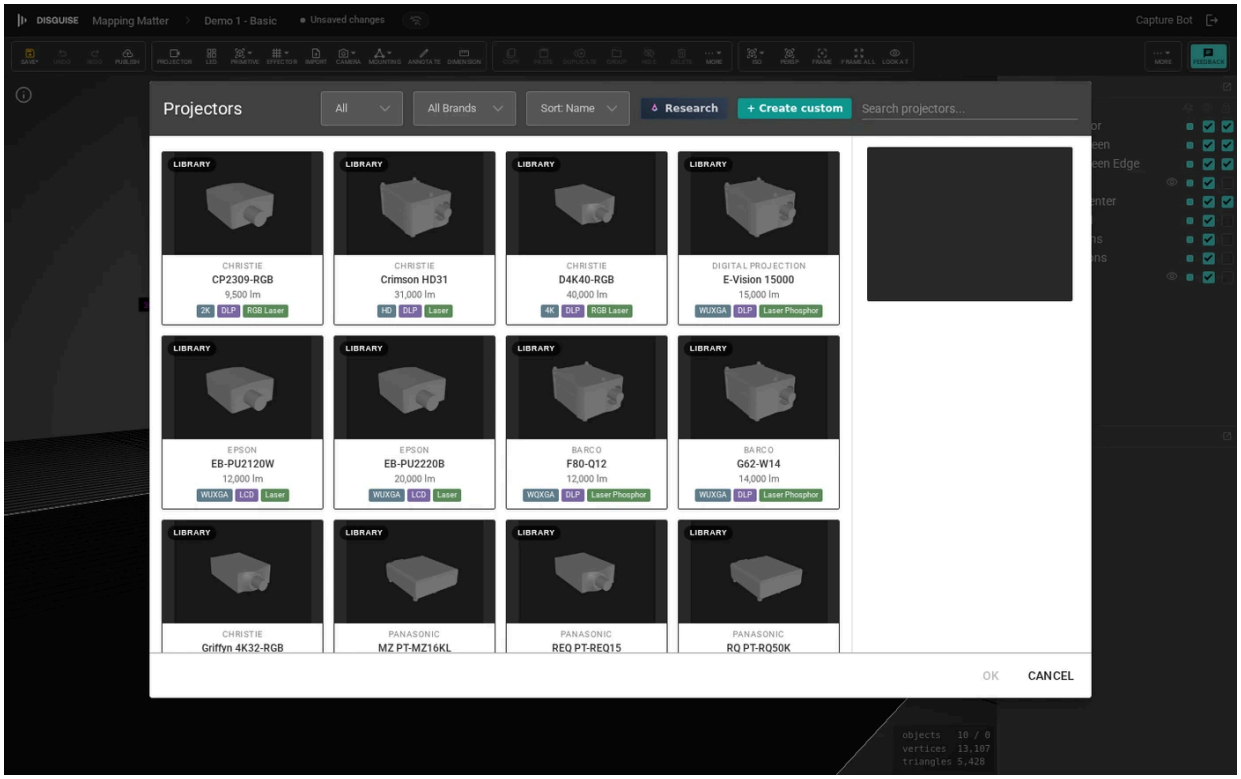
Plan changes are managed in Disguise Cloud organisation settings, not in Mapping Matter. See the organisation settings page, or contact **support@disguise.one**.

Projectors

Projectors are the core authoring object in Mapping Matter. Each projector carries real specifications from the catalogue (Panasonic, Christie, Barco, and others) including throw ratio, lens shift and lumens. You position projectors in 3D, aim them, and see the resulting beam, image and coverage on the geometry in the scene.

Add a projector

Click **Projector** in the viewport toolbar's add cluster to open the projector library overlay. Browse by manufacturer, search by model, or filter by lumens and resolution.



Double-click a projector to add it to the centre of the viewport. You can also drag a model from the library onto the scene tree.

If a catalogue entry has wrong specifications (incorrect throw ratio, missing lens, rated lumens that don't match the datasheet), click the small flag icon on the projector card to send a targeted report to the Disguise team. The dialog pre-fills the model name and the suspect values, so the report comes through with the right context attached. The same flag is available on LED tile and truss library cards.

Aim the beam

A projector's beam is aimed at its **target point**, a small handle in the viewport. Drag the target to point the beam; the projector rotates to face it. The aim can also be set numerically in the projector's Properties panel.

To rotate the projector body independently of the aim, use the Rotate gizmo on the projector directly.

Focus simulation

Real projector lenses have a depth of field, so surfaces nearer or farther than the focal plane look soft. Mapping Matter approximates this with a **Focus** overlay: surfaces that fall outside the projector's focal depth are drawn with diagonal banding, with denser, brighter bands the further out of focus they are.

Toggle the simulation with the **Focus** button in the toolbar's display cluster. Behind that button are three modes, set in **Viewport settings** (bottom Panels strip) under **Focus Mode**:

- **Off**: no overlay.
- **Per Projector**: only the selected projector contributes. Use this to read one fixture at a time when several beams overlap.

- **All Projectors**: every projector's focus depth is overlaid simultaneously. Useful for catching surfaces that no projector resolves cleanly.

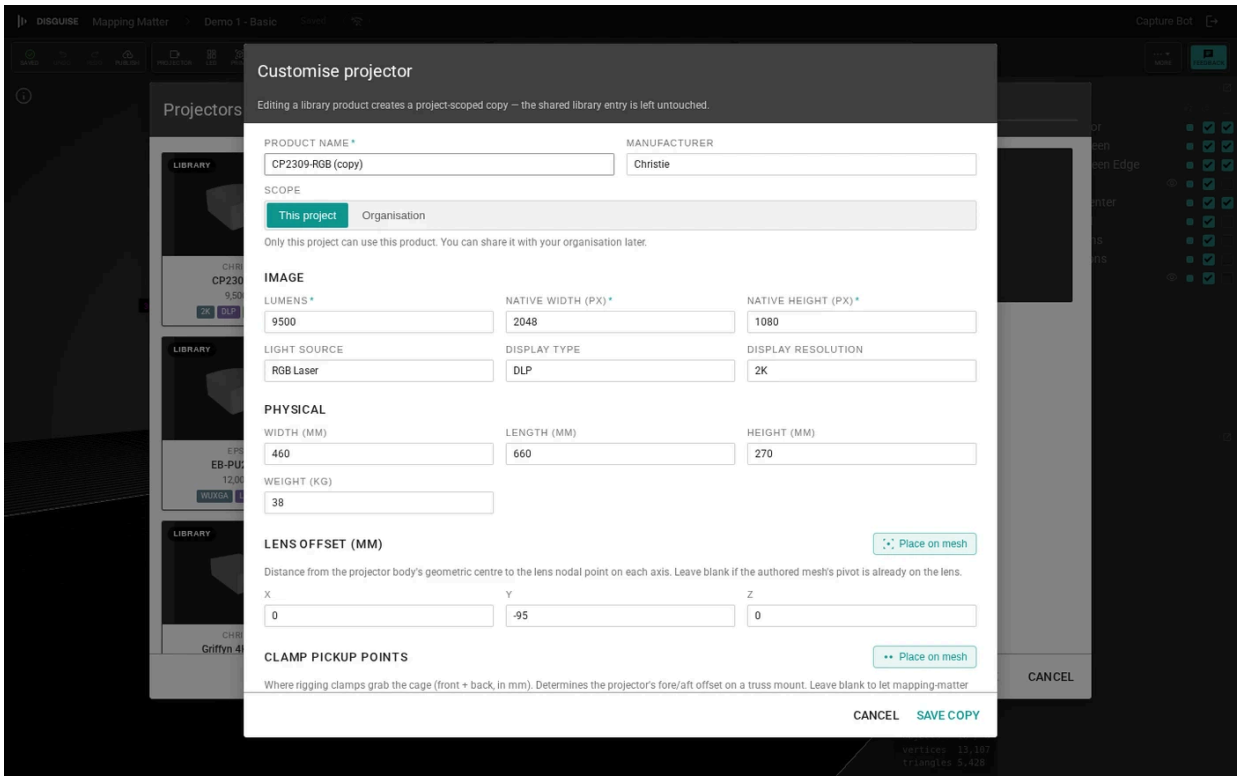
The two thresholds on the same panel control where the bands appear:

- **Focus T1**: the tight in-focus tolerance, expressed as a fraction of the projector's nominal throw distance. Surfaces within ±T1 are treated as fully sharp.
- **Focus T2**: the broader "near focus" tolerance. Between T1 and T2 surfaces render with the lighter banding; beyond T2 they get the heavier banding.

Defaults (T1 = 0.10, T2 = 0.30) approximate a typical mid-range zoom. Tighten T1 to model a long-throw lens; widen it for a short-throw / UST head.

Edit a projector

Select a projector to expose its full Properties panel:



- **Name**: label shown in the scene tree.
- **Position** / **Rotation**: XYZ values in the active scene unit; matches the gizmo.
- **Change Projector...**: swaps the model, preserving position, orientation and aim.
- **Lens**: the active lens preset for the projector. Each preset carries its own throw-ratio and lens-shift ranges; selecting one applies the geometry.

- **Resolution**: the active SDI/HDMI mode for projectors that ship multiple supported resolutions (e.g. 16:9 1920 × 1080 vs 16:10 1920 × 1200 on the same panel). The dropdown is hidden when the catalogue lists a single native resolution. Picking a mode overrides the projector's reported resolution everywhere (test pattern, projection width × height, the sidebar header) while the underlying library entry stays intact.
- **Throw Ratio**: image width as a multiple of throw distance. The field's allowed range follows the active lens; the row turns yellow near the lens limit and red beyond it.
- **Projection Distance**: distance from the projector to the surface it's aimed at. Accepts values below 1 m for ultra-short-throw lenses; the near plane of the frustum adapts so the image isn't clipped on short throws.
- **Lens Shift (%)**: horizontal and vertical optical shift expressed as a percentage of the image extent (100% = half the image dimension, matching Barco/Christie conventions). The row colours the same way as throw ratio when out of range. Some lenses publish an **asymmetric** envelope (e.g. shift up 50%, shift down 30%); the sliders honour the asymmetry. Values typed or scrolled into the number field are clamped to the active lens's shift envelope, so the input never shows a value the projector didn't apply. Lenses that publish a **firmware-locked** or **no-shift** envelope disable the sliders entirely; the optical offset baked into the lens (e.g. a UST lens's large fixed upward offset) still applies.
- **Brightness Factor (%)**: scales output lumens between 1% and 200%, useful for derated or aged units.
- **Visible** / **Locked** / **Powered**: visibility, transform lock, and on/off state.

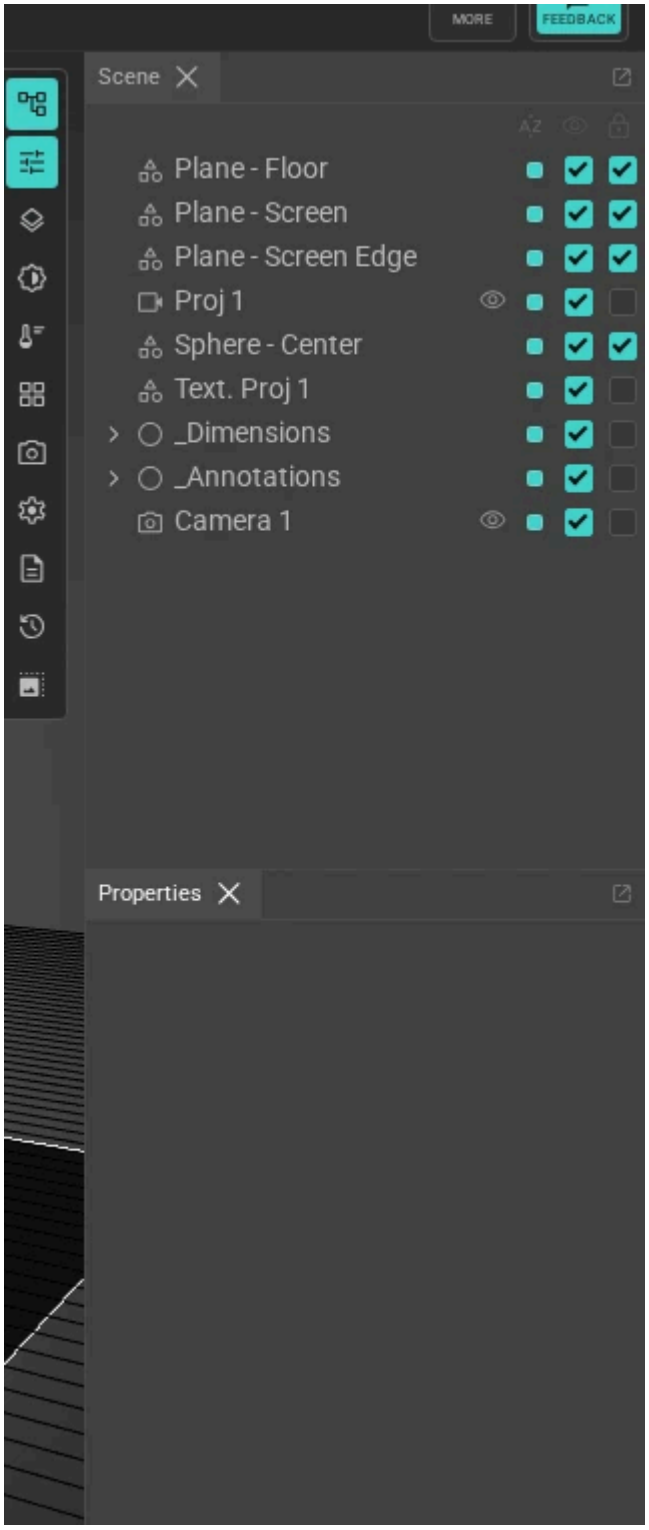
The **Information** collapsible shows derived geometry: Horizontal FOV, Vertical FOV and the equivalent Focal Length (computed for a 24 mm film height).

For projector identity (brand, model, lumens, native aspect ratio) the panel includes a read-only info box. When stacking is on, the box also shows **Total Stack Lumens**.

Projector image and test patterns

The **Projector Image** collapsible controls what the projector outputs. Each option is an independent toggle; Border, Grid and Checkers can all be enabled at once, and any of them can sit over an assigned Image.

- **Image**: assign a still or video texture. Press space to play a video texture.
- **Border**: draw a coloured frame around the projected image. Set the colour with the swatch and the thickness as a percentage of the frustum.
- **Grid**: overlay a grid; set the cell count along the H and V axes (independent values, 0–8192).
- **Checkers**: overlay a black-and-white checkerboard; set the cell count along H and V (independent values, 0–8192).



The Border / Grid / Checkerboard patterns are intentionally lightweight test patterns for verifying alignment and pixel density without needing a content file. Combine them with the Photometric analysis toggle to validate coverage as you align the rig.

Rear projection

By default a projector only lights the **front** of each surface it hits: the side whose face normal points back toward the projector. For rear-projection screens (translucent screens lit from behind) that means the image lands on the wrong side of the geometry.

To enable rear projection, open the target surface's Properties panel and change its material **Side** from `Front` to **Back** (rear-projection screen) or **Double** (lit from either side). Projectors aimed at the back of the surface then resolve and illuminate it as you'd expect. The same setting also controls back-side visibility in the viewport.

Use **Double** when one screen is shared between a stage projector and a rear unit; use **Back** when the screen is only ever lit from behind and the back-only face culling matches the physical install.

Stacking

Open the **Projector Stack** collapsible to overlay duplicate projectors at a single position for additional lumens:

- **Add Dummy Projectors**: slider, 1–20, the number of clones to add.
- **Automatic Lumens Multiplication**: when on, the read-only info box reports total stack lumens.
- **Offset** (X/Y/Z): physical spacing between the stacked units.

Mirror

A projector can drive an attached mirror to fold its beam, useful for short-throw, snorkel and bounce configurations. Open the **Mirror** collapsible in the selected projector's Properties panel and toggle **Enabled**. See Mirror for the full workflow.

Mounting on a truss

Projectors can be clamped to a truss with a per-instance clamp position, hang direction (below / above / left / right of the chord) and height offset. The **Mounting** collapsible in the Properties panel covers the cage toggle, clamp pickups, and the Ground tower / Flown truss / Existing truss quick-attach buttons. See Trusses & mounting for the full workflow.

Custom projectors and the nodal-point editor

If a projector model or lens you need is not in the catalogue, click **Projector** in the toolbar, then **+ Create custom** at the top of the library overlay. Custom projectors have an ownership scope

(set on creation and changeable later) that decides whether the model is private to this Production or shared with your whole organisation. The custom-product form asks for:

1. **Brand and model**.
2. **Dimensions** (mm): width, length, height. Optional but used by the nodal-point editor to scale the body mesh.
3. **Body mesh**: a `.glb`, `.fbx`, `.obj` or `.dae` upload. Converted to GLB client-side.
4. **Lens offset** (X/Y/Z): where the lens nodal point sits relative to the mesh origin.
5. **Lenses**: one or more lens presets, each with:
   - **Mount slug**, part number, manufacturer.
   - **Optical offset**: a *fixed* V/H beam offset baked into the lens, expressed as a percentage of image height (or half-height, per the convention dropdown; Christie uses half-height, DP/Epson/Sony use full-height).
   - **Adjustable shift envelope**: the **mode** (motorised, manual, firmware-locked, or none), the envelope **shape** (rectangular or rhomboid), and asymmetric `v_up / v_down / h_left / h_right` percentages. Firmware-locked and no-shift lenses disable the shift inputs but keep the fixed optical offset.
   - **Throw-ratio range** and a **throw reference offset** to mark where the lens's published throw is measured from.

AI ghost-fill on create

As soon as you've typed both a manufacturer and a model into the create form, Mapping Matter fires a background AI research call and shows an **AI suggestions ready** banner at the top of the form. Click **Apply all** to fill every still-empty field with the suggested specs; user-typed values are never overwritten. The form's lens name and lens-mount fields are also autocomplete-driven: typing into either pops a suggestion list pulled from the product DB (and falls back to a fresh AI lookup if there's no DB match).

To place the **nodal point** visually rather than by typing offsets, upload a body mesh first, then click **Place on mesh** under "Lens offset (mm)". The form panel switches to an embedded 3D view of your uploaded mesh with a teal gizmo at the current offset. Drag the gizmo onto the lens centre on the mesh, then click **Save** to write the new XYZ values back into the form. Click **Cancel** to keep the previous offset.

Saved custom projectors appear in the projector library under a "Project copies" group at the top, and behave identically to catalogue models in the rest of the editor. Each tile in that group has a delete affordance; confirm the prompt to remove the projector from the project library. Catalogue (manufacturer) rows are read-only and don't show the delete button.

The create dialog only closes via **Cancel** or `Escape`; clicking outside it does nothing, so an accidental backdrop click can't lose your edits.

Photometric and brightness analysis

Once projectors are placed, see Viewport & analysis to validate luminance, coverage, and overlap.

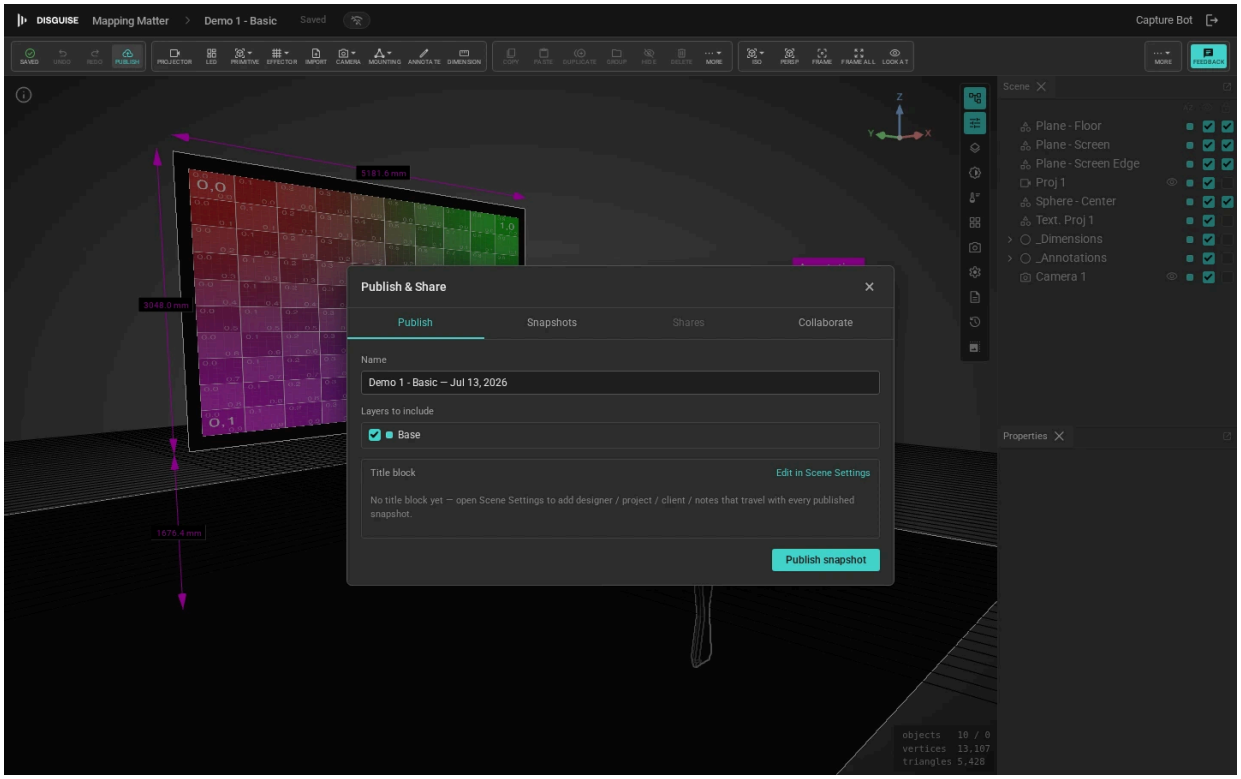
Publish and Share

When a design is ready for review, publish a snapshot and share it. Shares come in two flavours: **link shares** are anonymous and can be opened by anyone with the URL (with an optional password), and **user shares** invite specific people by email.

Publish a snapshot

Click **Publish & share** on the toolbar (the cloud-upload icon, far-left cluster) to open the Publish & Share dialog. On the **Publish** tab, enter a name and confirm the title block before clicking **Publish snapshot**.



In the dialog:

- **Name**: a short label for the snapshot (e.g. “v1 client review”).
- **Title block**: project name, designer, version, date, free-text notes.
- **Included layers**: pick which scene layers to include in the snapshot. Hidden layers are not published.
- **Visibility**: read-only is the default; the viewer cannot edit, but can toggle layer visibility within the included layers.

Click **Publish** to create the snapshot. You can then add one or more shares.

Share a snapshot

In the snapshot's overflow menu, choose **Add share...**

Link share (anonymous)

A link share generates a long, unguessable URL that anyone with the link can use. Optionally set a **password**; if set, the viewer must enter it before they can see the scene.

Link shares are good for client review where you don't want to know everyone who'll see the design, or where the recipient list is large.

User share (per-email invite)

A user share grants access to a single email address. If the email matches a Disguise Cloud account, the recipient sees the snapshot in their dashboard; if not, they receive an invitation email with a sign-in link.

User shares are auditable: you see exactly who has access and can revoke individual recipients.

Manage shares

The snapshot's panel lists all of its shares with:

- **View count**: number of times the share has been opened.
- **Last viewed**: most recent open.
- **Revoke**: disable the share. Existing viewers lose access immediately; the share row stays visible for audit.

You can also **revoke the snapshot itself** to invalidate every share in one go.

The viewer experience

When a recipient opens a share, they land on a read-only viewer with:

- The scene in a navigable 3D viewport.
- The title block, designer name, and notes.
- A layer-visibility panel limited to the layers the snapshot includes.
- A switch for the brightness viewport if it's enabled on the snapshot.

The viewer never sees the original scene, your project structure, or other users' identities. There is no edit affordance.

Revoking and rotating

If a link leaks, revoke it. To replace a revoked link with a new URL, add a new share. There is no “rotate” action that keeps the URL but changes the secret.

Migration from legacy viewer-only links

The old viewer-only link is replaced by link shares. Old links continue to work but no longer accept new viewer-imported content; for that workflow, use a collaboration seat instead.

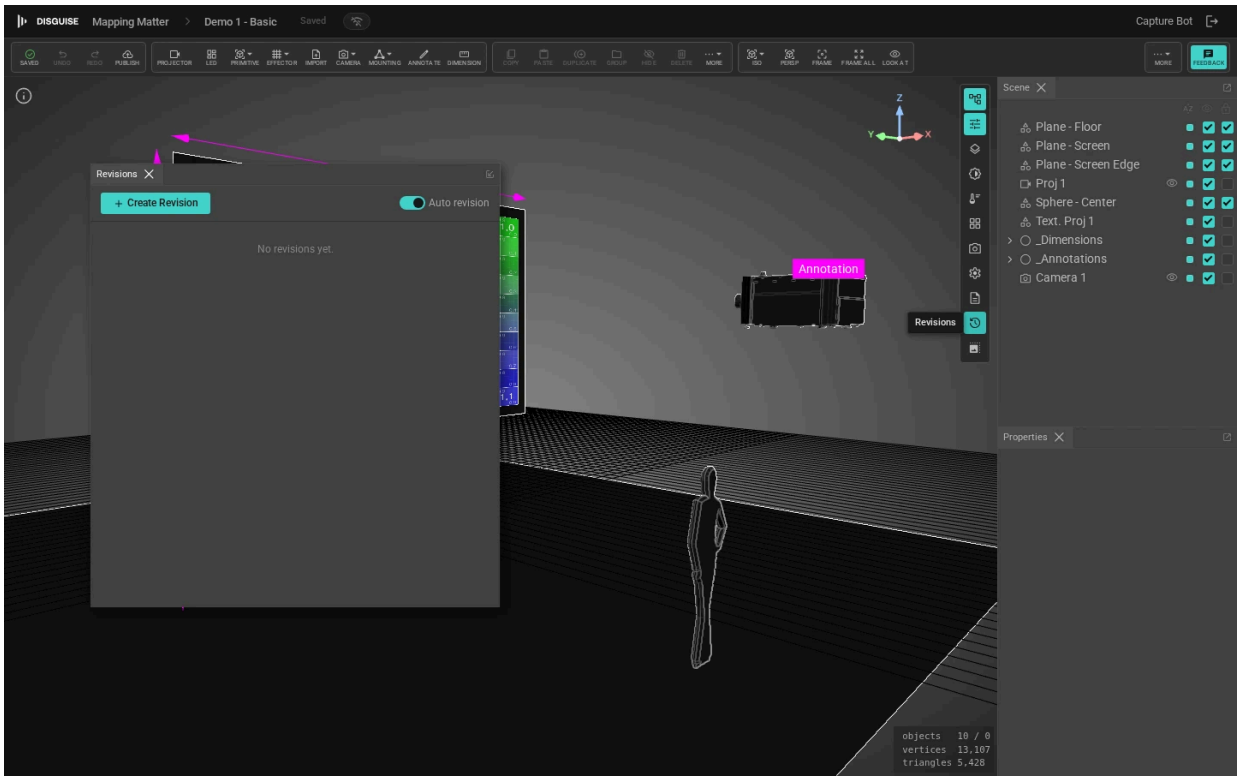
Snapshots and Revisions

Mapping Matter has two complementary forms of versioning: **revisions**, the rolling per-edit history of your scene, and **snapshots**, locked publishes used for sharing and milestones.

Revisions: your edit history

As you work, Mapping Matter auto-saves the scene a few seconds after each edit, so you don't need to save manually. A new revision is cut only when editing settles (after a couple of minutes of idle, or when you close the scene), so a long edit session produces one revision per checkpoint rather than one per save.

Click **Revisions** in the bottom Panels strip to see the timeline:



For each revision you can:

- **Preview**: load the scene state at that revision without committing.
- **Restore**: overwrite the current scene with that revision's state. This creates a new revision so nothing is lost.
- **Name**: mark a revision with a label (e.g. "client review v1") to make it easy to find later.

Revisions are retained for the lifetime of the scene. Renaming or deleting the scene removes its revisions too.

Snapshots: locked publishes

A snapshot is a named, locked copy of the scene at a moment in time. Once published it can't be edited, only revoked. Snapshots are how you share design intent with people outside the editor: clients, external collaborators, internal stakeholders who don't need edit access.

A snapshot:

- Carries its own copy of all scene data, including assets. Snapshots are independent of the live scene, so editing the source scene does not change a published snapshot.
- Records a **title block** (project name, designer, version, date, notes) similar to a CAD drawing.
- Can include only specific layers, useful for selectively publishing the lighting layer to a sound designer, or the projection layer to a content team.
- Can be **revoked**, which immediately disables all of its shares.
- Tracks **view counts** so you know whether a client has opened the link.

To publish a snapshot, see Publish & share.

When to use which

Use case	Use
Undo something I just did	Revision: restore the previous revision
Mark a milestone for myself	Revision: name it ("v3 - mirror added")
Send a draft to a client for review	Snapshot
Hand off to a colleague who'll edit further	Add them as a project member in Disguise Cloud, then they open the scene from the launcher (see Collaboration)
Archive the design at sign-off	Snapshot with a descriptive title block

System Requirements

The specifications below are the hardware and software recommended for running Mapping Matter. Mapping Matter runs in a web browser as part of Disguise Cloud, with nothing to install.

Browser and graphics support

Mapping Matter runs entirely in Google Chrome using WebGL, with no local install. All project data is stored on AWS.

As it renders real-time 3D graphics inside a browser tab, its performance is set by the client machine's GPU, CPU and available memory, plus network quality, since every project lives in the cloud and syncs continuously.

Specifications

Component	Specification
Browser	Google Chrome (latest) with hardware acceleration enabled in browser settings
GPU	Discrete GPU with at least 4 GB video memory (min. 2 GB) for large or high-poly imported meshes
CPU	At least 6 cores, 12 threads and 3.0 GHz base frequency (min. 4 cores, 8 threads and 2.3 GHz base frequency)
Memory	16 GB (min. 8 GB)
Network	25 Mbps down / 10 Mbps up (min. 10 Mbps down / 5 Mbps up)

Notes

Browser

The application relies on WebGL; users on locked-down corporate machines should confirm WebGL is not disabled by IT policy.

GPU

A discrete GPU is recommended for any project involving multiple imported meshes, large textures, or several simulated projectors/LED panels at once.

CPU and Memory

CPU and RAM minimums assume a single active Mapping Matter tab; running other heavy applications alongside it will need headroom above the minimum.

16GB+ RAM is recommended for scenes approaching the 100MB per-asset import ceiling, or projects combining several large assets.

Network

Mapping Matter has no offline mode. All projects, assets and edits sync to AWS continuously, so a dropped connection interrupts work in progress.

Uploading large 3D assets (up to the 100MB limit) will be noticeably slower on the minimum upload speed. The recommended upload speed reflects a smoother experience.

Trusses and Mounting

Trusses, bases and the mounting workflow let you build the physical rigging plot alongside the projection design. Projectors and LED tiles attach to a truss by clamp position and hang direction; deleting or moving the truss carries everything mounted on it.

Object types

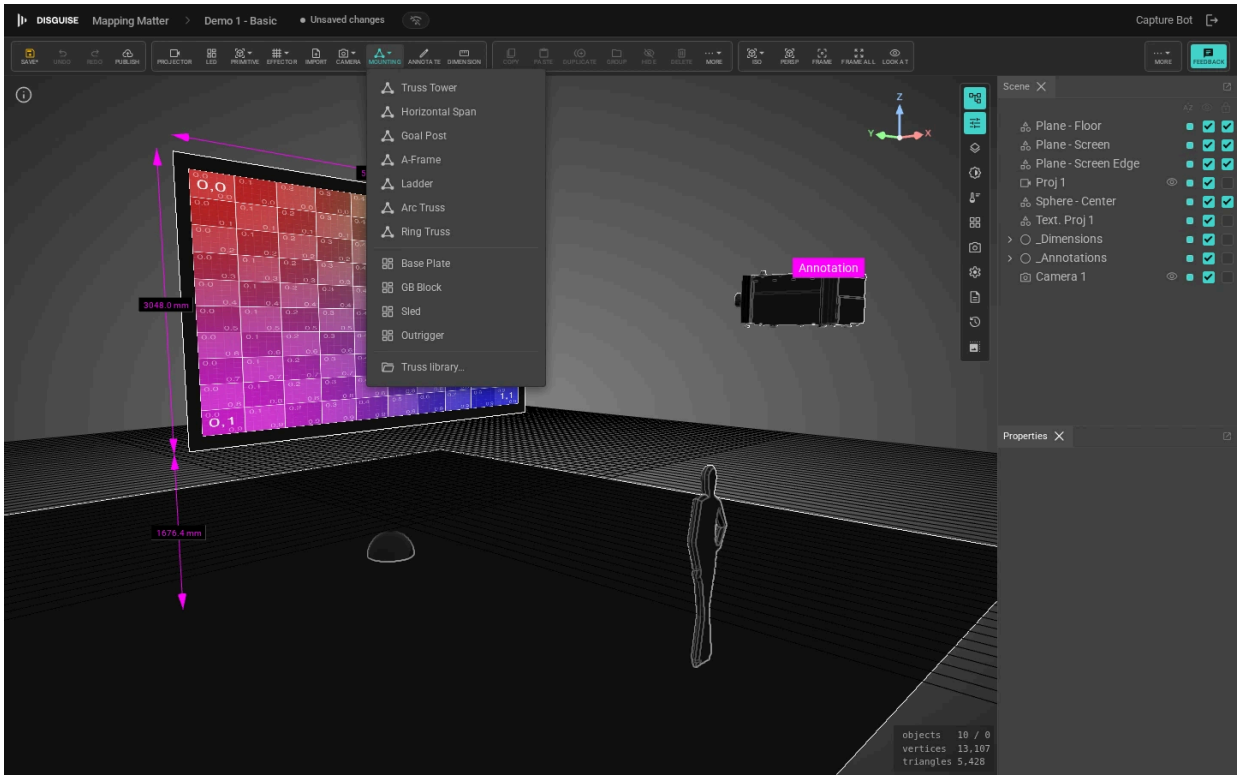
- **Truss**: a rigging member with a procedural chord-polyline geometry. Seven shapes are supported: Tower, Horizontal Span, Goal Post, A-Frame, Ladder, Arc, Ring. Each truss owns a chord profile (e.g. *Square 12" Truss*) drawn from the catalogue.
- **Base**: a procedural box that sits under a Tower / Goal Post / A-Frame, or stands alone as a load-spreader. Sizes are driven by a footprint in mm.

Trusses and bases live in the Scene panel as first-class objects with their own type-dot colour.

Add a truss or base

Click **Mounting** in the viewport toolbar's add cluster to open the popover. Pick one of:

- A truss type (Truss Tower, Horizontal Span, Goal Post, A-Frame, Ladder, Arc Truss, Ring Truss). Tower, Goal Post and A-Frame instantiate with their default base attached; the others stand alone.
- A base (Base Plate, GB Block, Sled, Outrigger): adds a standalone base mesh.
- **Truss library...**: opens the full catalogue with cross-section filters and the option to instance a saved custom truss.



Truss properties

Click the truss in the viewport, or pick it from the Scene panel, and the sidebar shows:

- **Type**: switch between the seven truss shapes; geometry rebuilds in place.
- **Profile**: the chord cross-section (Square 12”, Square 20”, etc.). Drawn from the truss product catalogue.
- **Length / Span / Diameter / Apex height**: dimension fields specific to the type. Goal Post exposes both leg and span lengths; Arc and Ring expose radius and arc angle.
- **Base**: when present, links to the Base child the Tower / Goal Post / A-Frame was created with. A Base sidebar appears once you select it.

Custom trusses and bases

The truss library overlay's **+ Create custom** button opens the same form pattern used for projectors. Set the truss shape, chord profile, span and weight; for bases, set the footprint and mass. Saved custom rows appear under "Project copies" in the library and instance like catalogue rows. Catalogue rows are read-only.

Mount a projector or LED tile

Select a projector or LED tile and expand the **Mounting** collapsible in its Properties panel.

- **Show cage**: toggles the visual cage / yoke around the projector body. Cage visibility is independent of mounting; you can have a cage in free space, or a mounted projector without one.
- **Clamp pickups**: the points on the projector body that hang on a truss chord. Most catalogue projectors ship with their factory pickup positions baked in; **Edit...** opens the Clamp Pickup editor to add per-instance overrides. **Reset** drops the override and falls back to the catalogue default.
- **Mounted to**: choose between *Nothing* (free transform) and *Truss* (clamped to a truss centreline).

When mounting is set to *Truss* but no truss is picked yet, three quick-action buttons appear:

- **Ground tower**: spawns a fresh Truss Tower, parents the projector to it, drops it onto the floor.
- **Flown truss**: spawns a Horizontal Span at the projector's current height and parents the projector to it.
- **Existing truss**: dropdown listing every Truss already in the scene.

Once mounted, the sidebar surfaces the truss-relative pose:

- **Clamp position**: the parameter `t` along the truss centreline (0 = start, 1 = end). Drag the slider to slide the projector along the chord.
- **Hang from**: Below chord, Above chord, Side of chord (left), Side of chord (right). Switches which face of the chord the projector clamps to.
- **Height offset**: distance from the clamp face along the hang direction, in mm. Useful for chain-motor drops below a flown truss, or stand-off plates on the side of a tower.
- **Unmount**: returns the projector to free transform, leaving its current world pose intact.

The same Mounting block appears on the LED-tile sidebar with the same fields.

Cage

Toggling **Show cage** draws the projector's yoke / cage rig over the body, independent of mounting, so a free-standing projector can carry a cage too. When the projector is on a truss, the cage moves with the body as you slide the clamp position.

Mounting arrays

Mounting a Symmetry-wrapped projector carries the whole array onto the truss, so every copy stays in lockstep. Edit the clamp position once and every projector in the array follows.

Grouped undo

Mounting is a multi-step operation (reparent, set clamp, set offset). Mapping Matter wraps it in an undo group so a single `Ctrl+Z` reverts the entire flow rather than peeling it back one signal at a time.

Snap to truss on drag

Drag an unmounted projector close to a truss and Mapping Matter prompts:

- **Snap**: clamp it to the nearest centreline point and switch the projector into mounted mode.
- **Always snap this session**: same as Snap, plus suppresses the prompt for subsequent near-truss drags for the rest of the session.
- **Don't snap**: leaves the projector where you dropped it.

The “Mount on nearest truss” action in the Mounting toolbar popover applies the same nearest-centreline logic without needing a drag.

Collision warnings

Trusses get a continuous spatial-collision check against scene meshes (Reference imports, Primitives). If a truss intersects geometry, its outline pulses red. Move the truss or resize the geometry to clear the warning.

The collision outline is purely a guidance overlay; it does not block the placement.

Selecting a clashing truss surfaces an **AId3n suggests** hint that names the offending object by its imported file name (e.g. `chair.glb`, the same label you see in the scene tree) rather than a raw sub-mesh identifier. **Translate to clear** in the hint nudges the truss along the shortest axis so the whole imported asset is out of the way, not just one sub-mesh.

The **Clash** button in the viewport toolbar’s display cluster toggles these warnings on and off, useful when you want to position a truss inside a structural column on purpose without the red pulse drawing attention away from the rest of the scene. The setting is per-scene and saved with the project.

Delete with attachees

Deleting a truss that has projectors or LEDs mounted to it opens a 3-way prompt:

- **Delete attachees too**: removes the truss and everything mounted on it.
- **Unmount and keep**: deletes the truss only; the attachees revert to their last truss-relative pose in world space.
- **Cancel**: closes the prompt without changing anything.

Truss BOM CSV

The toolbar’s **Export** menu includes **Truss BOM as CSV**, a rigging bill of materials (BOM). The file rolls up:

- One row per truss (type, profile, dimensions, mass).
- One row per base (product, footprint, mass).
- Per-truss attachees rolled up: projectors and LED tiles walked through any Symmetry copies so the count reflects what’s actually rigged.

Use the BOM as a handoff artefact for the rigger or to sanity-check loading totals before sign-off.

Viewport and Analysis

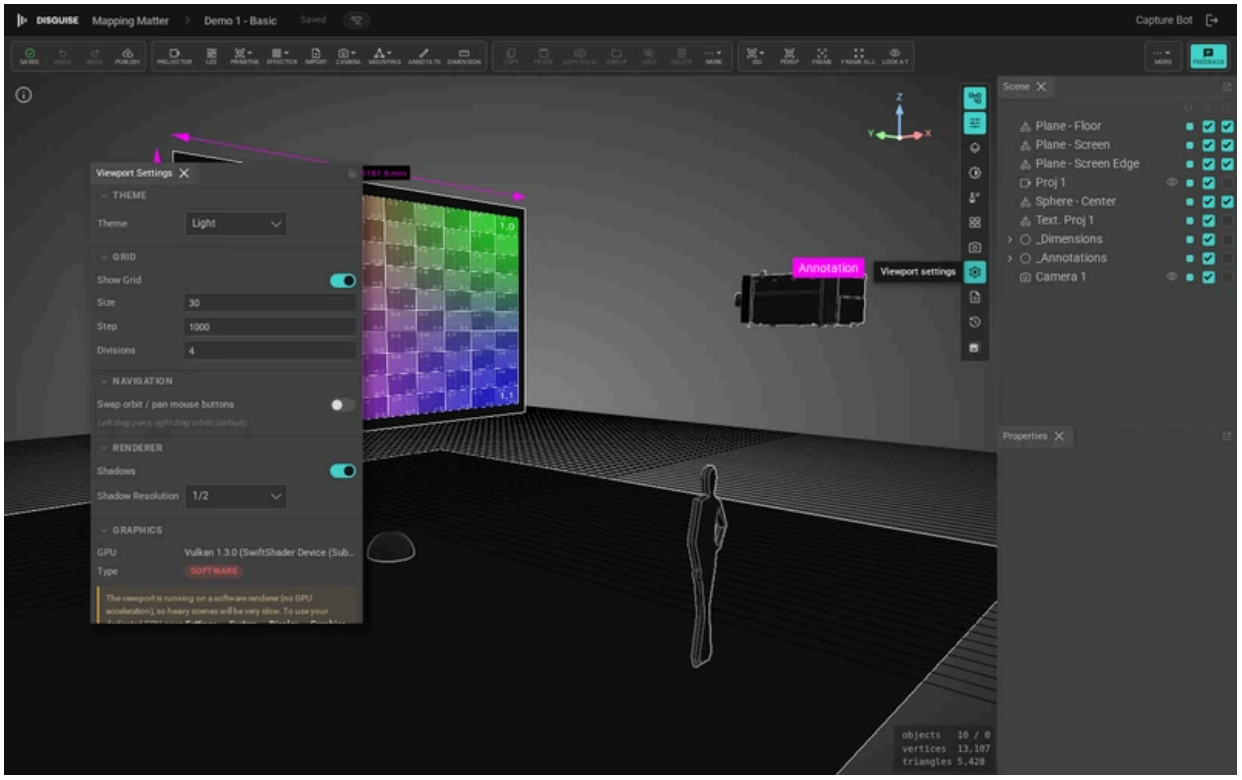
Four analysis tools share the viewport. Photometric, Projection Accuracy and Brightness are mutually exclusive: turning one on switches the others off. Human Acuity is a separate overlay that runs on top of any of them, but only from an Observer's eye view.

- **Photometric**: lux per surface, plus coverage and overlap statistics. Toggle with the **Lux** button on the toolbar's display cluster.
- **Projection accuracy**: pixel density or pixel stretch heatmaps. Toggle the viewport overlay with **Pixels** on the toolbar, and configure the mode and scale in the **Accuracy** panel.
- **Brightness**: live lux heatmap with a configurable colour bar. Controlled from the **Brightness** panel.
- **Human acuity**: colour-codes every projected pixel and LED pixel against the 1-arcminute (20/20) visual acuity threshold. Toggle with **Acuity** in the toolbar's camera-views cluster while looking from an Observer.

Viewport display settings

Open **Viewport settings** from the toolbar to toggle:

- **Perceptual luminance**: gamma-correct shading to match human perception.
- **Object edges**: render wireframes over all objects.
- **Projector beams**: show every projector's beam, even those not selected.
- **Projection distance helper**: colour-codes each surface by its distance from the nearest projector, useful for catching focus issues.
- **Grid**: quantity, size, subdivisions.
- **Background**: flat colour or gradient.
- **Material override**: replace all materials with a neutral grey for blocking checks.



Snap modes

The **Snap** button in the toolbar's Overlays cluster opens a popover with five global snap modes that govern gizmo translation:

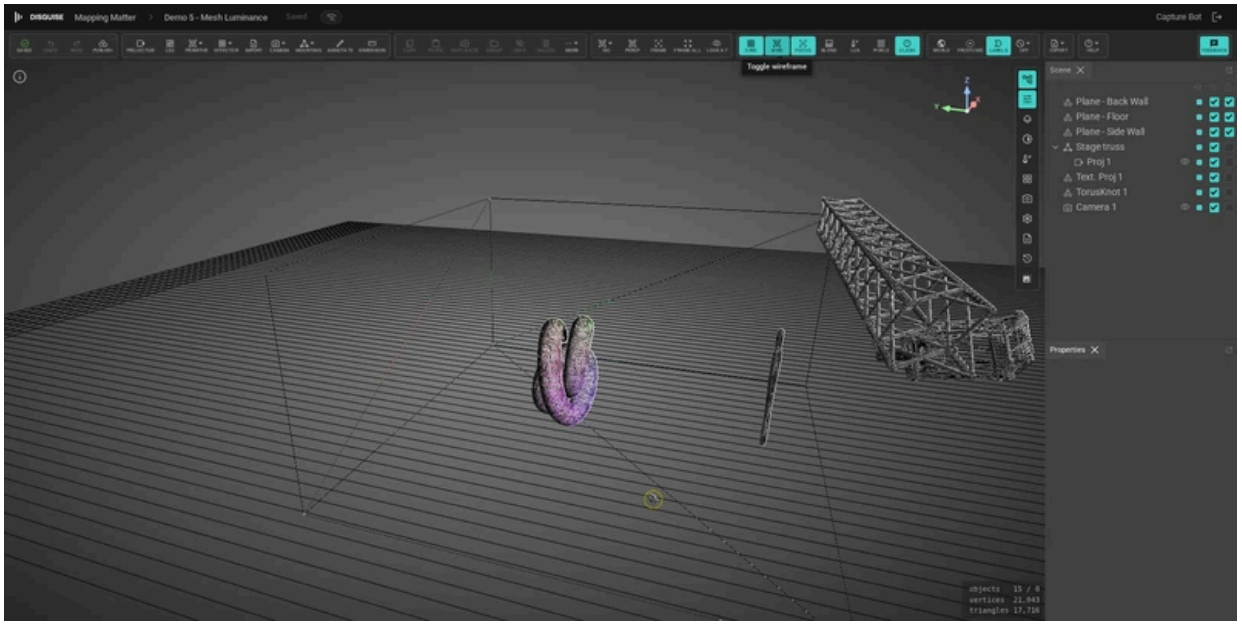
- **Off**: no snapping.
- **Grid**: clamps the drag delta to the grid spacing. A grid-step input appears in the popover while this mode is active.
- **Vertex**: snaps the gizmo origin to the nearest vertex on another mesh.
- **Edge**: snaps to the nearest edge segment.
- **Surface**: snaps to the surface point under the cursor.

Vertex, edge and surface modes treat every visible mesh as a candidate target, including truss members and the observer figure, so you can align a projector to a truss chord or an audience-side mesh without first picking it. A green disc appears at the snap target while you drag; the trigger button's icon and label reflect the active mode so you can see the current state without opening the popover.

> **Note**
>
> Snap defaults to **Off**. Previously, grid snap was always on at 1000 mm with no user-facing toggle; pick **Grid** explicitly if you want that behaviour back.

Wireframe

The display cluster's **Wire** button flips every mesh in the scene to a wireframe overlay, useful when you want to inspect geometry topology or see through a solid model without hiding it. The toggle is session-scoped: it doesn't save with the scene, so it always comes back off when you next open the editor.

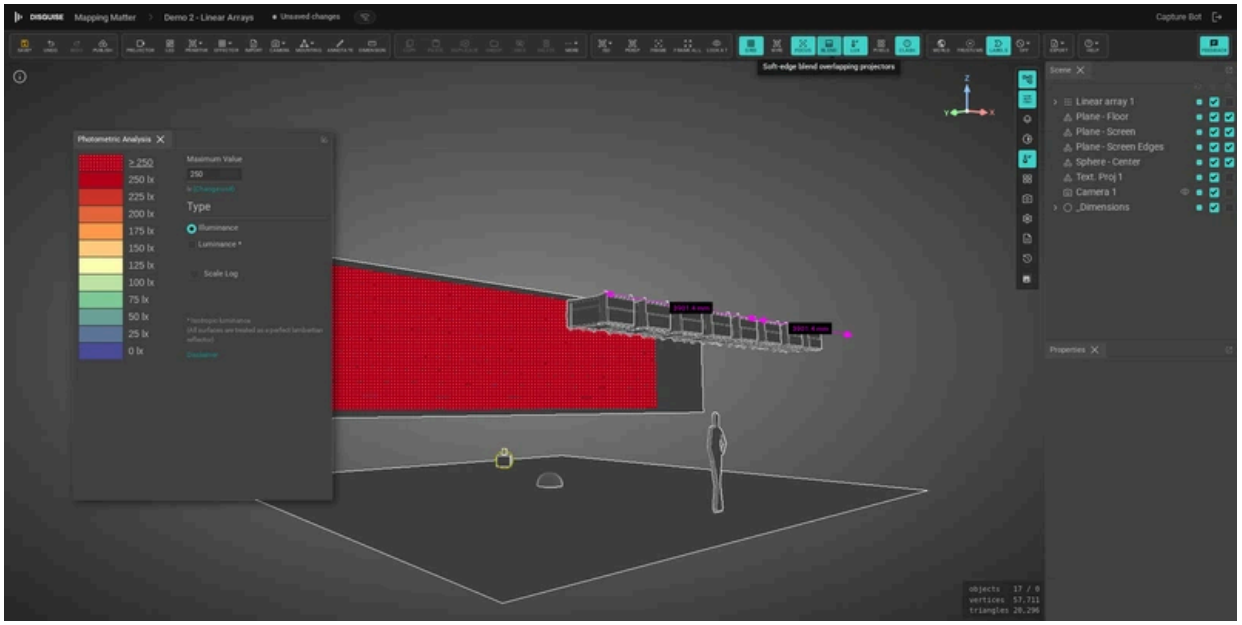


Blend mode

The display cluster includes a **Blend** toggle that controls how overlapping projector contributions are summed. By default, the viewport renders the literal physics: two projectors hitting the same surface combine their lux and look twice as bright. With **Blend** turned on, the renderer assumes those overlaps are soft-edge blended in production, and only counts a single projector's contribution in the overlap region (whichever delivers the most light there).

The setting affects both the shaded viewport and the photometric **Lux** / **Luminance** heatmap, so the readouts match what you'd measure on a properly blended rig. **Pixel density** and **Human acuity** are unaffected; they are geometric and don't care about overlap. **LED screens** are also unaffected; overlapping LED panels stack as before.

Use Blend on when you want to evaluate the final, blended deliverable; turn it off when you need to spot raw overlap zones that the operator will need to soft-edge in the first place.



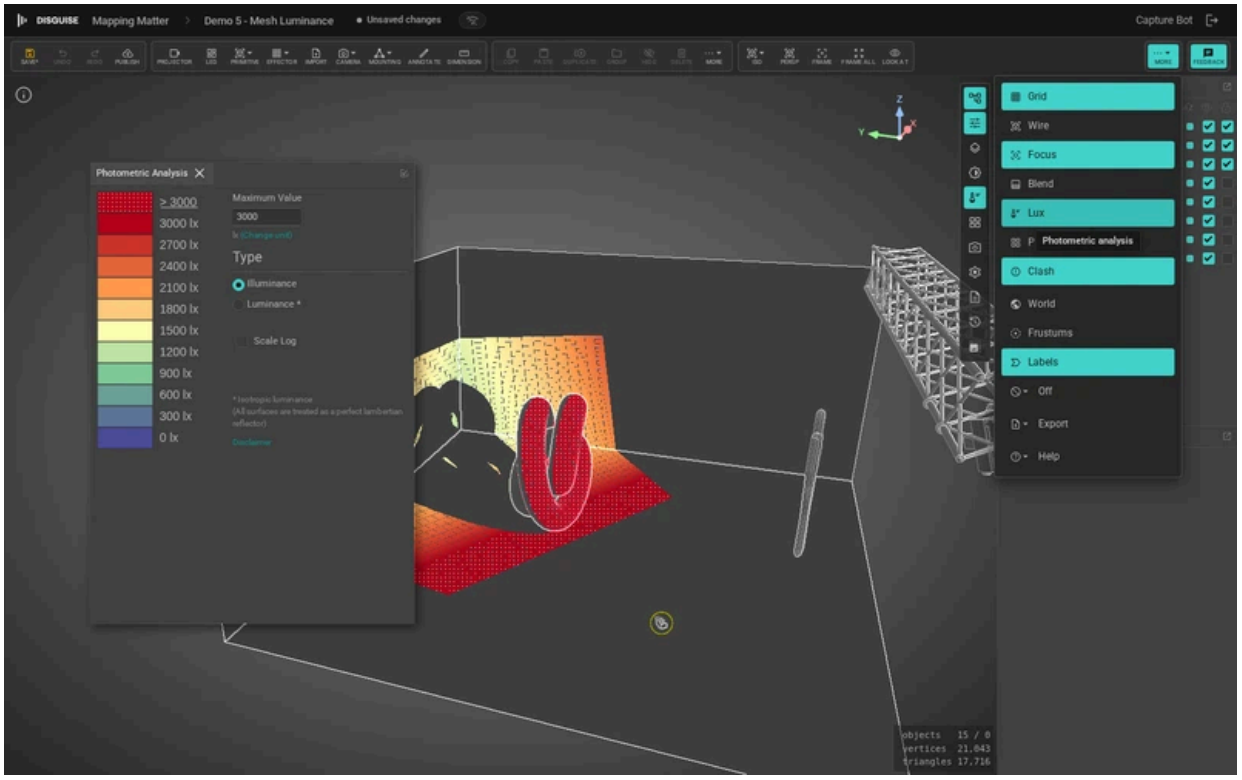
The toggle is persisted with the scene, defaults to off, and is also available from **Viewport settings** for keyboard-driven workflows.

Photometric analysis

The photometric viewport evaluates the projector contribution to each surface. Click **Lux** in the toolbar display cluster to toggle it on.

For each surface in the scene it reports:

- **Illuminance**: lux on the surface from all projectors combined.
- **Luminance**: light reflected from the surface back toward a chosen viewpoint.
- **Coverage**: % of the surface covered by at least one projector.
- **Overlap**: % of the surface covered by two or more projectors (for blending).
- **Contrast ratio**: luminance ratio across the surface; 5:1 is a minimum, 10:1 is ideal.



Photometric calculations consider only projector and LED contribution. Ambient and directional light in the scene are excluded from the calculation; use the **Brightness viewport** below for a full energy view.

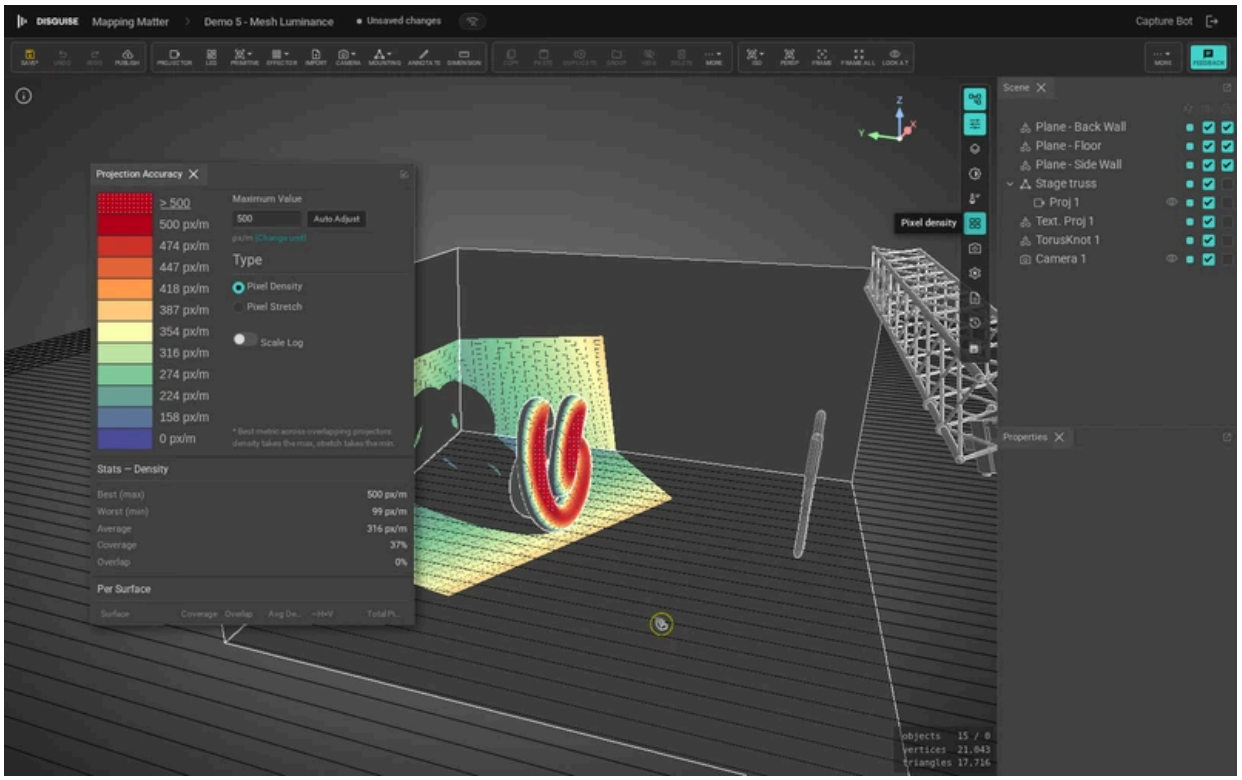
LED screen readouts use the **panel's native brightness**: the rated nits of the tile spec multiplied by the screen's brightness factor. The content being displayed (test pattern, video clip) is ignored, so the lux numbers match what you'd measure with an instrument rather than depending on whatever's playing. This matches the projector behaviour where output is independent of the projector image.

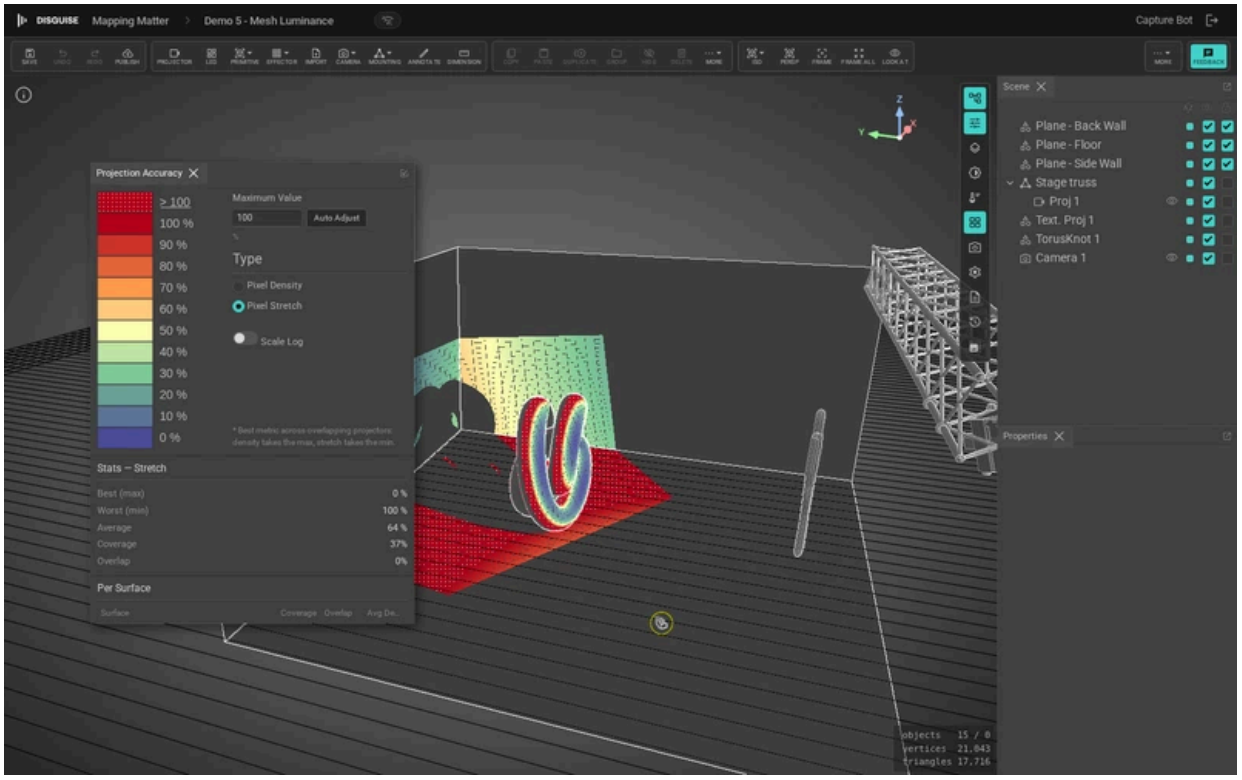
Projection accuracy

The Accuracy analysis answers a different question from Photometric: *how well does each projector resolve to the surface it's hitting?* Open **Pixel density** in the bottom Panels strip and pick a mode:

- **Pixel Density**: pixels per unit length on the surface, in the active scene unit. Set the **Maximum Value** to the density that should map to the top of the colour bar; areas at or above max render red, areas at the bottom render blue. Useful for confirming that a wall is hit with the resolution you sold to the client.
- **Pixel Stretch**: the anisotropy ratio between the projector's horizontal and vertical pixels on the surface. A perfectly square pixel is 1.0; the further from 1 the more distorted (oblique angles, off-axis projectors). Maximum tops out at 5×.

Toggle **Scale Log** to spread the colour bar across very different densities. The panel also reports aggregate stats (best, worst, average, and coverage) across all visible surfaces. The stats are sampled across each surface in world space and don't depend on the current camera view, so a sphere or curved wall reports its true coverage no matter how you orbit.





The **Pixels** button on the toolbar's display cluster is the in-viewport overlay for whichever mode the Accuracy panel last had selected. Use it as a quick on/off while the panel stays in the side dock.

Human acuity

The Human Acuity overlay tells you whether each projector or LED pixel is *resolvable to a human standing at the observer's eye*. The 1-arcminute (20/20) threshold is the reference. Place an Observer, use **Look from** to enter their view, then click **Acuity** on the toolbar to enable the overlay.

While looking from the observer you can walk around with `WASD` and free-look with **Mouse look** (toolbar button or hold the cursor); the acuity bands update live as the observer moves, so you can validate seat-by-seat coverage by stepping through the audience plot rather than guessing from a fixed POV.

The colour key (relative to the 1-arcminute threshold):

Band	Meaning
Blue / cyan	Pixels much smaller than acuity: finer than the eye can resolve. Wasted resolution.
Green	Pixels at or near acuity: the sweet spot.
Yellow / orange	Pixels larger than acuity: visible structure.

Band	Meaning
Red	Pixels far above acuity: clearly pixellated to the observer.

Acuity only renders from an Observer's eye view; leaving look-from mode (or selecting a non-observer view) clears the overlay. Use it together with **pixel density** to balance specified resolution against perceived resolution.

Brightness viewport

The brightness viewport renders the live lux distribution across all surfaces as a colour heatmap with a configurable colour bar.

In the **Brightness** panel:

- **Auto range**: fit the colour bar to the current scene's min/max lux.
- **Log scale**: apply a log mapping so dim regions are still discernible.
- **Projection texture overlay**: overlay each projector's assigned texture on the surface, regardless of beam visibility.
- **Ambient light**: overall scene fill; affects shading but not photometric numbers.
- **Directional light**: sun-like fill with yaw and pitch; affects shading and the brightness viewport.

Measurements and annotations

Within either analysis mode you can place numeric dimensions and freehand annotations; see Measurements & annotations.

What's New

Modern Mapping Matter is a ground-up rewrite of the design tool many of you already know. The familiar shape is still here (projectors, screens, rigging, photometric and brightness analysis, shareable snapshots), but the platform underneath is new, and almost every workflow has been rebuilt around real-time collaboration, layered scenes, AI-assisted product creation, deeper truss and LED workflows, and a publishing pipeline that finally treats your design as the deliverable.

This page is the tour. Each section calls out what's new or materially better than the previous version, with deep links to the full documentation for each feature. If you're carrying scenes across, your legacy work is one click away in the launcher's **Migratable** tab; see Open or create a scene.

Designed together, in real time

Mapping Matter is now a collaborative editor. Two or more designers can be in the same scene at once, with live cursors, presence avatars in the header, and short-lived scene locks that prevent conflicting writes. See Collaboration.

For the rest of the world (clients, lighting designers, freelancers, the production manager who needs to sign off the rig) publishing is now first-class. A **snapshot** is a named, locked, independent copy of the scene at a moment in time. You publish a snapshot then attach as many shares as you need: anonymous URLs (with optional password), per-email invitations that surface in the recipient's Disguise Cloud dashboard, or both. View counts surface on every share, individual recipients can be revoked, and the whole snapshot can be invalidated in one click without losing the source scene. See Publish & share.

A new Layers system organises the scene the way drawings have always been organised. Every object lives on a named layer with a colour swatch in the Scene panel, and the Layers panel lets you toggle whole groups visible or hidden in bulk. The same picker is in the Publish & Share dialog, so you can send the lighting designer a snapshot of only the lighting layer, or the venue a snapshot with just the structural layer, without touching the source scene.

Revisions are no longer a "last 10 opens" rolling buffer. Every committed edit lands in an **auto-save** that flushes in seconds, and a new revision is cut whenever editing settles (or when you close the scene), so an evening's work reads as named checkpoints in the Revisions panel, each restorable in place.

Smarter modelling, smarter snapping

The transform gizmo has a brand-new global **Snap** control in the viewport toolbar. Pick one of five modes (**Off**, **Grid**, **Vertex**, **Edge**, or **Surface**) and the gizmo locks onto the nearest target on

any visible mesh as you drag, including truss members and observer figures. A green disc indicator confirms the snap target live. See Snap modes.

The 3D **asset library** now reports an imported mesh's bounds in your scene's active dimension unit (feet, metres, mm, anything) instead of forcing you to read millimetres. A new **Scale Reference** picker drops either a 1.8 m human figure or a 1 m^3 wireframe cube next to the mesh while the Import Settings overlay is open, so you can confirm scale at a glance before committing. See Import Settings.

Object hierarchy works the way you expect: drag any node in the Scene panel onto another to reparent in place, with a visible drop indicator and the same parent rules as the Properties Parent dropdown. Multi-selections move as a unit. See Reparenting in the Scene panel.

The whole editor is dockable. The Scene, Properties, Layers, Brightness, Pixel density, PDF layouts, Revisions, Scene settings and viewport-tuning panels are all in a bottom-edge **Panels** strip; click any to open or close it. Drag a panel's tab to any edge to dock it as a rail, drop it on another tab strip to merge them, or drag it onto the viewport to float it. Your layout persists per scene, so a projector-heavy rig and an LED-only rig can have completely different workspaces.

LED screens, first-class

Where legacy Mapping Matter focused on projection, modern Mapping Matter treats **LED walls** as full peers. Click **LED** in the toolbar's add cluster to open the LED library overlay (catalogue tiles plus any custom tiles you've added) and lay out a wall with horizontal and vertical tile counts up to 100 × 100. The Properties panel exposes pixel pitch, tile model, brightness in nits, mounting style and content texture, with a derived read-out for total resolution, dimensions, weight and power draw aggregated across every tile. See LED screens.

Walls can be **curved**, either concave (toward the viewer) or convex (away), around the horizontal or vertical axis. Sweep the **Tile Angle** parameter and the panel shows live derived geometry (radius, total curvature, chord length, depth) so you can size a wall to a venue's structural curve in feet of arc, not trial and error.

LED walls plug into every other system. They contribute to the **brightness viewport** heatmap and surface coverage statistics. They can be **mounted on a truss** via the same Mounting collapsible projectors use. They can be **duplicated through effectors**: the Polar Array and Fan modes are particularly useful for stacked LED rings and toed-in walls. And the new **Layers** system means an LED-only snapshot is a single click away.

AI-assisted product creation

If a projector or lens isn't in the catalogue, hit **+ Create custom** in the projector library and start typing a manufacturer and model. Modern Mapping Matter fires a background AI research call against the manufacturer's specs and shows an **AI suggestions ready** banner at the top of the form. One click on **Apply all** populates every still-empty field (throw range, fixed optical offset,

adjustable shift envelope, mount slug) with sourced values; any field you typed yourself is left untouched. The lens name and lens-mount fields are also autocomplete-driven, pulling matches from the product DB and falling back to a fresh AI lookup when there's no DB hit. See Custom projectors.

The custom-product workflow knows about ultra-short-throw optics specifically. Pick a UST lens (catalogue or custom) and the projector sidebar surfaces a **UST lens: add a fold mirror?** banner with an **Add suggested mirror** button that drops a 45° fold plate aimed at the projector's current target, sized to catch the chief ray. From there you fine-tune like any other mirror. See Suggested mirror for UST lenses.

Custom projectors save into a per-project "Project copies" group at the top of the library overlay and behave identically to catalogue models everywhere else in the editor.

Trusses and mounting, rebuilt

Modern Mapping Matter ships a complete **truss and base library** under a new **Mounting** popover in the toolbar's add cluster. Seven truss profiles (Tower, Horizontal Span, Goal Post, A-Frame, Ladder, Arc, Ring) and four base types (Base Plate, GB Block, Sled, Outrigger), with parameterised geometry, custom variants, and a full catalogue overlay you can search by cross-section. See Trusses and mounting and the Truss library.

Mounting a projector or LED wall onto a truss is a drag away. Drop the projector near a truss and Mapping Matter offers to clamp it to the nearest centreline; once mounted, the projector tracks the truss as you reposition the rig and slides freely along the chord via the **Clamp position** slider in the Mounting collapsible. Effectors mounted on a truss carry every copy with them, so a polar array of projectors moves and tilts as a single unit.

Trusses also get a continuous **clash check** against scene meshes. Any truss that intersects geometry pulses red so a hire-house operator can spot the conflict at a glance. Toggle the warnings via the **Clash** button in the viewport toolbar's display cluster. See Collision warnings.

Analysis, end to end

Every analysis mode from the previous version is here, faster and richer.

Photometric analysis computes lux per surface, plus coverage and overlap, and now reports contrast ratio per surface so you can validate a wall against a 5:1 minimum at a glance. **Projection accuracy** splits into two modes: **Pixel Density** for resolution-on-wall checks (px / mm^2, px / ft^2, whatever your scene unit is) and **Pixel Stretch** for projector keystoning, with an Auto Adjust that snaps the colour bar to the current scene peak. Both have a quick on/off in the toolbar's display cluster and a full configuration panel in the Panels strip. The **Brightness viewport** is a live lux heatmap with draggable min/max range handles and per-scene auto-fit, and adds a **projection texture overlay** so you can preview content directly on the rendered surface, regardless of beam visibility.

A new **POV camera** treats each saved camera as a real Three.js camera with its own resolution, FOV, focal length and sensor size. Pick one from the toolbar's Camera popover, and an inset preview opens in the viewport showing what the camera sees. See POV camera.

Observers are a new class of camera shaped like a person (head, body, eye-level bar) that you drop into the audience plot and walk through with `WASD`. Switch the toolbar's **Acuity** button on and a new **Human Acuity** overlay colour-codes every projected and LED pixel by how it compares to the 1-arcminute (20/20) acuity threshold from the observer's eye. The colour bands update live as you walk, so you can validate seat-by-seat coverage instead of guessing from a fixed POV. See Observer and Human acuity.

Rounding out the viewport tools: **Projection distance helper** colour-codes each surface by its distance from the nearest projector for focus-zone planning; **Object edges** shows wireframes over everything; **Material override** swaps every surface to a neutral grey for blocking checks; **Mouse look** captures the cursor for free POV navigation.

Output and handover

The **PDF layouts** system turns the editor into a producible-document tool. A layout is a reusable page template (title block, table of projector specs, page size, viewport pose) that you save from the Export dropdown and reuse on any scene. See Export & PDF layouts. CSV exports cover projector and tile data for downstream media-server prep.

The viewer side of publishing is the **`mapping-matter-viewer`** plugin: a public, account-optional, read-only renderer that opens any share link. Recipients see the scene in a navigable 3D viewport with the title block, designer name, the layers the snapshot included, and an optional brightness toggle. No sign-in required, no access to the source scene, no edit affordance.

Tooltips, slider polish, and other quality-of-life

A lot of small things add up. Every icon-only button in the viewport toolbar, the object sidebars, and the dock panels has a PrimeVue tooltip with the keyboard shortcut rendered as a teal-bordered chip. Panel sliders are now full-width with a larger thumb and a bigger hit target for precise mouse drags. The Mounting toolbar popover lists every truss type, every base type, and a one-click **Mount on nearest truss** action. The keyboard reference is one `F1` keystroke away (the in-app shortcut dialog is up to date with every binding).

For the deeper rabbit holes (collaboration locks, snapshot internals, RLS, the migration tool architecture) the FAQs cover the most-asked questions and link out to the per-page docs.

What's gone or changed

A handful of features from the previous Mapping Matter don't carry over verbatim. The modern editor handles them differently:

- **Viewer-only links** are replaced by snapshot **link shares**: anonymous, optionally password-protected, revocable, with view counts. See Share a snapshot.
- The **always-on 1000 mm grid snap** is now an opt-in **Grid** mode in the Snap popover; the default is **Off**. Pick **Grid** explicitly if you want the legacy behaviour back.
- The **Save** button is gone. Auto-save runs continuously and the Revisions panel is the rollback path.
- **Per-file scenes** are now **one scene per Disguise Cloud project**; switch projects from the launcher dashboard to work on a different scene.
- The **"last 10 opens" snapshot system** is replaced by an unlimited revision history and named locked snapshots.

Where to start

A suggested first session:

1. Open a demo scene from the launcher's **Demos** tab; `Demo 5 - Mesh Luminance` is the most analysis-rich.
2. Toggle the **Lux**, **Pixels** and **Acuity** buttons in the toolbar's display cluster to see the analysis overlays.
3. Drop a custom projector via **+ Create custom** and watch the AI suggestion banner populate.
4. Open the **Snap** popover and try **Vertex** or **Surface** while dragging a projector.
5. Publish a snapshot from the **Publish & Share** button and open the resulting link in a fresh window.

When you're ready to bring your own work across, the **Migratable** tab in the launcher walks each legacy scene through the migration. The original stays untouched unless you opt in to marking it as migrated.

Latest updates

New this release:

- **User-definable projection studies**: the PDF output has been rebuilt from three fixed generators into a template-plus-slot layout editor with a live preview. Pick ISO A4–A0 or US Letter, add per-projector, per-LED or per-observer pages, and set each render slot's mode to projection output, pixel density, pixel stretch, illuminance, luminance, or human acuity. Generated PDFs are real vector output, not screen captures. See Export & PDF layouts.

- **Organisation-scoped projectors**: custom projectors now have an ownership scope. Promote them from **Project** to **Organisation** so the rest of your team can pull the same custom model into any of their scenes; a launcher dashboard section lets an admin manage the whole org library. Legacy Mapping Matter customers can import straight into the org library without opening a scene. See Ownership scope.
- **Wireframe display toggle**: a new **Wire** button in the display cluster flips every mesh to a wireframe overlay, useful for topology checks without hiding geometry.
- **Delete assets from the 3D library**: user-imported meshes now have a **Delete asset** action with a 90-day retention window; the platform demo library stays read-only.
- **Inline material editing for single-material References**: when an imported mesh has one default material, its material controls appear inline in the Properties panel below the **Edit Reference** button; no need to enter edit mode to change colour or texture.
- **Full read-only enforcement for viewers**: every mutation entry point is disabled and greyed for viewer and unlicensed users, so there are no controls that appear active but silently fail on write.
- **What's New announcements + reload prompt**: the launcher header has a sparkle icon that opens the Disguise **What's New** panel; long-lived editor sessions surface a non-blocking **Reload** banner in the top-right when a new build is deployed.
- **Persistent library filters and sort**: the launcher dashboard, projector library and LED library remember your sort order, scope filter, and brand/origin filters per browser.
- **Numpad-free keyboard shortcuts**: every numpad view shortcut (`Num 0` – `9`) also fires on the top-row digit keys, so laptops without a numpad drive them the same way.
- **Swap orbit / pan**: a Scene Settings preference for Blender / Maya users flips the viewport bindings so left-drag orbits and right-drag pans.
- **View-independent accuracy stats**: the Accuracy panel's coverage, overlap, density and stretch numbers are now sampled across each surface in world space, so numbers on spheres and curved walls stay stable no matter how you orbit.
- **Better measurement snap and picking**: vertex snap works across meshes, and orbit-drags while placing a point no longer drop a stray point on release.
- **Truss collision hints name the file**: the AId3n suggests hint refers to the offending mesh by its imported file name, and **Translate to clear** clears against the whole imported asset.
- Under the hood, **large-scene load and save reliability** got a large lift: mesh caching, incremental scene diffs, material dedup, retry-on-blob-upload, and IndexedDB mesh caching all landed. Heavy scenes should open and autosave noticeably faster.

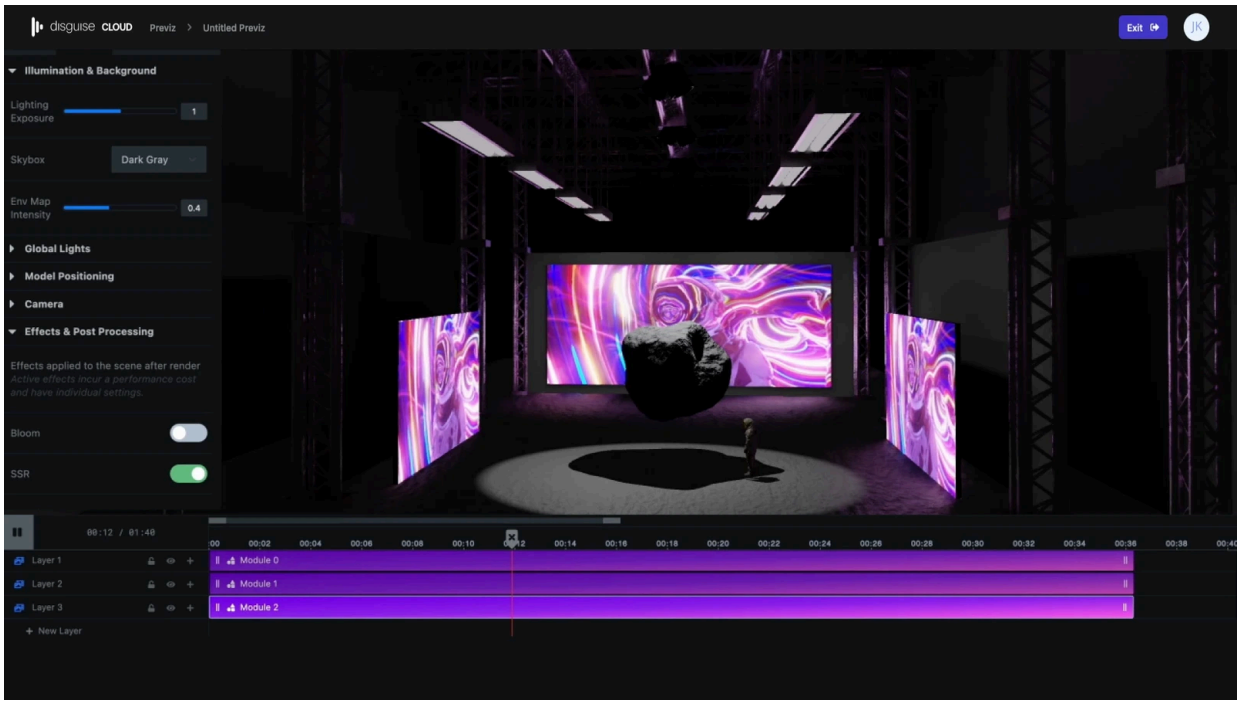
About Previz



Previz is a flexible, user-friendly, pre-production workflow for transforming ideas into incredible experiences.

It's been conceived to improve the collaborative working environment and communication of different event professionals, wherever they may be.

Previz features:

- A direct connection to disguise drive, comprehensive Content Management System that supports images, videos, and sequences.
- A real-time interactive 3D Scene editor and viewer that supports textures, lighting and cameras.
- A feature rich Sequencer to combine and integrate 3D scene data, production images and video assets into a timeline.
- Shareable view pages to provide clarity and alignment, helping with the review and approval process of your project.

Compatibility

To display 3D content in real-time we use WebGL, which is a standard in most modern browsers. You can check if your browser is compatible on **https://get.webgl.org/**

For more technical details about WebGL on your machine, see **https://webglreport.com**

Desktop

Previz is compatible with the following browsers:

- Mozilla Firefox
- Google Chrome
- Opera
- Safari
- Edge

Mobile

- iOS 8+
- Android 4.0

Troubleshooting

WebGL

If you run into problems in the 3d viewer, make sure your graphics driver and browser are up-to-date. If that doesn't help, try one of the other browsers listed above. **https://get.webgl.org/** is a good place to start troubleshooting.

Sometimes, your browser may disable WebGL based on your GPU. If you are using a compatible browser, but you see an incompatible warning or the viewer performs very badly, try forcing the browser to use your GPU:

Chrome

1. Go to Sys tem Settings (chrome://settings/ > Advanced > System) and make sure **Use hardware acceleration when available** is enabled.
2. Go to chrome://flags/#ignore-gpu-blacklist and enable the **Override software rendering list** flag.

Firefox

In Firefox, type about:config into the address bar and enable **webgl.force-enabled**.

Touch Screen / Tablets

Sometimes, navigating a model may not work on a touch screen or tablet device. This is especially common on certain Windows 10 devices. In Chrome, for example, visit chrome://flags/#touch-events and enable the "Touch Events API" flag.

Creating a Previz Project

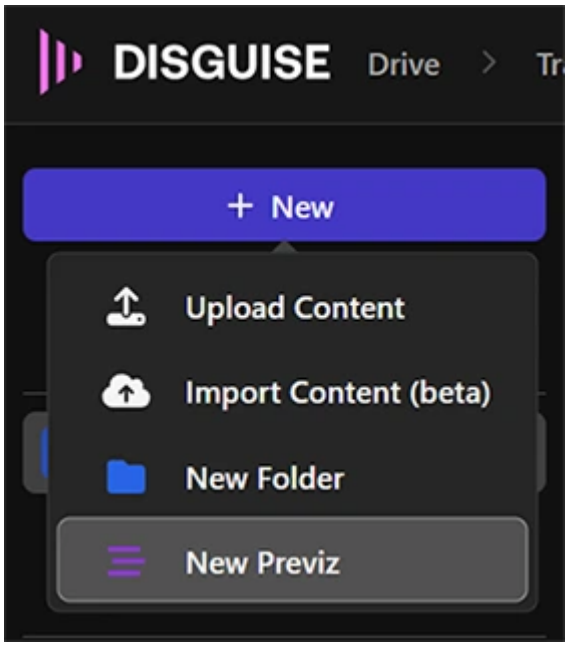
With Previz you can plan and preview your content in a real-time 3D environment.

Sequences in Previz can contain a range of different media including images, videos, 3d and scenes.

Create a new Previz Project

To create a new Previz Project:

1. Select **New** from Drive.
2. Then select **New Previz** next to the team name in the team sidebar.
3. Enter the name for your new Previz.



Create a Previz Project

Creating a Share Link

You can share specific files (including scenes and sequences) with external guests such as clients or project stakeholders.

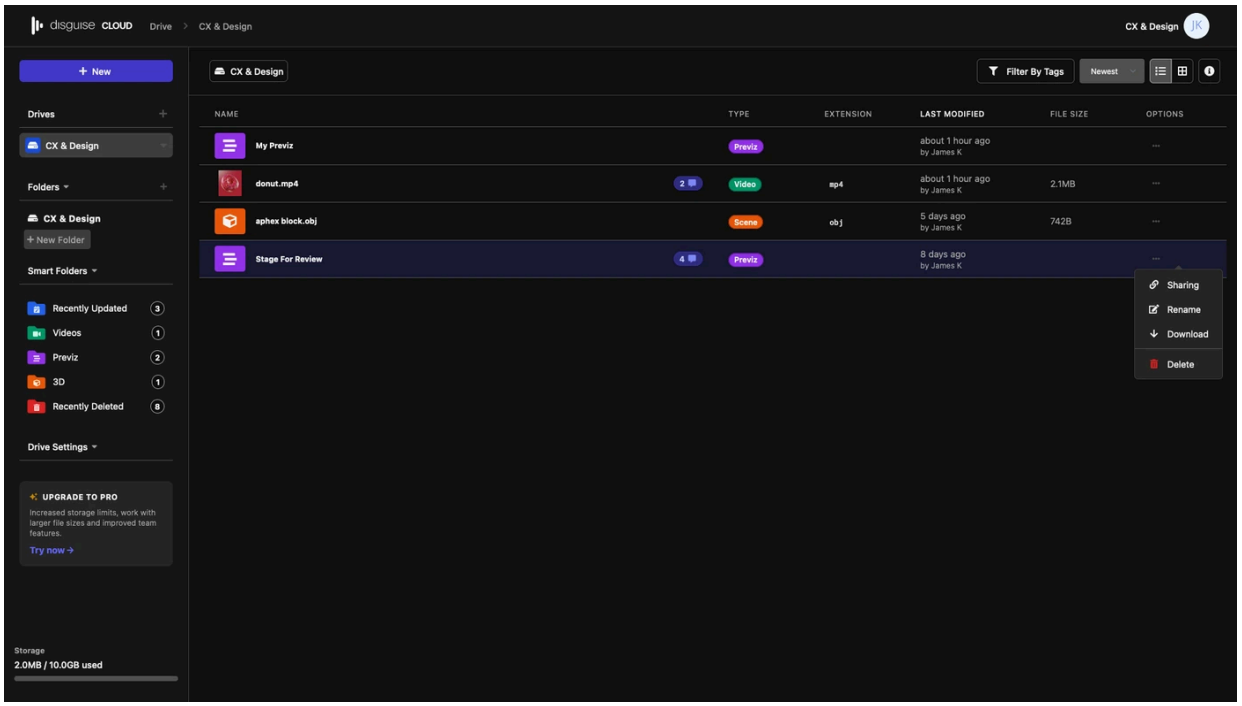
Creating a share link enables these users outside your team to be able to view your files.

There are two ways to create a share link:

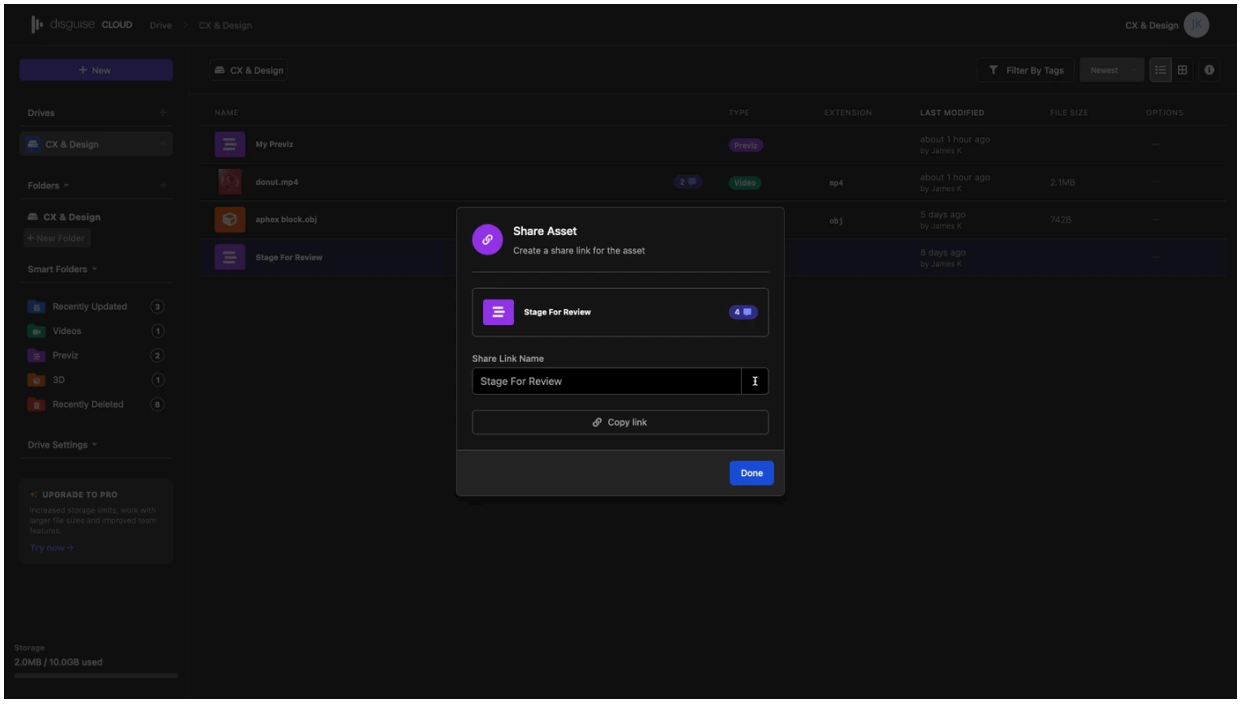
1. From the edit mode of an item. OR
2. From the view mode of an item.

Create a Share Link in View Mode

1. Navigate to the content view within a project.
2. Select the asset you want to share to open it.
3. In the sidebar click “Create Link”.
4. In the modal that opens you’ll have the option to add a title.
5. Next you’ll need to enable link sharing for the asset. You can do this by toggling the enable option or clicking the “Enable Link Sharing” button.
6. This will generate a link that you can copy.



Select the asset to share



Confirm the share link name

Customizing a project

Guides lead a user through a ‘specific’ task they want to accomplish, often with a sequence of steps. Writing a good guide requires thinking about what your users are trying to do.

- Read the Disguise help guide

Editing Scenes

Global Settings

Previz offers you a convenient way to tweak your basic model settings including lighting and positioning to make sure your model is rendered exactly the way you want it. These options can all be controlled in the Viewer tab in the scene editor. Changes are rendered in real time and saved automatically.

Illumination

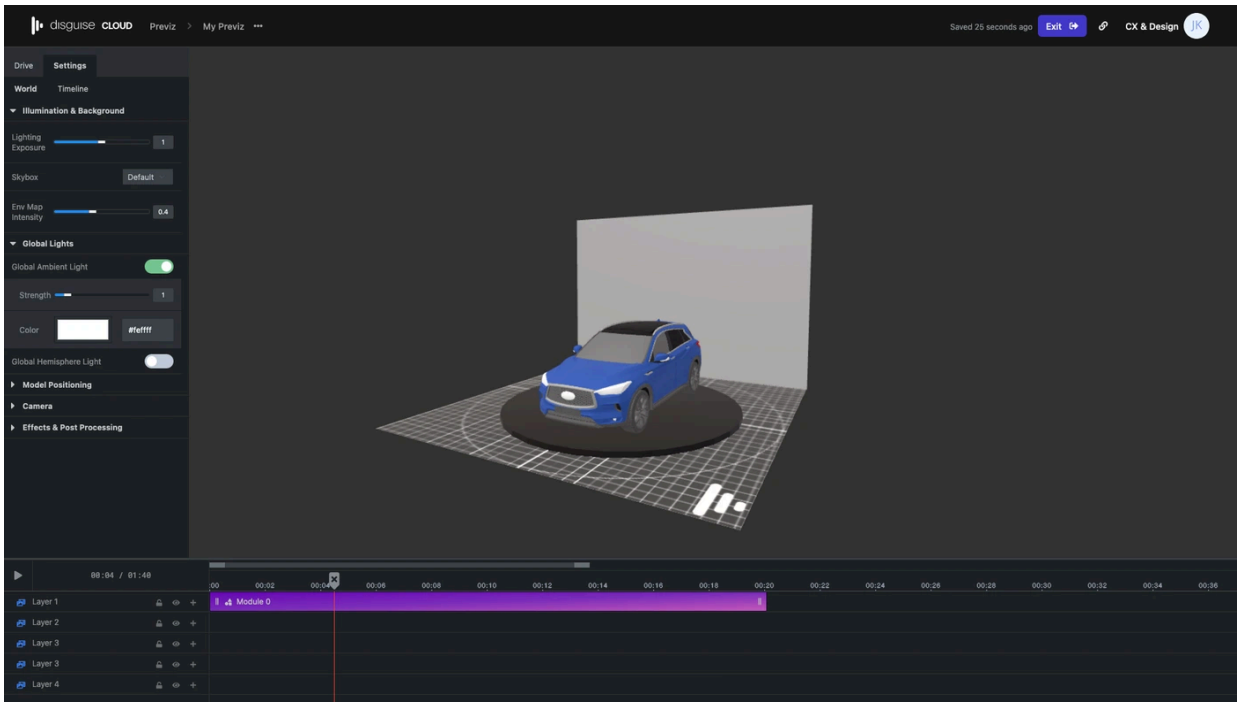
The illumination field allows you to edit the lighting exposure for the scene.

Note: This is independent of any lights you may have within your scene.

To edit the lighting exposure:

1. In the content view pick the scene you wish to edit.
2. Whilst in edit mode in the sidebar navigate to the Viewer tab and then the World sub-tab.
3. In the Illumination field adjust the lighting exposure by either clicking and adjusting the slider or by editing the number input field.

Note: The slider adjusts a range from 0 to 2. The number input will allow any value.



Illumination & background

Global Lighting

There are two lights added to every scene by default.

1. Global Ambient Light
2. Global Hemisphere Light

It is up to you whether to use these or not. If you have setup lighting in your imported 3D scene it is likely that you will want to turn both of these off.

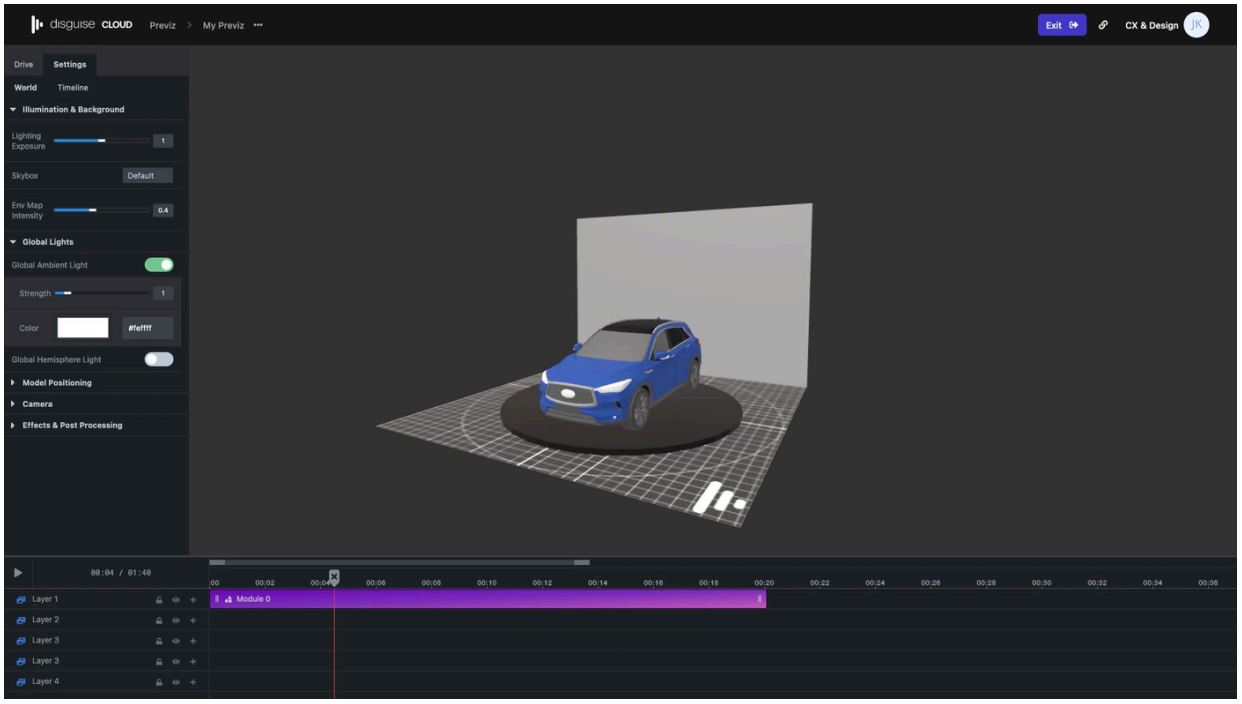
Global Ambient Light

This light globally illuminates all objects in the scene equally. This light cannot be used to cast shadows as it does not have a direction.

1. In the content view pick the scene you wish to edit.
2. Whilst in edit mode in the sidebar navigate to the **Viewer** tab and then the **World** sub-tab.
3. In the Illumination field adjust the lighting exposure by either clicking and adjusting the slider or by editing the number input field.

Global Hemisphere Light

1. In the content view pick the scene you wish to edit.
2. Whilst in edit mode in the sidebar navigate to **Settings**.
3. In the Illumination field adjust the lighting exposure by either clicking and adjusting the slider or by editing the number input field.



Global lights and illuminations

Model Positioning

There are three ways in which you can edit your model position.

1. World Scale
2. World Position
3. World Rotation

World Scale

Editing **World Scale** allows you to set the relative scale of your model in relation to the world space.

To edit the world scale:

1. In the content view pick the **scene** you wish to edit.
2. Whilst in edit mode in the sidebar navigate to the **Viewer** tab and then the **World** sub-tab.
3. In the **World Scale** field adjust the scale by either clicking and adjusting the slider or by editing the number input field.

Note: The slider adjusts a range from 0 to 2. The number input will allow any value.

World Position

Editing **World Position** allows you to adjust the XYZ coordinates.

To edit the world position

1. In the content view pick the **scene** you wish to edit.
2. Whilst in edit mode in the sidebar navigate to the **Viewer** tab and then the **World** sub-tab.
3. In the **World Position** field adjust the coordinates by entering your desired values in the number fields.

Note: You can also adjust these input fields by clicking and dragging.

World Rotation

Editing **World Scale** allows you to set the relative scale of your model in relation to the world space.

To edit the world scale

1. In the content view pick the **scene** you wish to edit.
2. Whilst in edit mode in the sidebar navigate to the **Viewer** tab and then the **World** sub-tab.
3. In the **World Rotation** field adjust the coordinates by entering your desired values in the number fields.

Note: You can also adjust these input fields by clicking and dragging.

Set to Defaults

To reset the model position click **set to defaults.**

Exporting .glTF files from Blender

To export from Blender

Go to **File > Export > glTF 2.0 (.glb/.gltf)**

File Format Variations

The glTF specification identifies different ways the data can be stored.

To export for the Previz platform

Select glTF Binary (.glb)

This produces a single .glb file with all mesh data, image textures, and related information packed into a single binary file.

Include

If you want to export your entire scene make sure that Selected Objects is **not checked**.

Transform

This option should be selected by default. Ensure it is to export your file using the glTF convention, +Y up.

Geometry

Make sure all options are selected by default.

Animation

glTF allows multiple animations per file, with animations targeted to particular objects at time of export. To ensure that an animation is included, either (a) make it the active Action on the object, (b) create a single-strip NLA track, or (c) stash the action.

Supported

Only certain types of animation are supported:

- Keyframe (translation, rotation, scale)
- Shape keys
- Armatures / skinning

Animation of other properties, like lights or materials, will be ignored.

Default Options

The following image shows default options for a scene file with cameras, lights and animation included.

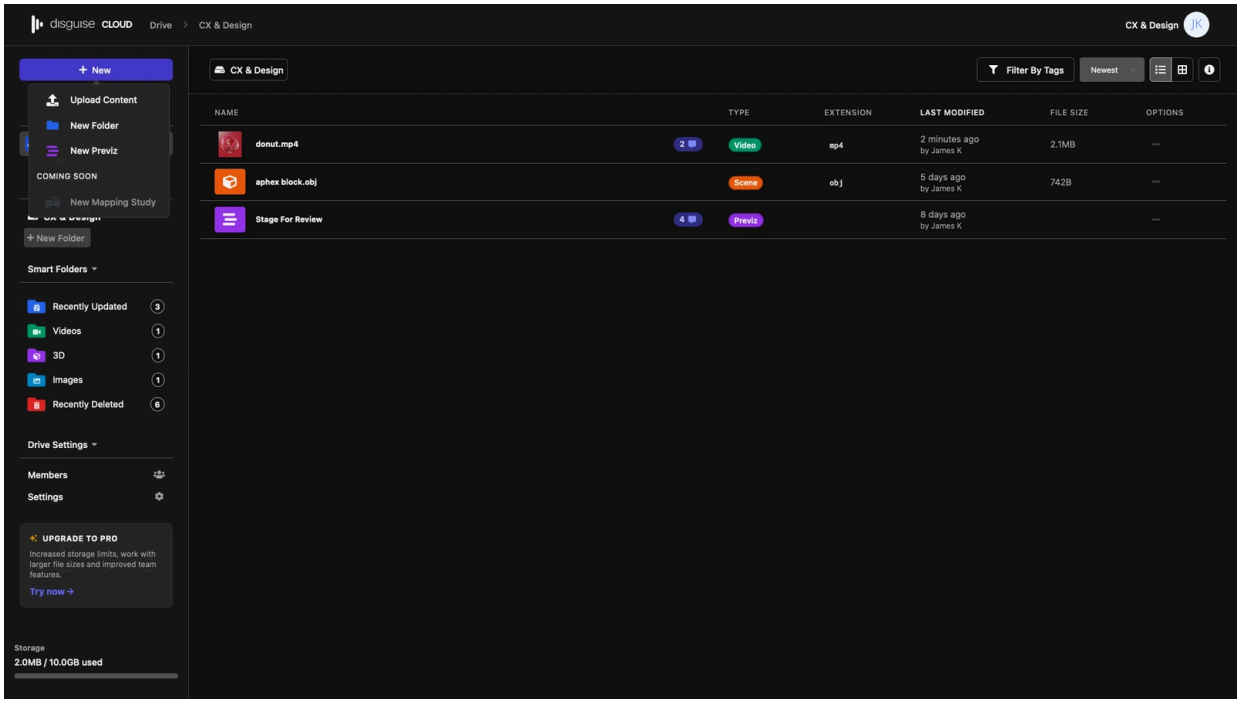
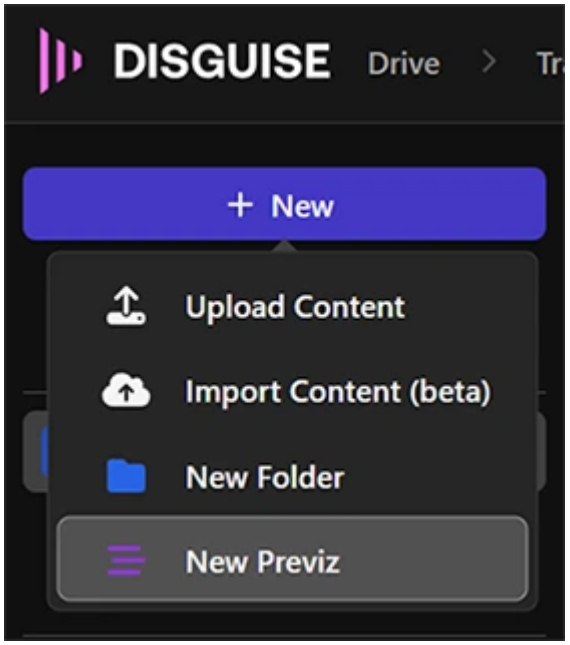
Getting started with Previz

If you have signed up for Disguise Cloud, then you can get access to the web-based Previz application. If not, you can create a Disguise Cloud account here.

Accessing Previz from Cloud

In Cloud Drive, you can create a new Previz project by clicking **New > New Previz**.





DISGUISE
Drive
+ New
Upload Content
Import Content (beta)
New Folder
New Previz

Navigating the Viewer

Viewer Controls

- **Orbit** - To orbit around the scene click and drag with your mouse. If you are on a touch device pointing and dragging will have the same affect.
- **Pan** - To pan, right-click and drag. Use two fingers on a touch device.
- **Zoom** - To zoom, scroll the mouse or pinch and zoom on a touch device.

Preparing Scenes

Preparing Scenes for Upload

The Previz platform is optimised to use the glTF (GL Transmission Format) 3d file format.

glTF reduces the size of 3D models and the runtime processing needed to unpack and render those models.

glTF Feature Support

The Previz platform supports the following glTF 2.0 features:

- Meshes
- Materials (Principled BSDF) and Shadeless (Unlit)Textures
- Cameras
- Punctual lights (point, spot, and directional)
- Animation (keyframe, shape key, and skinning)

Checklist before exporting to Previz

- Make sure geometries from CAD / LIDAR files have:
  - No orphan vertices
  - Only manifold objects
  - No inner faces
- Objects are logically regrouped into single meshes
- Each mesh has an unique name
- UV sets are properly named:
  - Mapping unique to a single mesh have an unique name
  - Mappings shared between several meshes have the exact same name
- A nice props look is baked into a texture

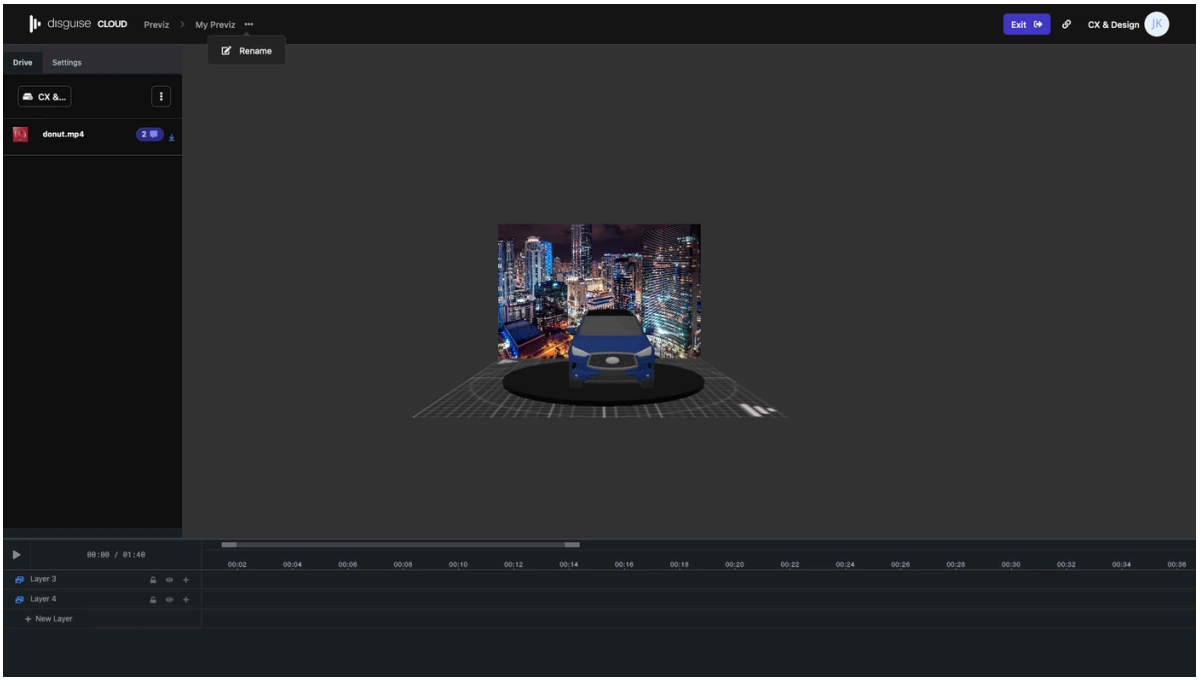
After checking these points, the scene is ready to be exported to Previz.

Renaming a Previz

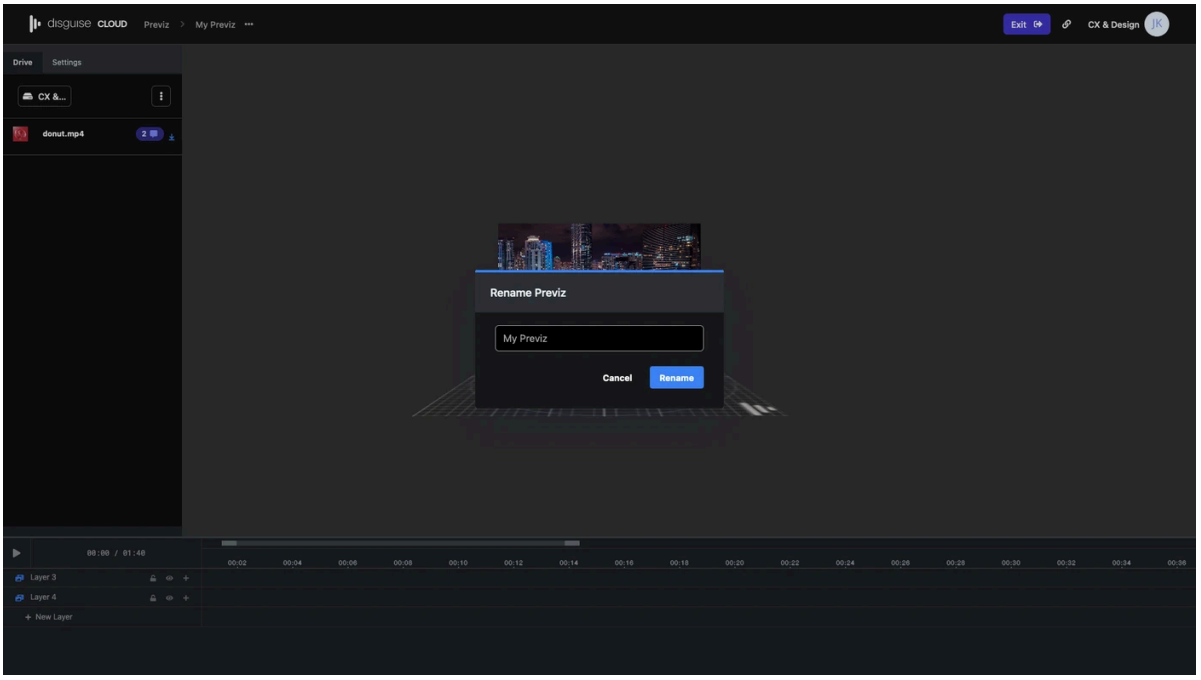
Select the ellipsis in the main navigation next to the Previz sequence. From the dropdown menu select Rename. This will trigger a modal where you will be able to rename your project.

Rename a Previz

1. Select **My Previz** > **Rename** from the menu.



2. Enter the new name for the Previz and click **Rename**.



Scenes

Upload your scenic data and share with unlimited guests for review and approval. Guests can interact with your scene directly in their browser.

Scenes are a way to present set designs and geometry. Each scene file can contain data such as objects and materials as well as lights and cameras. These scenes first need to be created in your 3D program of choice.

General Considerations

- We support .glb files (.glb is the binary version of the glTF 2.0 file format).
- Your .glb must be under 20MB in total. The smaller the better.
- Strip out unused data whenever possible. Unused vertex colors, UV's, etc. all add to the file size.
- Use PNG or JPEG files for textures.
- Use JPEG files unless you need transparency. This will make your files much smaller.
- Textures must be power-of-2 in each dimension (512x1024 for example).
- Textures can be up to 4k, but try to keep them under 2k. _ Once you have a .glb file, you can just drag it into the content area, pick a background color and share it.

Reference Links

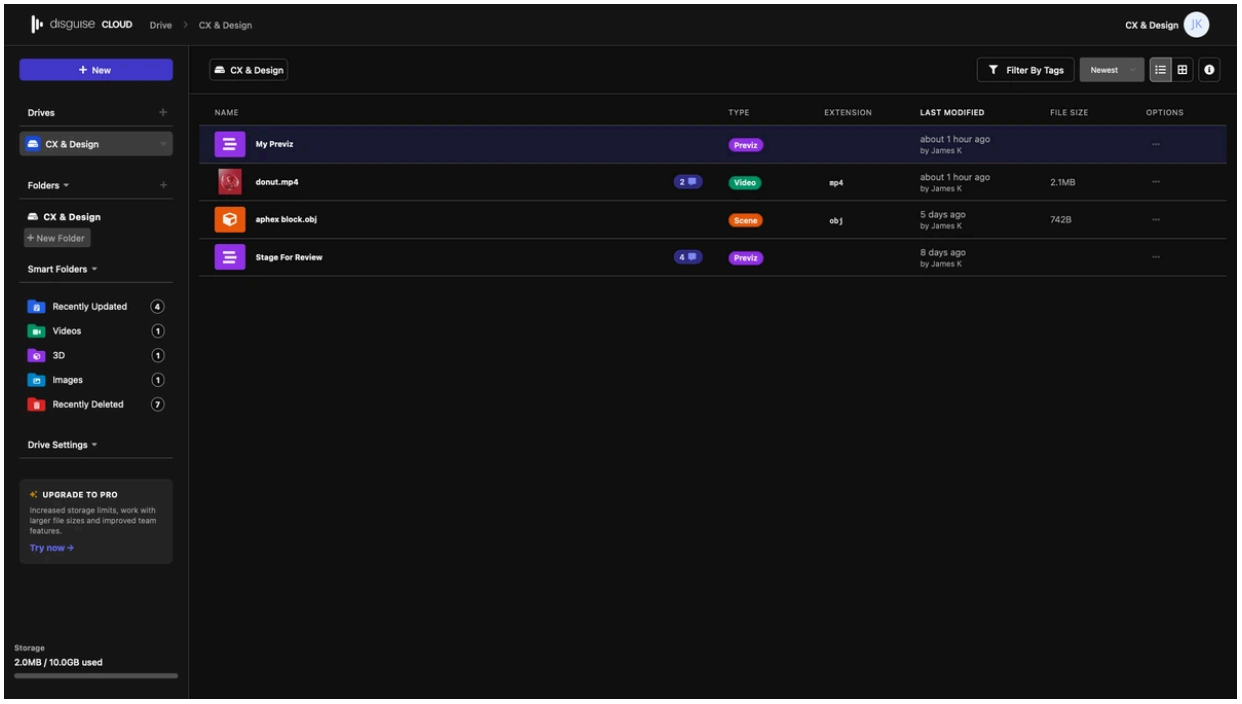
- Blender glTF reference
- Cinema 4D reference

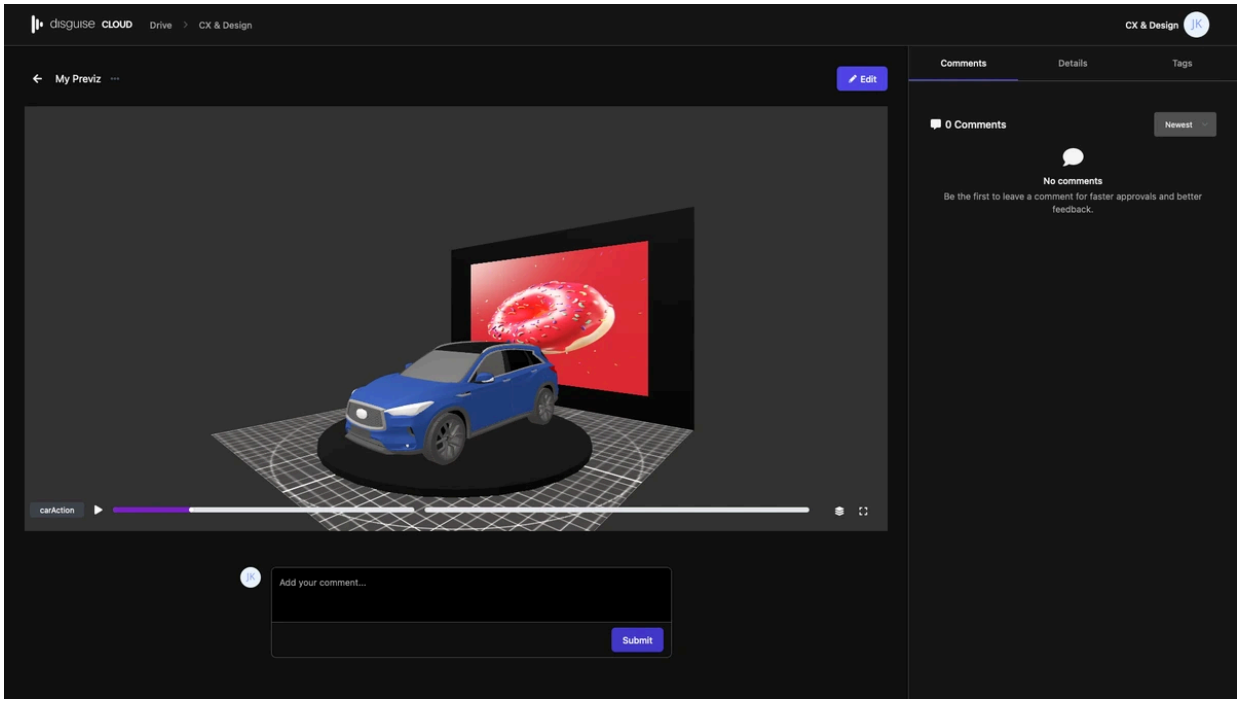
View modes

Sequences can be accessed by two different view modes - view mode and edit mode. You can switch between these modes when you are viewing a scene or sequence. You can access the view switcher in the top right corner is a view mode button to toggle between views.

Preview Mode

Preview mode is a way of previewing your content or current published state. It is the same view external guests have when you share an item with them.

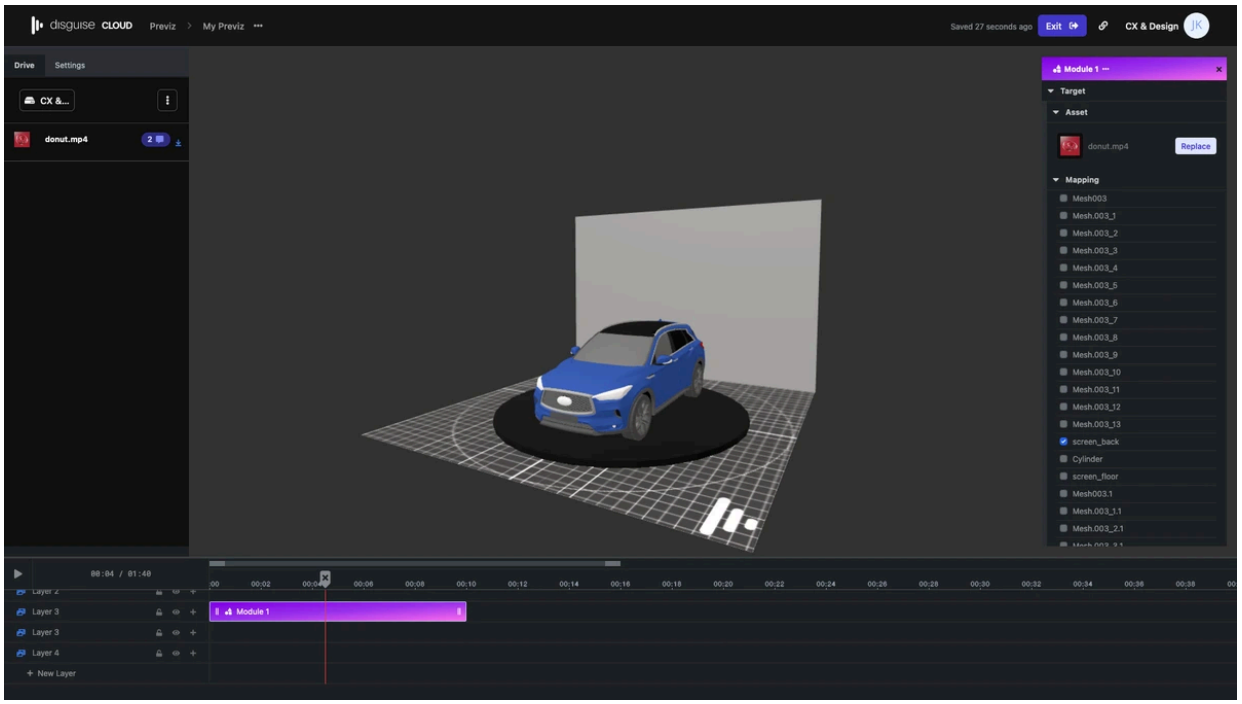




Edit Mode

View mode is a way of previewing your content or current published state. It is the same view external guests have when you share an item with them.

> **Note**
>
> Your access to the Edit Mode is dependent on your team permission settings.

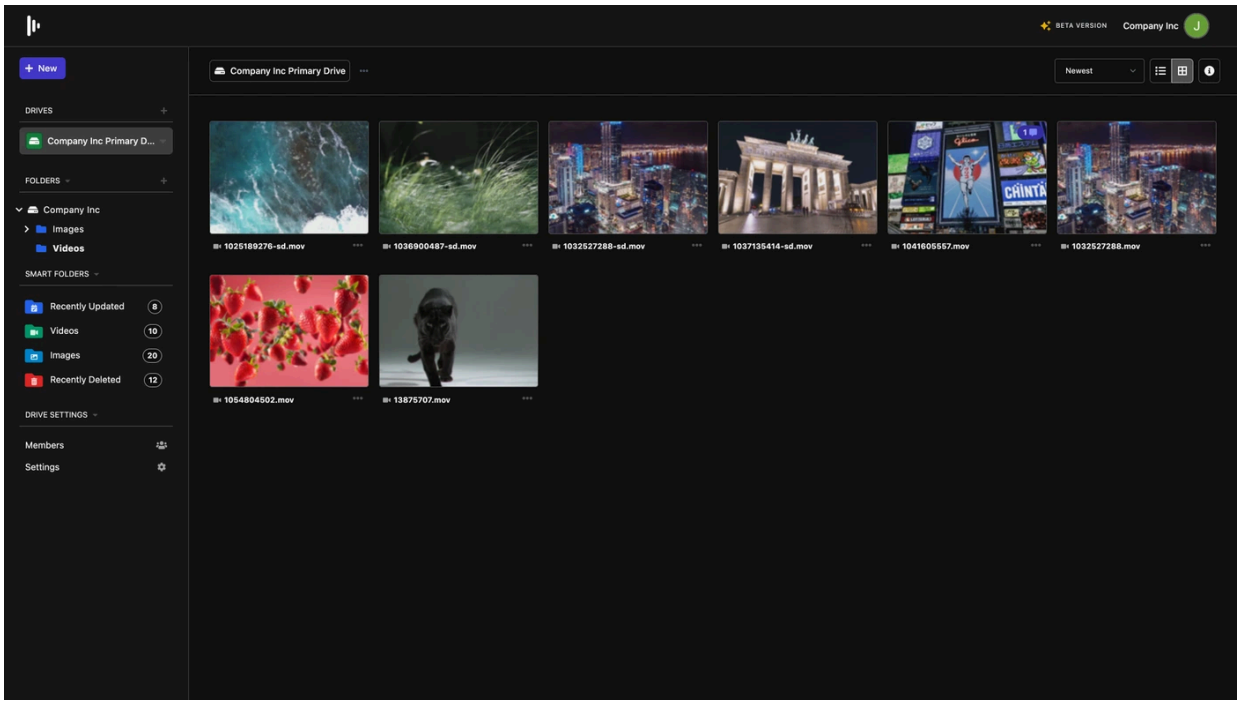


View and open files

With Previz you can view content including videos, images and 3D scene files.

View a file

In your Drive, when you open a scene or sequence, it will open in View Mode. Note: there are two tpes of view modes for and sequences.



Play Videos

To play your video:

1. Single-click a file to select it.
2. Press the play icon in the play controls at the bottom of the video.
3. To play full-screen, at the bottom, click **Fullscreen**.

OmniCal API

The OmniCal Application Programming Interface (API) provides programmable control of the OmniCal feature within Designer, accessible via d3Net.

Designer version r32.4 introduced the ability to perform OmniCal RigCheck directly from the API. RigCheck allows remote re-calibration of proven OmniCal Plans that were set up and calibrated earlier. This new API offers endpoints to trigger a new RigCheck, query the OmniCal result and take further action based on this information.

To access the OmniCal API, navigate to the base URL **localhost/docs/**.

For more in-depth information on the available API calls, please visit the **Disguise Developer docs**.

General OmniCal API endpoints

These currently include endpoints to:

- Query or request OmniCal camera discovery state.
- Query basic information about OmniCal Plans in Designer.

RigCheck API endpoints

These currently include endpoints to control most of the RigCheck workflow, except for making alignment adjustments.

- Query basic information about RigCheck Results in Designer.
- Execute a new RigCheck.
- Monitor progress of ongoing RigCheck via WebSockets stream.
- Query the status and success of the current RigCheck.
- Accept or revert the current RigCheck Result.
- Clean up old RigCheck Results.

RigCheck API Endpoints

APIs Overview

In Designer version r21, we introduced the ability to perform a number of controls from an API.

In Designer version r23.2, we released new APIs. With the release, we launched a new documentation portal specifically detailing our new suite of APIs.

Since the first release of our APIs, we have added new ones and updated existing ones. You can find the Designer APIs, RenderStream SDK, SMC API and others documented on the **Developer Portal**.

What is an API?

An API (Application Programming Interface) is a set of rules and protocols that allows one software application to interact with another. It defines the methods and data formats that programmes can use to request and exchange information. Essentially, an API serves as a bridge that allows different software systems to communicate with each other.

Disguise's APIs are used to make calls to Designer from an external, virtual, or actual physical interface to Designer projects to trigger a change or event. To make the call command, users must provide references to specific existing Designer projects and items within those. This is done by referencing the **Unique Identifier** (UID) for the object you want to interact with.

The Disguise approach to APIs

The **Developer Portal** supports the control and monitoring of Disguise media servers and Designer software using a comprehensive HTTP API.

An HTTP API is an API that uses Hypertext Transfer Protocol as the communication protocol between the two systems. HTTP APIs expose endpoints as API gateways for HTTP requests to have access to a server. Disguise APIs typically use `GET` requests to retrieve information and `POST` requests to modify data or execute actions.

Workflow Centric

APIs and SDKs designed to compliment and integrate with Disguise workflows.

Developer Focused

The developer portal has been designed with the developer experience in mind.

Integration Support

We are happy to support integrations with our products. Contact us at integrations@disguise.one for integration support and partnerships.

d3manager OpenAPI Documentation

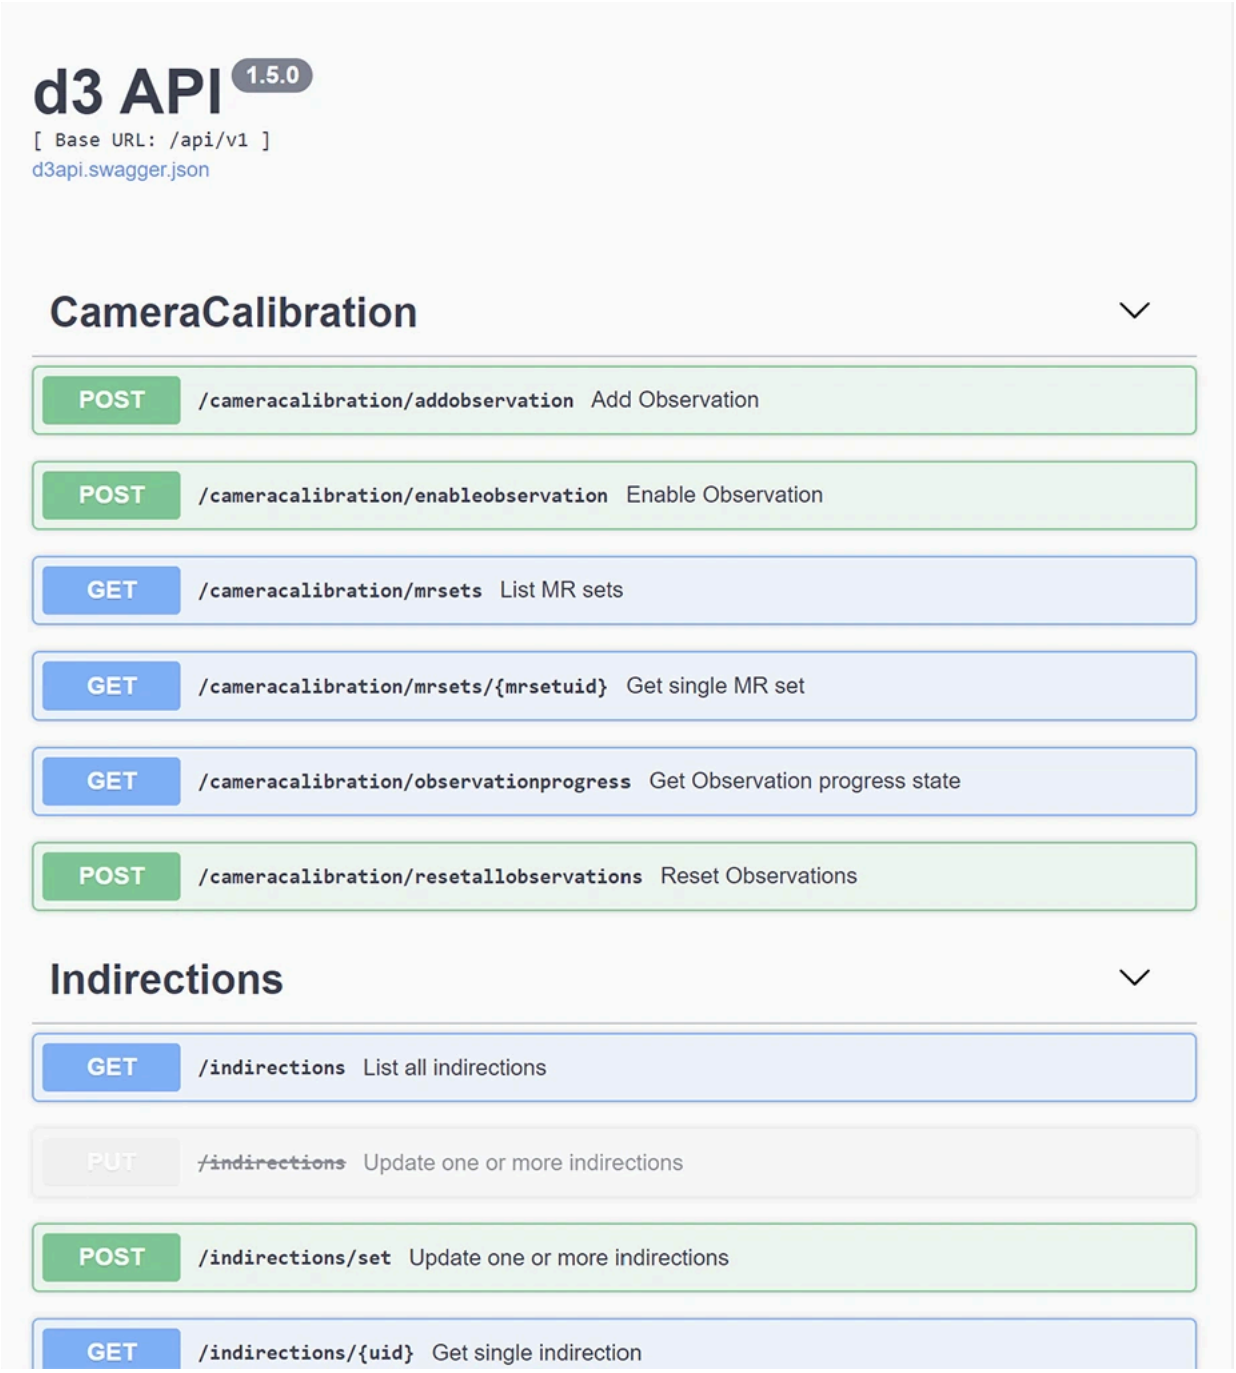
Documentation for our Disguise Designer APIs is also hosted within Designer.

To access API documentation from d3manager navigate to **Help > Open API Documentation**.

Note that this documentation uses the OpenAPI format which means that you can execute APIs from within the documentation.

Opening API Documentation

Designer uses an OpenAPI format (Swagger Docs) for the d3 API.



To access the API, open **d3Manager**, click **Help**, and select **Open API Documentation**.

[Animated GIF: Open API Documentation]

Configuring API

By default the API uses **TCP Port 80**. This can be can be changed in d3Manager.

1. Open d3Manager.

2. Select **Machine Settings > Advanced Network Configuration**.
3. Change the port specified under **API http port**.

To disable the API entirely, so no ports are open. Set the port to 0.

What is a UID?

A unique identifier (UID) is a numeric or alphanumeric string that is associated with a single entity within a given system.

Every item in Designer has a numeric UID assigned to it. API `GET` requests typically return a `Locator` that contains the UID and filename of an object. The UID can be used in many `POST` requests to uniquely identify the object that should be modified.

A UID is specified as a string containing either a decimal or hexadecimal number. For example, the following query excerpts refer to the same object:

- `"uid" : "2276480868532234653"`
- `"uid" : "0x1F97AF49E2D6299D"`

For more information, please see **Locator** on the Disguise Developer Portal.

- Designer Plugins

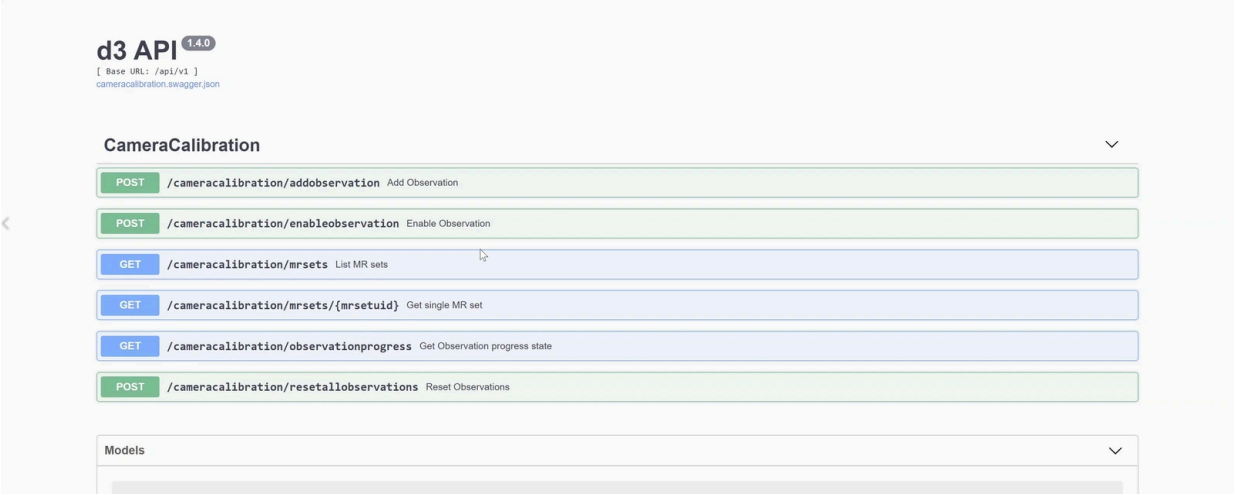
API xR Calibration

This topic covers the basic steps of aligning the physical and virtual worlds within Designer, using the API.

What is the API?

The xR API is an application programming interface accessible via d3Net that allows direct access to specific software functionality within the Designer software.

Designer version r20 introduced the ability to perform a spatial calibration directly from the API, allowing remote access to the functionality while reducing the number of people required to execute this process to one.



To access the API, navigate to the base URL `http://localhost/docs/v1/index.html`

Workflow

A well-calibrated stage will reveal no seams or visual artifacts that break the seamless blend between the real and virtual environments, and with adequate preparation, can be fully calibrated in less than a few hours.

Preparation

Prior to beginning spatial calibration, ensure that:

1. A camera tracking system is set up and is receiving reliable data.
2. The xR project has been configured with an MR set, accurate OBJ models of the LED screens, and tracked cameras with video inputs assigned.

3. The cameras, LED processors, and all servers are receiving the same genlock signal.
4. The feed outputs have been configured and confirmed working.
5. The **Delay Calibration** has been completed.

Calibration

A **Calibration** is a set of data that is contained within an individual camera object. The calibration process uses tracking data as a base against structured light patterns to determine the reality in relation to the raw tracking data.

Observations

An **observation** is a set of images of the stage captured by the camera of white dots on a black background (called structured light). The user determines the number of dots and their size/spacing.

- **Observations** are used as data points for the predefined algorithm Disguise will use to align the tracked camera with the stage and set up the lens characteristics.

There are two types of observations used in the process: **Primary and Secondary (P and S)**.

- **Primary observations** are the positional or spatial observations used to align the real world and virtual cameras. A minimum of five Primary observations is required for the solving method to compute, so aim for five good observations when you begin your calibration process. Primary or secondary status is defined by the most common zoom and focus values in the pool of observations.
- **Secondary observations** comprise the zoom and focus data that create the lens intrinsics file. Each new zoom and focus position will create a new **Lens Pose**.

Taking observations

There is no need to assign a zero point in Designer. Minimal offsets and transforms should be applied to align the tracking data and Disguise origin point prior to starting the Primary calibration.

Start by taking primary observations at a single locked zoom and focus level. This Primary Calibration will calibrate the offsets between the tracking system and Disguise's coordinate system.

- After each observation, the alignment should look good from the current camera position. If the alignment begins to fail, review all observations and remove suboptimal ones.
- The Secondary calibration calibrates the zoom and focus data. This will align the virtual content and the real-life camera zoom and focal changes.

Lens Pose

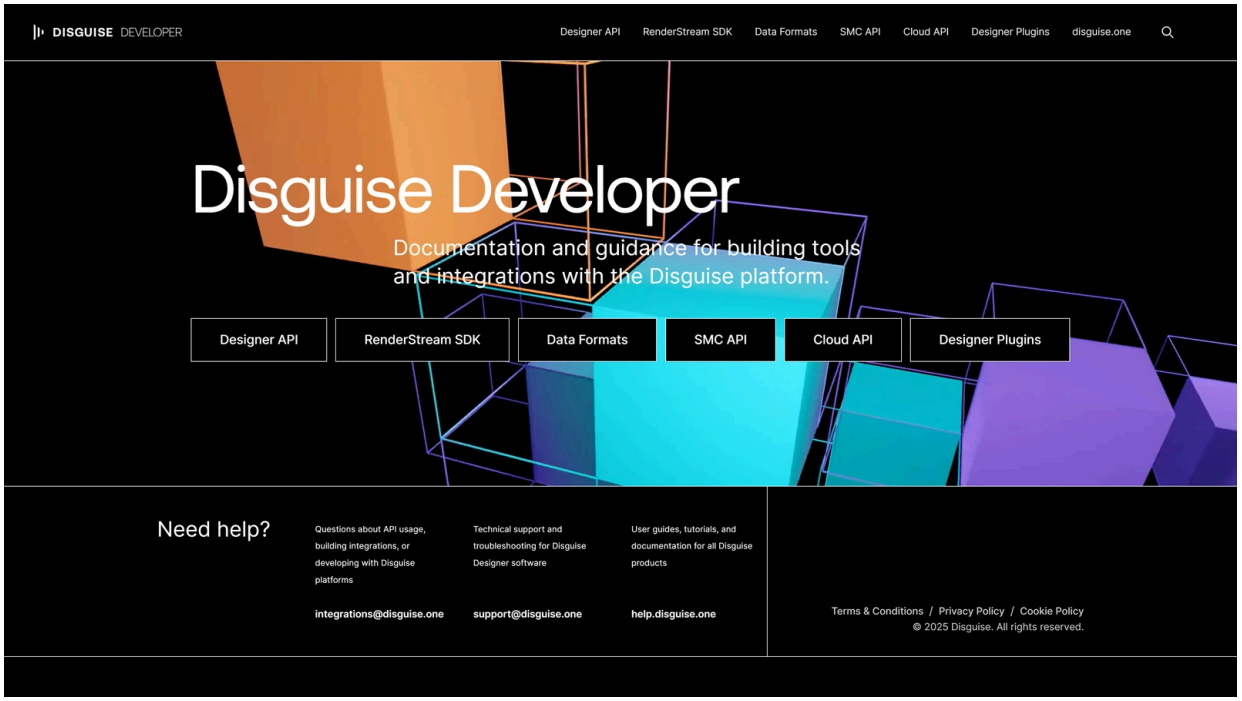
A **Lens Pose** is the result of the data captured in the observation process. They are different checkpoints that Disguise will intelligently interpolate between. The number of lens poses you will end up with will be dependent on the range of your camera's lens.

- A new lens pose is created for every new combination of zoom and focus values. The most common zoom/focus combination will be the **Primary** lens pose, attributed to the **Primary** calibration.

Disguise Developer Portal

What is the Disguise Developer Portal?

Documentation and guidance for building tools and developing integrations for Disguise products.



You can find documentation for all of Disguise's Designer APIs at the **Developer Portal**.

See API Overview for general information on Disguise APIs.

SMC API

The SMC API allows access to information related to the Disguise hardware.

The SMC is a management system that allows for:

Constant and up-to date access to information about the status of the main Disguise server it is contained within such as:

- Power state
- VFC cards currently inserted
- Network adapter details and configuration
- d3Net session details
- Communication with the BMC on the Motherboard allowing for:
  - Turning on and off machines remotely
  - Monitoring physical metrics such as power draw and temperature

To make life easier, all this information is generally available in three different ways:

- OLED screen on the front of the servers
- Webpage
- REST API

To access the SMC API, navigate to the base URL `http://{smc-ip}/api`

Default time for how many seconds to display the OLED notification for
}

Output Audio to DA Converters

Single system

If you are working with one machine it is relatively straightforward to setup audio output with a digital-analog converter.

1. Run an optical cable from the sound card on the Disguise system into your DA converter.
2. Set up the DA to receive a sync clock from an external device.

You should now have 1-8 channels of analogue audio coming out of your DA converter.

Multiple systems

If you have a backup (understudy) there are 2 ways to do:

1. Do as described above utilizing a dedicated DA for the master and a dedicated DA for the understudy.
2. Synchronise multiple machines to one DA or a Mixing Desk.

> **Note**
>
> This presumes your DA has 2 ADAT convertors (RME ADI-8 QS, RME ADI-8 DS, MOTU 2408mk3) i.e. the ability to output 16 channels of analogue audio.

In the scenario of multiple machines and one DA, the audio sample clocks of the master and understudy both need to be synchronised with the DA converter.

How to set up multiple systems

Your external DA will be the audio sync clock master so make sure the clock source is internal You will probably also have to set your correct sample rate and bit depth.

Your RME settings in your machine should be set to Clock source: ADAT IN, however, it should auto-detect if not otherwise specified.

Both of the optical cables needs to be connected; one is for signal and one is for sync.

The bottom outlet (grey) is the signal output from the Disguise system and goes into the input on the DA converter.

The output on the DA converter (sync) is going into the top input on the Disguise system (Black).

You should see in the RME settings menu on the Disguise system that it is receiving sync signal over the optical cable.

Repeat this step for the understudy as well and you should be good to go.

Troubleshooting

Audio playing in Designer/windows but no audio is converted in the DA convertor or very small sporadic instances of audio is coming out of the DA.

- Check the sample rate and bit depth of the entire signal path and make sure they are all set the same parameters (44.1/48 16 bit)

Clicks and pops are heard in the audio from either of the machines

- The audio sampling is not synced correctly, please check the entire signal path for synchronization e.g. ADAT clock internal on, clock receive ADAT in.

Audio Overview

Disguise works with audio in two distinct ways: audio can be inserted directly onto the Track or added to a layer on the timeline.

To achieve PA audio quality (including per machine patching) it is recommended to embed uncompressed audio within a video file or to use the Audio Layer

Track audio (.mp3, .wav, or .aiff) can be quantised and used as a guide audio track, allowing a show to be sequenced to the beat.

For file format information, see supported file formats.

Quantising a track and sequencing to the beat

An audio file can be attached directly to the Track. It is then possible to quantise the audio track. Quantising involves editing a beatgrid to snap Track events to the beat, enabling content to be sequenced to the beat.

For step-by-step instructions on how to quantise an audio track please see the below sub-chapter Quantising an audio track.

> **Note**
>
> Please note: at present only music with a 4/4 time signature is supported. These deficiencies will be addressed to in a future release.

Outputting high quality audio

The 4U, Pro Range and Gx Range hardware can output balanced stereo from its professional RME audio card.

For more information please see the sub-chapter Outputting audio.

AudioAnalyser

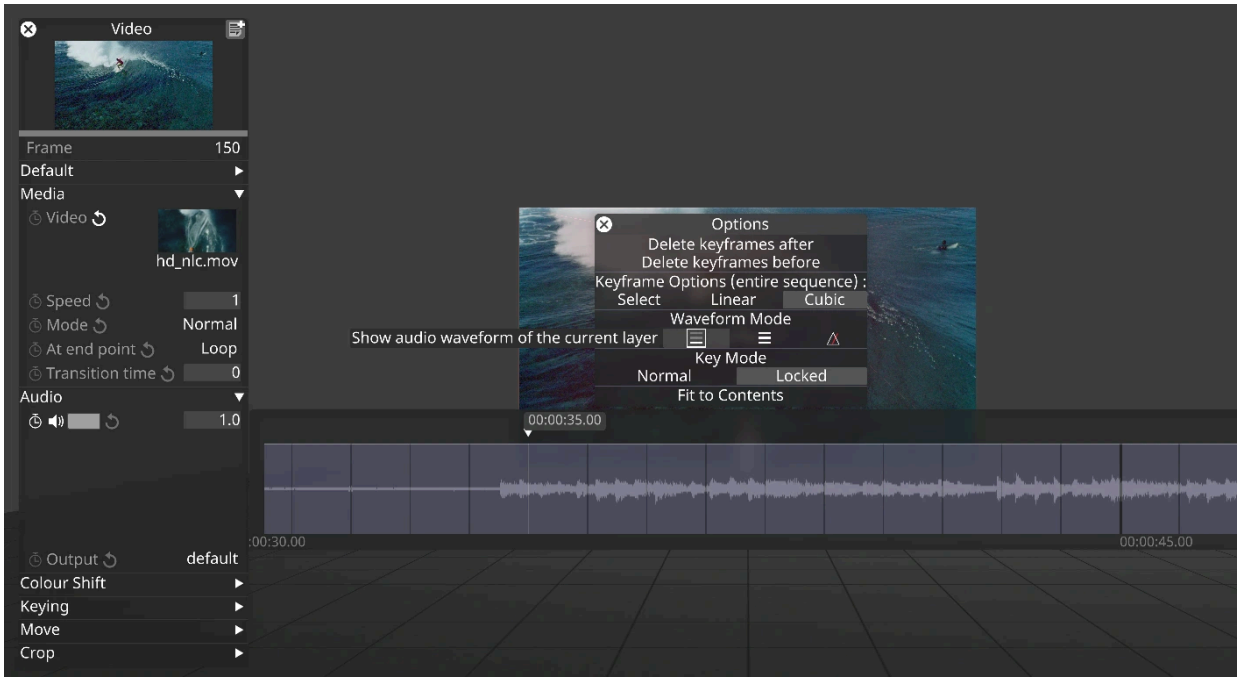
The AudioAnalyser displays the audio waveform. For more information on using the AudioAnalyser, visit this page.

Audio Waveform View

The audio waveform allows users to visualise the audio output of a single layer, a collection of layers or the quantized audio track while working in the keyframe editor. This permits them to add keyframes while taking audio output as a consideration at a glance.

The Waveform viewer supports both Audio layers, and Video layers where the content has embedded audio.

To visualize the audio waveform of one or more layers:



1. Create one or more layers.
2. Set the video clip or audio track of the layer(s).
3. Open a keyframe editor.
4. Right-click in the keyframe editor area to access keyframe Options.

The available options are:

- Delete keyframes after
- Delete keyframes before
- None
- Layer

- Combined
- Quantised

5. Select one of the following options:

   a. Layer to visualize the waveform of the currently opened layer

   b. Combined to visualize the collective waveform of multiple layers

To visualize the audio waveform of the quantized audio

1. Add an audio track to the Track.
2. Open a keyframe editor.
3. Right-click in the keyframe editor area to access the options
4. Select Show quantised audio waveform to visualize the waveform of the timeline audiotrack.

Output Multichannel Audio

The RME audio card in the VX range, GX range (not GX 1), plus range (optional) and classic range machines supports up to eight channels of audio via ADAT over an optical TOSLink cable.

The ADAT outputs present themselves in stereo pairs. For example **ADAT (1+2) (RME HDSP 9632)**.

The process explained in the previous sub-chapter, Outputting audio can be used to output multi-channel audio. However, each Video layer can only output two channels. Therefore, four Video layers will need to be created to output the eight audio channels.

Known limitations

- Audio files do not currently support versioning.
- Audio embedded in video files does not support more than two channels.
- We cannot re-mix the channels inside Designer.
- To output true multi-channel audio you need to set the RME interface into multi-channel mode. This is done externally to Designer.

Outputting multi-channel audio with the Video layer

1. Separate the audio track into 4 different video files, one for each stereo pair.
2. Map each channel depending on which ADAT channel the audio is to be assigned.
3. Render out a video for each stereo pair. The video file format is outlined in the previous sub-chapter Outputting audio.
4. Follow the steps explained in the previous sub-chapter Outputting audio for each of the four video files.

Outputting multi-channel audio with the Audio layer

1. Change the ADAT mode in the audio card software to multi-channel.
2. Select the now visible, multi-channel ADAT device from the audio output patch.
3. Add an Audio layer and define your multi-channel audio file.

ASIO multi-channel audio with the Audio layer

1. Select the ASIO audio device in the audio output patch editor.
   - For 5.1 audio use Adat 1 => Adat 6
   - For 7.1 audio use Adat 1 => Adat 8
2. Select output channels.

WASAPI multi-channel audio with the Audio layer

1. Select the WASAPI audio device in the audio output patch editor, it will have the name ADAT 1-8.
2. Select output channels.

WASAPI channel numbering

- LEFT - `ADAT 1`
- RIGHT - `ADAT 2`
- CENTER - `ADAT 3`
- SUB - `ADAT 4`
- SIDE LEFT - `ADAT 7`
- SIDE RIGHT - `ADAT 8`
- BACK LEFT - `ADAT 5`
- BACK RIGHT - `ADAT 6`

Output professional audio

Designer can play back a quantised audio file attached to the Track. However, to achieve PA audio quality, it is recommended to embed uncompressed audio within a video file and play that audio back as a Video layer. The audio can be either embedded in the same video file as the video content, or as a separate 16x16px DXV video file.

Audio format restrictions when embedding audio into a video file (pre r15.2)

44.1kHz, 16bit samples, stereo, uncompressed .wav embedded into a 16x16 pixel Quicktime .mov (DXV preferably)

Playing back audio in a separate video file

The advantage of rendering the audio into a separate low-res video file, as opposed to embedding it in the same video file as the video content, is that if the audio or video is updated the embedded video file does not have to be re-rendered.

To play back audio in a separate video file:

1. Render the audio into a 16x16px black DXV video using for example Adobe After Effects. Make sure to have the DXV codec installed.
2. Copy the video file with the embedded audio to the VideoFile folder in the specific Project folder. See the Placing media files for a project topic to understand where to copy a video file.
3. Create a Video layer.
4. Select the video file containing the audio and drop it onto the Video key-frame editor.
5. Create a new screen of the type Screen and rename it to Audio dummy screen.
6. Set the resolution of the screen to 16x16px and set the offset values so it's positioned far away from the other video screens in the Stage. This screen will only be used for audio output and has therefore no visual function.
7. Select the mapping type used for theAudio dummy screen for the Video layer. This will direct the Video layers output to the Audio dummy screen screen.
8. In the Output Feed level, add a Feed rectangle to the Audio dummy screen screen. This will copy the Audio dummy screen screens content from the Stage level to a Feed scene in the Feed level. Hit Enter or select the Play button to output the audio to a PA.

To play the audio in sync with video content, create a second Video layer, position the video file at the same position on the Video key-frame editor as the video file containing audio, and map the second Video layer to a separate screen.

Output Video-Embedded Audio

Disguise can play back a quantised audio file attached to the Track to a single audio device. However, for more flexible control of volume, timing, and output routing, it is recommended to use an Audio layer.

Audio format restrictions when embedding audio into a video file

PCM 16bit.

Playing back video-embedded audio

By default, audio embedded in video files is only played back when the video layer is mapped to an active screen on a given machine. If you wish to play back audio regardless of mapping settings, either render a separate audio file and use the Audio Layer, or following the steps in the section below.

1. Copy the video file with the embedded audio to the VideoFile folder in the specific Project folder. See the Placing media files for a project topic to understand where to copy a video file.
2. Create a Video layer.
3. Select the video file containing the audio and drop it onto the Video keyframe editor.
4. Select the audio output or outputs (as of r17.4, Disguise supports multi-channel audio from video files) and ensure the audio outputs are patched in the Audio Output Patch Manager.

Playing back video-embedded audio without a mapping

1. Content can be mapped to screen with a special “Audio dummy screen” mapping, which causes the video’s audio content to be permanently output. As this is a “dummy screen”, it is recommended that you render it as a 16x16 black video. This would likely be most useful only if audio embedded in content, or use of a dedicated audio track with the Audio layer, is not an option.
2. Create a new screen and rename it to Audio dummy screen.
3. Set the resolution of the screen to 16x16px and set the offset values so it’s positioned far away from the other video screens in the Stage. This screen will only be used for audio output and has therefore no visual function.
4. Select the mapping type used for the Audio dummy screen for the Video layer. This will direct the Video layers output to the Audio dummy screen screen.

5. In the Output Feed level, add a Feed rectangle to the Audio dummy screen screen. This will copy the Audio dummy screen screens content from the Stage level to a Feed scene in the Feed level.

Hit Enter or select the Play button to output the audio to a PA.

Quantised Audio

Copying an audio file to the correct folder

To set up for quantising your audio, the audio files need to be copied into the **AudioFile** folder in the specific Project folder. See the Placing media files for a project sub-chapter to understand where to copy an audio file. Also save the file to a supported file format.

Adding an audio file to a track

A track containing non audio regions will display its bars in red and/or blue.

Non-audio regions for a track are displayed in red and/or blue

To add an audio file to the track

1. Right-click the first bar of the track and select set audio track from the popup menu. You will then get an AudioTracks manager.
2. Left-click the audio file you want and the display will change: the audio file becomes the guide audio for the track. To indicate this, the bars will colour green and the name of the audio track will be displayed on the title bar :

Quantising Audio

> **Note**
>
> **Please note**: Before proceeding with the steps listed below for quantising audio, please see the sub-chapter **Setup Quantising**.

> **Note**
>
> **Please note**: a handy tip when you are quantising an audio track is to use the keyboard shortcuts [and] to navigate the quantiser window left and right. To learn more useful shortcuts please see the sub-chapter **Keyboard Shortcuts**.

Quantising an audio track

Quantising means dragging beatmarkers over the audio track to tell Designer where the beats are. To quantise an audio track you need to open the quantiser window.

To open the quantiser window for the current audio track:

1. Hit Alt-Q. Hitting Alt-Q again closes the quantiser window once it is open.
2. Play the track until you find the first beat and drag the closest marker to it.
3. Then drag the next marker to the following beat.
4. Now play forward; you will see a series of dotted markers that gradually drift offtime. The dotted markers are autogenerated by Designer.
5. At any point, you can grab a dotted marker and drag it to bring it in line with the nearest beat. At this point it becomes a solid line. Dotted markers between your manually positioned markers move to space themselves equally.
6. At any time, you can zoom in or out using the mouse scroll wheel. This allows you to see more detail and thus position the markers more accurately.
7. The metronome button plays each marker as an audible beat to check how well the beatgrid lines up. The Metronome button has a Volume control next to it. Left-click the white volume bar or text field to modify the Metronome volume. You can fill in any number between 0 (mute) and 255 (full) in the text field. These are the minimum and maximum values.
8. Hit Alt Q to close the quantiser when you have finished quantising your track.

> **Note**
>
> **Please note**: that the metronome will only output on the Director machine in a Director/Actor/Understudy environment due to the quantiser only being drawn on the Director.

Quantiser properties

The quantiser contains further editing options.

To open the Quantiser menu:

Right-click the quantiser windows title bar.

The editing options are:

Unquantise : This option will delete any markers previously positioned over the track and close the quantiser window.

Shift all markers one frame left : This option will take all of your positioned markers and move them one frame to the left. This is useful if your markers are positioned too late in relation to the beats in the track but you want to move all of the markers uniformly.

Shift all markers one frame right : This option will take all of your positioned markers and move them one frame to the right. This is useful if your markers are positioned too early in relation to the beats in the track but you want to move all of the markers uniformly.

Replace audio : This option will replace the current audio file in the track with another audio file. This is useful if, for example, you are rehearsing a music show and the rehearsal crew want to test different versions of the same song.

To replace audio:

1. Left-click replace audio from the Quantiser editor. This will open the AudioFiles manager which displays a list of all of the audio files saved on your local hard-drive in the AudioFile folder.

See the **Placing media files for a project** sub-chapter to understand where to copy an audio file. Also save the file to a **supported file format**.

2. Left-click the audio file you want to replace the current audio file. The name of the audio track will be updated on the Track Player and quantiser windows title bars.

Set bpm : This option will reset the current tracks beats per minute to whatever value the user sets.

Advanced Quantiser Settings

Inserting bars of silence

At any point, you can insert extra bars into your Track (for example if the audio file changes, but you don’t have access to a new version).

To insert bars of silence:

1. Right-click the bar at the point where you want to insert time. This will open the Track bars menu.
2. Type the number of bars you want to add in the Insert Bars text field and hit Enterdisguise will insert the appropriate number of silent bars for you. In this example we have inserted five bars of silence.

Adding more than one audio file to a track

For some applications (for example rock shows), it makes sense to have one audio file per track. For other shows (such as theatre) it makes more sense to have multiple audio files on

the same track, separated by silences. This allows smooth transitions from one musical section to another.

To add an audio track:

1. Extend the length of the track. For information on how to extend the length of the track, see the **Editing tracks** sub-chapter.
2. Right-click an audio free section (shown as red or blue bars) to open the Track bars menu.
3. Left-click Insert Audio Track. This will open the Audio Tracks Manager.
4. Left-click the Audio Tracks Manager to add the audio file to the point of the currently selected Track bar.
5. Move the cursor in that region and hit ALT Q to open the quantiser window.

> **Note**
>
> **Please note**: It is recommended that you quantise the audio file before you start animating content layers in the region. The software will re-time content events, but may not do so perfectly accurately.

Duplicating Track bars

You can also select any number of bars and duplicate them:

1. Select a Timeline region by holding down the left Shift key and then dragging the cursor across the bars at the bottom of the window.
2. Right-click the grey region and select Duplicate Bars:

Removing bars

Select a timeline region by holding down the left Shift key and dragging the cursor across the bars you want to remove, as illustrated in the previous section. Then rightclick the grey region and select **Remove Bars**.

> **Note**
>
> Removing bars will remove all content layers and events within the removed region. The undo function, **CTRL-Z**, is your friend.

Setup Audio Output

Output devices

Disguise offers the ability to patch timeline audio to various devices with flexibility.

- Patching can be done per machine on a d3Net setup.
- Particular patches can be monitored on local headphones/speakers.
- External sound cards are auto-detected and made available to the patch.

> **Note**
>
> **Please note**: At this stage audio input, LTC and quantised audio tracks cannot be patched.

Concepts

Audio output is managed by the **Audio Output Patch Manager**, accessible via the **Devices menu** item.

Audio Patches are essentially 'virtual slots' from which you can patch to physical audio for each machine in your Disguise setup. You can have as many **Audio Patches** as you wish. Each **Audio Patch** is two channels; a stereo pair.

Each **Audio Patch** (columns) can be configured per machine (rows) in the d3Net Manager set up.

Clicking a cell in the table, presents you with the physical stereo pairs available on the machine. Audio output devices listed are auto-detected over d3Net, including external audio devices. If the remote machine is not currently connected, the list is derived from the **Machine Type** selected in **d3Net Manager** and will present the outputs of the internal sound device.

If the local machine is not part of a d3Net network, a single row for the local machine will be presented.

Configuration - Step by Step

To configure an Audio Patch follow these steps:

1. Ensure your audio output device source is connected correctly. (XLR connection etc.)
2. Right-click devices in the State editor.

3. Left-click Audio Output Patch.
4. Create an Audio Patch by pressing the + icon.
5. Enter a name for the patch and click OK. A new column will have been created in the Audio Patch Manager.
6. In the cells under the column, use the drop down to select the audio output on the physical audio device you wish to map the audio to.
7. You can now pipe Video Content Layer audio on the timeline into the Audio Patch which will accordingly output it to the physical audio device output from the mapping.

> **Note**
>
> **Please note**: You can monitor **Audio Output Patches** using the **Monitor Audio** menu item in the **State** menu. This will pipe the selected patch to the local machines Primary Audio Device (as set by Windows).

Working with audio on the timeline

Audio can either be embedded in videos or added in an audio layer to be played back.

If embedded in a Video, then in the **Video Layer** under **Audio**, the **Output** field allows you to select the Audio Patch you wish to output the audio to.

Sample rates

All audio outputs' sample rates should be set to match that of the content (and conversely, when the output sample rate is fixed the content should be rendered to match).

The currently configured sample rate for the patched audio output is displayed in the Audio Output Patch for each machine.

Below are details of how to change the sample rate on the RME audio interfaces in servers and generic instructions for devices that use the Windows audio settings (which applies for most consumer audio devices). For other professional audio devices, please consult the manufacturer's documentation.

Changing the sample rate

As of r15.2, changing the sample rate must be done outside of Designer in the RME audio device settings. Pre r15.2, the sample rate is set in Designer audio patch editor.

> **Warning**
>
> Warning: It is important to set the sample rate to be the same across all machines

1. Right-click on the **Hammerfall DSP** icon in the System Tray and select **Settings**.
2. Select the desired sample rate from the drop down menu.
3. Right-click on the audio icon in the System Tray and select **Playback devices**.
4. Double click on the relevant audio device
5. On the Advanced tab, select the desired sample rate from the drop-down list.

ACES

> **Note**
>
> ACES workflows can now be achieved using OCIO. For new projects, we recommend using OCIO mode, as future development of colour workflows will focus on OCIO rather than ACES mode. For example, ACES 2.0 is supported in OCIO mode after r32.3.

The Academy Colour Encoding System (ACES) is a colour space management workflow specifically designed to make capturing and displaying video in the correct colour format easier to achieve in film pipelines.

ACES (Academy Color Encoding System) is an open device-independent color management and image interchange system. It enables creation of digital masters suitable for long term archiving. It is also a set of developer tools: a suite of encoding specification, transform definitions and guidelines, archive-ready image data and metadata container specification. In simple language - it allows color transformation/conversion across screens.

Supporting ACES inside of Designer allows Disguise to be used as part of a colour-managed workflow alongside other ACES-compatible software such as Davinci Resolve, Autodesk Maya, Foundry Nuke and Unreal Engine.

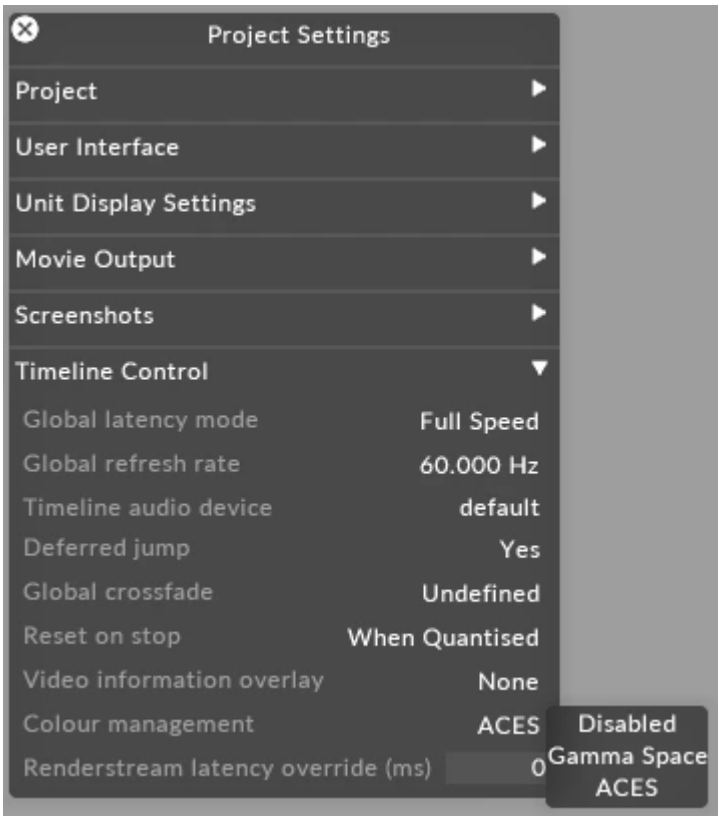
For more information on colour spaces and colour management please visit the colour management page.

Workflows

Within Designer

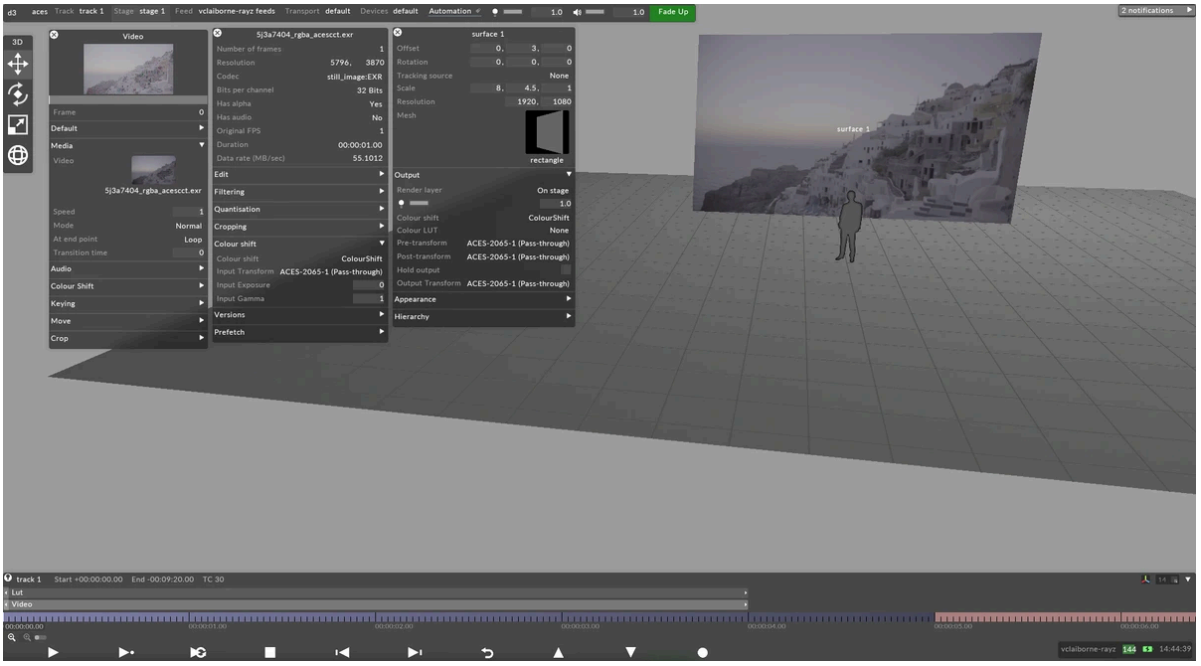
1. Right-click the d3state editor in the dashboard and select **Project Settings**.

2. Set the **Colour Management** option to **ACES**. The transform options will not be available unless the project is set to ACES mode.

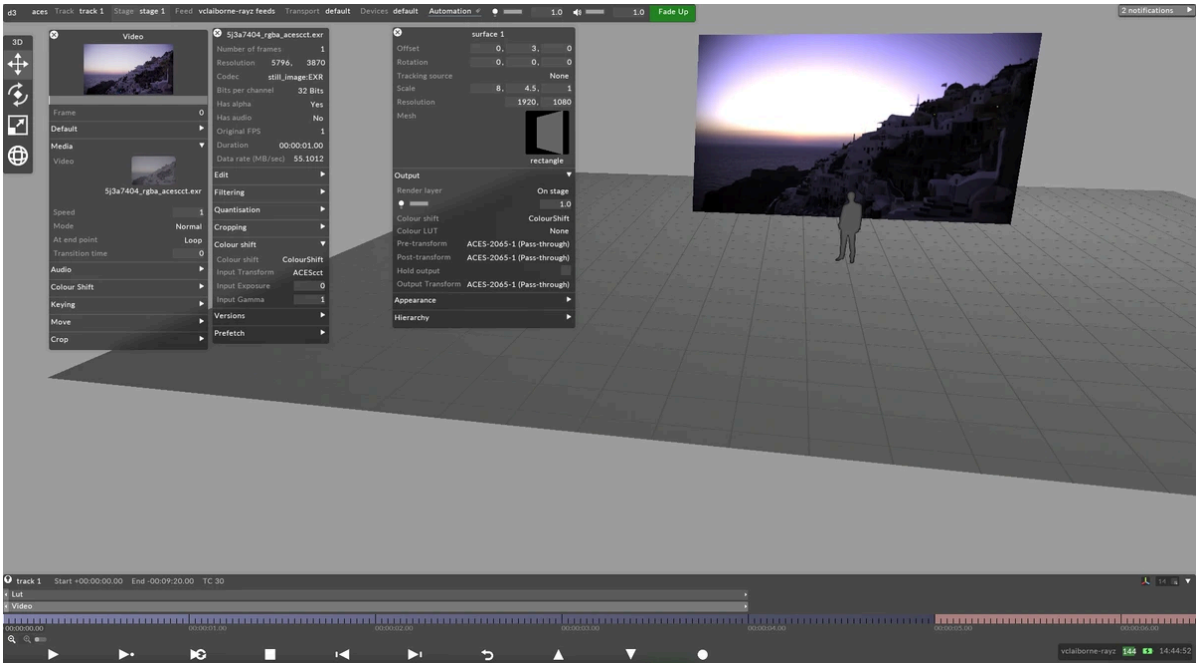


3. On every video clip/asset, right-click on the thumbnail from the Media field of any content layer.
4. Expand the **Colour shift** tab.

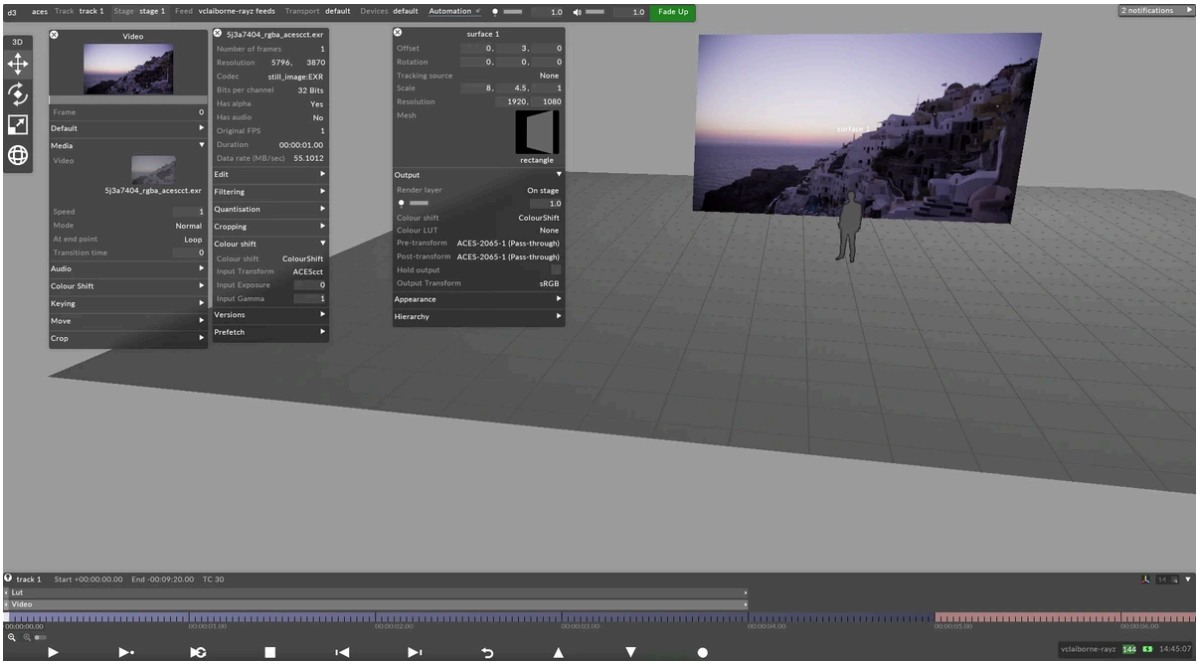
5. Set the **Input transform** to the format that the content was authored in.



6. The content should reflect more accurately in the visualizer. Note that you can view the content library in table form and use **Select All** to bulk change a whole folder.



7. On all LED screens in the visualizer, right-click and set the **Output transform** to the desired format for the LED processors. Note that all screens can be bulk selected from the stage editor and edited at once.



8. Optional: A LUT file can be applied using a LUT layer.

> **Note**
>
> In previous versions of Disguise, LUTs had to correspond with the colour space of the project. Now in the LUT layer, a pre and post transform can be applied to mix LUTs and colour spaces by conforming to the ACES workflow.

On the connected hardware

Set the output transform to match the chosen format set on the LED screen objects.

> **Note**
>
> Note that Disguise does not embed any HDR metadata in the video signal so the display device must be set at the other end to the matching format.

Additional notes:

- Author any static video content in the colour space and gamma curve that you are intending to use.
- For true HDR video playback from video content, a DPX 10-bit image sequence is best.

- For Generative Layers there is no Input Transform to pick.

RenderStream - Render Engine Workflow

If the Disguise project is configured for ACES transforms, the incoming RenderStream content from a third party render engine can be configured to HDR for compatibility. In this example we demonstrate with Unreal, but the ACES workflow may also be used with other render engines.

In the Unreal project

1. Choose your colour space in Unreal.
2. Set Execute Console Command nodes:

   - `r.HDR.Display.OutputDevice`
   - `r.HDR.Display.ColorGamut`

3. Set after Event BeginPlay in the project blueprint: these settings tell the project to output in this format when the stream begins.

In the Disguise project

1. In the **Project Settings**, set the **Colour management** option to **ACES**.
2. In the RenderStream Layer layer in Designer, right-click the asset to enable ACES Colour Management and set transform to the incoming format as determined in the Unreal output settings.

> **Note**
>
> The ACEScg format is tested in house and supported by Unreal for 10bit and HDR.

3. On all LED screens in the visualizer, right-click and set the output transform to the desired format for the LED processors.

> **Note**
>
> Note that all screens can be bulk selected from the stage editor and edited at once.

On the connected hardware

- Set the output transform to match the chosen format set on the LED screen objects.

Note that Disguise does not embed any HDR metadata in the video signal so the display device must be set at the other end to the matching format.

ACES and the colour-managed workflow

- ACES intends to provide a universal base for a colour-managed workflow, replacing individual bespoke systems, to allow for accurate interchange between organisations as well as within, and for archival purposes.
- ACES makes use of two important core concepts, “display-referred content” and “scene-referred content”. Before your content enters an ACES pipeline, generally, it is “scene-referred”. Once it has left the ACES pipeline, generally, it is “display-referred”.
- Content which is produced by a camera or by a 3D renderer is “scene-referred”; that is, the values stored in the image are interchangeable only with other images from that camera or renderer using the same settings.
- By contrast, “display-referred” content has a direct relationship between the values stored in the image and the expected colour and intensity of the image when displayed on a calibrated display.
- As a user of imaging software outside of a colour-managed workflow, there are some unintuitive aspects of using a colour-managed workflow. The ACES pipeline is designed to bring your content from designated input or intermediate formats, such as ARRI LogC, Canon CLog3, or ACEScg to designated display output formats such as sRGB, rec2020 or P3-DCI. While ACES provides transforms for bringing output content back into ACES space, and these transforms are often necessary (e.g. if you have a camera that outputs rec709 content), the intention is that the pipeline is end-to-end with a single output stage. Bringing display-referred content into ACES and putting it through a pipeline again is not transparent.

Visit this **link** for a helpful ACES colourspace to RGB converter.

CDL

The ASC-CDL, more commonly expressed and known simply as the CDL, was created through a joint operation between the American Society of Cinematographers' Technology Committee, production / post production vendors, and colour scientists to standardize the exchange of primary colour adjustments. The specification was first released in 2007 and is now widely adopted among several software and hardware manufacturers.

The CDL stands for Colour Decision List. Just like how an EDL communicates basic edit data, a CDL carries a subset of colour-correction data.

Although all colour-correction systems offer their own basic grading controls, **Lift**, **Gain**, and **Gamma** are implemented differently from vendor to vendor. Their definitions of LGG can vary in sensitivity and response. The strength of a CDL- based workflow is its software-agnostic nature. CDL compliant hardware and software can create, modify, and reproduce consistent colour results exported from any other supported platform. In other words, it's all about the perfect interchange of colour modifications.

The parameters of a CDL replace the traditional Lift, Gamma, and Gain you're probably used to manipulating. However, each set of CDL controls behave very differently from one another

- `Slope` is to `Gain`
- `Offset` is to `Lift`
- `Power` is to `Gamma`

Workflows

All these workflows should be performed with the colour management option in the project setting set to **ACES** or **OCIO**.

LUT workflow

Previously pre- and post-transform were set on the layer editor. Now the fields exist on the LUT object instead.

CDL workflows

1. Create a **CDL** layer:
2. Either create a CDL object, or add a .cc .ccc or .cdl file to the **LutFiles** folder in the project directory.
3. Select your **CDL** in the layer.
4. See that layers arrowed into the CDL layer have an effect applied.

5. Adjust the scale, offset, power and saturation parameters on the CDL object and see that the image outputted changes.

Blackmagic Gen5 CDL Workflow

1. Acquire footage from a Blackmagic camera recorded with Gen5 colour.
2. Place the footage in a d3 project in a format d3 can read.
3. Open the VideoClip editor for the footage.
4. Change the input transform to **Blackmagic Gen5**.
5. See that the footage displays correctly when mapped to a display.

Linear exposure and gamma controls on video layer

1. Create a video layer.
2. Set a video clip.
3. Adjust the exposure and gamma fields on the video layer and see that they have effect.
4. Adjust the exposure and gamma fields on the videoclip editor and see that they have cumulative effect with those on the layer.

RGBColour layer IDT

1. Create an RGBColour layer
2. See that there is an input transform field.
3. Set a value for the colour on the layer.
4. Change the IDT and see that the colour changes.

Non-stylised primaries and transforms

1. Create a video layer.
2. Set a video clip.
3. Open the video clip editor and find the input transform.
4. Set the input transform to one of the options under **Utility**. See that both a transform and a colour space can be set + mixed and matched.
5. Create an LED screen and open the editor.
6. Find the output transform.
7. Set the output transform to one of the options under **Utility**.

See as above. N.B. with the colour insider changes, output transforms no longer affect the stage visualiser.

Colour Inspector

The Colour Inspector can be opened in various places in Designer to inspect the specific colour values of pixels within an image. It is useful for verifying content and colour workflows.

> **Note**
>
> The Colour Inspector is only available in ACES and OCIO colour management modes.

Workflows

To open the Colour Inspector

The Colour Inspector can be opened from the following places in Designer:

- **Layer Editors**: Click the Colour Inspector button in the Default separator.
- **Displays/Cameras/Projectors**: Click the Colour Inspector button in the Output separator.
- **Feed Rects**: Right-click on the feed rect and click the Colour Inspector button.

Using the Colour Inspector

After opening the Colour Inspector, the following settings can be changed to inspect a pixel's colour values:

- **Pixel**: The coordinates of the pixel which is being inspected. This can be set by clicking on the image preview, or by editing the field to precise coordinate values. The chosen pixel is shown by a circle in the image preview.
- **Pause**: Press this button to pause the current video frame so that its pixel values can be inspected.
- **Number format**: This can be changed to control how the numeric value of the colour is displayed. Choose between floating-point and 8/10/12 bit options.
- **Colour space**: The colour space to measure the pixel values in. This can be chosen from the following options:
  - **Working**: The current working space.
  - **Input/Output**: Where available, the relevant input space (e.g. the video clip's input transform for a video layer) or output space (e.g. the output transform for a display).
  - **CIE spaces**: Various space colour coordinates defined by CIE standards.
  - **Custom**: Choose a custom colour space from all available spaces.

> **Note**
>
> Pixel values are transformed from the working space to the selected space. This means that if an Input space is selected, the inverse of the input transform will be applied. This may not give exactly the same values as the original input, as some operations such as saturations cannot be inverted.

Colour Checker

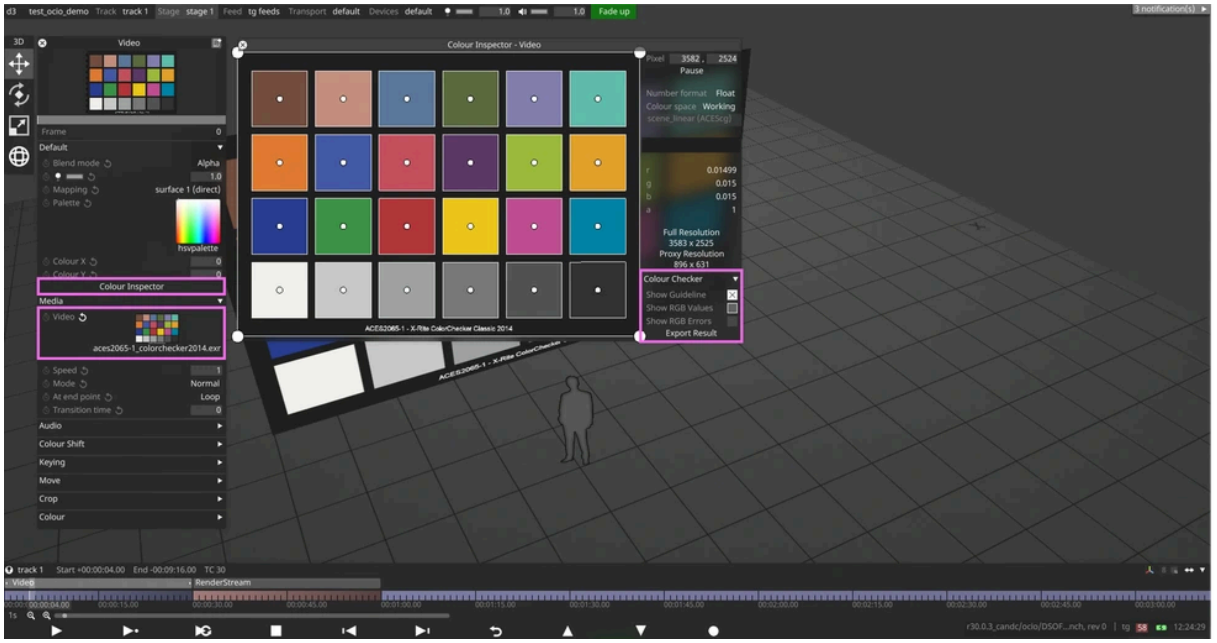
The Colour Checker Chart (also known as the **Macbeth ColorChecker**) is a tool used for colour calibration. It has 24 coloured squares arranged in a frame (See: **ColorChecker Wiki**).

The **Colour Checker** allows you to validate the colour pipeline using a colour checker. This enables you to inspect the colour of multiple sample points in a colour checker. It works similarly to the Colour Inspector, extracting values based on the colour space defined in the **Colour Space** field. It will display either RGB values, errors or both depending on your selection.

Workflow

Follow these steps to use the **Colour Checker**:

1. Assign Colour Checker content to the desired layer:
   - This applies to any layer supporting content ingestion, such as RenderStream or Video Layer.
   - For RenderStream, refer to the Unreal OCIO Setup to configure the Colour Checker with Unreal Engine RenderStream.
   - For the video layer, assign the Colour Checker image in **Media | Video**.
2. Open the **Colour Inspector** widget from the desired stage of rendering (See: How to Open the Colour Inspector).
3. Expand the **Colour Checker** field in the Colour Inspector.
4. Enable **Show Guideline** to start sampling and calculating the transformed colour of each colour box.
5. Enable **Show RGB Values** to display transformed RGB values in each colour box.
6. Enable **Show RGB Errors** to display the error between the expected colour and the incoming colour.

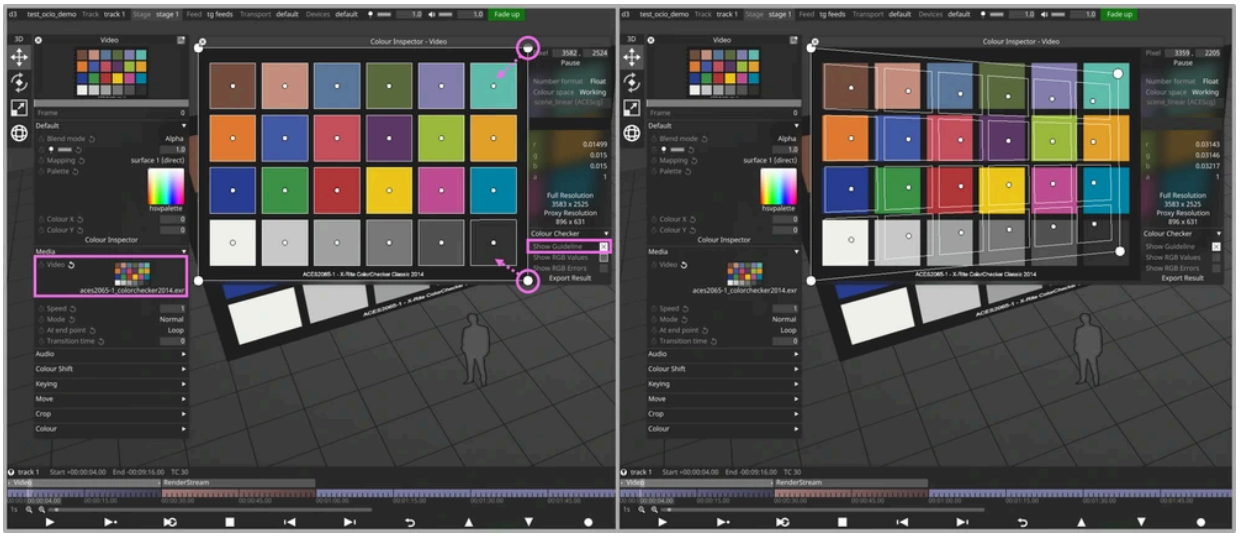


Colour Checker

Show Guideline

When **Show Guideline** is enabled, the **Colour Inspector** samples pixels from each colour box in the Colour Checker and calculates their transformed colour values. If **Show Guideline** is disabled, all other fields will become greyed out.

- Four white control points appear at the corners of the guideline. Drag these points to adjust the colour checker and sampling areas.



Displayed guideline (left), adjusted guideline (right)

> **Note**
>
> **Performance Impact**: Enabling this feature may affect frame rate. Optimisation is planned for a future release.

Show RGB Values

Enabling **Show RGB Values** displays the transformed RGB values for each colour box at the top left corner. These values are based on the colour space defined in the **Colour Space** field.

RGB values of each colour

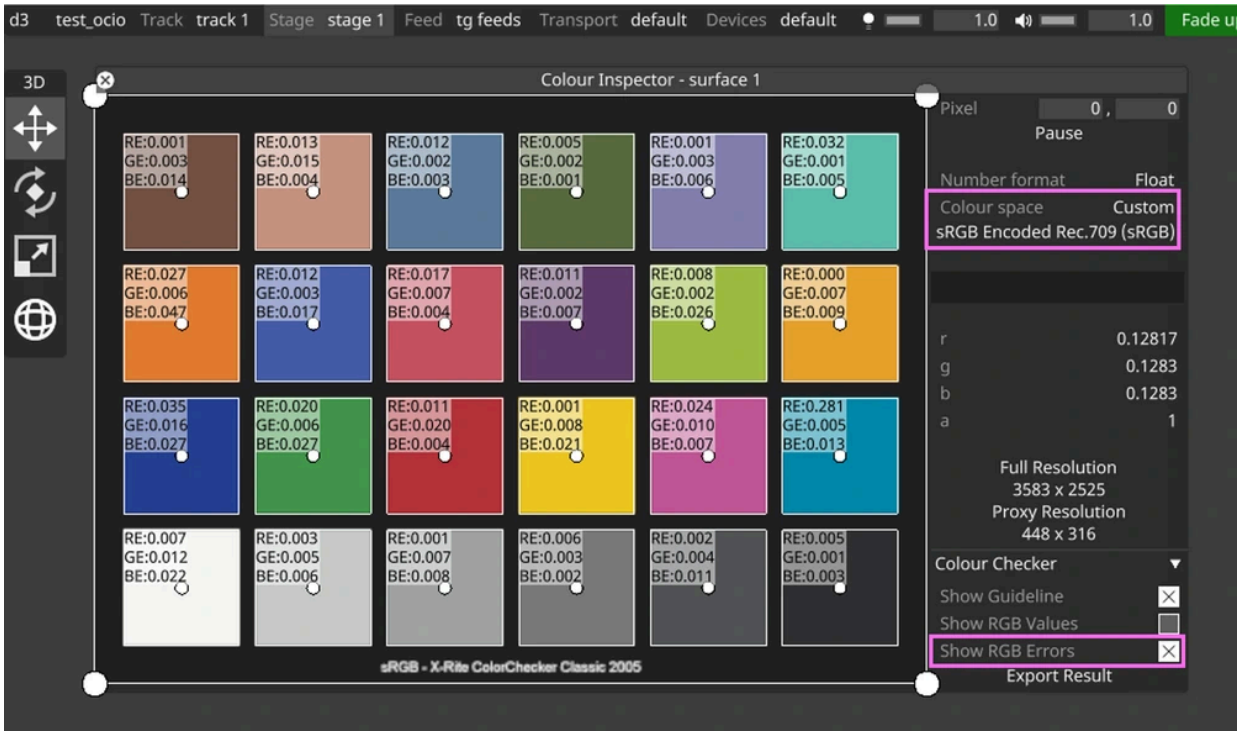
Show RGB Errors

> **Warning**
>
> To ensure the error values are meaningful, set the Colour Space to **sRGB Encoded Rec.709 (sRGB)** (or **sRGB - Texture** if using OCIO version lower than 2.4).

Enabling **Show RGB Errors** displays the error between the expected and incoming colours. You can identify discrepancies with this feature. The error is calculated using the following formula:

```
error = abs(colourExpected - colourContent)
```

- **Expected Colour**: The reference value defined in sRGB colour space and are sourced from the ColorChecker Wiki (See: Designer Colour Inspector).
- **Content Colour**: The sampled value from the content.



RGB error values of each colour

> **Note**
>
> The expected colour values are lifted from the X-Rite Colour Checker specification.
>
> See: X-Rite specification.

Colour Management

Designer has powerful colour management tools to ensure that your content plays back exactly as it was created.

What is Colour Management?

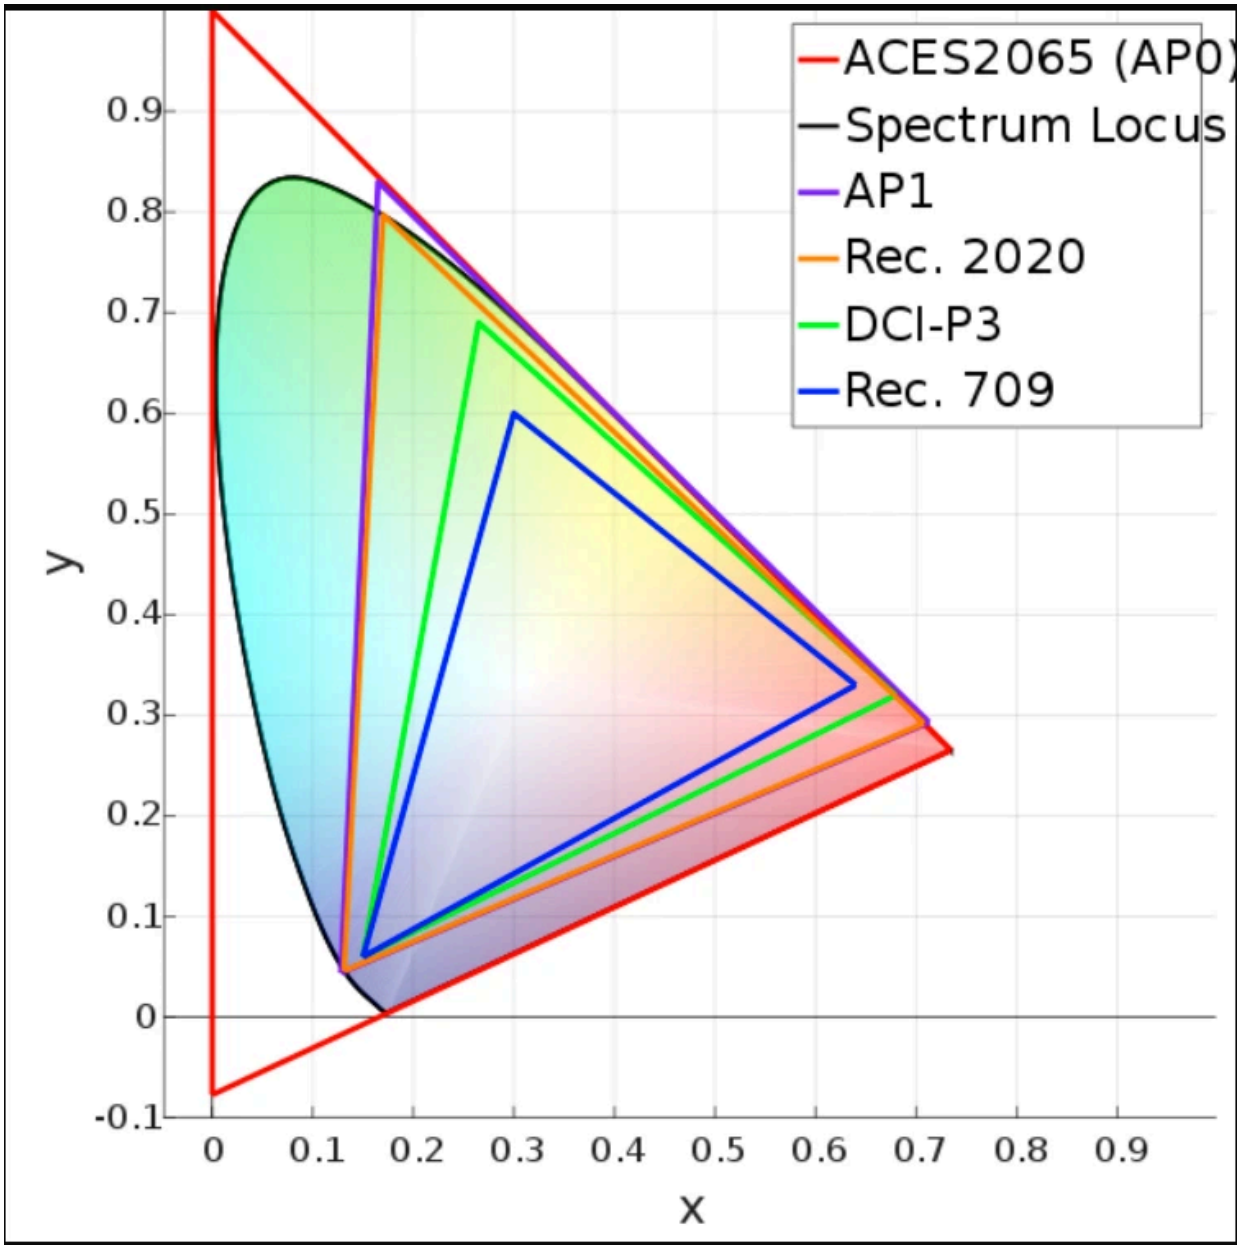
Colour management refers to the workflow for preserving the colour space that the content was created in throughout the entire creation to playback pipeline.

What is a Colour Space?

A colour space, in simplistic terms, is a mathematical definition of how a triple of red, green and blue values (or X, Y, Z, or Y, U, V, or L, a, b or any other three-way breakdown) interact to produce a specific colour.

Colour is derived from different wavelengths of lights hitting our eyes. While each pure wavelength has a distinct colour, the blending of different wavelengths produces more colours still. The CIE colour space diagram provides a visualisation of all possible colours at a given intensity of light (or brightness, although the word has other meanings in this context.)

The colours that a particular colour space can represent can be displayed as a triangle drawn onto the CIE diagram:



Here we can see that sRGB, the standard colour space computer monitors operate in, is a relatively small triangle compared to rec2020, or ACES AP0/AP1.

Colour Bit Depth

The reason a relatively small space was chosen is that using 8-bit values, only **255-255-255** values are available to specify a colour location. To be able to display smooth gradients, more extreme greens, reds and blues were excluded. Now, as 8+bit displays become more widespread, wider colour spaces which capture more of the possible colours become viable. rec2020 and P3-DCI are two widely used industry standards.

The default working colour space in Designer is sRGB, and it is capable of storing 16bit colour values, which allows for bit depths to always be preserved throughout the colour-managed

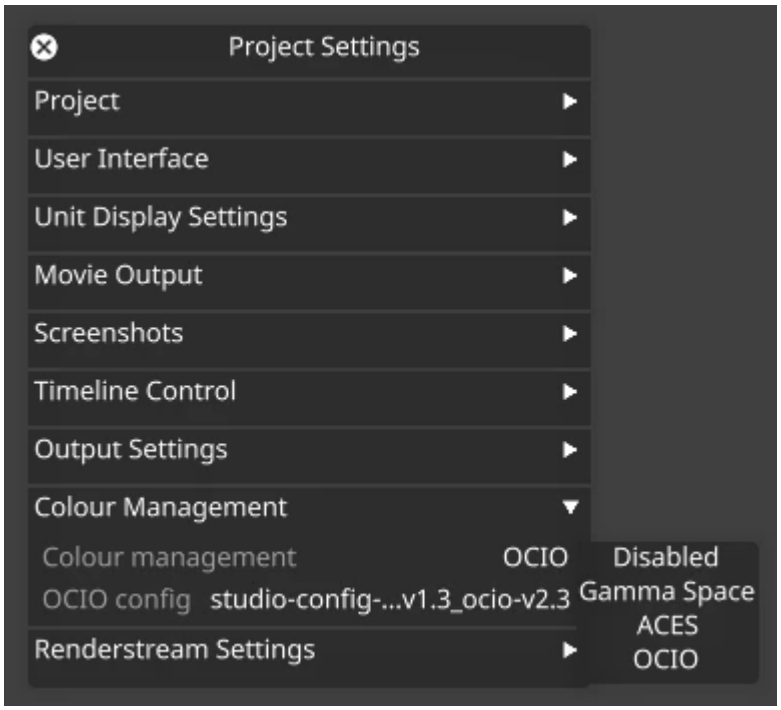
workflow.

Colour-managed workflow

Broadly, a colour-managed workflow is a workflow that can maintain and interchange accurate colour information between different stages in a process that brings image data from the point at which it is generated to the point at which it is displayed. This process might involve one application such as Designer, or it might involve several.

These workflows were pioneered for the visual effects industry, to ensure that images scanned from a camera could be combined, edited, composited, graded and printed back onto film in a way that did not corrupt or alter the colours contrary to artistic intent.

Modes



Designer currently supports four separate modes for colour management, selectable from inside project settings. These are **Disabled**, **Gamma Space**, **ACES**, and **OCIO**, with **Gamma Space** being the default.

> **Note**
>
> ACES workflows can now be achieved using OCIO. For new projects we recommended using OCIO mode, as future development of colour workflows will focus on OCIO rather than ACES mode.

Disabled

Disabled mode removes all colour transforms from Designer pipeline. This is useful when you want to bring content into Designer and have no colour processing applied as it goes out to displays.

- Colour values of content are not altered, gamma curves are baked in, and the type of output device is not specified.
- This option can't support HDR properly.
- Perfect for sRGB/~Rec.709 all in/out situations
- Zero cost in GPU time.

Gamma Space

Gamma Space mode is the existing colour management workflow within Designer. It has a range of input and output transforms, broken down into colour space and gamma function. All content is maintained internally as sRGB.

- This colour management option also means all content is blended with its gamma space applied (sRGB gamma curve). However mixed content (like Rec.709 and Rec.2020) will be more 'correctly' blended and converted to the output transform specified.
- Supports HDR and Wide Colour Gamut displays.
- Only leverages the GPU when the content or display isn't sRGB.

ACES

ACES mode enables the ACES pipeline.

- Only **ACES** colour space has linear gamma 1.0, where e.g. sRGB content will have the sRGB gamma curve removed and colour space rotated to AP0 i.e. extended to the widest possible area.
- All content is blended in ACES and then transformed back out to the selected output transform.

For more information on ACES, visit this link.

OCIO

OCIO mode enables the OCIO pipeline.

- Colour spaces and transforms are configured by artists or studios and stored in a .ocio file.
- The .ocio file is loaded into Designer and used to configure the colour transforms for input content and output sources.

For more information on OCIO, visit this link.

Colour Profiles

A colour profile is an object within Designer that allows you to specify what colour space the content was produced in, and what colour space the content is output in which allows Designer to convert between the two colour spaces, to preserve colour detail as required.

A feature of Designer is the ability to apply a colour profile to both screens as well as pieces of content.

A colour profile consists of a colour space specification and a gamma curve.

Colour profiles are supported on LED Screen, DMX Screen and DMX Lights screen objects.

Colour Space

A colour space defines the range of colours achievable with a particular signal chain (content source -> display device). Different signal chains enable different colour spaces - this is not directly related to the colour depth (8 bit or 10 bit), but there is a relationship - you can think of the colour depth as increasing the resolution of the available colour space.

Colour space becomes important when considering content chains, as the colour space which the content is produced in should be preserved throughout the chain to ensure it can be output in the same colour space.

Designer's colour space is sRGB - also known as Rec.709.

Gamma

When expressing a color in RGB (red, green, blue), what we are specifying is the amount of light which will be emitted from each phosphor, as a fraction of full power. What we are actually specifying is however the voltage which will be applied to pixel on the output device (projector, LED processor, etc). These devices don't respond linearly to the voltage, and the gamma curve is a way to correct for the non-linear relationship between content and display.

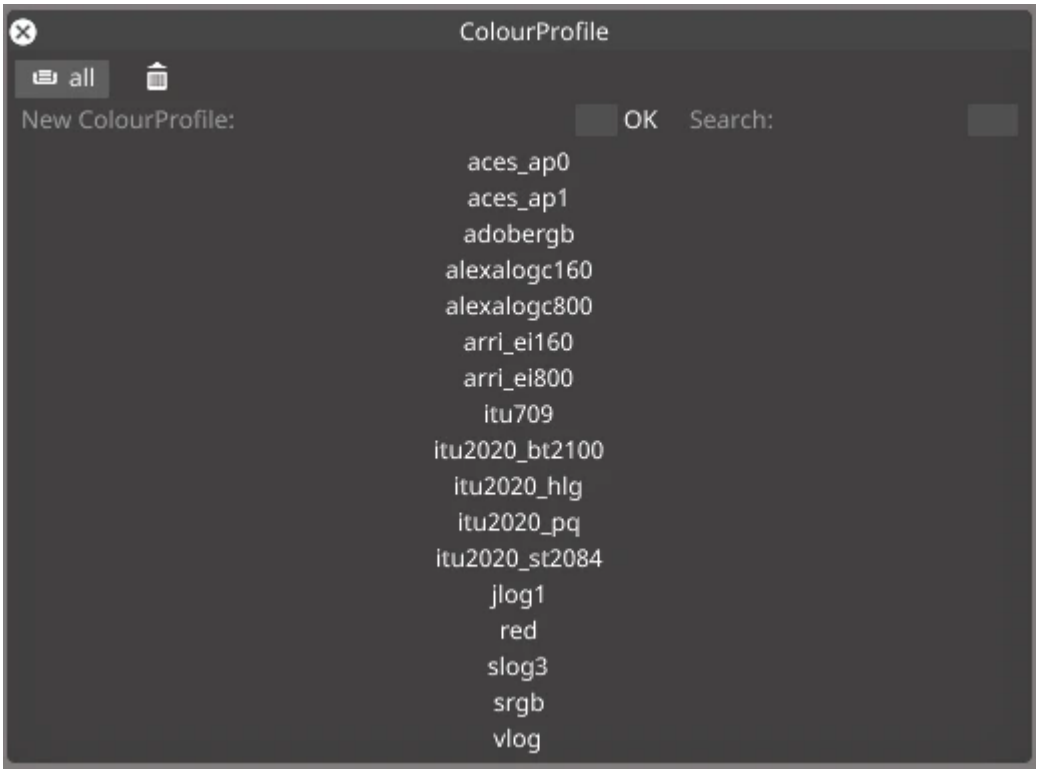
Workflow

A colour profile is a discrete object within Designer that can be applied to a piece of content. The workflow consists of two parts, creating a new colour profile in the colourprofile manager, and applying that profile to the content.

Applying a colour profile to content

1. Open your content layer.
2. Right-click the content thumbnail.

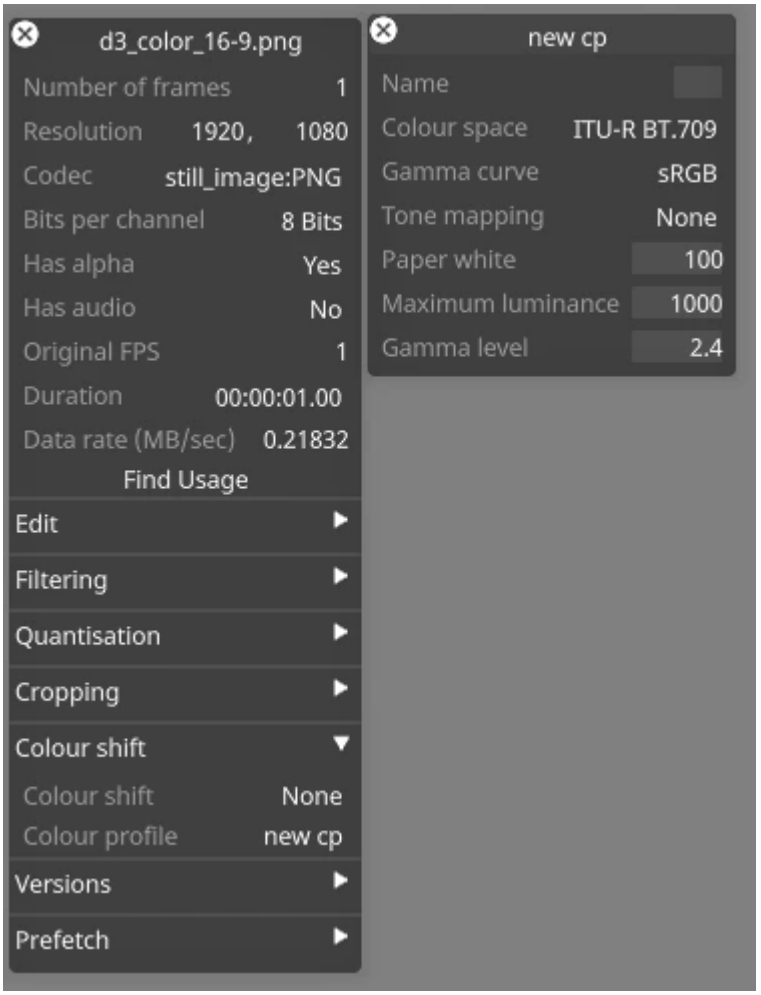
3. Navigate to the **Colour shift** tab.
4. Apply a new Colour profile to the clip using the Colour profile property.



Creating a colour profile

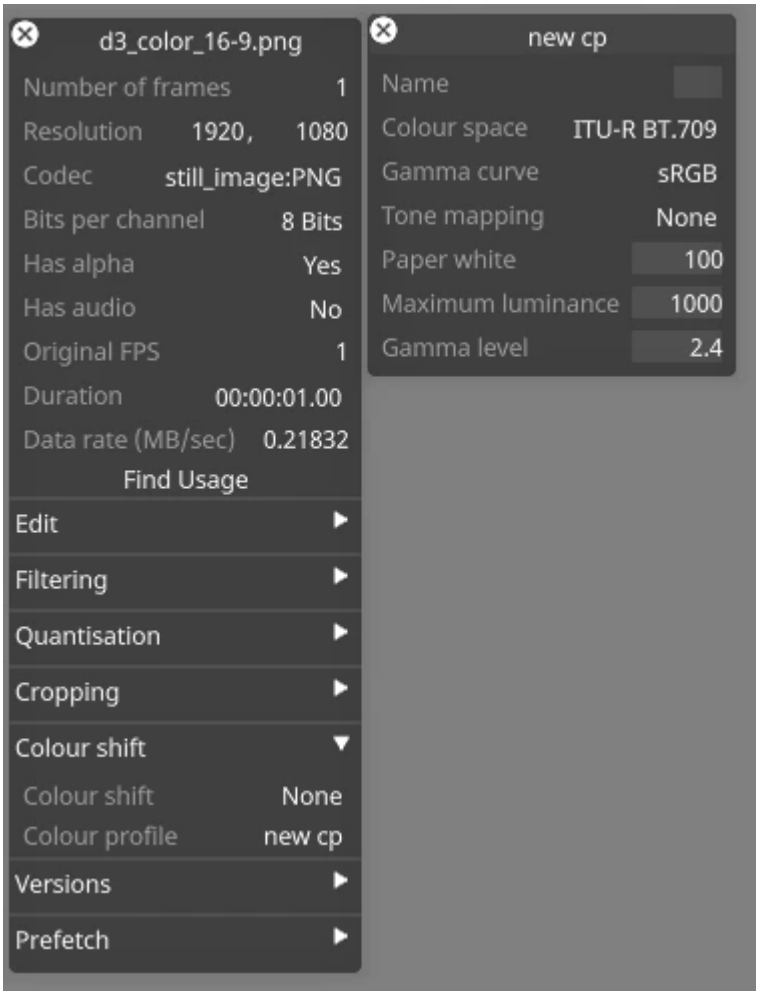
1. Open a Video layer and apply a piece of content.
2. Right-click on the Media thumbnail and expand the Colour shift tab.

3. Create a new Colour profile.



4. Enter a the name for your new profile in the naming field.
5. Press Enter or click OK.

6. In the profile editor, specify your Colour space and Gamma curve.



Colour Shifts

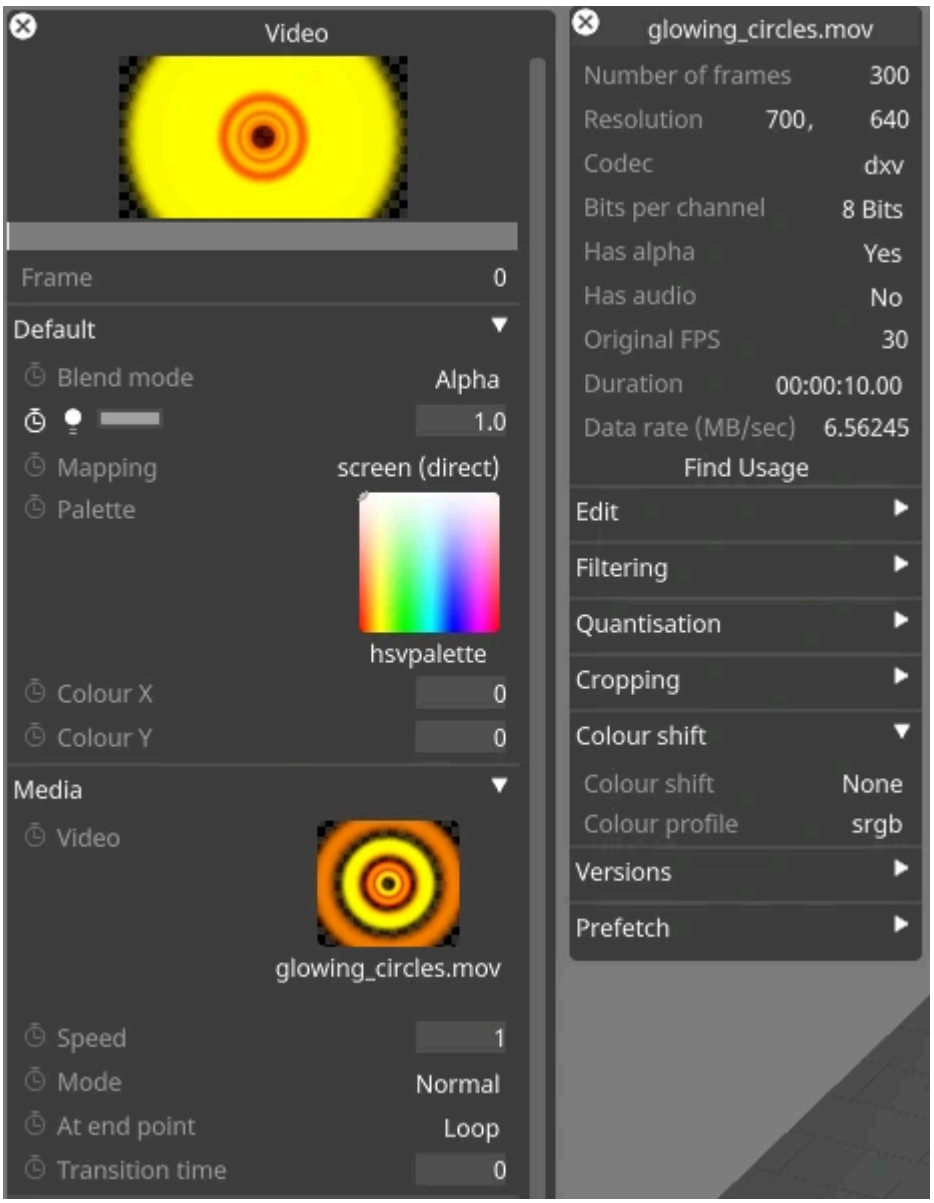
A colour shift is a discrete object within Designer that allows you to alter the colour properties of a piece of content.

Applying colour shifts to video clips

It is possible to attach a colour shift object to an individual video clip so that every time you use that video clip it will colour shift in the same way. You can then place these video clips onto the key-frame editor and sequence these video clips. To do this:

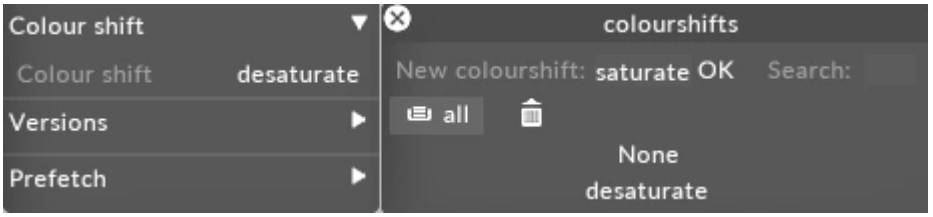
1. Create a Video layer.

2. Open the Video Clip editor by right-clicking on the media thumbnail in the layer editor.

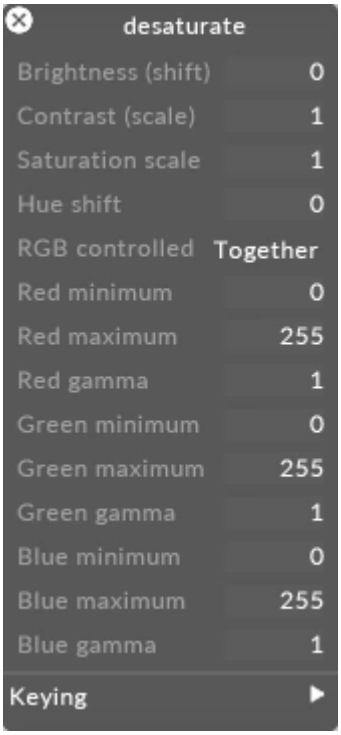


3. Note: making changes to properties of a clip alters the state of the clip, and any changes made will appear in each instance where the clip is used. For this reason, it is recommended to make a duplicate of the clip and then make changes to the duplicate, keeping the original in its unaltered state. To duplicate the video clip, begin by right-clicking the header of the clip options and typing the name of the new video clip into the duplicate text field and hitting Enter. You will notice the title bar of the Video Clip editor change; it is now the object editor for your new video clip. The video clip will also be added to the Video keyframe editor at the current playhead position.

4. Left-click **colour shift** from the Video Clip editor. This will open the Colour Shift manager showing a list of colour shift objects. The colour shift object assigned to a video clip may be untitled, in which case it is unique to that clip. Renaming the colour shift object will add it to the ColourShift manager, allowing it to be used by multiple clips.



5. Create and attach the colour shift object to the video clip by typing the name of the new colour shift object, for example **desaturate**, into the **new colourshift** text field and hitting **Enter**. This will open the Colour Shift editor.



For information on the Colour shift properties please visit the section 'Colour Shift' in the Common Layer Properties sub-chapter.

6. Edit the properties. In this example we have desaturated the video clip by decreasing the saturation scale property to 0.

Colour Transforms

Transforms are used to transform an image from one colour space to another.

Input and Output transforms

Input transform

A formula or LUT mapping the values from a camera or stored in a file into the ACES colour space. Also known as the IDT.

Output transform

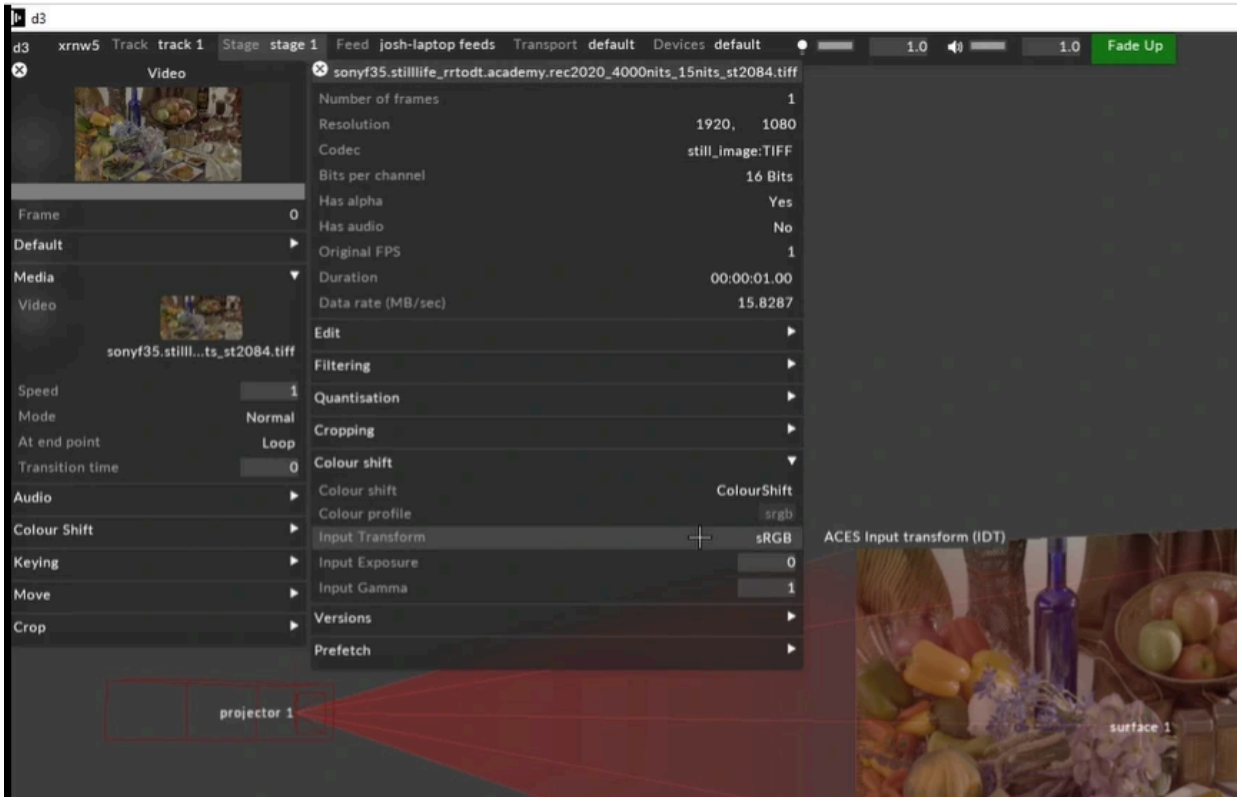
A formula or LUT mapping values from the ACES colour space to the output of a specific device or device specification, e.g. to PQ or HLG or rec709. The output transform is the collective name for the RRT and ODT.

By using transforms, you can ensure that your content will be displayed correctly on the displays.

Workflow

Input Gamma and Exposure Transforms

For video inputs it is possible to enter a number to specify a gamma transform (in Input Gamma field), or enter an amount in stops (in Input Exposure field) to make an image more or less exposed.



1. Open a Video layer.
2. Right-click on the media clip used on the layer.
3. Open the video clip editor
4. Enter the number for Input Gamma or Input Exposure.

All content inputs i.e. video files, RenderStreams, anything that is coming into Designer that has colour and has image data has an “Input Transform” field. Upon configuring the input, you will see a dropdown list with the ACES standard list of colour spaces that are supported for input. This includes both scene-referred content derived from cameras (such as ARRI LogC), and display-referred content mastered to an output standard (such as ST 2084).

All display outputs have an “Output Transform” field. You will see a dropdown box with the ACES standard list of colour spaces that are supported for output; and you simply choose the appropriate one for your display.

Output Transform - ACES ODT (added on virtual devices such as camera and projector: Output → OT) Input Transform - ACES IDT (beneath: Video → Media → Edit media menu → Colour Shift → IT)

For video module: 2 fields were added:

Input Gamma Transform (IGT) - control the brightness (user can set less or more contrast using numbers)

Input Exposure Transform (stops) (IET) - changing the brightness of the image accordingly:

- less exposure darker, more exposure: brighter,
- users can specify the level of exposure by entering the number.

Additional Information

Differences between a Colour Tranform and a Transfer Function

A given piece of content will have both a relationship to a colour space, which will be independent of intensity, and a function of some kind that describes how intensity is encoded into the colour values. So a colour transform will affect how colour is represented relative to the CIE colour diagram, while a transfer function will not. A transfer function will change the perceived intensity or contrast of an image, where a colour transform will not.

In addition to this, there are specifications such as rec709 and sRGB that define a colour space as well as a transfer function, as well as transfer functions that are independent of colour space and colour spaces that are used independently of transfer functions.

Linear Transfer Function

When we say an image is ‘linear’, we mean that the transfer function is linear, i.e. there is no curve applied and a value that is twice another value will be twice as intense. This is useful for mathematical accuracy in visual effects, but is inefficient for display.

Curves

The sRGB and rec709 curves are closely related but different, although they’re often used interchangably with each other as well as with a 2.2 gamma curve. This is the most common curve in graphics and is the current ‘default’ curve in Designer, which content is assumed to be in if no other choice is specified.

The PQ and HLG curves are for displaying HDR content on HDR displays.

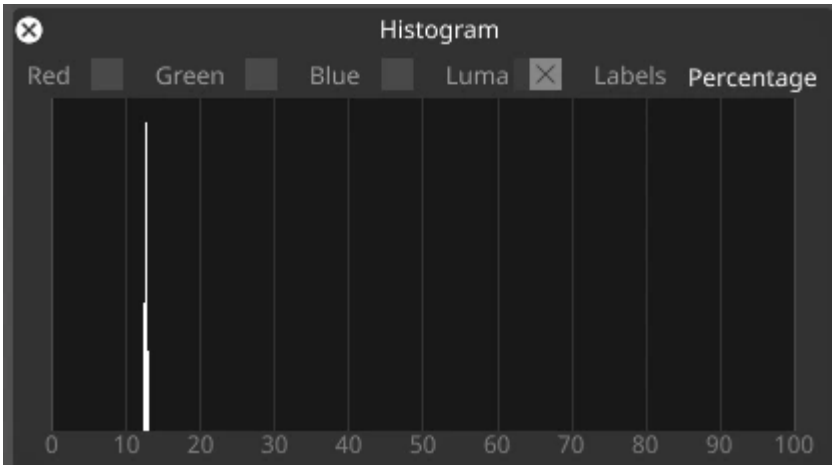
Camera-specific formats, as well as ACEScc, are “log” formats that use a log curve on intensity.

Histogram

Overivew

The histogram shows the number of pixels that are a certain value.

Histograms are mainly used to verify the end-to-end signal of an image. This is particularly useful when there is a known value in the content, and we want to make sure that it remains at that value throughout the signal chain.



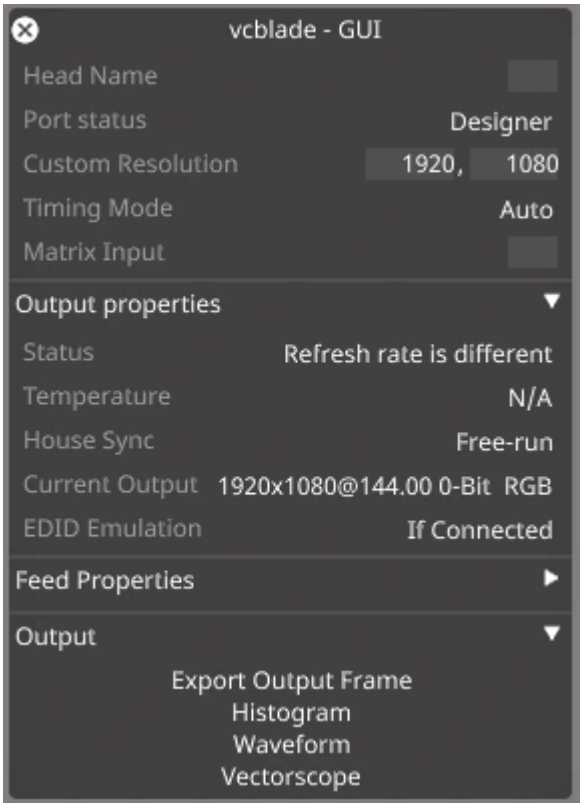
Opening the Histogram

A histogram can be used to verify the signal chain at these points:

- On a Video Input within the Video Input patch Editor- After capture into Disguise and any layer stack modifications.
- The feed output - after being transformed into the final 8- or 10-bit format going to the display.

1. Open the Feed Output window by clicking on Feed in the dashboard

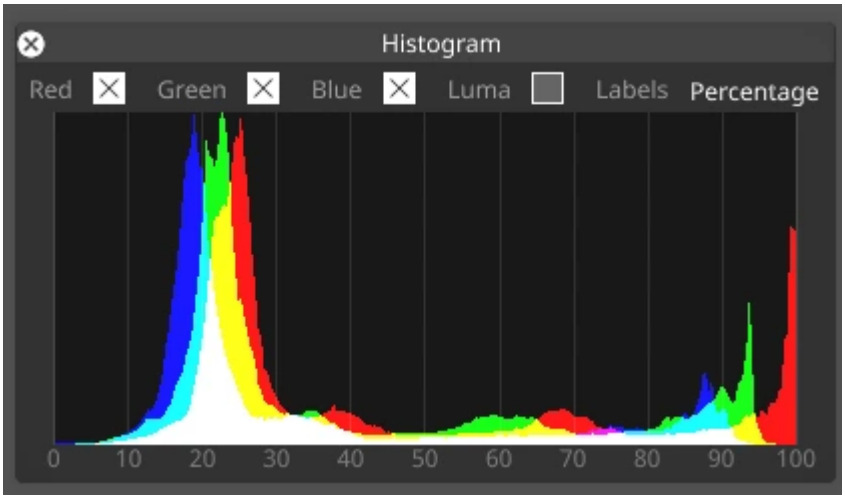
2. Right-click on the border of an output to open the **Output Properties** window.

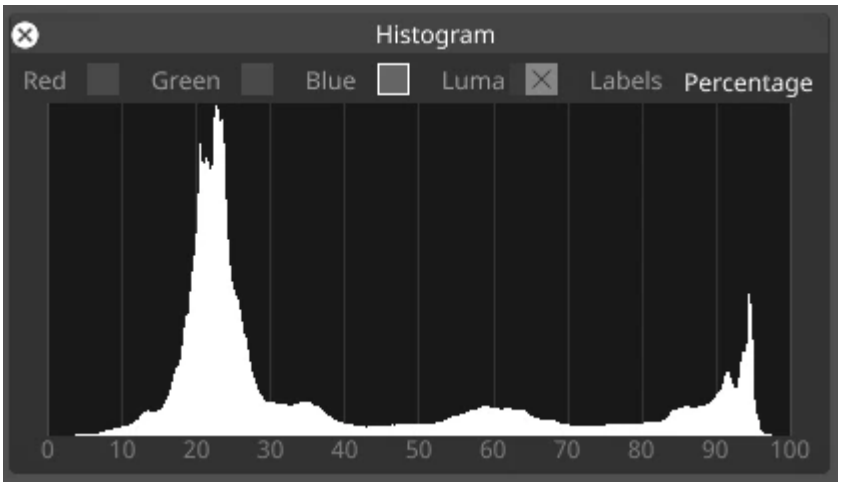


3. Click on **Histogram** in the Output tab.

Understanding the Histogram

The histogram can take its value either from the red, green or blue channels, or from the combined luma value i.e. brightness:





- The horizontal axis shows the value
- The vertical axis is the percentage of pixels at that value.
- The left side of the histogram is the lowest value (e.g. black)
- The right hand side is the highest value (e.g. white).
- A peak means that the majority of the image is at that value

The horizontal axis can be :

- Unlabelled
- Labeled by raw value (0...255 for 8-bit images, 0-1023 for 10-bit images, 0..1 for floating point images).
- A percentage from 0 to 100.
- A nit value on the Perceptual Quanitizer (PQ) scale – which is common for HDR outputs.

Livegrade Studio Integration

Pomfort Livegrade Studio comes with support for interactive CDL control of Disguise systems. This feature enables you to grade content such as a video layer in a Disguise system via a network connection.

Pomfort Livegrade Studio is a **Mac** only product. This feature is only available in **Livegrade Studio**.

Livegrade Studio comes with support for interactive CDL control of Disguise systems. This feature enables you to grade content like a video layer in a Disguise system via a network connection.

You can control CDLs in a Disguise Designer project on a machine in a network you connect to via IP (LAN or Wifi depending on your connection).

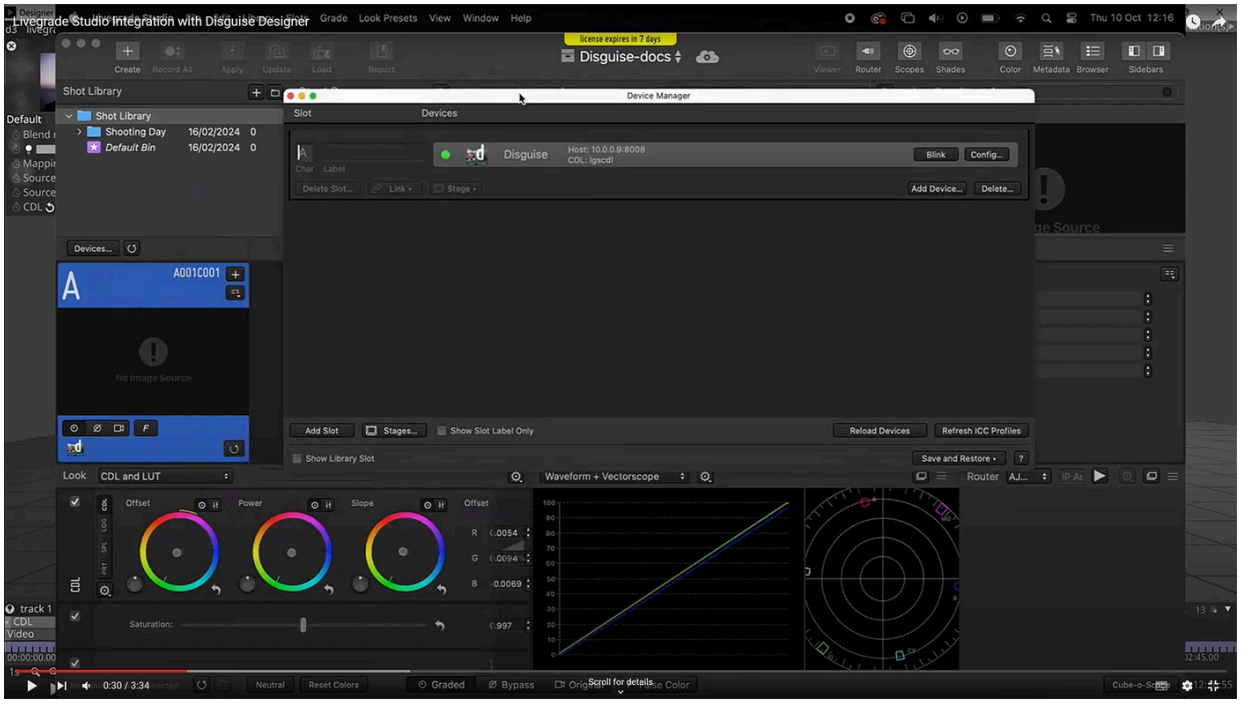
Make sure there is at least one CDL (or multiple CDLs) set up in your Disguise Designer project. You can choose the CDL you want to grade from a CDL list loaded upon adding the Disguise system to a slot.

When working with Livegrade and CDLs, the Pre Transform and Post Transform of the CDL should be set to the working space of Livegrade, which is ACEScc or ACEScct.

For more information on the ACES CDL Grading Mode, see the **Pomfort Aces Grading Mode documentation**.

With the introduction of the Livegrade Studio 6.5, the Port of a Disguise device can be set manually.

Connecting Livegrade Studio to Disguise



Click the video image to watch in YouTube

Workflow

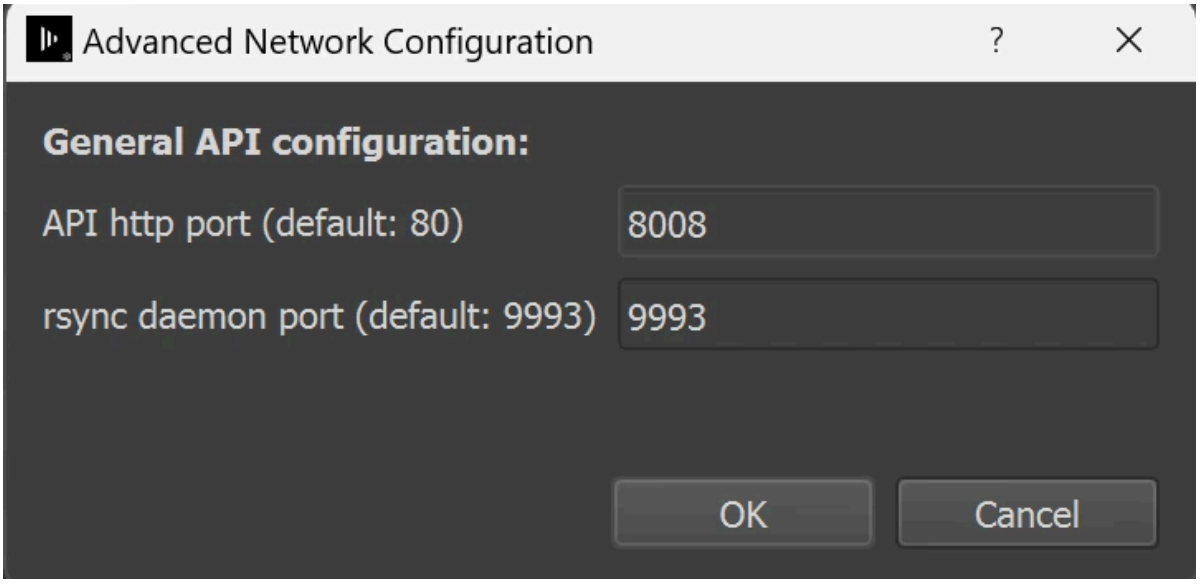
Prerequisites

- At least one Colour Decision List (CDL), or multiple CDLs, set up in your Disguise Designer project.
- Livegrade Studio installed on a Mac. Free trials are available for a short period of time, once this has expired you will need to purchase a license from Pomfort.

Setting up the connection

1. Set up a CDL in Designer by following the CDL worflow steps on the CDL page.
2. Ensure Designer is running on a machine in your network.
3. Using a Mac on the same network, open the **Livegrade Studio** application.
4. From the main menu, click **Slots > Add Device** and select **Disguise System**. Alternatively, add the device using the **device manager**.
5. In the **Add Disguise System** dialog window, add the IP address of the Disguise system running Designer.

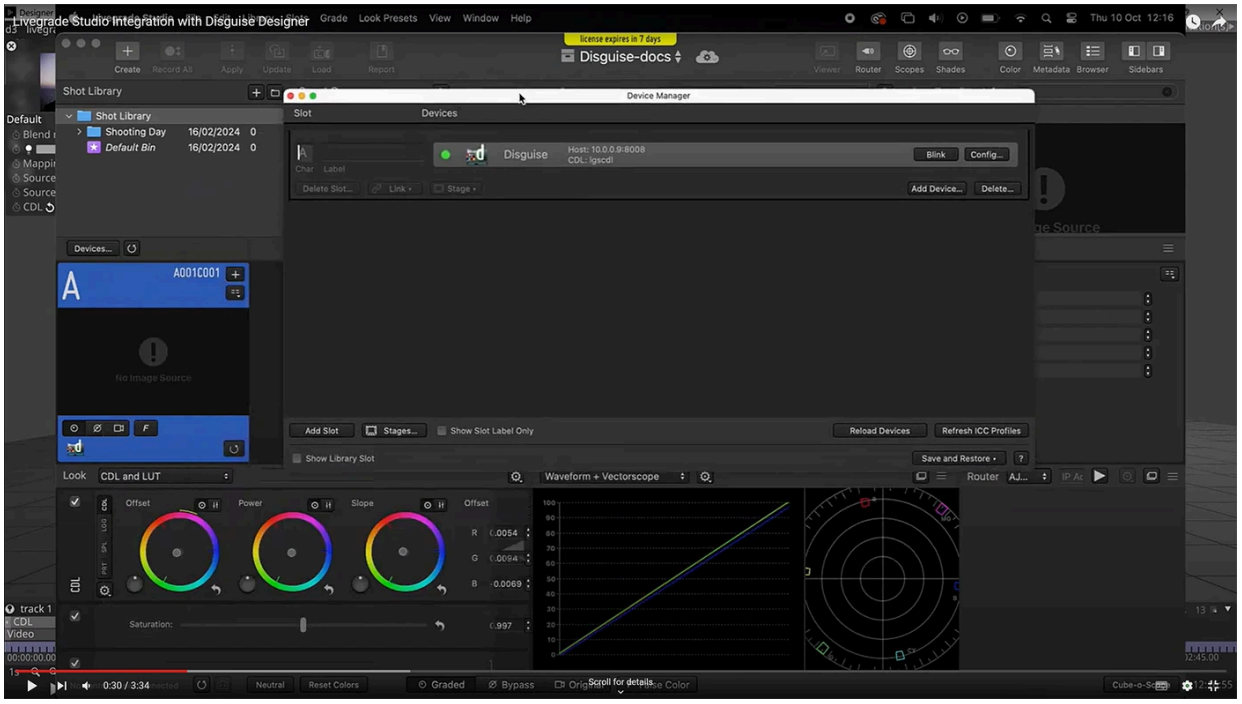
6. Add the port number. In our example we use Port 8008, but with the introduction of Livegrade Studio 6.5, the Port number is customisable. The port specified in Livegrade must match the API configured in Disguise under **d3Manager > Machine Setting > Advanced Network Configuration**.



7. In the **Remote CDLs**, select the CDL that you are using in Designer.
8. Next, select the grading type as required. There are two types of grading are available to send the *look* to the Disguise system:

- **Interactive**: is used for grading the look of the Designer image interactively
- **Manual**: is used to upload the image look manually. To do this use the **Upload** button in the toolbar.

10. Confirm the configuration settings by clicking **Add Disguise System**.



Active connection in device manager

> **Note**
>
> **Please note**: If you want to control multiple Disguise CDLs, you can add each CDL you want to grade to a separate slot.

Once the set up is complete, the device manager can be reopened at any time and will show a connected Disguise system under Devices.

> **Note**
>
> The integration only supports CDL-based look modifications. Consequently, loading a LUT into Livegrade's LUT node will not affect the look in the Disguise system.

Please refer to the article **Color Controls and Grading Modes** for more information on grading controls in Livegrade Studio.

For more help with Livegrade Studio visit the **Pomfort documentation: Setting up Disguise System**.

LUT Files

A LUT can be used as a Pre or Post transform.

LUTs

From r21 onwards, Designer's LUT Format Support has expanded.

When calibrating LED screens for large VP volumes, industry-standard solutions use two sets of LUT files - a 1D LUT for adjusting brightness, contrast, and gamma, and a 3D LUT file for adjusting colours. Initially, only 3D LUT was supported, and meant that manual adjustments still had to be made on the LED processor to achieve a linear colour reproduction.

From r21, Designer also supports 1D LUT files. View the Workflow tab on this page for more details.

Prior to r18, LUTs were essentially defined by the context they were used in. A user entering a LUT layer on the timeline was expected to have authored the LUT to transform from whatever space the image they were connecting to was in, and the output was expected to either be in sRGB or some other colour space that the user was going to manually preserve through Designer to output.

With ACES enabled, LUTs now have a pre- and post-transform option, so the user can specify which space the LUT expects to receive and which space will be output from the LUT, and Designer will be able to convert that content safely back into the ACES-2065-1 space Designer uses internally, for output via any one of the output transforms.

Applying a pre- and post-transform has now moved from the LUT layer to the LUT itself.

Supported LUT file types

Disguise supports:

- `.spi1d` and `.lut` for 1D LUTs
- `.spi3d` and `.3dl` for 3D LUTS
- `.cube` files which can be 1D or 3D

Interpolation

3D LUTs can be applied using one of two interpolation methods, selectable on each LUT resource. Choose the method the LUT was authored against, so the result in Designer matches the preview in your colour grading tool.

- **Tetrahedral** (default) — select this if the LUT was authored against tetrahedral interpolation. This is the standard default in most colour grading tools.
- **Trilinear** — select this if the LUT was authored against trilinear interpolation, or to reproduce the output of earlier Designer releases, which always applied LUTs trilinearly.

The interpolation method is set per LUT resource — inspect the LUT object (for example, by inspecting the LUT assigned to a LUT layer's **Colour LUT** property) to access the **Interpolation** dropdown.

Interpolation only affects 3D LUTs; 1D LUTs are unaffected.

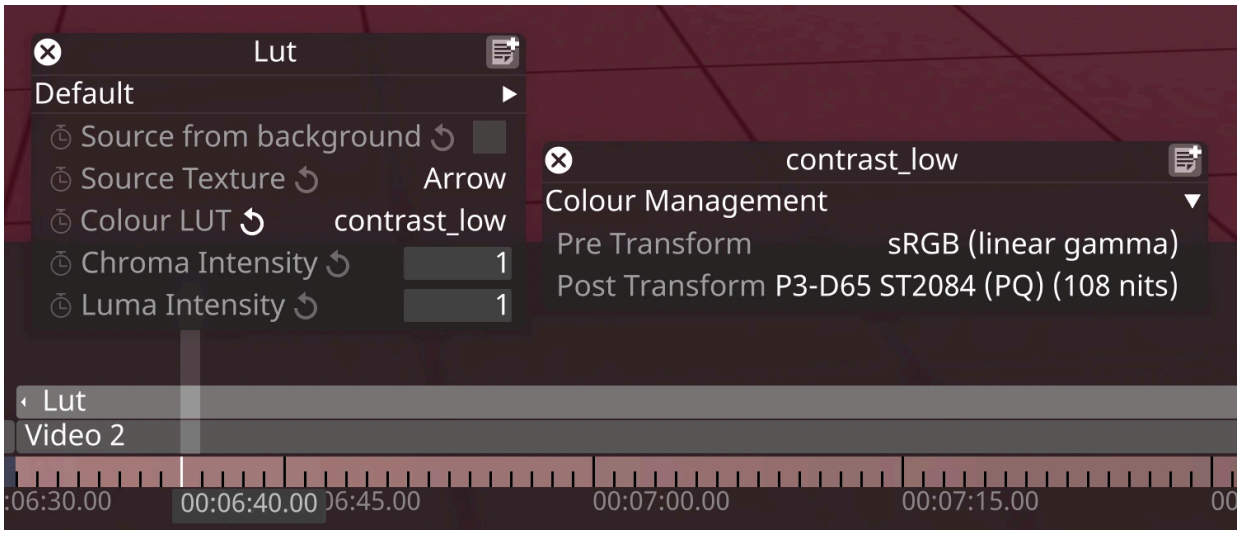
Workflow

Expanded LUT Format Support:

1. Acquire a LUT in each of the new file formats and place them within the lutfiles folder within a d3 project.
2. Launch a Designer project.
3. Create a LUT layer and open the editor.
4. Confirm that the files placed within the LutFiles folder have appeared as LUT objects.
5. Create a video layer, assign some content and arrow it into the LUT layer.
6. Assign each LUT in turn to confirm that the expected LUT effect appears on the targeted display.

LUT Layer Colour Management

Inspect the LUT layer, and then inspect the LUT assigned to the layer, and there access the Colour Management options.



Example 1

LUTs generated from Davinci Resolve in ACES mode operate on the ACEScc colour space.

So, a user can generate a cube LUT from Resolve, then specify the pre- and post- transforms in the LUT within Designer to “ACEScc”.

Designer will transform the content from the ACES-2065-1 space to ACEScc, apply the LUT, then transform the output content from ACEScc back to ACES-2065-1 space.

OCIO

Open Color IO (OCIO) is a colour management solution designed for seamlessly sharing colour spaces and transforms between applications, across an entire production pipeline. Artists and studios can author their own colour transforms, which are encoded within a .ocio file which is used to ensure consistent colours across all supported applications.

The **OpenColorIO** website contains various open source tools and instructions for building your own .ocio config files. Standard configs such as ACES can also be downloaded, although some of these are already included as built-in configs within Designer. Alternatively, studio provided configs can be loaded into Designer to maintain consistency with other production tools.

Supporting OCIO inside of Designer allows Disguise to be used as part of a colour-managed workflow alongside other OCIO-compatible software such as Adobe After Effects, Autodesk Maya, Foundry Nuke and Unreal Engine.

For more information on colour spaces and colour management please visit the colour management page.

Core Principles

- The colour spaces and transforms are stored in a .ocio **Config** file. For instructions and tools for authoring config files, see the **OpenColorIO** website.
- **Colour Spaces** can be selected on input content and output sources to define the space to read from or write to.
- The **Working Space** can be set within the config editor to define the colour space in which compositing operations in Designer are carried out.
- Transforms may have configurable parameters such as exposure and gamma which are provided via **Dynamic Properties**.
- **LUTs** and **CDLs** can be applied in various places in Designer to transform the colours of an image. OCIO can be used to define what colour spaces these are applied in.

Support

It's important to ensure your OCIO workflow is compatible with the OCIO library used in your specific version of Designer.

OCIO support within Designer is summarised in the table below:

Designer Version	OCIO version
r32.2 or higher	2.5.0

Designer Version	OCIO version
r29.1 to r32.1	2.4.1
< r29.1	Not supported

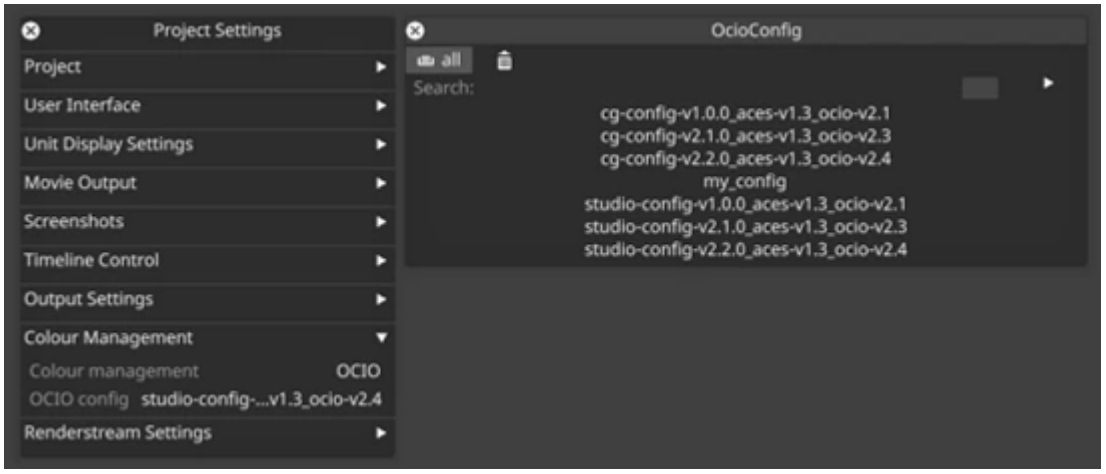
> **Caution**
>
> If you intend to use a custom OCIO config within Designer, it's important to ensure its `ocio_profile_version` does not exceed the OCIO library version used within your Designer instance. Doing so could result in serious configuration incompatibilities and errors.

Workflows

Configs

To set an OCIO config in Designer

1. Right-click d3 in the dashboard and select **Project Settings**.
2. Under **Colour Management**, set the Colour management option to **OCIO**.
3. By default, the **OCIO config** field is set to the latest ACES studio config. Several other built-in configs are also available.
4. To use a custom .ocio config file, copy the file into the project's objects/OCIO folder, then select this from the list of available configs.

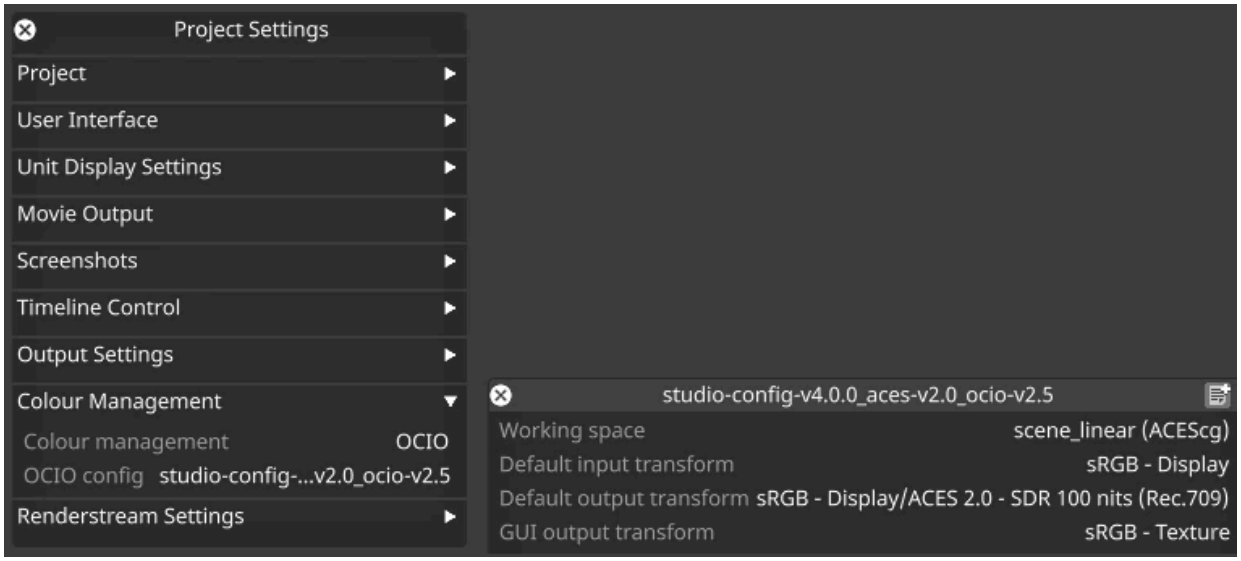


> **Note**
>
> .ocio files will automatically be synchronised from Director to Actor machines. They will not be synchronised from Actors or Editors.

The **OCIO config** resource in Designer has options to allow users to set the working space and default input and output spaces.

To set the working and default colour spaces

1. Right-click on the **OCIO config** to open its editor.
2. Change the working space in the **Working space** field.
3. Change the default input/output spaces in their respective fields. Note that these defaults are dynamic - anything which has its colour space set to Default will always resolve to whatever is currently set in these fields.



> **Caution**
>
> We recommend that a scene-linear colour space is used as the working space, otherwise certain compositing operations may not perform as intended

To set the GUI output transform

The **GUI output transform** property in the OCIO config editor can be used to set the colour space of the user interface. This enables colours to be viewed properly on monitors with wider colour gamuts than standard sRGB displays. Note that this property does not change any colours in the machine outputs.

1. Load an **OCIO config** which has a colour space matching your monitor's specifications.

2. Right-click on the **OCIO config** to open its editor.
3. Change the **GUI output transform** to the required colour space.

Colour spaces

Input and output colour spaces can be set on Resources to define the colour space a particular piece of content or output hardware is expecting. Content is transferred from input colour spaces to the working space before any compositing is done, and from the working space to output colour spaces when content is applied to the outputs.

Input colour space fields are added to the appropriate content sources in Designer, including:

- VideoClip
- DxTexture
- LogicalVideoInDevice
- RenderStreamAsset

Output colour space fields are added to the relevant outputs, including:

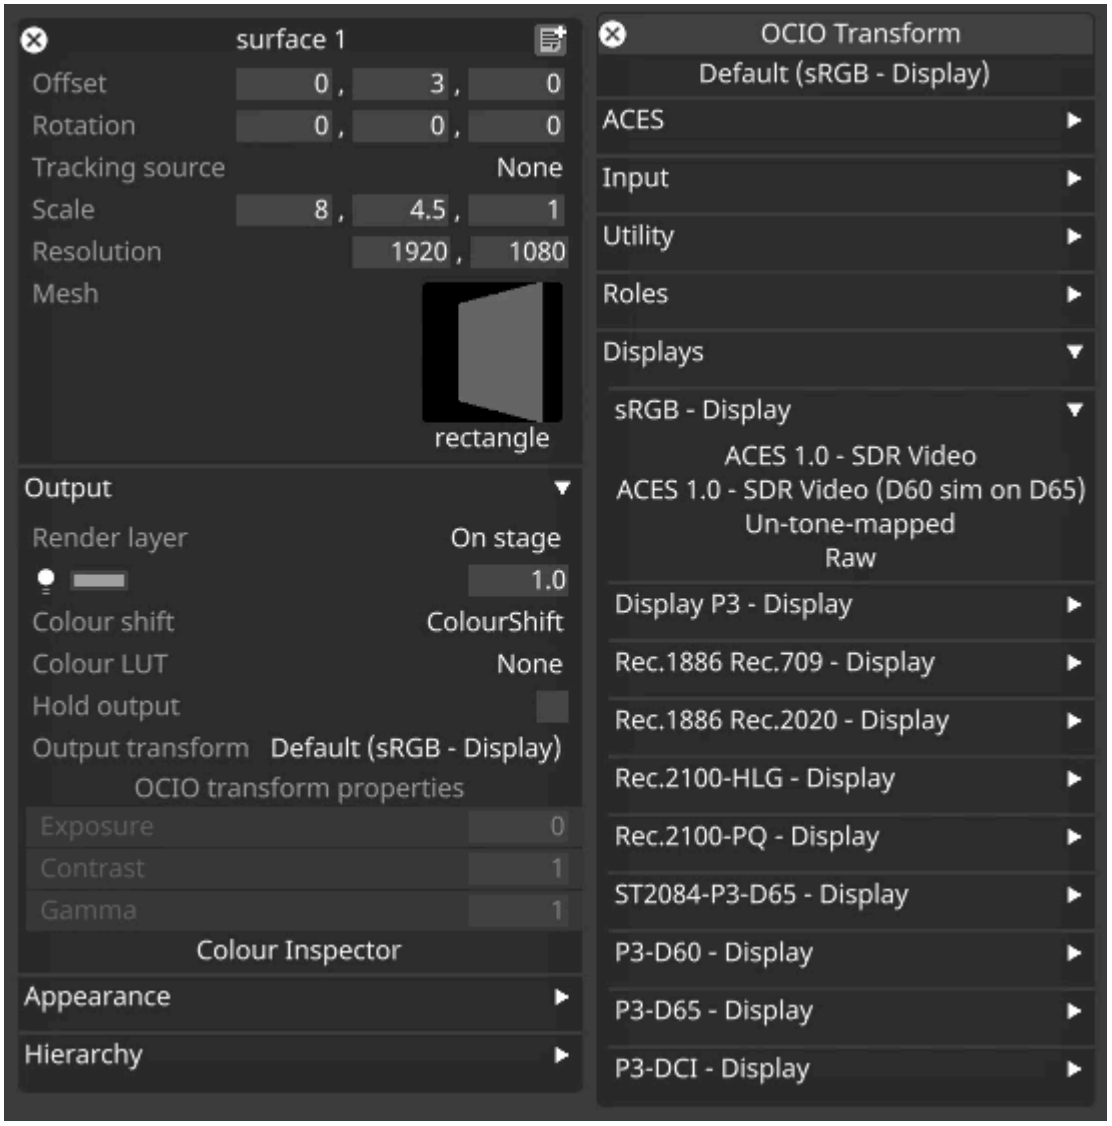
- LedScreen
- DmxScreen
- Camera
- Projector

To select the input colour space for a video clip

1. Set the colour management mode to OCIO and set up the config.
2. Create a Video layer and select a VideoClip from the video folder.
3. Right-click on the VideoClip to open its editor.
4. Under **Colour shift**, click to select the Input colour space.
5. By default this will be set to **Default**, which resolves to the default input transform set in the config.
6. Select a different transform if required to match the media encoding.

To select the output transform for an LED screen

1. Set the colour management mode to OCIO and set up the config.
2. Open the editor for the LED screen.
3. Under **Output**, click to select the Output colour space.
4. By default this will be set to **Default**, which resolves to the default output transform set in the config.
5. Select a different colour space or display/view combination if required to match the colour space the LED processor is expecting.



> **Note**
>
> Changing the output transform of a display will not make any noticeable difference in the Designer visualiser. The output transform will only be applied to the image as it goes out to the screen.

Dynamic Properties

Several OCIO transforms provide a number of modifiable parameters which can be used for live adjustment, similar to the exposure and gamma controls in ACES mode. These are known as **Dynamic Properties** and are applied using an **ExposureContrastTransform**. Designer exposes three values from this transform:

- Exposure
- Contrast

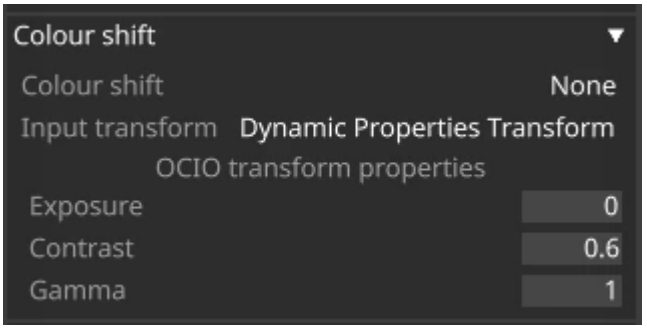
- Gamma

If the selected colour space does not contain an ExposureContrastTransform in the config, Designer will add one internally, placed after an input transform or before an output transform to apply the properties in working space. If an ExposureContrastTransform is included in the colour space defined in the config, the properties of this transform will be exposed. This allows users to control where in the chain of operations the properties are applied.

> **Note**
>
> If a colour space contains an ExposureContrastTransform, and a fixed value is defined for one of the properties in the config, the dynamic property will be greyed out and the fixed value will be used. To make the property editable, remove the fixed value in the config file.

To use dynamic properties

1. Navigate to an appropriate editor in Designer, e.g a Video Clip editor.
2. Select the desired colour space.
3. The dynamic properties will be added to the editor in Designer when available. Adjust these fields to change the values of these properties in that particular instance of the colour space.



> **Note**
>
> We currently do not provide any interfaces or support for Grading controls in Designer. We will be looking to include these in a later version.

Layers

Certain layers have fields which can be used to define the colour management settings in OCIO mode. Layers which don't have any explicit colour management settings will generally render in sRGB space, and will automatically be transformed into working space.

The following layers apply colour management in OCIO mode:

- Video layer: Uses the Input colour space defined in the VideoClip to transform the video into working space
- Notch layer: Notch blocks authored in Notch version 1.0 or greater can be set up to render in one of several available colour space. Older blocks are always rendered in sRGB. The Notch layer communicates with the block to ensure that the correct colour space transforms are applied, with no user input required.
- RenderStream layer: Uses the Input colour space defined in the RenderStream Asset to transform the received streams into working space. This space should be set to match the colour space set up for the asset in the render engine.
- 2.5D layer: Videos and images applied to 2.5D plates are transformed from the Input colour space defined in the VideoClip to working space. The stage render of the 2.5D plates is then done in working space, to ensure no colour information is lost.
- LUT layer: See **below**
- CDL layer: See **below**

LUTs

The LUTs in OCIO mode follows the conventional LUT workflow of d3 (LUT).

When OCIO is enabled, LUTs will include an **OCIO transform** field. This field indicates the color space where the LUT transform happens. The transformation process involving the LUT will follow these steps:

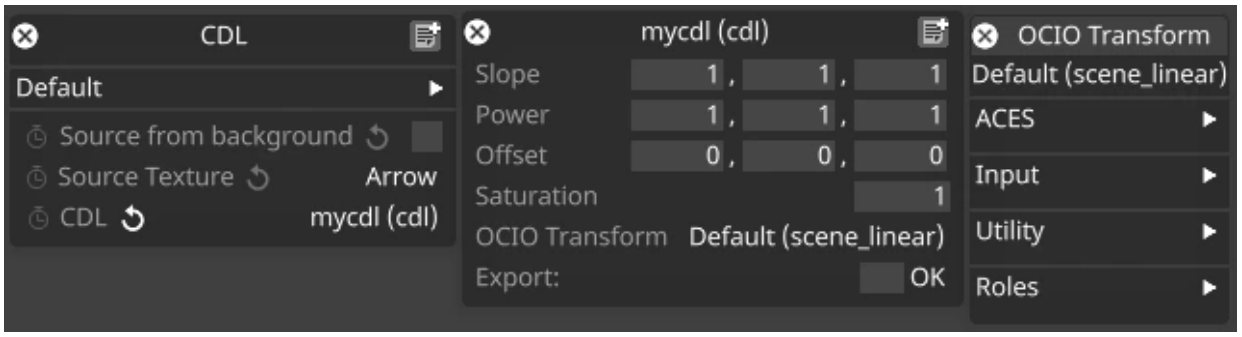
1. Apply a color space transform from **Working space** defined in the OCIO config to the **OCIO transform**.
2. Apply LUT transform.
3. Apply a color space transform from the **OCIO transform** back to the **Working space** defined in the project settings.

CDL

The handling of CDL in OCIO mode follows the conventional CDL workflow of d3 (CDL).

Note that there is a field named **OCIO transform**. If the **OCIO transform** is set to default, it will apply the CDL transform without any colour space transform; however, if the **OCIO transform** is set to a value other than the default, the colour transform process will follow these steps:

1. Apply a colour space transform from the **Working space** defined in the OCIO config to the **OCIO transform**.
2. Apply a CDL transform using the **Slope**, **Power**, **Offset**, and **Saturation** parameters.
3. Apply a colour space transform from the **OCIO transform** back to the **Working space**.



Custom Gamut Output Transform

If a non-standard gamut is required for an output device such as a monitor or LED wall, this can be configured through the `.ocio` config file. The required colour space for the custom gamut can be added in the `.ocio` config file, which will be populated in the OCIO Output transform widget once the config file is selected from Designer project settings. Disguise provides an open-source utility tool, **ocio-custom-gamut**, that helps convert custom gamuts into OCIO config files.

Vectorscope

The Vectorscope plots the chroma of the image. Chroma is the colour information that is left when you remove the luma. This would typically be used to confirm colour accuracy against known test patterns, or to colour correct images objectively.

Vectorscope Overlays

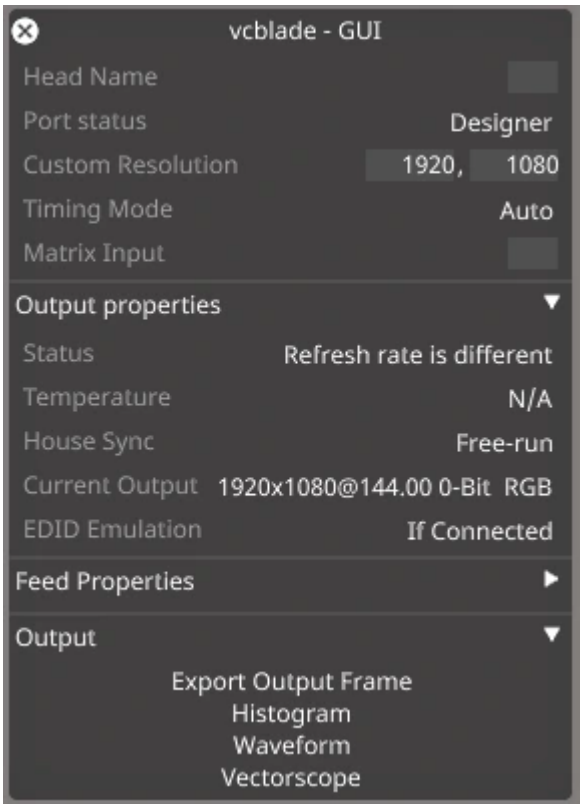
The Vectorscope has two overlays that can be combined or used separately:

- RGBCMY - red, green, blue, cyan, magenta, and yellow markers at 75% or 100% saturation
- IQ lines - aka the “skin tone” line, which can be used to correct skin tones

Workflows

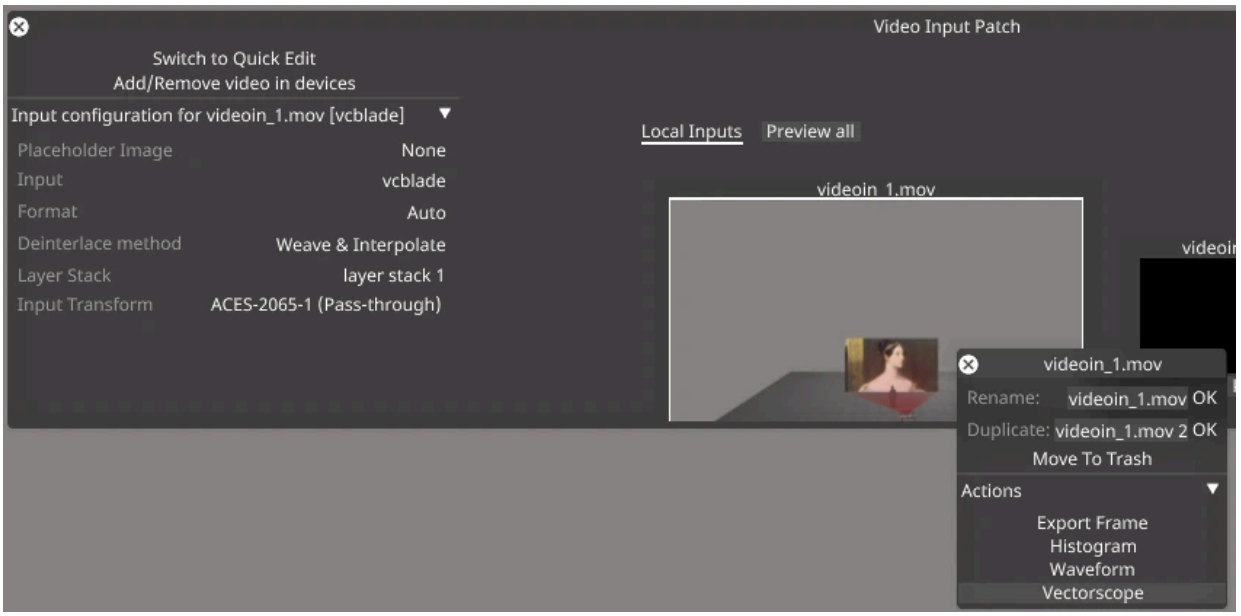
To open the Vectorscope on an Output

1. Open the Feed Output window by clicking on **Feed** in the d3 dashboard.
2. Right-click on the border of an output to open the **Output Properties** window.



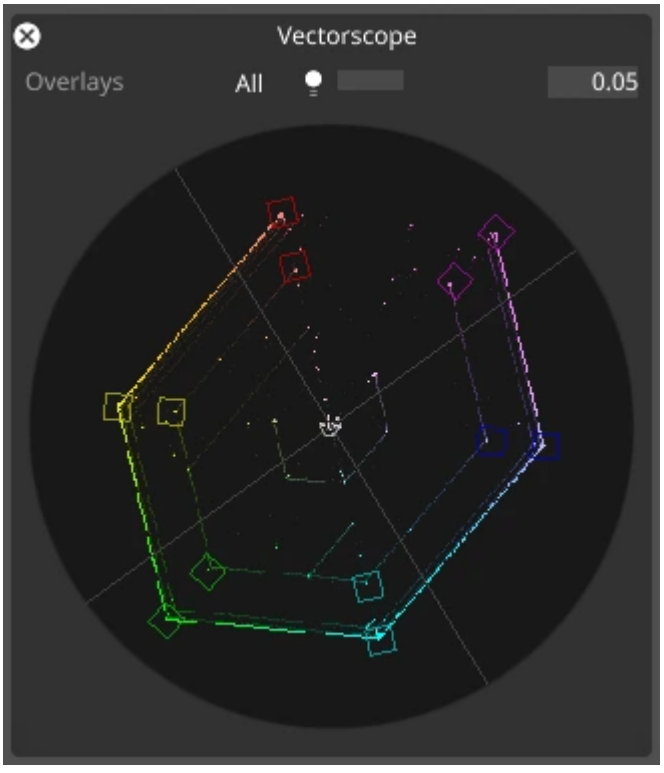
3. Click on **Vectorscope** in the Output tab.

The Vectorscope may also be opened on a video input by opening the Video Input Patch Editor and then right-clicking on a local input's thumbnail.



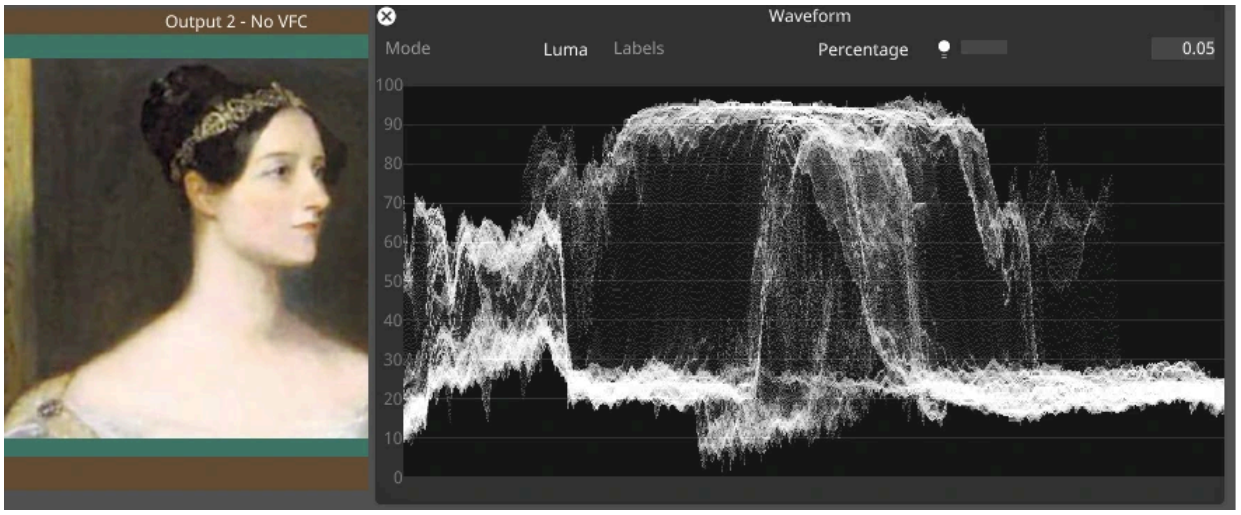
How to use Vectorscope

This graph is a circular UV plot indicating where each additional pixel hitting at the same point additively increases intensity.



Waveform

The waveform is a histogram for each column of pixels in the image.



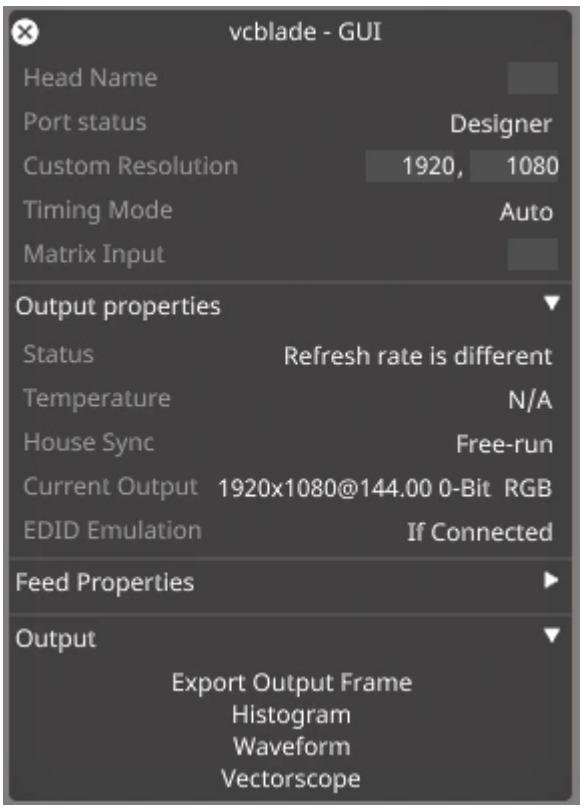
Opening the Waveform scope

A waveform scope can be used to verify the signal chain at these points:

- On a Video Input within the Video Input patch Editor.
- After capture into Disguise and any layer stack modifications.
- The feed output - after being transformed into the final 8- or 10-bit format going to the display.

1. Open the Feed Output window by clicking on **Feed** in the dashboard.

2. Right-click on the border of an output to open the **Output Properties** window.

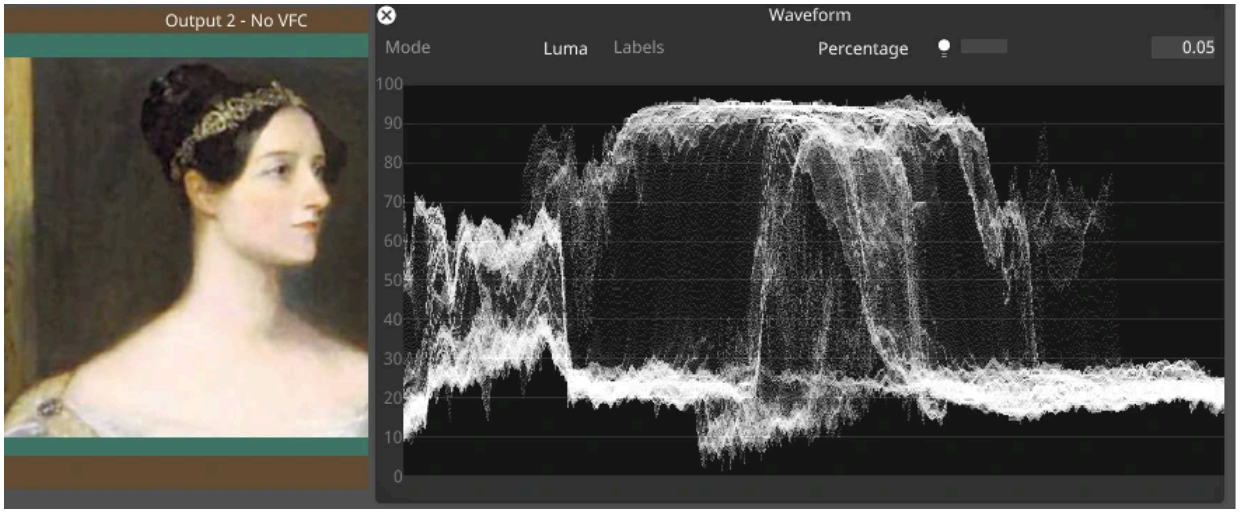


3. Click on **Waveform** in the Output tab.

For more information on Histograms, please visit this link.

Understanding the Waveform

Waveforms are typically used to ensure that the image is within safe limits i.e. above a minimum black level or below a maximum white level, and are also used to balance the red, green and blue channels.

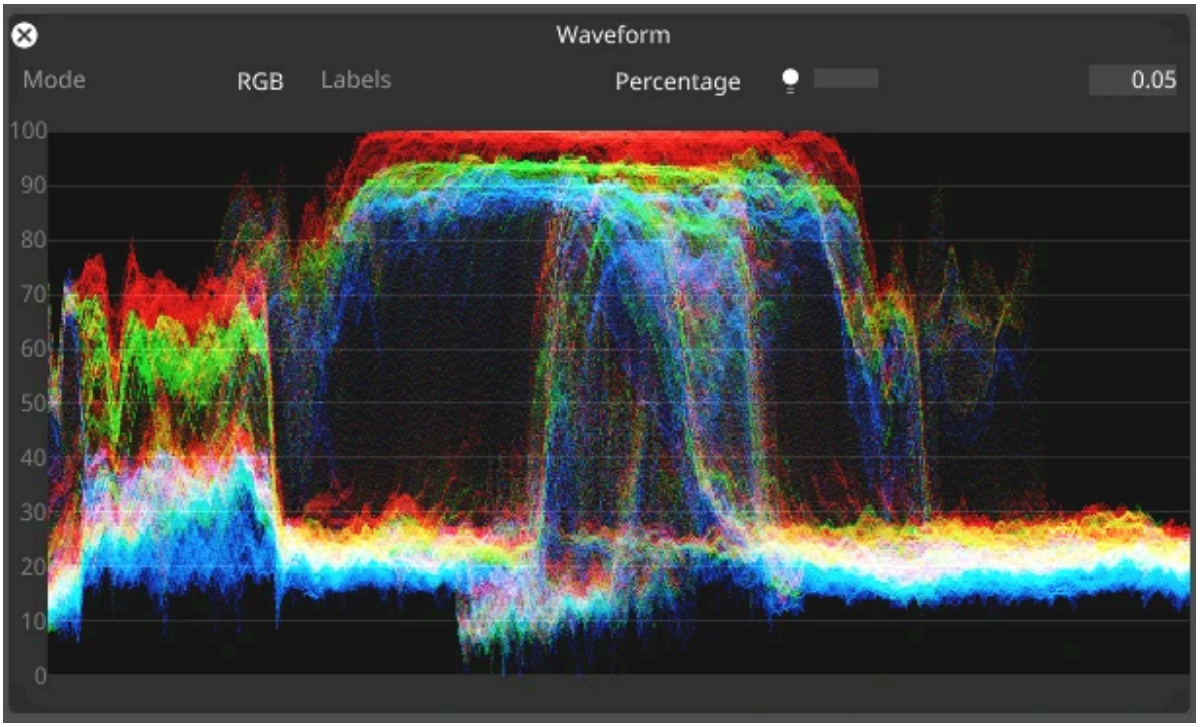


- The horizontal axis is the same as the image's horizontal axis i.e. left of the waveform is the left of the image, and right of the waveform is the right of the image. This means that panning the image will have the same pan effect on the waveform.
- The vertical axis is the value of the pixel. Down on the waveform vertical axis is the lowest value (e.g. black), and up is the highest value (e.g. white).
- The brightness at each point in the waveform is the amount of pixels at that value.

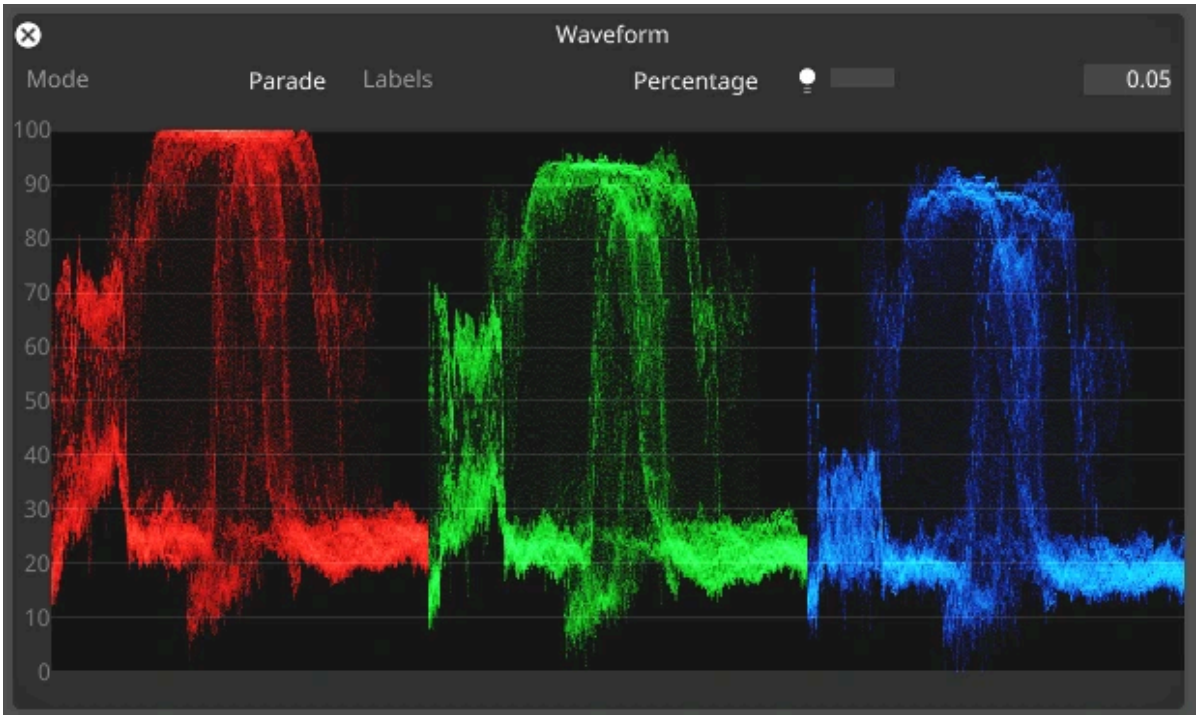
The waveform has three modes which can be accessed by clicking on the 'Mode" button on the waveform:

- Luma - (shown above) the same brightness value from the histogram

- RGB - red, green and blue values are overlaid on each other



- Parade - red, green and blue values side-by-side



The values of the waveform can be presented as a value, a percentage or as PQ nits.

BlackTrax Integration Setup

BlackTrax (BT) is a vision-based tracking system available from CAST, capable of tracking both objects and people. Tracking data from BT can be input into Disguise software and mapped to objects or props within the Disguise visualiser.

The BT system uses an array of cameras placed on the stage rig to observe IR markers (small LEDs) placed on the talent or prop. These active markers generate rigid body information that is sent to Disguise as they are observed by an array of cameras mounted on the truss/staging. As long as the marker is observable by two cameras, an accurate positional fix is possible.

The markers are attached to a small BT Beacon unit (usually attached to the talents belt). This unit provides power and control to the IR markers.

BlackTrax can integrate in two ways:

- Actor/talent tracking
- Prop/screen tracking (used for movable scenic pieces)

A BlackTrax server contains the software programs required for configuring a BT system, including BTWYG, BlackTrax, and Motive.

⚠️ Please be aware that the workflow outlined below may be outdated workflow outlined below may be outdated. This section is under review, and updated information will be added as newer workflows are evaluated and confirmed.

For additional information and training on using BlackTrax, please visit the CAST website

Disguise Project Setup

Your visualiser must be set up to resemble the real world environment as closely as possible to avoid any issues that may occur when calibrating. Follow these steps to set up your project in Designer.

1. Create a project and enable tracking

1. Create a project.
2. In the d3 project, the project's **internal** folder.
3. Open the **dlls** and open **dlls.txt**.
4. Add **tracking.dll**, then save the text file.

2. Open the project and add a tracking point

1. Open the project, then open the visualiser camera by right-clicking **Stage > Camera > Visualiser camera > Visible**
2. Open the visibility tab and make **tracking point** and **tracking labels** visible.

3. Set the projector properties

Set the projector's properties such as resolution, lens, and position. Also, set the resolution on the feeds; if not set correctly this can influence the calibration process. **The real-world projector must not have any warping, Keystone, lens shift or zoom.**

4. Add a visual reference

Add a mesh of known dimensions (e.g., a rectangular mesh) at the origin (0,0,0) of the stage within the visualizer. This mesh will act as a visual reference to assess any orientation discrepancies of objects and will later serve as a datum point for calibration procedures.

Integration

Environment Registration

After setting up and configuring the BlackTrax system, the next step is to register a BlackTrax device within your project. Follow the steps below to integrate and align the device for accurate positional tracking:

1. **Create the BlackTrax Device** In the dashboard, right-click within the device list and select Add Automation Device. Choose BlackTrax from the available options.
2. **Assign the Driver** Once the device is created, its editor window will open automatically. Navigate to the Driver tab and assign the **BlackTraxDriver**. **Note**: Upon successful creation, provisional BlackTrax tracking data will begin streaming into the system. This is visually represented in the visualizer as green points, corresponding to beacon string positions.
3. **Prepare the Registration Area** Begin the environment registration process to align coordinate systems between BlackTrax and Disguise:

- Mark a 90-degree angle centred on the stage using the same dimensions as the reference mesh created earlier.
- Position tracking stringers at the centre stage (CS) point, and at both endpoints of the right angle (defining the X and Z directions).

Note: Ensure the physical markings precisely match the dimensions and orientation of the virtual datum mesh.

4. **Open the Registration Tool** Right-click on the existing BlackTrax device and open its editor. Go to the **Registration** tab.

5. **Place Reference Points** The cursor will change to a placement tool, indicating readiness to define registration points. Drop three reference points onto the datum mesh:

- Center Stage (CS)
- Positive X direction
- Positive Z direction

6. **Link Virtual and Real-World Points** Using the registration UI, link each of the dropped reference points to their corresponding live BlackTrax beacon positions. After successfully registering all three points, proceed to finalization.
7. **Finalize the Registration** Select the Finalise field in the registration UI. This step applies the computed transformation, aligning the virtual space with the real-world BlackTrax coordinate system.

Once complete, the GUI will display aligned reference and tracking points, confirming a successful calibration.

Note: The system receives positional data from BlackTrax at a frequency of 100 Hz, enabling real-time tracking accuracy.

Note: receives positional information from the BT system at a rate of 100Hz.

OSC Setup

At this point all the basic setup of the project will be done. The next section demonstrates how to integrate the OSC external hardware required. The reason for this is because it is the easiest way to control the calibration process in Disguise (note in older versions of the software the only way to calibrate the system is with an OSC interface). Follow these steps to set up OSC:

1. Create an OSC device in Disguise by right-clicking on the “device” in the dashboard. Once open there will be a plus and minus field, use this to add and remove devices from the project.
2. Select the **+**, this will then give you the option to select from a list of commonly used devices. In this list there will be a device called OSC1. Select this device to add it to the project.

3. Once added ensure all the fields in the device are filled incorrectly (use the below table for help):

OSC Hardware	Disguise OSC
Host	d3net port address
Port (Outgoing)	Port receive
Port (incoming)	Port send
Local IP address	OSC hardware IP

4. Sync the OSC layout to the hardware with the **TouchOSC editor**. Now if you change something on the OSC controller you will see the OSC device indicator in the dashboard emit green to show it is receiving a signal.

TouchOSC layout explained

The TouchOSC layout for BlackTrax-based projector calibration can be downloaded from the **OSC section of the Resources page**.

- **Start:** Starts the calibration process.
- **Cancel:** Cancels last placed point so it can be redone.
- **Done:** Finishes calibration process.
- **Skip:** Used in case a projector will not be calibrating a point at this time; for instance because it does not have coverage onto the current position of the stringer. Gets used when frustum extremities of singular projectors are being calibrated.
- **Trackpad:** Used for quick rough placement of the crosshair.
- **Directional key**Used for fine control per click, or movement of the crosshair on a single axes. Crosshair will move faster the longer the button is held.
- **Rotate left & right:** Used for aligning the movement direction of the crosshair to the orientation of the user that is calibrating.
- **Previous & Next:** Used to jump between modes of operation.

Projector Calibration

1. Open the BT device, at the bottom of the editor select the field called “BtProjectorCalibrator” this will then open the BT calibration editor.
2. Assign the OSC device that will be used to calibrate. (Note: set this device even if not being used).
3. Assign the tracked point; this is the string that will be used for the calibration process.
4. Assign the projectors used in the BT system.
5. Now open touch OSC with the given layout. (or the GUI interface, which can be found under the tab “Remote Calibrator”)

6. Press start on the OSC to start the process (A test pattern will flash on the output to show the full output size this is normally the colour of the projectors wireframe)
7. Place the stringer in the projectors output. (for example, bottom right of the coloured output)
8. Press next on the OSC app, this will now launch a line up grid
9. Move the cross-air in the OSC editor to move the cross-air in the projector output. Line this up with the string to calibrate the space.
10. When in the correct position click next on the OSC app.
11. The software will now show the second projector line up grid and overlap. If the point is in the next projectors field of view, then use the string as a reference point. When lined up push next.
12. Repeat step 7 to 11 and create at least 6 reference points per-projector.
13. Several points will now be seen in the GUI; these points represent the calibration points.
14. When you have finished placing points push Done on the OSC app.

Note: Same steps are used for the GUI interface as it works with the same process.

Note: Calibrate point at different heights and depths to gain the best calibration possible. The more information the system has to process the better to calibration will be.

Now you will see the projector values greyed out, now the space is calibrated, and video will be able to track objects.

Some points may affect the calibration in a bad way in the same way a badly calibrated point in QuickCal can ruin a line up. This can be checked with the following steps:

1. Open the editor for one of the projected used for the BlackTrax process.
2. Open the projector calibration.
3. View the calibration scores, if the sore is poor try muting point to improve the calibration results.

Rigid bodies

The next step is to assign objects to strings so the object can be tracked. To start this process, follow the steps below:

1. Open the BlackTrax device by right-clicking on the device in the device list, this then will open the device editor.
2. Open the tab “Rigid Body” this will then present you with a plus and minus field, use this to add and remove objects.
3. Once you have created a rigid body an editor will open. This will contain the fields seen on the next page:
4. Select the desired object.
5. The cursor will be a point to represent that it is ready to drop points, drop four reference points on the object. This will be used a static reference points.

6. Under the points tab, add as many fields as you would like to track.
7. Set your static points and set the tracked points which will be the BlackTrax beacons that are being used.
8. Select “calibrate: snap to fixed point” field.
9. Now the real-world object should match the orientation and position of the object in the GUI. When the real-world object moves the visualised object should follow
10. Edit the different thresholds to make the movement smoother.

Terminology

Object: Select the object intended to become a RigidBody.

Engaged: Enable or disable tracking for the RigidBody.

Status: Not Calibrated means the object will not be tracked. Can be manually set to calibrated to enable tracking of the body onto the object. When done so the object selected will jump to line up its fixed points to the selected tracked points.

Secondarily, the Calibrated option will be the result of pressing the Calibrate button explained under Points.

Skip: Used in case a projector will not be calibrating a point at this time; for instance because it does not have coverage onto the current position of the stringer. Gets used when frustum extremities of singular projectors are being calibrated.

Iterations: The RigidBody solver is iterative, meaning that for `n` iterations (max number iterations being defined by this number) will attempt to resolve a position rotation matrix which best represents where the RigidBody should be in the co-ordinate system.

Solver mode RigidBody or Actor.

Set to **RigidBody** will allow tracking of X, Y, Z position and rotation.

Set to **Actor** will allow for X, Y, Z position tracking, but no rotation. Both solver modes will technically track from 1+ visible stringers and up, though this is not a great idea for rigid bodies in most cases. In case of RigidBody solver multiple stringers are required to be seen to calculate rotation. Actor solver will average incoming and reference positions and calculate the difference on each update. We update at 100Hz, as per the refresh rate of the Motive settings.

Movement Threshold: Keeps Dynamic Blend from recomputing when set to a non-zero value. This is used when static oscillation on almost static objects becomes an issue.

Rotation Threshold: Keeps Dynamic Blend from recomputing when set to a non-zero value.

This is used when static oscillation on almost static objects becomes an issue.

Points: Points are where you select a number of fixed points, placed by clicking on vertices of your rigid body models, and tie them to stringers. Simply select the correct points and set

offsets where required.

Tweak: Tweak is used to more accurately align projection onto your rigid body. Use its offsets on XYZ position and rotation until projection lines up. It should be noted that sometimes you may be better off rescaling your model instead, depending on your results.

Constraints: Set these on all axes where you would like to restrict movement. 1 turns on, 0 turns off.

Tracking lost: On tracking lost settings allow you three forms of behaviour in case tracking data is lost.:

Do nothing: Does nothing.

Reset allows you to define a position that rigid bodies will jump to in case tracking data is lost.

Follow sequencing means will follow any ScreenPositionModule programmed on the timeline as a form of redundancy.

BlackTrax Motive Setup

This page describes the BlackTrax hardware setup, and the Motive setup and calibration.

⚠️ Please be aware that the workflow outlined below may be outdated. This section is under review, and updated information will be added as newer workflows are evaluated and confirmed.

Hardware Setup

1. Plug the BlackTrax server into the switch (using the BTnet Port which is normally port 1)
2. Plug the Timekeeper and eSync Controller into the network switch. The Timekeeper will also need linking to the eSync with the provided din cable. (This will ensure that all the system works in time)
3. Plug in the BlackTrax Router into the network switch
4. Plug in the Charging Station to the network switch (this is not virtual and is only used to configure the beacons)
5. Install the BlackTrax cameras, these will then need to be linked back to the network switch.
6. The network switch is a Power Other Ethernet (POE). This means that most of the external hardware will receive its power from the switch.
7. Once the above is done the BlackTrax hardware is setup. The next section covers how you set up different aspects of the system.

Motive Setup

Motive is the software used to calibrate space and track objects. To set this up, follow these steps:

1. Select the Aiming layout in the drop down tab.
2. Select the group and set the camera's exposure to full.
3. Set the gain to level 8
4. Set the image type to High Quality MPEG 4. Now you should be able to see a black and white image from the BlackTrax cameras.
5. Change the Filter Switching to Visible Spectrum.
6. To aim the cameras, push the button on the back of the camera this will make the camera view fullscreen and change the image to a high quality grayscale.

Now in this mode you should be able to point the camera and get a good quality focus.

Repeat step 5 and 6 for each camera in the BlackTrax system.

At this point the system should be reset to its original state:

- Exposure: 4000
- Gain: Medium (4)
- Image type: Object mode
- Filter Switching: InfraredFilter

Motive Calibration

The process of calibration is called *wanding*. See steps below to start the process.

1. Open the Calibration window in the dropdown tabs.
2. Once open turn the active marker labeling from true to false (this now sets the system to track a continues IR light source from the wand).
3. Set the size of your wand.
4. Select the field labelled “start wanding”; this will then prompt you to save the calibration. Once saved all the cameras will have a red board to show that the process has started.
5. Plug in and turn on the BlackTrax wand. Move it in a figure 8 motion throughout the space, this should show as sample in the Motive GUI (the software will only sample if it is seen by 3 or more cameras) .
6. When the system can see a good amount of coverage in all cameras you can tell the Motive system to calibrate the information it has received from the process. Do this by selecting the Calibration field.

Once done it will score your calibration to let you know if the wanding was poor. If good you can continue to the next step.

7. The system will now require you to set a ground plane, to do this place the BlackTrax ground plane in the center of your space (what would be 0,0,0) then select the calibrate option.
8. Turn the active marker labeling back to True once finished.

BlackTrax Overview

BlackTrax connects to different third-party applications, such as robotic lights, media servers, and any other third party that accepts the RTTrPM open protocol.

BlackTrax (BT) is a vision-based tracking system available from **CAST**, capable of tracking both objects and people. Tracking data from BT can be input into and mapped to objects or props within the Disguise visualiser.

The BT system uses an array of cameras placed on the stage rig to observe IR markers (small LEDs) placed on the talent or prop. These active markers generate rigid body information that is sent to Disguise as they are observed by an array of cameras mounted on the truss/staging. As long as the marker is observable by two cameras, an accurate positional fix is possible.

The markers are attached to a small BT Beacon unit (usually attached to the talent's belt). This unit provides power and control to the IR markers.

BlackTrax can integrate with Disguise in two ways:

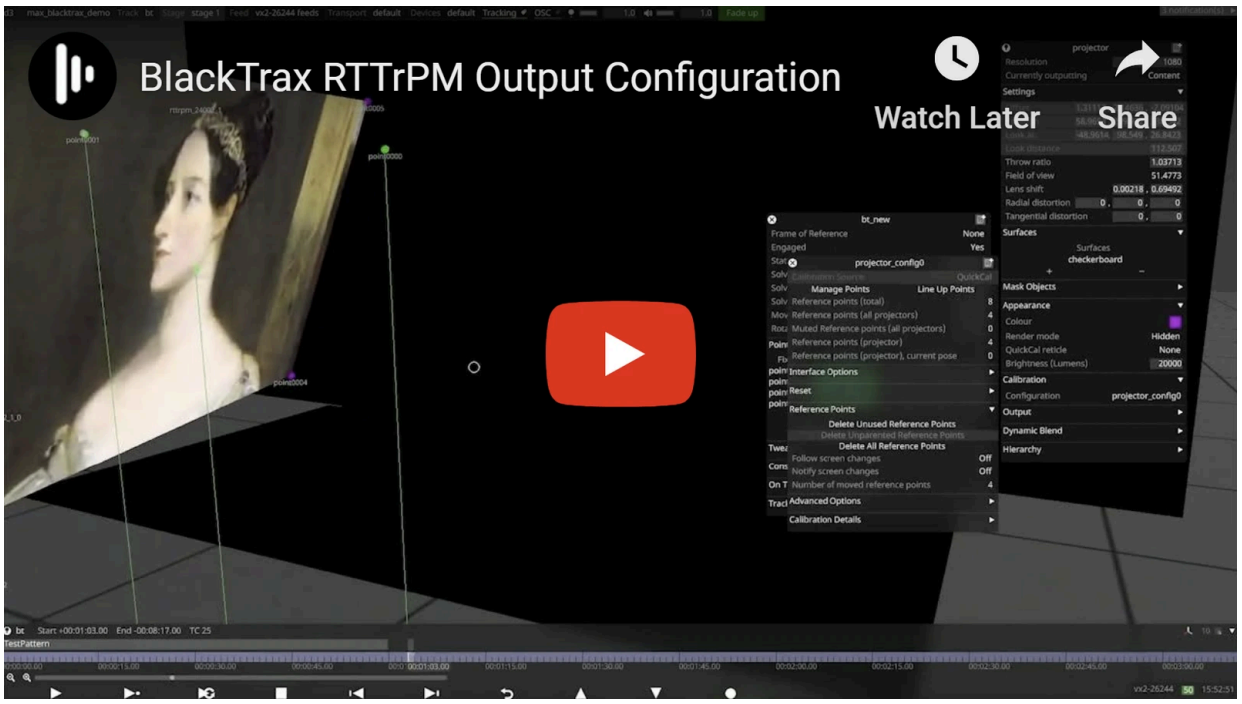
- Actor/talent tracking
- Prop/screen tracking (used for movable scenic pieces)

A BlackTrax server contains the software programs required for configuring a BT system, including BTwyg, BlackTrax, and Motive.

For additional information and training on using BlackTrax, please visit the **CAST** website

RTTrPM

BlackTrax RTTrPM Output Configuration



Applications like the BlackTrax real-time tracking system use RTTrPL and RTTrPM to interface with other lighting and third-party applications (such as media servers, robotic cameras, and spatial audio systems) to provide tracking for automated lights and projection mapping. With BlackTrax, RTTrPM is sent at a fixed rate of 100Hz.

BlackTrax RTTrpm

- BlackTrax sends out RTTrPM packets at a rate of 100Hz.
- BlackTrax by default sends out a heartbeat, or an empty RTTrP header with an RTTrPM signature if no Beacon or LED data is available in the current frame.
- BlackTrax can add and remove different modules at any given time.
- In the BlackTrax implementation of the Trackable module with Timestamp, the Timestamp value is equal to the frame ID of the cameras in the BlackTrax system, as determined by the TimeKeeper.
- Euler Orientation modules always send with an order of `0x0123 (X1, Y1, Z1)`.
- The Tracked Point modules correspond to the LEDs on a BlackTrax Beacon (trackable), the Index is either `0x01`, `0x02` or `0x03`.
- The context field in the RTTrP header is always set to the value of the current BlackTrax chapter (0x00000001, etc.), regardless of whether the current Trackable is present in the chapter, or if no Trackables are present in the RTTrPM packet (i.e. just the heartbeat is being sent). When in standby, the Context field is set to 0xFFFFFFFF.

- The Zone Collision Detection module should only send Zone Sub-Modules that the Trackable is actively colliding (inside) with. If a Zone Sub-Module is not sent, it is assumed the collision is not happening and the Trackable is outside of the Zone.

The BlackTrax Implementation of RTTrPM and RTTrPL in GitHub

Accessing External Protocols

There are many protocols supported by Designer, and expressions are one method to access that data in a way which can enhance interactivity and creativity.

It is quite common to use the data sources described here to control layers.

OSC

OSC is a common, versatile method for transmitting data within production environments. Designer interacts with OSC via OSC devices. OSC devices build a series of addresses which can be referenced by expressions.

> **Note**
>
> If the user wishes to directly control many fields on a Layer from an OSC controller, OSC Sockpuppet may be a more appropriate choice than manually entering expressions.

OSC works in terms of addresses and data values. One or more data values are stored at each address, in an array.

For example an external tool may send an OSC value to address `/container/parameter` and the value may be `5.0` - meaning, the value at `/container/parameter` is the floating point number `5.0`.

In order to access the value at that OSC address, the user must translate that address into expression-compatible syntax, as well as identifying the lookup as a request to find something from the OSC devices.

There are several expressions which would find the data in the example above:

- `osc:.container.parameterName` - The leading `.` character represents the leading `/` in the address. While this is not necessary, it can be convenient to remember that `/` characters are replaced by `.`s in OSC expressions.
- `osc:container.parameterName` - The leading `.` character is omitted in this example.
- `oscdevice_1:container.parameterName` - In this case, the specific device (“oscdevice 1”) is specified - if the user has multiple OSC devices set up, this helps disambiguate which OSC device specifically the user wants to gather the value from. Note that only OSC devices whos name begins with “osc” can be supported using this scheme.

OSC value arrays

Expressions also support more than one OSC argument per address. This allows the user to use things like XY touchpad to control colour X and colour Y values.

This uses array indexing syntax, e.g. `osc:my.address[0]` - this returns the first value sent to the address in a single message. Note this does not refer to values sent one after the other, the values need to be grouped together in a single OSC message to be addressable in this way.

In order to refer to both elements in an example scenario with a touchpad, the user would need to create two expressions:

- `osc:my.touchpad.xy[0]` - refers to the X component
- `osc:my.touchpad.xy[1]` - refers to the Y component

Missing OSC addresses

Before an OSC value has ever been sent to Designer on a specific OSC address, an expression which looks up that address will evaluate to `0.0`. That is, the expression `osc:this.was.never.sent` will evaluate to `0.0`. This is convenient in a number of circumstances, but sometimes finer-grained control is needed. For example in the case of string or text parameters, or where 0 is not the desired default value.

To achieve this, the same `osc:` syntax above can be changed to `valid_osc:` (or `valid_oscdevice_1:`) to check whether the OSC address has data associated with it.

For example: `valid_osc:my.address` will return `0.0` if the local instance of Designer has never received a value for that address, and `1.0` if it has.

> **Tip**
>
> `valid_osc:` can be used in `if` function calls to switch between behaviours based on whether the incoming OSC address is available.
>
> For example `if(valid_osc:my.address, osc:my.address, 1.0)` returns a default value of `1.0` if the OSC address `/my/address` has never been received, and the value at that address if it has.
>
> This allows the value at `/my/address` to reach `0.0` without ambiguity between receiving `0.0` and evaluating to `0.0` due to never being received.
>
> Large blocks of conditional logic using `valid_osc` can be abstracted and made easier to read using an expression variables device to build a function variable.

DMX

DMX512-derived network protocols are well supported by Designer. Designer interacts with DMX protocols using DMX Devices and associating them with the internal universe map held within Designer. Expressions use internal Designer universe numbers, which start from 1.

> **Note**
>
> If the user wishes to directly control many fields on a Layer from a DMX controller or lighting desk, DMX Sockpuppet may be a more appropriate choice than manually entering expressions.

It is useful to access DMX data from one of these internal universes using a variety of expressions. All addresses in expressions are 1-based (i.e. universe 1 is the first universe, and channels range from 1 to 512.) This is in opposition to other indexing within expressions, which are 0 based, so needs to be kept in mind.

The given `universe` and `channel` placeholders in the syntax demonstrations below are always integer literals (no variables.)

- `dmx:universe.channel` - Read 8 bit dmx value.
  - For example: `dmx:1.28` reads a single byte (0-255) from universe 1, channel 28.
- `dmx16:universe.channel` - Read 16bit dmx value (2 channels are used.)
  - For example: `dmx16:1.28` reads two bytes (0-65,535) from universe 1, channel 28 and universe 1, channel 29.
  - 16 bit data is read as coarse data in the first channel, and fine in the second. This is often referred to as “big endian”.

As with all name lookups, it is possible to continue to extend the expression with functions and operators to compute the desired result. e.g. `dmx:1.28 / 255` returns the same value scaled down to lie between 0 and 1.

When the expression has been accepted the layer property will turn green.

Missing DMX universes

Sometimes, expressions need to consider whether DMX has been received by Designer recently. For example, a desk may be offline, and the show should fall back to timeline-based sequencing.

To achieve this, the same `dmx:` syntax above can be changed to `valid_dmx:` to check whether the DMX channel has recent (within the last 10 seconds) data associated with it.

`valid_dmx:1.1` will return `0.0` if the local instance of Designer has not received any data on universe 1, regardless of whether any values actually changed, within the last 10 seconds. Note this is per universe, even though the syntax specifies the channel number.

> **Tip**
>
> `valid_dmx:` can be used in `if` function calls to switch between behaviours based on whether the incoming DMX is being received.
>
> For example, on a layer field `if(valid_dmx:1.1, dmx:1.1, self)` uses the field's sequencing if there was no DMX received on universe 1 recently, and the value of universe 1, channel 1 if there was.

MIDI

MIDI is often used as a control interface for some shows. It is possible to use MIDI devices as a source of data for expressions. All MIDI expressions are based on CC (Control Change) MIDI messages,

`mididevice:name.c[0]` - Get float value from mididevice control 0 (the first control in the device.)

For example, you have a MIDI device named bcf2000, which has a total of 32 controls. You want to read the third control value and multiply it by the animated value coming from the timeline.

The correct expression to use would be:

```
self * mididevice:bcf2000.c[2]
```

Note that the control values are the damped values provided by the midi device.

Audio Expressions

Using the Audio analyser device, it is possible to include audio-reactive elements within expressions. Once the audio analyser is set up to analyse an audio line, the audio line is available to provide frequency analysis to expressions.

`audioline:name.c[lower..upper]` - Get the max damped level from a selection of frequency ranges, inclusive of the `lower` value, and exclusive of the `upper`.

For example, a project contains an audio analyser set up with the line_left audio line selected. The lowest 10 (out of 127) frequency buckets are queried for the maximum damped value using the following expression. This would check for bass frequencies.

`audioline:line_left.c[0..10]`

What does the expression mean?

The diagram below is broken up into sections with a letter underneath. A description of each section is located below the diagram.

A: `255` = Multiplies the result by 255 (audioline frequency responses are in the range of `0.0` to `1.0`)

B: `audioline` = identifies the following text as an audio expression

C: `line_left` = which audio line to use

D: `.c[0..10]` = the frequency range to analyse

How do I choose which frequencies to analyse?

The audio spectrum has 127 steps across the frequency range.

The audio analyser builds 127 frequency buckets across the full frequency range of the line in.

Any frequency from 0 to 127 or a range of frequencies can be analysed using part D of the expression described above. For example,

- To analyse just the bass frequencies select a range similar to `[0..10]`.
- To analyse just the high frequencies select a range similar to `[100..127]`.

It is recommended to experiment with the range based on a range of recordings of expected live inputs to ensure the result is robust.

Accessing Resources

Disguise uses a concept called Resources to represent everything from a Layer to a Feed Rectangle in Designer. It is often useful to reference fields on various Resources within the system inside expressions.

Once a specific Resource has been identified, it can be referenced in order to access fields (and sub-fields) of that Resource, allowing the user to access almost all aspects of the designer system.

It should be noted that not all fields are documented, nor can they be definitely relied upon to continue to use the same name over versions of the software. This is because expressions expose a raw access to the internal data model used in designer, and it is possible that new features and improvements change the name of fields. It is rare that a feature is totally lost, and this document provides some guidelines on how a user can find the fields they require.

Once a value has been accessed from one or more Resources, then the values can be combined or modified futher using the functions and operators of the expression system. The text which makes up the reference to the Resource can be treated as any other variable held by the expression system.

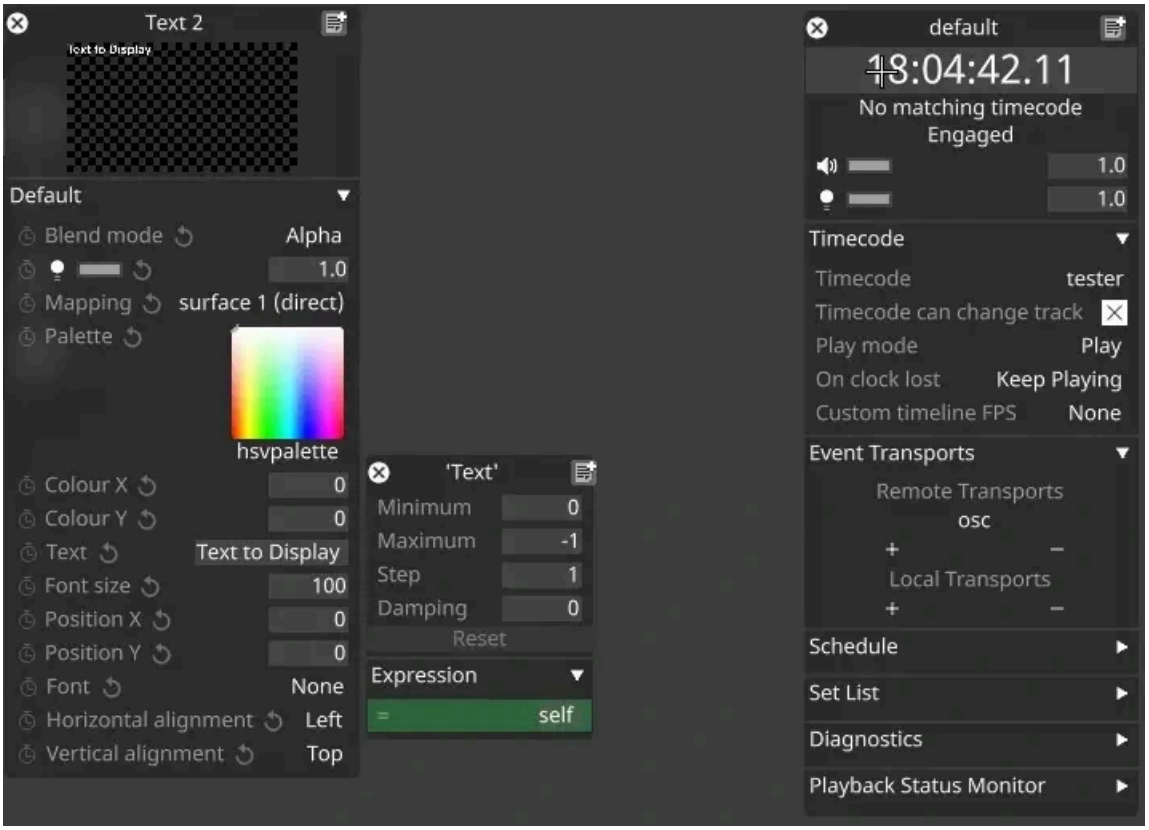
In summary, the general flow of accessing other part of Designer using expressions goes as follows:

1. Identify a piece of information in the designer user interface.
2. Create a connection to an expression field by using Alt + Left mouse drag from the element in the user interface.
3. Understand the reference expression that Designer builds.
4. Continue to add other expressions referencing other data needed to build the desired result.
5. Edit the expression to build the desired value from the various expressions noted earlier in the process.

Creating a connection using mouse drag

Often simply linking a value from another part of the user interface is enough for the expression writer to accomplish their goal.

There is a shortcut to build the expression using the user interface, accessed by holding the **alt** key and left-dragging the mouse from the field of interest to the field which can accept expressions.



> ⚠ **Warning**
>
> It is rare, but not all fields are valid for access in this way. Some fields in the user interface are not backed by real Resource fields, and therefore are not accessible via expressions.

Identifying Resources

In order for the expression to use whichever Resource the user wishes to, we first need to identify the Resource in question. There are two methods for doing this:

1. By type and name
2. By UID

Accessing Resources by name

The simplest and most readable method for building a reference to a known Resource in the system is to use the `type:name` syntax to refer to a Resource.

This is the technique used by Designer when the user asks it to write an expression for them by holding Alt and dragging the mouse from a field of interest to the expression. This is the recommended method used to learn the names of Resources and the general naming convention for fields of interest to the user.

For example, to reference a Projector, the expression `projector:"projector 1"` is used to refer to the Projector itself. To reference a video clip which originates from a file in a subfolder, `videoclip:"sample/george.jpg"` can be used.

> ⚠ Warning
>
> In older versions of Designer, the quoted name syntax is not available. It is instead possible to reference names using a “sanitised” identifier.
>
> The name of “projector 1” referenced in the expression above would be sanitised to `projector_1`. Names in expressions are unable to contain spaces, dashes and other characters, which are valid for names in Designer. Any character which is not a letter in the alphabet, a number or an underscore must be replaced by an underscore (`_`). In older versions, this is not available for `/` characters.

Accessing Resources by UID

UID stands for Unique IDentifier. The identifier is unique across the project and does not change when renaming the Resource. It is also used when the Resource is “unnamed” - this is when the Resource is embedded within another, larger Resource.

One use case for this technique is to have a persistent method for creating a reference to a Layer, even if that Layer were to be renamed. Note this will not follow any duplication or copying of Resources referenced this way.

In order to build a reference in this way, the user must follow the steps outlined here:

1. Open the editor for the Resource in question (e.g. click on a Layer.)
2. Right-click on the titlebar of the editor window which pops up.
3. Click “Copy UID” in the menu which appears.
4. Create an expression using the following function call: `getByUID(<paste the copied number here>)`

The end result is an expression which looks like `getByUID(0x123875234)` - this is an immutable reference to the Resource the editor was opened, and will only fail if the Resource in question is deleted.

Using this technique, it is useful to store these difficult to read expression in a function-type variable, instead of using them directly. The user can create an expression variables device or layer to hold the difficult to read `getByUID(...)` text. This allows easier named references to the Resource in the users other expressions. This is especially useful if the user wishes to refer to the same Resource in multiple locations.

Accessing Resource fields

Once the user has found the Resource they wish to reference for data, then accessing fields is accomplished by using the `.` operator. This operator acesses a named field on a Resource or most other objects in the system.

For example, all Resources have a `description` field, which is sometimes useful to validate that the user has accessed the Resource they intended to. In that case, the user would type the expression `projector:projector_1.description` - this produces a text result which contains the real name of the Resource (without the `_` character decoration.) i.e. “projector 1”.

Common Resource fields include:

- `offset` - the position of an object in the stage, relative to its parent. Further specify the x, y or z coordinates by using the `.` operator again e.g. `projector:projector_1.offset.x`
- `rotation` - the rotation of an object in the stage, relative to its parent. Available as individual euler angles e.g. `projector.projector_1.rotation.y`

Many other fields exist on Resources in the system, and while no guarantee can be given to their long-term stability, the data provided is exactly what designer uses internally, so there can be no doubt as to its accuracy.

Accessing fields set to None

In some cases, it is possible to access fields which are set to None in the user interface. This means that there is no object to find in that field. Attempting to access properties when there is no object will fail and the expression will not evaluate. It is recommended to ensure this does not occur.

It is possible to test if an object is valid by using an `if`, for example `if(transportmanager:default.timecode, "has timecode", "no timecode")` but there is no method to conditionally access fields - i.e. the expression `if(transportmanager:default.timecode, transportmanager.default.timecode.description, "no timecode")` would fail.

Expression Backward Compatibility

In release r27.10, a number of backwardly-incompatible changes were made to the expressions system. This page provides a reference for any projects which used expressions (specifically variable assignment) before that release.

r27.10 changes

- Expression variables are cleared at the start of every frame. This ensures that variables are never stale values from other parts of the timeline or the results of previous frames evaluation.
- It is no longer possible to redefine a variable multiple times within the same frame - this is now an error and the expression error will inform you which object defined it earlier in the frame.
- Expressions are no longer case-insensitive - variables, fields and functions are looked up in a case-sensitive manner, and the identifiers test and Test are different.
- Expressions which format strings now require a `format::` prefix (which is automatically added during upgrades of previous projects, and added when dragging arrows to populate expressions.)
- It is now possible to call functions on Resources within expressions. This is an advanced feature and not intended for normal use. For example you can use the expression `track:track_1.sectionToBeat(1)` to return the time in beats for the second section on track 1. These functions are not documented due to the internal and potential for change in future.

Handling undefined variables

The most-impactful change described above is the change to the lifetime of variables. Previously, it was possible to define a variable at the start of an early checkout track and leave it active for the rest of the show run. This was dangerous for a number of reasons, including stale data, extra latency, failure if machines left & rejoined the session, etc.

To work around cases where variables were used this way, Disguise recommends the following:

Using an expression variables device

Expression variables devices define variables and ensure they are always available. This is useful to ensure the variables are always available, but for dynamically changing values, this can pose some issues. To get started, create an expression variables device.

- For static values, select the type (usually float) and enter the desired value.

- For dynamic (e.g. externally controlled) values, select the function type, and enter the expression which controls the dynamic value. Everywhere the variable was previously used, it now needs to be called (since it is a function.) i.e. `myvar` becomes `myvar()`

Using an expression variables layer

Expression variables layers define variables for the duration they exist on the timeline. This can be easy to work with in a multi-transport or a single-track show during the upgrade process. To get started, create an expression variables layer.

Expression variables layers need to be below all uses of the variables in the composition stack.

The variables are only available while the layer is under the the playhead.

Updating existing assignments in other layer types

Variable assignment continues to work, but care must be taken to ensure the variables are defined before they are used.

Variables are defined in layer composition order, and from top to bottom in field order within each layer. Therefore a layer which uses a variable which it defines itself must define that variable in a field closer to the top of its layer editor.

Note composition order is bottom to top for Layers and Transports (when using multi-transport.) Within layers, the fields are evaluated top-to-bottom.

Related changes

In addition to the changes to the core expression system, the new expression variables layer and device was added. This allows you to:

- Create any number of groupings of global variables within multiple expression variable devices within the device manager. These variables will be available across all timelines.
- Create time-dependent variables using any number of expression variable layers on tracks. The variables are available to layers above the expression variable layer in the compositing order.
- Create string variables which contain predefined text values which you want to refer to elsewhere.
- Create float variables which contain predefined numeric values which you want to refer to elsewhere.
- Create function variables which can be called using `myVariable()` calling syntax, which are evaluated at the point they are called at, to provide shared expression logic.

Common Datatypes

There are a number of common datatypes available in expressions. These allow users to work with compound values more easily.

Colour

The function `Colour(r, g, b, a)` allows the creation of a `Colour` object. This object has `r`, `g`, `b`, `a` fields, which are floating point values, which are expected to be between 0 and 1.

`Colour.mix(otherCol, ratio)`

Mixing Colour values is a common operation. The `mix` function performs a lerp on each of the `r`, `g`, `b`, `a` components using the given `ratio`. An example expression should help explain how it is used:

```
Colour(1, 0, 0, 1).mix(Colour(0, 1, 0, 1), 0.5)
```

This produces a `Colour` value which contains `r=0.5, g=0.5, b=0.0, a=1.0`, which can then be referenced elsewhere in the system.

`ColourFromHSL(hue, saturation, lightness)`

This function is convenient for creating a colour value from a Hue, Saturation, Lightness wheel representation of colour. It produces a regular `Colour` object which contains RGB components which correspond to the HSL values. For example `ColourFromHSL(0.0, 1.0, 1.0)` is equivalent to `Colour(1.0, 0.0, 0.0, 1.0)` because the 0 degree hue is a red primary.

- Hue is a float value representing the number of degrees around the edge of a colour wheel. The value is between 0 and 360 (which are equivalent to one another).
- Saturation is a float value from 0 to 1. As the value approaches 0, the resulting colour approaches the Lightness value in grey.
- Lightness is the intensity of the colour. It is also a value from 0 to 1, where 0 is black, and 1 is full intensity. This is also called ‘value’ in some software.

Vec2 (float2)

The function `Vec2(x, y)` allows the creation of a `Vec2` object. This object has `x`, `y` fields, which are floating point values.

`Vec2` is aliased by `float2` for convenience.

Vec3 (float3)

The function `Vec3(x, y, z)` allows the creation of a `Vec3` object. This object has `x`, `y`, `z` fields, which are floating point values.

`Vec3` is aliased by `float3` for convenience.

Vec4 (float4)

The function `Vec4(x, y, z, w)` allows the creation of a `Vec4` object. This object has `x`, `y`, `z`, `w` fields, which are floating point values.

`Vec4` is aliased by `float4` for convenience.

Vector functions

The `Vec<N>` family of data types have a number of convenience functions exposed:

`v1.dot(v2)`

Performs the dot product between 2 vectors.

`v1.abs()`

Provides the absolute value of the components.

Vector properties

Vector types have computed properties, as well as functions. These are accessed without calling.

`v1.minComponent`

Provides the minimum value of the components

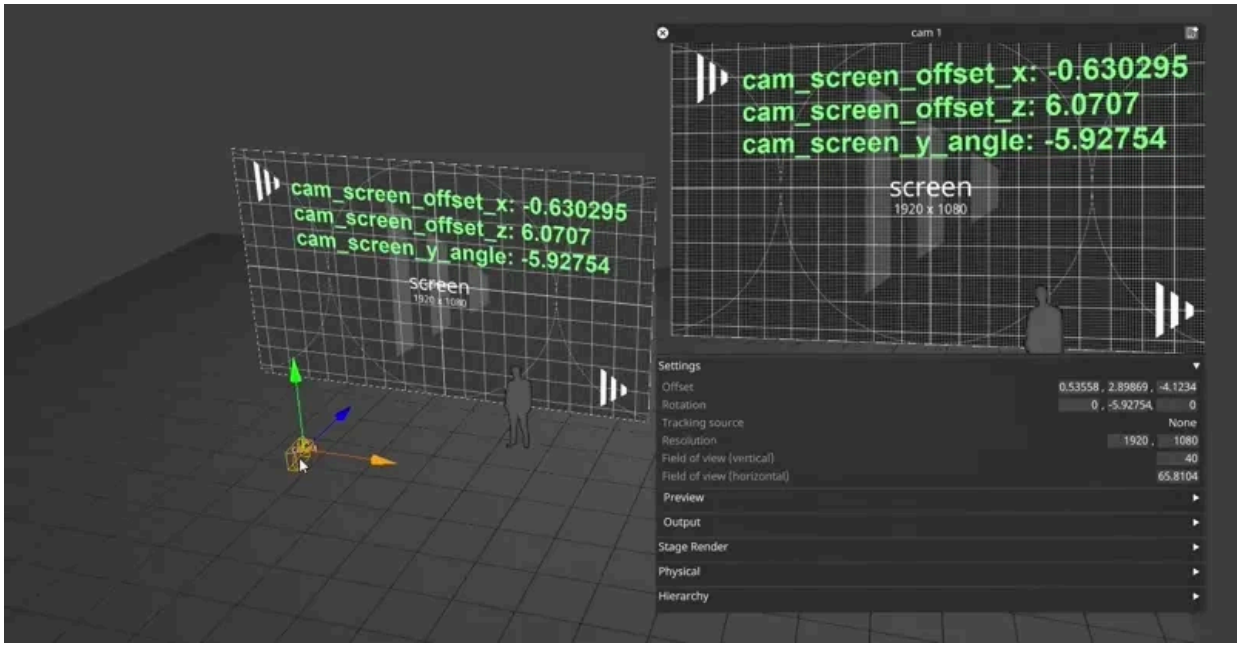
`v1.maxComponent`

Returns the minimum value of the components.

Using Expressions to drive camera angle

In this example, we will build a system which drives the rotation of a camera to always point at a specific screen.

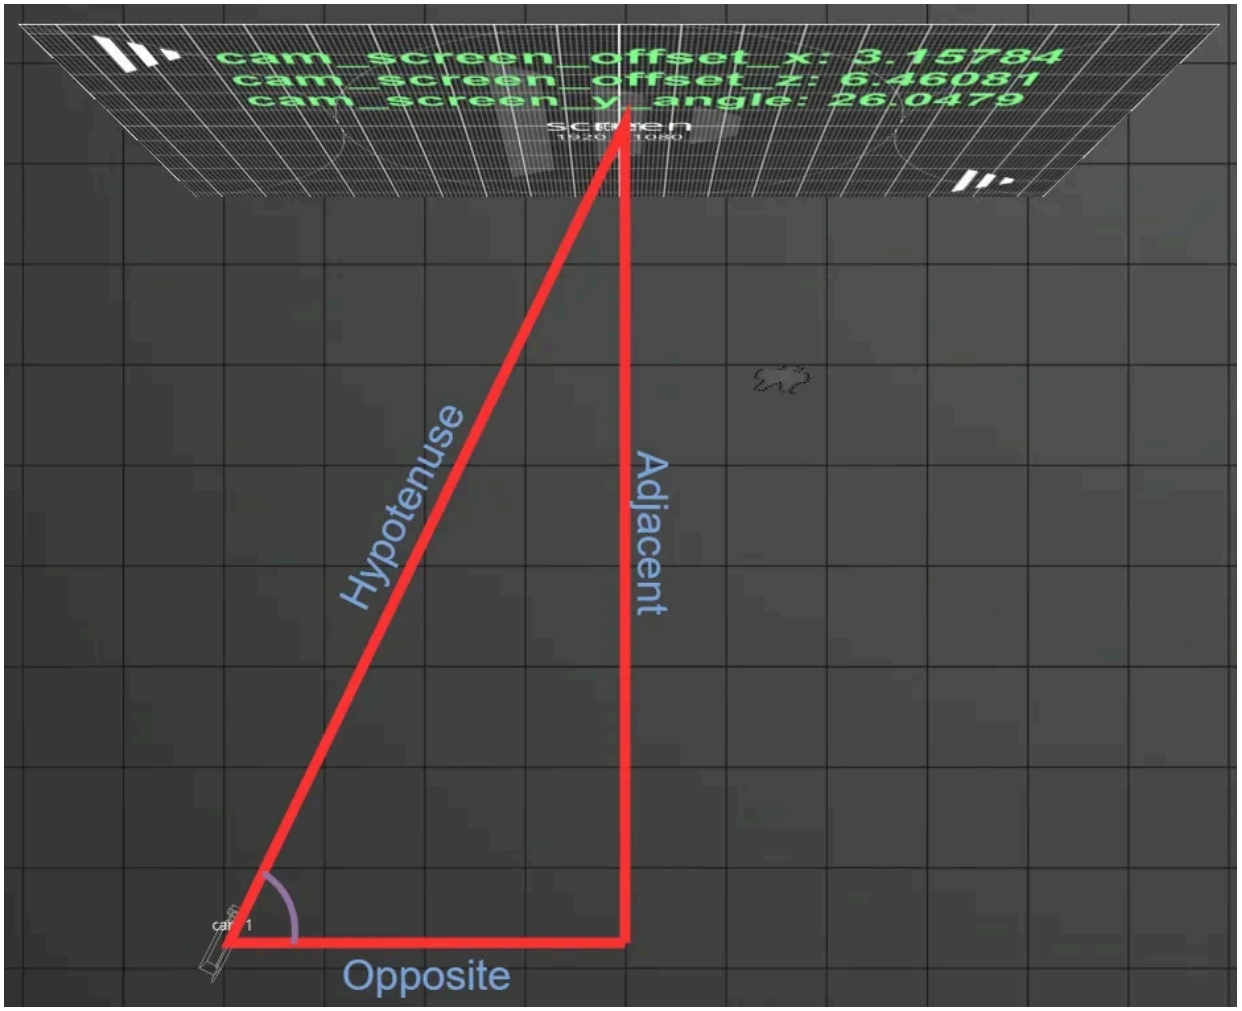
The goal is to ensure that a camera will always point at a given screen, no matter where either one moves along the floor. The example doesn't attempt to compensate for changes in height, only position changes on the X and Z axis within the stage.



How the example works

The idea is to build a right-angled triangle laying on the floor between the camera and the target screen. Using trigonometry, we are able to calculate the angle from the camera to the screen.

The basic functionality of this example is provided by the function `atan2`. We use it to calculate the opposite angle of the triangle we construct from the relative positions of the camera and target screen.



Determining the angle

In order to construct the triangle above, we must build the two straight sides, one for the X axis (side to side) and one for the Z axis (forward and back.) We will do this by first creating an ExpressionVariables device to hold our variables, and define each side individually.

Constructing the triangle sides

The two expressions will be named `cam_screen_offset_x` and `cam_screen_offset_z`. These will be function variables, that is they are small expressions which can be used later in other expressions to aid readability, validate the results are as expected and show the thought process which built the system.

Let's look in detail at how to calculate `cam_screen_offset_x`

```
ledscreen:screen.offset.x - camera:cam_1.offset.x
```

This is the difference between the camera's position on the X axis compared to the screen's X position. This creates the opposite side of the triangle above.

We can repeat this for the Z axis by simply replacing the `.x` with `.z` for both the screen and camera. This creates the adjacent side of the triangle.

> **Tip**
>
> The expressions above use object-space offsets. If the expression writer needs to consider the object hierarchy, the sub-expression `offset` could instead be substituted with `world.getTranslation()`. This produces the position of the object in world space, which is comparable across object hierarchy positions.
>
> The result of `world.getTranslation()` is the same as `offset` if the objects are parented to the stage.

Calculating the angle

Once the sides of the triangle are constructed, we are able to use trigonometry to build the desired angle. We will again use an expression variable to calculate this and give it a name we can use elsewhere, in this example, we will use `cam_screen_y_angle`.

This expression needs to convert from the side lengths to the desired angle. This is accomplished by using the `atan2` function, which takes 2 arguments, `x` and `y`. It computes the inverse of the tangent which would be created by `x / y`, however it is also aware of the sign of these values and can compensate for that, giving accurate values for any inputs.

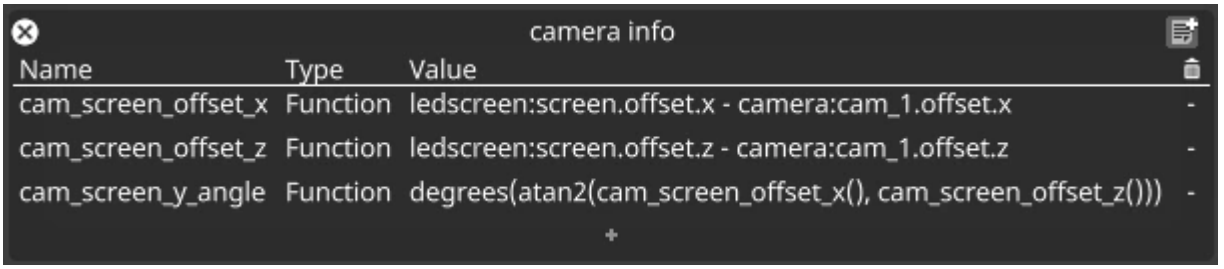
Since we know that the tangent of the angle is equal to opposite / adjacent, we can use the `cam_screen_offset_x()` as the opposite, and `cam_screen_offset_z()` as the adjacent. Therefore:

`atan2(cam_screen_offset_x(), cam_screen_offset_z())` will return the opposite angle, in radians. Since we want to convert to degrees we can wrap that further in a call to `degrees`, like so:

```
degrees(atan2(cam_screen_offset_x(), cam_screen_offset_z()))
```

The expressions in place

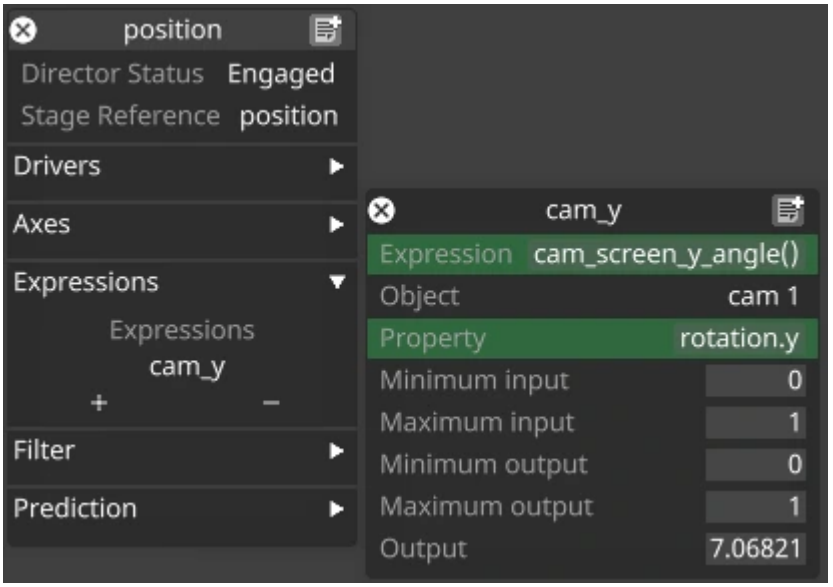
Once the above expressions are determined, the expressions variable device will look something like the following:



Applying the angle

Once the angle has been determined, the expression `cam_screen_y_angle()` would evaluate to the angle the camera's Y rotation field would need to be set to in order to point at the target screen.

We can accomplish this by creating a position receiver device, and an axis expression to control the camera's Y rotation.



Further work

It can be possible to extend systems like this, for example the target of the camera can be switched by replacing the `ledscreen:screen` with yet another function variable which returns the target screen. This itself could be driven by an External protocol and an `if` function to select which screen is returned.

Alternatively, the system could be duplicated to allow for targeting upon changing the relative height of the camera & screen.

Expressions Overview

Expressions can be used to build dynamic behaviour and link parts of Designer together. Expressions are evaluated every frame and result in "values" which are either numbers or text. The value is used in the context of the expression. For example, in layers the value is used to populate the property the expression is attached to.

Expressions are a small programming language which allows the user to build custom behaviours into the software.

They are used in a number of areas, such as layers and automation.

When you type in an expression, the property field turns green when the expression has been correctly understood. If there is a mistake, the property field turns red; moving the mouse over the property field will open up a text message telling you what went wrong.

An expression can also be temporarily disabled, in which case the field turns a muted green to show that the formula is retained but not currently being evaluated. See Enabling and disabling an expression.

Creating Expressions without writing code

It is possible to create some basic expressions which reference other parts of Designer by Creating a connection using mouse drag. This is the easiest way of getting started with expressions.

Expression syntax

Expressions mimic common syntax found in many programming languages. Expressions consist broadly of:

- constants (a number like `123` or text such as `"hello world"`.)
- variables (a symbol e.g. `my_value` which refers to a value defined elsewhere.)
- functions (a behaviour which generates a value from other inputs e.g. `max(1, 2)` which results in the higher value, 2.)
- operators (a mathematical operator which performs arithmetic on values, e.g. `+` or `-`.)

There are a number of predefined functions and variables documented in the relevant locations.

It is also possible to define your own functions and variables by using an expression variables device or expression variables layer.

Expressions are case-sensitive, so a variables or functions called `hello` are distinct from another called `HELLO` or yet another called `Hello`, and so on.

Prefixes

Prefixes are used to alter the result of an overall expression. They take the form of a word, followed by two colon characters, followed by an expression, like so:

```
scale::<expression>
```

Apart from text formatting, below, layer expressions also use prefixes.

Text formatting

Text-type expressions may wish to forego mathematical evaluation and instead want to embed values within plain human readable language. It is possible to change the expression syntax from evaluating variables to 'string interpolation' scheme. This is a piece of text with placeholders. Upon evaluation, the placeholders are evaluated as expressions and formatted in-place in the text.

For example, the following expression is mostly text, but a dynamic expression is embedded within it. The focus changes from evaluation to presentation.

```
format::This is my information: The system has been running for {int(uptime / 60)} minutes and {int(uptime % 60)} second
```

Would result in

```
This is my information: The system has been running for 2 minutes and 15 seconds
```

Text formatting is documented here

Functions Reference

Functions help perform actions with values in expressions, this page documents the predefined functions to help with a variety of tasks.

Logic Functions

These functions are useful for building conditional logic into expression results.

They are paired with 2 constant values `true` and `false` to represent positive and negative logic signals, mostly used for testing your expressions behave as you expect.

Values evaluate to true if they result in a non-zero result. That is, only `0` evaluates to false. Comparison operators return true or false as expected from their mathematical definitions.

`if` - Conditional evaluation

Usage: `if(cond, if_true, if_false)`

- `cond` (boolean) : The value to check
- `if_true` (anything) : The value to return if `cond` is true
- `if_false` (anything) : The value to return if `cond` is false

Evaluates the condition `cond` and returns one of the 2 following values, depending on if it evaluates to true or not.

For example, this function can be used as a part of a larger expression to 'switch' between different values. For example `if(osc:myaddr > 0, osc:myaddr, self)` only allows the animated values in a layer if the value at OSC address `/myaddr` is greater or equal to `0`.

The graph shows the result of `if(x > 0.5, 1, -1)`

`and` - Logical AND operation

Usage: `and(x, y)`

- `x` (number) : The first value to check
- `y` (number) : The second value to check

Returns 1 if both `x` and `y` test as true.

The graph shows the result of `and(x, 1)`

`or` - Logical OR operation

Usage: `or(x, y)`

- `x` (number) : The first value to check
- `y` (number) : The second value to check

Returns 1 if either `x` or `y` test as true, or both.

The graph shows the result of `or(x, 0)`

`step` - Activation function

Usage: `step(x, y)`

- `x` (number) : The first value to compare
- `y` (number) : The second value to compare

Returns 1 if `x >= y`, otherwise returns 0.

Can be used as a part of a larger expression to 'turn on' a source of data. For example `step(osc:myaddr, 0.5) * self` only allows the animated values in a layer if the value at OSC address `/myaddr` is greater or equal to `0.5`.

The graph shows the result of `step(x, 1)`

Trigonometric functions

These functions are useful for working with angles and geometry.

A predefined constant `pi` contains the value of PI, approximately `3.14159`.

`sin` - Trigonometric sine

Usage: `sin(x)`

- `x` (radians) : The angle to convert

Returns the sine of the given angle

`cos` - Trigonometric cosine

Usage: `cos(x)`

- `x` (radians) : The angle to convert

Returns the cosine of the given angle

`tan` - Trigonometric tangent

Usage: `tan(x)`

- `x` (radians) : The angle to convert

Returns the tangent of the given angle

`asin` - Trigonometric arcsine

Usage: `asin(x)`

- `x` (sine) : The sine to convert

The arcsine, or inverse of sine. Converts from the sine of an angle (x) to the initial angle, measured in radians.

The sine of an angle can be thought of as the y coordinate of a point on the circumference of a unit circle.

`acos` - Trigonometric arccosine

Usage: `acos(x)`

- `x` (cosine) : The cosine value to convert

The arccosine, or inverse of cosine. Converts from the cosine of an angle (x) to the initial angle, measured in radians.

The cosine of an angle can be thought of as the x coordinate of a point on the circumference of a unit circle.

`atan` - Trigonometric arctangent

Usage: `atan(x)`

- `x` (tangent) : The tangent value to convert

The arctangent, or inverse of tangent. Converts from the tangent of an angle (x) to the initial angle, measured in radians.

`atan2` - Trigonometric arctangent (2-argument variant)

Usage: `atan2(x, y)`

- `x` (distance) : The position along the X axis to build an angle from
- `y` (distance) : The position along the Y axis to build an angle from

This is equivalent of `atan(y / x)`, but in the case where x is 0 or either values could be negative, this provides an accurate angle.

The graph shows the result of `atan2(x, -4)`

This function is useful to determine the angle between two objects on the plane of a given axis.

`radians` - Convert from degrees to radians

Usage: `radians(x)`

- `x` (degrees) : The angle to convert

This converts from degrees to radians, which is then suitable for use in the above functions.

The conversion is a linear function - simply multiply by `pi / 180`.

`degrees` - Convert from radians to degrees

Usage: `degrees(x)`

- `x` (radians) : The angle to convert

This converts from radians to degrees, which is then suitable for displaying to humans who are used to working in degrees.

The conversion is a linear function - simply divide by `pi / 180`.

Mathematical functions

`exp` - Exponent

Usage: `exp(x)`

- `x` (number) : The exponent

Raise `e` (Euler's number, approximately equal to `2.71828`) to the power of `x`. Note `e` is also a constant in disguise expressions.

`log` - Natural logarithm

Usage: `log(x)`

- `x` (number) : The value

Takes the logarithm of the input number `x` against the base `e`. This means this is the inverse of `exp`.

`log10` - Base 10 logarithm

Usage: `log10(x)`

- `x` (number) : The value

Takes the logarithm of the input number `x` against the base `10`. This can be used to get the number of digits after the most significant number (e.g. `log10(1000)` returns `3`.)

`sqrt` - Square root

Usage: `sqrt(x)`

- `x` (number) : The value

Returns the value which, when multiplied by itself, results in the input.

`pow` - Power function

Usage: `pow(x, y)`

- `x` (number) : The base
- `y` (number) : The exponent

Returns a value which is x raised to the power of y. To implement `exp`, one would write `pow(e, x)`.

`abs` - Absolute value

Usage: `abs(x)`

- `x` (number) : The signed value

Returns the absolute (positive) number, no matter the sign of the input value.

`floor` - Rounding down

Usage: `floor(x)`

- `x` (number) : The value

Returns the input value, rounded down to the integer value below it.

`ceil` - Rounding up

Usage: `ceil(x)`

- `x` (number) : The value

Returns the input value, rounded up to the integer value above it.

`max` - Maximum value

Usage: `max(x, y)`

- `x` (number) : A candidate value
- `y` (number) : A candidate value

Returns the maximum of the 2 inputs provided.

The graph shows the result of `max(x, 2)`

`min` - Minimum value

Usage: `min(x, y)`

- `x` (number) : A candidate value
- `y` (number) : A candidate value

Returns the minimum of the 2 inputs provided.

The graph shows the result of `min(x, 2)`

`clamp` - Restrict within the given range

Usage: `clamp(x, min, max)`

- `x` (number) : The value to clamp
- `min` (number) : The minimum bounds of the operation
- `max` (number) : The maximum bounds of the operation

Returns the input value `x` if it is between `min` and `max`, otherwise it remains at those values.

The graph shows the result of `clamp(x, -1, 2)`

`lerp` - Remap a value to a new range

Usage: `lerp(low, high, amount)`

- `low` (number) : The value returned when `amount` is 0
- `high` (number) : The value returned when `amount` is 1

When `amount` is between `0` and `1`, the function returns some fraction between low and high. When `amount` is outside the range of `0` and `1`, the function linearly interpolates outside the range of low and high.

The graph shows the result of `lerp(2, 4, x)`

Integer operations

Normal operators like `%` and `/` are performed using floating point. This means for example that `3 / 2` would result in approximately `1.5`.

However there are cases where we want to consider the operations in terms of whole numbers.

`%` - Remainder operator

Usage: `x % y`

- `x` (number) : The numerator
- `y` (number) : The denominator

Operator for getting the remainder after integer division of two numbers (e.g. `5 % 2 == 1`)

The graph shows the result of `x % 2`

`int` - Integer conversion

Usage: `int(x)`

- `x` (number) : The number to convert

Returns a rounded-down version of the input value. This is equivalent to `floor`.

The `int()` function can also convert a string to an integer. For example, `int("42")` returns `42`. Additionally, `int()` accepts an optional second argument that specifies the base of the number in the given string. This is useful when working with non-decimal representations, for example:

- Hexadecimal (base 16): `int("FF", 16)` returns `255`
- Octal (base 8): `int("77", 8)` returns `63`
- Binary (base 2): `int("101", 2)` returns `5`

`idiv` - Integer division

Usage: `idiv(x, y)`

- `x` (number) : The numerator
- `y` (number) : The denominator

Returns an integer version of the numerator divided by an integer version of the denominator, returning an integer value.

The graph shows the result of `idiv(x, 2)`

Timecode functions

These functions convert a time value in seconds into a human-readable timecode string. They are particularly useful when combined with video layer properties such as `tSecElapsed` and `tSecRemaining` (see using video layer time in expressions).

`formatTimecode` - Format seconds as timecode

`formatTimecode(seconds, fps)`

- `seconds` (number) — the time in seconds to format
- `fps` (number) — the frame rate to use for the frames component

Converts a time value in seconds to a timecode string in `hh:mm:ss.ff` format, where `ff` is the frame number derived from the given `fps`.

For example, to display the elapsed time of a video layer named `video` as a timecode string:

```
formatTimecode(module:video.tSecElapsed, module:video.video.fps)
```

`formatTimecodeDF` - Format seconds as drop-frame timecode

```
formatTimecodeDF(seconds, fps)
```

- `seconds` (number) — the time in seconds to format
- `fps` (number) — the frame rate to use for the frames component

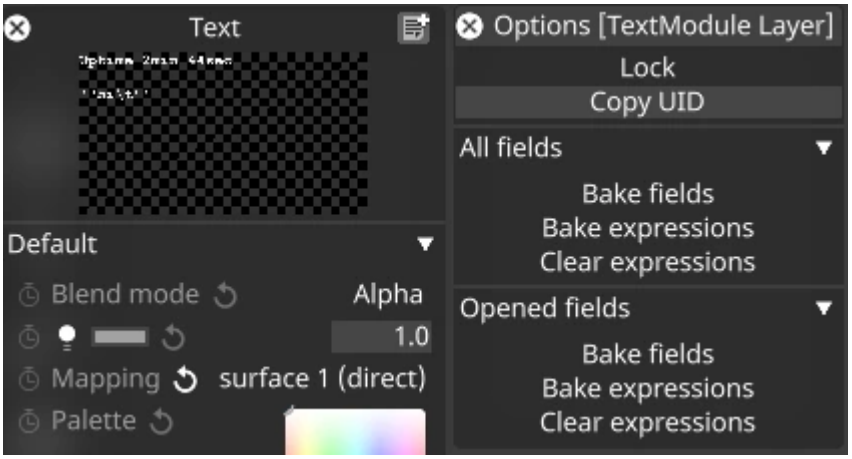
Converts a time value in seconds to a drop-frame timecode string. This is intended for use with 29.97fps drop-frame workflows (SMPTE 2997DF).

Resource access function

`getByUID` - Resource access

Accessing properties from Resources in the system is a very powerful method for enhancing expressions. Referencing resources is normally performed by name. However, it's possible to refer to Resources by UID instead. This allows for a strong reference to the original Resource, at the expense of readability. The benefit of this less readable approach is that the reference remains even if the Resource (e.g. a Layer) is renamed. Expressions are not updated in response to rename operations. This is described further in Accessing Resources by UID.

A user will right-click the title bar of a Resource editor, and select `Copy UID`. They will then paste that UID as the argument of this function.



For example: `getByUID(0x123456789012345).description` returns the name of the Resource the user right-clicked on.

The set of properties on Resources is subject to change. See Accessing Resources for more information.

Using Expressions in Layers

To set up an Expression, right-click the property you want to control in the Layer editor.

This will open up the Metafield which shows min/max/step, which allows you to edit the limits of the property and the value step used while animating.

Below the min/max/step properties is a field called Expression, which initially contains a single word: `self`. This is the expression we will be editing.

The default expression: `self`

`self` is a special variable defined in the context of Layer expressions. It is not valid or may mean something different in other places which accept expressions. `self` refers to the normal animated value of the property the expression is controlling. The default expression being `self` means that by default the value set on the Layer property is used as-is, without modification.

`self` is a number for numeric properties, and text for text properties.

By deleting the value completely, disguise will auto-fill `self` as the value of the expression. Therefore, simply deleting the text in the Expression field is a quick way of resetting back to the default behaviour of using the Layer property as-is.

Using `self` in expressions

`self`, like many other variables can be built into more complex expressions. A simple expression might be `self * 2`, which doubles the animated value of the property.

Other variables in layer expressions

Some variables are defined by the system for convenience. In the case where the expression is evaluated by a layer, the following variables are available:

- `time` - track time in seconds since the start of the track.
- `self` - the keyframed value, as described above.
- `self.min` - minimum value for this field.
- `self.max` - maximum value for this field.

Example: Emergency layer fade down

A common use case is to use an expression for the brightness property on a Layer. For example, it may be necessary to have a fader or other live control have an emergency cut-out option for live video. In this example, we will say that this control is implemented using OSC, but could be done with any live input protocol supported by disguise.

```
self * (1 - osc:video.emergency_cut_out)
```

In this example, we take the normal animated value of the property (`self`) and multiply it by 1 - the value sent on OSC address `/video/emergency_cut_out`. Normally, that OSC value would be `0`, and so `1 - 0` is `1` and `self * 1` is just `self`, so normal animated values are respected.

However, if `/video/emergency_cut_out` is set to `1`, then the expression will evaluate to `self * 0` which, since any number multiplied by 0 is 0, would ensure the brightness of the layer is 0 and therefore will not be shown.

Using expressions to control layers

> **⚠ Warning**
>
> Warning: Expressions need special handling for Resource names that have spaces in them, for example a Layer called “video explosions”. Expressions require the user to refer to it as “video_explosions” instead (replacing the space with an underscore `_`).
>
> Names can only contain the characters `a-z A-Z 0-9 _`.
>
> This can cause conflicts when two Resources share the same name after normalisation, and it may be necessary to rename layers to ensure they are uniquely identifiable if they are being used in expressions.

It is possible to have designer write simple linking expressions automatically. The method is to hold the Alt key and drag the mouse from the desired value in the designer GUI to the layer field you wish to control. It is possible to do this from most places in the GUI, including other layers. (To open multiple layers at the same time, hold Ctrl and click on the Layers you wish to open simultaneously.) See Creating a connection using mouse drag for more information.

Example: Link brightness between multiple layers

Open an editor for the 2 layers the user wishes to link, and Alt+Drag from one layer's brightness property to the other's. Designer will write an expression referring to the first layer's brightness into the second (destination) layer.

From that point on, animation and edits of the layer the user dragged from controls both layers. The process can be repeated (we recommend dragging from the same first layer every time, not in a chain.) to control as many layers as the user desires.

Note that layer references are only valid for the period of time that the layer is active on the timeline. Attempting to access a layer property for a layer which is not currently under the playhead will fail. This is because there is no coherent value for a layer property outside its timeline extents.

Using video layer time in expressions

Video layers expose time-based properties that can be accessed in expressions. For a video layer named `video`, the following properties are available on the module:

- `module:video.tSecElapsed` — time in seconds since the current clip started playing
- `module:video.tSecRemaining` — time in seconds until the current clip ends

These return values in seconds, which can be used directly in calculations or formatted as timecode using the `formatTimecode` and `formatTimecodeDF` functions.

For example, to display the elapsed time of a video clip as a timecode string in a text expression:

```
format::Elapsed: {formatTimecode(module:video.tSecElapsed, module:video.video.fps)}
```

Or to trigger an action when less than 5 seconds remain:

```
if(module:video.tSecRemaining < 5, 1, 0)
```

Example: Using a video layer frame number to animate brightness

Video Layer's `frameNumberDisplay` provides the current frame readout at the top of the video layer. This isn't something the user needs to remember - instead, open the Layer editor for a video module named `video`. Alt + Drag from the frame readout at the top of the layer, and drop it onto the brightness property of another layer (e.g. a chevron layer.)

This will result in the following expression being written into the brightness property of the Chevron layer: `module:video.frameNumberDisplay`.

That property can then be used as a variable by the expression. For example, set the brightness to 0 until the video reaches frame 50, then snap to 1:

```
if(module:video.frameNumberDisplay < 50, 0, 1)
```

Or to smoothly fade up over the first 50 frames:

```
min(1, lerp(0, 1, module:video.frameNumberDisplay / 50.0))
```

Enabling and disabling an expression

Every expression field has an `=` button beside its text box. Click it to temporarily disable the expression: the label changes to `//`, evaluation is suspended, and the field falls back to its underlying keyframe value. The formula itself is preserved, so you can switch it back on at any time by clicking the button again. While an expression is disabled, the field is tinted a muted green to distinguish it from an active, evaluating expression.

This is a non-destructive alternative to clearing the formula or baking the expression — both of which would lose the original expression or strip its external control.

To toggle every expression on a layer at once, right-click the layer's title bar. A single **Enable expressions** / **Disable expressions** button appears under each grouping — All fields, Opened fields and Visible fields — and its label reflects the current state of the expressions in that grouping.

The disabled state is saved with your project, so it is preserved across save and reload.

Layer prefixes

Layer prefixes make the job of targetting a potentially unknown range of values expected by a given field easier. They are used by the built-in alt+drag functionality for building readable expressions from common components like DMX or MIDI inputs.

The field range is available as variables in `self.min` to `self.max`.

- `limit::` - Limits result to the field range. This is equivalent to `clamp(expr, self.min, self.max)`
- `scale::` - Scales 0 - 1 values to the field range, ignoring limits. This is equivalent to `lerp(self.min, self.max, expr)`

Linking Layers with Expressions

Use this Expression to link one layer to another:

Navigate to the expressions text field of any numerical property and type in:

```
module:NameOfModule.brightness*0.5
```

This expression will take the brightness value of the other layer called NameOfModule and multiply it with 0.5.

> **Note**
>
> **Please note**: You cannot have any spaces in the layer name when using the name in the expression. This will generate a syntax error marked by a brown expressions field.

Alternately, there are additional methods for using Expressions to link layers:

- Open a field on the source layer and type in the name of the attribute `= self` (for example `posy = self`)
- Open the properties window for the layer to be linked and type in the name of the attribute (example: `posy`)
- Now, when you change the numeric value on the source layer, the same attribute in the linked layer will also be adjusted at the same time.

See Creating a connection using mouse drag to create the Expression automatically.

Note: Hold down **Ctrl** to open up multiple layers or keyframe editors.

Operators

Operators allow the expression writer to perform mathematical operations on numbers, compare values, and work with variables within an expression.

There are standard expressions used by many programming languages which are available in Designer expressions. This page provides an overview and brief description of the available operators.

Comparison operators

Comparison operators are useful when working with Logic functions.

- *less* `<` - (`a < b`) returns true if `a` is strictly less than `b`
- *less equal* `<=` - (`a <= b`) returns true if `a` is less than or equal to `b`
- *greater* `>` - (`a > b`) returns true if `a` is strictly greater than `b`
- *greater equal* `>=` - (`a >= b`) returns true if `a` is greater than or equal to `b`
- *not equal* `!=` - (`a != b`) returns true if `a` is not equal to `b`
- *equal* `==` - (`a == b`) returns true if `a` is exactly equal to `b`

Note that for non-integer numeric values (i.e. floating point values) comparisons can be surprising. When comparing floating point values, consider reworking the comparison to be fuzzier. For example, `a == b` could be rewritten to be `abs(a-b) < 0.01` which ensures that even if there is a tiny difference between the numbers, the comparison does what the expression writer would expect.

Comparing text

The comparison operators also work on text (string) values. `==` and `!=` compare two strings by their exact contents, while `<`, `>`, `<=` and `>=` compare them alphabetically (lexicographically). For example, `"apple" < "banana"` returns true.

Text and numbers cannot be compared with each other. An expression such as `"5" == 5` results in an error, as there is no automatic conversion between the two. Text values also only support the comparison operators. Arithmetic operators such as `+` cannot be used to combine strings.

This is useful for reacting to incoming text, such as a string sent to an OSC address. For example, `if(osc:.address == "go", 1, 0)` returns `1` when the value received at the OSC address `/address` is the text `go`, and `0` otherwise.

Logical operator

The logical not operator is useful when working with Logic functions.

- *not* `!` - (`!a`) flip the truth value of the variable or sub-expression following the operator (true->false, and false->true)

Index operator

The index operator allows indexing into arrays of data.

- *square brackets* - `[]` - (`array[i]`) returns the `i` th value within the `array` variable

It is also possible to index into arrays using negative indexes - `array[-1]` would select the last item in the array, and `array[-2]` would select the second from last. Note that the array must contain enough elements to support this, otherwise the expression will result in an error.

Arithmetic operators

Arithmetic operators allow the writer to combine numeric values within expressions using common arithmetic operations.

- *addition* - `+` - (`a + b`) returns the sum of `a` and `b`
- *subtraction* - `-` - (`a - b`) returns the result of subtracting `b` from `a`
- *multiplication* - `*` - (`a * b`) returns the product of `a` and `b`
- *division* - `/` - (`a / b`) returns the quotient of `a` divided by `b`
- *modulus* - `%` (`a % b`) returns the remainder of `a` divided by `b`

> **Tip**
>
> Division and Modulus are useful together.
>
> An expression writer may want to write `int(a / b)` to get the whole number quotient of the division operation. To get the remainder, they can write `a % b`.
>
> This can help display division-related information more clearly to readers, e.g.
> `format::There are {int(apples / kids)} apples per kid, with {apples % kids} apples remaining.`
> (where apples and kids are variables defined by an ExpressionVariable layer, for example)

String Manipulation

String manipulation is separate to text formatting, which is a more common use case. String manipulation alters a string value in some way to change the contents of the text. It is possible to use string manipulation functions to enhance text formatting operations in more advanced use cases.

To compare two strings rather than alter them, use the comparison operators.

`split(text, delimiter)`

Splits the `text` at every instance of `delimiter`, returning an array of strings. For example, `split("hello world", " ")` returns an array of two text objects: `["hello", "world"]`. Use array indexing with `[]` brackets to access an element. For example `split("hello world", " ")[0]` returns `"hello"`.

`replace(text, old, new)`

Replaces every instance of `old` in `text` with `new`. `old` and `new` do not have to be the same length. For example, `replace("myfile.png", ".png", "")` returns `"myfile"`.

`strip(text)`

Removes any instance of blank spaces or tabs at the beginning or end of the string. `strip(" abc ")` returns `"abc"`.

`title(text)`

Replaces characters at the beginning of the word, or immediately after any space character with the uppercase version. For example, `title("lorem ipsum")` returns `"Lorem Ipsum"`.

`upper(text)`

Replaces all characters with the uppercase version. For example, `upper("lorem ipsum")` returns `"LOREM IPSUM"`.

`lower(text)`

Replaces all characters with the lowercase version. For example, `lower("LOREM IPSUM")` returns `"lorem ipsum"`.

Text Formatting

All text formatting expressions start with the prefix `format::` to switch the expression engine into "string interpolation" mode. This only makes sense to use in expressions which are intended to evaluate to text values. All formatting expressions allow multiple lines.

Motivation

Text typed directly into a format expression shows as-is in the output. For example the expression `format::Hello world` would result in the text "Hello world" with no modification.

In order to make format expressions useful, string interpolation is used to embed expressions within the text. This is done by inserting *replacement fields* into the text. For example `format::Running for {uptime / 60}min` would result in "Running for 20.563min" (if the system had been running for approximately 20 minutes.)

Usually, when working with values defined by computers there is a lot of extra detail which the expression writer doesn't want to include. In the example above, the extra decimal places after the whole number of minutes are probably not wanted. To fix this, the writer can include replacement fields to change how the content is formatted.
`format::Running for {uptime / 60:.0f}min` would result in "Running for 20min", as desired.

Non-formatted text expressions

Text fields which are driven by an expression which does not include the `format::` prefix will simply convert the result to text using the default formatting rules. In some cases, it is not possible to convert a result to text (for example a function name on its own does not evaluate to a value which can be converted to text.) This results in an expression error.

Replacement field syntax

Formatting is using the same language as C++ std::format.

Replacement fields are identified by the surrounding braces (`{}`.) If the expression writer needs to surround text with a literal `{}`, double the braces, like so:
`format::{{ hello, no evaluation happens here }}` ->
`{{ hello, no evaluation happens here }}`

Within a replacement field normal expression evaluation syntax is used to call functions, read variables, use operators and everything else available to all expressions.

Additionally, after the expression syntax, an optional `:` is added to the field. This separates the expression from the format specification, and controls how the value is converted to text.

Format specification

The power of the text formatting system is the degree of control over how the value is converted to text. This is accomplished through a small DSL (domain specific language) which has a focus on a compact representation of common text formatting operations.

Width, fill and align

It is sometimes useful to fill and align the text within a certain number of characters.

The alignment and fill behaviours have a series of defaults - the default fill is space ( ) and the default alignment is to the right. By default, there is no width to apply this fill or alignment to.

For all formatting examples here, we enclose the replacement field in single quote marks, to clarify the exact behaviour of the replacement field. This is not necessary in normal usage.

Therefore all of the following expressions result in the identical text " 123".

- `format::'{123:6}'`
- `format::'{123:>6}'`
- `format::'{123: >6}'`

The space between the `:` and `>` is the *fill* character. In the final example above, this can be replaced with an arbitrary other single character (e.g. `format::'{123:x>6}'` results in "xxx123")

Similarly, the `>` character is the *align* operator, which can be any of:

- `>` - right alignment (`format::'{123:x>6}'` -> "xxx123")
- `<` - left alignment (`format::'{123:x<6}'` -> "123xxx")
- `^` - center alignment (`format::'{123:x^6}'` -> "x123xx")

Finally, the `6` is the *width* and can be any integer. If the width is specified to be less than the number of characters needed to represent the value, the width is ignored.

Normally, the order of these operators is extremely important, but there is one exception - when the fill character is a `0`, the align operator can be skipped. That means that `format::'{123:06}'` results in "000123". Note that there are no other numeric fill characters - an attempt to write `format::'{123:16}'` results in a 16 character width, rather than a fill using `1` characters within a 6 character space.

While the examples here use integer values, string and floating point values also work with this feature. e.g. `format::'{"hello":^10s}'` -> "" hello ""

> **Note**
>
> Text layer will not render multiple consecutive spaces, so testing this functionality with text layer and a space fill character may be confusing.

Precision

In addition to the *width* above, for numbers which have decimal places, the *precision* specifier allows the writer to limit the amount of detail presented.

Precision is a number following a period `.` after the optional *width*. It must always be followed by the floating point specifiers `f` or `g` (discussed below.) For example:

`format::'{123.456:.1f}'` -> ""123.5"" (note the rounding is correct)

Width does not change meaning or in any way affect the number of places before the decimal point.

So for example, `format::'{123.456:1.1f}'` -> ""123.5"", but extending the *width* to beyond the 5 characters the field replacement rendered to begins to insert padding as discussed above - `format::'{123.456:6.1f}'` -> "" 123.5"". All fill and alignment rules above apply equally. Precision changes the text which is rendered for the given number, whereas width, fill and align adjust where it is presented within the specified *width* characters.

> **Note**
>
> Precision is only valid for numeric values which are floating point numbers. It will not function correctly for integer values. The expression `format::'{123:.1f}'` is an error, because there is no decimal precision for the integer `123`.

Sign

Inserting a `+` in front of the width (or on its own without a width) ensures the sign of the number is always written. e.g. `format::'{123:+6}'` results in "" +123"", whereas `format::'{-123}'` would always result in "'-123"". `format::'{123:+}'` results in "'+123""

`-` is also a valid sign operator, but that simply marks the default behaviour as being in some way expected.

Base prefix

For some types (see below) the base of the integer being formatted is changed. It is often useful to use a standard *base prefix* to identify the base of the number. This is accomplished by inserting the `#` character before the *width*. See **integer types** for more details.

Type

The type specifier is the final character in the format specification. Based on the type of the value the expression evaluates to, it can change the representation of that value to be useful in different circumstances.

The type specifier is therefore grouped into sections based on the type of the value the expression evaluates to:

Integer types

- `b` or `B` (base prefix: “0b” or “0B”). Formats the integer as a binary number (base 2). e.g. `format::'{256:#16b}'` -> ““0b0000000100000000””
- `o` (base prefix: “0”). Formats the integer as an octal number (base 8). e.g. `format::'{256:#o}'` -> ““0400””
- `x` or `X` (base prefix: “0x” or “0X”). Formats the integer as a hexadecimal number (base 16, using characters 0-9 and a-f). e.g. `format::'{256:#x}'` -> ““0x100””
- `d` (no base prefix). The default behaviour - does not need to be specified. Formats the integer as a decimal number (base 10). e.g. `format::'{256:#d}'` -> ““256““

Floating point types

- `g` - the default behaviour (used when not specifying a type or format specification at all) Formats the number in a compact representation, up to *precision* characters. When the number exceeds *precision* (default 6) characters in decimal notation, it shifts to scientific notation and rounds. e.g. `format::'{1.5:g}'` -> ““1.5””.
- `f` - format with “fixed” formatting, without using scientific (exponent) notation. e.g. `format::'{1.5:f}'` -> ““1.500000”” *precision* can help tune the result of this format option.
- `a` - format with precise machine readable hexadecimal formatting, used by some computer systems to transfer floating point numbers without loss of precision due to string conversion. e.g. `format::'{1.5:a}'` -> ““0x1.8p+0““

String types

- `s` - the default behaviour. Formats the text by simply rendering the text as-supplied. e.g. `format::'{"hi\nthere":s}'` -> ““hi
there””
- `?` - format text with escaping and quoting. Useful if there are strange characters or the string is otherwise unexpected. e.g. `format::'{"hi\nthere":?}'` -> ””“hi\nthere””“

Expression Variables

Variables in expressions are powerful tools for sharing values between multiple expressions. They are also very useful to split up complex expressions into more easily understood and manageable chunks.

Variables are a named storage location for a value to be used by expressions. In order to have a place to store the value represented by a variable, they need to be defined. Variable definition can happen in a number of different ways.

Note that variables are not considered defined if they were only evaluated on an earlier frame. Variables are defined as the frame progresses within Designer, which means that things that happen earlier in a frame (such as device evaluation) cannot access variables defined later in the frame (such as during layer composition.) This is especially true when working with stacks of Layers - Layers can only define variables which are used by other Layers which would composite on top of the Layer which defined a variable.

Variable definition locations

Global constants

While these are technically variables, these constants do not change.

- `pi` - the mathematical constant π, often used with trigonometric functions.
- `e` - the mathematical constant e (Euler's constant), often used with mathematical functions.

Global system variables

Designer defines one variable which is accessible everywhere.

- `uptime` - the time of the current frame, which is synchronized across all servers and is therefore equal (within approximately 2ms) in a multi-machine session. This is also referred to as frame time in some places.

Local system variables

Some variables are defined only for certain contexts. For example, when working with layers, the `self` variable is defined to be the current value of the animated property the expression is controlling.

Variable assignments

When evaluating an expression, it is possible to save the value it evaluates to, as well as using it. For example, the user may enter a complex expression for brightness, but then want to share it across multiple layers. They could enter `myvar = sin(uptime / 20)`, and then, in another layer (which must appear later in the composition stack) they could then set brightness to be simply `myvar`.

It is important to note that the variable is only defined for as long as the layer (or other expression which defines the variable) is active. As soon as the layer becomes inactive (i.e. not under the play head) the variable is no longer defined, and references to it will no longer be valid.

To reference the variables defined by an assignment, the user must ensure the layer is below the user of the variable in the composition stack. i.e. The variables defined by variable assignment are only available to layers which would composite on top of the defining layer. Similarly, if the assignment is performed by some other Resource in the system, then the variable is defined only after that Resource has run within the frame.

ExpressionVariable layers

There are cases where the user wishes to create animated variables on the timeline, but does not want to explicitly tie them to a layer which is used for content (perhaps they are concerned that the layer may be moved or otherwise reprogrammed without consideration of the variable.)

The user can create an ExpressionVariable layer as they would any other layer. The configuration section allows them to create new variables and change their properties, and then animate them as they would any other property on a layer in the timeline.

In order to reference the variables defined by an ExpressionVariable layer, the user must ensure the layer is below the user of the variable in the composition stack. i.e. The variables defined by ExpressionVariable layers are only available to layers which would composite on top of the ExpressionVariable layer.

ExpressionVariable devices

In some cases, the variable the user wants to define is more global, and isn't limited by a specific location on the timeline or does not need to be animated.

An ExpressionVariable device can be created in the device manager and used to create variables there.

Variable definition behaviour

Variables are defined every frame by the various locations described above.

If those locations are no longer run, the variable is no longer defined, and expressions which used it are no longer valid. An example is when a layer which defined a variable is not under the play head anymore, or a device is removed from the device manager.

If there are multiple locations which define the same variable on a frame, the second location which attempts to define the variable will be in an error state, and be unable to define the variable. It will indicate where the variable was first defined, for the user to determine how to resolve this conflict.

Variable naming

Variables must be named according to the syntax of the expression language. Some key points are:

1. **Case-sensitivity** - variables named `hello` and `Hello` are distinct variables which can have very different or even incompatible values (e.g. a number or text)
2. **No special characters** - variables must start with an underscore (`_`) or an English alphabet letter, and consist of letters, underscores or numbers thereafter. This means no spaces or other special characters are valid. Unfortunately, at present this means non-English characters are not supported.

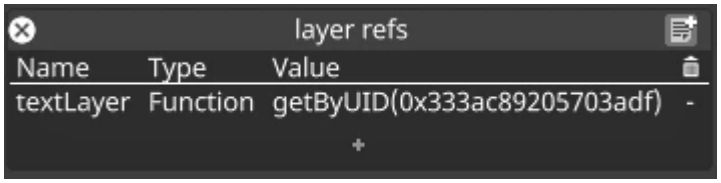
Users should also take care to use a consistent naming scheme when building projects with many variables. It is easy to create many variables with different meanings and purposes. Organization using devices and layers are useful for grouping variables into common locations for definition.

Function variables

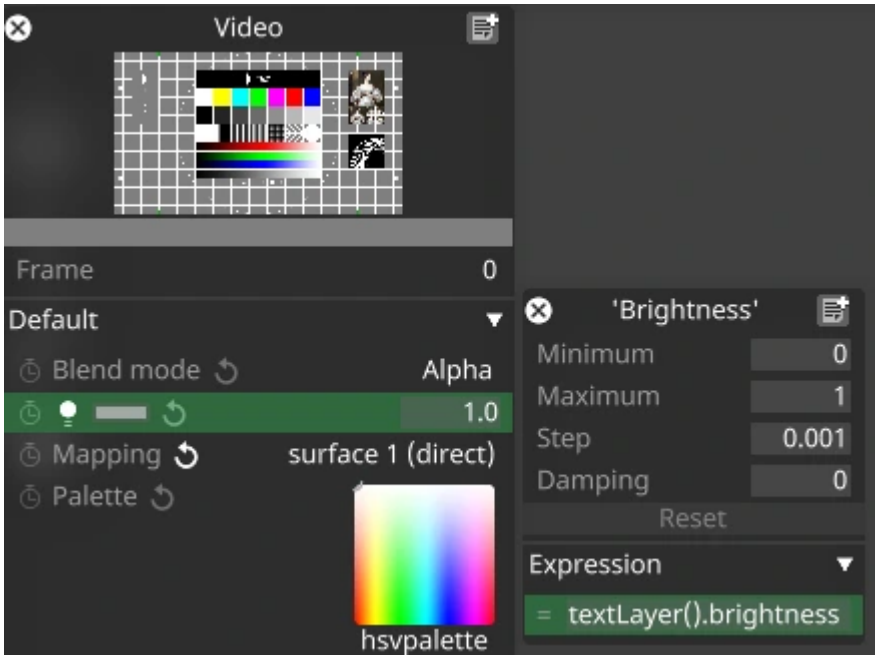
Sometimes, when working with more complex or verbose logic functions such as `if`, it is useful to break out parts to be reused or simply to make the process of reading the expression easier.

For example, one use of function variables is to return the result of accessing a Resource using `getByUID`:

To build a function variable, the writer should create an expression variables device or layer. A variable defined this way can be switched to *Function* type, and the desired expression can be written.



Copy the UID of the Layer (or other Resource) as required and write the `getByUID` expression. There is no need to access a specific property, but that may make reusing the function elsewhere easier. The writer should consider what they are attempting to abstract when creating the function variable. In this example, the function `textLayer` will return the chosen layer.



When using the function variable, the call syntax is required to evaluate the function, in this case that is `textLayer()` which evaluates to the same value as the expression within the function variable. When returning Resources, this means that properties can be accessed directly from the returned value. If the expression evaluates to a number or text, it can be used directly as-is.

Passing parameters to functions

In advanced use cases, it is possible to create a parameter (or argument) to function variables. This is done by changing the name of the function variable to include the parameter names the user wishes to use.

For example, a user creates a function `maybe_override` which performs some override behaviour if a condition is met, or alternatively will fall back to regular sequencing. The override needs to be different for every field which uses the function. We can therefore define the function as follows:

Name	Type	Value
`maybe_override(value)`	Function	`if(osc:show.override, value, self)`

The function above is designed to be applied to a layer. It provides `value` if the OSC address `/show/override` is non-zero, otherwise it falls back on existing sequencing.

When applying this, the user would enter different expressions on each applicable field, for example, `maybe_override(osc:show.field1)` on one field and `maybe_override(osc:show.field2)` on another field.

Context dependent evaluation

Functions are evaluated in the context of the calling expression. This means that the function variable can use a variable or other context which is defined after the function variable is, as long as the calling expression has access to that variable.

`self` in function variables

One useful implication of this is that function variables can access the `self` variable. `self` has its normal meaning according to the location the function is evaluated at. This can be used for example when working with OSC expressions in function variables. The following function expression can be written:

`if(valid_osc:my.address, osc:my.address, self)` - this uses normal sequencing until a value is received on the OSC address `/my/address`.

`this` in function variables

The `this` variable is also available in function variables and refers to the Resource currently evaluating the expression. This is particularly useful when you want a function variable to access properties of the Resource it is used on.

Unlike typical variables, `this` is accessed using the resource access syntax. For example, to reference the `brightness` property of the current layer (module), use `module:this.brightness`. This ensures the expression always refers to the property of the Resource that is executing the expression, regardless of where the function variable is used.

`this` is also a useful shortcut to avoid needing to pass the Resource as a parameter to the function variable, and is robust against issues like a Layer being renamed or duplicated.

Genlock Configuration

Genlock, from the phrase *generator locking*, is a common technique where a specific reference signal from a signal generator is used to synchronise other image or video sources together.

At Disguise, we use genlock as a mechanism to sync multiple Disguise Media server outputs. The Sync Card on each server receives a **Genlock Signal** from a central **Clock Source** (usually a dedicated piece of hardware) and individually locks the outputs of all of its heads to that incoming genlock signal. Genlock keeps multiple Disguise servers in sync and also allows external integration with cameras/LED devices.

Framelock is a mechanism within GPUs that keeps individual outputs of the same server in sync. **Internal Sync** is a mechanism within GPUs to individually lock to a locally generated genlock source.

Genlock synchronises the refresh intervals of all displays to an external signal. While framelock synchronises the frame rate of each display to a signal generated internally by the hardware.

Configuring Genlock

Genlock and framelock can be configured directly in the following ways:

- Using the Feed View in Designer (Recommended)
- Using the Graphics Card control panels directly

In general, genlock should always be configured within the Designer software. We recommend using this workflow because you can apply genlock across all your machines with one button press.

In rare circumstances, such as custom workflows, or if you encounter a bug, you may need to configure synchronisation using the AMD or NVIDIA Control Panel directly. We have outlined both workflows below.

The genlock status of Disguise servers can be monitored in the Network Status Widget and is generally configured from the Feed View.

There are 2 types of genlock signals that Disguise Media servers support:

- BlackBurst
- Tri-Level

> **Note**
>
> **BlackBurst** (also known as bi-level sync) originated as a standard-definition reference signal, whereas **Tri-Level** sync was developed for high-definition formats. For this reason, we generally do not recommend BlackBurst as a genlock reference at resolutions above 1080p. It may work in some setups, but a stable lock cannot be guaranteed at these resolutions. For resolutions above 1080p, opt for a Tri-Level sync source instead.

Applying Genlock in Designer

To lock to genlock in Designer you should first access the Feed View

To genlock a Disguise Media Server correctly the following conditions must be met:

- VFC slot resolutions across all output heads must be the same
- VFC slot refresh rates across all output heads must be the same
- VFC slot timing modes across all output heads must be the same

These are requirements imposed by AMD and NVIDIA Hardware and apply to all graphics cards.

To apply genlock using Designer:

1. Ensure that a genlock cable with a valid genlock signal is plugged into the BNC port marked “Genlock” on the back of the server.
2. In the Dashboard, left-click on **Feed** to access the **Feed View**.
3. Validate that the genlock signal is being received by the server by looking for a message underneath the Machine name in the Feed View. This should say “Genlock: Present (unused)”.
4. Left-click **Apply Genlock** to configure all machines in the session. **A machine does not need to be running Designer to have feed settings applied**.

   
   Group Actions Buttons
5. Disguise will now begin configuring the GPU on all machines to accept the correct genlock signal. The screen will go black and there will be status text explaining the process.

6. Wait for the process to finish. This may take a few minutes. Once finished, you will see a coloured icon within each VFC card header indicating whether that VFC card is genlocked. If the indicator is green, this means that the machine has locked successfully.

Genlocked Feed Scene Example

You can follow the same process to apply genlock to a single machine without affecting the others by right-clicking on the Machine name in the left of the output heads in the Feed View and selecting the **Apply Genlock** button.

When genlock is not present on a system the **Apply Genlock** button is replaced with an **Apply Framelock** button which only applies framelock. This is also true on systems that do not support genlock, like the Solo.

> **Note**
>
> Pressing **Apply Feed Settings** will also apply genlock. Pressing **Apply Genlock** will not apply feed settings. Pressing **Apply Feed Settings** will not do anything to Non-Dedicated Directors, but pressing **Apply Genlock** will.

Applying Genlock outside of Designer

We always recommend applying genlock in Designer because you can do it across multiple machines and it is less error-prone.

If you encounter issues with this workflow sometimes a good fallback is to use the NVIDIA or AMD-provided genlock configuration.

For AMD this will be via the **AMD Software: Pro Edition** Control panel.

For NVIDIA this will be via the NVIDIA driver Control Panel settings.

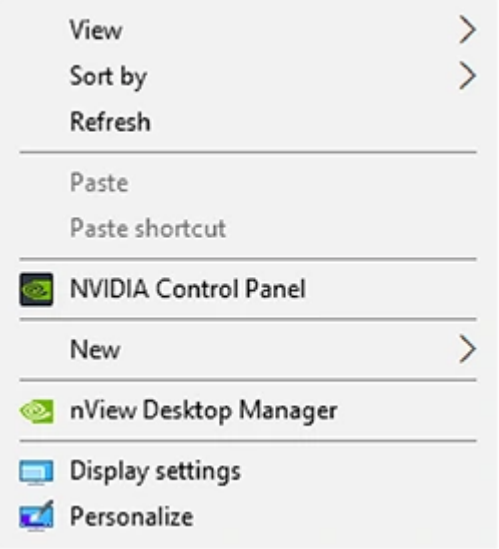
For assistance with configuring genlock please contact **Support**.

Configuring Sync using Graphics Card-Provided Control Panels:

Genlock

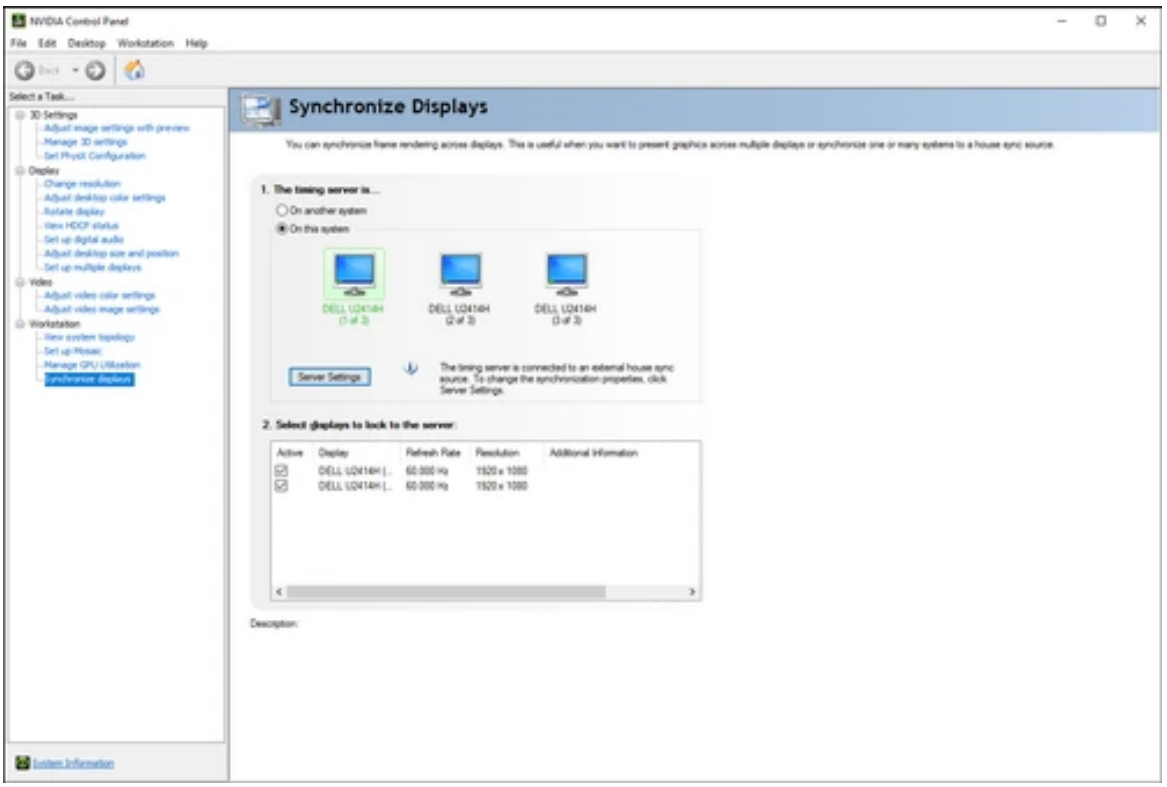
To apply genlock on NVIDIA Machines:

1. Right-click on the desktop and open the **NVIDIA Control Panel**.

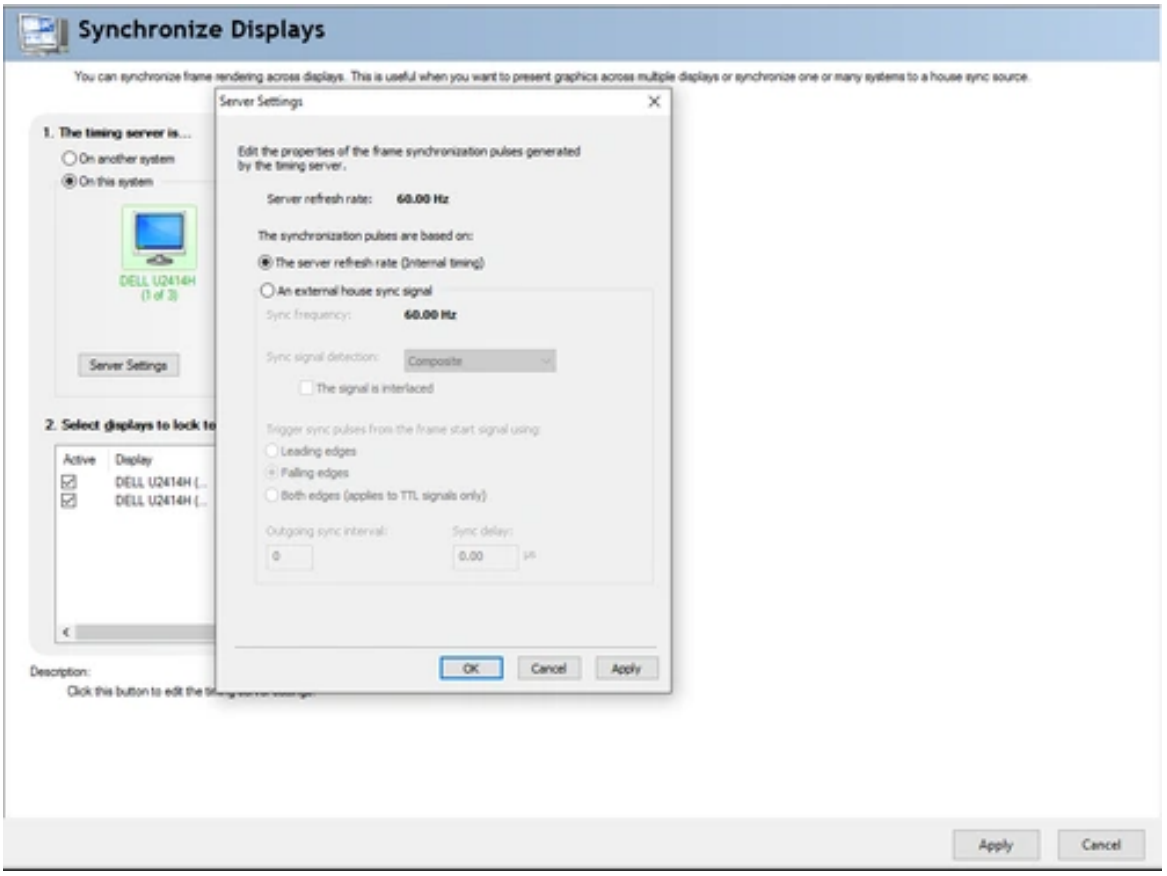


2. Click **Synchronize Displays** under Workstation.
3. In the open **Synchronize Displays** tab, under **1. The timing server is...** select **On this system**.
4. Select the displays to genlock to the server and ensure that the checkboxes are ticked below under **Select displays to lock to the server:**.

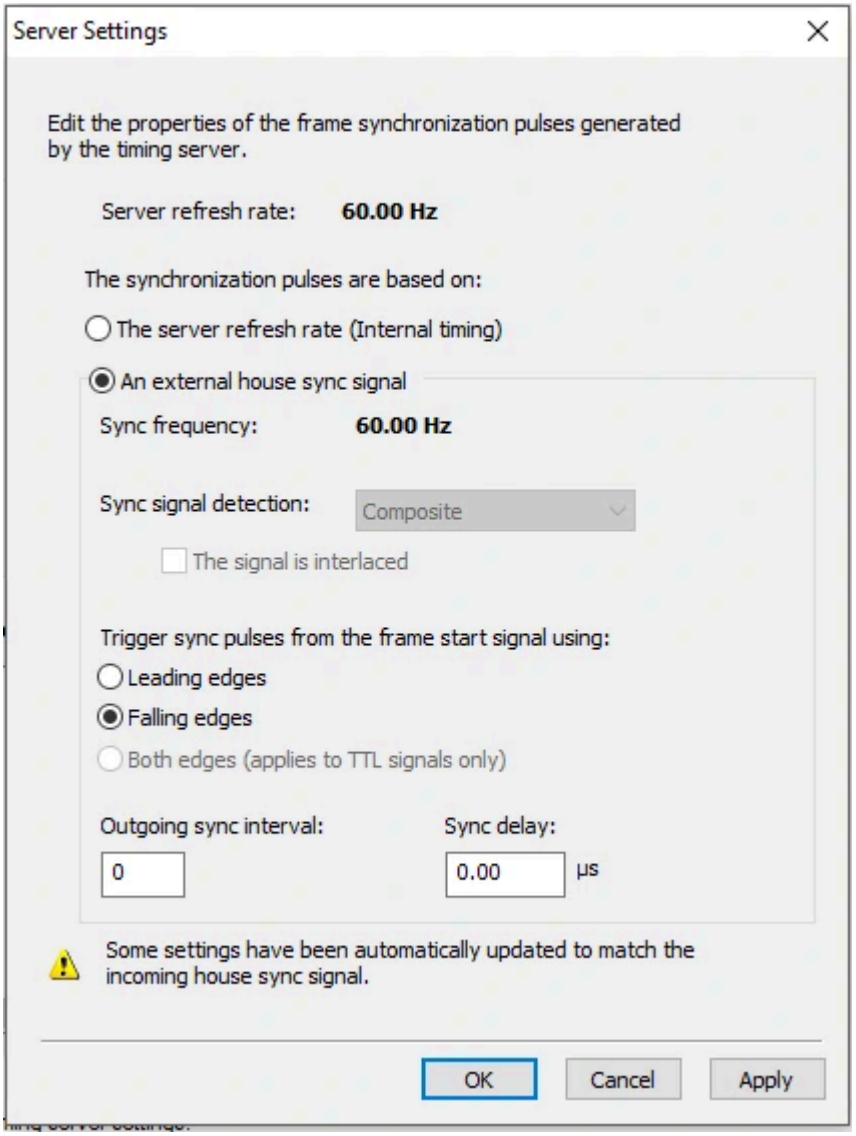
5. With all displays selected, select your main display and click the **Server Settings** button.



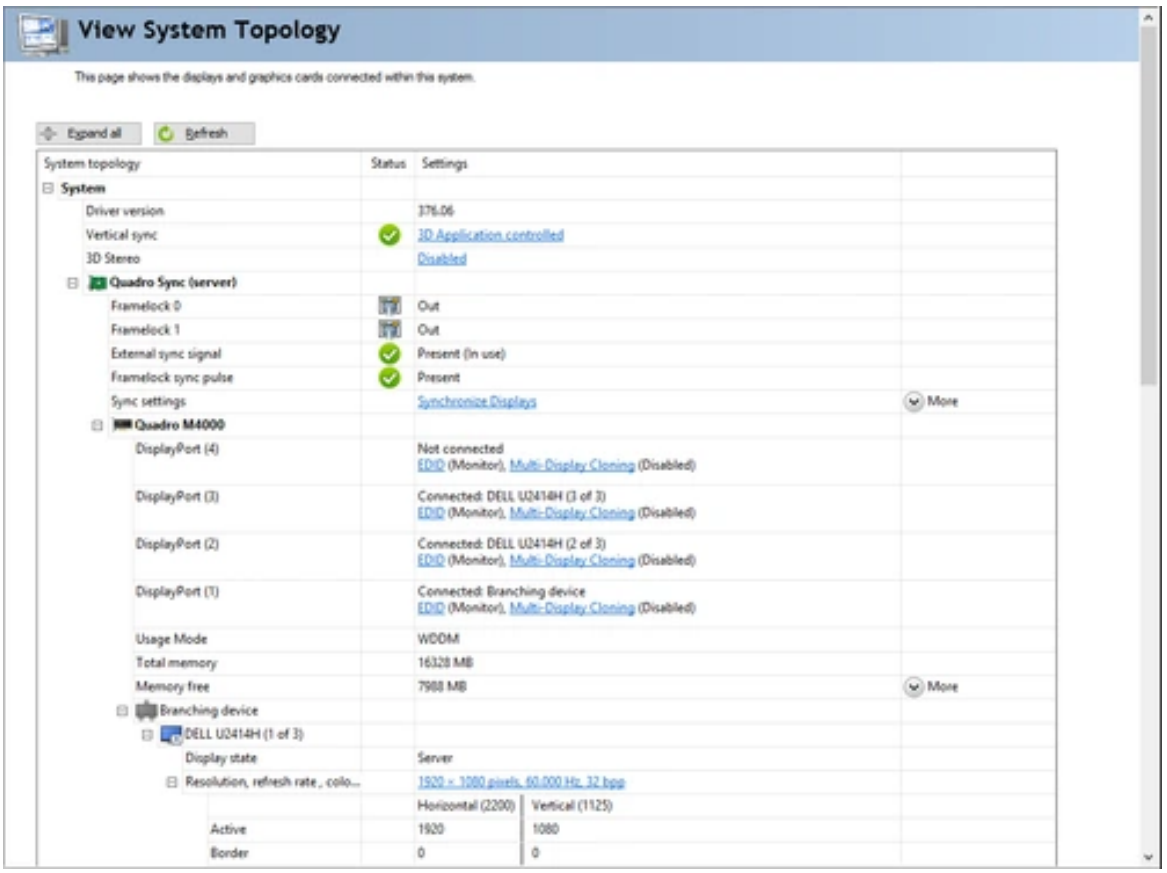
6. The Server Settings pane shows the current synchronisation settings. Under **The sychronization pulses are based on:**, select **An external house sync signal** and click **Apply** to confirm the changes before clicking **OK**.



7. Select **View System Topology** under Workstation. Genlock has been completed if the **External sync signal** has a green tick next to it and the settings are **Present (In use)**.



8. Click **Refresh** to update the configuration.

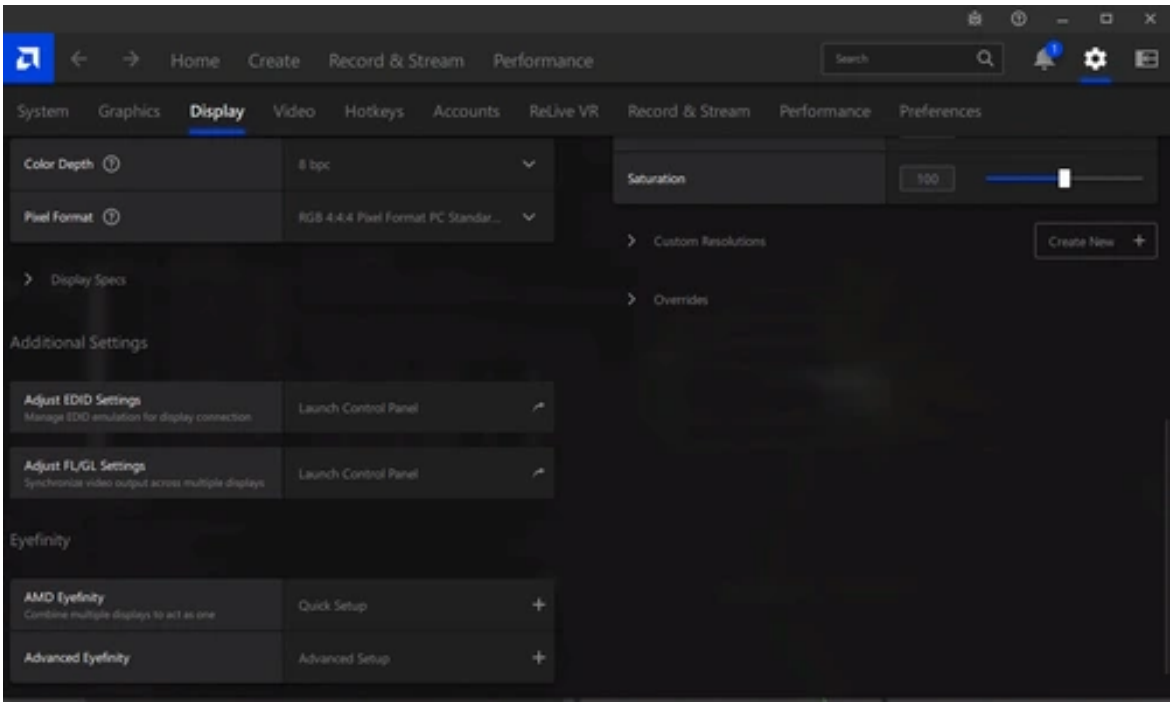


> **Note**
>
> The VX 4 OS and VX 4+ OS both have different driver options but do have almost identical workflows, the images below should help clarify, but if you have issues please contact **support**

Accessing Genlock settings is different for the VX 4 and VX 4+:

Right-click on the desktop and select **AMD Radeon Pro Advanced Settings**.

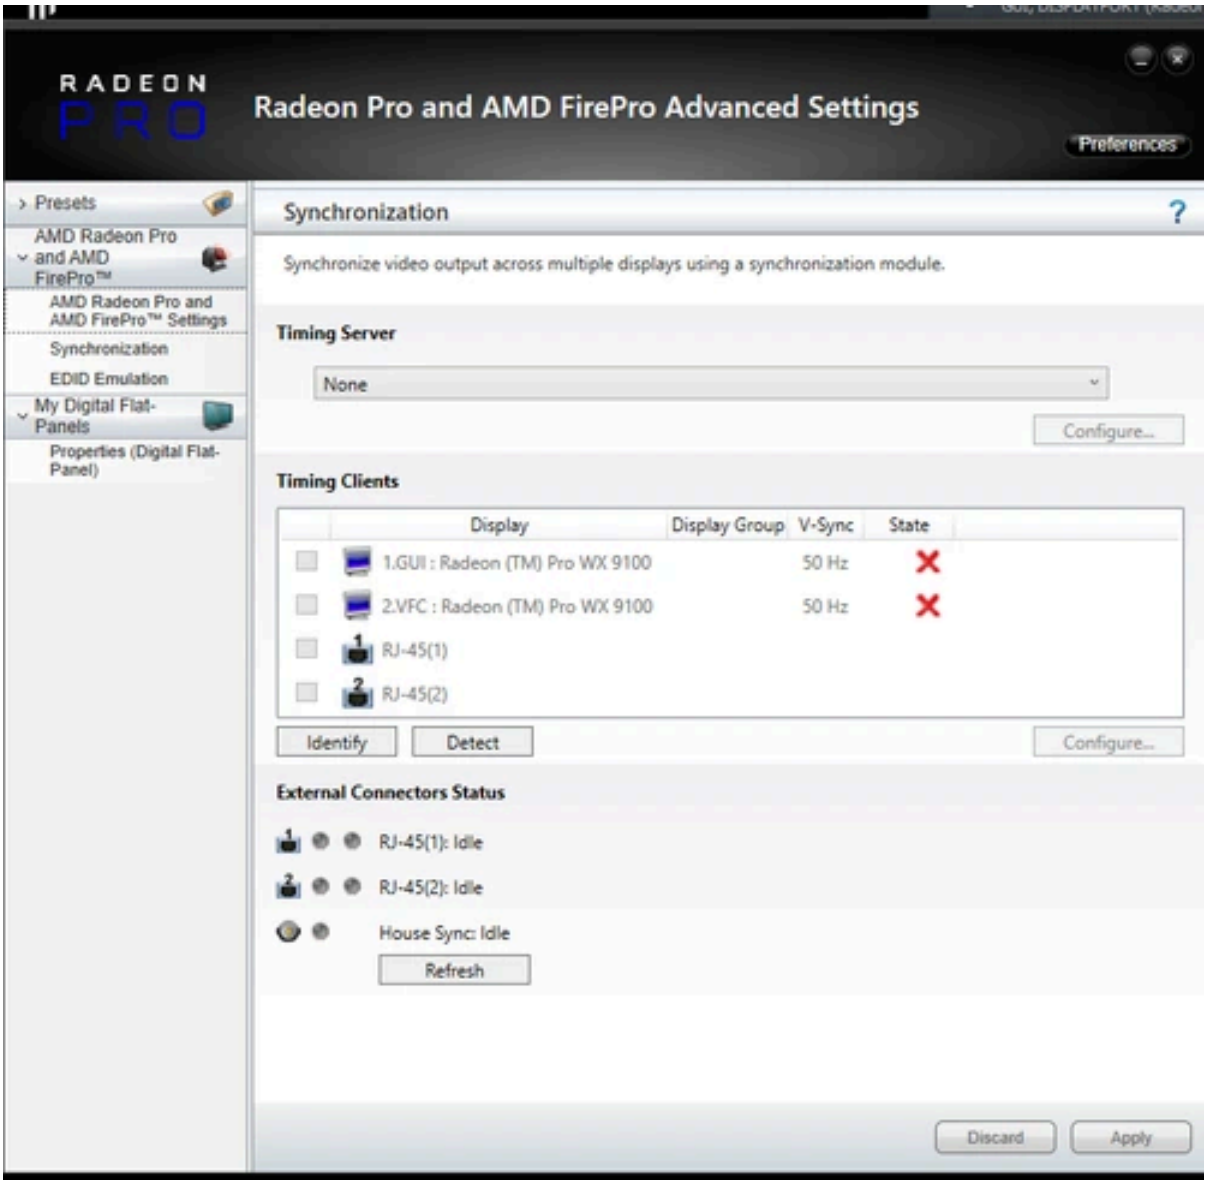
This will open up a reskinned version of the AMD Control Panel.



1. Right-click on the desktop and open the VX 4+ AMD Driver.
2. Select the **Displays** tab.
3. Scroll down and select the Adjust FL/GL **Launch Control Panel**.
4. This will open up a reskinned version of the AMD control panel in Blue workstation graphics branding.

Once you've got the correct GUI open follow these instructions:

Shared Advanced Pages and Syncronisation

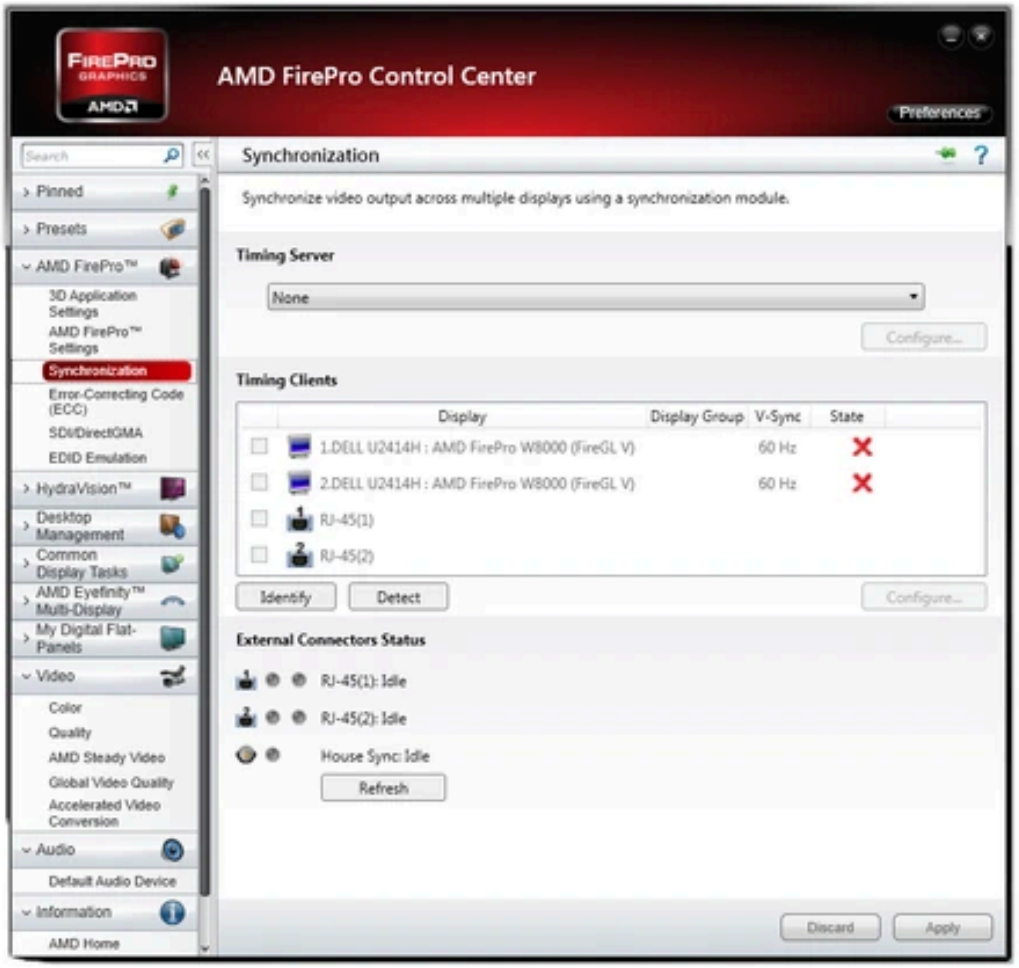


1. Under the syncronisation tab, left-click **Refresh** under House Sync.
2. Wait for the House Sync indicator to go green, indicating displays are receiving Genlock.
3. Select each display under **Timing Clients** that you wish to lock to the Genlock source and click **Apply**.
4. Your selected displays are now genlocked.
5. Under the syncronisation tab, click refresh under House Sync.

For any AMD machines that were released before the VX 4 follow these steps:

1. Right-click on the desktop and select **AMD Fire Pro Control Center**.

2. Open the **AMD Fire Pro** tab and click on **Synchronization**.



3. Under the **Syncronisation** tab, left-click refresh under House Sync.

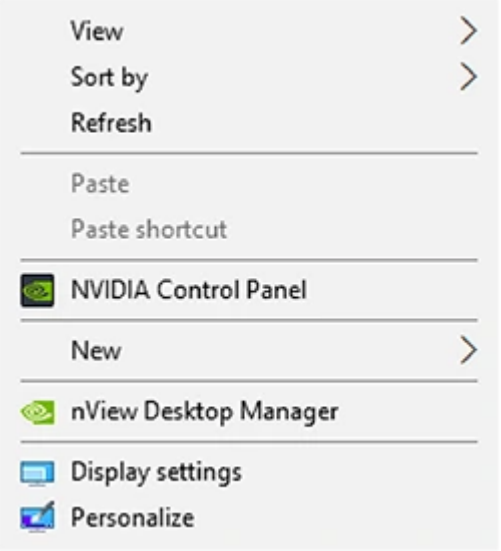
4. Wait for the House Sync indicator to go green, indicating displays are receiving genlock.
5. Select each display under **Timing Clients** that you wish to lock to the genlock source and click **Apply**.
6. Your selected displays are now genlocked.
7. Under the **Syncronisation** tab, click **refresh** under House Sync.

Framelock

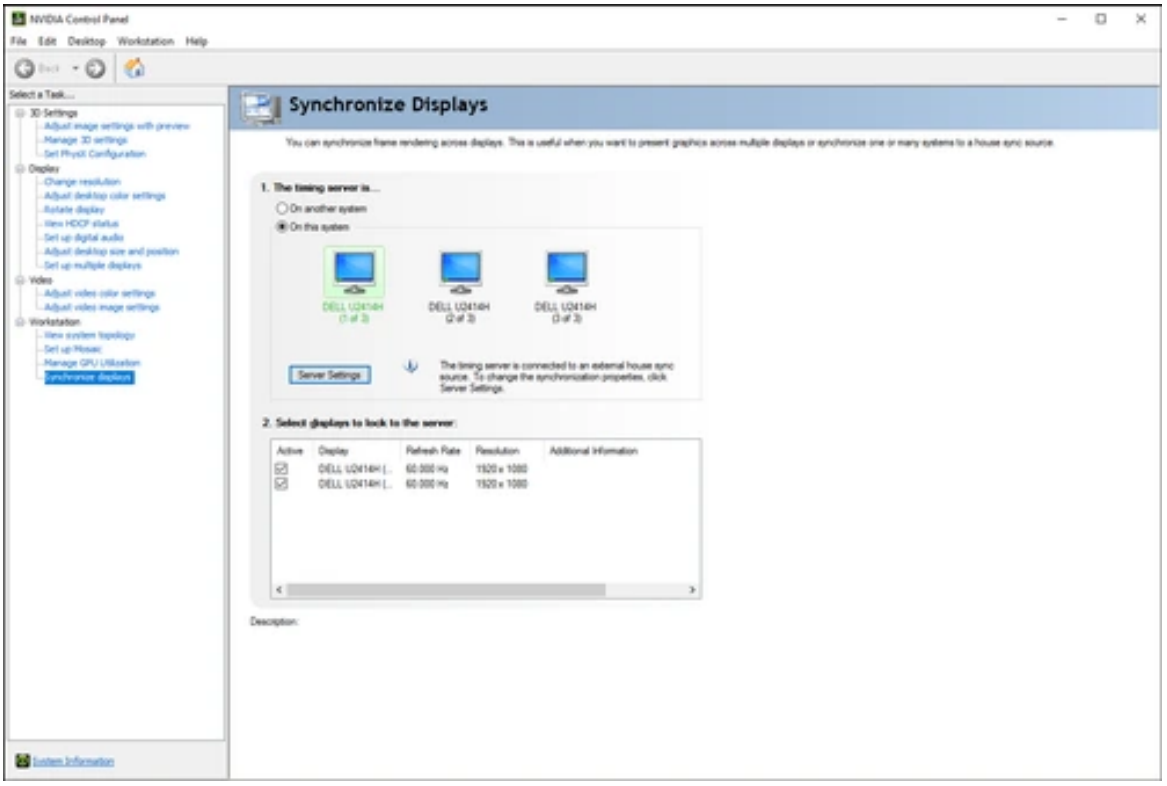
You can also apply Framelock directly in the NVIDIA or AMD software.

To access the Nvidia Control Panel for Internal Timing:

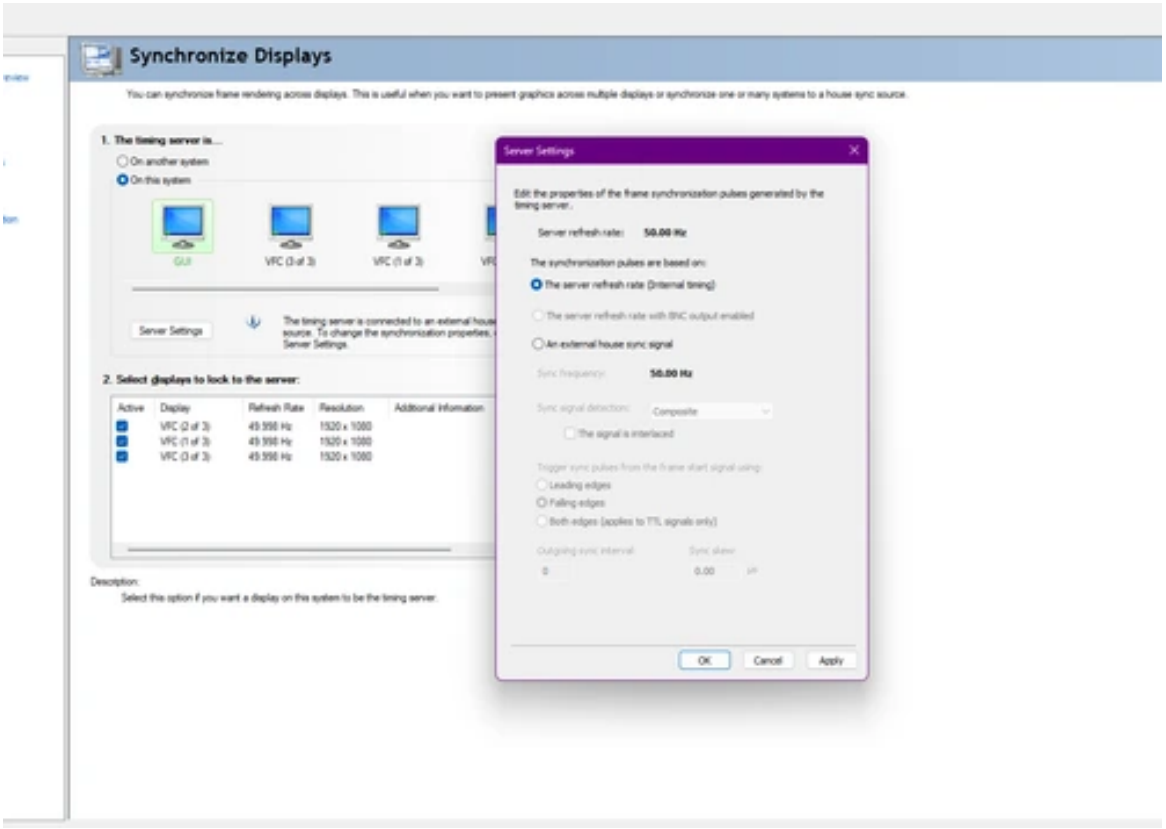
1. Right-click on the desktop and select the **NVIDIA Control Panel**.



2. The Synchronize displays tab should automatically open. Ensure that the boxes are ticked below. After all displays are selected go back to highlighting your main display and select the **Server Settings** button.



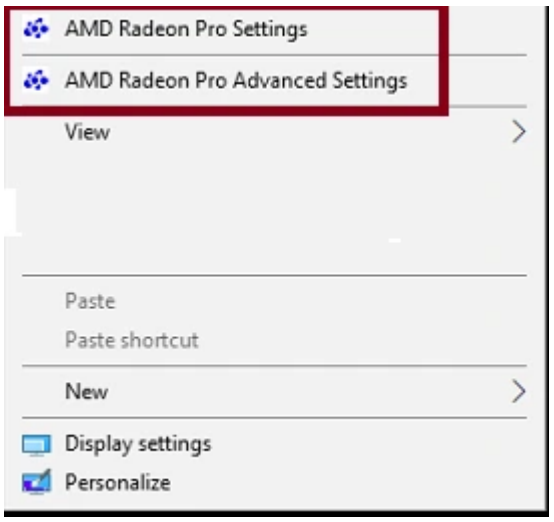
3. The Server Settings popup will show what the current Synchronization is. Change the selection from Internal timing



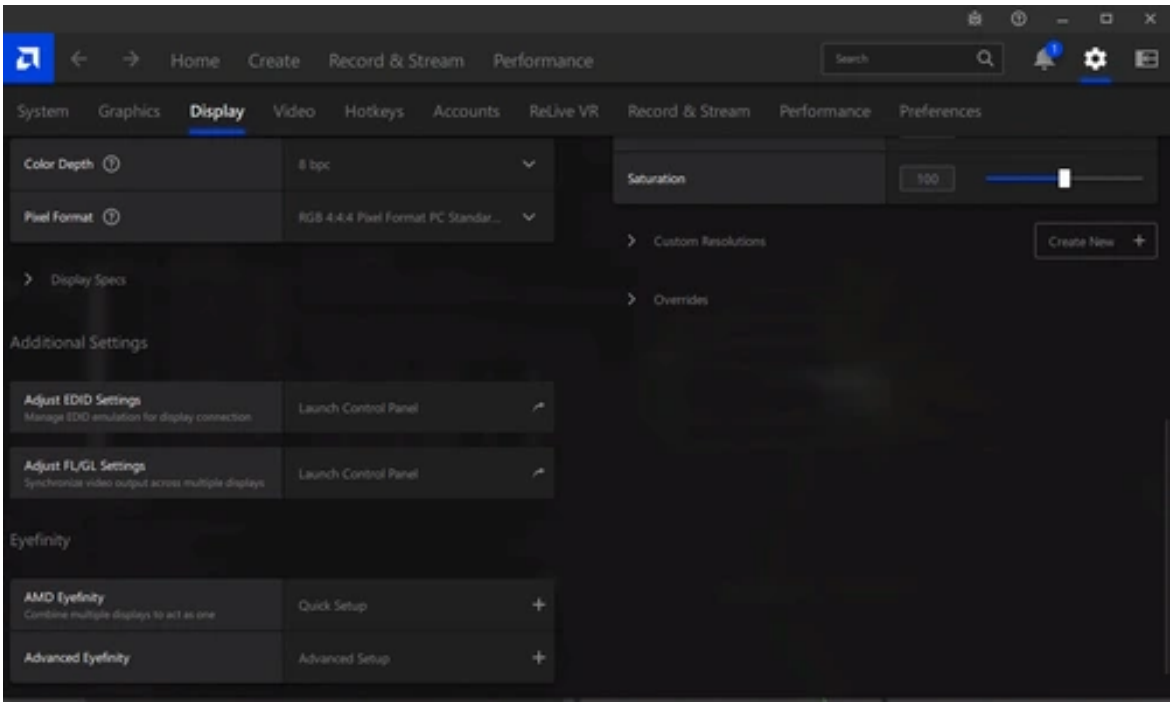
> **Note**
>
> The 4X4/VX 4/VX 4+ have different driver options with almost identical workflows, the images below should help, but if you have issues please contact support

To access the driver settings, please see the relevant machine types below:

1. Right-click on the desktop and select **AMD Radeon Pro Advanced settings**.



This will open up a reskinned version of the AMD control panel

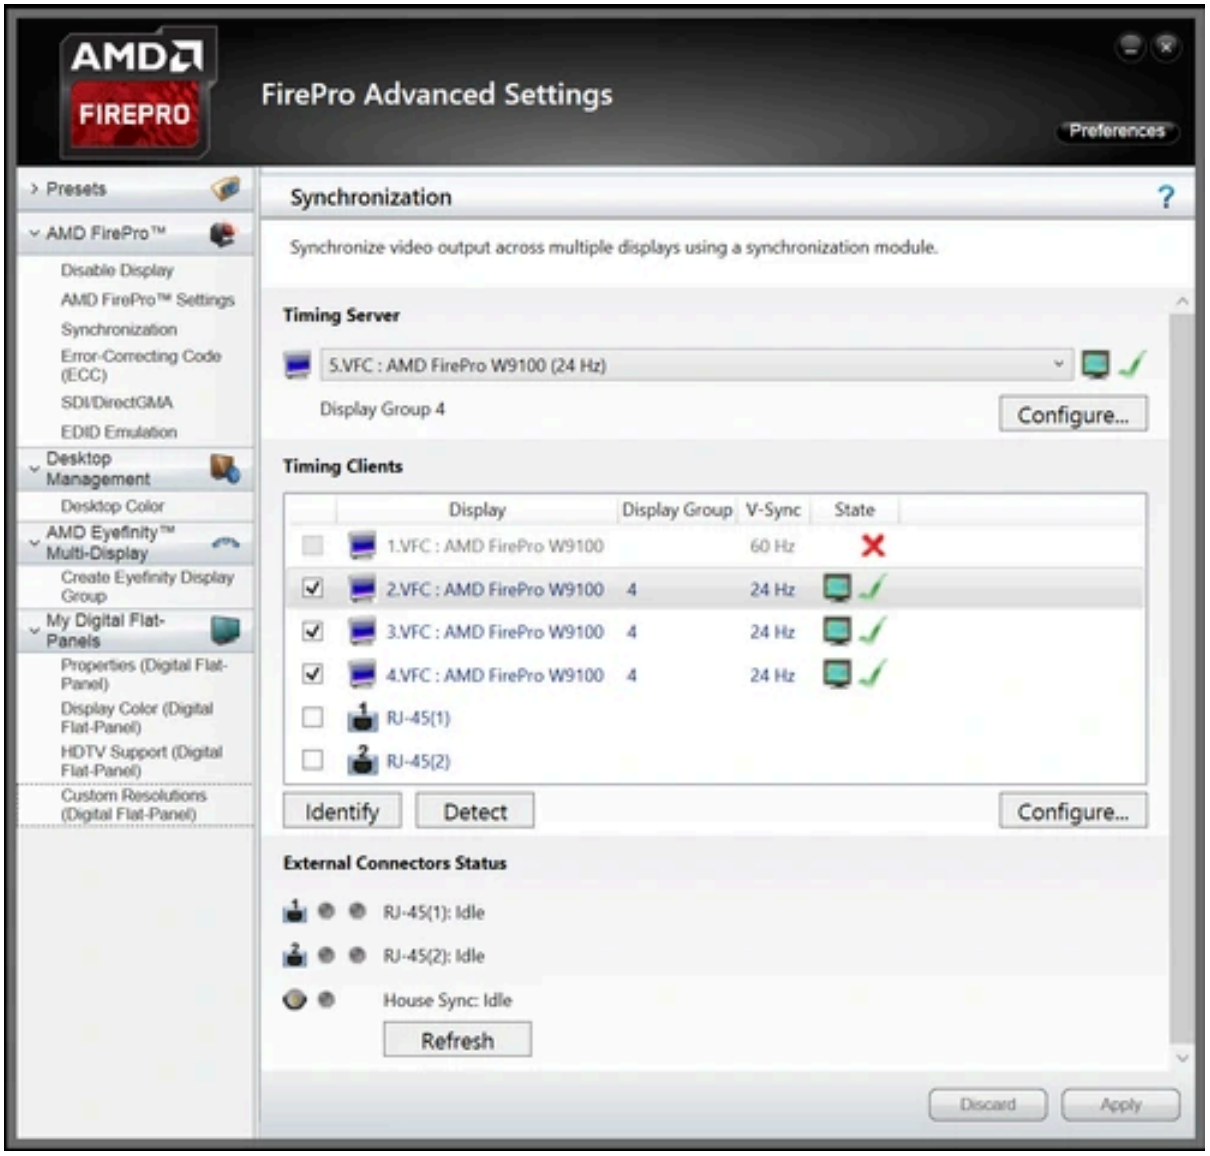


1. Right-click on the desktop and open the VX 4+ AMD Driver.
2. Navigate to displays.
3. Scrolling down, select the Adjust FL/GL **Launch Control Panel**.
4. This will open up a reskinned version of the AMD control panel in Blue workstation graphics branding.

Once the driver has been accessed below, please see the following images and instructions:

1. Click on **Synchronization**.
2. Under the Timing Server tab, select the last listed display, (for example in the image shown it is number 5.)
3. Tick all screens that you wish to sync in the list below.
4. Your selected displays are now Internally Framelocked.

Use the reference image below to see how the correct setup will look.



System Configuration Recommendations

To ensure output and data synchronisation across your cluster of machines, Disguise Media servers should be genlocked where possible.

When to Genlock Machines?

We recommend genlocking your machines whenever possible. Here are some examples of instances where it is particularly critical to performance and synchronisation:

- **Multi-Machine Setups**: When you are using multiple disguise media servers or machines in a synchronized environment, genlocking is essential to ensure that all machines output frames at the same time, preventing/reducing tearing. While it is not strictly required to also genlock a Dedicated Director in a multi-machine setup, it is still recommended.
- **Camera-Server Configurations**: If you are working with a camera-server setup, genlocking is crucial to synchronize the camera's output with the server's frame output. This synchronization helps to ensure the camera and output are capturing the same frames consistently while also reducing camera latency.
- **External House Sync Requirements**: If your production environment requires synchronization with an external House Sync signal, you should Genlock your machines to ensure they are in sync with the house signal.

When to Internally sync machines?

We recommend Genlocking your machines whenever possible. Here are some examples of instances where internal sync may also be sufficient:

- **Singular-Machine Setups** When you are using one or two disguise servers or legacy machines such as the Solo / Machines without Genlock cards, you may find that framelock keeps the outputs of a server in sync. A good example of this would be a singular Director/Understudy, since only one machine is outputting, machines do not need to be frame accurate between each other.
- **No Camera Input Shows** If no cameras are being utilised and timing with external systems is not needed you may find that Genlock is not required and framelock will keep outputs consistent.

Interlaced Genlock and VFC Behaviour

When using the SDI VFC cards with an interlaced video signal there is a chance that the output signal from the VFC card will not match the field of the incoming Genlock signal. To correct this state it is necessary to repeat the **Apply Feed Settings** process, this will re-sync the VFC card and reset which field is being output.

Due to GPU genlock limitations, this process may need to be repeated until the VFC card field sync matches that of the incoming genlock signal. In a session with multiple machines, this should be repeated across all machines at the same time to ensure they are locked to the same field together.

Glossary terms

- **Genlock**: A mechanism to synchronise multiple devices to a “clock source,” allowing them to coordinate with each other and external equipment. Genlock keeps multiple Disguise servers in sync allowing external integration with cameras/LED devices
- **Framelock**: A mechanism within GPUs that keeps individual outputs of the same server in sync.
- **Internal Sync**: A mechanism within GPUs to individually lock to a locally generated Genlock source.

Indirections

Indirections are primarily used for switching out pre-programmed content on the fly. They can be used for situations where the user may wish to change objects under certain scenarios such as triggering of an external system or changing playback to match different talent performing on stage.

Indirections are controlled by Indirection Controllers, which are available in the following types:

Manual

Holds a single resource that the Indirection uses. They can be manually controlled via the UI or via the new Indirections API, documentation for which can be found at **http://localhost/docs/v1/index.html** when Designer is installed.

List

The list controller type holds a list of objects and has an index for which object they refer to. The list can be controlled manually via the UI or via the Indirections API.

SequencedIndirectionController

The Indirection Control layer allows indirections to be sequenced on the timeline. Users can sequence indirection changes on the timeline. One Indirection Control layer controls one indirection. This is controlled by keyframes in an IndirectionControl layer.

Learn more about the IndirectionControl layer **here**.

OSC

The OSC controller holds an address, for example - “/d3/indirection/name” and an OSC device. It’s controlled by sending a string to Designer via OSC in the following format:

Address: /d3/indirection/nameOfIndirectionToControl

Message: sample/george.jpg

Sending a message with an empty string will set the value to **None**. We expect to only receive OSC messages when the string changes. Sending the same path repeatedly will incur a performance cost.

DMX

The DMX controller holds a channel and a universe. It's controlled by sending a value on that channel/universe that corresponds to a DMX bank & slot.

> **Warning**
>
> OSC and DMX Indirection controllers can be set to any object that you've specified or put in a bank/slot which means you must take care to select the correct type of object. If you set a keyframe indirection to an object that does not match the key sequence it is sequenced in (i.e. you set your Indirection to reference a mapping when it expects a videoClip) the indirection will instead switch to holding None.

UDP & TCP

The UDP & TCP controllers hold a string-keyed list of objects. They are controlled by sending a raw UDP or TCP message with the specified string to select the associated object.

UDP sockets can only be bound to one port, this means that a UDP ports can only be used by one Indirection controller at a time.

> **Warning**
>
> OSC, DMX, UDP and TCP Indirection controllers do not hold their values through restarts of Designer.

Workflow

- An Indirection acts like a "dynamic" keyframe.
- The dynamic keyframe has a controller attached to it.
- The controller gets values sent to it.
- Based on those values the resulting output can be changed temporarily.

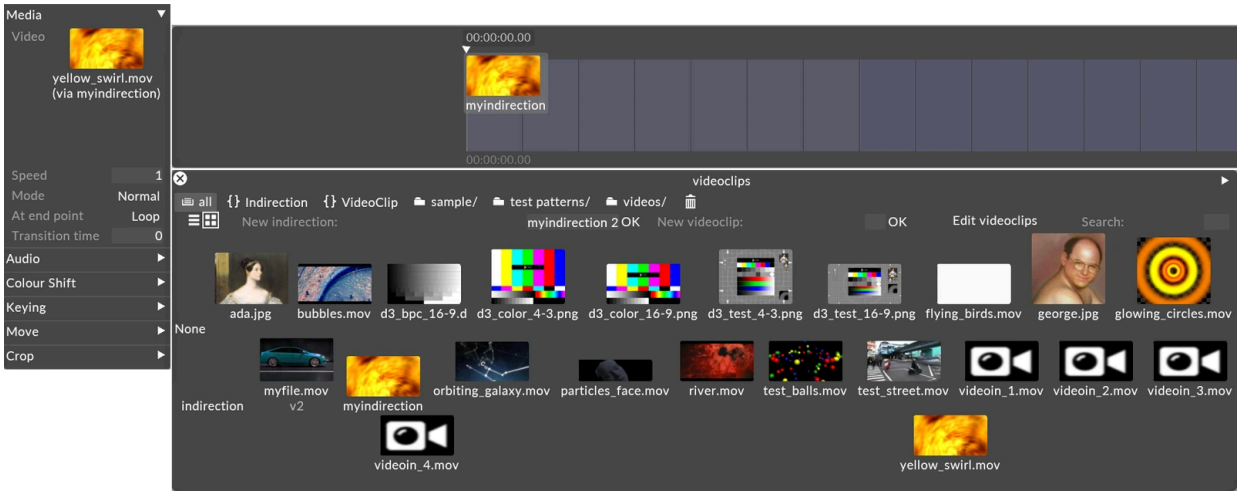
Examples

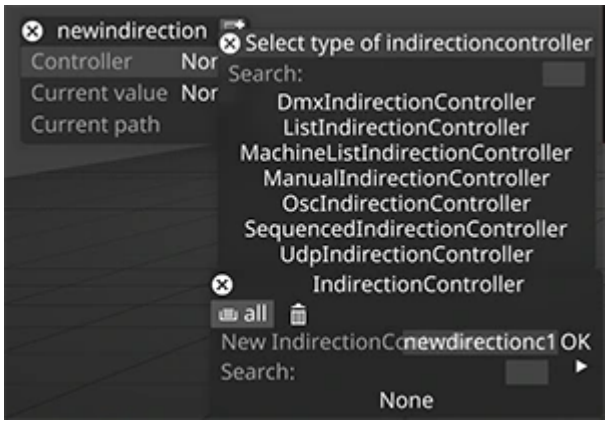
Manual

Manual indirections are extremely useful if you want to make a quick change to a defined resource via Designer user interface. For example, swap out a logo during a corporate event.

1. Open a content layer, such as Video.
2. Open the keyframe editor for the resource you wish to change, i.e. videoClip.

3. Create a new Indirection.
4. Give the Indirection a unique name.
5. In the Indirection create a controller.
6. Choose the manual controller type.
7. In the manual controller, choose a resource to assign to the controller.
8. Once this is done, the resource can be changed and the layer is updated.





List

List is a useful controller for when you have a small selection of resources you wish to change out or swap between. For example toggling between two pieces of media for when a different performer is covering for someone during a show.

1. Open a content layer, such as Video.
2. Open the keyframe editor for the resource you wish to change, i.e. videoClip.
3. Create a new Indirection.
4. Give the Indirection a unique name.
5. In the Indirection create a controller
6. Choose the list controller type
7. In the list controller, choose resources to assign to the controller. a. Resources can be re-ordered like other lists in Designer. Drag the items up and down to re-order. b. The index value cycles through resources, so the ordering of the list is important. c. The Index value can have an expression which can be linked to an external device, for example a midi controller. This expression can be temporarily switched off and on with the `=` / `//` button beside it, in the same way as a layer expression.
8. Once this is done, the resource can be changed and the layer is updated.

OSC

The OSC indirection is useful if you want to create a more complex front end interface on a device such as an iPad, or apply logic to your Indirections.

1. Open a content layer, such as Video.
2. Open the keyframe editor for the resource you wish to change, i.e. videoClip.
3. Create a new Indirection.
4. Give the Indirection a unique name.
5. In the Indirection create a controller.
6. Choose the OSC controller type.
7. In the OSC controller, choose values to assign to the controller.
    - Set the OSC device that the controller is receiving data from.
    - Set the OSC address that the controller is listening to.
8. Once this is done, the resource can be changed and the layer is updated.

DMX

DMX is useful for being able to change Indirections via a lighting desk, much in the same way sockpuppet works, but without needing to set up a full sockpuppet programming workflow.

1. Open a content layer, such as Video.
2. Open the keyframe editor for the resource you wish to change, i.e. videoClip.
3. Create a new Indirection.
4. Give the Indirection a unique name.
5. In the Indirection create a controller.
6. Choose the DMX controller type.
7. In the DMX controller, choose values to assign to the controller.
    - Set the universe & address.
    - Ensure the resources you wish to control are exposed in the bank assignments, much like sockpuppet.
8. Once this is done, the resource can be changed and the layer is updated.

UDP & TCP

The UDP Indirection is useful for more complex use cases where an external system is running logic to decide which Indirections are being used.

1. Open a content layer, such as Video.
2. Open the keyframe editor for the resource you wish to change, i.e. videoClip.
3. Create a new Indirection.
4. Give the Indirection a unique name.
5. In the Indirection create a controller.
6. Choose the UDP or TCP controller type.

7. In the UDP or TCP controller, choose resources to assign to the controller.
    - Set the key(s) for your resource(s).
8. Once this is done, the resource can be changed and the layer is updated.

Scheduling Events

A **Schedule** is useful for long-term running or permanent installations. It allows you to schedule track change events that occur regularly over long periods of time (days, weeks or even months).

> **Note**
>
> **Please note**: the Scheduler is merely a device for switching tracks based on the specified time. It is not a mechanism for powering down hardware or quitting Designer. It is possible to schedule a time for Designer to exit and close using the **Scheduled Exit** feature. For more information please see the Exiting a project sub-chapter.

How the Scheduler works

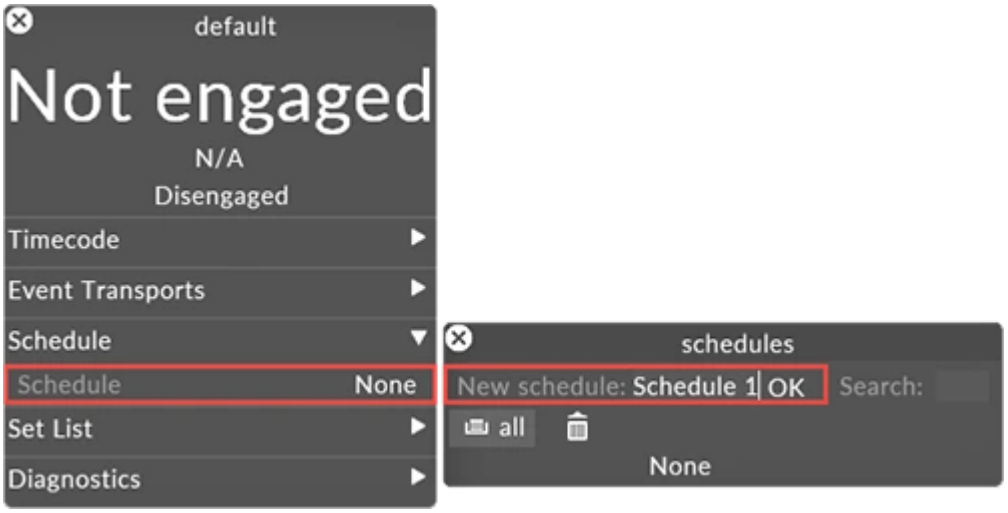
The scheduler behaves in the following manner:

1. The scheduler will go down the list of events to see what to do
2. The scheduler will keep going down the list until it finds an active event
3. As soon as it finds an event that is active it will switch to it
4. Repeat the above steps.

To move the events up/down the scheduler list, simply drag and drop them

Create a schedule

1. Left-click the schedule property in the Transport Editor. This will open the Schedules manager which contains a list of all of the schedules available.
2. Type the name of the new Schedule into the new schedule text field.
3. Hit Enter. This will create the new schedule, add it to the Schedules manager, and open the Schedule manager. The Schedule manager consists of an ordered list of events.



Events are also referred to as schedule items. A schedule item specifies a track trigger event. For example, a schedule item can say: trigger track X for a set duration, repeating on a chosen interval, between the hours of A and B and on dates C to D.

Schedule properties

On startup

The playmode the Schedule sets when the project starts: **Stop**, **Play**, **Play to end section**, or **Loop section**.

Transition

How the Scheduler switches between tracks:

- **Cut** — a hard cut straight to the new track.
- **Fade** — fades to black between tracks.

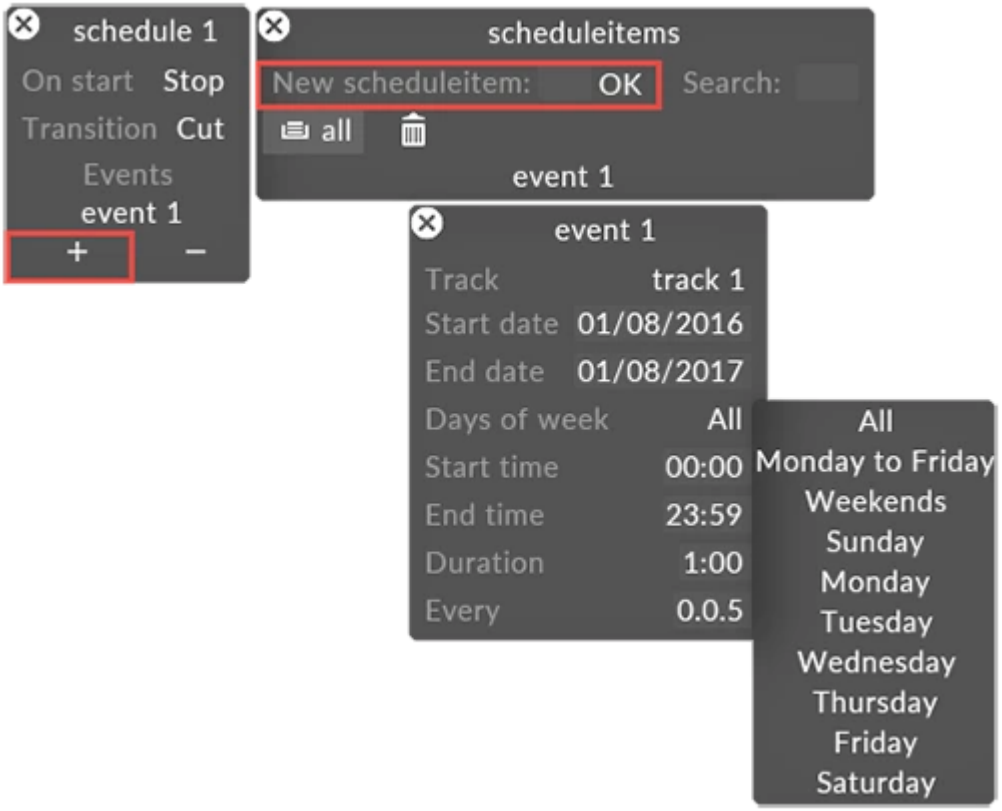
Events

The ordered list of schedule items. The first active item in the list wins, so place higher-priority items (for example, a track that must play on the hour) nearer the top.

Add a schedule item to the Schedule

1. Left-click **+**. This will open the scheduleitems manager which contains a list of all of the schedule items.
2. Type the scheduleitem name into the new scheduleitem text field, in this example the event morning.

3. Hit Enter. This will add the schedule item to the schedule menu and open the Scheduleitems editor.



As an example, the Schedule object called schedule 2 has been edited to contain one event called morning. Morning will be active for five minutes every hour, starting at 9am and ending at 4pm, between the 1st of November and the 15th of December, all days of the week.

Schedule item properties

Track

Specifies the track that will be triggered.

Start date, end date

Specifies the date range over which the event is active. The format is `dd/mm/yyyy` (a two-digit year is also accepted).

Days of week

Specifies which days the item applies on: **All**, **Monday to Friday**, **Weekends**, or a single day (**Sunday** to **Saturday**).

Start time/end time

Specifies the time range during the day that the event will be active. The format must be `hh:mm`.

Duration

Specifies how long the track stays active each time the event triggers. The format is `hh:mm`.

Every

Specifies how often the event re-triggers within its time window — the repeat interval. The format is `hh:mm`.

10-bit Content

10-bit content is a newly supported feature in r16. This topic aims to show some of the known workflow challenges to be aware of.

- 10-bit content is added to project just like any other content. See placing media files for more information.
- 10-bit content can be played back regardless of whether is in 8-bit or mode.
- Only DPX content has received a full performance test.
- DPX files cannot have alpha channels.
- NotchLC is supported. This is technically the highest performance format supports.
- Embedded HDR data is not currently supported. Tone maps (LUT file's) must be applied on the output.
- The bit depth of DPX sequences is not given when in 8-bit mode.

10-bit file format support is as follows:

- Files loaded from objects/DxTexture are downgraded to 8-bit in r16 regardless of original bit depth or current bit depth of d3.
- Files loaded from objects/VideoFile are downgraded to the current bit depth of d3.
- PNGs may be subject to some processing during downgrade.

Alembic Files

Alembic (.abc) files are animated 3D mesh objects that can be imported and used in Designer.

Configuring an Alembic file within Disguise

1. Open your project folder.
2. Copy your working Alembic file into the Mesh folder.
3. Run your project.
4. Right-click on the **Stage** menu.
5. Left-click on the venue to assign one to the project. If the default 'none' is selected, create a new venue.
6. Right-click on the venue name and click on the **+** symbol to add a new prop. A prop can be a regular mesh or Alembic file located in the Mesh folder.
7. Right-click on the name of the newly created prop and under the Mesh property, select the Alembic file.

Playing back an animated Alembic Mesh

The recommended way to play back an animated Alembic Mesh is using the scene animation layer.

Alternatively, the legacy workflow is as follows:

1. In the timeline, create an **AnimateObjectPreset** layer.
2. Left-click on the layer to open it's layer editor, and open the keyframe editor for the Config tab.
3. Create a new screen configuration named "off" and hit the + icon to add the Alembic prop to the layer. Leave all fields at the default `0`.
4. Duplicate this configuration and name it "on"
5. Right-click on the header bar to open the "on" configuration's properties menu, and set the **Animate** field to 1.
6. Keyframe these two configurations to have the Alembic file animate in the visualizer. The time between the "on" and "off" configurations will determine the speed the animation plays back.
7. Enter a playmode in the timeline to see the file animate.

Recommended Blender settings for object animation and export

> **Note**
>
> If you have any questions about the UI or specific animation workflow of Blender, it is best to contact Blender support. This guide is intended only for the specific export settings needed with the Disguise workflow.

1. Set the project's units to **Meters**.
2. Import or create the mesh of your prop object in Blender.
3. Create an empty and animate it with either the keyframe or graphs editor.
4. Attach this null to your object using an object constraint or modifier.
5. Play your animation to ensure that the object is now attached to the null.
6. Select the null and the object.
7. Export the Alembic file using the below settings:
   - Renderable Objects Only
   - UVs
   - Pack UV Islands
   - Normals

Important Notes about Alembic Files

Alembic files can be used both as prop objects and as content screens. As with OBJ files, an Alembic file used as a content screen must be UV-mapped.

There are some restrictions on the types of Alembic files supported in Disguise. Please refer to these recommended Alembic export settings if your custom Alembic file is not rendering within Disguise.

The object must not contain:

- Curves
- Points
- Camera
- SubD
- NuPatches
- FaceSet
- Light
- Material
- Custom data

Archive Unused Objects

Archive Unused Objects is a legacy tool designed to provide utilities to quickly remove unused files from a project. It allows you to do 2 things:

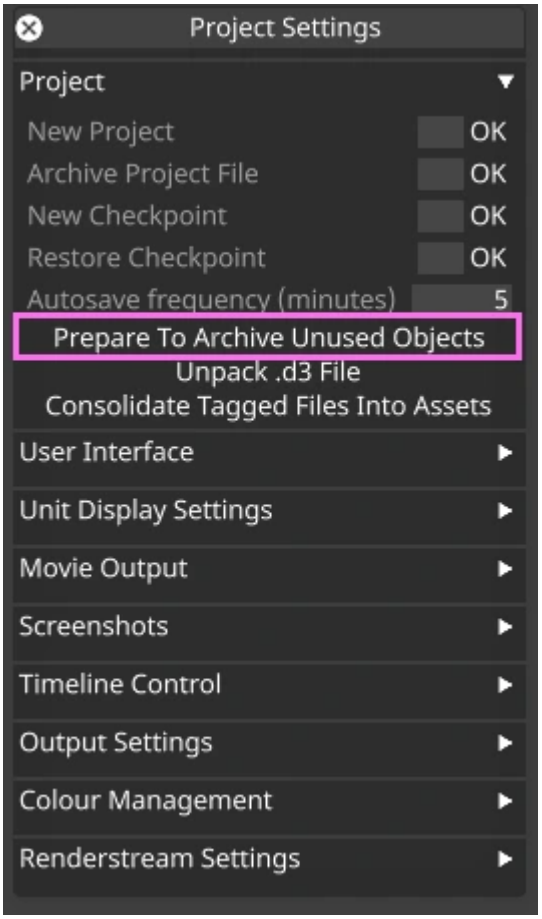
- Move all unused media out of your objects folder and into an archive folder.
- Copy your project to a clean folder with only the used media.

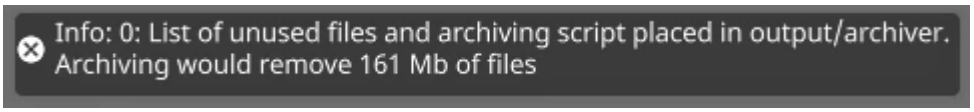
“Media” refers to anything in the `objects` folder, including video files, audio files, notch blocks, images, meshes, etc. A piece of media is considered “Unused” if it is in the `objects` folder but is not sequenced anywhere on any track or any layer (including exported or saved layers). Old versions of media are still considered “Used” if that media is sequenced somewhere. If you want to remove old versions of media, you can use the manage old media workflow.

Preparing to Archive Unused Objects

To archive unused objects, follow these steps:

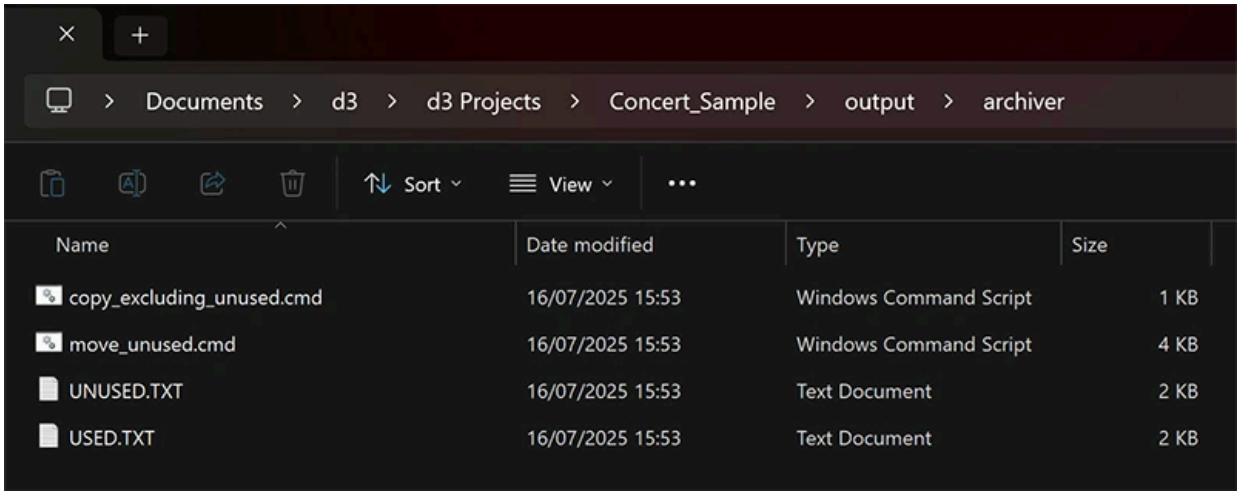
1. In Designer, right-click **d3** to open the **d3 State** menu in the dashboard.
2. Left-click **Project Settings**.
3. Left-click **Prepare to Archive Unused Objects** under the **Project** drop-down.





This causes Designer to create a new folder within the project folder called `output/archiver`, which contains two text files:

- **USED.TXT**: a list of all the media that is currently used somewhere in the project
- **UNUSED.TXT**: a list of all the media that is present in the `objects` folder but is not used in the project.



It also contains two scripts for performing the two available actions:

- **move_unused.cmd**: This will move all of the unused video files within the `objects` folder to a new `archive` folder next to the project file. This will remove them from the `objects` folder if Designer is closed.
- **copy_excluding_unused.cmd**: This will make a full copy of the project folder in a location of your choosing and will exclude anything that was identified as `unused`.

> **Note**
>
> The scripts and text files are generated when you click **Prepare to Archive Unused Objects** and are not dynamically updated as changes happen to the project, so you must press the button each time you want to perform either archive script action after new content has been sequenced or ingested.

Running the Archive Scripts

To use each script, follow these steps:

Running the “Move Unused” Script

To remove all unused media from the `objects` folder with the **move_unused.cmd** script, complete the following steps:

1. Close Designer.
2. Double-click on **move_unused.cmd**.

Running **move_unused.cmd** with **Designer open** will **NOT** remove the files from the `objects` folder but will still copy them to the `archive` folder. Running the command with **Designer**

closed will only remove objects that are **NOT** already in the `archive` folder, so it is best to run this script with an empty `archive` folder.

Running the “Copy Excluding Unused” Script

To make a copy of the project folder with all the unused media removed using the **copy_excluding_unused.cmd** script, complete the following steps:

1. Create a folder in Explorer that you want to make the copy in.
2. Make sure that **UNUSED.TXT** and **USED.TXT** are still in place (the script will read these).
3. Drag that folder on-top of the **copy_excluding_unused.cmd** script in Explorer to run the script.

Content Management Overview

Content management is divided into three broad areas which consist of content version control, proxy management and frame replacement.

Content Version Control

- The software understands version tags in video filenames (_vXXX where XXX is one or more numerals, optionally followed by a letter).
- You can copy new content versions to actors while the software is running (as long as you're not trying to overwrite a file that's currently being played).
- When a new version of a file arrives, the software will automatically replace older versions on the timeline wherever they occur.
- You can drop any asset back to an older version instantly.
- Once new content arrives on a machine, it becomes available instantly, without having to refresh.
- If content is unavailable on actors, will warn you by colouring layers on the timeline (yellow for wrong version, red for no content).

Proxy Management

- In order to sequence large shows with multiple large video files on a laptop, you can substitute them with low-resolution versions (proxies).
- Proxy files are indicated by adding '_proxyXYZ' to the video filename, where XYZ is any number. Higher numbers indicate lower resolutions.
- In the visualiser, use your camera position (in stage view) or view position and zoom (in feed view) to select which proxy level to display.

Frame Replacement

- A new version of a video file can replace a subset of frames of the overall video file.
- Add the tag '_frameXYZ' after the Version Control tag ('XYZ' should be a frame number), and Designer will interpret the video file as a 'patch' to the file.
- This saves time when you want to replace single corrupted or erroneous frames in a clip, or short runs.

The Frame Replacement feature requires a Version Control tag greater than the file that's being replaced.
For example, to replace content from frame 130 of a file called "Video_v1.mov" one would need to name their replacement file as follows: "Video_v2_frame130.mov".

Media Ingestion History Tool

- Disguise analyses new content and displays them in the Media Ingestion History Tool.
- This is used to find and fix naming or spelling errors in filenames when they occur.

Content Versioning

Content versioning is a powerful feature of Designer that allows you to easily version and subsequently replace media files based on their file name. This is useful for shows where content development continues throughout rehearsals and Disguise programmers need a quick way of changing between different versions of an asset.

For more information on where to put media files, including video content see Placing Media Files.

New files may either contain :

- no version tag `myfile.mov`
- a numeric version tag `myfile_v2.mov`
- a date version tag `myfile_v20210602a.mov`.

Date version tags should be formatted **YYYYMMDDL**, where L is a, b, c... and so on.

Date version tags can also be extended to **YYYYMMDDHHMM** where **HH** is hour and **MM** is minute.

Version tags are sorted alphabetically, i.e. `_v20210602b` is considered a more recent version than `_v20210602a`.

Designer will remove the version tag to create a stem filename, and create a new VideoClip with the stem name.

There may be more than one occurrence of the version tag in the overall pathname, i.e. it is permissible to create a folder for each version date, if you wish. However, please note that this introduces the risk of errors, i.e. if you make a mistake and add a different version tag to the filename, the result will be indeterminate.

To add a new version of a file, simply copy it into the VideoFile folder alongside the older versions. Designer will automatically match the stem filename with the existing clip and load the new version, which will play immediately.

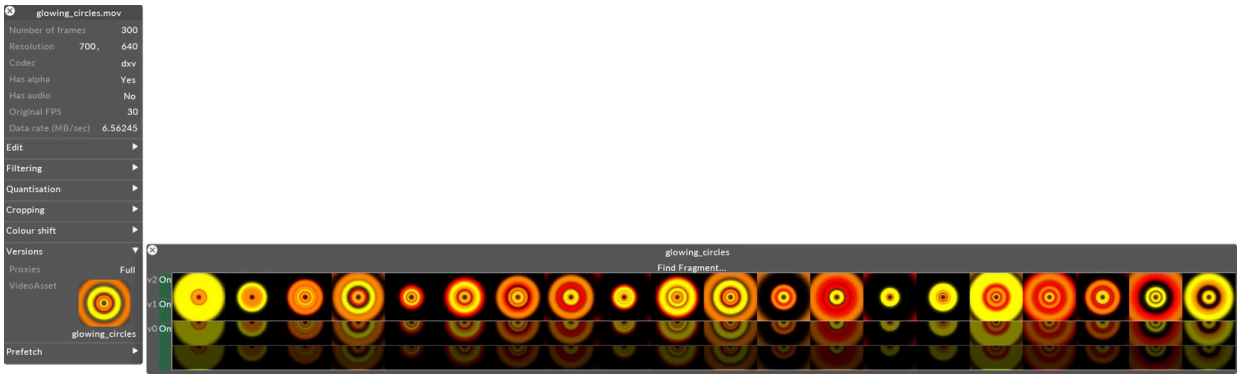
Designer will automatically replace older versions of the file wherever it occurs in the timeline.

Examples

File Path	Read File Name	Version	Notes
myfile.mov	myfile.mov		No version supplied
myfile_v1.mov	myfile.mov	1	You can prefix the version with either '_v'
myfile.v1.mov	myfile.mov	1	... or '.v'
myfile_1.mov	myfile_1.mov		But without those the version will just be part of the stem
/v1/myfile.mov	myfile.mov	1	Alternatively, you can put the version in a folder (without the '_' or '.')
/v1/myfile_v1.mov	myfile.mov	1	You can even include it multiple times if you wish
/v1/myfile_v2.mov		ERROR	...but if the versions don't match, it will cause an error
/1/myfile.mov	/1/myfile.mov		If you're putting the version into a folder name, but if it doesn't start with 'v' then it will just be part of the stem
myfile_v1b.mov	myfile.mov	1b	Version tags can include letters too

Viewing an assets version

1. Open the Video layer editor, expand the Media tab, and right-click on the Video thumbnail.
2. Expand the Versions tab and right-click on the Video asset to view a simple graphical view of the file contents.



VideoClip and VideoAsset editors for glowing_circles.mov', after adding'glowing_circles_v2.mov

> **Note**
>
> You can drop back to previous versions of the file by opening the **VideoAsset** editor and clicking **On** next to each version, and setting it to **Off**.

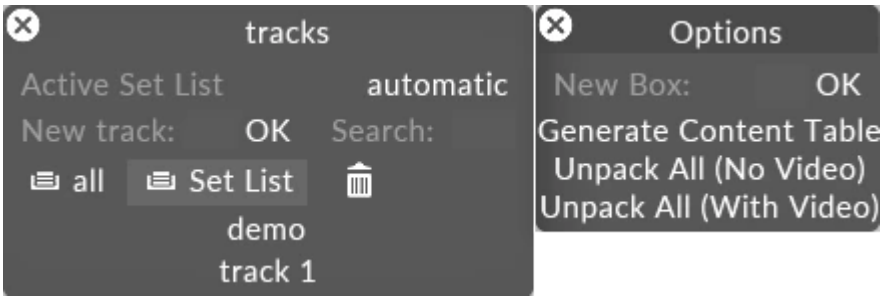
Content version information is also contained in a content table. For more information on how to generate a content table, see Generate Content Table.

Generate Content Table

Generate Content Table allows users to export a list of content used in the project.

Generating a content table

1. Open the track manager by left-clicking **Track** from the dashboard.
2. Right-click the **All** box (or whichever box you wish to export a table of).



3. Click the **Generate content** table option.
4. A notification will appear upon successful generation of the content table.

Viewing a content table

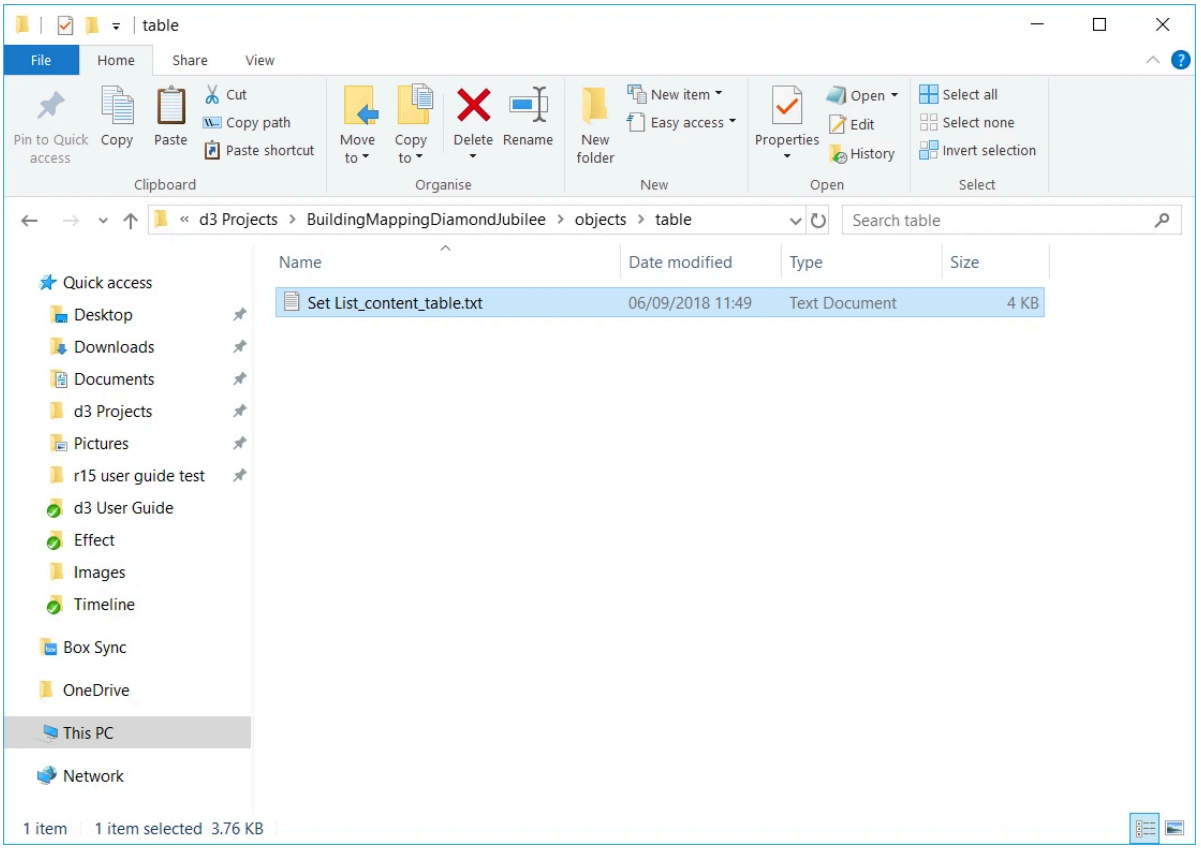
The content table is written as a text file (.txt) to a newly created **Table** folder inside the **Objects** folder of the project.

Open your project folder by navigating through the windows file structure to its location.

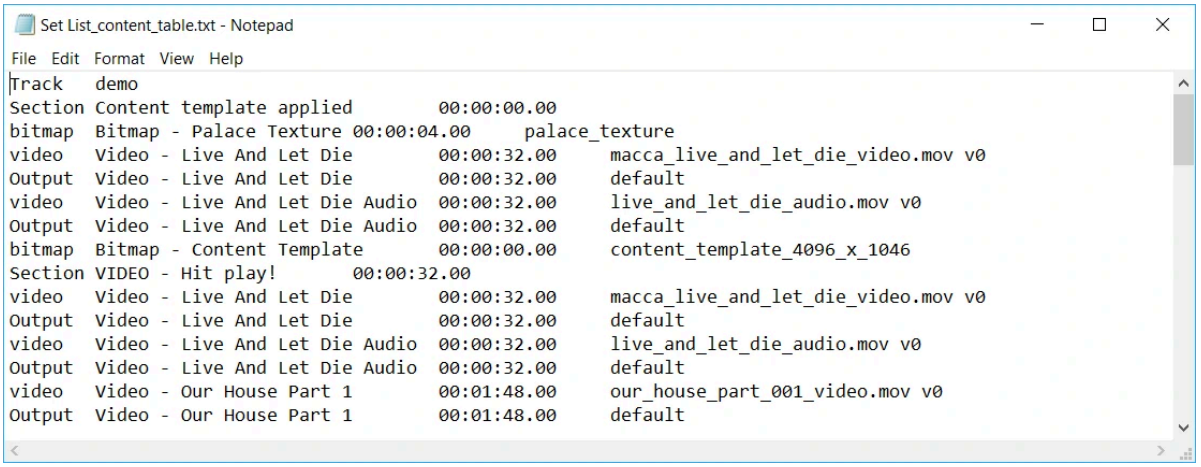
For more information see Project structure.

1. Open the **Objects** folder.

2. Open the **Table** folder.



3. Open the newly created .txt file in the Table folder.



Content table structure

The content table is arranged by **Track**. Within each **Track**, it is arranged by **Section**. The **Section** name (if there is a **Note** on the same beat as the section break) and the **Section** start time (in Timecode format) are listed on the same line.

Under a **Section**, each row describes a content file used in that section, and is laid out as:

Sequence name	Layer name	Timecode of keyframe	Content description

For video files, the content description includes the most recent enabled versions of the file. The versions include all versions up to the latest non frame-replacement version. For more information about frame replacements, see Content Management.

> **Note**
>
> For a **Layer** that span across multiple **Sections**, each **Section** lists the contents of that **Layer**. This way every **Section** is a self-contained list of content.

Generating a Proof of Play

Proof of Play is a method of generating a record of video files played by the timeline.

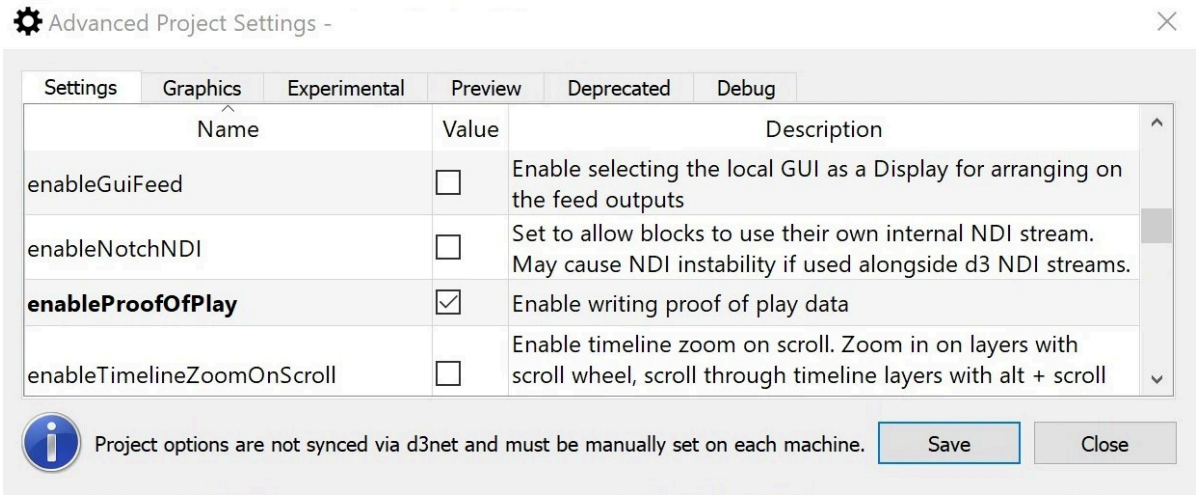
Proof of Play is available in all Designer versions after and including r17.1. It is a tool for producing a .csv file which contains a list of video files that were played in the timeline. This feature is valuable for installations or venues where ad revenue is received as a proof of exactly how long a video has played, or to check which content files are dropping frames.

> **Note**
>
> Proof of Play tracks video files only. It is not available for RenderStream or other non-video content types.

How to enable Proof of Play

Proof of Play is an Advanced Project Setting and must be enabled on each machine in the system.

1. Right-click on the name of the project folder in d3manager.
2. Select **Advanced project settings**.
3. Under the **Settings** tab, set `enableProofOfPlay` to on by ticking the box. Proof of Play is now enabled.



> **Note**
>
> In a network with multiple servers, Proof of Play will only write a csv of content that an individual machine outputs. If one screen is being fed by only one server, the *proofofplay.csv* will only record the pieces of content that were sent to the individual screen by that individual machine. The .csv file does not compile a list of all media within the project.

4. Open the project and enter a play mode in the Timeline.
5. Quit the project and open the project folder at the Windows level.
6. In the **output** folder there will now be a **proofofplay.csv** file containing information about all of the videos that were played in the project session.

> **Note**
>
> The *proofofplay.csv* file is written as the content plays in the Designer project. If the file is open while running the project, it will not update.

Example: proofofplay.csv details

	A	B	C	D	E	F	G
1	Start time	End time	Layer	Video	Frames played	Total frames	
2	2020-06-23T10:50:32.126-04:00	2020-06-23T10:50:36.057-04:00	container 1	video samples/002 orbiting_galaxy.mov	119	300	
3	2020-06-23T10:50:36.075-04:00	2020-06-23T10:50:46.960-04:00	container 2	video samples/005 test_street.mov	300	300	
4	2020-06-23T10:50:46.978-04:00	2020-06-23T10:50:49.927-04:00	container 3	video samples/002 orbiting_galaxy.mov	90	300	
5							
6							

proofofplay.csv open containing details about 3 videos

Each line is a discrete video entry:

Start time - Time file began playing.

End time - Time file finished playing. This is based off computer time.

Layer - The container on the timeline the video was played back in.

Video - Name of video file, including path to access it.

Frames played - How many frames of the video were played. If you drop frames during playback, this will be less than total frames even if the video plays to completion.

Total Frames - Total video length in frame.

Accessing Proof of Play data via API

The same playback data is also available in real time via the Disguise Developer API, without needing to wait for the session to end or the CSV to be written. This is useful for integrating with content management systems or third-party reporting platforms.

See the **Proof of Play API guide** on the Disguise Developer site for details.

Image Sequences

An Image Sequence enables the playback of a contiguous sequence of images as a video.

Enabling image sequences

Any folder inside VideoFile with a name ending in **.seq** will be ingested as an image sequence. As long as it matches the requirements described in this topic, it will behave just like a conventional video file.

Supported Formats:

- TGA
- TIFF
- DPX

8-bit and 10-bit are supported where applicable. All formats support the use of an alpha channel (with the exception of 10-bit DPX), and any framerate.

> **Note**
>
> Although other formats may work, only those listed above are formally supported.

Sequence Requirements

Alongside supported formats, there are rules that must be followed when creating image sequences for them to be recognised by Designer. These rules are in place to ensure reliable and predictable playback performance.

- The names of images within the folder must end with their frame number. For example: `My_video_00035.tif` would be the 36th frame in the sequence.
- As an additional precaution, the name of the images should be prefixed with the folder name.
- Eg: `My_video.seq\My_video_00035.tif`.
- The numbering must start from 0.
- There must be no gaps in the numbers between frame 0 and the final frame of the sequence.
- File formats cannot be mixed within the same image sequence folder.

Ingesting image sequences

Image sequences will always be imported at 30fps. The playback fps can be changed in the clip properties.

Additional frames can be added to a sequence while it is running and will be available for playback immediately. We do not recommend playing back the sequence while receiving extra frames, as this will affect playback.

In much the same way, gaps in image sequences can be filled in while it is running, and once complete, the sequence will become available.

Frames cannot be removed from a sequence without first exiting the project.

Any errors in image sequence formatting will be announced by a notification.

Content management

Version, frame replace, and proxy tags behave in the same way as with regular videos, as long as the **.seq** portion of the folder name stays at the end.

For example: `My_video_v2_frame150.seq` would be a frame replacement for `My_video.seq` starting from frame 150. Tags are only ever applied to the .seq folders, never the image files themselves.

The rules for frame numbering are the same for frame replacements - the frames inside `My_video_v2_frame150.seq` must still be numbered from 0.

If a sequence is accidentally imported without **.seq** at the end of the file name, the several thousand image files ingested can be removed by taking the following steps:

1. Exit the project.
2. Add the missing **.seq** to the folder name.
3. Start the project.
4. Right-click the **missing** tab in the videoclips editor and select **Remove Missing**. After a brief pause, the images will be removed.

Performance

Due to specific performance optimisations, the preferred settings for TGA and TIFF are as follows.

TGA

- Do not use RLE compression
- Render at 24-bits per pixel. Only include an alpha channel if required.

TIFF

- Use IBM PC byte order
- Do not use LZW compression
- Segment size should be equal to the height of the frame (this is often the default and not editable).
- Render at 24-bits per pixel. Only include an alpha channel if required.

DPX

- Render at 8-bits per channel unless working in a fully 10-bit pipeline.

> **Tip**
>
> EXR image sequences can technically be loaded and played; however, if they are HD resolution and higher they require significant machine resources to play, which makes them unsuitable for most production use cases.

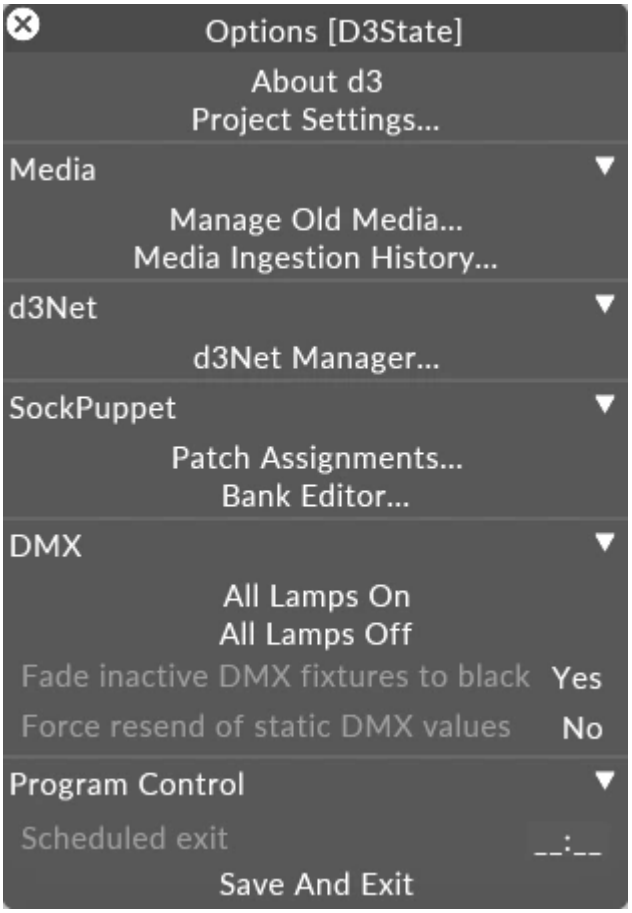
Manage Old Media Editor

Manage old media is a tool within Designer that allows the user to generate a list of unused versioned media within the project and archive it. As this tool only works specifically with versioned content files, it is generally used to clean up the project and remove 'old' versions of content that are no longer used.

Versioned content uses tags such as `File_v1` or `File_20170602a`. For more information, please refer to the Content Versioning topic.

Accessing 'Manage Old Media' Editor

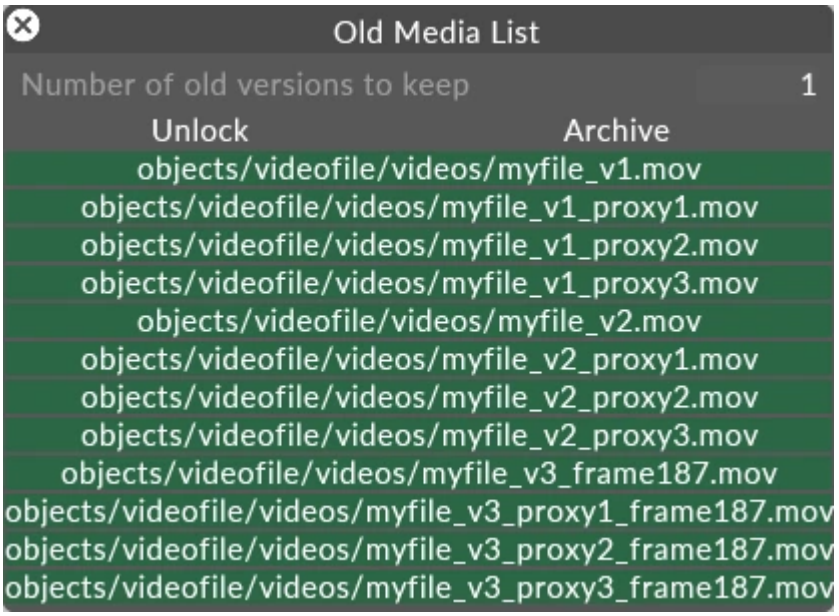
1. Right-click the d3 state menu in the dashboard.
2. Left-click **Manage Old Media.**



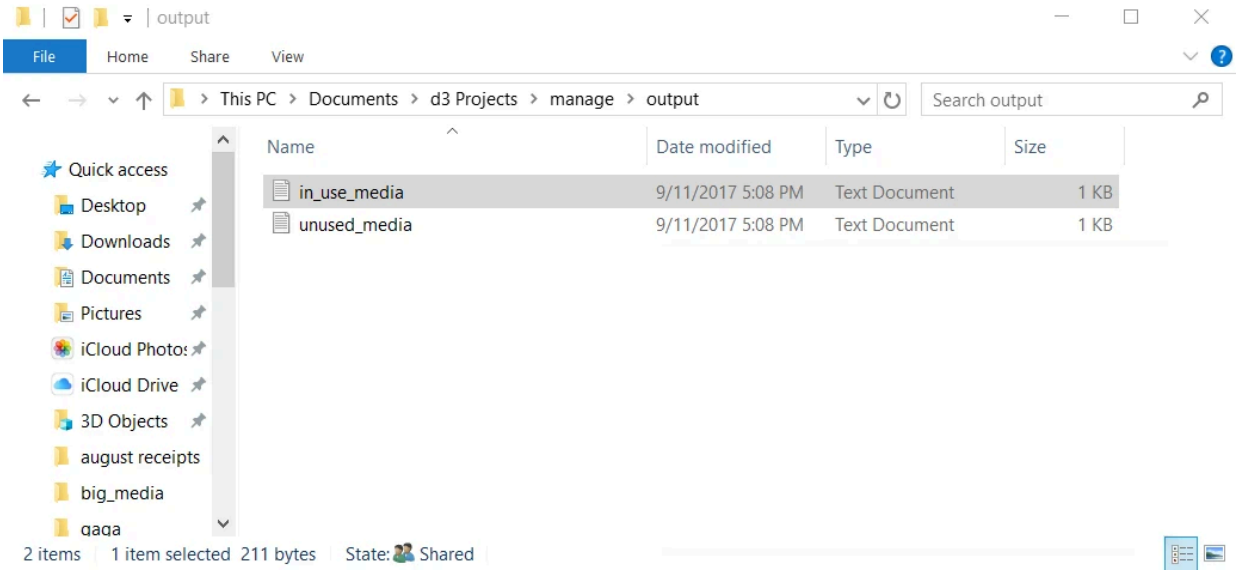
Manage old media option

Using the 'Manage Old Media' Editor

1. Left-click the **Unlock** button in the Manage Old Media Editor. The button will generate two lists, **in use media** and **unused media**, in the output folder of the project file. These are for manual reference and deletion.
2. Left-click the archive button and an automated process will move unused media to the **Archiver** folder in your project's **output** folder. This can be deleted or transferred to a new location or external storage location.



Manage old media editor, with all files selected.



Text files written to the output folder, following an archive process.

> **Note**
>
> You can specify a number of old versions to keep in the Manage Old Media editor.

Media Distribution

The Media Distribution feature provides a built-in mechanism to easily ensure that the exact required media files are present on each d3 machine involved in a d3 session. There are two parts to the Distribute system:

1. Sync/copy missing media - copying media used by the d3 project and needed by a machine's feed mapping.
2. Delete unused media - removing media that is not used by the d3 project.

To use the Media Distribution feature

1. Access the GUI of the Director machine. Only the Director machine can access the Media Distribution interface.
2. Right-click on the d3 menu and select **Media Distribution...** to open the Media Distribution Widget.
3. Expand both collapsible widgets to see the details of what media files are missing and unused copies.
4. **Include Mobile Editors** is defaulted OFF as they may wish to manage their own files, but the option is available.
5. Either click on **Sync** or **Delete** next to each item to sync or delete individual files on the target machines, or alternatively click **Sync All** or **Delete All** to action all the items in the respective tables.
    1. For copying large files, it will display the copy progress as a percentage.
    2. At the end of a copy, it will display the task state as either **Success** or **Failed**. For
6. Click on **Clear Finished Tasks** above the sync table to remove syncs that completed successfully and reset the status on syncs that failed.

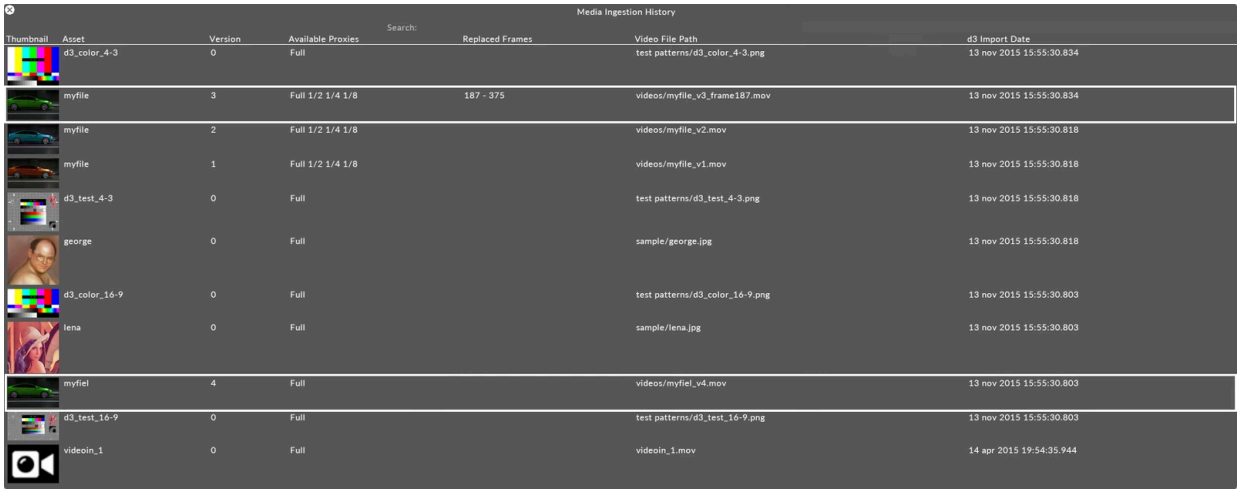
Media Ingestion History

There are two ways to access the Media Ingestion History:

- Right-click the d3 state menu in the dashboard and select Media Ingestion History
- In the VideoAsset editor (by pressing the 'find fragment -' button).

In the latter case, the media import history editor is brought up with the search field pre-populated with the name of the asset.

The Media Ingestion History can highlight any spelling or version number mistakes with the file naming which may affect the Content Version Control.



Media Import History showing misspelled file stem name myfiel instead of myfile

There is a search feature for finding files. The search is fuzzy, so it will find all misspellings as well as correct files.
Errors can be fixed directly in the Media Ingestion History by doing the following:

1. Right-click incorrect asset name.

2. Select the option ‘move to asset’ and click the correct asset.

Correcting an erroneous import caused by the spelling mistake

> **Note**
>
> **Please note**: You can clear the media ingestion history from a project prior to running the project; right-click on the project file in the d3Manager and select “Clear Ingestion History”. This will cause Disguise to rescan all media when the project is launched.

Missing and Unused Media

In large projects, it is common to end up with lots of iterations of things like videos, meshes, notch blocks and other on-disk media. All on-disk media that you place in the `objects` folder of your Designer project will generate an in-designer representation of that object. This is very convenient, but because these objects are generated automatically, it is common for them to become a pain over time on more complex projects with lots of media revisions.

Designer has some special tools to allow for the management of the in-Designer representations of this on-disk media and keep your projects simple and un-cluttered. For this guide we will focus on Video Clips which are the in-Designer representation of on-disk media files, but the same principals apply to all objects.

The relationship between Video Clips and Video Files on-disk

Whenever a video file is placed in the `objects/VideoFiles` folder on disk of a Designer project on **ANY** machine in session, Designer will automatically create an in-project representation of that media called a Video Clip. This clip has a range of user configurable settings, but it also is the in-project representation of the on-disk media, and as such it can be in a few different states based on the state of your on-disk media and your project file:

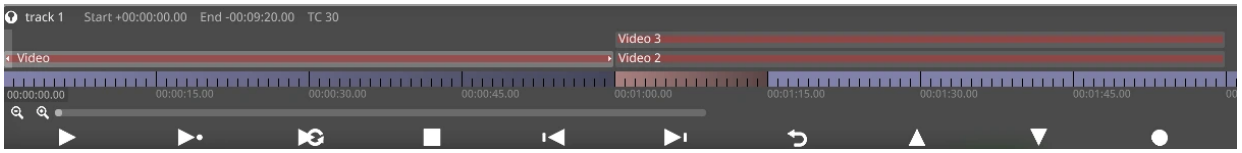
- **Missing** - At least one machine in the session that **NEEDS** that media does not have it on-disk.
- **Unused** - No video layers, layer stacks, video inputs, or other parts of Designer need this Video Clip to do their function (It's not sequenced anywhere).

Missing Media

Missing media means that an on-disk asset is missing on a particular server but it is needed by that server to play that content. For example:

In a 2 server session with a Director and an Actor, I have a single video layer where I have **Ada.jpg** as my video clip. The **Ada.jpg** file only exists on the Director, so this content is **Missing** on the Actor.

When media is missing the layer that uses it will be highlighted in red like this and if you mouse-over the layer a tooltip will explain which content is missing on which machine:



Missing Media Example

The Director machine reports the missing status of any media missing on Undertudies and Actors only. Editor machines are not included, however they do report their own missing media on their own GUIs, but this information does not get shared with other Editors or the Director to avoid visual clutter.

When media is **Missing** AND the media is not **Unused** you should make sure to sync that content to the machines where it is missing. This can be done via the Designer native Content Management tool, or can be performed with 3rd party tools like **Free File Sync** for more granular control.

Unused Media

Unused media means that a Video Clip exists, but no machines in your session need that media for anything. For example:

In a 1 Non-Dedicated Director setup, I have a video in my folder called **George.jpg** but I only have 1 video layer and it has a different video seqenced, so this content is **Unusued** on my Non-Dedicated Director and indeed across my session.

Designer does not explicitly report unused media like we do for missing media, but we do provide a few tools for identifying it and removing it:

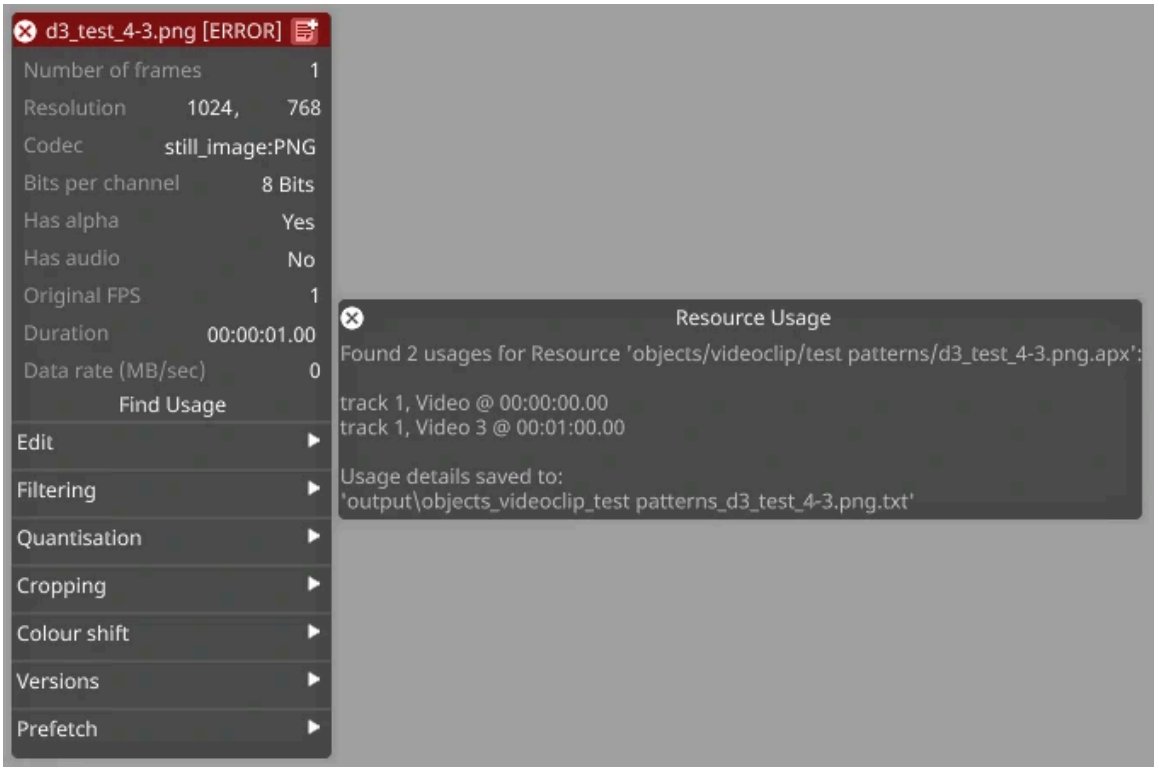
- Archive Unused Media is a legacy workflow for moving unused media to another folder location.

- Once **Unused** media has been archived, it will now also be **Missing** and you can **Remove Missing Resources** following these steps:
  1. Open any video layer.
  2. Left-click on the **Video** thumbnail to open the **Video Clip** library.

  3. Right-click on the **missing** box at the top of the VideoClip library window.

  4. Left-click on **Remove Missing Resources**. All missing media that is not referenced in any layer within the project will be removed from the VideoClips library.

5. If missing media is not removed from the VideoClips library at this point, this means that the clip is being referenced elsewhere in the project. Right-click on the red box for that media, and then left-click on **Find Usage** to locate the instances where the media is still being referenced in the project.



Placing media files

Where do I place the media files for my project?

The media files for a project are stored inside the **objects** folder. The **objects** folder is located inside the specific Project folder.

For information on where your specific Project folder is located pleasesee the above sub-chapter Projects. location/structure. To read about the exact specifiation of the media formats read the Supported file formats page.

Within the **objects** folder are the following sub-folders:

- **AudioFile** which contains all audio files (.mp3 .wav, .aiff). Notice that this audio is just for audio which is to be quantised on the timeline.
- **DxTexture** which contains all texture files (.png .jpeg .bmp .tif) including pixel masks and palette files.
- **LutFile** which contains LUT files used in the project. Visit this link for information on LUT files.
- **Mesh** which contains all 3D object meshes (.obj)
- **Notchfile** which contains notch blocks exported from Notch.
- **RecordingFile** which contains device recording files generated by Designer's Device Recording feature.
- **sdpfile** Session Description Protocol; these are network files that are used to send and request information from a network stream
- **textfont** stores all fonts used by them Text layer.
- **VideoFile** which contains all video files (.mov).

  > Still images can be placed in the **Objects/VideoFile** folder and they'll work just like video files. A benefit of this is when you have to work with proxy content while waiting for the real content to arrive; when you ingest the real content into the system, the content manager will make sure it supersedes the proxy.

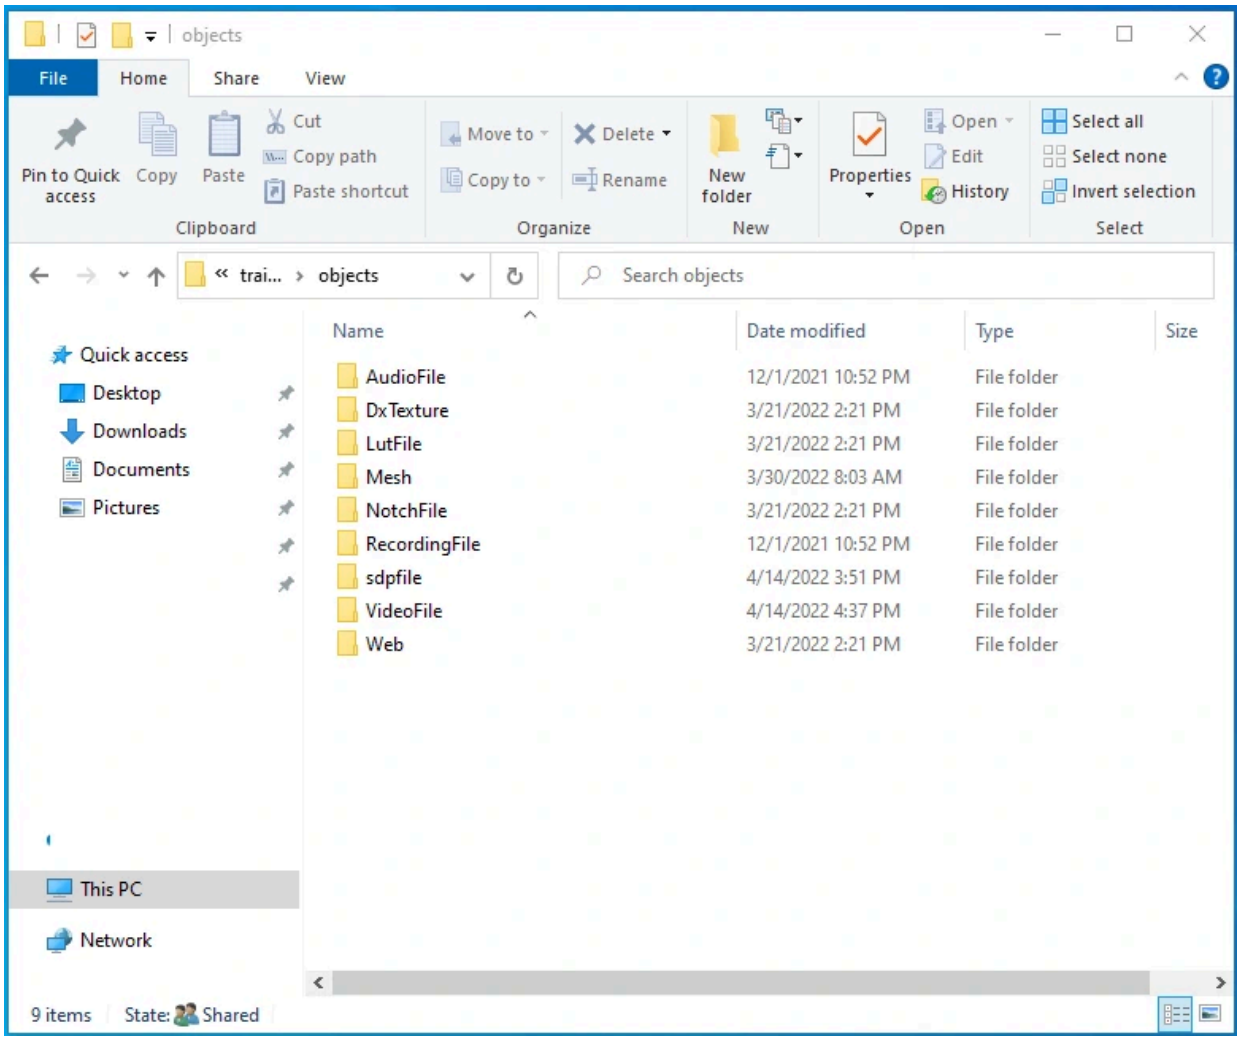
- **Web** which stores custom html files used by the Web layer.

Using Stills as Textures on props

Still images intended to be used as textures should be placed in the **Objects/DXTexture** folder.

The maximum texture size supported is 16k x 16k.

Still image files can be stored in either the DxTexture or VideoFile folder. Files stored in the DxTexture folder are available for use only in the Bitmap Layer. Files stored in the VideoFile folder are available for use only in the Video Layers.



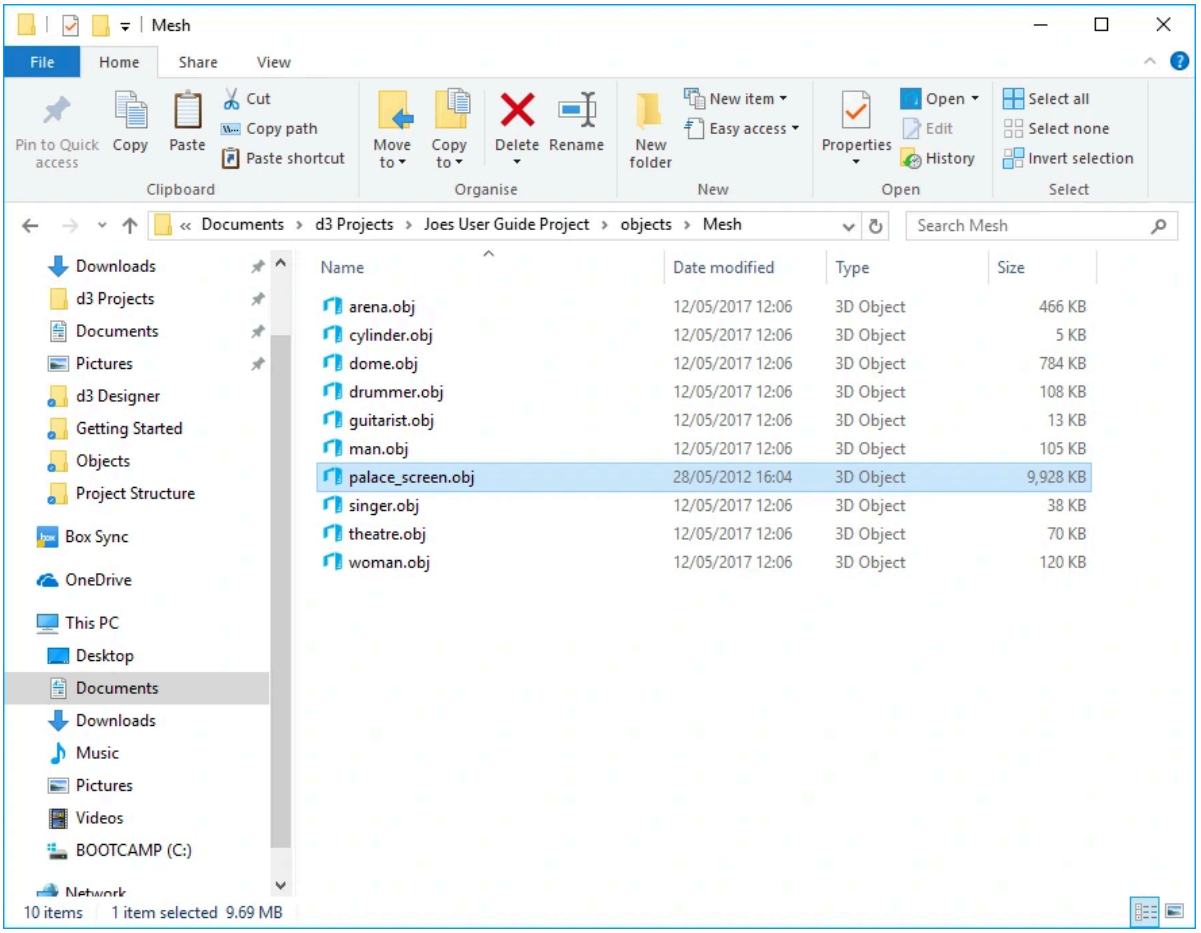
Object folder contains by default sub-folders which are used to store the media files for a specific project.

By default a new project contains a series of media files. For example, the **mesh** folder contains mesh files. For more information on the mesh folder please see the sub-chapter Venues/props overview.

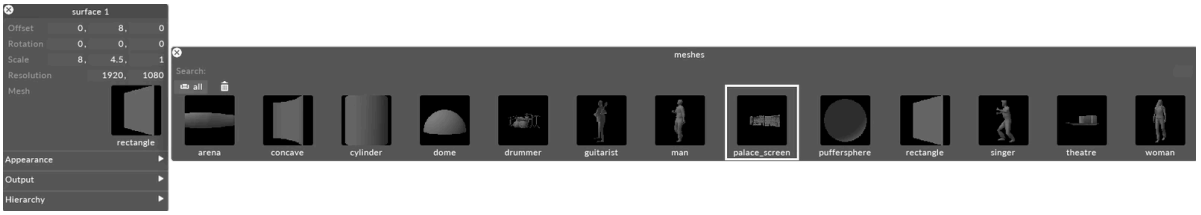
How to place media files and access them in your project

1. Ensure the media file is saved to a supported file format.
2. Open the **objects** folder.

3. Place the media file inside the appropriate sub-folder depending on the media file type. Once the media file has been added to the folder it will be added to the corresponding object library in the software. In this example a custom mesh file called **palace_screen** has been placed inside the **mesh** folder.



4. Run the software.
5. Select the media file from the appropriate [object library]



Palace screen mesh file can now be accessed in the software from the Mesh object library of the specific project.

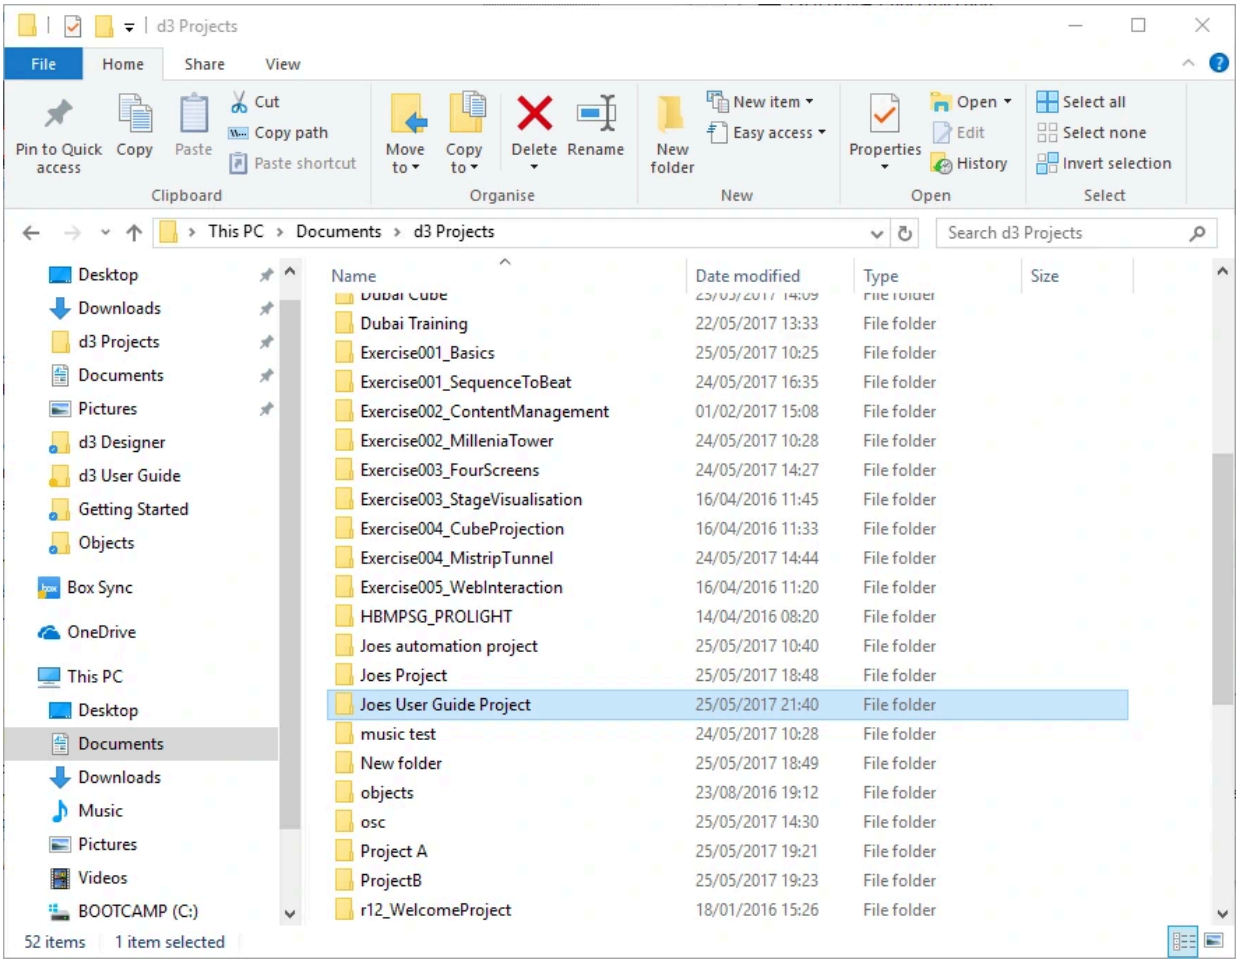
> **Note**
>
> All media files for a project must be stored in the specific Project folder. This ensures that when you copy the specific Project folder from one device to another, all relevant files will be copied as well.

Project Location

Where are all of my projects stored?

All of the specific project folders are stored in the assigned **d3 Projects** folder which is set during the installation of Designer. The default location is **My Documents/d3 Projects**

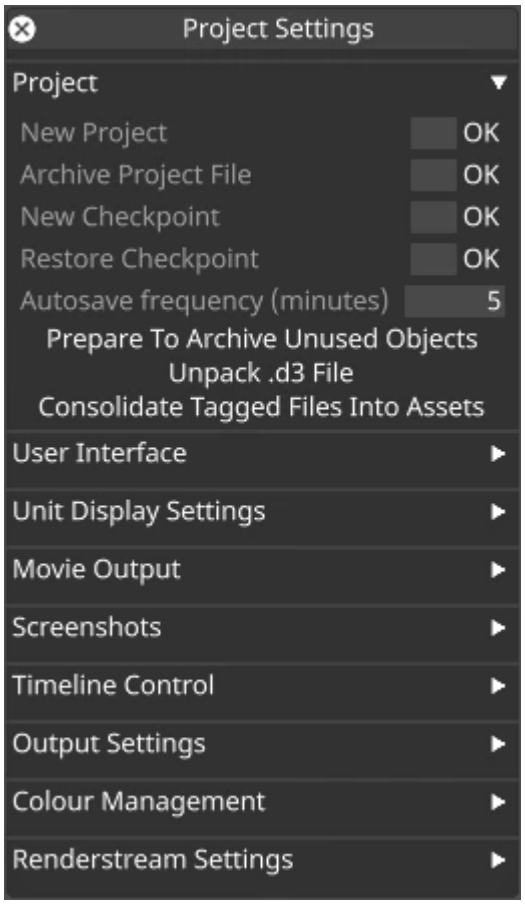
Alternatively, you assign a project folder in a different location on the server from within the d3Manager window. For more information on how to assign a new project folder location, please visit this [Managing Project Folders]



Project Settings

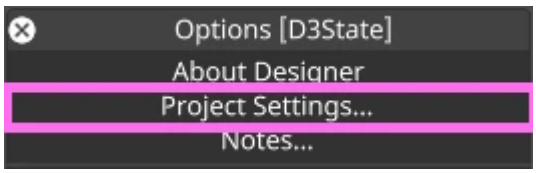
Designer provides some standard project settings which can be accessed through the state menu.

This page provides an explanation for each setting in the menu, as well as how to access it.



Project Settings editor with first tab open

Accessing the Project Settings



*Button to open **Project Settings** highlighted in pink*

1. Right-click on “d3” in the top left corner of the interface on the dashboard; this will open the d3State Options window.

2. Left-click **Project Settings** from the menu to open the Project Settings menu.

Project tab

New Project

Creates a new Project

Archive project file

Essentially a “save as”. Type in a name and it creates a project file in the history folder with the name you defined..

New Checkpoint

Creates a Checkpointed project. Checkpointed projects are frozen in time and locked to a specific Disguise version.

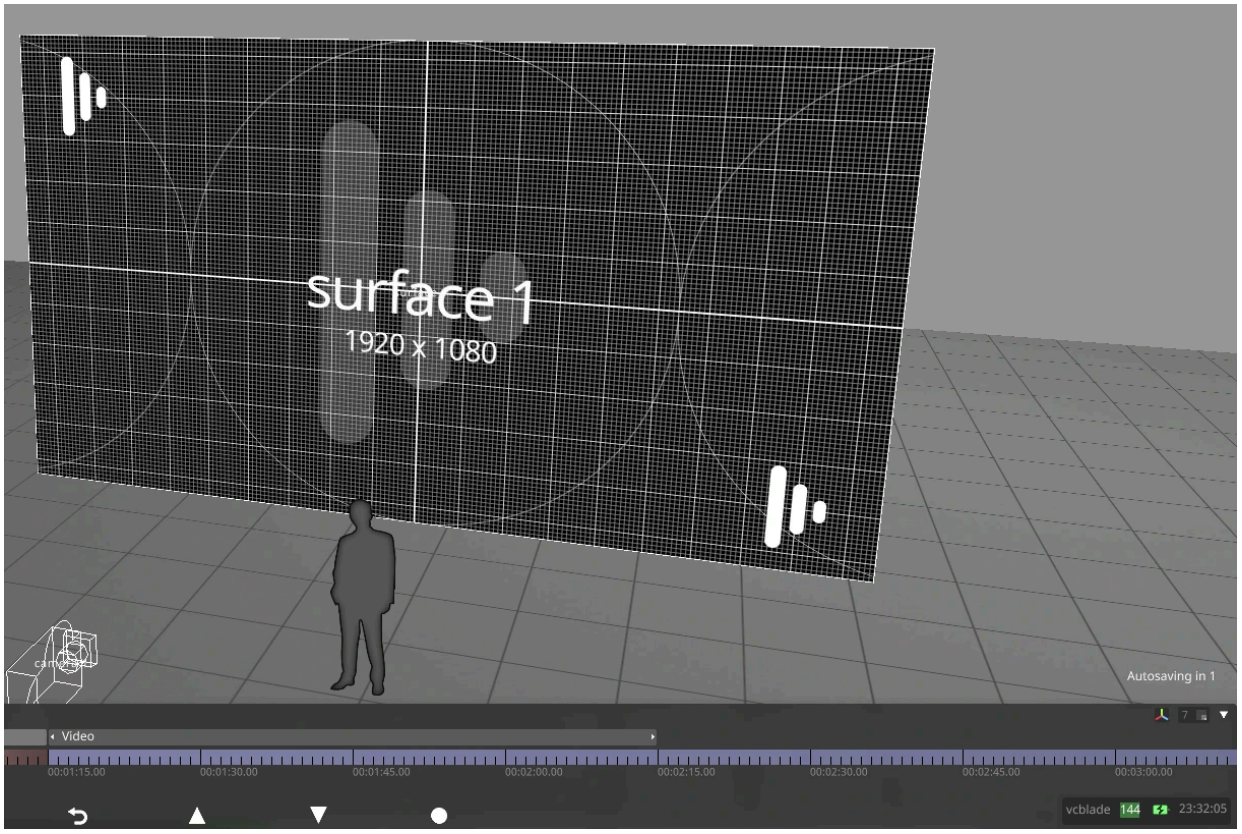
Restore Checkpoint

Restores a previously made Checkpoint.

Autosave Frequency

Defines the autosave frequency expressed in minutes. This defaults to 5 minutes.

A new ‘Autosaving’ indicator with a 5 second countdown has been added in the bottom right hand corner above the timeline.



Autosaving Example

Prepare to archive unused objects

Generates a batch file for you to then define an archive directory outside of the project file, thus releasing the files from Designer. See Archive old media topic for more information.

Unpack d3 file

Unpack the contents of the .d3 project file into a new 'unpack' folder, for advanced use cases. For further information, see importing and exporting objects.

Consolidate tagged files into assets

This is used to upgrade old projects to use versioning.

User Interface tab

Framerate fraction

The fraction of the framerate that the GUI renders at. This option is used to sacrifice responsiveness for performance. This option is not suitable for lower latency modes.

Options for this setting are:

- **1** represents full framerate
- **1/2** represents half framerate
- **1/3** represents one third framerate

DPI Scale

The DPI scale determines the font and icon size in Designer. The `Default` option follows the Windows DPI scale, while other options apply the selected scale directly.

Options for this setting are:

- `Default`
- `100%`
- `125%`
- `150%`
- `175%`
- `200%`
- `225%`
- `250%`

Maximum visualiser proxy

Designer uses a proxy system to render content at the level of detail (LOD) required on each machine. For displays which are not mapped to the current machine's feed outputs, navigating the visualiser camera or zooming in and out will change the LOD the display is rendered at. This can increase the load on the machine resulting in reduced framerate, particularly for high-resolution displays.

The **maximum visualiser proxy** setting limits the LOD of displays viewed in the GUI only, i.e. visualiser, feed previews, editors etc. Displays which are mapped to feed outputs are not affected, and are always rendered at full resolution. This setting is applied across all machines in the session.

Options for this setting are:

- **1:1**: Display LOD can match its full resolution
- **1:2**: Display LOD is capped at half resolution
- **1:4**: Display LOD is capped at quarter resolution
- **1:8**: Display LOD is capped at one eighth resolution
- **1:16**: Display LOD is capped at one sixteenth resolution

The **maximum visualiser proxy** can also be edited from the 3D manipulators toolbar

Tooltips

Controls when tooltips appear in.

Options for this setting are:

- Only when F1 is pressed
- After 1 second **(default)**
- After 2 seconds
- After 3 seconds

Persistent Key Widgets

When enabled, key widgets will remain open on creation or on selection of a new layer with the same property.

Disable UI Transparency

Untick this setting to turn off transparency for UI windows to save performance.

Disable key frame editor film strip

Untick this setting to turn off rendering intermediate frames of videos inside keyframe editors which can increase performance when viewing video clips.

Global layer colour rules

Select the default rules that will determine the colours of layers on any tracks that do not have their own Layer colour ruleset. For more information about layer colour rules see the Layer Colour Rules page.

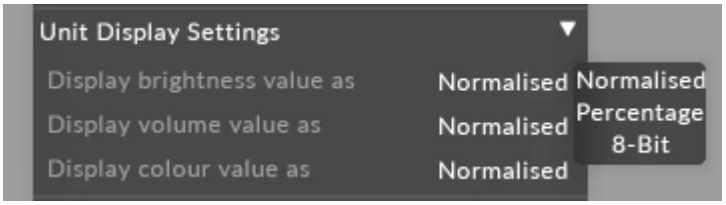
Unit Display Settings tab

Display value as

Defines the way the numerical values are displayed for Brightness, Volume, and Colour.

The options are:

- Normalised (0-1)
- Percentage (0-100%)
- 8-bit (0-255)



Unit Display

Measurement unit

Determine the units that measurements are displayed in.

The options are:

- Metric
- Imperial

Movie Output tab

Output movie format

Defines the output format for Stage & Feed movies. For more information about outputting Stage & Feed movies see our Stage and Feed Movies page.

Options for this setting are:

- Photo-JPEG (no audio)
- Animation (no audio)
- MPEG-4 (with audio) **(default)**
- Photo-JPEG mov (OLD QuickTime players)
- HAP (no audio)
- DPX image sequence (no audio)
- WEBM vp9 (audio as Vorbis output)

Output movie FPS

Sets the FPS the output movies should be rendered at.

Stage movie size

Sets the resolution Stage movies should be rendered at.

Below, the actual output movie size is displayed after licensing restrictions are applied.

Add head to output movie

Adds additional seconds to the start of the output movie.

Add tail to output movie

Adds additional seconds to the end of an output movie.

Animation movie format

Select the 3D format to use when writing an Animation movie.

Encoding Options

Bitrate (Kb)

Sets the target bitrate of your output movies. Setting this to 0 will allow Designer to use it's best-guess per codec.

Screenshots tab

Output format

Defines the output format for Screenshots.

Options for this setting are:

- JPEG
- BMP
- PNG **(default)**
- TIF
- DPX
- EXR

Timeline Control tab

Global latency mode

Defines the levels of buffering and the rendering interval of the video output system.

Options for this setting are:

- Full speed ultra low latency (no buffering)
- Full speed low latency (one frame buffer)
- Full speed **(default)** (two frame buffers)

- Half speed low latency (halves the frame rate, one frame buffer)
- Half speed (halves the frame rate, two buffers)

Frame buffers are on the video output system, other system processing will add further latency.

Sometimes it is very useful to use half speed mode to swap between 2 framerates quickly without needing to re-apply genlock. In this case, always make sure you are genlocked to the full framerate. If you genlock to the half-framerate you may get tearing between machines when in half speed mode.

Global refresh rate

Sets the project refresh rate. For more information see the Setting Project Refresh Rate topic.

Project bit depth

Sets the bit depth the project will output at. This setting will not take effect until Feed Settings have been applied. For more information about applying feed settings visit our Configuring Output Settings page.

Timeline audio device

Sets the default timeline audio device.

Deferred jump

With this feature activated, you can now hit the left or right Arrow keys (while playing) to jump Track bars without losing sight of the original bar you jumped from (this bar will also continue to flash).

Global crossfade

Sets the Universal crossfade mode for all tracks and sections by default. This can be overridden on a per track and per section basis.

Reset on stop

This defines the behaviour of the Stop button. You can either reset to the start of the bar, or stay where you are.

Options for this setting are:

- Always
- When Quantised **(default)**
- Never

Output Settings tab

Video information overlay

Overlays debug information on the content of video layers.

Options for this setting are:

- None **(default)**
- Resolution
- Smoothness - A white line that moves across the image to assess playback smoothness.
- Frame/Time - A readout of what frame is currently displayed.
- Regions/Tiles - Each mapping region in SLC.

Fade up/down duration (seconds)

Sets how long, in seconds, the Fade up and Fade down controls take to complete.

Colour Management tab

Colour Management

This defines what model for colour management disguise uses.

Options for this setting are:

- Disabled
- Gamma Space **(default)**
- ACES
- OCIO

More information about colour management can be found on our Colour Management page.

Default ingest profile

This defines the default colour profile that will be applied to all media when it is ingested. This does not apply retroactively to media that has already been ingested or had another colour profile set.

Default display profile

This defines the default colour profile that will be applied to all displays when they are created. This does not apply retroactively to displays that have already been created or had another colour profile set.

RenderStream Settings tab

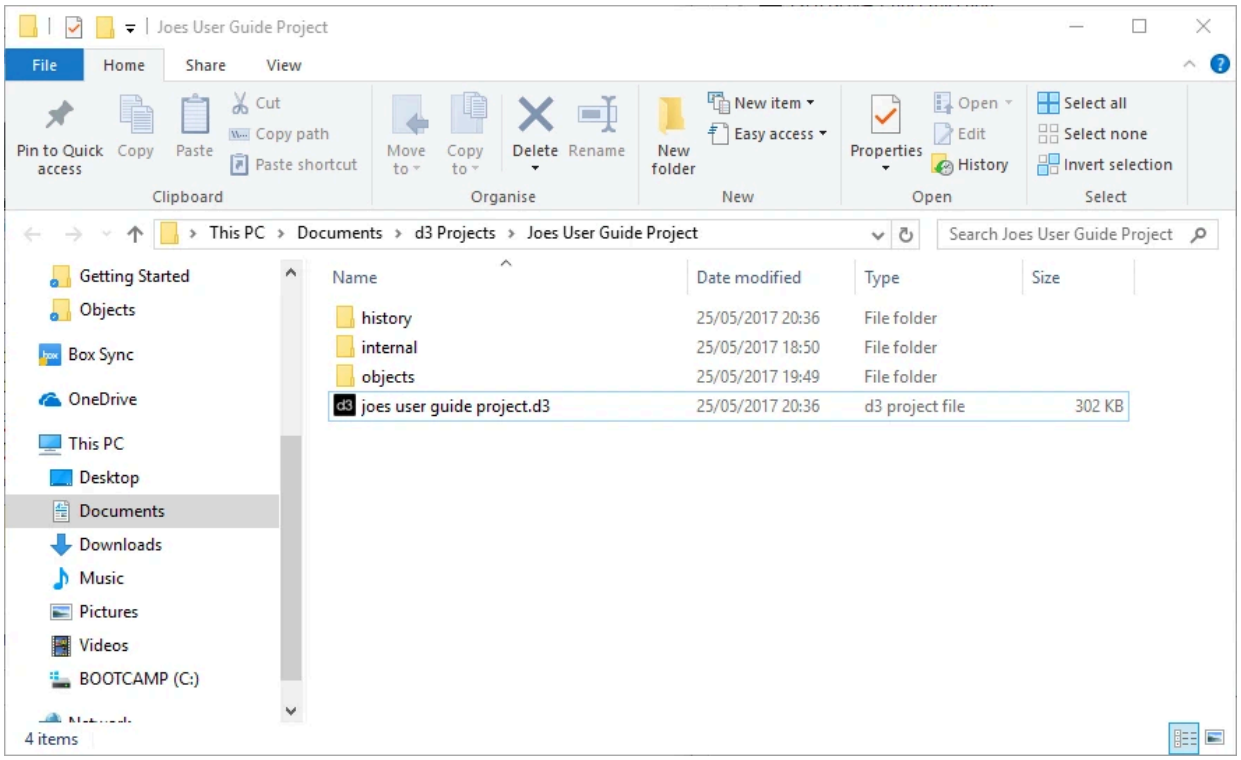
RenderStream latency override (ms)

This can be set to define a fixed latency for all RenderStream workloads in the project. Frames received more than this latency after the previous frame will always be dropped. Leaving this setting at 0 will allow Designer to automatically measure and set an optimal RenderStream latency for your specific network configuration.

Project Structure

Each specific Project folder contains the **.d3** project file. For example, if you have a project called **my project**, the Project file will have the name: **my project.d3** and a number of sub-folders:

- **History**: contains auto save files and shows after a project has been running long enough for auto save to occur.
- **internal**: contains files internal to the software, such as thumbnails.
- **objects**: contains all media files.
- **Packages**: used to package data and move it between projects, this is a user-created folder and is not present by default.



By default, each Project folder contains the Project file and two sub-folders, Internal and Objects.

> **Note**
>
> All media files for a project must be stored in the specific Project folder. This ensures that when you copy the specific Project folder from one device to another, all relevant files will also be copied.

Read more about Managing Project Folders and how to use history files.

Rendering Feed Movies

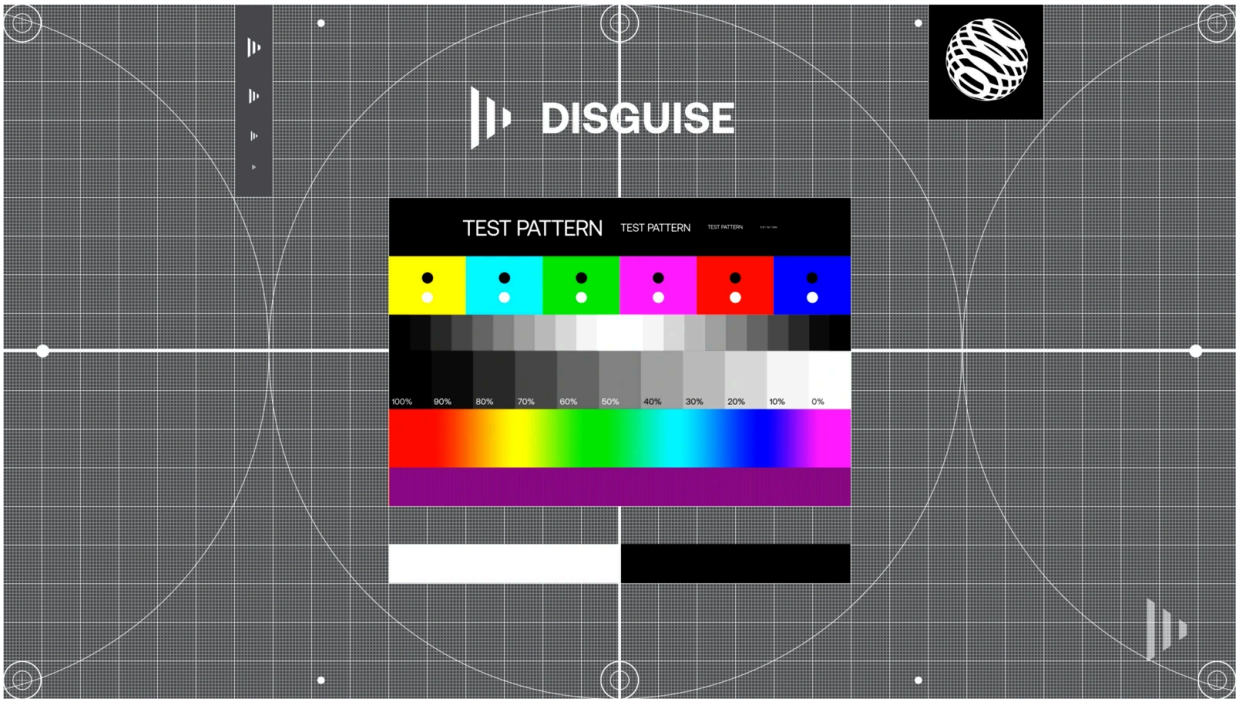
Feed movies render the feed outputs in the Feed level, allowing rendered project content to be played back on a conventional media server.

For more information on configuring outputs please see the chapter Feed Outputs.

Feed movies generated from **Designer Starter** are watermarked and limited to a maximum resolution of 2160x2160 pixels (2K UHD).

Feed movies generated from **Designer Full** are watermarked and limited to a maximum resolution of 4096×2160 pixels (4K UHD), when using a Designer Pro license. On Disguise servers there is no watermark.

The watermark is a semi-transparent Disguise logo with a size of approximately one-tenth of the movie's vertical resolution that appears in the bottom right corner.

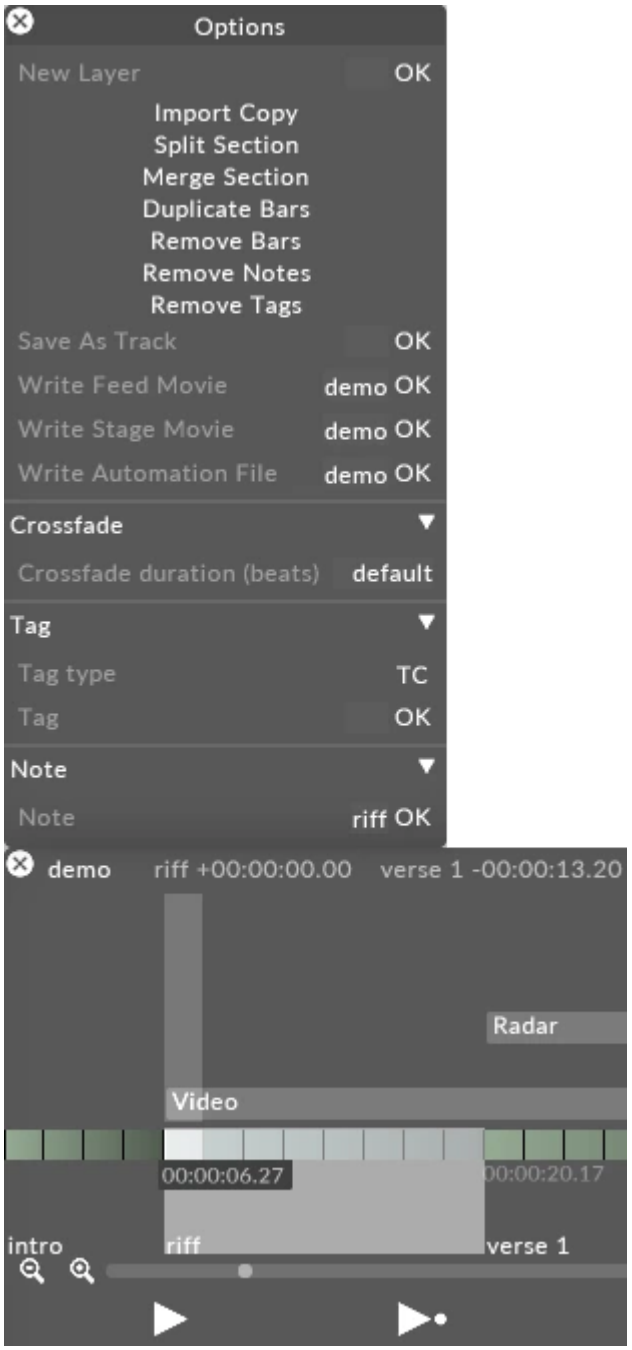


Watermark

How to render Feed movies

1. Specify the settings of the Feed movie as described in the previous sub-chapter video output settings.
2. Hold down the left **Shift** key and click-drag a rectangle across the Track bars to be rendered.

3. Open the Track bars menu by right-clicking the selection rectangle.
4. Type in the name of the Feed movie into the **write feed movie** text field.
5. Hit **Enter** to render the Feed movie. The Feed movie will be saved in a new folder called **output** inside the specific Project folder. For information on where the specific Project folder is located please see the sub-chapter Project structure.



Write Feed Movie option from the Track bars menu is used to render a Feed movie, opened by right-clicking the grey selection rectangle.

Rendering Media Overview

Stage/Feed movies

Stage movies and Feed movies can be rendered in Designer. Stage movies can be used to provide the client or production team with the latest update on the project, and Feed movies allow rendered project content to be played back on a conventional media server.

Before rendering the Stage or Feed movies please specify the video output settings, you can learn how on the video output settings page.

The table below shows the distinctions between different Stage and Feed movies.

Designer	Watermarked Feed Movies	Watermarked Stage Movies	Resolution Limit
Designer Starter	Yes	Yes	Max resolution: 2K (2160×2160)
Designer Full (Pro)	Yes	No	Max resolution: 4K (4096×2160)
Server Starter	Yes	Yes	Max resolution: 2K (2160×2160)
Server Full	No	No	None

Screenshots

If there is not enough time for rendering a movie, screenshots can be made. See the Rendering Screenshots topic to see how.

Rendering Screenshots

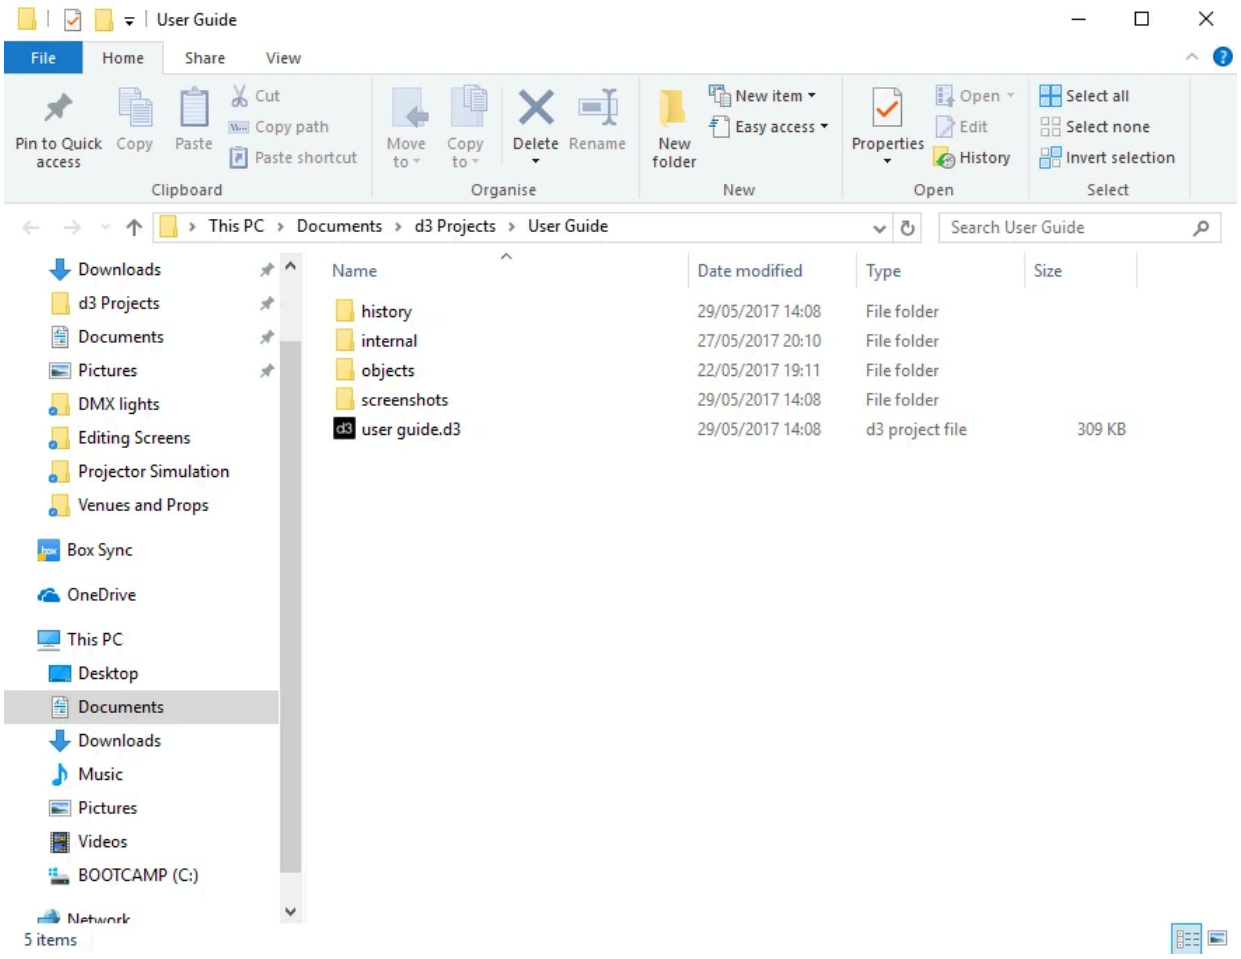
Screenshots can be made of the Stage or Feed levels.

These can be used for:

- Allowing the client or entire production team to know exactly what the latest update is on the project, particularly if there is not enough time for rendering Stage movies.
- matching the position of the Feed rectangles in their Display heads to an LED processor when configuring outputs.

How to make a screenshot:

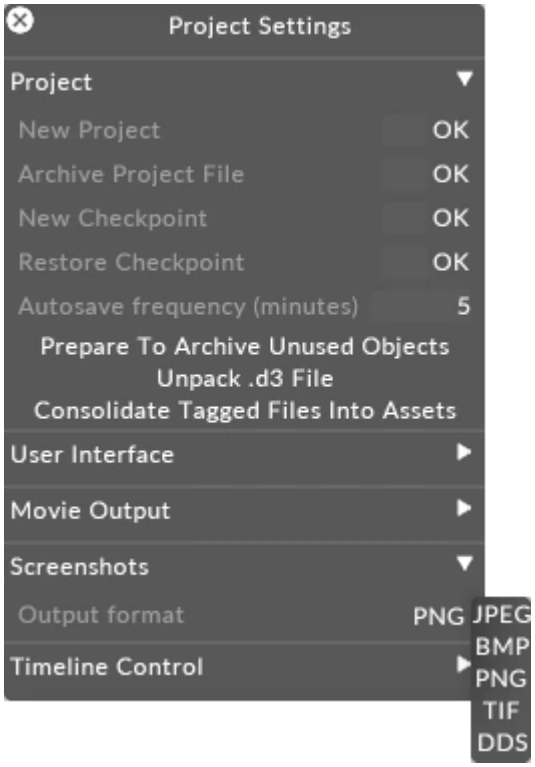
1. Specify the file format used for saving screenshots as described in the section below.
2. If the Track Player is obscuring part of the shot close it by left-clicking the x icon in the top left corner of the Track Player. To re-open the Track Player, left-click **track** in the d3 State editor (bar at the top of the screen).
3. Hit **Alt-X** . The screenshots are saved in a new folder called **screenshots** inside the specific Project folder. For information on where the specific Project folder is located please see the sub-chapter Projects location/structure.



If screenshots are renamed or deleted, the continuity of the file numbering could be lost. For example, if you have 3 screenshots `screenshot_00000`, `screenshot_00001`, and `screenshot_00002`, then delete `screenshot_00001`, the next screenshot will be called `screenshot_00001`, and then the next one after that will be called `screenshot_00003`.

Specifying the screenshot file format

1. Open the Projects Settings menu by right-clicking **d3** from the dashboard (bar at the top of the screen) and selecting project settings.
2. In the **Screenshots** tab, Select an option from the menu of file formats by left-clicking **output format**. There are five file formats to choose from: **.png .jpeg .bmp .tif .dds**.



Output Screenshot Format property within the Program Settings menu points to the five screenshot file saving formats

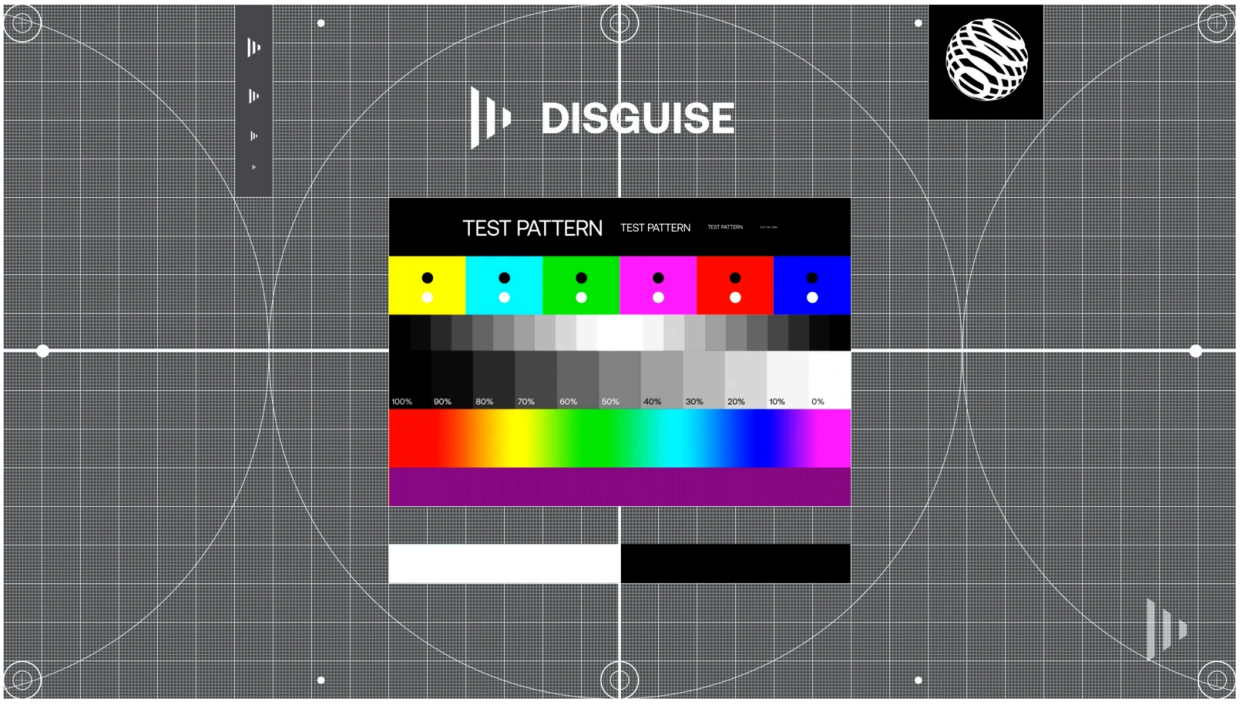
Rendering Stage Movies

Stage movies render the content in the Stage levels Stage Visualiser, allowing the client or entire production team to know exactly what the latest update is on the project.

Stage movies generated from **Designer Starter** are watermarked and limited to a maximum resolution of 2160x2160 pixels.

Stage movies generated from **Designer Full** are not watermarked, but limited to a maximum resolution of 4096×4096 pixels.

The watermark is a semi-transparent Disguise logo with a size of approximately one-tenth of the movie's vertical resolution that appears in the bottom right corner.

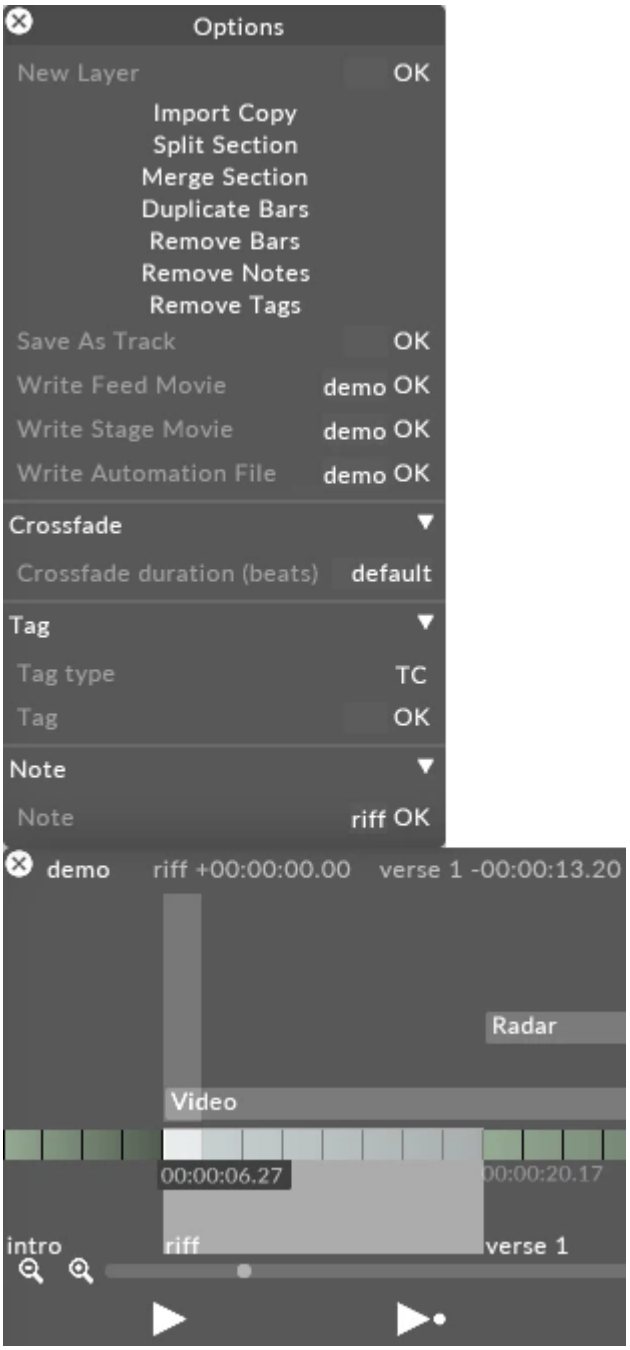


Watermark

> **Note**
>
> Before rendering a Stage movie, the AnimateCamera2 layer can be used to create camera flythroughs of the show. Please see the AnimateCamera Preset layer subchapter for more information.

How to render Stage movies

1. Specify the settings of the Stage movie as described in the previous sub-chapter [video output settings](#).
2. Hold down the left **Shift** key and click-drag a rectangle across the Track bars to be rendered.
3. Open the Track bars menu by right-clicking the selection rectangle.
4. Type in the name of the Stage movie into the **write movie (stage)** text field.



5. Hit **Enter** to render the Stage movie. The Stage movie will be saved in a new folder called **output** inside the specific Project folder. For information on where the specific Project folder is located please see the sub-chapter Project structure.

If there is not enough time to render a Stage movie screenshots of the stage may suffice. For more information on this useful feature please see the rendering screenshots sub-chapter.

Slideshows

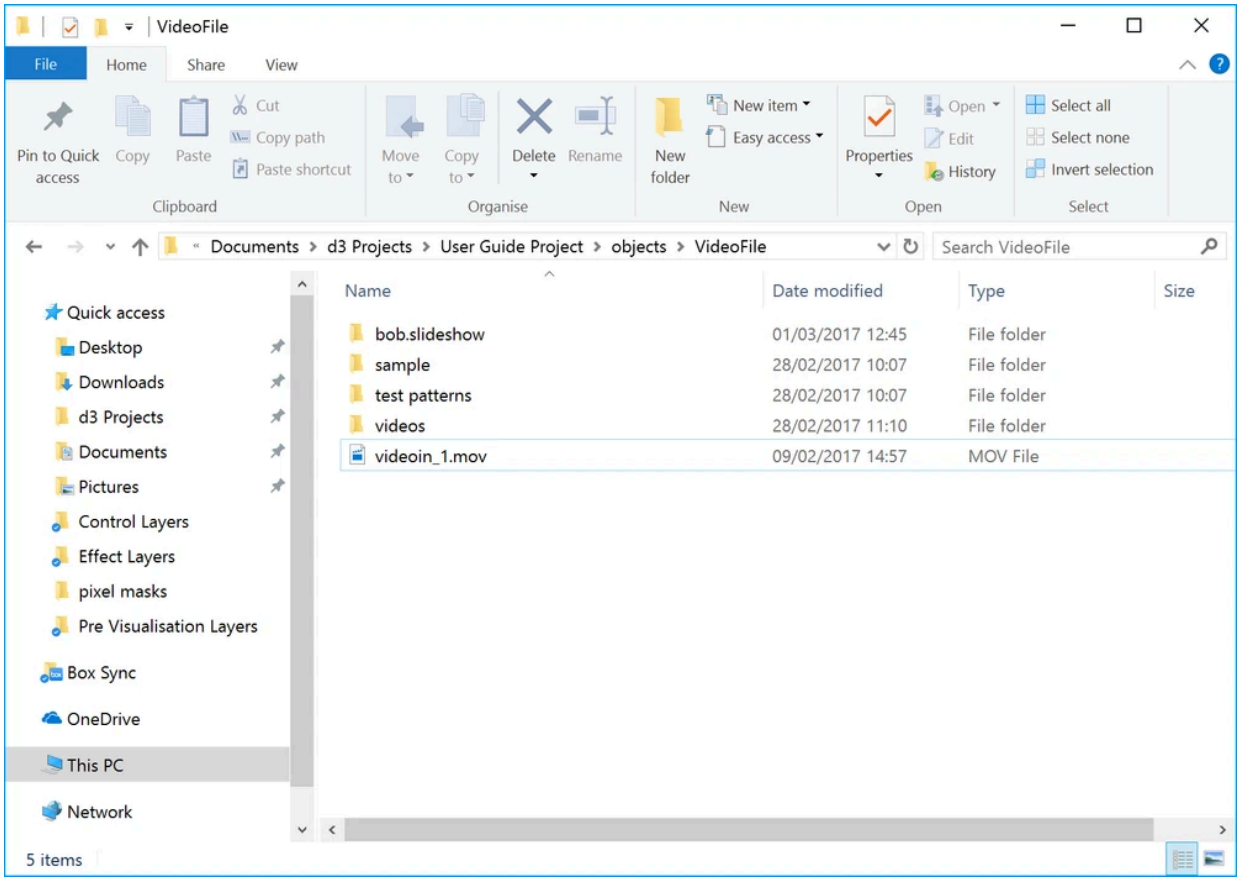
Slideshow is a new feature of r14.1 that enables fast and easy output of a sequence of content with a minimum of sequencing time.

Although these sequences rely on file location and name, they can be edited while the software is running.

They allow an automated slideshow style operation of video or still images within the software. A good example of this is running advertisements pre-show. It would take too long to sequence the adverts individually within , so utilising a slideshow allows you to place one piece of content within that may consist of many pieces of content in reality. It also allows you to change the content outside of without affecting the sequencing.

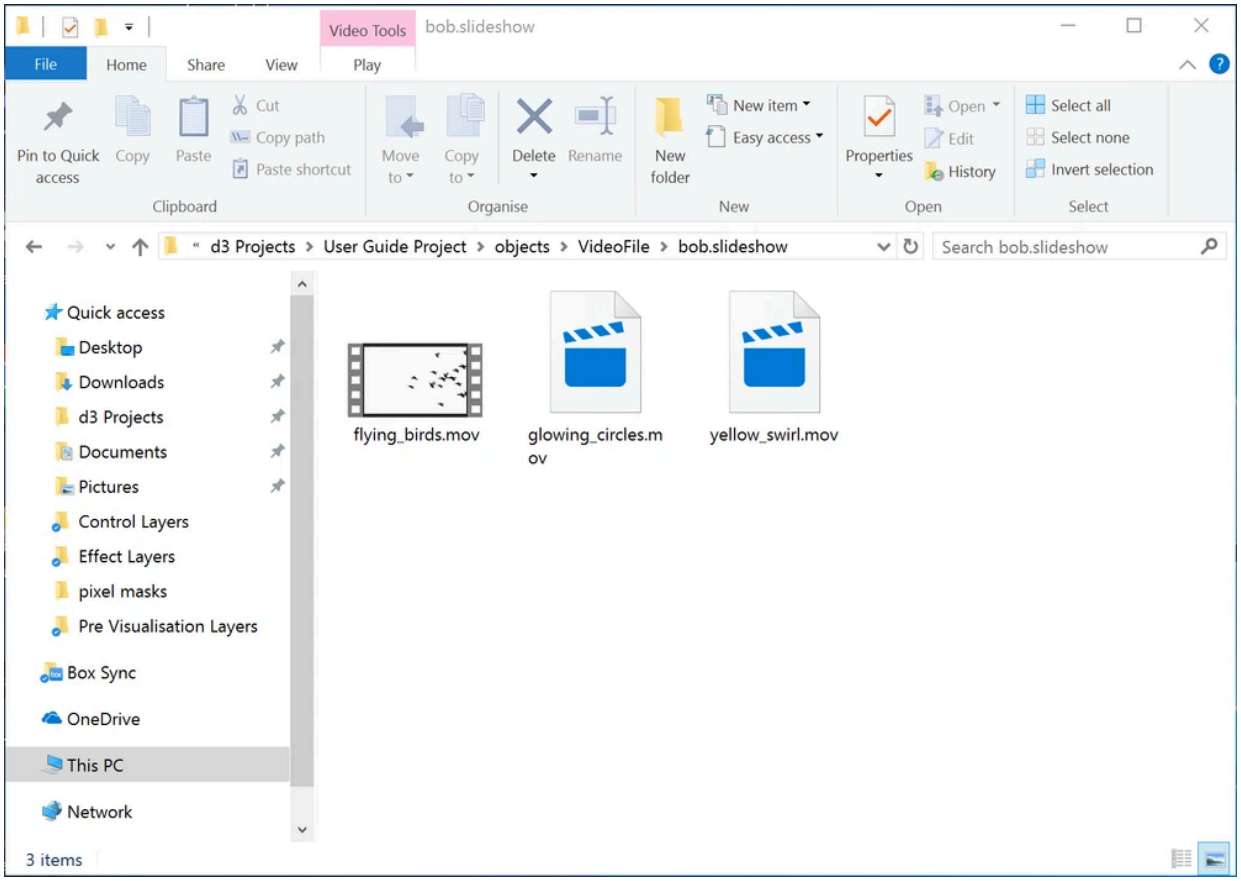
Creating slideshows

A slideshow is any folder within VideoFile that ends in ".slideshow". This functions similarly to the versioning or proxy tags, and tells d3 that the contents of the folder is to work as a single clip made up of multiple files.



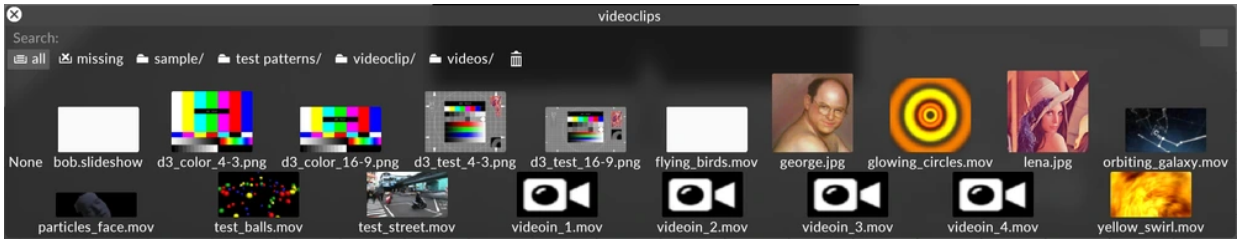
Video file folder

Slideshows can be populated with any filetype that could be placed inside the VideoFile folder, in any combination. The order that the slideshow plays back these pieces of content is determined by their filenames - slideshow works in alphabetical order.



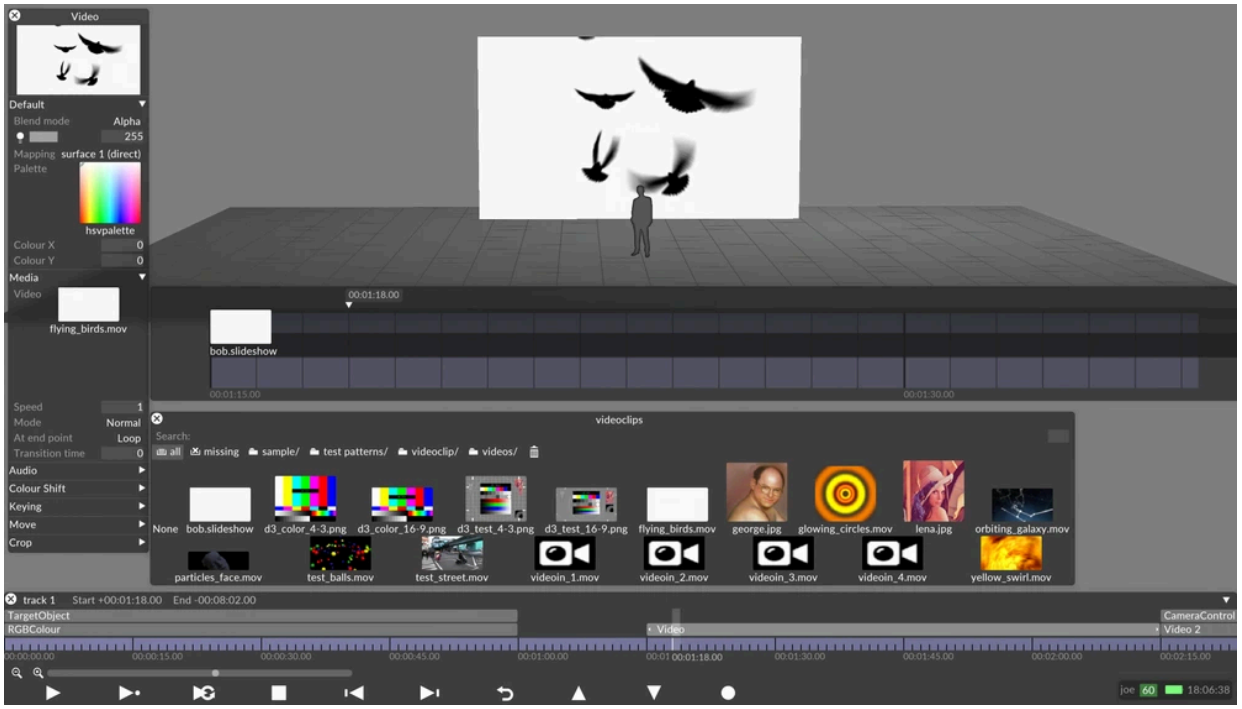
bob.slideshow showing 3 videos

Slideshows are accessed inside , just in the way normal videofile content is. On the video layer, open your media object keyframe and select your slideshow.



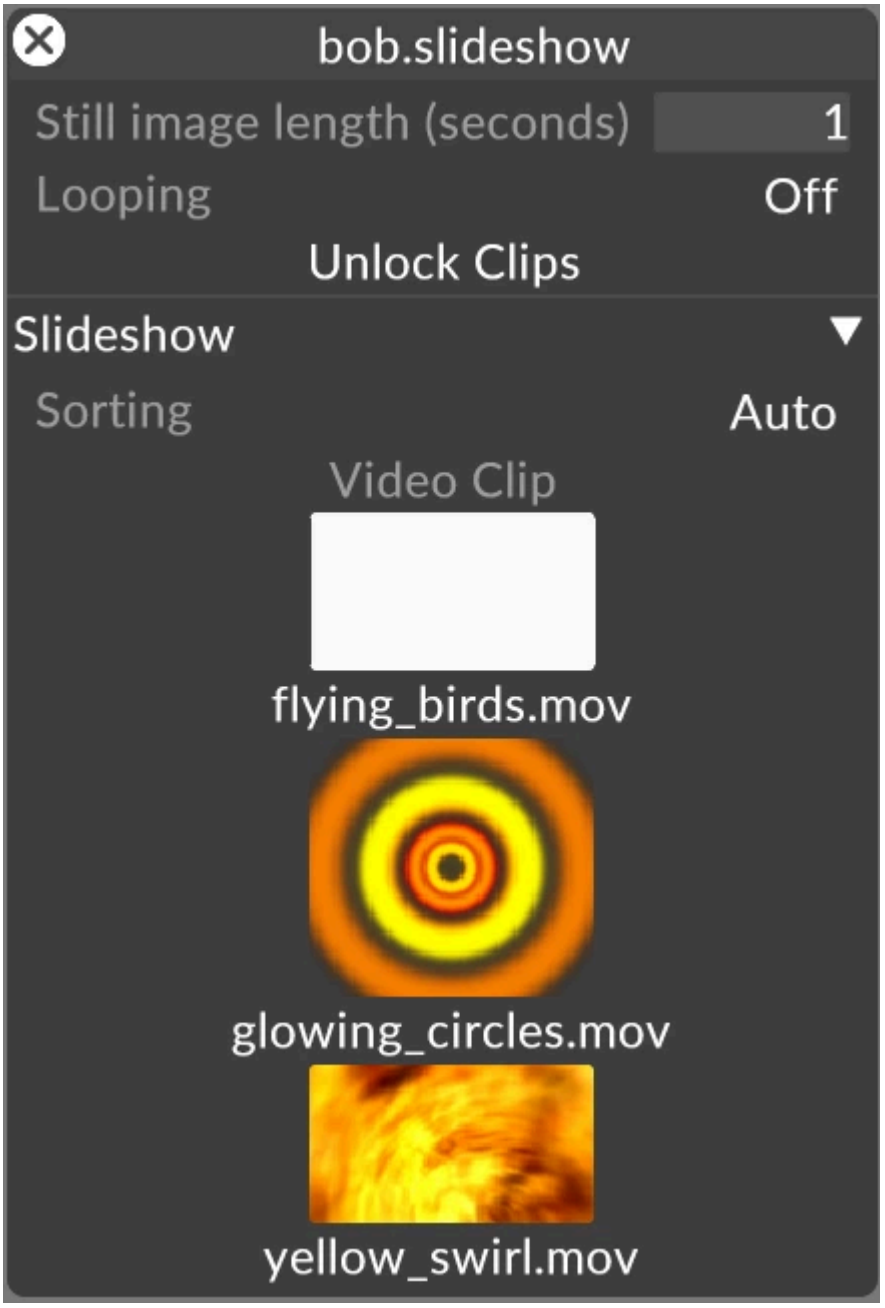
bob.slideshow now available as standard video content

The slideshow behaves just like a regular video file in , so playmodes, colourshift, audio routings, etc are all applicable. Transition Time will enable a crossfade between each piece of content, as if each piece of content were separately keyframed into the module.



bob.slideshow on the video keyframe editor

Clicking unlock clips will allow you to rename (ie: reorder), and delete slideshow clips without having to restart d3. When in unlocked mode, the slideshow cannot be played back.



Content management and slideshows

Versions, proxies and frame replacements are all compatible with slideshows. Versions can exist within the same .slideshow folder. The software will automatically use the highest version content it can find.

VideoClip Object

When sequencing video files in Designer, you are actually sequencing VideoClip objects, which are the container Designer uses to identify the media file, its properties, versions as well as other specific propertie

VideoFile is the piece of content you place in the VideoFile folder which lives inside your Objects folder in your project file.

VideoClip is an object inside Designer that contains the VideoFile (or VideoFiles when versioning is being used) as well as properties that you can apply to that file, outside of the normally keyframable parameters. These properties are things such as FPS, In & Out frames and are covered in more detail in the content properties topic.

Duplicating VideoClip objects

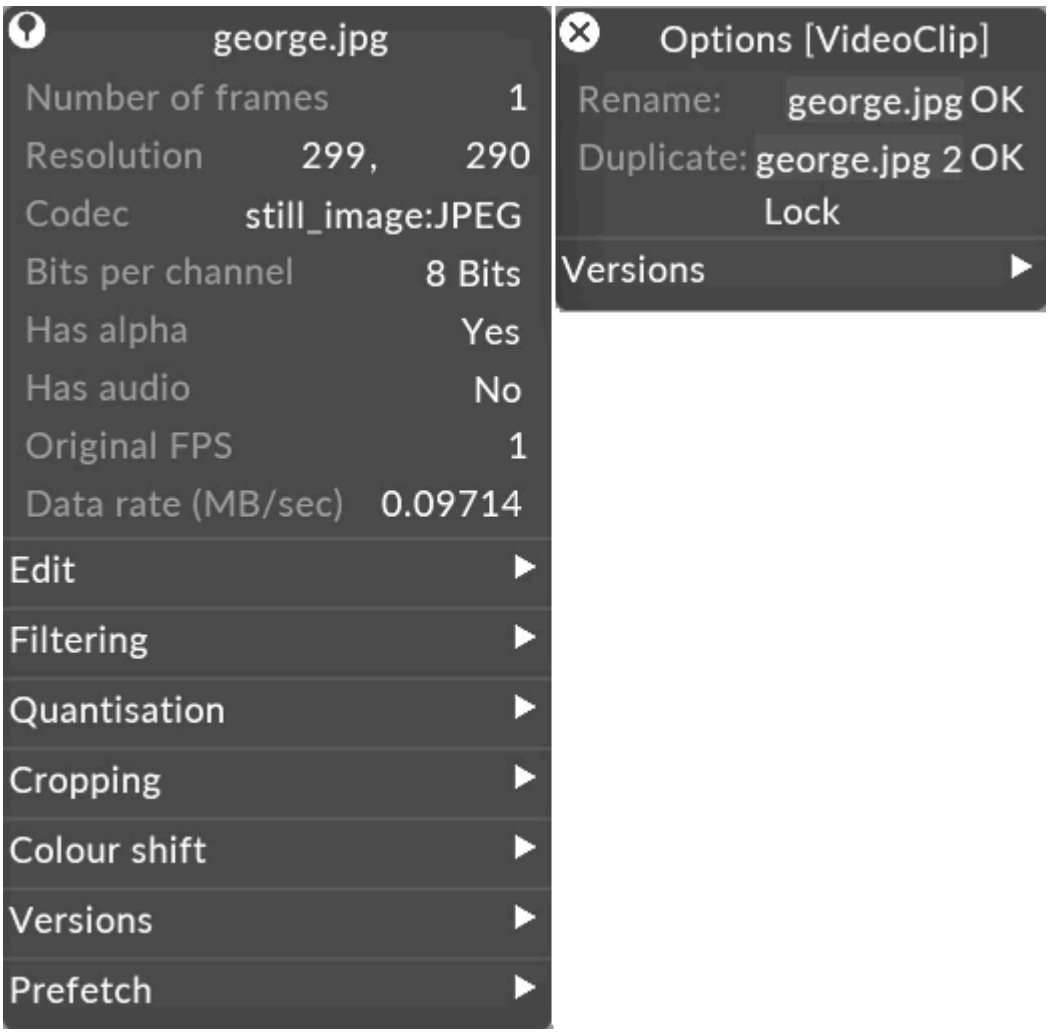
Sometimes it's useful to have a single video file that has different settings for different parts of the show. For example, you may wish to have Video 1 with in and out frames at default in one part of the show, but change the in and out frames to a different setting later one. Instead of making a hard copy of the file in the VideoFile folder of the project, you can simply duplicate the VideoClip object in Designer and change the VideoClip object properties. This saves media drive space, and also allows for better internal handling of the media files.

To duplicate a VideoClip object

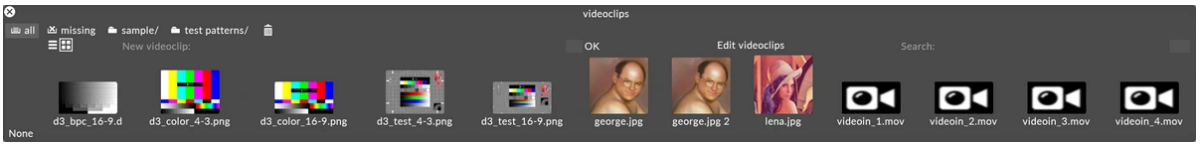
1. In the VideoClips editor, which can be accessed via the Video, Legacy video or VideoTrigger layers, left-click the Video property under the media tab. The VideoClips manager opens.

2. Right-click a **VideoClip**. The VideoClip editor will open, containing the properties of that VideoClip.
3. Right-click the header of the VideoClip editor

4. Select **Duplicate**, give the duplicate a name, and then hit Enter or OK.



5. You will now see the duplicate VideoClip available in the manager, but only one piece of content will be in the VideoFile folder. You can edit the settings of the duplicate clip to be different to the original.



Multi-Editing VideoClip objects

Its possible to Multi-Edit most objects in Designer, but due to the VideoClip objects being items used for sequencing, the method to multi-edit them is slightly different.

To multi-edit a VideoClip

1. In the VideoClips editor, which can be accessed via the Video, Legacy video or VideoTrigger layers, left-click the Video property under the media tab. The VideoClips manager opens.

2. Left-click the Edit VideoClips button.
3. The Multi Editor opens, select clips by using CTRL or SHIFT and alter their properties accordingly.

VideoClip

Name	FPS	Start	End	In	Out	Bilinear filtering	Frame blending	Colour profile	Colour shift	Deinterlace method
d3_bpc_16-9.d	1	0	1	0	0	On	Auto	itu709	ColourShift	Weave & Interpolate
d3_color_4-3.png	1	0	1	0	0	On	Auto	itu709	ColourShift	Weave & Interpolate
d3_color_16-9.png	1	0	1	0	0	On	Auto	itu709	ColourShift	Weave & Interpolate
d3_test_4-3.png	1	0	1	0	0	On	Auto	itu709	ColourShift	Weave & Interpolate
d3_test_16-9.png	1	0	1	0	0	On	Auto	itu709	ColourShift	Weave & Interpolate
george.jpg	1	0	1	0	0	On	Auto	itu709	ColourShift	Weave & Interpolate
george.jpg 2	1	0	1	0	0	On	Auto	itu709	ColourShift	Weave & Interpolate
lena.jpg	1	0	1	0	0	On	Auto	itu709	ColourShift	Weave & Interpolate
videoin_1.mov	0	0	1	0	0	On	Auto	itu709	ColourShift	Weave & Interpolate
videoin_2.mov	0	0	1	0	0	On	Auto	itu709	ColourShift	Weave & Interpolate
videoin_3.mov	0	0	1	0	0	On	Auto	itu709	ColourShift	Weave & Interpolate
videoin_4.mov	0	0	1	0	0	On	Auto	itu709	ColourShift	Weave & Interpolate

See the Multi-Edit topic for more information.

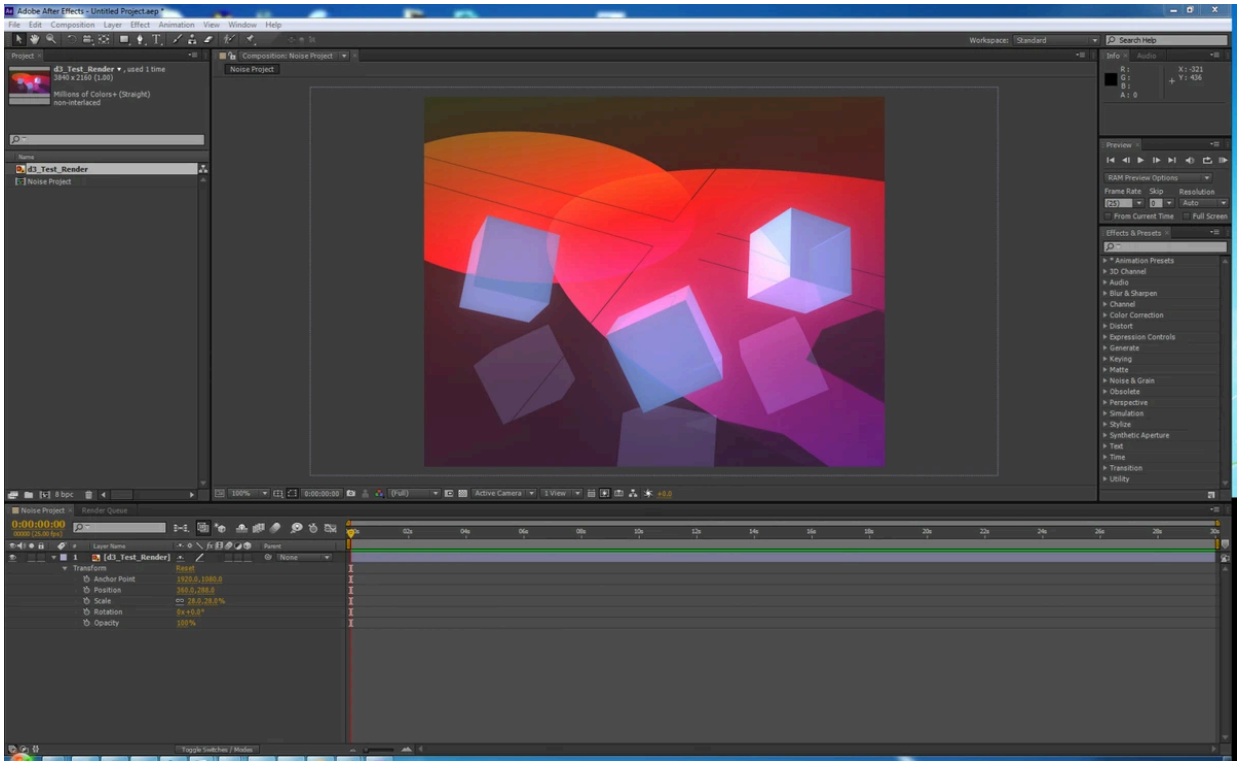
Adding Noise in After Effects

Adding a small amount noise before converting media to any codec is a good way to reduce compression artifacts.

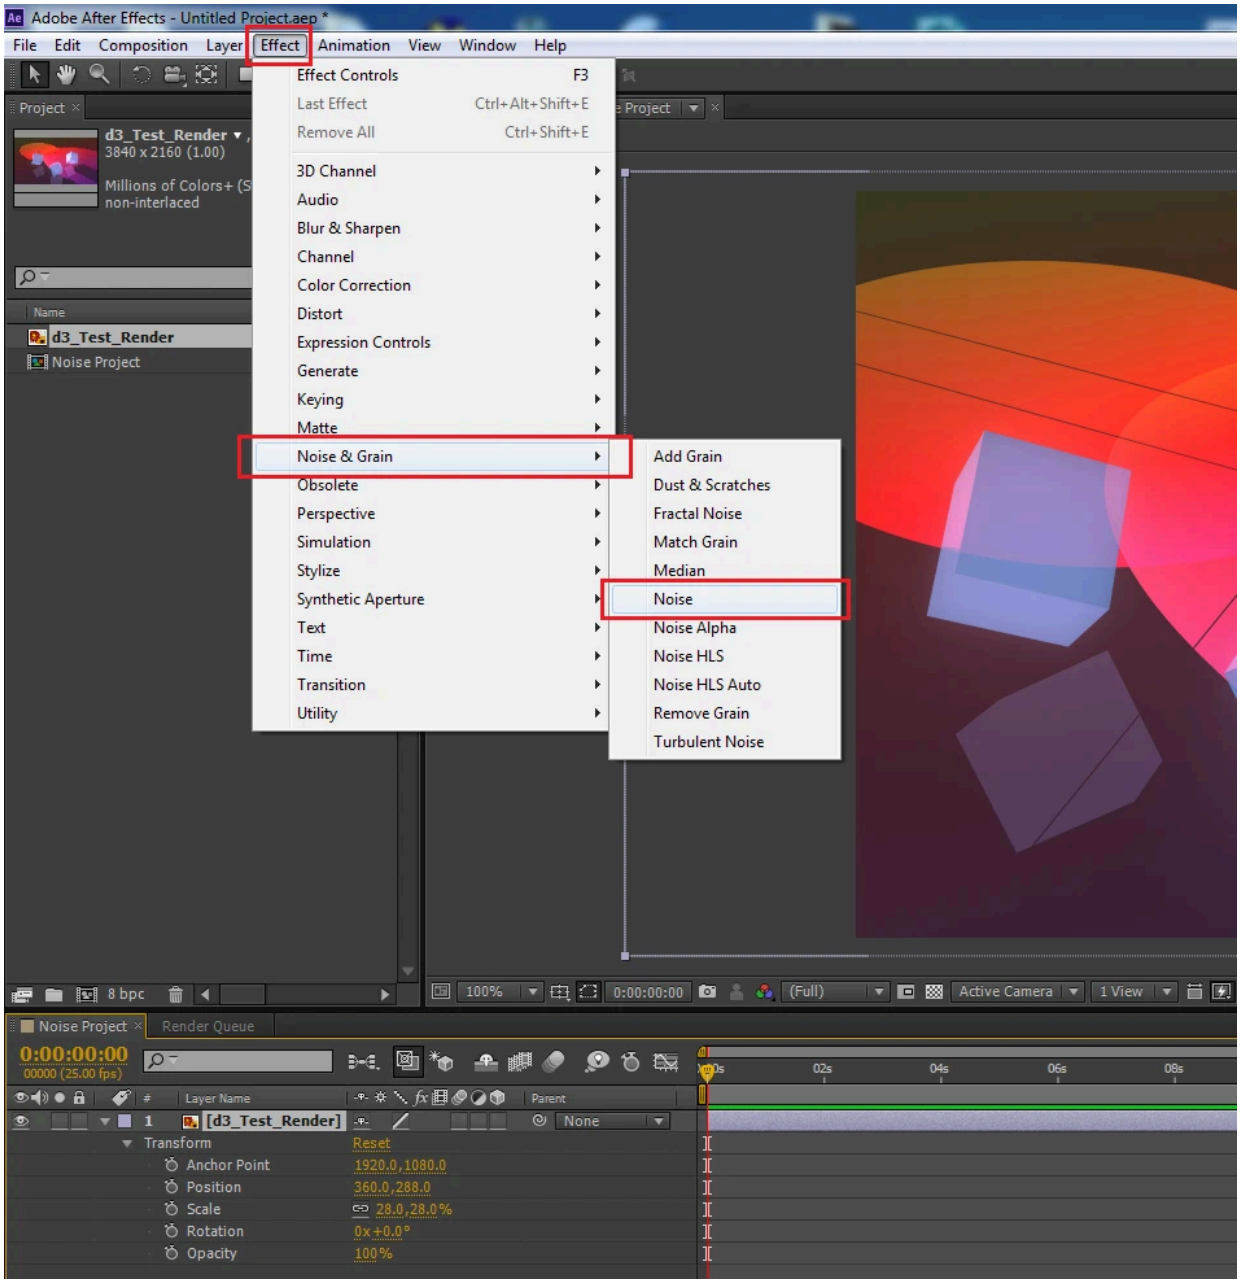
The easiest way is to use the noise effect in After Effects.

Example

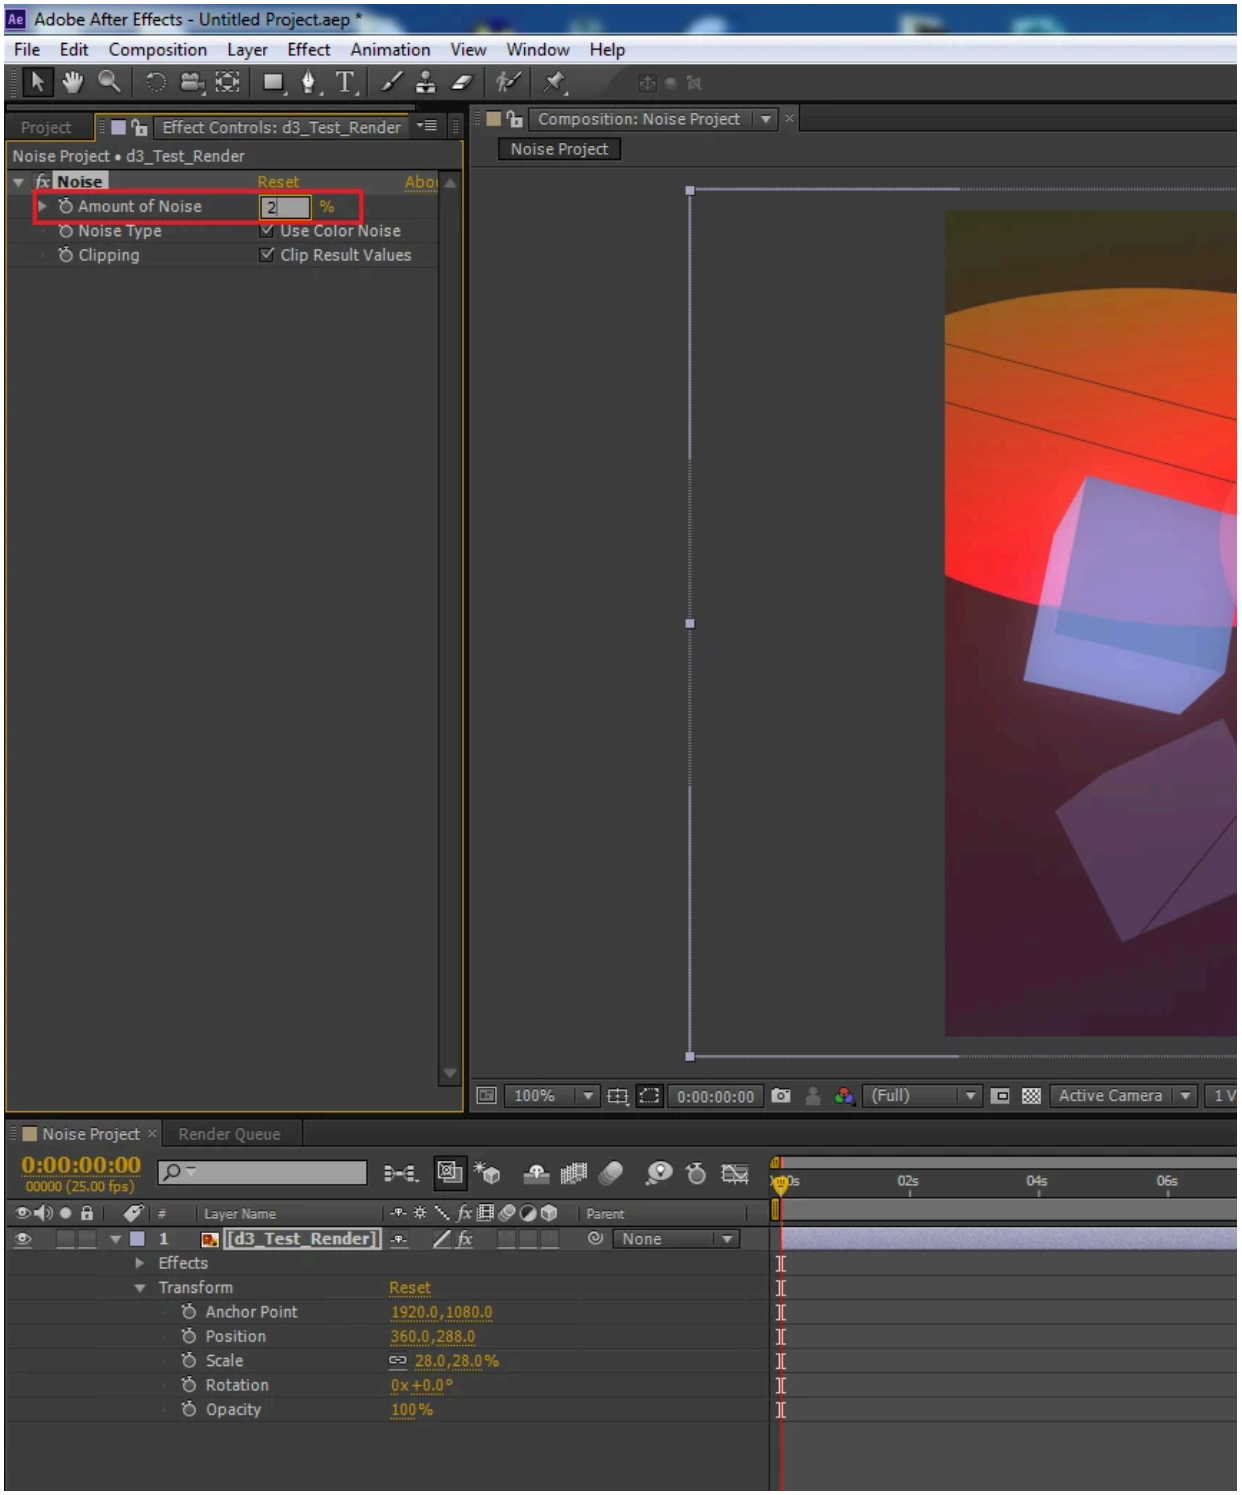
1. Create a new After Effects project and composition, and add your content as a layer.



2. Next, select your content layer. and from the toolbar choose **Effect > Noise & Grain > Noise**. Or apply a preset to your content by clicking here and importing it into the After Effects composition.



3. Now in the effects property box, set the amount of noise to be applied. Settings the noise to 2 - 3% works well.



4. Now you can render out your content.

DXV 2.1.1 Codec

The DXV 2.1.1 codec performs all decompression on the GPU. All codecs have unique performance characteristics due to the various compression methodologies and DXV 2.1.1 is no exception.

DXV 2.1.1 provides excellent results and quality to size ratio. When playing back **filmed video** content, it performs very well without any changes to workflow. See the **Filmed Video** visual comparison section below.

When playing back **graphics with strong gradients**, noise can be added to the video during render to reduce compression artefacts. See the **Graphics & Gradients** visual comparison section below.

Download the DXV 2.1.1 Codec

Download the DXV 2.1.1 Codec on our **Resources page**.

> **Note**
>
> **DXV3 is not supported.**

Filmed Video

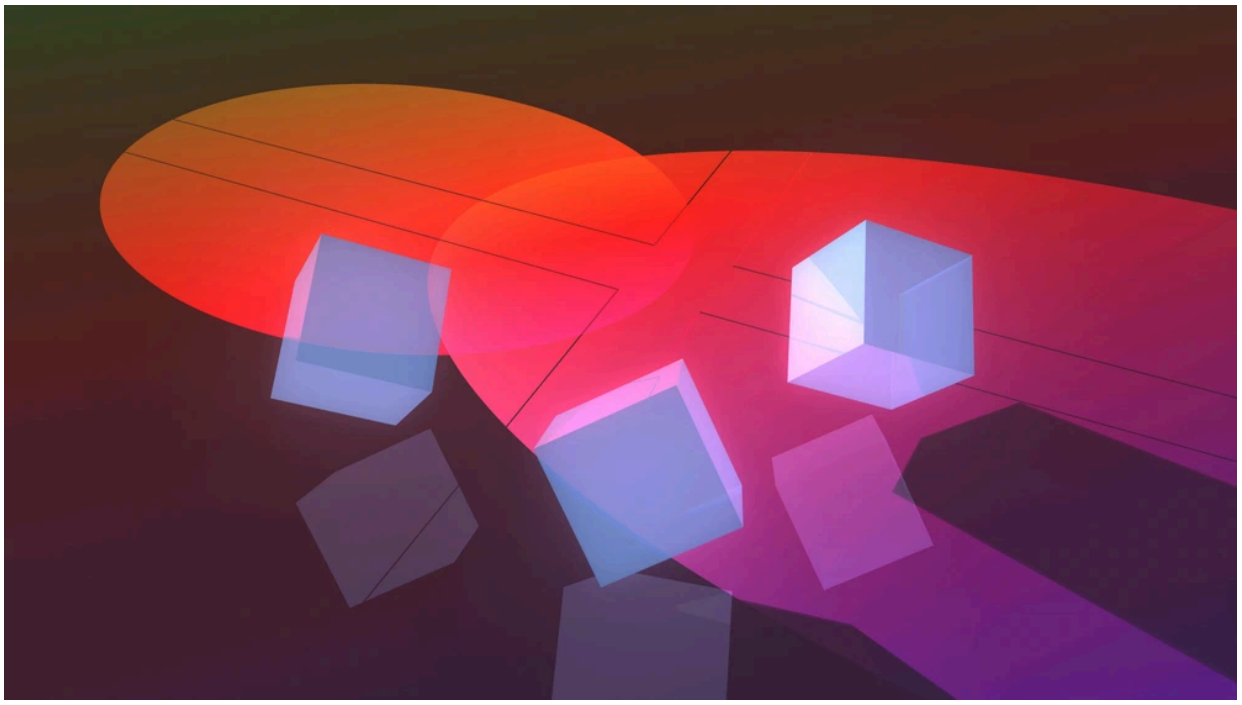
Stills from the short film **Tears of Steel**. Source media, 1920 x 800 PNG.

DXV 2.1.1

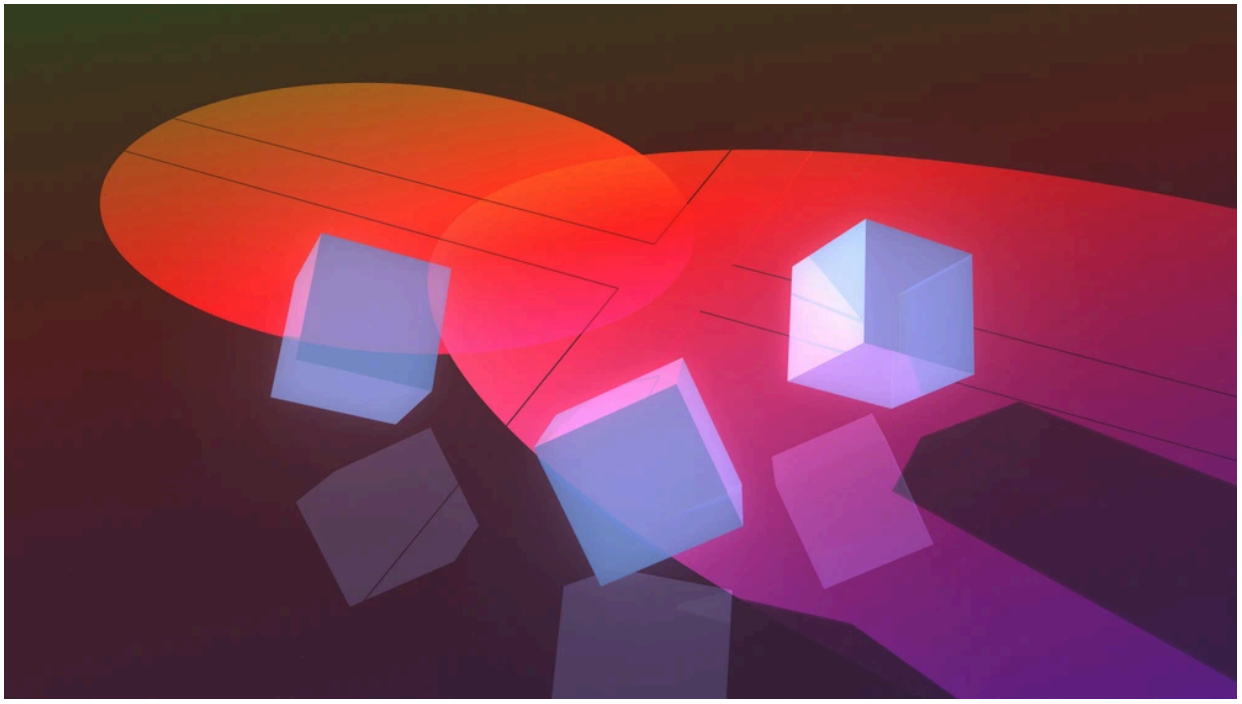
Photo JPEG

Graphics with Gradients

With the DXV 2.1.1 codec there can be artefacts after compression in certain cases. One issue that can occur is *banding* in gradients, however this can be eased by adding a small amount of noise to the media before conversion.



DXV



DXV + 3% Noise

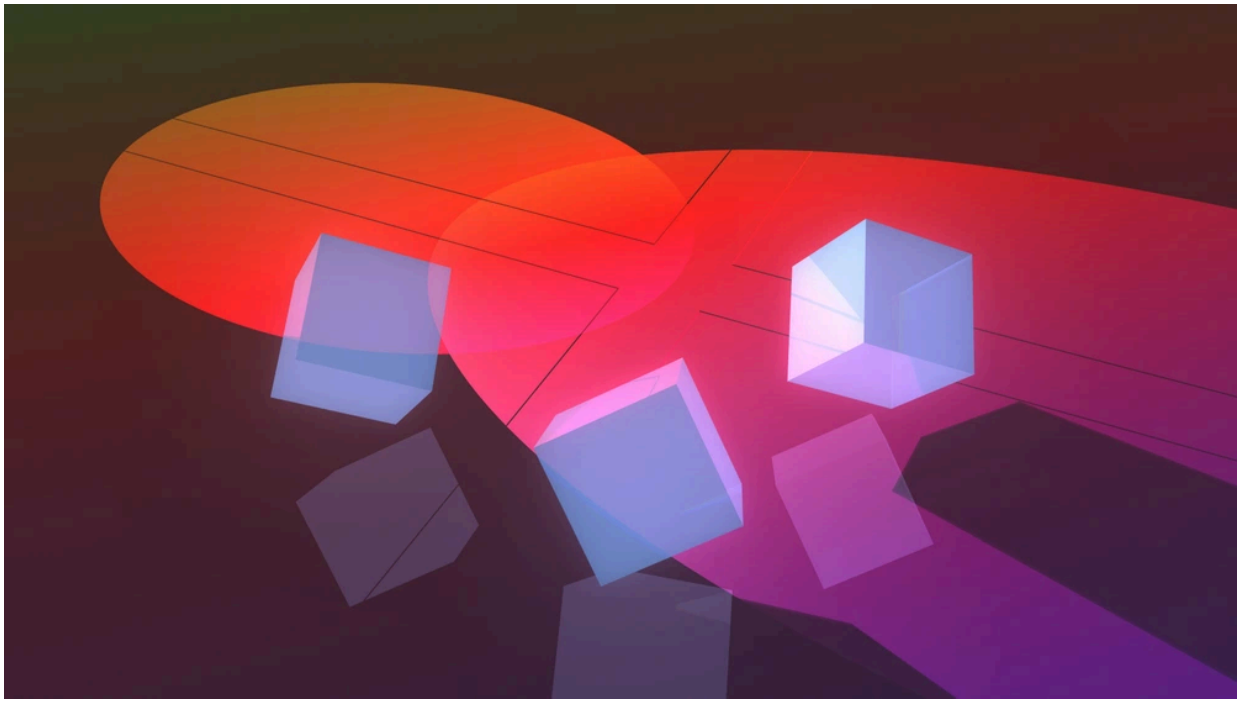


Photo JPEG

HAP / HAP-Q Codec

The HAP family comes in multiple flavours for different purposes.

HAP

Enables very large canvases at lower bitrates, with some trade-off for compression. HAP is very similar to DXV in terms of compression profile, but allows much larger canvases. If you are preparing canvases over HD, we recommend using HAP. When preparing shot footage, HAP is often the go to choice for bandwidth and compression.

HAP-Q

Utilises twice the bandwidth of HAP, but offers much better detail in tone, which is especially important in rendered content where tone gradients are utilised.

HAP Alpha

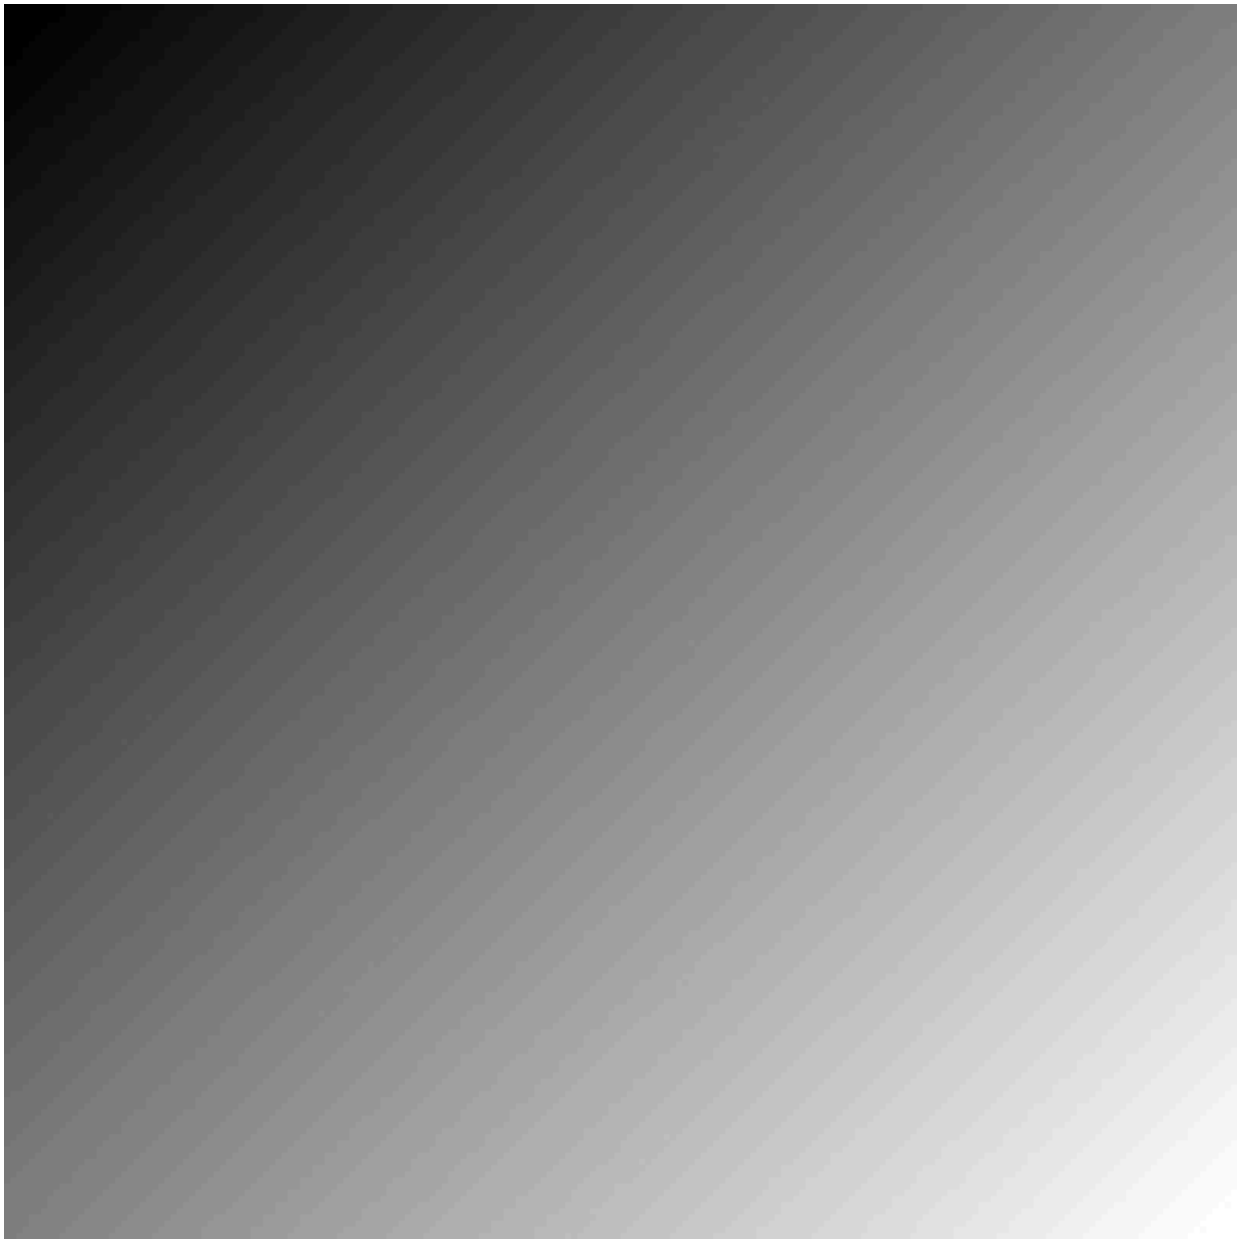
HAP Alpha has the same image quality as HAP, and supports an Alpha channel. HAP Alpha has roughly the same bandwidth as HAP-Q.

> **Note**
>
> Download the HAP/HAP-Q Codec here.

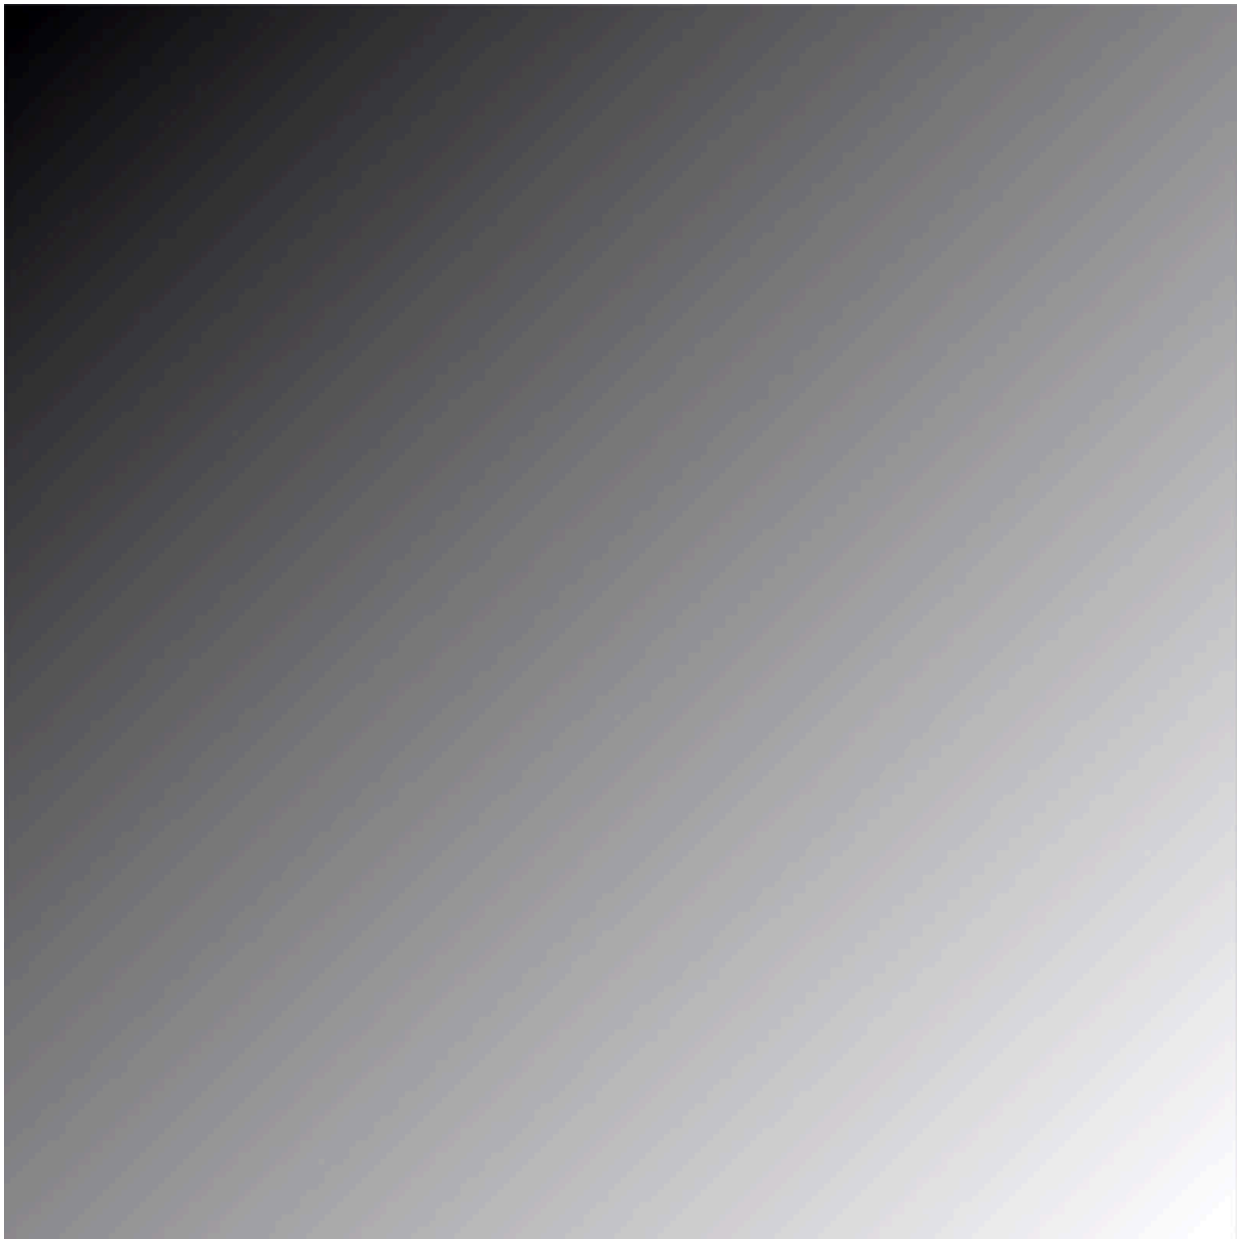
> **Warning**
>
> Designer does not support Hap-Q Alpha.

Graphics with Gradients usage of HAP-Q

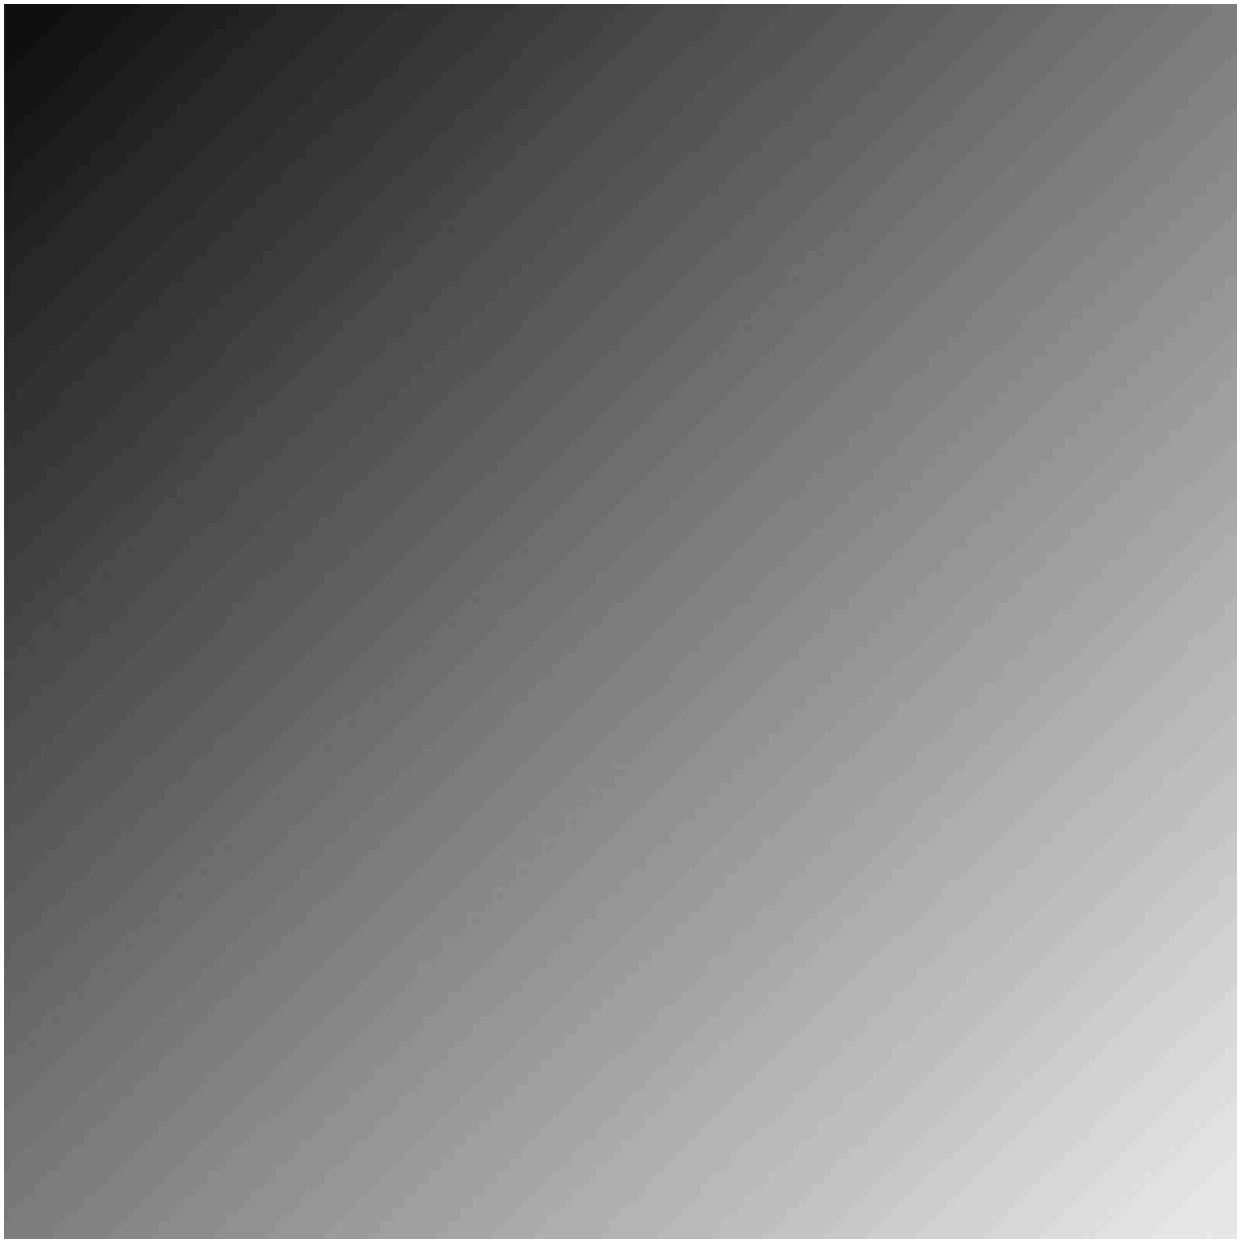
Most lossy codecs are very sensitive to gradients through tone. Below is a comparison of HAP-Q and HAP performance on a gradient through tone in order of quality. Click the image for full size.



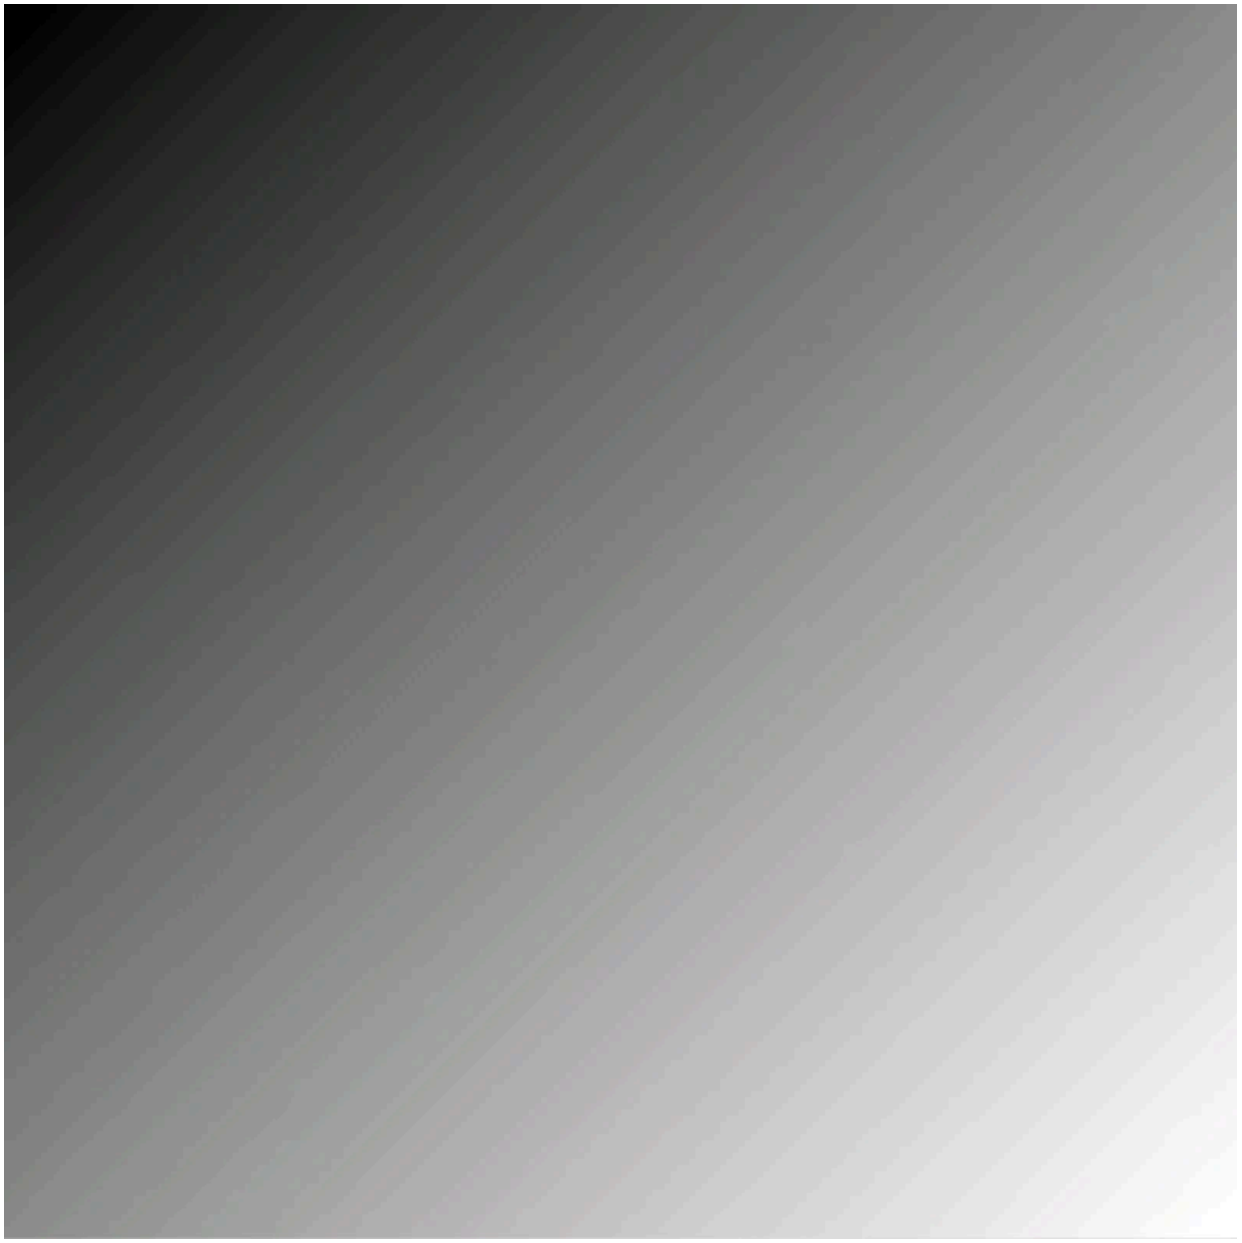
Original



HAP-Q



PhotoJPEG



HAP/DXV

ProRes Codec

The Apple ProRes family is a suite of high-quality codecs developed for professional video production. It delivers excellent image fidelity while keeping file sizes manageable. Designer supports multiple ProRes variants tailored to different quality bandwidth requirements.

ProRes 422

ProRes 422 is the standard variant that provides excellent quality for most professional video applications. It offers a good balance between file size and image quality, making it ideal for broadcast and post-production workflows. ProRes 422 supports up to 10-bit colour depth and is ideal for most video content.

ProRes 4444

ProRes 4444 is the highest quality variant in the ProRes family, supporting up to 12-bit colour depth and an alpha channel for transparency. This codec is designed for visual effects work and high-end post-production where maximum image quality is required. ProRes 4444 provides virtually lossless compression with larger file sizes.

ProRes HQ (High Quality)

ProRes HQ offers higher quality than standard ProRes 422 while maintaining reasonable file sizes. It provides enhanced detail preservation and is particularly useful for content that will undergo multiple generations of processing or when the highest quality is needed within the 422 colour space.

ProRes codecs are widely supported across professional video applications and provide excellent quality for high-end video production workflows.

> ⚠ **Performance Consideration**
>
> Check the performance capabilities of the individual server you intend to playback ProRes on, as performance may be more limited than GPU accelerated codecs like HAP/DXV and NotchLC.

Best Practices

- Use ProRes 422 for standard broadcast and streaming content.
- Choose ProRes 4444 when alpha channel support or maximum quality is required.
- Select ProRes HQ for content requiring enhanced detail preservation.

Quality Comparison

ProRes codecs are designed to maintain high image quality across different compression levels and file size:

- **ProRes 4444**: Highest quality, supports alpha channel, largest file size,.
- **ProRes HQ**: Enhanced quality over standard 422, moderately larger file sizes.
- **ProRes 422**: Standard quality, a good balance of quality and file size.

Choose the appropriate variant based on your quality needs, storage capacity, and whether alpha channel transparency support is required.

Further Information

Read more about Apple ProRes on the **Apple Support website**.

Transcoding Software

Designer supports playing back a range of video codecs. A common part of any production is encoding or transcoding your content in to the correct format. We recommend using standard rendering applications such as Adobe Media Encoder or the freeware MPEG Streamclip for transcoding and encoding.

The following codecs are supported in the standard install of most media transcoding applications:

- ProRes
- TIFF
- DXV
- EXR

Other Codecs typically require a plugin to transcode. These include:

- HAP/HAP-Q
- NotchLC

You can find quick links to transcoding plugins and codecs for all of our supported formats on our Resource page.

Video Codec Overview

Designer uses the QuickTime .mov video container for playing back various codecs, and advanced GPU codecs DXV/HAP/HAP-Q which allow for excellent quality/ performance trade-offs.

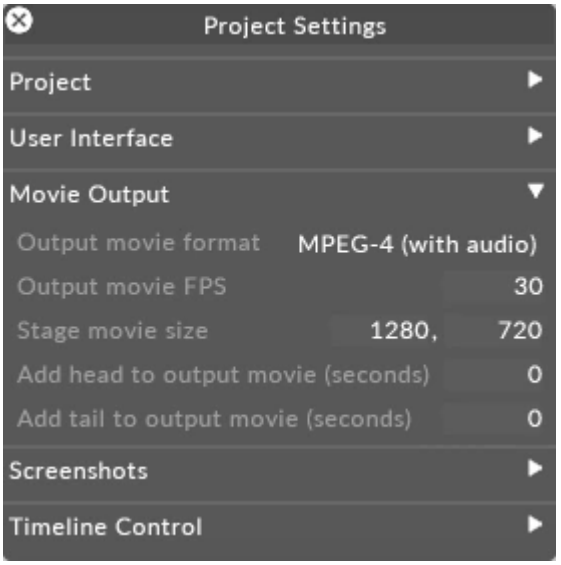
- HAP / DXV : Two very similar GPU based codecs that allow for high numbers of simultaneous video to be played at a good quality. Utilise HAP for resolutions greater than HD.
- HAP-Q : Utilises twice the bandwidth of HAP/DXV, but delivers higher tonal fidelity especially in rendered content, or content with tonal gradients (such as skylines)
- **Animation** - A totally lossless, but very high bandwidth codec.
- ProRes : A high-quality suite of Apple codecs—ProRes 422, 4444, and HQ—fully supported by Designer.
- **Notch LC** - 10bit ltd have developed a new video codec which is intended to fit in between HAP and lossless image sequences in terms of both visual quality and performance. All users who are currently unsatisfied with HAP, but are unable to justify the cost of lossless playback will benefit from this addition.

View the **Resource page** for Video Codec download information.

Video Output Settings

Before rendering a Stage or Feed movie it is important to set the size, frames-per-second and codec used for the output video. To do this:

1. Open the Program Settings menu by right-clicking **d3**from the dashboard (bar at the top of the screen).
2. Select **Project settings...**
3. The **Movie Output** section contains the properties used to specify the settings of the Stage/Feed movie.



Movie Output Properties

Output movie format

This selects the codec for the video.

Options are:

- **Photo- JPEG (no audio)**
- **Animation (no audio)**
- **MPEG-4 (with audio)**
- **Photo- JPEG mov (OLD quicktime players)**
- **HAP (no audio)**
- **DPX image sequence (no audio)**

- **WEBM vp9 (audio as Vorbis output)**

Only the **MPEG-4** option writes audio to the file. In general, the first two options are used for writing Feed movies for playback since they do not need audio. The **MPEG-4** option is used mainly for Stage movies since Stage movies most likely need audio and also need to be as compact as possible to be sent via the internet.

Output movie fps

The output movie speed, in frames-per-second. Any frame-rate can be used, but common values are 24, 25, 29.97 or 30.

Output movie size

The output movie size, in pixels.

Add head to output movie (in seconds)

This option will add an extra number of seconds to the beginning of the file. This can be useful when writing out short sections for playback on other systems.

Add tail to output movie (in seconds)

This option will add an extra number of seconds to the end of the file. This can be useful when writing out short sections for playback on other systems.

Advanced Machine Settings

Colloquially known as **option switches**, Advanced machine settings allow you to alter the default state of a project and enable behaviour not available in the core product.

Option switches can be enabled on a per machine or per project basis.

Advanced machine settings take precedence over project settings.

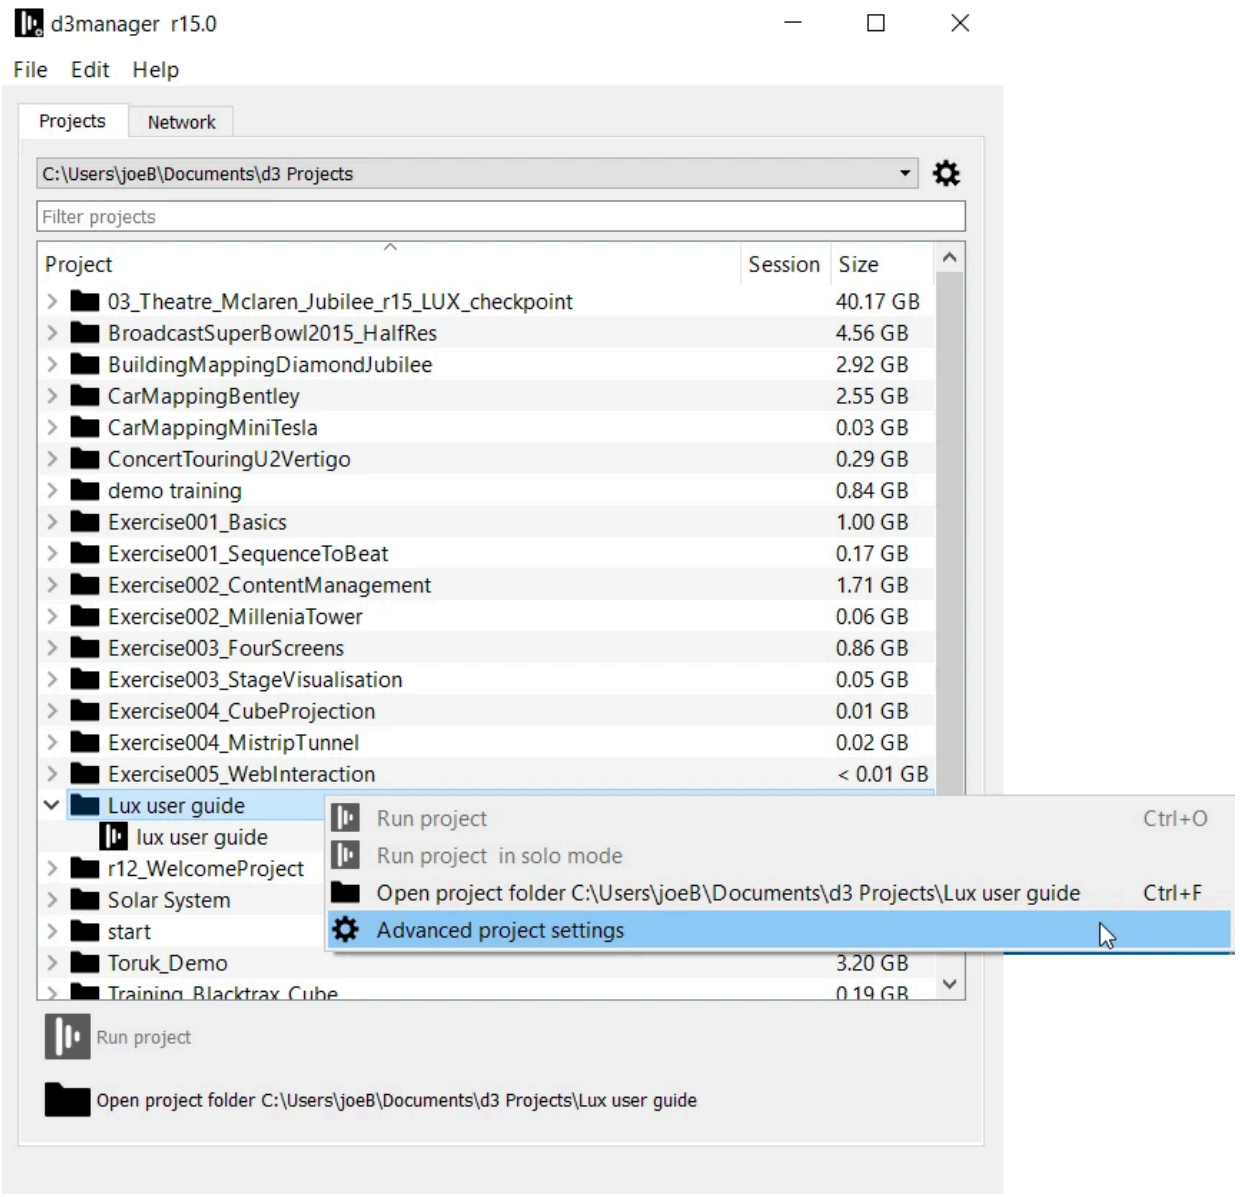
Advanced machine settings are roughly the same as setting a `machine.ini` text file containing option preferences prior to r15.

Setting project options is roughly the same as editing the options.ini file in a project folder prior to r15.

Accessing Advanced project settings

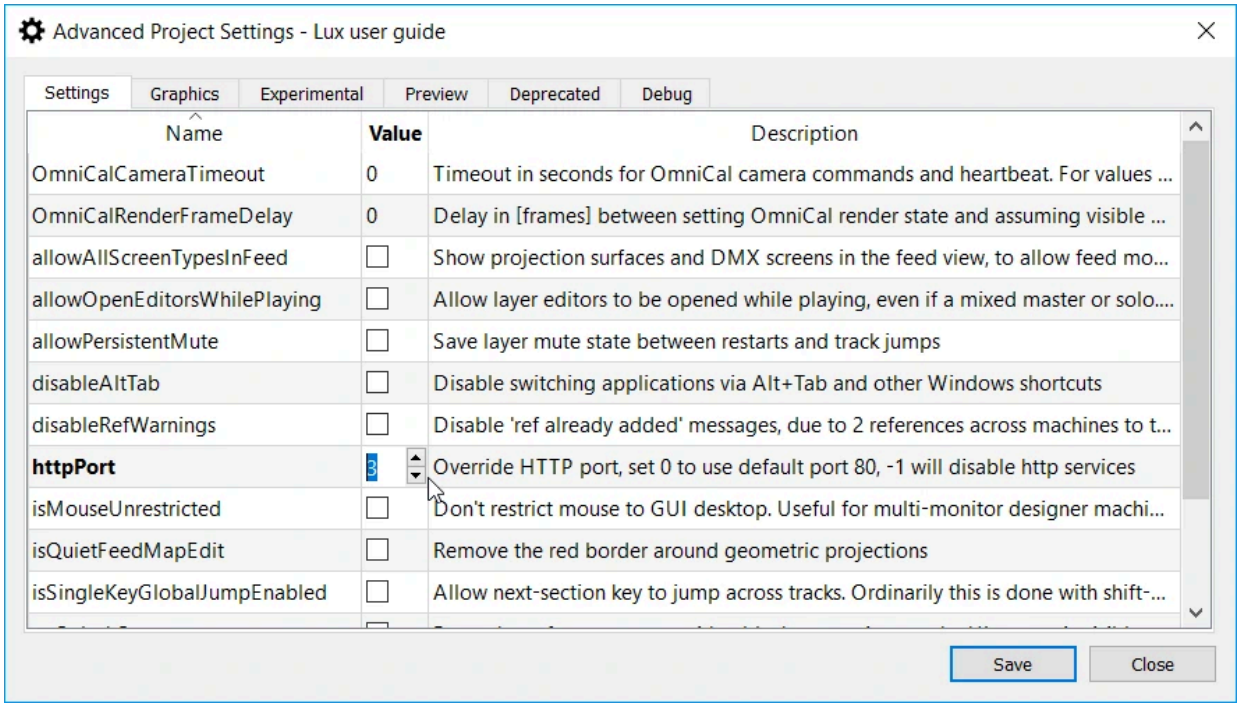
1. In Manager, right-click on a project folder.
2. Select **Advanced project settings** from the list.

> **Note**
>
> It is important to right-click the project folder as options are set per folder, not per .d3 file.



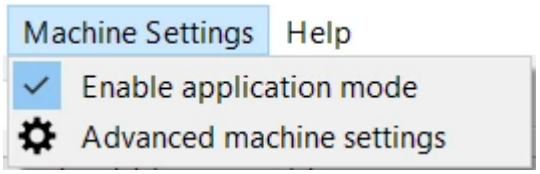
Applying Advanced project settings

1. Access the **advanced project settings** dialogue.
2. Select tick boxes to enable Boolean options, or double-click on Integer value options to set them to the desired value.
3. Click **Save** to close and save the desired settings. Or click Close to close the window without saving.



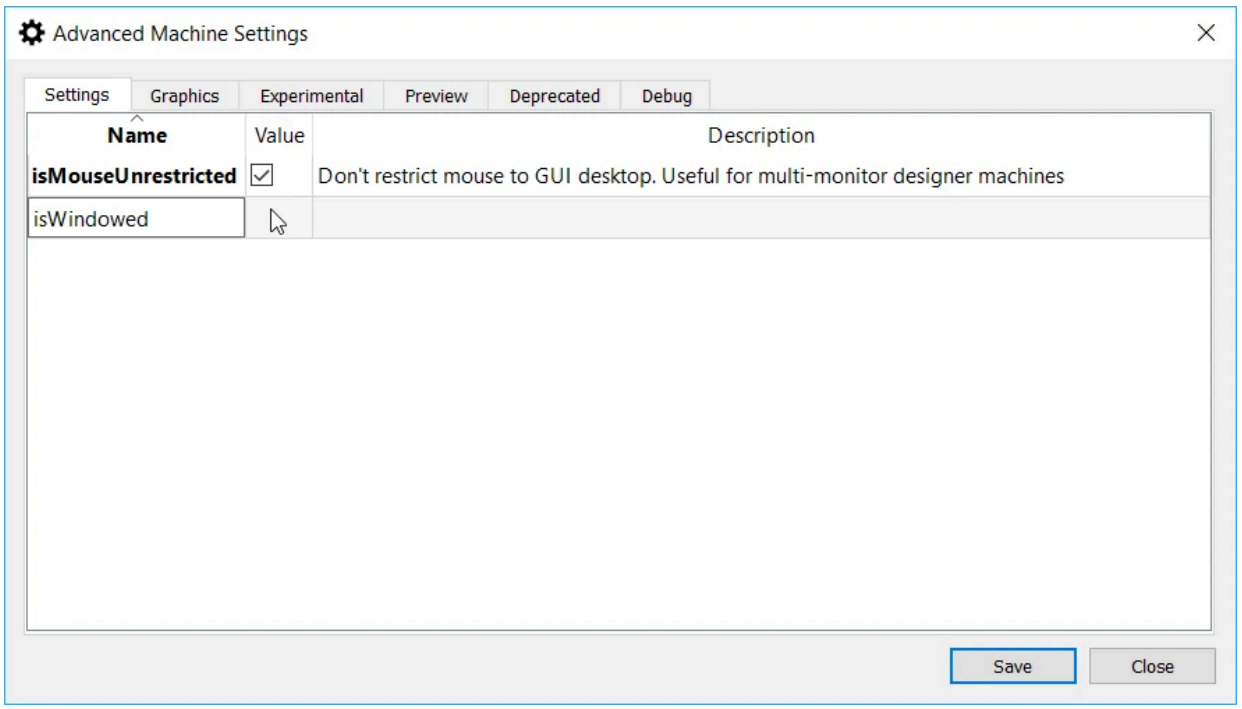
Accessing Advanced machine settings

1. In Manager, expand the **Machine Settings** menu.
2. Left-click **Advanced machine settings** to open the editor.



Applying Advanced machine settings

1. Open the **Advanced machine settings** editor.
2. Double-click on a name cell.
3. Enter the value from the defined list of settings.
4. Click save to **save** settings, or **close** to exit without saving settings



Application mode

Under the Machine Settings menu, there is an Enable Application Mode button from r17.2 onwards. This is simply a shortcut to pre-set the following options:

- `isMouseUnrestricted`
- `isWindowed`
- `maxHeads`
- `useApplicationWindow`

Application mode allows Designer to run in a windowed mode with access to minimise, maximise and close buttons, as well as keeping the windows taskbar visible. This is default on Designer machines, but not rackmount machines.

> **Warning**
>
> Windowed mode should not be used during a running production; doing so can negatively impact your system's performance.

Option Switches

Name	Type	Category	Description
`disableOverlayMessages`	Boolean	Debug	Suppress pop-up overlay messages on startup
`disableConfirmationDialog`	Boolean	Debug	Suppress confirmation di on mass actions
`enableSLC`	Boolean	Preview	Enable support for larger canvases
`enableProjectorDeviceRetries`	Integer	Debug	Enable support for retryin projector device comman Enter number of retries (e the first call to device). -1 disable.
`enableProjectorDeviceLogging`	Integer	Debug	Enable logging level for pr device commands. 0 = disable, 1 = enable
`enableSeparateRotationAndSpatialDelays`	Boolean	Settings	Add a field to the Camera allows you to set a separa delay for position and rota data
`projectorDeviceThreadPoolSize`	Integer	Debug	Override the number of w threads for servicing proje device comms.
`projectorDeviceMaxActiveTasks`	Integer	Debug	Override the max number tasks which task manage run on each process call servicing projector device comms. Set to 0 to use sy default. System default =
`enableVicon`	Boolean	Preview	Enable Vicon Datastream driver
`allowOpenEditorsWhilePlaying`	Boolean	Settings	Allow layer editors to be o while playing, even if a no dedicated director or solo default to prevent frame d that can happen when th is opened
`allowPersistentMute`	Boolean	Settings	Save layer mute state bet restarts and track jumps
`audioLinePcmSize`	Integer	Experimental	Increase size of window f in the audio analyser

Name	Type	Category	Description
`audioStreamBufferSize`	Integer	Experimental	Set the audio file buffer si bytes
`audioMinFadeRamp`	Integer	Settings	Minimum audio volume fa ramp in milliseconds. Default is 50
`debugMediaManager`	Boolean	Debug	Enable detailed console lo about video file loading.
`defaultDetachedBankEditorResources`	Boolean	Experimental	Open the bank editor with objectView detached by d
`disableUnsupportedEmbeddedAudioNotification`	Boolean	Settings	Disable notification for unsupported audio forma video files
`disableAltTab`	Boolean	Settings	Disable switching applicat Alt+Tab and other Windo shortcuts
`disableActiveLatencyPhaseAdjustment`	Boolean	Graphics	Do not adjust active laten render streams to the clo frame time
`disableOutputModeHotkeys`	Boolean	Settings	Disable keyboard shortcu toggle the global output r (Fade, Hold)
`disableAudioInput`	Boolean	Settings	Disable audio input in cas conflicts with other applic
`audioInputDriver`	Integer	Debug	Sets the audio input drive 0 = WASAPI, 1 = Legacy DirectSound, 2 = Both
`disableAudioASIODriver`	Boolean	Settings	Disable ASIO support in c conflicts with other applic
`disableDllVersionCheck`	Boolean	Debug	If dll exports have not cha allow dlls to load with mismatching version num DANGEROUS.
`disableFullscreenCheck`	Boolean	Graphics	Disable the attempt to ma fullscreen mode
`disableInputInCameraEditor`	Boolean	Settings	The small preview in the d editor ignores all input if th set
`disableProxyMaker`	Boolean	Deprecated	Disable the proxy maker

Name	Type	Category	Description
`disableRefWarnings`	Boolean	Settings	Disable 'ref already added messages, due to 2 refere across machines to the sa on-disk resource
`enableShadowResourceDomain`	Boolean	Debug	To use the resources API endpoint. Warning may ha performance side-effects complex projects.
`disableTelnetNotification`	Boolean	Debug	Disable the notification fo out telnet connections
`disableTrackSanityChecks`	Boolean	Debug	Disable the track sequenc sanity checks
`disableVideoclipThumbnailVersions`	Boolean	Settings	Hide version numbers underneath video clip thu
`disableVFCConfigOnStartup`	Boolean	Experimental	Prevent reconfiguration of outputs when d3 starts
`disableDmxPacketSendWait`	Boolean	Debug	Disable waiting for DMX p to be sent and instead dr Can improve performance remote node does not ex network.
`disableVR`	Boolean	Settings	DebugOptionsDescriptior
`enableGuiFeed`	Boolean	Settings	Enable selecting the local a Display for arranging on feed outputs
`enableIPSDIExperimentalModes`	Boolean	Experimental	Allow the use of Quad mo and 720p resolutions in S mode on an IP VFC
`enableMultiview`	Boolean	Preview	Enable a multi-view style input. Subdivides a single input into multiple inputs. for pure director or editor scenarios
`enableNotchNDI`	Boolean	Settings	Set to allow blocks to use own internal NDI® stream. cause NDI® instability if us alongside d3 NDI® stream
`enableProofOfPlay`	Boolean	Settings	Enable writing proof of pla
`enableRenderStreamNDI`	Boolean	Settings	Set to allow RenderStrear the NDI® transport. Does work with image paramet

Name	Type	Category	Description
`enableTimelineZoomOnScroll`	Boolean	Settings	Enable timeline zoom on s Zoom in on layers with sc wheel, scroll through time layers with alt + scroll whe
`enableUnusedMediaManagement`	Boolean	Settings	Enable Unused Media Management part of Mec Distribution widget
`etwLevel`	Integer	Debug	ETW log level. 0 = default value(= 4); 1=Critical, 2=Error, 3=Warning, 4=Informational, 5=Verbose
`forcePIDTimecodeChase`	Boolean	Experimental	Force timecode chase to use PID correction instead BangBang
`forceOutputBitDepth`	Integer	Debug	Force output window bit-d (0 = auto, 8 or 10 for bit de
`forceVsyncOnPrimary`	Integer	Graphics	Force vsync behaviour for primary desktop. 0 = Auto, -1 = Force Off, 1 = Force On
`enableCrashReporting`	Boolean	Settings	Enable crash dump captu unhandled exception by c
`GPUFanSpeedPercentOverride`	Integer	Debug	Override the fan speed se for rackmount machines.
`isMouseUnrestricted`	Boolean	Settings	Don't restrict mouse to GU desktop. Useful for multi-m designer machines
`isQuietFeedMapEdit`	Boolean	Settings	Remove the red border ar geometric projections
`isSingleKeyGlobalJumpEnabled`	Boolean	Settings	Allow next-section key to across tracks. Ordinarily th done with shift-key comb
`isWindowed`	Boolean	Settings	Run in windowed mode ir of fullscreen. Useful for de machines
`maxHeads`	Integer	Settings	Limit the number of outpu Useful for designer machi with multiple monitors. Re

Name	Type	Category	Description
			option or set 0 to restore outputs
`mouseOrbitInvertY`	Boolean	Settings	Invert Y mouse movemen orbiting the Camera.
`multicastSACNTTL`	Integer	Settings	Set the TTL for multicast s packets. Default=1 Max=255
`noSplashScreen`	Boolean	Settings	Force the software to sta black screen, in case the output is visible to the auc
`noStartupStatus`	Boolean	Settings	Force the software to sta black screen, in case the output is visible to the auc
`notchCameraSwitchingResetInstances`	Boolean	Settings	Reset the notch scene du camera switching
`notchDisableLiveLoading`	Boolean	Debug	Disable live reloading of N blocks
`notchLazyLoading`	Boolean	Debug	Disable preloading of Not blocks on startup
`notchMaxFramerateFraction`	Integer	Graphics	Useful for setting on mac which are unable to keep their Notch workload, whi keeping output machines controlled via the timeline Recommended to be set machine-wide, rather tha project-specific options. Set to 2 for all Layers to ru most 1/2 rate, for example
`notchLCKeepAlive`	Integer	Debug	Keep NotchLC decoders a N frames (0 for default of
`notchLCMinBuffers`	Integer	Debug	Minimum no. CPU decom buffers to keep around at times (default 0)
`notchUseDisguiseClippingPlanes`	Boolean	Settings	Use the clipping planes d in disguise, not the notch Useful in AR/XR effects to the scene in depth.

Name	Type	Category	Description
`notchAutoPurgeVram`	Boolean	Debug	Purge block VRAM pool a module is not in use is deactivated. May save me but also causes stutters
`omniCalBackupCapturesEnabled`	Boolean	Debug	Backup capture folder ea a capture completes. Help order to send OmniCal de info back to HQ.
`omniCalEnableBlobDetectionMasks`	Boolean	Experimental	Enables hidden feature to per-camera mask images are applied during Blob Detection. Mask images r be placed in the plan fold named '_mask.png'.
`omniCalEnableResumeCaptures`	Boolean	Experimental	Enables ability to resume partial captures which fail to device timeout errors c cancellation. Should be us caution as it assumes cap settings and physical cam and projectors have not c since last capture.
`omniCalEnableProjectorCalibrationRetry`	Boolean	Experimental	Enables OmniCal initial pr calibration to retry with di algorithms to select best
`omniCalIgnoreMeasuredCameraIntrinsics`	Boolean	Experimental	If pre-measured camera i parameters are ignored in OmniCal initial calibration
`omniCalCameraDistance`	Integer	Experimental	Camera distance in [m] us when choosing from pre-measured initial intrinsic parameters. Possible values: 3, 8 (default), 130.
`omniCalCameraTimeout`	Integer	Settings	Timeout in seconds for O camera commands and heartbeat. For values <= 0 default of 10s is used.
`omniCalMaxThreadsPng`	Integer	Settings	Maximum number of CPU threads to use for encodi images in the machine vis capture process. Default i of CPU hardware threads on a VX 4 server), and ma is 50%.

Name	Type	Category	Description
`omniCalMaxBlobDetectionConcurrency`	Integer	Settings	Maximum number of CPU threads to use for blob de For debugging CPU starva issues. Default is 50% of (hardware threads (e.g. 8 c 4 server).
`omniCalUseProjectorDevicesInSimulation`	Boolean	Debug	Send shutter and warp commands to projectors simulated captures. Helpf order to test projector dev stacking simulations.
`overrideUnpatchedMediaFields`	Boolean	Settings	When fields pertaining to in the SockpuppetVideoM are un-patched, use clip f values instead of sequenc ones. Effected Fields: Fram index, Trim frames, Loop I Loop Outframe
`pythonApiExecutionTimeout`	Integer	Experimental	Any python script receive python execute api endpo interrupted if its executior exceeds this amount in m negative to disable.
`pythonApiOutputRequestsToProject`	Boolean	Experimental	Save python api executio requests to project.
`renderstreamActiveLatencyOffset`	Integer	Settings	Number of extra frames a the calculated active later Default is 0
`renderstreamActiveLatencyPercentile`	Integer	Settings	Permille (0-1000) of the la histogram used for active calculation. Lower values yield a more stable active but may underestimate th required latency — use renderstreamActiveLatenc to compensate. Default is (99.5%).

Name	Type	Category	Description
`renderstreamOutputSyncDelay`	Integer	Settings	Number of frames to wait actors are ready to start presenting a workload. Th additional delay is used to compensate for network communication latency. S to disable RenderStream sync (each fragment of a workload starts presentin soon as possible). Default
`reportMainThreadHangMsec`	Integer	Experimental	Interval [ms] for timeout to for hanging main thread
`rmaxReceiverPool`	Boolean	Settings	Used if uncompressed str are started and stopped r show.
`useLegacySLCRegionTag`	Boolean	Settings	Use legacy video tag for identifying SLC region slic
`useLegacyMaskBlendModeBehaviour`	Boolean	Settings	Mask blend modes apply every layer above the ma layer in the mapping, inste only the layer directly abo Default: off (single-layer behaviour).
`useLegacyProjectViewBlending`	Boolean	Settings	Use legacy projector view blending behaviour.
`sessionStartNodeDiscoveryDelay`	Integer	Debug	Time to wait [seconds] fo discovering sessions on t network
`sessionSyncTimeout`	Integer	Debug	Time to wait [seconds] fo and understudies to sync the director before the dir carries on without them. - wait forever, 0 is a default minutes.
`smoothVideoInputFramesDelay`	Integer	Experimental	Video input in video layers forced to be delayed by th many frames to maintain playback. Default 0. Off -1
`suppressActorsAtStartup`	Boolean	Debug	Don't start actors when st director

Name	Type	Category	Description
`useApplicationWindow`	Boolean	Settings	Use standard application window instead of border requires isWindowed to b
`useApproximateGamma`	Boolean	Graphics	Use faster approximate (l accurate) gamma curve f
`useAutomaticProfiling`	Integer	Experimental	Use automatic detection drop to generate d3 performance profiles. Valu percentage threshold of frames that should trigge profile. Default is 0.
`lockMouseWhileOrbiting`	Boolean	Settings	Lock mouse to point you' orbiting around the stage
`enableChromaKeyModule`	Boolean	Experimental	Enable basic Chroma Key module for testing purpos intended for production u
`commsProcessingTime`	Integer	Debug	Time in ms to process co messages
`forceDXGISwapEffect`	Integer	Experimental	Debug swap effect. 0 = Auto, 1 = Flip Discard, 2 = Flip Sequential, 3 = No Flip
`useSwapGroup`	Boolean	Experimental	Use nvidia swap group fo synchronisation
`deferActorStartup`	Boolean	Debug Defer actor startup until director has fully started	
`generateWorkloadHTTPCommands`	Boolean	Experimental	Generates HTTP commar RenderStream workloads project start
`profileGPUPoolFromLaunch`	Boolean	Debug	Start profiling GPU pool allocations from launch (d false)
`blackMagicMatrixSendDelay`	Integer	Deprecated	For BlackMagic matrix de delay in milliseconds betv establishing Telnet conne and sending command. S 10ms for 12G matrix devic Default is 0ms.

Name	Type	Category	Description
`additionalCommandLatency`	Integer	Debug	Additional latency (in fram wait for synchronisation b issuing transport comma (default: 0)
`forcePrimaryOutputTo8Bit`	Boolean	Settings	Force gui to 8-bit colour e outputs are 10-bit
`copyIPVfcMulticastOnFailOver`	Boolean	Settings	On failover when the und copies the failed machine configuration it will includ VFC multicast IP addresse (default off)
`enableResourceFileDeletion`	Boolean	Experimental	Allow deletion of files on filesystem, e.g. video files

Checkpointing projects

Once you have finalised your show, you can lock it to the version of the software that you built it with, by creating a “checkpoint”.

Checkpoints are useful if you want to lock your project to a specific software version for portfolio purposes, to have a known-working state you can go back to, e.g. for demos. We recommend to create checkpoints only after a project has been finished.

Checkpoints are intended for archiving / demonstration purposes, not for running shows.

> **Note**
>
> Checkpoints are not intended for - running shows - they are intended for archiving / demonstration purposes and saving **project file** backups; Designer automatically saves your **project file** regularly and on exit.

> **Warning**
>
> At present, Director/Actor operation is not guaranteed to work for projects with active checkpoints. Disable the checkpoint if you encounter issues starting a Director/Actor session.

> **Warning**
>
> Generated checkpoints do not make backup copies of media files (audio files, still images, mesh files and video files). You should make regular backup copies of the entire specific Project folder(s) and store them on an external hard drive or network store.

What a checkpoint does

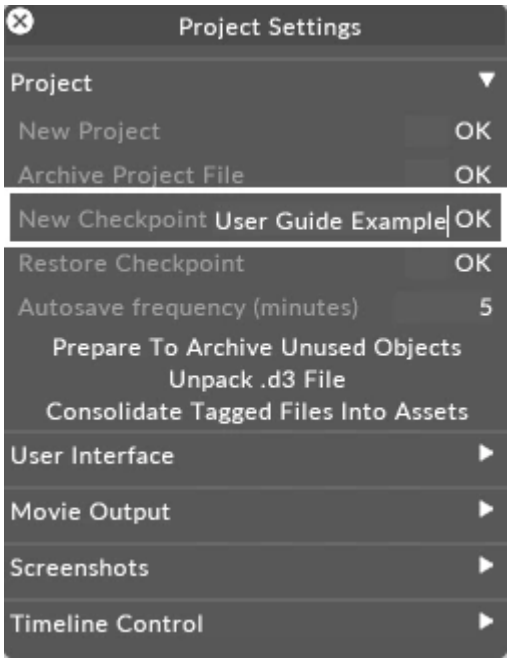
A checkpoint means that:

- A backup of the .d3 file is stored in the checkpoints folder.
- A backup of the entire software install is stored in the checkpoints folder.
- The project is “locked” to the version of software that you built it in. Instead of the installed version (e.g. r21), the one from the checkpoint (e.g. r18) is executed.
- Therefore you can freely upgrade to the newest version of the software, knowing that the show will continue to run exactly the same way as the day you built it.

- You can still upgrade the show later on (See “How to disable a checkpoint” below).

How to create a checkpoint

1. Right-click d3 from the dashboard (bar at the top of the screen), and select **Project Settings**.
2. Type the name of the new checkpoint into the **new checkpoint** text field and hit **Enter**.
3. Wait until a label saying d3 checkpoint complete pops up. This should not take more than a few seconds but may be longer depending on the size and number of resources of the project.



This will create a new folder called **checkpoint** in the specific Project folder. For information on where the specific Project folder is located please see the sub-chapter **Projects location/structure**. Assuming that you do not rename this folder the project will now run from this local folder, rather than the main Disguise installer.

Opening a checkpointed project created in an old release

1. All checkpointed projects created in an earlier release than r11 **need** to be copied to `c:/blip/data/d3`.
2. Open the project from the d3Manager but make sure to add a projects folder that links to `c:/blip/data/d3`.

How to disable a Checkpoint

1. Make a copy of the **.d3** file.
2. Rename the **checkpoint** folder, for example `_checkpoint_old_`.

The Disguise project will now run from the main Designer installer on your system.

> **Note**
>
> When you upgrade a .d3 project file, it may become incompatible with older versions of Disguise (such as the checkpointed version). If you want to go back to the checkpoint (by restoring the “checkpoint” folder) you may also need to restore a backup copy of your .d3 project file from your history folder.

Creating a new project

You can create a new project either outside Disguise in Windows using the d3manager, or within the software itself.

Create a new project in d3manager

1. Run **d3manager**.
2. Click **File** followed by **New Project**. Or alternatively, use the keyboard shortcut **CTRL+N**.
3. Enter a name for the project and click **Create**.

[Animated GIF: Creating a project in d3manager]

Create a new project in Designer

1. Run Designer.
2. Right-click d3 from the dashboard (bar at the top of the screen) and left-click Project Settings...
3. Type in the name of the new project in the new project text field and hit Enter.
4. Exit the software, go to the new folder and run the new .d3 file.

[Animated GIF: Creating a new project in Designer]

Creating snapshots

Project Snapshots allows users the ability to save the state of a project at a time as a Snapshot. Users can then recall these snapshots to compare different points in time within a project.

Project snapshots are an advanced saving function of Designer. They are intended to allow users to restore a known state of the project in a single action (a snapshot). The use case for this feature was for recording “shots” on a film set, but they can be used for many other functions.

Workflow

Snapshots are created in a similar way to saving the project

1. Press CTRL + S to save a snapshot, or use the Snapshot manager.
2. Name the snapshot if needed (this is recommended).
3. Restore the snapshot later to restore the entire project state and revert once you wish to go back to the current state.

Example

Creating New Snapshots

Using Shortcut

Snapshots saved with a shortcut are applied with a default name, to save with default names open the snapshot manager.

To save a Snapshot press [CTRL+S] (Saving a snapshot will save the projects current state and all resources)

Using Snapshot Manager Saving a Snapshot with the snapshot manager allows users to give snapshots custom names

1. To save a snapshot first open the snapshot manager [CTRL +O]
2. Type a name of the snapshot into the snapshot name entry field at the top of the snapshot manager. (Designer will automatically timestamp the saved Snapshot name).
3. Press the OK button. (The snapshot will be added the list below).

Browsing Snapshots

The previously saved Snapshots will be added to the Snapshot List within the Snapshot Manager. Snapshots are filtered by their timestamp of the creation. To browse a Snapshot created at a certain time simply expand the corresponding separator to view the Snapshots contained. Snapshots are filtered by the following:

- **Restored Snapshot** - The last snapshot you restored.
- **Restore Backup** - Revert to the state before the last snapshot was restored
- **Last Hour** - Snapshots created in the last hour
- **Last 24 Hours** - Snapshots created today
- **Last 48 hours** - Snapshots created yesterday
- **Last 7 Days** - Snapshots created this week
- **Last 30 Days** - Snapshots created within the last month
- **Older** - Snapshots created older than a month ago

Restoring a Snapshot

A saved Snapshot can be recalled to return to another state of the project.

Left-click on a Snapshot within the Snapshot List to restore to that state.

The Snapshot List will update to show the current restored snapshot.

Recover Backup

A backup of the current project state occurs every time a snapshot is restored.

Left-click on Recover Button to revert to a backup.

Backups are overwritten when a new snapshot is restored.

> **Note**
>
> When a project snapshot is restored on another machine in the d3Net session, the sequencing changes made as part of that project snapshot do not transfer over to the other machines running in the d3Net session. To fix this, manually restart the session after restoring the snapshot.

Renaming a Snapshot

1. Right-click on a Snapshot within the Snapshot List to open an options widget
2. In the rename field type a new name.
3. Click **OK**.

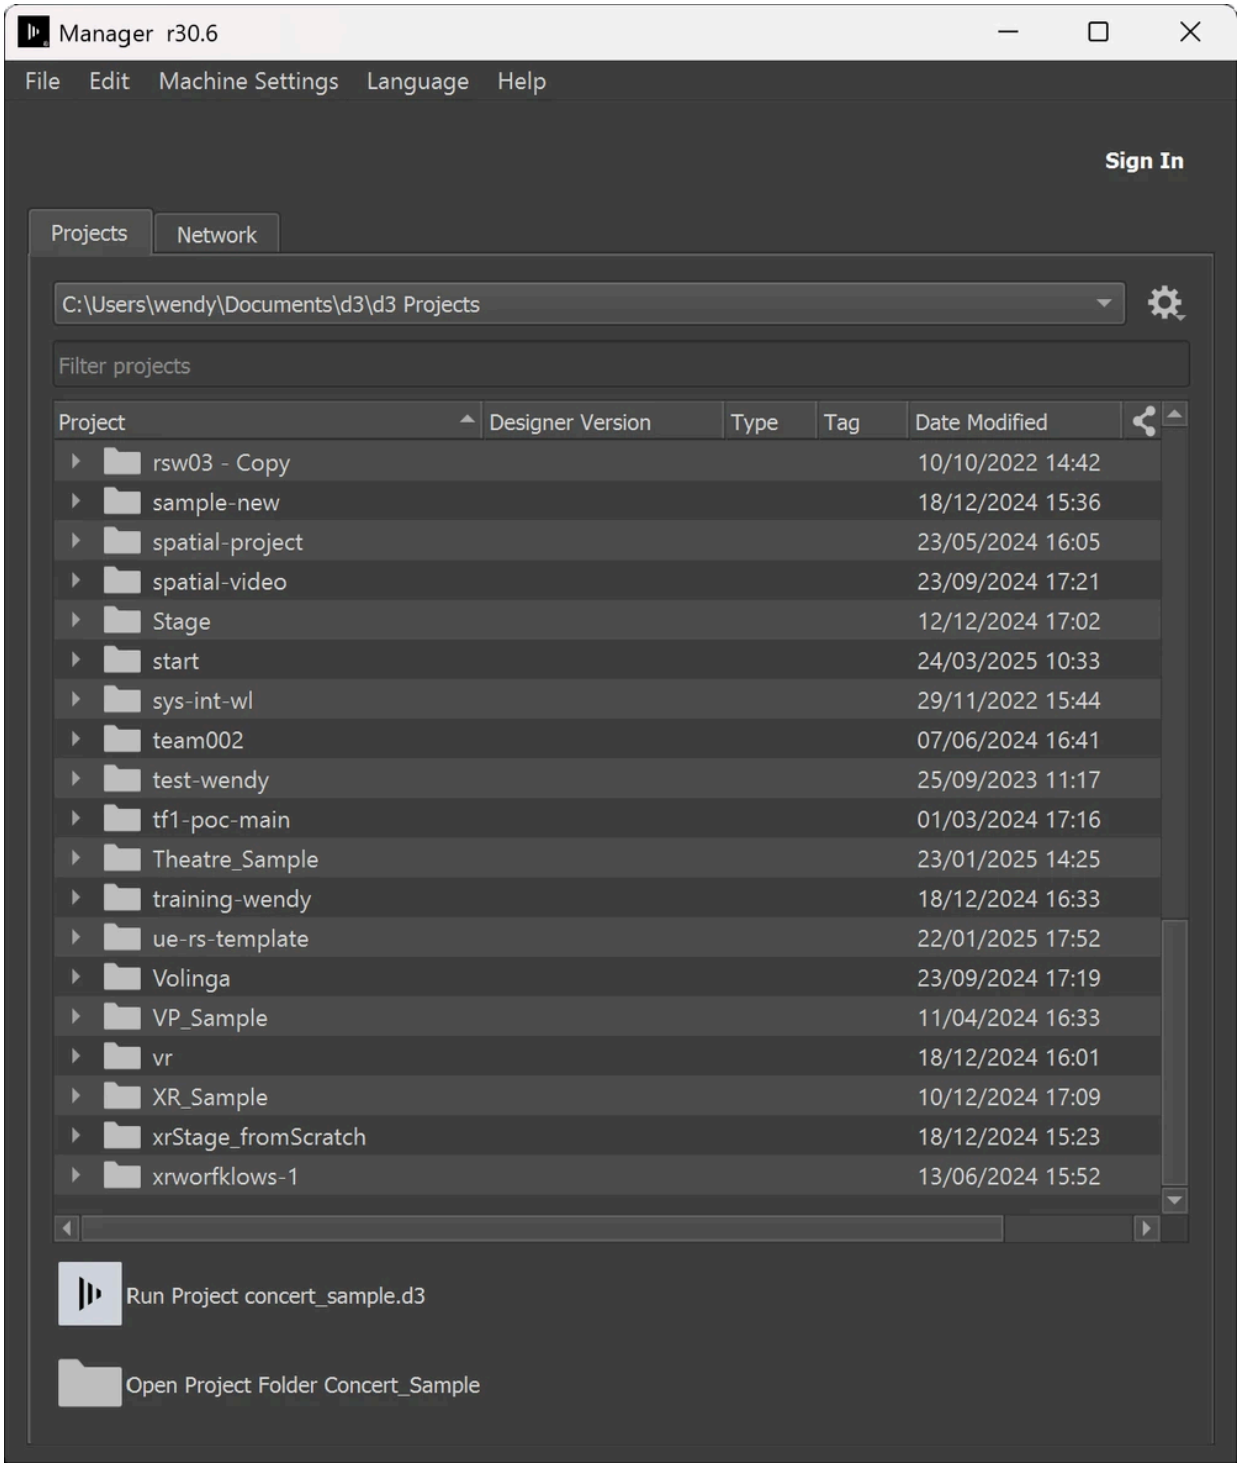
Archiving a Snapshot

1. Right-click on a Snapshot within the Snapshot List to open an options widget.
2. Click **OK** on Archive Snapshot.

(Archiving a snapshot will move the snapshot file on disk to an archive folder, archived snapshots will be removed from the archive list).

d3Manager

The installation of Designer also includes the installation of d3Manager. d3Manager allows users to organise their d3 Projects and launch the Designer application. However, d3Manager is far more than a project management tool and a launcher with many more menu options and settings available for users.



Manager

With the introduction of the new Designer licensing changes, d3Manager now shows projects that your licensing type supports. Projects that do not share the same license are greyed out. Designer Starter allows you to open both Starter and Pro files, however will only save projects as `.d3starter`. However, Designer Pro does not allow users to open Designer Starter .d3starter projects.

d3Manager functionality

The following menu options are available:

File menu

- Create a new project
- Open the projects folder
- Exit the application.

Edit menu

- Expand or collapse the folders in the project view.

Machine Settings menu

- Enable application mode
- Edit the Advanced Machine Settings
- Access the Advanced Network Configuration settings such as add a custom API http port, and rsync daemon port.
- Advanced Machine Settings allow users to, for example, enable/disable Option Switch Settings.

Language menu

- Select from a language from the list.

Help menu

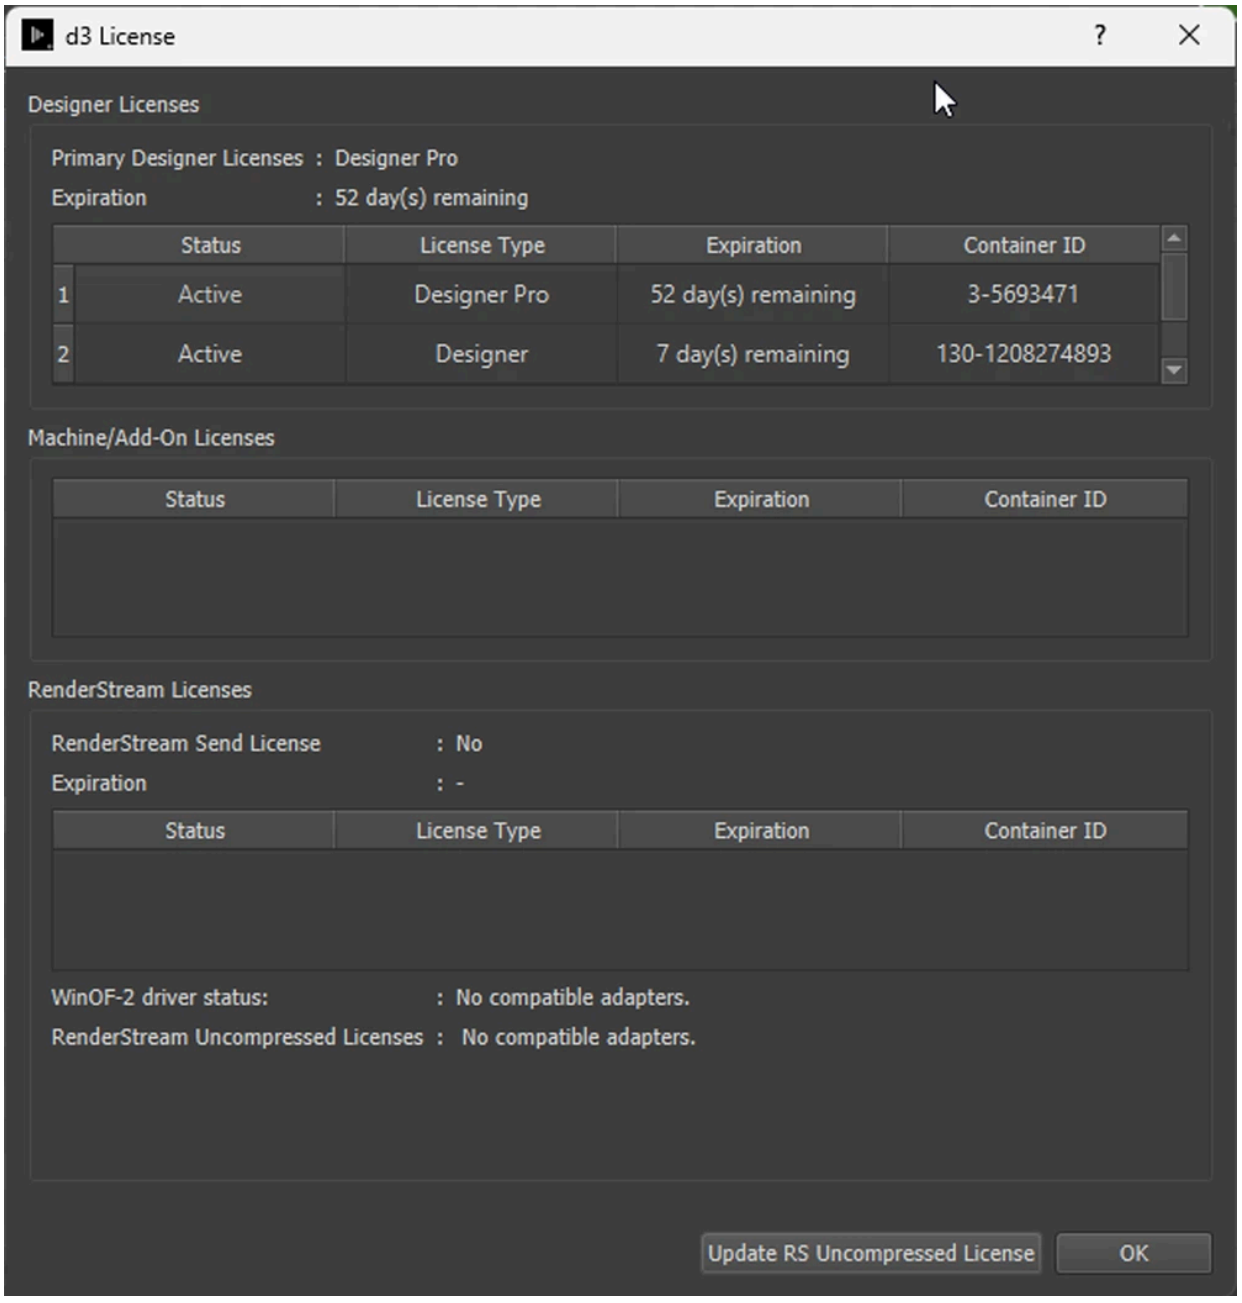
Quick links:

- User Guide
- Disguise Learn
- Disguise Release Notes

Also:

- Open a project in assistance mode
- Open API documentation
- Create a Project diagnostic
- Create a System diagnostic
- Create System diagnostics on selected machines
- Open Bluefish tools folder
- Open Console
- Open Console folder

- d3 Licenses
- Notch Licenses
- Licenses Acknowledgements
- About qt
- About Manager



Designer Licenses

Sign in

Clicking on Sign in opens a browser tab so you can confirm your Disguise Cloud account using a code. This is a Device Confirmation.

Projects tab

- File path of d3 Projects
- Filter projects
- Settings icon
  - Add d3 Projects folder
  - Remove d3 Projects folder

The contextual menu found by right-clicking a project:

- Open folder
- Advanced project settings
- Set as template for new projects
- Show history
- Rename project
- Duplicate project
- Delete project

The contextual menu found by right-clicking a file:

- Open project
- Open project in solo mode
- Open folder
- Set as current project
- Clear ingestion history
- Rename project
- Duplicate project
- Duplicate project file
- Delete project
- Delete project file

Additional Quick links:

- Run Project [project name]
- Open Project Folder [project folder]

Network tab

- Set Network Adapter
- View machine name (Channel), IP Address, d3 version, Machine type, Status

Plus quick links:

- Install d3 remotely
- Advanced machine settings

Summary

In summary, d3Manager lets you do the following things:

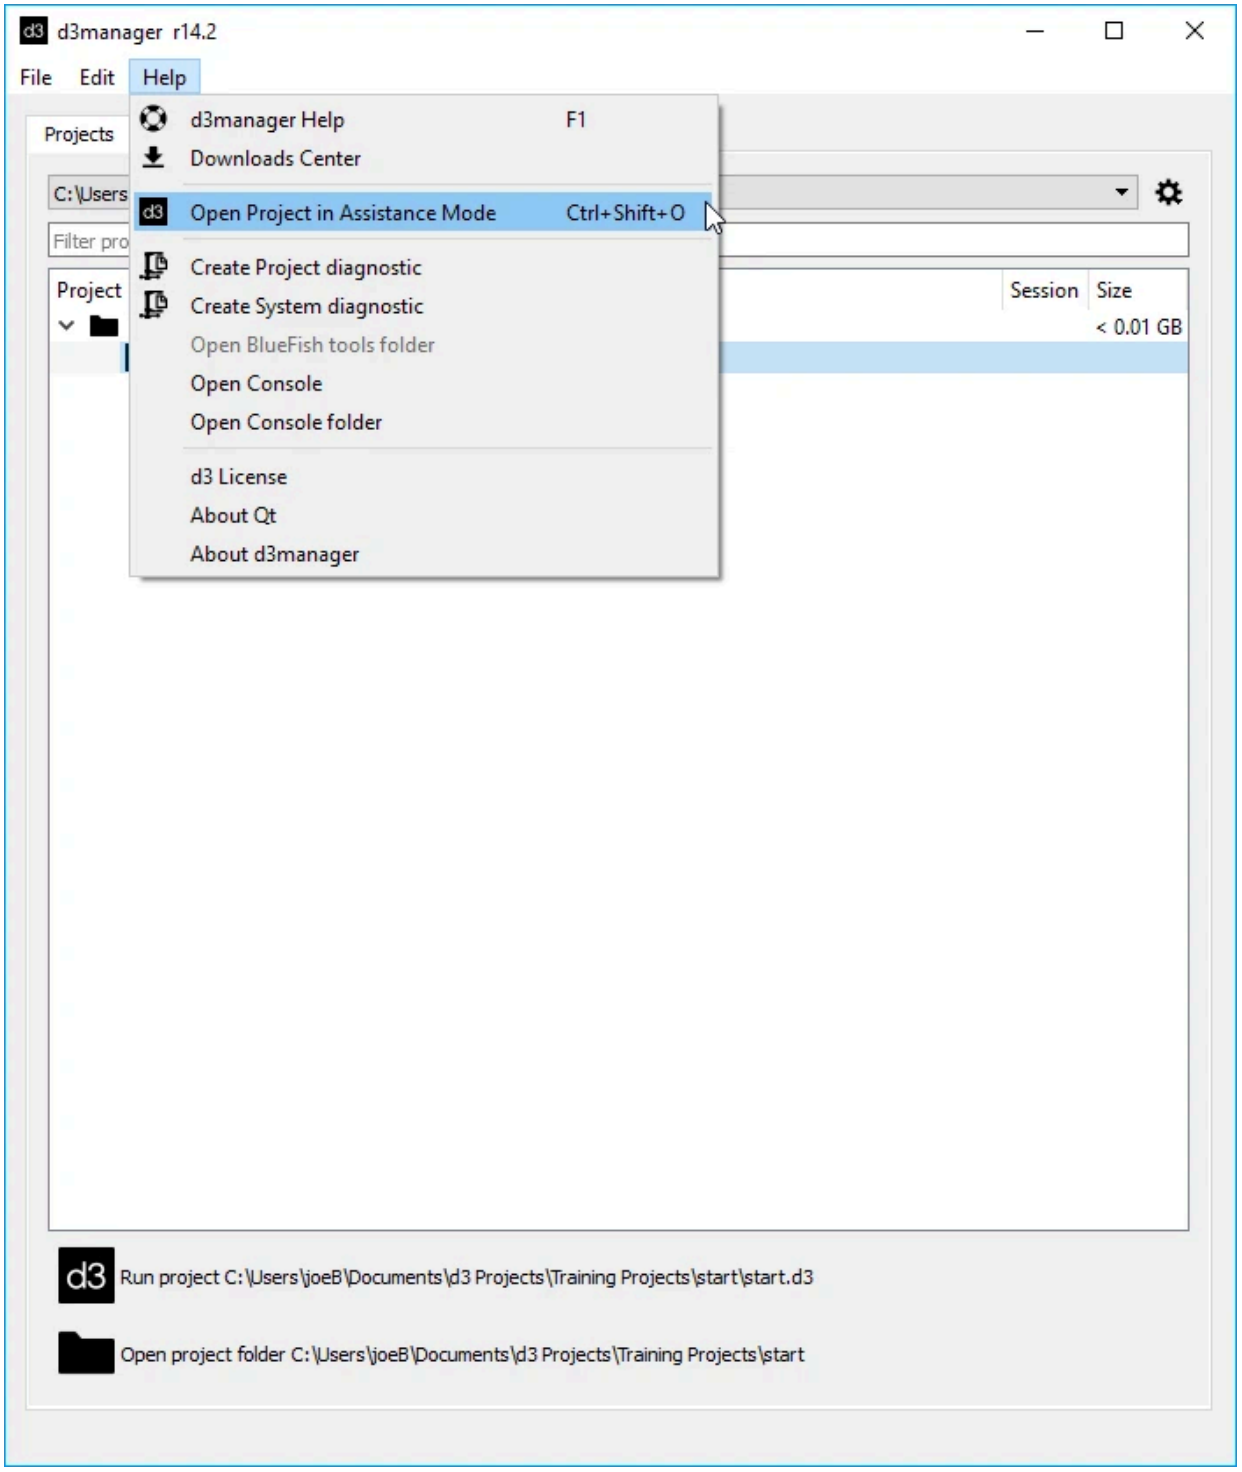
- See which version of Designer you're running in the d3Manager title bar.
- See what projects are installed on your machine.
- See what multi-machine sessions are running on the network.
- See which machines on the network are running Designer and which version they are running.
- Remote install d3 on media servers on the network.
- Navigate quickly to any local project folder.
- Run any local project.
- View the projects folder size.
- Run a local project in assistance mode (for remote diagnostic sessions, for example over Skype).
- Join a multi-user editing session as an editor.
- Create a diagnostic archive (containing the project, non-media files, consoles and telemetry) to send to **support@disguise.one**

Enabling Assistance Mode

This allows the user to join a network session as an editor and allow remote support for the user if a problem occurs.

To open a project in assistance mode

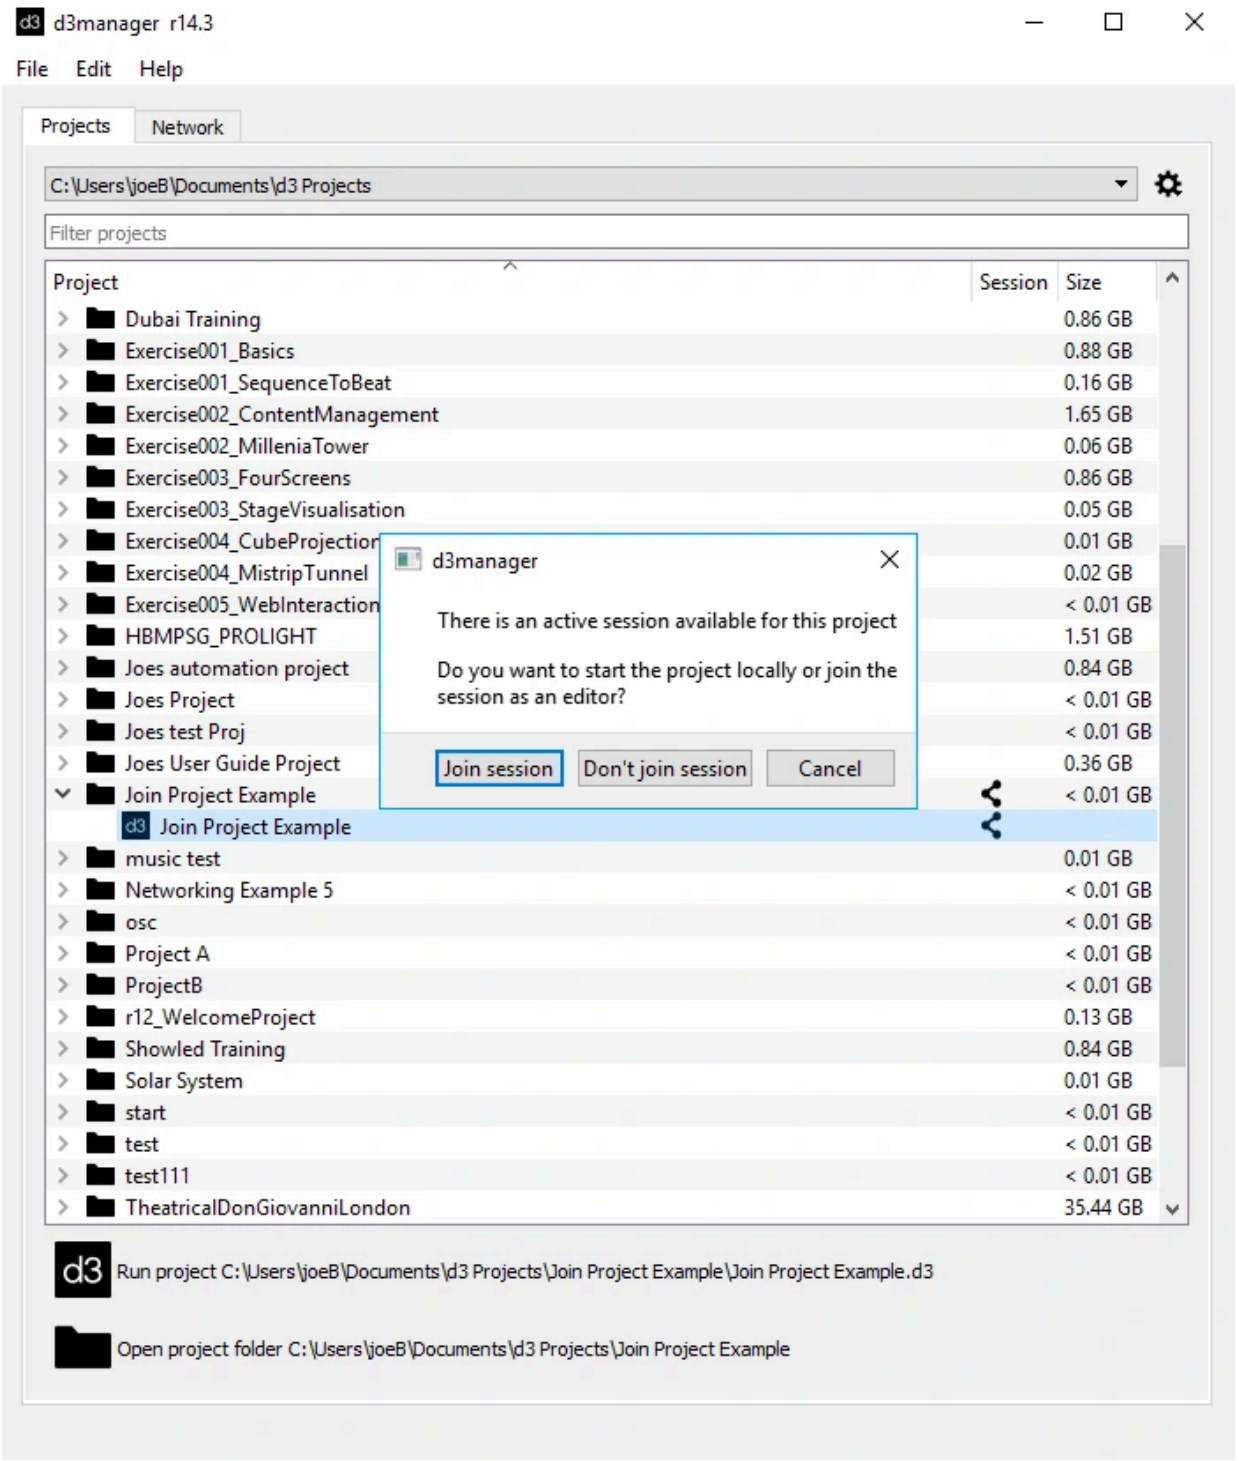
1. In the projects list, first select the project you would like to open.
2. Select **Help** from the menu bar.
3. Select **Open project in assistance mode** from the drop down selection.



To join session in assistance

1. Ensure that the session icon is visible in the session column. If not you may have a networking issue or you haven't set up your **Director-Actor network** correctly.
2. Select the project name in the project list.

3. Under the **Help** menu select the **Select Join session in assistance mode** from the drop down selection.



Quitting a Project

Option 1: using the keyboard shortcut

- Hold down **Esc** , then hit **Enter**

This will save your project, and exit the software.

Option 2: using the interface

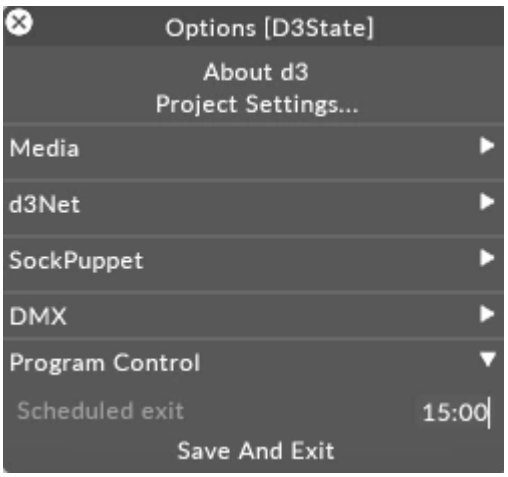
1. Right-click the d3 icon at the top left to open the Program Settings menu.
2. Left-click save and exit.

Scheduled exit

If you want to schedule exit at a certain time do the following:

1. Right-click the d3 icon at the top left to open up the Program Settings menu.
2. Left-click scheduled exit to highlight the text field.
3. Type in the time when you would like Designer to close, using the format `hh:mm`.
4. To remove the scheduled exit, delete the entered data so the field is empty, it will reset to `__:__`

For example, the below image shows it is scheduled to close at 15:00.



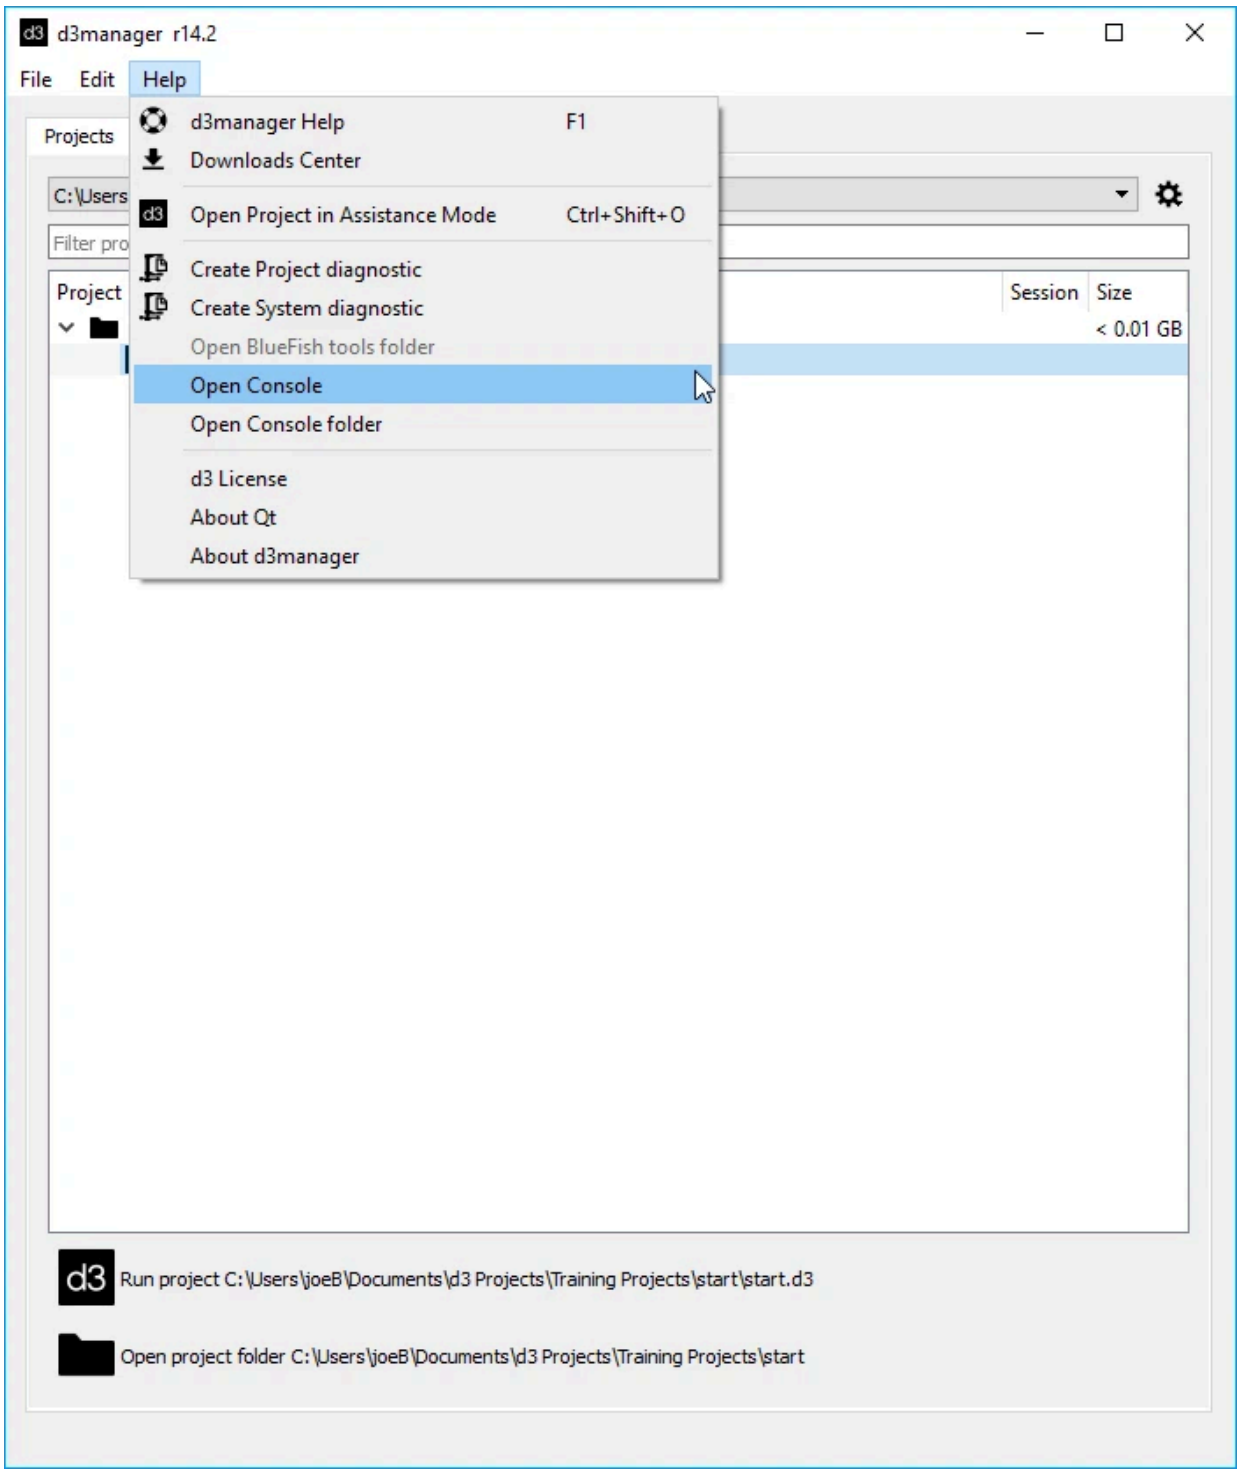
Quitting using the Project Settings menu

Generating console files

If any unpredicted problems arise during pre-production of your show just send the auto-generated console file, i.e. the “blackbox” data of your session, to the Support team. By reading the console file, the support team can quickly decipher what may have caused the problem and immediately respond with an appropriate solution.

Finding the console

1. Open the d3Manager.
2. Open the help menu and choose **open console**.



> **Note**
>
> It is also possible to view the console within the software itself. Simply hit **Alt-C** to bring up the console. For other shortcuts please see the Shortcuts sub-chapter.

> **Warning**
>
> The console file gets overwritten every time the software runs! If you experience a problem, quit Designer, save the console file to a unique name and then re-run the project.

Opening the latest console file

The console file is a background file that records the load up and running of Disguise. This is often requested for support calls.

To open the latest console file

1. Select Help from the menu bar.
2. Select Open console from the drop down selection.

Opening the console folder

The console folder contains all the console files from running Designer. Each session creates a new console file with the old one being archived here.

To open the console folder

1. Select **Help** from the menu bar.
2. Select **Open console folder** from the drop down selection.

Generating Diagnostic Archives

d3Manager allows you to create **diagnostic zip archives**, which bundle together the files from the last 30 days. These are required by Disguise Support to investigate software, system, and project-related issues.

When contacting Disguise Support, we recommend sending a **Project Diagnostic** wherever possible, as this also includes a **System Diagnostic**.

Diagnostic types

System Diagnostic

A **System Diagnostic** contains machine-level information and logs, including:

- Designer console logs
- Designer software crash dumps
- Windows Event Logs
- Installed applications
- License logs
- Disguise OS information
- `sysinfo` data

> **Note:** System Diagnostics do **not** include Windows memory dump or minidump files due to their potentially large size.

Project Diagnostic

A **Project Diagnostic** includes **everything in a System Diagnostic**, Console files, plus:

- A skeleton Designer project file

The skeleton project **excludes** the following large media directories:

- `VideoFile`
- `DxTexture`

If media may be relevant to your issue, please **zip and send these folders separately**.

Important note on Windows Blue Screen errors

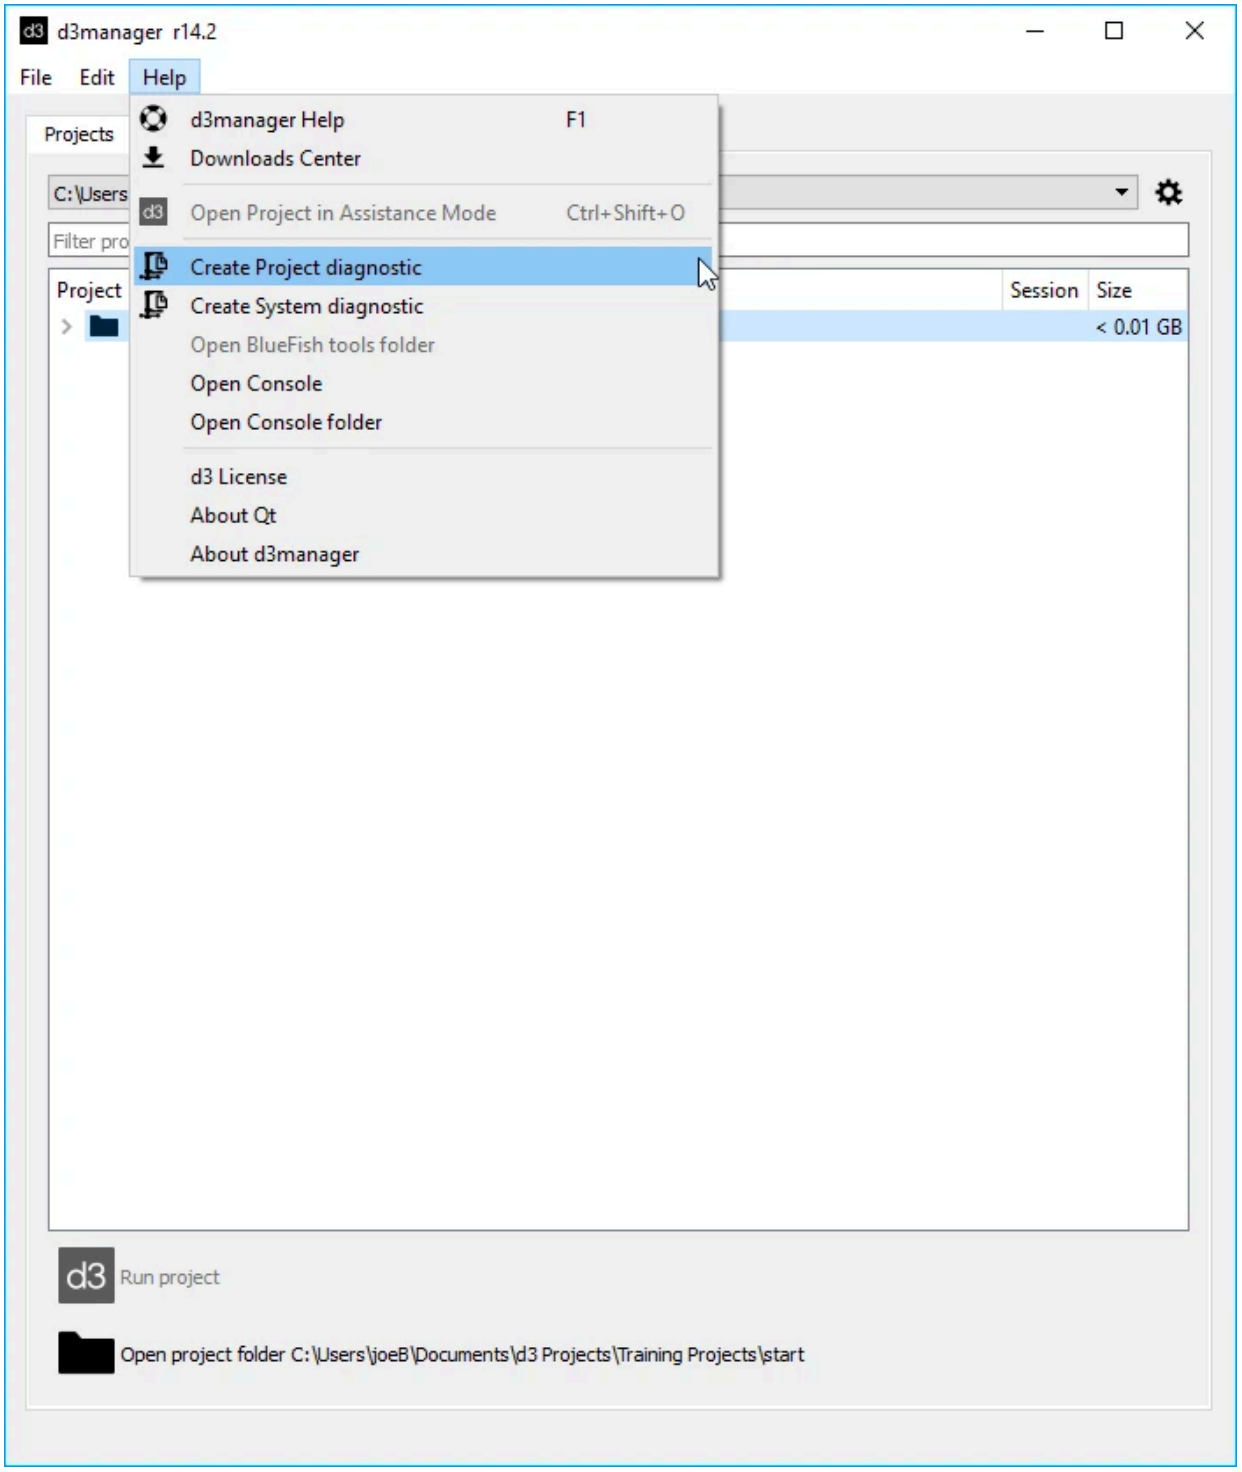
Our diagnostic archives **do not include Windows memory dump files**.
If you experience a **Windows Blue Screen**, please also zip and send the following files

separately, if present:

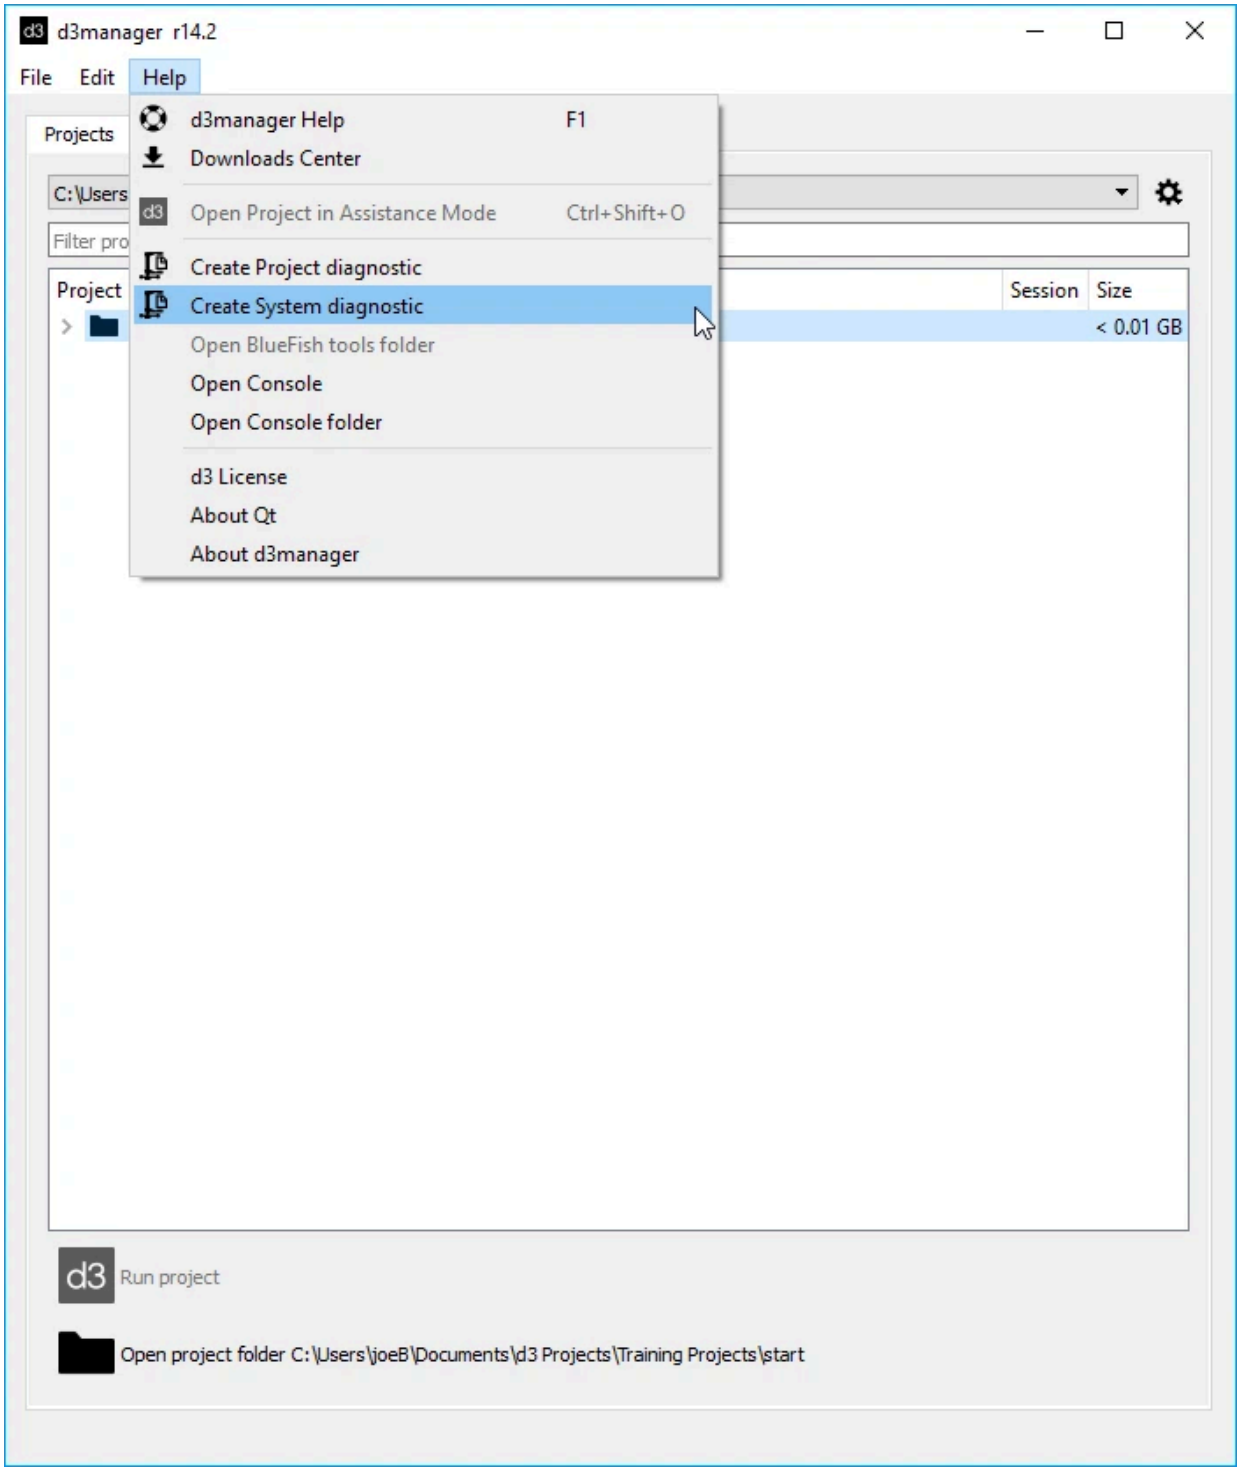
- `C:\Windows\MEMORY.DMP`
- `C:\Windows\Minidump`

Create a diagnostic zip on your local machine

1. Open **d3Manager**.
2. Select the relevant project (for Project Diagnostics).
3. Go to the **Help** menu and choose **Create project/system diagnostic**.
4. The diagnostic zip file will be created automatically.



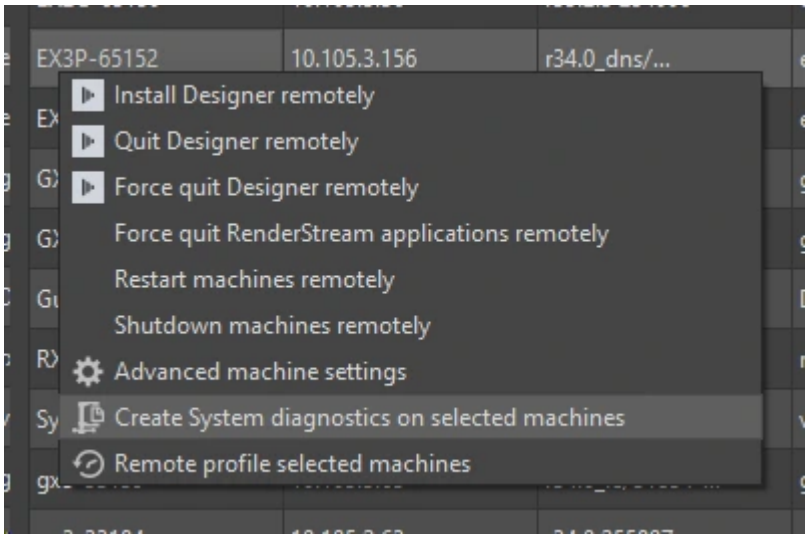
Create project diagnostic



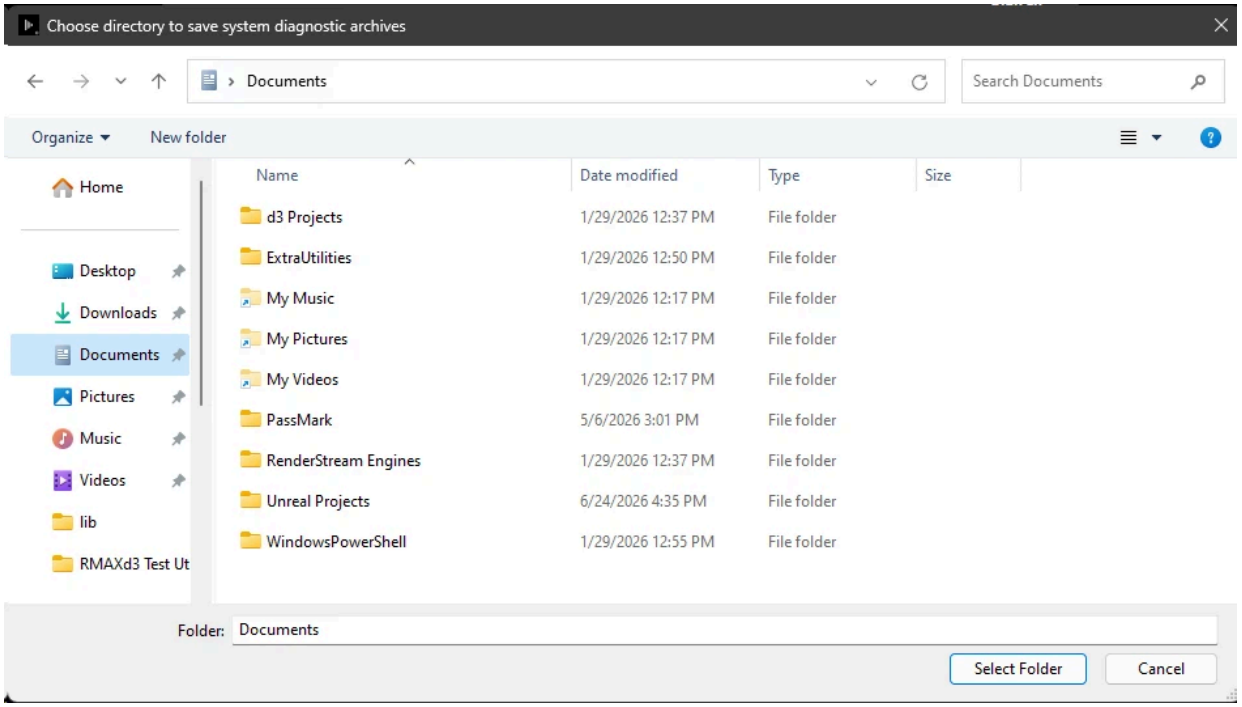
Create system diagnostic

> **Note**
>
> Take note of the filename and location of the generated diagnostic zip.
> This information is displayed in the command window during creation.
>
> System Diagnostics are typically saved in your local AppData directory. You may need to adjust Windows Explorer settings to view hidden folders.

Create a system diagnostic for a remote machine



1. Open d3Manager.
2. Go to the **Network** tab.
3. Select one or more machines you would like to create diagnostics from.
4. Right-click on the selection.
5. Click **Create System Diagnostic on selected machines**.
6. Select a folder on the local machine for the diagnostics to be downloaded to.



The diagnostic zip file will also be placed in the local AppData directory on the remote machine:

```
%localappdata%/d3/SystemDiagnostics
```

Accessing the remote System Diagnostic

The quickest way to get to this is as follows:

1. In the **Network** tab of d3Manager, double-click the machine where you created the remote System Diagnostic.
2. Navigate to the **d3 Logs** section.
3. Open the **System Diagnostic** logs.

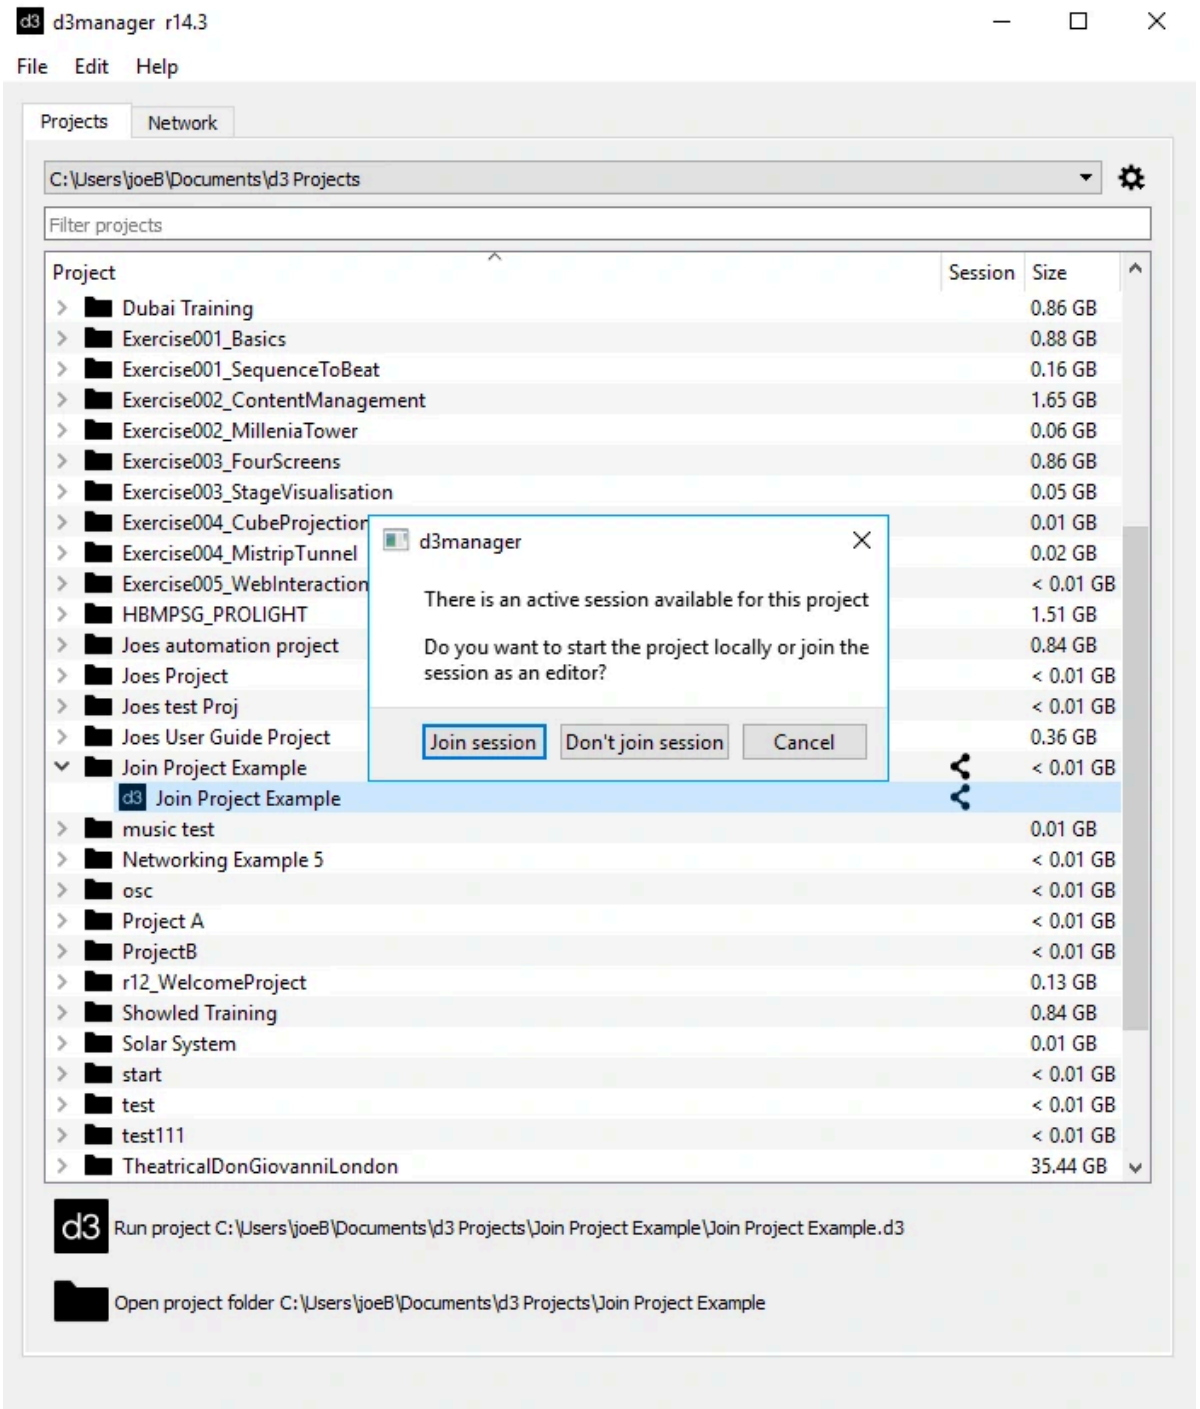
Joining a session from file list

Join session allows users with to access projects over the network for multi-user editing.

To join a session from the file list

1. Ensure that the session icon is visible in the session column. If not you may have a networking issue or you haven't set up your Director/Actor network correctly.
2. Double-click the project in the file list.

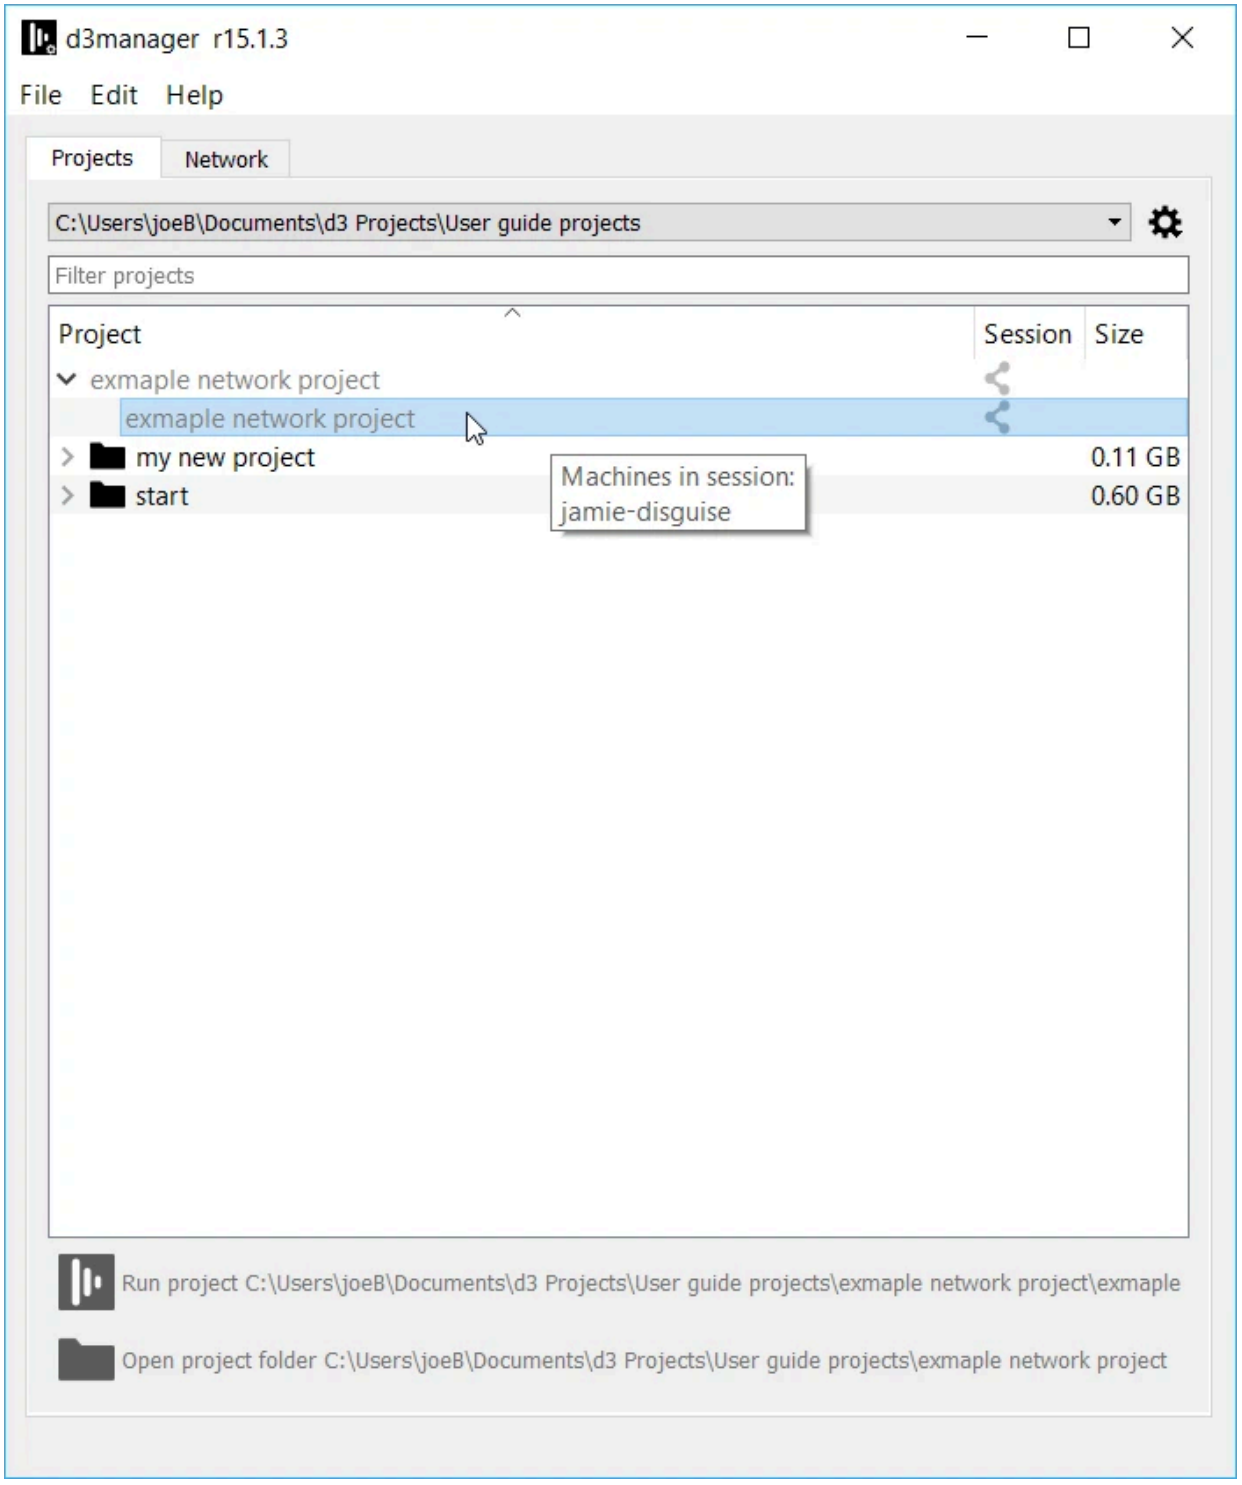
3. Select **Join session** from the popup selection.



Viewing machines in a session

It's possible to view which machines are in a session, without joining it.

Hover your mouse over the **.d3** file in **Manager** to see the machine names currently in that session.



Hovering over the file shows the name of machines in that session.

Manage Networked Machines

Manage Networked Machines

d3manager network view

You can view: The machines name, the version of software it currently has installed, the type of hardware the machine is, and the status.

Install Designer remotely

It is possible to install the current build you have installed on your machine onto another machine on the network through the d3manager. This can be useful for updating software on slave machines from a Director or editor.

d3manager network view

You can view: The machines name, the version of software it currently has installed, the type of hardware the machine is, and the status.

1. Select the machine you wish to install Designer on.
2. Select the **install remotely** button.

d3manager Accessing project folders on networked machines

To access the projects folder on a networked machine via the d3Net manager, follow these steps:

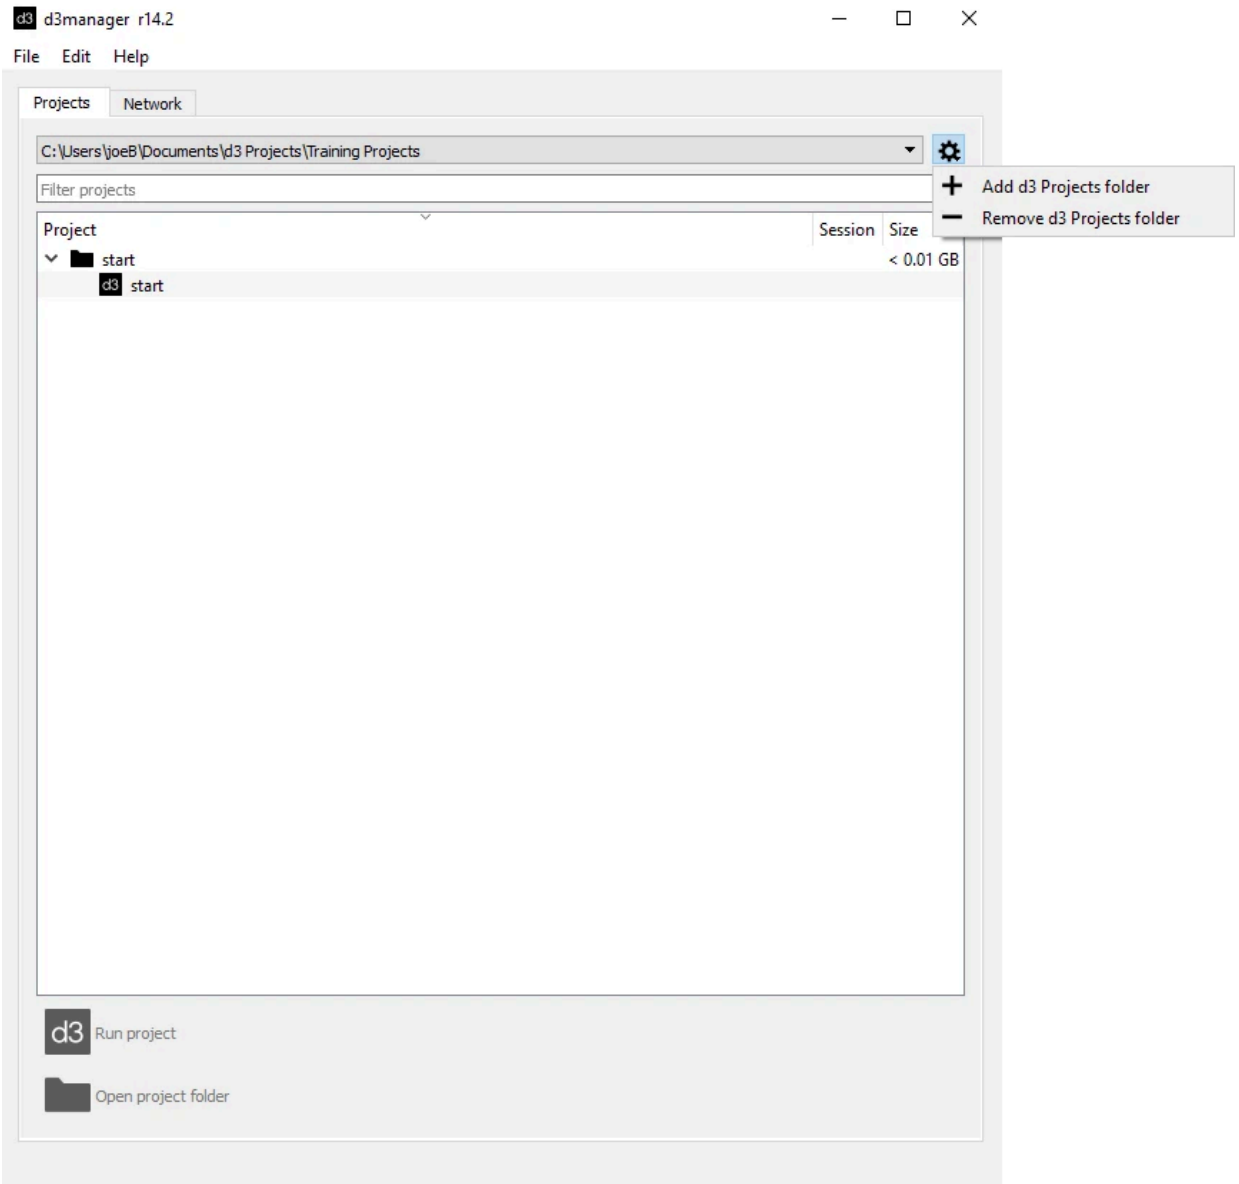
1. Navigate to the network tab in the d3Net manager.
2. Select the desired active machine.
3. Double click on the machine name to open the projects folder.

Managing project folders

Adding and removing project folders allows you to add or remove multiple project folder locations, enabling you to have multiple project locations simultaneously.

Adding a project folder

1. Click the settings icon +
2. Click + Add Disguise Projects folder in the drop down selection and select a new folder.



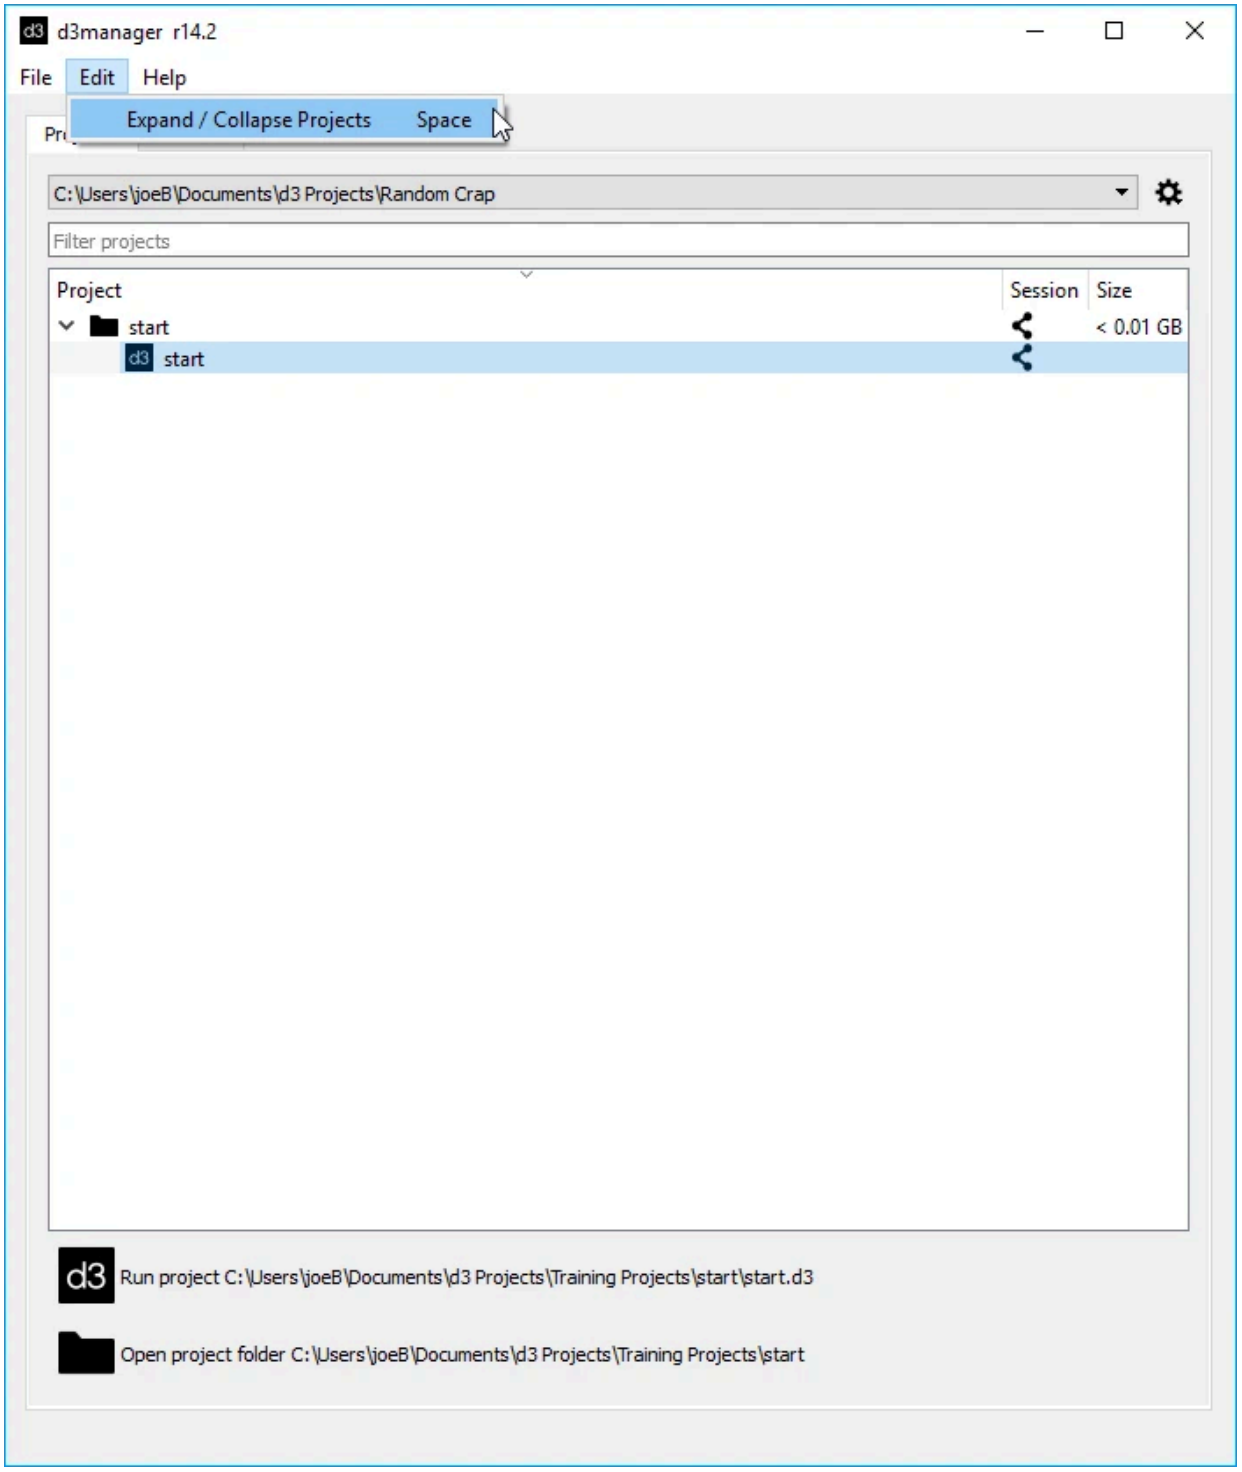
Removing a project folder

1. Click - Remove Disguise Projects folder. Notice that this will not delete the actual content of the folder, it just gets removed from the d3manager.

Expanding and collapsing projects folders

This allows you to expand and collapse your project folder which enables you to see multiple project files within your project.

1. Select **Edit** from the menu bar.
2. Select **Expand / Collapse** from the drop down selection.



Project history files

Every time you run Designer, the .d3 project file (for example, myProject.d3) is automatically copied to a folder called History in your project folder.

Backup files location for a project, used in case the current .d3 project file becomes corrupted or fails to load

The file name of the backup copy is stamped with the date and time. The software manages the files in your history folder so that you always have ten versions created within the last hour, 24 within the last day, 7 within the last week, 4 within the last month, and 12 within the last year. If you should happen to lose or corrupt your project file for any reason, therefore, you can always access the project as it was five minutes ago (or whatever your auto save duration is; see the next section on 'configuring auto save').

Restoring an backed up .d3 project file

To restore a backup version of the project: 1.Copy the .d3 project file from the History folder up into your project folder. 2.Remove the date suffix and double-click it to run it.

> **Note**
>
> Please note: if you do not rename the copied .d3 file without the date suffix the auto-backed up .d3 file will create two date suffixes after each other.

> **Note**
>
> Please note: All timestamps are in UTC and not the current timezone of the machine.

Restoring an object after permanently deleting it

Objects emptied from the trash-can are permanently deleted in the current .d3 project file. To retrieve an object, restore a previous .d3 project file in the History folder. It is even possible to rollback an object to a previous version.

> **Warning**
>
> Automated saves do not make backup copies of media files (audio files, still images, mesh files and video files). You should make regular backup copies of the entire specific Project folder(s) and store them on an external hard drive or network store.

Autosave

By default, the software saves the complete project every 5 minutes, as long as video is not playing (this is because saving takes time, which interrupts video playback). Autosave also generates a snapshot of the current project in the history folder contained within the project folder.

Changing the frequency of autosave

1. Right-click the State tab to open up the Program settings menu. Select **Project Settings**.
2. Edit the **autosave frequency (min)** property to the number of minutes between saves.

Autosave Frequency (Minutes) property of the Program Settings menu is used to edit the number of minutes between saves.

Manual save

To force the software to save all objects, press **Alt+w**. Only objects that have changed will be saved.

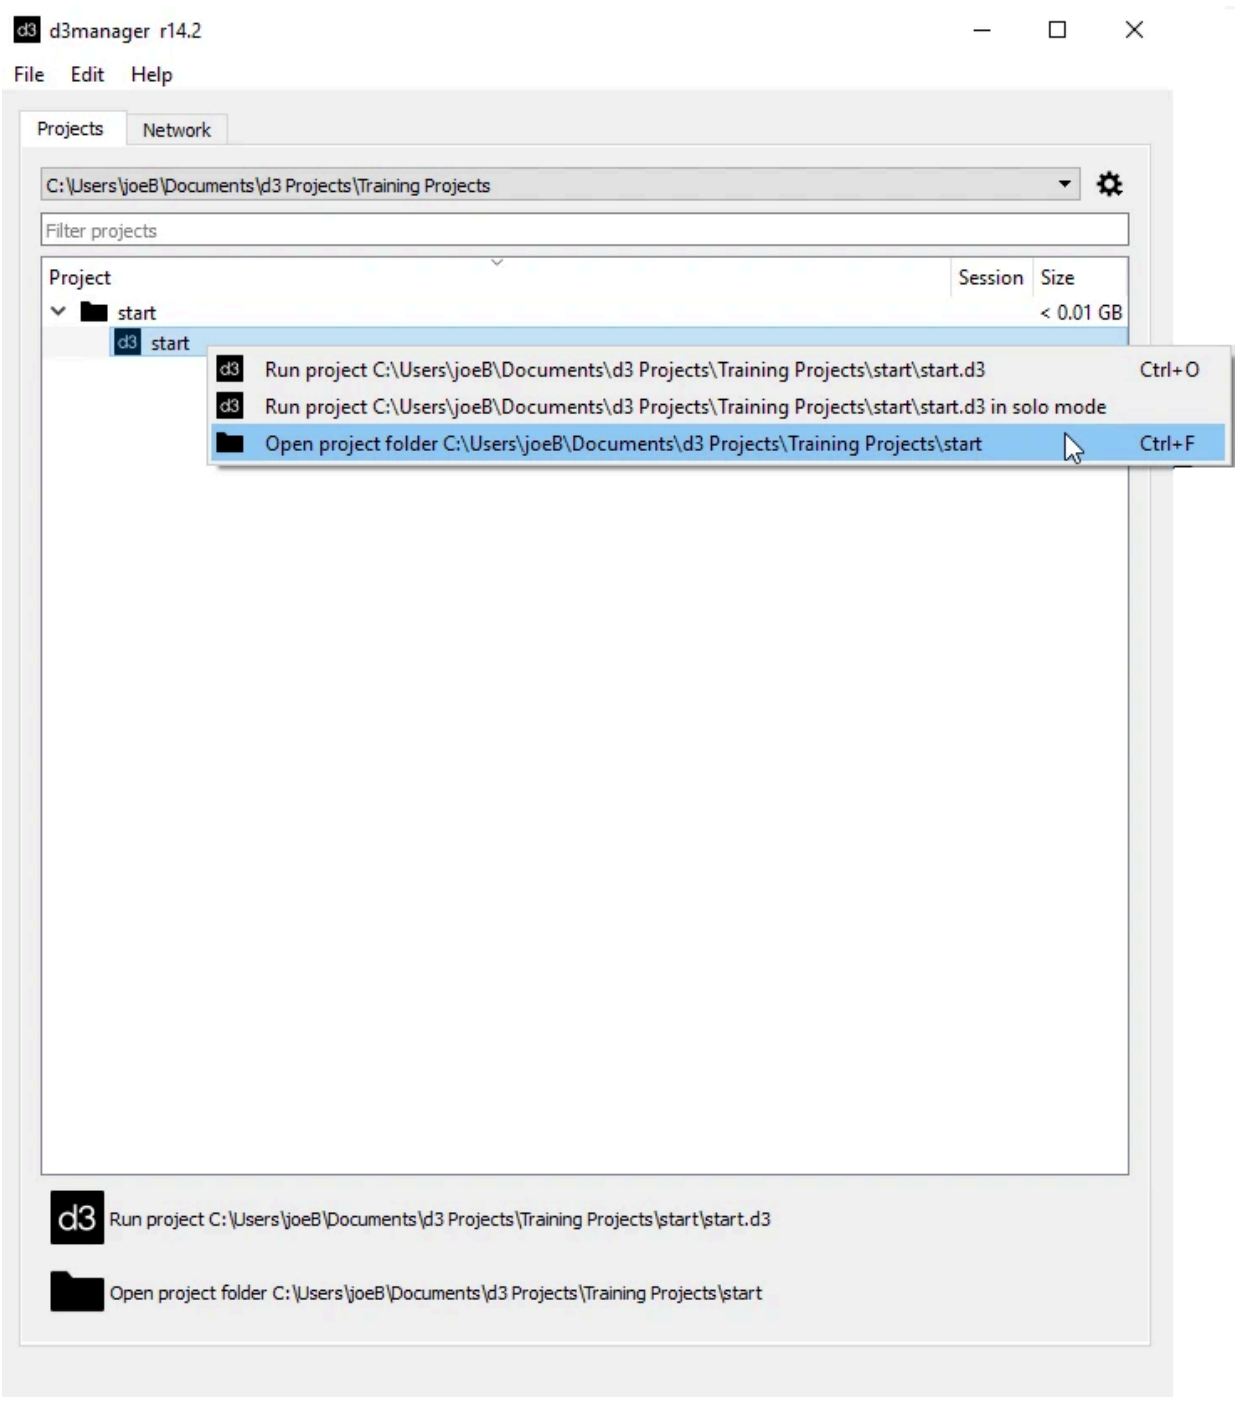
> **Warning**
>
> Warning: automated saves do not make backup copies of media files (audio files, still images, mesh files and video files). You should make regular backup copies of the entire specific Project folder(s) and store them on an external hard drive or network store. For more information on where your specific Project folder is located please see the sub-chapter Projects location/structure.

Opening a project from the file list

This opens the project from the file list allowing access to the media files and other files associated with the project. If nested expand the project folder by clicking on it or pressing the spacebar.

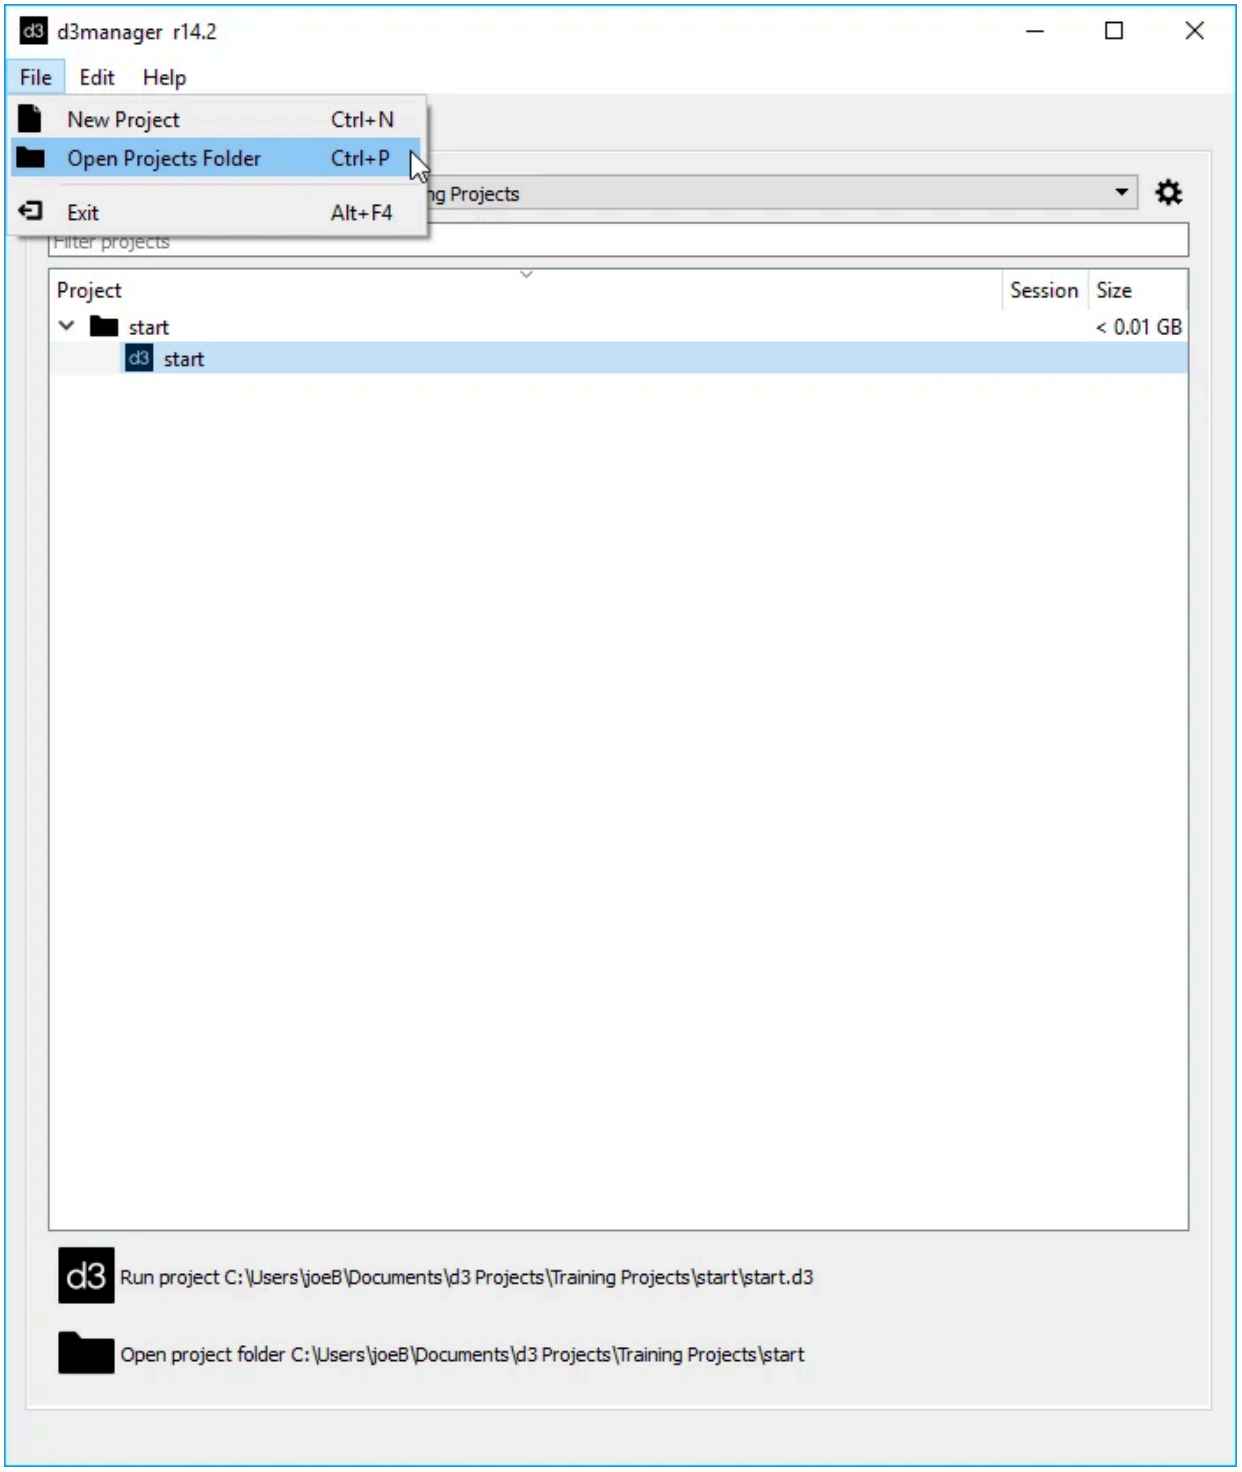
To open the project from the file list

Double-click on the project in the file list.



Or alternatively:

1. Right-click the project in the file list.
2. Select **Open project folder** from the drop down selection.



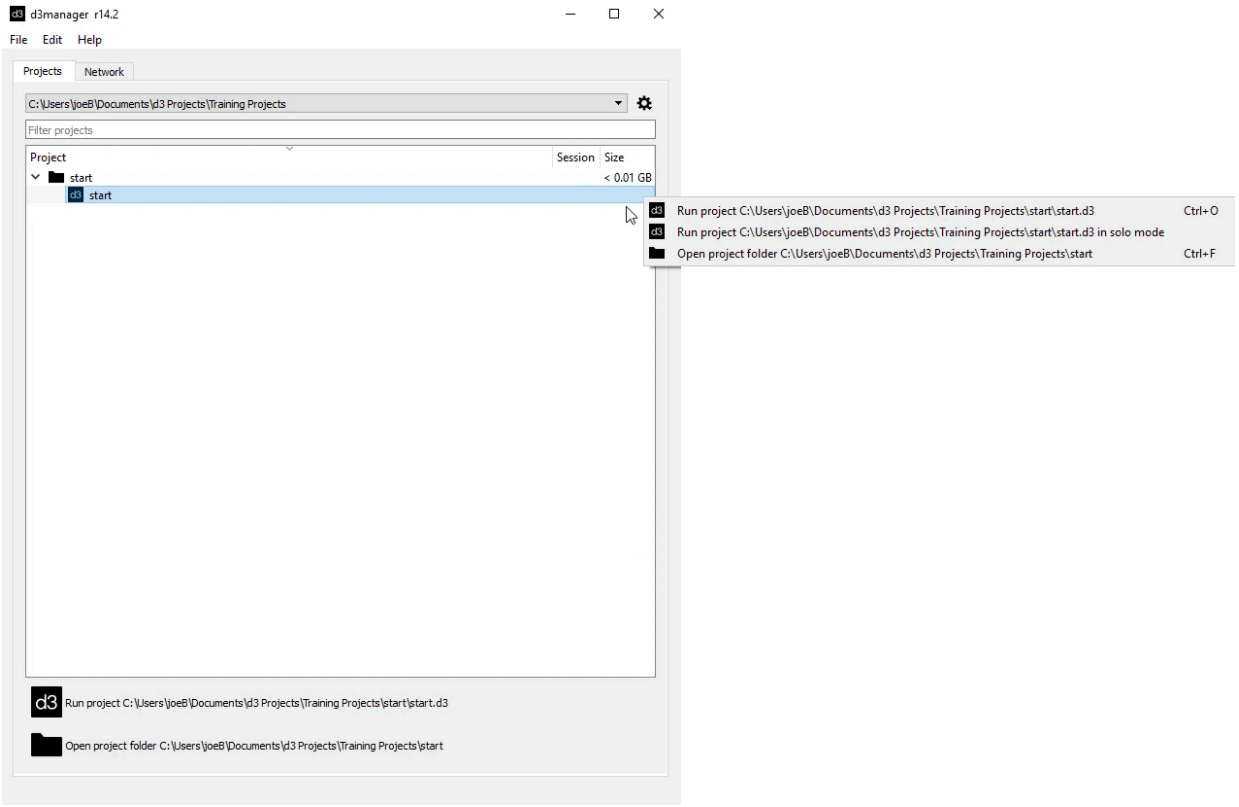
To run the project from the file list

Double-click on the project in the file list.

Or alternatively:

1. Right-click the project in the file list.

2. Select **Run project** from the drop down selection.



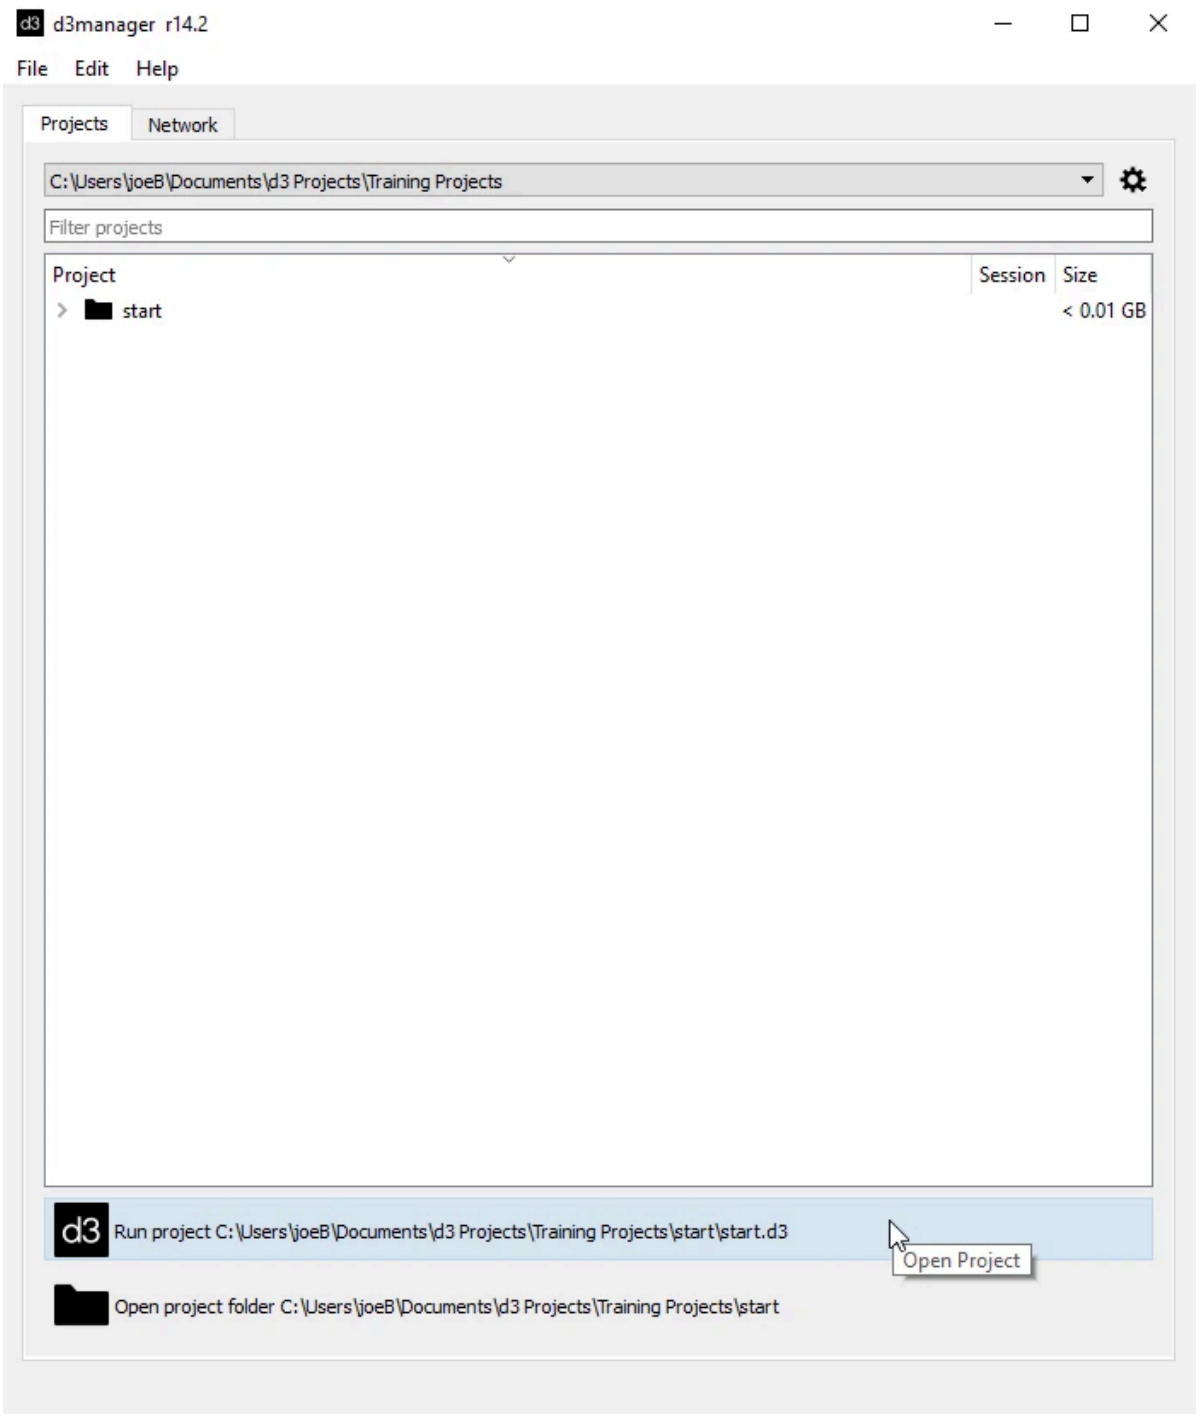
Relaunching the last active project

This allows you to relaunch the last active project that was open.

To open the last active project

1. Open the d3manager.

2. Click the Disguise Icon at the bottom.



Notice that as soon as you select any project in the list the last active project can no longer be opened using the **Disguise Icon**.

Creating a Remote Profile

A remote profile is a JSON file that helps developers understand where the program is spending most of its time. If you experience performance issues, our Support team may ask you for a remote profile to share with our developers. The file is not very useful for non-developers, but it can be opened using Google Chrome's tracing tool if you're curious.

Follow these steps to create a remote profile in d3 manager:

1. Run **d3Manager**.
2. Click the **Network** tab.
3. Select all of the machines you wish to profile.
4. Right-click on one of the machines selected.
5. Click **Remote profile for selected machines**.
6. Select a destination folder.
7. Set the desired Child threshold value (or leave it at the default)

[Animated GIF: Creating a remote profile in d3Manager]

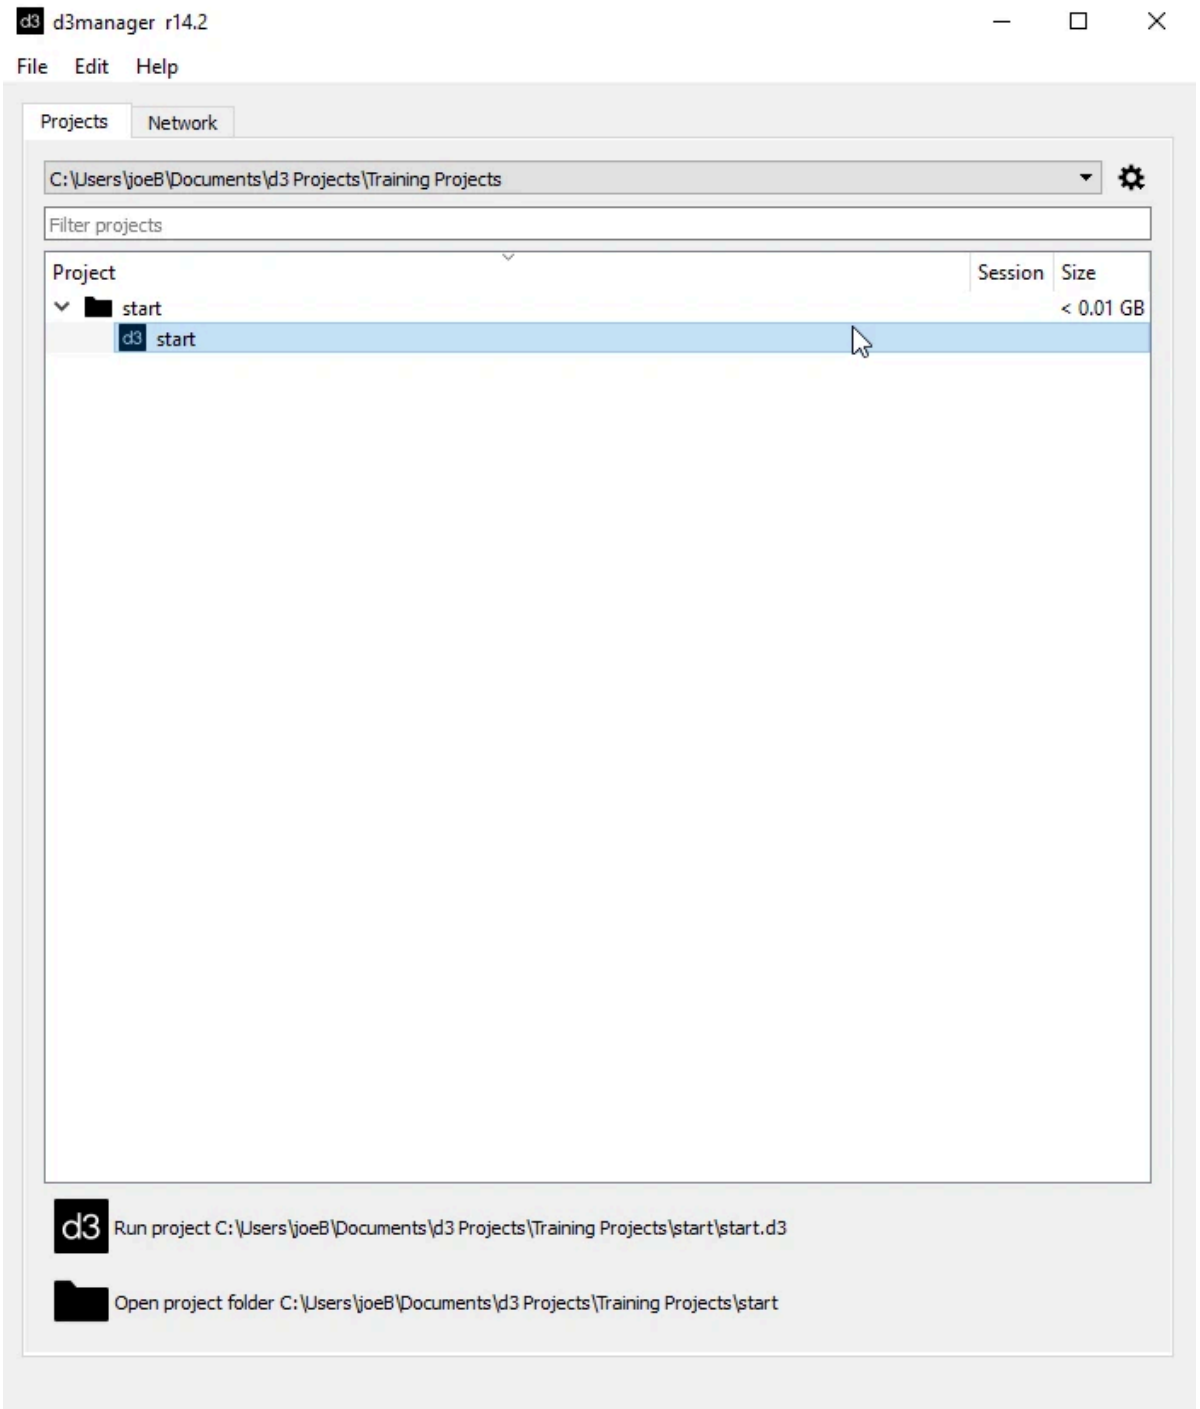
Designer will profile the selected machines for 100 frames, and then create a JSON file for each of these inside of the chosen destination folder.

Starting an existing project

To start an existing project

1. Select the project name in the projects list.
2. Click the arrow next to the project name to view all the project files inside the projects folder.

3. Double-click a project file to launch the project.



Alternatively, select the project and click the Disguise icon at the bottom of d3manager. d3manager will now launch the selected project file.

Upgrading and downgrading Designer projects

Designer projects can be opened in any version of Designer newer than the version it was built in and in some cases can be opened in older versions too. Any time a designer project is opened it will be automatically updated to the version that it is opened in.

Upgrading projects to newer versions of Designer

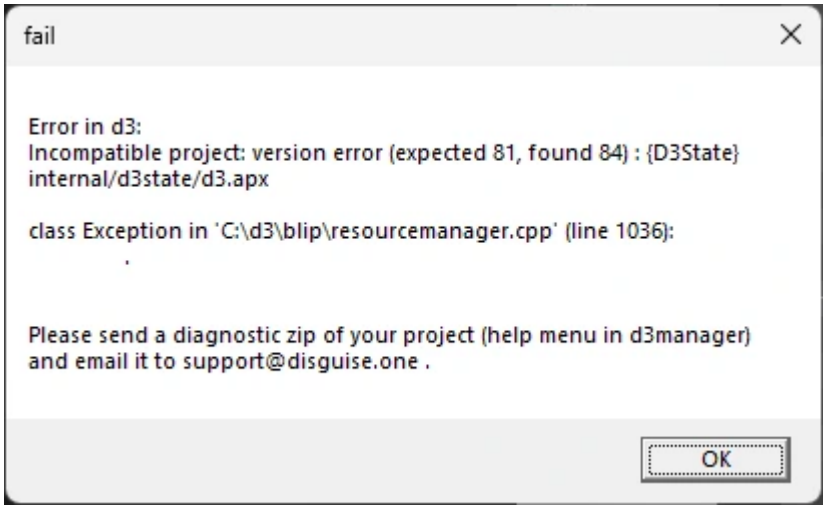
We always support upgrading a project to a newer version of Designer. This can be accomplished by simply opening the project in the newer version. If you encounter any problems when upgrading, please contact support. We always produce a history file before updating to the new version so you can always revert back to that history file.

> **Note**
>
> We recommend always updating directly to the newer version that you intend to use, rather than updating incrementally. Updating the versions incrementally can mean that if there are any update issues with intermediate versions you will be impacted by them.

When working with Disguise media servers you can upgrade to a minor or hotfix version for the same major version without compatibility concerns. When updating to a new major version (e.g. r29.2.2 -> r30) please read the release notes for the new major version carefully. Some major versions require an update the OS on one or all server models. If this is the case, installing the new Designer version will require you to reimage your server to the compatible OS.

Downgrading projects to older versions of Designer

In most cases we do **NOT** support opening a project file in an older version of Designer. If you attempt to do this you will be met with a cryptic message about an “Incompatible project: version error” which looks like this:



Example of a project downgrade error

There is one **EXCEPTION** to this rule which is that we **DO** support downgrading to older version of Designer on the same minor version. For example, you can open a project created in r28.7.3 in any of the following versions:

- r28.7
- r28.7.1
- r28.7.2

But you cannot open that same project in r28.6.5 because it is on a lower minor version.

For more information about Designer versions and their meaning see our page on release versioning conventions

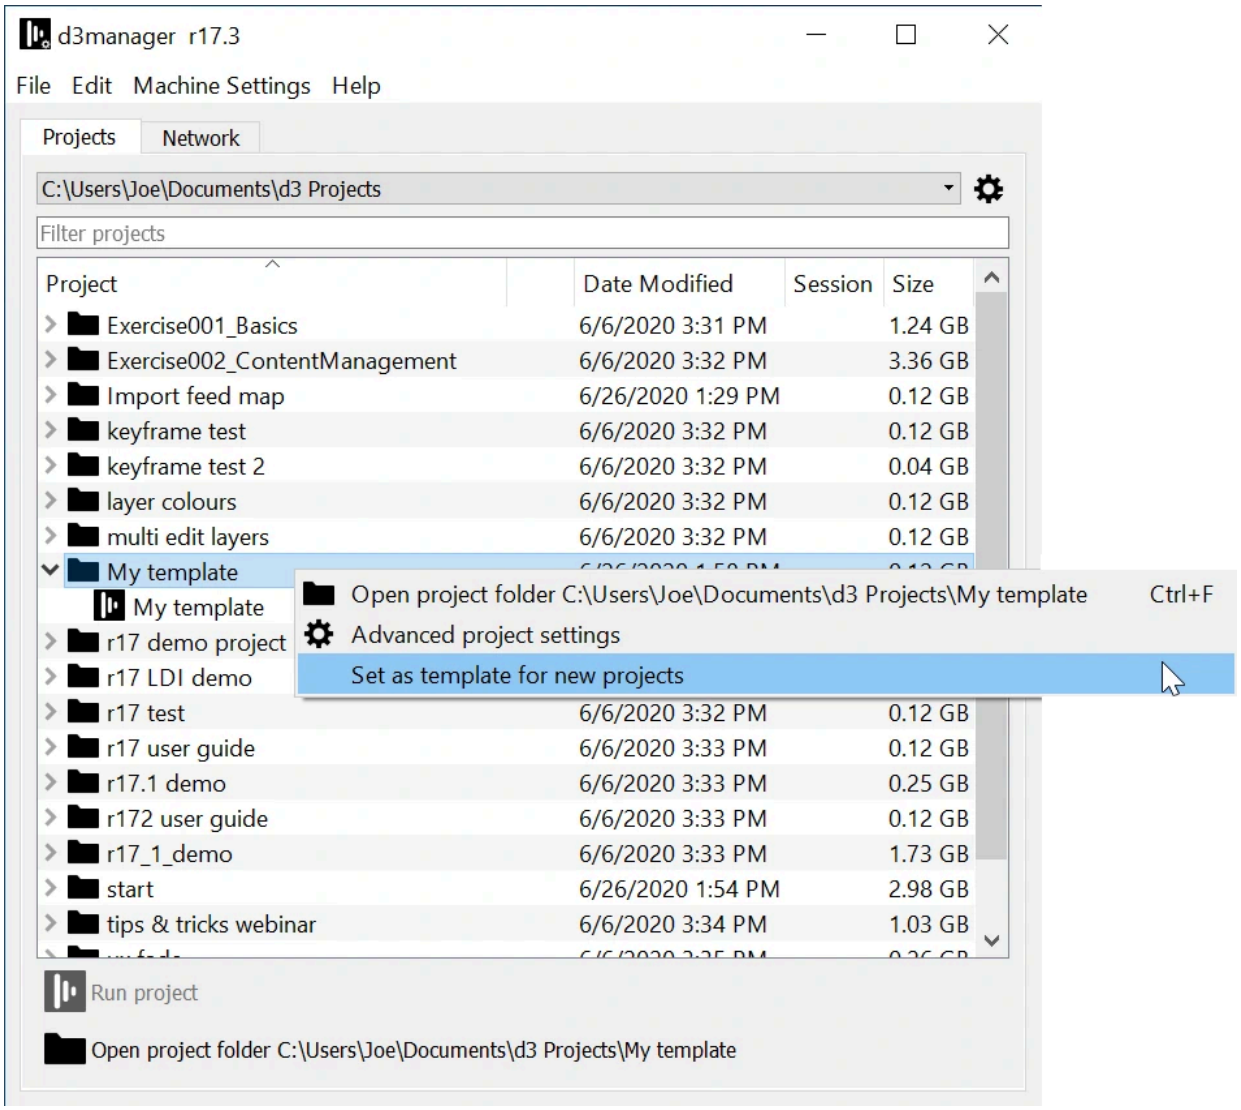
Working with Templates

You can define a template project that all new projects are created from.

A template project can be any project that you have already created in the d3manager. Whenever you define a template project, next time you create a new project, the template project will be copied. Once you have created the new project, the template is not referenced in any way, and changes in either project will need to be updated manually.

Define project template

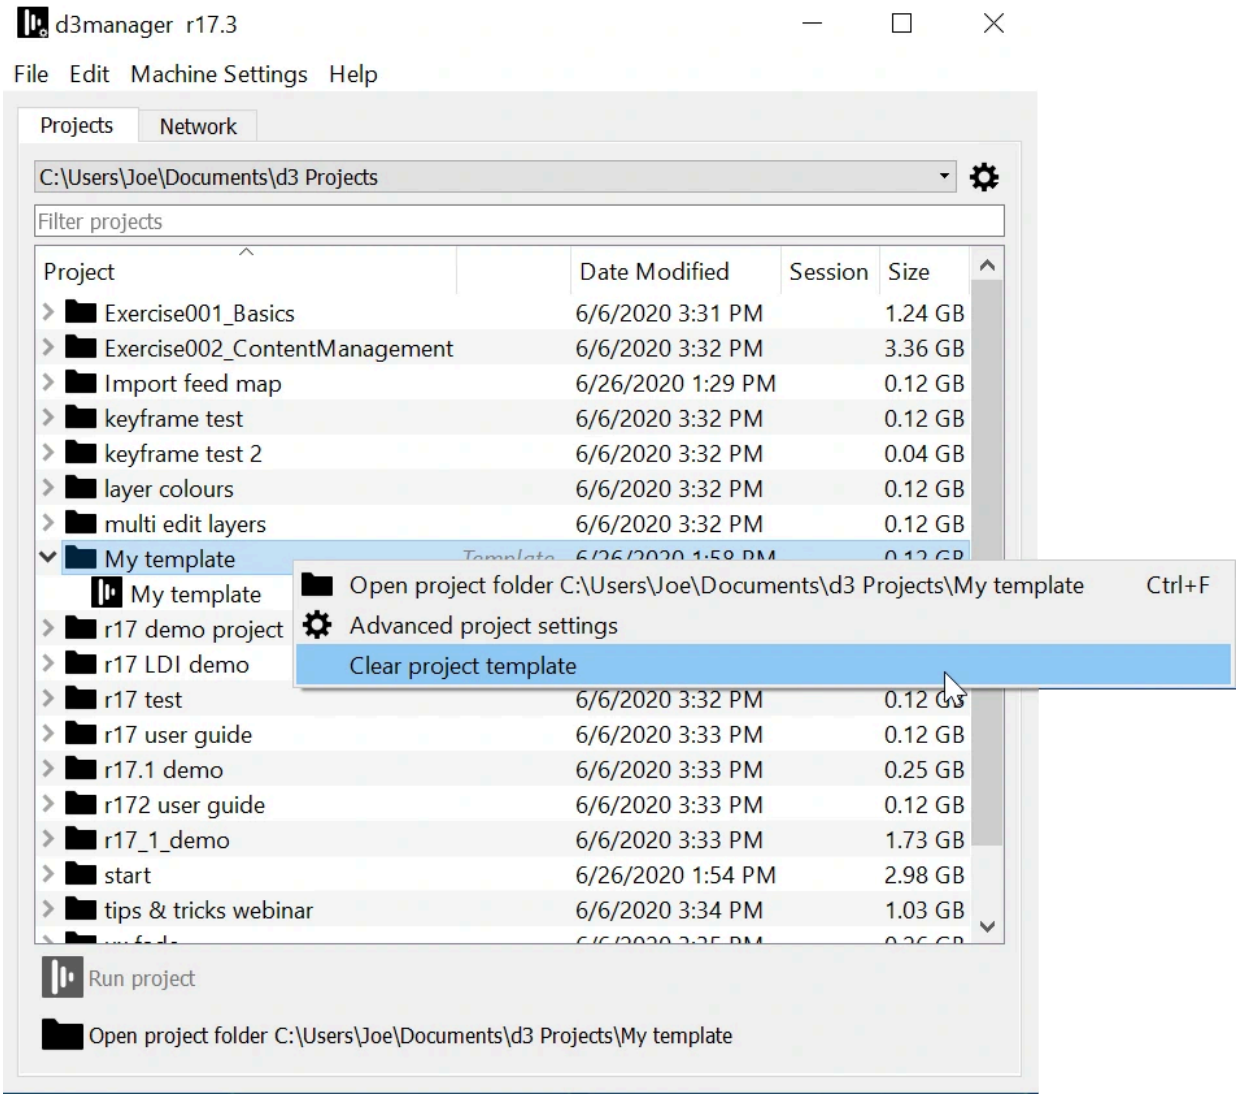
1. Right-click a project folder in d3manager.
2. Choose the **Set as template for new projects** option.



The project will now have a template indicator in Manager.

Remove template

1. Right-click the template project folder in d3manager.
2. Left-click the **Clear project template** option.



Manager will no longer use this project as the template for new projects.

Agile Camera Device

This topic outlines the Agile ARC 360 camera setup using a Disguise media server.

Agile Camera Setup

Ensure you can meet all of the requirements, and follow the workflow steps below to complete the Agile Camera Setup.

Requirements

- Agile Camera that supports IP connectivity and SDI output.
- Optional Agile HW Controller.
- PoE switch (for supplying power to the camera).
- Optional Disguise machine with a capture card (only if you want to use the camera as a live video input).

Currently the Agile Camera doesn't support absolute PTZ (Pan, Tilt and Zoom) commands. Therefore, in order to send the camera absolute PTZ values, it's necessary to create presets.

Workflow

The following steps outline the Agile Camera Setup workflow.

1. Create a UDP device from Device Manager.
   - Set the IP Address
   - Set the Port on the UDP device
2. Create an Agile Camera device from Device Manager.
   - Set the Address.
   - Set the Control Device to the UDP device.
   - Set the Camera Model.
3. Create a CameraControl layer on the timeline.
   - Set the Camera field to the camera that was created earlier.
   - Click the Command field to open up the keyframe editor.
   - Create and keyframe your desired commands for the camera.
4. Map the Camera to the video input.

1. Create a UDP device

1. Right-click **devices** in the dashboard. This will open the Device Manager, which contains a list of active devices.
2. Select **+** to open the Device library. This lists which internal or external devices are available.
3. Type in the name of the new device into the **new device** text field.
4. Hit **Enter**. This will open a list of device types available in .
5. Select the appropriate device type. In the case of Agile camera, a UDP device is needed.

The new device will be added to the Device Manager's active device list, and to the Device library. The device's editor will also open.

Always right-click on the **default** device object to add devices to it. If left-clicking you will be prompted to create a whole new device manager which is rarely required.

2. Create an Agile camera device

1. Right-click **devices** from the dashboard. This will open the Device Manager, which contains a list of active devices.
2. Select **+** to open the Device library. This lists which internal or external devices are available.
3. Type in the name of the new device into the **new device** text field.
4. Hit **Enter**. This will open a list of device types available in .

5. Select the **AgileCamera** device type.

3. Controlling the camera

1. Create a CameraControl layer and add it to the timeline. For more information see Creating layers.
2. Create presets & keyframe accordingly.

For more information, see CameraControl layer.

4. Mapping the camera to a video input

To bring the camera's live video feed through Designer and output it to a physical screen:

1. Patch the capture input to a Video Input Clip (e.g. `videoin_1`) in the Video Input Patch manager.
2. Create a Video layer.
3. Set the layer's **media** property to the Video Input Clip from step 1.

Agile Camera properties

The following properties are available to configure the Agile Camera device.

Address

The device ID used when sending commands to the camera. Range **1–255**. Use **255** to broadcast — also set the IP in the UDP device to `255.255.255.255` so messages are broadcast on the network.

Control Device

Defines which device in the device manager is communicating with the physical camera.

Camera Model

The type of camera using the Agile UBus protocol. Currently only **ARC360** is supported.

New Address

Lets the user change the camera address.

1. Enter a new value in the new address field.
2. Left-click **Set**.

Preset

Specifies which preset is saved or recalled. There are 256 preset slots, 0–255.

Left-click **Recall** to manually recall the selected preset number.

Presets are saved within the camera device, and only support Pan, Tilt, and Zoom.

Presets can also be triggered from the CameraControl layer, using the `CameraRecallPreset` command.

Pan Tilt Jog

Left-click and drag in the jog control to manually position the camera.

Zoom Jog

Left-click and drag in the jog control to manually change the zoom of the camera.

Invert Pan

Flips the value sent to the camera during jog for the pan axis. Boolean (Normal / Inverted).

Invert Tilt

Flips the value sent to the camera during jog for the tilt axis. Boolean (Normal / Inverted).

Invert Zoom

Flips the value sent to the camera during jog for zoom. Boolean (Normal / Inverted).

Supported commands

The following commands are supported for use with the CameraControl layer.

- `CameraAutoFocus` — Enables automatic focus. When on, manual focus via `CameraFocus` is disabled.
- `CameraBlack` — Black level (0–1).
- `CameraBlueGain` — Blue channel gain (0–1). Only takes effect when `CameraExposureMode` is set to Manual.
- `CameraExposureMode` — Exposure mode: **Auto**, **Manual**, **Iris priority**, or **Shutter priority**. Manual gain, black level and white-balance commands only take effect outside Auto mode.
- `CameraFocus` — Manual focus (0–1). Only applies when `CameraAutoFocus` is off.
- `CameraGain` — Camera gain (0–1). Only takes effect when `CameraExposureMode` is set to Manual.
- `CameraGammaMode` — Gamma curve: **Straight** or **Standard**.
- `CameraGoToPreset` — Recalls a preset slot (0–255). Pan, Tilt and Zoom are stored in the camera's preset memory and recalled together.
- `CameraImageMirrorMode` — Image orientation: **Desktop Normal**, **Desktop Mirror**, **Hanging Normal**, **Hanging Mirror**.
- `CameraIris` — Iris aperture (0–1).
- `CameraNightMode` — Toggles night mode on the camera.
- `CameraOnOff` — Toggles the camera power on or off.
- `CameraRedGain` — Red channel gain (0–1). Only takes effect when `CameraExposureMode` is set to Manual.
- `CameraShutter` — Shutter speed (0–1).
- `CameraVideoOutputMode` — Sets the SDI output format: NTSC/PAL analogue, or 1080i / 1080p / 720p at various refresh rates. The camera must be power-cycled using `CameraOnOff` after changing this value.
- `CameraWhiteBalanceMode` — White balance mode: **Auto**, **Indoor**, **Outdoor**, **One Push**, **Auto Tracing**, **Manual**, **One Push Trigger**, plus Auto/Outdoor variants that include sodium lamp sources, and a fixed Sodium Lamp Source mode.

Audio Analyser

The **AudioAnalyser** device captures audio from a connected source and exposes its level and frequency content for use in expressions, letting audio drive parameters in Designer.

Before starting ensure an audio source is connected to the line inputs on the RME breakout. Please see the Hardware sub-chapter Audio breakout for more information. Make sure that there is a good signal level.

Setting up an audio analyser

1. Create an AudioAnalyser device. Please see the earlier sub-chapter Creating devices for step-by-step instructions on how to create a device, and select **AudioAnalyser** from the menu of different device types.
2. Open the AudioAnalyser device editor which contains an empty list to select audio lines. This can be used to add audio lines to analyse.

AudioAnalyser menu contains two audio lines

3. Right-click on an audio line, in this example **line left**, to open the audio line editor. The audio line editor is used to specify how the audio is to be inputted.
4. Open the audio device selection list by left-clicking the **line** property.
   - Audio device selection list is used to specify how the audio is to be inputted
5. Select an appropriate audio device from the audio device selection list. An audio spectrum should now be displayed.

Audio spectrum should now be displayed for the audio device selected

6. To achieve an appropriate level it may be necessary to adjust the gain level. To adjust the gain level, adjust the **gain** field. 1 means no adjustment, < 1 reduces gain and > 1 increases gain.
7. To check the gain level left-click the audio spectrum; this will switch the display to an audio waveform. If the audio waveform has red in it the audio level is too high and is 'peaking.
8. Adjust the gain level until the audio waveform has no red in it.
9. Once the level is clean, left-click the audio waveform and the display will return to an audio spectrum.

Using Audio Analyser in Expressions

Once the Audio Analyser is set up, it is available for use in expressions (for example controlling a field on a Layer), using special syntax to gather damped levels over a number of frequency ranges. The exact method is discussed under Audio expressions

Camera Tracking Device

Camera tracking allows the position and lens characteristics of Camera objects to be driven by the values of a real-world camera, allowing virtual scenes to be rendered from the camera's point of view. This is particularly important for xR and VP workflows.

Disguise Designer has integrations with many different camera tracking and automation systems. See the Devices Index for the full list of available drivers. These can be used to apply tracking data to the positional and/or lens properties of a camera.

Workflows

Add a tracking source to a camera

1. Under **Devices** add a **PositionReceiver**.
2. In the **PositionReceiver** under Drivers, add the relevant tracking driver and set it up to receive tracking data.
3. Engage the position receiver.
4. Create a **Camera** in the **Stage**.
5. Under the Camera's Settings, select the tracking source. This should have been automatically generated by the driver once tracking data started to be received.
6. Data from the Tracking Source should start overwriting the values in the camera.

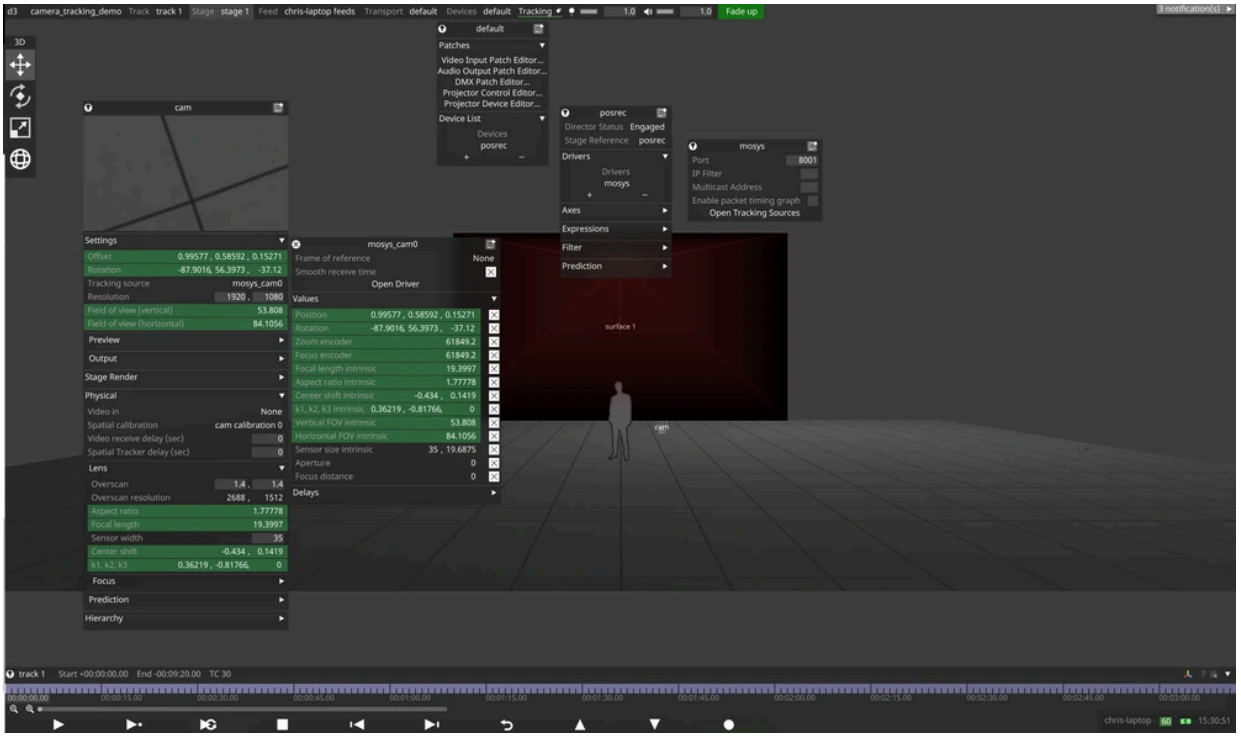
> **Note**
>
> Values received from the tracking system may not align with the Designer coordinate system, unless the tracking system has been calibrated to achieve this. Designer provides a spatial calibration workflow which can be used to align positional and lens tracking data with the positions of LED screens represented in Designer.

Toggle values applied from the tracking source

1. From the **Camera**, open the **Tracking Source** editor.
2. Expand the Values section.
   - Values highlighted in green are being received from the tracking source.
   - Values with a dark grey background are not being received.
   - Values with a light grey background are received but toggled off.
3. Untick the checkbox to stop the value being applied in the camera.
4. Tick the checkbox to apply values again.

Toggle receive time smoothing

To toggle receive time smoothing, check or uncheck the **Smooth receive time** box in the tracking source. Turning this on should result in smoother tracking data, but may add a small amount of latency.

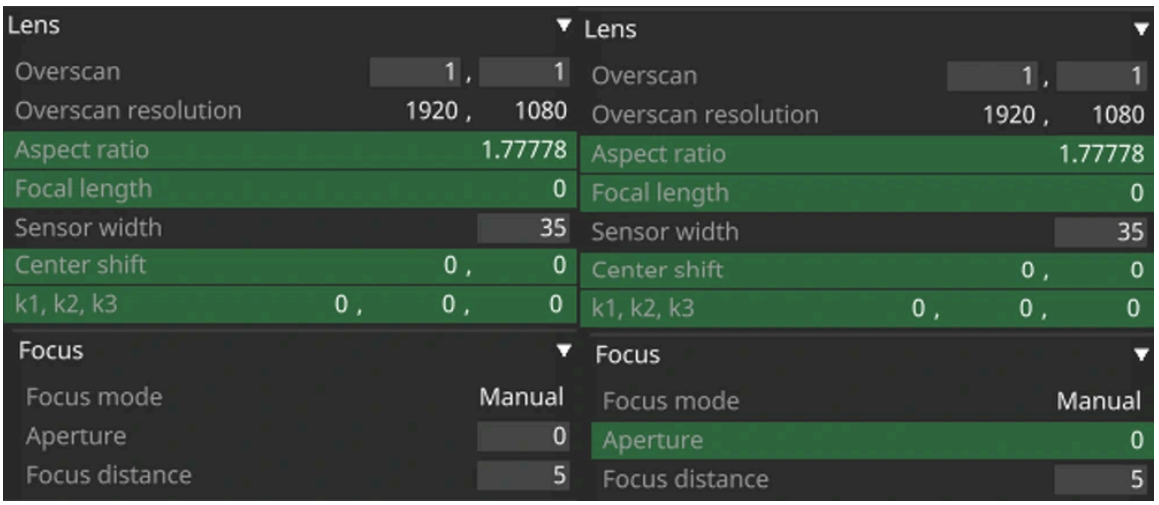


Camera Tracking Widget

Use lens focus parameters in Unreal Engine

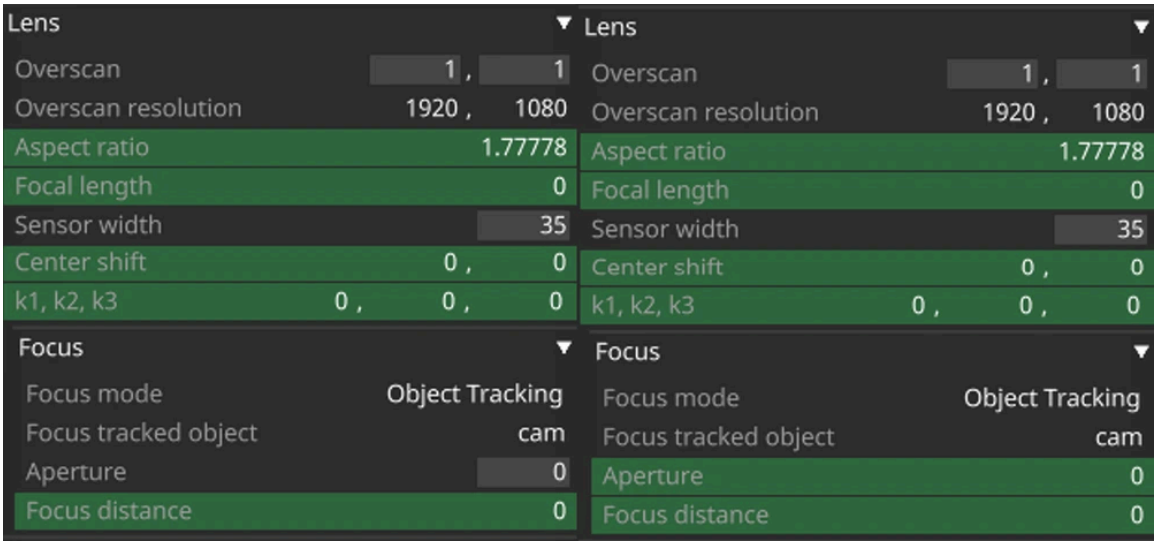
1. Set up a **RenderStream** layer using an Unreal asset that has a channel created from a CineCamera. Map the channel to a Camera or MR set's backplate or frontplate.
2. Start the **RenderStream** workload.

3. Adjust the **Focus mode** under **Camera > Physical > Lens > Focus**. There are three options:
   - **Disabled**: no depth of field.
   - **Manual**: set the focus distance and aperture manually to adjust the depth of field. If the tracking data contains a focus distance or aperture value, the tracked value overrides the manual setting.



Manual focus mode

   - **Object tracking**: select an object in Designer to use as the focus target. The focus distance is calculated from the camera to this object. The aperture can be set manually, but if the tracking data contains an aperture value, the tracked value is used instead.



Object tracking focus mode

4. Adjusting the lens focus parameters on the camera updates the depth of field effect in Unreal Engine.

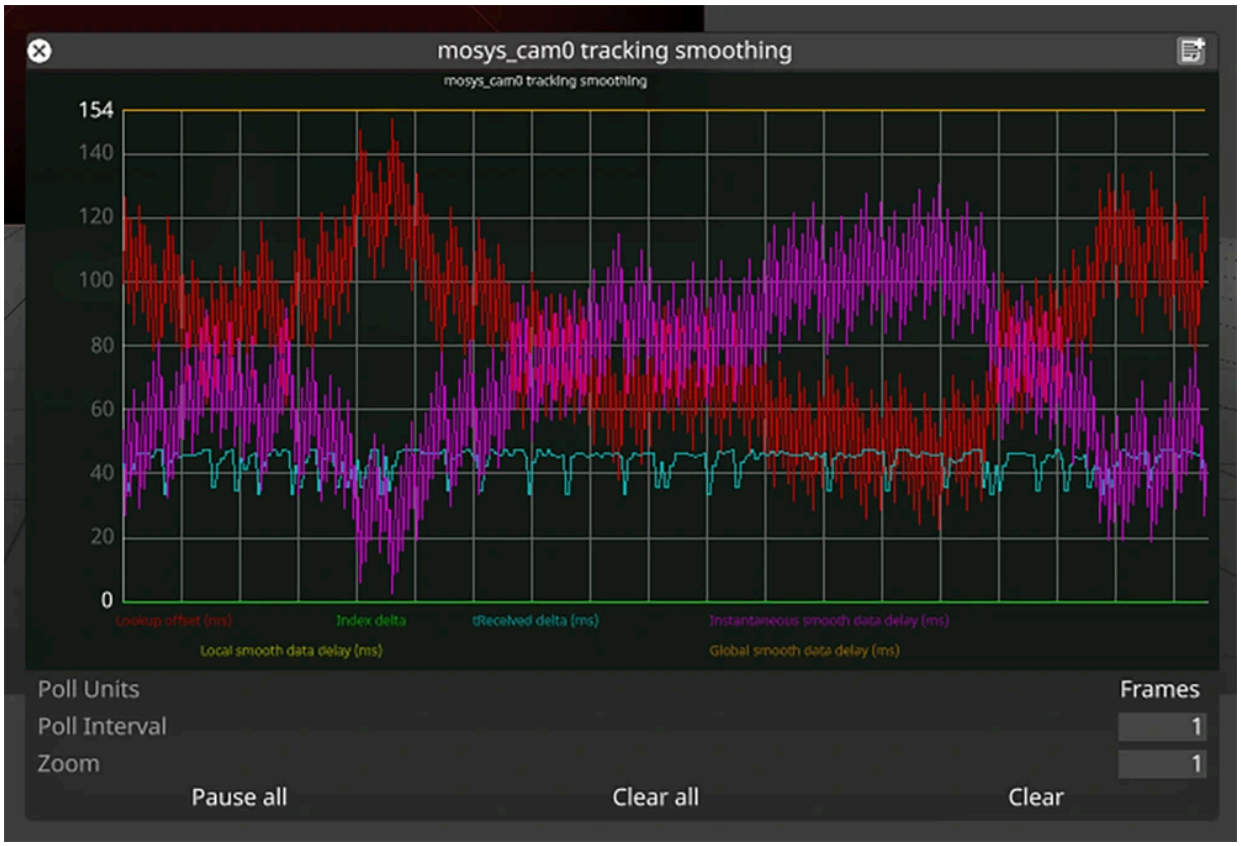
Troubleshooting

FAQs

What should I do if the logs contain 'Attempted to access tracking data beyond end of buffer'?

We dynamically adjust the point at which we look back in the buffer to find smooth data, based on the history of tracking data receive times. You may occasionally see this message if tracking data comes in later than expected. You should find that the message stops after a second or two as the buffer lookup updates dynamically to account for the latest data. If this error appears constantly, then most likely the incoming tracking data is not reliable. Double-check the sender device and network routes to resolve the problem. If the issue persists, please take a Device Recording and send it to Disguise support for further investigation.

How do I read the tracking smoothing graph?



New tracking smoothing graphs have been added to help debug tracking issues. The lines in the graph can be interpreted as follows:

- **Lookup offset**. This is the time in ms between the smooth tracking data we are looking up and the latest data received. This should almost never go below zero, as that would mean we received tracking too late to be able to smooth it. If it is consistently much greater than zero, that means we are adding unnecessary additional latency while waiting to receive smooth data.
- **Index delta** is the change in index of the tracking data we look up in the buffer each frame, e.g. if the tracking frame rate is twice the frame rate this would be around 3. The smoothness of this line shows the success of the receive time smoothing - we are aiming for a consistent index offset between each packet of tracking data we look up.
- **tReceived delta** is the change in the receive time of the tracking data each frame. This shows us how smooth the tracking data would be without receive time smoothing - it can be compared against the index delta line to check that receive time smoothing is working.
- **Instantaneous smooth data delay** tells us how far we would have to look in the buffer to ensure we have received tracking, based on the latest received packet. This is aggregated over time to give a stable lookup time.
- **Local smooth data delay** is a maximum over time of the instantaneous smooth data delay, for this machine. It shouldn't change often.
- **Global smooth data delay** is the maximum smooth data delay over all machines, which is particularly relevant when we are redistributing tracking data across machines. It should provide a consistent period to look back in the buffer to ensure we have smooth tracking data.

CITP Device

CITP (Controller Interface Transport Protocol) is an open network protocol used by lighting consoles, media servers, and visualisers to exchange information, such as the transfer of thumbnails and asset-specific naming for media previewing during programming. Designer supports the integration of CITP-enabled lighting consoles for media preview and thumbnail distribution.

Using CITP

- grandMA2 3.1.2.5 supported. Version after 3.2.2.3 should also work.
- Hog OS 3.5.0 supported.
- CITP devices join with both multicast addresses, 224.0.0.180 and 239.224.0.180, and in that order.
- Only thumbnail exchange is supported.

In Designer

1. Right-click on **Devices**.
2. Create a new DMX Device.
3. Insert the desk's IP Address (this should ideally be set up on an isolated Art-Net switch).
4. Create a CITP Device and assign the DMX Device to it.
5. Add a Video layer, assign a DMX patch to it.
6. Open the Bank Editor and populate the Video banks.

In grandMA2

1. Go to **Setup > CITP Network Configuration**.
2. In the top-right corner of the windows that opens, ensure you set CITP to **Enabled** (the box should look green once you click it).
3. Right-click on **New** under the MediaServers tab.
4. The Disguise machine should appear in the list here. Click to select it.
5. Select a fixture layer (one with a Video layer fixture patched to it).
6. Select a Library SubAttribute (any sub-attribute seems to work as Disguise doesn't use this.)
7. Select an Image SubAttribute (this needs to be set to Video Slot).
8. Click on **Update Thumbnails**.
9. Select the Video layer fixture and navigate to the Video Slot attribute.
10. Clicking on the attribute should now display clickable thumbnails and file names on the lighting desk software.

> **Note**
>
> If the machine does not appear in the MediaServers list, double-check connection settings (use the DMX Monitor to ensure DMX is being received) and ensure the CITP Device is in the Device List.

Creating Devices

1. Right-click devices from the dashboard. This will open the Device Manager, which contains a list of active devices.
2. Select + to open the Device library. This lists which internal or external devices are available.
3. Type in the name of the new device into the new device text field.
4. Hit Enter. This will open a list of device types available in Designer.
5. Select the appropriate device type.

The new device will be added to the Device Manager's active device list, and to the Device library. The device's editor will also open.

[Animated GIF: Creating a device]

> **Note**
>
> Always right-click on the **default** device object to add devices to it. If left-clicking you will be prompted to create a whole new device manager which is rarely required.

Device Monitor

The device monitor lists every source that the local machine is currently receiving data from — for example, every MIDI port, OSC sender, DMX universe or tracking system feeding that recorder. It allows the user to easily inspect the incoming data and is available whenever the data is present, regardless of whether the recorder is in Live, Play or Record mode.

Each row in the monitor shows:

- **Name** — the name of the source.
- **Monitor** — a live preview of the most recent value received.
- **Receiving** — whether the source is currently sending data.
- **Last Received** — the timestamp of the most recently received command.

Opening the monitor

To open a device monitor:

1. Right-click the data monitor heading for the relevant data type (for example, **MIDI** or **OSC**) in the d3state bar at the top of the Designer window. A list of the devices associated with that data type appears.
2. Select the device whose data you want to inspect.
3. Click **Monitor**.

Filtering, sorting and clearing

Over a long session the monitor can build up many sources, including ones that have stopped sending. The following controls make it easier to find a specific source:

- **Filter** — type into the Filter box at the top of the monitor to show only rows whose Name contains the entered text. The match is case-insensitive and the list updates as you type.
- **Clear** — removes any sources that are no longer receiving data, leaving only those currently active. Sources that resume sending will reappear automatically.
- **Sort** — click a column header to sort by that column. Click the same header again to reverse the direction. The **Last Received** column sorts newest-first by default, which is the quickest way to find the most recently active source. The **Monitor** column is not sortable. The active sort column is highlighted while the other column headers appear dimmed.

The current filter text, sort column and sort direction are retained for that monitor window across sessions.

Device Recording

Device Recording is a tool to record the incoming data streams of different Devices (DMX, Automation and MIDI) for later playback without needing the device attached.

Once a device recording is deleted, it **cannot** be retrieved. This is because Designer treats recording files as content.

This is useful for recording specific automation control data so a programmer can play it back into the system without the operator needing to be on hand.

> **Note**
>
> Device recordings only exist on the bottom-most transport in multi-transports.

Using device recording

There are three modes for Device Recording; Live, Play and Record.

- **Live**: Only the incoming 'Live' data will be actively allowed into Designer.
- **Play**: Only the recorded data will be actively played back into Designer.
- **Record**: That device is primed to record the incoming data into Designer.

To set it up:

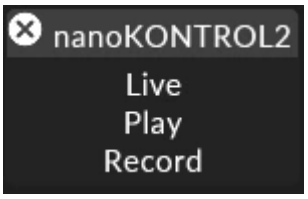
1. Add either a MIDI, DMX, or Automation Device to your device list and set it up appropriately.
2. Observe the change to the GUI:

These headings are created in the d3state bar to show that there are devices that are able to be recorded. There is a little symbol next to each indicating the mode the device is currently sitting in. As shown in the image above, these are currently set to live and will react to the incoming data. A small triangle *play* symbol indicates the device is set to playback the recordings available, and a small circle indicates it is primed for recording.

3. If you right-click on the heading of the device you would like to set up for recording, a new window appears.

Here you see the list of MIDI devices that are ready for recording. The devices are listed to the left, with the current mode on the right.

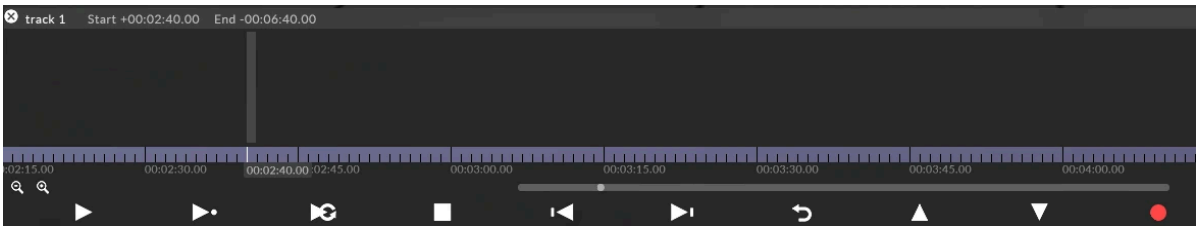
4. A right-click on the mode for each device will bring up another window where you can change the mode of the device.



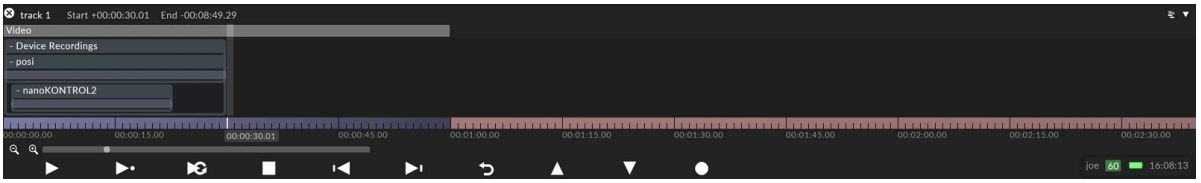
Whereas, the buttons along the bottom of the window are the global mode controls for the device type (changes all modes for the recorder).

5. If we take the nanoKONTROL2 for example, it is currently set to **Live** and we want to record this device's input. To do this, right-click on the mode for the device and set it to record. This will tell Designer we want to record this device's input.

6. If you look to the transport controls on the timeline, you will notice an addition to the UI. A Small circle has been added next to the track change controls, this is the record button for Device Recording. With the device set up as above, this can be selected to prime the recording fully. If no device has been set to record, a pop up will appear alerting that this cannot be used as no devices are ready for recording. When it is primed successfully, it will turn red to show the change.



7. Now the track is ready to record the input so simply hitting play will start the recording and you will notice a new layer being created as the input stream is being received. This will grow as the recording grows with it. When you have captured all the data you want to record, hitting stop will cease the recording. All device recordings are saved under this tab and individual tabs are created for each device that has made a recording. The recordings that have been made cannot output yet as they need to be set to 'Play' in the mode of the recorder.



8. Each recording that is made has 3 settings when right-clicked on;
   - **Disable** — stops outputting the recording.
   - **Reset** — puts the recording back to where it originated if it has been moved or edited.
   - **Delete** — removes the recording.

Delete removes the recording entirely — this **cannot** be undone.

Recordings are saved as `.rec` files and stored in the object folder under `recordingfiles`. These are treated like any other asset, but they are highly reliant on project-specific settings such as sections, cues, notes, and so on — so they may not work in other projects. As with any asset, they will need copying over to other machines in the same network environment (for example, an Actor) for them to function correctly.

Devices Index

Designer supports a number of devices. The Devices section includes documentation about how to create, use and record devices. It also covers information about all of the devices we support, including motion control systems, automation devices, matrices, routers, and video inputs.

Using Devices

The following pages describe how to create and record devices.

- Creating Devices
- Device Recording

Using Motion Control Systems

The following pages describe how to use Motion Control System with Designer.

- Motion Control Systems
- Position Drivers
- Creating a New Motion Controller
- Axes
- Creating Driver Axes
- Tracking Source
- Position Axis Expressions

Devices

To find the list of devices available in Designer, right-click **Devices** in the dashboard. This opens the **Device Manager**, where the full menu of active devices is listed.

Device menu listing the devices, including Matrices available in r32.1.2

- Agile Camera : A virtual camera device enabling programmable and keyframed camera moves within Designer.
- Audio Analyser : Analyses an audio source so its level and frequency content can drive parameters in Designer.
- CITP Device : Supports the integration of CITP-enabled lighting consoles for media preview and thumbnail distribution.
- DMX Device : Sends and receives DMX channels for lighting, automation, or external control. Supports protocols Art-Net, Enttec, ezDMX, KiNET v1, KiNET v2, sACN, and SoundLight.
- DMX Machine Control : Sends remote and shutdown commands to Designer to remotely shutdown Disguise machines.
- DMX Projector Control : Provides DMX-based control for external projectors.

- Expression Variables : Defines variables that can be used in Designer to build dynamic, custom behaviours.
- JSON Machine Control : Allows for the querying of machine list and machine status via JSON.
- MIDI Device : Allows triggering, automation, and control through standard MIDI messages.
- OSC Device : Sends and receives OSC messages for flexible, network-based control.
- OSC Machine Control : Allows restart and shutdown commands to be sent from an external OSC device.
- OSC Tester : Allows users to test incoming and outgoing OSC messages from Designer.
- Position Receiver : Receives real-time positional data for tracking objects or performers.
- Projector Calibrator : Automatically aligns projectors to physical surfaces using tracked reference points.
- Shot Recorder : Allows users to record and export parameters from within Designer, ready for use in post-production workflows.
- String Projector Control : Used to control external devices while optionally simulating their behaviour inside the visualiser.
- Telnet Device : Used to send commands over a TCP network connection to 3rd party products.
- UDP Device : Used to send commands over a network via UDP to 3rd party products.
- Visca Camera : Controls VISCA-compatible PTZ cameras over network connection.

Matrix Switches

Designer supports the following Matrix Switches:

- Analog Way OPS300 : Supports routing control for the Analog Way OPS300 switcher.
- Barco Encore (External Link)
- Barco MatrixPro : Enables routing operations for Barco MatrixPro systems.
- Gefen Matrix (External Link)
- Lightware Matrix : Integrates with Lightware matrices for video routing and monitoring.
- PureLink Matrix : Provides control for PureLink AV matrix devices.
- Telnet Matrix : Generic matrix control using Telnet-based command sets.

Routers

Designer supports the following routers:

- Blackmagic Smart Videohub : Controls Videohub routing and crosspoint configurations.
- Riedel MediorNet : Communicates with MediorNet systems for routing and management.

Tracking

A number of tracking and automation drivers are supported in Disguise. They appear in the driver picker when you add a driver to a Position Receiver device.

The driver picker shown when adding a driver to a Position Receiver. Picker contents may change with Designer releases.

Here, drivers are grouped by function — see the **Position Drivers** and **Generic Receivers** sections in the sidebar. The full list, organised by what each driver does, is below. Note: DMX-family protocols (Art-Net, sACN, KiNET, etc.) are output options on the DMX Device rather than standalone drivers — they appear under **DMX Device** in the sidebar.

Position Drivers

Position Drivers decode positional data from a motion control system and emit it onto PositionAxis objects inside a Position Receiver device. Grouped below by what they sense.

Tracking System Drivers

Camera, object, and people tracking systems.

- Camera Tracker Observations Tester : Used for validating and troubleshooting observation data received from external camera-tracking systems.
- Camera Tracker Tester : A type of PositionDriver that can be used to simulate camera tracking data.
- EzDriver : Receives tracking data over the network via the EZ protocol.
- FreeD Driver : Receives FreeD camera-tracking protocol data.
- LDS Driver : Receives lens aperture and focus distance from ARRI cameras via the LDS protocol.
- Mo-Sys F4 Driver : Connects to Mo-Sys F4 tracking hardware.
- MoveAI Driver : Real-time markerless motion-capture data from MoveAI systems.
- NatNet Driver : Receives tracking data using the NatNet protocol.
- Ncam Driver : Supports Ncam camera tracking for virtual production.
- NG360 Driver : Receives positional data from NG360 tracking systems.
- RTTrPM Driver : Connects to RTTrPM real-time BlackTrax tracking systems.
- Skeleton Tracker Tester : Simulated skeleton tracking.
- Stype Driver : Integrates Stype camera-tracking data.
- Trackmen Driver : Trackmen camera tracking.
- Vicon Datastream Driver : Vicon tracking data stream.

Stage Automation Drivers

Stage motion, rigging, and screen-positioning systems.

- CPS Driver : Interfaces with CPS automation systems (motor positions).
- D3SSI Driver : Receives single-axis encoder position data over the D3SSI protocol via UDP.
- DCS Driver : Interfaces with DCS stage automation/control systems.
- DMX Screen Position Driver : Tracks screen or object position via DMX.
- HMC Driver : Integrates with Hudson Motion Control systems over UDP.
- Kinesys Driver : Controls Kinesys motion systems for lifts, winches, and rigs.
- LCPUSB Driver : USB-based industrial PC controller for automation.
- Movecat Driver : Interfaces with Movecat kinetic systems.
- Navigator Driver : Integrates with Navigator automation controllers.
- PosiStageNet Driver : Tracks performer or object motion via PSN.
- Posital Driver : Posital encoder/sensor positional input.

- PRG Driver : Integrates with PRG motion systems.
- PRG Stage Command Driver : Supports Stage Command for PRG automation.
- SIMOTION Driver : Interfaces with Siemens SIMOTION controllers.
- SKV Driver : SKV control system driver (varies by setup).
- Stage Kinetics MoveCat Driver : Controls Movecat motion via Stage Kinetics protocol.
- STS Driver : Connects to STS automation hardware.
- Unican Open Cue Driver : Receives position data from Unican Open Cue (OpenPosIP) automation systems over UDP port 16000.
- VisualAct Driver : Communicates with VisualAct winches and lifts.

Generic I/O Drivers

Generic protocol carriers that operate as Position Drivers.

- OSC Driver : Enables automation control using OSC routing.

Generic Receivers

Generic I/O and data receiver drivers — protocol carriers for custom integration or testing.

- gRPC Receiver Driver : Receives structured gRPC data.
- Test Receiver Driver : Internal test data receiver.
- UDP Receiver Driver : Generic UDP packet input.

Video Input

Video Inputs supported by Disguise include:

- 4K Quad Link Capture : Allows ingest of 4K video over quad-link SDI.
- ST 2110 Video Capture : Receives uncompressed IP video signals using ST 2110.
- Setup Video Input : Walkthrough for configuring and routing video inputs.
- Video De-Interlacing Methods : Explains how Designer de-interlaces video.

DMX Device

This topic explains how to configure Disguise to prove DMX input and output, using an Art-Net device as an example.

> ⚠ **Warning**
>
> It is possible to map a DmxDevice to conflicting address ranges. This will result in unpredictable behaviour.

Designer also uses a number of other converter device types: sACN, Enttec, SoundLight, EzDMX, KiNET v1 and KiNET v2.

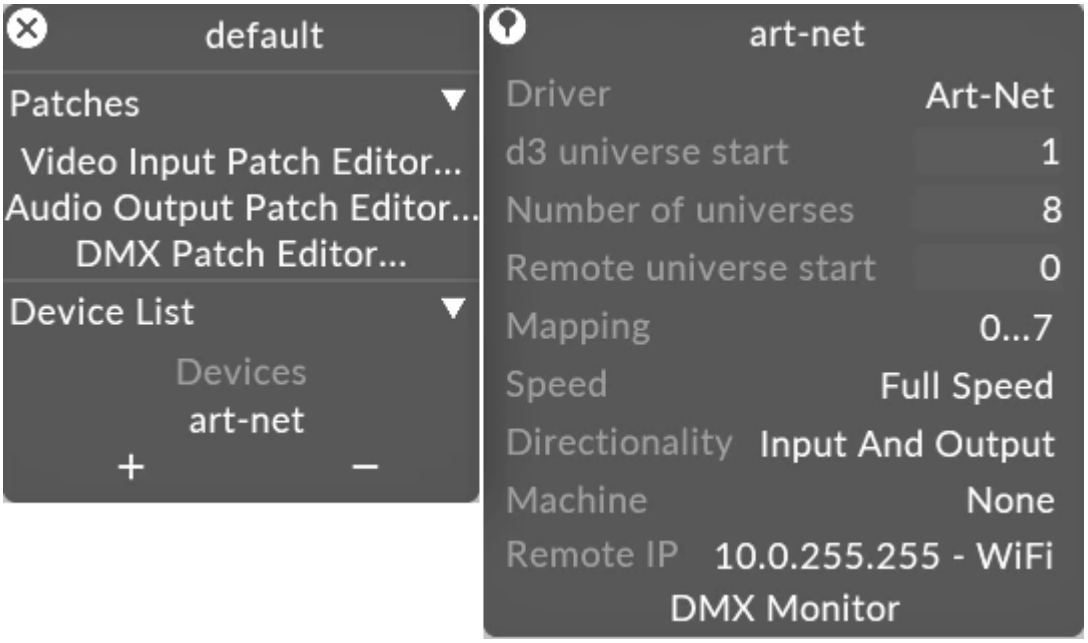
To setup the Art-Net connection you first need to create a DmxDevice. A DmxDevice represents a physical output device that connects to the computer (via USB or ethernet) and outputs and/or receives DMX to/from physical devices. Designer supports a number of such DMX converters and protocols. You will need to create a separate DmxDevice for each physical converter device.

Create a DMX Device

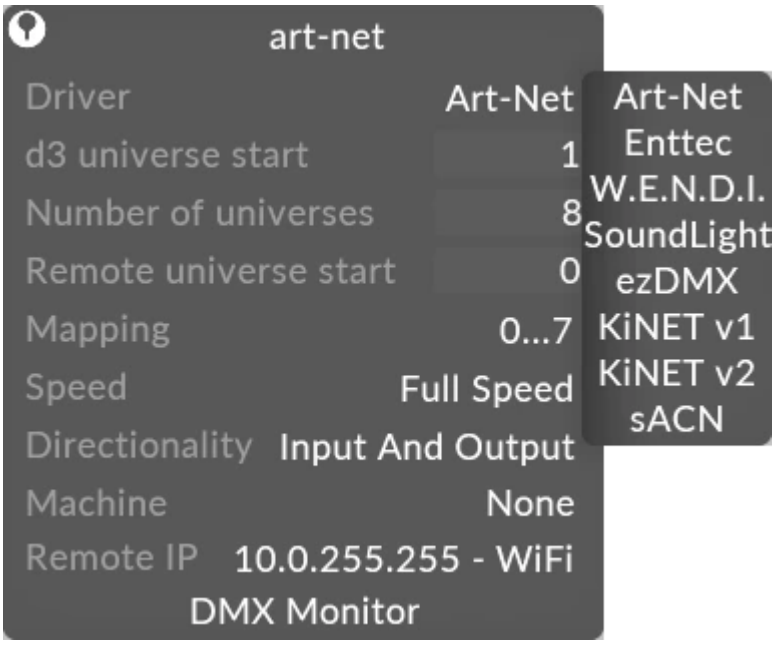
A DmxDevice is created in the same way as any other device type. Please see Creating devices for step-by-step instructions on how to create a device, and select DmxDevice from the menu of different device types.

Edit the DMX Device

1. Right-click the new DmxDevice, in this case Art-Net, to open the DmxDevice editor.



2. Left-click **driver**. This is an option switch that selects the converter device type.



Driver property points to different options of converter device types

Protocols Supported

The following options are supported:

Art-Net

An Art-Net device acts as a bridge between a standard Ethernet network and traditional DMX lighting systems, handling both input and output. This is the most commonly used DMX-over-ethernet protocol. Art-Net can transmit up to 32,768 Universes of data via a single ethernet cable.

Art-Net Broadcast

Art-Net broadcast is the initial transmission method for the Art-Net lighting protocol, where a signal is sent to all devices on a network to discover and configure lighting nodes. To do Art-Net Broadcast, set the remote IP of the device to be the broadcast address of the network. For example, if the node's IP is `2.0.0.1` and the subnet mask is `255.0.0.0` then the broadcast IP will be `2.255.255.255`.

Art-Net IP Address Filtering

We've modified the way we manage Art-Net/sACN connections to allow for more precise layering of DMX data. This means that Disguise is now more strict regarding which IP address it will receive data from, as opposed to the previous behaviour in which it would listen to the entire subnet. In light of this change, users will now need to be more specific when entering remote IP addresses, ensuring that either the correct unicast address or the subnet's broadcast address is used.

sACN

Streaming-ACN, also known as ANSI E.1 31-2016, is an alternate DMX-over-Ethernet protocol that is supported by Disguise. Unlike Art-Net, which is a broadcast (or unicast) protocol, sACN is a multicast protocol and can transmit up to 63,999 Universes of control data via an ethernet network.

When selecting an adapter for multicast traffic in Designer, it loads the list of the adapters present on the local machine. Note that the name of the adapter that is being used to transmit the sACN signal must be labelled the same way on each of the servers in the network in order to connect properly.

Incorrect example:

```
Server A (Director) NIC B labeled "B - sACN 1Gbit"
Server B (Actor) NIC B labeled "B - Artnet 1Gbit" (NIC B will not receive DMX)
```

Correct example:

```
Server A (Director) NIC B labeled "B - sACN 1Gbit"
```

```
Server B (Actor) NIC B labeled "B - sACN 1Gbit"
```

ENTTEC

This is the protocol supported by the popular ENTTEC Datagate conversion devices.

SoundLight

This is a USB-based protocol communicating with DMX devices made by SoundLight Inc.

EzDMX

This is a USB-based protocol communicating with Avolites EzDMX devices.

Kinet V1 and V2

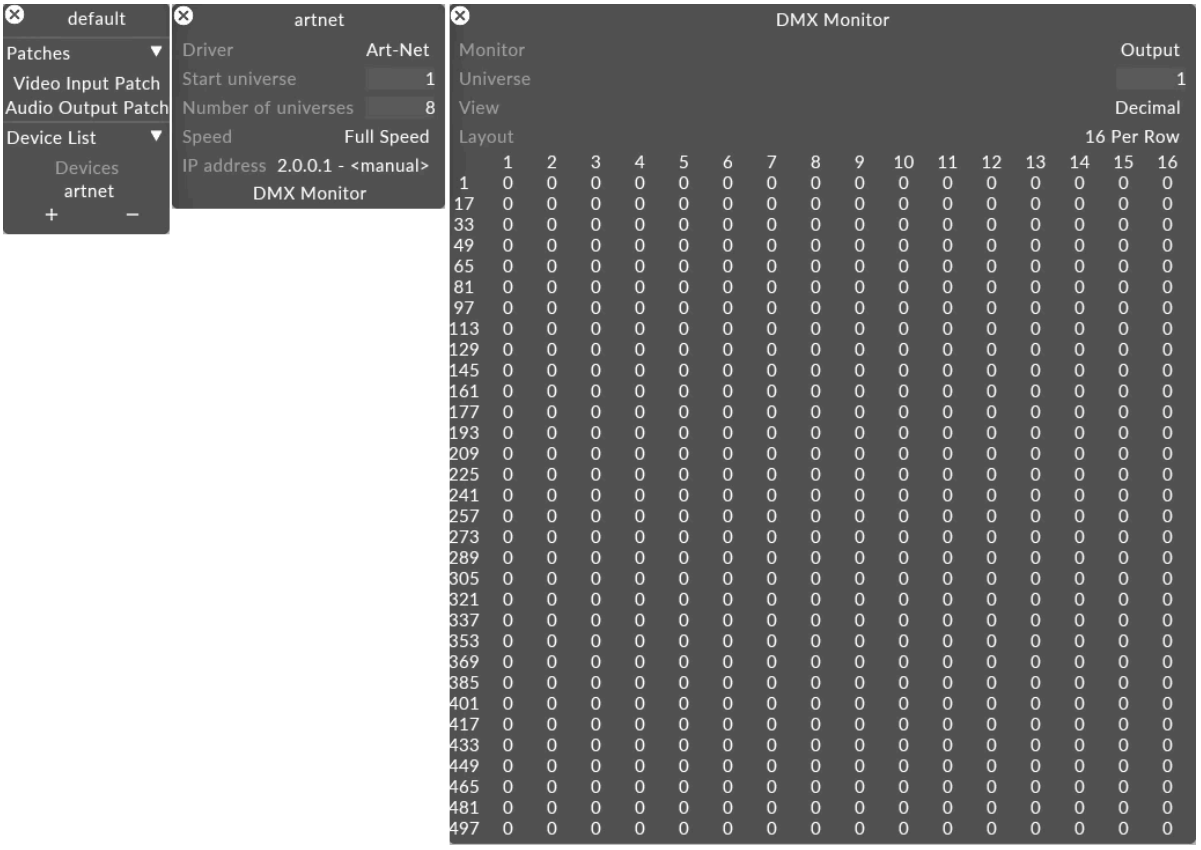
This is a lighting control protocol supported by Color Kinetics devices.

For this example:

- Select **Art-Net** from the list of driver converter types.
- Left-click **IP-address** to open the IP address editor. Ethernet-based protocols (Art-Net, ENTTEC, WENDI) identify each physical device with a different IP address. This property has no function for USB-based protocols (SoundLight, EzDMX).
- Left-click **Manual address** to open the **Select Remote Node** window and type in the IP address of the device. In this example, the IP address for a GrandMA lighting desk is being typed in.
- Left-click **OK** when you have finished typing in the IP address.
- Type in the **start universe** value; universe numbers always start from 1. The **start universe** property specifies the first universe number of the device. Designer makes an arbitrary number of DMX universes available to you and maps ranges of universes to individual DMX converter devices. This number specifies the universe number of the first universe mapped to this device.
- Type in the **universes** value. This specifies the number of universes to be mapped to the DMX device. In the example above, universes 1 through 8 are mapped to the Art-Net device located at 10.0.0.83.

Prove DMX input/output

1. Open the DMX monitor by left-clicking DMX monitor in the Device editor. The DMX monitor is used to prove DMX input and output, in this example for an Art-Net device.



DMX monitor is used to prove DMX input and output, opened by left-clicking DMX Monitor from the DmxDevice editor

2. Type in the universe value to prove DMX input on that specific universe.
3. Left-click on **Monitor** to change the value from Output to Input.
4. Check if the values are coming into Designer.

Art-Net Driver

The **Art-Net Driver** enables Disguise to send and receive DMX-style control data over IP using the **Art-Net protocol**. Art-Net is one of the most commonly used lighting network standards and provides a flexible way to manage large numbers of DMX universes across Ethernet-connected devices.

Disguise uses the Art-Net Driver whenever DMX values need to be transmitted to lighting fixtures, media servers, or automation hardware, or when external systems need to control parameters within Designer.

Uses

Use the Art-Net Driver when your show requires:

- DMX output from Disguise to lighting fixtures, dimmers, LED controllers or automation gateways.
- DMX input from lighting desks to control layers or drive parameters in Designer.
- Integration with lighting networks where Art-Net is the primary protocol.
- Routing DMX universes over IP, reducing cabling and simplifying show distribution.
- Synchronisation between media and lighting, allowing lighting desks to control timeline elements.
- Testing or visualising DMX data coming from or going to external equipment.

Art-Net Broadcast

To send Art-Net data using **broadcast**, set the Remote IP of the device to the **broadcast address** of the network.

Example: If a device has:

- IP: **2.0.0.1**
- Netmask: **255.0.0.0**

Then the broadcast address is:

- **2.255.255.255**

Broadcast sends data to all devices on the network segment.

Use this only when required, as it can increase network load in busy environments.

Art-Net IP Address Filtering

Disguise now uses **strict IP filtering** for Art-Net (and sACN) to allow more precise layering of DMX data.

This means:

- Disguise **only listens to the specific IP address** configured in the Remote IP field.
- It no longer automatically listens to the entire subnet.
- You must specify either:
  - the **correct unicast address**, or
  - the **broadcast address** if using broadcast mode.

This improves reliability in multi-source DMX networks and prevents accidental data conflicts.

Driver Properties

Port

The UDP port for Art-Net communication (typically **6454**).

This should match the configuration of any connected Art-Net device.

Remote IP

The IP address from which Disguise will accept Art-Net data.

- Use a **specific device IP** for unicast.
- Use the **network broadcast address** if broadcasting.
- Required due to Disguise's strict IP filtering behaviour.

Universe Assignment

Specifies which Art-Net universe Disguise will use for DMX input or output.

Art-Net supports up to **32,768 universes** (Net / Subnet / Universe format).

Mode

Determines whether the driver is outputting DMX, receiving DMX, or disabled.

- **Output** — Disguise sends Art-Net
- **Input** — Disguise receives Art-Net
- **Disabled** — No DMX activity

Broadcast / Unicast Setting

Defines whether Art-Net packets are transmitted:

- **Broadcast** — to all devices in the network segment
- **Unicast** — to a single destination IP

Unicast is recommended for large or complex networks.

Developer Documentation

Enttec Driver

The **Enttec Driver** allows Disguise to receive automation or control data from Enttec-compatible devices.

This driver is commonly used in workflows where Enttec hardware is transmitting DMX or serial-based values that need to be interpreted and applied within Disguise. These values can be used to drive automation axes or provide real-time parameter control.

In most setups, the default driver settings provide reliable operation. Adjustments should only be made when your Enttec device or network is configured differently, or when troubleshooting communication issues.

Uses

The **Enttec Driver** is used whenever DMX data from an Enttec device needs to influence automation behaviour inside Disguise. By reading raw DMX values from a connected controller, the driver allows lighting desks, faders, and hardware interfaces to control parameters or movement in real time.

This driver is especially useful when:

- Connecting an Enttec DMX USB Pro or Enttec DMX-over-Ethernet device to Disguise.
- Driving automation axes using DMX values.
- Driving behaviours or presets from a lighting console.
- Testing or monitoring DMX input from Enttec hardware.
- Integrating small-scale, low-cost DMX controllers into interactive workflows.

Driver Properties

> **Note**
>
> Enttec devices primarily supply DMX values. Unlike position-tracking drivers, they do not expose specialised properties, just the basic input configuration required to receive DMX correctly.

Port

Specifies the Enttec device or interface port being used for DMX input.

This determines which connected Enttec unit the driver listens to.

Universe

The DMX universe being read from the Enttec device.

Channel

The starting DMX channel where the incoming value will be read.

Additional channels may be read depending on how many bytes your automation mapping requires.

Input Mode

Determines how the incoming DMX bytes are interpreted—for example:

- **Single Channel** (0-255)
- **2-byte value**
- **4-byte value**

(Available modes may vary depending on the Enttec device used.)

Developer Documentation

ezDMX Driver

The **ezDMX Driver** enables Disguise to receive DMX-based positional or control data using the ezDMX protocol.

This driver is typically used when integrating DMX-driven automation sources that transmit multi-channel values requiring interpretation inside Disguise.

In most configurations, the default driver settings offer reliable operation.

Adjust the settings only if your ezDMX device or network requires specific port, channel, or addressing changes.

Uses

This driver is especially useful when:

- Integrating ezDMX-compatible devices that transmit positional or movement data.
- Receiving DMX values from lighting desks or controllers that use ezDMX format.
- Driving automation axes or parameters using direct DMX input.
- Testing and monitoring DMX streams during installation or calibration.
- Using cost-effective DMX controllers in smaller or decentralised automation setups.

The driver provides a straightforward way to convert incoming DMX channels into meaningful numerical values that Disguise can use in real-time workflows.

Driver Properties

Universe

The DMX universe from which data is received.

Channel

The starting DMX channel containing the value to be interpreted.

Port

Specifies the ezDMX device or network port used as the data source.

Input Mode

Determines how many DMX bytes are read and how the value is formed.

Examples may include:

- Single Channel
- 2-byte value
- 4-byte value

(Exact modes displayed depend on the ezDMX hardware in use.)

Developer Documentation

KiNET v1 Driver

The **KiNET v1 Driver** enables Disguise to receive data from devices that communicate using the **KiNET Version 1 protocol**.

KiNET is commonly used by lighting and LED control hardware to transmit real-time control or positional information over an IP network.

This driver allows Disguise to interpret incoming KiNET v1 messages and use them within automation or control workflows.

In most configurations, the default driver settings are appropriate, and changes are only required when working with custom port assignments, IP restrictions, or specific network topologies.

Uses

Use the KiNET v1 Driver when integrating lighting or LED control systems that transmit control data using the KiNET Version 1 protocol. This driver allows Disguise to receive structured KiNET messages and convert them into automation or control values that can influence content, behaviours, or visual logic inside a project.

This driver is especially useful when:

- Receiving real-time lighting control data from fixtures or processors using KiNET v1.
- Synchronising LED system states or parameters with media playback or automation in Disguise.
- Building interactive experiences where lighting hardware influences virtual content.
- Monitoring KiNET traffic during setup or troubleshooting.
- Bridging lighting and media workflows for tightly coordinated installations.
- Working with legacy or KiNET v1-only controllers still used in permanent or touring systems.

As KiNET v1 is widely adopted in LED and lighting infrastructure, the driver offers a reliable way to connect physical lighting behaviour to real-time media systems.

Driver Properties

Port

The port number the automation data is coming in on.

IP Filter

The remote IP that the data is coming in on (optional).

Multicast Address

The multicast address the data is coming from (optional).

Developer Documentation

KiNET v2 Driver

The **KiNET v2 Driver** allows Disguise to receive data from devices that use the **KiNET Version 2 protocol**.

KiNET v2 is widely used in advanced lighting and LED control systems to transmit structured control data over IP networks.

This driver enables Disguise to interpret incoming KiNET messages and convert them into usable automation or control values.

In most setups, the default configuration is sufficient unless your lighting controller or network infrastructure uses custom port or addressing settings.

Uses

Use the KiNET v2 Driver when integrating lighting or LED control systems that transmit data using the KiNET Version 2 protocol. This driver allows Disguise to receive and interpret KiNET messages as automation or control values, enabling tight synchronisation between lighting systems and real-time media or virtual environments.

This driver is especially useful when:

- Receiving real-time control data from lighting consoles, LED processors, or media servers that output KiNET v2.
- Synchronising lighting system states with content or automation inside Disguise.
- Monitoring KiNET data streams to drive effects or interactive elements.
- Bridging lighting data into Disguise workflows for media-light integration.
- Creating installations where lighting positions, intensities, or parameters influence generative or reactive content.
- Testing or validating KiNET network output in controlled environments.

As KiNET v2 is IP-based and supports structured, high-throughput messaging, the driver is suitable for productions requiring precise coordination between lighting and visual content.

Driver Properties

Port

The port number the automation data is coming in on.

IP Filter

The remote IP that the data is coming in on (optional).

Multicast Address

The multicast address the data is coming from (optional).

Developer Documentation

sACN Driver

The **sACN Driver** allows Disguise to transmit and receive DMX data using the **Streaming ACN (E1.31)** protocol. sACN is a widely used, network-based lighting control standard that supports large channel counts and multiple universes over Ethernet.

Disguise systems use the sACN driver whenever DMX data needs to be shared with lighting consoles, media servers, or other devices that support the E1.31 protocol.

Uses Notes

Use the sACN Driver when your workflow involves:

- **Sending DMX values** from Disguise to lighting desks, fixtures, media servers, or stage automation receiving sACN.
- **Receiving DMX control** from lighting consoles to drive parameters, timelines or triggers inside Disguise.
- **Synchronised multi-universe output**, ensuring all connected systems update simultaneously.
- **Redundant or multi-source DMX environments**, where packet priority can decide which device controls output.
- **Lighting, projection, or show-control networks** that rely on a unified DMX-over-IP protocol.

sACN is particularly suitable for productions requiring scalable DMX output, network efficiency, and sync-safe delivery across many devices.

Driver Properties

Force Synchronisation

When enabled, Disguise will wait for sACN synchronisation packets before updating any DMX values.

If synchronisation stops, receivers will continue holding their last valid state even after the usual 2.5s timeout.

Use this when working in **fully synchronised lighting networks** where frame-accurate updates are required.

Priority

Defines the DMX packet priority when multiple sACN sources send data to the same universe.

Higher values take precedence.

Useful in systems that include **fallback, backup consoles, or layered DMX control**.

Sync Address

The sACN universe number used for synchronisation messaging.

When a sync packet is received on this universe, Disguise will apply buffered updates to all relevant universes.

Enable Synchronisation

When enabled, Disguise sends an sACN sync packet at the end of each DMX frame.

This ensures all receivers update **simultaneously**, reducing visible stepping or lag.

Sync Packet Delay

The delay (in seconds) between finishing DMX output for a frame and sending the synchronisation packet.

This allows network traffic to settle before distributing the sync message.

Example: `0.02` sends the sync packet 20ms after DMX output completes.

Developer Documentation

SoundLight Driver

The **SoundLight Driver** allows Disguise to communicate with SoundLight DMX interfaces.

SoundLight devices are commonly used as compact DMX output or input nodes, enabling DMX data to be sent from or received into a Disguise system as part of a wider lighting or show-control workflow.

Use this driver whenever your production relies on SoundLight hardware for DMX connectivity, patching, or bridging between physical fixtures and the Disguise project.

Uses

The SoundLight Driver is typically used for:

- **Outputting DMX from Disguise** to lighting fixtures via a SoundLight interface
- **Receiving DMX control** from a lighting console or external controller
- **Integrating small or distributed DMX nodes** into larger networked lighting systems
- **Testing, monitoring, or routing DMX universes** in show workflows
- **Providing hardware-level DMX connectivity** for installations or compact production setups

SoundLight interfaces offer simple, reliable DMX-over-IP bridging, making them suitable for both small and large DMX deployments.

Driver Properties

Depending on the SoundLight device model and configuration, the driver may expose:

DMX Input / Output Mode

Defines whether the connected device is used to receive DMX into Disguise, output DMX from Disguise, or both.

Universe Assignment

Specifies which DMX universe the SoundLight interface will transmit or receive.

Device Address / Network Configuration

IP and network configuration for discovering and communicating with the SoundLight hardware.

Refresh Rate / Update Frequency

Controls how frequently DMX packets are transmitted when outputting from Disguise.

> **Note**
>
> Specific options may vary depending on the SoundLight hardware connected and firmware version in use.

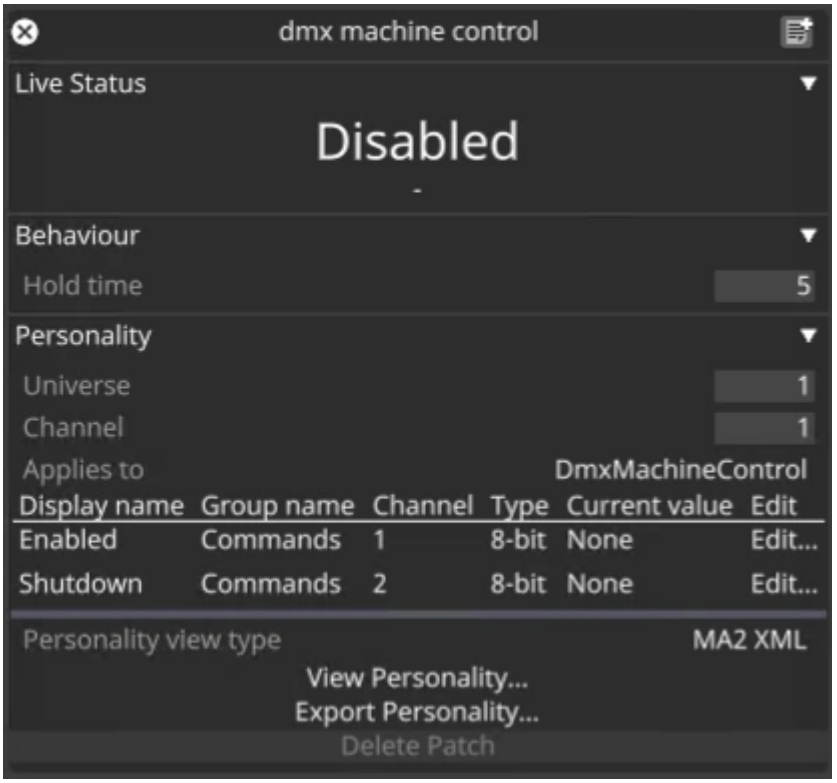
Developer Documentation

DMX Machine Control Device

The DMXMachineControl Device allows restart and shutdown commands to be sent to Designer from an external DMX device, such as a lighting console.

The DMXMachineControl Device is used for remote shutdown and restart of Disguise machines using DMX commands.

1. Create a DMX device from the Device Manager. See Creating Devices for more detailed information.
2. Create a **DMXMachineControl** Device.
   - Set the **Universe** and **Channel** values.
   - Configure the command and personality ranges to suit personal preference, or use the default settings.
3. Export the personality to the lighting console in either .txt, GDTF or MA2 XML format from the Export tab of the device.
   - The exports will be written to the output folder of the project folder.
4. Send values from the lighting console to remotely trigger a machine restart or shutdown.



Live Status

Monitors the status of DMX commands being received.

Behaviour

Hold Time

The Hold time, specified in seconds, defines how long Designer will wait before acting on a Restart or Shutdown command.

Personality

Universe

The Universe property defines the Universe number that the commands will come from.

Channel

The Channel property defines the Channel number that the commands will come from.

Enable Channel

The Enable channel defines which DMX channel will send the Enable command to the Disguise machine — this allows the command to be triggered. The enabled range can be viewed and edited by clicking on the **Edit...** button on the Enabled row.

Shutdown Channel

The Shutdown channel defines which DMX channel will send the shutdown command to the Disguise machine. The Idle, Restart, and Shutdown ranges can be viewed and edited by clicking on the **Edit...** button on the Shutdown row.

Personality view type

Here, we can select whether to view and export the personality as a GDTF file, a text-formatted chart, or a (deprecated by MA) MA2 XML file.

View Personality

Opens a window displaying the personality with the chosen Personality view type.

Export Personality

Exports the personality as a file with the chosen Personality view type.

DMX Projector Control Device

The DMX Projector Control Device is intended for controlling external devices via DMX while optionally simulating their behaviour inside the visualiser.

Projector control can be simulated as well as output to real projectors. The intention is to be able to recall presets for the projectors that contain pan/tilt, zoom, focus, lens shift, intensity and projector configuration objects (for recalling different calibration states).

Workflow

1. Create a DMX device from the Device manager — see DMX Device for details.
2. Create a **DmxProjectorControlDevice**.
   - Set the Universe and Address values.
   - Configure the command and personality ranges to suit personal preference, or use the default settings.

Properties

Projector

The virtual projector object in the visualiser.

Values

Pan/Tilt, Focus, Zoom, Lens Shift (V/H), Intensity: the current values being sent to the external device. Modifying these values will cause the device to send out commands to the external device.

Simulation

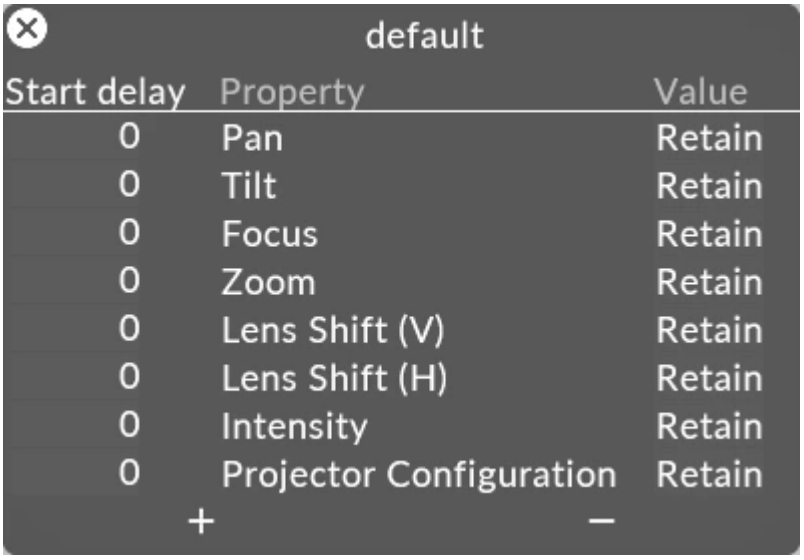
- **Simulation configuration** - the projector configuration that the device modifies to simulate the behaviour of the external device. Always use a dedicated projector configuration for this as its settings will be overwritten by the simulation.
- **Home rotation** - the starting rotation when the device's pan/tilt are at zero.
- **Rotation speed** - the animation speed of rotation between different pan/tilt values.
- **Pan axis** - the axis controlled by the pan value.
- **Tilt axis** - the axis controlled by the tilt value.

Default recall

- **Recall** - the default order of the commands sent to the device. This allows delays between starting the pan/tilt, focus, zoom and other actions.

For example, you may want to delay intensity moves for a set period of time to allow zoom, focus and position to be set before the projector is visible. The delay value is expressed in seconds.

The editor is capable of multi-edit functionality, so does not behave in the same way as a normal editor. See multi-edit for more information.



DMX

Universe and channel of the external DMX device.

Commands

- **Default commands** - DMX commands sent to the DMX device for each action in addition to the specific actions' DMX commands.
- **Startup commands** - DMX commands sent to the DMX device when the projector control device is started or added to the device manager.
- **Shutdown commands** - DMX commands sent to the DMX device when the projector control device is stopped or removed from the device manager.

Common properties

Coarse and fine channels for each projector control action. The range will be used to map the current value to a 16-bit DMX value. A channel of 0 will disable that slot.

Zoom

Focus

Lens Shift

Intensity

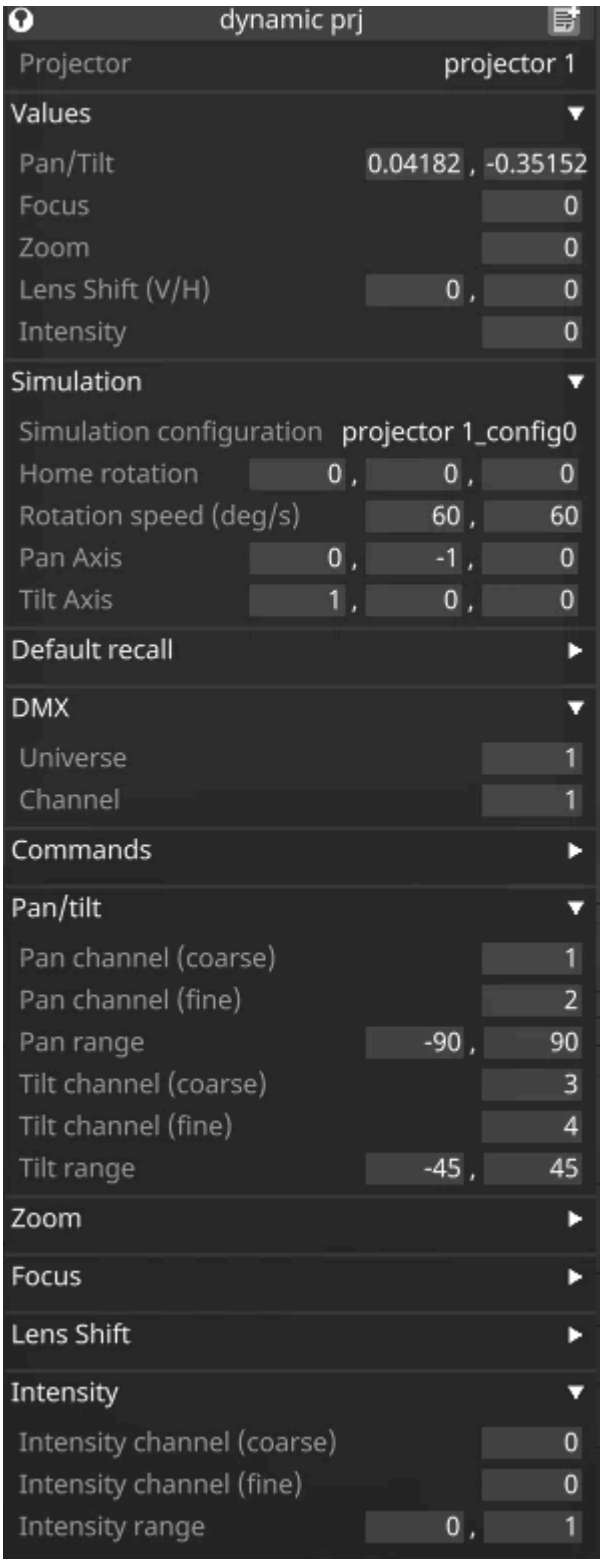
Dynamic Projection Integration

The DmxProjectorControlDevice can be used for controlling moving mirrors and projector yokes using the following steps:

1. Add an Art-Net device to your scene and set it up accordingly for universe etc.

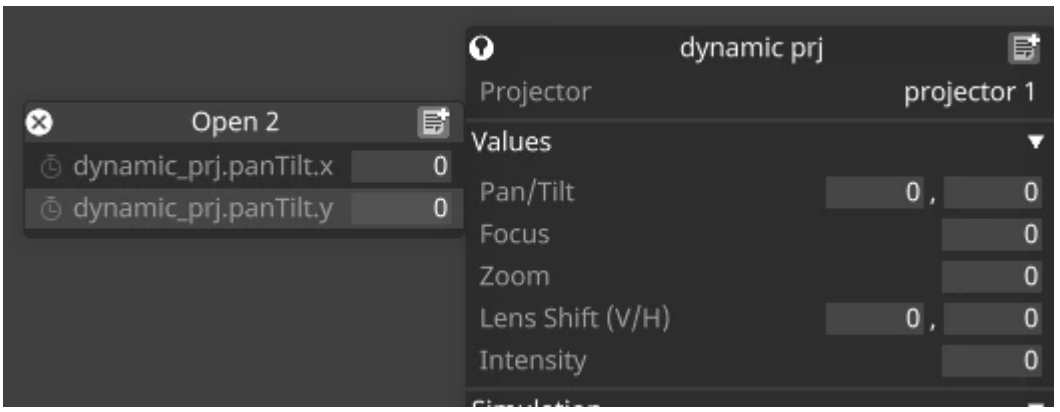
2. Set up the dynamic mirror unit following the recommended settings from the manufacturer and assign Universe and Start Address for Art-Net control.
3. Add a projector to your scene.
4. Add a **DmxProjectorControlDevice**.
5. Set the DMX for the Universe and DMX start channel for your chosen device.
6. Set the Pan/Tilt DMX addresses — for example on a unit with start address 1, the settings are as below in the image.
7. Assign your projector to the simulation configuration.
8. Assign the projector and set the rotation speed deg/s.

9. When the unit is in Normal mode the settings for pan and tilt ranges are as follows:



The unit does have an extended mode which is a total of 160 degrees of tilt.

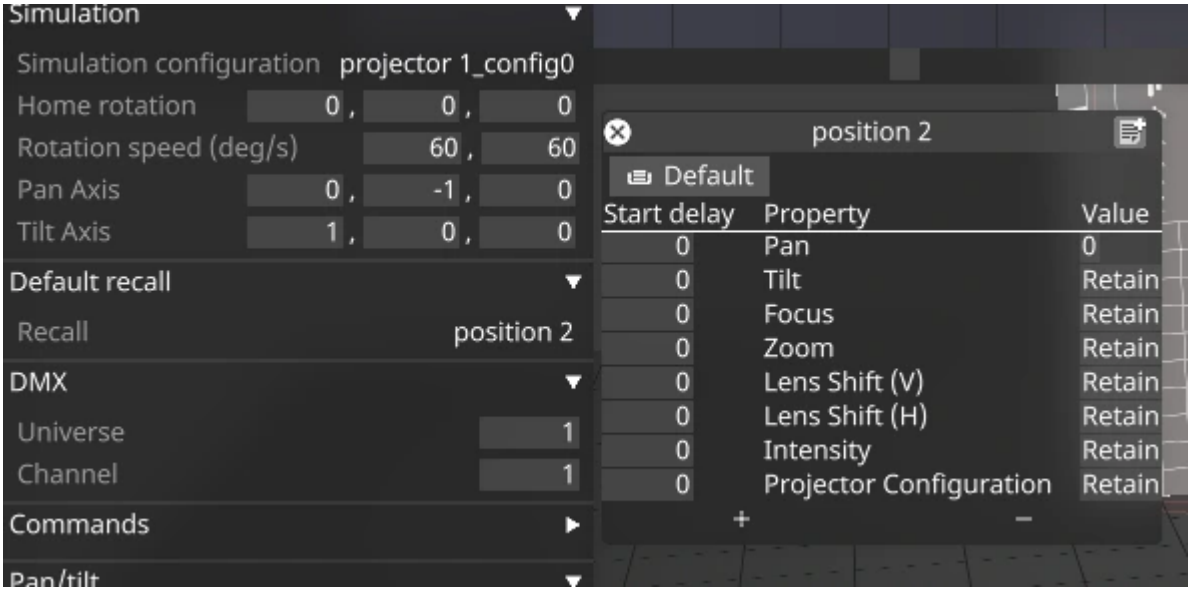
10. Using a Control layer you can keyframe values:



Position Recall

You can save positions by creating a position:

1. Right-click the Recall field and create a new position.
2. In the GUI window that opens, enter values in the value column.
3. This Default recall can then be linked to an open layer and the positions recalled on the timeline.

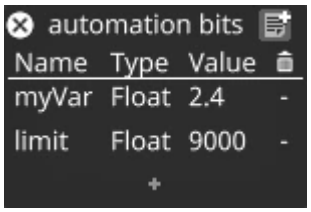


Expression Variables Device

The ExpressionVariables device defines variables for use in expressions which are made available to the vast majority of the locations expressions can be used.

Each ExpressionVariables device is used to define a group of variables. It is expected that the device is used to group the variables to be used for different purposes.

Using the ExpressionVariables device



Variables are presented in a list format for editing within the device. Users press the + button to add a new variable, and every row has a - button at the end to remove the variable from the device.

Variables must be named correctly (see variable naming) and have the desired type selected before the desired value for the variable can be entered.

Value ranges

It is possible to edit the range and granularity of `Float` type variables in the device. To do this, right-click on the value to bring up a MetaField. Altering the MetaField allows the user to change how the value is edited within Designer.

Arranging variables

The variables defined in the device can be rearranged by left-mouse dragging the rows in the device up or down. This allows variables to be reordered to improve readability or because some variables may depend on others, and need to be defined in a specific order.

Using variables defined by the device

Variables defined by the ExpressionVariables device are valid for use in devices which appear later (further down) in the device manager devices list, and become invalid if the device is not

present in the active device manager. They are available everywhere else that expressions are accepted.

GrpcReceiver Driver

The **GrpcReceiver Driver** enables Disguise to receive automation or tracking data over **gRPC**, a modern, high-performance communication protocol commonly used for real-time systems.

This driver allows external applications or services that expose gRPC endpoints to stream structured data directly into Disguise, where it can be used to drive automation, positional values, or other dynamic behaviours.

This method is particularly useful when integrating custom software tools, middleware, or services that require efficient, low-latency communication with Disguise.

In most cases, the default driver configuration provides reliable operation, but settings may require adjustment depending on the gRPC server implementation or network setup.

Uses

The **GrpcReceiver Driver** is ideal for scenarios where structured, low-latency data needs to flow from custom software into Disguise. It provides a flexible way to integrate bespoke control systems, middleware, or data services using modern streaming communication.

This driver is especially useful when:

- Integrating custom-built tools or applications that output gRPC telemetry.
- Receiving tracking or automation values from real-time services.
- Streaming structured parameter data into Disguise for interactive or adaptive workflows.
- Building installations where high-frequency, low-latency data updates are required.
- Prototyping or testing new control systems without needing DMX, FreeD, or hardware-based protocols.
- Connecting cloud or local services to drive automation behaviour in real time.

As gRPC supports structured message types, it is well suited to transmitting multiple parameters or data fields in a single, efficient stream.

Driver Properties

Port

The port number on which the driver listens for incoming gRPC connections.

This must match the output configuration of the gRPC server.

IP Filter

(Optional) Limits accepted connections to a specific IP address.

Useful when multiple services operate on the same network or when isolating trusted sources.

Service Definition / Message Format

Determines the structure of the incoming gRPC messages.

This is defined by the gRPC server and must match the expected format used by the driver.

Connection Mode

Specifies whether the driver should accept a single connection or multiple connections, depending on workflow requirements.

Timeout Settings *(if exposed)*

Defines how long the driver should wait for data before considering the connection inactive.

Used mainly for troubleshooting or ensuring consistent behaviour in unstable networks.

Developer Documentation

Test Receiver Driver

The **Test Receiver Driver** is a diagnostic and development tool used within Disguise to simulate incoming automation or positional data. It behaves like a standard screen position receiver, allowing users to test automation behaviour, axis mapping, and content responses without requiring a live hardware controller or third-party automation system.

This driver is typically used during development, troubleshooting, or training where synthetic motor or axisdata is helpful for validating a workflow.

Uses

Use the Test Receiver Driver when you need to:

- Simulate automation data without a physical device.
- Verify how Disguise maps motor or axis channels.
- Test content behaviour as if real automation were connected.
- Train operators on automation workflows in a safe, offline environment.
- Debug timelines and conditional logic that depend on automation input.
- Prototype automation-driven interactions before hardware arrives on site.

As it emulates the behaviour of a real receiver, the Test Receiver Driver is ideal for early-stage development or internal testing.

Driver Properties

Number of Motors

Specifies how many simulated motors or axes the driver should expose.

Each motor behaves like a standard automation channel inside Disguise, allowing users to test mapping, logic, and motion-driven content.

Developer Documentation

UDP Receiver Driver

The UDP Receiver Driver provides a simple way for Disguise to ingest raw data sent via UDP. It is commonly used for lightweight custom integrations, device triggers, telemetry streams, or any workflow where external systems broadcast or multicast small packets of information.

Uses

Use the UDP Receiver Driver when you want to:

- Receive custom UDP messages from third-party devices or scripts.
- Listen for broadcast or multicast data on the network.
- Filter incoming packets by sender IP.

Driver properties

Port

The UDP port the driver listens on for incoming data.

This must match the port configured on the device or system sending the UDP packets.

IP Filter

An optional network filter that limits incoming data to a specific sender IP address.

Use this when multiple devices are active on the network and you want to ensure only one source is accepted.

Leave blank to allow data from any IP.

Multicast Address

The multicast group the driver should subscribe to when receiving multicast UDP traffic.

Only required when your workflow involves multicast delivery, leave blank for standard broadcast or unicast setups.

Developer Documentation

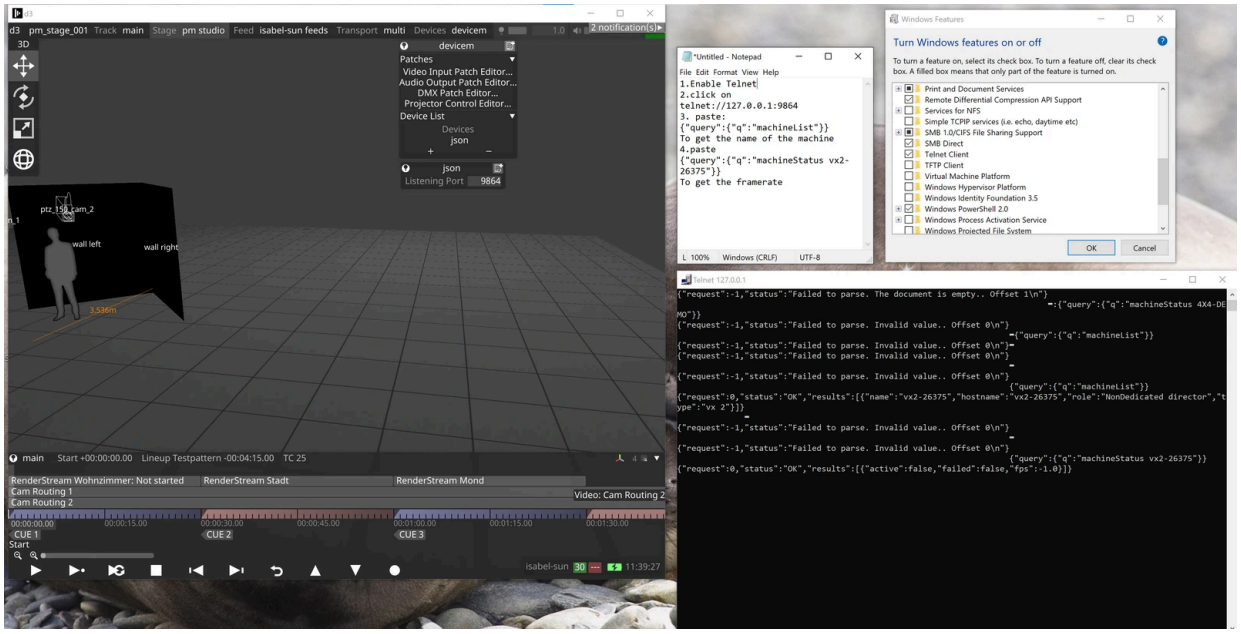
JSON Machine Control Device

JSONMachineControl Device allows for the querying of machine list and machine status via JSON.

Telnet setup

A JSONMachineControl Device requires the use of Telnet. Follow these steps to properly configure the Disguise server for Telnet communication:

1. Enable Telnet by navigating to **Control Panel > Programs > Turn on Windows Features > Telnet Client**.
2. Click on the link **telnet://127.0.0.1:9864**.
3. To get the name of the machine, enter: `{"query":{"q":"machineList"}}`.
4. To get the framerate, enter: `{"query":{"q":"machineStatus hostName"}}`.



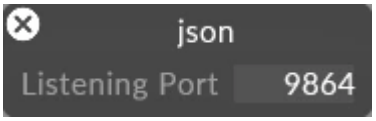
Using Live framerate is recommended. The following Python script can be used to retrieve the Live framerate:

```
import json
from telnetlib import Telnet
from socket import gethostbyaddr
hostIP = "127.0.0.1"    # stick the server IP here
port = 9864
host_name = gethostbyaddr(hostIP)
print(f'd3 name is: {host_name[0]}')
q = '{"query":{"q":"machineStatus ' + host_name[0] + '"}}'
print(f"sending - {q.encode('ASCII').decode('ASCII')} -  to {host_name[0]}")
def readFPS():
    with Telnet(hostIP, port) as tn:
        tn.write(q.encode('ASCII') + b'\r\n')
        buf_as_dict = json.loads(tn.read_until(b"}]}"))
    return buf_as_dict['results'][0]['fps']
if __name__ == '__main__':
    while True:
        fps = readFPS()
        print(fps)
```

Creating a JSONMachineControl Device

A **JSONMachineControl device** is created in the same way as any other device type. See Creating Devices for step-by-step instructions on how to create a device, then select **JSONMachineControl** from the menu of different device types. This will open the device editor (explained below).

JSONMachineControl Device properties



Listening Port

The TCP port the device listens on for incoming Telnet queries. Defaults to **9864**.

JSONMachineControl queries

Machine list: `{"query":{"q":"machineList"}}`

Returns a list of dictionaries containing information about each machine: d3 name, hostname, role, and machine type.

Example return:

```
{"request":0,"status":"OK","results":[{"machine":"4x4-DEMO","hostname":"4X4-DEM
O","role":"Dedicated director","type":"4x4pro"}]}
```

Machine status: `{"query":{"q":"machineStatus 4X4-DEMO"}}`

Returns extra information about a machine: session status, failover status, and current FPS.

Example return:

```
{"request":0,"status":"OK","results":[{"active":true,"Failed":false,"fps":32.345
558166503909}]}
```

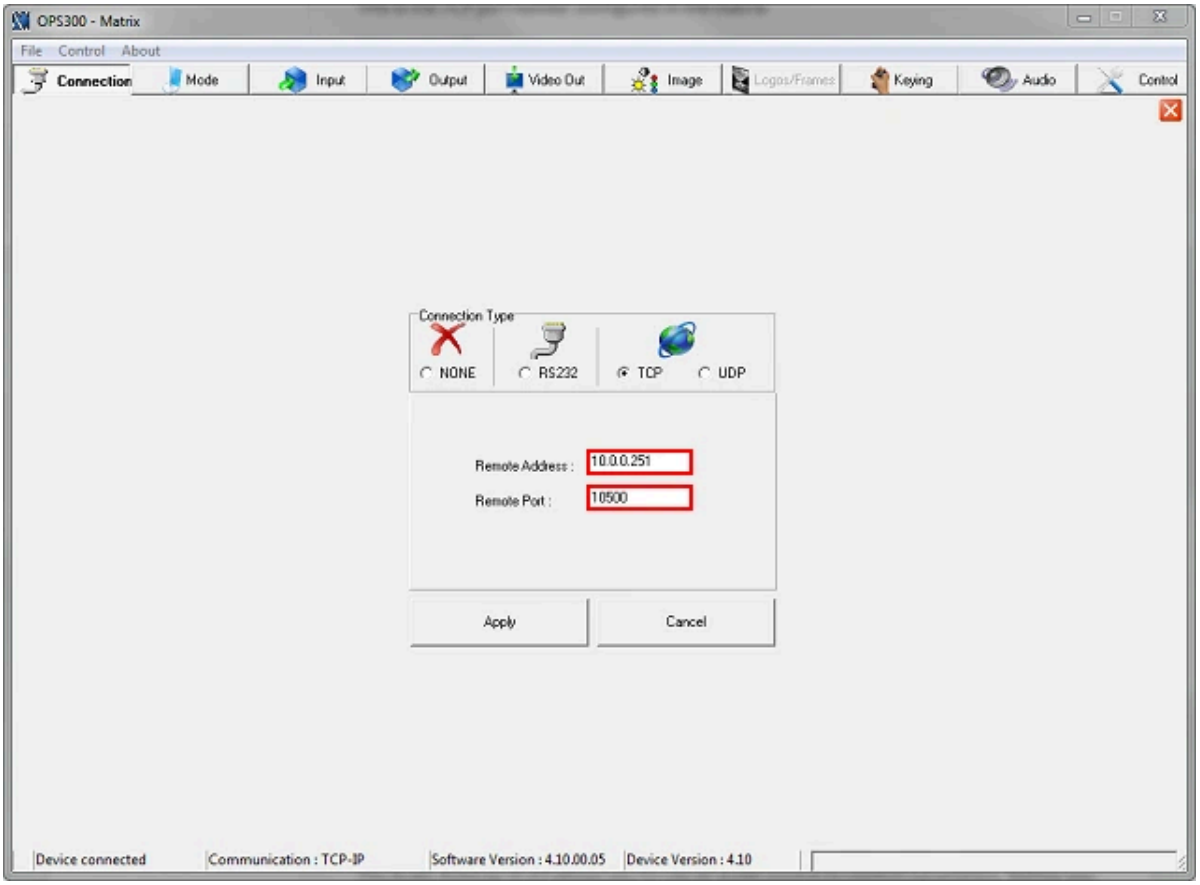
Analog Way OPS300 Matrix Setup

In Designer, the Analog Way OPS300 matrix device supports routing control for the Analog Way OPS300 switcher.

The Analog Way OPS300 is a multi-layer mixer, scaler, and seamless switcher designed for professional audio-visual (AV) environments. It offers seamless switching between digital and analog sources, multiple live effects like picture-in-picture (PiP) and keying, and flexible output options. It can be configured in a **Multi-Layer Mixer** mode for live shows or a **Seamless Native Matrix** mode, supporting up to six layers of content simultaneously.

Setting up an Analog Way OPS300

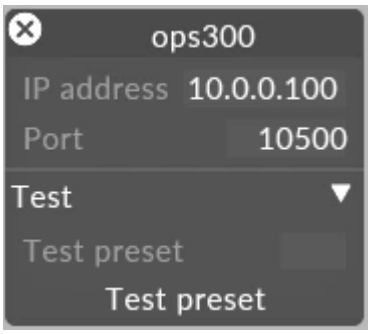
1. Navigate to the **Network Settings** page of the Analog Way OPS300 interface. Note down the **Remote Address** and **Remote Port** numbers used or set your own. Please see your device manual for more instructions.



2. Note down the Remote Address and Remote Port numbers used or set your own from the Analog Way OPS300 Network Settings page
3. Set the matrix to be in the same IP range as the system.

4. In Designer, create an **AnalogWayOPS300** device. An AnalogWayOPS300 device is created in the same way as any other device type. Please see Creating devices for step-by-step instructions on how to create a device, and select **AnalogWayOPS300** from the menu of different device types. This will open the AnalogWayOPS300 device editor.
5. Configure the AnalogWayOPS300 device editor by referring to the device properties below.

AnalogWayOPS300 device properties



AnalogWayOPS300 device editor

IP address

The IP address of the matrix.

Port

The TCP port number configured in the matrix. Defaults to **10500**.

Test preset

The test preset number

Test

This button will set the matrix to the preset set in the **test preset #** property.

Barco MatrixPro Setup

Barco MatrixPro is a line of professional video matrix switchers that route digital and analog video signals. It can either be controlled via Serial or TCP-IP. If creating a Serial Device it will take priority over the IP configuration.

Setting up a Barco MatrixPro

- In Designer, create a **BarcoMatrixPro** device. A BarcoMatrixPro device is created in the same way as any other device type. Please see the Creating devices section for step-by-step instructions on how to create a device, and select **BarcoMatrixPro** from the menu of different device types. This will open the BarcoMatrixPro device editor.

Serial control

- In the **Port** property create a new **SerialDevice**. Use the same process as that for creating the BarcoMatrixPro device, but select **SerialDevice** from the menu of different device types. If creating a Serial Device, it will take priority over the IP configuration.

TCP-IP control

1. Configure the Barco MatrixPro to the same IP network as the Director/Actor network.
2. Configure the BarcoMatrixPro device editor by referring to the device properties below.

BarcoMatrixPro device properties

BarcoMatrixPro device editor

Port

The TCP (Telnet) port to send commands on. Defaults to **23**.

IP address

The IP address of the matrix.

Test preset

The test preset number.

Test

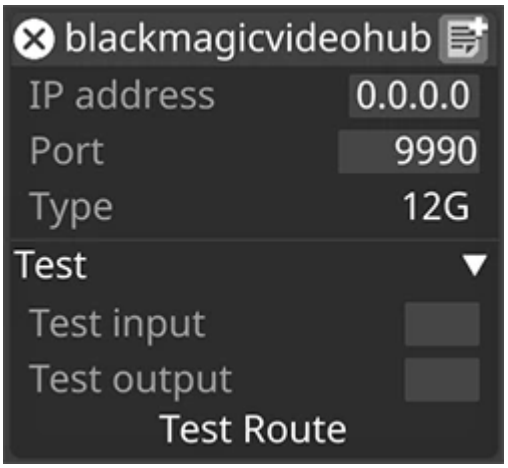
This will set the matrix to the preset set in the **test preset** property.

Blackmagic Smart Videohub Setup

The Blackmagic Smart Videohub is used within a Disguise workflow as an external video router or matrix switch that allows the Disguise media server to electronically switch between multiple SDI video sources and direct them to different destinations (screens, recorders, LED processors, etc.) without manually re-cabling.

Blackmagic Videohub models 3G, 6G and 12G are all supported.

Options



IP address

The IP of the target Blackmagic Smart Videohub to interact with through this device.

Port

The port of the target Blackmagic Smart Videohub to interact with through this device.

Type

Whether the target Blackmagic Smart Videohub model is 3G-SDI or 12G-SDI. If it is a 6G-SDI model then setting this setting to 3G will yield the expected behaviour.

Using a Blackmagic Smart Videohub for failover in a Director and Understudy setup

1. Add a **BlackmagicVideoHubMatrix**.

2. Add the IP address and port number.
3. Test the routing working by entering an input/output routing.
4. In d3Net Manager, assign the Director and Understudy.
5. Then assign the patch accordingly in the **matrix inputs**.
6. On Failover, this will switch the device routing as specified.

Known issues and workarounds in older versions of Designer

Use the tabs below to find out the expected working behaviour for the various previous versions of Designer as well as any workarounds possible.

- Upgrading to r32.2 and newer
- r27.2.2 to r32.1.3

- r26.2.2 to r27.2.1
- r26.2.1 and older

When upgrading a project from a version that has the option switch available (r27.2.2 to r32.1.3) Designer will attempt to upgrade existing `BlackMagicVideoHubMatrix` devices smartly. This means that if:

A project has got the option switch set to `10`

All existing devices will automatically have their type set to 12G.

A project has got the option switch set to `0` (default)

All existing devices will automatically have their type set to 3G.

But all new devices will still default to 12G.

Direct Matrix Routing

What is Direct Matrix Routing?

Designer supports direct matrix routing, which sends individual routing instructions ("map input X to output Y") to the matrix. Designer allows multiple matrix devices to be controlled, and allows fanout (a single feed output can be mapped to more than one physical output, for backup).

When a feed is assigned to a machine, Designer generates an appropriate set of routing instructions and sends this to all connected matrix devices.

Using Direct Matrix Routing

To set it up, you need to tell two things:

- For each machine, which matrix input each physical head connects to.
- For each feed, which matrix output(s) drive each feed head.

When a feed is assigned to a machine, Disguise generates an appropriate set of routing instructions and sends this to all connected matrix devices.

Setting up Direct Matrix Routing

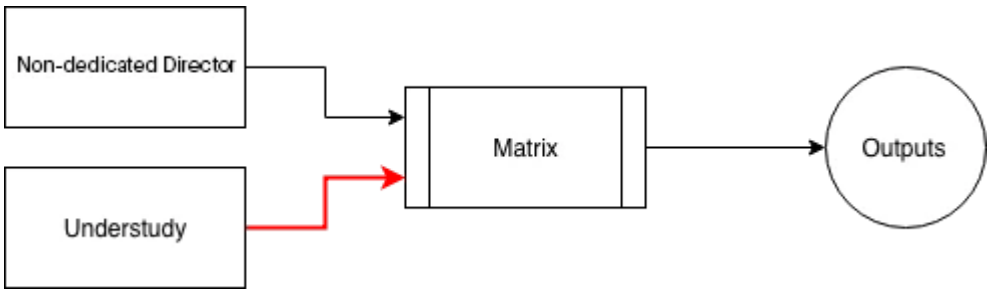
1. Add one or more matrix devices to your Devices list and set them up appropriately. Note that the order these devices are in the **Device Manager** is what defines them as Matrix 1, Matrix 2 etc. You can drag matrices up & down in the Device Manager to re-order them.
2. Access your feed scene by left-clicking **Feeds** from the dashboard.
3. Right-click the coloured border of a feed output.

4. For the Matrix input & Matrix output parameter, write in a comma-separated list of (matrix number, input number),eg. “1.1,1.2” means “outputs 1 and 2 of matrix 1”.

> **Warning**
>
> There should be no spaces between matrix routing strings, except around the pipe `|` operator where they are required. Any other spaces in the input field will cause the routing to fail.

For more information on supported DVI matrices, see the Matrix switches overview.

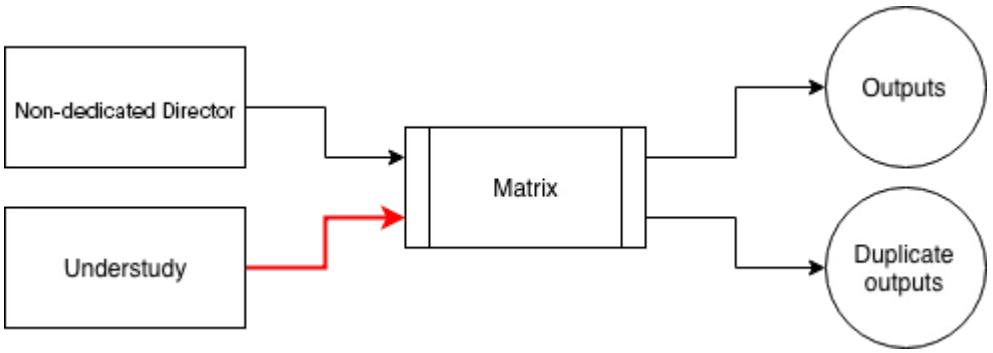
Basic routing example



Machine	Routing	Routing	Routing	Routing
Director In	1	2	3	4
Director Out	1	2	3	4
Understudy In	5	6	7	8

This is the easiest configuration to work with. In its most basic form, matrix routing will use a single matrix to swap the inputs on failover. This notation is as simple as typing each input and output number into the feed properties of each machine. This matrix is using a 1-to-1 routing, and on failover inputs 5-8 are used to receive from the Understudy.

Matrix DA routing example

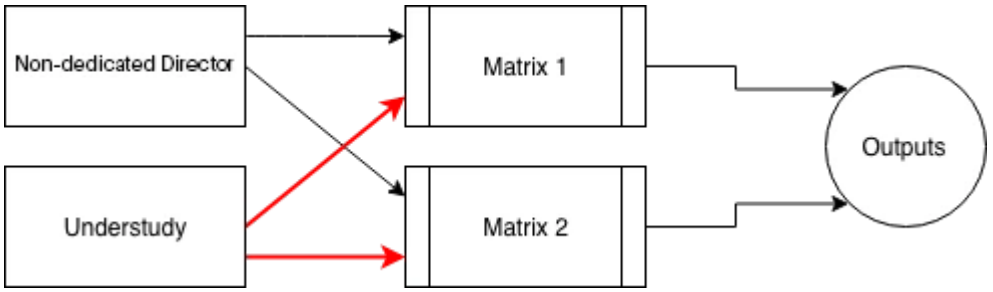


Machine	Routing	Routing	Routing	Routing
Director In	1	2	3	4
Director Out	1,5	2,6	3,7	4,8
Understudy In	5	6	7	8

In this example, each matrix output is doubled up and sending a duplicate output. In Designer the notation for this is to comma separate the output numbers. This example shows input 1

being sent to outputs 1 and 5, 2 to 2 and 6, and so on. On failover, 5 is routed to 1 and 5, etc. The comma only works in the output field of each routing

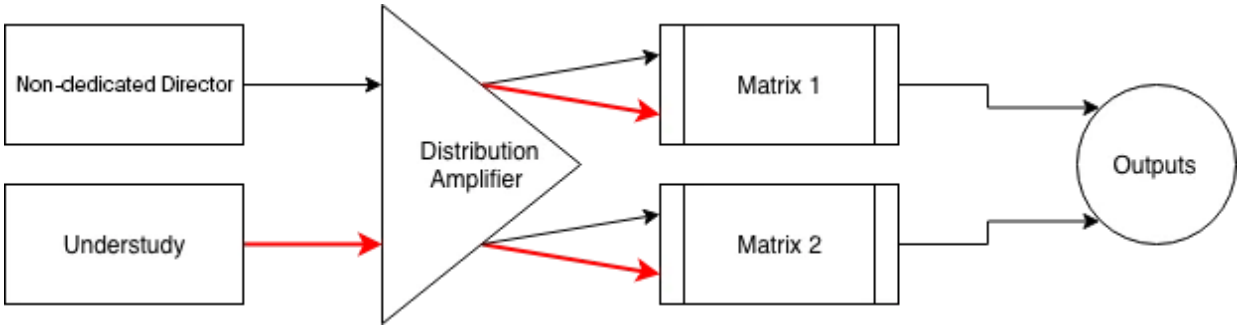
Multiple matrices routing example



Machine	Routing	Routing
Director In	1.1 1.2 1.3 1.4	2.1 2.2 2.3 2.4
Director Out	1.1 1.2 1.3 1.4	2.1 2.2 2.3 2.4
Understudy In	1.5 1.6 1.7 1.8	2.5 2.6 2.7 2.8

This is the same 1-to-1 routing as the first example, except doubled-up. The Director and Understudy each have 8 outputs, sending 4 of each to the 2 matrices. In order to delineate between the 2 matrices, which are separate devices in the **Device Manager**, the above **Dot** notation is used. The number before the dot is the matrix's ID, and the number after is the input or output routing number on that specific matrix. The ID number is determined by the order of the matrix-type devices in the device list, starting from the top.

Cascading matrices routing example



Machine	Routing	Routing	Routing	Routing
Director In	1.1 | 2.1	1.2 | 2.2	1.3 | 2.3	1.4 | 2.4

Machine	Routing	Routing	Routing	Routing
Director Out	1.1 |1.2	1.3 | 1.4	2.1 | 2.2	2.3 | 2.4
Understudy In	1.5 | 1.6	1.7 | 1.8	2.5 | 2.6	2.7 | 2.8

This more complex notation is able to send two or more commands for each input or output routing. In this example, a distribution amp or similar is doubling every signal before it reaches the matrices, so each output from Designer reaches more than one matrix at once.

The **Pipe** notation is able to send multiple whole commands per feed output. The order the routing is written in is important: one routing is before the pipe, the other is after. On failover, the understudy would route 1.5 to 1.1 and 2.5 to 2.1 at the same time, and so on.

Note that the Pipe operator requires a space either side of it (`|`), unlike other operators.

This needn't stop at two routings per output; a second pipe can be used if a third matrix needed to be controlled **(1.1 | 2.1 | 3.1)**. The dot notation is also in use because more than one matrix is being controlled. All three - comma, dot and pipe - can be mixed and matched to suit the exact configuration of matrices in use.

Lightware Matrix Setup

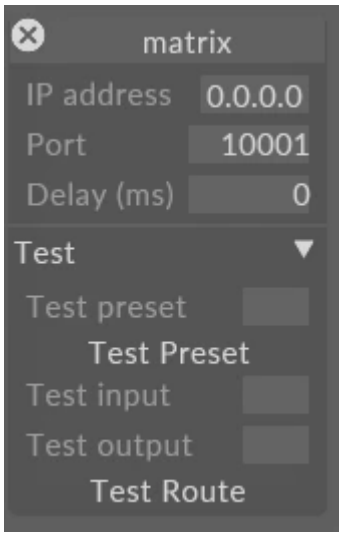
The Lightware Matrix device is designed to be a virtual representation of a physical Lightware Matrix within Designer. It defines how Designer should send messages to this Matrix during failover. It also allows you to send test commands to make sure everything is connected properly. During failover the commands that Designer sends will be determined by the input/output routing configured in the Feed View.

Setting up a Lightware matrix

1. Configure the real Lightware Matrix to be on the same IP network as the Director/Actor network.
2. Choose port `10001` in the real matrix configuration. (Other ports can be used, provided the same port is configured in Designer).
3. In Designer, create a **LightwareMatrix** device. A LightwareMatrix device is created in the same way as any other device type. Please see the Creating devices section for step-by-step instructions on how to create a device, and select **LightwareMatrix** from the menu of different device types. This will open the LightwareMatrix device editor.
4. Configure the LightwareMatrix device to have the correct IP address and Port.
5. Test the connection using the controls in the “Test” section of the LightwareMatrix editor.

Once the device is configured

LightwareMatrix device properties



Lightware Matrix device properties

The LightwareMatrix device has these controls that control it's behaviour on failover:

- **IP Address**: The IP address of the real matrix.
- **Port**: The TCP port number configured in the real matrix. We suggest using `10001`.
- **Delay (ms)**: Number of milliseconds to wait after failover to send the Matrix commands. This can be set higher than 0 to allow for other failover operations to occur before triggering a matrix preset or route switch.

Test

This section allows you to test the Lightware behaviour. Note that the values entered here are not stored between project restarts. There are two ways to test: either send **Preset** commands, or send specific **Routes**. Here we describe these fields:

- **Test Preset**: The index of the preset on the Lightware Matrix to trigger.
  - Test this control by pressing the **Test Preset** button.
- **Test input**: The index of the input to route to the output.
- **Test output**: The index of the output to route the input to.
  - Test this control by pressing the **Test Route** button.

Matrix Switches Overview

Designer can switch presets of various matrices and switchers. Presets can be animated using the MatrixControl layer but in a Director/Actor environment the presets can be changed through an automated process using the d3Net manager.

Which matrix switches are supported?

Designer has built-in drivers for the following matrices and switchers:

- Analog Way OPS300
- Barco MatrixPro
- Barco Encore (External link).
- Blackmagic Smart Videohub
- Gefen Matrix (External Link)
- Lightware Matrix
- Riedel MediorNet Matrix : Communicates with MediorNet systems for routing and management.
- PureLink Matrix : Provides control for PureLink AV matrix devices.
- Telnet Matrix : Generic matrix control using Telnet-based command sets.

Other devices to be controlled

For devices that currently do not have built-in drivers can also send serial commands using the Control layer assuming you first set up the Serial Device.

PureLink Matrix Setup

The PureLink Matrix device provides control for PureLink AV matrix devices in Designer.

Setting up a PureLink matrix

1. Configure the PureLink matrix to the same IP network as the Director/Actor network.
2. Choose **port 23** in the matrix configuration.
3. In Disguise, create a PureLinkMatrix device. A PureLinkMatrix device is created in the same way as any other device type. Please see the Creating devices section for step-by-step instructions on how to create a device, and select PureLinkMatrix from the menu of different device types. This will open the PureLinkMatrix device editor.
4. Configure the PureLink matrix device editor by referring to the device properties below.

Pure LinkMatrix device properties

IP address

The IP address of the matrix.

Port

The TCP port number configured in the matrix. Set it to 23.

Router ID

The ID number set on the matrix.

Test Input

This input allows you to specify a test input.

Test Output

This input allows you to specify a test output.

Test route

Once you have selected a test input & output, click the **Test route** button to confirm whether the routing works.

Riedel MediorNet Matrix Setup

In Designer, the Riedel MediorNet device can be configured to communicate with MediorNet systems for routing and management.

Riedel MediorNet is a real-time media network platform that transports and routes broadcast-quality video, audio, and data signals over a fibre-based infrastructure. It is used in broadcast facilities, stadiums, and live events to create a unified and flexible signal backbone, simplifying signal management and reducing the need for external processing devices. The system is modular and scalable, with a decentralised approach that provides redundancy and low latency.

Setting up a Riedel MediorNet device

Prerequisites

This topic assumes you have already configured the matrix via the Riedel web interface. It is important to enable the Ember+ 3rd Party interface and assign IDs to the inputs and outputs, as these will be the indices used in Designer. Remember to do both **Directions**, **In** and **Out**. For more information, refer to the **Riedel Matrix documentation**.

There is a known limitation where only video channel connections can be modified.

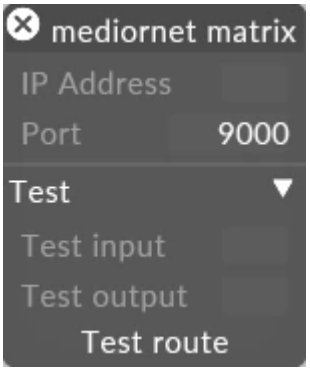
Create the Riedel MediorNet device

- In Designer, create a **MediorNet Matrix** device. A Riedel MediorNet device is created in the same way as any other device type. Please see Creating devices for step-by-step instructions on how to create a device, and select **MediorNet Matrix** from the menu of different device types. This will open the MediorNet Matrix device editor.

Configure TCP-IP control

1. Configure the MediorNet Matrix to the same IP range as the Director/Actor network.
2. Configure the device using the properties contained in the MediorNet Matrix device editor.

MediorNet Matrix device properties



MediorNet Matrix device editor

IP address

The IP address of the matrix.

Port

The TCP port to send commands on. The Ember+ protocol uses port **9000** by default.

Test input

The test input number.

Test output

The test output number.

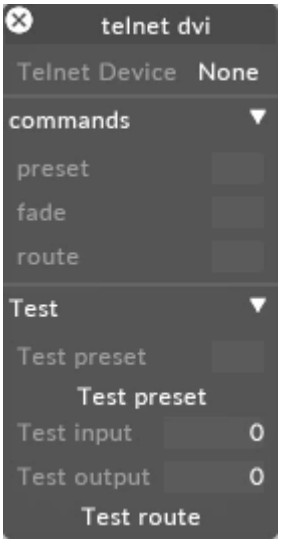
Telnet Matrix Setup

In Designer, the Telnet Matrix device can control any matrices that support Telnet-based commands.

Setting up a TelnetMatrix

- In Designer, create a **TelnetMatrix** device. A TelnetMatrix device is created in the same way as any other device type. Please see Creating devices for step-by-step instructions on creating a device, and select **TelnetMatrix** from the menu of different device types. This will open the TelnetMatrix device editor.

TelnetMatrix device properties



TelnetMatrix device editor

Telnet Device

Defines the Telnet device to send commands to.

Commands

- **Preset** - Defines the command sent for changing a preset.

  This is used in the Failover of the `DVI matrix preset` field is set on a Machine.

- **Fade** - Defines the command sent for executing a fade.

  This is used when triggering a fade via the DVIMatrixControl layer.

- **Route header** - This is data sent as a prefix to the body of the route command.
- **Route** - Defines the body of the route command.

  This is sent when using Direct Routing and Failover.
- **Route footer** - Defines the data sent as a suffix to the body of the route command.

The TelnetMatrix uses the same syntax for the preset, route, and fade commands as the control layer except for the following constants:

- **Preset** : `$1` = preset as ASCII, `%1` = preset as binary
- **Route** : `$1` = input as ASCII, `%1` = input as binary, `$2` = output as ASCII, `%2` = output as binary
- **Fade** : `$1` = transition time as ASCII, `%1` = transition time as binary

When sending a route command, the header is prepended to the data generated by the route command, and the footer is appended to the data.

For example:

- **Route header** = `START\n`
- **Route** = `$1 $2\n`
- **Route footer** = `END\n\n`

When executed with the inputs 1, 2, 3, 4 and outputs 4, 3, 2, 1; the final output would be:

```
START\n
1 4\n
2 3\n
3 2\n
4 1\n
END\n
\n
```

Common strings for TelnetMatrix device

- **Kramer DVI Matrix** - `#35PRST-RCL $1\n`
- **Extron DMS 3600 Matrix** - `$1.`
- **Gefen 8x8 DVIKVM DL** - `#callpreset $1\n` would send `#callpreset 6\n` if you recalled preset 6.

`#doroute $1 $2\n` would send `#doroute` 3 5\n" if you switched input 3 to output 5.

- **Extron Matrix Switcher** - `\27R$1PRST\13\10`

- **Barco Encore2 (E2)** - `PRESET -a $1\r\n`

`ROUTE $1 $2` Where 1 is input, 2 is output.

- **Barco MatrixPro** - `RPRST $1\r`
- **IDK Matrix** - `Preset - @RPM,$1\r\n`

`Route - @IOS,$1,$2\r\n`

> **Note**
>
> **Please note**: Typically, using **\13\10** or **\r\n** (Carriage Return) at the end of a command string is required. More examples of ASCII and Hex command strings can be found here.

Test

This section provides utility functionality for testing the previously defined commands.

- **Test preset** - Enter the preset to test, and click the **Test Preset** button to send a preset command.
- **Test input** - A comma-separated list of inputs for a route command. E.g. `1,2,3,4`.
  It must have the same number of inputs as outputs specified in **Test output**
- **Test output** - A comma-separated list of outputs for a route command. E.g. `4,3,2,1`.
  It must have the same number of outputs as inputs specified in **Test input**

The above example will route input 1 to output 4, 2 to 3, 3 to 2 and 4 to 1.

- **Test Route** - Once the input and output are defined, click the **Test Route** button to test the matrix routing.

MIDI Device

The MIDI Device allows triggering, automation, and control through standard MIDI messages.

Setting up a MIDI device

Designer includes the following pre-built MIDI control surfaces:

- Behringer BCF 2000
- M-Audio Oxygen 8
- M-Audio UC-33

If you wish to use a MIDI control surface other than the ones provided by default, you can use the **MidiDevice** device type to create a virtual replica of the real-world MIDI control surface. This control surface can then be used to send MIDI to and from Designer.

1. Create a **MidiDevice**. A MidiDevice is created in the same way as any other device type. See Creating Devices for step-by-step instructions, then select **MidiDevice** from the menu of different device types. The MidiDevice is initially just a title bar displaying its name as the device currently has no features or properties.

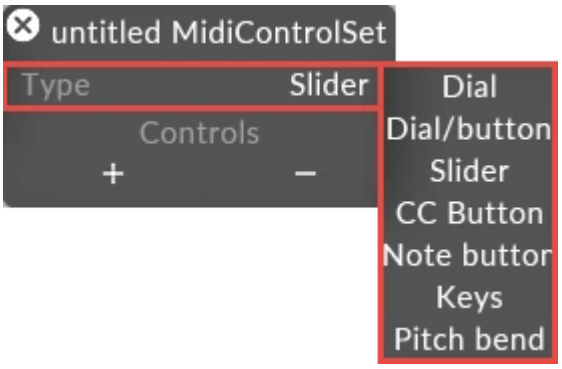
   

   New MidiDevice, in this example Midi_creation; currently the device has no properties.
2. To open the MidiDevice editor, right-click on the title bar and select **edit**. The MidiDevice editor is used to create the MIDI control surface.

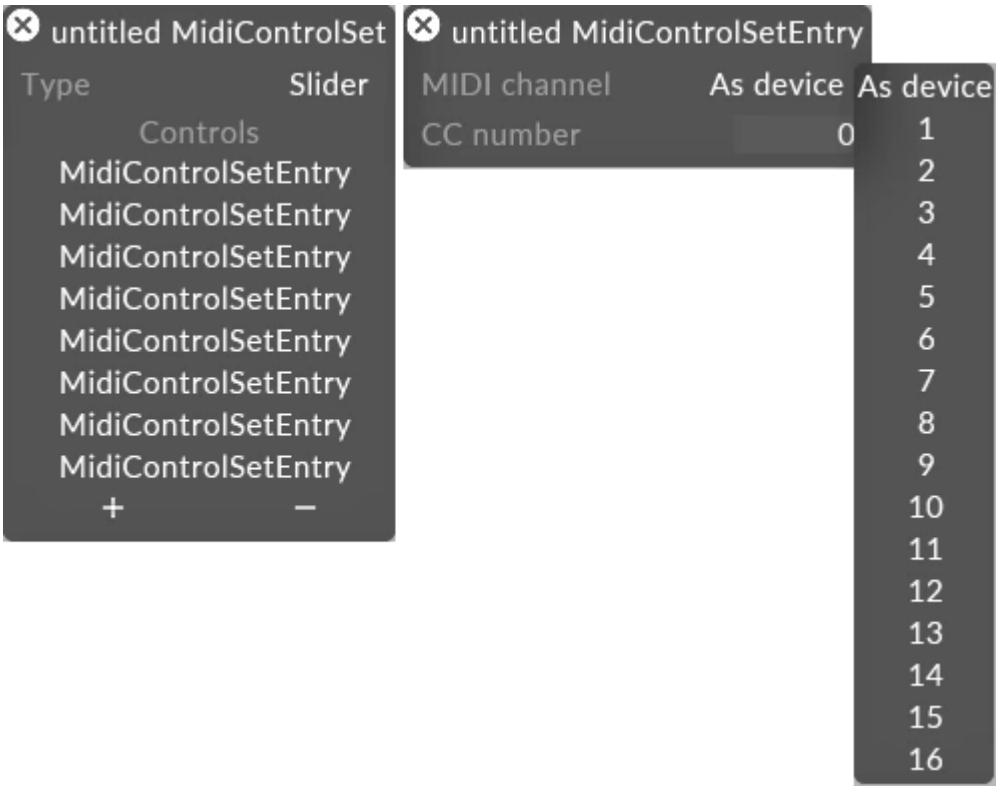
   

3. Set the **midi in/midi out** properties to the appropriate MIDI port. HDSP9632 are the MIDI ports on the RME breakout cable, or AOI Midi on newer systems.

4. Under **control sets**, select the **+** button to open the MidiControlSets manager. The MidiControlSets manager contains a list of all the control sets. Note that Designer comes with a series of control sets by default.
5. To create a new control set, type the control set name into the **newmidicontrolset** text field, in this example **sliders**, and hit **Enter**.

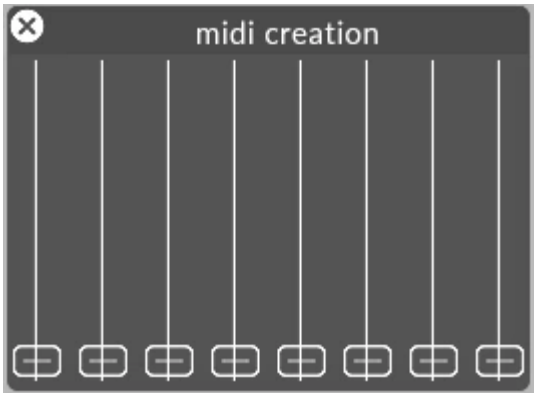


The new control set will be added to the list of control sets in the MidiDevice editor and MidiControlSets manager, and the Control Sets editor will open.



6. To specify the type of control set, right-click **type** and select a control set type from the menu. Options are **dial**, **slider**, **button**, **keys** and **dial/button**. This example uses the **slider** control set type.
7. Select the **+** button to add the desired number of control objects. In this example ten sliders have been created.

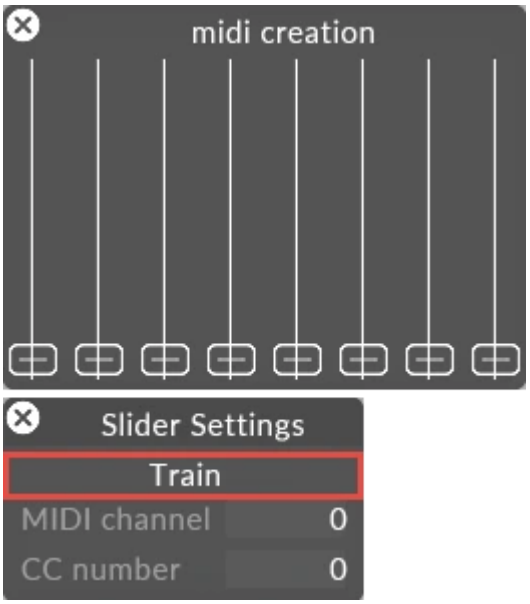
8. Set the **mode** property to **in**, **out** or **bidirectional** depending on how the MIDI data should be sent. **bidirectional** will set the MIDI data to be sent to Disguise as well as from Designer.
9. Repeat the above steps to create the required number of dials/sliders/buttons/keys.
10. Once all of the required controls have been created, close and reopen the MidiDevice by right-clicking the device from the Devices menu. Notice that the MidiDevice is no longer a title bar, but is now a virtual replica of a MIDI control surface.



Assigning controls to a control surface

The next task is to assign the controls to a control surface.

1. To link a control to a control surface, right-click on the specific control, for example **slider 1**.

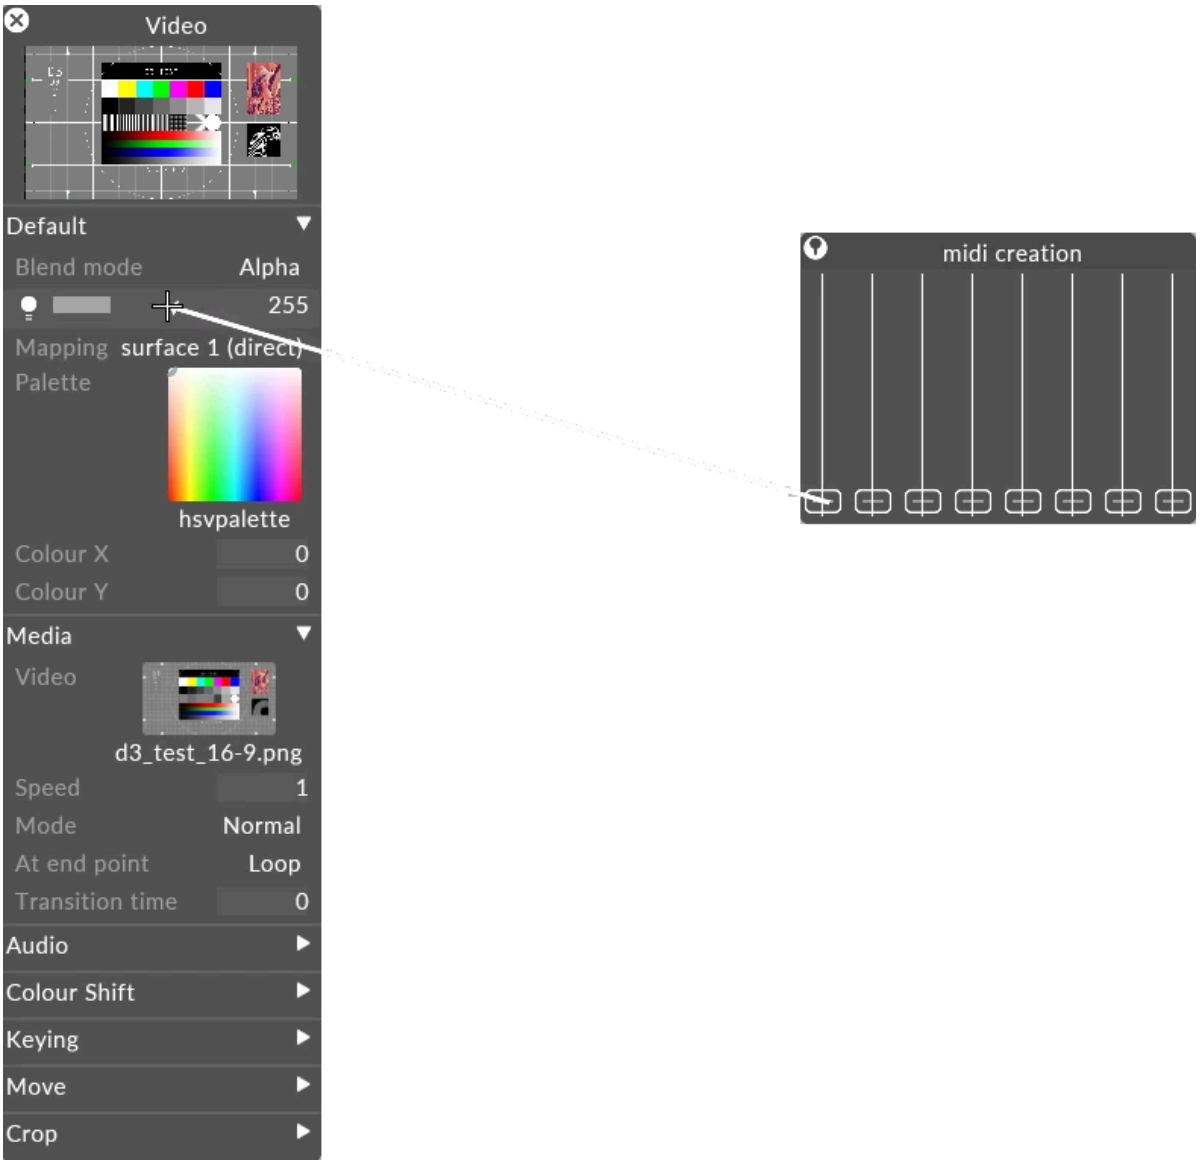


Dial Settings being used to link a control to a control surface, opened by right-clicking on the specific control.

2. Move or change the encoder value on the control surface. Disguise will learn the encoder and store it. Repeat this step for the encoders that are to be used.

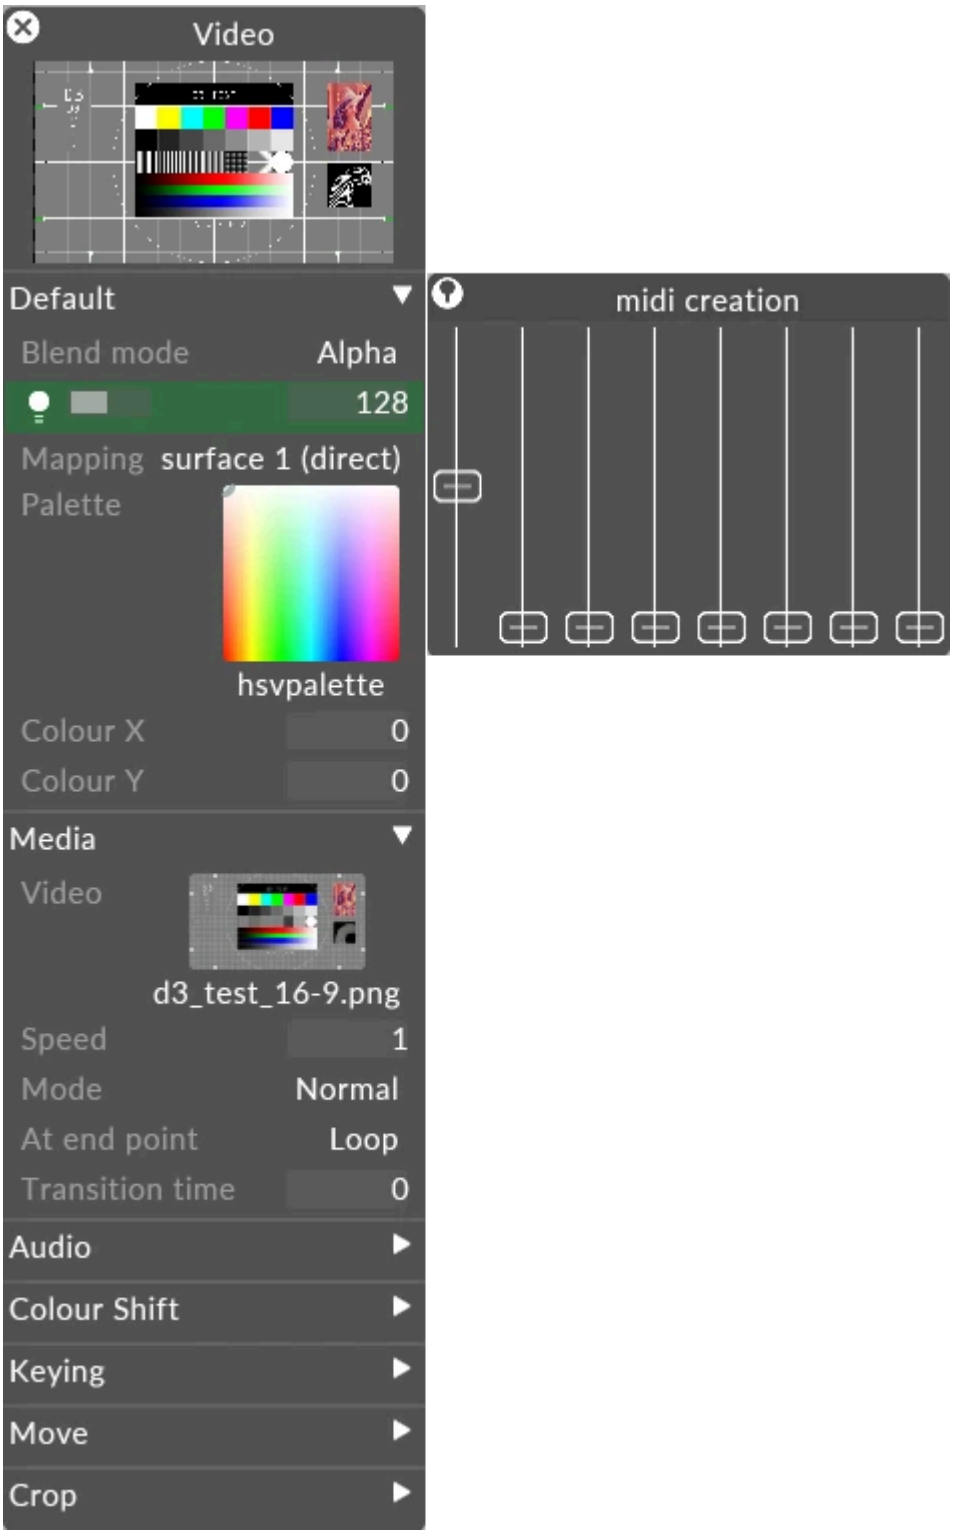
Assign a MIDI control to a layer property

1. Hold **Alt** and left-click and drag from the encoder to a layer property to apply MIDI control to that property. This will draw a white arrow. For more information on Arrows, see [Compositing layers using Arrows](#).



Arrows being used to assign a MIDI control to a layer property.

2. Release the mouse button to assign the encoder to the specific layer property. The layer property will turn green once the link has been successfully created.



The Brightness property of the Colour layer has turned green, indicating that this property has successfully been assigned to a MIDI control.

3. To check the expression that is being used by a layer property, right-click on the specific property. This will open a small editor containing the expression.

For more information on expressions see Expressions.

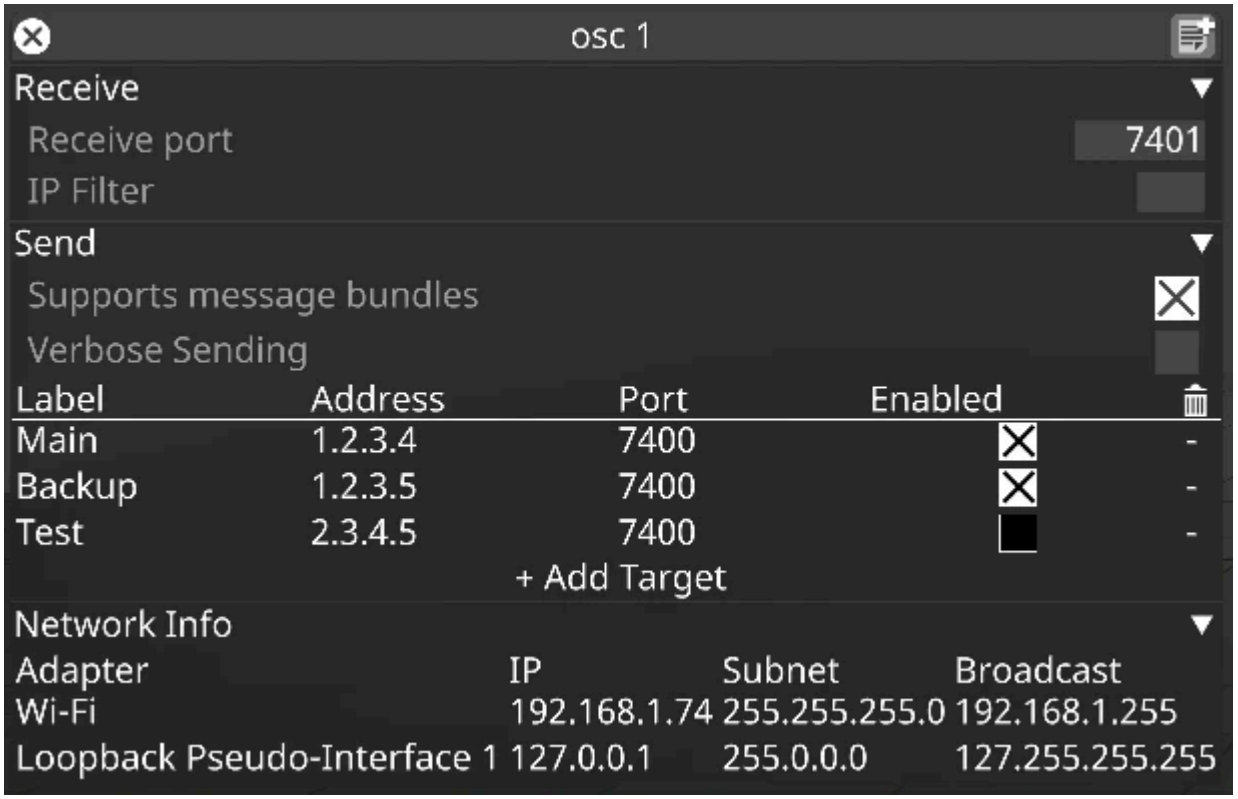
OSC Device

The OSC Device sends and receives Open Sound Control (OSC) messages for flexible, network-based control.

Creating OSC Devices

An OSC Device is created in the same way as any other device type. Please see Creating Devices for step-by-step instructions on how to create a device, and select **OscDevice** from the menu of different device types. Alternatively, by default Disguise contains an OSC Device called `osc 1`, which can be selected from the Devices manager.

OSC Device properties



Receive

The OSC Device can receive incoming messages on one port, from any number of devices.

Receive port

This property specifies the port number for incoming messages. By default this is port 7401.

For more information on setting the IP address, please see Set up IP addresses.

IP Filter

This property filters incoming OSC messages by IP address; if set only messages from the given address will be processed. If left blank no filtering is performed.

Send

The OSC Device can send to any number of devices, which can be specified via the Send Targets widget. Messages are queued and sent once per frame.

Supports Message Bundles

If set, the Device will send all queued messages in one bundle instead of sending them separately.

Verbose Sending

If set, the Device will log every outgoing message to the console. It is recommended that you turn this off for Devices which you expect to send on most or every frame.

Send Targets

This table lets you specify one or more targets to send OSC messages to.

Label

This is a human-readable name for convenience; it is not a hostname and is not used for addressing.

Address

The IP address of the machine to send messages to.

Port

The port of the machine to send messages to. By default this is set to 7400.

Enabled

When checked, this target will be sent messages.

Trash

This column lets you delete a send target from the Device.

Network Info

This table shows the adapter name and IP addresses of all connected Network Interface Cards on the local machine for reference.

OSC Transport Control

For information on how to use OSC expressions on the timeline, see the OSC Transport Control page.

OSC Applications

There are several applications available for iOS that are capable of sending OSC messages. Two applications that we recommend are **Liine by Lemur** and **TouchOSC by hexler.net**.

To download examples of TouchOSC and Lemur layouts, visit the **OSC Downloads** page.

> **Note**
>
> The sliders within the TouchOSC application are set as float values between 0 and 1.

Controlling layer properties with OSC

For information on how to use OSC expressions to control layer properties please see the Controlling layer properties with OSC page.

Example Workflow

Setting up a device to control Disguise through OSC

1. Download the example Lemur layout from the **Disguise Resources** page.
2. Download the Lemur application to the iPhone device that will be sending commands to Designer.
3. Import the Lemur layout to your iPhone. If you are using a Mac computer you can AirDrop the layout to the iPhone and it will automatically import to Lemur. Otherwise, you can do it manually from the Lemur app settings.

4. If you are using a Disguise server, configure your network settings to assign the IP of the server the OSC device will send commands to. If you are using a Designer machine, you can have it connected to a WiFi connection.
5. Run your Disguise project.
6. Right-click on the Devices editor.
7. Press the + icon to create a new device, or to add the default loaded `osc 1` device.
8. Right-click on the device name to open its network configuration settings.
9. Under the Send tab, add a Send Target for Disguise to send commands to. In the Lemur application, this IP can be accessed through the app's settings as the "Lemur IP".
10. In the Lemur settings, set the OSC host as the IP address of your machine. This will be reflected under the Adapter tab in the OSC device window.
11. Under the Receive tab's Port field, assign the port number the Lemur app will send commands to. This is the number reflected in the Lemur OSC settings.
12. Toggle an OSC command from the Lemur profile to see if the OSC device indicator turns green. That will verify the connection has been made.
13. You can also create an OSC Tester device linked to your OSC device to verify the connection has been made.

OSC Machine Control Setup

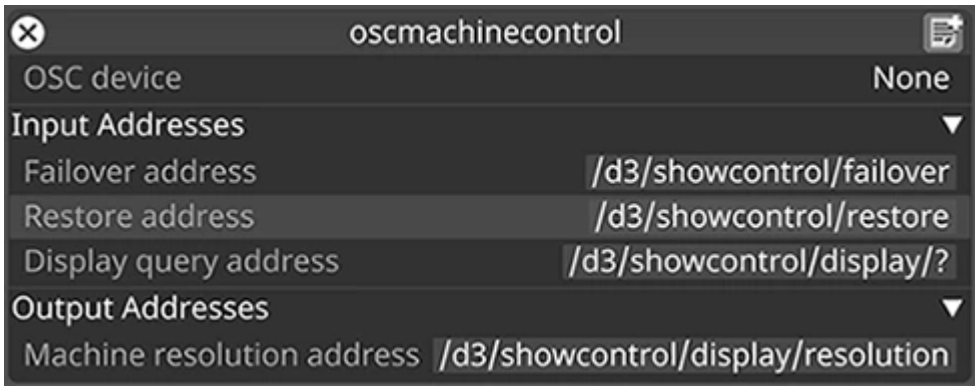
The OSCMachineControl device allows restart and shutdown commands to be sent to Designer from an external OSC device.

This topic outlines the setup steps for the OSCMachineControl device, which is used for remote failover and restore of machines using OSC commands.

Setting up OSC Machine Control

1. Create an OSC device from the device manager — see OSC Device for details.
2. Create an OSCMachineControl device from the device manager.
   - Set the OSC device to an existing OSC device (or create a new one).
   - Configure the input and output message strings to your preferences, or use the default strings.
   - The exports will be written to the output folder of the project folder.
3. Send values from the OSC device to remotely trigger a machine restart or shutdown.

OSC Machine Control properties



OSC Device

Defines the OSC device that the commands will be sent to and from.

Input Addresses

Failover address

Causes a machine failover. Accepts a string parameter — the machine host name that should be failed over.

Restore address

Restores a machine from failover. Accepts a string parameter — the machine host name that should be restored.

Display query address

The string used to query display resolutions using the machine name.

Output Addresses

Machine resolution address

The string used to define the response to the Display query, with two integer values for x and y resolution. For example:

```
/d3/showcontrol/display/resolution/myMachine/0/0 1920 1080
```

OSC Tester Device

OSC Tester is a device that allows users to test incoming and outgoing OSC messages from Designer. It exists as a standard device.

Creating a new device

1. Right-click devices from the dashboard. This will open the Device Manager, which contains a list of active devices.
2. Select + to open the Device library. This lists which internal or external devices are available.
3. Type in the name of the new device into the new device text field.
4. Hit Enter. This will open a list of device types available in Designer.
5. Select the appropriate device type.

The new device will be added to the Device Manager's active device list, and to the Device library. The device's editor will also open.

[Animated GIF: Creating a device]

> **Note**
>
> Always right-click on the **default** device object to add devices to it. If left-clicking you will be prompted to create a whole new device manager which is rarely required.

Testing incoming messages

1. Set the OSC device to be the OSC device you are expecting to received messages from.

2. Set the Receive address filter, if you wish to filter only specific OSC messages.
3. Send the values from the OSC device.
4. Values received should be shown in the Received Messages area at the bottom of the widget.

Testing sending messages

1. Set the OSC device to be the OSC device you are expecting to send messages to.
2. Set the message limit, or use the default setting.
3. Define the OSC string by typing it into the **OSC Message** field.
4. Send the values to the OSC device by clicking **OK**.

Camera Tracker Observations Tester

The **Camera Tracker Observations Tester** is designed for validating and troubleshooting observation data received from external camera-tracking systems.

It allows you to view, inspect, and verify the positional and rotational data being sent into Disguise, ensuring the information is accurate and updating as expected.

Uses

This tool is especially useful when:

- Integrating a new tracking system.
- Diagnosing issues with unstable or incorrect tracking data.
- Confirming that observations are arriving on the correct port or data channel.
- Reviewing how real-time camera motion is being interpreted by Disguise.

By monitoring the incoming data, you can quickly identify configuration errors, malformed observations, or inconsistencies that may affect virtual camera alignment, AR workflows, or xR calibration.

Driver Properties

Observation

Selects which observation packet to read from the tracking system.

Source Camera

The target camera that will receive pose updates from the observation.

View

Identifies which view index the data belongs to (e.g., stereo left/right, multi-camera setups).

Developer Documentation

Camera Tracker Tester

The CameraTrackerTester driver is a type of PositionDriver that can be used to simulate camera tracking data. The Camera Tracker Tester is useful whenever you need to simulate or prototype a camera-tracking workflow without a physical tracking system connected. It allows you to drive a virtual camera using the position and movement of another camera in the scene.

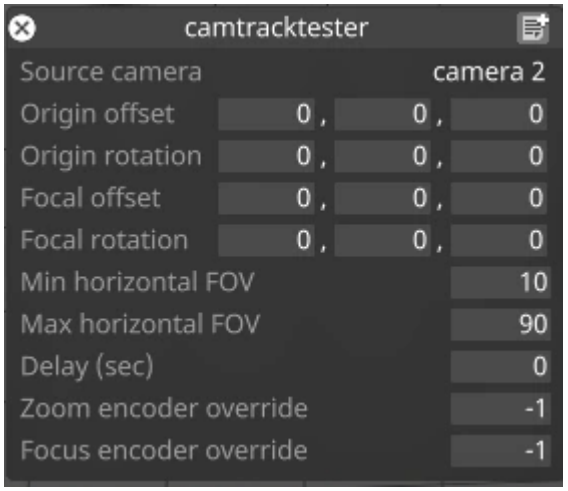
Uses

This tool is especially helpful when:

- Testing camera-tracking behaviour before hardware is available.
- Prototyping AR, xR, or virtual production setups in an offline environment.
- Validating how positional or rotational offsets affect the final camera output.
- Simulating tracking latency using adjustable delays.
- Developing or tuning workflows for zoom/focus response without requiring real encoder data.
- Demonstrating camera-tracking behaviour in training or educational environments.

By simulating tracking output from another camera in the Stage view, the Camera Tracker Tester provides a safe and convenient way to experiment with tracking behaviour, understand FOV dynamics, and fine-tune camera behaviour before integrating real-world tracking hardware.

Driver Properties



Source camera

Camera used as the source of the positional data.

Origin Offset/Rotation

Offset/Rotation to be applied to the source camera's position.

Focal offset/Rotation

Offset/Rotation to be applied to the camera's focal plane.

Min/Max Horizontal FOV

Min/Max values of the range used to scale the camera's FOV.

Delay (sec)

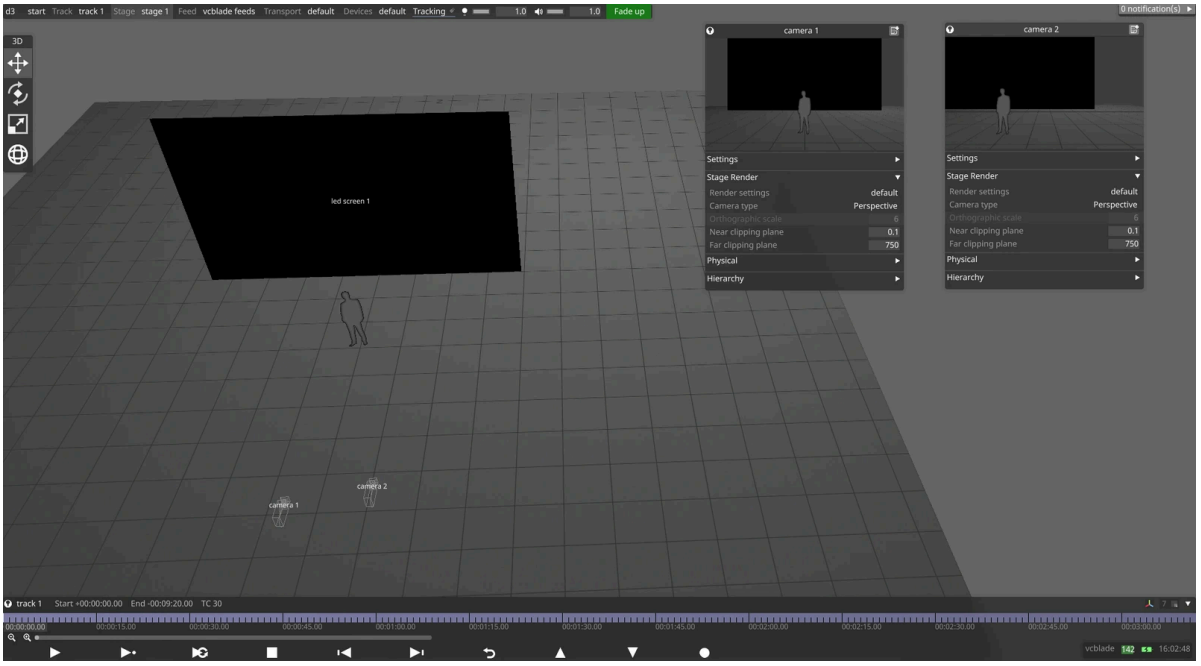
Artificial delay time that can be added to the source camera tracking data.

Zoom/Focus Encoder Override

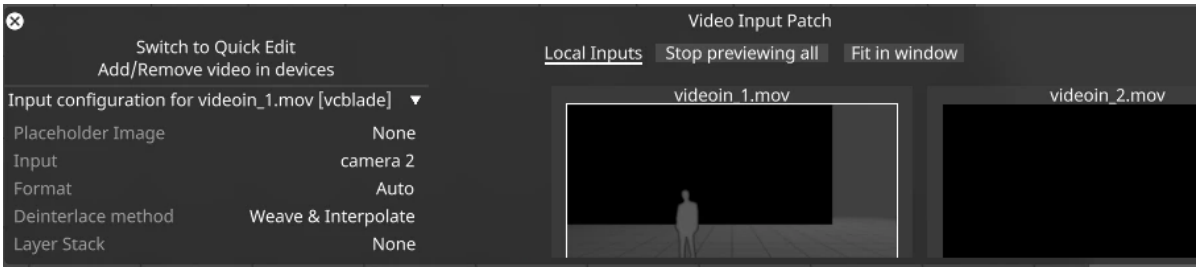
Overrides for the Zoom/Focus encoder value.

Setup a Camera Tracking Simulation

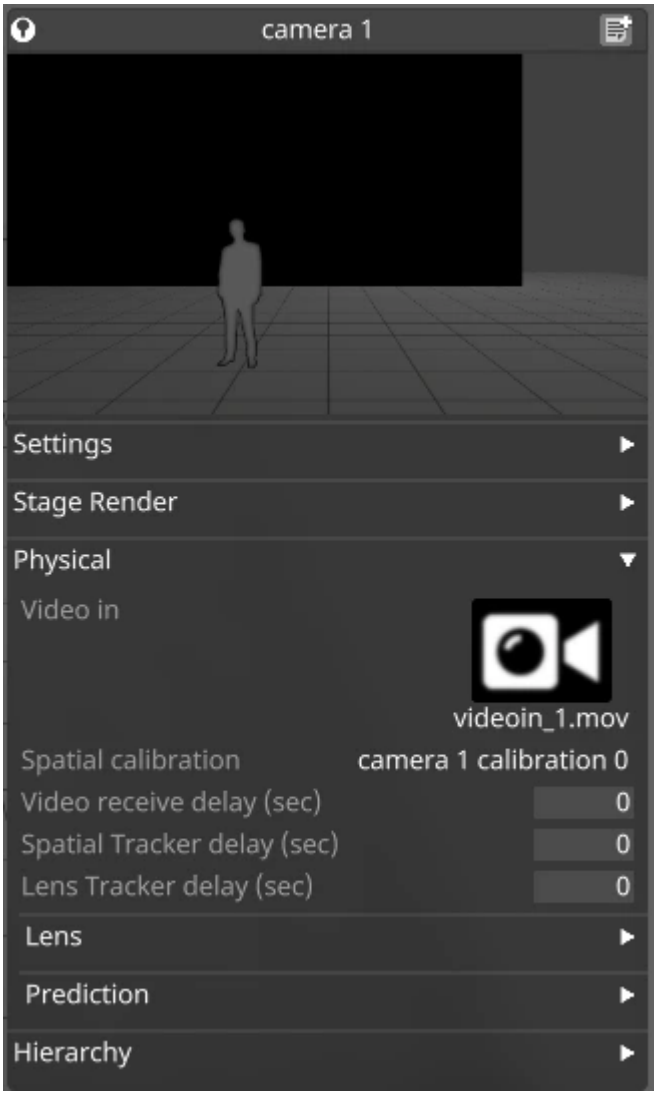
1. Create two new cameras in the Stage menu; camera 2 will be used to represent the camera tracking system that sends tracking data to camera 1.



2. Open the **Video Input Patch Editor**.
3. Patch Camera 2 to an empty video input (the image below shows Camera 2 mapped to video input 1).



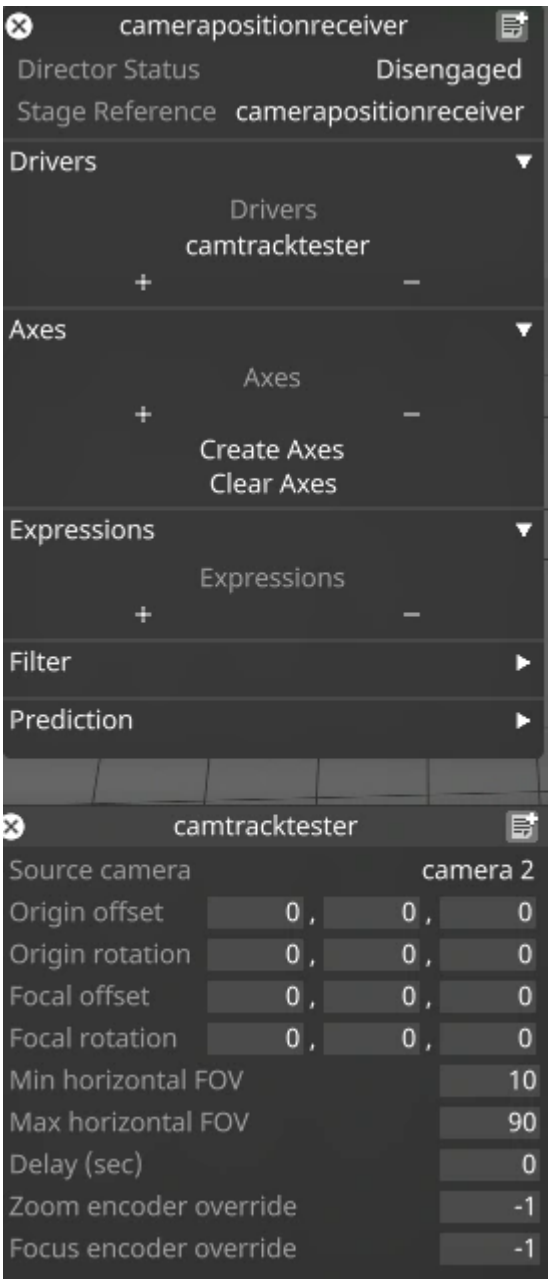
4. Open the camera 1 properties menu, expand the Physical tab, and assign the **Video in** field to **videoin_1.mov**. You should now see the output of camera 2 within the camera 1 preview thumbnail.



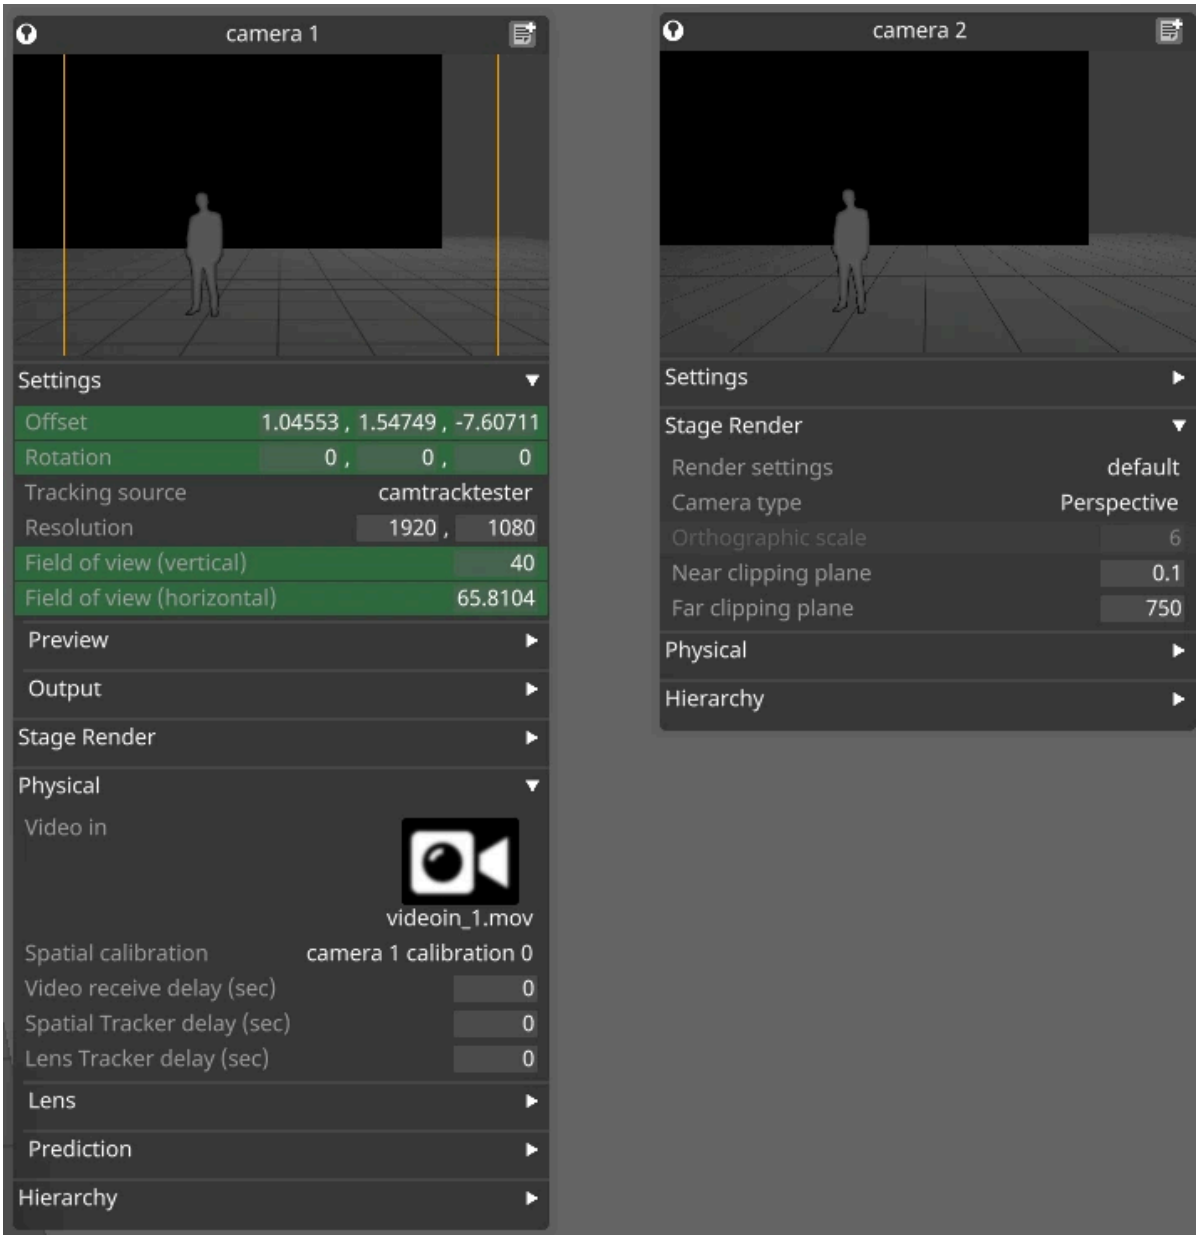
5. Open the Devices menu and add a new **PositionReceiver Device**.

6. Add a new driver to the and choose the PositionReceiver Device from the list of Position Drivers.

7. Assign the source camera for the CameraTrackerTester to Camera 2.



8. Return to the properties menu of Camera 1 and in the **Tracking source** field, assign the **CameraTrackerTester** as the source. The Offset, Rotation, and Fields of view will now appear green.



9. Now, as you move Camera 2 in the Stage view, Camera 1 will automatically track along.

Developer Documentation

CPS Driver

The **CPS Driver** receives automation data from systems that communicate using the **CPS protocol**. CPS is used by certain motion-control and automation devices to send positional or status information that can drive content alignment or provide positional feedback inside Disguise.

In most cases, the default driver settings are sufficient. Only adjust these settings if your automation network requires specific ports, multicast addressing, or IP filtering.

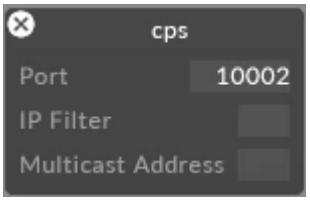
Uses

Use the CPS Driver when your production involves:

- **Automation devices or controllers** that output motion or position data using the CPS protocol
- **Synchronising content** with real-world movement such as lifts, winches, or tracked scenic elements
- **Triggering timeline behaviour** based on machine motion
- **Monitoring automation positions** directly inside Disguise
- **Lightweight motion feeds** where only core positional or state data is needed

CPS is commonly used in installations or productions requiring simple, reliable position updates.

Driver Properties



This driver listens on UDP port **10002** by default.

Port

The UDP port on which the driver receives data. Set this to match the port configured on the sending device or controller.

IP filter *(optional)*

Restricts incoming data to a specific source **IP address**. Useful when several sources are present on the network, or to isolate a single sender. Leave blank to accept data from any IP.

Multicast address *(optional)*

The multicast group address used by your system. Only required when the sender is configured for multicast — enter the exact multicast address used by the emitter. Leave empty for unicast or broadcast configurations.

Developer Documentation

D3SSI Driver

The **D3SSI Driver** receives encoder position data over the D3 Synchronised System Interface (D3SSI) protocol. The protocol carries a `MessageFromEncoder` packet — Designer consumes the **angle** field (mod 1800°) as a single position axis.

In most setups, the default driver settings are sufficient. Only adjust these values if your system or network has been configured differently.

Uses

Use this driver when:

- Integrating a D3SSI-compatible rotary encoder into a Disguise workflow.
- Driving content alignment, screen positioning, or stage automation from a single rotary axis.
- Working within installations or productions that standardise on the D3SSI protocol.
- Testing or validating D3SSI-based data streams within a controlled environment.

Driver Properties

This driver listens on UDP port **8989** by default.

Port

The UDP port on which the driver receives data. Set this to match the port configured on the sending device or controller.

IP filter *(optional)*

Restricts incoming data to a specific source **IP address**. Useful when several sources are present on the network, or to isolate a single sender. Leave blank to accept data from any IP.

Multicast address *(optional)*

The multicast group address used by your system. Only required when the sender is configured for multicast — enter the exact multicast address used by the emitter. Leave empty for unicast or broadcast configurations.

Developer Documentation

DCS Driver

The **DCS Driver** receives automation data from systems that communicate using the DCS protocol.

It allows Disguise to interpret incoming positional and control information so it can be used within automation workflows.

In most instances, the driver requires minimal configuration, but settings may need adjustment depending on the controller or network setup being used.

Uses

This driver is especially useful when:

- Integrating hardware that outputs DCS-formatted tracking or sensor data.
- Receiving positional information from external controllers.
- Feeding real-time sensor values into Disguise for automated behaviour.
- Testing, validating, or monitoring DCS data streams during setup.
- Working with systems that require minimal-latency UDP-based communication.

Driver Properties

Port

The UDP port on which the driver receives data. Set this to match the port configured on the sending device or controller.

IP filter *(optional)*

Restricts incoming data to a specific source **IP address**. Useful when several sources are present on the network, or to isolate a single sender. Leave blank to accept data from any IP.

Multicast address *(optional)*

The multicast group address used by your system. Only required when the sender is configured for multicast — enter the exact multicast address used by the emitter. Leave empty for unicast or broadcast configurations.

Sensor Width

Defines the physical width of the sensor (in millimetres).

This value is used by the system to correctly interpret incoming DCS data based on the sensor's real-world dimensions.

Developer Documentation

DMX Screen Position Driver

The **DMX Screen Position Driver** receives positional values over DMX to drive screen or object movement within Disguise. Each value is read from a specific universe and channel, then decoded according to the selected encoding format.

This allows Disguise to interpret multi-byte DMX data as signed or unsigned integers for use in automation workflows.

Uses

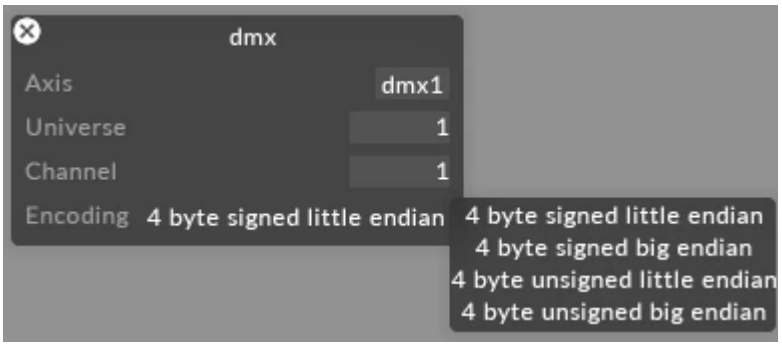
The **DMX Screen Position Driver** is used to translate incoming DMX values into positional information that can influence screens, objects, or stage elements inside Disguise. It enables DMX-based control systems or lighting consoles to send movement data directly into an automation workflow.

This driver is especially useful when:

- Integrating DMX motion controllers or lighting consoles with Disguise.
- Driving real-time movement of screens or scenic elements.
- Receiving multi-byte positional data over DMX.
- Monitoring or testing incoming DMX values during setup.
- Creating hybrid workflows where lighting desks send positional cues.

By selecting the correct encoding type, the driver accurately converts raw DMX bytes into usable positional values.

Driver Properties



Axis

User defined axis name.

Universe

The universe address of the automation system.

Channel

The channel address of the automation system.

Encoding

Determines how the incoming DMX bytes are interpreted and converted into a numerical value. Choose the encoding type that matches the format used by your DMX controller or automation system.

4-byte Signed (Little Endian)

Reads 4 bytes **from right to left** (least significant byte first).
Range: **-2,147,483,648** to **2,147,483,647**

4-byte Signed (Big Endian)

Reads 4 bytes **from left to right** (most significant byte first).
Range: **-2,147,483,648** to **2,147,483,647**

4-byte Unsigned (Little Endian)

Reads 4 bytes **from right to left** (least significant byte first).
Range: **0** to **4,294,967,295**

4-byte Unsigned (Big Endian)

Reads 4 bytes **from left to right** (most significant byte first).
Range: **0** to **4,294,967,295**

Developer Documentation

EzDriver

The **EzDriver** enables Disguise to receive automation data from systems using the EZ protocol.

It provides a simple interface for accepting positional or control values, allowing them to be used within Disguise's automation workflows. In typical installations, the default driver settings are sufficient, and adjustments are only required when working with custom network or device configurations.

Uses

This driver is especially helpful when:

- Receiving continuous positional or parameter data from EZ-compatible hardware.
- Integrating lightweight tracking devices or controllers that output EZ protocol messages.
- Monitoring real-time value changes from external systems for use in automation.
- Testing or validating EZ data streams during setup or troubleshooting.
- Building custom automation workflows that require low-latency UDP-based communication.

Driver Properties

Port

The UDP port on which the driver receives data. Set this to match the port configured on the sending device or controller.

IP filter *(optional)*

Restricts incoming data to a specific source **IP address**. Useful when several sources are present on the network, or to isolate a single sender. Leave blank to accept data from any IP.

Multicast address *(optional)*

The multicast group address used by your system. Only required when the sender is configured for multicast — enter the exact multicast address used by the emitter. Leave empty for unicast or broadcast configurations.

Packet Timing Graph

Enables logging of incoming packet timing to a graph.

This is primarily a diagnostic tool used to analyse data rate stability or troubleshoot irregular packet delivery from EZ protocol devices.

This tool helps with troubleshooting EZ device connectivity, and verifying consistent UDP transmission.

Developer Documentation

FreeD Driver

The **FreeD Driver** allows Disguise to receive positional and rotational camera-tracking data using the FreeD protocol.

FreeD is widely used in broadcast, virtual production, and augmented reality environments to transmit real-time camera movement information.

The driver enables Disguise to interpret this data and apply it to virtual cameras or automation workflows.

In most setups, the default driver configuration is sufficient. Adjust settings only when integrating hardware that uses custom ports, addressing, or communication parameters.

Uses

The **FreeD Driver** is used whenever Disguise needs to receive real-time camera tracking information from FreeD-compatible systems. It provides a direct way to map physical camera movement into the virtual scene.

This driver is especially useful when:

- Integrating broadcast camera-tracking systems that output FreeD.
- Driving virtual cameras in AR, xR, or virtual studio environments.
- Synchronising live camera movement with 3D content.
- Receiving lens parameters such as zoom, focus, or FOV.
- Testing or validating FreeD data streams during setup or troubleshooting.
- Working in mixed reality workflows where low-latency positional tracking is required.

By interpreting positional and rotational data accurately, the FreeD Driver helps ensure real-world camera motion aligns correctly with virtual content.

Driver Properties

> **Note**
>
> FreeD devices generally transmit data over UDP. Only a small number of user-facing settings are required for successful communication.

Port

The UDP port on which the driver receives data. Set this to match the port configured on the sending device or controller.

IP filter *(optional)*

Restricts incoming data to a specific source **IP address**. Useful when several sources are present on the network, or to isolate a single sender. Leave blank to accept data from any IP.

Multicast address *(optional)*

The multicast group address used by your system. Only required when the sender is configured for multicast — enter the exact multicast address used by the emitter. Leave empty for unicast or broadcast configurations.

Enable packet timing graph

Logs the timing of incoming packets to a graph in the monitoring manager. Useful for diagnosing latency or dropped packets during setup or troubleshooting.

Developer Documentation

HMC Driver

The **HMC Driver** receives axis position data from systems using the **Hudson Motion Control (HMC)** protocol, originally developed for Hudson scenic and stage automation systems. The protocol (header `HATx`) can carry position, speed, motor-status, and cues-running information — Designer consumes only the position value for each axis.

In most cases, the default settings are suitable; adjustments are only required when your automation system or network uses non-standard ports, IP filters, or multicast addressing.

Uses

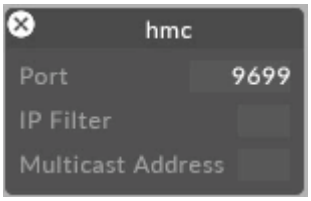
The **HMC Driver** is used when Disguise needs to receive axis position data from hardware that transmits using the HMC protocol. It enables real-time positional input from Hudson-style automation systems, which can be mapped to PositionAxis objects to drive content alignment or screen positioning.

This driver is particularly useful when:

- Integrating Hudson-controlled scenic automation hardware into a Disguise workflow.
- Receiving continuous axis position updates over UDP.
- Driving content alignment or screen positions from real-world stage motion.
- Monitoring or validating HMC data during setup or troubleshooting.

As HMC is lightweight and network-friendly, it is well suited for real-time automation where consistent, low-latency position updates are essential.

Driver Properties



This driver listens on UDP port **9699** by default.

Port

The UDP port on which the driver receives data. Set this to match the port configured on the sending device or controller.

IP filter *(optional)*

Restricts incoming data to a specific source **IP address**. Useful when several sources are present on the network, or to isolate a single sender. Leave blank to accept data from any IP.

Multicast address *(optional)*

The multicast group address used by your system. Only required when the sender is configured for multicast — enter the exact multicast address used by the emitter. Leave empty for unicast or broadcast configurations.

Developer Documentation

Kinesys Driver

Kinesys is a motion control system that provides **six axes of freedom** (X, Y, Z translation and X, Y, Z rotation). It sends positional and rotational data over the network to Disguise using the **UDP protocol**.

Designer supports both **Vector** & **K2** products.

> **Important**
>
> Ensure that your system is connected to the Kinesys controller via a **network switch or direct connection**.
>
> Routing through a firewall or router may cause data loss, latency, or inconsistent behaviour.

Uses

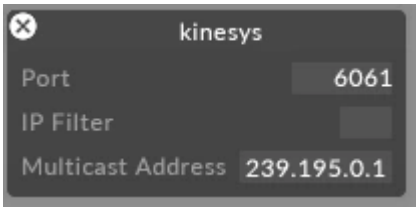
The **Kinesys Driver** is used to receive real-time motion data from Kinesys motors and controllers, allowing physical movement to drive automation or virtual objects inside Disguise. This enables seamless synchronisation between real-world rigging systems and virtual or media-driven elements.

This driver is especially useful when:

- Integrating Kinesys motion systems with virtual production or stage automation.
- Synchronising physical movement (hoists, trusses, screens) with media playback.
- Visualising real-world Kinesys motion in real time within Designer.
- Creating interactive or reactive environments that depend on live motor positions.
- Testing and validating axis behaviour before committing to full show programming.
- Monitoring Kinesys data streams during installation, rehearsal, or operation.

By receiving engine and parameter data directly from K2 or Vector, the driver allows each axis of a Kinesys system to be mapped to corresponding screen or object movement inside Disguise.

Driver Properties



This driver listens on UDP port **6061** by default.

Port

The UDP port on which the driver receives data. Set this to match the port configured on the sending device or controller.

IP filter *(optional)*

Restricts incoming data to a specific source **IP address**. Useful when several sources are present on the network, or to isolate a single sender. Leave blank to accept data from any IP.

Multicast address *(optional)*

The multicast group address used by your system. Only required when the sender is configured for multicast — enter the exact multicast address used by the emitter. Leave empty for unicast or broadcast configurations.

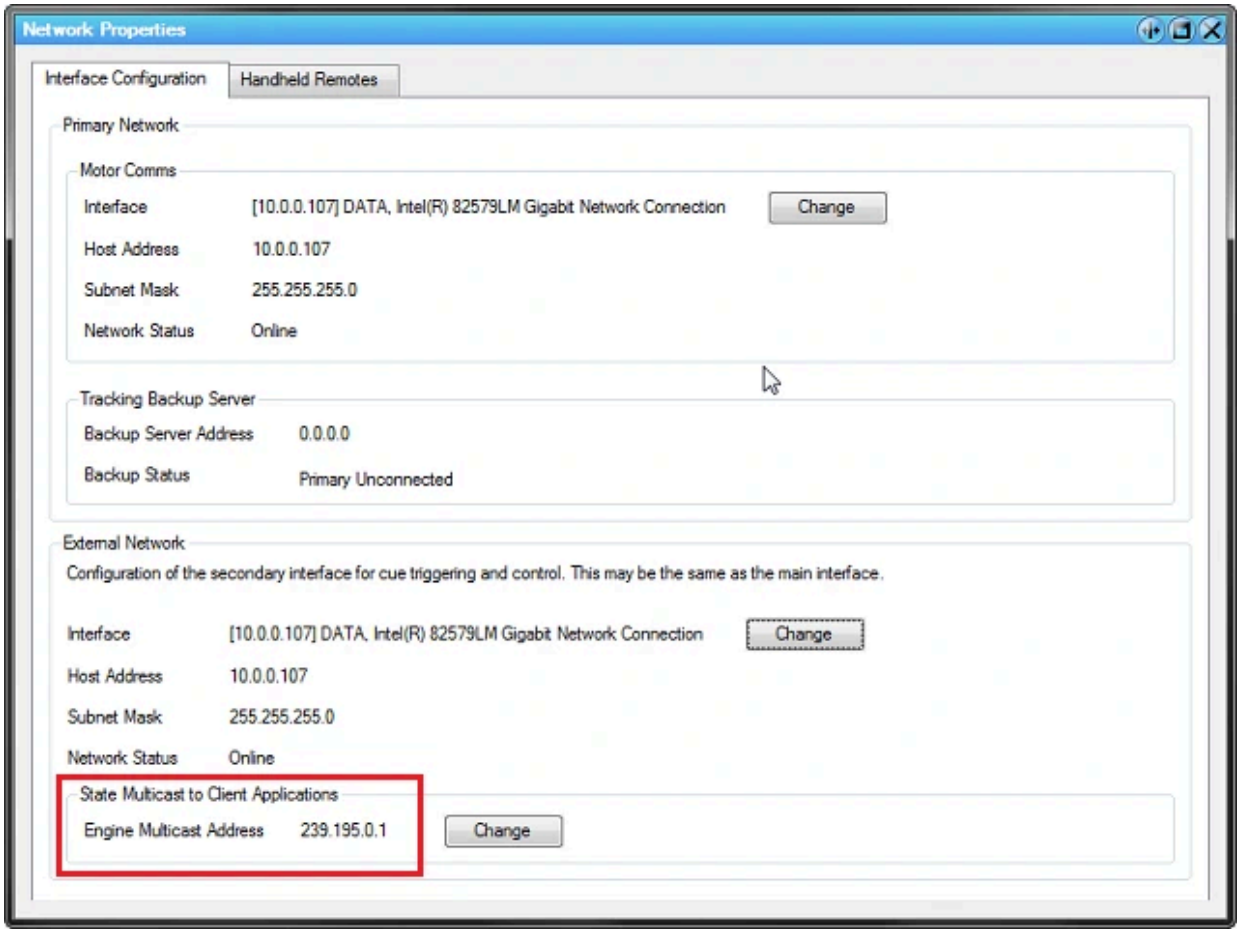
Finding Multicast and Parameter Addresses in Kinesys K2

Outside of Disguise, use the **K2 software** to locate the engine multicast address and parameter addresses. If you are unfamiliar with the K2 interface, consult your Kinesys representative or operator.

Engine Multicast Address

This is the address used by K2 to broadcast positional data.

It appears in the K2 interface as shown below:

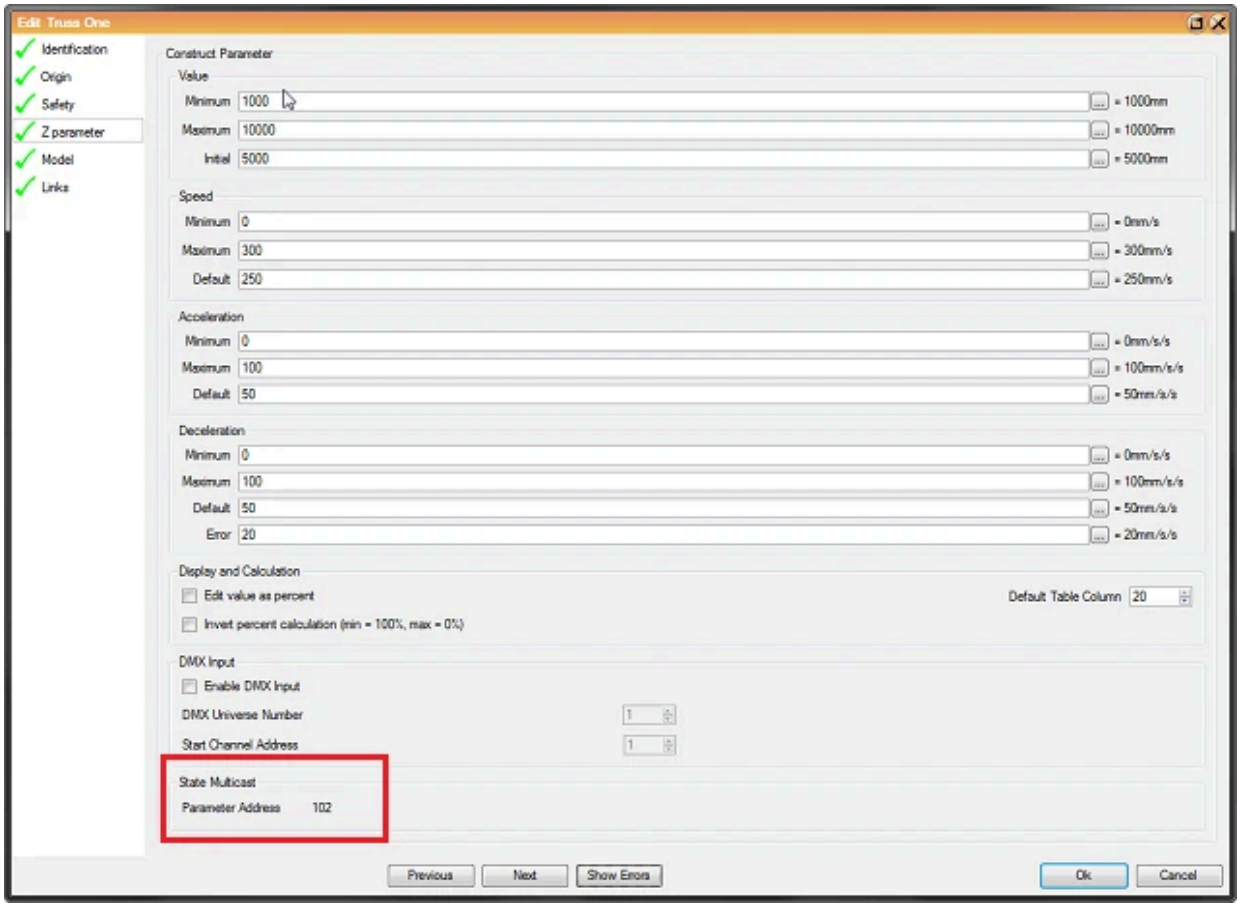


The Engine Multicast Address is highlighted in the red rectangle.

Parameter Address

Each motion parameter (e.g., X, Y, Z, rotation axes) has an individual **parameter address**.

This acts as the data identifier for each axis.



The Parameter Address is highlighted in the red rectangle.

Configuring the Kinesys Driver in Disguise

1. Enter the **Engine Multicast Address** into the **Multicast address** field of the Kinesys Driver.
2. Create a **ScreenPositionAxis** object for each axis you wish to control (e.g., Position X, Rotation Z). See Creating PositionAxis objects for more information.
3. Copy the **K2 Parameter Address** for each parameter and paste it into the **id** field of the corresponding ScreenPositionAxis.

Developer Documentation

LCPUSB Driver

> ⚠ **Specialist driver — limited support**
>
> The **LCPUSBDriver** is provided for specialist USB-based hardware integration and falls outside Disguise's generally-supported driver set. For new productions, we recommend using a network-based driver where possible.

The **LCPUSBDriver** is used to receive automation data from LCPUSB-compatible hardware connected directly to the machine via USB. This driver listens to data transmitted by the device and converts it into automation values that can be used within Disguise. As the driver handles USB communication directly, it does **not** require any network configuration such as ports, IP filters, or multicast settings.

In most cases, the default settings provide stable operation. Adjustments should only be made when working with custom hardware behaviour or filtering requirements.

Uses

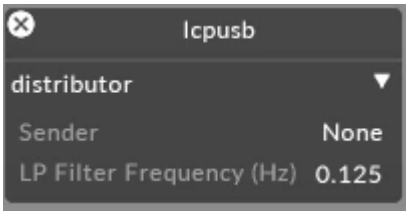
Use the **LCPUSBDriver** when working with automation devices that communicate directly over USB rather than through a network connection. The driver reads positional, sensor, or control data from LCPUSB-compatible hardware and makes those values available inside Disguise for automation, logic, or interactive behaviours.

This driver is especially useful when:

- Connecting USB-based motion controllers, sensors, or custom hardware interfaces.
- Receiving low-latency data from devices that do not support network protocols.
- Prototyping or testing custom automation hardware in a controlled environment.
- Integrating compact or embedded microcontroller devices into automation workflows.
- Applying smoothing to noisy signals using the built-in low-pass filter.
- Ensuring stable communication when working without network infrastructure.

As LCPUSB communicates directly via USB, it is ideal for setups where reliability, simplicity, or portability is required—such as laboratory environments, small installations, or rapid prototyping workflows.

Driver Properties



Sender

Displays the **active USB device** acting as the data source.

If no compatible LCPUSB device is connected, this field will show **None**.

Select the appropriate device from the dropdown if multiple supported devices are available.

LP Filter Frequency (Hz)

Applies a **low-pass filter** to the incoming automation data.

Use this to smooth noisy or rapidly fluctuating values from the hardware device.

- Higher values → less smoothing, faster response

The default value is suitable for most workflows, but it can be tuned depending on the behaviour of the connected hardware.

Developer Documentation

LDS Driver

The **LDS Driver** allows Disguise to receive camera and lens metadata such as **aperture** or **focus distance** from ARRI cameras that support the **Lens Data System (LDS)** — part of ARRI's Electronic Control System. LDS-capable lenses report their current settings to the camera body, which can then forward that data onto the network for Disguise to consume.

For the current list of LDS-compatible cameras and lenses, see the **ARRI Lens Data System FAQ**.

Designer supports LDS protocol versions **1.02** and **1.03**. Note that while the LDS protocol can carry a lot of additional camera and lens metadata, the Disguise LDS Driver currently exposes only the following features:

- focal length and the encoder zoom position value
- aperture, but not the encoder iris value
- focus distance and the encoder focus value

In Designer the LDS Driver is a **position driver** — it is configured inside a Position Receiver device rather than as a standalone device.

Uses

Use the LDS Driver when:

- Synchronising a Disguise virtual camera's aperture and focus distance to a live ARRI camera.
- Driving depth-of-field and focus effects on a virtual camera from the physical lens.
- Recording live aperture/focus-distance values alongside content for post-production reference.

Workflow

1. Connect your ARRI camera's LDS output to the Disguise machine so that lens data can be received on the network.
2. In Designer, add a **Position Receiver** device.
3. Inside the Position Receiver, add a new driver and select **LdsDriver**.
4. Configure the driver properties below to match your camera and network setup.
5. Map the incoming values (aperture, focus distance) to the axes or virtual camera parameters that need to track them. See Creating Driver Axes for how to wire the data through.

Driver Properties

This driver listens on UDP port **5432** by default.

Port

The UDP port on which the driver receives data. Set this to match the port configured on the sending device or controller.

IP filter *(optional)*

Restricts incoming data to a specific source **IP address**. Useful when several sources are present on the network, or to isolate a single sender. Leave blank to accept data from any IP.

Multicast address *(optional)*

The multicast group address used by your system. Only required when the sender is configured for multicast — enter the exact multicast address used by the emitter. Leave empty for unicast or broadcast configurations.

Sensor width (mm)

The camera sensor's width in millimetres.

Set this to match your camera body's sensor size so that the driver can interpret incoming LDS values correctly.

Open Tracking Sources

Configure or inspect the camera tracking data source.

Developer Documentation

Mo-Sys F4 Driver

The **Mo-Sys F4 Driver** is used to receive camera tracking data from Mo-Sys F4 systems.

This driver integrates directly with the Mo-Sys tracking workflow to provide real-time positional and rotational camera information for use in Disguise's virtual production, xR, and AR environments.

Most installations work reliably using the default settings. Adjust the driver properties only when working with multi-camera setups or when your Mo-Sys system requires specific configuration.

Uses

Use the Mo-Sys F4 Driver when receiving live camera tracking data from Mo-Sys F4 systems for virtual production, xR, and broadcast environments. The driver provides a direct link between the physical camera and Disguise, ensuring accurate alignment between real-world camera movement and virtual scene elements.

This driver is especially useful when:

- Integrating Mo-Sys F4 camera tracking for AR graphics, virtual studios, or xR workflows.
- Synchronising real camera movement with virtual content, environments, or set extensions.
- Working with multiple tracked cameras, each requiring unique identifiers.
- Calibrating or validating Mo-Sys positional and rotational data within Disguise.
- Ensuring lens and camera motion is correctly interpreted for real-time rendering.
- Monitoring tracking performance during live production or rehearsal.

The Mo-Sys F4 Driver allows Disguise to interpret incoming tracking data with minimal configuration, making it suitable for both high-end broadcast installations and flexible real-time production setups.

Driver Properties

This driver listens on UDP port **8051** by default.

Port

The UDP port on which the driver receives data. Set this to match the port configured on the sending device or controller.

IP filter *(optional)*

Restricts incoming data to a specific source **IP address**. Useful when several sources are present on the network, or to isolate a single sender. Leave blank to accept data from any IP.

Multicast address *(optional)*

The multicast group address used by your system. Only required when the sender is configured for multicast — enter the exact multicast address used by the emitter. Leave empty for unicast or broadcast configurations.

Enable packet timing graph

Logs the timing of incoming packets to a graph in the monitoring manager. This is useful for diagnosing latency or dropped packets.

Developer Documentation

MoveAI Driver

The **MoveAI Driver** integrates real-time markerless motion-capture data from MoveAI systems into Disguise.

MoveAI generates high-quality skeletal tracking data using computer vision, allowing performers' movements to drive virtual characters, animation systems, and automation workflows within a Disguise project.

The driver provides controls for how Disguise interprets and visualises incoming skeletal data, including optional automatic creation of tracked points for each joint.

The workflow includes configuring the **Position Receiver** device and adding a **Position Driver > MoveAI**.

Uses

Use the **MoveAI Driver** when bringing MoveAI's markerless performance capture into Disguise for real-time animation, visualisation, or interactive control.

This driver is especially useful when:

- Driving **virtual characters** or digital doubles using live performer movement.
- Controlling **scene objects, effects, or logic** with joint-based motion.
- Integrating MoveAI tracking into **AR, xR, or virtual production** workflows.
- Previewing live skeletal poses inside Disguise during rehearsal or setup.
- Creating interactive systems where body motion triggers events or behaviours.
- Recording movement sequences for Previz or real-time playback.

MoveAI's skeletal data is well-suited for high-precision movement, full-body performance capture, and real-time character animation.

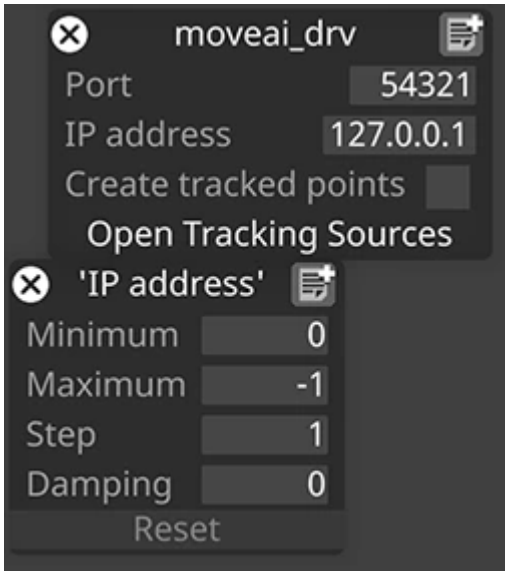
Workflow

Connecting MoveAI to Disguise involves both Designer-side and MoveAI-side configuration:

1. **Add a** Position Receiver device in Disguise.
2. **Add a MoveAI Position Driver** to the Position Receiver — select **MoveAI** from the driver picker.
3. **Configure the driver** — see Driver Properties below.
4. **Configure MoveAI** — in MoveAI Studio/Live, enable network streaming, set the **Destination IP** to the Disguise machine, and ensure the **output port** matches the **Port** property below.

5. **Verify the connection** — check the Position Receiver status to confirm packets are arriving. With **Create tracked points** enabled, skeleton joints appear in the Stage tree and update in real time.

Driver Properties



Port

Default: **54321**

The UDP network port on which Disguise receives MoveAI skeleton data.

This must match the port configured in the MoveAI streaming settings.

IP address

Specifies the **source IP address** of the MoveAI system streaming skeletal data.

Set this if you want to filter incoming data to a specific device — leave blank to accept data from any IP on the network.

Create tracked points

When enabled, Disguise automatically creates a **Tracked Point** for every joint in the MoveAI skeleton.

This allows you to:

- View and inspect each joint position directly within Disguise.
- Reference individual joints in **automation**, **logic**, or **timeline** sequence.

- Drive scene objects, alignment markers, or VFX elements based on skeletal data.
- Visualise the entire body structure within the stage environment.

Disable this option if:

- You only need body-level/global movement.
- You want to reduce scene clutter.
- You want to optimise performance for complex scenes.

Open Tracking Sources

These settings define how incoming tracking values are processed before being applied to axes or objects.

IP address

Specifies which MoveAI source IP is used for this tracking entry.

Minimum / Maximum

Sets the **input value range** used to normalise incoming motion data.

Useful when calibrating individual joints or limiting movement ranges.

Setup

Configures the **initial alignment** or offset between the incoming data and your scene setup.

Damping

Reduces sudden or rapid movements by applying smoothing to the incoming data.

Useful for stabilising jittery joint motion.

Developer Documentation

Movecat Driver

The **Movecat Driver** receives automation data from Movecat motion control systems. Movecat systems are commonly used for stage hoists, kinetic movement, and automation elements that require precise positional and motion feedback. The driver allows Disguise to receive real-time movement data over the network and use it to drive automation axes within a project.

In most installations, the default driver settings are sufficient. Configuration changes should only be made if your Movecat system uses custom network parameters or you need to limit incoming data to a specific device.

Uses

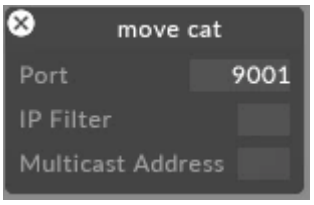
Use the Movecat Driver when integrating Movecat motion control systems with Disguise to synchronise real-world movement with virtual or media-driven elements. Movecat systems provide precise positional and motion feedback from hoists, winches, and kinetic stage machinery, allowing Disguise to react dynamically to physical movement in real time.

This driver is especially useful when:

- Receiving live positional data from Movecat hoists, trolleys, or kinetic systems.
- Synchronising virtual objects or content with physical scenic movement.
- Visualising real-world motion inside Designer for alignment, rehearsal, or pre-programming.
- Driving automation axes based on continuous movement feedback.
- Monitoring multiple Movecat devices during complex motion cues.
- Ensuring media, lighting, and virtual elements track accurately with stage automation.

Thanks to Movecat's reliable high-frequency updates, the driver is well-suited for productions requiring smooth, accurate motion synchronisation between physical and virtual systems.

Driver Properties



This driver listens on UDP port **9001** by default.

Port

The UDP port on which the driver receives data. Set this to match the port configured on the sending device or controller.

IP filter *(optional)*

Restricts incoming data to a specific source **IP address**. Useful when several sources are present on the network, or to isolate a single sender. Leave blank to accept data from any IP.

Multicast address *(optional)*

The multicast group address used by your system. Only required when the sender is configured for multicast — enter the exact multicast address used by the emitter. Leave empty for unicast or broadcast configurations.

Developer Documentation

NatNet Driver

The **NatNet Driver** receives real-time tracking data from OptiTrack systems using the NatNet protocol. NatNet is a widely used motion-capture streaming API that transmits rigid body positions, markers, skeletons, and metadata over a network for use in virtual production, xR, and real-time environments.

The driver allows Disguise to subscribe to an OptiTrack server and stream incoming tracking data directly into your project. Most setups require only the correct multicast address and data port, while additional connection information helps verify communication and server status.

Uses

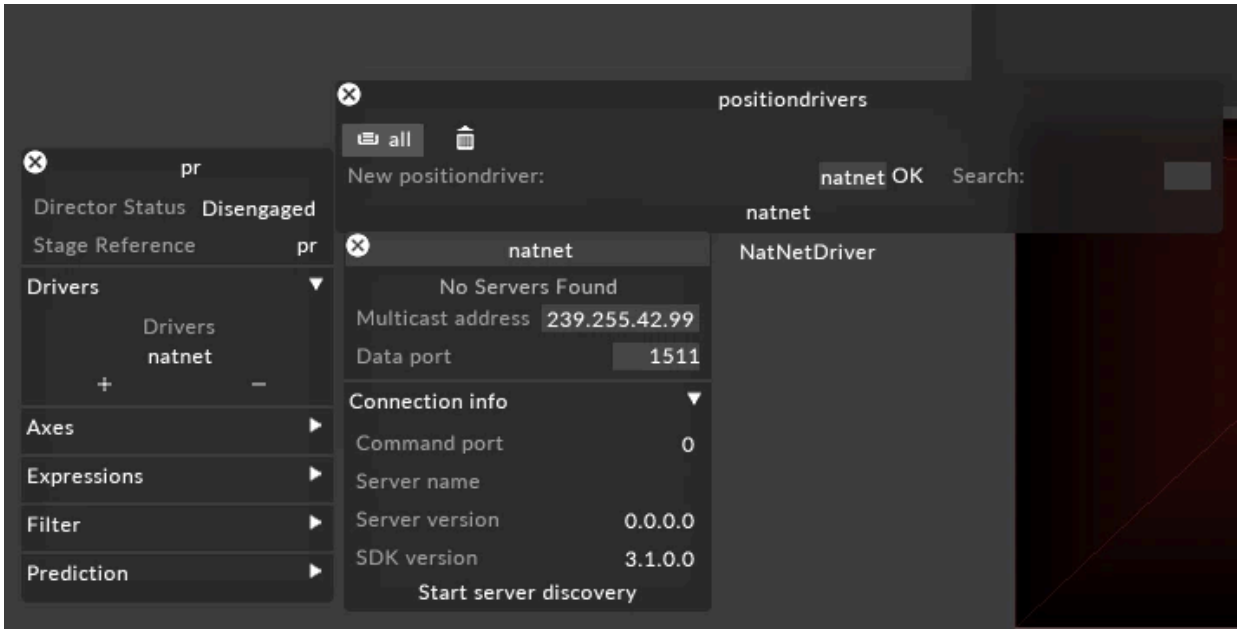
Use the NatNet Driver when integrating OptiTrack motion-capture data into Disguise for virtual production, xR workflows, or real-time automation. The driver streams rigid body tracking data directly from Motive, allowing virtual objects, cameras, characters, or environments to follow real-world motion with high precision.

This driver is especially useful when:

- Bringing OptiTrack rigid body tracking into virtual production or xR scenes.
- Driving virtual cameras using motion-capture camera rigs.
- Tracking performers, props, or handheld objects for real-time interaction.
- Synchronising physical motion with 3D environments or media playback.
- Testing or validating NatNet streaming using Motive's live mocap data.
- Monitoring server connection details (versions, ports, discovery status) to ensure stable network communication.

As NatNet supports high-frequency, low-latency data streaming, this driver is well suited for fast, precise tracking where real-world motion must match virtual content accurately.

Driver Properties



Multicast Address

Specifies the **multicast group address** from which NatNet tracking data is received.

This should match the multicast address set in your OptiTrack Motive configuration.

Data Port

The **UDP port** on which NatNet sends its motion data stream.

Ensure this matches the “Data Port” configured in Motive.

Connection Info

This section displays diagnostic information about the connection between Disguise and the NatNet server.

- **Command Port** — The port used for command/control communication with the NatNet server.
- **Server Name** — The name of the connected Motive/OptiTrack server.
- **Server Version** — The NatNet server version currently in use.
- **SDK Version** — The NatNet SDK version supported by the driver.
- **Start Server Discovery** — Initiates a scan to automatically detect available NatNet servers on the network.

Use this information to verify that Disguise is correctly connected to your OptiTrack system and running compatible versions of Motive/NatNet.

Developer Documentation

Navigator Driver

The **Navigator Driver** receives axis data from FTSI Navigator motion control systems.

Navigator sends real-time positional and velocity information over UDP, which Disguise converts into automation axes. The driver requires the incoming data to follow a specific packet structure to ensure correct parsing and axis updates.

Uses

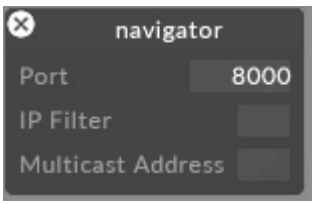
Use the Navigator Driver when integrating FTSI Navigator motion control systems with Disguise. The driver converts real-time positional and velocity data into automation axes, allowing physical movement to drive virtual objects, scenic elements, or synchronised media playback.

This driver is especially useful when:

- Receiving live axis data from FTSI Navigator-controlled winches, hoists, or tracked systems.
- Synchronising virtual objects or content with physical stage machinery.
- Visualising Navigator motion data inside Designer for rehearsal or alignment.
- Driving complex automation behaviours based on continuous motor position and velocity.
- Testing or validating Navigator output formatting during setup or troubleshooting.
- Handling multi-axis systems where several motion channels are streamed in a single packet.

As Navigator supports high-frequency updates, this driver is well suited for accurate, real-time motion tracking in media-driven or interactive production environments.

Driver Properties



This driver listens on UDP port **8000** by default.

Port

The UDP port on which the driver receives data. Set this to match the port configured on the sending device or controller.

IP filter *(optional)*

Restricts incoming data to a specific source **IP address**. Useful when several sources are present on the network, or to isolate a single sender. Leave blank to accept data from any IP.

Multicast address *(optional)*

The multicast group address used by your system. Only required when the sender is configured for multicast — enter the exact multicast address used by the emitter. Leave empty for unicast or broadcast configurations.

FTSI Navigator UDP Packet Format

Designer requires the Navigator system to send data in a specific format. Each axis should send data in the following format.

```
ID:POS,VELOCITY;
```

ID = Axis ID

POS = Axis position as a floating point number

VELOCITY = Axis velocity as a floating point number

Example (single axis)

```
1:-24.034,1.323;
```

Example (multiple axes in a single message)

Navigator messages may contain multiple axis entries in sequence:

```
ID:POS,VELOCITY;ID:POS,VELOCITY;ID:POS,VELOCITY;.....
```

```
1:-24.034,1.323;2:5.346,12.098;3:9.064,2.511;
```

> ⚠ **Warning**
>
> A common formatting mistake is omitting the **final semicolon**.
>
> If the last `;` is missing, the final axis entry **will not be processed** by Disguise.

Developer Documentation

Ncam Driver

The **Ncam Driver** receives real-time camera tracking data from an Ncam system.

Ncam is widely used in virtual production, AR, and broadcast environments to provide high-precision positional, rotational, and lens metadata.

The driver connects directly to the Ncam server using the configured IP address and port, translating incoming data into automation values within Disguise.

The driver also includes diagnostic tools to help monitor packet timing and assess the health of the network data stream.

Uses

Use the **Ncam Driver** when you need to bring real-time camera tracking information from an Ncam system into Disguise. This enables virtual cameras, AR graphics, and xR scenes to remain perfectly aligned with the physical camera.

This driver is particularly useful when:

- Integrating Ncam tracking for **AR**, **xR**, or **virtual studio** productions.
- Receiving **positional, rotational, and lens metadata** from the Ncam server.
- Ensuring accurate spatial alignment between real and virtual cameras.
- Monitoring the performance and stability of the tracking data stream.
- Diagnosing issues such as packet loss, jitter, or inconsistent update rates.
- Synchronising tracked camera movement with realtime content playback.

Whether you are using Ncam for high-end real-time rendering or simple alignment tasks, the driver provides a direct and reliable link between Ncam hardware and Disguise.

Driver Properties

IP address

Specifies the **IP address** of the Ncam server supplying tracking data.

This must match the address configured on the Ncam system.

Port

The **Port** used by Ncam to transmit tracking data to Disguise.

Set this to the same port number configured in the Ncam server settings.

Enable packet timing graph

Enables detailed logging and visualisation of incoming packet timing.

Useful for diagnosing:

- dropped or delayed packets
- inconsistent tracking data
- network jitter
- timing irregularities in the data stream

When enabled, Disguise displays a timing graph to assist with troubleshooting.

Developer Documentation

NG360 Driver

The **NG360 Driver** receives automation data from NG360 encoder devices.
These devices typically provide rotational or positional encoder values that can be used to drive automation axes inside Disguise. The driver supports both standard network configuration and additional NG360-specific properties used to identify the encoder, define the serial communication port, and manage axis distribution.

Most installations operate correctly with the default configuration. Update the settings only when your NG360 device is using custom addressing or connected via a specific COM port.

Uses

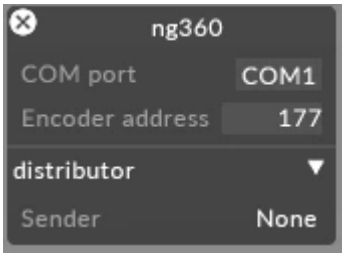
Use the NG360 Driver when integrating NG360 encoder hardware that outputs precise rotational or positional data for automation workflows inside Disguise. NG360 devices are commonly used in mechanical systems, robotics, motion rigs, optical encoders, and installations requiring accurate real-time movement tracking.

This driver is especially useful when:

- Receiving continuous encoder values for driving automation axes.
- Synchronising virtual objects or content with physical rotation or motion.
- Monitoring encoder behaviour during rehearsal, calibration, or system testing.
- Differentiating between multiple NG360 devices through unique encoder addresses.
- Using serial-connected NG360 units when working without network infrastructure.
- Creating feedback-driven systems where encoder movement influences logic or scene behaviour.
- Controlling or validating mechanical movement in interactive or media-driven installations.

As NG360 devices deliver highly stable encoder readings, this driver is well suited for workflows that require precise rotation, incremental motion tracking, or synchronisation between physical hardware and virtual content.

Driver Properties



Network Properties

Port

The **UDP port** on which NG360 data is received.

Modify this if your encoder system broadcasts on a non-default port.

IP Filter *(optional)*

Limits incoming data to a specific **source IP address**.

Useful when multiple devices are broadcasting on the same network or to ensure data is received only from the intended encoder.

Multicast Address *(optional)*

The **multicast group** from which NG360 data is transmitted.

Set only if your system is explicitly configured for multicast routing.

NG360-Specific Properties

Encoder Address

Identifies the encoder address that this driver instance should listen to.

Use this when multiple encoders are active or when addressing is required to differentiate units on the network.

COM Port

Specifies the **serial COM port** used by the NG360 device when connected locally.

Required when the NG360 encoder communicates via USB/serial rather than over the network.

Distributor

Controls how incoming NG360 encoder data is routed to automation axes inside Disguise.

In most cases, the default option (**None**) is sufficient and passes values directly to the configured axes.

Some versions of the interface may display a **Sender** field, which represents the internal routing method used by the distributor.

If **None** is the only available option, no alternative routing modes are supported for this driver.

Use this setting only when working with advanced setups that require custom routing or value distribution.

Developer Documentation

OSC Driver

The **OSC Driver** receives Open Sound Control (OSC) messages from external devices or applications and converts them into automation values within Disguise. OSC is a flexible, network-based protocol widely used in show control, lighting, interactive media, audio systems, and real-time visual environments.

The driver exposes two key properties: the OSC device that provides the messages, and an optional address filter that determines which OSC messages should be processed.

Uses

Use the OSC Driver when you need to bring real-time OSC messages into Disguise to control automation axes, trigger behaviours, or drive interactive elements. OSC is a flexible protocol used across creative, live, and interactive industries, making this driver ideal for workflows that rely on external systems sending numerical or event-based data.

This driver is especially useful when:

- Driving automation axes from software such as TouchDesigner, Max/MSP, QLab, Unreal, Unity, Ableton, or other OSC-capable tools.
- Triggering cues, animations, or logic events through OSC messages.
- Integrating interactive installations where sensors, cameras, or custom scripts output OSC.
- Bridging media servers, lighting consoles, sound systems, or control devices into Disguise.
- Prototyping and testing real-time data streams without specialised hardware.
- Filtering and routing OSC messages when multiple devices share the same OSC network.

As OSC supports arbitrary data structures and address paths, the driver is well-suited for custom workflows, creative prototyping, and interactive designs where flexible control is required

Driver Properties

OSC Device

Selects the **OSC device** that Disguise should listen to.

This may represent:

- A software source (e.g., TouchDesigner, QLab, Max/MSP, Unreal).
- A hardware controller that outputs OSC messages.
- Any OSC-capable system configured as a sender.

Disguise will receive all messages routed from the chosen device, subject to the address filter.

Address Filter

Allows you to specify the **OSC address path prefix** for messages Disguise should process.

- Enter the OSC address *excluding the axis name*.
- Leave this field **empty** to receive **all OSC messages**.

Examples:

- `/d3/oscspr/`
- `/stage/pos/`
- `/camera/zoom/`

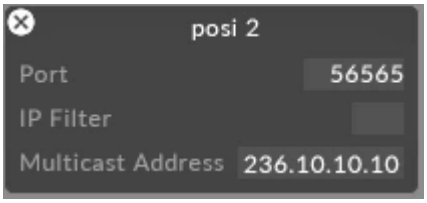
This filter is useful for isolating a subset of OSC messages when multiple systems or scripts share the same OSC network.

Developer Documentation

PosiStageNet Driver

The **PosiStageNet (PSN) Driver** receives real-time positional data transmitted using the PosiStageNet protocol.
PSN is a widely adopted standard in the live events and motion control industry, providing accurate 3D position and velocity data for automation, tracking, and synchronisation workflows. Disguise uses this information to drive automation axes, track objects, or integrate motion data into virtual production environments.

Most installations function correctly with the default configuration. Adjust network settings only if your PSN system uses custom addressing or multiple tracking devices operate on the same network.



Uses

Use the PosiStageNet (PSN) Driver when integrating real-time positional data from motion tracking systems that support the PSN protocol. PSN provides precise 3D coordinates and velocity information, making it ideal for synchronising virtual objects, media, or automation with physical movement on stage.

This driver is especially useful when:

- Tracking performers, props, cameras, or scenic elements in live events.
- Synchronising virtual production or xR environments with real-world movement.
- Controlling automation axes using continuous 3D positional data.
- Integrating tracking workflows from systems such as BlackTrax, Stype, zactrack, or any PSN-capable emitter.
- Driving interactive or reactive content that needs to follow real-time stage positions.
- Aligning lighting, visuals, or projection-mapped elements with tracked objects.
- Monitoring, testing, or validating incoming PSN data streams during setup or calibration.

As PSN is highly accurate and low-latency, it is widely used across touring productions, installations, theatres, broadcast studios, and virtual production stages where motion-to-media synchronisation is essential.

Driver Properties

This driver listens on UDP port **56565** by default.

Port

The UDP port on which the driver receives data. Set this to match the port configured on the sending device or controller.

IP filter *(optional)*

Restricts incoming data to a specific source **IP address**. Useful when several sources are present on the network, or to isolate a single sender. Leave blank to accept data from any IP.

Multicast address *(optional)*

The multicast group address used by your system. Only required when the sender is configured for multicast — enter the exact multicast address used by the emitter. Leave empty for unicast or broadcast configurations.

Developer Documentation

Posital Driver

The **Posital Driver** receives data from Posital encoders, supporting multiple encoder inputs through polling and network communication. Posital encoders are commonly used for motion tracking, position feedback, and automation workflows requiring precise rotational or linear encoder measurements.

The driver allows configuration of encoder lists, polling intervals, timestamp behaviour, and debugging options. It also provides functions for adding and removing encoders dynamically.

Driver Properties

Bridge IP

The IP address of the **Posital bridge device** that aggregates encoder data or communicates with multiple encoders on the network.

Encoder IDs

A list of encoder **identifiers** associated with this driver. Each ID corresponds to a specific Posital encoder device.

Used together with the `ips` property when addressing multiple encoders.

Encoder IPs

A list of **IP addresses** for each encoder connected to the system.

Each entry pairs with the corresponding encoder ID in the `ids` list.

Polling Interval (ms)

Defines how frequently (in milliseconds) the driver polls encoders for updated position data.

Shorter intervals produce faster updates but increase network and processing load.

Timestamp Mode

Selects the timestamp source used for encoder data.

Options include:

- **0 — Time of Receipt**
  Timestamp applied when Disguise receives the packet.

- **1 — Incoming Timestamp**
  Uses timestamp embedded in the encoder's transmitted data.
- **2 — Time of Poll**
  Timestamp generated at the moment the driver polls the encoder.

Choose the mode based on your synchronisation workflow and encoder capabilities.

Trace Logging

Enables or disables diagnostic tracing of encoder communication.

Options:

- **0 — Off**
- **1 — On**

Useful for debugging encoder communication or timing issues.

Developer Documentation

Position Drivers

A **PositionDriver** is an object in Designer that decodes positional data transmitted from a motion control system. Typically, each driver is bespoke to a particular system or protocol, translating its proprietary data stream into values that Designer can apply to `PositionAxis` objects.

For the architectural context — how a PositionDriver fits between a `PositionReceiver` device and `PositionAxis` objects — see Motion Control Systems.

Supported position drivers

The following drivers are supported for automation integration with Designer. Each entry links to its full driver reference page.

- Camera Tracker Tester — simulated camera-tracking data for development and validation.
- CameraTrackerObservationsTester — validates observation data received from external camera-tracking systems.
- CPS Driver — CPS automation systems (legacy driver).
- D3SSI Driver — internal D3SSI positional tracking driver.
- DCS Driver — DCS stage automation and control systems.
- DMX Screen Position Driver — generic positional data over DMX.
- Ez Driver — generic EZ-series data/DMX device driver.
- FreeD Driver — FreeD camera-tracking protocol.
- HMC Driver — Hudson HMC motion-control protocol.
- Kinesys Driver — Kinesys Vector and K2 rigging/motion systems (**manufacturer**).
- LDS Driver — LDS positional input.
- LCPUSB Driver — USB-based industrial PC controller (inclinometer).
- Mo-Sys F4 Driver — Mo-Sys F4 tracking hardware.
- MoveAI Driver — real-time markerless motion-capture data from MoveAI systems.
- Movecat Driver — Movecat kinetic systems (**manufacturer**).
- NatNet Driver — tracking data using the NatNet protocol.
- Navigator Driver — Tait Navigator automation (**manufacturer**).
- Ncam Driver — Ncam camera-tracking for virtual production.
- NG360 Driver — positional data from NG360 tracking systems (**manufacturer**).
- OSC Driver — positional data routed over OSC.
- PosiStageNet Driver — performer/object motion via PSN (**protocol**).
- Posital Driver — Posital encoder/sensor positional input.
- PRG Driver — UDP receiver for PRG screen automation protocol.

- PRG Stage Command Driver — PRG Stage Command system (**manufacturer**).
- RTTrPM Driver — RTTrPM real-time BlackTrax tracking (**protocol**).
- Simotion Driver — Siemens SIMOTION controllers (**manufacturer**).
- Skeleton Tracker Tester — simulated skeleton tracking.
- SKV Driver — SKV control system driver.
- Stage Kinetics MoveCat Driver — MoveCat motion via Stage Kinetics protocol.
- STS Driver — STS automation hardware (**manufacturer**).
- Stype Driver — Stype camera-tracking data.
- Trackmen Driver — Trackmen camera tracking.
- Unican Open Cue Driver — Open Cue automated cueing (**manufacturer**).
- Vicon Datastream Driver — Vicon tracking data stream.
- VisualAct Driver — VisualAct winches and lifts (**manufacturer**).

PRG Driver

The **PRG Driver** allows Disguise to receive positional or automation-related data over UDP using the **PRG Screen Automation protocol**.

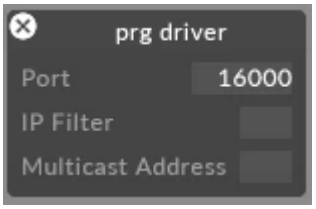
This protocol is used in certain PRG workflows for sending screen-related or positional information, and is separate from the more advanced **PRG Stage Command System (SCS)** protocol.

Use this driver when your PRG system outputs lightweight positional data for tasks such as:

- Tracking or aligning moving screens
- Receiving simple positional feedback
- Triggering state changes based on PRG data

This driver does *not* interface with the PRG Stage Command System. For SCS-based automation (winches,hoists, deck movement, etc.), use the PRG Stage Command driver instead.

Driver Properties



This driver listens on UDP port **16000** by default.

Port

The UDP port on which the driver receives data. Set this to match the port configured on the sending device or controller.

IP filter *(optional)*

Restricts incoming data to a specific source **IP address**. Useful when several sources are present on the network, or to isolate a single sender. Leave blank to accept data from any IP.

Multicast address *(optional)*

The multicast group address used by your system. Only required when the sender is configured for multicast — enter the exact multicast address used by the emitter. Leave empty for unicast or broadcast configurations.

Developer Documentation

PRG Stage Command Driver

The **PRG Stage Command Driver** enables Disguise to receive real-time motion-control data from the **PRG Stage Command System (SCS)**, PRG's flagship automation platform used to control winches, hoists, tracks, revolves, lifts, and other multi-axis scenic elements.

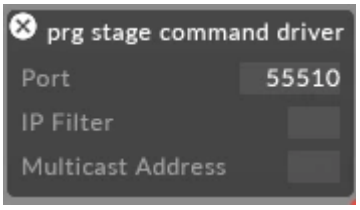
Unlike the simpler PRG Screen Automation protocol, the **Stage Command System** provides structured, high-resolution positional data and operational status for multiple axes of movement.
This driver should be used whenever your production relies on PRG automation hardware controlled through SCS and needs Disguise content to synchronise with the actual physical motion on stage.

Typical use cases include:

- **Flying screens or LED walls** operated by PRG SCS
- **Automated scenic pieces** (portals, set pieces, moving architecture)
- **Deck automation** such as **tracks, elevators, and revolves**
- **Multi-axis movement** requiring accurate positional feedback
- **Synchronising media playback with live stage motion**
- **Reacting to PRG machinery state changes** as the machinery reaches specific positions or states

The PRG Stage Command Driver listens for structured SCS network messages and exposes them in Disguise as automation axes that can drive tracking, camera calibration offsets, or timeline logic.

Driver Properties



Port

The UDP port that the PRG SCS system outputs its automation data to.

This must match the port configured by the PRG automation team.

IP Filter

The specific SCS controller IP address that data will be accepted from (optional).

Useful in large network environments or multi-controller setups.

Multicast Address

The multicast group the SCS system is publishing positional data to (optional).

Required only if your PRG SCS configuration uses multicast distribution.

Additional Notes

- SCS may expose **multiple axes**, each corresponding to a physical device or motion group.
- Axes can be mapped in Disguise to drive screen positions or content tracking.
- For simple PRG UDP feeds *not* originating from SCS, use the standard PRG Driver, not this one.

Developer Documentation

RTTrPM Driver

RTTrPM (Real-Time Tracking Protocol – Motion) is an open-source protocol used to transmit real-time tracking information. It is the protocol used by **BlackTrax** and several other tracking systems.

Disguise systems can use RTTrPM data to drive real-time positional information inside a project, enabling content to follow performers, props, cameras or other tracked objects.

The RTTrPM Driver is a type of Position Receiver and is added through the standard workflow for a Position Receiver device.

Once an RTTrPM Position Receiver has been added to the project, Disguise can receive tracking data from any third-party manufacturer that supports the RTTrPM specification.

For a current list of devices that support RTTrPM, visit:
https://rttrp.github.io/RTTrP-Wiki/index.html

What RTTrPM Data Includes

RTTrPM provides a structured set of motion-related values. Depending on the tracking system, an RTTrPM stream may include:

- **3D position** (X, Y, Z coordinates)
- **Orientation** (directional facing or rotation of the tracked object)
- **Tracking confidence or quality metrics**
- **Unique object identifiers**
- **Timestamps** for synchronising data across systems

Not all devices output every field, but all RTTrPM-compatible systems provide core 3D positional data.

Uses

- **Performer and Object Tracking**

  RTTrPM can drive content that needs to follow a moving performer, prop or scenic element. This is commonly used for interactive media, spatial content alignment and dynamic projection mapping.

- **Camera Tracking**

  When used with compatible tracking systems, RTTrPM can feed positional data into Disguise for virtual production or AR workflows that require accurate camera movement.

- **Multi-Object Support**

  RTTrPM streams may include several tracked objects at once. These appear in Disguise as individual axes or tracked points, enabling multi-character or multi-prop workflows.

- **Confidence Handling**

  Some systems provide tracking confidence values. These can be used within Disguise to influence logic, blending, or fallback behaviour.

- **Coordinate Alignment**

  Ensure the tracking system's coordinate space matches the Disguise stage space. Adjustments may be made within the Position Receiver or via project calibration.

Driver Properties

Port

The UDP port on which the driver receives data. Set this to match the port configured on the sending device or controller.

IP filter *(optional)*

Restricts incoming data to a specific source **IP address**. Useful when several sources are present on the network, or to isolate a single sender. Leave blank to accept data from any IP.

Multicast address *(optional)*

The multicast group address used by your system. Only required when the sender is configured for multicast — enter the exact multicast address used by the emitter. Leave empty for unicast or broadcast configurations.

Developer Documentation

Siemens SIMOTION Driver

The **Siemens SIMOTION Driver** allows Disguise to receive positional data from **Siemens SIMOTION** motion controllers. Siemens SIMOTION systems are commonly used in industrial automation, robotics, and precision motion-control applications.

When connected to Disguise, they can supply axis position information that drives content alignment or positional offsets.

We recommend using the default driver settings unless your system requires a specific network configuration.

Uses

Use the Siemens SIMOTION Driver when your workflow includes:

- Motion-controlled scenic elements driven by Siemens SIMOTION hardware.
- Linear or rotary axes where real-world motion must inform content movement in Disguise.
- Industrial or engineering-grade automation systems integrated into a live environment.
- Synchronising content with machinery, such as lifts, tracks, arms, or precision-driven components.

Siemens SIMOTION is typically used in environments where **high positional accuracy** and **deterministic motion** are required. The driver allows these axes to be represented inside Disguise as automation sources.

Driver Properties

ID prefix

If set, this string is added to the beginning of each incoming axis ID.

This is useful when naming conventions are required, or when working with multiple SIMOTION sources whose axis identifiers need differentiation.

Port

The UDP port on which the driver receives data. Set this to match the port configured on the sending device or controller.

IP filter *(optional)*

Restricts incoming data to a specific source **IP address**. Useful when several sources are present on the network, or to isolate a single sender. Leave blank to accept data from any IP.

Multicast address *(optional)*

The multicast group address used by your system. Only required when the sender is configured for multicast — enter the exact multicast address used by the emitter. Leave empty for unicast or broadcast configurations.

Developer Documentation

Skeleton Tracker Tester

The **Skeleton Tracker Tester** is a diagnostic and development tool within Disguise used to test and validate skeleton-based tracking workflows. It allows users to supply or simulate skeletal tracking data for evaluation, calibration, and content testing without requiring a live external tracking system.

This tool is commonly used during setup or development to confirm that skeleton data is mapped correctly, that joints behave as expected, and that content responds accurately to tracked body motion.

Uses

Use the Skeleton Tracker Tester when you need to:

- **Test skeletal tracking behaviour** without a live tracking feed
- **Preview how content reacts to tracked body joints**, e.g. head, hands, feet, or custom markers
- **Debug or validate joint mapping** before integrating a real tracking system
- **Apply positional and rotational offsets** to align a skeleton with stage coordinates
- **Prototype motion-driven content** when hardware is not available
- **Verify skeleton compatibility** with your project's tracking configuration

This tool is especially helpful for virtual production, AR workflows, and interactive performances that rely on rigid body-based tracking.

Driver Properties

Origin Offset

A positional offset applied to the skeleton's source camera position.

Use this when aligning the skeleton's origin with the Disguise stage space or adjusting its placement relative to your scene.

Origin Rotation

A rotational offset applied to the skeleton's source camera orientation.

Useful for correcting orientation mismatches or adapting the skeleton to a different coordinate basis.

Source Skeleton

The skeleton asset used as the input data source.

This determines which joint hierarchy and naming structure the tester will emulate or interpret.

Developer Documentation

SKV Driver

The **SKV Driver** enables Disguise to receive positional and status data from SKV-compatible motion or automation systems.

It exposes incoming motor positions and system state information as axes inside Disguise, allowing content to follow physical movement or respond to hardware status changes.

This driver also includes optional smoothing controls to stabilise noisy or rapidly changing position data.

Uses

Use the SKV Driver when your production involves:

- Motion-controlled scenic elements driven by SKV-compatible systems.
- Receiving multiple motor positions as tracked axes inside Disguise.
- Filtering or smoothing incoming positional values to ensure stable content motion.
- Monitoring automation system status for safety logic or system health.
- Synchronising content with real-world mechanical movement.

The driver is suitable for both high-precision tracking and general-purpose automation integration.

Driver Properties

Interface

UDP Listen Port

The UDP port on which Disguise listens for incoming SKV data. This must match the sending configuration of the SKV controller.

Smoothing

These properties help stabilise the positional data coming from SKV motors, especially if the values update rapidly or contain noise.

Use Smoothing

Enables or disables smoothing for incoming motor data.

Jump Threshold

The maximum allowed instantaneous change before the system treats the update as a “jump.”

Useful for preventing sudden spikes in the data from affecting content.

kP / kI / kD / kF

PID/F filter parameters used to shape how smoothing behaves.

These values determine how strongly the driver reacts to changes in incoming data, allowing you to fine-tune responsiveness versus stability.

Status

Motors Received

The number of motor channels currently being received from the SKV controller.

Status

A numerical code representing the general state of the SKV data connection or controller.

Interpretation may vary depending on the originating SKV system.

Developer Documentation

Stage Kinetics MoveCat Driver

The **Stage Kinetics MoveCat Driver** allows Disguise to receive positional and status data from **MoveCat** stage automation systems. MoveCat systems are widely used for precise movement of hoists, lifts, trolleys and other scenic elements in live events.

Using this driver, Disguise can synchronise content with real-world motion or drive timelines based on incoming axis positions.

We recommend using the default driver settings unless your MoveCat or network configuration requires specific adjustments.

Uses

Use the Stage Kinetics MoveCat Driver when your production includes:

- **MoveCat-controlled hoists or chain motors**
- **Tracking or synchronising content to flown scenic objects**
- **Dynamic video surfaces** that move in 3D space
- **Show automation systems** where Disguise must follow or react to live mechanical movement
- **Multi-axis movement** that needs to be represented inside Disguise in real time

This driver enables accurate content alignment and automation-driven behaviour whenever MoveCat is part of the show environment.

Driver Properties

This driver listens on UDP port **16000** by default.

Port

The UDP port on which the driver receives data. Set this to match the port configured on the sending device or controller.

IP filter *(optional)*

Restricts incoming data to a specific source **IP address**. Useful when several sources are present on the network, or to isolate a single sender. Leave blank to accept data from any IP.

Multicast address *(optional)*

The multicast group address used by your system. Only required when the sender is configured for multicast — enter the exact multicast address used by the emitter. Leave empty for unicast or broadcast configurations.

Protocol version

Specifies the MoveCat protocol version used by the driver.

The default setting is **V2**, which is the current standard for MoveCat automation data.

Only change this if your MoveCat installation requires a different protocol version.

Developer Documentation

STS Driver

The **STS Driver** allows Disguise to receive position or status information from systems using the **STS automation protocol**. STS is used in certain stage-control environments to transmit lightweight automation data for moving scenic elements, providing real-time positional updates that can be used to drive content alignment inside Disguise.

We recommend using the default driver settings unless your installation requires specific network configuration changes.

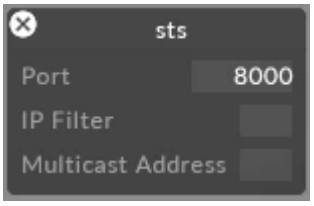
Uses

Use the STS Driver when your production includes:

- Basic stage automation systems outputting STS position data.
- Moving scenic elements such as lifts, trolleys, or simple motorised objects.
- Synchronising content with known positions of mechanical elements.
- Triggering content changes based on automation movement.
- Lightweight or legacy automation hardware that outputs STS rather than a more complex protocol.

STS is suitable for productions where motion data is relatively simple, and where Disguise needs only positional or movement status rather than advanced multi-axis automation information.

Driver Properties



This driver listens on UDP port **8000** by default.

Port

The UDP port on which the driver receives data. Set this to match the port configured on the sending device or controller.

IP filter *(optional)*

Restricts incoming data to a specific source **IP address**. Useful when several sources are present on the network, or to isolate a single sender. Leave blank to accept data from any IP.

Multicast address *(optional)*

The multicast group address used by your system. Only required when the sender is configured for multicast — enter the exact multicast address used by the emitter. Leave empty for unicast or broadcast configurations.

Developer Documentation

Stype Driver

The **Stype Driver** allows Disguise to receive real-time camera-tracking data from **Stype** systems, including Stype RedSpy, StypeLand and other encoders using the Stype protocol. Stype provides precise camera position, rotation, lens metadata and timing information for virtual production, augmented reality and camera-tracked workflows.

We recommend using the default driver settings unless your Stype system or network setup requires custom configuration.

Uses

Use the Stype Driver when your workflow requires:

- **Real-time camera tracking** for xR, AR or virtual production
- **Accurate lens metadata** including zoom, focus and distortion parameters
- **Synchronising CG environments** with live-action camera movement
- **Virtual set extensions** that follow the tracked camera
- **Motion capture or encoded crane tracking** (e.g., Stype's encoded heads and jibs)
- **Latency and timing analysis** using the packet timing graph option

Stype data is commonly used in LED volumes, green-screen stages, broadcast AR, and any workflow where a tracked camera must drive rendered content inside Disguise.

Driver Properties

Enable packet timing graph

When enabled, Disguise logs the timing of all incoming Stype packets and visualises them as a graph.

This is useful for diagnosing network jitter, dropped packets or inconsistent tracking frequency.

Port

The UDP port on which the driver receives data. Set this to match the port configured on the sending device or controller.

IP filter *(optional)*

Restricts incoming data to a specific source **IP address**. Useful when several sources are present on the network, or to isolate a single sender. Leave blank to accept data from any IP.

Multicast address *(optional)*

The multicast group address used by your system. Only required when the sender is configured for multicast — enter the exact multicast address used by the emitter. Leave empty for unicast or broadcast configurations.

Developer Documentation

Trackmen Driver

The Trackmen Driver allows Disguise to receive real-time tracking data from Trackmen systems. It converts incoming tracking packets into camera and object transforms that Disguise can use for virtual production, broadcast graphics, and other real-time workflows.

Uses

Use the Trackmen Driver when you want to:

- Drive virtual or AR cameras in Disguise using a physical camera tracked by Trackmen.
- Synchronise real-world camera movement with a virtual set or scene.
- Monitor the quality and timing of tracking data coming from a Trackmen system.
- Troubleshoot latency or jitter issues in your tracking network.

Driver Properties

Port

The UDP port on which the driver receives data. Set this to match the port configured on the sending device or controller.

IP filter *(optional)*

Restricts incoming data to a specific source **IP address**. Useful when several sources are present on the network, or to isolate a single sender. Leave blank to accept data from any IP.

Multicast address *(optional)*

The multicast group address used by your system. Only required when the sender is configured for multicast — enter the exact multicast address used by the emitter. Leave empty for unicast or broadcast configurations.

Enable packet timing graph

- **Purpose:** Turns on a diagnostic graph that logs the timing of incoming tracking packets.
- **When to use:**
  - You want to verify that data is arriving regularly from the Trackmen system.
  - You are diagnosing latency, jitter, or dropped packets in the tracking feed.

Recommended for testing and troubleshooting. You can disable it again during normal operation once the tracking feed is stable.

Developer Documentation

Unican Open Cue Driver

The **Unican Open Cue Driver** receives position data from Unican Open Cue (OpenPosIP) automation systems over UDP. Each packet carries multiple drive IDs with their position values (in millimetres); the driver decodes each as a tracking axis inside Designer.

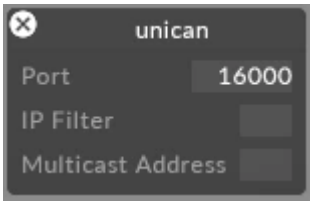
In most setups, the default settings are suitable; adjustments are only required when your Unican system uses non-standard ports, IP filters, or multicast addressing.

Uses

Use this driver when you need to:

- Receive position data from Unican Open Cue automation hardware over UDP.
- Map drive positions to PositionAxis objects for content alignment or stage motion synchronisation.
- Integrate Unican-controlled motion into a Disguise workflow.
- Support both unicast and multicast network configurations.

Driver Properties



This driver listens on UDP port **16000** by default.

Port

The UDP port on which the driver receives data. Set this to match the port configured on the sending device or controller.

IP filter *(optional)*

Restricts incoming data to a specific source **IP address**. Useful when several sources are present on the network, or to isolate a single sender. Leave blank to accept data from any IP.

Multicast address *(optional)*

The multicast group address used by your system. Only required when the sender is configured for multicast — enter the exact multicast address used by the emitter. Leave empty for unicast or broadcast configurations.

Developer Documentation

Vicon DataStream Driver

The Vicon DataStream Driver allows Disguise to receive real-time tracking information from Vicon motion-capture systems.

This tracking data can be used to drive virtual cameras, objects, or characters within Disguise, enabling highly accurate virtual production and motion-tracking workflows.

> **Note**
>
> The Vicon DataStream driver is a **Preview** feature. Enable the `enableVicon` option switch in d3Manager's advanced machine settings for the driver to appear in the driver picker.

Uses

Use this driver when you need to:

- Receive live mocap or object tracking data from a Vicon system.
- Synchronise a physical camera's movement with a virtual camera in Disguise.
- Integrate Vicon tracking into xR stages, AR graphics, or complex choreography.
- Connect to a Vicon DataStream server over the network using its IP address and port.

Driver Properties

IP endpoint

The IP address and port of the Vicon DataStream server to connect to.

Logging

Enables logging for the driver.

Developer Documentation

VisualAct Driver

Introduction

The VisualAct Driver allows Disguise to receive positional data from VisualAct systems.

This enables synchronised motion control workflows where moving scenic elements, lifts, or tracking systems send real-time data directly into Disguise.

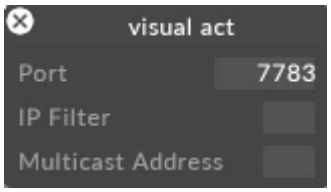
Default settings are suitable for most installations unless your VisualAct system is configured with custom network parameters.

Uses

Use this driver when you need to:

- Receive movement or automation state data from VisualAct hardware.
- Synchronise motion-controlled elements with virtual scenes or content.
- Integrate scenic automation into Disguise timelines or triggering systems.
- Support multicast or unicast delivery depending on your VisualAct setup.

Driver Properties



Port

The UDP port used to receive VisualAct automation data.

This must match the port configured on the VisualAct system that is transmitting the data.

IP filter

An optional filter that restricts incoming packets to a specific sender IP address.

Use this when multiple devices are on the network and you want to ensure only the intended VisualAct source is accepted.

Multicast address

The multicast group the driver listens to when receiving VisualAct data via multicast.

Only required if your workflow uses multicast delivery, leave blank for standard unicast setups.

Developer Documentation

Position Receiver Device

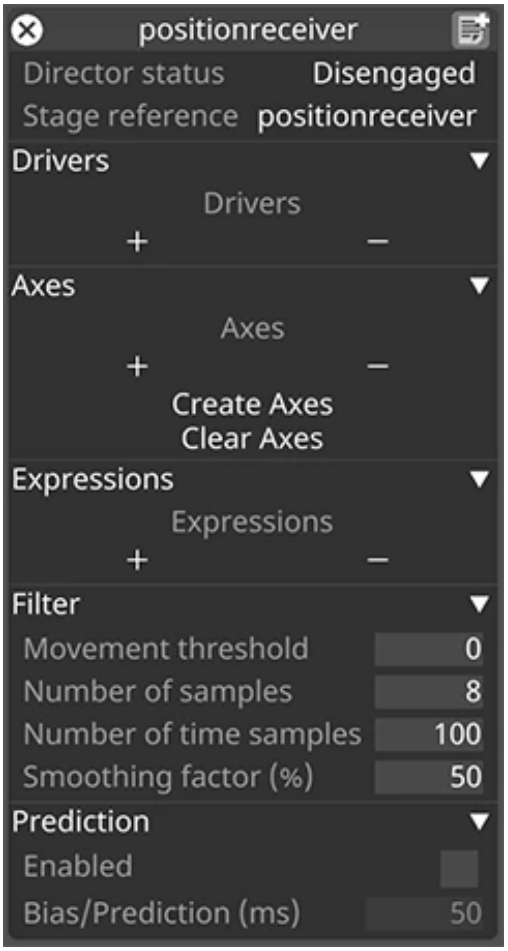
The Position Receiver device receives real-time positional data for tracking objects or performers.

Creating a Position Receiver Device

A Position Receiver Device is created in the same way as any other device type.

See Creating Devices for step-by-step instructions on how to create a device, then select **PositionReceiver** from the menu of different device types. This will open the editor (explained below).

Position Receiver Device properties



PositionReceiver Device editor

Director Status

Toggles whether the device is active — **Engaged** or **Disengaged**.

Stage Reference

Sets the frame of reference for the incoming data, such as `d3`.

Drivers

The object that decodes the data sent from the motion control system. Most of the time a driver is bespoke to a particular system.

See Position Drivers for more information on the types of position drivers supported by Designer.

Axes

A list of objects that control the movement of individual objects along each axis. Includes **Create Axes** and **Clear Axes** controls.

Expressions

A list of PositionAxisExpression objects. An AxisExpression object evaluates the data from the PositionAxis objects using an arithmetic expression and sends the result to the objects.

For example:

```
((Axis A + Axis B) @/ 2)
```

Filter

- **Movement threshold** — minimum change needed before updating the output value. Helps when data has unwanted movement when intended to be static. `0` disables the threshold.
- **Number of Samples** — number of position samples to filter.
- **Number of Time Samples** — number of time samples to filter.
- **Smoothing Factor** — smooths the data. Use caution when setting higher values as this can increase latency.

Prediction

- **Enabled** — used to predict tracked positions at a later time.

- **Bias/Prediction (ms)** — compensates for time latency between received data and projector output.

For information on configuring a tracking source, see Tracking Source.

Projector Calibrator Device

The **Projector Calibrator Device** is used to calibrate projectors by pairing tracked reference points in the scene with their projected positions on the physical surface. Once calibrated, Designer knows each projector's position, orientation, focal length and lens shift, so content can be accurately mapped onto the target surfaces. The **Projector Calibrator Device** uses similar algorithms to QuickCal, but can achieve more accurate calibration results because the 3D input data comes from external tracking systems instead of a 3D model.

The device relies on tracking data — a Position Receiver Device or equivalent tracking source typically provides the real-world 3D coordinates for the reference points used during calibration. For an overview of Designer's calibration methods (Manual, QuickCal and OmniCal), see the Projector Calibration overview.

Uses

Use the Projector Calibrator Device when:

- Aligning one or more projectors to a 3D space using tracked reference points.
- Iteratively refining projector positions by stepping through reference points with remote controls.
- Working with tracking systems that deliver real-world coordinates for calibration markers.

Workflow

1. Add the **Projector Calibrator Device** in Designer.
2. Under **Projectors**, click **+** to add each projector to be calibrated.
3. Provide tracked point data — typically via a connected tracking system routed through a Position Receiver.
4. Select a **Reference point** and pair its 3D **Tracked point position** with its corresponding 2D **Projector position**.
5. Use the **Remote Calibrator** controls to step through reference points, adjusting and confirming each placement and 2D lineup.
6. Enable **Draw test lines** and adjust **Test blob size** to visually verify the alignment.

Projector Calibrator Properties

Add Projectors

Adds a projector to the device's projector list.

OSC

OSC integration for remote control of the calibrator.

Tracked point

The currently selected tracked reference point.

Mode

The active calibration mode.

Test blob size

The size of the on-screen test pattern used during visual alignment.

Draw test lines

Toggles the display of test lines used to verify projector alignment.

Projectors

Projectors list

The list of projectors currently managed by this device.

Tracked point position

The 3D position of the tracked reference point in the stage.

Projector position

The computed position of the projector, derived from the current calibration.

Reference point name

An identifier for the current reference point.

Remote Calibrator

Controls for performing calibration remotely, without direct access to Designer's interface.

- **Start** — Begin a remote calibration session.
- **Done** — End the current remote calibration session.
- **Prev Step** / **Next Step** — Move backwards or forwards through the reference points.

- **Rotate Left** / **Rotate Right** — Rotate the current calibration pattern.
- **Up** / **Down** / **Left** / **Right** — Nudge the current calibration pattern.
- **Undo Reference Point Placement** — Revert the last reference point placement.

Shot Recorder Device

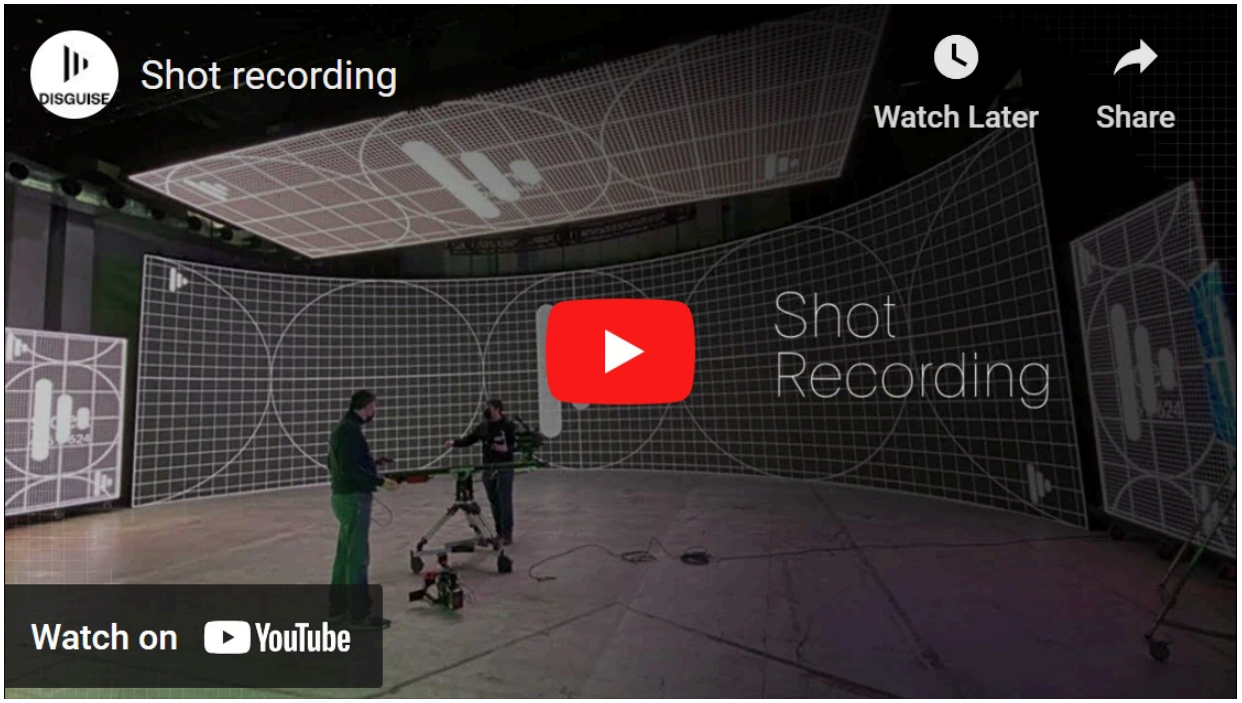
The Shot Recording system allows users to record and export parameters from within Designer, ready for use in post-production workflows.

What is the Shot Recording System?

The Shot Recording system is designed as a generic system to allow users to record any fields or properties displayed in the GUI. Users can build up their own collections of parameters they want to record. In addition, the system has a quick and easy workflow for recording commonly-used sets of parameters, such as camera tracking.

Unlike device recordings, which are played back within Designer, the data recorded by the ShotRecorder Device can be used by external applications.

See How it Works



Components of the Shot Recorder

The main components of the ShotRecorder Device are:

- The **ParameterCollection** containing the parameters to be recorded.
- A **TimecodeTransport** used to assign timestamps to the recorded parameters.
- Recording and export settings.

Parameter Collection

ParameterCollection is a resource that allows users to create several different collections and switch between them when selecting which parameters to record. It contains an array of ParameterSources, each of which is one **parameter** (i.e. field or property to record).

ParameterCollections can also contain a list of nested ParameterCollections, allowing users to build up collections in a modular way and add them all to one outer collection which is used for recording.

Some ParameterCollections are auto-created with sets of parameters which are commonly required. For example, each Camera auto-creates a **tracking** collection containing all the parameters commonly required for recreating camera tracking data. Similarly, each **SpatialMap** also creates a similar tracking ParameterCollection - the main difference is that this accounts for offsets of the world zero point in the spatial map. It also references the currently active camera if using an MR set.

Parameter Sources

ParameterSources contain a list of field ParameterSources for compound types (e.g. Vec contains x, y, and z, Resource can contain its fields). For compound types, the value of the ParameterSource is found by populating the values of its fields. By contrast, the values for basic types are populated using the expression system, which can return floats or strings. Any limitations of the expression system, or particular fields which cannot be accessed by expressions, will also be limitations of the shot recording system.

Setting up the Shot Recording system

1. Create a **ShotRecorder Device** in the current Device Manager. This device will become the master of the shot recording system.
2. Name the **Slate** for the current shot.
3. Create a new ParameterCollection in the **Parameters** field and add the desired parameters. ParameterCollections are a collection of different parameters that we are interested in recording and getting the data out of — for example, camera tracking, MR set, etc.
4. Add the desired Timecode provider to the **Timecode** field.
5. The **Take Snapshot** and **Take Screenshot** options can be selected to take a project snapshot and/or screenshot at the end of each take.

To add parameters to a ParameterCollection for recording

1. Open the ParameterCollection editor.
2. Alt+drag from the Sources **+** button to any field in the UI to add it as a parameter source

3. Several ParameterCollections are automatically created for convenience, such as camera tracking collections. These, or other user-created ParameterCollections, can be added to the ParameterCollections list in the editor to allow the parameters to be organised into smaller separate collections.
4. Click the arrow on the right hand side of a parameter to expand it and view its fields. Resource parameters do not have their fields added by default, but they can be added by clicking the plus button on the right hand side of the parameter.
5. Timecode can be set up inside the shot recorder in order to reference timecode in the recordings using **TimeCodeTransport**.

To make a recording

1. To start a recording, click the button displaying **Disengaged** to engage the recorder and start recording.
2. Click the same button again to stop the recording. The take number will automatically increment, or it can be changed manually.
3. Alternatively, use the API commands documented at `http://localhost/docs/v1/index.html` to start and stop recordings externally
4. Slates will be listed under the **Recordings** separator. Right-click on a slate to see the takes for that slate.

To export recordings

1. Select the desired formats under the **Export** tab.
2. Either click **Export all recordings**, or export recordings individually under the **Recordings** tab
3. Select **Auto-export** to automatically export in the selected formats when each take is finished.
4. Click **Export comparison table** to export a CSV table comparing the first value of each parameter for each recording
5. You can also enable to take a snapshot or a screenshot of each recording if desired.

Recordings can currently be exported in the following formats

- **JSON**: A compact JSON representation which contains the changed parameter values for each timestamp, similar to the .shot file
- **CSV (Compact)**: A compact CSV representation which contains only the changed parameter values for each timestamp
- **CSV (Dense)**: A dense CSV representation which contains all values for each parameter at each timestamp

- **FBX**: An FBX file containing meshes and pose information (position, rotation, scale etc.) of all recorded objects, where available. Any additional properties not represented within the FBX specification are recorded as custom properties.

A new sub-folder will be created in the project called ‘output’. Within there we have ‘shots’ and in there will be the slate. In the slate, there will be the .shot recording in addition to the recording in the chosen format

Limitations

- The shot recording system only writes data out of Designer. There is no capability to read recordings back into Disguise directly to replay the data. This is what device recordings should be used for.
- The shot recording system and the device recording systems do not interact with each other. They can still both be used at the same time.
- There is not currently an easy way to get all the recorded camera tracking data into Unreal Engine to re-render shots. Epic have outlined an **FBX import/export workflow** which allows camera positions, rotations, and FoV to be imported.

String Projector Control Device

The String Projector Control Device is intended for controlling external devices while optionally simulating their behaviour inside the visualiser.

Projector control can be simulated as well as output to real projectors. The intention is to be able to recall presets for the projectors that contain pan/tilt, zoom, focus, lens shift, intensity and projector configuration objects (for recalling different calibration states).

Configure the String Projector Control Device

Device setup

1. Create a **StringProjectorControlDevice**.
2. Associate the device with a projector.
3. Create a control device if using the string control version.
4. Assign the simulation configuration to the selected projector config.
5. Create presets either via the ProjectorControl Editor or the layer preset editor. The former is the preferred workflow, as it allows for multi-edit.

Timeline keyframing

1. Create a projector control layer.
2. Create a mapping (group of projectors to control).
3. Create presets for the projectors to recall as the timeline plays.

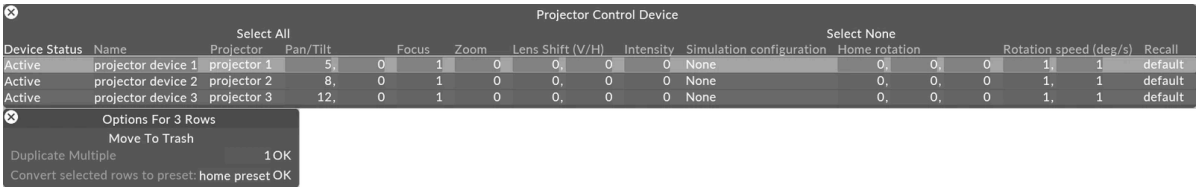
Configure the device

1. Define which projector is controlled by the device.
2. Choose whether simulation configuration is enabled or disabled. This controls whether the projector will move in the stage or not.
   - In the case of the String Projector Control Device, define a control device and create a corresponding serial, telnet or UDP device to send the data out of Designer.
3. Configure any Default, Startup and Shutdown commands, as appropriate.

Configure presets

ProjectorControlPresets can be created either through the ProjectorControl layer or through the String Projector Control Device Editor. Performing this functionality through the editor is a better choice as this editor fully supports multi-edit functionality, as well as converting hard values to presets for more time saving functionality.

1. Open the String Projector Control Device Editor from the Device manager.
2. Select each projector and apply the desired values. Either individually or by using the multi-edit functionality.
3. Select multiple rows and use the **Convert Selected Rows to Preset** function, to store the contents of the selected rows into a preset that can be recalled later. For example - Home position, Position 1, Position 2 and so on.



Control the projector

See ProjectorControl layer for more information.

Properties

Projector

- The virtual projector object in the visualiser.

Values

- Pan/Tilt, Focus, Zoom, Lens Shift (V/H), Intensity: the current values being sent to the external device. Modifying these values will cause the device to send out commands to the external device.

Simulation

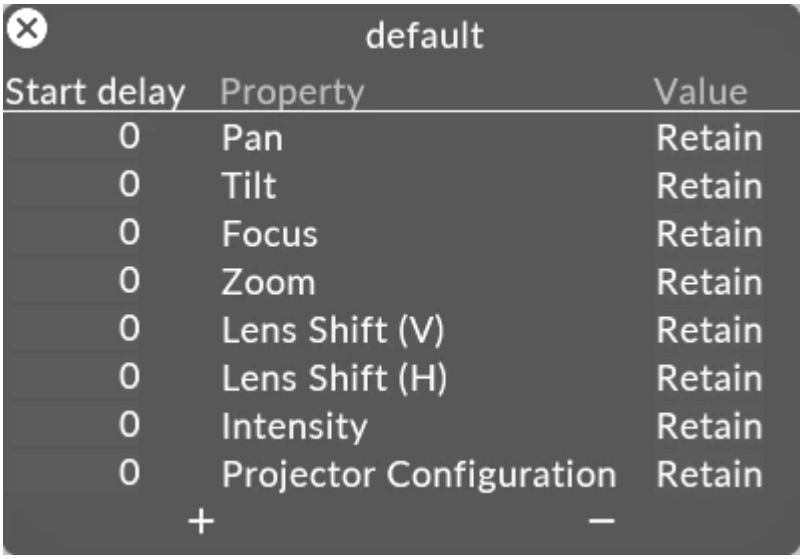
- **Simulation configuration** — the projector configuration that the device modifies to simulate the behaviour of the external device. Always use a dedicated projector configuration for this as its settings will be overwritten by the simulation.
- **Home rotation** — the starting rotation when the device's pan/tilt are at zero.
- **Rotation speed (deg/s)** — the animation speed of rotation between different pan/tilt values, in degrees per second.
- **Pan Axis** — the axis controlled by the pan value.
- **Tilt Axis** — the axis controlled by the tilt value.

Default Recall

- **Recall** — the default order of the commands sent to the device. This allows delays between starting the pan/tilt, focus, zoom and other actions.

For example, you may want to delay intensity moves for a set period of time to allow zoom, focus and position to be set before the projector is visible. The delay value is expressed in seconds.

The editor is capable of multi-edit functionality, so does not behave in the same way as a normal editor. See multi-edit for more information.



Device

- **Control device** — the network device (Serial, Telnet, UDP) that commands are sent over.

Commands

- **Default commands** — string commands sent to the network device before any specific actions' DMX commands.
- **Startup commands** — string commands sent to the network device when the projector control device is started or added from the device manager.
- **Shutdown commands** — string commands sent to the network device when the projector control device is stopped or removed from the device manager.

Common properties

Control strings for each of these projector control actions can be created. The range will be used to scale the current value before exposing it as a binary (%) or decimal ($) number.

Pan/tilt

- **Pan command** — the string sent to the control device when the pan value changes.
- **Pan range** — the scaling range applied to the pan value before it is exposed to the command. Defaults to -90 to 90 degrees.
- **Tilt command** — the string sent to the control device when the tilt value changes.

- **Tilt range** — the scaling range applied to the tilt value before it is exposed to the command. Defaults to -90 to 90 degrees.

Zoom

- **Zoom command** — the string sent to the control device when the zoom value changes.
- **Zoom range** — the scaling range applied to the zoom value before it is exposed to the command.

Focus

- **Focus command** — the string sent to the control device when the focus value changes.
- **Focus range** — the scaling range applied to the focus value before it is exposed to the command.

Lens Shift

- **Vertical shift command** — the string sent to the control device when the vertical lens shift value changes.
- **Vertical shift range** — the scaling range applied to the vertical lens shift value before it is exposed to the command.
- **Horizontal shift command** — the string sent to the control device when the horizontal lens shift value changes.
- **Horizontal shift range** — the scaling range applied to the horizontal lens shift value before it is exposed to the command.

Intensity

- **Intensity command** — the string sent to the control device when the intensity value changes.
- **Intensity range** — the scaling range applied to the intensity value before it is exposed to the command.

Telnet Device

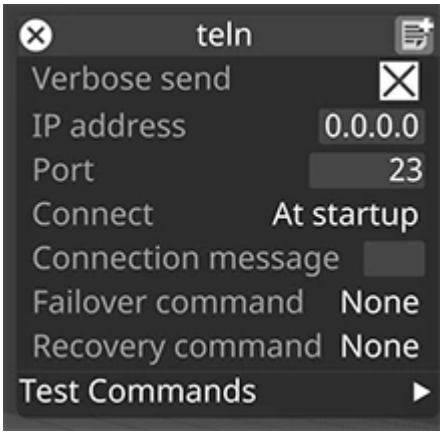
TelnetDevice sends commands to 3rd party products over a TCP network connection using the Telnet protocol — typically on port 23. It is used to remotely control hardware that exposes a text-based command interface.

TelnetDevices are used by the Control Layer and the Matrix Control layer.

Creating a Telnet Device

A **TelnetDevice** is created in the same way as any other device type. Please see the earlier sub-chapter Creating devices for step-by-step instructions on how to create a device. This will open the **TelnetDevice** editor (explained below).

Telnet Device properties



Verbose send

When enabled, the device logs every message sent over Telnet to the console. This option is intended for debugging and troubleshooting only. We recommend disabling it for devices that send messages frequently, as it can generate excessive console output.

IP address

The IP address of the destination 3rd party hardware. You must ensure that your network topology is configured to allow communications between the two machines.

Port

The network port of the destination 3rd party hardware. Telnet is traditionally port 23.

Connect

The Telnet port can be opened once **At startup** of Designer and held open or can be opened for **Every send** of a command.

Connection message

A message sent when the Telnet connection is established. Leave blank to disable.

Failover command

A control string sent to the device over Telnet when failover is triggered.

Recovery command

A control string sent to the device over Telnet when failover recovery is triggered.

Test Commands

The following Test Commands are available:

- **Send Failover**
- **Send Recovery**

Axes

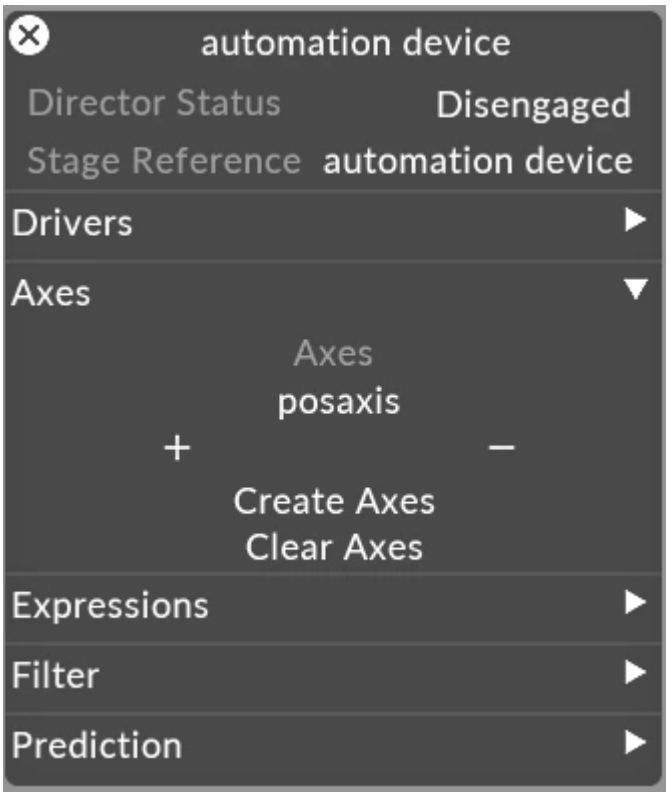
The Axes section of the PositionReceiver Device editor is used to create PositionAxis objects which control the movement of individual screens or props along each axis.

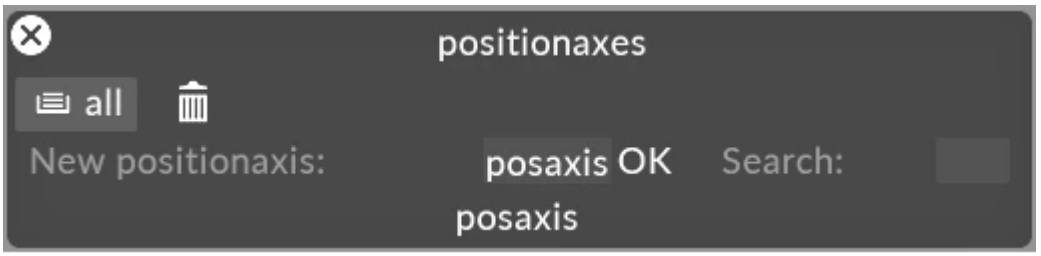
Axes are discrete objects themselves, but can be automatically created by reading the axis data the automation system is sending to Designer.

Creating PositionAxis objects

To create a object:

- Select the + button within the **Axes** section of the editor, type the name of the new object into the text field and hit **Enter**.

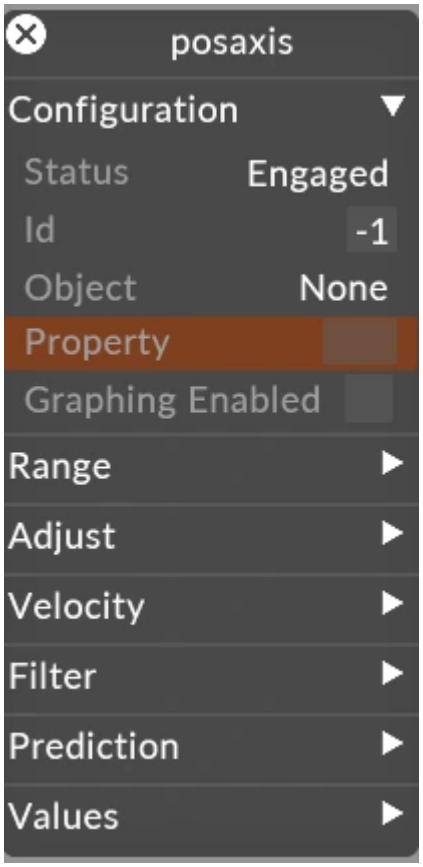




- Click the **Create Axes** button to automatically read the incoming axes from the Automation driver.

Axis Properties

Configuration



Status

Axis 'Engage' and 'Disengage' options. Allows the user to allow/disallow stage objects being updated in the visualiser. Can also be used during calibration to prevent automation data passing through to the stage objects.

ID

The unique identifier for the axis normally being sent by the automation system. In r14.2 onwards you shouldn't have to edit this field

Object

The Screen that the automation is affecting, ie Surface 1.

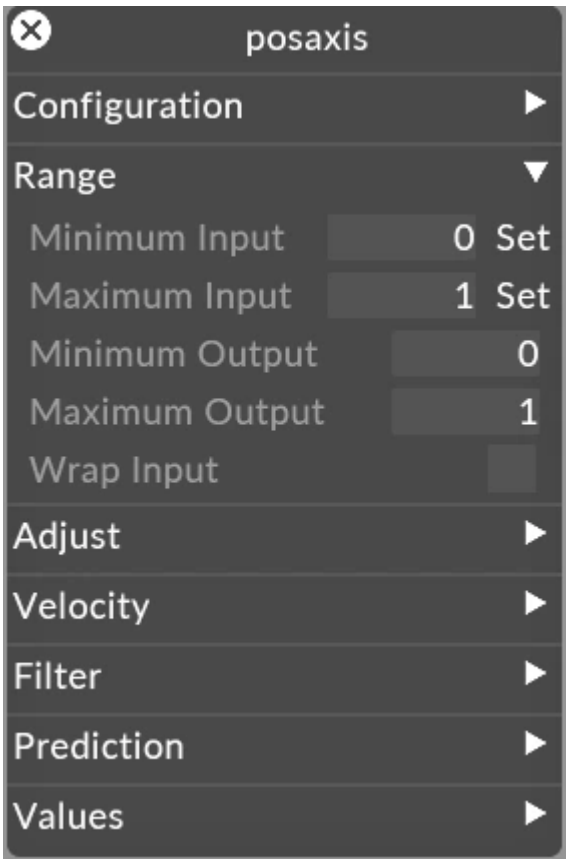
Property

Which property of the stage object will be automated. E.g. **offset.x**, **offset.y**, **offset.z**, **rotation.x**, **rotation.y**, **rotation.z**.

Graphing Enabled

Allows the user to switch on/ off the graphing/ monitoring of incoming packet data (position/ velocity) and filtered position data.

Range



Minimum/Maximum Input

Maximum/ Minimum Input: Set the Min and Max Input in Designer to the real world values coming into the software from the automation system. The set button for Maximum and Minimum Input fields can be used to mark the in and out positions (range) of the automated object. This will reference the current Input Value and therefore when pressed it will paste the current input value into the field. Therefore, making it easier to set these values. Designer works in metres and degrees so the user should set appropriate scaling if the received values are not in metres.

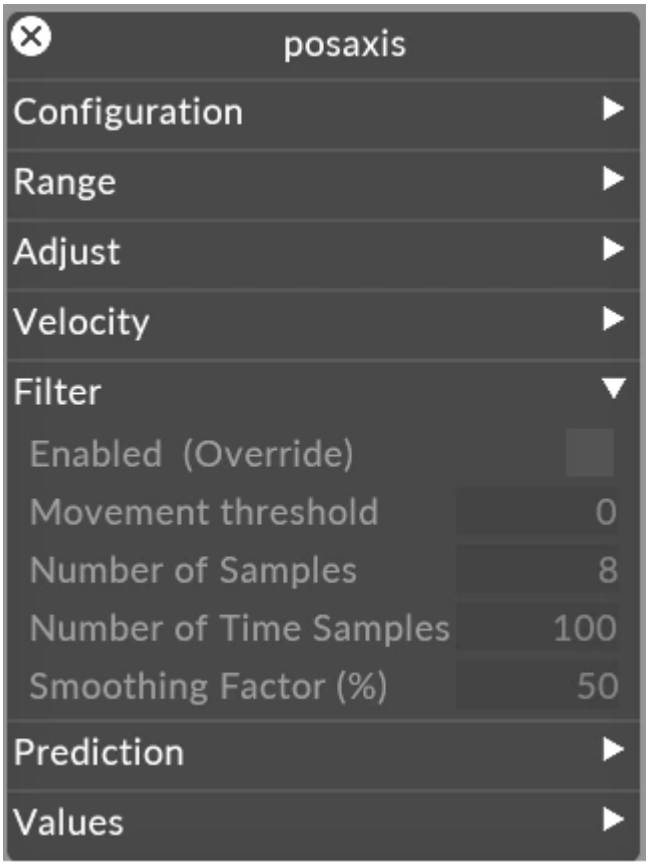
Minimum/Maximum Output

The Minimum and Maximum Output fields allow the user to scale the input range to a local range in the visualiser.

Wrap Input

Wrap input allows the user to specify that the automated object has rotary motion and the data will wrap. For example, a revolve going from 0-359 and wrapping back to 0.

Filter



Enabled (override)

Default - Off

When switched on, filter parameters override the parent devices parameters.

Movement threshold

Minimum change needed before updating output value. This helps when data has unwanted movement when intended to be static. 0 means no threshold (disabled).

Number of samples

Number of samples to filter. Use 0 to disable. More samples will introduce higher latency with more smoothing effect. Fewer samples will introduce less latency with less smoothing effect.

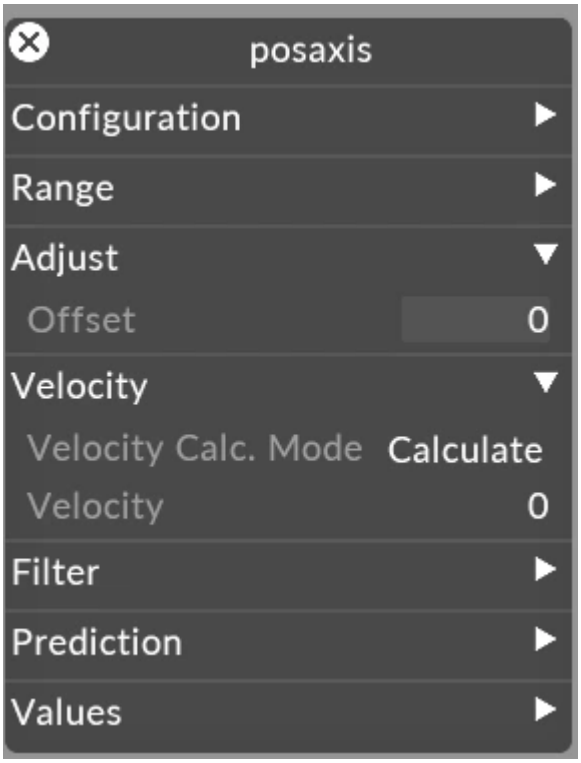
Number of time samples

Number of time samples to filter. Use 0 to disable. More samples will introduce higher latency with more smoothing effect. Fewer samples will introduce less latency with less smoothing effect.

Smoothing factor

Smoothing factor %. Higher values will smooth the data more but will increase latency and therefore the need for prediction.

Velocity



Velocity Calc Mode

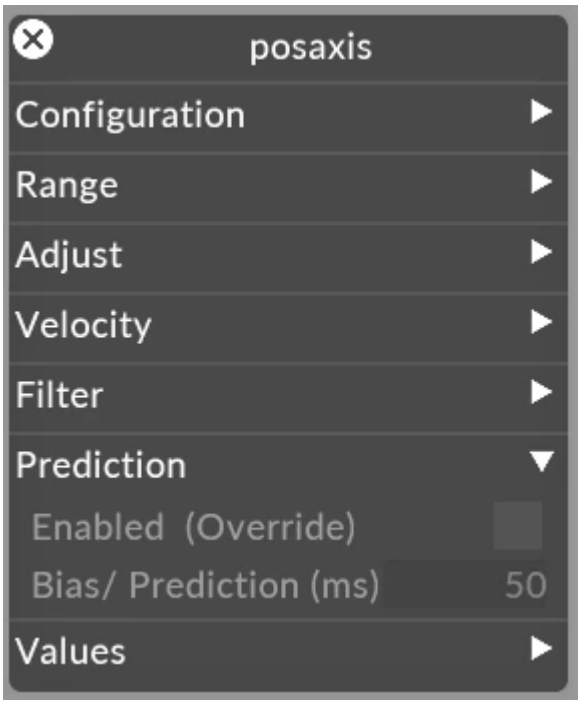
This is for prediction and determines the method for calculating the speed between samples within Designer in order to predict the position ahead of time. When in Calculate mode, Disguise will calculate the speed between the latest and previous packet. When From Packet is selected, the speed information should be received within the packet itself.

> **Note**
>
> : Note that the velocity units will be calculated/ received in the units in which the source is sending position and/ or velocity. E.g. If the source is sending position/ velocity in mm/s2 then the velocity is calculated in mm/s2 or when From Packet is selected, the velocity received would be in mm/s2. Therefore, any scaling (min/ max values for input/ output) is applied after the velocity prediction step. The scaling is used in order to scale input values into metres which is what Disguise uses. Disabled sets velocity to 0 and consequently turns prediction off.

Velocity

Updates only when in Calculated or From Packet modes and displays the velocity that is being calculated/ received from the automation system for the axis.

Prediction



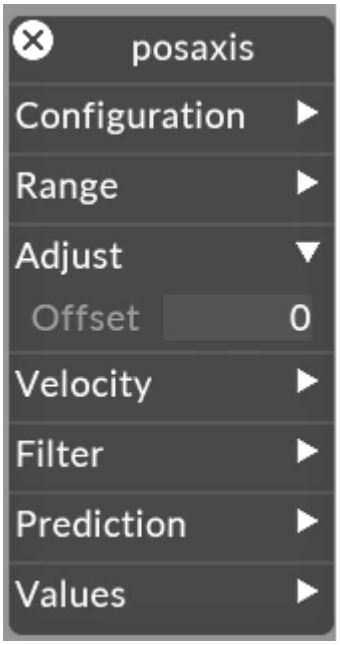
Enabled (override)

When switched on, prediction uses the **bias** roperty to predict tracked positions at a future time.

Bias/Prediction (ms)

Compensate for time latency between received data and projector output. Use 0 to disable.

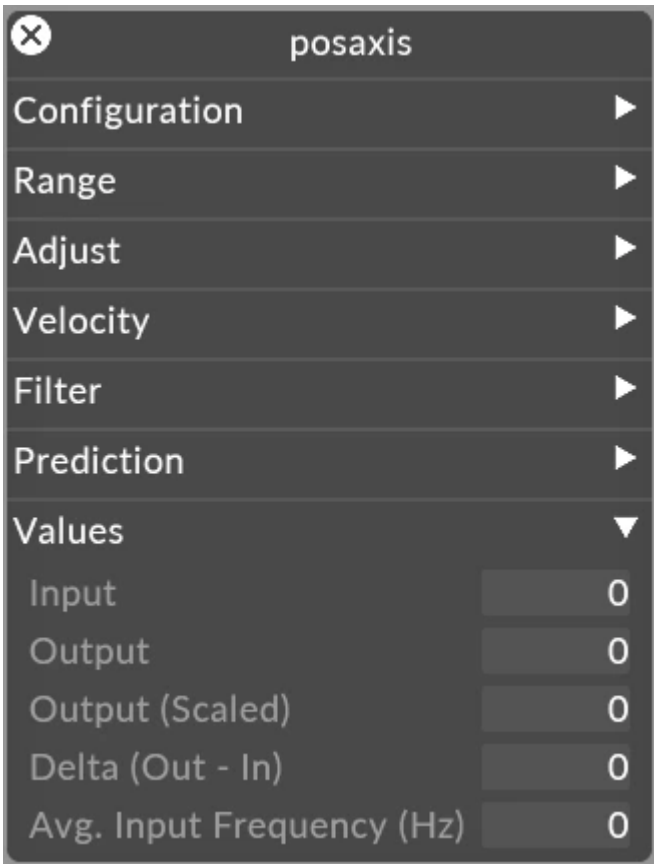
Adjust



Offset

Allows the user to offset the position of the object relative to the incoming position data.

Values



Input

The values of the incoming data, from here one can determine the Min and Max Input of data.

Output

The output including any prediction.

Output Scaled

Scaled output velocity comparing the Input and Output levels.

Delta (in - Out)

The difference between the incoming position data and output position data. For good output should be twitching between -0 and 0 value.

Avg Input Frequency (hz)

The field displays the average frequency that automation data is being received for the axis. It's important to monitor this field and ensure that the rate is at least 30 Hz or higher and

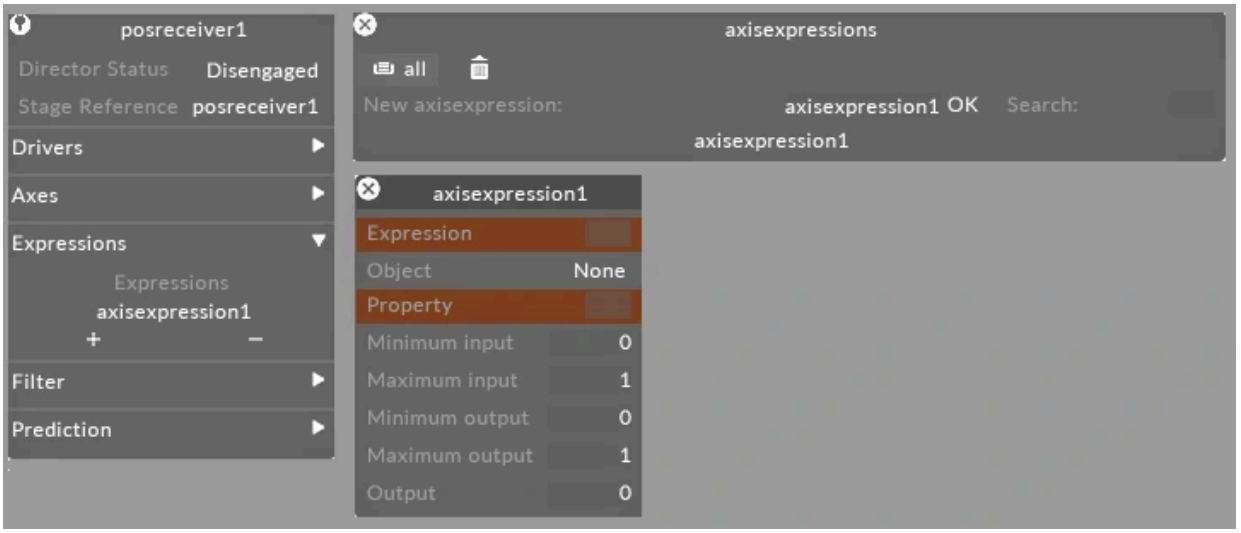
consistently at the rate specified by the automation system. I.e. avoid large swings/ fluctuations in the input frequency.

Screen Position Axis Expressions

Screen Axis Expressions can be used to perform arithmetic on values outputted from ScreenPositionAxis objects and sent to a property of a defined screen.

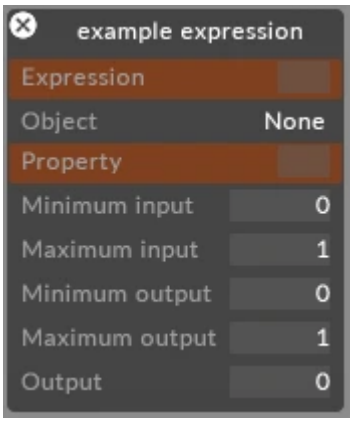
Creating expressions

To create an expression, select the **+** button within the **Expressions** section of the PositionReceiver editor, type the name of the new object into the text field, and hit **Enter**.



The Expressions editor

Expressions properties



Expression editor is used to perform arithmetic on values outputted from ScreenPositionAxis objects to a property of a defined screen

Expression

These are the arithmetic expressions performed on the defined axes. The **ScreenPositionAxis** objects are defined by their name. For example,

```
(ledscreenx*ledscreeny)/2
```

Where **ledscreenx** and **ledscreeny** are ScreenPositionAxis objects.

Screen

The screen you want to move and rotate. You should leave the property field of the object blank if you want to use the output of the expression rather than the axis.

Min input

The minimum input value that will be received from the ScreenPositionAxis objects.

Max input

The maximum input value that will be received from the ScreenPositionAxis objects.

Min output

The minimum output value of the defined property.

Max output

The maximum output value of the defined property.

Output

The current output value.

Creating a New Motion Controller

A Motion Controller is the device type that is necessary to receive positional data from a motion control system.

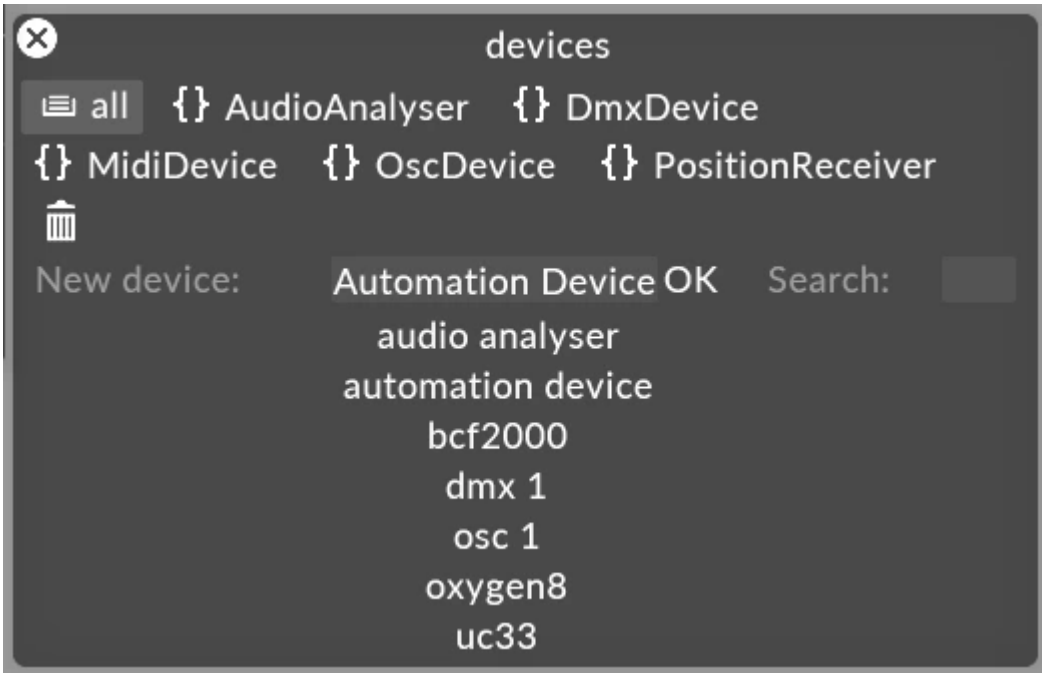
The process for creating a new motion controller is the same, no matter what kind of driver is being used.

Automation Devices

Creating an Automation Device

For example, to create a connection between PosiStageNet and , we would do the following:

1. Right-click the **Devices menu** on the dashboard and create a new device. Call it **Automation**.



2. The software will ask what kind of device this is, select **PositionReceiver Device** as the type.

3. The Automation Device now needs a **Driver** added. The Driver is the connection that receives data from the external system.
   Under the 'Driver' tab of the Automation device, press the **+** button to add and name the relevant driver.
   Additional information may be required, such as the IP Address the data is coming from.

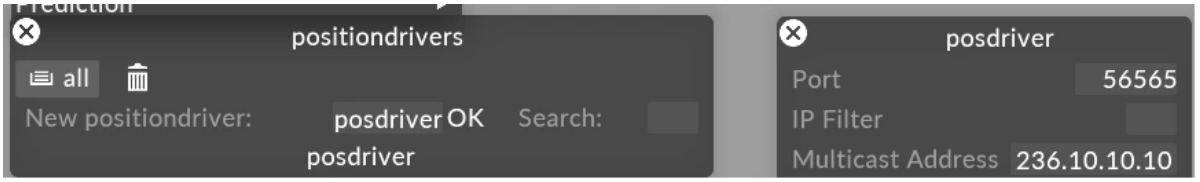
4. Input the port that is set on the sending Automation system. Further filtering can be done by IP if necessary.

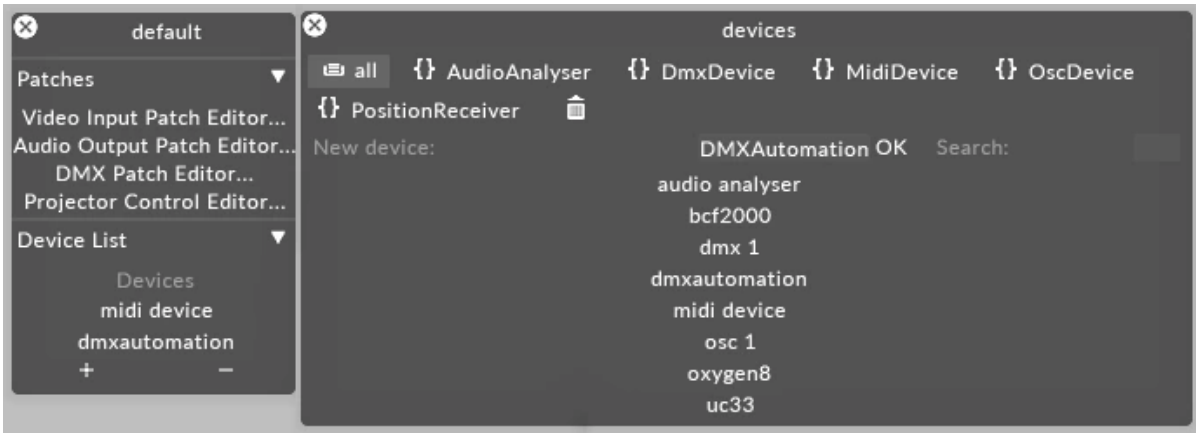


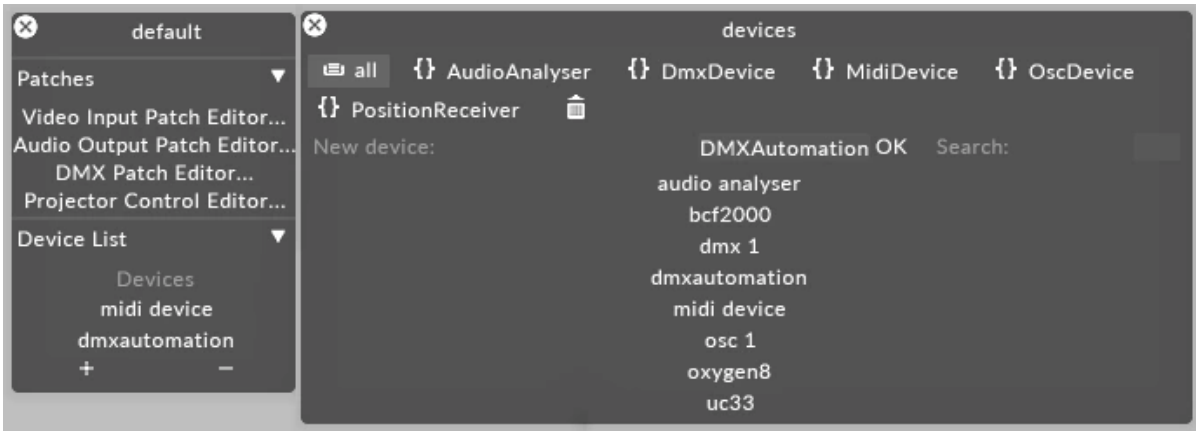
5. If Designer is receiving data from the device, the device recording menu will show a green bar, as shown here:

DMX Screen Position Receiver

To create an Automation device that can be controlled by DMX, follow these steps:

1. Open the devices menu and create a new type of device.





2. Next, expand the Drivers section and left-click on the + to add a new driver.

3. Select DMXScreenPositionDriver from the list.

4. Edit the properties of the driver as needed.

For additional information on these DMX Screen Position Driver properties, visit DMX Screen Position Driver.

> **Note**
>
> **Please note::**DMX Screen Position Driver supports 32bit, so when using a DMX console that outputs just 16bits, set the 3 and 4 bytes to 0 and use little endian encoding.

5. Ensure the device is engaged, and if needed, access additional properties of the DMX Screen Position Receiver by right-clicking on the name of the device in the Stage Reference field.

To create axes click on the + or use the Create Axes if the data is being detected within Designer. For additional information on Axes, please visit Axes.

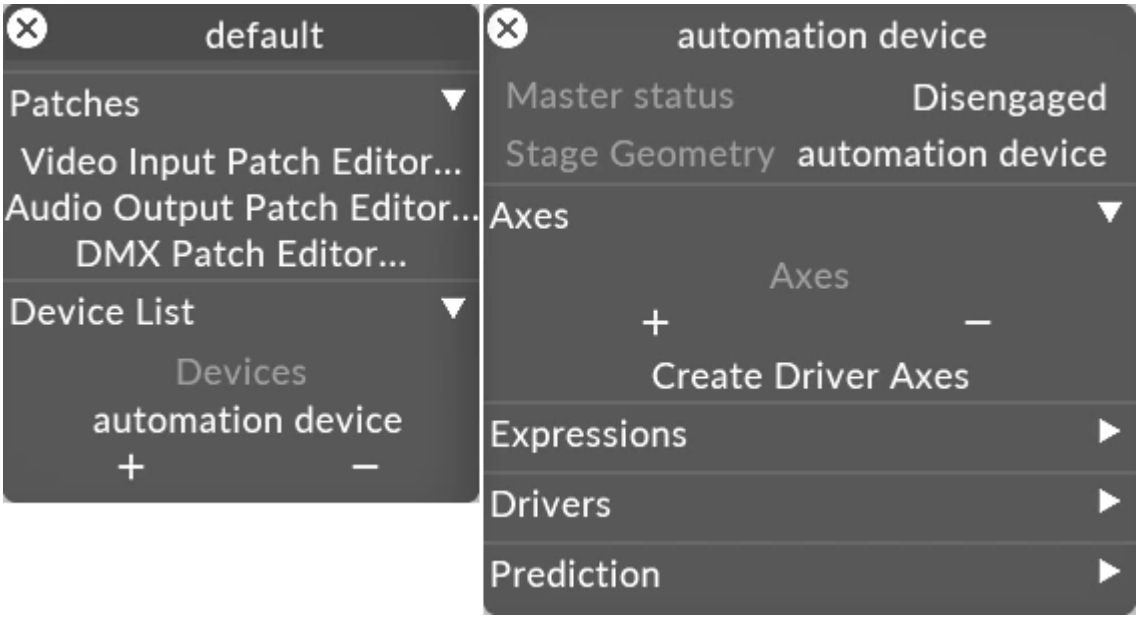
Creating Driver Axes

Create Driver Axes is a function that allows an automation device to automatically detect what axes the connected device is sending data for and thus save the user from manually creating all of the axes for the automation system

1. Once you successfully add & configure an automation device with its associated driver, clicking the Create Driver Axes button will show all the axes that automation driver is sending into Designer.



2. Right-clicking an Axis allows you to link that Axis to an object, for example Surface 1 and then to assign it a property, for example Offset.x' so that surface 1 is linked to the x offset of that axis.

3. Another piece of useful functionality, is the ability to set minimum & maximum inputs. For example, set the Automation system to the minimum point of reference, press **Set**, Disguise will read that value and input it for you, and repeat for the maximum.

> **Note**
>
> Note that when an axis is controlled by a driver, the driver always defines the position, even when overridden.

Motion Control Systems

Disguise has the ability to receive positional data from various motion control systems using the PositionReceiver Device. This data can be used to animate screens or props within the Stage level. This device will be the main interface between Disguise and the various motion control systems that are currently supported. It is possible to have multiple PositionReceiver Device devices. Depending on the system used objects in a stage can be moved and rotated in all three axes, matching the real world positions of the actual objects. This provides an accurate toolkit for previsualising a project.

Components of a motion control system

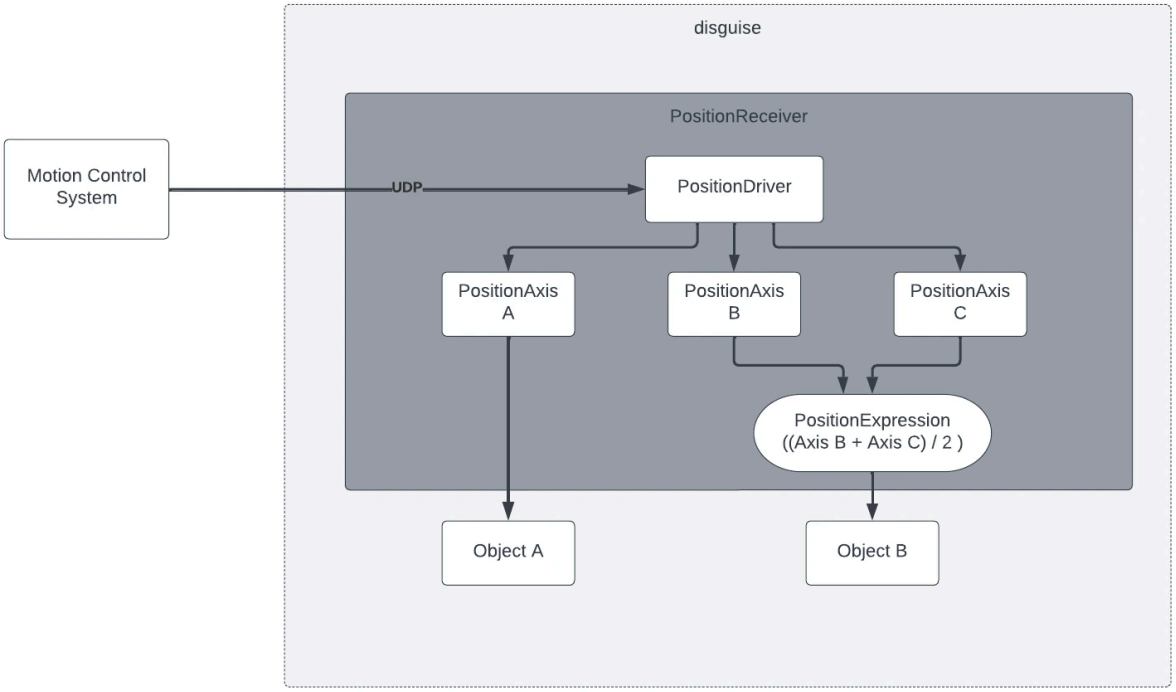


Diagram illustrating the flow of data from a motion control system to objects in.

Diagram illustrating the flow of data from a motion control system to screens/props in.

The motion control system sends data over the network (via UDP).

1. The system receives the data and passes it to the position receiver device and onto the PositionDriver.
2. The PositionDriver decodes the data and passes it onto the PositionAxis objects.
3. The Axis , named ‘A’, sends the position straight to thedefined parameter of Screen / Prop A .

4. The PositionExpression takes the values from both axes, ‘B’ and ‘C’, and evaluates it using the expression ((Axis B + Axis C) / 2) and sends the result to the defined parameter of Screen / Prop B .

Tracking Source

This field allows users to set up relationships between automation axes and objects in the stage.

All objects have a field called **Tracking Source** that allows the object to be controlled by a automation source. Follow these steps to configure the **Tracking Source**:

Begin by creating a PositionReceiver device

1. Right-click **devices** from the dashboard. This will open the Device Manager, which contains a list of active devices.
2. Select **+** to open the Device library. This lists which internal or external devices are available.
3. Type in the name of the new device into the **new device** text field.
4. Hit Enter. This will open a list of device types available in Designer.
5. Select the appropriate device type.

The new device will be added to the Device Manager's active device list, and to the Device library. The device's editor will also open.

[Animated GIF: Creating a device]

> **Note**
>
> **Please note**: Once the PositionReceiver device has been created correctly, then it can be used to link automation data to an object in the stage. There are two options for how this can be configured:

Once the **PositionReceiver** device has been created correctly, then it can be used to link automation data to an object in the stage. There are two options for how this can be configured:

Assign Tracking Source to Stage Objects

1. Right-click a surface (or puck, a venue, or anything that's an object)
2. Click the **Tracking Source** field.
3. Assign a **Tracking Source** to a surface.
4. Offset and Rotation fields should turn green to indicate that they are being controlled by automation, and the surface will be moved by the position and rotation information received from the tracking source

5. To clear, click the **Tracking Source** field and select **None**.

Assign Tracking Source to Stage Objects - Per Axis Workflow

1. Ensure axes have been created in the **PositionReceiver** device.
2. Right-click a surface (or puck, a venue, or anything that's an object)
3. Click the **Tracking Source** field.
4. Enter a new **objecttrackingsource** name and click OK.
5. An editor will open that allows you to assign individual axes from the **PositionReceiver** device to Position XYZ and/or Rotation XYZ on the object. Assign any axes that have been created in the **PositionReceiver** device to Pos XYZ and Rot XYZ in the required order.
6. The surface should then respond to the assigned axes motion and move as selected in step 5. For example, if axis 1 is assigned to position X for an object, moving that axis will cause the object to move in the X direction.
7. Offset and Rotation fields should turn green to indicate that they are being controlled by automation.
8. Try different axes/ automation data combinations to test further.
9. To clear, click the **Tracking Source** field and select **None**.

UDP Device

UdpDevices can be used to send commands over a network via UDP to 3rd party products.

UdpDevices are used by the Control Layer and the MatrixControl layer.

Creating a UdpDevice

A **UdpDevice** is created in the same way as any other device type.

See Creating Devices for step-by-step instructions on how to create a device, then select **UdpDevice** from the menu of different device types. This will open the **UdpDevice** editor.

UdpDevice properties

Verbose send

When enabled, the device logs every UDP message sent to the console. This option is intended for debugging and troubleshooting only. We recommend disabling it for devices that send messages frequently, as it can generate excessive console output.

IP address

The IP address of the destination 3rd party hardware. You must ensure that your network topology is configured to allow communications between the two machines.

Port

The network port of the destination 3rd party hardware. The 3rd party vendor will need to specify this value.

Failover command

A control string sent to the device over UDP when failover is triggered.

Recovery command

A control string sent to the device over UDP when failover recovery is triggered.

Test Commands

The following Test Commands are available:

- **Send Failover**
- **Send Recovery**

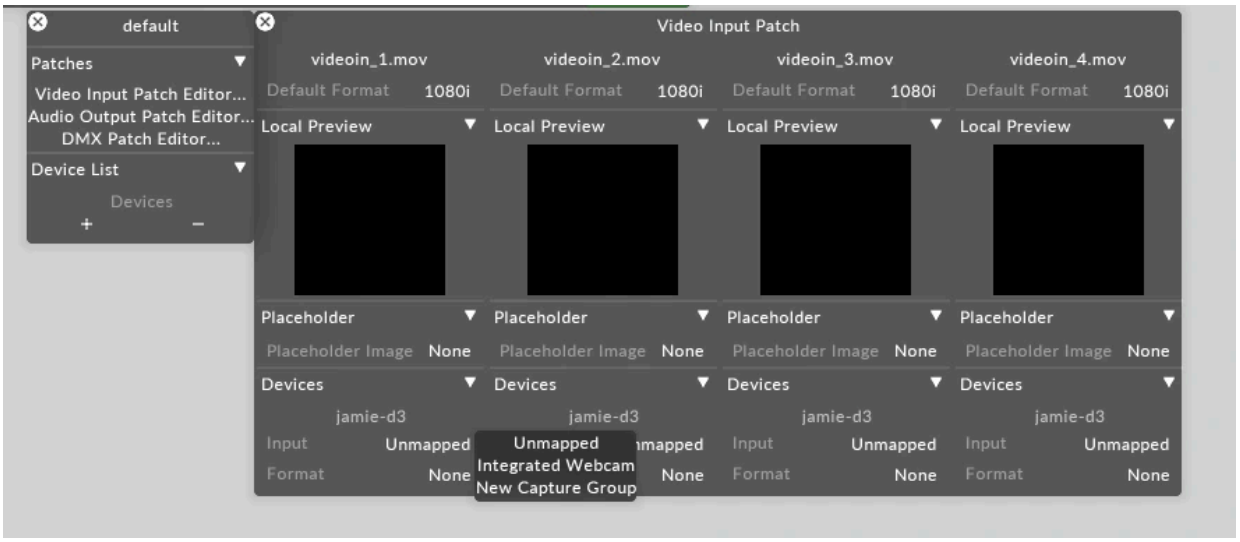
4K Quad Link Capture

r14.3 introduced additional video capture functionality to enable 4K Quad Link Capture over SDI.

> ⚠ **Warning**
>
> 4K Quad Capture is only supported on Pro and GX machines, with the exception of GX 1.

Setting up Quad Link 4K Capture

Right-click on **Devices** and then click onto **Video Input Patch Editor...**. When opening the editor and left-clicking on Input on one of the Video In Patches, there is the option for **New Capture Group** in the **Input** field.



When selecting this you will get an unmapped quad capture group.

From there you can select and choose the input for that quad capture group i.e. Bluefish 1A/1B/1C/1D.

> **Note**
>
> *Please note**:you cannot choose the integrated Webcam or any external capture cards for this feature.

To be able to do dual capture group, press the minus - symbol at the bottom of the capture group to make it Dual rather than Quad.

A key part to remember is to respect the Bandwidth of the Capture card.

For more information contact **Disguise Support**.

HDMI Video Capture

The EX 3+ and EX 2C servers support 4K DCI HDMI 2.0 video capture, in addition to 12G-SDI capture. This enables flexible combinations of HDMI and SDI inputs, depending on the server model and licensing.

Supported Input Configurations

That means the EX 3+ can support simultaneously:

- 1x 4K DCI HDMI 2.0 capture (HDMI connector)
- 2x 12G SDI inputs via Ports A and C (HD-BNC connector), or 4x 3G SDI inputs (HD-BNC connector)

That means the EX 2C can support simultaneously:

- 1x 4K DCI HDMI 2.0 capture (HDMI connector)
- 1x 12G SDI inputs via Port A (HD-BNC connector), or 4x 3G SDI inputs (HD-BNC connector)

or

- 2x 12G SDI inputs via Ports A and C (HD-BNC connector)

Requirements

To enable HDMI video capture, all of the following requirements must be met:

- Designer **r32.2.4** or later
- The appropriate **25Q3 OS image** or later must be installed for the server model, as specified in the Product Compatibility table.

Server Support Summary

The table below summarises the input and output capabilities for HDMI.

	EX 2C	EX 3+	Solo (Legacy)
4K Inputs	1x HDMI 2.0 and 2x 12G inputs for 2x 4K inputs, or 4x 3G inputs (HD-BNC)	1x HDMI 2.0 and 2x 12G inputs for 3x 4K input, or 4x 3G inputs (HD-BNC)	2x HDMI 1x 4096x2160 @30 Hz or 2x 1920x1080p @60Hz

	EX 2C	EX 3+	Solo (Legacy)
4K Outputs	2x 4K outputs (DisplayPort 1.4)	3x 4K outputs (DisplayPort 1.4)	N/A

Licensing Considerations

Licensing imposes the following limitations:

EX 2C

The EX 2C is licensed to accept up to two **4K / 12G input** at a time.

If both **12G-SDI inputs** are active, any **4K HDMI** signal presented to the HDMI capture input will be rejected.

EX 3+

The EX 3+ supports three concurrent 4K / 12G inputs, which may be any combination of **HDMI 2.0**, and **12G-SDI**.

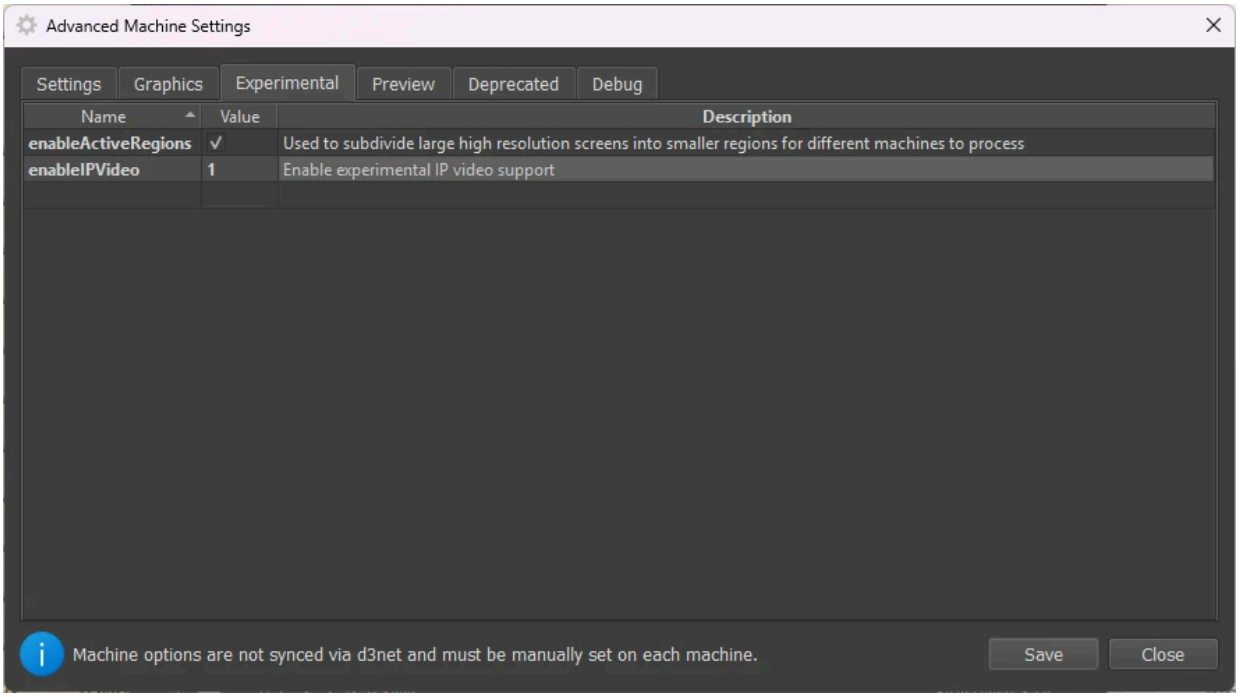
These limits are enforced at runtime and cannot be overridden.

ST 2110 Video Capture (Prerelease)

ST 2110 video capture is currently in prerelease and may have unresolved performance issues or instability. The feature allows capturing ST 2110 content over the network via the Mellanox network card included with VX and GX range machines. EX range machines are not supported.

Enabling IP Video

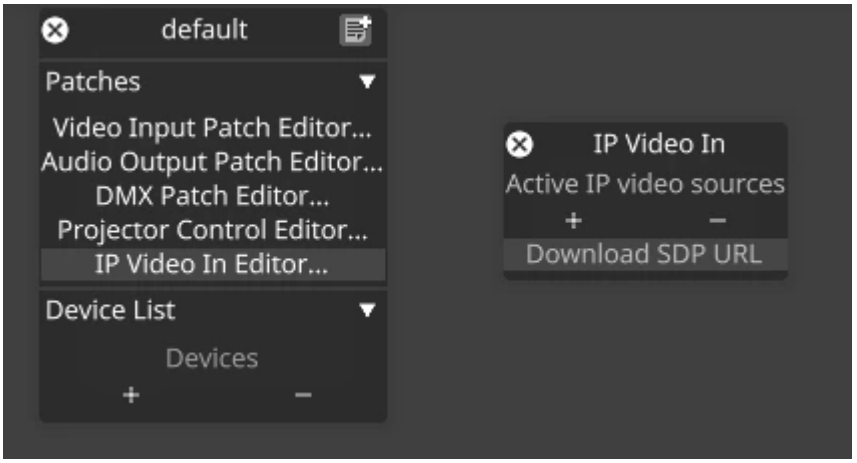
Before using ST 2110 video capture in Designer you must set the `enableIPVideo` option switch to 1.



Enable the option switch

Capturing ST 2110

ST 2110 capture devices are configured using the **IP Video In Editor** available in the device manager menu when the option switch is enabled.

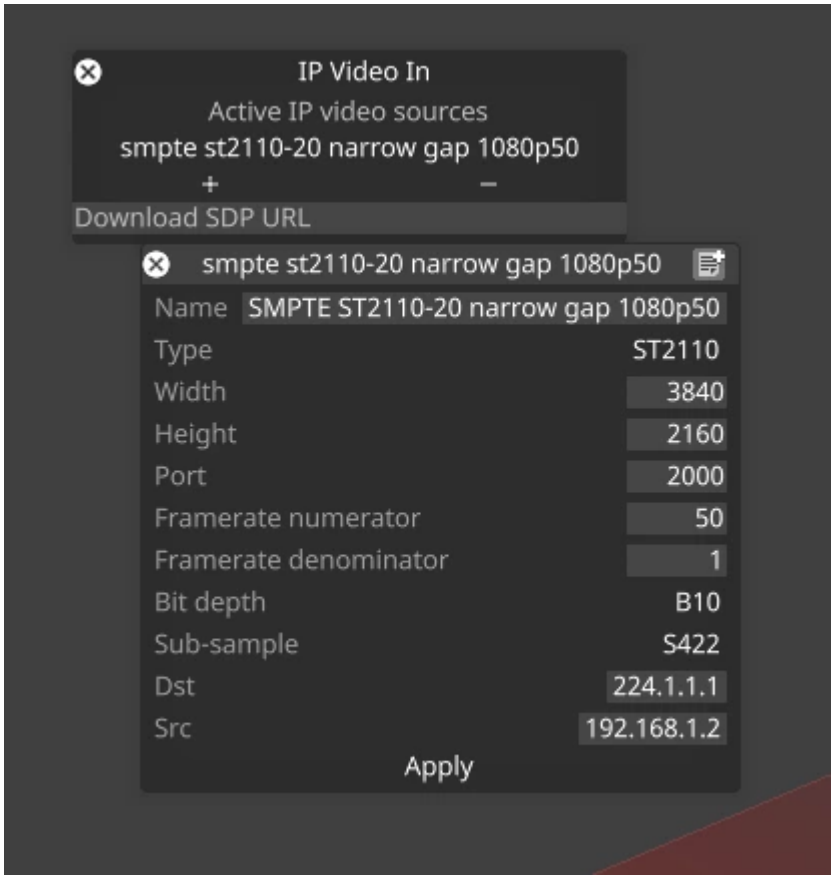


IP Video In Editor window

There are currently three functions to this editor:

- The list of enabled IP video sources can be added to or removed from. These objects (of type `PersistentIPVideoIn`) contain the definition of an ST 2110 video source in Designer.
- A URL to an SDP file can be pasted into the grey box at the bottom of the editor. When the 'enter' key is pressed, the URL will be downloaded and the SDP file parsed into a new `PersistentIPVideoIn` object. This is the primary means of registering an ST 2110 video source in Designer currently.
- If using NMOS a list of NMOS senders can be displayed for the user to select from. This will download the SDP file from the sender and connect the two.

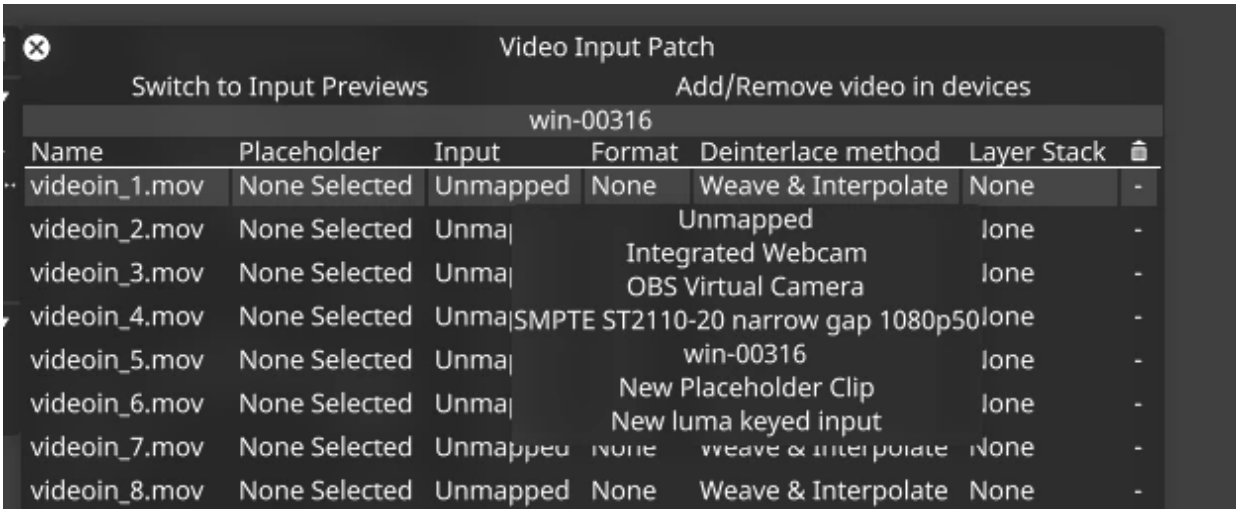
It is also possible to create a `PersistentIPVideoIn` object by placing a `.txt` SDP file in the `SDPFile` directory of the Designer project. Once a source has been registered, it can be right-clicked to open an editor where the details of the ST 2110 video stream can be checked:



The persistent IP Video Editor with ST 2110 options displayed

The fields are used as follows:

- **Name**: this is used to label the stream in the video input patch editor.
- **Type**: this should be set to “ST2110” or “NMOS”. Using NMOS means the other details will be set when a sender connects via NMOS.
- **Width**: the expected width of the incoming stream in pixels.
- **Height**: the expected height of the incoming stream in pixels.
- **Port**: the port to receive the multicast stream on.
- **Framerate numerator and denominator**: the expected rate of the incoming stream. This is only used for validating the timestamps on the received frames.
- **Bit depth**: the expected bit depth of the incoming stream.
- **Sub-sample**: the expected sub-sample format of the incoming stream.
- **Dst**: the multicast address that the incoming stream is being broadcast on.
- **Src**: the source address of the device sending the incoming stream. If present this is used to filter the packet flow.
- **Apply**: the apply button will update any active instances of the video capture with any changed values in this editor. Once a `PersistentIPVideoIn` object has been created (and so long as it remains in the active IP video sources) it will then appear to select in the video input patch editor to be patched like any other source:



The video input patch editor with a ST 2110 source mapped

Designer does not perform any active synchronisation of 2110 inputs. If Designer's output is synchronised to the same timing source (e.g. PTP via an IP-VFC) as the inputs, ST 2110 timing will ensure that input frames finish being received immediately before Designer begins drawing a new frame, allowing for minimal latency. If inputs are free-running or Designer is not locked to the same source as the inputs, an additional frame of latency may be incurred and input frames may not be displayed in alignment.

NMOS

If using NMOS, Designer will create an NMOS receiver for each IP Video instance which is of a type ST2110 or NMOS. If one is created as an NMOS type the other fields will be made read only. The NMOS receiver will be advertised with its full capabilities, allowing any sender to connect to it. When connected, the properties of the sender will be updated in the IP Video fields. This allows users to create a disconnected IP Video, where the sender and SDP file will be assigned later.

Debug view

The status of the ST 2110 capture can be viewed in the **VideoIn** section of the debug window. Some number of dropped packets is expected on beginning to receive the stream and on dropped frames in Designer, but the number should remain mostly static. Any dropped packet will result in a bad frame. The 'corrupt' and 'zero' counters are not used.

The video in debug widget with an ST 2110 capture active

Limitations

- ST 2110 captures will compete for bandwidth with RenderStream Uncompressed streams. Care should be taken that the total bandwidth required does not exceed the capability of the network adapter.
- Testing was performed with both the ST 2110 source and the Disguise server directly attached to a Disguise Fabric switch. Other switches and brands have not been tested. Receipt of a stream depends on the ability to correctly request receipt of the multicast packets via IGMP.
- Receipt of redundant ST 2022-7 streams is not currently supported. This feature is planned; in the meantime it is possible to create the two redundant streams as separate `PersistentIPVideoIn` objects and switch between the two to provide non-seamless redundancy.
- 8, 10 and 12 bit sources are supported. 16 and 16f are not.

- 4:2:2, 4:4:4 and RGB subsample formats are supported. The YCbCr transformation is performed using the BT.709 matrix. All YCbCr formats are limited-range, RGB is full-range.
- Interlaced and pSF sources are not supported.
- Framerate must be expressed with a denominator of either 1 or 1001.
- ST 2110 capture cannot be enabled on EX range machines.

Known issues

- If no network connection is made to the Mellanox card, mapping a ST 2110 capture device will result in a repeating “Unable to create video capture stream” notification.
- If packets are not being received to the network adapter once the IGMP request has been made, a message “RiverMax: RMAXd3 stream stall recovery., status = RMAX_ERR_UNKNOWN_ISSUE” will repeat in the console.
- An irregular notification about timestamp errors may appear in the notification zone; if no other issue is observed this can be safely ignored.
- Actors restarting their project may lose their ST 2110 capture devices. Removing and readding the device to the active IP video group should restore them.
- Adding SDP files to the SDPFile folder may not result in a device being created.

Setup Video Input

This topic covers how to set up video inputs in Designer, including SDI and NDI® sources.

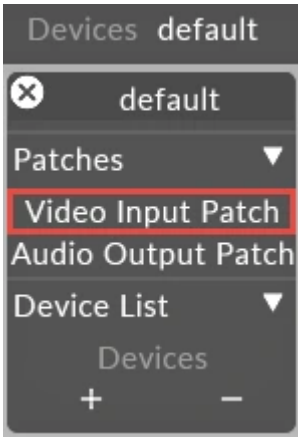
Sources

Disguise offers the ability to capture video from a number of sources.

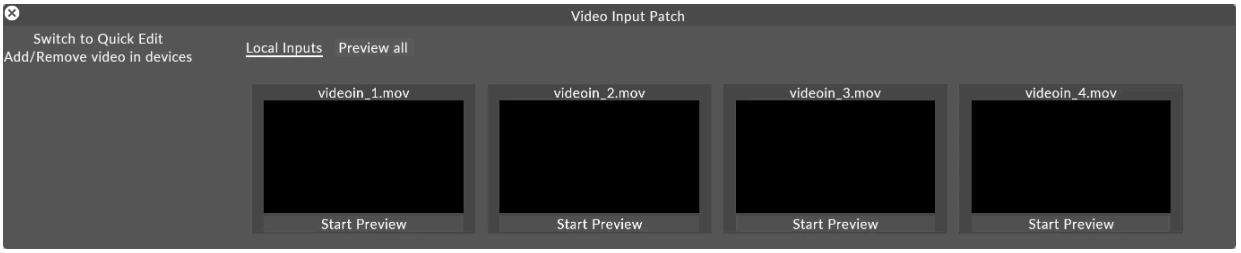
- 3G/HD/SD-SDI capture sources on hardware. See hardware manual for capabilities.
- DirectShow devices (intended for testing only, limited support, not for use on shows)
- NDI® sources, when an NDI® source is present on the network.

Concepts

Video capture is managed by the Video Input Patch manager, accessible via the Devices menu item.



Video Input Clips are essentially 'virtual slots' into which you can patch physical capture inputs for each machine in your Designer setup. You can have as many Video Input Clips as you wish, they are labelled **videoin_1.mov** and upwards by default.



Local inputs: shows only the local incoming signals on the selected machine.

Preview all: shows all incoming signals on the selected machine.

Switch to quick edit: changes the format of the editor to a list view, for quick group editing of properties.

Add/Remove video in devices: opens the logicalVideoIn editor, allowing you to create new inputs and duplicate existing ones.

A Video Input Clip can be selected by left-clicking its thumbnail in the editor, this will display the following properties:

Placeholder image: If no capture device is mapped locally for this video input clip, the placeholder image will be shown instead. This is useful for pre-site sequencing.

Input: The physical input that the source is coming through on the machine.

Format: The desired format that you wish to capture for this Video Input Clip. If the desired capture format is not supported on the mapped capture device, Disguise will attempt to find the closest match.

Deinterlace method: Deinterlacing method to use on incoming video, details of available methods can be found here.

Process HDMI RGB Limited as Full: Only shown on servers with HDMI capture. Sometimes a video source sending RGB Full doesn't state this correctly and will be detected as RGB Limited. Selecting this option will process it as the RGB Full data it really is, so no colour depth is lost.

Layer stack: The layer stack to apply to the incoming video, to apply time-independent visual effects. More information on layer stacks can be found here.

Crop size: The crop rectangle size in pixels to apply to the incoming video. The applied crop will be centered on the frame e.g. a horizontal crop of 1600px on a 1920px original frame will remove 160px on the left hand side and 160px on the right hand side.

Crop offset: The offset in pixels to apply to the crop rectangle. Offsetting the crop rectangle more than half the crop size in an axis will cause the crop rectangle to shrink in order to stay within the original frame.

Local Preview: A preview of the input selected on the local machine. You can start and stop the preview using the button below the thumbnail.

Start/Stop preview: this button below the thumbnail will toggle from showing nothing, to showing the current input. When you select **stop preview**, the thumbnail will return to black,

but the video input is still being received.

Configuration

To configure a Video Input Clip execute the following steps

1. Ensure your video source is connected correctly (via SDI etc).
2. Right-click **devices** in the dashboard.
3. Left-click **Video Input Patch**. By default, four Video Input Clips will be presented to you. Or if you are on a piece of Disguise hardware, whatever number of physical inputs the hardware has, will be displayed. In the **Devices** section, you will find your local machine as the first item. Select the input source connection for your local machine (e.g. Bluefish 1A or Phoenix 1A).
4. For 4U v2.5 and older systems, you will need to select the **Format** of the source signal. On Pro and GX range machines, the signal will be auto-detected.

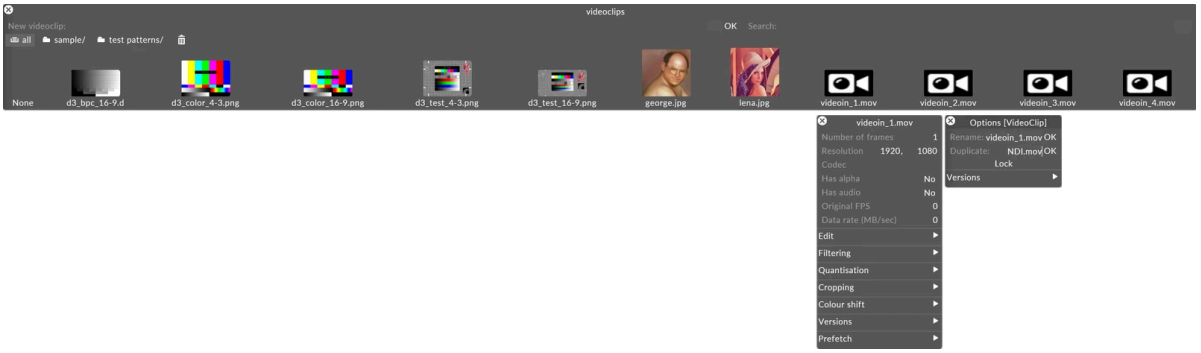
The live picture from this capture source will now show in the **Local Preview** section (only once you have clicked **start preview**).

You can now use the videoin_1.mov clip as a live source in the Video Content Layer on the timeline (see below).

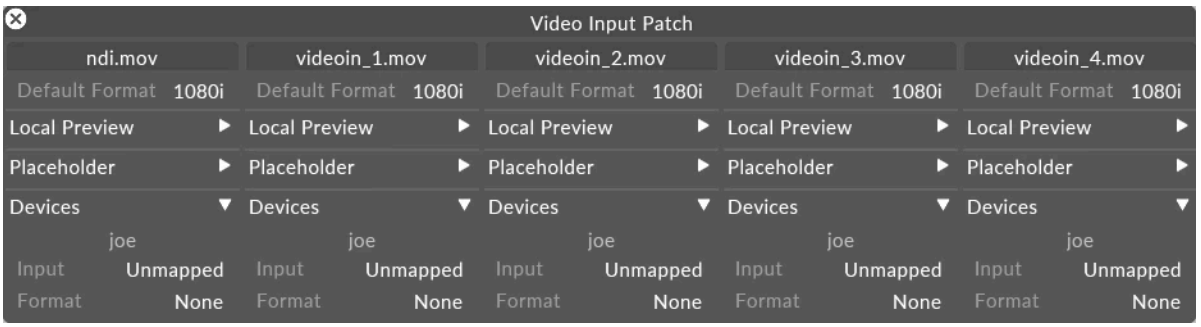
Duplicating video input sources

Sometimes it may be necessary to duplicate the video input sources, to gain additional virtual capture 'slots'. This can be useful for looping back internal cameras or for use with NDI®.

1. Open the video clip editor by right-clicking a video clip from the media picker.
2. Select **duplicate** and give the new input a name.



3. The new video input will now be available in the video input patch editor.



Working with live video on the timeline

Live video is applied to the video keyframe editor using the special Video Input Clips: **videoin_1**, **videoin_2**, **videoin_3** and **videoin_4** respectively. As soon as the video inputs are configured, they are treated just like normal video clips.

- For example, drop **videoin1** onto the keyframe editor to route video from the first sampler in the device manager, and so on.
- Use the appropriate Mapping type to map the camera input to the screens.
- Right-clicking the **videoin** thumbnail lets you edit colour correction and other clip properties, just like normal clips.

Input latency

By default, Designer delays incoming video by one frame in order to ensure smooth playback across inputs.

This figure can be adjusted using the `smoothVideoInputFramesDelay` options switch.

Video De-Interlacing Methods

Designer is able to de-interlace incoming interlaced video.

While Disguise does not recommend interlaced formats, there are a number of options to attempt to reduce the visual artifacts which are visible with these legacy formats. For the majority of cases, using a 720p signal results is better quality imagery.

Interlaced formats consist of time and space separated fields which are half the height of the full progressive frame. These fields contain even or odd lines from different points in time. They are offset from each other by one pixel vertically and by the field rate in time.

De-interlacing methods attempt to reconstruct as close to a true progressive frame as possible from this reduced data. As with all systems which create new data, this may not be what was truly captured in the first instance.

The following de-interlacing methods are available:

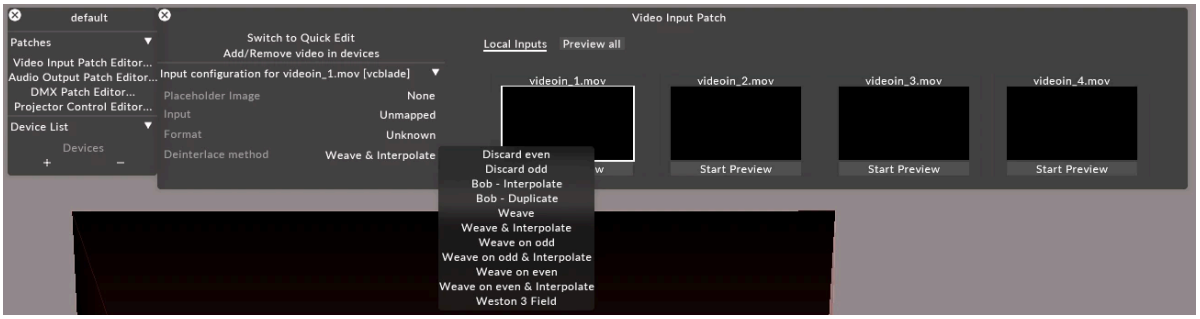
- Discard even
- Discard odd
- Bob - Interpolate
- Bob - Duplicate
- Weave
- Weave & Interpolate
- Weave on odd
- Weave on odd & Interpolate
- Weave on even
- Weave on even & Interpolate

Each of these methods has a tradeoff with different types of content, depending on vertical detail frequency, and horizontal movement.

Accessing the de-interlacing methods

1. Right-click on the **Devices** tab in the dashboard.
2. Left-click on the Video Input Patch Editor.
3. Select the desired Video Input and expand its properties menu.

4. Expand the **Deinterlace method** tab.



Discard methods

The discard methods discard either the even or the odd field, thus removing 50% of the received data. If this option looks best with the captured data, then consider switching to a lower frame rate progressive signal, as the effective frame resolution is half height and half field rate. Slowly scrolling thin horizontal features can ‘disappear’ into the other field using these techniques, leaving a low frame rate flickering result in the worst case.

Bob methods

The bob methods render every field one by one, enabling full field rate display of the data, but can result in a vertical bobbing motion, especially visible at high contrast edges. The interpolate method is generally less noticeable, due to the fuzzing of these edges. The vertical bobbing motion comes from the contrast between the two fields - if there are a series of red lines, followed by a series of white lines, the area which transitions from red to white will flicker due to the last red line only being visible 50% of the time.

Weave Methods

The weave methods use 2 fields to reconstruct the progressive frame. These methods resolve issues with high frequency vertical features disappearing between fields, but introduce issues with horizontal motion. When horizontal motion is active, and the weaved fields are separate in time (i.e. not PSF) then the change in position during that time creates a comb-like effect, showing the horizontal movement. Against a high contrast background, this is not pleasant.

The interpolating variants of the weave methods attempt to reduce this combing by combining 50% of the most recent field with the older field. When working with moving images, this blurs out the combing effect, and it’s possible to believe the effect is similar to motion blur. However, this method shares similar issues with the bob methods, in that if the most recent field does not have the same information as the line it is being blended with, a darkening effect can occur.

Weave takes the 2 most recent fields, even across different frames, and presents them immediately. This can result in some flickering artifacts with the interpolating method, as the most recent field which was received takes precedence. This is mitigated with Weave on even, which always takes the most recent full frame, and weaves pairs of fields in the same way every frame. The cost here is frame rate, which is halved by waiting for both pairs to become available before showing them.

Weave on even is useful for interpreting PSF formats. Interpolation should not be necessary with PSF, as PSF is effectively an interlaced transport for a progressive frame - there is no temporal offset between the fields.

Weave on odd can be useful if at some point in the upstream signal chain, the interlaced fields have been switched to the wrong order.

Weston 3 Field also known as W3FDIF, is a 3-field vertical-temporal de-interlacing method developed by the BBC and included in ffmpeg.

Visca Camera Device

A VISCA camera is a professional video camera that uses the VISCA protocol (Video System Control Architecture), to allow external devices to remotely control its functions. This protocol is used to adjust settings like zoom, focus, and white balance, and is common in pan-tilt-zoom (PTZ) cameras used in broadcasts, video conferencing, and live streaming. The control can be sent over serial connections or, more commonly now, over an IP network.

Disguise supports controls sent over an IP network only.

This topic outlines the setup steps in order to control VISCA-compatible PTZ cameras over network using a Disguise media server.

Visca Camera Setup

Requirements

- VISCA Camera that supports IP connectivity.
- Optional Disguise machine with a relevant capture card (only if you want to use the camera as a live video input).

Workflow

1. Create a UDP device from Device Manager.
   - Set the IP Address
   - Set the Port on the UDP device
2. Create a Visca Camera device from Device Manager.
   - Set the Address.
   - Set the Control Device to the UDP device.
   - Set the Camera Model.
3. Create a CameraControl layer on the timeline.
   - Set the Camera field to the camera that was created earlier.
   - Click the Command field to open up the keyframe editor.
   - Create and keyframe your desired commands for the camera.

Creating a UDP device

For detailed steps on creating a UDP device, see UDP Device.

Create a ViscaCamera device

1. Right-click **devices** from the dashboard. This will open the Device Manager, which contains a list of active devices.
2. Select **+** to open the Device library. This lists which internal or external devices are available.
3. Type in the name of the new device into the **new device** text field.
4. Hit **Enter**. This will open a list of device types available in Designer.
5. Select the **ViscaCamera** device type. Type the name exactly — one word, capital V and C — variations such as “Visca Camera” will not match.

Controlling the camera

1. Create a CameraControl layer and add it to the timeline. For more information see Creating layers.
2. Create presets and keyframe accordingly. For more information, see CameraControl layer.

Mapping the camera to a video input

To bring the camera’s live video feed through Designer and output it to a physical screen:

1. Patch the capture input to a Video Input Clip (e.g. `videoin_1`) in the Video Input Patch manager.
2. Create a Video layer.
3. Set the layer’s **media** property to the Video Input Clip from step 1.

Address

The VISCA address of the camera being controlled. Multiple cameras on the same network are distinguished by address.

Control Device

The device in the device manager that communicates with the physical camera — typically the UDP Device created earlier.

Camera Model

Select the type of camera that supports the VISCA protocol. Currently supported models: **300H** and **360SHE**.

10-Bit Displays

Requirements

- A display that is capable of outputting 10-bit.
- A machine capable of outputting 10-bit such as the VX, GX or EX ranges.

Workflow

1. Bit depth can be set globally for the whole project in the **Feed View > Global Settings > Project Bit Depth**. The options are 8-bit or 10-bit.
2. Bit depth can be set per machine, independent of the project bit depth in the machine editor widget.
   - Right-click on the machine and navigate to the Display Management separator.
   - Select from Use Project Bit Depth, 8 bit and 10 bit.
3. Click **Apply Feed settings** after changing bit depth.

HDR

In order to enable HDR within Disguise, follow these steps:

1. DO NOT set HDR in Windows or on the graphics card; this is not necessary.
2. Set and apply 10-bit bit depth as described in the section above.
3. Apply output transform or colour profile according to the display requirements.

> **Note**
>
> **Please note**: Disguise does not send metadata - ensure the output device is set to match the profile.

> **Note**
>
> **Please note**: HDR displays must be set to force their profile due to the InfoFrame not being set by Designer and therefore is not able to be detected by the screen.

10-Bit Test Pattern

The test pattern we use is a greyscale consisting of multiple rows, each with a gradient of greyscale blocks that represent different steps between black and white. Each row is designed to contain more steps than the last, corresponding to higher bit depths. The 8th row has 256 steps, while the 10th row represents 10-bit with 1024 steps. If your media server and output devices are set up correctly to handle 10-bit, you will be able to distinguish between each of the steps in the 10-bit row. The 8th row will therefore be visually distinct from the rows above it.

Note, ensure you are applying the 10-bit test pattern without scaling. Scaling could squash the graduated steps making it difficult to see the difference in rows.

Known Issues

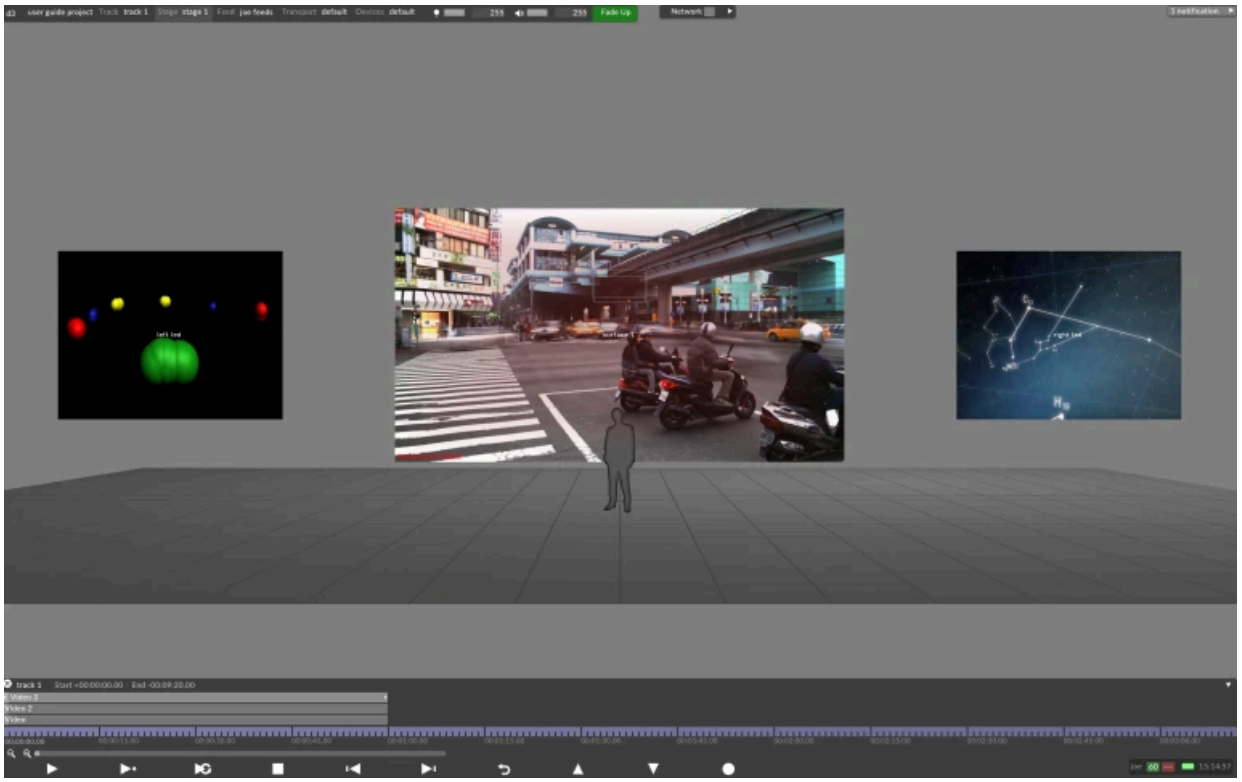
- DVI VFC cards cannot run 10-bit content or input and so will not function when 10-bit mode is enabled.
- When using 4K 50hz/60hz with HDMI 2.0, the HDMI available bandwidth means you need to make use of 4:2:2 chroma subsampling. Currently Designer only creates 4:4:4 EDIDs when applying feed settings, so this setting will need to be set in the GPU control panel. View the Managing EDIDs page for more information.
- Depending on what the display device is, it may need to be in a specific mode to enable 10-bit. This could be known as high performance, high colour mode or true colour mode. Refer to the manufacturer specifications on how to enable the 10-bit mode for your display of choice.

For more information on 10-bit workflows, please contact **Support**.

Adding a Feed Rectangle for Screens

> **Warning**
>
> Feed rectangles flash blue, every 5 minutes in the GUI. This is to prevent the GUI head being used as an un-authorised output. The blue flash is not visible on the outputs.

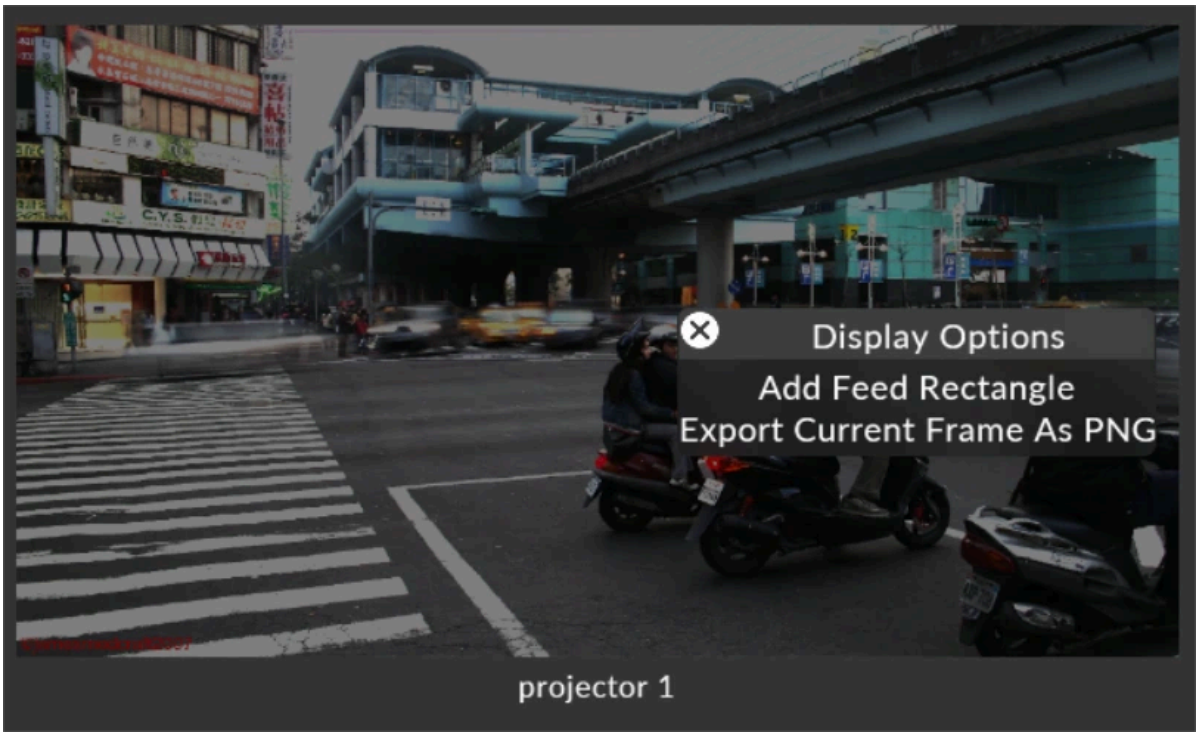
The image here shows a Screen in the Stage Visualiser:



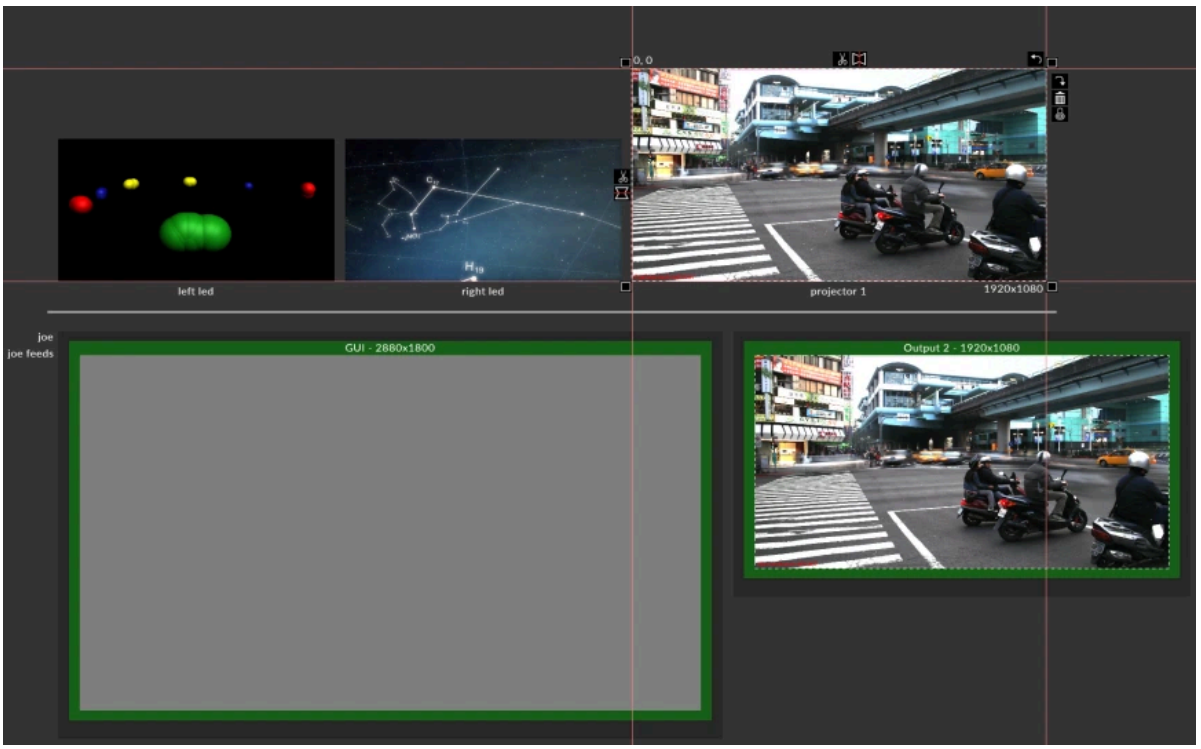
1. Left-click feed in the State editor (bar at the top of the screen). This will switch the Stage level with the Feed level. The Screen section (top half of the Feed level) now shows a simplified view of the Screen or the virtual projector output, depending on the type.

   Screens from the Stage level are displayed in the Screen section (top half of the Feed level)

2. Right-click the Screen you want to create a Feed rectangle for. This will open the Feed rectangle menu.



3.Left-click add feed rectangle. This will create the Feed rectangle.



Feed rectangle samples content from the Screen you right-clicked to the output head, in this example Output 2

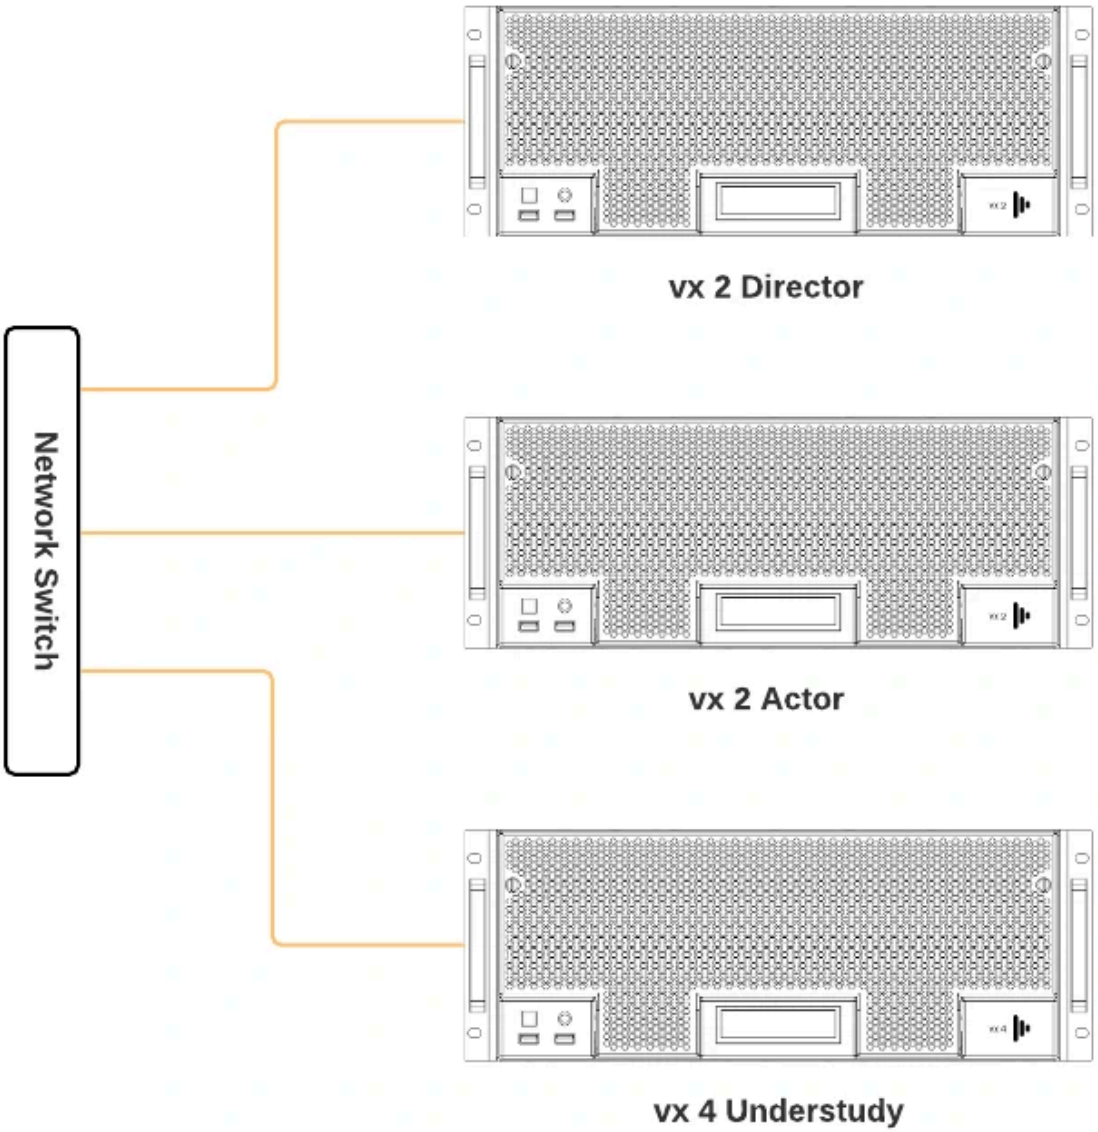
The Feed rectangle samples the whole of the Screen you right-clicked. The output head of the Feed rectangle, in this example Output 2, represents the area of the output display the content is copied to.

> **Note**
>
> Feed rectangles can also be easily and quickly created using the Alt+Left Click shortcut to drag an arrow from a screen onto an output. To do this, simply press and hold the Alt key as you left-click, hold and drag the mouse from a stage screen above the line to a desired output below it.

Alternate Feed Scenes

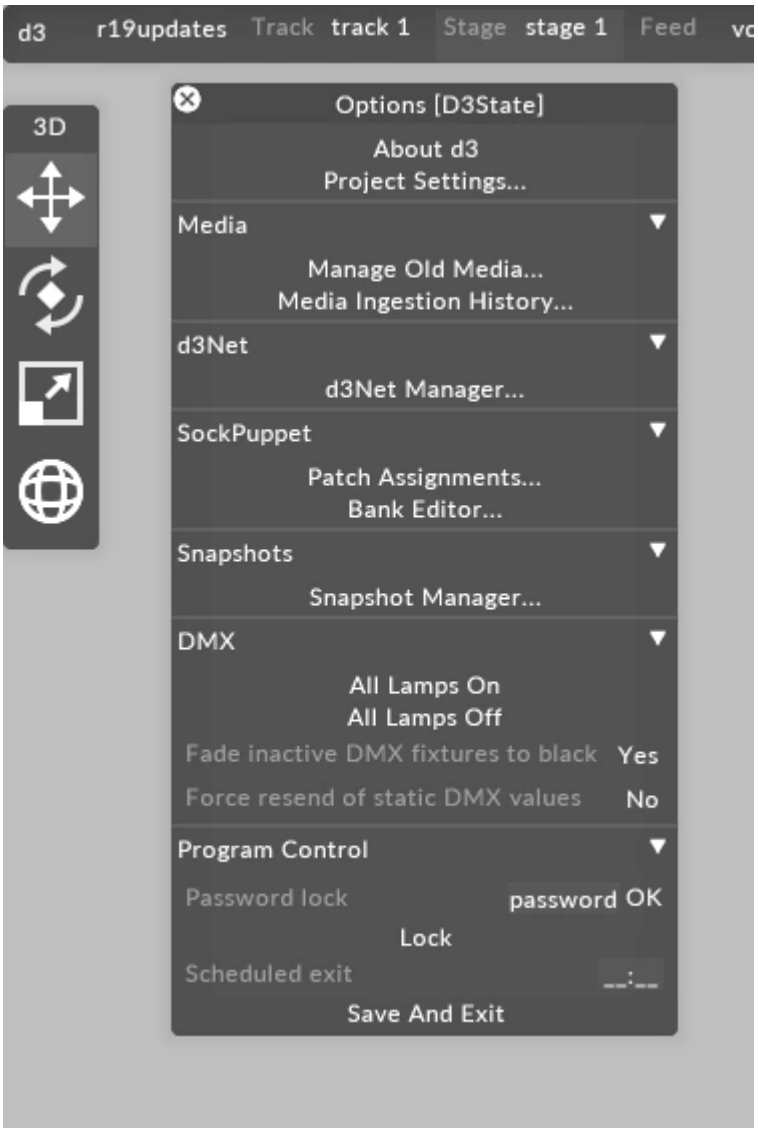
In the scenario where you may have several types of Disguise servers serving as Director, Actor, and Understudy roles in a single d3net network, then it may be necessary to use an alternate feed scene to direct the content of certain screens to the correct outputs on the Understudy depending on the role that it takes on during a failover.

For example, this system is using 2 vx 2 machines as Director and Actor, and a vx 4 as an Understudy.



The vx 2 Director has 2 HDMI VFC Cards but the vx 2 Actor has 1 HDMI card and 1 Quad SDI card. For the vx 4 to properly be able to take on either role during failover, we will need to create two Feed Scenes in order to correctly map the outputs for both Director and Actor vx 2 servers to the correct outputs on the vx 4 Understudy. Here's how to set this up:

1. Right-click **d3** in the dashboard to open the **d3State - Options** window, then navigate to the **d3net Manager**:



2. In the **d3Net Manager**, add and configure a Director, Actor, and an Understudy to match the types of Disguise servers being used:

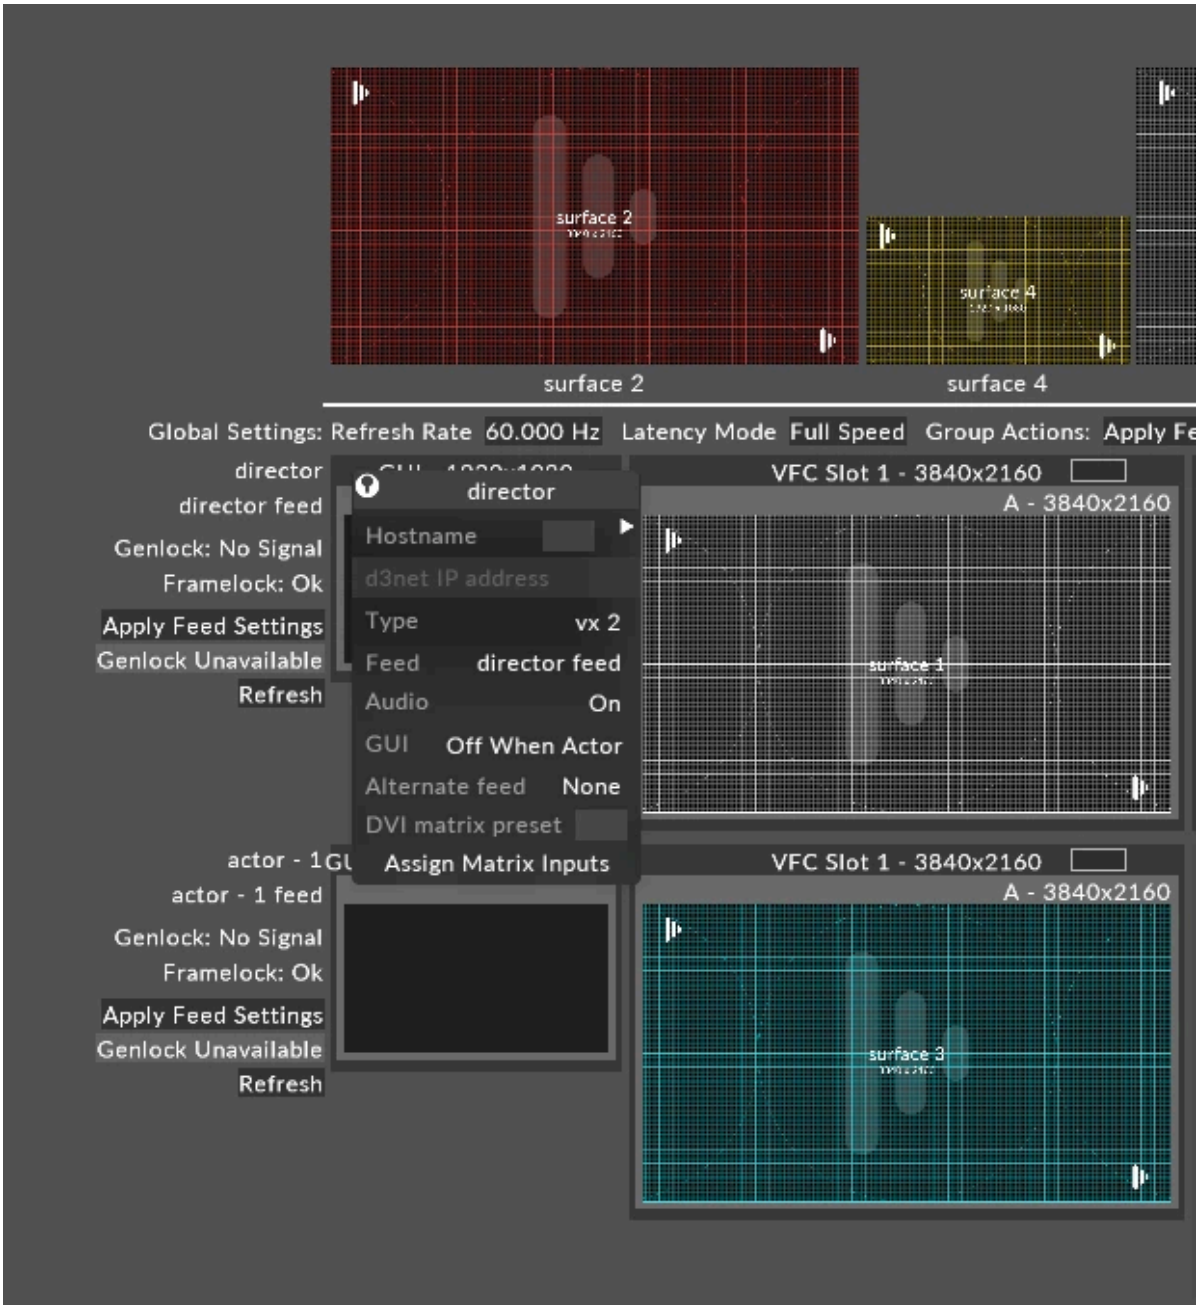
d3Net machines

3. Left-click on **Feed** in the dashboard to switch to the Output Feed Level.
4. Configure the VFC slots for each of the vx 2 machines according to the types of VFC cards in each machine.
5. Configure the feed scenes to assign the screens to outputs as desired.

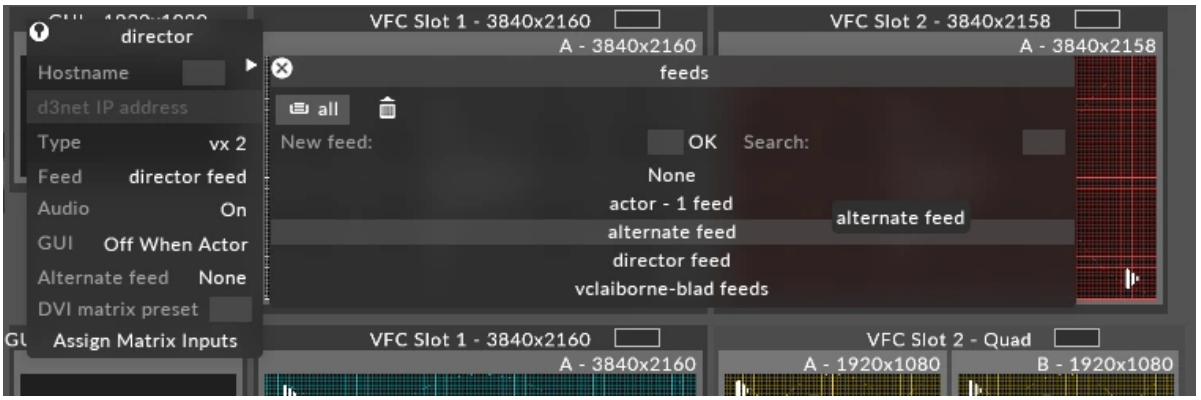
Note: The Director and Actor will each have their own unique feed scene.

To create the Alternate Feed Scene

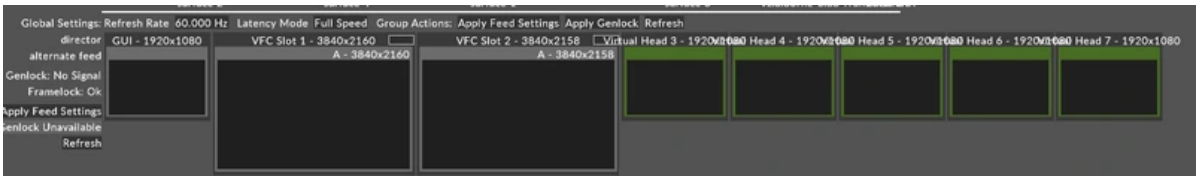
1. First, right-click on the name of the Director machine (to the left of the Director GUI); this will open the d3Net Machine manager for the Director.



2. Once open, left-click on the Director feed name to open the feeds list. Create a new feed in this window (in our example we have used the name alternate feed):

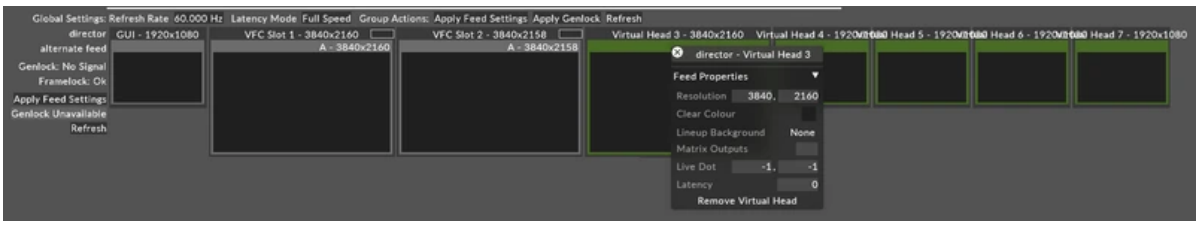


3. Add additional virtual heads to the alternate feed scene (on the Director) to match the number of outputs available across the entire Director/Actor system. In this example we've added 7 total outputs to our Director feed because of the Quad SDI VFC card being used in the Actor. These outputs are indexed numerically from left to right as Outputs 1-7.

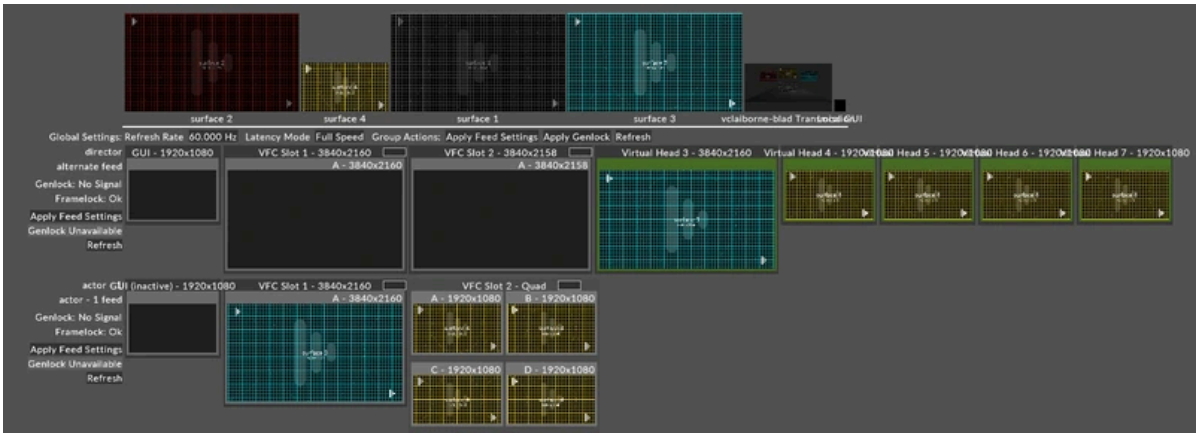


> **Note**
>
> **Please note**: Virtual heads are used because the vx 2 has 2 physical outputs while the vx 4 has 4 outputs.

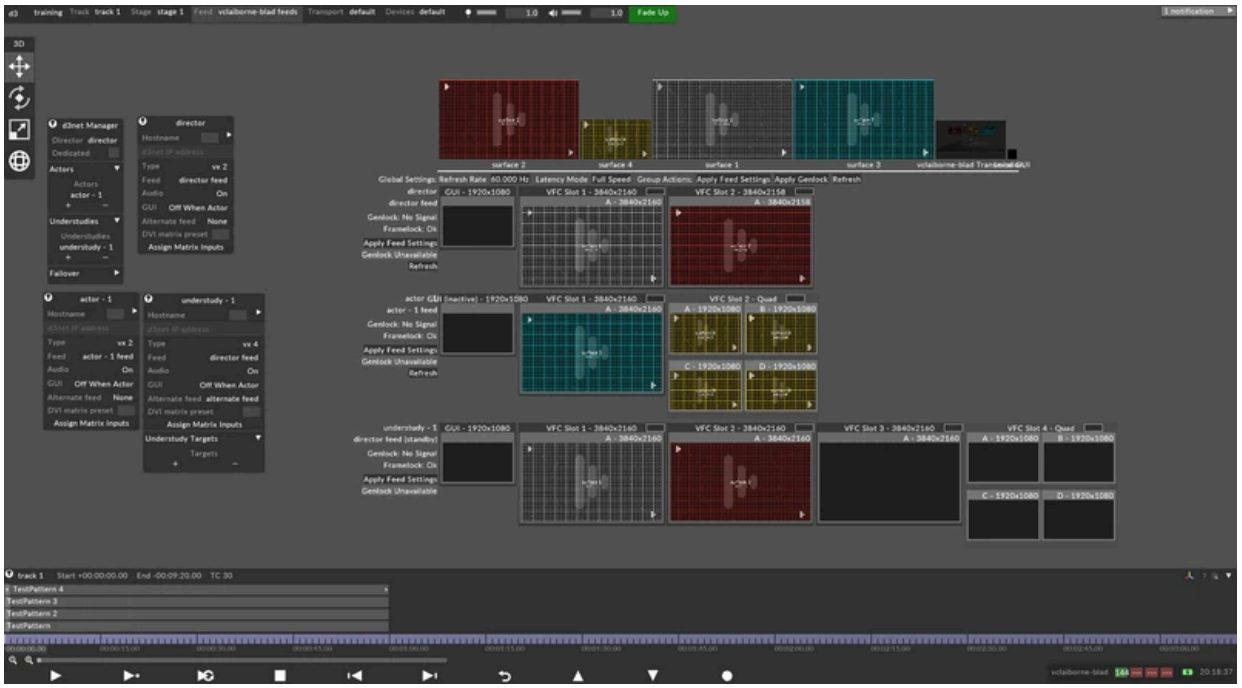
4. The first VFC card in our Actor vx 2 is an HDMI card, so we will change the resolution of virtual head 3 on the Director to 3840x2160 px.



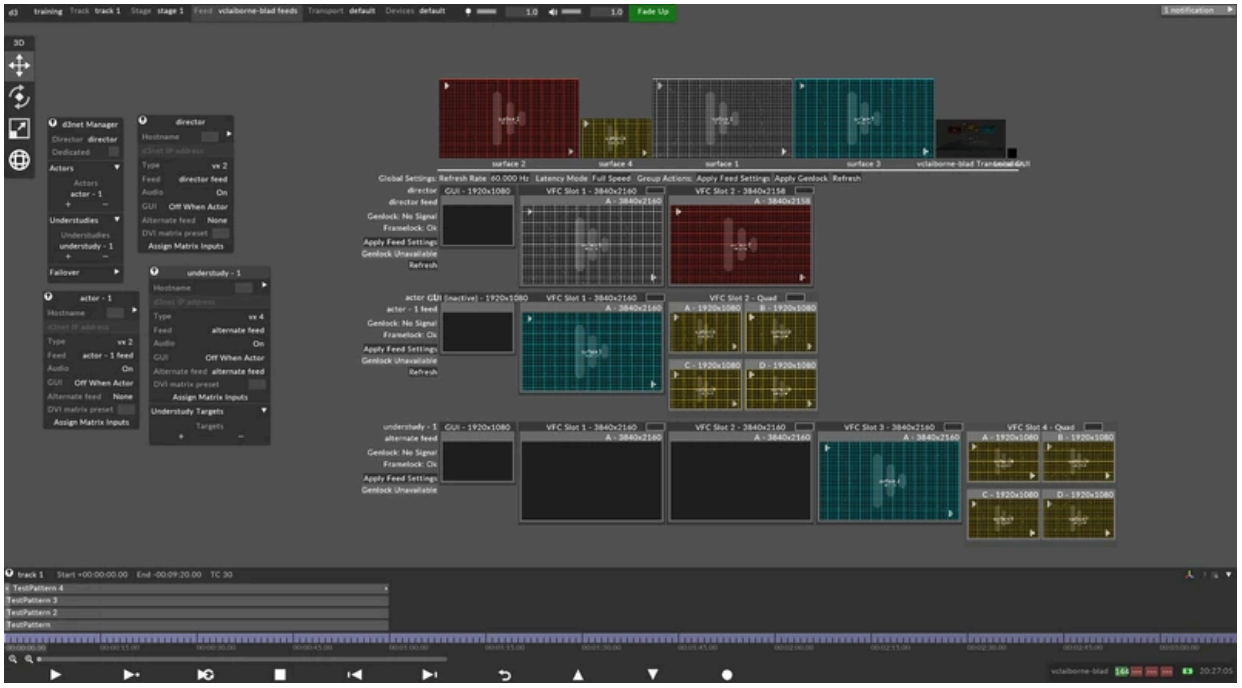
5. Next, create Feed Rectangles on outputs 3 -7 in the Director Feed scene. The screen to output mappings for these feed rectangles should be identical to the feed scene configuration for the Actor outputs 1 & 2:



6. Reset the Director's feed scene back to the primary Director feed and set the Understudy to the Director feed scene as well. Then, in the Understudy machine manager select the alternate feed scene from the list. In this example the alternate feed scene is called alternate feed. At this point, the Understudy is setup to take on the feed scene for the Director and Actor machines along with the required screen to output mappings.



Understudy configured to Director Feed



Understudy configured to Alternate Feed

Apply Feed Settings

Applying feed settings pushes a machine's pending output changes, such as a new resolution or timing mode, to its physical outputs so they take effect. Designer holds these hardware-level changes until you apply them. Applying briefly interrupts the outputs, so you can set up a head fully and commit everything in one step rather than disrupting them with each edit.

Applying feed settings is the final step of configuring an output. First edit a head's resolution, timing or feed properties on the Head Configuration page, then apply the settings to commit those changes to the hardware.

> **Warning**
>
> Applying feed settings will cause the GUI and outputs to refresh several times as the settings are applied, and may take longer than 10 seconds to complete. Please be patient while the process completes!

When you need to apply feed settings

Most feed changes update live and need no action. These include rearranging Feed Rectangles, background colour, live dot, head naming and similar feed-scene properties.

Changes that reconfigure the **physical output**, however, must be manually applied before they take effect:

- **Resolution**
- **Timing mode / refresh rate**
- **Bit depth**, which also requires a reboot (see **Changes that require a reboot** below)

A head with unapplied changes of this kind is shown in orange in the feed view. The full head colour status system is documented under Output Head Colour on the Head Configuration page.

Applying feed settings

To apply the settings for a single feed, left-click the **Apply Feed Settings** button to the far left side of that feed.

To apply the settings for every machine in the current feed scene at once, use the global **Apply Feed Settings** button in the feed toolbar. You will be asked to confirm before the settings are applied.

While the settings are being applied, the head shows an **Applying Feed Settings...** status and flashes blue and grey in the feed view.

> **Note**
>
> Designer machines and dedicated Directors have no feed settings to apply, so the global **Apply Feed Settings** button is unavailable when only those machines are present.

Applying feed settings to another machine

When applying feed settings to another machine (for example, applying feed settings on an Actor from a Director), the output heads of the other machine will flash blue and grey in the local machine's feed view for the duration of the process.

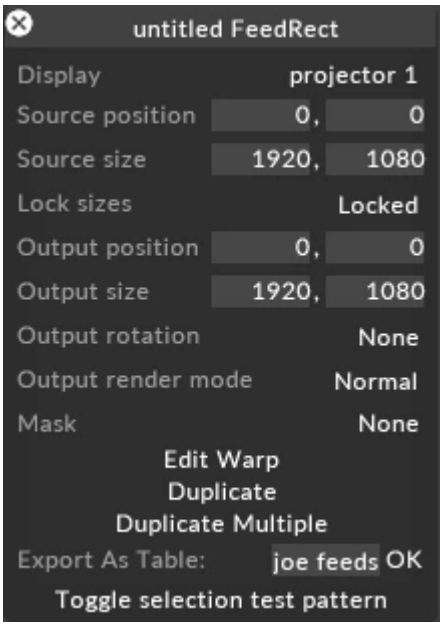
Changes that require a reboot

If applying feed settings changes a machine's output **bit depth**, Designer warns that the change requires a reboot. The machine must be manually rebooted for the new bit depth to take effect.

Blending and Masking Outputs

Designer allows the user to generate custom softedge textures and masks inside it. You can then apply the softedge texture directly on the output and update the shape, gradient and gamma settings in real-time.

Create a softedge mask on the output

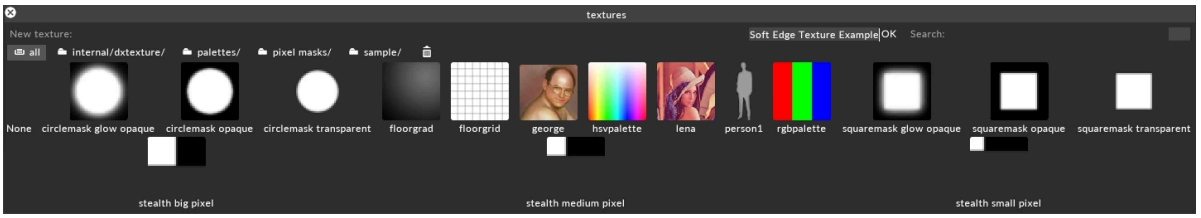


Select Mask option is used to create a custom SoftEdgeTexture mask

This will open the Texture object library which shows all of the still image files saved on your local hard-drive in the **DxTexture** folder. For more information on the **DxTexture** folder and other folders please see the sub-chapter Placing media files for a project.

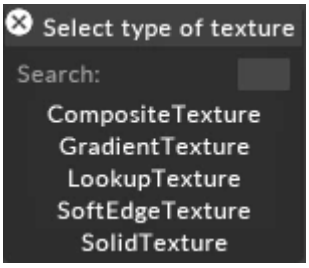
1. In the top-left corner of the library, where it says **new texture**, type in the name of the softedge mask, for example **Output1_softedge**.
2. Hit **Enter** and select the texture type **SoftEdgeTexture**.

3. Open the Feed level by left-clicking **Feed** from the dashboard (bar at the top of the screen), right-click the appropriate output and select select mask from the options list.

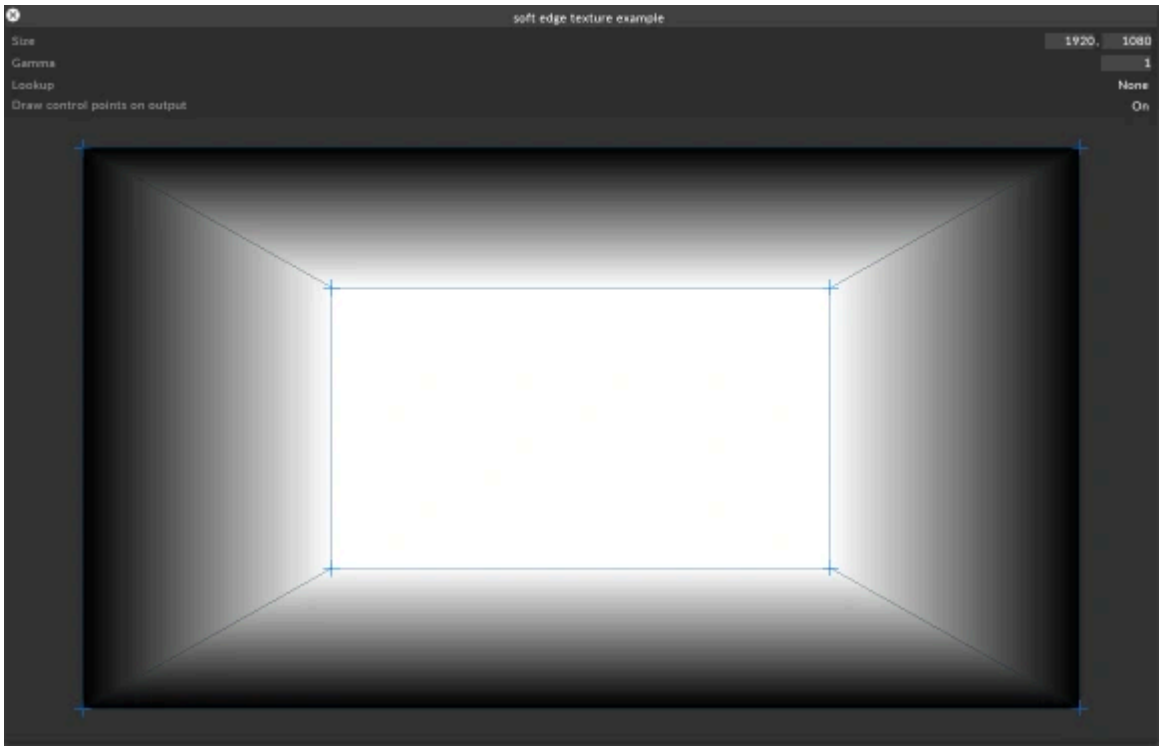


Texture object library being used to create a SoftEdgeTexture mask.

4. Create a new Texture, and choose SoftEdge Texture when prompted.



Softedge editor



Resolution

The resolution values are shown in the top right corner of the softedge editor. The resolution is automatically set to the resolution of the output head.

Adjust global gradients through gamma

The gamma value adjusts the global gradient between the inner and outer points in the softedge mask.

Select and move points

Select individual points, pairs of inner and outer points, or drag-select multiple points to adjust the blend level.

Add and remove points

- Add more points by holding down **Ctrl** and left-clicking between existing points.
- Remove points by right-clicking a point.

Adjust local gradients

Adjust the gradient between an inner and outer point by dragging them further apart, or closer together.

> **Note**
>
> **Please note**: press Esc to exit texture editing. Right-click the output feed and select 'Edit mask (Name) to edit the texture again.

Create a mak rather than a softedge

To create a mask rather than a softedge, set either **gamma** to 0 (this will set a sharp edge between the inner and outer points regardless of spacing between them) or move the inner and outer points closer together.

Composite multiple textures

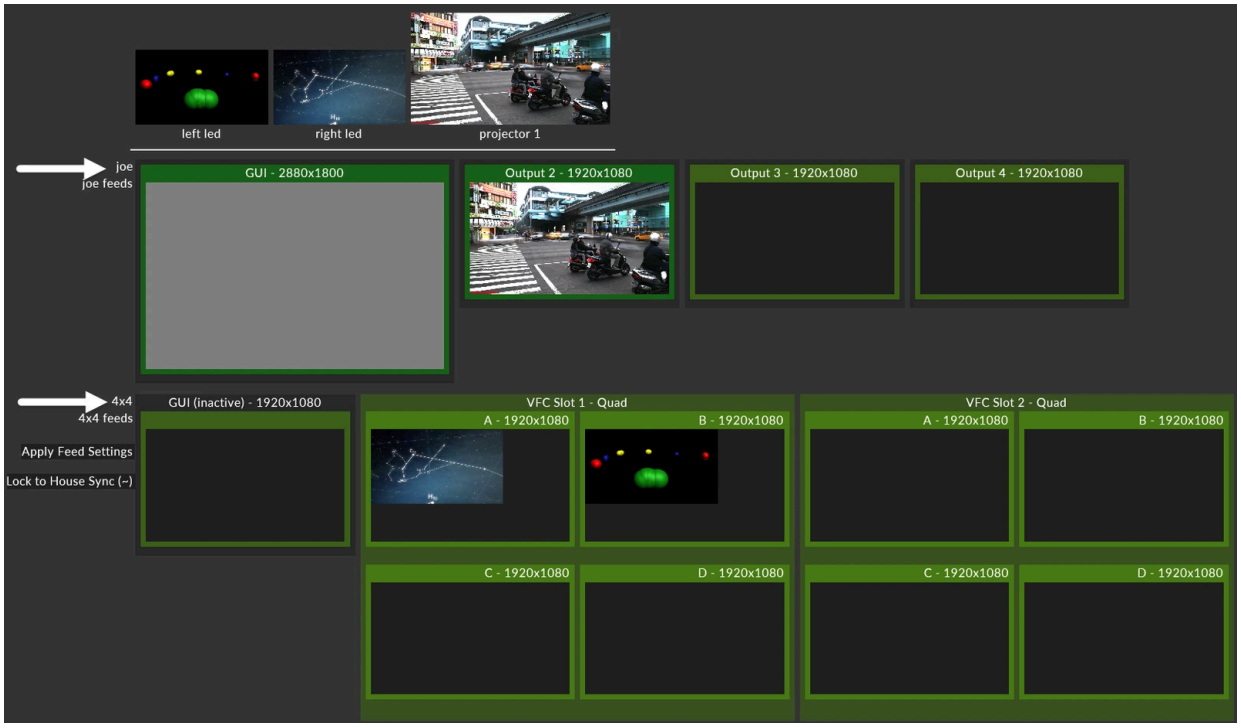
Disguise allows the user to generate two different textures and composite them into one single texture.

To do composite multiple textures:

1. Create two different textures. They do not have to be of the type **SoftEdgeTexture** but can also be of the types **GradientTexture** and **SolidTexture**.
2. Repeat the same process as above when creating a texture but this time choose the texture type **CompositeTexture** and name it, for example, **SoftEdge_output1** and **Gradient_output1**.
3. After creating the the CompositeTexture texures, their corresponding outputs will turn grey. This is because the CompositeTexture textures need to be told what textures they contain.
4. Right-click the output head and select edit mask **(SoftEdge_output1)** and edit mask **(Gradient_output1)** in the options window.
5. Set the resolution of the CompositeTexture texture.
6. Add the first texture by left-clicking **add new layer**, and then selecting the image from the Texture library.
7. Click **add new layer** again and select the second image.
8. To multiply the two images together, set the blend mode of image two to **multiply**.
9. Press **Esc** to exit texture editing.

Configuring d3Net Feed Settings

The feed view closely links d3Net settings with the Feed Scene, allowing users to quickly access d3Net settings and assign feeds by simply right-clicking a machine's name.

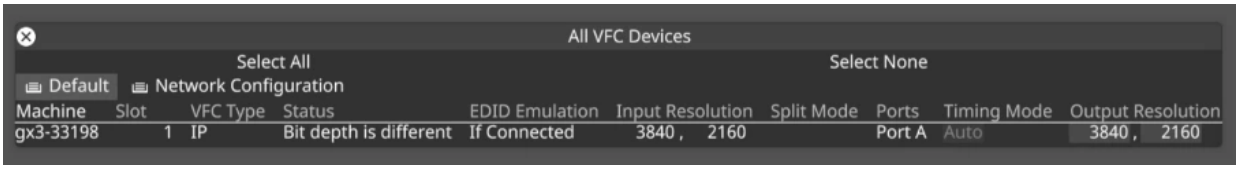


From those settings, you can assign and create new feeds for each machine connected to the network.

For more information on how to set up and configure d3Net, please refer to our d3Net overview section and sub-sections.

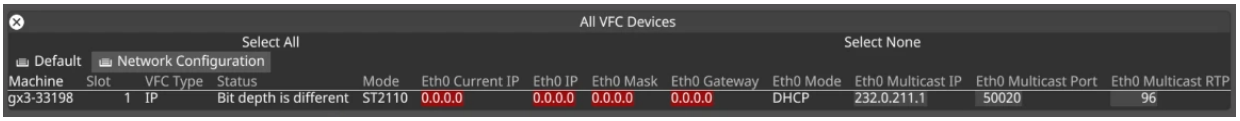
Configuring Multiple VFC Cards

As well as configuring individual VFC Card slots and ports via their editors, it's also possible to configure multiple VFC cards at the same time via the **All VFC Devices Editor**. This is accessible via the **Edit** button in the main button row.



Like all List Editors this widget lets you configure multiple VFC cards at the same time by multi-selecting.

Network Configuration



If a machine has one or more IP-VFC cards present, then a second **Network Configuration** tab will appear. This lets you set the same settings as the IP-VFC's port editor.

Non-IP-VFC cards and IP-VFC cards outputting in SDI mode are still shown in this editor but cannot be edited.

You can also use this widget to import and export configurations via the standard steps for all List Editors.

Configuring Output Settings

Output settings control how each physical output head is driven: its resolution, timing, sync status and feed properties.

An **output head** is a single physical video output that the server sends a feed to, for example a port on a VFC card or a standard graphics output. Heads are named Output 1, 2, etc. on non-VFC machines, and A, B, C and D for each Quad VFC card. Each head is configured independently.

Configuring an output is a two-part workflow: edit a head's settings, then apply those settings to the hardware so they take effect.

1. **Configure each head**: set its resolution, timing mode, latency and matrix routing, and monitor its colour-coded status.
2. **Apply the feed settings**: push resolution, timing and bit-depth changes to the physical outputs so they take effect.

Head Configuration

Each output head has a settings menu for monitoring its status and editing its resolution, timing mode, latency and feed properties. The feed view also shows a colour-coded status for every head; this **Output Head Colour** system is documented on the Head Configuration page.

Apply Feed Settings

Resolution, timing mode and bit-depth changes must be applied to the physical outputs before they take effect; most other changes update live. The Apply Feed Settings page covers the full rule and the orange "unapplied" status.

Configuring VFC Card Ports

Individual ports on each VFC slot can be further configured. To access this menu for any port, simply right-click the VFC port's displayed name or the coloured box containing the port.

For more information on configuring VFC slots, please visit this link. It's also possible to configure multiple VFC cards via the All VFC Devices editor.

For an overview on VFC cards, please visit this link.

General Options

Head Name

Allows the user to give each port a friendly name as seen in the feed view.

Display Mode

Allows the user to select the desired output modes (resolution, interlaced/progressive scan, bit rate, colour format) from a list of available modes at the current project refresh rate. The list of modes will vary between different VFC card models.

Custom Resolution

Allows the user to override the Display Mode resolution. For Mirror/Quad modes, the total resolution tiled across all the ports should fit within a maximum output resolution of 4096x2400. For Quad 4K, the resolution should fit within the same limit.

> **Note**
>
> The Quad SDI VFC and IP VFC cards do not support setting custom resolutions.

Timing Mode

Allows the user to force timing mode of the output signal, e.g. SMPTE, CVT. Setting it as AUTO works out the best timing in the following order:

1. DMT
2. CEA
3. CVT
4. CVT-RB

5. CVT-RBv2

Matrix Input

Allows the user to directly route inputs when connected to a video matrix. On machine failover, Designer sends a command to the matrix to route the understudy's outputs to the matrix's outputs. For more details on setting up matrix routing, please see this page.

Output Properties

> **Note**
>
> The Output Properties fields do not apply to Quad DVI and SDI cards.

Port Status

View the current status of the port. The status will indicate if a configuration field is different from the card's current settings, e.g. 'Refresh rate does not match project refresh rate', or if there is an error, e.g. 'Incompatible VFC'.

Temperature

View the current temperature of the port in degrees Celsius.

House Sync

View the current status of the Genlock signal.

Current Output

View the current output format (resolution interlaced/progressive scan, bit rate, colour format etc.) of the port. If this differs from the selected Display Mode, the Port Status field will tell the user what is different. Apply feed settings to resolve the difference.

EDID Emulation

Allows the user to select how Designer manages EDID emulation of this port. For more details please see this page.

Feed Properties

Background colour

Allows the user to set a background colour on the port. This can be used for identifying individual output ports and slots. It can also be used to validate that there is output from Designer.

Lineup Background

Allows the user to select a background texture to help with lining up feed rectangles.

Matrix Outputs

Allows the user to directly route outputs when connected to a video matrix. For more details on setting up matrix routing, please see this page.

Live Dot

Allows the user to set the xy coordinates of a flashing pixel that gives confidence that outputs are working correctly.

Latency

Allows the user to delay the output of the port by a number of frames. Negative values delays all other heads.

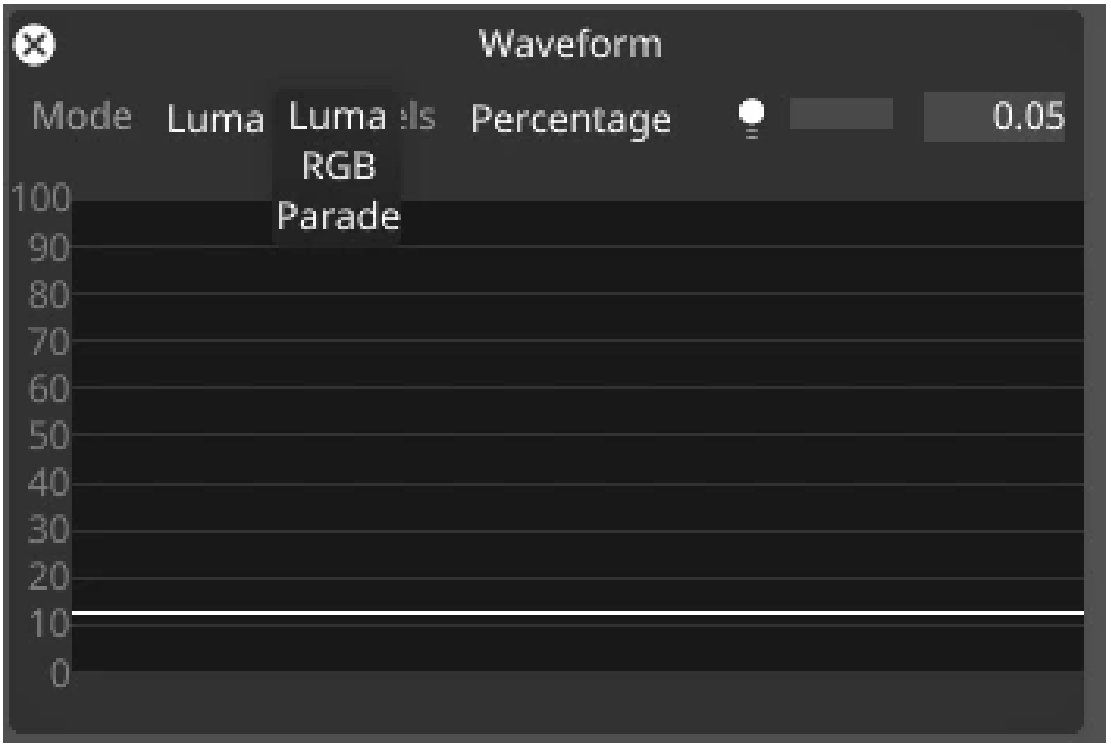
Output Options

Export Output Frame

Exports the port's current output as an image. The image format can be changed under Project Settings. For more details please see this link

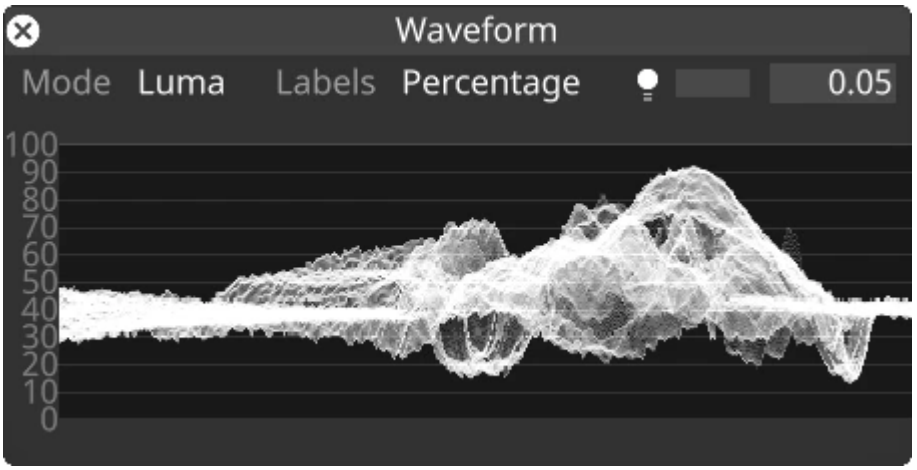
Histogram

Opens a live histogram, displaying the distribution of colour and luma, of the current output.



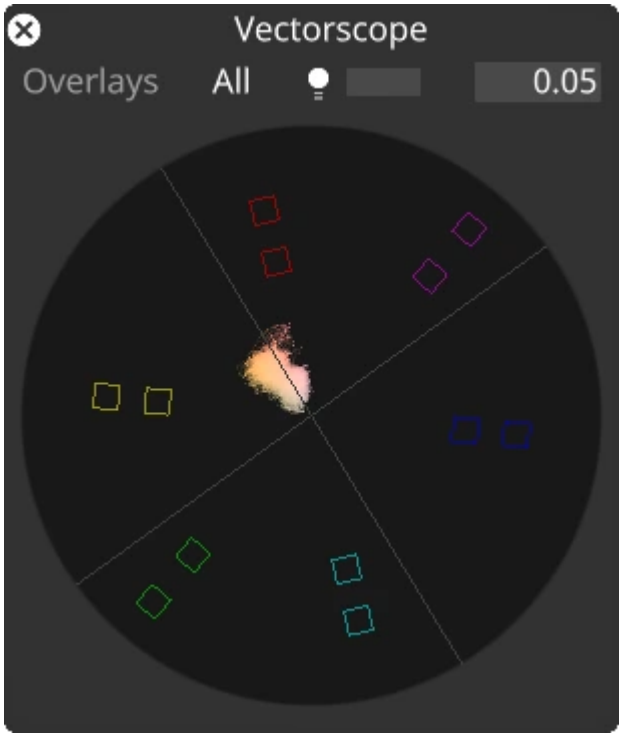
Waveform

Opens a live waveform diagram, displaying intensity of colour and luma, across the current output.



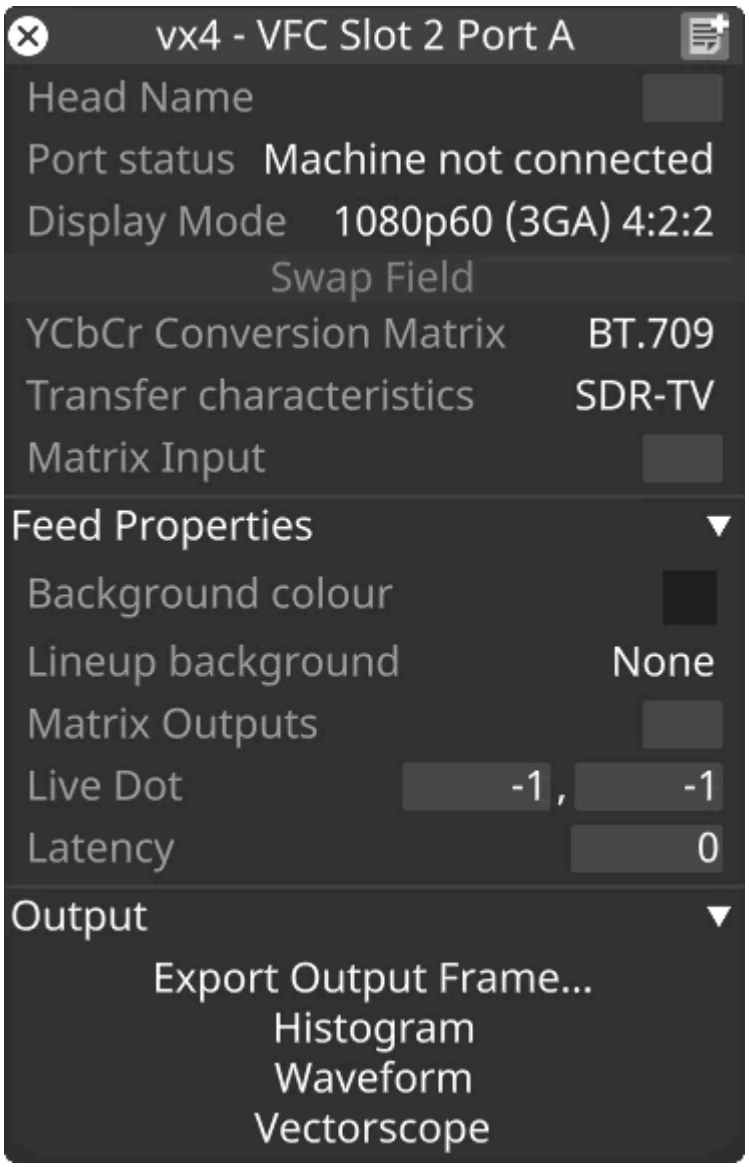
Vectorscope

Opens a live vectorscope, displaying the UV chroma channels on an x-y plot, of the current output.



Vectorscope
Overlays
All
0.05

Options Specific to Quad SDI Card



Swap Field

For interlaced output, this button allows the user to swap between aligning the odd or even fields with the incoming genlock signal.

Colour Conversion Matrix

Allows the user to define a colour conversion matrix (e.g. Rec.709, Rec.2020). This field is included in the SMPTE-425 video Payload Identifier. For outputting HDR video, Rec.2020 is required, combined with Transfer Characteristics field described below.

Transfer Characteristics

Allows the user to define the transfer characteristics (e.g. SDR, HLG, PQ). This field is included in the SMPTE-425 video Payload Identifier. For outputting HDR video, HLG or PQ is required, combined with the Rec.2020 Colour Conversion Matrix described above.

> **Note**
>
> **Please note**: For HLG and PQ transfer characteristics with Rec.2020 colour space, the SDI VFC card utilises the full video data range, including 'super white' and 'super black'. See the bottom of Table 5 of the BT.2020 standard for more details.

Options Specific to HDMI Card

Reset HDMI Card

This button power cycles the HDMI card. This could help resolve issues such as an intermittent loss of card detection by Windows.

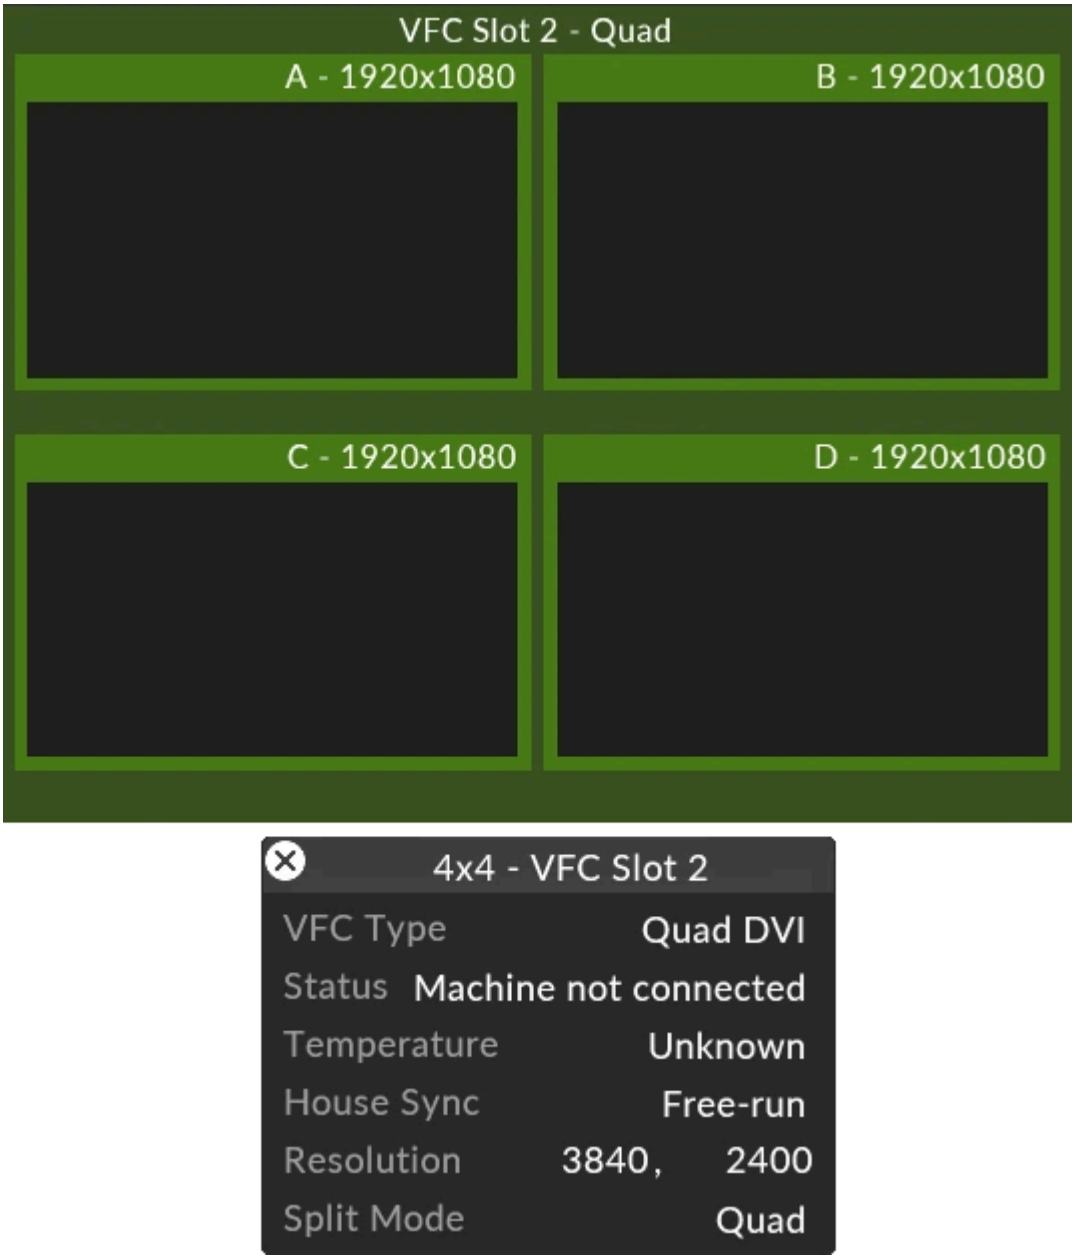
Options Specific to IP VFC Card

There are a number of options specific to the IP VFC card. For more details please see this page.

Configuring VFC Card Slots

Thanks to the new Feed UI, VFC card users are now able to configure and monitor each individual card slot through the VFC slot configuration menu.

To access this menu for any VFC slot, simply right-click the VFC card's displayed name or the outer box containing the output heads (which represents the VFC slot):



For more information on configuring VFC ports, please visit this link. It's also possible to configure multiple VFC cards via the All VFC Devices editor.

For an overview on VFC cards, please visit this link.

VFC type

Allows the user to select which type of VFC card a virtual machine is using prior to the machine being connected. Useful when working on a show off-site from a designer machine. These settings are auto-detected and do not need to be selected while a machine is connected.

Status

Allows the user to monitor the current status of the card. Issues such as display mode differences and connection problems are displayed here. If no issues are found, the status will appear as Normal.

Resolution

Displays the overall resolution of the VFC slot. This setting can only be changed manually on DP Passthrough cards.

Split mode

Enables the user to split the VFC card output in three different ways:

Mirror: One identical HD output repeated on all screens connected to the slot. Only one screen is displayed in the feed when in Mirror mode.

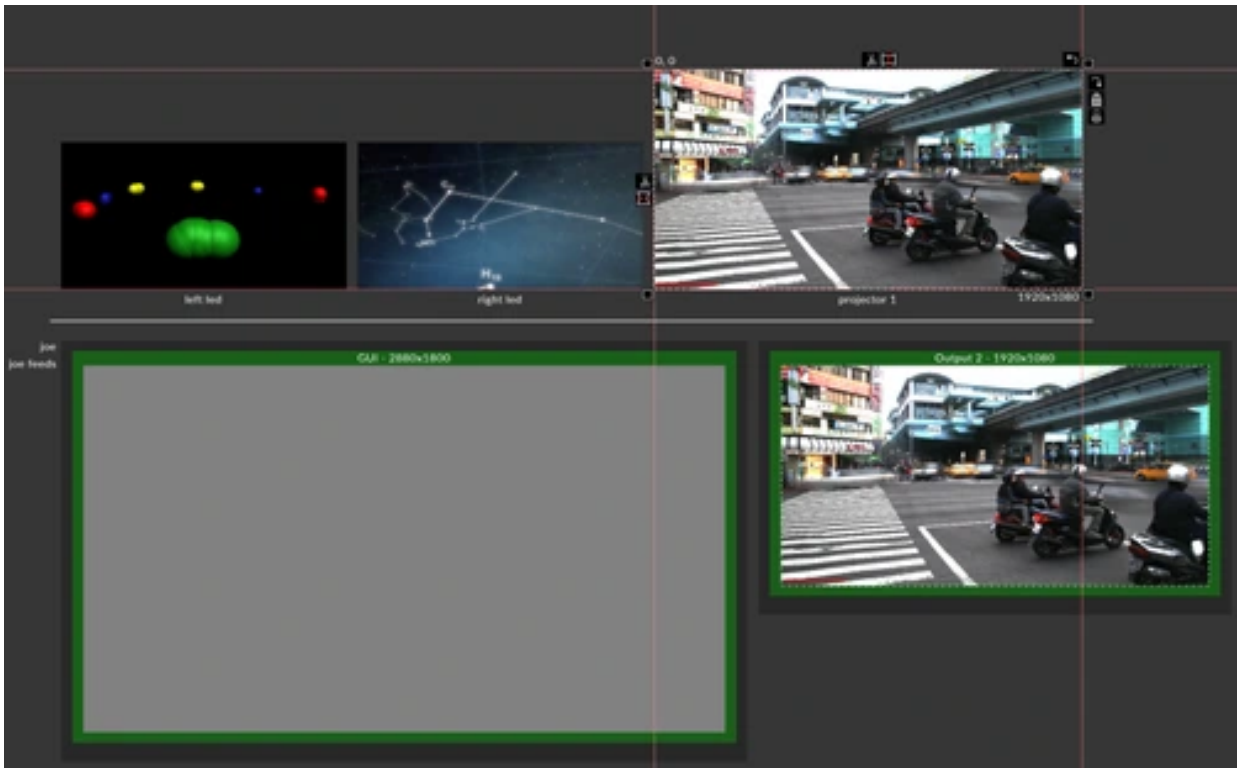
Quad: Four different HD capable screens, each with their own content

Quad 4k: Four HD “panels” arranged into a single 4k output.

> **Note**
>
> **Please note**: The split options are only available with Quad DVI or SDI cards.

Editing a Feed Rectangle

Left-click the Feed rectangle. This will select the Feed rectangle and show a series of controls.



Quick editing controls for a Feed/sample rectangle, opened by left-clicking a Feed/sample rectangle

Resize

The square shaped controls enable you to resize a Feed rectangle.

Square shaped controls are used to resize a Feed/sample rectangle

> **Note**
>
> **Please note**: hold Shift whilst resizing to maintain the rectangles aspect ratio.

Lock

The Lock control locks the current scale factor between the source and destination rectangles.

Lock control is used to lock the current scale factor between a sample rectangle and a Feed rectangle

Resize while unlocked

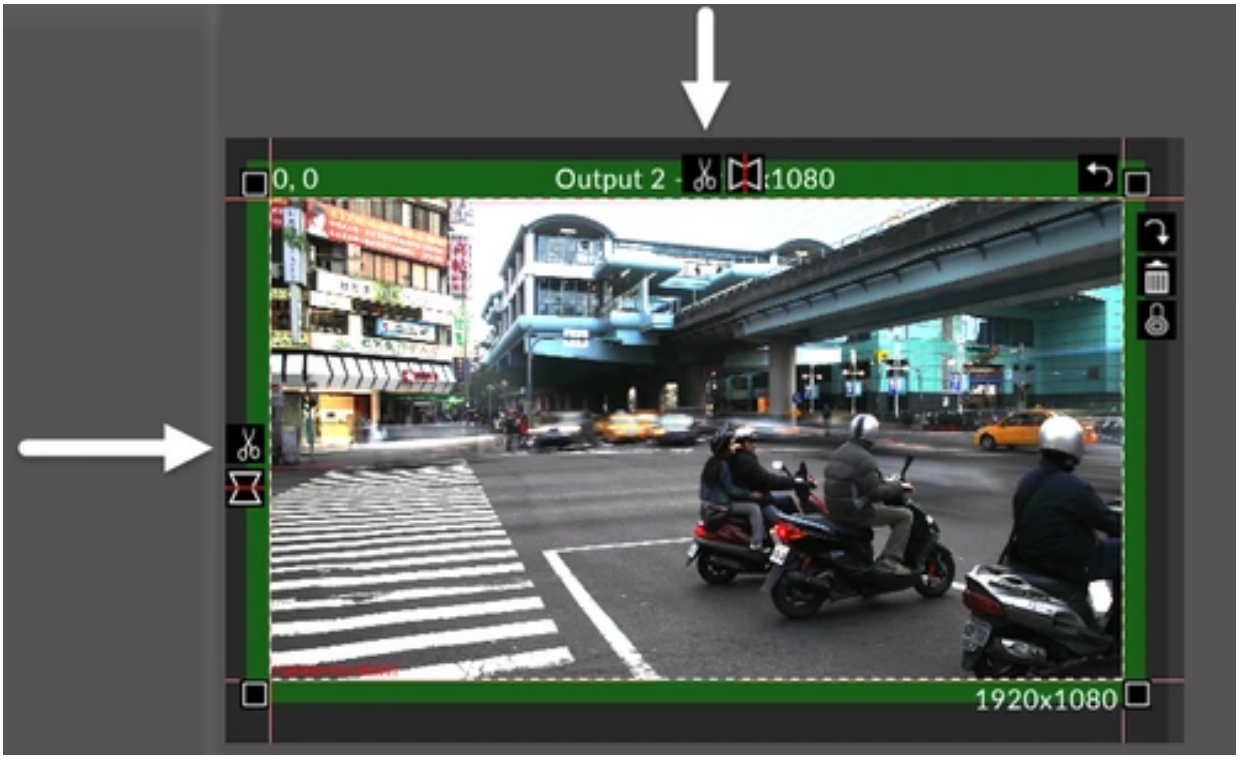
When the Feed rectangle is locked, resizing the Feed rectangle resizes the Sample rectangle and vice versa.

Left-click and drag a square shaped control to resize the Feed rectangle. In this example, we have used the right middle control to reduce the size of the Feed rectangle.

Lock control is locked causing the sample rectangle to resize when the Feed rectangle is resized, and vice versa

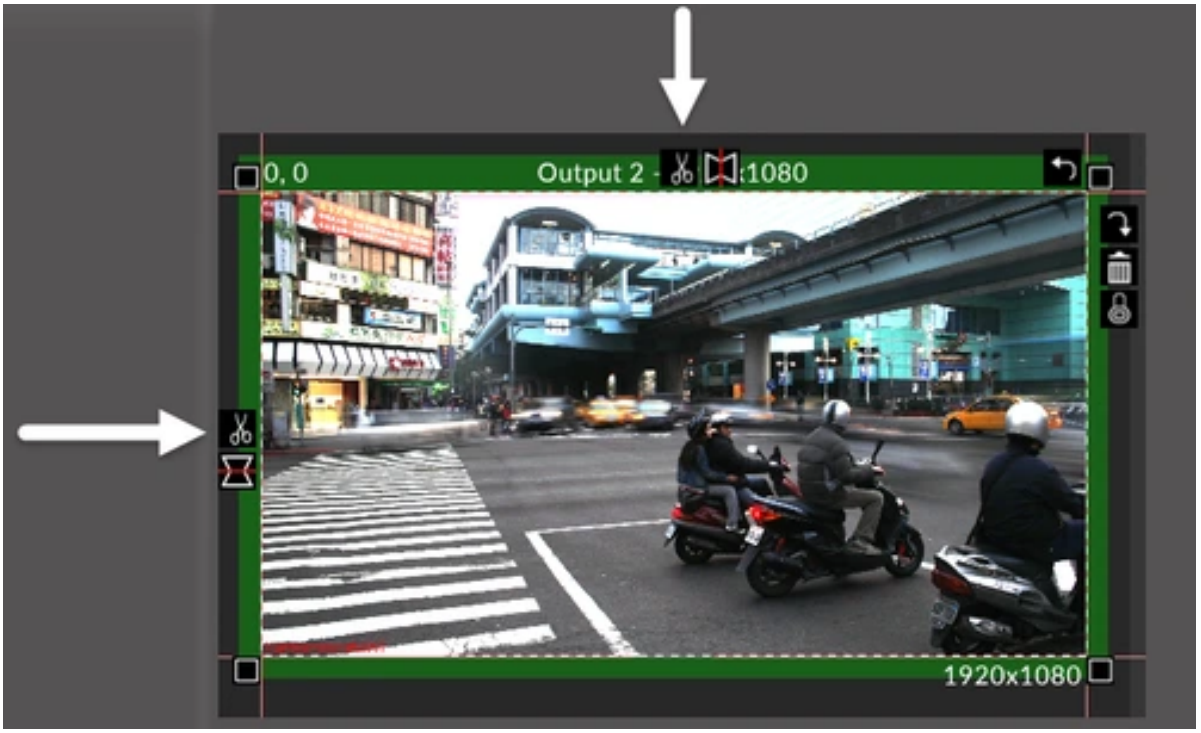
Split

The Scissor control enables you to split a Feed rectangle into smaller Feed rectangles.



Scissor controls are used to split a Feed/sample rectangle into smaller Feed/sample rectangles

1. Left-click and drag the scissor. You will see a dashed white line that represents the line where the Feed rectangle will be split.



Splitting a Feed rectangle by click-dragging a Scissor control, the white dashed line represents where the Feed rectangle will be split

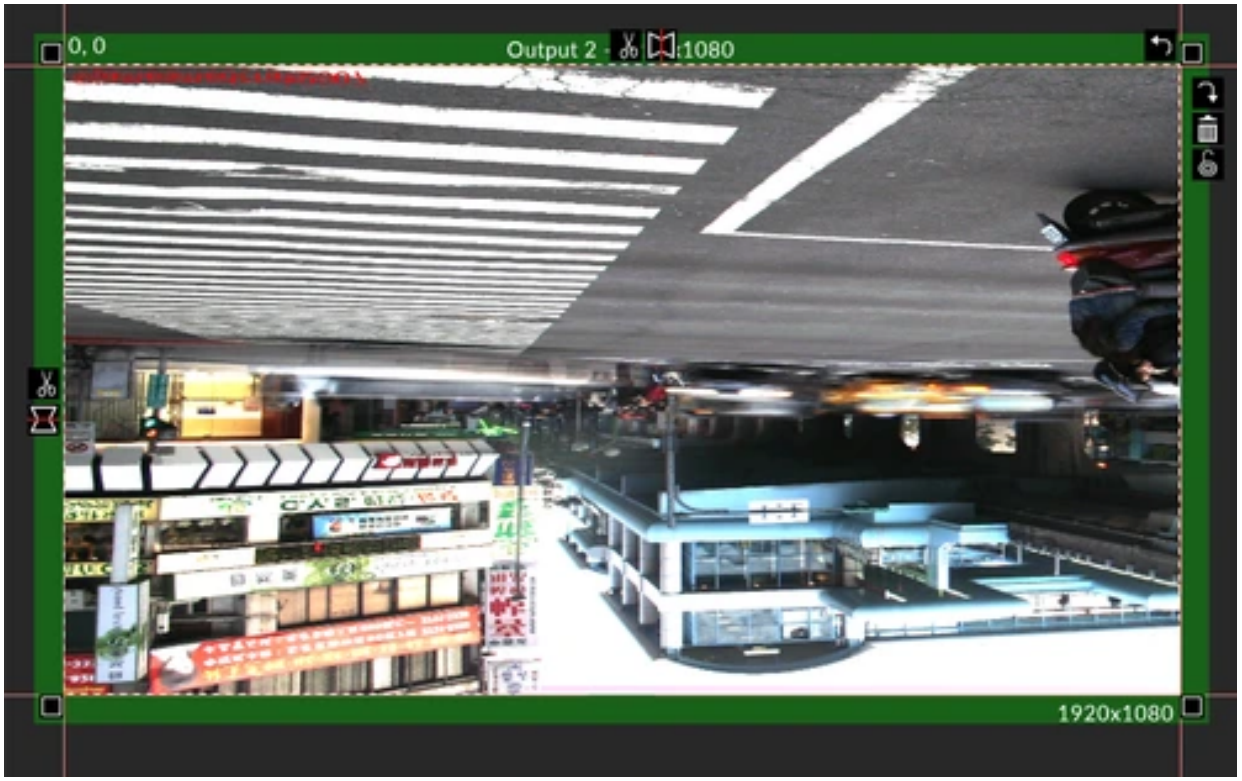
2. Release the left mouse button when you are happy with the position of the splitting line. The Feed rectangle will now be split into two rectangles.

Mirror

The Mirror control enables you to flip the Sample rectangle or Feed rectangle horizontally or vertically.

Mirror controls are used to flip a Feed/sample rectangle horizontally or vertically

- Left-click a Mirror control to mirror the Sample rectangle or Feed rectangle. In this example, we have used the top Mirror control to mirror the Feed rectangle horizontally. The left Mirror control will mirror the Sample rectangle or Feed rectangle vertically.



Mirroring a selected Feed rectangle, in this example horizontally, by left-clicking the top Mirror control

Trash can

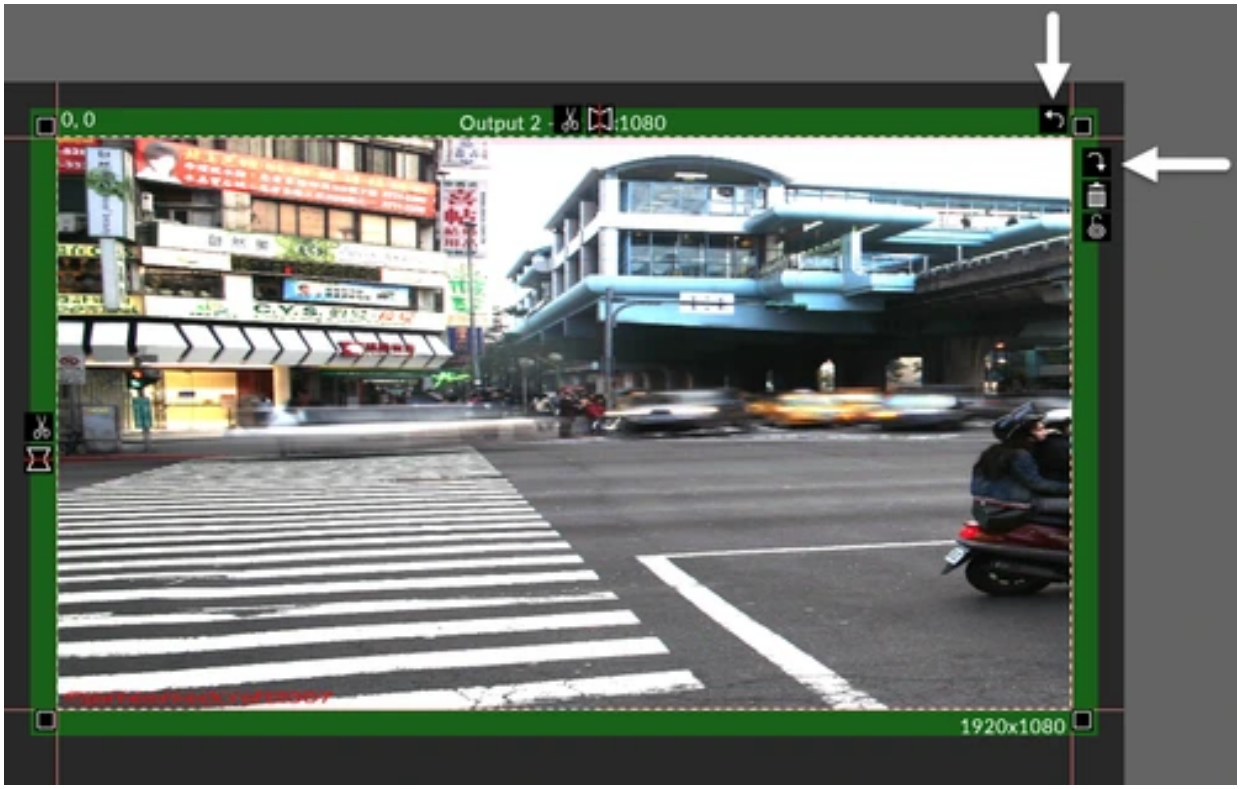
The Trash can control allows you to delete Sample rectangles or Feed rectangles.

Trash can control is used to delete Feed/sample rectangles

1. Left-click the Feed rectangle or Sample rectangle you want to delete to open the rectangles controls.
2. Left-click the Trash can icon or hit delete.

Rotate

The Rotate controls enable you to rotate the selected Sample or Feed rectangle(s) by 90 degrees clockwise or anti-clockwise.



Rotate controls are used to rotate a Feed/sample rectangle 90 degrees clockwise or anti-clockwise

- Left-click a Rotate control to rotate the Sample rectangle or Feed rectangle.

Positioning - click and drag

1. Left-click the Feed rectangle to select it.

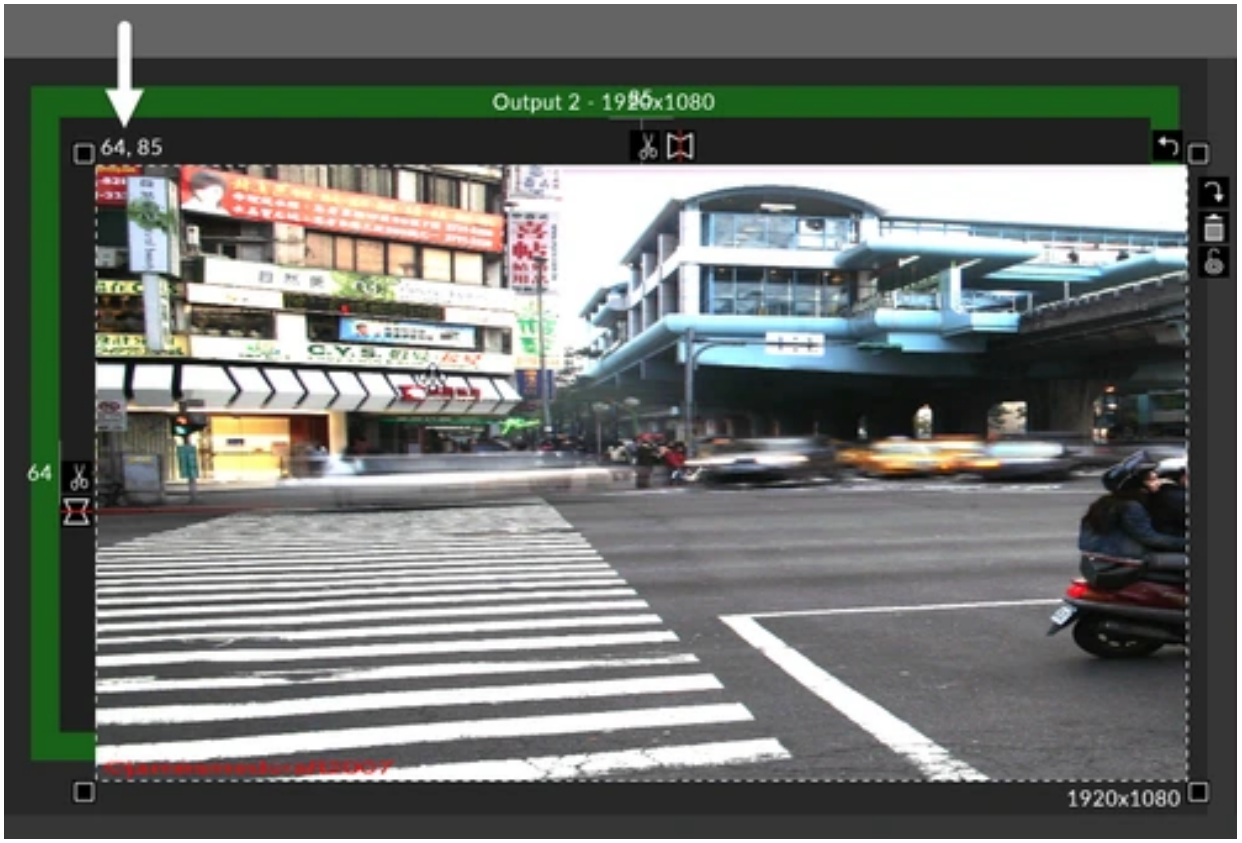
2. Position your mouse cursor over the middle of the Feed rectangle; arrow heads will appear on the edges of the cross shaped cursor.

3. Left-click and drag the Feed rectangle to the desired position. Note how Disguise displays the distance of the Feed rectangle from the top, left and bottom edges of the Display head in 3 separate boxes. These boxes measure the distance in pixels between the top, left and bottom edges of the Display head and Feed rectangle. The top left of the Display head starts at 0, 0

> **Note**
>
> **Please note**: zoom in for a finer control over moving the Feed rectangle by clicking and dragging. Alternatively, read the two other options below.

Positioning - insert coordinates

The top left of the Feed rectangle displays the x and y coordinates of the top left corner of the Feed rectangle. These coordinates are measured in pixels.



Inserting x,y coordinates, measured from the top left of the display head, is another method for repositioning a selected Feed/sample rectangle

> **Note**
>
> **Please note**: you can also edit the resolution of your Feed rectangle, displayed in the bottom right hand corner, in exactly the same way as how you edited the Feed rectangles x and y coordinates.

To insert co-ordinates:

1. Left-click the x and y coordinates to highlight their text fields.
2. Type the new coordinates. The Feed rectangle will now move to the new coordinates specified.

Positioning - nudge

1. Left-click the Feed rectangle to select it.
2. Use the keyboard arrow keys. Each press of the arrow key will nudge the Feed rectangle by 1 pixel.

Background colour

1. Right-click the Head.
2. Select a background colour using the colour picker accessed through the **Background Colour** property.
3. Feed level options window being used to open the Feed editor, opened by right-clicking the background of the Feed level

This will open the Feed editor. The Feed editor is explained in the sub-chapter Configuring Feed scenes.

Feed Level Navigation

Panning the viewport

- Hold down the mouse scroll wheel and drag.
- Hold down the **Tab** key and move the mouse left/right/up/down.

> **Note**
>
> **Please note**: do not hold down either mouse button; this will only work when the Feed level has focus.

Zooming in and out

Option 1

Scroll the mouse wheel up/down to zoom in/out.

Option 2

- Hold down the right mouse button and drag the mouse down to to zoom in.
- Hold down the right mouse button and drag the mouse up to to zoom out.

More options

- Hit **1** to go to 1:1 zoom level (where each pixel on the monitor is equal to one pixel on the actual output head).
- Hit **F** to focus on selected rectangles.
- Hit **A** to view all of the Screens and output heads

Toggling between Display heads

Hit Alt-F to view the Feed rectangles in your Display heads pixel-perfectly.

Repeat hitting Alt-F to toggle each display head in pixel-perfect full screen mode in chronological order. This is very useful for when you want to make a pixel-perfect screenshot of the output display. To do so, first toggle to the output display and click Alt-X . You can also export the position and pixel dimension data as a table (readable in for example Excel). For

more information please scroll down to the section Export as table in the Feed rectangle editor sub-chapter.

> **Note**
>
> **Please note**: these will only work if the Feed level has mouse focus; i.e. you should have clicked the background before these will work.

Selecting Feed Rectangles

Select a rectangle

Left-click a rectangle to select a rectangle. When you continue clicking, you uncover more rectangles that may overlay each other.

Selecting multiple rectangles

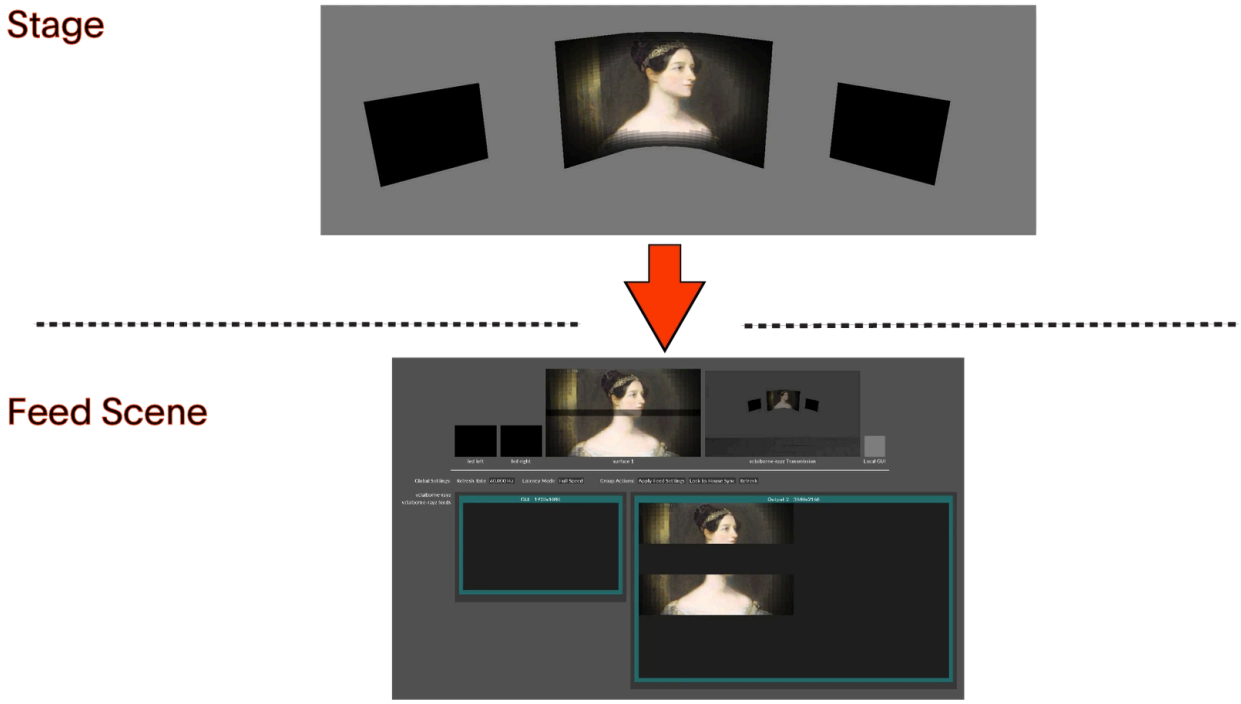
Working with more than one Feed rectangle at a time is very common. Multi-select the rectangles by holding down the left-mouse button and drag.

Toggling through rectangles

Ctrl -clicking Feed rectangles toggles their selection, allowing you to extend the selection across areas which are not next to one another.

Feed Outputs Overview

The **Feed View** contains **Feed Scenes**, which determine how content from the Stage is arranged and delivered to your physical output heads.



Conceptual diagram illustrating how Feeds Scenes in the Feed level are used to copy content arranged from screens in the Stage level.

What is a Feed Scene?

A **Feed Scene** defines how visual content is transferred from Screens in the Stage level to your system's output heads.

It acts as a mapping layer that extracts portions of Stage content and positions them precisely on the output devices.

Each Feed Scene contains multiple **Feed Rectangles**, which specify:

- **Source Screen** – where the content originates.
- **Content region** – which area of the Screen is being used.
- **Transformations** – crop, scale, rotate, and position.
- **Destination** – where the content appears on the output head.

This enables Designer to copy and re-arrange content flexibly, accommodating a wide range of display configurations.

Why use multiple Feed Rectangles?

A single Feed Scene can contain multiple Feed Rectangles for each Screen. This allows you to:

- Divide a Screen into multiple content regions.
- Reassemble Screen content in a different order.
- Map cropped Screen areas to LED processors.
- Adapt visuals for unconventional display layouts or projector setups.

Whether you are working with LED walls, projection systems, or complex multi-output designs, Feed Rectangles provide fine-grained control over what is sent to each output.

> **Note**
>
> All blending and compositing of content in Designer is configured in the track and the 3D stage via mappings. The Feed View cannot be used to composite feeds together in 2D, as it does not support blending or consistent ordering of Feed Rectangles. This is a major difference between 3D compositing engines like Designer and other 2D compositing tools.

Rendering Feed Movies

Designer can also render the output of Feed Scenes into **Feed Movies** which is useful when pre-rendered content is required for installation, playback or pre-visualisation.

For more information, see the Rendering Feed Movies and Rendering Media pages.

Feed Outputs documentation

The following pages explain how to view and navigate the Feed view, configure hardware-related feed settings, set refresh rates, and adjust video signal behaviour. They focus on understanding the Feed view environment and configuring the system components that influence how outputs are generated.

Feed level and system configuration

- Viewing the Feed Level
- Feed Level Navigation
- Configuring d3Net Feed Settings
- Configuring VFC Card Slots

- Configuring VFC Card Ports
- Configuring Multiple VFC Cards
- Setting the Project Refresh Rate
- Video Timings
- 10-bit Displays

Output settings

The following pages describe the tools and workflows used to define Feed Rectangles, map screen content to outputs, duplicate or modify rectangles, and adjust the output geometry through blending, masking, and warping. They focus on hands-on output layout, editing, and manipulation.

Configuring an output head is a two-part workflow, documented across three pages: Configuring Output Settings is an overview of the process, Head Configuration covers monitoring and editing each head's settings (including the head colour status), and Apply Feed Settings explains how to push resolution and timing changes to the physical outputs.

- Configuring Output Settings
- Head Configuration
- Apply Feed Settings
- Selecting Feed Rectangles for Screens
- Editing a Feed Rectangle
- Adding Feed Rectangles for Screens
- Using Duplicate Multiple
- Alternate Feed Scenes
- Importing and Exporting Feed Scenes
- Blending and Masking Outputs
- Warping Outputs

Head Configuration

An **output head** is a single physical video output on a server, such as a port on a VFC card or a standard graphics output. Each head is configured on its own from its settings menu, and you can check its status at a glance from the colour-coded feed view.

To configure a head:

1. Right-click the head's name, or anywhere in its coloured box, to open its settings menu.
2. Edit the properties you need, such as its resolution, timing mode or latency (see **Output Head Properties** below).
3. Apply the feed settings to push any resolution or timing changes to the physical output. Other changes take effect live.
4. Check the head's colour in the feed view to confirm its status.

Output Head Colour

The Feed UI enables users to maintain a visual reference of the status of each head through a simple, colour-coded system. This means users are now able to quickly and easily identify which display needs attention, as well as the severity of any issue encountered, simply by looking at the head's colour.

Green - Head configured

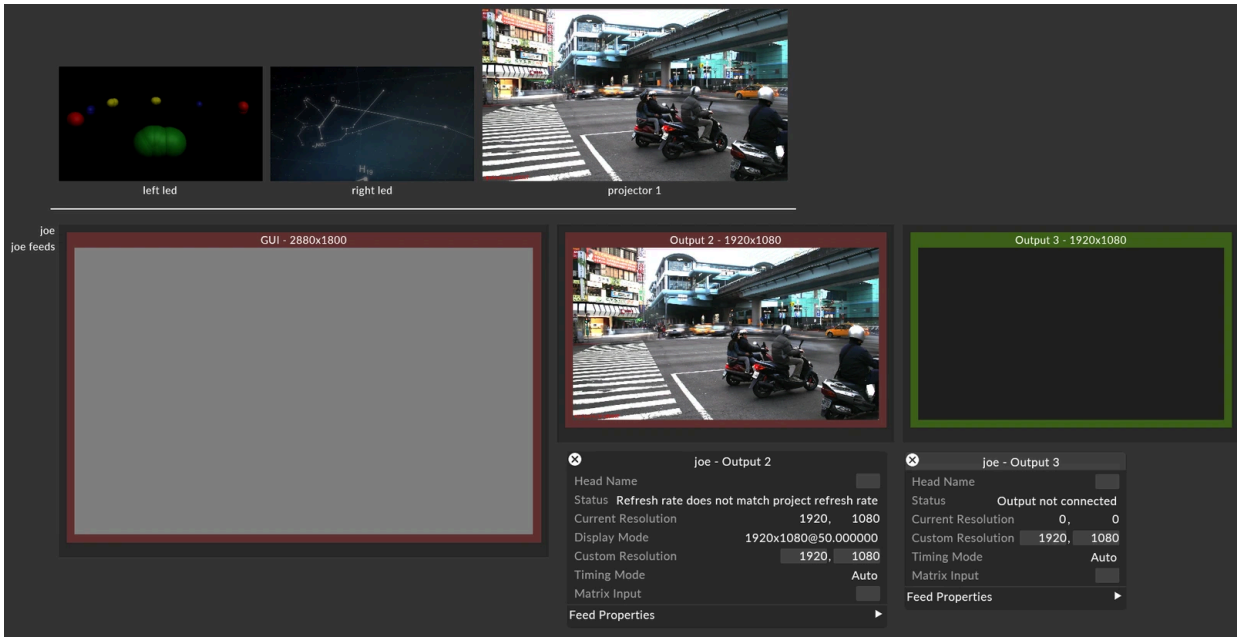
Red - Refresh rate is different

Orange - Head settings have changed, you must apply feed settings for the changes to take effect

Blue - Designer machine

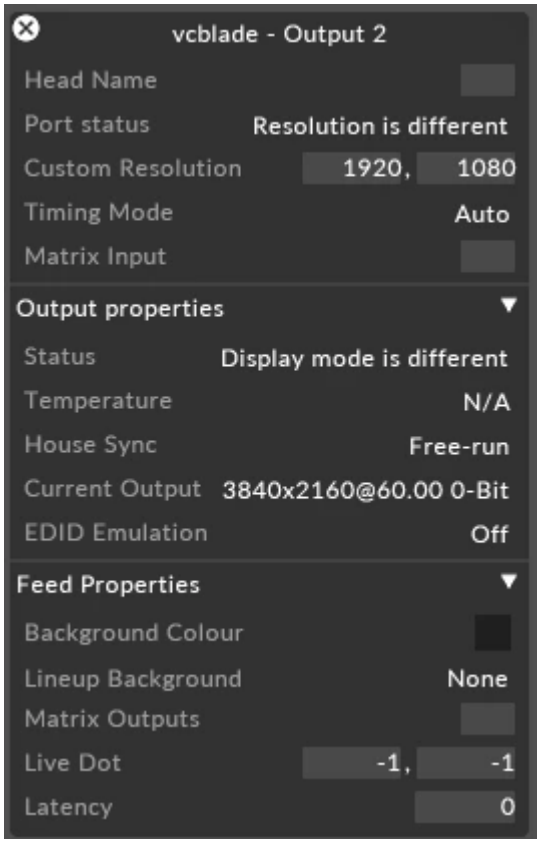
Grey - output not connected or no machine present

Flashing Blue and Grey - Machine is currently applying feed settings



Output Head Settings

Each output head's settings menu lets you both monitor and modify the head's settings. The properties available are described below.



> **Note**
>
> For optimal performance, all output heads should be configured with identical refresh rate and resolution, with all heads **genlocked** if a sync signal is present, or set to **none/internal** if no sync signal is present.

Output Head Properties

Head Name

Allows users to type in specific names for each output head. Those names are set as Output 1, 2, etc by default on non-VFC machines, and as A, B, C and D for each individual Quad VFC head.

Port Status

Allows users to monitor the status of each head. Any problems encountered will be listed here (see above section on Output Head Colour). If no problems are detected, it will say **Normal**, and the head colour will be green.

Custom Resolution

This field is used to set a custom resolution for ports that support it.

> **Note**
>
> Any resolution changes need to be applied by using the **Apply Feed Settings** button to the left of the feed scene. See Apply Feed Settings.

Timing Mode

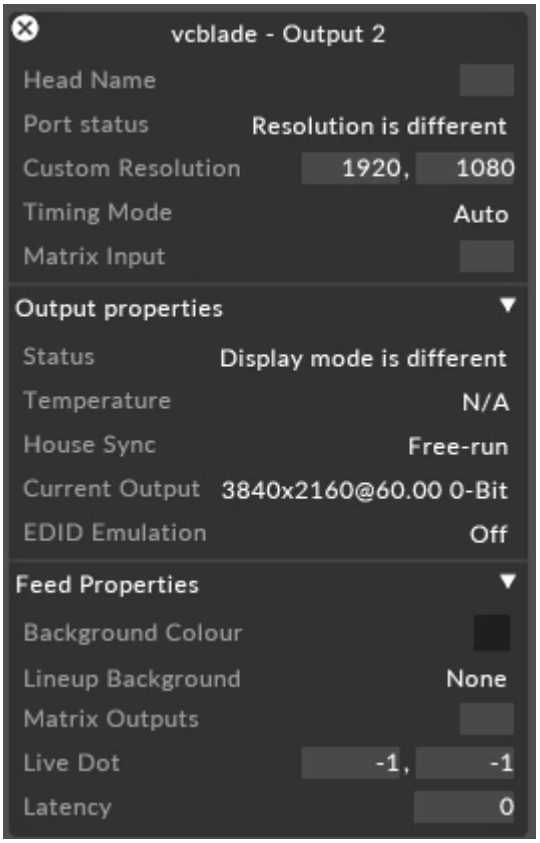
Sets how the output's video signal timing is determined:

- **Auto**: Designer uses the standard timing for the output's resolution and refresh rate.
- **SMPTE**: forces a standard broadcast (SMPTE) signal timing for SDI outputs that must conform to a specific broadcast specification.

Matrix Inputs

Allows users to directly route inputs when connected to a matrix. For more information, please refer to the Direct Matrix Routing page.

Output Properties



Status

Indicates the status of the output's configuration and reports any issues if detected

Temperature

Displays the current operating temperature for the output

House-Sync

Shows whether this output is **genlocked**, meaning it is locked to an external "house sync" reference signal so its frame timing stays aligned with every other output and machine sharing that signal. Frame-accurate synchronisation across machines requires all outputs to be genlocked to a shared reference.

Current Output

The current Resolution and Refresh rate for this output.

EDID Emulation

EDID is the data a display sends back to identify itself and the resolutions and timings it supports. Media-server outputs often drive LED processors or displays that don't present a usable EDID, or need to hold a fixed resolution regardless of what is connected. Designer can therefore present a stored ("emulated") EDID to the GPU, so the output stays stable even when no display is plugged in.

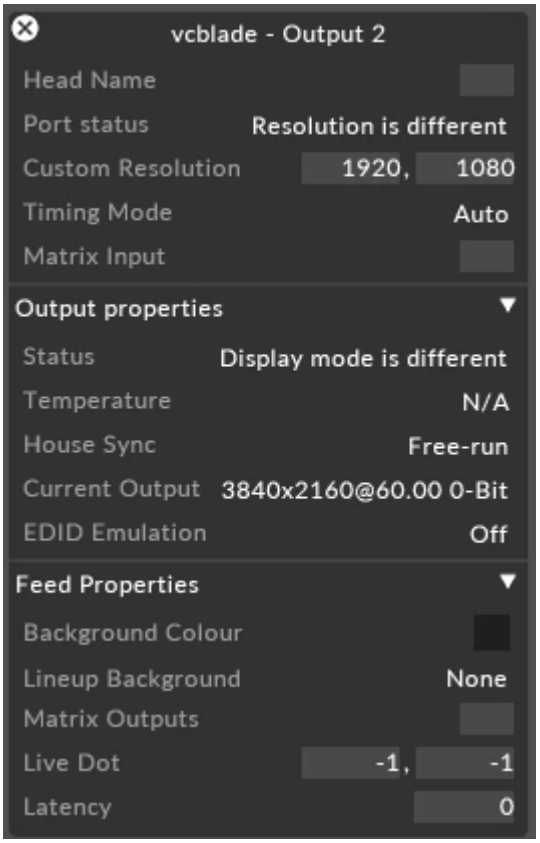
The available EDID emulation modes are:

- **Always**: emulate the EDID at all times, even when no display is connected.
- **If Connected**: emulate the EDID only while a display is connected to the output.
- **Unmanaged**: leave the current EDID emulation untouched.
- **Force Off**: don't emulate an EDID, and remove an existing emulated one if set.

> **Note**
>
> Outputs cannot genlock if their resolutions match but their EDIDs differ, so keep EDID emulation consistent across heads you intend to synchronise.

Feed Properties

The Feed Properties drop-down menu contains changes that are mostly related to the way a head appears in the feed scene:



Background Colour

This option allows users to change the background colour of each head by using a colour from the colour picker. It is output to the connected display.

Lineup Background

Allows the user to put a background image on the output to line up feed rectangles to. It is NOT output to the connected display.

Matrix Outputs

Allows users to directly route outputs when connected to a matrix. For more information, please refer to the Direct Matrix Routing page.

Live Dot

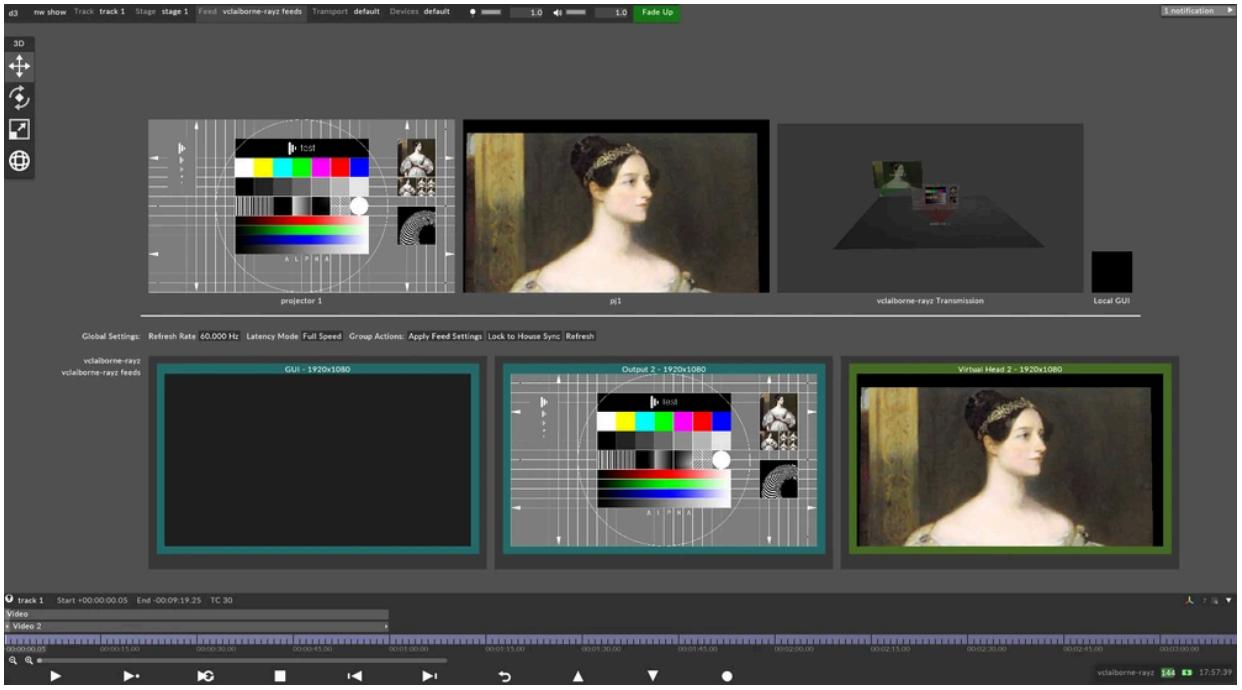
Allows users to add a single flashing pixel to provide visual reassurance that the output is in working order. Useful when outputting black or still content.

Latency

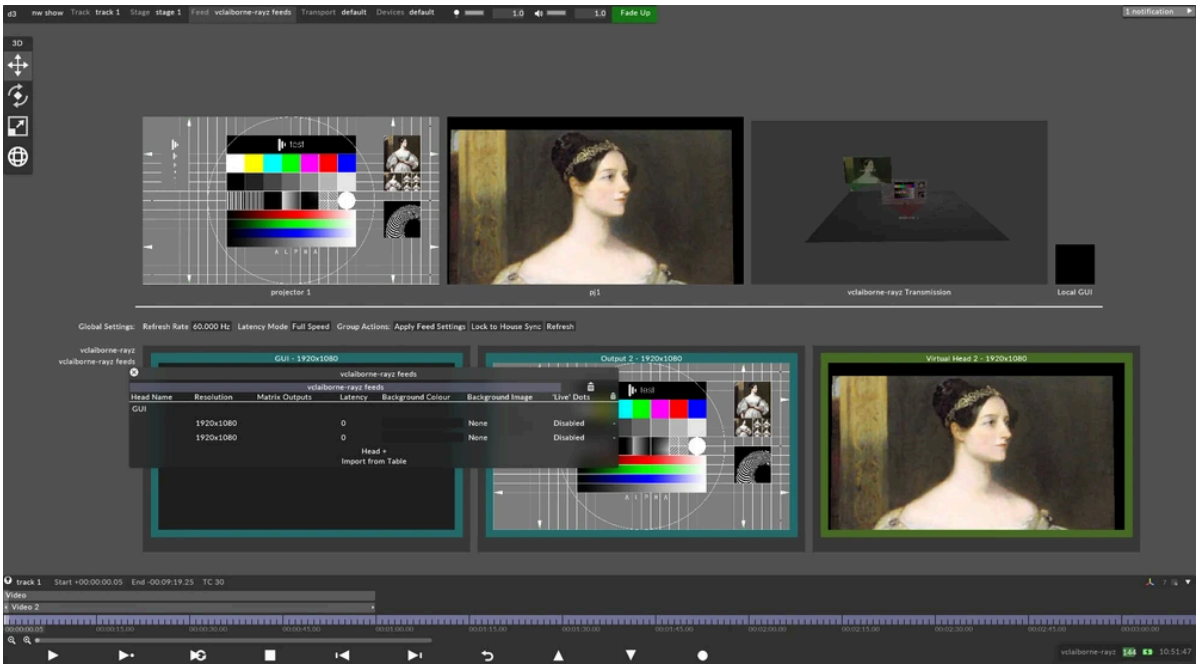
Delays this output head by a number of frames, so you can align it with other heads or downstream equipment. The range is −30 to +30 frames. A positive value delays this head; a **negative value instead delays all other heads**, which is useful when this head is running late and you want to hold the others back to match it.

Importing & Exporting Feed Scenes

A Feed rectangle layout, known as a Feed Scene can be exported and imported between projects:

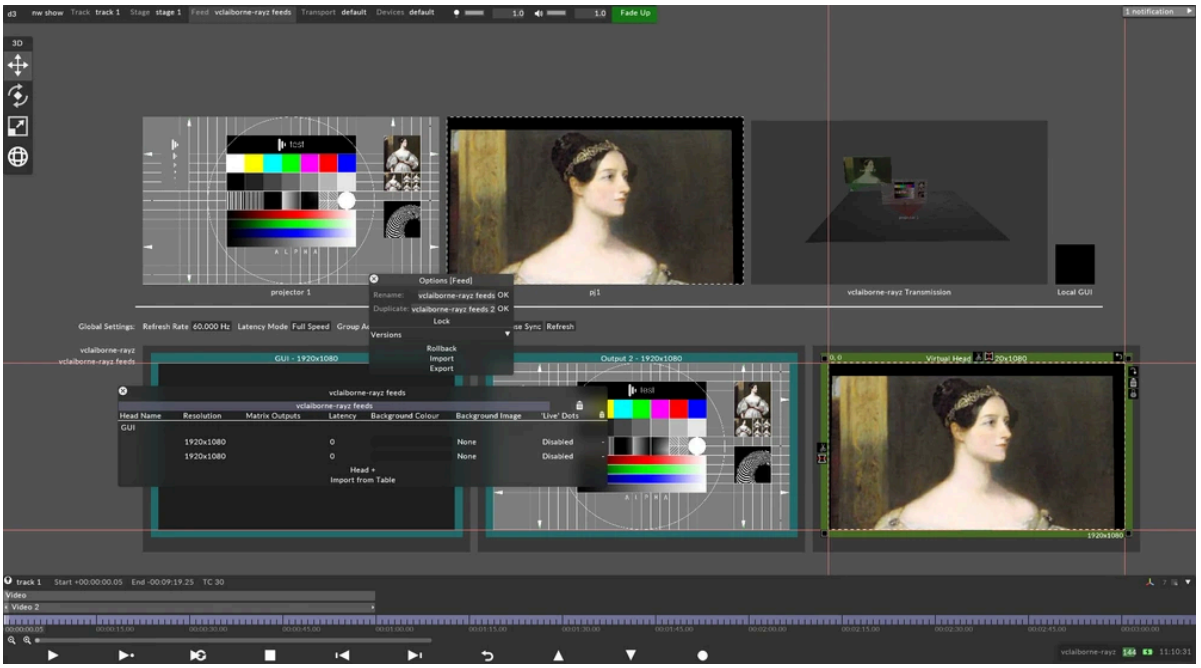


1. To open the editor for the current Feed Scene, right-click on the current Feed Scene; this is located to the left of the GUI in the Feed level.

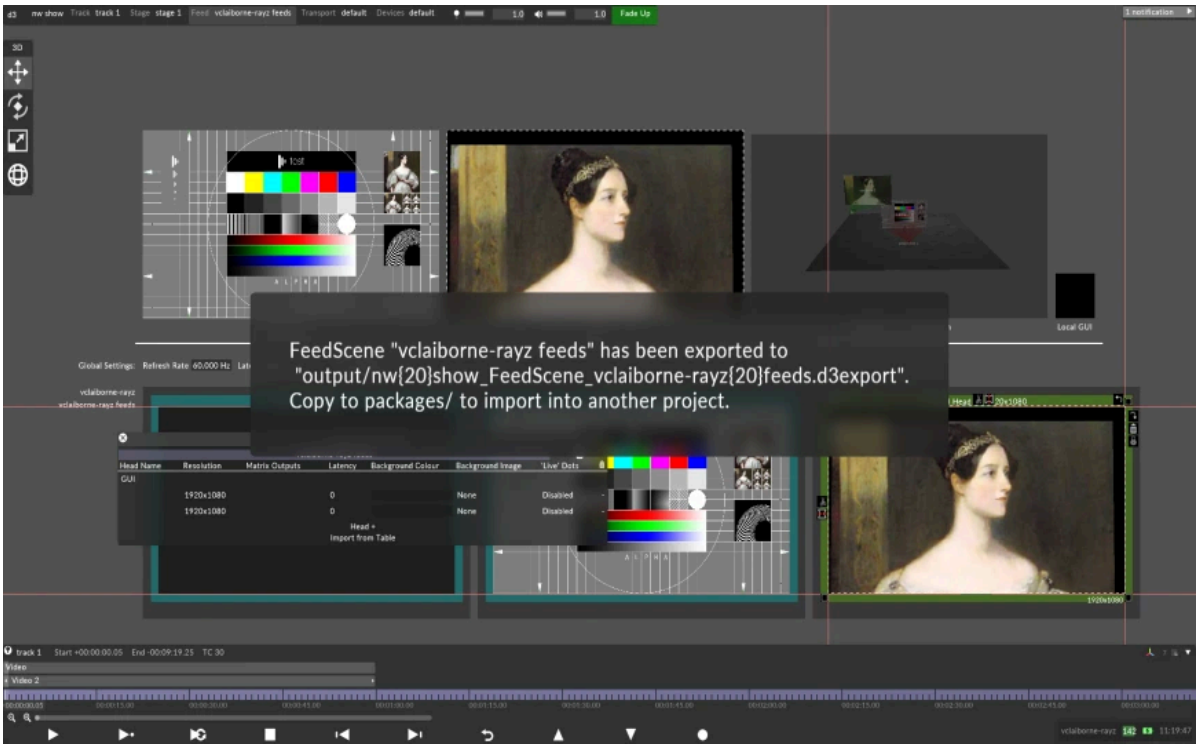


Screen configuration shown is for the active Feed Scene

2. To export the current Feed Scene, right-click on the header of the Feed Scene editor:

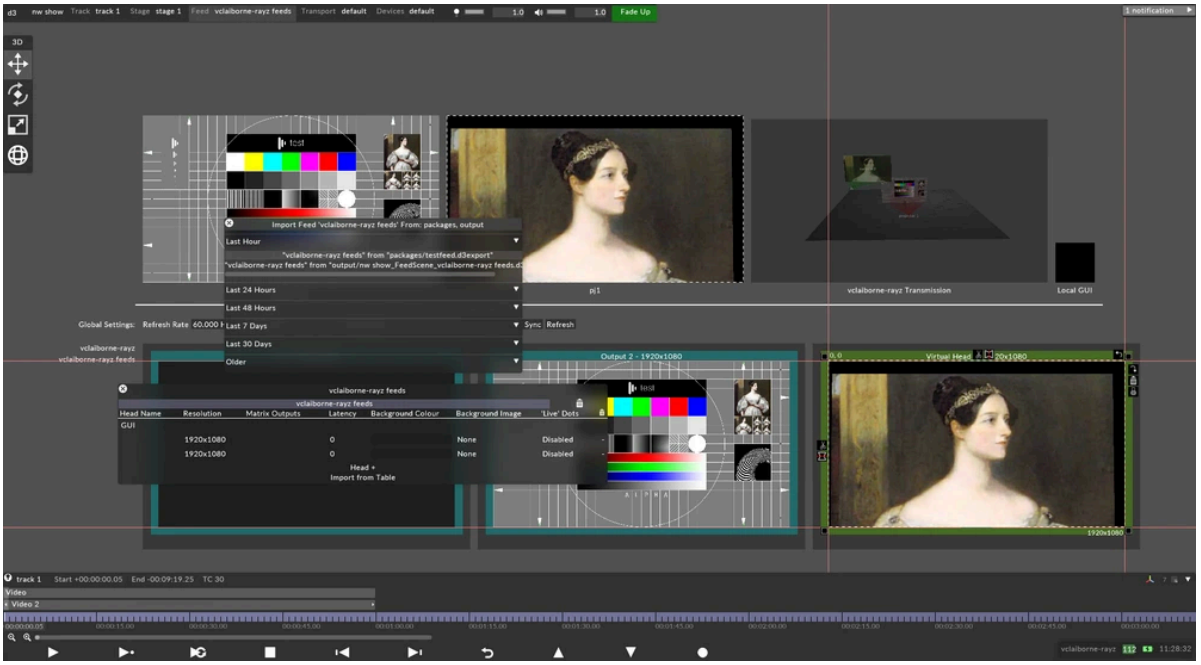


3. Left-click Export. This will export the Feed scene and place it into the Output folder of your project.



Confirmation of Feed scene export including location and instructions for importing As the confirmation message explains, if you wish to use this Feed Scene in another project, then you will need to place a copy into the Packages folder of the desired project (this folder is not created automatically).

4. To import a Feed Scene that has been exported, begin by right-clicking on the header of the Feed Scene editor; then left-click on Import in the list. In the window that opens, select the Feed scene that you wish to import from the list:



Notes

- If the scene does not appear in the list, then it is not placed in the Packages folder within the project.
- Feed scenes can also be created in a .csv file and imported from a Table.

Selecting Feed Rectangles

There are three techniques for selecting rectangles:

Uncovering Rectangles

Left-click a Rectangle to selects one rectangle. When you continue clicking, you uncover more rectangles that share the same position but are hidden behind another rectangle.

Selecting multiple Rectangles

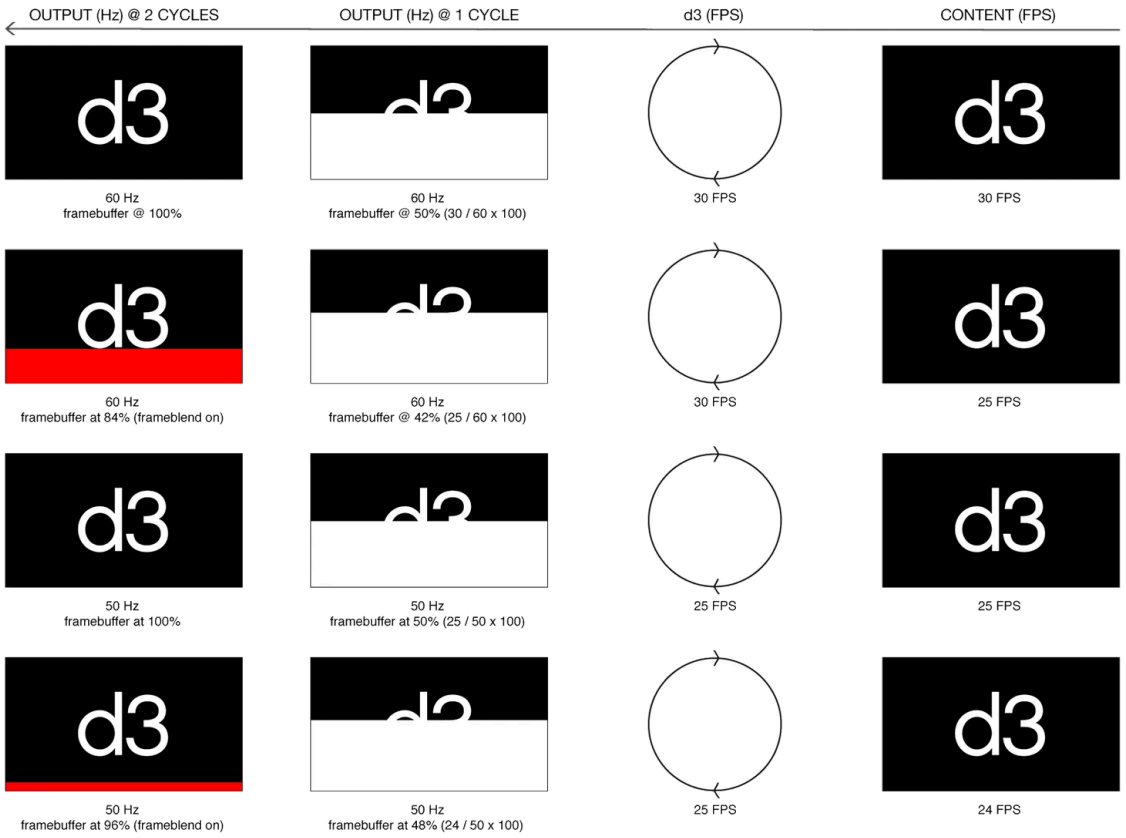
Working with more than one Feed Rectangle at a time is very common. Left-clicking and dragging the mouse will selects all rectangles which touch the area dragged over by the mouse.

Toggling through Rectangles

Ctrl + clicking Feed Rectangles toggles their selection, allowing you to extend the selection across areas which are not next to one another.

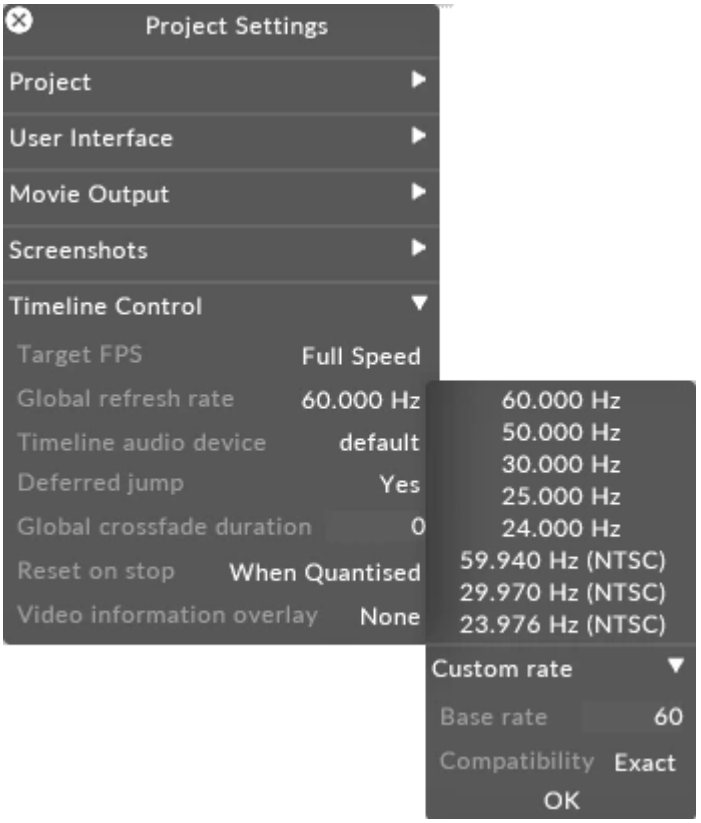
Setting Project Refresh Rate

The refresh rate that a project is set to is inherently important for maintaining optimal d3 performance. The image shows the relationship between project refresh rate, content, timeline and Disguise's frame buffer.



Setting the project refresh rate

1. Open the state editor by right-clicking the d3 icon in the left handside of the dashboard.
2. Open the Project Settings menu by left-clicking the option in the state menu.
3. Set the project refresh rate to the desired setting.
4. In the feed view, click apply feed settings to apply the new project refresh rate.



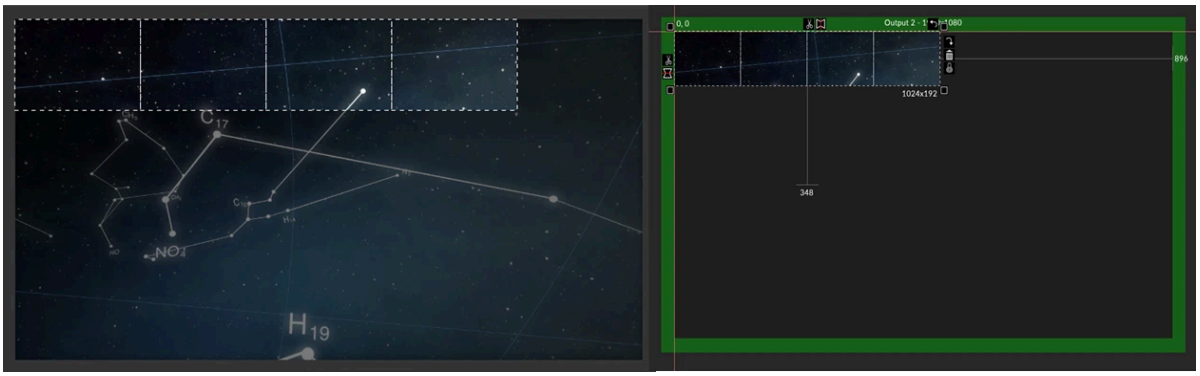
Setting a custom project refresh rate

1. Open the state menu by right-clicking the d3 icon in the left handside of the dashboard.
2. Open the Project Settings menu by left-clicking the option in the state menu.
3. Set the custom project refresh rate to the desired setting and click OK.
4. In the feed view, click apply feed settings to apply the new project refresh rate.

Using Duplicate Multiple

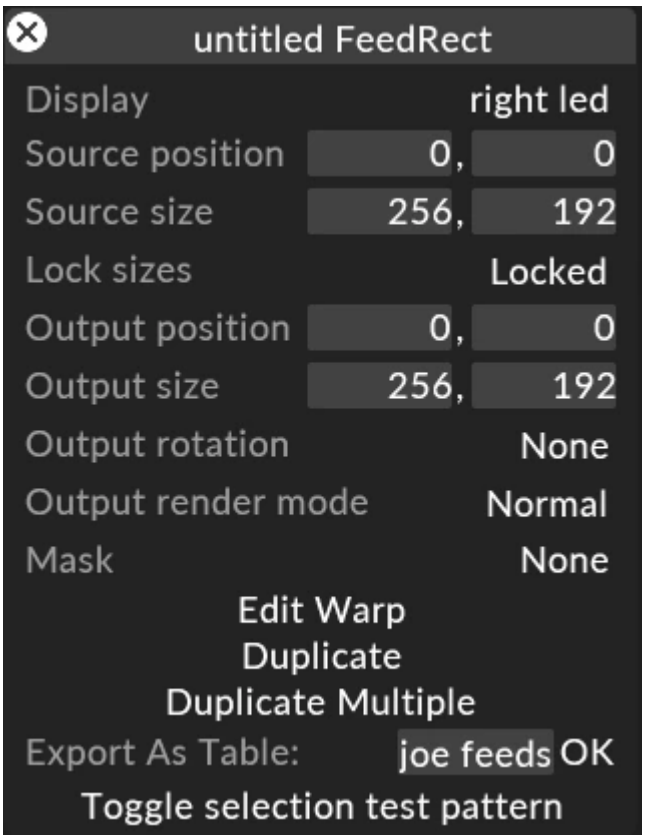
Using duplicate multiple is an effective way of creating lots of Feed rectangles that follow a pattern.

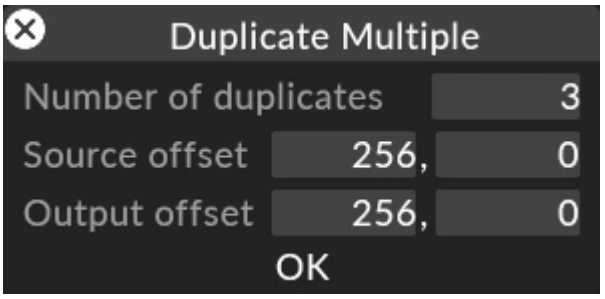
1. Add a Feed rectangle with a size of 256x192 at the position 0,0 on both the source and the output.



2. Right-click the Feed rectangle. This will open up the Feed Rectangle Editor .

3. Left-click duplicate multiple in the Feed rectangle editor.





Duplicate Multiple option is used as a quick method of creating lots of Feed rectangles that follow a pattern

This will open up a window with the following options:

Number of duplicates

This is the number of times you want to duplicate the Feed rectangle.

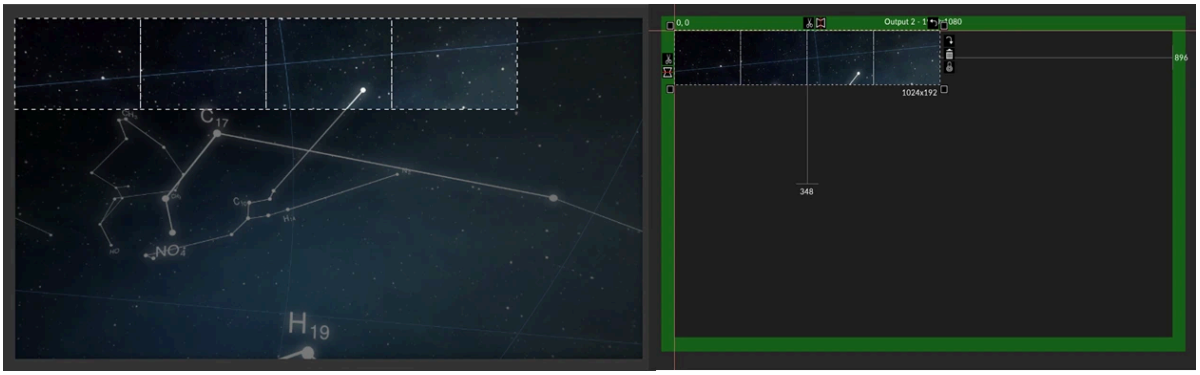
Source offset

This is the offset from the original Feed rectangle in the source that you want to increment. The input is x, y.

Destination offset

This is the offset from the original Feed rectangle in the feed output that you want to increment. The input is x, y.

1. Set the **number of duplicates** to 3 to duplicate it 3 times.
2. Set the x coordinate of the **source offset** and **output offset** to 256 and the y coordinate to 0.
3. Left-click **ok**. This will create 3 Feed rectangles at x + 256 (with x being the x coordinate of the previous Feed rectangle) and at y + 0, placing them directly next to each other. This will create your first row.



4. Select all the feed rectangles in the first row.
5. Set the **number of duplicates** to 3 to duplicate it 3 times.
6. Set the x coordinate of the **source offset** and **output offset** to 0 and the y coordinate to 192.
7. Left-click **ok**. This will duplicate each row below the previous row, completing the grid of Feed rectangles. As you can see, Designer will name the feed rectangles sequentially in the order they are created.

Video Timings

When outputting video from d3, we can use various timing methods. A timing method is a set of parameters that define aspects such as:

- **Horizontal blanking**: The interval between the end of one line and the start of the next.
- **Vertical blanking**: The interval between frames.

The values for these parameters can vary depending on the chosen method.

Considerations for video timings

- The type of timing used may need to be compatible with downstream devices to ensure a specific type of timing will be understood at the other end. For example, some monitors may not display the video at all if the timing format is unsupported.
- The video timing will adjust the amount of data the video stream requires, so if devices are limited on bandwidth, then some timing modes may not be able to be used.

> **Caution**
>
> When using IP-VFC cards, we recommend only using IP-VFC cards and not mixing these with other VFC cards, as we cannot guarantee genlock with other cards. We are aiming to address this in future releases.

Timing mode selection in the Feed screen

In the Feed screen, users can select the timing mode for each output, provided it's an HDMI or DisplayPort VFC, or a direct output (e.g. from the EX range). The available timing modes are:

- SMPTE
- CVT
- CVT Reduced Blanking (CVT-RB)
- CVT Reduced Blanking 2 (CVT-RB2)
- AUTO

> **Note**
>
> What we refer to as SMPTE in d3 is actually CEA timing. However, it is widely used in the film industry under the SMPTE standards - especially for devices using SDI input/output, where fixed bandwidths are expected.

How AUTO timing works

When AUTO is selected for one or more outputs, d3 will attempt to find a common timing method across all outputs. This provides more chance of achieving genlock across different VFC types and generally smoother output requiring less single output adjustments to stay synchronised. We do this in two passes.

First pass

The first pass will simply find the best timing method for each single output by testing each method in the following order until one fits within the bandwidth constraints of the output type:

- DMT (not directly selectable)
- SMPTE (CEA)
- CVT
- CVT-RB
- CVT-RB2

Each output type has a different bandwidth limit. For example:

- DisplayPort 1.4: ~26 Gbps
- DisplayPort 1.2: ~17 Gbps
- HDMI 2.0: ~14.4 Gbps
- DVI: ~8 Gbps

Higher resolutions, frame rates, bit depths and colour formats require more bandwidth, which can affect the timing mode the first pass selects.

Second pass

On the second pass d3 will find the best timing method, which was chosen in the first path and which is within the bandwidth limit for all AUTO outputs and assign all of them that method.

Combining AUTO timing with chosen timings

If there are outputs with chosen (non-AUTO) timings mixed with outputs using AUTO timing, d3 will use the chosen timing on each AUTO output where it fits within the bandwidth limit of that output. If it exceeds the bandwidth limit, we fall back on choosing a timing using the first pass process.

If more than one specific timing method is used, d3 will choose the higher-ranking method for the outputs using AUTO. Higher ranking is decided by how many outputs are using it, and then the order of best to worst is described above. For example, if we have four outputs and two are assigned CVT-RB and one is assigned SMPTE and one AUTO, the AUTO output will be

assigned CVT-RB. If we have four outputs and one is CVT-RB, one SMPTE and two AUTO, d3 will assign the AUTO outputs to SMPTE because it's ranked higher than CVT-RB.

Bandwidth and colour format

The colour format also affects bandwidth usage:

- RGB Full (RGB 4:4:4), RGB Limited, YCbCr 4:4:4: ~3 bytes per pixel
- YCbCr 4:2:2: ~2 bytes per pixel
- YCbCr 4:2:0: ~1.5 bytes per pixel

> **Important Note**
>
> A downstream device may reject a signal if the required timing mode isn't supported.
>
> As of version r30.5, d3 now logs the selected AUTO timing mode in the console when feeds are applied. Previously, this was not recorded.

Passthrough vs non-passthrough VFCs

- With passthrough VFCs (e.g. HDMI, DP), the timing mode set on the GPU output via EDID is passed directly to the connected device.
- With non-passthrough VFCs (e.g. QSDI, QDVI, IP), we convert the GPU timing mode:
  - **QSDI**: The GPU uses CVT-RB, while the QSDI VFC outputs use SMPTE/CEA, which is standard for SDI devices.
  - **IP cards**: Typically use CVT-RB2, unless running under 25fps, where CVT or AUTO might be used.

We do not currently support genlocking IP outputs with other VFCs, but this is a planned improvement that we hope to make available in future.

Genlock Basics

Genlock is the process of synchronising the display of each frame on each output of a machine to an external clock signal. This external signal is typically distributed to multiple machines, allowing them to stay in perfect sync — essential for multi-display or multi-machine setups.

A similar concept applies to **internal genlock**, also known as **framelock**, where one output on a machine acts as the timing master, and the other outputs synchronise to it.

Key Points:

- **Synchronisation Scope**: Genlock applies only to outputs that are outputting nearly identical amounts of data. This means the resolution, frame rate, and format must match across all outputs being genlocked.
- **Resolution Limitations**: Attempting to genlock outputs using different resolutions usually results in failure — typically, only one will successfully genlock while others will not.
- **Output Type**: Genlock operates at the GPU output level, not at the VFC (Video Format Converter) output level. So synchronisation happens before any format conversions are applied downstream.

Genlock ensures that multiple displays or machines present frames in lockstep, which is crucial for seamless visuals in video walls, immersive environments, or high-end simulation systems. But to work properly, all genlocked outputs must match in resolution and timing characteristics.

Read more about Genlock Configuration here.

Timing Differences

When using different timings across outputs, the amount of data being transmitted can vary enough that genlock no longer works — even if the resolution is the same. This is because genlock relies not only on resolution, but also on how data is clocked out of the outputs.

It's common to encounter genlock issues when using different VFCs in the same machine. Different VFCs often default to different timing modes depending on the output type, which can disrupt genlock synchronisation.

Troubleshooting

1. Avoid Mixing Incompatible Timing Modes

Genlock requires outputs to use very similar timings, not just the same resolution and frame rate.

If one output is using SMPTE and another uses CVT, genlock may fail even if the resolutions match.

Solution: Manually set a consistent timing mode (e.g. CVT or CVT-RB2) across all outputs.

Do not leave any outputs on AUTO if you are using different VFC types.

2. Be Cautious When Mixing VFC Types

Some VFC types (e.g. **QSDI** or **IP-VFC**) use fixed timing modes internally (such as CVT), while others (like HDMI or DP) allow timing selection.

If mixing passthrough cards (e.g. HDMI + DP):

- Choose a specific timing manually for each.

If mixing passthrough and non-passthrough cards:

- Try aligning GPU timings manually to match the known default of the non-passthrough card (e.g. CVT for QSDI).

3. SMPTE Timing May Not Genlock with Some Cards

If you're using SMPTE timing on an HDMI or DP output and cannot genlock with other VFCs (e.g. QSDI), try switching to:

- **CVT-RB when pairing with QSDI**
- **CVT-RB2 when pairing with IP-VFC**

4. Check for Bandwidth Conflicts

For high resolutions (especially with DP1.4 or 4K outputs), the selected timing mode must also be within the bandwidth limits of the VFC.

A timing mode that exceeds the card's capabilities will fail silently or block genlock.

> **Tip**
>
> If unsure, start testing with lower-bandwidth formats (e.g. 1080p60) and scale up once genlock is successful.

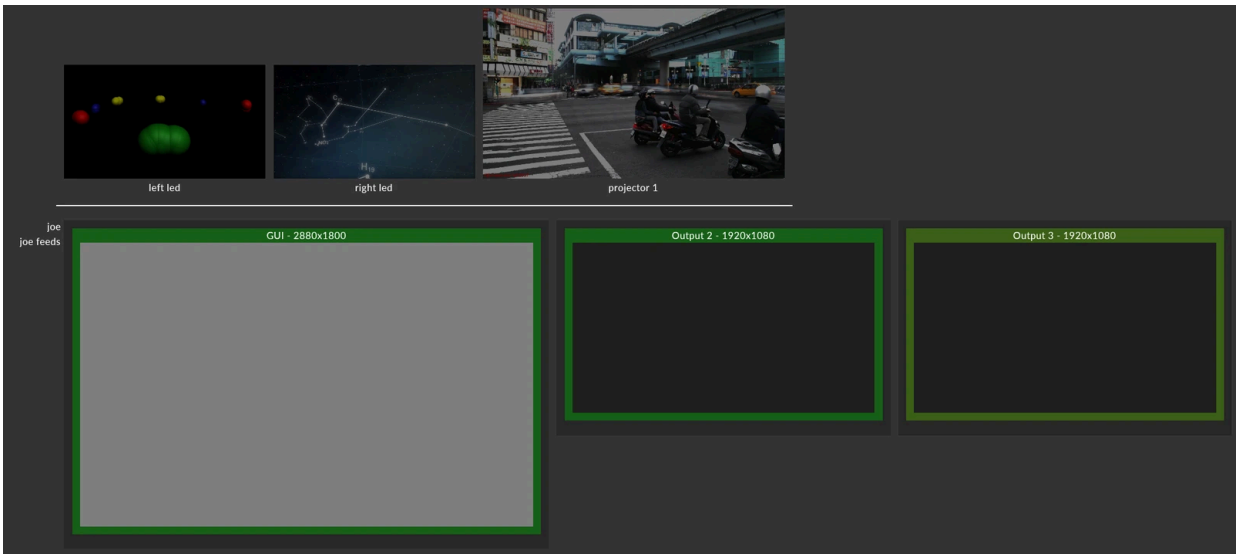
5. Use Consistent Output Settings Across Machines

If synchronising multiple machines, make sure:

- The **same timing mode**, **resolution**, and **framerate** is used across all outputs that require genlock.
- Avoid **AUTO** timing modes in multi-machine setups unless fully matched.

Viewing the Feed Level

To see what the current Feed scene looks like, left-click Feed in the dashboard. This swaps the Stage Visualiser with the Feed Visualiser view.



The Feed level is split into two sections: Screen section and Feed scenes, separated by a white horizontal line

The display is split into two sections, separated by a thick white horizontal line which separates the screen rectangles in the current stage above the line from the physical outputs below the line.

Screen section

Above the line, you see a simplified view of the Screens in the Stage. Each Screen is represented by a rectangle containing its content. In the Screen section, the screen rectangle represents the area of the screen the rectangle copies content from.

Feed scene

Below the white line, you see a virtual view of each of the output heads on your machine, or a virtual machine if you are using Designer, for example. In this Feed scene below the line, the green rectangles represent the area of the output display the content is to be copied to.

Each Feed rectangle is visible in both sections.

The Feed section is made up of a series of different displays.

GUI (Graphial User Interface)

The GUI always represents the first display in the Feed scene and is therefore visually represented as the output display to the very left of the Feed scene. Note that the GUI can also be used as an output display if you add one (or more) Feed rectangles to the GUI display.

Display/Virtual Displays

The Display always represents the second or more displays in the Feed scene and is therefore visually represented as the output display to the very right of the Feed scene. Designer will automatically detect the graphic capabilities of the machine it's connected to and create output heads based on that information.

Warping Outputs

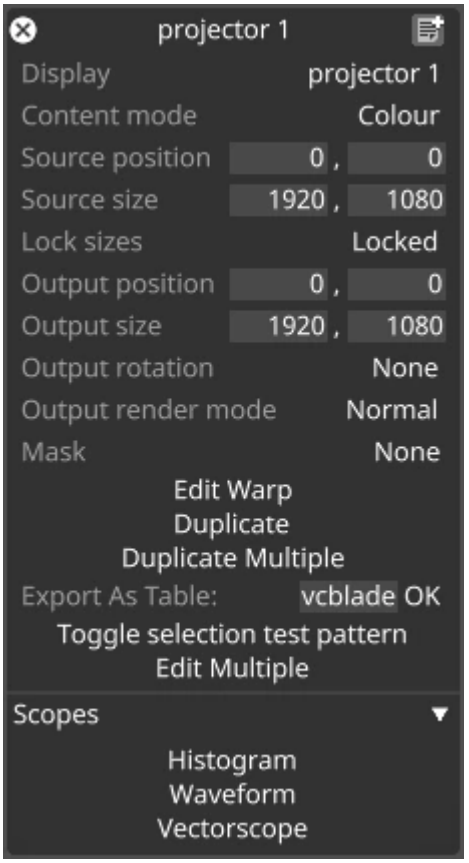
In cases where the projection surface does not match the virtual 3D model (i.e. where the lineup from the manual or automatic calibration needs a slight fine-tune), Designer provides a number of powerful warping layers that can be applied directly to the output. By using these tools, there is no requirement for projector keystoning or any other warping inside the physical projector.

> ⚠ **Warning**
>
> If you're considering warping due to poor calibration, double-check that no warps were active on the projector during calibration, as this can affect the results. Also, consider whether warping is necessary for your setup.

Adding and Using Warping Layers

To add a warping layer to an output:

1. Left-click **Feed** in the dashboard at the top of the screen.
2. Right-click the relevant output.
3. Select **Edit Warp** from the context menu options list.

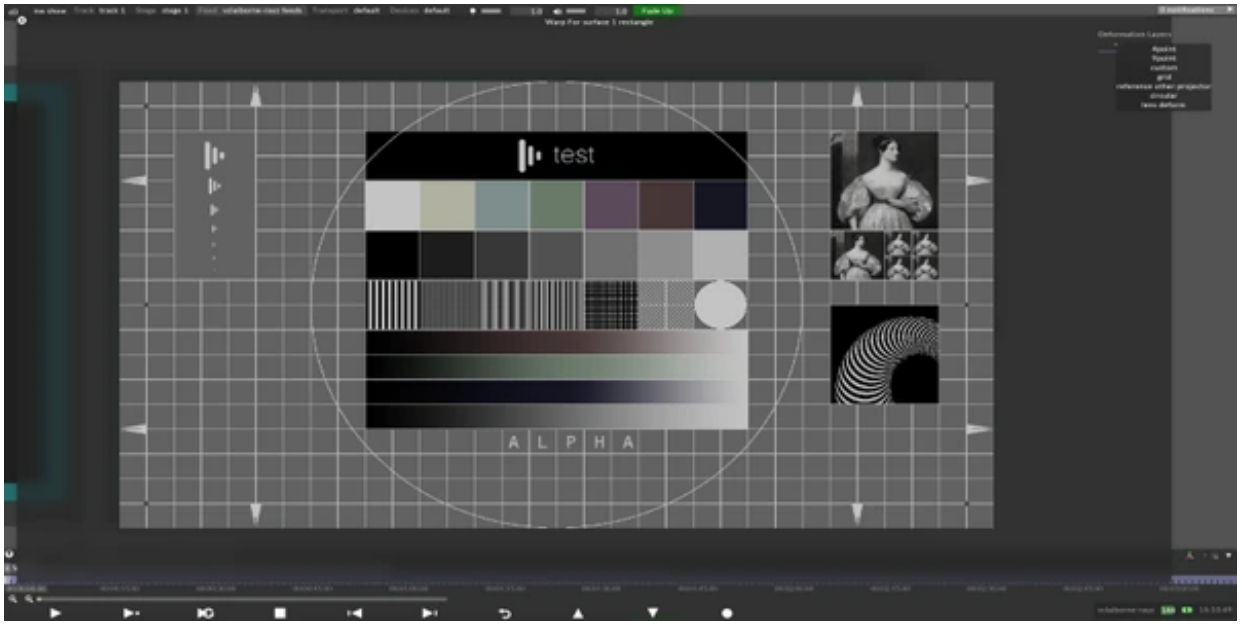


For more information on the dashboard layout and functionality, refer to the Designer User Interface section.

Deformation Layers for Warping an Output Feed

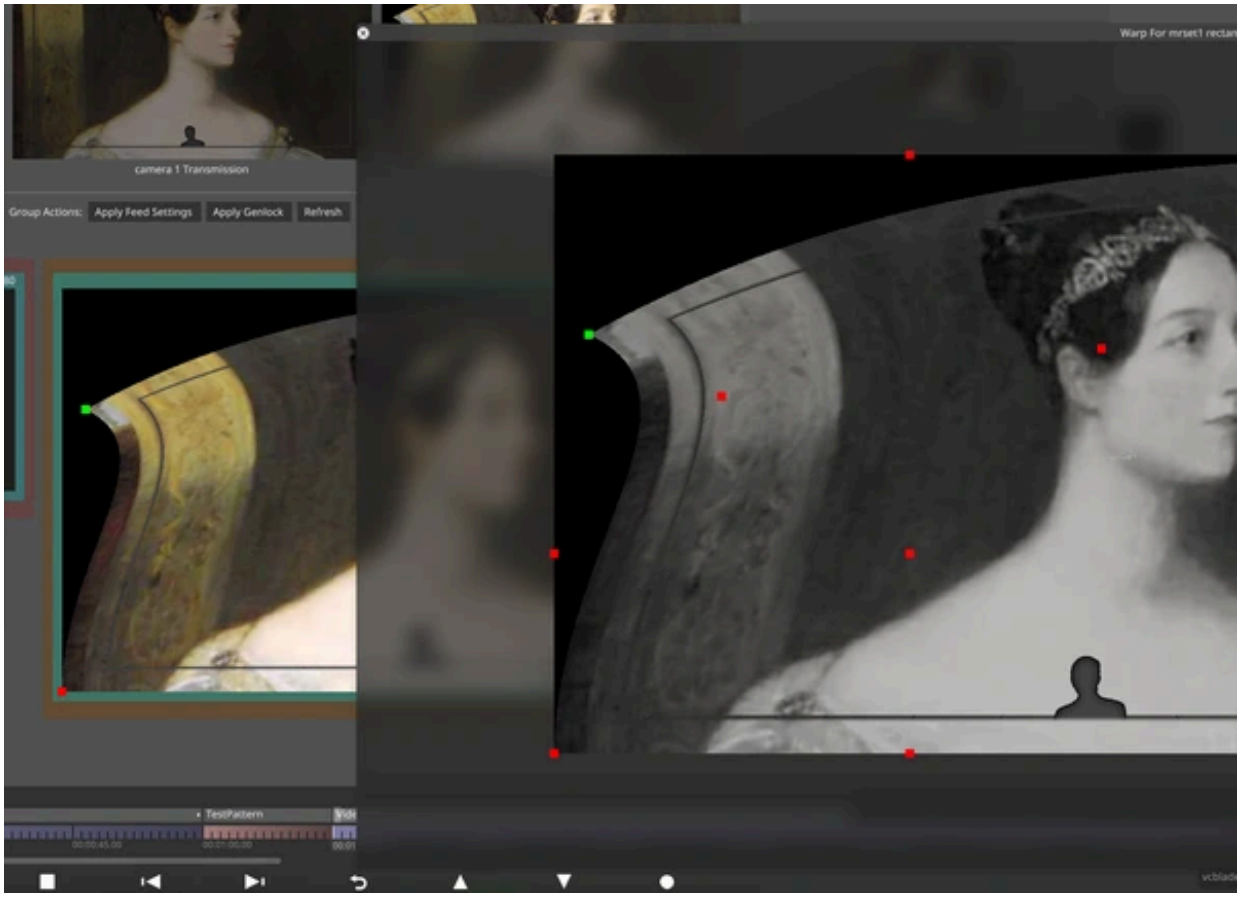
In the editing window, left-click the + button under the **Deformation layers** title.

This will display a list of deformation layers.



Deformation layers for warping an output feed, opened by left-clicking + under the Deformation Layers title

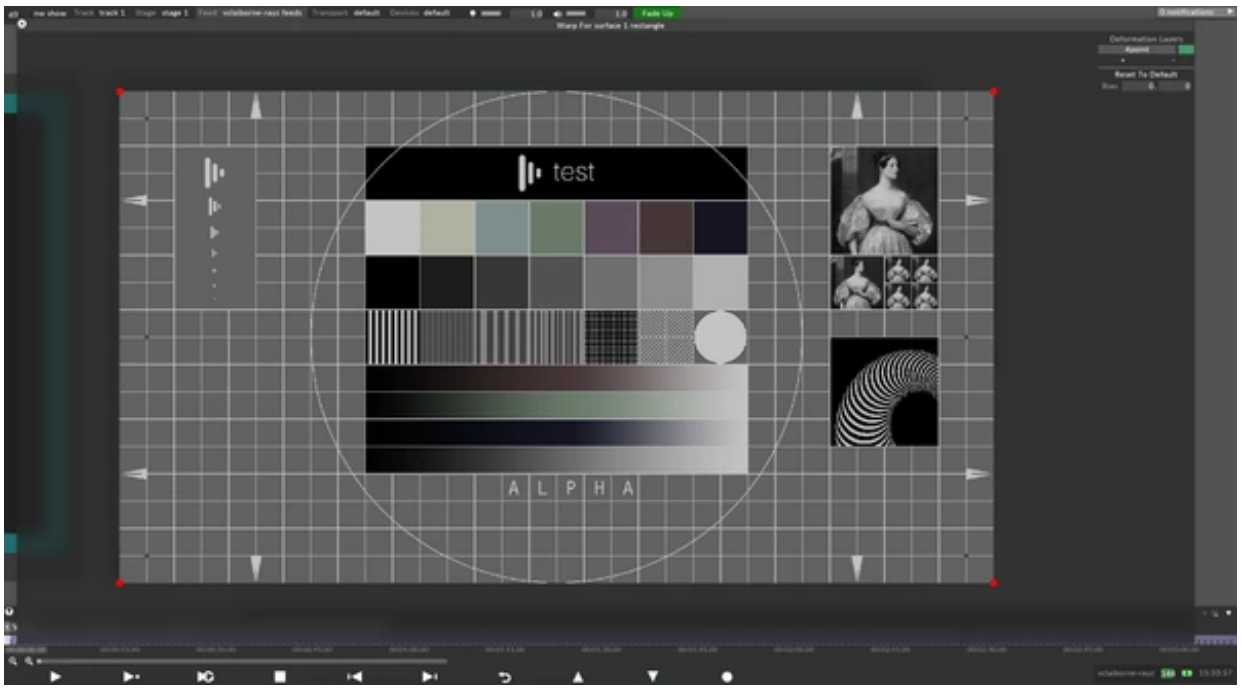
> **Tip**
>
> Warp points can be added to the output so you can see exactly which part of the output is being manipulated.



Warp points being added to an output

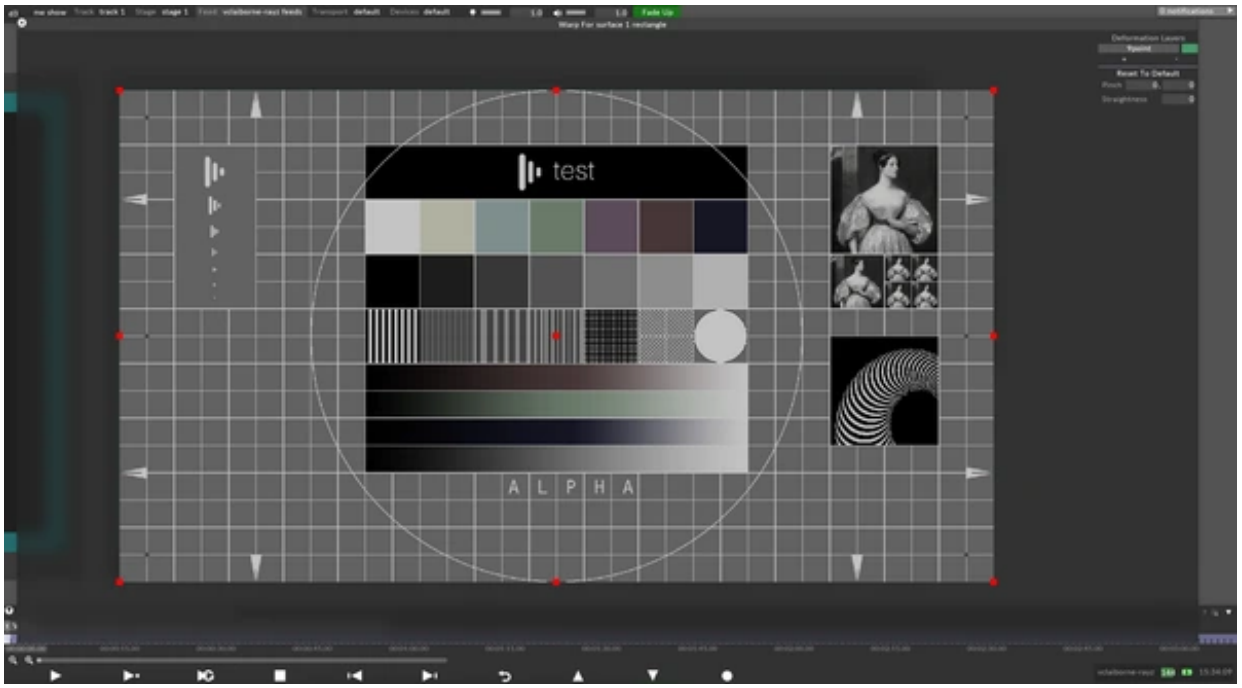
Warping Layer Types

4point



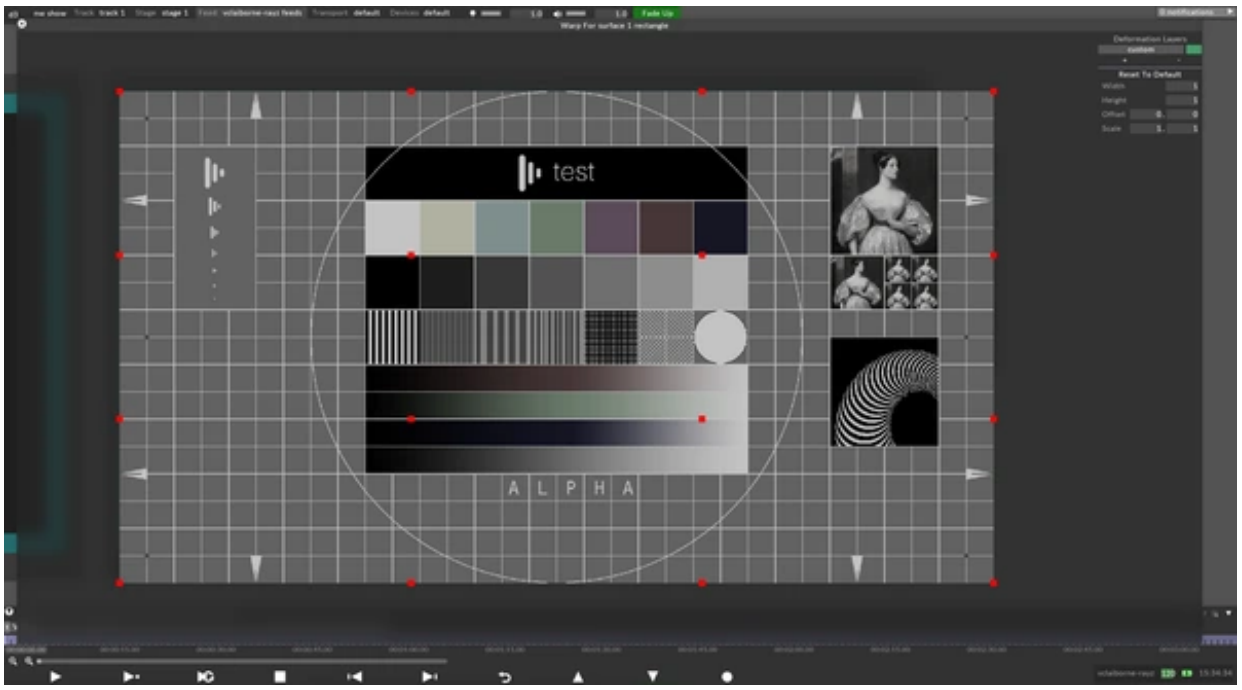
Drag any of the 4 points inwards to globally adjust the warping of the output. Adjust the horizontal and vertical bias to shift-scale the content.

9point



9point warp allows you to drag 9 points inwards and adjust the pinch and straightness between them. This feed warp is useful when projecting onto a cylindrical screen when not using Projector Simulation. It easily conforms a rectangular output to fit to a cylindrical screen.

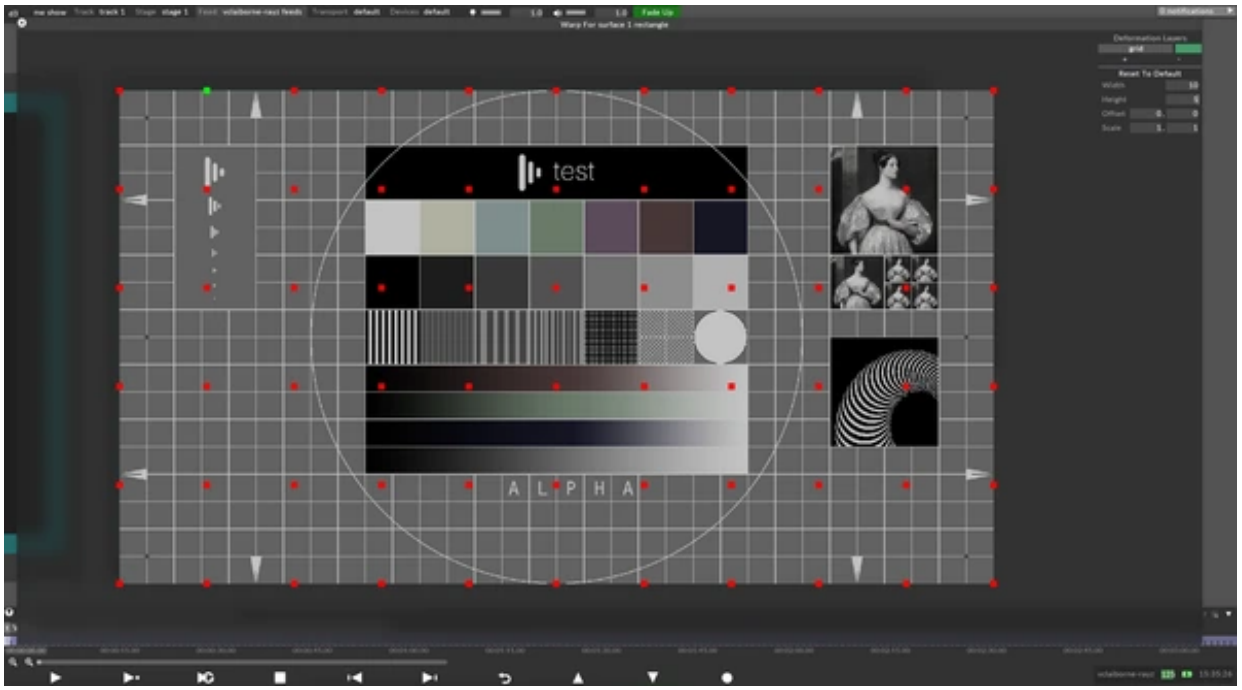
Custom



Creates an arbitrary number of grid points on the output that can be individually or group-selected. You can use this when local warping on an object is required.

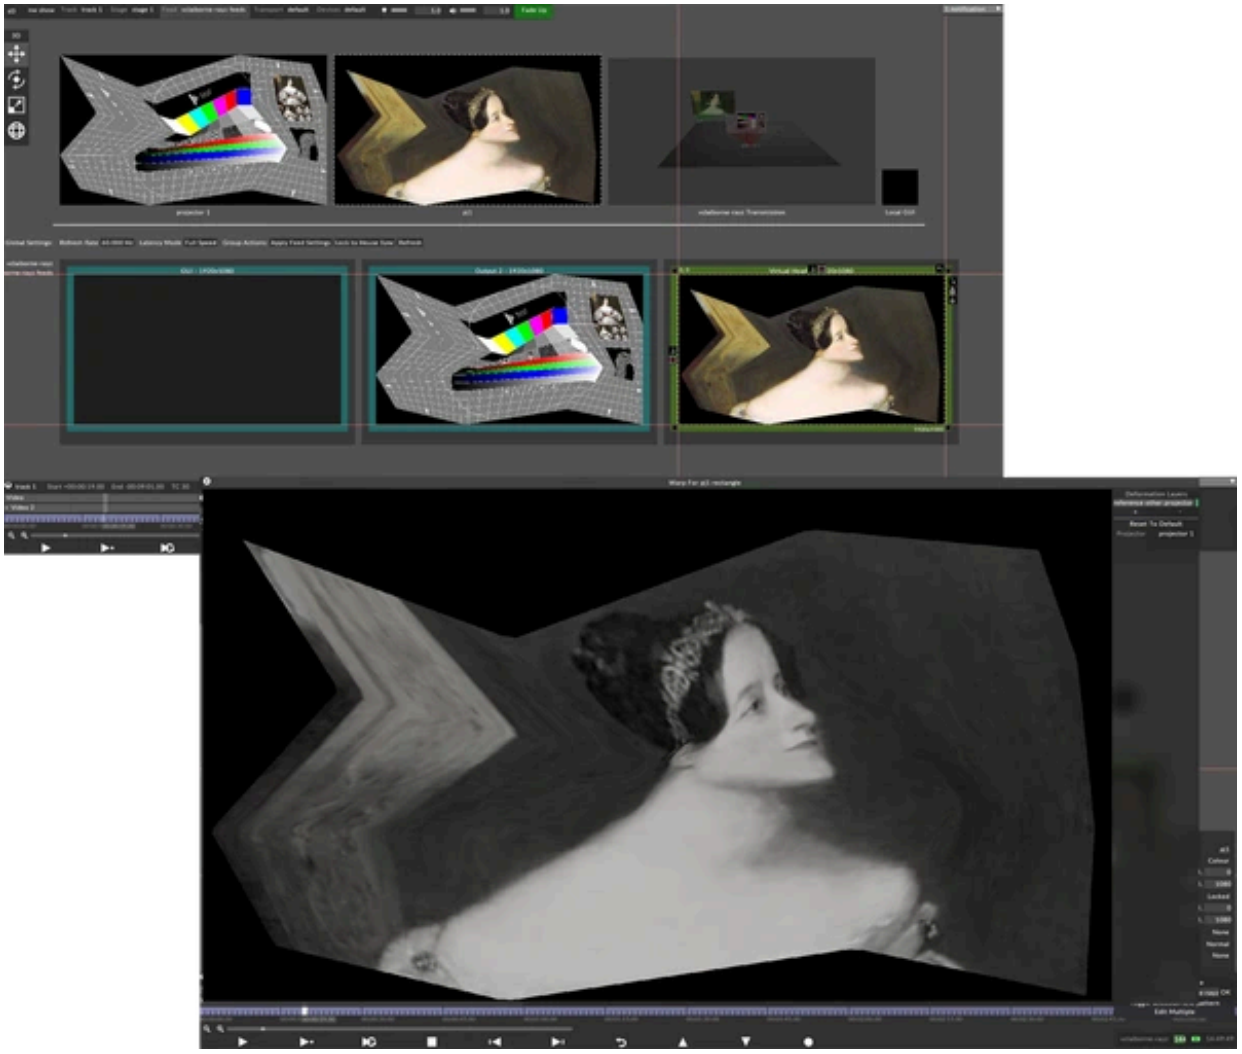
Grid

Provides a regular grid of points for more structured and uniform warping adjustments across the output



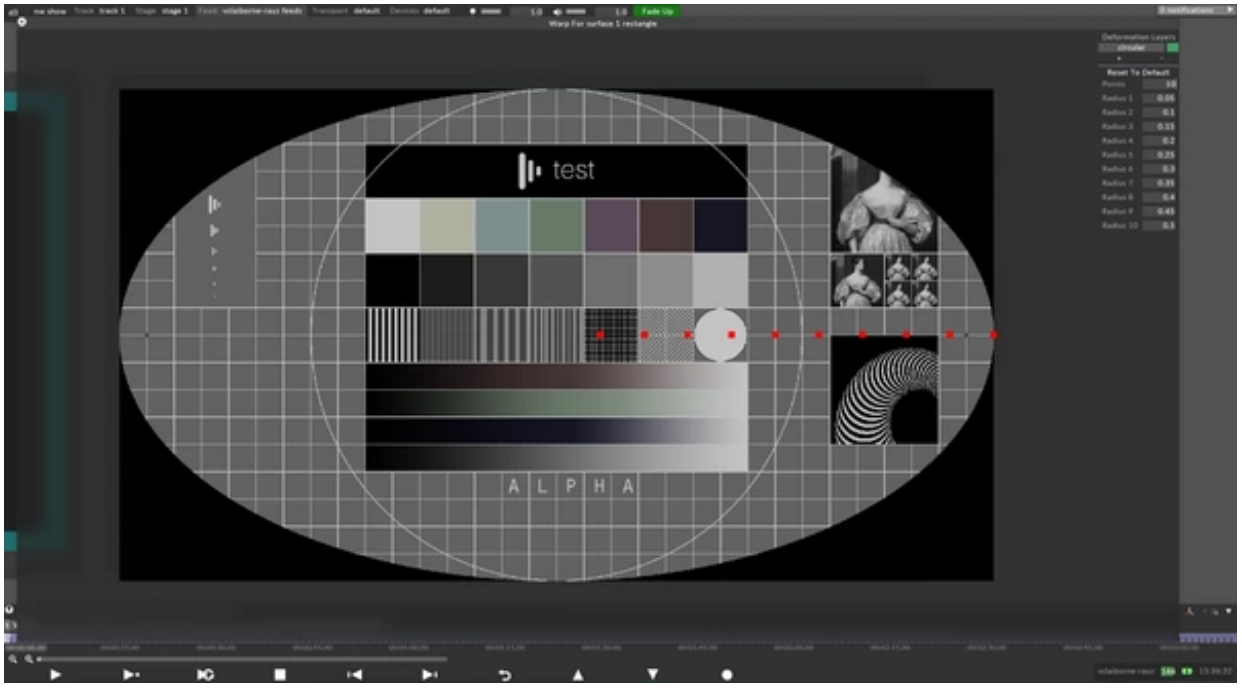
Reference other projector

Uses the deformation of another projector as a reference to synchronise output warping across multiple devices.



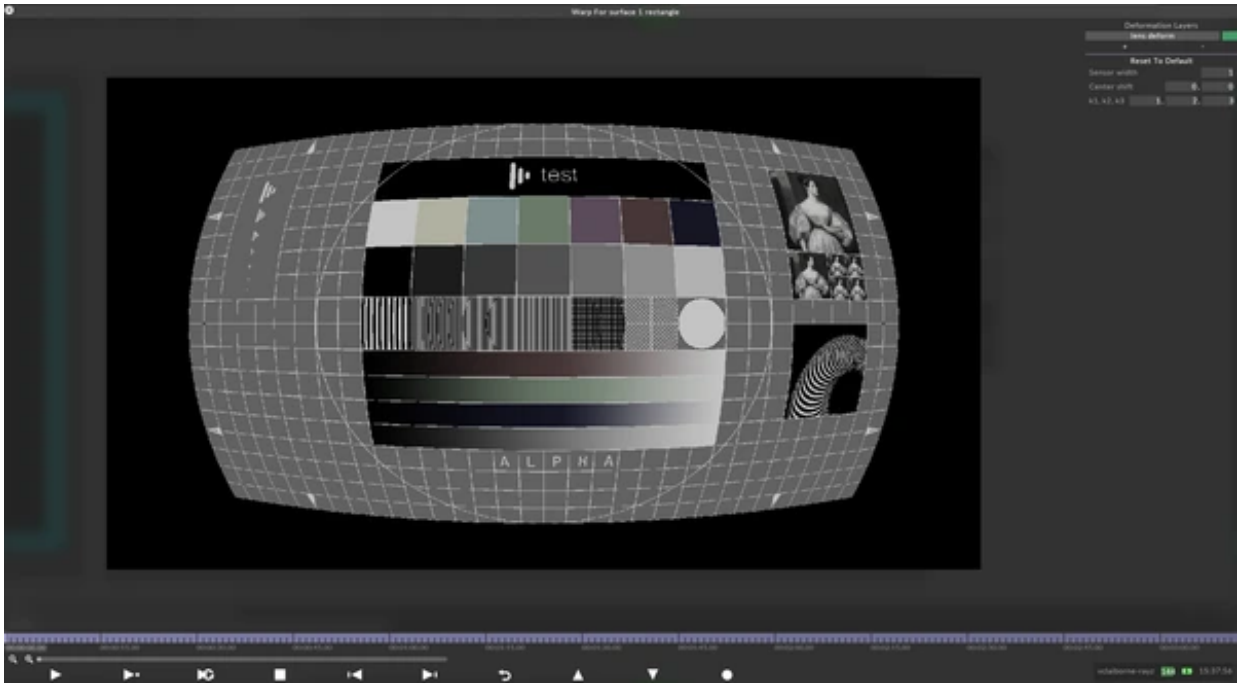
Circular

Applies circular deformation for radial-based warping needs, useful for dome or spherical projections.



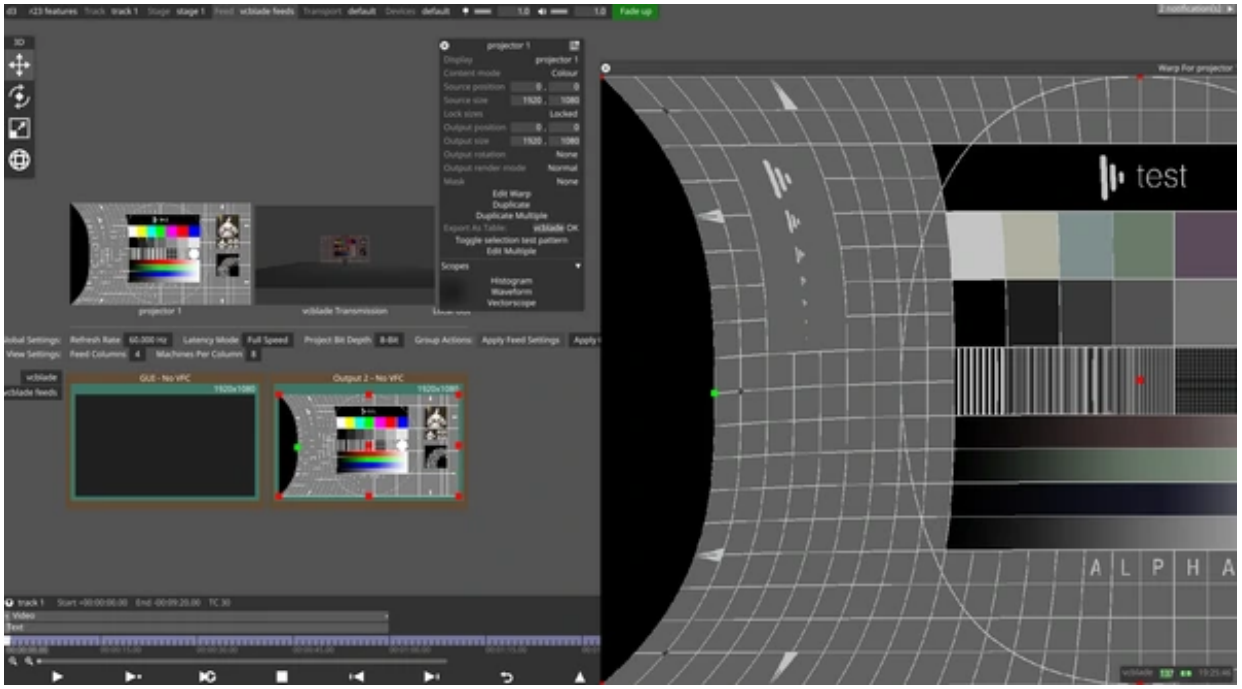
Lens Deform

Simulates lens distortion effects, allowing correction or emulation of barrel or pincushion distortion.



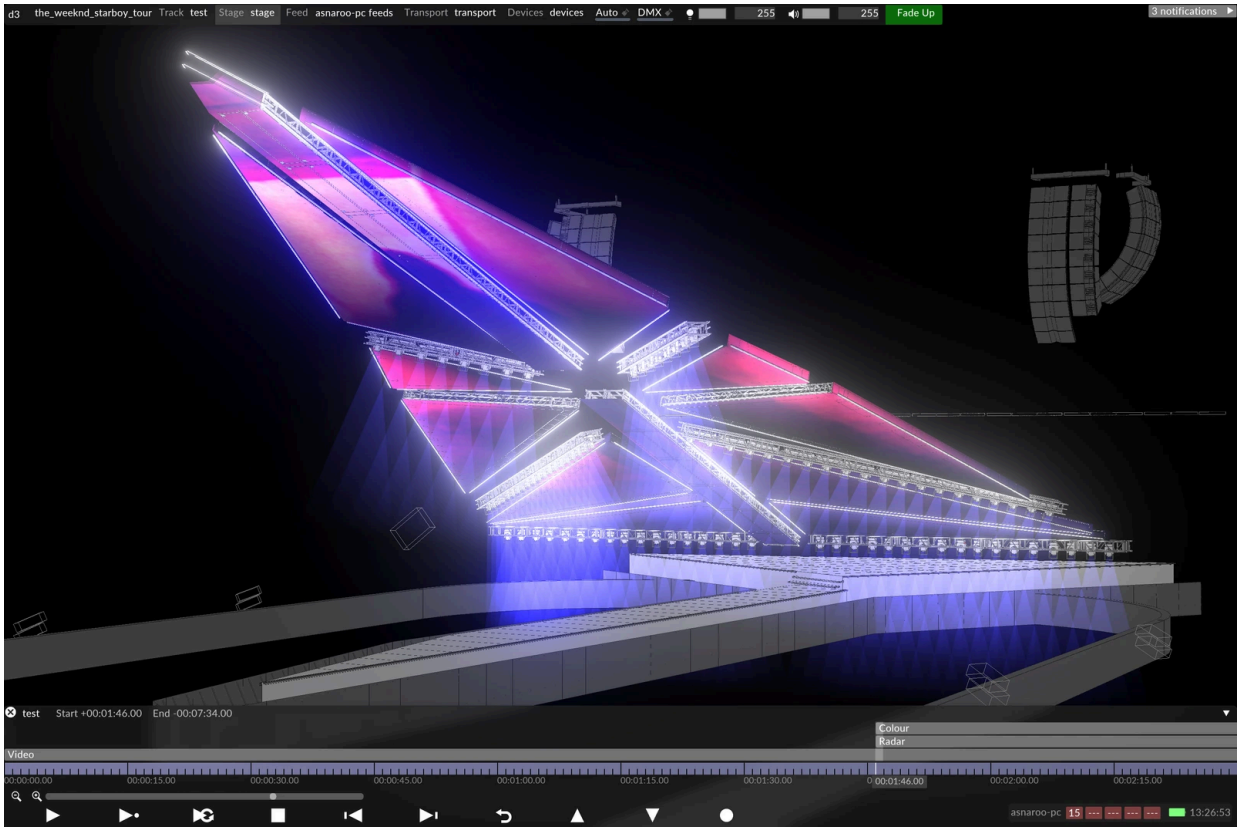
Draw control points on output

Visually place and adjust control points directly on the output for precise manipulation.



Designer Overview

Designer is the Disguise software to design, visualise, sequence and run visual experiences for creative industries including live, location based experiences and virtual production.



Designer enables you to design, configure, and present your show using your own laptop or desktop computer, and then transfer to a Disguise media server for showtime. In production rehearsals, Designer also allows you to multi-edit the show from your laptop. For more info about the Designer product see the **Designer** page on the **Disguise website** where you can download the latest version.

Designer on Disguise Servers

Designer is the core software which powers the Disguise media servers. Disguise servers are supplied fully licensed for Designer. Designer can be upgraded on Disguise servers using the Designer Full installer.

Designer for PC or laptop

There are two Designer options available for users working on a PC or laptop:

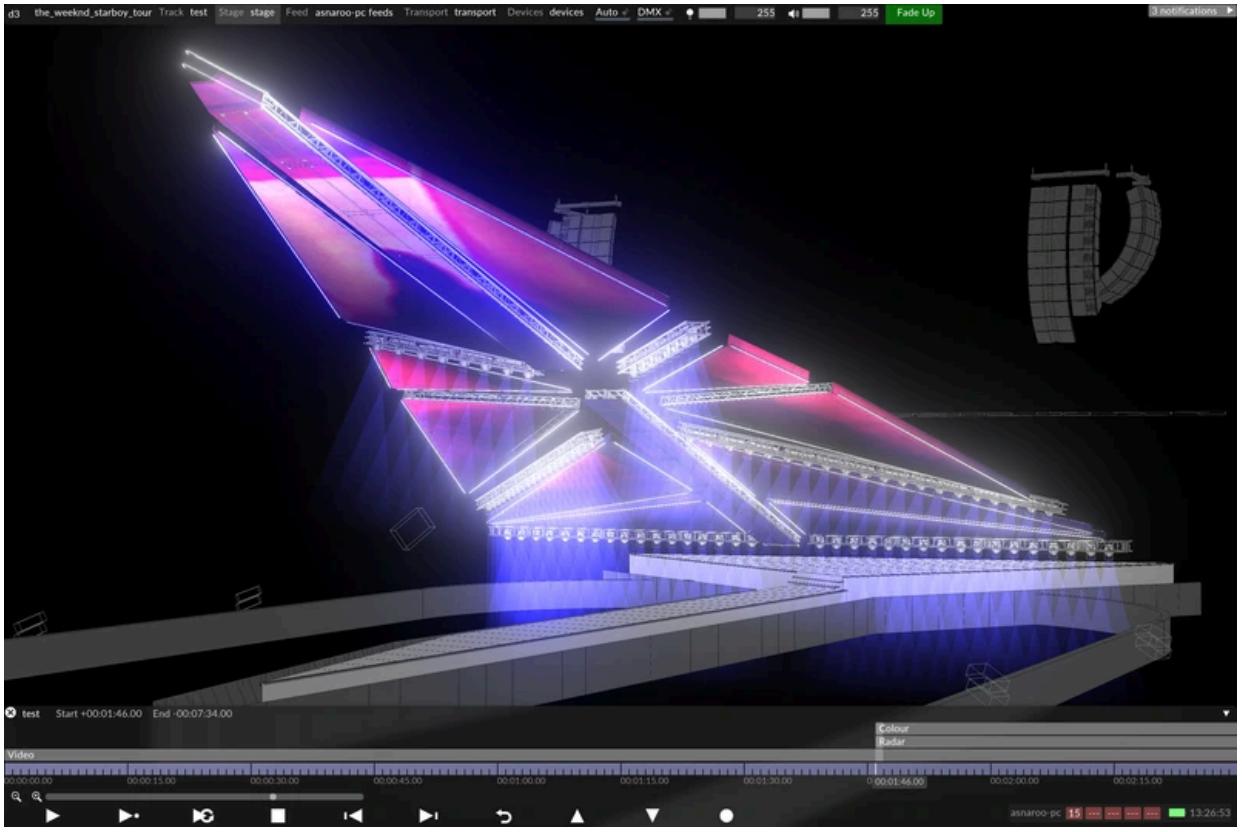
- Designer Starter, which is ideal for learning and evaluating. It is free to use, provided you have a Disguise Cloud account which is used to sign in to d3Manager, the Designer launcher. Designer Starter has a specific Designer Starter installer.
- Designer Pro, which is for programming and editing projects that will be running on a Disguise server. This requires a paid license subscription which is obtained through Disguise Cloud. Designer Pro uses the Designer Full installer.

You can read more about Designer Starter here, and Designer Pro here.

The Designer website has a comparison chart **here**, and Designer Licensing FAQs here.

Designer Elements

Disguise Designer is a real-time 3D simulation and pre-visualisation tool that allows users to design, program, and simulate complex multimedia productions before deploying them in real-world environments.



The Weeknd Starboy Tour stage visualiser

Key Features of Designer

- Integrates lighting, LED screens, and projection mapping into a single workflow.
- Real-time 3D simulation for show pre-visualisation.
- Compatible with Disguise media servers for live event execution.
- Used in concerts, theatre productions, corporate events, and virtual production.

Disguise Ecosystem

- Disguise Media Servers (e.g., VX and GX series) power large-scale live productions.
- Disguise Designer is the software for pre-visualisation and programming.
- Disguise's XR & Virtual Production tools are widely used in film and broadcast.

Pre-production

Disguise integrates a real-time 3D stage visualiser, media playback, and a timeline. It lets you model the stage, view it instantly from any angle, drop video or still content onto the timeline and play it back onto the stage, without time-consuming re-renders. It is therefore a very useful communication tool in the early stages of a project. Showing a real-time simulation of a proposed design is faster, cheaper and more effective than traditional renderings and fly-throughs. In the preproduction stage, it allows designers, clients and artists to quickly visualise content and make artistic decisions, without having to actually build the stage. Stage visualiser used as an essential 3D visualisation and simulation tool in the pre-production phase.

Rehearsals and live production

However, Disguise goes further than mere visualisation. It is designed to integrate with the traditional tools of show delivery (lighting desks, audio and automation systems). Designer contains all the video playback functions you would expect to find in a conventional media server, together with a sophisticated timeline-based show control mechanism. Coupled with the Stage Visualiser, Disguise allows the designer to edit and sequence a complete show, present it to the client and get a sign-off, long before the real stage is built.

Once the real stage is set up, you bring Disguise (with the completely sequenced show) into the production rehearsal, plug it in, and press play. Thanks to the Stage Visualiser, a highly realistic simulation of the actual stage, you are guaranteed that the show will look the same on the real screen as it does in the Stage Visualiser, aside from a bit of tweaking (and we give you an arsenal of tools to do this).

Disguise being used in the production rehearsals of The Weeknd Tour 2017.

The added value of this is simple it saves time, and therefore money. Disguise allows you to shift crucial work forward in time, so you can spend time on making the right decisions before you go into production rehearsals and start spending money. Disguise acts as a central focus for the production team, making sure that everyone can review everything so that mistakes are caught early, aesthetic blind avenues are identified and avoided, and content is made to maximise the potential of the stage.

Disguise used as an essential tool to successfully deliver The Weeknd show onto the stage, on time and on budget.

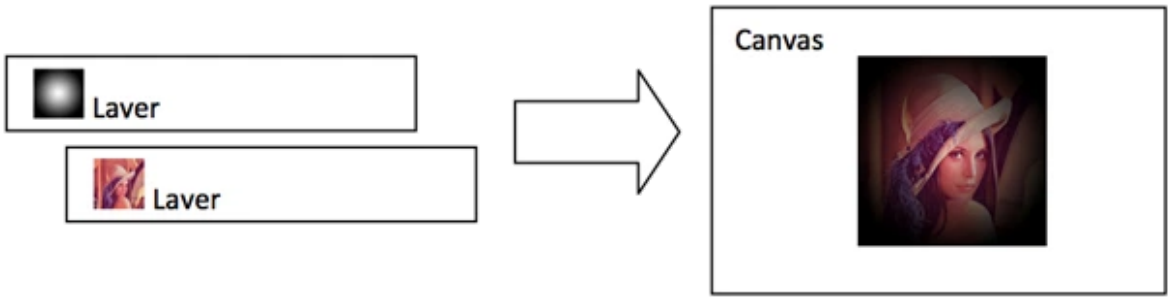
Main Elements

Designer comprises three main elements: the Timeline level, the Stage level and the Feed level.

Timeline level

The Timeline level consists of a timeline containing a number of content layers. On the timeline, you can create multiple layers of video or generative content and position it on the timeline. By adding keyframes you can control properties such as playback speed, brightness, colour, etc. Multiple layers can be combined onto one single output canvas by using a selection of blending modes. This environment is familiar to users experienced with commercial video editing software tools.

Disguise's key insight is to separate these three levels and to perform the mapping between them in real time. Changes to any level can be made independently of the others; a change in the screen layout or output formatting does not require a change of content.



Timeline Concept _

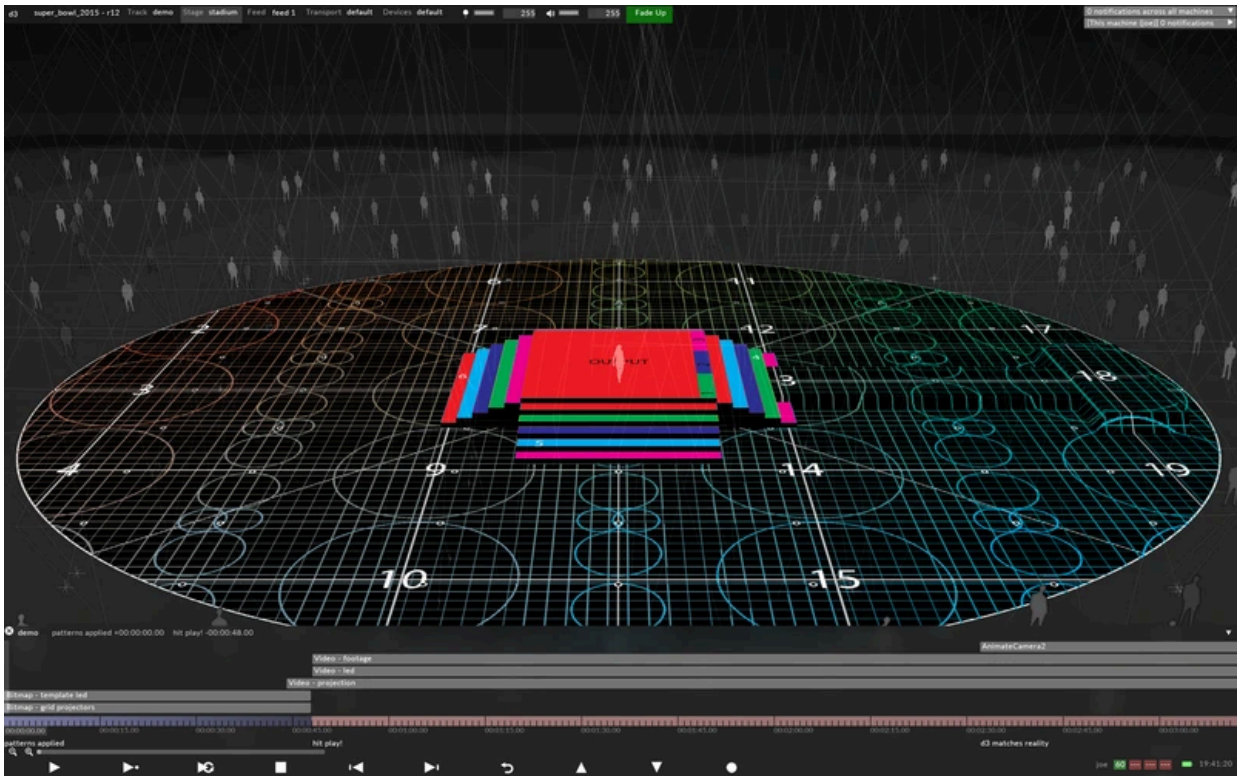
Timeline level sequencing video and generative content

Stage level

The Stage level simulates your stage. It allows you to create any number of screens in all kinds of shapes. Each screen can be placed at any position, orientation, scale and set to any resolution (up to 8k in one direction) within the 3D scene. In addition, each screen has its own target canvas with an adjustable resolution. You can turn anything you want into a screen, even entire 3D buildings, and design your content with projectors, LED screens, or DMX lighting fixtures in mind.

The Stage can be created to precisely simulate the real stage that disguise will be connected to, with each and every pixel represented. Content generated by the layers in the Timeline is mapped onto the target canvases of the screens, allowing you to visualise the content in 3D from any point of view.

Stage level concept

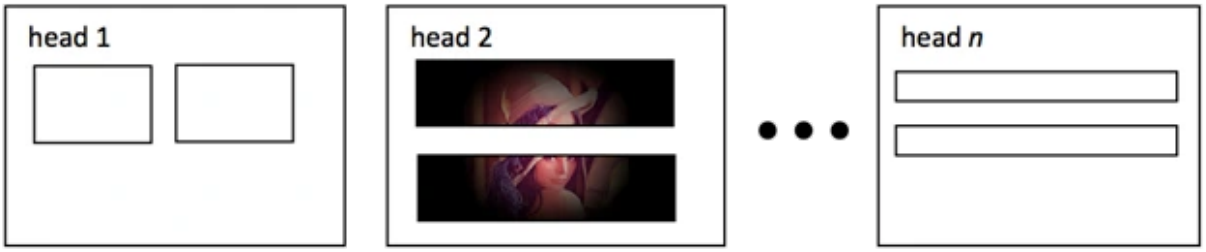


Stage level visualising and simulating the set of the Superbowl.

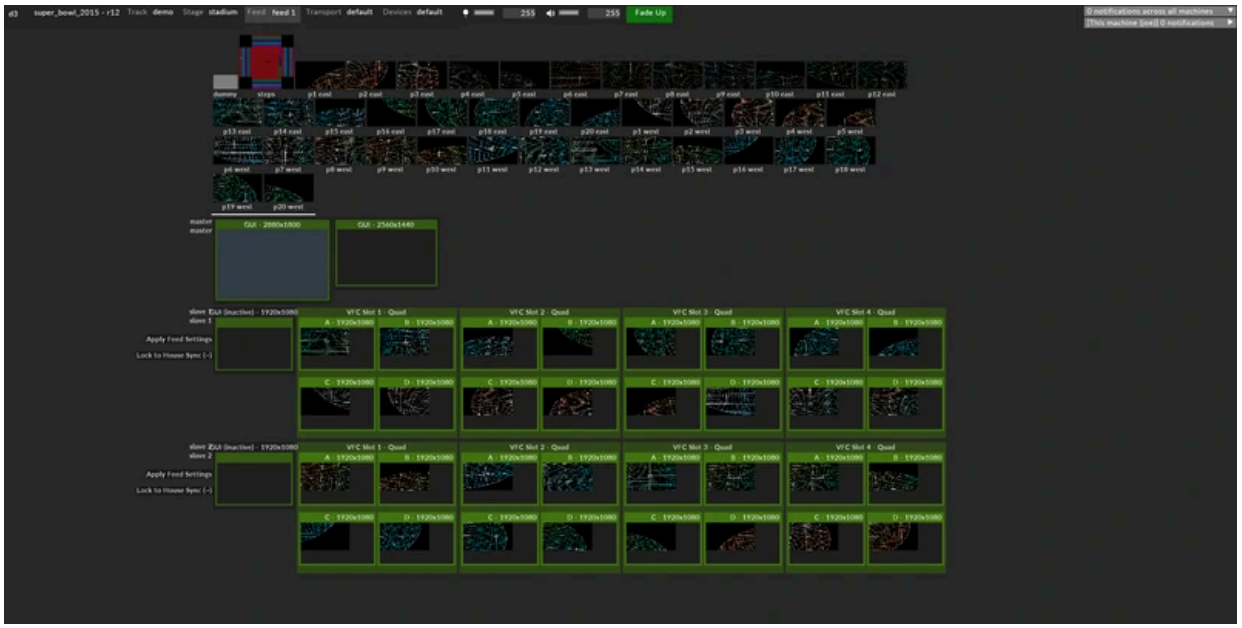
Feed level

The lowest level, the Feed level, comes into play when you connect d3 to the real world: the LED screens, projectors, plasma displays, or DMX lights on your stage. It allows for the 2D

output screen content to be formatted according to the requirements of the receiving LED processor, projector, or lighting system.



Feed level concept



Feed level formatting the screen content to a projector system for the Superbowl.

Real-time mapping

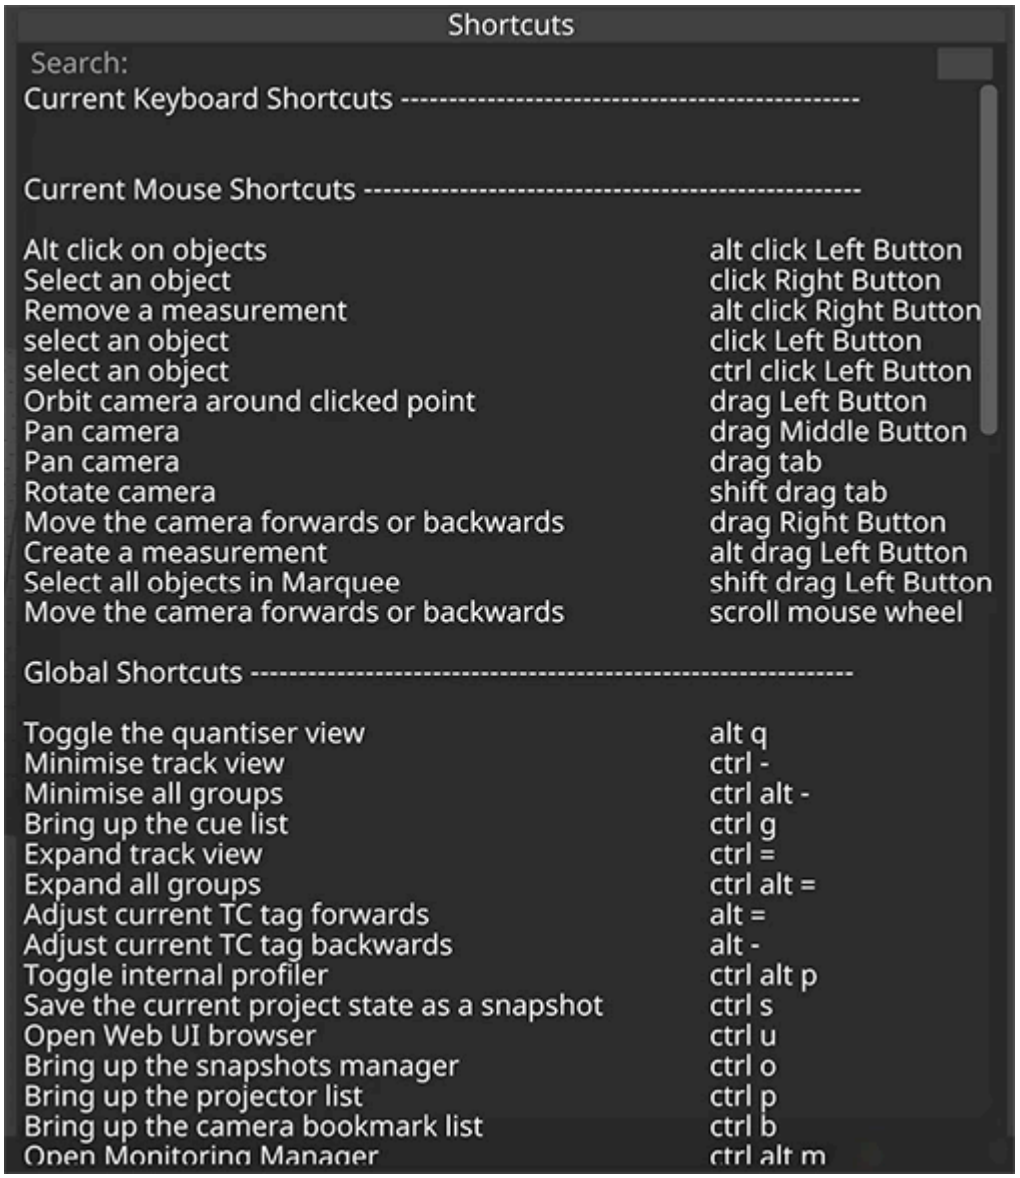
Disguise's key insight is to separate the Timeline level, Stage level and Feed level and perform the mapping between them in real time. Changes to any level can be made independently of the others; a change in the screen layout or output formatting does not require a change of content.

Designer Keyboard Shortcuts

Many of the functions within Designer are mapped to keyboard shortcuts.

To display a full list of keyboard shortcuts:

- Press F1. Use the Search field at the top to quickly find the shortcut needed.



Shortcuts window within the Stage level accessed by pressing F1

- Press F1 to close the shortcuts window.

Please note: The F1 window is context sensitive and will change depending on the currently active level. For example, the Feed level will display a different list than the Stage level.

> **Note**
>
> This is not a definitive list, but is generated to the local machine so may have local and language variants

Pressing F1 will also enable Designer to display explanations of object properties. For more information on this feature scroll down to the section 'Object property explanations in the Editing objects sub-chapter.

Shortcuts

General

Action	Shortcut
Quit	ESCAPE ENTER
Save	ALT W
Console*	ALT C
Debug Console*	ALT D
Profiler*	CTRL ALT P
Hold/Unhold	ALT P
Sticky Window (pin)**	CTRL + Left-click X on Header
Close Last Window	ESCAPE
Close All Windows (Except pinned)	SHIFT + ESCAPE

Stage movies max resolution	2K (2160×2160)	4K DCI (4096×2160)	4K DCI (4096×2160)	2K (2160×2160)	4K DCI (4096×2160)

Designer Pro

Designer Pro brings a host of powerful new features. It offers the complete functionality of the software, enabling seamless programming and real-time editing of live projects. Users can collaborate within a session alongside Disguise servers or other Pro license instances, unlocking improved creative control and efficiency. Activation of the Designer Pro license is required.

Features

Functionality

- Fully featured Designer software.
- Programme and pre-visualize projects beyond the Starter ecosystem.
- Real-time project editing with other Disguise servers and Designer Pro instances.
- Access to the new Plugin Framework and AI Workflow Assistant.
- Support for uncompressed RenderStream without watermarks (requires RenderStream license and compatible hardware).

Activation and Installer

- Installed via the standard Full Designer installer used on Disguise media servers.
- CodeMeter-based license, can be installed on a dongle or as a software license.
- No d3Manager Cloud login is required.
- An internet connection is required only for initial license activation. Subscriptions require periodic online verification to automatically download monthly/annual license updates.
- Designer Pro subscription for yourself or your team can be managed in Disguise Cloud.

Watermarks and Restrictions

- You can open any Designer project file except one authored in Disguise Starter.
- Designer projects created and saved in Designer Pro can be used with Pro or Starter. However, once opened in Starter, Designer projects created or saved in Starter cannot be used by Designer Pro.
- If you click on an object in Designer and export it from Designer Starter, it is not possible to import it into Designer Pro.
- Designer Pro project files are saved as .d3, whereas Designer Starter project files are saved as `.d3starter`.
- Feed outputs include an intermittent blue flash watermark.

- Feed and Stage movies are watermarked with a semi-transparent Disguise logo with a size of approximately one-tenth of the movie's vertical resolution in the bottom right corner.
- Feed and Stage movies have a maximum resolution of 4096×2160 pixels (4K UHD).
- Designer Pro and Designer Starter cannot join the same session or recognise each other on a network.

Learn more about license activation here, and Designer Starter here.

The Designer website has a comparison chart here, and Designer Licensing FAQs here.

Designer Pro License Transfer

A Disguise license is stored in a CodeMeter Container (CmContainer), which can reside either on your computer or a USB dongle. In some cases, you may need to transfer a Disguise license to another container, for example, when moving a **Designer Pro** license from one laptop to another.

To do this, you must first **deactivate** the license on the current CmContainer then **re-host** it on the WebDepot and then **reactivate** it on the new CmContainer. The following steps will guide you through this process.

> **Note**
>
> The following licenses are not eligible for transfer:
>
> - Disguise hardware licenses
> - Disguise X range licenses
> - RenderStream licenses
>
> Designer Starter licensing is built into the installer and no activation or transfer is necessary.

Re-host an existing license

On the computer that has the relevant license activated (either on a physical USB dongle or a software CmAct container) follow the steps below to re-host the existing license. This will move the license back to the WebDepot, where you can activate it later on another container.

Requirements

To re-host a license you will need:

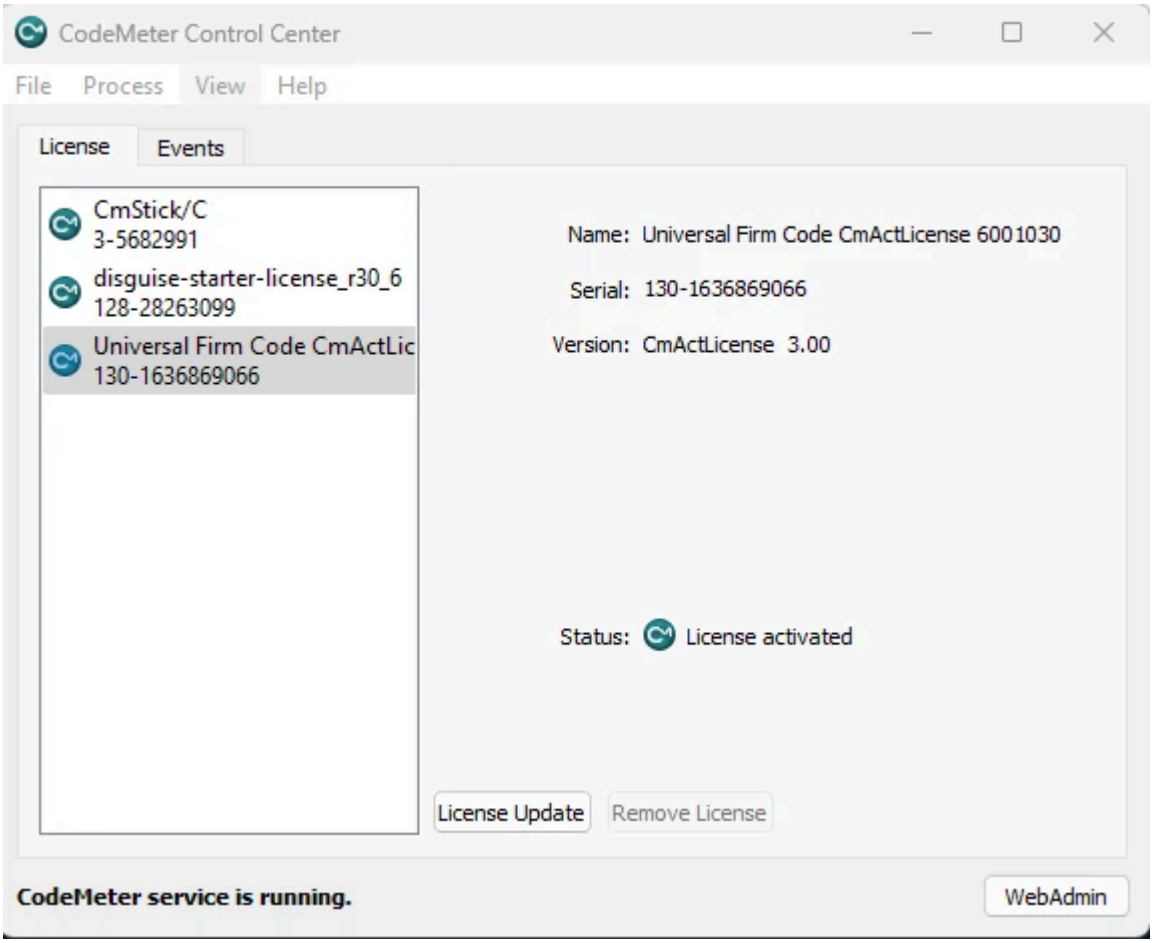
- Access to the computer or CodeMeter container which holds the license.
- The **License Ticket ID** for the license you want to transfer.

Find the Ticket ID for the license

A **License Ticket ID** uniquely identifies a license (e.g. for a Designer Pro subscription). It consists of 5 groups of 5 alpha-numeric characters each, e.g.:
`1ABCD-2EFGH-3IJKL-4MNOP-5QRST`

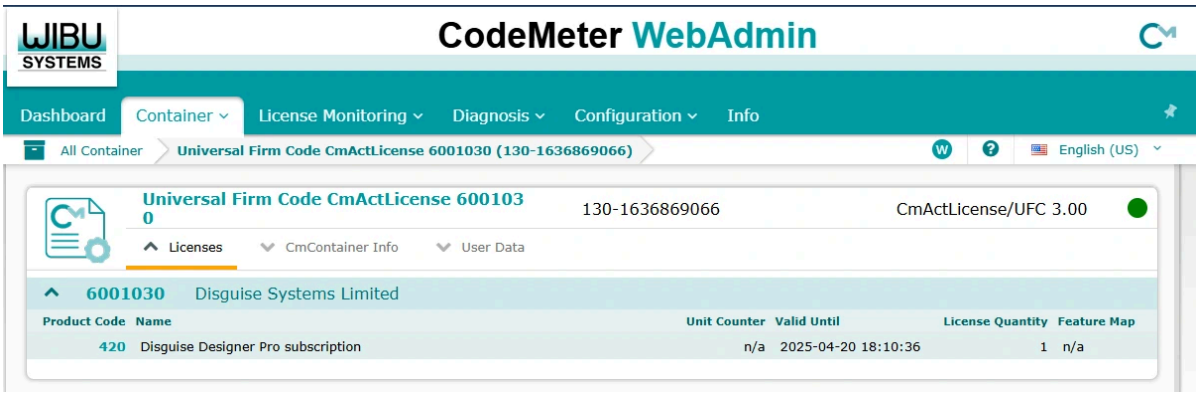
Follow these steps to find your **License Ticket ID**:

1. Using the computer that has the license you want to transfer, Open **CodeMeter Control Center** via the Windows Start menu. This was installed automatically when you installed Designer.
2. Select the CmContainer in the left panel that contains the license you want to transfer.



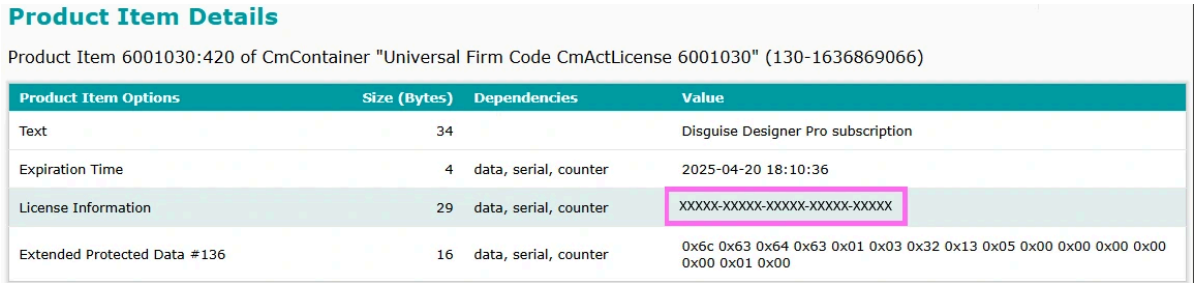
CodeMeter Control Center

3. Open **WebAdmin** by clicking the button in the bottom right in CodeMeter Control Center. This will open in your web browser.
4. Click on the Product Code of the license you want to transfer, e.g. “420” for Designer Pro.



CodeMeter WebAdmin

5. The **License Ticket ID** can be found in the **License Information** row and **Value** column. Copy this to a safe place, you will use it later.



Product Item Details

Product Item 6001030:420 of CmContainer "Universal Firm Code CmActLicense 6001030" (130-1636869066)

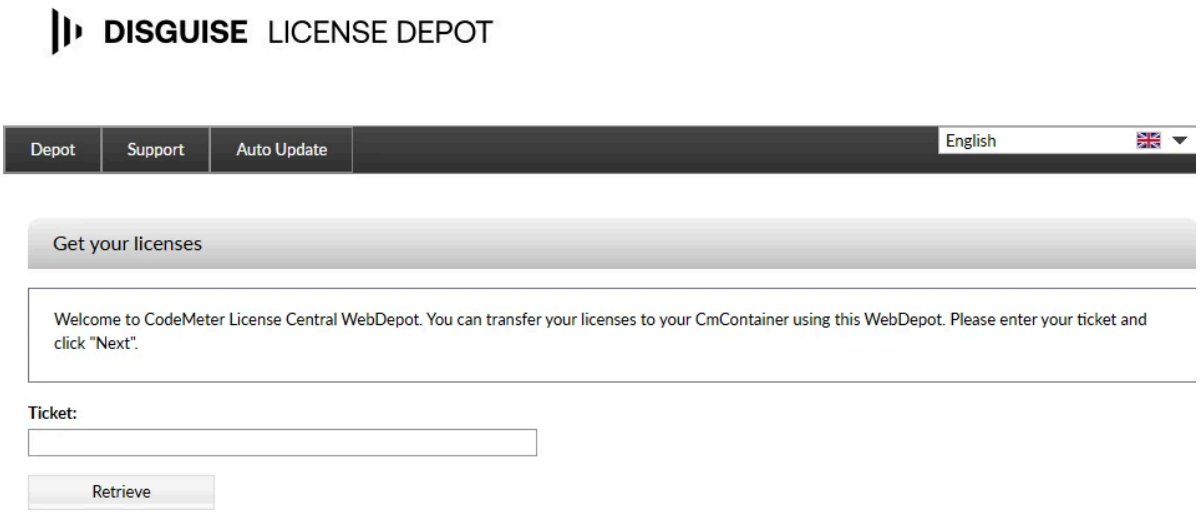
Product Item Options	Size (Bytes)	Dependencies	Value
Text	34		Disguise Designer Pro subscription
Expiration Time	4	data, serial, counter	2025-04-20 18:10:36
License Information	29	data, serial, counter	XXXXX-XXXXX-XXXXX-XXXXX-XXXXX
Extended Protected Data #136	16	data, serial, counter	0x6c 0x63 0x64 0x63 0x01 0x03 0x32 0x13 0x05 0x00 0x00 0x00 0x00 0x00 0x00 0x01 0x00

License Ticket ID highlighted in pink

Deactivate and Re-host the license back to the WebDepot

Follow these steps to deactivate and re-host your license:

1. On the machine that has access to the CodeMeter container with the relevant license, navigate to the Disguise CodeMeter License Central Web Depot.



Disguise CodeMeter License Central Web Depot

2. Enter the **License Ticket ID** that you got from the previous section in to the **Ticket** field and select **Retrieve**.
3. Ensure your ticket details are listed, then click **Re-Host Licenses**.
4. Select the licenses you want to re-host and click **Deactivate Selected Licenses Now**.
   Please note that some licenses may not be eligible for re-hosting.
   This will only work if the container with the license is on the current machine.
5. Wait a few seconds for the WebDepot communication to complete.
6. Once the process has completed you will see a **License transfer completed successfully!** message. Click **OK** to continue.

Reactivate the license from the WebDepot

After re-hosting a license you can leave it deactivated on the WebDepot until you are ready to activate it again on another machine or CodeMeter dongle. The clock will continue to count down whether the license is activated or not.

To activate your license follow the steps on the Designer Licenses and Activation Process page.

Finding your License Ticket ID without a CmContainer

If you don't have access to the CodeMeter container with the license, then you can find your **License Ticket ID** in one of these alternative ways:

- In the original email when the license was first issued.
- In your Disguise Cloud Dashboard

How to find License Ticket IDs in Disguise Cloud

To view the **License Ticket ID** in your Disguise Cloud Dashboard follow these instructions:

1. Login to Disguise Cloud.
2. Click on your organisation in the top-right, and select **Subscriptions** from the menu.
3. Under **Active Subscriptions** find the tile for the product you want and click **View**.
4. Next to each License you can find the **License Ticket ID** by selecting the eye icon on the right.

Designer Starter

Designer Starter is a free version ideal for learning and exploring the features of Designer. It can be easily downloaded and installed through Disguise Cloud using a dedicated Starter installer. Starter users must log in to Disguise Cloud in d3Manager for authentication before launching Designer. There is no need to activate a license because it is already included in the installer.

Features

Functionality

- Feature-rich Designer software including all current functionality such as APIs, RenderStream, and access to the new Plugin Framework.
- Programme and pre-visualise projects in the Starter ecosystem.
- Real-time project editing with other Designer Starter instances.
- Support for uncompressed RenderStream without watermarks (requires RenderStream license and compatible hardware).

Activation and Installer

- Users must log in to d3Manager with their Cloud account to activate the license. While d3Manager remains functional without logging in, you will be unable to open a project without a Disguise Cloud account login.
- The dedicated Designer Starter installer already includes the license required to run Starter. There is no individual Designer Starter license, and Starter does not interact with Designer Pro licenses.
- Designer Starter runs regardless of whether or not a Pro license is present on the server.

Watermarks and Restrictions

- Designer Starter supports the new Plugin Framework, but does not include the Ask AId3n AI Workflow Assistant.
- Designer projects created or saved with Designer Starter cannot be opened with the Pro license. However, Designer Pro projects can be opened with Designer Starter, but can only be saved as Designer Starter projects.
- Designer Starter files are saved as .d3starter, rather than .d3. Designer Pro project files continue to use .d3.
- Feed outputs have an intermittent blue flash watermark.

- Feed movies and Stage movies are watermarked with a semi-transparent Disguise logo with a size of approximately one-tenth of the movie's vertical resolution in the bottom right corner.
- Feed and Stage movies have a maximum resolution of 2160×2160 pixels (2K UHD).
- If you click on an object in Designer and export it from Designer Starter, it is not possible to import it into Designer Pro.
- Supports watermarked RenderStream if Designer Starter is installed on the render nodes.
- A Designer Starter can only join a d3 session with other Starter Designer instances. Designer Pro machines will not be visible on the network.

Upgrading to Pro

To upgrade from the Designer Starter to Designer Pro, you will need to purchase a Designer Pro license and install the Full version of Designer. Once upgraded, you will have access to all the advanced features, including the Ask AId3n AI Workflow Assistant.

Please refer to our **Designer Starter v Pro comparison page on the Disguise website** for more information.

If you have any specific queries, please refer to the Designer Licensing FAQ page or contact our **support team**.

Training Courses

If your training course does not require a Disguise server, Designer Starter is the ideal choice, as it provides full access to Designer's core functionality without restrictions. Students should sign up for Disguise Cloud, install Designer Starter, and log in to d3Manager using their Disguise Cloud account.

For courses that do involve a Disguise server, you have two options:

1. Using Designer Starter: Install Designer Starter on the Disguise server and log in to d3Manager on the server with a Disguise Cloud account. Additional Starter instances can then join a d3 session with the server. Note that outputs will display an intermittent blue flash.
2. Using Designer Pro: If students require Designer Pro, please contact your account manager to discuss options for obtaining Pro licenses for the training course.

Learn more about Designer Pro here.

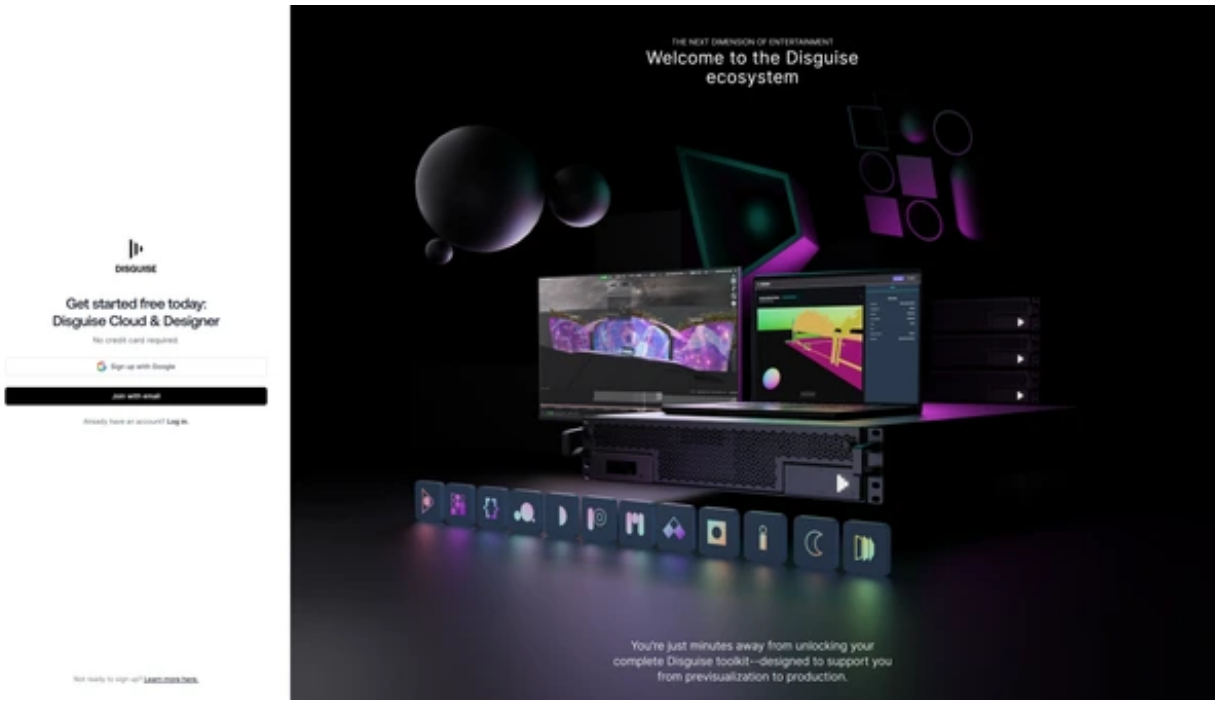
The Designer website has a comparison chart **here**, and Designer Licensing FAQs here.

Designer Pro Subscriptions

Subscribe to Designer Pro

To subscribe to Designer Pro, you need a Disguise Cloud account and an organisation to associate with the Designer Pro subscription.

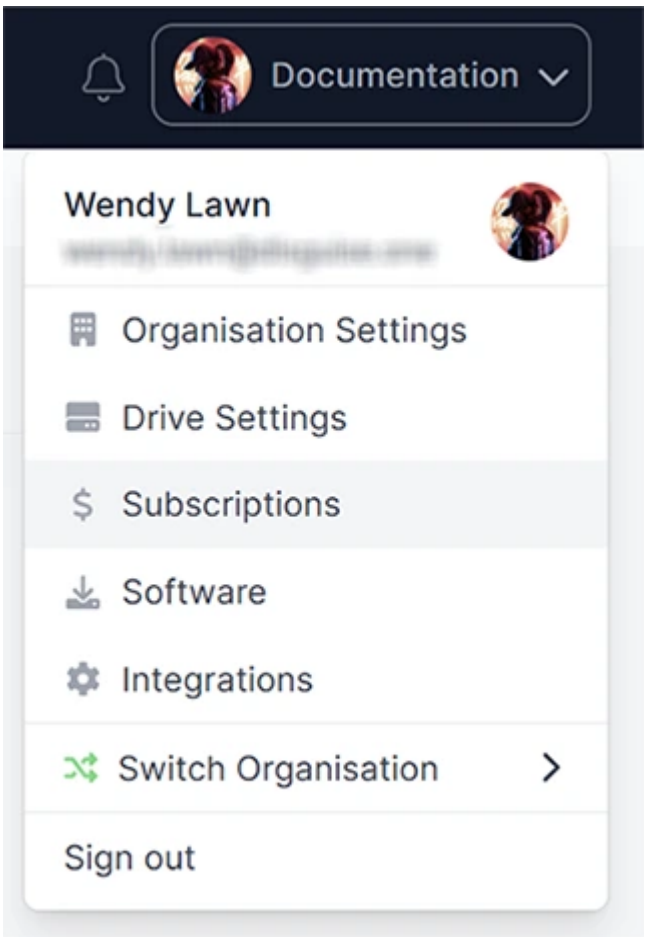
If you do not have a Disguise Cloud account, you can sign up for one here.



Sign up to Disguise cloud

1. Log in to Disguise Cloud.
2. In Cloud Dashboard, the name of the organisation that you are are currently using is displayed on the top-right corner profile menu. If this is not the organisation that you wish to purchase under you can switch organisation. To switch organisations, click on the organisation name and open the Profile menu. Then select **Switch Organisation**.

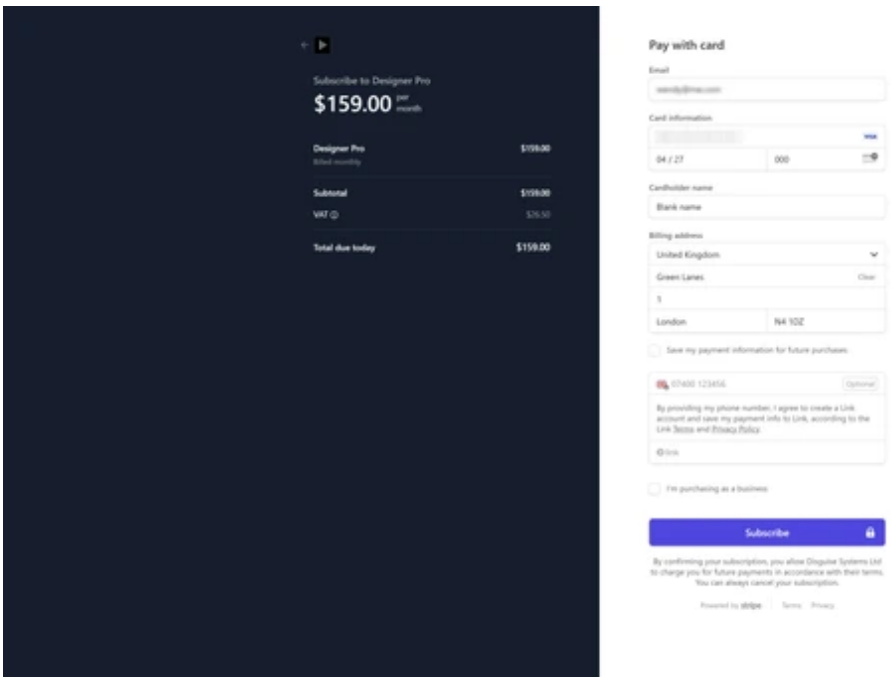
3. Click **Subscriptions** in the profile menu.



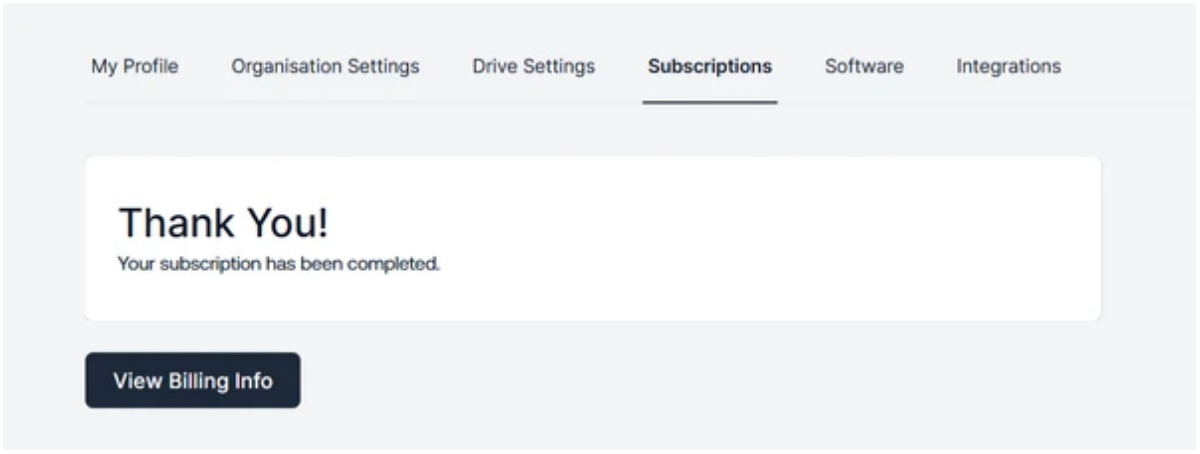
Profile menu

4. Navigate to the **Designer Pro** subscription listed under **Designer Software** and click **Subscribe**.
5. Select your license type (monthly or yearly) and the number of license you require and proceed to checkout.
6. If you have a coupon to redeem, paste the code into the **Add Promotion Code** field.

7. Enter your payment details and click **Subscribe**.



8. Once you receive the confirmation that the subscription has been completed, you can navigate to the **Software** tab to download Designer Pro's *Full installer*. You can also click **View Billing Info** to check the details.



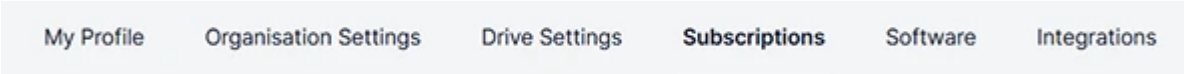
Alternatively, you can click **Subscribe to Pro**, in the Cloud Dashboard.

Select Monthly or Yearly, and the number of licenses you require. Then proceed to the checkout.

You will also receive an email confirmation of your Designer Pro subscription.

View your active subscriptions

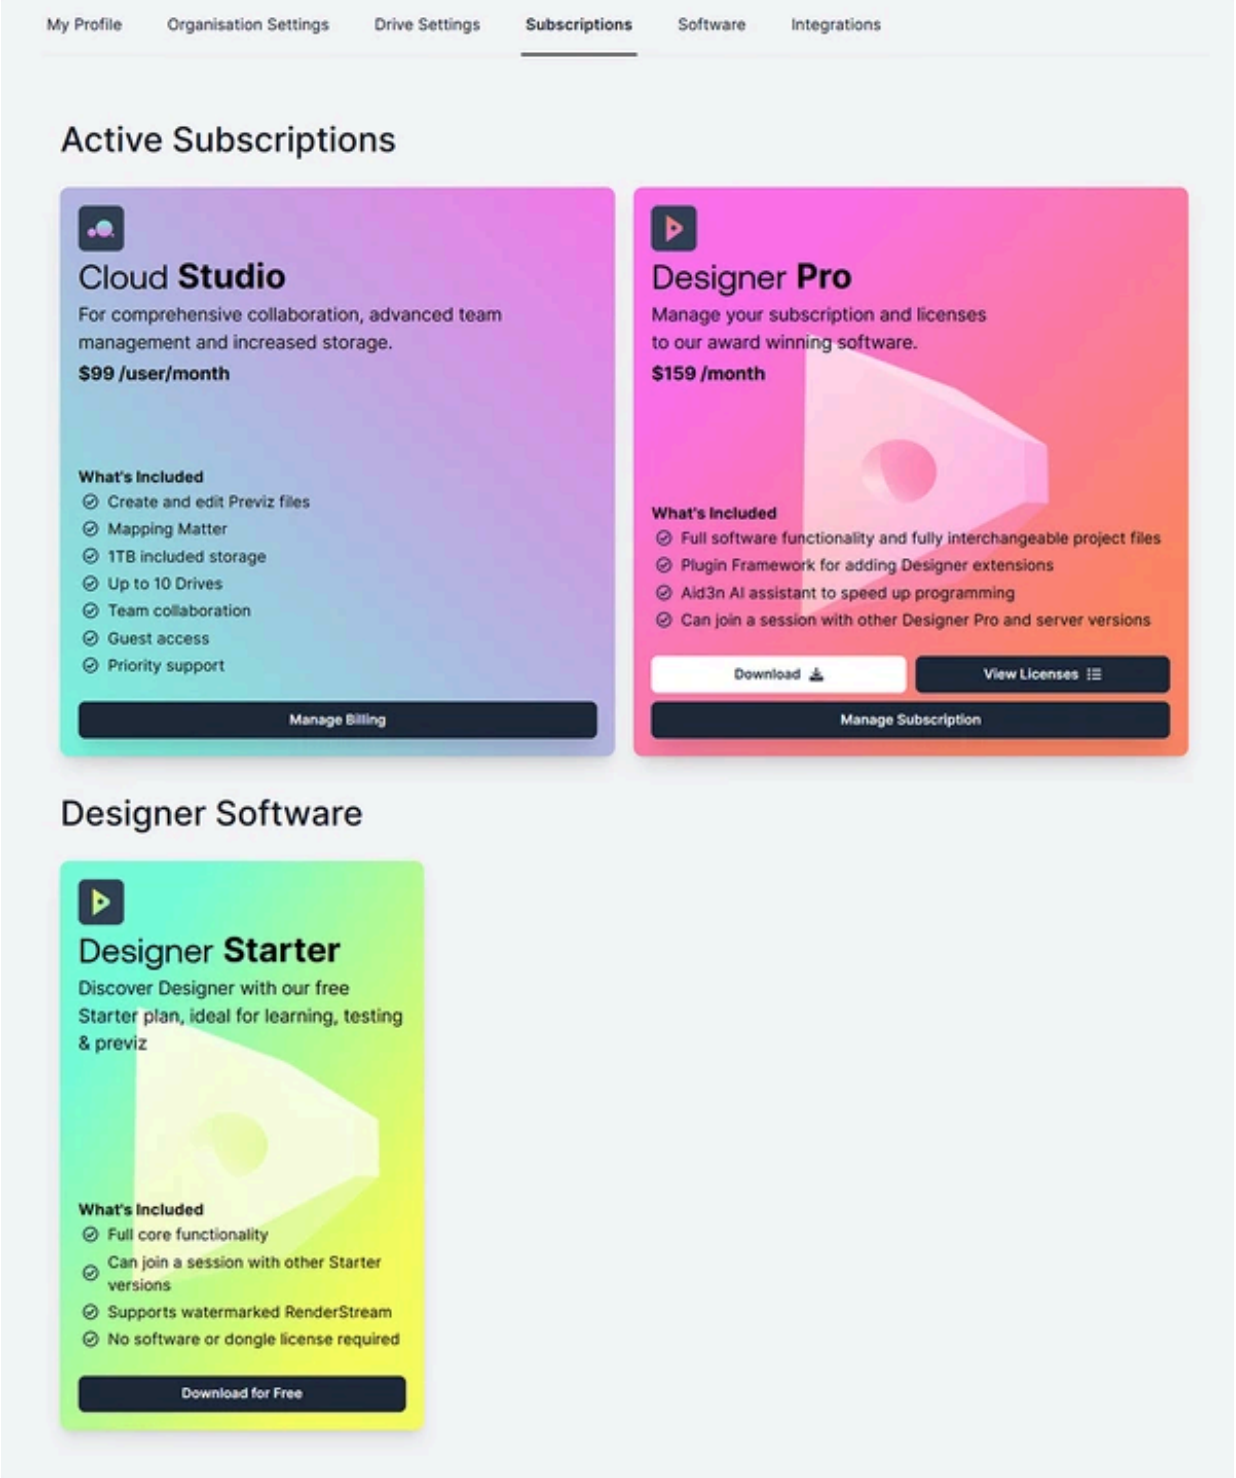
Ensure that you are managing the correct organisation, then click the **Subscriptions** tab.



Subscriptions tab

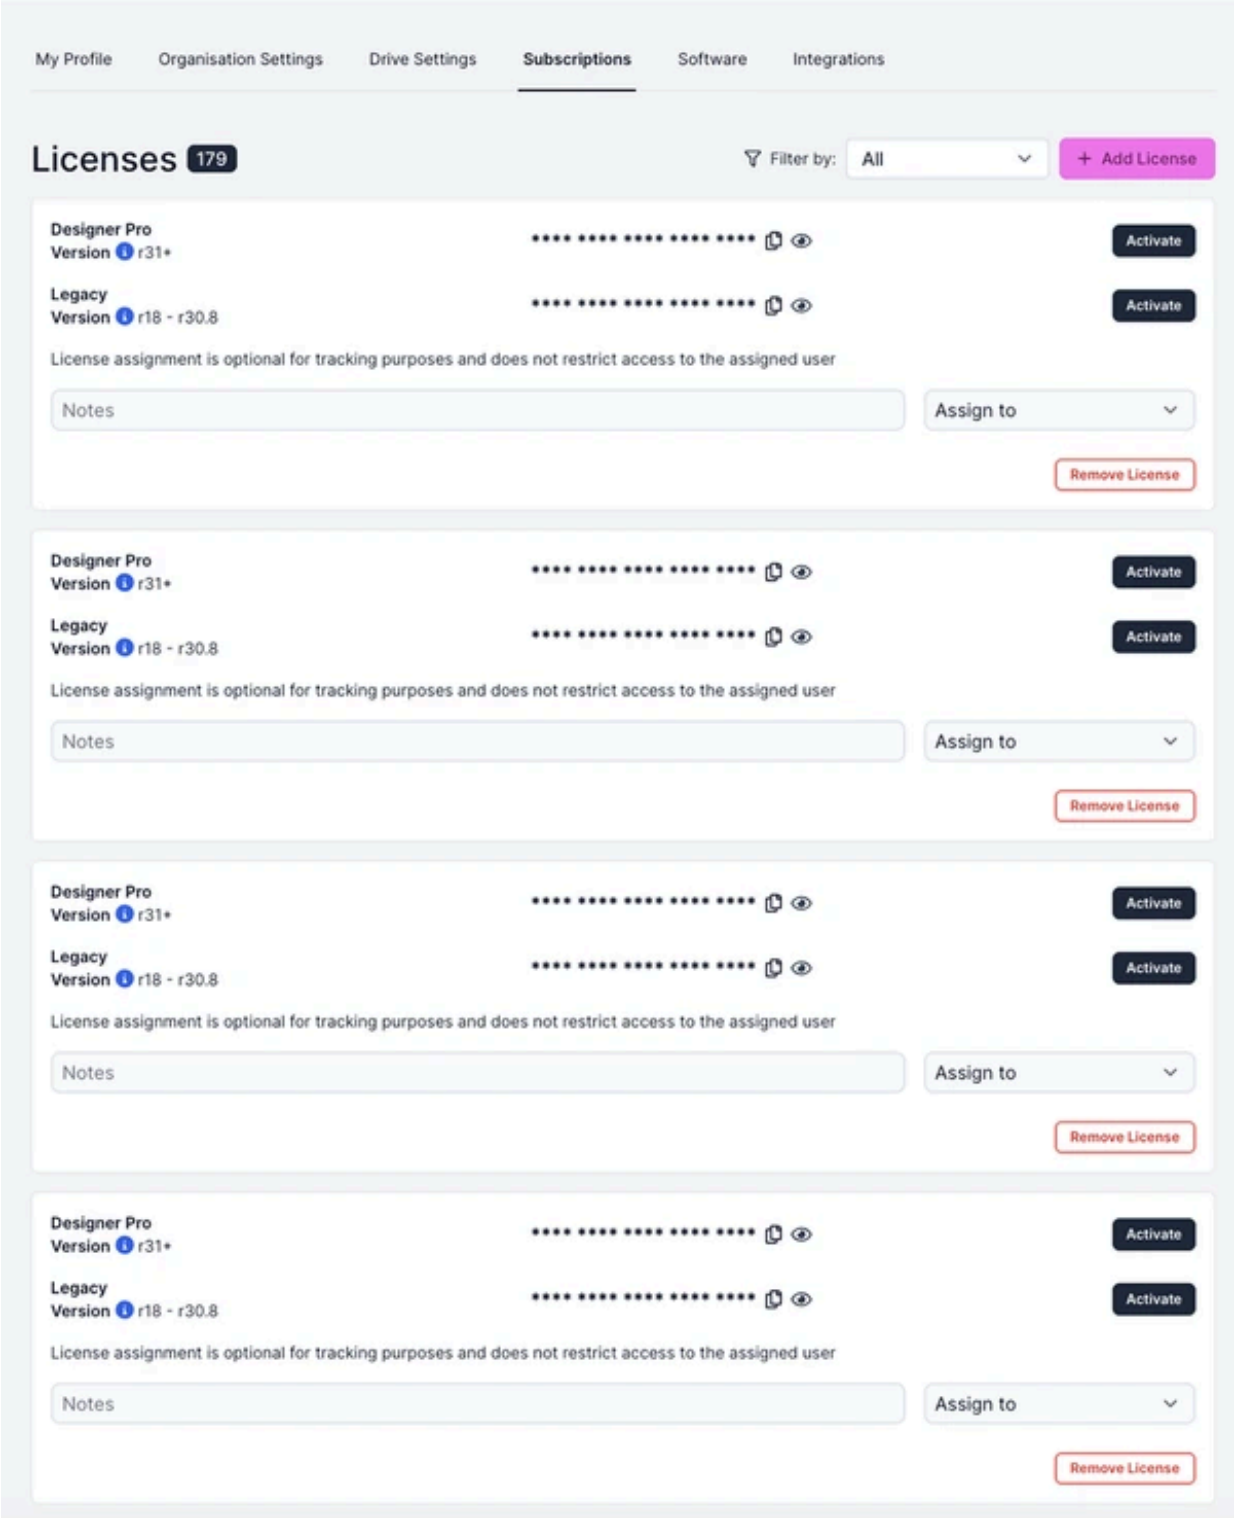
Manage licenses

From the Subscriptions page, click **View Licenses** under Designer Pro.



On the licenses page you will have the following options:

- **Activate** – begins the license activation process in CodeMeter.
- **Add license** – allows you to add another license to your subscription.
- **Assign to** – assign a license to yourself or a team member, and optionally reassign it later.
- **Remove license** – removes the license from CodeMeter immediately and adjusts your billing accordingly.

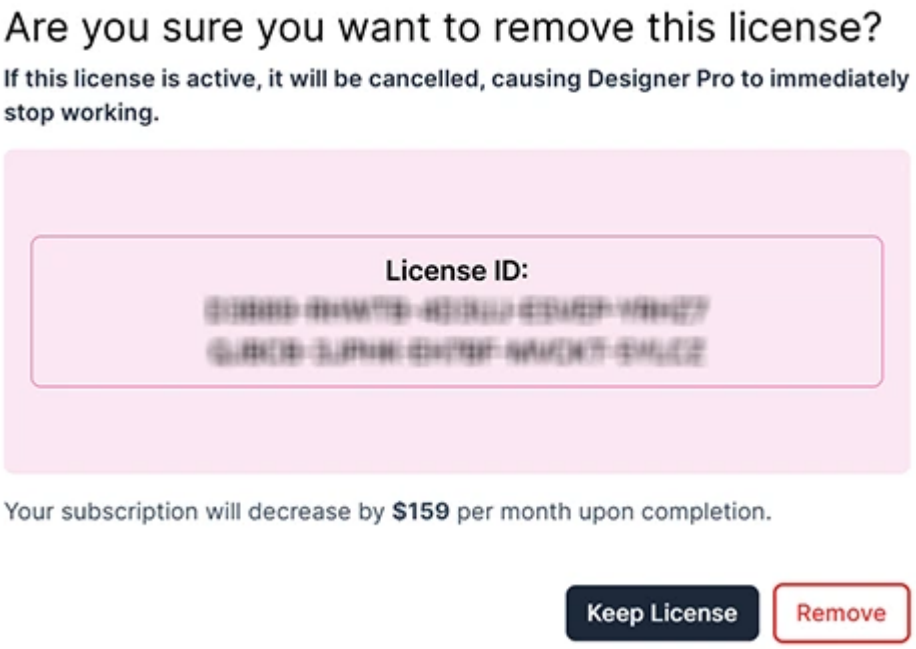


Licenses page

Designer Pro and Legacy licenses are both listed on the License page. To read more about legacy licenses, view this page.

Remove license

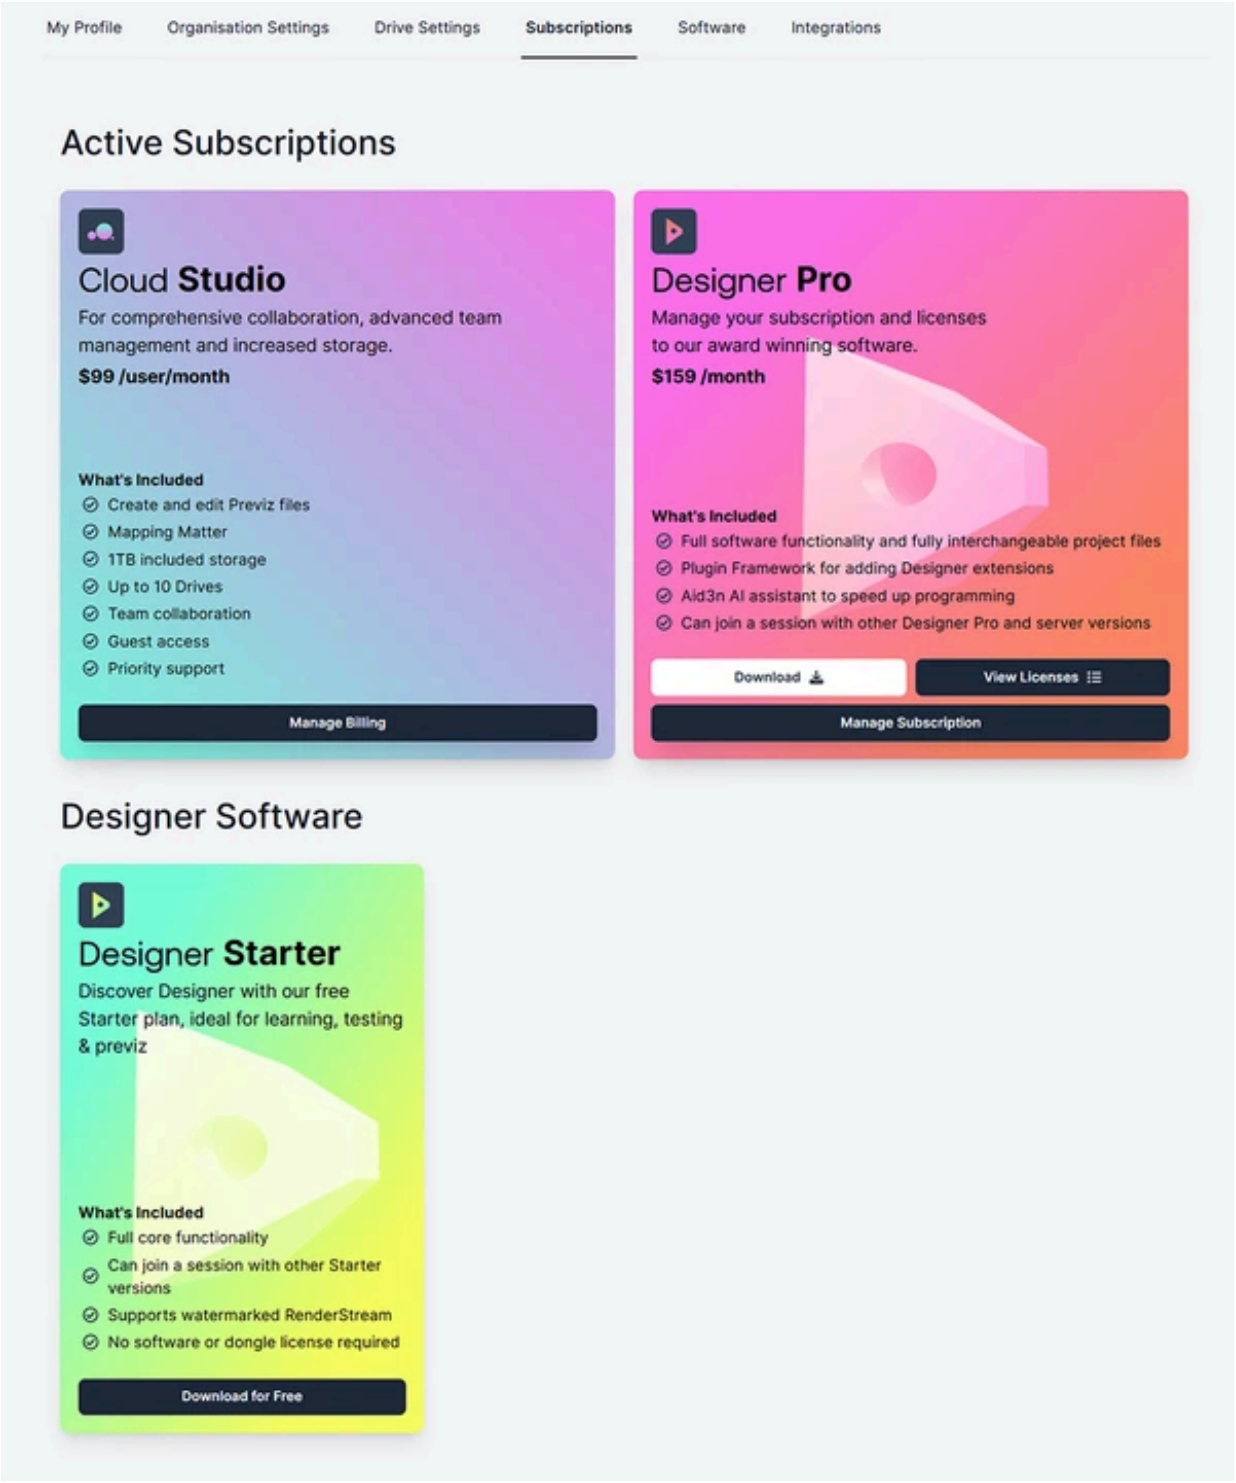
1. To remove a license, click **Remove License**.
2. Click **Remove** to confirm that you wish to remove the license, or click **Keep license** to return to the license page.



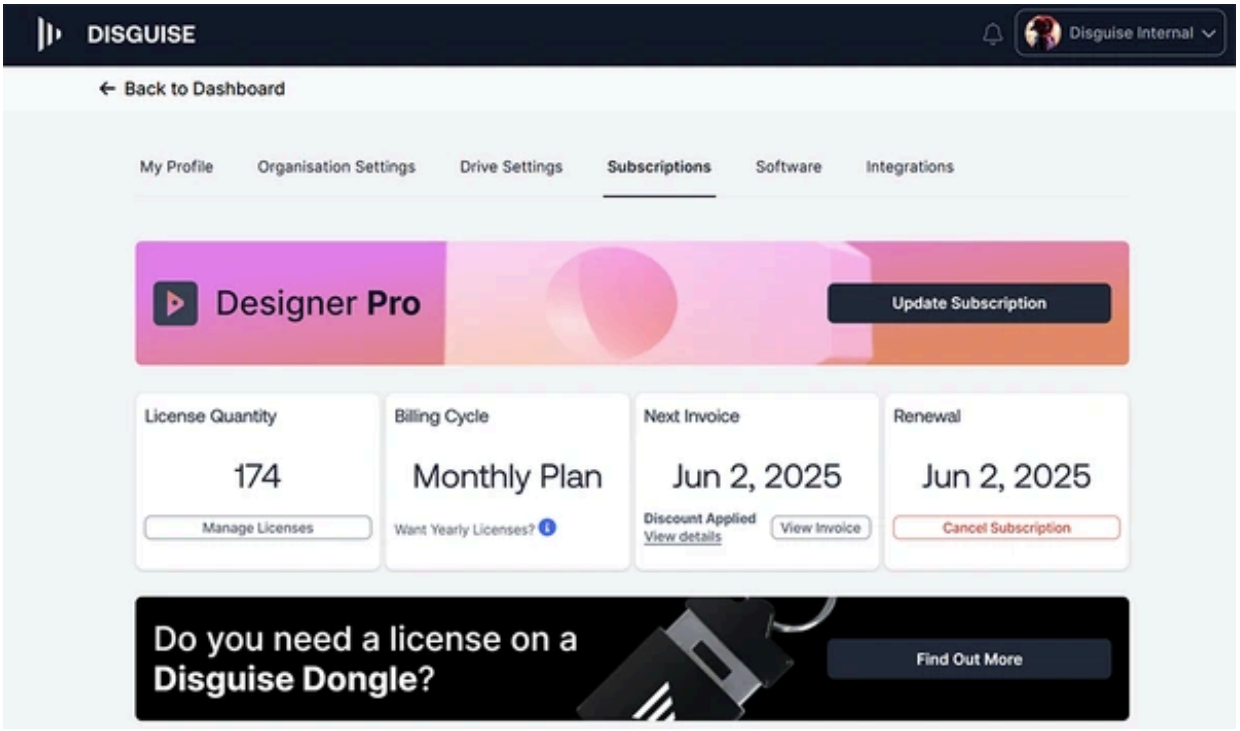
> **Note**
>
> When you remove a license, this immediately withdraws the license from CodeMeter. If you would prefer to cancel the subscription, you will have the option to resume the subscription until the end of the billing cycle. See the **Cancel subscription** section shown below.

Cancel subscription

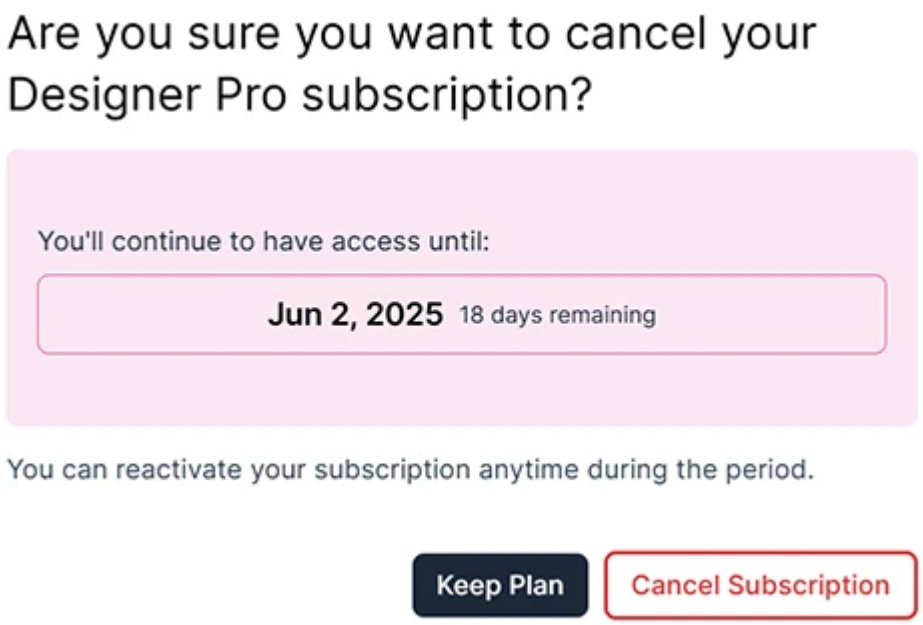
1. From the Subscriptions page, click **Manage Subscription** under Designer Pro.



2. Click **Cancel subscription**.



3. Click **Cancel subscription** again to confirm you wish to cancel, or click **Keep plan** if you want to keep your subscription.



> **Note**
>
> Cancelling a subscription allows the CodeMeter license to remain active until the end of the current billing cycle (monthly or yearly). During the grace period, you will have the option to resume the subscription. If you prefer to remove the license immediately from CodeMeter, please see the **Remove license** section above.

Order a Physical Dongle

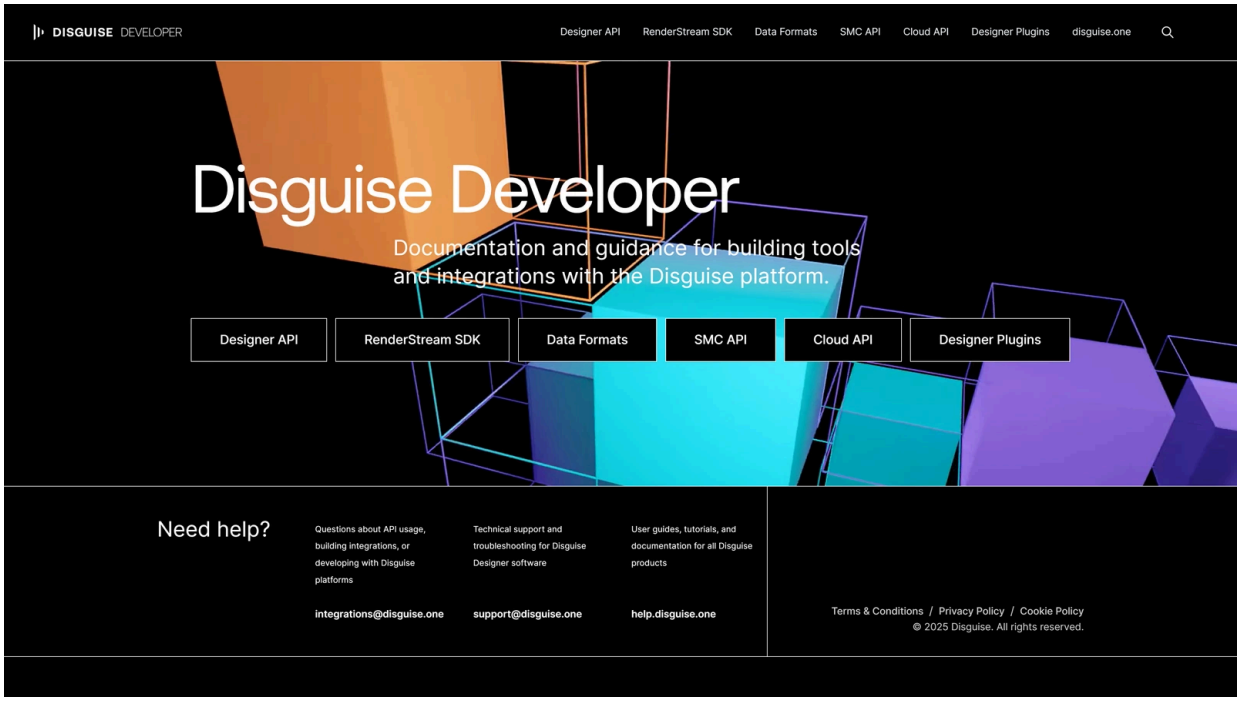
The USB Dongle can be purchased through the **Disguise Store**.

Disguise USB Dongle

Disguise Developer Portal

What is the Disguise Developer Portal?

Documentation and guidance for building tools and developing integrations for Disguise products.



You can find documentation for all of Disguise's Designer APIs at the developer portal, **developer.disguise.one**. The developer portal supports the control and monitoring of Disguise media servers and Designer software using a comprehensive HTTP API. An HTTP API is an API that uses Hypertext Transfer Protocol as the communication protocol between the two systems. HTTP APIs expose endpoints as API gateways for HTTP requests to have access to a server.

The Disguise approach to APIs

Workflow Centric

APIs and SDKs designed to compliment and integrate with Disguise workflows.

Developer Focused

The developer portal has been designed with the developer experience in mind.

Integration Support

We are happy to support integrations with our products. Contact us for integration support and partnerships.

d3manager OpenAPI Documentation

Documentation for our Disguise Designer APIs is also hosted within Designer.

To access API documentation from d3manager navigate to **Help > Open API Documentation**.

Note that this documentation uses the OpenAPI format which means that you can execute APIs from within the documentation.

Designer Download & Installation

There are two installers available for Designer: Starter and Full. The Starter installer is used for Designer Starter only. All other uses of Designer require the Full installer: media servers, Designer Pro and X1.

For details of Designer license types see here, or dive into the details of Designer Starter, Designer Pro and X1.

Designer Starter uses a `.d3Starter` project file format, whereas Full Designer uses the `.d3` project file format. Designer Starter can open `.d3` files, but only save `.d3Starter` files. The Designer Starter file format cannot be opened by Full Designer with any license type.

> **Note**
>
> Before updating the software make a manual backup copy of your .d3 project file (not the whole projects folder), which is located in the specific Projects folder. If there is a problem running the new release you will need to revert to the backed up .d3 file.

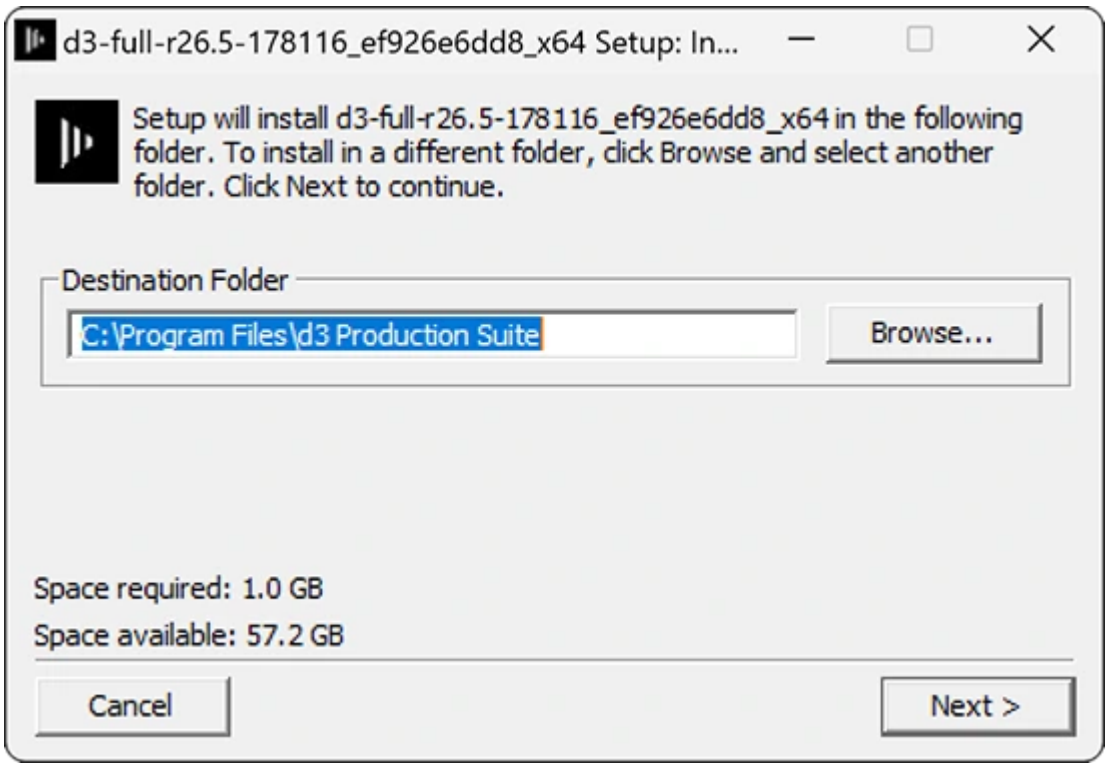
Downloading the installer

1. Ensure your PC is connected to the internet.
2. Download the latest Designer release installer from **Disguise Cloud**.
3. Run the downloaded installer.

Install location

On the first screen you will be prompted to select an installation directory for the program files.

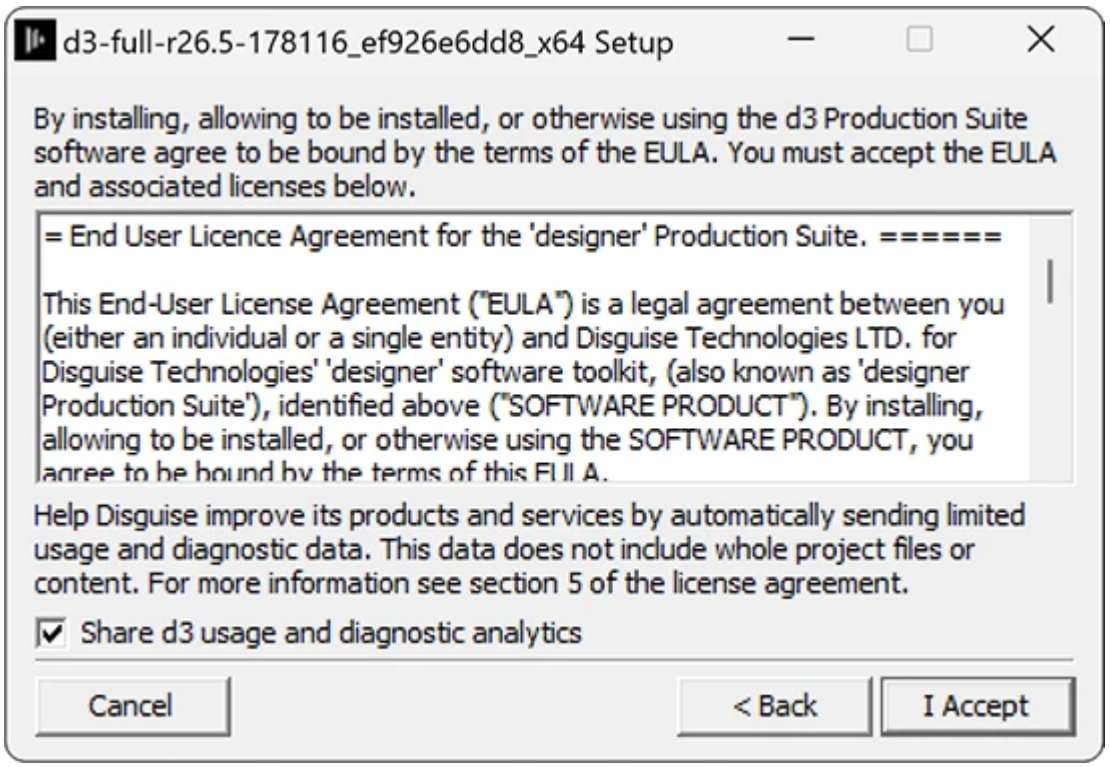
1. Select **Browse** to change your installation directory.
2. Select **OK** to return to the Designer installer window.
3. Select **Next** once you are happy with the installation directory. If you are upgrading an existing installation of Designer, the installer will detect and use your current installation directory.



Selecting an installation directory for the Disguise program file

End User License Agreement (EULA)

1. Read the EULA and all associated license information.
2. You may optionally choose to Share d3 usage and diagnostic analytics. This setting will persist through re-installs and remote installs of Designer.
3. Click **I Agree** to continue.



Accept the End User License Agreement for the Disguise Production Suite

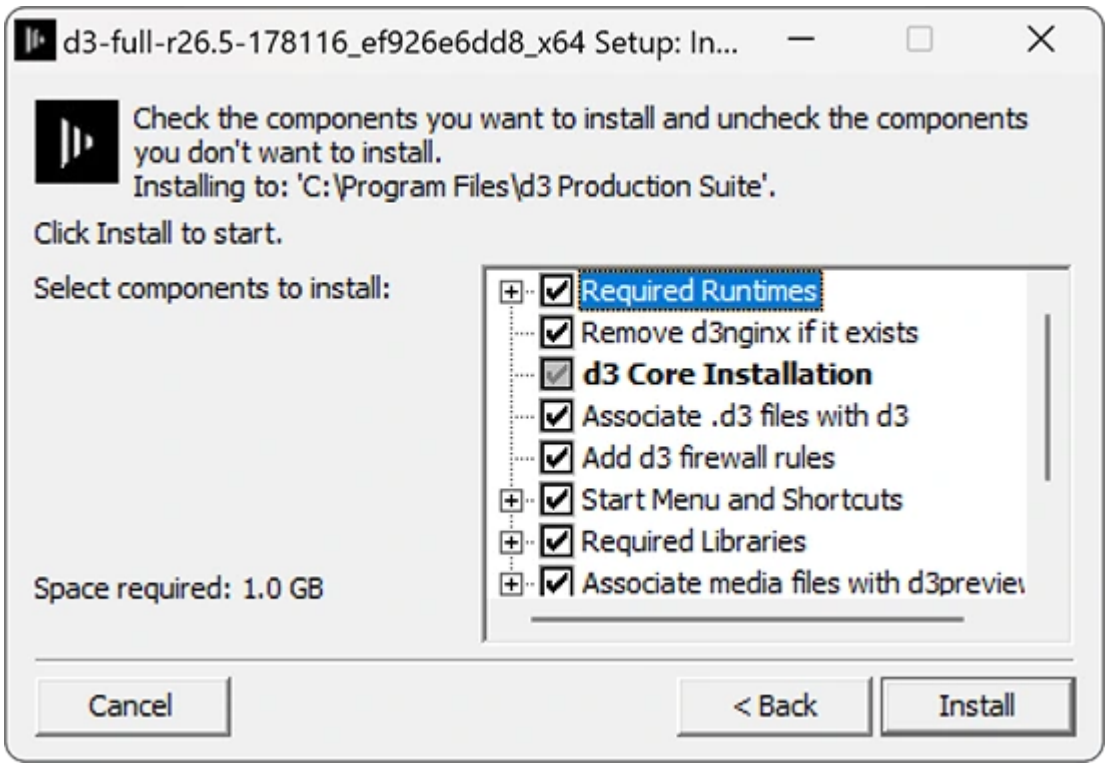
Component selection

Next, you will be prompted to select which components you wish to install. Designer installs several required runtime libraries and drivers, including:

- Microsoft Visual C++ Redistributable (x64)
- CodeMeter Runtime
- NewTek NDI® Runtime

If the installer detects that you already have a given supporting component installed (e.g. CodeMeter drivers), the installer may deselect that component to avoid unnecessary re-installation.

1. Select the boxes to tick or untick components.
2. Select **Next** once you are happy with the selected components.



Select the components to install

Leaving the **Share d3 projects folder** ticked will cause the installer to share the d3 projects folder. If it is unticked, no share settings will be modified. On a remote install, the installer will behave as the previous full installer did, i.e. if the check box was checked last time the installer was run, the remote installer will act as if its checked and vice versa. In the situation that a full installer has never been run, a remote installer will act as if the box has been checked.

Installation

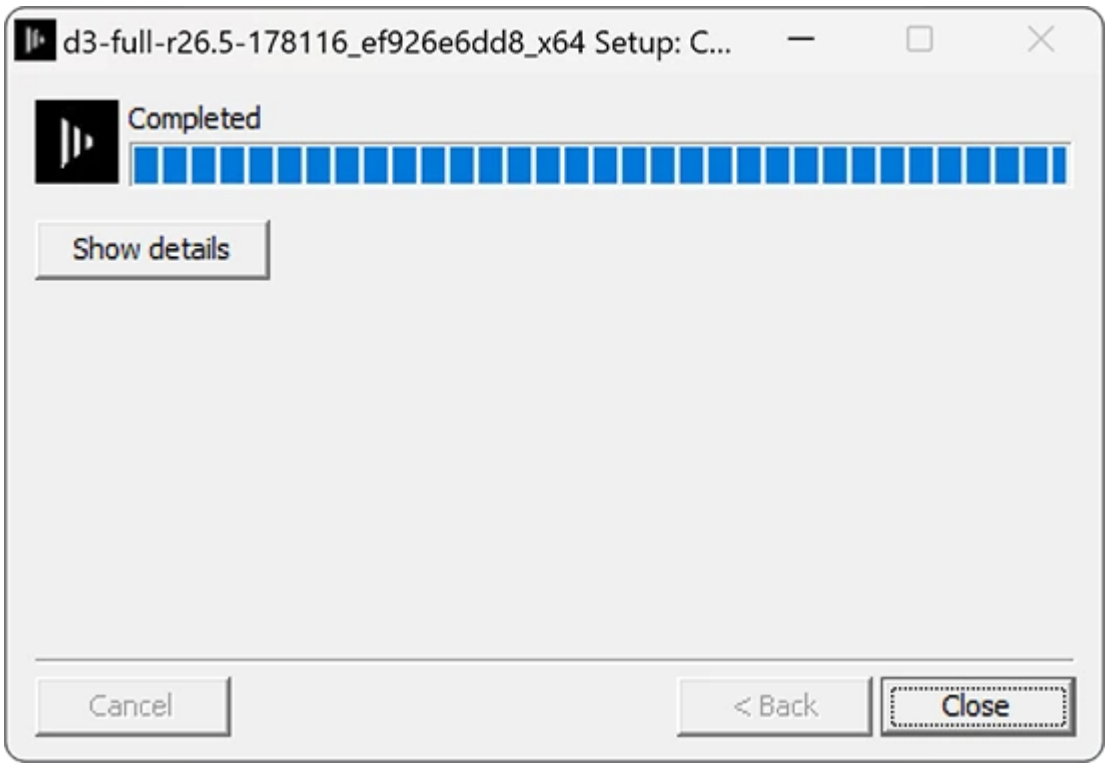
The Designer files will now install into their appropriate location.

The installer also adds Windows Start Menu shortcuts, Windows Firewall rules and file associations for Disguise-related file types.

Installing for the first time: if you are installing Designer for the first time you will prompted to choose a directory for your Designer projects. By default, this is placed in your Documents folder but you may prefer to place it in another fast storage drive like an SSD drive.

Upgrading from a previous version: if you are upgrading from a very old version of Disguise (pre-r10) the system will automatically detect and use the current Projects folder and you will not see the screen where you can change your Project folders directory. From r10 onwards you are free to choose the location of your Projects folder.

Click **Close** once the installation is complete.



Installation complete

Uninstalling Designer

Any third-party programs installed by Designer (e.g. CodeMeter drivers, QuickTime or NDI®) will **not** be removed during the uninstall process. These applications will need to be uninstalled separately, if necessary.

> **Note**
>
> We don't recommend uninstalling the CodeMeter Runtime. Always keep the latest version of CodeMeter installed, see also here.

1. Open the Windows Start menu (bottom left of screen).
2. Type **Installed apps** and open the Windows Settings page of that name. In older Windows versions, this may be called "Apps & features" or "Programs & Features".
3. Click on the three dots next to **Disguise Designer** and select "Uninstall". Note: Older Designer versions were listed as "d3".
4. Follow the on-screen instructions.

> **Note**
>
> If any unexpected errors or problems arise during installation/uninstallation, please create a System Diagnostic archive and send it to **support@disguise.one**. For step-by-step instructions on how to do this please see the Generating diagnostics page.

Automatic Installer backup

After a successful Designer installation, the installer is automatically backed up.

- On a **Disguise server**, the backup is stored in the Media drive at: **D:\d3\installers**
- On any **non-Disguise server**, the backup is stored in: **C:\Program Files\d3\installers**

These backups are used during the re-imaging process and allow Designer to be restored to the previously installed version.

From r32.2, all backups are stored on the D drive.

> **Note**
>
> The automatic backup can be skipped by providing /noinstallerbackup flag when running the installer.

Educational Designer Licenses

For several years, Disguise offered Educational Designer Licenses configured for local network environments. These licenses allowed institutions to validate a set number of seats without the hassle of distributing, monitoring, or managing multiple physical dongles for students.

With the introduction of Designer Starter and Designer Pro this has changed. You can use Designer Starter by downloading the Starter installer from Disguise Cloud and use it for learning Disguise. There is no fee for this. However, Designer Starter applies a watermark to content.

Disguise servers can also be set up for use with the Starter ecosystem, if needed. All media servers should then install the same Designer Starter release as the other PCs in the session. Educational institutions will still need Pro licenses to create watermark-free content.

Training Courses

If your training course does not include the use of a Disguise server, then Designer Starter is ideal, as there is no restriction on core functionality. Students should sign up for Disguise Cloud, install Designer Starter, and then log in to d3Manager with their Disguise Cloud account.

If your training course includes the use of a Disguise server, then there are two options:

1. Install Designer Starter on the Disguise server and log in to d3Manager on the server with a Disguise Cloud account. All other Starter instances can then join a d3 session with the server. Note that an intermittent blue flash will be present on outputs.
2. Students use Designer Pro. Please contact your account manager to discuss options for obtaining Pro licenses for your training course.

If you teach Disguise at an educational institution and would like more information, please contact **sales**.

For more information about the capabilities of Pro and Starer licenses, please see the following pages:

- Designer Starter
- Designer Pro
- Designer Download and Installation
- License Activation

The Designer website has a comparison chart **here**, and Designer Licensing FAQs **here**.

Identifying the Designer Version

Designer varies with Designer license types, release versions, installer versions, and build versions.

Designer configurations vary based on installer versions, license types, release versions, and build versions:

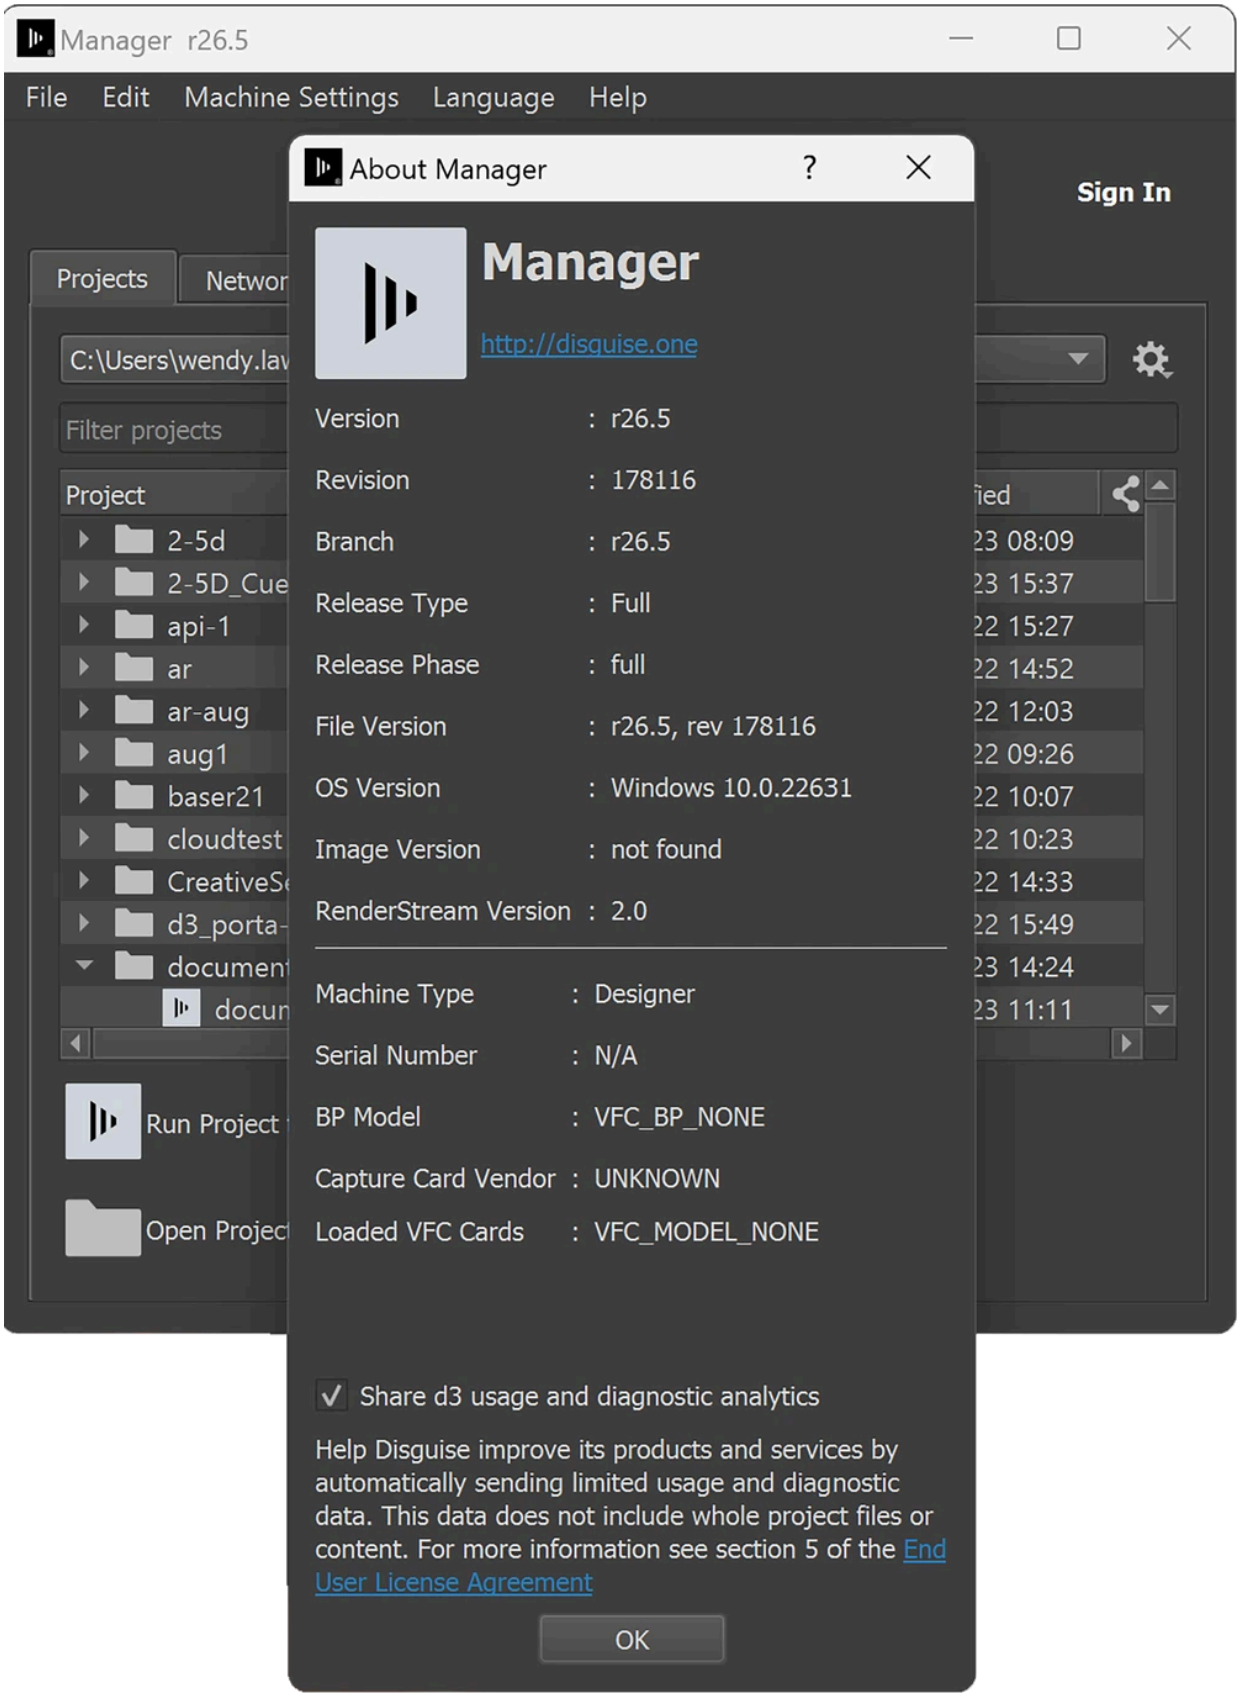
- Installer versions – Available as either a Full installer (for Designer Pro and Disguise media servers) or a Starter installer.
- License types – There are several license options:
  - Designer Starter only uses its built-in license bundled in the installer.
  - The Full installer supports Designer Pro, as well as the built-in license of any Disguise server that is supported in a given release.
- Release versions – Regular product releases introducing new features, improvements, and fixes. Learn about our versioning conventions here.
- Build versions – Can differ even within the same release version. These may include beta releases for a specific show or feature.

The information provided on this page will enable you to identify the version of Designer you are running in a number of different ways.

> **Note**
>
> Please note that you may only have one version of Designer installed at a time.

Option 1

To see what current release you have installed on your system, in Designer, go to **Manager > Help > About Manager**.



Manager r26.5
File
Edit

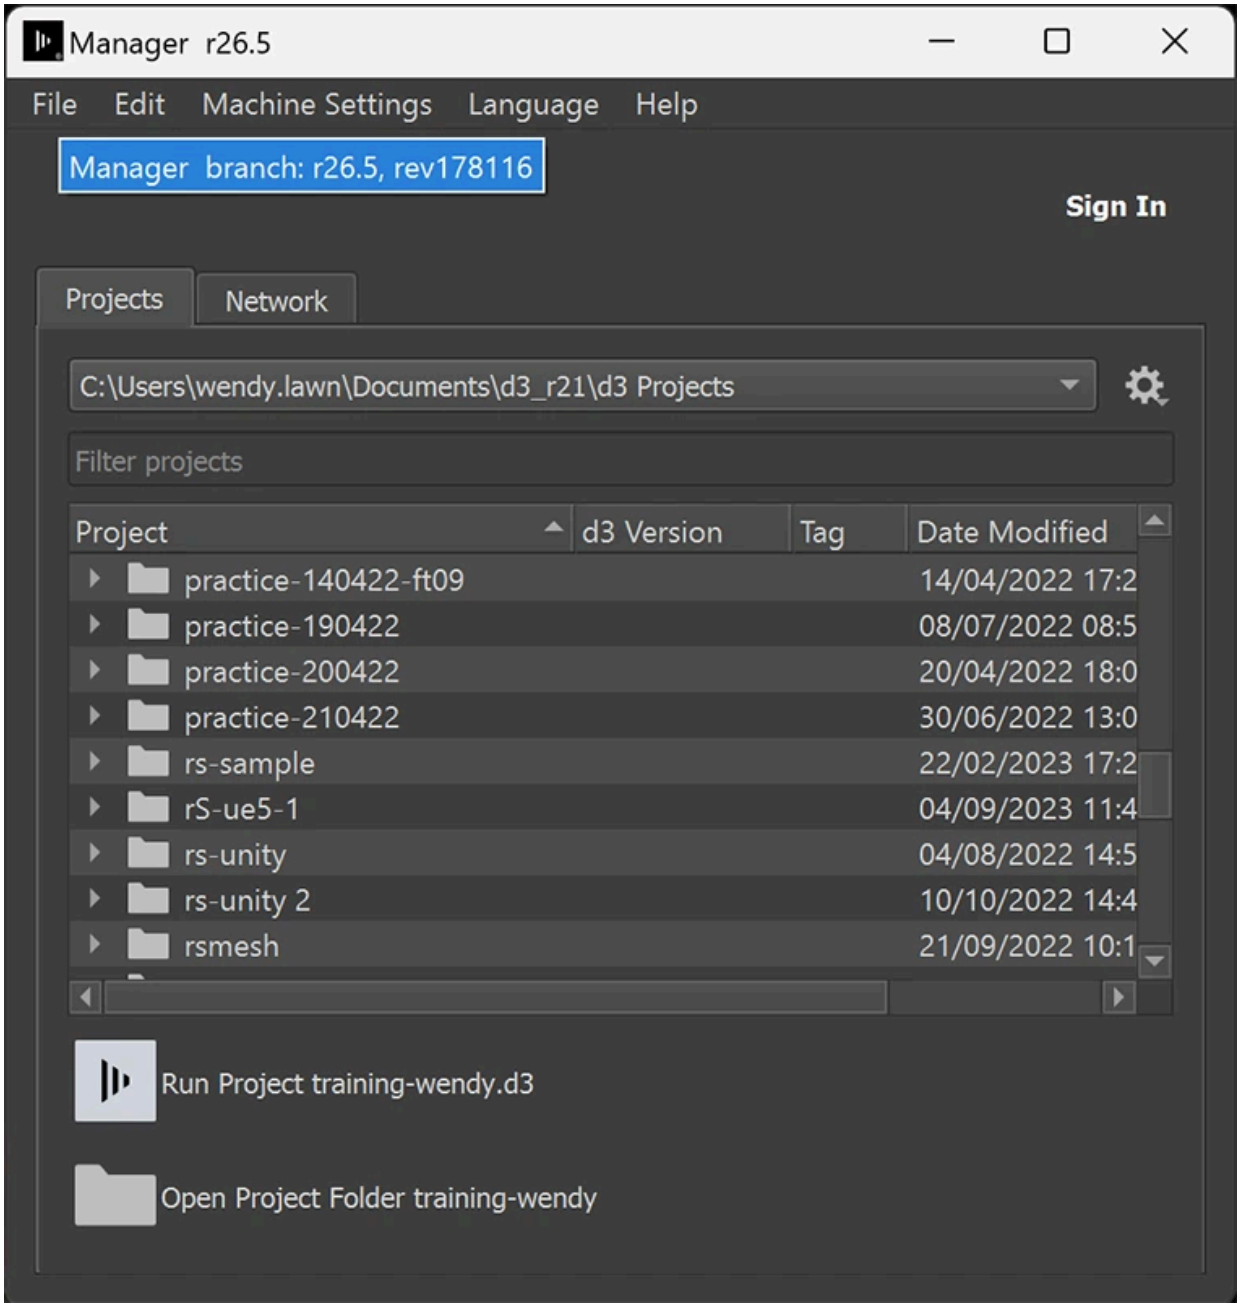
Share d3 usage and diagnostic analytics
Help Disguise improve its products and services by automatically sending limited usage and diagnostic data. This data does not include whole project files or content. For more information see section 5 of the End User License Agreement
OK

Option 2

Additionally, in d3Manager you can hover the mouse over the menu bar to reveal a tooltip box displaying the current version number.



A tooltip box with the version number activated by placing the mouse over the menu bar.

Option 3

Alternatively, when you start Designer, it displays a startup screen while loading the project. This consists of the logo at the bottom right of the screen, along with the version identifier.

This consists of two numbers: the major release (such as Release 13, 14 and 15 etc) and the build revision (for example revision 35000, 36000, etc).

Current release and build revision number displayed whilst project is loading

Option 4

You can also see which release and build revision you are running in the d3 Options menu.

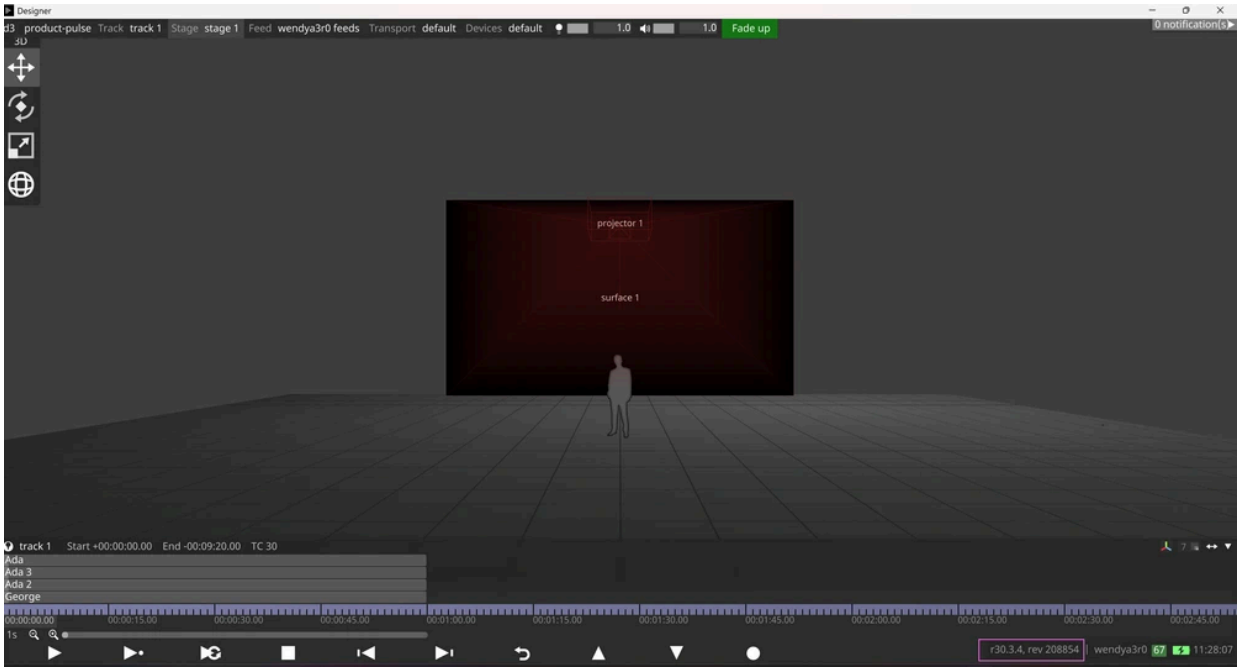
To open the d3 Options menu:

1. Right-click d3 from the Dashboard (bar at the top of the screen).
2. Left-click **About d3**.

Current release and build revision number displayed in the d3 Options menu.

Option 5

The release version and build number appears in the bottom right of the Designer GUI.



Current release and build revision number displayed in the Designer GUI.

Known Issues

There are known issues when running Designer on some machines.

Macbook Pro Retina driver issues

In 2012 Apple released a range of Macbook Pro's with Retina displays containing the NVidia 650M. Apple shipped a set of Bootcamp drivers (used to support Windows on a MBP) with these machines and have since released updates. The Bootcamp drivers that ship with the Macbook Pro present varying screen resolutions to the program as it tries to start. This can cause failure to start issues for Designer.

Solution

Install the latest NVidia Drivers for the 650M from **http://www.nvidia.co.uk/page/drivers.html**

Disable Aero Theme:

1. Right-click on the Windows Desktop.
2. Click Personalize.
3. Select the 'Windows 7 Basic' theme.

Disable Aero Peek Preview (in Windows 7)

1. Right-click the Windows task bar and choose Properties.
2. Disable the check box: Use Aero Peek to preview the desktop.

Completing these three actions should solve the majority of issues with the Retina Macbook Pro. However, if you are still facing issues, please contact the **Support Team**.

Viruses and malware

Viruses and other malware are potential problems that should be considered when using any software.

Recommended virus scanner

One option you can use to scan your machine for viruses and malware without reducing performance is **ClamWin**. ClamWin is an open source virus scanner that does not have any

active background scanning and can be run from a USB pen drive or other. You can also download ClamWin Portable, which is a very handy portable app.

Licensing for Older Designer Versions

Designer licensing for non-Disguise servers changed in April 2025 to the Designer Starter and Designer Pro scheme.

Older versions of Designer require the legacy licensing scheme.

For those who currently have one or multiple legacy software licenses, you will be issued with new legacy licenses matching the ones you held before, and with the same expiry date as your current Designer Pro license. All you need to do is activate these new legacy licenses, following the exact same steps as your Pro license activation.

> **Important**
>
> From Designer r30.5, Designer automatically checks for license changes in the background, so if you're on a monthly license you don't need to manually update your license each month when the expiry gets extended for another month after the monthly subscription payment is taken.
>
> However, earlier versions of Designer (r30.4 and below) do not support automatic license updates. If you're using one of these versions, you'll need to manually update your license each month (or annually, if you're on an annual plan) to apply the new expiry date.

Designer versions and their license requirements

The table below shows which Designer versions require which license, and how to obtain this license.

Version	Licensing Requirement	Requires Dongle	How to Obtain a License
r17.6.2 and earlier [1]	pre-r18 Legacy license (predating any modern licenses)	Yes [2]	Contact **Disguise Support**.
r18.0 to r30.8	Supports the legacy [3] Designer license	No	Issued automatically when subscribing to Designer Pro [4]
r29.3 & r30.5 to r30.8.6	Supports *both* the legacy Designer license and Designer Pro license	No	Subscribe via Disguise Cloud

Version	Licensing Requirement	Requires Dongle	How to Obtain a License
r31 and later	Supports Designer Pro license only	No	Subscribe via Disguise Cloud

[1] For pre-r18 licensing requests and any queries, please reach out to **Disguise Support**. There is no charge for issuing these legacy licenses, and this process will not change.

[2] Support for software-based licenses (CmAct containers) was first introduced in r18.0. Earlier versions require a physical USB CodeMeter dongle to activate licenses to. Dongles can be **purchased in our online shop**. Note that old CodeMeter dongles cannot hold any modern Disguise licenses (see **table below**).

[3] The legacy licensing scheme displayed two product codes in CodeMeter: one with a Product Code of 400, this previously had no expiry date, however the 400 license on its own does not enable Designer to run, it was used as an identifier for Designer to differentiate it from other license types; another with a Product code of 100, this is the license which enables Designer to run, and usually has a time limit, displayed in the Valid Until field in CodeMeter. Older Disguise servers also use Product Code 100, but without a time-limit. Going forwards, any legacy licenses issued will also set an expiry date for the Product Code 400 license to avoid confusion. Note that Designer Pro only uses one ProductCode license entry in CodeMeter.

[4] An additional legacy license for r18.0 to r30.8 is issued automatically when subscribing to Designer Pro, matching the duration of Designer Pro. Legacy licenses are retrieved from the Subscriptions tab of Disguise Cloud, using the same activation procedure as the Designer Pro license.

For more information on subscribing to Designer Pro through Disguise Cloud, visit Designer Subscriptions

CodeMeter Container Support

Licenses issued by Disguise can be activated on different types of CodeMeter containers. Physical containers, called `CmDongle` exist in various form-factors, see the **manufacturer's website**. The most common physical container is a USB dongle.
Dongle-less licensing is enabled via software-based `CmAct` containers that are bound to a particular machine.

Physical Container Hardware Revisions

Physical containers come in different hardware revisions, which are indicated by the first digit in their serial number. Each new hardware revision adds new features, so older dongles will not have the same capabilities as newer ones.

When Designer was first released in March 2012, all Designer licenses required a physical CodeMeter dongle. A newer dongle hardware revision was issued since 2016, enabling support for the CodeMeter feature “Universal FirmCode” (UFC), that simplifies license handling for both `CmDongle` and `CmAct` containers. In 2020, with the release of r18.0, Disguise introduced dongleless CmAct licenses, based on the UFC feature. Since June 2023 all Designer licenses (except the pre-r18 Legacy license) are exclusively based on UFC, and so require a newer CodeMeter dongle (or activation on a `CmAct` container).
Dongles can be **purchased in our online shop**

Container Type	Hardware Revision	Serial Number	Issued since	Issued until	Can hold pre-r18 legacy license	Can hold modern licenses
CmDongle	2	`2-xxxxxxx`	2012	2015	Yes	No
CmDongle	3	`3-xxxxxxx`	2016	-	Yes	Yes
CmAct	-	`130-xxxxxxxxxx`	2020	-	Yes	Yes

Further information

- License Activation
- Offline License Activation
- Transfer a Designer Pro License

Designer Licenses and Activation Process

A license activation process is required for Designer Pro, however it is not necessary for Designer Starter. Designer Pro requires a license to launch projects, whereas Designer Starter requires a Cloud log in to authenticate the user when using Designer.

Starting with Designer r30.5, the software automatically checks for license updates in the background. If you're on a monthly license, there's no need to manually refresh it — your license will be extended automatically each month once your subscription payment is processed.

However, earlier versions of Designer (r30.4 and below) do not support automatic license updates. If you're using one of these versions, you'll need to manually update your license each month (or annually, if you're on an annual plan) to apply the new expiry date.

Designer installers

Designer has two different installers and so it is important that you use the correct one, either the Designer Full installer, or the Designer Starter installer.

The Designer Full installer is the correct installer to use for Designer Pro and Disguise servers.

License deployment

Designer Pro licenses have two license deployment mechanisms available: USB dongle-based license and software-based license. Each requires a slightly different activation process.

1. USB dongle-based licenses

The physical dongle is USB-based and can also host other supported licenses obtained from third parties such as Notch and TouchDesigner, as well as Designer. The USB Dongle can be purchased through the **Disguise Store**.

Using a dongle may be preferable if the license is to be shared in the same physical location.

Disguise USB Dongle

2. Software-based licenses

The software-based option is tied to your physical machine. It can be moved between machines by following license transfer process. The software-based option is ideal for customers who do not often switch machines or are looking to share a license between geographically separate locations.

Software-based licenses (dongle-less) do not require a physical USB dongle and can be activated on a computer as soon as they are generated in Disguise Cloud. No purchase of the physical dongle is necessary.

Note that a license deployed to a USB dongle can later be converted into a software license and vice versa.

If you are unsure which license deployment method is best for you, the table below compares the two license deployment methods.

Feature	USB Dongle-based License	Software-based License
Portability	Yes	Yes
Notch pre-visualisation	Yes	No
Run Designer without a dongle	No	Yes

Once you have your license and have chosen your deployment method, you can proceed to activate your license. Follow the activation instructions below for each license deployment type.

> **Warning**
>
> Licenses for Notch playback and pre-visualisation still require a physical CodeMeter dongle. This is due to a Notch licensing limitation.

Other types of Disguise Licenses

The Designer Pro license uses expiration time. This means that once the Designer Pro subscription is purchased, the license is valid for the duration purchased from the date of purchase.

By contrast, RenderStream is a Usage Period license. This means that the duration of the license starts when the license is first used, regardless of the date of purchase. In addition, a RenderStream license cannot be moved to other machines once the license period has started. This is a technical limitation of the Usage Period mechanism.

Obtaining a Designer license

The Designer Pro license is available as a subscription from Disguise Cloud, and can be stored on your dongle or on your physical machine.

Sign up or sign in to Disguise Cloud to obtain your license **here**.

Once signed in, navigate to the Subscriptions tab for your Organisation. Here you can subscribe to Designer Pro.

Note that Designer Starter does not require a license, but does require you to have a Disguise Cloud account which you use to log into d3Manager in order to launch Designer Starter projects.

> **Note**
>
> If you are using Designer for the first time, please check system requirements here.

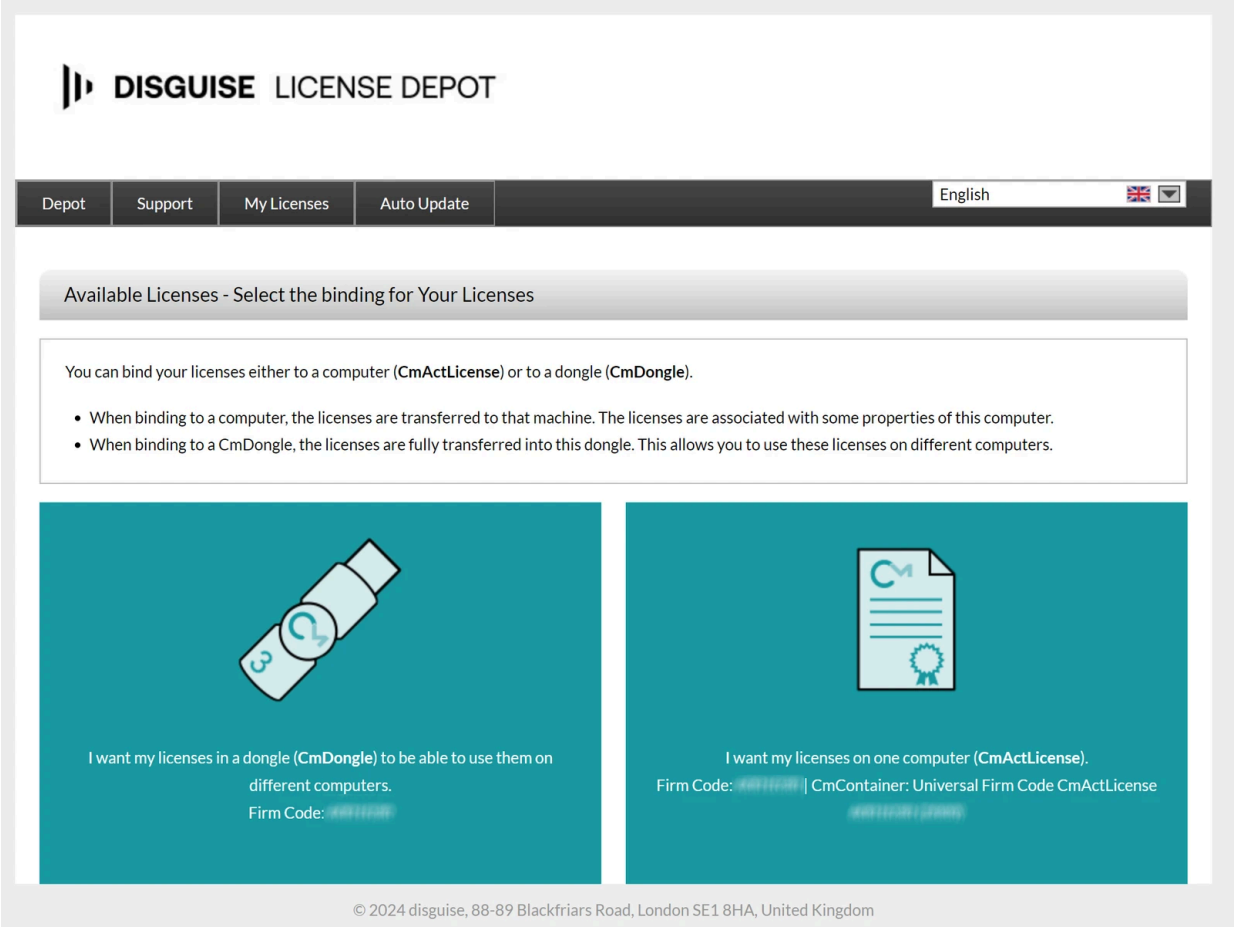
How to obtain a USB Dongle

If you wish to use a USB Dongle to host your license, it can either be purchased from the **Disguise Store**, or users can add the license to another CodeMeter dongle such as one for Notch, or TouchDesigner. The Designer license can then be activated on your dongle by following the steps below.

Activation

License activation requires the CodeMeter Runtime (bundled with every Designer installer to be installed.

The activation method is very similar for each license type. However, the important difference is how the license binding is applied, whether you want your license in a dongle, or on a computer.



Selecting the binding type for your license

1. Activating a license on a USB dongle

1. Download and install the latest version of the Designer software. This is available in the Disguise Cloud **Software** tab of your profile. Sign in required.
2. Ensure your USB dongle is plugged in.
3. Go to **Disguise Cloud** and navigate to the Subscriptions tab for your Organization. Here you can manage and view your licenses.
4. The ticket ID format will be XXXXX-XXXXX-XXXXX-XXXXX-XXXXX. Click **Activate** next to the license. This will bring you to a **CodeMeter management** page.

5. Select the binding for your license. To bind it to a USB dongle, select “I want my licenses in a dongle”.
6. Click **Activate Selected Licenses** to begin Online License Transfer.
7. When your license transfer has been completed successfully click **OK**.
8. Your license is now activated.

Your Designer license is now on the USB dongle.

2. Activating a license on your physical machine

1. Download and install the latest version of the Designer software from Disguise Cloud. Sign in and navigate to the **Software** tab of your profile.
2. Go to **Disguise Cloud** and navigate to the Subscriptions tab for your Organization. Here you can manage and view your licenses.
3. The ticket ID format will be XXXXX-XXXXX-XXXXX-XXXXX-XXXXX. Click **Activate** next to the license. This will bring you to a **CodeMeter management** page.
4. Select the binding for your license. To add it to your physical machine, select **Physical Machine (CmAct)**.
5. Click **Activate Selected Licenses** to begin Online License Transfer.
6. When your license transfer has been completed successfully click **OK**.
7. Your license is now activated.

⏱️ Your Designer license is now attached to your local machine.

Launching Designer

Once your license is activated, you can proceed to launch or create a project to load Designer.

Viewing your license information

License information is available in d3Manager by navigating to **Help > d3 licenses**.

Troubleshooting

Contact the **Disguise Support Team** team if you are experiencing any licensing issues.

CodeMeter Runtime versions

It is recommended to always keep the latest version of the CodeMeter Runtime installed. Do not uninstall or overwrite any newer CodeMeter Runtime versions when downgrading to an older Designer version!

CodeMeter is backwards-compatible, but not always forwards-compatible:

Some older versions are e.g. unable to recognise CmAct software license containers modified by newer CodeMeter Runtime versions. If your license was activated on a CmAct container (see **above**) then CodeMeter Runtimes v7.51 and older may not see your licenses. To fix this, install CodeMeter Runtime version 7.60 or higher, either via a newer Designer installer, or from the **official Wibu Systems website**.

- Transfer a Designer Pro License

Designer Licensing FAQs

I. Designer Licensing Overview

How is Designer licensed?

Disguise media servers come with a perpetual Designer license. For Designer on non-Disguise media servers, there are several license options available:

- Designer Starter is free and does not require a license. It is aimed at learning, training and evaluating.
- Designer Pro requires a subscription, which can be purchased via Disguise Cloud.
- Disguise X1 requires a subscription, which can be purchased via a Disguise Account Manager.

II. Transition for Users on Older Designer licenses

I have a license which was issued previously for free. Will this still work?

Licenses for Designer issued before April 2025 expired at midnight on March 31st, 2025. You will have to select a new license type (either Starter or Pro). Designer Pro and Starter installers and subscription options can be found in Cloud dashboard. Designer Pro will be available from March 17th and managed through the Disguise Cloud dashboard. If you don't already have a Cloud account, you'll need to create one to continue using Designer. Read more about subscribing to Designer Pro here.

You will also need to activate your Designer Pro license using your Cloud account. Designer Starter does not require activation, but you must log in to Disguise Cloud in d3Manager when using Designer. License activation information can be found here.

Why do I need to activate a new Designer license if I already have one?

Previously, Designer licenses required renewal every six months. These licenses expired at midnight on March 31st, 2025, marking the transition to our new licensing model. All users will need to activate a new license to continue using Designer.

Why do I need a Disguise Cloud account to access and activate my Designer license?

Managing licenses through Disguise Cloud allows for easier access, streamlined renewals, and better integration with other tools and services within the Disguise ecosystem, including Mapping Matter.

I'm already paying for Disguise Cloud. Will there be a Disguise Cloud plus Designer Pro package?

We will be announcing Disguise Cloud and Designer Pro bundles later this year.

III. License Types and Features

What is the difference between Designer Starter and Designer Pro?

Designer Starter is designed for training and learning purposes and includes the current functionality of our Designer software with the exception of joining a session with Full Designer instances (Disguise media servers or machines with Designer Pro licenses). Designer Pro will also cover the full functionality of the software but with the ability to programme live projects, as well as edit them in real-time in a session with other Disguise servers or Pro license instances.

For more info on Designer Pro, view the Designer Pro page. For more info on Designer Starter, view the Designer Starter page.

If I have a Disguise server, will my server license be impacted by these new pricing changes?

No. This new licensing model applies strictly to the Designer instance running on a laptop or PC. It **will not** impact the versions of Designer running directly on your Disguise servers.

What license do I need to join a session as an editor with a Disguise media server that has reached the end of support and/or end of life i.e. the 4x4 or the Solo?

As outlined in the Product Lifecycle page, we will move hardware products that are no longer produced to end of support and/or end of life. This involves moving a product to a long-term release model where we only fix show-critical issues that do not require large changes for 1 year.

Users will need to use a Pro license instance on a Disguise media server that has reached end of support and/or end of life in order to join a session as an editor when running a Designer software version later than the last supported version for that product. A table that outlines the compatibility on Disguise hardware and software products can be found here.

Will I lose access to my existing projects if I don't purchase a Pro license?

No, your existing projects will remain accessible. If you switch to the Designer Starter, you'll still be able to open and work on your projects using the software's core features, however once saved in Starter, the project cannot be opened in Pro.

If I mistakenly open up a Designer project in Designer Starter, is there a way to recover it so it can be used on a server or in Designer Pro?

Designer will automatically take a backup of a non-Designer Starter project when it is first opened in Designer Starter, so you can easily revert to your previous project as it was.

IV. Education Use Cases

I work in Education and own Disguise products, has my license changed?

This new licensing model applies strictly to the Designer instance running on a laptop or PC. It **will not** impact the versions of Designer running directly on your Disguise servers. For licenses running on a laptop or PC please speak to your Account Manager about your change or email support@disguise.one.

I run Disguise training courses. What options do I have with this new scheme?

If your training course does not include the use of a Disguise server, then Designer Starter is ideal, as there is no restriction on core functionality. Students should sign up to Disguise Cloud, install Designer Starter, and then log in to d3Manager with their Disguise Cloud account.

If your training course includes the use of a Disguise server, then there are two options:

1. Install Designer Starter on the Disguise server and log in to d3Manager on the server with a Disguise Cloud account. All other Starter instances can then join a d3 session with the server. Note that an intermittent blue flash will be present on outputs.

2. Students use Designer Pro. This will be required if you have a Disguise server, which is an integral part of the teaching, and watermarked output is not practical, for example, because of use in assessments, productions, coursework, etc. In this case, please contact your account manager so we can issue the appropriate licenses.

I'm a Certified Disguise Trainer and run courses on Disguise, am I expected to pay for Designer Pro?

All Disguise Certified Trainers will be given a Designer Pro subscription free of charge.

V. Managing Your License

Does Designer Pro require a dongle?

Designer Pro works with both a hardware dongle or software deployment for the license. There are pros and cons for each deployment method.

The software-based license has the benefit of not needing to manage physical keys, but transferring a license between machines requires checking a license in and out of the license depot. The physical dongle is easier to move between machines if they are co-located, but can make sharing licenses more difficult across multiple locations.

If you deploy a license as software, it can be moved to a dongle later and vice versa.

USB license dongles can be purchased at the **Disguise Store**.

Will my existing dongle still work?

The Designer Pro license can be either loaded onto a dongle or used as a software license. In other words, your existing dongle is compatible to load on a Designer Pro license. If you have an existing dongle with a license that has been activated through the current free Disguise Cloud mechanism, then this will expire on April 1st. If you have a pre-existing license on your dongle, then it depends on the type of license which is loaded on. You can reach out to **support@disguise.one** to check this, giving the name of the license as listed in CodeMeter WebDepot.

Note that CodeMeter dongles with serial numbers starting with 2- are no longer supported, those starting with 3- are compatible for loading on the Designer license.

If I buy several licenses for my company, does everyone using the licenses need to be signed up to Disguise Cloud and in my Disguise Cloud organisation?

Once the licenses have been purchased, they can be managed in the Subscriptions section of Disguise Cloud by those with Admin, Owner, or Billing roles.

Admin, Owner, or Billing roles can share the Activation Code with a user outside their Cloud organisation via another method, this is not restricted.

There is a convenient **Assign** button in this tab to indicate which users in the Disguise Cloud organisation the license is for. However, this functionality is strictly for labelling purposes and does not restrict license usage to the assigned user.

Do I need to manage the license keys myself or will Disguise Cloud help me do this?

Disguise Cloud helps management of the license keys with the **Notes** and **Assign** features in the Subscriptions tab; however it is not mandatory to use these features.

Does the Assign function in Disguise Cloud lock that license to the user it has been assigned to?

No, the Assign feature is only available to Admin, Owner, and Billing roles for labelling and tracking purposes. It therefore does not restrict the license to only that user.

I was given a perpetual license in the past. Will that still work?

Perpetual licenses were not commonly provided, and so it is unlikely that your license is perpetual. The old licensing system displayed two product codes in CodeMeter:

- One with a Product Code of 400. This had no expiry date, however, the 400 license on its own does not enable Designer to run. It was used as an identifier for Designer to differentiate it from other license types.
- One with a Product code of 100. This is the license which enables Designer to run, and usually has a time limit, displayed in the Valid Until field in CodeMeter. Older Disguise servers also have this code, but without a time limit.

Going forwards, Designer Pro will have only one license entry in CodeMeter.

VI. Software Version Compatibility

What versions of Designer support the Designer Pro license?

The following Designer versions support the Designer Pro license: r29.3 as the latest supported legacy version, and any version since r30.5.

I need to use a version of Designer between r18 and r29.2, what do I do?

When subscribing to Designer Pro, your Designer Pro license activation codes will be available in your Disguise Cloud account. In addition, you will automatically receive an email with a second license which is valid for Designer versions between r18 and r29.2. At launch, this license will be valid until June 30th; we will later send out a legacy license with an expiry to match the duration of your Pro subscription.

I need to use Designer r17 or earlier, what do I do?

Designer r17 and earlier releases use the older Designer Legacy license structure. This is not compatible with any license issued via Disguise Cloud. In this case, you will need to continue to use the Legacy license on a physical CodeMeter dongle. This process remains unchanged. Read more about older licenses on our Legacy Licenses page.

Please contact **Disguise Support** if you need to request or extend a Legacy license. These licenses are issued on a request-only basis.

VII. Renewing licensing across multiple servers

What happens if you miss the 2-day renewal window?

Subscription renewals are issued 48 hours before the license expires. If the machine using the license does not connect to the internet within that period, the local license will expire.

As soon as the machine connects to the internet again, the license's expiry date will be automatically updated.

We therefore recommend keeping machines with Designer Pro or X1 licenses connected to the internet around the time of the subscription renewal, to prevent issues when they are later used in offline show environments.

What happens if you have multiple dongles? How do you update them all?

Connect each dongle to a machine with internet access so the updated expiry date can be applied. You can confirm the update in d3Manager or CodeMeter WebAdmin.

There is no limit to how many dongles can be connected at the same time. For example, you can connect all dongles to one machine and restart it. Shortly after d3service starts during Windows boot, it checks for license updates and applies them to each dongle in turn.

VIII. Support

Where can I find support if I have questions during the transition?

Our team is here to help! You can reply to any of our communications, reach out to your account manager, or contact our support team at **support@disguise.one** for assistance with licensing, activation, or understanding the new licensing changes.

Offline License Update

Disguise licenses can also be updated and activated without an internet connection. This applies to any machines, but is typically relevant for RenderStream subscriptions where the RX server that should receive the license is airgapped without internet access.

License files must be transferred between the receiving server and a separate machine with internet access for offline license updates. This transfer can happen using a LAN or physical drive, such as a USB drive or an external HDD/SSD.

To complete the update, 3 files need to be exchanged:

- A **request file** (`.WibuCmRaC`):
  - This must be uploaded to generate the license update file.
- The **license update file** (`.WibuCmRaU`):
  - This must be downloaded to activate the license.
- The license **receipt file** (also uses `.WibuCmRaC` extension):
  - This must be uploaded as proof of an activated license.

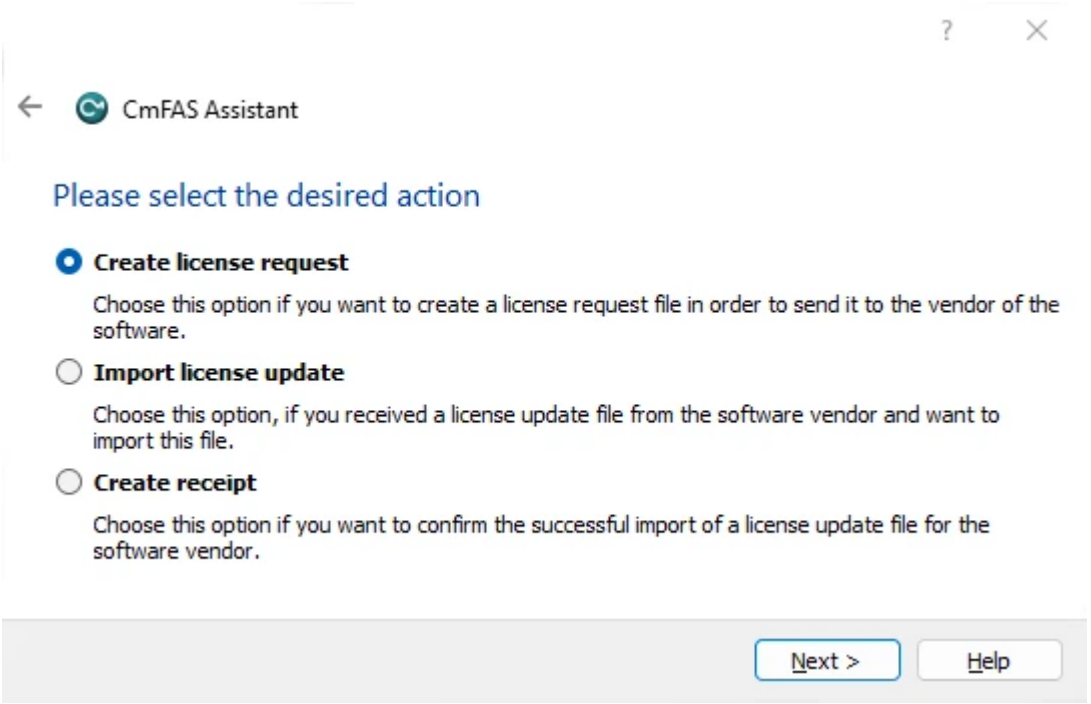
> **Note**
>
> By default, *CodeMeter Control Center* will use the serial number of the license container for the filename. When activating multiple servers, you may want to use a more descriptive name (e.g. the machine hostname), so it's easier to see which file needs to be copied to which server.

Offline License Updates

Follow the steps below to update your license.

1. Create a license update request on the server without an internet connection

1. Open **CodeMeter Control Center**.
2. Click **License Update** and click **Next**.
3. Select **Create license request** and click **Next**.
4. Select **Extend existing license**.



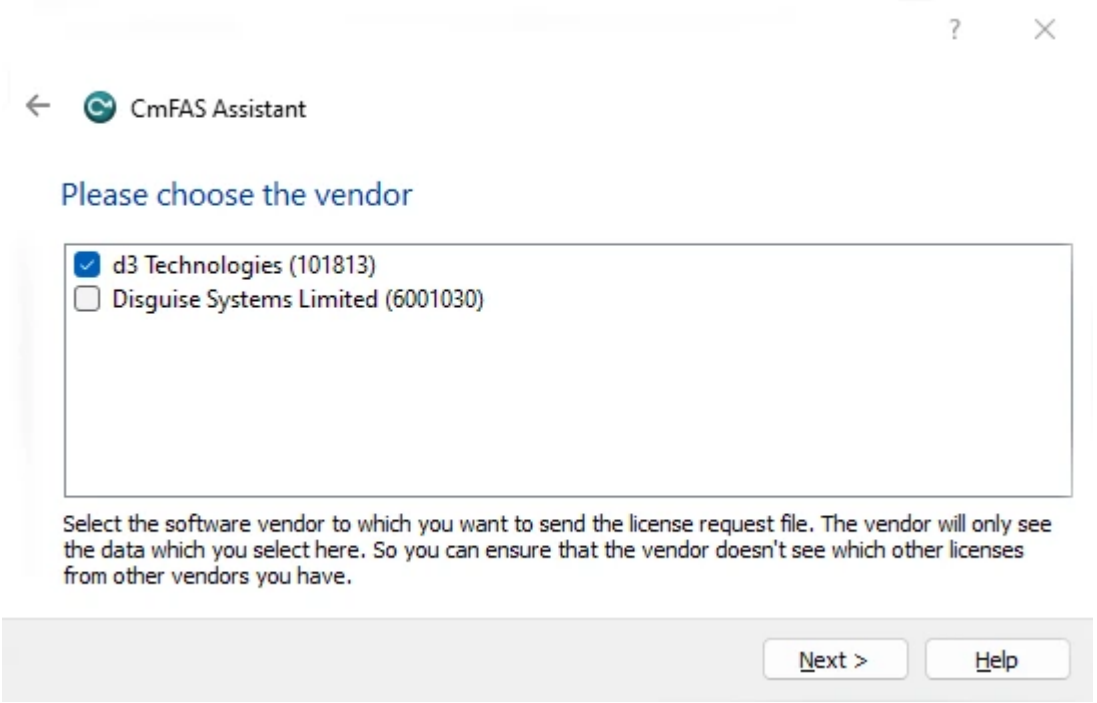
5. Select the appropriate FirmCode

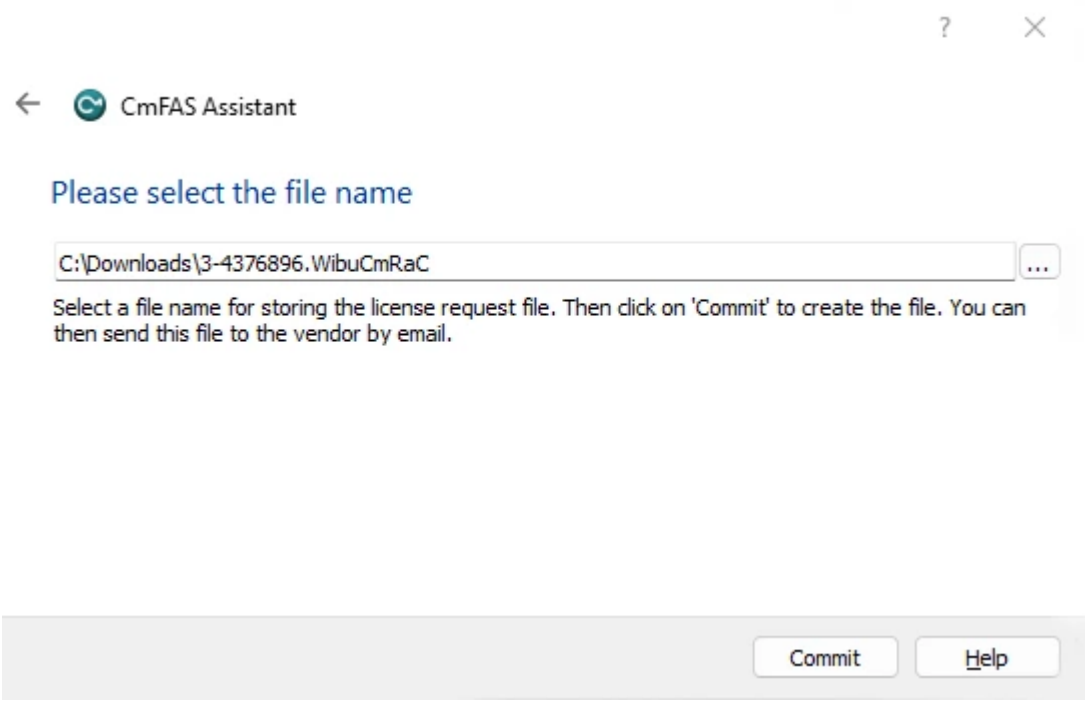
If you have multiple licenses installed, select the appropriate Disguise FirmCode to update. Note that instead of “Disguise”, the description may say “d3 Technologies”.

You can only create one license request at a time, for example:

- `101813` for current RenderStream licenses
- `6001030` for Designer licenses

6. Click **Next**, select a memorable filename for the request, then click **Commit**.
7. Copy this `.WibuCmRaC` file to the computer with an internet connection.

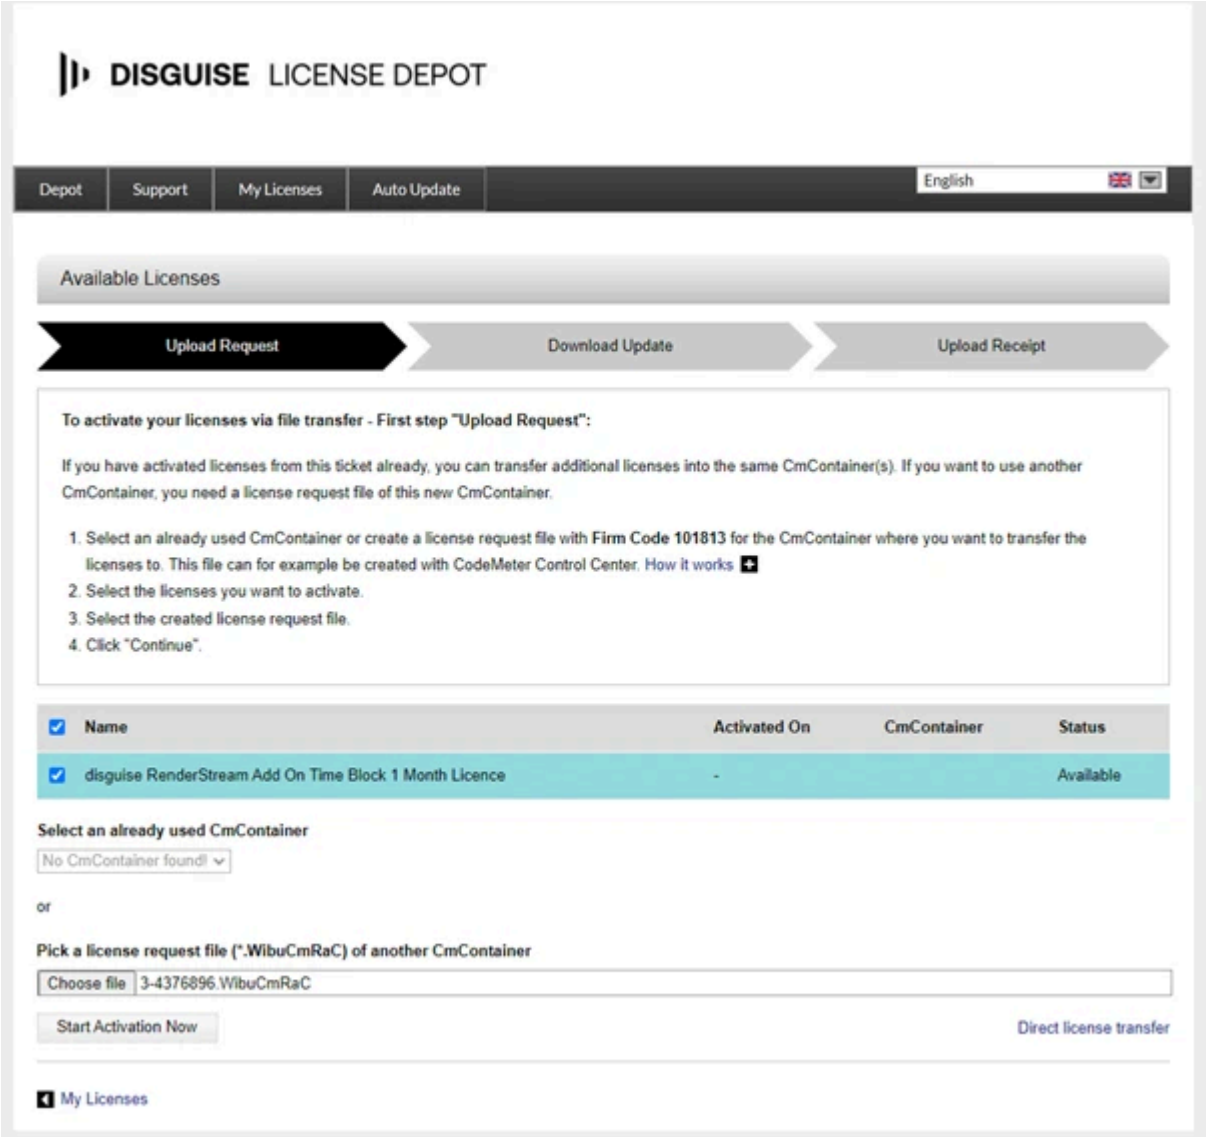




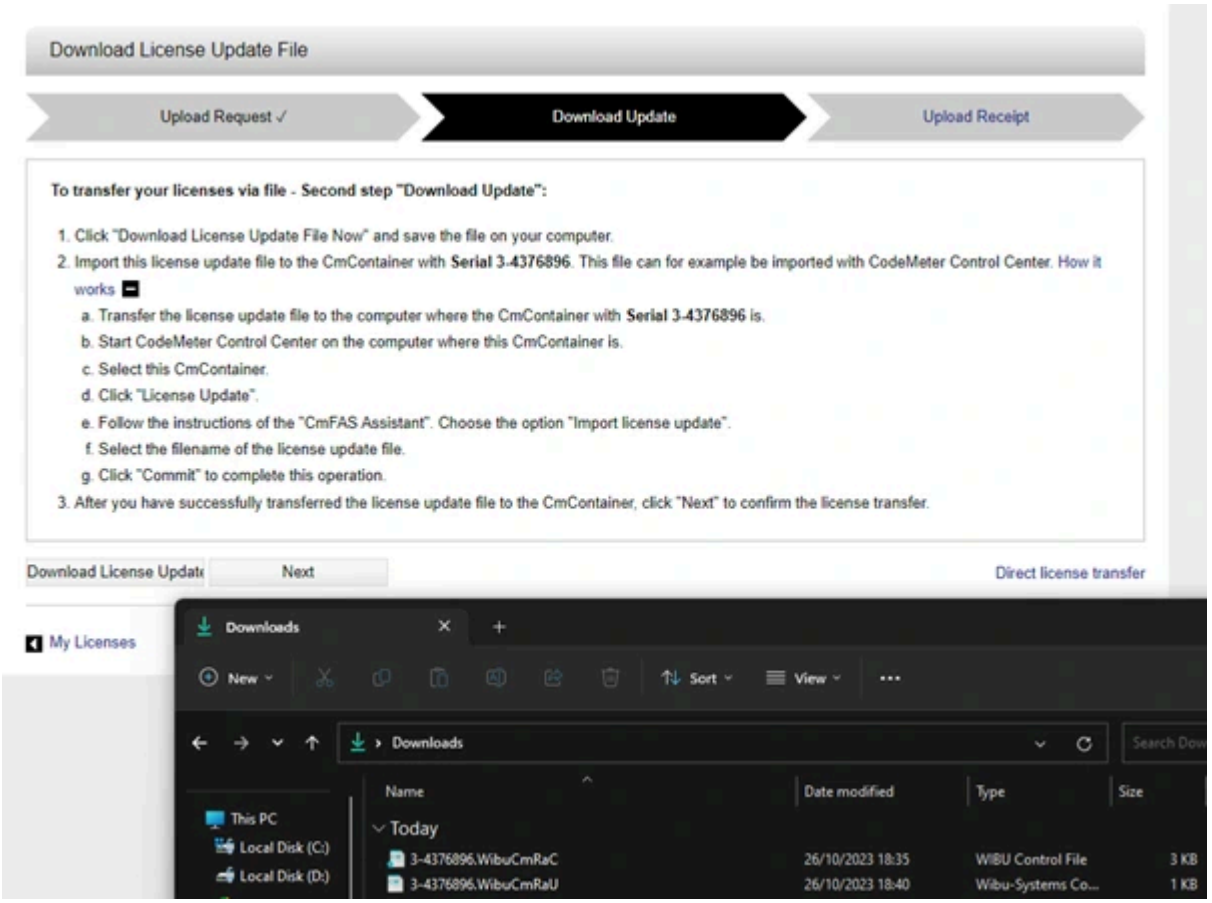
2. Create a license update file on a machine with an internet connection

1. Open the URL for the file-based transfer in a browser, https://lc.codemeter.com/64700/depot/autoUpdate.php.
2. Click **File-based license transfer** in the bottom right of the window.

3. Select the `.WibuCmRaC` request file you copied from the offline machine.
4. click **Start Activation Now**.
5. This will take a short time to process.

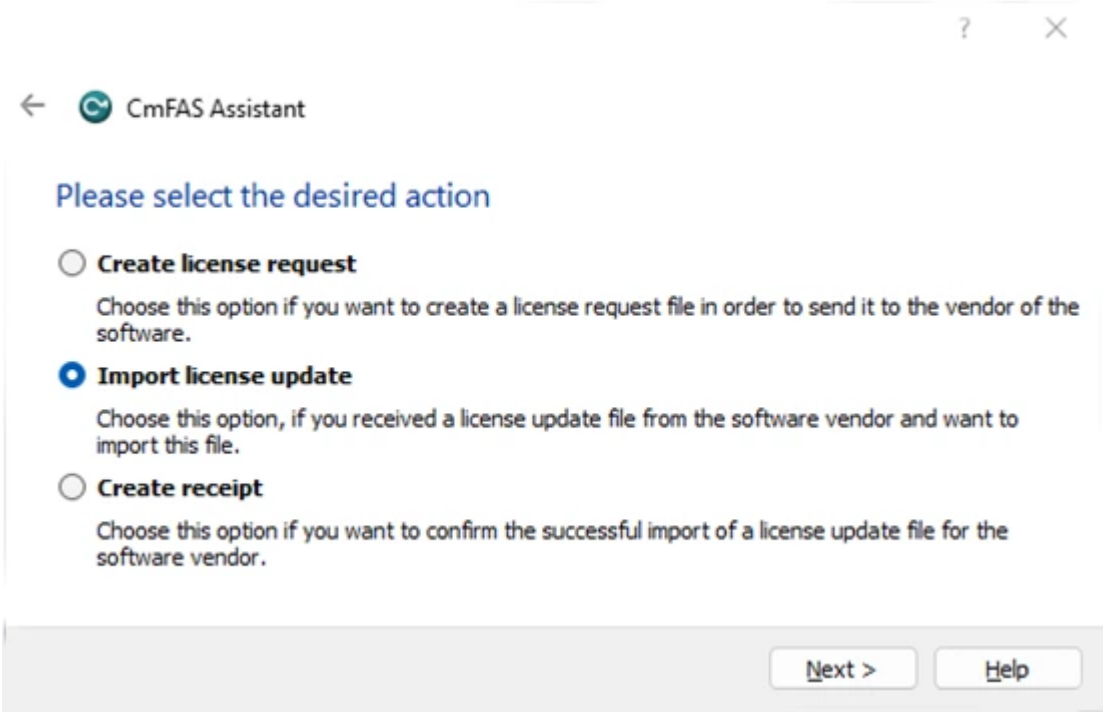


6. On the next screen, click **Download License Update**. This downloads the license update file ending with a `.WibuCmRaU` extension.
7. Keep the browser window open until the download has completed.
8. Copy the `.WibuCmRaU` update file to the offline server.



3. Import the license update on the server to create a receipt

1. Reopen the **CodeMeter Control Centre**.
2. Click on **License Update**.
3. Click **Next**.
4. Select **Import license update** and click **Next**.
5. Select the `.WibuCmRaU` update file you copied from the online machine.
6. Click **Commit** to activate the license on the offline server.



CmFAS Assistant

Help

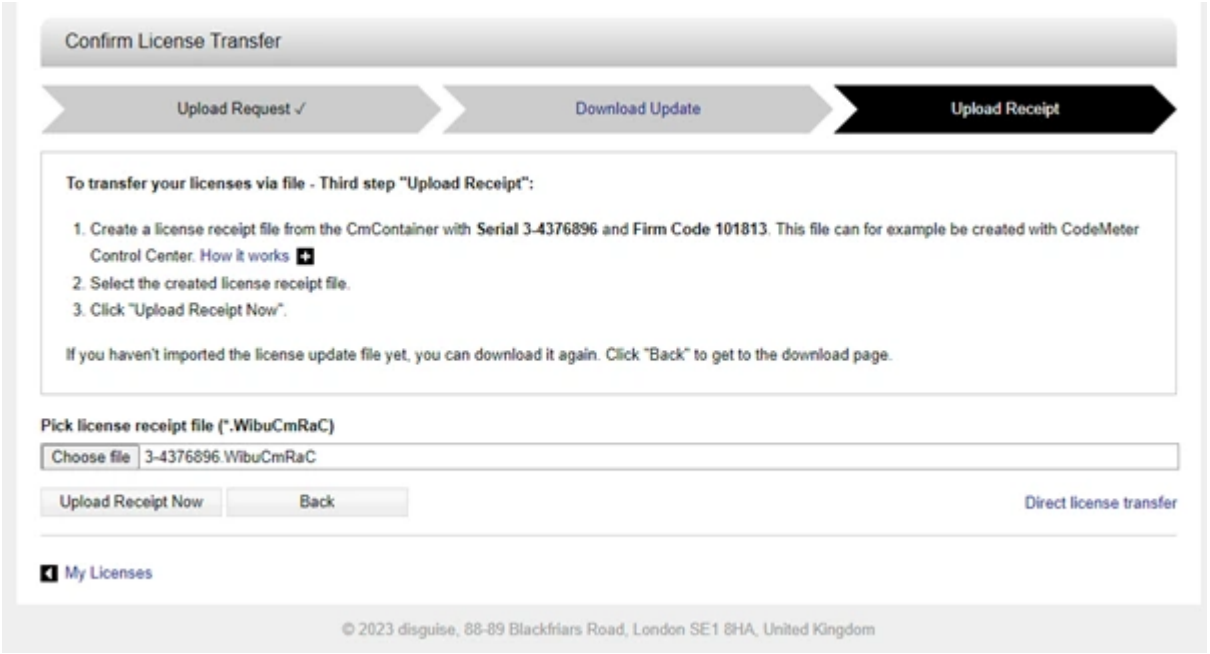
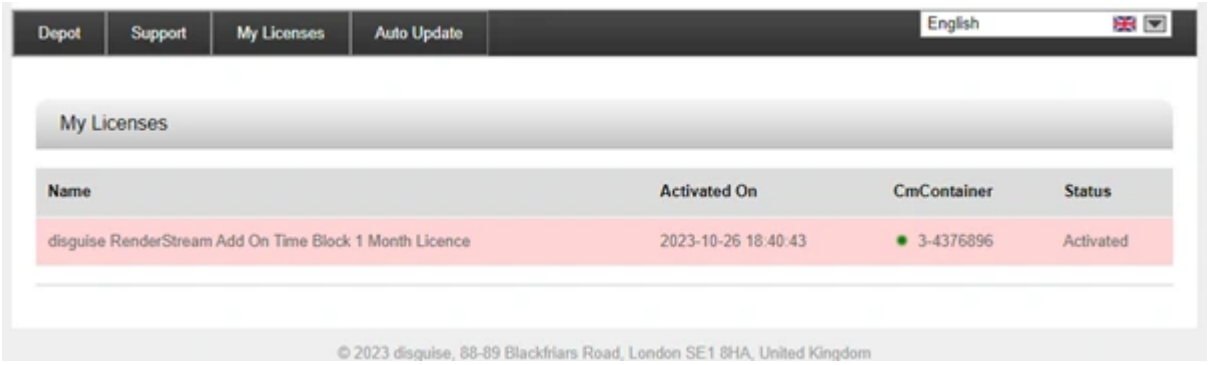
4. Apply the license receipt on a machine with an internet connection

1. Return to your browser and ensure you have the option to **Download License Update File** in WebDepot.
2. Click **Next**.
3. Select the `.WibuCmRaC` receipt file you copied from the offline machine.
4. Click **Upload Receipt Now**.



5. Click **OK** on the next screen.
6. Finally, you should see that the license now has a red background in WebDepot. This indicates that the WebDepot and the CodeMeter License Central database have received the update and confirmed the license activation.



Restoring a CodeMeter License

Sometimes users may need to restore CodeMeter licenses, for example if a dongle was lost, or a software license got accidentally deleted while formatting a hard drive. The Disguise Support team has a process to restore licenses in such circumstances. To avoid abuse, this process requires approval and needs to be actively trigged by our Support team, upon a user request.

> **Note**
>
> Please note that our Support team can only restore licenses provided and controlled by Disguise. To restore any 3rd party licenses, please get in touch with the Support team of the license provider.

Why the license may need restoring

The following sections describe possible scenarios where a license may be eligible for restoration. It also covers how these issues can appear or can be identified by users.

Lost license due to Windows re-install

A typical case of a lost license happens when a user forgets to deactivate a license from their (dongleless) CmAct container before doing a complete wipe or re-image of their PC. Re-formatting the drive where Windows resides, or re-installing Windows can destroy the CmAct container, and all licenses on it are lost.

To prevent his, please always deactivate all licenses from your dongleless CmAct containers before formatting your hard drive. Then you can simply reactivate them afterwards without the need to contact Disguise Support.

Lost or stolen CodeMeter dongles

Theft or loss of a physical CodeMeter container (dongle) is another obvious use case for license restoration. Restoring a license and activating it on another container will also invalidate the license instance on the lost/stolen container.

In case of theft it may also be desirable to add the container serial number to a global block list, which will make the dongle itself unusable. That way the thief gets no benefit at all from the stolen dongle.

Non-returned rental license

As of 2025, Disguise does not yet offer a rental process to lease or borrow licenses; but this is planned as a future feature.

At the moment license borrowing relies on all parties adhering to the terms agreed between each other. This is especially important for returning licenses after the end of the rental period. The license receiver needs to return the borrowed licenses back to the owner using the deactivation process, which requires access to the container where the license currently is activated on.

If a license is not returned in time to the owner (e.g. rental house) using the re-hosting mechanism, then this may also be a valid use case to restore the license.

> **Note**
>
> The rental house must contact the current license holder before contacting **Disguise Support**.

It is important to note, however, that restoring the license should be seen as a *last resort*, since it may affect somebody actively using the license in that very moment.

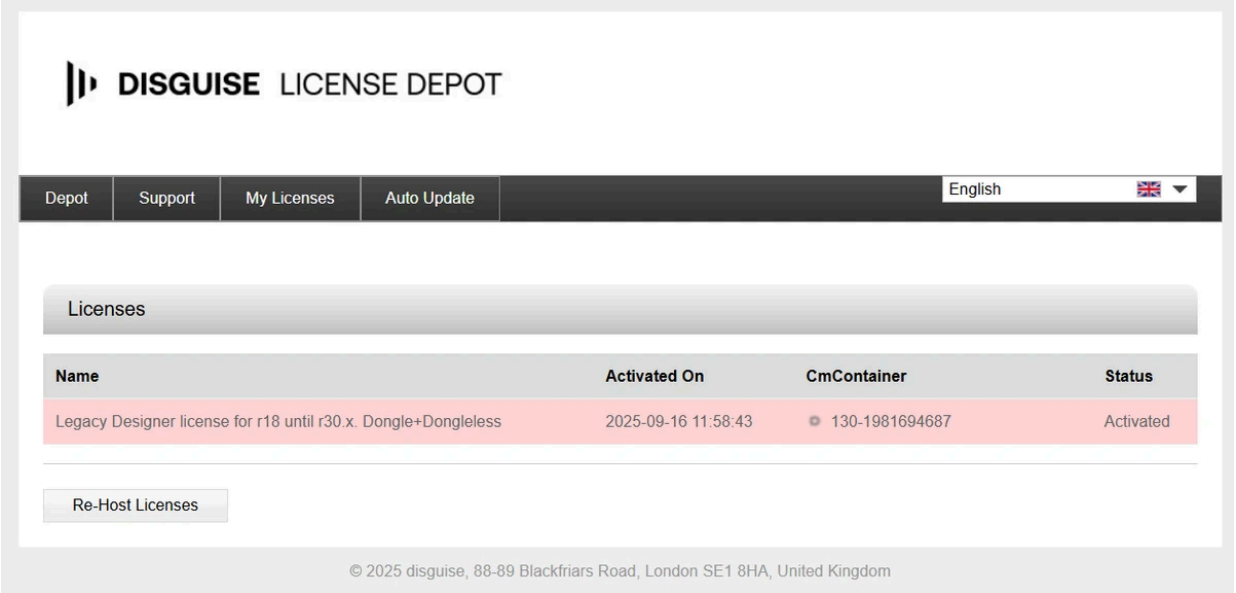
Restoring a license

Restoring a license is very similar to normal license activation, but there are also some key differences:

- The CodeMeter management interface looks slightly different.
- Restoring licenses comes with some additional conditions (see **step 2. below**). Users should carefully read these before proceeding.
- When a license gets restored, the old instance of the license will get automatically withdrawn from its current container. Other licenses on that container will remain unaffected.

Before requesting to restore a license

1. Find the Ticket ID for the licenses that need restoring in the **Disguise Cloud** account.
2. Go to the **CodeMeter management** activation page and enter the Ticket ID.
3. If the license is not currently activated (i.e. it is ready to be activated or re-hosted), then there is no need to restore it. It can be activated as usual.
4. If the license is currently activated, then the **CodeMeter management** will not allow another activation of this TicketID. It will show a page similar to this:



Requesting to restore a license

To get a license restored please email **Disguise Support** with any relevant information, including:

- Required:
  - Ticket ID of the license(s) to restore.
  - Reason for restoring, e.g. loss, theft, accidental deletion of software license, etc.
- If possible:
  - Serial number of the affected CodeMeter container. This is particularly relevant for stolen dongles, since it may be necessary to add those to a global block list.

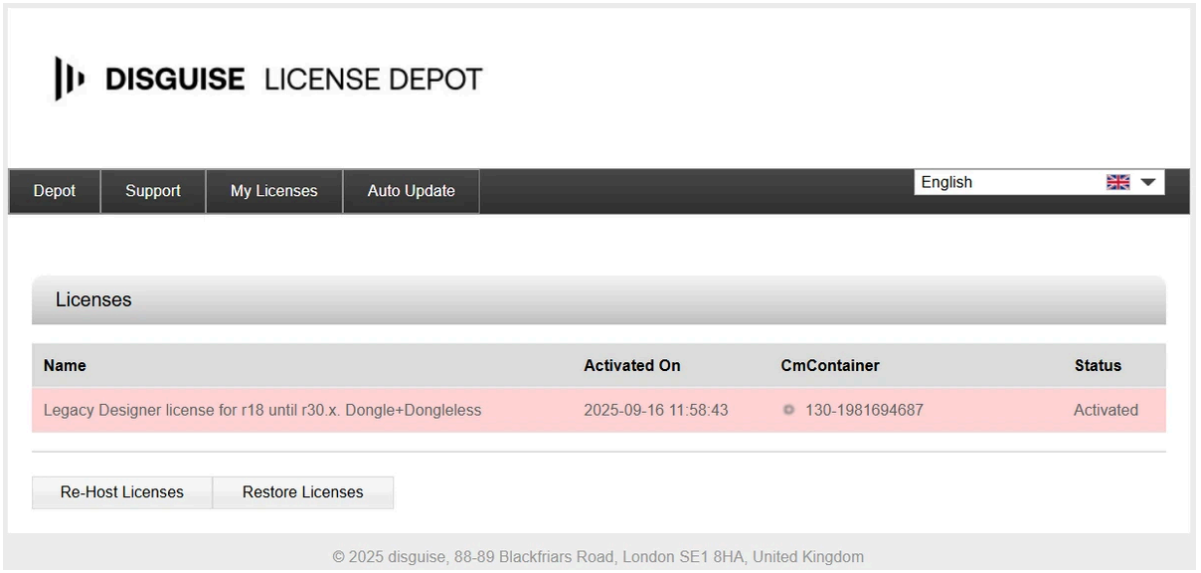
The Support team will then check this information against our database and enable restoration for the affected licenses.

> **Note**
>
> Please note that restoration works on a per-license level. If multiple licenses need to be restored from a CodeMeter container, then provide the TicketID for all these licenses.

License restoration steps

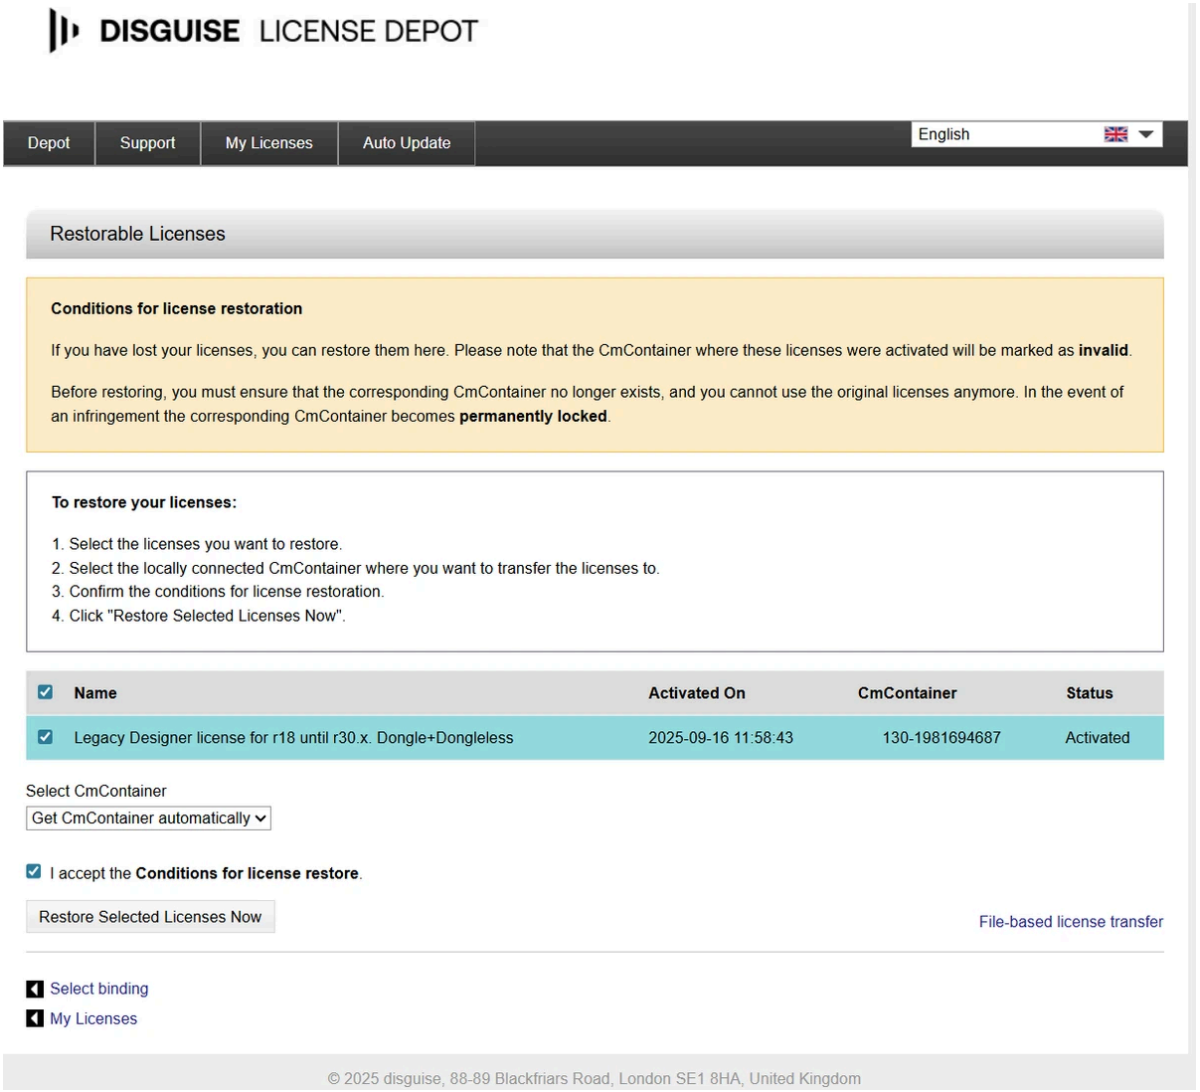
1. Open the **CodeMeter management** and enter the Ticket ID.

2. The activation screen will now have a new **Restore Licenses** button.



3. Click **Restore Licenses** to progress to the usual “container binding” screen.
4. Select dongle or CmAct license binding, as desired.
5. The **Restorable Licenses** screen is shown.
6. Select the licenses from the list that need restoring (in case the Ticket ID contains more than one license).
7. Read and accept the “Conditions for license restoration” by ticking the respective box.

8. Click the **Restore Selected Licenses Now** button. The activation process will progress as usual.



Repeat this process for every Ticket ID that has licenses to be restored.

Creating Support Cases

We understand that things can occasionally go wrong, but rest assured, the Disguise Support team is here to help you as much as possible to resolve any issues you encounter. This page outlines the information we need to troubleshoot more efficiently, allowing us to identify and resolve issues as quickly as possible.

Throughout the user guide we mention contacting support. The best method for doing this is by email to **support@disguise.one**.

The key information we need is:

- Error
- Diagnostic file
- Setup
- Additional project files
- Critical deadline
- Other useful information

Error

- What was the actual error message you received?
- What happened that caused the error?
- Can you reproduce the error?
- If you're able to provide a video showing the steps it will be extremely helpful.
- Can you recreate this error in a new project or the 'start' project?

Diagnostic Log File

The log file is a critical part of the troubleshooting process as it helps us determine what may have caused the error. Disguise support will always ask for a diagnostic file so you can help us by providing the log file when you contact us.

How to create a d3 diagnostic file

1. Open the manager and select the project name.
2. Run your project to generate the error.
3. If possible, provide us with the time the error occurred. This will help us quickly locate the error in the logs.

4. Go to the **Help** menu in d3Manager and choose **Create project diagnostic** which contains both project and system diagnostics, or **Create system diagnostic** which specifically includes system information.

The diagnostic zip file will be generated in your **projects** folder.

> **Tip**
>
> If you experience a Windows Blue Screen, these files will not be included in a system diagnostic. If you experience a Windows bluescreen please include the dump files MEMORY.DMP found in C\Windows along with any dump files found in C:\Windows\minidump

Setup

Understanding your setup is extremely useful.

Providing us with:

- Short description of your setup / hardware
- Output resolution
- d3 version
- Does the error occur with other versions of d3?

Project Files

A skeleton project file is included with your Project diagnostic this will help give us your basic setup however this will not include any content. If you are experiencing a specific issue with a piece of content (for example frame drops in a specific video layer) this content will need to be provided separately to us.

Critical Deadlines

We understand that errors happen at the most inconvenient times and we are here to help you. Please let us know in advance if your issue is urgent and has a tight deadline so that we can prioritise accordingly.

Other Useful Information

- Key deadlines
- Impact the issue is causing

- Details of the show:
  - Show title
  - Production status (pre production, live etc)
  - Type of show (eg stage, tour, xr, location experience)
  - Region of the show so we can ensure your case is handled in the right time zone.

For more information on what happens to a support case once it has been created, please see this article in the Support Portal.

Supported file formats

Designer supports multiple content formats for Video, Audio, Still image and 3D model files. It is important that these formats are used for optimal performance. Only formats listed here are officially supported.

Video files

Designer supports Quicktime .mov files using the following codecs:

- **QuickTime DXV version 2.**

> Download the DXV codec for Mac or Windows from the *Content tools and codecs* section of the **Resource section**

- **QuickTime HAP, HAP Alpha and HAP-Q.**

> Download the HAP codec for Mac or Windows from the *Content tools and codecs* section of the **Resource section**.

- **QuickTime Animation**

> **Warning**
>
> We do not support Delta frames. Videos need to be exported with keyframes at every frame..

- **NotchLC**
- **ProRes**

> A high-quality suite of Apple codecs—ProRes 422, 4444, and HQ—fully supported by Designer.

Filename Tag Issues

Please note that if you use any of the following filename tags, you may encounter issues in Designer. These tags are reserved for media file versioning, and proxy functionality.

- `_region`
- `_slc_region`
- `_v`
- `_frame`
- `_proxy`

Premultiplied vs. straight/matted alpha

Alpha can be rendered into videos and images with subtle differences which can affect how they appear when composited upon output. Premultiplied vs straight alpha will require different blend modes depending on which is used. There is no preference in Designer to either one, but if using content with premultiplied alpha, it should utilize the **Premult Alpha** blend mode, rather than **Alpha**, which should be reserved for straight alpha.

Also note that **Premult Alpha** is usually the only option available when creating fuzzy edges against an alpha background, as the pure alpha workflow requires the colour which is being faded from to be available at full intensity throughout the gradient, while only fading the alpha component. That sort of thing is tricky to create in content creation packages, so falling back on **Premult Alpha** makes more sense in those cases.

Maximum resolutions of video files and still images

Designer supports video files and still images up to 16384x16384.

For audio embedded in video files:

- Uncompressed
- Stereo 16 bit
- 44.1 KHz. Currently d3 **only** supports 44.1 KHz, any other frequency will generate an error.

Audio files prior to r14.3

Quantised tracks option 1:

- .mp3
- Stereo 16 bit
- 44.1 KHz, constant bitrate. Currently d3 only supports 44.1 KHz, any other frequency will generate an error.
- 256 Kb/sec is a recommended balance between quality and file size.

Quantised tracks option 2:

- .wav
- Stereo 16 bit
- 44.1 KHz

Quantised tracks option 3:

- .aiff
- Stereo 16 bit
- 44.1 KHz. Currently d3 only supports 44.1 KHz, any other frequency will generate an error.

> **Note**
>
> To read about multi-channel audio support, see the Output multi-channel audio page.

Audio files after r14.4

These audio file formats can be used on the audio layer.

Uncompressed WAV files with the following properties

- Unsigned 8 bit, Signed 16 bit, 24 bit or 32 bit PCM, 32-bit or 64-bit floating point encoding
- Sample rates up to 192 kHz
- 1 or 2 channels

Uncompressed AIFF files with the following properties

- Unsigned 8 bit, Signed 16 bit, 24 bit or 32 bit PCM, 32-bit or 64-bit floating point encoding
- Sample rates up to 192 kHz
- 1 or 2 channels

MP3 with the following properties

- CBR up to 320kps (variable bit-rate not supported)
- 8 kHz, 11.025kHz, 12kHz, 16kHz, 22.05kHz, 24kHz, 32kHz, 44.1kHz, 48kHz sample rates
- Stereo, joint stereo or mono

> **Note**
>
> The software internally uses a 32-bit floating point audio pipline, so best performance can be achieved by using 32-bit uncompressed WAV encoding, at a sample rate that matches your audio output.

Audio files after r15.2

These audio file formats can be used on the audio layer.

Uncompressed WAV files with the following properties

- Unsigned 8 bit, Signed 16 bit, 24 bit or 32 bit PCM, 32-bit or 64-bit floating point encoding
- Sample rates up to 192 kHz

Uncompressed AIFF files with the following properties

- Unsigned 8 bit, Signed 16 bit, 24 bit or 32 bit PCM, 32-bit or 64-bit floating point encoding

- Sample rates up to 192 kHz

MP3 with the following properties

- CBR up to 320kps (variable bit-rate not supported)
- 8 kHz, 11.025kHz, 12kHz, 16kHz, 22.05kHz, 24kHz, 32kHz, 44.1kHz, 48kHz sample rates
- Stereo, joint stereo or mono

Still images

Disguise supports several still image formats that are listed below:

- .png (supports alpha-channel)
- .jpeg (does not support alpha-channel)
- .bmp (supports alpha-channel)
- .tiff (supports alpha-channel)
- .exr (supports alpha-channel, no support for image sequences)

> **Note**
>
> Loading large still images can be slow, and Disguise does not provide benchmarks or measure load time. This means that when swapping between large still images you may experience a brief flash to black while the new image loads. The best way to mitigate this is to re-encode the image in to a more performant format, like a single frame of a Video Format.

Image sequences

- TGA
- TIFF
- DPX

8-bit and 10bit is supported where applicable. All formats support the use of alpha channel (with the exception of 10bitDPX), and any framerate.

> **Note**
>
> Although other formats may work, only those listed above have received enough testing to formally support.

For more information, see Image Sequences.

3D meshes - .abc, .fbx, and .obj

.abc

Designer supports Alembic (.abc) files, which are particularly useful for animated meshes. Place the file in the project's mesh object folder and select it as you would an OBJ. Like an OBJ, an Alembic file can be used either as a prop or as a UV-mapped video screen.

.fbx

- .fbx files without materials, textures, and animations. For more information, contact support@disguise.one.

.obj

- .obj files used as the mesh file for video screens need to be UV mapped.
- .obj files used as the mesh file for Props do not need to be UV mapped.

> **Note**
>
> To read more about preparing 3D meshes for Designer, see the 3D Fundamentals sub-chapter.

Currently supported:

- Xform
- PolyMesh

Not currently supported

- Curves
- Points
- Camera
- SubD
- NuPatches
- FaceSet
- Light
- Material
- Custom data
- Writing Alembic files

System Requirements

The following table lists the recommended system configuration for running Designer, along with the minimum requirements:

Component	Specification
Operating System	Windows 10 or 11, 64-bit
GPU	Discrete GPU with at least 16 GB video memory (min. 8 GB), DX11 compatible
CPU	At least 4 cores, 8 threads and 3.4 GHz base frequency (min. 2 cores, 4 threads and 1.9 GHz base frequency)
Memory	16 GB (min. 8 GB)
Audio	Any permitted
Storage	50+ GB (min. 20 GB)

> ⚠ **Caution**
>
> Disguise requires a 64-bit operating system.

Operating system

To run the latest version of Designer your system needs to have a Designer license. Licenses can be obtained via the Disguise Cloud, and either installed directly on the machine (dongle-less solution), or they may be installed on a USB Codemeter dongle, available for purchase from the Disguise webstore.

Virtual Machines - Parallels

Virtual Machines like Parallels do not run Designer, since Disguise requires DirectX11. Bootcamp may be used, but only if you are working on a pre-M1/M2 Mac platform.

Designer software

For information on how to install the latest version of Designer please see the sub-chapter Updating the software.

If you encounter any issues with the installation of the Designer software or license, please contact the **Support Team** for assistance.

Sharing Designer Usage Analytics

When installing Designer using either the Starter installer or Full installer, you have the option to share usage analytics with us. This helps us understand how you use Designer so we can prioritise and design tools that best support your workflows.

You can toggle this option on or off at any time by going to `d3Manager > Help > About Manager` and clicking the checkbox at the bottom labelled **Share Designer usage and diagnostic analytics**. This setting, whether set in the installer or via d3Manager, will persist through machine restarts and Designer re-installs, but with **NOT PERSIST THROUGH RE-IMAGES** (like all of our other settings!).

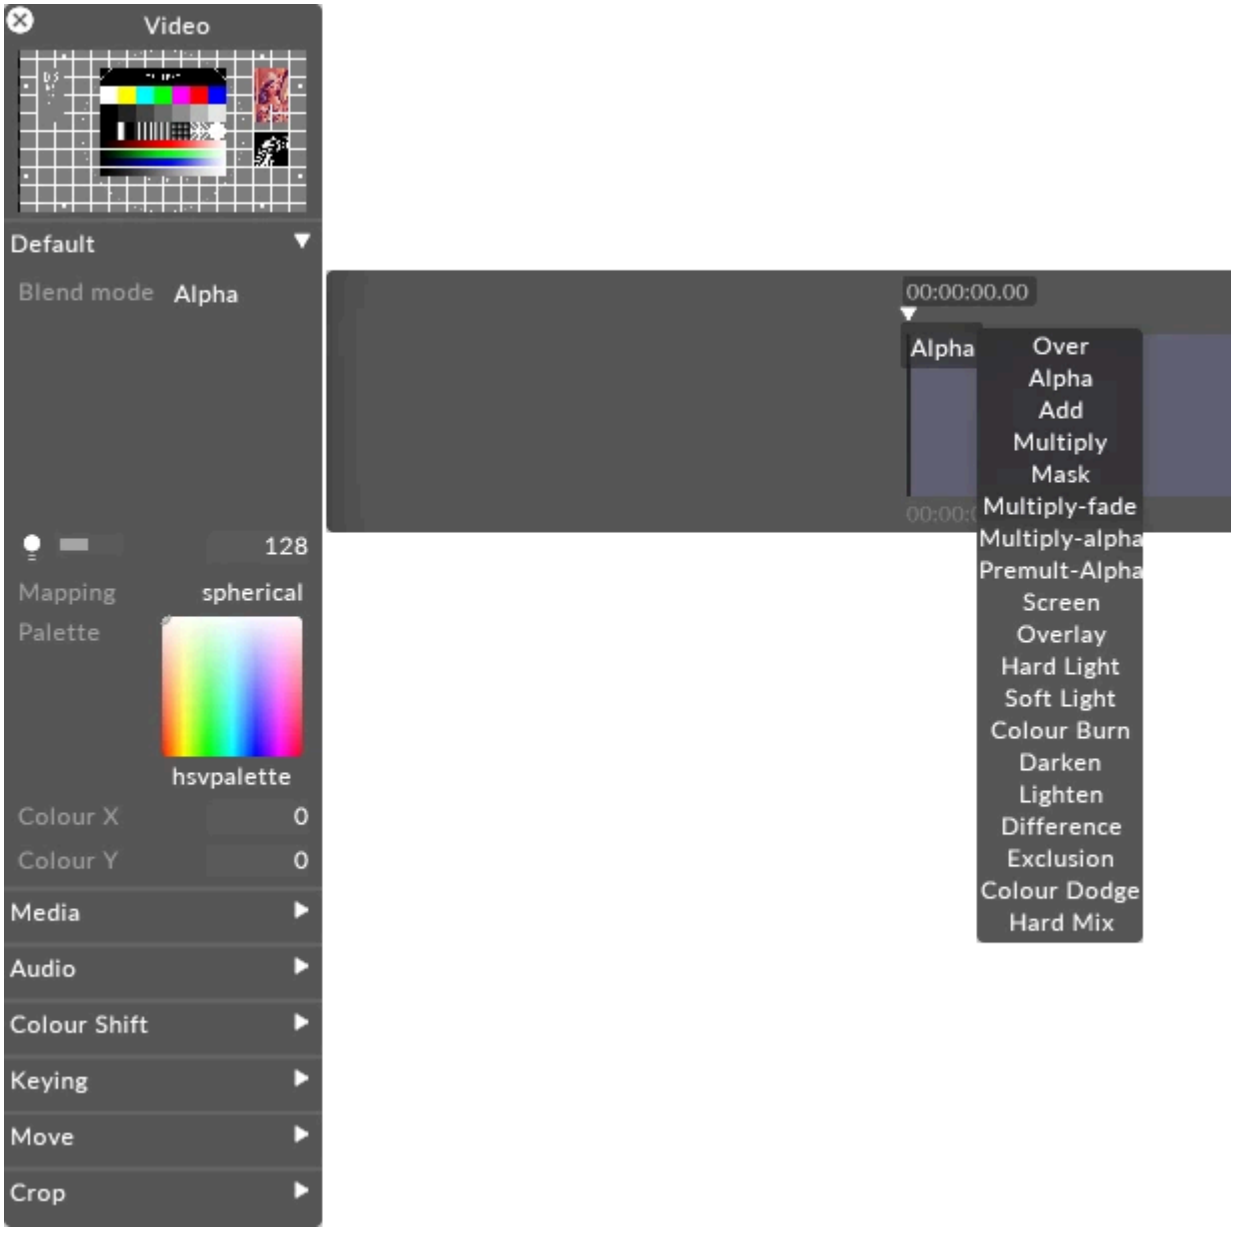
We understand that in some cases our users are building projects under strict NDAs or have other reasons to turn this feature off. For this reason, we will describe the data that this feature shares with us, so you can make an informed decision about whether to disable this option.

Toggling the option **ON** will share with us:

1. Minimal event logs in the system that tell us things at the system level, such as:
   - What time Designer was launched and closed.
   - When a user logs in via d3Manager.
   - What Disguise media server model is being powered on or off.
   - What Designer software version has been installed.
   - What CodeMeter License is being used to license Designer.
   - etc.
2. Specific user events and actions while programming such as:
   - When a layer was added or removed from the timeline and what type it was.
   - When a track is added or removed from the project.
   - When certain device drivers are started and stopped.
   - etc.
3. A project summary which includes a snapshot of the project on the close of a Director and/or Editor.
   - This includes a list of most serialized objects and what they link to. This allows us to infer information like:
     - `Media File: <MyVideo> is sequenced on Track: <MyTrack> in Video Layer: <MyLayer>`
     - etc.
   - This data is **FULLY ANONYMIZED** via hashing, so no project, media or user-configurable text is identifiable to us.
     - So what we can infer from the example above is **ACTUALLY**:
     - `Media File: ANON17272503146233135311 is sequenced on Track: ANON15467174445949765117 in Video Layer: ANON1895260`
     - This allows us to analyse and understand **how** our users are building projects, without being able to know anything about the **specifics** of the project itself.
     - After r32.3, this anonymization happens when the file is written. Before r32.3, this anonymization happens after it is uploaded.

Blend Mode

BlendMode controls how the output of the layer is composited with the layers below. Layers are rendered in a bottom-up order: layers at the top can modify the output of the layers below.



Changing brightness of a content layer in Designer is actually controlling the value of the alpha of the layer. Even when displaying a HAP video, the software will composite the layer with a controllable layer of alpha - one per layer.

There are two ways of expressing alpha in an image:

Straight alpha is an alpha channel which functions just like RGB. Alpha acts as a fourth channel of information per pixel which is as independent of the other three as R, G and B are of each other. For example, with straight alpha it is possible to have RGB = 255 (white) and alpha = 0 (fully transparent) on the same pixel. Internally generated content, such as gradient layer, are generated with straight alpha. This is the preferable style of alpha and considering the cleaner method of the two.

Premultiplied alpha takes the alpha and applies it to the values of the RGB channels per pixel. The more transparent something gets with premultiplied alpha, the closer it gets to black - as if the content is sitting on a black table. Premultiplied is the default output of Adobe Photoshop or AfterEffects. The result is our pixel at 255 RGB (full white) with 0 alpha would be calculated as a black pixel in the final image.

Here are explanations of what each individual blend mode will do.

Over

Makes a layer fully opaque. Premultiplies all alpha onto the RGB value of each pixel. Alpha = black, so adjusting the brightness of a layer in Over blend mode makes it darker.

Alpha

Default blend mode. It will apply alpha values as a transparency if the alpha is present. Brightness changes will make the layer more or less transparent.

Add

Adds the value of each RGB pixel together. Always creates a brighter result. Values clamp at 255.

Multiply

Reads the level of each subpixel as a level between 0.0 and 1.0, and multiplies source with blend. The result is always a darker image overall. For example: white x grey = 0.5. White turns transparent, black takes precedence. Alpha is applied in the same fashion as the Over Blend mode.

Mask

Applies a mask to the single layer **above** in the stack, irrespective of mapping. See **Mask blending** for more information.

Luma-Matte

This mode creates a Luma Matte by using a layer's **Rec. 709 luminance** to control the alpha channel of the layer **above**, irrespective of mapping.

To determine transparency, the luminance of each pixel is calculated using a weighted average of its red, green, and blue channels. The luminance value is then used as the alpha (opacity) value for the corresponding pixels in the upper layers.

As a result, white areas render the layer above fully opaque, black areas make them fully transparent, and grey areas create proportional semi-transparency. This is a specialized **Mask** blend mode; for more details on the underlying behaviour, see **Mask blending**.

Inv-Luma-Matte

The Inverse Luma Matte mask works the same as the **Luma Matte** mask but the transparency is inverted meaning white regions are transparent and black regions are opaque.

Multiply-Fade

The same as Multiply, but will make use of the alpha channel to calculate transparency in the source and blend layers. Since maximum transparency is premultiplied, alpha results in black. This will ignore black created through premultiplying.

Multiply-Alpha

Multiply with straight alpha. This mode assumes that the alpha has not been premultiplied onto the RGB values and will not apply a correction to the semi-transparent pixels.

Premultiply Alpha

Like how Multiply-fade will ignore the darkening caused by premultiplying, this blend mode will do the same with Alpha.

Colour Burn

Blend mode increases the contrast to darken the base colour while reflecting the blend colour. The darker the blend colour, the more intensely the colour will be applied in the base image. White as the blend colour produces no change. Using the colour burn blend mode can produce some harsh results at full opacity. The colour burn blend mode can be used to make tonal and colour adjustments to a layer.

Screen

This blend mode looks at each channels colour information and multiplies the inverse of the blend and base colous. The result is always a lighter colour. Screening with black leaves the colour unchanged. Screening with white produces white. The effect is similar to projecting multiple images on top of each other - where bright white is fully opaque, black is fully transparent and 50% grey is 50% transparent.

Overlay

Multiplies or screens the colours, depending on the base colour. Patterns or colours overlay the existing pixels while preserving the highlights and shadows of the base colour. The base colour is not replaced, but mixed with the blend colour to reflect the lightness or darkness of the original colour.

Hard Light

Multiplies or screens the colours, depending on the blend colour. The effects is similar to shining a harsh spotlight on the image. If the blend colour (light source/top layer) is lighter than 50% grey, the image is lightened as if it were screened. This is useful for adding highlights to an image. If the blend colour is darker than 50% grey, the image is darkened as if it were multiplied. This is useful for adding shadows to an image. Painting with pure black or white results in pure black or white.

Soft Light

Darkens or lightens the colours, depending on the blend colour. The effect is similar to shining a diffused spotlight on the image. If the blend colour (light source/top layer) is lighter than 50% grey, the image is lightened as it if were dodged. If the blend colour is darker than 50% grey, the image is darkened as if it were burned in. Painting with pure black or white produces a distinctly darker or lighter area, but does not result in pure black or white.

Darken

Looks as the colour information in each channel and selects the base or blend colour - whichever is darker - as the result colour. Pixels lighter than the blend colour are replaced and pixels darker than the blend colour do not change.

Lighten

Looks at the colour information in each channel and selects the base or blend colour - whichever is lighter - as the result colour. Pixels darker than the blend colour are replaced and pixels lighter than the blend colour do not change.

Difference

Looks at the colour information in each channel and subtracts either the blend colour from the base colour or the base colour from the blend colour depending on which has the greater brightness value. Blending with white inverts the base colour values and blending with black produces no change.

Exclusion

Creates an effects similar to but lower in contrast than the difference mode. Blending with white inverts the base colour values. Blending with black produces no change.

Colour Dodge

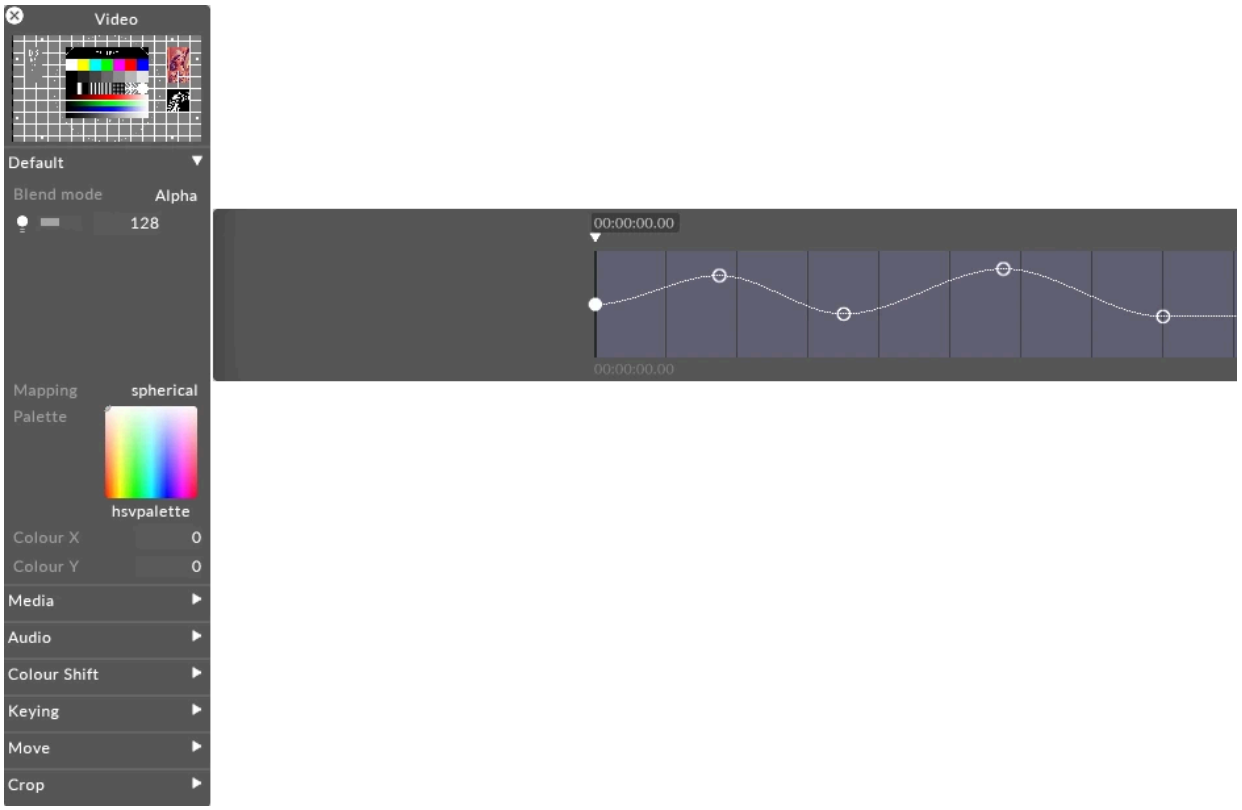
Looks at the colour information in each channel and brightens the base colour to reflect the blend colour by decreasing contrast between the two. Blending with black produces no change.

Hard Mix

Adds the RGB channels of the blend colour to the RGB values of the base colour. If the resulting sum for a channel is 255 or greater, it receives a value of 255; if it is less than 255 it receives a value of 0. Therefore all blended pixels have RGB channels of either 0 or 255. This changes all pixels to primary additive colours (RGB), white or black.

Brightness

This property (which appears as a light bulb icon) controls the brightness of the layer output.



If the layers blend mode is set to Alpha, then reducing the brightness to 0 also reduces the opacity of the layer to 0. This can be useful when you want to dissolve from one layer to the next. In that case, you can place the new layer above the old layer and increase its brightness level.

> **Note**
>
> Layers that are patched to Sockpuppet (DMX, OSC or HTTP) are made Dormant when their brightness is set to 0. This means they will not do any rendering or consume any resources until their brightness is changed to > 0. You can find more information about this here: Sequencing with Sockpuppet. Layers without a sockpuppet patch do not behave in this way.

Colour Shift

The colour shift property allows you to perform a number of colour-correction operations on the output of a layer.

Colour Shift objects can also be attached to individual video files within the Video layer.

Colour Shift property performs colour-corrections on the output of a visual layer

Colour Shift properties are:

Brightness (shift)

Changes the floor of brightness to the constant given.

When set to 0, the range of brightness is 0 to 1, thus no change is applied to the image. When set to -1, the range of brightness is -1 to 0, thus the entire image is black. When set to 1, the range of brightness is 1 to 2, thus the entire image is white.

Brightness (shift) (from left to right): -1, -0.5, 0, 0.5, 1

Contrast (scale)

When set to 1, no change is applied to the image. When set to 0, all values have been pulled together to 50% grey, thus the image is entirely grey. When set to 2, the values are pulled in the opposite direction to meeting at mid grey, thus resulting in crushed white and black values.

Contrast (scale) (from left to right): 0, 0.5, 1, 1.5, 2

Gain

Multiplies the RGB output of the layer by a constant, leaving the alpha channel untouched. Use **Gain** to dim or boost the brightness of a layer multiplicatively.

When set to 1, no change is applied to the image. When set to 0, the output is solid black while the layer remains compositionally present, so a layer with reduced alpha still blends normally with the layers below. When set to 2, the image is brightened, with any pixel values above 1 clipped to white.

Gain is applied after **Brightness (shift)** and **Contrast (scale)**, so the multiplier acts on the result of those adjustments.

Saturation scale

When set to 1, no change is applied to the image. When set to 0, the image is desaturated to black and white. When set higher than 1, the image is hypersaturated.

Saturation scale (from left to right): 0, 0.5, 1, 2, 4

Hue shift

RGB controlled

This property controls how the min/max levels and gamma corrections are applied. If set to together, then the min, max and gamma values set for the red channel are mirrored to the green and blue channels, values set on the green and blue channels will be ignored. If set to separate , the min,max and gamma values can be controlled separately for red, green and blue. The latter setting allows you to apply fine colour balance controls to the image.

Min

This sets the lowest brightness level found in the image. All pixels at this level are scaled down to zero brightness. Increasing this value enforces shadows and dark levels in the image and can be used to reduce low-level compression artifacts in an image or video frame.

Increasing min equally across red, green and blue enforces shadows, whereas increasing min on an individual channel has the effect of shifting the colour balance away from that colour. For example, increasing red min shifts the image towards cyan.

With `RGB controlled` set to *Together* (from left to right): 0, 0.3, 0.8

With `RGB controlled` set to *Separate*, red min (from left to right): 0, 0.3, 0.8

Max

This sets the highest brightness level found in the image. All pixels at this level are scaled up to the maximumm level, i.e. 1. Decreasing this value brightens any highlights in the image. This is useful when the source image is too dark.

With `RGB controlled` set to *Together* (from left to right): 1, 0.7, 0.2

With `RGB controlled` set to *Separate*, red max (from left to right): 1, 0.7, 0.2

Tip

If you set min to 255 and max to 0, the image (or single channel) will be inverted.

Invert all (left), invert red (right)

Gamma

When gamma is set to 1, no change is made to the image. Reducing gamma brightens highlights while increasing gamma darkens lowlights. The maximum and minimum brightness levels remain the same.

With `RGB controlled` set to *Together* (from left to right): 0.1, 1, 4

With `RGB controlled` set to *Separate*, red gamma (from left to right): 0.1, 1, 4

Common Layer Properties

Most of the Disguise layers share the same properties.

These are:

- Preview Thumbnail
- Blend mode
- Brightness
- Mapping
- Palette
- xCol, yCol
- Content
- Colourshift

To see a comparison table of each layer type, view the following pages:

- Content
- Control
- Effect
- Generative
- Legacy
- Previsualisation

Content

This points to the still image/video file (depending on the layer type) that defines the Bitmap/Video layers content. Selecting this property will open the Texture/Videoclip object library, which shows all of the still image/video files saved on your local hard-drive in the **DxTexture/VideoFile** folder.

To change the content inputted into the layer:

1. Left-click bitmap / video (depending on the layer type) to open the Texture/Videoclip object library.
2. Left-click the still image/video file you want to input into the layer.

> **Note**
>
> Please note: Designer does not provide video clips by default. If you want to use video or content other than the standard still images provided in Designer, you will need to import a custom still image/video file.

See the Placing media files for a project sub-chapter to understand where to place a custom still image file/video file andhow to access it in . Also save the file to a supported file format.

Content properties

Content properties are sometimes known as Video clip properties and can be accessed be right-clicking a content file thumbnail from a layer.

Content properties are unique to a content file. So, by changing the content properties on a piece of content, these properties will apply whenever that clip plays on **any** layer. The exception to this is if you've duplicated the clip instance within the VideoClip library.

Accessing content properties

Content properties can be access by right-clicking an asset from acontent layer such as:

- Video
- LegacyVideo
- Bitmap
- Audio
- Web.

[Animated GIF: Opening layer properties]

General properties

All properties displayed at the top of the editor are read only.

Number of frames

Specifies the number of frames within the file.

Resolution

Specifies the file resolution.

Codec

Specifies the Codec for the file.

Bits per Channel

Specifies the bits per channel of the file.

Has Alpha

Specifies whether the file has an Alpha channel or not.

Has Audio

Specifies whether the file has embedded Audio or not.

Original FPS

Specifies the original Frames Per Second of the file.

Data rate

Specifies the data rate in megabytes per second of the file.

Edit

The Edit properties can all be altered to suit user requirements.

FPS

Sets the Frames Per Second for the content. For example, doubling the FPS will cause to display the same frame twice in a row, and half the FPS would cause to display every other frame.

Start

Clip start: Specifies the start frame.

End

Clip end: Specifies the end frame.

In

Loop in: Specifies the in frame.

Out

Loop out: Specifies the out frame.

Filtering

Bilinear filtering

Specifies whether Bilinear filtering is on or off for that content.

Bilinear filtering is a texture filtering method used to smooth textures when displayed larger or smaller than they actually are.

Frame blending

Specifies whether frame blending is On, Off or Auto for the content.

Auto will enable frame-blending if the FPS of the content in the clip, after speed is applied from the layer, is lower than the project refresh rate.

Quantised video clips always frame blend when Auto is selected.

Deinterlace method

This option is only available for live video inputs and allows you to specify a deinterlacing method. For more information, see Interlaced video capture.

Quantisation

Quantised

When set to No, the content will play at its defined frame rate. When set to Yes, the content will play at the specified number of beats.

Beats

The number of beats the content should play back to when the Quantised property is set to Yes.

Cropping

Clip type

Specifies the clip type the content should use. This property used to be held in the direct mapping in previous versions of .

Clip to canvas: Clips the content to the canvas.

Fit into canvas: Fits the content to the canvas, but can result in 'black bars' of empty space along one axis of the content.

Stretch to canvas: Stretches the content so it fits the whole canvas, while ignoring aspect ratio.

Pixel-perfect: Displays the content, pixel perfect and does not stretch or scale in any way.

Zoom point

Crop left/right/top/bottom

Crop can be used to crop the canvas manually. Entering minus values creates additional black space around the content.

Colour shift

Colour shift

Defines the colour shift for the clip. Colour shifts allow you to specify brightness (shift), contrast (scale), saturation scale, Hue shift, RGB control as well as Keying threshold, Hardness and Key colour. See Colour shifts for more information.

Colour profile

This property allows you specify a colour profile for the content. Colour profiles consist of a colour space and gamma curve specification. See Colour profiles for more information.

Versions

Proxies

This property shows the available proxy files for the content. For example Full, 1/2, 1/4 and 1/8 resolution.

VideoAsset

This defines which video file is being played. Right-clicking this thumbnail will open the version control editor which allows for specifying which version of content is being used. For more information see Content versioning.

Mapping

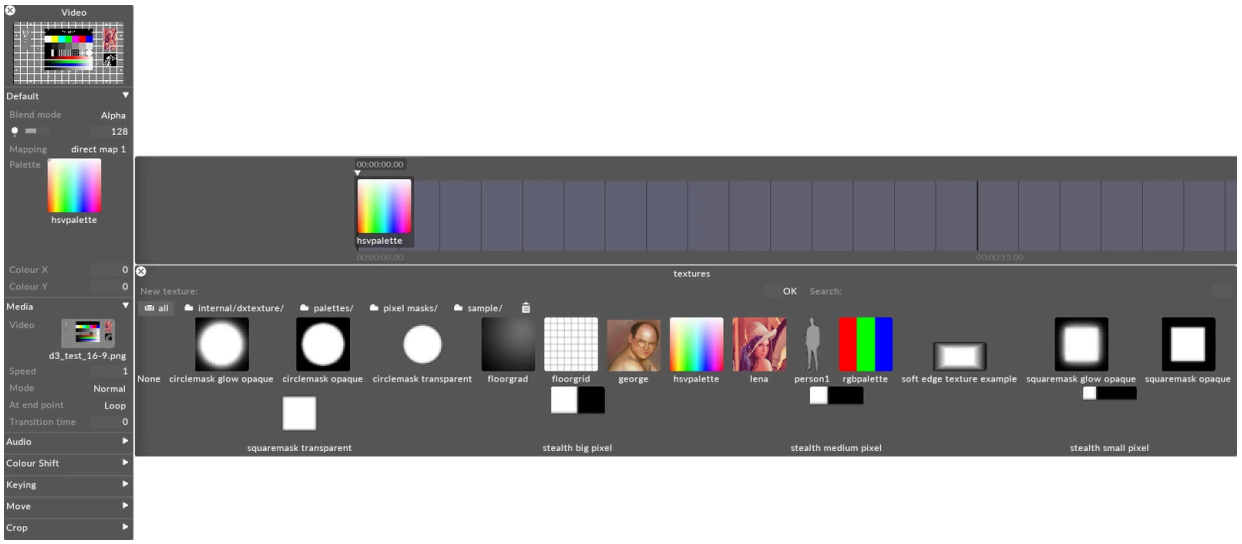
The mapping property controls how the layer output is mapped onto the screen(s) in the Stage level.

For information on mapping, including how to use the different mapping types offered by Designer, please see the chapter Content Mapping.

Palette

This points to the still image file that defines the bitmap from which the tint colour is taken. The default palette (HSVPAL) consists of the complete range of hues and saturations. Selecting this property will open the Texture object library, which shows all of the still image files saved on your local hard-drive in the **DxTexture** older.

To control the location within the current palette bitmap, and thus control the colour, you have to edit the **xCol** and **yCol** values (see the section for xCol, yCol).



To change the current palette bitmap:

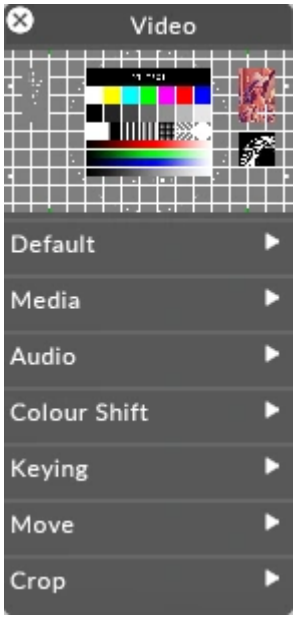
1. Left-click **palette** to open the Texture object library.
2. Left-click the still image file you want to use for the palette bitmap.

If you want to use a palette bitmap other than the standard still images provided in Designer, you will need to use a custom still image file.

See the Placing media files for a project sub-chapter to understand where to place a custom still image file and how to access it in Designer. Also save the file to a supported file format.

Preview Thumbnail

This property is a small preview window at the top of the editor showing you what the layer output looks like.

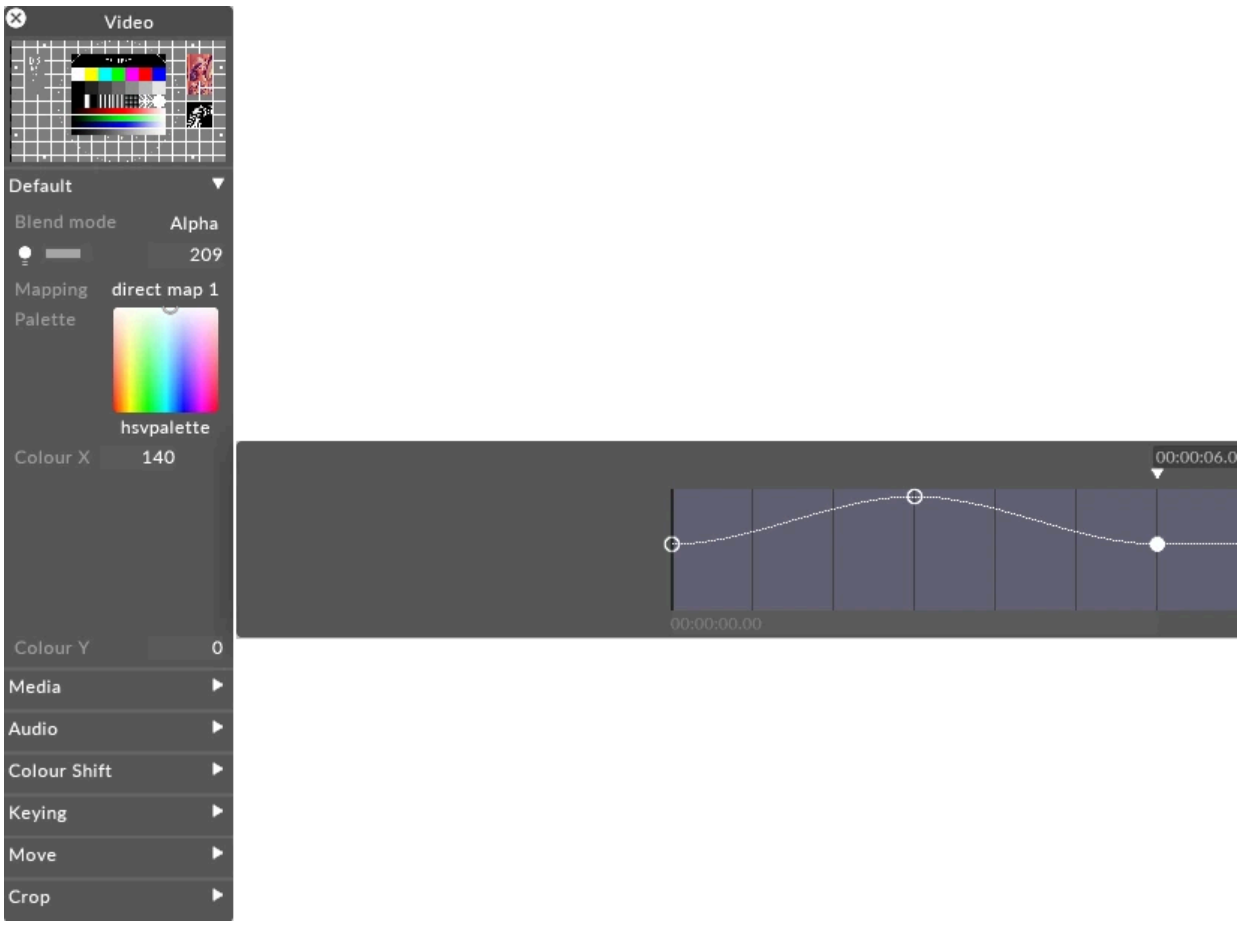


xCol yCol

These properties control the coordinates within the current palette bitmap where the output colour is sampled from. The default value is 0,0 which points at the color white (if you are using the HSVPAL palette). Multiplying white with the colors of the chosen content simply generates the original content colors. **Colour X** controls the horizontal position, where 0 is the leftmost edge and 255 is the rightmost edge. **Colour Y** controls the vertical position, where 0 is the top edge and 255 is the bottom edge.

For example, to saturate the video clip red, change the **Colour Y** value to 255 and use 0 for the **Colour X** value. These coordinates refer to the color red in the palette which is being multiplied with the colors of the existing content.

When you are using the default palette HSVPAL , Colour Y controls saturation, and Colour X controls hue.

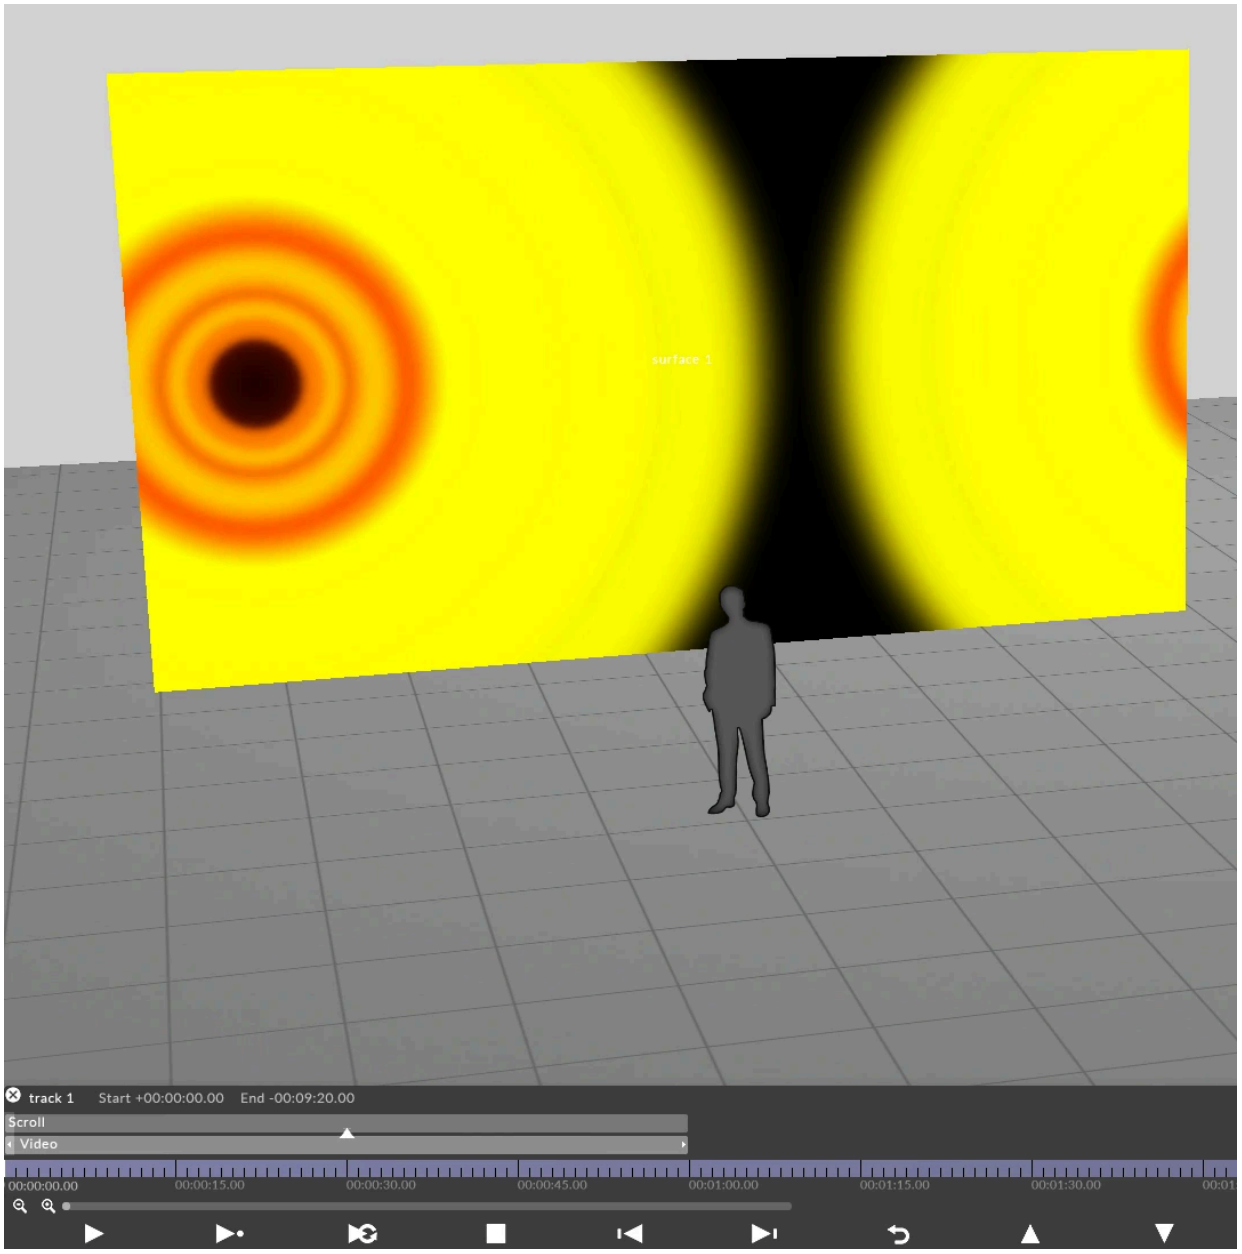


Compositing Layers

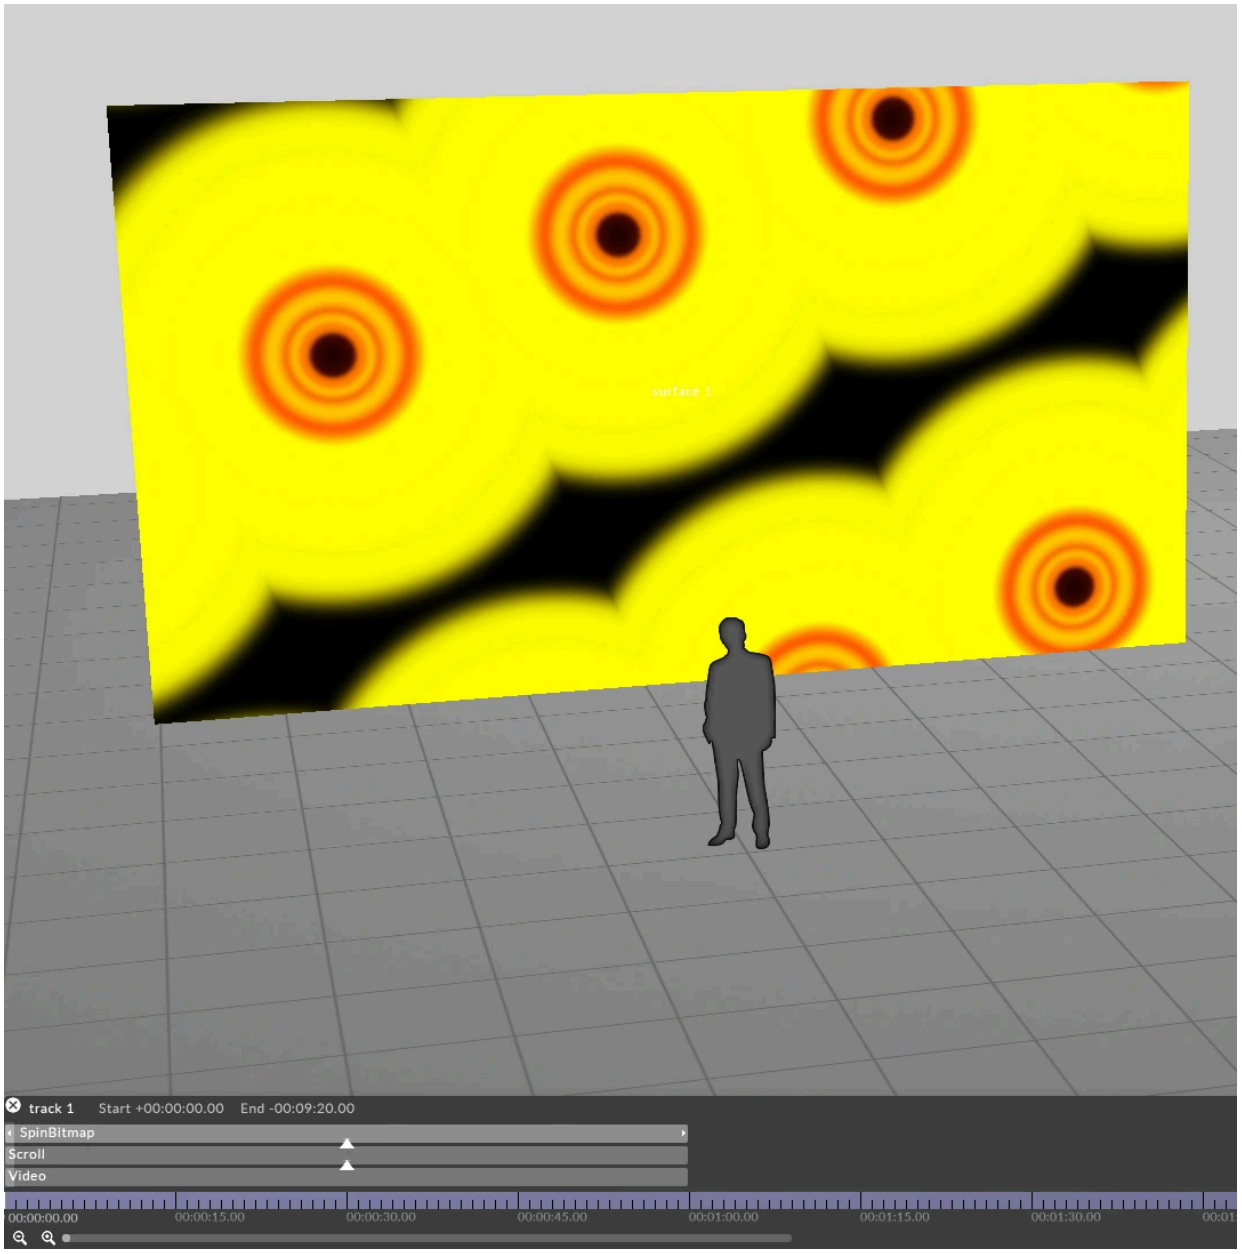
Arrows provide a way of compositing multiple layers together. For instance, you could take the output of a Video layer and pipe it into a Scroll layer, to scroll the video from side to side.

Multiple layers can be chained together, so for example, you could take the output of the Scroll layer and pipe it into a SpinBitmap layer.

1. To create an arrow between two layers, make sure the source layer is below the destination layer in the layer stack (because layers are rendered from the bottom up).
2. Position the cursor over the source layer, hold down the Alt key, press the mouse button and drag away from the source layer. You will see an arrow appear that is following the cursor.
3. Now move the mouse cursor to the destination layer and release the mouse button. This will create a new arrow between the source and destination layers.



Scrolling video content created by using an Arrow to pipe a Video layer into a Scroll layer.



To remove an arrow, hold down the Alt key and right-click the root of the arrow.

Arrow-supported layers

All content layers can be used for piping in content into another layer. However, not all layers support being piped into.

Currently, only the Bitmap and Effect Layers can be piped into.

Copying & Pasting Layers

A layer can be copied and pasted in the current track or even copied and pasted onto another.

Copying a layer

1. Right-click the layer to open the Layer menu.
2. Left-click **copy**.

[Animated GIF: Copying a layer]

[Animated GIF: Copying a layer]

Copying a layer will copy all of the layers keyframe events. It is recommended that you rename the layer to avoid future confusion. However you cannot copy and paste groups of layers. To do this, you can export and import layers. Please read the section Exporting / importing layers for more information on this feature.

Pasting a layer

1. Right-click the Track bar where you want to insert the layer on the Timeline. This will open the Track bars menu.
2. Left-click **paste layer 'LayerName'** to insert the layer copy at the currently selected point on the Timeline.

[Animated GIF: Pasting a layer]

[Animated GIF: Pasting a layer]

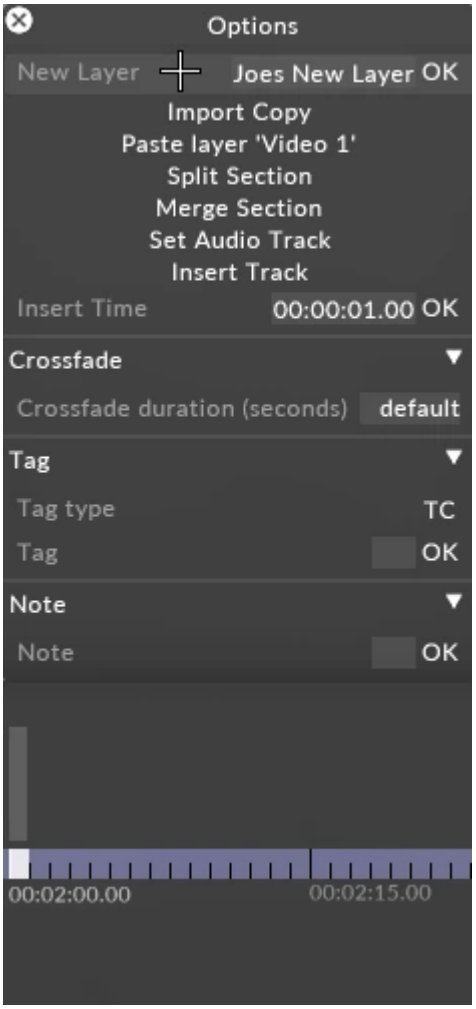
Creating Layers

A layer can be created using two methods.

You can create a layer without a name, but it is recommended that you name your layers so that the Timeline is easier to understand.

Option 1

1. Right-click the Track bar at the point on the Timeline where you want to create the layer. This will open the Track bars menu.
2. Type the name of the layer in the **new layer** text field and hit **Enter**.



A good format for naming your layers is **Layer-type description**, for example **Bitmap-layer front screen projection**. This will open a list of all of the layers available in Designer.

3. The layer menu is separated into different layer categories (content, control, effects, generative and previsualisation) with each category grouped under a collapsible separator.

4. Typing into the search box opens up separators automatically to show you matching layer types.
5. Left-click the layer you want to create. This will create the new layer at the point on the Timeline you selected. The layers editor should also open in the top-left corner of your screen. You can now edit the layer or restructure the layer.

[Animated GIF: Creating a group]

Option 2

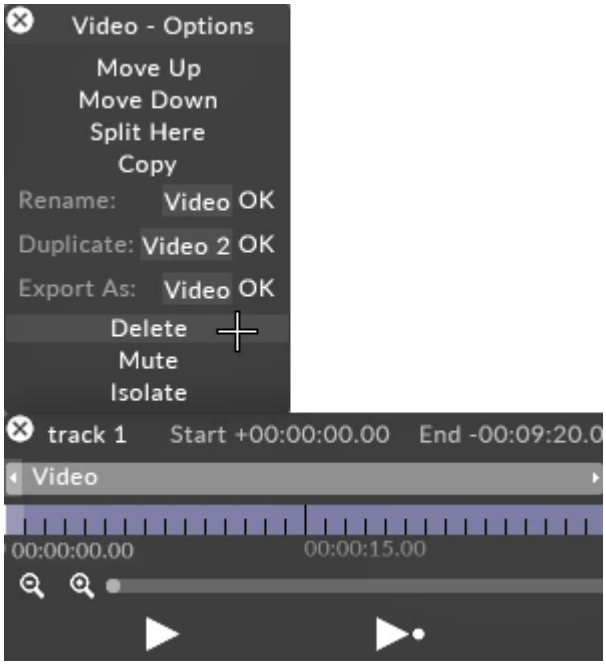
1. Select a Track bar at the point on the Timeline where you want to create a layer.
2. Hit **Ctrl+L**. A list of all of the layers available in will open.
3. Left-click the layer you want to create. This will create the new layer at the point on the Timeline you selected. You can now edit the layer or restructure the layer.

[Animated GIF: Creating a layer shortcut]

Deleting Layers

Deleting a layer

1. Right-click the layer to open the Layer menu.
2. Left-click delete. The layer will be immediately deleted from the Content Layer section.



Deleting multiple layers

1. Hold down the left Shift key and left-click and drag a selection rectangle in the Content Layer section over the layers you want to select.
2. Right-click the selection rectangle to open the Multiple Layer menu.
3. Left-click delete. The selected layers will be immediately deleted from the Content Layer section.

Disabling Layers

You can disable a layer to exclude it from rendering, sequencing, and state updates. Unlike muting, which is a temporary session-level control, disabling a layer is a project-level setting that persists across track changes, project saves, and restarts.

Use disable when sequencing isn't currently needed by the show, but took significant time to implement and may be needed again later. This allows you to preserve your work without it affecting show playback or performance.

Disabled layers are excluded from:

- Rendering and prefetch operations
- Sequencing and state updates
- Timecode-related transport behavior
- Layer stack processing

Visual indicators

When a layer is disabled:

- The layer appears with dimmed colour in the timeline
- **[DISABLED]** text is appended to the layer name
- The layer remains visible in the timeline but does not affect output

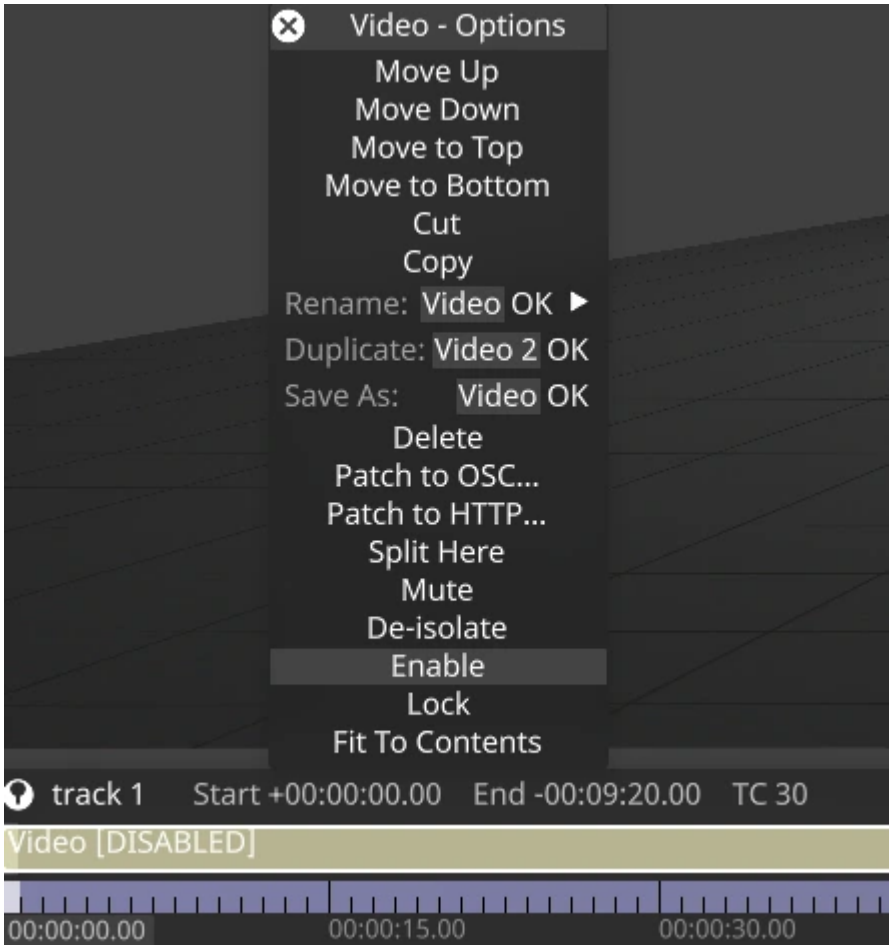
Disabling a layer

1. Hold down the **D** key and left-click the layer.

Or alternatively

1. Right-click on the layer to open the Layer menu.
2. Select **Disable**.

The layer will display with dimmed colour and show **[DISABLED]** in the timeline.



Enabling a layer

1. Hold down the **D** key and left-click the disabled layer again.

Or alternatively

1. Right-click on the disabled layer to open the Layer menu.
2. Select **Enable**.

The layer will return to its normal appearance and resume normal operation.

Disabling group layers

When you disable a group layer, all child layers within that group are also disabled. This allows you to quickly disable entire sections of your timeline structure.

Disabled vs Muted

Disabled and muted layers serve different purposes:

Feature	Disabled	Muted
Purpose	Persistent exclusion from rendering and sequencing	Temporary visual toggle
Scope	Project-level (affects all machines)	Session-level (per machine)
Persistence	Saved with project, survives track changes and restarts	Resets on track change or restart
Visual indicator	Dimmed colour + [DISABLED] text	Dark grey colour
Activation	D + click or right-click > Disable/Enable	M + click or right-click > Mute

Use **Disable** when you need to preserve complex sequencing that isn't currently needed by the show but may be required later. Use **Mute** or **Isolate** when troubleshooting to check whether specific layers are behaving as expected.

Temporary layer control

If you need a quick temporary toggle to hide a layer during the current session without affecting the project file, use the **Mute** or **Isolate** features instead of Disable. These are particularly useful for troubleshooting and checking whether specific layers are behaving as expected during show development. See Muting Layers and Isolating Layers for more information.

Duplicating Layers

Right-click the layer to open the Layer menu.

Type the new layer name in the duplicate text field (if different from the default layer name) and hit Enter. The default layer name in the text field will be the name of the layer you are duplicating with a number added to the end.

[Animated GIF: Duplicating a layer]

Dynamic Layer Naming

This feature allows users to rename layers with tags that will be automatically replaced in the rename process by specific values in the layer.

> **Note**
>
> The feature does not keep updating the names as you sequence, the rename is a one-time action.

Workflow

When renaming a layer either by right-clicking on the layer or pressing Ctrl+r this feature is available.

1. In the layer's Rename field insert words between curly braces { } to create a dynamic tag.

2. Press **Enter** or click **OK**. The text is automatically replaced with special values based on the tags entered.

Example using "blend mode" as a tag

The tags that are supported are:

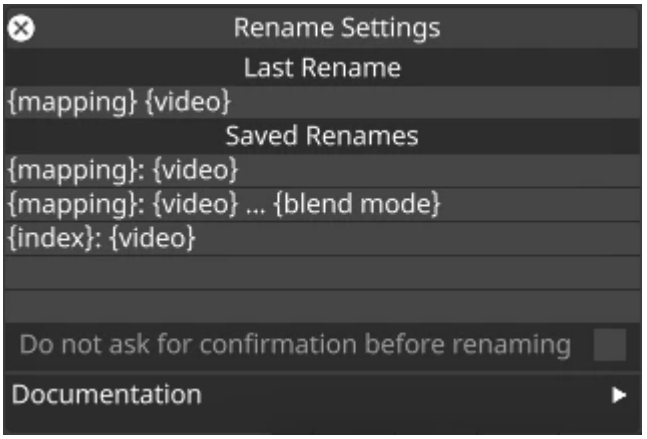
- `{type}` is replaced by the type of the layer.
- `{index}` is replaced by an incrementing index starting from 1.
  - You can append a number after "index" as the start number (e.g. `{index5}`).
- `{currentname}` is replaced by the current name of the layer.
- `{field}` will be replaced with the name of the first keyframe in the field specified.
  - **Examples**: `{mapping}`, `{speed}`, `{blend mode}`.
  - If any field in the rename is not present in the layer the `{field}` text will be removed from the final name.

> **Note**
>
> Typing in a layer name with mismatching { } tags will stop renaming and make the 'Rename' widget turn **red** with the error explained in a tooltip.

Reusing rename patterns

Sometimes you might want to reuse the same rename tag pattern for several layers as you are working.

Clicking on the arrow next to the rename field will open the "Rename Settings" widget:



Rename Settings widget

This widget is auto-populated with the last rename pattern and includes some user-editable text boxes for the user to store renames that they would like to reuse. The contents of these text boxes will persist through closing the widget and restarting the project.

Renaming multiple layers

When renaming multiple layers the user is presented with a confirmation dialogue showing a preview of the renames to be generated. At this stage, the user can either abort or finish renaming the layer.

This dialogue can be toggled off with a toggle.

Documentation

You can find in-app documentation of the supported tags in the Rename Settings widget at the bottom for quick reference.

Editing Layers

Editing layers involves using the Layer editor and the Keyframe editor

What is the Layer editor?

The Layer editor contains a series of properties which are specifically set for each individual layer. All of these properties can be edited.

Opening / closing the Layer editor

To open the Layer editor:

- Left-click the layer from the Timeline.

For information on how to create a layer please see the sub-chapter Creating layers.

If the currently selected Track bar is underneath the extent of the layer (not including the extender tabs on either side), the Layer editor will open at the top left of your screen. If the currently selected Track bar is outside the extent of the layer, Designer will close the editor. This is to ensure that you only see editors for layers that are active.

The layer editor looks like a standard object editor, except that it has a small preview window at the top of the editor showing you what the layer output looks like.

To close the Layer editor:

- Left-click the layer in the Timeline, or left-click the close button (x icon) in the top-left corner of the Layer editor.

Hit Ctrl whilst left-clicking a layer in the Timeline to view multiple Layer editors simultaneously.

Layer properties

Each layer in Designer has a specific set of properties. Please read the chapter Layer types to understand each layer types individual properties. In addition, please read the next sub-chapter Common Layer Properties which explains the properties that are shared by most layers that produce visual output.

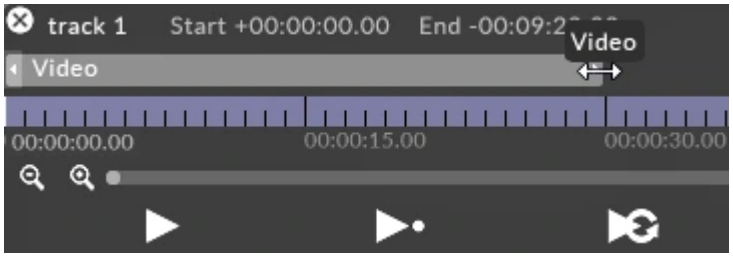
Extending Layers

You may want to extend a layer so that it renders content for a longer section of the Timeline.

Extending a layer

1. Left-click the layer to open two small tabs at the layers edges.
2. Hover your mouse cursor over the layers edges. You will notice the cursor change from a cross hair to a double ended arrow.
3. Left-click and drag the layers extender tabs to the left or right to extend the layer.

[Animated GIF: Extending a layer]



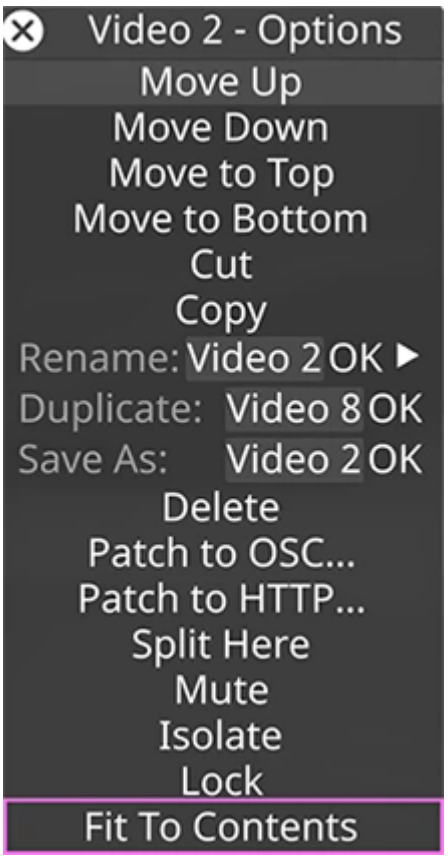
Extending a layer does not modify its keyframe events, they remain in the same position. If you reduce the extent of a layer, any key-frame events outside the layers extent remain there; if and when you extend the layer again, those key-frame events become accessible again.

A Layer that is currently Locked or Anchored cannot be extended.

Fit To Contents

To fit the layer to its contents:

Right-click the layer to open its context menu, then select the appropriate option.



This action updates both the clip's duration and the visual length of the layer on the timeline.

- If the media clip is shorter than the current layer duration, the layer will shrink to match the actual duration.
- If the media clip is longer than the current layer duration, the layer will extend to fully display its content.

Grouping Layers

When working with large numbers of layers, it is convenient to group related layers together. This reduces the vertical height of the Timeline and makes it easier to move large numbers of layers.

To arrow a layer in to an existing group, the layer needs to be on top of the group in the compositing order before arrowing. Arrowing a layer from elsewhere on the timeline will not work.

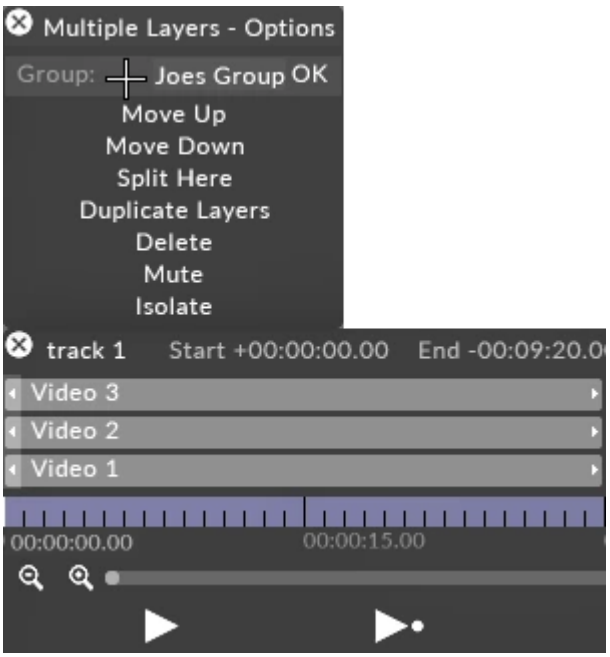
You can also import and export a group of layers to the current track, or even onto another track in the Timeline. Please read the 'Importing and exporting layers section above for more information on this very useful feature.

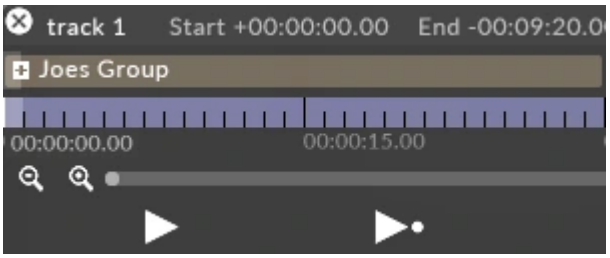
How to group layers

1. Hold down the left **Shift** kkey and left-click and drag a selection rectangle in the Content Layer section over the layers you want to group.
2. Right-click the highlighted layers to open the Layer menu.

3. Type the name of your group into the **group** text field and hit **Enter**. The grouped layers will turn orange.

[Animated GIF: How to group layers]





Editing grouped layers

Left-click the + to expand the group layer.

The layers are revealed below the group layer and can be edited in the normal way.

Collapsing a group of layers

Click the - button on the Group layer.

Ungroup a grouped layer

1. Right-click the Group layer to open the Layer menu.
2. Left-click **ungroup**.

Removing a layer from the group

1. Make sure the group is expanded
2. Right-click on the layer you wish to remove from the group
3. Left-click on **Extract**

Adding a layer to a group

Hold down the **Alt** key and left-click drag an arrow from the layer to be group, to the group layer.

The layer will be added to the group layer.

Isolating Layers

Sometimes it is useful to only see the output of a single layer when you have a stack of layers.

To see the output of a single layer:

1. Hold down the **I** key and left-click the layer. The other layers turn grey to indicate that the selected layer has been isolated.
2. Left-click anywhere in the Content Layer section to return the screen to the normal view.

Or alternatively

- Right-click on the layer and select the Isolate option.

Layer Colour Rules

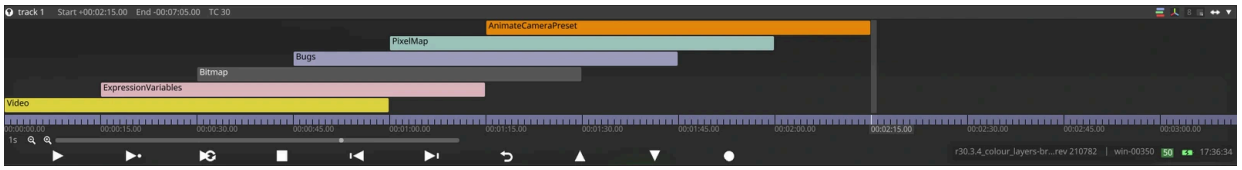
This feature allows users to setup rules that will determine the colour of layers on the timeline based on the specific properties of the layer.

The Colour Layer Rules feature is available in designer versions r30.8 and above.

There is a global layer colour ruleset which can be found under in the dashboard under **d3 > Project Settings > User Interface**. For convenience, we have supplied a default layer colour ruleset based on the category of each layer called “categories” here. If you want to use a different default you can do so by setting up a new template project in d3Manager.

Each track can also be assigned it’s own layer colour ruleset which will override the global one. This can be found under **Track > Special Settings**. You can always access the layer colour ruleset used by the current track by clicking on the new layer colour ruleset button next to the 3D manipulators button to the right of the Track widget.

Both global and track rulesets can be set to **None** to disable the feature.



Coloured Layers

If you want to customize your layer colours you can follow these workflows.

Selecting and Creating Rulesets

Layer colour rulesets are like any other object in Designer. You can select, edit, create and delete them by left/right-clicking on them either in project settings or in a specific track.

If a track has a ruleset assigned it will apply it’s own ruleset instead of the global one. If it has None assigned it will use the global one. The same ruleset can be assigned to multiple tracks and globally at the same time. Layerstacks always use the global ruleset.

Editing Rulesets

To edit a layer colour ruleset, right-click on it. A ruleset is composed of a set of individual rules. These rules apply in order from top-to-bottom in the editor. If a rule is found to be true for a particular layer it will take that colour, prioritising the rules at the top of the ruleset. To re-order the priority of rules simply left-click and drag to change their order in the editor. The priority change will only apply after the dragged rule is released.

Rules are added to rulesets by selecting the ”+” button at the bottom of the ruleset editor and can be removed by pressing the ”-” button on the far right of each rule.

Editing Rules

Each rule can be edited by clicking on the fields in the ruleset editor. They have the following fields:

- **Enabled** - Turns the rule on or off (which will persist)
- **Key** - This determines the “Key” of the layer that will be evaluated by the rule. Options for this are:
  - **Name** - Name of the layer
  - **Property** - The first keyframe of a property the layer (e.g. brightness)
  - **Type** - The type of the layer (e.g. “VideoLayer”)
  - **Category** - The category the layer falls under (e.g. “Content”)
- **Property** - If **Property** is selected as the key, this determines the name of the property to test.
- **Comparison** - The comparison function to match the key against. Options for this are:
  - **Contains** - (e.g. “video”, “background” etc.)
  - **Equals** & **!=** (Not Equals) - approximate when using numerical values
  - **>**, **<**, **<=**, **>=** - Only valid for numerical values
- **Value** - This is the user-entered values to match the key against. If the key matches this value, then the rule applies.
- **Colour** - The colour to apply if the key matches the value.

Importing and Exporting Ruleset

Layer colour rulesets can be exported and imported like normal resources. You can learn about how to do this here. Layer colour rulesets have no dependent resources to exporting them is very easy.

Rulesets in Multi-Machine Sessions

Rulesets are shared between all machines in a multi-machine session and are editable by any user like all other resources. They can also be locked and unlocked like normal resources. This allows you to setup a consistent colour layer look for all users in your project.

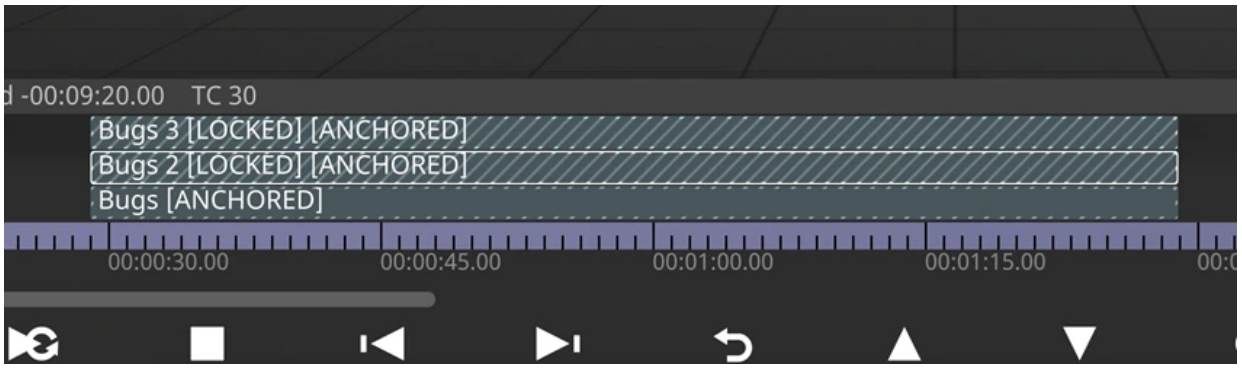
Other Layer Colours

Layer colours are not solely determined by ruleset. When a layer is coloured for another reason it will override the colour of the ruleset.

Here are some examples of rule overrides:

- Externally controlled layers are always green.
- Group layers are always beige and do not react to layer colour rulesets.
- Muted layers are always black.
- Colours that are in error are always red.
- Layers will missing media or missing versions will have the error colour overlaid on top of the ruleset colour.

Locking and Anchoring Layers



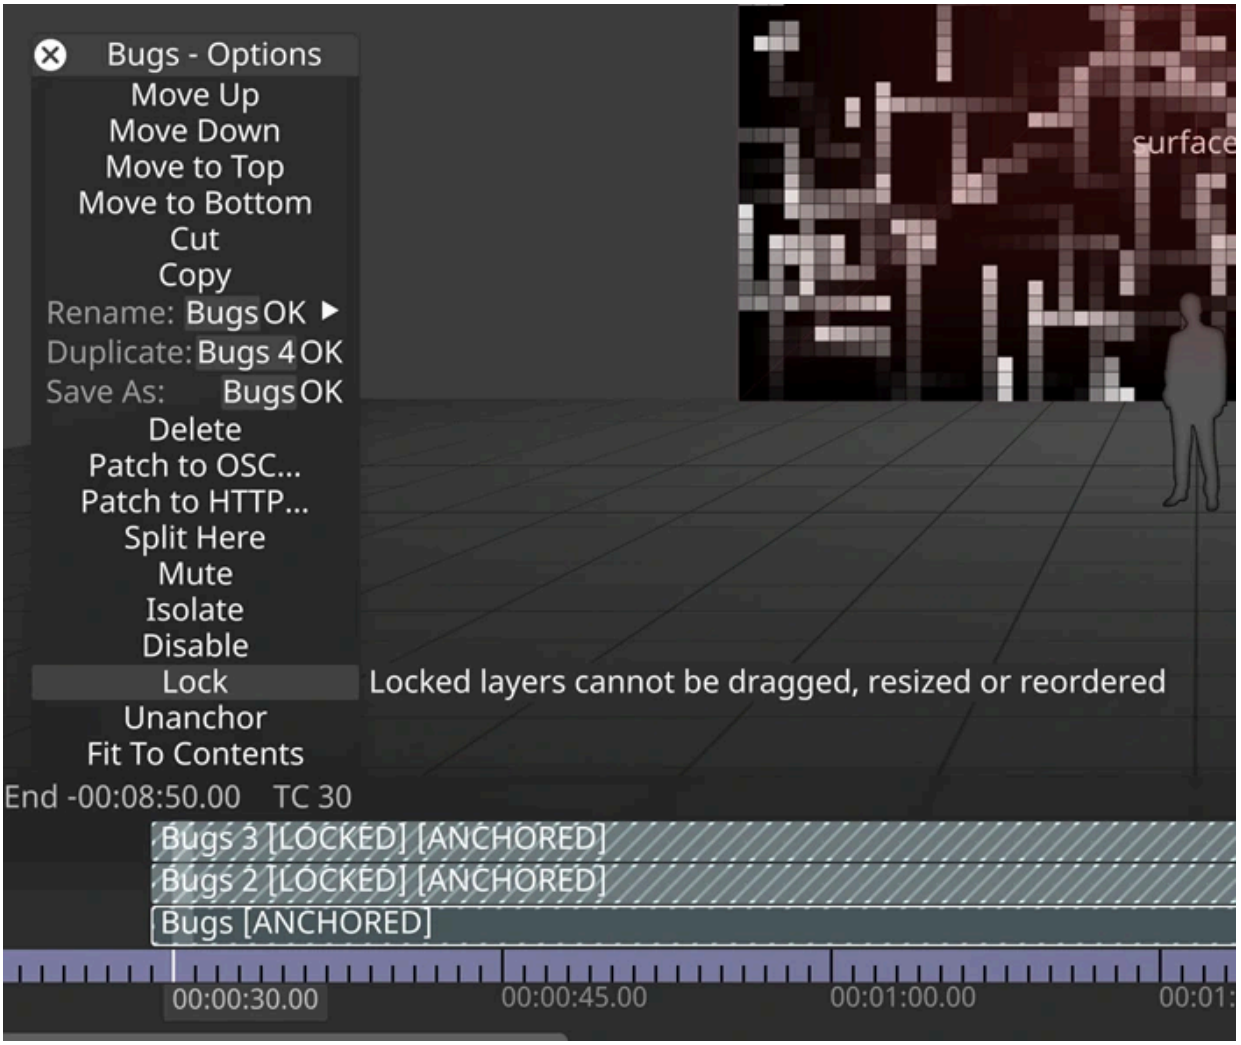
To prevent accidentally changing sequenced layers, Designer supports two different forms of restriction: Locking and Anchoring.

A Locked layer cannot be edited at all until unlocked, while an Anchored layer cannot be moved, resized or split but can otherwise be edited as normal. Locking a layer does not modify any values or keyframe events.

A Layer can be both Locked and Anchored; this has no effect beyond Locking, but a Locked Anchored Layer remains Anchored if unlocked.

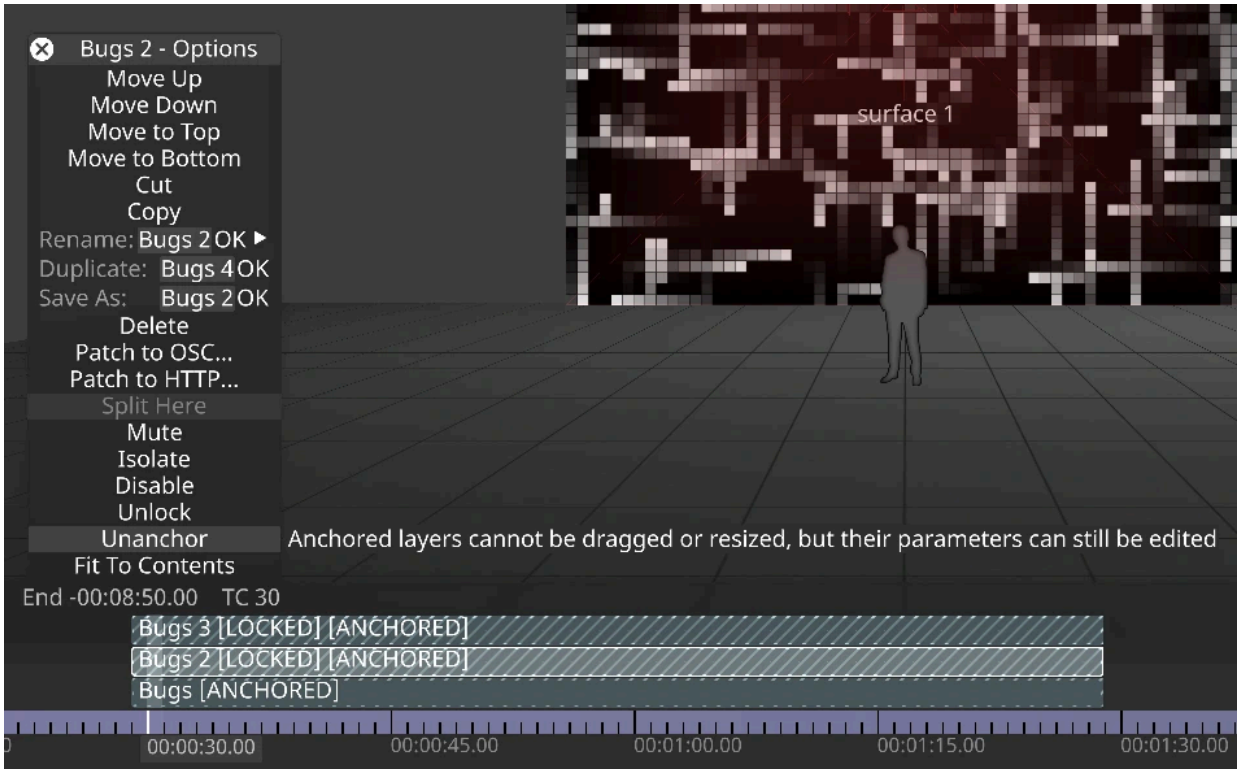
To lock or anchor a layer

1. Right-click the layer to open the **Layer** menu.
2. Left-click **Lock** or **Anchor**.



To unlock or unanchor a layer

1. Right-click the layer to open the **Layer** menu.
2. Left-click **Unlock** or **Unanchor**. This will unlock the layer and allow the user to edit it again.



Layers can also be locked and anchored from the main Layer Editor by right-clicking the header.

Moving Layers

Moving and re-ordering layers is particularly useful when you have a stack of layers.

Layers arranged in a stack are rendered in bottom up order: layers at the top are composited over layers at the bottom.

Moving/re-ordering a layer can be done in three ways.

Option 1

- Left-click and drag the layer left or right. You cannot drag the layer up or down. This method can be used to move multiple layers when you have a selection rectangle. Please read the Selecting layers section for more information on selection rectangles.

Option 2

1. Right-click the layer to open the Layer menu.
2. Left-click **move up** or **move down**.

Option 3

- Left-click the layer and hold **Ctrl**+ **Alt**whilst using the keyboard arrow keys to move the layer up, down, left or right. Moving a layer moves all keyframe events.

A Layer that is currently Locked or Anchored cannot be moved along the timeline, but an Anchored layer can be reordered within the layer stack.

MultiLayer Editor

In r17.3 multiple layers can be edited simultaneously making it easier to assign common values or objects across a selection of layers in one action.

Using the MultiLayerEditor

1. Hold **Shift**, left-click and drag a selection over multiple layers
2. Left-click your selection and a MultiLayerEditor will open that contains all common values to the layers selected.

[Animated GIF: MultiEdit Layers]

Tips for using the MultiLayerEditor

- Shift + Click to add an un-selected layer to the selection, or remove a layer from the selection.
- A MultiLayerEditor is created for a layer selection, when more than one layer is selected.
- A MultiLayerEditor is also created when a single GroupLayer is selected.
- If a selection contains only GroupLayers, a MultiLayerEditor is not created.
- If a selection contains Layers and GroupLayers, a MultiLayerEditor is created for the Layers only.
- Opening a MultiLayerEditor will not close existing Layer editors for the selected layers.
- Adding a layer to the selection or removing one from the selection will create a new MultiLayerEditor with the new selection.
- A MultiLayerEditor can only be opened for layers when the track cursor is within all of the selected layers.
- The MultiLayerEditor will show all the common fields of all selected layers. The fields will be under the same tabs.
- The fields in the MultiLayerEditor show an aggregation of all the values of the selected layers.
- The tooltip of the ValueBox will contain the current values and associated layer names.
- Dropping a new keyframe will create a new keyframe in all selected layers.
- Modifying an existing keyframe will modify the keyframe in the layers where the keyframe exists.
- Deleting a keyframe will delete the keyframe in the layers the keyframe exists.
- Popup menu actions in the keywidget, like changing interpolation type apply to all selected layers.

- Keyframe navigation is the same as the Layer editor.

Limitations

- Keyframes for each layer are all visible in the same keyframe editor, which can make it hard to know which keyframe belongs to which layer. There is no preview in the MultiLayerEditor
- Keyframes for layer are all visible in the same keyframe editor, which can make it hard to know which keyframe belongs to which layer.
- Some fields may have the same display name but different internal names and will therefore not appear. Some fields may also have the same name but different values, these should not appear. An example is: multi-selecting audio and video layers misses volume control and at-endpoint control.
- The MultiLayerEditor cannot aggregate fields that are dynamically created by a custom layer editor. Therefore OpenModule is not compatible and neither are dynamic fields of a notch block.
- Some fields may have the same name, but represent different things and therefore appear when they shouldn't. An example is: TimecodeReadout and Gradient Position X and Position Y parameters are incompatible with one another.

Muting Layers

You can mute a layer to temporarily disable it, allowing you to see layers behind it in a stack of layers.

Mute is a **session-level control** that affects only the current machine. The mute state remains active while the corresponding track is selected. Each time the track is changed or the project is restarted, all layers are reset to the default unmuted state.

Muting a single layer

1. Hold down the **M** key and left-click the layer.

Or alternatively

1. Right-click on the layer and left-click the Mute option.

The layer will turn dark grey to indicate that the selected layer has been muted.

Unmuting a single layer:

1. Hold down the **M** key and left-click the layer again.

Or alternatively

1. Right-click on the layer and left-click the unmute option.

The layer will return to its original colour.

Persistent layer exclusion

If you need a layer to remain excluded from rendering and sequencing across track changes, project saves, and restarts, use the **Disable** feature instead of Mute. See Disabling Layers for

more information.

Renaming Layers

To rename a layer:

1. Right-click the layer to open the **Layer** menu.
2. Type the new layer name in the **rename layer** text field and hit **Enter**. The layers name will update instantly. A good layer naming format is Layer-type + description.

Save as and importing layers

Layers can be saved to the layers library, from where they can be imported back onto the Timeline in another location.

Importing a layer makes a copy of the saved layer; changing the layer that you saved to the layer library does not change the copies.

This allows you to transfer layers or groups of layers in the current track, or even from one track into another track. This is extremely useful when sequencing, as you can store these saved layers in the Layers Library as templates to avoid having to repeat actions when creating layers

This functionality used to be called Import & Export in previous releases.

Saving a layer

1. Right-click the layer to open the Layer menu.
2. Type the name of your exported layer (if different from the defaultlayer name) in the **Save as** text field and hit **OK**. This will save the layer in the Layers Library.

   [Animated GIF: Saving a layer as a group]

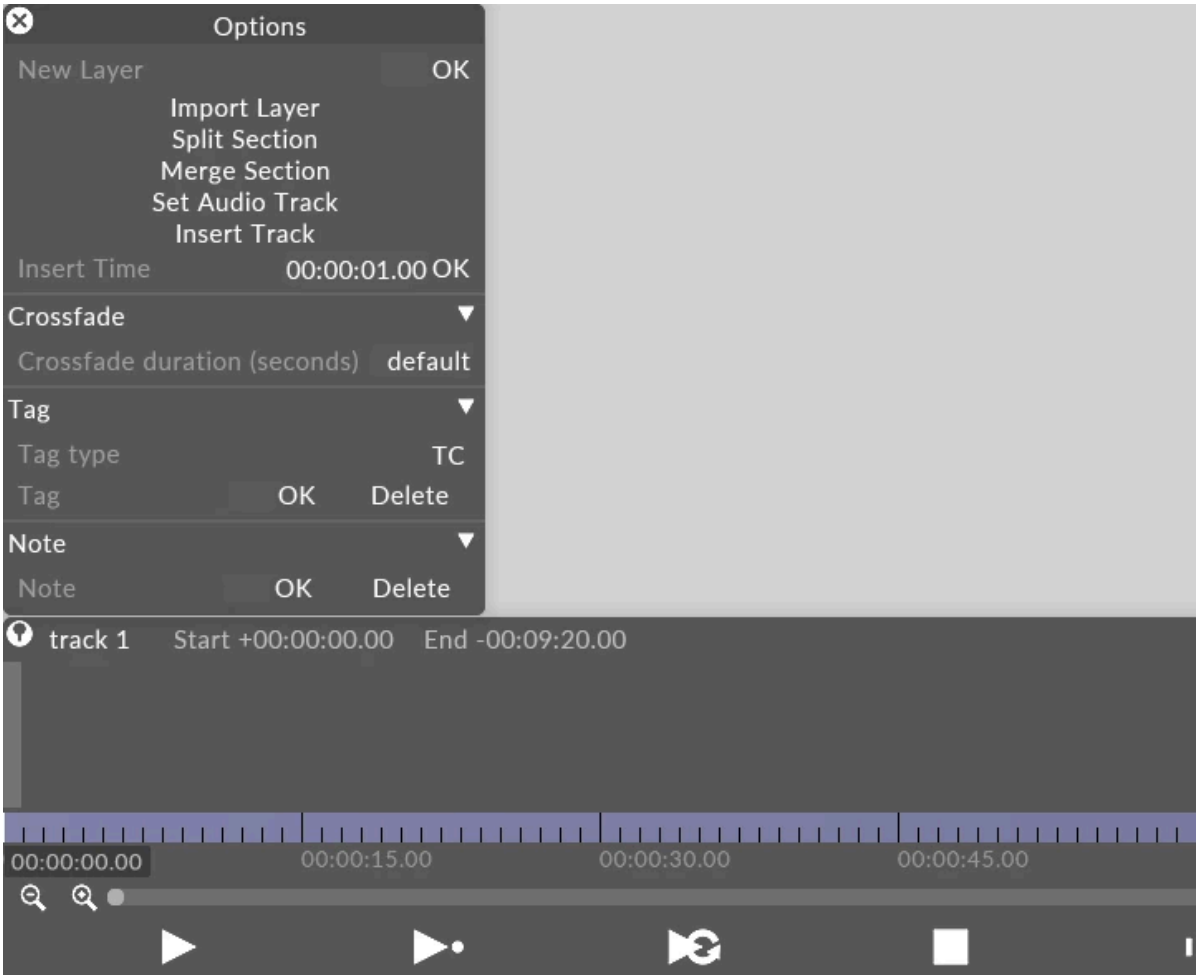
   Saving a layer will copy all of the layers keyframe events.

   [Animated GIF: Saving a layer as a group]

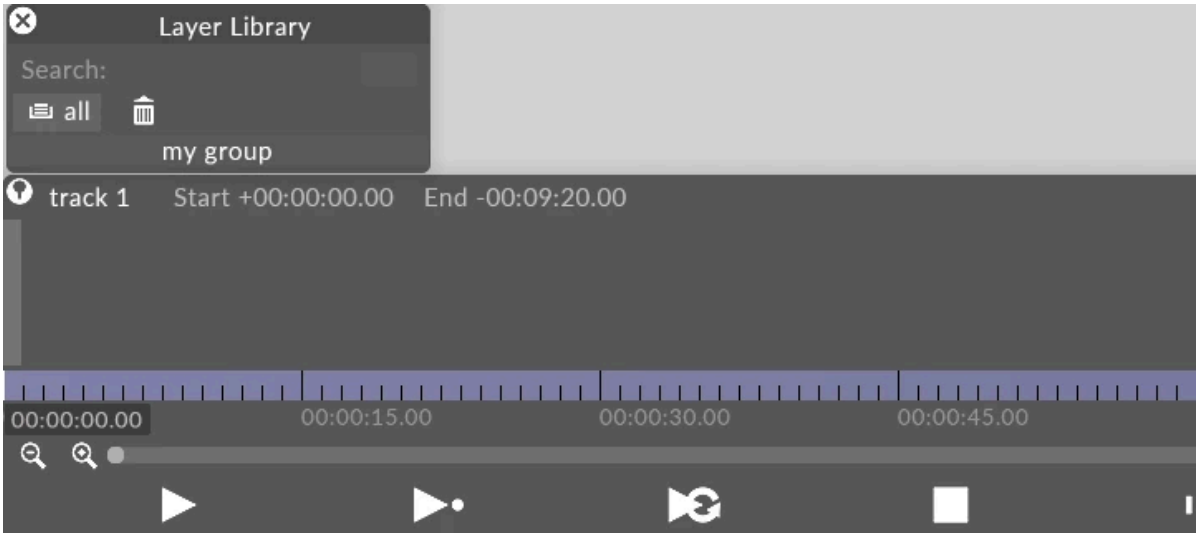
Importing a layer

1. Right-click the Track bar at the point where you want to import the layer on the Timeline. This will open the Track bars menu.

2. Left-click **import layer**. This will open the Layers Library.



3. Left-click the saved layer from the Layers Library.

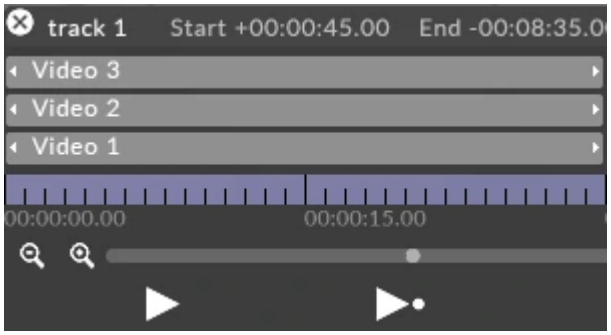


The layer will be added to the track at the currently selected point on the Timeline.

Selecting Multiple Layers

To select multiple layers:

- Hold down the left **Shift** key and left-click and drag a selection rectangle in the Content Layer section over the layers you want to select. This allows you to select a range of layers.



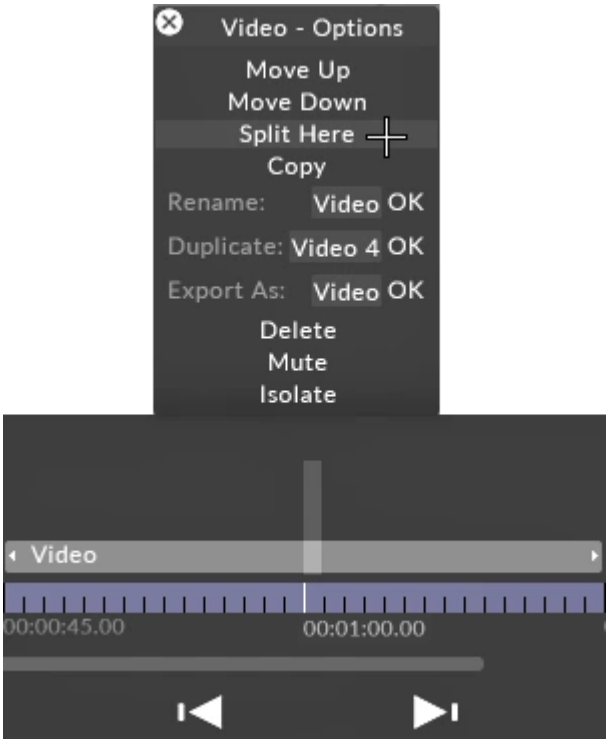
Selecting multiple layers will copy the selected layers keyframe events.

- Left-click anywhere in the Content Layer section to clear the selection rectangle.

Splitting Layers

To split a layer

1. Left-click a Track bar at the point on the Timeline where you want to split the layer.
2. Right-click the layer to open the Layer menu.
3. Left-click **split**. This will split the layer at the currently selected Timeline position into two shorter layers.



Splitting a layer does not modify its keyframe events, they remain in the same position. If you split the layer, any key-frame events outside the layers extent remain there; if and when you extend the layer again, those key-frame events become accessible again.

A Layer that is currently Locked or Anchored cannot be split.

Working with Layers

This section includes:

- Editing Layers
- Multi Layer Editing
- Creating Layers
- Deleting Layers
- Copy & Pasting Layers
- Duplicating Layers
- Moving Layers
- Extending Layers
- Saving and Importing Layers

- Numeric Keyframes
- Object Keyframes
- Option Keyframes
- Multiple Keyframes
- Keyframe Toggle

Keyframing Toggle

Keyframes can easily be stripped from a keyframe editor with the click of a button.

Keyframe Toggle

With the new Keyframe toggle available for every keyframable attribute on a layer, you can quicky clean up your sequencing on the timeline by simply toggling timeline keyframes off.

Keyframing Overview

Keyframing is used to animate a layer's property over time.

What is the Keyframe editor?

Keyframing enables you to animate a layer's property over time. A layer's property can be accessed from its layer editor.

If you are unfamiliar with the Layer editor, we recommend reading Editing layers.

Opening a Keyframe editor

To open a Keyframe editor

- Left-click a Layer property to open the Keyframe editor. Opening a Keyframe editor will close any other open Keyframe editors.

Keyframe toggles

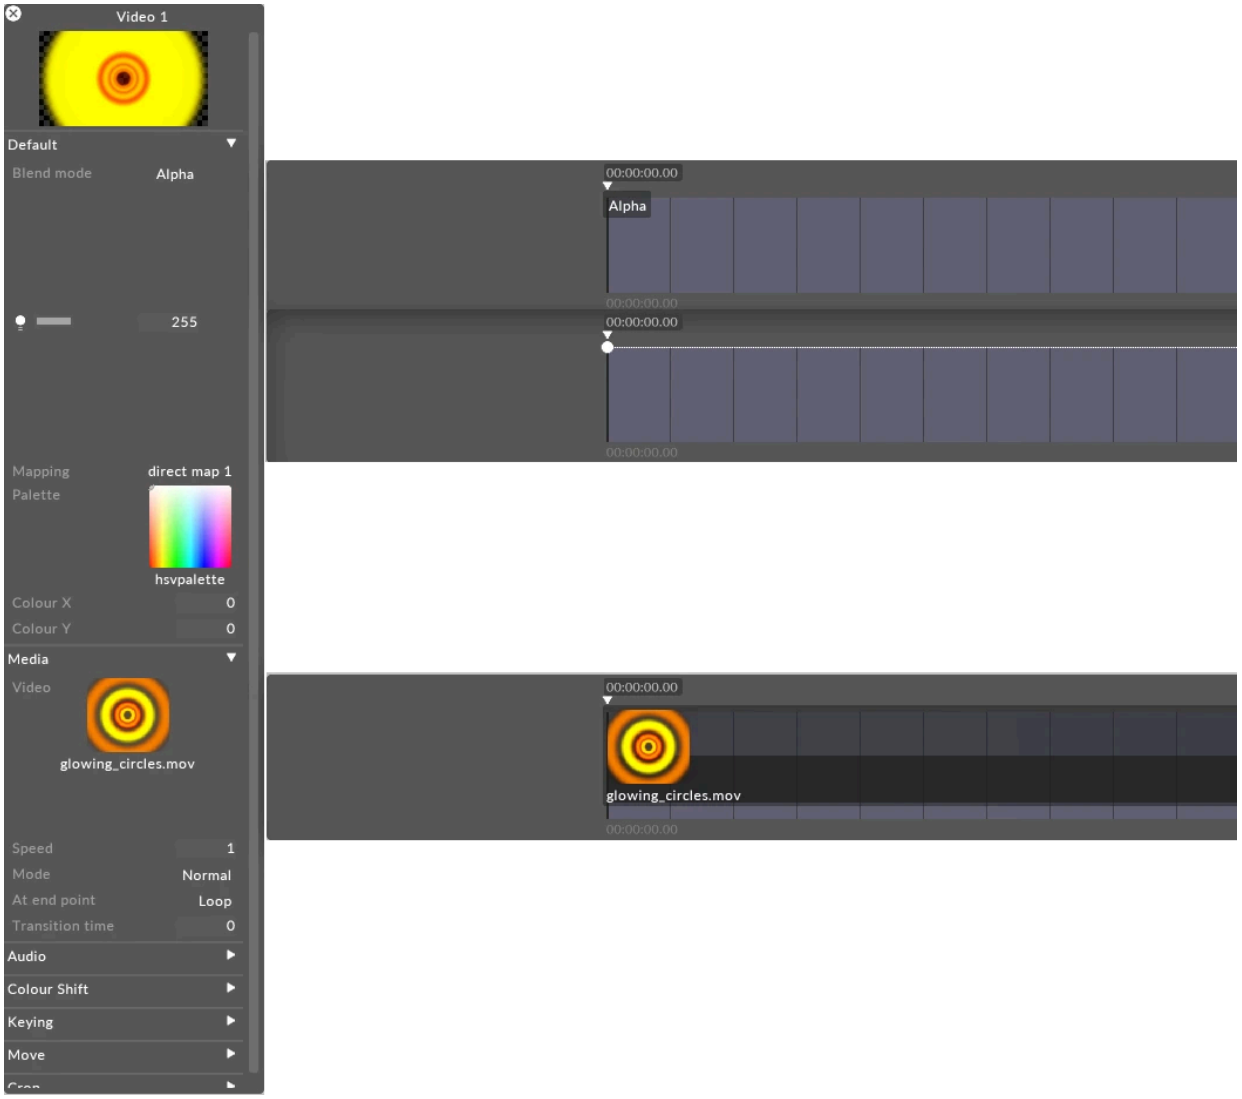
- Beginning with r20, Keyframe toggles have been added, allowing you to reset all keyframes for an attribute within a layer. Enable and disable keyframes easily by clicking on the keyframe toggle icon. For more information on Keyframe Toggles, please visit this link.

Opening multiple Keyframe editors

- Hold **Ctrl** whilst left-clicking the properties of a layer editor to open multiple Keyframe editors.

Keyframe editor types

There are three different types of Keyframe editors. Examples of these three types are described below using the example of a Bitmap layer and its editor, and in the three following sub-chapters. Please read the Editing objects sub-chapter for more information on object property types.



Keyframe types

Numeric

A numeric Keyframe editor allows you to animate a numeric value when editing a numeric property, in this example, **brightness**.

Option

When animating an option-based property, the Keyframe editor restricts you to a fixed **option** list of valid values. For example, when animating blendMode, you can only choose from the supported blend modes.

Object

An object Keyframe editor refers to another object when animating an object property.

Navigating Keyframe editors

1. Left-click a Track bar in the Timeline to play forwards or backwards in the currently selected Track. Notice that as you navigate the Timeline, the currently open Keyframe editor will adjust accordingly. The Keyframe editor shows a bar of time just before the current Timeline position and a certain number of bars after it. The number of bars depends on the screen width and the current zoom factor.
2. Left-click the Keyframe editor and hold **Alt** whilst moving the mouse scroll wheel to zoom in or out (you can also use the - and = keys while the Keyframe editor is selected). The mouse must remain focused on the Keyframe editor to successfully zoom.

Snapping

The snapping behaviour in the Keyframe editor is relative to the zoom level of the editor. By default, this zoom level will be in sync with the Timeline zoom level unless you have manually adjusted it as explained above. Snapping behaves in 3 different ways based on your zoom level:

Zoom Level	Snapping Behaviour	Example
`1s`, `2s`, `5s`, `15s`, `Max`, and quantised tracks regardless of zoom level	**Quarter Second** Keyframes will snap to the nearest* quarter second interval in frames.	With a 30fps Timeline keyframes will snap to the 0th, 7th, 15th and 22nd frame of a each second.
`15f`, `10f`, and `5f`	**Half Timestep** Keyframes will snap to the nearest* interval determined by the half of the zoom level. So if the zoom level is `10f` the snapping will be every 5 frames.	With a 30fps Timeline and a zoom level of 5f keyframes will snap to the 0th, 2nd, 5th, 7th, 10th, 12th, etc... frame of a each second.
`1f`	**One Frame** Keyframes will snap to every individual frame defined by the Timeline's frame rate.	N/A

** Snapping of all types is relative to the frame rate of the Timeline and will always round **down** when the interval lands in the middle of two frames.*

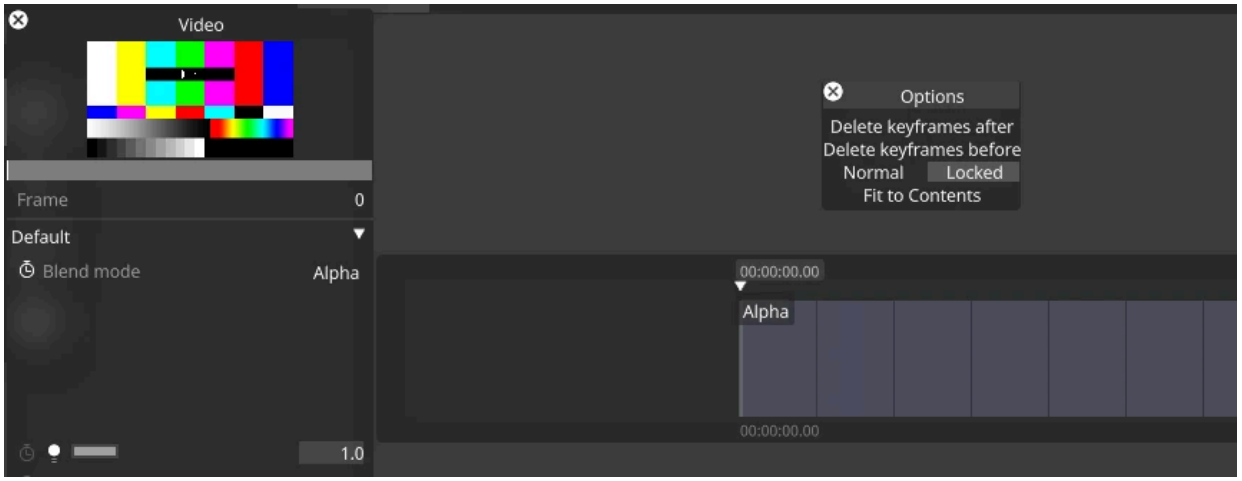
Common Keyframe properties

All three Keyframe editor types have the following things in common:

- They consist of a sequence of **Keyframe** or **key values**, which can be either **option** choices, **numeric** values or **objects**. In the case of numeric properties, the value between the keyframes is generated according to a line or curve that passes through the keyframes.
- A beat of time appears as a single vertical line. Each group of four lines represents a single Track bar and is marked with a bar number just below it. The background colour of the Keyframe editor matches the colour of the corresponding Track bar in the Timeline.

- Just above the Keyframe editor is a small triangle with a timecode just above it. This is the 'Now' pointer; it indicates the Timeline position that is currently being rendered to the stage. Editing a Keyframe moves the now pointer to the time of that Keyframe, thus allowing you to instantly see the effect of changing the value.

Keyframe Options



Keyframe options

Right-click on the border of a keyframe timeline, and the Options window will appear with the following options:

- **Delete keyframes after**
- **Delete keyframes before**
- **Normal:** When there are looping keyframes after a section break and the playhead hits that section break, it will play the keyframes after the section break anyway.
- **Locked:** When there are keyframes after a section break and the playhead hits that section break, it respects the section break and will not play the keyframes.
- **Fit to Contents**: Shortens the layer length to the same length of time as the last keyframe of that layer.

Keyframes in the Track Widget

From r30.8, all keyframes on layers will appear in the timeline as small ticks at the bottom of each layer.

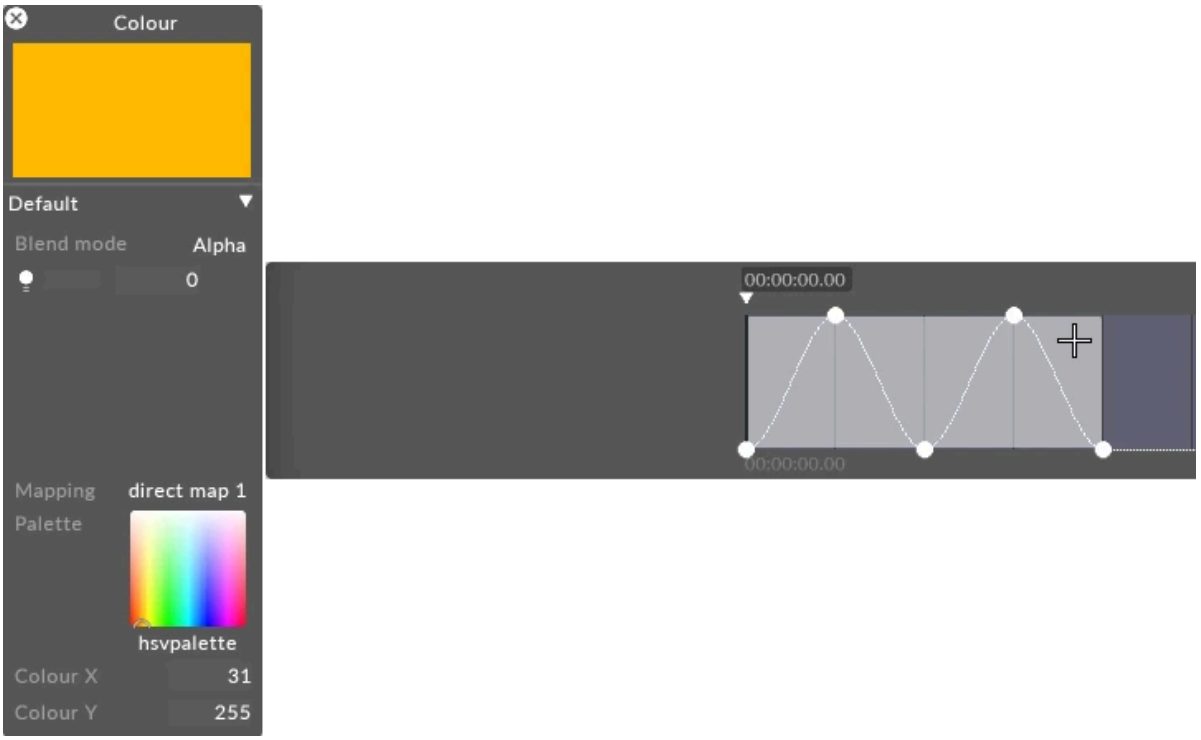
Keyframes and their indicators on the track

Multiple Keyframes

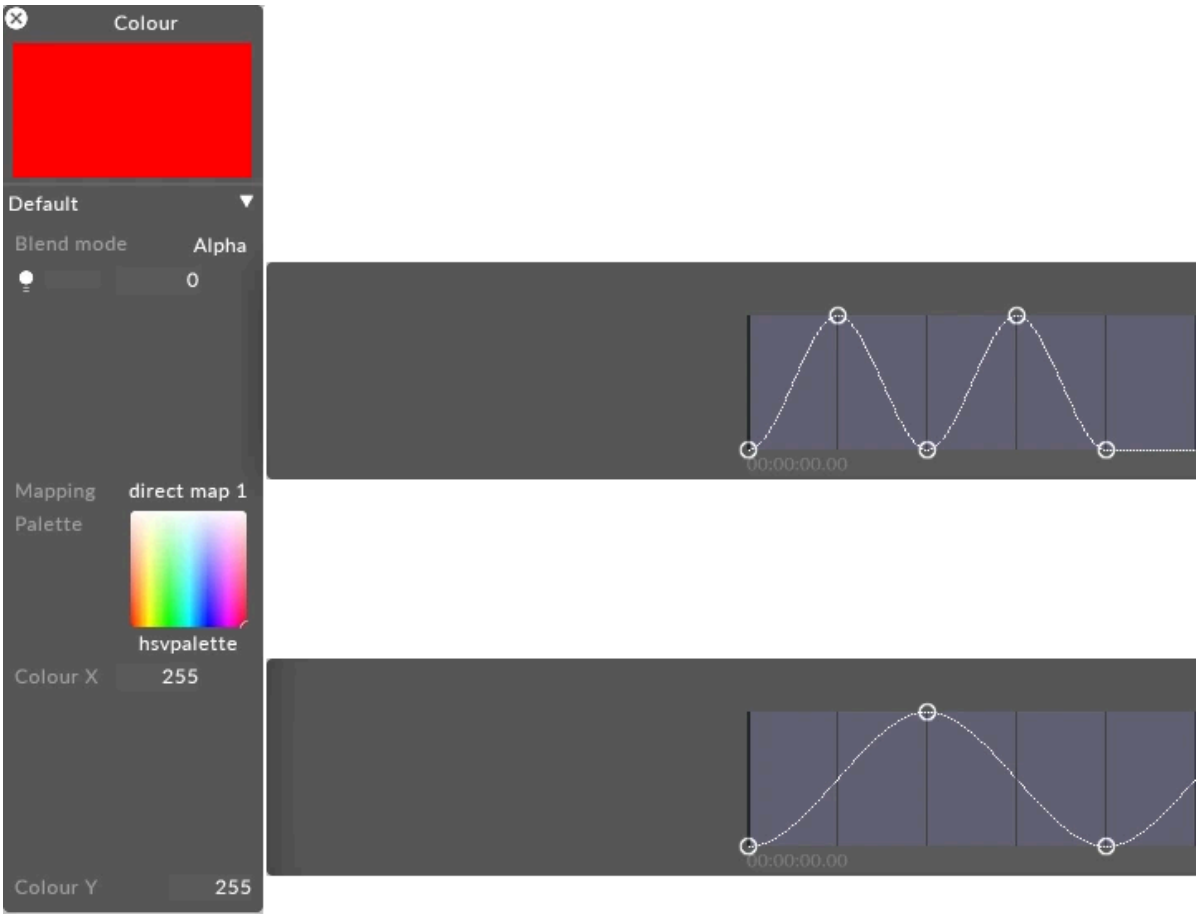
Editing actions apply to all three types of keyframe editors mentioned above and can be applied to a single keyframe editor or multiple keyframe editors of multiple layers.

Selecting a range of keyframes

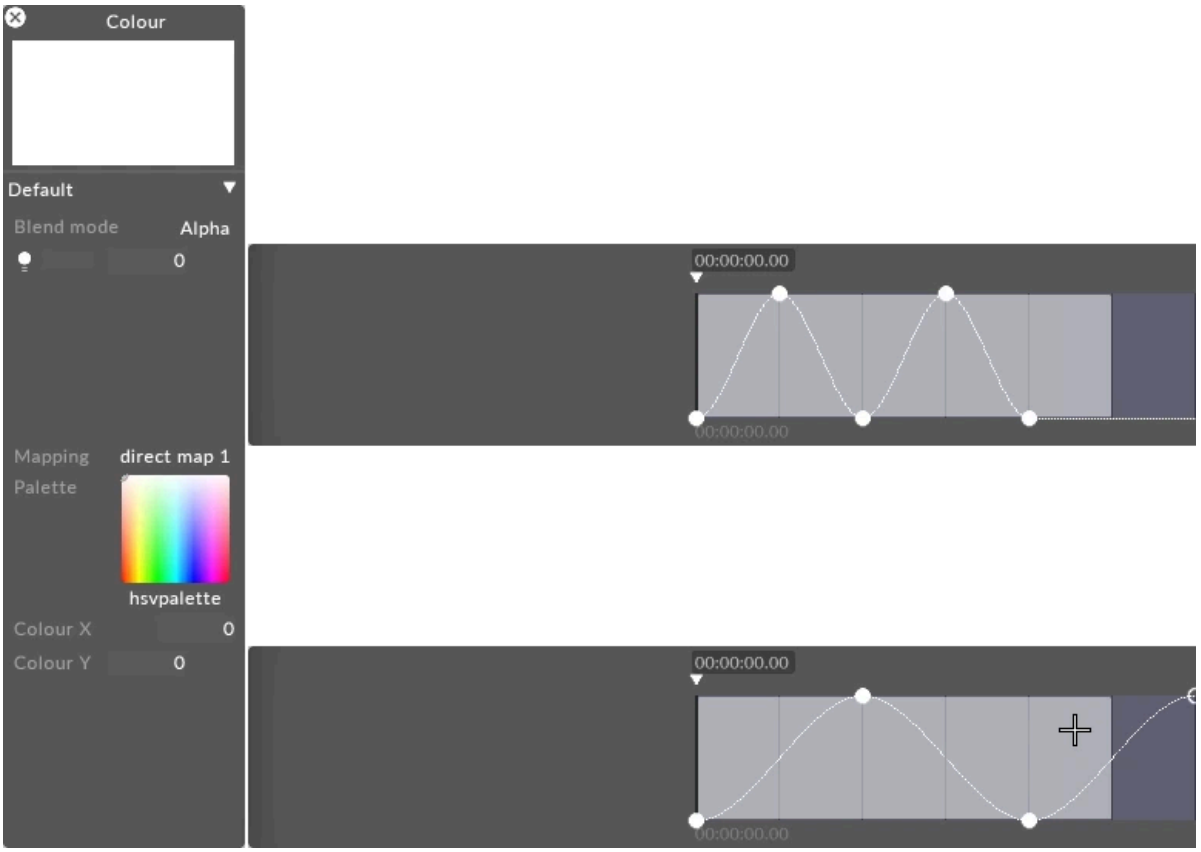
1. Hold down the left **Shift** ey and drag a rectangle around the keyframes you want to select inside the keyframe editor. Keyframes that fall under the selection rectangle are displayed as solid white dots.



2. To open more than one keyframe editor, hold down the **Ctrl** key when selecting the properties.

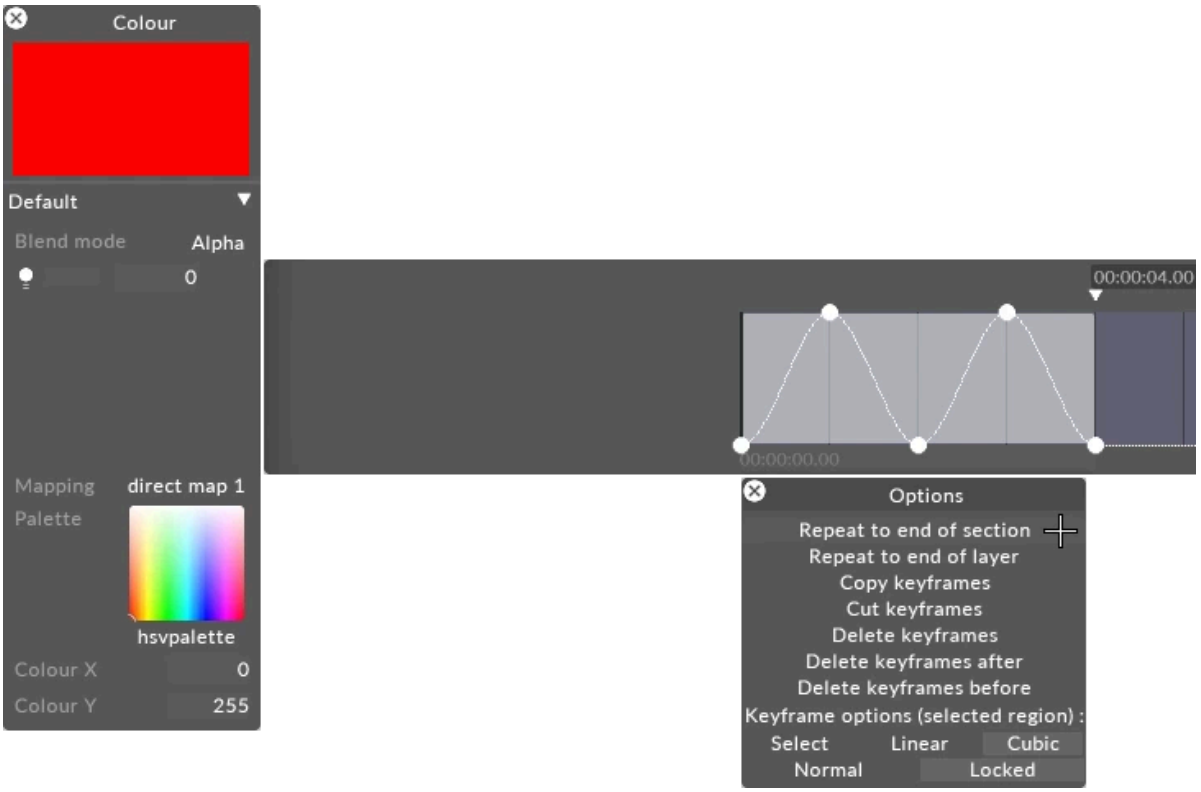


3. With multiple keyframe editors open, you can now select and edit keyframes from more than one keyframe editor simultaneously.



Editing a range of keyframes

- Right-clicking inside the keyframe editor with a selected range of keyframes allows you to change the interpolation type between only the selected keyframes. The popup menu gives you a list of options to choose from.



Repeat a range of keyframes

1. Hold down the left **Shift** key to select a whole number of bars.
2. Right-click the keyframe editor.
3. Select either **repeat to end of layer** or **repeat to end of section** .

Cut / copy / paste

1. Hold down the left **Shift** key to select a range of keyframes.
2. Right-click the keyframe editor and select **cut keyframes** or **copy keyframes** .
3. Move to a different section of the timeline, rightclick the ribbon and select **paste keyframes** .

Clear a range of keyframes

1. Hold down the left **Shift** key to select a range of keyframes.
2. Right-click the keyframe editor and select **delete keyframes** .

Numeric Keyframes

Numeric keyframes are used for properties that use a numeric range such as 0-255 or 0-1.

Workflow

Create a numeric keyframe

- Left-click the keyframe editor of a layer at the point where you want to create a new keyframe. This will create a keyframe with the same value as the previous keyframe in the timeline.

Move a numeric keyframe

1. To move a keyframe, click it and drag it upwards, downwards, left or right. You can also adjust the keyframe using the mouse scroll wheel.
2. You can add a keyframe and position it in a single action; just click in the timeline and drag the new keyframe without releasing the mouse button.

Remove numeric keyframes

- To remove one keyframe, rightclick it.
- To remove multiple selected keyframes, hold down **Shift** and drag-select the keyframes. Hit the **Delete** button on the keyboard.

Editing min/max values

As with standard numeric properties, you can set min/max constraints to limit the positions of your Keyframes to a certain range.

1. Right-click a numeric property from the Layer editor to open the Numeric property editor.

2. Type the min/max values you want to set in the **min** / **max** fields.

3. Edit the value in the numeric propertys text field in the Layer editor. If you input a value beyond the range specified in the min/max text fields, the value will automatically default to the min/max value (whichever is nearer) when you click anywhere on the screen. However, you can override this by manually moving the Keyframes on the Keyframe editor.

This will apply to all the layers of that type across the whole project.

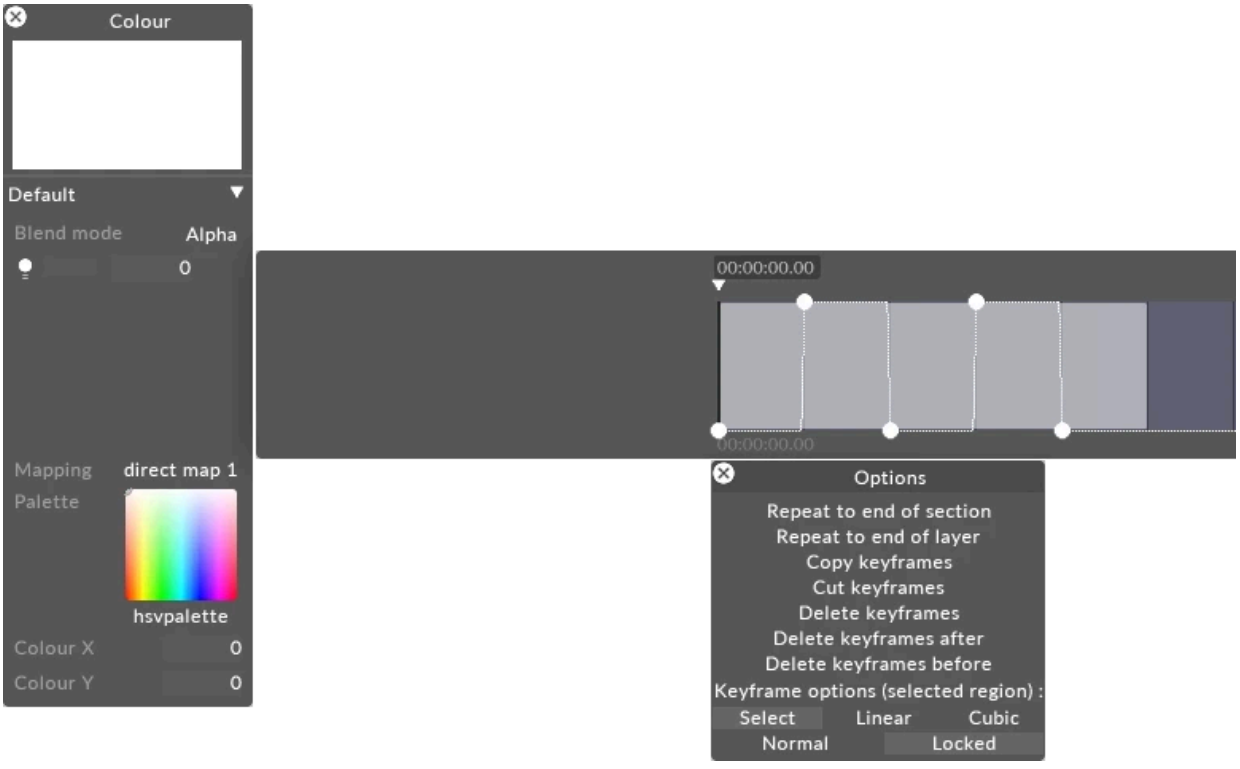
For more information on **step**, **damping**, and editing numeric properties in general please read the 'Editing numerical properties section in the Editing objects sub-chapter.

Numeric keyframe options

Right-click the keyframe editor to set the curve for all keyframes, or select a subset by holding shift and dragging a selection box over them. This will open an option menu that allows you to change the interpolation type (i.e. the shape of the curve that goes through the key values). There are three options:

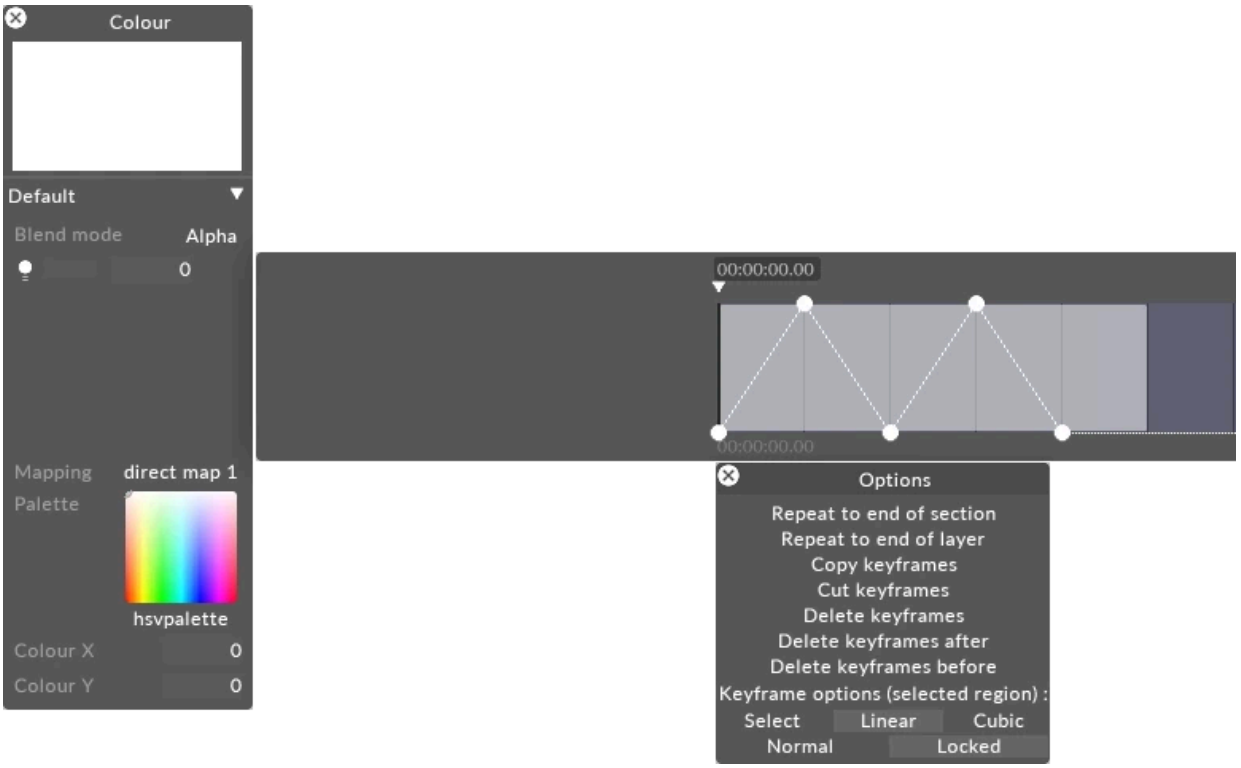
Select

The output value remains static until the next keyframe.



Linear

The output follows a straight line between adjacent keyframes.



Cubic

The output value follows a cubic curve with zero in and out speed.

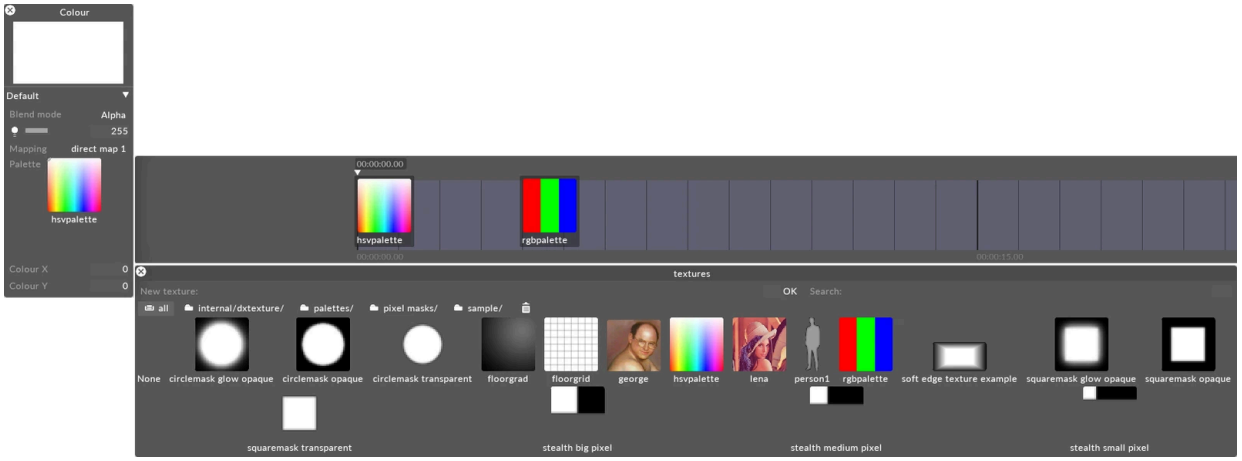
Object Keyframes

The object keyframe editor consists of keyframes appearing as object thumbnails. The object library for that type opens up just below the keyframe editor, allowing you to drag thumbnails onto it.



Creating an object keyframe

- Either drag a thumbnail from the object library onto the keyframe editor or left-click a thumbnail in the library to create a new keyframe at that current position.

Moving an object keyframe

- Left-click the thumbnail in the keyframe editor and drag it left or right.

Removing object keyframes

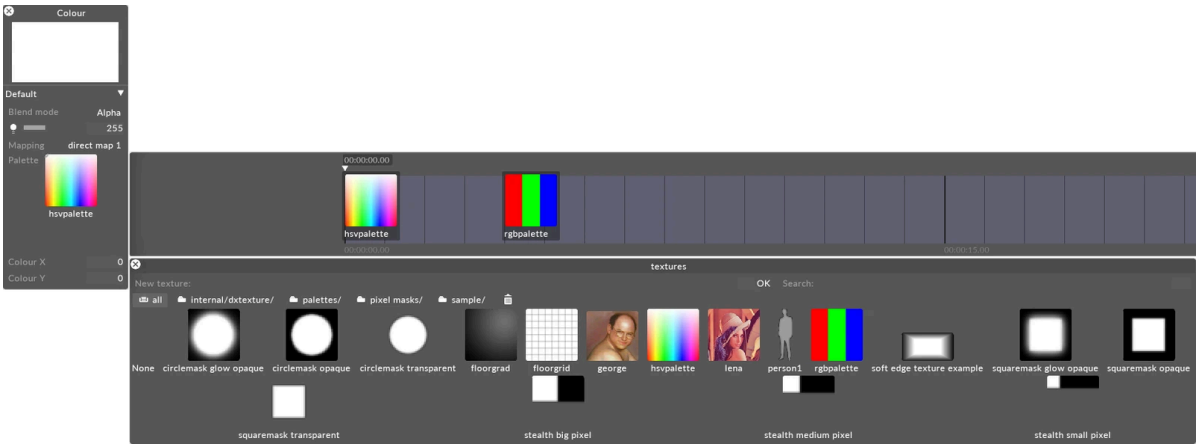
- Right-click the object thumbnail in the keyframe editor.

Option Keyframe

Option property keyframe editors also consist of a series of keyframes, but each keyframe has an option choice. Option property keyframe editors behave similarly to numeric keyframe editors.

Creating an option keyframe

- Left-click the keyframe editor at the point where you want to create a new keyframe. This will create the keyframe and open an options menu for edting the keyframe.



Modifying an option keyframe

1. Left-click the keyframe and drag it left or right to change its time.
2. To select a different option, left-click the keyframe and release the mouse button immediately to open up the option list so you can choose a different value.

Removing an option keyframe

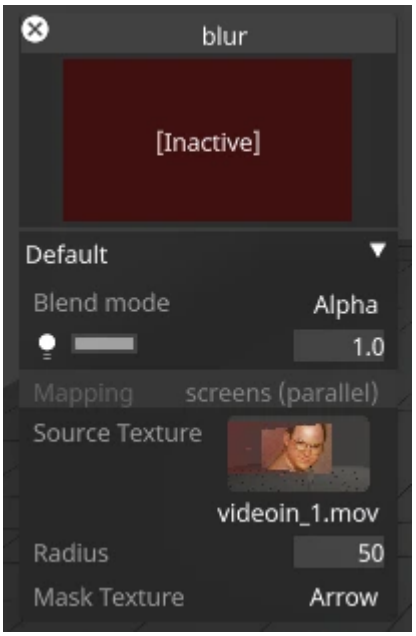
- Right-click the keyframe to remove it.

Layer Stacks

As of r20, there is a new time-independent feature designed to allow you to easily assign and manage layers of treatments to a live video input.

Workflow

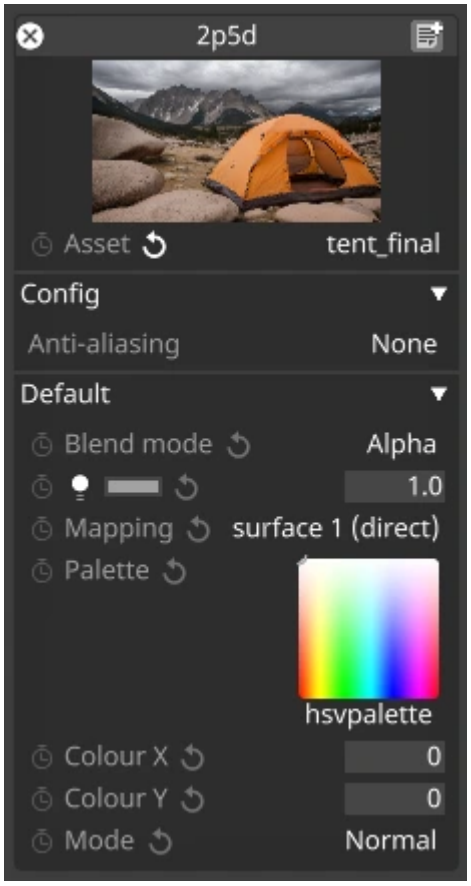
1. Open the Video Input Patch Editor and assign a camera to the Input field of a video input.
2. Click **Start Preview** to confirm your input is connected.
3. In the Layer Stack field, create a new by left-clicking the **None** field and adding a new to the list.
4. Next, right-click on the and add a new layer.
5. Once the new layer has been added, left-click on the layer to open its **Layer Editor**.
6. Select the video input that you are creating the for as the **Source Texture** and then edit the properties of the layer as needed.



7. Add additional layers to the as desired.
8. Once all layers in the stack have been configured, close the **Video Input Patch** editor and add a new Video layer to the timeline. In the new Video layer, simply select the same Video input that you configured as the Media source. At that point, you will see the composition of the Video Input with its layer stack.

2.5D Layer

The 2.5D layer creates parallax scenes from layered image or video plates with depth, bridging 2D video and full 3D workflows. See 2.5D workflow for an overview of workflows that can be achieved using this layer.



2.5D layer

Workflow

The 2.5D layer holds a 2.5D **Asset** and maps its rendered output onto the stage. There are two common ways to get started.

Use an existing .2p5d asset

Use this path when receiving assets from Cuebric or another project.

1. Copy the **.2p5d** file to **objects/2p5DFile** in the project folder.
2. Add a 2.5D layer to the timeline.

3. In the 2.5D layer editor, click the **Asset** field and select the copied asset. It will load and become visible in the stage.
4. In the **Mapping** property, select the desired 3D mapping, e.g. MR set backplate.

Create a new asset

Use this path to build a layered parallax scene from scratch.

1. Add a 2.5D layer to the timeline.
2. In the 2.5D layer editor, click the **Asset** field and create a new 2.5D asset.
3. Add and compose plates in the asset, then set the **Mapping** as above.

For detailed asset and plate configuration, depth of field, and advanced workflows, see the 2.5D workflow.

2.5D layer properties

Asset

The **Asset** property holds the 2.5D asset rendered by the layer. Click the field to select an existing 2.5D asset or create a new one. The asset is a separate Object that acts as the container for all plates; its properties (origin, field of view, maximum depth, mode, and the plates themselves) are edited in the asset editor and described in the 2.5D workflow.

Depth of field can be applied to the rendered asset when the layer is mapped to a camera or MR set frontplate/backplate, using the camera's focus settings. See Camera Properties for more information.

Anti-aliasing

Use this property to apply mean-square anti-aliasing (MSAA) to the layer. This smooths the edges of rendered plates to avoid a jagged appearance. The available options are:

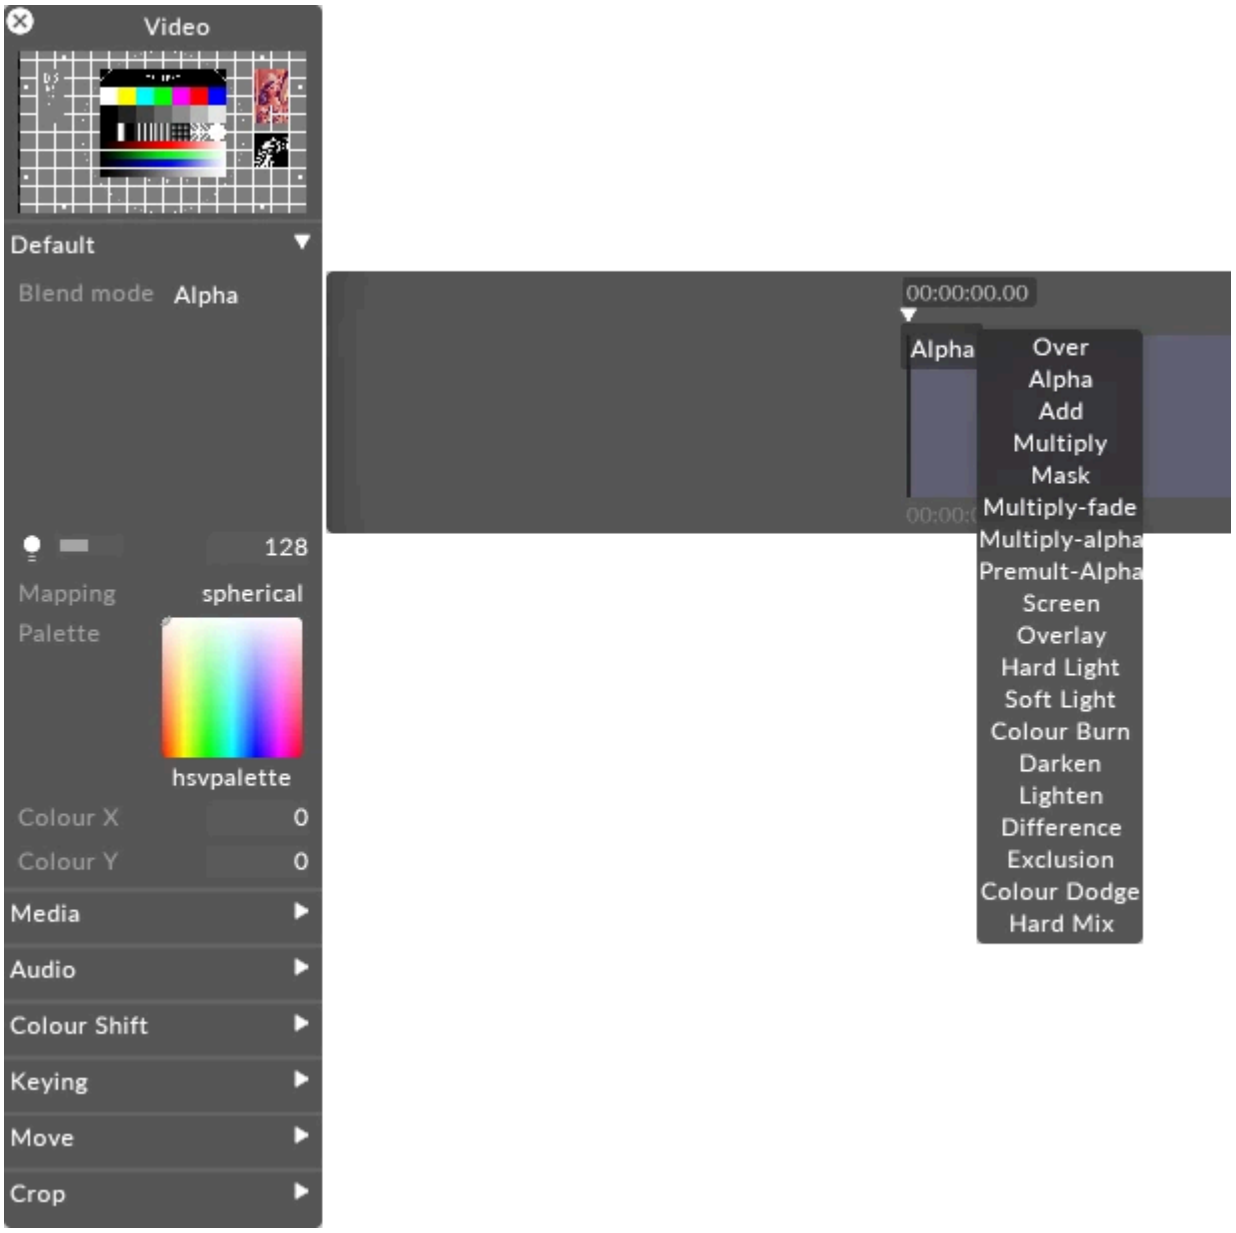
- **None**
- **MSAA 2X**
- **MSAA 4X**
- **MSAA 8X**

The multiplier relates to the number of samples taken per output pixel - increasing this can improve edge smoothness but comes at a performance cost.

Common layer properties

Blend mode

BlendMode controls how the output of the layer is composited with the layers below. Layers are rendered in a bottom-up order: layers at the top can modify the output of the layers below.



Changing brightness of a content layer in Designer is actually controlling the value of the alpha of the layer. Even when displaying a HAP video, the software will composite the layer with a controllable layer of alpha - one per layer.

There are two ways of expressing alpha in an image:

Straight alpha is an alpha channel which functions just like RGB. Alpha acts as a fourth channel of information per pixel which is as independent of the other three as R, G and B are of each other. For example, with straight alpha it is possible to have RGB = 255 (white) and alpha = 0 (fully transparent) on the same pixel. Internally generated content, such as gradient layer, are generated with straight alpha. This is the preferable style of alpha and considering the cleaner method of the two.

Premultiplied alpha takes the alpha and applies it to the values of the RGB channels per pixel. The more transparent something gets with premultiplied alpha, the closer it gets to black - as if the content is sitting on a black table. Premultiplied is the default output of Adobe Photoshop or AfterEffects. The result is our pixel at 255 RGB (full white) with 0 alpha would be calculated as a black pixel in the final image.

Here are explanations of what each individual blend mode will do.

Over

Makes a layer fully opaque. Premultiplies all alpha onto the RGB value of each pixel. Alpha = black, so adjusting the brightness of a layer in Over blend mode makes it darker.

Alpha

Default blend mode. It will apply alpha values as a transparency if the alpha is present. Brightness changes will make the layer more or less transparent.

Add

Adds the value of each RGB pixel together. Always creates a brighter result. Values clamp at 255.

Multiply

Reads the level of each subpixel as a level between 0.0 and 1.0, and multiplies source with blend. The result is always a darker image overall. For example: white x grey = 0.5. White turns transparent, black takes precedence. Alpha is applied in the same fashion as the Over Blend mode.

Mask

Applies a mask to the single layer **above** in the stack, irrespective of mapping. See **Mask blending** for more information.

Luma-Matte

This mode creates a Luma Matte by using a layer's **Rec. 709 luminance** to control the alpha channel of the layer **above**, irrespective of mapping.

To determine transparency, the luminance of each pixel is calculated using a weighted average of its red, green, and blue channels. The luminance value is then used as the alpha (opacity) value for the corresponding pixels in the upper layers.

As a result, white areas render the layer above fully opaque, black areas make them fully transparent, and grey areas create proportional semi-transparency. This is a specialized **Mask** blend mode; for more details on the underlying behaviour, see **Mask blending**.

Inv-Luma-Matte

The Inverse Luma Matte mask works the same as the **Luma Matte** mask but the transparency is inverted meaning white regions are transparent and black regions are opaque.

Multiply-Fade

The same as Multiply, but will make use of the alpha channel to calculate transparency in the source and blend layers. Since maximum transparency is premultiplied, alpha results in black. This will ignore black created through premultiplying.

Multiply-Alpha

Multiply with straight alpha. This mode assumes that the alpha has not been premultiplied onto the RGB values and will not apply a correction to the semi-transparent pixels.

Premultiply Alpha

Like how Multiply-fade will ignore the darkening caused by premultiplying, this blend mode will do the same with Alpha.

Colour Burn

Blend mode increases the contrast to darken the base colour while reflecting the blend colour. The darker the blend colour, the more intensely the colour will be applied in the base image. White as the blend colour produces no change. Using the colour burn blend mode can produce some harsh results at full opacity. The colour burn blend mode can be used to make tonal and colour adjustments to a layer.

Screen

This blend mode looks at each channels colour information and multiplies the inverse of the blend and base colous. The result is always a lighter colour. Screening with black leaves the colour unchanged. Screening with white produces white. The effect is similar to projecting multiple images on top of each other - where bright white is fully opaque, black is fully transparent and 50% grey is 50% transparent.

Overlay

Multiplies or screens the colours, depending on the base colour. Patterns or colours overlay the existing pixels while preserving the highlights and shadows of the base colour. The base colour is not replaced, but mixed with the blend colour to reflect the lightness or darkness of the original colour.

Hard Light

Multiplies or screens the colours, depending on the blend colour. The effects is similar to shining a harsh spotlight on the image. If the blend colour (light source/top layer) is lighter than 50% grey, the image is lightened as if it were screened. This is useful for adding highlights to an image. If the blend colour is darker than 50% grey, the image is darkened as if it were multiplied. This is useful for adding shadows to an image. Painting with pure black or white results in pure black or white.

Soft Light

Darkens or lightens the colours, depending on the blend colour. The effect is similar to shining a diffused spotlight on the image. If the blend colour (light source/top layer) is lighter than 50% grey, the image is lightened as it if were dodged. If the blend colour is darker than 50% grey, the image is darkened as if it were burned in. Painting with pure black or white produces a distinctly darker or lighter area, but does not result in pure black or white.

Darken

Looks as the colour information in each channel and selects the base or blend colour - whichever is darker - as the result colour. Pixels lighter than the blend colour are replaced and pixels darker than the blend colour do not change.

Lighten

Looks at the colour information in each channel and selects the base or blend colour - whichever is lighter - as the result colour. Pixels darker than the blend colour are replaced and pixels lighter than the blend colour do not change.

Difference

Looks at the colour information in each channel and subtracts either the blend colour from the base colour or the base colour from the blend colour depending on which has the greater brightness value. Blending with white inverts the base colour values and blending with black produces no change.

Exclusion

Creates an effects similar to but lower in contrast than the difference mode. Blending with white inverts the base colour values. Blending with black produces no change.

Colour Dodge

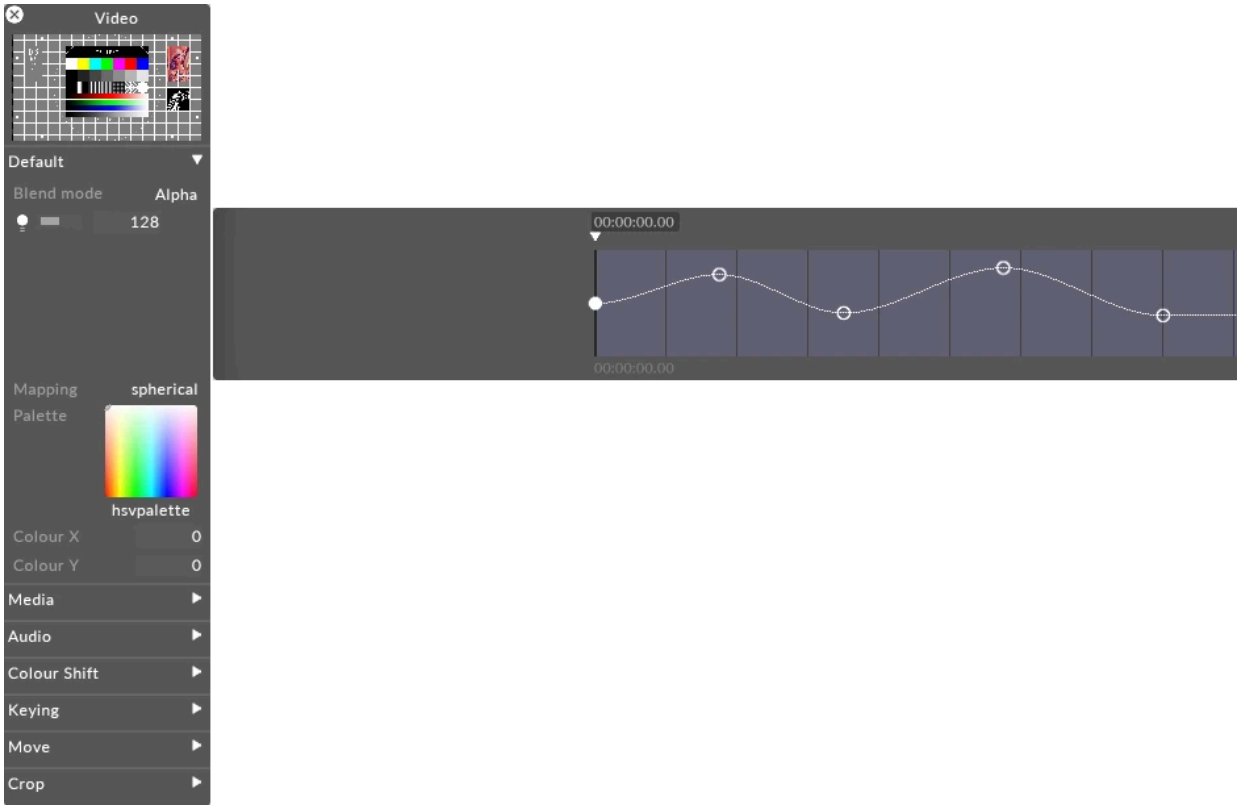
Looks at the colour information in each channel and brightens the base colour to reflect the blend colour by decreasing contrast between the two. Blending with black produces no change.

Hard Mix

Adds the RGB channels of the blend colour to the RGB values of the base colour. If the resulting sum for a channel is 255 or greater, it receives a value of 255; if it is less than 255 it receives a value of 0. Therefore all blended pixels have RGB channels of either 0 or 255. This changes all pixels to primary additive colours (RGB), white or black.

Brightness

This property (which appears as a light bulb icon) controls the brightness of the layer output.



If the layers blend mode is set to Alpha, then reducing the brightness to 0 also reduces the opacity of the layer to 0. This can be useful when you want to dissolve from one layer to the next. In that case, you can place the new layer above the old layer and increase its brightness level.

> **Note**
>
> Layers that are patched to Sockpuppet (DMX, OSC or HTTP) are made Dormant when their brightness is set to 0. This means they will not do any rendering or consume any resources until their brightness is changed to > 0. You can find more information about this here: **Sequencing with Sockpuppet**. Layers without a sockpuppet patch do not behave in this way.

Mapping

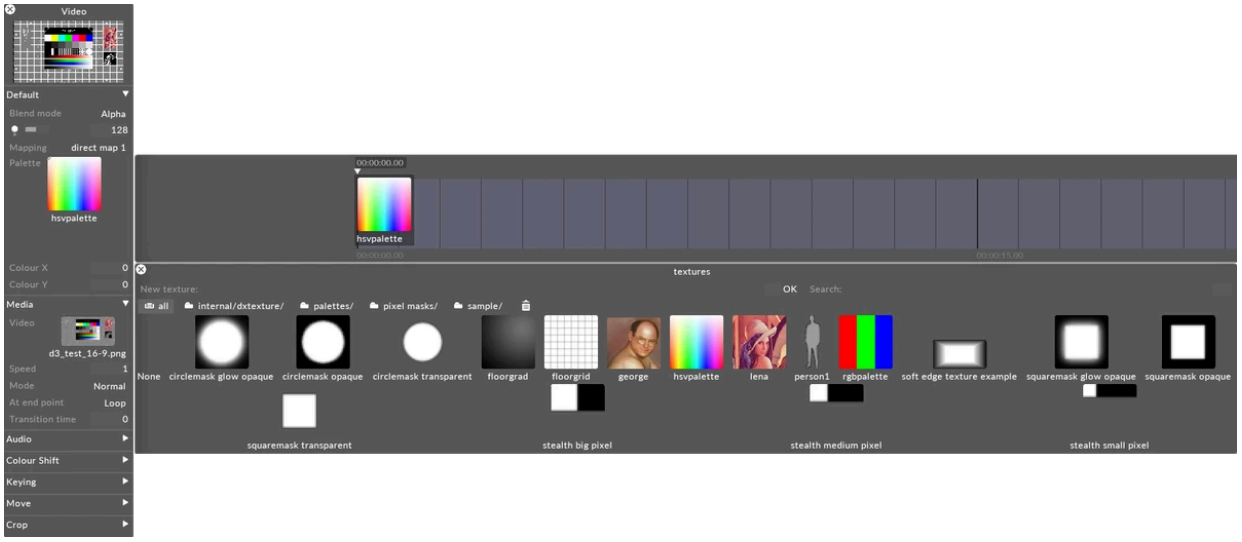
The mapping property controls how the layer output is mapped onto the screen(s) in the Stage level.

For information on mapping, including how to use the different mapping types offered by Designer, please see the chapter **Content Mapping**

Palette

This points to the still image file that defines the bitmap from which the tint colour is taken. The default palette (HSVPAL) consists of the complete range of hues and saturations. Selecting this property will open the Texture object library, which shows all of the still image files saved on your local hard-drive in the **DxTexture** older.

To control the location within the current palette bitmap, and thus control the colour, you have to edit the **xCol** and **yCol** values (see the section for xCol, yCol).



To change the current palette bitmap:

1. Left-click **palette** to open the Texture object library.
2. Left-click the still image file you want to use for the palette bitmap.

If you want to use a palette bitmap other than the standard still images provided in Designer, you will need to use a custom still image file.

See the **Placing media files** for a project sub-chapter to understand where to place a custom still image file and how to access it in Designer. Also save the file to a **supported file format**.

Xcol, YCol

These properties control the coordinates within the current palette bitmap where the output colour is sampled from. The default value is 0,0 which points at the color white (if you are using the HSVPAL palette). Multiplying white with the colors of the chosen content simply generates the original content colors. **Colour X** controls the horizontal position, where 0 is the leftmost edge and 255 is the rightmost edge. **Colour Y** controls the vertical position, where 0 is the top edge and 255 is the bottom edge.

For example, to saturate the video clip red, change the **Colour Y** value to 255 and use 0 for the **Colour X** value. These coordinates refer to the color red in the palette which is being multiplied

with the colors of the existing content.

When you are using the default palette HSVPAL , Colour Y controls saturation, and Colour X controls hue.

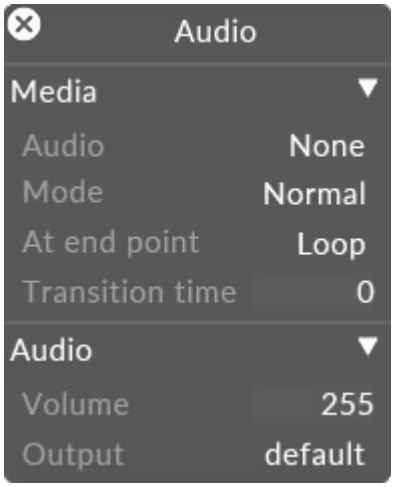
- MR set
- Cuebric Integration
- Depth Workflows
- Depth Map Mesh

Audio Layers

The Audio layer allows you to play audio files from Disguise, without the need for embedding those files into a video file first.



Workflow

1. Add the audio files to the AudioFile folder in the Designer project folder.
2. Add an audio layer to the timeline.
3. Assign the layer an audio patch (assuming a logical audio out has already been configured).

Audio Layer Properties

Media

Audio

Opens the audio file list.

Mode

Normal

When the play head stops, the audio will also stop and the frame number will lock to the timeline position. When the play head continues to play or holds at the end of a section, the audio will play continuously. Jumping around the timeline while playing does not affect which part of the audio is being played.

Locked

If the play cursor continues to play or stops at the end of a section, the audio locks to the timeline and thus stops playing.

At End Point

Loop

When playback reaches the end of the video clip, the clip will loop immediately back to the beginning and will start playing again from there.

Ping-pong

When playback reaches the end of the video clip, the clip will play in reverse back to the beginning.

Pause

When playback reaches the end of the video clip, the clip will pause on the last frame.

Transition Time

The transition property specifies the dissolve time, in seconds, when switching from one audio clip to the next on the timeline. By default, this is set to 0, so the player cuts immediately from one clip to the next. Setting this value to 1 causes the player to dissolve from one clip to the next over 1 second.

Audio

Volume

You can specify any number between 0 (mute) and 255 (full) in the text field to set a constant volume, or open the properties key-frame editor to fade volume in or out.

Balance

You can balance the playback of a file to either right or left by altering the value of the parameter.

Output

This controls which audio output device the audio is played to.

Content Layers Overview

In Designer, the function of content layers is to play back pre-rendered content. The following content layers are available:

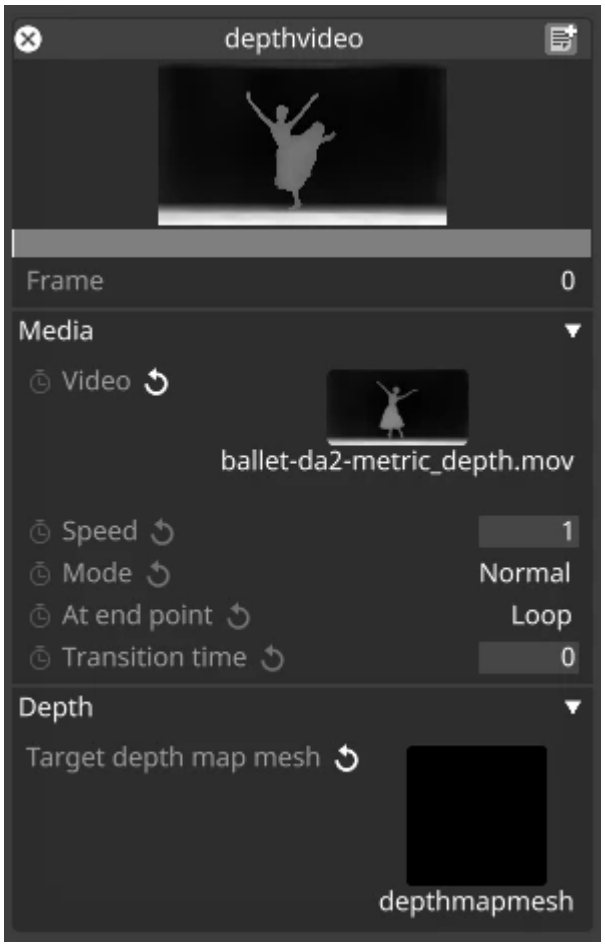
- Audio
- DepthVideo
- RenderStream
- RenderStream Local
- StageRender
- Video
- VideoTrigger
- VirtualLineup
- Web

Depth Video Layer

The Depth Video layer applies a depth map video directly to a Depth Map Mesh. The video should be a black and white depth map defining relative depths of objects in an image. The z positions of the vertices of the Depth Map Mesh will adjust dynamically based on the content mapped to it using the Depth Map Mapping.

The Depth Video layer is a subtype of the Video Layer.

> **Caution**
>
> The recommended workflow for applying content to a Depth Map mesh is to use a Depth Map Mapping, which is more flexible and can be used with different layers. However, the Depth Video Layer can be useful for cases where a mapping is not available, such as within a Layer Stack.



The Depth Video Layer

Workflow

1. Create a new Depth Map Mesh and assign it as the mesh of a stage object such as a screen.
2. Add a depth-map image or video to the project's `objects/VideoFile` folder.
3. Create a new **Depth Video Layer** and choose the Depth Map Mesh as its **Target depth map mesh**.
4. The stage object's geometry now deforms in real time based on the values in the depth-map content.

Properties

Developed as a subclass of the Video layer, most properties in the Depth Video Layer match those of the standard Video Layer.

The key difference is that instead of using a **Mapping**, the Depth Video Layer exposes a **Target depth map mesh** property. This determines which mesh receives the video-driven depth deformation.

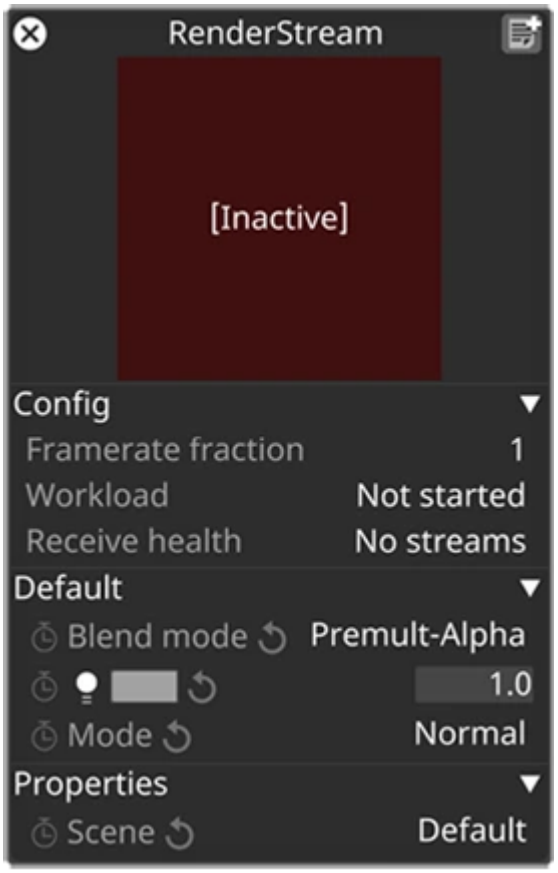
- Depth Workflows

RenderStream Layer

The RenderStream Layer is used to control third party render engines running externally to Designer.



Layer properties

There are six main sections within the RenderStream layer, and several subsections:

- Options
- Media Thumbnail

- Config
  - Framerate fraction
  - Workload
    - Cluster Workload
      - Configure
      - Channel mappings
      - Texture parameters
      - Bandwidth estimate
      - Control
      - Machine
      - Actions
  - Receive health
- Default
  - Blend mode
  - Brightness
  - Mode
- Properties
  - Scene

Additionally, as parameters in the Render Engine scene are exposed, those properties will also appear listed in the RenderStream layer.

1. Options section

These options include:

- Lock
- Copy UID
- All fields
  - Bake fields
  - Bake expressions
  - Clear expressions
- Opened fields
  - Bake fields
  - Bake expressions
  - Clear expressions

2. Media Thumbnail section

This area will display an image of the active stream being received. When there is no stream, it will show `[Inactive]`.

Note that in a multi-channel environment, this will only show the Camera in UE that has the RS component attached to it.

Media Thumbnail

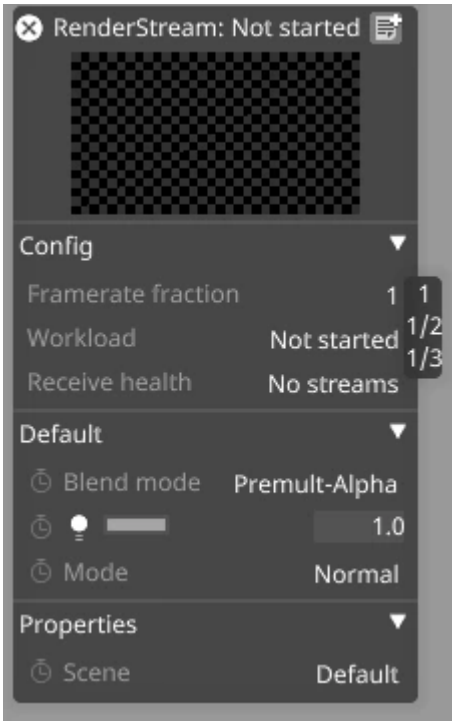
3. Config section

This section of the is where you will configure properties such as **Asset** and **Cluster Pool**, as well as monitor workload and engine health in real time.

- **Framerate fraction**

The framerate of each stream is determined by the global refresh rate set within d3. The Framerate Fraction setting indicates the fraction of the framerate this layer renders at.

The options are 1, 1/2, 1/3, and 1/4.

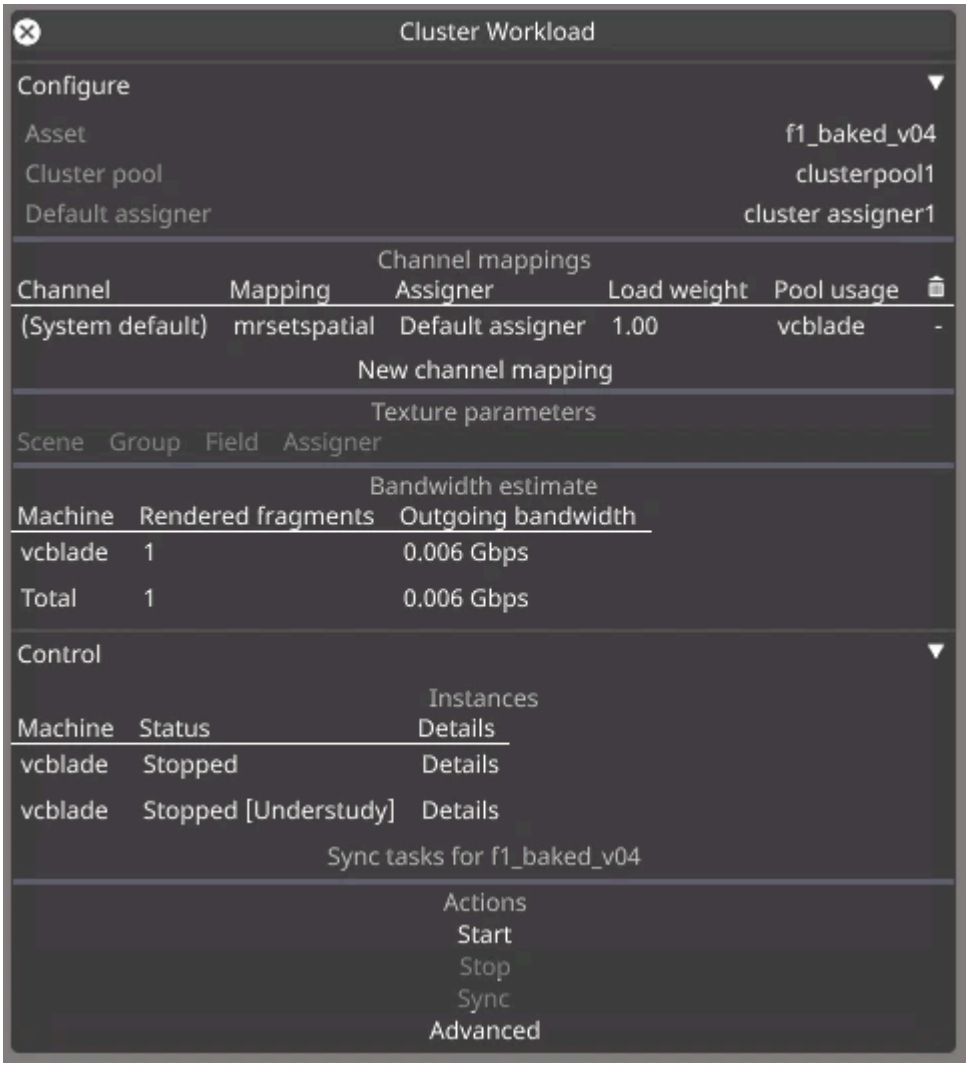


Framerate fraction

4. Workload section

- **Cluster Workload**

The Cluster Workload window contains the elements required for configuring a Cluster.



It contains the following sections:

- **Configure**

> The Configure section contains these elements of a Cluster:
>
> - `Asset`
>   - RenderStreamAsset
> - Cluster pool
>   - Cluster pool - New ClusterPool, Search
>   - Render machines, RenderStream understudies

- `Default`
  - Splitting strategy
  - Splitting overlap (pixels)
  - Padding (pixels)
  - Maximum tile size (pixels)
  - Effective tile size (pixels)
  - Transport format
  - Alpha
  - Scale factor
  - Proxy streams
  - Preferred Network
- `Channel mappings`
  - Channel
  - Mapping
  - Assigner
  - Load weight
  - Pool usage
- `Texture parameters`
  - Scene
  - Group
  - Field
  - Assigner
  - Channel
  - Controller
- `Bandwidth Estimate`
  - Machine
  - Rendered fragments
  - Outgoing bandwidth
  - Incoming bandwidth

- `Asset`

This Asset is the Render Engine project or Notch block that will be controlled by the layer. In order for the asset to be visible here, it must be present in the RenderStream projects folder.

Right-click on the asset name listed in RenderStreamAsset to open the **Asset** properties editor:

Properties include:

- Asset Discovery Name: Name of UE folder/project.
- Target Engine: Name of the Render Engine.
- Engine Settings: Engine version.
- Colour shift: Apply colour correction to entire asset.
- Content Source Machine: The render node that is running the render engine project. This is the machine that the project will be synced from.
- Available: Status indicator displaying if the Asset is available. Not a tick box.
- Channels: displays active channels defined by the CameraActors in your UE project.

- `Cluster Pool`

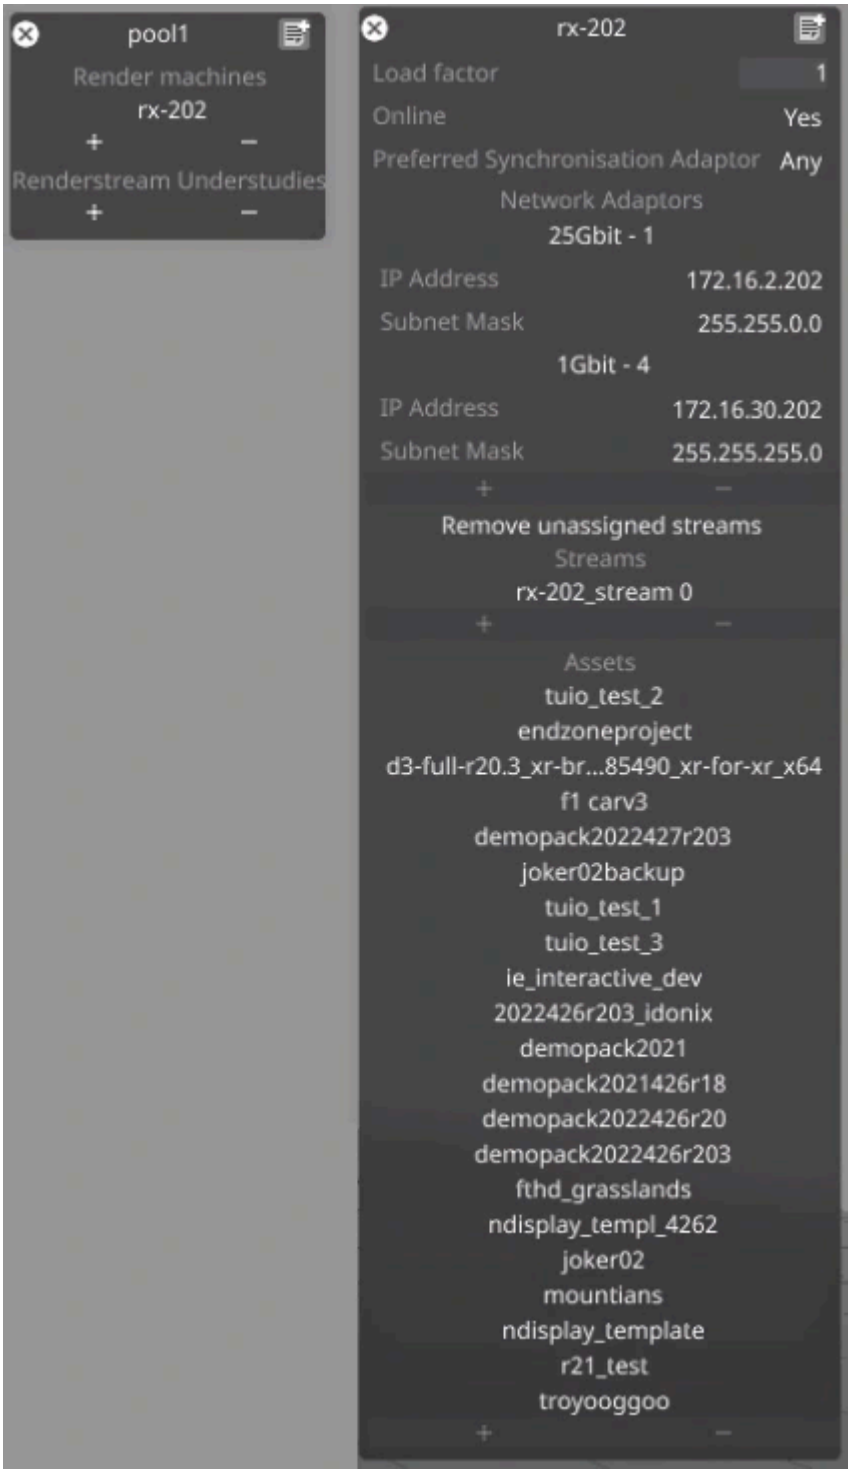
The **Cluster Pool** will automatically detect all available machines on the same network. Once detected, you can assign as many machines to the **Cluster Pool** as needed and inspect each machine in the pool to see network status, IP address, current Streams and available Assets.

Cluster Pool

Properties include:

- Render Machines: The list of render nodes that the content will be distributed across.
- Understudies: Backup nodes in case of failover.

Right-click on the name of a machine in the **Cluster Pool** to edit additional properties related to that machine:



`Cluster Pool Machine`

Properties include:

- **Load Factor**: Relative load weight this machine can handle. Weight is relative to other nodes in pool. The workload can be spread evenly across the cluster by the user using a load factor. This allows you to take into account each machine's spec and assign loads accordingly.

- Online status
- **Preferred Synchronisation Adaptor**: This setting allows you to pick a subnet to use for Renderstream asset synchronization. You should pick something fast - preferably capable of 100Gbps or more. It is also used by nDisplay inter-machine communication when using Unreal Engine.

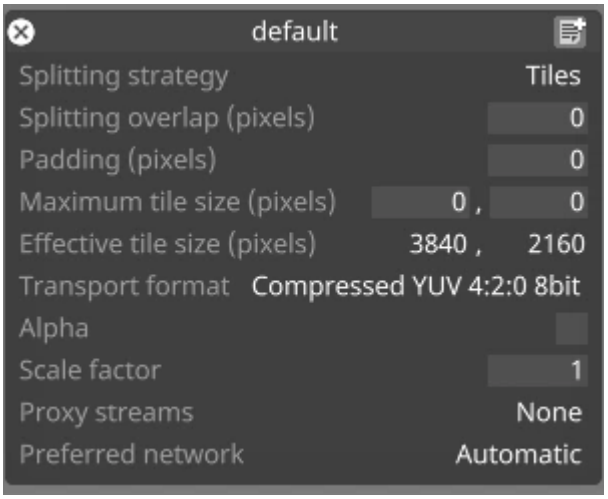
> **Note**
>
> We recommend selecting a specific `Preferred Synchronisation Adaptor` rather than defaulting to `Any` as it may produce unpredictable results.

- **Network Adaptors and settings**: Non-editable list of network adaptors available on the node. To configure the system for Cluster Rendering, all machines within a Cluster Pool must be on the same subnet. If a machine is reporting an unexpected IP address (e.g. loopback address), make sure to select the specific network adaptor within the 'Network' tab of d3manager.
- **Streams**: non-editable list of RS output from the node.
- **Assets**: non-editable list of assets resident on the node.

Default Assigner

The **Default Assigner**, also known as *Cluster Assigner*, is where we control the settings for the distribution of the content across all the machines in the **Cluster Pool**.

Cluster Assigners are used to create definitions as to how channels are delivered from the nodes. You can create as many Cluster Assigners as needed.

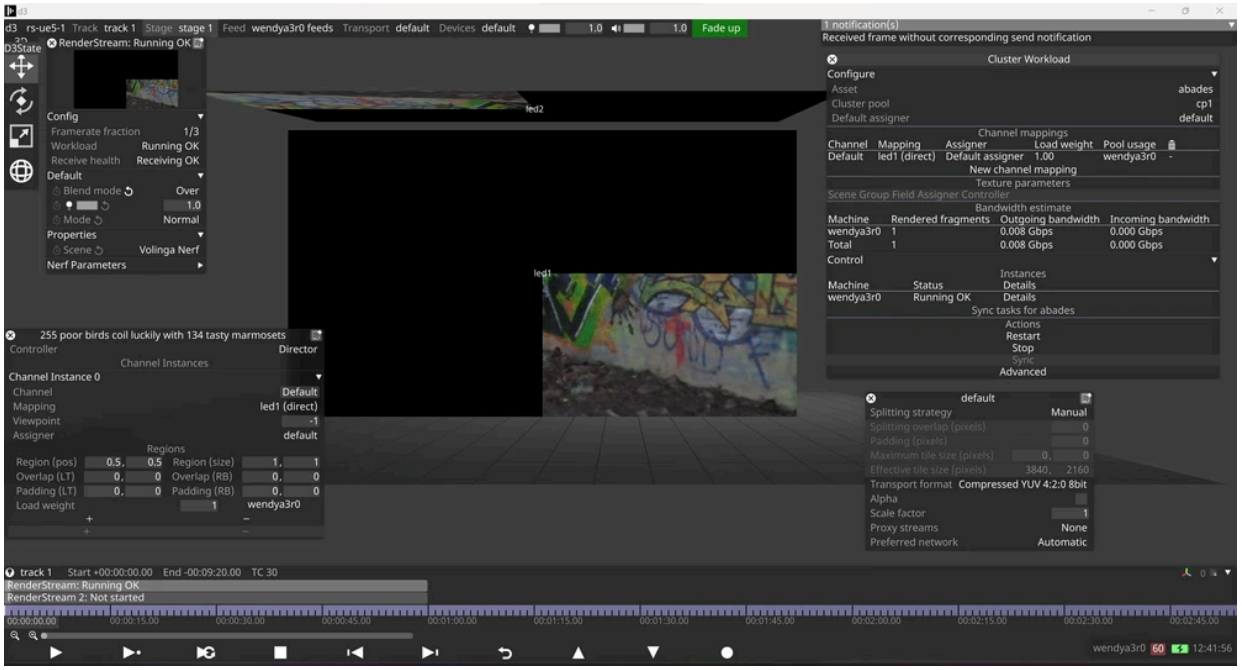


Cluster Assigner

Properties include:

- **Splitting Strategies**

- These are used to generate the sub-regions needed for distributing content across a set of render nodes.
- There are 3 types of splitting strategies:
  1. **Tiles** - lets Designer split up the content as it sees fit to the mapped channels. Note: this splitting strategy DOES NOT work with Mesh Policy.
  2. **Full frame** - Sends the entire stream to the mapped channel.
  3. **Manual** - splits each Viewport according to user specified instructions. When using the 'Manual' splitting strategy, the options for specifying how to split frames can be found within the Advanced workload settings.



In Advanced workflow settings, note that region pos. has a range between 0 and 1. The screenshot shows both regions (pos) set to 0.5. Other property values in this editor also range from 0 to 1.

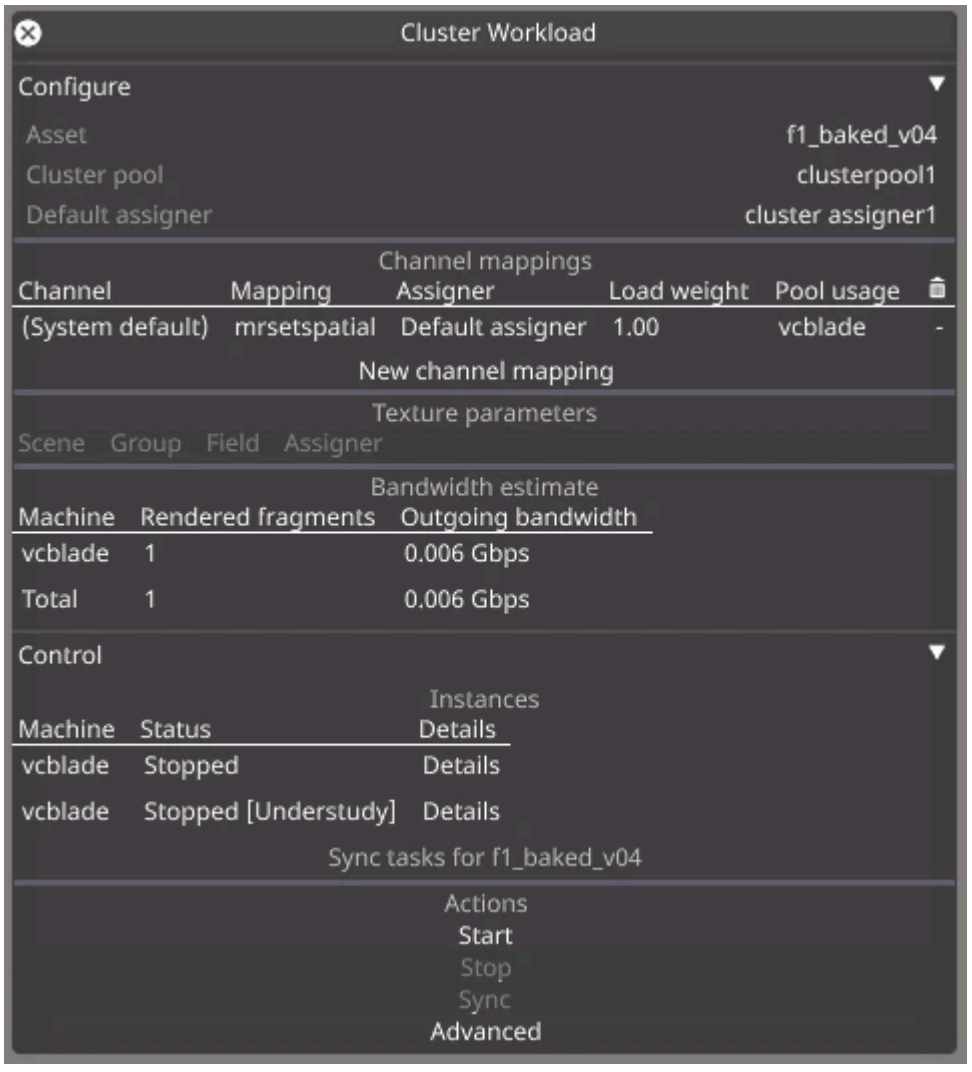
- **Splitting Overlap**: The Splitting Overlap option can be used to define a blend region at each split that hides imperfections at the seams.
- **Padding (Pixels)**:The Padding option enlarges the rendered area at each split, but does not stream the padded area, cutting off edge artifacts.
- **Load Weight**: Load Weight allows you to set a priority for the Cluster Assigner. The higher the weight of the assigner, the more machines will be assigned to render the content and thus more splits will be made.
- **Transport format**:The options to pick between 'Compressed' and 'Uncompressed' , 'RGB 4:4:4', 'YUV 4:2:2', and 'YUV 4:2:0', and 8-bit, 10-bit and 12-bit transport bit-depths are available.
- **Alpha**: The option to enable or disable the Alpha channel on the content is available.
- **Scale factor**: Scale factor for the resolution.

- **Proxy Streams**: A compressed stream at a lower quality or resolution used for providing a preview on ma chines where receivingthe full-quality stream is undesirable or impossible.
- **Preferred network**: Select the adaptor to use for video transport on any channel the assigner is associated with.

> **Note**
>
> We recommend that the `preferred adaptor` is not left as the default: `Any` and is instead set to a specific network. It should be configured to match the network interface you wish to receive RS streams over. For uncompressed RenderStream this must be a port on your high bandwidth Network Interface Card (NIC). In our servers, this is the Mellanox brand NIC.

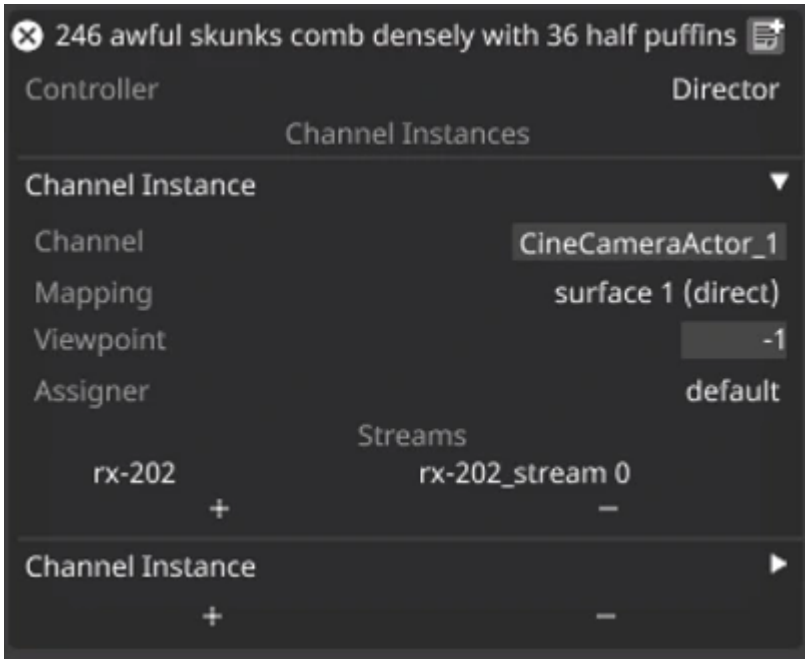
- **Control**

> Once the cluster has been configured, the stream's playback is managed via the Cluster Workload controls.



The options for managing the workload are:

- **Instances:** there can be only one workload instance running at a time in the same cluster pool. When started, the Instances table will be populated with the machines that have been sent the start signal.
- **Start:** sends signal to all machines in the pool to launch the Asset according to config settings
- **Stop:** Sends signal to cease outputting a stream and quit the process sending it. The workload log can be opened by left-clicking on the status within the Instances table
- **Sync:** begins the process of content sync. Content is synced from the source machine to all other machines available within the cluster pool; copies only the necessary directories and files needed.
- **Advanced:** right-click to open the workload's advanced options:

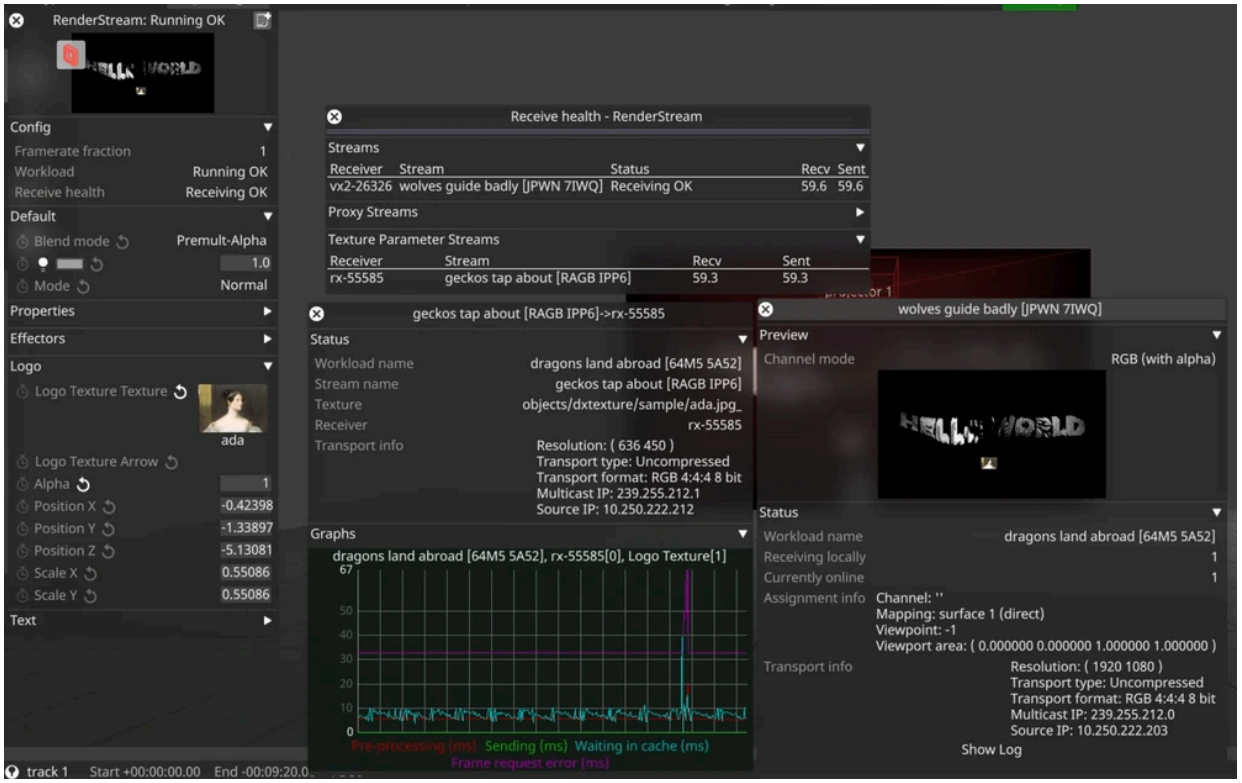


> **Note**
>
> **Please note**: Any changes to the Assigner require a restart of the workload

Receive Health

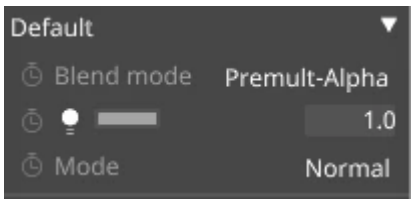
Status of entire cluster receiving streams, dynamically reported while stream is running.

Right-click on **Receive health** to open the machine-specific window:



4. Default section

In the Default section of the RenderStream Layer, there are four Common Layer Properties:



- **Blend Mode**: Premult-Alpha is needed for content that contains alpha data.
- **Brightness**: Layer intensity.
- **Mode**: This is used to determine the timeline's playback behavior as the layer is playing.

5. Properties section

The last section of the RenderStream layer is asset specific and will display all exposed parameters from the asset as well as their keyframe editors

Workflow overview

Set up your environment including installation of the Render Engine and required plugin.

Use the RenderStream Layer to control the third party render engine.

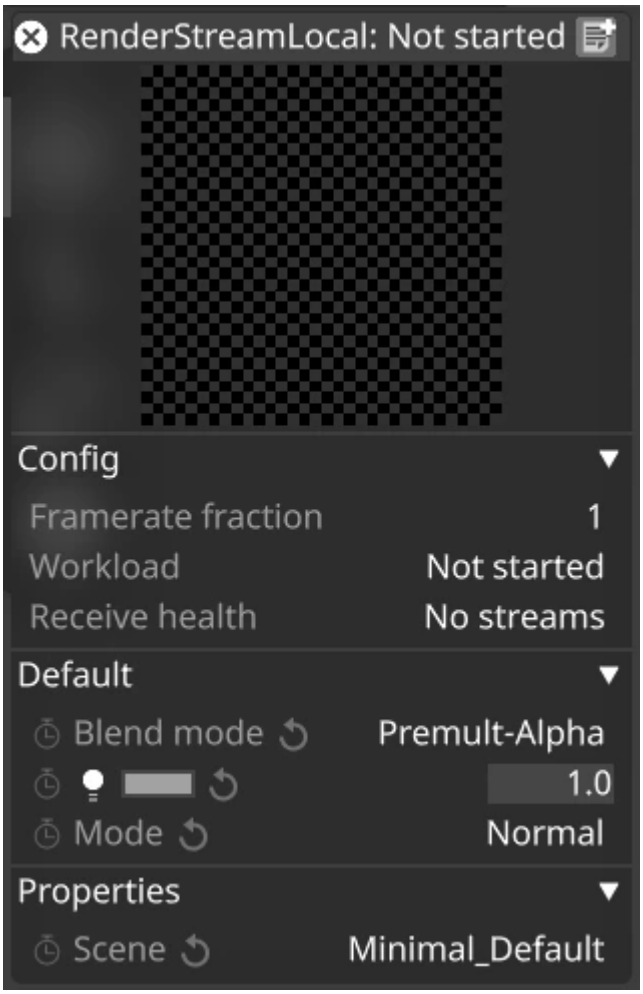
- Notch
  - Plugin - included in Designer.
  - Documentation
- Touch Designer
  - Plugin
  - Documentation
- Unity
  - Plugin
  - Documentation
- Unreal Engine
  - Plugin
  - Documentation

RenderStream Local Layer

The RenderStream Local Layer is used to control third-party render engines running externally to Designer locally on a VX or GX server. The RenderStreamLocal layer is a local RenderStream mode used to sequence instances of Unreal Engine, Unity, and TouchDesigner using the same RenderStream plugins as RenderStream in remote mode. Support for Notch is built into Designer.

The VX 4 and VX 4+ do not currently support RenderStream Local.

TouchDesigner is the only RenderStream plugin type which is enabled on the EX range via RenderStream Local. Notch block playback is currently not supported using the RenderStream Local layer, and should use the Notch layer instead.



There are four main sections within the RenderStreamLocal Layer:

- Media Thumbnail
- Config

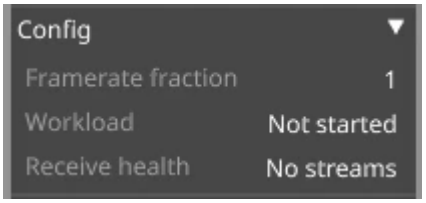
- Default
- Properties

Media Thumbnail

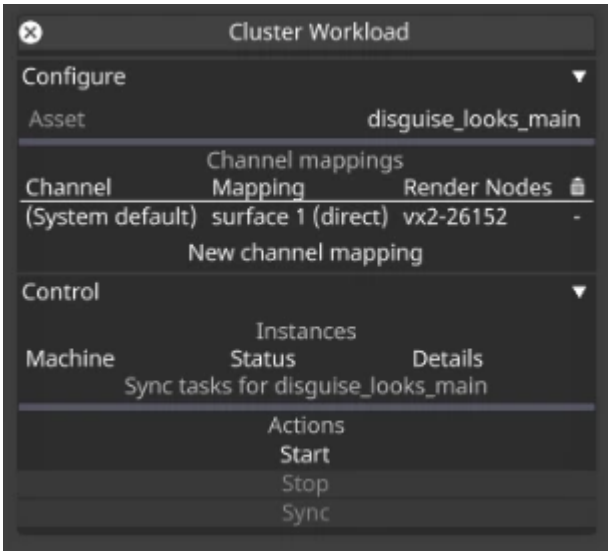
This area will display an image of the active stream being received. Note that in a multi-channel environment, this will only show the Camera in UE that has the RS component attached to it.

Configuration

This section describes the configuration properties, real-time workload monitoring and engine health monitoring.



Cluster Workload



The Cluster Workload window contains the elements required for configuring a workload. It contains **Configure** and **Control** sections.

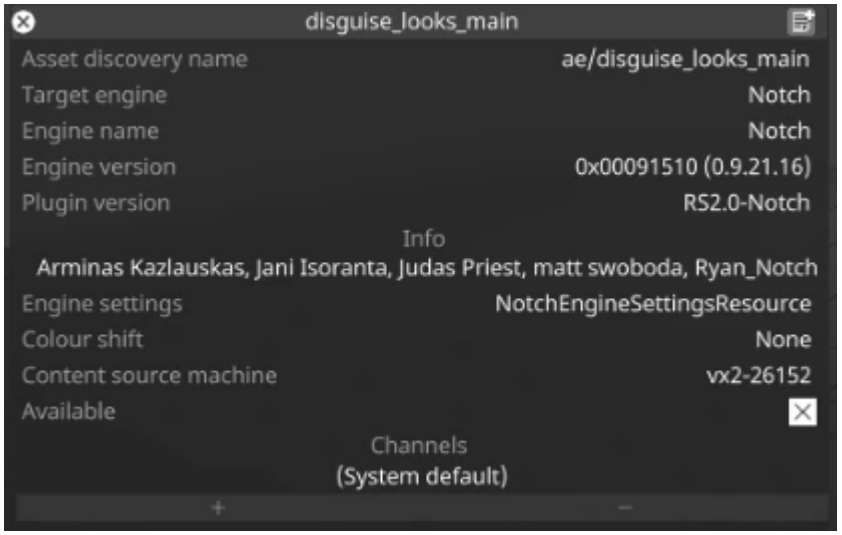
Configure

The Configure section contains elements to set up a workload.

Asset

This is the Render Engine project or Notch block that will be controlled by the layer. In order for the asset to be visible here, it must be present in the RenderStream projects folder of the render machines.

Right-click on the asset name to open the **Asset** properties editor:



Properties include:

- **Asset discovery name**: Name of the folder/project.
- **Target engine**: Name of the Render Engine.
- **Engine version**: Engine version.
- **Plugin version**: Plugin version.
- **Engine settings**: Engine-specific settings.
- **Colour shift**: Apply colour correction to entire asset.
- **Content source machine**: The render machine that is running the render engine project. This is the machine that the project will be synced from.
- **Available**: Status indicator displaying if the Asset is available. Not a tick box.
- **Channels**: Active channels defined in the render engine project.

Channel Mappings

Channel Mappings include properties such as:

- **Channel:** active channel, editable field.
- **Mapping:** active mapping, editable field.
- **Render Nodes:** non-editable list of render machines.

> **Note**
>
> The Render Nodes field is empty by default. A machine will be automatically added to the list when the content is mapped to the machine's output display head in the Feed Editor.

Control

The Control section allows to manage the workload.

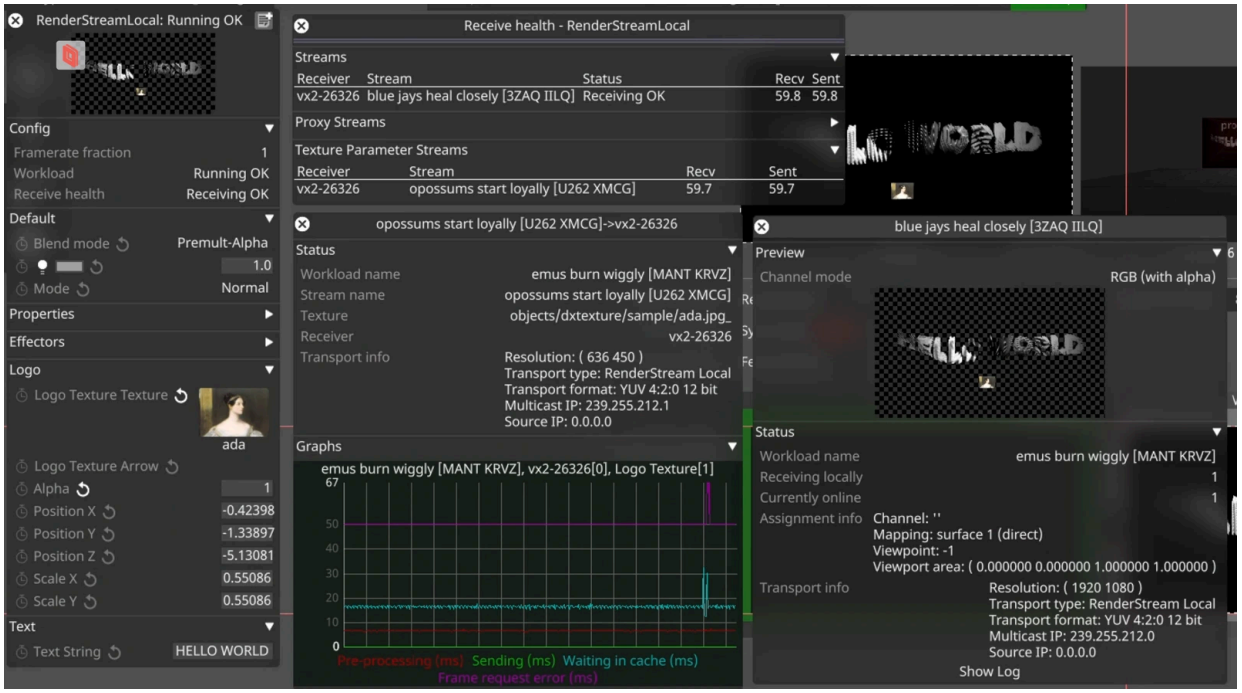
- **Instances:** when started, the Instances table will be populated with the machines that have been sent the start signal.
- **Start:** sends signal to all machines in the Render Nodes list to launch the Asset according to config settings.
- **Stop:** Sends signal to cease outputting a stream and quit the process sending it. The workload log can be opened by left-clicking on the status within the Instances table
- **Sync:** begins the process of content sync. Content is synced from the source machine to all other available Render Nodes; copies only the necessary directories and files needed.

> **Note**
>
> Any changes to the settings require a restart of the workload.

Receive Health

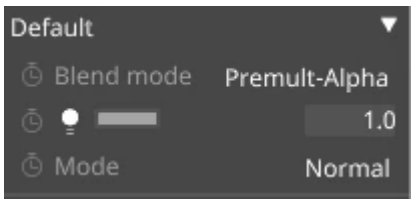
Status of all render machines are dynamically reported while stream is running.

Right-click on **Receive health** to open the machine-specific window:



Default

In the Default section of the RenderStreamLocal Layer, there are four common layer properties:



- **Blend Mode**: Premult-Alpha is needed for content that contains alpha data.
- **Brightness**: Layer intensity.
- **Mode**: This is used to determine the timeline's playback behaviour as the layer is playing.

Properties Section

The last section of the RenderStreamLocal layer is asset specific and will display all exposed parameters from the asset as well as their keyframe editors

> **Note**
>
> Current release version does not support remote texture sharing.

Workflows

View the RenderStream Local section to learn about RenderStream Local workflows.

StageRender Layer

Using the StageRender layer, you can assign any type of content to your virtual wall while being able to control the position of where the content will be rendered.

The StageRender layer is a 3D layer type, like the RenderStream Layer and the Notch layer. It is used to render backplate stage objects that are also mapped to an MR set.

This layer is created to improve a workflow. Prior to r19, if any other content was added to the MR set backplate, it would render on top of the virtual screen, regardless of the order of the layers in the timeline. Using the StageRenderlayer, you can utilize normal content and assign it to your virtual wall while being able to control the position by changing the order of the layers.

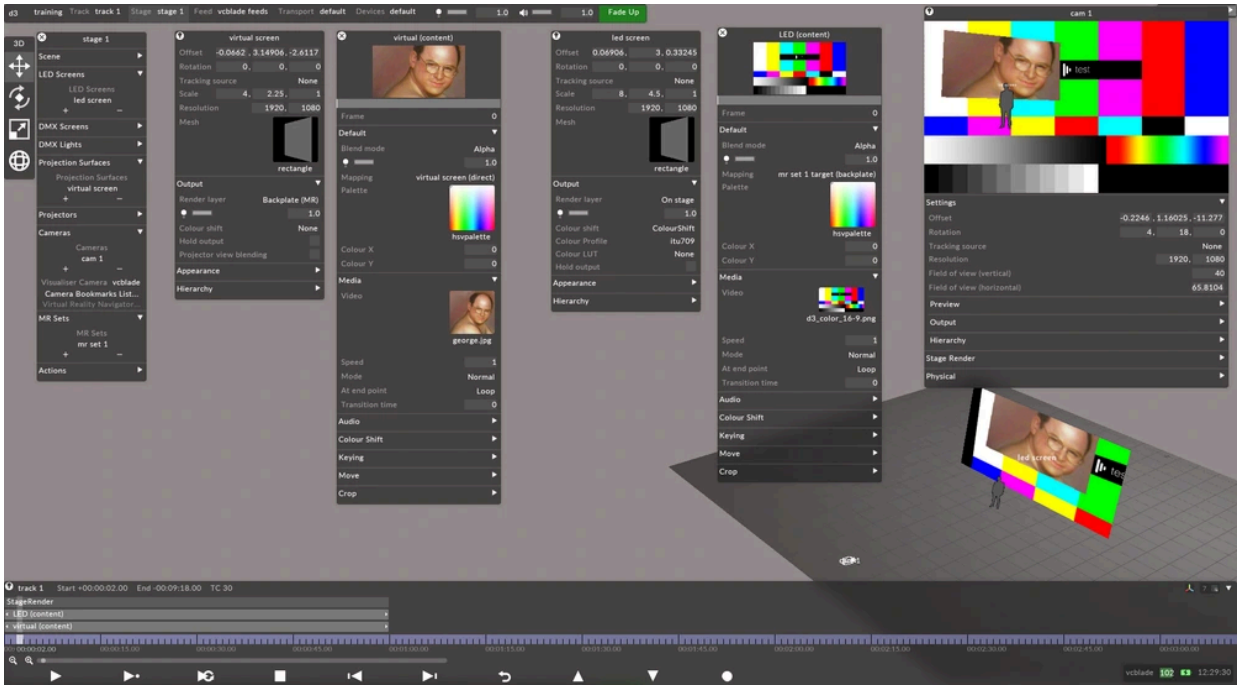
Workflows

Backplate workflow

1. Create an MR set with a camera and an LED screen.
2. Check that the Render layer is set to **On stage**.
3. Create a Video layer and map content to the LED screen using the mapping type **mrset target (backplate)**.
4. Create a new projection surface and change the render layer of the surface from **On stage** to **Backplate (MR)**. It will not be rendered.
5. Create a Video layer and map content to the virtual surface using the surface's Direct mapping.
6. Create a **StageRender** layer, and map it to the **mrset target (backplate)**.
7. The position the **StageRender** layer appears in the layer stack determines its composite order, like other layers.
8. Move the video layer below the virtual screen content in the timeline in order for the virtual screen to appear in front of the LED screen.

Result: The Video layer will respect the position of the layer in the timeline. It can be placed in front of or behind the virtual content in the LED by changing the order of the layers.

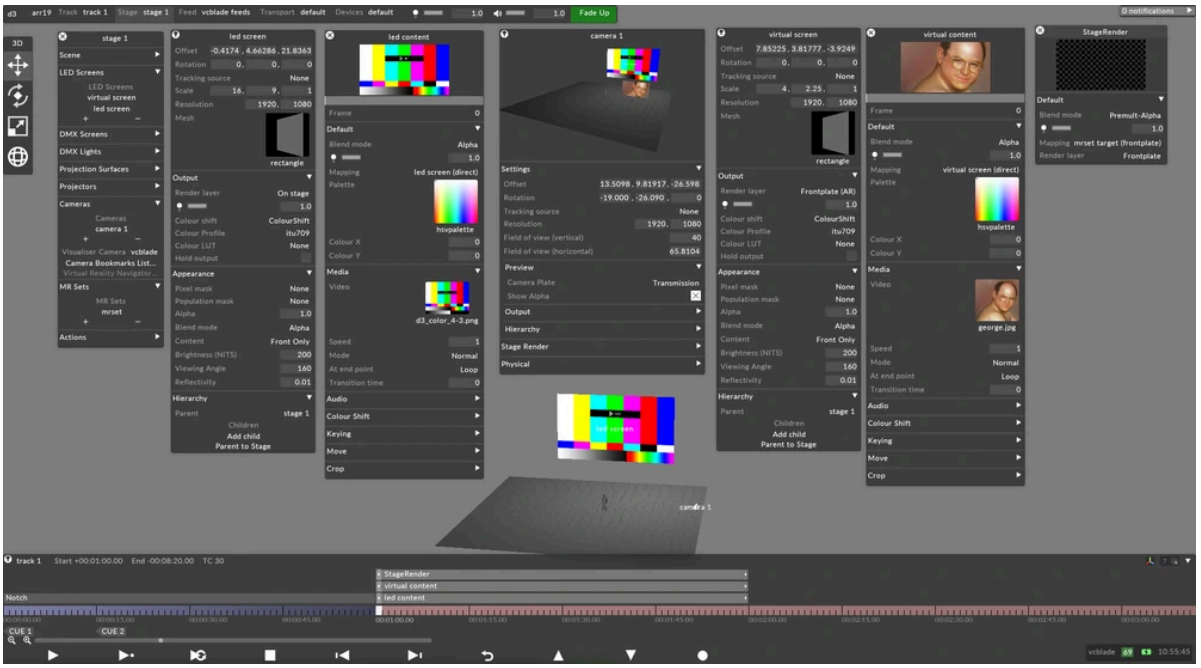
> **Note**
>
> Please note: Individual layers rendering to the virtual screen do not get interleaved - they are all rendered to the virtual screen in one go before the on-stage screens and backplate are composited.



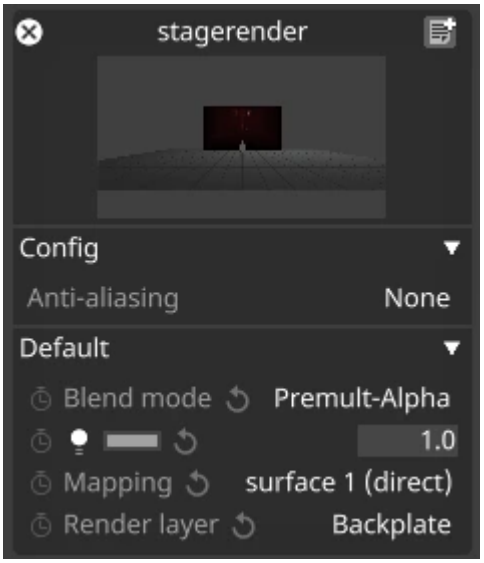
Frontplate workflow

1. Create an MR set with a camera and an LED screen.
2. Check that the Render layer of the LED screen surface is set to **On stage**.
3. Create a Video layer and map content to the LED screen using the Direct mapping type.
4. Create a new projection surface and change the render layer of the surface from **On stage** to **Frontplate (AR)**. It will not be rendered.
5. Create a Video layer and map content to the virtual surface using the surface's Direct mapping.
6. Create a **StageRender** layer, and map it to the **mrset target (frontplate)**.
7. The position the **StageRender** layer appears in the layer stack determines its composite order, like other layers.

8. Move the video layer below the virtual screen content in the timeline in order for the virtual screen to appear in front of the LED screen.



StageRender layer properties



Anti-aliasing

Use this property to apply mean-square anti-aliasing (MSAA) to the layer. This smooths the edges of rendered objects to avoid a jagged appearance. The available options are:

- **None**

- MSAA 2X
- MSAA 4X
- MSAA 8X

The multiplier relates to the number of samples taken per output pixel - increasing this can improve edge smoothness but comes at a performance cost.

Render layer

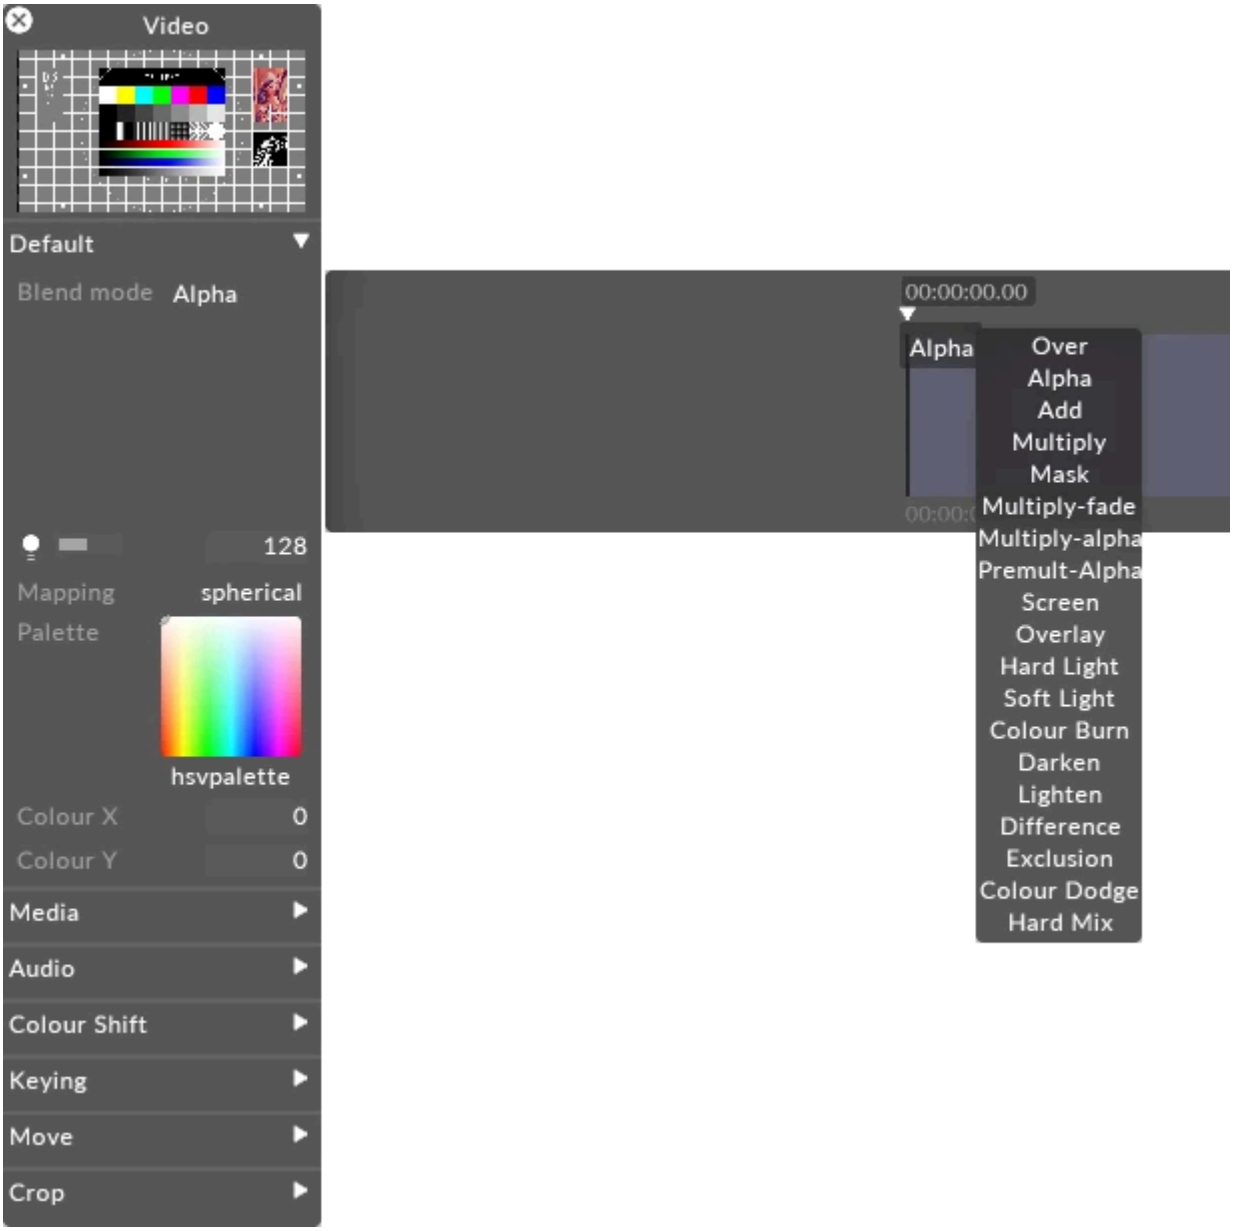
Choose **Frontplate** to render all screens whose **Render layer** is assigned to **Frontplate**, or choose **Backplate** to render all screens whose **Render layer** is assigned to **Backplate**.

Common Layer Properties

The Stage Render layer has the following Common Layer Properties:

Blend Mode

BlendMode controls how the output of the layer is composited with the layers below. Layers are rendered in a bottom-up order: layers at the top can modify the output of the layers below.



Changing brightness of a content layer in Designer is actually controlling the value of the alpha of the layer. Even when displaying a HAP video, the software will composite the layer with a controllable layer of alpha - one per layer.

There are two ways of expressing alpha in an image:

Straight alpha is an alpha channel which functions just like RGB. Alpha acts as a fourth channel of information per pixel which is as independent of the other three as R, G and B are of each other. For example, with straight alpha it is possible to have RGB = 255 (white) and alpha = 0 (fully transparent) on the same pixel. Internally generated content, such as gradient layer, are generated with straight alpha. This is the preferable style of alpha and considering the cleaner method of the two.

Premultiplied alpha takes the alpha and applies it to the values of the RGB channels per pixel. The more transparent something gets with premultiplied alpha, the closer it gets to black - as if the content is sitting on a black table. Premultiplied is the default output of Adobe Photoshop or AfterEffects. The result is our pixel at 255 RGB (full white) with 0 alpha would be calculated as a black pixel in the final image.

Here are explanations of what each individual blend mode will do.

Over

Makes a layer fully opaque. Premultiplies all alpha onto the RGB value of each pixel. Alpha = black, so adjusting the brightness of a layer in Over blend mode makes it darker.

Alpha

Default blend mode. It will apply alpha values as a transparency if the alpha is present. Brightness changes will make the layer more or less transparent.

Add

Adds the value of each RGB pixel together. Always creates a brighter result. Values clamp at 255.

Multiply

Reads the level of each subpixel as a level between 0.0 and 1.0, and multiplies source with blend. The result is always a darker image overall. For example: white x grey = 0.5. White turns transparent, black takes precedence. Alpha is applied in the same fashion as the Over Blend mode.

Mask

Applies a mask to the single layer **above** in the stack, irrespective of mapping. See **Mask blending** for more information.

Luma-Matte

This mode creates a Luma Matte by using a layer's **Rec. 709 luminance** to control the alpha channel of the layer **above**, irrespective of mapping.

To determine transparency, the luminance of each pixel is calculated using a weighted average of its red, green, and blue channels. The luminance value is then used as the alpha (opacity) value for the corresponding pixels in the upper layers.

As a result, white areas render the layer above fully opaque, black areas make them fully transparent, and grey areas create proportional semi-transparency. This is a specialized **Mask** blend mode; for more details on the underlying behaviour, see **Mask blending**.

Inv-Luma-Matte

The Inverse Luma Matte mask works the same as the **Luma Matte** mask but the transparency is inverted meaning white regions are transparent and black regions are opaque.

Multiply-Fade

The same as Multiply, but will make use of the alpha channel to calculate transparency in the source and blend layers. Since maximum transparency is premultiplied, alpha results in black. This will ignore black created through premultiplying.

Multiply-Alpha

Multiply with straight alpha. This mode assumes that the alpha has not been premultiplied onto the RGB values and will not apply a correction to the semi-transparent pixels.

Premultiply Alpha

Like how Multiply-fade will ignore the darkening caused by premultiplying, this blend mode will do the same with Alpha.

Colour Burn

Blend mode increases the contrast to darken the base colour while reflecting the blend colour. The darker the blend colour, the more intensely the colour will be applied in the base image. White as the blend colour produces no change. Using the colour burn blend mode can produce some harsh results at full opacity. The colour burn blend mode can be used to make tonal and colour adjustments to a layer.

Screen

This blend mode looks at each channels colour information and multiplies the inverse of the blend and base colous. The result is always a lighter colour. Screening with black leaves the colour unchanged. Screening with white produces white. The effect is similar to projecting multiple images on top of each other - where bright white is fully opaque, black is fully transparent and 50% grey is 50% transparent.

Overlay

Multiplies or screens the colours, depending on the base colour. Patterns or colours overlay the existing pixels while preserving the highlights and shadows of the base colour. The base colour is not replaced, but mixed with the blend colour to reflect the lightness or darkness of the original colour.

Hard Light

Multiplies or screens the colours, depending on the blend colour. The effects is similar to shining a harsh spotlight on the image. If the blend colour (light source/top layer) is lighter than

50% grey, the image is lightened as if it were screened. This is useful for adding highlights to an image. If the blend colour is darker than 50% grey, the image is darkened as if it were multiplied. This is useful for adding shadows to an image. Painting with pure black or white results in pure black or white.

Soft Light

Darkens or lightens the colours, depending on the blend colour. The effect is similar to shining a diffused spotlight on the image. If the blend colour (light source/top layer) is lighter than 50% grey, the image is lightened as it if were dodged. If the blend colour is darker than 50% grey, the image is darkened as if it were burned in. Painting with pure black or white produces a distinctly darker or lighter area, but does not result in pure black or white.

Darken

Looks as the colour information in each channel and selects the base or blend colour - whichever is darker - as the result colour. Pixels lighter than the blend colour are replaced and pixels darker than the blend colour do not change.

Lighten

Looks at the colour information in each channel and selects the base or blend colour - whichever is lighter - as the result colour. Pixels darker than the blend colour are replaced and pixels lighter than the blend colour do not change.

Difference

Looks at the colour information in each channel and subtracts either the blend colour from the base colour or the base colour from the blend colour depending on which has the greater brightness value. Blending with white inverts the base colour values and blending with black produces no change.

Exclusion

Creates an effects similar to but lower in contrast than the difference mode. Blending with white inverts the base colour values. Blending with black produces no change.

Colour Dodge

Looks at the colour information in each channel and brightens the base colour to reflect the blend colour by decreasing contrast between the two. Blending with black produces no change.

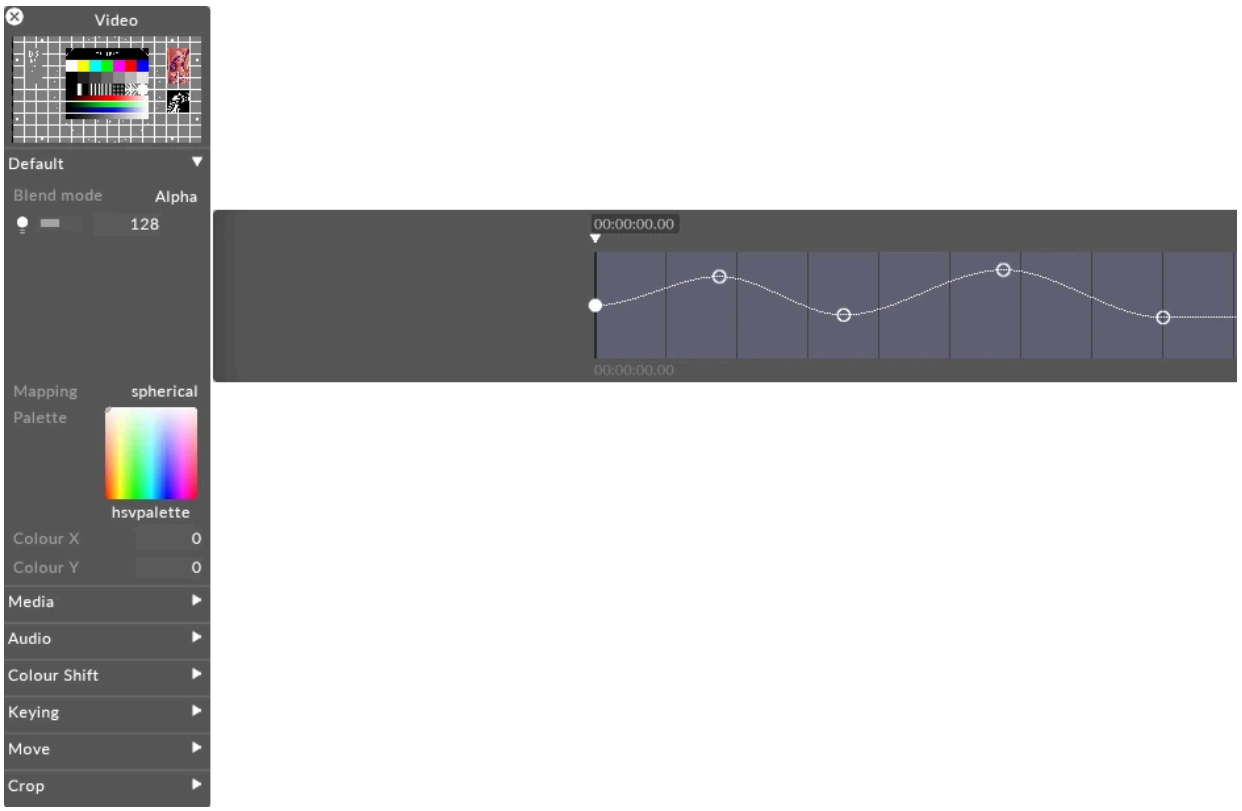
Hard Mix

Adds the RGB channels of the blend colour to the RGB values of the base colour. If the resulting sum for a channel is 255 or greater, it receives a value of 255; if it is less than 255 it

receives a value of 0. Therefore all blended pixels have RGB channels of either 0 or 255. This changes all pixels to primary additive colours (RGB), white or black.

Brightness

This property (which appears as a light bulb icon) controls the brightness of the layer output.



If the layers blend mode is set to Alpha, then reducing the brightness to 0 also reduces the opacity of the layer to 0. This can be useful when you want to dissolve from one layer to the next. In that case, you can place the new layer above the old layer and increase its brightness level.

> **Note**
>
> Layers that are patched to Sockpuppet (DMX, OSC or HTTP) are made Dormant when their brightness is set to 0. This means they will not do any rendering or consume any resources until their brightness is changed to > 0. You can find more information about this here: **Sequencing with Sockpuppet**. Layers without a sockpuppet patch do not behave in this way.

Mapping

The mapping property controls how the layer output is mapped onto the screen(s) in the Stage level.

For information on mapping, including how to use the different mapping types offered by Designer, please see the chapter **Content Mapping**

Video Layer

The Video layer plays pre-rendered video files and can include embedded audio.

It provides editable colour and effects controls, along with keying, movement, cropping, and timeline control.

Playback speed can be adjusted while the clip is playing. Unlike the legacy Video layer, speed can vary between keyframes.

Video layer properties

Media

Video

The Video property points to the still media file that defines the content to be used on the layer. Selecting this property will open the VideoClip object library, which shows all of the still image files saved on your local hard-drive in the VideoFile folder.

To change the current piece of content:

1. Left-click Video to open the VideoClip object library.
2. Left-click the media file you want to use.

See the Placing media files for a project sub-chapter to understand where to place a custom still image file and how to access it in Designer. Also save the file to a supported file format.

Speed

Selects playback speed. When this is set to 1, the video is played at its normal framerate; when set to 2, the video is played at double speed, when set to -1, the video is played at normal framerate in reverse and so on.

Mode

This specifies the playback mode. There are two modes - **Normal** and **Locked**. Each one has a specific behaviour that is useful for a different situation:

- **Normal**: When the play cursor stops, the video will also stop and the frame number will lock to the timeline position. When the cursor continues to play or holds at the end of a section, the video will play continuously. Jumping around the timeline while playing does not affect which frame is being played.
- **Locked**: If the play cursor continues to play or stops at the end of a section, the video frame number is locked to the playhead position on the timeline.

At end point

This specifies what happens when playback reaches the end of the video clip. There are three options to choose from:

- **Loop**: When playback reaches the end of the video clip, the clip will loop immediately back to the beginning and will start playing again from there.
- **Ping-pong**: When playback reaches the end of the video clip, the clip will play in reverse back to the beginning.
- **Pause**: When playback reaches the end of the video clip, the clip will pause on the last frame.

Transition Time

The transition property specifies the dissolve time, in seconds, when switching from one video clip to the next on the timeline. By default, this is set to 0, so the player cuts immediately from one clip to the next. Setting this value to 1 causes the player to dissolve from one clip to the next over 1 second.

Volume

Some video clips may contain audio. You can fill in any number between 0 (mute) and 255 (full) in the text field to set a constant volume, or open the propertys key-frame editor to fade volume in or out.

Output

If the video has an audio track, this controls which audio output device the audio is played to.

Threshold

The threshold of the keying. Colours closer than (threshold) to the key colour become transparent.

Hardness

The hardness of the keying. Lower numbers produce softer edges and higher numbers produce harder edges between transparent and opaque areas.

Key colour rgb

The value of the key colour, 0 255, causing the key colour to become transparent.

Scale

Controls the size of the video.

Aspect

Controls the aspect ratio of the video, higher numbers make the frame taller.

Pos xy

Position of the video:

- x = horizontal position
- y = vertical position
- 0 = centre of canvas
- -1 = top edge of canvas
- +1 = bottom edge

Rotation

Rotation (in degrees) of the video.

Crop left, right, top, bottom

Crops the frame from the respective edge. 0 = no crop, 1 = entire frame crop.

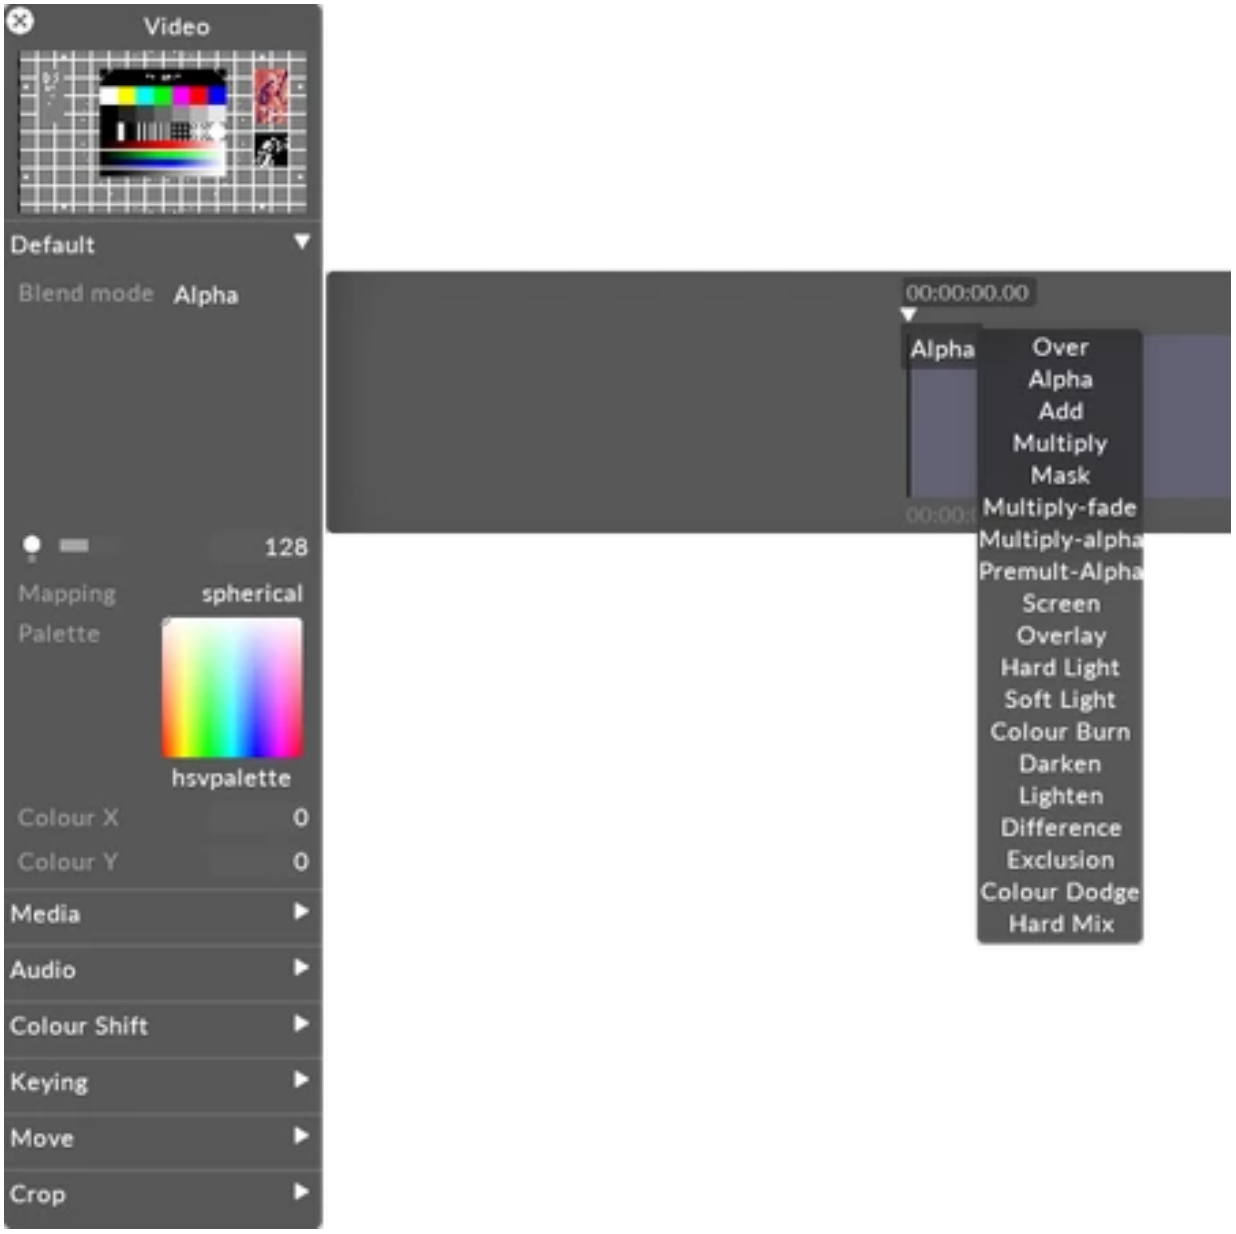
Vignette

Adds a vignette effect by softening the edges of the crop.

Common Layer Properties

Blend Mode

BlendMode controls how the output of the layer is composited with the layers below. Layers are rendered in a bottom-up order: layers at the top can modify the output of the layers below.



Changing brightness of a content layer in Designer is actually controlling the value of the alpha of the layer. Even when displaying a HAP video, the software will composite the layer with a controllable layer of alpha - one per layer.

There are two ways of expressing alpha in an image:

Straight alpha is an alpha channel which functions just like RGB. Alpha acts as a fourth channel of information per pixel which is as independent of the other three as R, G and B are of each other. For example, with straight alpha it is possible to have RGB = 255 (white) and alpha = 0 (fully transparent) on the same pixel. Internally generated content, such as gradient layer, are generated with straight alpha. This is the preferable style of alpha and considering the cleaner method of the two.

Premultiplied alpha takes the alpha and applies it to the values of the RGB channels per pixel. The more transparent something gets with premultiplied alpha, the closer it gets to black - as if the content is sitting on a black table. Premultiplied is the default output of Adobe Photoshop or AfterEffects. The result is our pixel at 255 RGB (full white) with 0 alpha would be calculated as a black pixel in the final image.

Here are explanations of what each individual blend mode will do.

Over

Makes a layer fully opaque. Premultiplies all alpha onto the RGB value of each pixel. Alpha = black, so adjusting the brightness of a layer in Over blend mode makes it darker.

Alpha

Default blend mode. It will apply alpha values as a transparency if the alpha is present. Brightness changes will make the layer more or less transparent.

Add

Adds the value of each RGB pixel together. Always creates a brighter result. Values clamp at 255.

Multiply

Reads the level of each subpixel as a level between 0.0 and 1.0, and multiplies source with blend. The result is always a darker image overall. For example: white x grey = 0.5. White turns transparent, black takes precedence. Alpha is applied in the same fashion as the Over Blend mode.

Mask

Applies a mask to the single layer **above** in the stack, irrespective of mapping. See **Mask blending** for more information.

Luma-Matte

This mode creates a Luma Matte by using a layer's **Rec. 709 luminance** to control the alpha channel of the layer **above**, irrespective of mapping.

To determine transparency, the luminance of each pixel is calculated using a weighted average of its red, green, and blue channels. The luminance value is then used as the alpha (opacity) value for the corresponding pixels in the upper layers.

As a result, white areas render the layer above fully opaque, black areas make them fully transparent, and grey areas create proportional semi-transparency. This is a specialized **Mask** blend mode; for more details on the underlying behaviour, see **Mask blending**.

Inv-Luma-Matte

The Inverse Luma Matte mask works the same as the **Luma Matte** mask but the transparency is inverted meaning white regions are transparent and black regions are opaque.

Multiply-Fade

The same as Multiply, but will make use of the alpha channel to calculate transparency in the source and blend layers. Since maximum transparency is premultiplied, alpha results in black. This will ignore black created through premultiplying.

Multiply-Alpha

Multiply with straight alpha. This mode assumes that the alpha has not been premultiplied onto the RGB values and will not apply a correction to the semi-transparent pixels.

Premultiply Alpha

Like how Multiply-fade will ignore the darkening caused by premultiplying, this blend mode will do the same with Alpha.

Colour Burn

Blend mode increases the contrast to darken the base colour while reflecting the blend colour. The darker the blend colour, the more intensely the colour will be applied in the base image. White as the blend colour produces no change. Using the colour burn blend mode can produce some harsh results at full opacity. The colour burn blend mode can be used to make tonal and colour adjustments to a layer.

Screen

This blend mode looks at each channels colour information and multiplies the inverse of the blend and base colous. The result is always a lighter colour. Screening with black leaves the colour unchanged. Screening with white produces white. The effect is similar to projecting multiple images on top of each other - where bright white is fully opaque, black is fully transparent and 50% grey is 50% transparent.

Overlay

Multiplies or screens the colours, depending on the base colour. Patterns or colours overlay the existing pixels while preserving the highlights and shadows of the base colour. The base colour is not replaced, but mixed with the blend colour to reflect the lightness or darkness of the original colour.

Hard Light

Multiplies or screens the colours, depending on the blend colour. The effects is similar to shining a harsh spotlight on the image. If the blend colour (light source/top layer) is lighter than

50% grey, the image is lightened as if it were screened. This is useful for adding highlights to an image. If the blend colour is darker than 50% grey, the image is darkened as if it were multiplied. This is useful for adding shadows to an image. Painting with pure black or white results in pure black or white.

Soft Light

Darkens or lightens the colours, depending on the blend colour. The effect is similar to shining a diffused spotlight on the image. If the blend colour (light source/top layer) is lighter than 50% grey, the image is lightened as it if were dodged. If the blend colour is darker than 50% grey, the image is darkened as if it were burned in. Painting with pure black or white produces a distinctly darker or lighter area, but does not result in pure black or white.

Darken

Looks as the colour information in each channel and selects the base or blend colour - whichever is darker - as the result colour. Pixels lighter than the blend colour are replaced and pixels darker than the blend colour do not change.

Lighten

Looks at the colour information in each channel and selects the base or blend colour - whichever is lighter - as the result colour. Pixels darker than the blend colour are replaced and pixels lighter than the blend colour do not change.

Difference

Looks at the colour information in each channel and subtracts either the blend colour from the base colour or the base colour from the blend colour depending on which has the greater brightness value. Blending with white inverts the base colour values and blending with black produces no change.

Exclusion

Creates an effects similar to but lower in contrast than the difference mode. Blending with white inverts the base colour values. Blending with black produces no change.

Colour Dodge

Looks at the colour information in each channel and brightens the base colour to reflect the blend colour by decreasing contrast between the two. Blending with black produces no change.

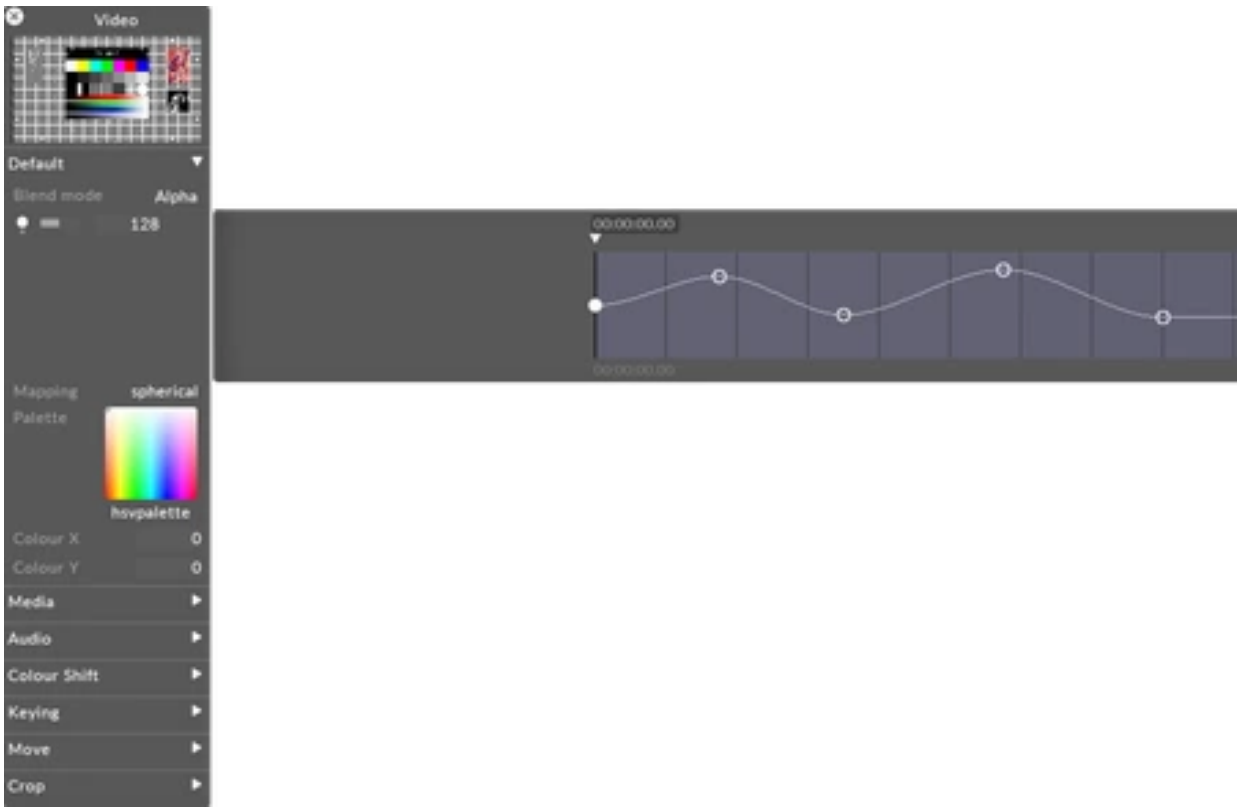
Hard Mix

Adds the RGB channels of the blend colour to the RGB values of the base colour. If the resulting sum for a channel is 255 or greater, it receives a value of 255; if it is less than 255 it

receives a value of 0. Therefore all blended pixels have RGB channels of either 0 or 255. This changes all pixels to primary additive colours (RGB), white or black.

Brightness

This property (which appears as a light bulb icon) controls the brightness of the layer output.

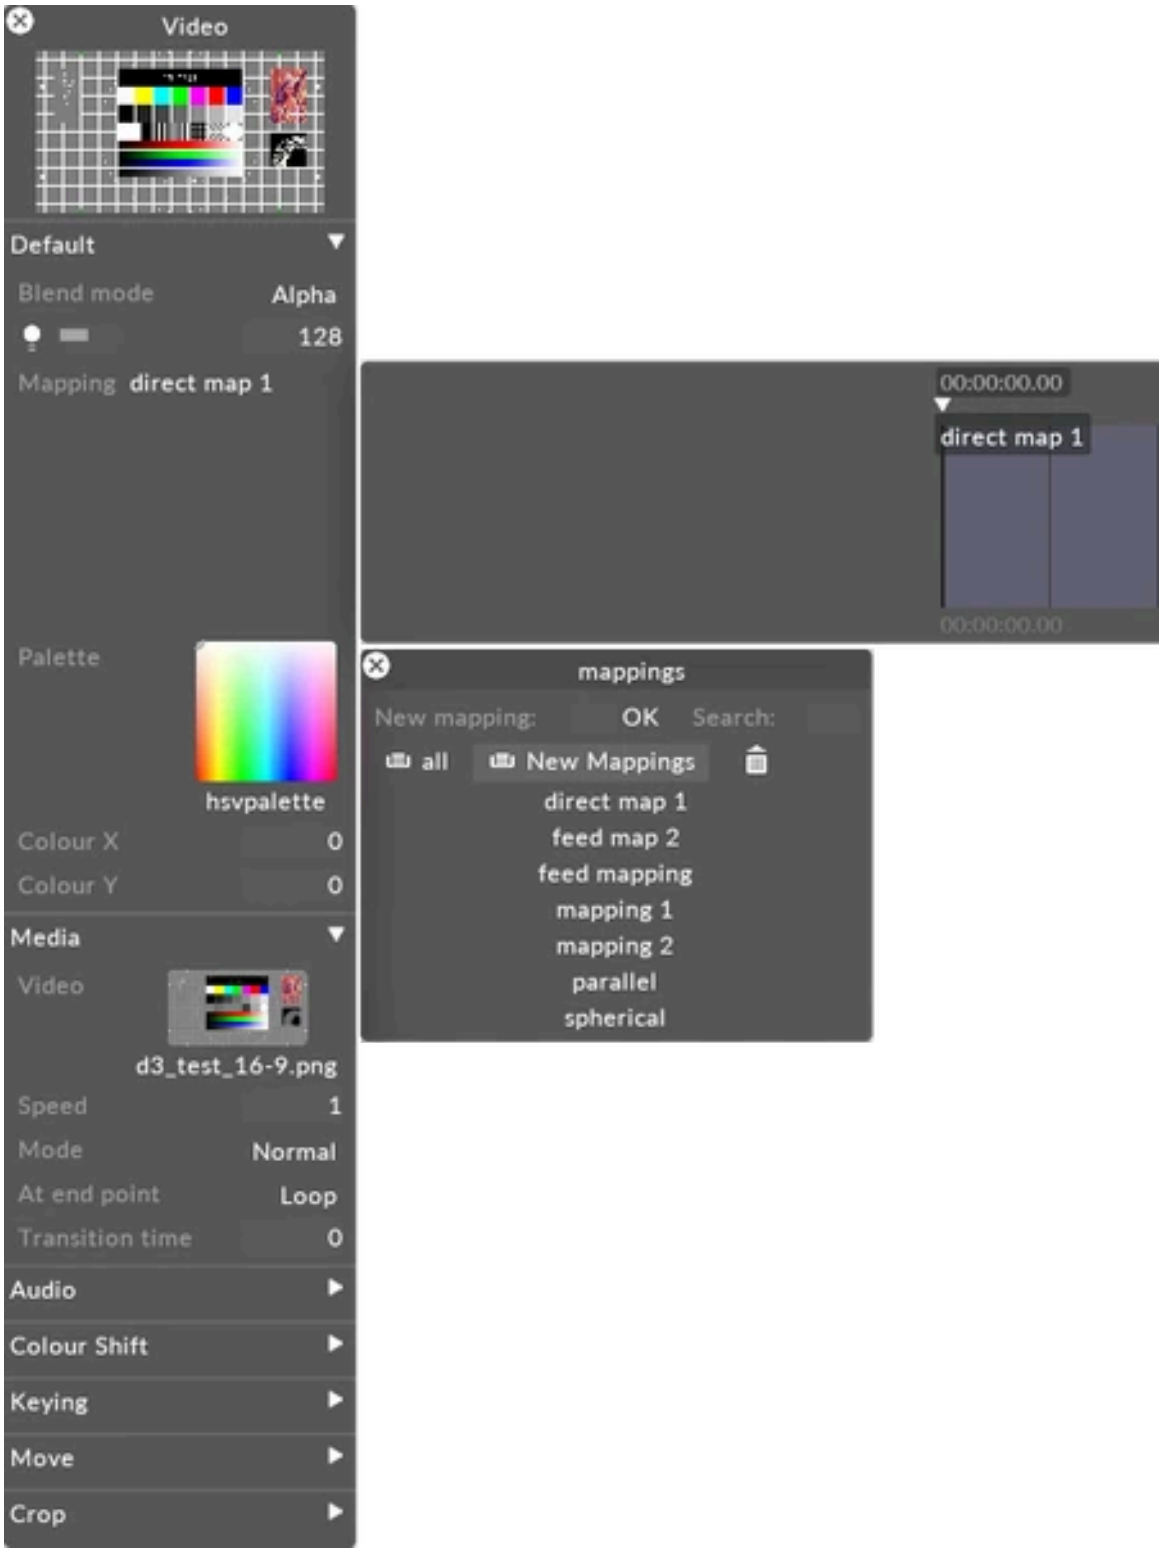


If the layers blend mode is set to Alpha, then reducing the brightness to 0 also reduces the opacity of the layer to 0. This can be useful when you want to dissolve from one layer to the next. In that case, you can place the new layer above the old layer and increase its brightness level.

> **Note**
>
> Layers that are patched to Sockpuppet (DMX, OSC or HTTP) are made Dormant when their brightness is set to 0. This means they will not do any rendering or consume any resources until their brightness is changed to > 0. You can find more information about this here: **Sequencing with Sockpuppet**. Layers without a sockpuppet patch do not behave in this way.

Mapping

The mapping property controls how the layer output is mapped onto the screen(s) in the Stage level.



For information on mapping, including how to use the different mapping types offered by Designer, please see the chapter **Content Mapping**

Palette

This points to the still image file that defines the bitmap from which the tint colour is taken. The default palette (HSVPAL) consists of the complete range of hues and saturations. Selecting this property will open the Texture object library, which shows all of the still image files saved on your local hard-drive in the **DxTexture** older.

To control the location within the current palette bitmap, and thus control the colour, you have to edit the **xCol** and **yCol** values (see the section for xCol, yCol).

To change the current palette bitmap:

1. Left-click **palette** to open the Texture object library.
2. Left-click the still image file you want to use for the palette bitmap.

If you want to use a palette bitmap other than the standard still images provided in Designer, you will need to use a custom still image file.

See the **Placing media files** for a project sub-chapter to understand where to place a custom still image file and how to access it in Designer. Also save the file to a **supported file format**.

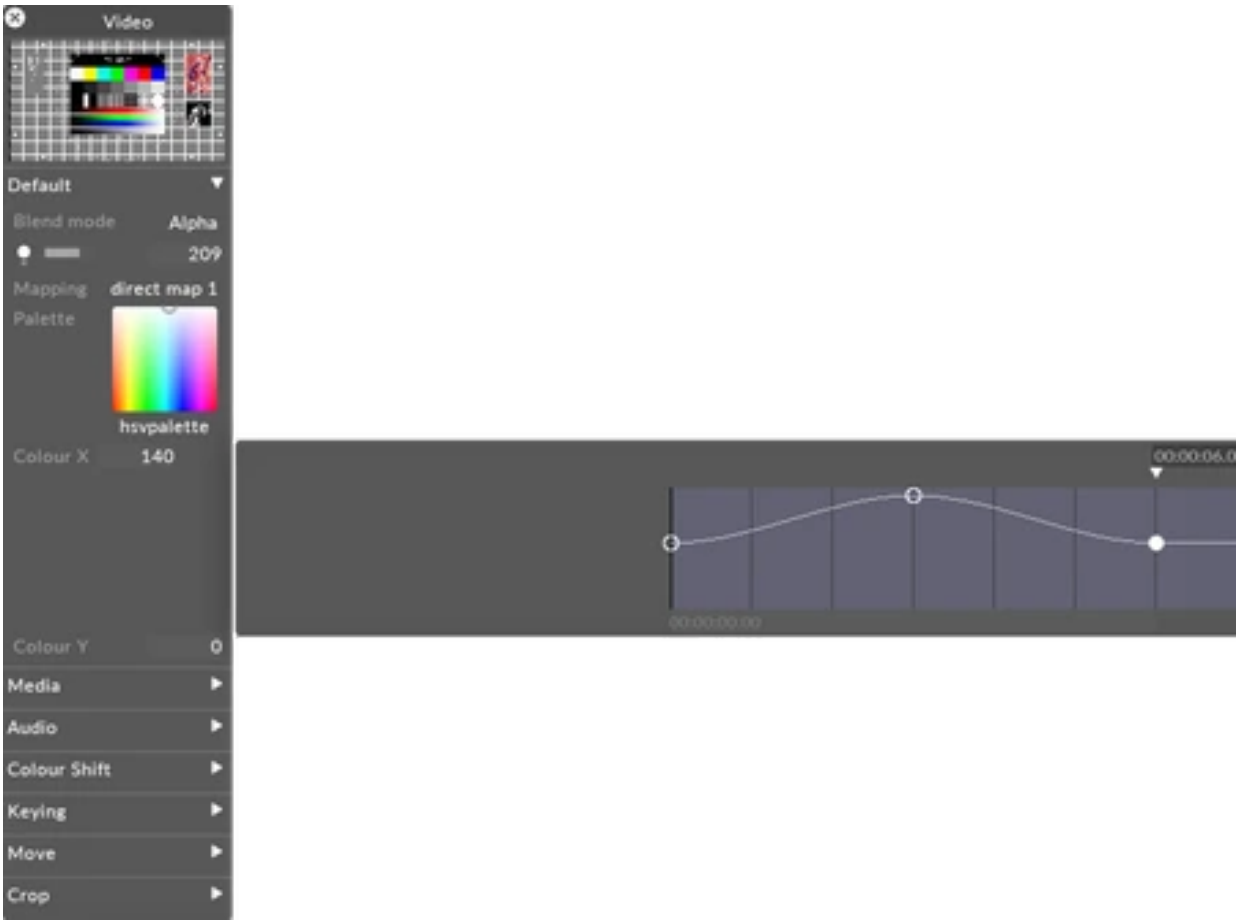
Xcol, YCol

These properties control the coordinates within the current palette bitmap where the output colour is sampled from. The default value is 0,0 which points at the color white (if you are using the HSVPAL palette). Multiplying white with the colors of the chosen content simply generates the original content colors. **Colour X** controls the horizontal position, where 0 is the leftmost

edge and 255 is the rightmost edge. **Colour Y** controls the vertical position, where 0 is the top edge and 255 is the bottom edge.

For example, to saturate the video clip red, change the **Colour Y** value to 255 and use 0 for the **Colour X** value. These coordinates refer to the color red in the palette which is being multiplied with the colors of the existing content.

When you are using the default palette HSVPAL , Colour Y controls saturation, and Colour X controls hue.



Colour Shift

The colour shift property allows you to perform a number of colour-correction operations on the output of a layer.

Colour Shift objects can also be attached to individual video files within the Video layer.

Colour Shift property performs colour-corrections on the output of a visual layer

Colour Shift properties are:

Brightness (shift)

Changes the floor of brightness to the constant given.

When set to 0, the range of brightness is 0 to 1, thus no change is applied to the image. When set to -1, the range of brightness is -1 to 0, thus the entire image is black. When set to 1, the range of brightness is 1 to 2, thus the entire image is white.

Brightness (shift) (from left to right): -1, -0.5, 0, 0.5, 1

Contrast (scale)

When set to 1, no change is applied to the image. When set to 0, all values have been pulled together to 50% grey, thus the image is entirely grey. When set to 2, the values are pulled in the opposite direction to meeting at mid grey, thus resulting in crushed white and black values.

Contrast (scale) (from left to right): 0, 0.5, 1, 1.5, 2

Saturation scale

When set to 1, no change is applied to the image. When set to 0, the image is desaturated to black and white. When set higher than 1, the image is hypersaturated.

Saturation scale (from left to right): 0, 0.5, 1, 2, 4

Hue shift

This property changing the hue of colours in an image, design, or graphic while maintaining other colour properties like saturation and brightness.

RGB controlled

This property controls how the min/max levels and gamma corrections are applied. If set to together, then the min, max and gamma values set for the red channel are mirrored to the green and blue channels, values set on the green and blue channels will be ignored. If set to separate , the min,max and gamma values can be controlled separately for red, green and blue. The latter setting allows you to apply fine colour balance controls to the image.

Min

This sets the lowest brightness level found in the image. All pixels at this level are scaled down to zero brightness. Increasing this value enforces shadows and dark levels in the image and can be used to reduce low-level compression artifacts in an image or video frame.

Increasing min equally across red, green and blue enforces shadows, whereas increasing min on an individual channel has the effect of shifting the colour balance away from that colour. For example, increasing red min shifts the image towards cyan.

With `RGB controlled` *set to Together (from left to right): 0, 0.3, 0.8*

With `RGB controlled` *set to Separate, red min (from left to right): 0, 0.3, 0.8*

Max

This sets the highest brightness level found in the image. All pixels at this level are scaled up to the maximumm level, i.e. 1. Decreasing this value brightens any highlights in the image. This is useful when the source image is too dark.

With `RGB controlled` *set to Together (from left to right): 1, 0.7, 0.2*

With `RGB controlled` *set to Separate, red max (from left to right): 1, 0.7, 0.2*

Tip

If you set min to 255 and max to 0, the image (or single channel) will be inverted.

Invert all (left), invert red (right)

Gamma

When gamma is set to 1, no change is made to the image. Reducing gamma brightens highlights while increasing gamma darkens lowlights. The maximum and minimum brightness levels remain the same.

With `RGB controlled` *set to Together (from left to right): 0.1, 1, 4*

With `RGB controlled` *set to Separate, red gamma (from left to right): 0.1, 1, 4*

Sockpuppet

When running a layer in sockpuppet mode there are a number of behaviour changes and additions to the video layer.

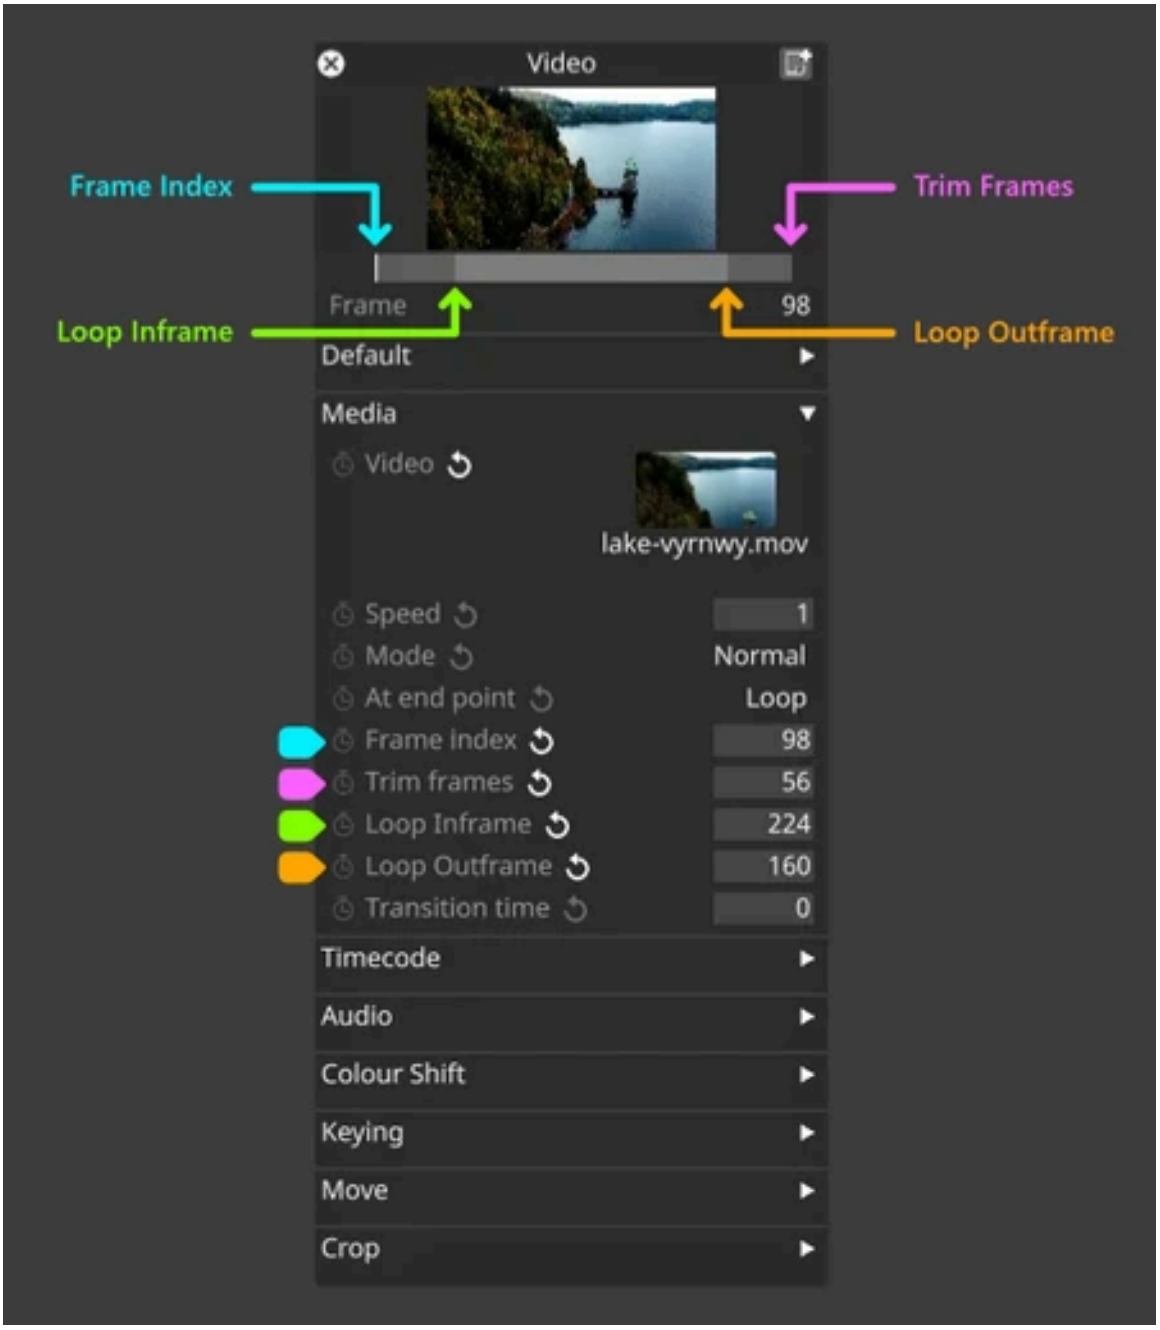
Mode

There are various different play modes when the video layer is sockpuppeted, they are detailed in the following table:

Mode	Effect
Normal	Play forward
Locked	This is the same as setting the mode to Normal, Sockpuppet does not care about track time.
Reset	Reset to the **Frame Index** or the first frame in the clip and hold
Pause	Pause at the current frame
Inframe	Go to the **Frame Index** and hold
Outframe	Go to the **Trim Frame** and hold
Reverse	Play the clip backwards, this is the same as setting the **Speed** field to -1
Timecode	Playback will trigger on the timecode set in the **Timecode section**
LoopInFrame	Go to the **Loop Inframe** and hold
LoopOutFrame	Go to the **Loop Outframe** and hold

Frame Controls

Along with the new play modes, there are additional fields to control where the playback starts, ends and loops.



Frame Index

This field sets where in the video the playback should start from in frames.

Trim Frame

This field sets where the playback of the clip should end if the endpoint behaviour is set to Pause.

It is calculated as frames from the end of the clip e.g. if a clip is 200 frames and it should stop at frame 150 then the value set should be 50 = 200 - 150.

Loop Inframe

This field sets where in the video playback a loop should continue from if the end point behaviour is set to Loop or Ping-Pong.

If the **Frame Index** is greater than this then it will be used instead.

Loop Outframe

This field sets where in the video playback a loop should start from, if the end point behaviour is set to Loop or Ping-Pong.

This is calculated the same as **Trim Frame** where this value should be a positive number subtracted from the total frames in the video clip.

If the **Trim Frame** is greater than this value then it will be used instead.

Timecode

On Clock Lost

This new field can override the behaviour of the Transport Manager On Clock Lost field for this layer. It will do nothing if left at default.

Hours, Minutes, Seconds, Frames

When the **Play Mode** is set to `Timecode` these fields will act as a trigger once valid timecode has played past the specified time.

Move

Clip Type

This new field can override the Video Clip's Clip Type field for this layer. It will do nothing if left at default.

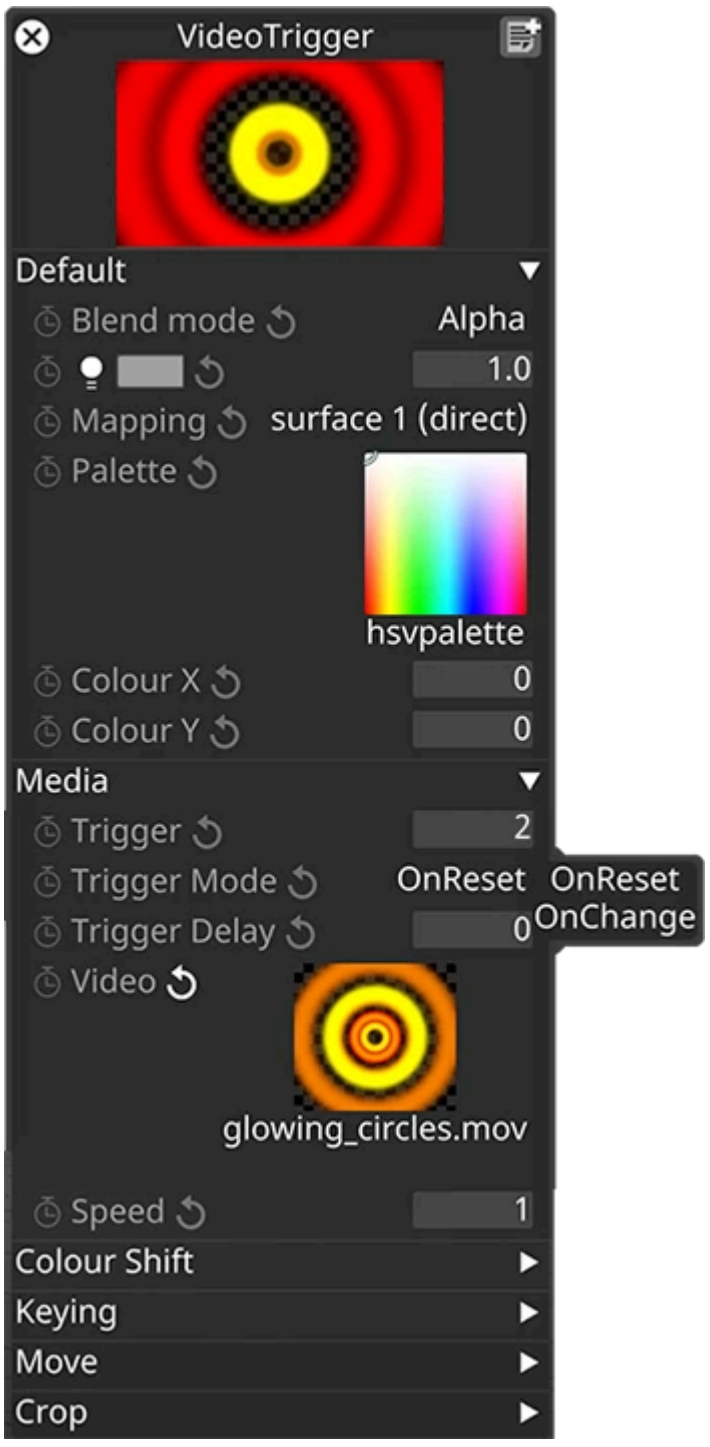
VideoTrigger Layer

The VideoTrigger layer triggers pre-rendered videos using timecode or cues.

The VideoTrigger layer works in the same way as the Legacy Video layer, with the main exceptions being that it does not support audio playback, and does not have a play mode, at end point, or transition time property.

VideoTrigger Layer Properties

Media



The trigger property allows for a video file to be triggered for playback either when a value changes from 0-1 (or 255 if using a DMX lighting console) (OnReset), or changing to another value (OnChange).

OnReset will cause the video file to playback once before returning to no content being shown. If you wish to trigger the file again, the trigger value needs to be reset to 0 before another value of 1 can be sent.

OnChange will cause the video file to playback when the trigger value changes to a new value.

Trigger Delay time can be added to delay the start of the video until a specific frame count.

Video

The Video property points to the still media file that defines the content to be used on the layer. Selecting this property will open the VideoClip object library, which shows all of the still image files saved on your local hard-drive in the VideoFile folder.

To change the current piece of content:

1. Left-click Video to open the VideoClip object library.
2. Left-click the media file you want to use.

See the Placing media files for a project sub-chapter to understand where to place a custom still image file and how to access it in Designer. Also save the file to a supported file format.

Speed

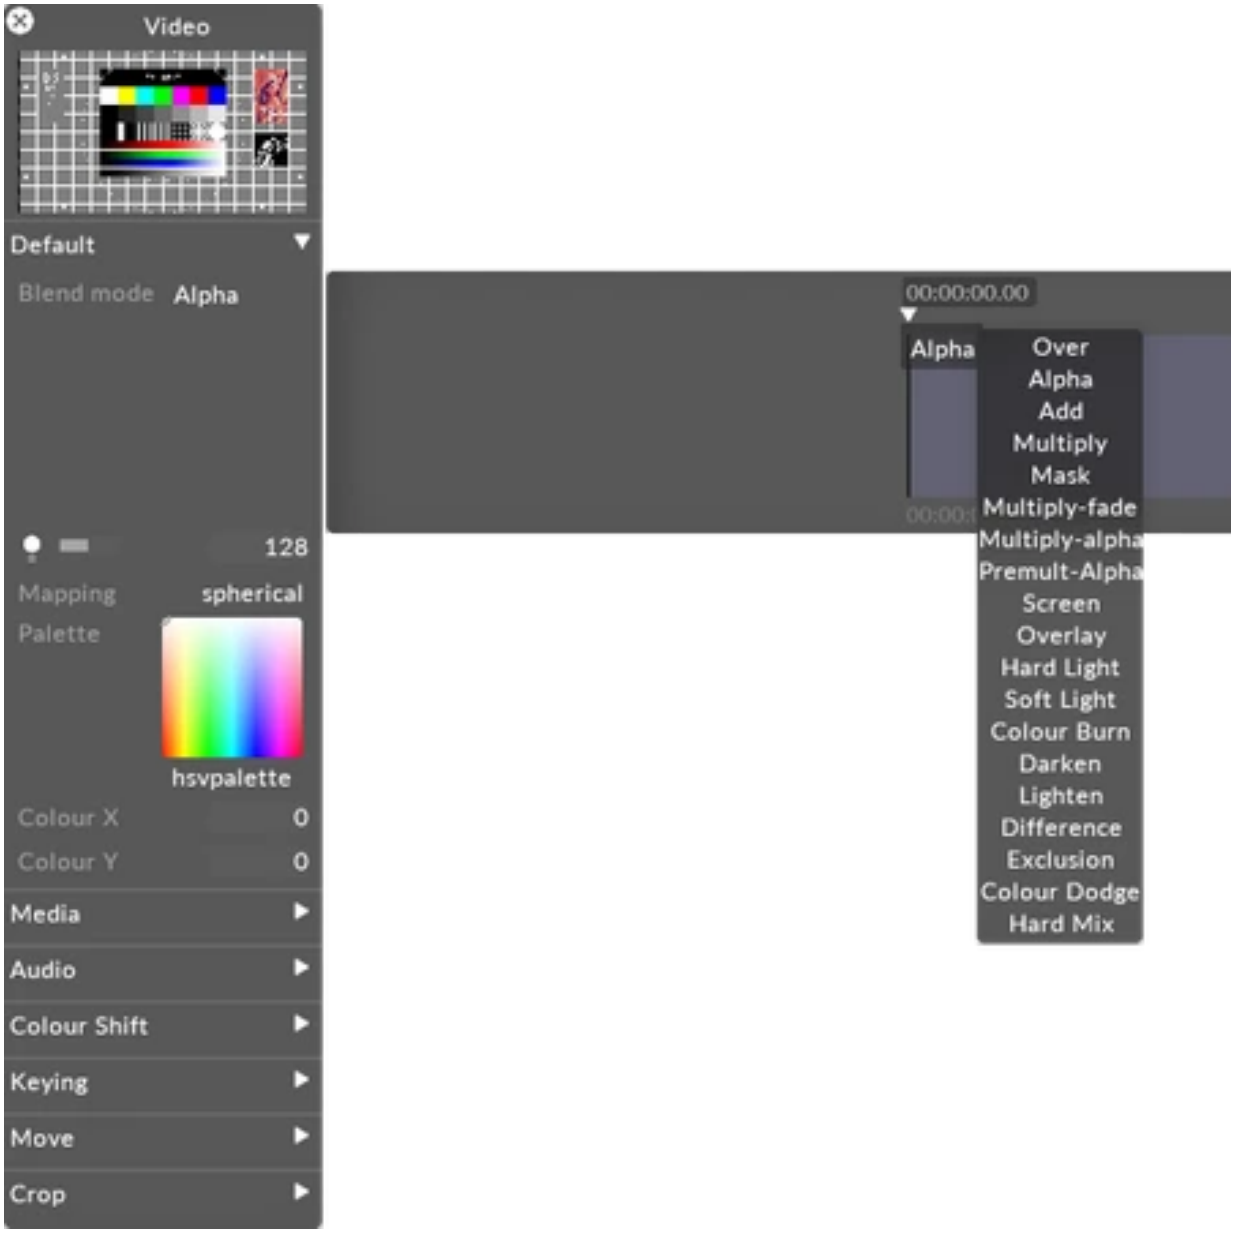
Selects playback speed. When this is set to 1, the video is played at its normal framerate; when set to 2, the video is played at double speed, when set to -1, the video is played at normal framerate in reverse and so on.

Common Layer Properties

The VideoTrigger layer has the following Common Layer Properties:

Blend Mode

BlendMode controls how the output of the layer is composited with the layers below. Layers are rendered in a bottom-up order: layers at the top can modify the output of the layers below.



Changing brightness of a content layer in Designer is actually controlling the value of the alpha of the layer. Even when displaying a HAP video, the software will composite the layer with a controllable layer of alpha - one per layer.

There are two ways of expressing alpha in an image:

Straight alpha is an alpha channel which functions just like RGB. Alpha acts as a fourth channel of information per pixel which is as independent of the other three as R, G and B are of each other. For example, with straight alpha it is possible to have RGB = 255 (white) and alpha = 0 (fully transparent) on the same pixel. Internally generated content, such as gradient layer, are generated with straight alpha. This is the preferable style of alpha and considering the cleaner method of the two.

Premultiplied alpha takes the alpha and applies it to the values of the RGB channels per pixel. The more transparent something gets with premultiplied alpha, the closer it gets to black - as if the content is sitting on a black table. Premultiplied is the default output of Adobe Photoshop or AfterEffects. The result is our pixel at 255 RGB (full white) with 0 alpha would be calculated as a black pixel in the final image.

Here are explanations of what each individual blend mode will do.

Over

Makes a layer fully opaque. Premultiplies all alpha onto the RGB value of each pixel. Alpha = black, so adjusting the brightness of a layer in Over blend mode makes it darker.

Alpha

Default blend mode. It will apply alpha values as a transparency if the alpha is present. Brightness changes will make the layer more or less transparent.

Add

Adds the value of each RGB pixel together. Always creates a brighter result. Values clamp at 255.

Multiply

Reads the level of each subpixel as a level between 0.0 and 1.0, and multiplies source with blend. The result is always a darker image overall. For example: white x grey = 0.5. White turns transparent, black takes precedence. Alpha is applied in the same fashion as the Over Blend mode.

Mask

Applies a mask to the single layer **above** in the stack, irrespective of mapping. See **Mask blending** for more information.

Luma-Matte

This mode creates a Luma Matte by using a layer's **Rec. 709 luminance** to control the alpha channel of the layer **above**, irrespective of mapping.

To determine transparency, the luminance of each pixel is calculated using a weighted average of its red, green, and blue channels. The luminance value is then used as the alpha (opacity) value for the corresponding pixels in the upper layers.

As a result, white areas render the layer above fully opaque, black areas make them fully transparent, and grey areas create proportional semi-transparency. This is a specialized **Mask** blend mode; for more details on the underlying behaviour, see **Mask blending**.

Inv-Luma-Matte

The Inverse Luma Matte mask works the same as the **Luma Matte** mask but the transparency is inverted meaning white regions are transparent and black regions are opaque.

Multiply-Fade

The same as Multiply, but will make use of the alpha channel to calculate transparency in the source and blend layers. Since maximum transparency is premultiplied, alpha results in black. This will ignore black created through premultiplying.

Multiply-Alpha

Multiply with straight alpha. This mode assumes that the alpha has not been premultiplied onto the RGB values and will not apply a correction to the semi-transparent pixels.

Premultiply Alpha

Like how Multiply-fade will ignore the darkening caused by premultiplying, this blend mode will do the same with Alpha.

Colour Burn

Blend mode increases the contrast to darken the base colour while reflecting the blend colour. The darker the blend colour, the more intensely the colour will be applied in the base image. White as the blend colour produces no change. Using the colour burn blend mode can produce some harsh results at full opacity. The colour burn blend mode can be used to make tonal and colour adjustments to a layer.

Screen

This blend mode looks at each channels colour information and multiplies the inverse of the blend and base colous. The result is always a lighter colour. Screening with black leaves the colour unchanged. Screening with white produces white. The effect is similar to projecting multiple images on top of each other - where bright white is fully opaque, black is fully transparent and 50% grey is 50% transparent.

Overlay

Multiplies or screens the colours, depending on the base colour. Patterns or colours overlay the existing pixels while preserving the highlights and shadows of the base colour. The base colour is not replaced, but mixed with the blend colour to reflect the lightness or darkness of the original colour.

Hard Light

Multiplies or screens the colours, depending on the blend colour. The effects is similar to shining a harsh spotlight on the image. If the blend colour (light source/top layer) is lighter than

50% grey, the image is lightened as if it were screened. This is useful for adding highlights to an image. If the blend colour is darker than 50% grey, the image is darkened as if it were multiplied. This is useful for adding shadows to an image. Painting with pure black or white results in pure black or white.

Soft Light

Darkens or lightens the colours, depending on the blend colour. The effect is similar to shining a diffused spotlight on the image. If the blend colour (light source/top layer) is lighter than 50% grey, the image is lightened as it if were dodged. If the blend colour is darker than 50% grey, the image is darkened as if it were burned in. Painting with pure black or white produces a distinctly darker or lighter area, but does not result in pure black or white.

Darken

Looks as the colour information in each channel and selects the base or blend colour - whichever is darker - as the result colour. Pixels lighter than the blend colour are replaced and pixels darker than the blend colour do not change.

Lighten

Looks at the colour information in each channel and selects the base or blend colour - whichever is lighter - as the result colour. Pixels darker than the blend colour are replaced and pixels lighter than the blend colour do not change.

Difference

Looks at the colour information in each channel and subtracts either the blend colour from the base colour or the base colour from the blend colour depending on which has the greater brightness value. Blending with white inverts the base colour values and blending with black produces no change.

Exclusion

Creates an effects similar to but lower in contrast than the difference mode. Blending with white inverts the base colour values. Blending with black produces no change.

Colour Dodge

Looks at the colour information in each channel and brightens the base colour to reflect the blend colour by decreasing contrast between the two. Blending with black produces no change.

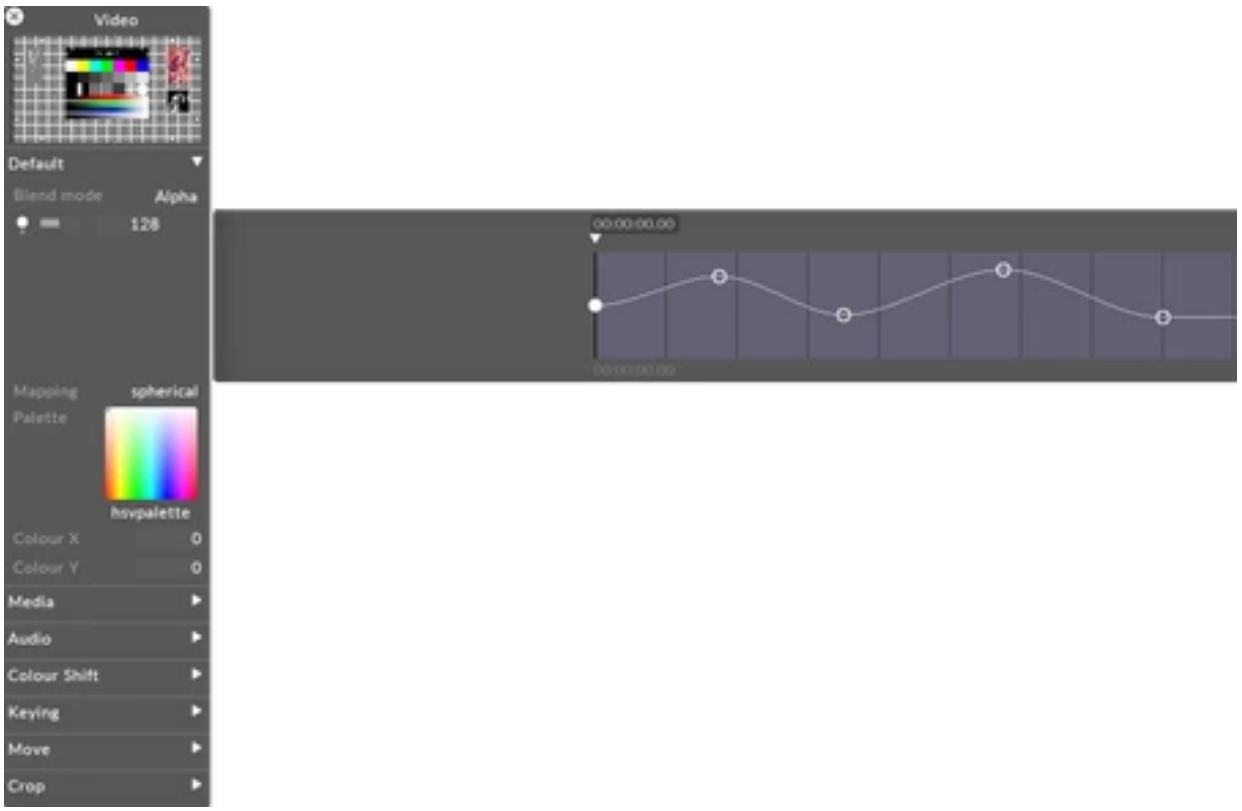
Hard Mix

Adds the RGB channels of the blend colour to the RGB values of the base colour. If the resulting sum for a channel is 255 or greater, it receives a value of 255; if it is less than 255 it

receives a value of 0. Therefore all blended pixels have RGB channels of either 0 or 255. This changes all pixels to primary additive colours (RGB), white or black.

Brightness

This property (which appears as a light bulb icon) controls the brightness of the layer output.

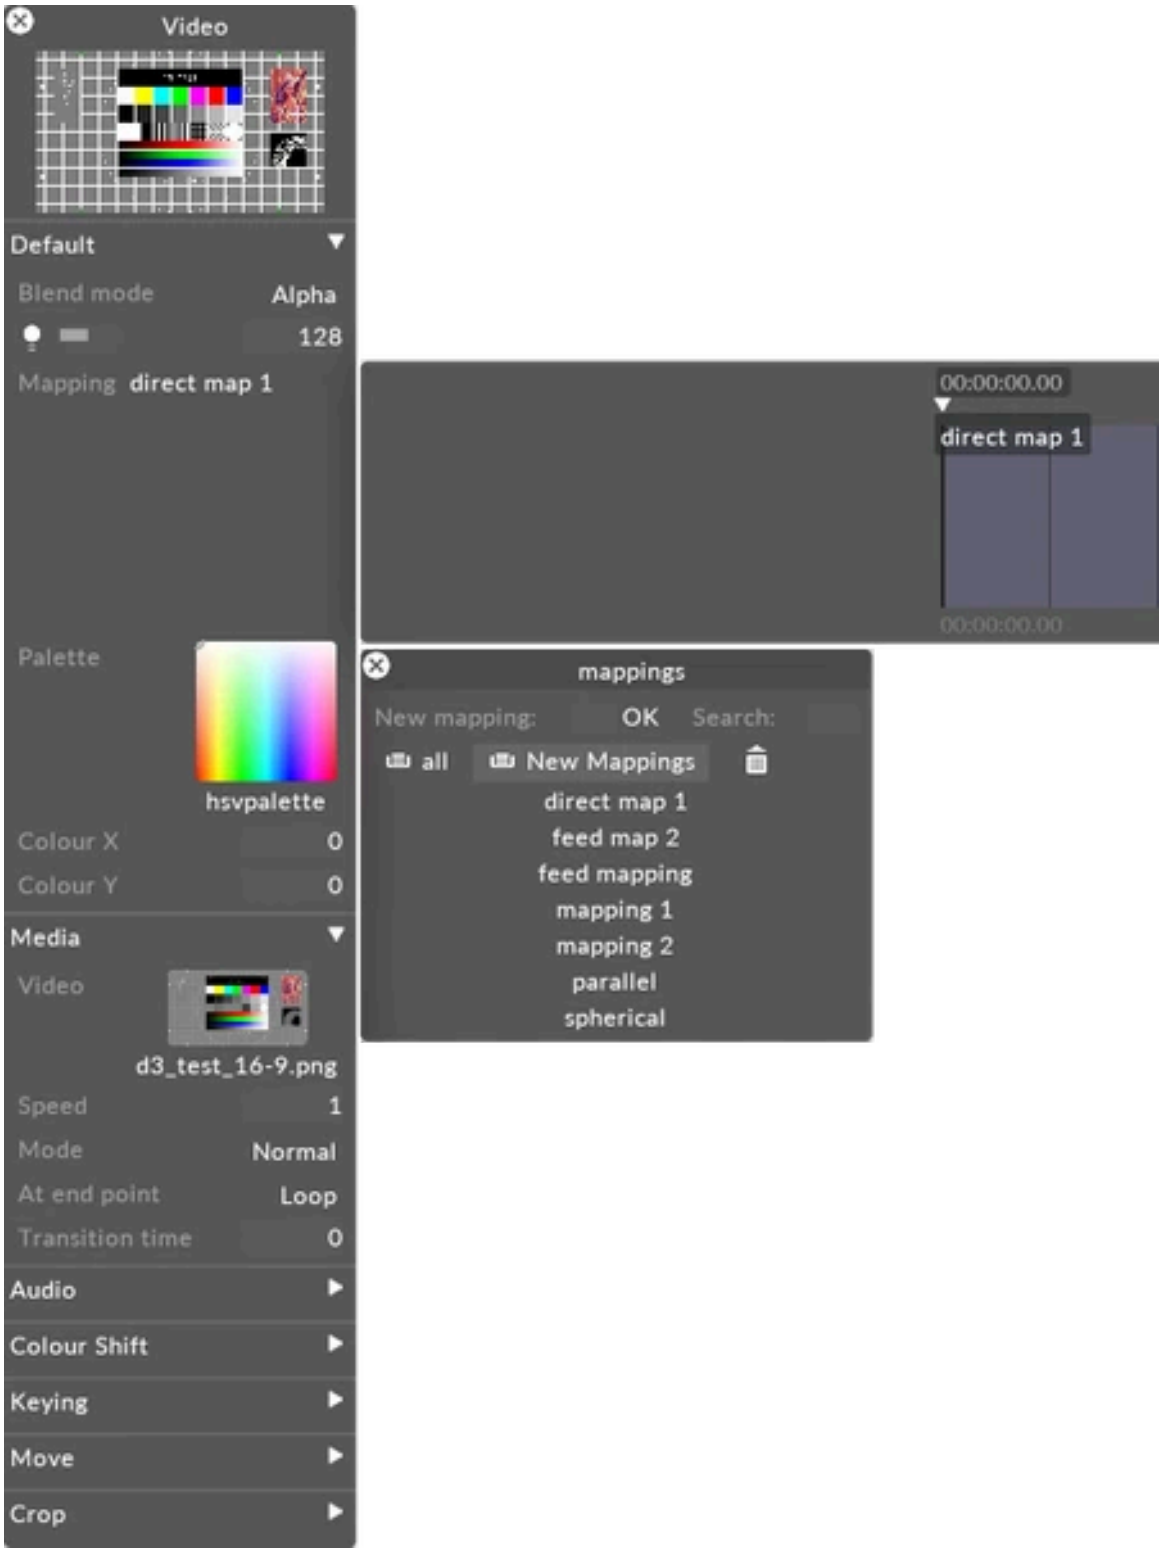


If the layers blend mode is set to Alpha, then reducing the brightness to 0 also reduces the opacity of the layer to 0. This can be useful when you want to dissolve from one layer to the next. In that case, you can place the new layer above the old layer and increase its brightness level.

> **Note**
>
> Layers that are patched to Sockpuppet (DMX, OSC or HTTP) are made Dormant when their brightness is set to 0. This means they will not do any rendering or consume any resources until their brightness is changed to > 0. You can find more information about this here: **Sequencing with Sockpuppet**. Layers without a sockpuppet patch do not behave in this way.

Mapping

The mapping property controls how the layer output is mapped onto the screen(s) in the Stage level.



For information on mapping, including how to use the different mapping types offered by Designer, please see the chapter **Content Mapping**

Palette

This points to the still image file that defines the bitmap from which the tint colour is taken. The default palette (HSVPAL) consists of the complete range of hues and saturations. Selecting this property will open the Texture object library, which shows all of the still image files saved on your local hard-drive in the **DxTexture** older.

To control the location within the current palette bitmap, and thus control the colour, you have to edit the **xCol** and **yCol** values (see the section for xCol, yCol).

To change the current palette bitmap:

1. Left-click **palette** to open the Texture object library.
2. Left-click the still image file you want to use for the palette bitmap.

If you want to use a palette bitmap other than the standard still images provided in Designer, you will need to use a custom still image file.

See the **Placing media files** for a project sub-chapter to understand where to place a custom still image file and how to access it in Designer. Also save the file to a **supported file format**.

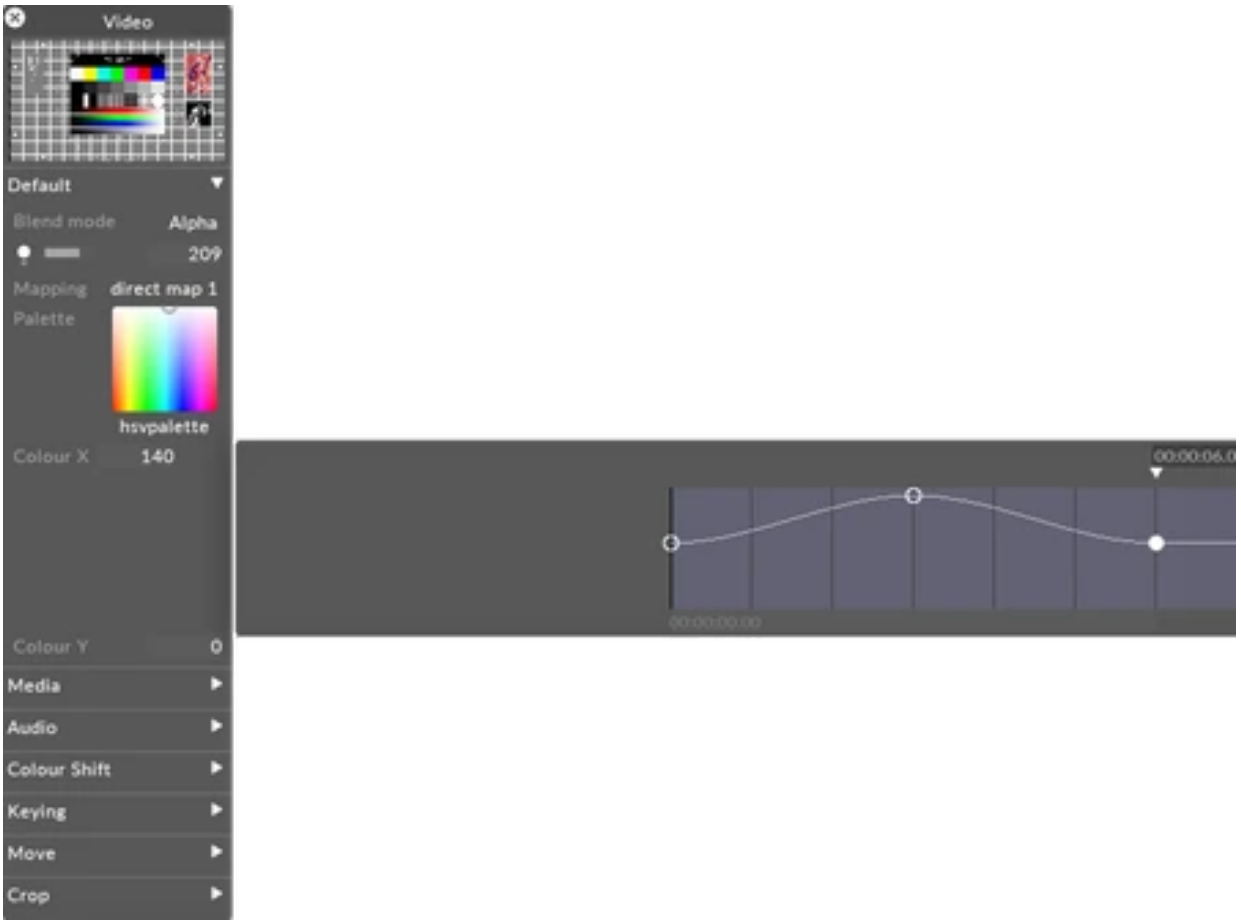
Xcol, YCol

These properties control the coordinates within the current palette bitmap where the output colour is sampled from. The default value is 0,0 which points at the color white (if you are using the HSVPAL palette). Multiplying white with the colors of the chosen content simply generates the original content colors. **Colour X** controls the horizontal position, where 0 is the leftmost

edge and 255 is the rightmost edge. **Colour Y** controls the vertical position, where 0 is the top edge and 255 is the bottom edge.

For example, to saturate the video clip red, change the **Colour Y** value to 255 and use 0 for the **Colour X** value. These coordinates refer to the color red in the palette which is being multiplied with the colors of the existing content.

When you are using the default palette HSVPAL , Colour Y controls saturation, and Colour X controls hue.



ColourShift

The colour shift property allows you to perform a number of colour-correction operations on the output of a layer.

Colour Shift objects can also be attached to individual video files within the Video layer.

Colour Shift property performs colour-corrections on the output of a visual layer

Colour Shift properties are:

Brightness (shift)

Changes the floor of brightness to the constant given.

When set to 0, the range of brightness is 0 to 1, thus no change is applied to the image. When set to -1, the range of brightness is -1 to 0, thus the entire image is black. When set to 1, the range of brightness is 1 to 2, thus the entire image is white.

Brightness (shift) (from left to right): -1, -0.5, 0, 0.5, 1

Contrast (scale)

When set to 1, no change is applied to the image. When set to 0, all values have been pulled together to 50% grey, thus the image is entirely grey. When set to 2, the values are pulled in the opposite direction to meeting at mid grey, thus resulting in crushed white and black values.

Contrast (scale) (from left to right): 0, 0.5, 1, 1.5, 2

Saturation scale

When set to 1, no change is applied to the image. When set to 0, the image is desaturated to black and white. When set higher than 1, the image is hypersaturated.

Saturation scale (from left to right): 0, 0.5, 1, 2, 4

Hue shift

This property changing the hue of colours in an image, design, or graphic while maintaining other colour properties like saturation and brightness.

RGB controlled

This property controls how the min/max levels and gamma corrections are applied. If set to together, then the min, max and gamma values set for the red channel are mirrored to the green and blue channels, values set on the green and blue channels will be ignored. If set to separate , the min,max and gamma values can be controlled separately for red, green and blue. The latter setting allows you to apply fine colour balance controls to the image.

Min

This sets the lowest brightness level found in the image. All pixels at this level are scaled down to zero brightness. Increasing this value enforces shadows and dark levels in the image and can be used to reduce low-level compression artifacts in an image or video frame.

Increasing min equally across red, green and blue enforces shadows, whereas increasing min on an individual channel has the effect of shifting the colour balance away from that colour. For example, increasing red min shifts the image towards cyan.

With `RGB controlled` *set to Together (from left to right): 0, 0.3, 0.8*

With `RGB controlled` *set to Separate, red min (from left to right): 0, 0.3, 0.8*

Max

This sets the highest brightness level found in the image. All pixels at this level are scaled up to the maximumm level, i.e. 1. Decreasing this value brightens any highlights in the image. This is useful when the source image is too dark.

With `RGB controlled` *set to Together (from left to right): 1, 0.7, 0.2*

With `RGB controlled` *set to Separate, red max (from left to right): 1, 0.7, 0.2*

Tip

If you set min to 255 and max to 0, the image (or single channel) will be inverted.

Invert all (left), invert red (right)

Gamma

When gamma is set to 1, no change is made to the image. Reducing gamma brightens highlights while increasing gamma darkens lowlights. The maximum and minimum brightness levels remain the same.

With `RGB controlled` *set to Together (from left to right): 0.1, 1, 4*

With `RGB controlled` *set to Separate, red gamma (from left to right): 0.1, 1, 4*

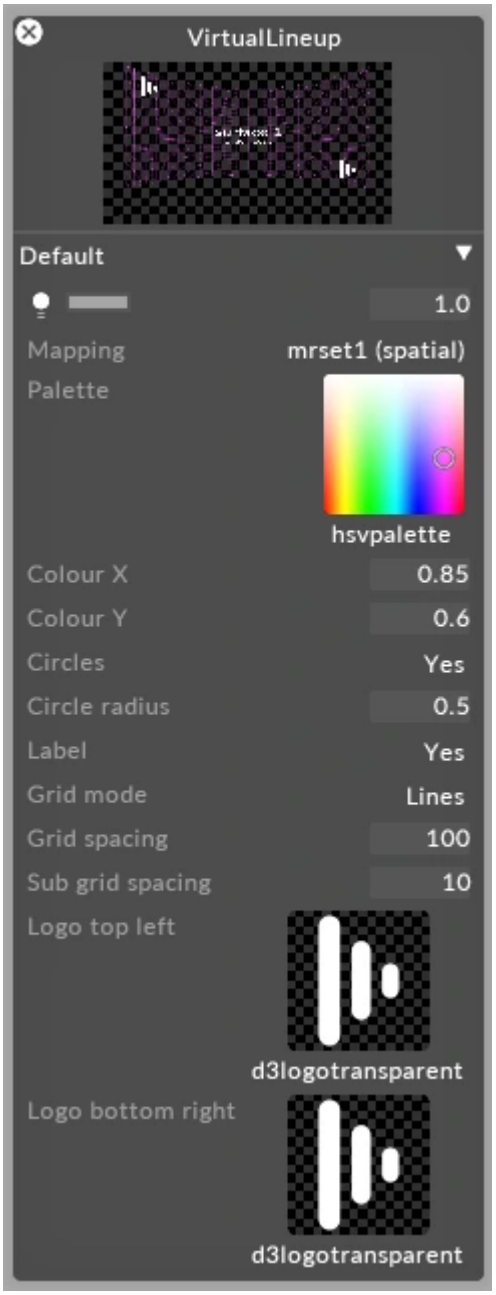
VirtualLineup

The VirtualLineup layer is used to line up the virtual world to a test pattern that is simultaneously displayed on the LED walls of an MR set.

An MR set is used for spatial mapping. Read about MR sets here.

Workflow

1. Create a new **VirtualLineup** layer.
2. Map the layer to the MR set using a spatial mapping.



VirtualLineup layer properties

The VirtualLineup layer has the following additional properties:

- Circles
- Circles Radius
- Label
- Grid mode
- Grid spacing
- Sub grid spacing

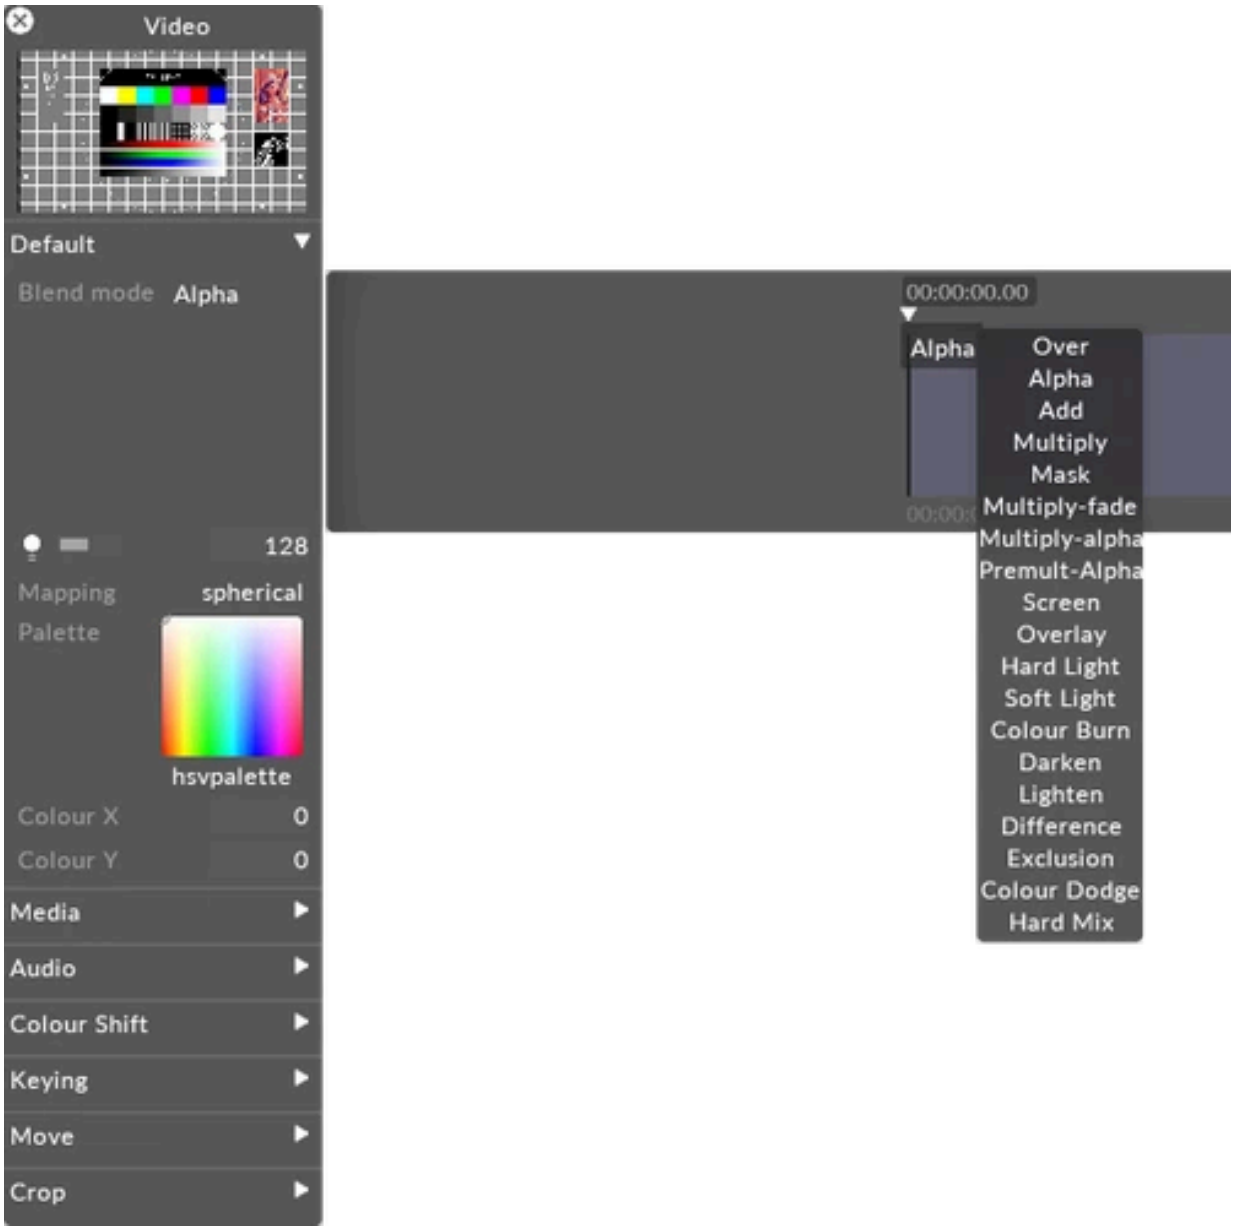
- Logo top left Logo top right

Common Layer Properties

The VideoLineup layer has the following Common Layer Properties:

Blend Mode

BlendMode controls how the output of the layer is composited with the layers below. Layers are rendered in a bottom-up order: layers at the top can modify the output of the layers below.



Changing brightness of a content layer in Designer is actually controlling the value of the alpha of the layer. Even when displaying a HAP video, the software will composite the layer with a

controllable layer of alpha - one per layer.

There are two ways of expressing alpha in an image:

Straight alpha is an alpha channel which functions just like RGB. Alpha acts as a fourth channel of information per pixel which is as independent of the other three as R, G and B are of each other. For example, with straight alpha it is possible to have RGB = 255 (white) and alpha = 0 (fully transparent) on the same pixel. Internally generated content, such as gradient layer, are generated with straight alpha. This is the preferable style of alpha and considering the cleaner method of the two.

Premultiplied alpha takes the alpha and applies it to the values of the RGB channels per pixel. The more transparent something gets with premultiplied alpha, the closer it gets to black - as if the content is sitting on a black table. Premultiplied is the default output of Adobe Photoshop or AfterEffects. The result is our pixel at 255 RGB (full white) with 0 alpha would be calculated as a black pixel in the final image.

Here are explanations of what each individual blend mode will do.

Over

Makes a layer fully opaque. Premultiplies all alpha onto the RGB value of each pixel. Alpha = black, so adjusting the brightness of a layer in Over blend mode makes it darker.

Alpha

Default blend mode. It will apply alpha values as a transparency if the alpha is present. Brightness changes will make the layer more or less transparent.

Add

Adds the value of each RGB pixel together. Always creates a brighter result. Values clamp at 255.

Multiply

Reads the level of each subpixel as a level between 0.0 and 1.0, and multiplies source with blend. The result is always a darker image overall. For example: white x grey = 0.5. White turns transparent, black takes precedence. Alpha is applied in the same fashion as the Over Blend mode.

Mask

Applies a mask to the single layer **above** in the stack, irrespective of mapping. See **Mask blending** for more information.

Luma-Matte

This mode creates a Luma Matte by using a layer's **Rec. 709 luminance** to control the alpha channel of the layer **above**, irrespective of mapping.

To determine transparency, the luminance of each pixel is calculated using a weighted average of its red, green, and blue channels. The luminance value is then used as the alpha (opacity) value for the corresponding pixels in the upper layers.

As a result, white areas render the layer above fully opaque, black areas make them fully transparent, and grey areas create proportional semi-transparency. This is a specialized **Mask** blend mode; for more details on the underlying behaviour, see **Mask blending**.

Inv-Luma-Matte

The Inverse Luma Matte mask works the same as the **Luma Matte** mask but the transparency is inverted meaning white regions are transparent and black regions are opaque.

Multiply-Fade

The same as Multiply, but will make use of the alpha channel to calculate transparency in the source and blend layers. Since maximum transparency is premultiplied, alpha results in black. This will ignore black created through premultiplying.

Multiply-Alpha

Multiply with straight alpha. This mode assumes that the alpha has not been premultiplied onto the RGB values and will not apply a correction to the semi-transparent pixels.

Premultiply Alpha

Like how Multiply-fade will ignore the darkening caused by premultiplying, this blend mode will do the same with Alpha.

Colour Burn

Blend mode increases the contrast to darken the base colour while reflecting the blend colour. The darker the blend colour, the more intensely the colour will be applied in the base image. White as the blend colour produces no change. Using the colour burn blend mode can produce some harsh results at full opacity. The colour burn blend mode can be used to make tonal and colour adjustments to a layer.

Screen

This blend mode looks at each channels colour information and multiplies the inverse of the blend and base colous. The result is always a lighter colour. Screening with black leaves the colour unchanged. Screening with white produces white. The effect is similar to projecting

multiple images on top of each other - where bright white is fully opaque, black is fully transparent and 50% grey is 50% transparent.

Overlay

Multiplies or screens the colours, depending on the base colour. Patterns or colours overlay the existing pixels while preserving the highlights and shadows of the base colour. The base colour is not replaced, but mixed with the blend colour to reflect the lightness or darkness of the original colour.

Hard Light

Multiplies or screens the colours, depending on the blend colour. The effects is similar to shining a harsh spotlight on the image. If the blend colour (light source/top layer) is lighter than 50% grey, the image is lightened as if it were screened. This is useful for adding highlights to an image. If the blend colour is darker than 50% grey, the image is darkened as if it were multiplied. This is useful for adding shadows to an image. Painting with pure black or white results in pure black or white.

Soft Light

Darkens or lightens the colours, depending on the blend colour. The effect is similar to shining a diffused spotlight on the image. If the blend colour (light source/top layer) is lighter than 50% grey, the image is lightened as it if were dodged. If the blend colour is darker than 50% grey, the image is darkened as if it were burned in. Painting with pure black or white produces a distinctly darker or lighter area, but does not result in pure black or white.

Darken

Looks as the colour information in each channel and selects the base or blend colour - whichever is darker - as the result colour. Pixels lighter than the blend colour are replaced and pixels darker than the blend colour do not change.

Lighten

Looks at the colour information in each channel and selects the base or blend colour - whichever is lighter - as the result colour. Pixels darker than the blend colour are replaced and pixels lighter than the blend colour do not change.

Difference

Looks at the colour information in each channel and subtracts either the blend colour from the base colour or the base colour from the blend colour depending on which has the greater brightness value. Blending with white inverts the base colour values and blending with black produces no change.

Exclusion

Creates an effects similar to but lower in contrast than the difference mode. Blending with white inverts the base colour values. Blending with black produces no change.

Colour Dodge

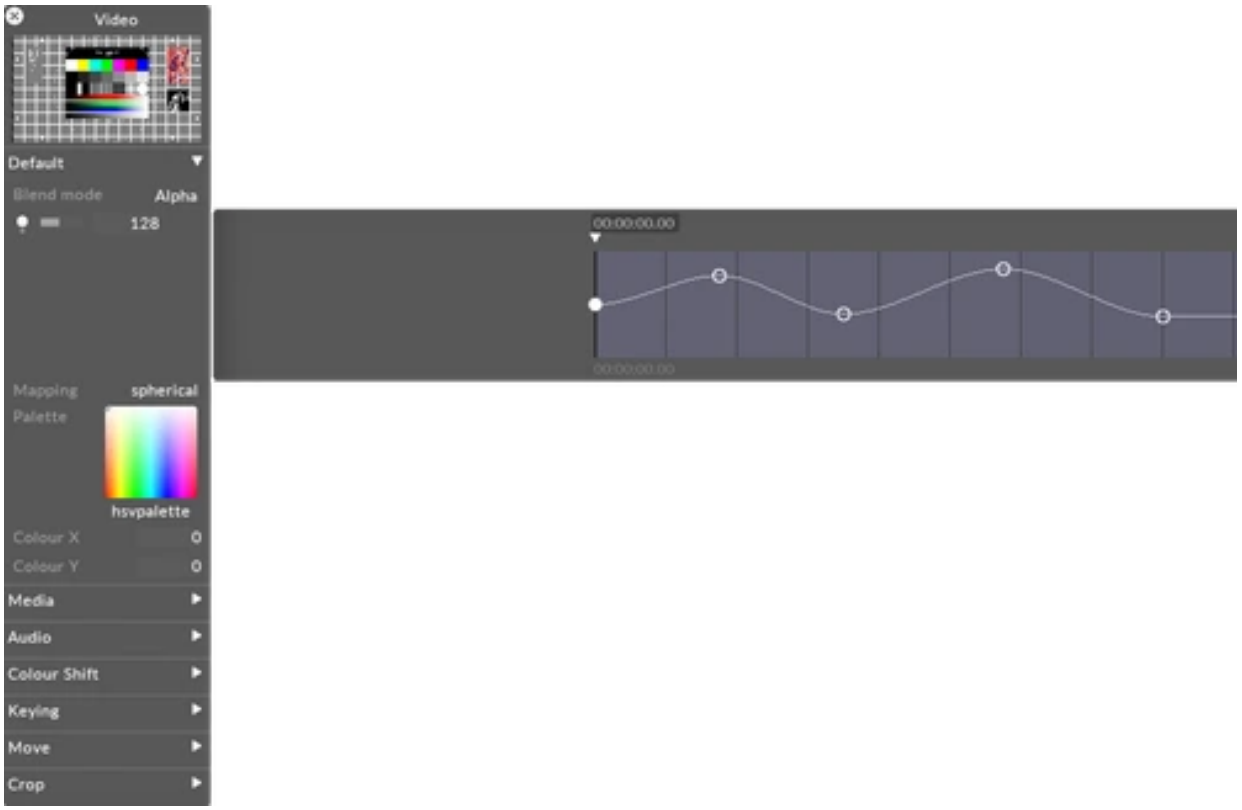
Looks at the colour information in each channel and brightens the base colour to reflect the blend colour by decreasing contrast between the two. Blending with black produces no change.

Hard Mix

Adds the RGB channels of the blend colour to the RGB values of the base colour. If the resulting sum for a channel is 255 or greater, it receives a value of 255; if it is less than 255 it receives a value of 0. Therefore all blended pixels have RGB channels of either 0 or 255. This changes all pixels to primary additive colours (RGB), white or black.

Brightness

This property (which appears as a light bulb icon) controls the brightness of the layer output.



If the layers blend mode is set to Alpha, then reducing the brightness to 0 also reduces the opacity of the layer to 0. This can be useful when you want to dissolve from one layer to the

next. In that case, you can place the new layer above the old layer and increase its brightness level.

> **Note**
>
> Layers that are patched to Sockpuppet (DMX, OSC or HTTP) are made Dormant when their brightness is set to 0. This means they will not do any rendering or consume any resources until their brightness is changed to > 0. You can find more information about this here: **Sequencing with Sockpuppet**. Layers without a sockpuppet patch do not behave in this way.

Mapping

The mapping property controls how the layer output is mapped onto the screen(s) in the Stage level.

For information on mapping, including how to use the different mapping types offered by Designer, please see the chapter **Content Mapping**

Palette

This points to the still image file that defines the bitmap from which the tint colour is taken. The default palette (HSVPAL) consists of the complete range of hues and saturations. Selecting this property will open the Texture object library, which shows all of the still image files saved on your local hard-drive in the **DxTexture** older.

To control the location within the current palette bitmap, and thus control the colour, you have to edit the **xCol** and **yCol** values (see the section for xCol, yCol).

To change the current palette bitmap:

1. Left-click **palette** to open the Texture object library.
2. Left-click the still image file you want to use for the palette bitmap.

If you want to use a palette bitmap other than the standard still images provided in Designer, you will need to use a custom still image file.

See the Placing media files for a project sub-chapter to understand where to place a custom still image file and how to access it in Designer. Also save the file to a **supported file format**.

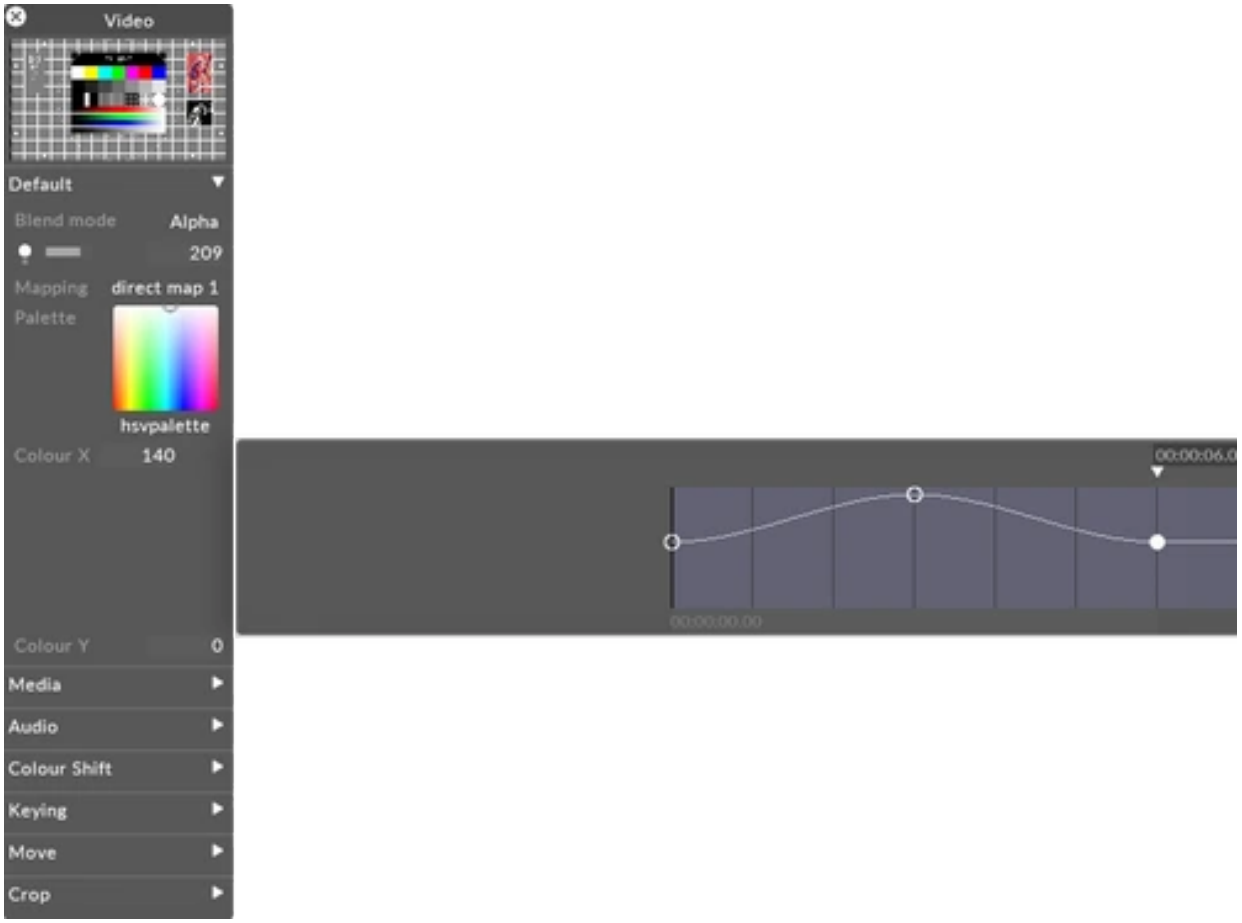
Xcol, YCol

These properties control the coordinates within the current palette bitmap where the output colour is sampled from. The default value is 0,0 which points at the color white (if you are using the HSVPAL palette). Multiplying white with the colors of the chosen content simply generates the original content colors. **Colour X** controls the horizontal position, where 0 is the leftmost edge and 255 is the rightmost edge. **Colour Y** controls the vertical position, where 0 is the top edge and 255 is the bottom edge.

For example, to saturate the video clip red, change the **Colour Y** value to 255 and use 0 for the **Colour X** value. These coordinates refer to the color red in the palette which is being multiplied

with the colors of the existing content.

When you are using the default palette HSVPAL , Colour Y controls saturation, and Colour X controls hue.



ColourShift

The colour shift property allows you to perform a number of colour-correction operations on the output of a layer.

Colour Shift objects can also be attached to individual video files within the Video layer.

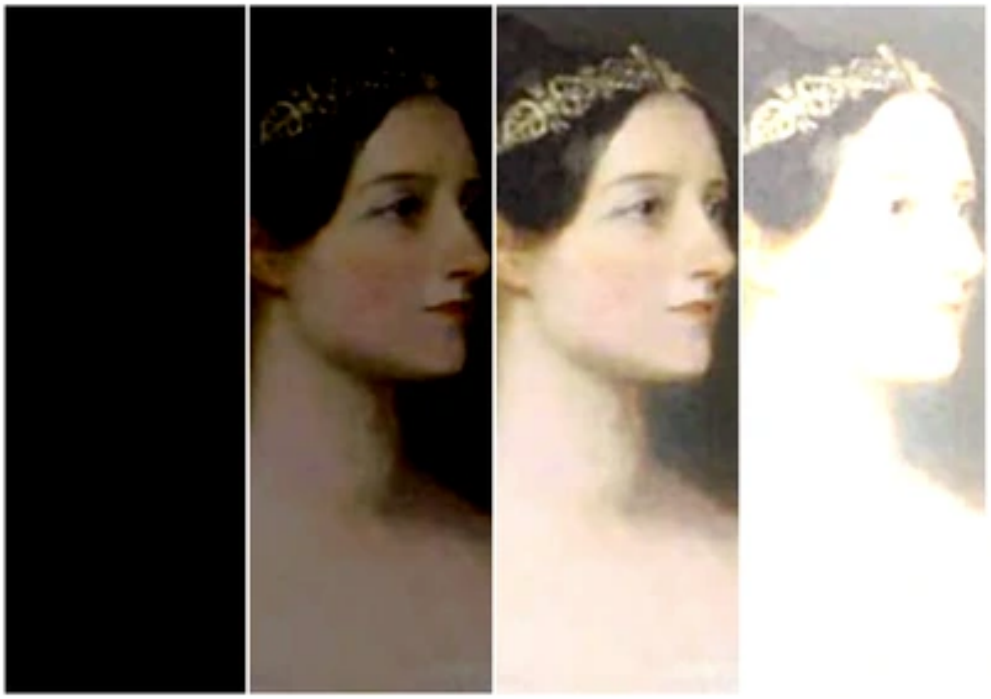
Colour Shift property performs colour-corrections on the output of a visual layer

Colour Shift properties are:

Brightness (shift)

Changes the floor of brightness to the constant given.

When set to 0, the range of brightness is 0 to 1, thus no change is applied to the image. When set to -1, the range of brightness is -1 to 0, thus the entire image is black. When set to 1, the range of brightness is 1 to 2, thus the entire image is white.



Brightness (shift) (from left to right): -1, -0.5, 0, 0.5, 1

Contrast (scale)

When set to 1, no change is applied to the image. When set to 0, all values have been pulled together to 50% grey, thus the image is entirely grey. When set to 2, the values are pulled in the opposite direction to meeting at mid grey, thus resulting in crushed white and black values.

Contrast (scale) (from left to right): 0, 0.5, 1, 1.5, 2

Saturation scale

When set to 1, no change is applied to the image. When set to 0, the image is desaturated to black and white. When set higher than 1, the image is hypersaturated.

Saturation scale (from left to right): 0, 0.5, 1, 2, 4

Hue shift

This property changing the hue of colours in an image, design, or graphic while maintaining other colour properties like saturation and brightness.

RGB controlled

This property controls how the min/max levels and gamma corrections are applied. If set to together, then the min, max and gamma values set for the red channel are mirrored to the green and blue channels, values set on the green and blue channels will be ignored. If set to separate , the min,max and gamma values can be controlled separately for red, green and blue. The latter setting allows you to apply fine colour balance controls to the image.

Min

This sets the lowest brightness level found in the image. All pixels at this level are scaled down to zero brightness. Increasing this value enforces shadows and dark levels in the image and can be used to reduce low-level compression artifacts in an image or video frame.

Increasing min equally across red, green and blue enforces shadows, whereas increasing min on an individual channel has the effect of shifting the colour balance away from that colour. For example, increasing red min shifts the image towards cyan.

With `RGB controlled` *set to Together (from left to right): 0, 0.3, 0.8*

With `RGB controlled` *set to Separate, red min (from left to right): 0, 0.3, 0.8*

Max

This sets the highest brightness level found in the image. All pixels at this level are scaled up to the maximumm level, i.e. 1. Decreasing this value brightens any highlights in the image. This is useful when the source image is too dark.

With `RGB controlled` *set to Together (from left to right): 1, 0.7, 0.2*

With `RGB controlled` *set to Separate, red max (from left to right): 1, 0.7, 0.2*

Tip

If you set min to 255 and max to 0, the image (or single channel) will be inverted.

Invert all (left), invert red (right)

Gamma

When gamma is set to 1, no change is made to the image. Reducing gamma brightens highlights while increasing gamma darkens lowlights. The maximum and minimum brightness levels remain the same.

With `RGB controlled` *set to Together (from left to right): 0.1, 1, 4*

With `RGB controlled` *set to Separate, red gamma (from left to right): 0.1, 1, 4*

Web Layer

The Web layer provides the ability to render HTML5 webpages as content in Designer. However, Disguise goes further and allows you to 'hook' and integrate your web pages to the time.

Key features of the layer

- Bookmarks for navigation (with thumbnails).
- Ability to send **JavaScript Commands** to the open web page (see field called Command) i.e. PageTransitions.nextPage(2, 1).
- Ability to send 5 custom timeline float values into the page via JavaScript. Provides the ability to animate items in your web page in sequence with the timeline, or change font sizes.
- Ability to send various standard timeline clock information into the page via JavaScript.
- Support for transparent background pages. E.g. `body { background-color: rgba(0, 0, 0, 0); }`, hence allowing you to composite items into (like a twitter feed).
- Support for simple user interaction with the page from 3 (see the **Interact** button at the top of the Web Layer).
- Locally hosted HTML5 pages.

Browser feature support

The browser has the following attributes:

- Utilises software renderer (as Designer has exclusive lock of the GPU).
- Browsers are 'sand boxed' in separate processes to prevent negative impact on Designer.
- Supports HTML5.
- Utilises WebKit -> Based off Chromium (check "about:version" URL for exact version using this path: Interact → URL: "about:version" → go).
- Adobe Flash is not supported, but the system is capable of running limited Flash Plugin functionality. Flash must be installed independently on the machine in question.
- WebGL is not supported.
- three.js and other libraries that utilise hardware GPU rendering are not supported.

> **Warning**
>
> Layer instances reset every time universal crossfade is triggered. This means that web layers will fade out/into themselves even if the same page is used across sections.

> **Note**
>
> For more information about the browser and specific feature support, visit our Chromium Web Integration page here.

Web Layer Properties

Interact

Opens an interaction window so that you can control the web page in real time.

Bookmark

The bookmark for the web page you wish to browse. If you change the bookmark along the timeline, the new webpage will load in the background and then be presented.

Command

The JavaScript command you wish to issue. You can fire commands along a timeline that manipulate the site, such as turning the page, etc.

Size

Two modes:

Match Mapping - this sets the size of the website canvas to match that of the Mapping it is being applied to.

Custom - allows you to manually set the size (Width/Height) of the web browser. The browser canvas will then be scaled up to match the Mapping.

Custom Parameters

Name X: The name of the JavaScript function you wish to call every frame. The function name in JavaScript will be `d3.*customParam1*(x)`.

Value X: The value you wish to pass into the JavaScript function.

Clear Cache

Clears the web browsers cache.

Reset Browser

Tears down and resets the web browsing session.

Bookmarks

Bookmarks are the way you select your web layers content.

The options in a bookmark are:

URL

This address can be a web address or file address.

- Web addresses are prefixed with `http://` or `https://`
- File addresses relate to HTML5 files contained within your d3 project folder structure. All locally stored html5 files should be under project_folder/objects/Web/sub_folder. For example, a sample page is located in every new project at “file:///sample pages/slide heading.html”.

Background

The web layer is capable of rendering pages with transparent backgrounds to allow you to composite, or with white backgrounds.

For transparent backgrounds to function correctly, the web page must set its background to be transparent.

Example CSS: ** `body { background-color: rgba(0, 0, 0, 0); }`

Zoom

Allows you to text zoom with correctly rendered fonts. This is similar to pressing Ctrl+/- in a regular browser.

Interact

You are able to directly interact with web pages using a small browser. To open the browser, click the interact button.

While this window has focus, you are able to interact with the webpage including:

- Typing
- Clicking links

- Scrolling with the mouse wheel

You can change the size of the interaction window with the Scale or 50%/100% buttons.

JavaScript Commands

Creating JS commands is very straightforward.

1. Create a JS Command and fill in the JavaScript you want executed in the browser.
2. Place the command on the timeline at the time you want it executed.

When the timeline is playing and crosses over the keyframe for the command, it will be executed.

JavaScript Functions

The Web layer contains five pairs of Name/Value.

Every frame will call a function in your web page with **Name** entered in that string (in the 'd3.' namespace), passing it a single float 'Value'.

d3.customParam1(1.0)

Essentially is 'pushing' the data into your webpage.

You can then write the corresponding function to do with as you please.

NB: functions must be in the d3 namespace.

```
var g_size = 0 // here's an example global variable which d3 will set
```

```
var d3 =

{
    /* You can specify the names of custom functions in d3. Below are some defau
lts. */
    /* Every function is called every frame */

    customParam1: function(myVal) { g\_size = myVal }, // set the global
    variable in this function

    customParam2: function(myVal) {},
    customParam3: function(myVal) {},
    customParam4: function(myVal) {},
    customParam5: function(myVal) {},

    /* Below are the inbuilt d3 functions that give your custom HTML5 content a
context*/

    lockedTime: function(tBeats) {

    },

    normalTime: function(tBeats) {

    },

    globalTime: function(tBeats) {

    },

    bpm: function(tBeats) {

    },

    status: function(statusString) {

    },

    dmxUniverses: function(universe, data) {

    }
}

    function setup() {
        createCanvas(1920, 1080);
        background(222);
    }

    function draw() {
    ellipse(mouseX, mouseY, 50 + 50 \* g\_size, 50 + 50 \* g\_size);
    // use the global variable to modify content.
}
```

You can download an example project using JS/HTML from our Resources page in the Web Interaction section at this link.

Standard JavaScript Functions

These JavaScript functions are designed to allow the web page to respond to changes to the Disguise timeline. They are called every frame on the web browser. If the HTML5 page has been coded to respond to these functions, then it will according

`d3.lockedTime(float)` — Time in beats within the current layer.

`d3.normalTime(float)` — Time in beats within the current layer, but carries on counting up. (See video player behaviour to get the idea).

`d3.globalTime(float)` — Time in beats within the whole track.

`d3.bpm(float)` — Current BPM of the track.

`d3.status(string)` — Provides the play head status. Either: “playing”, “holding”, “stopped”.

`d3.dmxUniverses(array[int], array[array[int]])` — Provides a dump of the universes selected in the layer editor.

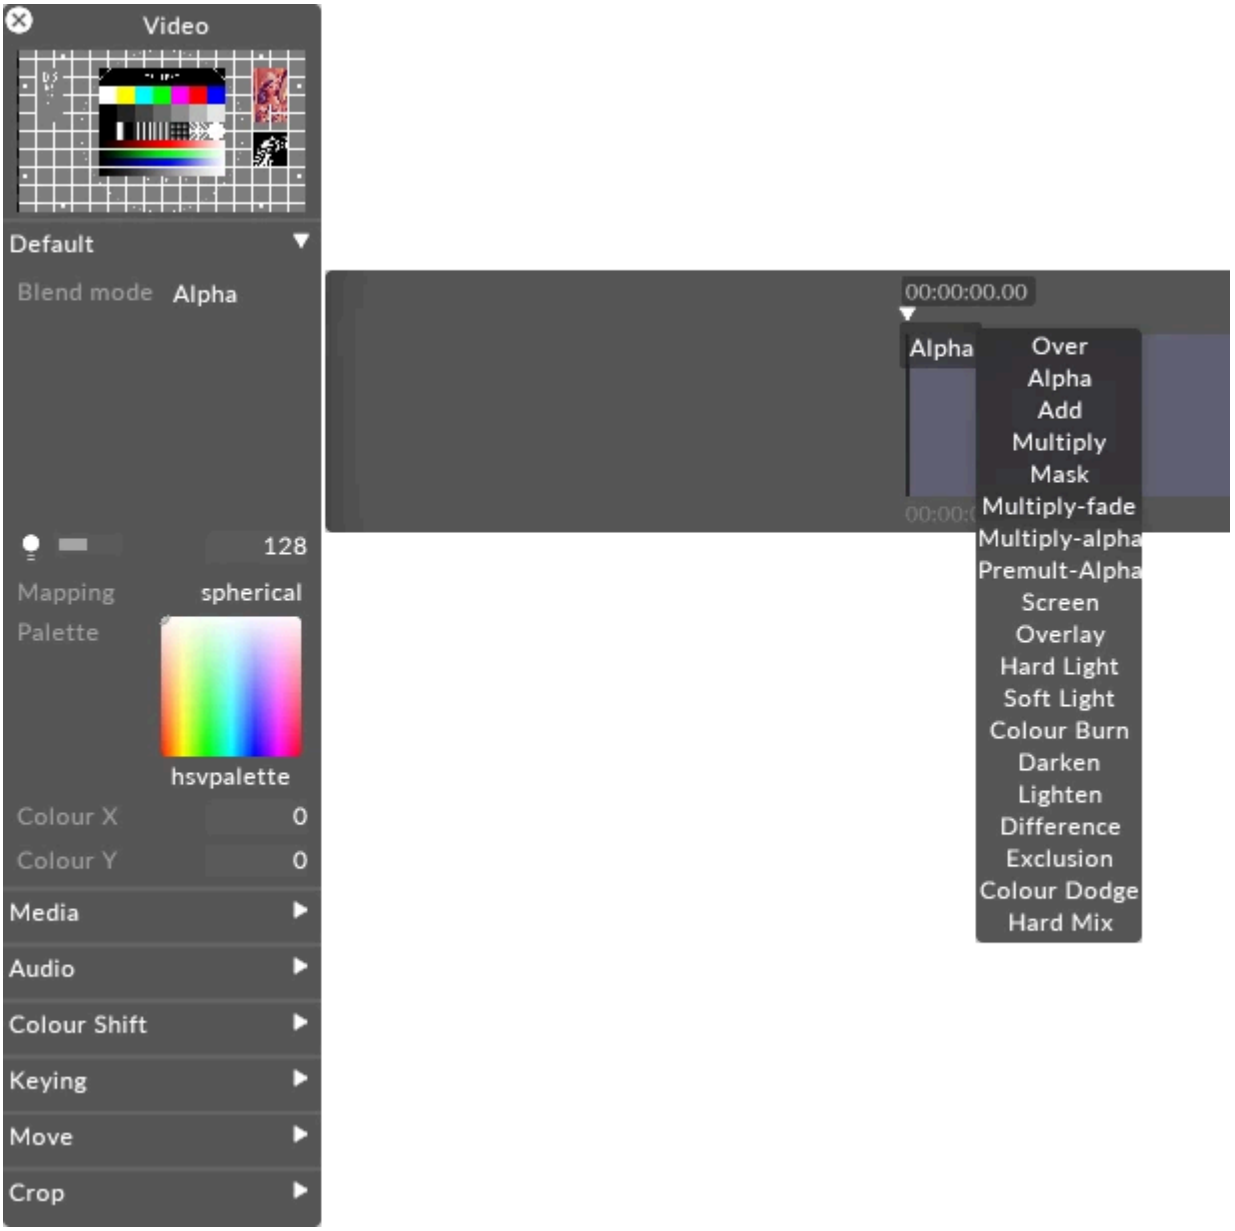
Proprietary video codecs (like h264) are not supported currently.

Common Layer Properties

The Web layer has the following Common Layer Properties:

Blend Mode

BlendMode controls how the output of the layer is composited with the layers below. Layers are rendered in a bottom-up order: layers at the top can modify the output of the layers below.



Changing brightness of a content layer in Designer is actually controlling the value of the alpha of the layer. Even when displaying a HAP video, the software will composite the layer with a controllable layer of alpha - one per layer.

There are two ways of expressing alpha in an image:

Straight alpha is an alpha channel which functions just like RGB. Alpha acts as a fourth channel of information per pixel which is as independent of the other three as R, G and B are of each other. For example, with straight alpha it is possible to have RGB = 255 (white) and alpha = 0 (fully transparent) on the same pixel. Internally generated content, such as gradient layer, are generated with straight alpha. This is the preferable style of alpha and considering the cleaner method of the two.

Premultiplied alpha takes the alpha and applies it to the values of the RGB channels per pixel. The more transparent something gets with premultiplied alpha, the closer it gets to black - as if the content is sitting on a black table. Premultiplied is the default output of Adobe Photoshop or AfterEffects. The result is our pixel at 255 RGB (full white) with 0 alpha would be calculated as a black pixel in the final image.

Here are explanations of what each individual blend mode will do.

Over

Makes a layer fully opaque. Premultiplies all alpha onto the RGB value of each pixel. Alpha = black, so adjusting the brightness of a layer in Over blend mode makes it darker.

Alpha

Default blend mode. It will apply alpha values as a transparency if the alpha is present. Brightness changes will make the layer more or less transparent.

Add

Adds the value of each RGB pixel together. Always creates a brighter result. Values clamp at 255.

Multiply

Reads the level of each subpixel as a level between 0.0 and 1.0, and multiplies source with blend. The result is always a darker image overall. For example: white x grey = 0.5. White turns transparent, black takes precedence. Alpha is applied in the same fashion as the Over Blend mode.

Mask

Applies a mask to the single layer **above** in the stack, irrespective of mapping. See **Mask blending** for more information.

Luma-Matte

This mode creates a Luma Matte by using a layer's **Rec. 709 luminance** to control the alpha channel of the layer **above**, irrespective of mapping.

To determine transparency, the luminance of each pixel is calculated using a weighted average of its red, green, and blue channels. The luminance value is then used as the alpha (opacity) value for the corresponding pixels in the upper layers.

As a result, white areas render the layer above fully opaque, black areas make them fully transparent, and grey areas create proportional semi-transparency. This is a specialized **Mask** blend mode; for more details on the underlying behaviour, see **Mask blending**.

Inv-Luma-Matte

The Inverse Luma Matte mask works the same as the **Luma Matte** mask but the transparency is inverted meaning white regions are transparent and black regions are opaque.

Multiply-Fade

The same as Multiply, but will make use of the alpha channel to calculate transparency in the source and blend layers. Since maximum transparency is premultiplied, alpha results in black. This will ignore black created through premultiplying.

Multiply-Alpha

Multiply with straight alpha. This mode assumes that the alpha has not been premultiplied onto the RGB values and will not apply a correction to the semi-transparent pixels.

Premultiply Alpha

Like how Multiply-fade will ignore the darkening caused by premultiplying, this blend mode will do the same with Alpha.

Colour Burn

Blend mode increases the contrast to darken the base colour while reflecting the blend colour. The darker the blend colour, the more intensely the colour will be applied in the base image. White as the blend colour produces no change. Using the colour burn blend mode can produce some harsh results at full opacity. The colour burn blend mode can be used to make tonal and colour adjustments to a layer.

Screen

This blend mode looks at each channels colour information and multiplies the inverse of the blend and base colous. The result is always a lighter colour. Screening with black leaves the colour unchanged. Screening with white produces white. The effect is similar to projecting multiple images on top of each other - where bright white is fully opaque, black is fully transparent and 50% grey is 50% transparent.

Overlay

Multiplies or screens the colours, depending on the base colour. Patterns or colours overlay the existing pixels while preserving the highlights and shadows of the base colour. The base colour is not replaced, but mixed with the blend colour to reflect the lightness or darkness of the original colour.

Hard Light

Multiplies or screens the colours, depending on the blend colour. The effects is similar to shining a harsh spotlight on the image. If the blend colour (light source/top layer) is lighter than

50% grey, the image is lightened as if it were screened. This is useful for adding highlights to an image. If the blend colour is darker than 50% grey, the image is darkened as if it were multiplied. This is useful for adding shadows to an image. Painting with pure black or white results in pure black or white.

Soft Light

Darkens or lightens the colours, depending on the blend colour. The effect is similar to shining a diffused spotlight on the image. If the blend colour (light source/top layer) is lighter than 50% grey, the image is lightened as it if were dodged. If the blend colour is darker than 50% grey, the image is darkened as if it were burned in. Painting with pure black or white produces a distinctly darker or lighter area, but does not result in pure black or white.

Darken

Looks as the colour information in each channel and selects the base or blend colour - whichever is darker - as the result colour. Pixels lighter than the blend colour are replaced and pixels darker than the blend colour do not change.

Lighten

Looks at the colour information in each channel and selects the base or blend colour - whichever is lighter - as the result colour. Pixels darker than the blend colour are replaced and pixels lighter than the blend colour do not change.

Difference

Looks at the colour information in each channel and subtracts either the blend colour from the base colour or the base colour from the blend colour depending on which has the greater brightness value. Blending with white inverts the base colour values and blending with black produces no change.

Exclusion

Creates an effects similar to but lower in contrast than the difference mode. Blending with white inverts the base colour values. Blending with black produces no change.

Colour Dodge

Looks at the colour information in each channel and brightens the base colour to reflect the blend colour by decreasing contrast between the two. Blending with black produces no change.

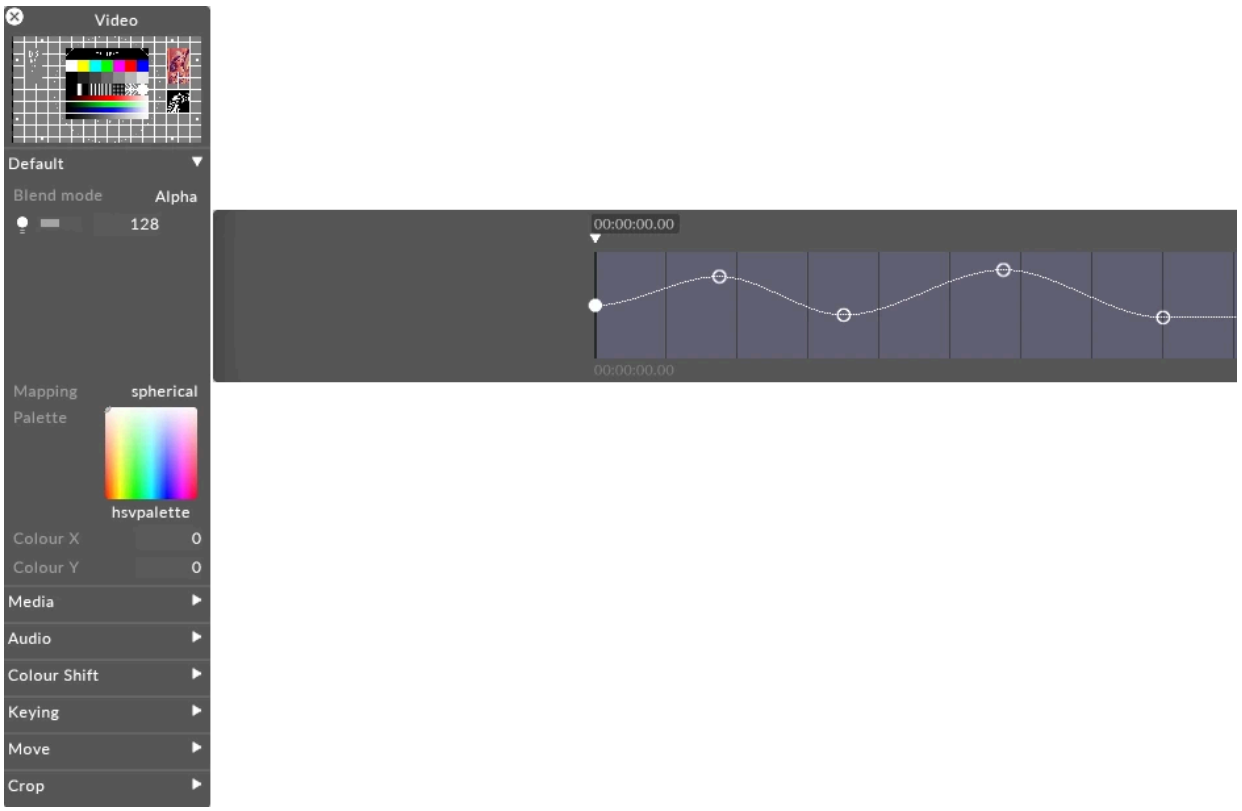
Hard Mix

Adds the RGB channels of the blend colour to the RGB values of the base colour. If the resulting sum for a channel is 255 or greater, it receives a value of 255; if it is less than 255 it

receives a value of 0. Therefore all blended pixels have RGB channels of either 0 or 255. This changes all pixels to primary additive colours (RGB), white or black.

Brightness

This property (which appears as a light bulb icon) controls the brightness of the layer output.



If the layers blend mode is set to Alpha, then reducing the brightness to 0 also reduces the opacity of the layer to 0. This can be useful when you want to dissolve from one layer to the next. In that case, you can place the new layer above the old layer and increase its brightness level.

> **Note**
>
> Layers that are patched to Sockpuppet (DMX, OSC or HTTP) are made Dormant when their brightness is set to 0. This means they will not do any rendering or consume any resources until their brightness is changed to > 0. You can find more information about this here: **Sequencing with Sockpuppet**. Layers without a sockpuppet patch do not behave in this way.

Mapping

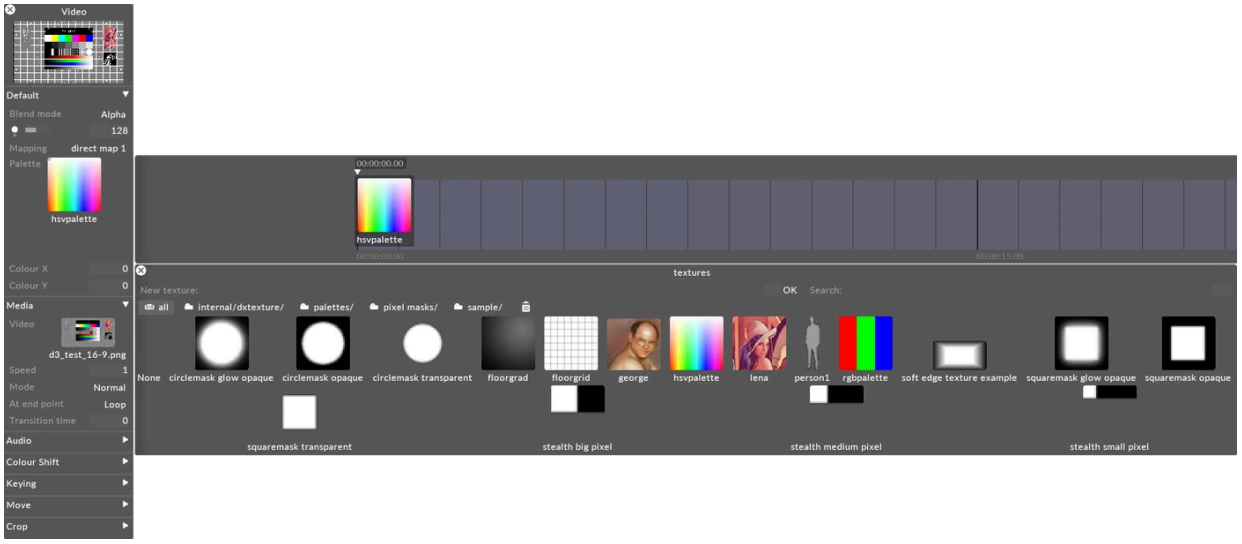
The mapping property controls how the layer output is mapped onto the screen(s) in the Stage level.

For information on mapping, including how to use the different mapping types offered by Designer, please see the chapter **Content Mapping**

Palette

This points to the still image file that defines the bitmap from which the tint colour is taken. The default palette (HSVPAL) consists of the complete range of hues and saturations. Selecting this property will open the Texture object library, which shows all of the still image files saved on your local hard-drive in the **DxTexture** older.

To control the location within the current palette bitmap, and thus control the colour, you have to edit the **xCol** and **yCol** values (see the section for xCol, yCol).



To change the current palette bitmap:

1. Left-click **palette** to open the Texture object library.
2. Left-click the still image file you want to use for the palette bitmap.

If you want to use a palette bitmap other than the standard still images provided in Designer, you will need to use a custom still image file.

See the **Placing media files** for a project sub-chapter to understand where to place a custom still image file and how to access it in Designer. Also save the file to a **supported file format**.

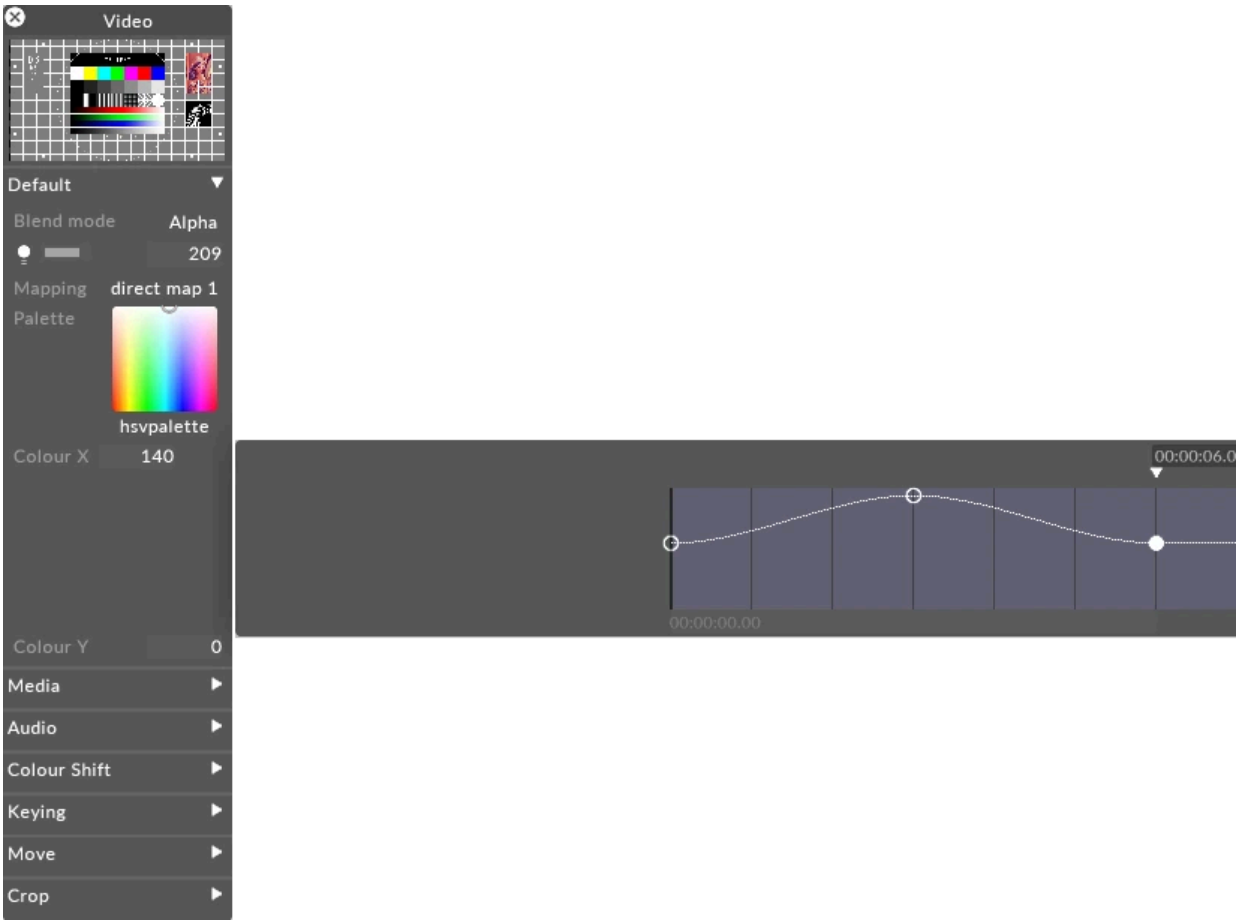
Xcol, YCol

These properties control the coordinates within the current palette bitmap where the output colour is sampled from. The default value is 0,0 which points at the color white (if you are using the HSVPAL palette). Multiplying white with the colors of the chosen content simply generates the original content colors. **Colour X** controls the horizontal position, where 0 is the leftmost

edge and 255 is the rightmost edge. **Colour Y** controls the vertical position, where 0 is the top edge and 255 is the bottom edge.

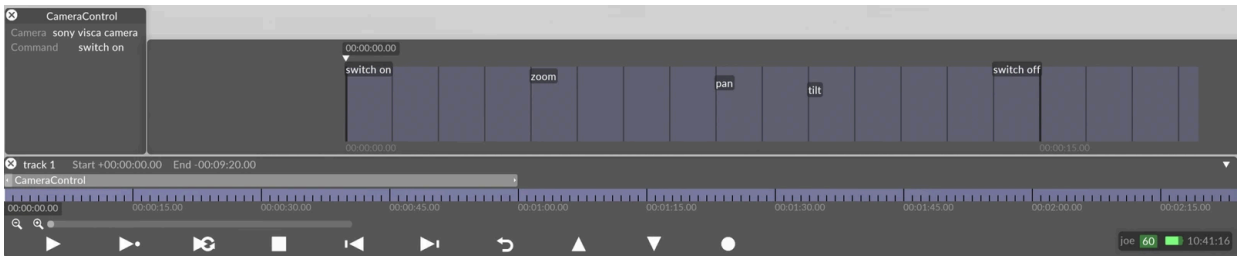
For example, to saturate the video clip red, change the **Colour Y** value to 255 and use 0 for the **Colour X** value. These coordinates refer to the color red in the palette which is being multiplied with the colors of the existing content.

When you are using the default palette HSVPAL , Colour Y controls saturation, and Colour X controls hue.



CameraControl

The CameraControl layer controls Sony Visca Cameras configuration



CameraControl layer properties

Camera

The camera object to use.

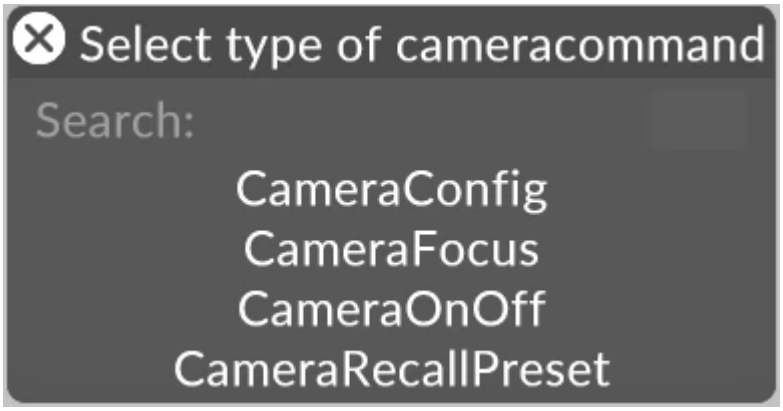
Command

The camera command to send.

Creating/sequencing CameraControl commands

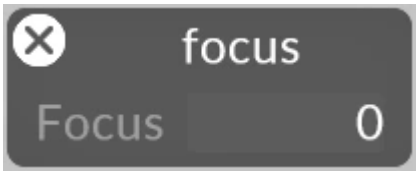
The process used to create/sequence CameraControl commands is done by placing key-frames onto the Command key-frame editor, and is therefore the same as any other layer type that uses key-frame editors, for example the AnimateCameraPreset layer. For an example on how to create and animate key-frames using the key-frame editor please follow the step-by-step instructions in the AnimateCameraPreset sub-chapter.

There are three types of CameraControl commands:



Editing CameraControl commands

Each CameraControl command type opens a specific camera command editor.



CameraConfig editor

Zoom : sets the cameras zoom, 0 100%

Focus : sets the cameras focus, 0 100%

Exposure mode : sets the exposure mode to auto, manual, iris or shutter.

Shutter : sets the shutter value, 0 100%. Only valid in shutter mode.

Iris : sets iris value, 0 100%. Only valid in iris mode.

Gain : sets the cameras gain, 0 100%.

Pan : sets the cameras pan, in degrees.

Tilt : sets the cameras tilt, in degrees.

Camera Focus

sets the cameras focus, 0 100%

CameraOnOff editor

Switch : turns the camera on or off .

CameraRecallPreset editor

Preset : sets the preset number assigned to the Sony Visca Camera. A Sony Visca Camera can have up to four presets.

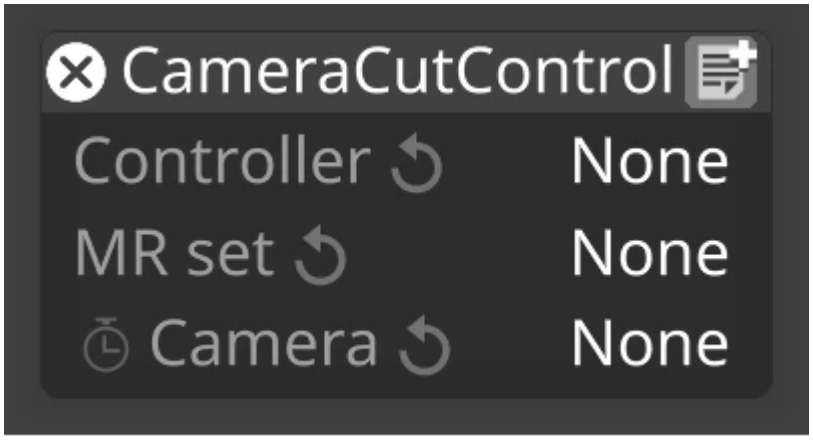
CameraCutControl

The camera cut control module allows camera switches to be sequenced on the timeline for XR workflows. It takes account of the calibrated delays to ensure that the switch happens on the keyframed beat

The CameraCutControl module is a subclass of the Indirection Control Module. It calculates the total switching delay for any given frame, and uses that to work out when to trigger the indirection change so that it lands on the correct beat. The most complex scenario occurs when modules are rendering at fractional frame rates. Ordinarily switches are not possibly on every frame in this case.

Therefore the CameraCutControl module uses `MixedRealitySet::applySwitchRenderOffset` to tell the MR set to delay the switch until the correct frame.

CameraCutControl Layer Properties



Request

This requires a new HttpControlRequest. When a new HttpControlRequest is created, it has the properties Url, Method, Headers and Body.

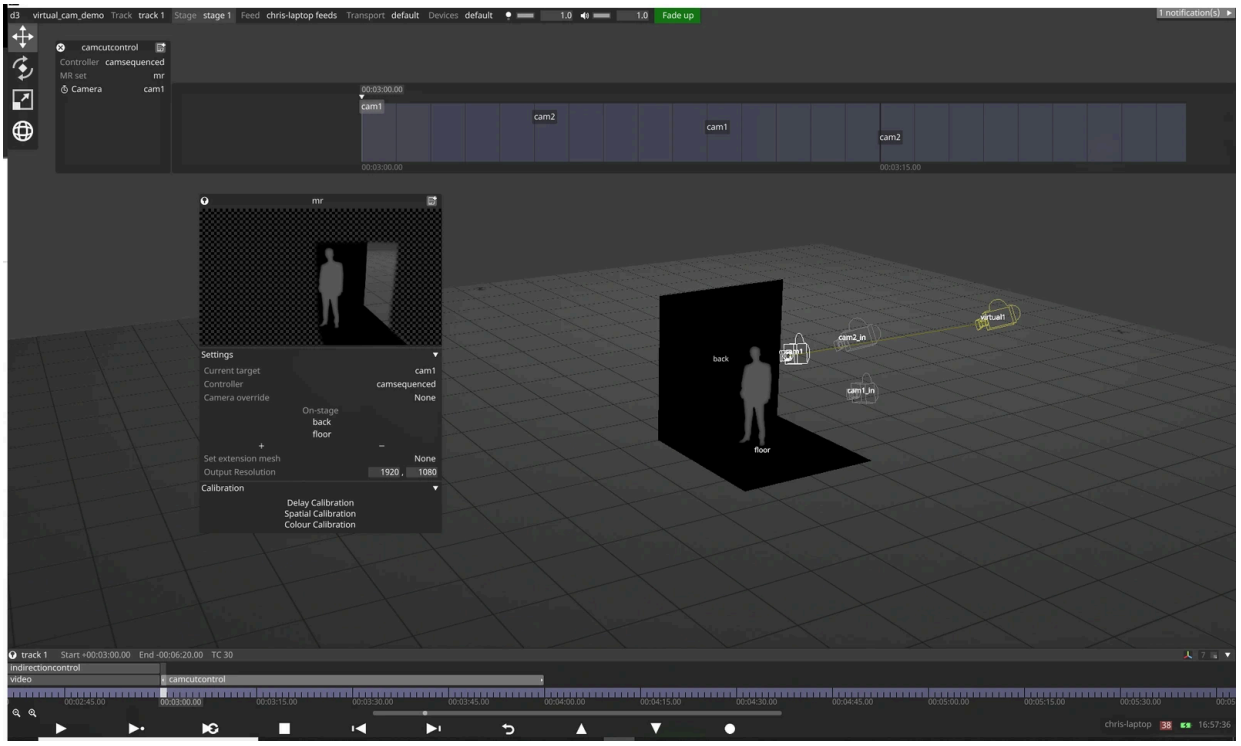
Trigger

The trigger options available are **Always** and **When Playing**. Expressions can also be used to extend the functionality.

Creating CameraCutControl commands

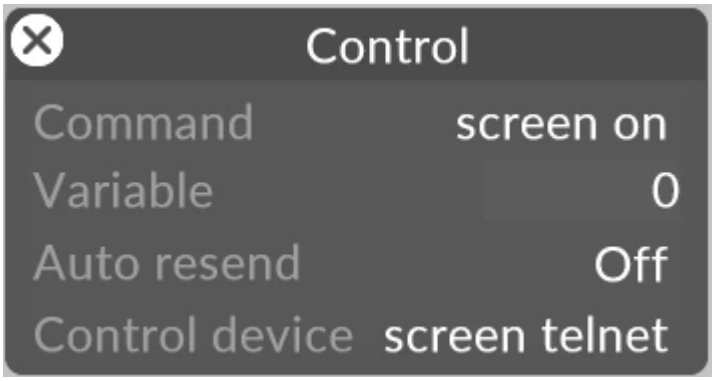
To sequence camera switches:

1. Set up and fully calibrate an XR stage.
2. Add a SequencedIndirectionController as the camera indirection controller in the MR set.
3. Add a CameraCutControl module to the timeline.
4. Select the controller and MR set.
5. Add keyframes to the Camera property.



Control

The Control layer allow for the definition of custom commands that can be sequenced on the timeline to perform functions at certain times. The custom commands are command strings which can be written in normal character format (ASCII) or in Hex.



Command

The selected command to be executed at this point on the timeline.

The **variable** to be passed into the command, if the command syntax contains the use of variables. The values can be sequenced on the timeline. Use **Auto Resend** to control when values are sent.

Auto resend

When set to 'On' the command will be executed everytime the **variable** changes, as well as on normal command issuing.

Control Device

The protocol device through which the command should be issued, either a Serial device, Telnet or UDP device.

> **Note**
>
> Ensure you that your protocol device is in the Device manager. Often it is better to create the devices from the manager and then select them in your layers, to avoid confusion.

Command Syntax

Commands are made up of a string. The string can be ascii or hex. The \ escape character is used to send special data.

The command can contain a variable set in the Control Layer, which is a timelined event.

Special Characters	Description
$	Variable value as string
%	Variable value as binary byte
\13	Carriage return
\10	New Line
\xYY	Send YY as hex value, example, \xF5
\	Send special ASCII character (0-255). Used to send characthers outside the normal range, e.g 1-31, 96 and up. Example, \37 will send '%' character.

A useful ASCII/Hex lookup table can be found **here**.

Ascii examples

- To send the command "START 568" followed by the enter key we would use the command string: `START 568\13`
- To send the command "CUE XXX" where XXX is the variable value, we would use the command string: `CUE \$`

Hex examples

- To send the byte values of 42, 62, 93 in sequence, you would use the string: `\x2A\x3E\5D`
- If you wished for the last value to be the variable value in a byte/uchar fashion you would use: `\x2A\x3E\%`

Real World Example

To control a Lightware matrix you would use the following examples:

- Load preset (using a variable) via telnet: `{%\$}`
- To route a particular input (using a variable) to output 1: `{1@\$}`

Control Layer Overview

The Control layer is tool for executing custom commands on 3rd party products via the following protocols - Serial, Telnet or UDP.

Types of Control layers

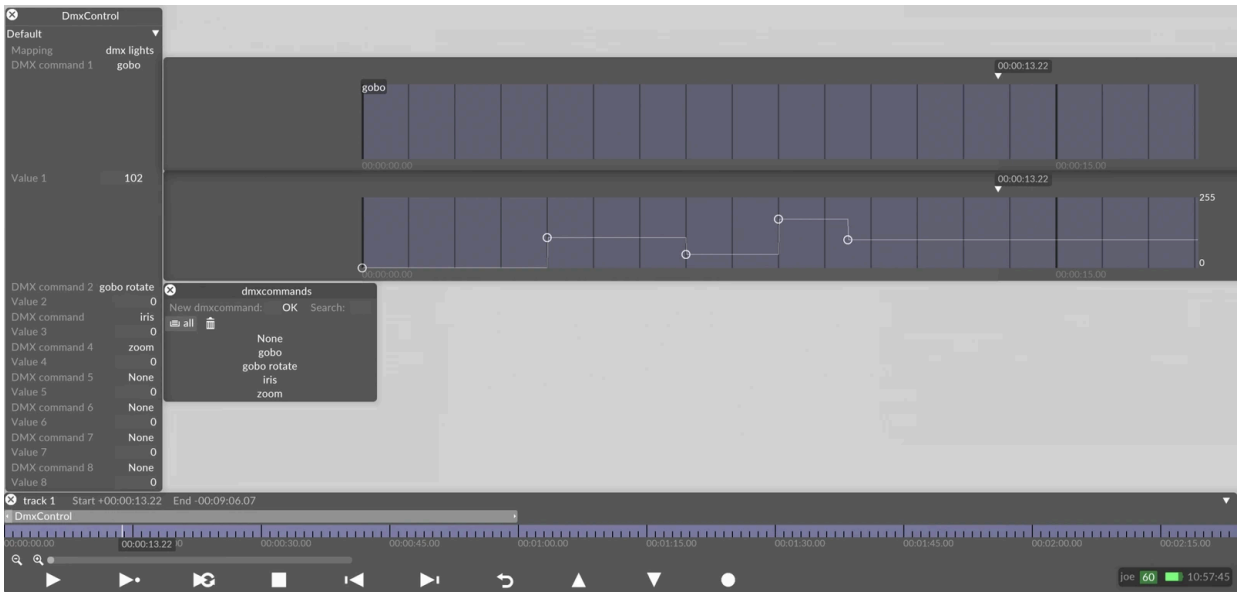
There are several types of Control layers available within Designer:

- Camera Control
- CameraCutControl
- Control
- DMXLightsControl
- DMXShare
- ExpressionVariables
- HTTPControl
- IndirectionControl
- MDC
- MTC
- MasterBrightness
- MatrixControl
- MidiNote
- Open
- OscControl
- PlayMode
- ProjectorControl
- TargetObject
- TimecodeMode
- TrackJump
- TransportBrightnessLocal
- TransportControl
- TransportVolumeLocal

DMXLightsControl

The layer can add DMX commands and animate their values using a key-frame editor.

> **Warning**
>
> The layer can only output DMX when a DMX device is set up. See DMX device for information on setting up a device.



DMXLightsControl layer properties

Dmx Command 1-8

The DMX command to send.

The image above shows that the DMXLightsControl layer has eight dmx command properties. By left-clicking the property a key-frame editor will open. It is important to note that only one DMX command can be added per key-frame editor, so a maximum of eight different DMX commands can be added in one DMXLightsControl layer.

However, multiple DMXLightsControl layers can each contain a set of specific DMX commands. For example, one DMXLightsControl layer can include DMX commands that control the beam effects of a particular fixture, whilst another DMXLightsControl layer can control the strobe options, etc.

Value 1-8

The animated value to substitute into the command.

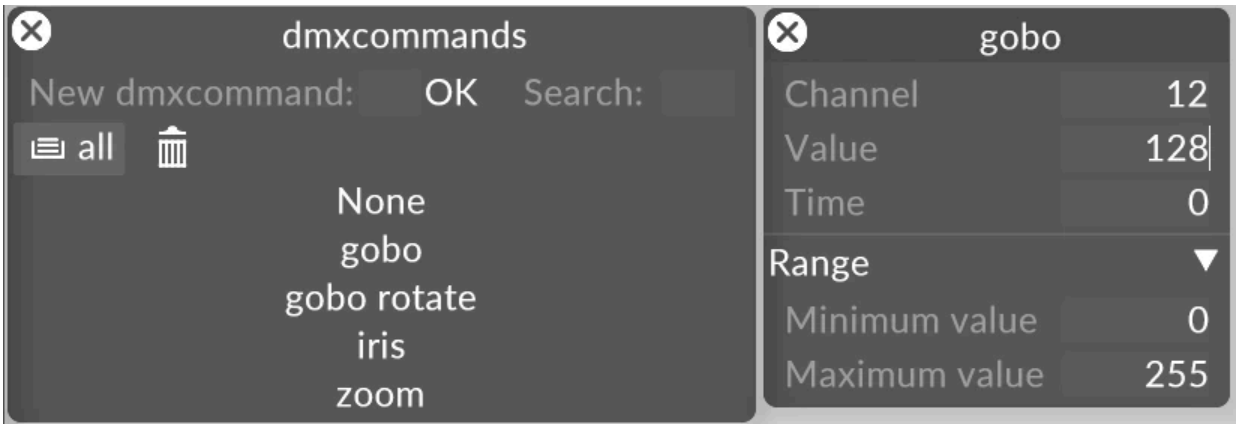
The image below shows that the gobo DMX command is set to send a value of 128 on channel 8 to the mac2k lighting fixtures. However, by using the Value 1 key-frame editor, as shown in the image above, the value of the gobo DMX command is able to change over time.

Creating commands

The process used to create DMX commands is done by placing key-frames onto the Dmx Command key-frame editor, and is therefore the same as any other layer type that uses key-frame editors, for example the AnimateCameraPreset layer. For an example on how to create and place key-frames using the key-frame editor please follow the step-by-step instructions in the AnimateCameraPreset topic.

Editing commands

- Right-click a DMX command from the DmxCommands manager to open the DmxCommands editor.



Lamp or fixture commands require you to send a particular value on a particular channel to, for example, control the focus, iris or gobo. These commands are created using the DmxCommands manager which displays a list of all of your DMX commands, and configured using the DmxCommands editor inside the driver editor of the fixture. Therefore for information on the properties of the DmxCommands editor please scroll down to the section DmxCommand in the GenericLampDrivers section.

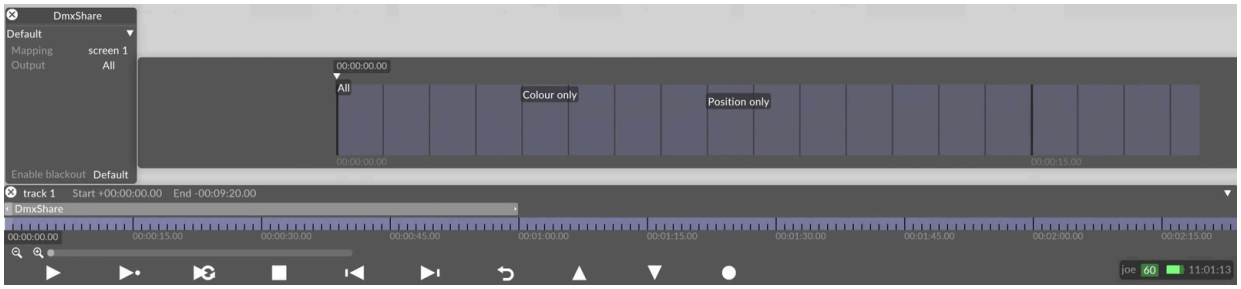
DMXShare Layer

The DMXShare layer enables you to specify whether you want to:

- control all DMX channels from
- control the colour of the DMX fixture only
- control the position and orientation of the DMX fixture only

The advantage of the DMXShare layer is that in some shows you may want to control lights using both a conventional lighting desk and Designer. For example, Disguise is an extremely useful tool for creating pixel mapping content for the lights using the advanced content mapping system, but also for sequencing lights exactly to the beat by quantising an audio track.

Designer is also very good for controlling the movements of groups of lights. However, lighting desks give you more control over the movement of individual lights and are specialised to control lights very quickly. Based on these facts, there is a requirement to share the control of the lights between Designer and a lighting desk.



DMXShare layer properties

Output

Controls what properties of a DMX fixture should control and output.

Options are:

- **all** control all properties of the fixture;
- **colour only** control the colour of the fixture only
- **position only** control the position and orientation of the fixture only (applies to moving head fixtures).

Enable blackout

Controls whether the DMX fixture/screen is muted (blacked out) from within Designer.

For advice on what hardware to use for merging DMX, please contact the **Support team**.

ExpressionVariables Layer

The ExpressionVariables layer defines variables for use in expressions later in the composition on a given frame.

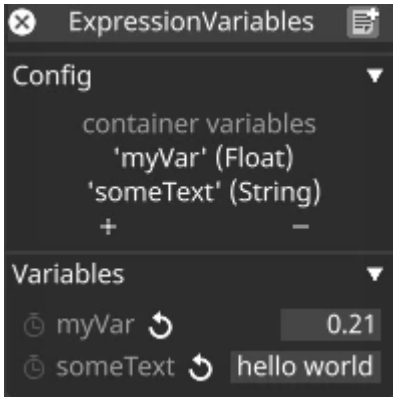
Variables defined by the ExpressionVariables layer are only valid for layers composited after the layer, and are also only valid for the duration of the layer on the timeline. They are useful in 'control' style transports in multi-transport workflows, and for animating common values on the timeline.

ExpressionVariables layer properties

The layer is split into two sections, representing the different phases of use:

1. Configure - define which variables the layer should be responsible for creating, and information about what they are and how they are edited.
2. Control - sequence and otherwise manipulate the variables defined in the first phase.

The intent is that users are able to collapse the 'Config' section after defining the variables they need, and focus entirely on controlling the values of those variables by editing or animating their values.



Config

This section of the layer editor allows the user to create new variables for use elsewhere.

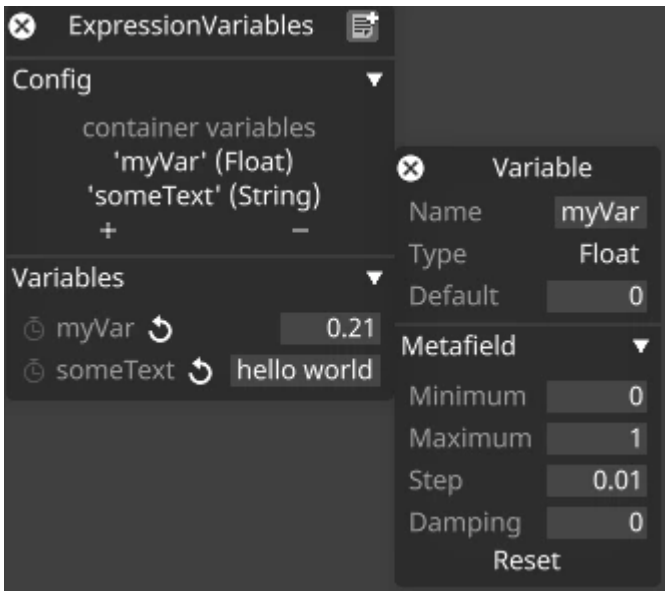
Variables are added, removed and edited in the usual array management workflows.

Editing variable properties

By adding a new item to the 'container variables' list in the editor, the metadata associated with a variable definition can be edited.

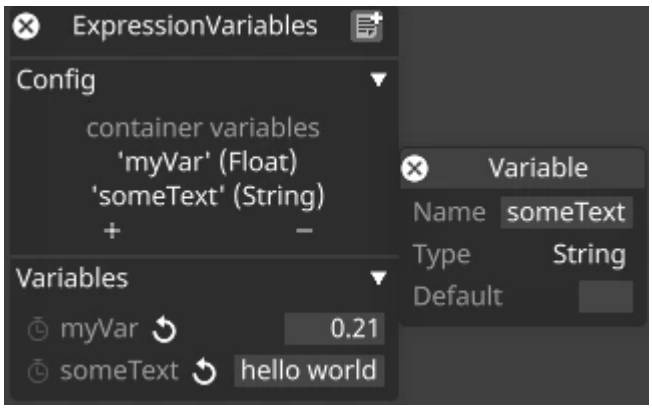
All variables have a name and a type. The name is the name of the variable as used elsewhere, and the type determines how and where the variable can be used.

Defining numeric variables



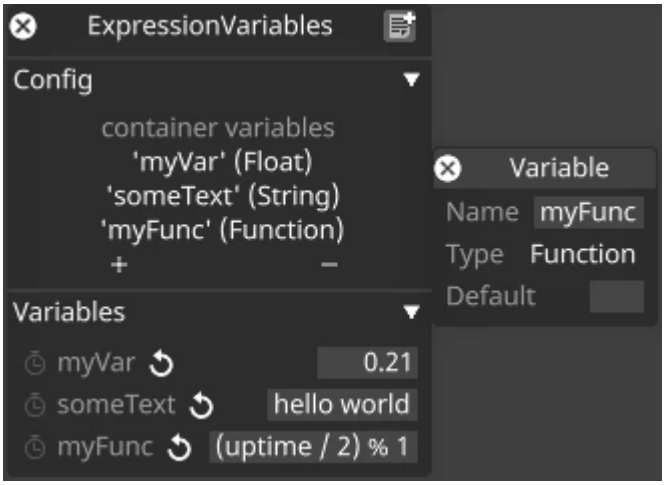
Numeric variables store a number, and can be used with numeric expressions or string formatting. The definition of the metadata for numeric variables includes setting minimum and maximum values for the expected range the variable should take, as well as a step to aid in editing the variable value. The numeric variable also includes a default value which can be used to reset the value of the variable to a default in the control portion of the user interface.

Defining string variables



String variables store text, and can be used with string formatting expressions or other text fields, such as in a text layer. The metadata for string variables only includes the default value which can be used to reset the control portion of the interface, if required.

Defining function variables



Function variables store an expression which can be evaluated in another expression. This can be used for more complex behaviour changes. When using a function variable, the expression which uses the variable should use the call syntax `()` (e.g. `myFunc()`.) Function variables also has metadata for the default value which users can reset the function text to, if required in the control section.

Variables

Every variable defined in the Config section appears as an editable, animatable value in the Variables section.

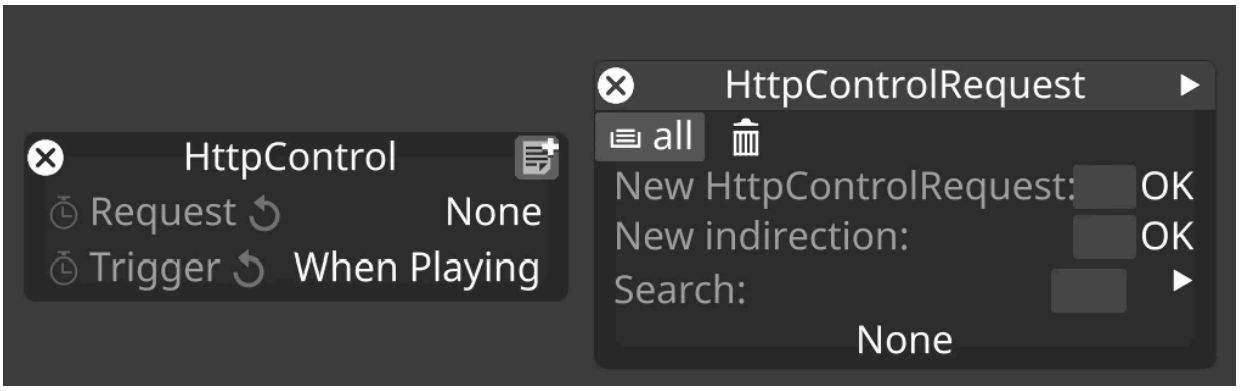
Variables can be edited and animated as with any other layer field.

The value in the editor shows the active value the variable resolves to at any given time.

HTTPControl Layer

HTTPcontrol module is designed to interface with APIs.

HTTPcontrol module is designed to interface with APIs. The Http Patch within the HttpControl module has been enabled to support the integration with partner APIs.



HTTPControl Layer Properties

Request

This requires a new HttpControlRequest. When a new HttpControlRequest is created, it has the properties Url, Method, Headers and Body.

Trigger

The trigger options available are **Always** and **When Playing**. Expressions can also be used to extend the functionality.

IndirectionControl Layer

The Indirection Control layer allows indirections to be sequenced on the timeline. One Indirection Control layer controls one Indirection.

The Indirection Control layer is implemented with two new classes:

- **SequencedIndirectionController:** The controller added to control the Indirection.
- **IndirectionControl layer:** The layer used for sequencing the Indirection on the timeline.

The Indirection Control layer updates the selected SequencedIndirectionController when it hits a new keyframe.

IndirectionControl Layer Properties

Controller

The SequencedIndirectionController.

Resource

The content, such as video or 2D image.

Sequencing IndirectionController commands

The process used to create/sequence IndirectionControl commands is done by placing keyframes on the Resource keyframe editor.

1. Add a video layer.

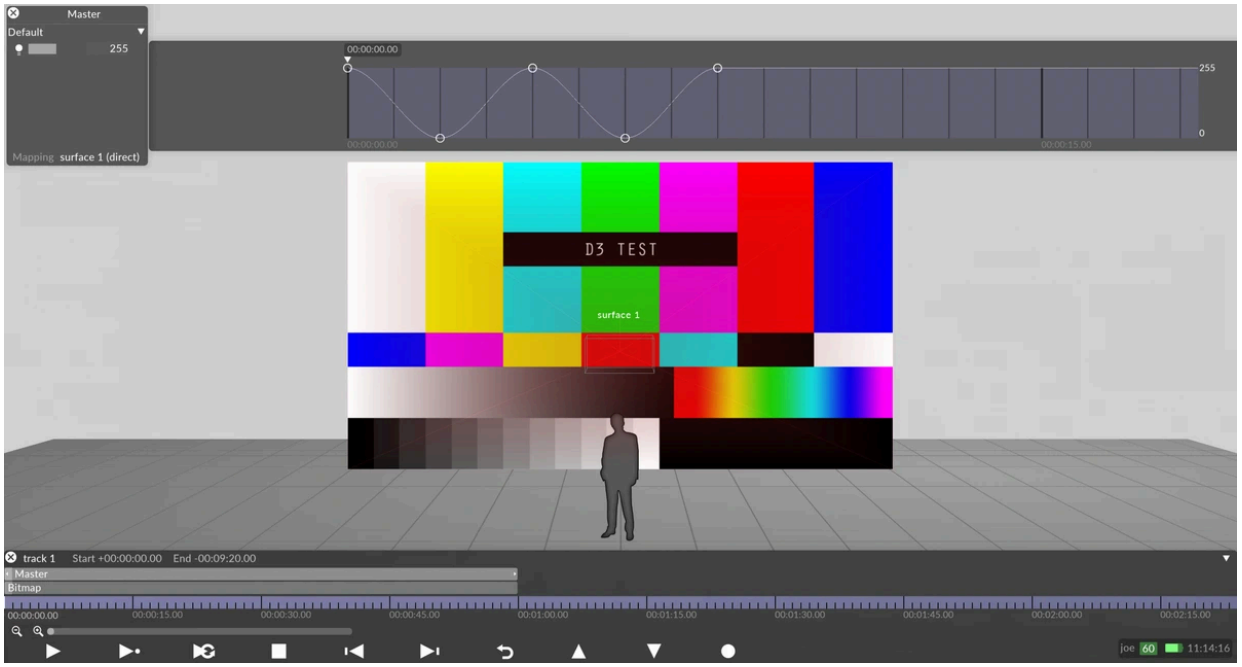
2. In the video layer editor, expand the **Media** section and left-click **None** to open the VideoClip editor.
3. Create a **New indirection** by typing in the input field and clicking OK.
4. Add a controller by clicking **None** and by typing in the input field and clicking OK.
5. Select **SequenceIndirectionController**.
6. Create an **IndirectionControl** layer on the timeline in the same section as the video layer.
7. Select the **SequenceIndirectionController.**
8. Activate the **Resource** property keyframe editor.
9. Add media to the keyframe editor.

Learn more about configuring Indirections **here**.

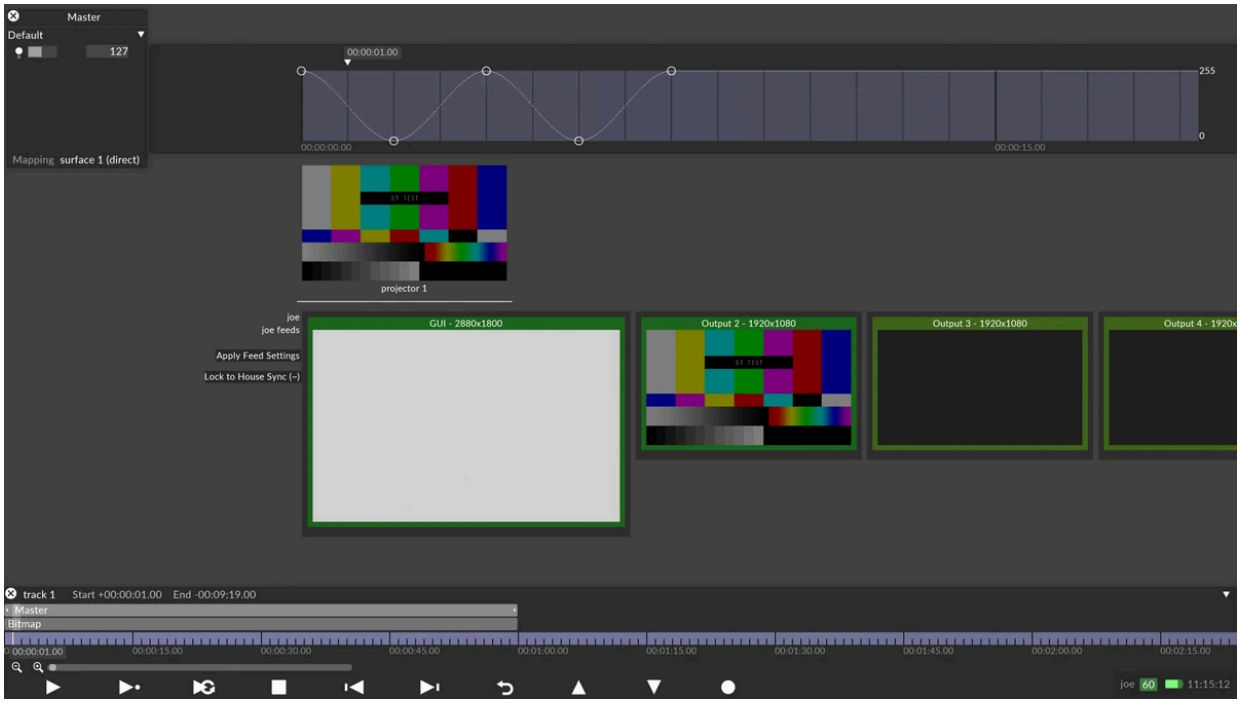
MasterBrightness Layer

The MasterBrightness layer allows you to control the output (master) brightness of a number of layers without having to individually change their brightness levels. You can also use it to control the output brightness of any Screen or collection of Screens.

> ⚠ **Warning**
>
> Once he master brightness of a screen is set, it will retain that value until another MasterBrightness layer resets it. A common mistake is to set the master brightness of a screen to 0, then jump to another part of the timeline without a MasterBrightness layer and wonder why there is no output on the screen. For this reason, the use of the MasterBrightness layer is discouraged except in emergencies.



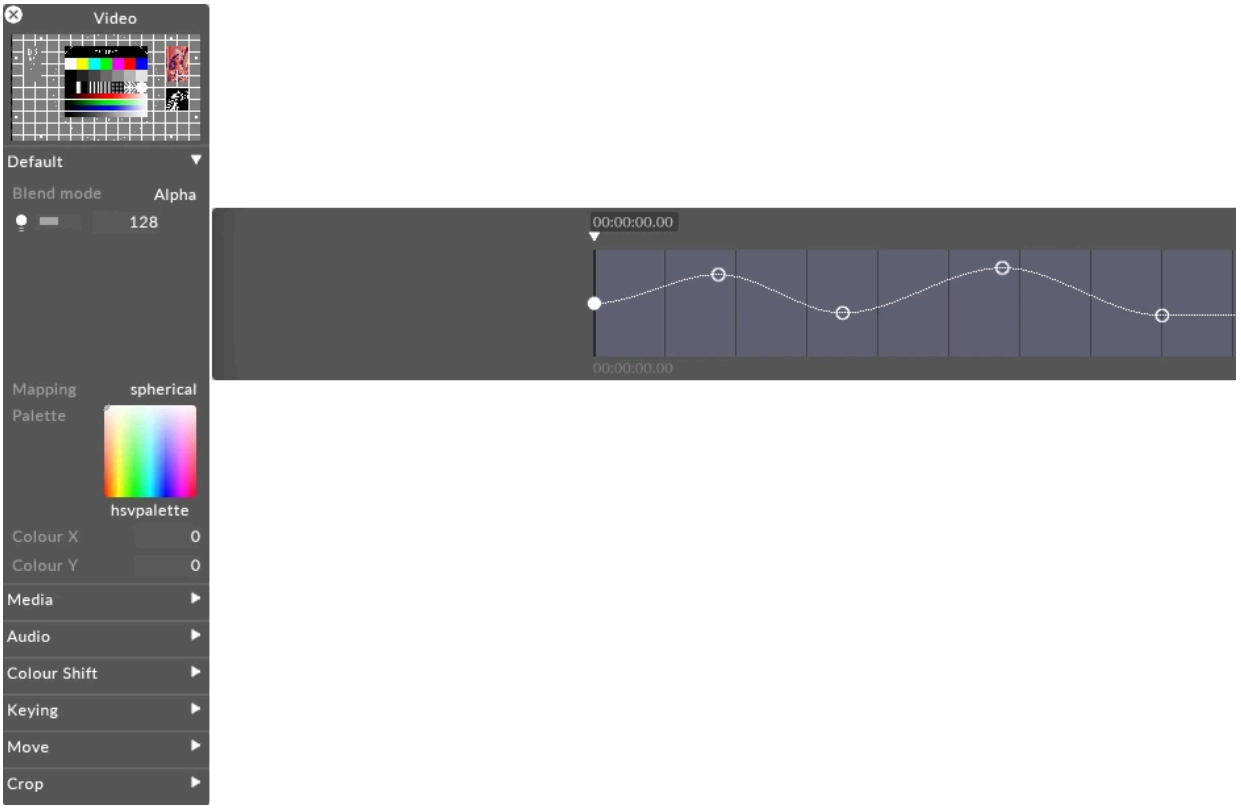
As you can see below, the output brightness is only visualised in the Output Feeds level.



MasterBrightness layer properties

Brightness

This property (which appears as a light bulb icon) controls the brightness of the layer output.



If the layers blend mode is set to Alpha, then reducing the brightness to 0 also reduces the opacity of the layer to 0. This can be useful when you want to dissolve from one layer to the next. In that case, you can place the new layer above the old layer and increase its brightness level.

Mapping

The mapping property controls how the layer output is mapped onto the screen(s) in the Stage level.

For information on mapping, including how to use the different mapping types offered by Designer, please see the chapter Content Mapping.

MatrixControl Layer

The MatrixControl layer allows you to animate matrix presets on the Timeline. Currently, Designer has built in matrix devices for a number of matrix.

MatrixControl layer properties

Matrix

The matrix device you want to control.

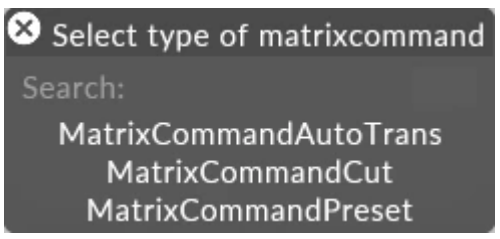
Command

The preset you want to trigger.

Creating & sequencing MatrixControl commands

The process used to create/sequence DVI matrix presets is done by placing keyframes onto the Command keyframe editor, and is therefore the same as any other layer type that uses keyframe editors, for example the AnimateCameraPreset layer.

There are three types of matrix presets:



Editing MatrixControl commands

Each command type opens a specific command editor.

MatrixCommandAutoTrans

Transition with a specified **transition time**. Only applicable for the Barco Encore.

MatrixCommandCut

Transitions with a hard cut. Only applicable for the Barco Encore.

MatrixCommandPreset

Changes the **preset** of the matrix. This will only work if you already configured a DVI matrix.

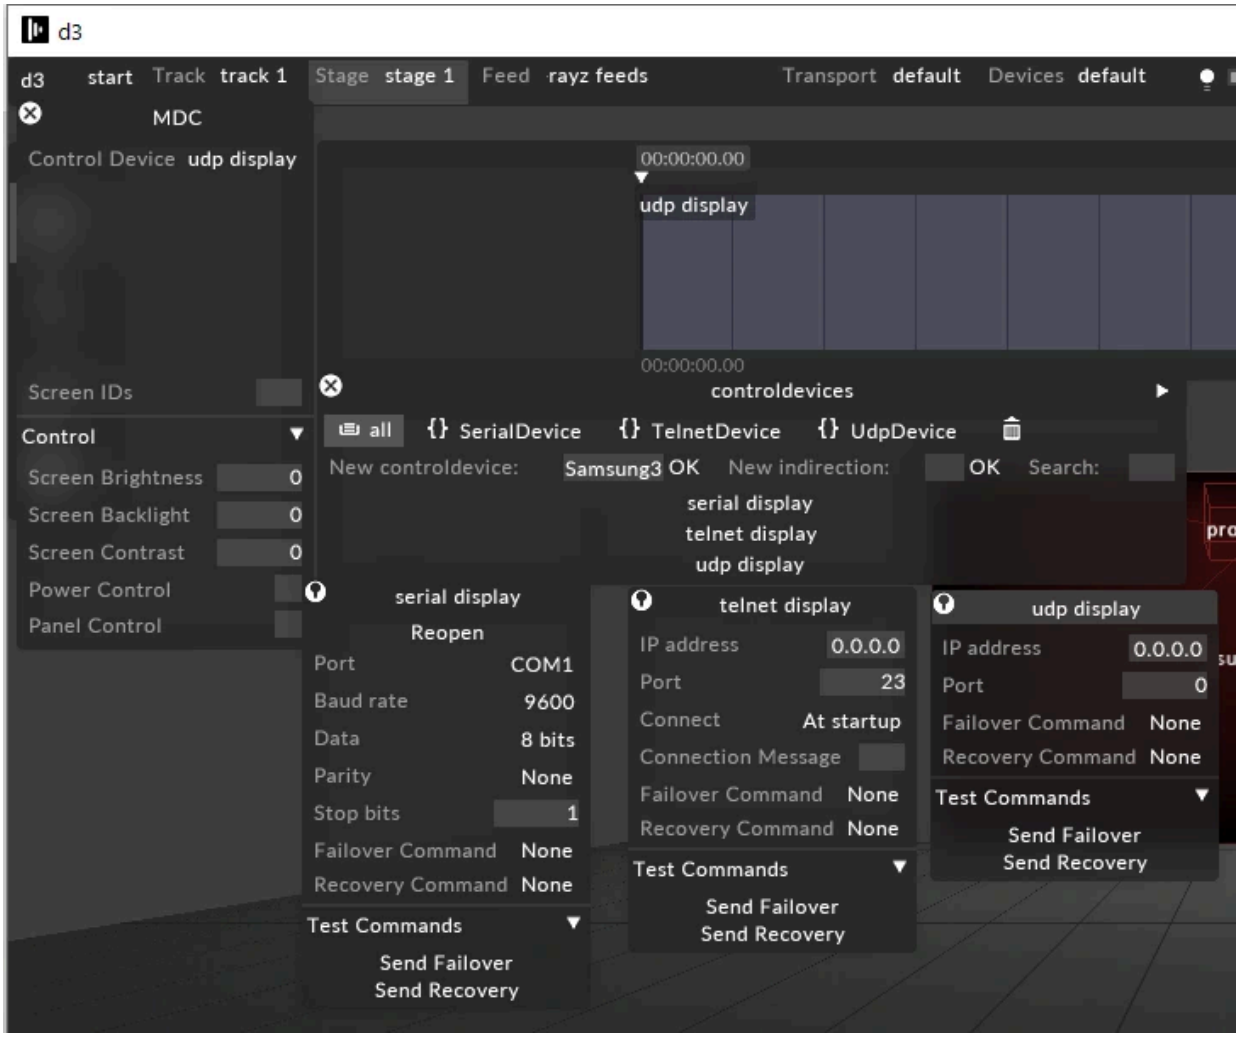
Using the MatrixControl layer

1. First, create a new matrix device in the Device manager, for example Lightware matrix or BarcoMatrixPro. Make sure the ip-address of the matrix device is in the same network as your Director/Actor network.
2. Create a new layer.
3. Choose the matrix device you just created.
4. Create a new command. For a matrix preset, choose the **MatrixCommandPreset**.
5. Type in the number of the preset.
6. To animate presets, drag and drop them onto the keyframe editor.

MDC Layer

The MDC layer allows you to control a system of multiple displays over a serial connection, TelNet or UDP from within Designer.

MDC, the free multi-display control software created by Samsung, is used to control and exchange information between a variety of different sources including Samsung displays and the networked computers used to control the displays.



Three types of devices can be configured from the MDC layer:

- Serial
- TelNet
- UDP

MidiNote Layer

The MidiNote layer sends a midi note.

MidiNote layer properties

Device

The midi port to use.

Channel (1-base)

The channel to send the note.

Note

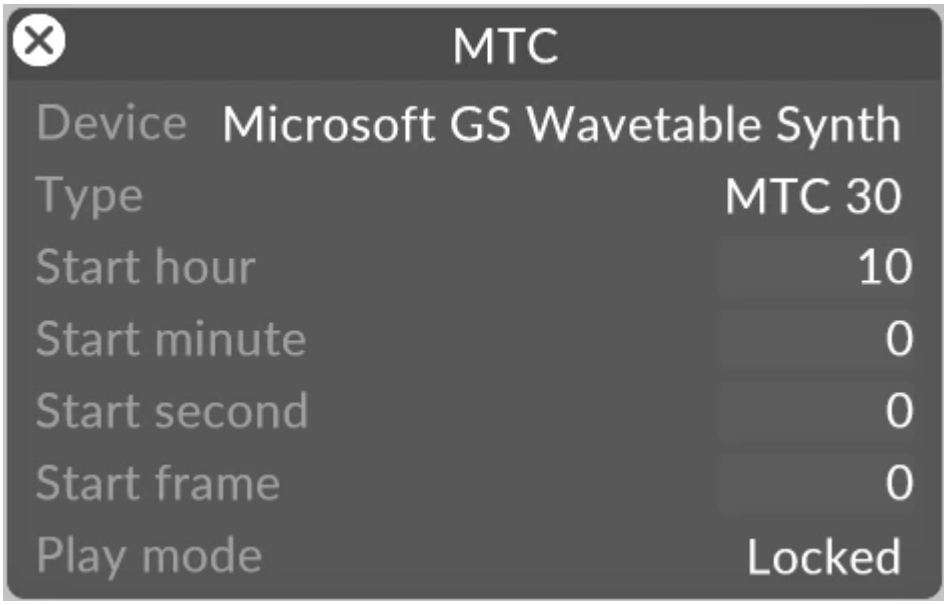
The note to send, in decimal format.

Velocity

The velocity value of the note.

MTC Layer

The MTC layer allows you to output MIDI timecode in a controlled way so that external devices such as lighting desks can be synchronised precisely with events on the timeline.



The MTC layer lets you set a timecode start value from the time posititon on the timeline, a frames-per-second value and an output device. When the play cursor first enters the extent of the layer, Designer starts a clock at the value specified and then outputs timecode as long as the play cursor remains under the layer extent.

If moving the play cursor away from under the extent of the layer will stop the output clock. When the play cursor re-enters the layer extent, the clock will restart.

MTC Layer Properties

iDevice

This specifies the index of the MIDI device used to output timecode. In the standard machine, this should always be set to **AIO Midi**. The other option is **Microsoft GS Wavetable Synth** .

Type

Choose from the following options: 24, 25, or 30 frames per second.

Start Hour, Min, Sec, Frame

This specifies the start time of the output clock. Whenever the play cursor enters the layer extent, the output clock is reset to this value.

Play mode

There are two options:

Locked: sets the timecode value to the position of the play cursor on the Timeline.

Normal: allows the time to ticks upwards regardless of cursor position on the Timeline. For example, if the play mode is set to Play-to-end-of-section, where the Play cursor will only progress untilit reaches the end of a section (i.e. just before the next cue point) and enters in a holding state, the time code will still tick upwards.

Open Layer

The Open layer is the Swiss army knife of layers. It allows you to control any property of any object in Designer, even if that object was not previously animatable using a Key-frame editor. This ability to use a Key-frame editor for properties which were not previously animatable is the key advantage of the Open layer.

> **Warning**
>
> Use the Open layer carefully. A common mistake is to have a short Open layer on the Timeline that changes the value of that property and then move the play cursor somewhere else on the Timeline. You might, for example, change the output master brightness to 0, then move the cursor to another location and wonder why there is no output.

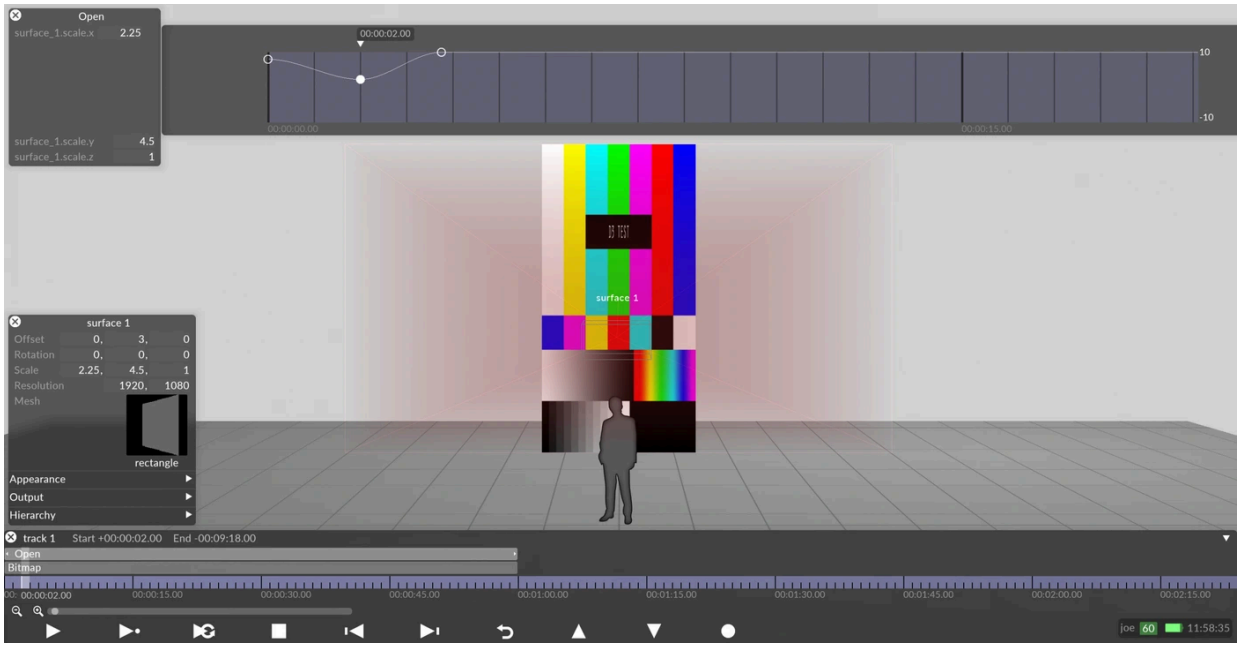
When you first create an layer, all you will see is a title bar, with no properties beneath it.

To control a property of another object:

1. Right-click an object to open its object editor, in this example Screen 1.
2. If you want to open multiple editors click **Ctrl** on the objects of interest.
3. Hold down **Alt**, left-click and drag from the Open layer titlebar, you will see a white arrow appear. For more information on Arrows please see the Composing layers with Arrows topic.

4. Drag the arrow-head over the property you want to control, in this example **scale**.

5. Release the mouse button and **Alt** ; the Open layer now has a new property named after the property you dragged the arrow to. By left-clicking the property a key-frame editor will open. This can be used to animate the property.



Scale property has now become a property of the Open layer

OscControl Layer

The OscControl layer is a tool for sending custom commands to 3rd party products via Open Sound Control (OSC).

The layer allows for the definition of custom commands that can be sequenced on the timeline to perform functions at certain times. The custom commands are OSC messages defined by a fixed OSC address and any amount of OSC arguments (Integer, Float, String, Blob).

Command

The selected command to be executed at this point on the timeline.

Variable 1-4

The **variable** to be passed into the command, if the command syntax contains the use of variables. The values can be sequenced on the timeline. Use **Auto Resend** to control when values are sent.

Auto resend

There are three possible modes for triggering commands:

1. 'On command keyframe' triggers when the playhead starts playing, as well as when the command keyframe changes.
2. 'Whenever a variable changes' triggers every time a **variable** changes.
3. 'Command keyframe or variable changes' triggers when the conditions for either modes 1. or 2. is met.

OSC Device

The protocol device through which the command should be issued.

> **Note**
>
> **Please note**: Ensure you that your device is in the Device manager. Often it is better to create the devices from the manager and then select them in your layers, to avoid confusion.

Command Syntax

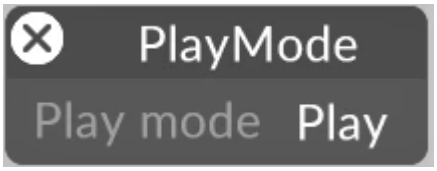
Commands are made up of an OSC address and any number of OSC arguments. The arguments have a type (Integer, Float, String or Blob) and a string value.

The string value of Integer and Float arguments can contain a variable set in the Control Layer, which is a timelined event, or a fixed numerical value. 4 define which variable to use.

The string value of a Blob argument should be in hex.

PlayMode Layer

The PlayModelayer overrides the current play mode set in the Timeline.



PlayMode Layer Properties

Play Mode

The play mode to be in. The options are:

Any : this mode has no effect; the current play mode specified in the Timeline will not be overridden.

Play: this mode does not respect section boundaries; when the end of a section is reached, the cursor continues into the next section, stopping only at the end of the track.

Play to end of section: in this mode the Play cursor will only progress until it reaches the end of a section (i.e. just before the next cue point).

Loop section: in this mode,the Play cursor will progress until it reaches the end of a section, i.e. just before the next cue point. At this point, the cursor will loop back immediately to the beginning of the section and will continue playing from there.

For more information on these play modes see the sub-chapter Navigating the Timeline

ProjectorControl Layer

The ProjectorControl layer animates projector parameters in the stage, and in turn, those parameters can be output to real projectors.

ProjectorControl layer properties

Mapping

The projector(s) being controlled by the layer.

Presets

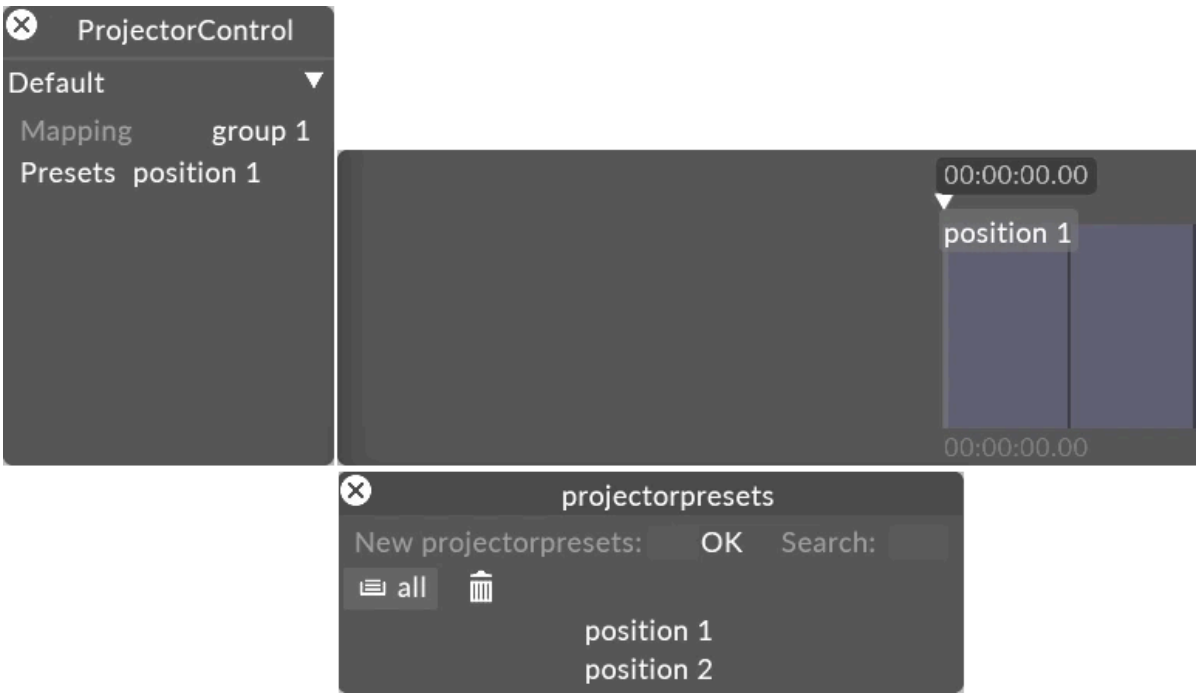
The preset the projector(s) get their data from.

Creating a preset

The preferred workflow is to create presets in the projector control editor, as detailed in the ProjectorControl device topic. However, this functionality can also be achieved directly through the layer if required.

1. Open the layer.
2. Choose which mapping (group of projectors) you wish to control using the mapping property.
3. Left-click the **presets** parameter.
4. The presets manager will open.

5. In the **New projectorpresets** field enter a name for the preset. For example, position 1.



[Animated GIF: Projector presets]

6. Add the desired projectors to the preset using the + and - buttons in the preset editor.
7. Choose values for their Pan/Tilt, Focus, Zoom, Lens Shift (V/H), Intensity, Recall and Configuration properties.

Outputting to a projector

Once your layer is animating projectors, the output to the physical projector is controlled via the ProjectorControl device.

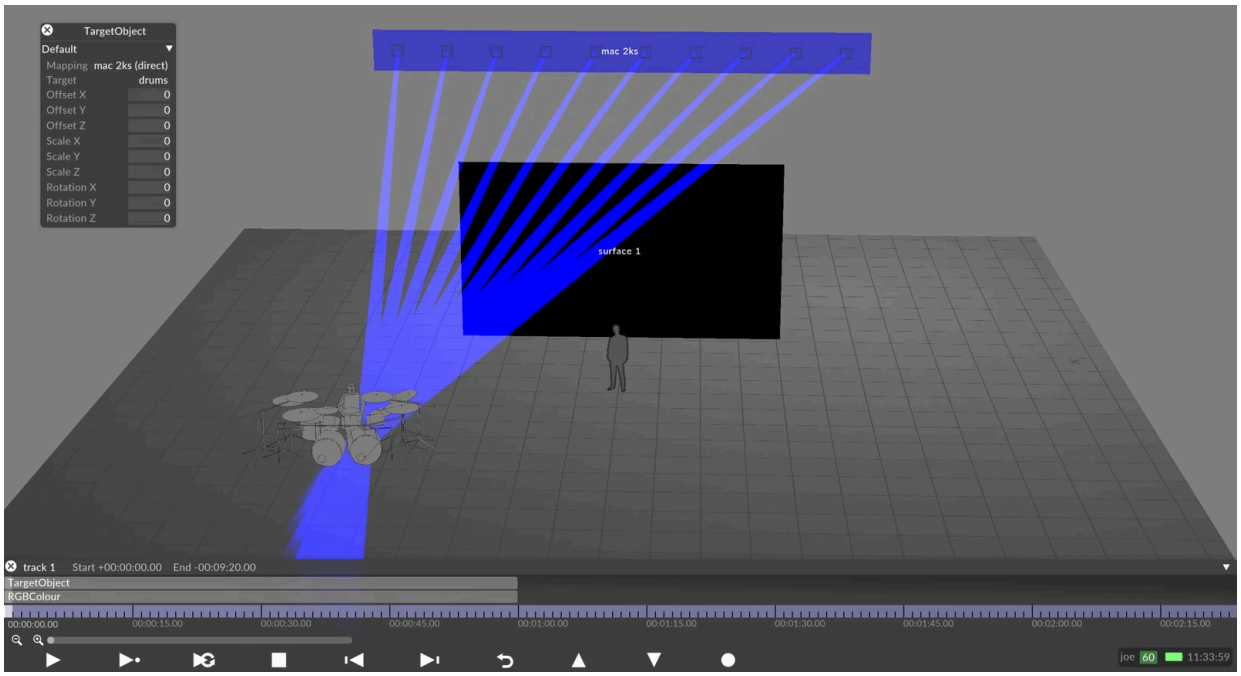
TargetObject Layer

The layer is similar to the TargetControl iin that it allows to control the movement of moving head lights. The only difference being that instead of using virtual target points the TargetObject allows you to use an object as the target.

> ⚠ **Warning**
>
> **Warning**: The fixture defined in the DMXLight needs to set to **aimable**. If not, the layer will have no effect.

Please read the sub-chapter Creating DMX Lights for information on how to create a DmxLights screen. Afterwards please read the sub-chapter [Creating a fixture (../../../stage-setup/dmx-screens-lights/dmx-lights/creating-a-fixture) for information on how to add a fixture to a DmxLights screen.

For step-by-step instructions on how to control moving head lights using the Target layer please see the sub-chapter Targeting fixtures



TargetObject Layer Properties

Mapping

Determines what mapping of DMXLight screens to use. Notice that any Mapping Type can be created using DMXLight screens.

Target

This property allows you to select the object that you want to use as the target.

Offset

This value is added to the (x, y, z) stage position of each fixture. To move the fixture targets left and right, change the x property, to move them up and down, change the y property and to move them in and out, use the z property.

Scale

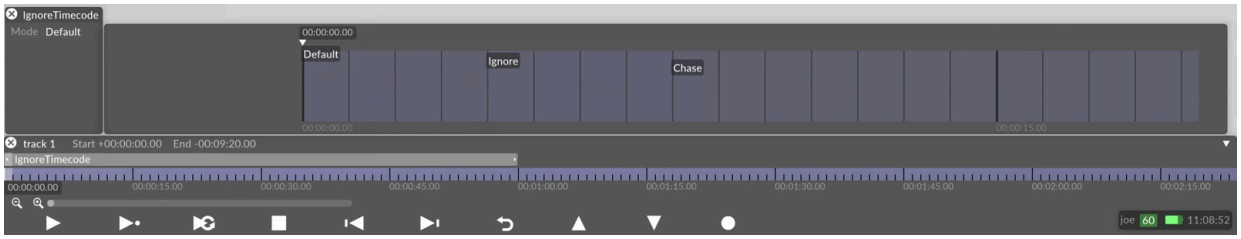
This scales the target points in each of the three axes x, y and z. Values higher than 1 increase the size of the target grid, causing the beams to splay outwards; values lower than 1 reduce the size of the target grid and setting the scale to 0 causes all beams to converge.

Rotation

This rotates the target grid around each of the x, y and z axes (angles specified in degrees).

TimecodeMode Layer

The TimecodeMode layer controls whether the system chases timecode or ignores timecode. If it is set to **default**, then the layer will have no effect.



The layer allows you to change between the following timecode modes:

Default - The layer will have no effect.

Ignore - The layer will ignore incoming timecode for the duration of where the layer covers.

Chase - The layer will chase timecode. The chase mode is effectively saying, “The timecode tags on this area of the timeline will be triggered”.

TrackJump Layer

The TrackJump layer allows you to automatically jump between tracks. This can be useful in situations where you have a permanent or semi-permanent fixed installation that needs to continue running all day, switching from one track to the next or jumping between sections within the same track.

This layer works as follows: whenever the play cursor enters the extent of the layer and the cursor continues to move forward (and thus does not stop), Designer will jump to the Track and Cue specified in the TrackJump layer and perform the specified action.

TrackJump Layer Properties

Track

This specifies which track should jump to. If set to **None** or left empty, no track jump is issued and stays in the same track.

Cue

When the Play Head is positioned beneath a Track Jump Layer and the layer is selected, a widget will appear. At the bottom of this widget, you can select the Cue within the track that you would like the Playhead to jump to once it reaches the layer.

> **Note:**
> You can move individual tags/notes by holding `Alt` and dragging with the left mouse button. To move the entire Cue, hold `Ctrl + Alt` and drag.
>
> If you move a Cue after selecting it in the Track Jump Layer, the jump will still function as expected—the Playhead will jump to the Cue's new beat position.

Play mode

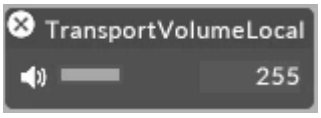
This specifies the transport control mode that should enter when jumping to its destination. The options to choose from are **stop, play, play-to-end-of-section**, and **loop** section.

TransportBrightnessLocal Layer

The TransportBrightnessLocal layer replaces the need to use the Open layer to control the master brightness via keyframes changes on a track. The layer will work whenever it is on a track which is being played by the currently active Transport.

TransportVolumeLocal Layer

The TransportVolumeLocal layer replaces the need to use the open layer to control the master volume control via keyframes changes on a track. The layer will work whenever it is on a track which is being played by the currently active Transport.



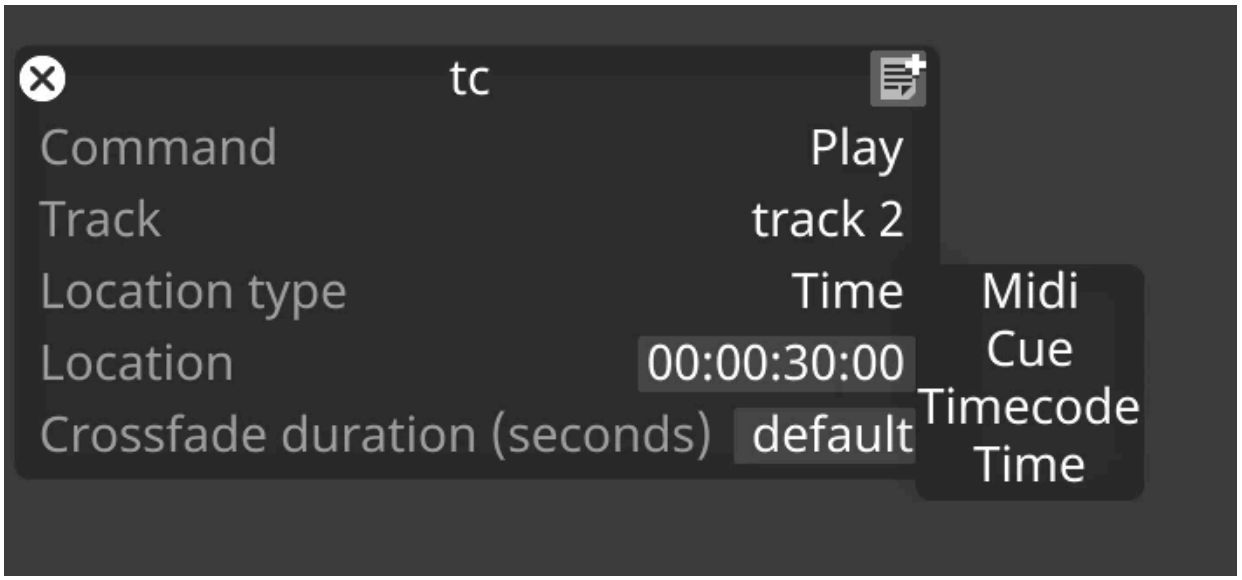
TransportControl Layer

The TransportControl layer is a tool for triggering secondary transports from another transport.

The TransportControl layer is used for triggering other transports from the timeline. One important factor to be aware of with this layer is that it cannot control its own transport. Use of this layer requires multiple transport managers, assigned to a different Set List with different sets of tracks with different sets of tracks within each Set List.

As of r26.0, an additional **Location Type** field has been added to the**Transport Jump Commands**. Previously, you would enter a prefix of **CUE** to specify the location is a cue tag, otherwise it would default to a time relative to the start of the track.

From r26 onwards, the **Location Type** allows you to specify that the property is **MIDI**, **Cue**, **Timecode** or **Time**.



The *Location type* properties work as follows:

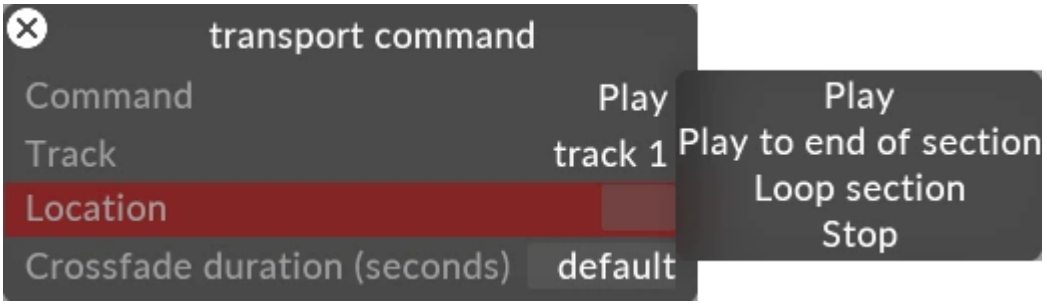
- **MIDI**: jump to midi tag <x>
- **Cue**: jump to cue tag <x>
- **Timecode**: jump to track timecode, relative to TC tags `hh:mm:ss:ff`
- **Time**: jump to absolute track timecode, unaffected by TC tags `hh:mm:ss:ff`

Also, prior to r26.0, any timecode values entered in the location field were absolute track time.

TransportControl properties

Transport - defines the transport manager that should be triggered (cannot be the transport manager that contains the track that this layer is on).

Command - Allows for sequencing of TransportJumpCommand keyframe objects. This object specifies the Command (Play, Play to end of section, Loop section and Stop), the track to target, the location within the track (by specifying a cue number or timecode tag) and a crossfade duration.



Trigger - Defines whether the command is triggered **Always** or **When playing**.

Blur Layer

The Blur layer blurs the content coming from another layer's output.

Blur layer properties

Source texture

The input content to blur. Select an Arrow source or a Texture.

Radius

The amplitude of the blur effect. The default value is 6. The min/max values are 0 and 50. Decreasing the value from 6 to 0 will sharpen the content, whilst increasing the value from 6 to 50 will gradually amplify the blurriness of the content. Setting the radius of the blur above 50 will result in banding and degredation of the output image. This is a limitation of the blur method.

Mask texture

Applies blur based on a grey-scale still image. White areas will generate maximum blur; black areas will ignore blur.

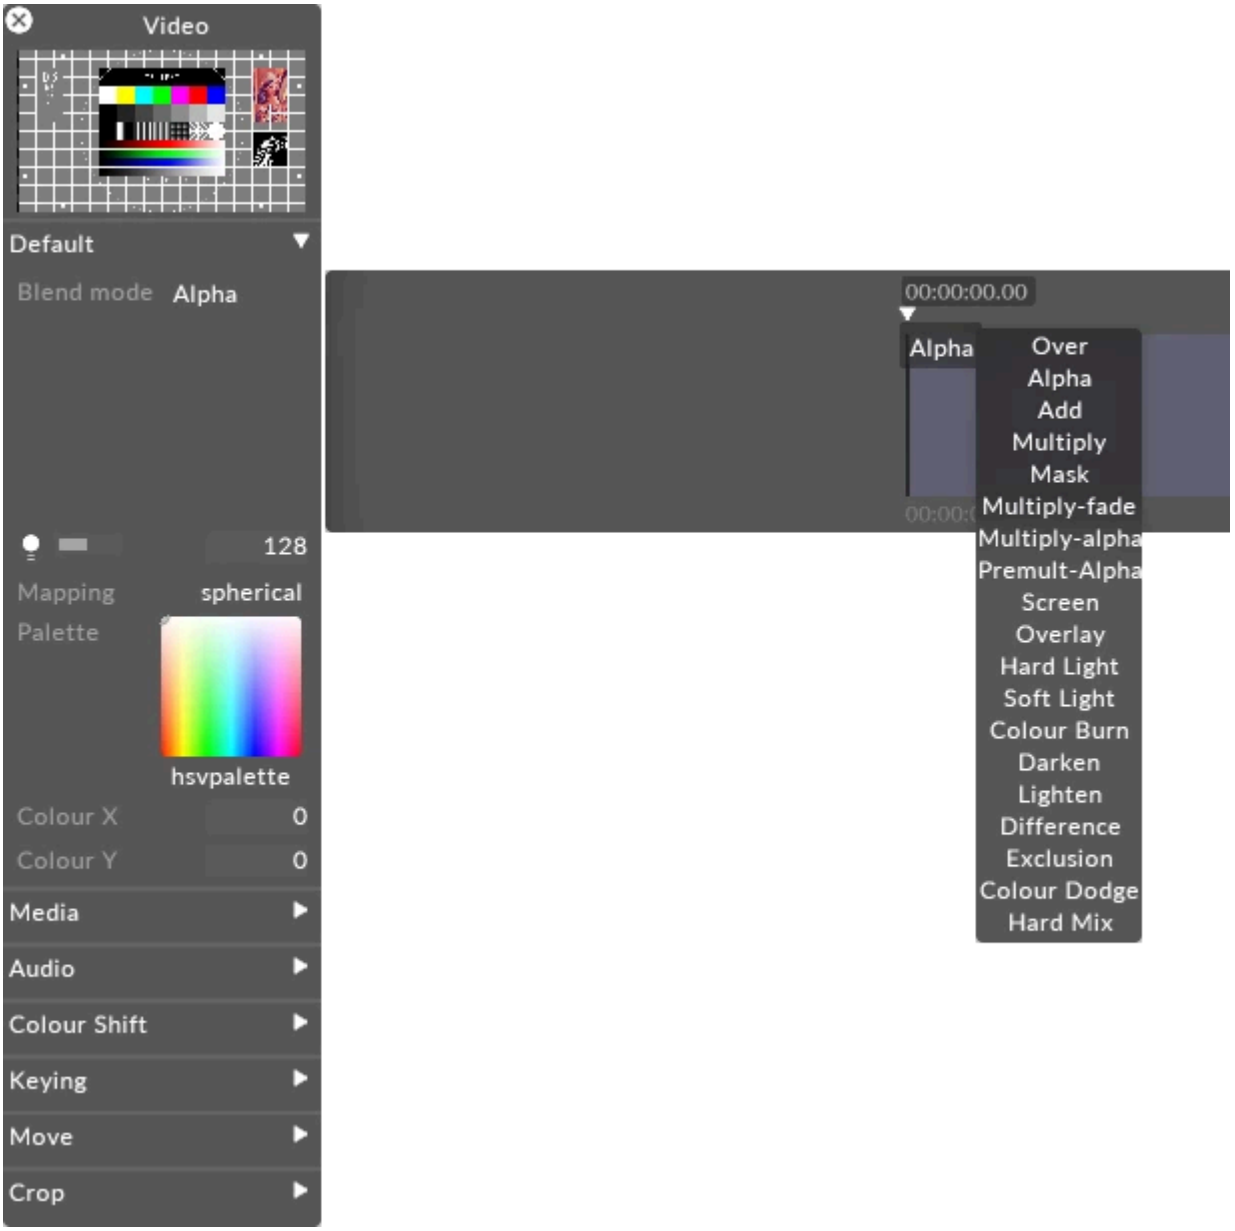
Wrap around

Wraps the blur effect around the horizontal edge of the image, blurring the left and right edges into each other.

Common Layer Properties

Blend Mode

BlendMode controls how the output of the layer is composited with the layers below. Layers are rendered in a bottom-up order: layers at the top can modify the output of the layers below.



Changing brightness of a content layer in Designer is actually controlling the value of the alpha of the layer. Even when displaying a HAP video, the software will composite the layer with a controllable layer of alpha - one per layer.

There are two ways of expressing alpha in an image:

Straight alpha is an alpha channel which functions just like RGB. Alpha acts as a fourth channel of information per pixel which is as independent of the other three as R, G and B are of each other. For example, with straight alpha it is possible to have RGB = 255 (white) and alpha = 0 (fully transparent) on the same pixel. Internally generated content, such as gradient layer, are generated with straight alpha. This is the preferable style of alpha and considering the cleaner method of the two.

Premultiplied alpha takes the alpha and applies it to the values of the RGB channels per pixel. The more transparent something gets with premultiplied alpha, the closer it gets to black - as if the content is sitting on a black table. Premultiplied is the default output of Adobe Photoshop or AfterEffects. The result is our pixel at 255 RGB (full white) with 0 alpha would be calculated as a black pixel in the final image.

Here are explanations of what each individual blend mode will do.

Over

Makes a layer fully opaque. Premultiplies all alpha onto the RGB value of each pixel. Alpha = black, so adjusting the brightness of a layer in Over blend mode makes it darker.

Alpha

Default blend mode. It will apply alpha values as a transparency if the alpha is present. Brightness changes will make the layer more or less transparent.

Add

Adds the value of each RGB pixel together. Always creates a brighter result. Values clamp at 255.

Multiply

Reads the level of each subpixel as a level between 0.0 and 1.0, and multiplies source with blend. The result is always a darker image overall. For example: white x grey = 0.5. White turns transparent, black takes precedence. Alpha is applied in the same fashion as the Over Blend mode.

Mask

Applies a mask to the single layer **above** in the stack, irrespective of mapping. See **Mask blending** for more information.

Luma-Matte

This mode creates a Luma Matte by using a layer's **Rec. 709 luminance** to control the alpha channel of the layer **above**, irrespective of mapping.

To determine transparency, the luminance of each pixel is calculated using a weighted average of its red, green, and blue channels. The luminance value is then used as the alpha (opacity) value for the corresponding pixels in the upper layers.

As a result, white areas render the layer above fully opaque, black areas make them fully transparent, and grey areas create proportional semi-transparency. This is a specialized **Mask** blend mode; for more details on the underlying behaviour, see **Mask blending**.

Inv-Luma-Matte

The Inverse Luma Matte mask works the same as the **Luma Matte** mask but the transparency is inverted meaning white regions are transparent and black regions are opaque.

Multiply-Fade

The same as Multiply, but will make use of the alpha channel to calculate transparency in the source and blend layers. Since maximum transparency is premultiplied, alpha results in black. This will ignore black created through premultiplying.

Multiply-Alpha

Multiply with straight alpha. This mode assumes that the alpha has not been premultiplied onto the RGB values and will not apply a correction to the semi-transparent pixels.

Premultiply Alpha

Like how Multiply-fade will ignore the darkening caused by premultiplying, this blend mode will do the same with Alpha.

Colour Burn

Blend mode increases the contrast to darken the base colour while reflecting the blend colour. The darker the blend colour, the more intensely the colour will be applied in the base image. White as the blend colour produces no change. Using the colour burn blend mode can produce some harsh results at full opacity. The colour burn blend mode can be used to make tonal and colour adjustments to a layer.

Screen

This blend mode looks at each channels colour information and multiplies the inverse of the blend and base colous. The result is always a lighter colour. Screening with black leaves the colour unchanged. Screening with white produces white. The effect is similar to projecting multiple images on top of each other - where bright white is fully opaque, black is fully transparent and 50% grey is 50% transparent.

Overlay

Multiplies or screens the colours, depending on the base colour. Patterns or colours overlay the existing pixels while preserving the highlights and shadows of the base colour. The base colour is not replaced, but mixed with the blend colour to reflect the lightness or darkness of the original colour.

Hard Light

Multiplies or screens the colours, depending on the blend colour. The effects is similar to shining a harsh spotlight on the image. If the blend colour (light source/top layer) is lighter than

50% grey, the image is lightened as if it were screened. This is useful for adding highlights to an image. If the blend colour is darker than 50% grey, the image is darkened as if it were multiplied. This is useful for adding shadows to an image. Painting with pure black or white results in pure black or white.

Soft Light

Darkens or lightens the colours, depending on the blend colour. The effect is similar to shining a diffused spotlight on the image. If the blend colour (light source/top layer) is lighter than 50% grey, the image is lightened as it if were dodged. If the blend colour is darker than 50% grey, the image is darkened as if it were burned in. Painting with pure black or white produces a distinctly darker or lighter area, but does not result in pure black or white.

Darken

Looks as the colour information in each channel and selects the base or blend colour - whichever is darker - as the result colour. Pixels lighter than the blend colour are replaced and pixels darker than the blend colour do not change.

Lighten

Looks at the colour information in each channel and selects the base or blend colour - whichever is lighter - as the result colour. Pixels darker than the blend colour are replaced and pixels lighter than the blend colour do not change.

Difference

Looks at the colour information in each channel and subtracts either the blend colour from the base colour or the base colour from the blend colour depending on which has the greater brightness value. Blending with white inverts the base colour values and blending with black produces no change.

Exclusion

Creates an effects similar to but lower in contrast than the difference mode. Blending with white inverts the base colour values. Blending with black produces no change.

Colour Dodge

Looks at the colour information in each channel and brightens the base colour to reflect the blend colour by decreasing contrast between the two. Blending with black produces no change.

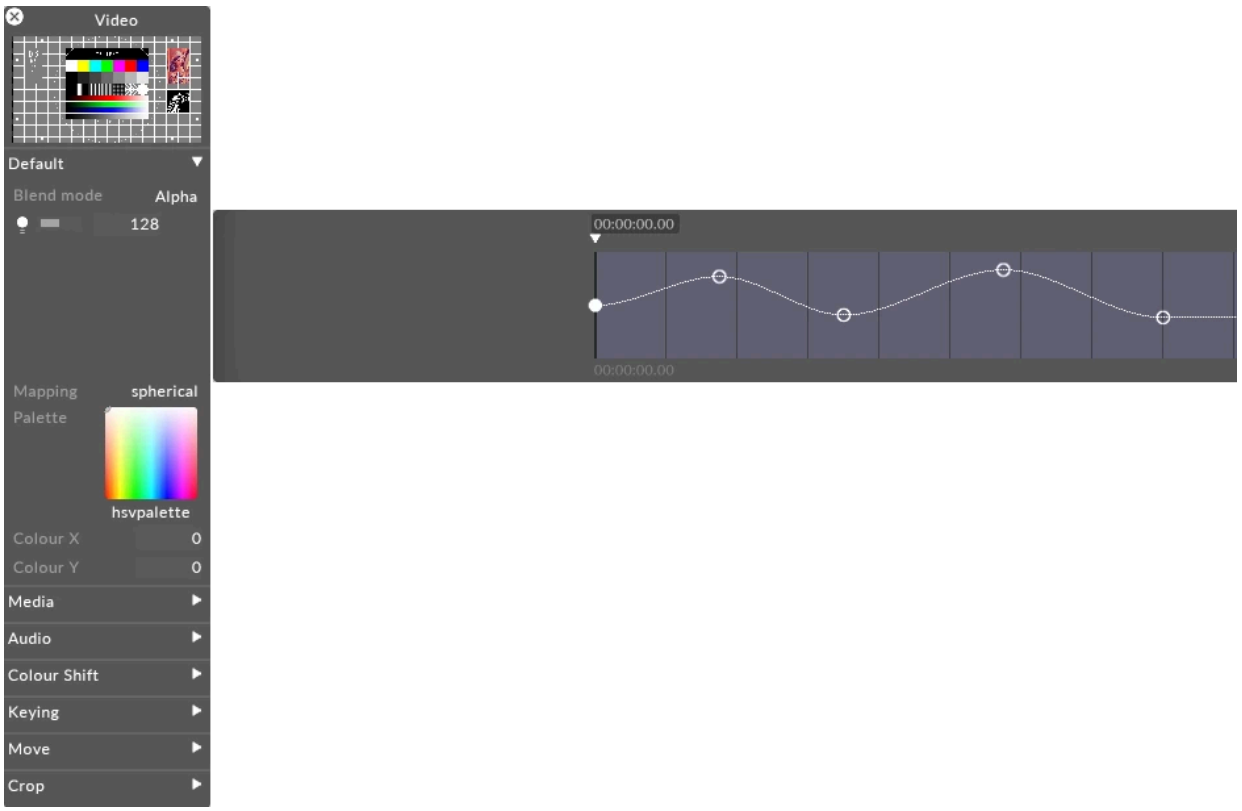
Hard Mix

Adds the RGB channels of the blend colour to the RGB values of the base colour. If the resulting sum for a channel is 255 or greater, it receives a value of 255; if it is less than 255 it

receives a value of 0. Therefore all blended pixels have RGB channels of either 0 or 255. This changes all pixels to primary additive colours (RGB), white or black.

Brightness

This property (which appears as a light bulb icon) controls the brightness of the layer output.



If the layers blend mode is set to Alpha, then reducing the brightness to 0 also reduces the opacity of the layer to 0. This can be useful when you want to dissolve from one layer to the next. In that case, you can place the new layer above the old layer and increase its brightness level.

> **Note**
>
> Layers that are patched to Sockpuppet (DMX, OSC or HTTP) are made Dormant when their brightness is set to 0. This means they will not do any rendering or consume any resources until their brightness is changed to > 0. You can find more information about this here: **Sequencing with Sockpuppet**. Layers without a sockpuppet patch do not behave in this way.

Mapping

The mapping property controls how the layer output is mapped onto the screen(s) in the Stage level.

For information on mapping, including how to use the different mapping types offered by Designer, please see the chapter **Content Mapping**

CDL Layer

The CDL (Colour Decision List) layer applies CDL colour correction. A CDL carries a defined subset of colour-grading data that can be shared consistently across pipelines.

The CDL layer supports both **ACES** and **OCIO**.

Workflow

1. Create a **CDL** layer.
2. Create a CDL object, or add a `.cc`, `.ccc`, or `.cdl` file to the **LutFiles** folder in the project directory.
3. Select the required CDL in the layer properties.
4. Confirm that layers routed into the CDL layer have the correction applied.
5. Adjust **Slope**, **Offset**, **Power**, and **Saturation** on the CDL object and observe the resulting image changes.

See CDL and the Colour Management section for more information.

CDL layer properties

Source from background

When enabled, the background is used as the source texture.

Source texture

Source selection — either Arrow source or a Texture. It is useful to select a PreCompTexture here.

CDL

ASC CDL format colour grading in **Slope**, **Offset**, **Power** and **Saturation** controls.

New CDL

Create a new CDL.

New Indirection

Create a new Indirection.

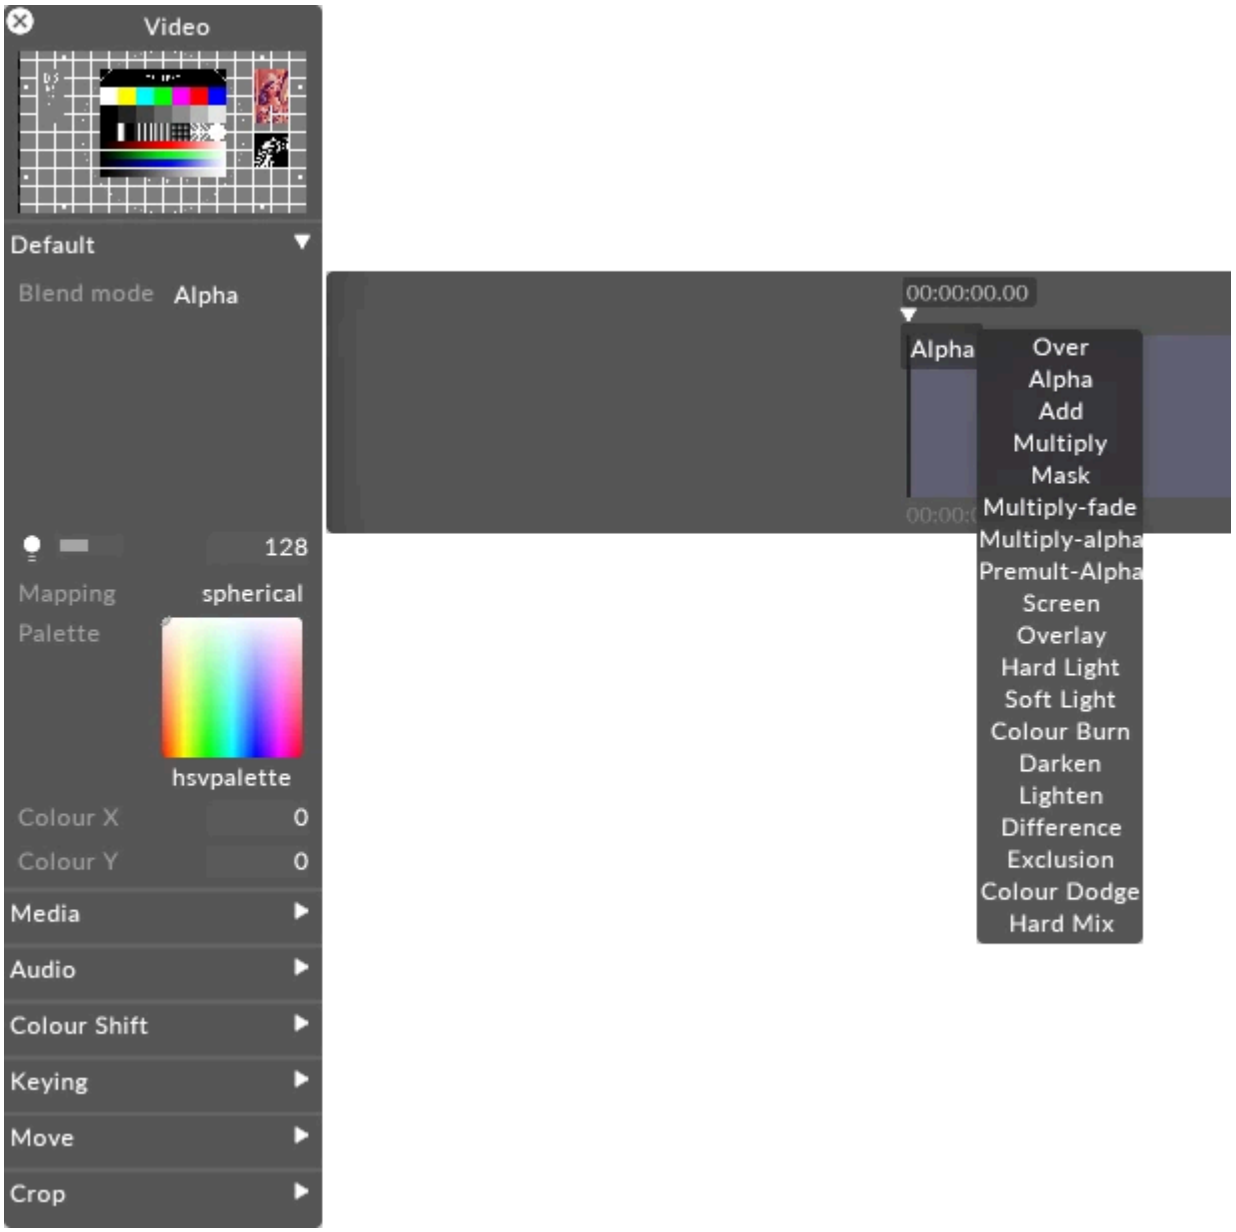
Search

Search for an existing CDL.

Common layer properties

Blend mode

BlendMode controls how the output of the layer is composited with the layers below. Layers are rendered in a bottom-up order: layers at the top can modify the output of the layers below.



Changing brightness of a content layer in Designer is actually controlling the value of the alpha of the layer. Even when displaying a HAP video, the software will composite the layer with a

controllable layer of alpha - one per layer.

There are two ways of expressing alpha in an image:

Straight alpha is an alpha channel which functions just like RGB. Alpha acts as a fourth channel of information per pixel which is as independent of the other three as R, G and B are of each other. For example, with straight alpha it is possible to have RGB = 255 (white) and alpha = 0 (fully transparent) on the same pixel. Internally generated content, such as gradient layer, are generated with straight alpha. This is the preferable style of alpha and considering the cleaner method of the two.

Premultiplied alpha takes the alpha and applies it to the values of the RGB channels per pixel. The more transparent something gets with premultiplied alpha, the closer it gets to black - as if the content is sitting on a black table. Premultiplied is the default output of Adobe Photoshop or AfterEffects. The result is our pixel at 255 RGB (full white) with 0 alpha would be calculated as a black pixel in the final image.

Here are explanations of what each individual blend mode will do.

Over

Makes a layer fully opaque. Premultiplies all alpha onto the RGB value of each pixel. Alpha = black, so adjusting the brightness of a layer in Over blend mode makes it darker.

Alpha

Default blend mode. It will apply alpha values as a transparency if the alpha is present. Brightness changes will make the layer more or less transparent.

Add

Adds the value of each RGB pixel together. Always creates a brighter result. Values clamp at 255.

Multiply

Reads the level of each subpixel as a level between 0.0 and 1.0, and multiplies source with blend. The result is always a darker image overall. For example: white x grey = 0.5. White turns transparent, black takes precedence. Alpha is applied in the same fashion as the Over Blend mode.

Mask

Applies a mask to the single layer **above** in the stack, irrespective of mapping. See **Mask blending** for more information.

Luma-Matte

This mode creates a Luma Matte by using a layer's **Rec. 709 luminance** to control the alpha channel of the layer **above**, irrespective of mapping.

To determine transparency, the luminance of each pixel is calculated using a weighted average of its red, green, and blue channels. The luminance value is then used as the alpha (opacity) value for the corresponding pixels in the upper layers.

As a result, white areas render the layer above fully opaque, black areas make them fully transparent, and grey areas create proportional semi-transparency. This is a specialized **Mask** blend mode; for more details on the underlying behaviour, see **Mask blending**.

Inv-Luma-Matte

The Inverse Luma Matte mask works the same as the **Luma Matte** mask but the transparency is inverted meaning white regions are transparent and black regions are opaque.

Multiply-Fade

The same as Multiply, but will make use of the alpha channel to calculate transparency in the source and blend layers. Since maximum transparency is premultiplied, alpha results in black. This will ignore black created through premultiplying.

Multiply-Alpha

Multiply with straight alpha. This mode assumes that the alpha has not been premultiplied onto the RGB values and will not apply a correction to the semi-transparent pixels.

Premultiply Alpha

Like how Multiply-fade will ignore the darkening caused by premultiplying, this blend mode will do the same with Alpha.

Colour Burn

Blend mode increases the contrast to darken the base colour while reflecting the blend colour. The darker the blend colour, the more intensely the colour will be applied in the base image. White as the blend colour produces no change. Using the colour burn blend mode can produce some harsh results at full opacity. The colour burn blend mode can be used to make tonal and colour adjustments to a layer.

Screen

This blend mode looks at each channels colour information and multiplies the inverse of the blend and base colous. The result is always a lighter colour. Screening with black leaves the colour unchanged. Screening with white produces white. The effect is similar to projecting

multiple images on top of each other - where bright white is fully opaque, black is fully transparent and 50% grey is 50% transparent.

Overlay

Multiplies or screens the colours, depending on the base colour. Patterns or colours overlay the existing pixels while preserving the highlights and shadows of the base colour. The base colour is not replaced, but mixed with the blend colour to reflect the lightness or darkness of the original colour.

Hard Light

Multiplies or screens the colours, depending on the blend colour. The effects is similar to shining a harsh spotlight on the image. If the blend colour (light source/top layer) is lighter than 50% grey, the image is lightened as if it were screened. This is useful for adding highlights to an image. If the blend colour is darker than 50% grey, the image is darkened as if it were multiplied. This is useful for adding shadows to an image. Painting with pure black or white results in pure black or white.

Soft Light

Darkens or lightens the colours, depending on the blend colour. The effect is similar to shining a diffused spotlight on the image. If the blend colour (light source/top layer) is lighter than 50% grey, the image is lightened as it if were dodged. If the blend colour is darker than 50% grey, the image is darkened as if it were burned in. Painting with pure black or white produces a distinctly darker or lighter area, but does not result in pure black or white.

Darken

Looks as the colour information in each channel and selects the base or blend colour - whichever is darker - as the result colour. Pixels lighter than the blend colour are replaced and pixels darker than the blend colour do not change.

Lighten

Looks at the colour information in each channel and selects the base or blend colour - whichever is lighter - as the result colour. Pixels darker than the blend colour are replaced and pixels lighter than the blend colour do not change.

Difference

Looks at the colour information in each channel and subtracts either the blend colour from the base colour or the base colour from the blend colour depending on which has the greater brightness value. Blending with white inverts the base colour values and blending with black produces no change.

Exclusion

Creates an effects similar to but lower in contrast than the difference mode. Blending with white inverts the base colour values. Blending with black produces no change.

Colour Dodge

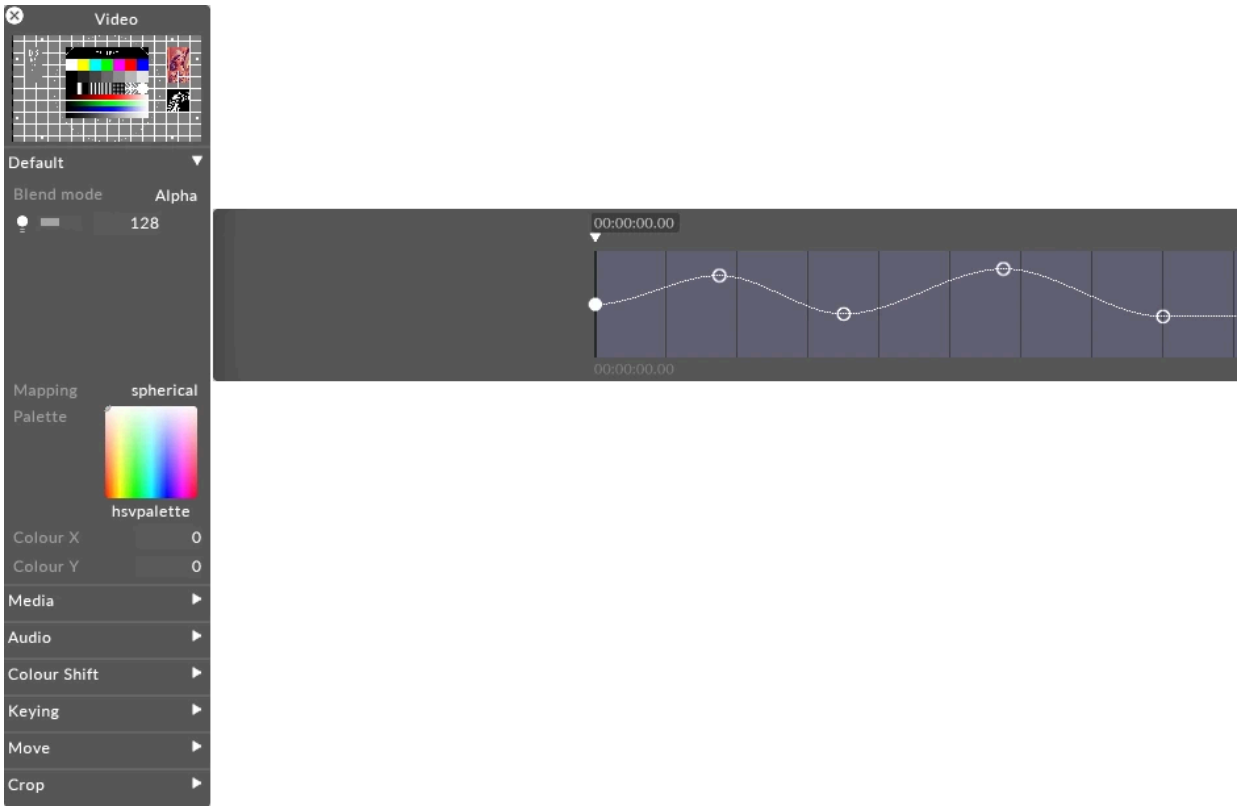
Looks at the colour information in each channel and brightens the base colour to reflect the blend colour by decreasing contrast between the two. Blending with black produces no change.

Hard Mix

Adds the RGB channels of the blend colour to the RGB values of the base colour. If the resulting sum for a channel is 255 or greater, it receives a value of 255; if it is less than 255 it receives a value of 0. Therefore all blended pixels have RGB channels of either 0 or 255. This changes all pixels to primary additive colours (RGB), white or black.

Brightness

This property (which appears as a light bulb icon) controls the brightness of the layer output.



If the layers blend mode is set to Alpha, then reducing the brightness to 0 also reduces the opacity of the layer to 0. This can be useful when you want to dissolve from one layer to the

next. In that case, you can place the new layer above the old layer and increase its brightness level.

> **Note**
>
> Layers that are patched to Sockpuppet (DMX, OSC or HTTP) are made Dormant when their brightness is set to 0. This means they will not do any rendering or consume any resources until their brightness is changed to > 0. You can find more information about this here: **Sequencing with Sockpuppet**. Layers without a sockpuppet patch do not behave in this way.

Mapping

The mapping property controls how the layer output is mapped onto the screen(s) in the Stage level.

For information on mapping, including how to use the different mapping types offered by Designer, please see the chapter **Content Mapping**

ChannelRouter Layer

The ChannelRouter layer creates an RGBA image made up from any combination of the RGBA components from up to two input sources. This can be used to correct problems with a source image, to verify the components of the input sources or for many artistic purposes.

All Effect layers take their source from other layer types - either content or generative - by use of an arrow. Linking two layers with an arrow defines the arrowed from layer as the source, and the arrowed to layer as the destination. If you have an arrow between a content layer and effect layer, it is said that the content layer is being 'piped in' to the effect layer. For more information on arrows, see the Compositing layers.

To draw an arrow between two layers, hold down **ALT** and left-click & drag between the source and destination layer.

> **Note**
>
> The order and direction of arrowing between layers is important. `Source 1` will always be the first layer to be piped into the ChannelRouter layer, `Source 2` will always be the second. Any further layers that are piped in will be disregarded.
>
> In the above screenshot the layer named `Video` was piped in first, then the layer named `Video 2` piped in second. Then the ChannelRouter layer has been set to use the Red Channel of `Video 2` as the Alpha Channel, thus creating the block effect.

Potential uses for the ChannelRouter Layer

Alpha channel substitution

- Take the alpha from one input and apply it to the other. This can be used for artistic masking effects. Settings: R=Source 1 Red, G=Source 1 Green, B=Source 1 Blue, A=Source 2 Alpha.

Alpha channel removal

- Remove the alpha channel from a source image by setting the layer's alpha component to a constant value of 1. Settings: R=Source 1 Red, G=Source 1 Green, B=Source 1 Blue, A=Constant 1

Synthesising an alpha channel

- Input sources that you require to have an alpha channel but do not can often have satisfactory alpha channels synthesised from their luma channel. Settings: R=Source 1 Red, G=Source 1 Green, B=Source 1 Blue, A=Luma 1

Channel correction

- An image supplied in BGR format can be fixed by rearranging it to RGB. Settings: R=Source 1 Blue, G=Source 1 Green, B=Source 1 Red, A=Alpha 1

Image debugging

- Separately view each component from an input source to verify that they are all appear as expected. Settings: R=Source 1 Red, G=Source 1 Red, B=Source 1 Red, A=Constant 1.

ChannelRouter Layer Properties

R Component

Determines which input component appears in the red channel of the layer's output.

G Component

Determines which input component appears in the green channel of the layer's output.

B Component

Determines which input component appears in the blue channel of the layer's output.

A Component

Determines which input component appears in the alpha channel of the layer's output.

Source 1 from background

When enabled, all the layers that are below the UVLookup layer on the timeline and also share the same mapping as the UVLookup layer, are used as the source texture.

Source 1 Texture

This can be a texture applied directly in this field or by using an arrow from another content source layer as described above in the **overview**.

Source 2 from background

When enabled, the existing screen content is used as the source texture. If **Source 1 from background** is also enabled then this will be the same content.

Source 2 Texture

This can be a texture applied directly in this field or by using an arrow from another content source layer as described above in the **overview**.

R Component

Determines which input component appears in the red channel of the layer's output.

G Component

Determines which input component appears in the green channel of the layer's output.

B Component

Determines which input component appears in the blue channel of the layer's output.

A Component

Determines which input component appears in the alpha channel of the layer's output.

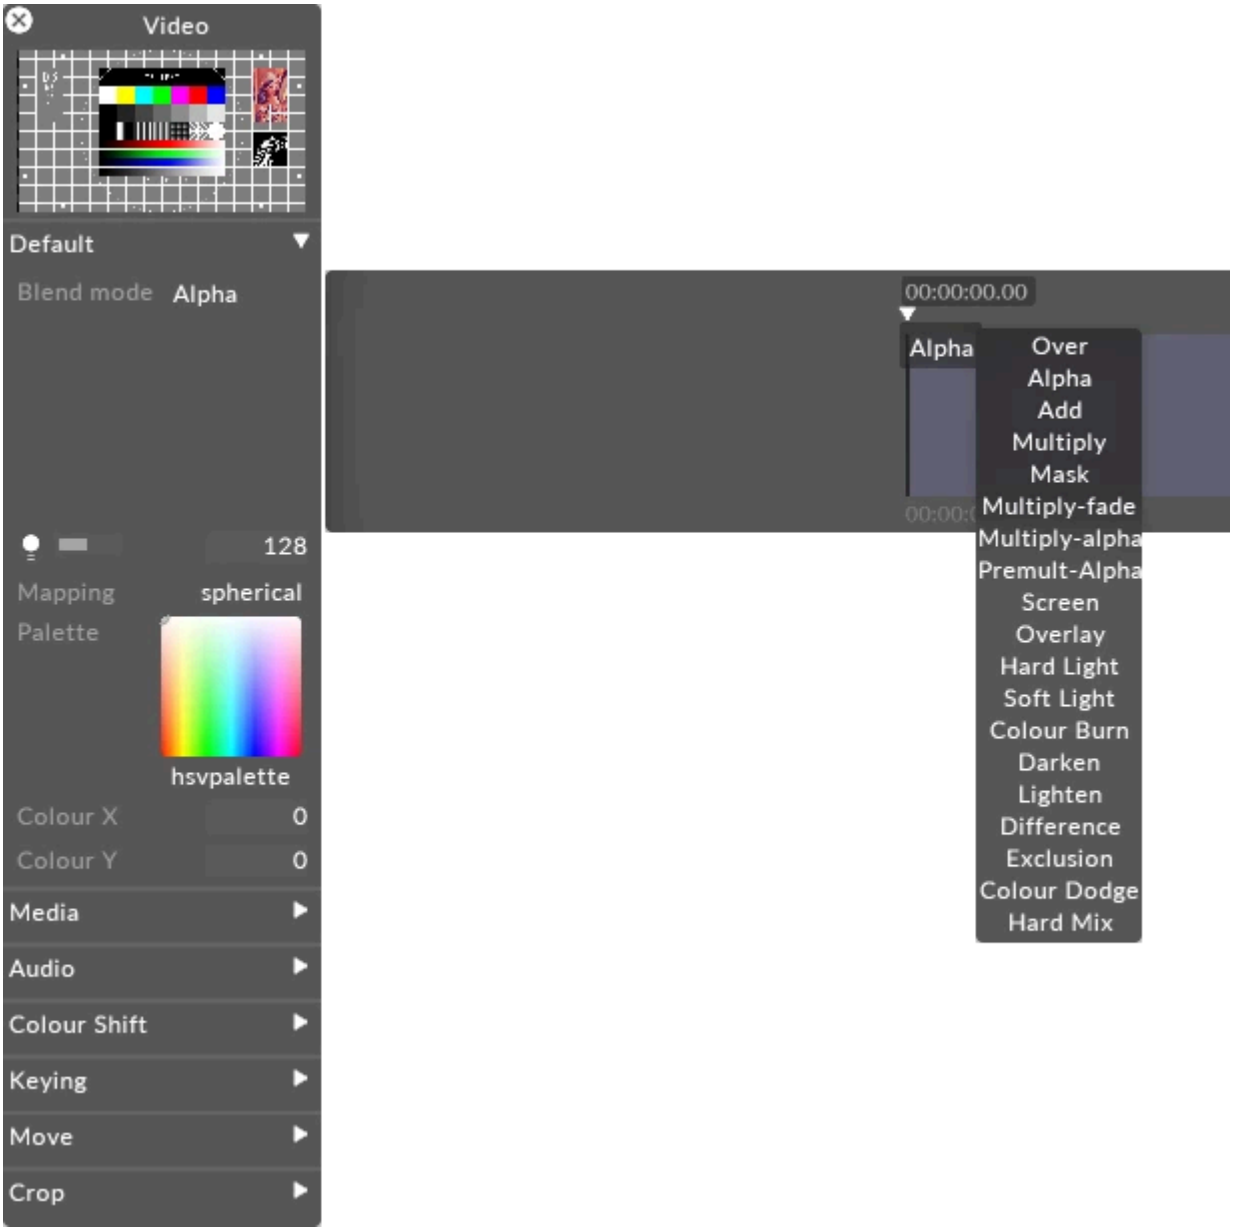
The value for each of the four component properties above can be selected from the following list:

- Source 1 Red - Red component of source 1
- Source 1 Green - Green component of source 1
- Source 1 Blue - Blue component of source 1
- Source 1 Alpha - Alpha component of source 1
- Source 1 Luma - Luma (effectively similar to greyscale) value of source 1
- Source 1 Max RGB - Strongest of source 1's red, green and blue components
- Source 1 Min RGB - Weakest of source 1's red, green and blue components
- Source 2 Red - Red component of source 2
- Source 2 Green - Green component of source 2
- Source 2 Blue - Blue component of source 2
- Source 2 Alpha - Alpha component of source 2
- Source 2 Luma - Luma (effectively similar to greyscale) value of source 2
- Source 2 Max RGB - Strongest of source 2's red, green and blue components
- Source 2 Min RGB - Weakest of source 2's red, green and blue components
- Constant 0 - A constant value of 0
- Constant 1 - A constant value of 1

Common Layer Properties

Blend Mode

BlendMode controls how the output of the layer is composited with the layers below. Layers are rendered in a bottom-up order: layers at the top can modify the output of the layers below.



Changing brightness of a content layer in Designer is actually controlling the value of the alpha of the layer. Even when displaying a HAP video, the software will composite the layer with a controllable layer of alpha - one per layer.

There are two ways of expressing alpha in an image:

Straight alpha is an alpha channel which functions just like RGB. Alpha acts as a fourth channel of information per pixel which is as independent of the other three as R, G and B are of each other. For example, with straight alpha it is possible to have RGB = 255 (white) and alpha = 0 (fully transparent) on the same pixel. Internally generated content, such as gradient layer, are generated with straight alpha. This is the preferable style of alpha and considering the cleaner method of the two.

Premultiplied alpha takes the alpha and applies it to the values of the RGB channels per pixel. The more transparent something gets with premultiplied alpha, the closer it gets to black - as if the content is sitting on a black table. Premultiplied is the default output of Adobe Photoshop or AfterEffects. The result is our pixel at 255 RGB (full white) with 0 alpha would be calculated as a black pixel in the final image.

Here are explanations of what each individual blend mode will do.

Over

Makes a layer fully opaque. Premultiplies all alpha onto the RGB value of each pixel. Alpha = black, so adjusting the brightness of a layer in Over blend mode makes it darker.

Alpha

Default blend mode. It will apply alpha values as a transparency if the alpha is present. Brightness changes will make the layer more or less transparent.

Add

Adds the value of each RGB pixel together. Always creates a brighter result. Values clamp at 255.

Multiply

Reads the level of each subpixel as a level between 0.0 and 1.0, and multiplies source with blend. The result is always a darker image overall. For example: white x grey = 0.5. White turns transparent, black takes precedence. Alpha is applied in the same fashion as the Over Blend mode.

Mask

Applies a mask to the single layer **above** in the stack, irrespective of mapping. See **Mask blending** for more information.

Luma-Matte

This mode creates a Luma Matte by using a layer's **Rec. 709 luminance** to control the alpha channel of the layer **above**, irrespective of mapping.

To determine transparency, the luminance of each pixel is calculated using a weighted average of its red, green, and blue channels. The luminance value is then used as the alpha (opacity) value for the corresponding pixels in the upper layers.

As a result, white areas render the layer above fully opaque, black areas make them fully transparent, and grey areas create proportional semi-transparency. This is a specialized **Mask** blend mode; for more details on the underlying behaviour, see **Mask blending**.

Inv-Luma-Matte

The Inverse Luma Matte mask works the same as the **Luma Matte** mask but the transparency is inverted meaning white regions are transparent and black regions are opaque.

Multiply-Fade

The same as Multiply, but will make use of the alpha channel to calculate transparency in the source and blend layers. Since maximum transparency is premultiplied, alpha results in black. This will ignore black created through premultiplying.

Multiply-Alpha

Multiply with straight alpha. This mode assumes that the alpha has not been premultiplied onto the RGB values and will not apply a correction to the semi-transparent pixels.

Premultiply Alpha

Like how Multiply-fade will ignore the darkening caused by premultiplying, this blend mode will do the same with Alpha.

Colour Burn

Blend mode increases the contrast to darken the base colour while reflecting the blend colour. The darker the blend colour, the more intensely the colour will be applied in the base image. White as the blend colour produces no change. Using the colour burn blend mode can produce some harsh results at full opacity. The colour burn blend mode can be used to make tonal and colour adjustments to a layer.

Screen

This blend mode looks at each channels colour information and multiplies the inverse of the blend and base colous. The result is always a lighter colour. Screening with black leaves the colour unchanged. Screening with white produces white. The effect is similar to projecting multiple images on top of each other - where bright white is fully opaque, black is fully transparent and 50% grey is 50% transparent.

Overlay

Multiplies or screens the colours, depending on the base colour. Patterns or colours overlay the existing pixels while preserving the highlights and shadows of the base colour. The base colour is not replaced, but mixed with the blend colour to reflect the lightness or darkness of the original colour.

Hard Light

Multiplies or screens the colours, depending on the blend colour. The effects is similar to shining a harsh spotlight on the image. If the blend colour (light source/top layer) is lighter than

50% grey, the image is lightened as if it were screened. This is useful for adding highlights to an image. If the blend colour is darker than 50% grey, the image is darkened as if it were multiplied. This is useful for adding shadows to an image. Painting with pure black or white results in pure black or white.

Soft Light

Darkens or lightens the colours, depending on the blend colour. The effect is similar to shining a diffused spotlight on the image. If the blend colour (light source/top layer) is lighter than 50% grey, the image is lightened as it if were dodged. If the blend colour is darker than 50% grey, the image is darkened as if it were burned in. Painting with pure black or white produces a distinctly darker or lighter area, but does not result in pure black or white.

Darken

Looks as the colour information in each channel and selects the base or blend colour - whichever is darker - as the result colour. Pixels lighter than the blend colour are replaced and pixels darker than the blend colour do not change.

Lighten

Looks at the colour information in each channel and selects the base or blend colour - whichever is lighter - as the result colour. Pixels darker than the blend colour are replaced and pixels lighter than the blend colour do not change.

Difference

Looks at the colour information in each channel and subtracts either the blend colour from the base colour or the base colour from the blend colour depending on which has the greater brightness value. Blending with white inverts the base colour values and blending with black produces no change.

Exclusion

Creates an effects similar to but lower in contrast than the difference mode. Blending with white inverts the base colour values. Blending with black produces no change.

Colour Dodge

Looks at the colour information in each channel and brightens the base colour to reflect the blend colour by decreasing contrast between the two. Blending with black produces no change.

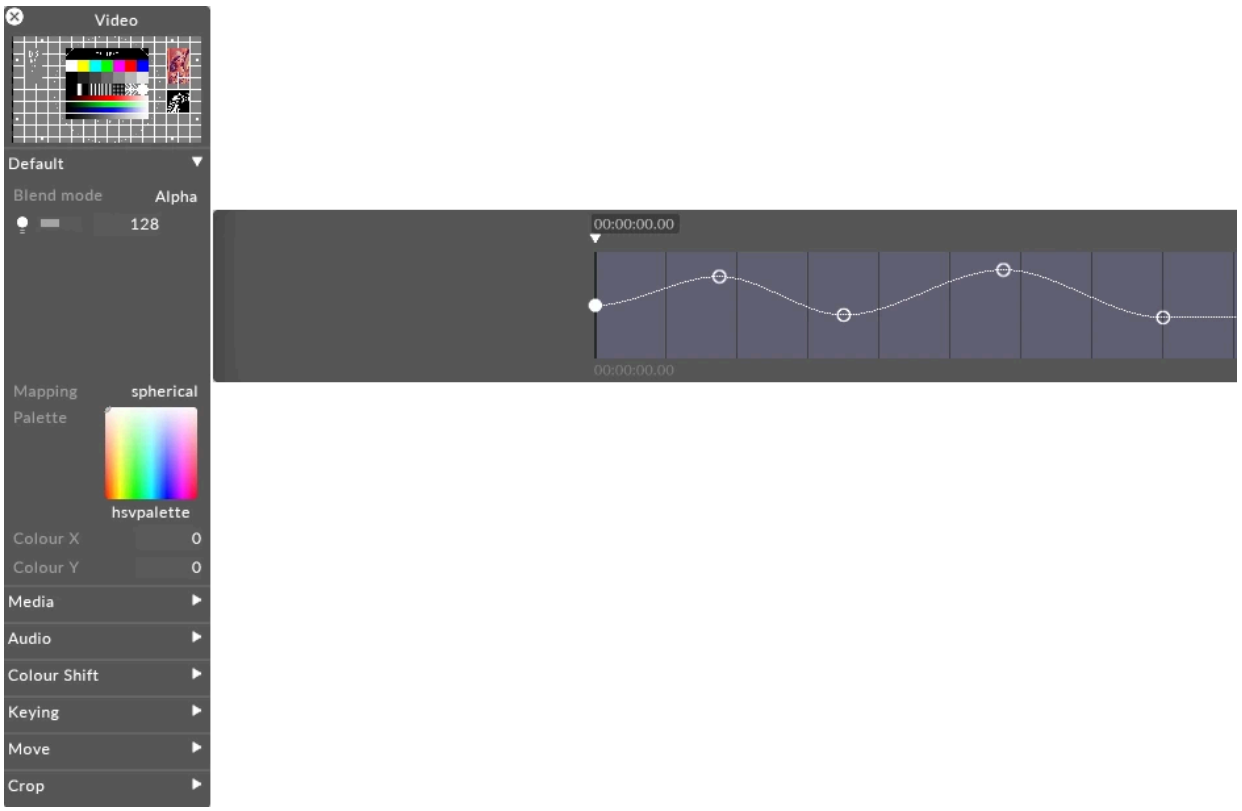
Hard Mix

Adds the RGB channels of the blend colour to the RGB values of the base colour. If the resulting sum for a channel is 255 or greater, it receives a value of 255; if it is less than 255 it

receives a value of 0. Therefore all blended pixels have RGB channels of either 0 or 255. This changes all pixels to primary additive colours (RGB), white or black.

Brightness

This property (which appears as a light bulb icon) controls the brightness of the layer output.



If the layers blend mode is set to Alpha, then reducing the brightness to 0 also reduces the opacity of the layer to 0. This can be useful when you want to dissolve from one layer to the next. In that case, you can place the new layer above the old layer and increase its brightness level.

> **Note**
>
> Layers that are patched to Sockpuppet (DMX, OSC or HTTP) are made Dormant when their brightness is set to 0. This means they will not do any rendering or consume any resources until their brightness is changed to > 0. You can find more information about this here: **Sequencing with Sockpuppet**. Layers without a sockpuppet patch do not behave in this way.

Mapping

The mapping property controls how the layer output is mapped onto the screen(s) in the Stage level.

For information on mapping, including how to use the different mapping types offered by Designer, please see the chapter **Content Mapping**

ColourAdjust

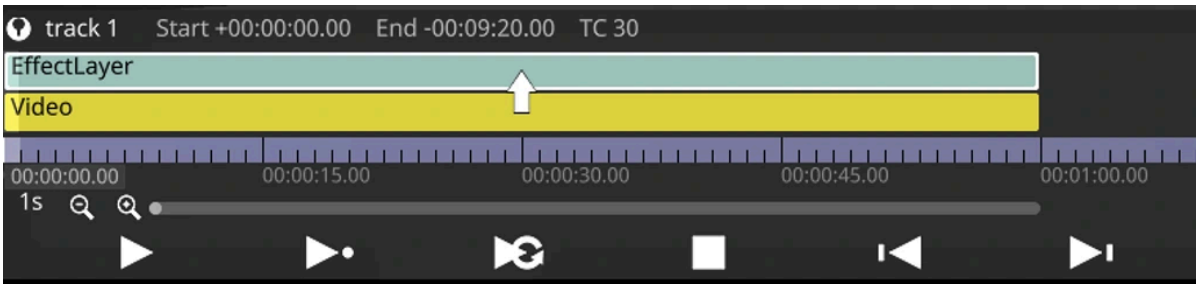
The ColourAdjust layer is best suited to changing colour properties in a familiar set values. It is designed to control white balance and tint either through presets or discrete amounts.

Workflow

Effect layers receive their source from other layer types - either content or generative - through arrows. An arrow connects a source layer to a destination layer; the source layer is said to be “piped in” to the destination Effect layer. For more information on arrows, see the **compositing layers** topic.

To draw an arrow between two layers, hold down **ALT** and left-click & drag from the source layer to the destination layer.

1. Add an Effect layer to your track. For more information about adding layers, see **creating layers**.
2. Draw an arrow from your content layer to the Effect layer so the compositing order looks something like the following image.



A Video layer piped into an Effect layer on the timeline.

3. Adjust the Effect layer properties to achieve the desired result.

ColourAdjust layer properties

White balance preset

This property defines which White balance preset is used.

The following options are available.

- None
- Custom
- Daylight
- Shade

- Cloudy
- Tungsten
- Florescent
- Flash

Once you have selected a preset, you cannot keyframe Kelvin & Tint.

Kelvin

This property controls the Kelvin in degrees kelvin.

Tint

This property controls tint and allows you to fine-tune the green/magenta balance. The scale on the slider represents the actual Kelvin value, which is subject to slight variations from camera to camera.

Contrast

This property controls contrast.

Brightness

This property controls brightness.

Saturation

This property controls saturation.

Levels

Levels is a tool in the **ColourAdjust** layer which can move and compress the brightness levels of an image histogram. It has the power to adjust brightness, contrast, and tonal range by specifying the location of complete black, complete white, and midtones in a histogram. Since every piece of content's histogram is unique, there is no single way to adjust the levels for all your content. A proper understanding of how to adjust the levels of an image histogram will help you better represent tones in the final image.

Shadow

Shadow defines the lowest brightness value in the source image. Any pixels at or below this value are pushed towards `0.0`.

Midtone

The midtone can be considered as a gamma adjustment. It adjusts the midtone response or overall curve between black and white, allowing to brighten or darken mid-level tones without heavily altering the extremes.

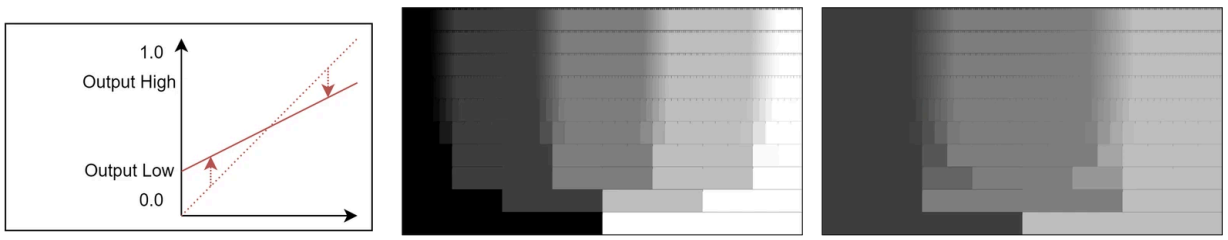
Highlight

Highlight defines the highest brightness value in the source image. Any pixels at or above this value are pushed towards `1.0`.

Compress

The colour level can be compressed using **Output Low** and **Output High**. For example, the colour range of `[0.0, 1.0]` will be compressed into `[Output Low, Output High]`. This shifts the entire colour range while minimising the loss of detail in the darkest and brightest regions.

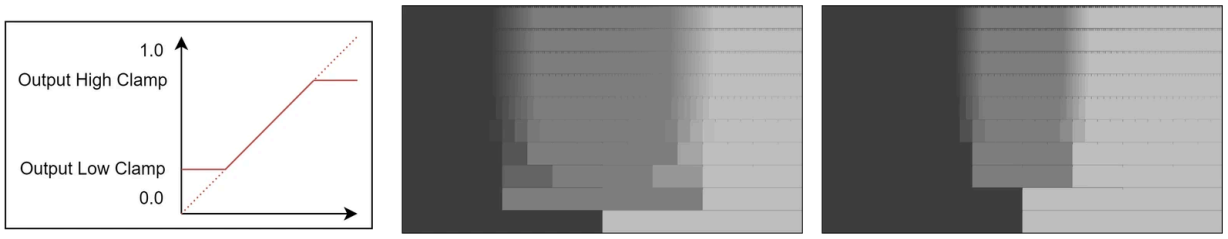
- **Output Low** sets how dark the darkest pixels in the result will be.
- **Output High** sets how bright the brightest pixels in the result will be.



Graph (left), Original (mid), With compress [0.2, 0.8] (right)

Clamp

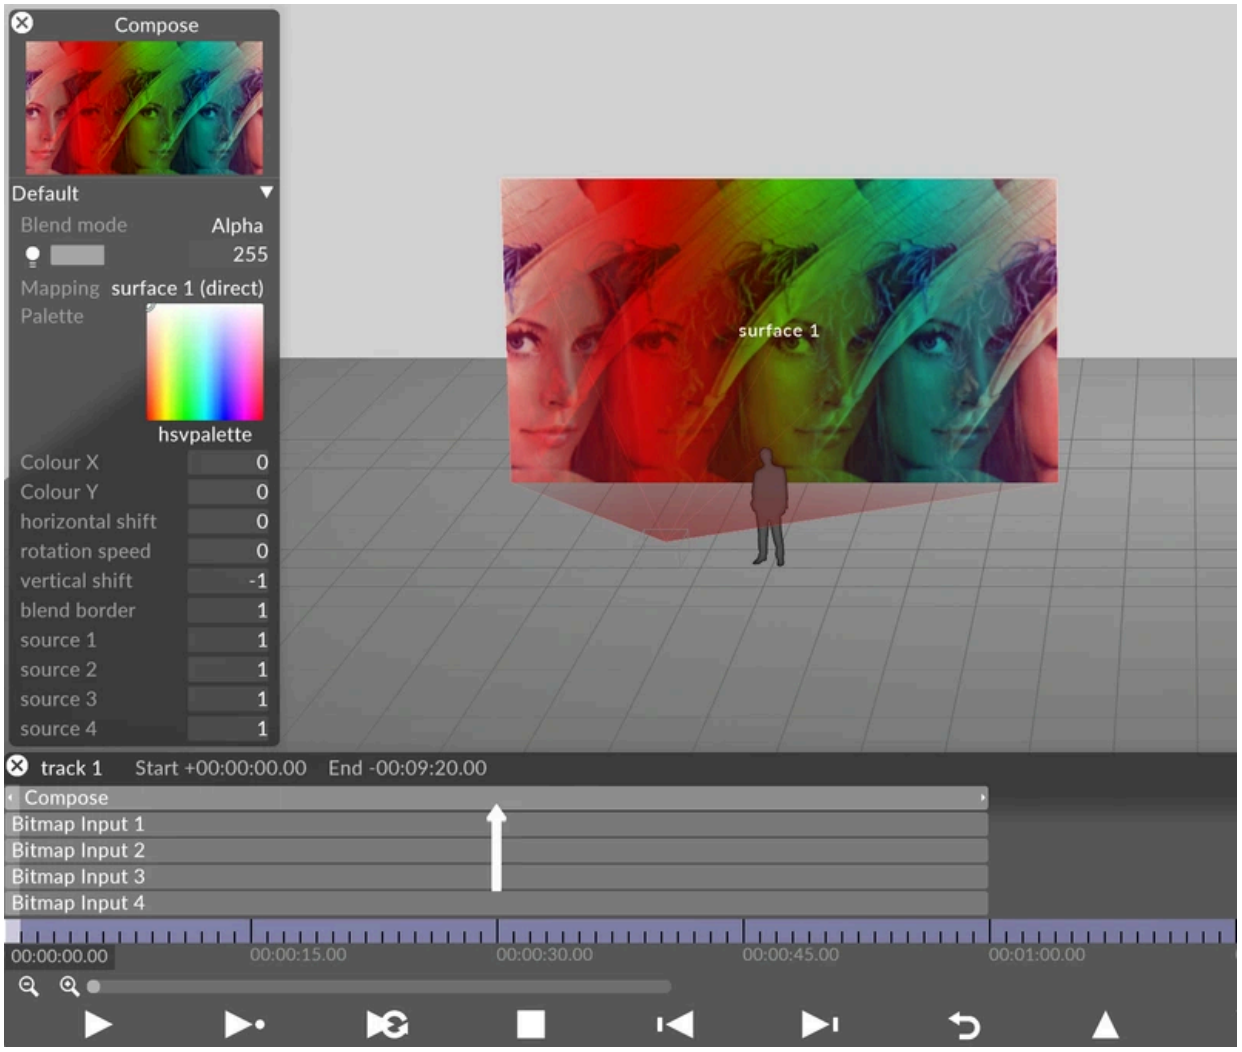
To prevent colour shift, clamping can be applied. As the name suggests, colours will be restricted within the range of `[Output Low Clamp, Output High Clamp]`. This means that colours within the clamp range will be preserved, while colours outside the range will be capped and lost.



Graph (left), With compress [0.2, 0.8] (mid), With clamp [0.2, 0.8]

Compose Layer

The Compose layer takes multiple inputs, for example live camera input, and composes the inputs next to each other on a screen. The Compose layer can also blur the edges between the inputs enabling seamless edges.

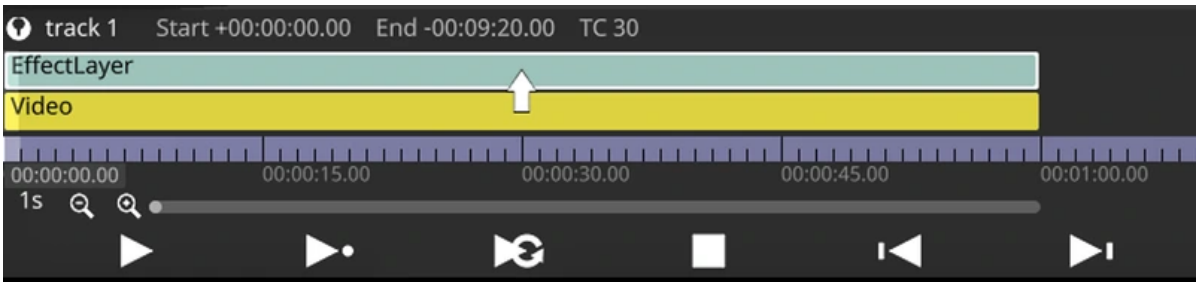


Workflow

Effect layers receive their source from other layer types - either content or generative - through arrows. An arrow connects a source layer to a destination layer; the source layer is said to be “piped in” to the destination Effect layer. For more information on arrows, see the compositing layers topic.

To draw an arrow between two layers, hold down **ALT** and left-click & drag from the source layer to the destination layer.

1. Add an Effect layer to your track. For more information about adding layers, see creating layers.
2. Draw an arrow from your content layer to the Effect layer so the compositing order looks something like the following image.

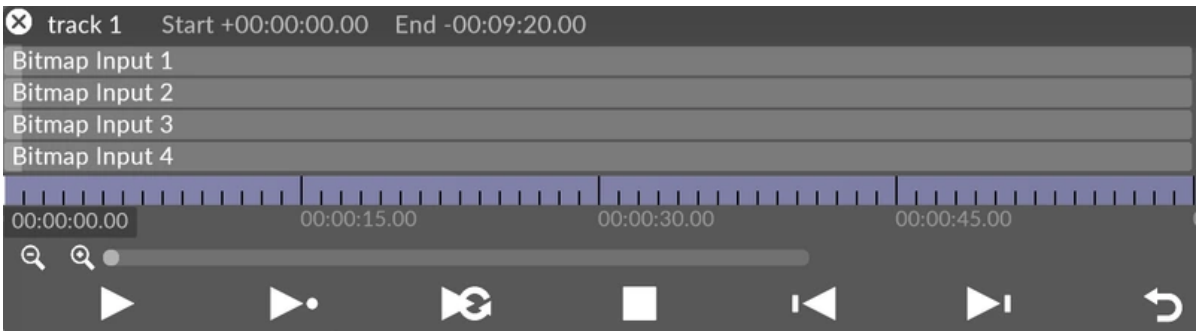


A Video layer piped into an Effect layer on the timeline.

3. Adjust the Effect layer properties to achieve the desired result.

Using the Compose layer

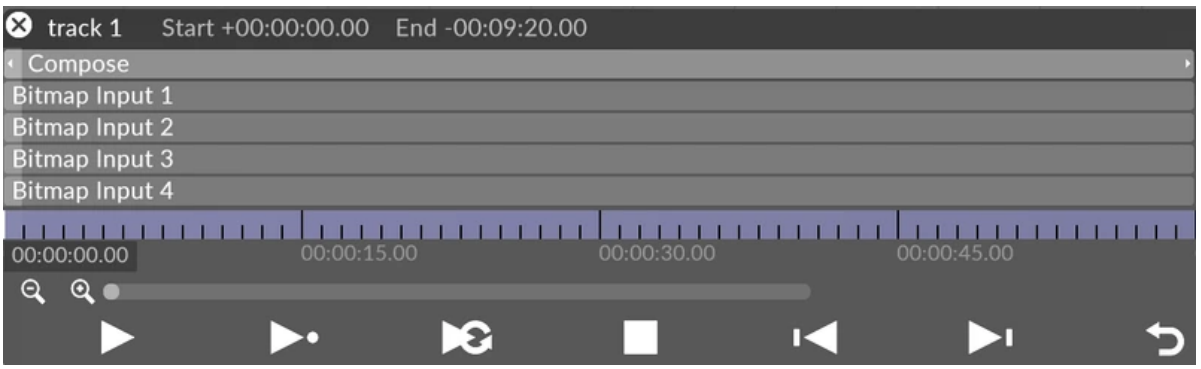
1. Create the input layers. These can be any content layer (Bitmap layer, Video layer , etc) or a combination. For the example here we are using Bitmap layers.



Content layers, in this example four Bitmap layers, will be used as input into a Compose layer

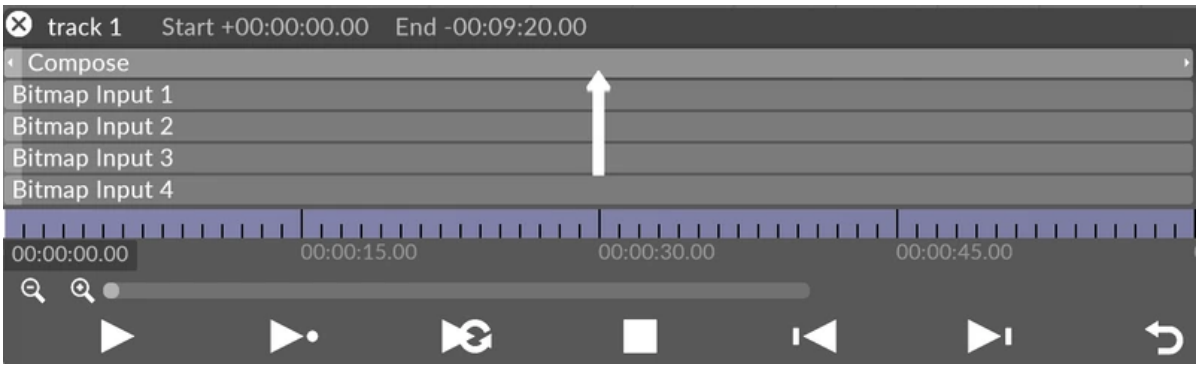
2. Edit the s properties as you wish. The content layers used in this example have had their Colour Shift properties edited. For more information on editing Colour Shift properties scroll down to the section Colour Shift in the Common Layer Properties chapter.
3. Create a Direct mapping with the same resolution as the source content. For example, if the image in the Bitmap layer is 256x256 pixels, create a Direct mapping type with a 256x256 resolution . As the mapping type only acts as a temporary container which is piped into the Compose layer, there is no need to add a screen.

4. Create a Compose layer. Make sure this layer is positioned at the top of your layer order.



The Compose layer should be positioned at the top of the input layers

5. Drag an Arrow from each input layer into the Compose layer. For information on Arrows please see the sub-chapter Composing layers using arrows. In the Compose layers preview window you can now see the inputs composed next to each other.



Input layers piped into the Compose layer using Arrows and mapped onto Screen1 using a Direct mapping

6. Edit the Compose layer properties as you wish. It is also possible to blur the edges between the inputs enabling seamless edges, as shown in the first image of this sub-chapter.

Compose Layer Properties

Horizontal shift

Moves the composed content left or right.

Rotation speed

Adjusts the horizontal rotation speed of the content.

Vertical shift

Moves the content up or down.

Blend border

Adjusts the blending level between the input sources.

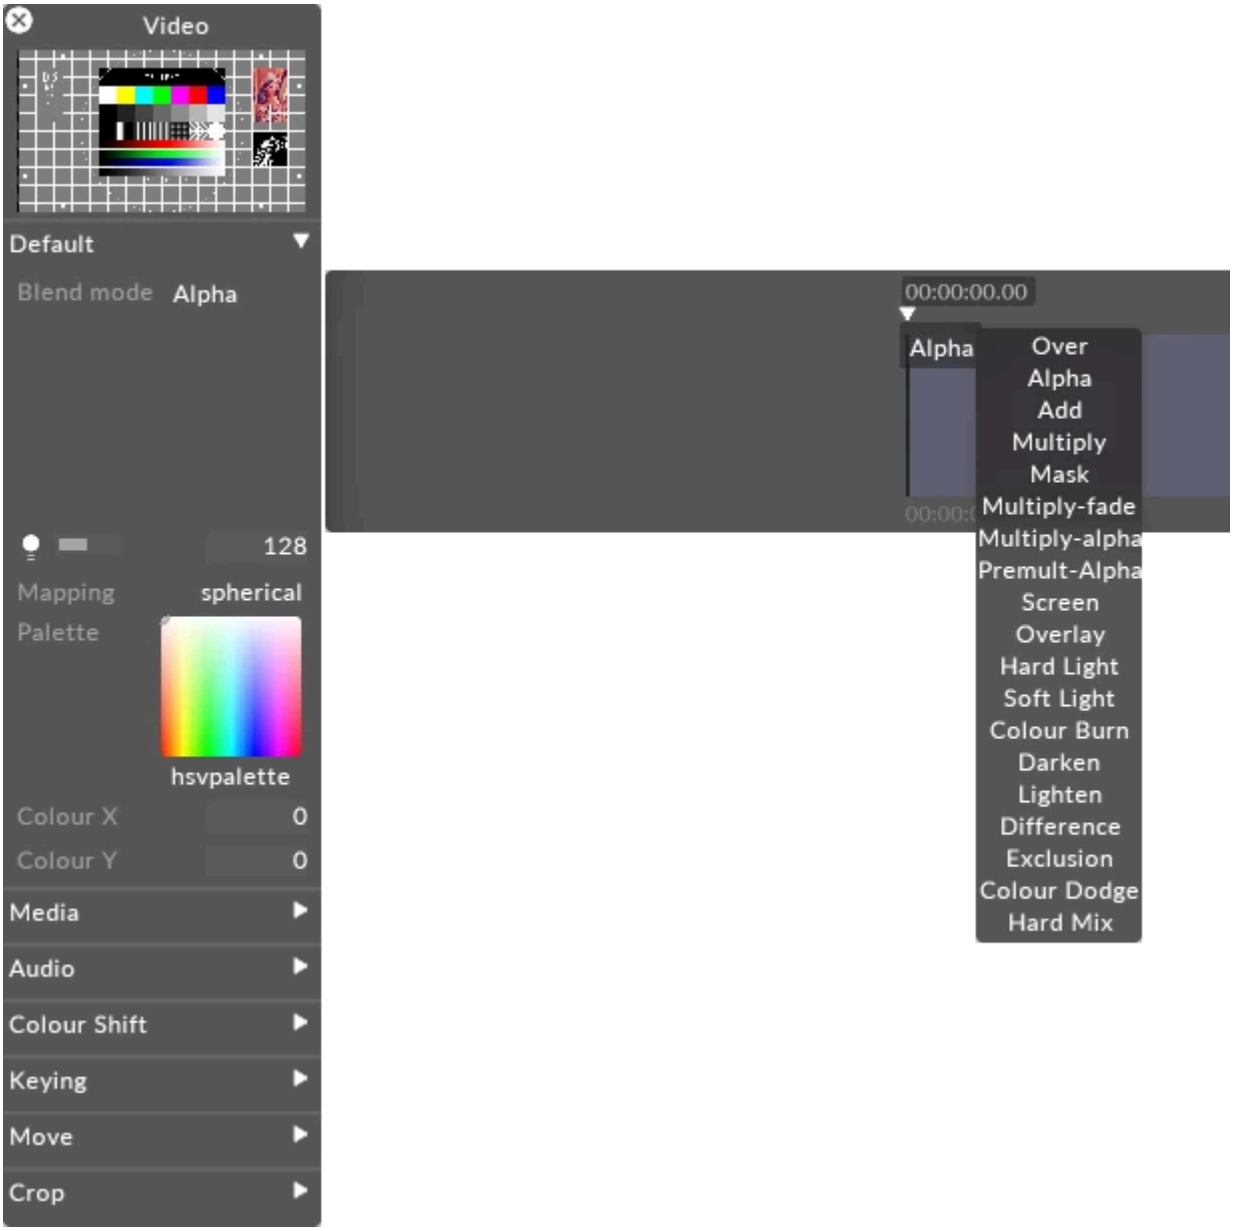
Source 1,2,3,4

Adjust what inputs to show, hide or partially show. When you set the value to 1, it shows the input, 0 hides the input. As inputs are being hidden, note that Designer maintains the aspect and therefore scales the inputs on the screen.

Common Layer Properties

Blend Mode

BlendMode controls how the output of the layer is composited with the layers below. Layers are rendered in a bottom-up order: layers at the top can modify the output of the layers below.



Changing brightness of a content layer in Designer is actually controlling the value of the alpha of the layer. Even when displaying a HAP video, the software will composite the layer with a controllable layer of alpha - one per layer.

There are two ways of expressing alpha in an image:

Straight alpha is an alpha channel which functions just like RGB. Alpha acts as a fourth channel of information per pixel which is as independent of the other three as R, G and B are of each other. For example, with straight alpha it is possible to have RGB = 255 (white) and alpha = 0 (fully transparent) on the same pixel. Internally generated content, such as gradient layer, are generated with straight alpha. This is the preferable style of alpha and considering the cleaner method of the two.

Premultiplied alpha takes the alpha and applies it to the values of the RGB channels per pixel. The more transparent something gets with premultiplied alpha, the closer it gets to black - as if the content is sitting on a black table. Premultiplied is the default output of Adobe Photoshop or AfterEffects. The result is our pixel at 255 RGB (full white) with 0 alpha would be calculated as a black pixel in the final image.

Here are explanations of what each individual blend mode will do.

Over

Makes a layer fully opaque. Premultiplies all alpha onto the RGB value of each pixel. Alpha = black, so adjusting the brightness of a layer in Over blend mode makes it darker.

Alpha

Default blend mode. It will apply alpha values as a transparency if the alpha is present. Brightness changes will make the layer more or less transparent.

Add

Adds the value of each RGB pixel together. Always creates a brighter result. Values clamp at 255.

Multiply

Reads the level of each subpixel as a level between 0.0 and 1.0, and multiplies source with blend. The result is always a darker image overall. For example: white x grey = 0.5. White turns transparent, black takes precedence. Alpha is applied in the same fashion as the Over Blend mode.

Mask

Applies a mask to the single layer **above** in the stack, irrespective of mapping. See **Mask blending** for more information.

Luma-Matte

This mode creates a Luma Matte by using a layer's **Rec. 709 luminance** to control the alpha channel of the layer **above**, irrespective of mapping.

To determine transparency, the luminance of each pixel is calculated using a weighted average of its red, green, and blue channels. The luminance value is then used as the alpha (opacity) value for the corresponding pixels in the upper layers.

As a result, white areas render the layer above fully opaque, black areas make them fully transparent, and grey areas create proportional semi-transparency. This is a specialized **Mask** blend mode; for more details on the underlying behaviour, see **Mask blending**.

Inv-Luma-Matte

The Inverse Luma Matte mask works the same as the **Luma Matte** mask but the transparency is inverted meaning white regions are transparent and black regions are opaque.

Multiply-Fade

The same as Multiply, but will make use of the alpha channel to calculate transparency in the source and blend layers. Since maximum transparency is premultiplied, alpha results in black. This will ignore black created through premultiplying.

Multiply-Alpha

Multiply with straight alpha. This mode assumes that the alpha has not been premultiplied onto the RGB values and will not apply a correction to the semi-transparent pixels.

Premultiply Alpha

Like how Multiply-fade will ignore the darkening caused by premultiplying, this blend mode will do the same with Alpha.

Colour Burn

Blend mode increases the contrast to darken the base colour while reflecting the blend colour. The darker the blend colour, the more intensely the colour will be applied in the base image. White as the blend colour produces no change. Using the colour burn blend mode can produce some harsh results at full opacity. The colour burn blend mode can be used to make tonal and colour adjustments to a layer.

Screen

This blend mode looks at each channels colour information and multiplies the inverse of the blend and base colous. The result is always a lighter colour. Screening with black leaves the colour unchanged. Screening with white produces white. The effect is similar to projecting multiple images on top of each other - where bright white is fully opaque, black is fully transparent and 50% grey is 50% transparent.

Overlay

Multiplies or screens the colours, depending on the base colour. Patterns or colours overlay the existing pixels while preserving the highlights and shadows of the base colour. The base colour is not replaced, but mixed with the blend colour to reflect the lightness or darkness of the original colour.

Hard Light

Multiplies or screens the colours, depending on the blend colour. The effects is similar to shining a harsh spotlight on the image. If the blend colour (light source/top layer) is lighter than

50% grey, the image is lightened as if it were screened. This is useful for adding highlights to an image. If the blend colour is darker than 50% grey, the image is darkened as if it were multiplied. This is useful for adding shadows to an image. Painting with pure black or white results in pure black or white.

Soft Light

Darkens or lightens the colours, depending on the blend colour. The effect is similar to shining a diffused spotlight on the image. If the blend colour (light source/top layer) is lighter than 50% grey, the image is lightened as it if were dodged. If the blend colour is darker than 50% grey, the image is darkened as if it were burned in. Painting with pure black or white produces a distinctly darker or lighter area, but does not result in pure black or white.

Darken

Looks as the colour information in each channel and selects the base or blend colour - whichever is darker - as the result colour. Pixels lighter than the blend colour are replaced and pixels darker than the blend colour do not change.

Lighten

Looks at the colour information in each channel and selects the base or blend colour - whichever is lighter - as the result colour. Pixels darker than the blend colour are replaced and pixels lighter than the blend colour do not change.

Difference

Looks at the colour information in each channel and subtracts either the blend colour from the base colour or the base colour from the blend colour depending on which has the greater brightness value. Blending with white inverts the base colour values and blending with black produces no change.

Exclusion

Creates an effects similar to but lower in contrast than the difference mode. Blending with white inverts the base colour values. Blending with black produces no change.

Colour Dodge

Looks at the colour information in each channel and brightens the base colour to reflect the blend colour by decreasing contrast between the two. Blending with black produces no change.

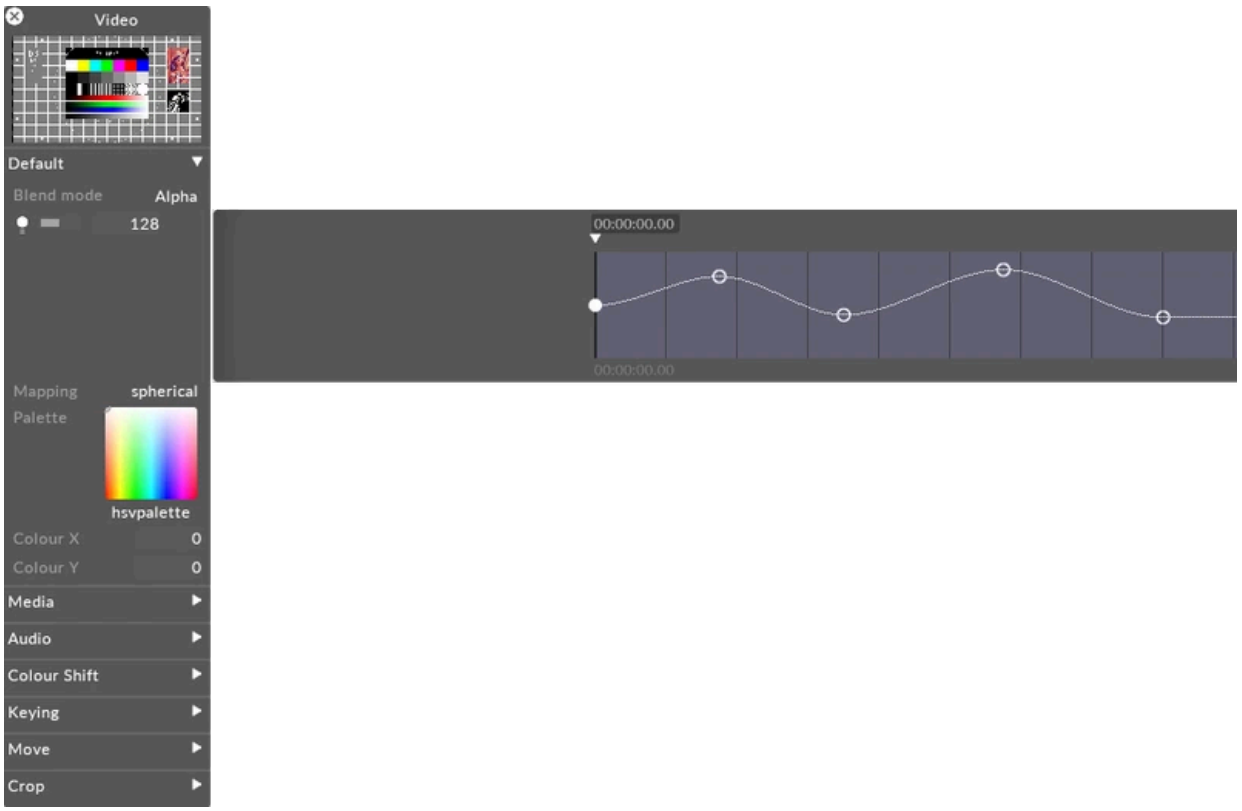
Hard Mix

Adds the RGB channels of the blend colour to the RGB values of the base colour. If the resulting sum for a channel is 255 or greater, it receives a value of 255; if it is less than 255 it

receives a value of 0. Therefore all blended pixels have RGB channels of either 0 or 255. This changes all pixels to primary additive colours (RGB), white or black.

Brightness

This property (which appears as a light bulb icon) controls the brightness of the layer output.



If the layers blend mode is set to Alpha, then reducing the brightness to 0 also reduces the opacity of the layer to 0. This can be useful when you want to dissolve from one layer to the next. In that case, you can place the new layer above the old layer and increase its brightness level.

> **Note**
>
> Layers that are patched to Sockpuppet (DMX, OSC or HTTP) are made Dormant when their brightness is set to 0. This means they will not do any rendering or consume any resources until their brightness is changed to > 0. You can find more information about this here: **Sequencing with Sockpuppet**. Layers without a sockpuppet patch do not behave in this way.

Mapping

The mapping property controls how the layer output is mapped onto the screen(s) in the Stage level.

For information on mapping, including how to use the different mapping types offered by Designer, please see the chapter **Content Mapping**

EdgeFilter Layer

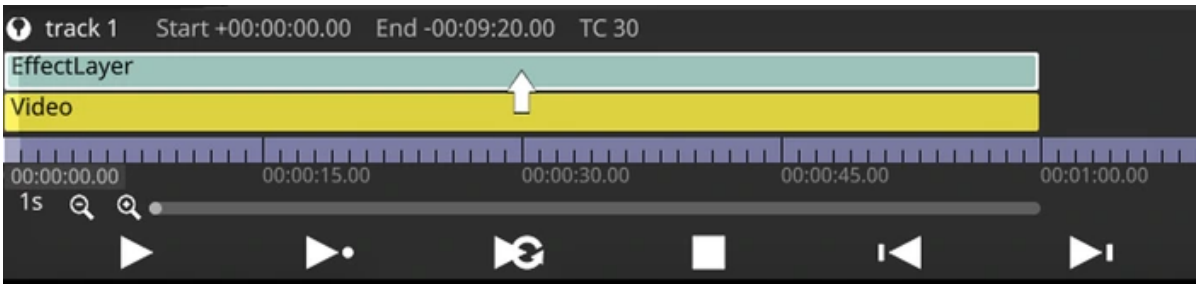
The EdgeFilter layer filter can be used to detect the edges within a video/bitmap.

Workflow

Effect layers receive their source from other layer types - either content or generative - through arrows. An arrow connects a source layer to a destination layer; the source layer is said to be “piped in” to the destination Effect layer. For more information on arrows, see the **compositing layers** topic.

To draw an arrow between two layers, hold down **ALT** and left-click & drag from the source layer to the destination layer.

1. Add an Effect layer to your track. For more information about adding layers, see **creating layers**.
2. Draw an arrow from your content layer to the Effect layer so the compositing order looks something like the following image.

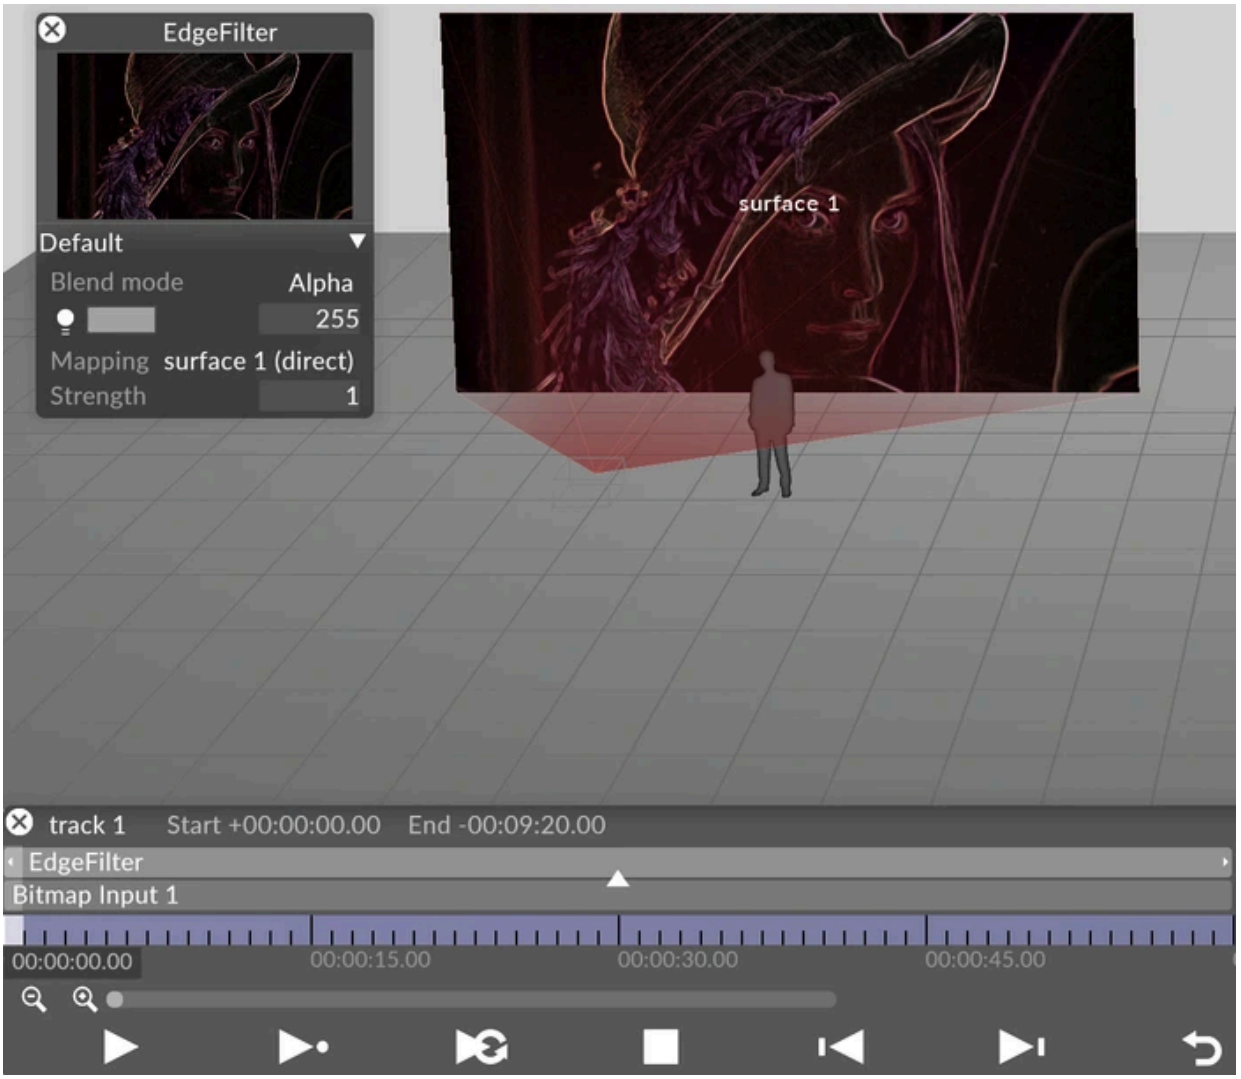


A Video layer piped into an Effect layer on the timeline.

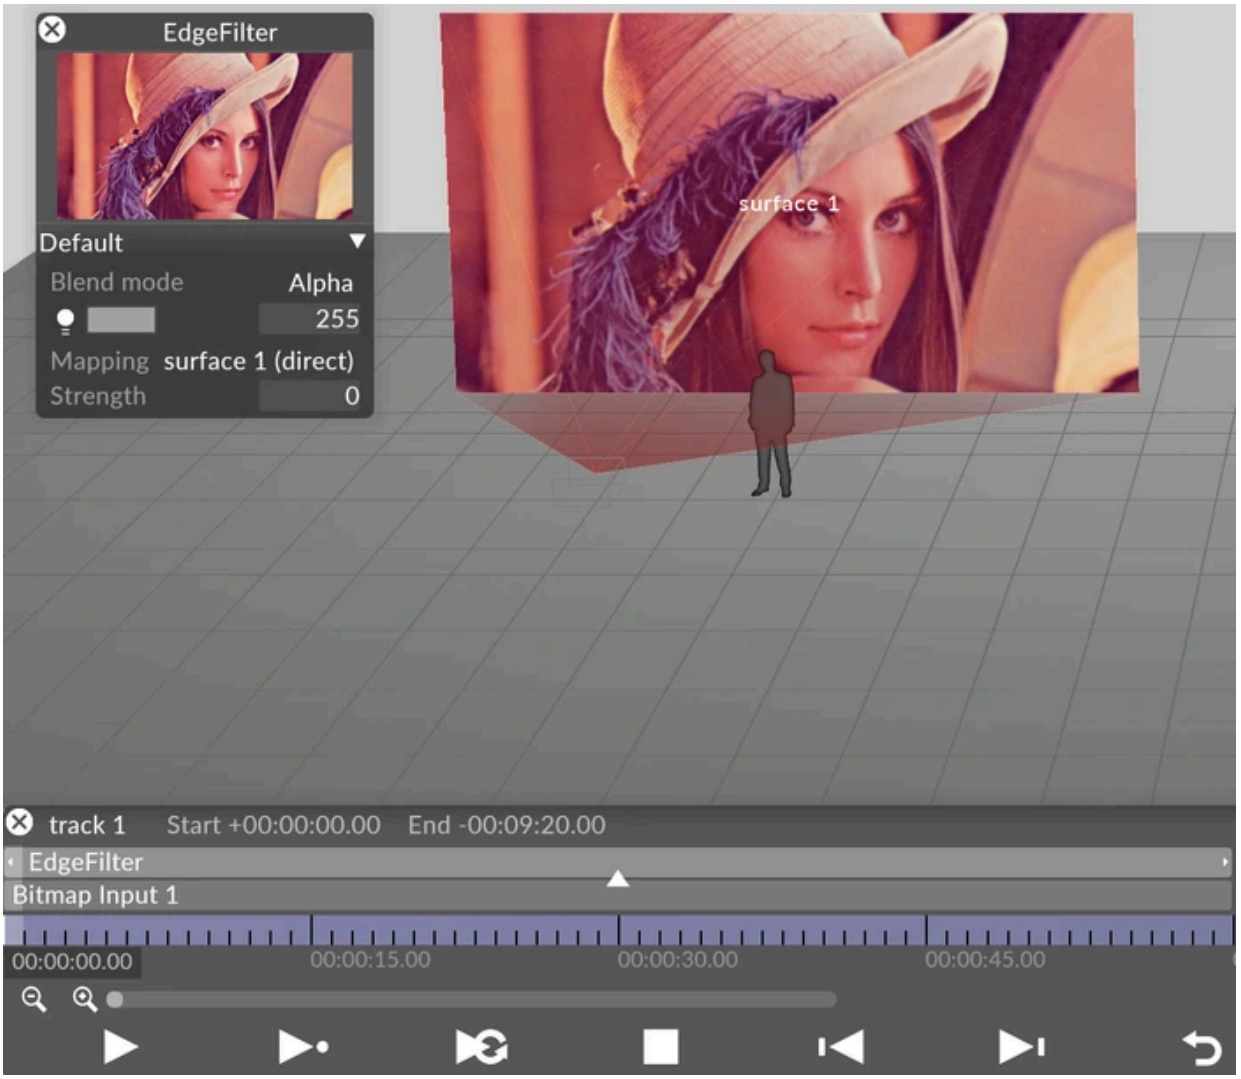
3. Adjust the Effect layer properties to achieve the desired result.

Configure Properties

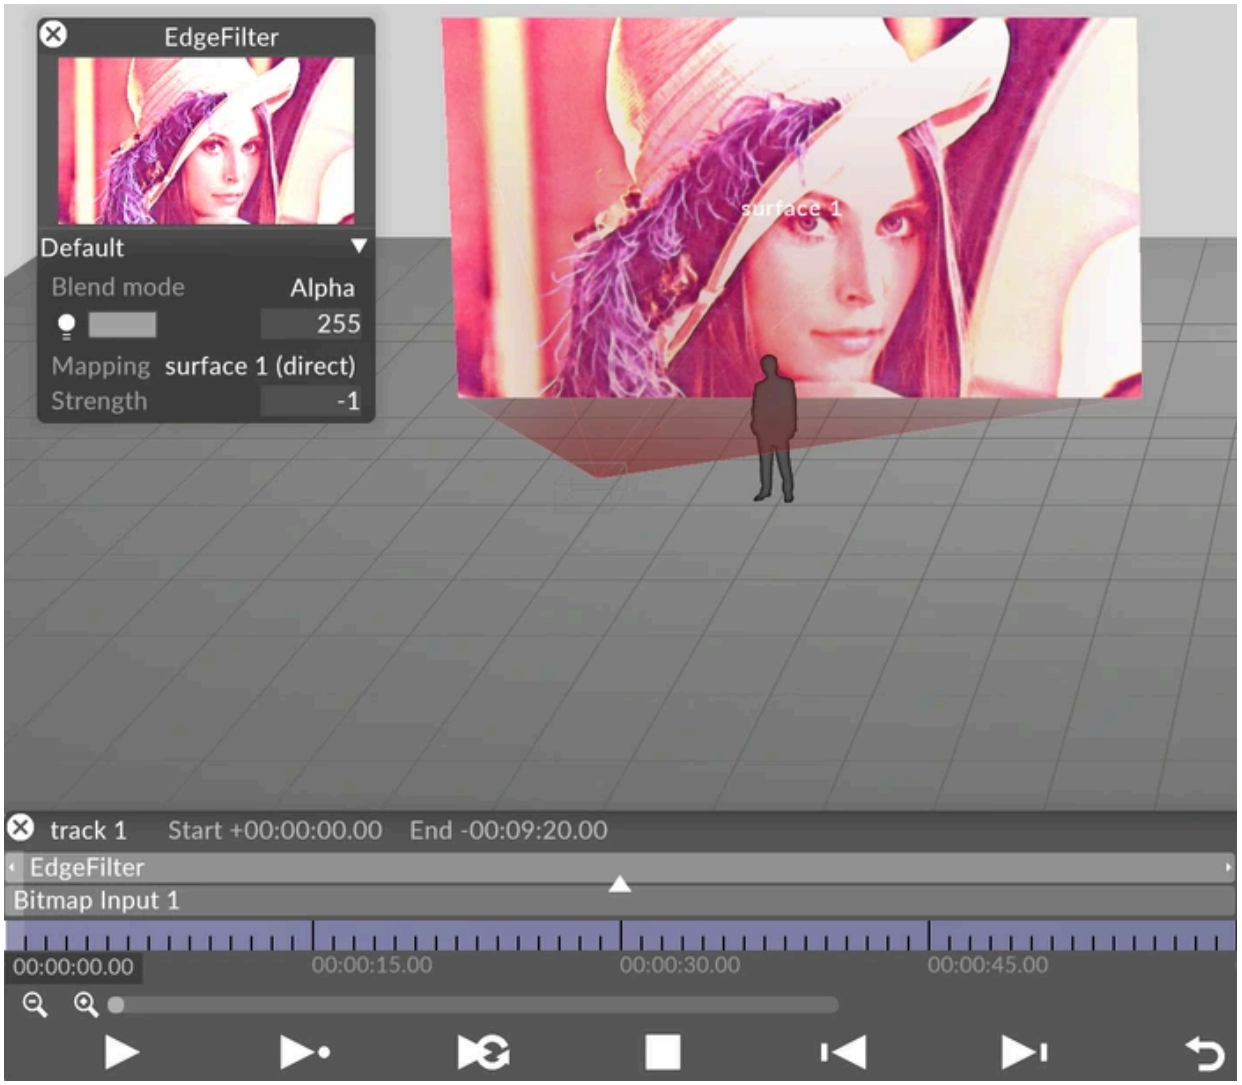
By adjusting the stength parameter you can change how the layer affects the image. Setting the stength to 0 will have no effect. Setting the strength to 1 will highlight the edges and exclude the rest of the image. Setting the strength to -1 will exclude the edges and highlight the rest of the image.



layer set to 0.



layer set to 1.



layer set to -1.

EdgeFilter layer properties

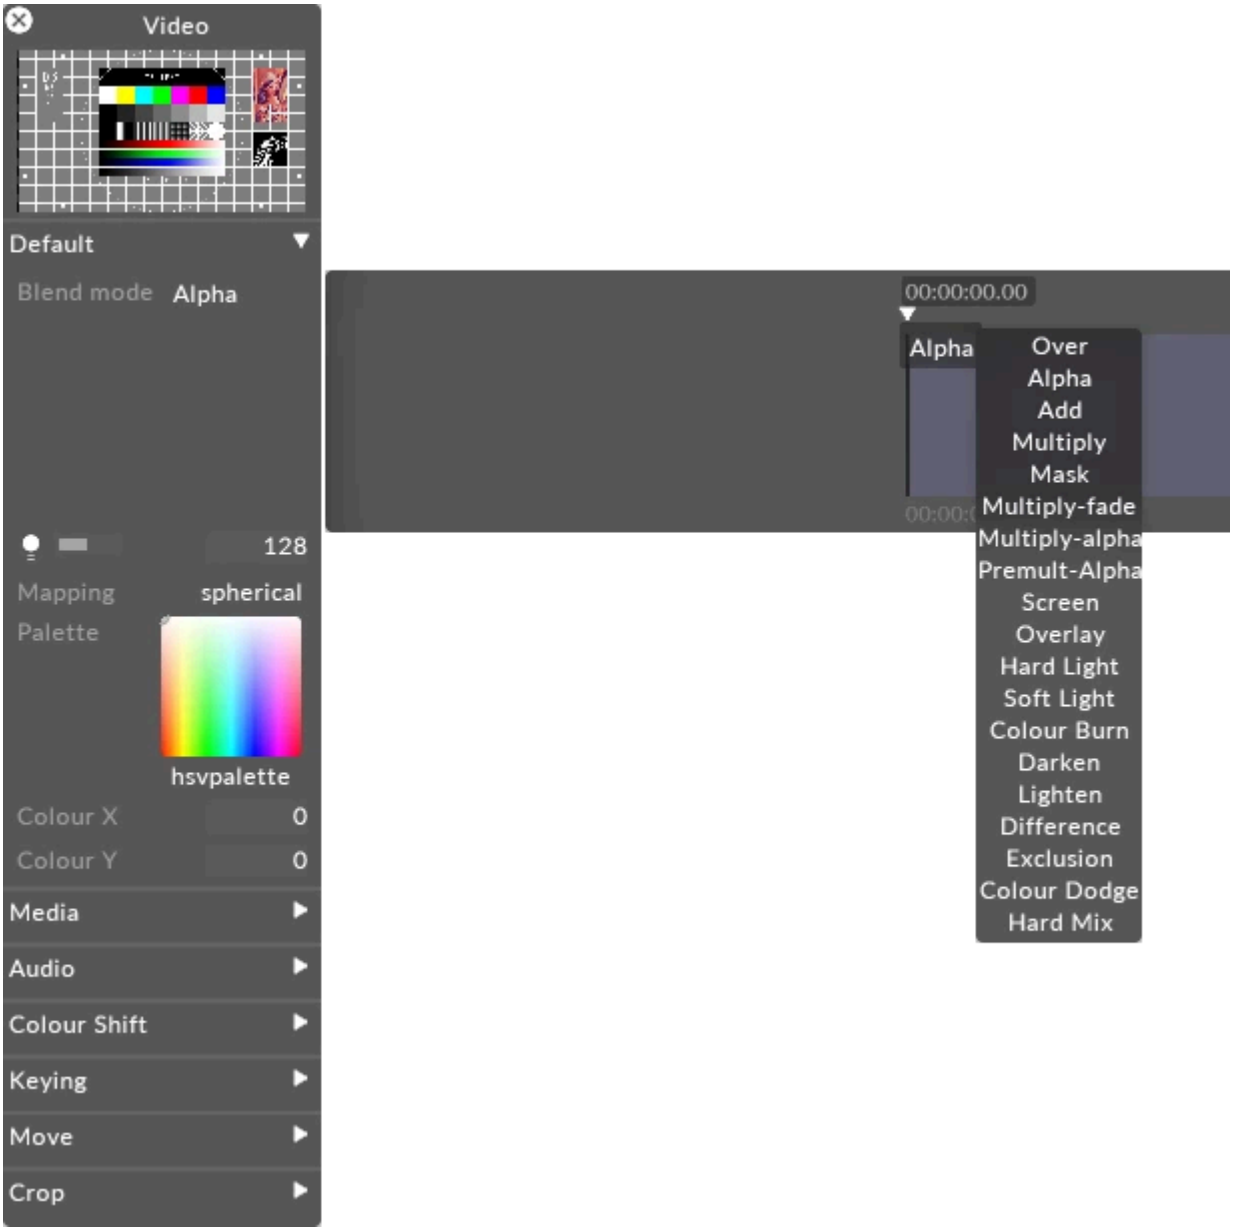
Strength

Strength controls how strong the edge filter is applied.

Common Layer Properties

Blend Mode

BlendMode controls how the output of the layer is composited with the layers below. Layers are rendered in a bottom-up order: layers at the top can modify the output of the layers below.



Changing brightness of a content layer in Designer is actually controlling the value of the alpha of the layer. Even when displaying a HAP video, the software will composite the layer with a controllable layer of alpha - one per layer.

There are two ways of expressing alpha in an image:

Straight alpha is an alpha channel which functions just like RGB. Alpha acts as a fourth channel of information per pixel which is as independent of the other three as R, G and B are of each other. For example, with straight alpha it is possible to have RGB = 255 (white) and alpha = 0 (fully transparent) on the same pixel. Internally generated content, such as gradient layer, are generated with straight alpha. This is the preferable style of alpha and considering the cleaner method of the two.

Premultiplied alpha takes the alpha and applies it to the values of the RGB channels per pixel. The more transparent something gets with premultiplied alpha, the closer it gets to black - as if the content is sitting on a black table. Premultiplied is the default output of Adobe Photoshop or AfterEffects. The result is our pixel at 255 RGB (full white) with 0 alpha would be calculated as a black pixel in the final image.

Here are explanations of what each individual blend mode will do.

Over

Makes a layer fully opaque. Premultiplies all alpha onto the RGB value of each pixel. Alpha = black, so adjusting the brightness of a layer in Over blend mode makes it darker.

Alpha

Default blend mode. It will apply alpha values as a transparency if the alpha is present. Brightness changes will make the layer more or less transparent.

Add

Adds the value of each RGB pixel together. Always creates a brighter result. Values clamp at 255.

Multiply

Reads the level of each subpixel as a level between 0.0 and 1.0, and multiplies source with blend. The result is always a darker image overall. For example: white x grey = 0.5. White turns transparent, black takes precedence. Alpha is applied in the same fashion as the Over Blend mode.

Mask

Applies a mask to the single layer **above** in the stack, irrespective of mapping. See **Mask blending** for more information.

Luma-Matte

This mode creates a Luma Matte by using a layer's **Rec. 709 luminance** to control the alpha channel of the layer **above**, irrespective of mapping.

To determine transparency, the luminance of each pixel is calculated using a weighted average of its red, green, and blue channels. The luminance value is then used as the alpha (opacity) value for the corresponding pixels in the upper layers.

As a result, white areas render the layer above fully opaque, black areas make them fully transparent, and grey areas create proportional semi-transparency. This is a specialized **Mask** blend mode; for more details on the underlying behaviour, see **Mask blending**.

Inv-Luma-Matte

The Inverse Luma Matte mask works the same as the **Luma Matte** mask but the transparency is inverted meaning white regions are transparent and black regions are opaque.

Multiply-Fade

The same as Multiply, but will make use of the alpha channel to calculate transparency in the source and blend layers. Since maximum transparency is premultiplied, alpha results in black. This will ignore black created through premultiplying.

Multiply-Alpha

Multiply with straight alpha. This mode assumes that the alpha has not been premultiplied onto the RGB values and will not apply a correction to the semi-transparent pixels.

Premultiply Alpha

Like how Multiply-fade will ignore the darkening caused by premultiplying, this blend mode will do the same with Alpha.

Colour Burn

Blend mode increases the contrast to darken the base colour while reflecting the blend colour. The darker the blend colour, the more intensely the colour will be applied in the base image. White as the blend colour produces no change. Using the colour burn blend mode can produce some harsh results at full opacity. The colour burn blend mode can be used to make tonal and colour adjustments to a layer.

Screen

This blend mode looks at each channels colour information and multiplies the inverse of the blend and base colous. The result is always a lighter colour. Screening with black leaves the colour unchanged. Screening with white produces white. The effect is similar to projecting multiple images on top of each other - where bright white is fully opaque, black is fully transparent and 50% grey is 50% transparent.

Overlay

Multiplies or screens the colours, depending on the base colour. Patterns or colours overlay the existing pixels while preserving the highlights and shadows of the base colour. The base colour is not replaced, but mixed with the blend colour to reflect the lightness or darkness of the original colour.

Hard Light

Multiplies or screens the colours, depending on the blend colour. The effects is similar to shining a harsh spotlight on the image. If the blend colour (light source/top layer) is lighter than

50% grey, the image is lightened as if it were screened. This is useful for adding highlights to an image. If the blend colour is darker than 50% grey, the image is darkened as if it were multiplied. This is useful for adding shadows to an image. Painting with pure black or white results in pure black or white.

Soft Light

Darkens or lightens the colours, depending on the blend colour. The effect is similar to shining a diffused spotlight on the image. If the blend colour (light source/top layer) is lighter than 50% grey, the image is lightened as it if were dodged. If the blend colour is darker than 50% grey, the image is darkened as if it were burned in. Painting with pure black or white produces a distinctly darker or lighter area, but does not result in pure black or white.

Darken

Looks as the colour information in each channel and selects the base or blend colour - whichever is darker - as the result colour. Pixels lighter than the blend colour are replaced and pixels darker than the blend colour do not change.

Lighten

Looks at the colour information in each channel and selects the base or blend colour - whichever is lighter - as the result colour. Pixels darker than the blend colour are replaced and pixels lighter than the blend colour do not change.

Difference

Looks at the colour information in each channel and subtracts either the blend colour from the base colour or the base colour from the blend colour depending on which has the greater brightness value. Blending with white inverts the base colour values and blending with black produces no change.

Exclusion

Creates an effects similar to but lower in contrast than the difference mode. Blending with white inverts the base colour values. Blending with black produces no change.

Colour Dodge

Looks at the colour information in each channel and brightens the base colour to reflect the blend colour by decreasing contrast between the two. Blending with black produces no change.

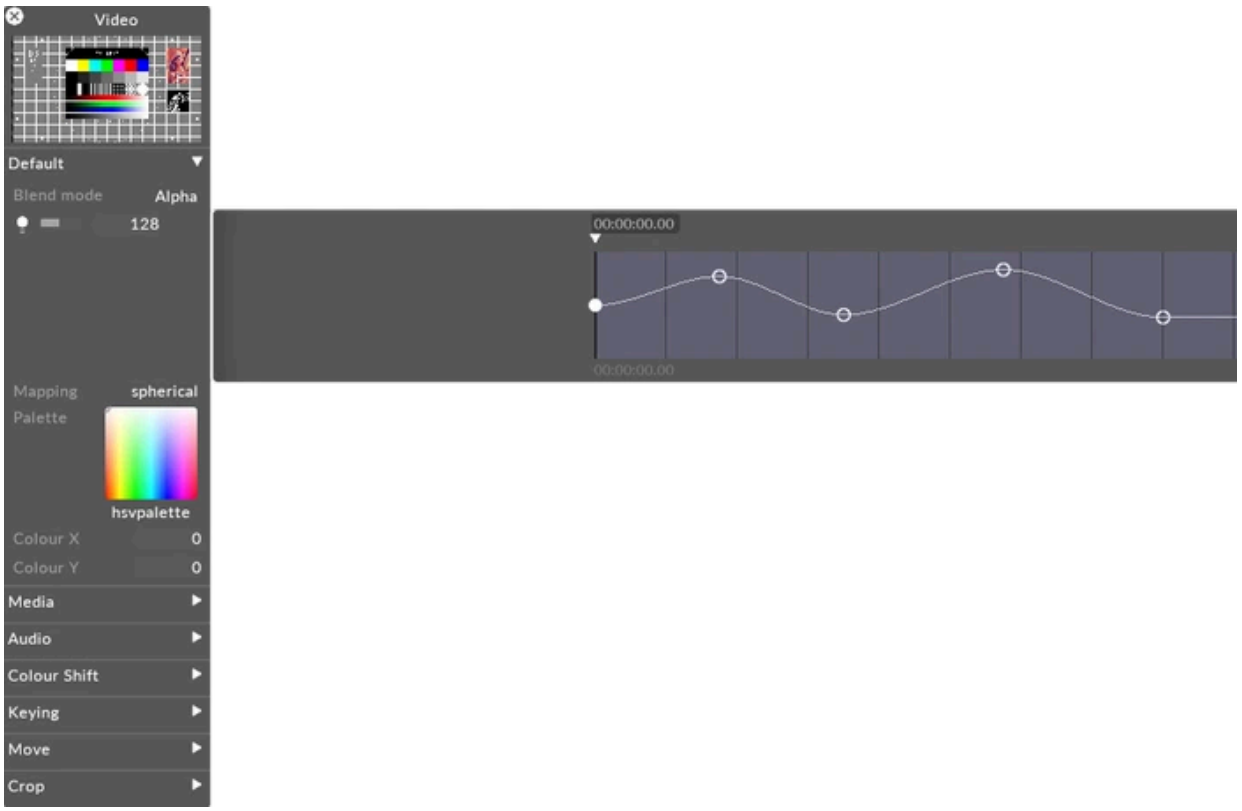
Hard Mix

Adds the RGB channels of the blend colour to the RGB values of the base colour. If the resulting sum for a channel is 255 or greater, it receives a value of 255; if it is less than 255 it

receives a value of 0. Therefore all blended pixels have RGB channels of either 0 or 255. This changes all pixels to primary additive colours (RGB), white or black.

Brightness

This property (which appears as a light bulb icon) controls the brightness of the layer output.



If the layers blend mode is set to Alpha, then reducing the brightness to 0 also reduces the opacity of the layer to 0. This can be useful when you want to dissolve from one layer to the next. In that case, you can place the new layer above the old layer and increase its brightness level.

> **Note**
>
> Layers that are patched to Sockpuppet (DMX, OSC or HTTP) are made Dormant when their brightness is set to 0. This means they will not do any rendering or consume any resources until their brightness is changed to > 0. You can find more information about this here: **Sequencing with Sockpuppet**. Layers without a sockpuppet patch do not behave in this way.

Mapping

The mapping property controls how the layer output is mapped onto the screen(s) in the Stage level.

For information on mapping, including how to use the different mapping types offered by Designer, please see the chapter **Content Mapping**

Effect Layers Overview

Effect Layers can be used to apply visual effects to other layer types such as Video layers.

Types of Effect layers

There are several types of Effect layers available within :

- Blur
- ChannelRouter
- ColourAdjust
- Compose
- EdgeFilter
- Fade
- FilmicGrain
- Kaleidoscope
- Lut
- MotionBlur
- Noise
- OCIO
- PixelMap
- Pixelate
- Scroll
- SpinBitmap
- Trigger
- UVLookup
- VideoTransition

Common Layer Properties

The symbols in the tables below indicate whether a specific layer shares a common property (✔) or not (✘).

Effect Layers Part (i) A - D

	Blur	CDL	Channel Router	Colour Adjust	Compose
Blend modes	✔	✔	✔	✔	✔

	Blur	CDL	Channel Router	Colour Adjust	Compose
Brightness	✓	✓	✓	✓	✓
Mapping	✓	✓	✓	✓	✓

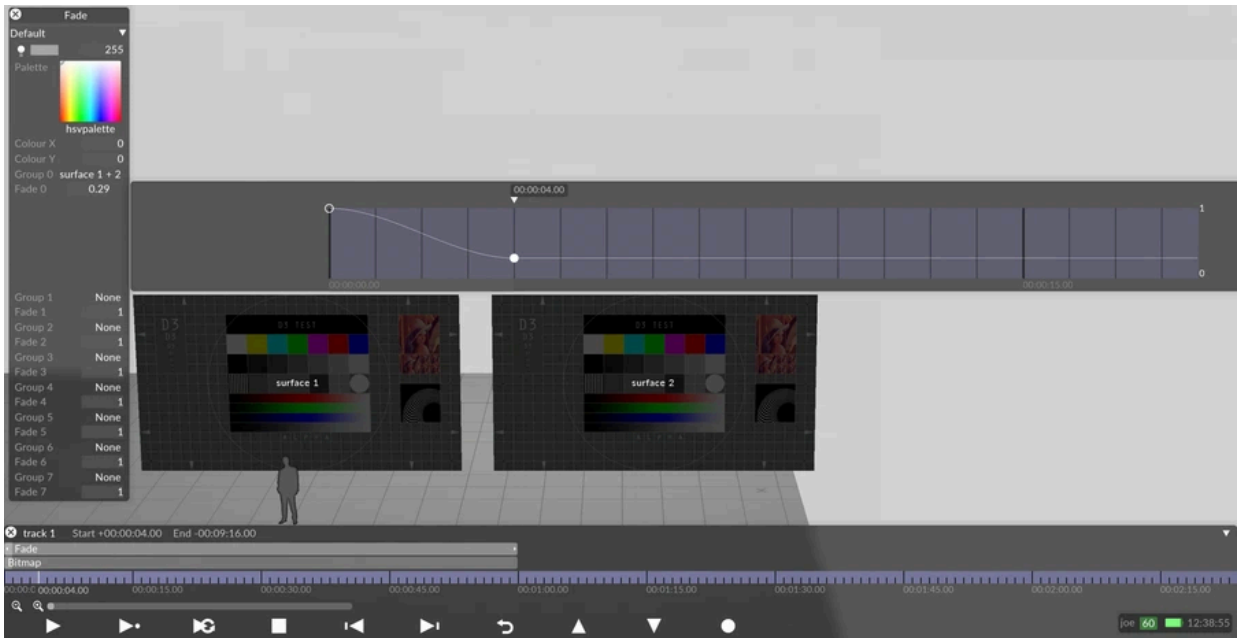
Fade Layer

The Fade layer allows control of the brightness of all screens within a mapping.



Fade Layer Properties

Group 0..7

The mapping to use as the group.

Fade 0..7

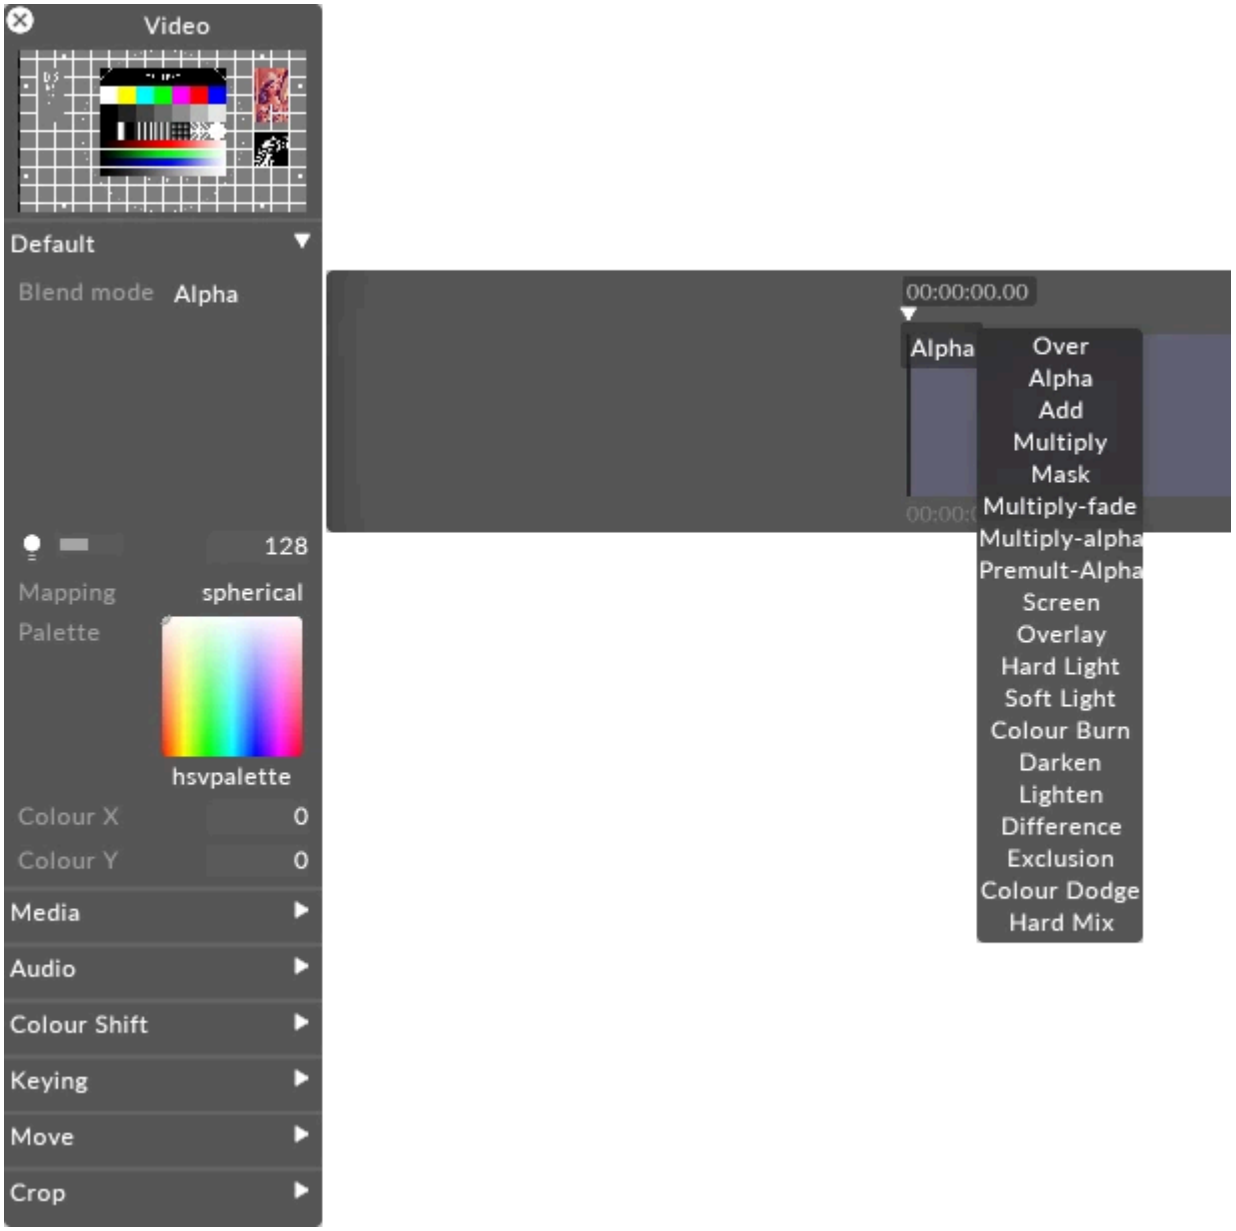
The brightness of all layers outputting to the mapping. 0 is black, 1 is maximum brightness. The example above shows the Fade layer being used to fade the brightness of two screens.

Colour x, colour y, and fade are applied to all screens within all groups.

Common Layer Properties

Blend Mode

BlendMode controls how the output of the layer is composited with the layers below. Layers are rendered in a bottom-up order: layers at the top can modify the output of the layers below.



Changing brightness of a content layer in Designer is actually controlling the value of the alpha of the layer. Even when displaying a HAP video, the software will composite the layer with a controllable layer of alpha - one per layer.

There are two ways of expressing alpha in an image:

Straight alpha is an alpha channel which functions just like RGB. Alpha acts as a fourth channel of information per pixel which is as independent of the other three as R, G and B are of each other. For example, with straight alpha it is possible to have RGB = 255 (white) and alpha = 0 (fully transparent) on the same pixel. Internally generated content, such as gradient layer, are generated with straight alpha. This is the preferable style of alpha and considering the cleaner method of the two.

Premultiplied alpha takes the alpha and applies it to the values of the RGB channels per pixel. The more transparent something gets with premultiplied alpha, the closer it gets to black - as if the content is sitting on a black table. Premultiplied is the default output of Adobe Photoshop or AfterEffects. The result is our pixel at 255 RGB (full white) with 0 alpha would be calculated as a black pixel in the final image.

Here are explanations of what each individual blend mode will do.

Over

Makes a layer fully opaque. Premultiplies all alpha onto the RGB value of each pixel. Alpha = black, so adjusting the brightness of a layer in Over blend mode makes it darker.

Alpha

Default blend mode. It will apply alpha values as a transparency if the alpha is present. Brightness changes will make the layer more or less transparent.

Add

Adds the value of each RGB pixel together. Always creates a brighter result. Values clamp at 255.

Multiply

Reads the level of each subpixel as a level between 0.0 and 1.0, and multiplies source with blend. The result is always a darker image overall. For example: white x grey = 0.5. White turns transparent, black takes precedence. Alpha is applied in the same fashion as the Over Blend mode.

Mask

Applies a mask to the single layer **above** in the stack, irrespective of mapping. See **Mask blending** for more information.

Luma-Matte

This mode creates a Luma Matte by using a layer's **Rec. 709 luminance** to control the alpha channel of the layer **above**, irrespective of mapping.

To determine transparency, the luminance of each pixel is calculated using a weighted average of its red, green, and blue channels. The luminance value is then used as the alpha (opacity) value for the corresponding pixels in the upper layers.

As a result, white areas render the layer above fully opaque, black areas make them fully transparent, and grey areas create proportional semi-transparency. This is a specialized **Mask** blend mode; for more details on the underlying behaviour, see **Mask blending**.

Inv-Luma-Matte

The Inverse Luma Matte mask works the same as the **Luma Matte** mask but the transparency is inverted meaning white regions are transparent and black regions are opaque.

Multiply-Fade

The same as Multiply, but will make use of the alpha channel to calculate transparency in the source and blend layers. Since maximum transparency is premultiplied, alpha results in black. This will ignore black created through premultiplying.

Multiply-Alpha

Multiply with straight alpha. This mode assumes that the alpha has not been premultiplied onto the RGB values and will not apply a correction to the semi-transparent pixels.

Premultiply Alpha

Like how Multiply-fade will ignore the darkening caused by premultiplying, this blend mode will do the same with Alpha.

Colour Burn

Blend mode increases the contrast to darken the base colour while reflecting the blend colour. The darker the blend colour, the more intensely the colour will be applied in the base image. White as the blend colour produces no change. Using the colour burn blend mode can produce some harsh results at full opacity. The colour burn blend mode can be used to make tonal and colour adjustments to a layer.

Screen

This blend mode looks at each channels colour information and multiplies the inverse of the blend and base colous. The result is always a lighter colour. Screening with black leaves the colour unchanged. Screening with white produces white. The effect is similar to projecting multiple images on top of each other - where bright white is fully opaque, black is fully transparent and 50% grey is 50% transparent.

Overlay

Multiplies or screens the colours, depending on the base colour. Patterns or colours overlay the existing pixels while preserving the highlights and shadows of the base colour. The base colour is not replaced, but mixed with the blend colour to reflect the lightness or darkness of the original colour.

Hard Light

Multiplies or screens the colours, depending on the blend colour. The effects is similar to shining a harsh spotlight on the image. If the blend colour (light source/top layer) is lighter than

50% grey, the image is lightened as if it were screened. This is useful for adding highlights to an image. If the blend colour is darker than 50% grey, the image is darkened as if it were multiplied. This is useful for adding shadows to an image. Painting with pure black or white results in pure black or white.

Soft Light

Darkens or lightens the colours, depending on the blend colour. The effect is similar to shining a diffused spotlight on the image. If the blend colour (light source/top layer) is lighter than 50% grey, the image is lightened as it if were dodged. If the blend colour is darker than 50% grey, the image is darkened as if it were burned in. Painting with pure black or white produces a distinctly darker or lighter area, but does not result in pure black or white.

Darken

Looks as the colour information in each channel and selects the base or blend colour - whichever is darker - as the result colour. Pixels lighter than the blend colour are replaced and pixels darker than the blend colour do not change.

Lighten

Looks at the colour information in each channel and selects the base or blend colour - whichever is lighter - as the result colour. Pixels darker than the blend colour are replaced and pixels lighter than the blend colour do not change.

Difference

Looks at the colour information in each channel and subtracts either the blend colour from the base colour or the base colour from the blend colour depending on which has the greater brightness value. Blending with white inverts the base colour values and blending with black produces no change.

Exclusion

Creates an effects similar to but lower in contrast than the difference mode. Blending with white inverts the base colour values. Blending with black produces no change.

Colour Dodge

Looks at the colour information in each channel and brightens the base colour to reflect the blend colour by decreasing contrast between the two. Blending with black produces no change.

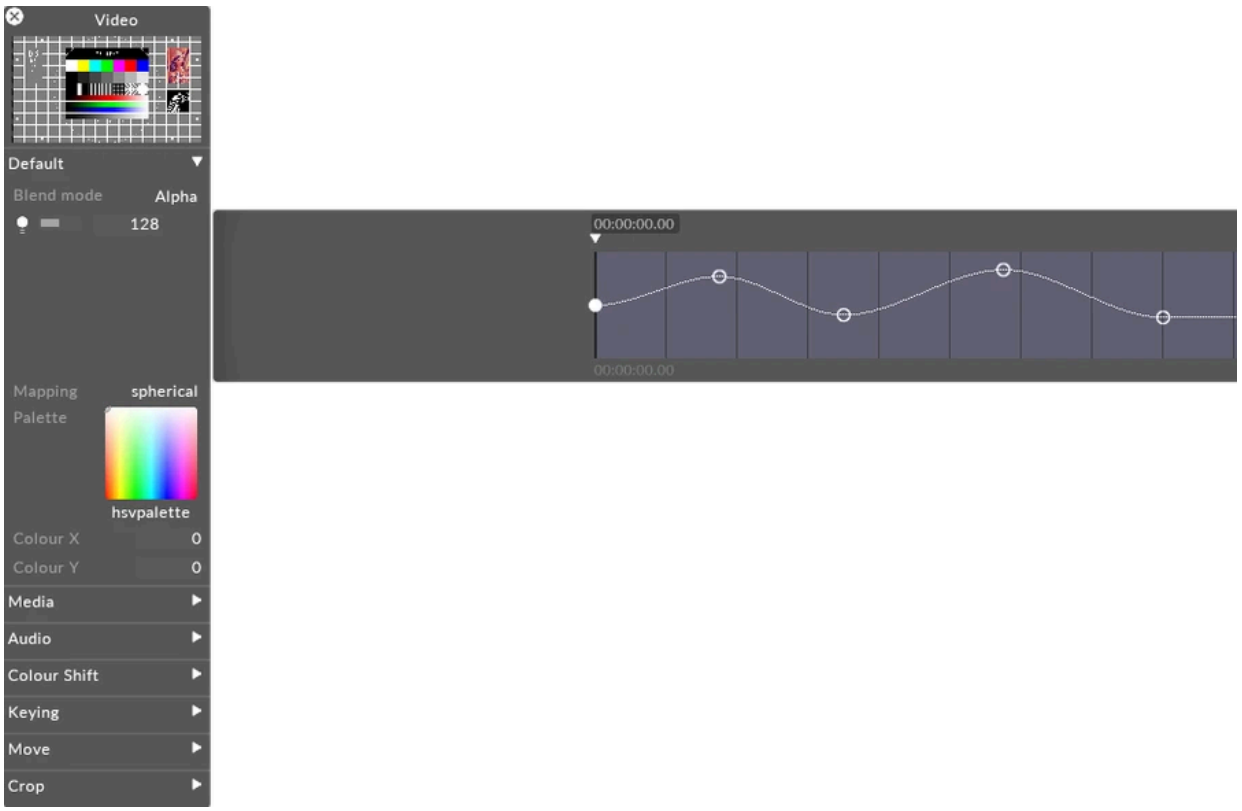
Hard Mix

Adds the RGB channels of the blend colour to the RGB values of the base colour. If the resulting sum for a channel is 255 or greater, it receives a value of 255; if it is less than 255 it

receives a value of 0. Therefore all blended pixels have RGB channels of either 0 or 255. This changes all pixels to primary additive colours (RGB), white or black.

Brightness

This property (which appears as a light bulb icon) controls the brightness of the layer output.



If the layers blend mode is set to Alpha, then reducing the brightness to 0 also reduces the opacity of the layer to 0. This can be useful when you want to dissolve from one layer to the next. In that case, you can place the new layer above the old layer and increase its brightness level.

> **Note**
>
> Layers that are patched to Sockpuppet (DMX, OSC or HTTP) are made Dormant when their brightness is set to 0. This means they will not do any rendering or consume any resources until their brightness is changed to > 0. You can find more information about this here: **Sequencing with Sockpuppet**. Layers without a sockpuppet patch do not behave in this way.

Mapping

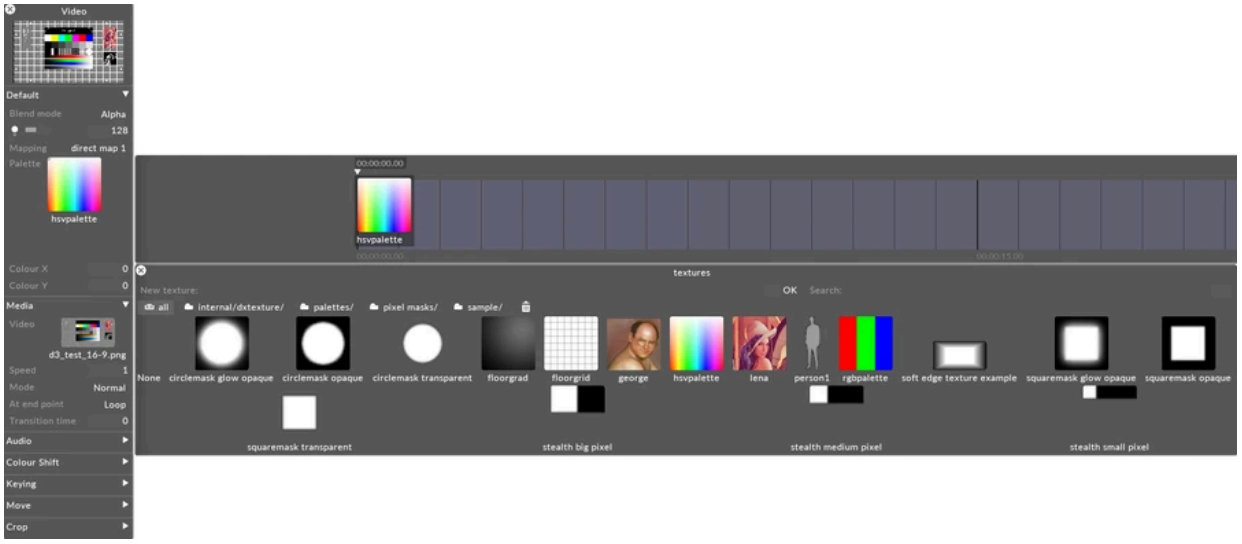
The mapping property controls how the layer output is mapped onto the screen(s) in the Stage level.

For information on mapping, including how to use the different mapping types offered by Designer, please see the chapter **Content Mapping**

Palette

This points to the still image file that defines the bitmap from which the tint colour is taken. The default palette (HSVPAL) consists of the complete range of hues and saturations. Selecting this property will open the Texture object library, which shows all of the still image files saved on your local hard-drive in the **DxTexture** older.

To control the location within the current palette bitmap, and thus control the colour, you have to edit the **xCol** and **yCol** values (see the section for xCol, yCol).



To change the current palette bitmap:

1. Left-click **palette** to open the Texture object library.
2. Left-click the still image file you want to use for the palette bitmap.

If you want to use a palette bitmap other than the standard still images provided in Designer, you will need to use a custom still image file.

See the **Placing media files** for a project sub-chapter to understand where to place a custom still image file and how to access it in Designer. Also save the file to a **supported file format**.

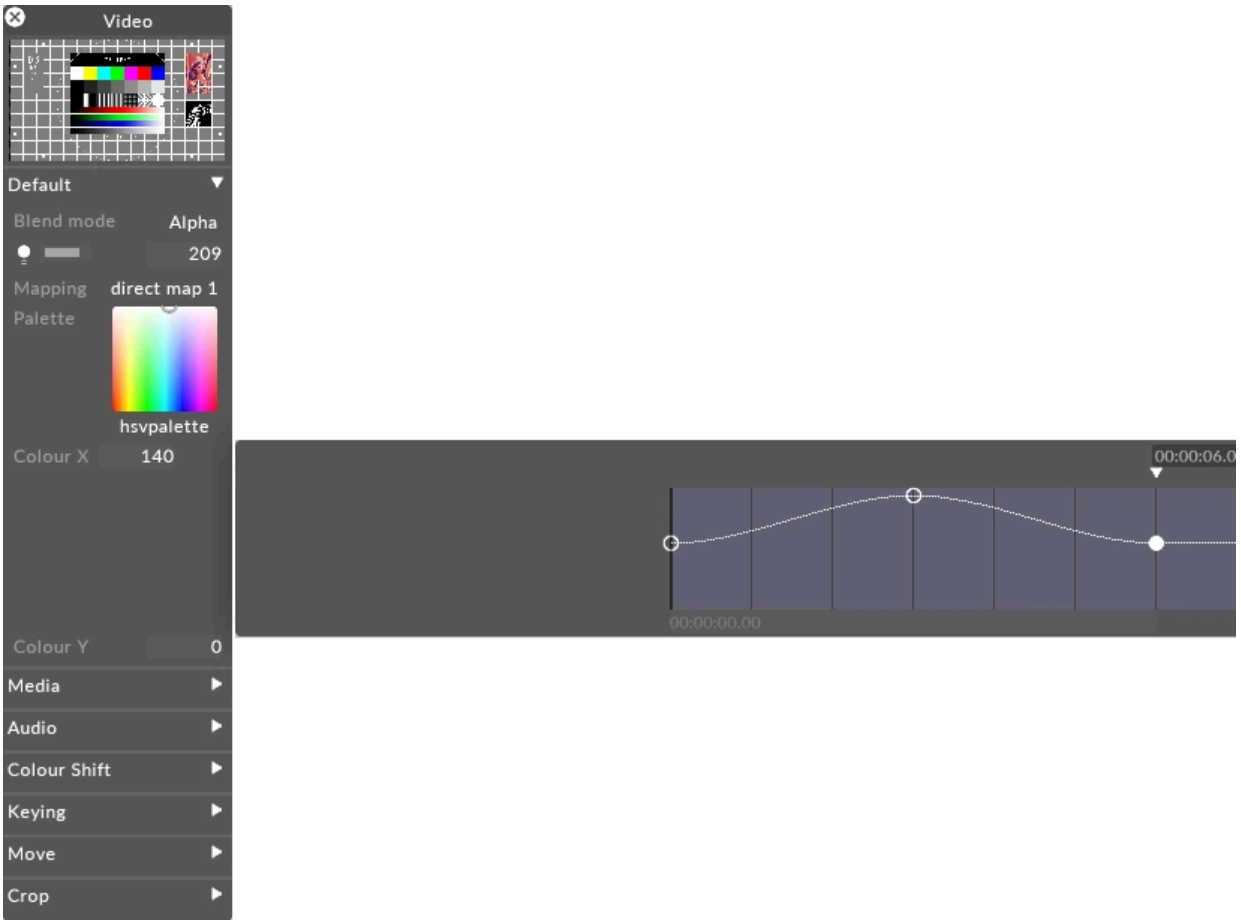
Xcol, YCol

These properties control the coordinates within the current palette bitmap where the output colour is sampled from. The default value is 0,0 which points at the color white (if you are using the HSVPAL palette). Multiplying white with the colors of the chosen content simply generates the original content colors. **Colour X** controls the horizontal position, where 0 is the leftmost

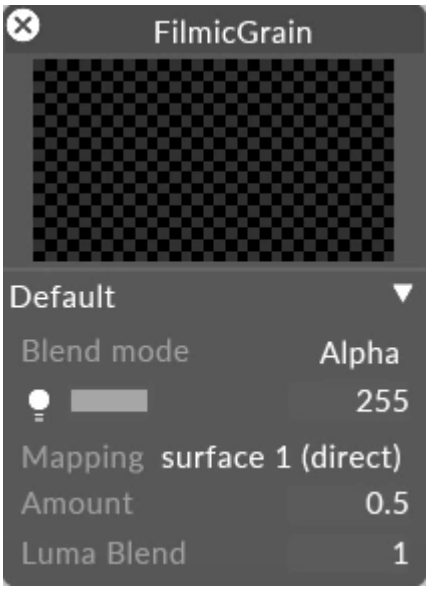
edge and 255 is the rightmost edge. **Colour Y** controls the vertical position, where 0 is the top edge and 255 is the bottom edge.

For example, to saturate the video clip red, change the **Colour Y** value to 255 and use 0 for the **Colour X** value. These coordinates refer to the color red in the palette which is being multiplied with the colors of the existing content.

When you are using the default palette HSVPAL , Colour Y controls saturation, and Colour X controls hue.



FilmicGrain Layer



The FilmicGrain layer is designed to add animated, film grain style noise to a piece of content.

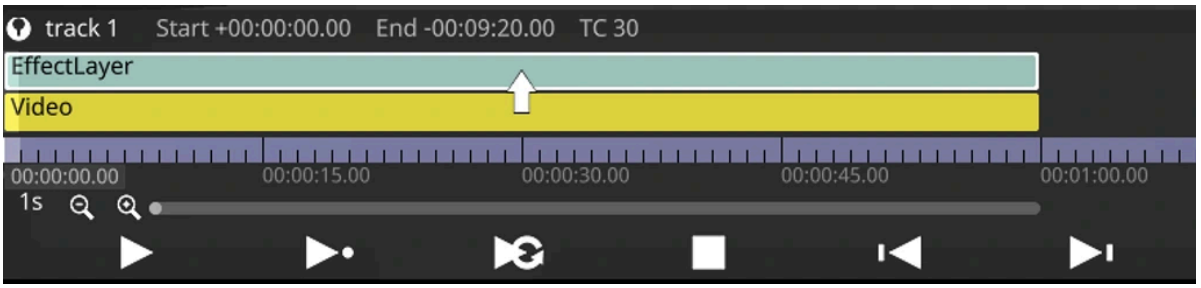
Workflow

Effect layers receive their source from other layer types - either content or generative - through arrows. An arrow connects a source layer to a destination layer; the source layer is said to be “piped in” to the destination Effect layer. For more information on arrows, see the **compositing layers** topic.

To draw an arrow between two layers, hold down **ALT** and left-click & drag from the source layer to the destination layer.

1. Add an Effect layer to your track. For more information about adding layers, see **creating layers**.

2. Draw an arrow from your content layer to the Effect layer so the compositing order looks something like the following image.



A Video layer piped into an Effect layer on the timeline.

3. Adjust the Effect layer properties to achieve the desired result.

FilmicGrain Layer Properties

Amount

This property controls the amount grain added to the original content.

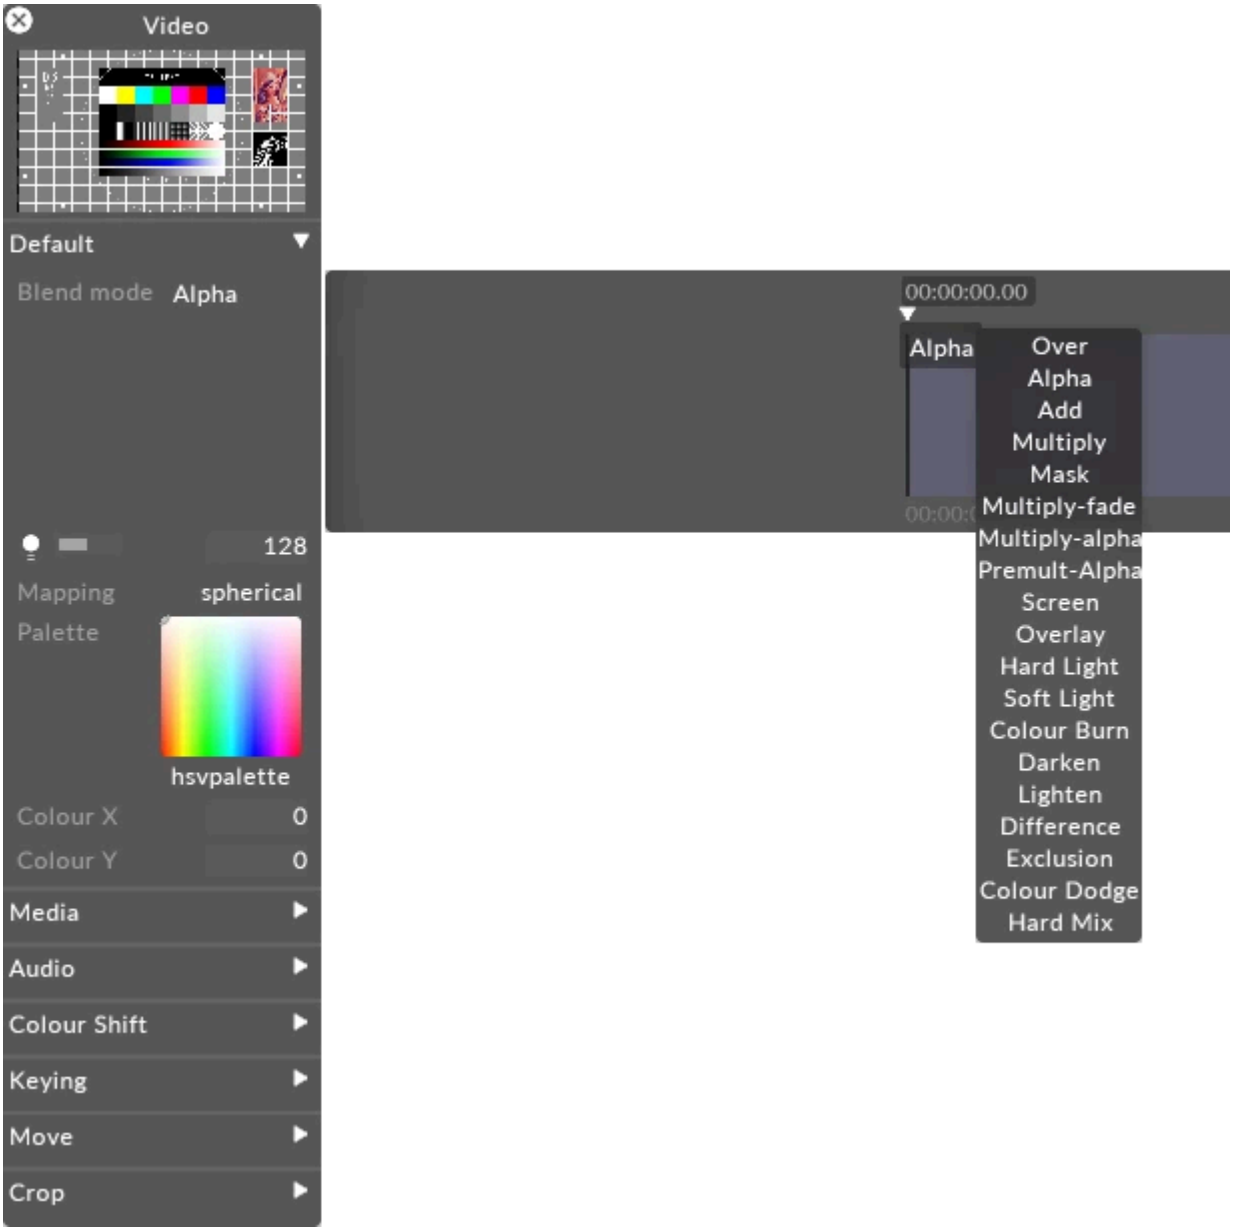
Luma blend

This property controls the Luma blend. The Luma controls whether the grain is applied to the mid tones only and not applied in bright highlights. In other words, if it is white, there will be no grain whereas if it is very dark content then it will have lots of grain.

Common Layer Properties

Blend Mode

BlendMode controls how the output of the layer is composited with the layers below. Layers are rendered in a bottom-up order: layers at the top can modify the output of the layers below.



Changing brightness of a content layer in Designer is actually controlling the value of the alpha of the layer. Even when displaying a HAP video, the software will composite the layer with a controllable layer of alpha - one per layer.

There are two ways of expressing alpha in an image:

Straight alpha is an alpha channel which functions just like RGB. Alpha acts as a fourth channel of information per pixel which is as independent of the other three as R, G and B are of each other. For example, with straight alpha it is possible to have RGB = 255 (white) and alpha = 0 (fully transparent) on the same pixel. Internally generated content, such as gradient layer, are generated with straight alpha. This is the preferable style of alpha and considering the cleaner method of the two.

Premultiplied alpha takes the alpha and applies it to the values of the RGB channels per pixel. The more transparent something gets with premultiplied alpha, the closer it gets to black - as if the content is sitting on a black table. Premultiplied is the default output of Adobe Photoshop or AfterEffects. The result is our pixel at 255 RGB (full white) with 0 alpha would be calculated as a black pixel in the final image.

Here are explanations of what each individual blend mode will do.

Over

Makes a layer fully opaque. Premultiplies all alpha onto the RGB value of each pixel. Alpha = black, so adjusting the brightness of a layer in Over blend mode makes it darker.

Alpha

Default blend mode. It will apply alpha values as a transparency if the alpha is present. Brightness changes will make the layer more or less transparent.

Add

Adds the value of each RGB pixel together. Always creates a brighter result. Values clamp at 255.

Multiply

Reads the level of each subpixel as a level between 0.0 and 1.0, and multiplies source with blend. The result is always a darker image overall. For example: white x grey = 0.5. White turns transparent, black takes precedence. Alpha is applied in the same fashion as the Over Blend mode.

Mask

Applies a mask to the single layer **above** in the stack, irrespective of mapping. See **Mask blending** for more information.

Luma-Matte

This mode creates a Luma Matte by using a layer's **Rec. 709 luminance** to control the alpha channel of the layer **above**, irrespective of mapping.

To determine transparency, the luminance of each pixel is calculated using a weighted average of its red, green, and blue channels. The luminance value is then used as the alpha (opacity) value for the corresponding pixels in the upper layers.

As a result, white areas render the layer above fully opaque, black areas make them fully transparent, and grey areas create proportional semi-transparency. This is a specialized **Mask** blend mode; for more details on the underlying behaviour, see **Mask blending**.

Inv-Luma-Matte

The Inverse Luma Matte mask works the same as the **Luma Matte** mask but the transparency is inverted meaning white regions are transparent and black regions are opaque.

Multiply-Fade

The same as Multiply, but will make use of the alpha channel to calculate transparency in the source and blend layers. Since maximum transparency is premultiplied, alpha results in black. This will ignore black created through premultiplying.

Multiply-Alpha

Multiply with straight alpha. This mode assumes that the alpha has not been premultiplied onto the RGB values and will not apply a correction to the semi-transparent pixels.

Premultiply Alpha

Like how Multiply-fade will ignore the darkening caused by premultiplying, this blend mode will do the same with Alpha.

Colour Burn

Blend mode increases the contrast to darken the base colour while reflecting the blend colour. The darker the blend colour, the more intensely the colour will be applied in the base image. White as the blend colour produces no change. Using the colour burn blend mode can produce some harsh results at full opacity. The colour burn blend mode can be used to make tonal and colour adjustments to a layer.

Screen

This blend mode looks at each channels colour information and multiplies the inverse of the blend and base colous. The result is always a lighter colour. Screening with black leaves the colour unchanged. Screening with white produces white. The effect is similar to projecting multiple images on top of each other - where bright white is fully opaque, black is fully transparent and 50% grey is 50% transparent.

Overlay

Multiplies or screens the colours, depending on the base colour. Patterns or colours overlay the existing pixels while preserving the highlights and shadows of the base colour. The base colour is not replaced, but mixed with the blend colour to reflect the lightness or darkness of the original colour.

Hard Light

Multiplies or screens the colours, depending on the blend colour. The effects is similar to shining a harsh spotlight on the image. If the blend colour (light source/top layer) is lighter than

50% grey, the image is lightened as if it were screened. This is useful for adding highlights to an image. If the blend colour is darker than 50% grey, the image is darkened as if it were multiplied. This is useful for adding shadows to an image. Painting with pure black or white results in pure black or white.

Soft Light

Darkens or lightens the colours, depending on the blend colour. The effect is similar to shining a diffused spotlight on the image. If the blend colour (light source/top layer) is lighter than 50% grey, the image is lightened as it if were dodged. If the blend colour is darker than 50% grey, the image is darkened as if it were burned in. Painting with pure black or white produces a distinctly darker or lighter area, but does not result in pure black or white.

Darken

Looks as the colour information in each channel and selects the base or blend colour - whichever is darker - as the result colour. Pixels lighter than the blend colour are replaced and pixels darker than the blend colour do not change.

Lighten

Looks at the colour information in each channel and selects the base or blend colour - whichever is lighter - as the result colour. Pixels darker than the blend colour are replaced and pixels lighter than the blend colour do not change.

Difference

Looks at the colour information in each channel and subtracts either the blend colour from the base colour or the base colour from the blend colour depending on which has the greater brightness value. Blending with white inverts the base colour values and blending with black produces no change.

Exclusion

Creates an effects similar to but lower in contrast than the difference mode. Blending with white inverts the base colour values. Blending with black produces no change.

Colour Dodge

Looks at the colour information in each channel and brightens the base colour to reflect the blend colour by decreasing contrast between the two. Blending with black produces no change.

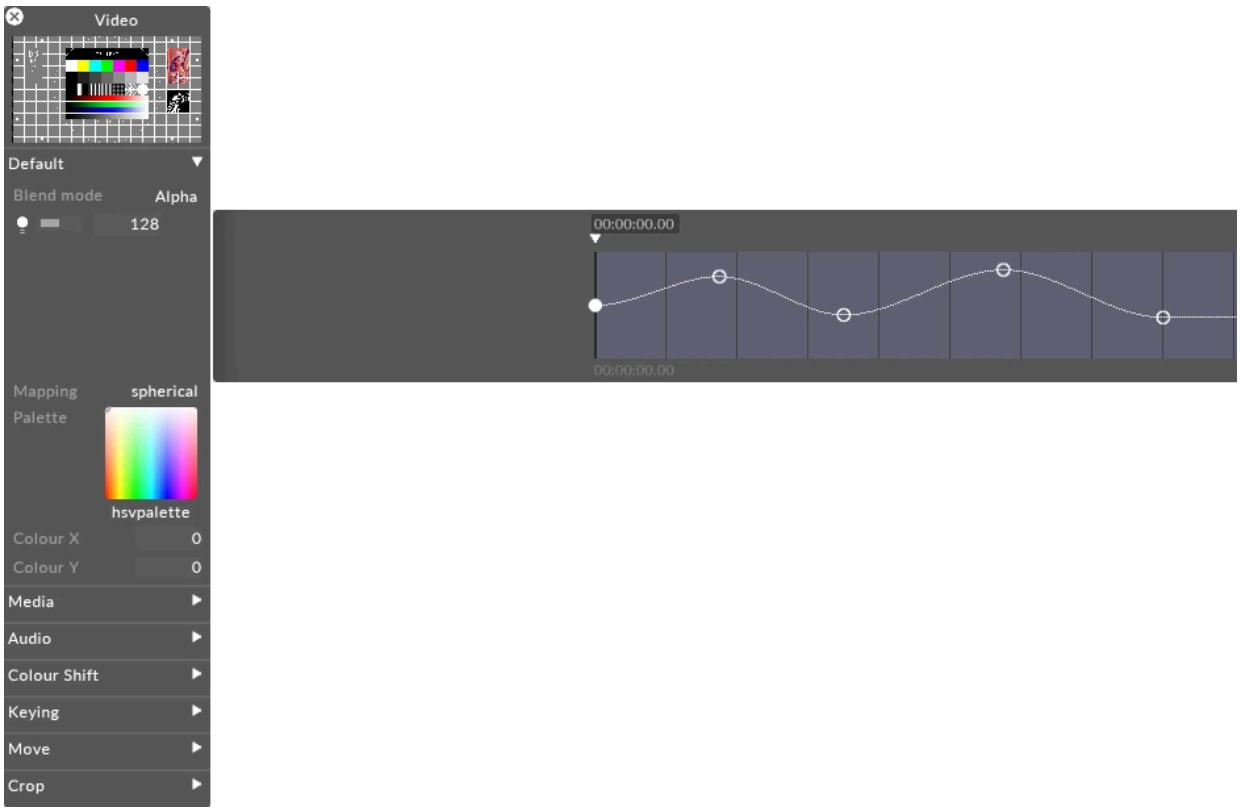
Hard Mix

Adds the RGB channels of the blend colour to the RGB values of the base colour. If the resulting sum for a channel is 255 or greater, it receives a value of 255; if it is less than 255 it

receives a value of 0. Therefore all blended pixels have RGB channels of either 0 or 255. This changes all pixels to primary additive colours (RGB), white or black.

Brightness

This property (which appears as a light bulb icon) controls the brightness of the layer output.



If the layers blend mode is set to Alpha, then reducing the brightness to 0 also reduces the opacity of the layer to 0. This can be useful when you want to dissolve from one layer to the next. In that case, you can place the new layer above the old layer and increase its brightness level.

> **Note**
>
> Layers that are patched to Sockpuppet (DMX, OSC or HTTP) are made Dormant when their brightness is set to 0. This means they will not do any rendering or consume any resources until their brightness is changed to > 0. You can find more information about this here: **Sequencing with Sockpuppet**. Layers without a sockpuppet patch do not behave in this way.

Mapping

The mapping property controls how the layer output is mapped onto the screen(s) in the Stage level.

For information on mapping, including how to use the different mapping types offered by Designer, please see the chapter **Content Mapping**

Kaleidoscope Layer

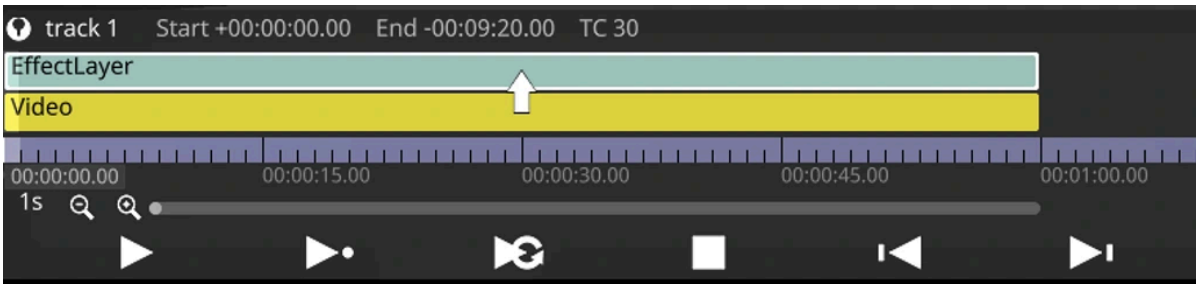
The effect layer can be used to create style patterns when it is composed with another content layer.

Workflow

Effect layers receive their source from other layer types - either content or generative - through arrows. An arrow connects a source layer to a destination layer; the source layer is said to be “piped in” to the destination Effect layer. For more information on arrows, see the **compositing layers** topic.

To draw an arrow between two layers, hold down **ALT** and left-click & drag from the source layer to the destination layer.

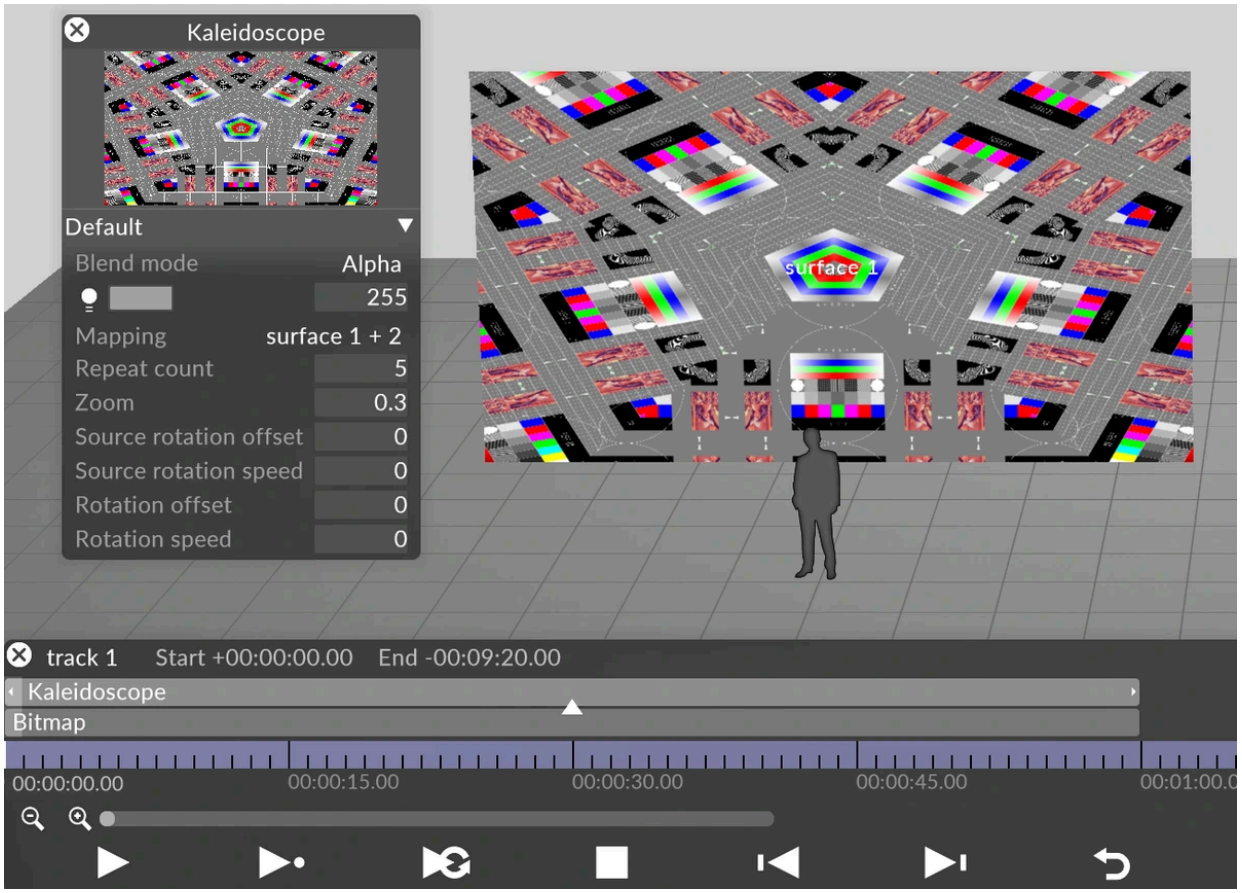
1. Add an Effect layer to your track. For more information about adding layers, see **creating layers**.
2. Draw an arrow from your content layer to the Effect layer so the compositing order looks something like the following image.



A Video layer piped into an Effect layer on the timeline.

3. Adjust the Effect layer properties to achieve the desired result.

Kaleidoscope Layer Properties



Repeat count

The number of times the content is repeated in the pattern

Zoom

Increase value to zoom in on the content

Source rotation offset

Increase value to rotate the content offset

Source rotation speed

The speed of the rotation of the content

Rotation offset

The rotation offset for the kaleidoscope effect

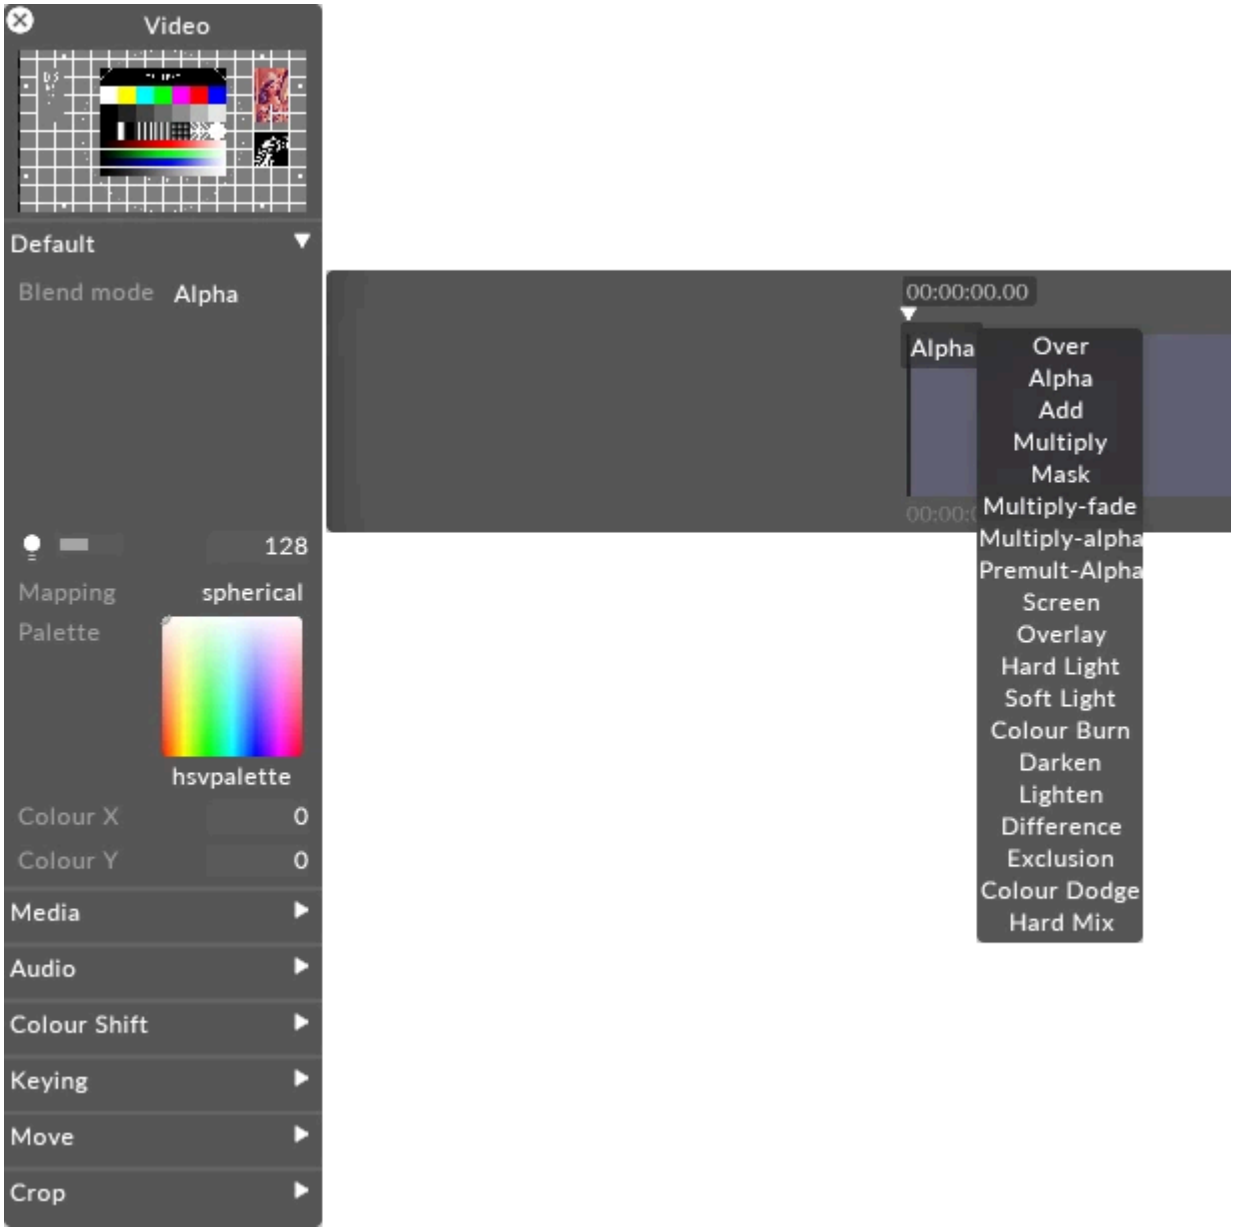
Rotation speed

The rotation speed of the kaleidoscope effect

Common Layer Properties

Blend Mode

BlendMode controls how the output of the layer is composited with the layers below. Layers are rendered in a bottom-up order: layers at the top can modify the output of the layers below.



Changing brightness of a content layer in Designer is actually controlling the value of the alpha of the layer. Even when displaying a HAP video, the software will composite the layer with a

controllable layer of alpha - one per layer.

There are two ways of expressing alpha in an image:

Straight alpha is an alpha channel which functions just like RGB. Alpha acts as a fourth channel of information per pixel which is as independent of the other three as R, G and B are of each other. For example, with straight alpha it is possible to have RGB = 255 (white) and alpha = 0 (fully transparent) on the same pixel. Internally generated content, such as gradient layer, are generated with straight alpha. This is the preferable style of alpha and considering the cleaner method of the two.

Premultiplied alpha takes the alpha and applies it to the values of the RGB channels per pixel. The more transparent something gets with premultiplied alpha, the closer it gets to black - as if the content is sitting on a black table. Premultiplied is the default output of Adobe Photoshop or AfterEffects. The result is our pixel at 255 RGB (full white) with 0 alpha would be calculated as a black pixel in the final image.

Here are explanations of what each individual blend mode will do.

Over

Makes a layer fully opaque. Premultiplies all alpha onto the RGB value of each pixel. Alpha = black, so adjusting the brightness of a layer in Over blend mode makes it darker.

Alpha

Default blend mode. It will apply alpha values as a transparency if the alpha is present. Brightness changes will make the layer more or less transparent.

Add

Adds the value of each RGB pixel together. Always creates a brighter result. Values clamp at 255.

Multiply

Reads the level of each subpixel as a level between 0.0 and 1.0, and multiplies source with blend. The result is always a darker image overall. For example: white x grey = 0.5. White turns transparent, black takes precedence. Alpha is applied in the same fashion as the Over Blend mode.

Mask

Applies a mask to the single layer **above** in the stack, irrespective of mapping. See **Mask blending** for more information.

Luma-Matte

This mode creates a Luma Matte by using a layer's **Rec. 709 luminance** to control the alpha channel of the layer **above**, irrespective of mapping.

To determine transparency, the luminance of each pixel is calculated using a weighted average of its red, green, and blue channels. The luminance value is then used as the alpha (opacity) value for the corresponding pixels in the upper layers.

As a result, white areas render the layer above fully opaque, black areas make them fully transparent, and grey areas create proportional semi-transparency. This is a specialized **Mask** blend mode; for more details on the underlying behaviour, see **Mask blending**.

Inv-Luma-Matte

The Inverse Luma Matte mask works the same as the **Luma Matte** mask but the transparency is inverted meaning white regions are transparent and black regions are opaque.

Multiply-Fade

The same as Multiply, but will make use of the alpha channel to calculate transparency in the source and blend layers. Since maximum transparency is premultiplied, alpha results in black. This will ignore black created through premultiplying.

Multiply-Alpha

Multiply with straight alpha. This mode assumes that the alpha has not been premultiplied onto the RGB values and will not apply a correction to the semi-transparent pixels.

Premultiply Alpha

Like how Multiply-fade will ignore the darkening caused by premultiplying, this blend mode will do the same with Alpha.

Colour Burn

Blend mode increases the contrast to darken the base colour while reflecting the blend colour. The darker the blend colour, the more intensely the colour will be applied in the base image. White as the blend colour produces no change. Using the colour burn blend mode can produce some harsh results at full opacity. The colour burn blend mode can be used to make tonal and colour adjustments to a layer.

Screen

This blend mode looks at each channels colour information and multiplies the inverse of the blend and base colous. The result is always a lighter colour. Screening with black leaves the colour unchanged. Screening with white produces white. The effect is similar to projecting

multiple images on top of each other - where bright white is fully opaque, black is fully transparent and 50% grey is 50% transparent.

Overlay

Multiplies or screens the colours, depending on the base colour. Patterns or colours overlay the existing pixels while preserving the highlights and shadows of the base colour. The base colour is not replaced, but mixed with the blend colour to reflect the lightness or darkness of the original colour.

Hard Light

Multiplies or screens the colours, depending on the blend colour. The effects is similar to shining a harsh spotlight on the image. If the blend colour (light source/top layer) is lighter than 50% grey, the image is lightened as if it were screened. This is useful for adding highlights to an image. If the blend colour is darker than 50% grey, the image is darkened as if it were multiplied. This is useful for adding shadows to an image. Painting with pure black or white results in pure black or white.

Soft Light

Darkens or lightens the colours, depending on the blend colour. The effect is similar to shining a diffused spotlight on the image. If the blend colour (light source/top layer) is lighter than 50% grey, the image is lightened as it if were dodged. If the blend colour is darker than 50% grey, the image is darkened as if it were burned in. Painting with pure black or white produces a distinctly darker or lighter area, but does not result in pure black or white.

Darken

Looks as the colour information in each channel and selects the base or blend colour - whichever is darker - as the result colour. Pixels lighter than the blend colour are replaced and pixels darker than the blend colour do not change.

Lighten

Looks at the colour information in each channel and selects the base or blend colour - whichever is lighter - as the result colour. Pixels darker than the blend colour are replaced and pixels lighter than the blend colour do not change.

Difference

Looks at the colour information in each channel and subtracts either the blend colour from the base colour or the base colour from the blend colour depending on which has the greater brightness value. Blending with white inverts the base colour values and blending with black produces no change.

Exclusion

Creates an effects similar to but lower in contrast than the difference mode. Blending with white inverts the base colour values. Blending with black produces no change.

Colour Dodge

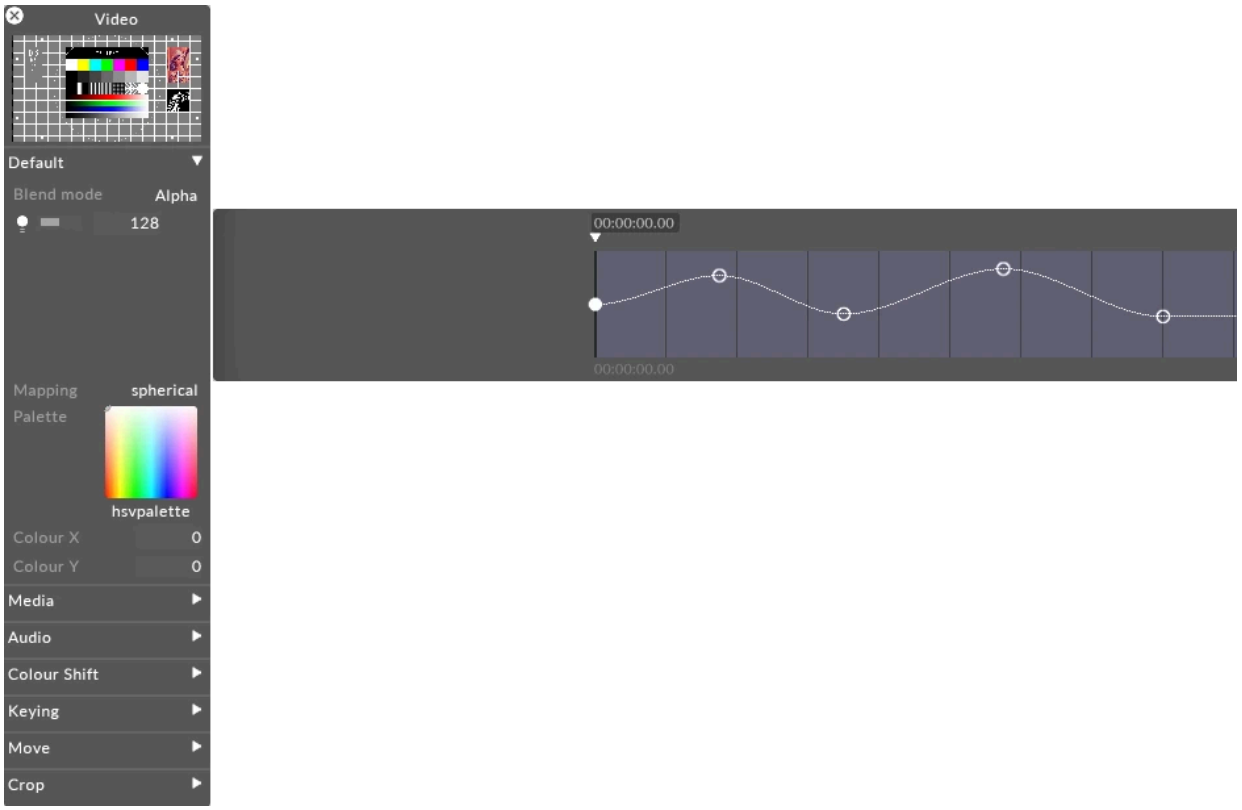
Looks at the colour information in each channel and brightens the base colour to reflect the blend colour by decreasing contrast between the two. Blending with black produces no change.

Hard Mix

Adds the RGB channels of the blend colour to the RGB values of the base colour. If the resulting sum for a channel is 255 or greater, it receives a value of 255; if it is less than 255 it receives a value of 0. Therefore all blended pixels have RGB channels of either 0 or 255. This changes all pixels to primary additive colours (RGB), white or black.

Brightness

This property (which appears as a light bulb icon) controls the brightness of the layer output.



If the layers blend mode is set to Alpha, then reducing the brightness to 0 also reduces the opacity of the layer to 0. This can be useful when you want to dissolve from one layer to the

next. In that case, you can place the new layer above the old layer and increase its brightness level.

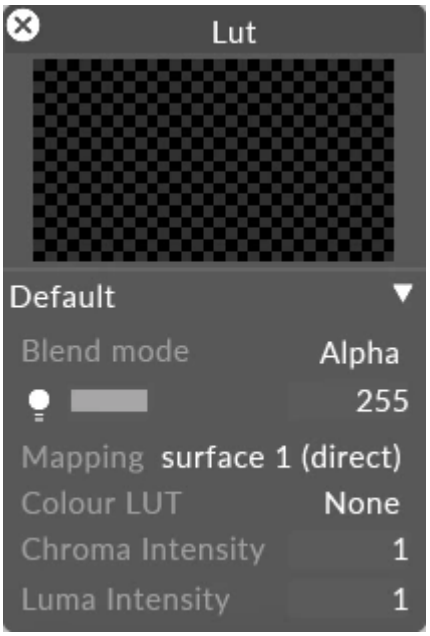
> **Note**
>
> Layers that are patched to Sockpuppet (DMX, OSC or HTTP) are made Dormant when their brightness is set to 0. This means they will not do any rendering or consume any resources until their brightness is changed to > 0. You can find more information about this here: **Sequencing with Sockpuppet**. Layers without a sockpuppet patch do not behave in this way.

Mapping

The mapping property controls how the layer output is mapped onto the screen(s) in the Stage level.

For information on mapping, including how to use the different mapping types offered by Designer, please see the chapter **Content Mapping**

LUT Layer



The Lut layer is designed to create movie style looks & for technical Luts to support conversion workflows. Lut files are commonly created and exported from image editing programs and have a .cube file extension.

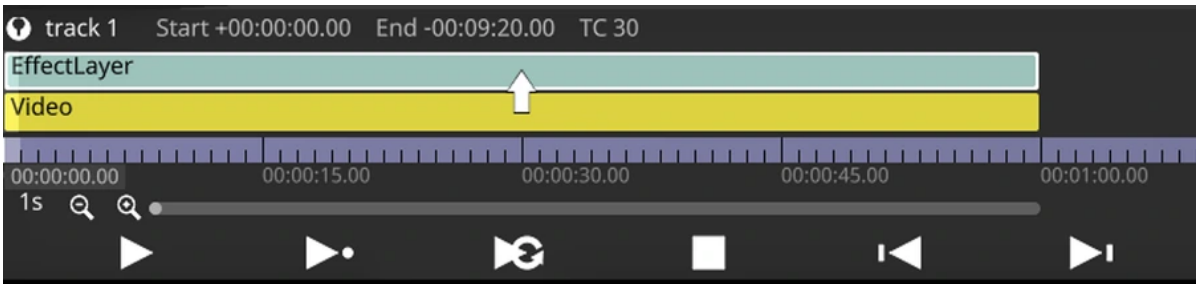
Workflow

Effect layers receive their source from other layer types - either content or generative - through arrows. An arrow connects a source layer to a destination layer; the source layer is said to be “piped in” to the destination Effect layer. For more information on arrows, see the **compositing layers** topic.

To draw an arrow between two layers, hold down **ALT** and left-click & drag from the source layer to the destination layer.

1. Add an Effect layer to your track. For more information about adding layers, see **creating layers**.

2. Draw an arrow from your content layer to the Effect layer so the compositing order looks something like the following image.

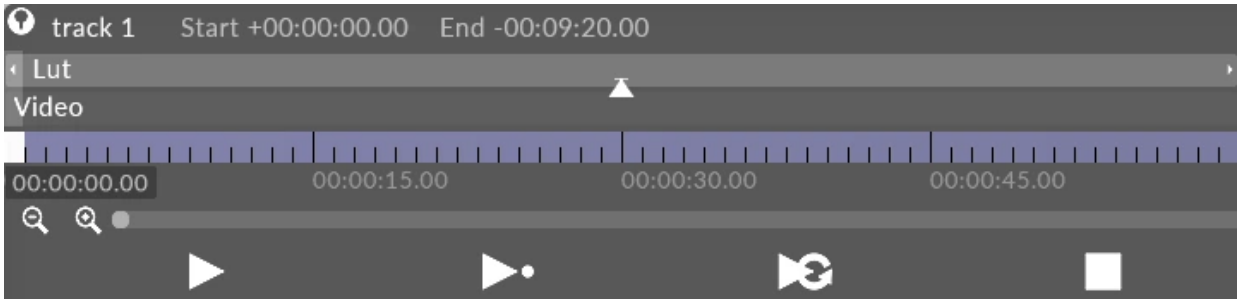


A Video layer piped into an Effect layer on the timeline.

3. Adjust the Effect layer properties to achieve the desired result.

Configure LUT

1. Add your Lut files to the LutFile folder inside your project folder. The LutFile folder is contained within the Objects folder. For more information see placing media files.
2. Add a Lut layer to your track. For more information about adding layers see creating layers.
3. Arrow from your media layer to the Lut layer so the compositing order looks something like the following image. Video layer piped into a Lut layer on the timeline.
4. Adjust the Lut layer properties to suit your desired sequencing.



LUT Layer Properties

Colour LUT

This property allows you to select a lut file from the project folder. Lut files live in a specified folder inside the Objects folder. For more information see Project Structure.

Chroma intensity

This property controls the chroma intensity. If the Chroma intensity is at 0, then the content is using the original chroma, whereas if it is at 1 its the chroma specified in the lut file. You can alter the max value by right-clicking the property which will simply multiply the original Chroma value by the new max value.

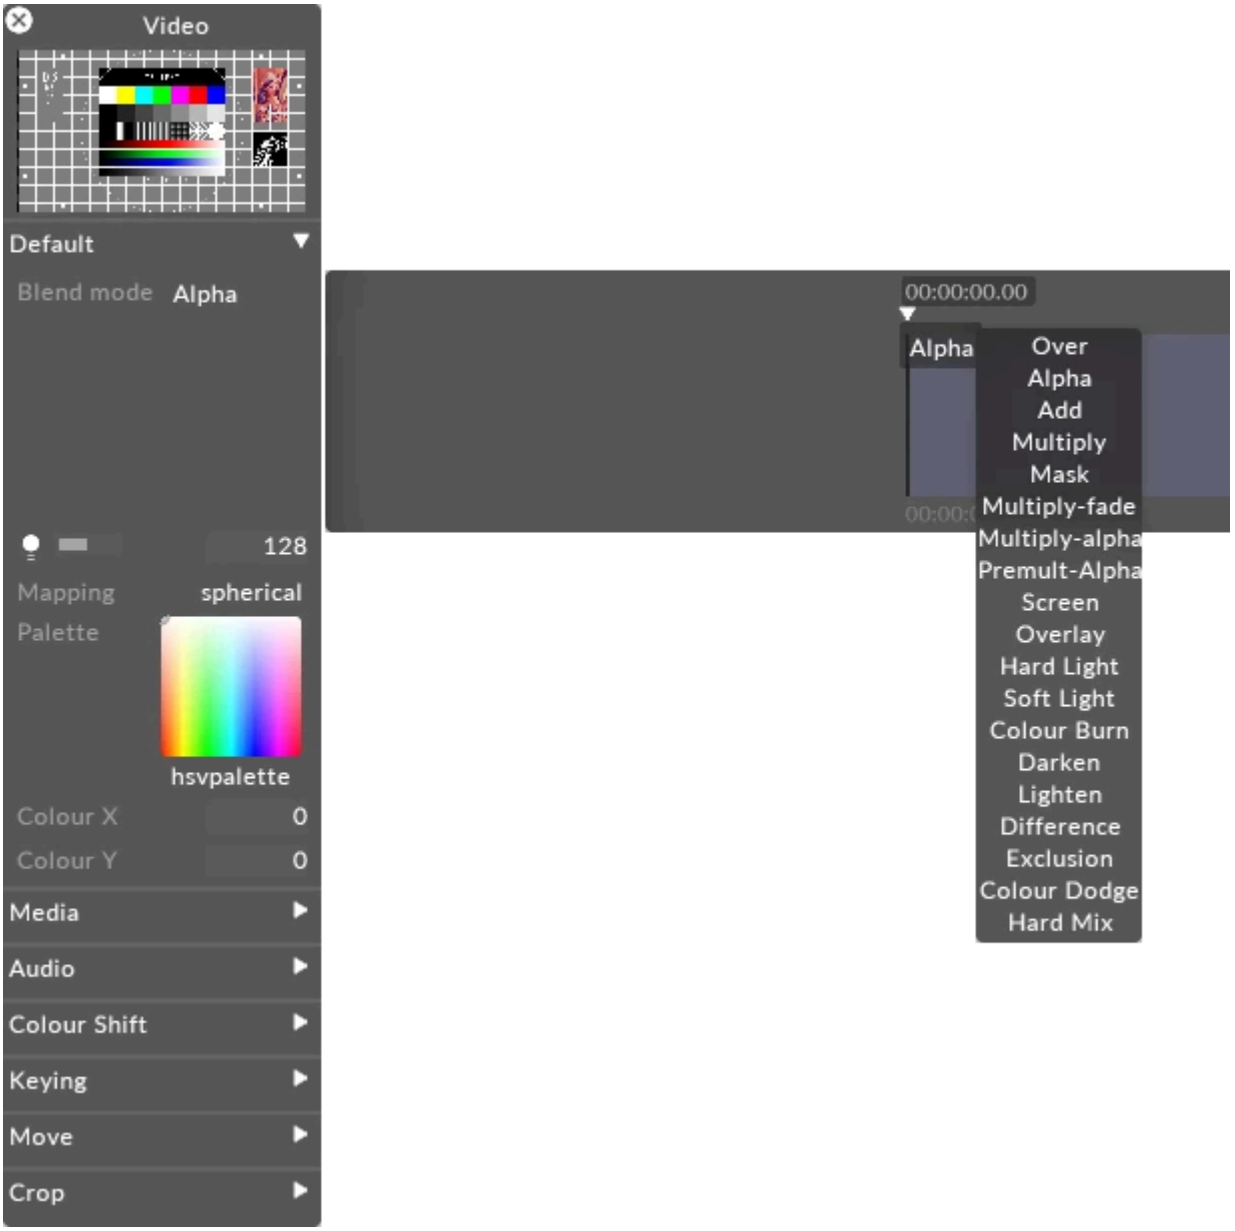
Luma intensity

This property controls the Luma intensity. If the Luma intensity is at 0 then the luminosity will be the same as the original content, where as if it is at 1 then it will be the Luma specified in the lut file. You can alter the max value by right-clicking the property which will simply multiple the original Luma value by the new max value.

Common Layer Properties

Blend Mode

BlendMode controls how the output of the layer is composited with the layers below. Layers are rendered in a bottom-up order: layers at the top can modify the output of the layers below.



Changing brightness of a content layer in Designer is actually controlling the value of the alpha of the layer. Even when displaying a HAP video, the software will composite the layer with a controllable layer of alpha - one per layer.

There are two ways of expressing alpha in an image:

Straight alpha is an alpha channel which functions just like RGB. Alpha acts as a fourth channel of information per pixel which is as independent of the other three as R, G and B are of each other. For example, with straight alpha it is possible to have RGB = 255 (white) and alpha = 0 (fully transparent) on the same pixel. Internally generated content, such as gradient layer, are generated with straight alpha. This is the preferable style of alpha and considering the cleaner method of the two.

Premultiplied alpha takes the alpha and applies it to the values of the RGB channels per pixel. The more transparent something gets with premultiplied alpha, the closer it gets to black - as if the content is sitting on a black table. Premultiplied is the default output of Adobe Photoshop or AfterEffects. The result is our pixel at 255 RGB (full white) with 0 alpha would be calculated as a black pixel in the final image.

Here are explanations of what each individual blend mode will do.

Over

Makes a layer fully opaque. Premultiplies all alpha onto the RGB value of each pixel. Alpha = black, so adjusting the brightness of a layer in Over blend mode makes it darker.

Alpha

Default blend mode. It will apply alpha values as a transparency if the alpha is present. Brightness changes will make the layer more or less transparent.

Add

Adds the value of each RGB pixel together. Always creates a brighter result. Values clamp at 255.

Multiply

Reads the level of each subpixel as a level between 0.0 and 1.0, and multiplies source with blend. The result is always a darker image overall. For example: white x grey = 0.5. White turns transparent, black takes precedence. Alpha is applied in the same fashion as the Over Blend mode.

Mask

Applies a mask to the single layer **above** in the stack, irrespective of mapping. See **Mask blending** for more information.

Luma-Matte

This mode creates a Luma Matte by using a layer's **Rec. 709 luminance** to control the alpha channel of the layer **above**, irrespective of mapping.

To determine transparency, the luminance of each pixel is calculated using a weighted average of its red, green, and blue channels. The luminance value is then used as the alpha (opacity) value for the corresponding pixels in the upper layers.

As a result, white areas render the layer above fully opaque, black areas make them fully transparent, and grey areas create proportional semi-transparency. This is a specialized **Mask** blend mode; for more details on the underlying behaviour, see **Mask blending**.

Inv-Luma-Matte

The Inverse Luma Matte mask works the same as the **Luma Matte** mask but the transparency is inverted meaning white regions are transparent and black regions are opaque.

Multiply-Fade

The same as Multiply, but will make use of the alpha channel to calculate transparency in the source and blend layers. Since maximum transparency is premultiplied, alpha results in black. This will ignore black created through premultiplying.

Multiply-Alpha

Multiply with straight alpha. This mode assumes that the alpha has not been premultiplied onto the RGB values and will not apply a correction to the semi-transparent pixels.

Premultiply Alpha

Like how Multiply-fade will ignore the darkening caused by premultiplying, this blend mode will do the same with Alpha.

Colour Burn

Blend mode increases the contrast to darken the base colour while reflecting the blend colour. The darker the blend colour, the more intensely the colour will be applied in the base image. White as the blend colour produces no change. Using the colour burn blend mode can produce some harsh results at full opacity. The colour burn blend mode can be used to make tonal and colour adjustments to a layer.

Screen

This blend mode looks at each channels colour information and multiplies the inverse of the blend and base colous. The result is always a lighter colour. Screening with black leaves the colour unchanged. Screening with white produces white. The effect is similar to projecting multiple images on top of each other - where bright white is fully opaque, black is fully transparent and 50% grey is 50% transparent.

Overlay

Multiplies or screens the colours, depending on the base colour. Patterns or colours overlay the existing pixels while preserving the highlights and shadows of the base colour. The base colour is not replaced, but mixed with the blend colour to reflect the lightness or darkness of the original colour.

Hard Light

Multiplies or screens the colours, depending on the blend colour. The effects is similar to shining a harsh spotlight on the image. If the blend colour (light source/top layer) is lighter than

50% grey, the image is lightened as if it were screened. This is useful for adding highlights to an image. If the blend colour is darker than 50% grey, the image is darkened as if it were multiplied. This is useful for adding shadows to an image. Painting with pure black or white results in pure black or white.

Soft Light

Darkens or lightens the colours, depending on the blend colour. The effect is similar to shining a diffused spotlight on the image. If the blend colour (light source/top layer) is lighter than 50% grey, the image is lightened as it if were dodged. If the blend colour is darker than 50% grey, the image is darkened as if it were burned in. Painting with pure black or white produces a distinctly darker or lighter area, but does not result in pure black or white.

Darken

Looks as the colour information in each channel and selects the base or blend colour - whichever is darker - as the result colour. Pixels lighter than the blend colour are replaced and pixels darker than the blend colour do not change.

Lighten

Looks at the colour information in each channel and selects the base or blend colour - whichever is lighter - as the result colour. Pixels darker than the blend colour are replaced and pixels lighter than the blend colour do not change.

Difference

Looks at the colour information in each channel and subtracts either the blend colour from the base colour or the base colour from the blend colour depending on which has the greater brightness value. Blending with white inverts the base colour values and blending with black produces no change.

Exclusion

Creates an effects similar to but lower in contrast than the difference mode. Blending with white inverts the base colour values. Blending with black produces no change.

Colour Dodge

Looks at the colour information in each channel and brightens the base colour to reflect the blend colour by decreasing contrast between the two. Blending with black produces no change.

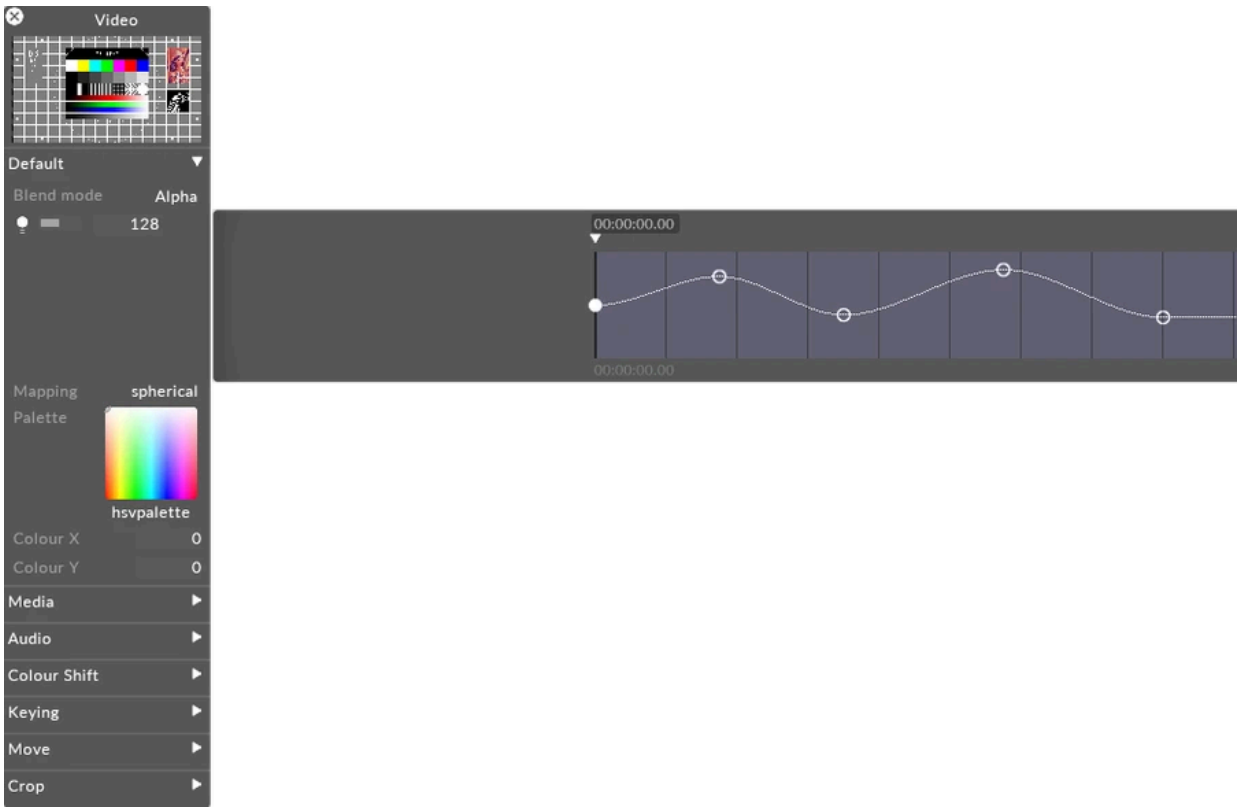
Hard Mix

Adds the RGB channels of the blend colour to the RGB values of the base colour. If the resulting sum for a channel is 255 or greater, it receives a value of 255; if it is less than 255 it

receives a value of 0. Therefore all blended pixels have RGB channels of either 0 or 255. This changes all pixels to primary additive colours (RGB), white or black.

Brightness

This property (which appears as a light bulb icon) controls the brightness of the layer output.



If the layers blend mode is set to Alpha, then reducing the brightness to 0 also reduces the opacity of the layer to 0. This can be useful when you want to dissolve from one layer to the next. In that case, you can place the new layer above the old layer and increase its brightness level.

> **Note**
>
> Layers that are patched to Sockpuppet (DMX, OSC or HTTP) are made Dormant when their brightness is set to 0. This means they will not do any rendering or consume any resources until their brightness is changed to > 0. You can find more information about this here: **Sequencing with Sockpuppet**. Layers without a sockpuppet patch do not behave in this way.

Mapping

The mapping property controls how the layer output is mapped onto the screen(s) in the Stage level.

For information on mapping, including how to use the different mapping types offered by Designer, please see the chapter **Content Mapping**

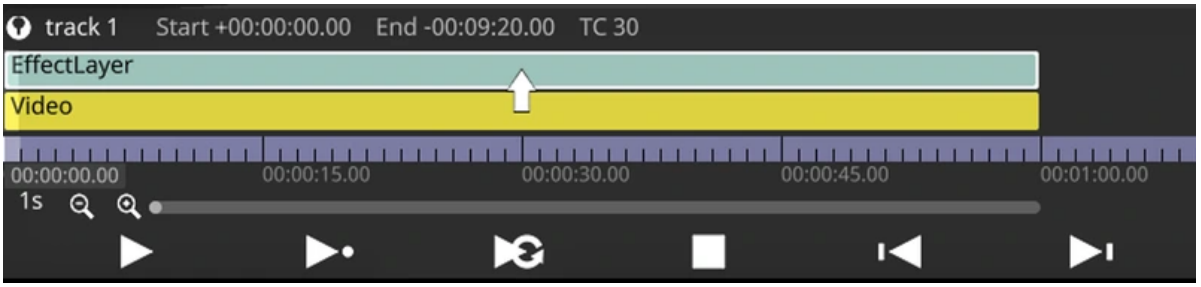
MotionBlur Layer

Workflow

Effect layers receive their source from other layer types - either content or generative - through arrows. An arrow connects a source layer to a destination layer; the source layer is said to be “piped in” to the destination Effect layer. For more information on arrows, see the compositing layers topic.

To draw an arrow between two layers, hold down **ALT** and left-click & drag from the source layer to the destination layer.

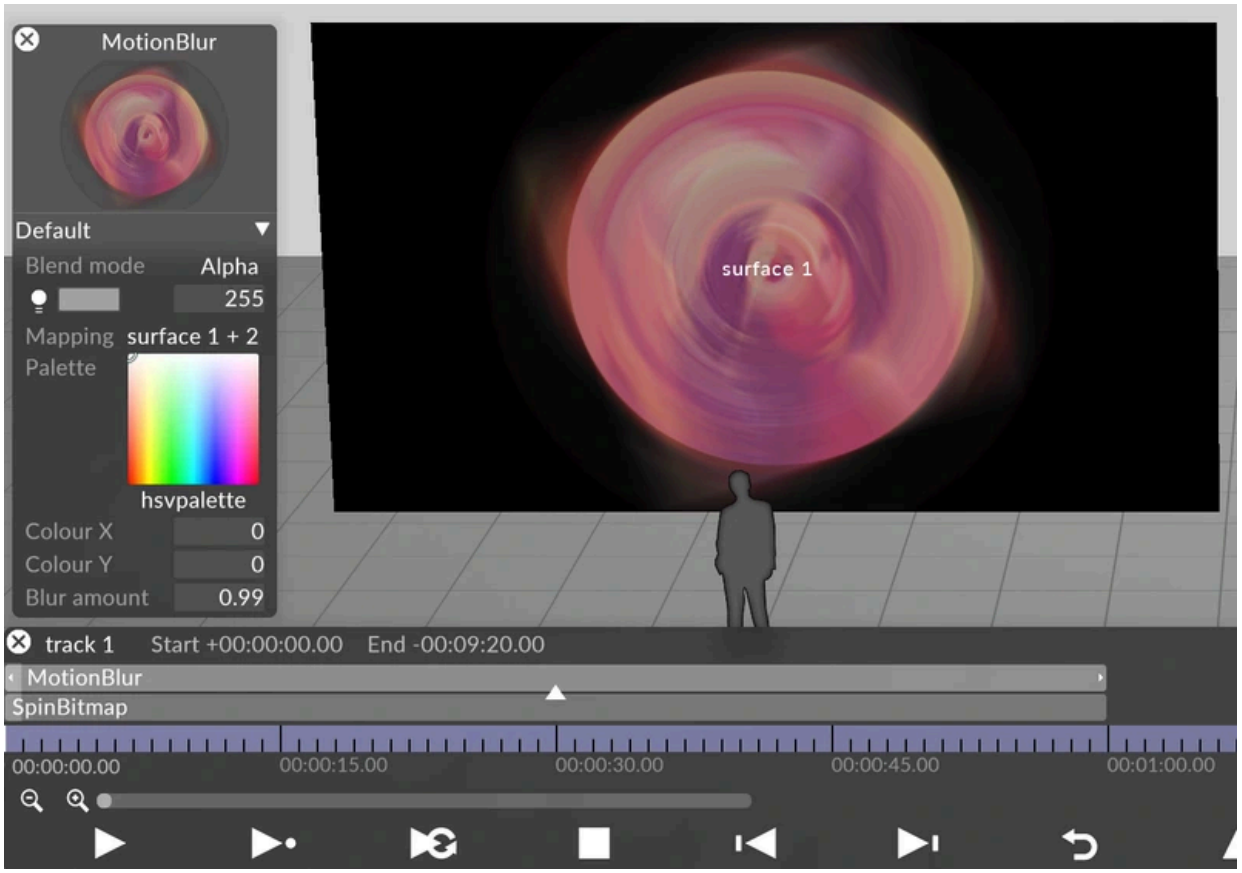
1. Add an Effect layer to your track. For more information about adding layers, see creating layers.
2. Draw an arrow from your content layer to the Effect layer so the compositing order looks something like the following image.



A Video layer piped into an Effect layer on the timeline.

3. Adjust the Effect layer properties to achieve the desired result.

MotionBlur Layer Properties



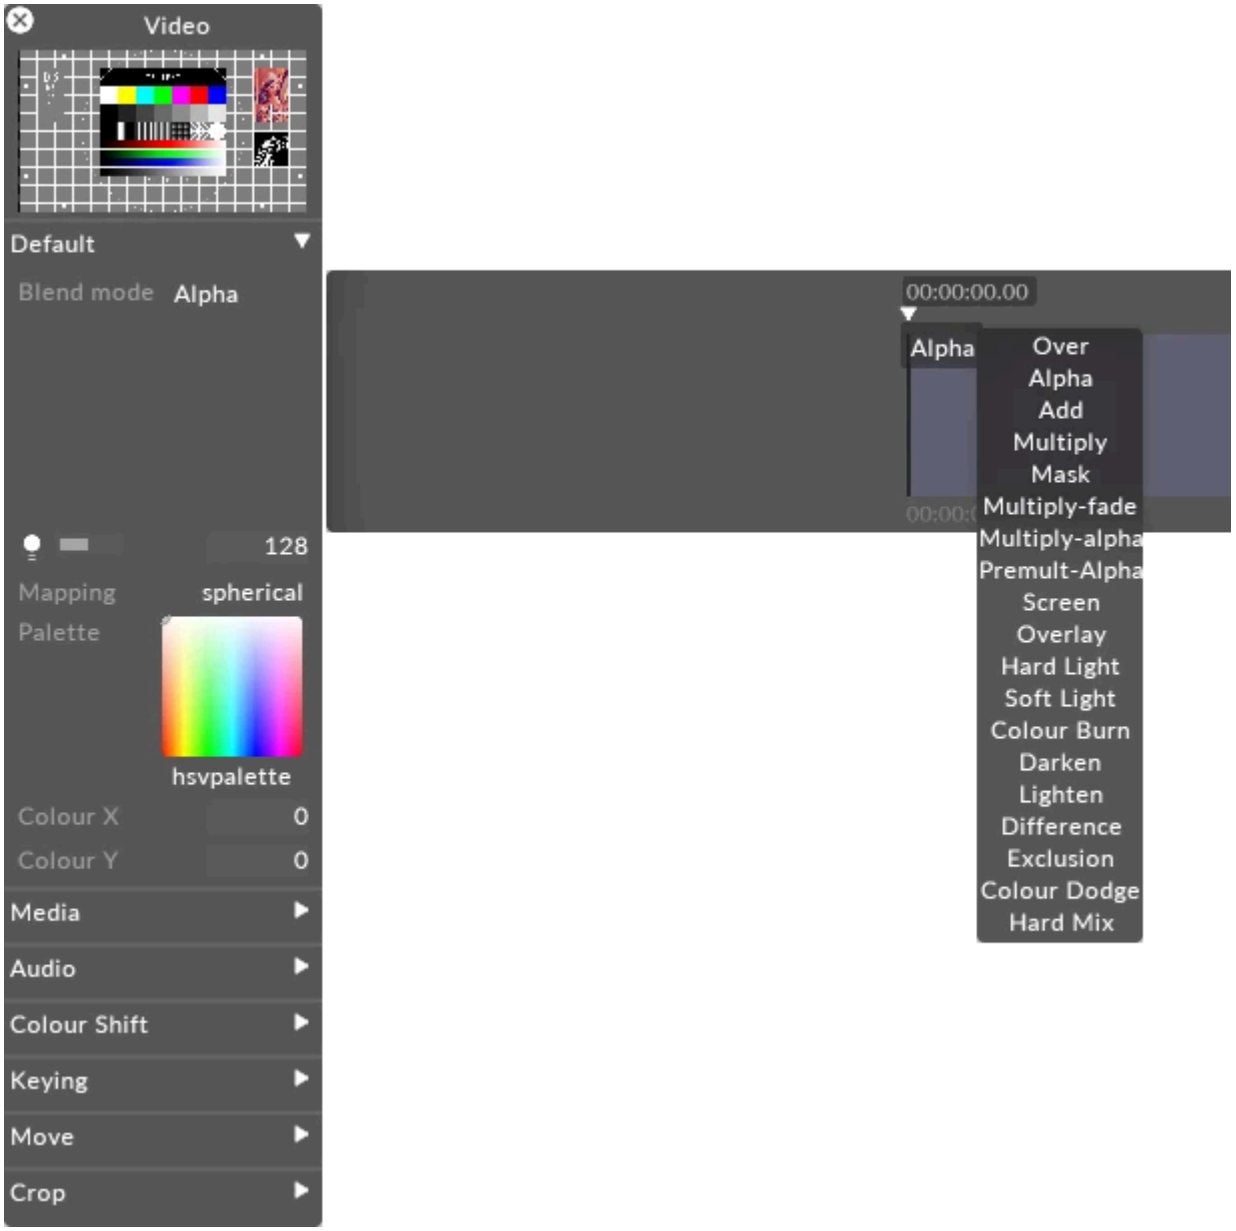
Blur amount

The amplitude of the blur effect. Default value is 0.5. The min/max values are 0 and 1. Decreasing the value from 0.5 to 0 will sharpen the content, whilst increasing the value from 0.5 to 1 will gradually amplify the blurriness of the content.

Common Layer Properties

Blend Mode

BlendMode controls how the output of the layer is composited with the layers below. Layers are rendered in a bottom-up order: layers at the top can modify the output of the layers below.



Changing brightness of a content layer in Designer is actually controlling the value of the alpha of the layer. Even when displaying a HAP video, the software will composite the layer with a controllable layer of alpha - one per layer.

There are two ways of expressing alpha in an image:

Straight alpha is an alpha channel which functions just like RGB. Alpha acts as a fourth channel of information per pixel which is as independent of the other three as R, G and B are of each other. For example, with straight alpha it is possible to have RGB = 255 (white) and alpha = 0 (fully transparent) on the same pixel. Internally generated content, such as gradient layer, are generated with straight alpha. This is the preferable style of alpha and considering the cleaner method of the two.

Premultiplied alpha takes the alpha and applies it to the values of the RGB channels per pixel. The more transparent something gets with premultiplied alpha, the closer it gets to black - as if the content is sitting on a black table. Premultiplied is the default output of Adobe Photoshop or AfterEffects. The result is our pixel at 255 RGB (full white) with 0 alpha would be calculated as a black pixel in the final image.

Here are explanations of what each individual blend mode will do.

Over

Makes a layer fully opaque. Premultiplies all alpha onto the RGB value of each pixel. Alpha = black, so adjusting the brightness of a layer in Over blend mode makes it darker.

Alpha

Default blend mode. It will apply alpha values as a transparency if the alpha is present. Brightness changes will make the layer more or less transparent.

Add

Adds the value of each RGB pixel together. Always creates a brighter result. Values clamp at 255.

Multiply

Reads the level of each subpixel as a level between 0.0 and 1.0, and multiplies source with blend. The result is always a darker image overall. For example: white x grey = 0.5. White turns transparent, black takes precedence. Alpha is applied in the same fashion as the Over Blend mode.

Mask

Applies a mask to the single layer **above** in the stack, irrespective of mapping. See **Mask blending** for more information.

Luma-Matte

This mode creates a Luma Matte by using a layer's **Rec. 709 luminance** to control the alpha channel of the layer **above**, irrespective of mapping.

To determine transparency, the luminance of each pixel is calculated using a weighted average of its red, green, and blue channels. The luminance value is then used as the alpha (opacity) value for the corresponding pixels in the upper layers.

As a result, white areas render the layer above fully opaque, black areas make them fully transparent, and grey areas create proportional semi-transparency. This is a specialized **Mask** blend mode; for more details on the underlying behaviour, see **Mask blending**.

Inv-Luma-Matte

The Inverse Luma Matte mask works the same as the **Luma Matte** mask but the transparency is inverted meaning white regions are transparent and black regions are opaque.

Multiply-Fade

The same as Multiply, but will make use of the alpha channel to calculate transparency in the source and blend layers. Since maximum transparency is premultiplied, alpha results in black. This will ignore black created through premultiplying.

Multiply-Alpha

Multiply with straight alpha. This mode assumes that the alpha has not been premultiplied onto the RGB values and will not apply a correction to the semi-transparent pixels.

Premultiply Alpha

Like how Multiply-fade will ignore the darkening caused by premultiplying, this blend mode will do the same with Alpha.

Colour Burn

Blend mode increases the contrast to darken the base colour while reflecting the blend colour. The darker the blend colour, the more intensely the colour will be applied in the base image. White as the blend colour produces no change. Using the colour burn blend mode can produce some harsh results at full opacity. The colour burn blend mode can be used to make tonal and colour adjustments to a layer.

Screen

This blend mode looks at each channels colour information and multiplies the inverse of the blend and base colous. The result is always a lighter colour. Screening with black leaves the colour unchanged. Screening with white produces white. The effect is similar to projecting multiple images on top of each other - where bright white is fully opaque, black is fully transparent and 50% grey is 50% transparent.

Overlay

Multiplies or screens the colours, depending on the base colour. Patterns or colours overlay the existing pixels while preserving the highlights and shadows of the base colour. The base colour is not replaced, but mixed with the blend colour to reflect the lightness or darkness of the original colour.

Hard Light

Multiplies or screens the colours, depending on the blend colour. The effects is similar to shining a harsh spotlight on the image. If the blend colour (light source/top layer) is lighter than

50% grey, the image is lightened as if it were screened. This is useful for adding highlights to an image. If the blend colour is darker than 50% grey, the image is darkened as if it were multiplied. This is useful for adding shadows to an image. Painting with pure black or white results in pure black or white.

Soft Light

Darkens or lightens the colours, depending on the blend colour. The effect is similar to shining a diffused spotlight on the image. If the blend colour (light source/top layer) is lighter than 50% grey, the image is lightened as it if were dodged. If the blend colour is darker than 50% grey, the image is darkened as if it were burned in. Painting with pure black or white produces a distinctly darker or lighter area, but does not result in pure black or white.

Darken

Looks as the colour information in each channel and selects the base or blend colour - whichever is darker - as the result colour. Pixels lighter than the blend colour are replaced and pixels darker than the blend colour do not change.

Lighten

Looks at the colour information in each channel and selects the base or blend colour - whichever is lighter - as the result colour. Pixels darker than the blend colour are replaced and pixels lighter than the blend colour do not change.

Difference

Looks at the colour information in each channel and subtracts either the blend colour from the base colour or the base colour from the blend colour depending on which has the greater brightness value. Blending with white inverts the base colour values and blending with black produces no change.

Exclusion

Creates an effects similar to but lower in contrast than the difference mode. Blending with white inverts the base colour values. Blending with black produces no change.

Colour Dodge

Looks at the colour information in each channel and brightens the base colour to reflect the blend colour by decreasing contrast between the two. Blending with black produces no change.

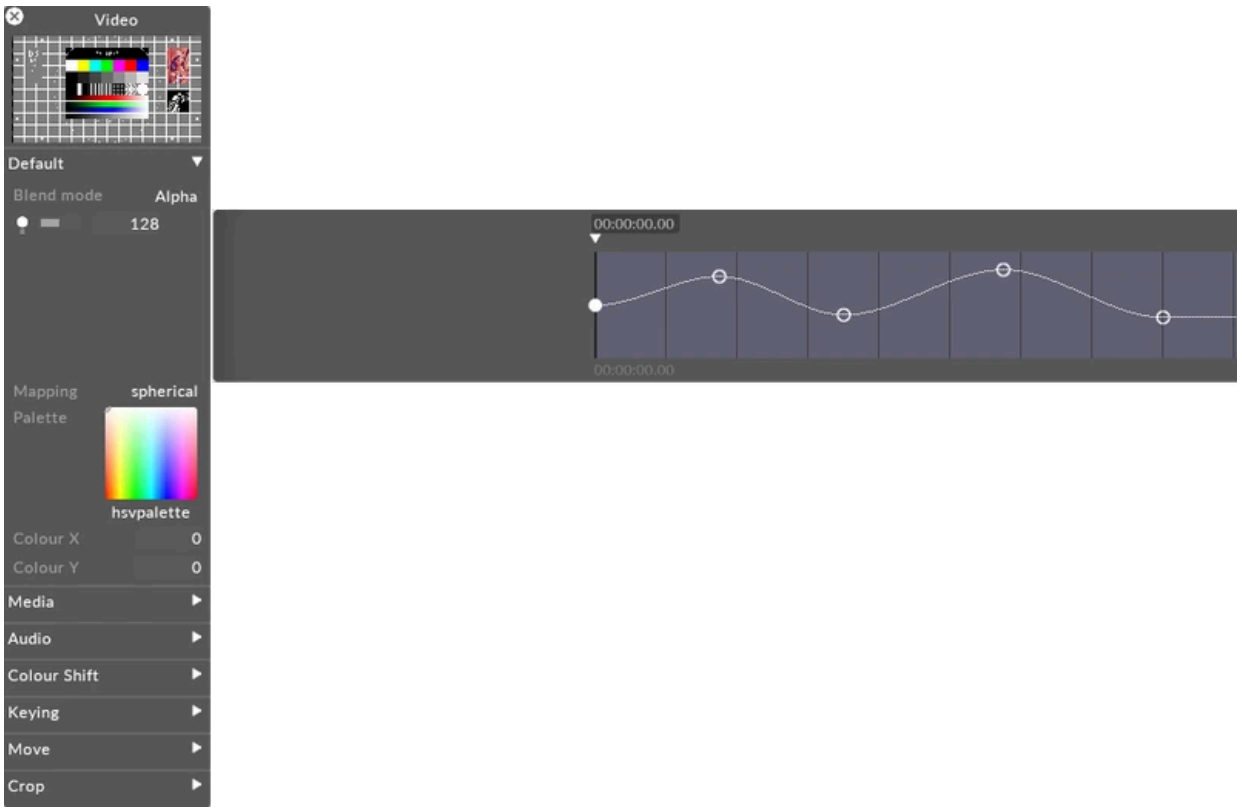
Hard Mix

Adds the RGB channels of the blend colour to the RGB values of the base colour. If the resulting sum for a channel is 255 or greater, it receives a value of 255; if it is less than 255 it

receives a value of 0. Therefore all blended pixels have RGB channels of either 0 or 255. This changes all pixels to primary additive colours (RGB), white or black.

Brightness

This property (which appears as a light bulb icon) controls the brightness of the layer output.



If the layers blend mode is set to Alpha, then reducing the brightness to 0 also reduces the opacity of the layer to 0. This can be useful when you want to dissolve from one layer to the next. In that case, you can place the new layer above the old layer and increase its brightness level.

> **Note**
>
> Layers that are patched to Sockpuppet (DMX, OSC or HTTP) are made Dormant when their brightness is set to 0. This means they will not do any rendering or consume any resources until their brightness is changed to > 0. You can find more information about this here: **Sequencing with Sockpuppet**. Layers without a sockpuppet patch do not behave in this way.

Mapping

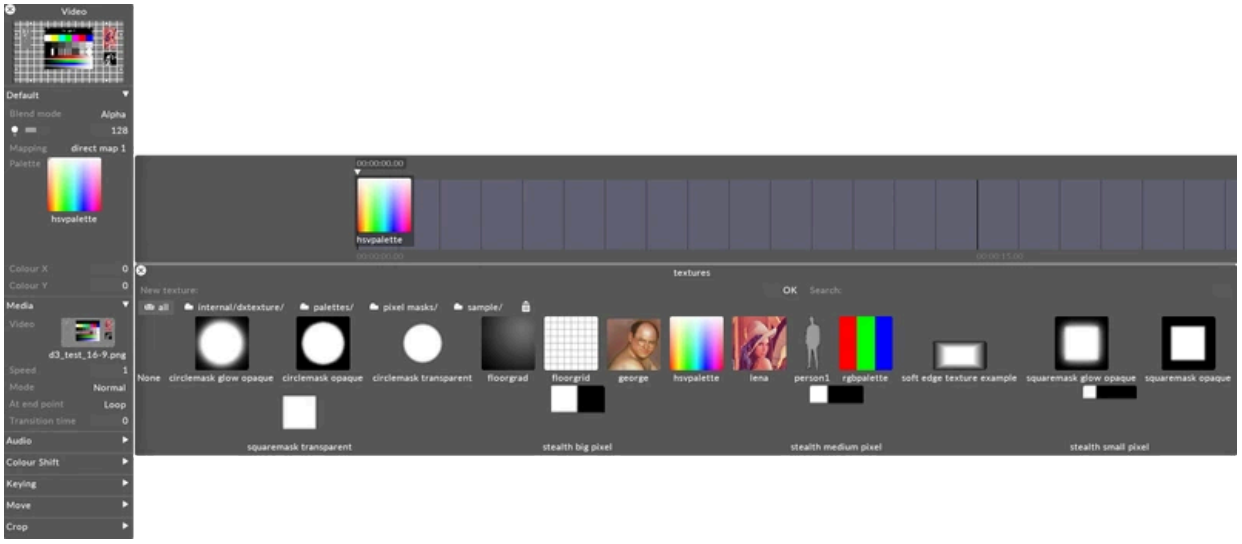
The mapping property controls how the layer output is mapped onto the screen(s) in the Stage level.

For information on mapping, including how to use the different mapping types offered by Designer, please see the chapter **Content Mapping**

Palette

This points to the still image file that defines the bitmap from which the tint colour is taken. The default palette (HSVPAL) consists of the complete range of hues and saturations. Selecting this property will open the Texture object library, which shows all of the still image files saved on your local hard-drive in the **DxTexture** older.

To control the location within the current palette bitmap, and thus control the colour, you have to edit the **xCol** and **yCol** values (see the section for xCol, yCol).



To change the current palette bitmap:

1. Left-click **palette** to open the Texture object library.
2. Left-click the still image file you want to use for the palette bitmap.

If you want to use a palette bitmap other than the standard still images provided in Designer, you will need to use a custom still image file.

See the **Placing media files** for a project sub-chapter to understand where to place a custom still image file and how to access it in Designer. Also save the file to a **supported file format**.

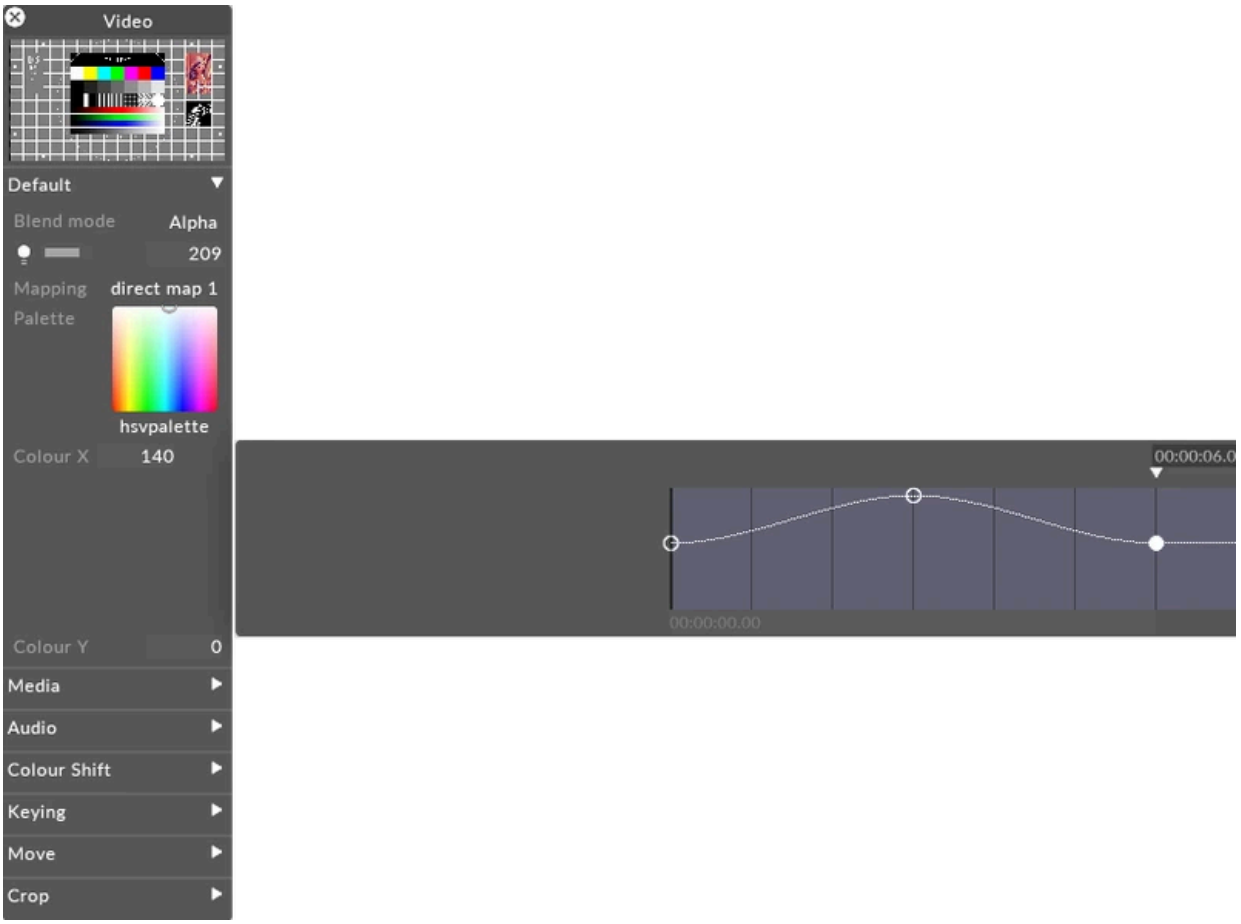
Xcol, YCol

These properties control the coordinates within the current palette bitmap where the output colour is sampled from. The default value is 0,0 which points at the color white (if you are using the HSVPAL palette). Multiplying white with the colors of the chosen content simply generates the original content colors. **Colour X** controls the horizontal position, where 0 is the leftmost

edge and 255 is the rightmost edge. **Colour Y** controls the vertical position, where 0 is the top edge and 255 is the bottom edge.

For example, to saturate the video clip red, change the **Colour Y** value to 255 and use 0 for the **Colour X** value. These coordinates refer to the color red in the palette which is being multiplied with the colors of the existing content.

When you are using the default palette HSVPAL , Colour Y controls saturation, and Colour X controls hue.



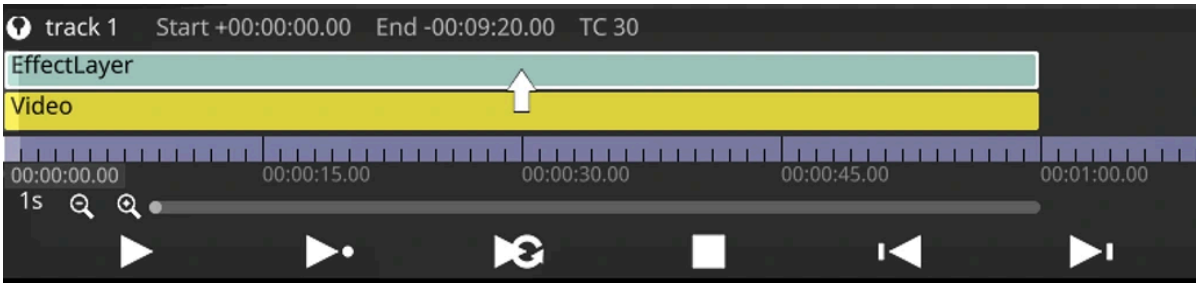
Noise Layer

Workflow

Effect layers receive their source from other layer types - either content or generative - through arrows. An arrow connects a source layer to a destination layer; the source layer is said to be “piped in” to the destination Effect layer. For more information on arrows, see the compositing layers topic.

To draw an arrow between two layers, hold down **ALT** and left-click & drag from the source layer to the destination layer.

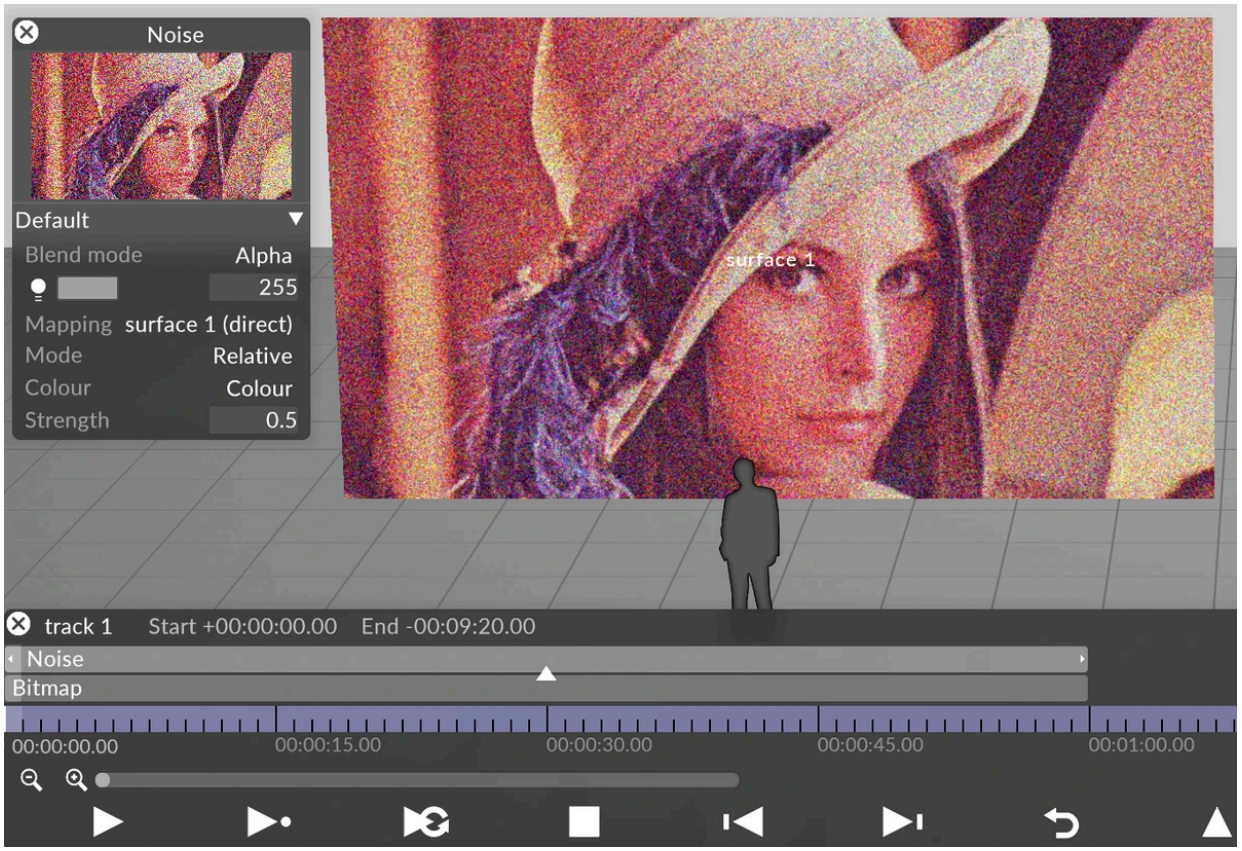
1. Add an Effect layer to your track. For more information about adding layers, see creating layers.
2. Draw an arrow from your content layer to the Effect layer so the compositing order looks something like the following image.



A Video layer piped into an Effect layer on the timeline.

3. Adjust the Effect layer properties to achieve the desired result.

Noise Layer Properties



Mode

- **Relative**
- **Absolute** - Noise value is added to the source image

Colour

- **Colour** - Noise is composed of random colour values
- **Greyscale** - Noise is composed of random greyscale values

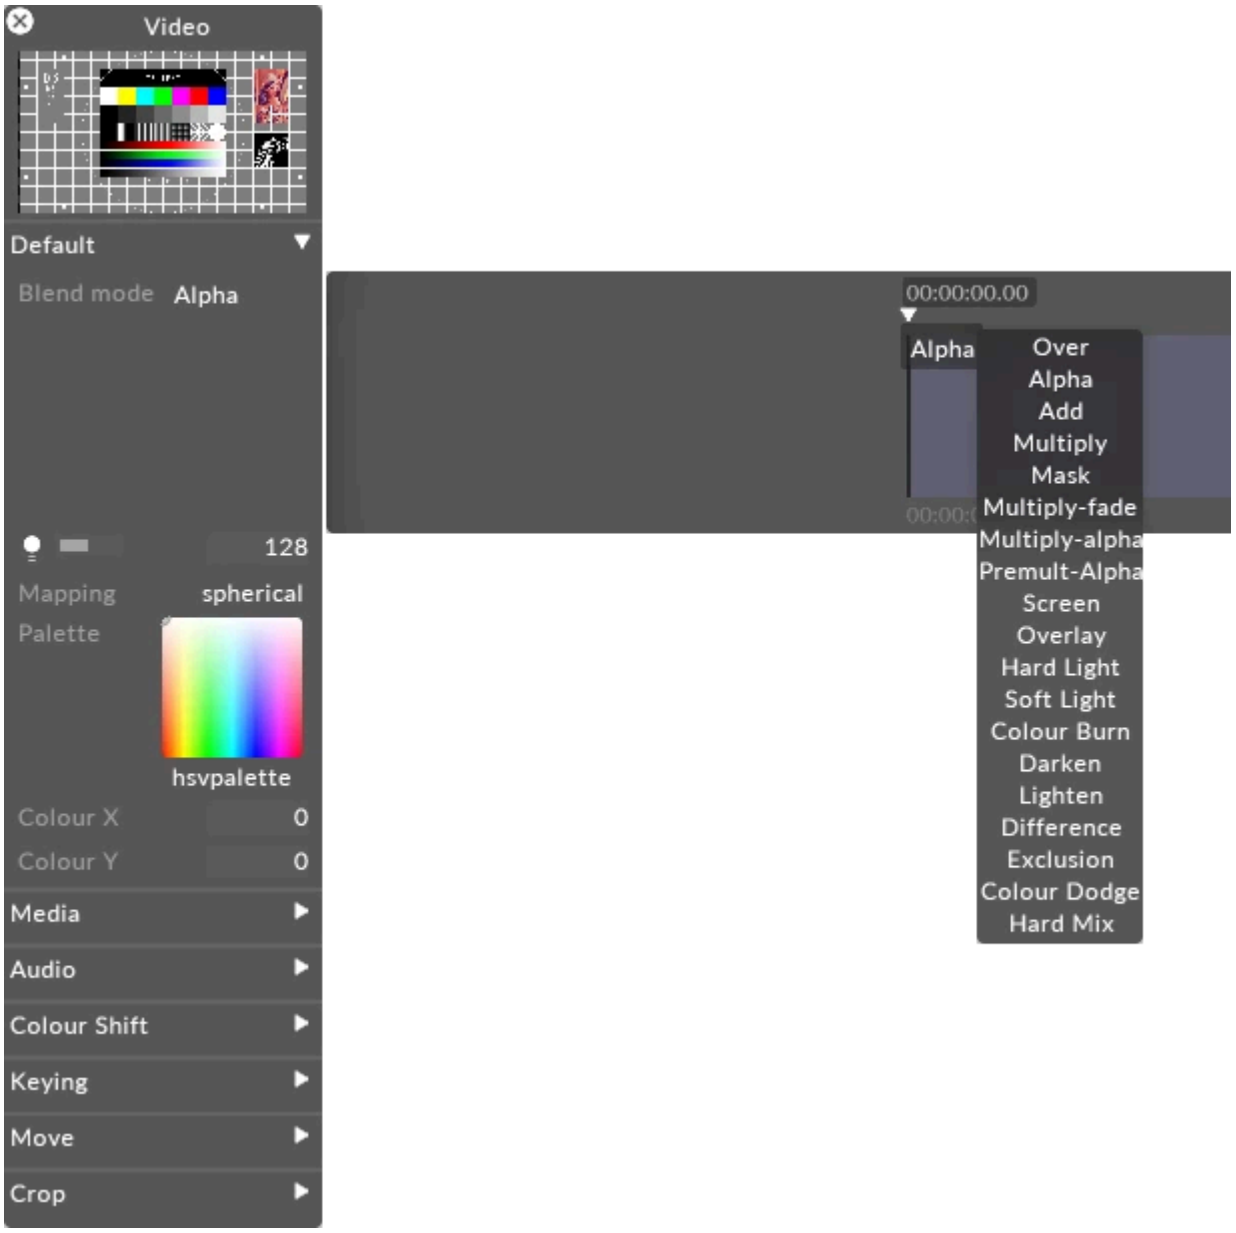
Strength

Adjust the strength of the noise

Common Layer Properties

Blend Mode

BlendMode controls how the output of the layer is composited with the layers below. Layers are rendered in a bottom-up order: layers at the top can modify the output of the layers below.



Changing brightness of a content layer in Designer is actually controlling the value of the alpha of the layer. Even when displaying a HAP video, the software will composite the layer with a controllable layer of alpha - one per layer.

There are two ways of expressing alpha in an image:

Straight alpha is an alpha channel which functions just like RGB. Alpha acts as a fourth channel of information per pixel which is as independent of the other three as R, G and B are of each other. For example, with straight alpha it is possible to have RGB = 255 (white) and alpha = 0 (fully transparent) on the same pixel. Internally generated content, such as gradient layer, are generated with straight alpha. This is the preferable style of alpha and considering the cleaner method of the two.

Premultiplied alpha takes the alpha and applies it to the values of the RGB channels per pixel. The more transparent something gets with premultiplied alpha, the closer it gets to black - as if the content is sitting on a black table. Premultiplied is the default output of Adobe Photoshop or AfterEffects. The result is our pixel at 255 RGB (full white) with 0 alpha would be calculated as a black pixel in the final image.

Here are explanations of what each individual blend mode will do.

Over

Makes a layer fully opaque. Premultiplies all alpha onto the RGB value of each pixel. Alpha = black, so adjusting the brightness of a layer in Over blend mode makes it darker.

Alpha

Default blend mode. It will apply alpha values as a transparency if the alpha is present. Brightness changes will make the layer more or less transparent.

Add

Adds the value of each RGB pixel together. Always creates a brighter result. Values clamp at 255.

Multiply

Reads the level of each subpixel as a level between 0.0 and 1.0, and multiplies source with blend. The result is always a darker image overall. For example: white x grey = 0.5. White turns transparent, black takes precedence. Alpha is applied in the same fashion as the Over Blend mode.

Mask

Applies a mask to the single layer **above** in the stack, irrespective of mapping. See **Mask blending** for more information.

Luma-Matte

This mode creates a Luma Matte by using a layer's **Rec. 709 luminance** to control the alpha channel of the layer **above**, irrespective of mapping.

To determine transparency, the luminance of each pixel is calculated using a weighted average of its red, green, and blue channels. The luminance value is then used as the alpha (opacity) value for the corresponding pixels in the upper layers.

As a result, white areas render the layer above fully opaque, black areas make them fully transparent, and grey areas create proportional semi-transparency. This is a specialized **Mask** blend mode; for more details on the underlying behaviour, see **Mask blending**.

Inv-Luma-Matte

The Inverse Luma Matte mask works the same as the **Luma Matte** mask but the transparency is inverted meaning white regions are transparent and black regions are opaque.

Multiply-Fade

The same as Multiply, but will make use of the alpha channel to calculate transparency in the source and blend layers. Since maximum transparency is premultiplied, alpha results in black. This will ignore black created through premultiplying.

Multiply-Alpha

Multiply with straight alpha. This mode assumes that the alpha has not been premultiplied onto the RGB values and will not apply a correction to the semi-transparent pixels.

Premultiply Alpha

Like how Multiply-fade will ignore the darkening caused by premultiplying, this blend mode will do the same with Alpha.

Colour Burn

Blend mode increases the contrast to darken the base colour while reflecting the blend colour. The darker the blend colour, the more intensely the colour will be applied in the base image. White as the blend colour produces no change. Using the colour burn blend mode can produce some harsh results at full opacity. The colour burn blend mode can be used to make tonal and colour adjustments to a layer.

Screen

This blend mode looks at each channels colour information and multiplies the inverse of the blend and base colous. The result is always a lighter colour. Screening with black leaves the colour unchanged. Screening with white produces white. The effect is similar to projecting multiple images on top of each other - where bright white is fully opaque, black is fully transparent and 50% grey is 50% transparent.

Overlay

Multiplies or screens the colours, depending on the base colour. Patterns or colours overlay the existing pixels while preserving the highlights and shadows of the base colour. The base colour is not replaced, but mixed with the blend colour to reflect the lightness or darkness of the original colour.

Hard Light

Multiplies or screens the colours, depending on the blend colour. The effects is similar to shining a harsh spotlight on the image. If the blend colour (light source/top layer) is lighter than 50% grey, the image is lightened as if it were screened. This is useful for adding highlights to an image. If the blend colour is darker than 50% grey, the image is darkened as if it were multiplied. This is useful for adding shadows to an image. Painting with pure black or white results in pure black or white.

Soft Light

Darkens or lightens the colours, depending on the blend colour. The effect is similar to shining a diffused spotlight on the image. If the blend colour (light source/top layer) is lighter than 50% grey, the image is lightened as it if were dodged. If the blend colour is darker than 50% grey, the image is darkened as if it were burned in. Painting with pure black or white produces a distinctly darker or lighter area, but does not result in pure black or white.

Darken

Looks as the colour information in each channel and selects the base or blend colour - whichever is darker - as the result colour. Pixels lighter than the blend colour are replaced and pixels darker than the blend colour do not change.

Lighten

Looks at the colour information in each channel and selects the base or blend colour - whichever is lighter - as the result colour. Pixels darker than the blend colour are replaced and pixels lighter than the blend colour do not change.

Difference

Looks at the colour information in each channel and subtracts either the blend colour from the base colour or the base colour from the blend colour depending on which has the greater brightness value. Blending with white inverts the base colour values and blending with black produces no change.

Exclusion

Creates an effects similar to but lower in contrast than the difference mode. Blending with white inverts the base colour values. Blending with black produces no change.

Colour Dodge

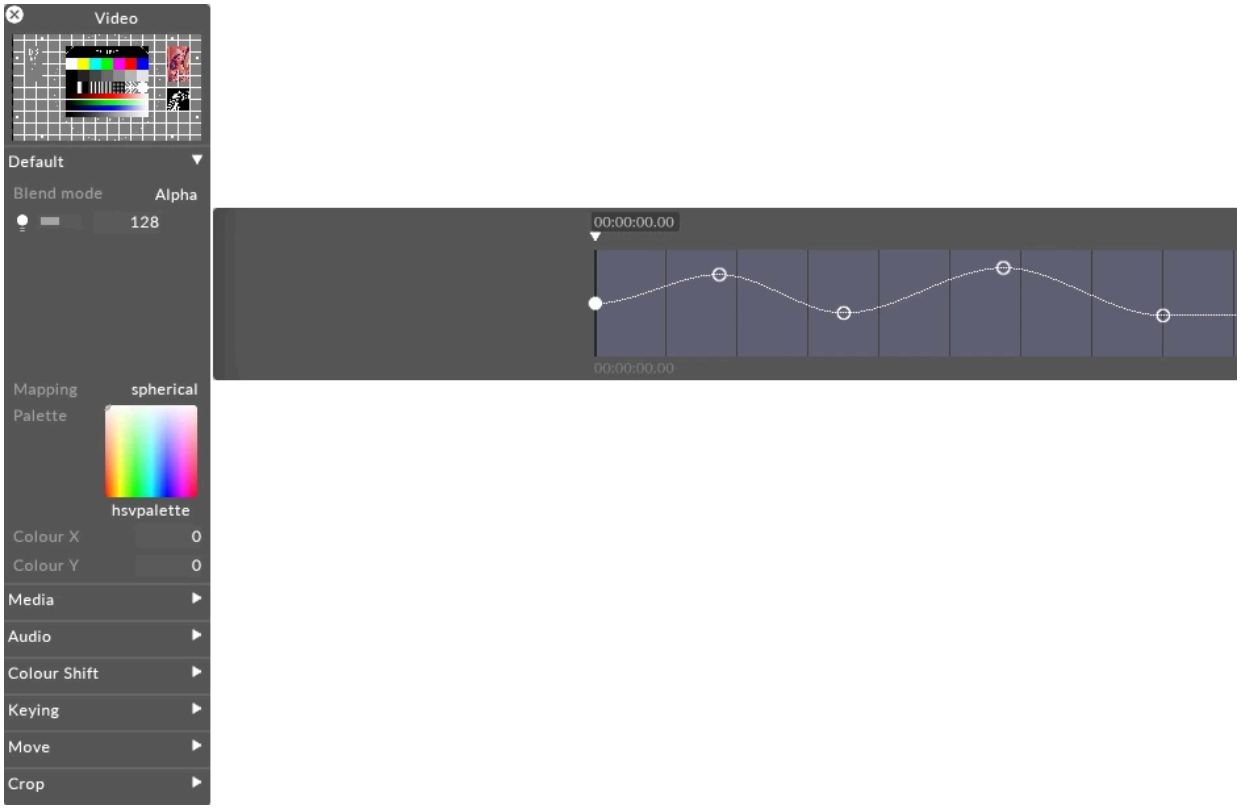
Looks at the colour information in each channel and brightens the base colour to reflect the blend colour by decreasing contrast between the two. Blending with black produces no change.

Hard Mix

Adds the RGB channels of the blend colour to the RGB values of the base colour. If the resulting sum for a channel is 255 or greater, it receives a value of 255; if it is less than 255 it receives a value of 0. Therefore all blended pixels have RGB channels of either 0 or 255. This changes all pixels to primary additive colours (RGB), white or black.

Brightness

This property (which appears as a light bulb icon) controls the brightness of the layer output.



If the layers blend mode is set to Alpha, then reducing the brightness to 0 also reduces the opacity of the layer to 0. This can be useful when you want to dissolve from one layer to the next. In that case, you can place the new layer above the old layer and increase its brightness level.

> **Note**
>
> Layers that are patched to Sockpuppet (DMX, OSC or HTTP) are made Dormant when their brightness is set to 0. This means they will not do any rendering or consume any resources until their brightness is changed to > 0. You can find more information about this here: **Sequencing with Sockpuppet**. Layers without a sockpuppet patch do not behave in this way.

Mapping

The mapping property controls how the layer output is mapped onto the screen(s) in the Stage level.

For information on mapping, including how to use the different mapping types offered by Designer, please see the chapter **Content Mapping**

OCIO Layer

The OCIO layer is an effect layer that applies a stacked list of OCIO transforms in an optimised manner. All supported OCIO transform types can be created, configured, and stacked to achieve a customised colour pipeline as needed.

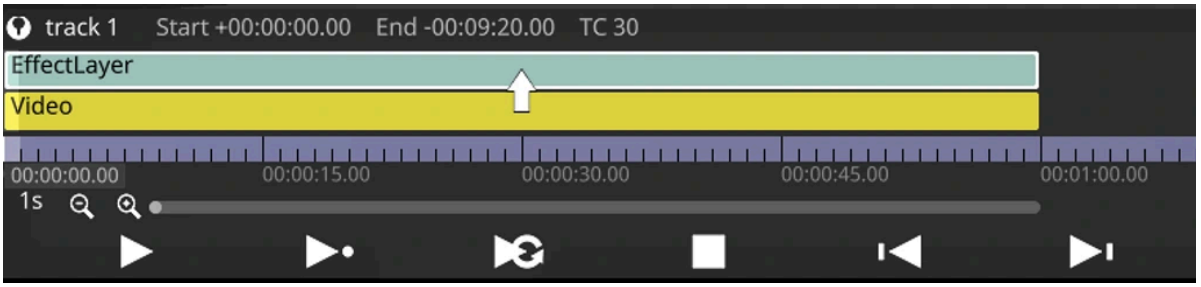
> **Note**
>
> For most simple cases we recommend using the standard OCIO workflow with an OCIO field on each component (e.g. **Input transform** in Video layer or **Output transform** in Display). See OCIO for further details.

Workflow

Effect layers receive their source from other layer types - either content or generative - through arrows. An arrow connects a source layer to a destination layer; the source layer is said to be “piped in” to the destination Effect layer. For more information on arrows, see the **compositing layers** topic.

To draw an arrow between two layers, hold down **ALT** and left-click & drag from the source layer to the destination layer.

1. Add an Effect layer to your track. For more information about adding layers, see **creating layers**.
2. Draw an arrow from your content layer to the Effect layer so the compositing order looks something like the following image.



A Video layer piped into an Effect layer on the timeline.

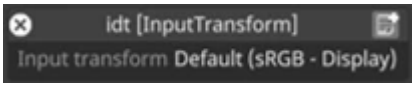
3. Adjust the Effect layer properties to achieve the desired result.

OCIO layer properties

OCIO transforms

The list of OCIO transforms to define the colour pipeline can be configured here. The order of the transforms matters, and it is bottom-to-top (the bottom of the list is applied first, and the top of the list is applied last). Each transform shows the order by index number as a prefix of the transform name, and the transform type is added as a postfix (e.g. `1. myTransform [ColourTransform]`). The transform is a `Resource` type, so you can create one and reuse it across other OCIO layers. Stacking duplicate OCIO transform resources in the OCIO layer is also allowed.

InputTransform



InputTransform applies a colour transform from the selected **Input transform** colour space into the currently selected **Working space** in the OCIO config (see OCIO Configs).

- **Input transform**: the source colour space to transform from.

OutputTransform

OutputTransform applies a colour transform from the currently selected **Working space** into the selected **Output transform** colour space in the OCIO config (see OCIO Configs).

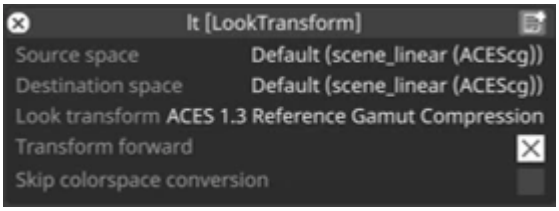
- **Output transform**: the destination colour space to transform to.

ColourSpaceTransform

ColourSpaceTransform applies a colour transform from the **Source colour space** to the **Destination colour space**.

- **Source colour space**: the source colour space to transform from.
- **Destination colour space**: the destination colour space to transform to.

LookTransform

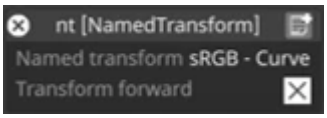


LookTransform applies a creative colour transform using a defined **look** from the OCIO config file. A look modifies the appearance of an image in a creative way, rather than performing a technical colour space conversion. It typically works alongside a viewing transform. For example, a look could be a neutral grade applied to film scans before VFX work, or a per-shot grade chosen by the director.

> See: OCIO's Looks Example

- **Source space**: source colour space to transform from.
- **Destination space**: destination colour space to transform to.
- **Look transform**: look transform to apply.
- **Transform forward**: transform from source space to destination if enabled, reversed direction if disabled.
- **Skip colourspace conversion**: skip the colour space transform if enabled.

NamedTransform



NamedTransform provides a set of colour transforms that are independent of the colour space being processed. For example, a utility curve transform where there is no need to convert to or from a reference space.

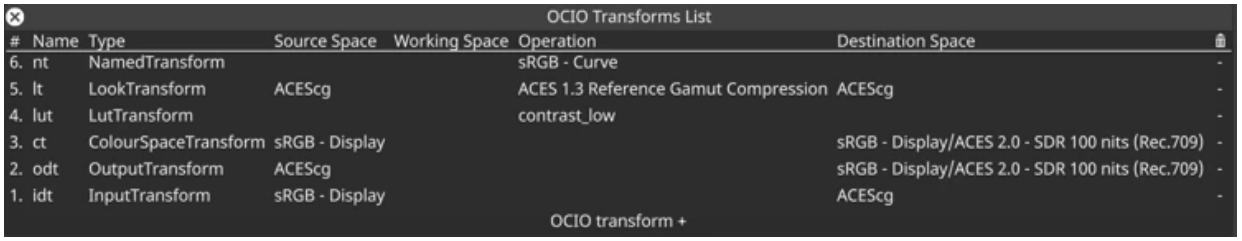
- **Named transform**: the named transform to apply.
- **Transform forward**: apply transform forward if enabled, inverted if disabled.

LutTransform

LutTransform allows applying a LUT between other OCIO transforms. The LUT file can be located like any other LUT in Designer (see LUT Layer). In addition to the traditional interpolation method of the LUT Layer in Designer, LutTransform offers various OCIO-supported methods.

- **LUT transform**: the LUT to apply, discovered from `objects/LutFile`
- **Transform forward**: apply LUT if enabled, apply inverse LUT if disabled.
- **Interpolation**: interpolation method to use:
  - `Nearest`: nearest neighbour
  - `Linear`: linear interpolation (trilinear for Lut3D)
  - `Tetrahedra`: tetrahedral interpolation (Lut3D only)
  - `Cubric`: cubic interpolation (not supported)
  - `Default`: the default interpolation type
  - `Best`: the 'best' suitable interpolation type

OCIO Transforms Lists



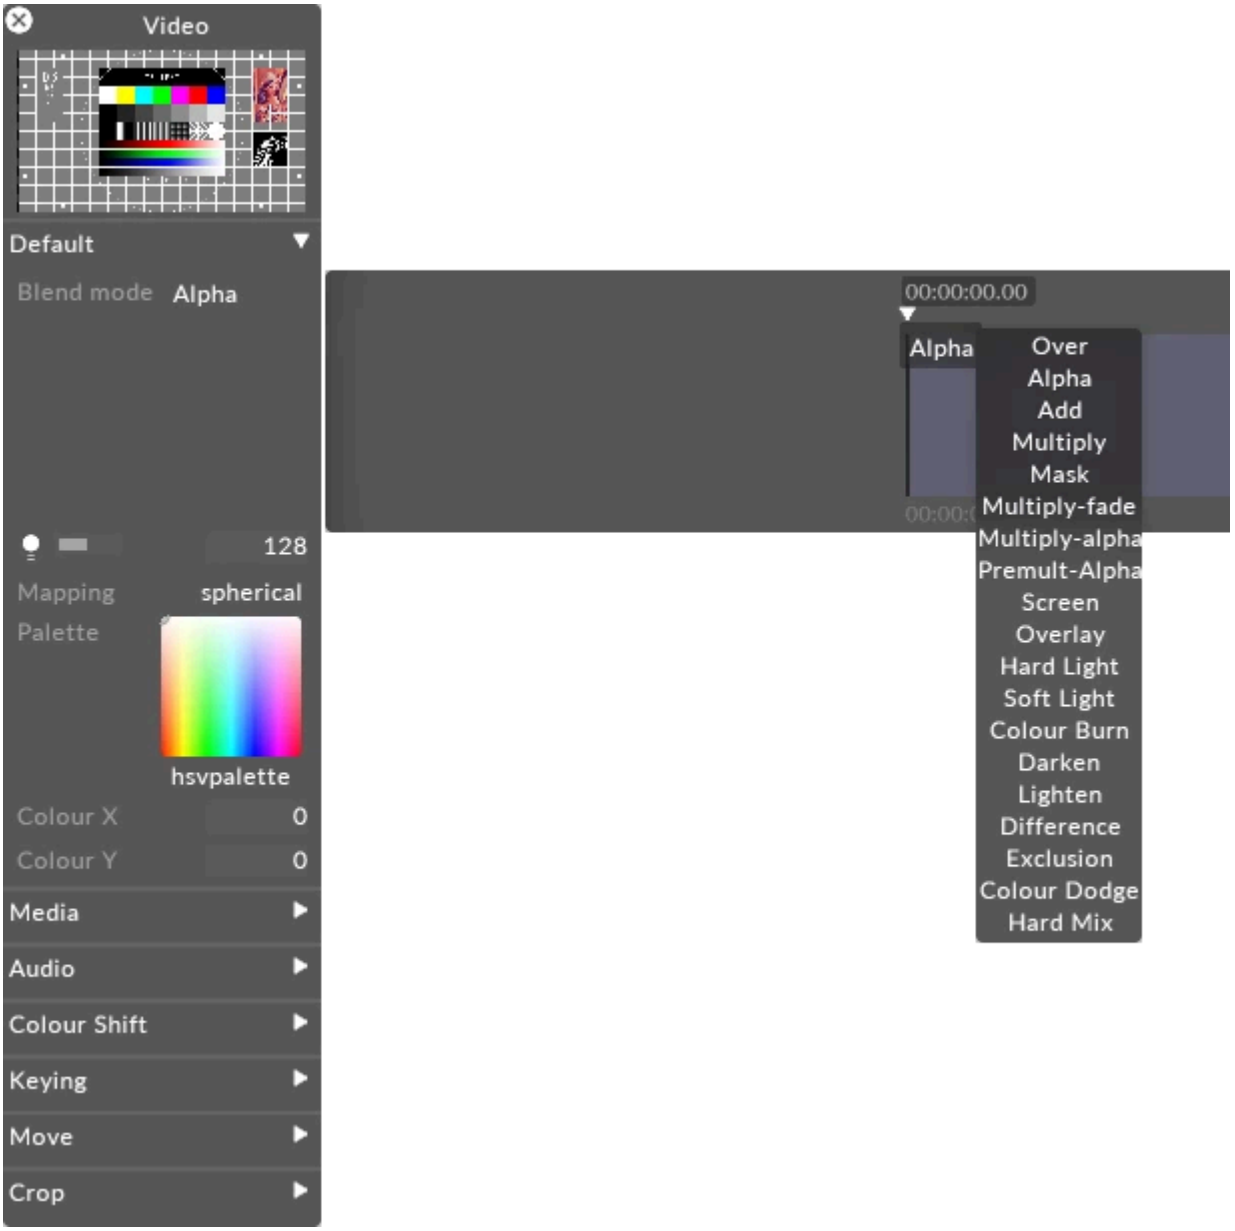
The OCIO transform table can be used to visualise and edit the list of OCIO transforms. There are a few actions you can use to edit your colour pipeline:

- Swap the order by dragging the transforms.
- Open the OCIO transform widget by right-clicking the row.
- Edit the transform element (e.g. source colour space) by left-clicking the field.
- Add a new OCIO transform by clicking **OCIO transform +**.
- Remove an OCIO transform by clicking the trash button **-**.

Common Layer Properties

Blend Mode

BlendMode controls how the output of the layer is composited with the layers below. Layers are rendered in a bottom-up order: layers at the top can modify the output of the layers below.



Changing brightness of a content layer in Designer is actually controlling the value of the alpha of the layer. Even when displaying a HAP video, the software will composite the layer with a controllable layer of alpha - one per layer.

There are two ways of expressing alpha in an image:

Straight alpha is an alpha channel which functions just like RGB. Alpha acts as a fourth channel of information per pixel which is as independent of the other three as R, G and B are of each other. For example, with straight alpha it is possible to have RGB = 255 (white) and alpha = 0 (fully transparent) on the same pixel. Internally generated content, such as gradient layer, are generated with straight alpha. This is the preferable style of alpha and considering the cleaner method of the two.

Premultiplied alpha takes the alpha and applies it to the values of the RGB channels per pixel. The more transparent something gets with premultiplied alpha, the closer it gets to black - as if the content is sitting on a black table. Premultiplied is the default output of Adobe Photoshop or AfterEffects. The result is our pixel at 255 RGB (full white) with 0 alpha would be calculated as a black pixel in the final image.

Here are explanations of what each individual blend mode will do.

Over

Makes a layer fully opaque. Premultiplies all alpha onto the RGB value of each pixel. Alpha = black, so adjusting the brightness of a layer in Over blend mode makes it darker.

Alpha

Default blend mode. It will apply alpha values as a transparency if the alpha is present. Brightness changes will make the layer more or less transparent.

Add

Adds the value of each RGB pixel together. Always creates a brighter result. Values clamp at 255.

Multiply

Reads the level of each subpixel as a level between 0.0 and 1.0, and multiplies source with blend. The result is always a darker image overall. For example: white x grey = 0.5. White turns transparent, black takes precedence. Alpha is applied in the same fashion as the Over Blend mode.

Mask

Applies a mask to the single layer **above** in the stack, irrespective of mapping. See **Mask blending** for more information.

Luma-Matte

This mode creates a Luma Matte by using a layer's **Rec. 709 luminance** to control the alpha channel of the layer **above**, irrespective of mapping.

To determine transparency, the luminance of each pixel is calculated using a weighted average of its red, green, and blue channels. The luminance value is then used as the alpha (opacity) value for the corresponding pixels in the upper layers.

As a result, white areas render the layer above fully opaque, black areas make them fully transparent, and grey areas create proportional semi-transparency. This is a specialized **Mask** blend mode; for more details on the underlying behaviour, see **Mask blending**.

Inv-Luma-Matte

The Inverse Luma Matte mask works the same as the **Luma Matte** mask but the transparency is inverted meaning white regions are transparent and black regions are opaque.

Multiply-Fade

The same as Multiply, but will make use of the alpha channel to calculate transparency in the source and blend layers. Since maximum transparency is premultiplied, alpha results in black. This will ignore black created through premultiplying.

Multiply-Alpha

Multiply with straight alpha. This mode assumes that the alpha has not been premultiplied onto the RGB values and will not apply a correction to the semi-transparent pixels.

Premultiply Alpha

Like how Multiply-fade will ignore the darkening caused by premultiplying, this blend mode will do the same with Alpha.

Colour Burn

Blend mode increases the contrast to darken the base colour while reflecting the blend colour. The darker the blend colour, the more intensely the colour will be applied in the base image. White as the blend colour produces no change. Using the colour burn blend mode can produce some harsh results at full opacity. The colour burn blend mode can be used to make tonal and colour adjustments to a layer.

Screen

This blend mode looks at each channels colour information and multiplies the inverse of the blend and base colous. The result is always a lighter colour. Screening with black leaves the colour unchanged. Screening with white produces white. The effect is similar to projecting multiple images on top of each other - where bright white is fully opaque, black is fully transparent and 50% grey is 50% transparent.

Overlay

Multiplies or screens the colours, depending on the base colour. Patterns or colours overlay the existing pixels while preserving the highlights and shadows of the base colour. The base colour is not replaced, but mixed with the blend colour to reflect the lightness or darkness of the original colour.

Hard Light

Multiplies or screens the colours, depending on the blend colour. The effects is similar to shining a harsh spotlight on the image. If the blend colour (light source/top layer) is lighter than

50% grey, the image is lightened as if it were screened. This is useful for adding highlights to an image. If the blend colour is darker than 50% grey, the image is darkened as if it were multiplied. This is useful for adding shadows to an image. Painting with pure black or white results in pure black or white.

Soft Light

Darkens or lightens the colours, depending on the blend colour. The effect is similar to shining a diffused spotlight on the image. If the blend colour (light source/top layer) is lighter than 50% grey, the image is lightened as it if were dodged. If the blend colour is darker than 50% grey, the image is darkened as if it were burned in. Painting with pure black or white produces a distinctly darker or lighter area, but does not result in pure black or white.

Darken

Looks as the colour information in each channel and selects the base or blend colour - whichever is darker - as the result colour. Pixels lighter than the blend colour are replaced and pixels darker than the blend colour do not change.

Lighten

Looks at the colour information in each channel and selects the base or blend colour - whichever is lighter - as the result colour. Pixels darker than the blend colour are replaced and pixels lighter than the blend colour do not change.

Difference

Looks at the colour information in each channel and subtracts either the blend colour from the base colour or the base colour from the blend colour depending on which has the greater brightness value. Blending with white inverts the base colour values and blending with black produces no change.

Exclusion

Creates an effects similar to but lower in contrast than the difference mode. Blending with white inverts the base colour values. Blending with black produces no change.

Colour Dodge

Looks at the colour information in each channel and brightens the base colour to reflect the blend colour by decreasing contrast between the two. Blending with black produces no change.

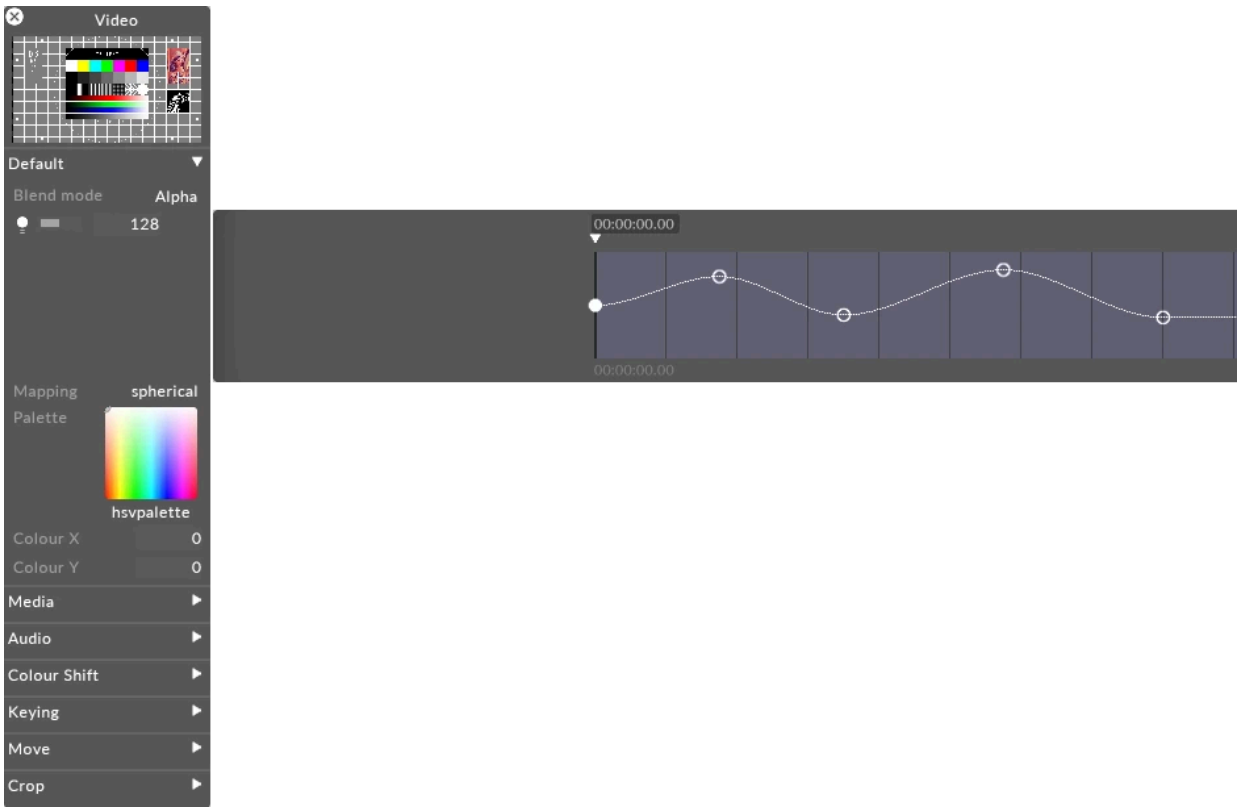
Hard Mix

Adds the RGB channels of the blend colour to the RGB values of the base colour. If the resulting sum for a channel is 255 or greater, it receives a value of 255; if it is less than 255 it

receives a value of 0. Therefore all blended pixels have RGB channels of either 0 or 255. This changes all pixels to primary additive colours (RGB), white or black.

Brightness

This property (which appears as a light bulb icon) controls the brightness of the layer output.



If the layers blend mode is set to Alpha, then reducing the brightness to 0 also reduces the opacity of the layer to 0. This can be useful when you want to dissolve from one layer to the next. In that case, you can place the new layer above the old layer and increase its brightness level.

> **Note**
>
> Layers that are patched to Sockpuppet (DMX, OSC or HTTP) are made Dormant when their brightness is set to 0. This means they will not do any rendering or consume any resources until their brightness is changed to > 0. You can find more information about this here: **Sequencing with Sockpuppet**. Layers without a sockpuppet patch do not behave in this way.

Mapping

The mapping property controls how the layer output is mapped onto the screen(s) in the Stage level.

For information on mapping, including how to use the different mapping types offered by Designer, please see the chapter **Content Mapping**

Pixelate Layer

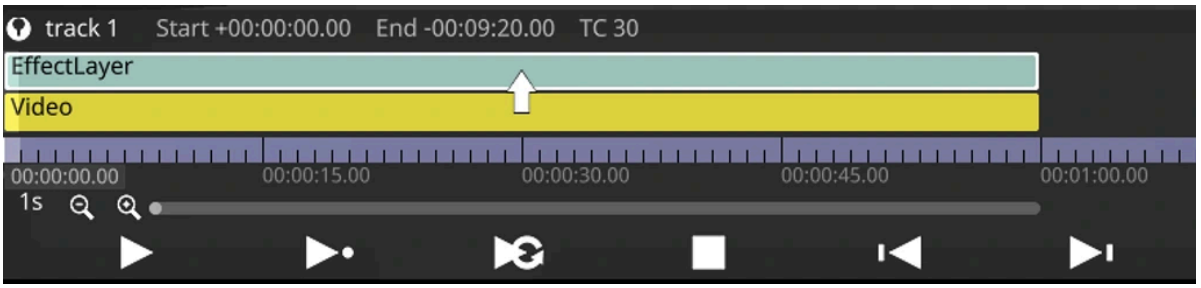
The Pixelate layer supports the use of Arrows, allowing content layers to be piped into the Pixelate layer.

Workflow

Effect layers receive their source from other layer types - either content or generative - through arrows. An arrow connects a source layer to a destination layer; the source layer is said to be “piped in” to the destination Effect layer. For more information on arrows, see the **compositing layers** topic.

To draw an arrow between two layers, hold down **ALT** and left-click & drag from the source layer to the destination layer.

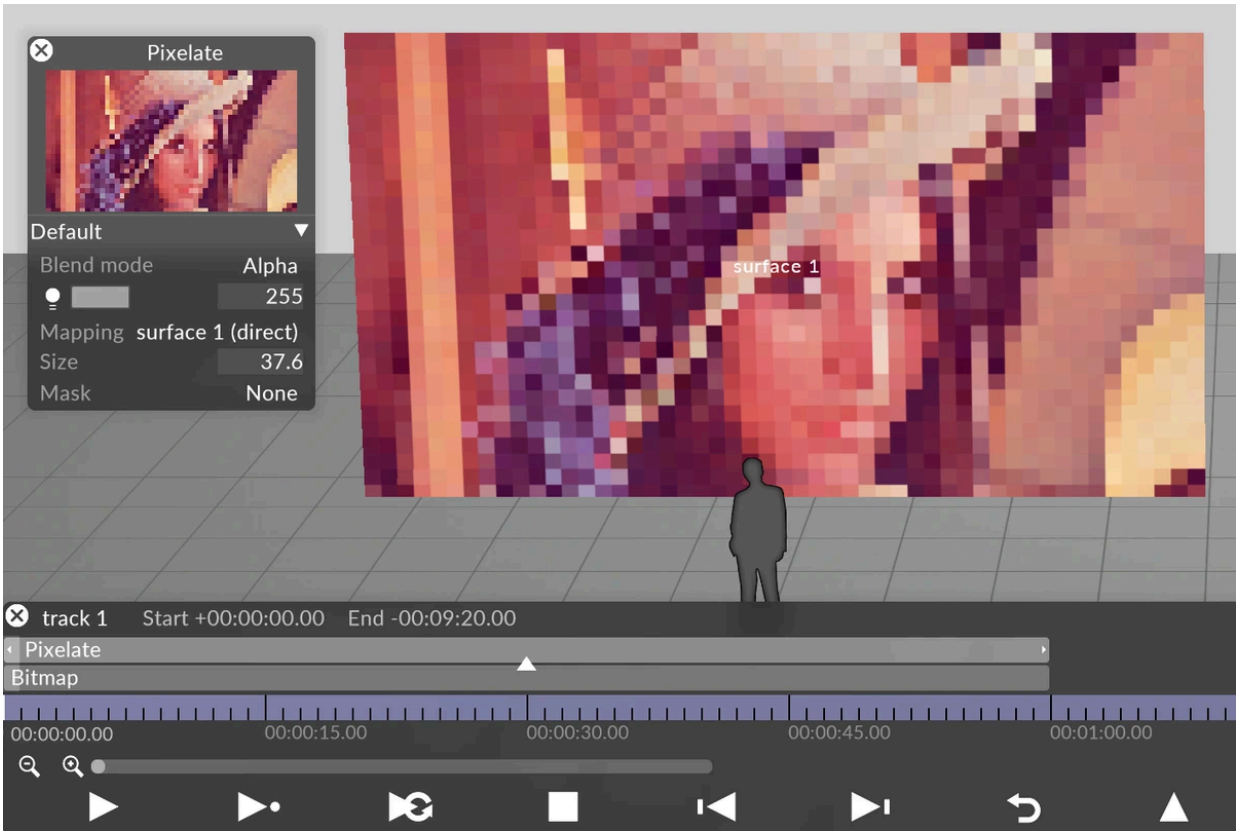
1. Add an Effect layer to your track. For more information about adding layers, see **creating layers**.
2. Draw an arrow from your content layer to the Effect layer so the compositing order looks something like the following image.



A Video layer piped into an Effect layer on the timeline.

3. Adjust the Effect layer properties to achieve the desired result.

Pixelate Layer Properties



Pixelate layer and editor

Size

The size of each pixel.

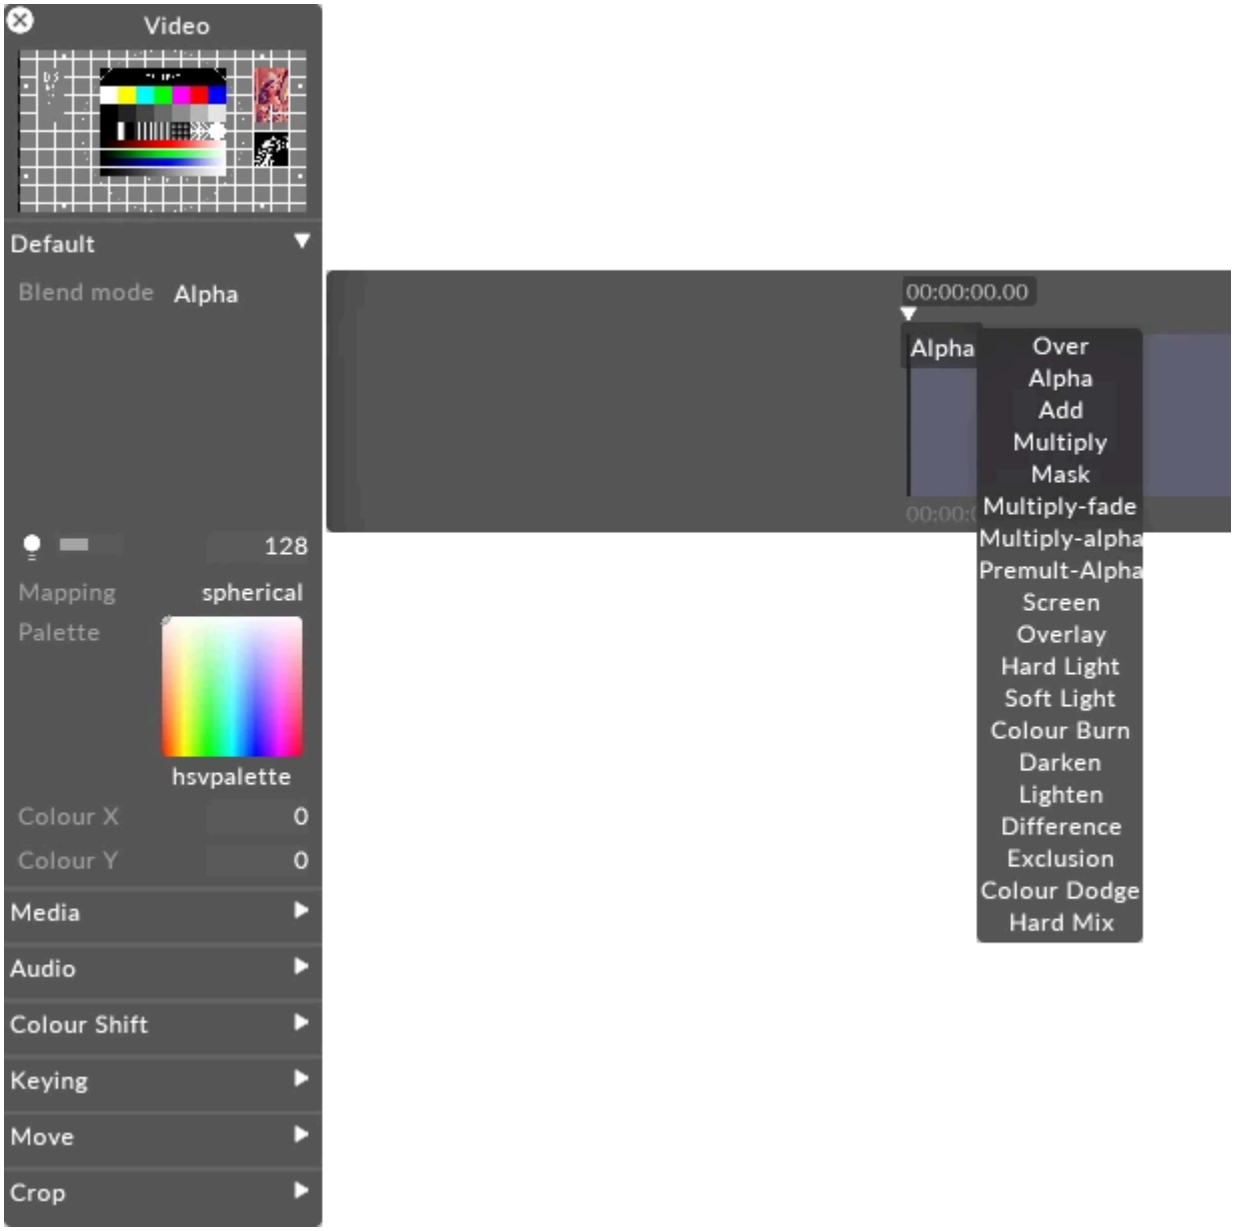
Mask

Optional bitmap to mask the pixelate effect.

Common Layer Properties

Blend Mode

BlendMode controls how the output of the layer is composited with the layers below. Layers are rendered in a bottom-up order: layers at the top can modify the output of the layers below.



Changing brightness of a content layer in Designer is actually controlling the value of the alpha of the layer. Even when displaying a HAP video, the software will composite the layer with a controllable layer of alpha - one per layer.

There are two ways of expressing alpha in an image:

Straight alpha is an alpha channel which functions just like RGB. Alpha acts as a fourth channel of information per pixel which is as independent of the other three as R, G and B are of each other. For example, with straight alpha it is possible to have RGB = 255 (white) and alpha = 0 (fully transparent) on the same pixel. Internally generated content, such as gradient layer, are generated with straight alpha. This is the preferable style of alpha and considering the cleaner method of the two.

Premultiplied alpha takes the alpha and applies it to the values of the RGB channels per pixel. The more transparent something gets with premultiplied alpha, the closer it gets to black - as if the content is sitting on a black table. Premultiplied is the default output of Adobe Photoshop or AfterEffects. The result is our pixel at 255 RGB (full white) with 0 alpha would be calculated as a black pixel in the final image.

Here are explanations of what each individual blend mode will do.

Over

Makes a layer fully opaque. Premultiplies all alpha onto the RGB value of each pixel. Alpha = black, so adjusting the brightness of a layer in Over blend mode makes it darker.

Alpha

Default blend mode. It will apply alpha values as a transparency if the alpha is present. Brightness changes will make the layer more or less transparent.

Add

Adds the value of each RGB pixel together. Always creates a brighter result. Values clamp at 255.

Multiply

Reads the level of each subpixel as a level between 0.0 and 1.0, and multiplies source with blend. The result is always a darker image overall. For example: white x grey = 0.5. White turns transparent, black takes precedence. Alpha is applied in the same fashion as the Over Blend mode.

Mask

Applies a mask to the single layer **above** in the stack, irrespective of mapping. See **Mask blending** for more information.

Luma-Matte

This mode creates a Luma Matte by using a layer's **Rec. 709 luminance** to control the alpha channel of the layer **above**, irrespective of mapping.

To determine transparency, the luminance of each pixel is calculated using a weighted average of its red, green, and blue channels. The luminance value is then used as the alpha (opacity) value for the corresponding pixels in the upper layers.

As a result, white areas render the layer above fully opaque, black areas make them fully transparent, and grey areas create proportional semi-transparency. This is a specialized **Mask** blend mode; for more details on the underlying behaviour, see **Mask blending**.

Inv-Luma-Matte

The Inverse Luma Matte mask works the same as the **Luma Matte** mask but the transparency is inverted meaning white regions are transparent and black regions are opaque.

Multiply-Fade

The same as Multiply, but will make use of the alpha channel to calculate transparency in the source and blend layers. Since maximum transparency is premultiplied, alpha results in black. This will ignore black created through premultiplying.

Multiply-Alpha

Multiply with straight alpha. This mode assumes that the alpha has not been premultiplied onto the RGB values and will not apply a correction to the semi-transparent pixels.

Premultiply Alpha

Like how Multiply-fade will ignore the darkening caused by premultiplying, this blend mode will do the same with Alpha.

Colour Burn

Blend mode increases the contrast to darken the base colour while reflecting the blend colour. The darker the blend colour, the more intensely the colour will be applied in the base image. White as the blend colour produces no change. Using the colour burn blend mode can produce some harsh results at full opacity. The colour burn blend mode can be used to make tonal and colour adjustments to a layer.

Screen

This blend mode looks at each channels colour information and multiplies the inverse of the blend and base colous. The result is always a lighter colour. Screening with black leaves the colour unchanged. Screening with white produces white. The effect is similar to projecting multiple images on top of each other - where bright white is fully opaque, black is fully transparent and 50% grey is 50% transparent.

Overlay

Multiplies or screens the colours, depending on the base colour. Patterns or colours overlay the existing pixels while preserving the highlights and shadows of the base colour. The base colour is not replaced, but mixed with the blend colour to reflect the lightness or darkness of the original colour.

Hard Light

Multiplies or screens the colours, depending on the blend colour. The effects is similar to shining a harsh spotlight on the image. If the blend colour (light source/top layer) is lighter than

50% grey, the image is lightened as if it were screened. This is useful for adding highlights to an image. If the blend colour is darker than 50% grey, the image is darkened as if it were multiplied. This is useful for adding shadows to an image. Painting with pure black or white results in pure black or white.

Soft Light

Darkens or lightens the colours, depending on the blend colour. The effect is similar to shining a diffused spotlight on the image. If the blend colour (light source/top layer) is lighter than 50% grey, the image is lightened as it if were dodged. If the blend colour is darker than 50% grey, the image is darkened as if it were burned in. Painting with pure black or white produces a distinctly darker or lighter area, but does not result in pure black or white.

Darken

Looks as the colour information in each channel and selects the base or blend colour - whichever is darker - as the result colour. Pixels lighter than the blend colour are replaced and pixels darker than the blend colour do not change.

Lighten

Looks at the colour information in each channel and selects the base or blend colour - whichever is lighter - as the result colour. Pixels darker than the blend colour are replaced and pixels lighter than the blend colour do not change.

Difference

Looks at the colour information in each channel and subtracts either the blend colour from the base colour or the base colour from the blend colour depending on which has the greater brightness value. Blending with white inverts the base colour values and blending with black produces no change.

Exclusion

Creates an effects similar to but lower in contrast than the difference mode. Blending with white inverts the base colour values. Blending with black produces no change.

Colour Dodge

Looks at the colour information in each channel and brightens the base colour to reflect the blend colour by decreasing contrast between the two. Blending with black produces no change.

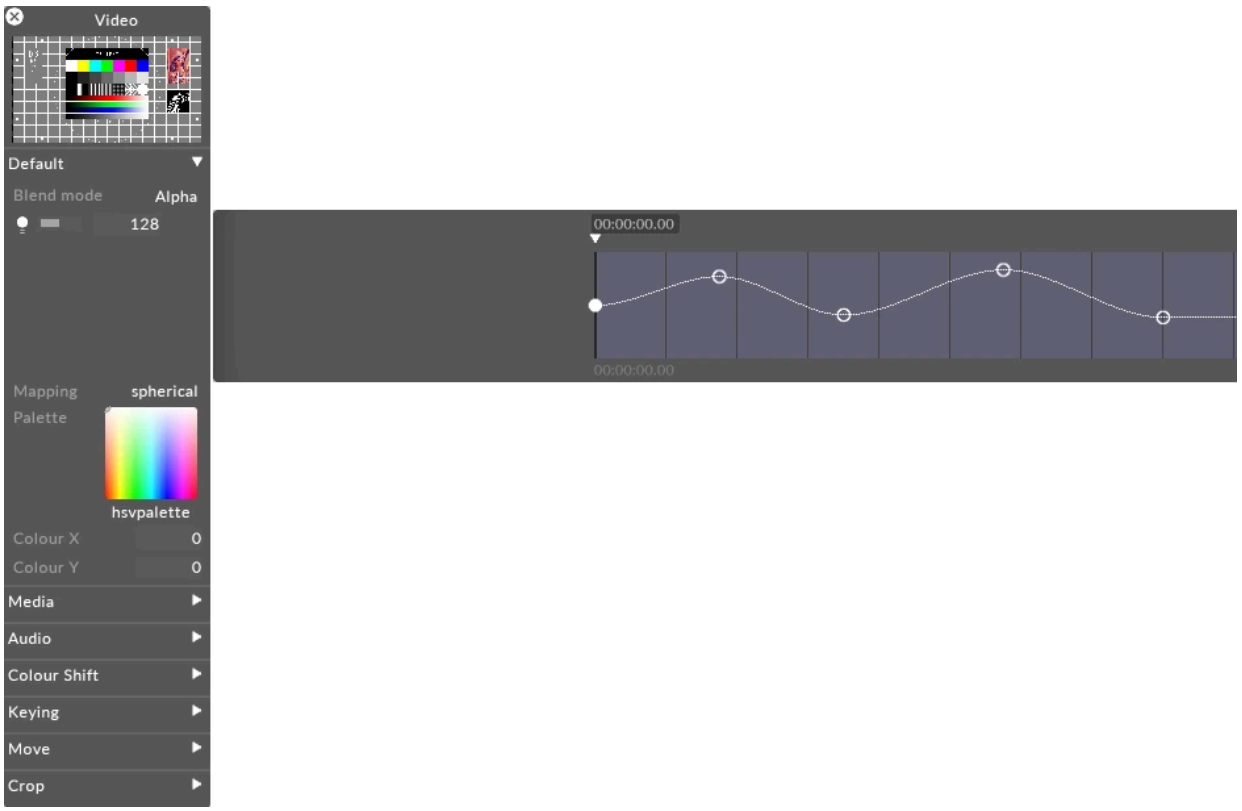
Hard Mix

Adds the RGB channels of the blend colour to the RGB values of the base colour. If the resulting sum for a channel is 255 or greater, it receives a value of 255; if it is less than 255 it

receives a value of 0. Therefore all blended pixels have RGB channels of either 0 or 255. This changes all pixels to primary additive colours (RGB), white or black.

Brightness

This property (which appears as a light bulb icon) controls the brightness of the layer output.



If the layers blend mode is set to Alpha, then reducing the brightness to 0 also reduces the opacity of the layer to 0. This can be useful when you want to dissolve from one layer to the next. In that case, you can place the new layer above the old layer and increase its brightness level.

> **Note**
>
> Layers that are patched to Sockpuppet (DMX, OSC or HTTP) are made Dormant when their brightness is set to 0. This means they will not do any rendering or consume any resources until their brightness is changed to > 0. You can find more information about this here: **Sequencing with Sockpuppet**. Layers without a sockpuppet patch do not behave in this way.

Mapping

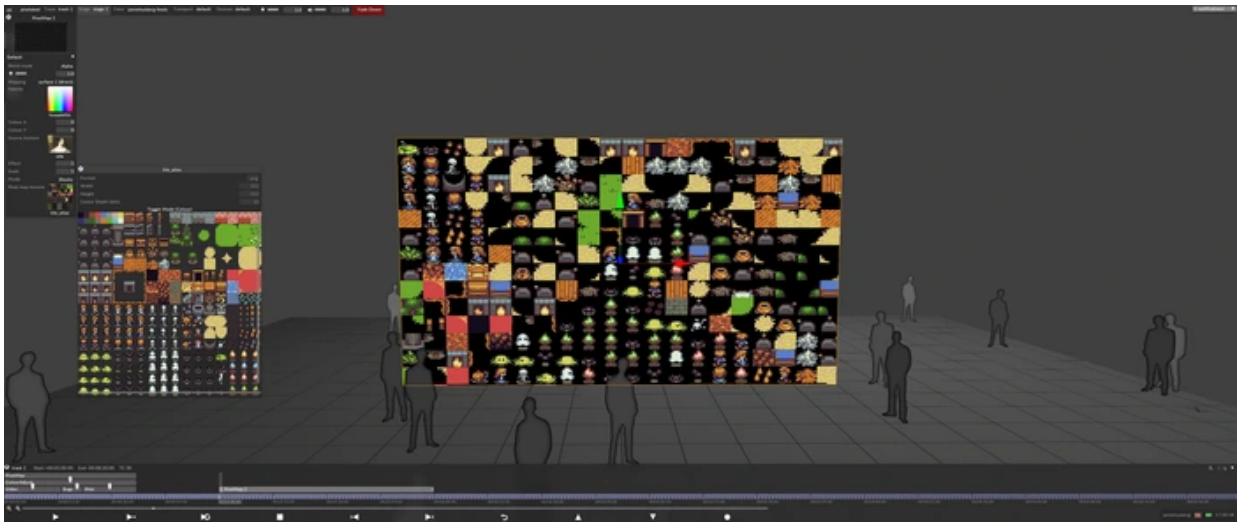
The mapping property controls how the layer output is mapped onto the screen(s) in the Stage level.

For information on mapping, including how to use the different mapping types offered by Designer, please see the chapter **Content Mapping**

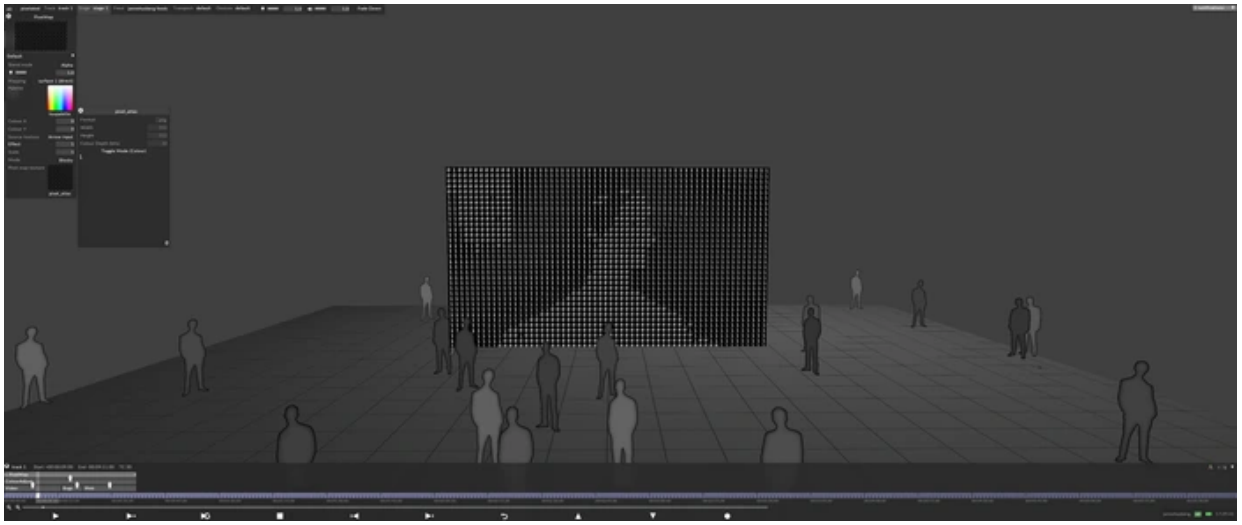
Pixelmap Layer

The PixelMap layer allows for a pixelmap input to be used to create a pixelating effect. The pixel map can be created from an external program, for example Photoshop, allowing you to create and customise your own pixel maps.

The **Pixelmap** EEffect layer is used to create a pixelating effect that is based on the input of a pixelmap. The pixelmap determines the tile atlas for the max value of each pixelated pixel which is fixed to a 16 x 16 grid.



pixel atlas



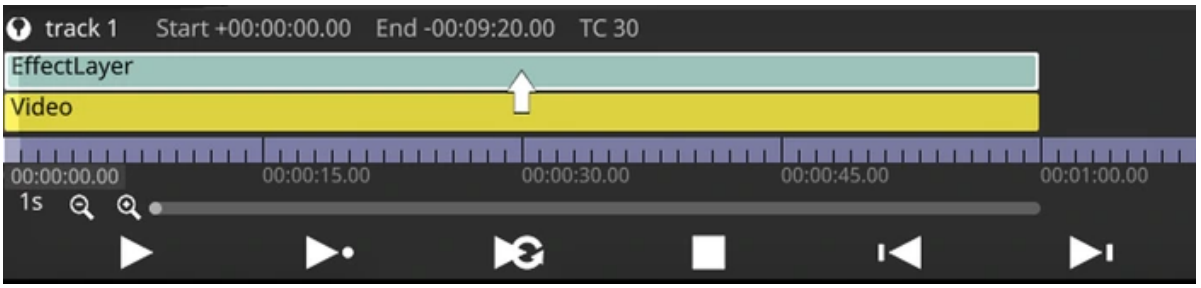
tile atlas

Workflow

Effect layers receive their source from other layer types - either content or generative - through arrows. An arrow connects a source layer to a destination layer; the source layer is said to be “piped in” to the destination Effect layer. For more information on arrows, see the **compositing layers** topic.

To draw an arrow between two layers, hold down **ALT** and left-click & drag from the source layer to the destination layer.

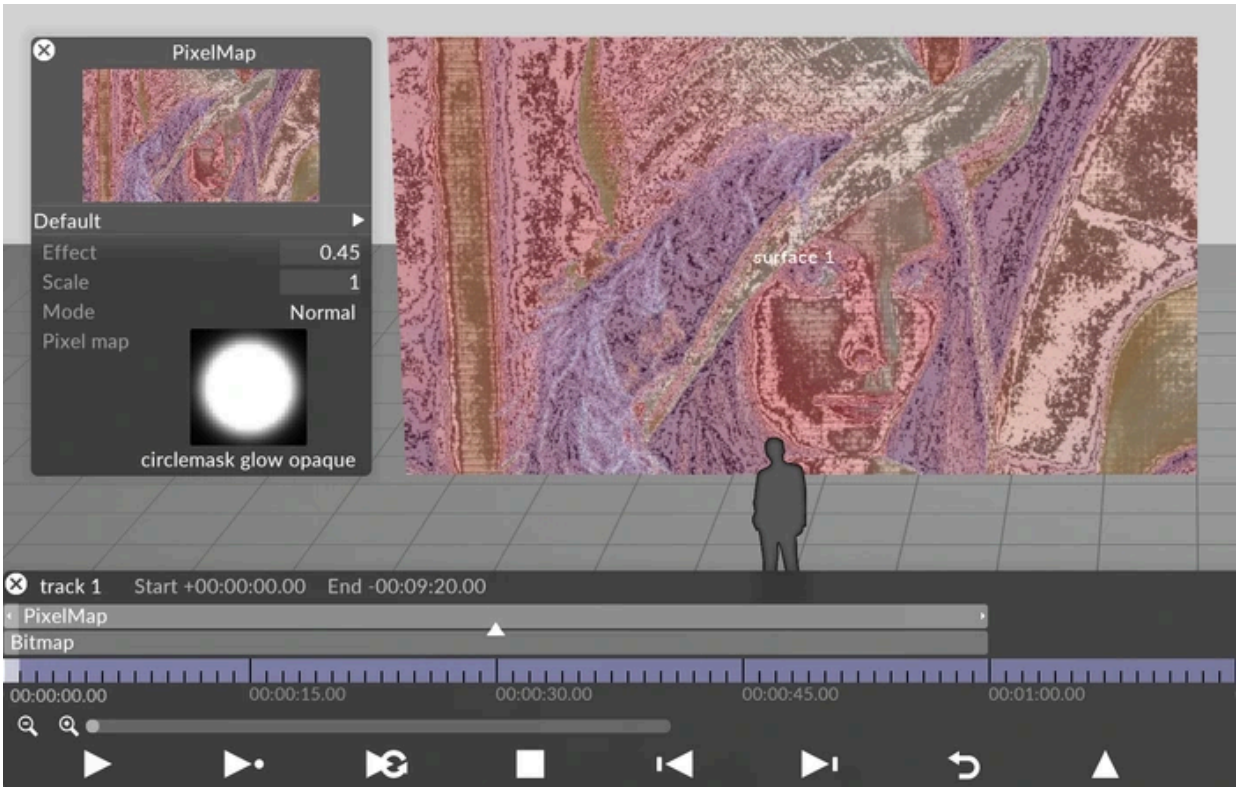
1. Add an Effect layer to your track. For more information about adding layers, see **creating layers**.
2. Draw an arrow from your content layer to the Effect layer so the compositing order looks something like the following image.



A Video layer piped into an Effect layer on the timeline.

3. Adjust the Effect layer properties to achieve the desired result.

PixelMap Layer Properties



The **Pixelmap** Effect layer is used to create a pixelating effect that is based on the input of a pixelmap. The pixelmap determines the tile atlas for the max value of each pixelated pixel, which is fixed to a 16 x 16 grid.

Effect

Default value is 1. The min/max values are 0 (no effect) and 1 (maximum effect). Decreasing the value from 1 to 0 will reduce the effect of the Pixel map on the content.

Scale

Default value is 1. The min/max values are 1 and 16. Increasing the value from 1 to 16 will increase the size of the Pixel map by a specific scale factor. For example, a value of two means the PixelMaps width and height will double, a value of three means the Pixel maps width and height will triple etc.

Mode

- **Normal**
- **Blocky**

Creating a PixelMap

This points to the still image file that defines the PixelMap. Selecting this property will open the Texture object library, which shows all of the Texture still image files saved on your local hard drive in the **DxTexture** folder. However, before placing a Pixel map you will need to create it.

To create a Pixel map:

1. Create a .png image using a program such as Adobe Photoshop. The Pixel map can only be increased by a maximum scale factor of sixteen, so if it is going to be applied to the whole screen, make sure the Pixel maps resolution is high enough.
2. Make the areas to be see-through in the screen see-through in the Pixel map.
3. Make the areas to be illuminated in the screen white in the Pixel map.
4. Make the areas to be black in the screen black in the Pixel map.

See the Placing media files for a project sub-chapter to understand where to place a custom still image file and how to access it in Designer Also, save the file to a supported file format.

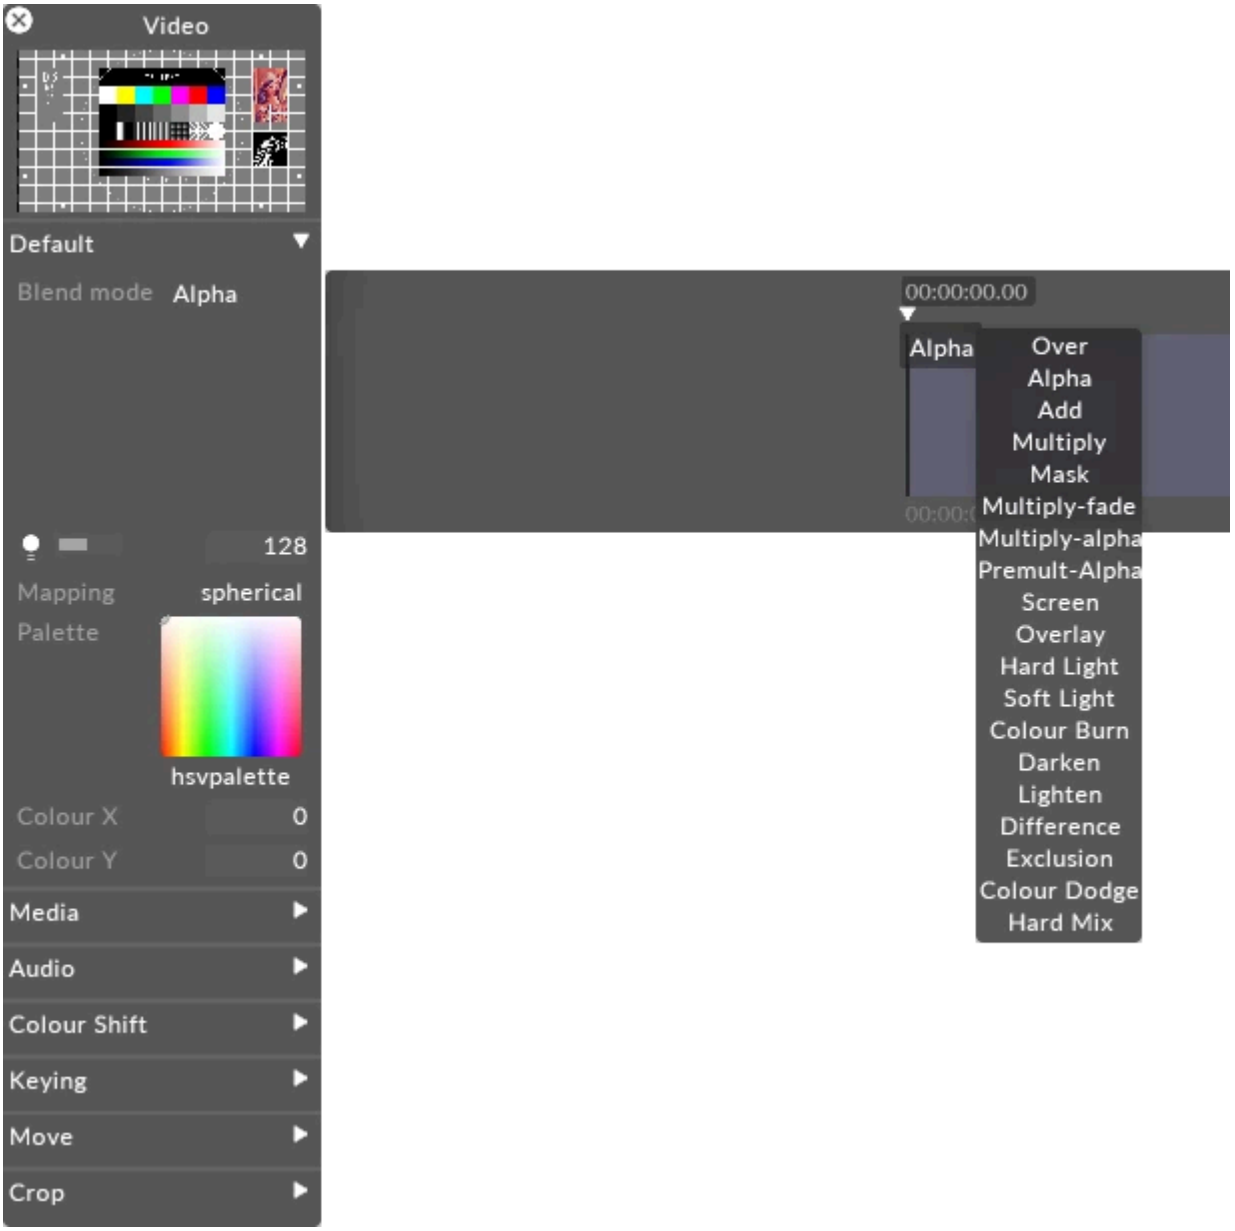
The Pixel map will be applied to the screen on a pixel-by-pixel basis. Placing media files for a project sub-chapter to understand where to place a custom still image file and how to access it. Also, save the file to a supported file format.

The Pixel map will be applied to the screen on a pixel-by-pixel basis.

Common Layer Properties

Blend Mode

BlendMode controls how the output of the layer is composited with the layers below. Layers are rendered in a bottom-up order: layers at the top can modify the output of the layers below.



Changing brightness of a content layer in Designer is actually controlling the value of the alpha of the layer. Even when displaying a HAP video, the software will composite the layer with a controllable layer of alpha - one per layer.

There are two ways of expressing alpha in an image:

Straight alpha is an alpha channel which functions just like RGB. Alpha acts as a fourth channel of information per pixel which is as independent of the other three as R, G and B are of each other. For example, with straight alpha it is possible to have RGB = 255 (white) and alpha = 0 (fully transparent) on the same pixel. Internally generated content, such as gradient layer, are generated with straight alpha. This is the preferable style of alpha and considering the cleaner method of the two.

Premultiplied alpha takes the alpha and applies it to the values of the RGB channels per pixel. The more transparent something gets with premultiplied alpha, the closer it gets to black - as if the content is sitting on a black table. Premultiplied is the default output of Adobe Photoshop or AfterEffects. The result is our pixel at 255 RGB (full white) with 0 alpha would be calculated as a black pixel in the final image.

Here are explanations of what each individual blend mode will do.

Over

Makes a layer fully opaque. Premultiplies all alpha onto the RGB value of each pixel. Alpha = black, so adjusting the brightness of a layer in Over blend mode makes it darker.

Alpha

Default blend mode. It will apply alpha values as a transparency if the alpha is present. Brightness changes will make the layer more or less transparent.

Add

Adds the value of each RGB pixel together. Always creates a brighter result. Values clamp at 255.

Multiply

Reads the level of each subpixel as a level between 0.0 and 1.0, and multiplies source with blend. The result is always a darker image overall. For example: white x grey = 0.5. White turns transparent, black takes precedence. Alpha is applied in the same fashion as the Over Blend mode.

Mask

Applies a mask to the single layer **above** in the stack, irrespective of mapping. See **Mask blending** for more information.

Luma-Matte

This mode creates a Luma Matte by using a layer's **Rec. 709 luminance** to control the alpha channel of the layer **above**, irrespective of mapping.

To determine transparency, the luminance of each pixel is calculated using a weighted average of its red, green, and blue channels. The luminance value is then used as the alpha (opacity) value for the corresponding pixels in the upper layers.

As a result, white areas render the layer above fully opaque, black areas make them fully transparent, and grey areas create proportional semi-transparency. This is a specialized **Mask** blend mode; for more details on the underlying behaviour, see **Mask blending**.

Inv-Luma-Matte

The Inverse Luma Matte mask works the same as the **Luma Matte** mask but the transparency is inverted meaning white regions are transparent and black regions are opaque.

Multiply-Fade

The same as Multiply, but will make use of the alpha channel to calculate transparency in the source and blend layers. Since maximum transparency is premultiplied, alpha results in black. This will ignore black created through premultiplying.

Multiply-Alpha

Multiply with straight alpha. This mode assumes that the alpha has not been premultiplied onto the RGB values and will not apply a correction to the semi-transparent pixels.

Premultiply Alpha

Like how Multiply-fade will ignore the darkening caused by premultiplying, this blend mode will do the same with Alpha.

Colour Burn

Blend mode increases the contrast to darken the base colour while reflecting the blend colour. The darker the blend colour, the more intensely the colour will be applied in the base image. White as the blend colour produces no change. Using the colour burn blend mode can produce some harsh results at full opacity. The colour burn blend mode can be used to make tonal and colour adjustments to a layer.

Screen

This blend mode looks at each channels colour information and multiplies the inverse of the blend and base colous. The result is always a lighter colour. Screening with black leaves the colour unchanged. Screening with white produces white. The effect is similar to projecting multiple images on top of each other - where bright white is fully opaque, black is fully transparent and 50% grey is 50% transparent.

Overlay

Multiplies or screens the colours, depending on the base colour. Patterns or colours overlay the existing pixels while preserving the highlights and shadows of the base colour. The base colour is not replaced, but mixed with the blend colour to reflect the lightness or darkness of the original colour.

Hard Light

Multiplies or screens the colours, depending on the blend colour. The effects is similar to shining a harsh spotlight on the image. If the blend colour (light source/top layer) is lighter than

50% grey, the image is lightened as if it were screened. This is useful for adding highlights to an image. If the blend colour is darker than 50% grey, the image is darkened as if it were multiplied. This is useful for adding shadows to an image. Painting with pure black or white results in pure black or white.

Soft Light

Darkens or lightens the colours, depending on the blend colour. The effect is similar to shining a diffused spotlight on the image. If the blend colour (light source/top layer) is lighter than 50% grey, the image is lightened as it if were dodged. If the blend colour is darker than 50% grey, the image is darkened as if it were burned in. Painting with pure black or white produces a distinctly darker or lighter area, but does not result in pure black or white.

Darken

Looks as the colour information in each channel and selects the base or blend colour - whichever is darker - as the result colour. Pixels lighter than the blend colour are replaced and pixels darker than the blend colour do not change.

Lighten

Looks at the colour information in each channel and selects the base or blend colour - whichever is lighter - as the result colour. Pixels darker than the blend colour are replaced and pixels lighter than the blend colour do not change.

Difference

Looks at the colour information in each channel and subtracts either the blend colour from the base colour or the base colour from the blend colour depending on which has the greater brightness value. Blending with white inverts the base colour values and blending with black produces no change.

Exclusion

Creates an effects similar to but lower in contrast than the difference mode. Blending with white inverts the base colour values. Blending with black produces no change.

Colour Dodge

Looks at the colour information in each channel and brightens the base colour to reflect the blend colour by decreasing contrast between the two. Blending with black produces no change.

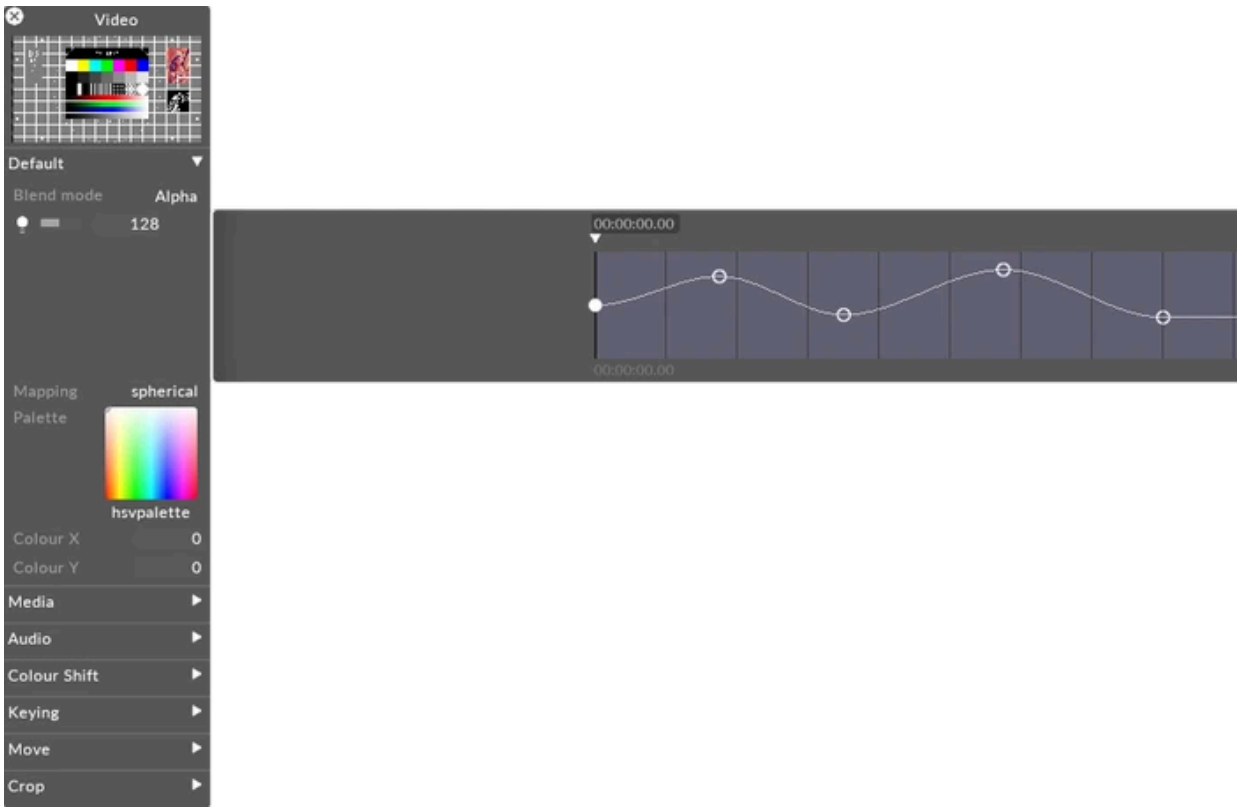
Hard Mix

Adds the RGB channels of the blend colour to the RGB values of the base colour. If the resulting sum for a channel is 255 or greater, it receives a value of 255; if it is less than 255 it

receives a value of 0. Therefore all blended pixels have RGB channels of either 0 or 255. This changes all pixels to primary additive colours (RGB), white or black.

Brightness

This property (which appears as a light bulb icon) controls the brightness of the layer output.



If the layers blend mode is set to Alpha, then reducing the brightness to 0 also reduces the opacity of the layer to 0. This can be useful when you want to dissolve from one layer to the next. In that case, you can place the new layer above the old layer and increase its brightness level.

> **Note**
>
> Layers that are patched to Sockpuppet (DMX, OSC or HTTP) are made Dormant when their brightness is set to 0. This means they will not do any rendering or consume any resources until their brightness is changed to > 0. You can find more information about this here: **Sequencing with Sockpuppet**. Layers without a sockpuppet patch do not behave in this way.

Mapping

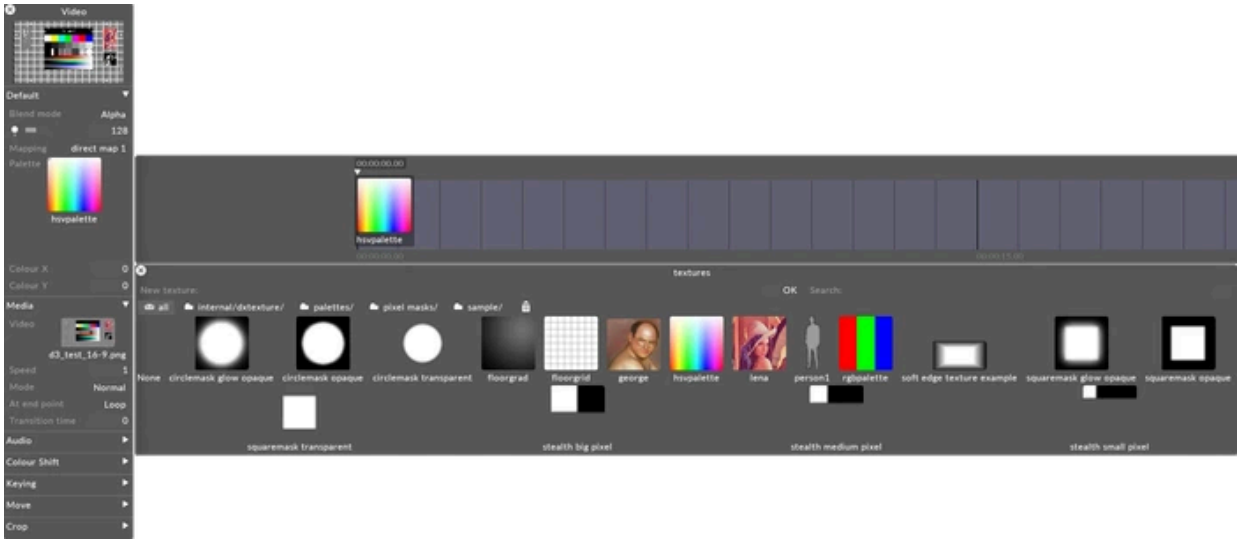
The mapping property controls how the layer output is mapped onto the screen(s) in the Stage level.

For information on mapping, including how to use the different mapping types offered by Designer, please see the chapter **Content Mapping**

Palette

This points to the still image file that defines the bitmap from which the tint colour is taken. The default palette (HSVPAL) consists of the complete range of hues and saturations. Selecting this property will open the Texture object library, which shows all of the still image files saved on your local hard-drive in the **DxTexture** older.

To control the location within the current palette bitmap, and thus control the colour, you have to edit the **xCol** and **yCol** values (see the section for xCol, yCol).



To change the current palette bitmap:

1. Left-click **palette** to open the Texture object library.
2. Left-click the still image file you want to use for the palette bitmap.

If you want to use a palette bitmap other than the standard still images provided in Designer, you will need to use a custom still image file.

See the **Placing media files** for a project sub-chapter to understand where to place a custom still image file and how to access it in Designer. Also save the file to a **supported file format**.

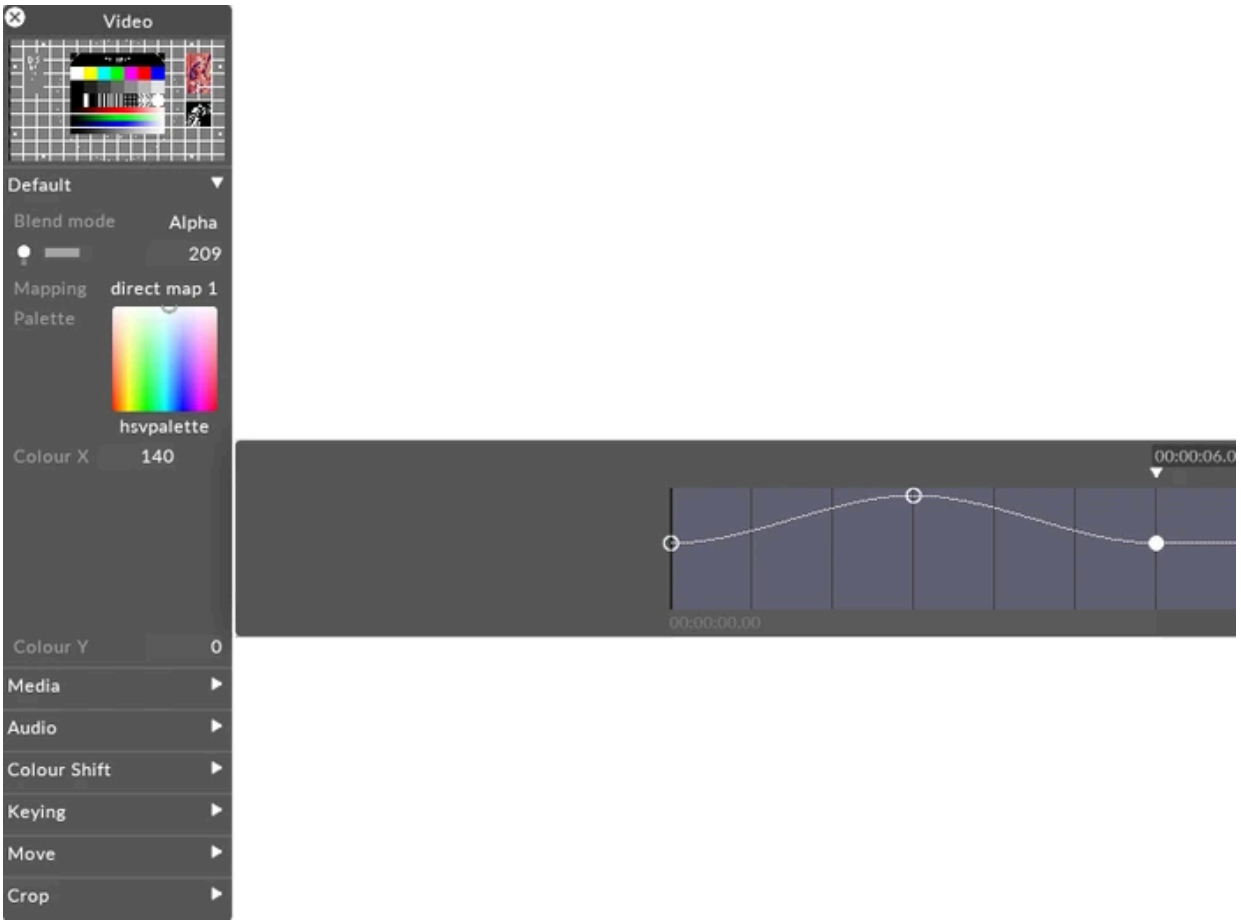
Xcol, YCol

These properties control the coordinates within the current palette bitmap where the output colour is sampled from. The default value is 0,0 which points at the color white (if you are using the HSVPAL palette). Multiplying white with the colors of the chosen content simply generates the original content colors. **Colour X** controls the horizontal position, where 0 is the leftmost

edge and 255 is the rightmost edge. **Colour Y** controls the vertical position, where 0 is the top edge and 255 is the bottom edge.

For example, to saturate the video clip red, change the **Colour Y** value to 255 and use 0 for the **Colour X** value. These coordinates refer to the color red in the palette which is being multiplied with the colors of the existing content.

When you are using the default palette HSVPAL , Colour Y controls saturation, and Colour X controls hue.



Scroll Layer

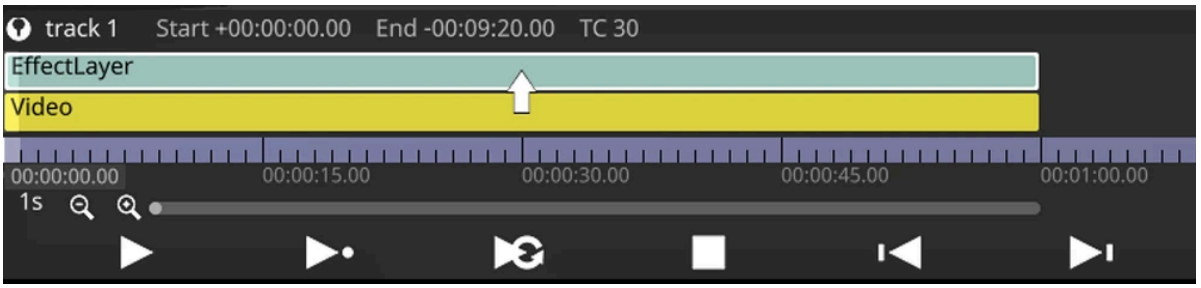
The Scroll layer takes any bitmap and scrolls it in a horizontal direction across the output canvas, repeating it when necessary. It is particularly useful in situations where you want to generate scrolling content and want to modulate the scrolling speed in real time (for instance, so that content moves at the right speed for television cameras). In these situations, the process of making a video containing scrolling content is too slow.

Workflow

Effect layers receive their source from other layer types - either content or generative - through arrows. An arrow connects a source layer to a destination layer; the source layer is said to be “piped in” to the destination Effect layer. For more information on arrows, see the **compositing layers** topic.

To draw an arrow between two layers, hold down **ALT** and left-click & drag from the source layer to the destination layer.

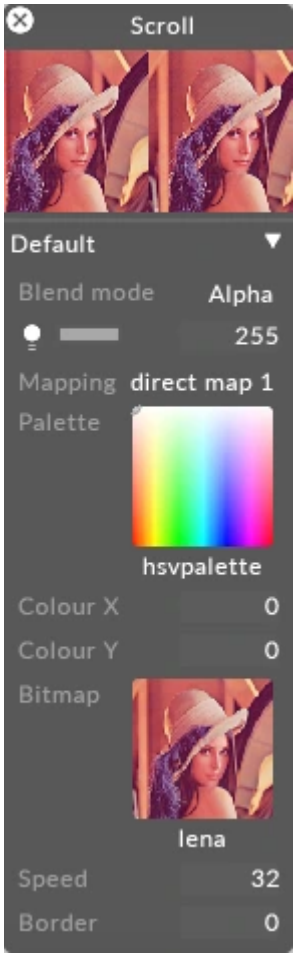
1. Add an Effect layer to your track. For more information about adding layers, see **creating layers**.
2. Draw an arrow from your content layer to the Effect layer so the compositing order looks something like the following image.



A Video layer piped into an Effect layer on the timeline.

3. Adjust the Effect layer properties to achieve the desired result.

Scroll Layer Properties



Speed

This controls the horizontal scrolling speed, measured in pixels per beat. Positive numbers scroll the image to the left; negative numbers scroll it to the right.

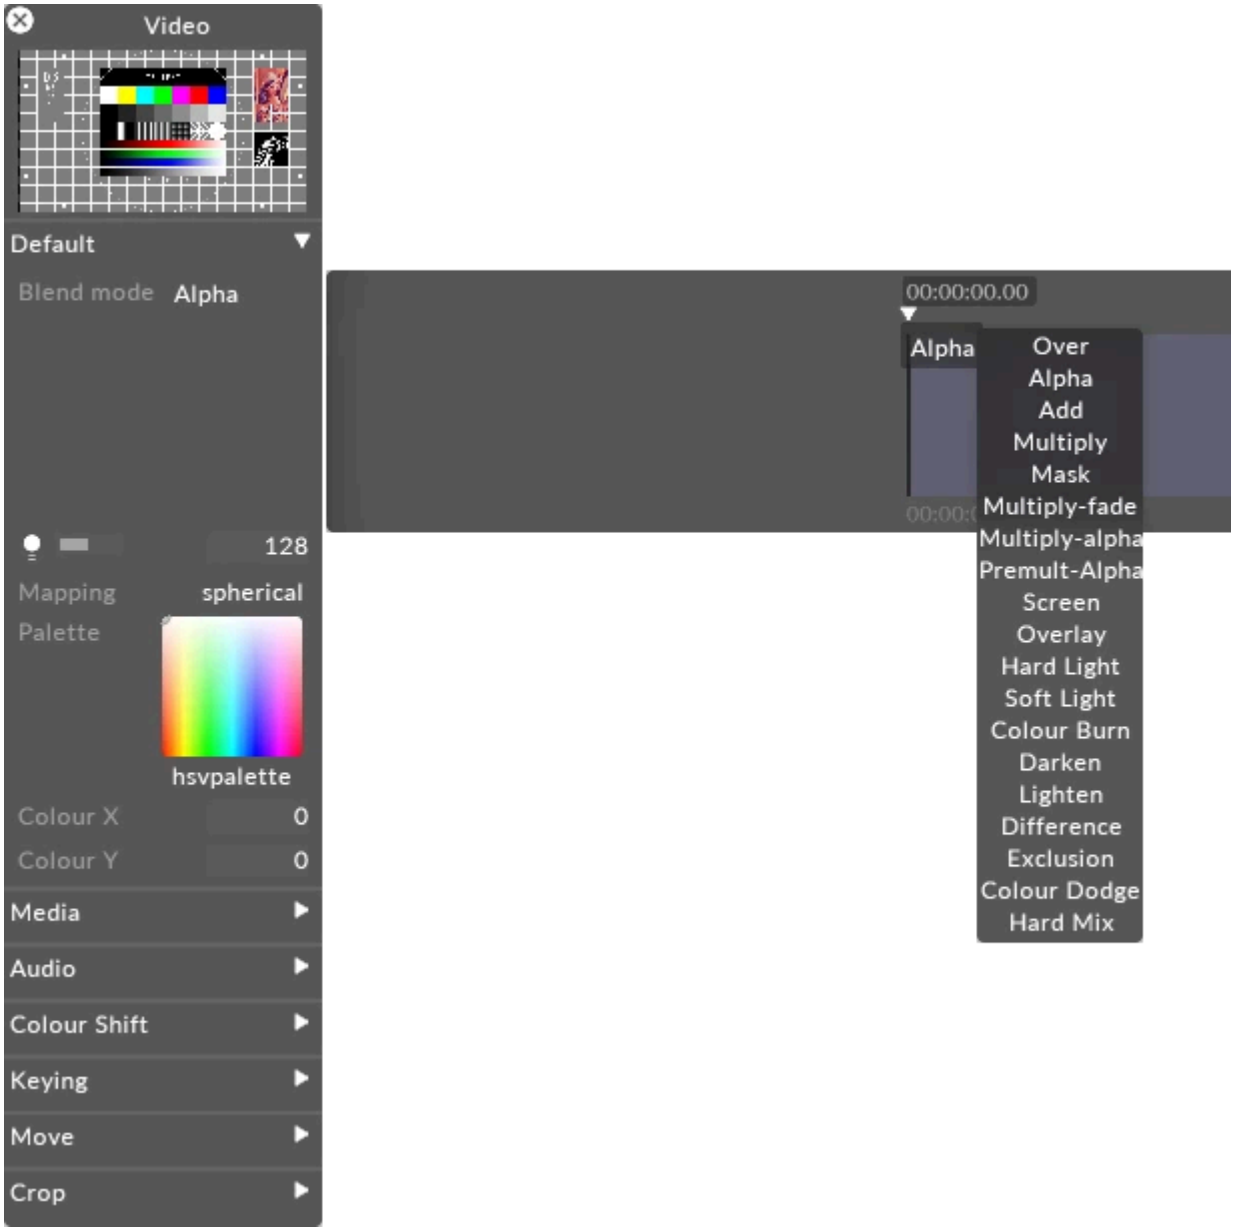
Border

The Scroll layer can generate a black border above and below the image, scaling the image down in the process. The **border** property controls the height of this border, in pixels.

Common Layer Properties

Blend Mode

BlendMode controls how the output of the layer is composited with the layers below. Layers are rendered in a bottom-up order: layers at the top can modify the output of the layers below.



Changing brightness of a content layer in Designer is actually controlling the value of the alpha of the layer. Even when displaying a HAP video, the software will composite the layer with a controllable layer of alpha - one per layer.

There are two ways of expressing alpha in an image:

Straight alpha is an alpha channel which functions just like RGB. Alpha acts as a fourth channel of information per pixel which is as independent of the other three as R, G and B are of each other. For example, with straight alpha it is possible to have RGB = 255 (white) and alpha = 0 (fully transparent) on the same pixel. Internally generated content, such as gradient layer, are generated with straight alpha. This is the preferable style of alpha and considering the cleaner method of the two.

Premultiplied alpha takes the alpha and applies it to the values of the RGB channels per pixel. The more transparent something gets with premultiplied alpha, the closer it gets to black - as if the content is sitting on a black table. Premultiplied is the default output of Adobe Photoshop or AfterEffects. The result is our pixel at 255 RGB (full white) with 0 alpha would be calculated as a black pixel in the final image.

Here are explanations of what each individual blend mode will do.

Over

Makes a layer fully opaque. Premultiplies all alpha onto the RGB value of each pixel. Alpha = black, so adjusting the brightness of a layer in Over blend mode makes it darker.

Alpha

Default blend mode. It will apply alpha values as a transparency if the alpha is present. Brightness changes will make the layer more or less transparent.

Add

Adds the value of each RGB pixel together. Always creates a brighter result. Values clamp at 255.

Multiply

Reads the level of each subpixel as a level between 0.0 and 1.0, and multiplies source with blend. The result is always a darker image overall. For example: white x grey = 0.5. White turns transparent, black takes precedence. Alpha is applied in the same fashion as the Over Blend mode.

Mask

Applies a mask to the single layer **above** in the stack, irrespective of mapping. See **Mask blending** for more information.

Luma-Matte

This mode creates a Luma Matte by using a layer's **Rec. 709 luminance** to control the alpha channel of the layer **above**, irrespective of mapping.

To determine transparency, the luminance of each pixel is calculated using a weighted average of its red, green, and blue channels. The luminance value is then used as the alpha (opacity) value for the corresponding pixels in the upper layers.

As a result, white areas render the layer above fully opaque, black areas make them fully transparent, and grey areas create proportional semi-transparency. This is a specialized **Mask** blend mode; for more details on the underlying behaviour, see **Mask blending**.

Inv-Luma-Matte

The Inverse Luma Matte mask works the same as the **Luma Matte** mask but the transparency is inverted meaning white regions are transparent and black regions are opaque.

Multiply-Fade

The same as Multiply, but will make use of the alpha channel to calculate transparency in the source and blend layers. Since maximum transparency is premultiplied, alpha results in black. This will ignore black created through premultiplying.

Multiply-Alpha

Multiply with straight alpha. This mode assumes that the alpha has not been premultiplied onto the RGB values and will not apply a correction to the semi-transparent pixels.

Premultiply Alpha

Like how Multiply-fade will ignore the darkening caused by premultiplying, this blend mode will do the same with Alpha.

Colour Burn

Blend mode increases the contrast to darken the base colour while reflecting the blend colour. The darker the blend colour, the more intensely the colour will be applied in the base image. White as the blend colour produces no change. Using the colour burn blend mode can produce some harsh results at full opacity. The colour burn blend mode can be used to make tonal and colour adjustments to a layer.

Screen

This blend mode looks at each channels colour information and multiplies the inverse of the blend and base colous. The result is always a lighter colour. Screening with black leaves the colour unchanged. Screening with white produces white. The effect is similar to projecting multiple images on top of each other - where bright white is fully opaque, black is fully transparent and 50% grey is 50% transparent.

Overlay

Multiplies or screens the colours, depending on the base colour. Patterns or colours overlay the existing pixels while preserving the highlights and shadows of the base colour. The base colour is not replaced, but mixed with the blend colour to reflect the lightness or darkness of the original colour.

Hard Light

Multiplies or screens the colours, depending on the blend colour. The effects is similar to shining a harsh spotlight on the image. If the blend colour (light source/top layer) is lighter than

50% grey, the image is lightened as if it were screened. This is useful for adding highlights to an image. If the blend colour is darker than 50% grey, the image is darkened as if it were multiplied. This is useful for adding shadows to an image. Painting with pure black or white results in pure black or white.

Soft Light

Darkens or lightens the colours, depending on the blend colour. The effect is similar to shining a diffused spotlight on the image. If the blend colour (light source/top layer) is lighter than 50% grey, the image is lightened as it if were dodged. If the blend colour is darker than 50% grey, the image is darkened as if it were burned in. Painting with pure black or white produces a distinctly darker or lighter area, but does not result in pure black or white.

Darken

Looks as the colour information in each channel and selects the base or blend colour - whichever is darker - as the result colour. Pixels lighter than the blend colour are replaced and pixels darker than the blend colour do not change.

Lighten

Looks at the colour information in each channel and selects the base or blend colour - whichever is lighter - as the result colour. Pixels darker than the blend colour are replaced and pixels lighter than the blend colour do not change.

Difference

Looks at the colour information in each channel and subtracts either the blend colour from the base colour or the base colour from the blend colour depending on which has the greater brightness value. Blending with white inverts the base colour values and blending with black produces no change.

Exclusion

Creates an effects similar to but lower in contrast than the difference mode. Blending with white inverts the base colour values. Blending with black produces no change.

Colour Dodge

Looks at the colour information in each channel and brightens the base colour to reflect the blend colour by decreasing contrast between the two. Blending with black produces no change.

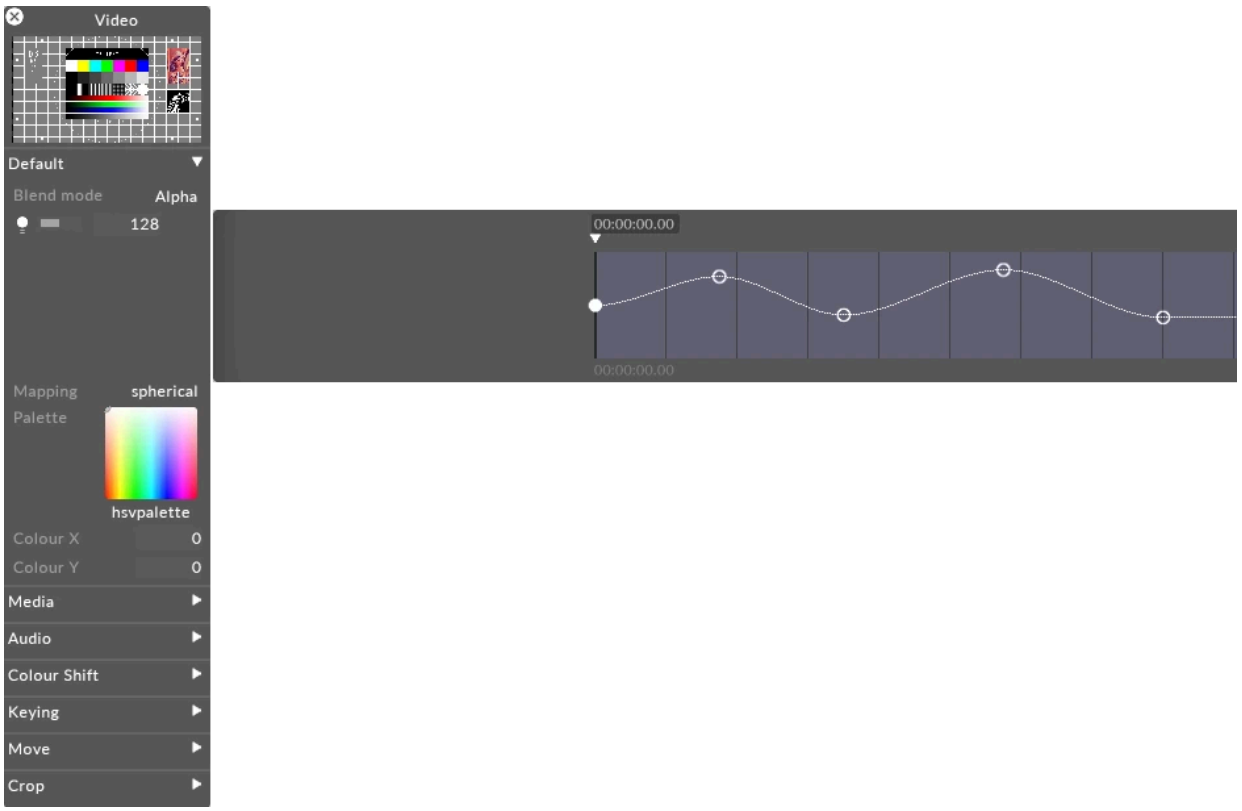
Hard Mix

Adds the RGB channels of the blend colour to the RGB values of the base colour. If the resulting sum for a channel is 255 or greater, it receives a value of 255; if it is less than 255 it

receives a value of 0. Therefore all blended pixels have RGB channels of either 0 or 255. This changes all pixels to primary additive colours (RGB), white or black.

Brightness

This property (which appears as a light bulb icon) controls the brightness of the layer output.



If the layers blend mode is set to Alpha, then reducing the brightness to 0 also reduces the opacity of the layer to 0. This can be useful when you want to dissolve from one layer to the next. In that case, you can place the new layer above the old layer and increase its brightness level.

> **Note**
>
> Layers that are patched to Sockpuppet (DMX, OSC or HTTP) are made Dormant when their brightness is set to 0. This means they will not do any rendering or consume any resources until their brightness is changed to > 0. You can find more information about this here: **Sequencing with Sockpuppet**. Layers without a sockpuppet patch do not behave in this way.

Mapping

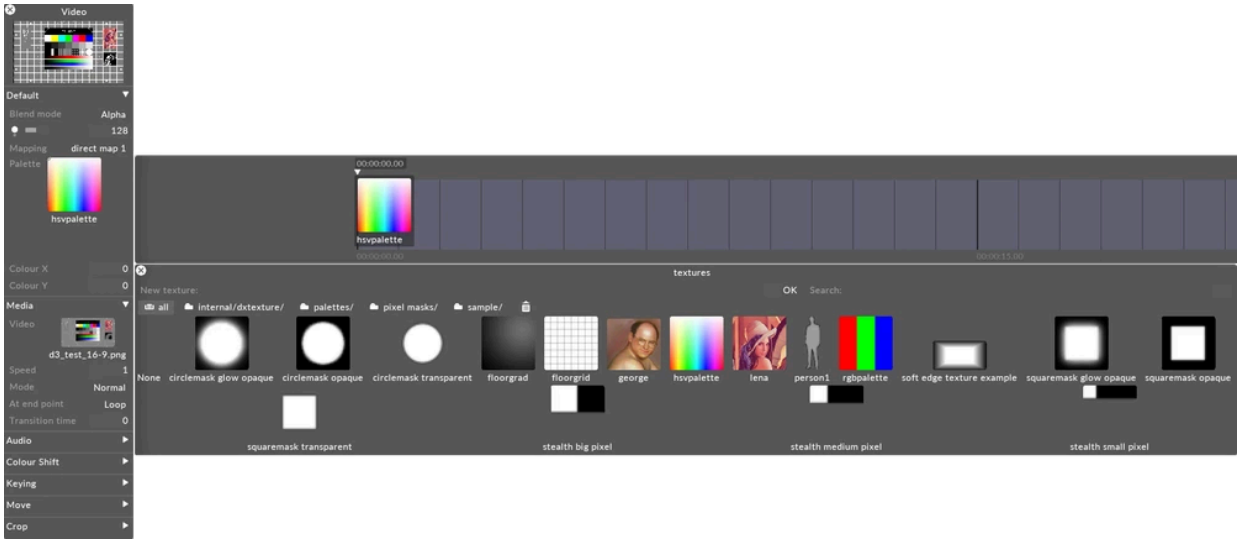
The mapping property controls how the layer output is mapped onto the screen(s) in the Stage level.

For information on mapping, including how to use the different mapping types offered by Designer, please see the chapter **Content Mapping**

Palette

This points to the still image file that defines the bitmap from which the tint colour is taken. The default palette (HSVPAL) consists of the complete range of hues and saturations. Selecting this property will open the Texture object library, which shows all of the still image files saved on your local hard-drive in the **DxTexture** older.

To control the location within the current palette bitmap, and thus control the colour, you have to edit the **xCol** and **yCol** values (see the section for xCol, yCol).



To change the current palette bitmap:

1. Left-click **palette** to open the Texture object library.
2. Left-click the still image file you want to use for the palette bitmap.

If you want to use a palette bitmap other than the standard still images provided in Designer, you will need to use a custom still image file.

See the **Placing media files** for a project sub-chapter to understand where to place a custom still image file and how to access it in Designer. Also save the file to a **supported file format**.

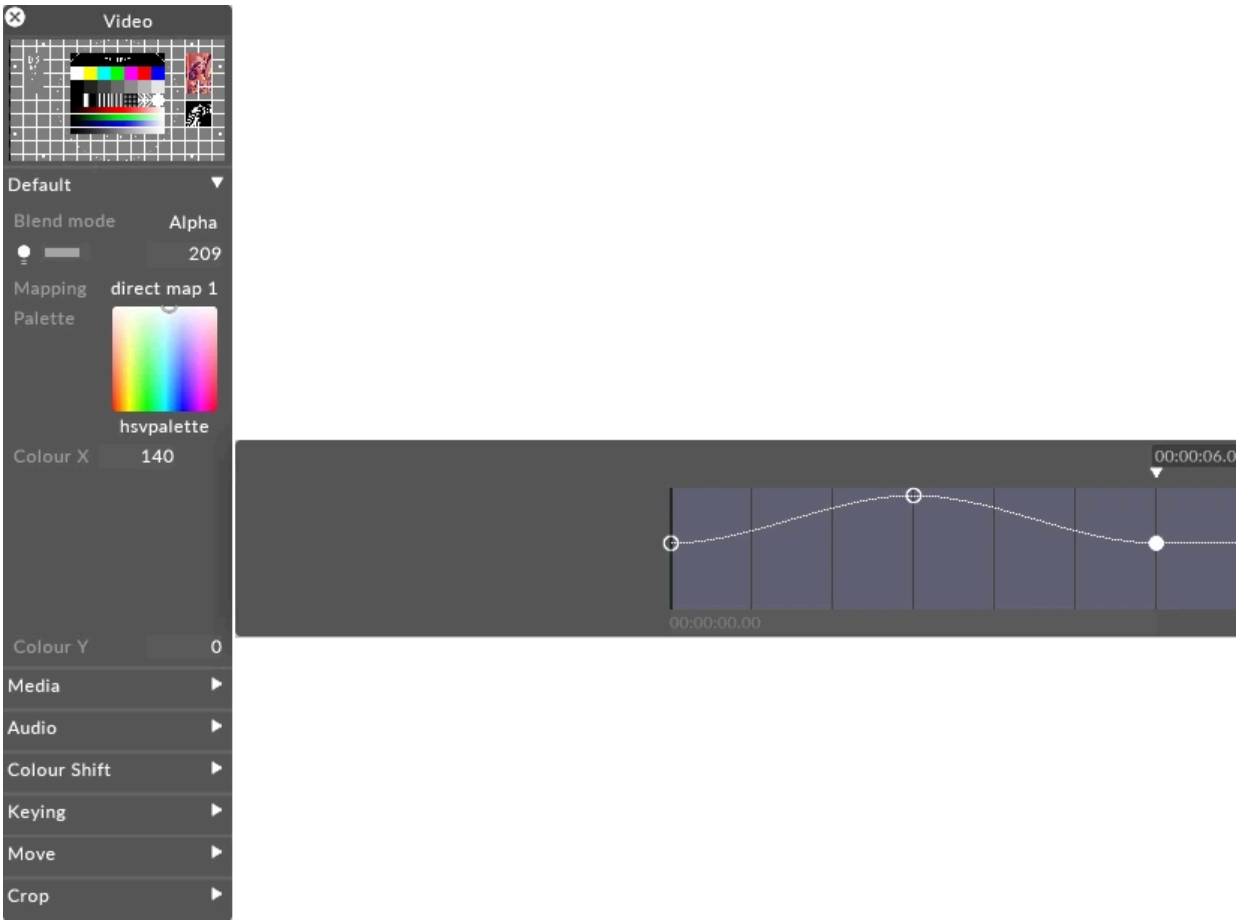
Xcol, YCol

These properties control the coordinates within the current palette bitmap where the output colour is sampled from. The default value is 0,0 which points at the color white (if you are using the HSVPAL palette). Multiplying white with the colors of the chosen content simply generates the original content colors. **Colour X** controls the horizontal position, where 0 is the leftmost

edge and 255 is the rightmost edge. **Colour Y** controls the vertical position, where 0 is the top edge and 255 is the bottom edge.

For example, to saturate the video clip red, change the **Colour Y** value to 255 and use 0 for the **Colour X** value. These coordinates refer to the color red in the palette which is being multiplied with the colors of the existing content.

When you are using the default palette HSVPAL , Colour Y controls saturation, and Colour X controls hue.



SpinBitmap Layer

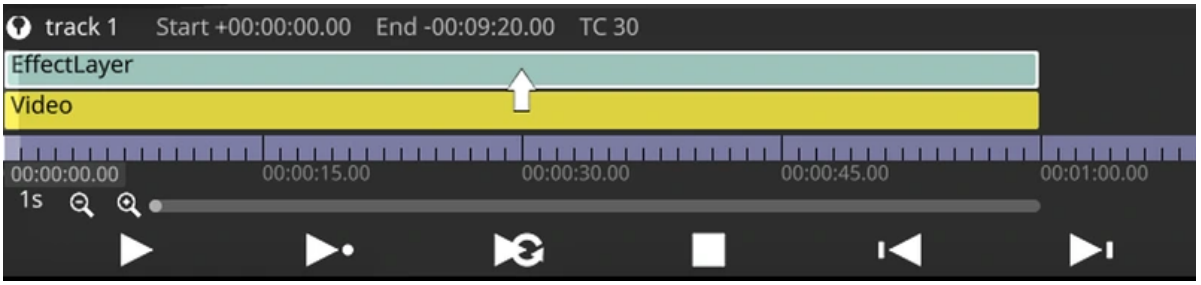
The SpinBitmap layer displays a moving, rotating bitmap. It is able to perform continuous rotation and can tile its image. Since a bitmap contains an alpha channel, this layer can display up to three layers of images, one behind the other.

Workflow

Effect layers receive their source from other layer types - either content or generative - through arrows. An arrow connects a source layer to a destination layer; the source layer is said to be “piped in” to the destination Effect layer. For more information on arrows, see the **compositing layers** topic.

To draw an arrow between two layers, hold down **ALT** and left-click & drag from the source layer to the destination layer.

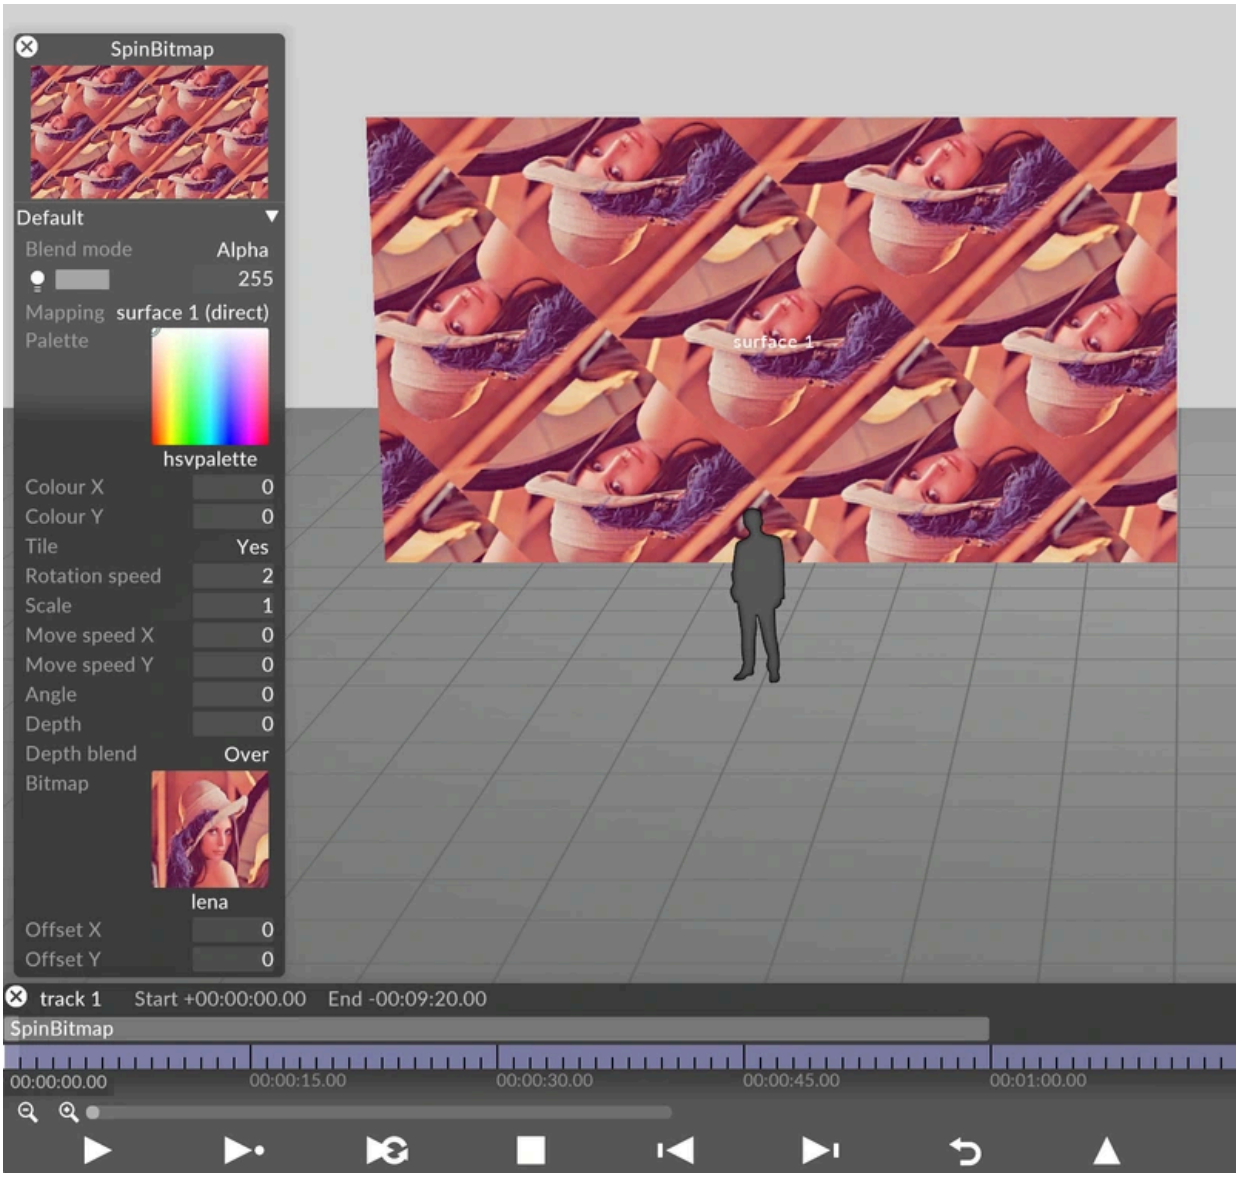
1. Add an Effect layer to your track. For more information about adding layers, see **creating layers**.
2. Draw an arrow from your content layer to the Effect layer so the compositing order looks something like the following image.



A Video layer piped into an Effect layer on the timeline.

3. Adjust the Effect layer properties to achieve the desired result.

Spinbitmap Layer Properties



Tile

If set to **off** , the central image is not tiled and the **move speed** property has no effect.

Rotation speed

If this is set to 0, the rotation angle is controlled by the **angle** property. Otherwise, this property controls the rotation speed in degrees per beat.

Scale

This controls the scaling of the bitmap. Somewhat counter-intuitively, increasing the number reduces the size of the bitmap and increases the number of tiled copies.

Move speed

This controls the movement speed of the image, in each of the x and y axes, in pixels per beat.

Angle

If **rotation speed** is set to 0, this property controls the **angle**. Otherwise, it has no effect.

Depth

With values ranging from 0 to 2, **depth** controls the number of layers displayed. This only results in a visual effect if the bitmap is partially transparent, i.e. contains an alpha channel.

Depth blend

This controls the blend mode applied between the multiple layers. The options to choose from are **add**, **over**, **alpha**, or **multiply**. For more information on blend modes, please see the blendMode section.

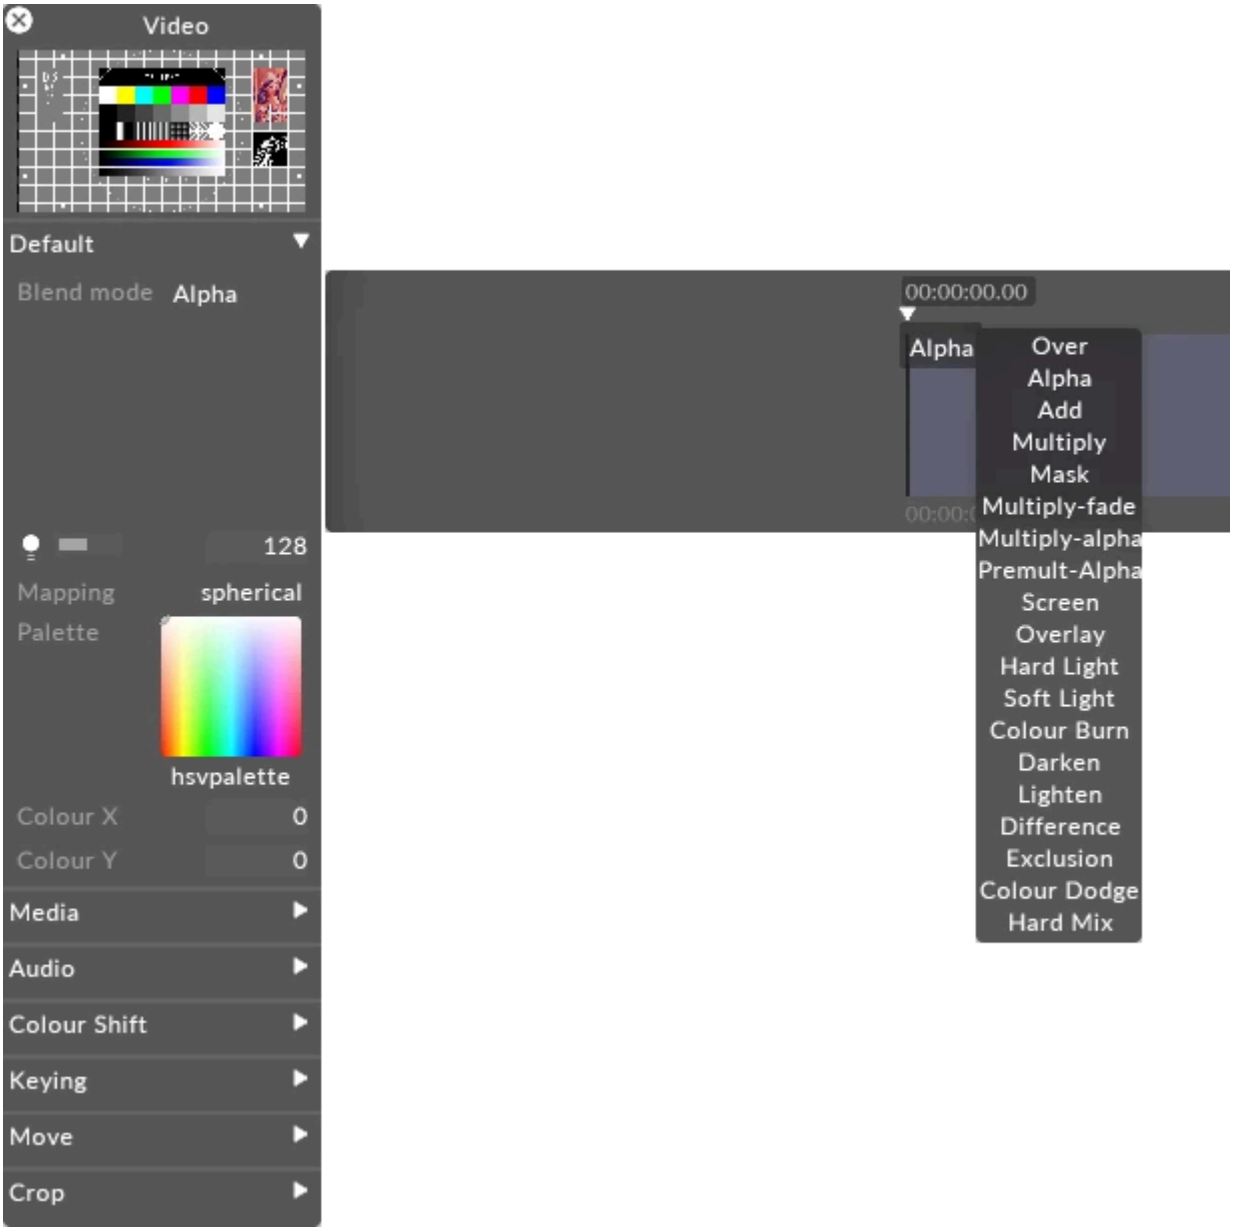
Offset

This shifts the entire field left or right, and is measured in pixels.

Common Layer Properties

Blend Mode

BlendMode controls how the output of the layer is composited with the layers below. Layers are rendered in a bottom-up order: layers at the top can modify the output of the layers below.



Changing brightness of a content layer in Designer is actually controlling the value of the alpha of the layer. Even when displaying a HAP video, the software will composite the layer with a controllable layer of alpha - one per layer.

There are two ways of expressing alpha in an image:

Straight alpha is an alpha channel which functions just like RGB. Alpha acts as a fourth channel of information per pixel which is as independent of the other three as R, G and B are of each other. For example, with straight alpha it is possible to have RGB = 255 (white) and alpha = 0 (fully transparent) on the same pixel. Internally generated content, such as gradient layer, are generated with straight alpha. This is the preferable style of alpha and considering the cleaner method of the two.

Premultiplied alpha takes the alpha and applies it to the values of the RGB channels per pixel. The more transparent something gets with premultiplied alpha, the closer it gets to black - as if the content is sitting on a black table. Premultiplied is the default output of Adobe Photoshop or AfterEffects. The result is our pixel at 255 RGB (full white) with 0 alpha would be calculated as a black pixel in the final image.

Here are explanations of what each individual blend mode will do.

Over

Makes a layer fully opaque. Premultiplies all alpha onto the RGB value of each pixel. Alpha = black, so adjusting the brightness of a layer in Over blend mode makes it darker.

Alpha

Default blend mode. It will apply alpha values as a transparency if the alpha is present. Brightness changes will make the layer more or less transparent.

Add

Adds the value of each RGB pixel together. Always creates a brighter result. Values clamp at 255.

Multiply

Reads the level of each subpixel as a level between 0.0 and 1.0, and multiplies source with blend. The result is always a darker image overall. For example: white x grey = 0.5. White turns transparent, black takes precedence. Alpha is applied in the same fashion as the Over Blend mode.

Mask

Applies a mask to the single layer **above** in the stack, irrespective of mapping. See **Mask blending** for more information.

Luma-Matte

This mode creates a Luma Matte by using a layer's **Rec. 709 luminance** to control the alpha channel of the layer **above**, irrespective of mapping.

To determine transparency, the luminance of each pixel is calculated using a weighted average of its red, green, and blue channels. The luminance value is then used as the alpha (opacity) value for the corresponding pixels in the upper layers.

As a result, white areas render the layer above fully opaque, black areas make them fully transparent, and grey areas create proportional semi-transparency. This is a specialized **Mask** blend mode; for more details on the underlying behaviour, see **Mask blending**.

Inv-Luma-Matte

The Inverse Luma Matte mask works the same as the **Luma Matte** mask but the transparency is inverted meaning white regions are transparent and black regions are opaque.

Multiply-Fade

The same as Multiply, but will make use of the alpha channel to calculate transparency in the source and blend layers. Since maximum transparency is premultiplied, alpha results in black. This will ignore black created through premultiplying.

Multiply-Alpha

Multiply with straight alpha. This mode assumes that the alpha has not been premultiplied onto the RGB values and will not apply a correction to the semi-transparent pixels.

Premultiply Alpha

Like how Multiply-fade will ignore the darkening caused by premultiplying, this blend mode will do the same with Alpha.

Colour Burn

Blend mode increases the contrast to darken the base colour while reflecting the blend colour. The darker the blend colour, the more intensely the colour will be applied in the base image. White as the blend colour produces no change. Using the colour burn blend mode can produce some harsh results at full opacity. The colour burn blend mode can be used to make tonal and colour adjustments to a layer.

Screen

This blend mode looks at each channels colour information and multiplies the inverse of the blend and base colous. The result is always a lighter colour. Screening with black leaves the colour unchanged. Screening with white produces white. The effect is similar to projecting multiple images on top of each other - where bright white is fully opaque, black is fully transparent and 50% grey is 50% transparent.

Overlay

Multiplies or screens the colours, depending on the base colour. Patterns or colours overlay the existing pixels while preserving the highlights and shadows of the base colour. The base colour is not replaced, but mixed with the blend colour to reflect the lightness or darkness of the original colour.

Hard Light

Multiplies or screens the colours, depending on the blend colour. The effects is similar to shining a harsh spotlight on the image. If the blend colour (light source/top layer) is lighter than

50% grey, the image is lightened as if it were screened. This is useful for adding highlights to an image. If the blend colour is darker than 50% grey, the image is darkened as if it were multiplied. This is useful for adding shadows to an image. Painting with pure black or white results in pure black or white.

Soft Light

Darkens or lightens the colours, depending on the blend colour. The effect is similar to shining a diffused spotlight on the image. If the blend colour (light source/top layer) is lighter than 50% grey, the image is lightened as it if were dodged. If the blend colour is darker than 50% grey, the image is darkened as if it were burned in. Painting with pure black or white produces a distinctly darker or lighter area, but does not result in pure black or white.

Darken

Looks as the colour information in each channel and selects the base or blend colour - whichever is darker - as the result colour. Pixels lighter than the blend colour are replaced and pixels darker than the blend colour do not change.

Lighten

Looks at the colour information in each channel and selects the base or blend colour - whichever is lighter - as the result colour. Pixels darker than the blend colour are replaced and pixels lighter than the blend colour do not change.

Difference

Looks at the colour information in each channel and subtracts either the blend colour from the base colour or the base colour from the blend colour depending on which has the greater brightness value. Blending with white inverts the base colour values and blending with black produces no change.

Exclusion

Creates an effects similar to but lower in contrast than the difference mode. Blending with white inverts the base colour values. Blending with black produces no change.

Colour Dodge

Looks at the colour information in each channel and brightens the base colour to reflect the blend colour by decreasing contrast between the two. Blending with black produces no change.

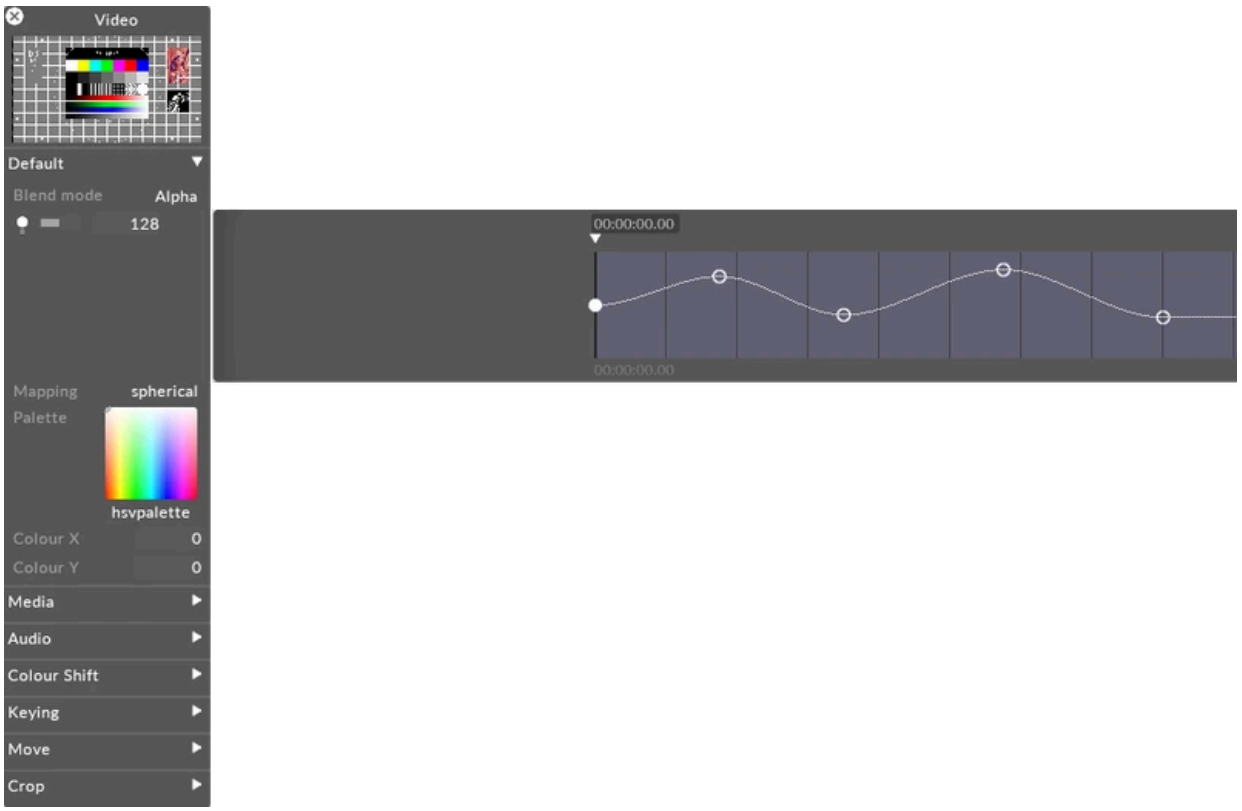
Hard Mix

Adds the RGB channels of the blend colour to the RGB values of the base colour. If the resulting sum for a channel is 255 or greater, it receives a value of 255; if it is less than 255 it

receives a value of 0. Therefore all blended pixels have RGB channels of either 0 or 255. This changes all pixels to primary additive colours (RGB), white or black.

Brightness

This property (which appears as a light bulb icon) controls the brightness of the layer output.



If the layers blend mode is set to Alpha, then reducing the brightness to 0 also reduces the opacity of the layer to 0. This can be useful when you want to dissolve from one layer to the next. In that case, you can place the new layer above the old layer and increase its brightness level.

> **Note**
>
> Layers that are patched to Sockpuppet (DMX, OSC or HTTP) are made Dormant when their brightness is set to 0. This means they will not do any rendering or consume any resources until their brightness is changed to > 0. You can find more information about this here: **Sequencing with Sockpuppet**. Layers without a sockpuppet patch do not behave in this way.

Mapping

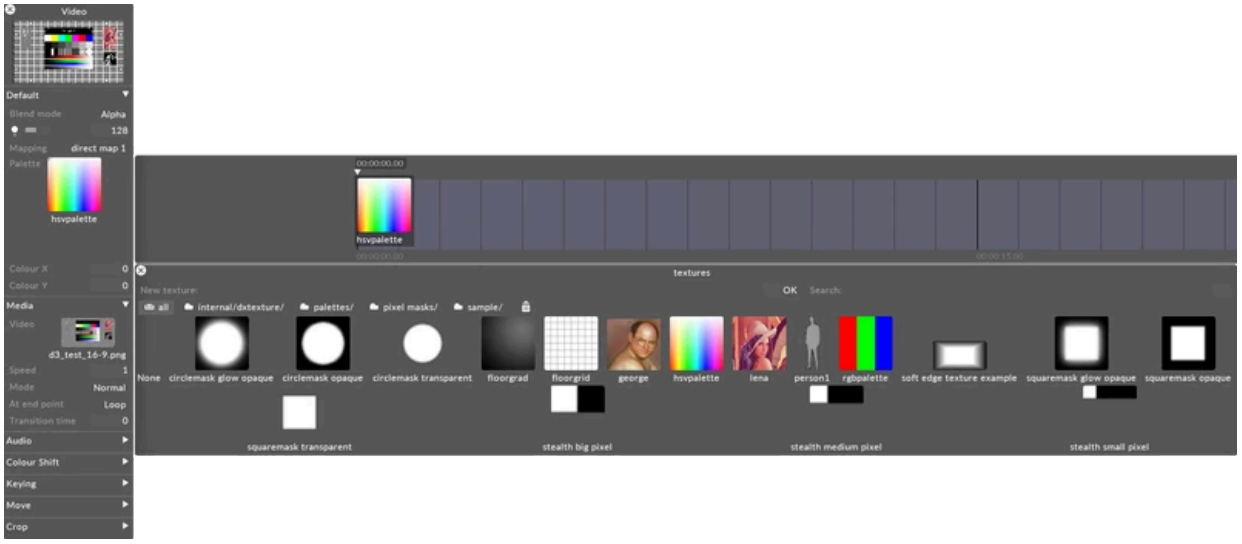
The mapping property controls how the layer output is mapped onto the screen(s) in the Stage level.

For information on mapping, including how to use the different mapping types offered by Designer, please see the chapter **Content Mapping**

Palette

This points to the still image file that defines the bitmap from which the tint colour is taken. The default palette (HSVPAL) consists of the complete range of hues and saturations. Selecting this property will open the Texture object library, which shows all of the still image files saved on your local hard-drive in the **DxTexture** older.

To control the location within the current palette bitmap, and thus control the colour, you have to edit the **xCol** and **yCol** values (see the section for xCol, yCol).



To change the current palette bitmap:

1. Left-click **palette** to open the Texture object library.
2. Left-click the still image file you want to use for the palette bitmap.

If you want to use a palette bitmap other than the standard still images provided in Designer, you will need to use a custom still image file.

See the **Placing media files** for a project sub-chapter to understand where to place a custom still image file and how to access it in Designer. Also save the file to a **supported file format**.

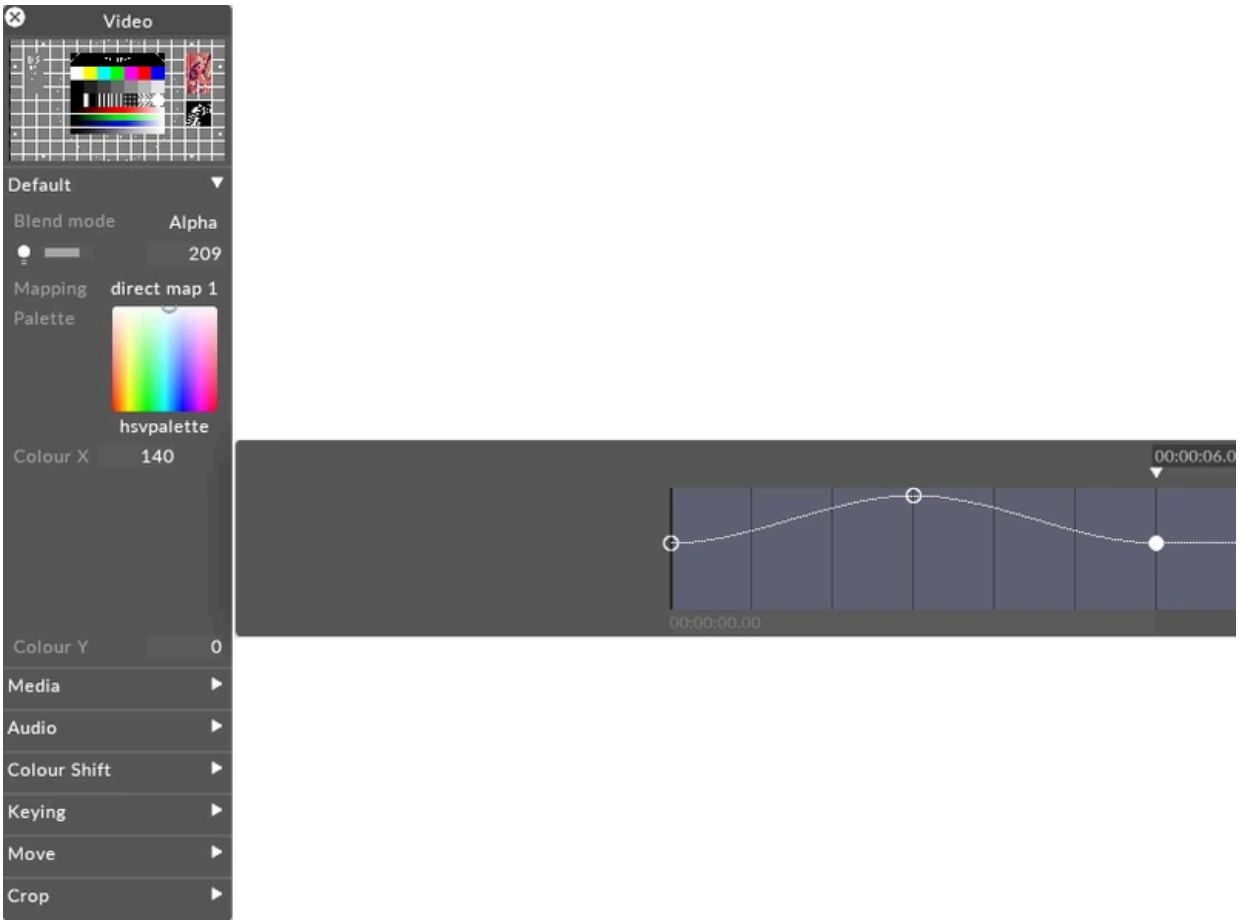
Xcol, YCol

These properties control the coordinates within the current palette bitmap where the output colour is sampled from. The default value is 0,0 which points at the color white (if you are using the HSVPAL palette). Multiplying white with the colors of the chosen content simply generates the original content colors. **Colour X** controls the horizontal position, where 0 is the leftmost

edge and 255 is the rightmost edge. **Colour Y** controls the vertical position, where 0 is the top edge and 255 is the bottom edge.

For example, to saturate the video clip red, change the **Colour Y** value to 255 and use 0 for the **Colour X** value. These coordinates refer to the color red in the palette which is being multiplied with the colors of the existing content.

When you are using the default palette HSVPAL , Colour Y controls saturation, and Colour X controls hue.



Trigger Layer

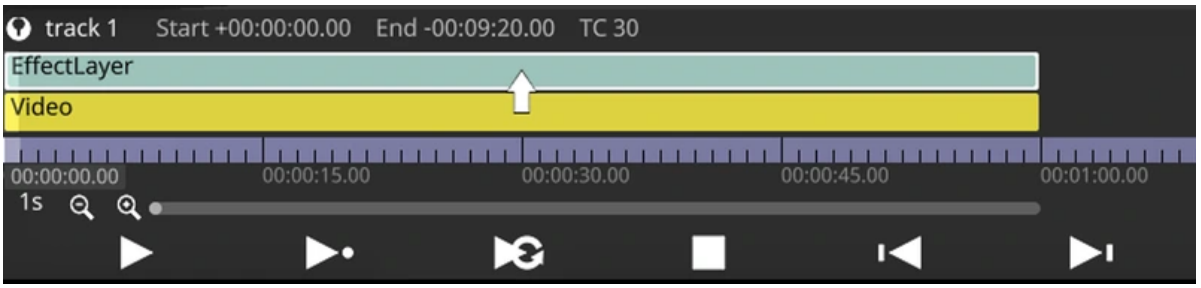
The Trigger layer allows you to trigger still image content at specific points of time on your screen(s).

Workflow

Effect layers receive their source from other layer types - either content or generative - through arrows. An arrow connects a source layer to a destination layer; the source layer is said to be “piped in” to the destination Effect layer. For more information on arrows, see the **compositing layers** topic.

To draw an arrow between two layers, hold down **ALT** and left-click & drag from the source layer to the destination layer.

1. Add an Effect layer to your track. For more information about adding layers, see **creating layers**.
2. Draw an arrow from your content layer to the Effect layer so the compositing order looks something like the following image.



A Video layer piped into an Effect layer on the timeline.

3. Adjust the Effect layer properties to achieve the desired result.

Trigger Layer Properties

Bitmap

Still image file to be placed in the key-frame editor.

Speed

The transition speed of the triggered content. Positive = bottom to top, negative = top to bottom.

Size x, y

The pixel size of the image.

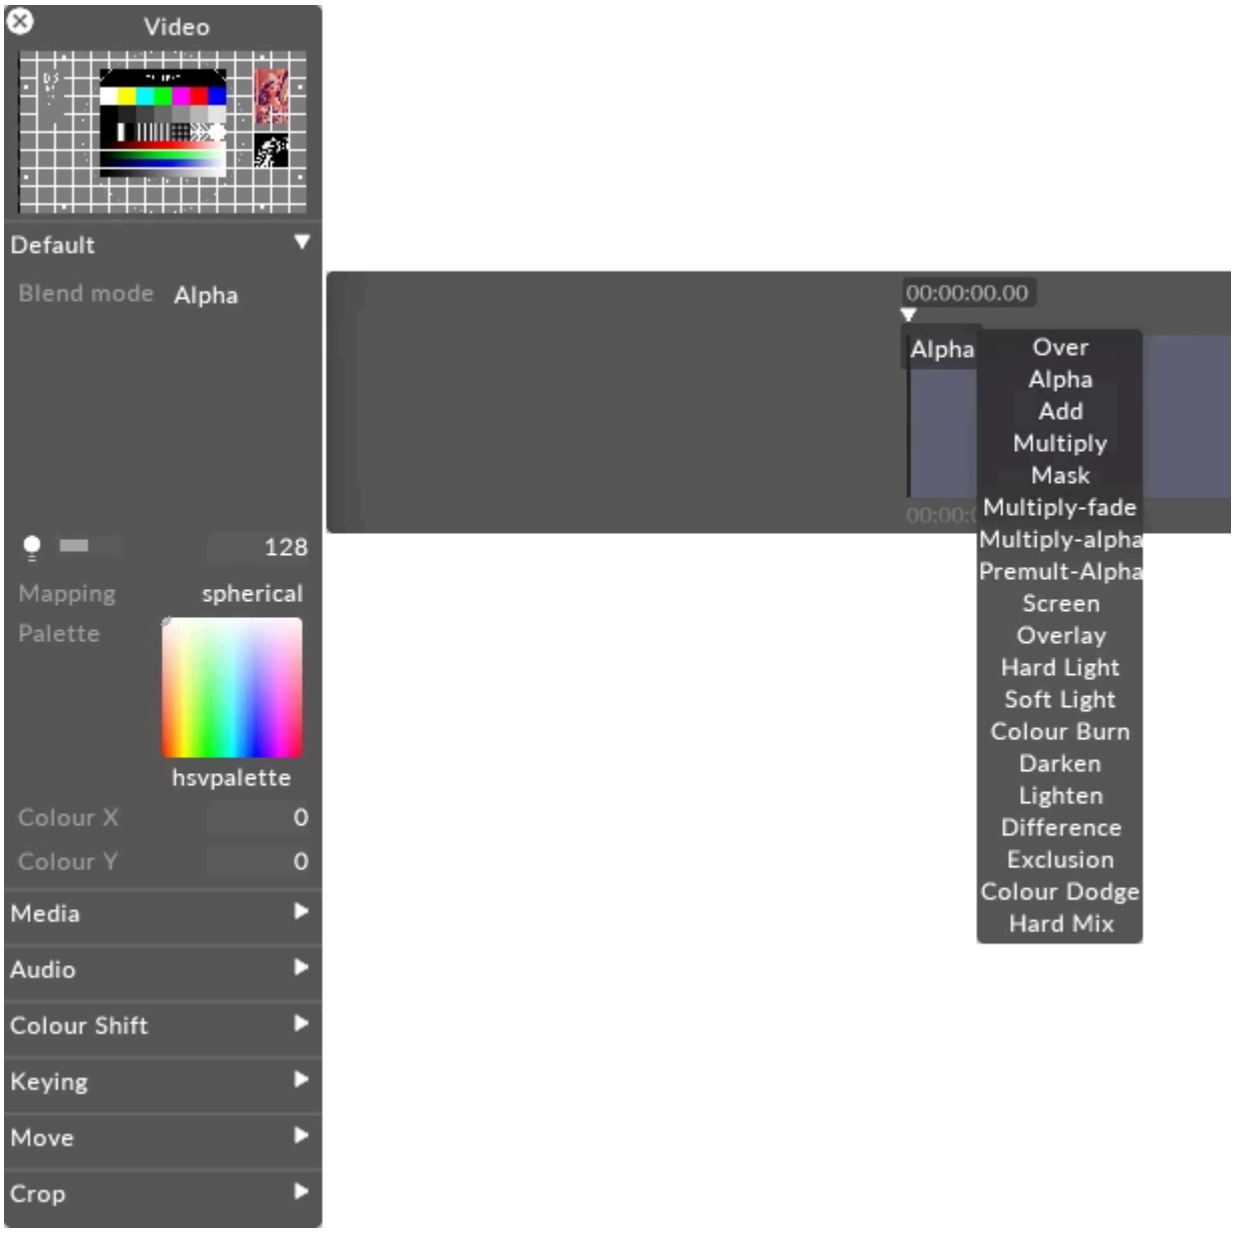
Trigger

Every trigger keyframe triggers the chosen image.

Common Layer Properties

Blend Mode

BlendMode controls how the output of the layer is composited with the layers below. Layers are rendered in a bottom-up order: layers at the top can modify the output of the layers below.



Changing brightness of a content layer in Designer is actually controlling the value of the alpha of the layer. Even when displaying a HAP video, the software will composite the layer with a controllable layer of alpha - one per layer.

There are two ways of expressing alpha in an image:

Straight alpha is an alpha channel which functions just like RGB. Alpha acts as a fourth channel of information per pixel which is as independent of the other three as R, G and B are of each other. For example, with straight alpha it is possible to have RGB = 255 (white) and alpha = 0 (fully transparent) on the same pixel. Internally generated content, such as gradient layer, are generated with straight alpha. This is the preferable style of alpha and considering the cleaner method of the two.

Premultiplied alpha takes the alpha and applies it to the values of the RGB channels per pixel. The more transparent something gets with premultiplied alpha, the closer it gets to black - as if the content is sitting on a black table. Premultiplied is the default output of Adobe Photoshop or AfterEffects. The result is our pixel at 255 RGB (full white) with 0 alpha would be calculated as a black pixel in the final image.

Here are explanations of what each individual blend mode will do.

Over

Makes a layer fully opaque. Premultiplies all alpha onto the RGB value of each pixel. Alpha = black, so adjusting the brightness of a layer in Over blend mode makes it darker.

Alpha

Default blend mode. It will apply alpha values as a transparency if the alpha is present. Brightness changes will make the layer more or less transparent.

Add

Adds the value of each RGB pixel together. Always creates a brighter result. Values clamp at 255.

Multiply

Reads the level of each subpixel as a level between 0.0 and 1.0, and multiplies source with blend. The result is always a darker image overall. For example: white x grey = 0.5. White turns transparent, black takes precedence. Alpha is applied in the same fashion as the Over Blend mode.

Mask

Applies a mask to the single layer **above** in the stack, irrespective of mapping. See **Mask blending** for more information.

Luma-Matte

This mode creates a Luma Matte by using a layer's **Rec. 709 luminance** to control the alpha channel of the layer **above**, irrespective of mapping.

To determine transparency, the luminance of each pixel is calculated using a weighted average of its red, green, and blue channels. The luminance value is then used as the alpha (opacity) value for the corresponding pixels in the upper layers.

As a result, white areas render the layer above fully opaque, black areas make them fully transparent, and grey areas create proportional semi-transparency. This is a specialized **Mask** blend mode; for more details on the underlying behaviour, see **Mask blending**.

Inv-Luma-Matte

The Inverse Luma Matte mask works the same as the **Luma Matte** mask but the transparency is inverted meaning white regions are transparent and black regions are opaque.

Multiply-Fade

The same as Multiply, but will make use of the alpha channel to calculate transparency in the source and blend layers. Since maximum transparency is premultiplied, alpha results in black. This will ignore black created through premultiplying.

Multiply-Alpha

Multiply with straight alpha. This mode assumes that the alpha has not been premultiplied onto the RGB values and will not apply a correction to the semi-transparent pixels.

Premultiply Alpha

Like how Multiply-fade will ignore the darkening caused by premultiplying, this blend mode will do the same with Alpha.

Colour Burn

Blend mode increases the contrast to darken the base colour while reflecting the blend colour. The darker the blend colour, the more intensely the colour will be applied in the base image. White as the blend colour produces no change. Using the colour burn blend mode can produce some harsh results at full opacity. The colour burn blend mode can be used to make tonal and colour adjustments to a layer.

Screen

This blend mode looks at each channels colour information and multiplies the inverse of the blend and base colous. The result is always a lighter colour. Screening with black leaves the colour unchanged. Screening with white produces white. The effect is similar to projecting multiple images on top of each other - where bright white is fully opaque, black is fully transparent and 50% grey is 50% transparent.

Overlay

Multiplies or screens the colours, depending on the base colour. Patterns or colours overlay the existing pixels while preserving the highlights and shadows of the base colour. The base colour is not replaced, but mixed with the blend colour to reflect the lightness or darkness of the original colour.

Hard Light

Multiplies or screens the colours, depending on the blend colour. The effects is similar to shining a harsh spotlight on the image. If the blend colour (light source/top layer) is lighter than 50% grey, the image is lightened as if it were screened. This is useful for adding highlights to an image. If the blend colour is darker than 50% grey, the image is darkened as if it were multiplied. This is useful for adding shadows to an image. Painting with pure black or white results in pure black or white.

Soft Light

Darkens or lightens the colours, depending on the blend colour. The effect is similar to shining a diffused spotlight on the image. If the blend colour (light source/top layer) is lighter than 50% grey, the image is lightened as it if were dodged. If the blend colour is darker than 50% grey, the image is darkened as if it were burned in. Painting with pure black or white produces a distinctly darker or lighter area, but does not result in pure black or white.

Darken

Looks as the colour information in each channel and selects the base or blend colour - whichever is darker - as the result colour. Pixels lighter than the blend colour are replaced and pixels darker than the blend colour do not change.

Lighten

Looks at the colour information in each channel and selects the base or blend colour - whichever is lighter - as the result colour. Pixels darker than the blend colour are replaced and pixels lighter than the blend colour do not change.

Difference

Looks at the colour information in each channel and subtracts either the blend colour from the base colour or the base colour from the blend colour depending on which has the greater brightness value. Blending with white inverts the base colour values and blending with black produces no change.

Exclusion

Creates an effects similar to but lower in contrast than the difference mode. Blending with white inverts the base colour values. Blending with black produces no change.

Colour Dodge

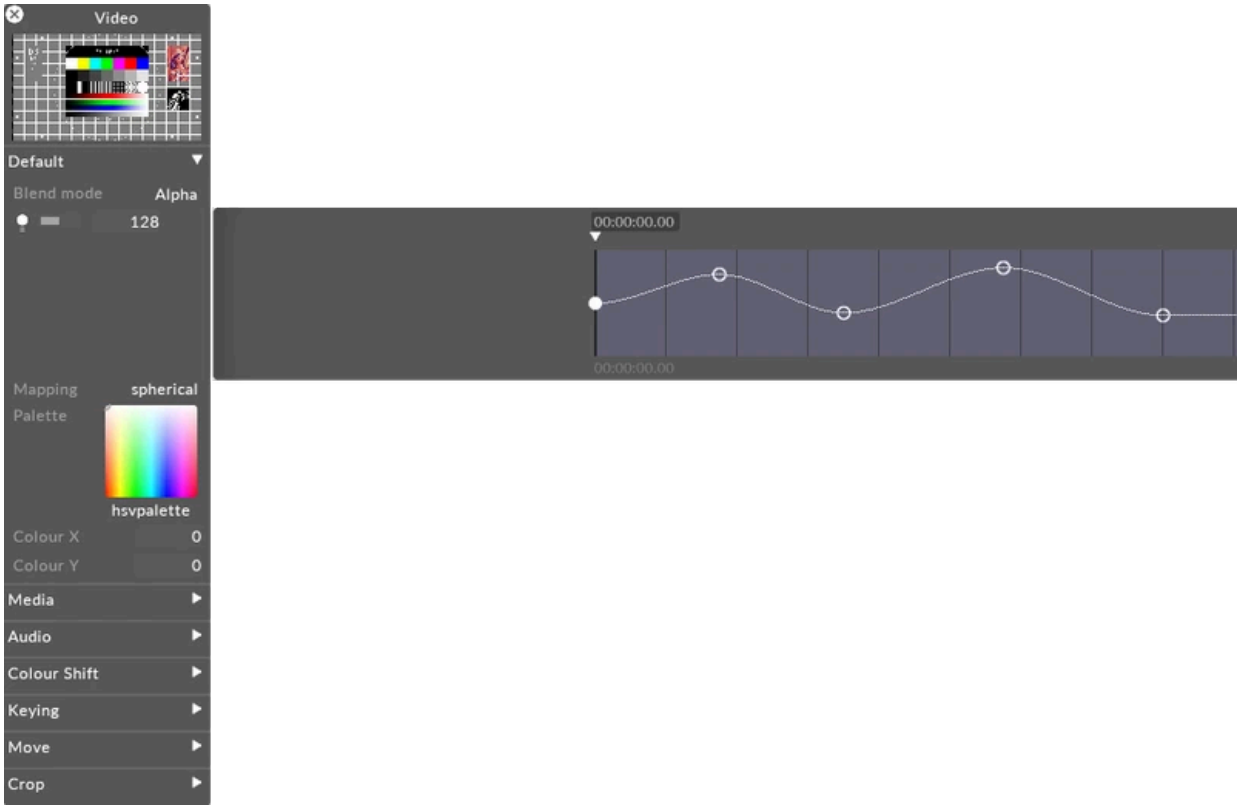
Looks at the colour information in each channel and brightens the base colour to reflect the blend colour by decreasing contrast between the two. Blending with black produces no change.

Hard Mix

Adds the RGB channels of the blend colour to the RGB values of the base colour. If the resulting sum for a channel is 255 or greater, it receives a value of 255; if it is less than 255 it receives a value of 0. Therefore all blended pixels have RGB channels of either 0 or 255. This changes all pixels to primary additive colours (RGB), white or black.

Brightness

This property (which appears as a light bulb icon) controls the brightness of the layer output.



If the layers blend mode is set to Alpha, then reducing the brightness to 0 also reduces the opacity of the layer to 0. This can be useful when you want to dissolve from one layer to the next. In that case, you can place the new layer above the old layer and increase its brightness level.

> **Note**
>
> Layers that are patched to Sockpuppet (DMX, OSC or HTTP) are made Dormant when their brightness is set to 0. This means they will not do any rendering or consume any resources until their brightness is changed to > 0. You can find more information about this here: **Sequencing with Sockpuppet**. Layers without a sockpuppet patch do not behave in this way.

Mapping

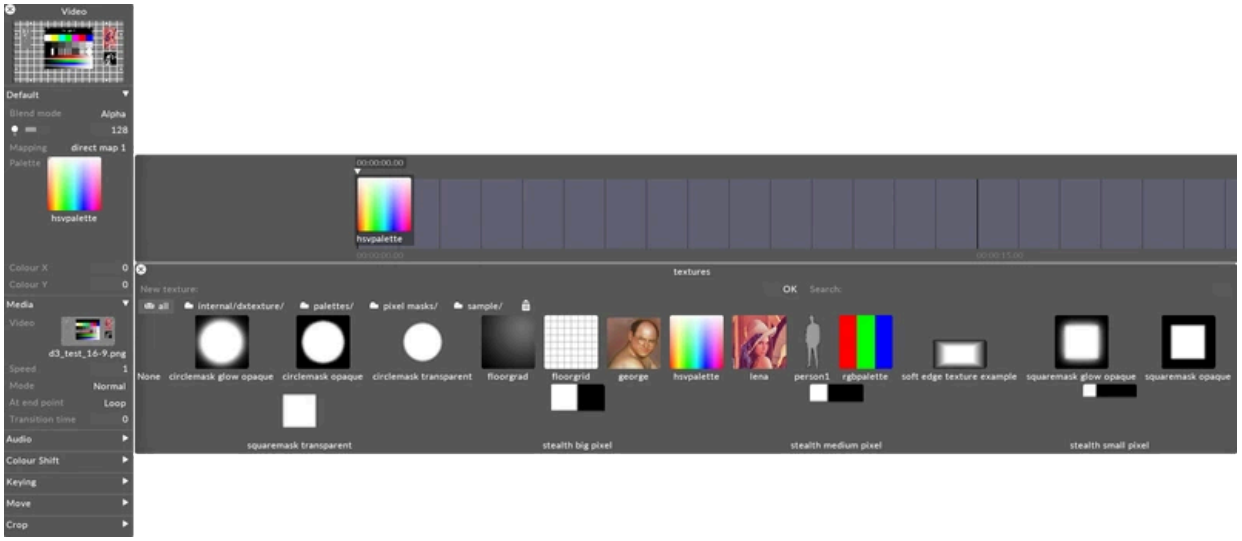
The mapping property controls how the layer output is mapped onto the screen(s) in the Stage level.

For information on mapping, including how to use the different mapping types offered by Designer, please see the chapter **Content Mapping**

Palette

This points to the still image file that defines the bitmap from which the tint colour is taken. The default palette (HSVPAL) consists of the complete range of hues and saturations. Selecting this property will open the Texture object library, which shows all of the still image files saved on your local hard-drive in the **DxTexture** older.

To control the location within the current palette bitmap, and thus control the colour, you have to edit the **xCol** and **yCol** values (see the section for xCol, yCol).



To change the current palette bitmap:

1. Left-click **palette** to open the Texture object library.
2. Left-click the still image file you want to use for the palette bitmap.

If you want to use a palette bitmap other than the standard still images provided in Designer, you will need to use a custom still image file.

See the **Placing media files** for a project sub-chapter to understand where to place a custom still image file and how to access it in Designer. Also save the file to a **supported file format**.

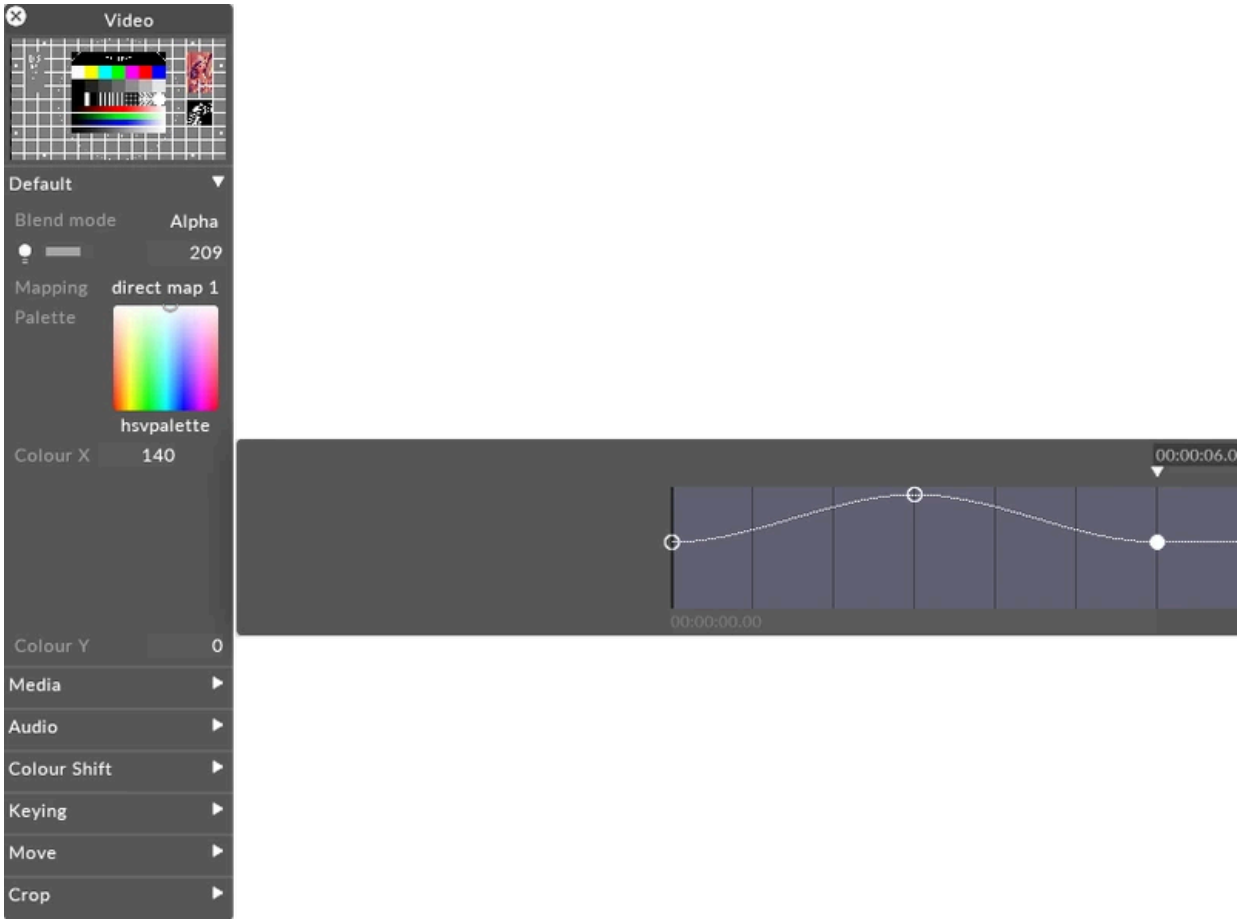
Xcol, YCol

These properties control the coordinates within the current palette bitmap where the output colour is sampled from. The default value is 0,0 which points at the color white (if you are using the HSVPAL palette). Multiplying white with the colors of the chosen content simply generates the original content colors. **Colour X** controls the horizontal position, where 0 is the leftmost edge and 255 is the rightmost edge. **Colour Y** controls the vertical position, where 0 is the top edge and 255 is the bottom edge.

For example, to saturate the video clip red, change the **Colour Y** value to 255 and use 0 for the **Colour X** value. These coordinates refer to the color red in the palette which is being multiplied

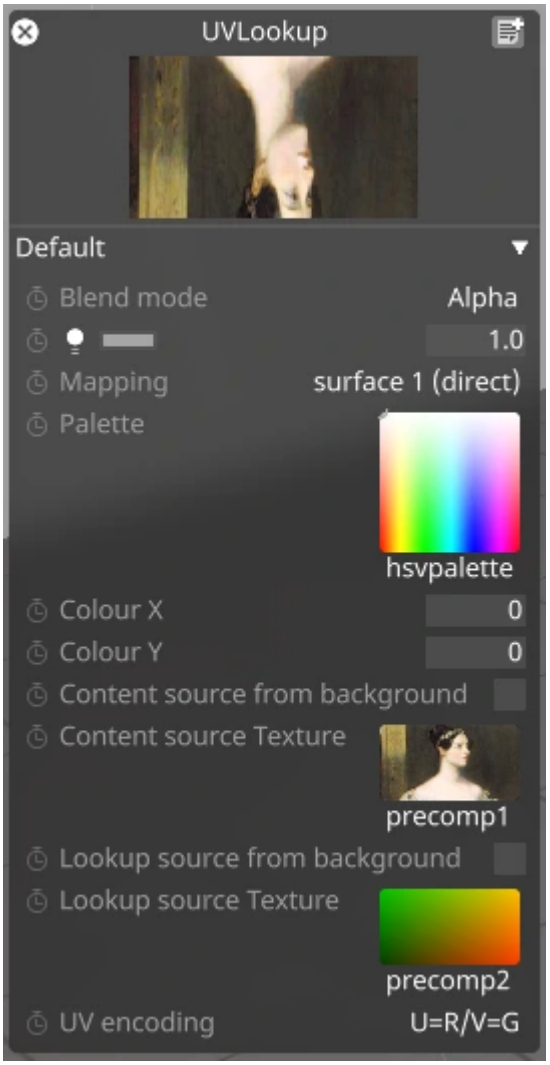
with the colors of the existing content.

When you are using the default palette HSVPAL , Colour Y controls saturation, and Colour X controls hue.



UVLookup Layer

The UVLookup layer allows you to to change the UV mapping of a source texture applied to an object based on colour information contained in a lookup texture Overview



Similar in function to *Youveelizer*, the plugin for After Effects that allows you to replace textures by using a UV map, the UVLookup layer is an effects layer available directly in Designer.

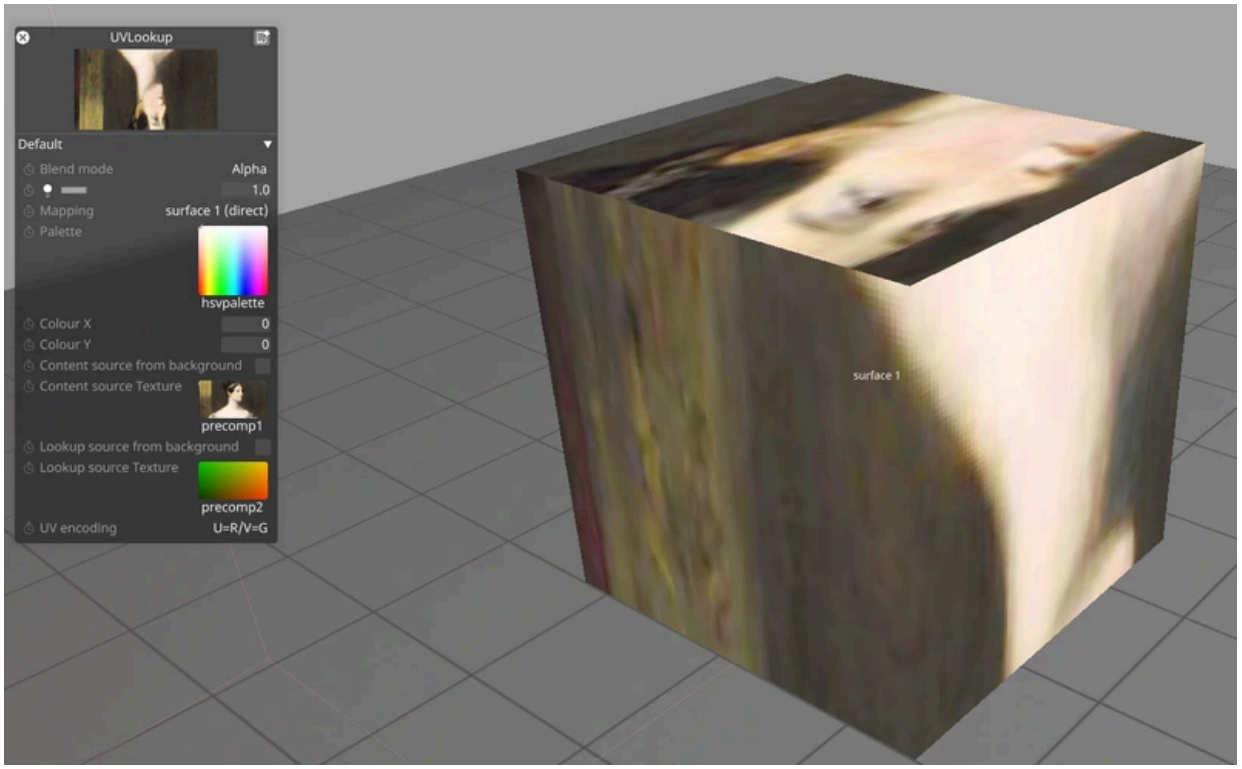
The data is packed as two 12bit coordinates, U & V, into a 24-bit RGB video.

Workflow

The UVLookup layer requires a Content source texture and a Lookup source texture. It is recommended to create PreComp textures and use these textures as the source textures within the UVLookup layer. For information on creating a PreComp visit thi link.

To configure the layer, follow these steps:

1. Open a UVLookup layer
2. Create a new PreComp texture, “PreComp 1”, and assign this as the Content source texture
3. Create a Video layer directly under the UVLookup layer, set the mapping of the layer to ” PreComp 1”, and select a piece of media for the Video layer.
4. Return to the UVLookup layer editor and create a second PreComp texture, “PreComp 2”
5. Add a second Video layer directly beneath the UVLookup layer, map it to “PreComp 2”, and select a piece of media for the Video layer. Ideally this content will be a UV pass rendered specifically for this application
6. In the UVLookup layer editor, change the UV encoding setting to match the desired UV mapping coordinates; U=R/V=G is shown in the image shown below:



UVLookup Layer Properties

Content Source

The texture that is mapped to the object. There are two options:

- **Lookup source from Background**- when enabled, the existing screen content is used as the source texture.
- **Content source Texture**-this can be a texture applied directly in this field or by using an arrow from another content source layer

Lookup Source

The texture that is to be used as the UV map for the content source.

There are two options:

- **Lookup source from Background**- when enabled, all the layers that are below the UVLookup layer on the timeline and also share the same mapping as the UVLookup layer, are used as the source texture.
- **Lookup source Texture**-this can be a texture applied directly in this field or by using an arrow from another content source layer

UV encoding

The UV mapping coordinates for the RGBA channels in the Lookup source texture.

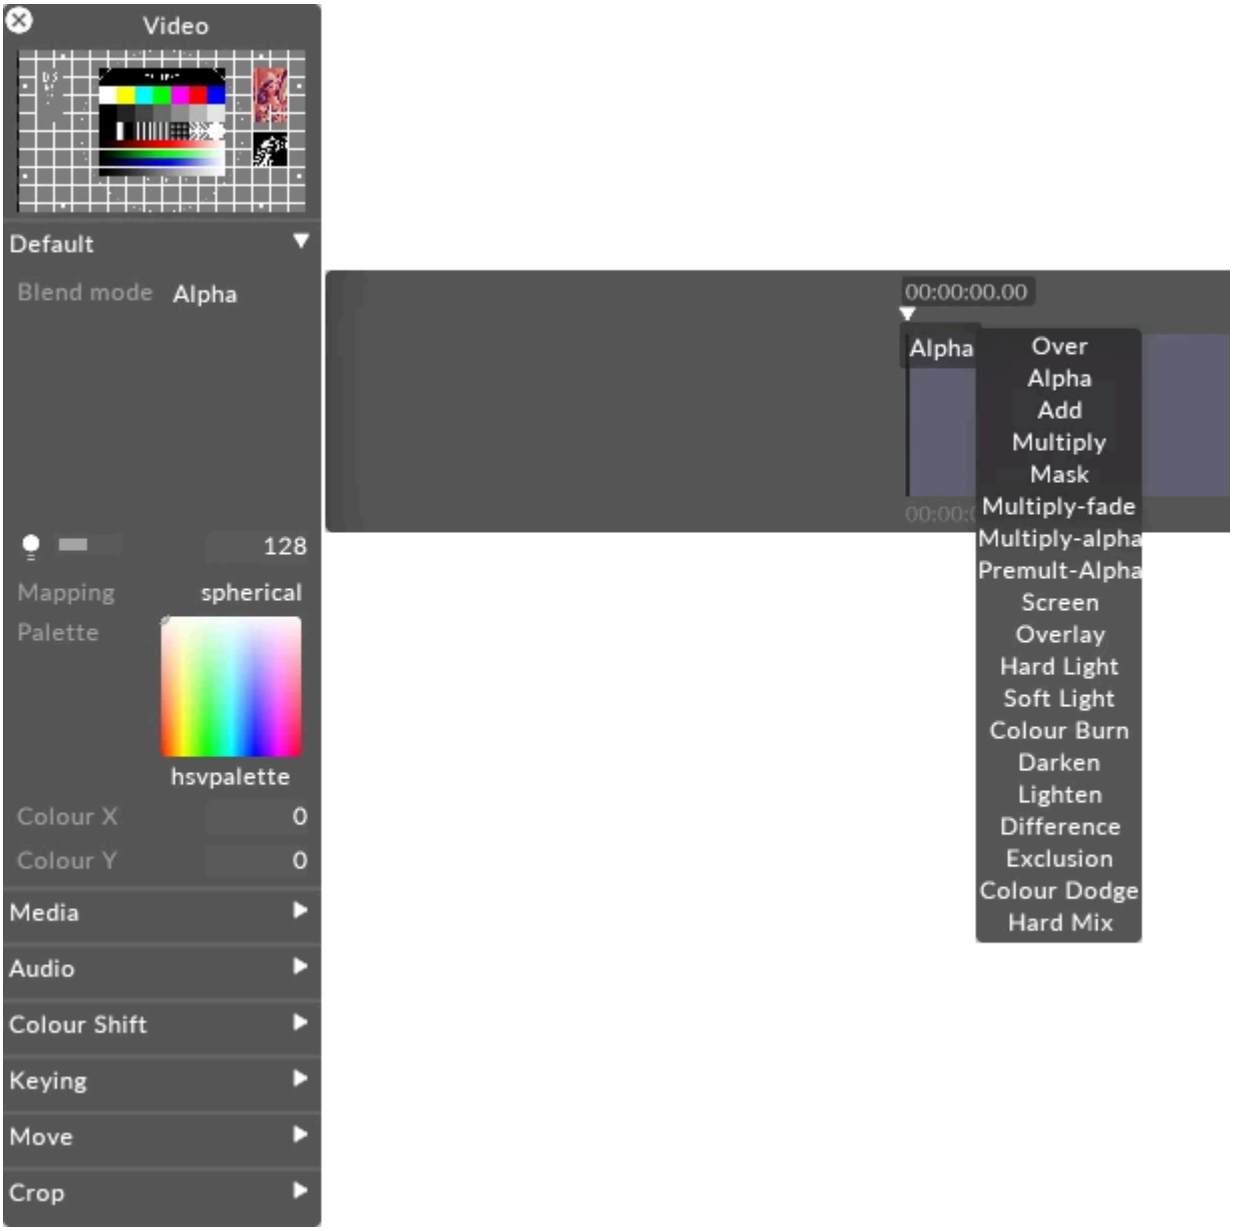
There are 4 options:

- **U-R/V=G**
- **U=R/V-B**
- **UV=RGB (Packed)**
- **U=RG/V=BA**

Common Layer Properties

Blend Mode

BlendMode controls how the output of the layer is composited with the layers below. Layers are rendered in a bottom-up order: layers at the top can modify the output of the layers below.



Changing brightness of a content layer in Designer is actually controlling the value of the alpha of the layer. Even when displaying a HAP video, the software will composite the layer with a controllable layer of alpha - one per layer.

There are two ways of expressing alpha in an image:

Straight alpha is an alpha channel which functions just like RGB. Alpha acts as a fourth channel of information per pixel which is as independent of the other three as R, G and B are of each other. For example, with straight alpha it is possible to have RGB = 255 (white) and alpha = 0 (fully transparent) on the same pixel. Internally generated content, such as gradient layer, are generated with straight alpha. This is the preferable style of alpha and considering the cleaner method of the two.

Premultiplied alpha takes the alpha and applies it to the values of the RGB channels per pixel. The more transparent something gets with premultiplied alpha, the closer it gets to black - as if the content is sitting on a black table. Premultiplied is the default output of Adobe Photoshop or AfterEffects. The result is our pixel at 255 RGB (full white) with 0 alpha would be calculated as a black pixel in the final image.

Here are explanations of what each individual blend mode will do.

Over

Makes a layer fully opaque. Premultiplies all alpha onto the RGB value of each pixel. Alpha = black, so adjusting the brightness of a layer in Over blend mode makes it darker.

Alpha

Default blend mode. It will apply alpha values as a transparency if the alpha is present. Brightness changes will make the layer more or less transparent.

Add

Adds the value of each RGB pixel together. Always creates a brighter result. Values clamp at 255.

Multiply

Reads the level of each subpixel as a level between 0.0 and 1.0, and multiplies source with blend. The result is always a darker image overall. For example: white x grey = 0.5. White turns transparent, black takes precedence. Alpha is applied in the same fashion as the Over Blend mode.

Mask

Applies a mask to the single layer **above** in the stack, irrespective of mapping. See **Mask blending** for more information.

Luma-Matte

This mode creates a Luma Matte by using a layer's **Rec. 709 luminance** to control the alpha channel of the layer **above**, irrespective of mapping.

To determine transparency, the luminance of each pixel is calculated using a weighted average of its red, green, and blue channels. The luminance value is then used as the alpha (opacity) value for the corresponding pixels in the upper layers.

As a result, white areas render the layer above fully opaque, black areas make them fully transparent, and grey areas create proportional semi-transparency. This is a specialized **Mask** blend mode; for more details on the underlying behaviour, see **Mask blending**.

Inv-Luma-Matte

The Inverse Luma Matte mask works the same as the **Luma Matte** mask but the transparency is inverted meaning white regions are transparent and black regions are opaque.

Multiply-Fade

The same as Multiply, but will make use of the alpha channel to calculate transparency in the source and blend layers. Since maximum transparency is premultiplied, alpha results in black. This will ignore black created through premultiplying.

Multiply-Alpha

Multiply with straight alpha. This mode assumes that the alpha has not been premultiplied onto the RGB values and will not apply a correction to the semi-transparent pixels.

Premultiply Alpha

Like how Multiply-fade will ignore the darkening caused by premultiplying, this blend mode will do the same with Alpha.

Colour Burn

Blend mode increases the contrast to darken the base colour while reflecting the blend colour. The darker the blend colour, the more intensely the colour will be applied in the base image. White as the blend colour produces no change. Using the colour burn blend mode can produce some harsh results at full opacity. The colour burn blend mode can be used to make tonal and colour adjustments to a layer.

Screen

This blend mode looks at each channels colour information and multiplies the inverse of the blend and base colous. The result is always a lighter colour. Screening with black leaves the colour unchanged. Screening with white produces white. The effect is similar to projecting multiple images on top of each other - where bright white is fully opaque, black is fully transparent and 50% grey is 50% transparent.

Overlay

Multiplies or screens the colours, depending on the base colour. Patterns or colours overlay the existing pixels while preserving the highlights and shadows of the base colour. The base colour is not replaced, but mixed with the blend colour to reflect the lightness or darkness of the original colour.

Hard Light

Multiplies or screens the colours, depending on the blend colour. The effects is similar to shining a harsh spotlight on the image. If the blend colour (light source/top layer) is lighter than

50% grey, the image is lightened as if it were screened. This is useful for adding highlights to an image. If the blend colour is darker than 50% grey, the image is darkened as if it were multiplied. This is useful for adding shadows to an image. Painting with pure black or white results in pure black or white.

Soft Light

Darkens or lightens the colours, depending on the blend colour. The effect is similar to shining a diffused spotlight on the image. If the blend colour (light source/top layer) is lighter than 50% grey, the image is lightened as it if were dodged. If the blend colour is darker than 50% grey, the image is darkened as if it were burned in. Painting with pure black or white produces a distinctly darker or lighter area, but does not result in pure black or white.

Darken

Looks as the colour information in each channel and selects the base or blend colour - whichever is darker - as the result colour. Pixels lighter than the blend colour are replaced and pixels darker than the blend colour do not change.

Lighten

Looks at the colour information in each channel and selects the base or blend colour - whichever is lighter - as the result colour. Pixels darker than the blend colour are replaced and pixels lighter than the blend colour do not change.

Difference

Looks at the colour information in each channel and subtracts either the blend colour from the base colour or the base colour from the blend colour depending on which has the greater brightness value. Blending with white inverts the base colour values and blending with black produces no change.

Exclusion

Creates an effects similar to but lower in contrast than the difference mode. Blending with white inverts the base colour values. Blending with black produces no change.

Colour Dodge

Looks at the colour information in each channel and brightens the base colour to reflect the blend colour by decreasing contrast between the two. Blending with black produces no change.

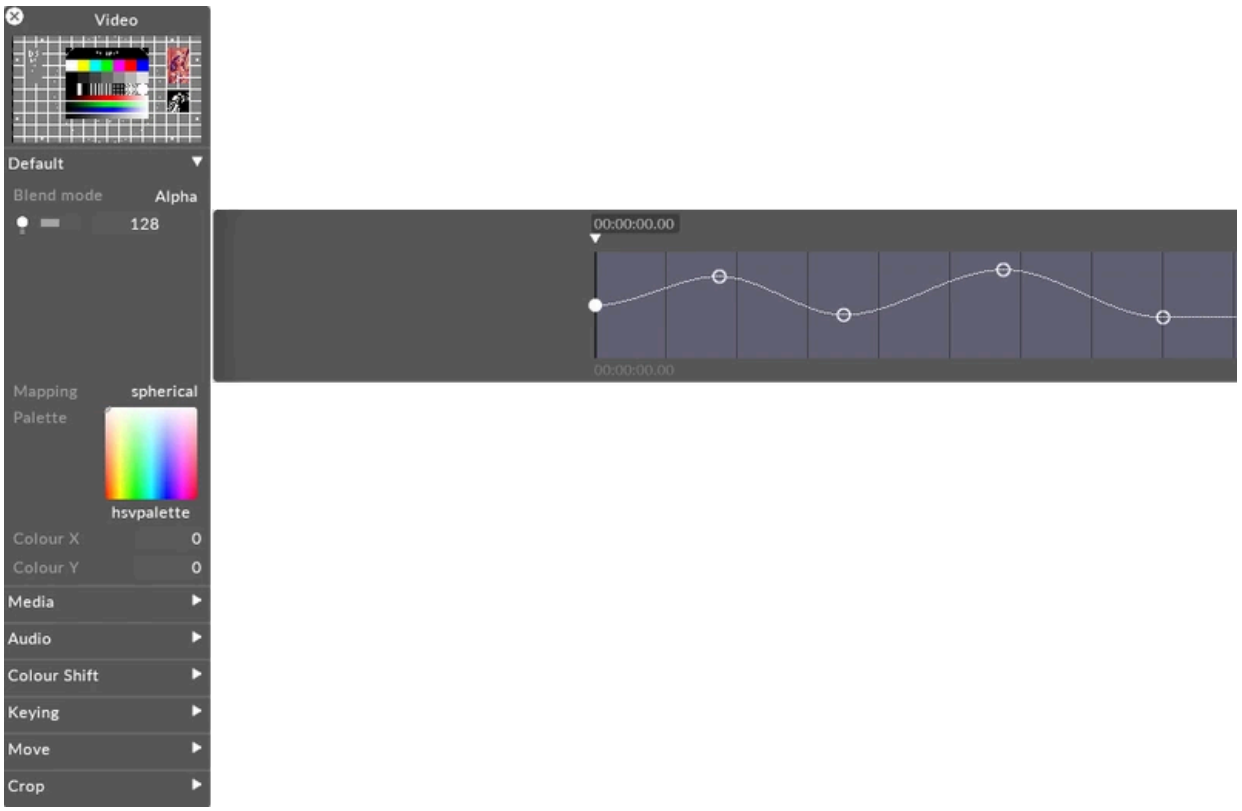
Hard Mix

Adds the RGB channels of the blend colour to the RGB values of the base colour. If the resulting sum for a channel is 255 or greater, it receives a value of 255; if it is less than 255 it

receives a value of 0. Therefore all blended pixels have RGB channels of either 0 or 255. This changes all pixels to primary additive colours (RGB), white or black.

Brightness

This property (which appears as a light bulb icon) controls the brightness of the layer output.



If the layers blend mode is set to Alpha, then reducing the brightness to 0 also reduces the opacity of the layer to 0. This can be useful when you want to dissolve from one layer to the next. In that case, you can place the new layer above the old layer and increase its brightness level.

> **Note**
>
> Layers that are patched to Sockpuppet (DMX, OSC or HTTP) are made Dormant when their brightness is set to 0. This means they will not do any rendering or consume any resources until their brightness is changed to > 0. You can find more information about this here: **Sequencing with Sockpuppet**. Layers without a sockpuppet patch do not behave in this way.

Mapping

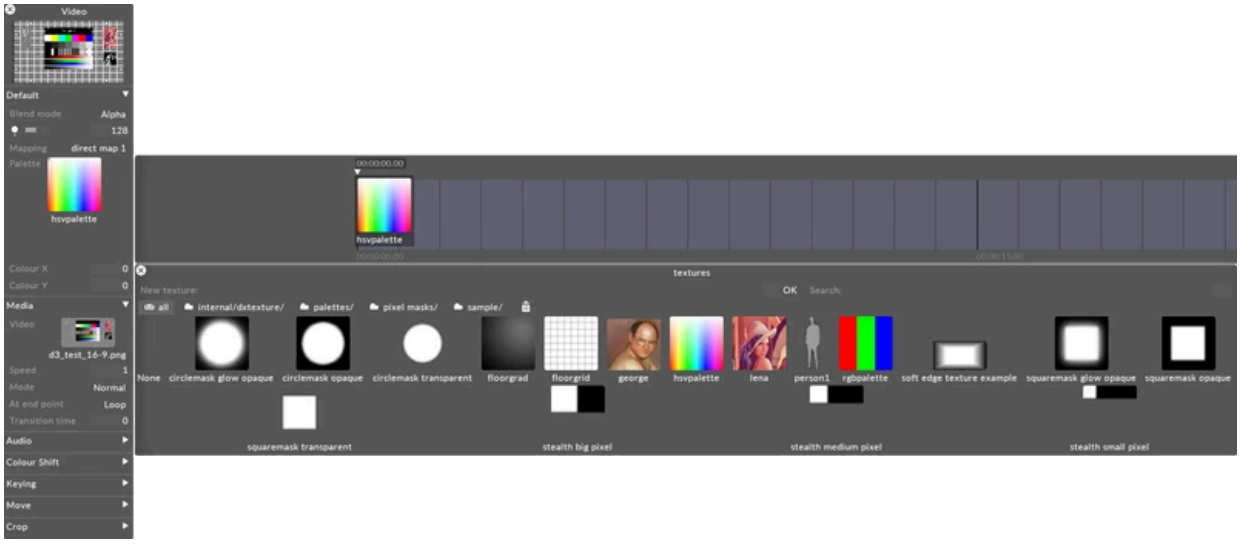
The mapping property controls how the layer output is mapped onto the screen(s) in the Stage level.

For information on mapping, including how to use the different mapping types offered by Designer, please see the chapter **Content Mapping**

Palette

This points to the still image file that defines the bitmap from which the tint colour is taken. The default palette (HSVPAL) consists of the complete range of hues and saturations. Selecting this property will open the Texture object library, which shows all of the still image files saved on your local hard-drive in the **DxTexture** older.

To control the location within the current palette bitmap, and thus control the colour, you have to edit the **xCol** and **yCol** values (see the section for xCol, yCol).



To change the current palette bitmap:

1. Left-click **palette** to open the Texture object library.
2. Left-click the still image file you want to use for the palette bitmap.

If you want to use a palette bitmap other than the standard still images provided in Designer, you will need to use a custom still image file.

See the **Placing media files** for a project sub-chapter to understand where to place a custom still image file and how to access it in Designer. Also save the file to a **supported file format**.

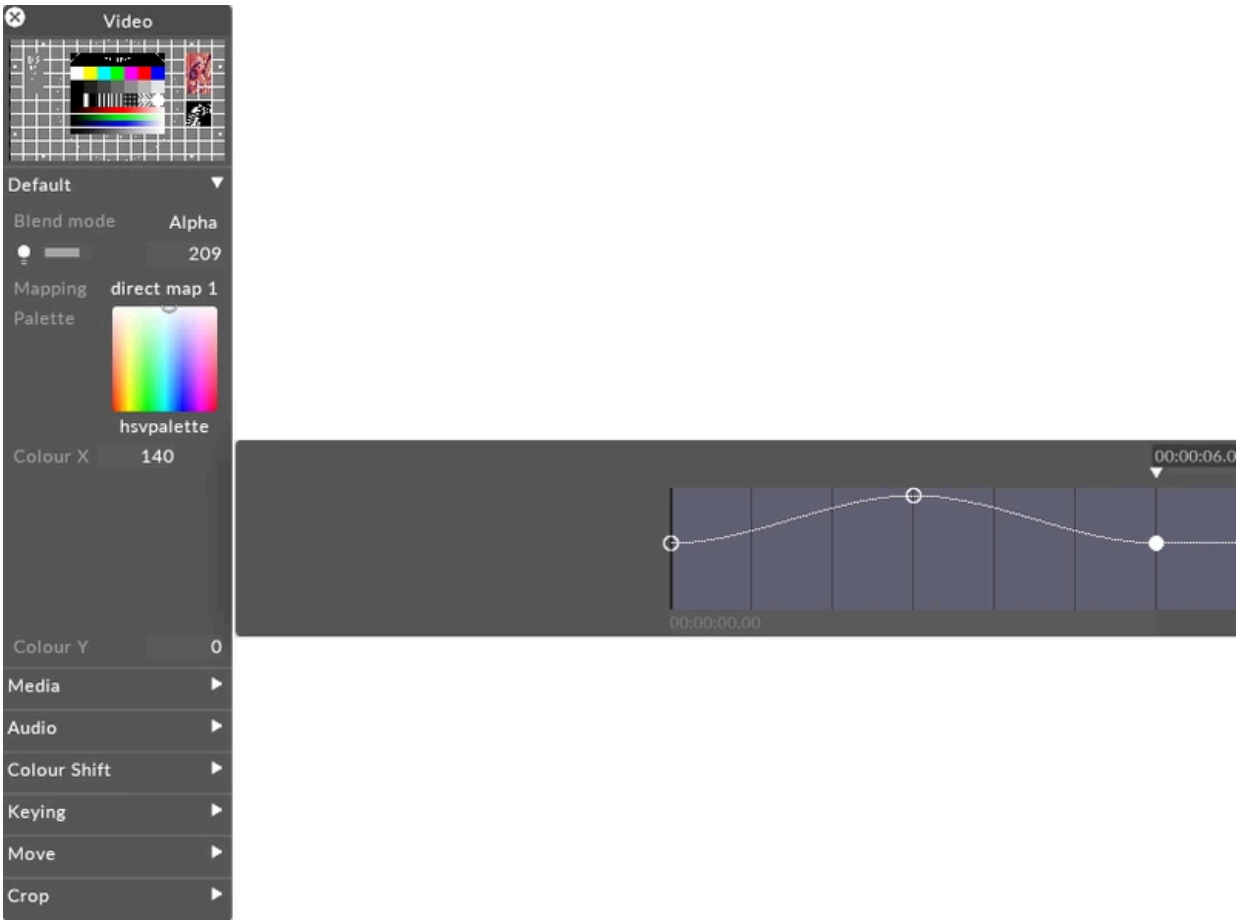
Xcol, YCol

These properties control the coordinates within the current palette bitmap where the output colour is sampled from. The default value is 0,0 which points at the color white (if you are using the HSVPAL palette). Multiplying white with the colors of the chosen content simply generates the original content colors. **Colour X** controls the horizontal position, where 0 is the leftmost

edge and 255 is the rightmost edge. **Colour Y** controls the vertical position, where 0 is the top edge and 255 is the bottom edge.

For example, to saturate the video clip red, change the **Colour Y** value to 255 and use 0 for the **Colour X** value. These coordinates refer to the color red in the palette which is being multiplied with the colors of the existing content.

When you are using the default palette HSVPAL , Colour Y controls saturation, and Colour X controls hue.



VideoTransition

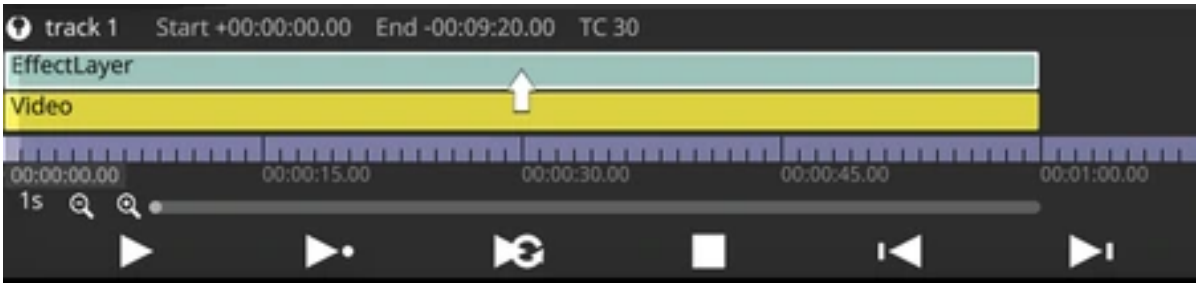
The VideoTransition layer is used as a quick and easy way to perform graphical video transitions between two sets of content. For example, the transition can be a left-to-right wipe or a star wipe. This is very similar functionality to that found on vision mixers.

Workflow

Effect layers receive their source from other layer types - either content or generative - through arrows. An arrow connects a source layer to a destination layer; the source layer is said to be “piped in” to the destination Effect layer. For more information on arrows, see the **compositing layers** topic.

To draw an arrow between two layers, hold down **ALT** and left-click & drag from the source layer to the destination layer.

1. Add an Effect layer to your track. For more information about adding layers, see **creating layers**.
2. Draw an arrow from your content layer to the Effect layer so the compositing order looks something like the following image.



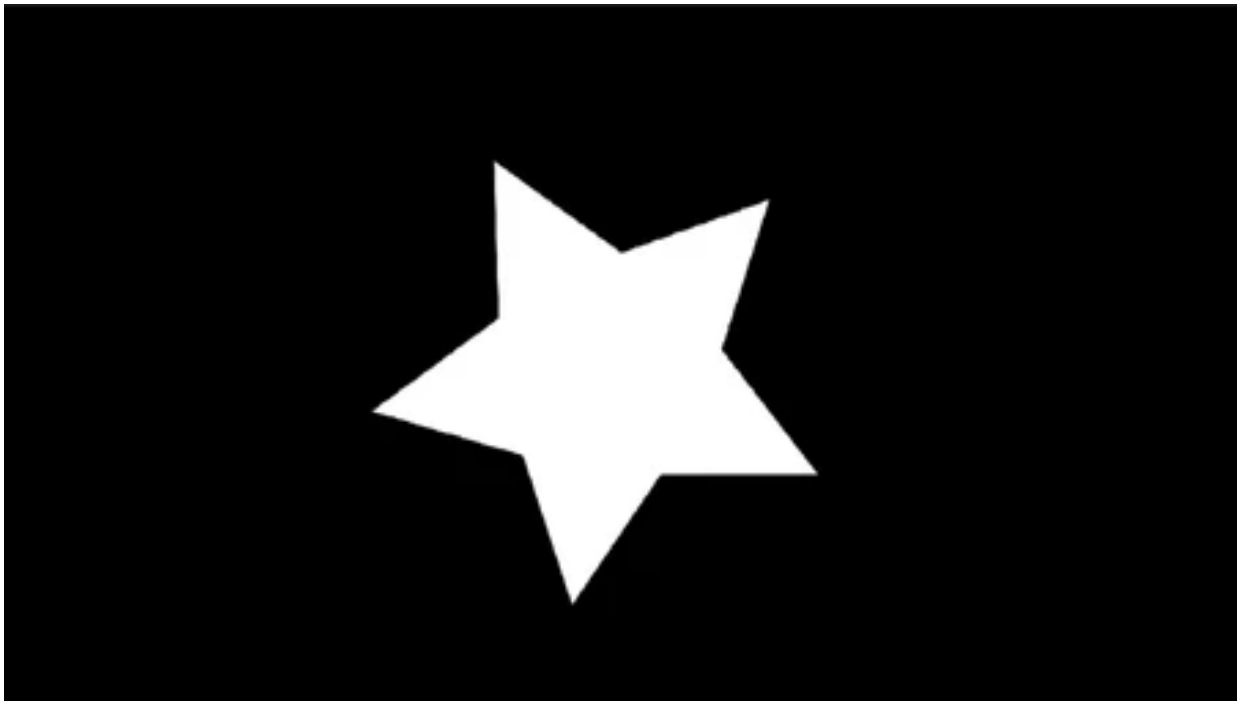
A Video layer piped into an Effect layer on the timeline.

3. Adjust the Effect layer properties to achieve the desired result.

Video Transition File Requirements

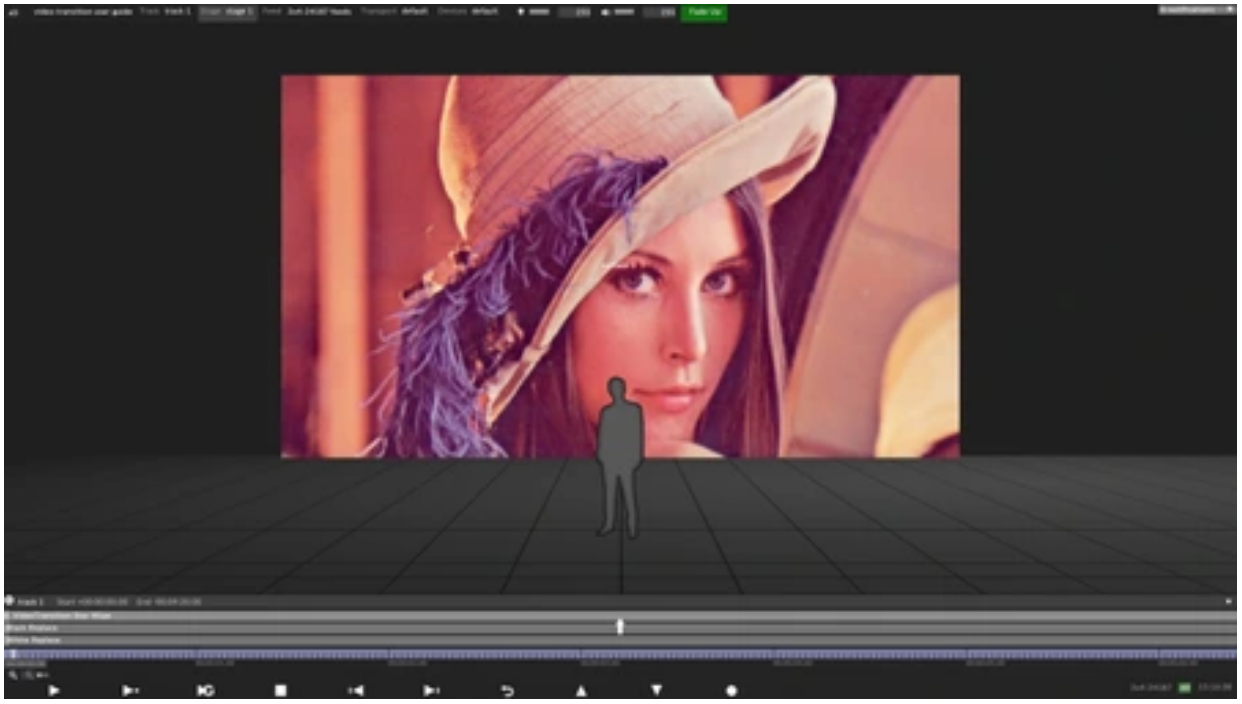
The transitions will need to be black and white, where video 1 will replace the white, and video 2 will replace the black. **These must be a movie** and **not a still image** like PNG or JPEG.

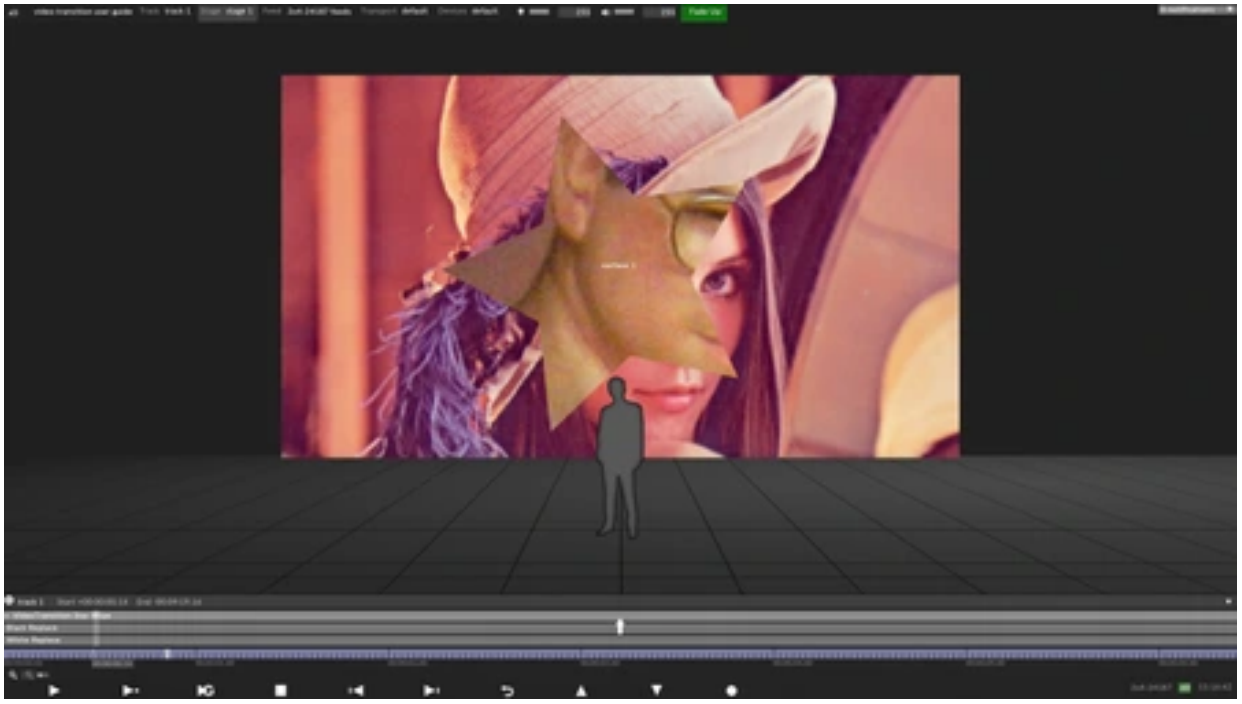
See screenshots here of how an example Video Transition looks using George, Lena and a greyscale Star.



End Result

After arrowing video layers into the Video Transition Layer, this is the effect produced.

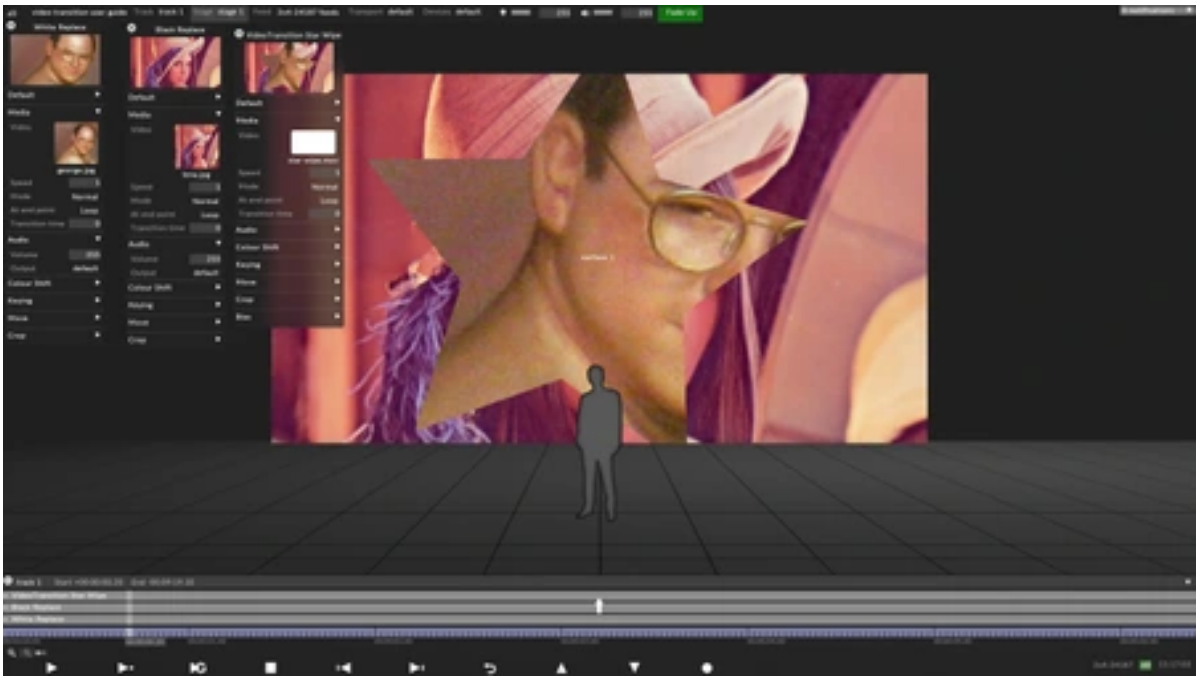




Example

1. Firstly, create two video layers and populate them with content. This can be any valid video file, including the Video Input.

2. Then add a **VideoTransition** layer above the two video modules. Next, hold down the Alt key and click on what video is replacing the Black of the video Transition, and drag that arrow to the Video Transition layer. Likewise, do the same for the video, replacing the White part.
3. Next, add your Video Transition Video into the Video Transition Layer.
4. If you hit play, you will see your desired effect. Here is an image of the Layers used and how they are populated

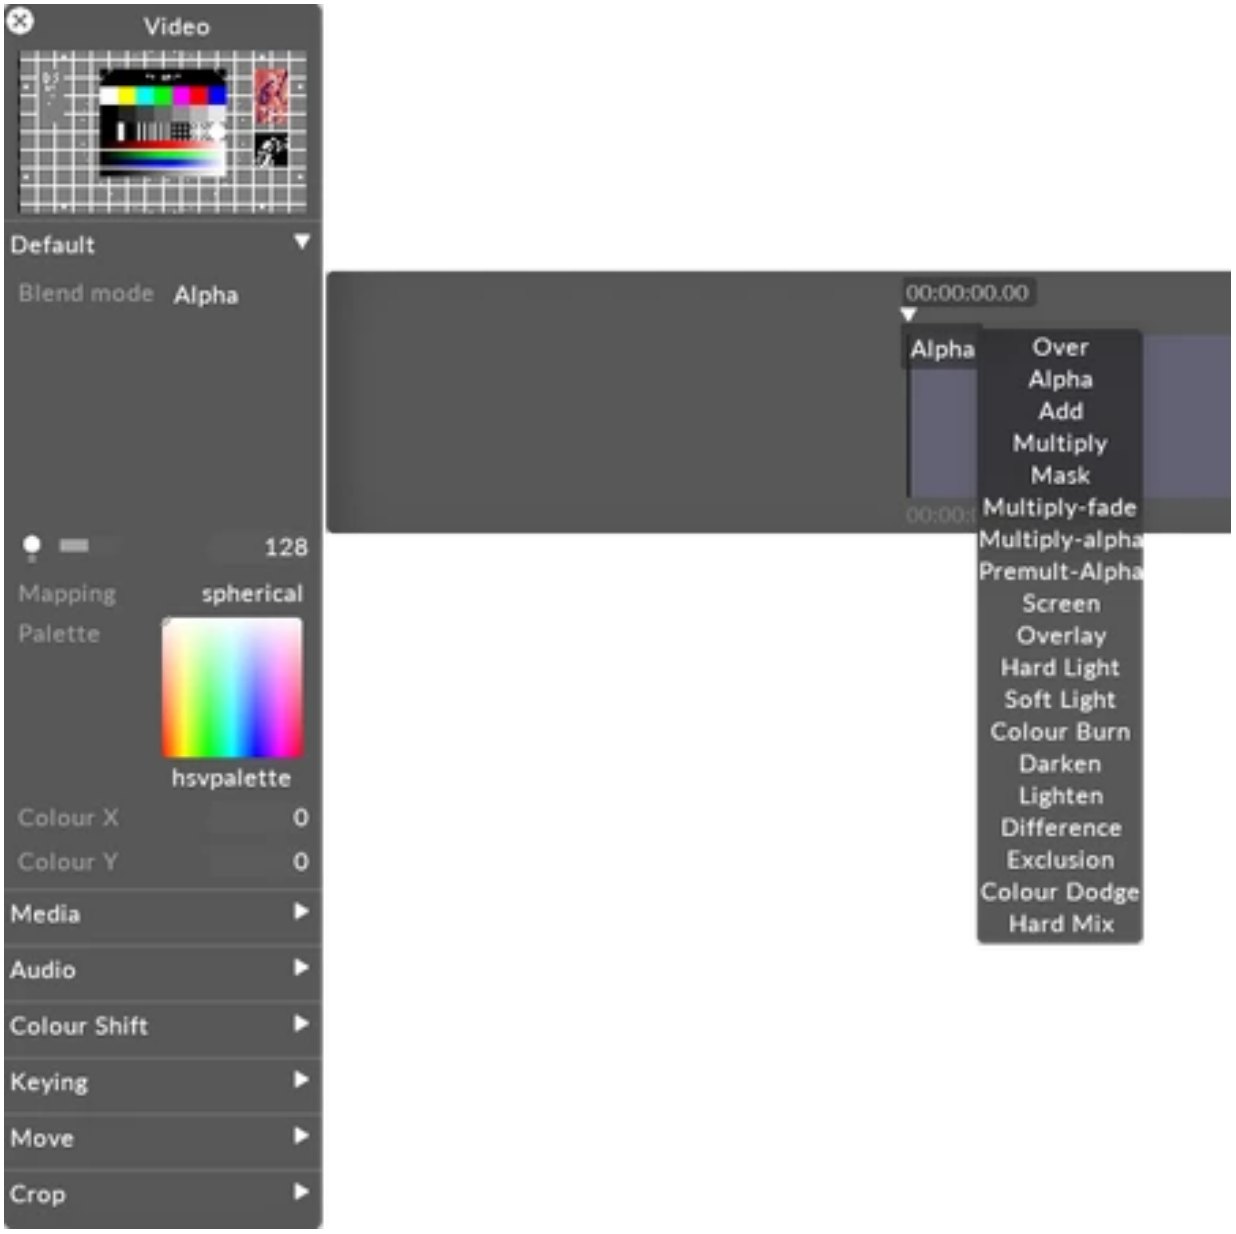


If you would like to reverse the Black and White of the Video Transition, then simply go into the 'Colour Shift' dropdown of the Layer and swap the RGB Maximum and Minimum values, so that the Minimum is now 255 and the Maximum is 0.

Common Layer Properties

Blend Mode

BlendMode controls how the output of the layer is composited with the layers below. Layers are rendered in a bottom-up order: layers at the top can modify the output of the layers below.



Changing brightness of a content layer in Designer is actually controlling the value of the alpha of the layer. Even when displaying a HAP video, the software will composite the layer with a controllable layer of alpha - one per layer.

There are two ways of expressing alpha in an image:

Straight alpha is an alpha channel which functions just like RGB. Alpha acts as a fourth channel of information per pixel which is as independent of the other three as R, G and B are of each other. For example, with straight alpha it is possible to have RGB = 255 (white) and alpha = 0 (fully transparent) on the same pixel. Internally generated content, such as gradient layer, are generated with straight alpha. This is the preferable style of alpha and considering the cleaner method of the two.

Premultiplied alpha takes the alpha and applies it to the values of the RGB channels per pixel. The more transparent something gets with premultiplied alpha, the closer it gets to black - as if the content is sitting on a black table. Premultiplied is the default output of Adobe Photoshop or AfterEffects. The result is our pixel at 255 RGB (full white) with 0 alpha would be calculated as a black pixel in the final image.

Here are explanations of what each individual blend mode will do.

Over

Makes a layer fully opaque. Premultiplies all alpha onto the RGB value of each pixel. Alpha = black, so adjusting the brightness of a layer in Over blend mode makes it darker.

Alpha

Default blend mode. It will apply alpha values as a transparency if the alpha is present. Brightness changes will make the layer more or less transparent.

Add

Adds the value of each RGB pixel together. Always creates a brighter result. Values clamp at 255.

Multiply

Reads the level of each subpixel as a level between 0.0 and 1.0, and multiplies source with blend. The result is always a darker image overall. For example: white x grey = 0.5. White turns transparent, black takes precedence. Alpha is applied in the same fashion as the Over Blend mode.

Mask

Applies a mask to the single layer **above** in the stack, irrespective of mapping. See **Mask blending** for more information.

Luma-Matte

This mode creates a Luma Matte by using a layer's **Rec. 709 luminance** to control the alpha channel of the layer **above**, irrespective of mapping.

To determine transparency, the luminance of each pixel is calculated using a weighted average of its red, green, and blue channels. The luminance value is then used as the alpha (opacity) value for the corresponding pixels in the upper layers.

As a result, white areas render the layer above fully opaque, black areas make them fully transparent, and grey areas create proportional semi-transparency. This is a specialized **Mask** blend mode; for more details on the underlying behaviour, see **Mask blending**.

Inv-Luma-Matte

The Inverse Luma Matte mask works the same as the **Luma Matte** mask but the transparency is inverted meaning white regions are transparent and black regions are opaque.

Multiply-Fade

The same as Multiply, but will make use of the alpha channel to calculate transparency in the source and blend layers. Since maximum transparency is premultiplied, alpha results in black. This will ignore black created through premultiplying.

Multiply-Alpha

Multiply with straight alpha. This mode assumes that the alpha has not been premultiplied onto the RGB values and will not apply a correction to the semi-transparent pixels.

Premultiply Alpha

Like how Multiply-fade will ignore the darkening caused by premultiplying, this blend mode will do the same with Alpha.

Colour Burn

Blend mode increases the contrast to darken the base colour while reflecting the blend colour. The darker the blend colour, the more intensely the colour will be applied in the base image. White as the blend colour produces no change. Using the colour burn blend mode can produce some harsh results at full opacity. The colour burn blend mode can be used to make tonal and colour adjustments to a layer.

Screen

This blend mode looks at each channels colour information and multiplies the inverse of the blend and base colous. The result is always a lighter colour. Screening with black leaves the colour unchanged. Screening with white produces white. The effect is similar to projecting multiple images on top of each other - where bright white is fully opaque, black is fully transparent and 50% grey is 50% transparent.

Overlay

Multiplies or screens the colours, depending on the base colour. Patterns or colours overlay the existing pixels while preserving the highlights and shadows of the base colour. The base colour is not replaced, but mixed with the blend colour to reflect the lightness or darkness of the original colour.

Hard Light

Multiplies or screens the colours, depending on the blend colour. The effects is similar to shining a harsh spotlight on the image. If the blend colour (light source/top layer) is lighter than

50% grey, the image is lightened as if it were screened. This is useful for adding highlights to an image. If the blend colour is darker than 50% grey, the image is darkened as if it were multiplied. This is useful for adding shadows to an image. Painting with pure black or white results in pure black or white.

Soft Light

Darkens or lightens the colours, depending on the blend colour. The effect is similar to shining a diffused spotlight on the image. If the blend colour (light source/top layer) is lighter than 50% grey, the image is lightened as it if were dodged. If the blend colour is darker than 50% grey, the image is darkened as if it were burned in. Painting with pure black or white produces a distinctly darker or lighter area, but does not result in pure black or white.

Darken

Looks as the colour information in each channel and selects the base or blend colour - whichever is darker - as the result colour. Pixels lighter than the blend colour are replaced and pixels darker than the blend colour do not change.

Lighten

Looks at the colour information in each channel and selects the base or blend colour - whichever is lighter - as the result colour. Pixels darker than the blend colour are replaced and pixels lighter than the blend colour do not change.

Difference

Looks at the colour information in each channel and subtracts either the blend colour from the base colour or the base colour from the blend colour depending on which has the greater brightness value. Blending with white inverts the base colour values and blending with black produces no change.

Exclusion

Creates an effects similar to but lower in contrast than the difference mode. Blending with white inverts the base colour values. Blending with black produces no change.

Colour Dodge

Looks at the colour information in each channel and brightens the base colour to reflect the blend colour by decreasing contrast between the two. Blending with black produces no change.

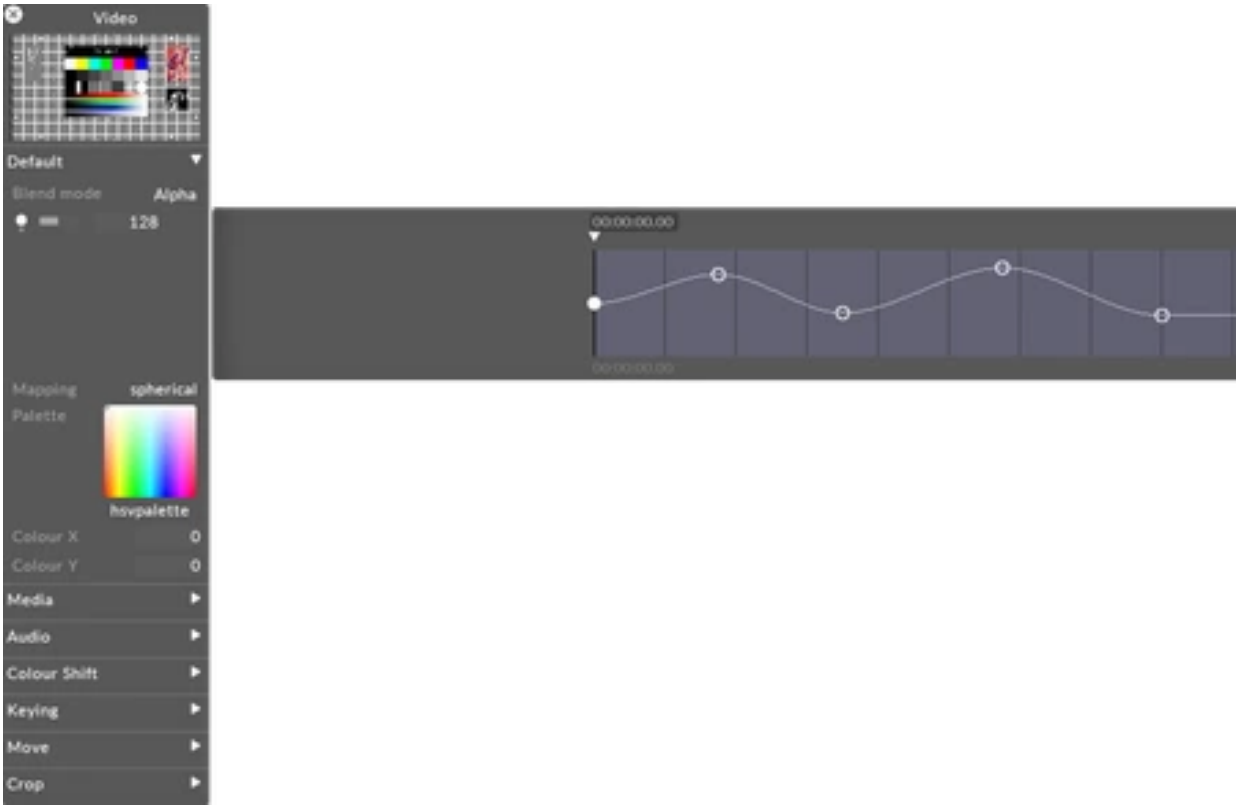
Hard Mix

Adds the RGB channels of the blend colour to the RGB values of the base colour. If the resulting sum for a channel is 255 or greater, it receives a value of 255; if it is less than 255 it

receives a value of 0. Therefore all blended pixels have RGB channels of either 0 or 255. This changes all pixels to primary additive colours (RGB), white or black.

Brightness

This property (which appears as a light bulb icon) controls the brightness of the layer output.

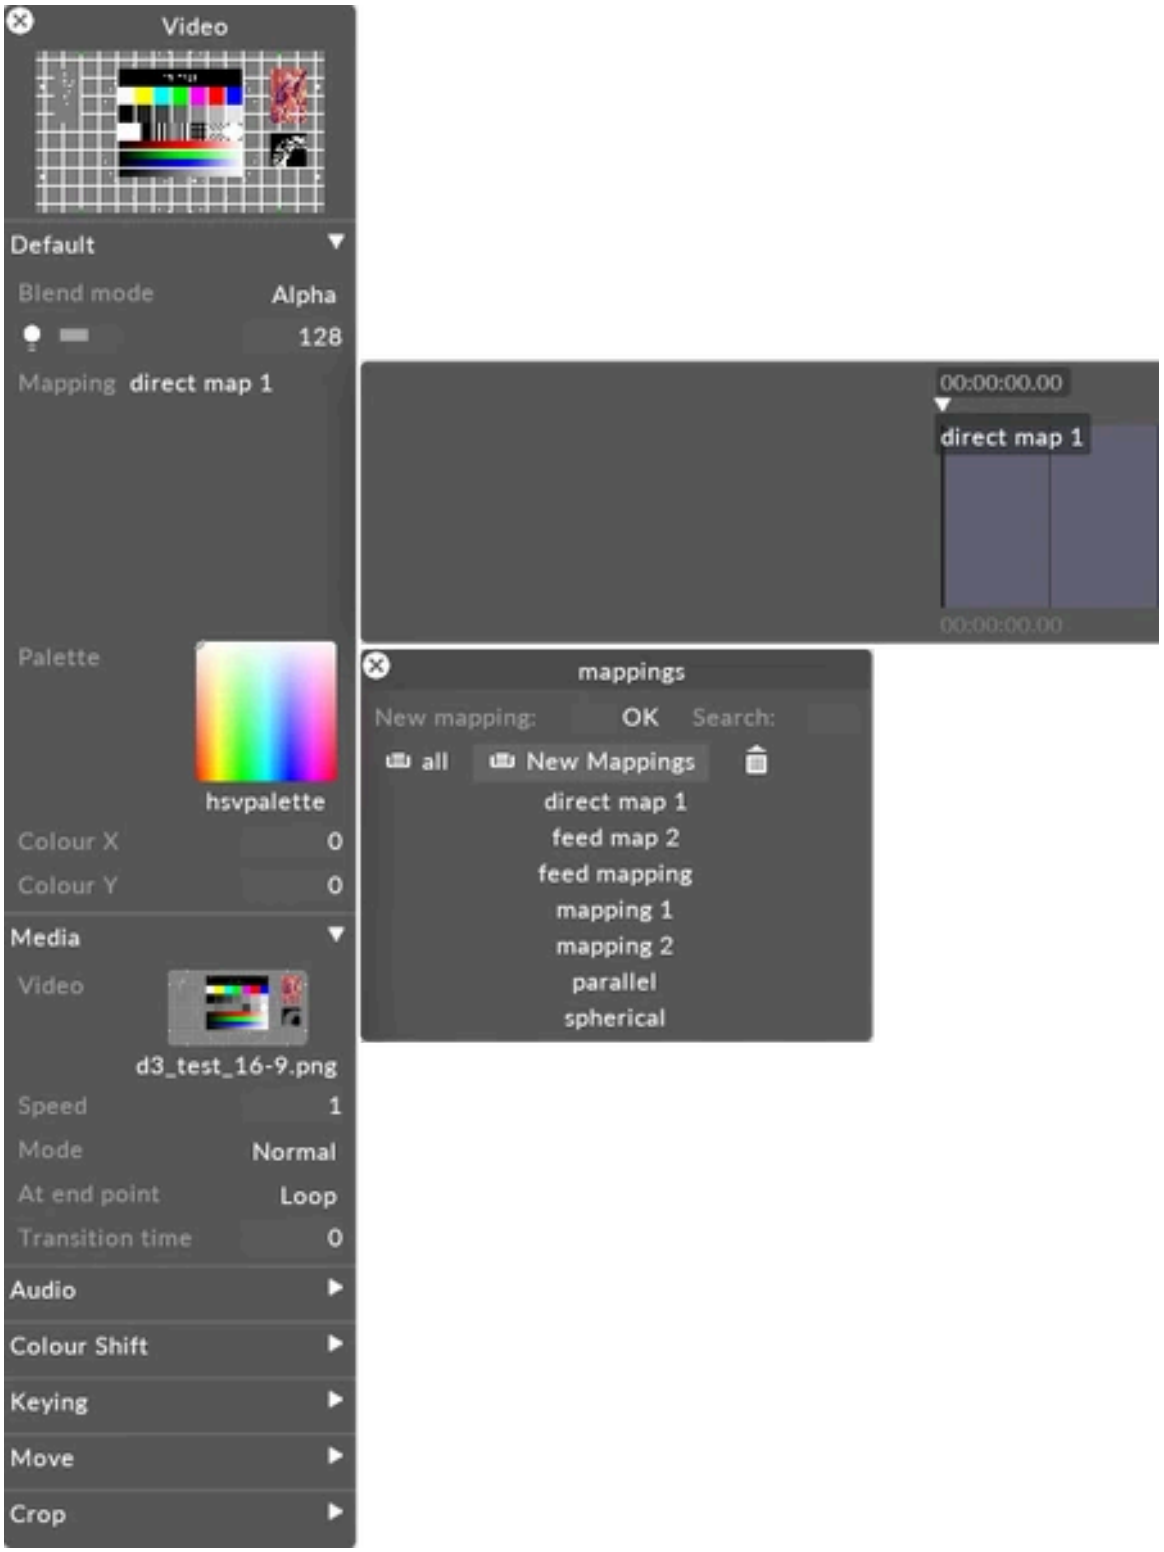


If the layers blend mode is set to Alpha, then reducing the brightness to 0 also reduces the opacity of the layer to 0. This can be useful when you want to dissolve from one layer to the next. In that case, you can place the new layer above the old layer and increase its brightness level.

> **Note**
>
> Layers that are patched to Sockpuppet (DMX, OSC or HTTP) are made Dormant when their brightness is set to 0. This means they will not do any rendering or consume any resources until their brightness is changed to > 0. You can find more information about this here: **Sequencing with Sockpuppet**. Layers without a sockpuppet patch do not behave in this way.

Mapping

The mapping property controls how the layer output is mapped onto the screen(s) in the Stage level.



For information on mapping, including how to use the different mapping types offered by Designer, please see the chapter **Content Mapping**

Palette

This points to the still image file that defines the bitmap from which the tint colour is taken. The default palette (HSVPAL) consists of the complete range of hues and saturations. Selecting this property will open the Texture object library, which shows all of the still image files saved on your local hard-drive in the **DxTexture** older.

To control the location within the current palette bitmap, and thus control the colour, you have to edit the **xCol** and **yCol** values (see the section for xCol, yCol).

To change the current palette bitmap:

1. Left-click **palette** to open the Texture object library.
2. Left-click the still image file you want to use for the palette bitmap.

If you want to use a palette bitmap other than the standard still images provided in Designer, you will need to use a custom still image file.

See the **Placing media files** for a project sub-chapter to understand where to place a custom still image file and how to access it in Designer. Also save the file to a **supported file format**.

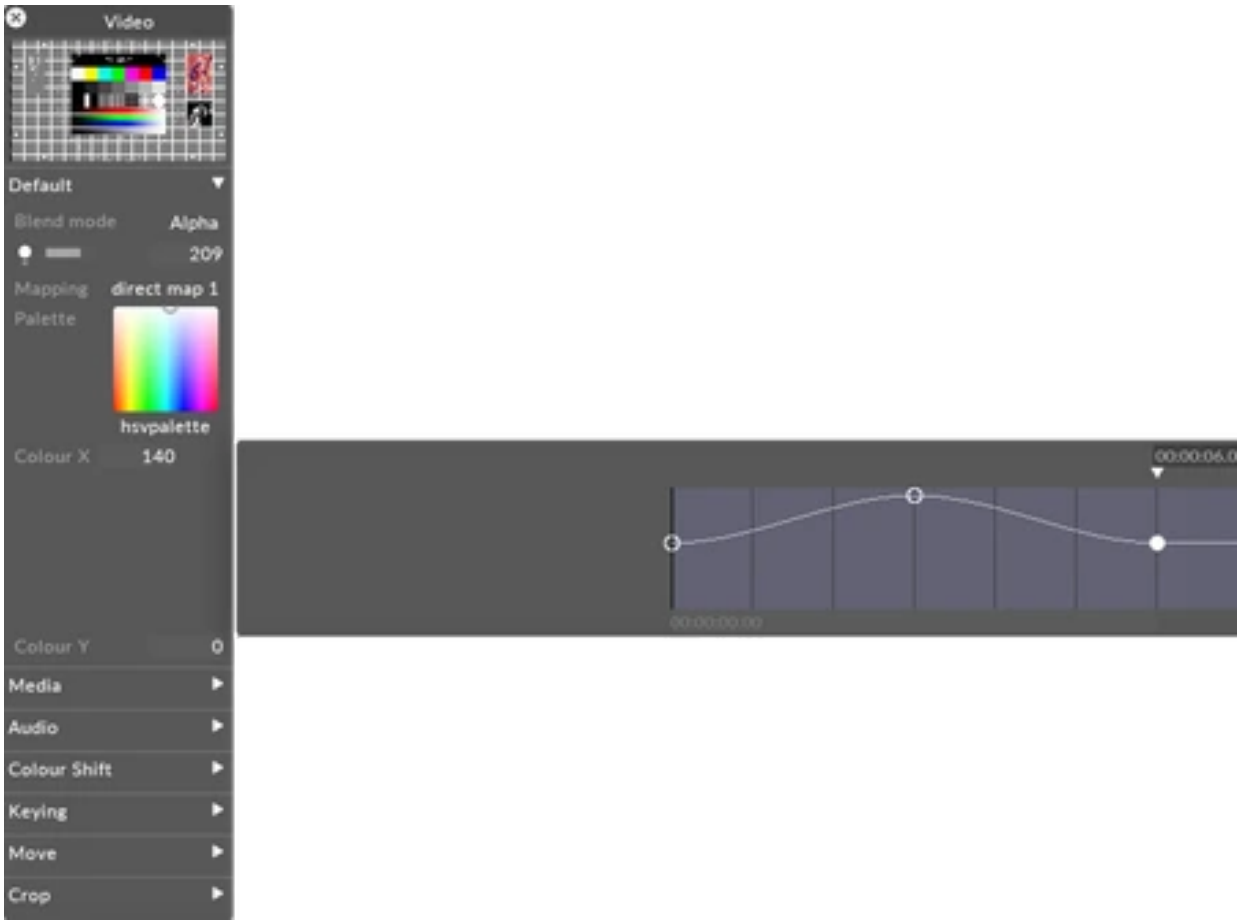
Xcol, YCol

These properties control the coordinates within the current palette bitmap where the output colour is sampled from. The default value is 0,0 which points at the color white (if you are using the HSVPAL palette). Multiplying white with the colors of the chosen content simply generates the original content colors. **Colour X** controls the horizontal position, where 0 is the leftmost

edge and 255 is the rightmost edge. **Colour Y** controls the vertical position, where 0 is the top edge and 255 is the bottom edge.

For example, to saturate the video clip red, change the **Colour Y** value to 255 and use 0 for the **Colour X** value. These coordinates refer to the color red in the palette which is being multiplied with the colors of the existing content.

When you are using the default palette HSVPAL , Colour Y controls saturation, and Colour X controls hue.



ColourShift

The colour shift property allows you to perform a number of colour-correction operations on the output of a layer.

Colour Shift objects can also be attached to individual video files within the Video layer.

Colour Shift property performs colour-corrections on the output of a visual layer

Colour Shift properties are:

Brightness (shift)

Changes the floor of brightness to the constant given.

When set to 0, the range of brightness is 0 to 1, thus no change is applied to the image. When set to -1, the range of brightness is -1 to 0, thus the entire image is black. When set to 1, the range of brightness is 1 to 2, thus the entire image is white.

Brightness (shift) (from left to right): -1, -0.5, 0, 0.5, 1

Contrast (scale)

When set to 1, no change is applied to the image. When set to 0, all values have been pulled together to 50% grey, thus the image is entirely grey. When set to 2, the values are pulled in the opposite direction to meeting at mid grey, thus resulting in crushed white and black values.

Contrast (scale) (from left to right): 0, 0.5, 1, 1.5, 2

Saturation scale

When set to 1, no change is applied to the image. When set to 0, the image is desaturated to black and white. When set higher than 1, the image is hypersaturated.

Saturation scale (from left to right): 0, 0.5, 1, 2, 4

Hue shift

This property changing the hue of colours in an image, design, or graphic while maintaining other colour properties like saturation and brightness.

RGB controlled

This property controls how the min/max levels and gamma corrections are applied. If set to together, then the min, max and gamma values set for the red channel are mirrored to the green and blue channels, values set on the green and blue channels will be ignored. If set to separate , the min,max and gamma values can be controlled separately for red, green and blue. The latter setting allows you to apply fine colour balance controls to the image.

Min

This sets the lowest brightness level found in the image. All pixels at this level are scaled down to zero brightness. Increasing this value enforces shadows and dark levels in the image and can be used to reduce low-level compression artifacts in an image or video frame.

Increasing min equally across red, green and blue enforces shadows, whereas increasing min on an individual channel has the effect of shifting the colour balance away from that colour. For example, increasing red min shifts the image towards cyan.

With `RGB controlled` *set to Together (from left to right): 0, 0.3, 0.8*

With `RGB controlled` *set to Separate, red min (from left to right): 0, 0.3, 0.8*

Max

This sets the highest brightness level found in the image. All pixels at this level are scaled up to the maximumm level, i.e. 1. Decreasing this value brightens any highlights in the image. This is useful when the source image is too dark.

With `RGB controlled` *set to Together (from left to right): 1, 0.7, 0.2*

With `RGB controlled` *set to Separate, red max (from left to right): 1, 0.7, 0.2*

Tip

If you set min to 255 and max to 0, the image (or single channel) will be inverted.

Invert all (left), invert red (right)

Gamma

When gamma is set to 1, no change is made to the image. Reducing gamma brightens highlights while increasing gamma darkens lowlights. The maximum and minimum brightness levels remain the same.

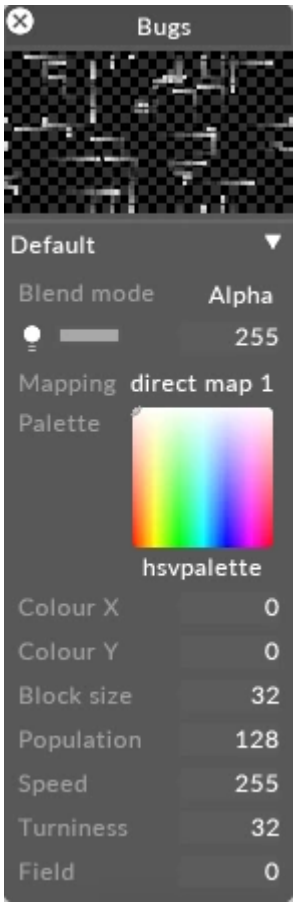
With `RGB controlled` *set to Together (from left to right): 0.1, 1, 4*

With `RGB controlled` *set to Separate, red gamma (from left to right): 0.1, 1, 4*

Bugs Layer

The Bugs layer is a simple generative layer that simulates a number of bugs.

A bug is a block of colour that moves across the canvas, leaving behind a fading trail of blocks. With each step, the bug may decide to change its direction or continue in the same direction.



Bugs Layer Properties

Block size

This controls the size of each bug, in pixels. When the block size is higher than 1, a one pixel black border is drawn around each bugs square. The smaller the size, the finer the pattern generated.

Population

This controls the number of bugs. When set to 255, the maximum number of bugs is drawn.

Speed

This controls how many times per beat the bugs update their position.

Turniness

This controls the ability of each bug to change direction at each step. When set to the minimum value 0, the bugs will move in straight lines and never change direction; when set to the maximum value 255, the bugs will turn at every opportunity.

Field

This controls the number of directions the bugs can choose from. The min/max Field values are 0 and 9. Different Field values control the directions the bugs move in in different ways.

The following Field values cause the bugs to move in the following directions:

0 : horizontally right and left + vertically up and down

1 : horizontally right and left

2 : vertically up and down

3 : diagonally up and down

4 : diagonally down into horizontal right and left

5 : vertically up

6 : vertically down

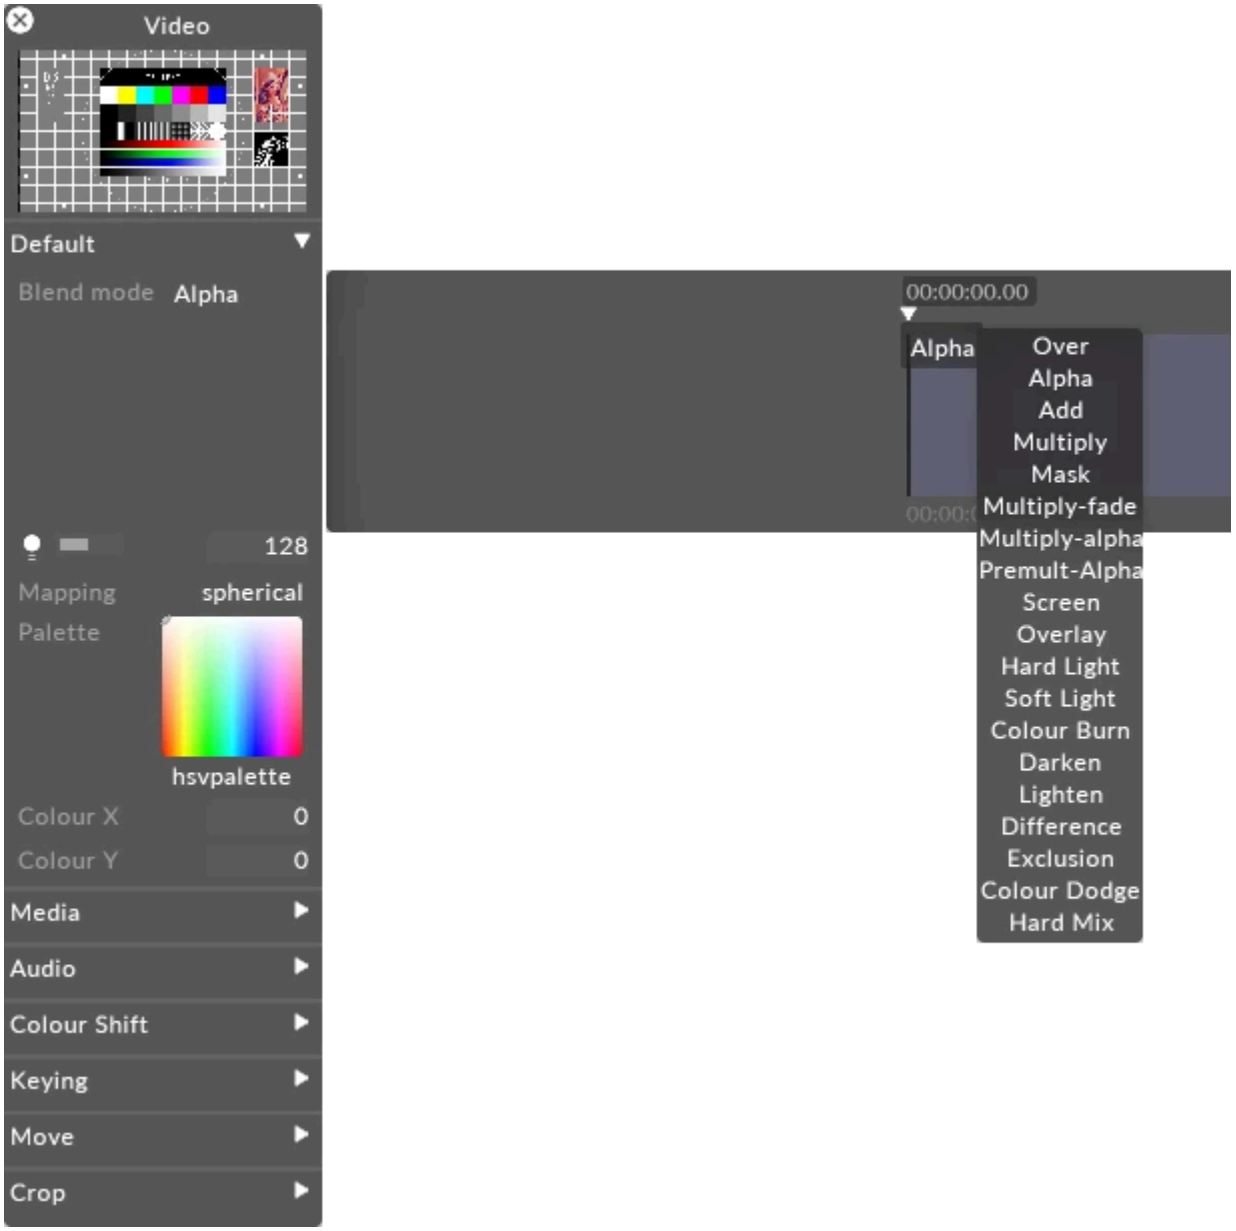
7 : horizontally right

8-9 : horizontally left

Common Layer Properties

Blend Mode

BlendMode controls how the output of the layer is composited with the layers below. Layers are rendered in a bottom-up order: layers at the top can modify the output of the layers below.



Changing brightness of a content layer in Designer is actually controlling the value of the alpha of the layer. Even when displaying a HAP video, the software will composite the layer with a controllable layer of alpha - one per layer.

There are two ways of expressing alpha in an image:

Straight alpha is an alpha channel which functions just like RGB. Alpha acts as a fourth channel of information per pixel which is as independent of the other three as R, G and B are of each other. For example, with straight alpha it is possible to have RGB = 255 (white) and alpha = 0 (fully transparent) on the same pixel. Internally generated content, such as gradient layer, are generated with straight alpha. This is the preferable style of alpha and considering the cleaner method of the two.

Premultiplied alpha takes the alpha and applies it to the values of the RGB channels per pixel. The more transparent something gets with premultiplied alpha, the closer it gets to black - as if the content is sitting on a black table. Premultiplied is the default output of Adobe Photoshop or AfterEffects. The result is our pixel at 255 RGB (full white) with 0 alpha would be calculated as a black pixel in the final image.

Here are explanations of what each individual blend mode will do.

Over

Makes a layer fully opaque. Premultiplies all alpha onto the RGB value of each pixel. Alpha = black, so adjusting the brightness of a layer in Over blend mode makes it darker.

Alpha

Default blend mode. It will apply alpha values as a transparency if the alpha is present. Brightness changes will make the layer more or less transparent.

Add

Adds the value of each RGB pixel together. Always creates a brighter result. Values clamp at 255.

Multiply

Reads the level of each subpixel as a level between 0.0 and 1.0, and multiplies source with blend. The result is always a darker image overall. For example: white x grey = 0.5. White turns transparent, black takes precedence. Alpha is applied in the same fashion as the Over Blend mode.

Mask

Applies a mask to the single layer **above** in the stack, irrespective of mapping. See **Mask blending** for more information.

Luma-Matte

This mode creates a Luma Matte by using a layer's **Rec. 709 luminance** to control the alpha channel of the layer **above**, irrespective of mapping.

To determine transparency, the luminance of each pixel is calculated using a weighted average of its red, green, and blue channels. The luminance value is then used as the alpha (opacity) value for the corresponding pixels in the upper layers.

As a result, white areas render the layer above fully opaque, black areas make them fully transparent, and grey areas create proportional semi-transparency. This is a specialized **Mask** blend mode; for more details on the underlying behaviour, see **Mask blending**.

Inv-Luma-Matte

The Inverse Luma Matte mask works the same as the Luma Matte mask but the transparency is inverted meaning white regions are transparent and black regions are opaque.

Multiply-Fade

The same as Multiply, but will make use of the alpha channel to calculate transparency in the source and blend layers. Since maximum transparency is premultiplied, alpha results in black. This will ignore black created through premultiplying.

Multiply-Alpha

Multiply with straight alpha. This mode assumes that the alpha has not been premultiplied onto the RGB values and will not apply a correction to the semi-transparent pixels.

Premultiply Alpha

Like how Multiply-fade will ignore the darkening caused by premultiplying, this blend mode will do the same with Alpha.

Colour Burn

Blend mode increases the contrast to darken the base colour while reflecting the blend colour. The darker the blend colour, the more intensely the colour will be applied in the base image. White as the blend colour produces no change. Using the colour burn blend mode can produce some harsh results at full opacity. The colour burn blend mode can be used to make tonal and colour adjustments to a layer.

Screen

This blend mode looks at each channels colour information and multiplies the inverse of the blend and base colous. The result is always a lighter colour. Screening with black leaves the colour unchanged. Screening with white produces white. The effect is similar to projecting multiple images on top of each other - where bright white is fully opaque, black is fully transparent and 50% grey is 50% transparent.

Overlay

Multiplies or screens the colours, depending on the base colour. Patterns or colours overlay the existing pixels while preserving the highlights and shadows of the base colour. The base colour is not replaced, but mixed with the blend colour to reflect the lightness or darkness of the original colour.

Hard Light

Multiplies or screens the colours, depending on the blend colour. The effects is similar to shining a harsh spotlight on the image. If the blend colour (light source/top layer) is lighter than

50% grey, the image is lightened as if it were screened. This is useful for adding highlights to an image. If the blend colour is darker than 50% grey, the image is darkened as if it were multiplied. This is useful for adding shadows to an image. Painting with pure black or white results in pure black or white.

Soft Light

Darkens or lightens the colours, depending on the blend colour. The effect is similar to shining a diffused spotlight on the image. If the blend colour (light source/top layer) is lighter than 50% grey, the image is lightened as it if were dodged. If the blend colour is darker than 50% grey, the image is darkened as if it were burned in. Painting with pure black or white produces a distinctly darker or lighter area, but does not result in pure black or white.

Darken

Looks as the colour information in each channel and selects the base or blend colour - whichever is darker - as the result colour. Pixels lighter than the blend colour are replaced and pixels darker than the blend colour do not change.

Lighten

Looks at the colour information in each channel and selects the base or blend colour - whichever is lighter - as the result colour. Pixels darker than the blend colour are replaced and pixels lighter than the blend colour do not change.

Difference

Looks at the colour information in each channel and subtracts either the blend colour from the base colour or the base colour from the blend colour depending on which has the greater brightness value. Blending with white inverts the base colour values and blending with black produces no change.

Exclusion

Creates an effects similar to but lower in contrast than the difference mode. Blending with white inverts the base colour values. Blending with black produces no change.

Colour Dodge

Looks at the colour information in each channel and brightens the base colour to reflect the blend colour by decreasing contrast between the two. Blending with black produces no change.

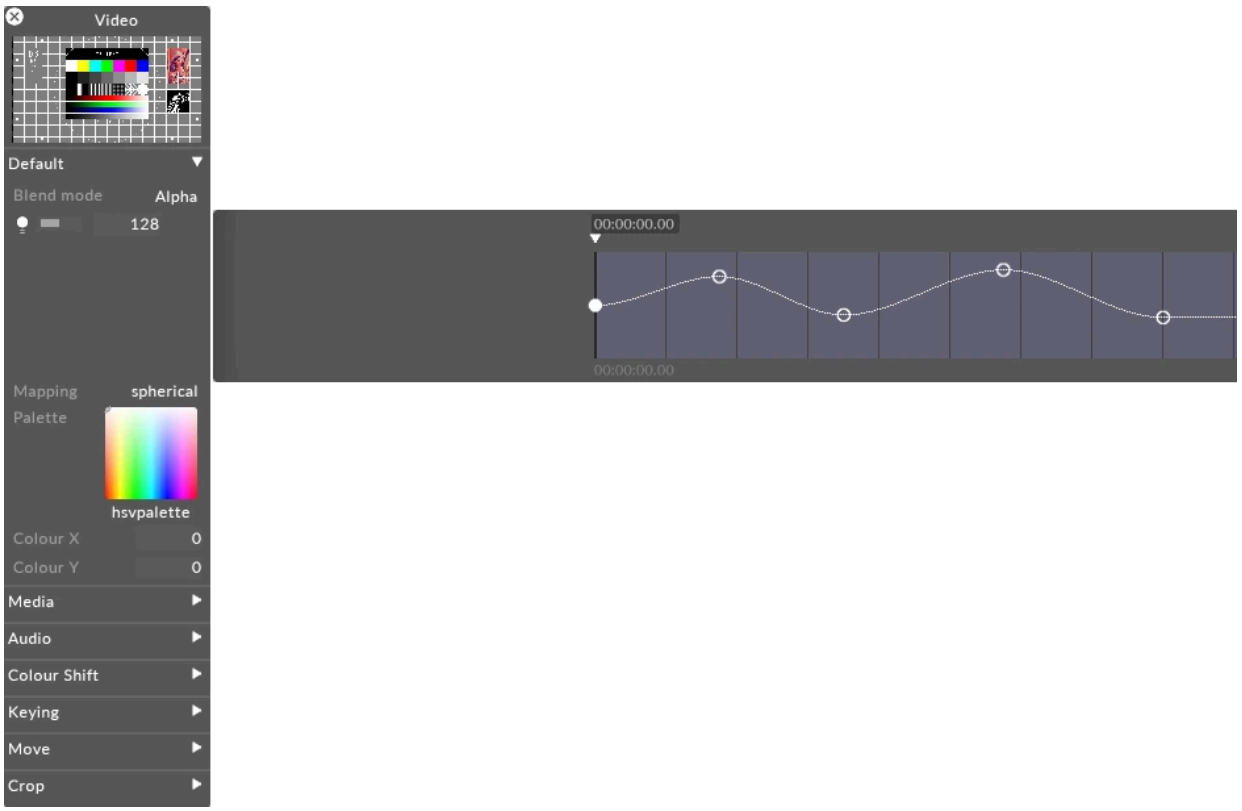
Hard Mix

Adds the RGB channels of the blend colour to the RGB values of the base colour. If the resulting sum for a channel is 255 or greater, it receives a value of 255; if it is less than 255 it

receives a value of 0. Therefore all blended pixels have RGB channels of either 0 or 255. This changes all pixels to primary additive colours (RGB), white or black.

Brightness

This property (which appears as a light bulb icon) controls the brightness of the layer output.



If the layers blend mode is set to Alpha, then reducing the brightness to 0 also reduces the opacity of the layer to 0. This can be useful when you want to dissolve from one layer to the next. In that case, you can place the new layer above the old layer and increase its brightness level.

> **Note**
>
> Layers that are patched to Sockpuppet (DMX, OSC or HTTP) are made Dormant when their brightness is set to 0. This means they will not do any rendering or consume any resources until their brightness is changed to > 0. You can find more information about this here: **Sequencing with Sockpuppet**. Layers without a sockpuppet patch do not behave in this way.

Mapping

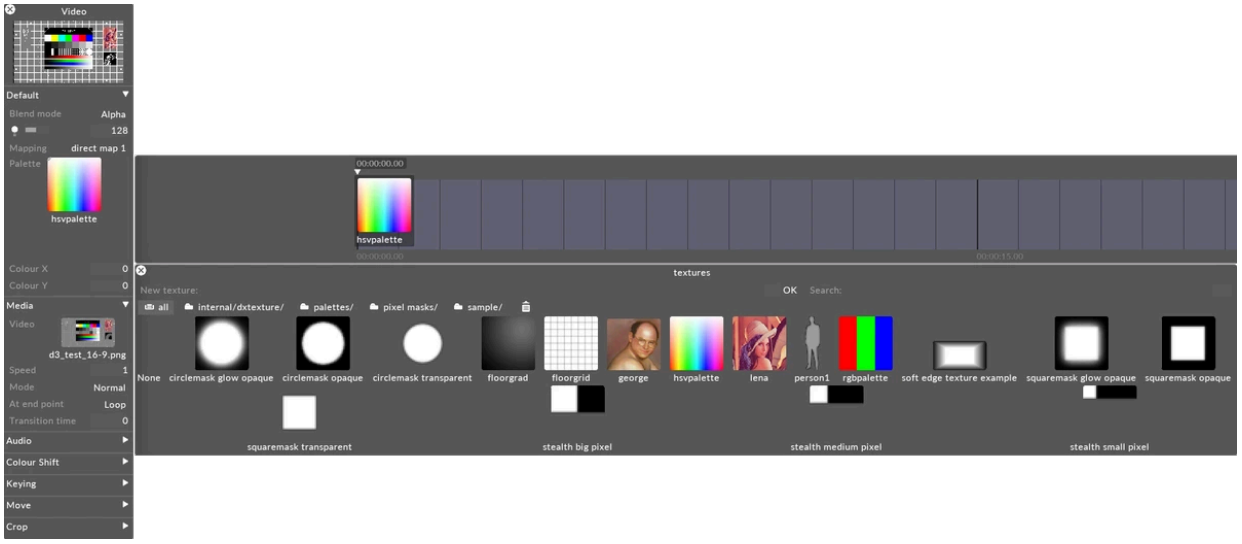
The mapping property controls how the layer output is mapped onto the screen(s) in the Stage level.

For information on mapping, including how to use the different mapping types offered by Designer, please see the chapter **Content Mapping**

Palette

This points to the still image file that defines the bitmap from which the tint colour is taken. The default palette (HSVPAL) consists of the complete range of hues and saturations. Selecting this property will open the Texture object library, which shows all of the still image files saved on your local hard-drive in the **DxTexture** older.

To control the location within the current palette bitmap, and thus control the colour, you have to edit the **xCol** and **yCol** values (see the section for xCol, yCol).



To change the current palette bitmap:

1. Left-click **palette** to open the Texture object library.
2. Left-click the still image file you want to use for the palette bitmap.

If you want to use a palette bitmap other than the standard still images provided in Designer, you will need to use a custom still image file.

See the **Placing media files** for a project sub-chapter to understand where to place a custom still image file and how to access it in Designer. Also save the file to a **supported file format**.

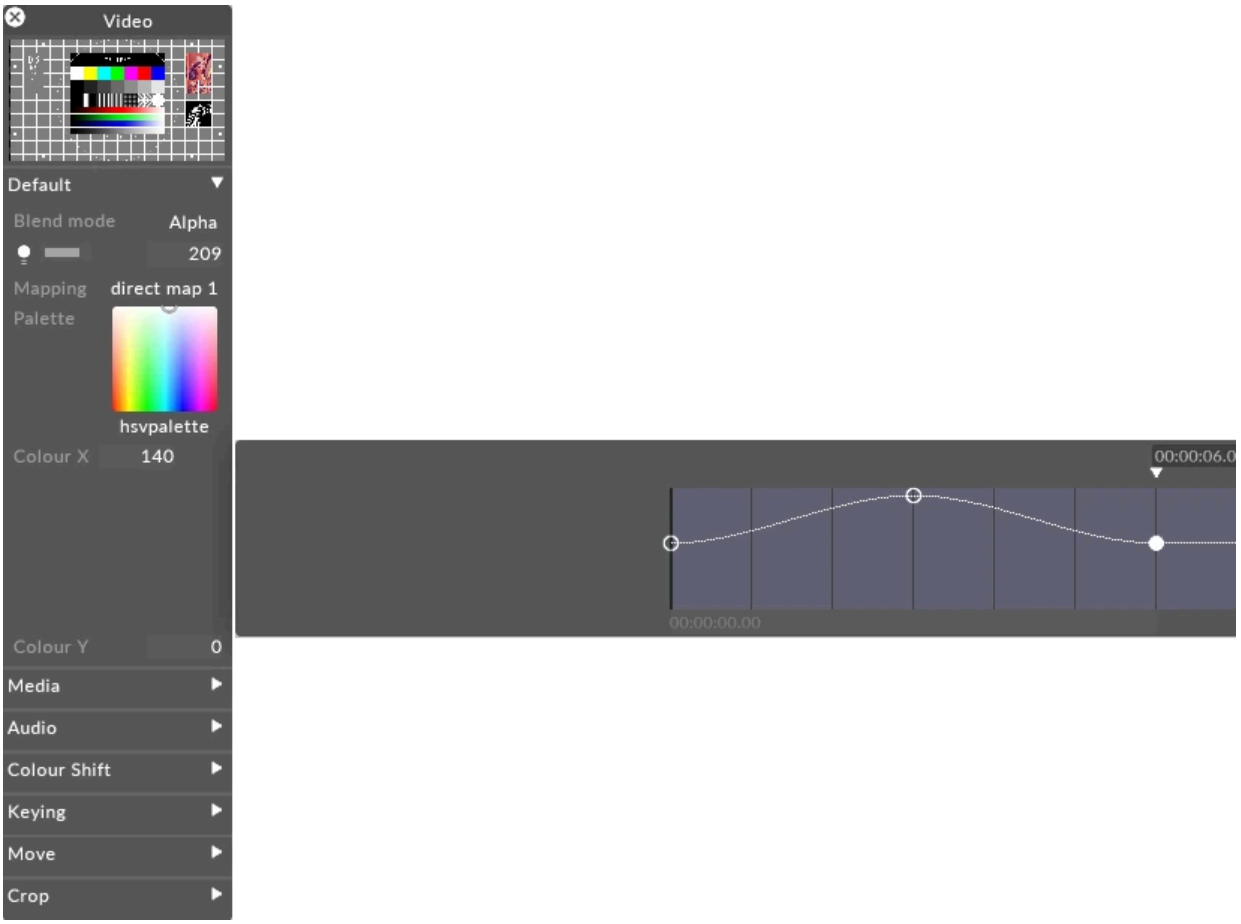
Xcol, YCol

These properties control the coordinates within the current palette bitmap where the output colour is sampled from. The default value is 0,0 which points at the color white (if you are using the HSVPAL palette). Multiplying white with the colors of the chosen content simply generates the original content colors. **Colour X** controls the horizontal position, where 0 is the leftmost

edge and 255 is the rightmost edge. **Colour Y** controls the vertical position, where 0 is the top edge and 255 is the bottom edge.

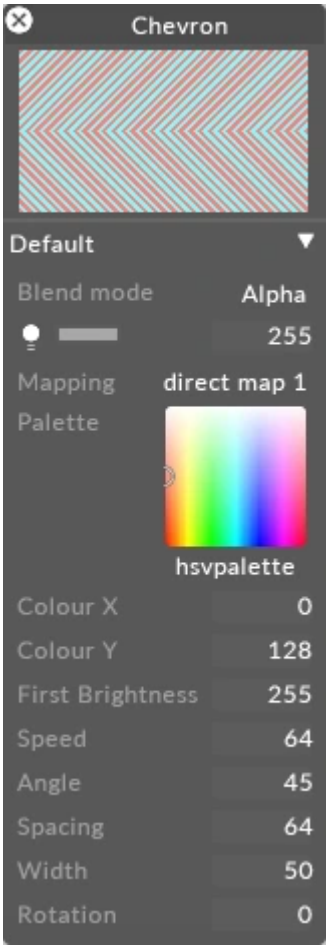
For example, to saturate the video clip red, change the **Colour Y** value to 255 and use 0 for the **Colour X** value. These coordinates refer to the color red in the palette which is being multiplied with the colors of the existing content.

When you are using the default palette HSVPAL , Colour Y controls saturation, and Colour X controls hue.



Chevron Layer

Sooner or later, everybody needs chevrons. Recognising this fact of life, Designer includes a Chevron layer for all of your chevron needs



Chevron Layer Properties

Speed

This controls the speed of the chevrons, in pixels per beat. Positivenumbers move the chevrons to the left; negative numbers move the chevrons to the right.

Angle

This controls the angle of the chevron fins, in degrees. Smaller numbers move the angle closer to horizontal.

Spacing

This controls the spacing between the chevrons, in pixels.

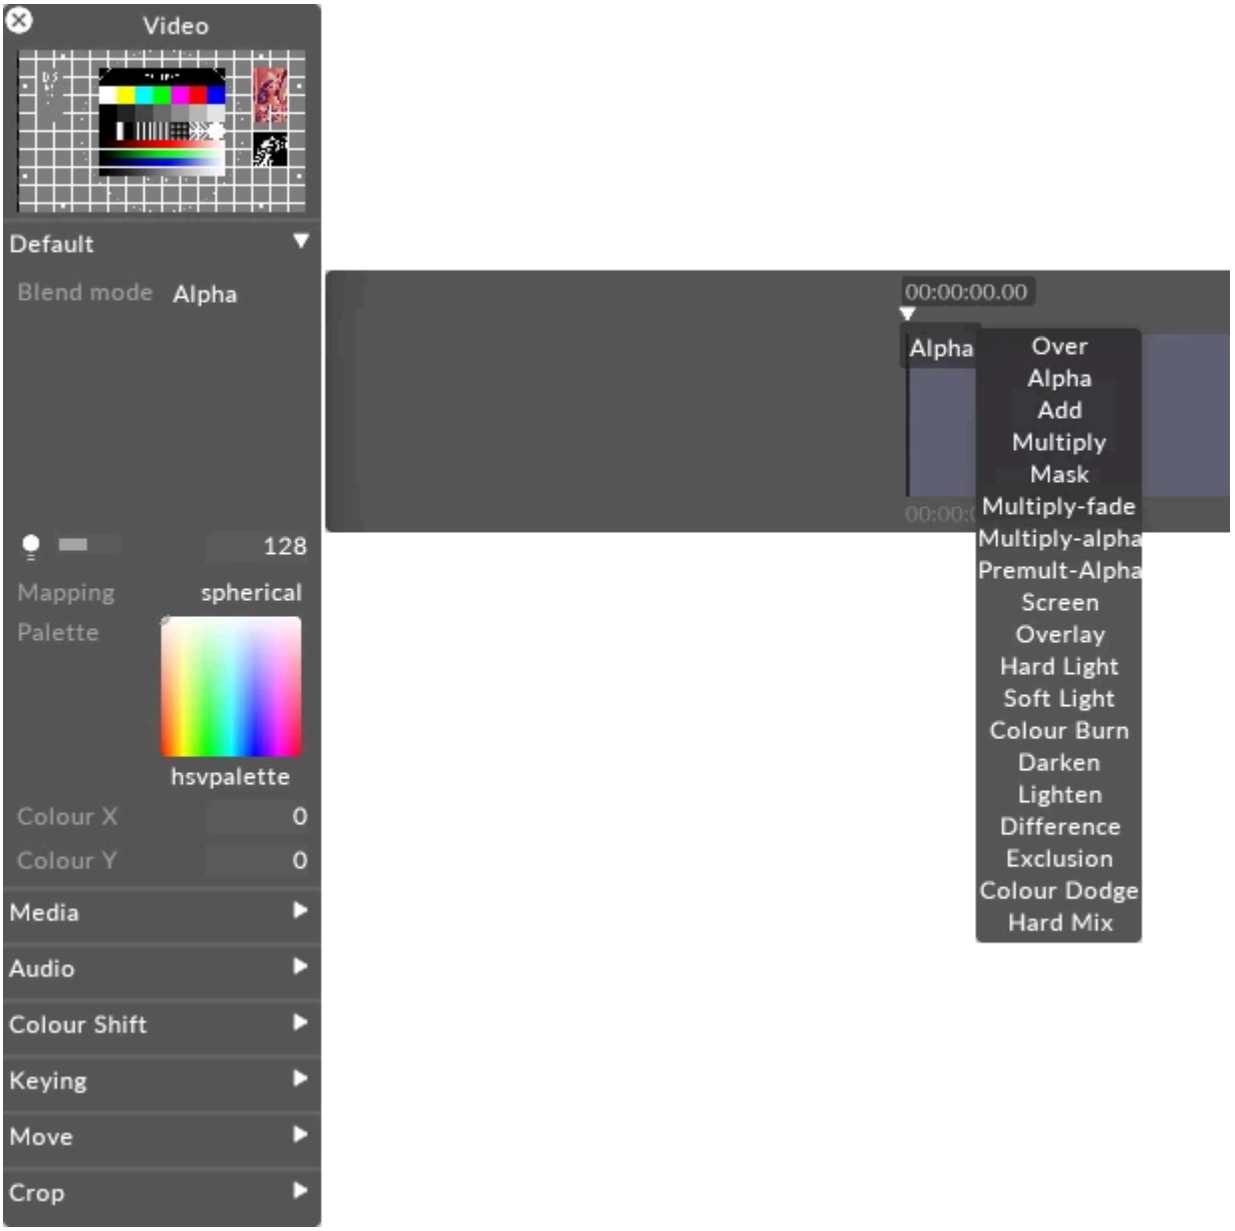
Width

This controls the width, as a percentage of the spacing, of the first colour band.

Common Layer Properties

Blend Mode

BlendMode controls how the output of the layer is composited with the layers below. Layers are rendered in a bottom-up order: layers at the top can modify the output of the layers below.



Changing brightness of a content layer in Designer is actually controlling the value of the alpha of the layer. Even when displaying a HAP video, the software will composite the layer with a controllable layer of alpha - one per layer.

There are two ways of expressing alpha in an image:

Straight alpha is an alpha channel which functions just like RGB. Alpha acts as a fourth channel of information per pixel which is as independent of the other three as R, G and B are of each other. For example, with straight alpha it is possible to have RGB = 255 (white) and alpha = 0 (fully transparent) on the same pixel. Internally generated content, such as gradient layer, are generated with straight alpha. This is the preferable style of alpha and considering the cleaner method of the two.

Premultiplied alpha takes the alpha and applies it to the values of the RGB channels per pixel. The more transparent something gets with premultiplied alpha, the closer it gets to black - as if the content is sitting on a black table. Premultiplied is the default output of Adobe Photoshop or AfterEffects. The result is our pixel at 255 RGB (full white) with 0 alpha would be calculated as a black pixel in the final image.

Here are explanations of what each individual blend mode will do.

Over

Makes a layer fully opaque. Premultiplies all alpha onto the RGB value of each pixel. Alpha = black, so adjusting the brightness of a layer in Over blend mode makes it darker.

Alpha

Default blend mode. It will apply alpha values as a transparency if the alpha is present. Brightness changes will make the layer more or less transparent.

Add

Adds the value of each RGB pixel together. Always creates a brighter result. Values clamp at 255.

Multiply

Reads the level of each subpixel as a level between 0.0 and 1.0, and multiplies source with blend. The result is always a darker image overall. For example: white x grey = 0.5. White turns transparent, black takes precedence. Alpha is applied in the same fashion as the Over Blend mode.

Mask

Applies a mask to the single layer **above** in the stack, irrespective of mapping. See **Mask blending** for more information.

Luma-Matte

This mode creates a Luma Matte by using a layer's **Rec. 709 luminance** to control the alpha channel of the layer **above**, irrespective of mapping.

To determine transparency, the luminance of each pixel is calculated using a weighted average of its red, green, and blue channels. The luminance value is then used as the alpha (opacity) value for the corresponding pixels in the upper layers.

As a result, white areas render the layer above fully opaque, black areas make them fully transparent, and grey areas create proportional semi-transparency. This is a specialized **Mask** blend mode; for more details on the underlying behaviour, see **Mask blending**.

Inv-Luma-Matte

The Inverse Luma Matte mask works the same as the **Luma Matte** mask but the transparency is inverted meaning white regions are transparent and black regions are opaque.

Multiply-Fade

The same as Multiply, but will make use of the alpha channel to calculate transparency in the source and blend layers. Since maximum transparency is premultiplied, alpha results in black. This will ignore black created through premultiplying.

Multiply-Alpha

Multiply with straight alpha. This mode assumes that the alpha has not been premultiplied onto the RGB values and will not apply a correction to the semi-transparent pixels.

Premultiply Alpha

Like how Multiply-fade will ignore the darkening caused by premultiplying, this blend mode will do the same with Alpha.

Colour Burn

Blend mode increases the contrast to darken the base colour while reflecting the blend colour. The darker the blend colour, the more intensely the colour will be applied in the base image. White as the blend colour produces no change. Using the colour burn blend mode can produce some harsh results at full opacity. The colour burn blend mode can be used to make tonal and colour adjustments to a layer.

Screen

This blend mode looks at each channels colour information and multiplies the inverse of the blend and base colous. The result is always a lighter colour. Screening with black leaves the colour unchanged. Screening with white produces white. The effect is similar to projecting multiple images on top of each other - where bright white is fully opaque, black is fully transparent and 50% grey is 50% transparent.

Overlay

Multiplies or screens the colours, depending on the base colour. Patterns or colours overlay the existing pixels while preserving the highlights and shadows of the base colour. The base colour is not replaced, but mixed with the blend colour to reflect the lightness or darkness of the original colour.

Hard Light

Multiplies or screens the colours, depending on the blend colour. The effects is similar to shining a harsh spotlight on the image. If the blend colour (light source/top layer) is lighter than

50% grey, the image is lightened as if it were screened. This is useful for adding highlights to an image. If the blend colour is darker than 50% grey, the image is darkened as if it were multiplied. This is useful for adding shadows to an image. Painting with pure black or white results in pure black or white.

Soft Light

Darkens or lightens the colours, depending on the blend colour. The effect is similar to shining a diffused spotlight on the image. If the blend colour (light source/top layer) is lighter than 50% grey, the image is lightened as it if were dodged. If the blend colour is darker than 50% grey, the image is darkened as if it were burned in. Painting with pure black or white produces a distinctly darker or lighter area, but does not result in pure black or white.

Darken

Looks as the colour information in each channel and selects the base or blend colour - whichever is darker - as the result colour. Pixels lighter than the blend colour are replaced and pixels darker than the blend colour do not change.

Lighten

Looks at the colour information in each channel and selects the base or blend colour - whichever is lighter - as the result colour. Pixels darker than the blend colour are replaced and pixels lighter than the blend colour do not change.

Difference

Looks at the colour information in each channel and subtracts either the blend colour from the base colour or the base colour from the blend colour depending on which has the greater brightness value. Blending with white inverts the base colour values and blending with black produces no change.

Exclusion

Creates an effects similar to but lower in contrast than the difference mode. Blending with white inverts the base colour values. Blending with black produces no change.

Colour Dodge

Looks at the colour information in each channel and brightens the base colour to reflect the blend colour by decreasing contrast between the two. Blending with black produces no change.

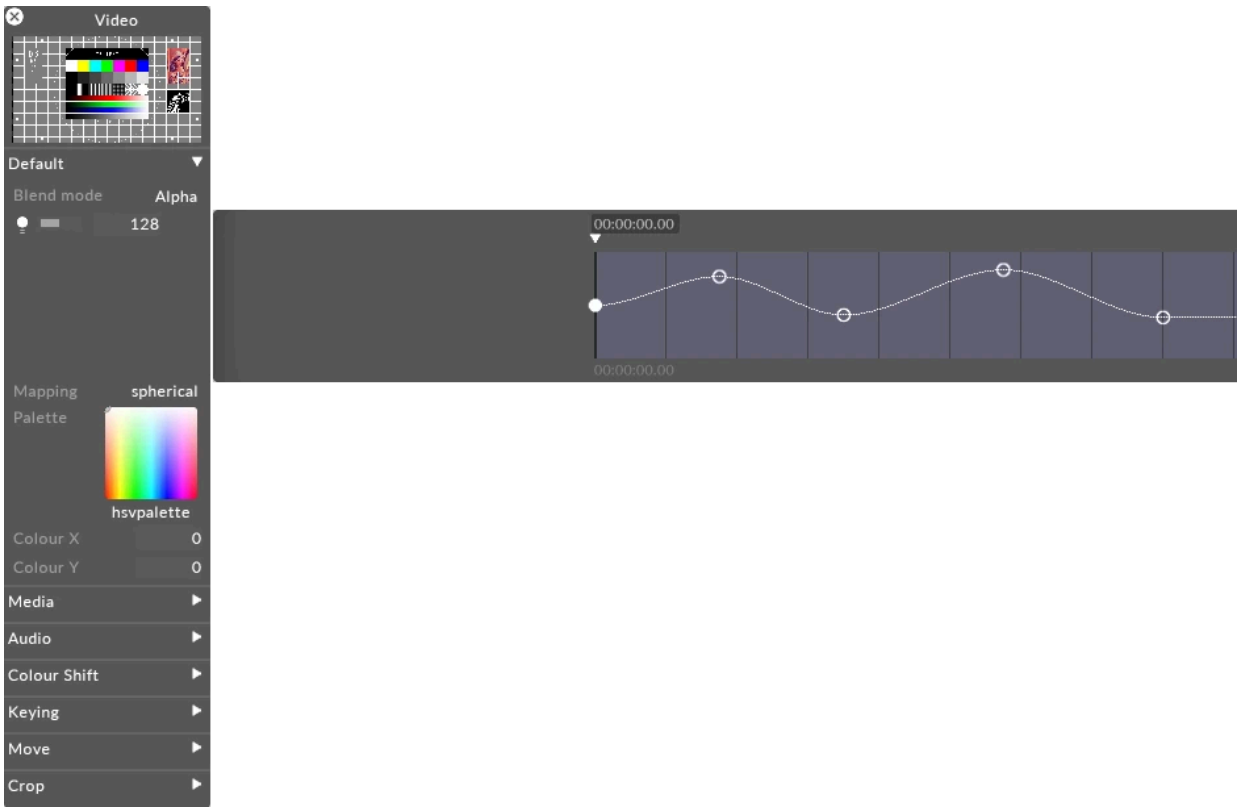
Hard Mix

Adds the RGB channels of the blend colour to the RGB values of the base colour. If the resulting sum for a channel is 255 or greater, it receives a value of 255; if it is less than 255 it

receives a value of 0. Therefore all blended pixels have RGB channels of either 0 or 255. This changes all pixels to primary additive colours (RGB), white or black.

Brightness

This property (which appears as a light bulb icon) controls the brightness of the layer output.



If the layers blend mode is set to Alpha, then reducing the brightness to 0 also reduces the opacity of the layer to 0. This can be useful when you want to dissolve from one layer to the next. In that case, you can place the new layer above the old layer and increase its brightness level.

> **Note**
>
> Layers that are patched to Sockpuppet (DMX, OSC or HTTP) are made Dormant when their brightness is set to 0. This means they will not do any rendering or consume any resources until their brightness is changed to > 0. You can find more information about this here: **Sequencing with Sockpuppet**. Layers without a sockpuppet patch do not behave in this way.

Mapping

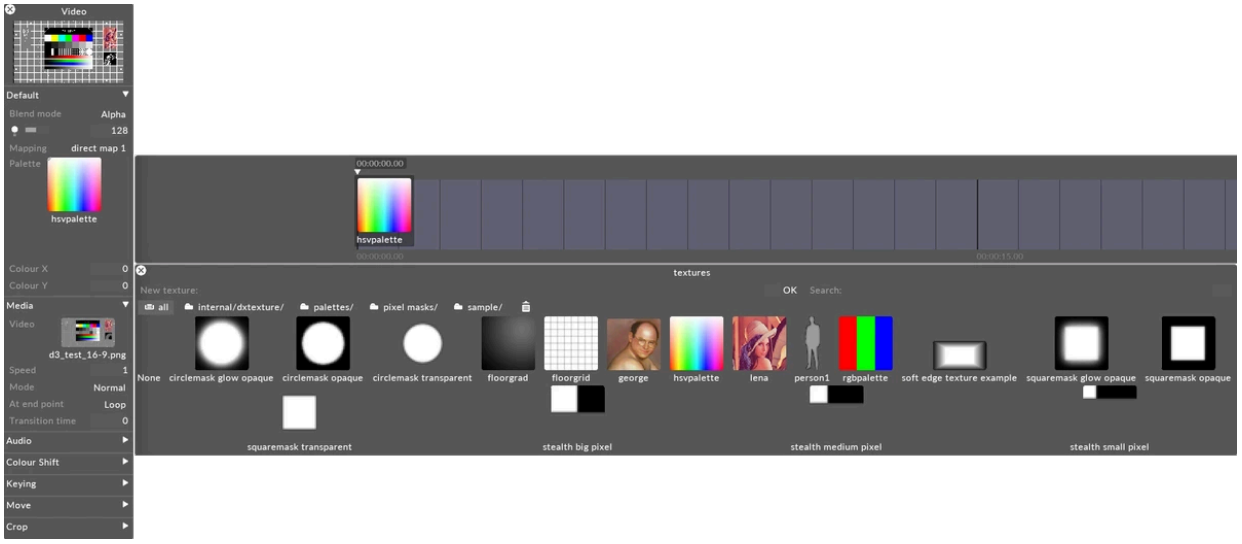
The mapping property controls how the layer output is mapped onto the screen(s) in the Stage level.

For information on mapping, including how to use the different mapping types offered by Designer, please see the chapter **Content Mapping**

Palette

This points to the still image file that defines the bitmap from which the tint colour is taken. The default palette (HSVPAL) consists of the complete range of hues and saturations. Selecting this property will open the Texture object library, which shows all of the still image files saved on your local hard-drive in the **DxTexture** older.

To control the location within the current palette bitmap, and thus control the colour, you have to edit the **xCol** and **yCol** values (see the section for xCol, yCol).



To change the current palette bitmap:

1. Left-click **palette** to open the Texture object library.
2. Left-click the still image file you want to use for the palette bitmap.

If you want to use a palette bitmap other than the standard still images provided in Designer, you will need to use a custom still image file.

See the **Placing media files** for a project sub-chapter to understand where to place a custom still image file and how to access it in Designer. Also save the file to a **supported file format**.

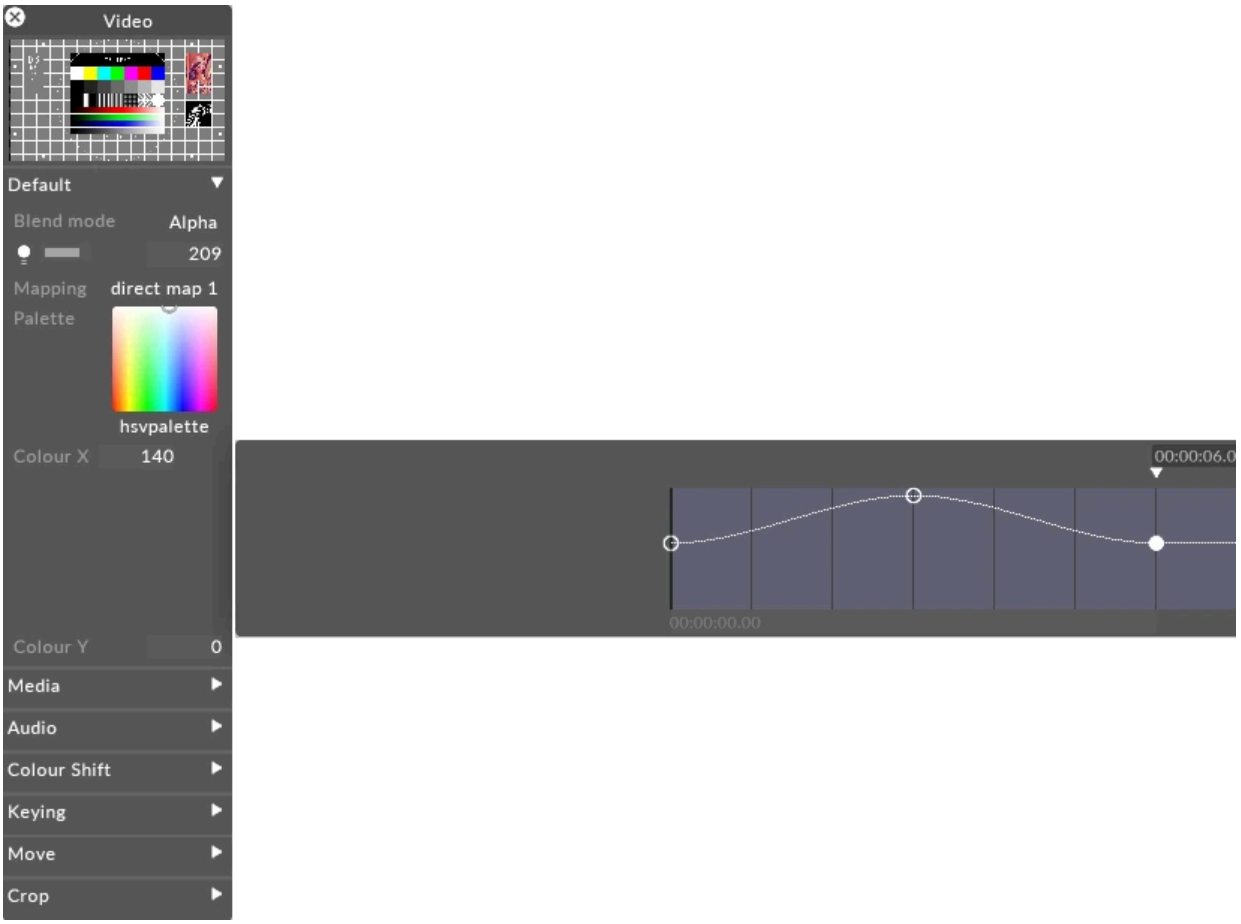
Xcol, YCol

These properties control the coordinates within the current palette bitmap where the output colour is sampled from. The default value is 0,0 which points at the color white (if you are using the HSVPAL palette). Multiplying white with the colors of the chosen content simply generates the original content colors. **Colour X** controls the horizontal position, where 0 is the leftmost

edge and 255 is the rightmost edge. **Colour Y** controls the vertical position, where 0 is the top edge and 255 is the bottom edge.

For example, to saturate the video clip red, change the **Colour Y** value to 255 and use 0 for the **Colour X** value. These coordinates refer to the color red in the palette which is being multiplied with the colors of the existing content.

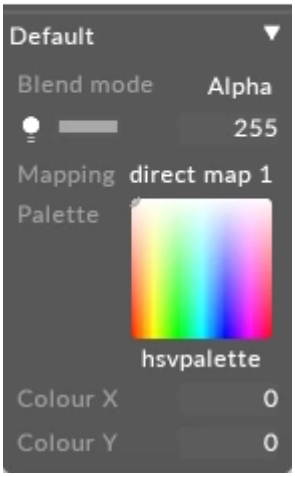
When you are using the default palette HSVPAL , Colour Y controls saturation, and Colour X controls hue.



Colour Layer

The Colour layer is a generative layer that generates a flat colour.

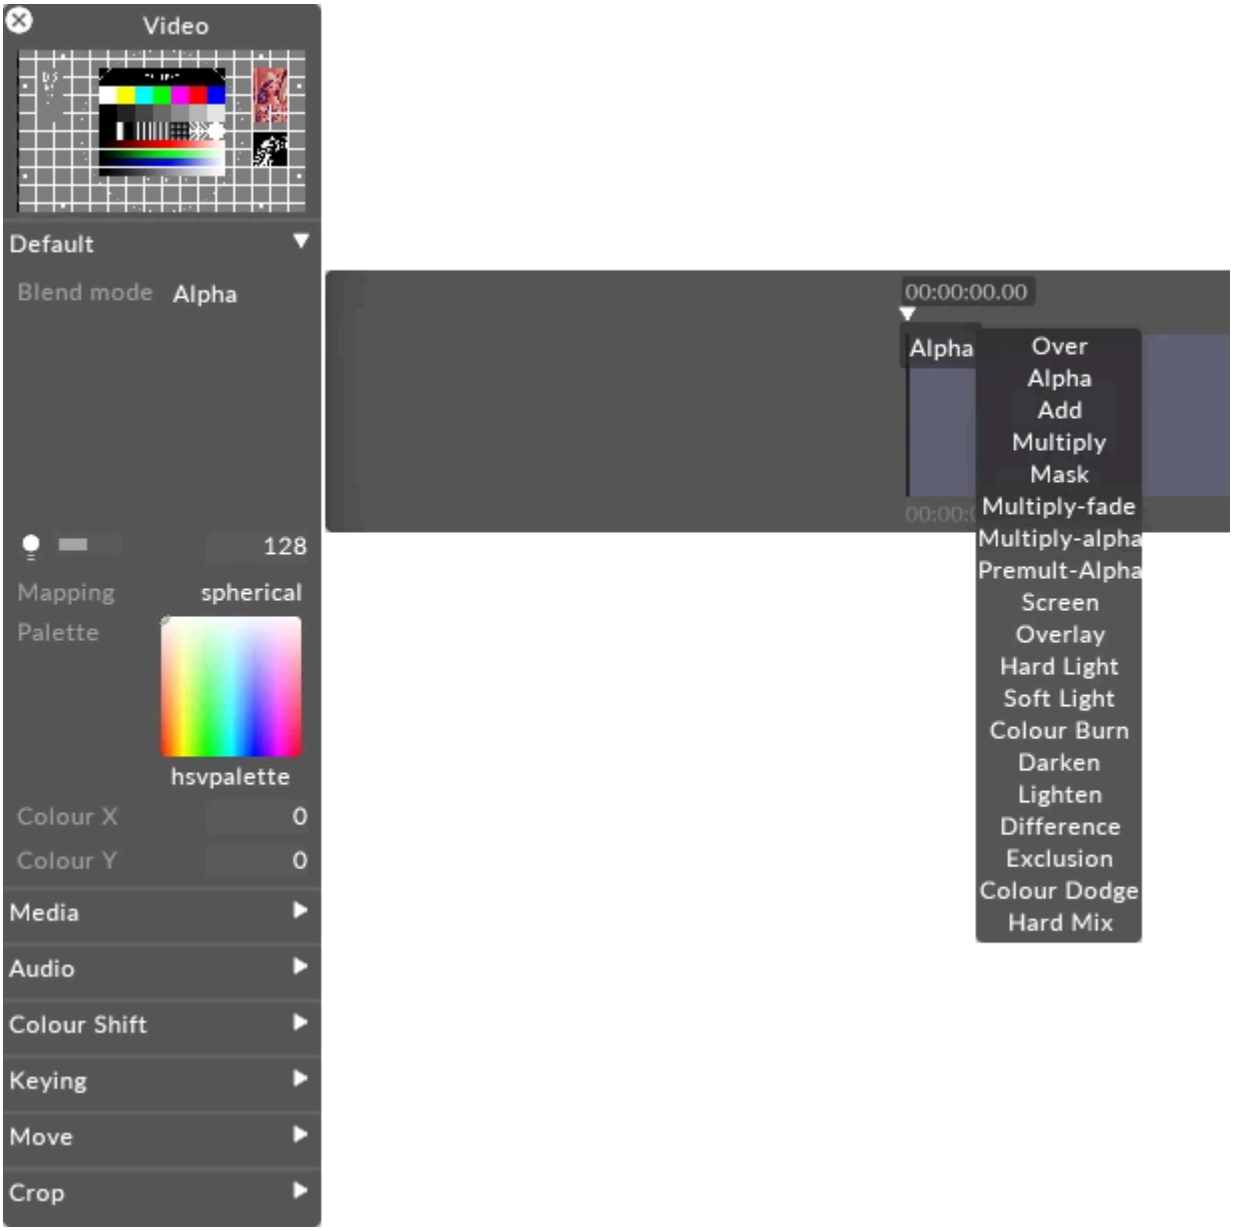
The Colour layer can be used in combination with other layers such as the Video layer and the RenderStream layer, and is used to tint the image being output from that layer.



Common Layer Properties

Blend Mode

BlendMode controls how the output of the layer is composited with the layers below. Layers are rendered in a bottom-up order: layers at the top can modify the output of the layers below.



Changing brightness of a content layer in Designer is actually controlling the value of the alpha of the layer. Even when displaying a HAP video, the software will composite the layer with a controllable layer of alpha - one per layer.

There are two ways of expressing alpha in an image:

Straight alpha is an alpha channel which functions just like RGB. Alpha acts as a fourth channel of information per pixel which is as independent of the other three as R, G and B are of each other. For example, with straight alpha it is possible to have RGB = 255 (white) and alpha = 0 (fully transparent) on the same pixel. Internally generated content, such as gradient layer, are generated with straight alpha. This is the preferable style of alpha and considering the cleaner method of the two.

Premultiplied alpha takes the alpha and applies it to the values of the RGB channels per pixel. The more transparent something gets with premultiplied alpha, the closer it gets to black - as if the content is sitting on a black table. Premultiplied is the default output of Adobe Photoshop or AfterEffects. The result is our pixel at 255 RGB (full white) with 0 alpha would be calculated as a black pixel in the final image.

Here are explanations of what each individual blend mode will do.

Over

Makes a layer fully opaque. Premultiplies all alpha onto the RGB value of each pixel. Alpha = black, so adjusting the brightness of a layer in Over blend mode makes it darker.

Alpha

Default blend mode. It will apply alpha values as a transparency if the alpha is present. Brightness changes will make the layer more or less transparent.

Add

Adds the value of each RGB pixel together. Always creates a brighter result. Values clamp at 255.

Multiply

Reads the level of each subpixel as a level between 0.0 and 1.0, and multiplies source with blend. The result is always a darker image overall. For example: white x grey = 0.5. White turns transparent, black takes precedence. Alpha is applied in the same fashion as the Over Blend mode.

Mask

Applies a mask to the single layer **above** in the stack, irrespective of mapping. See **Mask blending** for more information.

Luma-Matte

This mode creates a Luma Matte by using a layer's **Rec. 709 luminance** to control the alpha channel of the layer **above**, irrespective of mapping.

To determine transparency, the luminance of each pixel is calculated using a weighted average of its red, green, and blue channels. The luminance value is then used as the alpha (opacity) value for the corresponding pixels in the upper layers.

As a result, white areas render the layer above fully opaque, black areas make them fully transparent, and grey areas create proportional semi-transparency. This is a specialized **Mask** blend mode; for more details on the underlying behaviour, see **Mask blending**.

Inv-Luma-Matte

The Inverse Luma Matte mask works the same as the **Luma Matte** mask but the transparency is inverted meaning white regions are transparent and black regions are opaque.

Multiply-Fade

The same as Multiply, but will make use of the alpha channel to calculate transparency in the source and blend layers. Since maximum transparency is premultiplied, alpha results in black. This will ignore black created through premultiplying.

Multiply-Alpha

Multiply with straight alpha. This mode assumes that the alpha has not been premultiplied onto the RGB values and will not apply a correction to the semi-transparent pixels.

Premultiply Alpha

Like how Multiply-fade will ignore the darkening caused by premultiplying, this blend mode will do the same with Alpha.

Colour Burn

Blend mode increases the contrast to darken the base colour while reflecting the blend colour. The darker the blend colour, the more intensely the colour will be applied in the base image. White as the blend colour produces no change. Using the colour burn blend mode can produce some harsh results at full opacity. The colour burn blend mode can be used to make tonal and colour adjustments to a layer.

Screen

This blend mode looks at each channels colour information and multiplies the inverse of the blend and base colous. The result is always a lighter colour. Screening with black leaves the colour unchanged. Screening with white produces white. The effect is similar to projecting multiple images on top of each other - where bright white is fully opaque, black is fully transparent and 50% grey is 50% transparent.

Overlay

Multiplies or screens the colours, depending on the base colour. Patterns or colours overlay the existing pixels while preserving the highlights and shadows of the base colour. The base colour is not replaced, but mixed with the blend colour to reflect the lightness or darkness of the original colour.

Hard Light

Multiplies or screens the colours, depending on the blend colour. The effects is similar to shining a harsh spotlight on the image. If the blend colour (light source/top layer) is lighter than

50% grey, the image is lightened as if it were screened. This is useful for adding highlights to an image. If the blend colour is darker than 50% grey, the image is darkened as if it were multiplied. This is useful for adding shadows to an image. Painting with pure black or white results in pure black or white.

Soft Light

Darkens or lightens the colours, depending on the blend colour. The effect is similar to shining a diffused spotlight on the image. If the blend colour (light source/top layer) is lighter than 50% grey, the image is lightened as it if were dodged. If the blend colour is darker than 50% grey, the image is darkened as if it were burned in. Painting with pure black or white produces a distinctly darker or lighter area, but does not result in pure black or white.

Darken

Looks as the colour information in each channel and selects the base or blend colour - whichever is darker - as the result colour. Pixels lighter than the blend colour are replaced and pixels darker than the blend colour do not change.

Lighten

Looks at the colour information in each channel and selects the base or blend colour - whichever is lighter - as the result colour. Pixels darker than the blend colour are replaced and pixels lighter than the blend colour do not change.

Difference

Looks at the colour information in each channel and subtracts either the blend colour from the base colour or the base colour from the blend colour depending on which has the greater brightness value. Blending with white inverts the base colour values and blending with black produces no change.

Exclusion

Creates an effects similar to but lower in contrast than the difference mode. Blending with white inverts the base colour values. Blending with black produces no change.

Colour Dodge

Looks at the colour information in each channel and brightens the base colour to reflect the blend colour by decreasing contrast between the two. Blending with black produces no change.

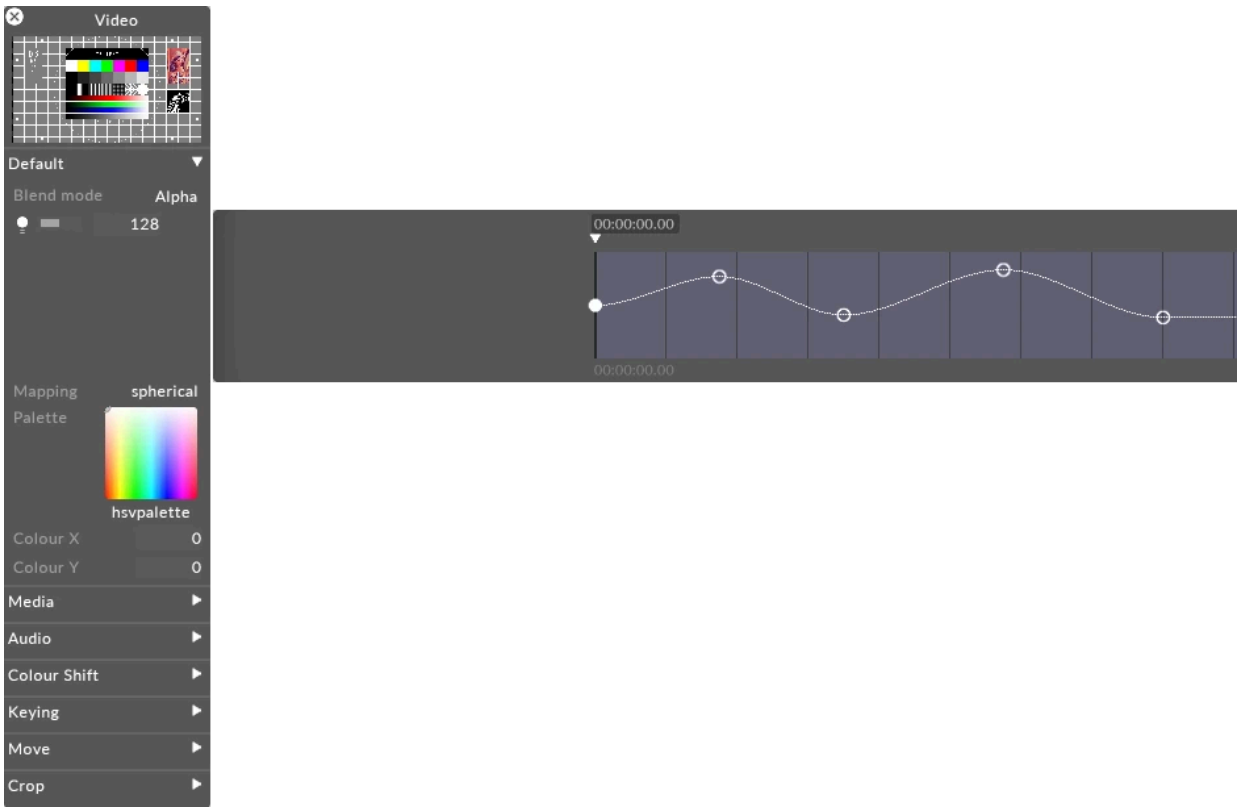
Hard Mix

Adds the RGB channels of the blend colour to the RGB values of the base colour. If the resulting sum for a channel is 255 or greater, it receives a value of 255; if it is less than 255 it

receives a value of 0. Therefore all blended pixels have RGB channels of either 0 or 255. This changes all pixels to primary additive colours (RGB), white or black.

Brightness

This property (which appears as a light bulb icon) controls the brightness of the layer output.



If the layers blend mode is set to Alpha, then reducing the brightness to 0 also reduces the opacity of the layer to 0. This can be useful when you want to dissolve from one layer to the next. In that case, you can place the new layer above the old layer and increase its brightness level.

> **Note**
>
> Layers that are patched to Sockpuppet (DMX, OSC or HTTP) are made Dormant when their brightness is set to 0. This means they will not do any rendering or consume any resources until their brightness is changed to > 0. You can find more information about this here: **Sequencing with Sockpuppet**. Layers without a sockpuppet patch do not behave in this way.

Mapping

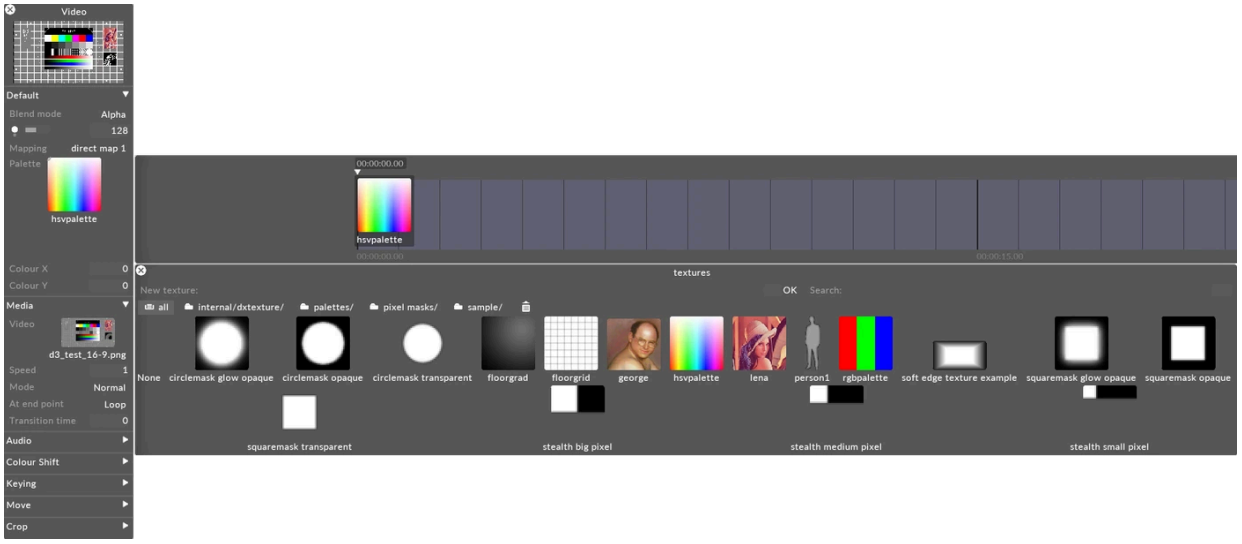
The mapping property controls how the layer output is mapped onto the screen(s) in the Stage level.

For information on mapping, including how to use the different mapping types offered by Designer, please see the chapter **Content Mapping**

Palette

This points to the still image file that defines the bitmap from which the tint colour is taken. The default palette (HSVPAL) consists of the complete range of hues and saturations. Selecting this property will open the Texture object library, which shows all of the still image files saved on your local hard-drive in the **DxTexture** older.

To control the location within the current palette bitmap, and thus control the colour, you have to edit the **xCol** and **yCol** values (see the section for xCol, yCol).



To change the current palette bitmap:

1. Left-click **palette** to open the Texture object library.
2. Left-click the still image file you want to use for the palette bitmap.

If you want to use a palette bitmap other than the standard still images provided in Designer, you will need to use a custom still image file.

See the **Placing media files** for a project sub-chapter to understand where to place a custom still image file and how to access it in Designer. Also save the file to a **supported file format**.

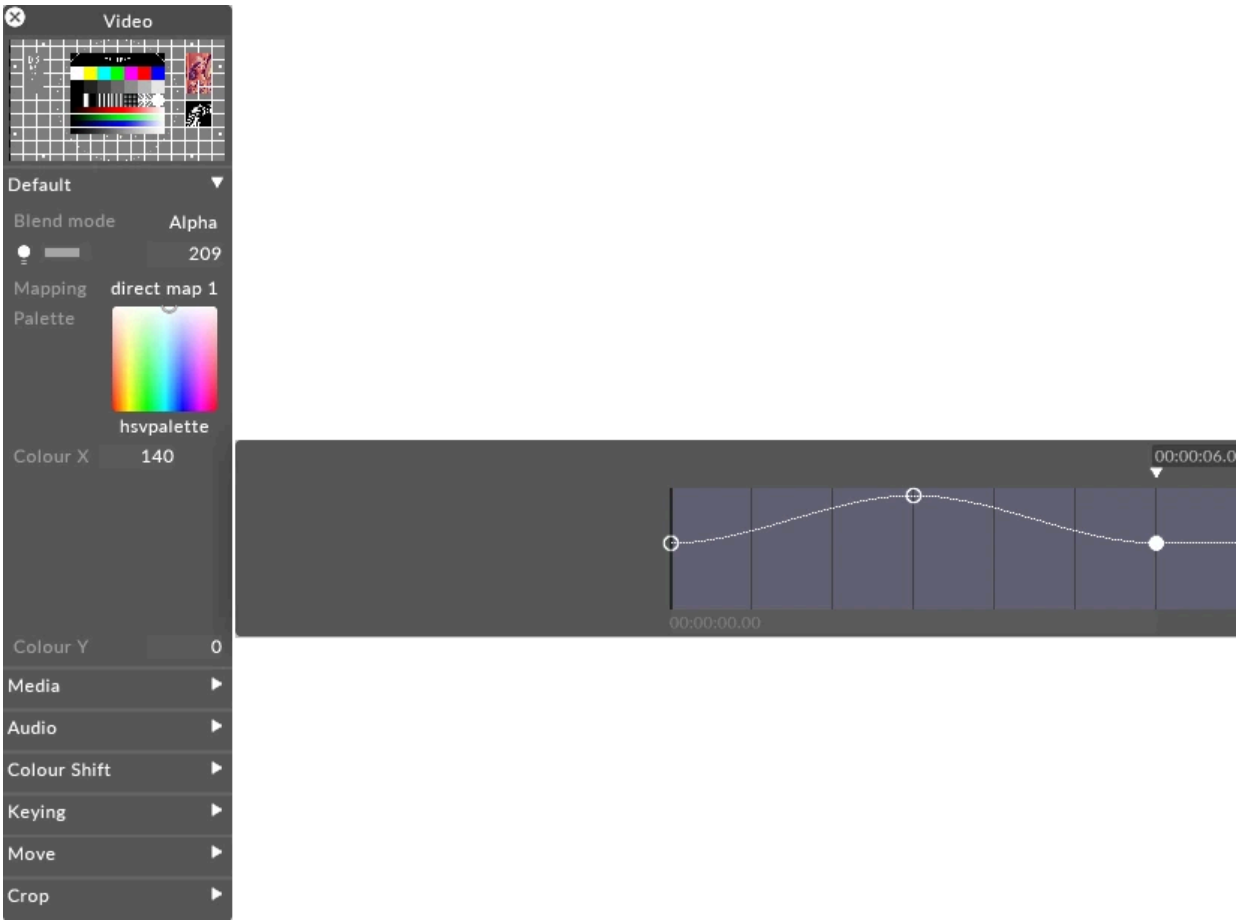
Xcol, YCol

These properties control the coordinates within the current palette bitmap where the output colour is sampled from. The default value is 0,0 which points at the color white (if you are using the HSVPAL palette). Multiplying white with the colors of the chosen content simply generates the original content colors. **Colour X** controls the horizontal position, where 0 is the leftmost

edge and 255 is the rightmost edge. **Colour Y** controls the vertical position, where 0 is the top edge and 255 is the bottom edge.

For example, to saturate the video clip red, change the **Colour Y** value to 255 and use 0 for the **Colour X** value. These coordinates refer to the color red in the palette which is being multiplied with the colors of the existing content.

When you are using the default palette HSVPAL , Colour Y controls saturation, and Colour X controls hue.



Generative Layers

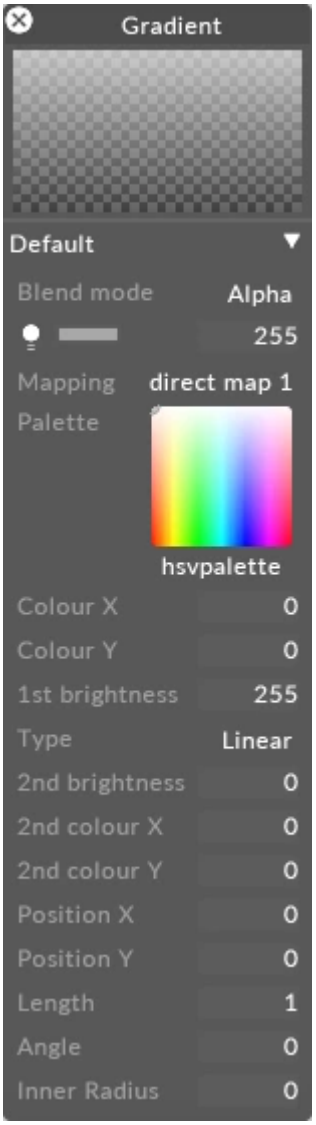
Designer has several types of layers that can be used to generate content in real-time known as Generative layers.

Types of Generative Layers

- Bugs
- Chevron
- Colour
- Gradient
- Notch
- Radar
- RGBColour
- Readout
- Scan
- Strobe
- Tennis
- Testpattern
- Text
- TrackingMarker

Gradient Layer

The Gradient layer draws real-time gradients composed of two colours. This means that the colours contained in the gradients can be keyframed and sequenced to change instead of being rendered into the content.



Layer Properties

Type

Either **linear** or **radial** .

2nd Brightness

This controls the brightness of the second colour in the gradient.

2nd xCol, 2nd yCol

This controls the second colour in the gradient (both colours must be taken from the same palette bitmap).

Position x, y

This controls the position (ranging from 1 to +1 on both axes) of the the gradient. In case you are using the **linear** gradient, this is the midpoint of the line; If you are using the **radial** gradient, this is the center of the circle.

Length

Length can have a value ranging from 0 to 1 (1 = complete canvas width) and controls the width of either the linear gradient or the radius of the circle.

Angle

This is only meaningful when using linear gradients. It controls the angle of the line, in degrees.

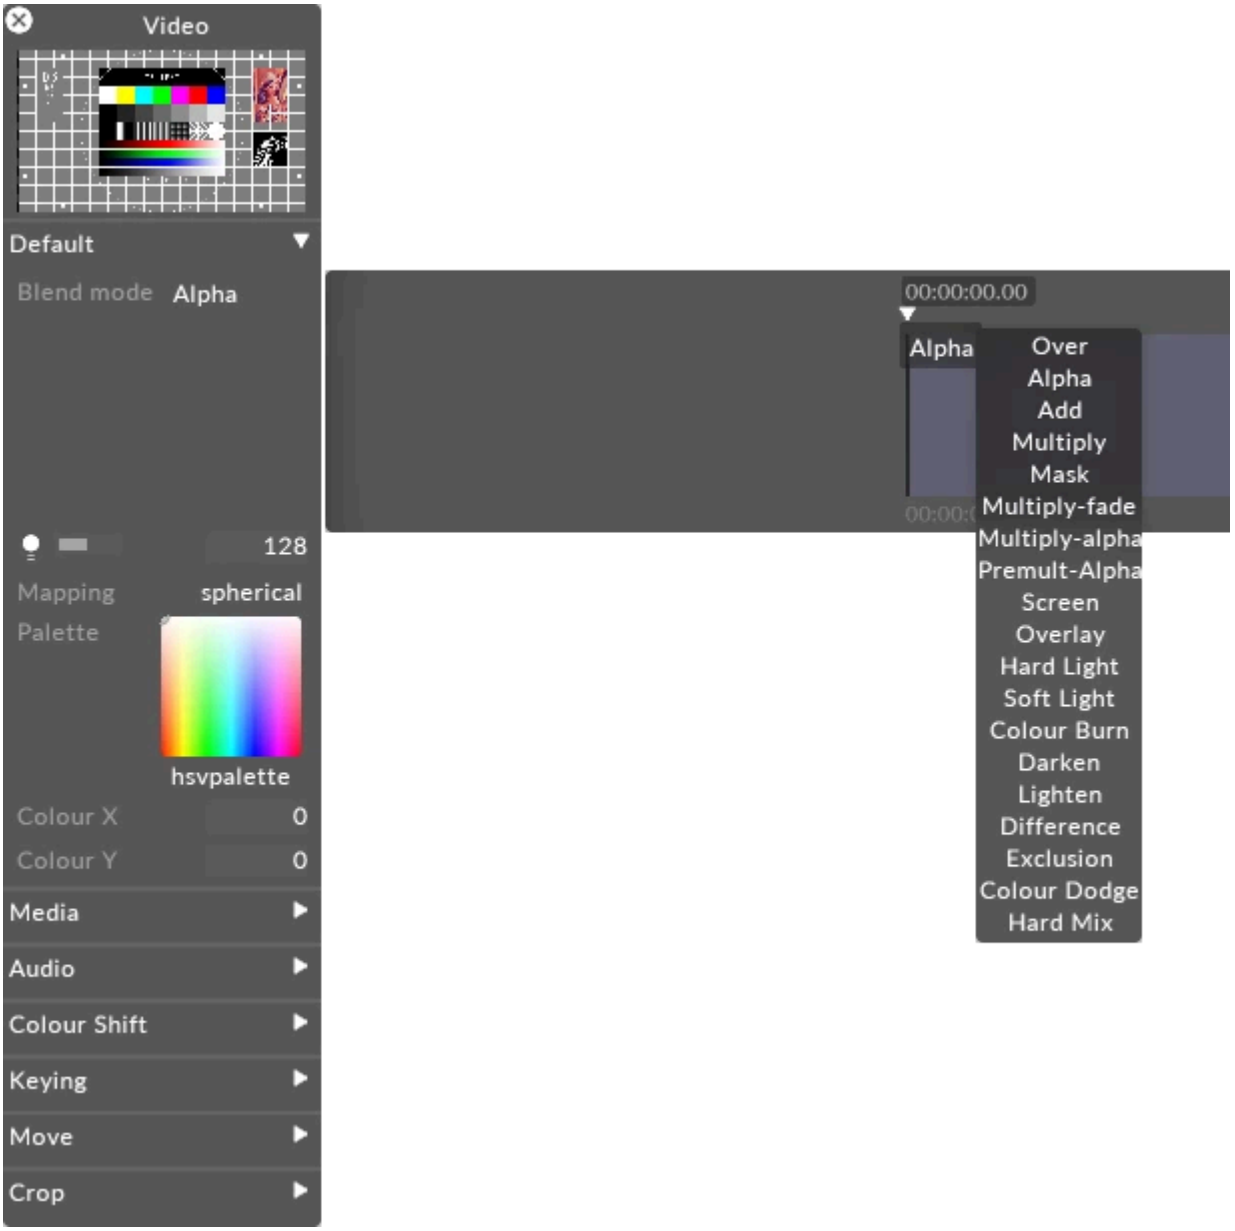
Inner Radius

Radial offset before the gradient occurs. Only applies when the gradient **Type** is **Radial**.

Common Layer Properties

Blend Mode

BlendMode controls how the output of the layer is composited with the layers below. Layers are rendered in a bottom-up order: layers at the top can modify the output of the layers below.



Changing brightness of a content layer in Designer is actually controlling the value of the alpha of the layer. Even when displaying a HAP video, the software will composite the layer with a controllable layer of alpha - one per layer.

There are two ways of expressing alpha in an image:

Straight alpha is an alpha channel which functions just like RGB. Alpha acts as a fourth channel of information per pixel which is as independent of the other three as R, G and B are of each other. For example, with straight alpha it is possible to have RGB = 255 (white) and alpha = 0 (fully transparent) on the same pixel. Internally generated content, such as gradient layer, are generated with straight alpha. This is the preferable style of alpha and considering the cleaner method of the two.

Premultiplied alpha takes the alpha and applies it to the values of the RGB channels per pixel. The more transparent something gets with premultiplied alpha, the closer it gets to black - as if the content is sitting on a black table. Premultiplied is the default output of Adobe Photoshop or AfterEffects. The result is our pixel at 255 RGB (full white) with 0 alpha would be calculated as a black pixel in the final image.

Here are explanations of what each individual blend mode will do.

Over

Makes a layer fully opaque. Premultiplies all alpha onto the RGB value of each pixel. Alpha = black, so adjusting the brightness of a layer in Over blend mode makes it darker.

Alpha

Default blend mode. It will apply alpha values as a transparency if the alpha is present. Brightness changes will make the layer more or less transparent.

Add

Adds the value of each RGB pixel together. Always creates a brighter result. Values clamp at 255.

Multiply

Reads the level of each subpixel as a level between 0.0 and 1.0, and multiplies source with blend. The result is always a darker image overall. For example: white x grey = 0.5. White turns transparent, black takes precedence. Alpha is applied in the same fashion as the Over Blend mode.

Mask

Applies a mask to the single layer **above** in the stack, irrespective of mapping. See **Mask blending** for more information.

Luma-Matte

This mode creates a Luma Matte by using a layer's **Rec. 709 luminance** to control the alpha channel of the layer **above**, irrespective of mapping.

To determine transparency, the luminance of each pixel is calculated using a weighted average of its red, green, and blue channels. The luminance value is then used as the alpha (opacity) value for the corresponding pixels in the upper layers.

As a result, white areas render the layer above fully opaque, black areas make them fully transparent, and grey areas create proportional semi-transparency. This is a specialized **Mask** blend mode; for more details on the underlying behaviour, see **Mask blending**.

Inv-Luma-Matte

The Inverse Luma Matte mask works the same as the Luma Matte mask but the transparency is inverted meaning white regions are transparent and black regions are opaque.

Multiply-Fade

The same as Multiply, but will make use of the alpha channel to calculate transparency in the source and blend layers. Since maximum transparency is premultiplied, alpha results in black. This will ignore black created through premultiplying.

Multiply-Alpha

Multiply with straight alpha. This mode assumes that the alpha has not been premultiplied onto the RGB values and will not apply a correction to the semi-transparent pixels.

Premultiply Alpha

Like how Multiply-fade will ignore the darkening caused by premultiplying, this blend mode will do the same with Alpha.

Colour Burn

Blend mode increases the contrast to darken the base colour while reflecting the blend colour. The darker the blend colour, the more intensely the colour will be applied in the base image. White as the blend colour produces no change. Using the colour burn blend mode can produce some harsh results at full opacity. The colour burn blend mode can be used to make tonal and colour adjustments to a layer.

Screen

This blend mode looks at each channels colour information and multiplies the inverse of the blend and base colous. The result is always a lighter colour. Screening with black leaves the colour unchanged. Screening with white produces white. The effect is similar to projecting multiple images on top of each other - where bright white is fully opaque, black is fully transparent and 50% grey is 50% transparent.

Overlay

Multiplies or screens the colours, depending on the base colour. Patterns or colours overlay the existing pixels while preserving the highlights and shadows of the base colour. The base colour is not replaced, but mixed with the blend colour to reflect the lightness or darkness of the original colour.

Hard Light

Multiplies or screens the colours, depending on the blend colour. The effects is similar to shining a harsh spotlight on the image. If the blend colour (light source/top layer) is lighter than

50% grey, the image is lightened as if it were screened. This is useful for adding highlights to an image. If the blend colour is darker than 50% grey, the image is darkened as if it were multiplied. This is useful for adding shadows to an image. Painting with pure black or white results in pure black or white.

Soft Light

Darkens or lightens the colours, depending on the blend colour. The effect is similar to shining a diffused spotlight on the image. If the blend colour (light source/top layer) is lighter than 50% grey, the image is lightened as it if were dodged. If the blend colour is darker than 50% grey, the image is darkened as if it were burned in. Painting with pure black or white produces a distinctly darker or lighter area, but does not result in pure black or white.

Darken

Looks as the colour information in each channel and selects the base or blend colour - whichever is darker - as the result colour. Pixels lighter than the blend colour are replaced and pixels darker than the blend colour do not change.

Lighten

Looks at the colour information in each channel and selects the base or blend colour - whichever is lighter - as the result colour. Pixels darker than the blend colour are replaced and pixels lighter than the blend colour do not change.

Difference

Looks at the colour information in each channel and subtracts either the blend colour from the base colour or the base colour from the blend colour depending on which has the greater brightness value. Blending with white inverts the base colour values and blending with black produces no change.

Exclusion

Creates an effects similar to but lower in contrast than the difference mode. Blending with white inverts the base colour values. Blending with black produces no change.

Colour Dodge

Looks at the colour information in each channel and brightens the base colour to reflect the blend colour by decreasing contrast between the two. Blending with black produces no change.

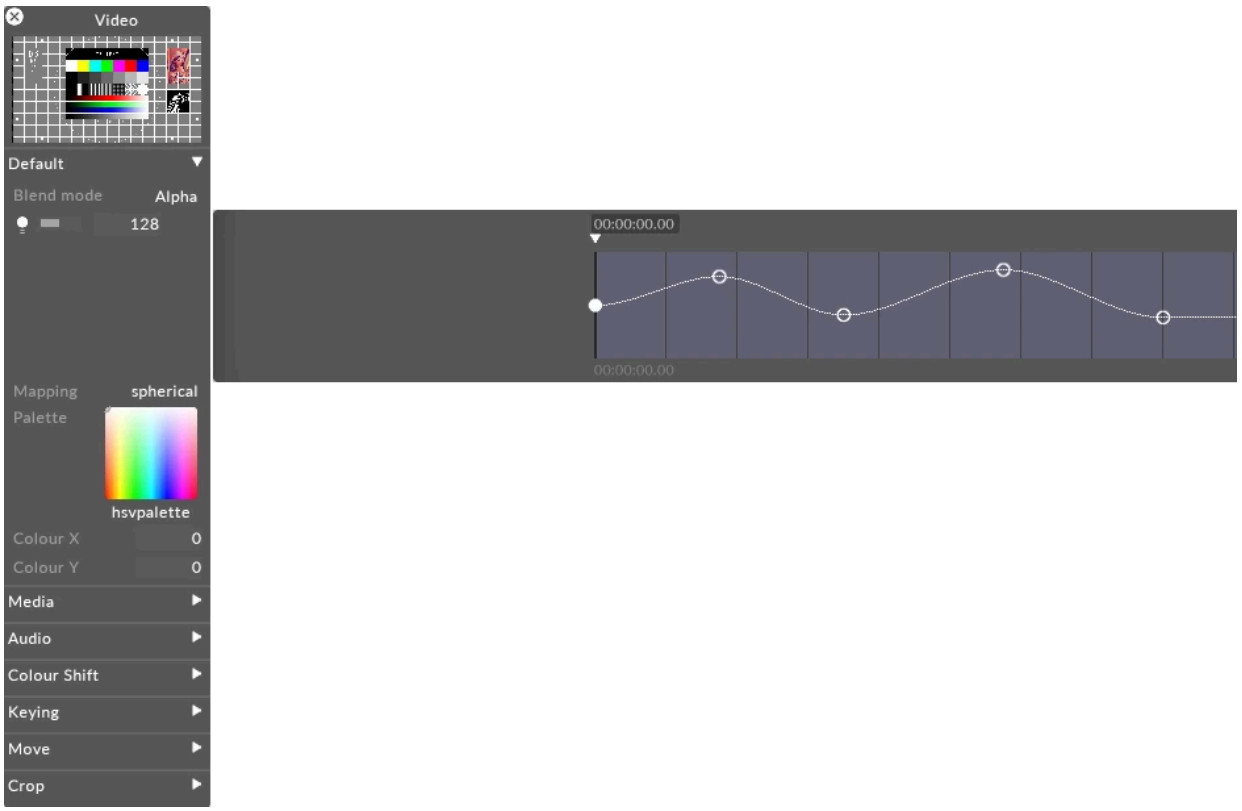
Hard Mix

Adds the RGB channels of the blend colour to the RGB values of the base colour. If the resulting sum for a channel is 255 or greater, it receives a value of 255; if it is less than 255 it

receives a value of 0. Therefore all blended pixels have RGB channels of either 0 or 255. This changes all pixels to primary additive colours (RGB), white or black.

Brightness

This property (which appears as a light bulb icon) controls the brightness of the layer output.



If the layers blend mode is set to Alpha, then reducing the brightness to 0 also reduces the opacity of the layer to 0. This can be useful when you want to dissolve from one layer to the next. In that case, you can place the new layer above the old layer and increase its brightness level.

> **Note**
>
> Layers that are patched to Sockpuppet (DMX, OSC or HTTP) are made Dormant when their brightness is set to 0. This means they will not do any rendering or consume any resources until their brightness is changed to > 0. You can find more information about this here: **Sequencing with Sockpuppet**. Layers without a sockpuppet patch do not behave in this way.

Mapping

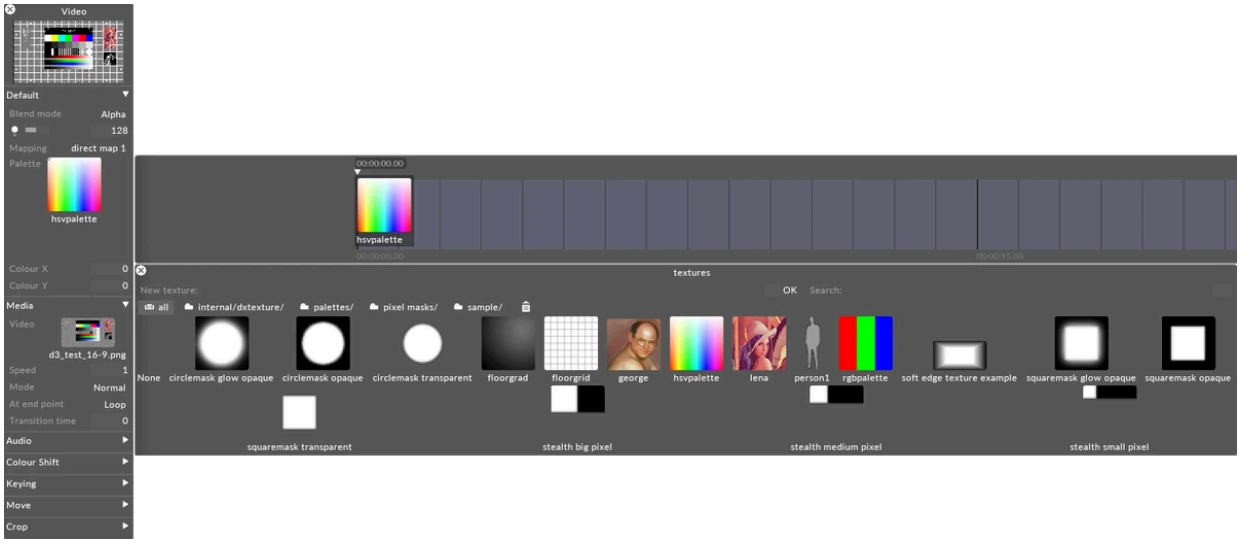
The mapping property controls how the layer output is mapped onto the screen(s) in the Stage level.

For information on mapping, including how to use the different mapping types offered by Designer, please see the chapter **Content Mapping**

Palette

This points to the still image file that defines the bitmap from which the tint colour is taken. The default palette (HSVPAL) consists of the complete range of hues and saturations. Selecting this property will open the Texture object library, which shows all of the still image files saved on your local hard-drive in the **DxTexture** older.

To control the location within the current palette bitmap, and thus control the colour, you have to edit the **xCol** and **yCol** values (see the section for xCol, yCol).



To change the current palette bitmap:

1. Left-click **palette** to open the Texture object library.
2. Left-click the still image file you want to use for the palette bitmap.

If you want to use a palette bitmap other than the standard still images provided in Designer, you will need to use a custom still image file.

See the **Placing media files** for a project sub-chapter to understand where to place a custom still image file and how to access it in Designer. Also save the file to a **supported file format**.

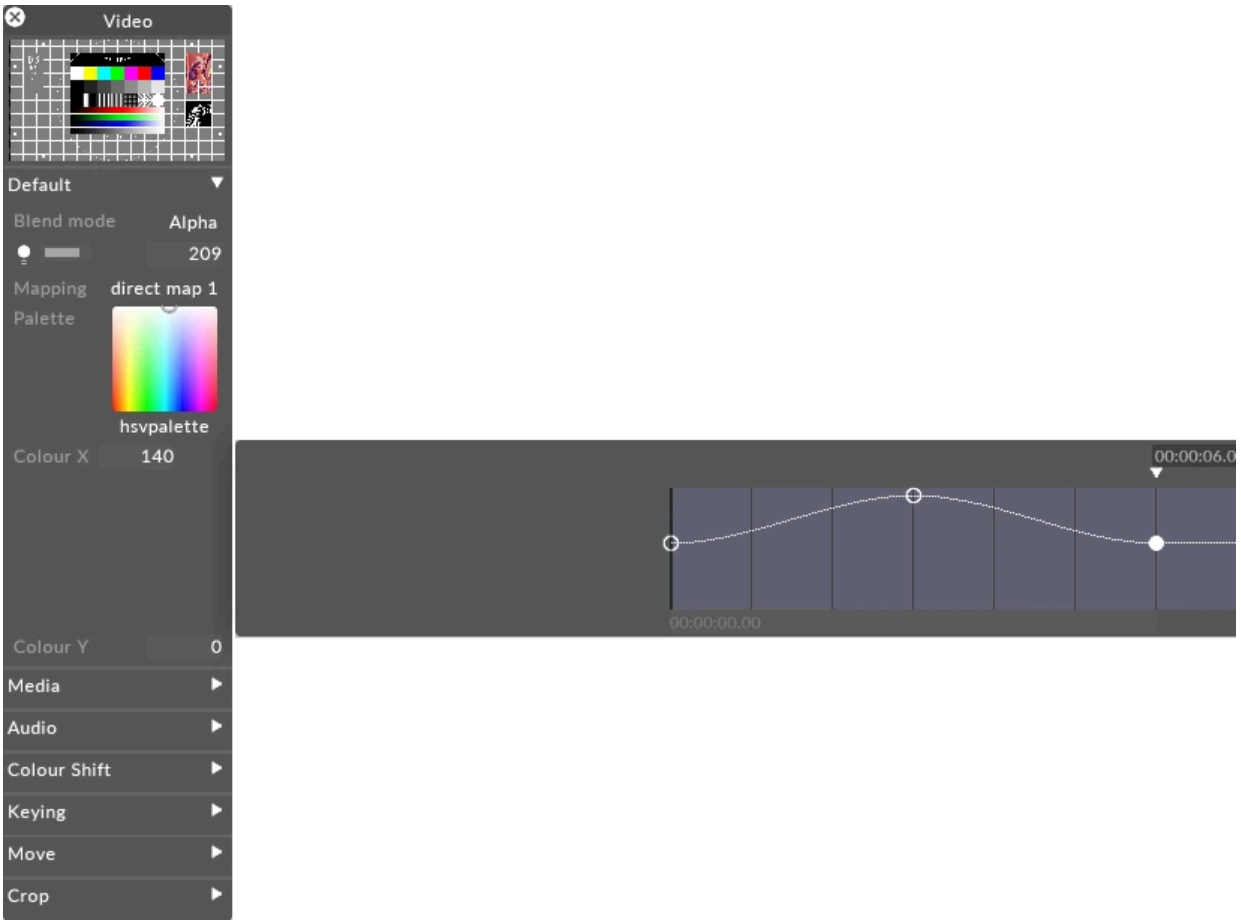
Xcol, YCol

These properties control the coordinates within the current palette bitmap where the output colour is sampled from. The default value is 0,0 which points at the color white (if you are using the HSVPAL palette). Multiplying white with the colors of the chosen content simply generates the original content colors. **Colour X** controls the horizontal position, where 0 is the leftmost

edge and 255 is the rightmost edge. **Colour Y** controls the vertical position, where 0 is the top edge and 255 is the bottom edge.

For example, to saturate the video clip red, change the **Colour Y** value to 255 and use 0 for the **Colour X** value. These coordinates refer to the color red in the palette which is being multiplied with the colors of the existing content.

When you are using the default palette HSVPAL , Colour Y controls saturation, and Colour X controls hue.



Notch Layer

The Notch layer allows users to use **Notch Blocks** exported from **Notch Builder**.

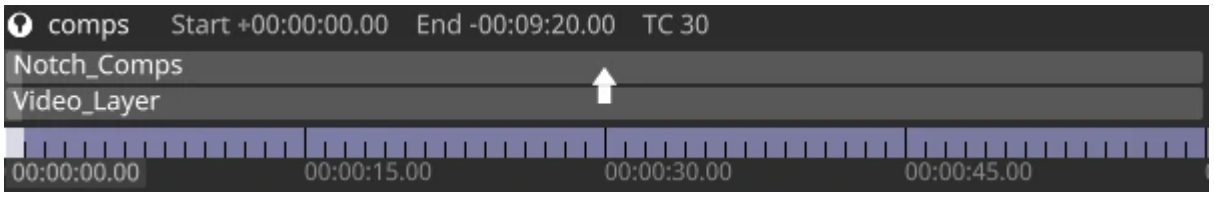
Notch content creation should be approached from a similar standpoint to that of rendered content, whereby the user specifies as much in advance as possible and tests the content on a real world system before show time to reduce the likelihood of performance related issues.

> ⚠ **Warning**
>
> Extremely demanding Notch blocks can cause an oversubscription of available memory resources - click **here** for full advisory.

Some Generative layers take their source from other layer types - either content or generative - by use of an arrow. Linking two layers with an arrow defines the arrowed from layer as the source, and the arrowed to layer as the destination. If you have an arrow between a content layer and effect layer, it is said that the content layer is being 'piped in' to the effect layer. For more information on arrows, see the compositing layer topic.

To draw an arrow between two layers, hold down **ALT** and left-click & drag between the source and destination layer.

On the Notch layer, you can specify which source the layer is using (either texture or an arrowed layer) by using the Video Loader parameter. The Video parameter of the layer will show a thumbnail of either the texture chosen, or the content coming from the arrowed layer (depending on the selection made).



Notch v1.0+

In 2024 Notch has released Notch v1.0 private beta. Designer officially supports notch v1.0+ beta blocks from Designer version r27.7 released on 12/06/2024.

We support for Notch's new colour management pipeline. You can find more information about Notch colour management at the bottom of this page.

> **Warning**
>
> While Notch v1.0+ beta blocks can be loaded and run on select servers with Designer r27.7+, Notch v1.0+ is still in beta, so care should be taken using them in real show environments. Please contact Notch support about your plans to use their beta tools.

The following limitations affect Notch v1.0 beta blocks:

1. Windows OS must be Windows 10 1607 or higher.
2. Notch v1.0 only supports Nvidia GPUs with Maxwell architecture or newer.
3. Notch v1.1 only supports Nvidia GPUs with Turing achitecture or newer.

Please see the compatibility table to work out if your machine supports Notch v1.0+ blocks:

Notch advice

> **Note**
>
> It's always recommended to combine multiple Notch blocks into one block, as opposed to using lots of small blocks in your project. Notch has functionality to combine blocks in Notch builder.

- Notch renders to the size of the resolution of the mapping being used on the Notch layer within Designer.
- Rotation is displayed in degrees within Notch, but shown as radians once exposed within Designer.
- The Y and Z axes are different in Notch and Designer, and need to be flipped/converted manually using an expression.
- The general consensus is that one should NOT use Universal Crossfade alongside Notch. Using Universal Crossfade adds twice as much load, and depending on the effect used it is unlikely to generate the desired effect.
- Only ever have one dfx file connected to a Kinect.
- When using a Notch block with Kinect input, to see this input the machine will need the Kinect SDK installed. You will also need to enable Kinect input via Devices in Notch Builder.
- For audio reactive, it's worthwhile to define the audio device being used on the server in your notch projects audio device (device > audio device).
- When using sockpuppet please advise the Notch content creators to create unified naming conventions for all exposed parameters (ie: FX1, FX2, Speed1, Speed2, Color1, Color2, Color3, etc.) otherwise end management will be difficult to manage.

- Any block that stores frames (i.e. frame delay) needs to be managed extremely carefully or it may eat up all memory resources. If VRAM resources are being eaten up inexplicably, it's worth checking whether the Notch block is storing frames for use anywhere.
- Also, as Notch blocks are not user-definable in terms of DMX assignment order, so it is always best to pre-determine the number of attributes one wishes to have exposed in the Master block.

Workflows

The layer is specifically for playing back Notch blocks. Depending on your application and production needs, there are several workflows you can employ to integrate Notch effects into Designer. Below are a few recommended workflows for their respective applications. Bear in mind that these are stripped to the bare minimum elements for simplicity, and users are required to have a valid Notch Builder software with export capabilities to follow along.

For more information on Notch Builder, see **here**.

IMAG effects

These are probably the most straight forward effects to implement on a show, as blocks are usually designed to be plug and play, with a video source and exposed parameters to control and interact with the effect. Below we denote the workflow.

In Notch

- Create a Notch effect with a node that accepts a video (usually Video Loader).
- Expose the Video property in the Video Loader and compile the block.

In Disguise

1. Create a Notch layer, load the IMAG Notch block into it.
2. Create a Video layer (or any layer you wish to output content from, i.e. generative layers).
3. Set Video Source to **Layer**.
4. Move the Notch layer above the other layer in the stack, then arrow the video layer to it.

You should now be able to see the IMAG effect applied to any content from the layer below. You can change the effects being applied under the parameter group's Notch Layer parameter if the effect is set up to use layers as individual effects.

Notes

- Designer does not yet support Video selection without layer arrowing. The Video parameter under Video Sources is mostly unused, though it can still be used for placeholder images. The images displayed under Video Sources are taken from the DxTexture folder.

- If multiple Notch layers are used and you wish the arrowed video to be the same for all of them, you will need to set up the exposed parameter's Unique Identifier in Notch to be the same for all exposed video sources.
- If multiple layers are arrowed into an effect that accepts multiple sources, the source layer is chosen in order of selection (i.e. the first layer selected will be the first Video source, the second will be the second, etc) regardless of the order of the parameters themselves within the list.

3D virtual lighting simulations

These workflows often involve a 3D mapped object with projectors simulating light sources moving and affecting the object in real-time. These effects rely on the virtual 3D space to match the real space and object, along with the coordinates systems of Designer and Notch.

In Notch

1. Add a 3D object node (or a Shape 3D node, etc) and add it to the scene.
2. Add a light source.
3. Create a UV camera node to output the lit textures onto the object's UVs.
4. Expose the appropriate parameters (light positions, object positions, etc).
5. Compile and export the block.

In Disguise

1. Create a surface with the same object used in Notch.
2. Calibrate the projectors to the surface with your preferred calibration method.
3. Create a Notch layer.
4. Apply the Notch layer via Direct mapping to the object.
5. Move the lights around to see the object UVs being affected.

Notes

> **⚠ Warning**
>
> While it's often advised to enable Deferred Rendering in Notch, it might negatively impact performance depending on the complexity of the scene. Use this functionality cautiously.

- For the Notch scene to match the scene within Designer, accurate measurements need to be taken on stage and an origin point reference needs to be determined from the start. Setting an origin point early in the process will make the line-up process easier.
- Lights can be linked to MIDI, OSC, or DMX controls like every parameter in Designer, or can be keyframed and sequenced on the timeline.
- The mapped object's movement can be linked to automation or tracking systems, and the positional data can then be used to drive the exposed position and rotation parameters.

- If multiple objects are in a scene, you will need to create a larger UV layout that accommodates each object in a separate UV area, and then match the overall lightmap resolution by setting the surface resolution within Designer. You can use the UV Output section of the 3D objects node in Notch to determine where in UV space a specific mesh will be output within the overall canvas.

Particles systems and tracking regions

A very common application of Notch is to use it alongside tracking systems such as BlackTrax to generate particles from specific points in space, to be either projected on a surface or displayed on an LED screen. Below is a broad outline of the workflow using an LED screen, the BlackTrax system, and region camera to specify the tracking regions:

In Notch

1. Create a particle system (Minimum required: Particle Root, Emitter, Renderer).
2. Create a Region Camera.
3. Expose the position parameters of the Particle Emitter, as well as the Region Camera's Top Left X and Y, and Bottom Right X and Y.
4. Compile the block, and export to Disguise.

In Disguise

1. Create an LED screen. This can be placed anywhere in the virtual stage, though it is recommended to place the LED in the correct position to match the physical space.
2. Ensure the BlackTrax system is connected and tracking data is being received from the beacons, then select a stringer to use as a tracked point for the Notch particles.
3. Create a Notch layer and load the exported block into it.
4. Set the Play Mode to Free-run, or press play on the timeline for the particles to begin spawning. They are a simulation and only spawn over a span of time.
5. Right-click on the BT point being tracked to open a widget that displays the point's current coordinates in 3D space.
6. With the Notch layer open and the Particle Emitter position parameters visible, navigate to the tracked point's widget, hover over one of the position values, then Alt + left-click and drag an arrow from there to the corresponding position parameter in the Notch block.
7. You should now see the particle effect either disappearing off-screen (if the beacon is not in range of the LED screen) or moving towards it.
8. If the world coordinates of Notch and Disguise do not match, and the particle effect is limited to a particular screen or mapped area, a Region Camera can be used to mark the boundaries of the tracking region instead.
9. To set the region camera, simply measure the XY position of the top-left corner of the LED screen, and do the same for the bottom-right, and enter these values in the exposed Region Camera parameters.

Notes

- An often quicker method of finding out the region camera values is to place a tracked BT point on the top left of the screen, and then the bottom right, and manually enter the xyz coordinates displayed on the tracked point's widget, as they are sure to match precisely.
- A common mistake that leads to oddities with tracking regions is when the wrong axes are used. As a rule of thumb, for vertical surfaces you'll need to take the X and Y position of the top left and bottom right corners, whereas for horizontal surfaces (i.e. for effects built to be displayed on the ground) you will need X and Z. This is also dependant on how the Notch block itself was built and the orientation chosen in the region camera node, so it's important to double-check these details beforehand.
- When using the region camera, particle size plays a fairly important role. It may be advisable to expose emitter size, particle size, and camera distance to achieve the desired result.
- If multiple machines are outputting the same set of particles but are seeing a different result, it is because both particle roots are running separate instances of the simulation on two machines. You can fix that by setting the Particle Root node for that emitter to Deterministic by ticking the box in the node editor in Notch Builder.

Notch Layer Properties

Notch layers are comprised of a set of default properties (detailed here) and additional properties that appear depending on what is actually in the Notch block. For explaination of properties beyond the default, please refer to your Notch content creator.

Effect

The Effect parameter defines which Notch DFX File the layer is looking at.

Blend Mode

Blend Mode controls how the output of the layer is composited with the layers below.

Brightness

This property (which appears as a light bulb icon) controls the brightness of the layer output.

Mapping

The mapping property controls how the layer output is mapped onto the screen(s) in the Stage level.

For information on mapping, including how to use the different mapping types offered by Designer, please see the chapter Content Mapping.

Processing Size

There are two options:

Output size - The resolution of the screen the effect is mapped to (not the mapping itself)

Input size - The resolution of the effect as set in the Notch Builder.

Dry-Wet Blend

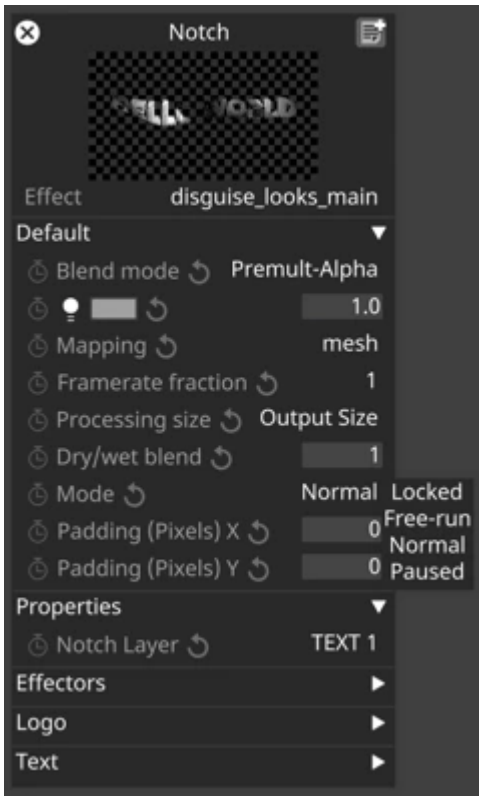
Global Intensity level for the effect on a scale of 0-1.

Framerate Fraction

The Framerate Fraction setting indicates the fraction of the project refresh rate this layer renders at. For example, if project refresh rate is 50Hz, and this setting is 1/2, the layer will be rendered at 25Hz, every other frame.

The options are 1, 1/2, and 1/3.

Mode



This specifies the playback mode.

There are four modes; each one has a specific behaviour that is useful for a different situation.

- **Locked**

When the play cursor stops, the block will also stop and the frame number will lock to the timeline position. When the cursor continues to play or holds at the end of a section, the block will also stop. Jumping around the timeline while playing will cause the block to jump to its corresponding point on its own internal timeline. Note, locked behaviour does not apply to effect type nodes in the Notch block.

- **FreeRun**

If the play cursor continues to play or stops at the end of a section, the block will play continuously. Jumping around the timeline while the cursor is playing or has stopped does not affect which frame is being played.

- **Normal**

When the play cursor stops, the block will also stop and the frame number will lock to the timeline position. When the cursor continues to play or holds at the end of a section, the block will play continuously. Jumping around the timeline while playing does not affect which frame is being played.

- **Paused**

The block will pause on the frame at which the **Paused** playmode was selected. Moving the play cursor around the timeline in any way will not affect which frame is held. Leaving the layer and re-entering the layer will also not affect which frame is held.

Padding X, Padding Y

This specifies the number of pixels to add in the X and Y directions for rendering, but cut off before compositing. This is useful for removing any screen-space edge artifacts. The pixels added are symmetrical to both sides.

Notch Colour Management

This section outlines Notch colour management tools and conventions in Notch.

Before Notch v1.0

Before Notch v1.0 all blocks expect inputs and output in sRGB Gamma 2.2 (x^2.2) colour space. This cannot be changed.

Notch v1.0+

Notch v1.0 introduces colour management options. You can now set the input/output format of a notch block to one of the following settings before exporting the Notch block:

- sRGB Linear
- sRGB 'Gamma 2.2' (Note: This actually uses the standard sRGB curve, not Gamma22 as the name might suggest)
- ACEScg

When Designer is set to **Disabled** or **Gamma** Colour modes, Designer will pass all textures in as sRGB Gamma 2.2. When Designer is in **ACES** or **OCIO** Colour modes, Designer will automatically detect the input and output transforms that the Notch block expects and will convert between Notch and Designer's working space when passing textures in and out of the block. This conversion is free when setting the Notch block to ACEScg mode as Designer also uses an ACEScg working space.

For more information about colour management in Designer see our colour transforms page.

For more information about colour management in Notch see Notch's colour management documentation here.

Notch v1.0+ Compatibility Table

Below is a compatibility table that outlines Notch v1.0+ compatibility with different Disguise media servers on their Current OS:

> ⚠ **Warning**
>
> Notch blocks built in 2026.1 can be loaded and run on select servers with Designer software version r27.7 onwards.

Server	Windows version in Current OS (as of r27.7 release date)	GPU (Generation shown in brackets)	Can I playback a Notch block exported from 2026.1 or later?
4x4pro	Windows 8.1	AMD (GCN 2.0)	✗
4x2pro	Windows 8.1	AMD (GCN v1.0)	✗
2x4pro	Windows 10 1607	Nvidia (Maxwell)	✓
2x2plus	Windows 8.1	Nvidia (Maxwell)	✗
Solo	Windows 10 1607	Nvidia (Pascal)	✓

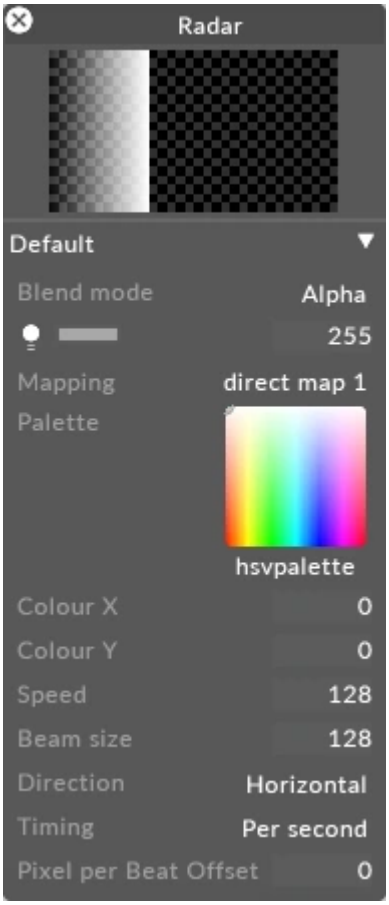
> **Note**
>
> Check your server's current driver on the hardware OS images page.

Radar Layer

The Radar layer is one of the simplest generative layers. It generates a moving beam with a bright leading edge that fades to a black trailing edge.

Workflow



Radar Layer Properties

Speed

This controls the speed of the beam movement. Positive numbers go rightwards/downwards; negative numbers go leftwards/upward

Beam Size

This controls the size of the beam. When set to 255, the width of the beam is the same as the width of the canvas.

Direction

This is an option property; the two options are **horizontal** and **vertical.**

Timing

This controls how the **speed** property is interpreted. The options are:

Per sec : the radar beam moves at x pixels per second, regardless of how the play cursor moves. This means that the radar beam position is not predictable anywhere on the timeline.

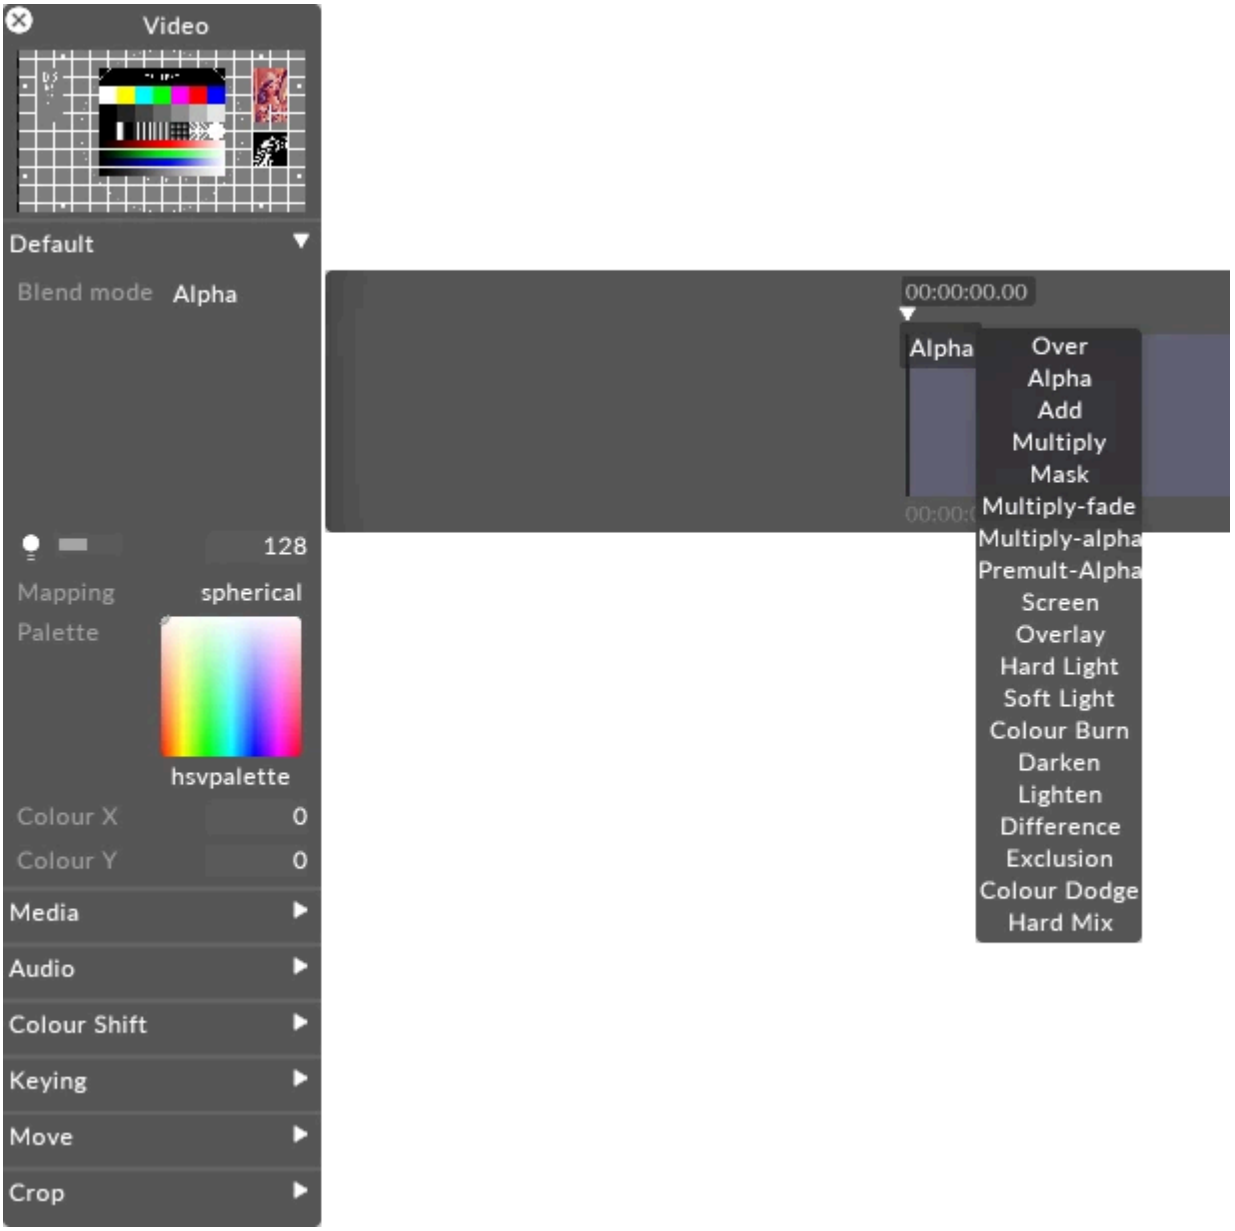
Per beat : the radar beam moves at a speed related to the current bpm, so that it moves an integer number of complete sweeps per beat. Furthermore, the position of the beam depends on the timeline position, so the beam is guaranteed to be at the same position at the start of every beat.

Per frame : the radar beam moves x pixels every frame.

Common Layer Properties

Blend Mode

BlendMode controls how the output of the layer is composited with the layers below. Layers are rendered in a bottom-up order: layers at the top can modify the output of the layers below.



Changing brightness of a content layer in Designer is actually controlling the value of the alpha of the layer. Even when displaying a HAP video, the software will composite the layer with a controllable layer of alpha - one per layer.

There are two ways of expressing alpha in an image:

Straight alpha is an alpha channel which functions just like RGB. Alpha acts as a fourth channel of information per pixel which is as independent of the other three as R, G and B are of each other. For example, with straight alpha it is possible to have RGB = 255 (white) and alpha = 0 (fully transparent) on the same pixel. Internally generated content, such as gradient layer, are generated with straight alpha. This is the preferable style of alpha and considering the cleaner method of the two.

Premultiplied alpha takes the alpha and applies it to the values of the RGB channels per pixel. The more transparent something gets with premultiplied alpha, the closer it gets to black - as if the content is sitting on a black table. Premultiplied is the default output of Adobe Photoshop or AfterEffects. The result is our pixel at 255 RGB (full white) with 0 alpha would be calculated as a black pixel in the final image.

Here are explanations of what each individual blend mode will do.

Over

Makes a layer fully opaque. Premultiplies all alpha onto the RGB value of each pixel. Alpha = black, so adjusting the brightness of a layer in Over blend mode makes it darker.

Alpha

Default blend mode. It will apply alpha values as a transparency if the alpha is present. Brightness changes will make the layer more or less transparent.

Add

Adds the value of each RGB pixel together. Always creates a brighter result. Values clamp at 255.

Multiply

Reads the level of each subpixel as a level between 0.0 and 1.0, and multiplies source with blend. The result is always a darker image overall. For example: white x grey = 0.5. White turns transparent, black takes precedence. Alpha is applied in the same fashion as the Over Blend mode.

Mask

Applies a mask to the single layer **above** in the stack, irrespective of mapping. See **Mask blending** for more information.

Luma-Matte

This mode creates a Luma Matte by using a layer's **Rec. 709 luminance** to control the alpha channel of the layer **above**, irrespective of mapping.

To determine transparency, the luminance of each pixel is calculated using a weighted average of its red, green, and blue channels. The luminance value is then used as the alpha (opacity) value for the corresponding pixels in the upper layers.

As a result, white areas render the layer above fully opaque, black areas make them fully transparent, and grey areas create proportional semi-transparency. This is a specialized **Mask** blend mode; for more details on the underlying behaviour, see **Mask blending**.

Inv-Luma-Matte

The Inverse Luma Matte mask works the same as the **Luma Matte** mask but the transparency is inverted meaning white regions are transparent and black regions are opaque.

Multiply-Fade

The same as Multiply, but will make use of the alpha channel to calculate transparency in the source and blend layers. Since maximum transparency is premultiplied, alpha results in black. This will ignore black created through premultiplying.

Multiply-Alpha

Multiply with straight alpha. This mode assumes that the alpha has not been premultiplied onto the RGB values and will not apply a correction to the semi-transparent pixels.

Premultiply Alpha

Like how Multiply-fade will ignore the darkening caused by premultiplying, this blend mode will do the same with Alpha.

Colour Burn

Blend mode increases the contrast to darken the base colour while reflecting the blend colour. The darker the blend colour, the more intensely the colour will be applied in the base image. White as the blend colour produces no change. Using the colour burn blend mode can produce some harsh results at full opacity. The colour burn blend mode can be used to make tonal and colour adjustments to a layer.

Screen

This blend mode looks at each channels colour information and multiplies the inverse of the blend and base colous. The result is always a lighter colour. Screening with black leaves the colour unchanged. Screening with white produces white. The effect is similar to projecting multiple images on top of each other - where bright white is fully opaque, black is fully transparent and 50% grey is 50% transparent.

Overlay

Multiplies or screens the colours, depending on the base colour. Patterns or colours overlay the existing pixels while preserving the highlights and shadows of the base colour. The base colour is not replaced, but mixed with the blend colour to reflect the lightness or darkness of the original colour.

Hard Light

Multiplies or screens the colours, depending on the blend colour. The effects is similar to shining a harsh spotlight on the image. If the blend colour (light source/top layer) is lighter than

50% grey, the image is lightened as if it were screened. This is useful for adding highlights to an image. If the blend colour is darker than 50% grey, the image is darkened as if it were multiplied. This is useful for adding shadows to an image. Painting with pure black or white results in pure black or white.

Soft Light

Darkens or lightens the colours, depending on the blend colour. The effect is similar to shining a diffused spotlight on the image. If the blend colour (light source/top layer) is lighter than 50% grey, the image is lightened as it if were dodged. If the blend colour is darker than 50% grey, the image is darkened as if it were burned in. Painting with pure black or white produces a distinctly darker or lighter area, but does not result in pure black or white.

Darken

Looks as the colour information in each channel and selects the base or blend colour - whichever is darker - as the result colour. Pixels lighter than the blend colour are replaced and pixels darker than the blend colour do not change.

Lighten

Looks at the colour information in each channel and selects the base or blend colour - whichever is lighter - as the result colour. Pixels darker than the blend colour are replaced and pixels lighter than the blend colour do not change.

Difference

Looks at the colour information in each channel and subtracts either the blend colour from the base colour or the base colour from the blend colour depending on which has the greater brightness value. Blending with white inverts the base colour values and blending with black produces no change.

Exclusion

Creates an effects similar to but lower in contrast than the difference mode. Blending with white inverts the base colour values. Blending with black produces no change.

Colour Dodge

Looks at the colour information in each channel and brightens the base colour to reflect the blend colour by decreasing contrast between the two. Blending with black produces no change.

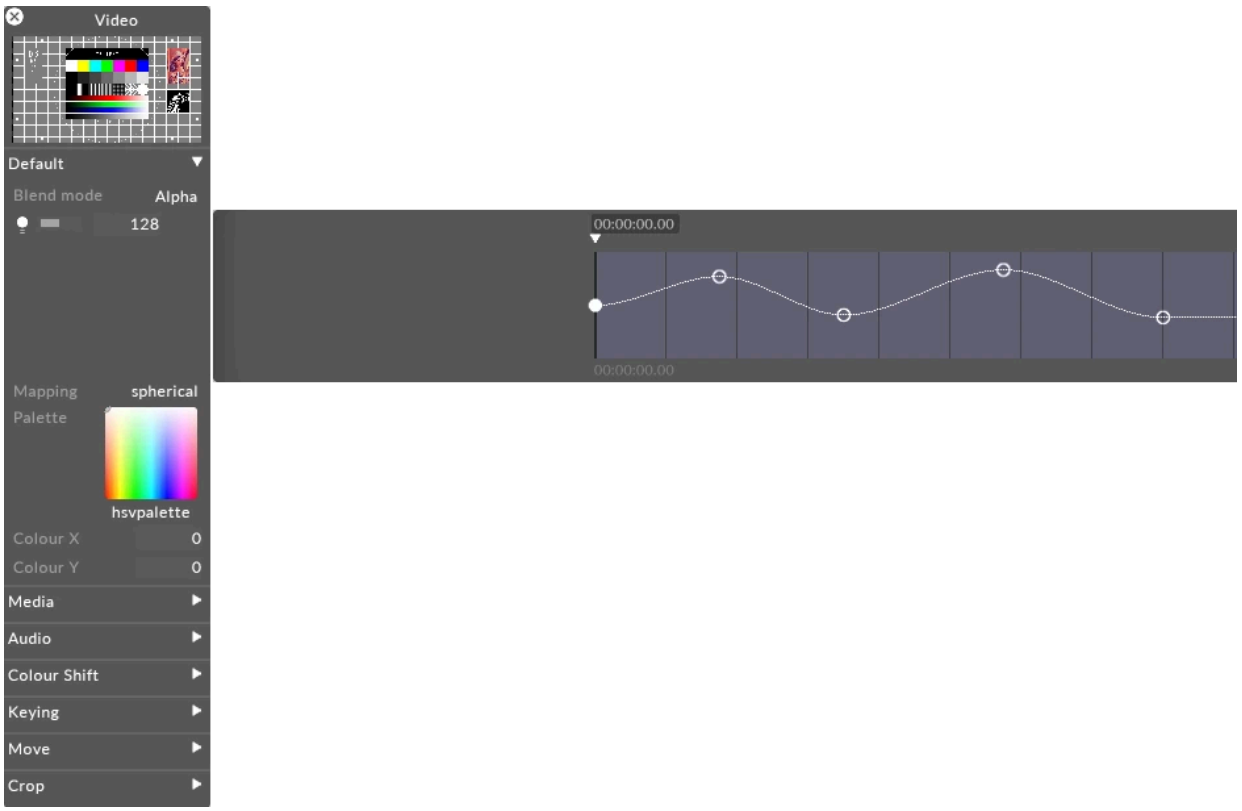
Hard Mix

Adds the RGB channels of the blend colour to the RGB values of the base colour. If the resulting sum for a channel is 255 or greater, it receives a value of 255; if it is less than 255 it

receives a value of 0. Therefore all blended pixels have RGB channels of either 0 or 255. This changes all pixels to primary additive colours (RGB), white or black.

Brightness

This property (which appears as a light bulb icon) controls the brightness of the layer output.



If the layers blend mode is set to Alpha, then reducing the brightness to 0 also reduces the opacity of the layer to 0. This can be useful when you want to dissolve from one layer to the next. In that case, you can place the new layer above the old layer and increase its brightness level.

> **Note**
>
> Layers that are patched to Sockpuppet (DMX, OSC or HTTP) are made Dormant when their brightness is set to 0. This means they will not do any rendering or consume any resources until their brightness is changed to > 0. You can find more information about this here: **Sequencing with Sockpuppet**. Layers without a sockpuppet patch do not behave in this way.

Mapping

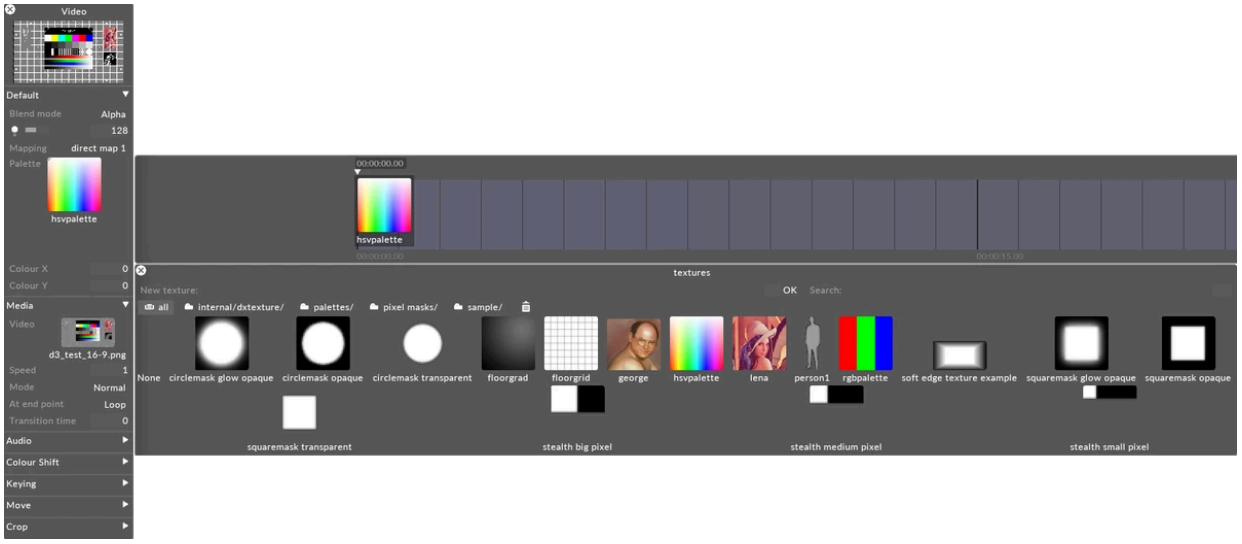
The mapping property controls how the layer output is mapped onto the screen(s) in the Stage level.

For information on mapping, including how to use the different mapping types offered by Designer, please see the chapter **Content Mapping**

Palette

This points to the still image file that defines the bitmap from which the tint colour is taken. The default palette (HSVPAL) consists of the complete range of hues and saturations. Selecting this property will open the Texture object library, which shows all of the still image files saved on your local hard-drive in the **DxTexture** older.

To control the location within the current palette bitmap, and thus control the colour, you have to edit the **xCol** and **yCol** values (see the section for xCol, yCol).



To change the current palette bitmap:

1. Left-click **palette** to open the Texture object library.
2. Left-click the still image file you want to use for the palette bitmap.

If you want to use a palette bitmap other than the standard still images provided in Designer, you will need to use a custom still image file.

See the **Placing media files** for a project sub-chapter to understand where to place a custom still image file and how to access it in Designer. Also save the file to a **supported file format**.

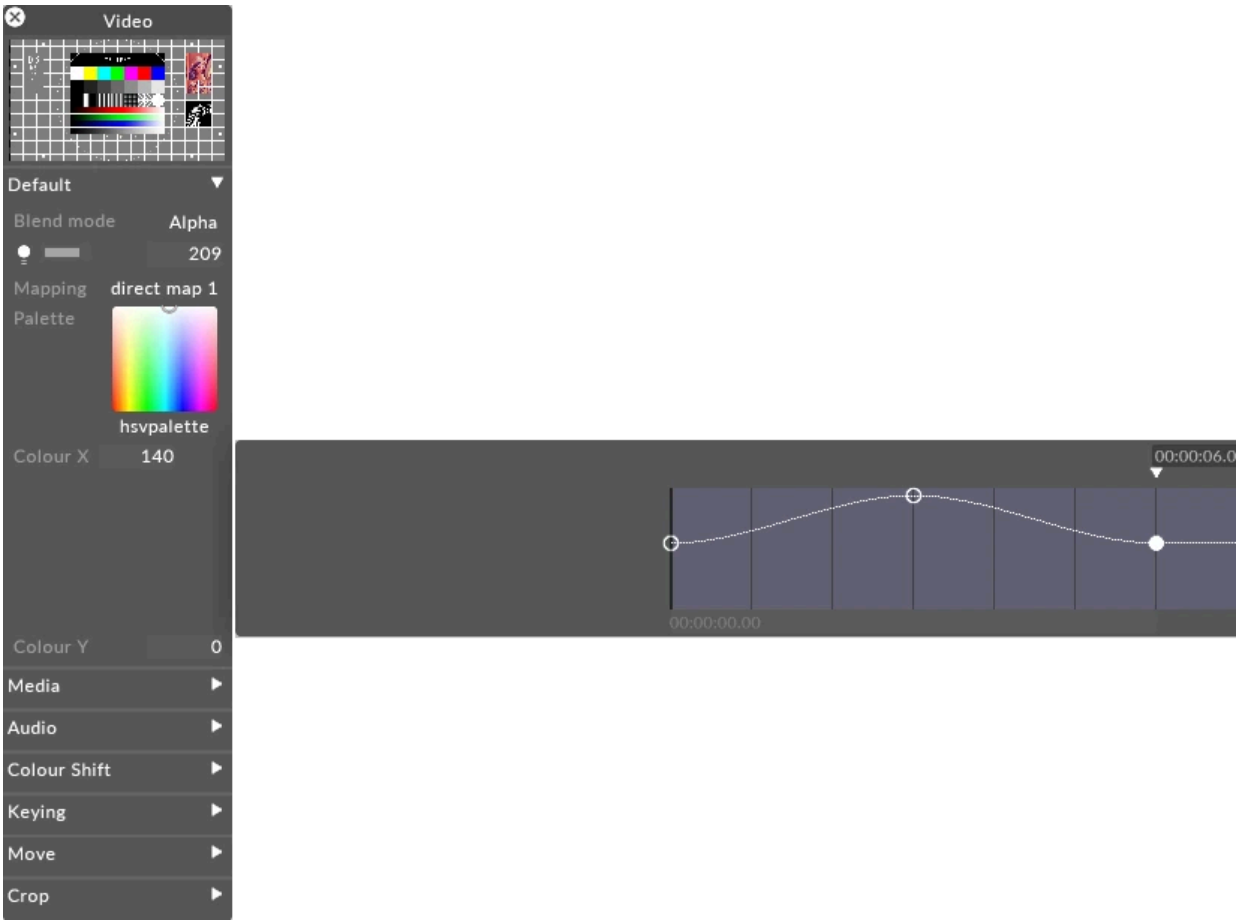
Xcol, YCol

These properties control the coordinates within the current palette bitmap where the output colour is sampled from. The default value is 0,0 which points at the color white (if you are using the HSVPAL palette). Multiplying white with the colors of the chosen content simply generates the original content colors. **Colour X** controls the horizontal position, where 0 is the leftmost

edge and 255 is the rightmost edge. **Colour Y** controls the vertical position, where 0 is the top edge and 255 is the bottom edge.

For example, to saturate the video clip red, change the **Colour Y** value to 255 and use 0 for the **Colour X** value. These coordinates refer to the color red in the palette which is being multiplied with the colors of the existing content.

When you are using the default palette HSVPAL , Colour Y controls saturation, and Colour X controls hue.

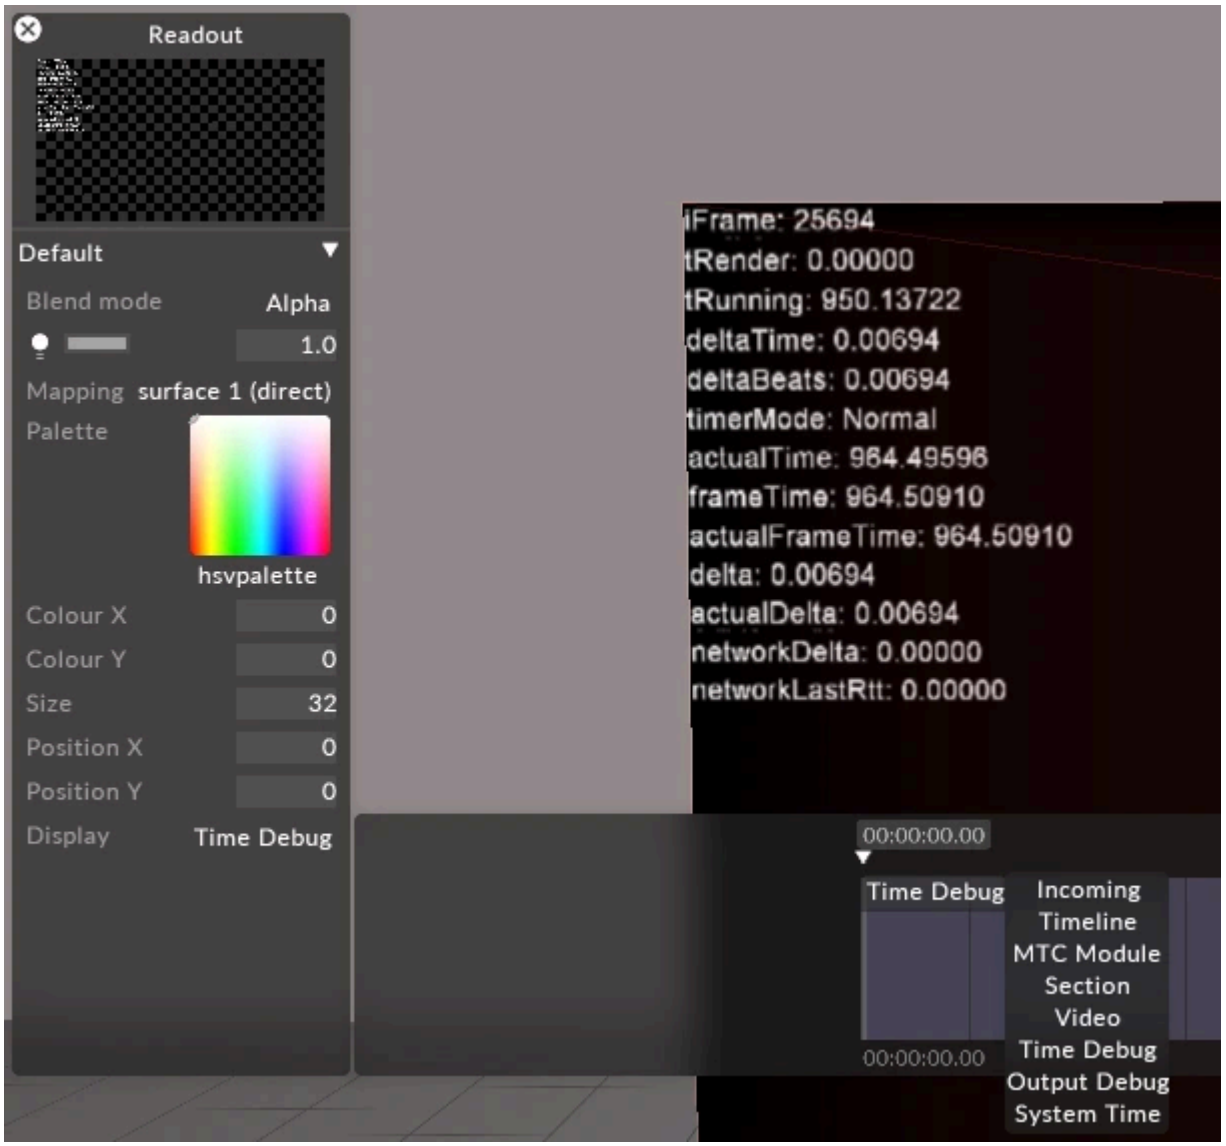


Readout Layer

The Readout layer allows you to assign the incoming timecode, remaining section time, or system time to a screen via a mapping to show on the output as well as in the stage.

Display property

The Display property allows you to switch between readouts for the incoming timecode, MTC layer, Timeline, Section, Video timecode, Time and Output Debuggers, and System time readouts.



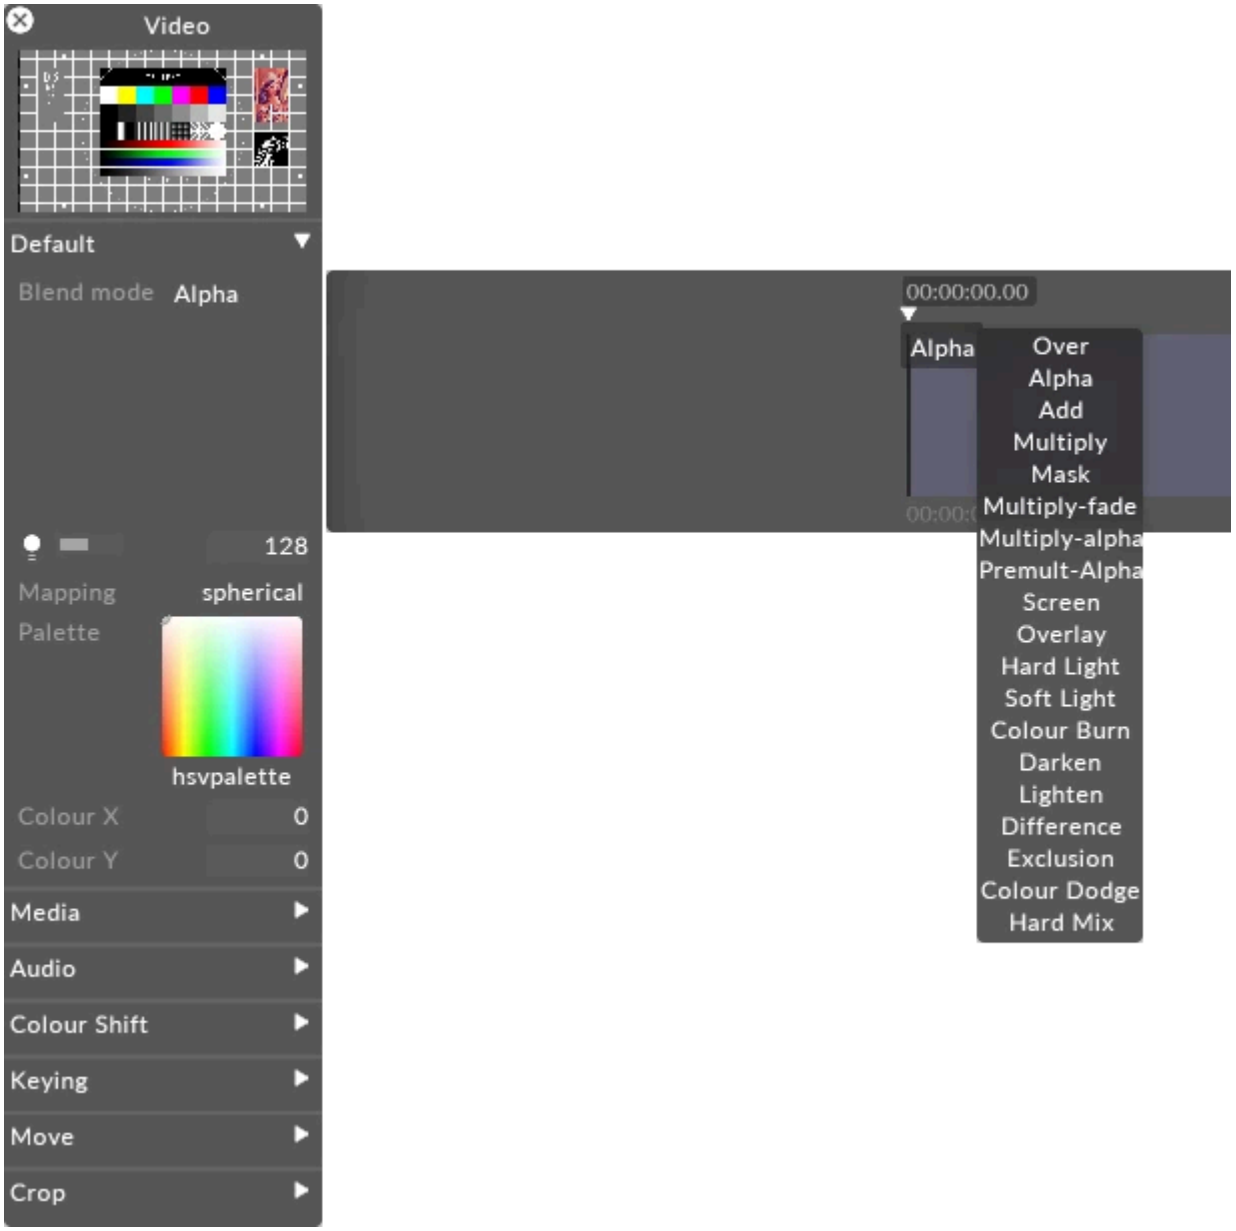
Common Layer Properties

For information on the Common Layer Properties “Mapping:, “Palette”, ” Colour x/y”, “Size”, and “Position x/y”, please visit this link.

Common Layer Properties

Blend Mode

BlendMode controls how the output of the layer is composited with the layers below. Layers are rendered in a bottom-up order: layers at the top can modify the output of the layers below.



Changing brightness of a content layer in Designer is actually controlling the value of the alpha of the layer. Even when displaying a HAP video, the software will composite the layer with a controllable layer of alpha - one per layer.

There are two ways of expressing alpha in an image:

Straight alpha is an alpha channel which functions just like RGB. Alpha acts as a fourth channel of information per pixel which is as independent of the other three as R, G and B are of each other. For example, with straight alpha it is possible to have RGB = 255 (white) and alpha = 0 (fully transparent) on the same pixel. Internally generated content, such as gradient layer, are generated with straight alpha. This is the preferable style of alpha and considering the cleaner method of the two.

Premultiplied alpha takes the alpha and applies it to the values of the RGB channels per pixel. The more transparent something gets with premultiplied alpha, the closer it gets to black - as if the content is sitting on a black table. Premultiplied is the default output of Adobe Photoshop or AfterEffects. The result is our pixel at 255 RGB (full white) with 0 alpha would be calculated as a black pixel in the final image.

Here are explanations of what each individual blend mode will do.

Over

Makes a layer fully opaque. Premultiplies all alpha onto the RGB value of each pixel. Alpha = black, so adjusting the brightness of a layer in Over blend mode makes it darker.

Alpha

Default blend mode. It will apply alpha values as a transparency if the alpha is present. Brightness changes will make the layer more or less transparent.

Add

Adds the value of each RGB pixel together. Always creates a brighter result. Values clamp at 255.

Multiply

Reads the level of each subpixel as a level between 0.0 and 1.0, and multiplies source with blend. The result is always a darker image overall. For example: white x grey = 0.5. White turns transparent, black takes precedence. Alpha is applied in the same fashion as the Over Blend mode.

Mask

Applies a mask to the single layer **above** in the stack, irrespective of mapping. See **Mask blending** for more information.

Luma-Matte

This mode creates a Luma Matte by using a layer's **Rec. 709 luminance** to control the alpha channel of the layer **above**, irrespective of mapping.

To determine transparency, the luminance of each pixel is calculated using a weighted average of its red, green, and blue channels. The luminance value is then used as the alpha (opacity) value for the corresponding pixels in the upper layers.

As a result, white areas render the layer above fully opaque, black areas make them fully transparent, and grey areas create proportional semi-transparency. This is a specialized **Mask** blend mode; for more details on the underlying behaviour, see **Mask blending**.

Inv-Luma-Matte

The Inverse Luma Matte mask works the same as the **Luma Matte** mask but the transparency is inverted meaning white regions are transparent and black regions are opaque.

Multiply-Fade

The same as Multiply, but will make use of the alpha channel to calculate transparency in the source and blend layers. Since maximum transparency is premultiplied, alpha results in black. This will ignore black created through premultiplying.

Multiply-Alpha

Multiply with straight alpha. This mode assumes that the alpha has not been premultiplied onto the RGB values and will not apply a correction to the semi-transparent pixels.

Premultiply Alpha

Like how Multiply-fade will ignore the darkening caused by premultiplying, this blend mode will do the same with Alpha.

Colour Burn

Blend mode increases the contrast to darken the base colour while reflecting the blend colour. The darker the blend colour, the more intensely the colour will be applied in the base image. White as the blend colour produces no change. Using the colour burn blend mode can produce some harsh results at full opacity. The colour burn blend mode can be used to make tonal and colour adjustments to a layer.

Screen

This blend mode looks at each channels colour information and multiplies the inverse of the blend and base colous. The result is always a lighter colour. Screening with black leaves the colour unchanged. Screening with white produces white. The effect is similar to projecting

multiple images on top of each other - where bright white is fully opaque, black is fully transparent and 50% grey is 50% transparent.

Overlay

Multiplies or screens the colours, depending on the base colour. Patterns or colours overlay the existing pixels while preserving the highlights and shadows of the base colour. The base colour is not replaced, but mixed with the blend colour to reflect the lightness or darkness of the original colour.

Hard Light

Multiplies or screens the colours, depending on the blend colour. The effects is similar to shining a harsh spotlight on the image. If the blend colour (light source/top layer) is lighter than 50% grey, the image is lightened as if it were screened. This is useful for adding highlights to an image. If the blend colour is darker than 50% grey, the image is darkened as if it were multiplied. This is useful for adding shadows to an image. Painting with pure black or white results in pure black or white.

Soft Light

Darkens or lightens the colours, depending on the blend colour. The effect is similar to shining a diffused spotlight on the image. If the blend colour (light source/top layer) is lighter than 50% grey, the image is lightened as it if were dodged. If the blend colour is darker than 50% grey, the image is darkened as if it were burned in. Painting with pure black or white produces a distinctly darker or lighter area, but does not result in pure black or white.

Darken

Looks as the colour information in each channel and selects the base or blend colour - whichever is darker - as the result colour. Pixels lighter than the blend colour are replaced and pixels darker than the blend colour do not change.

Lighten

Looks at the colour information in each channel and selects the base or blend colour - whichever is lighter - as the result colour. Pixels darker than the blend colour are replaced and pixels lighter than the blend colour do not change.

Difference

Looks at the colour information in each channel and subtracts either the blend colour from the base colour or the base colour from the blend colour depending on which has the greater brightness value. Blending with white inverts the base colour values and blending with black produces no change.

Exclusion

Creates an effects similar to but lower in contrast than the difference mode. Blending with white inverts the base colour values. Blending with black produces no change.

Colour Dodge

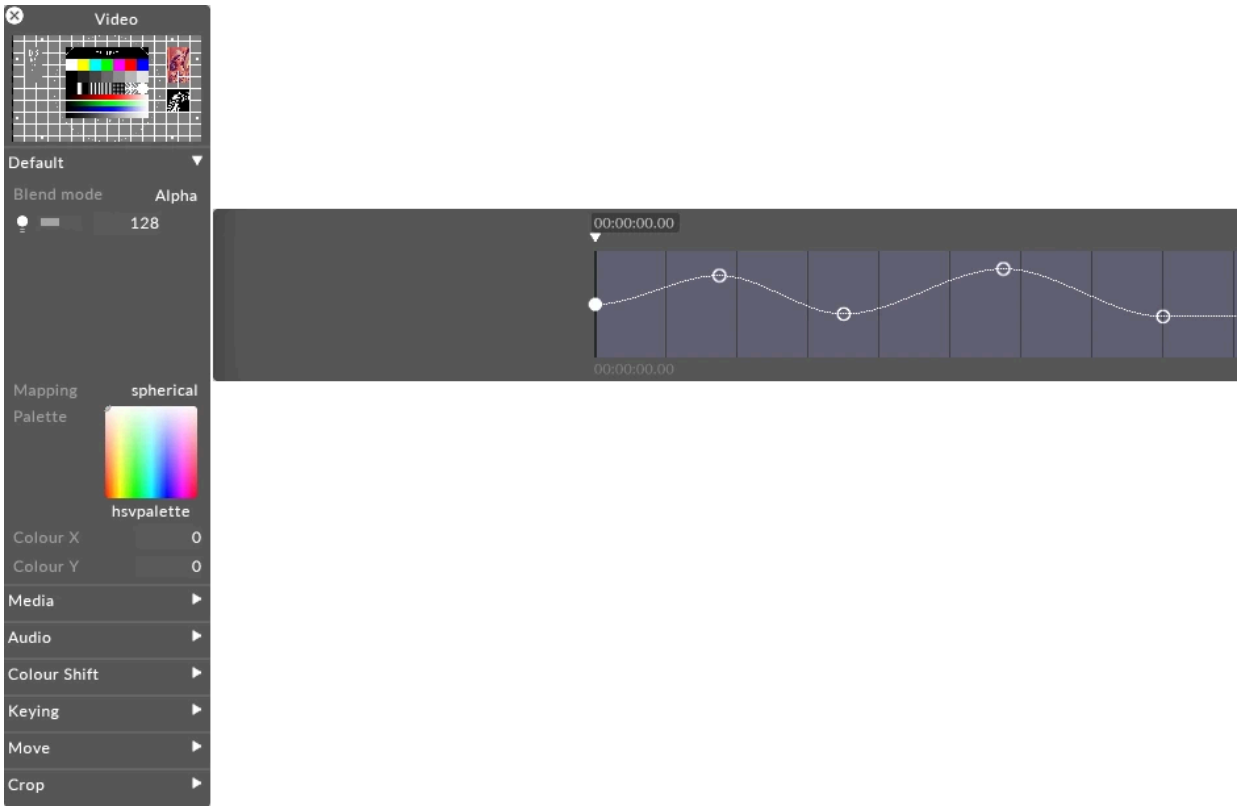
Looks at the colour information in each channel and brightens the base colour to reflect the blend colour by decreasing contrast between the two. Blending with black produces no change.

Hard Mix

Adds the RGB channels of the blend colour to the RGB values of the base colour. If the resulting sum for a channel is 255 or greater, it receives a value of 255; if it is less than 255 it receives a value of 0. Therefore all blended pixels have RGB channels of either 0 or 255. This changes all pixels to primary additive colours (RGB), white or black.

Brightness

This property (which appears as a light bulb icon) controls the brightness of the layer output.



If the layers blend mode is set to Alpha, then reducing the brightness to 0 also reduces the opacity of the layer to 0. This can be useful when you want to dissolve from one layer to the

next. In that case, you can place the new layer above the old layer and increase its brightness level.

> **Note**
>
> Layers that are patched to Sockpuppet (DMX, OSC or HTTP) are made Dormant when their brightness is set to 0. This means they will not do any rendering or consume any resources until their brightness is changed to > 0. You can find more information about this here: **Sequencing with Sockpuppet**. Layers without a sockpuppet patch do not behave in this way.

Mapping

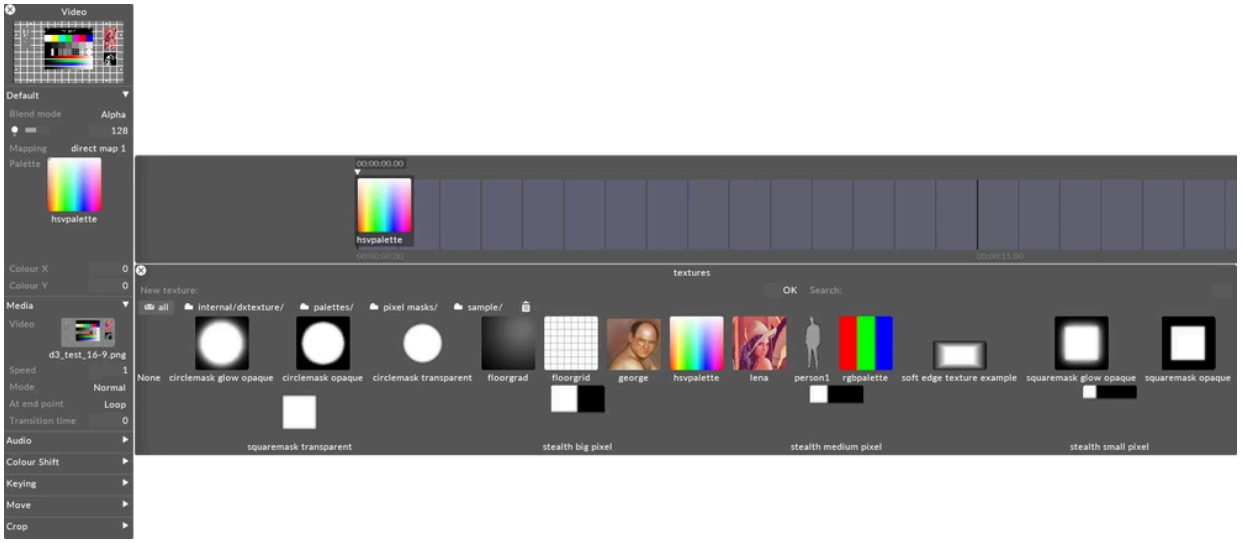
The mapping property controls how the layer output is mapped onto the screen(s) in the Stage level.

For information on mapping, including how to use the different mapping types offered by Designer, please see the chapter **Content Mapping**

Palette

This points to the still image file that defines the bitmap from which the tint colour is taken. The default palette (HSVPAL) consists of the complete range of hues and saturations. Selecting this property will open the Texture object library, which shows all of the still image files saved on your local hard-drive in the **DxTexture** older.

To control the location within the current palette bitmap, and thus control the colour, you have to edit the **xCol** and **yCol** values (see the section for xCol, yCol).



To change the current palette bitmap:

1. Left-click **palette** to open the Texture object library.
2. Left-click the still image file you want to use for the palette bitmap.

If you want to use a palette bitmap other than the standard still images provided in Designer, you will need to use a custom still image file.

See the **Placing media files** for a project sub-chapter to understand where to place a custom still image file and how to access it in Designer. Also save the file to a **supported file format**.

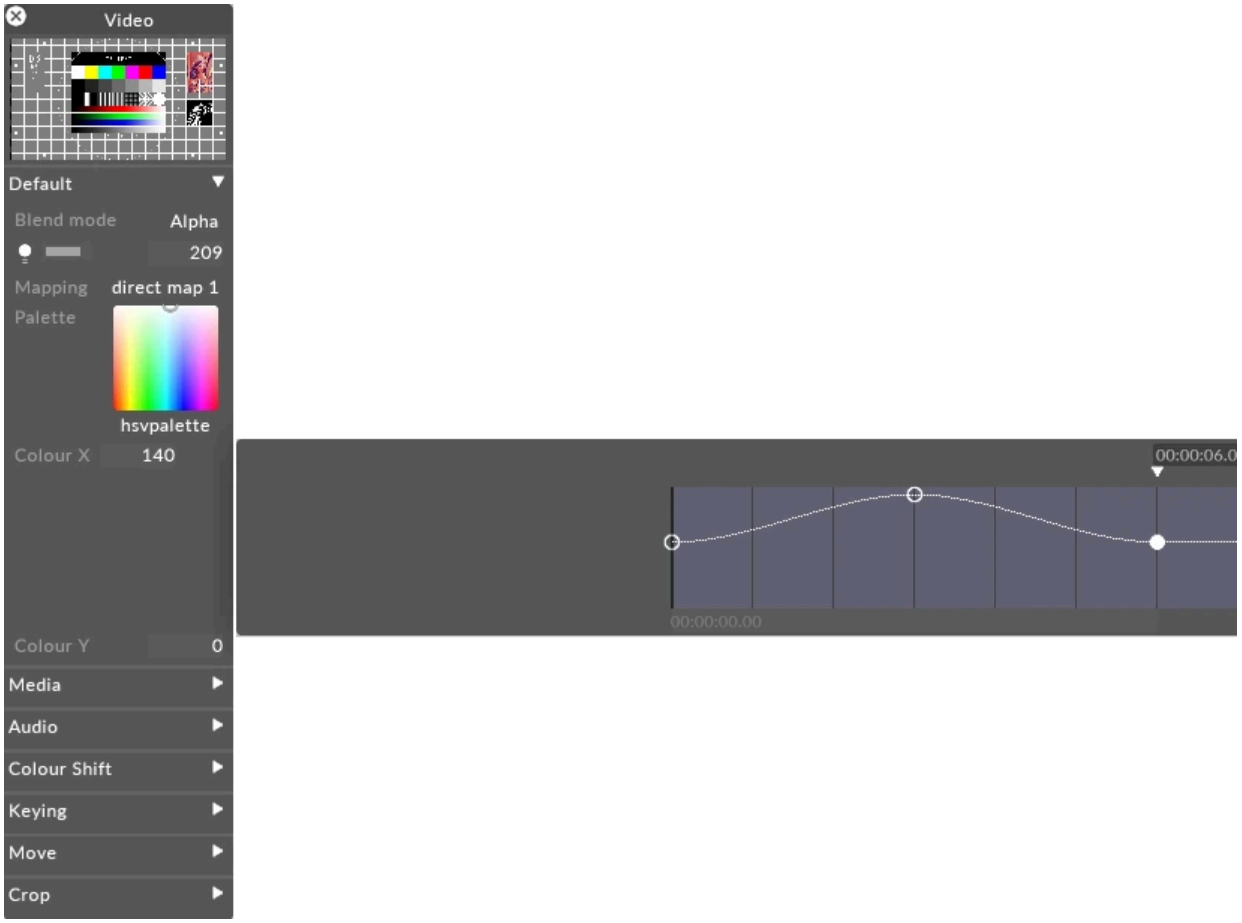
Xcol, YCol

These properties control the coordinates within the current palette bitmap where the output colour is sampled from. The default value is 0,0 which points at the color white (if you are using the HSVPAL palette). Multiplying white with the colors of the chosen content simply generates the original content colors. **Colour X** controls the horizontal position, where 0 is the leftmost edge and 255 is the rightmost edge. **Colour Y** controls the vertical position, where 0 is the top edge and 255 is the bottom edge.

For example, to saturate the video clip red, change the **Colour Y** value to 255 and use 0 for the **Colour X** value. These coordinates refer to the color red in the palette which is being multiplied

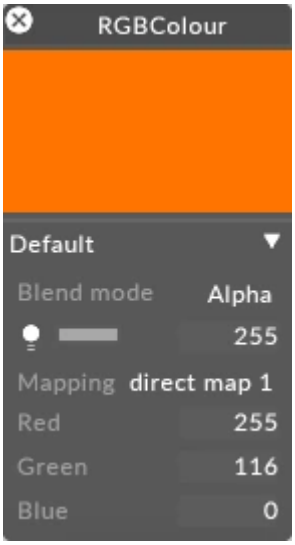
with the colors of the existing content.

When you are using the default palette HSVPAL , Colour Y controls saturation, and Colour X controls hue.



RGB Colour

The RGBColour layer is one of the most basic layers. It behaves in a very similar way to the Colour layer. Quite simply, it allows you to manually set RGBColour values to display a solid colour.



RGBColour Layer Properties

Red

Controls the Red additive colour mix.

RGreen

Controls the Green additive colour mix.

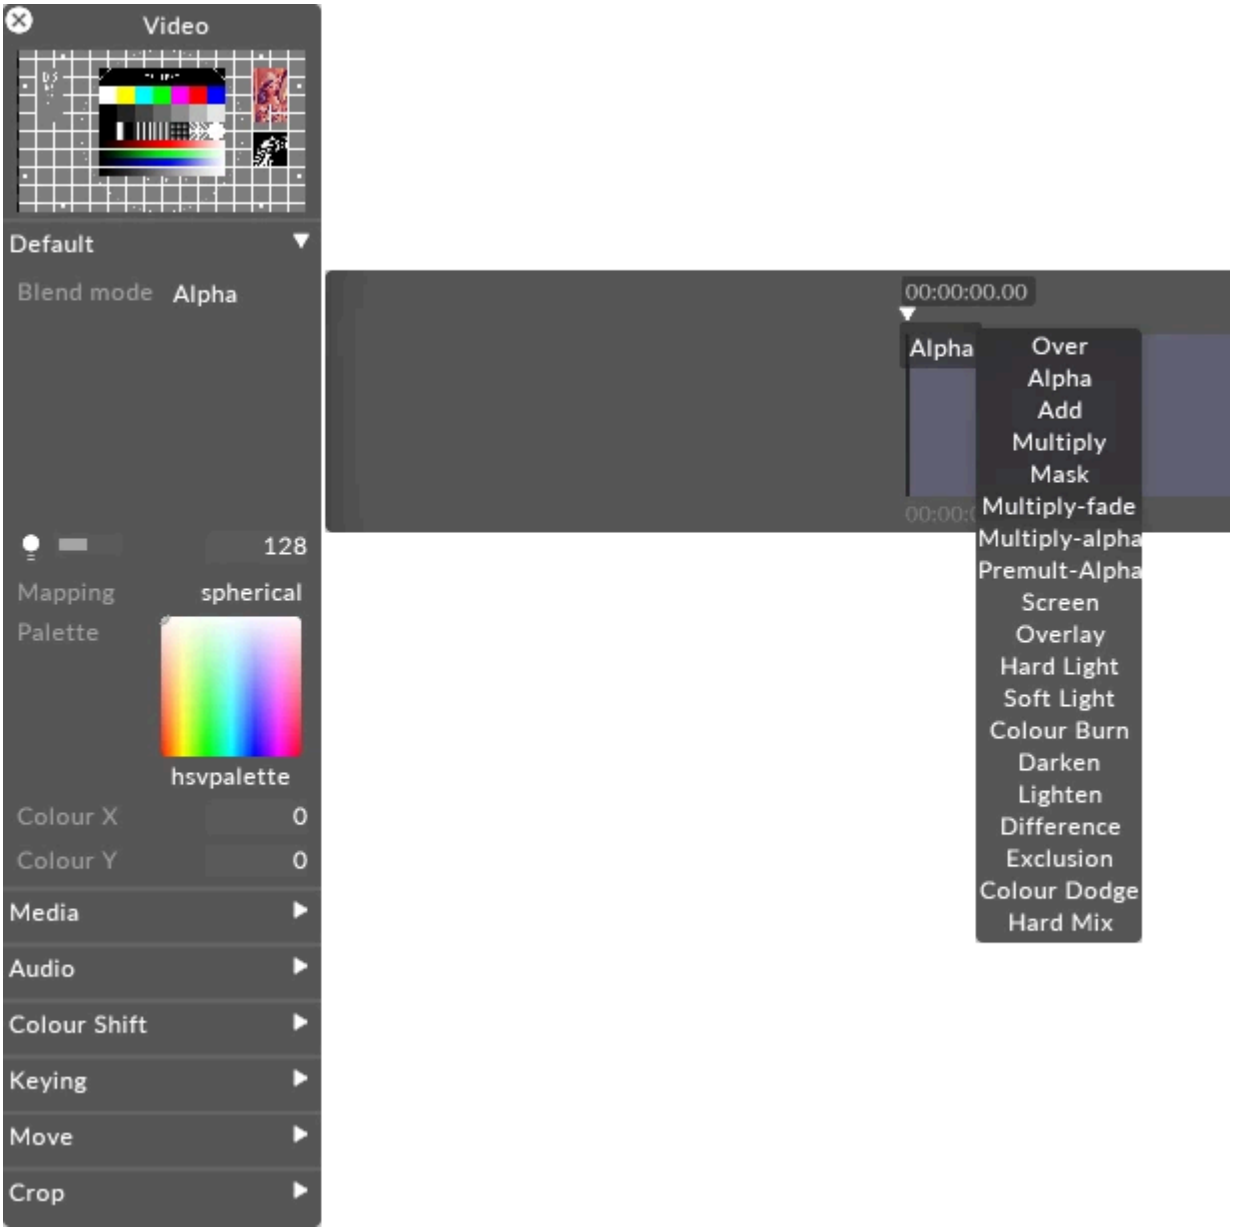
RBlue

Controls the Blue additive colour mix.

Common Layer Properties

Blend Mode

BlendMode controls how the output of the layer is composited with the layers below. Layers are rendered in a bottom-up order: layers at the top can modify the output of the layers below.



Changing brightness of a content layer in Designer is actually controlling the value of the alpha of the layer. Even when displaying a HAP video, the software will composite the layer with a controllable layer of alpha - one per layer.

There are two ways of expressing alpha in an image:

Straight alpha is an alpha channel which functions just like RGB. Alpha acts as a fourth channel of information per pixel which is as independent of the other three as R, G and B are of each other. For example, with straight alpha it is possible to have RGB = 255 (white) and alpha = 0 (fully transparent) on the same pixel. Internally generated content, such as gradient layer, are generated with straight alpha. This is the preferable style of alpha and considering the cleaner method of the two.

Premultiplied alpha takes the alpha and applies it to the values of the RGB channels per pixel. The more transparent something gets with premultiplied alpha, the closer it gets to black - as if the content is sitting on a black table. Premultiplied is the default output of Adobe Photoshop or AfterEffects. The result is our pixel at 255 RGB (full white) with 0 alpha would be calculated as a black pixel in the final image.

Here are explanations of what each individual blend mode will do.

Over

Makes a layer fully opaque. Premultiplies all alpha onto the RGB value of each pixel. Alpha = black, so adjusting the brightness of a layer in Over blend mode makes it darker.

Alpha

Default blend mode. It will apply alpha values as a transparency if the alpha is present. Brightness changes will make the layer more or less transparent.

Add

Adds the value of each RGB pixel together. Always creates a brighter result. Values clamp at 255.

Multiply

Reads the level of each subpixel as a level between 0.0 and 1.0, and multiplies source with blend. The result is always a darker image overall. For example: white x grey = 0.5. White turns transparent, black takes precedence. Alpha is applied in the same fashion as the Over Blend mode.

Mask

Applies a mask to the single layer **above** in the stack, irrespective of mapping. See **Mask blending** for more information.

Luma-Matte

This mode creates a Luma Matte by using a layer's **Rec. 709 luminance** to control the alpha channel of the layer **above**, irrespective of mapping.

To determine transparency, the luminance of each pixel is calculated using a weighted average of its red, green, and blue channels. The luminance value is then used as the alpha (opacity) value for the corresponding pixels in the upper layers.

As a result, white areas render the layer above fully opaque, black areas make them fully transparent, and grey areas create proportional semi-transparency. This is a specialized **Mask** blend mode; for more details on the underlying behaviour, see **Mask blending**.

Inv-Luma-Matte

The Inverse Luma Matte mask works the same as the Luma Matte mask but the transparency is inverted meaning white regions are transparent and black regions are opaque.

Multiply-Fade

The same as Multiply, but will make use of the alpha channel to calculate transparency in the source and blend layers. Since maximum transparency is premultiplied, alpha results in black. This will ignore black created through premultiplying.

Multiply-Alpha

Multiply with straight alpha. This mode assumes that the alpha has not been premultiplied onto the RGB values and will not apply a correction to the semi-transparent pixels.

Premultiply Alpha

Like how Multiply-fade will ignore the darkening caused by premultiplying, this blend mode will do the same with Alpha.

Colour Burn

Blend mode increases the contrast to darken the base colour while reflecting the blend colour. The darker the blend colour, the more intensely the colour will be applied in the base image. White as the blend colour produces no change. Using the colour burn blend mode can produce some harsh results at full opacity. The colour burn blend mode can be used to make tonal and colour adjustments to a layer.

Screen

This blend mode looks at each channels colour information and multiplies the inverse of the blend and base colous. The result is always a lighter colour. Screening with black leaves the colour unchanged. Screening with white produces white. The effect is similar to projecting multiple images on top of each other - where bright white is fully opaque, black is fully transparent and 50% grey is 50% transparent.

Overlay

Multiplies or screens the colours, depending on the base colour. Patterns or colours overlay the existing pixels while preserving the highlights and shadows of the base colour. The base colour is not replaced, but mixed with the blend colour to reflect the lightness or darkness of the original colour.

Hard Light

Multiplies or screens the colours, depending on the blend colour. The effects is similar to shining a harsh spotlight on the image. If the blend colour (light source/top layer) is lighter than

50% grey, the image is lightened as if it were screened. This is useful for adding highlights to an image. If the blend colour is darker than 50% grey, the image is darkened as if it were multiplied. This is useful for adding shadows to an image. Painting with pure black or white results in pure black or white.

Soft Light

Darkens or lightens the colours, depending on the blend colour. The effect is similar to shining a diffused spotlight on the image. If the blend colour (light source/top layer) is lighter than 50% grey, the image is lightened as it if were dodged. If the blend colour is darker than 50% grey, the image is darkened as if it were burned in. Painting with pure black or white produces a distinctly darker or lighter area, but does not result in pure black or white.

Darken

Looks as the colour information in each channel and selects the base or blend colour - whichever is darker - as the result colour. Pixels lighter than the blend colour are replaced and pixels darker than the blend colour do not change.

Lighten

Looks at the colour information in each channel and selects the base or blend colour - whichever is lighter - as the result colour. Pixels darker than the blend colour are replaced and pixels lighter than the blend colour do not change.

Difference

Looks at the colour information in each channel and subtracts either the blend colour from the base colour or the base colour from the blend colour depending on which has the greater brightness value. Blending with white inverts the base colour values and blending with black produces no change.

Exclusion

Creates an effects similar to but lower in contrast than the difference mode. Blending with white inverts the base colour values. Blending with black produces no change.

Colour Dodge

Looks at the colour information in each channel and brightens the base colour to reflect the blend colour by decreasing contrast between the two. Blending with black produces no change.

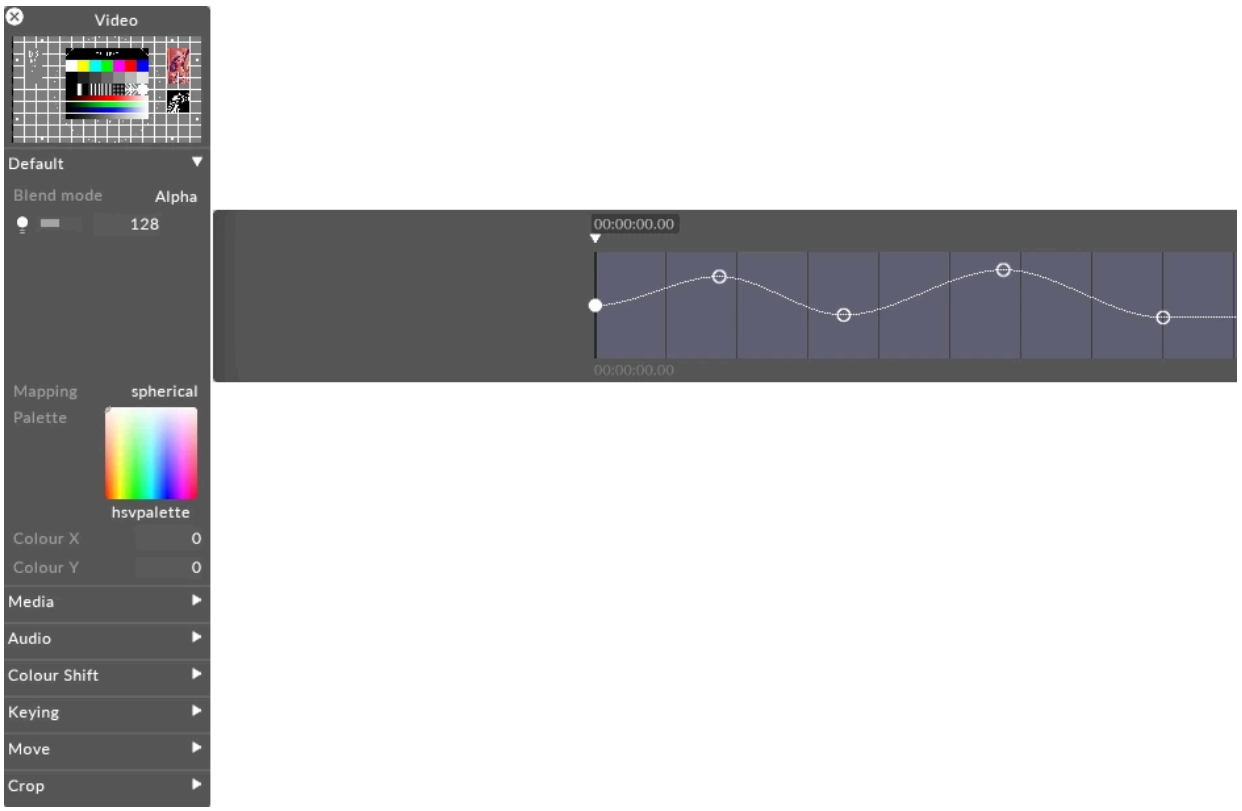
Hard Mix

Adds the RGB channels of the blend colour to the RGB values of the base colour. If the resulting sum for a channel is 255 or greater, it receives a value of 255; if it is less than 255 it

receives a value of 0. Therefore all blended pixels have RGB channels of either 0 or 255. This changes all pixels to primary additive colours (RGB), white or black.

Brightness

This property (which appears as a light bulb icon) controls the brightness of the layer output.



If the layers blend mode is set to Alpha, then reducing the brightness to 0 also reduces the opacity of the layer to 0. This can be useful when you want to dissolve from one layer to the next. In that case, you can place the new layer above the old layer and increase its brightness level.

> **Note**
>
> Layers that are patched to Sockpuppet (DMX, OSC or HTTP) are made Dormant when their brightness is set to 0. This means they will not do any rendering or consume any resources until their brightness is changed to > 0. You can find more information about this here: **Sequencing with Sockpuppet**. Layers without a sockpuppet patch do not behave in this way.

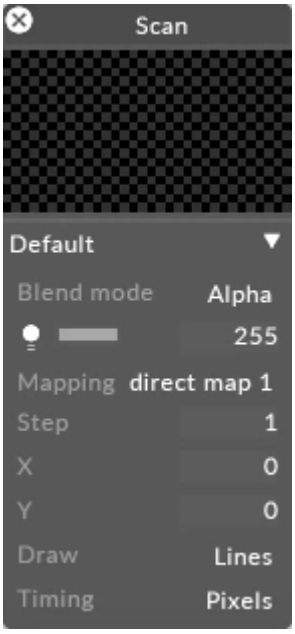
Mapping

The mapping property controls how the layer output is mapped onto the screen(s) in the Stage level.

For information on mapping, including how to use the different mapping types offered by Designer, please see the chapter **Content Mapping**

Scan Layer

The Scan layer is a simple test pattern generator that is useful for checking output signal timings. It generates a single-pixel wide horizontal red line and a single-pixel wide vertical blue line. Each line moves forward by a single pixel per frame.



It sometimes happens that downstream DVI processing devices such as switchers, scalers or LED processors skew the timing of the DVI signal, causing the appearance of jerky playback. At such times it is useful to be able to generate a visual signal that is visibly smooth on the computer, but clearly shows signal skews on the output devices.

The Scan layer is also useful for checking if the 3D screen models have been correctly imported into Designer. If the model has incorrect texture coordinates, you will see a single row or column either disappearing or spanning two separate sub-objects.

Scan Layer Properties

Step

This controls the movement speed of the lines. The number you fill is is the number of frames the lines moves forward per pixel. Increasing this number slows the line down. Setting **step** to 0 allows you to control the position of the lines manually using the **x** and **y** properties.

x, y

When **step** is set to 0, you can directly control the position of the lines by adjusting **x** and **y** . The position of the vertical blue line is controlled by **x** , while the position of the horizontal red line is controlled by **y** . Both are measured in pixels.

Draw

There are two options:

Lines : this shows red and blue lines which intersect to form a crosshair (useful for LED screens).

Dot : this shows a single white dot at position x, y. This option is more useful when calibrating singlepixel strings (useful for linear fixtures).

Timing

There are two options:

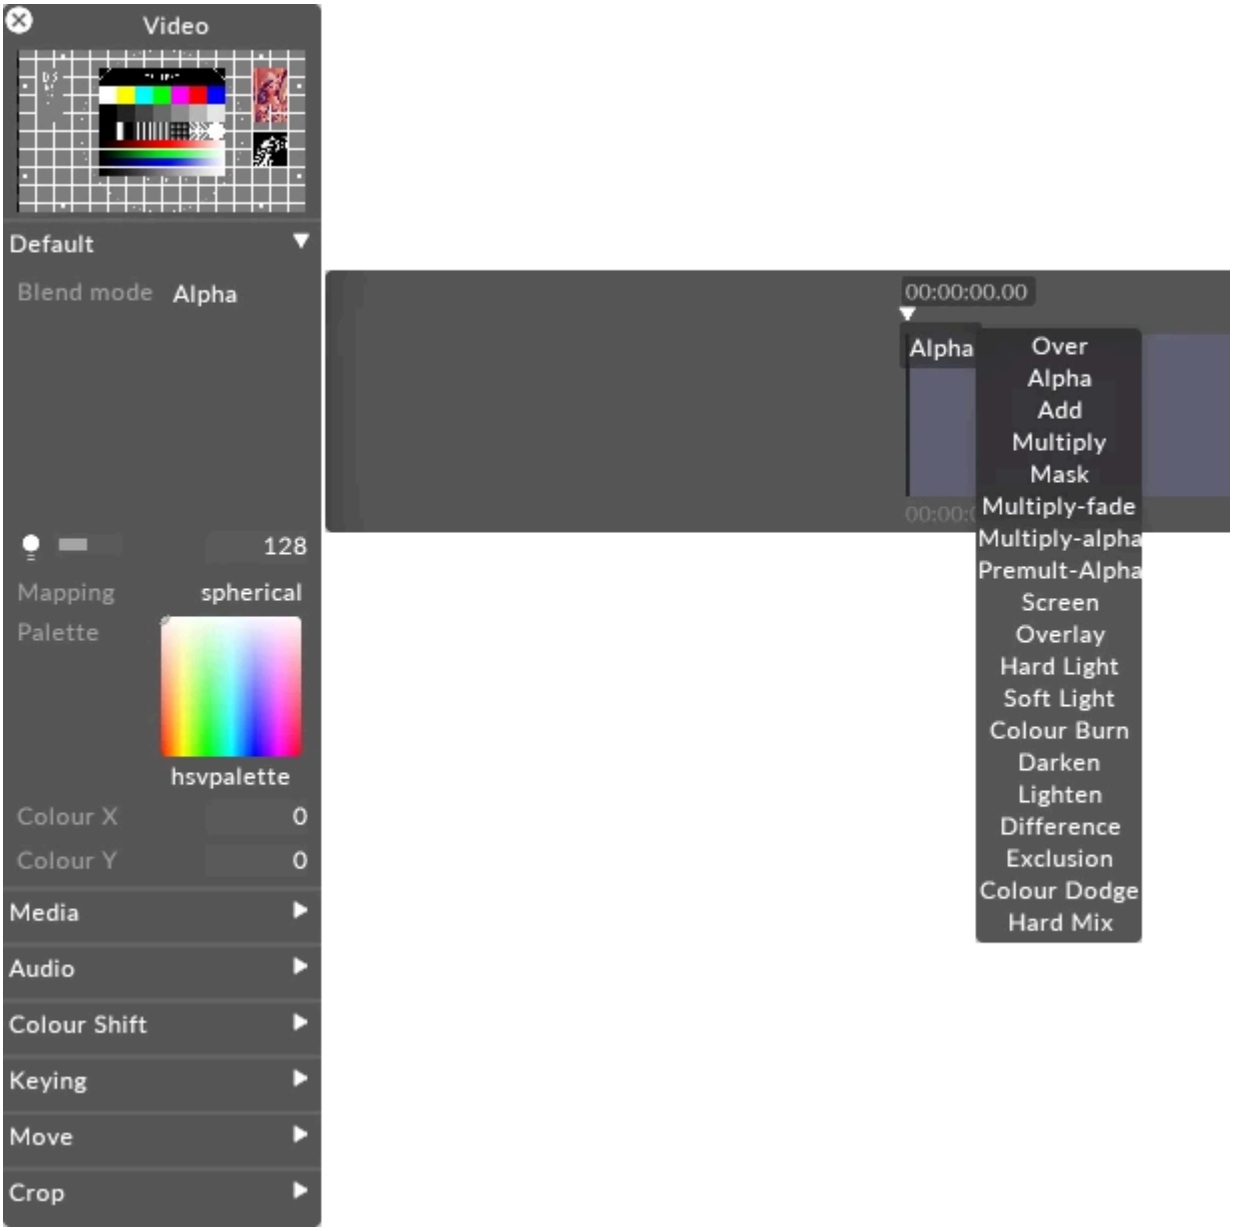
Pixels : if set to this, the crosshair moves one pixel every (step) frames.

Time : if set to this, the crosshair moves at (1/step) pixels per second.

Common Layer Properties

Blend Mode

BlendMode controls how the output of the layer is composited with the layers below. Layers are rendered in a bottom-up order: layers at the top can modify the output of the layers below.



Changing brightness of a content layer in Designer is actually controlling the value of the alpha of the layer. Even when displaying a HAP video, the software will composite the layer with a controllable layer of alpha - one per layer.

There are two ways of expressing alpha in an image:

Straight alpha is an alpha channel which functions just like RGB. Alpha acts as a fourth channel of information per pixel which is as independent of the other three as R, G and B are of each other. For example, with straight alpha it is possible to have RGB = 255 (white) and alpha = 0 (fully transparent) on the same pixel. Internally generated content, such as gradient layer, are generated with straight alpha. This is the preferable style of alpha and considering the cleaner method of the two.

Premultiplied alpha takes the alpha and applies it to the values of the RGB channels per pixel. The more transparent something gets with premultiplied alpha, the closer it gets to black - as if the content is sitting on a black table. Premultiplied is the default output of Adobe Photoshop or AfterEffects. The result is our pixel at 255 RGB (full white) with 0 alpha would be calculated as a black pixel in the final image.

Here are explanations of what each individual blend mode will do.

Over

Makes a layer fully opaque. Premultiplies all alpha onto the RGB value of each pixel. Alpha = black, so adjusting the brightness of a layer in Over blend mode makes it darker.

Alpha

Default blend mode. It will apply alpha values as a transparency if the alpha is present. Brightness changes will make the layer more or less transparent.

Add

Adds the value of each RGB pixel together. Always creates a brighter result. Values clamp at 255.

Multiply

Reads the level of each subpixel as a level between 0.0 and 1.0, and multiplies source with blend. The result is always a darker image overall. For example: white x grey = 0.5. White turns transparent, black takes precedence. Alpha is applied in the same fashion as the Over Blend mode.

Mask

Applies a mask to the single layer **above** in the stack, irrespective of mapping. See **Mask blending** for more information.

Luma-Matte

This mode creates a Luma Matte by using a layer's **Rec. 709 luminance** to control the alpha channel of the layer **above**, irrespective of mapping.

To determine transparency, the luminance of each pixel is calculated using a weighted average of its red, green, and blue channels. The luminance value is then used as the alpha (opacity) value for the corresponding pixels in the upper layers.

As a result, white areas render the layer above fully opaque, black areas make them fully transparent, and grey areas create proportional semi-transparency. This is a specialized **Mask** blend mode; for more details on the underlying behaviour, see **Mask blending**.

Inv-Luma-Matte

The Inverse Luma Matte mask works the same as the Luma Matte mask but the transparency is inverted meaning white regions are transparent and black regions are opaque.

Multiply-Fade

The same as Multiply, but will make use of the alpha channel to calculate transparency in the source and blend layers. Since maximum transparency is premultiplied, alpha results in black. This will ignore black created through premultiplying.

Multiply-Alpha

Multiply with straight alpha. This mode assumes that the alpha has not been premultiplied onto the RGB values and will not apply a correction to the semi-transparent pixels.

Premultiply Alpha

Like how Multiply-fade will ignore the darkening caused by premultiplying, this blend mode will do the same with Alpha.

Colour Burn

Blend mode increases the contrast to darken the base colour while reflecting the blend colour. The darker the blend colour, the more intensely the colour will be applied in the base image. White as the blend colour produces no change. Using the colour burn blend mode can produce some harsh results at full opacity. The colour burn blend mode can be used to make tonal and colour adjustments to a layer.

Screen

This blend mode looks at each channels colour information and multiplies the inverse of the blend and base colous. The result is always a lighter colour. Screening with black leaves the colour unchanged. Screening with white produces white. The effect is similar to projecting multiple images on top of each other - where bright white is fully opaque, black is fully transparent and 50% grey is 50% transparent.

Overlay

Multiplies or screens the colours, depending on the base colour. Patterns or colours overlay the existing pixels while preserving the highlights and shadows of the base colour. The base colour is not replaced, but mixed with the blend colour to reflect the lightness or darkness of the original colour.

Hard Light

Multiplies or screens the colours, depending on the blend colour. The effects is similar to shining a harsh spotlight on the image. If the blend colour (light source/top layer) is lighter than

50% grey, the image is lightened as if it were screened. This is useful for adding highlights to an image. If the blend colour is darker than 50% grey, the image is darkened as if it were multiplied. This is useful for adding shadows to an image. Painting with pure black or white results in pure black or white.

Soft Light

Darkens or lightens the colours, depending on the blend colour. The effect is similar to shining a diffused spotlight on the image. If the blend colour (light source/top layer) is lighter than 50% grey, the image is lightened as it if were dodged. If the blend colour is darker than 50% grey, the image is darkened as if it were burned in. Painting with pure black or white produces a distinctly darker or lighter area, but does not result in pure black or white.

Darken

Looks as the colour information in each channel and selects the base or blend colour - whichever is darker - as the result colour. Pixels lighter than the blend colour are replaced and pixels darker than the blend colour do not change.

Lighten

Looks at the colour information in each channel and selects the base or blend colour - whichever is lighter - as the result colour. Pixels darker than the blend colour are replaced and pixels lighter than the blend colour do not change.

Difference

Looks at the colour information in each channel and subtracts either the blend colour from the base colour or the base colour from the blend colour depending on which has the greater brightness value. Blending with white inverts the base colour values and blending with black produces no change.

Exclusion

Creates an effects similar to but lower in contrast than the difference mode. Blending with white inverts the base colour values. Blending with black produces no change.

Colour Dodge

Looks at the colour information in each channel and brightens the base colour to reflect the blend colour by decreasing contrast between the two. Blending with black produces no change.

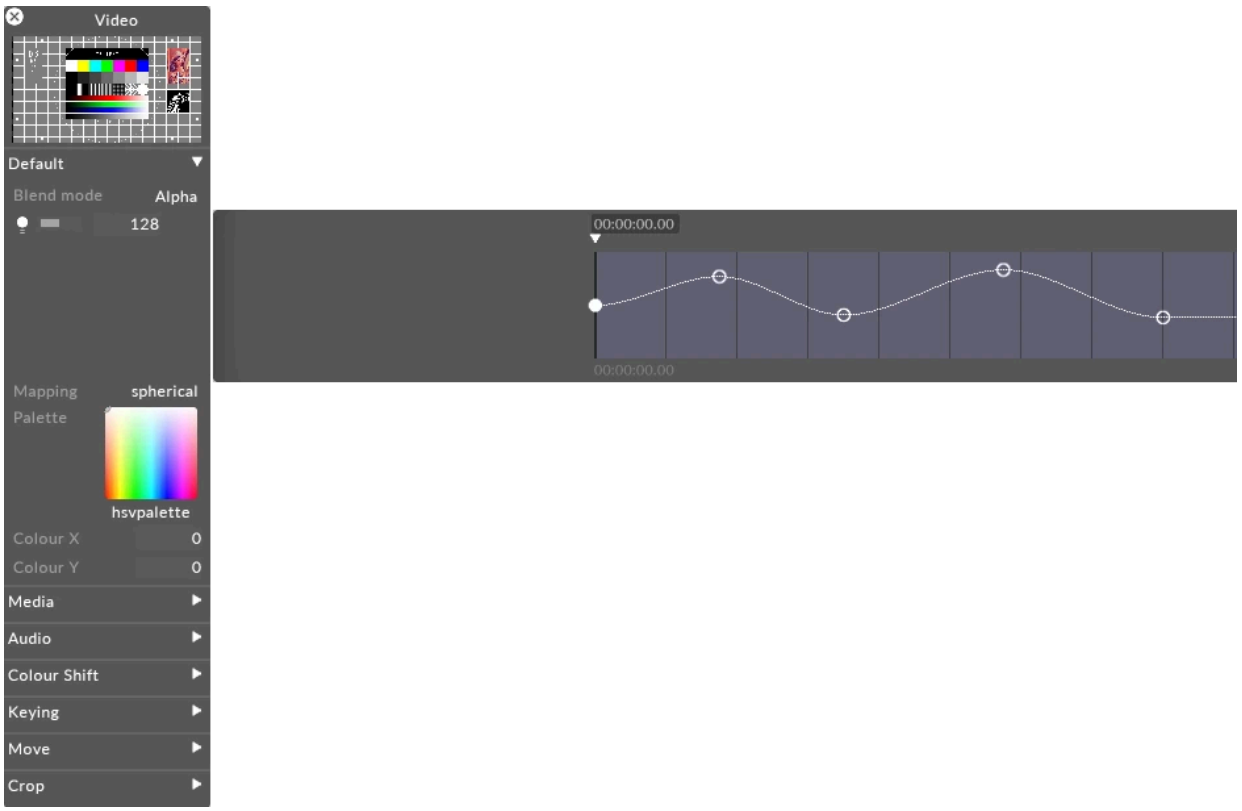
Hard Mix

Adds the RGB channels of the blend colour to the RGB values of the base colour. If the resulting sum for a channel is 255 or greater, it receives a value of 255; if it is less than 255 it

receives a value of 0. Therefore all blended pixels have RGB channels of either 0 or 255. This changes all pixels to primary additive colours (RGB), white or black.

Brightness

This property (which appears as a light bulb icon) controls the brightness of the layer output.



If the layers blend mode is set to Alpha, then reducing the brightness to 0 also reduces the opacity of the layer to 0. This can be useful when you want to dissolve from one layer to the next. In that case, you can place the new layer above the old layer and increase its brightness level.

> **Note**
>
> Layers that are patched to Sockpuppet (DMX, OSC or HTTP) are made Dormant when their brightness is set to 0. This means they will not do any rendering or consume any resources until their brightness is changed to > 0. You can find more information about this here: **Sequencing with Sockpuppet**. Layers without a sockpuppet patch do not behave in this way.

Mapping

The mapping property controls how the layer output is mapped onto the screen(s) in the Stage level.

For information on mapping, including how to use the different mapping types offered by Designer, please see the chapter **Content Mapping**

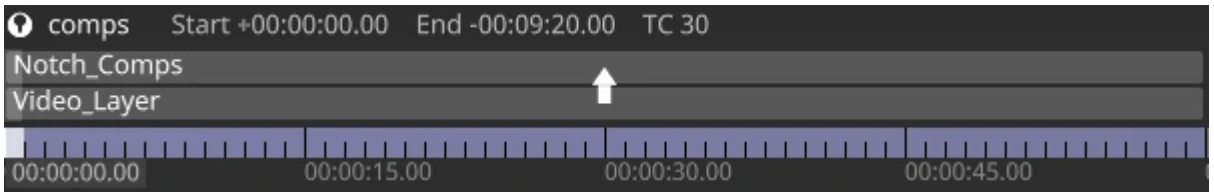
Strobe Layer

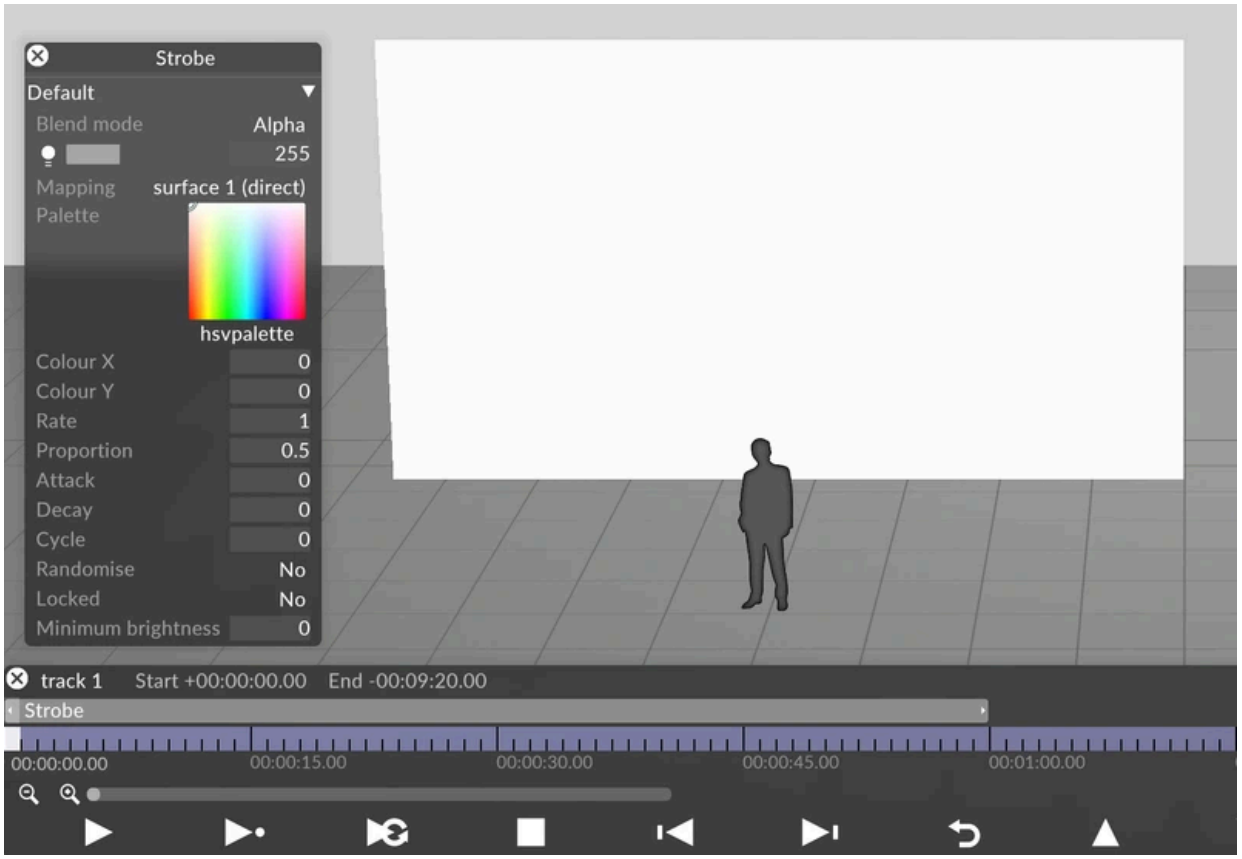
The Strobe layer creates a flashing strobe effect over multiple screens.

> **Warning**
>
> The layer only works using a Feed map. In order to turn each screen into “one flash”, scale each feed rectangle to 1 pixel and place each screen’s feed rectangles next to each other on the Mapping canvas.

Some Generative layers take their source from other layer types - either content or generative - by use of an arrow. Linking two layers with an arrow defines the arrowed from layer as the source, and the arrowed to layer as the destination. If you have an arrow between a content layer and effect layer, it is said that the content layer is being ‘piped in’ to the effect layer. For more information on arrows, see the compositing layers topic.

To draw an arrow between two layers, hold down **ALT** and left-click & drag between the source and destination layer.





Strobe Layer Properties

Rate

Speed of strobing, in cycles per beat. 0 = stop flashing.

Proportion

The amount of time within the cycle that the strobe is on. 0.5 = half the cycle time is white.

Attack

Speed of attack (ramping from 0 to full brightness). 1 = instant, 0 = slowest.

Decay

Speed of decay (raming from full brightness down to 0). 1 = instant, 0 = slowest.

Cycle

The cycle of the strobe. 0 = all screens flash together, 1 = screens flash in turn.

Randomise

The randomness of the cycle order. Yes = order of the screens is randomised, No = order of the screens is not randomised.

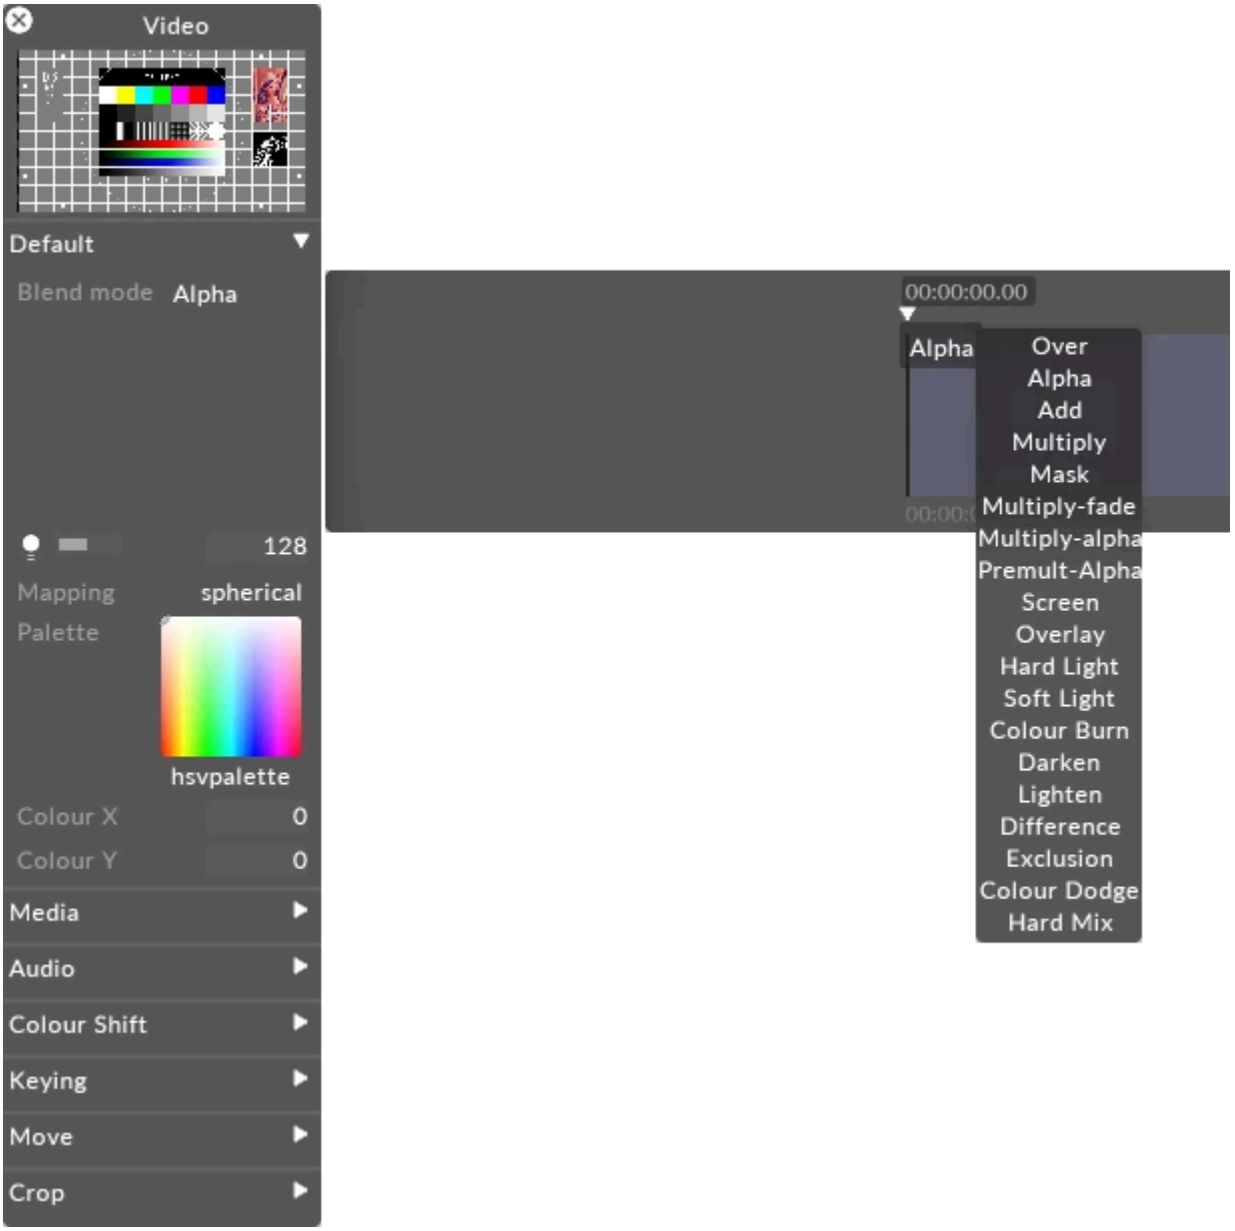
Min brightness

The minimum brightness outputted by the layer. 0 = 0%, 1 = 100%.

Common Layer Properties

Blend Mode

BlendMode controls how the output of the layer is composited with the layers below. Layers are rendered in a bottom-up order: layers at the top can modify the output of the layers below.



Changing brightness of a content layer in Designer is actually controlling the value of the alpha of the layer. Even when displaying a HAP video, the software will composite the layer with a controllable layer of alpha - one per layer.

There are two ways of expressing alpha in an image:

Straight alpha is an alpha channel which functions just like RGB. Alpha acts as a fourth channel of information per pixel which is as independent of the other three as R, G and B are of each other. For example, with straight alpha it is possible to have RGB = 255 (white) and alpha = 0 (fully transparent) on the same pixel. Internally generated content, such as gradient layer, are generated with straight alpha. This is the preferable style of alpha and considering the cleaner method of the two.

Premultiplied alpha takes the alpha and applies it to the values of the RGB channels per pixel. The more transparent something gets with premultiplied alpha, the closer it gets to black - as if the content is sitting on a black table. Premultiplied is the default output of Adobe Photoshop or AfterEffects. The result is our pixel at 255 RGB (full white) with 0 alpha would be calculated as a black pixel in the final image.

Here are explanations of what each individual blend mode will do.

Over

Makes a layer fully opaque. Premultiplies all alpha onto the RGB value of each pixel. Alpha = black, so adjusting the brightness of a layer in Over blend mode makes it darker.

Alpha

Default blend mode. It will apply alpha values as a transparency if the alpha is present. Brightness changes will make the layer more or less transparent.

Add

Adds the value of each RGB pixel together. Always creates a brighter result. Values clamp at 255.

Multiply

Reads the level of each subpixel as a level between 0.0 and 1.0, and multiplies source with blend. The result is always a darker image overall. For example: white x grey = 0.5. White turns transparent, black takes precedence. Alpha is applied in the same fashion as the Over Blend mode.

Mask

Applies a mask to the single layer **above** in the stack, irrespective of mapping. See **Mask blending** for more information.

Luma-Matte

This mode creates a Luma Matte by using a layer's **Rec. 709 luminance** to control the alpha channel of the layer **above**, irrespective of mapping.

To determine transparency, the luminance of each pixel is calculated using a weighted average of its red, green, and blue channels. The luminance value is then used as the alpha (opacity) value for the corresponding pixels in the upper layers.

As a result, white areas render the layer above fully opaque, black areas make them fully transparent, and grey areas create proportional semi-transparency. This is a specialized **Mask** blend mode; for more details on the underlying behaviour, see **Mask blending**.

Inv-Luma-Matte

The Inverse Luma Matte mask works the same as the Luma Matte mask but the transparency is inverted meaning white regions are transparent and black regions are opaque.

Multiply-Fade

The same as Multiply, but will make use of the alpha channel to calculate transparency in the source and blend layers. Since maximum transparency is premultiplied, alpha results in black. This will ignore black created through premultiplying.

Multiply-Alpha

Multiply with straight alpha. This mode assumes that the alpha has not been premultiplied onto the RGB values and will not apply a correction to the semi-transparent pixels.

Premultiply Alpha

Like how Multiply-fade will ignore the darkening caused by premultiplying, this blend mode will do the same with Alpha.

Colour Burn

Blend mode increases the contrast to darken the base colour while reflecting the blend colour. The darker the blend colour, the more intensely the colour will be applied in the base image. White as the blend colour produces no change. Using the colour burn blend mode can produce some harsh results at full opacity. The colour burn blend mode can be used to make tonal and colour adjustments to a layer.

Screen

This blend mode looks at each channels colour information and multiplies the inverse of the blend and base colous. The result is always a lighter colour. Screening with black leaves the colour unchanged. Screening with white produces white. The effect is similar to projecting multiple images on top of each other - where bright white is fully opaque, black is fully transparent and 50% grey is 50% transparent.

Overlay

Multiplies or screens the colours, depending on the base colour. Patterns or colours overlay the existing pixels while preserving the highlights and shadows of the base colour. The base colour is not replaced, but mixed with the blend colour to reflect the lightness or darkness of the original colour.

Hard Light

Multiplies or screens the colours, depending on the blend colour. The effects is similar to shining a harsh spotlight on the image. If the blend colour (light source/top layer) is lighter than

50% grey, the image is lightened as if it were screened. This is useful for adding highlights to an image. If the blend colour is darker than 50% grey, the image is darkened as if it were multiplied. This is useful for adding shadows to an image. Painting with pure black or white results in pure black or white.

Soft Light

Darkens or lightens the colours, depending on the blend colour. The effect is similar to shining a diffused spotlight on the image. If the blend colour (light source/top layer) is lighter than 50% grey, the image is lightened as it if were dodged. If the blend colour is darker than 50% grey, the image is darkened as if it were burned in. Painting with pure black or white produces a distinctly darker or lighter area, but does not result in pure black or white.

Darken

Looks as the colour information in each channel and selects the base or blend colour - whichever is darker - as the result colour. Pixels lighter than the blend colour are replaced and pixels darker than the blend colour do not change.

Lighten

Looks at the colour information in each channel and selects the base or blend colour - whichever is lighter - as the result colour. Pixels darker than the blend colour are replaced and pixels lighter than the blend colour do not change.

Difference

Looks at the colour information in each channel and subtracts either the blend colour from the base colour or the base colour from the blend colour depending on which has the greater brightness value. Blending with white inverts the base colour values and blending with black produces no change.

Exclusion

Creates an effects similar to but lower in contrast than the difference mode. Blending with white inverts the base colour values. Blending with black produces no change.

Colour Dodge

Looks at the colour information in each channel and brightens the base colour to reflect the blend colour by decreasing contrast between the two. Blending with black produces no change.

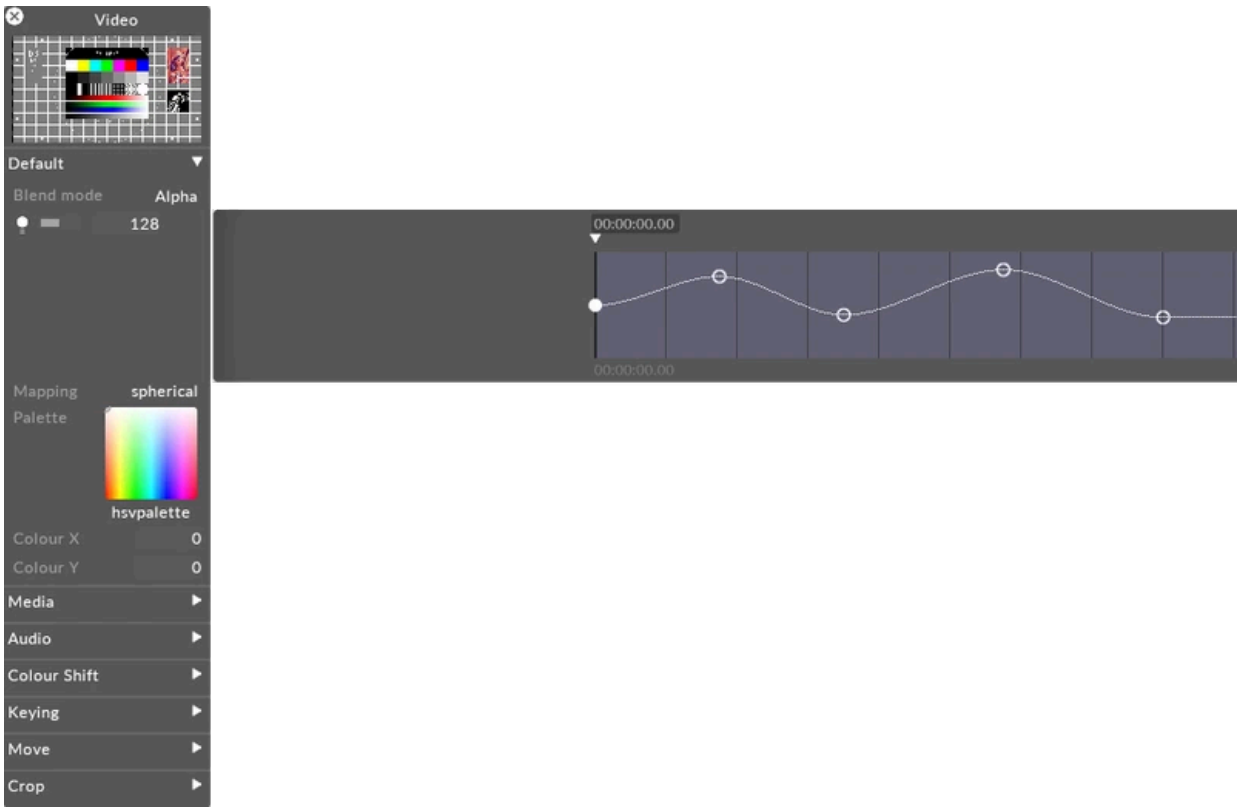
Hard Mix

Adds the RGB channels of the blend colour to the RGB values of the base colour. If the resulting sum for a channel is 255 or greater, it receives a value of 255; if it is less than 255 it

receives a value of 0. Therefore all blended pixels have RGB channels of either 0 or 255. This changes all pixels to primary additive colours (RGB), white or black.

Brightness

This property (which appears as a light bulb icon) controls the brightness of the layer output.



If the layers blend mode is set to Alpha, then reducing the brightness to 0 also reduces the opacity of the layer to 0. This can be useful when you want to dissolve from one layer to the next. In that case, you can place the new layer above the old layer and increase its brightness level.

> **Note**
>
> Layers that are patched to Sockpuppet (DMX, OSC or HTTP) are made Dormant when their brightness is set to 0. This means they will not do any rendering or consume any resources until their brightness is changed to > 0. You can find more information about this here: **Sequencing with Sockpuppet**. Layers without a sockpuppet patch do not behave in this way.

Mapping

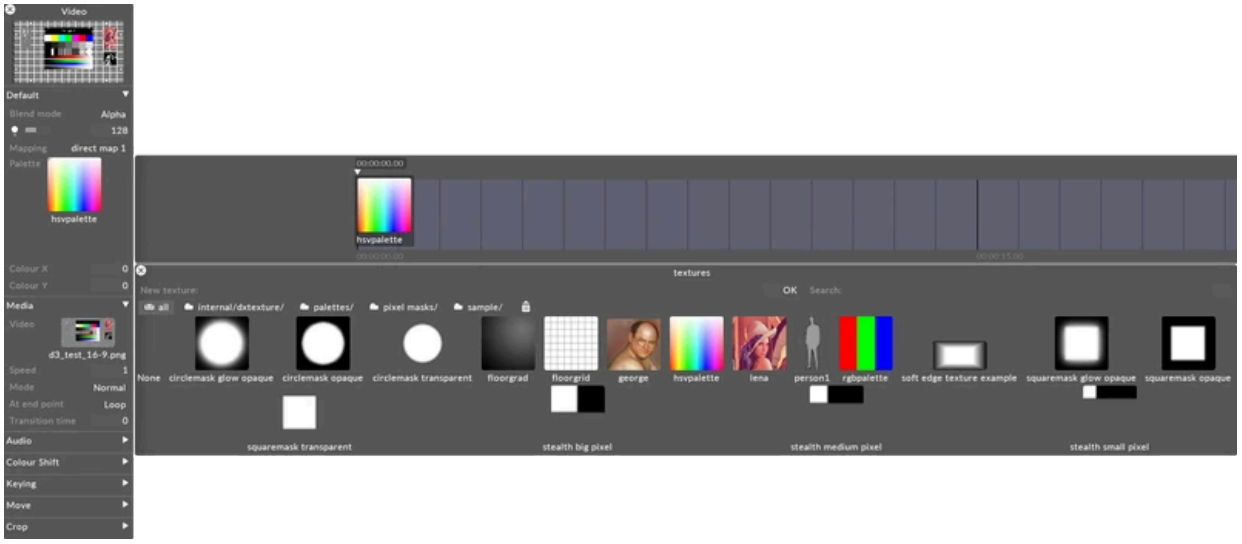
The mapping property controls how the layer output is mapped onto the screen(s) in the Stage level.

For information on mapping, including how to use the different mapping types offered by Designer, please see the chapter **Content Mapping**

Palette

This points to the still image file that defines the bitmap from which the tint colour is taken. The default palette (HSVPAL) consists of the complete range of hues and saturations. Selecting this property will open the Texture object library, which shows all of the still image files saved on your local hard-drive in the **DxTexture** older.

To control the location within the current palette bitmap, and thus control the colour, you have to edit the **xCol** and **yCol** values (see the section for xCol, yCol).



To change the current palette bitmap:

1. Left-click **palette** to open the Texture object library.
2. Left-click the still image file you want to use for the palette bitmap.

If you want to use a palette bitmap other than the standard still images provided in Designer, you will need to use a custom still image file.

See the **Placing media files** for a project sub-chapter to understand where to place a custom still image file and how to access it in Designer. Also save the file to a **supported file format**.

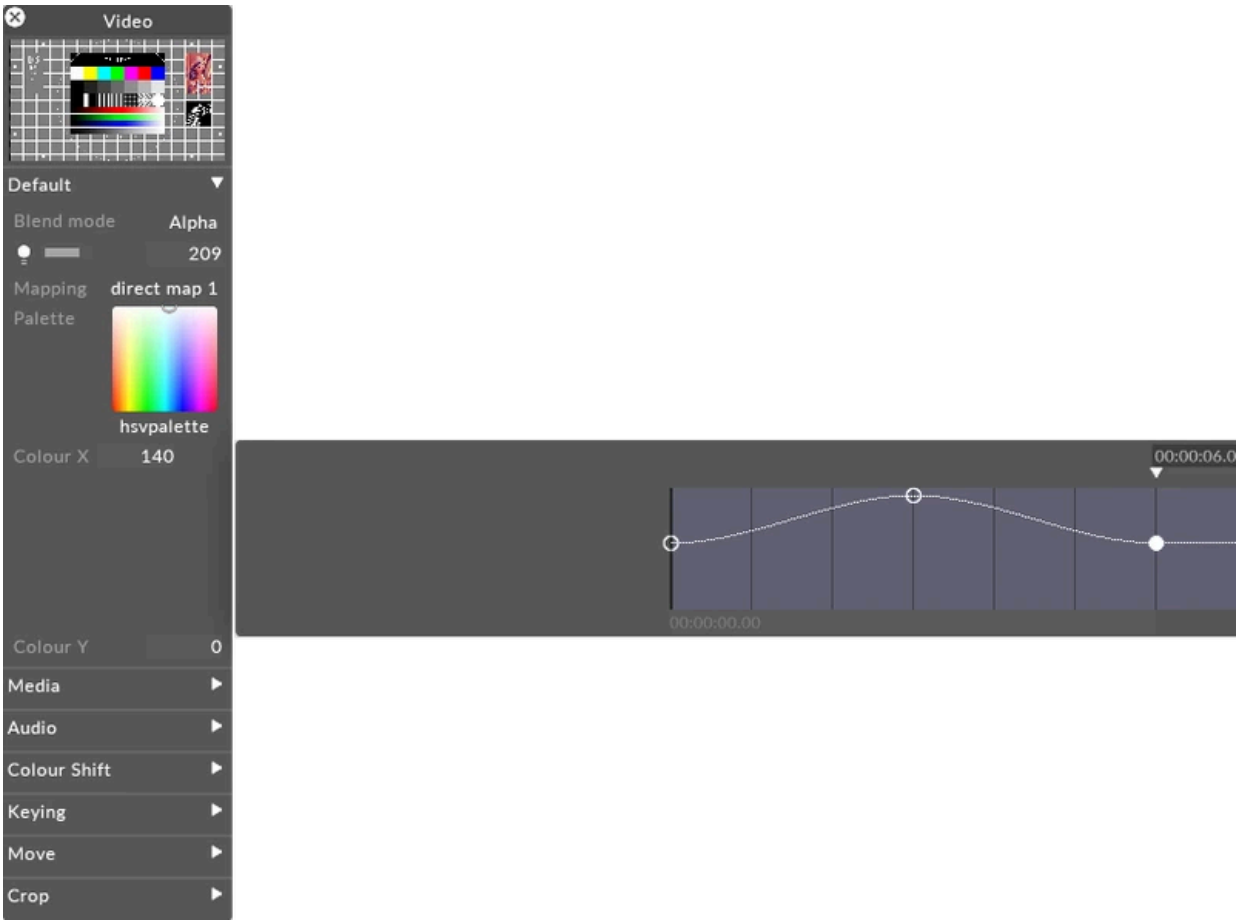
Xcol, YCol

These properties control the coordinates within the current palette bitmap where the output colour is sampled from. The default value is 0,0 which points at the color white (if you are using the HSVPAL palette). Multiplying white with the colors of the chosen content simply generates the original content colors. **Colour X** controls the horizontal position, where 0 is the leftmost

edge and 255 is the rightmost edge. **Colour Y** controls the vertical position, where 0 is the top edge and 255 is the bottom edge.

For example, to saturate the video clip red, change the **Colour Y** value to 255 and use 0 for the **Colour X** value. These coordinates refer to the color red in the palette which is being multiplied with the colors of the existing content.

When you are using the default palette HSVPAL , Colour Y controls saturation, and Colour X controls hue.



Tennis Layer

Tennis has been a staple of Designer since the early days, hidden until r17 and previously called Pong but renamed due to legal reasons. Best played using a midi controller.

Tennis Layer Properties

Preview Thumbnail Blend Mode Brightness Mapping Palette xCol y Col

Options

Ball speed

This controls the speed of the generated ball, in pixels per beat.

Bat size

This controls the size of each bat.

Bat padding

This controls padding on each bat.

Control

> **Note**
>
> **Please note**:We recommend using an external controller (such as a midi device with faders) to control the bats.

Left bat position

This controls the vertical location of the left bat.

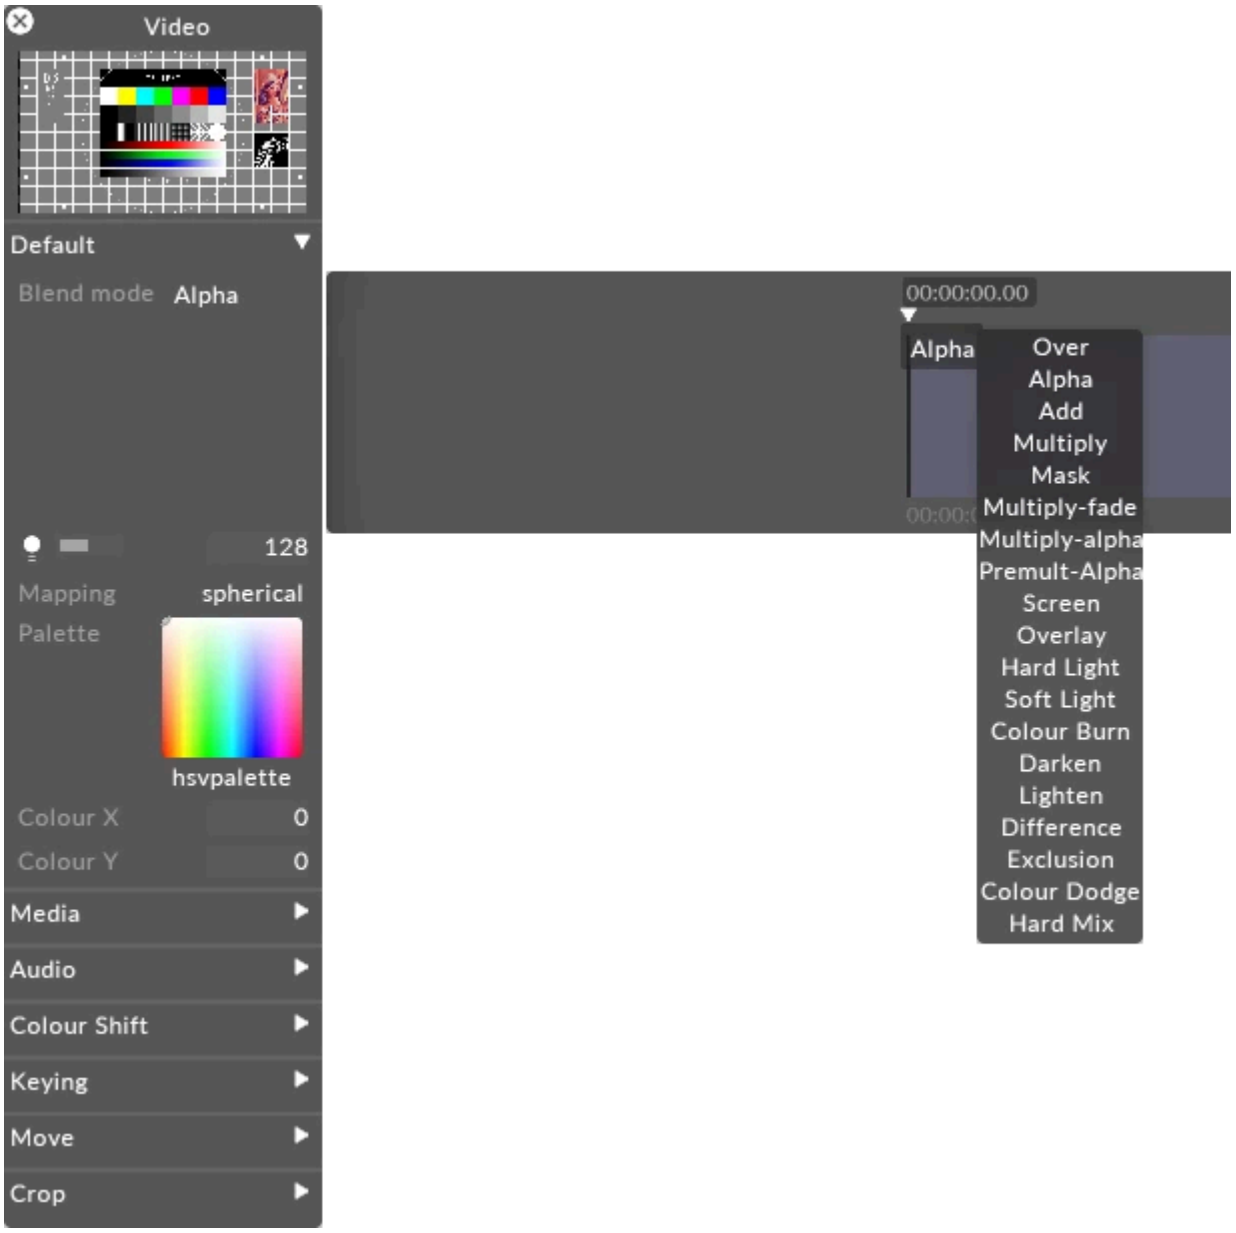
Right bat position

This controls the vertical location of the right bat.

Common Layer Properties

Blend Mode

BlendMode controls how the output of the layer is composited with the layers below. Layers are rendered in a bottom-up order: layers at the top can modify the output of the layers below.



Changing brightness of a content layer in Designer is actually controlling the value of the alpha of the layer. Even when displaying a HAP video, the software will composite the layer with a controllable layer of alpha - one per layer.

There are two ways of expressing alpha in an image:

Straight alpha is an alpha channel which functions just like RGB. Alpha acts as a fourth channel of information per pixel which is as independent of the other three as R, G and B are of each other. For example, with straight alpha it is possible to have RGB = 255 (white) and alpha = 0 (fully transparent) on the same pixel. Internally generated content, such as gradient layer, are generated with straight alpha. This is the preferable style of alpha and considering the cleaner method of the two.

Premultiplied alpha takes the alpha and applies it to the values of the RGB channels per pixel. The more transparent something gets with premultiplied alpha, the closer it gets to black - as if the content is sitting on a black table. Premultiplied is the default output of Adobe Photoshop or AfterEffects. The result is our pixel at 255 RGB (full white) with 0 alpha would be calculated as a black pixel in the final image.

Here are explanations of what each individual blend mode will do.

Over

Makes a layer fully opaque. Premultiplies all alpha onto the RGB value of each pixel. Alpha = black, so adjusting the brightness of a layer in Over blend mode makes it darker.

Alpha

Default blend mode. It will apply alpha values as a transparency if the alpha is present. Brightness changes will make the layer more or less transparent.

Add

Adds the value of each RGB pixel together. Always creates a brighter result. Values clamp at 255.

Multiply

Reads the level of each subpixel as a level between 0.0 and 1.0, and multiplies source with blend. The result is always a darker image overall. For example: white x grey = 0.5. White turns transparent, black takes precedence. Alpha is applied in the same fashion as the Over Blend mode.

Mask

Applies a mask to the single layer **above** in the stack, irrespective of mapping. See **Mask blending** for more information.

Luma-Matte

This mode creates a Luma Matte by using a layer's **Rec. 709 luminance** to control the alpha channel of the layer **above**, irrespective of mapping.

To determine transparency, the luminance of each pixel is calculated using a weighted average of its red, green, and blue channels. The luminance value is then used as the alpha (opacity) value for the corresponding pixels in the upper layers.

As a result, white areas render the layer above fully opaque, black areas make them fully transparent, and grey areas create proportional semi-transparency. This is a specialized **Mask** blend mode; for more details on the underlying behaviour, see **Mask blending**.

Inv-Luma-Matte

The Inverse Luma Matte mask works the same as the **Luma Matte** mask but the transparency is inverted meaning white regions are transparent and black regions are opaque.

Multiply-Fade

The same as Multiply, but will make use of the alpha channel to calculate transparency in the source and blend layers. Since maximum transparency is premultiplied, alpha results in black. This will ignore black created through premultiplying.

Multiply-Alpha

Multiply with straight alpha. This mode assumes that the alpha has not been premultiplied onto the RGB values and will not apply a correction to the semi-transparent pixels.

Premultiply Alpha

Like how Multiply-fade will ignore the darkening caused by premultiplying, this blend mode will do the same with Alpha.

Colour Burn

Blend mode increases the contrast to darken the base colour while reflecting the blend colour. The darker the blend colour, the more intensely the colour will be applied in the base image. White as the blend colour produces no change. Using the colour burn blend mode can produce some harsh results at full opacity. The colour burn blend mode can be used to make tonal and colour adjustments to a layer.

Screen

This blend mode looks at each channels colour information and multiplies the inverse of the blend and base colous. The result is always a lighter colour. Screening with black leaves the colour unchanged. Screening with white produces white. The effect is similar to projecting multiple images on top of each other - where bright white is fully opaque, black is fully transparent and 50% grey is 50% transparent.

Overlay

Multiplies or screens the colours, depending on the base colour. Patterns or colours overlay the existing pixels while preserving the highlights and shadows of the base colour. The base colour is not replaced, but mixed with the blend colour to reflect the lightness or darkness of the original colour.

Hard Light

Multiplies or screens the colours, depending on the blend colour. The effects is similar to shining a harsh spotlight on the image. If the blend colour (light source/top layer) is lighter than 50% grey, the image is lightened as if it were screened. This is useful for adding highlights to an image. If the blend colour is darker than 50% grey, the image is darkened as if it were multiplied. This is useful for adding shadows to an image. Painting with pure black or white results in pure black or white.

Soft Light

Darkens or lightens the colours, depending on the blend colour. The effect is similar to shining a diffused spotlight on the image. If the blend colour (light source/top layer) is lighter than 50% grey, the image is lightened as it if were dodged. If the blend colour is darker than 50% grey, the image is darkened as if it were burned in. Painting with pure black or white produces a distinctly darker or lighter area, but does not result in pure black or white.

Darken

Looks as the colour information in each channel and selects the base or blend colour - whichever is darker - as the result colour. Pixels lighter than the blend colour are replaced and pixels darker than the blend colour do not change.

Lighten

Looks at the colour information in each channel and selects the base or blend colour - whichever is lighter - as the result colour. Pixels darker than the blend colour are replaced and pixels lighter than the blend colour do not change.

Difference

Looks at the colour information in each channel and subtracts either the blend colour from the base colour or the base colour from the blend colour depending on which has the greater brightness value. Blending with white inverts the base colour values and blending with black produces no change.

Exclusion

Creates an effects similar to but lower in contrast than the difference mode. Blending with white inverts the base colour values. Blending with black produces no change.

Colour Dodge

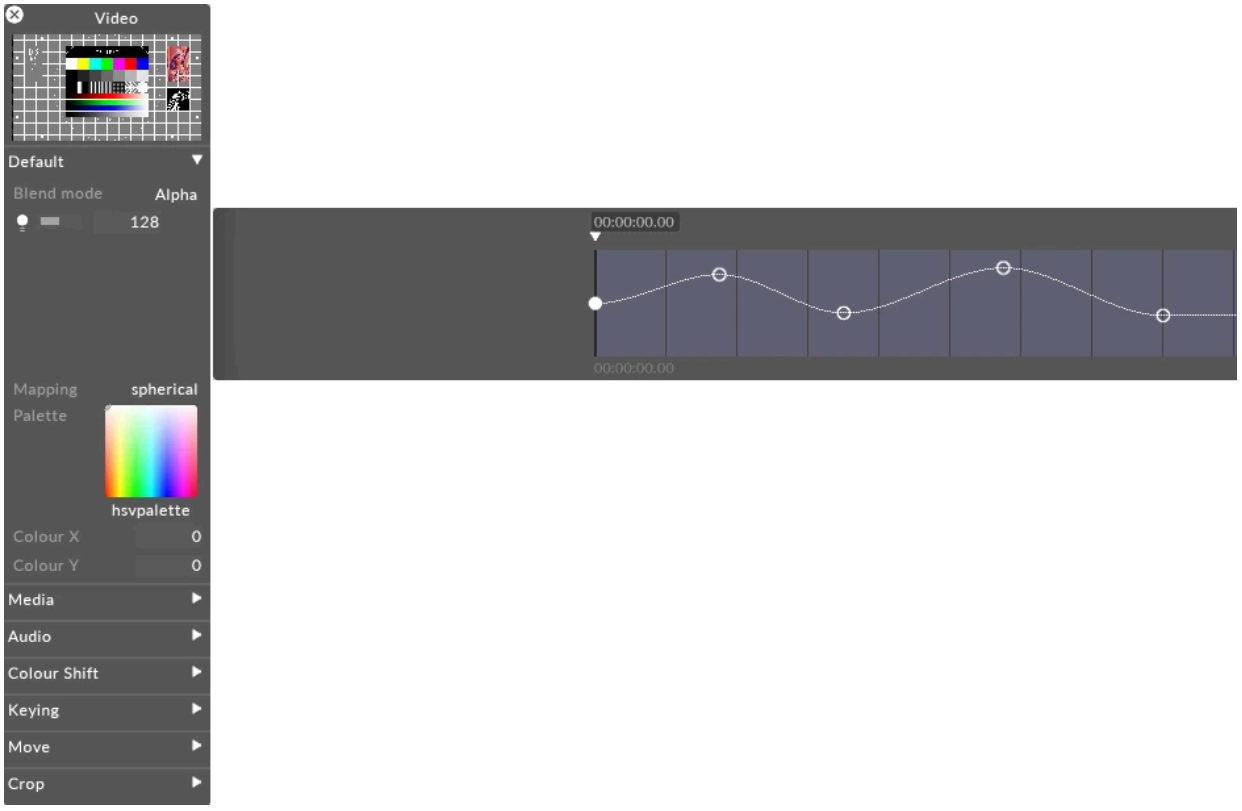
Looks at the colour information in each channel and brightens the base colour to reflect the blend colour by decreasing contrast between the two. Blending with black produces no change.

Hard Mix

Adds the RGB channels of the blend colour to the RGB values of the base colour. If the resulting sum for a channel is 255 or greater, it receives a value of 255; if it is less than 255 it receives a value of 0. Therefore all blended pixels have RGB channels of either 0 or 255. This changes all pixels to primary additive colours (RGB), white or black.

Brightness

This property (which appears as a light bulb icon) controls the brightness of the layer output.



If the layers blend mode is set to Alpha, then reducing the brightness to 0 also reduces the opacity of the layer to 0. This can be useful when you want to dissolve from one layer to the next. In that case, you can place the new layer above the old layer and increase its brightness level.

> **Note**
>
> Layers that are patched to Sockpuppet (DMX, OSC or HTTP) are made Dormant when their brightness is set to 0. This means they will not do any rendering or consume any resources until their brightness is changed to > 0. You can find more information about this here: **Sequencing with Sockpuppet**. Layers without a sockpuppet patch do not behave in this way.

Mapping

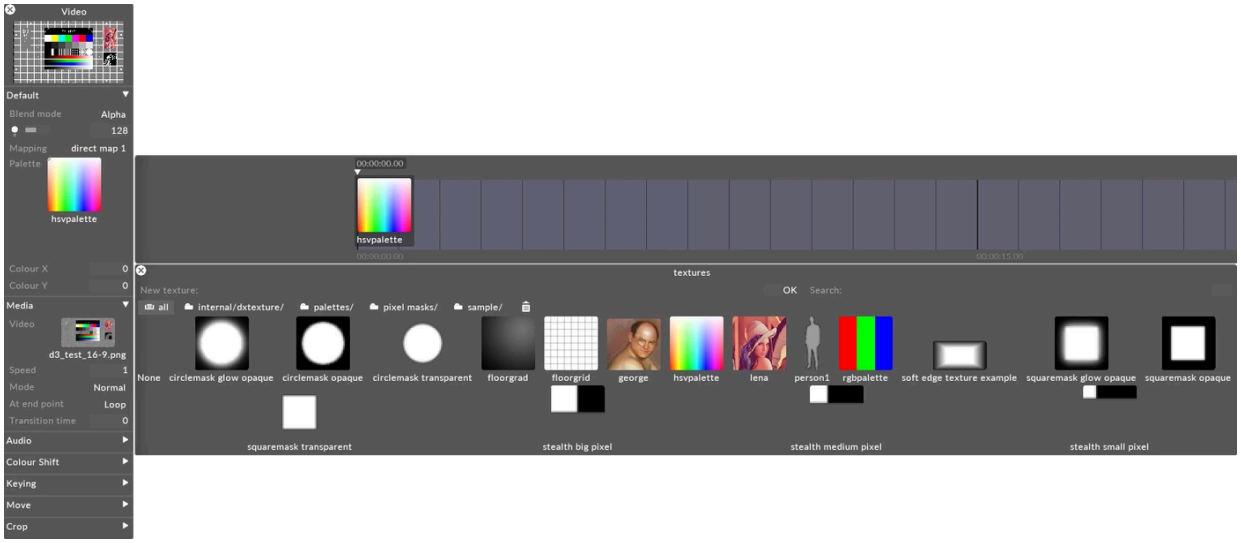
The mapping property controls how the layer output is mapped onto the screen(s) in the Stage level.

For information on mapping, including how to use the different mapping types offered by Designer, please see the chapter **Content Mapping**

Palette

This points to the still image file that defines the bitmap from which the tint colour is taken. The default palette (HSVPAL) consists of the complete range of hues and saturations. Selecting this property will open the Texture object library, which shows all of the still image files saved on your local hard-drive in the **DxTexture** older.

To control the location within the current palette bitmap, and thus control the colour, you have to edit the **xCol** and **yCol** values (see the section for xCol, yCol).



To change the current palette bitmap:

1. Left-click **palette** to open the Texture object library.
2. Left-click the still image file you want to use for the palette bitmap.

If you want to use a palette bitmap other than the standard still images provided in Designer, you will need to use a custom still image file.

See the **Placing media files** for a project sub-chapter to understand where to place a custom still image file and how to access it in Designer. Also save the file to a **supported file format**.

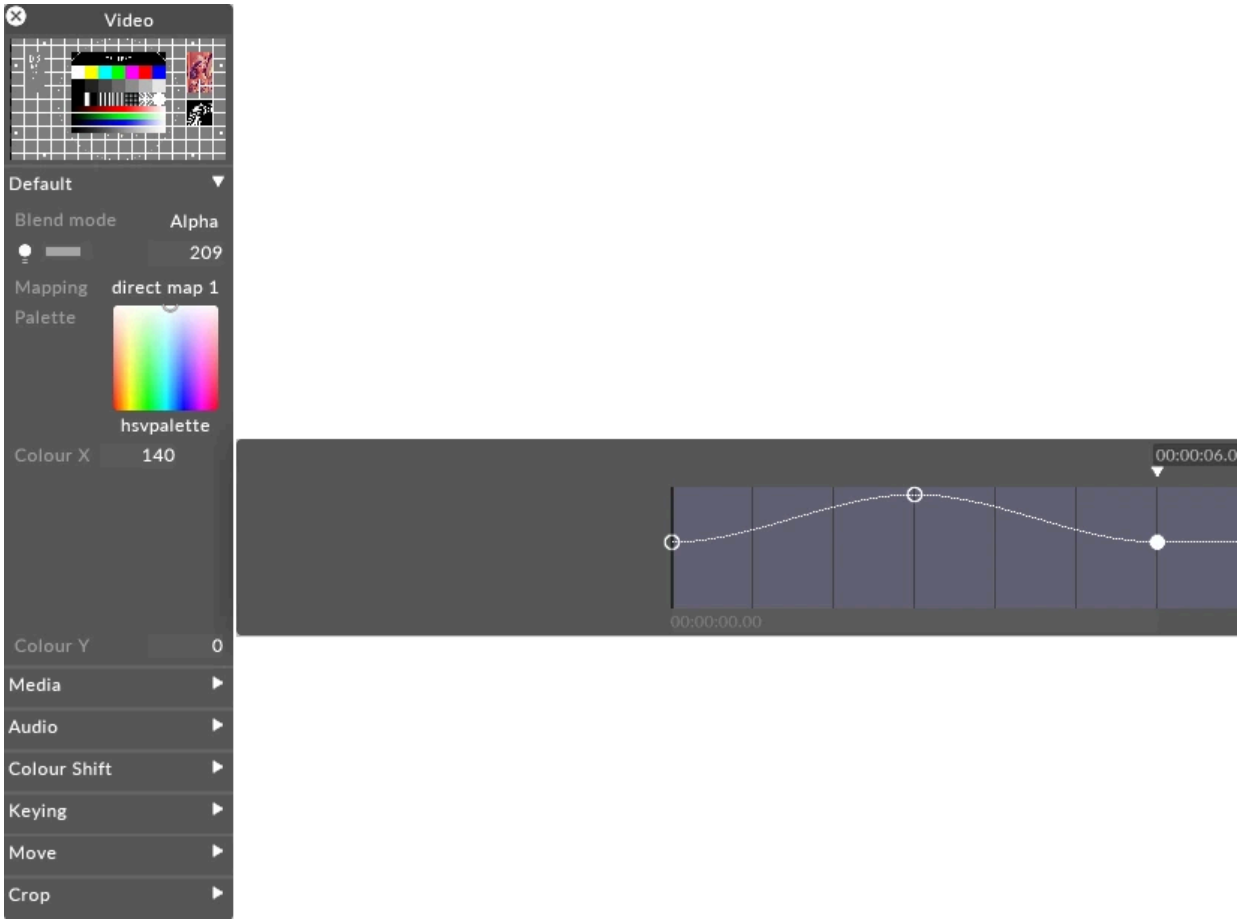
Xcol, YCol

These properties control the coordinates within the current palette bitmap where the output colour is sampled from. The default value is 0,0 which points at the color white (if you are using the HSVPAL palette). Multiplying white with the colors of the chosen content simply generates the original content colors. **Colour X** controls the horizontal position, where 0 is the leftmost edge and 255 is the rightmost edge. **Colour Y** controls the vertical position, where 0 is the top edge and 255 is the bottom edge.

For example, to saturate the video clip red, change the **Colour Y** value to 255 and use 0 for the **Colour X** value. These coordinates refer to the color red in the palette which is being multiplied

with the colors of the existing content.

When you are using the default palette HSVPAL , Colour Y controls saturation, and Colour X controls hue.



TestPattern Layer

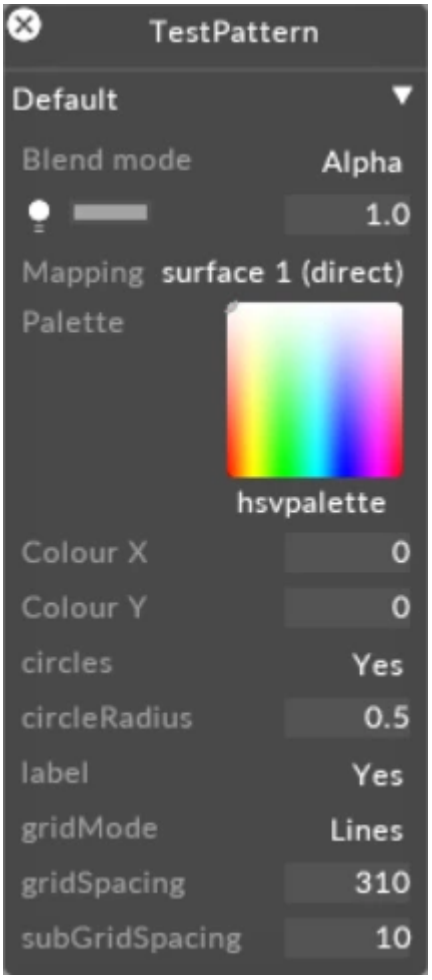
The TestPattern layer renders a calibration pattern made up of a configurable grid, concentric circles, the screen's label with its resolution, and corner logos. The pattern helps verify screen output, alignment, mapping, and resolution during setup, before content goes live.

Workflow

- Create a new layer
- Assign the layer to a mapping

> **Note**
>
> **Please note**: The TestPattern layer is unique in that it fills the entire area of the surface it's mapped to, thus any mapping type applied to this layer will function as a direct map.

- Define the circles, grid, and other parameters to suit



TestPattern Layer Properties

Circles

Defines whether the test pattern displays circles. Default: yes.

Circle radius

Defines the radius of the circles. Range: 0-1 (step 0.0125). Default: 0.5.

Label

Defines whether the screen or projector label is shown in the centre of the pattern. The label is followed by the screen's resolution (e.g. `1920 x 1080`). Default: yes.

Grid mode

Selects the grid style: **Off** or **Lines**. Default: **Lines**.

Grid spacing

Spacing between major grid lines, in pixels. Range: 1-1000. Default: 100.

Sub grid spacing

Spacing between minor grid lines (subdivisions within each major grid square), in pixels. Range: 1-1000. Default: 10.

Logo top left

Texture slot for the logo rendered in the top-left of the pattern. Defaults to the Disguise logo.

Logo bottom right

Texture slot for the logo rendered in the bottom-right of the pattern. Defaults to the Disguise logo.

Input Exposure

Input exposure transform applied to the test pattern, in stops. The available range depends on the active colour management mode — ACES: -5 to 5 (step 0.1); OCIO: -10 to 10 (step 0.1).

Input Contrast

Input contrast transform. Range: 0-5 (step 0.01). *OCIO mode only.*

Input Gamma

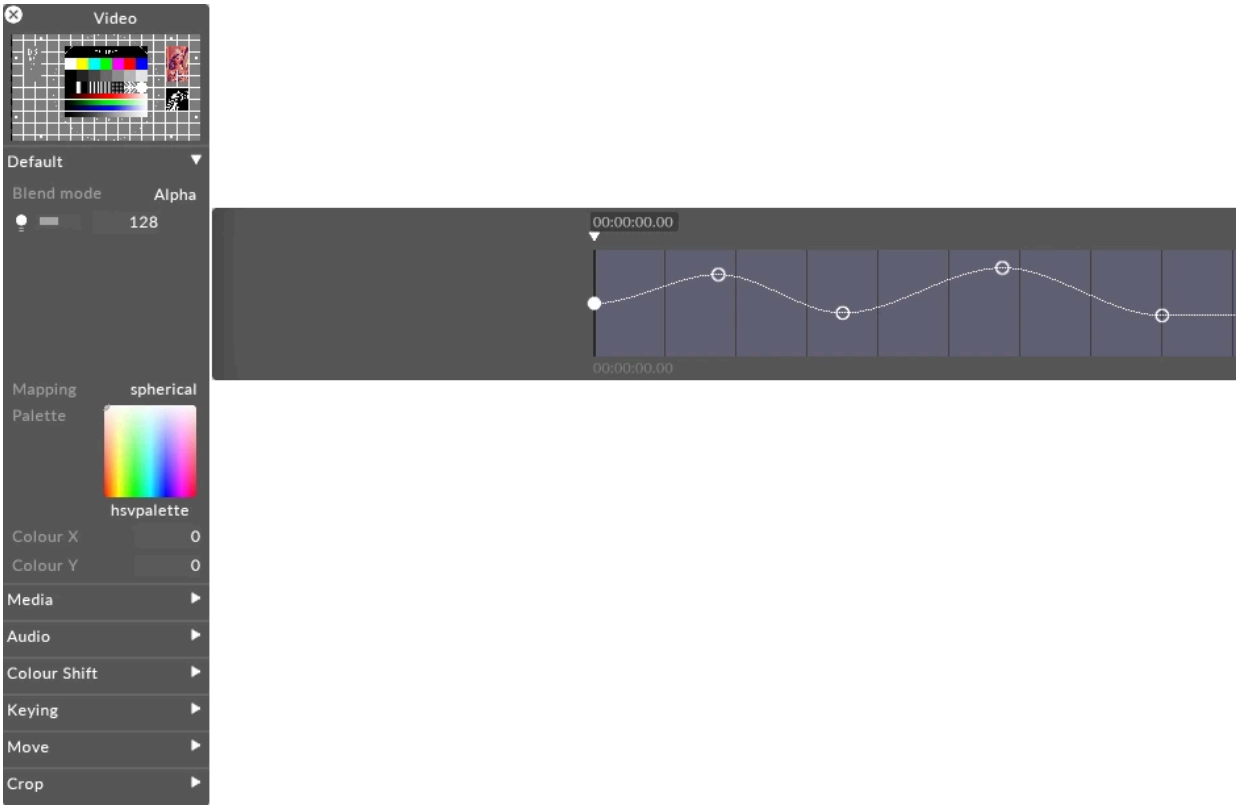
Input gamma transform. Range: 0-5.

Common Layer Properties

> **Note**
>
> The TestPattern layer does not expose **Blend Mode**.

Brightness

This property (which appears as a light bulb icon) controls the brightness of the layer output.



If the layers blend mode is set to Alpha, then reducing the brightness to 0 also reduces the opacity of the layer to 0. This can be useful when you want to dissolve from one layer to the next. In that case, you can place the new layer above the old layer and increase its brightness level.

> **Note**
>
> Layers that are patched to Sockpuppet (DMX, OSC or HTTP) are made Dormant when their brightness is set to 0. This means they will not do any rendering or consume any resources until their brightness is changed to > 0. You can find more information about this here: **Sequencing with Sockpuppet**. Layers without a sockpuppet patch do not behave in this way.

Mapping

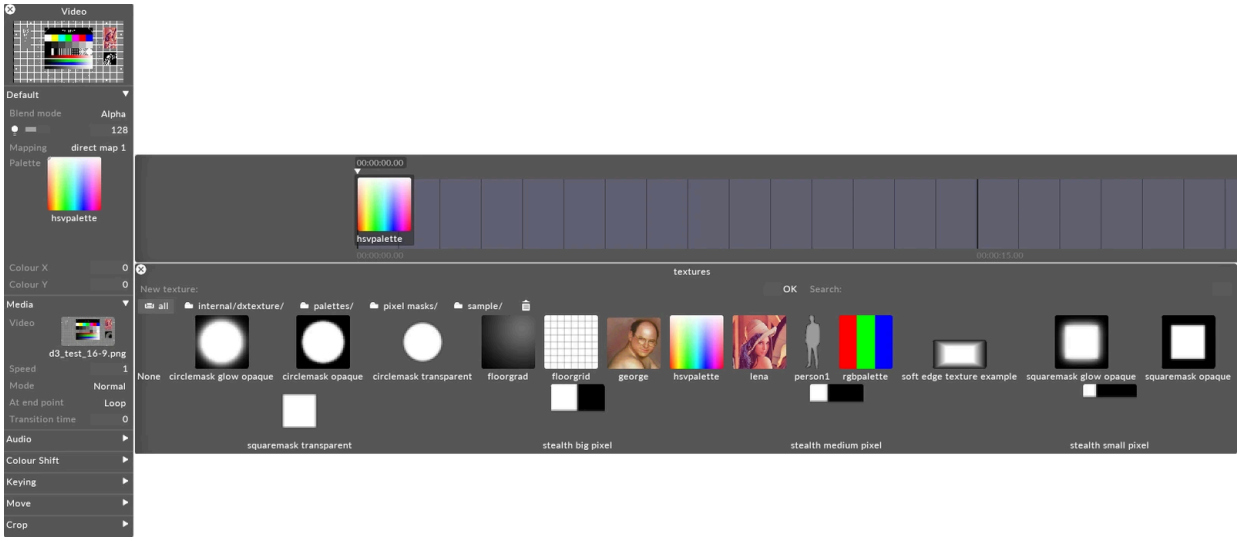
The mapping property controls how the layer output is mapped onto the screen(s) in the Stage level.

For information on mapping, including how to use the different mapping types offered by Designer, please see the chapter **Content Mapping**

Palette

This points to the still image file that defines the bitmap from which the tint colour is taken. The default palette (HSVPAL) consists of the complete range of hues and saturations. Selecting this property will open the Texture object library, which shows all of the still image files saved on your local hard-drive in the **DxTexture** older.

To control the location within the current palette bitmap, and thus control the colour, you have to edit the **xCol** and **yCol** values (see the section for xCol, yCol).



To change the current palette bitmap:

1. Left-click **palette** to open the Texture object library.
2. Left-click the still image file you want to use for the palette bitmap.

If you want to use a palette bitmap other than the standard still images provided in Designer, you will need to use a custom still image file.

See the **Placing media files** for a project sub-chapter to understand where to place a custom still image file and how to access it in Designer. Also save the file to a **supported file format**.

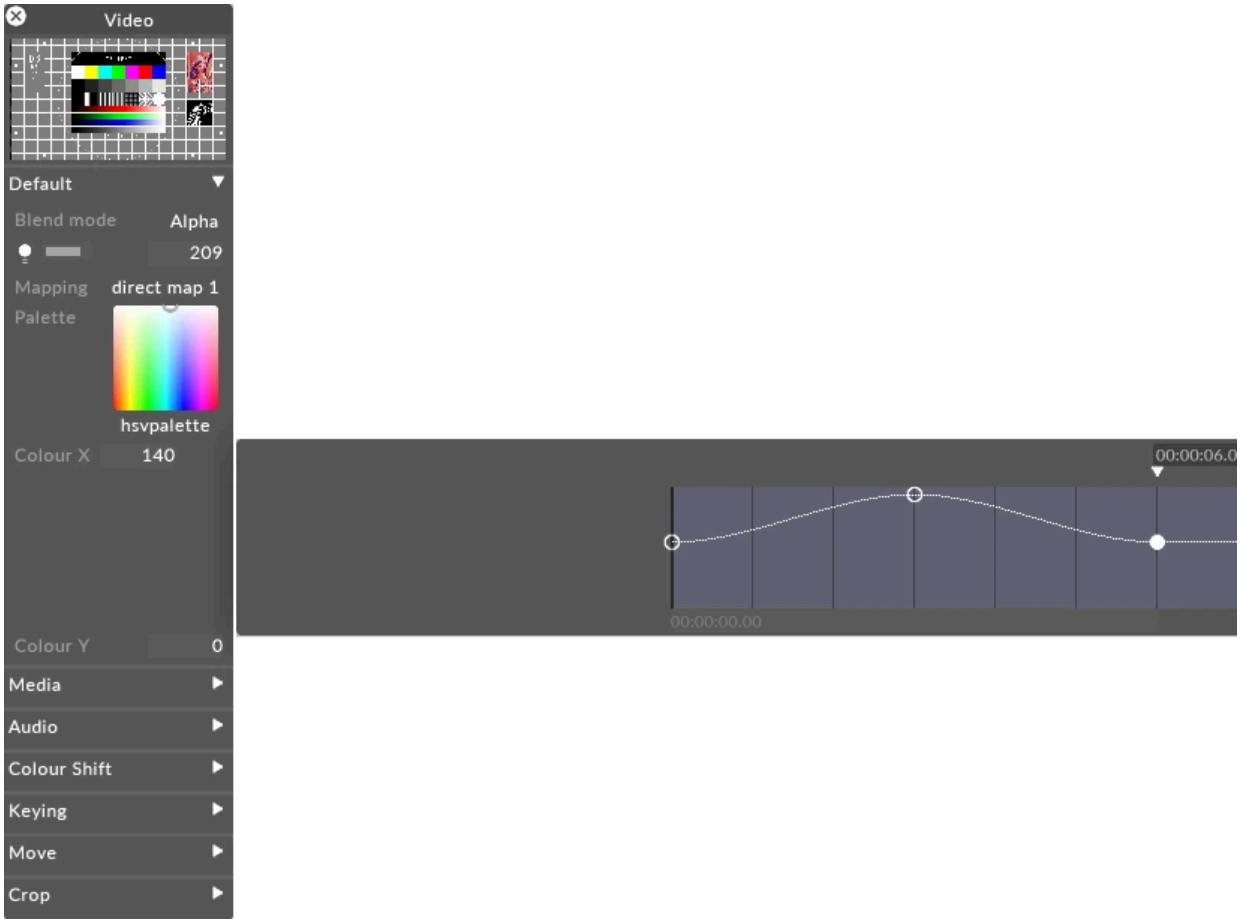
Xcol, YCol

These properties control the coordinates within the current palette bitmap where the output colour is sampled from. The default value is 0,0 which points at the color white (if you are using the HSVPAL palette). Multiplying white with the colors of the chosen content simply generates the original content colors. **Colour X** controls the horizontal position, where 0 is the leftmost edge and 255 is the rightmost edge. **Colour Y** controls the vertical position, where 0 is the top edge and 255 is the bottom edge.

For example, to saturate the video clip red, change the **Colour Y** value to 255 and use 0 for the **Colour X** value. These coordinates refer to the color red in the palette which is being multiplied

with the colors of the existing content.

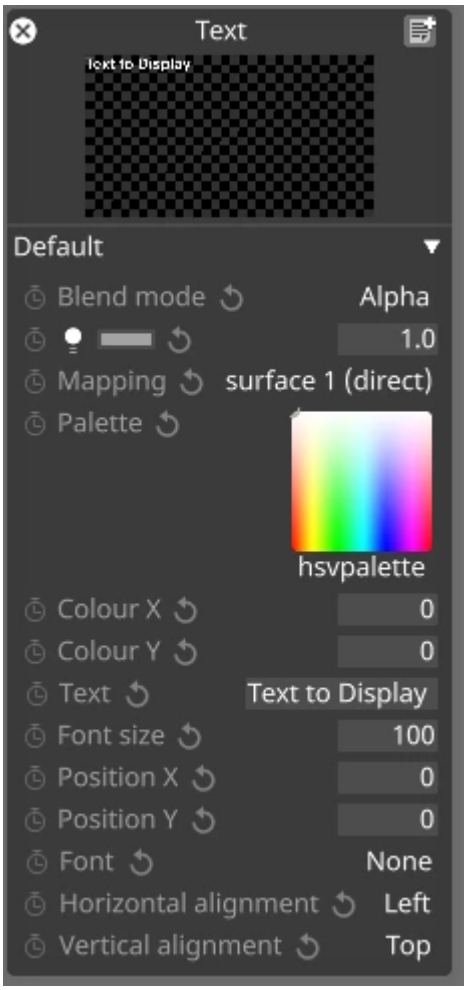
When you are using the default palette HSVPAL , Colour Y controls saturation, and Colour X controls hue.



Text Layer

The Text layer renders configurable text on a surface or screen. The content, font, size, position, and alignment can be controlled directly or driven by keyframes — useful for labels, captions, on-screen titles, and any timeline-driven text content.

Text Layer Properties



Text

The text to display. Multi-line content is supported — newlines in the input are rendered as line breaks. Default: `Text to Display`.

Font size

Text size in pixels. Range: 0-500. Default: 100.

Position X

Horizontal pixel offset from the alignment anchor. Range: 0-1920. Default: 0.

Position Y

Vertical pixel offset from the alignment anchor. Range: 0-1080. Default: 0.

Font

Selects the font used to render the text. Arial and Times New Roman are pre-loaded; additional fonts can be added by placing TTF files in the project's `objects/textfonts/` folder, after which they become selectable in this dropdown.

Horizontal alignment

Horizontal placement of text on the surface. Options: **Left**, **Center**, **Right**. Default: **Left**.

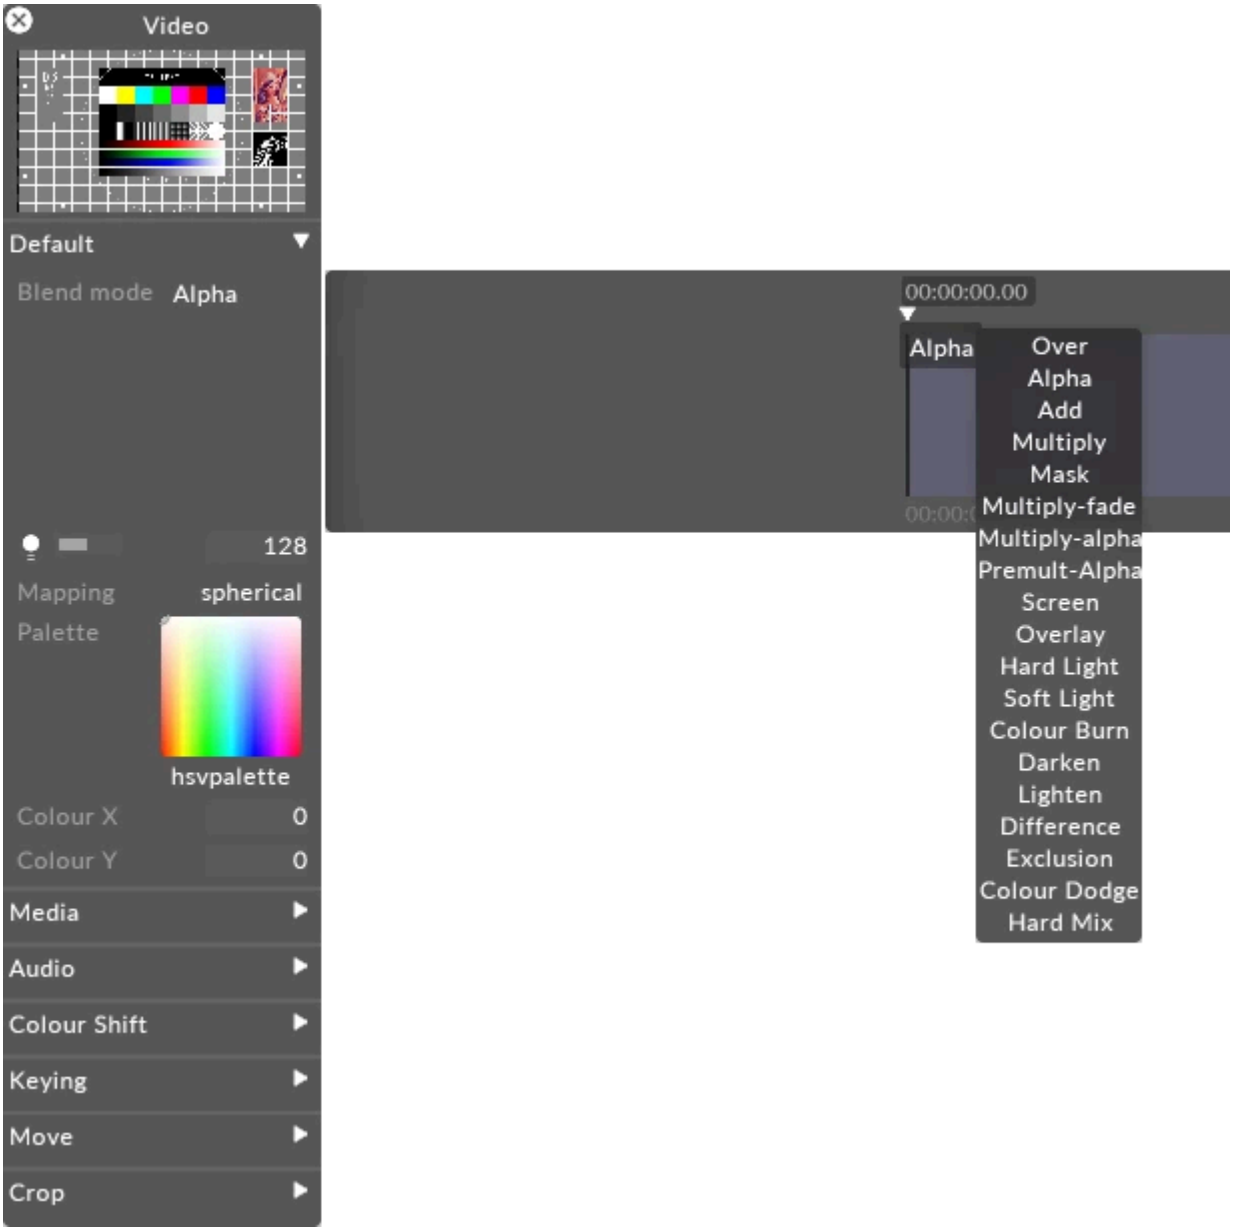
Vertical alignment

Vertical placement of text on the surface. Options: **Top**, **Center**, **Bottom**. Default: **Top**.

Common Layer Properties

Blend Mode

BlendMode controls how the output of the layer is composited with the layers below. Layers are rendered in a bottom-up order: layers at the top can modify the output of the layers below.



Changing brightness of a content layer in Designer is actually controlling the value of the alpha of the layer. Even when displaying a HAP video, the software will composite the layer with a controllable layer of alpha - one per layer.

There are two ways of expressing alpha in an image:

Straight alpha is an alpha channel which functions just like RGB. Alpha acts as a fourth channel of information per pixel which is as independent of the other three as R, G and B are of each other. For example, with straight alpha it is possible to have RGB = 255 (white) and alpha = 0 (fully transparent) on the same pixel. Internally generated content, such as gradient layer, are generated with straight alpha. This is the preferable style of alpha and considering the cleaner method of the two.

Premultiplied alpha takes the alpha and applies it to the values of the RGB channels per pixel. The more transparent something gets with premultiplied alpha, the closer it gets to black - as if the content is sitting on a black table. Premultiplied is the default output of Adobe Photoshop or AfterEffects. The result is our pixel at 255 RGB (full white) with 0 alpha would be calculated as a black pixel in the final image.

Here are explanations of what each individual blend mode will do.

Over

Makes a layer fully opaque. Premultiplies all alpha onto the RGB value of each pixel. Alpha = black, so adjusting the brightness of a layer in Over blend mode makes it darker.

Alpha

Default blend mode. It will apply alpha values as a transparency if the alpha is present. Brightness changes will make the layer more or less transparent.

Add

Adds the value of each RGB pixel together. Always creates a brighter result. Values clamp at 255.

Multiply

Reads the level of each subpixel as a level between 0.0 and 1.0, and multiplies source with blend. The result is always a darker image overall. For example: white x grey = 0.5. White turns transparent, black takes precedence. Alpha is applied in the same fashion as the Over Blend mode.

Mask

Applies a mask to the single layer **above** in the stack, irrespective of mapping. See **Mask blending** for more information.

Luma-Matte

This mode creates a Luma Matte by using a layer's **Rec. 709 luminance** to control the alpha channel of the layer **above**, irrespective of mapping.

To determine transparency, the luminance of each pixel is calculated using a weighted average of its red, green, and blue channels. The luminance value is then used as the alpha (opacity) value for the corresponding pixels in the upper layers.

As a result, white areas render the layer above fully opaque, black areas make them fully transparent, and grey areas create proportional semi-transparency. This is a specialized **Mask** blend mode; for more details on the underlying behaviour, see **Mask blending**.

Inv-Luma-Matte

The Inverse Luma Matte mask works the same as the **Luma Matte** mask but the transparency is inverted meaning white regions are transparent and black regions are opaque.

Multiply-Fade

The same as Multiply, but will make use of the alpha channel to calculate transparency in the source and blend layers. Since maximum transparency is premultiplied, alpha results in black. This will ignore black created through premultiplying.

Multiply-Alpha

Multiply with straight alpha. This mode assumes that the alpha has not been premultiplied onto the RGB values and will not apply a correction to the semi-transparent pixels.

Premultiply Alpha

Like how Multiply-fade will ignore the darkening caused by premultiplying, this blend mode will do the same with Alpha.

Colour Burn

Blend mode increases the contrast to darken the base colour while reflecting the blend colour. The darker the blend colour, the more intensely the colour will be applied in the base image. White as the blend colour produces no change. Using the colour burn blend mode can produce some harsh results at full opacity. The colour burn blend mode can be used to make tonal and colour adjustments to a layer.

Screen

This blend mode looks at each channels colour information and multiplies the inverse of the blend and base colous. The result is always a lighter colour. Screening with black leaves the colour unchanged. Screening with white produces white. The effect is similar to projecting multiple images on top of each other - where bright white is fully opaque, black is fully transparent and 50% grey is 50% transparent.

Overlay

Multiplies or screens the colours, depending on the base colour. Patterns or colours overlay the existing pixels while preserving the highlights and shadows of the base colour. The base colour is not replaced, but mixed with the blend colour to reflect the lightness or darkness of the original colour.

Hard Light

Multiplies or screens the colours, depending on the blend colour. The effects is similar to shining a harsh spotlight on the image. If the blend colour (light source/top layer) is lighter than

50% grey, the image is lightened as if it were screened. This is useful for adding highlights to an image. If the blend colour is darker than 50% grey, the image is darkened as if it were multiplied. This is useful for adding shadows to an image. Painting with pure black or white results in pure black or white.

Soft Light

Darkens or lightens the colours, depending on the blend colour. The effect is similar to shining a diffused spotlight on the image. If the blend colour (light source/top layer) is lighter than 50% grey, the image is lightened as it if were dodged. If the blend colour is darker than 50% grey, the image is darkened as if it were burned in. Painting with pure black or white produces a distinctly darker or lighter area, but does not result in pure black or white.

Darken

Looks as the colour information in each channel and selects the base or blend colour - whichever is darker - as the result colour. Pixels lighter than the blend colour are replaced and pixels darker than the blend colour do not change.

Lighten

Looks at the colour information in each channel and selects the base or blend colour - whichever is lighter - as the result colour. Pixels darker than the blend colour are replaced and pixels lighter than the blend colour do not change.

Difference

Looks at the colour information in each channel and subtracts either the blend colour from the base colour or the base colour from the blend colour depending on which has the greater brightness value. Blending with white inverts the base colour values and blending with black produces no change.

Exclusion

Creates an effects similar to but lower in contrast than the difference mode. Blending with white inverts the base colour values. Blending with black produces no change.

Colour Dodge

Looks at the colour information in each channel and brightens the base colour to reflect the blend colour by decreasing contrast between the two. Blending with black produces no change.

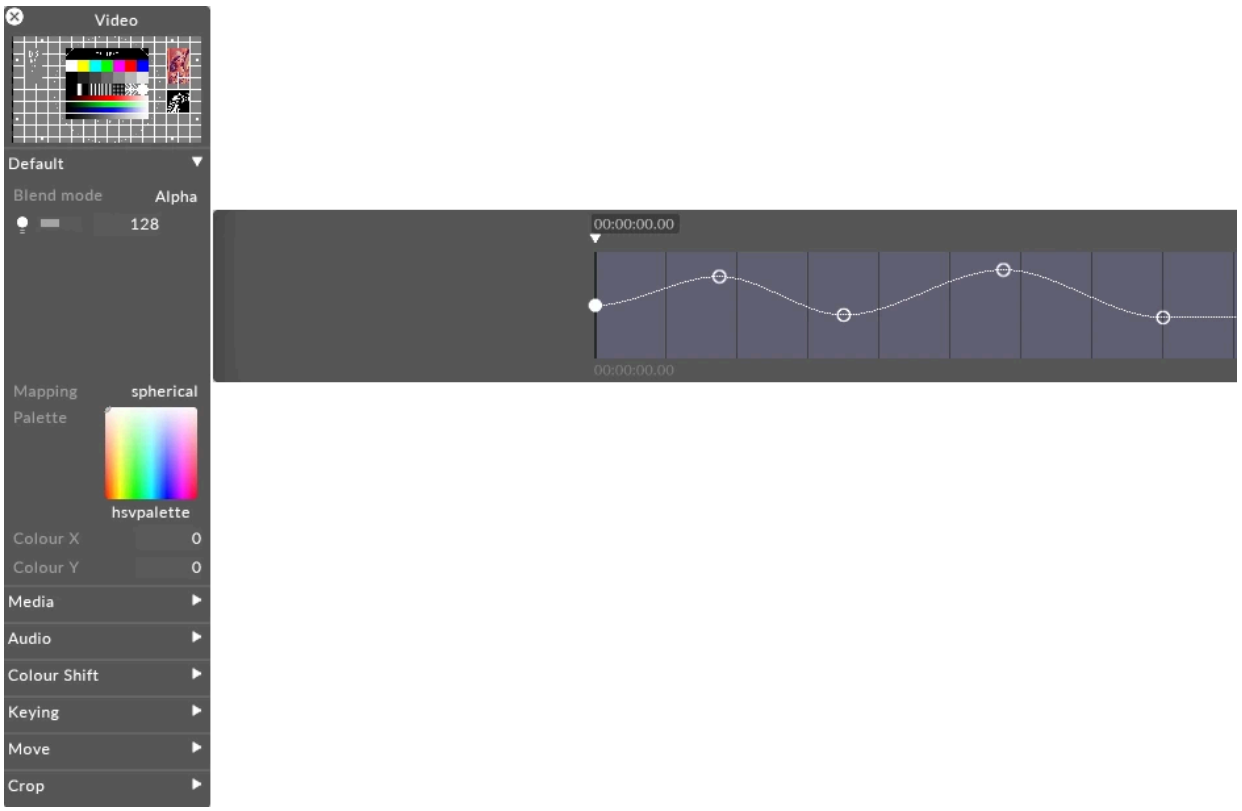
Hard Mix

Adds the RGB channels of the blend colour to the RGB values of the base colour. If the resulting sum for a channel is 255 or greater, it receives a value of 255; if it is less than 255 it

receives a value of 0. Therefore all blended pixels have RGB channels of either 0 or 255. This changes all pixels to primary additive colours (RGB), white or black.

Brightness

This property (which appears as a light bulb icon) controls the brightness of the layer output.



If the layers blend mode is set to Alpha, then reducing the brightness to 0 also reduces the opacity of the layer to 0. This can be useful when you want to dissolve from one layer to the next. In that case, you can place the new layer above the old layer and increase its brightness level.

> **Note**
>
> Layers that are patched to Sockpuppet (DMX, OSC or HTTP) are made Dormant when their brightness is set to 0. This means they will not do any rendering or consume any resources until their brightness is changed to > 0. You can find more information about this here: **Sequencing with Sockpuppet**. Layers without a sockpuppet patch do not behave in this way.

Mapping

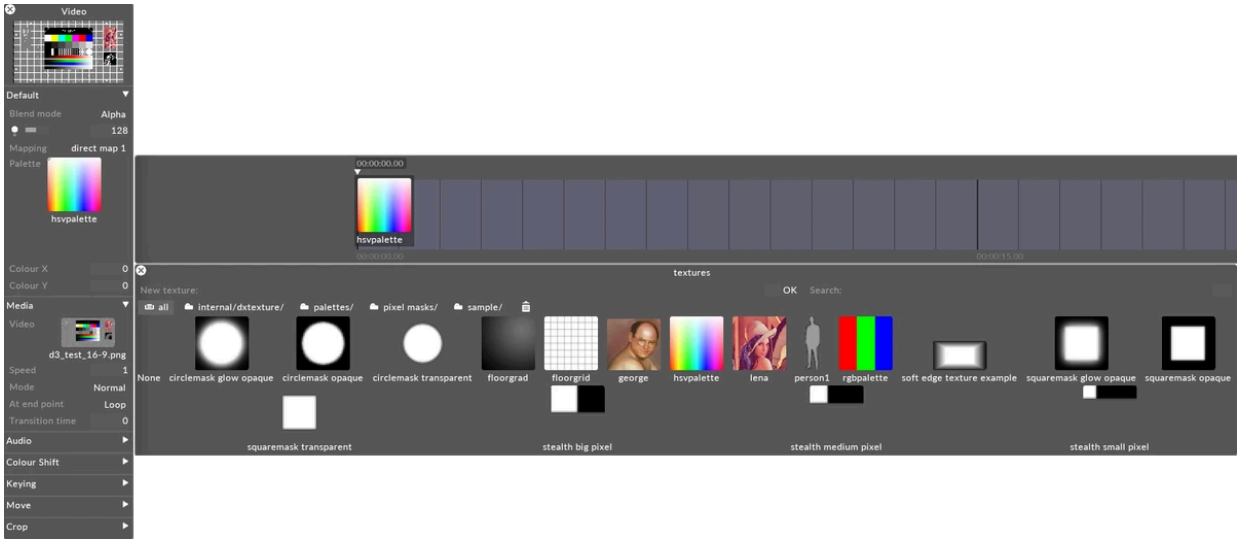
The mapping property controls how the layer output is mapped onto the screen(s) in the Stage level.

For information on mapping, including how to use the different mapping types offered by Designer, please see the chapter **Content Mapping**

Palette

This points to the still image file that defines the bitmap from which the tint colour is taken. The default palette (HSVPAL) consists of the complete range of hues and saturations. Selecting this property will open the Texture object library, which shows all of the still image files saved on your local hard-drive in the **DxTexture** older.

To control the location within the current palette bitmap, and thus control the colour, you have to edit the **xCol** and **yCol** values (see the section for xCol, yCol).



To change the current palette bitmap:

1. Left-click **palette** to open the Texture object library.
2. Left-click the still image file you want to use for the palette bitmap.

If you want to use a palette bitmap other than the standard still images provided in Designer, you will need to use a custom still image file.

See the **Placing media files** for a project sub-chapter to understand where to place a custom still image file and how to access it in Designer. Also save the file to a **supported file format**.

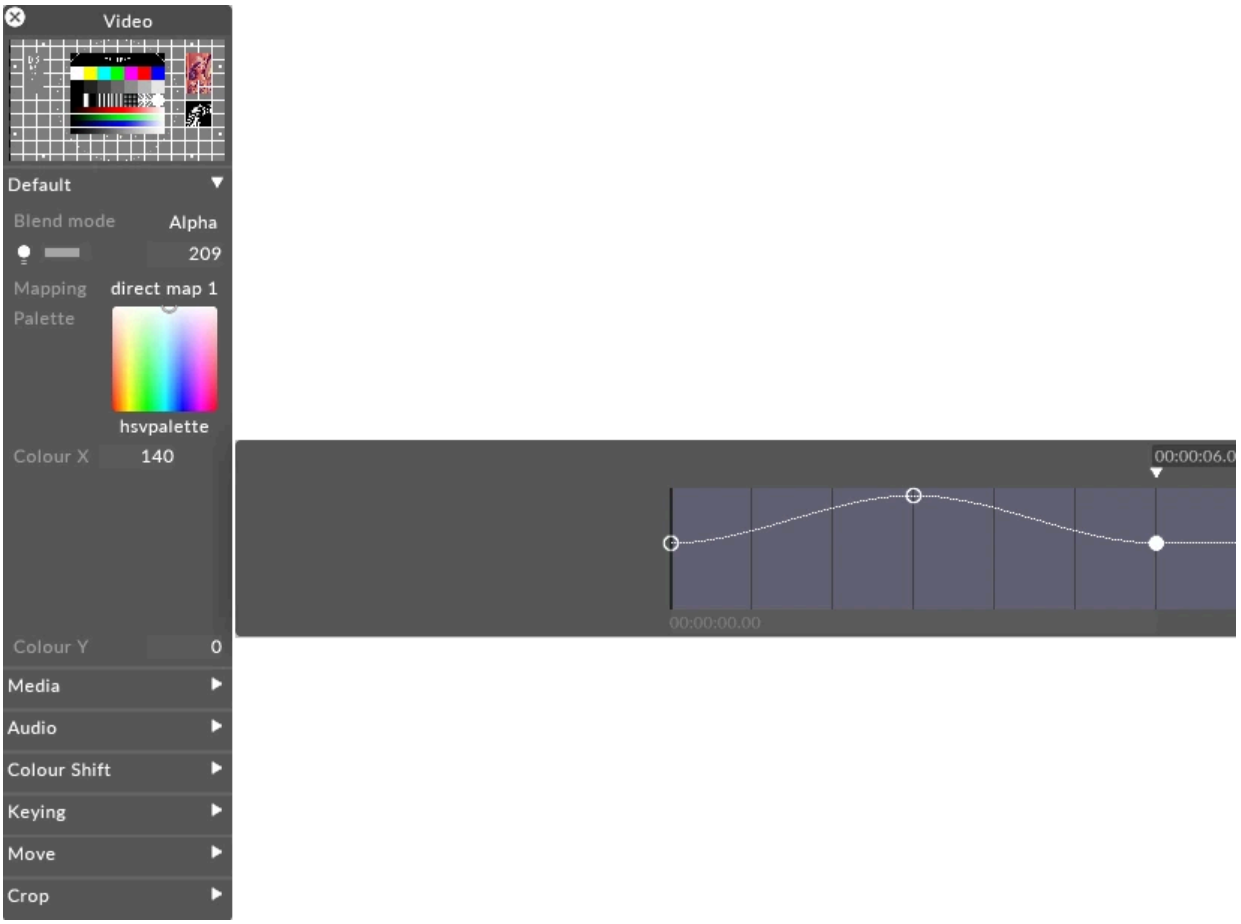
Xcol, YCol

These properties control the coordinates within the current palette bitmap where the output colour is sampled from. The default value is 0,0 which points at the color white (if you are using the HSVPAL palette). Multiplying white with the colors of the chosen content simply generates the original content colors. **Colour X** controls the horizontal position, where 0 is the leftmost

edge and 255 is the rightmost edge. **Colour Y** controls the vertical position, where 0 is the top edge and 255 is the bottom edge.

For example, to saturate the video clip red, change the **Colour Y** value to 255 and use 0 for the **Colour X** value. These coordinates refer to the color red in the palette which is being multiplied with the colors of the existing content.

When you are using the default palette HSVPAL , Colour Y controls saturation, and Colour X controls hue.

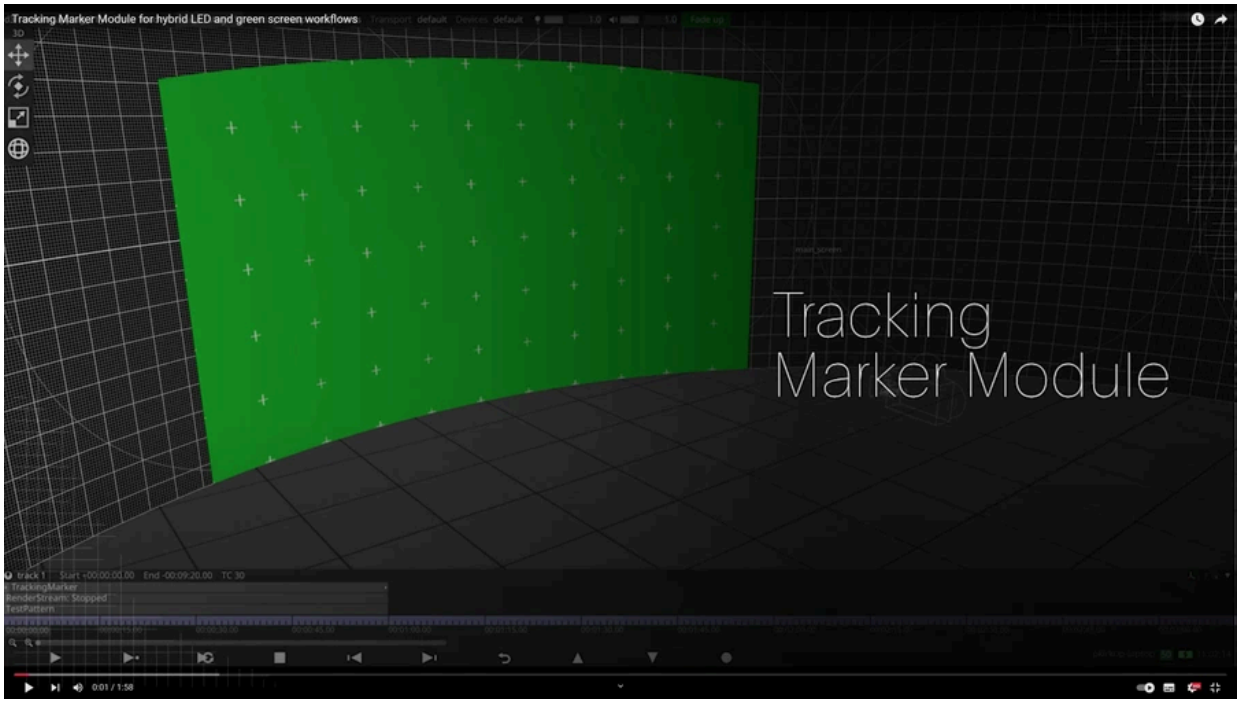


TrackingMarker Module

The TrackingMarker module is useful for virtual production workflows where some scenes require a green screen, either just within the camera frustum or on the whole of the LED screen.

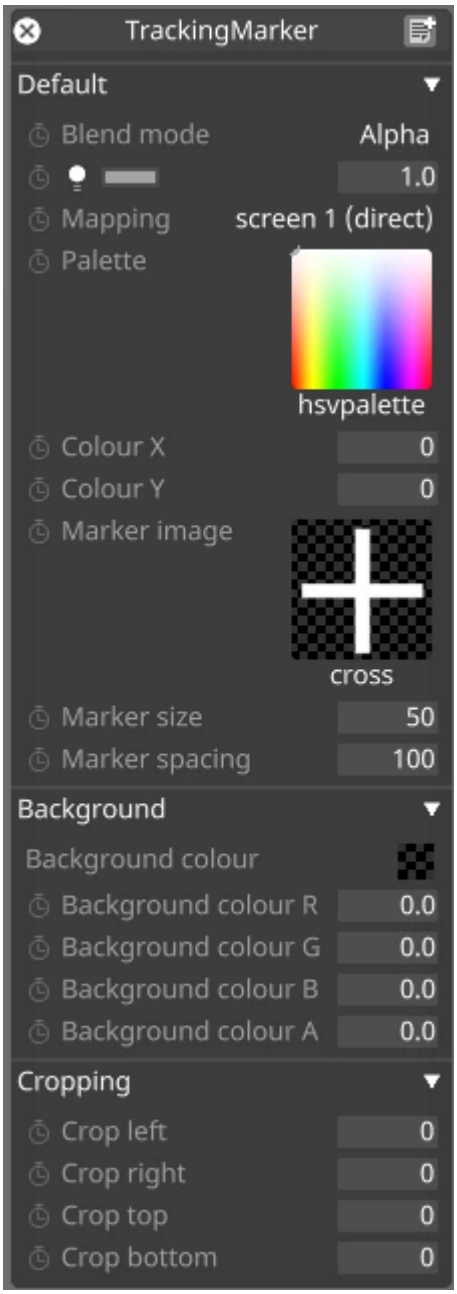
The tracking marker module generates a repeating pattern of markers on a coloured or transparent background. It is useful for virtual production workflows where some scenes require a green screen, either just within the camera frustrum or on the whole of the LED screen. It can be used for both 2D and 3D mappings, and the markers will appear fixed to the screens in both cases.

See How It Works



Click on the image to see the video in Youtube

TrackingMarker Layer Properties



Marker Image

The image used for the onscreen marker.

Marker Size

The size of the onscreen marker.

Marker Spacing

The spacing between each onscreen marker image.

Background Colour

Colour Controls for the background colour when Alpha is enabled

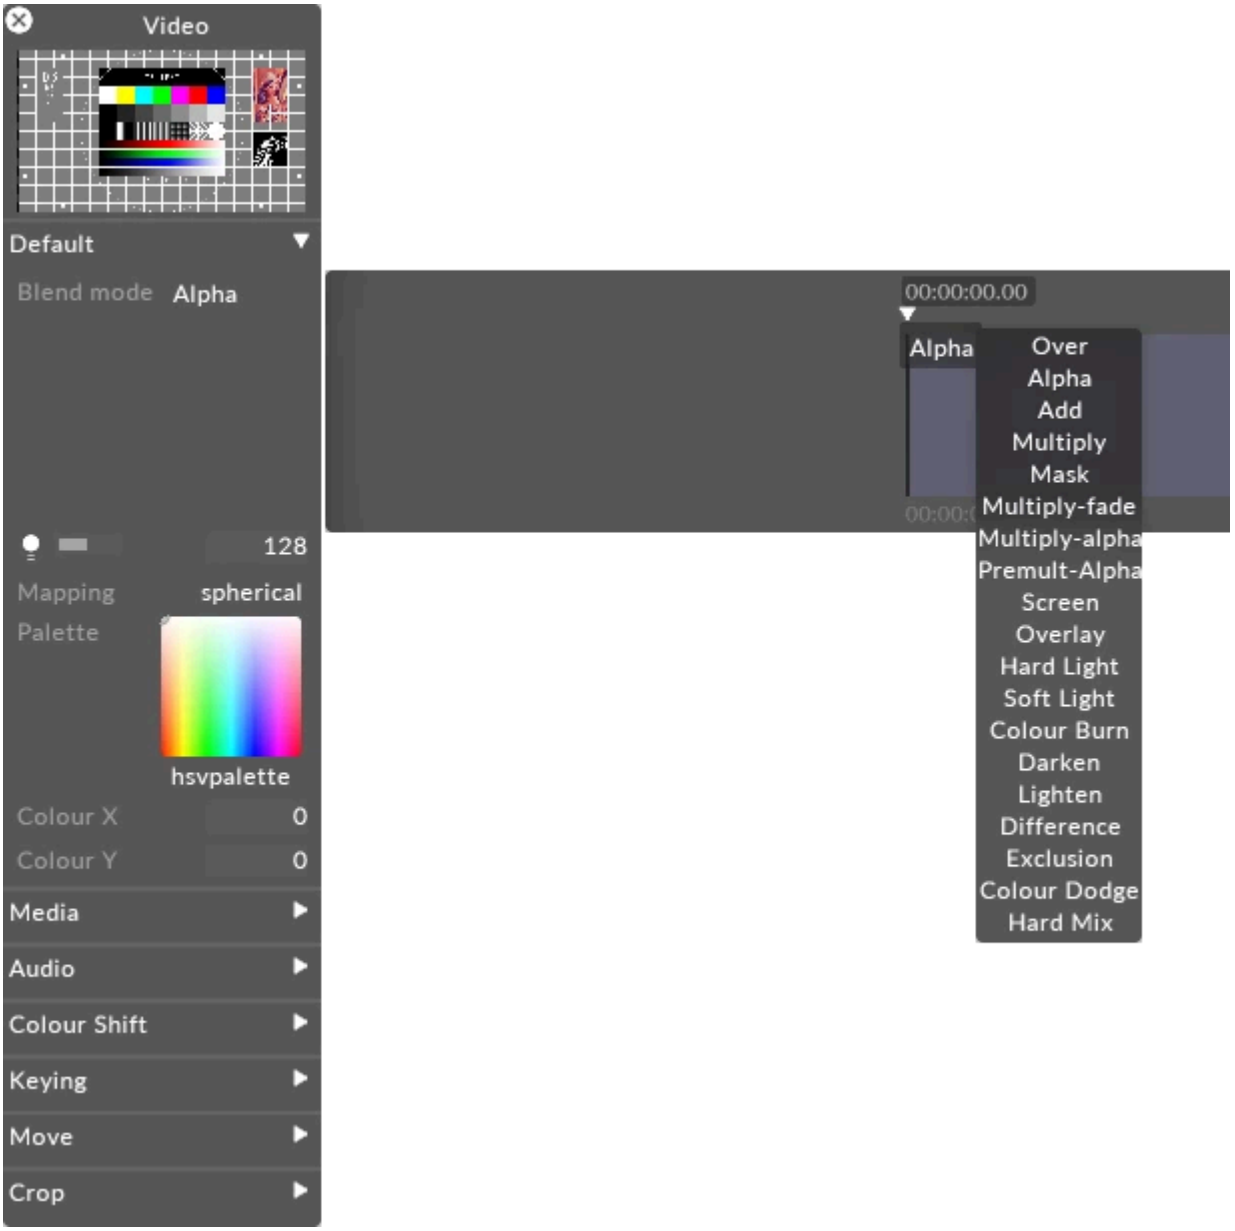
Cropping

Crops left, right, top and bottom of the marker overlay.

Common Layer Properties

Blend Mode

BlendMode controls how the output of the layer is composited with the layers below. Layers are rendered in a bottom-up order: layers at the top can modify the output of the layers below.



Changing brightness of a content layer in Designer is actually controlling the value of the alpha of the layer. Even when displaying a HAP video, the software will composite the layer with a controllable layer of alpha - one per layer.

There are two ways of expressing alpha in an image:

Straight alpha is an alpha channel which functions just like RGB. Alpha acts as a fourth channel of information per pixel which is as independent of the other three as R, G and B are of each other. For example, with straight alpha it is possible to have RGB = 255 (white) and alpha = 0 (fully transparent) on the same pixel. Internally generated content, such as gradient layer, are generated with straight alpha. This is the preferable style of alpha and considering the cleaner method of the two.

Premultiplied alpha takes the alpha and applies it to the values of the RGB channels per pixel. The more transparent something gets with premultiplied alpha, the closer it gets to black - as if the content is sitting on a black table. Premultiplied is the default output of Adobe Photoshop or AfterEffects. The result is our pixel at 255 RGB (full white) with 0 alpha would be calculated as a black pixel in the final image.

Here are explanations of what each individual blend mode will do.

Over

Makes a layer fully opaque. Premultiplies all alpha onto the RGB value of each pixel. Alpha = black, so adjusting the brightness of a layer in Over blend mode makes it darker.

Alpha

Default blend mode. It will apply alpha values as a transparency if the alpha is present. Brightness changes will make the layer more or less transparent.

Add

Adds the value of each RGB pixel together. Always creates a brighter result. Values clamp at 255.

Multiply

Reads the level of each subpixel as a level between 0.0 and 1.0, and multiplies source with blend. The result is always a darker image overall. For example: white x grey = 0.5. White turns transparent, black takes precedence. Alpha is applied in the same fashion as the Over Blend mode.

Mask

Applies a mask to the single layer **above** in the stack, irrespective of mapping. See **Mask blending** for more information.

Luma-Matte

This mode creates a Luma Matte by using a layer's **Rec. 709 luminance** to control the alpha channel of the layer **above**, irrespective of mapping.

To determine transparency, the luminance of each pixel is calculated using a weighted average of its red, green, and blue channels. The luminance value is then used as the alpha (opacity) value for the corresponding pixels in the upper layers.

As a result, white areas render the layer above fully opaque, black areas make them fully transparent, and grey areas create proportional semi-transparency. This is a specialized **Mask** blend mode; for more details on the underlying behaviour, see **Mask blending**.

Inv-Luma-Matte

The Inverse Luma Matte mask works the same as the Luma Matte mask but the transparency is inverted meaning white regions are transparent and black regions are opaque.

Multiply-Fade

The same as Multiply, but will make use of the alpha channel to calculate transparency in the source and blend layers. Since maximum transparency is premultiplied, alpha results in black. This will ignore black created through premultiplying.

Multiply-Alpha

Multiply with straight alpha. This mode assumes that the alpha has not been premultiplied onto the RGB values and will not apply a correction to the semi-transparent pixels.

Premultiply Alpha

Like how Multiply-fade will ignore the darkening caused by premultiplying, this blend mode will do the same with Alpha.

Colour Burn

Blend mode increases the contrast to darken the base colour while reflecting the blend colour. The darker the blend colour, the more intensely the colour will be applied in the base image. White as the blend colour produces no change. Using the colour burn blend mode can produce some harsh results at full opacity. The colour burn blend mode can be used to make tonal and colour adjustments to a layer.

Screen

This blend mode looks at each channels colour information and multiplies the inverse of the blend and base colous. The result is always a lighter colour. Screening with black leaves the colour unchanged. Screening with white produces white. The effect is similar to projecting multiple images on top of each other - where bright white is fully opaque, black is fully transparent and 50% grey is 50% transparent.

Overlay

Multiplies or screens the colours, depending on the base colour. Patterns or colours overlay the existing pixels while preserving the highlights and shadows of the base colour. The base colour is not replaced, but mixed with the blend colour to reflect the lightness or darkness of the original colour.

Hard Light

Multiplies or screens the colours, depending on the blend colour. The effects is similar to shining a harsh spotlight on the image. If the blend colour (light source/top layer) is lighter than

50% grey, the image is lightened as if it were screened. This is useful for adding highlights to an image. If the blend colour is darker than 50% grey, the image is darkened as if it were multiplied. This is useful for adding shadows to an image. Painting with pure black or white results in pure black or white.

Soft Light

Darkens or lightens the colours, depending on the blend colour. The effect is similar to shining a diffused spotlight on the image. If the blend colour (light source/top layer) is lighter than 50% grey, the image is lightened as it if were dodged. If the blend colour is darker than 50% grey, the image is darkened as if it were burned in. Painting with pure black or white produces a distinctly darker or lighter area, but does not result in pure black or white.

Darken

Looks as the colour information in each channel and selects the base or blend colour - whichever is darker - as the result colour. Pixels lighter than the blend colour are replaced and pixels darker than the blend colour do not change.

Lighten

Looks at the colour information in each channel and selects the base or blend colour - whichever is lighter - as the result colour. Pixels darker than the blend colour are replaced and pixels lighter than the blend colour do not change.

Difference

Looks at the colour information in each channel and subtracts either the blend colour from the base colour or the base colour from the blend colour depending on which has the greater brightness value. Blending with white inverts the base colour values and blending with black produces no change.

Exclusion

Creates an effects similar to but lower in contrast than the difference mode. Blending with white inverts the base colour values. Blending with black produces no change.

Colour Dodge

Looks at the colour information in each channel and brightens the base colour to reflect the blend colour by decreasing contrast between the two. Blending with black produces no change.

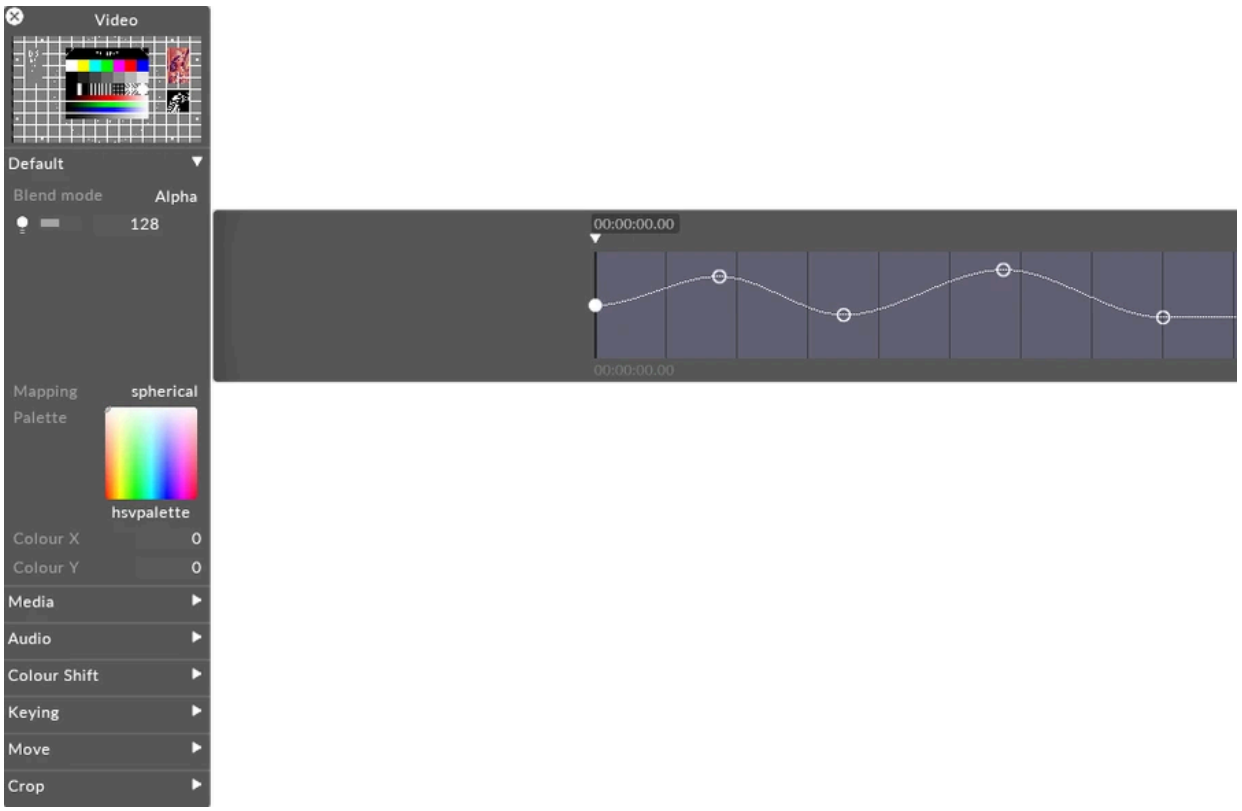
Hard Mix

Adds the RGB channels of the blend colour to the RGB values of the base colour. If the resulting sum for a channel is 255 or greater, it receives a value of 255; if it is less than 255 it

receives a value of 0. Therefore all blended pixels have RGB channels of either 0 or 255. This changes all pixels to primary additive colours (RGB), white or black.

Brightness

This property (which appears as a light bulb icon) controls the brightness of the layer output.



If the layers blend mode is set to Alpha, then reducing the brightness to 0 also reduces the opacity of the layer to 0. This can be useful when you want to dissolve from one layer to the next. In that case, you can place the new layer above the old layer and increase its brightness level.

> **Note**
>
> Layers that are patched to Sockpuppet (DMX, OSC or HTTP) are made Dormant when their brightness is set to 0. This means they will not do any rendering or consume any resources until their brightness is changed to > 0. You can find more information about this here: **Sequencing with Sockpuppet**. Layers without a sockpuppet patch do not behave in this way.

Mapping

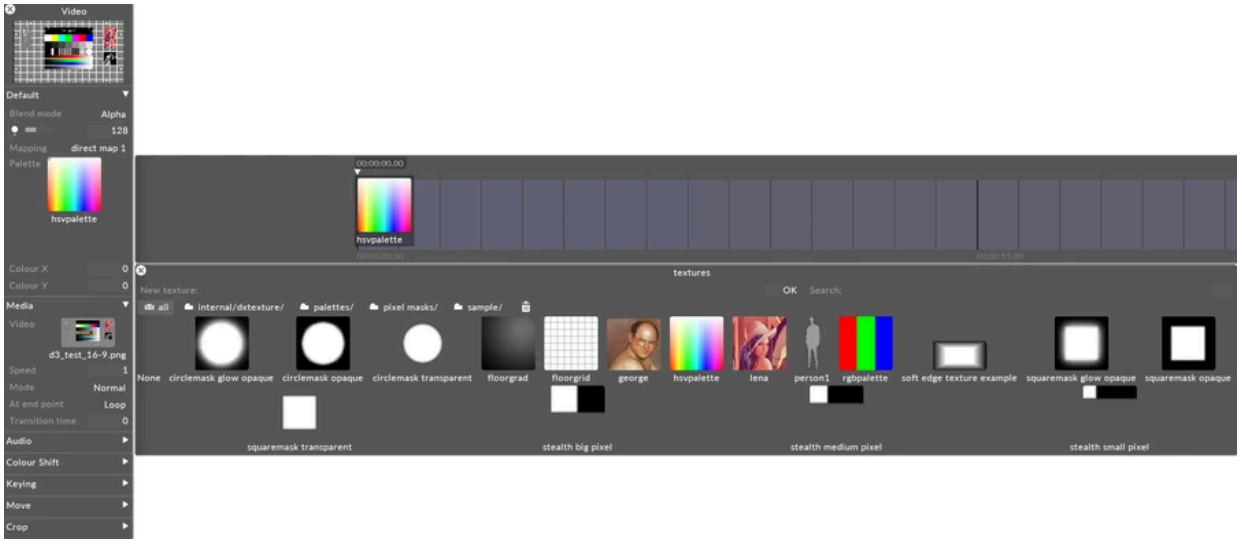
The mapping property controls how the layer output is mapped onto the screen(s) in the Stage level.

For information on mapping, including how to use the different mapping types offered by Designer, please see the chapter **Content Mapping**

Palette

This points to the still image file that defines the bitmap from which the tint colour is taken. The default palette (HSVPAL) consists of the complete range of hues and saturations. Selecting this property will open the Texture object library, which shows all of the still image files saved on your local hard-drive in the **DxTexture** older.

To control the location within the current palette bitmap, and thus control the colour, you have to edit the **xCol** and **yCol** values (see the section for xCol, yCol).



To change the current palette bitmap:

1. Left-click **palette** to open the Texture object library.
2. Left-click the still image file you want to use for the palette bitmap.

If you want to use a palette bitmap other than the standard still images provided in Designer, you will need to use a custom still image file.

See the **Placing media files** for a project sub-chapter to understand where to place a custom still image file and how to access it in Designer. Also save the file to a **supported file format**.

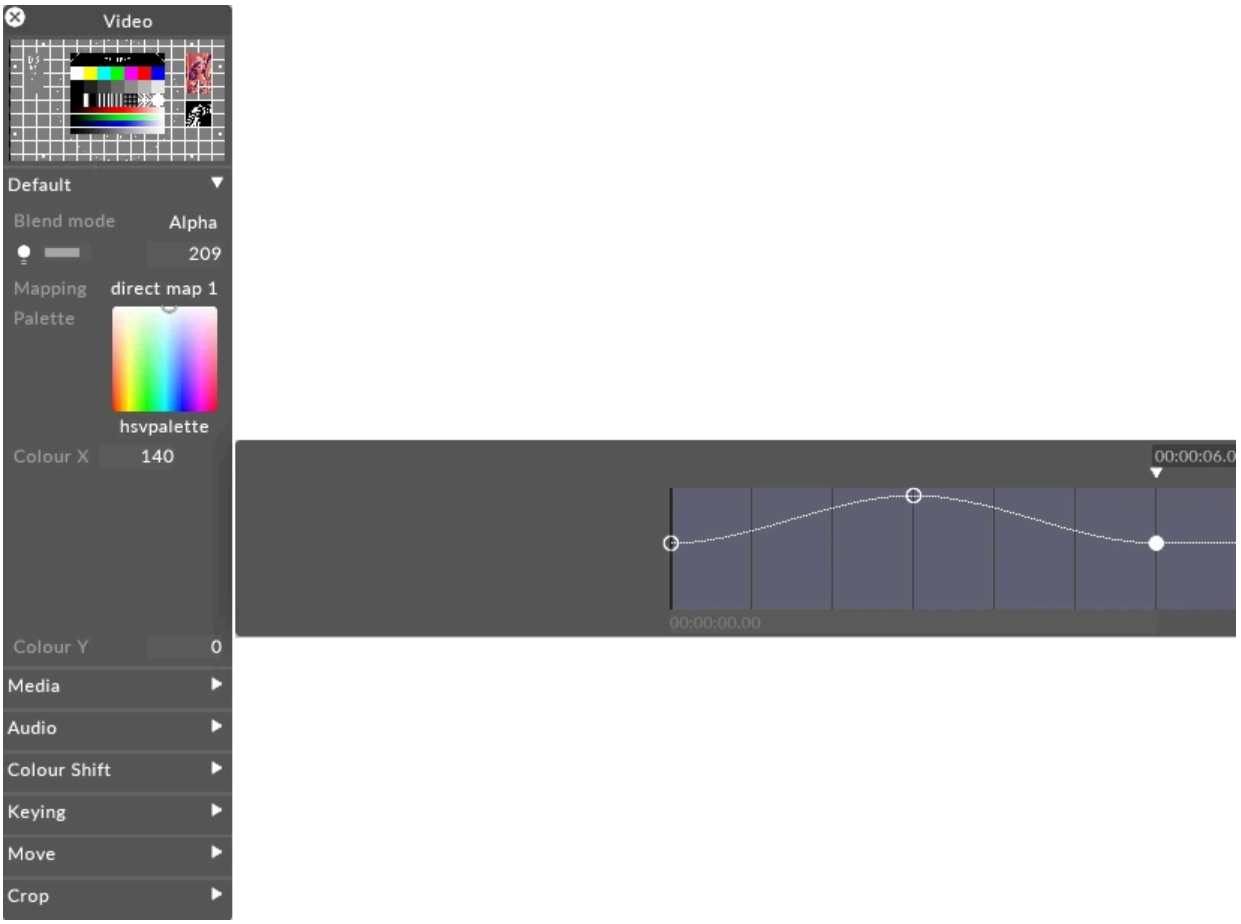
Xcol, YCol

These properties control the coordinates within the current palette bitmap where the output colour is sampled from. The default value is 0,0 which points at the color white (if you are using the HSVPAL palette). Multiplying white with the colors of the chosen content simply generates the original content colors. **Colour X** controls the horizontal position, where 0 is the leftmost

edge and 255 is the rightmost edge. **Colour Y** controls the vertical position, where 0 is the top edge and 255 is the bottom edge.

For example, to saturate the video clip red, change the **Colour Y** value to 255 and use 0 for the **Colour X** value. These coordinates refer to the color red in the palette which is being multiplied with the colors of the existing content.

When you are using the default palette HSVPAL , Colour Y controls saturation, and Colour X controls hue.



Layers Types Index

Designer includes six main layer types:

- Content layers
- Control layers
- Effects layers
- Generative layers
- Legacy layers
- Previsualisation layers

This section provides an overview of each type, explains their functions and features.

For guidance on creating and editing layers, see the working with layers section.

Content layers

The function of content layers is to play back pre-rendered content, map them onto screens and, if needed, apply a number of effects built into the layer.

- 2.5D: Creates parallax scenes from layered image or video plates with depth, bridging 2D video and full 3D workflows.
- Audio: Plays back audio files inside your Designer timeline, routed through Disguise's audio output system.
- Depth Video: Applies a depth-map video directly to a Depth Map Mesh, deforming its geometry in real time based on the content's depth values.
- RenderStream: Used to control third party render engines running externally to Designer.
- RenderStream Local: Used to control third party render engines running locally on a VX or GX range media server.
- StageRender: Renders surfaces assigned to **Frontplate** or **Backplate** render layers from a camera's point of view.
- Video: Plays pre-rendered video files, combining editable colour, effects, optional audio, keying, movement, and cropping functionality, with full timeline control.
- VideoTrigger: Plays pre-rendered video files triggered by a value change (OnReset or OnChange) rather than timeline playback.
- VirtualLineup: Aligns and calibrates camera views for xR stages using virtual tracking and calibration workflows.
- Web: Displays and interacts with HTML-based content or browser-rendered pages inside the Designer timeline.

Control layers

Control layers are technical layers that control other equipment in the show. For example, DVI matrices, switchers or DMX controlled equipment.

- Camera Control: Sends commands to control physical or virtual cameras, such as zoom, focus, or position.
- CameraCutControl: Sequences camera cuts on the timeline with calibrated delay compensation for xR workflows.
- Control: Sends custom serial, Telnet, or UDP commands to third-party devices directly from the timeline.
- DMXLightsControl: Controls DMX lighting fixtures by outputting DMX values.
- DMXShare: Shares and synchronises DMX values between layers or systems.
- ExpressionVariables: Animates or sets numeric variables that drive expressions or dynamic behaviours.
- HTTPControl: Sends HTTP requests (GET/POST/etc.) to trigger actions on web-enabled devices or APIs.
- IndirectionControl: Allows indirections to be sequenced on a timeline.
- MDC: Sends Motion Data Control commands to devices and systems using the MDC protocol.
- MTC: Sends MIDI Timecode to synchronise external devices with Designer.
- MasterBrightness: Sets the brightness level of all displays of a given projection.
- MatrixControl: Sends commands to video or signal routing matrices for switching sources and destinations.
- MidiNote: Sends MIDI note messages to trigger cues or behaviours.
- Open: Controls any property of any object in Designer from the timeline, even if not normally animatable.
- OscControl: Sends OSC messages to OSC-compatible systems and software.
- PlayMode: Changes the project's play state between modes like Play, Play to end of section, Loop section.
- ProjectorControl: Animates projector parameters in the stage, and in turn, those parameters can be output to real projectors.
- TargetObject: Sets the target used by other control layers that need to reference a specific object or device.
- TimecodeMode: Sets the timecode chase mode of the current transport manager to either Default, Force Chase, or Force Ignore.
- TrackJump: Jumps the playhead to a specific cue on a specific track.
- TransportBrightnessLocal: Adjusts the brightness of the current transport manager.
- TransportControl: Sends transport jump commands to a given transport manager.
- TransportVolumeLocal: Adjusts the volume for the current transport manager.

Effect layers

Effect layers can be used to apply visual effects to other layer types such as Video layers.

Input a bitmap, a video or an output from another content layer into Designer effects layers. For example, you can spin, pixelate, blur images or video, or add any effect to other inputs to create a new look.

- Blur: Softens the input image by applying a blur filter with adjustable strength.
- CDL: Applies ASC-CDL colour corrections (Slope, Offset, Power, Saturation) for standardised colour grading across pipelines.
- ChannelRouter: Re-routes colour channels or alpha channels from the input to create customised channel outputs.
- ColourAdjust: Adjusts brightness, contrast, gamma, saturation and other colour characteristics.
- Compose: Combines multiple inputs spatially on a single screen with optional edge blurring for seamless composition.
- EdgeFilter: Detects and highlights edges in the input image for stylised or technical looks.
- Fade: Fades a layer or input in and out over time using timeline-driven parameters.
- FilmicGrain: Adds film-style grain to the input for a textured or cinematic look.
- Kaleidoscope: Applies a kaleidoscope effect by mirroring and repeating the image.
- Lut: Applies a 1D or 3D LUT to recolour the input based on a lookup table.
- MotionBlur: Applies motion-based blur using velocity or temporal sampling to smooth movement.
- OCIO : Applies OpenColorIO (OCIO) colour space transformations to the input, ensuring consistent and standardised colour management (such as ACES) across your display pipeline.
- Noise: Overlays procedural noise for texture, distortion, or stylisation.
- PixelMap: Remaps pixels from one coordinate space to another using a pixel mapping texture.
- Pixelate: Reduces resolution to create a blocky, pixelated appearance.
- Scroll: Moves the input horizontally or vertically for looping or animated motion.
- SpinBitmap: Rotates the input bitmap around a pivot point over time.
- Trigger: Triggers still image content at specific points on your screens.
- UVLookup: Re-maps image pixels using UV coordinates from another texture.
- VideoTransition: Applies transitions (such as wipes, dissolves, or slides) between two video inputs.

Generative layers

Generative layers are packets of algorithms inside Designer that produce visuals based on a number of animatable properties. They share some of the same properties as all the other

layer types such as the Mapping property.

- Bugs: Generates swarming particle-based visuals with animatable motion properties.
- Chevron: Produces repeating angled chevron shapes with controllable colours and speed.
- Colour: Outputs a solid colour that can be animated or mapped like any other layer.
- Gradient: Generates multi-stop gradients with animatable direction and colour values.
- Notch: Plays real-time Notch Blocks for complex graphics, effects, or simulations.
- Radar: Creates radar-style sweeping graphics with rotating arms or pulses.
- RGBColour: Generates RGB colour bars or blocks for testing or stylised visuals.
- Readout: Displays numeric values or data readouts dynamically from variables or inputs.
- Scan: Produces a scanning bar or sweep effect similar to a sensor or line scan.
- Strobe: Generates rapid flashing or strobing patterns based on adjustable timing.
- Tennis: Creates bouncing animated “ball” visuals used mainly for testing and calibration.
- Testpattern: Outputs test pattern grids for calibration and system verification.
- Text: Renders vector text that can be animated, styled, and mapped.
- TrackingMarker: Generates a repeating pattern of tracking markers for xR, calibration, and virtual production workflows.

Legacy layers

Legacy layers remain for backwards compatibility with older projects.

- Bitmap: Displays still images. Still used with precomps, but for general use the Video layer is recommended.
- Legacy Video: Plays pre-rendered video files. Replaced by the modern Video layer.

Previsualisation layers

Previsualisation layers are usually used during the design and pre-production phases of the project when accurate visualisation is required, for example animating screens or creating camera fly-throughs.

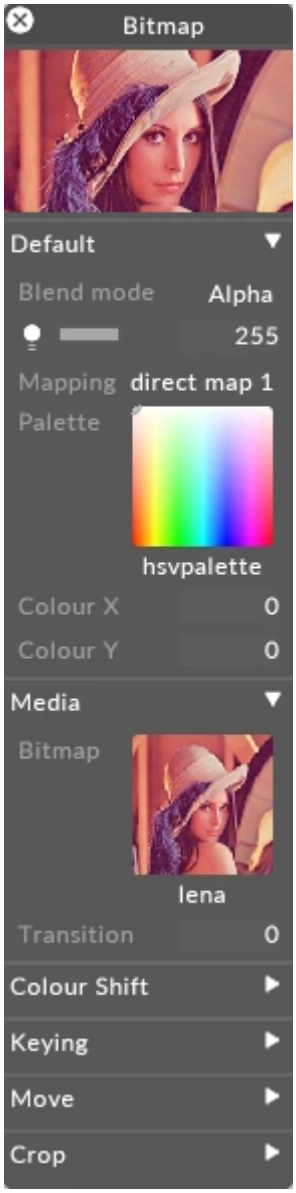
- AnimateCameraPreset: Animates transitions between saved camera presets for previz or fly-throughs.
- AnimateCameraControl: Drives camera movement directly using animatable timeline properties.
- AnimateObjectPreset: Animates transitions between object position/rotation presets.
- SceneAnimation: Plays back imported 3D scene animations (such as Alembic caches), allowing you to sequence stage automation, moving screens, or object movements directly on the timeline.
- TargetControl: Moves a camera or object to track or look at a specific target point.
- TargetPreset: Stores and animates transitions between different target positions.

Bitmap Layer

Using the Bitmap layer is the easiest way to display still images. The Bitmap layer takes over certain properties from the Colour layer and the Legacy Video layer. To see where to place media files in Windows see the Placing media files for a project page. To see what video file formats support see the Supported file formats page.

In release r13 onwards it is recommended to use a video layer for still images. For more information see the Placing media files for a project page.

The Bitmap layer supports the use of Arrows, allowing content layers to be piped into the Bitmap layer. For more information please see the sub-chapter Composing layers using Arrows.



Bitmap Layer Properties

Transition

Determines the crossfade (in seconds) between two adjacent bitmaps placed in the keyframe editor of the Bitmap layer.

Threshold

The threshold of the keying. Colours closer than (threshold) to the key colour become transparent.

Hardness

The hardness of the keying. Lower numbers produce softer edges and higher numbers produce harder edges between transparent and opaque areas.

Key colour rgb

The value of the key colour, 0 255, causing the key colour to become transparent.

Scale mode

Provides mapping options to apply to content of a certain resolution which does not match the resolution of the targeted canvas.

Scale

This controls the size of the image. When set to 1, the image is displayed at its normal size. Increasing the scale increases the size of the image; to display at double size, set **scale** to 2. To halve the image size, set **scale** to 0.5.

Aspect

This controls the aspect ratio of the image. When set to 1, the image is displayed at a 1:1 aspect ratio. Increasing the **aspect** value increases the height of the image in relation to its width.

Position

This controls the horizontal (x) and vertical (y) position of the image. When both are set to 0, the centre of the image is centred in the output canvas. Setting x to 1 moves the center to the left edge of the canvas; setting it to +1 moves the center to the right edge of the canvas. Setting y to 1 moves the center to the top edge of the canvas; setting it to +1 moves the center to the bottom edge of the canvas.

Rotation

This controls the rotation of the bitmap, in degrees.

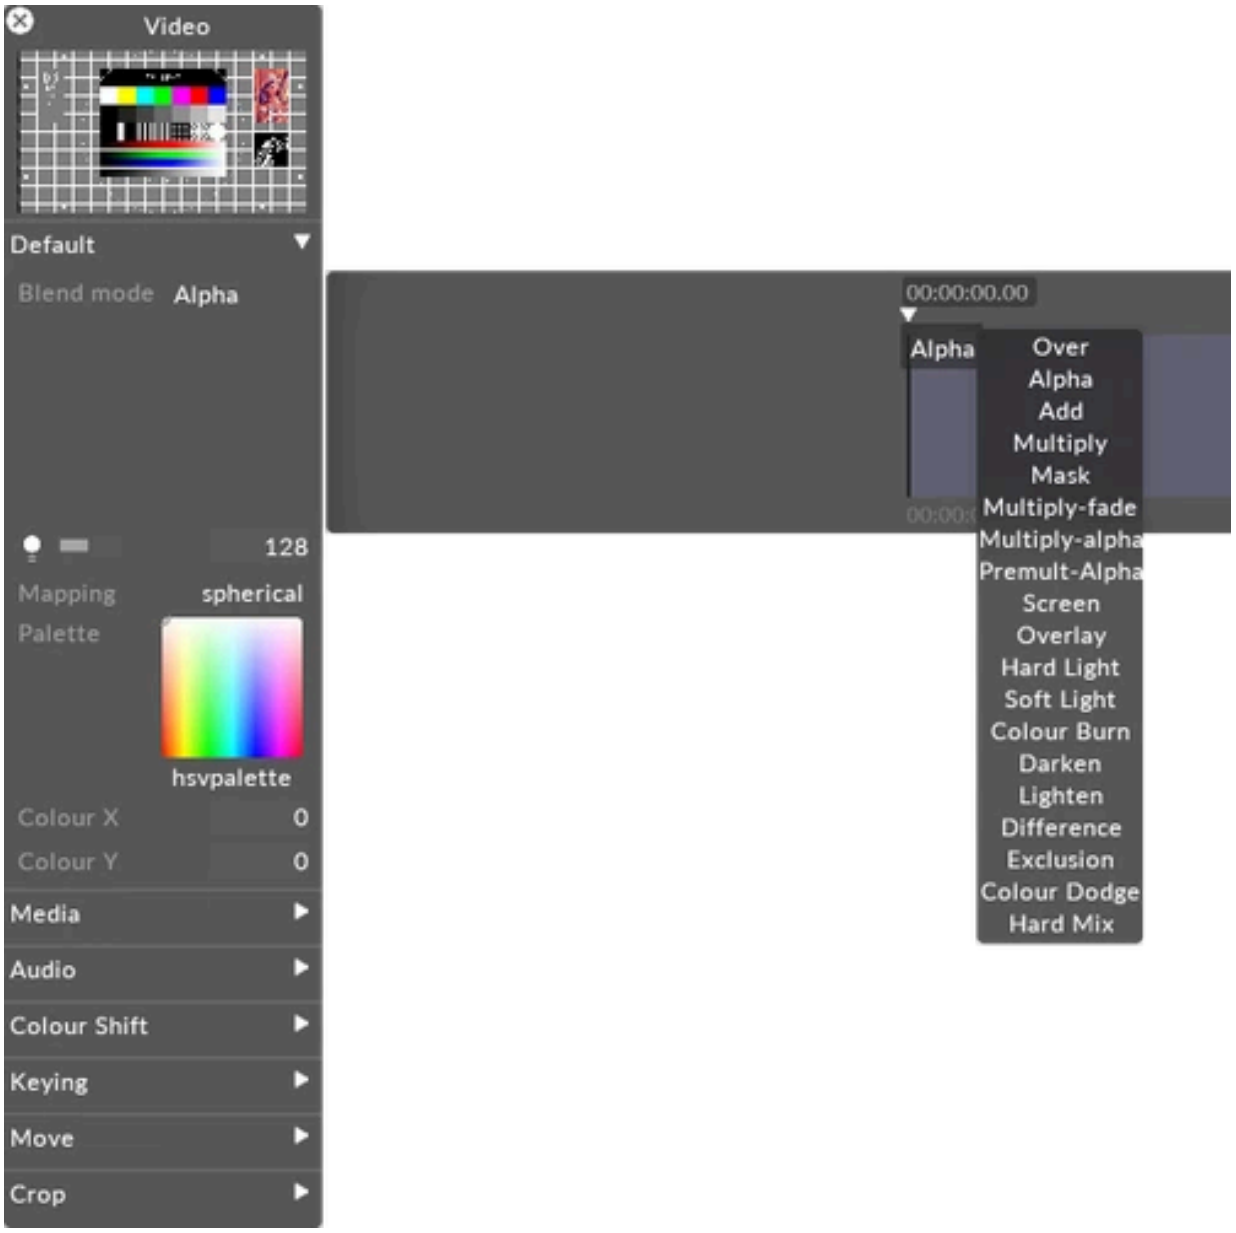
Crop

The **crop** pulldown tab contains a set of properties (**top**, **left**, **bottom**, **right**) that allow you to remove pixels from the edges of the bitmap. Each property specifies the number of pixels you want to remove from the corresponding edge. For example, setting top to 10 will clip 10 pixels off the top edge.

Common Layer Properties

Blend Mode

BlendMode controls how the output of the layer is composited with the layers below. Layers are rendered in a bottom-up order: layers at the top can modify the output of the layers below.



Changing brightness of a content layer in Designer is actually controlling the value of the alpha of the layer. Even when displaying a HAP video, the software will composite the layer with a controllable layer of alpha - one per layer.

There are two ways of expressing alpha in an image:

Straight alpha is an alpha channel which functions just like RGB. Alpha acts as a fourth channel of information per pixel which is as independent of the other three as R, G and B are of each other. For example, with straight alpha it is possible to have RGB = 255 (white) and alpha = 0 (fully transparent) on the same pixel. Internally generated content, such as gradient layer, are generated with straight alpha. This is the preferable style of alpha and considering the cleaner method of the two.

Premultiplied alpha takes the alpha and applies it to the values of the RGB channels per pixel. The more transparent something gets with premultiplied alpha, the closer it gets to black - as if the content is sitting on a black table. Premultiplied is the default output of Adobe Photoshop or AfterEffects. The result is our pixel at 255 RGB (full white) with 0 alpha would be calculated as a black pixel in the final image.

Here are explanations of what each individual blend mode will do.

Over

Makes a layer fully opaque. Premultiplies all alpha onto the RGB value of each pixel. Alpha = black, so adjusting the brightness of a layer in Over blend mode makes it darker.

Alpha

Default blend mode. It will apply alpha values as a transparency if the alpha is present. Brightness changes will make the layer more or less transparent.

Add

Adds the value of each RGB pixel together. Always creates a brighter result. Values clamp at 255.

Multiply

Reads the level of each subpixel as a level between 0.0 and 1.0, and multiplies source with blend. The result is always a darker image overall. For example: white x grey = 0.5. White turns transparent, black takes precedence. Alpha is applied in the same fashion as the Over Blend mode.

Mask

Applies a mask to the single layer **above** in the stack, irrespective of mapping. See **Mask blending** for more information.

Luma-Matte

This mode creates a Luma Matte by using a layer's **Rec. 709 luminance** to control the alpha channel of the layer **above**, irrespective of mapping.

To determine transparency, the luminance of each pixel is calculated using a weighted average of its red, green, and blue channels. The luminance value is then used as the alpha (opacity) value for the corresponding pixels in the upper layers.

As a result, white areas render the layer above fully opaque, black areas make them fully transparent, and grey areas create proportional semi-transparency. This is a specialized **Mask** blend mode; for more details on the underlying behaviour, see **Mask blending**.

Inv-Luma-Matte

The Inverse Luma Matte mask works the same as the **Luma Matte** mask but the transparency is inverted meaning white regions are transparent and black regions are opaque.

Multiply-Fade

The same as Multiply, but will make use of the alpha channel to calculate transparency in the source and blend layers. Since maximum transparency is premultiplied, alpha results in black. This will ignore black created through premultiplying.

Multiply-Alpha

Multiply with straight alpha. This mode assumes that the alpha has not been premultiplied onto the RGB values and will not apply a correction to the semi-transparent pixels.

Premultiply Alpha

Like how Multiply-fade will ignore the darkening caused by premultiplying, this blend mode will do the same with Alpha.

Colour Burn

Blend mode increases the contrast to darken the base colour while reflecting the blend colour. The darker the blend colour, the more intensely the colour will be applied in the base image. White as the blend colour produces no change. Using the colour burn blend mode can produce some harsh results at full opacity. The colour burn blend mode can be used to make tonal and colour adjustments to a layer.

Screen

This blend mode looks at each channels colour information and multiplies the inverse of the blend and base colous. The result is always a lighter colour. Screening with black leaves the colour unchanged. Screening with white produces white. The effect is similar to projecting multiple images on top of each other - where bright white is fully opaque, black is fully transparent and 50% grey is 50% transparent.

Overlay

Multiplies or screens the colours, depending on the base colour. Patterns or colours overlay the existing pixels while preserving the highlights and shadows of the base colour. The base colour is not replaced, but mixed with the blend colour to reflect the lightness or darkness of the original colour.

Hard Light

Multiplies or screens the colours, depending on the blend colour. The effects is similar to shining a harsh spotlight on the image. If the blend colour (light source/top layer) is lighter than 50% grey, the image is lightened as if it were screened. This is useful for adding highlights to an image. If the blend colour is darker than 50% grey, the image is darkened as if it were multiplied. This is useful for adding shadows to an image. Painting with pure black or white results in pure black or white.

Soft Light

Darkens or lightens the colours, depending on the blend colour. The effect is similar to shining a diffused spotlight on the image. If the blend colour (light source/top layer) is lighter than 50% grey, the image is lightened as it if were dodged. If the blend colour is darker than 50% grey, the image is darkened as if it were burned in. Painting with pure black or white produces a distinctly darker or lighter area, but does not result in pure black or white.

Darken

Looks as the colour information in each channel and selects the base or blend colour - whichever is darker - as the result colour. Pixels lighter than the blend colour are replaced and pixels darker than the blend colour do not change.

Lighten

Looks at the colour information in each channel and selects the base or blend colour - whichever is lighter - as the result colour. Pixels darker than the blend colour are replaced and pixels lighter than the blend colour do not change.

Difference

Looks at the colour information in each channel and subtracts either the blend colour from the base colour or the base colour from the blend colour depending on which has the greater brightness value. Blending with white inverts the base colour values and blending with black produces no change.

Exclusion

Creates an effects similar to but lower in contrast than the difference mode. Blending with white inverts the base colour values. Blending with black produces no change.

Colour Dodge

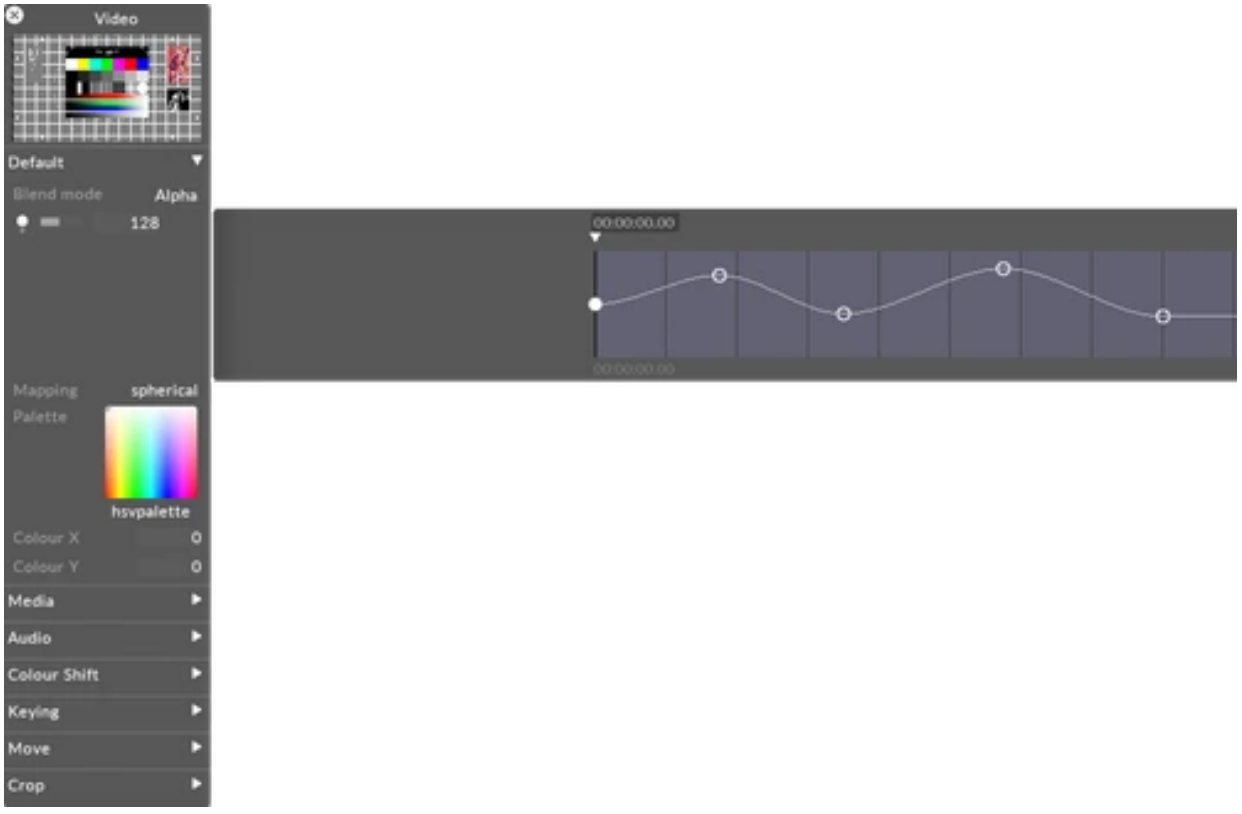
Looks at the colour information in each channel and brightens the base colour to reflect the blend colour by decreasing contrast between the two. Blending with black produces no change.

Hard Mix

Adds the RGB channels of the blend colour to the RGB values of the base colour. If the resulting sum for a channel is 255 or greater, it receives a value of 255; if it is less than 255 it receives a value of 0. Therefore all blended pixels have RGB channels of either 0 or 255. This changes all pixels to primary additive colours (RGB), white or black.

Brightness

This property (which appears as a light bulb icon) controls the brightness of the layer output.



If the layers blend mode is set to Alpha, then reducing the brightness to 0 also reduces the opacity of the layer to 0. This can be useful when you want to dissolve from one layer to the next. In that case, you can place the new layer above the old layer and increase its brightness level.

> **Note**
>
> Layers that are patched to Sockpuppet (DMX, OSC or HTTP) are made Dormant when their brightness is set to 0. This means they will not do any rendering or consume any resources until their brightness is changed to > 0. You can find more information about this here: **Sequencing with Sockpuppet**. Layers without a sockpuppet patch do not behave in this way.

Mapping

The mapping property controls how the layer output is mapped onto the screen(s) in the Stage level.

For information on mapping, including how to use the different mapping types offered by Designer, please see the chapter **Content Mapping**

Palette

This points to the still image file that defines the bitmap from which the tint colour is taken. The default palette (HSVPAL) consists of the complete range of hues and saturations. Selecting this property will open the Texture object library, which shows all of the still image files saved on your local hard-drive in the **DxTexture** older.

To control the location within the current palette bitmap, and thus control the colour, you have to edit the **xCol** and **yCol** values (see the section for xCol, yCol).

To change the current palette bitmap:

1. Left-click **palette** to open the Texture object library.
2. Left-click the still image file you want to use for the palette bitmap.

If you want to use a palette bitmap other than the standard still images provided in Designer, you will need to use a custom still image file.

See the **Placing media files** for a project sub-chapter to understand where to place a custom still image file and how to access it in Designer. Also save the file to a **supported file format**.

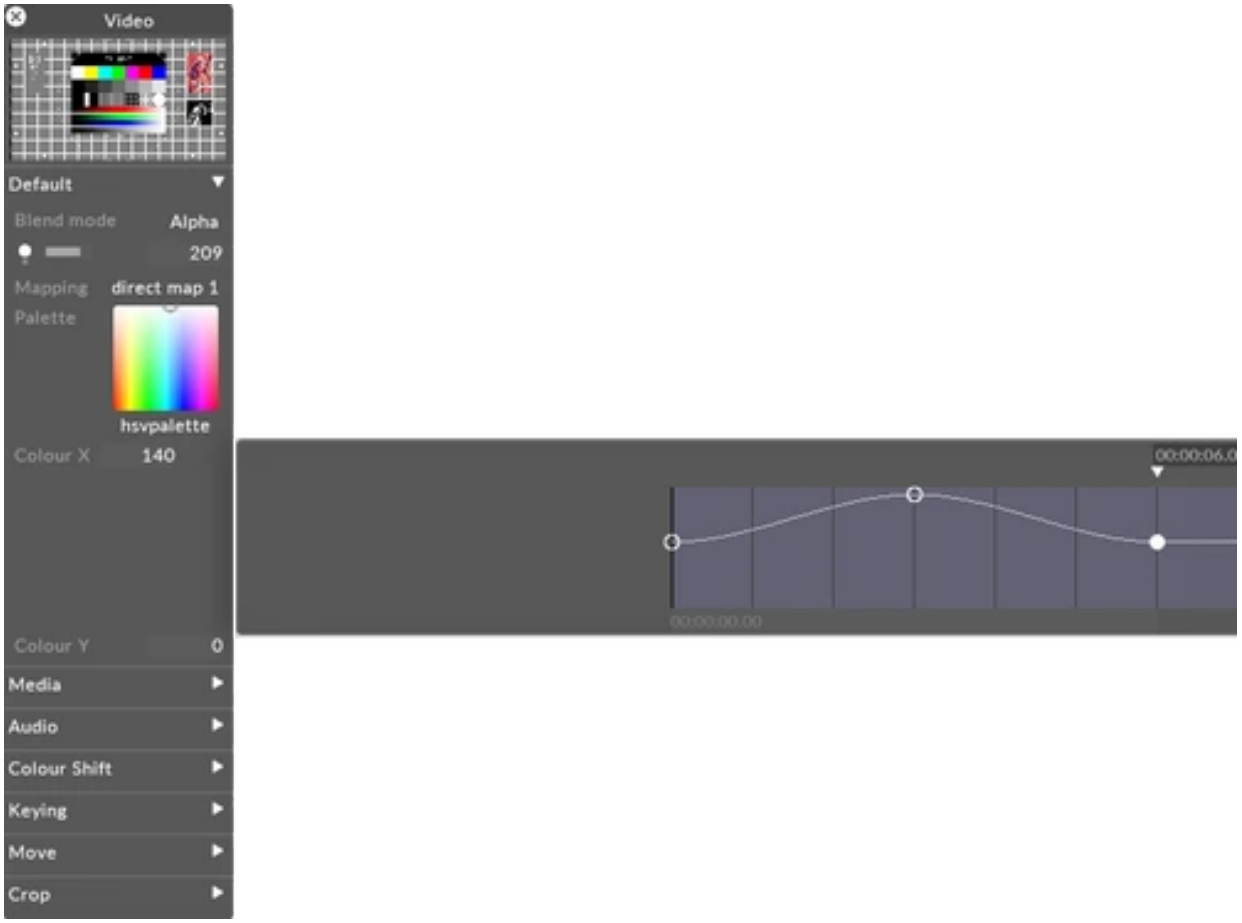
Xcol, YCol

These properties control the coordinates within the current palette bitmap where the output colour is sampled from. The default value is 0,0 which points at the color white (if you are using the HSVPAL palette). Multiplying white with the colors of the chosen content simply generates the original content colors. **Colour X** controls the horizontal position, where 0 is the leftmost edge and 255 is the rightmost edge. **Colour Y** controls the vertical position, where 0 is the top edge and 255 is the bottom edge.

For example, to saturate the video clip red, change the **Colour Y** value to 255 and use 0 for the **Colour X** value. These coordinates refer to the color red in the palette which is being multiplied

with the colors of the existing content.

When you are using the default palette HSVPAL , Colour Y controls saturation, and Colour X controls hue.



ColourShift

The colour shift property allows you to perform a number of colour-correction operations on the output of a layer.

Colour Shift objects can also be attached to individual video files within the Video layer.

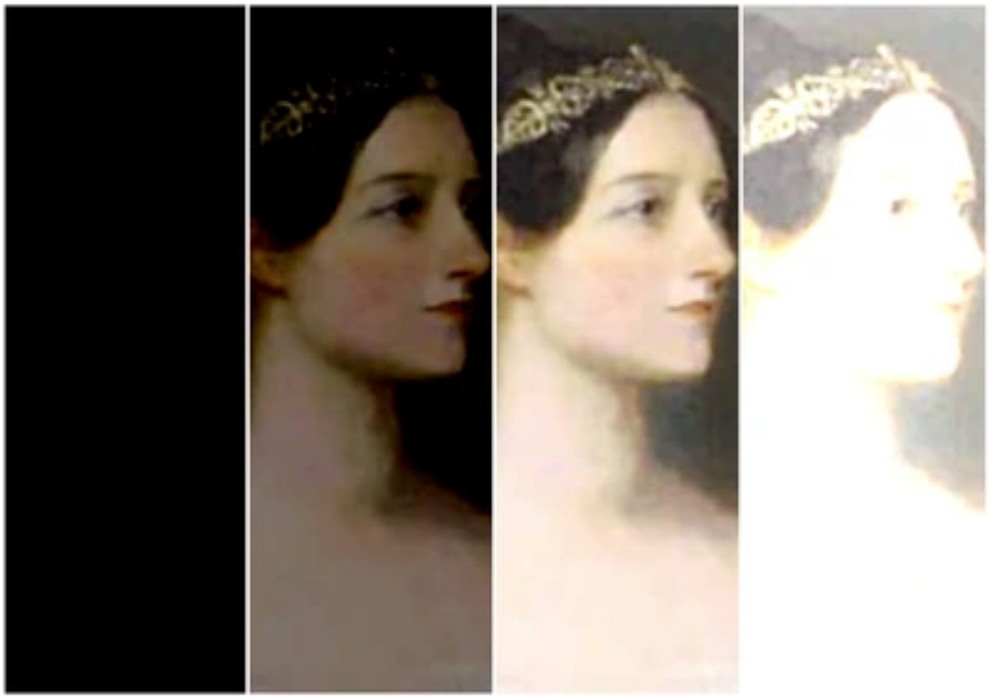
Colour Shift property performs colour-corrections on the output of a visual layer

Colour Shift properties are:

Brightness (shift)

Changes the floor of brightness to the constant given.

When set to 0, the range of brightness is 0 to 1, thus no change is applied to the image. When set to -1, the range of brightness is -1 to 0, thus the entire image is black. When set to 1, the range of brightness is 1 to 2, thus the entire image is white.



Brightness (shift) (from left to right): -1, -0.5, 0, 0.5, 1

Contrast (scale)

When set to 1, no change is applied to the image. When set to 0, all values have been pulled together to 50% grey, thus the image is entirely grey. When set to 2, the values are pulled in the opposite direction to meeting at mid grey, thus resulting in crushed white and black values.

Contrast (scale) (from left to right): 0, 0.5, 1, 1.5, 2

Saturation scale

When set to 1, no change is applied to the image. When set to 0, the image is desaturated to black and white. When set higher than 1, the image is hypersaturated.

Saturation scale (from left to right): 0, 0.5, 1, 2, 4

Hue shift

This property changing the hue of colours in an image, design, or graphic while maintaining other colour properties like saturation and brightness.

RGB controlled

This property controls how the min/max levels and gamma corrections are applied. If set to together, then the min, max and gamma values set for the red channel are mirrored to the green and blue channels, values set on the green and blue channels will be ignored. If set to separate , the min,max and gamma values can be controlled separately for red, green and blue. The latter setting allows you to apply fine colour balance controls to the image.

Min

This sets the lowest brightness level found in the image. All pixels at this level are scaled down to zero brightness. Increasing this value enforces shadows and dark levels in the image and can be used to reduce low-level compression artifacts in an image or video frame.

Increasing min equally across red, green and blue enforces shadows, whereas increasing min on an individual channel has the effect of shifting the colour balance away from that colour. For example, increasing red min shifts the image towards cyan.

With `RGB controlled` *set to Together (from left to right): 0, 0.3, 0.8*

With `RGB controlled` *set to Separate, red min (from left to right): 0, 0.3, 0.8*

Max

This sets the highest brightness level found in the image. All pixels at this level are scaled up to the maximumm level, i.e. 1. Decreasing this value brightens any highlights in the image. This is useful when the source image is too dark.

With `RGB controlled` *set to Together (from left to right): 1, 0.7, 0.2*

With `RGB controlled` *set to Separate, red max (from left to right): 1, 0.7, 0.2*

Tip

If you set min to 255 and max to 0, the image (or single channel) will be inverted.

Invert all (left), invert red (right)

Gamma

When gamma is set to 1, no change is made to the image. Reducing gamma brightens highlights while increasing gamma darkens lowlights. The maximum and minimum brightness levels remain the same.

With `RGB controlled` *set to Together (from left to right): 0.1, 1, 4*

With `RGB controlled` *set to Separate, red gamma (from left to right): 0.1, 1, 4*

Legacy Layers Overview

Legacy layers are available in Designer. These include:

- Bitmap layers
- Legacy Video layers

Legacy Video Layer

The Legacy video layer is used to play pre-rendered Quicktime video files.

To see what video file formats support see the Supported file formats page.

To see where to place media files in Windows see the Placing media files for a project page.

Legacy Video Layer Properties

Media

The Video property points to the still media file that defines the content to be used on the layer. Selecting this property will open the VideoClip object library, which shows all of the still image files saved on your local hard-drive in the VideoFile folder.

To change the current piece of content:

1. Left-click Video to open the VideoClip object library.
2. Left-click the media file you want to use.

Speed

Selects playback speed. When this is set to 1, the video is played at its normal framerate; when set to 2, the video is played at double speed, and so on.

Playback speed is set at the point where the video keyframe is encountered in the video keyframe editor. Once this is set, the playback speed does not change, even if it varies over time. To change the playback speed, drop a speed keyframe at the point where the video thumbnail appears in the video keyframe editor.

Mode

This specifies the playback mode. There are three modes - **Normal**, **Free-Run** and **Locked**.

Each one has a specific behaviour that is useful for a different situation.

Normal

When the play cursor stops, the video will also stop and the frame number will lock to the timeline position. When the cursor continues to play or holds at the end of a section, the video will play continuously. Jumping around the timeline while playing does not affect which frame is being played.

Locked

If the play cursor continues to play or stops at the end of a section, the video frame number locks to the timeline. When the play cursor holds at the end of a section, the video will play continuously.

Freerun

If the play cursor continues to play or stops at the end of a section, the video will play continuously. Jumping around the timeline while the cursor is playing or has stopped does not affect which frame is being played.

At end point

This specifies what happens when playback reaches the end of the video clip. There are three options to choose from:

Loop

When playback reaches the end of the video clip, the clip will loop immediately back to the beginning and will start playing again from there.

Ping-pong

When playback reaches the end of the video clip, the clip will play in reverse back to the beginning.

Pause

When playback reaches the end of the video clip, the clip will pause on the last frame.

Transition time

The transition property specifies the dissolve time, in beats, when switching from one video clip to the next on the timeline. By default, this is set to 0, so the player cuts immediately from one clip to the next. Setting this value to 1 causes the player to dissolve from one clip to the next over 1 beat.

Volume

Some video clips may contain audio. You can fill in any number between 0 (mute) and 255 (full) in the text field to set a constant volume, or open the propertys key-frame editor to fade volume in or out.

Output

If the video has an audio track, this controls which audio output device the audio is played to.

Threshold

The threshold of the keying. Colours closer than (threshold) to the key colour become transparent.

Hardness

The hardness of the keying. Lower numbers produce softer edges and higher numbers produce harder edges between transparent and opaque areas.

Key color RGB

The value of the key colour, 0 255, causing the key colour to become transparent.

Scale

Controls the size of the video.

Aspect

Controls the aspect ration of the video, higher numbers make the frame taller.

Pos x y

Position of the video:

- x = horizontal position
- y = vertical position
- 0 = centre of canvas
- -1 = top edge of canvas
- +1 = bottom edge

Rotation

Rotation (in degrees) of the video.

Crop left, right, top, bottom

Crops the frame from the respective edge. 0 = no crop, 1 = entire frame crop.

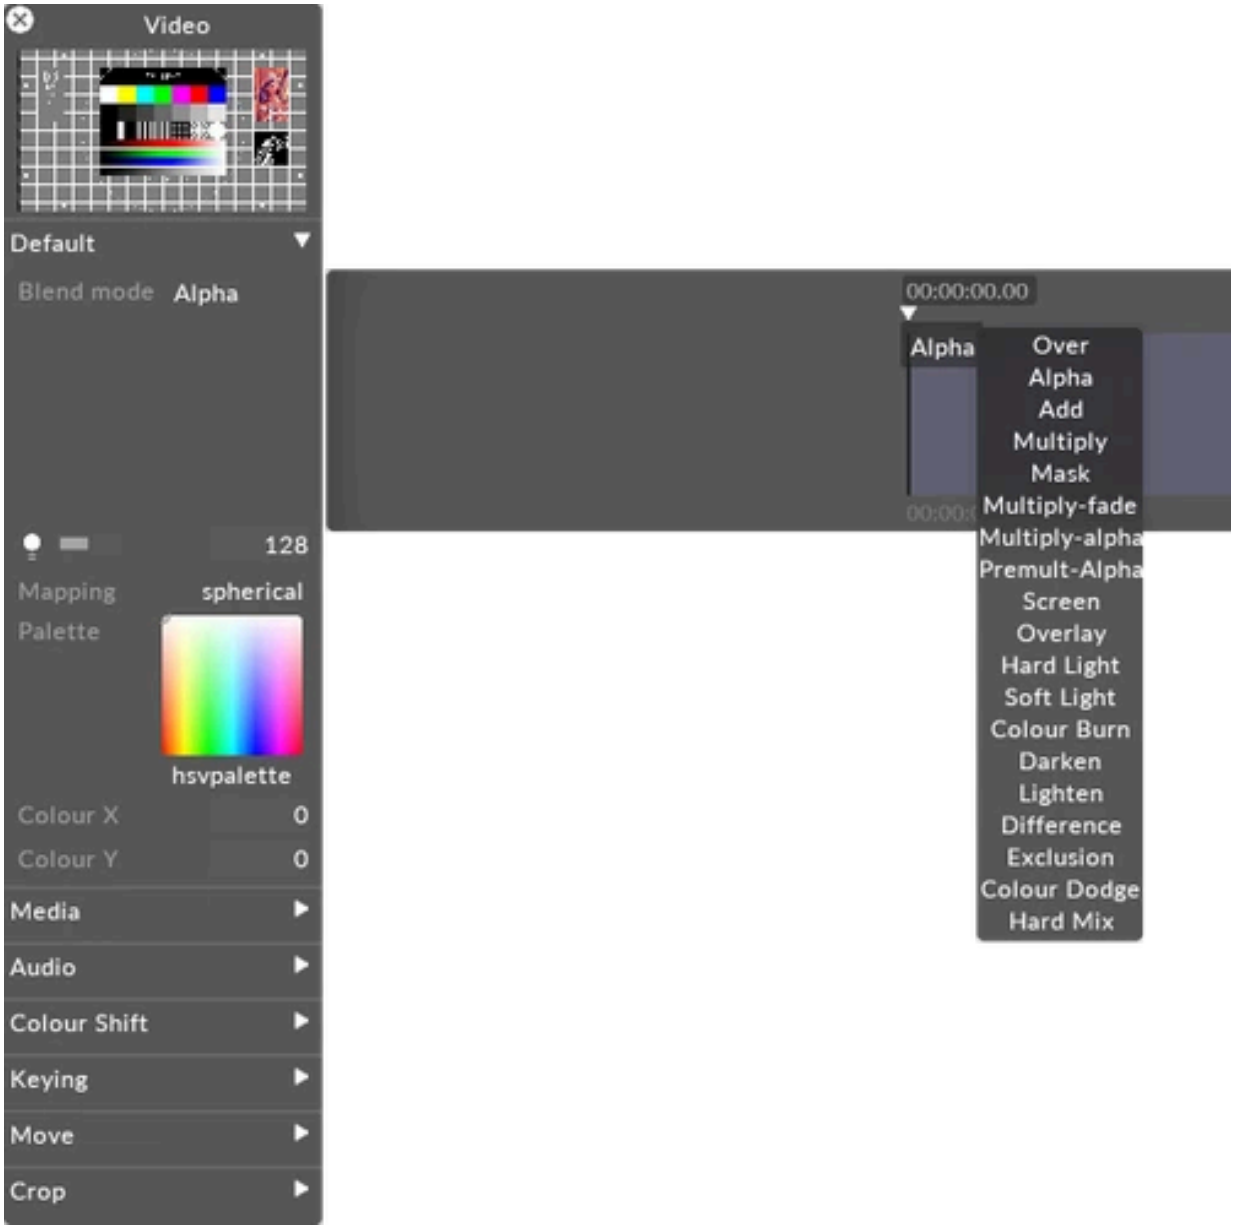
Vignette

Adds a vignette effect by softening the edges of the crop.

Common Layer Properties

Blend Mode

BlendMode controls how the output of the layer is composited with the layers below. Layers are rendered in a bottom-up order: layers at the top can modify the output of the layers below.



Changing brightness of a content layer in Designer is actually controlling the value of the alpha of the layer. Even when displaying a HAP video, the software will composite the layer with a

controllable layer of alpha - one per layer.

There are two ways of expressing alpha in an image:

Straight alpha is an alpha channel which functions just like RGB. Alpha acts as a fourth channel of information per pixel which is as independent of the other three as R, G and B are of each other. For example, with straight alpha it is possible to have RGB = 255 (white) and alpha = 0 (fully transparent) on the same pixel. Internally generated content, such as gradient layer, are generated with straight alpha. This is the preferable style of alpha and considering the cleaner method of the two.

Premultiplied alpha takes the alpha and applies it to the values of the RGB channels per pixel. The more transparent something gets with premultiplied alpha, the closer it gets to black - as if the content is sitting on a black table. Premultiplied is the default output of Adobe Photoshop or AfterEffects. The result is our pixel at 255 RGB (full white) with 0 alpha would be calculated as a black pixel in the final image.

Here are explanations of what each individual blend mode will do.

Over

Makes a layer fully opaque. Premultiplies all alpha onto the RGB value of each pixel. Alpha = black, so adjusting the brightness of a layer in Over blend mode makes it darker.

Alpha

Default blend mode. It will apply alpha values as a transparency if the alpha is present. Brightness changes will make the layer more or less transparent.

Add

Adds the value of each RGB pixel together. Always creates a brighter result. Values clamp at 255.

Multiply

Reads the level of each subpixel as a level between 0.0 and 1.0, and multiplies source with blend. The result is always a darker image overall. For example: white x grey = 0.5. White turns transparent, black takes precedence. Alpha is applied in the same fashion as the Over Blend mode.

Mask

Applies a mask to the single layer **above** in the stack, irrespective of mapping. See **Mask blending** for more information.

Luma-Matte

This mode creates a Luma Matte by using a layer's **Rec. 709 luminance** to control the alpha channel of the layer **above**, irrespective of mapping.

To determine transparency, the luminance of each pixel is calculated using a weighted average of its red, green, and blue channels. The luminance value is then used as the alpha (opacity) value for the corresponding pixels in the upper layers.

As a result, white areas render the layer above fully opaque, black areas make them fully transparent, and grey areas create proportional semi-transparency. This is a specialized **Mask** blend mode; for more details on the underlying behaviour, see **Mask blending**.

Inv-Luma-Matte

The Inverse Luma Matte mask works the same as the **Luma Matte** mask but the transparency is inverted meaning white regions are transparent and black regions are opaque.

Multiply-Fade

The same as Multiply, but will make use of the alpha channel to calculate transparency in the source and blend layers. Since maximum transparency is premultiplied, alpha results in black. This will ignore black created through premultiplying.

Multiply-Alpha

Multiply with straight alpha. This mode assumes that the alpha has not been premultiplied onto the RGB values and will not apply a correction to the semi-transparent pixels.

Premultiply Alpha

Like how Multiply-fade will ignore the darkening caused by premultiplying, this blend mode will do the same with Alpha.

Colour Burn

Blend mode increases the contrast to darken the base colour while reflecting the blend colour. The darker the blend colour, the more intensely the colour will be applied in the base image. White as the blend colour produces no change. Using the colour burn blend mode can produce some harsh results at full opacity. The colour burn blend mode can be used to make tonal and colour adjustments to a layer.

Screen

This blend mode looks at each channels colour information and multiplies the inverse of the blend and base colous. The result is always a lighter colour. Screening with black leaves the colour unchanged. Screening with white produces white. The effect is similar to projecting

multiple images on top of each other - where bright white is fully opaque, black is fully transparent and 50% grey is 50% transparent.

Overlay

Multiplies or screens the colours, depending on the base colour. Patterns or colours overlay the existing pixels while preserving the highlights and shadows of the base colour. The base colour is not replaced, but mixed with the blend colour to reflect the lightness or darkness of the original colour.

Hard Light

Multiplies or screens the colours, depending on the blend colour. The effects is similar to shining a harsh spotlight on the image. If the blend colour (light source/top layer) is lighter than 50% grey, the image is lightened as if it were screened. This is useful for adding highlights to an image. If the blend colour is darker than 50% grey, the image is darkened as if it were multiplied. This is useful for adding shadows to an image. Painting with pure black or white results in pure black or white.

Soft Light

Darkens or lightens the colours, depending on the blend colour. The effect is similar to shining a diffused spotlight on the image. If the blend colour (light source/top layer) is lighter than 50% grey, the image is lightened as it if were dodged. If the blend colour is darker than 50% grey, the image is darkened as if it were burned in. Painting with pure black or white produces a distinctly darker or lighter area, but does not result in pure black or white.

Darken

Looks as the colour information in each channel and selects the base or blend colour - whichever is darker - as the result colour. Pixels lighter than the blend colour are replaced and pixels darker than the blend colour do not change.

Lighten

Looks at the colour information in each channel and selects the base or blend colour - whichever is lighter - as the result colour. Pixels darker than the blend colour are replaced and pixels lighter than the blend colour do not change.

Difference

Looks at the colour information in each channel and subtracts either the blend colour from the base colour or the base colour from the blend colour depending on which has the greater brightness value. Blending with white inverts the base colour values and blending with black produces no change.

Exclusion

Creates an effects similar to but lower in contrast than the difference mode. Blending with white inverts the base colour values. Blending with black produces no change.

Colour Dodge

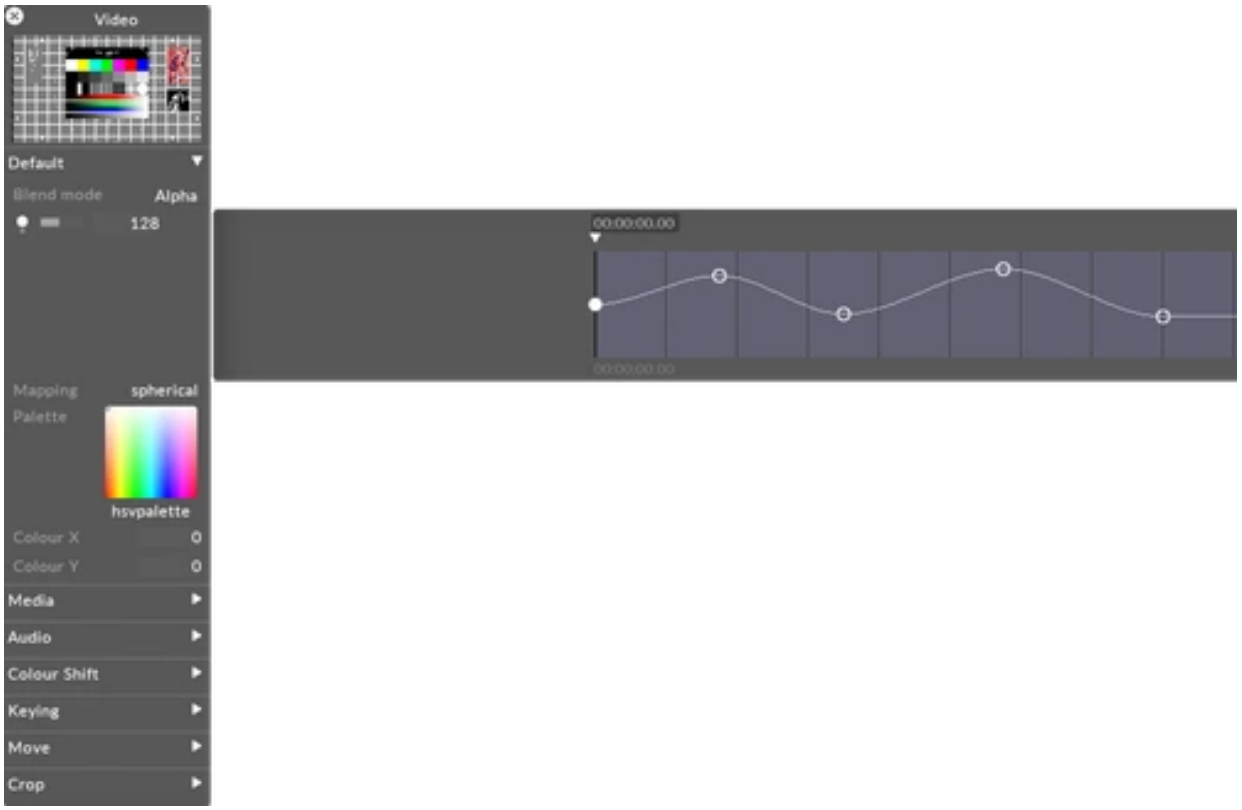
Looks at the colour information in each channel and brightens the base colour to reflect the blend colour by decreasing contrast between the two. Blending with black produces no change.

Hard Mix

Adds the RGB channels of the blend colour to the RGB values of the base colour. If the resulting sum for a channel is 255 or greater, it receives a value of 255; if it is less than 255 it receives a value of 0. Therefore all blended pixels have RGB channels of either 0 or 255. This changes all pixels to primary additive colours (RGB), white or black.

Brightness

This property (which appears as a light bulb icon) controls the brightness of the layer output.



If the layers blend mode is set to Alpha, then reducing the brightness to 0 also reduces the opacity of the layer to 0. This can be useful when you want to dissolve from one layer to the

next. In that case, you can place the new layer above the old layer and increase its brightness level.

> **Note**
>
> Layers that are patched to Sockpuppet (DMX, OSC or HTTP) are made Dormant when their brightness is set to 0. This means they will not do any rendering or consume any resources until their brightness is changed to > 0. You can find more information about this here: **Sequencing with Sockpuppet**. Layers without a sockpuppet patch do not behave in this way.

Mapping

The mapping property controls how the layer output is mapped onto the screen(s) in the Stage level.

For information on mapping, including how to use the different mapping types offered by Designer, please see the chapter **Content Mapping**

Palette

This points to the still image file that defines the bitmap from which the tint colour is taken. The default palette (HSVPAL) consists of the complete range of hues and saturations. Selecting this property will open the Texture object library, which shows all of the still image files saved on your local hard-drive in the **DxTexture** older.

To control the location within the current palette bitmap, and thus control the colour, you have to edit the **xCol** and **yCol** values (see the section for xCol, yCol).

To change the current palette bitmap:

1. Left-click **palette** to open the Texture object library.
2. Left-click the still image file you want to use for the palette bitmap.

If you want to use a palette bitmap other than the standard still images provided in Designer, you will need to use a custom still image file.

See the **Placing media files** for a project sub-chapter to understand where to place a custom still image file and how to access it in Designer. Also save the file to a **supported file format**.

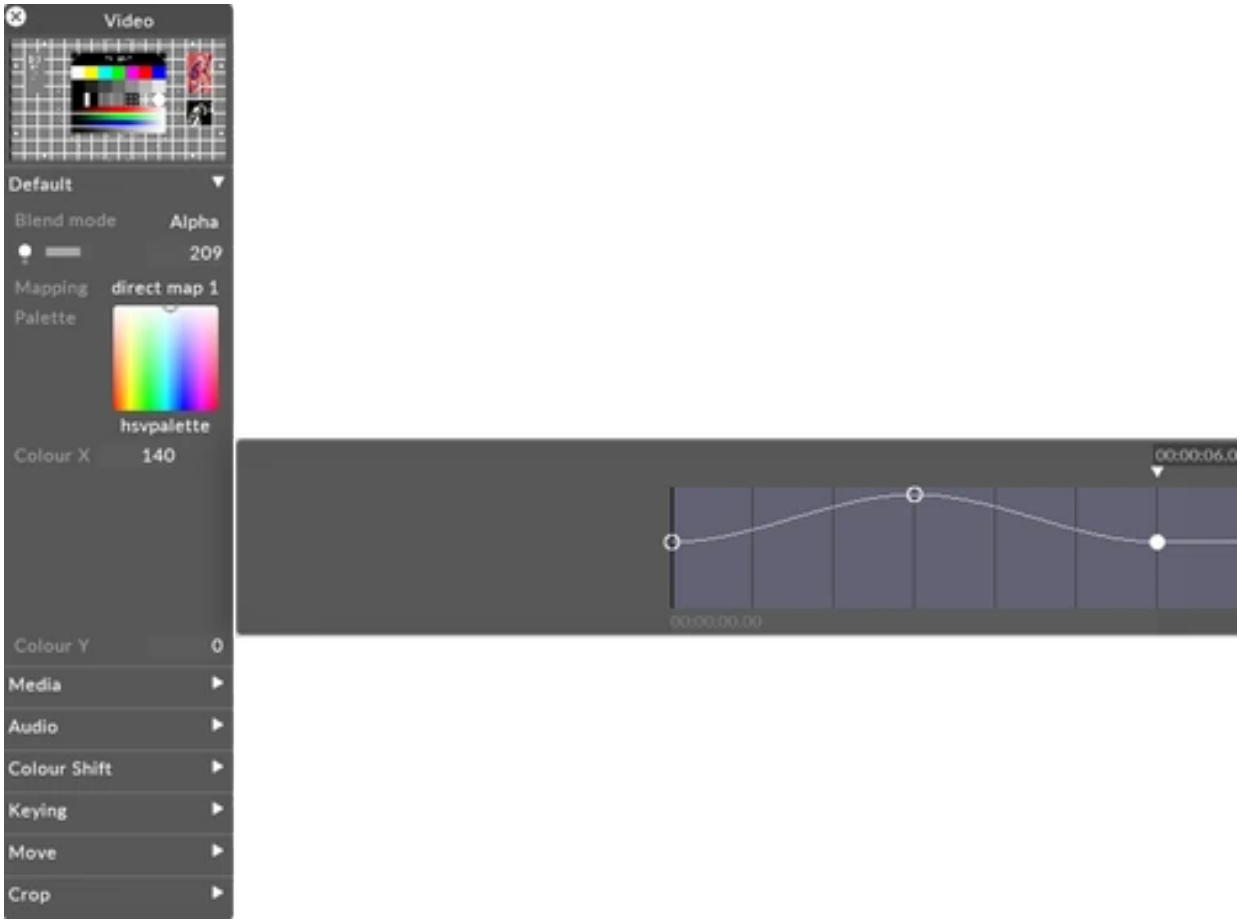
Xcol, YCol

These properties control the coordinates within the current palette bitmap where the output colour is sampled from. The default value is 0,0 which points at the color white (if you are using the HSVPAL palette). Multiplying white with the colors of the chosen content simply generates the original content colors. **Colour X** controls the horizontal position, where 0 is the leftmost edge and 255 is the rightmost edge. **Colour Y** controls the vertical position, where 0 is the top edge and 255 is the bottom edge.

For example, to saturate the video clip red, change the **Colour Y** value to 255 and use 0 for the **Colour X** value. These coordinates refer to the color red in the palette which is being multiplied

with the colors of the existing content.

When you are using the default palette HSVPAL , Colour Y controls saturation, and Colour X controls hue.



ColourShift

The colour shift property allows you to perform a number of colour-correction operations on the output of a layer.

Colour Shift objects can also be attached to individual video files within the Video layer.

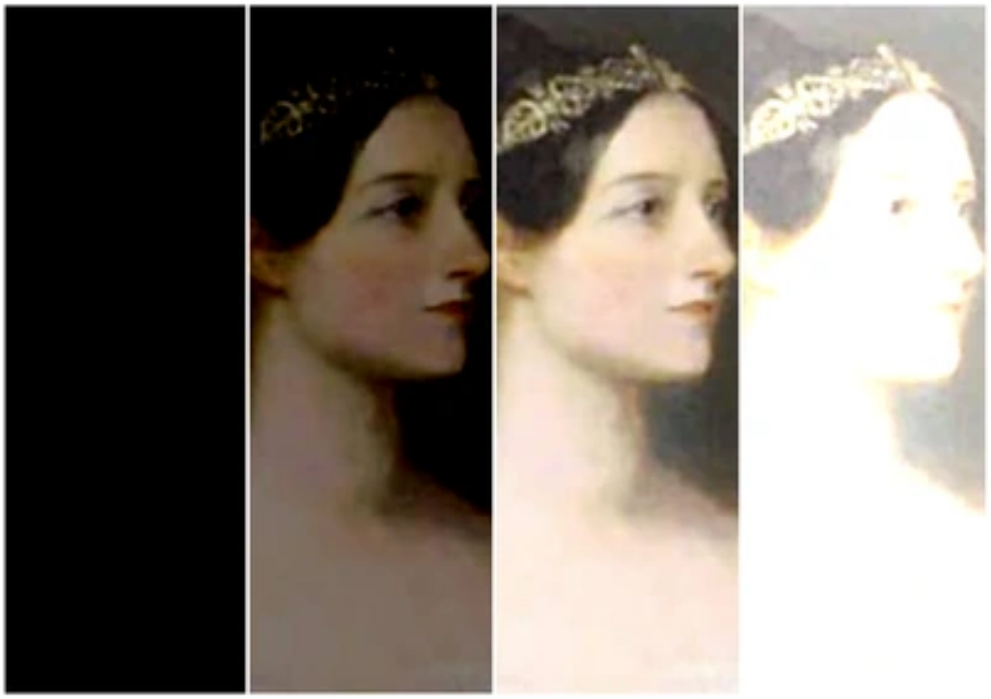
Colour Shift property performs colour-corrections on the output of a visual layer

Colour Shift properties are:

Brightness (shift)

Changes the floor of brightness to the constant given.

When set to 0, the range of brightness is 0 to 1, thus no change is applied to the image. When set to -1, the range of brightness is -1 to 0, thus the entire image is black. When set to 1, the range of brightness is 1 to 2, thus the entire image is white.



Brightness (shift) (from left to right): -1, -0.5, 0, 0.5, 1

Contrast (scale)

When set to 1, no change is applied to the image. When set to 0, all values have been pulled together to 50% grey, thus the image is entirely grey. When set to 2, the values are pulled in the opposite direction to meeting at mid grey, thus resulting in crushed white and black values.

Contrast (scale) (from left to right): 0, 0.5, 1, 1.5, 2

Saturation scale

When set to 1, no change is applied to the image. When set to 0, the image is desaturated to black and white. When set higher than 1, the image is hypersaturated.

Saturation scale (from left to right): 0, 0.5, 1, 2, 4

Hue shift

This property changing the hue of colours in an image, design, or graphic while maintaining other colour properties like saturation and brightness.

RGB controlled

This property controls how the min/max levels and gamma corrections are applied. If set to together, then the min, max and gamma values set for the red channel are mirrored to the green and blue channels, values set on the green and blue channels will be ignored. If set to separate , the min,max and gamma values can be controlled separately for red, green and blue. The latter setting allows you to apply fine colour balance controls to the image.

Min

This sets the lowest brightness level found in the image. All pixels at this level are scaled down to zero brightness. Increasing this value enforces shadows and dark levels in the image and can be used to reduce low-level compression artifacts in an image or video frame.

Increasing min equally across red, green and blue enforces shadows, whereas increasing min on an individual channel has the effect of shifting the colour balance away from that colour. For example, increasing red min shifts the image towards cyan.

With `RGB controlled` *set to Together (from left to right): 0, 0.3, 0.8*

With `RGB controlled` *set to Separate, red min (from left to right): 0, 0.3, 0.8*

Max

This sets the highest brightness level found in the image. All pixels at this level are scaled up to the maximumm level, i.e. 1. Decreasing this value brightens any highlights in the image. This is useful when the source image is too dark.

With `RGB controlled` *set to Together (from left to right): 1, 0.7, 0.2*

With `RGB controlled` *set to Separate, red max (from left to right): 1, 0.7, 0.2*

Tip

If you set min to 255 and max to 0, the image (or single channel) will be inverted.

Invert all (left), invert red (right)

Gamma

When gamma is set to 1, no change is made to the image. Reducing gamma brightens highlights while increasing gamma darkens lowlights. The maximum and minimum brightness levels remain the same.

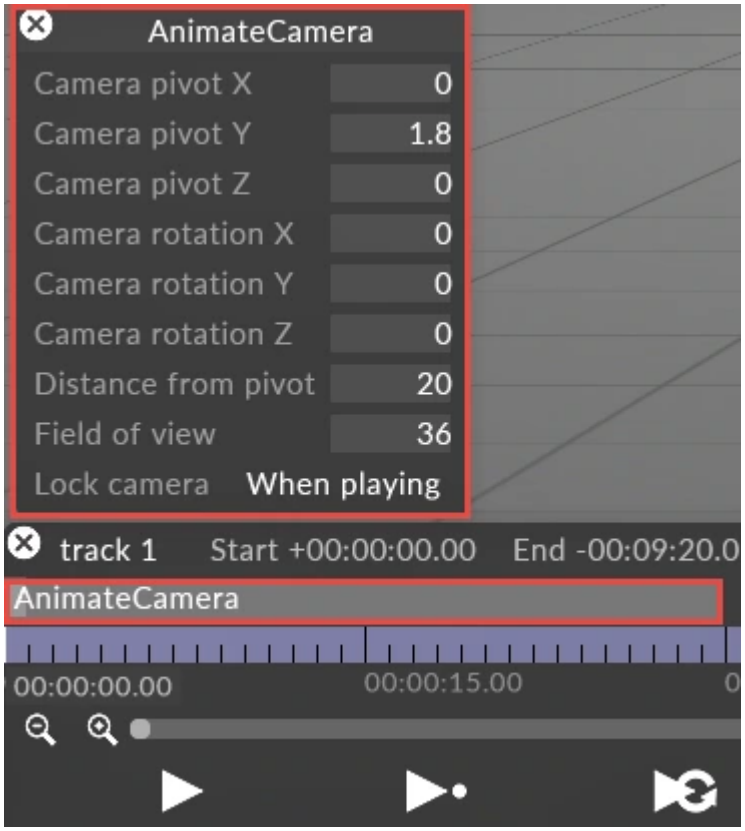
With `RGB controlled` *set to Together (from left to right): 0.1, 1, 4*

With `RGB controlled` *set to Separate, red gamma (from left to right): 0.1, 1, 4*

AnimateCameraControl

This layer allows you to script a fly-through of the stage so that you can create presentation videos, with or without audio.

> **Note**
>
> **Please note** While the Timeline play cursor is under the layers extent, the AnimateCameraControl layer overrides normal Stage navigation. To regain control of the normal Stage navigation, move the play cursor away from under the layer (or move the layer).



> **Note**
>
> **Please note**: AnimateCameraControl layer gives you full control of keyframes but is also more complex and harder to operate than the AnimateCameraPreset layer, which is based on animating between a number of pre-made configurations.

AnimateCamera Layer Properties

Camera pivot

This controls the position of the **pivot** the point where the camera is looking at. This is a 3 dimensional position, i.e. it has x, y and z components. These are all stage space coordinates, expressed in meters.

> **Note**
>
> **Please note**: in most cases the best approach is to have a static pivot point throughout the camera fly-through animation. Set the pivot point to the point of rotation, then animate the other properties. If not, you may get a sliding effect of the camera.

Camera rotation

This controls the rotation of the camera around the pivot point, in degrees around each of the x, y and z axes. Rotation around the x axis is equivalent to elevation, around the y axis is equivalent to heading, and the z axis rotates the camera around its viewing axis.

Distance from pivot

This controls the distance (in meters) from the camera to its pivot point. Increasing this number takes the camera away from the pivot point; decreasing it moves the camera closer to the pivot point.

View angle

A higher view angle will show more of the stage from a given point of view. View angle is measured in degrees.

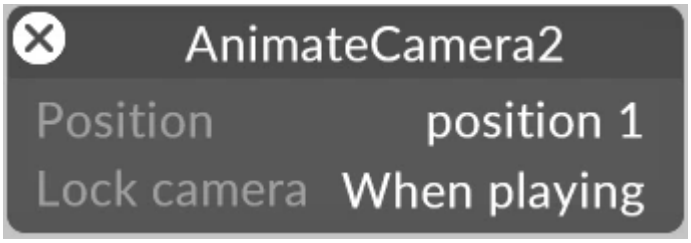
Camera locked

This manipulates how the layer controls the camera.

- Left-click **camera locked** to open the **camera locked** keyframe editor.
- Left-click **always** to open the option properties.
- Left-click **when playing** to set the layer so that it only controls the camera when the keyframe editor is playing, allowing you to move freely when the keyframe editor stops.
- Left-click **always** to set the layer so that it always control the camera.

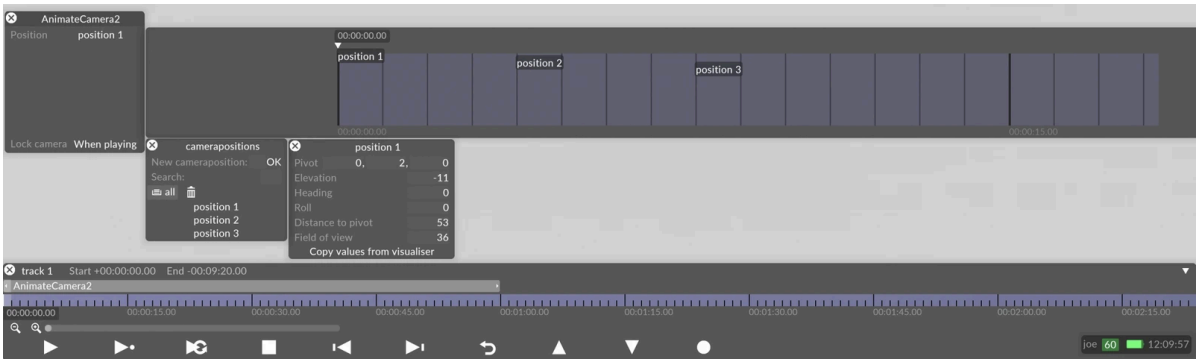
AnimateCameraPreset

The AnimateCameraPreset layer lets you create a camera fly through using a number of configurations which can be dropped onto the timeline. Designer will then animate the camera between the configurations.



Creating a camera position animation

1. Left-click **position**. This will open the **position** keyframe editor and a window where you can create a new camera position.
2. Left-click **new cameraposition** to highlight the text field.
3. Type in the name of your new camera, for example **east**.
4. Hit **Enter**. This will create the new camera position, add it to the **position** key-frame editor at the position of the currently selected Track bar, and open the Camera Position editor. The camera position key-frames can also be click-dragged from the Camerapositions manager to a specified point on the Position key-frame editor.



Process used to create a camera position, in this example position 1, and place it on the Position key-frame editor

5. Edit the values within the Camera Position editor (properties explained below).
6. Repeat the steps listed above to create as many new camera positions as required.
7. Hit **Shift** and **<** to jump to the first second of the track.
8. Hit **Enter** to trigger normal play mode and watch the camera animation.

Position

This property lets you create a new configuration of cameras you want to animate. Please see the section below **Creating a camera position animation** for step-by-step instructions on how to do this.

Camera locked

This manipulates how the layer controls the camera.

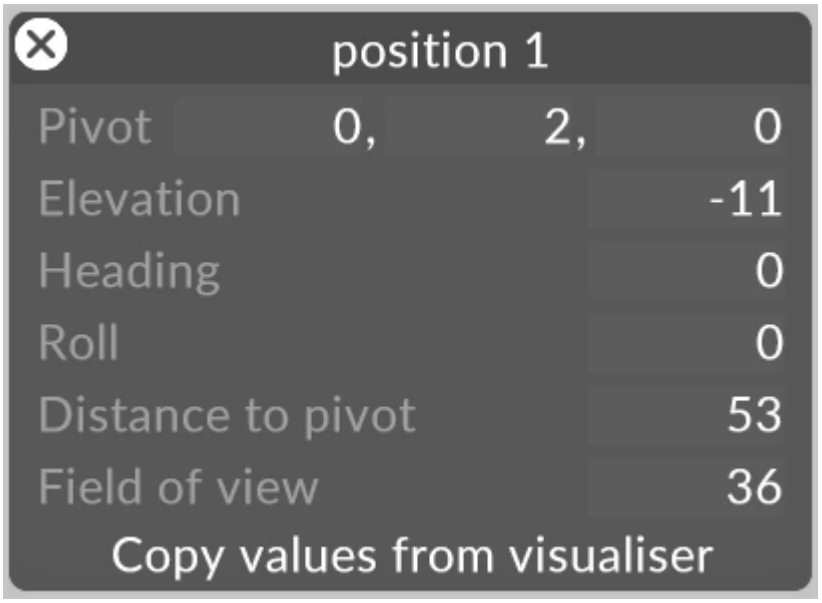
- Left-click **camera locked** to open the **camera locked** keyframe editor.
- Left-click **always** to open the option properties.
- Left-click **when playing** to set the layer so that it only controls the camera when the keyframe editor is playing, allowing you to move freely when the keyframe editor stops.
- Left-click **always** to set the layer so that it always control the camera.

As demonstrated above, you need to use the Camera Position editor as part of the process to animate a camera position.

Camera Position Properties

To open the Camera Position editor

Right-click a camera position in the Camerapositions manager.



Pivot

This controls the position of the pivot the point where the camera is looking at. This is a 3 dimensional position, i.e. it has components x, y and z; all are stage space coordinates, expressed in meters.

> **Note**
>
> **Please note**: in most cases the best approach is to have a static pivot point throughout the camera fly-through animation. Set the pivot point to the point of rotation, then animate the other properties. If not, you may get a sliding effect of the camera.

Elevation

This rotates the camera up and down and is expressed in degrees. Note that the Elevation value is based around the cameras pivot point.

Heading

This rotates the camera left and right, in degrees. Note that the Heading value is based around the cameras pivot point.

Roll

This rotates the camera around its own z-axis, in degrees.

Distance to pivot

This moves the camera closer to or further away from its pivot point, in meters.

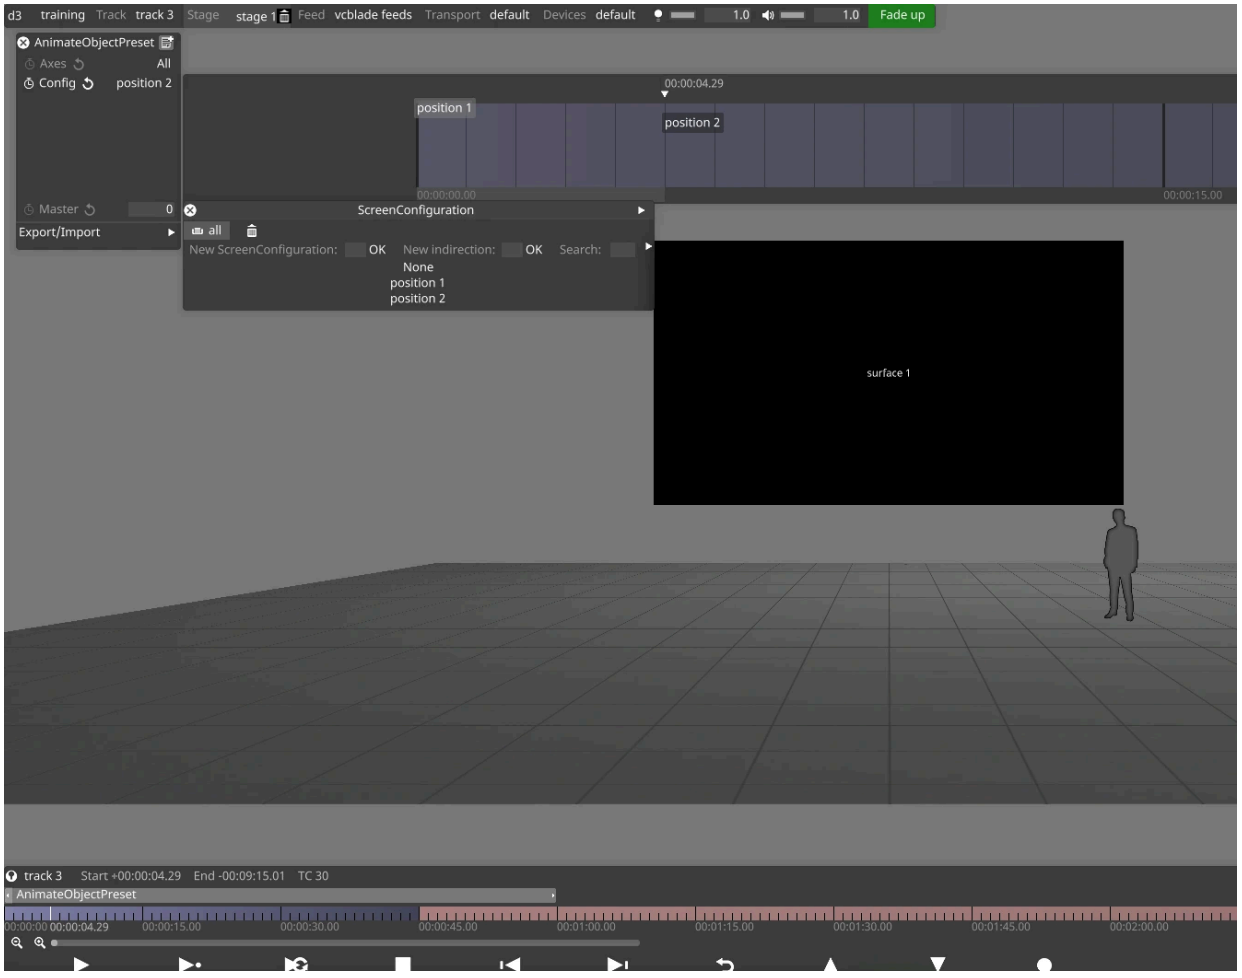
View angle

A higher view angle will show more of the stage from a given point of view. View angle is measured in degrees.

AnimateObjectPreset Layer

The AnimateObjectPreset layer allows you to simulate moving objects such as screens within the Stage Visualiser by placing key-frames onto the key-frame editor. Designer will then animate the object(s) between the configuration key-frame positions.

> **Note**
>
> **Please note**: Disguise does not output control instructions to automation systems. The AnimateObjectPreset layer is for previsualisation purposes only.



Workflow

1. Create an AnimateObjectPrese layer.
2. Create Position configurations.

3. Add screens or objects to the configurations.
4. Configure the properties of the configurations.
5. Playback the configuration keyframes on the keyframe editor timeline to animate objects around the stage.

Creating a animation

1. Create an AnimateObjectPrese layer and assign a mapping type that contains all of the screen or objects that you want to control. For information on mapping types please see the chapter Content Mapping.
2. Open the Config key-frame editor by left-clicking the keyframe editor icon next to **Config**, then create and place a Configuration keyframe. The process used to create/sequence Configuration keyframes is the same as any other layer type that uses keyframe editors, for example the AnimateCameraPreset.
3. Use the Configuration editor to edit the position of the screen or object.
4. Create as many Configuration key-frames as required and place these on the Config keyframe editor. Once all keyframes have been placed on the keyframe timeline, press the Play button and will animate the screen or objects between the Configuration keyframe positions.

Axes

There are five options to choose from:

All: this affects the properties **position**, **rotation** and **animate**.

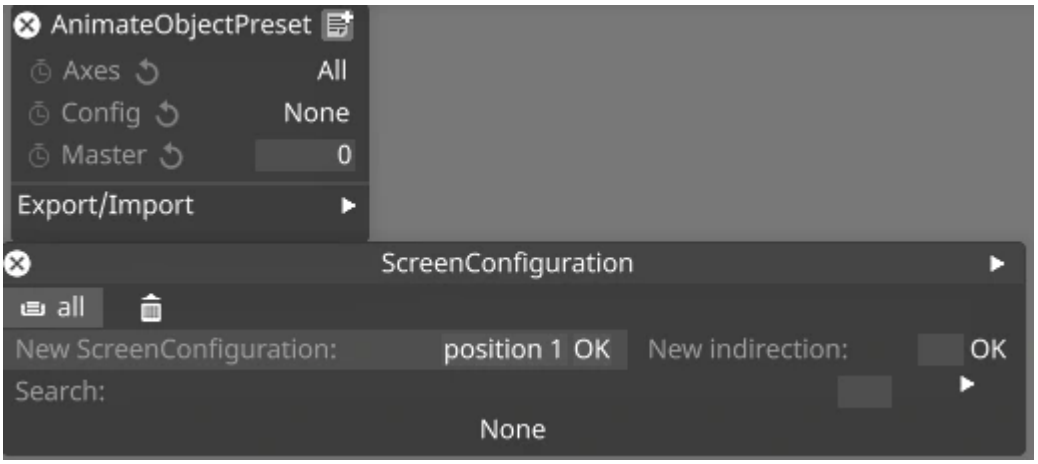
Position only: this affects only the **position** property.

Rotation only: this affects only the **rotation** property.

Animate only: this affects only the **animation** property of the screen type **Moving mesh** which is currently not in an official release.

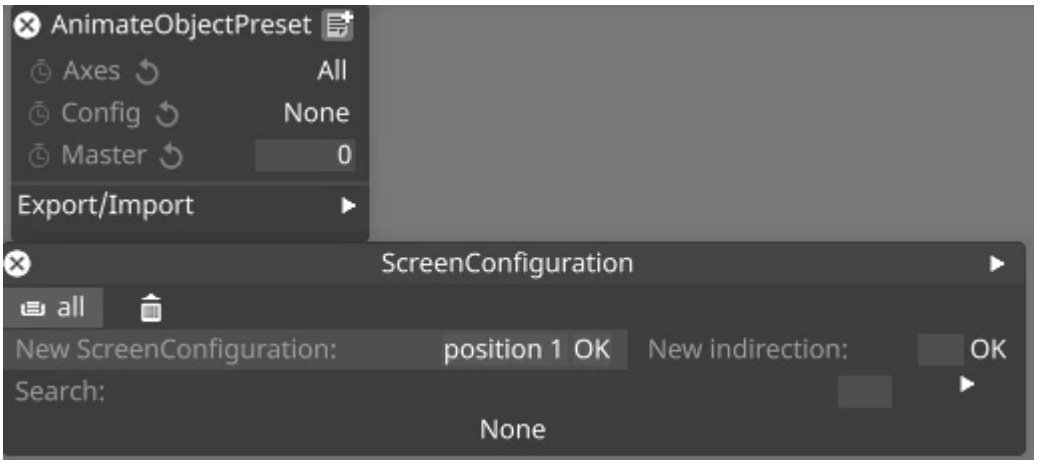
Position and rotation: this affects only the **position** and **rotation** properties.

Config



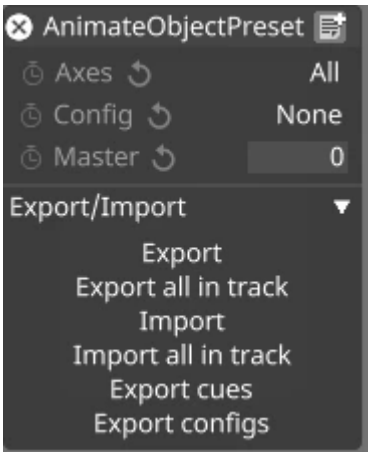
This property lets you create a new configuration of screens or object that you want to animate.

Master



The **Master** property allows you to exert fine control of the movement speed between configuration positions. By default, Designer generates a linear animation between configuration points. However, if there are any keyframes on the master timeline between the configuration endpoints, Designer will use the master curve to animate between the endpoints.

Export/Import



There are six options to choose from:

Export: makes a list of time based positions of screens when they change. This list is saved as a **.txt** file called **screenpos_yourlayername**.

Export all in track: Export all points from the track.

Import: Imports all previously exported points.

Import all in track: Imports all points for a specific track.

Export cues: makes a time list of when specific configuration names are key-framed. This list is saved as a **.txt** file called **screencues_yourlayername**.

Export configs: makes a list of configurations. This list is saved as a **.txt** file called **screenconfigs_yourlayername**.

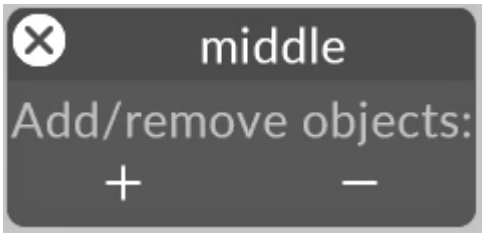
The **.txt** files are saved in a new folder called **table** inside the specific Project folder. For more information on where the specific Project folder is located please see the sub-chapter Projects location. You can open the **.txt** file with Microsoft Excel or Office.

> **Note**
>
> **Please note**: when using the layer import properties make sure your layer names and object names have no spaces or characters such as dashes or slashes etc otherwise the layers and screens will not import.

You need to use the Configuration editor as part of the process to animate a screen or object.

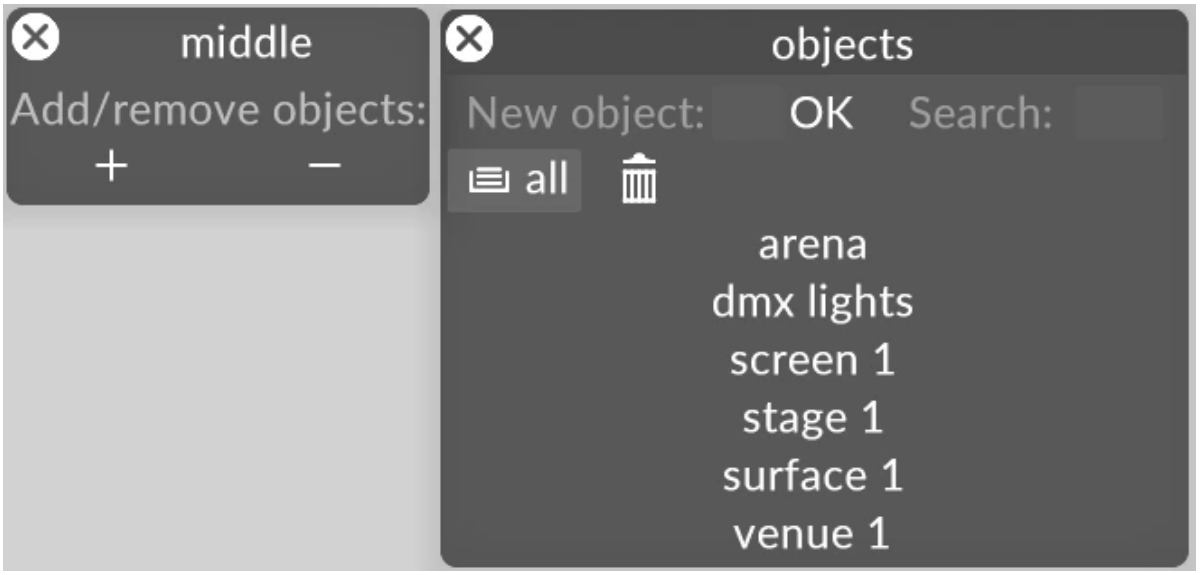
To open the Configuration editor

- Right-click a configuration from the Configurations manager

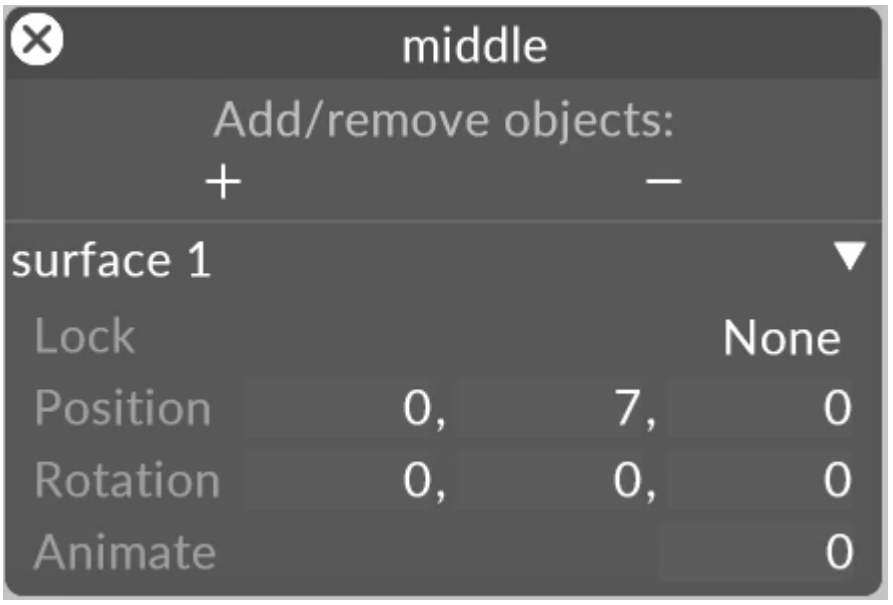


Add / Remove Screens or objects

1. To add a screen to the Configuration editor left-click the **+** button. This will open the Objects list manager.



2. Left-click the object you want to add, in this example Surface 1. This will add Surface 1 to the Configuration editor.



3. Edit the Configuration editors **position** or **rotation** properties.
4. To remove a screen from the Configuration editor left-click the button and select the corresponding screen from the Objects manager.

Position

This controls the object's **position** in the 3D space. There are three numbers laid out horizontally: respectively the x (left/right), y (up/down) and z (into/out of the screen) coordinates.

Rotation

This controls the **rotation** of the object, in degrees. The x component controls the rotation around the x axis; the y component around the y axis; and the z component around the z axis.

Animate

This property is used to control the animation of a 3D object such as an Alembic File.

Previsualisation Layers Overview

Previsualisation Layers allow virtual objects within the Stage view to be animated via keyframes.

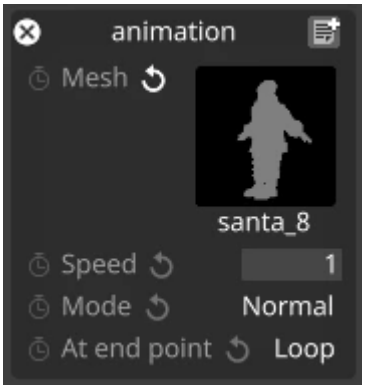
Types of Previsualisation layers

There are several types of Previsualisation layers available within :

- AnimateCameraPreset
- AnimateCameraControl
- AnimateObjectPreset
- SceneAnimation
- TargetControl
- TargetPreset

Scene Animation Layer

The SceneAnimation layer allows an animated Alembic or FBX scene to be controlled from the timeline. Animations are played back from the start of the layer, with similar controls to the video layer.



Controlling a scene animation

1. Add an animated Alembic or FBX file to the project's `objects/Mesh` folder.
2. Assign the mesh to a screen or other object you wish to animate.
3. Add a SceneAnimation layer at the point on the timeline where you wish the animation to play back.
4. Adjust the playback using the properties described below.

SceneAnimation layer properties

Speed

Selects playback speed. When this is set to 1, the animation is played at its normal speed; when set to 2, the animation is played at double speed, when set to -1, the animation is played at normal speed in reverse and so on.

Mode

This specifies the playback mode. There are two modes - **Normal** and **Locked**. Each one has a specific behaviour that is useful for a different situation:

- **Normal**: When the play cursor stops, the animation will also stop and the animation time will lock to the timeline position. When the cursor continues to play or holds at the end of a section, the animation will play continuously. Jumping around the timeline while playing does not affect which animation time is being played.

- **Locked**: If the play cursor continues to play or stops at the end of a section, the animation time is locked to the playhead position on the timeline.

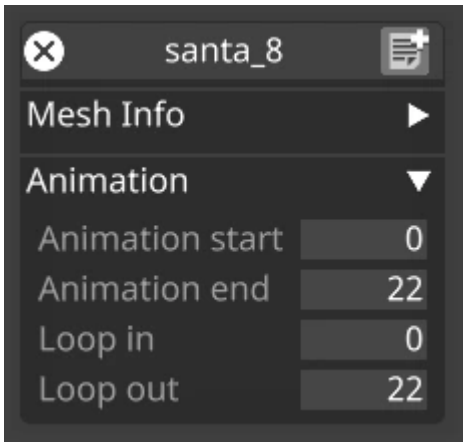
At end point

This specifies what happens when playback reaches the end of the animation. There are three options to choose from:

- **Loop**: When playback reaches the end of the animation, the animation will loop immediately back to the beginning and will start playing again from there.
- **Ping-pong**: When playback reaches the end of the animation, the animation will play in reverse back to the beginning.
- **Pause**: When playback reaches the end of the animation, the animation will pause on the last frame.

Mesh properties

There are several properties in the Mesh editor for FBX and Alembic meshes which can be used to control animation playback in a similar way to designer/content-management/video-clip-object video clips.



Animation start

The start time in seconds of the animation playback. Adjust this value to crop time off the start of the animation.

Animation end

The end time in seconds of the animation playback. Adjust this value to crop time off the end of the animation.

Loop in

Where in the animation playback a loop should continue from if the end point behaviour is set to Loop or Ping-Pong.

Loop out

Where in the animation playback a loop should start from, if the end point behaviour is set to Loop or Ping-Pong.

TargetControl Layer

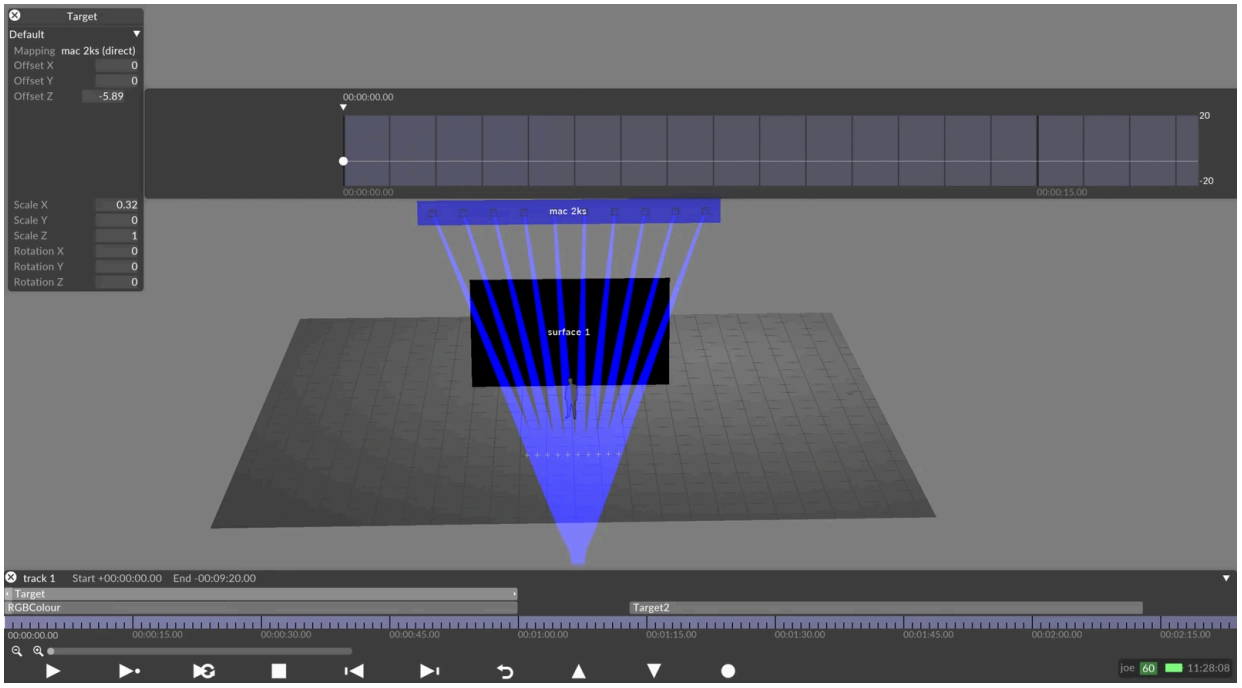
The layer is similar to the TargetPreset iin that it allows to control the movement of moving head lights. Each light in the target screen (which must be of the screen type DmxLights) has its own target point.

> ⚠ **Warning**
>
> **Warning**: The fixture defined in the DMXLight needs to set to **aimable**. If not, the layer will have no effect.

Workflow

The TargetControl layer allows you to control how these target points are generated from the lights base positions. The main difference is that while the TargetPreset layer is based on setting a number of configurations of the target offset, scale and rotation and then interpolate the movements between the configurations, the TargetControl layer allows to keyframe every frame of the offset, scale and rotation values. This gives the user more precise control of the movements but may be more diffucult to use for an inexperienced user. Notice that the fixture defined in the DMXLight needs to set to aimable. If not, the TargetControl layer will have no effect.

Please read the sub-chapter DmxLights for information on how to create a DmxLights screen. Afterwards please read the sub-chapter Creating a fixture for information on how to add a fixture to a DmxLights screen.



TargetControl Layer Properties

Offset

This value is added to the (x, y, z) stage position of each fixture. To move the fixture targets left and right, change the x property, to move them up and down, change the y property and to move them in and out, use the z property.

Scale

This scales the target points in each of the three axes x, y and z. Values higher than 1 increase the size of the target grid, causing the beams to splay outwards; values lower than 1 reduce the size of the target grid and setting the scale to 0 causes all beams to converge.

Rotation

This rotates the target grid around each of the x, y and z axes (angles specified in degrees).

For step-by-step instructions on how to control moving head lights using the Target layer please see the sub-chapter Targeting fixtures.

TargetPreset Layer

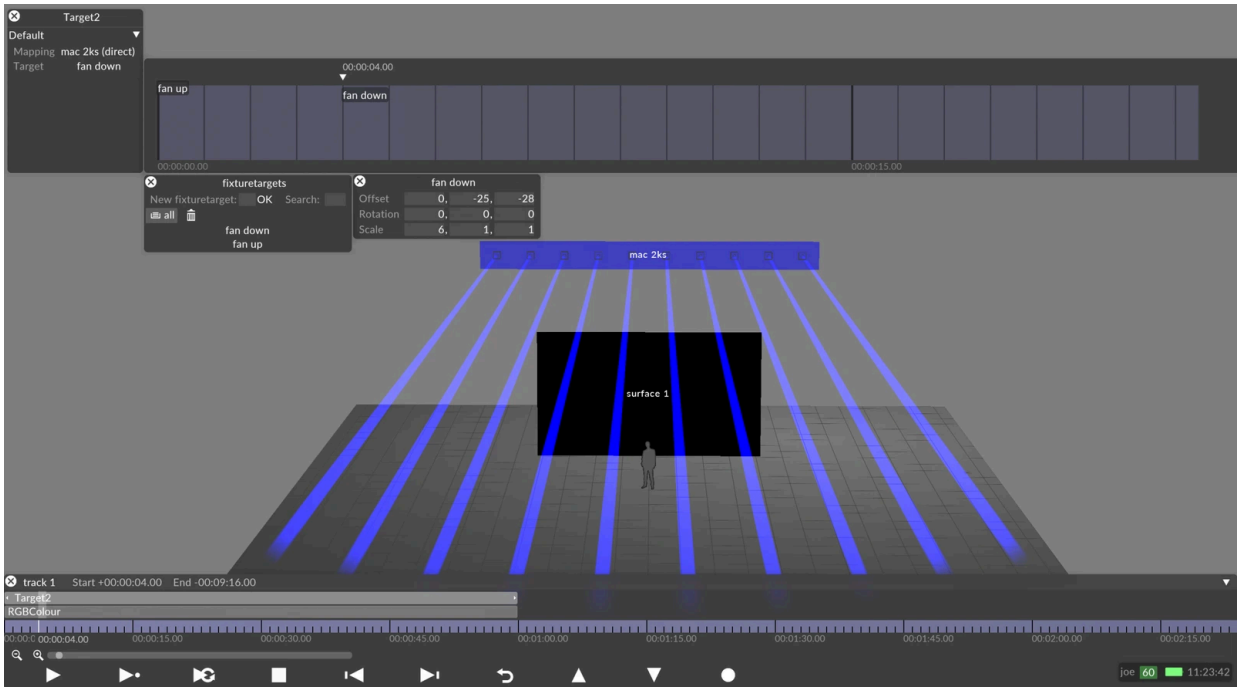
The TargetPreset layer is similar to the TargetControl in that it allows to control the movement of moving head lights. Each light in the target screen (which must be of the screen type DmxLights) has its own target point.

> **Warning**
>
> The fixture defined in the DMXLight needs to set to **aimable**. If not, the layer will have no effect.

Workflow

The TargetPreset (and TargetControl) layer allows you to control how these target points are generated from the lights base positions. The main difference is that while the TargetControl layer allows to keyframe every frame of the offset, scale and rotation values, the TargetPreset layer is based on setting a number of configurations of the target offset, scale and rotation and then interpolate the movements between the configurations. Notice that the fixture defined in the DMXLight needs to set to **aimable**. If not, the Target layer will have no effect.

Please read the sub-chapter DMXLights for information on how to create a DmxLights screen. Afterwards please read the sub-chapter Creating a fixture for information on how to add a fixture to a DmxLights screen.



Targeting/animating fixtures

1. Create a layer.
2. Target the fixtures by assigning a mapping type with the DMXLights you want to control. Make sure to set the fixture defined in the DMXLight to **aimable**.
3. Open the keyframe editor by left-clicking **target** and create and drag/drop a Target keyframe (configuration). The process used to create and sequence Target keyframes is the same as any other layer type that uses key-frame editors, for example the AnimateCameraPreset layer.
4. Right-click the the Target keyframe to edit the position of the fixture targetsm see below for more info.
5. Create as many Target keyframes as required and place these on the keyframe editor.
6. Press the Play button. The software will now animate the light's movements between the Target positions.

TargetPreset Layer Properties

Mapping

Determines what mapping of DMXLight screens to use. Notice that any mapping type can be created using DMXLightscreens.

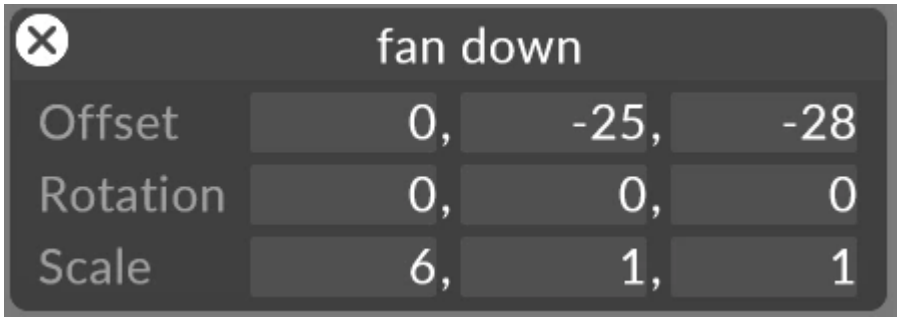
Target

This property lets you create a new configuration of fixture targets, each specifying a target position (offset, rotation, scale) set which can be animated. Please see the section below for step-by-step instructions on how to do this.

You need to use the Target editor as part of the process to animate movinghead fixtures.

Opening the Fixture Targets editor

- Right-click a target in the Targets manager.



Offset

This controls the **offset** of the fixture target, in meters, from the base light position.

Rotation

This controls the **rotation** of the fixture target, in degrees. The x component controls the rotation around the x axis; the y component around the y axis; and the z component around the z axis.

Scale

This controls the **scale** of the fixture target. 1 = no change, >1 = scale up. If all are set to 0, the lights will focus on a point; if two are set to zero, the lights will focus on a line.

Layers Overview

In Designer, a layer is an object which renders content in response to certain inputs.

Layers can generate colours or gradients, play video or display still bitmap images. Content is generated by creating layers, placing them on the Timeline, and animating their properties using Disguise's keyframe editor within the layer editor.

Designer uses mappings to control how layer content is copied from the Timeline to the screens in the Stage level. Please see the chapter Content Mapping for a full explanation of this powerful feature.

To learn how to work with layers, see the working with layers section.

Types of layers

There are five main layer types in Disguise: content layers, generative layers, previsualisation layers, effects layers and control layers. For more detailed information on layer types please read the sub-chapter Overview of layer types.

To see more information about the different types of layers, see the layer types section.

Controlling layer properties with DMX

Disguise can be configured to control layer properties with DMX (ArtNet or sACN) in two ways:

1. Using DMX expressions.
2. Using the DMX Sockpuppet workflow.

Controlling layer properties with OSC

Disguise can be configured to control layer properties with OSC (ArtNet or sACN) in two ways:

1. Using OSC expressions.
2. Using the OSC Sockpuppet workflow.

Mask Blending

Mask blend modes are a unique type of blend mode within Designer that applies a mask to the layer above it in the stack, unlike standard blend modes, which affect content below them. This mode enables blending operations that are independent of previously composited layers, providing granular control over masking elements. Mask blending applies across mappings.

In the following example, Ada has been composited on top of the chevron background and did not have an alpha channel of its own, but was correctly blended with the background:

Pre-r34 behaviour

In releases prior to r34, mask blending applies to **all** layers above the masking layer in the stack and would **only** affect layers within the same mapping.

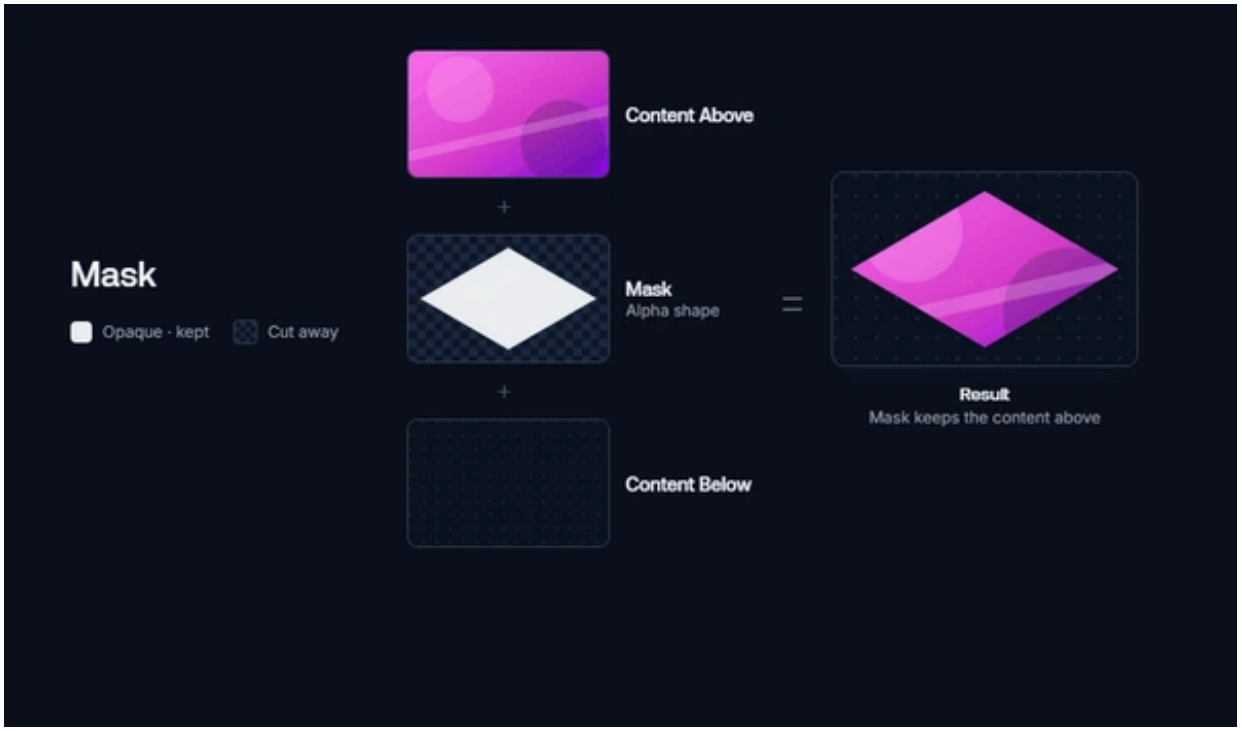
To use pre-r34 mask blend mode behaviour in later releases, enable the advanced setting useLegacyMaskBlendModeBehaviour.

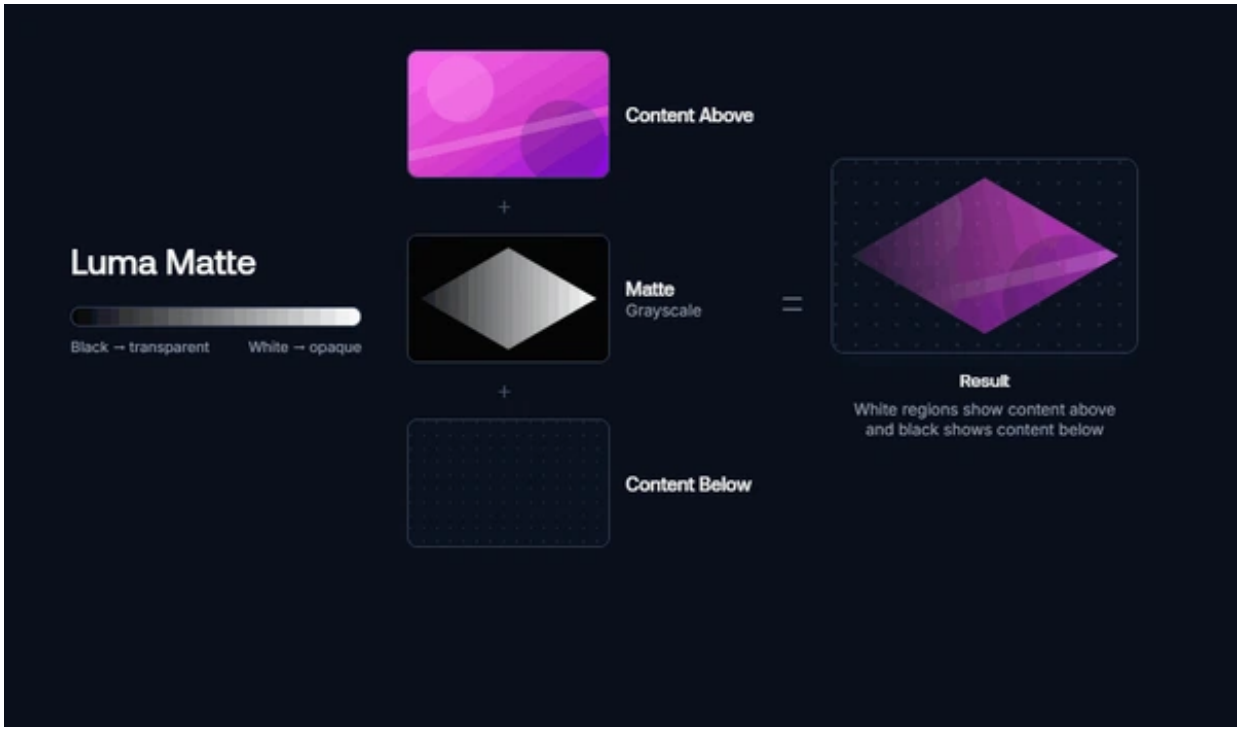
Masking mechanism

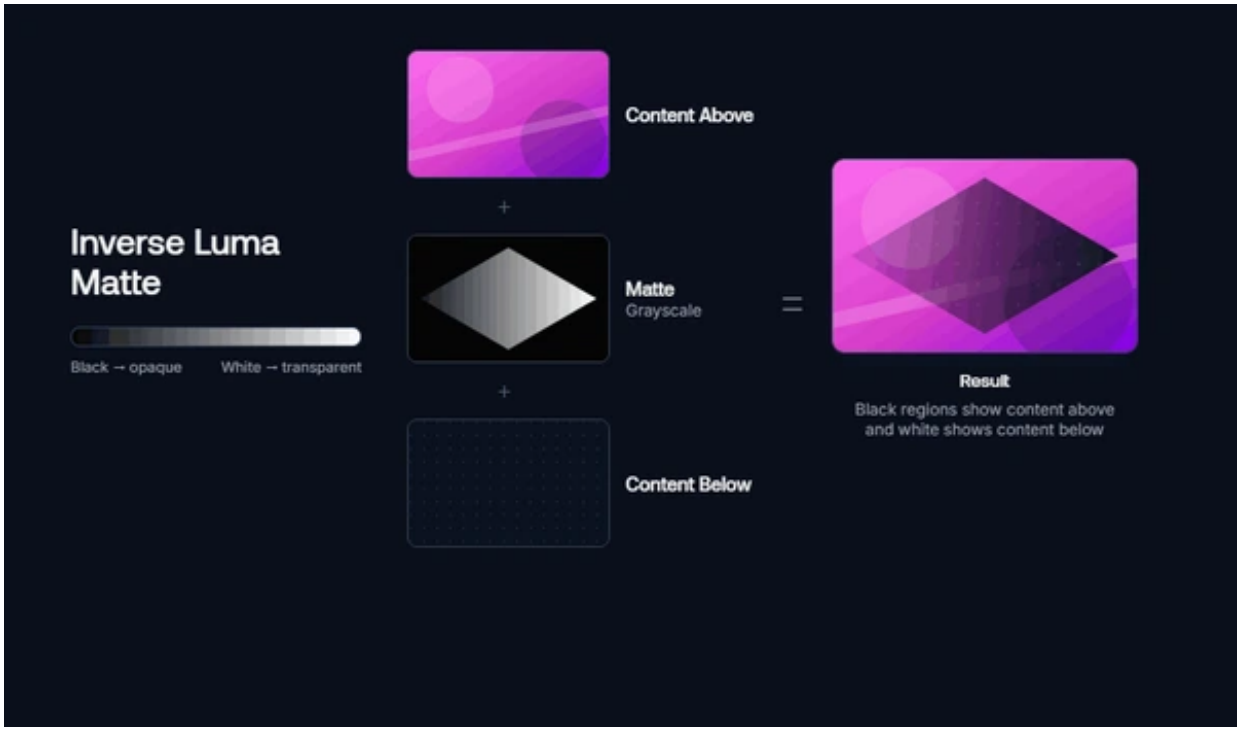
Mask blend modes provide a temporary override to a layer's mapping's mask. This override lasts for a single layer in a given track but it does not spill over between transports in multi-transport.

The way that mapping masks work is that every channel is combined with the content - a red mask with no green and blue components and full opacity alpha would isolate just the red and alpha channels of any subsequent content applied, setting the green and blue channels to 0.

Designer currently supports 3 types of Mask Blend Mode, these are shown below:







Examples

Mask blending

For the isolated Ada example above, the following layer configuration was used.

Note the Bitmap layer is above the Chevron but below the Video layer, its mapping is set to “surface 1”, and is set to Mask blend mode, so it is setting the mapping’s mask.

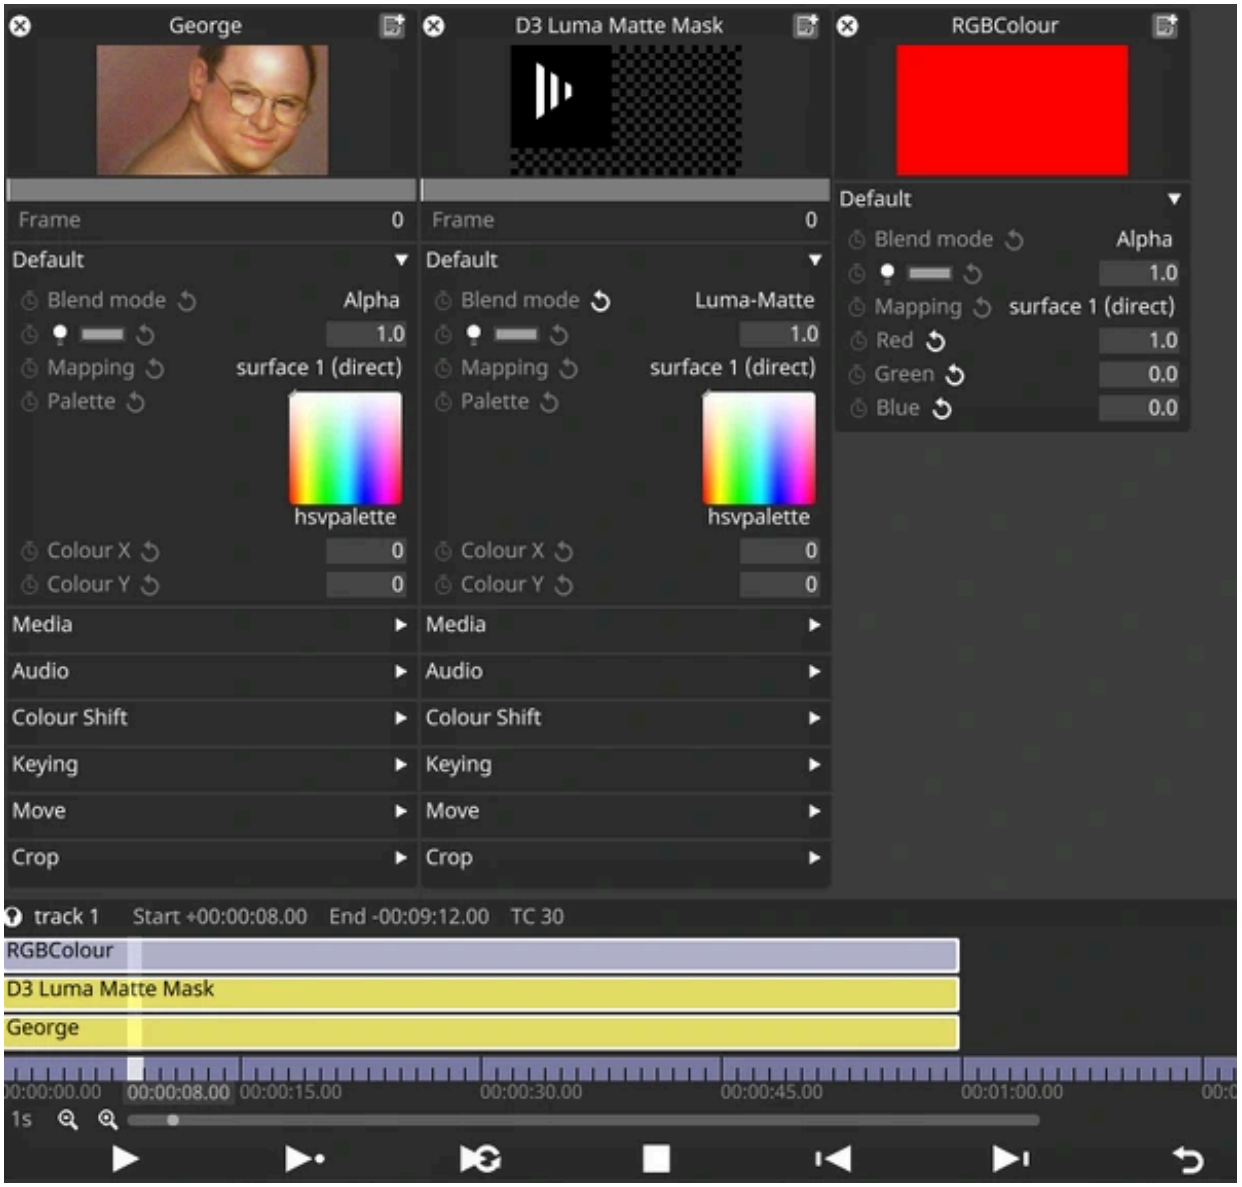
Luma Matte blending

Another example of a mask blend mode is the Luma Matte Mask. In the example above the brightest regions of the matte are made opaque to the layers below (with the above layers are layered on top) whilst the black regions become transparent.

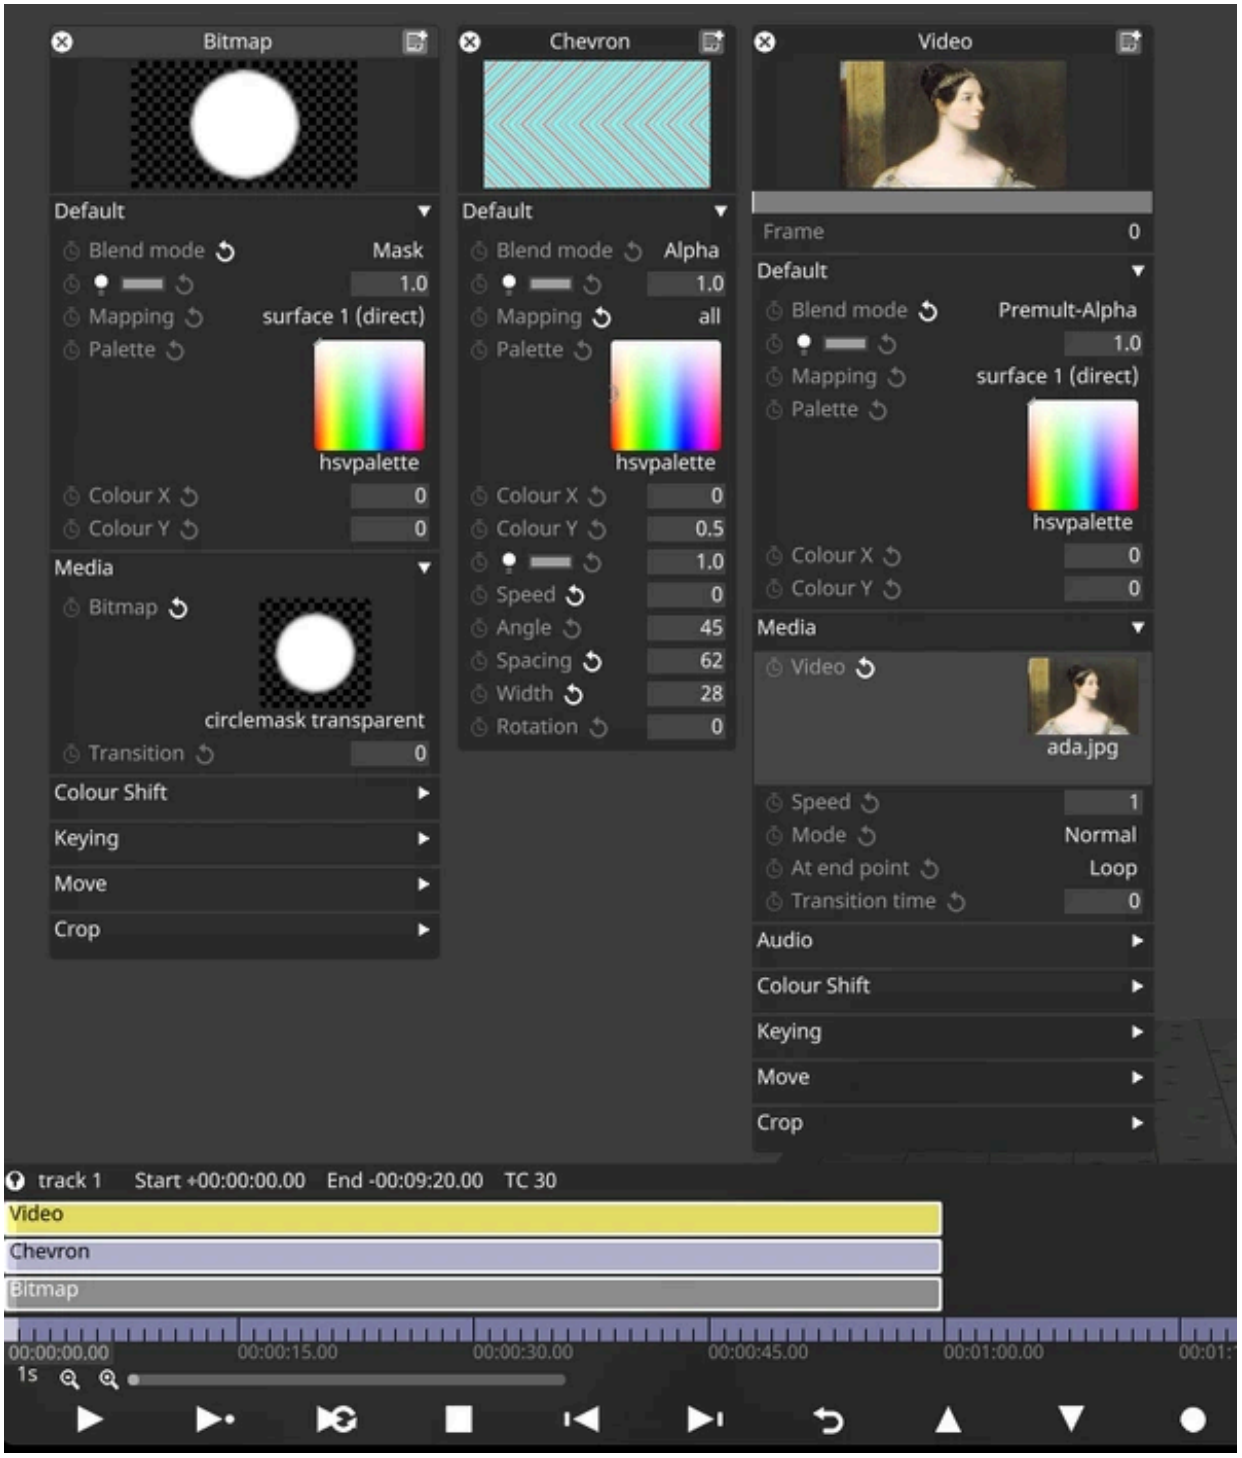


Pre r34 remarks

Ada example setup

For the isolated Ada example above, the following layer configuration is used in pre r34.

The Bitmap layer is **below both** the Chevron and the Video layer, its mapping is set to “surface 1”, and is set to Mask blend mode, so it is setting the mapping’s mask. As the chevron layer is using the “all” mapping it is unaffected by the mask.

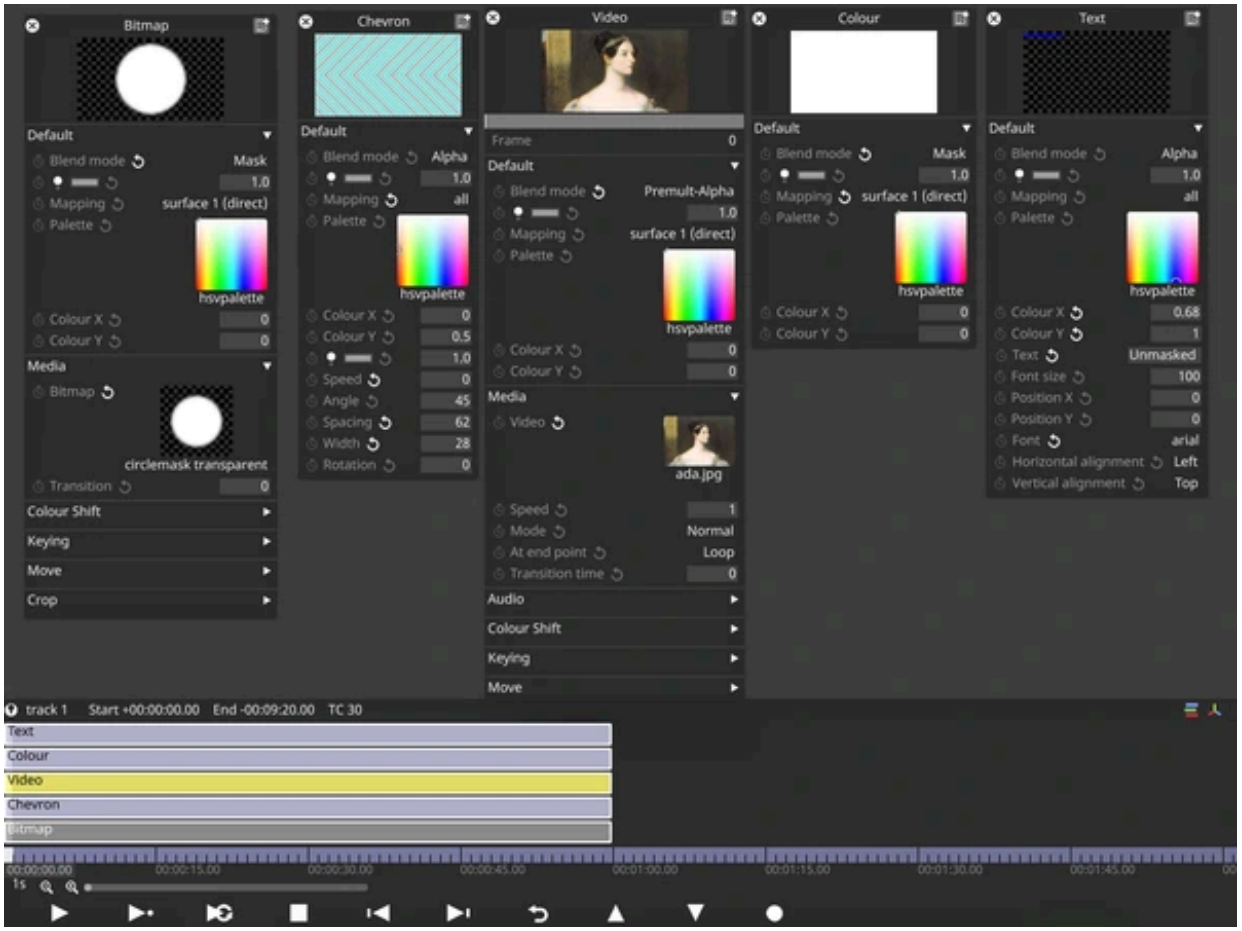


Resetting the mask

While it's not possible to reset the mask to the mask set originally on the mapping, it is possible to reset the mask's effect by inserting a white Colour layer into the layer stack, set to Mask blend mode and selecting the target mapping.

In this example, the Colour layer mapping is set to "surface 1" and Mask Blend mode. It outputs full opacity white.

The text layer also uses mapping “surface 1”, and is able to appear outside the originally masked area.



Unmasked

Common Mapping Properties

This section explains the properties that are shared by the different mapping types.

Filtering

- **Nearest**: Nearest neighbour filtering. Use nearest-neighbour sampling, to disable blending between pixels when scaling. Can be used to create pixellated looks, or to ensure hard edges on certain types of content.
- **Bilinear**: Bilinear filtering is a texture filtering method used to smooth textures when displayed larger or smaller than they actually are.
- **2x Multi-sample**: Multi-Sample filtering can help fix issues with scaled content, but can introduce some blurriness.

Resolution

This controls the canvas size the layer renders into, in pixels. The Direct mapping type starts with a 256x256 pixel canvas and automatically sets the canvas size to that of the first screen you add.

Screens

This is a list of screens that the selected mapping type can copy content to.

1. Left-click + to open the Screens manager.
2. Left-click **+** to add the Screens you want to map. This will copy the individual canvas content onto these three Screens simultaneously and will add the Screen names to the mapping object editor.
3. Left-click and drag the Screens listed in the mapping object editor to **-**. This will remove the canvas content from the Screens and delete the Screen names from the mapping object editor.

Mask

This points to the Texture file that defines a Mask bitmap. You can use this property to apply a Mask bitmap to the mapping canvas. Selecting this property will open the Texture object library, which shows all of the still image files saved on your local hard-drive in the **DxTexture** folder.

To apply a mapping mask you will need to create and import a custom still image file.

- The step-by-step instructions on how to create and import a custom Population mask can be used to create a custom mapping mask. The only difference is that the mapping masks resolution should be the same as the mapping canvas. For step-by-step instructions on how to create and import a Population mask into a d3 project visit to the section Population mask in the **Editing screens** sub-chapter.
- Alternatively, set any layers blend mode to **mask** to channel the layer content into the mapping mask.

Clip outside region

Clips pixels outside of rendered region, preserving existing colour. If not set, pixels outside the rendered region are set to the border colour.

BorderExpansion

UV islands on screens are expanded by this many pixels to cover edge sampling artifacts such as black fringing. Note that there must be an equivalent amount of empty space in the screen UV map to take advantage of this.

Find/Replace Usages

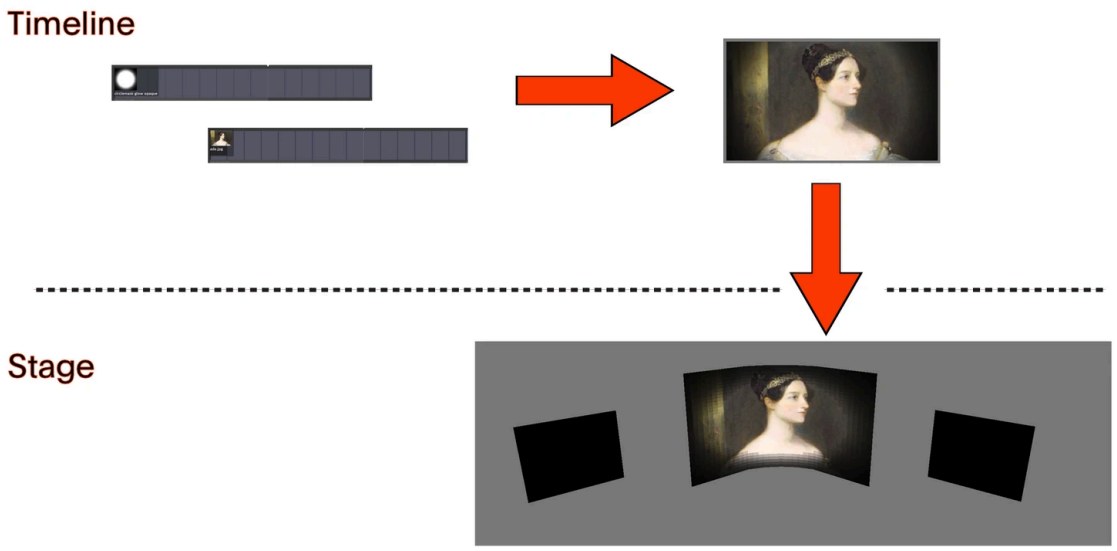
Finds all usages of the current mapping in the project, and allows these to be replaced with an alternative mapping. Note that replacement only works for sequenced, non-sockpuppeted mappings.

Hierarchy

The hierarchy section allows the mapping to be set as a parent or child of another object, like any other object. See Object Overview for details.

Content Mapping Overview

Mapping is the process of copying content from the Timeline level to the screens in the Stage level.



Conceptual diagram illustrating how mapping is used to control how content is copied from the Timeline to the Stage level.

All visual layers contain the property mapping, which is used to direct the layer output to the screens on the stage. For information on how to use the mapping property, please see the sub-chapter creating a new mapping.

Types of mappings

Several mapping types in Designer:

- Direct mapping
- Feed mapping
- Parallel mapping
- Perspective mapping
- Cylindrical mapping
- Radial mapping
- Spherical mapping

- CameraPlate mapping
- Spatial mapping
- Spherical mapping
- Depth Map mapping
- PreComps

These mapping types are able to: sample content across single or multiple screens with pixel perfect accuracy; map content onto 3D objects of any form; accurately project content onto static or moving screens; and project geometrically from virtual cameras in a number of different ways. For more detailed information on the mapping types please read the following topic Mapping types overview.

All visual layers contain the property **mapping**, which is used to redirect the layer output to the screen(s) in the stage. For information on how to use the **mapping** property please see the topic Creating a new mapping.

Creating a New Mapping

This guide covers how to create a new mapping, assign multiple mappings, and remove any mappings.

Creating a New Mapping

1. In your track, add a new visual layer. This can be a **content layer**, **generative layer**, or **effect layer**.
2. Left-click the new layer in the track to open the **Layer Editor**.
3. Under the **Default** tab, left-click the **Mapping** parameter. This shows a list of all of the available mappings in the project. By default, **screens** are assigned a **Direct Mapping** with the same name. **Cameras** are assigned a **Perspective Mapping** with the same name.
4. In the **New Mapping** text field, type a name for your new mapping. Select a **mapping type** from the list.
5. In the **Mapping Editor**, assign the screens to be used for the mapping, and specify the resolution of the content.
6. Adjust the mapping properties as needed.
7. Finally, assign a piece of content to the layer in your track. The content will be displayed on the **assigned screens** in both the **stage** and **feed output window**.

[Animated GIF: Creating a mapping]

Creating a mapping

Assigning multiple mappings

In the Mapping keyframe editor that will appear across the screen, move the play head and assign multiple mappings sequentially for each layer by left-clicking in the editor.

Removing mappings

Remove mappings from your project by left-clicking on the name of the mapping and dragging to the trash can icon within this menu. All mappings that are assigned to a screen or camera within the project but have been moved to the trash will appear highlighted in red.

> **Note**
>
> **Please note**: It is useful to organise the different mappings in boxes, particularly if there are a very large number of mappings. For information on how to create, edit and organise objects within boxes, please see the section 'Organising objects in boxes' in the Object libraries.

Generating Textures

Texture types

Composite Texture

Combines multiple textures into one. To blend the textures together, you can select different blend modes.

Gradient Texture

Gradient texture allows for generative gamma and gradient length options.

Soft Edge texture

Create as many points as you want and configure what gamma level and level of gradient you need to achieve the perfect blend between your projector outputs.

Solid texture

Texture that only allows one solid colour.

Lookup texture

This texture allows you to edit the brightness curve of a softedge texture.

PreComp Texture

This texture acts as a virtual screen that content can be written to. See the PreComp topic for more information.

Creating textures

To create a texture:

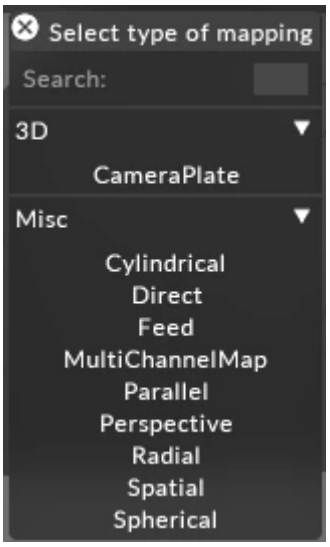
1. Open a **Bitmap** layer, a **Spinbitmap** layer or any other texture based layer.
2. Left-click **palette** from the layer editor.
3. Left-click **new texture** to highlight the text field.
4. Type in the name of your texture, for example **theatre surface** .
5. Click **Enter**. This will open a menu of five different types of textures.

Exporting textures

To Export a texture:

1. Open your texture from the **DxTexture** editor by right-clicking on it.
2. Left-click the **Actions** tab at the bottom of the editor.
3. Alter the name if needed, and then click **Enter** or left-click OK. The texture will be written to the output folder of the Project folder.

Mapping Types Overview



Direct mapping

Direct mapping is the easiest form of mapping. Simply select a piece of content and apply it directly onto some or all of your screens. If the content aspect is different from the screen aspect ratio, you can choose to crop, fit, stretch or apply the content pixel-perfect onto the screens.

Feed mapping

Feed mapping lets you specify an arbitrary number of rectangles within your content frame and map them to arbitrary rectangles on your screens. With Feed mapping, all your screens can easily be turned into one canvas, with pixel-perfect content applied. Individually move, scale, crop, chop or flip your sample rectangles to compensate for differences in pixel-density or to create interesting mapping effects.

Fisheye mapping

Fisheye mapping is used to map content generated using a fisheye lens. This mapping type is typically used for dome surfaces.

Parallel mapping

Parallel mapping allows you to position your content in a virtual emitter rectangle anywhere within the stage and to choose which screens and fixtures this affects. Designer then virtually projects the content out onto those fixtures. The content keeps the same size as it gets further away from the emitter.

Perspective mapping

Perspective mapping is similar to Parallel mapping, except that the content originates from an emitter point and gets larger as you get further away from the emitter, similar to a real projector. You can use perspective mapping to map 3D content onto a surface that looks perfect from the specified point of view.

Cylindrical mapping

Cylindrical mapping is similar to Parallel mapping, except that the Cylindrical mapping wraps content around a cylinder and fires it outwards (or inwards) at the screens you assign to it. It does not matter if the screen is moving or expanding, the Cylindrical mapping feature re-maps the content in real-time.

Radial mapping

Radial mapping is similar to the Cylindrical mapping, except that the emitter surface runs from the central axis to the cylinder rim, rather than being wrapped around the outside of the cylinder. The pixels inside the cylinder will therefore be mapped according to their height within the cylinder and their distance from the central axis.

Spherical mapping

Spherical Mapping works similarly to the Cylindrical mapping, except the top and bottom are ‘pinched’ to create a sphere.

CameraPlate mapping

A CameraPlate mapping is a 3D Camera based mapping that is fixed to the plate of the camera. Using a CameraPlate mapping is necessary when doing color adjusts on the set extension.

Spatial mapping

A Spatial mapping is a 3D Camera based mapping that maps into 3D space; it has a “space” or location so it can be moved around 3D environments.

Mesh mapping

A Mesh mapping is a 3D mapping that maps into the UVs of a mesh; it has a “space” or location so it can be moved around 3D environments and fills the full UVs of the mesh with content.

CameraPlate Mapping

The CameraPlate mapping always targets a specific camera.

The CameraPlate mapping was added for the Augmented Reality (AR) workflow, where virtual objects can be mapped within the scene. The CameraPlate mapping will essentially “stick” the content to the perceived lens of the camera and adjust the content to always appear in proportion despite the position or movement of the camera.

Creating a CameraPlate Mapping

1. In your track, add a new visual layer. This can be a **content layer**, **generative layer**, or **effect layer**.
2. Left-click the new layer in the track to open the **Layer Editor**.
3. Under the **Default** tab, left-click the **Mapping** parameter to display the Mappings manager which list all of the mappings in the project. By default, all screens are assigned a **Direct mapping** with the same name. All cameras are assigned a **Perspective Mapping** with the same name.
4. In the **New Mapping** text field, add a name for your new mapping. A list will appear prompting to you select a mapping type.
5. Select CameraPlate from the list. The CameraPlate Mapping editor will appear.
6. In the **Mapping editor**, assign the screens to be used for the mapping, and specify the resolution of the content.
7. Adjust the mapping properties as needed.
8. Finally, assign a piece of content to the layer in your track. The content will be displayed on the **assigned screens** in both the stage and feed output window.

Common Mapping Properties

This section explains the properties that are shared by the six different mapping types.

Filtering

- **Nearest**: Nearest neighbour filtering. Use nearest-neighbour sampling, to disable blending between pixels when scaling. Can be used to create pixellated looks, or to ensure hard edges on certain types of content.
- **Bilinear**: Bilinear filtering is a texture filtering method used to smooth textures when displayed larger or smaller than they actually are.
- **2x Multi-sample**: Multi-Sample filtering can help fix issues with scaled content, but can introduce some blurriness.

Resolution

This controls the canvas size the layer renders into, in pixels. The Direct mapping type starts with a 256x256 pixel canvas and automatically sets the canvas size to that of the first screen you add.

Screens

This is a list of screens that the selected mapping type can copy content to.

1. Left-click + to open the Screens manager.
2. Left-click **+** to add the Screens you want to map. This will copy the individual canvas content onto these three Screens simultaneously and will add the Screen names to the mapping object editor.
3. Left-click and drag the Screens listed in the mapping object editor to **-**. This will remove the canvas content from the Screens and delete the Screen names from the mapping object editor.

Mask

This points to the Texture file that defines a Mask bitmap. You can use this property to apply a Mask bitmap to the mapping canvas. Selecting this property will open the Texture object library, which shows all of the still image files saved on your local hard-drive in the **DxTexture** folder.

To apply a mapping mask you will need to create and import a custom still image file.

- The step-by-step instructions on how to create and import a custom Population mask can be used to create a custom mapping mask. The only difference is that the mapping masks resolution should be the same as the mapping canvas. For step-by-step instructions on how to create and import a Population mask into a d3 project visit to the section Population mask in the **Editing screens** sub-chapter.
- Alternatively, set any layers blend mode to **mask** to channel the layer content into the mapping mask.

Clip outside region

Clips pixels outside of rendered region, preserving existing colour. If not set, pixels outside the rendered region are set to the border colour.

Border Expansion

UV islands on screens are expanded by this many pixels to cover edge sampling artifacts such as black fringing. Note that there must be an equivalent amount of empty space in the screen UV map to take advantage of this.

Find/Replace Usages

Finds all usages of the current mapping in the project, and allows these to be replaced with an alternative mapping. Note that replacement only works for sequenced, non-sockpuppeted mappings.

CameraPlate mapping properties

Camera plate

Camera plate options include:

- Front Plate
- Back Plate
- Horizontal Back and Front Plates
- Front Plate Undistorted
- Back Plate Screens
- Back Plate Set Extension

Reprojection distance (m)

The reprojection distance in metres is a measure of the accuracy and real-world alignment of your virtual camera and the physical set. It indicates how closely the digital content is matching the real-world geometry from the camera's perspective.

Cylindrical Mapping

The Cylindrical mapping type wraps content around a cylinder and fires it outwards (or inwards) onto the selected screens. Similar to the Parallel mapping and the Perspective mapping types, the content is being virtually projected from the surfaces of the cylinder, both inwards and outwards.

Cylindrical mapping wraps content around a cylinder and emits it inward or outward towards the screens assigned to it. It does not matter if the screen is moving or expanding, the Cylindrical mapping re-maps the content in real-time to accommodate for the movement, similar to parallel mapping.

Creating a Cylindrical mapping

1. In your track, add a new visual layer. This can be a **content layer**, **generative layer**, or **effect layer**.
2. Left-click the new layer in the track to open the **Layer Editor**.
3. Under the **Default** tab, left-click the **Mapping** parameter to display the Mappings manager which list all of the mappings in the project. By default, all screens are assigned a **Direct mapping** with the same name. All cameras are assigned a **Perspective Mapping** with the same name.
4. In the **New Mapping** text field, add a name for your new mapping. A list will appear prompting to you select a mapping type.

   [Animated GIF: Create a new mapping]

5. Select Cylindrical from the list. The Cylindrical Mapping editor will appear.
6. In the **Mapping editor**, assign the screens to be used for the mapping, and specify the resolution of the content.
7. Adjust the mapping properties as needed.
8. Finally, assign a piece of content to the layer in your track. The content will be displayed on the **assigned screens** in both the stage and feed output window.

Common Mapping Properties

This section explains the properties that are shared by the different mapping types.

Filtering

- **Nearest**: Nearest neighbour filtering. Use nearest-neighbour sampling, to disable blending between pixels when scaling. Can be used to create pixellated looks, or to ensure hard edges on certain types of content.
- **Bilinear**: Bilinear filtering is a texture filtering method used to smooth textures when displayed larger or smaller than they actually are.
- **2x Multi-sample**: Multi-Sample filtering can help fix issues with scaled content, but can introduce some blurriness.

Resolution

This controls the canvas size the layer renders into, in pixels. The Direct mapping type starts with a 256x256 pixel canvas and automatically sets the canvas size to that of the first screen you add.

Screens

This is a list of screens that the selected mapping type can copy content to.

1. Left-click + to open the Screens manager.
2. Left-click **+** to add the Screens you want to map. This will copy the individual canvas content onto these three Screens simultaneously and will add the Screen names to the mapping object editor.
3. Left-click and drag the Screens listed in the mapping object editor to **-**. This will remove the canvas content from the Screens and delete the Screen names from the mapping object editor.

Mask

This points to the Texture file that defines a Mask bitmap. You can use this property to apply a Mask bitmap to the mapping canvas. Selecting this property will open the Texture object library, which shows all of the still image files saved on your local hard-drive in the **DxTexture** folder.

To apply a mapping mask you will need to create and import a custom still image file.

- The step-by-step instructions on how to create and import a custom Population mask can be used to create a custom mapping mask. The only difference is that the mapping masks resolution should be the same as the mapping canvas. For step-by-step instructions on how to create and import a Population mask into a d3 project visit to the section Population mask in the **Editing screens** sub-chapter.
- Alternatively, set any layers blend mode to **mask** to channel the layer content into the mapping mask.

Clip outside region

Clips pixels outside of rendered region, preserving existing colour. If not set, pixels outside the rendered region are set to the border colour.

Border Expansion

UV islands on screens are expanded by this many pixels to cover edge sampling artifacts such as black fringing. Note that there must be an equivalent amount of empty space in the screen UV map to take advantage of this.

Find/Replace Usages

Finds all usages of the current mapping in the project, and allows these to be replaced with an alternative mapping. Note that replacement only works for sequenced, non-sockpuppeted mappings.

Hierarchy

The hierarchy section allows the mapping to be set as a parent or child of another object, like any other object. See Object Overview for details.

Cylindrical mapping properties

Output

By default, this is set to **colour**. This implies that red, green and blue content channels are sent to the red/green/blue colour output channels of the screen (or converted to cyan, magenta and yellow if the output fixtures are CMY). However, content can also be channelled to other channels in the case of DMX-based fixtures. Currently, this is a beta functionality, so for the moment you are advised to leave this set to **colour**.

Anchor

As with the Parallel mapping type, you can anchor the cylinder around the centre, or the top or bottom points. Resize and rotation operations will keep the anchor point in the same place. With the anchor, the cyclinder can be moved/rotated around the top, middle, or bottom.

Select from the following:

- Centre
- Top
- Bottom

Projection mode

In cylindrical mapping, the projection mode determines the direction from which the texture is projected onto your 3D object.

Options are:

- Outside: Used for texturing the exterior of objects like pillars, bottles, cans, tree trunks, and character arms.
- Inside: Used for texturing the interior of hollow objects, such as the inside of a pipe, a tunnel, a cup, or a panoramic sky dome that surrounds your scene.

Position

This property is the position in X, Y, Z space.

Rotation

This rotates the cylinder around the anchor point; specified in degrees of rotation around the x, y and z axes respectively.

Size

This controls the size of the cylinder in metres, on the x, y and z axes respectively. The y property (the second value) controls the height; the two other properties control the radii in the x and z axes. Setting x and z to the same value keeps the cylinders cross section circular; setting them to different values makes it elliptical.

Using the cylindrical mapping type

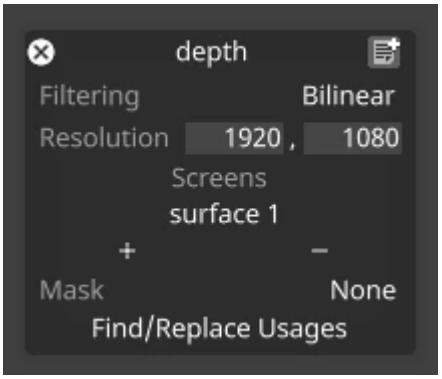
In addition to the property explanations provided above, it is important to:

- Base the resolution of the Cylindrical mapping on the aspect between the circumference of the cylinder and the height of the screen. The circumference can be calculated by taking the **diameter * pi, = size* 3.14** . Set the size x and z to the same value to establish as perfect circular shape.

Depth Map Mapping

A **Depth Map Mapping** applies a depth-map image or video to a Depth Map Mesh.

The input must be a **black-and-white depth map**, where pixel brightness encodes the **relative depth** of objects in the image. When mapped, the z-positions of the mesh's vertices deform dynamically based on the depth values.



Depth Map mapping

Using the Depth Map Mapping

1. Create a new Depth Map Mesh and assign it for the target screen.
2. Add a layer to the track which produces a depth map, for example a Video layer.
3. Add the target screen to the **Screens** list within the mapping configuration.
4. Verify that the screen's mesh dynamically updates based on the applied depth map content.

Common Mapping Properties

This section explains the properties that are shared by the different mapping types.

Filtering

- **Nearest**: Nearest neighbour filtering. Use nearest-neighbour sampling, to disable blending between pixels when scaling. Can be used to create pixellated looks, or to ensure hard edges on certain types of content.
- **Bilinear**: Bilinear filtering is a texture filtering method used to smooth textures when displayed larger or smaller than they actually are.
- **2x Multi-sample**: Multi-Sample filtering can help fix issues with scaled content, but can introduce some blurriness.

Resolution

This controls the canvas size the layer renders into, in pixels. The Direct mapping type starts with a 256x256 pixel canvas and automatically sets the canvas size to that of the first screen you add.

Screens

This is a list of screens that the selected mapping type can copy content to.

1. Left-click + to open the Screens manager.
2. Left-click + to add the Screens you want to map. This will copy the individual canvas content onto these three Screens simultaneously and will add the Screen names to the mapping object editor.
3. Left-click and drag the Screens listed in the mapping object editor to -. This will remove the canvas content from the Screens and delete the Screen names from the mapping object editor.

Mask

This points to the Texture file that defines a Mask bitmap. You can use this property to apply a Mask bitmap to the mapping canvas. Selecting this property will open the Texture object library, which shows all of the still image files saved on your local hard-drive in the **DxTexture** folder.

To apply a mapping mask you will need to create and import a custom still image file.

- The step-by-step instructions on how to create and import a custom Population mask can be used to create a custom mapping mask. The only difference is that the mapping masks resolution should be the same as the mapping canvas. For step-by-step instructions on how to create and import a Population mask into a d3 project visit to the section Population mask in the **Editing screens** sub-chapter.
- Alternatively, set any layers blend mode to **mask** to channel the layer content into the mapping mask.

Find/Replace Usages

Finds all usages of the current mapping in the project, and allows these to be replaced with an alternative mapping. Note that replacement only works for sequenced, non-sockpuppeted mappings.

- Depth Video Layer
- Depth Map Mesh

- Depth Workflows

Direct Mapping

Direct mapping is the default mapping applied to all screens and is a 1:1 ratio of content to screen. The content will stretch and shrink to the size and resolution of the assigned screen. You can choose to crop, fit, stretch or apply the content pixel-perfect onto the one or multiple screens, all within one direct mapping.

When you create a new screen, Designer automatically creates a new Direct mapping with the same name as the screen and only includes that screen.

The resolution of the Direct mapping type is automatically set to the highest resolution screen of the screens included in the Direct mapping.

Creating a Direct mapping

1. In your track, add a new visual layer. This can be a **content layer**, **generative layer**, or **effect layer**.
2. Left-click the new layer in the track to open the **Layer Editor**.

3. Under the **Default** tab, left-click the **Mapping** parameter to display the Mappings manager which list all of the mappings in the project. By default, all screens are assigned a **Direct mapping** with the same name. All cameras are assigned a **Perspective Mapping** with the same name.
4. In the **New Mapping** text field, add a name for your new mapping. A list will appear prompting to you select a mapping type.
5. Select Direct from the list. The Direct Mapping editor will appear.
6. In the **Mapping editor**, assign the screens to be used for the mapping, and specify the resolution of the content.
7. Adjust the mapping properties as needed.
8. Finally, assign a piece of content to the layer in your track. The content will be displayed on the **assigned screens** in both the stage and feed output window.

Common Mapping Properties

This section explains the properties that are shared by the six different mapping types.

Filtering

- **Nearest**: Nearest neighbour filtering. Use nearest-neighbour sampling, to disable blending between pixels when scaling. Can be used to create pixellated looks, or to ensure hard edges on certain types of content.
- **Bilinear**: Bilinear filtering is a texture filtering method used to smooth textures when displayed larger or smaller than they actually are.
- **2x Multi-sample**: Multi-Sample filtering can help fix issues with scaled content, but can introduce some blurriness.

Resolution

This controls the canvas size the layer renders into, in pixels. The Direct mapping type starts with a 256x256 pixel canvas and automatically sets the canvas size to that of the first screen you add.

Screens

This is a list of screens that the selected mapping type can copy content to.

1. Left-click + to open the Screens manager.
2. Left-click **+** to add the Screens you want to map. This will copy the individual canvas content onto these three Screens simultaneously and will add the Screen names to the mapping object editor.

3. Left-click and drag the Screens listed in the mapping object editor to -. This will remove the canvas content from the Screens and delete the Screen names from the mapping object editor.

Mask

This points to the Texture file that defines a Mask bitmap. You can use this property to apply a Mask bitmap to the mapping canvas. Selecting this property will open the Texture object library, which shows all of the still image files saved on your local hard-drive in the **DxTexture** folder.

To apply a mapping mask you will need to create and import a custom still image file.

- The step-by-step instructions on how to create and import a custom Population mask can be used to create a custom mapping mask. The only difference is that the mapping masks resolution should be the same as the mapping canvas. For step-by-step instructions on how to create and import a Population mask into a d3 project visit to the section Population mask in the **Editing screens** sub-chapter.
- Alternatively, set any layers blend mode to **mask** to channel the layer content into the mapping mask.

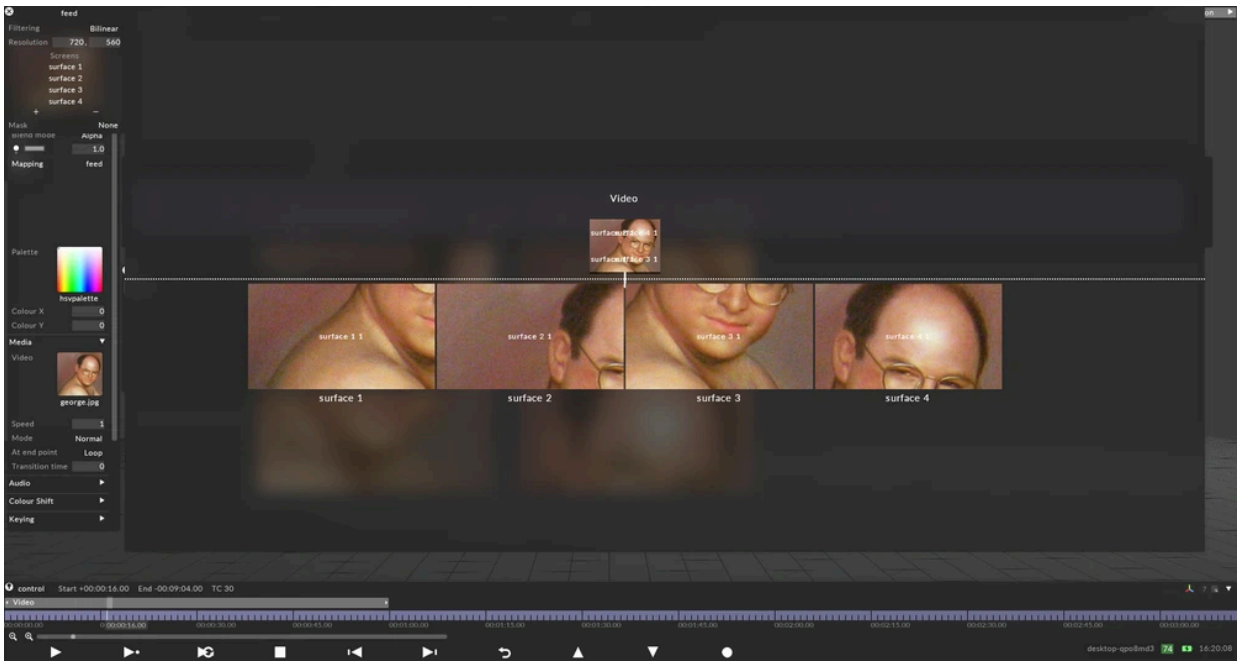
Find/Replace Usages

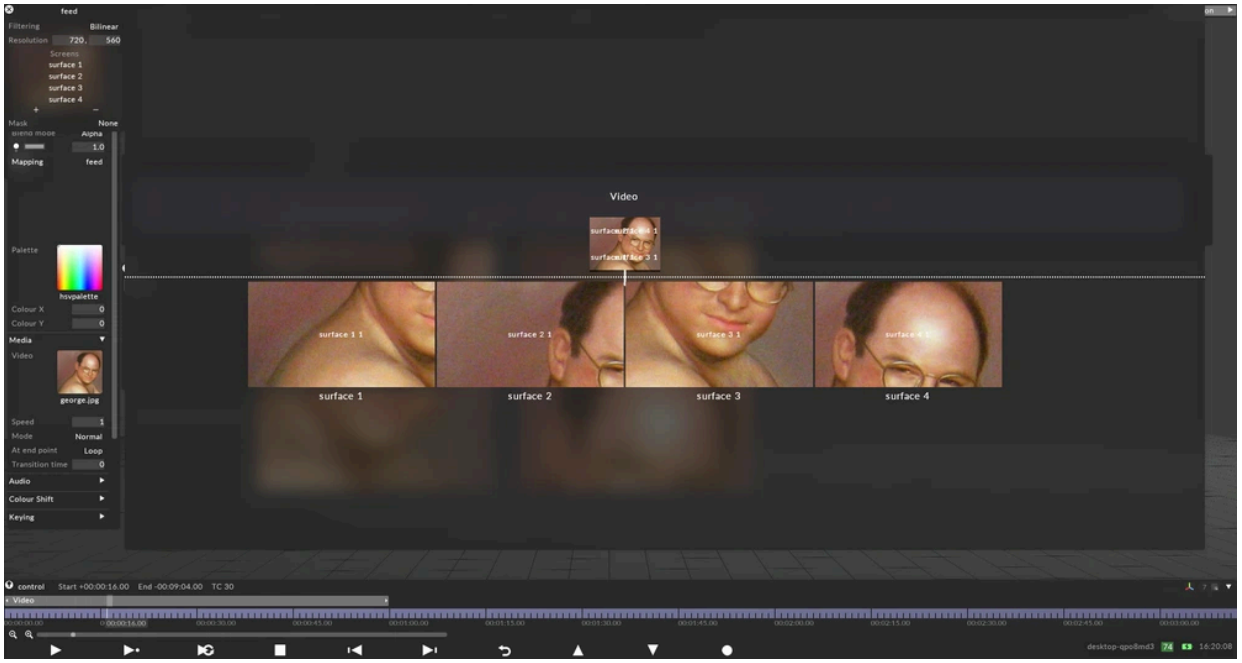
Finds all usages of the current mapping in the project, and allows these to be replaced with an alternative mapping. Note that replacement only works for sequenced, non-sockpuppeted mappings.

Feed Mapping

The Feed mapping type allows you to sub-sample rectangular areas in a content area (referred to as the Mapping canvas) and copy that content onto rectangles inside one or multiple screens.

Feed mapping lets you specify any number of source rectangles within your content and map them individually to multiple surfaces. With Feed mapping, all your screens can easily be turned into one overall raster, and content applied to each surface with pixel-perfect accuracy. Individually move, scale, crop, chop or flip your source rectangles to compensate for differences in pixel density or to create interesting mapping effects..





Creating a Feed Mapping

1. In your track, add a new visual layer. This can be a **content layer**, **generative layer**, or **effect layer**.
2. Left-click the new layer in the track to open the **Layer Editor**.
3. Under the **Default** tab, left-click the **Mapping** parameter. This shows a list of all of the available mappings in the project. By default, **screens** are assigned a **Direct Mapping** with the same name. **Cameras** are assigned a **Perspective Mapping** with the same name.
4. In the **New Mapping** text field, type a name for your new mapping. Select a **mapping type** from the list.
5. In the **Mapping Editor**, assign the screens to be used for the mapping, and specify the resolution of the content.
6. Adjust the mapping properties as needed.
7. Finally, assign a piece of content to the layer in your track. The content will be displayed on the **assigned screens** in both the **stage** and **feed output window**.

Common Mapping Properties

This section explains the properties that are shared by the different mapping types.

Filtering

- **Nearest**: Nearest neighbour filtering. Use nearest-neighbour sampling, to disable blending between pixels when scaling. Can be used to create pixellated looks, or to ensure hard edges on certain types of content.

- **Bilinear**: Bilinear filtering is a texture filtering method used to smooth textures when displayed larger or smaller than they actually are.
- **2x Multi-sample**: Multi-Sample filtering can help fix issues with scaled content, but can introduce some blurriness.

Resolution

This controls the canvas size the layer renders into, in pixels. The Direct mapping type starts with a 256x256 pixel canvas and automatically sets the canvas size to that of the first screen you add.

Screens

This is a list of screens that the selected mapping type can copy content to.

1. Left-click + to open the Screens manager.
2. Left-click **+** to add the Screens you want to map. This will copy the individual canvas content onto these three Screens simultaneously and will add the Screen names to the mapping object editor.
3. Left-click and drag the Screens listed in the mapping object editor to **-**. This will remove the canvas content from the Screens and delete the Screen names from the mapping object editor.

Mask

This points to the Texture file that defines a Mask bitmap. You can use this property to apply a Mask bitmap to the mapping canvas. Selecting this property will open the Texture object library, which shows all of the still image files saved on your local hard-drive in the **DxTexture** folder.

To apply a mapping mask you will need to create and import a custom still image file.

- The step-by-step instructions on how to create and import a custom Population mask can be used to create a custom mapping mask. The only difference is that the mapping masks resolution should be the same as the mapping canvas. For step-by-step instructions on how to create and import a Population mask into a d3 project visit to the section Population mask in the **Editing screens** sub-chapter.
- Alternatively, set any layers blend mode to **mask** to channel the layer content into the mapping mask.

Find/Replace Usages

Finds all usages of the current mapping in the project, and allows these to be replaced with an alternative mapping. Note that replacement only works for sequenced, non-sockpuppeted mappings.

Feed Mapping Properties

This section explains the properties that are shared by all the different mapping types.

Import from Table

Allows feed settings to be imported and update feed mappings.

See the **Import and Export feed maps** section below.

Feed View

Feed View provides a visual representation of the feed mapping for screens and content.

Using the Feed Mapping type

Feed Mapping guidelines

In addition to the property explanations provided above, it is important to:

1. Set the resolution of the Feed mapping to the same resolution as the content intended to be used for that Feed mapping. If the content is of a higher resolution than the resolution of the Feed mapping mapping canvas, Designer will by default crop away the sides of the content. If the content is of lower resolution, Designer will scale up the content inside the mapping canvas.
2. Add the screens to the Feed mapping in the same order as they appear in the visualiser, from left to right. If the screens are not listed in that order yet, you can re-order the screens in the screens list by selecting and dragging a screen up or dow

Adding a Feed rectangle to the mapping canvas

To add a Feed rectangle to the mapping canvas:

1. Right-click the red screen canvas and select **Add feed rectangle**.

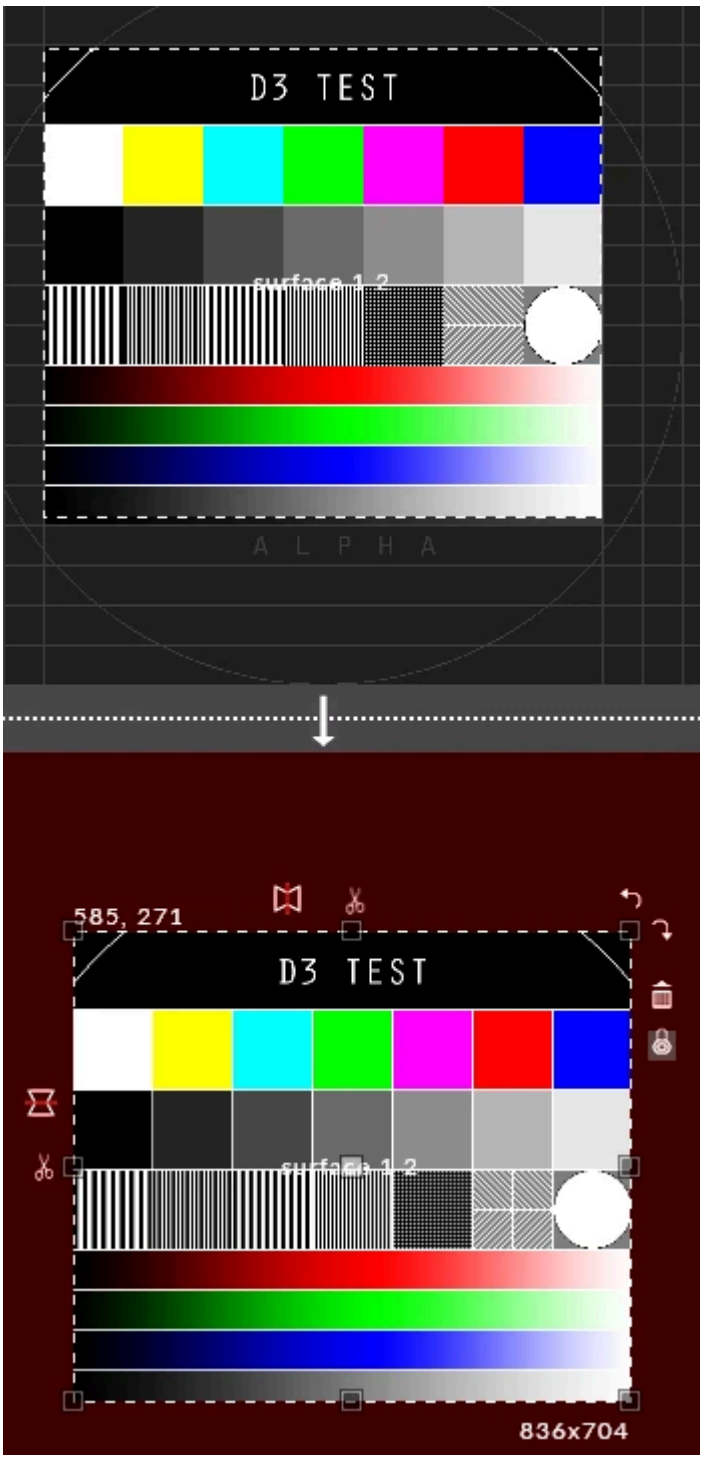
View of the Feed mapping editor when adding a new Feed rectangle

Note that the Feed rectangle is by default positioned in the top left corner of the mapping canvas. To change the position of the Feed rectangle, left-click it once, place the cursor in the middle and start moving it.

Editing a Feed rectangle

The Feed rectangle has a number of options for scaling, flipping and chopping the rectangle. These options are very similar to those used when editing a Feed rectangle in the Output Feeds level. For more information please see the sub-chapter Quick editing controls.

This image explains the various options associated with a Feed rectangle in the Stage level.



Feed rectangle quick editing controls

Item	Explanation
	The position of the sample rectangle placed on the Mapping Canvas, in pixels.

Item	Explanation
	The Scissor tool on the sample rectangle for vertical cuts. Left-click and hold down the mouse button to move the cut horizontally.-
	The Scissor tool on the sample rectangle for horizontal cuts. Left-click and hold down the mouse button to move the cut vertically.-
	The Bin . Left-click the bin icon once to delete the sample rectangle (and the Feed rectangle).-
	The size of the sample rectangle in pixels.
	The Flipping tool to flip the sample rectangle horizontally.
	The Scissor tool on the Feed rectangle for vertical cuts. Left-click and hold down the mouse button to move the cut horizontally.-
	The Rotate tool on the Feed rectangle for rotating the Feed rectangle 90 degree clock/anti-clockwise.-
	The Scissor tool on the Feed rectangle for horizontal cuts. Left-click and hold down the mouse button to move the cut vertically.-
	The Flipping tool to flip the sample rectangle vertically.
	
	The Lock button locks the size of the sample rectangle to the size of the Feed rectangle and vice versa. Left-click the Lock button once to unlock the dependency.
	The name of the screen.
	The size of the Feed rectangle in pixels.

Using these tools gives you a lot of freedom for configuring the Feed mapping on the screens in the Stage. Below, you can see an extreme example of this (for demonstration purposes

only). Note that the red color in the background on the left hand side will only show up if the Feed mapping editor is open. When closed, the background will remain black.

Using Feed Rectangle properties

Right-clicking a feed rectangle offers the following properties.

Add feed rectangle

This option adds another feed rectangle to the canvas.

Export current frame as PNG

A PNG of the feed rectangle is exported to the **screenshots** folder of your project folder. For more information see project structure.

Edit feed warping

This option allows you to draw a 2D warp on an individual feed rectangle. Useful for warping within the mapping layer as oppose to the feed level.

Select mask

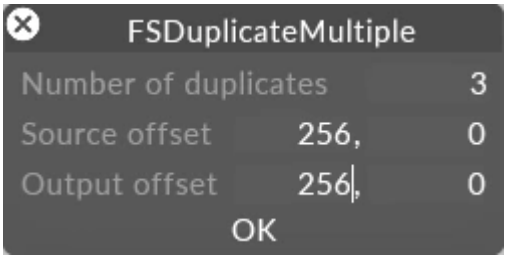
This option allows you to add a mask to the feed rectangle. Masks are read from the **DxTexture** folder of your Objects folder within your project folder. For more information see project structure.

Duplicate

This allows you to create a duplicate of the feed rectangle.

Duplicate multiple

This allows you to duplicated multiple source and destination feed rectangles to create arrays of feed rectangles within the mapping.



The duplicate multiple editor.

Turn snap off

This option toggles feed rectangle snapping on and off. When on, feed rectangle edges will snap to one another, and when off they do not do this (note the rulers still show with snapping off).

Import & Export feed maps

The easiest way to import and export feed maps from projects is via a table. A feed map can be exported to a text file from Designer and then imported to another project.

Export

1. In your Feedmap, right-click and choose **Export to table**.
2. Enter a name.
3. Click **OK**.

4. The feed map is now exported to a newly created table folder in the objects folder.

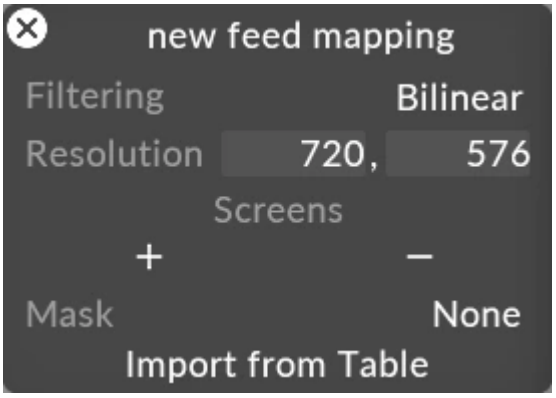
The table that is exported will look similar to this example:

	A	B	C	D	E	F	G	H	I	J	K	L
1	screen name	head	output rect x pos	output rect y pos	output rect width	output rect height	source rect x pos	source rect y pos	source rect width	source rect height	locked	rotation
2	left	2	0	0	960	540	0	0	960	540	1	0
3	right	2	960	0	960	540	0	0	960	540	1	0
4												
5												

“Screen Name” refers to the name of the feed rectangle while “Head” refers to the number of the output slot.

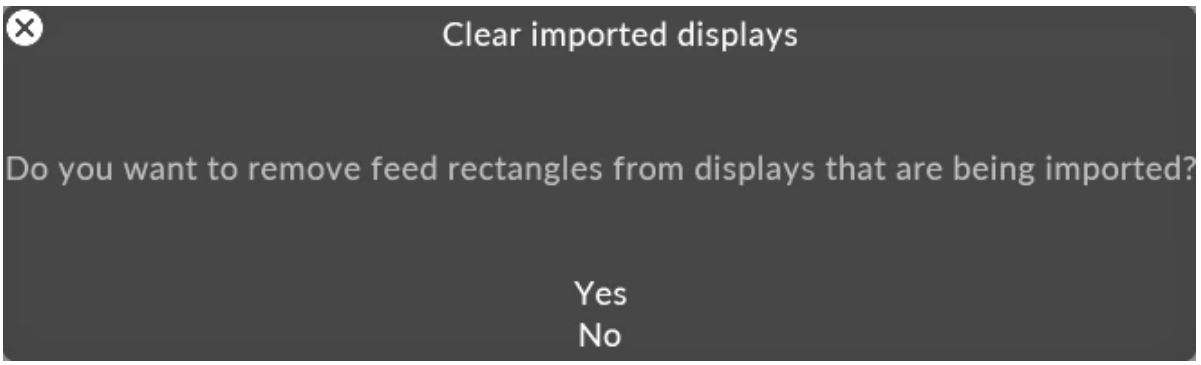
Import from a table

1. In your new project, create a feed mapping. The mapping does not need to share the same name as the one you are importing.
2. Left-click the Import from table option, this will only appear if there is a table folder present in the project folder.



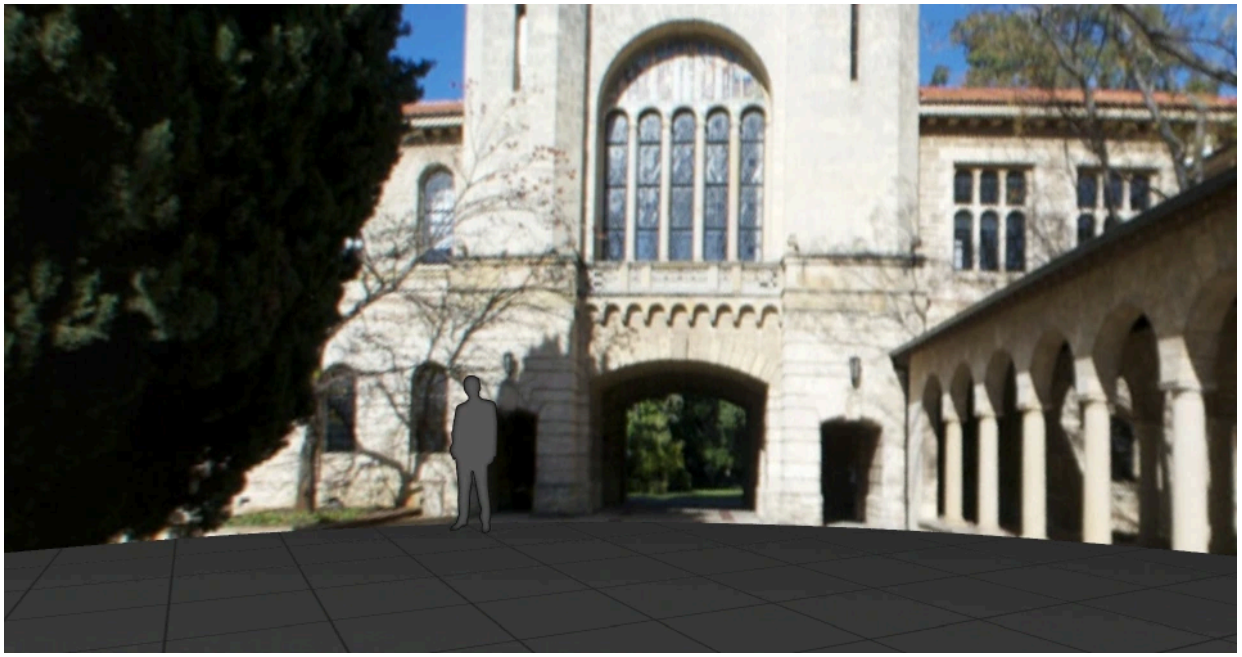
3. Left-click your table from the available list.

4. Choose yes when prompted to overwrite existing feed rectangles.



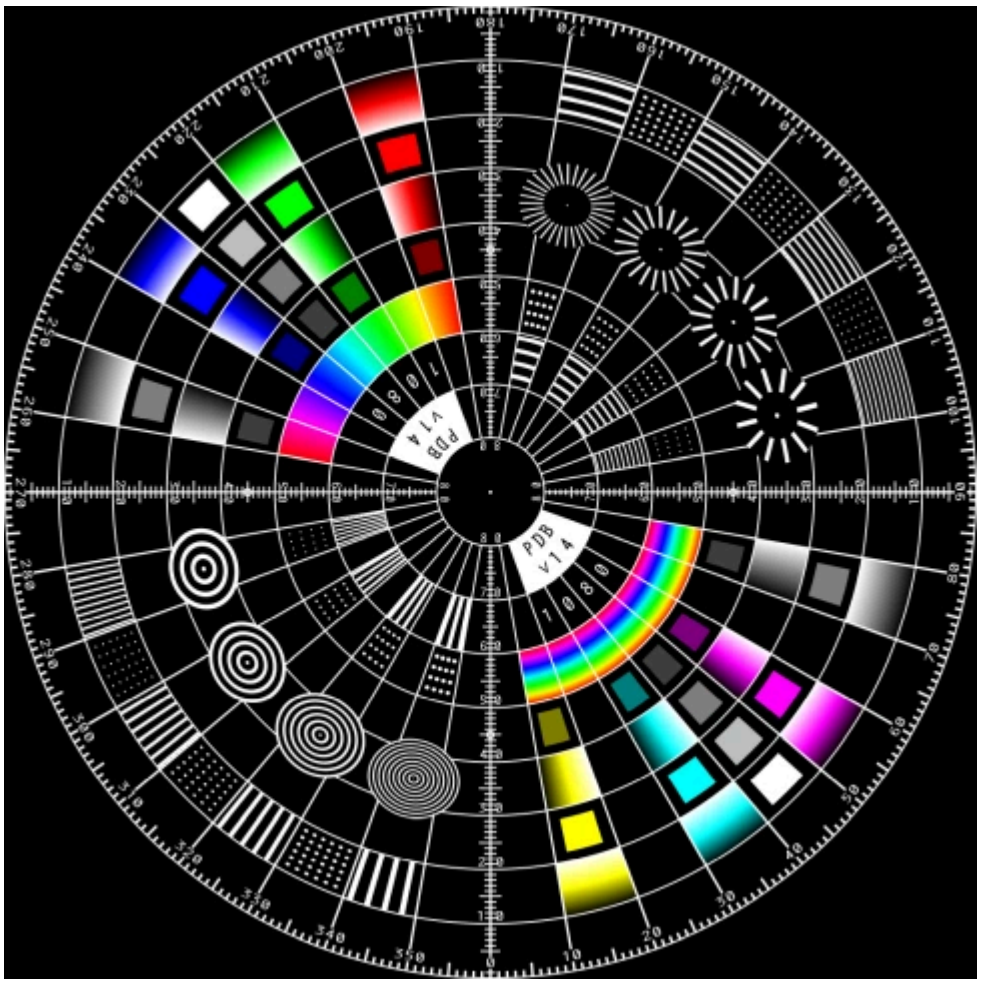
Fisheye Mapping

Fisheye mapping projects content onto screens using a fisheye projection, simulating the effect of a hemispherical lens. This mapping type is ideal for domes, curved surfaces, or any scenario where content needs to be distributed radially from a central point.



Fisheye mapping treats all assigned screens as a unified canvas, projecting a single fisheye-warped image over all surfaces. This eliminates the need for manual calculations of pixel density or screen spacing; Designer automatically handles the correct sampling and alignment, even as surfaces move or change orientation.

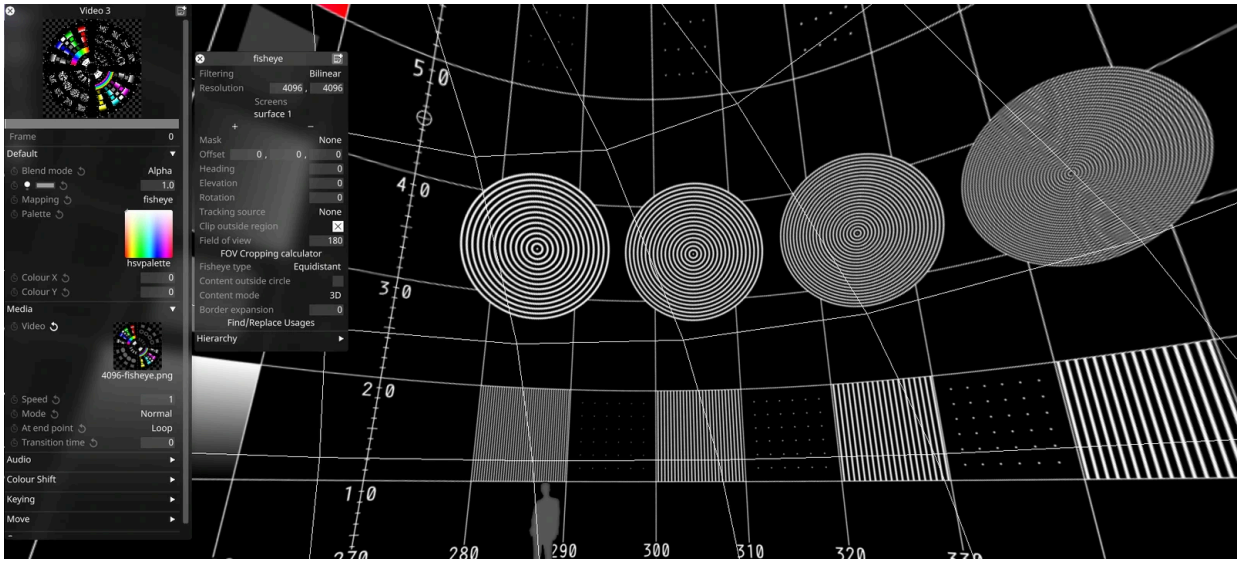
An example of fisheye content:



With credit to Paul Bourke. Fulldome test pattern by Paul Bourke. The images may be freely used under the condition it is not modified in any way. The image may be freely distributed as long as this license statement is included.

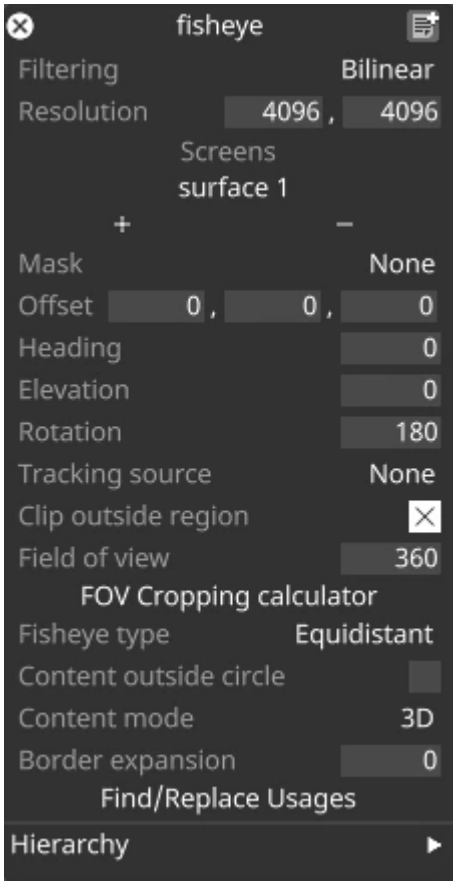
Creating a Fisheye Mapping

1. In your track, create a new visual layer (content, generative, or effect).
2. Select the layer to open the Layer Editor.
3. Under the Default tab, click the Mapping parameter to display available mappings.
4. In the mappings manager, create a new mapping and select **Fisheye** as the type.
5. An editor for the new fisheye mapping will appear.
6. Assign all screens to be used and enter the intended content resolution.
7. Assign content to the layer; it will be displayed fisheye-mapped across the assigned screens in the stage and feed output.
8. Adjust the specific fisheye mapping properties as needed.



When the Fisheye mapping editor opens, Designer highlights areas outside the mapped region and provides controls for projection parameters and cropping.

Mapping Properties



Filtering

- **Nearest**: Nearest neighbour filtering. Use nearest-neighbour sampling, to disable blending between pixels when scaling. Can be used to create pixellated looks, or to ensure hard edges on certain types of content.
- **Bilinear**: Bilinear filtering is a texture filtering method used to smooth textures when displayed larger or smaller than they actually are.
- **2x Multi-sample**: Multi-Sample filtering can help fix issues with scaled content, but can introduce some blurriness.

Resolution

This controls the canvas size the layer renders into, in pixels. The Direct mapping type starts with a 256x256 pixel canvas and automatically sets the canvas size to that of the first screen you add.

Screens

This is a list of screens that the selected mapping type can copy content to.

1. Left-click + to open the Screens manager.
2. Left-click **+** to add the Screens you want to map. This will copy the individual canvas content onto these three Screens simultaneously and will add the Screen names to the mapping object editor.
3. Left-click and drag the Screens listed in the mapping object editor to **-**. This will remove the canvas content from the Screens and delete the Screen names from the mapping object editor.

Mask

This points to the Texture file that defines a Mask bitmap. You can use this property to apply a Mask bitmap to the mapping canvas. Selecting this property will open the Texture object library, which shows all of the still image files saved on your local hard-drive in the **DxTexture** folder.

To apply a mapping mask you will need to create and import a custom still image file.

- The step-by-step instructions on how to create and import a custom Population mask can be used to create a custom mapping mask. The only difference is that the mapping masks resolution should be the same as the mapping canvas. For step-by-step instructions on how to create and import a Population mask into a d3 project visit to the section Population mask in the **Editing screens** sub-chapter.
- Alternatively, set any layers blend mode to **mask** to channel the layer content into the mapping mask.

Offset

Sets the position of the fisheye projection's anchor point in stage space (meters). This is relative to any parent object if the mapping is in a hierarchy.

Heading

Rotates the fisheye projection horizontally (degrees).

Elevation

Tilts the projection vertically (degrees).

Rotation

Rotates the content within the fisheye projection (degrees).

Tracking source

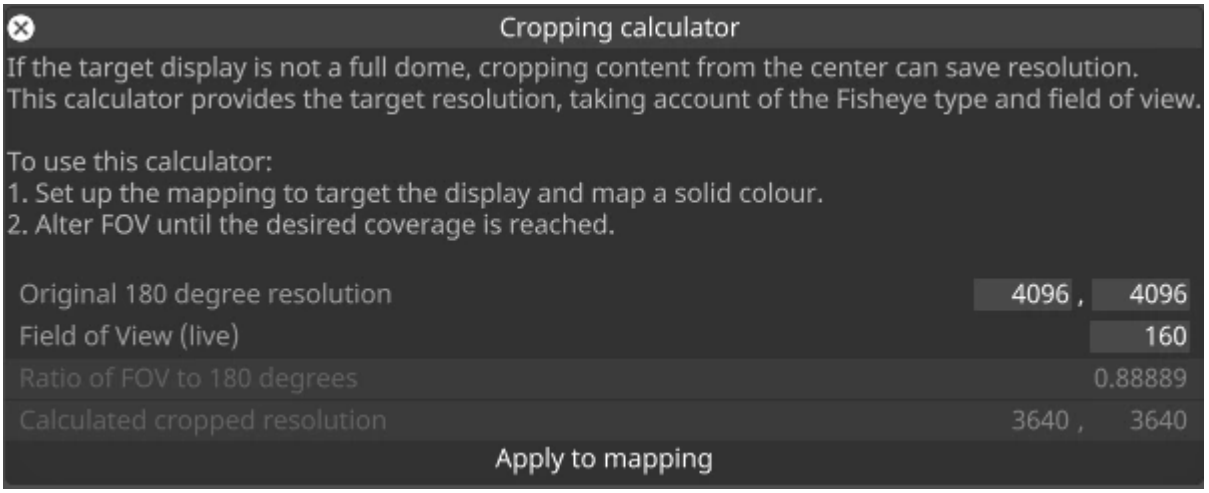
Attach the mapping to a tracked object.

Clip outside region

Clips pixels outside of rendered region, preserving existing colour. If not set, pixels outside the rendered region are set to the border colour.

Field of view & cropping calculator

Sets the angular extent of the fisheye projection (degrees). Increasing the FOV captures a larger area, and can extend to 360° for full spherical content. Decreasing the FOV focuses the mapping on a smaller area, and can be used to reduce file sizes. The default value is 180°.



The cropping calculator helps tune the FOV and its relationship with the mapping resolution. It provides live control over the FOV and calculates the resulting resolution as a factor of the original mapping resolution. This helps ensure that the content is sampled correctly for the intended display area.

Note that the fisheye type (below) also affects the resolution calculation, as different projection algorithms have varying sampling behaviour at different FOVs.

Fisheye type

Select the fisheye projection algorithm. Each type has different characteristics in terms of resolution distribution.

- **Equidistant**: Maps angles linearly to radius, providing a balanced distribution of resolution across the FOV. This is a common choice for general fisheye applications.
- **Equisolid**: Preserves area relationships, making it suitable for applications where equal-area representation is important, such as in planetarium projections.
- **Orthographic**: Projects points onto a plane, resulting in a more compressed image towards the edges. This can be useful for artistic effects or specific display requirements.
- **Stereographic**: Preserves angles, resulting in a larger apparent size of objects near the edge of the FOV.

Content outside circle

When disabled, content outside the circular fisheye area is clipped. When enabled, the entire rectangular mapping area is used. This can be useful if only small parts of the screen are outside of a given FOV, as the usually wasted area can be filled with content.

Content mode

Choose between 2D or 3D content mapping. In 3D mode, the lens is converted to a camera and sent to the 3D engine, allowing for true 3D perspective and parallax effects. In 2D mode, the content is always treated as a flat image, with no camera information.

Border Expansion

UV islands on screens are expanded by this many pixels to cover edge sampling artifacts such as black fringing. Note that there must be an equivalent amount of empty space in the screen UV map to take advantage of this.

Find/Replace Usages

Finds all usages of the current mapping in the project, and allows these to be replaced with an alternative mapping. Note that replacement only works for sequenced, non-sockpuppeted mappings.

Hierarchy

The hierarchy section allows the mapping to be set as a parent or child of another object, like any other object. See Object Overview for details.

Mesh Mapping

Mesh mapping enables you to project 3D content onto the entirety of one or more screens, automatically adjusting to the extent of the surfaces it targets. It can be very useful for mapping 3D content onto large projection installations, or rendering out-of-frustum content for VP/xR shoots.

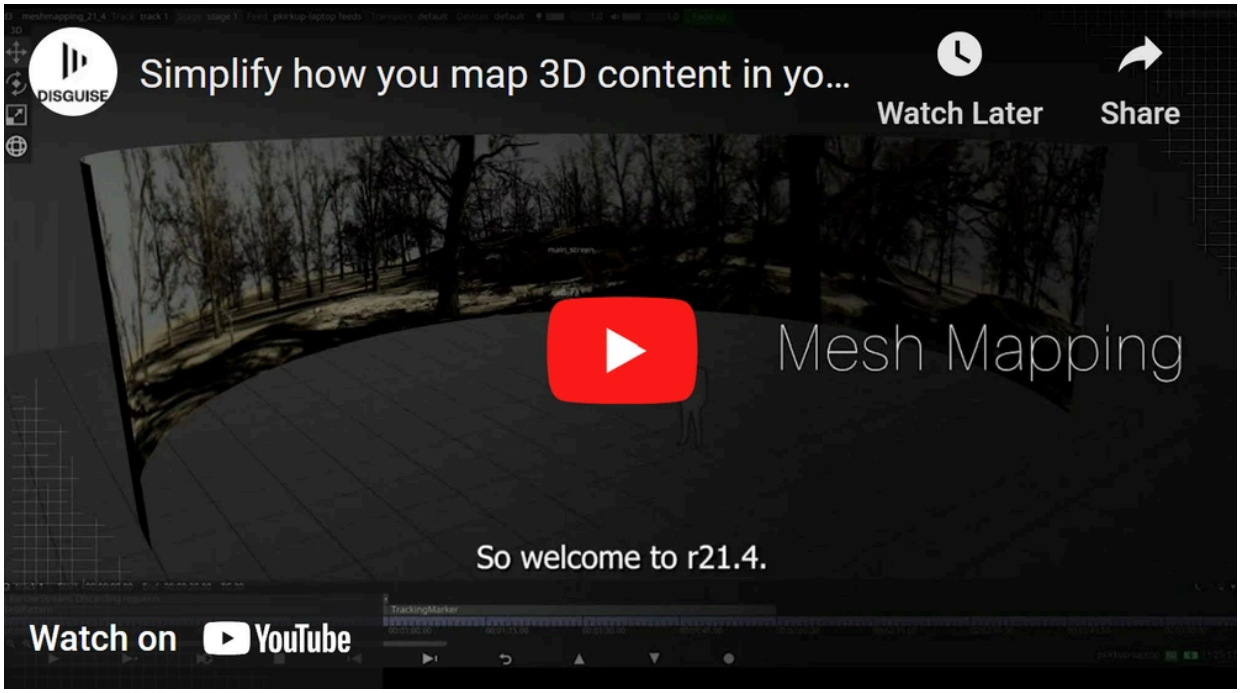
Mesh mapping is similar to a Perspective mapping, in that it projects content onto the screens from an eyepoint, and sends the projection viewpoint to 3D content engines so that the rendered content matches the viewpoint frustum.

The main differences between mesh and perspective mappings are:

- The mesh mapping viewpoint frustum is automatically calculated to tightly bound the extent of the screen, whereas the perspective mapping frustum properties (rotation, field of view etc.) must be set manually.
- When using RenderStream, mesh mapping applies the projection to the screen on the render node, then transports the image in UV space. This is more efficient as it avoids transporting pixels which will be lost in the projection. Perspective mapping transports the rendered image, then projects into UV space on the receiving machine.

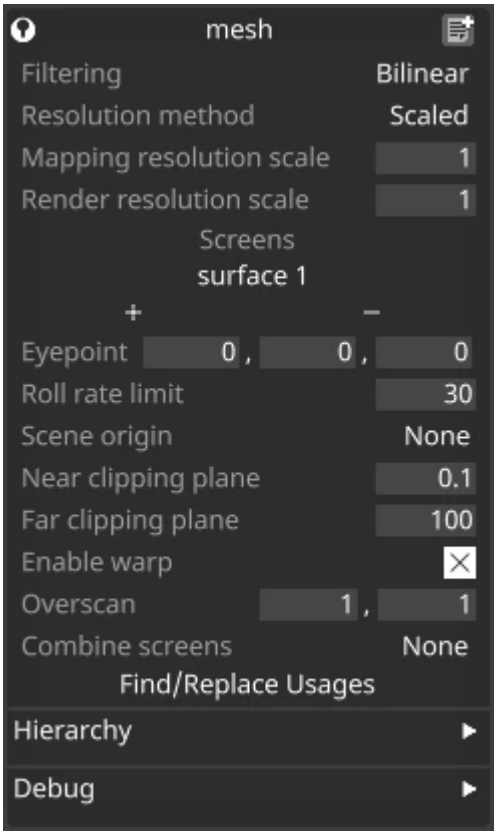
> **Caution**
>
> Mesh mapping isn't generally appropriate for 2D content, as it can apply unintended angles or cropping to the content. This is compensated for in 3D content by the viewpoint sent to the render engine.

See How it Works



Click the image to watch the video on YouTube

Mesh mappings are created like any other mapping type, from within a layer's **Mapping** field. Screens should then be added and other properties configured in the mapping editor.



Mesh mapping editor

Creating a Mesh Mapping

Mesh mappings can be created in a similar way to other mappings, however, once created, they must be further configured for 3D content.

1. In your track, add a new visual layer. This can be a **content layer**, **generative layer**, or **effect layer**.
2. Left-click the new layer in the track to open the **Layer Editor**.
3. Under the **Default** tab, left-click the **Mapping** parameter to display the Mappings manager which lists all of the mappings in the project.
4. In the **New Mapping** text field, add a name for your new mapping. A list will appear prompting you to select a mapping type.
5. Select Mesh from the list. The Mesh Mapping editor will appear.
6. In the **Mapping editor**, assign the screens to be used for the mapping, and specify the resolution of the content.

Add 3D content by following the RenderStream Workflows below.

Common Mapping Properties

This section explains the properties that are shared by the different mapping types.

Filtering

- **Nearest**: Nearest neighbour filtering. Use nearest-neighbour sampling, to disable blending between pixels when scaling. Can be used to create pixellated looks, or to ensure hard edges on certain types of content.
- **Bilinear**: Bilinear filtering is a texture filtering method used to smooth textures when displayed larger or smaller than they actually are.
- **2x Multi-sample**: Multi-Sample filtering can help fix issues with scaled content, but can introduce some blurriness.

Screens

This is a list of screens that the selected mapping type can copy content to.

1. Left-click + to open the Screens manager.
2. Left-click + to add the Screens you want to map. This will copy the individual canvas content onto these three Screens simultaneously and will add the Screen names to the mapping object editor.
3. Left-click and drag the Screens listed in the mapping object editor to -. This will remove the canvas content from the Screens and delete the Screen names from the mapping object editor.

Find/Replace Usages

Finds all usages of the current mapping in the project, and allows these to be replaced with an alternative mapping. Note that replacement only works for sequenced, non-sockpuppeted mappings.

Hierarchy

The hierarchy section allows the mapping to be set as a parent or child of another object, like any other object. See Object Overview for details.

Mesh Mapping Resolution Properties

Resolution method

Since mesh mapping creates different viewpoints for each screen it renders to, it has several different options for deciding how to set the mapping resolution for each viewpoint:

- **Constant**: Each viewpoint is rendered at the same constant resolution, defined in the mapping's **Resolution** property.
- **Scaled**: The resolution of each viewpoint is equal to the resolution of the screen it is mapped to, multiplied by the **Mapping resolution scale**.
- **Pixels Per Degree**. The resolution of each viewpoint is calculated based on the horizontal and vertical field of view of the frustum, to maintain a consistent angular resolution set in the **Pixels per degree** property.

Resolution

When the **Resolution method** is set to **Constant**, this property controls the resolution of all viewpoints, in pixels.

Mapping resolution scale

When the **Resolution method** is set to **Scaled**, the resolution that the content is rendered and projected for a given screen is equal to the screen's resolution, multiplied by the mapping resolution scale.

Pixels per degree

When the **Resolution method** is set to **Pixels Per Degree**, this property defines the angular resolution of the mapping.

Render resolution scale

When using mesh mapping with RenderStream, the render engine first renders a view of the scene at resolution *A*. This view is then projected onto the screen and transported over the network in UV-space, at resolution *B*. Occasionally helpful for screens with complicated UV maps, render resolution scale can be set to adjust the render resolution *A* relative to the mapping resolution *B*, so that:

- Resolution *B* is equal to the screen resolution multiplied by the **Mapping resolution scale**, as described above.
- Resolution *A* is equal to resolution *B* multiplied by the **Render resolution scale**.

Other Mesh Mapping Properties

Other properties which are specific to mesh mapping include:

Eyepoint

The point from which the 3D content is rendered and mapped to the screens. This is the point in the world from which the perspective of the 3D content will look correct.

Scene origin

This can be used to offset the origin of the 3D content from the Designer coordinate space, to modify the alignment of the scene relative to the screens.

Roll rate limit

It is possible to add the mesh mapping to a parent object, such as a camera, so that the eyepoint follows that camera (see **below**). Following a tracked camera can cause sudden jumps in the roll of the frustum, which can result in artefacts in the rendered content. Roll rate limit avoids these jumps by limiting how quickly the roll of the frustum can change.

Near clipping plane

The distance (in metres) from the eyepoint of your frustum's near clipping plane. Objects in the content closer than this are not rendered.

Far clipping plane

The distance (in metres) from the eyepoint of your frustum's far clipping plane. Objects in the content further than this are not rendered.

Enable warp

Mesh mappings render views of a 3D scene from the eyepoint, and then apply a perspective warp onto the meshes of the selected displays. If **Enable warp** is ticked, when using Renderstream the perspective warping will be applied on the render node, saving performance on the machine receiving the streams and avoiding streaming pixels which will ultimately be cut off in the perspective warping. If **Enable warp** is unticked, RenderStream will stream the rendered views, and the perspective warp will happen on the receiving machine. This option has no effect for locally rendered modules.

Overscan

Renders extra content outside the original canvas to compensate for edge effects. 1 means 100 % of the original size, 2 means 200 %, etc. Note that the resolution of the total rendered content doesn't change even though the field of view is increased. You may wish to increase the mapping resolution to account for the overscan added.

Combine Screens

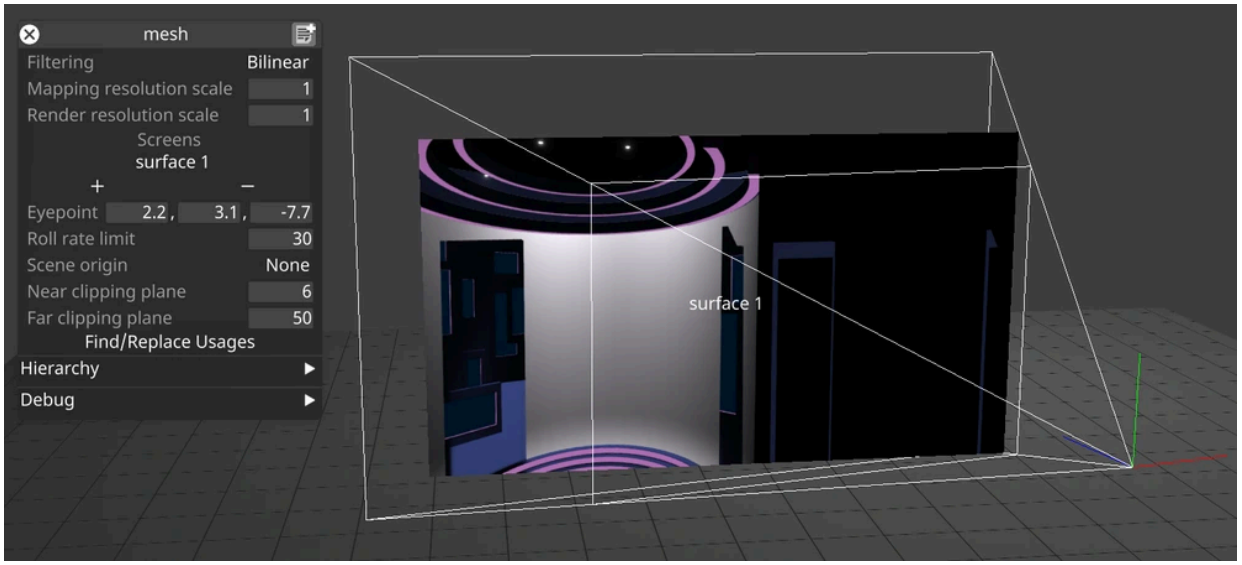
By default, Mesh Mapping renders a separate content viewpoint for each screen in the mapping. However, the **Combine Screens** option can be used to cover multiple screens with a single viewpoint. This can be helpful for improving performance in setups with lots of screens close together. The available options are:

- **None**: Each screen has its own separate viewpoint frustum (default).
- **All**: All screens share a single combined viewpoint frustum.
- **Non-Output**: Viewpoints are combined on non-output machines (e.g. Editor, Dedicated Director), separate on output machines (e.g. Actor, Non-Dedicated Director).
- **All Active**: Each machine combines its locally active screens into a single viewpoint. Note that this option does not work with RenderStream; RenderStream modules will render a separate viewpoint per screen as in **None** mode.

> ⚠ **Caution**
>
> When combining screens (using any option other than **None**), selecting **Scaled** for the **Resolution method** will use the first screen's resolution for the combined viewpoint. Using **Constant** or **Pixels Per Degree** instead is recommended for combined screen viewpoints.

Frustum Visualisation

When the mesh mapping editor is open, the viewpoint frustum(s) are drawn in the stage, which can be helpful for understanding how the content is projected.



Mesh mapping frustum

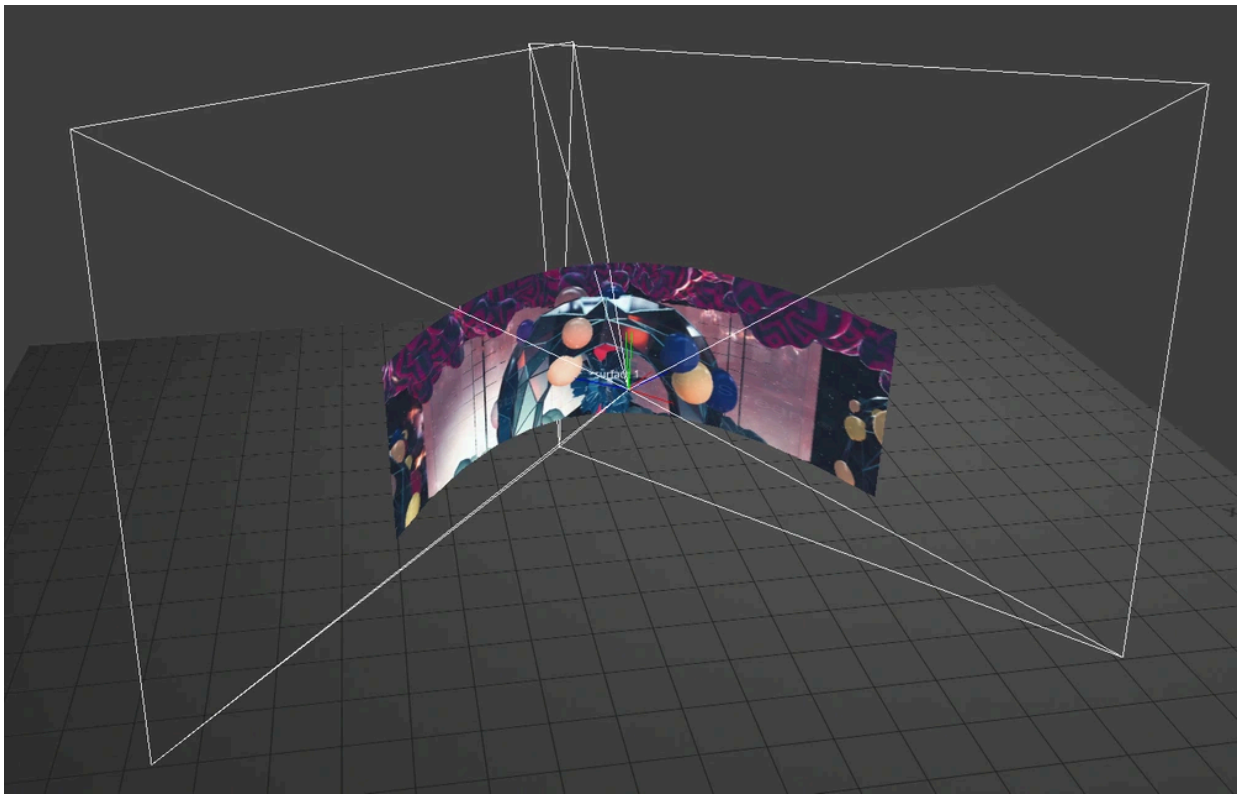
> ⚠ **Caution**
>
> Mesh mapping can only generate a viewpoint frustum with a field of view up to 180 degrees. For example, a curved screen may not render correctly if the eyepoint is within the curve of the screen. To get around this, split the screen content into fragments as discussed below.

RenderStream Workflows

Mesh mapping can be very helpful for 3D content workflows using RenderStream. As described above, mesh mapping projects content onto screens on the render node side, avoiding sending pixels over the network, which will subsequently be discarded. It also automatically creates a viewpoint frustum which tightly bounds the screen, maximising the efficiency of each rendered pixel.

RenderStream allows rendering of large canvases to be clustered across multiple render nodes (see RenderStream overview). Mesh mapping supports this workflow, generating a separate viewpoint frustum for each screen fragment, and combining the resulting renders together to give a single continuous view of the 3D scene. Padding and overlap can be used as normal to blend between the fragments.

Clustered rendering also allows mesh mapping to be used for screens which wrap around the eyepoint with a field of view over 180 degrees. Since a separate viewpoint is generated for each fragment, the mapping will look correct as long as each individual viewpoint has a field of view less than 180 degrees.



Mesh mapping with multiple fragments

RenderStream clustering can also be used to render in-frustum and out-of-frustum content simultaneously.

Cluster rendering workflow

To use a mesh mapping within a Cluster Workload for an in-frustum and out-frustum setup:

1. Set up a single channel within your **Cluster Workload** that is targeting **MR set (backplate)**
2. Create another channel that targets a mesh mapping. For a pool size of 2, this will generate 2 streams for the mesh when it is started.
3. Be sure to use the same scene origin object in both so that they have the same reference point.
4. Start the workload. You will see 3 total streams across the network as it receives the renders for both in-frustum and out-frustum.

> **Note**
>
> It's advisable not to place the mesh and the eyepoint at the exact same location as this can result in a frustum with an infinite field of view. If you want to reproduce the view on the origin 0,0,0, you may either place the mesh offset a bit within the Disguise stage or offset the eyepoint and use scene origin to 're-align' the offset.

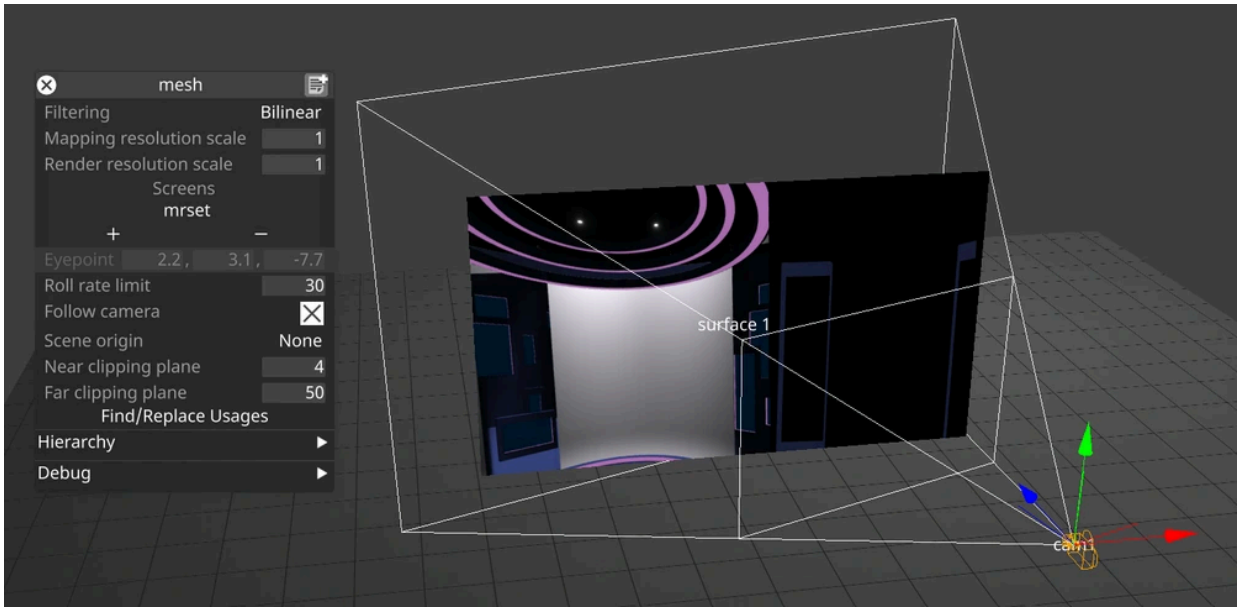
Following a camera

It is possible to set up a mesh mapping so that the eyepoint follows the position of a camera. This gives a mapping which adapts to the perspective of the camera like a Spatial or Camera Plate backplate mapping, but fills the whole screen rather than just the camera frustum.

> **Caution**
>
> Camera Plate and Spatial mappings use reprojection techniques to minimise perceived latency in the projected image. Mesh mapping doesn't do this, so it may appear to lag slightly when viewed through the camera, compared with these other mappings.

To set up a mesh mapping to follow a camera in an MR set:

1. Create an MR set, and add screens and a camera.
2. Create a mesh mapping and add the MR set to the list of screens. The mesh mapping will then automatically target the screens in the MR set.
3. The **Follow camera** field will appear in the mesh mapping editor. Tick this to make the eyepoint follow the camera position.
4. Alternatively, similar behaviour can be achieved by adding a camera to the list of screens in the mesh mapping, or by parenting the mesh mapping to any other object.



Mesh mapping following a camera

Troubleshooting

As the eyepoint moves around, the mesh mapping frustum can suddenly jump as it finds a more efficient way to bound the screen. This can cause blurriness or other artefacts in the rendered content. To compensate for this, set the **Roll rate limit** to reduce the speed at which the frustum is allowed to roll.

Moving the mesh mapping eyepoint can also result in sudden changes in focal length, which can cause blurriness if depth of field effects are enabled in the render engine (e.g. Unreal). Depth of field should not be enabled on cameras when using them for mesh mapping. Click here for instructions on how to do this in Unreal Engine.

Parallel Mapping

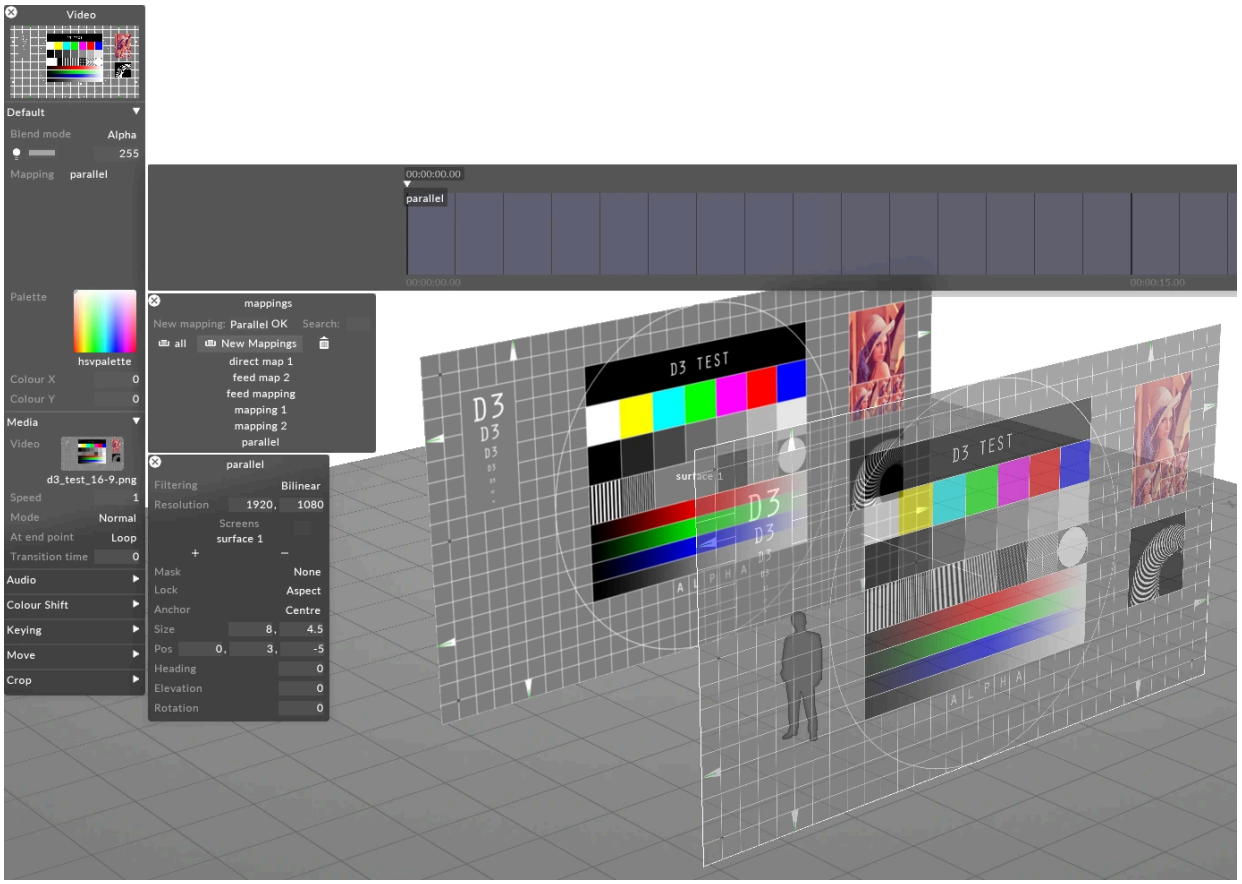
Parallel mapping projects content geometrically into the scene, as if virtually shooting content from an emitting rectangle. The mapped image does not increase in size the further away you go from the emitting rectangle. Instead, the image remains the same size, hence the term parallel.

Parallel mapping will emit content over multiple screens and treat the configuration as a single canvas, projecting one unified image over all assigned surfaces. There is no more need to calculate the exact distance and pixel density of the empty space between screens, Designer will maintain the correct content sampling even across moving surfaces.

Parallel mapping is also very useful when you want to apply content onto moving screens. As long as Designer receives the correct tracking signal, the system will automatically map the content onto the moving screens. See more about screen tracking in the sub-chapter Motion control systems.

Parallel mapping is a versatile method for integrating multiple display technologies—including LED systems with varying pixel pitches, projection, and DMX-based lighting—into a unified canvas. Since Disguise represents all outputs as pixel-based surfaces, whether LED, projection, or DMX fixtures such as moving heads, it enables precise spatial alignment and seamless blending of these diverse display types within a single coordinate space.

> **Note**
>
> Parallel mapping may not be useful when the screens are facing awkward angles in relation to the emitting rectangle of the Parallel mapping. The more they rotate away from the emitting rectangle, the more stretched the pixels will be on the screens. Ideally, the Parallel mapping should be used for straight-facing rectangular screens. For low-res sculptural screens, this is however not a problem.



Creating a Parallel Mapping

1. In your track, create a new visual layer. These layer types can include content layers, generative layers, and effect layers.
2. Left-click on the layer in the track to open the Layer Editor on the left side of the GUI.
3. Under the Default tab, left-click on the Mapping parameter to display a list of the mappings in the project.
4. A manager titled mappings will appear - this is a list of all mappings within your project. By default, all screens will be populated with a direct mapping sharing the same name, and all cameras will be populated with a perspective mapping sharing the same name.

5. Type directly into the 'New mapping:' text field to create a new mapping. A list will appear prompting to you select the mapping type.

   [Animated GIF: Create mapping]

6. An editor with the user assigned name of the mapping will appear once a mapping type is selected.
7. Assign all screens that will be used for the mapping and enter the resolution of the content that will be displayed on the screens.
8. Edit the specific properties of the chosen mapping type.
9. Assign a piece of content to the layer in the track, and the content will be displayed on the assigned screens of the mapping in the stage and the feed output window.

When the Parallel mapping editor initially opens, and assuming that the screens have been added, Designer will colour the region outside the projected image red and will give you the location and orientation details of the image source.ce.

Common Mapping Properties

This section explains the properties that are shared by the different mapping types.s.

Filtering

- **Nearest**: Nearest neighbour filtering. Use nearest-neighbour sampling, to disable blending between pixels when scaling. Can be used to create pixellated looks, or to ensure hard edges on certain types of content.
- **Bilinear**: Bilinear filtering is a texture filtering method used to smooth textures when displayed larger or smaller than they actually are.
- **2x Multi-sample**: Multi-Sample filtering can help fix issues with scaled content, but can introduce some blurriness.

Resolution

This controls the canvas size the layer renders into, in pixels. The Direct mapping type starts with a 256x256 pixel canvas and automatically sets the canvas size to that of the first screen you add.

Screens

This is a list of screens that the selected mapping type can copy content to.

1. Left-click + to open the Screens manager.

2. Left-click + to add the Screens you want to map. This will copy the individual canvas content onto these three Screens simultaneously and will add the Screen names to the mapping object editor.
3. Left-click and drag the Screens listed in the mapping object editor to -. This will remove the canvas content from the Screens and delete the Screen names from the mapping object editor.

Mask

This points to the Texture file that defines a Mask bitmap. You can use this property to apply a Mask bitmap to the mapping canvas. Selecting this property will open the Texture object library, which shows all of the still image files saved on your local hard-drive in the **DxTexture** folder.

To apply a mapping mask you will need to create and import a custom still image file.

- The step-by-step instructions on how to create and import a custom Population mask can be used to create a custom mapping mask. The only difference is that the mapping masks resolution should be the same as the mapping canvas. For step-by-step instructions on how to create and import a Population mask into a d3 project visit to the section Population mask in the **Editing screens** sub-chapter.
- Alternatively, set any layers blend mode to **mask** to channel the layer content into the mapping mask.

Clip outside region

Clips pixels outside of rendered region, preserving existing colour. If not set, pixels outside the rendered region are set to the border colour.

Border Expansion

UV islands on screens are expanded by this many pixels to cover edge sampling artifacts such as black fringing. Note that there must be an equivalent amount of empty space in the screen UV map to take advantage of this.

Find/Replace Usages

Finds all usages of the current mapping in the project, and allows these to be replaced with an alternative mapping. Note that replacement only works for sequenced, non-sockpuppeted mappings.

Hierarchy

The hierarchy section allows the mapping to be set as a parent or child of another object, like any other object. See Object Overview for details.

Parallel Mapping Properties

Lock

For convenience while editing, the mapping can either maintain its aspect ratio, which changes vertical size or resolution when you change horizontal size or resolution, and vice versa. The pixel density, which changes the vertical or horizontal size when you change the vertical or horizontal resolution can also be locked.

> **Note**
>
> If the aspect or the density of the source content is not locked the Parallel mapping may project stretched pixels onto the screens

Anchor

This controls the anchor point around which the mapping surface moves, scales and rotates. Select either **centre** to specify the position of the centre of the projection image or select **corner** to specify the bottom left corner of the image.

Size

This controls the size of the mapped image, in meters (horizontal and vertical).

Angle mask start (°)

This sets the starting point of the visible texture projection, measured in degrees around the axis. For example, a start angle of 0 degrees would typically be the “front” or a predefined reference direction.

Angle mask end (°)

This sets the ending point of the visible texture projection. The texture will only be visible between the start and end angles.

Position

The position, in stage space (in metres) of the anchor point of the mapping source. This can be either the centre of the image or the bottom left corner of the image.

Heading

This controls the direction of the mapping in the horizontal space, in degrees. Increasing the angles will make the direction to rotate clockwise.

- 0 degrees points North (positive z axis direction)
- 90 degrees points West (negative x direction)
- 180 degrees points South (negative z direction)
- 270 degrees points East (positive x direction)

Elevation

This controls the vertical elevation, in degrees, of the projection direction: 0 degrees is horizontal (i.e. parallel to the floor), 90 degrees is straight up and 90 degrees is straight down.

Rotation

This controls the rotation of the image around the mapping axis, clockwise in degrees.

Content mode

This defines the mode of content, either 2D or 3D.

Frame of reference

This setting dictates how the projected texture behaves when your object or the camera moves.

This is set to **None** by default.

Using the Parallel mapping type

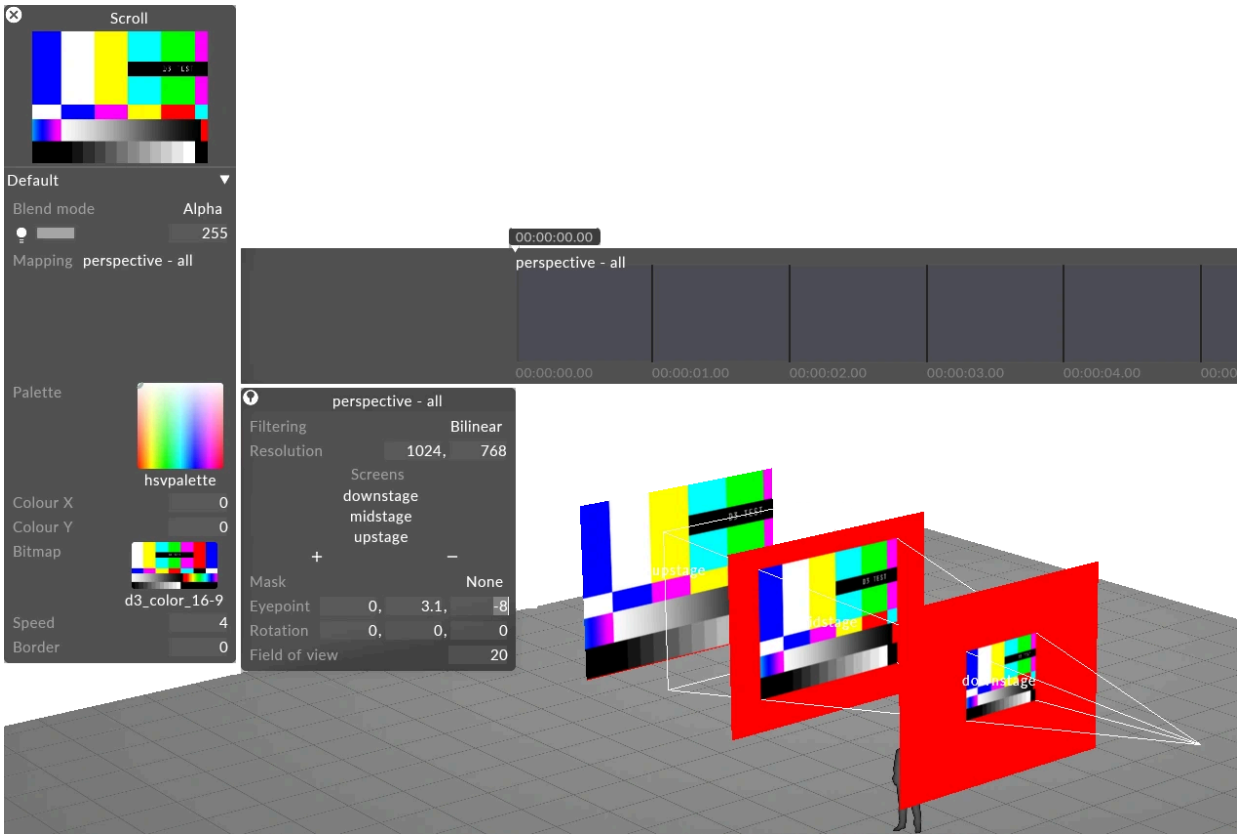
In addition to the property explanations provided above, it is important to:

1. Set the **aspect** property to **off** and set the resolution to match the resolution of the content intended to be used for this specific Parallel mapping.
2. Set the size of the emitting rectangle of the Parallel mapping to match the aspect of the resolution (and thereby the aspect of the content) and then set the aspect to **locked** . For example, if your content is 1920x1080, set the size to 19.2 10.8 and then set the aspect to **lock** . If the aspect or the density of the source content is not locked the Parallel mapping may project stretched pixels onto the screens.
3. Re-size the x or y coordinates to cover all areas of the screens (the red areas will gradually disappear as you re-size the emitting rectangle).
4. Make sure to specify content which has the same, or a slightly higher pixel density than the screen with the **highest** pixel density.

Perspective Mapping

Perspective mapping is similar to Parallel mapping, except that the content originates at an emitter point and gets larger in size as you go further away from the emitter, similar to a real projector. You can use Perspective mapping to make 2D content appear as 3D (not stereoscopic but rather as a 3D effect), but only from a specific point of view which is the same point as the position of the emitter.

Perspective mapping can map 3D content onto a surface from a specified vantage point of a virtual camera. This camera can be linked to a virtual camera in a generative software such as Notch to create an immersive 3D environment. The content being displayed by the mapping will begin emitting at the vantage point and get larger as that surfaces moves farther from it, similar to a real projector.



Perspective mapping type being used to project content onto three Screens, notice the content becomes larger as the Screens move further away from the emitter point

Creating a Perspective Mapping

1. **Add a New Layer**: In your track, create a new visual layer. This can be a content, generative, or effect layer.

2. **Open the Layer Editor**: Left-click on the newly added layer in the track. The Layer Editor will open on the left side of the interface.
3. **Access the Mapping Settings**: In the Default tab, left-click the Mapping parameter. A list of available mappings in your project will appear.
4. **View the Mapping Manager**: A panel titled Mappings will open. This displays all mappings in the project.

- By default, all screens have a direct mapping with matching names.
- All cameras have a perspective mapping with matching names.

5. **Create a New Mapping**: In the New Mapping field, type a name for your new mapping. A list of mapping types will appear, select **Perspective mapping**.
6. Open the Mapping Editor: After selecting a mapping type, an editor with your custom mapping name will open automatically.
7. **Configure Screen Assignments and Resolution**:

- Assign the screens that will use this mapping.
- Enter the resolution of the content that will be displayed on those screens.

8. **Edit Mapping Properties**: Adjust the specific settings related to the selected mapping type.
9. **Assign Content to the Layer**: Drag and drop a piece of content onto the layer in the track. The content will now appear on the assigned screens in both the Stage and Feed Output windows.

Common Mapping Properties

This section explains the properties that are shared by the different mapping types.

Filtering

- **Nearest**: Nearest neighbour filtering. Use nearest-neighbour sampling, to disable blending between pixels when scaling. Can be used to create pixellated looks, or to ensure hard edges on certain types of content.
- **Bilinear**: Bilinear filtering is a texture filtering method used to smooth textures when displayed larger or smaller than they actually are.
- **2x Multi-sample**: Multi-Sample filtering can help fix issues with scaled content, but can introduce some blurriness.

Resolution

This controls the canvas size the layer renders into, in pixels. The Direct mapping type starts with a 256x256 pixel canvas and automatically sets the canvas size to that of the first screen you add.

Screens

This is a list of screens that the selected mapping type can copy content to.

1. Left-click + to open the Screens manager.
2. Left-click + to add the Screens you want to map. This will copy the individual canvas content onto these three Screens simultaneously and will add the Screen names to the mapping object editor.
3. Left-click and drag the Screens listed in the mapping object editor to -. This will remove the canvas content from the Screens and delete the Screen names from the mapping object editor.

Mask

This points to the Texture file that defines a Mask bitmap. You can use this property to apply a Mask bitmap to the mapping canvas. Selecting this property will open the Texture object library, which shows all of the still image files saved on your local hard-drive in the **DxTexture** folder.

To apply a mapping mask you will need to create and import a custom still image file.

- The step-by-step instructions on how to create and import a custom Population mask can be used to create a custom mapping mask. The only difference is that the mapping masks resolution should be the same as the mapping canvas. For step-by-step instructions on how to create and import a Population mask into a d3 project visit to the section Population mask in the **Editing screens** sub-chapter.
- Alternatively, set any layers blend mode to **mask** to channel the layer content into the mapping mask.

Border Expansion

UV islands on screens are expanded by this many pixels to cover edge sampling artifacts such as black fringing. Note that there must be an equivalent amount of empty space in the screen UV map to take advantage of this.

Find/Replace Usages

Finds all usages of the current mapping in the project, and allows these to be replaced with an alternative mapping. Note that replacement only works for sequenced, non-sockpuppeted mappings.

Hierarchy

The hierarchy section allows the mapping to be set as a parent or child of another object, like any other object. See Object Overview for details.

Perspective Mapping Properties

Eyepoint

The Eyepoint specifies the source point (emitting point) of the Perspective mapping.

Rotation

The Rotation parameter specifies the rotation of the frustum of the Perspective mapping (i.e. the aiming point of the Perspective mapping).

Field of view

Defines the field of view of the Perspective mapping, in degrees (i.e. the size of the mapping coverage).

Content outside frustum

Enabling this option prevents the texture from repeating (tiling) outside the projection area, instead stretching the edge pixels to fill the rest of the object's surface.

- Enable/Disable checkbox

Overscan

Overscan extends the texture projection beyond its original boundaries to prevent visual artifacts like black edges or seams at the projection's edge.

Content mode

This defines the mode of content, either 2D or 3D.

Frame of reference

This setting dictates how the projected texture behaves when your object or the camera moves.

This is set to **None** by default.

PreComps

A PreComp (or pre-composition) in Designer acts as a virtual screen for you to write content to which can then be used as an input to another effect or composition. It also provides an alternative to the arrowing system which was limited to a one to one input, whereas a PreComp can be many inputs to many sources.

Creating a PreComp

A PreComp is created like other textures in Designer such as masks, from the Textures menu, which can be accessed from any layer that utilizes a texture input. Like any other texture, once it is created, it will be stored in the Textures menu and can be used in other locations.

1. Create a new layer and select a layer type that has a **Texture source** property. The Bitmap layer is the simplest one to use.
2. In the new texture field, enter a name for your PreComp. Choose PreComp Texture as the texture type.
3. Set the desired resolution for the PreComp, just as you would do if this was a real, physical screen. This should correspond to the resolution of the screen it will be mapped to.

Creating a PreComp

Render to PreComps

Once you have created a PreComp, a new default Direct mapping will now be present in the Mappings Manager, allowing you to route content into the PreComp from a content layer.

1. Create a layer and left-click on the content layer in the timeline to open the layer's properties.
2. Set the layer to display the desired content.
3. Under the Mapping properties field, select the mapping with the same name as the newly created PreComp.

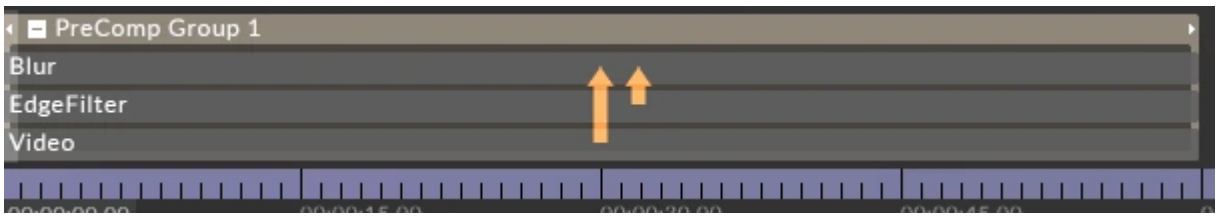
Now your layer is targeting the PreComp just like it would any screen in the project. PreComps can also be added to other mappings as if they were screens.

> **Note**
>
> A PreComp cannot be chained, i.e. a PreComp cannot feed into another PreComp.

Using PreComps as a source for an Effect Layer

The PreComp can be used as the Source texture input to an effect layer.

1. Create an Effect layer and position it above the source layers.
2. Set the Effect layer mapping to the screens the content will be shown on. **You may not select a mapping that targets another PreComp**.
3. Set the source layer mappings to target PreComp textures.
4. Set one or more source input fields on the effect layer to take the PreComp texture as input.
5. Once you do this you will see an orange arrow pointing from each layer rendering to a PreComp to the effect layer. This tells you your PreComps are configured correctly.



PreComp Stack

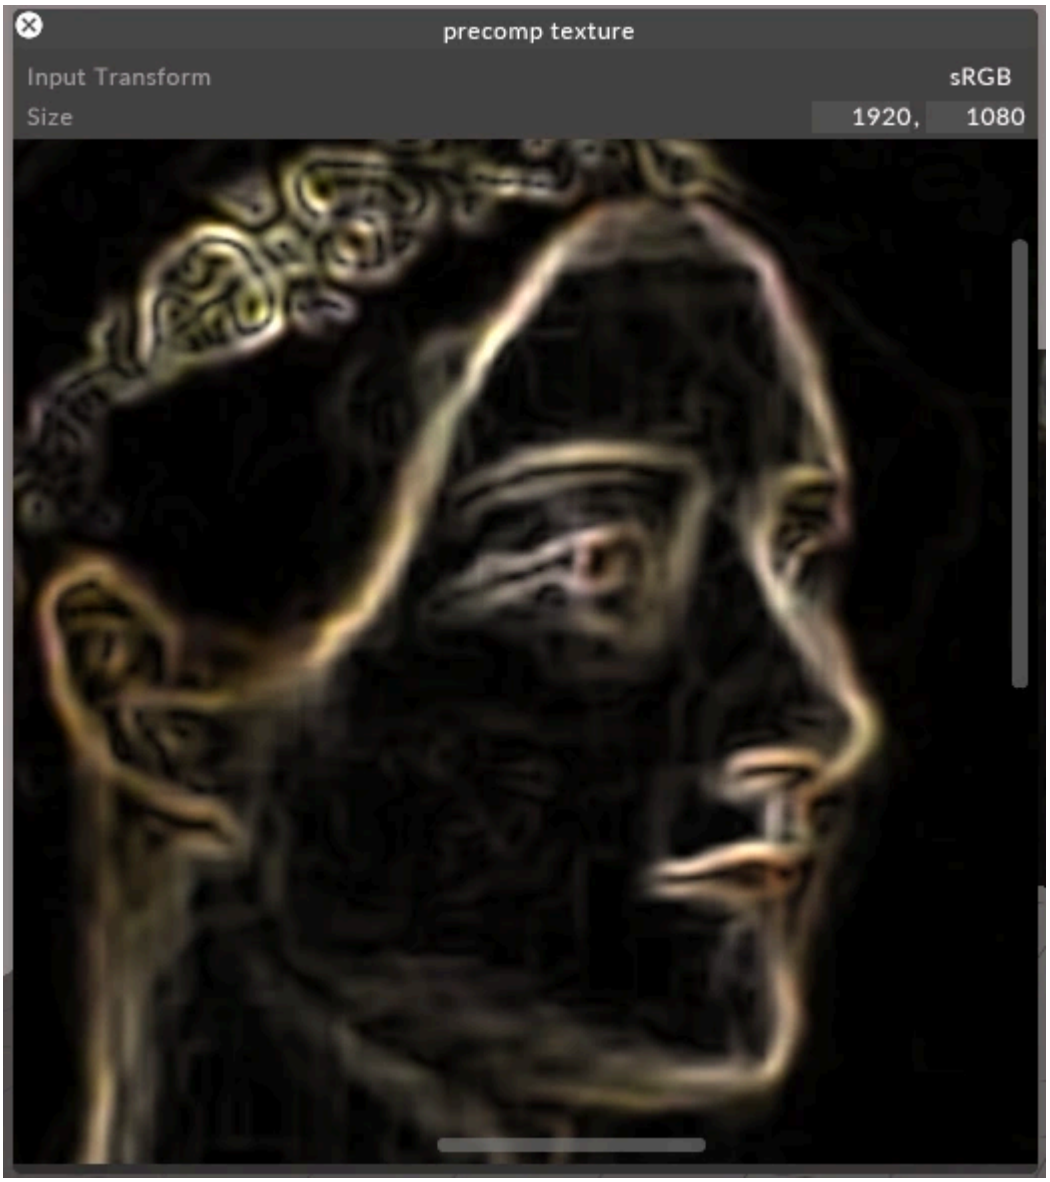
> **Note**
>
> **Please note**: The source layers that make up the PreComp have to be positioned under the Layer that is referencing the PreComp texture. The PreComp itself is a placeholder texture, so if you move elsewhere on the timeline and nothing is rendering to it, it will not have any content in it, and so the input to the effect layer will be empty.

Using PreComps in multiple tracks

Designer supports sharing PreComp textures between tracks. So long as one track has a layer targeting the PreComp under it's playhead, all other transports can utilize that PreComp. The tracks will composite to the PreComp in the same order they would to any screen, from bottom to top of the multi-transport.

Previewing a PreComp

1. Right-click on the thumbnail in the Layer properties window.
2. Use middle mouse button to pan around the expanded preview.

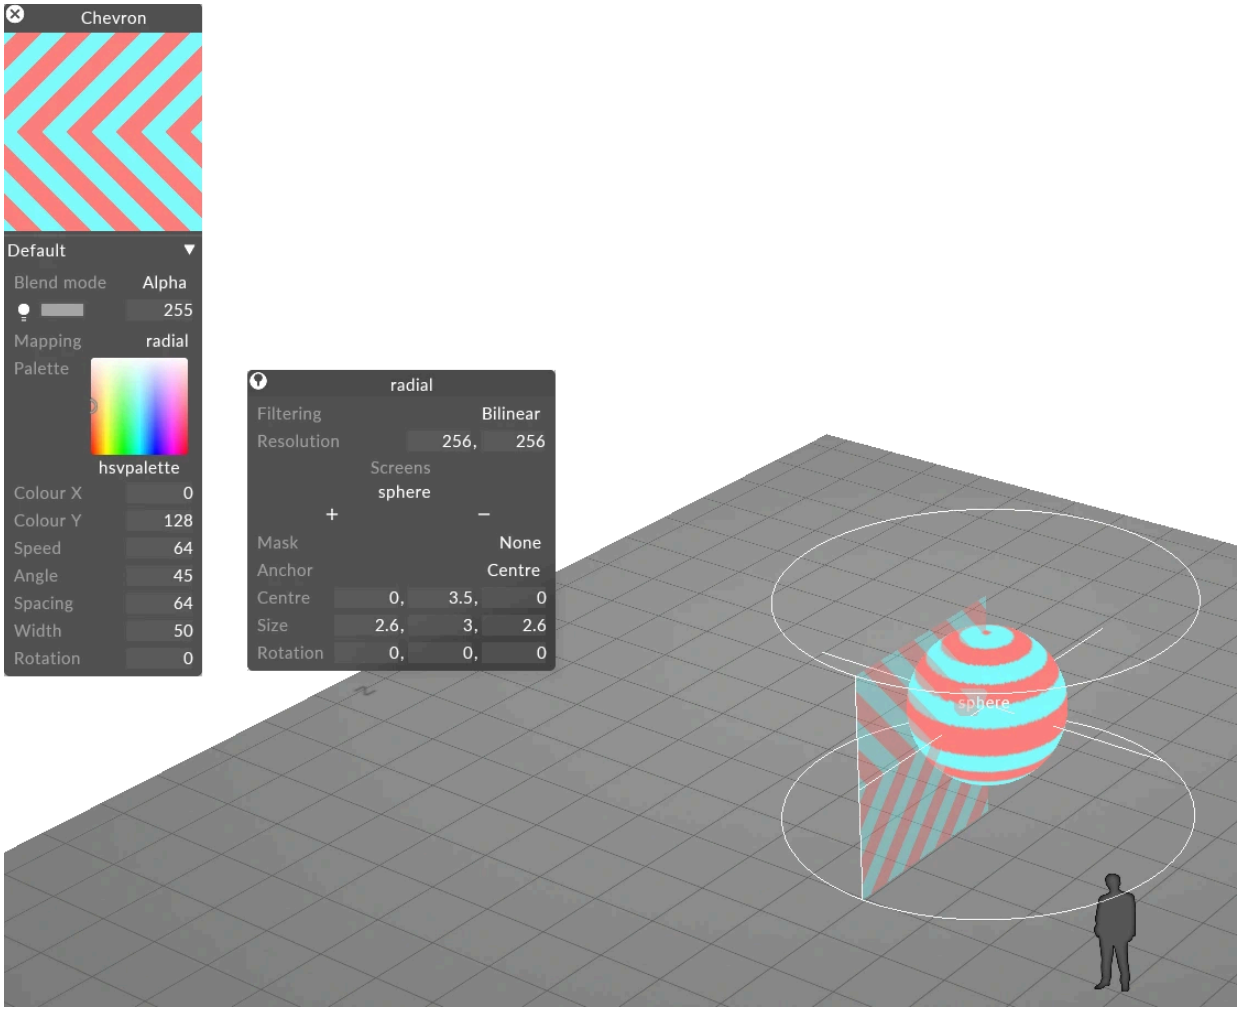


PreComp Texture Preview Interface

Radial Mapping

The Radial mapping is similar to the Cylindrical mapping type, except that the content surface runs from the central axis to the cylinder rim, rather than being wrapped around the outside of the cylinder. Any fixtures or pixels inside the cylinder will therefore be mapped according to their height within the cylinder (y coordinate) and their distance from the cylinders axis (x coordinate). Fixtures outside of the cylinder are not affected.

Radial mapping is similar to the Cylindrical mapping, except that the emitter surface runs from the central axis to the cylinder rim, rather than being wrapped around the outside of the cylinder. The pixels inside the cylinder will therefore be mapped according to their height within the cylinder and their distance from the central axis.



Radial mapping type is similar to Cylindrical mapping except that the content surface runs from the central axis to the cylinder rim

Creating a Radial Mapping

1. In your track, add a new visual layer. This can be a **content layer**, **generative layer**, or **effect layer**.
2. Left-click the new layer in the track to open the **Layer Editor**.
3. Under the **Default** tab, left-click the **Mapping** parameter to display the Mappings manager which list all of the mappings in the project. By default, all screens are assigned a **Direct mapping** with the same name. All cameras are assigned a **Perspective Mapping** with the same name.
4. In the **New Mapping** text field, add a name for your new mapping. A list will appear prompting to you select a mapping type.
5. Select Radial from the list. The Radial Mapping editor will appear.
6. In the **Mapping editor**, assign the screens to be used for the mapping, and specify the resolution of the content.
7. Adjust the mapping properties as needed.
8. Finally, assign a piece of content to the layer in your track. The content will be displayed on the **assigned screens** in both the stage and feed output window.w.

Common Mapping Properties

This section explains the properties that are shared by the different mapping types.

Filtering

- **Nearest**: Nearest neighbour filtering. Use nearest-neighbour sampling, to disable blending between pixels when scaling. Can be used to create pixellated looks, or to ensure hard edges on certain types of content.
- **Bilinear**: Bilinear filtering is a texture filtering method used to smooth textures when displayed larger or smaller than they actually are.
- **2x Multi-sample**: Multi-Sample filtering can help fix issues with scaled content, but can introduce some blurriness.

Resolution

This controls the canvas size the layer renders into, in pixels. The Direct mapping type starts with a 256x256 pixel canvas and automatically sets the canvas size to that of the first screen you add.

Screens

This is a list of screens that the selected mapping type can copy content to.

1. Left-click + to open the Screens manager.

2. Left-click + to add the Screens you want to map. This will copy the individual canvas content onto these three Screens simultaneously and will add the Screen names to the mapping object editor.
3. Left-click and drag the Screens listed in the mapping object editor to -. This will remove the canvas content from the Screens and delete the Screen names from the mapping object editor.

Mask

This points to the Texture file that defines a Mask bitmap. You can use this property to apply a Mask bitmap to the mapping canvas. Selecting this property will open the Texture object library, which shows all of the still image files saved on your local hard-drive in the **DxTexture** folder.

To apply a mapping mask you will need to create and import a custom still image file.

- The step-by-step instructions on how to create and import a custom Population mask can be used to create a custom mapping mask. The only difference is that the mapping masks resolution should be the same as the mapping canvas. For step-by-step instructions on how to create and import a Population mask into a d3 project visit to the section Population mask in the **Editing screens** sub-chapter.
- Alternatively, set any layers blend mode to **mask** to channel the layer content into the mapping mask.

Clip outside region

Clips pixels outside of rendered region, preserving existing colour. If not set, pixels outside the rendered region are set to the border colour.

Border Expansion

UV islands on screens are expanded by this many pixels to cover edge sampling artifacts such as black fringing. Note that there must be an equivalent amount of empty space in the screen UV map to take advantage of this.

Find/Replace Usages

Finds all usages of the current mapping in the project, and allows these to be replaced with an alternative mapping. Note that replacement only works for sequenced, non-sockpuppeted mappings.

Hierarchy

The hierarchy section allows the mapping to be set as a parent or child of another object, like any other object. See Object Overview for details.

Radial Mapping Properties

Anchor

Base point from which the scale of the Radial mapping has its origin.

- Centre
- Top
- Bottom

Position of the Radial mapping based on the centre point of the cylinder.

Position

The x, y, z position of the cylinder.

Rotation

The x, y, z rotation of the cylinder.

Size

The size of the Radial mapping. The x and z values represent the diameter of the cylinder.

Spatial Mapping

The Spatial map targets an MRset so it understands camera tally, and also allows for world offset between the d3 world and the content world.

The Spatial mapping was introduced for the AR & xR workflows, and allows for the camera's perspective and position to be relative to the virtual scene. The camera can travel around the 3D environment and accurately render it from any perspective.

Creating a Spatial Mapping

1. In your track, create a new visual layer. These layer types can include content layers, generative layers, and effect layers.
2. Left-click on the layer in the track to open the Layer Editor on the left side of the GUI.
3. Under the Default tab, left-click on the Mapping parameter to display a list of the mappings in the project.
4. A manager titled mappings will appear – this is a list of all mappings within your project. By default, all screens will be populated with a direct mapping sharing the same name, and all cameras will be populated with a perspective mapping sharing the same name.
5. Type directly into the New mapping: text field to create a new mapping. A list will appear prompting to you select the mapping type.

   [Animated GIF: alt text]

   An editor with the user assigned name of the mapping will appear once a mapping type is selected. Assign all screens that will be used for the mapping and enter the resolution of the content that will be displayed on the screens. Edit the specific properties of the chosen mapping type. Assign a piece of content to the layer in the track, and the content will be displayed on the assigned screens of the mapping in the stage and the feed output window.

Common Mapping Properties

This section explains the properties that are shared by the different mapping types.

Filtering

- **Nearest**: Nearest neighbour filtering. Use nearest-neighbour sampling, to disable blending between pixels when scaling. Can be used to create pixellated looks, or to ensure hard edges on certain types of content.

- **Bilinear**: Bilinear filtering is a texture filtering method used to smooth textures when displayed larger or smaller than they actually are.
- **2x Multi-sample**: Multi-Sample filtering can help fix issues with scaled content, but can introduce some blurriness.

Resolution

This controls the canvas size the layer renders into, in pixels. The Direct mapping type starts with a 256x256 pixel canvas and automatically sets the canvas size to that of the first screen you add.

Screens

This is a list of screens that the selected mapping type can copy content to.

1. Left-click + to open the Screens manager.
2. Left-click **+** to add the Screens you want to map. This will copy the individual canvas content onto these three Screens simultaneously and will add the Screen names to the mapping object editor.
3. Left-click and drag the Screens listed in the mapping object editor to **-**. This will remove the canvas content from the Screens and delete the Screen names from the mapping object editor.

Mask

This points to the Texture file that defines a Mask bitmap. You can use this property to apply a Mask bitmap to the mapping canvas. Selecting this property will open the Texture object library, which shows all of the still image files saved on your local hard-drive in the **DxTexture** folder.

To apply a mapping mask you will need to create and import a custom still image file.

- The step-by-step instructions on how to create and import a custom Population mask can be used to create a custom mapping mask. The only difference is that the mapping masks resolution should be the same as the mapping canvas. For step-by-step instructions on how to create and import a Population mask into a d3 project visit to the section Population mask in the **Editing screens** sub-chapter.
- Alternatively, set any layers blend mode to **mask** to channel the layer content into the mapping mask.

Clip outside region

Clips pixels outside of rendered region, preserving existing colour. If not set, pixels outside the rendered region are set to the border colour.

Border Expansion

UV islands on screens are expanded by this many pixels to cover edge sampling artifacts such as black fringing. Note that there must be an equivalent amount of empty space in the screen UV map to take advantage of this.

Find/Replace Usages

Finds all usages of the current mapping in the project, and allows these to be replaced with an alternative mapping. Note that replacement only works for sequenced, non-sockpuppeted mappings.

Spatial Mapping Properties

Camera plate

Camera plate options include:

- Front Plate
- Back Plate
- Horizontal Back and Front Plates
- Front Plate Undistorted
- Back Plate Screens
- Back Plate Set Extension

Reprojection distance (m)

The reprojection distance in metres is a measure of the accuracy and real-world alignment of your virtual camera and the physical set. It indicates how closely the digital content is matching the real-world geometry from the camera's perspective.

Scene origin

This can be used to offset the origin of the 3D content from the Designer coordinate space, to modify the alignment of the scene relative to the screens.

Engine Camera possible

- Active camera: Default is **None**. Select the active camera.
- Camera offset: x, y z
- Camera rotation: x, y, z

Initial

Initial Origin

Defines the origin of the bounding box before any offset is applied.

Initial Rotation

Defines the rotation of the bounding box before any rotation is applied.

Initial Size

Defines the size of the bounding box before any scaling is applied.

Spherical Mapping

The Spherical Mapping projects content outwards from an eye point in all directions. It can be used with 3D modules to project a complete spatial render of a virtual scene, or with 2D content to emit equirectangular images and videos from the surface of a sphere. It works similarly to the Cylindrical mapping, except the top and bottom are 'pinched' to create a sphere.

Creating a Spherical Mapping

1. In your track, create a new visual layer. These layer types can include content layers, generative layers, and effect layers.
2. Left-click on the layer in the track to open the Layer Editor on the left side of the GUI.
3. Under the Default tab, left-click on the Mapping parameter to display a list of the mappings in the project.

4. A manager titled mappings will appear – this is a list of all mappings within your project. By default, all screens will be populated with a direct mapping sharing the same name, and all cameras will be populated with a perspective mapping sharing the same name.
5. Type directly into the New mapping: text field to create a new mapping. A list will appear prompting to you select the mapping type.

   [Animated GIF: Create]

6. An editor with the user-assigned name of the mapping will appear once a mapping type is selected.
7. Assign all screens that will be used for the mapping and enter the resolution of the content that will be displayed on the screens.
8. Edit the specific properties of the chosen mapping type.
9. Assign a piece of content to the layer in the track, and the content will be displayed on the assigned screens of the mapping in the stage and the feed output window.

Common Mapping Properties

This section explains the properties that are shared by the six different mapping types.

Filtering

- **Nearest**: Nearest neighbour filtering. Use nearest-neighbour sampling, to disable blending between pixels when scaling. Can be used to create pixellated looks, or to ensure hard edges on certain types of content.
- **Bilinear**: Bilinear filtering is a texture filtering method used to smooth textures when displayed larger or smaller than they actually are.
- **2x Multi-sample**: Multi-Sample filtering can help fix issues with scaled content, but can introduce some blurriness.

Resolution

This controls the canvas size the layer renders into, in pixels. The Direct mapping type starts with a 256x256 pixel canvas and automatically sets the canvas size to that of the first screen you add.

Screens

This is a list of screens that the selected mapping type can copy content to.

1. Left-click + to open the Screens manager.
2. Left-click **+** to add the Screens you want to map. This will copy the individual canvas content onto these three Screens simultaneously and will add the Screen names to the mapping object editor.

3. Left-click and drag the Screens listed in the mapping object editor to -. This will remove the canvas content from the Screens and delete the Screen names from the mapping object editor.

Mask

This points to the Texture file that defines a Mask bitmap. You can use this property to apply a Mask bitmap to the mapping canvas. Selecting this property will open the Texture object library, which shows all of the still image files saved on your local hard-drive in the **DxTexture** folder.

To apply a mapping mask you will need to create and import a custom still image file.

- The step-by-step instructions on how to create and import a custom Population mask can be used to create a custom mapping mask. The only difference is that the mapping masks resolution should be the same as the mapping canvas. For step-by-step instructions on how to create and import a Population mask into a d3 project visit to the section Population mask in the **Editing screens** sub-chapter.
- Alternatively, set any layers blend mode to **mask** to channel the layer content into the mapping mask.

Border Expansion

UV islands on screens are expanded by this many pixels to cover edge sampling artifacts such as black fringing. Note that there must be an equivalent amount of empty space in the screen UV map to take advantage of this.

Find/Replace Usages

Finds all usages of the current mapping in the project, and allows these to be replaced with an alternative mapping. Note that replacement only works for sequenced, non-sockpuppeted mappings.

Hierarchy

The hierarchy section allows the mapping to be set as a parent or child of another object, like any other object. See Object Overview for details.

Spherical Mapping Properties

Horizontal arc

Defines the angular arc that the horizontal dimension of the content is mapped over, in degrees. 360 maps over a whole sphere, 180 renders over half a sphere.

Vertical arc

Defines the angular arc that the vertical dimension of the content is mapped over, in degrees. 180 maps from the North to South poles, 90 maps from the North pole to the equator.

Projection mode

Defines the direction that the content is mapped, **Outwards** or **Inwards**. This can be thought of as a spherical equivalent of mirroring the content.

Content mode

This can be set to 2D or 3D. The 2D content mode treats whatever image it is receiving from the modules as an equirectangular image. The 3D content mode sends the required content viewpoints to 3D modules, updating based on the positional properties of the mapping, and then stitches together the returned content into a spherical image.

Padding

Only available for 3D content, padding is extra pixel data added around the edges of your texture map to prevent visual artifacts like seams and pinching, especially at the poles.

Overlap

Only available for 3D content, overlap renders extra content for each rendered viewpoint, blending the extra content to reduce the appearance of seams.

Frame of reference

This setting dictates how the projected texture behaves when your object or the camera moves.

This is set to **None** by default.

Avoiding seams in content

Rendering of the spherical content is achieved under the hood by rendering the 6 faces of a cube, then combining and warping them to the correct spherical output. Certain screen-space effects used when rendering the virtual scene can cause visible seams between the faces. See UE scene optimisation for tips on how to avoid this in Unreal Engine.

If some screen-space effects are required for creative reasons, it is possible to mitigate their effects and avoid seams by setting **Padding** and **Overlap** in the spherical mapping:

- **Padding**: This value sets a number of additional pixels which are rendered outside each face, then cut away when combining the faces. This can be used to mitigate effects such as blur which exhibit edge effects on the extremities of the rendered image.
- **Overlap**: This value also renders additional pixels outside each face, then smoothly blends between the pixels of adjoining faces on each edge. This reduces the appearance of seams between faces by smoothing over the join, so you don't get a hard line.

> ⚠ **Caution**
>
> Both padding and overlap will increase the render resolution of each face, and therefore will increase the GPU resources required to render the content. It is recommended to set these to the smallest values required to remove visible seams.

Create a ProSet Team CMDLet

What is a VLAN?

A Virtual Local Area Network (VLAN) is a virtual network adaptor that operates over a physical network interface, such as a 1Gb, 10Gb, 25Gb, or 100Gb Ethernet port found on the back of a Disguise media server.

VLANs allow a single switched network to be segmented into multiple virtual networks using tagging. This eliminates the need for separate physical networks for different use cases, improving efficiency and flexibility.

A typical set of VLANs configured for a Disguise media server in a production or live experience may include:

- **d3Net**
- **KVM Net**
- **Media Net**
- **Automation Net (PSN)**
- **NDI® Net**
- **Internet**
- **sACN/Artnet**
- **OSC/Control**
- **OmniCal**
- **PTZ Camera Control**
- **MGMT**

The distinct separation of each network allows devices in:

- d3Net to be set in a `192.0.X.X` range.
- Whilst Artnet/SACN being in the Common `2.X.X.X` or `10.X.X.X`.

Yet both exist on the same network interface.

As outlined in the initial example, network protocols have different requirements and network settings.

This allows all data to exist in a singular physical interface but be be routed by a network switch.

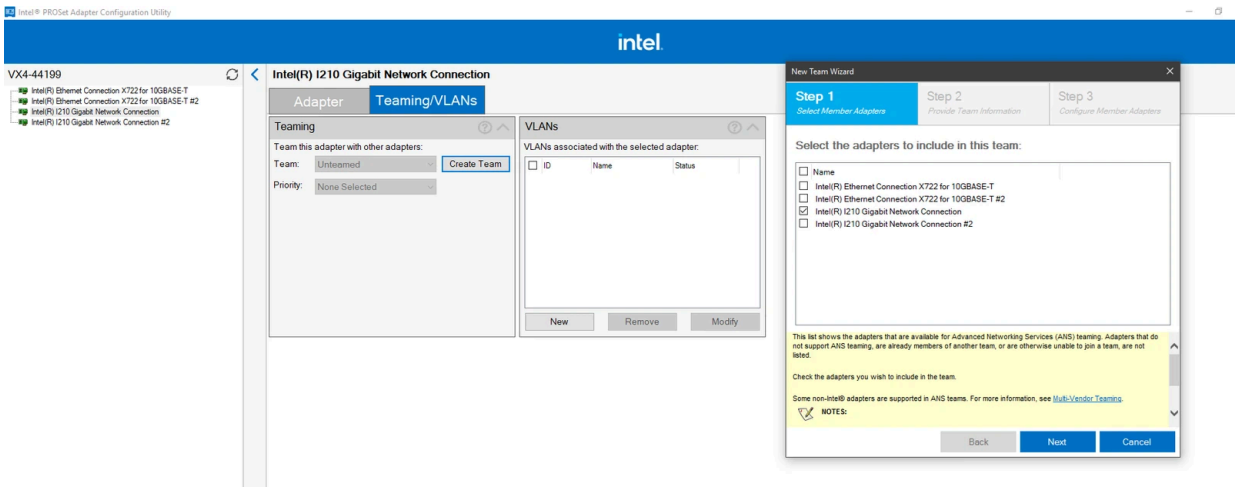
> **Note**
>
> OmniCal and Dante should be assigned to their own separate network interfaces. This ensures optimal performance and reduces the risk of network congestion or interference, which affects the precision and reliability of these systems.

Configuring VLANS and Teams

Within Disguise servers, VLANs can be created using different tools depending on the operating system:

- **Windows 10**: VLANs can be configured at the driver level using Intel PROSet.
- **Windows 11**: VLANs can be configured at the software OS level using Hyper-V.

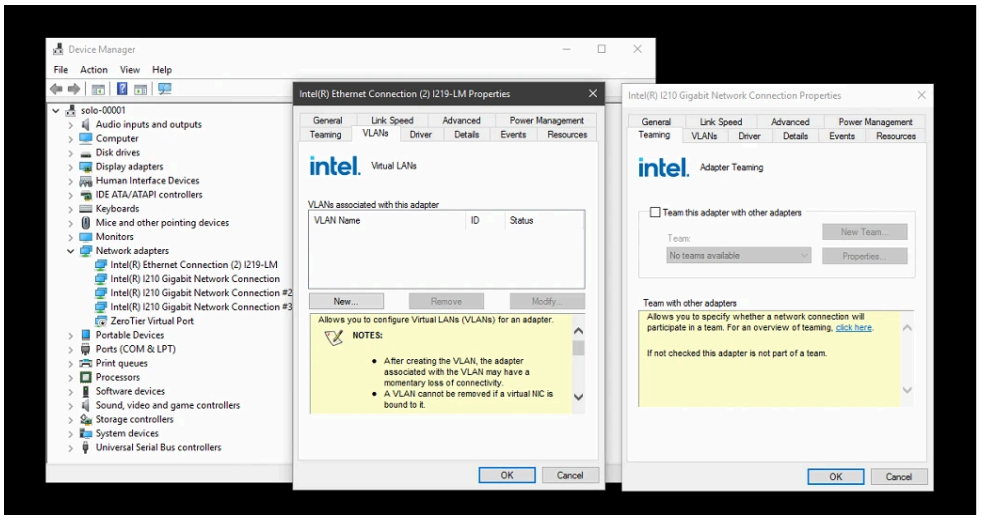
> ### Create PROSet Team Via GUI
>
> If your system supports the Intel PROSet GUI for Windows Device Manager, you can use its graphical interface to configure VLANs and NIC Teams easily.
>
> - **Sacrificial NIC**: At least one Intel integrated NIC or server-grade adapter must be part of the team to allow configuration. - You may notice X722 Network 10GB interfaces require the use of L210 network port to allow configuration via PROSet.
> - **VLAN Restrictions**: Ensure your switch supports the configured VLAN IDs and is set up accordingly.
>
> **Open the Intel PROSet GUI**:
>
> Machines such as the GX 2C/VX 1/2 have PROSet installed as an application



Intels PROSet interface

Older Servers such as the solo have PROSet built in to the NIC adaptor settings

- Launch Windows Device Manager.
- Navigate to the properties of an Intel-supported NIC.



Intels PROSet interface within devicemanager

2. **Create a Team**:
    - In the **Team/VLAN tab**, click on **Create Team**.
    - Select the adapters you want to include in the team. (X722 require an additional 1gb)
    - Choose a team mode (e.g., Adaptive Load Balancing, Static Link Aggregation). - Modes are outlined above the the guide.
3. **Configure VLANs**:
    - After creating the team, go to the TEAMEd interface and select the **VLANs tab**.
    - Scroll down and Select New Vlan
    - Click on **Add VLAN** and specify:
        - VLAN IDs (e.g., 10, 20, 30).
        - VLAN Name
    - Save your settings.

Create PROSet Team via CMDLETS

For systems without Intel PROSet GUI support (Intel X722), use the `IntelNetCmdlets` module to configure NIC Teams and VLANs.

Identify Adapters: Use the following command to list available adapters:

```
Get-IntelNetAdapter
```

Create a Team: Execute the command to create a NIC Team:

```
New-IntelNetTeam -TeamMemberNames "Adapter1", "Adapter2" -TeamMode AdaptiveLoadBalancing -TeamName "MyTeam"
```

Replace `Adapter1` and `Adapter2` with the actual adapter names obtained from `Get-IntelNetAdapter`.

Such as
`New-IntelNetTeam -TeamMemberNames "Intel(R) I210 Gigabit Network Connection","Intel(R) I210 Gigabit Network Connectior`

Check the team configuration:

Verify the Team:

```
Get-IntelNetTeam

**Set Team Properties (Optional)**:
Modify team settings using:
```powershell
Set-IntelNetTeam -TeamName "MyTeam" -Property "PropertyName" -Value "PropertyValue"
```

Steps to Create VLANs with PowerShell

Add VLANs to the Team: Use the `Add-IntelNetVLAN` cmdlet to create VLANs:

```
Add-IntelNetVLAN -ParentName "MyTeam" -VLANID 10,20,30
```

- Replace `"MyTeam"` with your team name.
- Replace `10,20,30` with the desired VLAN IDs.

View VLANs: Verify the VLAN configuration:

```
Get-IntelNetVLAN -ParentName "MyTeam"
```

Remove VLANs: Delete unwanted VLANs using:
```

```
Remove-IntelNetVLAN -ParentName "MyTeam" -VLANID 10

#### **Script Example for Automated Configuration**
Below is a sample PowerShell script to create a team and VLANs on Intel NICs:

```powershell
# Load IntelNetCmdlets module
Import-Module "C:\Program Files\Intel\Wired Networking\IntelNetCmdlets"

# List available adapters
Get-IntelNetAdapter

# Create a NIC team
New-IntelNetTeam -TeamMemberNames "Intel(R) Ethernet Connection X722 for 10GBASE-T", "Intel(R) I210 Gigabit Network Connect
ion" `
              -TeamMode AdaptiveLoadBalancing -TeamName "10GB_Team"

# Add VLANs to the team
Add-IntelNetVLAN -ParentName "10GB_Team" -VLANID 10,20,30,40

# Verify configuration
Get-IntelNetTeam
Get-IntelNetVLAN -ParentName "10GB_Team"
```
```

- **Sacrificial NIC**: At least one Intel integrated NIC or server-grade adapter must be part of the team to allow configuration.
- **VLAN Restrictions**: Ensure your switch supports the configured VLAN IDs and is set up accordingly.

This guide outlines both GUI and scripting methods, offering flexibility based on your system's capabilities.

Steps to Create VLANS with HYPER V

For Windows 11 Servers such as the RX3/EX2C/VX3

With Intel PROSet and Advanced Network Services (ANS) no longer supported on Windows 11, managing VLANs and network redundancy requires new workflows. This guide shows how to configure basic VLANs on Disguise media servers using Hyper-V and PowerShell.

Install Hyper-V

1. Open **Windows Features**:
   - Press `Win + S`, type **Windows Features**, and select **Turn Windows features on or off**.
2. Enable **Hyper-V**:
   - Check:
     - **Hyper-V Management Tools → Hyper-V Module for Windows PowerShell**
     - **Hyper-V Platform → Hyper-V Hypervisor**
3. Click **OK** and restart if prompted.

Identify Network Adapters**

To configure VLANs, you first need to identify the available network adapters.

1. Open PowerShell as Administrator.
2. Run the following command:

   ```
   GET-NETIPCONFIGURATION
   ```

   This will list all network adapters and# their details.

Example Output:

```
InterfaceAlias  : Ethernet 1
InterfaceIndex  : 4
IPAddress       : 192.168.1.100
...
```

Step 2: Create a Virtual Switch

Create a virtual switch in Hyper-V to route traffic through a specific network adapter.

1. Run the following command in PowerShell:

```
New-VMSwitch "disguise" -AllowManagementOS $true
```

   - Replace `"disguise"` with your desired switch name.
   - The `-AllowManagementOS $true` flag allows Windows to communicate through this switch.
2. When prompted, enter the name of the network adapter you identified in Step 1 (e.g., `Ethernet 1`).

> **Note**
> Do not attempt to assign multiple adapters to the switch. This can cause the setup to fail after a reboot.

Add a VLAN to the Virtual Switch

Now, create a VLAN on the newly created virtual switch.

1. Use this command:

```
Add-VMNetworkAdapter -ManagementOS -Name VLAN1-D3NET -SwitchName "disguise"
```

   - Replace `VLAN1-D3NET` with the desired VLAN name.
   - Replace `"disguise"` with the name of the virtual switch you created.

Hyper V Limitations and Considerations

No NIC Teaming: Windows 11 does not support NIC teaming, so redundancy for network port failure is not included. **Single Adapter**: Configure VLANs on only one adapter per virtual switch for stability. **Redundancy Options**: Consider using hardware redundancy with stacked switches.

By following this guide, you can successfully configure VLANs on a Disguise server using Windows 11.

OmniCal Networking

Disguise OmniCal is a calibration system designed to enhance projection mapping and screen alignment. It uses camera-based technology to:

- Automatically calibrate projectors using all visible physical surfaces.
- Correct for distortions and misalignments in projection.
- Allow flexible alignment, scaling and reshaping of projection surfaces.
- Ensure seamless visuals in complex setups, such as:
  - Large-scale projection mapping
  - Multi-projector configurations

OmniCal uses machine vision cameras that have specific requirements for network infrastructure. For more information, please refer to the detailed OmniCal Networking Guide.

RenderStream Networking

Disguise RenderStream is a protocol and technology developed to enable real-time streaming of rendering data between systems, such as media servers and rendering engines.

It is designed for synchronized, high-quality, and low-latency workflows, commonly used in applications like:

- Virtual production
- Live events
- Immersive experiences

Bandwidth Considerations

- RenderStream handles high-resolution, high-frame-rate content, including textures, video, and rendering data.
- Uncompressed data significantly increases bandwidth demands.

Uncompressed Streams: Require much higher bandwidth, especially for:

- High bit depths (e.g., 10-bit, 12-bit)

- Broad color gamuts and fidelity

Compressed Streams: Use codecs like H.264 or H.265 to reduce size while preserving quality, lowering bandwidth needs.

Hardware Considerations

- **Practical Throughput**:
  - Even with 100Gb Ports, actual throughput is typically around **80Gb** due to protocol overheads, error checking, and operational processes. Using the Assigner and predictions on workload traffic you can aim to calculate the expected throughput needed per workload.
- **Clustered Rendering**:
  - Distributing rendering tasks across multiple RX servers improves processing efficiency.
  - However, it also increases network traffic, which must be carefully managed to prevent bottlenecks

By using a structured and distributed system like **Fabric**, high-bandwidth, low-latency workflows become more manageable as this is included in our system designs, especially in complex rendering scenarios.

See RenderStream Networking Information

Create a VLAN with Hyper-V

For Windows 11 Servers such as the RX III/ EX 2C/ VX 3

With Intel PROSet and Advanced Network Services (ANS) no longer supported on Windows 11, managing VLANs and network redundancy requires new workflows. This guide shows how to configure basic VLANs on Disguise media servers using Hyper-V and PowerShell.

Install Hyper-V

1. Open **Windows Features**:
   - Press `Win + S`, type **Windows Features**, and select **Turn Windows features on or off**.
2. Enable **Hyper-V**:
   - Check:
     - **Hyper-V Management Tools → Hyper-V Module for Windows PowerShell**
     - **Hyper-V Platform → Hyper-V Hypervisor**
3. Click **OK** and restart if prompted.

Identify Network Adaptors

To configure VLANs, you first need to identify the available network adapters.

1. Open PowerShell as Administrator.
2. Run the following command:

```
GET-NETIPCONFIGURATION
```

   This will list all network adapters and# their details.

Example Output:

```
InterfaceAlias  : Ethernet 1
InterfaceIndex  : 4
IPAddress       : 192.168.1.100
...
```

Create a Virtual Switch

Create a virtual switch in Hyper-V to route traffic through a specific network adapter.

1. Run the following command in PowerShell:

```
New-VMSwitch "disguise" -AllowManagementOS $true
```

   - Replace `"disguise"` with your desired switch name.
   - The `-AllowManagementOS $true` flag allows Windows to communicate through this switch.
2. When prompted, enter the name of the network adapter you identified in Step 1 (e.g., `Ethernet 1`).

> **Note**
>
> Do not attempt to assign multiple adapters to the switch. This can cause the setup to fail after a reboot.

Add a VLAN to the Virtual Switch

Now, create a VLAN on the newly created virtual switch.

1. Use this command:

```
Add-VMNetworkAdapter -ManagementOS -Name VLAN1-D3NET -SwitchName "disguise"
```

- Replace `VLAN1-D3NET` with the desired VLAN name.
- Replace `"disguise"` with the name of the virtual switch you created.

Hyper V Limitations and Considerations

- **No NIC Teaming**: Windows 11 does not support NIC teaming, so redundancy for network port failure is not included.
- **Single Adapter**: Configure VLANs on only one adapter per virtual switch for stability.
- **Redundancy Options**: Consider using hardware redundancy with stacked switches.

By following this guide, you can successfully configure VLANs on a Disguise server using Windows 11.

Troubleshooting: How to Prevent Hyper-V from Reserving Specific Ports

When Hyper-V is enabled on a Windows machine, it automatically reserves multiple port ranges within the dynamic port range upon startup. This can cause conflicts if Windows happens to reserve a port required by another application—such as port `56565`, the default PSN port needed for a d3 project.

Prerequisites

- You must be logged in as an Administrator.
- **Important**: Disabling and re-enabling Hyper-V usually requires a system restart. Please save any open work before proceeding.

How to exclude ports

1. **Open PowerShell as an Administrator.** Right-click the Start button and select Windows PowerShell (Admin) or Terminal (Admin).
2. **Check currently reserved ports.** Run the following command to see which UDP ports are already reserved:
   `netsh interface ipv4 show excludedportrange protocol=udp`
3. **Temporarily disable Hyper-V.** Run the command below to disable the hypervisor. (Note: You may be prompted to restart your computer here. If so, restart, then reopen PowerShell as Administrator to continue).
   `Disable-WindowsOptionalFeature -Online -FeatureName Microsoft-Hyper-V-Hypervisor`
4. **Exclude your required port.** Run the following command to exclude your port.
   `netsh int ipv4 add excludedportrange protocol=udp startport=<port> numberofports=<number> store=persistent`
5. **Re-enable Hyper-V.** Once the port is successfully excluded, turn the hypervisor back on:
   `Enable-WindowsOptionalFeature -Online -FeatureName Microsoft-Hyper-V-Hypervisor`
6. **Restart your machine.** If you aren't automatically prompted to do so, restart your computer one final time to ensure Hyper-V is fully active and the new port rules have taken effect.

> **Note**
>
> In this example, we are setting startport=56565 and numberofports=1 to exclude exactly one port. Change these values if you need a different port or a wider range).

> **Tip**
>
> Once your computer has restarted, open PowerShell as an Administrator again and run the check command:
> `netsh interface ipv4 show excludedportrange protocol=udp`
>
> Look for your port (e.g., `56565`) in the list. It should appear with an asterisk (`*`) next to it, which indicates that it is a manually added, persistent exclusion.

Create a VLAN with PowerShell

Add VLANs to the Team:

Use the `Add-IntelNetVLAN` cmdlet to create VLANs:

```
Add-IntelNetVLAN -ParentName "MyTeam" -VLANID 10,20,30
```

- Replace `"MyTeam"` with your team name.
- Replace `10,20,30` with the desired VLAN IDs.

View VLANs**:

Verify the VLAN configuration:

```
Get-IntelNetVLAN -ParentName "MyTeam"
```

Remove VLANs:

Delete unwanted VLANs using:

```
Remove-IntelNetVLAN -ParentName "MyTeam" -VLANID 10

#### **Script Example for Automated Configuration**
Below is a sample PowerShell script to create a team and VLANs on Intel NICs:

```powershell
# Load IntelNetCmdlets module
Import-Module "C:\Program Files\Intel\Wired Networking\IntelNetCmdlets"

# List available adapters
Get-IntelNetAdapter

# Create a NIC team
New-IntelNetTeam -TeamMemberNames "Intel(R) Ethernet Connection X722 for 10GBASE
-T", "Intel(R) I210 Gigabit Network Connection" `
              -TeamMode AdaptiveLoadBalancing -TeamName "10GB_Team"

# Add VLANs to the team
Add-IntelNetVLAN -ParentName "10GB_Team" -VLANID 10,20,30,40

# Verify configuration
Get-IntelNetTeam
Get-IntelNetVLAN -ParentName "10GB_Team"
```
```

- **Sacrificial NIC**: At least one Intel integrated NIC or server-grade adapter must be part of the team to allow configuration.
- **VLAN Restrictions**: Ensure your switch supports the configured VLAN IDs and is set up accordingly.

This guide outlines both GUI and scripting methods, offering flexibility based on your system's capabilities.

d3Net Overview

Director/Actor operation allows you to sequence shows whose output requirements are greater than a single machines maximum.

The goal of Director/Actor operation is to allow you to sequence the entire show on a single machine (possibly a laptop) and then run the show on a network of machines. This network is called d3 Net.

There are 4 types of machine roles within a d3Net setup:

- **Director** - Director Machine
- **Actor** - Output Machine
- **Understudy** - Backup Machine
- **Editors** - Any machine used to edit the scene that doesn't have an output role (typically a PC or Laptop running Designer).

Only one Director is allowed on a network. Multiple Actors, Understudies and Editors are permitted.

Every Director & Actor is configured to output video to its assigned Feed scene. Please see the chapter Output Feeds for more information on Feed scenes. For example:

- The Director machine is outputting to 1 GUI monitor and 3 projectors.
- Actor 1 outputs to projectors 4,5,6,7, no GUI. Actor 2 outputs to projectors 8, 9.
- The understudy machine should not have any specific Feed scene assigned to it as it should be able to take over from any other machine.

The Director machine

A Director machine can either be Dedicated or Non-Dedicated. If a Director is not outputting to any screens other than the GUI, it should be set to Dedicated.

If a machine is Non-Dedicated, that means the machine controls all other Actors in the network but also outputs video through its remaining outputs. Dedicated means that the machine controls Actors, but does not output video to the stage; it is used only for visualisation and show sequencing.

The distinction is important because a Director that is Non-Dedicated will only play content destined for its output feed, the so called Feed Scene, for efficiency purposes. If you need to see all content in the visualiser, set the Director to Dedicated, or else ensure that all content in the project appears in the feed assigned to the Director.

Actor machines

Actor machines automatically follow the Director machine's timeline, regardless of what the Director is doing. Therefore, there is no need to input any MIDI timecode (or any other external trigger signal) to the Actors; the Director is responsible for passing these on.

If an Actor relies on external automation signals or audio inputs, you will need to ensure that these signals are also sent to the machines; at present the Director will not distribute these signals automatically. The same is true for live video signals.

Understudy machines

Designating a machine as an Understudy allows it to take over from any machine in the network if that machine fails, including the Director machine. The Understudy can be set to do this automatically or manually. It can also send a matrix present command to a matrix as it replaces the other machine. This can be useful for shows that need to run unattended but cope with potential machine failure.

Editors

MultiEdit allows multiple people to edit a project simultaneously, without manually merging projects. Edits from each Editor are propagated to all other machines via the Director in real time. Each editor machine can work on a different track, or on different regions of the same track, at the same time; Editors can also take control of the Director timeline position and control the stage.

Distributing signals

- The Understudy machine should also receive MIDI timecode or any other external trigger signal that the Director receives, in case it is needed to replace the Director machine.
- If controlling the timeline with DMX, there is no need to split the DMX signal to any other machine other than the Director's understudy - d3Net will automatically send the correct frames to all other machines.
- If you are recieving tracking data from a tracking or automation system, you should send that data to all machines in the network.
- If inputting SDI, split and distribute the SDI signal to all servers in the network.
- If inputting MIDI from a control surface such as the BCF2000, split the signal into all servers.

Redundancy

Redundant networking strategies can be implemented on the network architecture being used to host d3Net. M-LAG is commonly used to enable two or more network switches to appear

as a single logical device, and enables d3Net to still flow through the other active links in the event of network switch failure. MC-LAG can also be used with d3Net to provides redundancy at the switch level, so if one switch in the MC-LAG fails then the other switch continues to function without interruption. We strongly recommend testing this functionality before applying it to a show environment, and setting up monitoring tools and/or push notifications to observe the behaviour of the switches.

In the event of failure on the network architecture being used to host d3Net, all Actor machines running in the session will continue to output from their current position on the playhead. d3Net will reestablish a connection to any machines running in session once the network is restored.

Disguise System Network Configuration

Within the Disguise Ecosystem, live shows can increase in complexity and require large amounts of integration with third-party systems. The information below outlines workflows and best practices developed by our dedicated show support teams and freelancer community.

Creating a robust, efficient, and secure network infrastructure is a critical aspect of designing a show system. Disguise Video System designers often need to integrate with a wide variety of devices and technologies. A well-planned network ensures flexibility, precise control, and smooth collaboration across different teams and equipment.

When designing a system, careful consideration should be given to traffic management and access permissions. For example, guest stage engineers might not need access to NDA-protected content on the content network, while lighting engineers may require access to camera streams or internet connectivity. Balancing these requirements is key to ensuring a secure and streamlined operation.

Given that Disguise machines, as part of a video infrastructure, typically utilise large network traffic, especially with protocols like ST2110 or Consistent Media Transfers, it is important to accommodate their significant data demands.

Fast, stable, and secure connections are the cornerstone of effective network design.

What Can Go Wrong in shows?

1. Physical Failures: Network cables are susceptible to physical damage (e.g., tripping hazards, accidental unplugging, or wear and tear). Redundant cabling ensures continuity if a primary cable fails.
2. Seamless Failover: With properly configured redundancy (e.g., using LACP or failover policies), the transition between primary and secondary cables can occur without interruption, ensuring event continuity.

Utilizing both VLANing and teaming, along with switch stacking, can help mitigate risks and enhance network resilience in the event of issues.

Below, we outline some of the major network types and their use cases within a live show environment.

Key Networks in a Show System

In the tables below, there is a brief description of a range of common network devices you will most likely encounter in a larger Disguise system.

This information provides an outline of each use case and bandwidth considerations.

1. d3Net

Aspect	Details
Purpose	*Facilitates communication between Disguise machines and editors.*
Traffic	*Low, but speed is crucial (1Gb/10Gb networking recommended).*
Requirements	*Dedicated network to ensure quick and reliable machine-to-machine communication.*

2. KVM Net

Aspect	Details
Purpose	*Supports KVM (keyboard, video, mouse) systems with high PoE requirements.*
Traffic	*High; can saturate a network switch backbone.*
Usage	*Often shared across departments or used locally in large installations.*

3. Media Net

Aspect	Details
Purpose	*Handles large video file transfers (200–300GB or more).*
Traffic	*Extremely high; 25Gb/100Gb networking or trunked 10Gb uplinks are ideal.*
Requirements	*Critical for time-sensitive file transfers, often shared with third-party designers.*

4. Automation Net (PSN)

Aspect	Details
Purpose	*Used for communication with automation systems.*
Traffic	*Low, but reliability is essential.*

Aspect	Details
Usage	*Typically shared with automation teams for precise control.*

5. NDI® Net

Aspect	Details
Purpose	*Manages multicast streams like NDI® (Network Device Interface).*
Traffic	*Very high; a few 4K streams can saturate a 1Gb uplink.*
Requirements	*Requires a high-capacity network to support demanding video streams.*

6. Internet

Aspect	Details
Purpose	*Provides internet access for editors, utility equipment, and guests.*
Traffic	*Variable, depending on usage.*
Access Control	*Often restricted for Disguise machines to maintain security.*

7. sACN/Artnet

Aspect	Details
Purpose	*Shares data with lighting systems.*
Traffic	*Moderate to high; up to 64 universes (100Mb traffic).*
Characteristics	*Traffic can be spammy; requires careful management.*

8. OSC/Control

Aspect	Details
Purpose	*Facilitates control interfaces for lighting, stage management, iPads, and other devices.*
Traffic	*Low (TCP/UDP messages).*

Aspect	Details
Requirements	*Needs visibility across all connected networks.*

9. OmniCal

Aspect	Details
Purpose	*Supports the Omnical calibration system.*
Traffic	*Moderate but complex; best kept on a separate network.*
Usage	*Requires precise communication for accurate calibration.*

10. PTZ Camera Control

Aspect	Details
Purpose	*Manages pan-tilt-zoom camera systems.*
Traffic	*Similar to other control networks.*
Usage	*Can often share resources with OSC or control networks.*

11. MGMT (Management)

Aspect	Details
Purpose	*Provides access to network switches and third-party devices.*
Traffic	*Low; primarily used for configuration and monitoring.*
Requirements	*Best kept secure and separate to avoid interference.*

12. RenderStream

Aspect	Details
Purpose	*Used for Disguise communication and streaming with rendering engines.*
Traffic	*High bandwidth for uncompressed streams; lower with reduced bit depth and frame rates.*
Requirements	*25Gb/100Gb fibre recommended for uncompressed streams, typically using Disguise Fabric.*

d3Net Backbone

d3Net is a core component of Disguise's infrastructure, serving as the backbone for networked communication within a Disguise session. It plays a crucial role in synchronising

multiple Disguise servers, ensuring frame-accurate playback across a connected system.

d3Net enables:

- Remote communication between Disguise media servers. (Launch, Quit, Reboot etc.)
- Remote display management.
- Timeline and playback synchronisation.
- Failover and redundancy.
- Resource Transport to keep the project state in-sync between editors, actors, understudies and directors.
- Content synchronisation within Disguise.
- Renderstream workload control (Launch, Stop etc.)
- Multi-editor workflows.

d3Net must be configured to enable all Disguise servers and editors to access the same d3Net network. We suggest keeping the d3Net isolated from other networks to ensure seamless communication between all machines and to prevent any surrounding network issues from affecting Disguise operation. This also means that after a re-image, network settings can be recreated quickly, and as a result, network issues are simpler to debug and support.

Read more about d3Net on the d3Net Overview page.

Disguise System Network Configuration Guide

Recommended Practice

We have created a guide to networking recommended practice with Disguise systems which includes the following information:

- An Introduction to Disguise System Network Configuration
- What can go wrong in Shows?
- Key networks in a Show System
  - d3Net
  - KVM Net
  - Media Net
  - Automation Net (PSN)
  - NDI® Net
  - Internet
  - sACN/Artnet
  - OSC/Control
  - OmniCal
  - PTZ Camera Control
  - MGMT (Management)
  - RenderStream
- d3Net Backbone
  - NMOS
- Hardware Design
  - Server Storage and Ports
    - GX 3+
    - VX 1 / VX 2/ VX 4
    - GX 3 / VX 2+ / VX 3 / VX 4+
    - EX 2C / EX 3+ / RX III
    - GX 1 / GX 2 / GX 2C
    - Solo (Base)
    - RX / RX II

- Teaming
  - What is Teaming?
  - Common Teaming Modes
    - Active Load Balancing(ALB)
    - Static Link Aggregation (SLA)
    - Dynamic Link Aggregation (LACP)
    - Switch-Independent
    - Failover)
  - Implementing Redundancy at a Hardware Switch Level
  - What is Switch Stacking?
  - Advantages Over LACP
- VLAN
- Create a VLAN with Hyper-V
- Create a VLAN with PowerShell
- OmniCal Networking
- RenderStream Networking

Failover

Failover is the mechanism by which Understudies can take over from other machines in the network if a machine should fail. Failover can be triggered in 4 different ways:

- Automatically when a machine times out (For more information on automatic failover see Failover Timeout)
- Manually by a remote transport command
- Manually by a button in the Session widget
- Via the Failover API

Failing over a machine

Manual failover

Manual failover of a machine to its Understudy is conducted by pressing the **replace** button next to the machine that has failed.

> **Note**
>
> The replace buttons will only be visible when the replace action is available, i.e. the understudy is online, targeting the machine and has not already replaced another machine. For example, if the director has been replaced, the director will no longer be able to send failover commands.

What happens when I press replace?

The machine being replaced is now “failed”. The understudy replacing the failed machine will take on the characteristics of the failed machine, including role and feeds. If matrix routing has been configured, the understudy will automatically send the routing commands to the matrix to switch outputs from the failed machine to the Understudy. Matrix routing is sent as soon as the Understudy has been configured for its new role.

Designer cannot know why the machine has been replaced or assume to know what the failure condition might be. Designer therefore ignores any communication with the failed machine as it can’t make assumptions about its current state. No further communication from the failed machine is accepted by the rest of the session while it is marked as failed.

The failed machine is instructed to stop sending out any network data, but depending on how the machine failed Designer cannot guarantee that message will be received and acted upon; for example a networking related failure.

Failover and live update

Live update is the d3net network layer responsible for the distribution of showfile edits to all machines in session.

During failover live update is disconnected on the machine that failed to prevent it from sending or receiving edits while it's in a bad state.

> **Note**
>
> Restoring any machine does NOT reconnect Live Update for the previously failed machine. Live Update will remain disconnected for any machines until the project is launched anew in to the session.

Actors and Directors have different live update behaviours when failed over.

Actor failover and live update

When an actor is failed over, live update is disabled on that machine. The understudy that takes over for it is still in the live update session and continues to receive edits as normal.

Director failover and live update

When a dedicated or non-dedicated director is failed over, live update is disabled on that machine and for all machines in session. This is because the director is responsible for marshalling all the live update data in the session, and if it's in a bad state an understudy can't reliably take over this responsibility.

All edits made on any machine will no longer be transfered to any other machine in the session until the session is restarted. As such these edits should be avoided until live update can be reconnected.

Restoring after failover

Previously replaced machines can be restored to their original role by pressing "restore" next to the machine in the Session widget.

> **Warning**
>
> Live Update will not be restored. See details here

When can I restore a failed machine?

What happens between pressing replace and restore will depend on the nature of the failure. Depending on the circumstances in which the failover occurred, it may be possible to restore

without re-launching Designer on the failed machine, after re-launching Designer on the failed machine, or rebooting the machine. It is recommended to turn the server off and on again before restoring if there is any doubt as to the state of the machine.

What happens when I press restore?

The Understudy relinquishes its assumed role, and is reconfigured back as an Understudy. It then sends the matrix routing command (if matrix routing is configured) to switch the outputs back to the restored machine.

If edits are made on the acting Director and then the replaced machine is brought back into session, any edits already made on the acting Director will be synchronised to the machine joining the session as part of project sync. This will ONLY be the changes as captured at that moment in time.

Considerations and recommendations

In the scenario where an understudy is targeting multiple machines and has replaced a machine, Disguise does not recommend restoring back to the failed machine mid-show unless there is a good reason to do so, for example if another machine fails and you now need the understudy to replace that.

The act of reconfiguring a machine role and sending matrix commands over the network is additional work outside of normal show operation in a system which potentially is already non-normal, and is therefore not something recommended unless required.

If appropriate, the failed machine can be investigated, fixed and brought back into session, but remain as replaced until there comes a need for the understudy to take over another role. Should the need come, the returned machine can be restored and the newly failed machine replaced. Any scenario in which this would be needed is incredibly rare.

Hardware Network Design

Disguise servers typically follow the standard of a couple of 1Gb/10Gb network ports consisting largely of general Cat 5e/Cat 6e ports and a higher bandwidth fibre 25Gb/100Gb SFP set of ports in newer systems.

This configuration typically provides 2 lower bandwidth network ports and 2 higher bandwidth network ports, ensuring a balanced and efficient network setup.

Inside our operating systems, this is usually labelled as:

- **A - D3NET** (typically found on a 1Gb port)
- **B - ARTNET** (typically found on a 1Gb port)
- **C - MEDIANET** (typically found on a 10/25/100Gb port)
- **D - MGMT** (typically found on a 1Gb port or internal use)

Some servers have:

- E 25/100Gb (Typically allocated for Content / RenderStream)
- F 25/100Gb (Typically allocated for Content / RenderStream)

This means most servers have 4 Ports available, with some having 6 ports

Our modern systems currently follow higher bandwidth NIC Design and no longer have default IP names.

- **10Gb - 1**
- **10Gb - 2**
- **100Gb -3**
- **100Gb - 4**

This should encapsulate most simple show scenarios, providing high speed backbones for media content, and general access for both Disguise d3Net and general art-net uses.

Some users additionally choose to deploy ‘utility’ computers in racks, which host things like network management pages and remote management interfaces, this reduces traffic on the core d3 network where possible.

Server Storage and Ports

The following tables show port and storage options by server type.

VX1 / VX2 / VX4

Option	Storage	Ports
1GB	✓	1 User 1 SMC
10GB	✓	2
25GB	✓	2

GX 3+

Option	Storage	Ports
1GB	✓	1 SMC
10GB	✓	4
100GB	✓	2

GX 3 / VX 2+ / VX 3 VX 4+

Option	Storage	Ports
1GB	✓	1 User 1 SMC
10GB	✓	2
100GB	✓	2

EX 2C / EX 3+ / RX III

Option	Storage	Ports
10GB	✓	2
100GB	✓	2
SMC	✓	1

GX 1 / GX 2 / GX 2C

Option	Storage	Ports
1GB	✓	2

Option	Storage	Ports
10GB	✓	2

Solo (Base)

Option	Storage	Ports
1GB	✓	4

RX / RX II

Option	Storage	Ports
10GB	✓	2
1GB	✓	2
25GB	✓	2

Network Adaptor

It may be necessary to manually assign a network adaptor to Designer in complex network scenarios, or with machines that have multiple network connections.

This can be done in d3Manager before starting a project. Selecting a network adaptor will then ensure d3Net always uses that connector.

To select the adaptor, choose it from the dropdown list and then click the **Set Network adaptor** button. Once you have selected a network adaptor, Designer will prompt you to restart your machine.

Network Ports and Activity

Networking is a very important part of any Disguise system. Servers need to be in constant communication with each other and also with third-party software and hardware products. A well-configured network can save time and money on-site. To help our users configure their networks more effectively to run Disguise systems, here we will provide a general overview of how Designer and other Disguise systems communicate both internally and externally over a network.

Designer internal communication

Multiple computers running the same project on the same network are referred to as “In Session”. While in session, these servers are in constant network communication with each other. To facilitate this network communication we use both TCP and UDP transport layer protocols.

Disguise systems primarily rely on TCP (Transmission Control Protocol) for most d3Net communications. TCP ensures reliable, ordered, and error-checked delivery of data between applications running on hosts communicating over an IP network. This protocol is well-suited for the majority of d3Net functionality, where data integrity is crucial.

For timing-critical operations Disguise systems employ UDP (User Datagram Protocol). UDP is low latency and lower overhead compared to TCP. In Disguise systems UDP is used for:

- QTP (Quantized Time Protocol) messages in non-genlocked sessions (port 7542 and 7543)
- VSync messages in genlocked sessions (port 7968)
- Network time sync between machines (port 7892)

Quality of Service (QoS) Recommendation

In a managed network environment, it’s highly recommended to assign a high Quality of Service (QoS) priority to the UDP sync messages that Designer relies upon. This ensures that these critical timing packets are given preferential treatment in the network, minimizing latency and jitter. By prioritizing these sync messages, you can maintain tight synchronization between Disguise machines, which is essential for seamless multi-machine playback and output.

Tracking Systems and UDP

Tracking systems, which provide real-time positional data for objects or performers in a live environment, typically use UDP for data transmission. This choice is made for similar reasons as our sync packets:

1. **Low latency**: UDP’s lightweight nature allows for faster data transmission, crucial for real-time tracking.

2. **High frequency updates**: Tracking systems often send updates many times per second, making UDP's lower overhead beneficial.
3. **Tolerance for packet loss**: In tracking scenarios, getting the most recent data quickly is often more important than ensuring every packet arrives.

Given the critical nature of tracking data in many Disguise workflows, it's recommended to treat these UDP packets with the same high priority as our sync messages in your network configuration. This means:

- Assigning high QoS priority to the UDP ports used by your tracking system.
- Ensuring minimal network hops between the tracking system and Disguise machines.
- Monitoring and minimizing network congestion on the paths used by tracking data.

By prioritizing tracking system UDP traffic alongside Disguise sync messages, you can ensure the most responsive and accurate real-time tracking integration in your projects.

OmniCal network usage

The Disguise OmniCal system requires local network communication between the Director (or Solo) server and the machine vision cameras on a separate isolated network for exclusive use of GigEVision streaming. It also uses three ports for internal server communication between the Designer process and our camera capture application `VimbaCamServer`. These ports are only active if OmniCal is in use, i.e. any of the OmniCal windows are open on the Director.

For more information please see the OmniCal Networking Guide.

Network Ports and Activity

Below is a list of ports that Designer uses and a description of the activity we expect over that port.

Port	Protocol	Application	Description
80	TCP	d3nginx.exe	Web server, used for API commands (default, user configurable)
873	TCP	d3.exe	Used by rsync process spawned by Designer for project file synchronization between machines
3207	HTTP	d3.exe / nmos-node.exe	Used by Designer to send display updates to the NMOS node
3212	HTTP	nmos-node.exe	NMOS Node Query API
3215	HTTP	nmos-node.exe	NMOS Connection API
3216	HTTP	nmos-node.exe	NMOS Events API

Port	Protocol	Application	Description
3217	HTTP	nmos-node.exe	NMOS Events WS API
3218	HTTP	nmos-node.exe	NMOS Control API
3219	HTTP	nmos-node.exe	NMOS Channel Mapping API
4809	UDP	d3.exe	CITP service discovery
5568	UDP	d3.exe	sACN (streaming ACN)
5670	UDP Broadcast	Any d3Net application including RenderStream clients	Used by Designer for discovering new machines when joining a network
6454	UDP	d3.exe	Art-Net
7400	UDP	d3.exe	OSC output (default, user configurable)
7401	UDP	d3.exe	OSC input (default, user configurable)
7542	UDP Broadcast	d3.exe	Used for QTP (Quantized Time Protocol) messages
7543	UDP Broadcast	d3.exe	Used for QTP (Quantized Time Protocol) messages
7892	UDP Broadcast	d3.exe	Network time sync between machines
7968	UDP Broadcast	d3.exe	Used for VSync messages in genlocked sessions
8888	UDP Local	d3.exe	Used by Designer and spawned process for local communication with project file synchronization process
8889	UDP Local	d3.exe	Used by Designer and spawned process for local communication with project file synchronization process
9001	UDP Local	d3.exe	Used by Designer and spawned VimbaCamServer.exe process for local OmniCal discovery (OSC)
9864	TCP	d3.exe	Telnet JSON machine control (default, user configurable)
9993	TCP	rsync.exe	rsync daemon for project file synchronization (default, user configurable)
10101	UDP Local	d3.exe	Used by Designer and spawned VimbaCamServer.exe process for local OmniCal discovery (OSC)

Port	Protocol	Application	Description
10101	TCP Local	d3.exe	Used by Designer and spawned VimbaCamServer.exe process for local OmniCal communication
10102	TCP Local	d3.exe	Used by Designer and spawned VimbaCamServer.exe process for local OmniCal communication
10741	HTTP	nmos-node.exe	NMOS System API
49152-65535	TCP	d3.exe and other d3Net applications such as RenderStream clients	Used for d3Net functionality, dynamically negotiated and allocated
50500	UDP	RenderStream clients	Used for high bandwidth, uncompressed RenderStream video streams
50501	UDP	RenderStream clients	Used for compressed RenderStream video streams
54321	TCP	d3.exe	Remote transport controls (default, user configurable)
60668	TCP	d3.exe	CITP, spawns additional TCP connections on ports declared by connected CITP devices

In addition to the above, vendor specific protocols (such as tracking systems, matrix drivers, etc) may use additional ports. Disguise provides user configurable port numbers where possible and allowed by the protocol / SDK.

DNS-SD

Designer instances after r30.4 support DNS-SD discovery. This allows you to discover Designer instances on your network and connect to them, without prior knowledge of the hostname or port number. This includes access to both the Service and Session APIs. Learn more about the Discovery API in our **developer documentation**.

NDI®

NDI® is a network transport protocol for streaming video over the network. You can read more about it on the official **NDI® website**. Designer supports capturing NDI® streams as video inputs.

If you're using NDI® for video inputs, their SDK uses a variety of ports. See **NDI® Port usage** for more information.

Genlock and network time synchronisation

Starting in Designer version r28.0 Designer will broadcast and receive UDP messages over several different ports to maintain session-wide output synchronisation. Below is a summary of this behaviour:

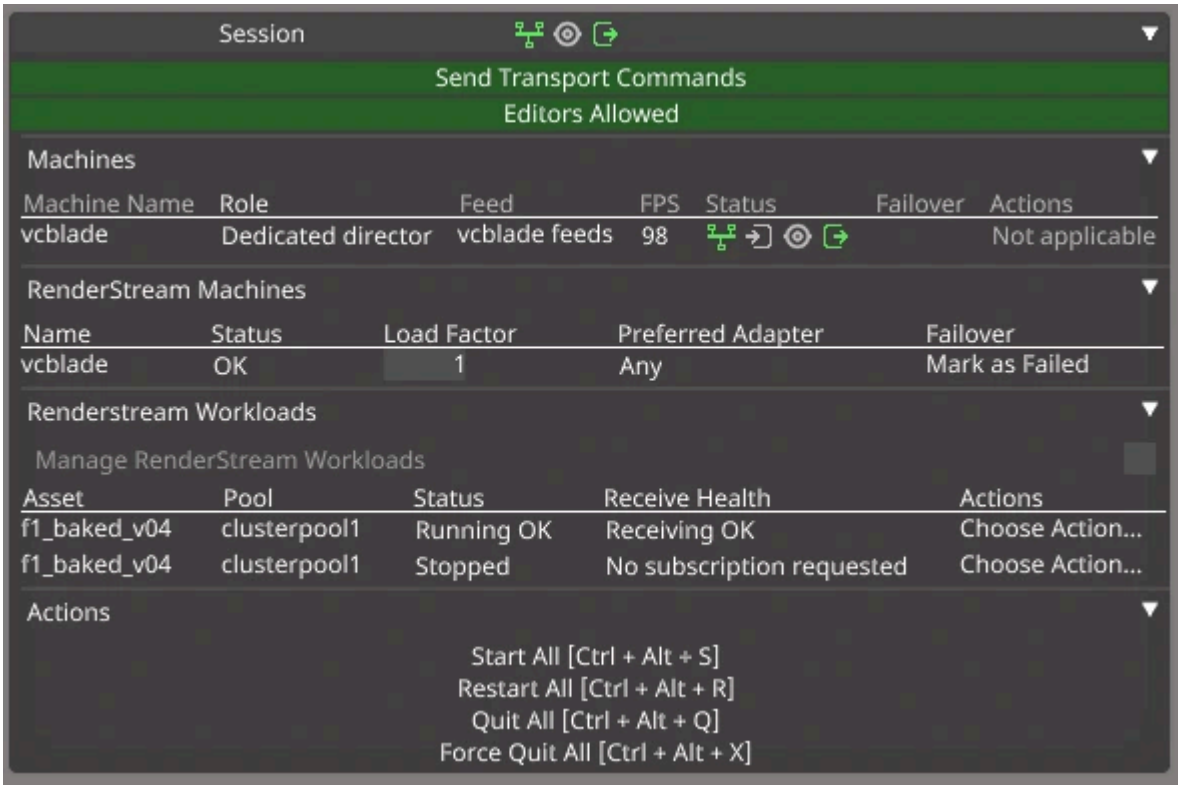
- **In non-genlocked sessions**: QTP messages are broadcast from the director on port 7542 and 7543.
- **In fully genlocked session**s: VSync messages are broadcast from the director on port 7968.
- **In partially genlocked sessions**: Both QTP (from director) and VSync (from first genlocked machine) messages are broadcast.
- To minimize network traffic, it's recommended to genlock all machines in the session.
- On larger networks, each machine should specify a specific network adapter in d3Manager rather than "Any" to avoid unnecessary broadcasts.

Network Status Widget

The Network Status widget monitors the status of the d3Net network, including RenderStream status and machine health.

The Network Status widget opens automatically when d3Net is configured.

Network Status Widget properties



Network Status Widget

Send Transport Commands

Toggles the ability for machines to start/stop playback on the tracks of other machines.

Editors Allowed

Toggles whether editors are allowed to join the session. It will not effect editors that are already in session.

Machines

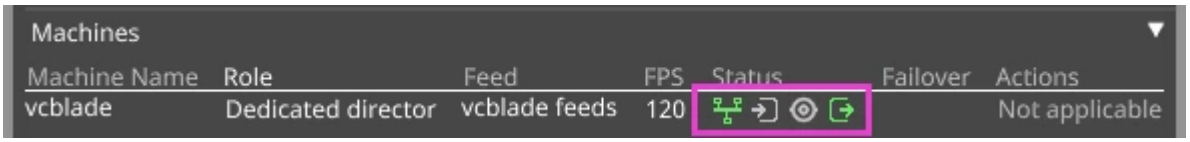
Lists all machines actively connected to the session and all actors and understudies specified in the d3net manager GUI even if they are offline. Each machine has 4 status icons which tell you about the status of that machine

Machine Status Icons

The Network Status Widget includes colour-coded status icons that indicate the status of the following for each machine (Icons listed in order from left to right):

- Network Status
- Devices Status
- Genlock Status
- Video Output Status

The Network, Genlock and Output icons are shown again at the top of the session widget at all times. These icons at the top summarise the statuses of all the machines.



Highlighted Machine Status Icons

These icons can be several colours which each represent the status of that aspect of the machine.

The colours are:

- Green: OK
- Orange: Warning
- Red: Error
- Blue: Busy
- Grey: Offline

The colour of the status icon is determined by the most important status of all the sub-statuses associated with that status icon.

You can hover over each status icon to see details of each sub-status that determines the colour of the status icon.

Network status icon

The network status icon indicates whether the machines can communicate with one another correctly over the network. It's colour is determined by up to 4 different sub-statuses:

Live update status:

This is the mechanism by which machines keep each other up-to-date with changes to the project file. The options it can have are:

Status	Description
Connected	Live update is running normally on this machine.
Director	Live update is running normally on this machine, and it's the director.
Not Connected	Live update has been intentionally disconnected. This is typically due to failover.
Blocked	This machine is unable to receive Live update changes; this could be due to a network error or due to a logic error in Designer (this state will also be accompanied by a large pop-up)
Director - Blocked	This machine is unable to receive Live update changes and it is the director, so no machines will be able to communicate live update changes.

Project sync status:

When Designer launches, the project is automatically copied from the director to all other machines. This can be in one of 4 states:

Status	Description
Succeeded	Project sync completed successfully.
Not Attempted	Project sync has not been initiated, but the machine is launching. This can be because project sync has been disabled with the `isSyncProjectFromDirectorDisabled` option switch.
Failed	Project sync has not been initiated, but the machine is launching. This can be because project sync has been disabled with the `isSyncProjectFromDirectorDisabled` option switch.
In Progress	Project sync is actively happening.

Transport control status:

This is the mechanism by which the playheads across multiple machines are kept in-sync with each other. This can be in one of 3 states:

Status	Description
In sync	Transport commands are being received regularly (at least once every 1/4 second).
Late	Transport commands are being received intermittently (at least once every second). This could indicate a network issue.

Status	Description
Out of sync	Transport commands have not been received for over 1 second. This could indicate a serious network issue or disconnect.

Remote status:

This indicates if all the other statuses have been updated recently for this machine or if you're looking at old data.

Status	Description
Up to date	The status you're looking at was updated in the last 2 seconds.
Stale	The status you're looking at was updated in the last 5 seconds.
Invalid	The status you're looking at has never been updated.
Offline	The status you're looking at was last updated more than 5 seconds ago.

Devices status icon

When the machine has started up, the devices status icon reflects whether or not each device capable of receiving data over the network is actively receiving that data. Mousing over the icon will list the devices and their statuses.

Each device configured to receive data has 2 possible statuses:

Status	Description
Receiving	This device is actively receiving data.
Idle	This device has not received data recently.

> **Note**
>
> OSC devices are not expected to constantly be receiving data so they always report that they are receiving as long as they are active.

Genlock status icon

The genlock status icon represents whether genlock is applied working correctly on each server. This has 4 possible statuses:

Status	Description
OK	Genlock is present and all connected outputs are genlocked.

Status	Description
Present, Not in use	Genlock is present but it is not all connected outputs have genlocked correctly, or genlock has not yet been applied.
Not present	A genlock signal cannot be detected.
Not supported	This machine does not support genlock (typical of editor laptops).

> **Note**
>
> The GUI head is not treated as a "connected output" for the purposes of this status icon, unless it is the only connected output.

Output status icon

The output status icon represents that status of your outputs from each server. It's colour is determined by up to 4 different sub-statuses:

Framelock: Whether or not the outputs of the machine are in-sync with each other.

Status	Description
OK	All output heads are presenting frames in sync with each other.
Out of sync	Outputs on the same machine are being presented at least more than 2ms out of sync with each other. This can be caused by genlock problems, outputs of differing resolution or other GPU issues.

Settings: Advanced project or machine settings which affect video output.

Status	Description
OK	No advanced project or machine settings that affect outputs are set.
Application window	`useApplicationWindow` is enabled. Outputs will not be in-sync and may not appear the way you expect.
Max heads limited	maxHeads is set to a value > 0. Some output heads may be disabled.
Windowed mode	`isWindowed` is enabled which means Designer won't be able to take Fullscreen which is required for synchronized outputs.

Status: When applying feeds the output icon is unreliable until the apply feeds process has completed, so it will turn blue.

Status	Description
Applying Feed Settings	Feed settings are currently being applied.

GUI: Whether the GUI is enabled or disabled on the machine. This is useful for troubleshooting performance problems on actors that should have their GUIs turned off.

Status	Description
GUI Off	The GUI is disabled.
GUI On	The GUI is enabled. On an actor this will appear Orange, on other machines this will appear Green.

RenderStream machines

Lists all render nodes visible to the session over d3net.

RenderStream Workload

Lists each RenderStream workload that this session has started and their current statuses.

Actions

Actions let you control all the machines in your session at once.

Networking Overview

Networking is essential for Disguise systems in most productions, enabling the key benefits in scalability and redundancy of the system. By connecting multiple servers together, Disguise enables users to handle larger projects and distribute processing power, allowing for easy expansion of capabilities as production demands grow. Simultaneously, this networked approach facilitates the implementation of failover systems, ensuring show continuity and minimizing the risk failures. These networking capabilities empower Disguise to deliver robust, scalable, and fault-tolerant solutions that can adapt to the most demanding show environments.

Disguise utilizes a proprietary networking system called d3Net, which allows for Director/Actor operation. This setup enables you to sequence shows whose output requirements exceed the capabilities of a single machine. With d3Net, you can design and sequence an entire show on one machine (such as a laptop) and then run it on a network of machines for the actual performance.

d3Net consists of different machine roles:

1. **Director**: The main control machine that manages the show and synchronizes all other machines.
2. **Actors**: Output machines that follow the Director's instructions and render content.
3. **Understudies**: Backup machines that can take over if any other machine fails.
4. **Editors**: Additional machines used for simultaneous project editing.

This networked approach offers several benefits:

- **Scalability**: Easily expand your setup to accommodate larger shows or more complex content.
- **Redundancy**: Implement backup systems to ensure show continuity in case of hardware failure.
- **Collaborative workflow**: Allow multiple team members to work on different aspects of the project simultaneously.
- **Distributed processing**: Spread the computational load across multiple machines for improved performance.

To fully leverage the power of networked Disguise servers, it's essential to set up your network correctly. This involves proper IP configuration, subnet management, and following best practices for network security and performance.

Network Configuration Recommended Practices

When setting up a network of Disguise media servers, it's crucial to follow recommended practices to ensure optimal performance and security. Here are the key points to consider:

1. **Set individual subnets for each interface**
   - Assign a unique subnet to each network interface on your media servers.
   - This helps in organising and isolating network traffic, improving overall network management.
2. **Set unique IP addresses for each machine**
   - Ensure that every machine in your network has a unique IP address, either via a static IP address or DHCP.
   - This prevents IP conflicts and allows for proper communication between devices.
3. **Ensure all machines are on the same subnet and can communicate via UDP and TCP on that subnet**
   - Ensure that all machines in your network can communicate with each other via UDP and TCP on the same subnet.
4. **Isolate d3Net traffic on a separate subnet**
   - If possible, isolate the d3Net traffic on a separate subnet from your other event networks.
   - This helps in preventing potential security risks and network congestion.

Network Isolation and Security:

Disguise is a media platform focussed on video playback and realtime rendering applications. If you need to use Disguise in a secure environment, please see Security, and for specific guidance on ports and firewalls, see this guide.

> **Note**
>
> Disguise will not provide support for, nor be liable for, any security issues arising from exposing these machines to public networks. Proceed with caution and at your own risk.

By following these guidelines, you can create a robust and secure network environment for your media servers, ensuring optimal performance while minimizing potential security risks.

NMOS in Disguise

Designer will now support using NMOS for ST 2110 video output from IP-VFC cards. We've taken the open source code solution developed by Sony named nmos-cpp and extended it to receive display updates from Designer when IP-VFC cards are outputting in ST 2110 format. This will run on each Disguise server when Designer runs to advertise the server as an NMOS node with each IP-VFC card an NMOS device and each ST 2110 stream an NMOS sender.

In summary, each Disguise server runs an NMOS node service that:

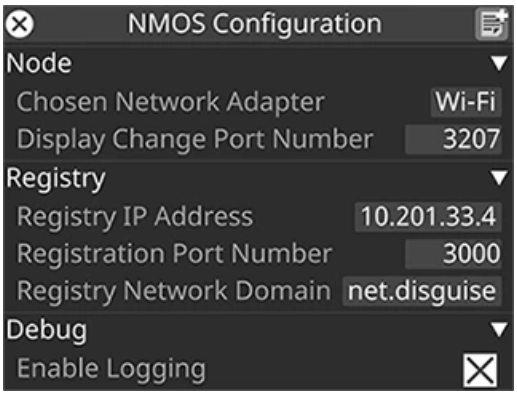
- Registers the server itself as an NMOS Node.
- Exposes each IP-VFC card as an NMOS Device.
- Publishes each ST 2110 stream as an NMOS Sender.
- Publishes each IP Video Capture instance as an NMOS Receiver for each machine in the session (e.g. if there are three machines, three NMOS Receivers will be seen for each IP Video to show that an ST 2110 stream can be received by any of those machines)

An active NMOS registry must be available on the network for node discovery and registration.

The NMOS Node, Device and Sender information sent to the registry will be presented according to the registry software, but it will look something like this:

Configuration

There's now an NMOS Configuration widget accessible from the d3 menu. This allows for specific NMOS registry details if the user wants to override the mDNS discovery.



Parameters

Chosen Network Adapter - This will be the network adapter that the NMOS node uses to communicate with the registry. It'll also use the IP address of this to advertise its APIs. If this is left blank, it will default to the user selected

network adapter in d3Manager.

Display Change Port Number - This is the port Designer uses to send the NMOS node updates in the display. It defaults to 3207 but can be changed if this clashes with something else.

Registry IP Address - If the NMOS node's auto discovery can't find the NMOS registry, or is connecting to a registry you don't want to use, this can be used to specify the IP address of the registry you want to use. If you want to use auto discovery, leave this empty.

Registration Port Number - Once the NMOS node finds the NMOS registry, it will register itself using the registration API. This will be on a specific port number. The default port of 3211 will be used, but depending which NMOS registry it is this can differ, so it can be set here.

Registry Network Domain - If the Disguise server is on a different domain to the registry it can be specified here. If you want to use auto discovery on the same domain, leave this empty.

Enable Logging - Used for debugging but off by default.

> **Note**
>
> After changing these values d3 needs to be restarted for them to take effect.

Troubleshooting

1. Check that the NMOS node is running and correctly configured:

- If the node is displaying the error *"An error occurred reading the nmos-config.json file"*, ensure that the file is in correct json format. If there's a comma missing, or a single quote " it will mean the whole file will be rejected. This file shouldn't be edited by users.
- The **nmos-node.exe** application is run by Designer on start up with the settings in the NMOS configuration widget. You can check various elements of this with a web browser by logging into the node's APIs.
- Check the node settings in a browser with `http://localhost:3209/settings/all/`.
  - If nothing comes up and it says the site can't be reached then either the node isn't running or the settings port has been changed from `3209` in the json config file.
  - If it does display the settings, ensure the registry_address and registration_port and domain are what you configured them to be in the NMOS configuration widget. If they aren't, restart Designer and they should be passed through on start up.
- Check that Designer is sending messages to the node in a web browser with `http://localhost:3207/displaychange/`.
  - The port number `3207` is configurable, so ensure this is correct in the NMOS Configuration widget.
  - If it says null or is empty the node hasn't received any updates from Designer yet.
    - This could be because it has no ST 2110 outputs. Make sure IP-VFC cards are in ST 2110 mode.
    - The IP-VFCs should also have a green border in the feed screen to indicate they're active and ready. If they don't, try applying feeds.
  - If it does have data it'll be the last message sent from Designer.
    - A field named **"last_update_date_time"** will show when it received this message.
    - It will also show the **"hostname"** it came from. This message should only ever be sent from Designer running on the same machine as the node.
    - It will include a list of NMOS devices, which in this case are IP-VFC cards. Each card can have up to four ports which equate to NMOS senders

- Check the node API is advertising its data correctly in a web browser with `http://localhost:3212/x-nmos/node/`
  - This will show the possible schema versions it's on. By default we use the latest, v1.3
  - After selecting the version you'll see all the device, flow, sender, receiver and source data it's storing.
  - Using `http://localhost:3212/x-nmos/node/v1.3/self/` will show the endpoints it's advertising to the registry.
- Check the SDP file in a web browser with `http://localhost:3215/x-nmos/connection/v1.1/single/senders/<sender id>/transportfile`
  - The `sender id` will look like this `803d9129-0000-1000-a000-401175c00600`. The second digit, in this case `0`, is the port number of the IP-VFC card and the last 12 characters are the IP-VFC's first mac address. The other numbers will always be the same.
  - The SDP file is a text based configuration file so it's human readable. You'll see properties like these which should match the current output of your IP-VFC card: `width=3840; height=2160; exactframerate=60; sampling=YCbCr-4:2:2; depth=10; colorimetry=BT709;`
  - For more detail on what's expected in these files, see https://en.wikipedia.org/wiki/Session_Description_Protocol

2. NMOS Registry not discovered

- Verify that an NMOS registry service is running and reachable on the network.
- Confirm that mDNS is permitted across your network. If mDNS is blocked, specify the registry's IP address and registration port manually in the NMOS Configuration widget and restart Designer.
- Check firewall rules on both the registry host and the Disguise server to ensure the correct ports are open.
- The NMOS settings for auto discovery should have a registry_address of `0.0.0.0` and a domain of `local.`. If these fields are empty in the NMOS Configuration widget, the node will default to these.

3. Node not appearing in registry

- Are you using ST 2110 video output or input? This could either be with IPVFC cards or IP Video In. The node will only be created in NMOS once there's a device to advertise.
- Check that the node is running correctly first following the instructions in step 1.
- Ensure the correct Chosen Network Adapter is selected. If left blank, it defaults to the adapter selected in d3Manager, which may not be on the registry subnet.
- If neither the Chosen Network Adapter or the User Selected network adapter in d3Manager are set, the node will advertise itself on all network adapters on that machine. This can have mixed results, as the registry may detect it more than once and become confused about where it's running. Setting a Chosen Network Adapter will prevent this.
- Confirm that the Registration Port Number matches the registry's API port.
- Restart d3 after changing configuration settings.

4. NMOS Senders missing or inactive

- Verify that the IP-VFC card is correctly configured for ST 2110 output in Designer
- It will have an NMOS sender for every active VFC port, so if it's in Quad mode in Designer there will be four corresponding NMOS senders
- Make sure all ports in Designer have a green background in the feeds screen. If they don't, try applying feeds

5. Streams appear but do not connect

- Confirm PTP synchronization is running correctly on the network. Without PTP lock, ST 2110 senders may register but not pass valid video
- Verify multicast routes are configured correctly on the switch.

NMOS specification coverage

IS-04 - Discovery and Registration

- The NMOS node application will run with Designer and connect to an NMOS registry on the network either by multicast DNS “Auto” discovery or to a specific IP Address and registration port number set in the NMOS configuration widget
- The NMOS node will advertise all Designer’s ST 2110 video senders and receivers
  - each Disguise server will be listed as an NMOS node
  - within that node each IP-VFC card will be listed as an NMOS device
  - each IP-VFC port set to output ST 2110 video will be listed as an NMOS sender
  - if Designer is using IP Video Capture it will create an NMOS device named IP Video Capture
  - under this each IP Video Capture instance will be listed as an NMOS receiver. If they’re created from a sender’s SDP file they’ll use the sender name in their own label. If they’re created with no SDP file they’ll advertise themselves as being capable of receiving a wide range of display properties to allow any NMOS sender to connect to them

IS-05 - Device Connection Management

- The NMOS node will propagate its local device information to the NMOS registry and connections can be made between senders and receivers on the network
- The node has a Connection API which the registry can push updates to
  - If it receives a request from a sender to connect to an IP Video Capture instance it will pass the SDP file contents to Designer, making it immediately ready to use as a logical video input that can be mapped accordingly
  - If it receives a request from a receiver to subscribe to a senders output and the request contains multicast IP addresses these will be sent to Designer to update those address on the IP-VFC card. Note that although you’ll see the values change in the VFC port editor, you’ll still need to apply feeds to actually push them to the card itself
- Also, if an IP Video Capture instance is created from an SDP url or from selecting a sender from the NMOS sender list, it will update the connection API on the node to propagate to the registry and the node of the sending device

Schema versions

- The NMOS node can support various schema versions depending on the schemas used by the NMOS registry
- Supported registry query schemas: v1.2 and v1.3
- Supported IS-04 schema: v1.2 and v1.3
- Supported IS-05 schema: v1.0 and v1.1

OmniCal Networking

Disguise OmniCal is a calibration system designed to enhance projection mapping and screen alignment. It uses camera-based technology to:

- Automatically calibrate projectors using all visible physical surfaces.
- Correct for distortions and misalignments in projection.
- Allow flexible alignment, scaling and reshaping of projection surfaces.
- Ensure seamless visuals in complex setups, such as:
  - Large-scale projection mapping
  - Multi-projector configurations

OmniCal uses machine vision cameras that have specific requirements for network infrastructure.

Further information

For more information about setting up OmniCal networks, please refer to the detailed OmniCal Networking Guide.

For information about used network ports, please see Network ports and activity.

Output Sync Test

Understanding Output Synchronisation

Output synchronisation ensures that multiple outputs from a Disguise server, and outputs from multiple servers, render in perfect alignment. It is essential for delivering a seamless visual experience, particularly in live events and XR applications.

When servers are not correctly synchronised this will often appear as tearing as illustrated in the image below:

Tearing between two outputs as viewed on a screen

Understanding the two key methods for achieving output synchronisation is important. These are Framelock and Genlock.

Additionally, if issues arise, it is crucial to follow a precise and scientific testing methodology to ensure accurate troubleshooting.

Key Components

- **Framelock**:A GPU-based mechanism that synchronises individual outputs within the same server to prevent visual inconsistencies. See the Network Status Widget page.

- **Genlock**: A synchronisation method that aligns multiple devices to a shared clock source, enabling coordination between Disguise servers and external equipment such as cameras and LED displays. See the Genlock Configuration page.

Testing Methodology

Disguise offers a few simple, easy and effective methods to test output synchronisation, troubleshoot issues, and ensure a flawless performance

Disguise Network Widget

Next to each server in the Network Status Widget there are indicators for Network Status, Genlock Status and Framelock Status. You can hover over each icon to see the sub-status that determines it's colour. All these status icons should be green in a correctly synchronised system.

The Network Status icon will indicate several statuses. The one most relevant to output synchronisation is "Transport control status". This must be "In sync" to ensure output synchronisation.

Server FPS

In the bottom right-hand side of the Designer GUI you will see the current FPS of each server in your cluster. If any of these values are not at the target refresh rate this means that that server is "dropping frames" because it is working too hard to keep up. While dropping frames, outputs will not be synchronised.

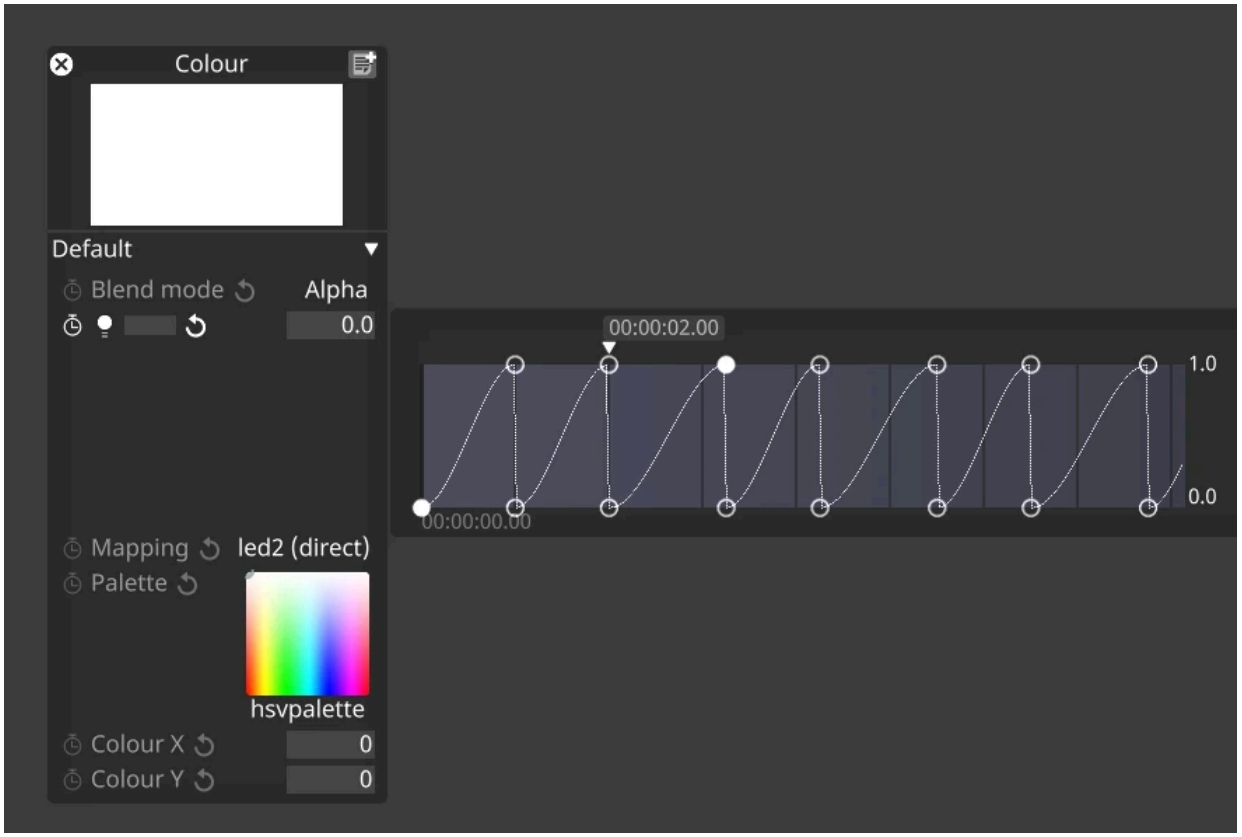
You can hover over any FPS value to see which server it is referring to. You can also see a list of swerver FPS values in the Network Status Widget.

Basic Colour Layer Test

This test can be used to eliminate variables outside of the XR workflow and verify that a simple shape is outputted across all outputs of a server and additionally check upstream systems such as LED Processors.

To run the Basic Colour Layer Test:

Create a simple colour layer with a keyframe of brightness repeating up and down.



When the output is directed to a range of monitors, it demonstrates the Disguise system's capability to synchronise video playback. However, if the video appears out of sync across multiple machines, it could indicate an improper Genlock configuration."

Reducing Variables

To ensure synchronisation, every device in the chain must be Genlocked or Framelocked. If the Disguise system can output video in sync to 2, 3, or 4 LED monitors, but issues like tearing or out-of-sync playback occur when connected to your XR stage or LED processors it indicates that either a converter or an LED processor is not correctly Genlocked. By reducing the number of converters and variables, we can identify which device is not correctly configured.

Performing due diligence here will help validate the core video architecture in your system before moving on to advanced workflows.

XR Workflow Testing

Once video playback has been guaranteed as part of our previous test, we can begin to look at XR workflows. See the Video Receive Delay page.

Completing the Delay Calibration in the XR workflow should now be possible with a single frame of white.

- **Camera/LED Genlock**: Verify that the camera and LED devices are correctly Genlocked. Most devices usually refer to this a G/LOCK or EXT SYNC. Please see your devices manual in how to observe if its receiving external lock
- **Frame Rates**: Ensure that all devices are operating at the same frame rate. Ensure that camera devices are setup to the same Genlock source.
- **Camera Settings** Shutter speed and angle are important to ensure that only a single frame of delivery is captured. These workflows are outlined in the XR workflow guides.
- **Clustered rendering**: If RX nodes or clusters of Engines are rendering different frames, this can also look like tearing.

It is important to narrow down whether this is the Disguise Video playback, core servers or the render nodes.

Narrowing this down to the colour test will then help you determine if engines are out of sync or if its simply the core system.

Troubleshooting

- **Tearing**: If tearing occurs, it suggests synchronisation issues. Check frame rates, Genlock settings, and network connections. Is this down to a render node or a core video output system?
- **Strobe Layers and Generative Effects**: Be aware that these effects may not synchronize across Disguise machines. You should avoid using STROBE/RADAR and CHEVRONS as a method of sync testing.
- **Disguise Readout test**: Whilst we eluded to both Framelock and Genlock, Disguise also communicates between machines to verify what the current time/frame is and whether displays are in Framelock.

A support engineer may ask you to use the **READOUT** layer mapped to each screen, filming this in slow motion can be used to provide more scientific data for our team to observe and look at.

Please contact **support@disguise.one** if you are having issues with output sync.

	Definition	Must be the same to sync
`iFrame` *(Frame number)*	Frame index d3 start since d3 start.	No
`tRender` *(Seconds)*	The frame on the playhead that the local machine is currently rendering.	Yes
`tRunning`	Starts counting up once you hit play, & resets when you transition from stop to play – similar/same to tRender.	Yes, must be same unless dropping frames
`deltaTime`	Difference between now and last frame in time, this should equal to 1 fps.	Yes, must be same, unless dropping frames
`deltaBeats`	Difference between now and last frame in beats, similar/same to deltaTime.	Yes, must be same, unless dropping frames
`timerMode`	- Network Mode - Normal Mode - Fixed Mode	Yes, must be set as Network
`actualTime`	Local timer since startup.	No, does not need to be same
`frameTime`	The time of the last frame update.	Yes, should always be in sync when Genlocked. If not, ensure Genlock is still working on all servers.

	Definition	Must be the same to sync
`actualFrameTime`	The time of the last frame update in local machine time.	No, does not need to be same

RenderStream Networking

Disguise RenderStream is a protocol and technology developed to enable real-time streaming of rendering data between systems, such as media servers and rendering engines.

It is designed for synchronised, high-quality, and low-latency workflows, commonly used in applications like:

- Virtual production
- Live events
- Immersive experiences

Bandwidth Considerations

- RenderStream handles high-resolution, high-frame-rate content, including textures, video, and rendering data.
- Uncompressed data significantly increases bandwidth demands.

Transport types

Streams in RenderStream can either be **compressed** or **uncompressed**.

Uncompressed streams

RenderStream Uncompressed Streams (sometimes shortened to RSUC) are low latency, high-quality, and require much higher bandwidth.

Uncompressed streams require specific hardware:

- **Network Interface Cards (NICs)**: 25Gb or 100Gb Mellanox network interface.
- **Multiple Machines**: dedicated render nodes render and send content via uncompressed streams to actor and director machines.
- **Genlock**: required when rendering multiple fragments that are output by multiple actor machines.

Supported uncompressed formats:

- RGB 4:4:4 8bit
- RGB 4:4:4 10bit
- RGB 4:4:4 12bit
- YUV 4:2:2 8bit
- YUV 4:2:2 10bit
- YUV 4:2:2 12bit

The transport format can be configured in the cluster assigner settings of the workload: RenderStream Layer

Compressed streams

Compressed streams use H.265 compression to reduce bandwidth needs while providing consistent content quality. Compressed streams use an order of magnitude less bandwidth than uncompressed and can be used on the 1G, 10G, or 25G+ networks. A limited number of streams can be encoded and decoded by the hardware on the cards.

Supported compressed formats:

- YUV 4:2:0 8bit

The transport format can be configured in the cluster assigner settings of the workload: RenderStream Layer

RenderStream Network Configurations
