Standard steps for all clinical skills/interventions xx
Text features xxii

## Unit 1 The evolution of the nursing profession

### Chapter 1 Nursing: the evolution of a profession *Katie Frankiewicz* 2

What is nursing? 3
Nursing practice in Australia 8
Professional nursing organisations 19
Nursing—the profession 19
Influences on nursing 23

### Chapter 2 Professional nursing practice: legal and ethical frameworks *Kalpana Raghunathan* 26

Introduction 27
Legal aspects of nursing practice 27
Areas of legal liability in nursing 30
Legal responsibilities of nursing students 40
Legal issues in the nursing specialties 41
Ethical aspects of nursing 41

### Chapter 3 Nursing research and evidence-based practice *Kate Stainton* 50

The Enrolled nurse and nursing research 51
Nursing research 52
Evidence-based practice 52
Research methods 55
The research process 58
Proposal writing for research approval 63
How is research utilised in practice? 64

## Unit 2 The contemporary healthcare environment

### Chapter 4 Australia's healthcare delivery system *Goetz Ottmann* 74

Introduction 75
Components of a healthcare system 75

### Chapter 5 Nursing informatics and technology in healthcare *Robert M Ribbons* 90

An introduction to nursing informatics 91
A brief history of computers and information technology 92
Fundamentals of computer systems 92
Fundamentals of information systems 95
Networks, communication technologies, the internet and world wide web 97
Contemporary technologies and software applications and their use in healthcare 99
Ethics, security, privacy and confidentiality 99
Data standards and nursing minimum data sets 101
Electronic health records: providing information across the care continuum 101
Using it to support education and research 102
Technical trends and issues in e-health and telehealth 104

### Chapter 6 Understanding and promoting health *Glenda Verrinder and Lyn Talbot* 107

Understanding health 108
The determinants of health 109
What is health promotion? 116
Clinical skill 6.1 Health teaching 125
Nursing and health promotion 128

### Chapter 7 Quality and safety in healthcare *Yvonne Elizabeth Wilkinson* 136

Quality and safety in the context of healthcare 137
Quality in healthcare 137
Safety in healthcare 141
Work health and safety issues 145

### Chapter 8 Communication and nursing practice *Maree Gault* 149

Components of the communication process 150
Elements of the communication process 151
Factors that influence the communication process 153
Forms of communication 154
Conflict and communication 157
Passive, aggressive and assertive communication 158
Therapeutic communication 159
Skills to facilitate therapeutic communication 159
Communicating with children, adolescents and older adults 164

Communicating with an individual's relatives, friends and significant others 165
Barriers that interfere with therapeutic communication 165
Culturally safe communication 167
Individuals with special requirements 167
Communication within the healthcare team 171

Chapter 9 Models of nursing care, management and leadership *Gabrielle Koutoukidis* 180

The Nurse as a leader and manager 181
Models of nursing care delivery 182
Leadership styles 183
Contemporary leadership theories 184
Management 185
The nurse as a delegator 188
Preparing nurse leaders for the future 189

Unit 3 Health beliefs, cultural diversity and safety

Chapter 10 Cultural competence and safety *Denise Wilson and Lesley Seaton* 194

Introduction 195
Values, beliefs and attitudes 196
What is culture? 196
Culture and wellbeing 201
Effective communication 203
Culture, the individual and their profession 205
Cultural diversity and individuals' experiences of the system 206
Culture in practice 207

Chapter 11 Australian Indigenous health *Juanita Sherwood and Jodie Hughson* 212

Worldviews 214
Land and country 214
Demographics 215
Divergent worldviews 216
Cultural respect, security and competence 217
Indigenous ways of viewing health 218
History taking: the context 219
Some of the hard data 222
Good news stories 224

Unit 4 Nursing care throughout the life span

Chapter 12 Nursing care across the lifespan: conception to late childhood *Andree Gamble* 230

Conception 231
Development of the placenta, membranes, liquor and cord 232
Intrauterine development and growth 234
Transition to extrauterine life 235
Theories of development 235
Growth and development 238
Growth and development of the infant 239
Health risks/problems 243
Growth and development of the child 244
Health risks/problems 247
Factors influencing growth and development 249
Cultural diversity 250
Health promotion 251
Paediatric nursing care 251
Child health services 253
Needs of infants and children 255

Chapter 13 Nursing care across the lifespan: late childhood to adolescence *Jean Elizabeth Ross* 258

Preadolescence 259
Growth and development of the preadolescent 259
Adolescence 260
Growth and development of the adolescent 260
Cultural diversity 270
Health risks 271
Health promotion 272
Nursing implications 272

Chapter 14 Nursing care across the lifespan: younger adulthood to middle adulthood *Vivienne Therese Decleva* 276

Emerging adulthood 277
Growth and development in early adulthood 277
Health risks/problems in early adulthood 279
Growth and development in middle-aged adults 282
Health risks/problems in middle-aged adults 285
Cultural diversity 286
Health promotion 287
Implementing the nursing process 287

Chapter 15 Nursing care across the lifespan: older adult *Margaret Webb* 291

The state of ageing in Australia 292
Ageism 292
Growth and development 293
Health risks/problems 297
Cultural aspects of ageing 301
Health assessment and promotion 303
Care settings 303
Nursing care of the ageing person 305
Implementing the nursing process 305

Unit 5 Critical thinking and reflective practice

Chapter 16 Critical thinking, problem-based learning and reflective practice in nursing care *Jennifer Marshall* 312

Introduction 313
Critical thinking 313
Problem-based learning 314
Reflective practice 316

Chapter 17 Nursing process: framework *Gillianne Meek* 322

An overview of the nursing process 323
Assessment 324

Identification 327
Planning 328
Implementation 329
Evaluation 329

### Chapter 18 Health information: nursing documentation and clinical handover *Leisa Bishop* 332

Purpose of documentation 333
Legal and ethical considerations 336
Documentation guidelines and principles 337
Documentation formats and approaches 338
Clinical skill 18.1 Documentation 340
Documentation in aged care 345
Clinical handover 345
Clinical skill 18.2 Clinical handover 352

## Unit 6 Health assessment

### Chapter 19 Health assessment frameworks: initial and ongoing *Kate Stainton and Gabrielle Koutoukidis* 362

Guidelines for conducting a general health assessment 363
Clinical skill 19.1 Pressure injury risk assessment 370
Clinical skill 19.2 Mental health assessment 374
Clinical skill 19.3 Falls risk assessment 376
Clinical skill 19.4 Venous thromboembolism assessment 381
Clinical skill 19.5 Nutritional assessment/weight, height and BMI 384
Assessment techniques 388
Clinical skill 19.6 Mobility assessment 389
Routine shift assessment 392
Diagnostic investigations 393
Recording and reporting 394
Teaching considerations 394
Clinical handover 394
Advance health directives 395

### Chapter 20 Vital sign assessment *Rachel Gilder* 398

Guidelines for taking vital signs 400
Body temperature 400
Steps in obtaining an accurate measurement of body temperature 403
Clinical skill 20.1 Assessing body temperature 407
Pulse 411
Clinical skill 20.2 Assessing pulse (radial) 413
Respiration 415
Clinical skill 20.3 Assessment of respirations 418
Pulse oximetry—measuring oxygen saturation 420
Blood pressure 421
Clinical skill 20.4 Measuring oxygen saturation (pulse oximetry, $SpO_2$) 422
Clinical skill 20.5 Measuring blood pressure 425
Recognising and responding to clinical deterioration in acute healthcare 429

### Chapter 21 Admission, transfer and discharge processes *Susan Jones* 433

Types of admission 434
Reactions to admission 434
The admission process 439
Clinical skill 21.1 Admission and discharge process 440
Admitting the person to the mental health unit 448
Admitting a child to a healthcare facility 448
Admitting an adolescent to a healthcare facility 451
Discharge planning 451

## Unit 7 Basic healthcare needs

### Chapter 22 Infection prevention and control *Teresa Lewis* 468

Healthcare-associated infection is preventable 469
Improving healthcare in Australia 469
Nature of infection 470
Microoganisms 470
Infection prevention and control in practice 481
Clinical skill 22.1 Handwashing/hand hygiene 488
Clinical skill 22.2 Donning and doffing PPE (gloves, gown, mask, eyewear) 492
Clinical skill 22.3 Open gloving (donning and removing sterile gloves) 502

### Chapter 23 Maintenance of health: hygiene and comfort care *Lindsay Bava* 515

Factors affecting personal hygiene 516
Skin and skin care 517
Bathing and showering 518
Clinical skill 23.1 Assisting with a shower or bath 521
Clinical skill 23.2 Performing a bed bath 526
Hair care 529
Eye, ear and nasal care 531
Clinical skill 23.3 Performing an eye toilet 531
Mouth care 533
Nail care 535
Clinical skill 23.4 Assisting with oral hygiene, cleaning teeth and dentures 536
Clinical skill 23.5 Performing special mouth care 537
Hygiene summary 539
Promoting comfort 539
Bed making 543
Clinical skill 23.6 Making an unoccupied bed 543
Clinical skill 23.7 Making a theatre bed 548
Clinical skill 23.8 Making the occupied bed 550
Comfortable positioning 552

### Chapter 24 Medication administration and monitoring *Heather Redmond* 558

Pharmacology 559
Pharmacokinetics 564
Pharmacodynamics 568
Safety and legal requirements in medication administration 570

Systems of measurement 578
Administering medications 581
Clinical skill 24.1 Administering oral medications 582
Clinical skill 24.2 Administering medications via enteral routes (nasogastric tube, percutaneous endoscopic gastrostomy tube, percutaneous endoscopic gastrojejunostomy tube) 585
Clinical skill 24.3 Inserting a rectal suppository or disposable enema 588
Clinical skill 24.4 Administering subcutaneous and intramuscular injections 595
Clinical skill 24.5 Establishing intravenous (IV) therapy (assisting) 597
Clinical skill 24.6 Intravenous management 598
Clinical skill 24.7 Administration of intravenous (IV) medications: infusion and bolus 600
Clinical skill 24.8 Removal of intravenous cannula 607
Clinical skill 24.9 Administration of a topical medication 608
Clinical skill 24.10 Applying transdermal medications 610
Clinical skill 24.11 Instilling eye drops or ointment 611
Clinical skill 24.12 Instilling ear drops 613
Clinical skill 24.13 Administration of a vaginal medication 614
Clinical skill 24.14 Administration of a medication via nebuliser 616
Clinical skill 24.15 Use of a hand held inhaler and spacer 618
Monitoring the effects of medications 619
Clinical skill 24.16 Administering nasal sprays and drops 620
Safe handling of hazardous substances 625
Safe storage, administration and disposal of medications 625
Medications and the older adult 625
Medications and the child 626
Continuation of medication regimen after discharge 626

## Unit 8 Health promotion and psychosocial and physiological nursing care

### Chapter 25 Nursing care of an individual: cardiovascular and respiratory *Kylie Porritt* 636

Structure of the respiratory system 637
Scientific principles of ventilation and respiration 641
Ventilation and respiration 642
Structure of the cardiovascular system 645
Clinical skill 25.1 Preparing and monitoring an individual undergoing a blood transfusion 650
Circulation of blood 653
Structure of the lymphatic system 655
Factors affecting the respiratory system 656
Pathophysiology related to the respiratory system 658
Specific disorders of the respiratory system 660
Factors affecting the cardiovascular system 663
Pathosphysiology related to the circulatory system 664
Specific disorders of the circulatory system 666
Respiratory diagnostic tests 670
Cardiovascular diagnostic tests 671
Clinical skill 25.2 Performing an ECG 672
Nursing an individual with a respiratory and/or cardiac system disorder 676
Clinical skill 25.3 Incentive spirometry 681
Clinical skill 25.4 Collection of sputum 683
Clinical skill 25.5 Collecting a nasopharyngeal (nasal) or nasalpharynx (throat) swab 684
Clinical skill 25.6 Oronasopharyngeal suction 685
The individual with an artificial airway 687
Nursing an individual with an artificial airway 688
Clinical skill 25.7 Tracheostomy suctioning and tracheal stoma care 689
The individual with thoracic drainage tubes 692
Clinical skill 25.8 Care of chest tube/drainage and dressing change 693
Nursing a person with a chest drain 695
Nursing practice and oxygen administration 696
Clinical skill 25.9 Oxygen therapy—nasal, mask 698
Education 703

### Chapter 26 Nursing care of an individual: fluid and electrolyte homeostasis *Kalpana Raghunathan* 707

Homeostasis 708
Fluid balance 712
Electrolyte imbalances 717
Nursing assessment of individuals with fluid and/or electrolyte needs 718
Intravenous therapy 724
Clinical skill 26.1 Fluid balance charting 725
Understanding acid–base balance 728

### Chapter 27 Promotion of health and wellbeing: rest and sleep *Heather Redmond* 734

Rest 735
Physiology of sleep 735
Sleep disorders 738
Factors affecting sleep 741
Assessing rest and sleep patterns 742
Sleep-promotion measures 745

### Chapter 28 Promotion of health and wellbeing: movement and exercise *Heather Wakefield* 752

The physiology of movement 753
Body mechanics 754
Disease processes that influence body mechanics 754
Development of movement and exercise through the lifespan 756

Overweight and obesity in Australia 757
The benefits of physical activity 758
Principles of muscle movement in exercise 760
Assessment of movement, mobility and the musculoskeletal system 762
Clinical skill 28.1 Assisting with transfer 763
Diagnosis of a musculoskeletal disorder 768
Nursing care of the individual with a musculoskeletal disorder 768
Treatment of bone injuries and musculoskeletal disorders 769
General treatment of musculoskeletal disorders 770
Clinical skill 28.2 Positioning individuals in bed 772
Ambulation after prolonged immobilisation 774
Walking aids 775
Complications associated with reduced mobility 777
Clinical skill 28.3 Application of anti-embolic stockings 778

**Chapter 29 Maintaining and promoting skin integrity and wound care** *Kerrie Coleman* **784**
The integumentary system 785
Wound healing 787
Types of wound 790
Types of healing 790
Wound management 791
Clinical skill 29.1 Wound swab 797
Clinical skill 29.2 Dressing a wound 801
Pathophysiological effects and major manifestations of skin disorders 802
Specific disorders of the skin 804
Care of the individual with a skin disorder 807
Pressure injuries 808
Clinical skill 29.3 Shortening a drain tube 816
Clinical skill 29.4 Assessment and management of skin tears 821
Leg ulcers 823
Burn injuries 826
Clinical skill 29.5 Packing a wound 827
Surgical wounds 838
Clinical skill 29.6 Removal of sutures and staples 839

**Chapter 30 Promotion of health and wellbeing: nutrition** *Lynelle Jenkinson* **846**
Nutrition overview 847
Nutrition assessment 848
Nutrients 858
Diets to meet individual needs 860
Nursing practice and nutritional needs 863
Clinical skill 30.1 Assisting with eating and drinking 867
Common disorders associated with nutrition 869
Clinical skill 30.2 Inserting a nasogastric tube 873
Clinical skill 30.3 Enteral feed 878

**Chapter 31 Nursing care: urinary elimination and continence** *Auxillia E Madhuvu* **885**
The urinary system 886
Alterations in urinary system functioning 888
Changes to voiding patterns 889
Clinical skill 31.1 Assisting with toileting: bedpan, urinal, commode 892
Clinical skill 31.2 Perineal care 894
Clinical skill 31.3 Urinalysis 896
Clinical skill 31.4 Mid-stream urine collection 898
Specific disorders of the urinary system 900
Incontinence 902
Catheters 904
Clinical skill 31.5 Applying a sheath/condom drainage device 905
Clinical skill 31.6 Catheterisation of females 907
Nursing interventions 910
Clinical skill 31.7 Emptying collection bags 912
Clinical skill 31.8 Removal of indwelling urinary catheter 913
Specialist urology nursing activities 914

**Chapter 32 Nursing care: bowel elimination and continence** *Kelly Gray* **921**
The digestive system 922
Disorders of the digestive system 933
Clinical skill 32.1 Changing an ostomy appliance 934
Clinical skill 32.2 Stool assessment/collection 940

**Chapter 33 Nursing assessment and management of pain** *Yangama Jokwiro* **944**
Fundamentals of pain 945
Pain management across the lifespan 946
Nursing interventions for an individual experiencing pain 953

**Chapter 34 Nursing assessment and management of sensory health** *Jodie Hughson* **964**
Classification of sense organs 965
Altered senses 965
Factors affecting sensory function 967
Assessing sensory function 968
Special sense organs 969
The eye 970
Disorders of the eye 972
Other disorders of the eye 978
Clinical skill 34.1 Application of eye pad 982
Clinical skill 34.2 Eye irrigation 983
The ear 985

**Chapter 35 Nursing assessment and management of neurological health** *Anne MacLeod* **994**
The function and structure of the neurological system 995

Pathophysiological influences and effects of disorders of the nervous system 1003
Assessing neurological status 1006
Clinical skill 35.1 Performing a neurological assessment 1008
Diagnostic tests 1011
Clinical skill 35.2 Neurovascular assessment 1014
Specific disorders of the nervous system 1016
Care of the individual with a nervous system disorder 1026
Care of the unconscious individual 1030

**Chapter 36 Nursing assessment and management of endocrine health** *John P Elias* **1045**
Structure and function of the endocrine system 1046
Endocrine disorders 1051
Care of the individual with an endocrine disorder 1064
Clinical skill 36.1 Measuring blood glucose 1065

**Chapter 37 Nursing assessment and management of reproductive health** *Christine Baker* **1076**
The male reproductive system 1077
Disorders of the male reproductive system 1078
Nursing interventions in male reproductive health 1086
The female reproductive system 1086
Disorders of the female reproductive system 1087
Assessment and diagnostic tests 1097
Women's health promotion 1099
Contraception 1100
Disorders of reproduction 1103
Sexual abuse 1104
Sexually transmitted infections 1104

## Unit 9 Healthcare in specialised practice areas

**Chapter 38 Nursing care in palliation** *Leigh Darcy* **1114**
Death and dying 1115
Palliative care 1116
Person- and family-centred palliative care 1117
Multidisciplinary palliative care 1117
Symptom management 1119
Loss and grief 1124
Care of the dying 1124
Care of the body after death 1126
Care of the bereaved 1127
Support for the nurse 1127

**Chapter 39 Mental health and mental illness** *Louise Alexander* **1130**
Concepts of mental health and mental illness 1131
The provision of care 1141
Historical perspectives and mental healthcare 1146
Care of consumers with specific emotional or behavioural challenges 1147
Legal and ethical aspects of mental health nursing 1167
Ethical issues and dilemmas 1169

**Chapter 40 Nursing care in rehabilitation** *Sally Moyle* **1174**
Aims and characteristics of rehabilitation 1175
Philosophy of rehabilitation 1177
Adjustment to disability 1177
The rehabilitation team 1178
The process of rehabilitation 1183
Planning and implementation 1184
Culturally relevant care 1186
Discharge planning 1187

**Chapter 41 Nursing care: chronic illness and disability** *Vicki Blair Drury* **1191**
Chronic disease 1192
Prevalence, classification and causes of chronic diseases 1193
Conceptual models of chronic care 1193
Disability 1194
Prevalence and causes of disabilities 1194
Classifications of disability 1194
Conceptual models of disability 1196
The philosophy of inclusion and normalisation 1199
Continuing challenges 1200
Approaches to management of individuals with chronic conditions or disabilities 1201
Caregivers of people with chronic disease or disability 1207
Health promotion: disability prevention 1208
Abuse and advocacy 1209

**Chapter 42 Nursing in the acute care environment** *Michelle Hall* **1213**
Scope of practice 1214
Where is acute care delivered? 1215
Impact of acute illness 1216
Acute disorders 1217
Clinical skill 42.1 Venepuncture 1228
Clinical skill 42.2 Central venous access device management: dressing, removal and medication administration 1230
Clinical pathways 1232

**Chapter 43 Nursing in the perioperative care environment** *Karen Stilo* **1238**
Perioperative care 1239
Surgery 1239
Preoperative care 1241
Intraoperative phase 1250
Postoperative care 1254
Clinical skill 43.1 Pre- and postoperative exercises 1259

**Chapter 44 Nursing in the emergency care environment** *Jennifer Jennings* **1272**
Introduction 1273
Recognising and responding to an emergency 1275
Changes in vital signs 1276
Basic life support 1278
Clinical skill 44.1 Cardiopulmonary resuscitation/basic life support 1279
Defibrillation with the automated external defibrillator 1285
Post-resuscitation care 1286
In-hospital MET documentation 1288
Staff debriefing 1290
Managing specific emergency situations 1290
Cardiac emergencies 1292

**Chapter 45 Nursing care: maternal and newborn** *Kate Stainton* **1298**
Pregnancy 1299
Prenatal care and preparation 1302
Labour 1303
Postnatal care 1309

**Chapter 46 Nursing in the community** *Kym Louise Strachan* **1321**
Community healthcare 1322
Community health nurse role 1325
Models of care in community health 1326
Issues for community health nurses in home care 1326
The nursing process and community nursing 1328

**Chapter 47 Nursing care in rural and remote areas** *Melissa Taylor* **1333**
Introduction 1334
Remote and rural Australia 1335
Health and illness patterns in rural and remote Australia 1336
Remote area and rural nursing 1338
Effective healthcare service delivery in remote settings 1339
Stress related to working in a remote health context 1342
Access to health services in rural and remote areas 1347

Credits 1351
Index 1372

# Foreword

Congratulations on choosing a rewarding and fulfilling career path.

The authors Gabrielle Koutoukidis, Kate Stainton and Jodie Hughson along with a team of worthy contributors have developed an essential learning resource for the Diploma of Nursing student in this the seventh edition of *Tabbner's Nursing Care: Theory and Practice*.

As you work from the fundamentals of nursing onto psychosocial and physiological nursing care you will be rewarded with the wealth of knowledge that fills the pages of this book. This book will not only contribute significantly to you as a learning tool but will remain a valuable resource to refer to as your career progresses.

*Tabbner's Nursing Care* is a user-friendly resource and the content throughout highlights developmental considerations, cultural aspects of care, current research and health education. All of the features will assist students in reflecting on their new-found knowledge and gaining a critical-thinking outlook. The comprehensive examples of Nursing Care Plans and Progress Notes throughout assist you in producing concise and accurate documentation while on placement and into your nursing career. There are examples of how to use the decision-making framework to best manage and develop your scope of practice and there is nothing more valuable in nursing than Lived Experiences—these experiences will become your most valuable developmental tools.

Enrolled Nurses have always been valuable members of the nursing team, giving hands-on care to individuals and their families/carers and being advocates for that care. As Enrolled Nurses become more involved in the multidisciplinary team they need increased IT skills, auditing (collecting and collating data) skills and quality and safety processing skills. Chapters on nursing informatics and technology in healthcare along with quality and safety in healthcare have been an important inclusion in the seventh edition of *Tabbner's Nursing Care*.

As an Enrolled Nurse you will never stop learning and developing new skills. Even when your formal education is complete I would encourage you to embrace all opportunities to learn, within your scope of practice.

Always remember: evidence-based practice underpins best practice.

**Louise Dearman**
*President*
*National Enrolled Nurse Association (NENA)*

# Publisher's dedication

**Alice Ray Tabbner**
*25 December 1919–13 December 1994*

Ray (as she preferred to be known) Tabbner was born in Birmingham, England. After working in the St John Ambulance in World War II where she said she 'became engrossed in nursing', she completed her training as a nurse in the 1940s. She moved to Australia in 1948 and worked in a number of Sydney hospitals before settling in Melbourne.

Ray established a career in nursing education in 1953 taking on the role of Tutor at the recently established Melbourne School of Nursing. In 1954 she successfully completed her Sister Tutors Diploma through the College of Nursing Australia and remained a Tutor at the school until 1961 when she was awarded the Inaugural Nurse Scholarship in Geriatrics from Mount Royal Hospital. As a consequence of receiving this award, Ray was appointed to the position of Deputy Matron of Geriatric Nursing at Mount Royal. She later established the Nursing Aides course at the Fairfield Hospital in Melbourne under the leadership of Vivian Bulwinkel, and in 1973 was appointed Deputy Director Nursing (Education), one of three executive positions at the Royal Melbourne Hospital.

An innovative educator and mentor, Ray Tabbner was one of the first nurses to call for the establishment of 'Nurse Banks' in Australia to ensure flexibility in the nursing workforce for those nurses wishing to pursue family or other interests while pursuing their chosen profession. She was also a great advocate of ongoing training to ensure nurses could maintain flexibility in their lives and return to nursing with confidence.

In 1975 she was appointed Principal Teacher at the Melbourne Nursing Aides School (later renamed Melbourne School for Enrolled Nurses), a position she occupied until 1978 when she retired to write. Originally titled *The Handbook for Nursing Aides*, this book was later renamed *Nursing Care: Theory & Practice*, and since the publication of the first edition in 1981, it has become known and loved by generations of nursing students as simply *Tabbner's*.

An article published in 1973 in the Melbourne *Sun* described her as being 'as flighty as your average banker. Her dark hair has streaks of steel grey and the creases in her dazzlingly white nurse's uniform would slice bread'. However, students from the 1950s to the 1970s remember her with great fondness and warmth. Ray Tabbner was said to be very approachable and a welcome relief from many 'military style' nurse educators. She taught everything from anatomy and physiology to bandaging and nursing care and made a great impression on her students. As one student from 1955 put it, 'Everything Miss Tabbner said, I learned'.

The Tabbner name has become synonymous with Enrolled Nurse/Registered Nurse Division 2 education not only throughout Australia—the influence of her name extends via this publication to New Zealand, the United Kingdom, the Middle East, Africa and the West Indies.

This seventh edition of *Tabbner's Nursing Care* is dedicated to her memory and her contribution to nurse education.

# Preface

The seventh edition of *Tabbner's Nursing Care* is a significant revision which reflects the scope of practice in contemporary enrolled nursing practice while still retaining the strengths of previous editions that have made it an essential resource for enrolled nursing students and their facilitators.

## The role of the Enrolled Nurse

The Enrolled Nurse is an essential member of the healthcare team, providing person-centred nursing care which includes recognising what is normal and abnormal in assessing, intervening and evaluating individual health and functional status. Enrolled Nurses' responsibilities also include providing support and comfort, assisting with activities of daily living to enable individuals to achieve their optimal level of independence and providing for the emotional needs of people. Where state and territory law and organisational policies allow, Enrolled Nurses may administer prescribed medicines or maintain intravenous fluids, in accordance with their educational preparation.

Enrolled Nurses are required to be information-technology literate, with specific skills in the application of healthcare technology. Enrolled Nurses demonstrate critical- and reflective-thinking skills in contributing to decision making, including reporting changes in health and functional status and individual responses to healthcare interventions. Enrolled Nurses work as part of the healthcare team to advocate for and facilitate the involvement of individuals, their families and significant others in planning and evaluating care and progress towards health outcomes. The role also requires them to act as preceptors for students and other healthcare workers.

Career opportunities for Enrolled Nurses are expanding and include acute care; perioperative, emergency, intensive and coronary care; aged care; rehabilitation; community and mental health nursing; and general practice settings. In addition, Enrolled Nurses work in specialty areas such as nursing education, diabetes education, continence management, dementia management, lactation consultancy, workplace safety and wound care. There are also increasing opportunities for Enrolled Nurses to move into management positions.

## Seventh edition of *Tabbner's Nursing Care*

Holistic, person-centred care is the approach used throughout the textbook, allowing students to appreciate the skill and scope required to be a safe and competent Enrolled Nurse. All chapters have been completely revised with a focus on critical thinking and problem solving, quality and safety and evidence-based practice, with national registration requirements addressed where appropriate.

Two new chapters have been included to highlight contemporary nursing issues:

- Nursing informatics and technology in healthcare
- Quality and safety in healthcare

The full-colour internal design enhances photos and illustrations to provide clear and meaningful visual aids to learning.

The seventh edition has been carefully developed to align with the Diploma of Nursing in the HLT Health Training Package for the enrolled nursing student. It provides a contemporary approach to nursing practice and is an invaluable teaching resource. The text provides the theoretical knowledge on the care that individuals may require in a range of healthcare settings and offers special features to enhance student learning of the material.

This edition is a culmination of the efforts of many nursing academics and professionals who are passionate about the education of Enrolled Nurses and the important role they play in healthcare settings. We are grateful for their enthusiasm and support throughout the writing process. In addition, we would like to thank the team at Elsevier for their hard work and perseverance in ensuring the publication of this edition.

**Gabby Koutoukidis**
**Kate Stainton**
**Jodie Hughson**

# Acknowledgments

I was delighted to be invited as an editor again for *Tabbner's 7E* and to have the opportunity to do this alongside two very good friends of mine—Kate and Jodie. This seventh edition is the culmination of work by many writers and nursing educators and I would like to thank all contributors for their enthusiasm and support for Enrolled Nurse education.

I would also like to acknowledge all the nursing students and teams I have worked with over the years who have inspired in me a passion for teaching and ensuring best nursing practice.

**Gabby Koutoukidis**

To my husband, Anthony, and children Ben, Alex and Maddy, thank you so much for your understanding and support throughout the work on this edition of *Tabbner's*.

As both a nurse educator and nurse myself, I realise the importance of a textbook that prepares students for the contemporary healthcare environment.

To my co-editors, the contributors, the reviewers and the team at Elsevier thank you for all your knowledge and hard work.

**Kate Stainton**

Once again my experience as an editor for the seventh edition of *Tabbner's Nursing Care* has been exciting and challenging. When a project like this is embarked upon it is not only oneself that makes sacrifices but all those around us, family and friends, and I appreciate the understanding my husband Stuart and the rest of our family have given to me throughout the last 2 years. This last year for me personally was a year of reflection and soul searching but it has strengthened my passion and commitment to my lifelong profession of nursing.

I also thank the Elsevier team for all the hard work in getting this edition to publication. I feel privileged to be working alongside my co-editors Gabby and Kate who are truly dedicated and inspirational women.

And for all the students reading this as they embark on the journey to becoming a nurse I would like you to reflect on these simple but moving words from a patient, given to nursing staff at a facility last year:

'Thank you. You saved my life.'

**Jodie Hughson**

The Editors and Publisher would like to specifically acknowledge the work of Dr Lesley Seaton, who co-authored Chapter 10, Cultural competence and safety, and pay tribute to her dedication, passion and invaluable contribution to nurse education in Australia and New Zealand.

# Standard steps for all clinical skills/interventions

These are the essential steps that must be done consistently with each individual contact in order to deliver responsible and safe nursing care.

| Before the procedure | |
|---|---|
| **Step 1** | • Mentally review the steps of the procedure beforehand<br>• Discuss the procedure with your instructor/supervisor/team leader, if required<br>• Confirm correct facility/organisation policy/safe operating procedures |
| **Step 2** | • Check the order in the chart, individual's healthcare record<br>• Review handover report to assess specific instruction or need of person (allergies)<br>• Gather equipment/supplies. If using a procedure trolley, ensure it is cleaned and place all equipment to be used on the bottom shelf<br>• Perform hand hygiene |
| **Step 3** | • Introduce yourself, explain and communicate the activity clearly to the individual and/or family.<br>• Identify the individual as per facility/organisational policy using three individual identifiers<br>• This may include but is not limited to identifying the individual's<br>> identification allocated healthcare number on hospital bracelet/band<br>> seeking verbal confirmation from the individual of given and family name<br>> date of birth<br>> gender<br>> address<br>> Medical record number<br>• Ensure therapeutic interaction. This may include but is not limited to:<br>> Introducing oneself<br>> Ensuring privacy before undertaking the procedure<br>> Why the procedure has been ordered<br>> Why the procedure will be undertaken and frequency<br>> What is involved in undertaking the procedure<br>> Listen to the individual's concerns or questions about the procedure before it is undertaken<br>> Ensure the individual is aware of their responsibilities required of them before undertaking the procedure<br>> Maintain professional boundaries<br>• Gain consent to perform the procedure<br>• Identify teaching needed<br>• Assess for pain relief as applicable to clinical skill/intervention |
| **Step 4** | • Assist the individual to assume an appropriate position of comfort<br>• Keep yourself safe e.g. raise the bed to appropriate working height<br>• Provide adequate lighting for the procedure<br>• Arrange supplies and equipment |

| | |
|---|---|
| **During the procedure** | |
| **Step 5** | • Perform hand hygiene<br>• Put on gloves following standard precautions as appropriate<br>• Place on eyewear, mask and gown as appropriate<br>• Ensure the individual's safety and comfort throughout procedure |
| **Step 6** | • Promote independence and involvement if possible<br>• Assess the individual's tolerance to the procedure |
| **After the procedure** | |
| **Step 7** | • Dispose of used supplies and sharps appropriately<br>• Remove eyewear and other protective equipment and discard or store appropriately<br>• Remove gloves (if worn) and perform hand hygiene. Remove eyewear and other protective equipment and discard or store appropriately<br>• Clean used equipment and store appropriately |
| **Step 8** | • Make the individual comfortable and inform them of how the procedure went, or of any results/values<br>• Restore the bed height, tidy the bed and surrounding area. Place call bell and personal items within reach<br>• Perform hand hygiene |
| **Step 9** | • Record and document assessment findings, details of the procedure performed and the individual's response<br>• Report abnormalities as required<br>• Reassess the individual to ensure there are no adverse effects/events from the procedure |

# Text features

Learning Outcomes assist students to focus on key information in each chapter

Key Terms are listed at the beginning of each chapter and defined within the text

Chapter Focus introduces the key concepts in each chapter

Lived Experiences are taken from actual clinical situations to help students understand a particular health experience from the point of view of individuals, their families or nurses and other health professionals

Nursing Care Plans provide comprehensive examples of an individual's care within a specific scenario

Case Studies provide context for practice and include questions for student reflection

Clinical Interest Boxes offer information on developmental considerations, cultural aspects of care, current research and teaching individuals

## Understanding and promoting health

*Glenda Verrinder and Lyn Talbot*

CHAPTER 6

### LEARNING OUTCOMES

At the completion of this chapter and with further reading, students should be able to:

- Discuss the difference between concepts of health, wellbeing, illness and disease
- Identify and discuss determinants of health
- Compare and contrast medical, behavioural and socioenvironmental models of health promotion
- Describe the principles underpinning health promotion practice
- Outline the action areas of the Ottawa Charter for Health Promotion
- Outline the major strategies within the Continuum of Health Promotion Practice
- Identify and source the literature on health promotion programs in Australia as it relates to nursing
- Discuss the role of the nurse in health promotion
- Facilitate person-centred education
- Utilise the nursing process in health promotion

### KEY TERMS

Australian Institute of Health and Welfare (AIHW)
Continuum of Health Promotion Practice
Declaration of Alma-Ata
determinants of health and illness
health inequalities
health inequities
health literacy
health promotion
homeostasis
illness
nursing process
Ottawa Charter for Health Promotion

### CHAPTER FOCUS

This chapter provides a focus for nurses from which to recognise the interrelationship of factors that determine health, wellbeing and illness. This perspective enables nurses to effectively facilitate health promotion with individuals and families and within the wider community. The chapter is presented in three parts. First, we discuss concepts of health, wellbeing and illness and what determines health. Second, we outline the emergence of health promotion, discuss what health promotion is and provide guidance for practice. Finally, we discuss the role of nurses in promoting health.

Overall the world's population is generally living longer and experiencing healthier lives. However, major disparities in health exist within and between countries. International leadership in reducing health inequalities comes from the World Health Organization (WHO) who defined health as 'a state of complete physical, mental and social well-being, and not merely the absence of disease or infirmity' (WHO 1946). This perspective of health and wellbeing leads us to health promotion practice where we employ medical, behavioural and socioenvironmental approaches depending on key priorities identified by evidence.

The role of the nurse in promoting health can be multilayered. Essentially, though, it is to gather evidence and work in collaboration with others to enable individuals, families and communities to reach their full health potential. In this chapter we introduce you to health promotion theories to guide practice; principally, the Ottawa Charter for Health Promotion (WHO 1986) and the **Continuum of Health Promotion Practice** (Talbot & Verrinder 2014), which highlight the collective role of health and other sectors, organisations and communities in achieving optimal health and wellbeing. Understanding theories that underpin health promotion practice is a key strategy for nurses in contributing to the enter- promoting health and reducing inequalities to improve health outcomes.

### LIVED EXPERIENCE

The refugee health program at the community health centre in which I work provides a range of services to facilitate settlement in Australia. On arrival to Australia, the lifestyle of refugees changes dramatically, including changes to diet and exercise; there is an increase in energy-dense diet and people become sedentary which increases the risk of chronic disease. In refugee camps the food is rationed and people are often hungry and high levels of incidental exercise are required to survive.

As the refugee nurse, I worked with Karen the community health nurse to develop a healthy lifestyle program. We found that the refugees in this community were not familiar with the notion of preventative healthcare. Furthermore, most health literature is in English and based on Western lifestyle. As part of the program we screened 30/32 refugees using the diabetes.

### NURSING CARE PLAN 8.1

Mary was not able to explain to me the medical procedure she was having today. She told me she was very frightened and thought she might die. I explained the procedure to her again and answered her questions. She was able to explain it back to me and told me that she doesn't feel as anxious any more. She stated that she will go ahead with the procedure. She informed me that she suffers from anxiety and is very worried about how she will cope when she is discharged.

**Assessment:** Anxiety due to concerns about ability to cope upon discharge
**Issue/s to be addressed:** Medication review—at present not on anti-anxiolytics or anti-depressants
**Goal/s:** Mary verbalises reduced level of anxiety and is able to state processes which are in place to improve her ability to cope when discharged

| Care/Actions | Rationale |
|---|---|
| 1. Spend time with Mary encouraging her to discuss her worries and concerns | If interest and concern are demonstrated Mary will be more likely to talk about her worries. Verbalising concerns |
| 2. Explain t that they | |
| 3. Provide relations | |
| 4. Collabor | |
| 5. Provide effects if commen | |
| 6. Monitor antidepr | |
| Evaluation | |
| Mary reporte Mary was ab | |

### CASE STUDY 41.1

Grace is 42 years old. She was born with a brain injury as a result of birth trauma. Her parents have been her primary carers since birth. Grace requires a high level of physical assistance. For example, every day of her life her father has lifted her from her bed in the morning and carried her to a recliner chair in the lounge and later returned her to bed the same way. Each day her mother has prepared the food and assisted Grace with her meals. Because of the difficulties Grace has with chewing and swallowing her food, mealtimes have always been a lengthy process. Personal care routines such as showering and dressing are provided by her parents. Sometimes Grace resists and yells out. Grace is incontinent of urine and her parents fit her with disposable pads every morning and change them frequently during the day. They take care of the pressure areas that sometimes develop.

After leaving her special developmental school at 17 years Grace began attending a day centre 3 days each week. She was taken there in a community bus specially designed to accommodate her wheelchair. Activity at the centre revolved mostly around the staff meeting the hygiene, toileting, medication, mobility and nutritional needs of the two dozen or more people with severe or profound disabilities who also attended. The staff reported that Grace spent a lot of her time there simply dozing.

On the days she is at home Grace has many things surrounding her that give her pleasure. She has a box containing many different pieces of material. She enjoys the feel of the different textures, especially the velvet and silk. Other times she holds on to colourful toys and, although she has a profoundly limited vocabulary, she is able to express her pleasure in her favourite television programs and music. Grace also enjoys being with her mother in the kitchen and sitting on the outside veranda watching people walk past the house. Many of the neighbours greet her cheerfully.

Grace's parents have been anxious for some time about their future ability to care for her, but now Grace's mother has fallen a admitted t available a

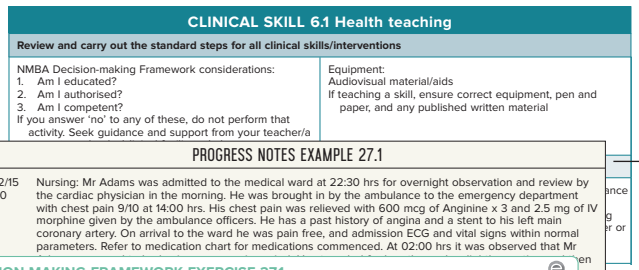
### CLINICAL INTEREST BOX 30.4 Refeeding syndrome

First discussed in prisoners of war post WWII, refeeding syndrome is the derangement of serum electrolytes, vitamins and fluid resulting from over-aggressive treatment of malnourished individuals. In response to carbohydrate load, insulin is released, leading to increased glycogen, fat and protein synthesis. This triggers sudden uptake of potassium, phosphate and magnesium. This intracellular movement results in hypokalaemia, hypophosphataemia and hypomagnesaemia (Khan et al 2011). Symptoms of lethargy, shortness of breath, muscle weakness, GI upset, ataxia and delirium are indicative of these electrolyte disturbances. Individuals at an increased risk of developing Refeeding syndrome are children, individuals with greater than 10% weight loss in 4 weeks, anorexia for more than 7 days and chronic alcoholism. It is recommended electrolyte abnormalities are corrected prior to commencement of refeeding at a rate of 10–20 kCal/kg/day before gradually increasing over week.

*(Sydney Children's Hospital 2013; Khan et al 2011)*

**Clinical Skills** are in a referenced, step-by-step format emphasising the nursing process and include rationales for each step



**CLINICAL SKILL 6.1 Health teaching**

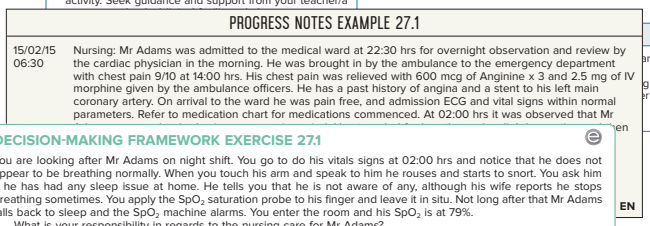
**Review and carry out the standard steps for all clinical skills/interventions**

NMBA Decision-making Framework considerations:
1. Am I educated?
2. Am I authorised?
3. Am I competent?

If you answer 'no' to any of these, do not perform that activity. Seek guidance and support from your teacher/a

Equipment:
Audiovisual material/aids
If teaching a skill, ensure correct equipment, pen and paper, and any published written material

**Progress Note Examples** show how a student might document care of an individual while on placement



**PROGRESS NOTES EXAMPLE 27.1**

15/02/15 06:30 Nursing: Mr Adams was admitted to the medical ward at 22:30 hrs for overnight observation and review by the cardiac physician in the morning. He was brought in by the ambulance to the emergency department with chest pain 9/10 at 14:00 hrs. His chest pain was relieved with 600 mcg of Anginine x 3 and 2.5 mg of IV morphine given by the ambulance officers. He has a past history of angina and a stent to his left main coronary artery. On arrival to the ward he was pain free, and admission ECG and vital signs within normal parameters. Refer to medication chart for medications commenced. At 02:00 hrs it was observed that Mr

**Decision-making Framework Exercises** are specific to the chapter content and the EN scope of practice

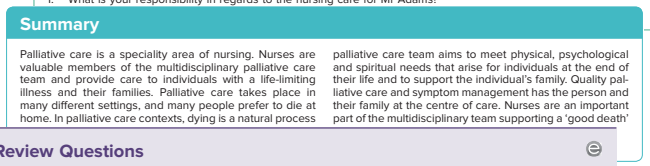
**DECISION-MAKING FRAMEWORK EXERCISE 27.1**

You are looking after Mr Adams on night shift. You go to do his vitals signs at 02:00 hrs and notice that he does not appear to be breathing normally. When you touch his arm and speak to him he rouses and starts to snort. You ask him if he has had any sleep issue at home. He tells you that he is not aware of any, although his wife reports he stops breathing sometimes. You apply the $SpO_2$ saturation probe to his finger and leave it in situ. Not long after that Mr Adams falls back to sleep and the $SpO_2$ machine alarms. You enter the room and his $SpO_2$ is at 79%.

1. What is your responsibility in regards to the nursing care for Mr Adams?

EN

**Summary** highlights the key points in the chapter content

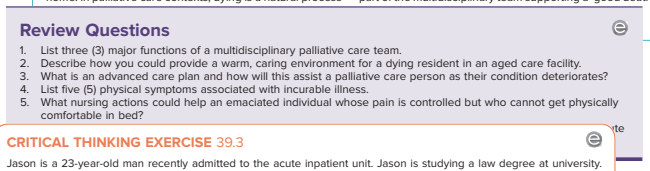


**Summary**

Palliative care is a speciality area of nursing. Nurses are valuable members of the multidisciplinary palliative care team and provide care to individuals with a life-limiting illness and their families. Palliative care takes place in many different settings, and many people prefer to die at home. In palliative care contexts, dying is a natural process

palliative care team aims to meet physical, psychological and spiritual needs that arise for individuals at the end of their life and to support the individual's family. Quality palliative care and symptom management has the person and their family at the centre of care. Nurses are an important part of the multidisciplinary team supporting a 'good death'

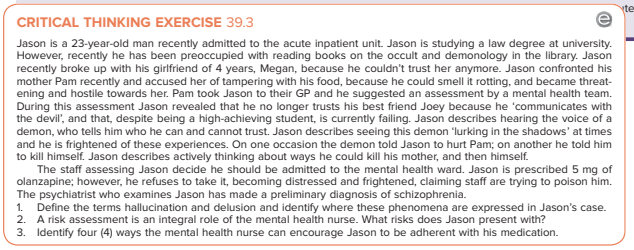
**Review Questions** assist students with comprehension and review of the chapter content



**Review Questions**

1. List three (3) major functions of a multidisciplinary palliative care team.
2. Describe how you could provide a warm, caring environment for a dying resident in an aged care facility.
3. What is an advanced care plan and how will this assist a palliative care person as their condition deteriorates?
4. List five (5) physical symptoms associated with incurable illness.
5. What nursing actions could help an emaciated individual whose pain is controlled but who cannot get physically comfortable in bed?

**Critical Thinking Exercises** stimulate the student to think critically and problem solve



**CRITICAL THINKING EXERCISE 39.3**

Jason is a 23-year-old man recently admitted to the acute inpatient unit. Jason is studying a law degree at university. However, recently he has been preoccupied with reading books on the occult and demonology in the library. Jason recently broke up with his girlfriend of 4 years, Megan, because he couldn't trust her anymore. Jason confronted his mother Pam recently and accused her of tampering with his food, because he could smell it rotting, and became threatening and hostile towards her. Pam took Jason to their GP and he suggested an assessment by a mental health team. During this assessment Jason revealed that he no longer trusts his best friend Joey because he 'communicates with the devil', and that, despite being a high-achieving student, is currently failing. Jason describes hearing the voice of a demon, who tells him who he can and cannot trust. Jason describes seeing this demon 'lurking in the shadows' at times and he is frightened of these experiences. On one occasion the demon told Jason to hurt Pam; on another he told him to kill himself. Jason describes actively thinking about ways he could kill his mother, and then himself.

The staff assessing Jason decide he should be admitted to the mental health ward. Jason is prescribed 5 mg of olanzapine; however, he refuses to take it, becoming distressed and frightened, claiming staff are trying to poison him. The psychiatrist who examines Jason has made a preliminary diagnosis of schizophrenia.

1. Define the terms hallucination and delusion and identify where these phenomena are expressed in Jason's case.
2. A risk assessment is an integral role of the mental health nurse. What risks does Jason present with?
3. Identify four (4) ways the mental health nurse can encourage Jason to be adherent with his medication.

Nursing: the evolution of a profession

CHAPTER 2
Professional nursing practice: legal and ethical frameworks

CHAPTER 3
Nursing research and evidence-based practice

CHAPTER 1

# Nursing: the evolution of a profession

*Katie Frankiewicz*

## KEY TERMS

Australian Commission on Safety and Quality in Health Care (ACSQHC)
Australian Health Practitioner Regulation Agency (AHPRA)
Australian Nursing and Midwifery Accreditation Council (ANMAC)
Australian Nursing and Midwifery Federation (ANMF)
Enrolled Nurse (EN)
International Council of Nurses (ICN)
National Safety and Quality in Health Service (NSQHS) standards
Nursing and Midwifery Board of Australia (NMBA)
Registered Nurse (RN)
Royal College of Nursing Australia (RCNA)
Standards for Practice
unregulated healthcare workers

## LEARNING OUTCOMES

At the completion of this chapter and with further reading, students should be able to:

- Define the key terms
- Discuss the historical development of nursing
- Define nursing theory
- Explain the purpose of nursing models
- Explain the differences in the educational preparation of Registered Nurses (RNs) and Enrolled Nurses (ENs)
- Discuss scope of practice
- List the five characteristics of a profession and discuss how nursing demonstrates these characteristics
- Discuss the reasons nursing is in a constant state of change
- List at least one nursing theory and discuss its impact on nursing today
- Discuss current influences on nursing

## CHAPTER FOCUS

To understand contemporary issues in nursing the student nurse needs to understand how nursing has evolved in Australia. This chapter includes a discussion of the history of nursing, factors influencing nursing practice, scope of practice and the role of the nurse in contemporary healthcare and professional nursing organisations. This chapter will help the student understand and appreciate the influences of the past, present and future on modern nursing. A study of nursing theory can help the student develop an understanding of the purpose of nursing practice. This chapter introduces the student to a variety of nursing theories that inform nursing practice.

## LIVED EXPERIENCE

I was 17 when I started training to be a nurse. I grew up on a farm in regional Victoria, and had to move to Melbourne and live in the nurses' quarters. I was so excited, but missed home terribly. Living in meant that you became close with your colleagues, and we all became family in a way. It was so hard in the early days, being the new nurse on the ward. I was so disoriented and didn't know what to do or where anything was. We all worked so hard, and the expectations were high. You did split shifts, night duty, whatever was asked of you, and you did it without complaining. I still remember the first time I was called 'Sister'. It made it all worthwhile.

**Ollie, Retired Nurse**

## WHAT IS NURSING?

Nursing is a profession with a specialised body of knowledge that draws from the social, the behavioural and the physical sciences. Nursing is a unique profession because it addresses responses of individuals and families to health promotion, health maintenance and health problems. Nursing is seen as being important both for the provision of safe, quality care and for the humane, compassionate treatment of the individual (Scott et al 2014). There are many philosophies and definitions of nursing. Over 100 years ago Florence Nightingale defined nursing as 'the act of utilising the environment of the patient to assist him in his recovery' (Nightingale 1969 (1860)). Nightingale considered a clean, well-ventilated and quiet environment essential for recovery. Often considered the first nurse theorist, Nightingale raised the status of nursing through education. Nurses were no longer untrained housekeepers but people educated in the care of the sick (Berman et al 2015).

Virginia Henderson was one of the first modern nurses to define nursing. The definition she posed in 1966 was adopted by the **International Council of Nurses (ICN)** in 1973 and still holds wide appeal in the nursing profession. Henderson defined nursing as:

*assisting the individual, sick or well, in the performance of those activities contributing to health, its recovery, promoting quality of life or to a peaceful death that the client would perform unaided if he or she had the necessary strength, will or knowledge.*

**(Henderson, in Crisp et al 2013)**

In 2014 the ICN reviewed the definition of nursing:

*Nursing encompasses autonomous and collaborative care of individuals of all ages, families, groups and communities, sick or well, and in all settings. Nursing includes the promotion of health, prevention of illness, and the care of the ill, disabled and dying people. Advocacy, promotion of a safe environment, research, participation in shaping health policy and in patient and health systems management, and education are also key nursing roles.*

**(ICN 2014)**

Nursing also helps individuals carry out prescribed therapy, to be independent of assistance and function to maximum potential as soon as possible (Crisp et al 2013).

There are themes that are common to the many definitions of nursing (Berman et al 2015):

- Nursing is caring
- Nursing is an art
- Nursing is a science
- Nursing is individual centred
- Nursing is holistic
- Nursing is adaptive
- Nursing is concerned with health promotion, health maintenance and health restoration
- Nursing is a helping profession.

In nursing, a combination of technical skill, clinical experience and theoretical knowledge is required. Historically there has been a tendency for nursing education to focus on the mastery of nursing skills. However, nursing practice is far more complex than technical skills alone. Nursing expertise is required for interpreting clinical situations and for complex decision making and case management. It is the basis for the advancement of nursing practice and the development of nursing science (Institute of Medicine 2011). When providing nursing care, the nurse makes clinical judgments about the care needed for individuals based on fact, experience and standards of care. Knowledge, expertise and lifelong learning are gained through the continual process of critical thinking (Crisp et al 2013).

## Patients, consumers or clients? What's in a name?

The nomenclature for persons receiving healthcare has changed in line with cultural changes in nursing and healthcare. Where the person was once referred to as the patient, they have also been referred to as the client or the consumer (Daly et al 2014). So why the change in terminology and what do these words mean? The word 'patient' originates from a Latin word meaning 'to suffer' or 'suffering' (Oxford Dictionaries 2015). In times past the term 'patient' was used for those who were waiting for or undergoing medical treatment and care in a hospital. Usually, people became patients when they sought assistance because of illness or for surgery. This term was understood to have implied connotations about the medical model of health: some believed that the term 'patient' implied passive acceptance of the decisions and care of health professionals (Berman et al 2015; McLaughlin 2009). Other terms are now frequently used by health professionals in place of 'patient'. Nurses and others are now increasingly using the term 'clients', 'consumers', 'customers' or 'service users' (McLaughlin 2009).

Many of the alternative terms proposed to replace the word 'patient' can also be found wanting (McLaughlin 2009). For example, a 'consumer' is defined as an individual, a group of people or a community that uses a service or commodity. Individuals who use healthcare products or services are consumers of healthcare. This implies the 'consumer' is a purposeful seeker of healthcare who expects to get what they came seeking. This has not previously been the case in most instances in healthcare, where the provider is more accountable to the manager and key performance indicators than to the needs and wants of the consumer (McLaughlin 2009). Today the National Safety and Quality Health Service (NSQHS) Standards focus on the importance of engaging consumers in partnership and using consumer experiences and expertise to drive the delivery of safe and high-quality healthcare (ACSQHC 2012; ACSQHC 2015). A 'customer' signifies that health is a commodity in which the customer possesses an understanding of their health needs and the services available equal to that of the health professional. It is well known in healthcare that a knowledge imbalance exists between 'consumer' and service provider.

A 'client' is a person who engages the advice or services of another who is qualified to provide this service. The health status of a client is the responsibility of the individual in collaboration with health professionals (Berman et al 2015).

None of these terms is without fault at defining those who seek healthcare, and all are used interchangeably in healthcare settings. The roles and relationships between those seeking and providing care have changed dramatically. Health literacy is considered to be vital to ensure partnerships between individuals and healthcare providers. These partnerships only work if everyone can give, receive, interpret and act on health and healthcare information (ACSQHC 2012; ACSQHC 2015).

Despite the connotations associated with the word 'patient' the **Australian Commission on Safety and Quality in Health Care (ACSQHC)** (2012; 2015) and the Australian Nursing and Midwifery Federation (ANMF) (2010) continue to embrace the term 'patient-centred care'. The National Safety and Quality Health Service Standards intend to 'create a health service that is responsive to patient, carer and consumer inputs and needs' (2012). The ICN (2012) tells us that 'the nurse's primary professional responsibility is to people requiring nursing care' and that nurses ensure that individuals receive accurate information to consent to care and treatment. The 2016 *Enrolled Nurse Standards for Practice* (NMBA) also refer to individuals/group throughout. As it is the person or individual who seeks healthcare this is the preferred nomenclature throughout this book with the exception of Chapter 7 where the term 'patient' is used and Chapter 39 where the term 'consumer' is used.

## Historical perspectives

### A brief history of nursing

Nursing is a profession steeped in tradition and history and historical accounts of nursing reflect the dynamic and evolving nature of the profession. The word 'nurse' is derived from a Latin word meaning to nourish or cherish and, as birth, illness, injury and death are common to all human beings, there has always been a need for someone to take on the task of caring for others. In earlier times, and still today in some cultures, superstition and witchcraft surround illness and form the basis of the treatment of illness. For some cultures it was, and still is, believed that sickness was a punishment for wrongdoing and that the signs of illness were evidence of the presence of evil spirits. Treatment was prescribed by witch doctors and priests and, although much of it was barbaric and caused more suffering than the illness, many old herbal remedies are still used in a modified form today. Until well into the eighteenth century those who suffered a mental illness were considered to be possessed by the devil and were treated with extreme cruelty.

Some of the earliest organised nursing was performed by men who staffed the hospitals founded by military religious orders during the crusades; for example, the Knights of St John of Jerusalem, the Teutonic Knights and the Knights of St Lazarus. During the twelfth and thirteenth centuries several secular orders were active in caring for the sick, whose members included men and women (Burchill 1993). Some of the orders were the Ursulines, the Poor Clares, the Beguines and the Benedictines. Also at this time a religious order called the Augustinian Sisters of the Hôtel Dieu was founded in Paris; this is the world's oldest order of nuns devoted purely to nursing.

During the sixteenth century, Henry VIII of England ordered the dissolution of the English monasteries and the confiscation of their property and enormous wealth. This meant that large numbers of sick and destitute people previously cared for by the religious orders were left to die. Workhouses were built to house the poor, many of whom were

sick. These people lived in appalling conditions and were required to work in return for the accommodation provided. Finally, conditions in the city of London became so dreadful that, after many petitions from the people of London, Henry VIII was forced to allow hospitals such as St Bartholomew's, St Thomas's and St Mary's to be re-founded, and others to be established. The hospitals were insufficiently staffed by untrained workers, many of whom were of very poor character. Patients were housed in dreary, grossly overcrowded wards (Russell 1990).

The period from the beginning of the eighteenth century to the middle of the nineteenth century has been termed the 'Dark Ages' of nursing, during which the care of the sick and the status of the nurse reached the lowest level imaginable. The squalid conditions in hospitals and the undesirable character of those attending the sick were publicised by people such as the prison reformers John Howard and Elizabeth Fry, and the writer Charles Dickens, who in *Martin Chuzzlewit* created the unsavoury characters Sairy Gamp and Betsy Prig to typify the nurses of the time—criminals and women of low moral standards who were uneducated and who themselves lived and worked in appalling conditions (Burchill 1993).

In 1836, with the help of his wife, a Lutheran clergyman named Theodor Fliedner established an institution called Kaiserwerth, situated near Dusseldorf in Germany. There they trained carefully selected women as deaconesses, and Kaiserwerth became famous for the high standard of training and the quality of care given to the sick. It became a centre of nurse training and received many trainees from overseas countries, some of whom set up similar institutions in their own countries (Burchill 1993).

Modern nursing has evolved as a result of the influence that Kaiserwerth had on people like Elizabeth Fry, who founded the Protestant Sisters of Charity in an attempt to ensure that the sick were cared for by women of good reputation, such as Agnes Jones. Jones revolutionised conditions in the workhouses and established a school of nursing to train nurses in the care of sick people in the workhouses, and Florence Nightingale, the founder of modern nursing, was inspired by Elizabeth Fry's training program (Burchill 1993).

Florence Nightingale was born in 1820 during a trip made by her English parents to the Italian city of Florence, after which she was named. Her parents were wealthy and cultured and Florence received an extensive education far beyond the standard usually received by the young women of her time. She travelled widely and led the full social life common to one in her place in society but, despite this, felt unhappy and dissatisfied. She was interested in nursing but this met with strong opposition from her family and it was not until she was over 30 years of age that she was able to realise her ambition. In 1850 she spent two weeks at Kaiserwerth and visited again in 1851, after which she was appointed Superintendent of the 'Establishment for Gentlewomen during Illness' in 1853 in London (MacDonnell 1970).

Florence Nightingale first achieved fame when, in 1854 during the Crimean War, she was asked to take a party of 38 nurses to Scutari in the Crimea. On arrival the nurses met with fierce opposition from the medical officers, who would not allow them to care for the sick and injured soldiers. Nightingale devoted her energies to improving the filthy conditions by introducing the principles of personal and communal hygiene, obtaining medical supplies, organising a good food supply and generally establishing sanitary conditions, such as handwashing, and the importance of fresh air. Within 2 or 3 weeks opposition had been overcome and the nurses were invited to take over the care of the sick. To the soldiers, Nightingale became an idol and, as she brought ease and comfort to the very sick by the light of the lamp she carried at night, she became known as the 'Lady of the Lamp' (Russell 1990).

After the Crimean War the English public raised £44 000 as a mark of appreciation of Nightingale's work. She used the money to establish a School of Nursing at St Thomas's Hospital in London. The first probationer nurses were admitted to the Nightingale School in June 1860 and given one year of training followed by two years of experience in the hospital. Many of these nurses became matrons of the large hospitals in London and elsewhere. By the time Florence Nightingale died in 1910 at the age of 90, not only had she facilitated remarkable progress in nursing services and education of nurses, she had made many significant achievements in public health matters of the time (MacDonnell 1970).

## Nursing in Australia—the beginning

The first people arrived in Australia from South-east Asia over 40 000 years before Europeans first landed in the seventeenth century. These were the first nations of Aboriginal people and they are acknowledged as the traditional caretakers of the land.

Australia's white colonisation began as a penal colony, which is where the beginnings of modern nursing in Australia commenced. The first hospital in Australia, Sydney Hospital, was opened in 1811. Most nurses were convict women, with some convict men also performing nursing duties. They were provided with their keep but no wages in exchange for their labour. The nurses were frequently described as being of poor character, with drunkenness while on duty common (Burchill 1993).

The first trained nurses, five Irish Sisters of Charity, arrived in Sydney in 1838 to provide care to the sick and infirm who, up to this stage, had been housed in squalid buildings and cared for by untrained staff (Schultz 1991).

In the 1840s the transportation of convicts to Australia ceased and the country was opened to free settlers. Gold was discovered in 1851 and once people in other countries heard about the gold mining boom many people rushed to Australia to make their fortune. However, the country lacked even the most basic infrastructure (fresh water supply, sewerage systems, healthcare) so these services had to be very rapidly developed as the country was colonised.

Prior to 1868 the state of nursing was, to say the least, substandard. Unskilled persons were often promoted to nursing roles despite no education or training—some could

not even read or write. Stories abound of 'nurses' attending patients in hospitals dishevelled and intoxicated, and leaving patients unattended most of the time. Conditions were so bad patients who went to hospital once vowed never to return (MacDonnell 1970).

### The Florence Nightingale nurses

The state of healthcare in Australia in the mid-nineteenth century had become so deplorable that a group of doctors sent a letter to Henry Parkes, then Colonial Secretary of New South Wales, urging him to do something. Henry Parkes responded by writing a letter to Florence Nightingale requesting her to provide a contingent of nurses to Australia to clean up the hospitals. A similar action was undertaken by leaders of the time in New Zealand. Florence Nightingale sent six of her best trainees to Australia to set up a training school. These six nurses were Lucy Osburn, Mary Barker, Bessie Chant, Eliza Blundell, Annie Millar and Haldon Turriff (MacDonnell 1970). (See Clinical Interest Box 1.1.)

Over time the Nightingale principles for the care of the ill were adopted. Nurses were trained in practical skills such as the application of dressings, leeching and administering enemas. Of equal importance were the character traits of punctuality, cleanliness, sexual purity and, above all, obedience. (See Clinical Interest Box 1.2.) A large proportion of nursing work was housekeeping, mostly domestic tasks. However, personal traits such as diligence and compassion were desirable characteristics in those who cared for the sick and were looked upon favourably (MacDonnell 1970).

## Australian nurses in wartime

Australian nurses have redeemed themselves and the reputation of nursing in the years since Australia's beginnings with their efforts and achievements. There are many amazing stories of nurses throughout Australia's history and nurses are particularly well represented in the heroic and inspiring stories from wartime (Australian War Memorial 2011).

### CLINICAL INTEREST BOX 1.1
### The Nightingale Pledge

I solemnly pledge myself before God and this assembly to pass my life to purity and in the practice of my profession faithfully.

I will abstain from what is deleterious and mischievous and will not take or knowingly administer any harmful drug.

I will do all in my power to elevate the standards of my profession

And will hold in confidence all private matters that come to my knowledge in the practice of my calling

With loyalty I will endeavour to aid the physician in his work

And devote myself to those committed to my care.

### Boer War

More than 60 Australian nurses went to the Boer War. Some were funded by governments or by privately raised funds, while others went at their own expense. The nurses served the sick and wounded under very harsh conditions. Three were awarded Royal Red Cross medals. The Boer War marked the death of nurse Frances Hines—the first Australian woman to die in a declared war (Australian War Memorial 2011).

### World War I

Prior to Australia's Federation in 1901, each colony controlled its own defence force, of which the nursing services formed a part. In July 1903 the nursing services of each colony combined to form the Australian Army Nursing Service. The

### CLINICAL INTEREST BOX 1.2
### Job description of a floor nurse (1887)

(Developed in 1887 and published in a magazine of Cleveland Lutheran Hospital)

In addition to caring for your 50 patients, each nurse will follow these regulations:

1. Daily sweep and mop the floors of your ward, dust the patients' furniture and window sills.
2. Maintain an even temperature in your ward by bringing in a scuttle of coal for the day's business.
3. Light is important to observe the patient's condition. Therefore, each day fill kerosene lamps, clean chimneys, and trim wicks. Wash windows once a week.
4. The nurse's notes are important to aiding the physician's work. Make your pens carefully. You may whittle nibs to your individual taste.
5. Each nurse on day duty will report every day at 7 A.M. and leave at 8 P.M., except on the Sabbath, on which you will be off from 12 noon to 2 P.M.
6. Graduate nurses in good standing with the Director of Nurses will be given an evening off each week for courting purposes, or two evenings a week if you go regularly to church.
7. Each nurse should lay aside from each pay a goodly sum of her earnings for her benefits during her declining years, so that she will not become a burden. For example, if you earn $30 a month you should set aside $15.
8. Any nurse who smokes, uses liquor in any form, gets her hair done at a beauty shop, or frequents dance halls will give the Director of Nurses good reason to suspect her worth, intentions, and integrity.
9. The nurse who performs her labour, serves her patients and doctors faithfully and without fault for a period of five years will be given an increase by the hospital administration of five cents a day providing there are no hospital debts that are outstanding.

*(Scrubs nd) (http://scrubsmag.com/a-list-of-rules-for-nurses-from-1887/)*

Service, which was part of the Australian Army Medical Corps, was made up of volunteer trained nurses who were willing to serve in times of a national emergency (see Figure 1.1).

At the outbreak of World War I staff were recruited from both the nursing service and the civilian workforce. They served at field and base hospitals in Australia as well as in Egypt, England, France, Belgium, Greece, Salonika, Palestine, Mesopotamia and India. (See Clinical Interest Box 1.3.) Two thousand one hundred and thirty-nine Australian nurses served in World War I (Australian War Memorial 2011).

### World War II

The Australian Army Nursing Service was one of only two women's services (the other being Voluntary Aid Detachments) that were active at the outbreak of war in 1939. Initially the enlisted nurses were the only females to serve outside Australia. Members served in England, Egypt, Palestine, Libya, Greece, Syria, Ceylon, Malaya, Singapore, Papua New Guinea and the Solomon Islands as well as throughout Australia. They served on hospital ships, troop transports, base and camp hospitals and some spent time in prisoner of war camps (Australian War Memorial 2011).

The first six Australian nurses were captured at Rabaul in January 1942. Shortly before Singapore fell, 65 nurses were evacuated on the *Vyner Brooke*. Twelve died when the ship was sunk off Sumatra and 21 in the Banka Island massacre on 16 February 1942. Thirty-two of these nurses became prisoners of war, held with civilian internees in camps on and around Palembang, in Sumatra. Conditions were horrendous and over three and a half years of captivity the nurses suffered with tropical disease and the effects of malnutrition. Eight of these nurses died in captivity (Australian War Memorial 2011).

**Figure 1.1** Portrait of Number 11 Australian General Hospital, matron and staff nurses, c. 1919

*(Australian War Memorial)*

## CLINICAL INTEREST BOX 1.3 Australian army nursing service pledge of service

I pledge myself loyally to serve my King and Country and to maintain the honour and efficiency of the Australian Army Nursing Service. I will do all in my power to alleviate the suffering of the sick and wounded, sparing no effort to bring them comfort of body and peace of mind. I will work in unity and comradeship with my fellow nurses. I will be ready to give assistance to those in need of my help, and will abstain from any action which may bring sorrow and suffering to others. At all times I will endeavour to uphold the highest traditions of Womanhood and of the Profession of which I am Part.

*(Australian Army Nursing Service (AANS) Pledge of Service. © Commonwealth of Australia)*

## Progress of nursing in Australia

### The history of nursing education in Australia

The late 1800s and early 1900s saw the spread of the Nightingale system across Australia, which was an import from the United Kingdom. This was a vocational training with theory and clinical components. Nurses were trainees, and were provided with board, lodging and uniforms and received a minimal wage in exchange for their services to the hospital. The Nightingale system was seen as the most advanced scheme in the world, and Florence Nightingale was seen as an ultimate authority in nursing matters. The quality of nursing services was so greatly improved with the introduction of the Nightingale system that any attempts to change the system were strongly resisted. For some 100 years this system provided hospitals with a cheap, heavily disciplined hospital workforce. The downside of this model of education was that the service needs of hospital took priority over the educational needs of the nurse. Provisions that today we take for granted, such as well-stocked, up-to-date libraries, classrooms and qualified nursing teachers, were often lacking. The theory component was always seen as being less important than the clinical component, with the limited theory component being delivered by medical staff, other healthcare workers or the Matron (Russell 2011). Unfortunately, because of the long hours of work, student nurses were frequently too tired to concentrate during such classes. During the twentieth century a move towards professionalism emerged and with it came considerable conflict between the view that nursing is a vocation, which should be inherently subordinate to medicine, and the view that nursing is a profession, different from, but of equal status with, medicine (Russell 1990).

The first state in Australia to pass relevant registration legislation was South Australia, in 1920. Western Australia followed in 1922, New South Wales and Victoria in 1924. The emerging sense of professionalism among nurses led to a greater focus on industrial issues. The Australian Nursing Federation (ANF) (now known as ANMF) held its first meeting in 1924 and through this forum the quest for greater professional recognition, increased wages and improved working conditions began—a quest that continues today (Crisp et al 2013).

From the early 1960s concerns were being voiced about problems with recruitment into nurse training, including poor retention and high attrition rates. Of the nurses who did complete training many who were eligible to practise as Registered Nurses did not enter the workforce. One of the strategies introduced to address recruitment and retention problems was the introduction of a second tier of nurses, the **Enrolled Nurse (EN)**.

The 1960s and 1970s saw Australia bombarded with expert committees and workshops to try to address the issues within nursing. While there was considerable disagreement over many of the recommendations from the resulting reports, the committees were generally in agreement over the problems with nurse education. All agreed that change was essential, and that it was necessary to:

- Find a more appropriate venue for nurse education
- Move away from the apprenticeship system, as the needs of the hospital were given greater priority than the needs of the training nurse
- Continue with the 2 levels of nursing education
- Change the required entry standard
- Urgently change the existing curricula.

Disagreement still existed over whether registration programs should remain within the healthcare sector or be moved to the higher education sector, and whether the program should be the responsibility of the Minster for Education or the Minister for Health. This was also a period of considerable unrest within the nursing profession. Nurses were increasingly dissatisfied with wages and conditions, and the role of the nurse was becoming increasingly complex due to social and technological changes.

'Pilot' programs began to emerge as alternatives for the education of Registered Nurses, and in 1983 a surprise announcement was made by the then Minister for Health in NSW that all basic nurse education would be transferred into the higher education sector by January 1985. In 1984 the Australian federal government announced full support for the transfer of nursing education into the tertiary sector. The College of Nursing Australia, NSW College of Nursing, Royal Australian Nursing Federation and NSW Nurses' Association, who had fought long and hard for a national decision, celebrated with jubilation.

In 1985 alone one university and 12 Colleges of Advanced Education offered the Diploma of Applied Science (Nursing) for the first time. The last intakes into hospital-based courses were to occur in 1990, with the full transfer of all pre-registration nursing programs into the higher education sector being achieved in 1993. In 1992 the nomenclature 'Bachelor of Nursing' was adopted (Russell 2011).

Enrolled Nurse education has seen marked changes over the years. Prior to 1987 the *Nurses Registration Act* of 1953 dictated that education was to consist of 75 hours of lectures during one year of practice. Emphasis was placed on undertaking set tasks under the guidance of the Registered Nurse, with very little underpinning theory. This included:

- Thirty hours of basic nursing techniques and procedures which included lifting and positioning patients; preventing bedsores; mouth, hair and nail care; and using bed pans and urinals
- Twelve hours on medical and surgical conditions and related nursing care
- Five hours of simple anatomy and physiology.

Change in the role and the education of the EN is attributed to employers seeking to expand the role of the EN. The Board insisted that with an expansion of the role a substantial strengthening of the theoretical education was required. In 1987 the 'nursing aide' title was changed to 'Enrolled Nurse', and a syllabus, approved by the Board, was instituted. Hospitals ceased to provide the theoretical component, and students attended Colleges of Technical and Further Education (TAFE) for 12 weeks, in which they received 360 hours of theoretical instruction. For the remaining 40 weeks of the year students rotated through various clinical areas as required by the Nurses Registration Board. TAFE NSW and the Sydney Adventist Hospital were the only providers of EN education in NSW.

Over time the qualification has increased, to an Advanced Certificate, Certificate IV and currently a Diploma of Nursing, with the Advanced Diploma of Nursing also being available as an additional study option to ENs.

The theoretical education for ENs has increased over 600% since 1987, with students now being required to undertake additional hours of theory with specified clinical placement requirements (Nurses and Midwives Board nd).

Table 1.1 outlines the major milestones in Australia's nursing history.

## NURSING PRACTICE IN AUSTRALIA

### Competency standards/standards for practice

To ensure that nurses continue to practise at a high standard that ensures safety of the public, the Australian Nursing and Midwifery Council (ANMC) developed the *National Competency Standards for the Registered Nurse* (NMBA 2010) and the *National Competency Standards for the Enrolled Nurse* (NMBA 2002). The **Nursing and Midwifery Board of Australia (NMBA)** is now responsible for the standards relating to the professional practice of nurses and midwives, and has recently replaced these with the *Enrolled Nurse Standards for Practice* (NMBA 2016a) and the *Registered Nurse Standards for Practice* (NMBA 2016b). Standards of nursing practice are developed and established from a basis of strong scientific research and the advice of clinical experts. Standards of nursing practice serve as objective guidelines for the provision of nursing care and as a means to evaluate that care. They provide a method to ensure that individuals receive high-quality individualised care, to ensure that nurses know what is necessary to provide expert nursing care and to ensure that measures are in place to determine that the care meets specific standards.

Educational institutions can recommend students for registration only if they have demonstrated the required standards. After registration or enrolment it becomes the

**TABLE 1.1 | Milestones in Australian nursing**

| | |
|---|---|
| 1811 | Sydney Hospital opens; nursing undertaken by convict men and women |
| 1836 | Deaconess Institute of Kaiserwerth, Germany, is founded |
| 1838 | Five Irish Sisters of Charity, Australia's first trained nurses, arrive in New South Wales |
| 1848 | Opening of Yarra Bend Asylum at what was to become known as Melbourne to enable the mentally ill to be transferred from gaol |
| 1860 | Florence Nightingale publishes *Notes on Nursing: What It Is and What It Is Not* |
| 1868 | Sir Henry Parkes requests Nightingale provide trained nurses for New South Wales<br>Arrival of Lucy Osburn and five Nightingale nurses at Sydney Infirmary (to become Sydney Hospital) |
| 1871 | Nightingale-trained matron appointed to the Alfred Hospital, Melbourne |
| 1899 | Australasian Trained Nurses Association is founded in New South Wales |
| 1933 | Australian Capital Territory nursing registration commences |
| 1949 | Formation of College of Nursing Australia (now RCNA) |
| 1952 | *Nursing Research*, a journal reporting on the scientific investigations of nursing, established in the United States |
| 1975 | First nursing diploma program in Australia in a College of Advanced Education (CAE) in Melbourne, followed quickly by programs in New South Wales, South Australia and Western Australia |
| 1983 | New South Wales announces that all nursing education in the state will be transferred to CAEs by 1985<br>International Council of Nurses embeds in new constitution the categories 'first-level nurse' (the Registered Nurse, RN) and 'second-level nurse' (the Enrolled Nurse, EN). Magnet Hospital research begins in the United States |
| 1990 | All nursing education transferred to tertiary sector and at degree level in Australia |
| 2000 | International nursing shortage is recognised and becomes a government priority in Australia<br>Increase in 'medical error' becomes an international concern |

| 2011 | Accreditation process for Nursing Courses in Australia is taken over by ANMC; ANMC becomes Australian Nursing and Midwifery Accreditation Council (ANMAC)<br>Unification of Royal College of Nursing, Australia (RCNA) and The College of Nursing (TCoN) to become Australian College of Nursing |

(ANMAC, Crisp et al 2013, NMBA, RCNA)

responsibility of the individual nurse to ensure that this minimum standard is maintained. The standards are broad and principle-based to allow practising nurses to use as a benchmark to assess competence in a range of settings. The responsibilities included in the standards are illustrative of the types of core activities that an EN would be expected to undertake on entry to practice. All ENs have a responsibility for ongoing professional development to maintain an up-to-date knowledge base and skill level.

The *Enrolled Nurse Standards for Practice* (NMBA 2016a) were developed to reflect three domains of EN practice: professional and collaborative practice, provision of care and reflective and analytical practice. There are 10 standards and each contains several indicators. The indicators are key generic examples of competent performance. Clinical Interest Box 1.4 outlines the *Enrolled Nurse Standards for Practice* (NMBA 2016a).

Patricia Benner's seminal research, *From Novice to Expert* (1984), explores how nurses progress in the development of expertise to explain the domains of nursing practice. Clinical Interest Box 1.5 outlines the development of nursing expertise.

## Scope of practice

The scope of nursing and midwifery practice is that which nurses and midwives are educated, competent and permitted by law to perform. The actual scope of an individual nurse's or midwife's practice is influenced by the:

- Settings in which they practise
- Health needs of people
- Level of competence and confidence of the nurse
- Service provider's policy requirements.

Supervision of Enrolled Nurses by Registered Nurses can be direct or indirect. Supervision is defined as access, in all contexts of care, at all times to a named and accessible RN for support and guidance.

- Direct supervision: the supervisor (RN) is actually present, observes, works with, guides and directs the person who is being supervised.
- Indirect supervision: the supervisor (RN) works in the same facility or organisation as the supervised person, but does not constantly observe their activities. The supervisor must be available for reasonable access. Reasonable access will depend on the context, the needs of the person receiving care and the needs of the person being supervised.

It is important to remember, however, that the EN retains responsibility for their own actions and remains accountable for providing delegated nursing care at all times (NMBA 2016; Brown et al 2015; Starr 2012). See Clinical Interest Boxes 1.6 and 1.7.

The global shortage of nurses and the expanding roles for nurses has seen health services and aged care services utilising unlicensed/**unregulated healthcare workers**.

These workers are employed as health services assistants (HSA) or assistants in nursing (AIN) in the acute sector, and personal care workers (PCW) or personal care attendants (PCA) in the aged care sector. While the role of the unregulated healthcare worker has been controversial in the past they are now accepted as an essential member of the care team, who works closely with the EN and RN, particularly in aged care. The debate is now largely centred on arrangements for adequate supervision by RNs, the ratio of carers to nurses and the regulation of carers.

## Decision-making frameworks

Since the introduction of the competency standards for the Enrolled Nurse in the early 1990s the role and scope of practice of the EN has developed substantially in Australia. To help nurses to act within their scope of practice, the decision-making framework nursing flowchart and summary guide were released in April 2007 and were rebranded by the NMBA in 2013 (NMBA 2013) (see Figures 1.2 and 1.3). Scope of practice tools, such as the decision-making framework nursing flowchart and summary guide, provide a tool for nurses and employers to use:

- When considering or determining practice and to clarify expectations of nursing practice
- When employers are creating, interpreting and planning policies that apply to nursing practice
- As a performance criterion for nurses
- To stimulate professional discussion related to decision making and scope of practice.
  (Willis 2012)

Nurses are both responsible and accountable for their individual practice, and scope of practice is dynamic and based on individual needs and benefit and legislative requirements. It is not limited to specific tasks or functions but is a combination of knowledge, judgment and skill that guides the nurse's practice. Scope of practice should be broad and flexible to allow for innovation, growth and change and to ensure that there is consistency with current health needs and that actions support improved health outcomes (International Council of Nurses (ICN) 2013).

To practise within the full scope of practice of the profession may require individuals to update or increase their knowledge, skills or competence. When participating in continuing professional education the EN must not assume that they have the right to engage in this practice in the workplace. Employers must support practice at a more advanced level. It is also important to remember that consumer needs and benefits do not override legal and organisational parameters for practice (Starr 2012). Case study 1.1 looks at the repercussions of acting outside your scope of practice, even in an emergency situation. Employers also have a responsibility to support nursing practice by not placing nurses in situations and environments where they need to act beyond their level of competence/legal scope of practice and providing safe, supportive environments that promote competent practice (ICN 2013).

## Code of ethics

The need for a code of ethics was acknowledged during the Australasian Nurse Registering Authorities Conference

## CLINICAL INTEREST BOX 1.4 NMBA *Enrolled Nurse Standards for Practice* (2016)

### Professional and collaborative practice

**Standard 1: Functions in accordance with the law, policies and procedures affecting EN practice**

**Indicators:**

1.1 Demonstrates knowledge and understanding of commonwealth, state and/or territory legislation and common law pertinent to nursing practice.
1.2 Fulfils the duty of care in the undertaking of EN practice.
1.3 Demonstrates knowledge of and implications for the NMBA standards, codes and guidelines, workplace policies and procedural guidelines applicable to enrolled nursing practice.
1.4 Provides nursing care according to the agreed plan of care, professional standards, workplace policies and procedural guidelines.
1.5 Identifies and clarifies EN responsibilities for aspects of delegated care working in collaboration with the RN and multidisciplinary health care team.
1.6 Recognises own limitations in practice and competence and seeks guidance from the RN and help as necessary.
1.7 Refrains from undertaking activities where competence has not been demonstrated and appropriate education, training and experience has not been undertaken.
1.8 Acts to ensure safe outcomes for others by recognising the need to protect people and reporting the risk of potential for harm.
1.9 When incidents of unsafe practice occur, reports immediately to the RN and other persons in authority and, where appropriate, explores ways to prevent recurrence.
1.10 Liaises and negotiates with the RN and other appropriate personnel to ensure that needs and rights of people in receipt of care are addressed and upheld.

**Standard 2: Practises nursing in a way that ensures the rights, confidentiality, dignity and respect of people are upheld.**

**Indicators:**

2.1 Places the people receiving care at the centre of care and supports them to make informed choices.
2.2 Practises in accordance with the NMBA standards codes and guidelines.
2.3 Demonstrates respect for others to whom care is provided regardless of ethnicity, culture, religion, age, gender, sexual preference, physical or mental state, differing values and beliefs.
2.4 Practises culturally safe care for (i) Aboriginal and Torres Strait Islander peoples; and (ii) people from all other cultures.
2.5 Forms therapeutic relationships with people receiving care and others recognising professional boundaries.
2.6 Maintains equitable care when addressing people's differing values and beliefs.
2.7 Ensures privacy, dignity and confidentiality when providing care.
2.8 Clarifies with the RN and relevant members of the multi-disciplinary healthcare team when interventions or treatments appear unclear or inappropriate.
2.9 Reports incidents of unethical behaviour immediately to the person in authority and, where appropriate, explores ways to prevent recurrence.
2.10 Acknowledges and accommodates, wherever possible, preferences of people receiving nursing care.

**Standard 3: Accepts accountability and responsibility for own actions.**

**Indicators:**

3.1 Practises within the EN scope of practice relevant to the context of practice, legislation, own educational preparation and experience.
3.2 Demonstrates responsibility and accountability for nursing care provided,
3.3 Recognises the RN[1] as the person responsible to assist EN decision-making and provision of nursing care.
3.4 Collaborates with the RN to ensure delegated responsibilities are commensurate with own scope of practice.
3.5 Clarifies own role and responsibilities with supervising RN in the context of the healthcare setting within which they practice.
3.6 Consults with the RN and other members of the multidisciplinary healthcare team to facilitate the provision of accurate information, and enable informed decisions by others.
3.7 Provides care within scope of practice as part of multidisciplinary healthcare team, and with supervision of a RN.
3.8 Provides support and supervision to assistants in nursing (however titled) and to others providing care, such as EN students, to ensure care is provided as outlined within the plan of care and according to institutional policies, protocols and guidelines.
3.9 Promotes the safety of self and others in all aspects of nursing practice.

[1]*Where an enrolled nurse is working in maternity services setting it is expected that they will be supervised by a midwife.*

*Continued*

## CLINICAL INTEREST BOX 1.4 NMBA *Enrolled Nurse Standards for Practice* (2016)—cont'd

### Provision of care

**Standard 4: Interprets information from a range of sources in order to contribute to planning appropriate care**

**Indicators:**

4.1 Uses a range of skills and data gathering techniques including observation, interview, physical examination and measurement.
4.2 Accurately collects, interprets, utilises, monitors and reports information regarding the health and functional status of people receiving care to achieve identified health and care outcomes.
4.3 Develops, monitors and maintains a plan of care in collaboration with the RN, multidisciplinary team and others.
4.4 Uses health care technology appropriately according to workplace guidelines.

**Standard 5: Collaborates with the RN, the person receiving care and the healthcare team when developing plans of care**

**Indicators:**

5.1 Develops and promotes positive professional working relationships with members of the multi-disciplinary team.
5.2 Collaborates with members of the multi-disciplinary healthcare team in the provision of nursing care.
5.3 Contributes to the development of care plans in conjunction with the multidisciplinary healthcare team, the person receiving care and appropriate others[2].
5.4 Manages and prioritises workload in accordance with people's care plans.
5.5 Clarifies orders for nursing care with the RN when unclear.
5.6 Contributes to and collaborates in decision-making through participation in multidisciplinary healthcare team meetings and case conferences.

**Standard 6: Provides skilled and timely care to people whilst promoting their independence and involvement in care decision making**

**Indicators:**

6.1 Provides care to people who are unable to meet their own physical and/or mental health needs.
6.2 Participates with the RN in evaluation of the person's progress toward expected outcomes and the reformulation of plans of care.
6.3 Promotes active engagement and the independence of people receiving care within the health care setting by involving them as active participants in care, where appropriate.
6.4 Demonstrates currency and competency in the safe use of healthcare technology.
6.5 Exercises time management and workload prioritisation.
6.6 Recognises when the physical or mental health of a person receiving care is deteriorating, reports, documents and seeks appropriate assistance.

**Standard 7: Communicates and uses documentation to inform and report care**

**Indicators:**

7.1 Collects data, reviews and documents the health and functional status of the person receiving care accurately and clearly.
7.2 Interprets and reports the health and functional status of people receiving care to the RN and appropriate members of the multidisciplinary healthcare team as soon as practicable.
7.3 Uses a variety of communication methods to engage appropriately with others and documents accordingly.
7.4 Prepares and delivers written and verbal care reports such as clinical handover, as a part of the multidisciplinary healthcare team.
7.5 Provides accurate and appropriate information to enable informed decision making by others.

### Reflective and analytical practice

**Standard 8: Provides nursing care that is informed by research evidence**

**Indicators:**

8.1 Refers to the RN to guide decision-making.
8.2 Seeks additional knowledge/information when presented with unfamiliar situations.
8.3 Incorporates evidence for best practice as guided by the RN or other appropriate health professionals.
8.4 Uses problem-solving incorporating logic, analysis and a sound argument when planning and providing care.
8.5 Demonstrates analytical skills through accessing and evaluating healthcare information and quality improvement activities.
8.6 Consults with the RN and other relevant health professionals and resources to improve current practice.

[2]*Appropriate others include those in direct association with the person receiving care (with his/her consent) such as family, unpaid and paid carers, volunteers and clergy.*

## CLINICAL INTEREST BOX 1.4 NMBA *Enrolled Nurse Standards for Practice* (2016)—cont'd

**Standard 9: Practises within safety and quality improvement guidelines and standards**

**Indicators:**

9.1 Participates in quality improvement programs and accreditation standards activities as relevant to the context of practice.

9.2 Within the multi-disciplinary team, contributes and consults in analysing risk and implementing strategies to minimise risk.

9.3 Reports and documents safety breaches and hazards according to legislative requirements and institutional policies and procedures.

9.4 Practises safely within legislative requirements, safety policies, protocols and guidelines.

**Standard 10: Engages in ongoing development of self as a professional**

**Indicators:**

10.1 Uses EN standards for practice to assess own performance,

10.2 Recognises the need for, and participates in, continuing professional and skills development in accordance with the NMBA's Continuing professional development registration standard.

10.3 Identifies learning needs through critical reflection and consideration of evidence-based practice in consultation with the RNs and the multidisciplinary healthcare team.

10.4 Contributes to and supports the professional development of others.

10.5 Uses professional supports and resources such as clinical supervision that facilitate professional development and personal wellbeing.

10.6 Promotes a positive professional image.

*(NMBA 2016a)*

## CLINICAL INTEREST BOX 1.5 Benner's stages of nursing expertise

**Stage I. Novice**

No experience (nursing student). Performance is limited, inflexible and governed by context-free rules and regulations rather than experience.

**Stage II. Advanced beginner**

Demonstrates marginally acceptable performance. Recognises the meaningful 'aspects' of a real situation. Has experienced enough real situations to make judgments about them.

**Stage III. Competent practitioner**

Has 2–3 years experience. Demonstrates organisational and planning abilities. Differentiates important factors from less important aspects of care. Coordinates multiple complex care demands.

**Stage IV. Proficient practitioner**

Has 3–5 years experience. Perceives situations as wholes rather than in terms of parts, as in Stage II. Uses maxims as guides for what to consider in a situation. Has holistic understanding of the individual, which improves decision making. Focuses on long-term goals.

**Stage V. Expert practitioner**

Performance is fluid, flexible and highly proficient. No longer requires rules, guidelines or maxims to connect an understanding of the situation to appropriate action. Demonstrates highly skilled intuitive and analytic ability in new situations. Is inclined to take certain action because 'it felt right'.

*(Benner 1984)*

## CLINICAL INTEREST BOX 1.6 Decision-making framework considerations

NMBA decision-making framework considerations:

1. Am I educated?
2. Am I authorised?
3. Am I competent?

If you answer 'no' to any of these, do not perform that activity. Seek guidance and support from your teacher/a nurse team leader/clinical facilitator/educator.

(ANRAC) in 1990. It was deemed that there was need for focus on ethical behaviour for Australian nurses and that a documented code of ethics would assist in achieving this focus. The *Code of Ethics for Nurses in Australia* (ANMC 2008) comprises eight value statements, each of which is further defined by several explanatory statements. The eight value statements are:

1. Nurses value quality nursing care for all people
2. Nurses value respect and kindness for self and others
3. Nurses value the diversity of people
4. Nurses value access to quality nursing and healthcare for all people
5. Nurses value informed decision making
6. Nurses value a culture of safety in nursing and healthcare
7. Nurses value ethical management of information
8. Nurses value a socially, economically and ecologically sustainable environment promoting health and wellbeing.

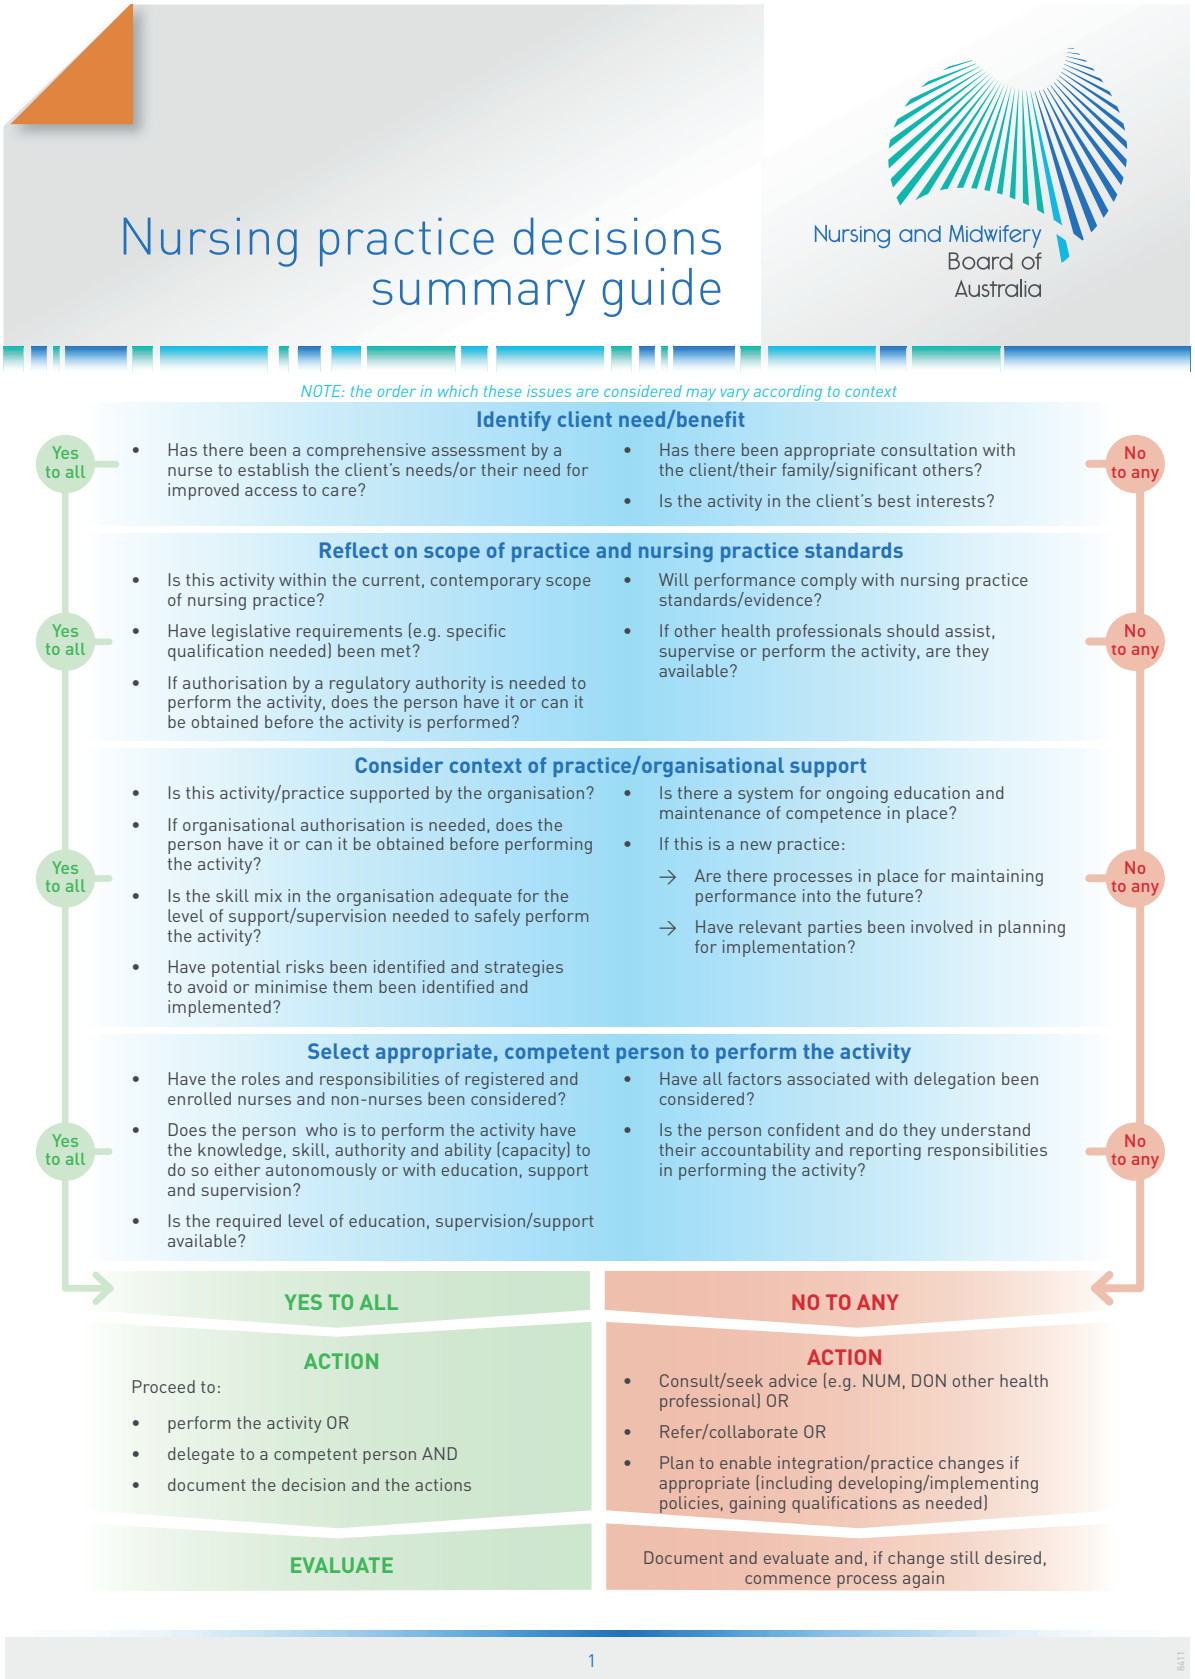

**Figure 1.2** NMBA nursing practice decisions summary guide
*(NMBA 2013)*

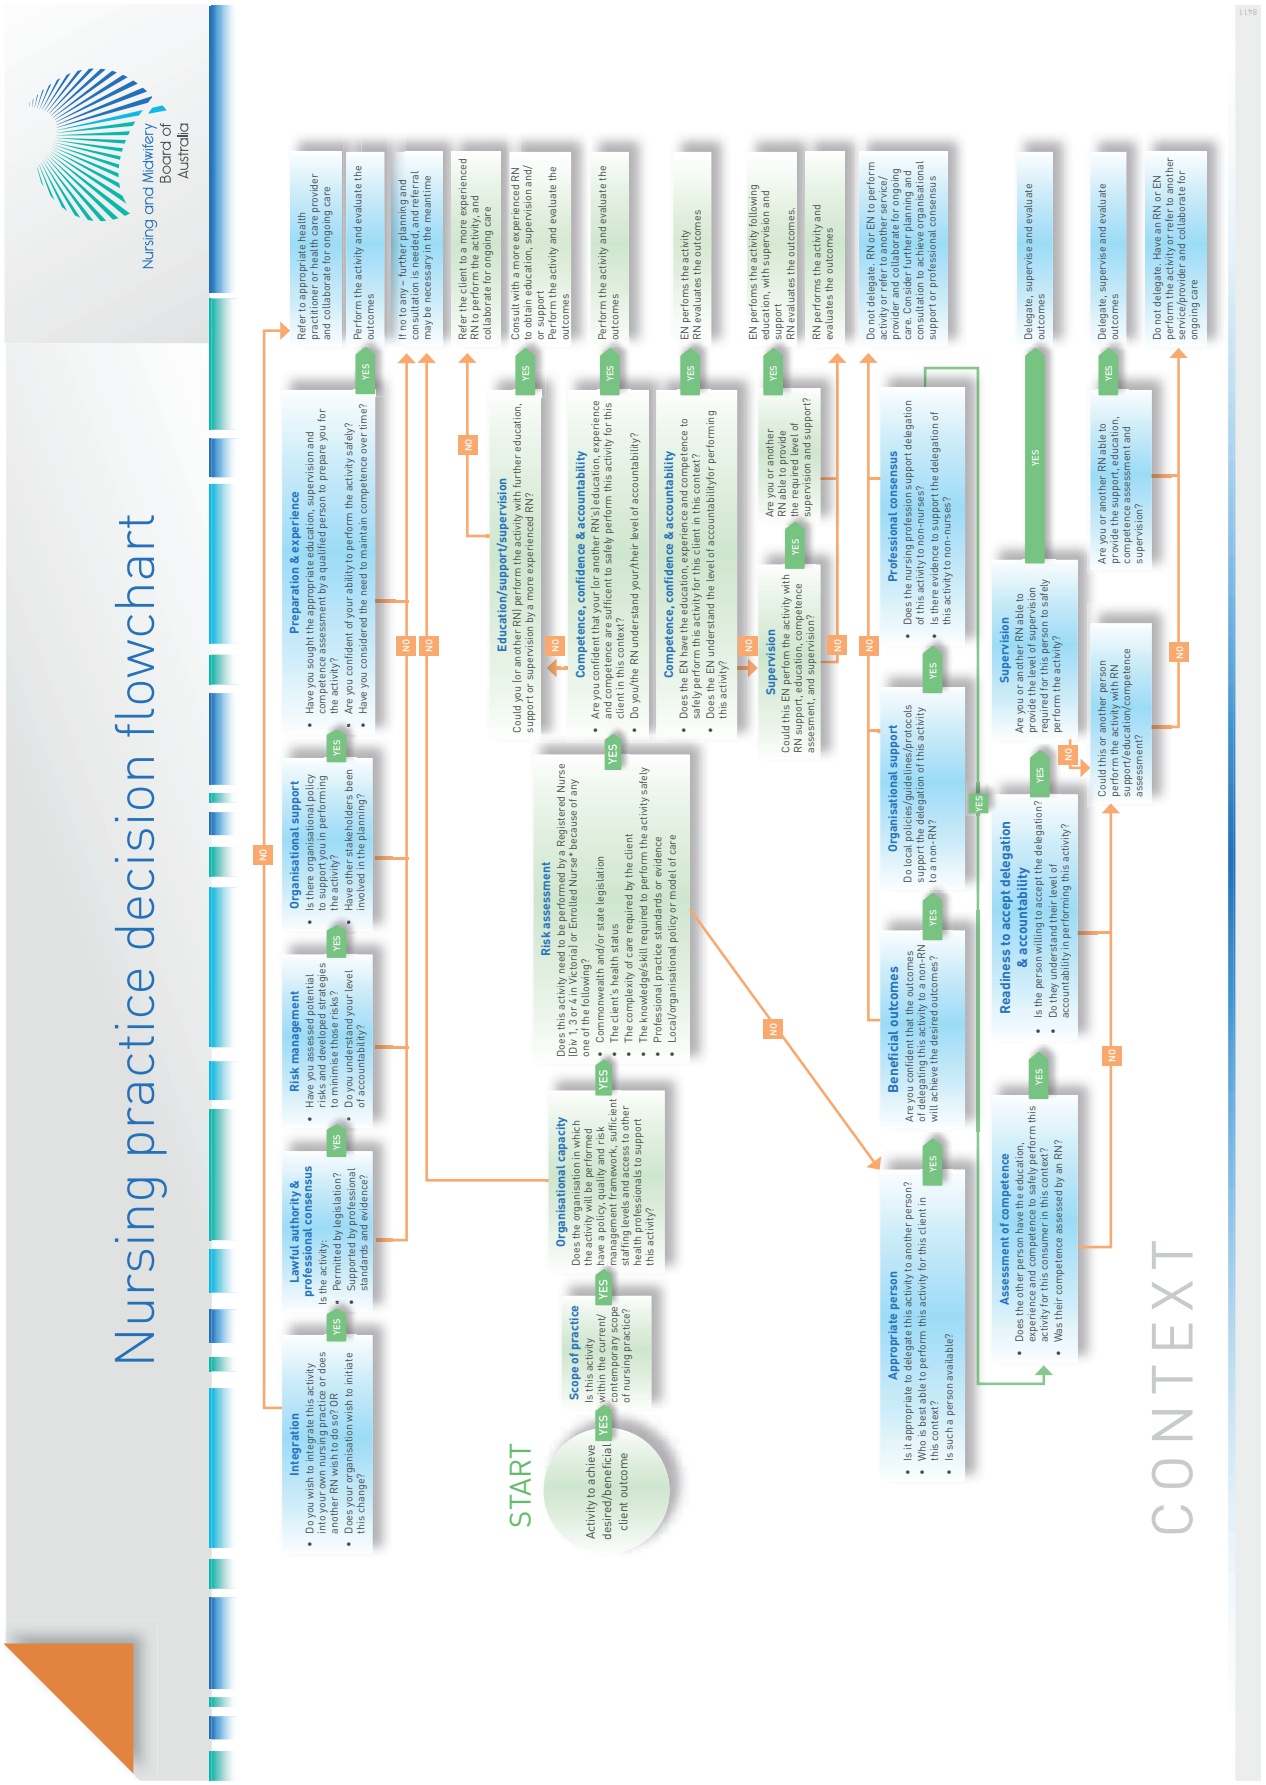

**Figure 1.3** NMBA nursing practice decision flowchart
*(NMBA 2013)*

## CLINICAL INTEREST BOX 1.7 Factors that influence scope of practice

The scope of practice of nursing practice is recognised as varied and diverse, responsive to meeting the broad range of individual/populations' healthcare needs. It is dependent on the context of practice, influenced by:

- Type of setting (e.g. healthcare agency, educational organisation, community health service)
- Location of the setting (e.g. urban, rural or remote, community, acute care)
- Characteristics of individuals (e.g. health status, age, learning needs)
- Focus of healthcare activities (e.g. health promotion, research, education)
- Complexity of practice (e.g. health acuity of the individual/population)
- Level of responsibility/accountability of the healthcare provider
- Resources that are available/accessible as part of the health service.

*(Willis 2012)*

## CASE STUDY 1.1

In 2011 a registered midwife (RM) was found guilty of unprofessional conduct, was reprimanded and had conditions placed on her registration after acting outside her scope of practice and hospital policies. During an emergency situation the RM performed a vacuum delivery, which she believed she had been accredited to perform after completing an Advanced Life Support in Obstetrics course. The Nursing and Midwifery Professional Standards Committee found that:

- She operated outside her scope of practice and contrary to hospital policy
- She was not accredited or authorised to perform the vacuum delivery
- Her years of experience should have prepared and guided her to a more appropriate path during an emergency.

As a result the midwife was cautioned and had conditions placed upon her registration (Nursing and Midwifery Professional Standards Committee of New South Wales 2011; Starr 2012).

1. Discuss the main factors that determine your scope of practice as a nurse.
2. Does your scope of practice change in an emergency situation?

These value statements are deliberately broad to reflect the variety of nursing practice areas, and variation in populations and their healthcare needs. The website for the NMBA contains information for nurses and for the public including codes, guidelines and position statements. Further discussion of the code of ethics can be found in Chapter 2.

## Registration

From 1 July 2010, with the introduction of the Health Practitioner Regulation National Law, 14 health professions, including nursing, are regulated by legislation that is consistent nationwide. Each health profession has its own national board that is responsible for regulating the health professionals. Primarily these boards protect the public and set standards and policies that registered practitioners need to meet. In order for nurses to register they need to prove that they meet the following registration standards, set by the national board for nursing, the NMBA:

- Continuing professional development
- Criminal history
- English language skills
- Professional indemnity insurance
- Recency of practice.

(Australian Health Practitioner Regulation Agency (AHPRA) 2014a; NMBA 2015)

Clinical Interest Boxes 1.8 and 1.9 provide more information on continuing professional development.

### Nursing and Midwifery Board of Australia

The NMBA has established state and territory boards to support the work of the national board in the national scheme. The national board will set policy and professional standards, and the state and territory boards will continue to make individual notification and registration decisions affecting individual nurses and midwives (see Case Study 1.2).

The functions of the NMBA include:

- Registering nursing and midwifery practitioners and students
- Developing standards, codes and guidelines for the nursing and midwifery profession
- Handling notifications, complaints, investigations and disciplinary hearings
- Assessing overseas-trained practitioners who wish to practise in Australia
- Approving accreditation standards and accredited courses of study (NMBA).

See Clinical Interest Box 1.10 for further information on the Nurses and Midwives Board of Australia.

### Australian Health Practitioner Regulation Agency

The **Australian Health Practitioner Regulation Agency (AHPRA)** supports the NMBA. The primary role of the board is to protect the public and set standards and policies that all registered health practitioners must meet. AHPRA:

- Supports the NMBA in its primary role of protecting the public
- Manages the registration processes for health practitioners and students around Australia

## CLINICAL INTEREST BOX 1.8 Continuing professional development

From 1 July 2010 Enrolled and Registered Nurses and midwives and nurse and midwife practitioners have been required to meet the Continuing Professional Development (CPD) Standard set by the NMBA (this standard does not apply to students or nurses and midwives with non-practising registration).

- Under this standard nurses are required to participate in at least 20 hours of CPD per year (nurses who are also registered as midwives must complete 20 hours as a nurse and 20 hours as a midwife)
- One active hour of learning equals one hour of CPD
- CPD must be relevant to the context of practice
- Written documentation must be kept to demonstrate evidence of a minimum of 20 hours of CPD per year
- Compulsory annual in-services can count towards CPD (e.g. annual infection control, CPR, fire training)
- Audits are conducted annually by the board on a number of nurses and midwives in Australia
- CPD activities can include attending conferences, seminars, courses and in-services, meetings, reading a journal article and reflecting on it, watching and reflecting on webinars.

### Documenting CPD

(See also Clinical Interest Box 1.9)

Documentation of CPD needs to include the date, activity undertaken, description of the outcomes and number of hours spent on each activity. Evidence needs to be verified (e.g. a certificate attached or signature from the person running the course).

Documentation needs to demonstrate that you have:

- Developed a learning plan based on learning needs (that is relevant to your context of practice)
- Identified and prioritised learning needs based on an evaluation of practice against competency or professional practice standards
- Participated in effective learning activities that are relevant to learning needs
- Reflected on the value of learning activities and their effect on your practice.

*(NMBA 2016c)*

## CLINICAL INTEREST BOX 1.9 Documenting CPD

| Identified learning need | Relevant planned activities | Achieved? |
|---|---|---|
| To be able to recognise a deteriorating patient and know when to refer them to other healthcare professionals | Complete 'Between the Flags' | Yes |

| | |
|---|---|
| Title: DETECT Between the Flags | Date: 22/5/2015 |
| Venue/Organisation: NSW Health e-learning | Presenter: E-learning |
| Evidence: Certificate | CPD hours: 4 |

*Briefly describe the content:*
This e-learning taught me how to detect deteriorating patients, undertake and evaluate, provide initial treatment, when it is necessary to escalate care and how to communicate in teams. It also taught me how to correctly use and interpret the associated observation chart.

*How did the information relate to your work/why did you undertake this learning?*
I undertook this learning as I did not feel that I had the appropriate knowledge and skills to know how to identify a deteriorating patient and provide appropriate treatment until help arrives. I picked this as a learning goal as it will help me to meet competency unit 7, manages nursing care of individuals and groups within the scope of enrolled nursing practice.

*The implications for my practice are:*
I know the warning signs to look out for when I am concerned about a patient.
I know how and when to escalate a situation.
I have learnt how to better communicate in teams.

*(Ausmed Education nd; Nurses for Nurses 2015; NSW Health 2009)*

- Has offices in each state and territory where the public can make notifications about a registered health practitioner or student
- On behalf of the boards, manages investigations into the professional conduct, performance or health of registered health practitioners, except in NSW where this is done jointly by the Health Professional Councils Authority and the Health Care Complaints Commission
- On behalf of the national board, publishes national registers of practitioners so important information about the registration of individual health practitioners is available to the public
- Works with the Health Complaints Commission in each state and territory to make sure the appropriate

## CASE STUDY 1.2

Margaret, 72, came into the Nursing and Midwifery Board of Australia's (NBMA) registration enquiry desk to ask for assistance. She stated that she had been a nurse for over 50 years and she did not understand why she had been refused her registration renewal. The nursing officer who attended to her enquiry asked her if she was currently working, she replied that she had not worked for 30 years but she did not see what that had to do with her nursing registration. She stated she had been a nurse for over 50 years and no one should have the right to take that away from her. She had sent her renewal with her payment every year and never been refused before.

When the nursing officer explained that registration was a licence to practise and as the NMBA had a duty to ensure nurses who had registration to practise were skilled and competent practitioners and that it was no longer acceptable to just renew your registration every year, Margaret became teary. She said, 'Well, if I cannot keep my registration I am not a nurse anymore!' The nursing officer advised her that she would always be a nurse, just not a practising one and she could apply for a non-practising nurse registration.

1. What standards do nurses need to meet in order to be registered to practise as a nurse?
2. How do these standards help to ensure that nurses are skilled and competent practitioners?
3. Think about what is involved in meeting registration standards. Which standards would Margaret no longer meet when attempting to renew her registration? Why?

organisation investigates community concerns about individual, registered health practitioners
- Supports the boards in the development of registration standards, and codes and guidelines
- Provides advice to the Ministerial Council about the administration of the national registration and accreditation scheme.

(AHPRA 2014b)

### Australian Nursing and Midwifery Accreditation Council

The role of the **Australian Nursing and Midwifery Accreditation Council (ANMAC)** is now, as Australia's independent accreditation authority for nursing and midwifery, to undertake:

- Development of accreditation standards
- Accreditation of Australian nursing and midwifery courses
- Accreditation of Australian providers of nursing and midwifery courses
- Assessment of, for the purposes of permanent migration, internationally qualified nurses and midwives
- Provision of policy advice on matters relating to accreditation and skilled migration of nurses and midwives.

(ANMAC 2014)

## CLINICAL INTEREST BOX 1.10 The Nursing and Midwifery Board of Australia

The Nursing and Midwifery Board of Australia has developed a professional framework for nursing practice using a set of national standards and codes. The core standards are:

Codes of ethics for:
- Midwives
- Nurses

Codes of professional conduct for:
- Midwives
- Nurses

Professional practice guidelines for:
- Nursing and midwifery—Advertising of regulated health services
- Nursing and midwifery—Guidelines for mandatory notifications

Guidelines covering:
- Competency standards/standards for practice
- Decision-making framework
- Registration standards
- Principles for the assessment of national competency standards/standards for practice
- Professional boundaries
- Re-entry to practice policy

These standards and codes can be used by:
- Individual nurses to assess his or her own performance or the performance of their peers.
- Regulatory authorities to assess nurses involved in professional misconduct matters.
- Higher and vocational education authorities who use competency standards as a framework for course development.
- Employers who use competency standards for employment assessment and development of job description forms.
- The profession, for communication to consumers of the standards which can be expected from a Registered or Enrolled Nurse.

#### Standards and codes

The *Code of Professional Conduct for Nurses* in Australia is a set of expected national standards of nursing conduct for Australian nurses.

The *Code of Ethics for Nurses* in Australia outlines the ethical standards expected and required of nurses practising in Australia.

*(NMBA 2015)*

**CRITICAL THINKING EXERCISE 1.1**

Discuss how the NMBA, AHPRA and ANMAC work together to regulate the nursing profession.

## PROFESSIONAL NURSING ORGANISATIONS

### Australian College of Nursing

In 2011 the **Royal College of Nursing, Australia (RCNA)** and The College of Nursing (TCoN) united to become the Australian College of Nursing (ACN). The ACN provides a strengthened base for the nursing profession that communicates with government, other sectors and the public. It fosters research, policy and strategic development and provides a foundation for professional development and education activities (RCNA 2011).

### Australian Nursing and Midwifery Federation

The Australian Nursing Federation (ANF) (now the **Australian Nursing and Midwifery Federation (ANMF)**) was established in 1924. It is the national union for nurses and the largest professional organisation in Australia. The ANMF's core business is the industrial and professional representation of nurses and nursing through the activities of a national office and branches in every state and territory. ANMF has an Enrolled Nurse special interest group, the National Enrolled Nurse Association (NENA), whose mission is to promote the value of ENs and raise awareness of the EN role within the community. The National Enrolled Nurse Association also provides a forum for all ENs to participate at a national level. In 2013, the ANF changed its name to the Australian Nursing and Midwifery Federation to recognise its midwife members (www.anmfvic.asn.au/about-us/history)

## NURSING—THE PROFESSION

Nursing is not simply a collection of specific skills, and the nurse is not simply a person trained to perform specific tasks. Nursing is a profession. No one factor absolutely differentiates a job from a profession, but the difference is important in terms of how nurses practise. When a person is said to act professionally, for example, it is implied that the person is conscientious in actions, knowledgeable in the subject and responsible to self and others. Although there is not universal agreement on a definition, a profession is generally expected to include the following characteristics:

- An extended and broad-based education of its members
- A theoretical body of knowledge leading to defined skills, abilities and norms
- The provision of a specific service
- Autonomy in decision making and practice
- The regulation of practice, both legally through legislation, and ethically through a code of ethics for practice.

Historically the dependent relationship between nursing and medicine made claiming nursing as a profession was problematic. Given this relationship, the areas of autonomy and decision making in practice were particularly controversial. Nowadays, nursing's claim to professional status is supported by consideration of the characteristics of a profession, education, theory, service, autonomy and a code of ethics (Crisp et al 2013) and the interdependent relationship enjoyed between nursing and medicine.

### Nurse education

Nursing education in Australia is regulated by ANMAC, NMBA and AHPRA. Education providers are required to deliver courses that meet the accreditation standards of ANMAC and are approved by the NMBA. Students must also be registered with AHPRA by their education provider. Both these organisations play a key role in protecting the public. ANMAC ensures high standards of nursing education that produces nurses who practise in a safe and competent manner. Registration with AHPRA allows the NMBA to act on matters that may impact the safety of the public, including student impairment or serious convictions (AHPRA 2014c; ANMAC 2014).

There are two types of nurse and thus nurse education in Australia. These nurses practise across a wide range of settings within health and community settings (Daly et al 2014). The **Registered Nurse (RN)**, or division one nurse, requires the completion of an undergraduate degree in the higher education or university sector. A stand alone nursing degree is of 3 years duration; however, some education providers offer the opportunity to gain a combined degree with, for example, midwifery in 4–5 years (AHPRA 2013). The RN practises nursing independently and interdependently and is regarded as responsible and accountable for all decisions and actions taken in relation to individual care. The RN is also responsible for delegating care to Enrolled Nurses and healthcare workers, taking into account education, training and context of care. Various career progression paths are available to RNs including clinical nurse specialist (CNS), clinical nurse consultant (CNC), nurse unit manager (NUM) and nurse educator (Daly et al 2014; NMBA 2010).

The Enrolled Nurse (EN) requires the completion of a Diploma of Nursing, generally through the vocational education and training (VET) sector. This program is of 18 months duration. Enrolled Nurses are able to complete an Advanced Diploma of Nursing to develop higher-level skills and work in specialty areas of healthcare. ENs are able to undertake further studies to become RNs. Many universities offer recognition of prior learning and thus a shorter degree program to ENs who wish to undertake the Bachelor of Nursing (AHPRA 2013; Daly et al 2014; Australian Government 2012a). The role of the EN was also discussed under Scope of Practice.

**Unregulated healthcare workers** are employed in healthcare facilities within Australia to undertake personal care tasks and activities of daily living. This is carried out under the supervision of the RN. Various titles are given to

people fulfilling this role, including Assistant in Nursing (AIN), nursing assistant, nursing support worker, individual service/support attendant. Many undergraduate nursing students undertake employment in this area while they are completing their degree. Other unregulated healthcare workers may have completed a Certificate III in Health Service Assistance through the VET sector (Australian Government 2012b; Daly et al 2014). See Case Study 1.3 and Decision-making Framework Exercise 1.1.

## Theories and models of nursing

The practice of professional nursing and development of nursing knowledge has to some extent evolved from nursing theories. Theoretical models serve as frameworks for nursing curricula, clinical practice and research. Nursing theories can help make sense of processes and practices. Nursing theories are an attempt to elucidate the nature of nursing practice, the principles on which practice is based and the proper goals and functions of nursing in society. In this way nursing theories help create an understanding of the practice of nursing, how nurses interact with individuals and how nursing actions and provision of nursing care is structured (Daly et al 2014).

The development of nursing theory was an essential part of establishing professional status and independence. Nursing theory has clearly demonstrated that nursing, as a profession, shares a common body of knowledge with medicine (Crisp et al 2013). However, nursing has a different perspective, namely to care rather than to cure. This perspective provides nursing with its own set of knowledge and theoretical assumptions.

### CASE STUDY 1.3

Gemma is a newly graduated EN working on the medical admission unit (MAU) of a large teaching hospital. On a busy morning shift she is team nursing 10 individuals with one RN and two unregulated healthcare workers (UHW), one of whom is a second-year Bachelor of Nursing student. One individual was particularly unwell, and the RN was caught up looking after her and asked Gemma to look after the remaining nine individuals on the ward as well as supervising the UHWs.

In the next hour Gemma knows that one individual needs IV antibiotics, two have schedule 8 medications due and another needs to have a catheter inserted prior to being transferred to another ward.

1. Discuss the roles of the RN, EN and unregulated healthcare workers.

## Defining theory and model

A *theory* is an abstract statement formulated to explain or describe the relationships between concepts or events. A nursing theory conceptualises an aspect of nursing for the purpose of describing, explaining, predicting and/or prescribing nursing care (Crisp et al 2013). A *model* is a conceptual framework developed from a set of concepts and assumptions; it is a conceptual representation of reality. A model provides the outline for which theory provides the functions. Thus, a model represents *structure* while a theory suggests *function*. Numerous conceptual models of nursing practice have been devised, most of which:

- Are based on sound theory
- Contain implied or explicit assumptions, values and goals
- Are implemented by the nursing process.

Nursing theories serve several essential purposes, as is illustrated in Clinical Interest Box 1.11.

### CLINICAL INTEREST BOX 1.11 Purposes of nursing theories and conceptual frameworks

In clinical practice:

- Assist nurses to describe, explain and predict everyday experiences
- Serve to guide assessment, intervention and evaluation of nursing care
- Provide a rationale for collecting reliable and valid data about the health status of individuals, which are essential for effective decision making and implementation
- Help to establish criteria to measure the quality of nursing care
- Help build a common nursing terminology to use in communicating with other health professionals. Ideas are developed and words defined
- Enhance autonomy of nursing by defining its own independent functions

In education:

- Provide a general focus for curriculum design
- Guide curricular decision making

In research:

- Offer a framework for generating knowledge and new ideas
- Assist in discovering knowledge gaps in the specific field of study
- Offer a systematic approach to identify questions for study, select variables, interpret findings and validate nursing interventions.

*(Berman et al 2015)*

### DECISION-MAKING FRAMEWORK EXERCISE 1.1

- Using the NMBA decision-making framework determine what the EN should do in Case Study 1.3.
- Do you accept this delegation from the Registered Nurse?
- What strategies could Gemma use in this situation? What alternative could you suggest to the Registered Nurse?

## Components of nursing theoretical models

A *domain* is a field or scope of knowledge of a discipline and contains the subject, central concepts, values and beliefs, phenomena of interest and the central problems of the discipline. The components of a discipline's domain are described in a paradigm. A *paradigm* is a model that explains the links to science, philosophy and theory accepted by the discipline. Nursing's paradigm directs the activity of the nursing profession and includes four major concepts—person, health, environment and nursing (Berman et al 2015; Crisp et al 2013).

## Overview of selected nursing theories

Many nursing theories have been developed in the past and many are still being developed today. The following selection of nursing theories is a historical overview that discusses nursing's four fields of interest: person, health, environment and nursing.

### Peplau's theory

In 1952 Hildegard Peplau made an attempt to analyse nursing action using an interpersonal theoretical framework. Her theory focuses on the relationships formed by people as they progress through each developmental stage. She viewed the goal of nursing as developing a relationship between the nurse and individual whereby the nurse acts as resource person, counsellor, teacher and surrogate (Crisp et al 2013).

### Abdellah's theory

In 1960 Fay Abdellah, with her colleagues, devised a theory that emphasised the delivery of nursing care to the whole person. Using a problem-solving approach the nurse formulates a plan to help individuals meet their physical, emotional, intellectual, social and spiritual needs. This model was progressive for its time as it referred to nursing diagnosis, which was not seen as part of the nursing role at the time (Crisp et al 2013; Nursing Theory 2013). Abdellah and colleagues identified 21 specific individual needs that fall into four key areas:

1. Comfort, hygiene and safety
2. Physiological balance
3. Psychological and social factors
4. Sociological and community factors.

(Crisp et al 2013)

### Henderson's theory

In 1966 Virginia Henderson described the goal of nursing as helping the individual to gain independence as rapidly as possible.

Henderson identified 14 basic needs that provide a framework for nursing care. These are to:

1. Breathe normally
2. Eat and drink adequately
3. Eliminate by all avenues of elimination
4. Move and maintain a desirable position
5. Sleep and rest
6. Select suitable clothing; dress and undress
7. Maintain body temperature within normal range
8. Keep the body clean and well groomed
9. Avoid dangers in the environment
10. Communicate with others
11. Worship according to faith
12. Work at something that provides a sense of accomplishment
13. Play or participate in various forms of recreation
14. Learn, discover or satisfy the curiosity that leads to normal development and health.

(Berman et al 2015; Crisp et al 2013)

### Johnson's theory

In 1968 Dorothy Johnson portrayed the goal of nursing as reducing stress so that the individual can recover as quickly as possible. Johnson viewed people as a collection of behavioural subsystems that interrelate to form a whole person, and her theory focuses on a person's needs in terms of the following behaviours:

- Security-seeking behaviour
- Nurturing-seeking behaviour
- Mastery of oneself and one's environment according to internalised standards of excellence
- Taking in nourishment in socially and culturally acceptable ways
- Ridding the body of waste in socially and culturally acceptable ways
- Sexual and role identity behaviour
- Self-protective behaviour.

Johnson saw the nurse's role as identifying the individual's inability to adapt to stress, and as providing the nursing care necessary to assist them in resolving problems to meet their needs (Crisp et al 2013).

### King's theory

Imogene King (1971, cited in Crisp et al 2013) viewed the goal of nursing as helping individuals and groups to attain, maintain and restore health, or to die with dignity. King saw nursing as a process of interaction between nurse and individual whereby, through communication, goals are set and agreement reached on ways to achieve goals.

### Orem's theory

In 1973 Dorothea Orem depicted the goal of nursing as helping the individual to achieve health through self-care (Crisp et al 2013). Orem saw nursing as a service required when individuals are unable to care for themselves, or unable to be cared for by others of significance to them; that is, when demands exceed their self-care abilities. The nurse identifies why an individual is unable to care for themself and implements measures that assist them to meet their needs. The overall goal of nursing care is to assist the individual to achieve self-care whenever possible.

### Roy's theory

Callister Roy viewed the goal of nursing as assisting people towards health by promoting and supporting their ability to adapt to various demands (Crisp et al 2013):

- Meeting basic physiological needs
- Developing a positive self-concept
- Performing social roles

- Achieving a balance between dependence and independence.

Roy saw nursing as being concerned with people as total beings, and intervening when necessary to assist them to adapt to one or more of these demands.

### Roper, Logan and Tierney's theory

Roper, Logan and Tierney in 1985 viewed the goal of nursing as helping people to prevent, alleviate, solve or cope with problems related to activities of living. Their model of nursing is based on their model for living and includes five main concepts:

1. Activities of living
2. Factors affecting activities of living
3. Life span
4. Dependence–independence
5. The nursing process.

The activities of living, which are the focus of the model, are:

- Maintaining a safe environment
- Communicating
- Breathing
- Eating and drinking
- Eliminating
- Personal cleansing and dressing
- Controlling body temperature
- Mobilising
- Working and playing
- Expressing sexuality
- Sleeping
- Dying.

(Crisp et al 2013)

Many of these theories influence the way Australian authorities promote the profession of nursing, by providing a framework for regulation, ethics and conduct.

## Relationship of theories to nursing process

The nursing process is a tool and framework for contemporary nursing practice. It is a series of planned steps that produces a particular end result. In simple terms, the nursing process is a method used to assess, plan, deliver and evaluate nursing care. Clinical Interest Box 1.12 illustrates the relationship of two theories to the nursing process. Providing the framework for nursing care, the nursing process consists of five components, each of which follows logically one after the other:

1. Assessment
2. Nursing diagnosis
3. Planning
4. Implementation
5. Evaluation.

The process is adaptable to different individuals and different care settings. In addition, the process offers a systematic approach to nursing practice, enhances research opportunities and is compatible with many other systems in the healthcare delivery system, such as computer-generated care plans, patient information systems and patient acuity systems. Although the nursing process is central to the domain of nursing it is not a

### CLINICAL INTEREST BOX 1.12 Selected nursing theories and the nursing process

#### Orem's general theory of nursing

**Assessing**

Involves collecting data about the individual's capacities (knowledge, skills and motivation) to perform universal, developmental and health–deviation self-care requisites. Determines self-care deficits.

**Diagnosing**

Stated in terms of the individual's limitations for maintaining self-care (a deficit in self-care agency).

**Planning**

Involves considering and designing, with the individual's participation, an appropriate nursing system (wholly compensatory, partially compensatory, supportive-educative or a mix) that will help the individual achieve an optimal level of self-care (i.e. enhance the individual's self-care agency).

**Implementing**

Assisting the individual by acting for or doing for, guiding, supporting, providing a developmental environment and teaching.

**Evaluating**

Determining the individual's level of achievement in resolving self-care deficits and in performing self-care.

#### Roy's adaptation model

**Assessing**

Involves two levels. First-level assessment includes collecting data about output behaviours related to the four adaptive modes (physiological, self-concept, role function and interdependence modes).

Second-level assessment includes collecting data about internal and external stimuli (focal, contextual or residual) that are influencing the identified behaviours.

**Diagnosing**

Focuses on adaptation problems and uses one of three alternative methods:

1. Stating behaviours within one mode with their most relevant influencing stimuli
2. Clustering behavioural information and labelling it according to indicators of positive adaptation and a typology of common adaptation problems related to each mode. Roy provides a typology of indicators of positive adaptation and a typology of commonly recurring adaptation problems according to each of the four modes
3. Labelling a behavioural pattern when more than one mode is being affected by the same stimuli.

**Planning**

Setting goals in terms of behaviours the individual is to achieve and planning nursing interventions to promote the effectiveness of the individual's coping mechanisms and adaptive behaviours.

## CLINICAL INTEREST BOX 1.12 Selected nursing theories and the nursing process—cont'd

**Implementing**

Altering and manipulating the focal, contextual and residual stimuli by increasing, decreasing or maintaining them.

**Evaluating**

Determining the individual's output behaviours with those identified in the goals.

*(Berman et al 2015:51)*

theory. It provides a process for the delivery of nursing care, not the knowledge component of the discipline. However, there have been attempts to build a comprehensive theory from the process and to use the nursing process in conjunction with other theories that lack a process element. (For more information on the nursing process refer to Chapter 17.)

### CRITICAL THINKING EXERCISE 1.2

Part of your education includes experiences in different types of healthcare settings. Choose a nursing theory and explain how the nursing theory is applied to the nursing process in your chosen setting using the headings assessing, diagnosing, planning, implementing and evaluating.

### Service

Nursing has always been a service profession, although in the past the service was usually viewed as a charitable one largely directed towards the care of the physically ill. Nurses today need to acknowledge and value the importance of nursing care across a broad range of practice settings and with different groups of clientele. Moreover, they need to work with the individual and family, individualising care, considering cultural and religious differences and providing support for the entire extended family.

### Autonomy

Autonomy is an essential element of professional nursing. Autonomy means that a person is reasonably independent and self-governing in decision making and practice (Crisp et al 2013). RNs attain increased autonomy through higher levels of education, through clinical competence and in diverse practice settings. RNs are increasingly taking on independent roles in nurse-run clinics, as nurse practitioners, and in collaborative practice and advanced-nurse practice settings. ENs also have increased autonomy in certain settings; for example, in the aged-care sector and in the community.

All nurses are accountable for the type and quality of nursing care provided. The degree to which nurses are held accountable for their actions reflects the level of education they have received, which in turn informs the degree of responsibility the nurse has in the workplace. The nursing profession regulates accountability through nursing audits and standards of practice.

## INFLUENCES ON NURSING

### Societal influences on nursing

The societal influences on nursing include developments in medical science and technology, which have impacted on the changing role and function of the nurse, and other factors such as demographic changes, cultural diversity and the consumer movement, which have also had an impact on the structure and practice of nursing.

### Demographic changes

Changes that have influenced healthcare in recent decades include the population shift from rural areas to urban centres, increasing lifespan, the higher incidence of long-term illness and increased incidence of substance abuse, mental illness and diseases such as cancers. Nursing as a profession responds to such changes by exploring new methods for providing care, by changing educational emphasis and by establishing practice standards in new areas (Crisp et al 2013).

### Cultural diversity

Australia is a multicultural society, which means that nurses frequently encounter individuals from cultures different from their own. Nurses need to be open to the challenges presented by cultural diversity and seek the information they require to provide culturally sensitive care. In Australia for many years there has been recognition of the multicultural nature of the country but little emphasis on the care of Indigenous people (Crisp et al 2013).

### Consumer movement

The availability of information through sources such as the internet means that healthcare consumers are potentially better informed than ever before. The public's concepts of health and nursing have changed, and consumers are an effective force in changing nursing practice to meet consumer needs. As people are searching for ways to be free of disease the media helps to emphasise messages of health promotion and disease prevention, further driving consumers to become active participants in making decisions about health and nursing care, with most consumers now believing that good health is a right of all people and that they must assume responsibility for their own health (Berman et al 2015).

The **National Safety and Quality in Health Service (NSQHS) Standards** include 'partnering with consumers'. It requires healthcare facilities to work in partnership with individuals and consumers to improve the safety and quality of care. Healthcare should be an active partnership between consumers and healthcare providers, with a healthcare service that is responsive to the needs and input of individuals, carers

and consumers. Evidence shows that healthcare provided in partnership with consumers is associated with:

- Improved clinical outcomes
- Decreased rates of healthcare-acquired infections
- Improved delivery of preventative care services
- Improved adherence to treatment regimens
- Improved functional status.

(Australian Commission on Safety and Quality in Health Care 2012)

As consumers are becoming more health literate through the increased availability of information, the consumer movement and partnerships in healthcare are becoming a greater factor in the delivery of healthcare. Health literacy is discussed further in Chapters 5 and 6.

## Human rights movement

Respect for the right of all people to the optimal standard of nursing and healthcare is central to the philosophy of the nursing profession. This view is reflected in the codes of ethics and standards of all nursing professional organisations. Nurses need to be consciously aware of personal values and where they are likely to impact on the quality of care given to a person. Where problems arise, advice or support should be requested (Crisp et al 2013).

## Summary

An overview of the theories and models of nursing helps to demonstrate how theory can inform the way in which we view the person, health, the environment and nursing itself. This allows nurses to establish connections and meaning in nursing and facilitates continuity of care. The utilisation and application of nursing theory (in the form of philosophies, models and theories) help nurses think critically for professional practice. Theory and research together lead to a systematic inquiry, which informs practice (Daly et al 2014).

The profession of nursing is in a constant state of change. The evolution of nursing has brought us to the point where there are endless opportunities to improve the health and welfare of our individuals and the communities in which we live. The role of the EN and the RN has changed from that of a vocation to a role that emphasises education and professional standards, exemplified by the development of competencies for the EN and the RN and codes of ethics, as well as the national framework for decision making for nursing practice. The role of the EN is expanding and embracing new areas such as technology in healthcare. Some states and territories have developed an Enrolled Nurse Advanced Practice role. The challenge for the future will be to incorporate these changes into the role of the EN while still maintaining the standards of the profession and to ensure that each nurse understands each other's role.

## Review Questions

1. What are the themes that are common to the many different definitions of nursing?
2. The scope of practice of the EN is influenced by what factors?
3. The *Enrolled Nurse Standards for Practice* (NMBA 2016a) reflect three (3) domains of EN practice. List these domains.
4. What are the purposes of nursing theories and conceptual frameworks?
5. What does autonomy mean? How is it relevant in nursing?
6. What factors have impacted on the changing role and function of the nurse?
7. What is the difference between a theory and a model?
8. What role do ANMAC, AHPRA and NMBA play in nurse education?
9. What characteristics are said to make nursing a profession rather than a job?

Answer guide for the Review Questions, Critical Thinking Exercises, Decision-Making Framework Exercises and Critical Thinking Questions in Case Studies are hosted on Evolve: http://evolve.elsevier.com/AU/Koutoukidis/Tabbner/

CHAPTER 2

# Professional nursing practice: legal and ethical frameworks

*Kalpana Raghunathan*

## KEY TERMS

accountability
advance directives
advocacy
assault and battery
bioethics
common law
consent
civil law
criminal law
documentation
do not resuscitate order
ethical decision making
ethical dilemma
ethical principlism
ethics
false imprisonment
jurisdiction
legal issues
legal liability
legal responsibilities of nurses
legislation
malpractice
mandatory reporting
moral problems
negligence
nursing ethics
obligation
open disclosure
regulation
responsibility
restraint
rights
standards of care
torts
vicarious liability

## LEARNING OUTCOMES

At the completion of this chapter and with further reading, you should be able to:

- Define key terms
- Explain the legal concepts that apply to nursing practice
- Describe the legal responsibilities and obligations of nurses and notion of accountability
- Identify the steps to, and apply the decision-making framework for, nurses in professional practice
- Identify standards for care and professional conduct for nurses
- Identify and discuss legal issues that arise in nursing and impact on nursing practice
- Examine ethical principles and the importance of ethics to nursing practice
- Critically examine nursing ethics, ethical responsibilities and obligations of nurses and advocacy
- Identify and discuss ethical and moral issues that arise in nursing and impact on nursing practice
- Critically examine ethical dilemmas or moral problems that may arise in nursing
- Identify the steps and apply ethical decision making to deal with moral problems in nursing
- Outline a plan of nursing care for individuals across a lifespan in a range of healthcare contexts within legal and ethical parameters of nursing practice

## CHAPTER FOCUS

In recent years the role and scope of practice of Enrolled Nurses (EN) has rapidly expanded and evolved. Safe professional practice requires a sound understanding of the legal and ethical responsibilities and obligations that apply to nursing practice. This chapter introduces the EN student to the fundamental legal and ethical concepts relevant to the practice of nursing. The chapter identifies the legal and ethical frameworks for professional nursing practice in caring for individuals across a lifespan in a range of healthcare contexts. A deeper understanding of these requirements requires further reading.

The ethical standards that guide professional nursing practice are universal. However, the legal and regulatory aspects of nursing are different between countries, and within Australia may even differ between states and territories. Also, the legal and regulatory guidelines for professional practice are constantly subject to changes in laws. It is therefore essential that nurses familiarise themselves and update their knowledge about changing legal requirements that govern clinical practice in the legal and regulatory system in which they practise.

## LIVED EXPERIENCES

I have previously worked as an Assistant in Nursing and therefore am aware of certain aspects of nursing. Now that I am studying the course it has made me more aware of the legal and ethical aspects of nursing. The *Code of Conduct for Enrolled Nurses* must be adhered to at all times. I have learnt that if it has not been documented then it didn't happen and the potential ramifications of this could lead to legal investigation and the potential to be sued. Nurses have a responsibility and duty of care for their clients and patients. I have learnt that there are laws, policies, protocols and procedures that are in place to enable safe working practices and so therefore I need to work within my scope of practice.

**Ben, Enrolled Nursing Student**

# INTRODUCTION

In healthcare, legal and ethical frameworks provide guidelines for standards of care and professional practice. Legal and ethical standards govern the clinical practice of healthcare professionals. Nurses at all levels and areas of practice as healthcare professionals have certain legal and ethical responsibilities and obligations.

The healthcare environment today is complex and inherent, with different kinds of legal and ethical concerns with implications for professional practice. Cost and resource restraints tend to push organisations to focus on business values. The emphasis on individual or person-centred care in today's healthcare environment requires the nurse to respond appropriately to situations, value the person's needs and act in the interest of the individuals in their care. It is therefore essential that nurses, as members of the healthcare team, understand the legal and ethical frameworks within which they function to ensure the provision of safe and competent care.

# LEGAL ASPECTS OF NURSING PRACTICE

In Australia, the legal framework around nursing practice is based on the common laws and Acts of the Parliament relevant to nursing practice. Nurses should be aware of their legally defined rights and responsibilities, and should have an understanding of the laws that govern their personal and professional lives. Ignorance of a law is not accepted as an excuse for violation of that law.

As healthcare professionals, nurses have the **legal responsibilities** common to all members of society, and also the responsibilities imposed by the nature of their work, which may be defined as responsibilities in respect of:

- The provision of safe, effective nursing care
- The health of the community
- The employing authority
- The nursing profession.

(Berman et al 2015)

The functions of law in nursing are summarised in Clinical Interest Box 2.1.

## Common law system

Australia is referred to as a common law country. The **common law** system has its origins in the legal system and principles developed in England around the fourteenth century, which became the basis for the legal systems of its colonies. The English common law system forms the basis for the complex and sophisticated legal system that exists in Australia today (Atkins et al 2014; Staunton & Chiarella 2013).

In common law countries the source of law and the legal system is based on a combination of:

- Common law
- Acts of Parliament.

### Common law

Common law is the body of law made by judges as a result of decisions in cases that come before the courts (Staunton & Chiarella 2013). These decisions form precedents (legal principles) and can then be applied in similar cases. This body

## CLINICAL INTEREST BOX 2.1
## Functions of law in nursing

The law serves a number of functions in nursing:

- It provides a framework for establishing which nursing actions in the care of individuals are legal
- It differentiates the nurse's responsibilities from those of other health professionals
- It helps establish the boundaries of independent nursing action
- It assists in maintaining a standard of nursing practice by making nurses accountable under the law.

*(Berman et al 2015)*

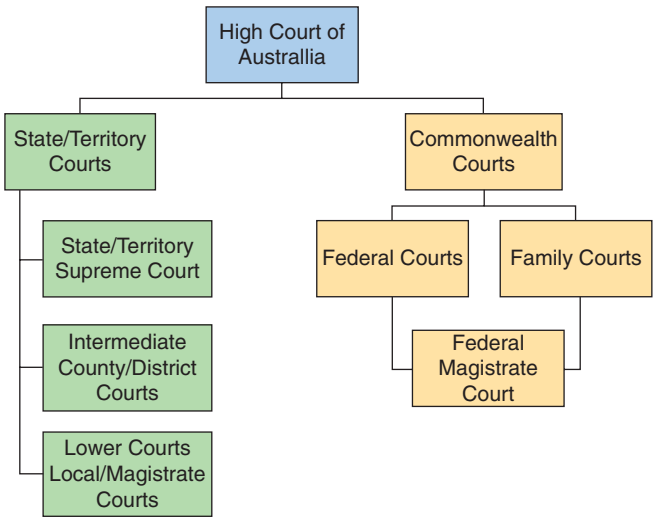

**Figure 2.1** Hierarchy of Courts in Australia

*(Adapted from Staunton & Chiarella 2013:12)*

of law is often referred to as case law and is equally as important as legislation (Forrester & Griffiths 2014). Some examples of common law that apply to nursing practice are the law of consent, the law of assault and battery and the law of contract (Kerridge et al 2013). In Australia there are different levels of courts consisting of judges and magistrates. The court systems for the Commonwealth and each state and territory are separate. The type of cases heard by each court will depend upon the relevant area of the constitution and the jurisdiction. Figure 2.1 shows the structure and hierarchy of the court system in Australia.

### Types of law

In understanding how laws function it is important to be aware of the distinctions between types of laws. Laws are classified as either:

- Criminal law or
- Civil law.

**Criminal laws** are concerned with offences against people and their property. The government makes rules as to what constitutes minimum levels of acceptable behaviour in society and seeks to enforce these rules through the police. A violation of a criminal law is called a crime, and it is sanctioned by some form of punishment, such as payment of a fine or imprisonment (Staunton & Chiarella 2013). Some examples of major criminal offences that can apply to nursing practice are murder, manslaughter, criminal assault and criminal negligence (Kerridge et al 2013).

**Civil laws** are concerned with the legal disputes between people and/or organisations and are concerned with differences over personal or property issues which people are unable or unwilling to resolve themselves (Staunton & Chiarella 2013). Such laws provide the means by which rights can be enforced and wrongs can be remedied. A person found to have broken a civil law will usually be required to pay monetary compensation to the person alleging personal or property loss or damage. Some examples of areas of civil law that can apply to nursing practice include legal and binding contracts, individual's safety, negligence, consent, freedom of movement and property. Under civil law, negligence and trespass to person is considered as a category of tort law.

**Torts** are civil wrongs committed by someone against a person or their property and interests, resulting in claims for compensation from the person responsible for causing injury or damage (Atkins et al 2014).

### Acts of parliament

The parliament has the power to make or unmake laws. Laws made by the Parliament are referred to as parliamentary or statutory laws and known as Acts of Parliament (Staunton & Chiarella 2013). Acts of parliament are the other major source of law and are commonly referred to as **legislation**.

Acts are accompanied by Regulations that give directions for the administration of the Act (Forrester & Griffiths 2014).

The Australian *Health Practitioner Regulation National Law Act 2009*, arising from the National Registration and Accreditation Scheme for health professions, is an example of an Act of Parliament. The Regulations accompanying this Act are administered by the Australian Health Practitioner Regulation Agency (AHPRA) which is responsible for ensuring that the intentions of this Act are followed in terms of regulating health professionals under the national accreditation scheme (see AHPRA website).

Nurses practising in Australia need to be aware that Acts may differ from state to state or territory and many health laws in relation to regulation of hospitals and healthcare services are within the **jurisdiction** of state and territory law. Some examples of Acts relevant to nursing practice are outlined in Clinical Interest Box 2.2. Nurses are bound by the laws of the place they reside and work in under state and territory jurisdiction. For example, if a health professional commits a legal offence in the line of work they are subject to the legal system in that state or territory.

### The employer

Healthcare institutions as employers are legally responsible for the acts committed by all employees during the course of

## CLINICAL INTEREST BOX 2.2 Specific Acts relevant to the nursing profession

- *Child Protection Act (or Children and Young Persons Act)*
- *Coroner's Act*
- *Drugs, Poisons and Controlled Substances Act*
- *Freedom of Information Act*
- *Health Practitioner Regulation National Law Act (Australia)*
- *Human Tissue Act, or Human Tissue and Transplant Act*
- *Mental Health Act*
- *Nurses Act*
- *Work Health and Safety Act*

their employment. This is referred to as the doctrine of **vicarious liability** and is relevant to all nurses. It renders an employer vicariously liable for an employee's actions committed during the course of employment (Brack 2014). For example, a hospital may be held liable due to negligence in duty of care for the person by the act or omission of care by a nurse causing harm or damage. However, the legal liability of the employer does not absolve a nurse from individual responsibility, and legal action can be taken against a hospital and a nurse or against a nurse as an individual if harm is caused by the actions of the nurse. Nurses have personal liability for activities carried out in the line of work and must ensure that they work within the scope of employment (Anselmi 2012). In the situation of nurses who are self-employed, they are solely responsible and liable for the harm caused by their actions.

It is the **responsibility** of healthcare employers to ensure that:

- Employees possess the required qualifications, registration and level of competence
- All legal requirements are met, including valid contracts of employment
- Safety standards are observed in relation to standards of care, buildings and equipment. (Staunton & Chiarella 2013)

## CRITICAL THINKING EXERCISE 2.1 Vicarious liability

A home care nurse is driving a health service car and runs over a pedestrian at a busy intersection. Consider the following scenarios:

- It is customary for home care nurses to drive service provider vehicles to make scheduled visits.
- The nurse was going home after completing all scheduled visits for the day.
- The nurse was eating her lunch in the car and was distracted at the intersection before the turn.

Was there negligence and, if so, is the home healthcare service provider liable?

## Nursing regulation

Broadly defined, **regulation** is any government measure enforced to seek control or change the behaviour of individuals or a group of people in society (Cusack et al 2013). The primary function of the nursing regulatory authority is to protect the health and safety of members of the public by ensuring that nurses are competent and fit to practise. The nursing profession in Australia is regulated by AHPRA under the National Registration and Accreditation Scheme for health professions. The *Health Practitioner Regulation National Law Act* came into effect on 1 July 2010, and the registration and accreditation of nurses is implemented through the national Nursing and Midwifery Board of Australia (NMBA). (See Online Resources at the end of this chapter for NMBA link.)

Note that the midwifery classification is separate to that of nursing. Under nursing there are three classifications:

1. Nurse practitioner
2. Registered Nurse
3. Enrolled Nurse.

By defining the terms under which a nurse may practise in each of the classifications of registration, the law protects the community by deeming the qualified nurse to be safe and competent to practise nursing. Nurses who do not fulfil the requirements of the standards, codes and guidelines for the nursing and midwifery profession may not practise as nurses or midwives. It is unlawful for a person to represent themselves as a nurse if they do not meet the requirements for practice. (See online resources for codes, guidelines and scope of practice for nurses.) (See Clinical Interest Box 2.3 for summary of *Code of Professional Conduct* and Chapter 1 for *Code of Ethics for Nurses*.)

As health professionals, an annual practising certificate or renewal of registration must be obtained from the nursing regulatory authority. The responsibility for ensuring that registration or enrolment fees are paid each year and demonstrating competence fit for practice rests with the individual nurse. Nurses have to meet the standards and requirements for registration or enrolment that govern professional practice. (See NMBA Online Resources and Chapter 1.)

The nursing regulatory authority is empowered to deregister nurses in certain circumstances; for example, a nurse's registration or enrolment may be cancelled if they unlawfully use a registration number or if they are found to be unfit for practice, guilty of misconduct or negligence in a professional respect.

In Australia it is a requirement that nursing students enrolled in an accredited program of study are also noted on the Australian Nursing and Midwifery Board student register. It is the responsibility of the education provider to ensure relevant details of students are provided to the regulatory

## CLINICAL INTEREST BOX 2.3
## Professional standards for nurses

**Professional codes for practice**

**Code of Professional Conduct for Nurses in Australia (Conduct Statements)**

1. Nurses practise in a safe and competent manner.
2. Nurses practise in accordance with the standards of the profession and broader health system.
3. Nurses practise and conduct themselves in accordance with laws relevant to the profession and practice of nursing.
4. Nurses respect the dignity, culture, ethnicity, values and beliefs of people receiving care and treatment, and of their colleagues.
5. Nurses treat personal information obtained in a professional capacity as private and confidential.
6. Nurses provide impartial, honest and accurate information in relation to nursing care and health care products.
7. Nurses support the health, wellbeing and informed decision making of people requiring or receiving care.
8. Nurses promote and preserve the trust and privilege inherent in the relationship between nurses and people receiving care.
9. Nurses maintain and build on the community's trust and confidence in the nursing profession.
10. Nurses practise nursing reflectively and ethically.

*(NMBA 2013b)*

## CLINICAL INTEREST BOX 2.4
## Recognising professional boundaries

*Questions to consider:*

- Is the nurse doing something the person needs to learn to do themself?
- Whose needs are being met—the person requiring care or the nurse's?
- Will performing this activity cause confusion regarding the nurse's role?
- Is the behaviour such that the nurse will feel comfortable in their colleagues knowing they had engaged in this activity, behaved in this way with a person in their care?

*(Australian Nursing and Midwifery Council and New Zealand Nursing Council 2010)*

authority on commencement of study. The primary purpose of the student register is to protect the health and safety of members of the public. There are greater numbers of nursing students in the clinical practice environment today and it is important to consider legal and ethical implications for clinical practice and safety of the students and the healthcare clients. (See NMBA Online Resources.)

### Professional boundaries

Professional nursing practice requires nurses to be aware of and understand the legal and professional boundaries within which they must function (Griffith & Tengnah 2013). Professional boundaries in nursing are the parameters within which nurses practise, to ensure that the limits of professional and therapeutic relationships with individuals in their care are not crossed. When a nurse crosses professional boundaries then that action is deemed as unprofessional conduct or behaviour. It is considered a misuse of the power vested in the professional over a vulnerable person in their care (Kerridge et al 2013).

Regardless of the healthcare setting, nurses in daily professional practice are faced with difficult decisions linked to professional boundaries. It is critical that nurses as healthcare professionals recognise the lines of separation from the person in their care and apply sound judgment in managing issues around professional boundaries. Common examples of professional boundary concerns in nursing practice are accepting gifts and services, entering into sexual relationships, entering into financial arrangements, access to health information and disclosing health information (Griffith 2013; Griffith & Tengnah 2013).

The professional boundaries for nursing practice in Australia are defined by guidelines and principles of safe practice prescribed by the Nursing and Midwifery Board of Australia. These are set out in the framework for professional practice guidelines, *Professional Boundaries for Nurses* (2010). The guidelines provide a framework of what constitutes the limits of professional behaviour in nurse–individual relationships and the decision-making tool is designed to assist with concerns relating to these situations. (See Clinical Interest Box 2.4.)

## CRITICAL THINKING EXERCISE 2.2
## Professional boundaries

The family of an elderly female resident at an aged care facility tell the nurse they would like to thank her for looking after their mother. They offer the nurse flowers and a box of chocolates. They also invite the nurse to visit them for a meal in their home.

What should the nurse do in this situation within the framework of professional boundaries?

# AREAS OF LEGAL LIABILITY IN NURSING

**Legal liability** means that a person is subject to certain legal **obligations**.

Nurses have legal responsibilities which arise from the fiduciary nature of the professional relationship with individuals in the health setting determined by laws and Acts (Atkins et al 2014). It is important for nurses to realise that

they are legally responsible for their own actions and that, although the EN works under the supervision of a Registered Nurse (RN), this does not relieve them of personal liability. Nurses have a responsibility, to themselves and the person in their care, to refuse to perform an activity if:

- They are asked to do something that is beyond the legal and professional scope of their role
- They have not been prepared to perform a function safely
- Directions are unclear, unethical, illegal or against the policies of the healthcare agency.

The nurse as a healthcare professional must work within their *scope of practice* and have a responsibility to be aware of the legal principles and concepts that impact on professional practice. The scope of practice for a nurse is determined by four factors:

1. The nurse's level of training and demonstrated competence
2. The nurse's context of practice and level of employment
3. State and Commonwealth legislation
4. The employer's policy framework.
   (Atkins et al 2014)

The framework for decision making with all professional encounters and work situations is outlined in the *Nursing Practice Decision Flowchart* (NMBA 2013a). The flowchart clearly identifies steps to guide nurses in making appropriate decisions in terms of evaluating the situation and the course of action to take (see Chapter 1). (See Decision-making Framework Exercise 2.1.)

## Contracts

A contract is an agreement between parties that is legally enforceable because of mutuality of agreement and obligation. A contract gives rise to **rights** and obligations that are protected and enforced by the law (Staunton & Chiarella 2013). The terms and conditions of the contract are binding on parties to the contract (Kerridge et al 2013).

A contract may be in writing or it may arise by implication, such as an agreement that is reached between an individual and a healthcare agency to which they are admitted. Although in this case the person is not required to sign a document, they will have entered into a contract as to the nature and extent of their proposed treatment with the healthcare agency or the medical officer. The expectation is that safe and appropriate care is provided.

An important form of contract for nurses is the contract of employment that nurses as employees enter into with their employer. Arising out of this contractual relationship are certain rights and obligations relevant to both the employee and the employer that are defined in a written contract of employment. Employment contracts are covered under the area of industrial law, and industrial awards impose specific provisions on employers relating to the health and safety of employees, the payment of wages and the provision of certain conditions. An industrial award is a document that sets out the wages and conditions of a particular group of employees and represents the contract of employment between the employer and the employee. A copy of each award can be obtained from the Fair Work Commission. Employers are required to have copies of the relevant awards available so that they are accessible to employees. Nurses have a responsibility to themselves to understand their contract of employment and their industrial award.

When starting each work shift, nurses engaged through nursing agencies are under contract to the health agency to which they have agreed to be allocated. A nursing agency is only an employment agency even though the nurse's pay may be processed through it.

## Standards of care

**Standards of care** are the guidelines or criteria for the standard of care that a nurse is expected to deliver (Kerridge et al 2013). Nurses have a responsibility to be familiar with the standard of care which includes the degree of care, skill and judgment they are expected to exercise and to understand the importance of not undertaking tasks outside their defined role and function. In the provision of healthcare delivery nurses must exercise a reasonable standard of care in order to meet the legal obligation for *duty of care* (Atkins et al 2014). There are a number of documents that help nurses to know the standard of care that is expected of them. Some are more binding and important than others, some documents set the minimum standards for practice and others clearly identify the standards to which nurses ought to aspire in daily practice. (See Online Resources for the range of documents including competency standards/standards for practice, codes and guidelines that identify standards of care.)

In Australia the *Enrolled Nurse Standards for Practice* (NMBA 2016) provide a regulatory and assessment framework to guide the scope of practice of Enrolled Nurses. These

### DECISION-MAKING FRAMEWORK EXERCISE 2.1

Mary, a 23-year-old female, is admitted for investigation and treatment. This is her second admission in six months. She presents with irritable bowel syndrome, chronic diarrhoea, severe weight loss and abdominal pain. Mary is fully investigated with no cause found. This time she confides in the nurse looking after her that she has been taking high doses of OTC aperient daily to keep her weight down. Mary has kept this a secret from her family and not told anyone.

How should you respond to this situation in accordance with legal and ethical aspects of nursing, and the decision-making framework for nurses?

documents are binding. For enrolled nursing students these documents set the minimum criteria for standards to be demonstrated to be eligible for entry into practice. Other sources of information to help nurses know the standard of care expected are healthcare agency policy and procedure manuals, government policy documents, professional organisations, evidence-based practice guidelines, nursing literature and specific **regulations** relevant to area of practice.

## Negligence

**Negligence** is a tort and means a civil wrong that relates to incidents where a person who suffers injury through a negligent act or omission can seek compensation from the person responsible for the negligence (Staunton & Chiarella 2013). If a nurse gives care that does not meet accepted standards, the nurse may be held liable for negligence; for example, if the nurse's actions result in harm to a person. Like other health professionals, nurses have a duty of care and, generally, negligence means failure by a nurse to take appropriate actions to protect the safety of the person in their care (Atkins et al 2014). This may involve failing to do something that should have been done, or doing something that should not have been done. Examples of negligence in nursing include incorrect administration of medications, failure to communicate important information about a person's condition, failing to take appropriate measures to prevent an injury and even failure to exercise reasonable care in giving advice to someone in their care.

### CRITICAL THINKING EXERCISE 2.3 Negligence

Mr Smith, 80, was admitted for cardiac surgery and is recuperating. On the day that the medical officer allows him to walk down the corridor with assistance, he asks you to help him do so. Mr Smith has thromboembolic disease (TED) stockings on and he has slippers in his locker. You get him out of bed and assist him to walk down the corridor, which has a newly polished linoleum floor. You forget to put on his slippers, although you knew about them. While walking down the hall, you turn to look out of the window at a commotion in the car park. As you are looking, Mr Smith's feet slip from under him and he falls to the floor and hurts his hip.

What are the elements of negligence and how do they apply to this case?

In the event of alleged negligence against a nurse the responsibility or the onus for proving negligence is with the plaintiff or the person alleging negligence. A plaintiff must prove four elements to succeed in an action for negligence:

1. That the nurse owed the plaintiff a duty of care
2. That the nurse breached this duty of care
3. That the plaintiff suffered injury or harm as a result of the breach
4. The harm was foreseeable.
(Atkins et al 2014)

### CLINICAL INTEREST BOX 2.5 Types of negligence that result in breach of duty of care and malpractice

- Failure to follow standards of care
- Failure to use equipment safely
- Failure to communicate adequately
- Failure to document adequately
- Failure to assess and monitor adequately.

*(Atkins et al 2014)*

The likelihood of injury to an individual and the risk of liability are reduced when the nurse adheres to the principles of sound nursing practice and follows the established policies relating to standards of care. The concepts of negligence and **malpractice** are often used together in legal terminology as negligent behaviour or actions can result in malpractice (Weld & Bibb 2009). The case of malpractice is more expansive and covers all conduct or actions that are improper during the course of performing duties that result in liabilities. Clinical Interest Box 2.5 lists categories of negligence that may result in malpractice.

## Defamation

The term 'defamation of character' refers to any communication, spoken or written, about an individual that injures their reputation. The term 'libel' is used when the communication is written, whereas the term 'slander' is used when the communication is spoken. With regard to nursing practice, everyone has a right to expect their privacy and confidentiality to be respected, and colleagues have a right to expect that their personal and professional reputations will not be harmed.

Nurses should therefore exercise extreme caution when discussing or documenting information relating to individuals in their care and when discussing members of staff. For example, a nurse may not be openly critical of the standard of care provided by another nurse. A nurse who is genuinely concerned about standards of nursing care should direct their concern through the proper channels and do so confidentially when making a complaint or report to senior administration (Mair 2014). Nurses should refrain from gossiping about colleagues, as this practice may lead to irreparable damage to an individual's personal or professional reputation. Nurses should avoid making statements in writing in healthcare records that may be interpreted as being of a defamatory nature. Nurses must ensure that all statements relating to a person are written in an objective rather than a subjective manner.

## False imprisonment

**False imprisonment** refers to the wrongful deprivation of a person's freedom of movement, such as restraining or detaining a person against their will (Atkins et al 2014). With

regard to nursing practice, there are certain situations in which a person may need to be restrained; for example, to protect them from injury, protect others from being injured or prevent damage of property. Nurses must be aware that the application of any **restraint** is only performed in consultation with the person's medical officer, and then only after very careful consideration. Written authorisation by a medical officer is generally required for the application of a restraint. Nurses need to know state laws and their organisation's policies regarding restraint of individuals. Apart from very specific instances, there are no powers to detain a person in a healthcare agency against their wishes, except when it is an involuntary admission under mental health legislation. The Department of Health and Ageing has guidelines for the use of restraints in health and aged care organisations. There must be a medical officer's order for the restraint which states the reason and time period. The order must be reviewed daily. Restraints can only be used after every other possible way of ensuring the safety of the person has been tried unsuccessfully. (See Chapter 15 for further discussion on the use of restraints.) All healthcare agencies have a document that a person is asked to sign if they decide to leave the agency against medical advice.

## Assault and battery

**Assault and battery** are considered criminal offences as well as breaches of civil law (Staunton & Chiarella 2013). Although the term 'assault' is used to describe both actions, there is a distinction between the two. Assault occurs when a threat to carry out unwanted and unlawful contact on another person is made, thereby causing that person to fear for their safety. Battery involves the direct, intentional and uninvited application of physical contact to another person's body that may or may not cause harm (Berman et al 2015).

### CRITICAL THINKING EXERCISE 2.4 Assault

A nurse became the subject of disciplinary action by the unit manager of an aged care facility after she was reported for assault by the family of a resident at the facility. The nurse was reported for sitting on the resident's bed and placing her hand on the resident's shoulder when she was visibly upset and distressed. The nurse had not asked the resident before doing so.

Has assault been committed in this situation? Give reasons for your answer.

In nursing practice, a nurse could intentionally or unintentionally commit an act of assault if they did anything in terms of touching someone in their care without consent. As many nursing activities involve direct physical contact with a person there is the possibility of committing assault and battery, which could result in an offence of trespass to the person if unwanted and unlawful contact is made (Mair 2014). The important factor in situations in which physical contact is involved is to make sure you have the person's consent.

## Consent

**Consent** is an agreement between two parties and can be provided in a number of ways (Staunton & Chiarella 2013). Consent is usually implied or expressed (Cole 2012; Rock & Hoebeke 2014). Implied consent is frequently given in the performance of nursing activities. For example, if a nurse requests a person in their care to hold out their arm so that they can measure their blood pressure, and the person does so, then they have implied their consent to that procedure. Expressed consent is given in verbal or written form. In the healthcare setting people frequently give consent verbally; for example, by agreeing to have a procedure performed. Written consent provides documentary evidence that consent was given. Before any invasive procedure or surgical intervention is performed a person is requested to sign a consent form. Although the primary responsibility for advising and informing the person about a particular treatment rests with the medical practitioner, frequently the task of witnessing the person's signature on consent forms is undertaken by nurses (see Clinical Interest Box 2.6).

Regardless of the form in which consent is given it must be valid. For consent to be valid it must be voluntarily and freely given. It should also cover the treatment to be carried out, and be given by a legally competent person who has sufficient information about the treatment or intervention to be performed. Nurses have a professional responsibility to ensure that the person receiving treatment or care is well informed, once the course of treatment is agreed upon (see Clinical Interest Box 2.7).

### CLINICAL INTEREST BOX 2.6 Steps to observe when witnessing a signature on written consent forms

- Ensure that all sections of the consent form are completed. Never ask the person to sign a blank consent form
- If the person wants to alter the consent form the treating medical practitioner must be informed immediately
- If the person asks questions about the nature of the procedure or treatment the treating medical practitioner must be informed immediately
- On contacting the treating medical practitioner, a relevant entry must be made in the health records including the medical practitioner's response
- If the person refuses to sign the consent form, the treating medical practitioner and appropriate administrative staff must be notified and the refusal documented in the health records.

*(Staunton & Chiarella 2013)*

## CLINICAL INTEREST BOX 2.7
### Elements of valid consent

1. That consent is given freely and voluntarily without coercion
2. That the person giving consent is fully informed
3. That the person giving consent is competent to make decisions.

*(Staunton & Chiarella 2013)*

## CRITICAL THINKING EXERCISE 2.5
### Consent

A graduate nurse wanted to observe and learn how to perform a complex wound dressing. This was an orientation week on a busy orthopaedic ward. The graduate nurse went into the patient's room and explained what she wanted. The patient agreed but her daughter who was in the room did not agree. The graduate nurse stayed and watched the procedure.

What are the issues or considerations in relation to consent in this situation?

Legal capacity to give consent is determined by age and the person's mental and intellectual function. Legal consent can only be given by a competent adult. If the person is unable to give consent specific legislation enables others to give consent on the behalf of that person (Staunton & Chiarella 2013). Parents and guardians can provide consent for children and minors. Under guardianship legislation a guardian or appointed authority may give consent for treating a mentally incompetent person. Mental health legislation allows non-consensual treatment of mentally ill persons. In circumstances when it is difficult to obtain consent, for example if the person is unconscious, consent can be obtained from someone legally authorised to give consent on behalf of them. If the situation arises that the person requires emergency treatment and it is impossible to obtain consent from that person, an authorised person may give consent. In the event of life-threatening situations, the overriding duty of care negates the need for consent and legislation enables medical intervention without consent. An example would be an unconscious person who has serious life-threatening injuries from a motor vehicle accident.

Informed consent is given when the person is provided with adequate information about, and understands, the procedure to which they are consenting. The person giving consent understands the risks and benefits involved as well as the actual procedure (Atkins et al 2014). When a nurse provides information to a person about the nursing procedure to be performed it is the responsibility of the nurse to ensure that the person consenting is competent to determine what treatment or care they will be subjected to. In the case of medical and surgical procedures it is the responsibility of the medical officer to provide the person with an adequate explanation of any proposed treatment. Informed consent for medical and surgical treatment is documented on a consent form, which is a legal record. This form is signed by the person giving consent to the treatment and the medical officer providing the information. In some healthcare facilities, a general medical treatment consent form is signed by the individual on admission for the treatment and care provided during the course of that admission. However, this does not include specific medical interventions that may be required to diagnose or treat the individual. Additional informed consent is required for diagnostics tests or procedures.

An important consideration with regard to consent is that a person has the right to withhold or revoke their consent at any time provided they are competent to do so. In this event they must be informed about any detrimental consequences of refusal (Atkins et al 2014). If either situation arises, the event must be reported immediately to the nurse in charge and the medical officer, and be documented.

### Right to receive information

Nurses as healthcare professionals are required to provide appropriate and sufficient information to the person in their care in accordance with the principles of informed consent. For example, nurses must inform the person before performing any procedures; this includes clearly explaining the purpose of the intervention or care, describing any potential issues or risks that may arise and obtaining permission from the person. The NHMRC (2004) *Guidelines for Medical Practitioners on Providing Information to Patients* set out the minimal information that needs to be communicated to patients by the medical practitioner. Nurses also have a professional responsibility to ensure that adequate information has been provided to the person about a particular treatment or procedure and to answer the person's questions in an honest and helpful way in relation to their care (Staunton & Chiarella 2013).

## Confidentiality and privacy

'Confidentiality' refers specifically to restrictions upon private information revealed in confidence, with an understanding that the information will not be disclosed to others; 'privacy' refers to ownership of one's own body or information about one's self (Kerridge et al 2013). Nurses have a legal and ethical obligation not to disclose confidential information acquired about individuals in their care, except when such disclosure occurs during the course of their professional duties (Griffith 2014). Information that may be classified as confidential and private may be anything related to the individual's condition, treatment being given, prognosis or anything relevant to a person's private life. Disclosure of such information may lead to legal action against the healthcare agency. Information concerning a person's health is protected by law. The requirement for nurses to observe a duty of confidentiality is stated in the Code of Conduct and *Code of*

*Ethics for Nurses*. (See Clinical Interest Box 2.3, Chapter 1 and Online Resources.)

Information communicated in nursing and medical records must be kept confidential and, therefore, nurses are responsible for protecting records from unauthorised readers. Information provided to other treating healthcare professionals should be kept to a need-to-know basis, and consent from the person must be obtained if a third party requires access to their healthcare records (Atkins et al 2014). A person's right to privacy must be respected and their affairs must not be discussed with other healthcare patients, non-professional staff or members of the general public. In the case of family members, information should only be divulged to the people involved in the care of the person. If someone has an appointed guardian, that person can have access to health information in order to make treatment decisions. For a child, the parent or appointed guardian is allowed access to the health information.

### CRITICAL THINKING EXERCISE 2.6 Confidentiality

Mrs Brown is a woman you are giving nursing care to. You know from her medical records and your handover report that she has been diagnosed with terminal cancer. You are told she does not want her family to know about her condition.

What do you say when Mrs Brown's daughter asks you if she is dying and why do you give this reply?

Discretion should be used by nurses during their off-duty hours and they should avoid careless chatter about the healthcare agency, any of the individuals in their care or staff members. Nurses must know the rules and policies that govern social media use and what information can or cannot be posted. In Australia the national board's social media policies and specific employer policies apply to all health practitioners—failure to comply can result in disciplinary action (Douglas 2014). See the *National Board Policy for Registered Health Practitioners: Social Media Policy* (AHPRA 2014). If approached at any time by a representative of an organisation, press, radio or television, a nurse should refrain from giving information but should refer the enquiry to the administrative section or other appropriate department of the healthcare agency. It is important that nurses are also alert to situations when a person asks them to keep a secret, because this information may relate to matters of harm to themselves or others, and will need to be acted upon appropriately as a healthcare professional.

### CRITICAL THINKING EXERCISE 2.7 Confidentiality and privacy

You are arriving at work and are in a crowded elevator. The conversation in the elevator revolves around a well-known celebrity who was admitted during the night following a motor vehicle accident.

How has this person's right to confidentiality been breached? What would you do in this situation?

## Mandatory reporting

In certain circumstances nurses as health professionals are compelled by law to disclose confidential information so that appropriate interventions or decisions can be made for the protection and safety of the persons in their care. This is referred to as **mandatory reporting** (Atkins et al 2014). The requirements for compulsory reporting and who is mandated to report vary slightly between states and territories. (See Clinical Interest Box 2.8.) In Australia nurses are legally bound to report suspected cases of child abuse or neglect by law as a health professional group, along with others who work with families, children and youth (Mathews & Walsh 2014). There are two types of duties under which nurses are required to report suspected child abuse and neglect: *duty of care* and *duties of professional or industrial policy.* Situations that require reporting, and who is mandated to report to child protection services, are clearly set out in the legislation, and these requirements vary between states and territories. The types of abuse or neglect that must be reported include physical or emotional abuse, physical or emotional neglect, sexual abuse and exposure. See the *Australian Institute of Family Studies Fact Sheet Mandatory Reporting of Child Abuse* (AIFS 2014). (See Clinical Interest Box 2.9.)

There are no mandatory reporting laws for reporting of elder abuse in Australia, but there are compulsory reporting requirements through the *Aged Care Amendment (Security and Protection) Act 2007*, whereby employers, staff, residents or anyone should report these cases to the Office of Aged Care Quality and Compliance. Elder abuse may include neglect or abuse that is physical, sexual, psychological, financial or social in nature (Atkins et al 2014:166).

Mandatory reporting is also an AHPRA requirement for all registered health professionals, their employers and

### CLINICAL INTERNET BOX 2.8 Situations that require mandatory reporting

- Certain deaths
- Injuries involving firearms
- Diseases that threaten public health
- Medical conditions that may result in harm to public
- Professional misconduct
- All crimes
- Abuse and sexual abuse of children
- Abuse of elderly
- Domestic violence (in Northern Territory)

*(Atkins et al 2014)*

education providers in order to protect the safety of the public and prevent individuals being placed at risk of harm. The Nursing and Midwifery Board of Australia *Guidelines for Mandatory Notification* (2014) provide nurses with a clear framework for understanding and interpreting legal obligations for reporting. Nurses have an obligation to report if there are reasonable grounds that a health practitioner has engaged in 'notifiable conduct' (see Clinical Interest Box 2.10).

## Documentation

Health records are important legal documents and it is therefore important that nurses keep accurate and complete records of all treatment and care administered to the person. Electronic health records are also becoming more common and it is essential that all health data is updated and stored appropriately. In the course of work a nurse is required to document information about the person on nursing care plans, progress notes, flow charts and any other care-specific documents used in the healthcare facility (see Progress Note 2.1). These health records are legal evidence of the interventions and care provided. A person's records may be required in legal proceedings; for example, as evidence in a case when treatment and care is disputed or where negligence has been alleged. Therefore, in addition to ensuring that any information is recorded accurately and concisely for the purpose of communication between members of the health team, accurate detailing of all relevant information is necessary to provide adequate explanation to a court of law. If a person's records are required in legal proceedings they will be subject to very close scrutiny by lawyers. Good quality **documentation** in such situations will provide a clear account and help nurses defend their case. Staunton and Chiarella (2013) list a number of important considerations for quality documentation (see Clinical Interest Box 2.11).

In the healthcare setting, guidelines and policies issued by the healthcare agency, professional organisations and state or territory governments must be adhered to in relation to healthcare records documentation and management. An example is the New South Wales Health Department *Policy Directive for Health Care Records: Documentation and Management* (NSW Health 2012). This policy document clearly sets guidelines for all aspects of healthcare records documentation and management (see Table 2.1 for a summary of the policy principles).

### CLINICAL INTEREST BOX 2.9 Grounds for reporting suspected abuse

- A person tells you that a child has been abused or neglected
- A child tells you that they have been abused or neglected
- Your own observations give you reason to believe that the child has been abused or neglected.

*(Atkins et al 2014)*

### CLINICAL INTEREST BOX 2.10 Notifiable conduct

Under section 140 of the *National Law*, 'notifiable conduct' is where a practitioner has:

- Practised the practitioner's profession while intoxicated by alcohol or drugs
- Engaged in sexual misconduct in connection with the practice of the practitioner's profession
- Placed the public at risk of substantial harm in the practitioner's practice of the profession because the practitioner has an impairment
- Placed the public at risk of harm because the practitioner has practised the profession in a way that constitutes a significant departure from accepted professional standards.

*(NMBA 2014)*

## Reporting of adverse events and clinical incidents

Nurses have an ethical and legal responsibility to report any accidents or incidents that occur within a healthcare agency. A written report must be made immediately after an accident or incident occurs in which the individual, a visitor or a member of staff was involved, even when no injuries appear to have been sustained or the incident seems trivial. Healthcare agencies have special forms, often an electronic incident reporting system, for this purpose. Reporting of adverse events and clinical incidents provides a source of information to improve the quality of care and to evaluate the effectiveness of policies (Staunton & Chiarella 2013). Requirements for reporting adverse incidents may vary between healthcare

### PROGRESS NOTE 2.1

| | |
|---|---|
| 21/02/2015<br>1645 hrs | Nursing: Mr Smith complained of mild pain to lower back at 1600 hours. Requested some analgesics. Administered as per PRN orders: Paracetamol 1000 mg, 6-hrly order. Assessed 1630 hours, patient states the pain is settling. To be reviewed by RMO on PM round. Nil other issues at time of report. (EN, Bloom, K.) |

## CLINICAL INTEREST BOX 2.11 Quality documentation

**Important considerations for quality documentation**

- Reports should be accurate, brief and complete
- Reports should be legibly written
- Reports should be objectively written
- Entries in reports should be made at the time a relevant incident occurs, or as soon as possible after the incident
- Abbreviations should not be used in reports unless they are accepted within the healthcare organisation and there is a policy acknowledging this or they are widely acknowledged medical abbreviations
- If medical terminology is used in reports, the nurse should be sure of the exact meaning, otherwise it could prove misleading
- Any errors made in recording should be dealt with by drawing a line through the incorrect entry and initialling it before continuing
- No entry concerning the person's treatment should be made on behalf of another nurse
- All reports need to be dated and signed.

To reduce the risk of an incorrect entry being made:

- Don't make an entry in a person's health record before checking the name on the record
- Don't make an entry in a person's health record by identifying room or bed number only
- Make sure the person's name and identifying number is on every sheet/page of the document before making an entry
- Avoid wherever possible making notes concerning a person on loose paper for rewriting later into the person's notes

*(Adapted from Staunton & Chiarella 2013)*

providers and within state and territory jurisdictions. The incident reporting systems within each state and territory are guided by policy developed in conjunction with the Australian Commission on Safety and Quality in Health Care (ACSQHC) *National Safety and Quality Health Service Standards*. An example of a reporting system is the Victorian Health Incident Management System (VHIMS) which is guided by the *Victorian Health Incident Management Policy* and provides a structured framework for reporting (State of Victoria Department of Health 2011). It is important that nurses familiarise themselves with the correct reporting requirements for their area of work and jurisdiction.

There is always a possibility that the 'aggrieved person' may take legal action, in which case the written report becomes a very important document. The information included in the report must be factual, clear, concise and objective. Personal opinions must not be included, and care must be taken to avoid using terms that could be misinterpreted. For further details on documentation and reporting skills, refer to Chapter 18. Examples of adverse events that may be reported are listed in Clinical Interest Box 2.12.

## Witnessing wills

In the healthcare setting a person wishing to make a will should be given all the assistance required but it is policy in most healthcare agencies that nurses cannot act as witnesses.

## Coroner's court

A coroner's court is presided over by a magistrate called a **coroner**. The coroner is a government official. The role of the coroner is to detect unlawful homicide and reportable deaths (Atkins et al 2014). The legislation and title of the Act dealing with the role and functions of coroners is the same in all states and territories, and is the *Coroners Act.* (See Clinical Interest Box 2.13.) A coroner is required to investigate any death that was unexpected, or if the person died in unusual or violent circumstances. An inquest into a death may be conducted as long as several years after the event occurred and, in the case of an inquest arising out of a person's death in a healthcare

**TABLE 2.1 | Example of policy principles for healthcare records**

| THE NSW HEALTH POLICY DIRECTIVES PRINCIPLES FOR CREATION, MANAGEMENT AND DISPOSAL OF HEALTHCARE RECORDS (NSW HEALTH 2012) | | |
|---|---|---|
| • Individual records | • Completeness and comprehensiveness | • Quality improvement, review, evaluation and research |
| • Continuity of care | • Responsibility for documentation | • Durability |
| • Confidentiality | • Timeliness of documentation | • Storage and security |
| • Authenticity | • Ownership | • Retention |
| • Relevance | • Access | • Disposal |

## CLINICAL INTEREST BOX 2.12 Examples of clinical incidents that must be reported

- Procedures involving the wrong patient or body part resulting in death or major permanent loss of function
- Suicide of an inpatient or serious self-harm, suicidal behaviour
- Retained instruments/material after surgery requiring re-operation/further surgical procedures
- Intravascular gas embolism resulting in death or neurological damage
- Haemolytic blood transfusion reaction resulting from ABO incompatibility
- Medication error resulting in death of a patient
- Maternal death or serious morbidity associated with labour or delivery
- Infant discharged to wrong family or infant abduction
- Adverse events resulting in serious patient harm or death
- Fetal complications associated with healthcare delivery
- Delay in recognising or responding to clinical deterioration
- Complications of resuscitation or anaesthetic management
- Complications of surgery
- Complications of an inpatient fall
- Infection control breaches
- Unexpected death of a mental health patient/consumer
- Absconding of any mental health patient/consumer
- Therapeutic equipment failure/medical device incident
- Hospital-acquired pressure injuries
- Clinical deterioration of a mental health patient resulting in harm (physical, verbal or sexual) to staff, other patients or other persons.
- Inappropriate treatment/s.

*(Department of Health, Western Australia 2015:6)*

agency, a nurse may be called upon to give evidence. If this situation arises, nurses are advised to seek legal advice before giving a statement to the police or appearing in court. The healthcare agency through which the nurse is employed will generally ensure that they are represented by the agency's legal representatives. Alternatively, a nurse can be represented by the professional nursing organisation of which they are a member.

All deaths that occur in the healthcare environment are not subject to a coronial inquest. It is only reportable deaths defined by the *Coroners Act* of the state or territory that are investigated by the coroner, and this varies between jurisdictions. See Clinical Interest Box 2.14 for examples of reportable deaths.

## CLINICAL INTEREST BOX 2.13 The role of the coroner

The primary task of the coroner is to establish the following facts in the event of a coronial investigation:

- That death occurred
- The identity of the deceased
- The date, place, manner and cause of death
- The cause of fires or explosives if relevant.

*(Staunton & Chiarella 2013)*

## CLINICAL INTEREST BOX 2.14 Examples of reportable deaths (this may vary between jurisdictions)

- The identity of the person who has died is unknown
- The death of the person was violent or unnatural
- The death of the person happened in suspicious circumstances
- A 'cause of death' certificate has not been issued and is not likely to be issued for the person
- The death of the person was a healthcare-related death
- The death of the person occurred in care
- The death of the person occurred in custody
- The death of the person occurred as a result of police operations.

*(Coroners Act 2003, Office of the Queensland Parliamentary Council. © The State of Queensland)*

## Right to refuse treatment

It is the legal right of a person to refuse medical treatment under the common law jurisdiction (Johnstone & Kanitsaki 2009). To give or force treatment without consent will result in the nurse being liable for charges of assault and battery. Examples of situations when a person's right to refuse treatment may arise in daily practice include decisions by the person to refuse their medication, refuse to have a procedure performed or refuse blood transfusions or organ donations due to their religious or personal values. In some situations, terminally ill individuals may decide not to have certain treatments. A person can also withdraw consent at any time during their treatment or care. (See Case Study 2.1.)

## End-of-life care

The most important considerations for nurses when caring for a person who is dying are to respect the wishes of the person and provide care that is appropriate to their needs. This requires the nurse to be familiar with important factors, including legal implications associated with providing end-of-life care (McGowan 2011). It is the responsibility of the nurse to ensure that the person's needs and concerns are

### CASE STUDY 2.1 RIGHT TO REFUSE TREATMENT

Mr Mill is a 73-year-old man diagnosed with pancreatic cancer. The treatment is to undergo a total pancreatectomy which will offer a 50% chance of curing the cancer. The operation carries a 5% risk of mortality and a 100% side effect of insulin-dependent diabetes and probable ongoing problems related to malabsorption syndrome. Without the surgery Mr Mill is likely to live reasonably well for the next 6 to 12 months. Beyond this period he will require palliative care and die from the cancer. Mr Mill discusses this with his family. He decides against the operation.

Will the legal right of the individual to refuse medical treatment apply in this case?

### CLINICAL INTEREST BOX 2.15 Advance care directives

Usually advance care directives are made by:

- The very elderly, who wish to avoid futile, painful and undignified care in the event of cardiac arrest or stroke
- Those with a terminal illness who do not wish to prolong their lives
- Those undergoing dangerous medical procedures.

*(Atkins et al 2014)*

communicated and discussed with everyone involved in their care. Nurses are required to ensure that every aspect of care and the discussions and planning of care are documented. Promoting quality end-of-life care and person-centred care is a primary focus in palliative care nursing. Nurses should ensure that special religious and cultural practices associated with providing end-of-life care are considered. Australia is a multicultural society and it is therefore important for nurses to become familiar with the special needs of people from different cultures. Nurses working with Indigenous people must respect the special rituals and practices related to death and care of the body. In Australia, approach to end-of-life care is guided by policy, legislation and set standards for care. Legislation pertaining to end-of-life care is placed at state and territory levels and there are variations in the application of these laws. There are two main areas of the legislation and these are concerned with nomination of a substitute decision maker and the laws concerning advance care directives (ACSQHC 2013a). The *Standards for Providing Quality Palliative Care for all Australians* (Palliative Care Australia 2005) provide guidelines for quality management of care. (See also Chapter 38.)

## Advance directives

**Advance care directives** are documented statements that enable a competent adult to specify their wishes with regard to parameters for future medical treatment that can assist healthcare providers in decision making in the event that the person is not able to participate in decisions regarding treatment (Atkins et al 2014). Examples of specific wishes may include decisions relating to artificial ventilation, organ donation, blood transfusion, nutrition and do not resuscitate orders. Advance directives may also incorporate instructions with regard to nominating another person with enduring power of attorney for medical treatment decisions on their behalf. Often a family member or relative may be identified to make health treatment decisions (Jeong et al 2010). In Australia, terms governing substitute decision making vary from state to state. There are some differences in the legislation related to advance directives between states and territories for healthcare procedures and in the event of future terminal or life-limiting illness (Atkins et al 2014). The *National Framework for Advance Care Directives* (AHMAC 2011) document identifies policy and best practice guidelines for advance care directives within the context of jurisdictional differences in law and processes. When following advance care directives nurses should take steps to ensure that care directives comply with legislation and policy, the wishes of the person are current and the document is up to date. For more information on advance care directives and care planning refer to the *Advance Care Planning Australia* website. (See Clinical Interest Box 2.15.)

## Do not resuscitate orders

The '**do not resuscitate order**' (DNR) is also referred to as 'not for resuscitation order' (NFR). This order is written by the medical practitioners in the person's medical record following a decision to not attempt to resuscitate the person if further intervention or treatment is considered futile or unwanted. Such decisions are made to prevent the use of cardiopulmonary resuscitation if the person stops breathing or their heart stops beating. The requirements for NFR orders vary between states and territories and nurses should consult the Department of Health policy guidelines. The order for NFR must conform to the law of consent, and is based on an expressed decision by the person, their family and medical practitioners. If the person is not capable, their family or agent with the medical power of attorney must be involved in the discussions. The reason behind the decision and the DNR or NFR order must be documented clearly in the person's medical records and reviewed regularly, including for each admission into the healthcare facility (Forrester & Griffiths 2014). Within the healthcare setting forms for documenting the NFR orders vary between facilities. An example of a NFR document is the *Medical Order for Life Sustaining Treatment* form which contains a DNR or NFR section for detailing decisions about and the extent of medical interventions.

## Open disclosure

**Open disclosure** is the open discussion of adverse incidents that have resulted in harm or potential harm while receiving

**TABLE 2.2 | Open disclosure framework**

**THE ELEMENTS OF OPEN DISCLOSURE**

- An apology or expression of regret, which should include the words 'I am sorry' or 'we are sorry'
- A factual explanation of what happened
- An opportunity for the individual, their family and carers to relate their experience
- A discussion of the potential consequences of the adverse event
- An explanation of the steps being taken to manage the adverse event and prevent recurrence.

| *The guiding principles of open disclosure framework* | *Open disclosure process (key considerations and actions)* |
|---|---|
| 1. Open and timely communication<br>2. Acknowledgement<br>3. Apology or expression of regret<br>4. Support, and meeting the needs and expectations of individuals, their families and carers<br>5. Support, and meeting the needs and expectations of those providing healthcare<br>6. Integrated clinical risk management and systems improvement<br>7. Good governance<br>8. Confidentiality | 1. Detecting and assessing incident<br>2. Signalling the need for open disclosure<br>3. Preparing for open disclosure<br>4. Engaging in open disclosure discussion<br>5. Providing for follow up<br>6. Completing the process<br>7. Maintaining documentation |

*(ACSQHC 2013b)*

healthcare with the person, their family and carers (ACSQHC 2013b:11). The open disclosure process involves communicating openly when healthcare does not go to plan and harm has been caused. Adverse incidents such as medical errors, near miss and no harm, procedural errors or injury during treatment or procedure should be disclosed to the person. The level of response required in these situations will be determined by the seriousness of the adverse event and its consequences. Open disclosure is embedded in professional ethics for health professionals and it is a legal requirement in line with acting in the best interests of the person, duty of care and the individual's right to information. The person affected should be informed of the errors or harm that may have been caused so that they can seek appropriate and timely interventions. Experienced or senior staff should facilitate the process of open disclosure. Care must be exercised with all documentation and communications as these records may be required as evidence in legal proceedings. There may be legal liability and disciplinary proceedings for staff involved depending on the nature of incident. The Australian Commission for Safety and Quality in Health Care *Australian Open Disclosure Framework* (2013b) provides clear guidelines for open disclosure. The framework for open disclosure is intended to contribute to improving the safety and quality of healthcare. Table 2.2 provides a summary of the framework. See Case Study 2.2.

### CASE STUDY 2.2 OPEN DISCLOSURE

Mr Cohen is an 85-year-old man admitted for a day procedure. He has a routine endoscopy for investigating abdominal pain. The nurse assisting the medical officer on this procedure is an Enrolled Nurse (EN). The EN has been working in the endoscopy theatre for 3 months. For the procedure a paediatric mouth bit was used to assist during the scope to protect Mr Cohen's mouth and teeth. The EN was responsible for managing the device during the procedure. When Mr Cohen was returned to the recovery unit after the procedure a broken tooth was found on his pillow.

Apply the principles and process for open disclosure in this case.

## LEGAL RESPONSIBILITIES OF NURSING STUDENTS

Nursing is a practice-based profession and this requires students to touch individuals when providing care and to be exposed to the professional environment in order to learn nursing skills properly. Therefore, those involved in the education and supervision of students, and the students themselves, all carry the responsibility for ensuring that students are properly supervised and are never put into a situation where the person's safety and wellbeing might be at risk in any way (Kerridge et al 2013). Supervisors and students should ensure that they are adequately prepared to undertake new skills in the clinical environment and also that they have had previous practice in nursing skills laboratories. Students must be supervised by an experienced and competent nurse either from their tertiary education institution or from the clinical environment in which the student is placed. If students are uncertain about procedures in the clinical

environment it is their responsibility to inform their supervisor and seek clarification.

During the course of their nursing studies many students often find work as Assistants in Nursing. In these situations it is important to recognise that, while such employment will undoubtedly provide valuable experience, the student is employed as an unqualified member of staff and should not take on responsibilities outside the scope of that role (Berman et al 2015).

In Australia, under national legislation nursing students enrolled in an approved program of study at a tertiary institution are registered with the Nursing and Midwifery Board of Australia for the duration of their education and clinical training as a student. The core role of this Board is to protect the public: everyone is entitled to expect to receive a safe standard of care, regardless of whether the care is delivered by a registered or student nurse. Education providers now require students to provide evidence of criminal checks prior to undertaking professional practice placements. The Nursing and Midwifery Board of Australia requires reporting of prior criminal history when applying for registration, and a person may be denied registration even though they have completed their qualifications if there is a criminal record. (See Online Resources at the end of this chapter for NMBA link for information about student registration.)

## LEGAL ISSUES IN THE NURSING SPECIALTIES

Professional nurses work in various areas of nursing specialties and it is important to be aware of specific **legal issues** that impact on these areas of practice. The situational context of professional practice requires nurses to be familiar with different expectations of the roles, organisational policies and procedures, and specific legislative elements that are related to the particular healthcare environment.

Some examples of issues in different nursing specialties or disciplines are highlighted in Table 2.3. Nurses must be aware of the specific issues that may impact on their daily practice when working in these areas. These issues also raise many important considerations in terms of adequacy of skills and staffing, supervision and scope of practice relevant to the area of work.

## ETHICAL ASPECTS OF NURSING

As healthcare professionals it is essential that nurses have an understanding of ethics and what it means to practise ethically in an increasingly complex and changing healthcare environment. Healthcare professionals are bound by a strict code of professional practice and ethical standards for conduct.

Whilst the legal aspects of nursing require nurses to act in accordance with the laws and regulations for professional practice, ethical practice is concerned with professional conduct guided by knowledge of what is right or wrong and what is expected and responsible behaviour when dealing with difficult and complex situations in professional practice (Johnstone 2011). Broadly stated, 'the law describes the minimum standards of acceptable behaviour and ethics delineates the highest standards of moral behaviour' (Dahnke & Dreher 2006).

The importance of attention to ethics in healthcare is necessary because of factors such as the rapid advances in medical care and technology, issues in allocation of limited healthcare resources, questions related to quality of life and issues in prolonging life, and the protection of individual rights. The primary concern of the healthcare team must be the provision of the very best standard of healthcare and, to achieve this, it is necessary for all team members to respect the abilities and functions of their co-workers and observe *ethical standards*. Professional groups each have a code of ethics that consists of standards of conduct that members of the group are expected to follow. Refer to Chapter 1 for the *Code of Ethics for Nurses*.

### Ethics

**Ethics** may be defined as a set of moral principles that imply a commitment unrelated to monetary reward or prestige and which are derived from a system of values and beliefs concerned with rights and obligations. Ethics is concerned with ascribing moral values to, or passing moral judgment on, such things as people, situations or actions. Ethics is also concerned with the justification of such moral ascriptions (Fry et al 2011; Johnstone 2011; Kerridge et al 2013).

Ethics involves different moral and philosophical positions regarding what is good and what may not be right. A number of different theoretical perspectives may be applied to guide ethical behaviour. The well-known ethical theories are deontological ethics, teleological ethics, moral rights theory, virtue ethics and ethical principlism. In nursing practice and healthcare 'ethical principlism' is a commonly applied framework for analysing ethical issues and moral decision making (Johnstone 2011). (See Clinical Interest Box 2.16.) Over time different important principles emerge and impose order in a situation, highlighting central considerations in solving complex issues and in assisting decision making (Grace 2014).

#### Ethics and morality

It is important to understand that the terms ethics and morality are used together and interchangeably in ethical discussions. The term 'ethics' comes from the ancient Greek *ethikos* and 'morality' comes from the Latin *moralitas*, and they both relate to 'custom and habit'. Essentially the terms ethics and morality are used to describe various ways of thinking about and understanding beliefs and values about morally right and wrong behaviour (Butts & Rich 2013; Grace 2014; Johnstone 2011).

In the course of daily practice nurses are frequently confronted by difficult ethical issues and moral dilemmas. Consequently, conflict may arise over philosophies, personal values and professional responsibility. It is most important that nurses have an understanding of their own values and how ethical problems may be resolved without compromising personal values (Johnstone 2014).

## TABLE 2.3 | Examples of legal and ethical issues in nursing specialities

### ISSUES IN DIFFERENT NURSING SPECIALTIES

| Medical/surgical nursing: | Critical care nursing: | Perioperative nursing: |
|---|---|---|
| • Restraint minimisation in acute settings<br>• Provision of appropriate standards of care by qualified nurses<br>• Ensuring informed consent for medical treatment and care<br>• Competency of nursing staff providing care<br>• Adequate staffing levels for safe and competent care<br>• Working with multidisciplinary healthcare team<br>• Emphasis on care across the lifespan and person-centred care | • Need for highly specialised skills and ongoing professional competence<br>• Adequate staffing ratios in intensive care areas<br>• Minimising reliance on intensive care setting apparatuses and equipment<br>• Focus on person-centred care and client assessment<br>• Decisions regarding life support or sustaining treatments<br>• Do not resuscitate orders and end-of-life issues<br>• Informed consent issues in critically ill individuals | • Anaesthetic and recovery room nursing specialised skills<br>• Ongoing professional competence<br>• Working with different individuals across the lifespan<br>• Legal liability for smooth functioning of operating room procedures<br>• Sterilisation of equipment, instrument and swab counts |
| **Gerontological/aged care nursing:** | **Community health nursing:** | **Hospital in the home:** |
| • Issues in caring for the elderly related to confusion and dementia<br>• Preventing and minimising use of restraint<br>• Physical layout and design of facilities suitable for the elderly<br>• Ensuring quality of life and choices for the elderly<br>• Protecting the rights of the elderly in residential care facilities<br>• Ensuring safety and accessibility for the elderly in different care environments<br>• Workforce issues and adequate staffing to provide appropriate standard of care<br>• Reporting of abuse | • Working with different individuals across the lifespan (e.g. family health, child health)<br>• Different role expectations in community settings (e.g. more autonomous practitioners)<br>• Working in different settings (e.g. schools, community centres, clinics, general practice settings, homes)<br>• Working collaboratively with other healthcare team members for timely and appropriate care<br>• Awareness of public and community health issues, immunisation, child abuse, workplace safety, personal safety | • Clinical specialisation<br>• Working with different individuals in their home settings<br>• Need for careful documentation of all aspects of care<br>• Initiating prompt referrals to other services or healthcare team members |
| **Rural and remote area nursing:** | **Indigenous health:** | **Accident and emergency department:** |
| • Lack of healthcare professionals<br>• Problems of remoteness, costs and limited access to healthcare services<br>• Issues of ensuring appropriate standards of care for the remote community<br>• Different role expectations as remote area healthcare professionals (e.g. lack of emergency services, sole practitioners, level of responsibility)<br>• Professional isolation and limited access for continuing professional development | • Providing culturally appropriate care<br>• Providing right type of care at the right time by the right person in the right place<br>• Lack of trained healthcare professionals<br>• Limited culturally acceptable services<br>• Problems of remoteness, costs and limited access to healthcare services<br>• Different role expectations as healthcare professionals<br>• Lack of emergency services<br>• Sole practitioners, greater level of responsibility, reporting issues | • Requirement for highly specialised skills<br>• Level of responsibility and decision making<br>• Dealing with aggressive and violent individuals, high-risk individuals, personal safety<br>• Premature departures by individuals without adequate screening<br>• Need for careful documentation of all emergency staff involved<br>• Reporting incidents to authorities (e.g. road accidents, crime injuries, abuse) |

**TABLE 2.3 | Examples of legal and ethical issues in nursing specialities—cont'd**

| Mental health nursing: | Child health: | |
|---|---|---|
| • Protecting rights of mentally ill individuals<br>• Ensuring appropriate treatment and supervision of mentally ill individuals<br>• Restriction on liberty of mentally ill persons<br>• Participation/involvement in decision making<br>• Voluntary and involuntary patients, community treatment orders, restraint<br>• Controversial treatment modalities for mentally ill persons<br>• Mental health legislation | • Specialist skills in children's health<br>• Suitability of healthcare facility areas for treating and caring for children<br>• Safety and security issues for children's wards<br>• Informed consent for treatment from parents or guardians on behalf of children<br>• Screening of healthcare staff working with children<br>• Screening of visitors in children's wards<br>• Mandatory reporting of child abuse | |

*(Crisp et al 2013; Eckermann et al 2010; Ellis et al 2014; Hutchinson & East 2014; Mathews & Kenny 2008; Staunton & Chiarella 2013; Willis & Black 2013)*

## CLINICAL INTEREST BOX 2.16 Ethical principlism

**Ethical principlism** is the view that ethical decision making and problem solving is best undertaken by appealing to sound moral principles. Four key bioethical principles guide moral reasoning in healthcare practice:

1. Autonomy
   Autonomy refers to a person's independent ability to decide. Applied in nursing and healthcare contexts, the principle of autonomy imposes on healthcare professionals a moral obligation to respect a client's choices regarding recommended medical treatment and associated care.
2. Non-maleficence
   Non-maleficence is avoiding harm or hurt. Applied in nursing and healthcare contexts, the principle of non-maleficence would provide justification for condemning any act that unjustly injures an individual or causes them to suffer an otherwise avoidable harm.
3. Beneficence
   The principle of beneficence is to act for the benefit of others; that is, to promote their welfare and wellbeing. Beneficent acts can include care, compassion, empathy, sympathy and kindness.
4. Justice
   Justice can be conceptualised in many ways, such as mercy, harmony, equality and fairness. Of pertinence to healthcare are the conceptualisations of justice as fairness and as an equal distribution of benefits and burdens.

*(Beauchamp & Childress 2013)*

## Nursing ethics

In Australia **nursing ethics** are strongly influenced by the bioethics movement. The principles underpinning moral reasoning are the 'four principles of bioethics': autonomy, non-maleficence, beneficence and justice (Beauchamp & Childress 2013). The term **bioethics** originates from the ancient Greek *bios* meaning 'life' and *ethikos*, *ithiki* meaning 'ethics'. The bioethics movement originated in the United States and its main focus is the rights and duties of healthcare clients and healthcare professionals; the rights and duties of research subjects and researchers; and the formulation of public policy guidelines for clinical care and biomedical research (Reich 1995 cited in Johnstone 2011:14). (See Clinical Interest Box 2.17.)

Nursing ethics is defined as 'the examination of all kinds of ethical and bioethical issues from the perspective of nursing theory and practice, which in turn rests on the core concepts of nursing' (Johnstone 2011:16). The nursing profession has its own code of ethics, which is a statement about expected standards of behaviour and which is used to guide ethically sound professional nursing conduct and practice. The International Council of Nurses (ICN) formulated an *International Code of Nursing Ethics* (1973) outlining the nurse's responsibilities to individuals, to society, to nursing practice, to co-workers and to the nursing profession.

The Code of Ethics is not a set of rules, but a guide for nurses to base their professional decision making upon. Society expects professional people such as nurses to behave with integrity, dignity, competence and compassion. The *International Code of Nursing Ethics* and the *Code of Ethics for Nurses in Australia* provide nurses with guidelines to assume personal responsibility for providing a standard of excellence in clinical practice. Every nurse is responsible for determining and implementing desirable standards of nursing practice and

## CLINICAL INTEREST BOX 2.17 Common bioethics topics

- Abortion
- Euthanasia and assisted suicide
- Organ transplantation
- Reproductive technology
- Person's right to privacy and confidentiality
- Informed consent
- Economic rationalisation of healthcare
- Research ethics
- Institutional ethics committees

*(Johnstone 2014)*

for following ethical standards in their professional conduct and in the care they deliver (Atkins et al 2014). The nurse has a responsibility to participate actively in developing a body of professional knowledge and the skills necessary to promote safe and effective nursing care as an integral part of continuing competence (see the NMBA website for requirements).

### Accountability and responsibility in nursing practice

Individual nurses assume responsibility for performing specific activities related to the care of individuals; that is, nurses are responsible for their own actions as professionals. It is, therefore, essential that all nurses understand the scope of functions and duties associated with their role.

The concept of **accountability** means that nurses are responsible, legally, ethically and professionally, to themselves, to individuals in their care, to their employing institution and to the nursing profession (Plant et al 2010). Whenever nurses deliver nursing care, they must be able to answer for their own actions. Even if a task is delegated to another nurse, accountability for the outcome of the action includes the nurse assigned to perform the task and the nurse delegating the task. For example, the nursing supervisor assigns the aspect of direct care to individual nurses on a shift but remains responsible and accountable for the overall supervision of the provision of care during the shift. The individual nurse is responsible and accountable for all the direct nursing care provided to the individuals during the shift.

Accountability for nurses includes the moral responsibility to report any behaviour that endangers a person's safety, providing individuals with adequate information about their care, maintaining high ethical standards in their own practice and following the policies and guidelines developed by their employing institution and their professional organisation to promote the delivery of safe and effective nursing care. The regulatory authorities can refer to the various codes to guide them when they are considering situations of alleged misconduct. The concept of accountability for nurses is incorporated into the professional standards and the codes for professional conduct and ethics.

## CRITICAL THINKING EXERCISE 2.8 Interpreting accountability and responsibility

Tom, a Registered Nurse, is the supervisor on duty at a residential aged care facility. The facility is divided into pods. After receiving handover from the night staff Tom delegates and allocates the care of residents to the team. The care team consists of Enrolled Nurses and personal care assistants. Medications are administered by delegated Enrolled Nurses for each pod in the wing. During morning tea one of the care team members finds some medication on the floor in one of the pods and reports it to Tom. The nurse tells Tom that it may be medication that was accidentally dropped this morning during the medication round.

How does the concept of accountability and responsibility apply in this situation?

In healthcare settings nurses and medical officers are a part of a greater team working for the benefit of the individuals in their care. While there is a common goal, the division of responsibility shows subtle but important differences. The medical officer is responsible for overall care of the person including assessment and investigating their medical condition, making a diagnosis and planning treatment. The nurse's role and responsibility is to participate in and supervise the implementation of the medical treatment plan both in caring for the person's physical requirements and in the administration of various therapies including medications and nursing procedures. The nurse's responsibilities also include providing feedback and advice to medical officers and allied medical personnel regarding the person's condition and progress through direct reporting, and through recorded physical observations and written progress records.

### Values

A value is a belief about the worth of a particular idea or behaviour, or something an individual views as desirable or important. Values are acquired or learned initially in childhood, from the family and other significant people and from experience. Values are derived from a number of sources such as the person's culture, society, family, education, professional training and work environment and they influence the way a person interacts with others and the decisions they make (Fry et al 2011; Rassin 2008).

Professional and personal values motivate and guide a person's behaviour and it is important to recognise that each person's set of values is unique. Some people have very few specific values while others have many and these values may change over time. Also, some values are more important than others and individuals prioritise some values over others (Fry et al 2011). People may value such things as honesty, skill, justice, responsibilities, altruism, privacy, friendship, material goods, physical wellbeing, knowledge, talent, wealth, courage and creativity. An example of an important professional value

## CLINICAL INTEREST BOX 2.18 Examples of professional values in nursing

- Caring
- Activism
- Trust
- Professionalism
- Justice

*(Weis & Schank 2009)*

for nurses is responsibility towards individuals (Rassin 2008). See Clinical Interest Box 2.18 for examples of important professional values for nurses.

Considering values becomes important when a person has to take a stand for that which they value. Ethical issues and moral dilemmas occur in healthcare when choices have to be made that involve putting one set of values against another. Morals relate to specific values and principles to which a person is committed, and a moral belief is a conviction that something is absolutely right or wrong. For example, some people believe in the value of pro-life and that abortion is absolutely wrong in all circumstances; a nurse who holds this view may choose not to work in this area.

## Ethical issues and moral dilemmas

Ethical issues arise in numerous areas of medical and nursing practice and may require nurses to be involved in resolving them. Johnstone (2014) categorises the ethical issues faced by nurses into three kinds: everyday practical ethical issues; broader mainstream bioethical issues; and the broader social justice issues associated with promoting the welfare, wellbeing and significant moral interests of highly vulnerable, stigmatised and marginalised groups of people. Clinical Interest Box 2.19 lists some of the specific and common ethical issues faced in the healthcare environment.

The complex and changing nature of the healthcare environment today generates many ethical challenges. Nurses are often faced with difficult moral dilemmas. Moral or **ethical dilemmas** are situations that involve two competing or conflicting moral choices, neither of which is a desirable option in terms of outcomes (Dahnke & Dreher 2006). Moral dilemmas in nursing practice may arise in a number of situations when there are value conflicts. For example, a nurse who values the sanctity of life who has to care for individuals terminating unwanted pregnancies, or a nurse has to care for a young person who is terminally ill and refuses treatment, but the nurse also knows that the person is suffering enormously from their condition, with a poor quality of life.

In order to correctly identify and deal with ethical issues and **moral problems** nurses must apply ethical reasoning and a moral decision-making process. The most important consideration is that nurses respond in the interests of the person and the individual's wellbeing and also act justly according to the expected standards of professional practice.

## CLINICAL INTEREST BOX 2.19 Common ethical issues

- Genetic engineering
- Artificial fertilisation
- Contraception
- Therapeutic abortion
- Child abuse
- Artificially prolonging life
- Voluntary euthanasia
- Not for resuscitation orders
- Selective non-treatment
- Informed consent
- Withholding information
- Right to refusal of treatment
- Quality versus quantity of life
- Organ transplantation
- End-of-life issues and dying with dignity
- Non-therapeutic research
- Use of restraints
- Confidentiality
- Conflict of values and beliefs between members of the health team
- Advance care planning
- Disclosing and reporting professional practice errors
- Veracity, duty and complications in truth telling
- Allocation of health resources

*(Atkins et al 2014; Fry et al 2011; Johnstone 2011; Johnstone & Kanitsaki 2009)*

## Ethical decision making

Models for **ethical decision making** in healthcare apply a problem-oriented approach, requiring rational and systematic reasoning. One of the most commonly used models for ethical decision making in nursing practice is the steps of the nursing process. This is a deliberate and systematic problem-solving approach that can be used to resolve moral problems in the healthcare environment (Crisp et al 2013). (See Clinical Interest Box 2.20.)

Often solving an ethical dilemma may seem almost impossible in some situations, but using the standards stated in a code of ethics helps the nurse to view such problems objectively. Nurses have an ethical obligation to ensure that decisions made are in the best interest of the person in their care and within professional guidelines for practice. (See Clinical Interest Box 2.21.)

When an ethical decision is to be made, the following factors must be considered:

- The ethical dilemma must be recognised and defined
- All the facts relevant to the issue and to the individuals involved must be obtained
- The people involved in making a decision must understand the relevant moral rules and principles involved and be able to apply them in an appropriate manner

## CLINICAL INTEREST BOX 2.20
## Models for ethical decision making

Ethical decision-making model:
- Clearly state the problem
- Get all the facts
- Consider the fundamental ethical principles
- Consider how the problem would look from another perspective or using another theory
- Identify ethical conflicts
- Make the ethical decision and evaluate the decision.

*(Staunton & Chiarella 2013)*

Steps of the nursing process in moral decision making:
- Assess the moral/ethical situation
- Identify (diagnose) the moral problem/s
- Set moral goals and plan a moral course of action
- Implement the moral plan of action
- Evaluate the moral outcomes of the action.

Revisit the steps from the beginning if the desired moral outcomes do not occur.

*(Crisp et al 2013)*

## CLINICAL INTEREST BOX 2.21
## Ethical challenges

Consider the following:
- The senior nurse working on a busy surgical ward is faced with the difficult decision to report the lack of adequate support and supervision for new nurses starting on the ward. This decision could mean that the number of new nurses working on that ward could be reduced. This action could cause some upset among colleagues.
- A nurse is faced with the difficult decision to withhold information from the daughter of a person in their care. The person was diagnosed with a terminal condition. He only has a few months to live. The person does not want his daughter to know because she would be very upset. The daughter is his only child and cares very deeply for her father. The daughter was very involved in her father's care during his hospitalisation and appreciative of all the care provided by the nursing staff. The individual's right to privacy binds the nurse from telling the truth if the daughter asks about her father.
- The medical code team is faced with the difficult decision of what to do next in a medical code situation for an individual in their care. The person is elderly and critically ill with a poor prognosis. Further intervention is seen as futile. His daughter has the medical power of attorney. The individual is to be resuscitated as per code status directives.

Analyse these situations within the ethical decision-making framework.

## CLINICAL INTEREST BOX 2.22
## Examples of nurses' obligations in ethical decisions

- Maximise the individual's wellbeing
- Balance the person's need for autonomy with family members' responsibilities for the person's wellbeing
- Support each family member and enhance the family support system
- Carry out hospital policies
- Protect other individuals' wellbeing
- Protect the nurse's own standards of care

*(Berman et al 2015)*

- Proper evaluation must be made of possible solutions to the problem and of the strategies to be implemented.

Moral dilemmas will continue to occur in healthcare as long as choices have to be made that involve putting one set of values against another. It is therefore important that nurses keep themselves informed and are involved in discussions and debates about ethical issues and dilemmas so that they are able to make ethical decisions in an informed way rather than on a purely emotional basis. See Clinical Interest Box 2.22 for examples of nurses' obligations in ethical decisions.

## Advocacy

In a nursing context, **advocacy** means that the nurse acts for and on behalf of the individual in their care (Cole et al 2014). To act as an advocate the nurse must ensure that the person is provided with adequate and accurate information relating to their care, and they must support the person in any informed decisions they make about their care. In this way the nurse meets the ethical requirement of honouring a person's right to self-determination. In nursing, the concept of advocacy is based in nursing ethics, and involves respecting a person's right to:
- Be informed
- Make decisions and choices
- Confidentiality
- Privacy and dignity
- Hold their own ethical and religious beliefs.

An important consideration when advocating for someone is to know when and how to advocate to ensure that the advocacy is within the legal and ethical guidelines of professional practice (Atkins et al 2014). The form of advocacy provided by nurses is informal, there is no legal power to act on behalf of the person and decisions are made by the individual. Formal advocacy involves legal capacity to make decisions on behalf of the person, such as in the case of court-appointed guardians and power of attorney. All nurses have a responsibility to ensure that, in relation to nursing practice, the person is assured of safe and competent care and that their rights will be protected. (See Case Study 2.3.)

### CASE STUDY 2.3 ADVOCACY

Mini is a 22-year-old female with a community-based mental healthcare service provider. Mini used street drugs regularly until a few months ago and ran into trouble with the law. She is now supported by the nurses from the community-based service regularly. Mini lives alone in a public housing flat and is following her treatment. Mini dropped out of school and has never held any jobs for more than a few weeks. She is separated from her family. The team of nurses looking after Mini are aware that she is interested in completing her schooling and getting some work locally.

What steps can the nurses take or how can they advocate for Mini in this situation?

## Summary

Nursing is practised within certain legal frameworks and ethical considerations that promote safe and effective care. Both are important considerations for nursing practice. Although the legal and ethical aspects of nursing are not the same, they overlap and require nurses to act within expected standards of professional behaviour. The legal aspect requires nurses to practise within the law and regulations of the profession and ethics require nurses to apply moral codes of conduct as healthcare professionals.

While the professional codes of conduct and codes of ethics for nurses in Australia provide frameworks to promote excellence in clinical practice, every nurse is responsible for determining and implementing desirable legal responsibilities and obligations and standards of practice, and for following ethical standards in their professional capacity. All nurses have a responsibility to promote safe and competent care as defined by the national competency standards/standards for practice and scope of practice.

## Review Questions

1. What are the legal responsibilities and obligations of the nurse?
2. Discuss the differences between criminal law and civil law.
3. When may a nurse be disqualified or deregistered from practice?
4. Who determines the standards of care by which a nurse should practise?
5. What must a plaintiff prove to succeed in an action of negligence?
6. How does a nurse ensure that it will not be possible to make a charge of defamation against them?
7. What is the difference between assault and battery? When could a nurse commit an act of assault?
8. When is consent for a medical procedure considered to be valid?
9. What type of information about a person is classified as confidential?
10. What action may happen to a nurse who discloses confidential information about an individual in their care?
11. What points should be remembered when documenting in a person's health records?
12. What type of information is required in an adverse event/clinical incident report? Give five (5) examples of adverse events that might be reported.
13. What are the elements of open disclosure?
14. What are some of the common ethical issues faced by nurses today?
15. What are the nurse's obligations in ethical decision making?

Answer guide for the Review Questions, Critical Thinking Exercises, Decision-Making Framework Exercises and Critical Thinking Questions in Case Studies are hosted on Evolve: http://evolve.elsevier.com/AU/Koutoukidis/Tabbner/

CHAPTER 3

# Nursing research and evidence-based practice

*Kate Stainton*

## KEY TERMS

data analysis
data collection
ethical principles
evidence-based practice (EBP)
hypothesis
informed consent
literature review
mixed methods
nursing research
qualitative research
quantitative research
reliability
research design
research problem
research question
systematic review
validity
variables

## LEARNING OUTCOMES

At the completion of this chapter and with further reading, students should be able to:

- Define the key terms
- Define nursing research
- Explain the relevance of research in nursing
- Describe the various ways to acquire knowledge
- Understand the basic differences between qualitative and quantitative approaches in research
- Outline the steps in conducting research
- Describe the way research, education and practice relate to each other
- Identify the importance of critical thinking and critical reading when undertaking a research project
- Discuss the importance of informed consent and ethics in relation to research
- Define evidence-based practice and understand its relevance to nursing practice
- Explain how Enrolled Nurses (ENs) can participate in nursing research
- Identify future trends in nursing research

## CHAPTER FOCUS

Nursing theory and education are recognised as the main contributors to the development of an accountable and professional nurse in the healthcare environment. Research is also recognised by healthcare professionals as being equally important in influencing practice by informing decisions about the delivery of care to individuals and their families. Today's evidence-based nursing practice integrates education, theory, practice and the findings from research to provide quality healthcare. Nurses are also acknowledging the need to develop skills in critically appraising research literature to enable consideration of its application to clinical practice (Schneider et al 2016).

The purpose of this chapter is to enable Enrolled Nurses (ENs) to develop an appreciation of the significance of research to them as nurses. It introduces evidence-based practice (EBP), the principles of nursing research, basic components of a research proposal, guidelines to critiquing a research article and an overview of both qualitative and quantitative research.

## LIVED EXPERIENCE

Learning about nursing research and evidence-based practice has helped me to use a questioning approach to the everyday care of individuals. I no longer take things for granted. It allows me to use an evidence-based approach to my practical nursing care. For example, if I want to decide on the best approach to wound care for a venous ulcer, I incorporate the evidence, the information gained from individual preferences, as well as my own experience and those of my more experienced colleagues. I know how to find the information, analyse it and apply it to my practice.

**Ben, Enrolled Nurse**

# THE ENROLLED NURSE AND NURSING RESEARCH

There are opportunities for ENs to have an active participation with nursing research (Clinical Interest Box 3.1 and Case Study 3.1). ENs may come across some research findings that can be very pertinent to their practice, and may intend to introduce the findings into their professional practice; for example, the 'new' way of managing wound care. The EN may feel that the introduction of a research idea that they have critically read has relevance to their practice.

Reading, reviewing and critiquing published research studies and using this knowledge in practice is the most common contact nurses have with research. By doing this it is hoped that nurses will accept research as a normal part of nursing practice, apply research findings to clinical practice,

### CASE STUDY 3.1

During an afternoon shift, an EN was undertaking vital signs on several of the admitted people under her care using an electronic BP machine. After recording the vital signs on the individuals' charts, the EN noticed a significant change in a number of the BPs from the previous shift. As a result of this, the EN rerecorded the BPs using a manual BP machine and established that the electronic BP machine was recording some of the BPs inaccurately. In discussion with the NUM/nursing team, a small study was commenced to determine the number of times an electronic BP machine recorded BPs correctly or inaccurately. This was done by taking a BP once with the electronic BP machine then taking the BP again with a manual machine and comparing the results.

1. Is this research better suited to a quantitative or qualitative approach?
2. If the nurse wanted to research literature on this topic, what would be considered a credible source?

### CLINICAL INTEREST BOX 3.1
### Example of practical application of research

In the Pilbara, Western Australia, an Enrolled Nurse undertook research into the prevention of constipation in aged care residents. She identified the need to make changes to residents' care routines in order to reduce the need for regular taking of laxatives. As a consequence she has implemented best practice guidelines for the management of constipation in older adults. She was awarded the WACHS Innovation Award for 2009 (www.cucrh.uwa.edu.au/about/chronicle.htm 2009).

Enrolled Nurses can also participate in and attend conferences. The National Enrolled Nurse Association (NENA) promotes the value of ENs and raises awareness of ENs' role within the community, while providing a forum for all ENs to participate at a national level. Check NENA's website (www.anf.org.au/nena) for information on future conferences.

influence colleagues on the use of research data and accept responsibility for their own professional development (Crookes & Davies 2004 in Daly et al 2014). Apart from utilising research findings into the practice settings, ENs have the opportunity to participate in nursing research activity; for example, by supporting the research team with data collection and data entry, or by undertaking their own research.

## NURSING RESEARCH

The term 'research' refers to a systematic way of studying or examining an issue so that the knowledge about that issue is validated. It requires an understanding of the existing knowledge about the issue so that new knowledge can be developed. Many words and terms specifically related to research are used in this chapter; they are defined in Table 3.1.

Nursing research involves a systematic search for and validation of knowledge about issues important to the nursing profession and links theory, education and practice. **Nursing research** is important for:

- Validating nursing as a profession
- Documenting the effectiveness of nursing interventions
- Providing a scientific knowledge base for practice
- Demonstrating accountability for the profession.

Research-based or evidence-based practice is essential if the nursing profession is to deliver safe, effective and efficient care.

The goal of nursing is to provide evidence-based care that promotes quality and effective outcomes for individuals, families, healthcare providers and the healthcare system (Burns et al 2013). Burns and colleagues describe EBP as involving the use of collective research findings in:

- Promoting the understanding of individuals' and families' experiences with health and illness
- Implementing effective nursing interventions to promote healthcare outcomes
- Providing quality, cost-effective care within the healthcare system.

The National Safety and Quality Health Service (NSQHS) Standards provide topics for nursing research which are very relevant to current practice. Much of nursing research into clinical safety and quality aligns with the NSQHS.

## EVIDENCE-BASED PRACTICE

**Evidence-based nursing practice** is built on the belief that decisions about the delivery of care to individuals should be informed by the best available and most current evidence (Borbasi & Jackson 2016; Richardson-Tench et al 2014). As a nurse, you will make decisions every day that will affect the care you deliver. You will be able to make clinical decisions based on research evidence to support your decisions. Another definition of EBP is that it is a process within which clinical decisions are made by practitioners using the best available research evidence, their clinical expertise and patient preferences, with consideration also of available resources (Schneider et al 2016; Moule & Goodman 2014). (See Figure 3.1.)

### CLINICAL INTEREST BOX 3.2
### Steps in evidence-based practice:

1. Ask a focused question.
2. Assess appropriate evidence.
3. Appraise evidence for validity, impact and precision.
4. Apply evidence accounting for patient values/preferences, clinical and policy issues.
5. Evaluate/audit your practice/personal skills.

*(Moule & Goodman 2014; Hoffman et al 2013)*

The five steps universally accepted as being necessary for EBP are presented in Clinical Interest Box 3.2 and described below (Hoffman et al 2013; Moule & Goodman 2014):

### Step 1: Ask a focused question

Formulating an answerable question is the first step in EBP. PICO (Patient/Population, Intervention/Indicator, Comparison/Control and Outcome) can help provide a structure for this and guide you in developing search terms.

PICO stands for:

- P: Patient/Population—characteristics
- I: Intervention/Indicator—what the health professional plans to do for that patient/population
- C: Comparison/control—the alternative choice
- O: Outcome—what the health professional plans to accomplish, improve or influence (LoBiondo-Wood & Haber 2014; Borbasi & Jackson 2016).

For example: does education about pain relief reduce the need for medication post surgical intervention?

**P**: Individual scheduled for surgery
**I**: The individual receives education about pain relief options post surgery
**C**: Standard information about postoperative care
**O**: Comparison of pain relief required by

1. Individuals who received standard information
2. Individuals who received information about different pain relief options.

### Step 2: Assess the evidence

Find the best evidence to answer the question. This is usually done by a thorough search of the evidence. This may include people with an interest in EBP and with specialist expertise, literature (including books and journals), the internet and specialist databases.

### Step 3: Critically appraise the evidence

The three main aspects of the evidence that need to be appraised are the validity (truthfulness: can you believe the results of the study?), impact (what is the clinical importance of the evidence?) and precision/applicability (can you apply the results of the study to your situation?).

**TABLE 3.1 | Common research terms**

| | |
|---|---|
| Bias | Any influence that may alter the outcomes of a research study |
| Clinical nursing research | Nursing research that has a direct impact on nursing interventions with individuals |
| Data | Measurable bits of information collected for the purpose of analysis |
| Data collection | Gathering of information necessary to address the research problem |
| Deductive reasoning | Logical system of thinking that starts with the whole and breaks it down into its component parts |
| Dependent variable | A variable that is affected by the action of the independent variable |
| Ethics committee | Committee responsible for review of research proposals to ensure that human subjects are protected from harm |
| Hypothesis | Statement of a predicted relationship or difference between two or more variables. A hypothesis contains at least one independent and one dependent variable |
| Independent variable | A variable that causes a change in the dependent variable |
| Inductive reasoning | Logical system of thinking that begins with the component parts and builds them into a whole |
| Informed consent | An agreement by a research subject to participate voluntarily in a study after being fully informed about the study and the risks and benefits of participation |
| Instrument | Device or technique used to collect data in a research study (e.g. questionnaires or interviews) |
| Literature review | A critical summary of available theoretical and research literature on the selected research topic. It places the research problem for a particular study in the context of what is currently known about the topic |
| Nursing research | Research usually conducted by nurses to generate knowledge that informs and develops the discipline and practice of nursing |
| Population | All known subjects that possess a common characteristic of interest to a researcher |
| Problem statement | A statement that describes the purpose of a research study, identifies key concepts and sets study limits |
| Qualitative research | Used to examine subjective human experiences by using non-statistical methods of analysis |
| Quantitative research | The systematic process used to gather and statistically analyse information that has been measured by an instrument and converted to numerical data |
| Reliability | Characteristic of a good instrument; the assessed degree of consistency and dependability |
| Research | A systematic process using both inductive and deductive reasoning to confirm and refine existing knowledge and to build new knowledge |
| Research design | The overall plan for collecting data in a research study |
| Research process | An orderly series of phrases identifying steps that allow the researcher to move from asking a question to finding an answer |
| Research question | Use of an interrogative format to identify the variables to be studied and possible relationships or differences between those variables |
| Sample | A subset of a population selected to participate in a research study |
| Systematic review | A rigorous review of all the evidence on an aspect of healthcare |
| Validity | A characteristic of a good instrument; the extent of an instrument's ability to measure what it states it will measure |
| Variable | A concept, characteristic or trait that varies within an identified population in a research study |

*(Borbasi & Jackson 2016; Schneider et al 2016; Burns et al 2013)*

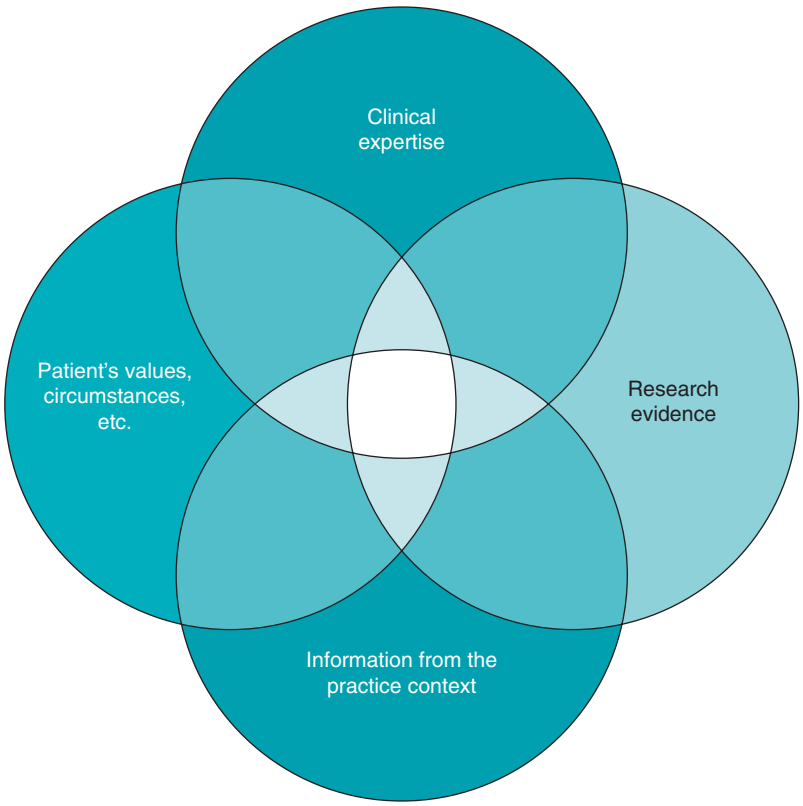

**Figure 3.1** Evidence-based practice
*(Hoffman et al 2013)*

## Step 4: Integrate/apply the evidence

Integrate/apply the evidence from the critical appraisal step with clinical expertise, the individual's needs/values, and the clinical practice context.

## Step 5: Audit/evaluate your practice

Evaluate the effect on the individual and reflect on the nurse's own performance—undertake audit or ask yourself self-reflective questions about steps 1 to 4 (e.g. Am I asking well-formulated questions? Am I searching the databases efficiently?).

In summary, the process of EBP involves synthesis of evidence, which is used to develop guidelines for practice, implement change in practice and evaluate outcomes through audit (Brown et al 2014).

## Evidence-based practice and nursing research

EBP bases current practice on research evidence. The evidence for EBP is gained by systematically searching for and analysing research reports accessed through databases and libraries. The databases include Medline, CINAHL and psychINFO, and library resources include the Cochrane Library. The Cochrane Collaboration is an evidence-based library that produces systematic reviews which inform decisions about healthcare using comprehensive, reliable and relevant sources of evidence.

There are several key organisations in Australia that focus on EBP. These include the National Institute of Clinical Studies and the Joanna Briggs Institute. The Joanna Briggs Institute (JBI) contributes to the development of an evidence base that brings together a range of practice-oriented research activities to improve the effectiveness of nursing practice and healthcare outcomes. It publishes best practice information sheets, systematic reviews, evaluation cycle reports and online practice manuals.

Clinical Interest Box 3.3 explains EBP. Table 3.2 explains the difference between a **systematic review** and a **literature review**.

### CRITICAL THINKING EXERCISE 3.1

Why is research important in informing the practice of nursing?

## The evolution of nursing research

In 1854, during the Crimean War, Florence Nightingale demonstrated the significance of research in the delivery of nursing care. On arrival at the Crimea in 1854, Nightingale

## CLINICAL INTEREST BOX 3.3 Evidence-based practice

**What is evidence-based practice?**

A process of:

- Synthesising research evidence
- Designing clinical practice guidelines
- Implementing practice changes
- Evaluating outcomes

**Why do we need evidence-based practice?**

- Rapid increase in amount of information
- Rapid increase in healthcare costs
- Determination of efficient and effective healthcare practices
- Increased emphasis on performance and outcome standards

**Where is evidence found?**

- Published research
- Systematic reviews (e.g. Cochrane Collaboration; available: http://www.cochrane.org/)*
- Special collections of EBP resources (e.g. Joanna Briggs Institute; available: http://www.joannabriggs.edu.au)

*Descriptions can be found at this website, but access to systematic reviews is by subscription only.
*(Brown et al 2014:13)*

found the military hospital barracks overcrowded, dirty and lacking in food and essential medical supplies. Men were dying from starvation and diseases such as cholera and typhus because of these conditions. By systematically collecting, organising and reporting data, Nightingale was able to implement sanitary reforms and prove a significant reduction in mortality rates. This is considered to be the first nursing research study (Berman et al 2015).

Research was slow to develop in nursing, with little formal research carried out by nurses until the late 1940s. Nursing schools evolved from military and religious roots and stressed order and obedience. Training was viewed as an apprenticeship, with long hours, and nurses had little say in their own training or work. Only when nursing began to move towards advanced education and affiliation with university settings did nursing research begin to emerge. This move began in the USA. In the 1960s and 1970s the number of nurses with advanced degrees and research skills increased and the push for doctoral preparation in nursing began. Nurses began to turn to nursing care and clinical practice to provide questions for research. Many researchers developed studies to improve nursing practice (Burns et al 2013). Nursing theories evolved; they attempted to describe and explain the practice of nursing and began to be tested by nurse researchers. Practice-related research flourished and by the end of the 1970s two new research journals were launched in the USA to handle the nursing research explosion (Borbasi & Jackson 2016).

Nursing research in Australia began to flourish in the 1970s and 1980s (Schneider et al 2016). This move was accompanied by a major increase in the level of research activity, which was directed at educational, disciplinary or professional issues, and other disciplinary areas of relevance to nursing. Recently, nurses have begun to place more emphasis on EBP. This is in part due to technology, which makes researching EBP more accessible. The goal is to use the current best evidence to deliver quality healthcare (Burns et al 2013). This involves gaining evidence for or substantiating clinical decisions through experience, trial and error, tradition, authority, logic or nursing research (Berman et al 2015). Some ideas that have been tested and demonstrated to be useful in practice are: moist wound healing; pressure-relieving devices for the prevention of pressure ulcers; patient information to improve self-care and healthy lifestyles; communication with people who are dying; and nutritional support of older people in hospital (Brown et al 2014).

### The future of nursing research

The value of research studies that increase understanding of clinical phenomena and provide direction for defining programs of research is well recognised and continues to develop in Australia. Nurse researchers and nurse leaders are visibly involved as consultants in educational, governmental and healthcare institutions to inform both professionals and consumers of best evidenced-based nursing practice (Beanland et al 2004; Schneider et al 2016).

One area in which quality research takes place is magnet hospitals, which are emerging in Australia. Magnet status is awarded by the American Nurses Credentialing Center, affiliated with the American Nurses Association, to hospitals that meet criteria designed to measure the strength and quality of their nursing. A magnet hospital is stated to be one where nursing delivers excellent patient outcomes, nurses have a high level of job satisfaction and there is a low staff nurse turnover rate and appropriate grievance resolution. Magnet hospitals aim to provide a commitment to staff development and training, effective systems for implementing and evaluating quality-based treatment and care, and sustainable long-term resourcing (Schneider et al 2016). The concept of a magnet hospital is to develop and sustain an environment where nursing- and midwifery-related EBP and practice change are more likely to occur. Three hospitals in Australia have achieved magnet hospital status. As an Enrolled Nurse, choosing to work in such a setting may increase satisfaction and retention for self and outcomes for individuals engaged in all aspects of healthcare.

## RESEARCH METHODS

Nursing research focuses on a full range of human experiences and nursing interventions and aims to improve the health status of individuals and gain understanding into differing phenomena. Nursing researchers use a wide range of approaches. The main methods used in nursing research take

**TABLE 3.2 | Difference between a systematic review and a literature review**

| | Systematic review | Literature review |
|---|---|---|
| Question/goals/objectives | Focused on a single question<br>Clearly defined and answerable<br>Eliminates bias | Can be focused on a single question, but may describe an overview or summary of topic<br>Objectives may or may not be identified |
| Background | Summaries of the available literature on a topic provided by both | |
| Inclusion and exclusion criteria | Criteria stated before the review is conducted | Criteria not specified |
| Search strategy | Comprehensive search conducted in a systematic way<br>Searches of all relevant databases performed | Not explicitly stated<br>Searches of one or more databases performed |
| Process of:<br>selecting articles<br>evaluating articles<br>extracting relevant information | Usually clear and explicit<br>Comprehensive evaluation of study quality<br>Usually clear and specific | Not described<br>May or may not include evaluation of study quality<br>Not clear or explicit |
| Results and data synthesis | Clear summaries of studies based on high-quality evidence | Summary based on studies where the quality of the articles may not be expected. May also be influenced by the reviewer's theories, needs and beliefs |
| Number of authors | Three or more | One or more |
| Timeline | Months to years | Weeks to months |
| Discussion | Written by an expert or group of experts with a detailed and well-grounded knowledge of the issues | |

*(Kysh 2013; Bettany-Saltikov 2010)*

a quantitative, qualitative or mixed methods approach (Berman et al 2015; Crisp et al 2013).

Nurse researchers use many methods because nurses are interested in acquiring knowledge about a wide range of human needs and responses to health problems. For example, a different research method may be used by a nursing researcher interested in developing a deeper understanding of a phenomenon and how it may be experienced by individuals, such as helping women deal with the consequences of incontinence after childbirth.

## Quantitative methods

**Quantitative research** methods involve the use of numbers and statistical analysis. This research approach is both logical and systematic in nature and gathers and analyses information that has been measured by an 'instrument', such as a questionnaire, and converted to numerical data (Borbasi & Jackson 2016). Quantitative nursing research is the investigation of nursing phenomena that lend themselves to a precise measurement, such as pain severity or rate of wound healing.

In quantitative research, the researcher changes one set of variables and observes the outcome or its influence on other variables.

**Variables** are concepts or traits that vary (Borbasi & Jackson 2016), such as characteristics of people or situations that can change or vary for many reasons. Temperature, pulse, respiration, blood pressure, height and weight are examples of variables. Quantitative measurement involves the magnitude of a variable as well as the unit being measured.

The variable that the researcher controls or manipulates is called the independent variable. The variable that varies or changes because of this is called the dependent variable (Borbasi & Jackson 2016). For example, consider the statement: 'Sitting upright in bed does not make breathing easy in an individual with asthma.' The independent variable relates to placing the individual in different positions, such as lying flat, semi-recumbent, lateral or upright. This is the variable the researcher can manipulate to study its influence on the dependent variable. The dependent variable is the measurement of breathing.

The main designs used in quantitative research are correlational, descriptive, experimental and quasi-experimental. Correlational research involves studies that explore the patterns of interrelationships between variables of interest, without any active intervention by the researcher. Descriptive research aims to accurately portray characteristics of

individuals, situations or groups and the frequency with which certain events or characteristics occur. In experimental and quasi-experimental studies the investigator controls the independent variable and randomly assigns subjects to different conditions. The major goal of this research is to determine causal relationships between the variables through a controlled investigation in which only the independent variable can be the cause of changes in the dependent variable. Quasi-experimental research has a lower level of control and is less powerful (Borbasi & Jackson 2016; Polit & Hungler 2013; Burns et al 2013; Richardson-Tench et al 2014).

## Qualitative methods

**Qualitative research** is a subjective approach used to explore phenomena and describe human experiences. This research approach collects data and obtains information from, for example, interviews rather than measurement (Burns et al 2013).

Qualitative researchers may wish to examine individuals and their stories and behaviour, organisations and their functioning, or cultures and their interactions and social movement. As the study methodology embraces the examination of subjective phenomena, these findings are only considered to be representative of a particular person or group of people, and in a particular setting, and not reflective of other people or other settings (Borbasi & Jackson 2016). Using the example above of the individual with asthma a qualitative approach may ask, 'What is it like for the families who provide care for relatives who suffer from asthma?'

Qualitative research may be classified by research design or theoretical perspective. The research designs most commonly used in a qualitative interpretive approach are descriptive exploratory, ethnography, phenomenology and grounded theory. Descriptive exploratory methodology is a 'general' approach that uses aspects of all qualitative approaches. Ethnography looks at the culture or subculture of a group of people. Phenomenology explores the lived experiences of people. Grounded theory explores social processes and structures. Data is collected, analysed and used to generate hypotheses for further research (Borbasi & Jackson 2016; Berman et al 2015; Moule & Goodman 2014; Schneider et al 2016). The researcher may use a qualitative critical approach such as action research, feminist or critical ethnographic. Action research is designed and carried out in the clinical setting and integrated into practice by practitioners in partnership with researchers. In nursing, action research is about improving practice and standards and generating new knowledge (Moule & Goodman 2014; Richardson-Tench et al 2014).

Table 3.3 outlines the differences between quantitative and qualitative research.

**TABLE 3.3 | Comparison of quantitative and qualitative research**

| Quantitative | Qualitative |
|---|---|
| Focuses on a small number of specific concepts and their relationships and differences | Attempts to understand the entirety or whole of some phenomenon within a prescribed context |
| Set on a predefined theoretical foundation. 'Educated guesses' made about relationship of concepts and study outcomes | No preconceived theoretical boundaries or preconceived notions about study outcomes |
| Researcher controls and interprets data | Focuses on people's interpretations of events and circumstances rather than researcher's |
| Tends to use larger samples | Uses smaller samples |
| Describes people in the study as 'subjects' | Describes people in the study as 'participants', 'informants' or sometimes 'co-investigators' |
| Uses language in a way that implies neutrality, such as writing in the third person | Can be written up using the first person |
| Uses structured procedures and formal instruments to collect information | Collects information without formal structured instruments |
| Collects information under conditions of control and manipulation | Doesn't attempt to control the context of research, but attempts to capture it in its entirety |
| Emphasises objectivity in collection and analysis of information. Attempts to exclude all forms of subjective 'bias' | Attempts to capitalise on the subjective as a means of understanding and interpreting human experiences. Is comfortable with the notion of 'bias' |
| Uses 'objective' tools to collect data | Researcher is the instrument of data collection |

*(Borbasi & Jackson 2016, Table 5.1, p. 126)*

There are strengths in both quantitative and qualitative approaches. The quantitative approach can support a theory or argue to disprove it, and can be very useful, for example, when hospitals or governments want to introduce policy changes. The qualitative approach, by contrast, has a human focus and allows researchers to know their subjects and collect information about attitudes and satisfaction levels that are vital to improve care provided by nurses.

### Mixed methods

Integration of both methods is also possible. Tashakkori and Teddlie (1998) found that the combined use of a mixed model is a powerful tool in health research. **Mixed methods** research combines methods, paradigms and qualitative and quantitative approaches, enabling a broader, more comprehensive analysis of the research topic than single method research (Schneider et al 2016; Borbasi & Jackson 2016; Moule & Goodman 2014; Richardson-Tench et al 2014; Schneider et al 2016); for example, using focus groups as well as a questionnaire to obtain rich data. If using the example of the individual with asthma, a mixed methods approach could involve the collection of quantitative data from medical records and the qualitative phase could involve focus group interviews with families to explain the qualitative results.

**CRITICAL THINKING EXERCISE 3.2**

If a researcher wanted to determine the perceptions of nursing staff of the importance of hand hygiene, what type of research method should be used for the study?

## THE RESEARCH PROCESS

There are several steps in conducting either quantitative or qualitative research.

### Step 1. The research problem

The **research problem** is refined through a process that proceeds from identifying a general idea of interest to defining a specific topic. A preliminary literature review reveals related factors that appear critical to the research topic and it should identify a gap in the literature on the specific topic. The significance of the research problem must be identified in terms of its potential contribution to both the individual and the nursing profession (Burns et al 2013). Choosing a problem that can be translated into policy is also important. Choosing the topic of interest may develop from:

- Discussing an issue of common interest with a colleague
- Reading about an issue in a journal, text or newspaper
- Identifying an area deficient in information
- An aspect of practice being introduced for the first time
- An aspect of practice that may have been observed but which needs to be validated
- Areas of work that may need to change
- Wanting to repeat a study that has already been conducted, to check the results.

### Step 2. The purpose

The purpose of the study states the aims or goals that the investigator hopes to achieve with the research. It includes what the researcher will do, who the participants will be and where the data will be collected (Berman et al 2015). An example of a purpose for a research problem investigating the link between obesity and type 2 diabetes might be 'Collect data from adults in the state of Victoria who have type 2 diabetes and compare this to their weight'.

### Step 3. Literature review

The overall purpose of conducting a review of the literature is to develop a strong knowledge base to carry out research and other consumer research activities in the educational and clinical practice settings. It is a comprehensive, in-depth, systematic and critical review of scholarly publications and available evidence focused on the research topic (LoBiondo-Wood & Haber 2014). Information may be gained from primary or secondary sources. A primary source is written by an individual(s) who developed the theory or conducted the research. Secondary sources are descriptions of studies written by someone other than the original researcher who developed the theory or conducted the research (LoBiondo-Wood & Haber 2014; Polit & Beck 2014). Therefore a literature review is often called 'secondary research', and conducting an original study is called 'primary research' (Daly et al 2014).

The literature review provides a way of checking what has already been studied in relation to the proposed study. It may also identify gaps in knowledge, and provide an understanding of the procedures, methods of analysis and variables that can influence the study (see Clinical Interest Box 3.4).

#### How to search successfully for information

To conduct a successful search for information about a particular subject, the researcher needs to define the topic of interest, select appropriate search resources and selectively review and evaluate the materials produced by a search (Borbasi & Jackson 2016; Schneider et al 2016). A search is conducted using indexes, abstracts and catalogues to find information about specific subjects. Books tend to give standard accepted information and practices. They provide good baseline data on a subject. Journals, however, provide more current information than books. They report changing trends and practices.

Several electronic indexes are used for nursing journals (see Clinical Interest Box 3.5), including the Cumulative Index to Nursing and Allied Health Literature (CINAHL), Index Medicus (a comprehensive index of peer-reviewed medical journals compiled by the US National Library of Medicine) and its online counterpart, MEDLINE (Medical Literature Analysis and Retrieval System (MEDLARS) online). Each index has a primary area of focus and advantages and limits. Electronic databases operate with a special

## CLINICAL INTEREST BOX 3.4 Overall purpose of a literature review

- Determines what is known and not known about a subject, concept or problem.
- Determines gaps, consistencies and inconsistencies in the literature about a subject, concept or problem.
- Discovers unanswered questions about a subject, concept or problem.
- Discovers conceptual traditions used to examine problems.
- Uncovers a new practice intervention(s) or provides evidence for current practice intervention(s).
- Generates useful research questions and hypotheses for the discipline.
- Describes the strengths and weaknesses of designs or methods of enquiry and instruments used in earlier works.
- Determines an appropriate research design or method (instruments, data collection and analysis methods) for answering the research question(s).
- Determines the need for replication of a well-designed study or refinement of a study.
- Promotes development of new or revised practice protocols, policies and projects or activities related to nursing practice and to the discipline.

*(Borbasi & Jackson 2016; Coughlan et al 2013; Hoffman et al 2013; Moule & Goodman 2014; Schneider et al 2016)*

## CLINICAL INTEREST BOX 3.5 Examples of nursing research journals

*Applied Nursing Research*
*Australian Journal of Advanced Nursing*
*Clinical Nursing Research*
*International Journal of Nursing Studies*
*Journal of Advanced Nursing*
*Journal of Nursing Education*
*Journal of Nursing Research*
*Journal of Nursing Scholarship*
*Nursing Outlook*
*Nursing Research*
*Nursing Science Quarterly*
*Qualitative Health Research*
*Research in Nursing and Health*

*(Berman et al 2015; Borbasi & Jackson 2016; Richardson-Tench et al 2014)*

vocabulary. However, the computer helps the researcher to define the preferred terms to use in a search. It is important to make the search as precise as possible; if there are several key terms, they should be used. Other limits such as gender, age and/or time factors should also be set. Ask for assistance from the librarian if there is difficulty finding information. It can be a challenging process searching for literature and finding the correct search words is often difficult. Librarians can help you in your search and help you choose the correct databases for your topic. Many professional information sources are also available on the internet, where there is access to a wide variety of databases, patient and nursing education resources, as well as some nursing journals. (See Online Resources at the end of this chapter.)

### Critical thinking and critical reading skills

When an article on the research topic is found, the next step is to use critical thinking and reading skills. Within the context of reviewing the literature, critical thinking is the rational examination of ideas, inferences, assumptions, principles and conclusions drawn from the readings (LoBiondo-Wood & Haber 2014). (See Clinical Interest Boxes 3.6 and 3.7.)

Critical reading involves the following stages:

*Skimming a source*. Have a brief look at the source to gain a broad overview of its content. Skimming through the article enables the reader to make a preliminary judgment about the value of a source and to determine whether it is a primary or secondary source (Burns et al 2013).

*Comprehending a source*. This requires that the source be read carefully, with the focus on understanding major concepts and the flow of ideas within the source. On a photocopy or an electronic version of the article, highlight the content considered to be important (Burns et al 2013; LoBiondo-Wood & Haber 2014; Schneider et al 2016).

*Analysis of a source*. Through careful analysis of the source, the reader can determine the value of the content for a particular study. The reader gains an understanding of the terms and parts of the study. This leads to a deeper understanding of the content and the merit of the study (LoBiondo-Wood & Haber 2014; Schneider et al 2016).

*Synthesis of a source*. This involves clarifying and establishing a meaning obtained from the source. The meanings obtained from all sources reviewed are then combined, to determine the current knowledge of the research problem. This forms the basis of the review of literature for research study (LoBiondo-Wood & Haber 2014; Schneider et al 2016; Burns et al 2013).

**CRITICAL THINKING EXERCISE 3.3**

You are reading an article that you need to critique for an assessment task. How can you determine the strengths and weaknesses of this article?

## CLINICAL INTEREST BOX 3.6 Highlights of critical thinking and critical reading strategies

- Read primary research articles from peer-reviewed journals.
- Read secondary research (critique/response/commentary) articles from peer-reviewed journals.
- Photocopy or print copies and make notations directly on the copy.
- While reading articles:
  - > keep a research text and a dictionary by your side
  - > review the chapters in a research text on the various steps of the research process, criteria used to critique, unfamiliar terms and so on
  - > list key variables at the top of the article
  - > highlight or underline new terms, unfamiliar vocabulary and significant sentences
  - > look up the definitions of new terms and write them on the article copy, and review old and new terms before subsequent readings
  - > highlight or underline identified steps of the research process
  - > identify the main idea or theme of the article—state it in your own words in one or two sentences
  - > continue to clarify terms that may be unclear on subsequent readings
  - > make sure you understand the main points of each reported step of the research process you identified before you critique the article.
- Determine how well the study meets the critiquing criteria:
  - > ask fellow students to analyse the same study using the same criteria and compare results
  - > consult faculty members about your evaluation of the study.
- Type a one-page summary and critical review of each study:
  - > cite bibliographic information of the reference at the top of the summary according to relevant reference style (e.g. the American Psychological Association, Harvard, Vancouver)
  - > briefly summarise each reported research step in your own words
  - > briefly describe strengths and weaknesses in your own words (bibliographical databases allow you to write a narrative for each paper reviewed).

*(Schneider et al 2016:15)*

## CLINICAL INTEREST BOX 3.7 Critiquing criteria

The following guidelines can be used as a guide in critiquing an article:

- Is it easy to read and understand; that is, no jargon or obscure phraseology?
- Is the topic important and relevant?
- Have the definitions, key terms and concepts been explained clearly?
- In the background to the study, is there enough information in the introduction to set the scene? Has the purpose of the study been identified?
- How did they conduct the study; that is, what is the methodology?
  - > Is there evidence of reliability and validity?
  - > How were the subjects selected?
  - > Are they a large or small group?
- What did the researchers find, and are the methods of analysis appropriate?
- Do the discussions and recommendations relate to study? Are the author's claims justified by the data? Were the suggestions made based on personal views and not on data? Are the recommendations based on reported findings?
- Is the language used understandable?
- Is the visual material (e.g. graphs, tables, charts) easy to follow and clearly marked?
- Comment on the study's strengths as well as its weaknesses.
- Justify criticisms; offer a rationale for how a different approach could have solved a problem.
- Try to be objective; try to avoid being overly critical of a study because of a personal lack of interest in the topic.
- Is the report or study written in an objective style or are the author's biases and viewpoints apparent?
- Does the author include a reference for every citation made in the text, so that readers can refer to earlier work on the topic?
- Check the credibility of the author.
- Check the year of publication—whether it is recent or old.

*(Borbasi & Jackson 2016; Ingham-Broomfield 2014; Hoffman et al 2013; Schneider et al 2016)*

## Step 4. Theoretical framework or conceptual framework

A theoretical framework uses a theory or theories to form a foundation or frame of reference for the research study. A theoretical framework helps the researcher explain or predict study outcomes and link these to the existing body of knowledge. Not all research studies use a theoretical framework, as sometimes a theory is not available if the area of research is new. A conceptual framework is a loosely related collection of concepts that have not yet been tested (Borbasi & Jackson 2016; Schneider et al 2016).

## Step 5. Hypothesis/research questions

When research questions are used, the purpose of the study is descriptive or exploratory and a theoretical framework is rarely identified. **Research questions** identify the variables to be studied and possible relationships or differences between

those variables. An example of a research question is, 'Do nursing staff undertake more hand hygiene than medical staff?'

A **hypothesis** tries to predict the relationships between variables and the expected outcomes of the study. A hypothesis predicts the relationship between two or more variables. The researcher makes educated guesses based on the review of the literature and the theoretical framework. A hypothesis is a statement of what the researcher thinks will be the outcome of an investigation. The results of the research study will either support or refute the hypotheses established (Borbasi & Jackson 2016). An example of a research hypothesis is, 'There is a higher level of compliance with hand hygiene in nursing staff than medical staff.'

Quantitative research tends to use a research hypothesis whereas qualitative research tends to use research questions.

## Step 6. Research design

The **research design** is the overall plan that guides the way the study is conducted and analysed (Borbasi & Jackson 2016). The research question determines the approach to be used in the design. The design of the study must be able to answer the question posed by the researcher. Determining the appropriate design is also accomplished through the theoretical framework and review of the literature.

Certain key aspects should be considered in a study design. They include:

- Intervention: if there are interventions in the study, they should be part of the design. The study should say what the interventions are (e.g. giving certain medication). What will be the procedure for the intervention? What will be the intensity of the intervention? How long will the duration of the intervention be? Who will perform it?
- Comparisons: in some studies, when making comparisons the design must clearly state what the central issue of the study is
- Extraneous variables: the researcher must mention in the design what measures will be taken to control the extraneous variables (the factors that influence the issue under study)
- Timing of data collection: the design should indicate when the data will be collected in relation to other steps of the research process
- Research location: the design must clearly specify the location for data collection
- Communication with the study participants
- In the research design, information given to participants must be clearly identified. When, what and how much information will be provided about the study to the participants?

## Step 7. Sample type and size

Once the research design has been established, the subjects and the setting are then considered. The subjects of interest for a research study are known as a population. These subjects possess certain common characteristics or traits that identify them as a part of the population. Populations are usually large, so the researcher chooses a part, or sample, of the population to make the study more feasible. Subjects are selected using a sampling process. The characteristics of the sample population must closely resemble the characteristics of the population as a whole. If this occurs, the study results can be applied to the whole population (Borbasi & Jackson 2016).

## Step 8. Legal and ethical issues

One of the primary concerns in research is to protect the subjects from any harm, discomfort, duress or coercion. Ethics approval is normally required before any data are collected that involve humans. If there is more than one agency involved in the study, the researcher must obtain ethical approval from each agency. Various agencies will have their own ethical guidelines (see Clinical Interest Box 3.8). In Australia one of the peak bodies for research is the National Health and Medical Research Council (NHMRC) (www.health.gov.au/nhmrc). A *National Statement on Ethical Conduct in Human Research* (2007) was jointly developed by the NHMRC, the Australian Research Council (ARC) and the Australian Vice-Chancellors' Committee (AVCC). Research involving Aboriginal and Torres Strait Islander peoples requires particular attention to ethical issues and is governed by separate guidelines (*NHMRC Guidelines on Ethical Matters in Aboriginal and Torres Strait Islander Health Research 1991*) (Borbasi & Jackson 2016; Schneider et al 2016).

When undertaking research while working in a healthcare facility, ENs would normally seek ethics approval from the hospital or healthcare facility's ethics committee. The three ethical standards that must be adhered to are beneficence,

### CLINICAL INTEREST BOX 3.8
### The broad role of human research ethics committees

- Risks to participants are minimised.
- Risks to participants are reasonable in relation to anticipated benefits, if any, and the importance of the knowledge that may reasonably be expected to result.
- Selection of participants is equitable.
- Informed consent will be sought.
- Informed consent will be appropriately documented.
- Adequate provision is made for monitoring the research to ensure the safety of participants.
- Appropriate provisions are made to protect the privacy of participants and the confidentiality of data.
- When vulnerable subjects are involved, appropriate additional safeguards are included to protect their rights and welfare.

*(Schneider et al 2016:92)*

justice and respect for persons (Borbasi & Jackson 2016) (see Chapter 2 for further explanation of these terms). Protection regarding storage, retrieval and destruction of data and all issues of confidentiality should be clearly explained for ethical approval of the study.

The NHMRC requires that all institutions involved in conducting research on humans or animals establish a relevant institutional ethics committee. This group reviews all studies conducted in the institution to ensure that **ethical principles** are observed, and determines the risk status of all research projects.

The nurse must also be aware of and advocate on behalf of the rights of individuals under their care. Nurses who work in settings where there is research on individuals or who participate in such research must ensure the following rights are upheld: right not to be harmed; right to full disclosure; right of self-determination; and right of privacy and confidentiality (Berman et al 2015).

### Informed consent

Study participants, or their guardians in cases of children or people with cognitive impairment, need to be fully aware of what the study involves, and what the benefits and risks of participating in the study are, in order to give **informed consent** (LoBiondo-Wood & Haber 2014). LoBiondo-Wood and Haber (2014) stated that research participants should have an understanding of the:

- Research purpose
- Procedures involved
- Risks/discomforts of participation
- Benefits of participation
- Expected duration of involvement
- Maintenance of confidentiality and anonymity.

Research participants should also be aware that they have a right to withdraw from a research study without detriment and if a participant does choose to withdraw, use of their data will cease by the research team. Whether an individual chooses to participate in a study or chooses to withdraw, the individual still has a right to confidentiality, meaning that their data will not be publicly divulged (LoBiondo-Wood & Haber 2014). Subjects should also be offered the opportunity to raise any concerns about the study at any stage of the study research.

## Step 9. Instruments or measurement tools

To examine the proposed research questions or hypotheses, the researcher must be able to collect measurable data on the variables. Data are collected using an 'instrument'. Data to be collected are usually physiological, behavioural or psychological in nature. Physical measurements could include using sphygmomanometers, electrocardiogram (ECG) machines, glucometers and thermometers. Behavioural data are generally collected through observation. Psychological measurements are used to collect data about knowledge, feelings and attitudes. These variables cannot be directly observed, so instruments such as questionnaires or interviews are used.

## Step 10. Validity and reliability

A quality instrument is an instrument that is valid and reliable. A valid instrument measures what it is supposed to measure, and a reliable instrument measures the variable consistently and accurately. Instruments used in research studies should be evaluated for **reliability** and **validity** before use in a study (Borbasi & Jackson 2016). For example, if undertaking a study that requires you to measure temperature, calibrate all thermometers to ensure accuracy and similarity of the readings.

## Step 11. Data collection procedure

The researcher puts the design into action and carries out the prescribed procedures. Treatments are conducted, instruments are administered and data generated and recorded. The most common methods of **data collection** in nursing are interviews, questionnaires, observation, focus groups, rating scales and biophysical measures (Berman et al 2015). If a qualitative approach is adopted focus groups could be used to ask in-depth questions to explore perceptions or feelings. Data must be collected in an ideal manner so that they capture the concept that is being researched in a way that is relevant, credible, accurate, unbiased and sensitive. Any small change to an aspect of data collection can influence the study and interfere with its integrity. After the data are collected, the researcher organises it into an appropriate form for analysis.

## Step 12. Data analysis

**Data analysis** occurs to answer the research questions or to see whether the hypothesis was true. Computer software may be utilised to assist in analysis of the data. In the qualitative approach, the analysis will begin almost immediately when data collection begins whereas, in the quantitative approach, all data has to be collected first before the analysis begins. The other difference is that the qualitative data has a lot of narratives and there is no systematic rule for analysing it. The absence of systematic analytical procedures makes it difficult for researchers to argue the case for validity. The absence of universally well-defined procedures makes qualitative study difficult to be replicated.

In the quantitative approach, statistical analysis enables the researcher to reduce, summarise, organise and give meaning to the data. Descriptive statistics are used to describe the specific characteristics of the data, such as how many cases fall into a particular category of measurement, typical values and the degree of interrelationship or correlation among measurements. Examples of descriptive statistics include averages and frequencies.

## Step 13. Results

The result section presents the research findings and data in statistical from (quantitative research) or narrative form (qualitative research). All results from the research should be presented in a clear, logical and concise way that answers each research question and/or hypothesis (LoBiondo-Wood &

Haber 2014). Tables and figures may be used to present and summarise large amounts of data clearly and concisely (Richardson-Tench et al 2014).

### Step 14. Discussion of findings and new findings

In the discussion section, researchers discuss and interpret the research results and give further meaning to the data. The researcher draws on the research aims, research literature and the theoretical framework used and interprets all the findings/results, whether these are supported by the literature or not, to highlight the outcomes of the study (LoBiondo-Wood & Haber 2014).

### Step 15. Implications, limitations and recommendations

Once the findings are stated and discussed, the researcher then makes recommendations for further research. Recommendations provide the reader with suggestions regarding the study's application to practice, theory and future research. The researcher also discusses any problems or limitations encountered while conducting the study. Identifying limitations informs future researchers so they do not repeat them when conducting a similar study.

### Step 16. References

All references that are cited in the article or research study are included at the end of a paper. The reference list supports the material presented by identifying sources in a manner that the reader can then follow up to obtain these references for their own use or for any clarification.

### Step 17. Communicating research results

Sharing the research findings can occur through several ways, such as presenting a paper or poster at conferences or seminars at local, national and international levels; or publication of articles in nursing research or specialty journals and reports, which leads to wider circulation of the study and research findings. It is sometimes said that if the findings are not presented or shared with the people who may benefit from them, the research process is not completed or the research is meaningless (Richardson-Tench et al 2014; Schneider et al 2016).

## PROPOSAL WRITING FOR RESEARCH APPROVAL

A research proposal is a written plan identifying the major elements of a study, including the research problem, the purpose of the research, the intended framework to be used and an outline of the proposed research methods and procedures to be used. Developing a research proposal is a formal way to communicate ideas about a proposed study, to apply for approval to conduct the study and, in some instances, to seek funding to support the research (Schneider et al 2016; Borbasi & Jackson 2016; Burns et al 2013). Funding, time and resource allocation are a consideration when designing a research project; for example, How much time do you have? What costs will be involved?

**CRITICAL THINKING EXERCISE 3.4**

Identify some possible areas for nursing research that arise from your clinical practice rotations. How might nursing research improve your practice in these areas?

### Writing a research proposal

A research proposal requires planning to convey the proposed research in a clear, concise and logical way in order to support the study. The depth and development of a proposal is determined by the guidelines developed by relevant institutes such as schools of nursing and healthcare institutes, where the research is to be undertaken and the type of research you plan to do (Burns et al 2013; Schneider et al 2016). Content considered to be critical in a proposal are:

- The background and significance of the research problem
- Purpose
- Framework
- Research objectives, questions or hypotheses
- Methodology or research design
- Research production plans (data collection and analysis plan, personnel, schedule and budget).

Essential sub-components of these critical elements of a research proposal include:

- Statement of the problem. This needs to:
  - be specific enough to be solved be in the form of a question or declaration statement. For example, if the study were about neglect of oral hygiene in nursing homes, the question might be, 'What is the impact of poor oral hygiene on residents in nursing homes?'
  - provide the background of the problem, such as how the problem came to be recognised and factors that contributed to the problem.
- Significance or importance of the problem:
  - includes the implications or possible applications of the knowledge that would be gained through the study.
- The research hypothesis (where appropriate), which should be:
  - reasonable
  - consistent with known facts or theories
  - stated in such a way that it can be tested and found to be probably true or false
  - stated in clear, simple terms.
- Assumptions and definitions:
  - all unusual terms that could be misinterpreted need to be defined
  - variables considered in the study should be defined.

- Review of related literature:
  - a brief summary of previous research and writings of recognised experts is included to provide evidence that the researchers are familiar with what is known and with what is still unknown and untested.
- An outline of the research procedure, which should include:
  - research design: a brief description of proposed mode of study
  - sampling protocol: population to be sampled, approximate sample size, characteristics and type of sample
  - specification of the proposed data gathering techniques (the actual instrument need not be included). Indicate only the data-gathering procedures, conditions for context of data collection and the time frame for data collection
  - analysis of data and methods to be used
  - projected timetable for various steps of the research
  - limitations and weaknesses of the study, as recognised by the researchers.
- Proposed budget:
  - include all necessary items and estimated costs.

A copy is typed for submission and should be free from errors in spelling, punctuation or grammar. A well-designed proposal is the first step to conducting a worthwhile research project.

### Content of a student proposal

Student researchers develop proposals to convey their research plan and projects to relevant nursing faculties, universities and research review committees. The content of a student proposal usually requires much detail and the proposed study is discussed in the future tense of what will be done in conducting the research (Burns et al 2013). Clinical Interest Boxes 3.9 to 3.11 present guidelines for quantitative and qualitative student research proposals and an example of a completed submission.

## HOW IS RESEARCH UTILISED IN PRACTICE?

Research utilisation refers to translating the knowledge that has been generated by research into clinical practice. The ultimate goal is to formalise research utilisation to promote research-based policies, procedures and clinical practice guidelines (Borbasi & Jackson 2016). However, there are many barriers to translating research into practice. These may include:

- Resistance to change
- Insufficient time and resources to implement changes to practice
- Lack of supportive infrastructure
- Lack of research skills, including an inability to critique
- Lack of professional autonomy to effect change

### CLINICAL INTEREST BOX 3.9 Quantitative research proposal guidelines for students

**Introduction**

- Background and significance of problem
- Statement of the problem and statement of the purpose
- Review of relevant literature
- Framework
- Development of a framework
- Formulation of objectives, questions or hypotheses
- Methods and procedures
- Description of research design
- Identification of population and sample
- Selection of a setting
- Presentation of ethical considerations
- Selection of measurement methods
- Plan for data collection
- Plan for data analysis
- Identification of limitations
- Discussion of communication of findings
- Presentation of a study budget and timetable

**References**

**Appendices**

*(Richardson-Tench et al 2014; Schneider et al 2016; Burns et al 2013)*

- Inability to access and engage with research findings (Borbasi & Jackson 2016; Grant et al 2012; Moule & Goodman 2014).

Clinical Interest Box 3.12 lists further barriers to research utilisation.

Solutions to barriers preventing the implementation of research results into practice may include educating future nurses on the importance of keeping up to date with the latest research in nursing and the importance of not resisting change based on new research outcomes. Having access to research articles and the distribution of the results of up-to-date research in the workplace is also important.

### Approaches to research utilisation

According to Borbasi & Jackson (2016), after a research study has been located and surveyed, it must be determined:

- Whether it is relevant to the clinical area (see Clinical Interest Box 3.13)
- Whether the study has rigour and the results have merit and are applicable to the area of work (see Clinical Interest Box 3.14)
- How to implement any relevant or applicable results (see Clinical Interest Box 3.15).

The top three facilitators of research utilisation as identified by Wang et al (2013) were enhancing managerial support, advancing education to increase knowledge base and increasing time for reviewing and implementation.

## CLINICAL INTEREST BOX 3.10 Qualitative research proposal guidelines for students

A qualitative research proposal might include some content similar to that of a quantitative proposal, but the guidelines are usually more flexible and abstract to accommodate the still-emerging design of the study.

### Introduction

- Identification of the phenomenon to be studied
- The study purpose and type of qualitative study
- Study question or aims
- Discussion of the significance of the study

### Research paradigm

- Identification of the research paradigm for the type of qualitative study to be conducted
- Description of the philosophical correlates of the research paradigm
- Explanation of research assumptions

### Research methods

- Researchers' credentials for conducting a particular type of qualitative study
- Identification of the research method for the study
- Selection of site and population
- The researchers' role
- Ethical considerations
- The data collection process
- Data analysis techniques
- Plan to document the research process during the study

### Preliminary findings, limitations and plans for communicating the study results

- Summary and relevant reference literature
- Identification of biases and previous experiences with research problem
- Disclosure of anticipated findings, hypotheses and hunches
- Discussion of how procedures will remain open to unexpected information
- Discussion of limitations of study
- Identification of a plan for communicating findings

### References

## CLINICAL INTEREST BOX 3.11 An example of a research proposal

### Student nurse retention and attrition in a TAFE setting

Investigator: Gabrielle Koutoukidis

### Introduction

The purpose of this descriptive study is to examine factors that contribute to the retention and attrition of students enrolled in the Certificate IV in Health (Nursing) at the Health Services Unit, Victoria University.

Factors that may impact on the issue of retention and attrition are identified and include work conflicts, personal problems, academic factors, being under-prepared versus being prepared for study, demographic factors and financial factors. The study will examine whether these factors differentiate between those who stay enrolled and those who leave the TAFE Nursing course.

A number of strategies and interventions to reduce attrition and increase retention of students have been introduced by the Health Services Unit over the past 5 years. These strategies are examined in terms of their effectiveness.

### Background to study

Focus groups and questionnaires conducted in 1997 within the Certificate IV in Health (Nursing) course at Victoria University revealed that students experienced stress in relation to study skills, time management, coping with social and

*Continued*

## CLINICAL INTEREST BOX 3.11 An example of a research proposal—cont'd

family roles, economic and financial issues. Students' inability to manage these stresses created difficulties in terms of their progression through successful completion of the course.

The Unit conducted a further study in 1997 that was quasi-experimental in design, with a non-equivalent control group to examine the effectiveness of various strategies to address the above issues. In this study the experimental group participated in an orientation program. This program aimed to provide them with knowledge about resources available on campus to assist them both academically with study and time-management skills and psychosocially with strategies and resources to cope with stress. Both groups were resurveyed 8–10 weeks later to compare their perception of stress and their level of skill, knowledge and ability to access resources available to support them. The stress reported by the experimental group was less than that of the control group.

This study made particular recommendations and from one of these has evolved an integrated 8-week timetabled academic skills assistance program to directly support students in the development of the academic skills necessary for successful completion of the course. Preliminary evaluation of this program indicates that students who attended this program had higher marks and higher course completion rates compared with students in past years, when there was no academic skills assistance program timetabled.

### Literature review

Much has been written on the attrition and retention of students in courses. McGrath and Braunstein (1997) state that causes of attrition vary and that the strategies designed to reduce it produce different results at different institutions. They recommended that administrators and faculty use surveys and focus groups to evaluate the effectiveness of the existing programs and strategies, and conduct semesterly and yearly statistical analyses to establish and measure strategic goals. They also recommended that college and university administrators and faculty should work together to conduct their own research regarding the retention of students rather than rely too heavily on findings in the related literature.

Conklin (1997), McGrath and Braunstein (1997) and Fralick (1993) state that work conflicts, personal problems, financial problems, demographic and social issues, health problems and child care difficulties are the major factors that lead to high attrition rates in courses. Fralick (1993) stated that research has shown that the most critical factor in student retention is a caring attitude by staff—in addition to orientation and advising, faculty and staff can contribute to student retention by developing advisement linkages with students through campus organisations, campus activities or college work–study programs.

### Framework

#### Aim

To explore the reasons why students decide to either leave or stay and complete the TAFE Nursing course.

#### Objectives

- To identify factors that contributed to student retention in the TAFE Nursing course.
- To identify factors that contributed to student attrition in the TAFE Nursing course.
- To recommend appropriate strategies for increasing retention within the TAFE Nursing course.

### Methodology

#### Design

This study will have a comparative descriptive survey design using questionnaires. Two questionnaires have been developed: one for students who voluntarily decide to leave the Certificate IV in Health (Nursing) course (colour-coded green (Appendix 1)); and a second questionnaire for students who complete the Certificate IV in Health (Nursing) course (colour-coded white (Appendix 2)).

The questionnaires are colour-coded to enable easy identification of the two different questionnaires when collating the data.

A comparative descriptive design examines differences in variables in two or more groups that occur naturally in the setting (Burns & Grove 1987:244).

Questionnaires were selected as the instrument because there is less opportunity for bias than in an interview (Burns & Grove 1987:311). Other advantages of a questionnaire include that subjects feel a greater sense of anonymity, that the format is standard for all subjects and is not dependent on the mood of the interviewer, and that a greater amount of data over a broad range of topics may be collected (Brink & Wood 1988:148).

A cover letter will accompany the questionnaire, explaining the purpose of the study, the name of the researcher and the approximate amount of time that will be required to complete the form (Burns & Grove 1987:313) (Appendix 3). The letter will be printed on Curtin University of Technology letterhead to add authenticity to the questionnaire.

A pilot test of the questionnaire will be performed with a small random sample of trainee students enrolled in the Certificate IV in Health (Nursing) course, who will be completing the course in July 2001. This is to determine the clarity of questions, effectiveness of instructions, completeness of response tests, time required to complete the questionnaire

## CLINICAL INTEREST BOX 3.11 An example of a research proposal—cont'd

and successfulness of data collection techniques (Burns & Grove 1987:313). In a pilot test the subjects and techniques should be as similar to those planned for the large study as possible (Burns & Grove 1987:313). This is the reason that the trainee students were chosen, and also because they will not be included in the study.

To ensure content validity, the questionnaire will also be submitted for review by three lecturers at Victoria University who are involved in nursing education and who are experts in developing questionnaires (Brink & Wood 1988:169).

### Subjects

The population for this study will be all students (male and female) who enrolled full-time and part-time in the Certificate IV in Health (Nursing) course in February 2001 (about 200 students). Both students who decide to leave the course voluntarily and students who successfully complete the course will be invited to participate in this study.

### Data collection

Stage 1. Questionnaires will be posted to the students, both full time and part time, who decided to voluntarily leave the course. A return envelope for the completed questionnaire will be included, with a return date indicated. These questionnaires will be posted when the students withdraw from the course. This mailing will start in July 2001 and continue until November 2001.

For the students who decide to complete the course, questionnaires will be administered during a class in the last week of the course in November 2001. A box will be placed in the student administration building at Sunbury Campus for students to return the questionnaires. Questionnaires will be collected daily for 1 week from this box.

Stage 2. To examine the variables that may have contributed to the retention and attrition rates of these TAFE nursing students. These may include work conflicts, personal problems, academic factors, being under-prepared versus being prepared for study, demographic factors and financial factors.

### Data analysis

Content analysis will be performed to extract meaning from open-ended questions in the questionnaire (Burns & Grove 1987:311). The categories derived from content analysis will be cross-tabulated with demographic data to examine the relationships between variables. Descriptive statistics will be used to describe sample characteristics that arise from the demographic data collected. The relationships between sample characteristics and data categories will be tested using Chi-square analysis (Brink & Wood 1988:267). Qualitative and quantitative analysis will also be performed on the data to examine the factors that contributed to the attrition and retention rates.

### Ethics

Only students enrolled in the Certificate IV in Health (Nursing) course in February 2001 will be selected for the purpose of this study. Participation is on a voluntary basis.

Participants will be informed of the purpose of the questionnaire via a cover letter, which will explain that all the information on the questionnaires will be collected anonymously. Anonymity will also be maintained through the fact that the names and addresses of participants will not be collected (Brink & Wood 1988:194). A consent form will not be required, as by completing the questionnaire, which has minimal or no risk attached to it, the participant is indicating consent (Burns & Grove 1987:353).

Confidentiality and anonymity can be further guaranteed, as the data that will be collected from the student database of the university will not include student identification numbers or names. No names will be linked to the data obtained on the questionnaires. In the data analysis, the data will be group-analysed so that individuals cannot be identified by their responses (Burns & Grove 1987:344), thus providing further safeguards for anonymity.

Data collected will be stored in a locked file for 5 years, as per recommendations from the NHMRC Statement on Human Experimentation.

**BUDGET**

| Budget items | Cost per item | Total cost | Funded by |
|---|---|---|---|
| Printing costs | 2500 pages @ 0.10 cents per page | $250.00 | Workplace & researcher |
| Supplies | | $400.00 | Workplace & researcher |
| Postage | 60 sent @ 45 cents each | $27.00 | Workplace |
| Return envelopes | 60 sent @ 45 cents each | $27.00 | Workplace |
| Travel costs (if researcher needs to fly to Perth for consultation) | | $1000.00<br>TOTAL: $1704.00 | Researcher |

### Appendices

(The appendices are the two questionnaires and cover letter, not included here)

*(Koutoukidis 2001)*

## CLINICAL INTEREST BOX 3.12 Other barriers to research utilisation

### The research itself

- Poorly designed and/or implemented research
- Research not replicated
- Relevant literature not compiled in one place
- Poorly supported results
- Poorly implemented or written statistical analysis

### Practising nurses

- Isolation from knowledgeable colleagues
- Nurses too new on the job to implement new ideas
- Lack of authority to implement changes

### Organisational settings

- No support of nursing research findings
- Changes in the healthcare environment
- Acuity rate
- Degree of nursing shortage
- Financial constraints to implement change

### The nursing profession

- Limited research-based journals
- Limited federal funding for nursing research
- Poor communication between practitioners and researchers
- Shortage of appropriate role models

*(Athanasakis 2013; Borbasi & Jackson 2016; Grant et al 2012; Moule & Goodman 2014)*

## CLINICAL INTEREST BOX 3.13 Criteria for determining clinical relevance of a study

- Is the study a clinical study?
- Is the problem being studied one you have seen in your clinical area?
- Is the setting used in the study similar to the setting you work in?
- Are the sample/participants in the study similar to individuals you work with in clinical settings?
- Do the study findings address issues that are within your scope of practice to change?
- Do they affect the activities of daily living?
- Do they have ramifications for the comfort and wellbeing of individuals under your care?
- Do they advocate system or procedural change?
- Do the study findings address issues that nursing and midwifery have the power to change?
- Are the study findings helpful to your clinical routine?
- Do they add to your knowledge base?

*(Borbasi & Jackson 2016)*

## CLINICAL INTEREST BOX 3.14 Criteria for determining clinical rigour of a study

- Are the steps of the research process followed?
- When you read the report does it clearly define the clinical problem?
- Are ideas concisely and comprehensively identified?
- Are participants, tools, methodology and types of analysis clearly defined? In other words, can you follow what was done and why it was done in that way?
- Are sampling methods clearly described? Are they appropriate to the study?
- Do the results make sense?
- Are the conclusions plausible?
- Do quantitative studies use reliable and valid instruments?
- Do qualitative studies address issues of auditability, transferability and credibility of data?
- In qualitative studies, does the final picture of the phenomena under study flow logically from the data?
- In quantitative studies, does the discussion section clearly identify who the results could be applied to? Are the findings clearly tied to existing knowledge?
- Have other studies been done that address the identified problem (that is, are there replications, meta-analysis or evidence in the literature of similar findings)?

*(Borbasi & Jackson 2016)*

## CLINICAL INTEREST BOX 3.15 Criteria for determining implementation possibilities for a study

- Who will be affected and in what numbers?
- What are the advantages of implementation?
- What are the risks of implementation?
- What are the risks of no implementation?
- Do the advantages outweigh the risks?
- How complex is the change (e.g. a simple intervention or a lengthy protocol that requires extensive retraining of personnel)?
- How much will it cost (e.g. need for staff training, equipment, supplies)?
- How many people need to be treated to observe a benefit?
- Who will be affected by the change besides nursing or midwifery (e.g. medical officers, pharmacy, housekeeping, billing, care services)?
- What are the tangible observable outcomes of the utilisation (e.g. will it decrease complications? Save money? Make the staff function better?)

*(Borbasi & Jackson 2016)*

## Summary

Nursing research improves the practice of nursing and raises the standards for the profession. Involvement in nursing research takes place in designing studies, being part of a research team, collecting data, using research findings to change clinical practice, improving individual outcomes and maintaining the cost of healthcare. Promoting research and research utilisation in practice increases the scientific knowledge base for nursing practice.

With the scope of practice constantly expanding for nurses, it is of importance that ENs are familiar with the research process, so that they can continue to provide quality care to individuals under their care. This chapter introduces some broad aspects of nursing research and its relevance to ENs.

### DECISION-MAKING FRAMEWORK EXERCISE 3.1

You are caring for Mrs Smith, a 69-year-old female who has been admitted for a venous ulcer. She tells you that her doctor has asked if she would participate in a trial of a new treatment for venous ulcers. She says she does not understand what the risks or benefits would be, but that she does not want to say no in case he refuses to treat her. How could you apply the decision-making framework for nurses to this situation?

## Review Questions

1. Explain the importance of research in nursing.
2. Summarise the main points of a literature review.
3. Outline the steps in conducting nursing research.
4. What is evidence-based practice?
5. What are the basic differences between qualitative and quantitative research?
6. What are some of the barriers to translating research into practice?

Answer guide for the Review Questions, Critical Thinking Exercises, Decision-Making Framework Exercises and Critical Thinking Questions in Case Studies are hosted on Evolve: http://evolve.elsevier.com/AU/Koutoukidis/Tabbner/

# Australia's healthcare delivery system

*Goetz Ottmann*

## KEY TERMS

aged care services
Commonwealth government
Council of Australian Governments (COAG)
disability services
e-health
evidence-based policy making
hospitals
integrated care
m-health
multidisciplinary teams
Pharmaceutical Benefits Scheme (PBS)
primary care
public health
social determinants of health
specialised health services
telemedicine
World Health Organization (WHO)

## LEARNING OUTCOMES

At the completion of this chapter and with further reading, students should be able to:

- Explain why healthcare decisions are political decisions
- Discuss the key building blocks of the WHO's conceptualisation of a healthcare system
- Outline key health policy reforms in Australia
- Explain what healthcare challenges are addressed by e-health
- Explain the main funding mechanisms of Australia's healthcare systems
- Discuss recent trends and challenges related to the healthcare workforce
- Discuss the basic components of the Australian PBS
- Explain the main components of Australia's healthcare delivery system
- Discuss the key challenges that healthcare policy makers face over the coming decades
- Discuss the idea of integrated care pathways and how they might impact on individuals

## CHAPTER FOCUS

The provision of effective healthcare requires the collaboration of health and community care professionals in many different parts of the health system. In order to provide responsive and person-centred healthcare, nurses must have a good understanding of the wider healthcare system and their role within it. This chapter provides an overview of the common building blocks of healthcare systems as defined by the **World Health Organization (WHO)** (2010) and outlines key features of recent healthcare reforms in Australia. In particular, the chapter focuses on leadership and governance, health financing, core medical products and technologies, health information systems, chronic illness management, the health workforce and health services delivery. Further focus is given to key issues facing Australian policy makers and healthcare professionals over the coming decades.

## LIVED EXPERIENCE

As an EN I started working at the local GP practice as a receptionist, where I occasionally assisted the GP with some procedures and obtained specimens. Over the years the practice has expanded and today the practice employs four practice nurses who are running chronic disease management programs (e.g. diabetes and asthma management), and one of the practice nurses runs a wound clinic. I work alongside the Registered Nurses as part of the team and am supported and supervised by them within my scope of practice.

**Madeline, 30 years old, Enrolled Nurse**

## INTRODUCTION

According to WHO, a health system consists of all the activities whose primary purpose is to promote, restore and/or maintain health (WHO 2013). Moreover, a good health system 'delivers quality services to all people, when and where they need them' (WHO 2010). While many Australians take their healthcare services for granted, health systems do not inevitably include the kind of services that give all people access to efficient healthcare that meets their needs (WHO 2010). Health systems are subject to powerful political forces and lobby groups that often override rational, **evidence-based policy making**. The outcome may be a disproportionate focus on specialist curative care; fragmentation and professional 'silos'; a multiplicity of competing programs, projects and institutions; the pervasive presence of commercial lobbies overriding the public interest; and poorly regulated systems (WHO 2010). Political actions shape the health and wellbeing of populations. Political decisions regarding the design of healthcare and welfare systems tend to affect population groups differently. This has clear implications for equity as some groups are better off, while others lose out (Duckett & Wilcox 2011). In other words, 'health policy is clearly as much about health as about politics' (Duckett & Wilcox 2011). Nurses are becoming increasingly aware of the role they can play in reshaping the healthcare system. They are important stakeholders and are able to exert political pressure to influence healthcare reform.

## COMPONENTS OF A HEALTHCARE SYSTEM

The quality of healthcare provided to citizens hinges on the quality of the healthcare system as well as underlying factors that shape the social determinants of health. **Social determinants of health** are the living conditions (i.e. access to clean water and air, income, education, employment, childhood development, food security, social connectedness, suitable housing and urban design, protection from weather and climate, trauma and accidents, workplace hazards, pathogens and toxins, and access to good healthcare) people experience. These factors have direct ramifications for a population's life expectancy, health and mortality rates. (See Table 4.1.)

WHO (2010) describes the main building blocks of a healthcare system in the following terms:

- Sound leadership and governance (stewardship)
- Health information systems
- Health financing
- Human resources for health
- Essential medical products and technologies
- Service delivery systems.

This chapter focuses on these six building blocks, explains challenges associated with improving the quality of health

### CRITICAL THINKING EXERCISE 4.1

The role of nurses in GP clinics has evolved considerably over the past decades. Nurse practitioner-led GP clinics are an example of this. GP nursing increasingly involves clinical contact and health promotion activities. Health and wellness promotion often require the collaboration of interdisciplinary teams to achieve the best outcomes. Imagine you are in charge of the chronic disease management program for older people at a GP clinic.

Which professional groups would you need to collaborate with?

**TABLE 4.1 | Life expectancy at birth and child mortality in six countries 1990–2013**

| Member state | Infant mortality rate (per 1000 live births) | | | Still-birth rate (per 1000) | Neonatal mortality rate (per 1000 live births) | | | Under-five mortality rate (per 1000 live births) | | |
|---|---|---|---|---|---|---|---|---|---|---|
| | 1990 | 2000 | 2013 | 2009 | 1990 | 2000 | 2013 | 1990 | 2000 | 2013 |
| Australia | 8 | 5 | 3 | 3 | 4 | 4 | 2 | 9 | 6 | 4 |
| New Zealand | 9 | 6 | 5 | 4 | 4 | 3 | 3 | 11 | 7 | 6 |
| USA | 9 | 7 | 6 | 3 | 6 | 5 | 4 | 11 | 8 | 7 |
| Thailand | 30 | 19 | 11 | 4 | 19 | 13 | 8 | 37 | 23 | 13 |
| Indonesia | 62 | 41 | 25 | 15 | 31 | 22 | 14 | 84 | 52 | 29 |
| Papua New Guinea | 65 | 58 | 47 | 15 | 31 | 28 | 24 | 89 | 78 | 61 |
| Nigeria | 126 | 113 | 74 | 52 | 49 | 46 | 37 | 213 | 188 | 117 |
| Malawi | 143 | 103 | 44 | 24 | 50 | 40 | 23 | 245 | 174 | 68 |

(*WHO Global Health Observatory Data Repository WHO 2014a*)

**CRITICAL THINKING EXERCISE 4.2**

What do life expectancy and neonatal mortality rates outlined in Table 4.1 tell you about the health system and the social determinants of health in Malawi? What are the key issues that might contribute to these poor outcomes?

systems and discusses some of the challenges policy makers face over the coming decades.

## Leadership, governance and reform

The quality of the health system depends largely on the quality of leadership and governance provided by governments. Governments not only set up and oversee the core structures of the healthcare system; they also ensure that the system is appropriately reformed to respond to the changing needs of the population. To that end, governments might increase spending allocations, re-prioritise and reallocate resources across programs, or change funding rules to access healthcare resources. They also negotiate with and assign responsibilities and accountabilities for health services to different tiers of government (Duckett & Wilcox 2011).

Australia's healthcare system is a complex fabric of often poorly integrated public and private providers. These providers deliver a wide variety of services ranging from aged care, public health and preventative services in the community, to primary healthcare, emergency health services, hospital-based treatment, rehabilitation, and aged and palliative care (AIHW 2014a). National leadership across the system as a whole remains a structural challenge (Bennett 2013).

Structures and processes underpinning healthcare reforms change in line with political opportunity and are therefore not set in concrete. In Australia, negotiations leading up to the National Health Agreement, a document that is reviewed in five-yearly cycles, are central to healthcare reform. Whereas in the past health ministers of all tiers of government played a key role in these negotiations, in recent years the **Council of Australian Governments (COAG)** has become increasingly important in shaping the reform agenda. Other mechanisms which have emerged over the past two decades and have gained increasing importance in Australia are public inquiries, ministerial working groups and independently commissioned reports. These mechanisms are used to manage the multitude of stakeholder demands, to make authoritative (truth) claims regarding the state of the health system and to determine strategies to improve the effectiveness and efficiency of the health system. Recent examples of public inquiries are Australia's National Health and Hospitals Reform Commission, the Preventative Health Task Force and the External Reference Group of primary care experts to inform the National Primary Health Care Strategy announced in 2008. Nursing peak bodies contribute to this process through submissions to reform commissions, media releases that seek to influence public opinion and direct lobbying campaigns targeting members of parliament or senior bureaucrats. Healthcare reforms are also the focus of reports tabled by international organisations such as the Organisation for Economic Co-operation and Development (OECD) whose verdicts carry weight among global financial entities and, hence, have repercussions for central governments.

Australians witnessed the start of a major health reform with the rise of the Labor (Rudd) government in 2007. Among the core promises of the health reform was to end political wrangling over governance responsibilities and financing of hospitals ('cost and blame-shifting') and to establish clear accountability structures. The reform impetus eventually led to a new Primary Care Reform strategy as well as

to the National Health and Hospitals Network reform (*National Health and Hospitals Network Act No 9 2011*). However, the initial proposal was significantly watered down in the political process leading to its ratification in 2011. In its current form, the Commonwealth will not assume full funding responsibility for primary healthcare and community-based services. Also, the Commonwealth will not assume the 60% funding responsibility for hospitals as initially envisaged, but will contribute a 45% share of growth in the 2014–15 financial period and a 50% share of growth from 2017–18 onwards (Bennett 2013). There are first signs that this reduced commitment by the Commonwealth does not end the blame shifting game—one of the key drivers of the reform agenda (Bennett 2013).

Since 2011, hospital funding has been tied to activities and a national efficiency index creating the basis for benchmarking and the identification of inefficiencies. Over the last decade, aged and disability care has seen major changes in Australia where community support packages are increasingly made available in the form of individual-directed care (also referred to as individualised funding) affording service users greater control over the services they receive. From July 2015, all Commonwealth-funded community aged care packages have to be delivered within a Consumer-Directed Care (CDC) framework. Moreover, the roll-out of the National Disability Insurance Scheme (NDIS) over the coming decade will generate a more entitlement- and market-focused approach to disability care.

## Consumers

Consumers are the main stakeholder in the delivery of health services. Current health policy recognises that health professionals should partner with consumers and their carers to provide services that are coordinated, responsive to consumer needs, safe and of high quality. Indeed, consumer involvement in health decision making has become a cornerstone of Australian health policy. The National Safety and Quality Health Services Standards (ACSQHC 2012; 2015) make it clear that 'partnering with consumers' and carers is a key requirement. Consumers are to be involved in decision-making processes leading to service planning, the design of care and the measurement and evaluation of services. This has important implication for health professionals, such as Enrolled Nurses. Enrolled Nurses should, wherever possible, plan activities and nursing practice in partnership with individuals. Enrolled Nurses should also ensure that consumers hold relevant health information and are enabled to make informed decisions about their health and wellbeing.

The demand for greater consumer involvement in healthcare decision making emerged during the 1950s and gained in strength during the 1960s and 1970s with the emergence of the individual rights movement. More recently, based on the mounting evidence that individual involvement in decision making potentially decreases mortality (Meterko et al 2010), readmission and healthcare-acquired infection rates (Boulding et al 2011), reduces the length of stay (DiGioia et al 2007) and improves functional status (DiGioia et al 2007) and adherence to treatment regimens (Arbuthnott & Sharpe 2009), as well as reduces operational costs and improves workforce satisfaction and retention rates (Charmel & Frampton 2008), consumer involvement has become a core element of recent Australian healthcare reforms (DoHA 2009). (See Clinical Interest Box 4.1.)

### CLINICAL INTEREST BOX 4.1 How do I involve a consumer in the decision-making process?

Individual preferences regarding involvement in decision-making processes differ considerably. There are different degrees of involvement and it is your responsibility to explore the degree to which your patient wants to be involved. While some consumers want to be making all major decisions regarding their care, others prefer for medical officers or nurses to take that responsibility. In some cases, it is absolutely crucial for the individual to be involved as the implications of a decision may have huge ramifications for their quality of life.

The important thing to remember is that individuals need to receive the right information to allow them to make informed decisions. In addition, they need to be involved in a conversation that encourages them to think about different options, deliberate about their preferences and communicate them to medical officers. It is your responsibility to ensure that individuals have received relevant information and have been informed that they have a choice!

## Health and information systems

The provision of accurate and timely health information has direct implications for the safety of individuals. Australia's service delivery environment is composed of thousands of geographically dispersed units providing hundreds of millions of services each year. Reliance on traditional, 'pen and paper'-based information records, manual processes and information flows potentially gives rise to a large margin for clinical error (Australian Health Ministers Conference (AHMC) 2008). It has been estimated that up to 18% of medical errors are the result of inadequate availability of individual information (AHMC 2008). Also, health information has to be available at short notice to professionals in different locations around Australia. Electronic-health (**e-health**) has the potential to facilitate and improve these outcomes. Australia's National e-health Strategy defines e-health as 'the means of ensuring that the right health information is provided to the right person at the right place and time in a secure, electronic form for the purpose of optimising the quality and efficiency of healthcare delivery' (AHMC 2008). Examples of e-health include clinical communication systems such as online referrals and e-prescribing, and electronic health records. Chapter 5 provides an overview of how informatics is being used in Australian healthcare.

The WHO differentiates between two rapidly growing sub-domains of e-health: m-health and telemedicine. WHO's working definition of '**m-health**' or mobile health is 'medical and public health practice supported by mobile devices, such as mobile phones, patient monitoring devices, personal digital assistants (PDAs), and other wireless devices' (WHO 2011a). The term '**telemedicine**' refers to the use of the internet and computer technology to improve individual outcomes by increasing access to care and medical information.

The Australian government has put in place e-health strategies (AHMC 2008). However, in Australia the development of a coherent e-health approach has lagged behind other developed countries. In part this has been due to a lack of political consensus regarding the need for and how to fund the substantial outlay for basic infrastructure (e.g. fast broadband networks), concerns about privacy and data protection, lack of information regarding its cost effectiveness, a lack of demand from physicians (WHO 2011c) and the relative lack of maturity of information technology within the health sectors. Medicare Locals represents a recent step to re-organise healthcare by making use of shared electronic records, telehealth and m-health to provide more integrated, responsive care to the community (see Case Study 4.1). A review of Medicare Locals was tabled in March 2014, resulting in recommendations that, if adopted, would lead to considerable change (Horvath 2014).

## CASE STUDY 4.1

Mr K is an 89-year-old married man with a number of comorbid conditions and multiple recent falls. He and his wife were invited to participate in an interprofessional team meeting as his primary care GP was concerned about his declining health and the growing caregiver burden on his wife. The meeting consisted of the GP, a practice nurse, a dietitian, a community nurse, a social worker, a pharmacist, an occupational therapist and a physiotherapist. Mr K's condition was deteriorating while the complexity of his case was increasing; therefore, an in-depth team assessment was sought to determine the best management plan and to assess his capacity to remain at home (his expressed preference). The Medicare Local team met with Mr K and his wife for a 2-hour video-linked interprofessional assessment. A comprehensive care plan was developed including specific recommendations for implementing change. After a brief visit to a local rehabilitation clinic, Mr K's care was returned to his regular family GP.

(Adapted from Bell et al 2011)

There is growing evidence that an effective management of multimorbidities requires the involvement of an interdisciplinary team. Reflect on the extent to which such teams have been implemented within a primary health setting you are familiar with. To what degree do you think such teams are available in Australia?

It is likely that due to the significant distances between rural and remote communities and a range of health specialist services, e-health will be of central importance over the coming decade. More information regarding health information and informatics is provided in Chapter 5.

## Health financing

In Australia, universal health insurance systems provide access to high-quality, low-cost healthcare to all citizens. In 2012–13, universal health insurance covered 68.3% (down from 69.9% in 2011–12) of Australia's health expenses (AIHW 2014b). The remainder is financed by private sector and not-for-profit organisations or by householders themselves.

In Australia, universal healthcare is known as Medicare and provides:

- Free or subsidised treatment (bulk-billing) provided by general practitioners (GPs), participating optometrists and dentists (oral surgery only); a capped number of allied health (including psychologists, physiotherapists and podiatrists) appointments upon completion of a GP care plan; and nurse practitioners and midwives[1]
- Free or subsidised accommodation as public patient in a public hospital
- Seventy-five per cent of the Medicare Schedule fee for services and procedures of private patients in a public or private hospital (does not include accommodation or certain theatre fees and medicines)
- Subsidies for prescribed medicines
- Substantial grants to state and territory governments to contribute to the costs of providing access to public hospitals
- Specific-purpose grants to state and territory governments and other bodies.

Medicare does not cover:

- Medical and hospital services which are not clinically necessary, or surgery solely for cosmetic reasons
- Ambulance services (PHIO 2013).

In addition, Commonwealth general-purpose funding grants to state and territory governments flow partly to health services. Figure 4.1 gives an overview of health expenditure by area of the health system in 2012–13.

Some Australians, such as members of the armed forces and veterans, are covered by additional special arrangements while remaining eligible for mainstream Medicare coverage. Some injuries and illnesses are covered by other forms of financing: for example, compulsory workers' compensation insurance covers work-related injuries and illnesses, and injuries from motor vehicle accidents may be covered by compulsory third-party motor vehicle insurance. Individuals may also be covered by private health insurance, or be self-funding.

Residential **aged care** is financed by the **Commonwealth government** by means of subsidies paid to service providers,

[1] In order to limit its financial exposure, among other strategies the Commonwealth restricts the health workforce that can claim Medicare rebates.

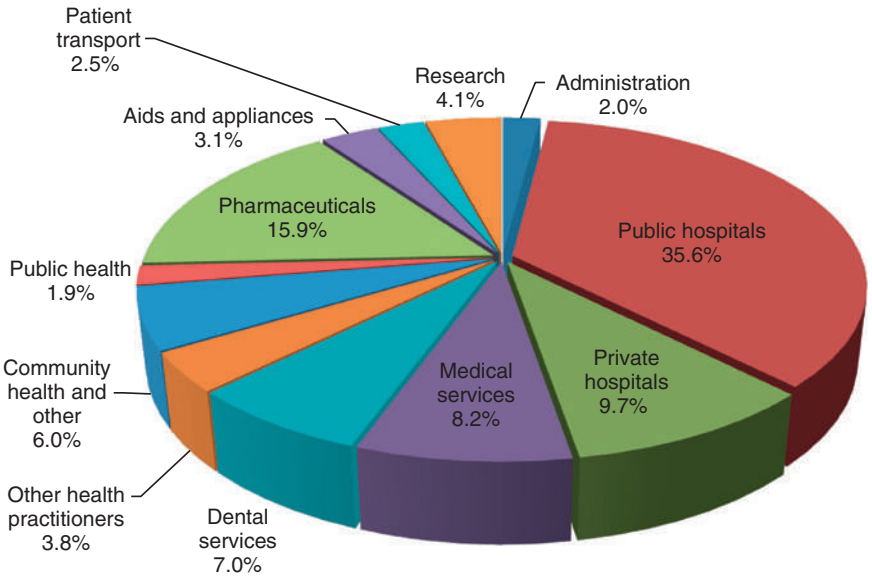

**Figure 4.1** Distribution of recurrent health expenditure by area of the health system, Australia, 2011–12 (*AIHW 2014a*)

based on the level and type of care needed by the individual. Residents have to make a means-tested contribution to care expenses.

Community care services for older citizens and people with disabilities aged 65 and over and who would like to remain living at home are jointly funded by the Commonwealth, state and territory governments. Community aged care support is available in the form of Home Care Packages. From July 2015, there will be four basic types of Home Care Packages available:

1. Level 1 (support for older people with basic care needs)
2. Level 2 (support for older people with low-level care needs—equivalent to the former Community Aged Care Packages)
3. Level 3 (support for older people with intermediate care needs)
4. Level 4 (support for older people with high-level care needs—equivalent to the former Extended Aged Care at Home and Extended Aged Care at Home Dementia Packages).

Community care individuals are charged fee contributions that vary with the individual's disposable income. At 30 June 2013, the Commonwealth funded 111.7 operational aged care places (including around 25 Home Care Packages) per 1000 people aged 70 or over. New residential care places are tendered out to providers on an annual basis.

### Specific federal government grants for healthcare services

Under Medicare the Commonwealth government provides a range of grants to government and non-government bodies to achieve specific healthcare objectives. These include:

- The provision of services to special needs groups such as people in rural and remote areas, Aboriginal and Torres Strait Islander peoples and people with mental illness
- Funding of medical services that involve the use of expensive equipment; for example, the capital component of radiotherapy services performed on specific approved equipment
- Improving general medical practitioner and associated services.

### Australia's Medicare levy

Medicare levy revenue provided the equivalent of only about 16.2% of Commonwealth recurrent healthcare expenses in 2012–13 (Australian Institute of Health and Welfare (AIHW) 2014b; Australian Government 2014). Medicare is funded by a range of taxes such as income tax, taxes on sales of goods and services and non-tax revenue, which together form consolidated revenue. Currently the Medicare levy is paid by individuals at a basic rate of 2% (including 0.5% earmarked for the National Disability Insurance Scheme) of taxable income above certain income thresholds. Taxpayers on high incomes who do not have private health insurance pay an additional 1% of taxable income as part of the levy.

## Private health insurance

Private health insurance funds a comparatively small share of healthcare expenses. In Australia, private health insurance covered about 8% of total national healthcare funding in 2011–12 (AIHW 2014a). For insured people, private health insurance provides added benefits such as choice of doctor, choice of hospital and choice of timing of procedure. Private insurance can also assist with meeting the costs of private sector services not covered by Medicare, such as dental, optical, physiotherapist and podiatrist services.

The Commonwealth government regulates private insurance policies offered by registered organisations to ensure that the principle of community rating is maintained. Community rating means that health funds must charge everyone

the same premium regardless of their health status or claims history. This ensures that private health insurance is open to a wide range of people in the community and that the aged and chronically ill are not priced out of private health insurance. To support community rating, a system of reinsurance redistributes the costs of claims for the elderly and those in hospital for an extended period across all private health insurance funds. This ensures that health funds with a high proportion of these higher-cost members are not disadvantaged.

The Commonwealth government has introduced measures to address the affordability, stability and attractiveness of private health insurance. These measures are designed to encourage people to take up private health insurance and decrease the pressure on the public system. For example, the Commonwealth government introduced a 30% rebate on private health insurance in January 1999. In 2005, the health insurance rebate was increased to 35% for people aged 65 to 69 and 40% for people aged 70+. People who join a private health fund aged 31 or older face a 2% increase in premiums over the base rate for every year they delay joining.

### Public and private hospital care

On admission to public hospitals, Australians may choose to be covered by the 'public' universal health insurance scheme or to pay expenses privately. If they choose to be 'public' patients (for non-elective surgery) they receive free medical and allied health or paramedical care from medical officers nominated by the hospitals, as well as free accommodation, meals and other health services while in hospital. Individuals who choose to be 'private' patients in public hospitals are charged fees by medical officers and are charged by the hospital for hospital care, usually at a rate less than the full cost of providing these services. If the patient holds private insurance this will usually cover all or nearly all of the charges of a public hospital. Universal health insurance pays benefits subsidising part of the cost of health professionals' fees, and private insurance pays an additional amount towards the fees charged by health professionals.

Private insurance benefits can also contribute to payment of the costs of allied health or paramedical and other costs (e.g. surgically implanted prostheses) incurred as part of the hospital stay. Individuals may choose to be treated in a private hospital and may choose their doctor. Private patients in private hospitals are charged fees by doctors and some allied health or paramedical staff and are billed by the hospital for accommodation, nursing care and other hospital services, such as use of operating theatres. If the individual holds private insurance it will contribute to these costs. If the individual is eligible for universal health insurance as a permanent resident of Australia, the medical officers' fees generally attract public subsidies.

### Publicly funded private specialist medical officers' services

For some kinds of specialist medical services (including pathology and imaging) to be covered by universal health insurance, the service has to be provided by a formally recognised specialist and a GP or family doctor has to refer the individual to the specialist. If these requirements are not met, either no benefit is payable or the benefit is lower.

## Human resources for health

Some professions within Australia's health workforce have experienced an increase in numbers. Between 2008 and 2012, the number of medical practitioners rose by 16% (AIHW 2014a). Between 2009 and 2013, the number of Registered Nurses increased by 9.8%; however, the number of Enrolled Nurses decreased by 3.5% (AIHW 2013). Projections for the workforce supply and demand for doctors and nurses reveal that by 2025, if current trends continue, there will be a shortage of a total of 2701 doctors and 109 490 nurses (Health Workforce Australia 2012, Vol. 1). When breaking down this data further, it emerges that not all roles are equally affected. For some nursing categories, the projected shortfall by 2025 will be very challenging for policy makers to deal with, even when taking a 5% productivity gain into account. For example, Table 4.2 outlines that the supply projection for registered aged care nurses for 2025 is a total of 16 618 nurses—around 10 104 nurses less than the projected demand for that year (Health Workforce Australia 2012, Vol. 2). Table 4.3 depicts the projections for Enrolled Nurses' numbers by job classification, highlighting a severe shortfall in all categories—even when taking a 5% productivity gain into account (Health Workforce Australia 2012, Vol. 2). General practitioner (GP) numbers, on the other hand, will experience a shortfall in the medium term only (Health Workforce Australia 2012, Vol. 3). Table 4.4 outlines the projected excess and shortage of GPs for 2025.

Moreover, despite numerous policy interventions, the healthcare workforce in Australia is unevenly distributed and is ageing faster than the total workforce. For example, with increasing remoteness, the numbers of GP and medical services delivered per capita declines and the average age of GPs increases. Also, in rural and regional general practice the workforce is much more reliant on international medical graduates. Indeed in 2010–11, the proportion of GP services delivered by GPs educated outside Australia in outer-regional (55%) and remote (51%) areas was much higher than in major cities and inner-regional (34%) areas (Health Workforce Australia 2012, Vol. 3). In 2013 around 70% of nurses and midwives were practising in major cities (AIHW 2014a).

Between 2003 and 2008, the share of the Australian healthcare workforce aged 55 years or older rose from 13% to 18% (equivalent figures for the non-health workforce were 12% to 15%). In 2013 the average age of Australian nurses remained 44 years (AIHW 2013). However, between 2009 and 2013, the proportion of nurses aged 50 years or older rose from 36.3% to 39.3% and the proportion of midwives aged 50 years or older rose from 53.4% to 56.6% (AIHW 2013). It is expected that this proportion of nurses and midwives aged 50 years or older will rise even further over the

*(World Health Statistics WHO 2014b)*

coming years. For some professional groups, the proportion is truly staggering. For instance, about 33% of Australia's medical specialists and primary care practitioners were aged 55 years or older in 2007 (AIHW 2010) and are likely to retire in the coming decade.

While Australia will be able to cushion some of the impact of these workforce challenges (i.e. through productivity gains, health sector reforms and by improving retention rates) there will be pressure on Australian politicians and policy makers to increase the intake of skilled migrants and international medical graduates in the future. That Australia has satisfied its demand for medical graduates by attracting overseas-trained professionals is nothing new. However, the inflow of international medical graduates has increased substantially over the past 25 years. For example, the proportion of GPs based in major cities whose basic qualifications were obtained overseas has increased from 25% in 1984–85 to 34% in 2010–11. In remote areas this figure increased from 25% to 41% over the same period (Health Workforce Australia 2012, Vol. 3). The top 10 source countries of international medical graduates were the United Kingdom (9350), India (6420), the Philippines (1850), South Africa (1770), Malaysia (1570), Ireland (1560), China (1380), Zimbabwe (1180), Canada (950) and the United States (830) (Hawthorne 2012).

Most developed countries source a part of their health workforce from developing countries. Hence, healthcare workforce pressures in the developed world have global implications. Table 4.5 provides a comparison of the density of the health workforce in Australia, New Zealand and six other countries.

**CRITICAL THINKING EXERCISE 4.3**

What implications will the nursing shortage forecast for developed countries have on a family in a rural village in the Philippines? Should Australia ban the recruitment of healthcare staff in developing countries? What is an argument favouring a ban? What is an argument against a ban?

## Essential medical products and technologies

In Australia, individuals have access to heavily subsidised medicines, pharmaceuticals and technologies prescribed by medical officers. The main subsidy mechanism for medicines and pharmaceuticals is the Commonwealth **Pharmaceutical Benefits Scheme (PBS)**. Medicines and pharmaceuticals to be included in the PBS are selected by panels of experts and prices are centrally negotiated with drug manufacturers to obtain the best price. Medication is funded up to a given cost-effectiveness threshold.

Currently the PBS provides subsidies for about 900 generic drugs available in 2200 formulations and marketed in about 4000 products (brands). While the Commonwealth funds community pharmaceuticals through the PBS, public hospital pharmaceuticals are funded from multiple sources, including the PBS. Additional drugs are added when assessed as meeting safety, quality, effectiveness and cost-effectiveness criteria. The importing and supply of medicines and medical devices is regulated by the Commonwealth Therapeutic

Goods Administration (TGA) to ensure the quality, safety and effectiveness of the products. Subsidised pharmaceuticals are sold by over 5000 pharmacies across Australia, regulated by Community Pharmacy Agreements.

Under the PBS all eligible persons fall into one of two categories:

1. Concession card holders
2. General patients.

General patients pay the cost of dispensed medicines up to a maximum amount per item ($37.70 in 2015). When the dispensed price of a drug is above that maximum, general patients pay that amount and the PBS pays the balance up to the listed price. If the prescription involves a more costly but equivalent brand, the subsidy may be limited to the lower-cost brand (the minimum pricing policy). Concessional patients pay a smaller amount per item ($6.10 in 2015) than general patients, and the PBS pays the balance up to the listed price. This is also subject to the minimum pricing policy.

Pharmaceuticals have been the fastest growing area of the health budget over recent decades, amounting to 13% in 2006–07 (AIHW 2010). Between 2000 and 2009, total pharmaceutical expenditure per capita increased from $336 to $541 (assuming US$ purchasing power parity) (Department of Health 2013). Between 1996 and 2008, community prescriptions rose by 46%. About two-thirds of this increase is due to an increased use of pharmaceuticals and higher prices, and about one-third is the result of population growth (Duckett & Wilcox 2011).

The Australian government has attempted to limit the expenses associated with the pharmaceutical benefits schemes. For instance, Australia promotes the use of cheaper generic pharmaceuticals rather than more expensive brands. However, other countries have been comparatively more successful in reducing the growth of national expenditure on pharmaceutical products. For example, New Zealand has successfully introduced an aggressive mix of reference pricing (where subsidies are only available at the level of the cheapest equivalent medication) and sole-supply tendering (when PHARMAC tenders to get the best price for a generic substitute when a drug patent expires). This has resulted in a condition where the cost of a single statin (a cholesterol-lowering agent) tablet is about 5 cents in New Zealand, whereas in Australia the same tablet costs $1 (Duckett & Wilcox 2011).

**CRITICAL THINKING EXERCISE 4.4**

What do you think is the reaction of pharmaceutical companies to reference pricing and competitive tendering? Why has the Australian government not pursued reference pricing and competitive tendering more aggressively?

## Service delivery systems

There are several ways service delivery systems have been conceptualised. Two common approaches include structural and sequential approaches: structural approaches take into account the way health systems are administered or funded (i.e. public health, primary care, hospitals and specialist health services); sequential approaches focus on where the individual journey services are located (i.e. primary care, secondary care and tertiary care). In this chapter a structural conceptualisation is employed using the headings public health, primary health, hospitals, specialised health services and aged and disability care services (see, for example, Duckett & Wilcox 2011).

- **Public health** comprises a wide range of activities, such as creating safer environments (air, water, food), occupational health, reducing the risk of disease transmission and the early identification of diseases, as well as campaigns promoting healthy lifestyles.
- **Primary care** provides 'first-level care' including a wide range of services, such as screening, episodic or acute services, health promotion and services for the chronically ill. Primary care ideally involves multidisciplinary teams.
- **Hospitals** generally provide emergency and acute care services.
- **Specialised health services** include mental health services, sub-acute, transition care and other step-down programs, as well as alcohol and other drug services, and palliative care services.
- **Aged care services and disability services** comprise community care services for the aged and people living with a disability, specialist services for people with impairments, specialist community care for older people and residential aged care.

### Public health

The Australian government has built quality healthcare systems that provide appropriate services to its population. However, in spite of several attempts to strengthen the focus on public health (e.g. the Better Health Commission in the 1980s and the National Public Health Partnership in the 1990s), health promotion has remained an under-developed component of the health system. The health reforms initiated in 2007 sought to address some of these issues with the formation of the Australian National Preventative Health Agency in 2011. The agency was disbanded in mid-2014 by the Abbott government and some of its essential functions were transferred to the Department of Health. In 2011–12 about 1.7% of the total health funding was dedicated to preventative care and health promotion (AIHW 2014c). Current preventative health strategies focus on obesity, diabetes and infectious disease prevention; mental health; cancer screening; tobacco, alcohol/drug consumption; and the promotion of healthier life styles (AIHW 2014c). In addition, the Australian government has launched public health programs aimed at improving the health of the Indigenous populations.

### Primary care

Primary care is the first health service visited by individuals with a health concern. GPs and increasingly nurse practitioners/practice nurses are the 'gatekeepers' of the health

system as they authorise access to other services. The primary care system addresses the bulk of the healthcare needs of Australians. In 2011–12, 84% of Australians consulted a GP at least once (ABS 2013). Medicare provided benefits for 123 million non-referred GP consultations (2011–12 figures) (AIHW 2014a). A significant proportion (about 35%) of all problems managed by GPs relate to chronic illnesses (Duckett & Wilcox 2011). In response, primary healthcare strategies place emphasis on the development of multidisciplinary primary healthcare teams including GPs, nurses, pharmacists and allied health professionals (including physiotherapists, dietitians, psychologists and occupational therapists). About 67% of Australians reported having seen a complementary and alternative healthcare worker during the previous 12 months (National Prescribing Service Ltd 2008). The dispensing of complementary healthcare is under-regulated.

## Hospitals

Australian hospitals are very diverse regarding their ownership, size and range of services offered. In 2012–13, there were 746 public and 592 private hospitals. More than half Australian hospitals (around 71%) are relatively small and operate up to 50 beds (AIHW 2014d). While hospital beds have declined over the last decade—mainly as a result of the shift of long-term occupants out of hospitals, changes in individual management, shorter treatment cycles and increasing treatment of individuals in the community—rates of hospital utilisation have increased because of the impact of new technology and hospital organisation in reducing length of stay (OECD 2014). Waiting times for elective surgery represent one of the key political drivers of hospital policy. Yet the core business of public hospitals is outpatients and non-admitted services, accounting for more than four times the volume (about 46 million separations) compared to emergency department and inpatient admissions in Australia (AIHW 2014d).

## Specialised health services

Specialised health services include sub-acute and transition care services such as stroke recovery, rehabilitation services and palliative care. They involve multidisciplinary teams providing rehabilitation, aids and equipment, alcohol and drug programs, and mental health services in hospital and community-based settings. They have the capacity to considerably reduce re-admissions of individuals to the acute system. About two-thirds of all rehabilitative care is provided in a hospital setting. Over the past two decades, the most significant reform of mental health was the mainstreaming and de-institutionalisation of services, replacing psychiatric hospitals with community-based mental health and general hospital services, and integrating mental healthcare into different settings. This was in part framed by the first National Mental Health Strategy adopted by governments in 1992 and the opening up of the Medical Benefits Schedule to mental health under the Better Outcomes in Mental Healthcare initiative. However, the outcomes of these reforms have been inconsistent, in part due to the lack of funding in the sector. In response to stakeholder concerns, the Australian federal government recently appointed a National Mental Health Commission with the remit to conduct a comprehensive review of mental health services. Moreover, the government has pledged funding for research and the expansion of the 'headspace' youth mental health centres across Australia.

### CRITICAL THINKING EXERCISE 4.5

Imagine that a 75-year-old woman with complex care and substantial rehabilitation needs resulting from a hip fracture is discharged from hospital. What are the professional groups and services that should assist her on her journey back to being self-sufficient in her own home? What happens if these professionals fail to collaborate effectively?

## Aged and disability care services

Australia's aged and disability care systems operate largely in isolation from each other. The aged care system is structured around two main forms of care delivery. It is comprised of 186 000 residential care (accommodation and various levels of nursing and/or personal care) places and 60 000 community care packages (ranging from delivered meals, home help and transport to intensive coordinated care packages for people who otherwise would need residential care). There is a substantial shortfall between the size of the eligible target populations and level of service provision (Duckett & Wilcox 2011). Residential services are mainly operated by the non-government sector, with about 60% being operated by religious and charitable organisations. Both public and non-government (mostly religious and charitable) sector organisations provide community care services under the Commonwealth-funded packaged care (Levels 1–4). From 1 July 2015, community aged care service providers are required to deliver services within a 'consumer-directed care' framework. Refer to Chapter 15 for further discussion of aged care packages.

### CRITICAL THINKING EXERCISE 4.6

Compare how many packages the Commonwealth allocates to residential and community aged care. Out of 1000 people aged 70 or over, how many do you think would require community aged care assistance? Hint: About one-quarter of all older people are living with a severe or profound disability. Why, in your view, is the Commonwealth funding so few community aged care packages?

There are a large number of packaged care arrangements for people with an impairment. These packaged care arrangements are under the governance of state and territory governments and are delivered by private sector or not-for-profit agencies. The Commonwealth government is beginning to

take carriage of these packages in the form of the National Disability Insurance Scheme (NDIS) formed in 2013. The NDIS provides access to individualised support funding for people with disabilities. Under the scheme, resources are made available as an entitlement and not as a welfare benefit. The NDIS is being rolled out across Australia in stages with seven trial sites currently in operation. It is envisaged that by 2019 the NDIS will be fully rolled out.

## Integrated care

**Integrated care** is a policy response to the rising prevalence of chronic disease. While the prevalence of deaths resulting from some chronic diseases such as coronary heart disease, stroke and respiratory illnesses has decreased over the past decades, the prevalence of other chronic diseases such as diabetes and chronic kidney disease have remained largely unchanged or, as in the case of obesity, have increased in recent years (AIHW 2014e). More importantly still, researchers have highlighted the fact that multimorbidity is quite common and that many Australians, and particularly older people, have more than one chronic illness. For example, of 9156 individuals presenting at a primary care clinic in 2005–06, 23.3% had one chronic illness and 37.1% had more than one chronic illness (Britt et al 2008). In the same study, 75% of people aged 65–74 were classified as having a multimorbidity. Also, 58.2% of those aged 75 or older had three or more, and 33.4% had more than four chronic illnesses. In an AIHW-commissioned report, based on the BEACH (Bettering the Evaluation And Care of Health) study involving 97 800 encounters with GPs, Britt and colleagues state that chronic problems accounted for 36% of the encounters and that over half of all chronic problems managed by GPs were hypertension (15.4%), diabetes (7.6%), depressive disorders (7.3%), arthritis (6.8%), lipid disorders (6%), oesophageal disease (4.7%) and asthma (3.9%) (Britt et al 2013). In the same study, around 60% of presentations involved overweight or obese adults (Britt et al 2013). The management of chronic diseases and, particularly, multiple chronic diseases has a strong relational and educational component; its main focus is on maintaining or restoring function and the prevention of complications that would require admission to an acute care setting. Keeping this in mind, it becomes evident that chronic disease management benefits from a different care regime than the one available in a conventional acute care setting. Integrated care is widely seen as a solution to this problem.

Australia's primary care-focused integrated care strategy was ratified in 2005. Australia's approach emphasises collaborative care as well as financial incentives for GPs to develop coordinated chronic disease management plans involving, where appropriate, team care arrangements (National Health Priority Action Council 2006). The Chronic Care Model (CCM) developed by Wagner has become the template for chronic disease management in many Australian jurisdictions. The evidence underpinning the CCM, updated to accommodate evidence on the management of multiple conditions, suggests that effective chronic disease management should be based on ongoing self-management support; the use of multidisciplinary teams including lay persons; targeted assessment and interventions; shared decision making; a non-judgmental approach; guideline-based case management; collaborative goal setting and problem solving; interventions improving individual self-efficacy; and linkages to evidence-based community-based self-management programs (Battersby et al 2010).

## Multidisciplinary teams

The rationale for involving **multidisciplinary teams** and/or the establishment of service provider networks in chronic disease management is based on the insight that the multifaceted risk factors underpinning chronic disease can be better addressed by a range of professional groups than by one single professional. As a result, comprehensive primary care should, alongside general practitioners, include other disciplines, such as nursing, allied health and social work. Indeed, recent attempts to reform Australia's primary care system have focused on the expansion of skill mixes. The composition of multidisciplinary care teams can vary considerably and depends largely on the chronic disease profile(s), as well as environmental, psychological and social determinants.

### CRITICAL THINKING EXERCISE 4.7

Think about an individual with Motor Neuron Disease (MND). What roles would a multidisciplinary team caring for this individual comprise?

### CRITICAL THINKING EXERCISE 4.8

There is growing evidence that an effective management of multimorbidities requires the involvement of an interdisciplinary team. Reflect on the extent to which such teams have been implemented within a primary health setting you are familiar with. To what degree do you think such teams are available in Australia?

Only a small percentage (around 10%) of individuals who would benefit from a referral to other service providers for more intensive interventions are being referred by GPs (Harris & Lloyd 2012) (see Clinical Interest Box 4.2 and Case Study 4.2).

## Key challenges

### Ageing of the population

The number of Australians over age 65 is increasing more rapidly than that of the general population. In 2006, people aged 65 and older made up 13% of the Australian population. It is expected that this will nearly double (to 24%) over the coming 30 years (AIHW 2007). Furthermore, the increased longevity in Australia is resulting in a marked growth in the numbers of people aged 85 or older. In 2006, people aged 85 and older made up 1.6% (double that of 1986 figures) of the Australian population, a figure that is projected to increase to 5.1% by 2050 (Productivity Commission 2011). This

## CLINICAL INTEREST BOX 4.2
## Referral to other service providers by GPs

In 2009, of 74.1% of individuals whose assessment revealed nutrition issues, 29.9% were given preventative advice, 8.3% were referred to dietitian or other services and 7.3% attended a nutrition-focused program (Harris & Lloyd 2012). It is not uncommon for GPs to express doubt about the effectiveness of referral options and a preference for managing individuals within their own practice. Other barriers include ill-defined communication pathways, waiting lists for certain public services, delayed access to group programs, suitability of time and place of programs and lack of individual acceptance of referral options. By ensuring that an individual is referred to an appropriate network of services beyond the general practice, you have the capacity to contribute towards their wellbeing.

## CASE STUDY 4.2

Joan is an Enrolled Nurse working for a regional community aged care provider. Joan is asked to coordinate the care of Harold Blakey (83), who lives in Tubbut with his son Michael. Tubbut is a village located at the border of the Snowy River National Park. Michael is employed as a park ranger and is home only on weekends. Harold has been recently discharged from hospital step-down services after a fall that fractured his hip. Harold requires extensive support as he is still not mobile enough to care for himself. Having met Harold, Joan forms the opinion that his fall could have been the result of Harold's poorly managed diabetes and that he still requires further physiotherapy. There are no health or aged care services available in Tubbut. The nearest service providers are in Buchan or Orbost (where Joan is located), both around 4 hours drive from Tubbut. Harold cannot physically get to Orbost as there is no public transport. What is an appropriate course of action for Joan to take? Think about developing a collaborative approach and check your answer against the national decision-making framework.

Put yourself in Joan's shoes. What would be your course of action? Are you authorised? Do you have the required education and experience to provide diabetes education and physiotherapy?

demographic shift is associated with increases in the prevalence of multimorbid health conditions, neurodegenerative diseases and related care needs that, in turn, might impact on healthcare costs (Britt et al 2008; Harrison et al 2013; AIHW 2014e). Multimorbidity is increasingly common in primary care and is associated with increased healthcare utilisation and cost across the healthcare system (Glynn et al 2011; Marengoni et al 2011; Bock et al 2014). (See Clinical Interest Box 4.3 and Figure 4.2.)

## CLINICAL INTEREST BOX 4.3
## Healthcare expenditure in Australia

Health expenditure as a percentage of GDP in Australia has increased steadily, rising from about 6.5% in 1975–76 to 9.7% in 2012–13 (see Figure 4.2). It is expected to continue growing mainly due to the increase in chronic disease, the ageing population, new medical technologies, rising incomes and changing consumer expectations (AIHW 2014b; Productivity Commission 2015).

### Equity of access

As waiting lists for elective surgery and out-of-pocket expenses for individuals increase, and as more people who can afford it take up private health cover, access to health services is becoming less equitable. Well-educated citizens with the purchasing power to access private health insurance tend to be healthier than their less privileged counterparts (Armstrong et al 2007). A recent government-sponsored survey revealed that 6% of Australians delayed seeing a GP during 2009, 10% delayed seeing a specialist and 9% did not buy prescription medication because of cost (ABS 2010). The health of some Aboriginal and Torres Strait Islander communities is particularly precarious. The reasons for this are complex and are strongly shaped by the colonisation process which led to spiritual and material dispossession, low socioeconomic status, poor physical environments, substance abuse and other issues (Burgess et al 2005).

Other population groups, such as people living with a disability, are also disadvantaged. People living with a disability tend to have higher health needs due to multiple comorbidities. Yet health promotion and prevention activities seldom target people with disabilities. Moreover, people with disabilities have less access to health services due to a lack of affordability, limited availability of appropriate services and physical barriers, as well as lack of appropriately skilled health workers (WHO 2011b).

### Quality of care

Adverse events, medical errors and lack of continuity of care all contribute to poor quality outcomes (Armstrong et al 2007). In 2006–07 about 17% of hospital admissions in Victoria led to conditions acquired in hospital that required treatment (McNair et al 2009) and a similar percentage of Australians with significant illnesses believed that they had experienced a medical error during the previous two years (Schoen et al 2005). In 2013–14 a total of 57 individuals in the care of Melbourne health facilities experienced a critical incident, 773 minimal harm and 1775 a near miss without harm due to medication error (Melbourne Health 2014). Quality measures are essential for the improvement of healthcare outcomes. See Chapter 7 for more information on safety and quality.

## Efficiency and effectiveness

Despite significant improvements in efficiency over the past few decades, inefficiencies persist in a number of areas in the healthcare system. For example, financing arrangements encourage overinvestment in Medicare-funded services, often at the expense of more effective or cheaper services (Duckett & Wilcox 2011). Also, several recent reports have pointed out that a significant number of hospitalisations could be avoided or hospital stays could be shortened (National Health and Hospitals Reform Commission 2009). To address this, one of the key points in health reform is the better integration of health and social care services. Integrated care depends on the coordinated collaboration of a wide range of health professionals or 'networks' working in different domains of the health system (Hudson 2007). Most countries are working towards building organisational and managerial structures geared to produce a seamless integration of services across the service spectrum, from disease prevention through primary and community care to hospital care.

## Acceptability of services

The past three decades have seen the rise of health consumer movements in Australia, suggesting a greater popular awareness and attitudinal change regarding healthcare. While the Australian healthcare system is more responsive to consumer preferences and individual engagement than that of comparable countries, many voters think that the quality of services provided by the healthcare system is unacceptable. Overall, about 20% of Australians believe that the healthcare system needs to be completely overhauled and about half of the surveyed population thinks that fundamental changes are required (Duckett & Wilcox 2011).

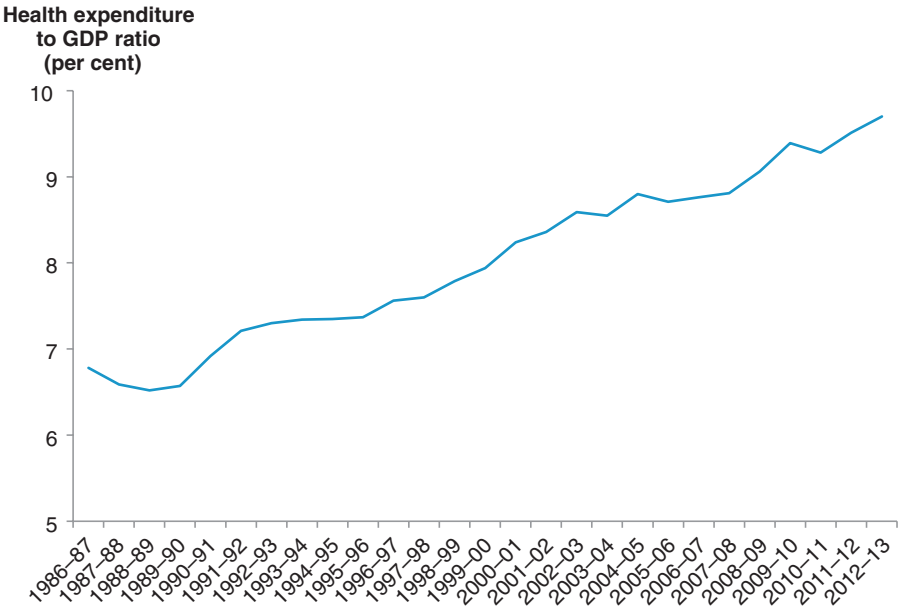

**Figure 4.2** Health expenditure ratio to GDP, Australia 1986–87 to 2012–13
(*AIHW 2014b*)

## Summary

This chapter provides an overview of the common building blocks of healthcare systems as developed by WHO. Following WHO's conceptualisation of a healthcare system, the chapter focuses on leadership and governance, health financing, core medical products and technologies, health information systems, the health workforce and health services delivery. The chapter also canvasses the development of quality standards and provides an overview of current approaches. Lastly, the chapter focuses on key issues facing Australian policy makers and healthcare professionals over the coming decades.

## Review Questions

1. What is the impact of a sub-standard healthcare system on the population of a country?
2. What is the Chronic Care Model and what are its key components?
3. What are the key challenges that will affect the healthcare system over the coming decades?
4. What is integrated care and why is it important?

*Continued*

5. What are the different funding responsibilities of the Australian Commonwealth and state and territory governments in relation to health services?
6. Why is e-health regarded as essential to the healthcare system?
7. Why was little progress made over the past decade implementing e-health in Australia?
8. Which levels of Australian government have a role in funding coordinated care for older people with chronic conditions?
9. What are the key challenges regarding the health workforce over the coming decade?
10. Which groups of Australians have a record of poor health status?
11. How is the Australian Medicare system financed?
12. What is the role and function of the PBS?
13. Identify the differences between the five levels of the healthcare services delivery system.
14. Who are the most important stakeholders within the healthcare system and what are your responsibilities regarding these stakeholders?

Answer guide for the Review Questions, Critical Thinking Exercises, Decision-Making Framework Exercises and Critical Thinking Questions in Case Studies are hosted on Evolve: http://evolve.elsevier.com/AU/Koutoukidis/Tabbner/

CHAPTER 5

# Nursing informatics and technology in healthcare

*Robert M Ribbons*

## KEY TERMS

email
protocol
browser
hardware
random access memory (RAM)
business analyst
health informatics
read only memory (ROM)
central processing unit (CPU)
hospital information system (HIS)
social networks
clinical information system (CIS)
local area networks (LANs)
software
management information system (MIS)
spreadsheet
convergent technology
telehealth
telenursing
data standards
nursing minimum data sets
universal serial bus (USB)
database
Personally Controlled Electronic Health Record (PCEHR)
e-health
picture archiving and communication system (PACS)
world wide web (WWW)
electronic health record (EHR)

## LEARNING OUTCOMES

At the completion of this chapter and with further reading, students should be able to:

- Define informatics, health informatics and nursing informatics
- List a brief history of computers and computing
- Discuss the fundamentals of information technology including concepts of hardware and software
- Discuss the role of the internet and world wide web in contemporary healthcare
- Demonstrate a beginning understanding of how specific software application (e.g. word processing, spreadsheet, database, presentation and statistics) may be applied to nursing practice, administration, education and research
- Describe the role of database, communication and network technology in the development, implementation and utilisation of information systems
- Understand issues related to informatics ethics, privacy and confidentiality
- Demonstrate a beginning understanding of the role of computer and network security in maintaining health information system integrity
- Describe the need for data standards and nursing minimum data sets
- Demonstrate an understanding of current trends in e-health including the use of social media and how they influence the development, implementation and utilisation of information systems
- Discuss specific clinical, administration, education and research information systems and determine their role in improving nursing care

## CHAPTER FOCUS

Today, the provision of effective healthcare by multidisciplinary teams requires access to timely, accurate health information data. As the electronic health record (EHR) becomes the source of health information and aids in the planning of individual care, it is essential that any health data generated is able to be collected, exchanged, stored and retrieved from healthcare information systems. In this increasingly technology-driven healthcare environment, nursing professionals will be required to possess not only computer literacy but, more importantly, information literacy skills.

This chapter examines the relationships between computers, information technologies and the provision of nursing care. Nursing graduates, both enrolled and registered, need to be cognisant of contemporary issues in nursing informatics and possess skills in the use of information technologies in healthcare settings.

## LIVED EXPERIENCE

I went to a seminar recently about digital hospitals. In this talk they discussed that individuals being admitted to a digital hospital will have a bar code on their identification band. Nurses will have smartphones and will scan the bar code and up on the phone will come all the individual's details, care plan, medications, medical and nursing history! These hospitals will be silent, with all messages and alerts coming up on the smartphones. Nurses will be able to find equipment—by searching on the phone—which will inform the nurse where the piece of equipment is, instead of looking everywhere for it in the hospital and phoning around wards. It sounded like something out of a James Bond movie. The emerging technologies in health are amazing!

**Siobhan Krikori, Enrolled Nurse, Acute Care Facility**

## AN INTRODUCTION TO NURSING INFORMATICS

It is hard to imagine conducting a transaction with a bank, purchasing an airline ticket or doing the grocery shopping without some involvement of computers or information technology. Information technology (IT) refers to all forms of technology used to create, store, exchange and use data, information and knowledge (Hebda & Czar 2013). IT essentially provides the infrastructure for a networked economy and in doing so forms a highly widespread component of modern society. It is so ubiquitous that often individuals are unaware of their interaction with the technology. In many respects, IT is not only taken for granted, it is expected. IT has made life easier and more convenient. At the same time, some might say it has made our lives more complex. One only needs to think how email has impacted the workplace. We are now inundated with information, much of it superfluous, but all of it requiring some form of attention.

The use of computers and information technology as a way of managing health information is also becoming almost ubiquitous (Weiser 1991) and has been the impetus for the rapid evolution of nursing and health informatics in the past few years. The development of information systems within healthcare usually involves a range of health professionals and their different practices such that we often see a number of healthcare professionals involved in the development of information systems.

**Health informatics** involves a wide collection of health professionals including doctors, nurses, radiographers, pharmacists, physiotherapists, health information managers, clinical researchers, administrators and computing professionals.

Nursing informatics works within the broader context of health informatics. In other words, nursing informatics is a sub-group of health informatics which deals with nursing-specific issues. Medical informatics is another sub-group comprised largely of doctors and dealing with health data from a medical perspective. Nursing informatics is a relatively new specialty and was first recognised as a specialty by the American Nurses Association in 1992 (Hebda & Czar 2013).

Graves and Corcoran (1989) defined nursing informatics as 'a combination of computer science, information science, and nursing science designed to assist in the management and processing of nursing data, information and knowledge to support the practice of nursing and the delivery of nursing care' (p. 227). In essence, nursing informatics is an amalgam of nursing science, information science and computer science for the purpose of managing health information to enhance the provision of quality healthcare.

Nursing informatics has had a somewhat difficult beginning and although it has been recognised as a nursing specialty for the past three decades, many nurses still do not understand the nature of this discipline. The definitions of nursing informatics have changed over time to reflect the developments in nursing practice and technologies. The most widely accepted definition now comes from the International Medical Informatics Association—Nursing Informatics (IMIA-NI) group who defined nursing informatics as 'science and practice (that) integrates nursing, its information and

knowledge, with management of information and communication technologies to promote the health of people, families, and communities worldwide' (American Medical Informatics Association 2015).

In their various roles and specialty areas, nurses handle large volumes of data; nursing informatics is concerned with all aspects of this. For example, it encompasses all aspects of access, retrieval and efficient use of data, information and knowledge to support decision making, which in turn enhances the quality, effectiveness and efficiency of nursing care. While information and communications technology is essential to nursing practice to support the development and dissemination of new knowledge, it can also support and empower an individual's decision making and healthcare choices (Conrick 2006). Nursing informatics offers a range of tools that assist in advancing nursing as a professional research-based discipline (Hebda & Czar 2013). Improved database technology enables the timely collection, storage and analysis of vast amounts of data. This is made available and retrievable as information in a manner that nurses require it to support their practice. It also allows nurses to critically review their practices based on the evidence that can be provided by these systems.

The role of nurses in an informatics context can vary from the routine user at the clinical interface, to a superuser assisting in the implementation of systems, to application specialists, system administrators and **business analysts**. In the US, suitably credentialled nurses holding postgraduate qualifications in informatics are able to take on the role of informatics nurse specialist (Hebda & Czar 2013). Recently, the Health Informatics Society of Australia, the Health Information Management Association of Australia and the Australasian College of Health Informatics have established an Australian informatics certification program in order to address the lack of formal recognition of health informatics knowledge and skills in Australia. The Certified Health Informatician Australasia (CHIA) certification ensures candidates are able to demonstrate the application of a number of health informatics core competencies to perform safely and effectively as a health informatics professional in a broad range of practice settings (Health Informatics Society Australia 2015).

## A BRIEF HISTORY OF COMPUTERS AND INFORMATION TECHNOLOGY

The history of computing can be traced back to around 5000 BC with the use of Persian clay boards. The abacus has been in use in China since around 2000–3000 BC (and is still in use today). However, the genesis of the computer as we know it today originates in 1642 with the invention of Pascal's mechanical counter. This device was able to add, subtract, multiply and divide much like a modern day calculator but with fewer functions. The history of modern computing could be considered as dating back to the 19th century when Charles Babbage created a mechanical mathematical problem-solving device and Herman Hollerith developed a punch card system where data analysis was carried out by passing long needles through trays of punch cards (Cesnik 1996). The impetus for the development of electronic computers came from the time of the World War II in the 1940s (Cesnik 1996) with the development of the electronic numerical integrator and computer (ENIAC), the first of such computers. Table 5.1 illustrates the development of computing from the 17th Century through to modern day.

Any cursory examination of the timeline of the development of computer and information technology will reveal the increasing speed of technological development. Technologies that did not exist a few years ago, such as Google Streetview, Facebook, Snapchat and Instagram, are today part of everyday life. In short, the pace of technological development continues to increase exponentially. Given the speed of development, the concept of ubiquitous computing, a notion first coined by Mark Weiser in 1991, could well become a reality in just a few years. Weiser observed that 'The most profound technologies are those that disappear. They weave themselves into the fabric of everyday life until they are indistinguishable from it' (Weiser 1991:94). Ubiquitous computing is comparable to writing with pencil and paper. This form of information technology is everywhere and barely requires active attention. Imagine a situation in which the use of a computer is as simple and accessible as jotting a message on a Post-it Note. Imagine the implications of this form of technology for nursing care.

## FUNDAMENTALS OF COMPUTER SYSTEMS

There is little doubt that nursing faces a plethora of opportunities and challenges in the next few years. Many of these will come in the form of increasing demands for improvements in quality and cost effective care. These demands will emanate from government, society and our colleagues in other health disciplines. Nursing needs to be in a position to address these issues within the context of an increasingly information-intensive environment. Before discussing information systems in more detail we will discuss a few fundamental computing concepts.

### Hardware

**Hardware** refers to the physical components of a computer system. Today computer systems consist of a **central processing unit (CPU)** and a variety of input and output devices. The CPU is the 'brain' of the computer and is the component that executes instructions in the form of programs, coordinates the flow of data from input devices and to output devices and directs the storage of data in memory. Memory is a temporary storage area for data and consists of **read only memory (ROM)** and **random access memory (RAM)**. ROM is a permanent (non-volatile) form of memory that remains even when the power is turned off. RAM, on the other hand, is volatile which means it requires the computer

**TABLE 5.1 | The history of computers**

| Year | Classification | Key feature |
|---|---|---|
| 1642 | Pascal's mechanical counter.<br>Pre-electrical calculator | Mechanical calculation using wheels and cogs |
| 1837 | Babbage's analytical engine pre-electrical computer | Used punched cards to execute instructions |
| 1944 | IBM Harvard Mark 1 | First large-scale digital computer |
| 1946 | ENIAC | Post-war computer capable of 5000 calculations per second |
| 1951–58 | First generation computers | Vacuum tube<br>Mainframe |
| 1959–64 | Second generation | Punch cards<br>Magnetic tape<br>Mainframe |
| 1965–74 | Third generation | Integrated circuits<br>Storage increased processing speeds |
| 1975–80 | Early fourth generation | Chemical etching onto a single silicon wafer chip<br>Apple II microcomputer |
| 1980s | Fourth generation | Mac, Apple, IBM PC (1982) |
| 1980s and 1990s | Fourth generation | Continued development of Intel chip sets |
| Late 1990s | Smaller reliable servers<br>Low cost PCs | WANs<br>The internet and WWW wireless technology |
| 1998 | Apple iMac | All-in-one design (computer built into monitor casing) |
| 2000 | Fifth generation | Artificial intelligence<br>Millennium bug<br>1 GHz Pentium |
| 2010 | Low-cost mobile devices | iPhone, iPad, android, tablet computers |
| 2015 | Wearable computing | Google Glass, Smart watch |
| 2020 and beyond | Ubiquitous computing | Computing can occur anywhere, in any format on any device |

*(Adapted from The Centre for Computing History 2014)*

to be switched on. When using a computer, it is RAM that allows programs such as a word processor or **spreadsheet** to be used. Both these forms of memory are referred to as primary storage. Another commonly used form of memory is called secondary storage. Secondary storage provides permanent storage of data and includes hard disk drives (HDDs), magnetic tape drives, compact disks (CDs), digital video disks (DVDs), Blu-ray, **universal serial bus (USB)** and cloud storage (data stored on the internet).

A computer will have a number of associated devices that allow for data to be captured (input device) or 'displayed' (output device). Input devices such as a keyboard, a mouse and a scanner and touch screen will be familiar. You will also be familiar with at least one example of source data automation from your visits to the supermarket, and many hospitals utilise barcoding to track supplies and identify individuals. Microphones, scanners and digital cameras are also input devices. There may also be technologies that you have not had the opportunity to interact with (e.g. voice recognition, radio frequency identification (RFID) and biometric recognition).

Having input data into a computer system we expect some form of output, most commonly via a monitor or a printer. However, as with input devices, there is a wide range of output devices. These include video data projectors, voice output, interactive whiteboards and music and other sound output devices.

Computers may be classified according to their size, although as Sewell and Thede (2013) commented, such classification is becoming much more difficult as new smaller computers are able to carry out the same and perhaps more functions than the bigger computers. Computer categories include:

Supercomputers: supercomputers are the most powerful computers, capable of carrying out complex and extensive mathematical calculations and processing millions of instructions per second. They focus on one task at a time, for example weather forecasting

Servers: the term 'server' is sometimes used to describe these increasingly compact units. A large healthcare organisation will typically have a series of 'servers'. Users initially interacted with a mainframe via a 'dumb terminal' but these have been replaced with thin individual PCs or desktop computers and, in a wireless (WiFi) network situation, a laptop, workstation on wheels (WOWs; Figure 5.1), notebook, iPad, tablet or smartphone to provide point of care (POC) computing

- Minicomputers: the minicomputer, with some of the processing power of the mainframe, allowed for multiple users, but was smaller and less expensive. Microcomputers were in common use in healthcare settings in the 1980s and 1990s and could be found in radiology and pathology departments
- Personal computers: personal computers (PCs) are microcomputers which are also referred to as desktop computers. PCs have an entire processing unit on one microprocessing chip. PCs may function independently or in a network situation such as when the PC may be connected to servers and other PCs
- Laptop computers/notebooks: the laptop/notebook is a version of a PC that is transportable and small enough to sit on the user's lap. Laptops are now smaller and more intelligent, and are commonly referred to as 'notebook' computers. The laptop/notebook may be plugged into a docking station on a desk which then allows for utilisation of a larger screen, keyboard and storage space, as well as connection to the Internet. in many healthcare settings these devises are mounted on trolleys to provide increased convenience and greater mobility in WiFi networks
- Wireless tablets: in a clinical environment the wireless tablet is often seen as a 'ruggedised' device roughly the size of a large laptop and usually weighing about 1 kg. These devices (such as the Motion by Xplore C5M, illustrated in Figure 5.2) are designed to withstand the rigors of use at the bedside. They can be cleaned using agents such as isopropyl alcohol and can withstand the bumps and drops that occur frequently in clinical settings. Tablets are now considered as having even greater utility than WOWs for point-of-care data entry in healthcare with their larger screens, the facilities for handwriting, individual ID scanning and digital photography functions
- iPads, iPhones and smart phones: these devices are essentially a **convergent technology** that provide computing, email, networking, voice recognition and internet connectivity. A number of healthcare applications (such as ECGs and picture archiving and communication systems) can download visual images to smartphones. This provides clinicians with the ability to review data about individuals anywhere at any time.

**Figure 5.1** Workstation on wheels
*(Source: © InterMetro Industries Corporation)*

## Software

**Software** refers to the set of instructions that operate the computer, directing the hardware to perform various tasks. Software is written in specific programming languages such as C, C++, Basic, Visual Basic, Java and SQL. Each of these languages is used to compile various programs or applications which then perform the various functions on a computer. Software can be divided into operating system software or application software.

**Figure 5.2** Motion by Xplore C5M
*(Reprinted with permission from Xplore Technologies Corporation of America. Photographer: Scott Van Osdol. © 2010)*

Operating systems are 'software in the background'. They consist of a number of programs that control the function of the computer (Sewell & Thede 2013). Application software systems are programs designed for a particular task such as word processing, rendering graphics or searching the internet. While even novice computer users tend to be familiar with application software such as word processing, operating system software tends to be less well understood.

The operating system (OS) holds the logic that controls the internal function of the computer and acts as a 'system manager'. It is responsible for directing the execution of programs that operate input and output devices (such as the keyboard, monitor and printer) and resource allocation such as multiprogramming. The OS acts as a bridge between the application software systems.

A user interface determines how the user interacts with the operating system in order to use the application software. The user interface may be MS DOS, characterised by prompts and command lines, or a graphic user interface (GUI) (e.g. Microsoft Windows and MacOS). Windows-based GUI operating systems feature icons and pop-up/pull-down menus. The term platform is used to refer to a combination of hardware and operating system software. An example of a platform would be Microsoft Windows with an Intel-based PC.

Microsoft Windows operating systems for professional use began with Windows 95. Subsequent generations are Windows 98, 2000, NT (New Technology), ME (Millennium Edition), XP and CE (Consumer Electronics). Microsoft Windows OS for home use began with Windows 95, followed by Windows 98, ME and XP. The latest operating systems from Microsoft are Windows Vista, Windows 7, Windows 8 and Windows 10.

The Macintosh operating system MacOS (1984) was the first commercial GUI. The most recent series of Mac operating systems have been OS7, OS8 released in 1997 and OS9, released in 1999. The most current MacOS is OS10.10, released in 2014. LINUX is another operating system that is popular with users who prefer to customise their computer or who may like to have a choice of operating systems. LINUX is categorised as open source software.

# FUNDAMENTALS OF INFORMATION SYSTEMS

The use of information systems can result in a number of benefits for nurses. These include the provision of data at the bedside for more informed decision making, the ability to establish workgroups, sharing data and expensive hardware and software, a reduction in the risk of data loss and reduced errors. Information systems can now store virtually unlimited data for administrative and clinical applications which can track individuals throughout a hospital stay and across geographical boundaries thanks to advances in standards and interoperability (Conrick 2006; Jonas 2013).

Information systems consist of hardware and software used to convert data into information in order to provide a solution to a particular problem (Hebda & Czar 2013). In a healthcare environment information systems generally consist of hospital information systems (HIS), administration information systems (incorporating human resources, accounting, scheduling and ancillary systems) and clinical information systems (CIS). All these systems rely on computer networks to function. These networks require a number of computers and other devices to be linked in some way.

## Hospital information systems

**Hospital information systems (HIS)** are used as the core of information for healthcare organisations. They provide critical data on individuals which other organisational computer systems are able to utilise. In many cases, the HIS is built around the patient administration system (PAS) or patient master index (PMI). These systems contain demographic information of an individual; their Medicare or Department of Veterans Affairs number; health record or UR number; information relating to their admission and discharge history; and current admission status, including treating doctor, admitting doctor, ward, bed number, next of kin, health insurance status and billing information to name but a few.

## Management information systems

The **management information system (MIS)** draws data from the PAS in order to assist management in the day-to-day running of the organisation and in future strategic planning. These systems are able to determine trends in service provision and resource utilisation. This assists all levels of management in the process of decision making. Nurse unit managers, for example, are better able to predict staffing requirements. Asset managers are able to determine when specific capital works will be required while quality and finance managers are able to monitor the effectiveness of the system in terms of individual outcomes and the cost of care.

## Clinical information systems

**Clinical information systems (CIS)** are systems which manage clinical data to support individual care and clinical decision making. The CIS is the system used by the majority of healthcare providers within the organisation. The primary goal of any clinical information system is to make information and knowledge available to healthcare providers during the process of care delivery. Data for the CIS is frequently derived from various feeder systems such as laboratory, radiology and pharmacy. The CIS is designed to assist clinicians in the provision of individual care via clinical decision support and by better managing healthcare resources.

Case Study 5.1 explores a scenario about retrieving patient history and records.

Clinical systems are purported to achieve a number of benefits including streamlining clinical workflows and eliminating repetitive tasks that reduce productivity and lead to errors (Aragon Penoyer et al 2014; Encinosa & Jaeyong 2013; Kirkendall et al 2013; Ronquillo 2012). Clinical decision support inherent in many clinical systems acts to safeguard the individual and the clinician, enhancing safe practice.

The CIS consists of a number of components including clinical documentation, order entry, results viewing and medication management. Automated clinical documentation may be incorporated in the CIS and is designed essentially to replace the traditional paper-based record. The purpose of this component of the CIS is to provide the clinician with a more time effective method of documenting individual care. Preloaded document templates provide for local customisation of documents. Standardisation of concepts in clinical documents is achieved through the integration of clinical dictionaries and clinical language systems such as the Systematized Nomenclature of Medicine (SNOMED), the International Classification of Diseases (ICD-10) and the North American Nursing Diagnosis Association (NANDA).

Order entry systems allow clinicians to electronically prescribe medications, order laboratory or radiological investigations or create referrals to other healthcare providers. Order entry systems can also save significant amounts of time as individuals' details do not need to be re-keyed into the service provider system. This also reduces the possibility of data entry mistakes. Figure 5.3 illustrates a well-designed order entry system interface. Abnormal results can be flagged in the CIS by using pre-defined rules—some systems automatically page or text an alert to the responsible clinician. Some systems will automatically re-order an investigation if an abnormal result is returned. Figure 5.4 illustrates the cumulating and subsequent graphing of pathology results in a CIS.

The use of clinical decision support systems (DSS) has been found to increase individual safety by decreasing the frequency of serious medication errors (Charles et al 2014; Encinosa & Jaeyong 2013; Forrester et al 2014; Jones et al 2014; Kirkendall et al 2013). Some of the strategies these decision support systems provide relate to performing error checks, providing relevant information quickly and improving communication to other clinicians.

A medication management system automates both the prescribing and the administration process, resulting in

## CASE STUDY 5.1 TRADITIONAL PAPER-BASED INFORMATION SYSTEMS

Mr Joe Lee is admitted to the emergency department unconscious following a single-vehicle motor traffic accident. Paramedics were able to stabilise his condition at the scene and have diagnosed a closed head injury. The ED staff are able to identify Mr Lee from his driver's licence. The admitting clerk searches the hospital patient administration system for previous admissions. The database reveals Mr Lee had an episode of care 3 years ago for the repair of an inguinal hernia. No other data is available as Mr Lee's history has been sent to the hospital's off-site archiving service.

A request is placed to have the history retrieved from the archive. However, it is 2.30 am and the storage facility is 30 km away. A courier from the storage facility has to be paged and requested to retrieve the history. The courier arrives at the facility and accesses the archive area, where the history was located, and then drives 30 km back to the hospital. All this takes more than 2 hours. In the meantime, the ED staff are 'flying blind' totally unaware of the Mr Lee's past history, allergies or regular medications.

What would have made access easier?

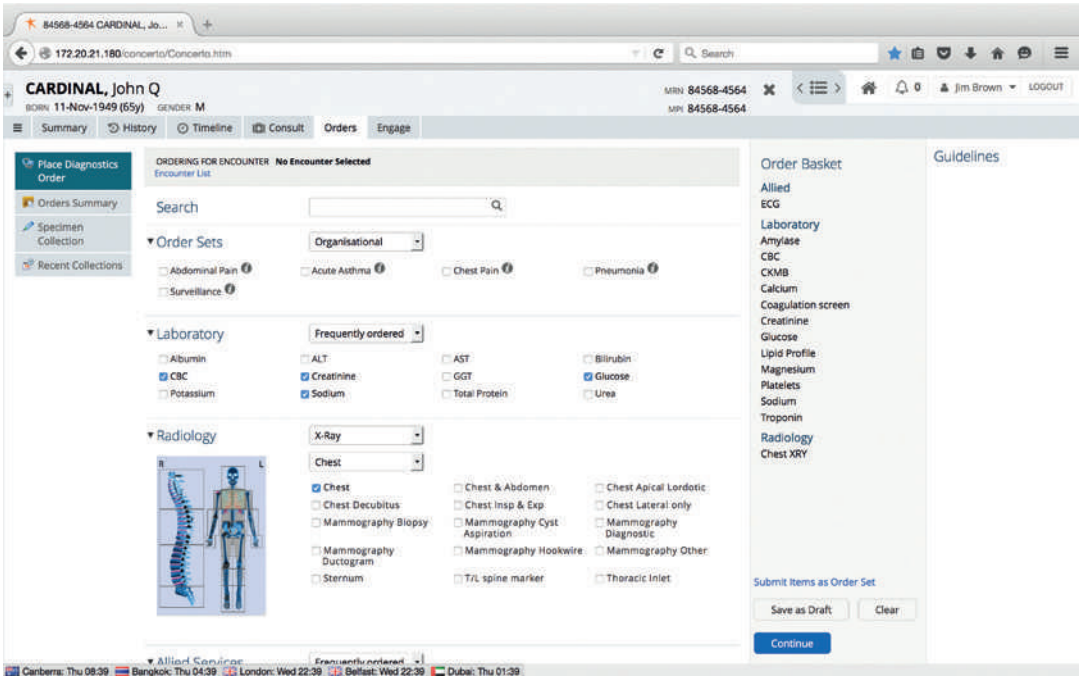

**Figure 5.3** An order entry system interface
*(© 2016 Orion Health)*

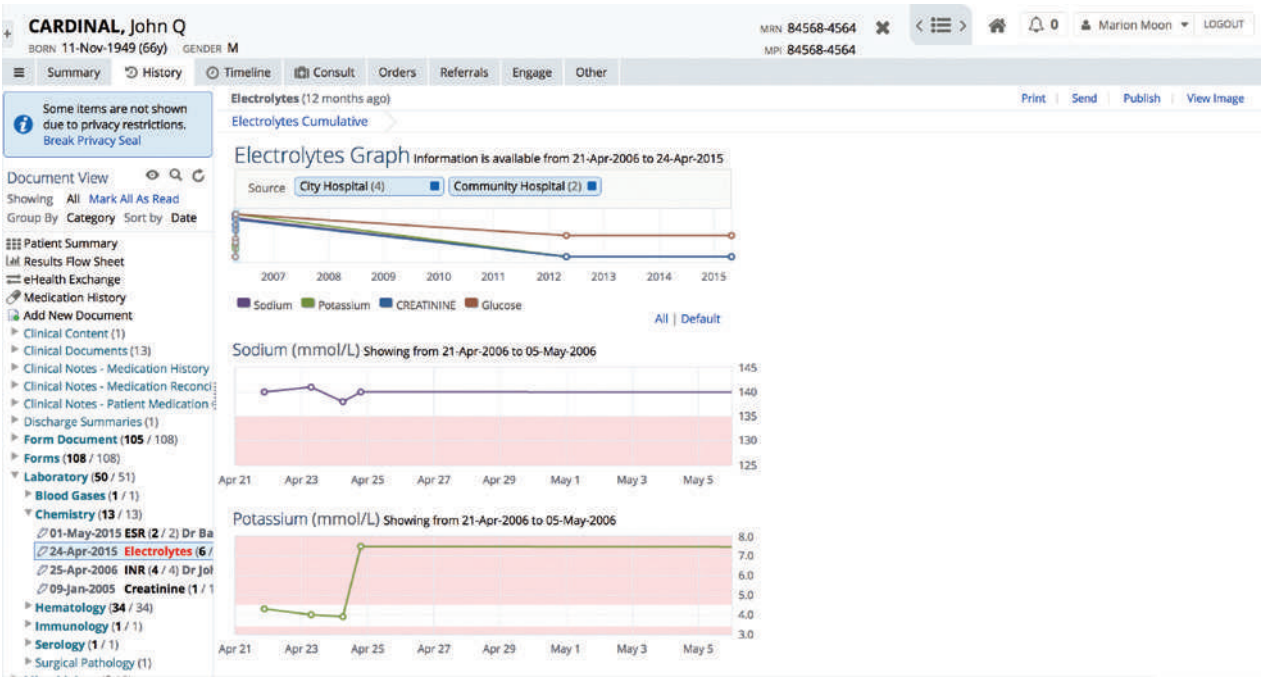

**Figure 5.4** Cumulating and graphing of pathology results in a CIS
*(© 2016 Orion Health)*

tangible improvements in an individual's safety and in the timeliness of medicating individuals (Charles et al 2014; Ghaemmaghami 2014). When coupled with barcode scanning technologies, medication management systems minimise the amount of manual documentation nurses are required to perform when administering medications.

## Ancillary systems

A number of other information systems can be found in many healthcare organisations and might include radiology information systems (RIS), **picture archiving and communications systems (PACS)**, laboratory and pathology systems and pharmacy systems. Often these systems are integrated with the PAS or with the CIS to provide data to or extract data from these systems.

### CRITICAL THINKING EXERCISE 5.1

You are working on a surgical ward. An individual arrives for admission with a number of printouts from web pages relating to their surgery. Some of these suggest alternative therapies to that for which they are scheduled. How do you deal with this situation?

# NETWORKS, COMMUNICATION TECHNOLOGIES, THE INTERNET AND WORLD WIDE WEB

## Network fundamentals

As discussed in the previous section all these systems rely on computer networks to function. These networks require a number of computers and other devices to be linked in some way. The most common form of network link is by twisted pairs of wire call unshielded twisted pair or UTP.

The other common method of connecting networks is by optical fibre. These cables consist of a central optical fibre core. This fibre is usually around the same diameter as a human hair. This central fibre is covered in glass and this layer is then covered with a protective outer layer. Data is converted to light impulses and beamed along the cable. The volume of data that can be transmitted far exceeds other types of cable. Most hospitals and health clinics now use WiFi technologies to support mobile computing applications. WiFi works by connecting the hardwired network to a wireless access point (WAP) which converts data from the hardwired network to a radio signal using a standard protocol for use with wireless (mobile) devices.

The term computer network architecture refers to the general design of both software and hardware within the network. The history of networked computers is based on mainframe technology. Mainframe computers were capable of millions of calculations per second and were used almost exclusively for financial management of hospitals. These systems initially consisted of the mainframe computer connected to a 'dumb' terminal. They were known as this because the terminal (essentially just a screen and keyboard) did not contain a central processing unit. In other words, it was unable to perform any processing functions and was therefore 'dumb'. Since the introduction of these first generation machines there has been a movement towards more sophisticated technology in the form of individual/server computing. In a client/server computing environment, information can be shared between multiple smaller computers known as

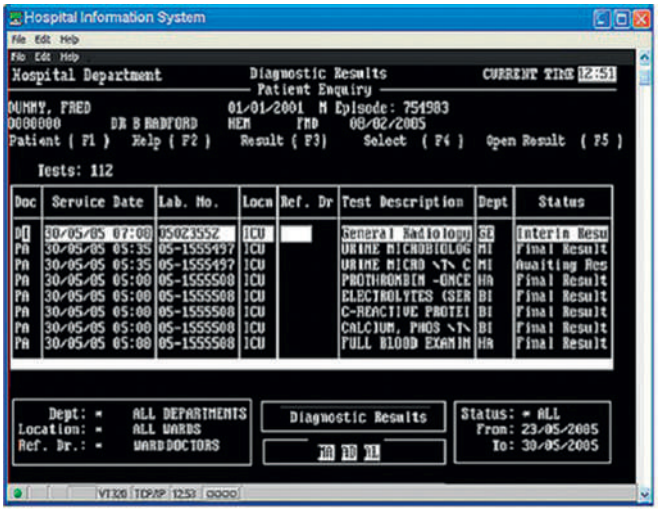

**Figure 5.5** Mock-up of a typical 'dumb terminal' character-based screen
*(R. M. Ribbons)*

clients that are all connected via a network to a powerful host computer known as a server. Figure 5.5 illustrates a 'mock-up' of what a typical 'dumb terminal' character-based screen might look like.

Any connection of computers that are physically close can be regarded as a **local area network (LAN)**. A LAN can exist in a single office with a number of workgroup users or could extend to a number of floors in the same building, the whole building or a number of buildings normally within the same geographical context. LANs can have as few as three or four users or hundreds. LANs are highly reliable even in the face of very high network demands. There are a number of reasons for this reliability. LAN software typically includes operations that detect and correct transmission errors and protect the system from a number of other errors and failures. LANs can also be set up to have backup servers, thus ensuring data is not lost in the event of the primary server failing. Users can continue to work using the secondary server while the primary server is repaired or rebooted.

Another feature of LAN technology is its ability to support a variety of security functions. LAN administrators are able to set levels of access to directories on the system based on user passwords. Some users will have access to directories that others may not even be able to see. Some networks can also utilise data encryption to enhance the security of data sent over LANs. Apart from the computers, a LAN requires three things: network software (e.g. Novell Netware, LANtastic etc.), a means of connecting the computers (e.g. Ethernet, unshielded twisted pair (UTP), fibre optics, wireless infrared or radio frequency) and a communication system or protocol.

## The internet and WWW

The internet is, in the broadest sense, a microcosm of our world. It reflects a vast variety of cultural and societal views and allows people across the planet to share ideas on a personal level never before possible. The internet is essentially a huge network of networks that interconnects computers and mobile devices located all over the world. It does not contain information itself but is the vehicle for transporting the information stored in files or documents on other computers. Some of the computers in the network are known as hosts or servers, because they 'serve' information in various ways to computer owners, known as clients or users. The use of the internet has expanded rapidly. The most recent internet users survey estimates this number to be 3 035 749 340 or 42.3% of the world's population (Miniwatts Marketing Group 2015). The same source in 1995 estimated the number of internet users was just 16 million or 0.4% of the world's population. In January 2015 the internet Domain Survey reported 1 012 706 608 host servers on the internet (Internet Systems Consortium 2015), an increase of 2 454 779 servers compared with the same time in 2014. This compares to 4 852 000 host servers just 10 years ago.

The internet consists of a number of **protocols** that exist in what is known as the application layer. These protocols represent a wide variety of applications, including the file transfer protocol which is used to transfer computer files from one host (computer) to another host over a network, such as the internet. It has been used almost since the inception of the internet to move large files from one computer to another. This is particularly useful when size of the file exceeds the limit of an email attachment. Today, FTP is built into most web browsers. This makes the transfer of files much easier than in the past.

**Email** is perhaps the most frequently used internet protocol (Hebda & Czar 2013). Email provides a communication vehicle that connects people from all over the world quickly and inexpensively. Email is a very convenient way of contacting friends, customers, employees, employers and students. While it might be seen as an efficient way of contacting individuals, the insecure nature of email prevents it from being used in health-related applications.

Hypertext transfer protocol is what makes up the **world wide web (WWW)** or 'the web'. Many people use the terms WWW and the internet interchangeably; however, the WWW is simply one part of the internet. The web is a global service supporting text, graphics, audio, videos and other multimedia content on the internet via hyperlinks. These links provide the user with access to electronic databases, web directories, search engines and online publications and journals via software applications called **browsers**.

Although the web is a sub-set of the internet, in reality, the web is in fact two separate entities. The first, the visible web, is what users access when using standard search engines such as Google, Yahoo, Hotbot or Ask. The second, the invisible or deep web, remains mainly hidden because of the inability of many standard search engines to access the type of material held there. The deep web was first described in 2001 (Bergman 2001) and is the most rapidly growing portion of the internet.

The surface web is a loosely organised collection of billions of documents on thousands of topics, written in

hypertext markup language (HTML). The deep web contains a sizeable proportion of government resources, **databases** and similarly structured materials that are not written in HTML. It is estimated the deep web is 500 times larger than the surface web; it is highly specialised, 95% cost-free and is the largest growth category on the web (Bergman 2001). The collections from the two webs are located on various websites, each containing potentially millions of web pages. These web pages use a variety of multimedia resources with a mixture of text, sound, graphics and video.

The expansion and adoption of the internet and the web have opened up vast communication, information and educational possibilities for the healthcare sector and for nurses. In fact, the web is a rich source of healthcare information for the healthcare consumer and the health professional. Increasingly, both consumers and health professionals are utilising the internet for health-related information. Specific web-based health-related information is increasing at an unprecedented rate. Not surprisingly, with this volume of information on the web, there are serious concerns about the quality, reliability, accuracy, authenticity and currency of health-related sites and the information they disseminate. For health professionals, this means the added responsibility of ensuring that the material accessed for use in professional and individual information is evidence-based and, also, that you as a health professional are able to help consumers assess material that they have accessed themselves. To do this, you will require a good working knowledge of search strategies, search engines, reliable databases and sites, as well as information evaluation tools.

## CONTEMPORARY TECHNOLOGIES AND SOFTWARE APPLICATIONS AND THEIR USE IN HEALTHCARE

The internet is changing all the time. Two things have marked its evolution recently: the social web and mobile technology. These two innovations have changed the way people use the internet. In the social web people have found a new way to communicate. For example, since its creation in 2004, Facebook has grown into a worldwide network of over 1.39 billion subscribers (Zephoria Internet Marketing Solutions 2015). Mobile technology has made possible a much greater reach of the internet, increasing the number of internet users everywhere.

### Social media

The past few years have seen the explosive growth of **social network** services on the web. Social media outlets, platforms and applications, including blogs, social networking sites, video- and photo-sharing sites, and online chat rooms and forums are now very much a part of social interaction. Services such as Facebook, Twitter, LinkedIn, Tumblr, Bebo, MySpace, Google+, Snapchat and Instagram have changed the way people interact online forever. Most social network services are accessed using a web interface or via a short message service (SMS) or mobile device application (app). These services provide a means for users to interact with other users over the internet, using communication tools such as email and instant messaging. Social network services allow individuals to create a representation of themselves on the web, usually in the form of a profile. Social media sites allow users to share ideas, activities, events and interests within their individual networks. Technologies such as Twitter have even been adopted by political parties as a way of connecting with their constituents.

The judicious use of social media can be of benefit in healthcare in a variety of ways. A number of authors have indicated social media is increasingly used to encourage professional connections and promote time-effective communication with individuals and family members (Costello 2014; Farrelly 2014). These networks may also be effective in educating and informing consumers and healthcare professionals (West & Verran 2013).

Nurses are increasingly using blogs, forums and social media sites to share workplace experiences, particularly events that have been challenging or emotionally charged. Sites such as Mahara provide a journalling and portfolio service that is transportable, much like LinkedIn. These technologies have almost become ubiquitous. So much so, that many use these communication platforms almost without thinking. Conversations that may once have remained in the tea room can now be posted and made instantly available on the internet. Nevertheless, once there, it is next to impossible to retrieve let alone delete them. Healthcare professionals using social media for personal or professional purposes must remain cognisant of the danger of inadvertently violating an individual's privacy and confidentiality (Bickhoff 2013).

## ETHICS, SECURITY, PRIVACY AND CONFIDENTIALITY

The privacy of the individual can be defined as the protection of that individual's personal mental and physical condition, to be able to determine what information is collected, how it is used and who has access to it (Hebda & Czar 2013). Individuals expect a certain level of privacy in their daily lives. In our increasingly connected global society, personal privacy is often seen as under threat. There are increasing concerns over the right to determine what information is collected, where it is stored, who has access to it and how this personal information might be used (Hebda & Czar 2013). Any potential threat to personal information has the potential to disrupt an individual's ability to maintain significant relationships that help to define that individual's personality. (See Clinical Interest Box 5.1.)

Confidentiality is an ethical as well as a legal concept. It relates to the disclosure or non-disclosure of information. Historically, a duty to honour confidentiality has been inherent in particular relationships such as between the healthcare provider and an individual (Department of Human Services 2014). Given the importance our Western culture places on privacy, it is not difficult to understand the significance of privacy in the relationship between healthcare provider and

## CLINICAL INTEREST BOX 5.1 Right to privacy

Do you have a right to privacy? While there is no reference to privacy in our Constitution, we do have a legislative right to piracy. The Privacy Act contains 13 Australian Privacy Principles which regulate the way we collect, store, provide access to, use and disclose personal information. The new Principles came into effect on 12 March 2014 and apply to public and private sector entities. The Privacy Act provides you with rights, including:

- Being told generally what kind of information is being collected and how it is to be collected
- Being told generally why your personal information is being collected
- Finding out what information is held about you and have it corrected if it is incorrect, out of date or incomplete; the Freedom of Information Act 1982 also supports this
- Ensuring that your personal information is stored securely and protected from interference or misuse (Department of Human Services 2014).

## CLINICAL INTEREST BOX 5.2 Passwords

Passwords are common tools for regulating access to information systems. These are generally safe if not passed on to others. There are some standard recommendations for selecting and using passwords. These include:

- They have at least six characters
- They combine upper and lower case letters, numbers and other symbols
- They do not contain proper names, people's initials or words taken from the dictionary
- Avoid using reversed words or syllables
- No dates, telephone numbers, vehicle registration numbers or numbers such as Medicare number
- They should never be stored in the computer, and must be kept private
- They need to be changed regularly and not reused for a significant length of time.

*(Hebda & Czar 2013)*

an individual. For example, the *Code of Professional Conduct* states that nurses have a duty to maintain in confidence personal information obtained in a professional capacity.

An effective security plan must be a balance between security of data and access to that data. Decisions regarding the level of security, disaster minimisation and/or recovery, user privileges, use of encryption, multiple passwords, system back-ups and audit trails need to be made as part of the security planning process. An attitude of 'It won't happen here' could leave the organisation vulnerable to significant risk.

With increasing growth in technology, there are people constantly attempting to find ways in which to obtain unauthorised access to information systems, or to corrupt data and information systems. We see this through regular alerts to new viruses and reports of hacking of various computer systems. As more and more health data is computerised, ongoing developments in security are also needed.

To look at data security, a good place to start is with defining people who should have access. This can be achieved in a number of ways. You probably have an ID badge that you wear within your workplace. This tells people that you are authorised to be there. Similarly, keys, badges or plastic cards are one way of limiting who has access to particular areas such as rooms where computers are located (see Clinical Interest Box 5.2). We know, however, that many ward-based computer terminals are located at the nurses' station in a relatively public area. Wearing a badge alone will generally not limit who can access these machines.

A security risk in computing terms is any situation in which there is loss or damage to computer hardware, software, data or information (Vermaat et al 2014). Social networking is a particular threat in terms of the theft of personal information (identity theft). Email is a very common method by which computers are put at risk. Many cybercriminals use malware to package and deliver computer viruses. These computer programs are intended to negatively alter the function of the device onto which it is loaded. Similar forms of malicious programs include:

- Worms. These are often downloaded from email attachments and subsequently copy themselves repeatedly, and are able to move from one infected machine to the next
- Trojan horses. These are malicious programs that purport to be a legitimate program, usually in the form of shareware. Once loaded, Trojan horses reveal themselves and infect the host computer
- Rootkit. These programs hide in an infected computer and allow someone in a remote location to take control of the computer and its functions (Vermaat et al 2014)
- Scareware. Attackers and scammers use online pop-up messages warning the user that their computer is infected. The user is tricked into downloading software to 'fix' the problem. In doing so, the user inadvertently loads a virus, worm or Trojan horse.

There are a number of strategies in place to ensure these risks either do not occur or are limited in their effect. One of the more exciting developments in information security involves the use of biometrics. This science works on measuring specific body characteristics and in doing so can verify whether a person seeking access to an area is in fact that person. Some of the ways in which this is done include fingerprint recognition, retinal scanning, voice recognition or facial recognition (Hebda & Czar 2013; Vermaat et al 2014).

Other means for promoting security of information systems include the use of firewalls, anti-viral software and audit trails:

- Firewalls employ a combination of software and hardware to create a barrier between systems, or different system parts. They increase system protection by blocking unauthorised use such as through hacking. It is also possible to obtain firewalls for individual personal computers to protect against unauthorised access through the internet.
- Antiviral software is commonly available software that searches your computer for viruses and, where possible, eliminates them or provides alternatives for the user. New viruses are always appearing that existing software will not be sensitive to. Consequently, antiviral software needs regular updating. Some companies provide downloaded upgrades from their websites after you initially purchase and install the software package.
- Audit trails allow for the tracking of data flows within a system, allowing for inappropriate use to be identified and addressed. Audits can keep records on who is accessing what data and when, for how long, and what was done to the data. Audit trails are very common in large systems where there are numerous users such as healthcare information systems.
- Cryptography is a security strategy used where data needs to be transmitted or communicated along a communications line. By encrypting data, it is encoded in a form that could not be recognised if the data was intercepted along the way to its destination. On arrival at its destination, the data is decoded by the computer that holds the encryption key, enabling sense to be made of it and the data to be read.

## DATA STANDARDS AND NURSING MINIMUM DATA SETS

Data represent the building blocks of information and, as such, reflect real world facts. As health information may be generated from multiple health speciality areas across various providers, it is important that the exchange of meaningful data be governed by a set of rules and definitions. A list of raw data is not meaningful unless it is given meaning. Computer data that has been allocated a code becomes meaningful as it can then be manipulated and managed (Conrick 2006). As the **electronic health record (EHR)** becomes the source of health information and aids the planning of an individual's care, it is essential that any health data generated is able to be collected, exchanged, stored and retrieved from healthcare information systems. **Data standards** allow for data retrieval and exchange and monitoring of quality care, and provide an avenue for the collation of clinical research data.

**Nursing minimum data sets (NMDSs)** comprise a minimum, common set of data, information, definitions and standards concerning a specific aspect or dimension of the healthcare system that should be used to collect and report data and which meets the essential needs of most users (McCormick et al 1997). Conrick (2006) elaborates on this definition by further describing a minimum data set as the least number of data elements required in a data set to do a particular job. The work of many associations and groups both here and overseas has resulted in the ongoing development of nursing minimum data sets.

The NMDS originated as a result of an attempt to standardise a collection of essential and comparable nursing data. The purpose of a NMDS is essentially to enable a comparison of data across clinical populations, settings, geographical areas and time, allowing for the prediction of trends. The NMDS enables selected nursing information from the EHR to support quality healthcare while maintaining data integrity. Furthermore, it helps to differentiate the contribution nursing makes to individual care from those of other health disciplines (Schwiran & Thede 2011). This becomes ever more important with the introduction of the EHR, as nursing's contribution to care needs to be incorporated into the EHR. The introduction of standardised nursing terminologies (SNTs) will enable more effective communication among nurses and other healthcare providers while increasing the visibility of nursing interventions. The use of data standards will improve individual care through the adherence to standards of care and provide robust data to determine the effectiveness of nursing interventions (Schwiran & Thede 2011).

## ELECTRONIC HEALTH RECORDS: PROVIDING INFORMATION ACROSS THE CARE CONTINUUM

The traditional paper-based medical record has existed now for almost a century. While the paper record has served the health system well over that time, with the increasing complexity of contemporary healthcare, more efficient ways of managing individual data need to be implemented. It has long been recognised that in order to improve overall quality of care by increasing efficiency, lowering costs and reducing the rates of medical errors a move to EHR will be required (Detwiller & Petillion 2014; Duffey-Rosenstein & Sinha 2013; Encinosa & Jaeyong 2013; Ronquillo 2012).

The term EHR causes some confusion as it tends to mean different things to different people. Some believe it simply refers to the electronic version of the traditional paper-based medical record (what might be called an electronic medical record or EMR). Others see it as a component of specific information systems such as a clinical information system or a nursing information system. Still others see it as more of a health summary document.

The benefits of an EHR are numerous. These include, for example, the ability for more than one healthcare provider to access the record at a time; the record is located where it can be readily retrieved; degrees of access will enable only authorised healthcare workers to see the entire record; there is provision for the individual to have input and ownership of the record and then there are the individual care benefits relating to improved access to appropriate care and improved quality of care based on completeness of the previous health information (Dennehy et al 2011).

The EHR is used to capture and store an individual's healthcare information to provide a more efficient, organised

method of charting and enabling immediate inclusion of information into the individual's record. Indeed, use of electronic healthcare records is proposed to significantly improve record accuracy and ongoing care for individuals (Detwiller & Petillion 2014). The use of this technology in healthcare settings can facilitate the implementation of the **Personally Controlled Electronic Health Record (PCEHR)**, now to be called 'My Health Record'. Currently an individual's health information can reside in a variety of locations: their GP's practice, hospitals, pathology and radiology providers, specialists and pharmacies. This fragmentation of the individual's health information works against the effective treatment of the individual by disrupting the continuity of care. No one health provider has the complete picture. Figure 5.6 illustrates the conceptual model of the Australian e-health record (My Health Record).

The PCEHR, which was launched in 2012, aims to provide healthcare providers with a more complete picture of the individual's health status. The system is based on a unique individual healthcare identifier. This number was allocated to all individuals enrolled in the Medicare program or those who are issued with a Department of Veterans' Affairs (DVA) treatment card, and others who seek healthcare in Australia. It is this number that allows the system to uniquely identify an individual within the system (Australian Government Department of Health 2015).

This system includes information about an individual's allergies and adverse reactions, medications and immunisations. In addition, summary information related to specific health issues, surgical interventions, investigations and pathology results can be populated from other systems (such as the GP's medical record system). Figure 5.7 illustrates the type of health information available in the health record overview screen of the PCEHR. In essence the PCEHR is an electronic summary of the individual's health information. It will provide clinicians and healthcare organisations with faster, easier access to more health information, creating a more efficient system, making continuity of care easier and improving treatment decisions.

### CRITICAL THINKING EXERCISE 5.2

The mother of a friend of yours has recently been discharged from the unit on which you are working. She knows you have access to the hospital clinical information system and asks you if you could access the system and print off a copy of her mother's discharge summary. How do you respond?

## USING IT TO SUPPORT EDUCATION AND RESEARCH

All nurses require some level of competency in informatics. While many younger nurses will be technologically literate, many do not have the informatics skills to be information literate. As a beginning nurse entering the field, there is the expectation of computer literacy and basic information management skills. These skills include but are not limited to using word processing, health databases, spreadsheets, presentation software and email. Having these basic information literacy skills enables the nurse to locate and evaluate appropriate data.

Advances in technology have provided multiple applications offering opportunities for educators to deliver content innovatively and dynamically (Conrick 2006). The benefits to learners have been researched extensively and are well supported by literature.

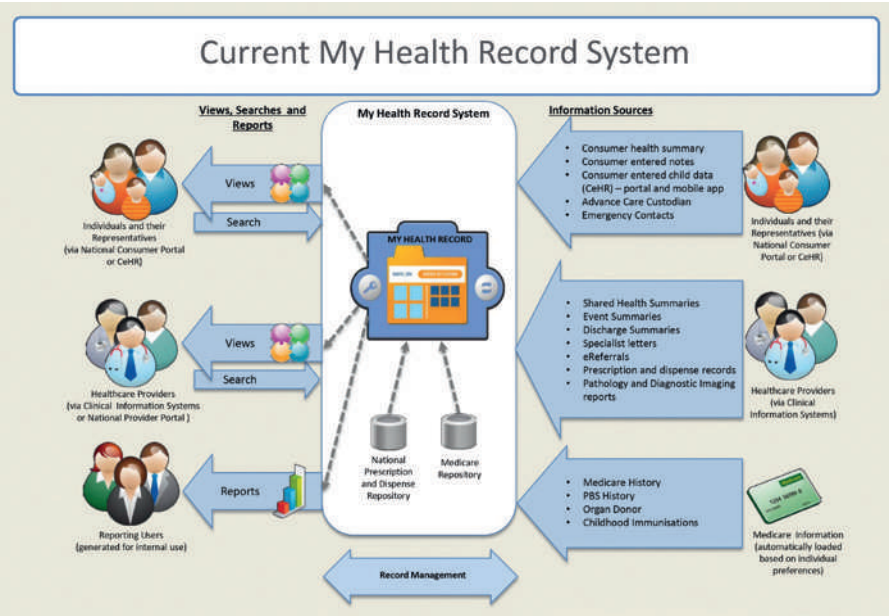

**Figure 5.6** Conceptual model of the Australian e-health record (My Health Record)
*(© My Health Record System Operator, Commonwealth Department of Health)*

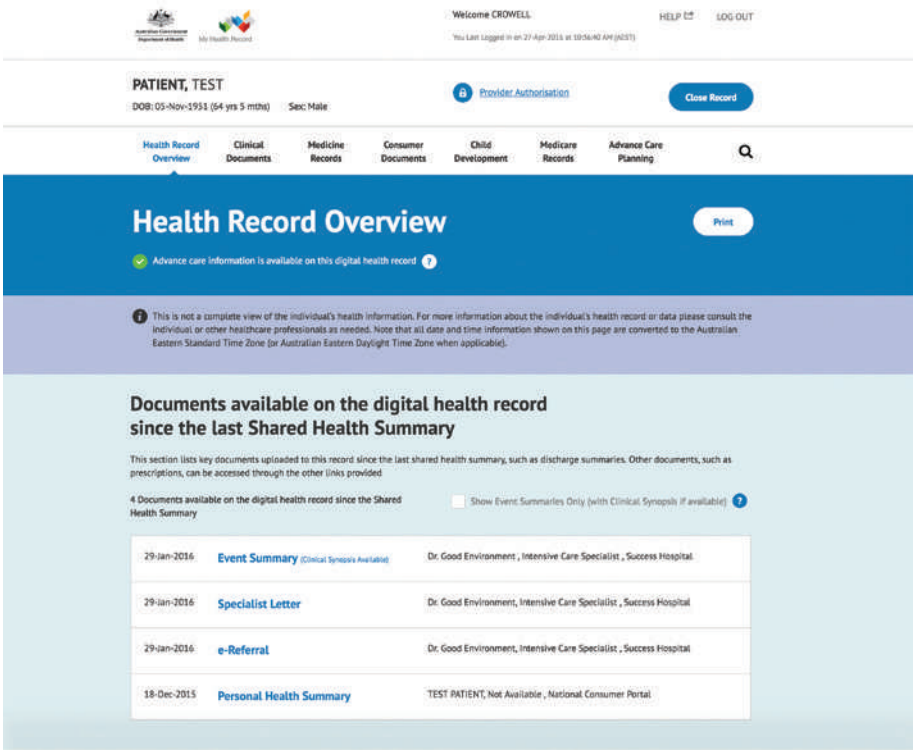

**Figure 5.7** Health record overview screen of the PCEHR
*(© My Health Record System Operator, Commonwealth Department of Health)*

With the advance of technology the opportunities for education delivery are almost endless and educators need to become facilitators of information, allowing learners to find, analyse and evaluate the information, and become a problem solver and critical thinker, which promote higher-order learning (Bastable 2008).

## Computers in education

Computers and IT provide a powerful tool to assist in the process of learning. E-learning strategies can offer multiple benefits over traditional learning. The delivery of nursing education material online allows nurses to work through academic courses and degrees while maintaining full- or part-time employment. This flexibility allows students to actively participate in educational activities while maintaining other responsibilities.

For many educational providers the delivery platform for educational material is in the form of learning management systems (LMS). These systems (such as MOODLE, Blackboard or Brightspace) provide a delivery method encompassing multimedia, social media functions, blogs, wikis and discussion forums. These systems provide a unified platform not only for the delivery of learning materials but also for submitting assignments and group work and can be used by faculty to monitor student performance and progress. Needless to say, the emergence of online education has not only been a significant milestone for information technology but for the nursing profession alike. When e-learning is utilised in nursing practice, it is vital to supplement the technological education resources with sound clinical experience and expertise to allow the learner to develop skills in the clinical environment. As technology advances the use of computer-mediated simulation will offer more realistic versions of reality that will allow nurses to engage in clinical events.

The development of e-books and the widespread introduction of bibliographic systems and databases such as the Cumulative Index of Nursing and Allied Health Literature (CINAHL) and Medline provide students with unparalleled access to information. Students now have access to learning materials all at the click of a mouse from anywhere in the world.

## Computers in research

As mentioned above, the introduction of electronic databases such as CINAHL and Medline have had a dramatic impact on students' ability to access the most up-to-date information. Students and clinicians alike are able to use these technologies to search the current literature to assist in the process of problem identification or to locate information to support evidence-based practice. The use of these databases allows the student or researcher to quickly search for specific full-text literature in a time-efficient manner. Once found, these items can be downloaded and stored on portable media such as a USB stick. No longer do students need to spend time and money photocopying journal articles, not to mention the paper that is saved. These articles can also be uploaded to bibliographic databases. Databases such as EndNote can be used when writing assignments or

conducting literature reviews to assist in managing in-text citations and referencing.

Computers are also instrumental in the development of research instruments and the collection of data. Software programs such as N-Vivo and Statistical Package for the Social Sciences (SPSS) can be used to assist in the interpretation of data. Once analysed, computers and IT can be used to disseminate research findings. Of course, findings can be submitted (electronically) to any number of journals, most of which are now available in electronic format.

## TECHNICAL TRENDS AND ISSUES IN E-HEALTH AND TELEHEALTH

The move towards increasing quantities of online health information represents the emergence of a phenomenon known as **e-health**. The term e-health has come from the use of similar 'e-words' such as e-commerce and e-business. The terms e-health, **telehealth** or **telenursing** are often used interchangeably and refer to the use of the internet, telecommunication and videoconferencing technologies in the provision of healthcare. E-health, however, does differ from telehealth (and the other tele disciplines) insofar as telehealth tends to be top down. In other words, the role of the healthcare provider (as expert) is the driving force for telehealth. E-health on the other hand has the individual/consumer as the driving force.

The World Health Organization defines e-health as 'the transfer of health resources and healthcare by electronic means' (World Health Organization 2010). It suggests there are three areas of application: the provision of health information via the internet and telecommunications, using a combination of IT and e-commerce to improve public health services and the application of e-commerce and e-business practices in health systems management (World Health Organization 2010). In short this suggests the electronic management of health information with the aim to deliver safe, efficient, better quality healthcare.

Telehealth, telemedicine and telenursing are not new concepts. They have all been utilised, to a certain extent, for a number of years. Telemedicine has been studied by governments, health departments and healthcare providers, as well as the medical practitioners who practise within the framework of telemedicine. Nurses have engaged in telehealth for many years using POTS or the plain old telephone system to maintain contact with individuals and provide advice and support. More recently, healthcare consumers have increasingly turned to the internet and the WWW for health information that healthcare professionals are being asked to evaluate and either confirm or refute. What has, however, emerged as the current challenge for healthcare providers and healthcare professionals is the enormity and rapidity of the changes and potential in the area of telehealth. Along with these dynamic and developing advances are calls for regulation, reimbursement and accountability.

## Summary

Technology is changing the way things are done in today's society and having a significant impact on the daily lives of nurses and the work they do. Nurses now need to be able to handle data to generate purposeful information, as well as be computer literate. However, with an ageing workforce, many nurses have managed for years without having to deal with technology as part of their nursing practice. They may not wish to take on the new challenges that information technology may pose. In contrast, young adults today leave school armed with well-developed computer and information-handling skills which they bring to the profession. This segment of the workforce may, therefore, be more likely to embrace the increasing use of healthcare technologies. This begs the question, then, with different generations of nurses what will the utilisation of technology by nurses look like in the next few years? Will it be resisted and put nursing behind other professions that are markedly ahead in their use of technology? Or will technology be embraced, placing greater pressures on nurses? Certainly, this is a simplistic approach with a range of other factors able to exert influence on healthcare technology. At this stage, it is hard to suggest in which direction this discussion may go.

While they are in their own evolutionary process, healthcare information technologies are advancing rapidly. Just as in other specialty areas, specialist courses need to be developed in order to meet the needs of changing nursing roles. As we witness the advent of ubiquitous computing, it is expected that information technology will eventually pervade all aspects of healthcare. In the not-too-distant future, it is anticipated that we will witness increasing use of integrated healthcare systems, with a focus on point-of-care technologies in the form of clinical decision support and documentation systems. Healthcare consumers will have greater control over their health information, where it is stored and how it is used. Genomics, data mining, nanotechnology and the use of robotics will all have an impact on clinical care. What this impact will actually look like is difficult to predict.

There is also a need for nursing informatics specialists. However, such a role in our current healthcare system is evolving and not yet well defined. Being able to describe what nursing informatics specialists do will help with guiding education and the development of the specialty. Just as we have seen with the Nursing and Midwifery Board of Australia's introduction of Standards for Practice, so too a set of practice competencies for nursing informatics specialists, which incorporates not only computer-related skills but knowledge, attitudes and other skills, will be required in the future.

## Review Questions

1. How can information technology benefit nurses and individuals to ensure improved quality of care?
2. What role do you think cloud computing and social media have in healthcare? How might security issues around these technologies be mitigated?
3. An individual indicates that they have been asked to sign up for the Australian Government Personally Controlled Electronic Health Record (PCEHR) but they are concerned about the security of their health record. How might you respond to this person?
4. What is a local area network? Explain how this technology configuration can benefit the provision of healthcare.
5. Nurses make for very effective project managers and business analysts. Why might this be the case?

Answer guide for the Review Questions, Critical Thinking Exercises, Decision-Making Framework Exercises and Critical Thinking Questions in Case Studies are hosted on Evolve: http://evolve.elsevier.com/AU/Koutoukidis/Tabbner/

# Understanding and promoting health

*Glenda Verrinder and Lyn Talbot*

CHAPTER 6

## LEARNING OUTCOMES

At the completion of this chapter and with further reading, students should be able to:

- Discuss the difference between concepts of health, wellbeing, illness and disease
- Identify and discuss determinants of health
- Compare and contrast medical, behavioural and socioenvironmental models of health promotion
- Describe the principles underpinning health promotion practice
- Outline the action areas of the Ottawa Charter for Health Promotion
- Outline the major strategies within the Continuum of Health Promotion Practice
- Identify and source the literature on health promotion programs in Australia as it relates to nursing
- Discuss the role of the nurse in health promotion
- Facilitate person-centred education
- Utilise the nursing process in health promotion

## KEY TERMS

Australian Institute of Health and Welfare (AIHW)
Continuum of Health Promotion Practice
Declaration of Alma-Ata
determinants of health and illness
health inequalities
health inequities
health literacy
health promotion
homeostasis
illness
nursing process
Ottawa Charter for Health Promotion
prerequisites for health
primary healthcare
primary prevention
secondary prevention
tertiary prevention
wellbeing

## CHAPTER FOCUS

This chapter provides a focus for nurses from which to recognise the interrelationship of factors that determine health, wellbeing and illness. This perspective enables nurses to effectively facilitate health promotion with individuals and families and within the wider community. The chapter is presented in three parts. First, we discuss concepts of health, wellbeing and illness and what determines health. Second, we outline the emergence of health promotion, discuss what health promotion is and provide guidance for practice. Finally, we discuss the role of nurses in promoting health.

Overall the world's population is generally living longer and experiencing healthier lives. However, major disparities in health exist within and between countries. International leadership in reducing health inequalities comes from the World Health Organization (WHO) who defined health as 'a state of complete physical, mental and social well-being, and not merely the absence of disease or infirmity' (WHO 1946). This perspective of health and wellbeing leads us to health promotion practice where we employ medical, behavioural and socioenvironmental approaches depending on key priorities identified by evidence.

The role of the nurse in promoting health can be multilayered. Essentially, though, it is to gather evidence and work in collaboration with others to enable individuals, families and communities to reach their full health potential. In this chapter we introduce you to health promotion theories to guide practice; principally, the Ottawa Charter for Health Promotion (WHO 1986) and the **Continuum of Health Promotion Practice** (Talbot & Verrinder 2014), which highlight the collective role of health and other sectors, organisations and communities in achieving optimal health and wellbeing. Understanding theories that underpin health promotion practice is a key strategy for nurses in contributing to the enterprise of promoting health and reducing inequalities to improve health outcomes.

## LIVED EXPERIENCE

The refugee health program at the community health centre in which I work provides a range of services to facilitate settlement in Australia. On arrival to Australia, the lifestyle of refugees changes dramatically, including changes to diet and exercise; there is an increase in energy-dense diet and people become sedentary which increases the risk of chronic disease. In refugee camps the food is rationed and people are often hungry and high levels of incidental exercise are required to survive.

As the refugee nurse, I worked with Karen the community health nurse to develop a healthy lifestyle program. We found that the refugees in this community were not familiar with the notion of preventative healthcare. Furthermore, most health literature is in English and based on Western lifestyle. As part of the program we screened 30/32 refugees using the Australian Diabetes Risk Tool (AUSDIAB) which showed a high or medium risk of developing type 2 diabetes.

Together we worked to develop and deliver a culturally and language-appropriate program to prevent the refugees' transition from high risk to type 2 diabetes. A workbook and presenter resource material was developed along with a pre- and post-test evaluation plan. Health information was provided on diabetes and risk factors, healthy eating, physical activity, emotional wellbeing and health goal setting.

Overall the outcomes were positive. We found that people felt they had increased their knowledge. There was a slight increase in vegetable and fruit consumption and exercise, and a decrease in sugar, salt and fat consumption. As a result of the evaluation a healthy eating resource that displays culturally appropriate food is planned.

**Christine, Refugee Health Nurse**

# UNDERSTANDING HEALTH

## Concepts of health, wellbeing and illness

Health, wellbeing and illness have many different definitions and meanings. Health is often understood to be an absence of disease or illness; however, the World Health Organization's (WHO) definition of health stated above is holistic in that it considers physical, psychological, social and environmental factors. In health promotion, health is seen as a positive concept, emphasising environmental, social and personal resources, as well as physical capacities. **Prerequisites for health** include peace, shelter, education, social security, social relations, empowerment of women, a stable ecosystem, sustainable resource use, social justice, respect for human rights and equity (WHO 1978). Factors that determine health and the health of populations depend on society's ability to understand and manage the interaction between them. Furthermore, people need access to opportunities, knowledge, services and resources to be healthy. **Health**, then, may be defined according to circumstances, context and perceptions, and experiences, which may vary between individuals and between communities.

Similarly, **wellbeing** is a positive conceptualisation of health: feeling healthy, happy or doing well in life. It signifies an individual's sense of general contentment with life (Eckersley 2001; Taylor 2008). People may possess a sense of

personal wellbeing even when they are in very deprived situations, during stressful life events or confronted with acute or chronic disease. **Illness** may be described as an abnormal event in which aspects of a person's social, physical, emotional or intellectual condition are impaired (Berman et al 2015). Illness is not simply the presence of a disease process; rather, it is directly related to the whole person and their total environment. **Disease** may be defined as a disturbance in structure and/or function of any aspect of a person (Crisp et al 2013). Diseases may be classified according to their cause, the way in which they are acquired or according to the body system affected. Disease is often construed to be a medical condition associated with specific signs and symptoms. However, it may be caused by many factors and may affect people differently physically, emotionally and socially.

It is important to recognise the interrelatedness of the determinants of health on each individual's state of health. Each system and subsystem within the human body continuously exchanges information to maintain a steady state or **homeostasis** in the face of actual or perceived change. When these adjustment processes fail to maintain an adequate physiological, psychological or social balance, disease or illness may result. Responses to both internal and external challenges to homeostasis vary according to the magnitude of the challenge and the capability of each individual to cope with change (see Case Study 6.1).

Concepts of health, wellbeing and illness are based on both objective scientific measurements derived from large and varied population studies, as well as the subjective experience of individuals. Scientific data provide information related to the **determinants of health** which incorporate both physical and psychological dimensions of the individual as well as broader societal influences, socioeconomic characteristics, health behaviours and biomedical factors.

### CASE STUDY 6.1 HEALTH AND WELLNESS

Mrs N, 89, has lived on her own since her husband's death many years ago. Although her sight is impaired because of macular degeneration, she pursues an active lifestyle, walking her dog for at least 30 minutes every morning through her leafy suburb, often chatting with her neighbours. She participates in the administration of a daycare program for the elderly, even though many of the program participants are younger than she is.

Mrs N has evidence of rheumatoid arthritis in her hands, as well as loss of height from pronounced scoliosis of the spine, and often experiences pain from these deformities. She will often reflect on her sadness at no longer being able to knit, sew or garden, as well as being annoyed with the clumsiness caused by her inflamed and disfigured finger joints and impaired vision.

However, while her body has a certain frailty that comes with advanced age, her voice is vibrant as she speaks animatedly to her neighbour who has come to visit. As she prepares fresh vegetables for her dinner, the smell of freshly cooked scones for the day centre pervades the kitchen. What sets Mrs N apart from many others is her philosophy on life—her commitment to reach beyond her physical limitations by actively contributing to her community. She has embraced the opportunities available through the use of audiotapes that substitute for letter writing, as well as being able to listen to 'talking' books. Mrs N maintains an interest in world affairs and has recently learnt to use an iPad so that she can keep in touch via Skype with her daughter, grandchildren and, lately, her great grandchildren, all of whom live overseas.

## THE DETERMINANTS OF HEALTH

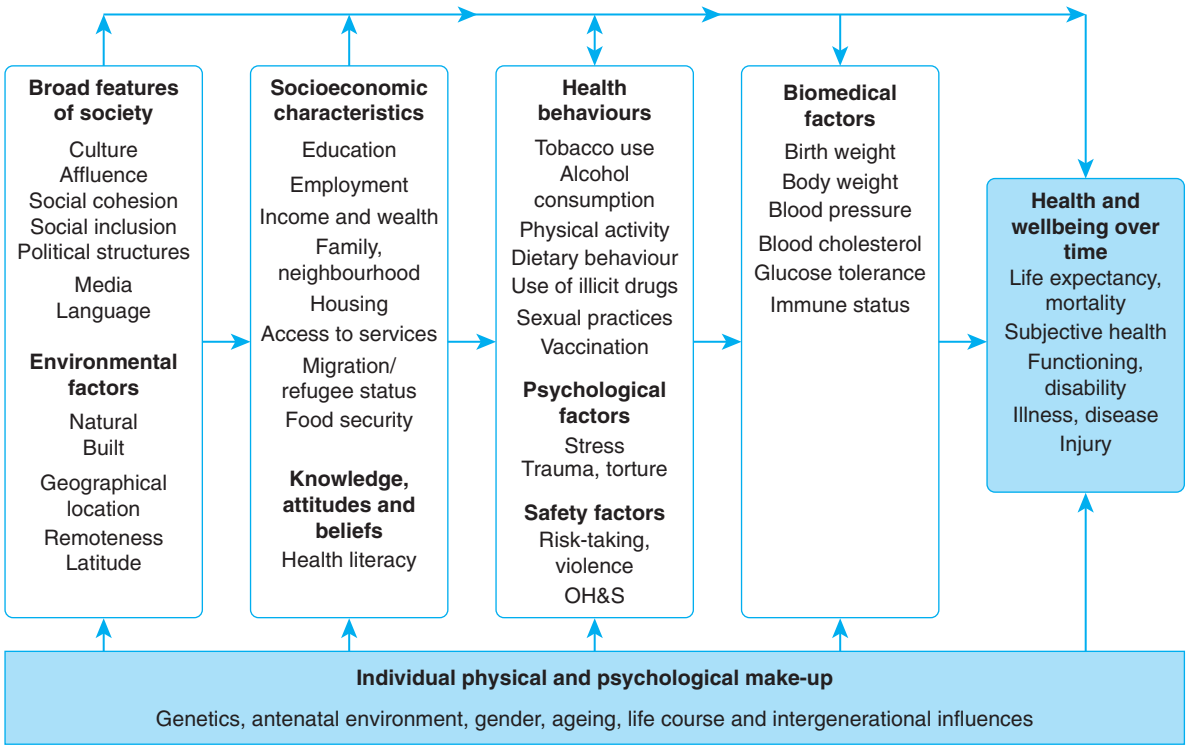
The **Australian Institute of Health and Welfare** (AIHW 2014) model for the determinants of health demonstrates the interrelationship between factors that determine health (see Figure 6.1). The determinants in the AIHW model are grouped into four main areas that show the direction of influence going from left to right. The broad features of society and environmental factors can determine the nature of another group such as socioeconomic characteristics which in turn can influence health behaviours which can then influence biomedical factors. That is, the model shows that life expectancy and how an individual experiences health, wellbeing, illness and disease is determined not only by their individual physical and psychological makeup including genetics, age and gender, but also their relationship to broad features of society such as culture and social inclusion, environmental factors such as geographical location and remoteness, socioeconomic characteristics such as education and employment, health behaviours such as tobacco use and vaccination, and biomedical factors such as birth weight and body weight.

This model is instructive for health promotion practice. For example, Australian data shows that social determinants of health explain a larger portion of the health gap than behavioural risk factors between Indigenous and non-Indigenous Australians (AIHW 2014). If we are going to promote health we need to understand the relationship between these determinants and, by necessity, we need to work in collaboration with others within and outside the healthcare system to reduce health inequalities and support vulnerable groups to reach their full health potential.

Health promoting factors include policies that facilitate generational and intergenerational equity, ensure ecosystem viability, develop convivial communities through urban planning strategies that encourage healthy lifestyles, support community inclusion and community-managed health services (Labonte 1997), as well as improving health literacy.

### Broad features of society

The broad features of society (see Figure 6.1) determine the health and wellbeing of individuals in indirect ways. Some of these features will be examined in the following section.



*Note*: Purple shading highlights selected social determinants of health.

**Figure 6.1** Australian Institute of Health and Welfare model *(AIHW 2014)*

## Spiritual factors/cultural beliefs

Cultural understandings of health, wellbeing and illness are an important factor in determining health (Julian 2009) and an essential aspect of planning healthcare. Culture can influence how illness is experienced, how that experience is communicated to health professionals and the type of care sought (Crisp et al 2013). Cross-cultural studies have shown that the experience of health can be categorised broadly in the following way:

- Feeling vital, full of energy
- Having good social relationships
- Experiencing a sense of control over one's life and living conditions
- Being able to do things one enjoys
- Having a sense of purpose in life
- Experiencing connectedness to community. (Labonte 1997)

Each culture has specific ideas about health, and these ideas are passed from one generation to another (Berman et al 2015). Traditional Chinese beliefs, for example, adopt a holistic view that emphasises the importance of environmental factors in increasing risk of disease. According to Chinese health beliefs, these factors influence the balance of the body's harmony, yin and yang. These are two opposite but complementary forces and together with qi (vital energy), they control the universe and explain the relationship between people and their surroundings. Any imbalance in these two forces, or in qi, results in illness. Spiritual and religious beliefs also affect health behaviour (Berman et al 2015). Seventh Day Adventist teaching, for example, prohibits the use of tobacco and alcohol and encourages vegetarianism. Religious coping methods such as prayer, reading of scripture, ritual meditation and talking with caregivers, ministers or clergy can have psychological, physical, spiritual and emotional benefit (Marche 2006).

Patterns of health and illness differ between people of different cultures and social classes and the health status of Aboriginal and Torres Strait Islander Australians is another example of the impact of broad features of society on health. In Australia the health status of Aboriginal and Torres Strait Islander peoples is typically worse than that of non-Indigenous Australians, although improvements in life expectancy have been made. Life expectancy is lower for Indigenous Australians by about 10 years (AIHW 2014). This is due to a constellation of features such as colonisation and the subsequent impact of displacement, Western culture and disease patterns, and culturally inappropriate healthcare systems. These broad features have, in turn, influenced socioeconomic characteristics such as housing and lower education and employment rates, as well as health behaviours in some communities such as higher smoking rates, risky alcohol consumption and poor nutrition. Furthermore, geographical location impacts on access to healthcare. The recognition of the social determinants of health is made in the National Aboriginal and Torres Strait Islander Health Plan 2013–2023. Health enablers are envisaged in this plan which includes the centrality of culture and the principles of health equality and human rights,

partnerships and accountability. These principles underpin health promotion practice.

### Social cohesion

A major determinant of health is social harmony which impacts on individuals, communities and a nation overall. Social cohesion is difficult to define but five domains have been proposed in Australian research (Markus 2014). They are:

1. Belonging: shared values, identification with Australia, trust
2. Social justice and equity: evaluation of national policies
3. Participation: voluntary work, political and cooperative involvement
4. Acceptance and rejection, legitimacy: experience of discrimination, attitudes towards minorities and newcomers
5. Worth: life satisfaction and happiness, future expectations.

Markus (2014) reports that Australia is a highly cohesive society and since 2007 evidence suggests that there has been a marginal upward movement in four of the five domains of social cohesion listed above, which tends to indicate, if correct, that policies aimed at improving these domains are working. The exception is in the social justice and equity domain which has a major impact on the health status of a nation (Wilkinson & Pickett 2009). All of these domains are highly dependent on the political structures. It is somewhat easier to understand the importance of these for health when one or more of these domains are low or undermined. Social trust is an important indicator of the strength or weakness of social cohesion (Laverack & Labonté 2008; Talbot & Walker 2007).

### Political structures

Political structures impact on health and wellbeing in significant ways and the principle of equity is key. For example, Wilkinson and Pickett (2009) examined health and social data from 25 of the richest countries in the world and 50 states of the US and found that in more unequal societies, life expectancy, educational performance and levels of trust are lower than in more equal societies. Indicators such as teenage pregnancies, homicide, imprisonment, mental illness, drug and alcohol addiction, infant mortality and obesity are higher. **Health inequalities** are differences in health status between population groups. **Health inequities** are differences in health status between population groups that are socially produced, systematic in their unequal distribution across the population, avoidable and unfair (VicHealth nda).

Talbot and Verrinder (2014) reported that key factors that influence health inequalities and health inequities within countries include equitable access to social resources. They argued that wealth redistribution through graded tax systems that impose higher taxes on the wealthiest citizens enables governments to fund more and better social services, such as universal healthcare, dental care, transport, childcare and housing assistance for their poor. Furthermore, governments who adopt a neoliberal (user-pays) approach to health policy increase health risks for vulnerable members of society by not redistributing wealth. Many autocratic governments have tended to increase the inequalities between rich and poor within the nation through their political structures and policies, including taxation systems.

Health promotion action includes increasing equity and reducing inequalities at the national level. At the organisational or local level this can mean improving access to affordable and socially acceptable services, and working with other sectors such as education, employment and housing. At the national and global level, reducing inequities and inequalities would not only make the socioeconomic system more stable but would make a major contribution to environmental sustainability (Wilkinson & Pickett 2009).

## Environmental factors

Degradation of the natural environment on which all life depends is having, and will increasingly have, an impact on human health. These are the major areas for consideration:

- There are direct and indirect, local and global, short- and long-term, negligible and devastating effects of degraded ecosystems on human health
- The associated health burden is borne by individuals and communities unequally
- The strain on the resources of the health sector is mounting because of this and we need to build capacity for predicted changes and challenges to health and healthcare.

(Talbot & Verrinder 2014:76–77)

*Environmental risk factors play a role in more than 80% of the diseases regularly reported by the World Health Organization. Globally, nearly one quarter of all deaths and of the total disease burden can be attributed to the environment … These findings have important policy implications, because the environmental risk factors … can be modified by established, cost-effective interventions. The interventions promote equity by benefiting everyone in the society, while addressing the needs of those most at risk.*

**(Prüss-Üstün & Corvalán 2006)**

There are biological, chemical, physical and social influences associated with the health of humans and the natural and built environment. Examples of biological factors include infectious agents associated with water (giardia), air (influenza), food (tetanus), zoonosis (Q-fever), pests (head lice) and infectious wastes (hepatitis-infected wastes). Indoor and outdoor pollutants and hazardous wastes such as asbestos, ozone and cytotoxic drugs are chemical hazards. Physical factors such as heat island effects, natural disasters, noise and overcrowding are major contributors to the burden of disease (AIHW 2012; Earl et al 2012:154–173). Furthermore, healthcare agencies are major contributors to waste including greenhouse gas emissions which are associated with a changing climate.

Climate change is upon us and is affecting human health. Extreme weather events are becoming more frequent and heat waves, droughts, floods, severe storms and bushfires are experienced in all regions of Australia (Bureau of Meteorology 2014). Extreme weather events impact on infrastructure and cause loss of life. The impact of climate change is felt unequally. Older people, children, outdoor workers and those

with inadequate housing, for example, are more vulnerable to heat stress. Those on lower incomes are affected more, as well as those who are already sick.

Health practitioners in Australia are among those trusted to provide truthful information (Leviston & Walker 2011) and so it is incumbent upon nurses to be informed about environmental factors that affect health. Health professional organisations often provide guidance for members; for example, the Australian Nursing Federation has a policy position on climate change (Australian Nursing Federation nd).

Nurses can contribute to health-promoting conditions in healthcare agencies which must include reducing greenhouse gas emissions and waste. At the community level, developing more walkable neighbourhoods improves the quality of life for citizens; people are more involved in their communities and have better self-reported health than those in less walkable neighbourhoods (Rogers et al 2011). People living in environments with more green space within a 1 kilometre radius of where they live have a lower prevalence for disease (Maas et al 2009). In rural areas health services and professionals need support from governments to adapt their services to meet the needs generated by the impacts of climate change so that they can in turn assist communities. Building on rural communities' local knowledge, resources and networks is an essential strategy (Verrinder & Talbot 2015).

### Geographical location

Many rural areas are vulnerable to climate change because of their direct dependence on the natural environment. Protracted drought, for example, has affected livelihoods, infrastructure and patterns of settlement of rural Australia (Verrinder & Talbot 2015). Rurality exacerbates the health status inequalities that increase with remoteness. People in rural and remote areas generally have higher rates of ill health and mortality than people living in larger cities (AIHW 2014). Refer to Chapter 47 for more information on rural and remote health. Inequality in health is due to a number of the broad features of society outlined in Figure 6.1 and partly due to greater distances to travel to appropriate healthcare. The higher proportion of Aboriginal and Torres Strait Australians in remote areas partially explains poorer health status of rural Australians too. Indigenous people are generally less healthy than other Australians; they seek medical care at a later stage in the illness, die at much younger ages and have more disability and a lower quality of life (AIHW 2014). This poorer health status is also connected to socioeconomic characteristics outlined in the next section.

## Socioeconomic characteristics

The interaction of socioeconomic determinants in health and wellbeing are far reaching and include the compounding effects of social status, physical location and standard of housing; education, employment and income levels; marital status, stability of the relationship and carer responsibilities; private health insurance; and access to, and use of, healthcare and information. These major risk conditions clearly highlight the relationship between the broad features of society on the left hand side of Figure 6.1 and health behaviours such as physical inactivity and tobacco use, which then influence biomedical factors and so health and wellbeing over time.

The health and quality of life of most Australians compares well with the rest of the world although, as we have said, there are some significant differences between population subgroups. Compared with those who have social and economic advantages, disadvantaged Australians such as Indigenous Australians are more likely to have shorter lives.

Migration and refugee status is also a determinant of health. While many migrants have better health on arrival than the average Australian because of the requirement of the immigration process, this advantage disappears the longer they have been in Australia because of race-based discrimination, different health habits from their country of origin and a lack of social support. Language barriers and cultural practices that make it difficult to access health services and participate in society more generally are challenges for refugees (AIHW 2012) and indicate a priority focus for health promotion work (see Lived Experience at the beginning of the chapter).

Exposure to ethnic and race-based discrimination is linked to poor mental health such as anxiety and depression, and physical health, such as diabetes, obesity and high blood pressure. It may affect people's ability to maintain healthy behaviours. Health promotion action includes building cultural competence within the healthcare system so that health professionals help people keep contact with their cultural communities to express and practise their faith and culture (VicHealth 2007) including culturally acceptable food.

Food security affects many Australians, especially those from disadvantaged backgrounds. Lack of security has far-reaching consequences on physical, mental and social wellbeing. Food security is dependent upon food supply and food access. Food security is when individuals or communities have regular 'access to safe, nutritionally adequate, culturally acceptable food from non-emergency sources' (VicHealth 2011). Short-term consequences of food insecurity include hunger, anxiety and lethargy. In the longer term food insecurity is related to malnutrition which can lead to a number of non-communicable diseases. Health promotion action includes ensuring fresh food is accessible which means ensuring food is affordable and can be transported, stored and cooked appropriately. This requires a systems approach by various levels of government (VicHealth ndb). Improving cooking skills, knowledge and confidence in preparing nutritious meals is part of developing health literacy overall which improves healthy choices and reduces risky behaviours.

## Knowledge, attitudes and beliefs

### Health literacy

Health literacy is a key determinant of health and one that is inextricably linked with other determinants of health such as education, income and culture. Health illiteracy follows

the social gradient and reinforces inequalities. Minority groups are most affected (Kickbusch et al 2013).

*Health literacy is linked to literacy and entails people's knowledge, motivation and competences to access, understand, appraise and apply health information in order to make judgements and take decisions in everyday life concerning health care, disease prevention and health promotion to maintain or improve quality of life during the life course.*

**(Kickbusch et al 2013:4)**

Health literacy is associated with health system costs particularly those associated with non-communicable diseases. Health literacy improves self-management of health and reduces the burden of disease overall, and so costs to individuals and societies; however, understanding disease and navigating the health system can be challenging even for the most resourceful (Kickbusch et al 2013).

Kickbusch and colleagues (2013) argued that there is a health literacy crisis but that there are promising action areas to assist in what is a system-wide and lifelong process for individuals. The promising action areas include, first, an intersectoral approach. Health literacy must be grounded in the settings of everyday life which means, second, that multiple stakeholders need to be involved. This includes community and faith-based organisations, the media, business and academic communities, adult and health educators as well as healthcare facilities. Third, developing plain language initiatives is important. Non-health professionals need to be able to understand the information the first time they hear it or read it. Attention therefore to cultures, gender and age is crucial. Finally, they suggest further research is needed to assess the 'friendliness' of health literacy systems.

Health literacy is part of health promotion action and will be presented more fully in the second part of this chapter as a key role for nurses. The aim is to enable individuals to make informed decisions about their health. This may require support in developing three levels of literacy: basic literacy skills; communicative/interactive literacy skills which require analysis that enables individuals to apply the knowledge in different situations; and critical literacy, where individuals can exert greater control over wider social situations (Nutbeam 2000; 2008). Health literacy is a precursor of developing healthy behaviours.

## Health behaviours

Health behaviours are influenced by socioeconomic characteristics such as education, income and family and broad features of society such as culture, social cohesion and political structures (see Figure 6.1). Smoking, excessive alcohol consumption, obesity, insufficient exercise and an inadequate intake of fruit and vegetables all contribute to chronic diseases such as cancer, cardiovascular disease and liver disease. These non-communicable (largely chronic) diseases account for about 85% of the total burden of disease in Australia (AIHW 2014).

Behavioural risk factors that contribute to death, disease and disability from these diseases are modifiable given the right conditions, which include policy, community and family support. Diet, activity levels and substance use are major targets for health promotion practice and comprehensive health promotion campaigns have proved successful in reducing the burden of disease for some non-communicable conditions.

### Family health practices/social support

The introduction or promotion of different healthcare practices must be commensurate with family values and lifestyle if they are to have a positive and lasting effect. Clinical Interest Box 6.1 lists examples of healthy lifestyle choices and Clinical Interest Box 6.2 is an example of a family's health beliefs. Family attitudes, values and behaviours are embedded in the cultural influences as part of the broad features of society outlined above. For children, in particular, they set the standard for how family members care for each other, the type of diet that is provided on a regular basis and the use of exercise both as a family activity and as a health routine (Crisp et al 2013). Family values also influence the use of health promotion activities such as children's immunisation schedules, age-appropriate health screening practices and conformity with road and vehicle safety regulations. Information about family health values and routines are important for nurses planning healthcare interventions.

### CLINICAL INTEREST BOX 6.1 Examples of healthy lifestyle choices

- Regular exercise
- Avoiding alcohol abuse and smoking
- Regular breast self-examination
- Seatbelt use
- Bike helmet use
- Weight control

### CLINICAL INTEREST BOX 6.2 Health beliefs

I remember my grandmother and mother applying turmeric paste, which is used for cooking in many Asian cuisines, on cuts and wounds. They used to tell me it was an ancient remedy and they believed turmeric had many therapeutic values. I still use this traditional method of wound management with my children when they come home with cuts and bruises from the playground and I have found that it is the cheapest, safest and most effective antiseptic cream you can get—straight out of the pantry.

**(Meera, mother of four young children)**

## Psychological factors

The World Health Organization's definition of health includes mental wellbeing; however, mental wellbeing is closely associated with the other determinants of health (see Figure 6.1) and health promotion action requires a multilayered approach. Mental and behavioural disorders are commonly associated with socioeconomic characteristics such as economic disadvantage, unemployment or under-employment, homelessness and reduced productivity (McLachlan et al 2013; Slade et al 2009). The disorders can be acute or chronic, severe or mild and, in Australia, rank only marginally behind cancer, muscular skeletal conditions and cardiovascular disease as causes of morbidity and mortality. Depression, anxiety and substance use are the most common (AIHW 2014:131). Mental and behavioural disorders affect individuals, families and the wider community. For those people with severe conditions, it can significantly interfere with their cognitive, emotional and/or social health. They are 'often isolated by the symptoms of their illness and may experience discrimination' (Morgan et al 2011). Health promotion action is directed at promoting psychological wellbeing in communities. Action is directed at some of the socioeconomic characteristics and knowledge, attitudes and beliefs underlying poor mental health. Working on health literacy levels and working with particular groups, families and individuals experiencing stigma and discrimination forms part of that action.

## Safety factors

### Violence

A large body of evidence shows that inequality increases the prevalence of violence within countries. The evidence is consistent across time and settings (Wilkinson & Pickett 2009).

*Where justice is denied, where poverty is enforced, where ignorance prevails and where any one class is made to feel that society is in an organised conspiracy to oppress, rob and degrade them, neither persons not property will be safe.*
**(Douglass 1889)**

It is argued that violence is associated with feelings of shame and humiliation. Status is at the heart of this notion and social inequalities feed the shame (Gilligan 1996 in Wilkinson & Pickett 2009). This inequality leads to increased social problems such as the prevalence of teenage pregnancy, drug abuse, obesity and other health behaviours. More abuse, bullying, fights and conflict are experienced by children. In more unequal societies there are intergenerational cycles of violence. Furthermore, fear of violence affects women and poor and minority groups more. Most people are not violent but most violent acts are perpetrated by men. The numbers for young men are higher than older men. Markers of status such as education, employment and housing seem to be buffers against societal violence within countries. Downward trends in violence have been seen when there have been improvements in the incomes of the poorest within a country (Wilkinson & Pickett 2009). This is consistent with other social problems such as risk-taking behaviour.

### Risk-taking

Younger people are more vulnerable to risk-taking behaviours such as substance abuse. The immediate effect of alcohol abuse, for example, 'lowers inhibitions, impairs decision-making, increases the risk of accidental injury, and increases vulnerability to unsafe situations [and] alcohol poisoning' (AIHW 2014:227). There may also be long-term consequences such as mental illness, malnutrition and sexually transmissible infections (AIHW 2014). Therefore, health promotion action includes working with people, particularly young people, to reduce these risky behaviours.

Reducing inequalities reduces social problems within countries (Wilkinson & Pickett 2009) and this lies at the heart of all health promotion action. Reducing stress in early life has an important influence of people throughout their lives. Health information, health education and creating supportive environments to improve psychological wellbeing are also part of the action. This in turn has an effect to improve some biomedical factors influencing health.

## Biomedical factors

Biomedical factors are the most obvious indicators of future health, wellbeing, illness and disability. Health promotion action is associated with immunisation to prevent disease and screening and monitoring to detect disease early or manage disease appropriately. These factors are influenced by health behaviours to the left in Figure 6.1 and mediated by individual physical and psychological factors at the bottom of the figure.

Three common biomedical factors contributing to the burden of non-communicable disease are high blood pressure, high blood cholesterol and impaired fasting glucose. These may be influenced by behavioural risk factors. For example, physical activity is recommended to improve all three biomedical factors and a diet low in saturated fats is recommended to maintain desirable blood cholesterol levels, as elevated levels contribute to cardiovascular disease. High blood pressure is considered a cardiovascular disease in its own right but is also a risk factor for stroke, heart disease and chronic kidney disease. When more than one biomedical factor is present the risks are greater and the longer a person lives with one or more risk factors, the greater the effect on their overall health and wellbeing (AIHW 2014). Health literacy is fundamentally important in reducing these risk factors.

### Immune status

'Vaccination is one of the most successful and cost-effective health interventions' (AIHW 2014:154). There are 16 diseases for which vaccines are provided free in Australia to people of particular age or risk groups such as the elderly and children. The aim is either to eliminate the disease altogether or limit severe disease in the most vulnerable. In Australia the majority of children are fully immunised; that is, they have received all vaccinations appropriate for their age (AIHW 2014).

Health promotion action aims to achieve herd immunity, which means that a sufficient pool of people must be immunised against the disease to prevent spread of that disease in the wider population (Talbot & Verrinder 2014). Improving access and knowledge, and recognising cultural factors will improve vaccine coverage. Other enablers include knowledge of services, flexibility in appointment times, public transport access and eligibility for free healthcare for newly arrived immigrants (Flego et al 2012).

### Dental health

Oral health has improved in Australia in recent decades overall and fluoridation of the water is considered to have been a major contributor to this improvement; however, recent trends indicate that tooth decay in children is rising. Change in diet that includes more sugar is considered a contributing factor to poorer oral health outcomes (AIHW 2014). Health promotion action would target diet, oral hygiene and access to affordable dental services as well as fluoridation of the water supply.

## Individual physical and psychological makeup

The health of an individual is also determined by factors such as genetics, antenatal environment, ageing, life course and intergenerational influences (AIHW 2014). These factors interact with each other and the determinants discussed in the four major groupings depicted in Figure 6.1.

### Genetics

Genetic makeup is a determinant of health. This determinant interrelates with social, cultural and environmental determinants of health. Some argue that Western culture has become 'geneticised' (Nelkin & Lindee 1995) as evidenced by the large investment in the Human Genome Project and that this impacts on investment in addressing many of the other determinants of health and the relationship between them. This project has been described as 'a logical extension of [our] medical obsession with the body as a machine' (Taylor 2012:67) and, furthermore, that genetic explanations appear to locate social problems within the individual rather than in society (Taylor 2012). However, there are individuals and families who have family histories of genetic disease and these families require accessible information, as discussed under health literacy. This information must be provided with the knowledge that concepts of genetic risks may vary considerably because of cultural and family beliefs about kinship and inheritance, and that these beliefs will influence behaviour (Taylor 2012).

### Life course

The life course perspective of health also suggests that our health is affected by the interrelationship between a wide range of determinants and can be applied to individuals, groups and communities, but it adds a historical or time dimension. It refers to the course of our lives from birth to death and the impact of one stage on another. Furthermore, the effects on an individual's health are cumulative (Fox 2012); that is, chronic diseases in adulthood, for example, are the result of cumulative development stressors in earlier life. This perspective challenges the dominance of adult health risk factors as the only determinant of health (Fox 2012) to include antenatal, intergenerational and family environments, and sociocultural aspects including gender and broader features of society outlined above. 'One way of viewing the life course is as a path or road—definitely not straight, but with corners, turns and twists' (Hutchinson 2010 in Fox 2012:215).

Health promotion action at every stage of the life course is important but it is the recognition of the critical role of promoting health in early child development and adolescents that is important to a healthy life course.

***Physical development*** At birth a baby's health depends initially on the antenatal environment, development and gestational age, genetic makeup and a healthy birth weight. These variables are largely related to maternal health, which in turn are influenced by socioeconomic status of the family as well as cultural norms and access to education. As the children grow, their health status will be influenced by exposure to disease and their immune status. Health beliefs play a part in disease prevention; for example, acceptance or rejection of immunisation schedules, and housing and sanitary conditions. Diet and exercise play an important role in further biological and psychosocial development, as do the health behaviours that are modelled by family members; for example, taking a drug, resting or massaging to relieve headache.

***Intellectual development*** The ability to critically appraise a wealth of information and to make informed choices about health practices depends on many factors; for example, cognitive development, access to adequate education and family values related to academic success, positive and negative personal health experiences, lifestyle choices and spiritual and religious beliefs.

***Emotional development*** Positive emotional experiences in early childhood influence the individual's adaptive capacities to meet the many demands of adulthood, including emotional stress and occasions of physical illness. The interrelationship of emotional and cognitive function with activation of the immune system relates to the individual's ability to heal from both biological and psychological trauma (Berman et al 2015). The body's physiological response to perceived stressful events is also initiated by the brain. The release of neurochemicals sets off a cascade of physiological reactions assisting well-balanced individuals to cope with a wide range of stress and anxiety without compromising their health beliefs and practices or their health status.

### Ageing

Healthy ageing is influenced by all of the determinants of health depicted in Figure 6.1. Arguably, each of these risk and protective factors are modifiable but the health system tends to concentrate on the biomedical factors and

health behaviours such as high blood pressure, high cholesterol levels, being overweight or underweight and substance use. While these are important determinants, enlightened approaches to health promotion for successful ageing include creating supportive environments to engage in social and productive activities and, furthermore, challenging the overall perception that ageing is more than chronic and degenerative diseases (Browning & Heine 2012). However, older Australians are affected by chronic disease more than others. Vision and hearing loss, arthritis or other musculoskeletal problems and elevated blood pressure or cholesterol levels are the most common (AIHW 2014) and so these need to be factored in to health promoting action.

'Despite the frequency of chronic disease in later life, two-thirds of older Australians aged 75 and over rate their health as good, very good or excellent' (AIHW 2014:101) and so health promotion action needs to include avoiding stereotyping older adults as unwell and incapable of change, and instead on creating environments that encourage optimal wellbeing while supporting vulnerable older citizens (Browning & Heine 2012). Many older Australians make economic and social contributions to family and community and many want to remain in the workforce. Many older people want to remain in their own homes (AIHW 2014). Facilitating social connection is important for the health of older people too. Research shows, for example, that those with internet access at home are more likely to organise spending time with friends and family and participate in their community than those without (AIHW 2014).

### Gender

The health of women and men is dependent upon all of the determinants of health but men and women experience health differently and have different health outcomes. Cultural norms and values dictate different roles and behaviours which can create gender inequalities, including inequalities in health status, health-seeking behaviour and access to healthcare. Males tend to have higher death rates at each life stage, resulting in a lower life expectancy. Gender norms and values which impact on health and wellbeing can change and reduce gender inequalities in health (WHO nd).

## Summary of the determinants of health

Understanding what determines health is part and parcel of evidence-based nursing practice. Health promotion practice should be tailored to different groups of people depending on their need. The AIHW (2014:345) suggests that while universal disease prevention is desirable for the entire population, we need to be cognisant of particular age groups such as early childhood, adolescence or the elderly, populations such as Aboriginal and Torres Strait Islander peoples, people from low socioeconomic status groups and refugees and people at high risk, such as injecting drug users or prisoners. Furthermore, to improve health outcomes all sectors need to put health on their agenda and be cognisant of the principles and actions underpinning health promotion practice, which will be the focus of the next section.

# WHAT IS HEALTH PROMOTION?

**Health promotion** is the process of enabling people to increase their control over, and to improve, their health; to help people to achieve the best possible state of wellness, and to prevent illness or detect it early so treatment can be effective. To reach a state of complete physical, mental and social wellbeing an individual or group must be able to identify and realise aspirations, satisfy needs and change or cope with the environment.

These descriptions of health promotion clearly emphasise that people take an active well-informed role in promoting and protecting their health. Health promotion is carried out by and *with* people, not on or to people. At the same time there is a clearly important role in health promotion for developing policy and organisational settings that make it easier for people to be healthy. For example, health promotion strategies encourage people to use sunscreen to prevent sunburn, and nurses have a clear health education role here but, in addition, a school health-protection policy may include outdoor sports activities being scheduled early or late in the day, and the school may erect shade sails to create a setting that shelters the students. Therefore, health promotion is not just the responsibility of the health sector but goes beyond strategies that focus on healthy lifestyles to those that promote wellbeing in order to reduce the negative impacts of all determinants of health (see Figure 6.1), that may include housing and shelter, nutrition, transport and education (WHO 1986). The World Health Organization provides leadership in promoting health internationally.

## The World Health Organization

WHO is responsible for shaping research and practice, providing technical support and monitoring and assessing health trends internationally (WHO nd). It was established by the United Nations in 1948 to deal with international health matters and concerns. There are 194 member countries of the World Health Assembly, which is the supreme decision-making body of WHO. This worldwide organisation agreed that 'Governments have a responsibility for the health of their peoples, which can be fulfilled only by the provision of adequate health and social measures' (WHO 1992). The **Declaration of Alma-Ata** came about after the 1978 WHO conference. This was to be the milestone for world health in that it set the philosophy or principles that should guide the way healthcare services are provided to all people. The declaration called for:

- Equity
- Fundamental human rights
- Community participation and maximal community self-reliance
- Use of socially acceptable technology
- Health promotion and disease prevention
- Involvement of government departments other than health departments
- Political action
- Cooperation between countries

- Reduction of money spent on armaments to increase funds for primary healthcare
- World peace.

These principles from the Declaration of Alma-Ata paved the way for the 'new' public health and health promotion action by providing the underpinning concepts for primary healthcare. **Primary healthcare** is essential care based on practical, scientifically sound and socially acceptable methods and technology, made universally accessible to people and families in the community through their full participation and at a cost that the community and country can afford to maintain at every stage of their development, in the spirit of self-reliance and self-determination (WHO 1978). These guiding principles of primary healthcare should be applied throughout the health system and adopted by all health workers to improve the health of populations (Talbot & Verrinder 2014; Wass 2000).

To distinguish between other, often misconstrued, concepts of primary healthcare, and to understand exactly what primary healthcare is, Wass (2000) provided an explanation of what primary healthcare is *not*:

- Primary healthcare is not primary medical care or primary care. This is medical care provided for people at their first point of contact with the health system, provided in the outpatients' section of a hospital, or by a general medical practitioner. Primary medical care is not necessarily universally accessible.
- Primary healthcare is also not primary nursing, as this is a system of nursing in which an individual nurse takes primary responsibility for specific individuals. Primary healthcare is not just community-based healthcare. The primary healthcare approach has implications throughout the entire health system.
- Primary healthcare is applicable to all countries of the world, not just developing countries, and consequently cannot be referred to as simply Third World healthcare.
- Primary care is not necessarily the same as primary healthcare unless it meets all of the criteria as outlined by the Declaration of Alma-Ata and spelt out in the definition of health above.

The new public health movement arose out of the recognition that ill health arises from social, biological, economic, environmental and emotional factors; the determinants of health outlined in Figure 6.1. Health promotion is the range of activities that can be planned to meet the needs created by unequal experiences of the determinants of health. Continued improvements in health status in any country will be related to improvements in these determinants using different health promotion approaches (Talbot & Verrinder 2014).

## Primary, secondary and tertiary prevention

The concepts of health promotion and illness prevention are closely related (see Clinical Interest Box 6.3). Leavell and Clark (1965) defined three levels of prevention: primary, secondary and tertiary, and nurses can have a health promotion role in each. **Primary prevention** is activities designed to prevent illness from occurring such as tackling the inequalities in health. Much of the healthy lifestyle advice, education and policy in areas including sun protection, not smoking, being physically active and eating a healthy diet fit into this category, as does immunisation. The effectiveness of primary prevention strategies is built with a combination of policy, education and financial incentives for taking the healthier choice or sanctions for taking the unhealthy choice, such as through taxation increasing the cost of cigarettes. **Secondary prevention** is the range of activities designed to detect and treat illness early before illness problems arise. Health screening including breast and cervical cancer screening, workplace health checks and skin and bowel cancer early detection are examples. **Tertiary prevention** is the ongoing monitoring once illness has occurred that is designed to maintain optimum wellness such as blood sugar and blood pressure monitoring, and follow-up re-screening after treatment for breast or cervical cancer.

Health promotion work can be quite diverse, ranging from working with groups in a community or workplace

### CLINICAL INTEREST BOX 6.3 Health promotion and illness prevention

Primary health promotion practices and illness prevention practices aim to avoid or delay occurrence of a specific disease or disorder. Examples include:

- Obtaining immunisations
- Maintaining ideal body weight
- Wearing seatbelts or safety helmets
- Minimal exposure to the sun, wearing hats and applying sunscreen when out of doors
- Consuming minimal or no alcohol when driving.

Secondary health promotion practices and illness prevention practices consist of steps to aid early diagnosis and prompt intervention in disease, shortening the disease process. Examples include:

- Having regular Papanicolaou (Pap) smears or prostate-specific antigen (PSA) tests
- Performing monthly breast or testicular self-examinations
- Regular glaucoma testing
- Bone density tests
- Brushing teeth and getting regular dental check ups.

Tertiary health promotion practices and illness prevention practices consist of rehabilitation measures after the disease or disorder has been stabilised and treating existing diseases or disorders. Examples include:

- Cardiac rehabilitation
- Recovery from joint-replacement surgery
- Learning to walk with a prosthesis after amputation
- Learning to walk after a stroke
- Complying with treatment programs for chronic diseases such as arthritis or asthma.

setting or forming a new policy to protect health rights through to working one-to-one in a health-screening service. Nurses work in slightly different ways in each of these settings, but it is all health promotion, and there are core values, knowledge and skills that apply in all settings.

## The Ottawa Charter for Health Promotion

Almost 10 years after the Declaration of Alma-Ata, the **Ottawa Charter for Health Promotion** arose from the international conference of the World Health Organization in Ottawa in 1986. The charter arose from the recognition that although the Declaration of Alma-Ata (WHO 1978) spelt out the principles to guide primary healthcare, there was insufficient guidance for health workers and others in 'how to do' health promotion. The Charter continues to be the mainstay for health promotion work internationally and it provides a simple framework that provides a universal and accessible language and guide to comprehensive health promotion practice, irrespective of the setting.

The Charter has three main principles about how one works in health promotion to assist people in gaining greater control over their lives (WHO 1986).

### Advocacy

Political, economic, cultural, environmental, behavioural and biological factors can all affect our health. Health promotion work aims to make these factors favourable for positive health through advocacy for health improvements, especially through policy change.

### Enabling

Health promotion focuses on achieving equity in health and aims to reduce differences in current health. The Ottawa Charter states that 'People cannot achieve their fullest health potential unless they are able to take control of those things which determine their health. This must apply equally to women and men' (WHO 1986). Equity is based on the principle of 'fairness'. Ensuring fair access to health services may mean that some people whose health is especially vulnerable to the negative aspects of the determinants of health, such as sole parents, people living with disability or Indigenous Australians, will need special assistance to access the services that are more easily accessible to other sectors of the community.

### Mediation

The health sector alone cannot ensure universal access to the prerequisites and prospects for health. Health promotion requires coordinated action by all concerned: governments, health and other social and economic sectors, non-governmental and voluntary organisations, local authorities, industry and the media. People are involved as individuals, families and communities. Professional and social groups and health personnel need to mediate between differing interests in society for population health gains. Health promotion strategies and programs should be adapted to the local needs and characteristics of individual countries and regions to take into account differing social, cultural and economic systems.

Health promotion recognises the need for governments and health bodies to work collaboratively. It further recognises the need to increase community control and to consider the importance of people's environments, where and how they live, as determinants of health.

Subsequent international conferences of the World Health Organization in Adelaide (1988), Sundsvall (1991), Jakarta (1997), Mexico (2000), Bangkok (2005), Nairobi (2009) and Helsinki (2013) have expanded on these fundamental issues, but the underlying principles set down in Alma-Ata and Ottawa continue to provide the guidelines for effective practice.

## Action Areas of the Ottawa Charter for Health Promotion

The Ottawa Charter provides a framework of five interconnected 'action areas' (see Clinical Interest Box 6.4) that are designed to be used collectively to ensure that health promotion action happens across sectors, settings and systems as well as with individual capacities and behaviours. The action areas can be used in many ways, including when planning an individual session or group program, when developing new policy in an organisational or community setting, when designing components of a program, or as a framework for evaluating the effectiveness of a program or session. The action areas briefly summarised are:

**Building healthy public policy**. Policy at all levels, from international, federal, state and local government to within organisations, has the potential to influence health both positively and negatively. The aim is to use policy, however defined, as a means of enshrining the decisions that protect

### CLINICAL INTEREST BOX 6.4 The Ottawa Charter for Health Promotion

As a response to growing expectations for a new public health movement around the world, the first International Conference on Health Promotion was held in Ottawa, Canada, in November 1986. The outcome of this conference was a charter for action to achieve 'Health for All by the Year 2000 and Beyond'. This charter is known as the Ottawa Charter for Health Promotion.

The charter states that actions to promote health require:

- Building healthy public policy
- Creating environments that support healthy living
- Strengthening community action
- Helping people develop their personal skills to promote health
- Reorienting healthcare.

*(The Ottawa Charter for Health Promotion, http://www.who.int/healthpromotion/conferences/previous/ottawa/en/)*

and enhance the health of the relevant group of people even when there is potential for the situation to change in that environment. When there is legislated policy it is harder to remove it even if there is a change of the party in power. Examples could include the whole range of strategies that arise from the tobacco control policy designed to minimise the risks to health from tobacco smoking, or a workplace decision that protects the health of staff in some way which is harder to take away if it is in the strategic plan of the organisation and the position descriptions of the staff. These are examples of the capability of policy to protect and enhance health. A recent illustration is the policy decisions that have led to Medicare which have meant equal access to medical and hospital treatment for all Australians. The proposed policy change to introduce a co-payment for doctors' visits had potential to put the health of many Australians at risk unfairly compared to others, and this was the basis of wide opposition to the proposal. Analyse policy on the basis of its impact on the social determinants of health; does the policy make it easier or harder to be healthy? Think of healthy public policy as your potential ally; cite policy when seeking funding or for resisting a change that will undermine health.

**Creating supportive environments**. Health promotion action is used to create situations and places that support healthy living. By using decisions and structures for the whole of a setting (school, park, state, nation) all people can benefit without taking extra individual action. Supportive environments mean protecting and nourishing natural environment places for the future health of the planet and the population. Supportive built environments means making considered changes that support health in the daily lives of people wherever they live. This can include anything from a shade sail at the swimming pool and tactile surfaces at pedestrian crossings, to financial assistance with childcare costs.

**Strengthening community action**. This means working with communities as they identify their strengths, needs and priorities, and assisting them to build their skills to bring about the changes they desire. Communities are experts about themselves; they don't need outside 'experts' coming in and telling them how to run their lives, but sometimes they need assistance to find their way or build their capacity. Strengthening community action is a key role in community development work.

**Developing personal skills.** This health promotion action area fits most closely with health education and building health literacy. This could mean that people need assistance with accessing the necessary information, learning and skills in order to make informed choices about their health and the health of those around them.

**Reorienting healthcare**. This action area relates to the important potential for health promotion work to intervene before illness occurs or before health is put at risk. Health promotion action is everybody's business and encompasses all sectors, such as housing, transport and schools in collaboration. For the current and future health of the population there needs to be a balance between prevention, protection and illness care services.

According to WHO, health promotion strategies are not limited to a specific health problem, nor to a specific set of behaviours. The WHO Ottawa Charter action areas apply the principles of, and strategies for, health promotion to a variety of population groups, risk factors and diseases, in various settings. Health promotion and the associated efforts put into education, community development, policy, legislation and regulation are as valid for the prevention of communicable diseases, injury and violence, and mental problems, as they are for the prevention of non-communicable diseases (WHO 2009).

## Health promotion in Australian government policy

Australian government policy on health promotion activity began in the mid-1980s. In 1986 the Better Health Commission formulated Australia's response to the goal of 'Health for All by the Year 2000'. Since then, goals and targets to improve the determinants of health, risk conditions and specific population groups have been developed. Epidemiological data and other research evidence is used to identify the population risk factors. At a federal level the basis for national approaches is to address risk factors that affect the widest cross-section of the population or have the greatest impact on life expectancy and those conditions that are most amenable to intervention. Policy acts as a strong lever and this is often supported by national social marketing campaigns to increase awareness and promote acceptance of the change. Changes in government and political philosophy tend to bring changes in the identified priorities, the name of the various government agencies and the amount of funding that is allocated to health promotion. Although we are generally a healthy nation and there is a good range of medically based health protection screening and services in place, Australia does spend only a comparatively small amount on health promotion. The Australian National Preventive Health Agency that developed after the 20/20 summit in 2008 was transferred to the Department of Health in 2014 and the National Partnership Agreement on Preventive Health was terminated. It is mooted that tobacco, obesity and harmful use of alcohol will be the focus of 'preventive health' at the national level in the future.

## Continuum of health promotion practice

It is useful to consider health promotion practice as falling along a continuum (see Figure 6.2) that illustrates how the different types of health promotion action relate to each other. The different forms of health promotion are closely aligned with medical, behavioural and socioenvironmental factors approaches to health promotion underpinning the determinants of health and in the AIHW model (see Figure 6.1). Activities for an individual, which are mostly implementing medical approaches, are at one end and those that involve working socioenvironmental approaches fall at the other end. Each category on the continuum is outlined briefly below.

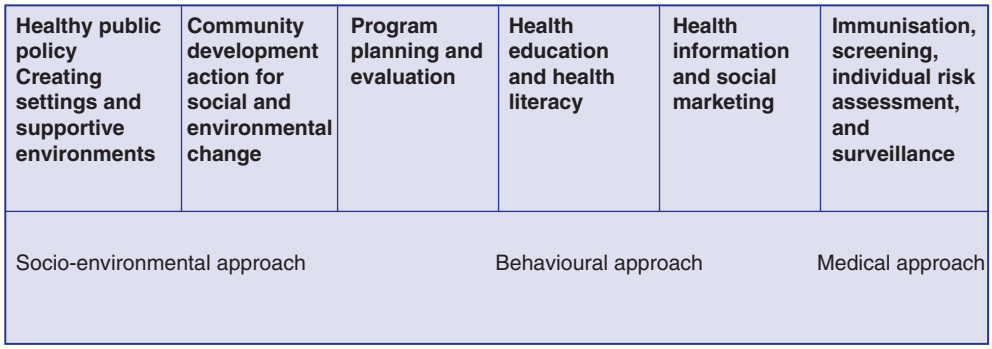


**Figure 6.2** Continuum of health promotion practice
*(Talbot & Verrinder 2014)*

## Healthy public policy—creating settings and supportive environments

Health promotion actions at this end of the continuum focus on bringing about changes in a place or an organisation that make it easier for people to be healthy. In the Ottawa Charter this is called a 'supportive environment'. Healthy public policy means the way that a national, state or local government policy or an organisational agreement can be used as a means of reducing people's health risks. There are a great many examples of this in smoking, driving and environmental legislation but policy can also apply in an organisation such as a preschool 'no hat no play outside' rule. The nurses' role in activities at this end of the continuum will mainly be in contributing to the development and implementation of new initiatives or policy that will ultimately be made possible by those with decision-making and financial power.

## Community development action for social and environmental change

Community development work involves nurses working in partnership with a community or group who have something in common, rather than being their 'leader' in charge of a project. In a nursing role the work usually happens in a community setting or with a vulnerable group that meets in an organisation such as a community health centre. The key skill in community development work is not to take over, but to let the group or community identify their needs and how they might achieve them, and then to partner with them to build their capacities and skills to achieve their aims (Green et al 2009). It can be a complex way of working because in many ways it seems more efficient to take over and do things on behalf of the community rather than letting the process unfold. In addition it is not usually possible to know in advance what skills the community development role will entail.

## Program planning and evaluation

Program planning and evaluation work encompasses the essential documentation and work steps that are undertaken to account for the funds and activities of a project or program. It may be that a new program is planned within a workplace or organisation to increase awareness about the risks to women of domestic violence, and to build the skills of staff to reduce the impacts. A series of steps are outlined, including assessing the needs so the program can be designed to meet these needs, designing the program activities, implementing it, collecting information so you can tell whether the program was implemented as planned and what worked and didn't work, reporting the evaluation and then deciding what should be changed if the program was to be implemented again.

These steps are closely aligned to the nursing process and are dealt with in more detail in the later section of this chapter.

## Health education and health literacy

In simple language **health education** means the process of effectively 'teaching' a health-related topic, whereas **health literacy** is a quality of the person being taught or who is learning, where they have understood the information to a level that enables them to be able to use it to make informed decisions about their own health or to apply and adapt that information to meet the learning needs of other people, such as family members (Nutbeam 2000). Health education to build health literacy is a key role for nurses and it can take place almost anywhere when a 'teachable moment' arises. The ability and willingness to take advantage of opportunities to enhance health learning are key skills for nurses, and they should take the opportunity to build professional skills in this area. Because of the importance of the health education role, this form of health promotion is dealt with in more detail later in this section. Health education may be anything from a brief one-to-one interaction during a nursing procedure to a formally conducted session for a group in the community, including interactive web-based health education forums for people who may be geographically distant. The main aims of health education and health literacy are that the person can make informed decisions about factors that affect their health, and can be supported to change their behaviour where needed.

## Health information and social marketing

Health information and social marketing relate to the use of marketing or advertising principles to 'sell' a health message

### CRITICAL THINKING EXERCISE 6.1

Collect a range of health information materials and resources, such as pamphlets and handouts from displays in your local community health agencies, that are designed for community members, rather than health professionals. This activity works best in partnership with at least one other student.

Ask yourselves the following questions of each resource:

1. What makes this information useful?
2. What makes you want (or not want) to read the information in full?

### CRITICAL THINKING EXERCISE 6.2

These days the internet is used as the first source of information by many people. Unsurprisingly it is also used as a deliberate strategy for social marketing.

View the YouTube social marketing clip 'Dumb Ways to Die' (see Online Resources). As you will see on the trailer, this has been an enormously popular clip.

There are no right or wrong answers to these questions, but use them for your own analysis of this clip, or as the basis for a discussion with another student.

What techniques are used to make the video attractive and engaging for viewers? What is the main message of the video—who is the sponsor?

The video takes the best part of 3 minutes to get to the core message. This would never work with other forms of social marketing (think about drink driving or Sunsmart messages for comparison).

Why does the message work in this format? How would you know the campaign was successful? Discuss the argument that this is engaging and effective as entertainment, but does not necessarily result in behaviour change (in whose view is it successful?).

(Donovan & Henley 2010). Usually health information is provided as printed materials such as booklets and pamphlets, or it may be included as pages on an internet site. Health information usually contains more detail about the risk condition and provides a detailed action plan for behaviour change and sometimes references, whereas social marketing covers the forms of materials, including stickers, give-aways and television commercials and placards that give a brief message, often accompanied by a catchy graphic, logo or tune. The purpose of health information is to support health education activities, maybe as a take-home reference after the information has been provided and explained verbally, especially with regard to creating positive attitudes to the desired behaviour. It is another way to support the development of health literacy. The aim of social marketing is to create awareness of the risk to health, reinforce positive values about a behaviour and provide a cue to initiate the activity (French et al 2009). Repetition of the message aims to make people associate the visual or tune with the positive behaviour: think of the red tick for heart healthy foods and success of the Slip! Slop! Slap! sun protection message.

### Immunisation, screening, individual risk assessment and surveillance

These health promotion activities are at the 'medical' end of the health promotion continuum, meaning that they rely on medical research and information, and medical interventions to be conducted. The nursing role is to provide care in accordance with the guidelines set down to ensure the intended outcome and no danger occurs to individuals or the wider population. A range of medical-based health promotion activities is directed at minimising the spread and health impacts of infectious diseases. There are very high risks to the population if infectious diseases are not controlled and their transmission limited, and this is the basis of immunisation programs. The aim of screening is to detect medical conditions early so treatment can be undertaken with the best chance of complete recovery. Individual risk assessment may be undertaken in workplaces or in health clinics with the aim of detecting risks the person may not be aware of, such as poor nutrition leading to hypertension, and reducing the risk through behaviour change and medical management. Surveillance is the observation of activities in the environment to detect factors that pose a risk to the population. Surveillance might include quarantine activities for animals to reduce the risk of disease.

## Theoretical models and frameworks to guide health promotion practice

Several models have been developed to provide practitioners, including nurses, with frameworks to assist people to achieve optimal health. A theoretical model is a diagrammatic representation of how various parts of a concept relate to each other to explain an outcome, or to predict what is likely to occur. A model informs the practitioner about the matters to consider when planning care, and the order in which to take actions. Models often have arrows or lines, which indicate the relationship between the different components.

Nurses' work in Australia has traditionally been influenced by Western medical models of healthcare that focus on the organic nature and cause of mental and physical disease, rather than on the influence of the many factors that determine health. This medical diagnostic-centred model centres on the individual which disregards those internal and external variables that influence health outcomes. However, the models presented in this chapter provide a broader perspective to the medical model and are discussed in the next section.

### Socioenvironmental models

We have presented a number of socioenvironmental theoretical models earlier in this chapter, including the determinants model from the AIHW (Figure 6.1), the Continuum of Health Promotion Practice (Figure 6.2) and the action areas of the Ottawa Charter for Health Promotion (WHO 1986)

that provide guidance to nursing practitioners and others. These models show the interrelationship of the determinants of health and the aim of health promotion is to address the inequalities in the broad features of society such as socioeconomic status, geographical remoteness or pollution.

## Behavioural models

Behavioural approaches to health promotion aim to improve behavioural risk factors such as poor nutrition, physical inactivity or stress management. They fit within the second and third major grouping of the AIHW model (Figure 6.1) which includes health literacy, and in the Ottawa Charter for Health Promotion (WHO 1986), behavioural approaches fit well with 'Developing personal skills'. In the Continuum of Health Promotion Practice model, behavioural approaches fit best within health education (Figure 6.2).

Many health promotion activities do not require the active involvement of people making deliberate changes to personal behaviour. Passive health promotion occurs when an individual benefits from the activities of others without necessarily acting themselves, such as in the fluoridation of drinking water. As described above these health promotion activities are designed to create a 'supportive environment' or setting, which makes it easier for people to reduce the risks to their health.

However, health promotion may require the active involvement of people in order to be effective. People will need to build the skills and motivation for change and nurses as health educators will draw on a wide range of skills. One of the challenges with behaviour-change approaches in health promotion is the assumption that, just because a person has the knowledge about a risk to their health and what would be the desirable behaviour to reduce that risk, they are able to make the necessary change. For various reasons, including peer pressure, financial barriers, culture and other social pressures, people find they are unable to make the necessary change. It is important that health promotion workers don't assume that change will automatically occur (because it's good for their health), and equally important that people are not judged negatively when they are not able to make, or sustain, a healthy change; this is called 'blaming the victim' (Mooney 2012; Talbot & Verrinder 2014).

Using a health education model helps ensure the education is well planned and will meet the learning needs of the participants. Two models are discussed in the next section.

Over a long period a number of behavioural models have been developed and refined. Some of these have been validated in research. Behavioural models have used two main approaches. The first group arose from the discipline of psychology, designed to assist individuals to understand their own risk-taking behaviour and to provide steps for guidance through a sustained change. The most widely validated of this group is the Transtheoretical Stages of Change model (Prochaska & Di Clemente 1984). The model gives recognition to how hard it is for people to make a change that would be good for their health, but would mean them giving up something they value. It is a five-step model that helps the person take one step at a time. It also builds in recognition that people may have 'false starts'. An example for using this model could be a personal plan to start regular exercise or quit smoking.

***Stages of Change Model*** According to the Stages of Change Model, the following steps make up the process individuals use to integrate change in their lives:

1. Pre contemplation—this describes when people are not yet considering change. This could be a stage where a health practitioner, such as a nurse, may ask about or suggest a change.
2. Contemplation—a person gives an indication of readiness to consider making a specific behaviour change ('I've been thinking about it …').
3. Preparation—the person is motivated to make the change and states their intention to change within the next month to another person (even better if it's in public). They have taken some steps towards this decision such as making bookings, seeking support from others or blocking out diary space.
4. Action—the stage at which the behaviour has commenced but is not yet habitual (less than 6 months); it is easy for lapses to occur at this stage. (Think of those un-used gym memberships and exercise bikes, or people having many attempts to quit smoking before they succeed.)
5. Maintenance—the change has become more of a habit and the person experiences the health benefits. They are more optimistic and positive about the change. Relapse may also be the fifth stage.
6. Termination—describes the stage, especially if it relates to an addictive behaviour, where the person has no temptation to relapse. This stage was added to the model by researchers wanting to add to the work of Prochaska and Di Clemente.

If the different stages that a person moves through when they wish to make behaviour change are well understood by the health practitioner then they can plan sessions or activities that positively reinforce the progress that has been made so far (Prochaska et al in Glanz et al 2008; Nutbeam et al 2010). Many behaviour-change therapeutic counselling approaches make use of this theoretical model.

Health education is so much more than giving information and expecting the person to be able to make, and sustain, the change.

The second group of behavioural models is designed to increase the health literacy of individuals or groups and they draw on Social Learning Theory as a basis (Glanz et al 2008; Nutbeam et al 2010). The models assist practitioners to understand factors that influence the behaviour of people with regard to their decisions about taking a health promotion action, and to design activities that build healthy decision making. The most widely used and validated model in this group is the Health Belief Model (HBM).

***The Health Belief Model*** The HBM (see Figure 6.3) (Glanz et al 2008; Nutbeam et al 2010) was developed to provide a

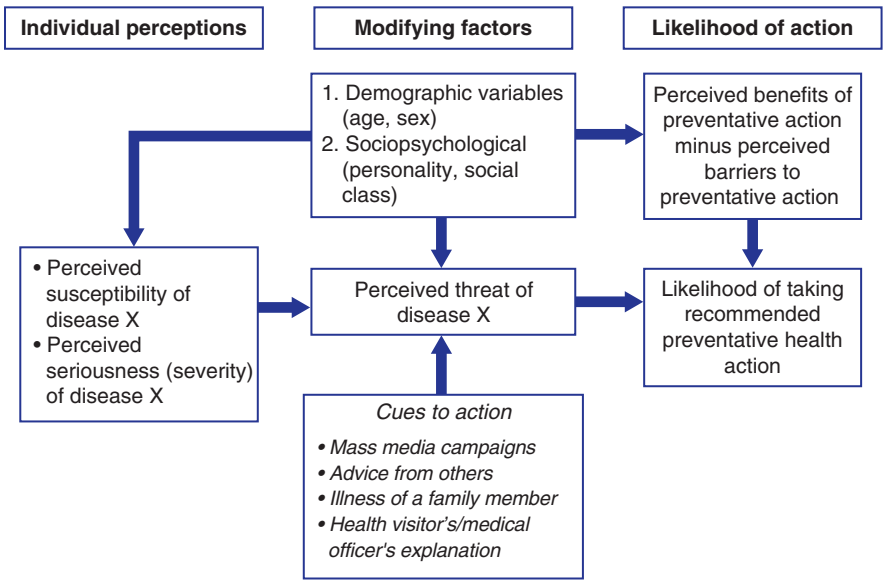

**Figure 6.3** The Health Belief Model
*(Talbot & Verrinder 2014)*

framework for explaining why some people take action to avoid a specific illness or condition and others do not. Doing a thorough analysis of the factors that may influence a person's decision provides very useful guidance about the social context and characteristics of the potential audience and about how to design a health education program that meets their needs and makes it easier for them to take the positive health action. The model is designed to be used when the health practitioner, in a top-down approach, is the 'expert'—not as part of a community development approach. As with most health education approaches, the program needs to give consideration to the wider social context of people's lives (Nutbeam et al 2010).

The relationship set out between concepts in the HBM suggests that a person, or group of people with similar characteristics will be convinced to change their behaviour based on the influence of four conceptual areas. Bear in mind this model is designed to be used in relation to one condition or situation, not health promotion generally; for example, quitting smoking to avoid lung cancer, or having a Pap test for early detection of cervical cancer. Refer to the HBM as a guide (see Figure 6.3), starting on the left side, when reading the explanation below.

1. The individual's perceptions are the person's views and current understanding about the risks and seriousness of a certain condition. Perceived susceptibility is a person's estimate of their likelihood of getting a health condition, based on their current level of understanding. Clearly, the role for the health educator is to ensure that accurate information is provided.
2. Perceived seriousness is the person's assessment of what it would be like to have the risk condition. The person may consider the impact on other people and their social situation, including work and family, so their perception will include the emotional impacts (represented by the arrow from the 'modifying factors' box). As the model also suggests the impacts of perceived susceptibility and seriousness amplify each other. Session planning would need to take account of these potential factors or else the person may be too overwhelmed to take action. For example, many women fail to attend screening for reasons such as differing cultural values, fear of the outcome or inappropriate education resources (Lee et al 2013).
3. People's views about the threat of a health risk and whether they will adopt the health behaviour change is influenced by two groups of modifying factors, as the model diagram outlines. Barriers to changing health-related behaviours include personal and financial cost to the individual, stated or anticipated family disapproval and low expectation of personal benefit related to the intended change. By recognising the subjective nature of perceived threats to health and the influence of family and cultural beliefs about health practices, the HBM can offer nurses a guide for a person's readiness to change. There is considerable evidence that people vulnerable to the social determinants of health are less likely to take health preventive behaviours (AIHW 2011) and thus health literacy programs need to take additional efforts in the planning to attract these 'difficult to engage' groups. The main purpose of social marketing strategies and resources in health education is to provide cues to commence a new behaviour. This can take the form of a reminder letter, advertisement, logo, photograph and so on. Other people, including family members, health practitioners and media stories can also be the cue.
4. The likelihood of taking action is the outcome of the individual's perceptions about the benefits of taking action to avoid or detect the condition, and whether the barriers to taking that action can be overcome.

Perceived barriers may be personal, such as fears about the embarrassment or unpleasantness, or may result from external or social factors including the costs or the change of habits. Emphasising the benefits and providing information and strategies to overcome the barriers are important components of the health education program.

The HBM assists the nurse to identify the optimal time for health education and the probability of the individual making a commitment to change. When using the HBM as a guide when planning health education approaches it is important to plan appropriate and varied content to address the concepts in each of the concept 'boxes'. Consider the way the arrows in the model relate concepts to each and use these as guides to the sequence in the way content in the program is presented.

This model may be best understood through the scenario in Case Study 6.2.

***Health education skills and techniques*** Both Registered and Enrolled Nurses play a pivotal role in health promotion, health maintenance and prevention of illness through provision of evidence-based information and education to build the health literacy of individuals, groups and communities. This requires knowledge of the range of resources available to build their skills to communicate and educate and to design sessions and programs that meet the needs of the people in their care.

Health education can be defined as 'any combination of learning experiences designed to facilitate voluntary actions conducive to health' (Green & Kreuter 2005). Health education can be any planned educational intervention people can voluntarily take that aims to look after their health or the health of others. Health education can include short spontaneous and serendipitous opportunities or more formally structured sessions for individuals or groups. Ewles and Simnett (2010) describe the dimensions of health education as:

- Concerned with the whole person, encompassing physical, mental, social, emotional, spiritual and societal aspects
- A lifelong process from birth to death, helping people to change and adapt at all stages
- Concerned with people at all points of health and illness, from the completely healthy to the chronically sick and handicapped, to maximise each person's potential for healthy living
- Directed towards individuals, families, groups and whole communities
- Concerned with helping people to help themselves and with helping people to work towards creating healthier conditions for everybody 'making healthy choices easier choices'
- Involved in formal and informal teaching and learning using a variety of methods
- Concerned with a range of goals, including giving information, attitude change, behaviour change and social change.

Refer to Clinical Skill 6.1 on health teaching.

Health education involves working with individuals, communities and society and may be guided by the principles of primary healthcare. If nurses are to influence the health of individuals and communities, they need to be clear about

## CASE STUDY 6.2 APPLICATION OF THE HEALTH BELIEF MODEL

Tom is a 50-year-old married man who has noticed a change in his personal level of fitness over the last few years. He acknowledged a gradual weight gain when his clothes were no longer comfortable and he began using the lift to his office because he became breathless when climbing a flight of stairs.

### Related health beliefs

Tom believes that weight gain is inevitable with advancing years because both his parents had become much heavier as they aged. Both Tom and his wife smoked cigarettes but were undeterred by the health warnings on the cigarette packets because no one in their family developed lung cancer or heart disease.

### Health-related event

Tom was forced to walk up stairs to his office when the lift was out of order. He was breathless from the exertion and experienced heaviness in his chest. His secretary called an ambulance and Tom was subsequently diagnosed with a myocardial infarction.

### Stimulus to change health behaviours

Tom made a good recovery but the experience had frightened him. He paid attention to the health education sessions in the cardiac step-down unit and sought advice about diet, exercise and cigarette smoking.

### Strength of the stimulus

Tom never forgot the pain in his chest and his fear of dying. He stopped smoking and gradually increased his level of fitness with the support of the cardiac rehabilitation team. His wife was scared Tom was going to die and supported him throughout his illness and rehabilitation. She cut back her cigarette smoking and didn't smoke in front of Tom but was unable to 'kick the habit'. Tom's parents were very supportive but thought they were too old to change their health behaviours.

## CLINICAL SKILL 6.1 Health teaching

**Review and carry out the standard steps for all clinical skills/interventions**

| **NMBA Decision-making Framework considerations:** | **Equipment:** |
|---|---|
| 1. Am I educated?<br>2. Am I authorised?<br>3. Am I competent?<br>If you answer 'no' to any of these, do not perform that activity. Seek guidance and support from your teacher/a nurse team leader/clinical facilitator/educator. | Audiovisual material/aids<br>If teaching a skill, ensure correct equipment, pen and paper, and any published written material |

| **Skill activity** | **Rationale** |
|---|---|
| Introduce self to individual, conduct a health assessment<br>Assess the individual's ability and willingness to learn—determine baseline knowledge, their cognitive status and ability to understand and speak English and culture<br>Explain the process to the individual and establish a suitable time for the health teaching to take place | Alleviates the individual's anxiety and provides reassurance<br>Ensures a baseline assessment of the individual<br>Enables resources to be organised prior to commencing any formal health teaching (interpreter, family member or carer, language/visual/hearing aids)<br>Ensures cooperation and involvement of the individual |
| **When conducting the health teaching**<br>Ensure the individual is comfortable and away from any distractions (this may be in a room away from the individual's bed area, or if in their bed/room ensure the curtains are closed or door closed)<br>Ensure only the relevant people are present<br>Ensure equipment for teaching a skill or any aids are within reach<br>Explain the purpose of the health teaching | Maintains focus and avoids distractions enabling better retention of information<br>Too many people in the room can distract the individual and cause interruptions to the process<br>Having equipment ready ensures not having to leave the individual and interrupt the session<br>Alleviates anxiety and reiterates the purpose of the education |
| Demonstration of a skill<br>The Enrolled Nurse demonstrates the skill from beginning to end with no interruptions<br>Demonstrate the skill again breaking down into steps, explaining each step clearly and as simply as possible<br>Explain the rationale of the skill and the reason for each step being performed in the way demonstrated | Shows the skill in its entirety so that the individual and/or carer can see what is involved<br>Alleviates anxiety and makes the skill easier to learn<br>Reinforces the need for accuracy and ensures the skill is learnt correctly to eliminate error |
| Ask the individual and/or carer to handle the equipment and go through each step with the nurse coaching them through it<br>If the individual/carer feels confident ask them to demonstrate again, this time coaching themselves | Gives the individual/carer the opportunity to demonstrate the skill and build their confidence with support from the nurse<br>The individual/carer may require another demonstration by the nurse if they are struggling to master the skill |
| Run through any troubleshooting issues which may occur with the equipment<br>Go through the manufacturer's guidelines with the individual/carer<br>Provide feedback | Allows the individual/carer to become familiar with some of the error readings or any issues with the equipment and what to do, care of the equipment and proper disposal of any waste<br>Promotes confidence in being able to perform the skill and may require further sessions |
| General health teaching<br>Go through the areas of health teaching pertaining to the session with the individual and/or carer using any aids or written materials<br>Ask the individual and/or carer to repeat any information in their own words and ask any questions<br>Do not overload them with information | Outlines the purpose of the health teaching and demonstrates efficiency<br>Determines a level of understanding and allows for repetition of any information<br>Too much information can confuse the individual and/or carer, making the learning harder<br>The nurse may need to follow through with another session |
| Document in the progress notes and report to the Registered Nurse and/or multidisciplinary team any relevant information | The individual and/or carer may need to be referred to other healthcare personnel for further teaching |

*Crisp & Taylor (2013); Tollefson et al (2012)*

what factors contribute to people's health and ill health. There is also a role for the individual to take responsibility for their own health, and a clear role for communities and government in tackling the root causes of ill health. The nurse needs to consider how and to what extent they can involve people in planning their own healthcare. Drawing on Adult Learning Principles (Knowles 1980), Talbot and Verrinder (2014:235) outlined the following principles for facilitating the teaching–learning process:

- Work with participants to *identify the learning needs* and preferred learning styles—allow them to direct the learning process. What the educator assumes they need to know may not be the same as what the learner needs or wants.
- *Get to know the learners' perspective*. The time spent on exploring learners' values, what they think and know about the subjects to arrive at mutual expectations about program content and outcomes will improve the outcomes for the learner.
- *Be aware of the context of people's lives* such as the social, educational, emotional factors they experience as barriers to health literacy. Use this background information as part of the learning process, and as the basis for real-life examples to illustrate the theoretical content.
- *Build on what people know*—extend learning rather than repeating what is known, or assuming they know more than they do.
- *Set realistic achievements* for the time available and what learners can do as a result of the teaching. If a new skill is being taught, the learner will need to understand the theory and have time to refine the skill with repeated practice.
- If it is a group session the educators will need to *accommodate the varied levels of learning* of the participants. A useful way to gauge current knowledge is to commence the session with a brief discussion with questions, or a pre-test in verbal or written format.
- *Present the information in a logical format*, from simpler, concrete information to more complex, conceptual information where the learner may need to adapt or apply the information into a different setting. An example of this is when teaching the principles of an aseptic technique for wound management. A session might include an explanation of the principles, a demonstration and practice in a hospital setting. This would be followed by discussion and practice in the home setting. Support this with written hand-out material where relevant.

Whether working with groups or individuals, certain skills are required to enable the nurse to facilitate health promotion and education, including:

- Use a theoretical framework as a guide when planning the content
- Gain an understanding of the person's concerns and position
- Be clear and unambiguous with simple language and relevant examples
- Be non-judgmental, be aware of other factors such as the views of significant people in the person's life and the individual's own self-esteem that could influence the communication process
- Have up-to-date knowledge and be informed of scope of practice
- Use effective communication skills such as using open-ended questions, listening, recognising any cultural implications, assessing body language and concise history taking and documentation
- Use written material to support the interpersonal communication. Ensure the cultural safety of the person and their cultural values.

The challenge for nurses is how and when to provide health education information. If a person has specific learning needs about health promotion, risk reduction or management of a health problem, it is useful to develop and implement a teaching plan with the person. A teaching plan includes assessment of the person's ability, need and readiness to learn, with identification of problems that can be resolved with teaching. The nurse then determines objectives with the person, delivers educational interventions and evaluates the effectiveness of the teaching. Clinical Interest Box 6.5 lists the principles to guide effective teaching and learning.

## Medical models

Medical approaches to health promotion aim to improve physiological risk factors such as high blood pressure, early cancer detection and immunisation. In the AIHW model (see Figure 6.1) and the Continuum of Health Promotion Practice (see Figure 6.2), health promotion action occurs on biomedical factors and health promotion action such as surveillance, risk assessment and immunisation, listed on the far right.

Other categories of models are explained briefly here, but it is recommended that students wishing to use them in their practice gain additional guidance from specialist texts on this subject (e.g. Nutbeam et al 2010; Crisp et al 2013).

### CRITICAL THINKING EXERCISE 6.3 Applying the Health Belief Model

Use the Health Belief Model as a basis to develop a plan for one session of health education for refugees who attend the community health facility where you work, which is designed to encourage them to have their children fully immunised at the free public sessions that are available.

A detailed assessment phase will be essential and the success of the program will depend on whether the program meets the issues identified in the assessment. Because of the different cultural characteristics of the potential participants, you cannot assume that a successful program offered to one immigrant group will automatically be relevant to a different group.

## CLINICAL INTEREST BOX 6.5 Principles to guide effective teaching and learning

| Principles | Teaching implications for the nurse |
|---|---|
| Allow the learner to direct the learning process. | Active participation is paramount.<br>Learning is most likely to occur if the learner sets the goals.<br>Learners need to have their say, use initiative, experiment and find out what works for them.<br>Identify which teaching technique is best for each learner.<br>The nurse is a facilitator to direct the learner to resources. |
| Get to know other people's perspectives. | Understand the background and ideas of other people.<br>Build new knowledge on past experience. |
| Be aware of the context of people's lives. | Centre the learning experience on real-life situations of the learner.<br>Readiness and motivation to learn are high when facing new tasks. |
| Pre plan. Establish agreed-on, written goals. | Develop and discuss the plan with the person. Introduce a role model to help illustrate therapeutic expectations. Enlist the aid of family and significant others. Revise expectations; learn to be satisfied with small achievements. |
| Build on what people already know. | Identify where it is easiest for the learner to begin learning.<br>Provide new material at a pace that is appropriate for the learner.<br>Treat mistakes as an opportunity to learn. |
| Planned achievements need to be realistic. | Set realistic achievable goals.<br>Find out what it is that the learner wants to know. |
| Take account of all levels of learning. | Consider whether there is a need for knowledge development, attitudes and values clarification or behaviour change and skills development. |
| Present information in logical steps. | Provide a logical sequence, whereby complex ideas are built on smaller ones. |
| Create opportunities for teaching. | Use all possible opportunities for teaching, such as when bathing or changing a dressing. Break teaching and practice into small time periods. |
| Documentation. | Carefully document what was taught and learnt. Screen teaching materials, |
| Broaden knowledge base. | Read, study, ask questions. Participate in other teaching sessions, observe more experienced nurse–teachers, attend classes. |
| Develop your own support system. | Recognise personal reaction to stress. Rely on friends and family for positive encouragement. Network with other nurses, health professionals and community leaders to change the situation. Become proactive in legislative processes affecting healthcare delivery. Advocate for time for teaching. |

*(Talbot & Verrinder 2014)*

## Holistic health models

Contemporary nursing care can be understood through a holistic model of healthcare, where the interplay of physical, psychological and spiritual dimensions of an individual's health is acknowledged and a broader reference to both traditional and non-traditional therapies is included. This model demonstrates respect for an individual's healthcare beliefs; their right to participate in their healthcare planning and the

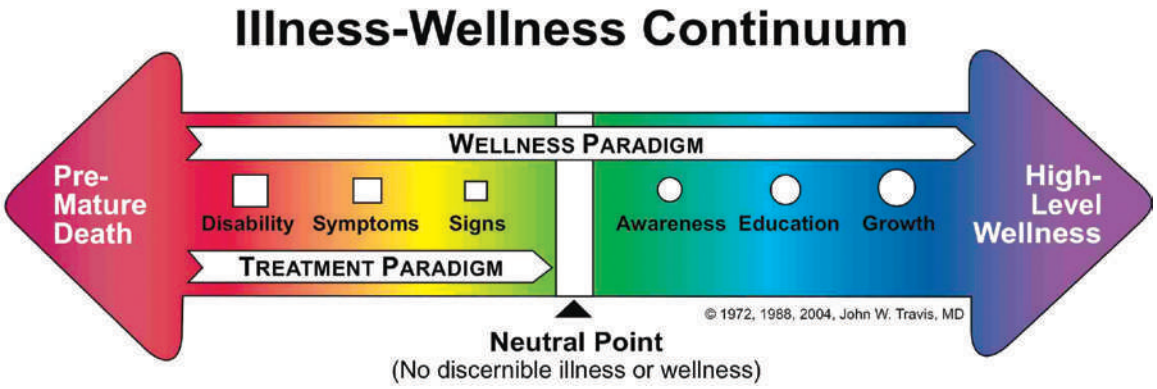

**Figure 6.4** The health–illness continuum

*(Travis & Ryan (2004). © 1972, 1981, 1988, 2004 by John W. Travis, MD. Reproduced with permission)*

need for collaboration between all carers in this planning (Crisp et al 2013). Ideally, this holistic model of healthcare delivery creates an empowering environment which enables individuals to assume a greater control over culturally appropriate healthcare options. One of the earliest models was developed in the 1940s by Abraham Maslow. He believed that a person's motivations and behaviour are formed by attempting to meet their basic needs. Maslow defined basic human needs as physiological needs, safety and security, love and belongingness, self-esteem and self-actualisation (Maslow 1970). Maslow's 'hierarchy of needs' emphasises that some needs are more basic than others and that the more basic needs need to be met before consideration of higher needs. Maslow's hierarchy has provided an important foundation for human services, including nursing, where it forms the basis of most nursing models.

### The health–illness continuum

The health–illness continuum model of healthcare is another model that can assist nurses to recognise individuals' states of health and wellness as a position on a continuum that ranges from a high level of wellness at one end to severe illness at the other (see Figure 6.4). This continuum represents mental and physical functionality based on vision, hearing, speech, mobility, dexterity, cognition, emotion, pain or discomfort rather than the continuum of health promotion practice discussed previously. The health–illness continuum model can also represent the level of individual risk for disease or illness in relation to age, socioeconomic status, cultural beliefs and geographical location. By placing high risk at one end of the continuum and low risk at the other, the comparison of age with risk of infectious childhood diseases such as mumps or rubella identifies young children as being at high risk. Population statistics identify a greater risk associated with car accidents for young people between the ages of 16 and 26 than for other age groups. Risk factors for infant mortality are related to socioeconomic status and geographical location, while the risk factors associated with tropical diseases such as malaria are much greater for people living near the equator compared with those who do not. Cultural and religious beliefs related to health practices may prohibit groups of people from the benefits of specific care options, thus increasing their associated risk factors. A continuum does not provide us with an absolute measure but, by identifying their position on the continuum, people can be encouraged to see a comparison between current and previous health states, or their position in relation to specific risk factors (Crisp et al 2013). This model describes the relationship between health and illness and provides a method of identifying an individual's level of health. This model is valuable when comparing an individual's present health status with their previous level of health and for then setting nursing goals and objectives to promote a future level of health (Crisp et al 2013).

**CRITICAL THINKING EXERCISE 6.4**

1. If the midpoint of the continuum/pathway represents the neutral point or no discernible illness or wellness, or represents little awareness of health status, where would you place yourself and/or your family members on the continuum?
2. What direction are you facing?
3. What steps can you and/or your family members take to achieve a greater sense of wellbeing?

## NURSING AND HEALTH PROMOTION

### The changing role of nursing

The focus of nursing care in the twenty-first century includes medical, behavioural and socioenvironmental models using theories and research as a basis for practice. Nursing has moved from being largely disease oriented to emphasising the importance of promoting, preserving and maintaining health. Furthermore, nurses now work in collaboration with others to enable individuals, families, groups and communities to reach their full health potential.

## The role of the nurse in health promotion

The role of the nurse in promoting health can fall anywhere within the action areas of the Ottawa Charter for Health Promotion (WHO 1986) or Continuum of Health Promotion Practice (Figure 6.2) discussed above. It is important for all nurses to work within the confines of their scope of training and practice but ways of working are summarised in Clinical Interest Box 6.6.

Nurses can make a contribution to the health and well-being of individuals by:

- Recognising there is a role for the nurse in the promotion of health and self-care
- Participating in providing health promotion interventions
- Being aware of the determinants of health when assessing and planning for individual needs
- Acknowledging the contributions of other professionals to meet the person's health needs.

Nurses can adopt a positive perspective to health promotion when nursing in the community by:

- Recognising that individuals live within families, groups and communities with specific needs
- Participating in health promotion activities
- Maintaining cultural awareness and sensitivity
- Learning and gaining knowledge about the community
- Creating empowering environments with others
- Networking and building on resources and partnerships
- Developing and improving personal skills required for practice.

## The nursing process in health promotion

Essentially, the **nursing process** is a series of planned steps that produce a particular result/health outcome. Specifically, the nursing process is a modified scientific method of systematic problem solving. In simple terms the nursing process is a method used to assess, plan, deliver and evaluate nursing care. The process of nursing, or scientific method of problem solving, remains the same whether the nursing care provided is a simple measure or a sequence of complicated nursing activities, and it can be adapted to individuals or communities. The nursing process (see Figure 6.5) can guide practice at any point along the Continuum of Health Promotion

### CLINICAL INTEREST BOX 6.6 Ways of working in health promotion

Talbot and Verrinder (2014) suggested working:

- *with* individuals, communities and populations
- *in* settings such as workplaces, schools, sporting venues and the arts
- *within* socioenvironmental, behavioural and medical models
- *around* issues including risk conditions such as discrimination, poverty and natural resource depletion, psychosocial risk factors such as social exclusion, behavioural risk factors such as poor nutrition, and physiological risk factors such as stress
- *by* policy development, community action for social change, health education, health information, screening and surveillance
- *using* frameworks such as the Ottawa Charter for Health Promotion as a guide.

To keep developing your skills and expertise in the area of health promotion you can:

- *Talk with your colleagues.* Discuss your ideas, your successes and your failures with anyone who is interested to learn with you.
- *Ask questions.* Successful people draw on the expertise of others.
- *Share your learning professionally by joining professional associations, attending conferences and presenting papers on your work.*
- *Work together, supporting and encouraging each other and promoting the health of the team.* A great many of the strategies need to be implemented within health organisations first. Developing the self-efficacy of everyone in the team is vital. Too often health workers write each other off, ignoring the strong socialisation processes that have impacted on each other. Work together, support and encourage each other and promote the health of the team. The ripples of this work will be felt far beyond the confines of the organisation and you will be able to establish a team environment that will achieve so much more than that which individuals alone may achieve.
- *Continue working to keep the development of a primary healthcare system on the agenda, and to ensure that the system develops towards a greater emphasis on the promotion of health.*
- *Reflect upon the impact of your actions*.

If **public health** or health promotion is to be a central concept in nurses' work, then nurses' role-perception, skills, knowledge and attitude to health promotion will have a vital impact on the success or failure of health promotion activities.

*(Talbot & Verrinder 2014)*

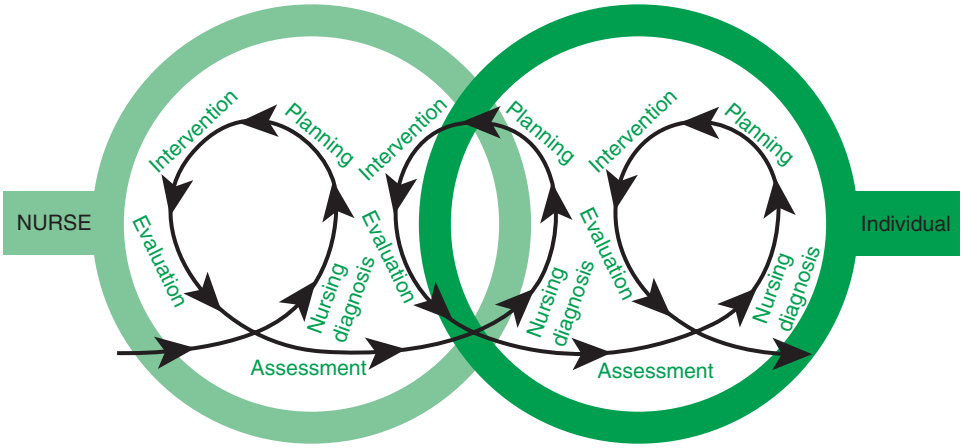

**Figure 6.5** The nursing process

Practice but it is a well-known process in program development and evaluation in that model. It is an ideal process to promote health in individuals as well as groups or communities and is essential in revising and updating any plan of care to meet an individual's or community's changing needs. By using the nursing process, specific needs are identified and a plan is developed and implemented to meet those needs. The effectiveness of any care given or program developed is continuously evaluated in terms of the individual's or community's needs. Furthermore, there must be a recognition that there may be many stakeholders such as family members, other health professionals, community members from various sectors as well as the wider community.

The overall objectives for health promotion activities can be varied to:

- Include the prevention of communicable and non-communicable disease
- Ensure that people are well informed and able to make healthy choices
- Change behaviour
- Help people acquire skills and confidence to take greater control over the factors influencing their community and their health
- Change policies such as organisational policies which foster cultural competence
- Change environments to facilitate healthy choices such as active transport
- Address the determinants of health such as poverty, housing and community inclusion.

Whether working with an individual or community the nursing process remains the same:

- Assessment—work with the individual or community to gather data
- Design the program/care—using evidence and theories and work with the individual or community to develop aims and objectives
- Develop an action plan—develop strategies
- Implement the plan
- Evaluate the goals and objectives—assessment of whether the aims and objectives have been achieved
- Redesign the program—in light of the evaluation
- Revaluation.

## Planning with an individual

Key questions to ask during the assessment phase are included in Clinical Interest Box 6.7.

After collecting the data the nurse is able to identify the problem or areas of need and is then able to make a nursing assessment based on these findings. For example, in Case Study 6.3 the nurse may make the assessment that Mary does not understand the implications of her current dietary habits and the need to make some changes. Once this has been determined the nurse is then able to plan the care needed for Mary to optimise activities to ensure health promotion.

Planning the care for Mary is the next phase. Planning involves setting goals, establishing priorities and determining nursing interventions to achieve the goals. This will require determining specific interventions aimed at achieving the ultimate goal for health promotion. There may be several levels of intervention, including individual one-on-one counselling on dietary changes, through to specialist diabetes education services. Some important questions to consider are:

- Have the issues clearly been defined?
- Who are the key stakeholders?
- What has been tried before?
- Are the goals that have been set achievable and realistic?

The principles of the nursing process can be adapted to health promotion planning at the community level. Planning tools for use in the community such as the Planning and Evaluation Wizard (http://www.flinders.edu.au/medicine/sites/pew/) can provide a step-by-step guide. Initially, research may need to be undertaken to obtain a community profile. This profile might be take into account the members of an organisation such as an aged care facility or it may be a profile of the wider community which takes into account the environment, policy, available services and resources, housing, finances and perhaps cultural considerations. Local community profiles are updated by governments and non-government

## CLINICAL INTEREST BOX 6.7 Assessment of characteristics that affect teaching individuals

**Characteristics and key questions**

**Physical**

- What are the person's age and sex?
- Is the person acutely ill?
- Is the person fatigued? In pain?
- What is the primary diagnosis?
- Are there additional diagnoses?
- What is the person's current mental status?
- What is the person's hearing ability? Visual ability? Motor ability?
- What drugs does the person take? Do they affect learning?

**Psychological**

- Does the person appear anxious, afraid, depressed, defensive?
- Is the person in a state of denial?
- What is the person's level of self-efficacy?

**Sociocultural**

- Is the person employed?
- What is the person's present or past occupation?
- How does the person describe their financial status?
- What is the person's educational experience and reading ability?
- What is the person's living arrangement?
- Does the person have family or close friends?
- What are the person's beliefs regarding their illness or treatment?
- What is the person's cultural/ethnic identity?
- Is proposed teaching consistent with the person's cultural values?

**Educational**

- What does the person already know?
- What does the person think is most important to learn first?
- What prior learning experiences establish a frame of reference for current learning needs?
- What has the person's healthcare provider told them about the health problem?
- Is the person ready to change behaviour or learn?
- Can the person identify behaviours/habits that would make the problem better or worse?
- How does the person learn best? Through reading, listening, doing things?
- In what kind of environment does the person learn best? Formal classroom? Informal setting, such as home or office? Alone or among peers?

*(Brown et al 2015)*

organisations; for example, Community Indicators Victoria (http://www.communityindicators.net.au/). Specific information about health status is updated by state and federal government departments; for example, AIHW.

## CASE STUDY 6.3 SUBJECTIVE AND OBJECTIVE ASSESSMENT

Mary, 52, has recently been diagnosed with type 2 diabetes mellitus. She states, 'I have always loved my food—in many ways it is my only enjoyment in life and now my doctor says I have to give up all the things I love to eat. I am finding it just too hard on the diet he has given me and I think I'll just give up.'

The nurse observes that Mary does not appear to have altered her lifestyle, as she eats constantly, and there are several chocolate wrappers on the bench.

Health promotion should start from the existing knowledge and beliefs of the individual. To plan the individual care needed for Mary and to begin the nursing process, it will be helpful for the nurse to first determine Mary's health beliefs and her understanding of the diagnosis she has been given. This will require building up trust and obtaining a detailed social and medical history. This phase of the nursing process is the assessment phase and basically requires the gathering of subjective and objective data.

Subjective data are the individual's, or other significant person's, perceptions, ideas and sensations about a health problem; for example, Mary has stated that she is finding it too hard and wants to give up. Objective data are the information observed or measured by the nurse; for example, the nurse has observed that Mary does not appear to have altered her lifestyle, she eats constantly and there are several chocolate wrappers on the bench.

Implementation means putting the plan into action; it is the actual performance of the activities that have been selected to help the community achieve the set goals. The community needs are reassessed continuously during the implementation stage so that any new needs can be identified and the plan modified or adapted.

After the planned interventions have been implemented, the nurse must then evaluate the results to determine whether the interventions were effective. Evaluation is the process of determining the extent to which the set goals or objectives have been achieved, and enables the nurse to monitor the effectiveness of the plan. Whether the plan was a success or not is determined by comparing the person's/community's response to the nursing interventions within the set goals and set time frame. Evaluation also enables the nurse to identify any new healthcare problems experienced by a person or the community. Clinical Interest Box 6.8 provides an example of the nursing process in an aged care facility.

Documentation occurs at all stages in the process of planning, implementing and evaluating the intervention. There are many ways of doing this. Organisations usually have their own requirements but there are some general rules. Examples of health promotion planning and evaluation templates are provided on websites recommended at the end of the chapter. Progress notes will document all aspects of the program.

## CLINICAL INTEREST BOX 6.8 Nursing process in aged care facility

An example of using the nursing process would be to develop an outline for a health promotion program you have been asked to prepare to encourage the independent-living residents in your aged facility to drink sufficient water.

### Assessment

A detailed assessment phase will be essential and the success of the program will depend on whether the program meets the issues identified in the assessment.

There are no right or wrong answers here but you may consider the assessment under 'personal' and 'environmental' headings.

Questions you will need to answer will include:

### Personal

- What is the variation in residents' current knowledge about the importance of good hydration? (A pre test may need to be prepared, or this could be gauged in an informal conversation.)
- Ask the residents what prevents them from drinking at least 2 litres of water (apart from other fluids) in a day.
- Does the age of some residents prevent them from recognising they are thirsty? (The sensation declines with age and illness, and is affected by some medications.)
- Take a detailed history of when residents drink water, and how much.

### Environmental

- Are there options for fresh water that meet the residents' needs? (hot, room temperature, cooled)
- Are people able to access their water needs? (perhaps restricted by access to designated areas, or 'rules')
- Are there prompts such as signs in dining areas, beside beds, toilet doors?
- Is water made appealing? (suitable containers and glasses etc.)

### Planning

- Collate the answers to your assessment.
- Plan to make necessary changes to the environmental limitations that will overcome stated barriers and identified barriers before you commence the education.
- Decide whether it is better to do individual or group sessions.
- Collect/prepare the necessary resources, including a prompt sheet and perhaps a social marketing prompt.
- Prepare a lesson plan using Adult Learning Principles as per the guidelines earlier in this chapter.

### Implementation

- Use different methods to create interest and relaxation, and to aid memory
- Talk through and/or demonstrate where applicable (How many mL in a glass, in a jug? What colour is healthy urine?)
- Test knowledge as you progress.

### Evaluation

How will you prepare to answer the following questions?

- Did you implement the training program exactly as you planned? Did you follow and complete the lesson plan? What was missed?
- Did the residents understand the guidelines in the session?
- Did they understand the messages and the purpose in the materials you provided them with? Were they able to put the concepts into their own words, and explain the meaning to you?
- Were they able to apply and adapt the principles for their own situation? Does weak black tea count? What about a milkshake?
- Did the program achieve the overall aim of the session? How will you know? Perhaps do a spot check on intake for the day.
- Note other forms of self-report (fluid intake, dryness of mouth, colour of urine etc.).

Using the antenatal health promotion program described in Decision-making Framework Exercise 6.1 you will have documented the goal or overall aim of the program, the objectives designed to meet that goal and the strategies that will help you meet the objectives. Strategies may change and it is important to note these for evaluation purposes and to prevent problems. For example, in your planning of the health promotion program in the antenatal service, you may have scheduled health education classes on a particular day and time and no one attended. This needs to be documented because you may now need to redesign your strategies. Why didn't people attend? Was this the best time? Does this program schedule line up with public transport timetables? Was there a cost and if so, was it beyond the means of potential participants? Were potential participants asked about these questions in the planning process? To meet the needs of potential participants better and to provide a rationale for any changes progress notes are important.

### DECISION-MAKING FRAMEWORK EXERCISE 6.1

You are an Enrolled Nurse who has just been employed in the antenatal outpatients' department at the hospital. Part of your role is to assist the Registered Nurse in charge to develop a new health promotion service to work with adolescent women who are considered to have 'at risk' pregnancies.

This role fits with the National Safety and Quality Health Service (NSQHS) Standards (ACSQHC 2012; 2015), in particular 'Partnering with consumers'.

Reflect on this developmental role and ask yourself the following questions:

1. Have I received the necessary education or training to perform this role?
2. Am I *authorised* by the regulatory authorities, laws, guidelines and policies to perform this role?
3. Do I have enough practice, experience or exposure to *competently* perform this role?
4. What strategies would you suggest to take on this role competently?
5. What action areas of the Ottawa Charter for Health Promotion would the 'Partnering with consumers' Standard of the NSQHS fit best with?

## Summary

Health promotion provides the key to minimising or eliminating disparities in world health and plays a fundamental role in achieving the goals and objectives as determined by WHO and countries such as Australia. The evidence demonstrates that political, economic, social, cultural, environmental, behavioural and biological factors can all have an impact on health. Health, then, may be defined according to circumstances, context and perceptions and experiences, which may vary between individuals and between communities.

Nurses are in an ideal position to participate in health promotion as they spend much time in professional relationships in a variety of settings. A sound knowledge of what determines health, evidence based practice, health conditions, awareness of health promotion theories and strategies and a keen eye for opportunities are key elements to making a difference in promoting and improving health.

## Review Questions

1. What is the difference between the notions of health, wellbeing, illness and disease presented in this chapter?
2. What is meant by the phrase determinants of health?
3. The AIHW (2014) determinants of health model represents the interrelationship between which major factors that affect health?
4. What is meant by primary healthcare?
5. What are the five action areas of the Ottawa Charter for Health Promotion (WHO 1986)?
6. What are the advantages of early disease detection?
7. What is the difference between screening and surveillance?
8. Why is it important to encourage mothers to make sure the full recommended infant immunisation schedule is completed?
9. Identify at least three (3) events that might influence change in a person's health behaviours.
10. Identify potential barriers to changes in health behaviours.
11. List some topics where social marketing strategies are used in the hospital or clinic setting.
12. What are the criticisms or potential shortcomings of social marketing strategies that are designed for large groups of the wider population?
13. Explain the difference between health promotion and illness prevention.
14. What is the role of the nurse in health promotion?

Answer guide for the Review Questions, Critical Thinking Exercises, Decision-Making Framework Exercises and Critical Thinking Questions in Case Studies are hosted on Evolve: http://evolve.elsevier.com/AU/Koutoukidis/Tabbner/

CHAPTER 7

# Quality and safety in healthcare

*Yvonne Elizabeth Wilkinson*

## KEY TERMS

accreditation
adverse event
audit
benchmark
clinical indicators
error management
governance
human error
human factors engineering
nursing-sensitive indicators
patient safety
preventable patient harm
quality
quality improvements
second victim
standards

## LEARNING OUTCOMES

At the completion of this chapter and with further reading, students should be able to:

- Understand quality and safety in the context of the health system, the nursing profession and person-centred care
- Appreciate your role in ensuring that individuals receive safe quality nursing care
- Contribute to quality and safety activities in your practice setting
- Understand the interplay between occupational health and safety and safe quality service delivery

## CHAPTER FOCUS

In any country, healthcare is a complex environment. In Australia, the health system has been described as a 'web of services, providers, recipients and organisational structures' (AIHW 2014:32) with further complexities of varying funding models, government and non-government service providers and diverse user demands. It is often asserted that Australians enjoy reasonably good health, with an average life expectancy at birth (both men and women) of currently 82.1 years (Duckett 2014; Jeyaratnam & Jackson-Webb 2014). Against other developed countries, this outcome could be seen as an indicator of a high quality safe healthcare system. Of course, a long life expectancy is also dependent on other social and political factors, with the system healthcare being a major contributor.

Achieving optimal quality and safety outcomes for healthcare in Australia remains a challenge, particularly in the context of the ageing population, increasing prevalence of chronic diseases and high costs of new medical technologies. Additionally, in Australia's complex healthcare system, where services are delivered by both government and non-government agencies at local, state and national levels, with extraordinary efforts made to promote choices with respect to treatment options, there is potential for duplication of services on the one hand and gaps in service provision on the other. To be confident that the system is working efficiently and effectively, our system needs governance, coordination and regulation (AIHW 2014:32).

## LIVED EXPERIENCE

As a nurse, no matter where you work, you will always try to give your best. I have worked in a few places, both in Australia and the United Kingdom, where I saw poor or suboptimal patient outcomes despite passionate and committed health professionals giving their best. As I reflect on these situations, it is clear to me that the missing element from these services is a strong focus to quality and safety. Of course they had standards that they had to meet, but it was a paper exercise at best, with most attention being given to collecting or creating evidence of compliance rather than a genuine attempt at improving the quality and safety of care. In these services, it was rare to discuss ways to improve the efficiency or effectiveness of our day-to-day practices. Although my colleagues were competent with respect to nursing skill and knowledge, there was little interest or motivation in making changes to improve our care. I now work in a facility that really values the healthcare workers' input into improving the quality and safety of our service. I am excited by the new standards that focus on high-risk issues such as clinical deterioration, falls, pressure injuries and medication safety. I feel that I am part of an industry that is walking the walk, not just talking the talk. I enjoy my work so much more when I know I make a real difference and improve patient outcomes.

**Sarah, Paediatric Nursing Specialist**

## QUALITY AND SAFETY IN THE CONTEXT OF HEALTHCARE

The community expects the system to deliver the right services to the right people, at the right time, using the right workforce with the right resources. Efforts to ensure our healthcare system meets the needs of Australians are supported by a range of governance mechanisms, each with differing purpose, function and application.

The Australian Safety and Quality Framework for Health Care (Australian Commission on Safety and Quality in Health Care 2010) demands all healthcare services are always consumer focused, always driven by information and organised for safety. Our community expects to trust our health service providers to provide quality care. Those who receive our services expect to receive safe quality care from health professionals. Nurses are a highly visible contributor to outcomes of the individual under our care, and as such they consistently strive to meet this expectation, delivering safe quality care resulting in a positive experience. To meet this goal there must exist an understanding of quality and safety in healthcare.

## QUALITY IN HEALTHCARE

**Quality** in healthcare is multidimensional, and as such is difficult to define in simple terms. It is often subjective, leading people to interpret their experiences differently. Some might believe that quality is about how much the health services for individuals and populations improve the health outcome for those individuals. Does their health improve as a result of the care? Additionally, quality can be determined in the context of the service that was provided using the best evidence available to the health practitioners and whether the care meets the expectations of the marketplace—that is, those potential future users of the service (Buttell et al 2007).

Quality can be a reflection of the 'extent to which a healthcare service or product produces a desired outcome' (Runciman et al 2007). This is a simplistic perspective, most notably that of the individual or their healthcare professional. However, at a system level, a quality healthcare service needs to be safe, person-centred, timely, effective, efficient and equitable to be considered a quality service (Institute of Medicine 2001).

In Australia, the nine dimensions for the assessment of health system performance include appropriate, effective, responsive, continuous, sustainable, accessible and capable, all considered relevant (along with the safety dimension) to the quality of healthcare services (AIHW 2015).

## Quality frameworks

For decades health service leaders have been engaged in bringing to their organisation robust systems of quality assurance and control. One of the early conceptual models proposed to examine and evaluate healthcare is the Donabedian model. Avedis Donabedian in 1966 argued that quality of care could be measured through the collection of information from three categories or dimensions of care: structure, process and outcome. The model assumes a unidirectional approach to measurement, commencing at structure, then process and onto outcome. It is also proposed that this model could be applied in a variety of healthcare contexts.

Structure refers to all the elements in the contexts in which care is delivered. Types of elements include the physical environment, equipment and human resources. They also include training, information and financial systems. These elements are the foundation for the processes and outcomes, and if they are inefficient and/or ineffective they will impact on the quality in the other categories of process and outcome.

Process is every action that makes up health service provision. The process category includes specific activities such as diagnosis, treatment, rehabilitation, health promotion and early intervention. This category includes examining the process of how care is delivered (in a technical sense). The effectiveness of interpersonal interactions is observed and measured to determine quality of care. The information is collected from records, direct observation or interviews with staff and people receiving services.

Outcome is the effects of healthcare. This can be at the individual or community level. Measures of health status changes, behaviour changes, level of satisfaction of the service user (individuals and family) and reported quality of life contribute to the inferences drawn about outcomes. Achieving positive outcomes for individuals in our care is considered the most important goal for healthcare professionals and can be sometimes interpreted as the most important indicator of quality. Unfortunately, establishing a proven cause and effect relationship between process and outcome in the context of quality is complex and challenging, resulting in few true connections being made between process and outcome in the healthcare environment.

Modern-day quality frameworks are based on the three dimensions of care, with the understanding that each of the three dimensions influences the others and that individuals and environmental factors play a critical role in measuring quality in healthcare.

## Aspects of quality

There are many players engaged in the healthcare environment. They include the health service users, the individuals in our care, their families, their community; the care givers, the healthcare practitioners, non-clinical support staff; and the healthcare system, the leaders and managers of the hospitals and clinics, the funders of the services such as government agencies. Each of these groups has a different motivation in understanding the level of quality of the healthcare service.

### Measurable quality

Measurable quality is simply compliance with standards relevant to that setting. This is commonly seen or experienced by nurses when the healthcare services in which they work are surveyed by an external agency for the purpose of '**accreditation**'. Essentially an external group reviews the structures and processes of that service, evaluating the levels of conformance or compliance with an agreed set of standards suitable to that setting. Being an accredited healthcare service provider meets the requirements for funding, assures the community that the services offered meet industry standards and assures the leaders and managers of the service that their organisation is delivering quality care.

### Appreciative quality

Peer review bodies primarily undertake this type of review. As part of the journey towards clinical excellence and quality improvements in clinical care, their peers will review health practitioners' clinical decisions and interactions. These activities will vary across services. In some settings, clinical information may be uploaded into national data collections. This will allow comparisons to be made and benchmarking activities to be undertaken.

### Perceptive quality

The perspective of the user of the service and their family is used to determine the quality of the experience of healthcare. These perceptions are commonly influenced by the attitudes and direct actions of the clinical and non-clinical staff. It is essential to step into the individual's shoes and understand the healthcare experience through their eyes.

## Governance

**Governance** is a term used to capture all the policies and processes needed for a system to deliver its outputs efficiently and effectively. This term is applied to a range of industries. Governance operates at all levels of the health system. The term governance is used at the national, state or funder/purchaser level; at health service level, the term clinical or care governance is preferred. No matter where it operates, governance is still about making sure that services are person centred, timely, effective and efficient.

At a national level, the government is committed to ensuring that the health service providers deliver care in an effective and efficient way. Their focus is on both quality and safety. In Australia, the federal and state governments fund or purchase a large proportion of health services. In the healthcare setting, the term clinical or care governance is applied to the system of monitoring the provision of services through the application of policies, procedures and processes that deliver safe high-quality care to service users.

## Health system

The Australian healthcare system is a mixed public/private model. The public healthcare system, while providing universal access to all Australians via Medicare, is a complex, complicated system of legislation and funding arrangements with the Commonwealth government providing each state with funding for public healthcare via the 'healthcare agreement'. Within this agreement there are various responsibilities for the states to comply with and in recent years the Commonwealth government has become more demanding of the states to provide outcome data to demonstrate improved healthcare for Australians. Australia's private health system includes private hospitals and user-pays options for other services that individuals can access, most using a private insurance payment scheme. Chapter 4 provides more detail on the Australian healthcare system.

An integral part of the governance mechanism is the Australian Commission on Safety and Quality in Health Care (ACSQHC). It was created by Health Ministers in 2006, and funded by all governments on a cost-sharing basis, to lead and coordinate healthcare safety and quality improvements in Australia. The aim of the ACSQHC is to support healthcare professionals, organisations and policy makers who work with individuals and carers. It reports to the Council of Australian Governments (COAG) Health Council and works with the Inter-Jurisdictional Committee, which is made up of senior safety and quality managers from the Commonwealth Department of Health, and each state and territory Department of Health.

Other bodies that provide governance to Australian healthcare are the National Health Performance Authority and the Independent Hospital Pricing Authority. Both of these agencies provide governance to all Australian healthcare settings through agreements based on achieving safe high-quality services. They offer transparency to the Australian community with respect to outcomes of monitoring and measuring activities.

## Measuring quality

To ensure confidence in our systems, processes and outcomes relating to healthcare, there is a need to monitor and measure them. Not every aspect in an episode of care will be able to be measured or monitored specifically, but across the system all aspects of care need scrutiny. Although not a perfect system, there are a number approaches to measurement and subsequently opportunities to improve on what we have. Some approaches are reliant on others, and collectively there is greater confidence in the reported level of quality and safety in that setting.

***Standards*** Measurement is made possible through the development of **standards**. Nurses are introduced to standards very early in their nursing career. During nursing studies, the term is often used in the context of meeting a predetermined level of attainment which is expected of all members of that cohort. This is similar in healthcare. A standard is a statement of action or activity that is established as a measure or model that similar entities must use to be measured against, as a comparative evaluation (Miller-Keane 2003). In other words, it is being able to compare apples with apples.

A standard must be measurable as it needs to be able to quantify or qualify an achievement in order to compare it with another like product or outcome. Standards are constructed to include the domains of structure, process and outcomes. Clinical Interest Box 7.1 gives more information about National Safety and Quality Health Service Standards.

The application of standards will vary from setting to setting. There are some standards that must be complied with for some settings. For example, from January 2013 all Australian Hospitals and Day Surgeries must comply with the National Safety and Quality Health Service (NSQHS) Standards. These Standards focus on both quality and safety. In aged care, the Quality of Care Principles 2014, which are embedded in legislation through the Aged Care Act 1997, describe the Standards for all aged care services, both residential and community. These Standards are known as the Aged Care Accreditation Standards for residential services and the Home Care Standards for community aged care services.

Additionally, some health or aged care services may elect to measure their care against additional standards appropriate to their setting, such as the Australian Council on Health Standards (ACHS) Evaluation and Quality Improvement (EQuIP). It is common for some to use International Standards Organisation (ISO) in addition to the compulsory NSQHS.

### CLINICAL INTEREST BOX 7.1 An example of a National Safety and Quality Health Service Standard

*'Clinical leaders and senior managers of a health service organisation implement systems to prevent and manage healthcare-associated infections and communicate these to the workforce to achieve appropriate outcomes. Clinicians and other members of the workforce use the healthcare-associated infection prevention and control systems.'*

When unpacked, this Standard can be measured from a structure, process and outcome perspective. For example:

*Undertaking quality improvement activities to reduce healthcare-associated infections through changes to practice.*

*Actions are:*

- *Quality improvement activities are implemented to reduce and prevent healthcare-associated infections (process)*
- *Compliance with changes in practice are monitored (structure if using technology, process)*

*The effectiveness of changes to practice are evaluated (outcome) (ACSQHC 2012:29).*

*(ACSQHC 2012:26)*

One of the most useful ways of measuring compliance to standards is to conduct an **audit**, which can be an internal activity or can be conducted by an external agency. Nurses will commonly assist in internal audits seeking level of compliance with the standards identified by the service as being relevant, as well as any relevant service-based procedures. An example of this activity is medication chart audits conducted at ward level. The audit tool used has been designed to capture any non-compliance between the documents and the standards and procedures. Undertaking an activity like an audit will often lead to the design and implementation of changes to systems and processes at local (or service) level. These changes are considered **quality improvements**.

Quality improvements can originate from a range of sources, including results of audits, examination of reported incidents and hazards, and through adopting ideas from the best available evidence. All nurses are encouraged to share their ideas for more effective and efficient evidence-informed practice.

***Benchmarking*** In healthcare, a **benchmark** is the point of output or outcome that is considered to be best practice in that area of service delivery. The benchmarking process incorporates finding that point of best practice, clearly defining it and disseminating this benchmark to others in the particular healthcare setting. A benchmark is generally aspirational, a standard of excellence but quickly becomes an expectation. Given that services are actively using the benchmark as part of their quality improvement process, benchmarks are not static as best practice and resulting improved performances will move these benchmarks reasonably quickly (Kay 2007). As a nurse you may be exposed to two types of benchmarking, internal and external.

Internal benchmarking is a process whereby the benchmark is developed over time focusing on internal processes. This may occur in two different ways. Firstly it can be within one setting. The primary actions would be monitoring and measuring performance over time in response to a quality improvement activity such as a practice change. Results may be captured and graphed using a balanced scorecard approach. Secondly, internal benchmarking may also occur across similar products or outputs within the same organisation with multiple sites. The key to this type of benchmark is that the services involved in the benchmarking process must be of similar size, offering similar services and using similar workforces.

External benchmarking is where agencies who would normally be competitors share performance information with others. In the healthcare sector, this information is often mandatory reporting as part of funding agreements. This is where particular benchmarks result from the scrutiny, interpretation and analysis of the reported data around a clinical issue, for example, hospital acquired pressure injuries, and determine the national benchmark for that issue. As the reporting process is ongoing, these benchmarks will change over time.

***Clinical indicators*** **Clinical indicators** are generally specific outcomes of care that may provide an understanding of the safety and quality of care provided by a service. The Australian Medical Association (AMA) in 2012 published a position statement on clinical indicators whereby they:

> *measure the extent to which set targets are achieved. They are expressed as numbers, rates or averages that can provide a basis for clinicians, organisations and planners aiming to achieve improvement in care and the process in which patient care is provided. They can be measures of structure, process and outcome, either as generic measures relevant for all diseases or disease-specific measures that describe the quality of patient care related to a specific diagnosis.*
>
> **(AMA 2012)**

The AMA further proposes that clinical indicators are developed from evidence and in collaboration with clinicians.

The use of **nursing-sensitive indicators** is beginning to become more prevalent in nursing teams. The types of indicators that may be considered nursing sensitive are those where nurses have primary responsibility for the care provided, such as hospital-acquired pressure injuries, hospital-acquired infections, use of restraints and injuries from falls.

***Accreditation*** In simple terms **accreditation** means that the service has been assessed against an agreed set of standards relevant to that setting. In some settings this may also be called a quality review. The function of accreditation is to give the community confidence that the healthcare service is delivering care that meets recognised standards. Participating in an accreditation or quality review process sends a message to the community that the service complies with regulations and legislation as well as being engaged in a continuous quality improvement process. Additionally, in many funding agreements accreditation may be a requirement for success in the funding round.

Accreditation is a cyclical process. The process starts when the service agrees to a particular set of standards to be accredited against. However, there will be mandated or required standards to be met. The service is supported by the accreditation agency to ensure that it is equipped to demonstrate meeting the standards. Most nurses at this point will be unaware of the accreditation process. It becomes more evident when internal audits are undertaken at service level prior to the accreditation survey. Some services will have regular audits occurring as a routine activity for the purpose of benchmarking or collecting data for nursing-sensitive indicators; therefore, audits for accreditation may not be obvious.

The survey period is the most obvious of all. This is when the surveyors attend the service setting and review the evidence collated to demonstrate how the service is meeting the standards. They will also interview staff (of any designation) with respect to any of the standards. Following the survey the service receives feedback regarding its performance against the agreed standards. The survey will commend good practice and identify areas that require improvement. Action plans are developed by the service to address the concerns and the service will be required to complete all actions within a specific timeframe.

**TABLE 7.1 | Accreditation benefits**

| Group | Accreditation assists with |
|---|---|
| Community | Confidence in the service to be potentially used in the future. No hesitation to access services as needed. Trust in the knowledge and skill of service providers. This means no delays, timely care |
| Person/user<br>Family/carer | Confidence in the treatment/advice provided, trust in the service providers, enough information to make decisions |
| Your peers/professional bodies | Seeking to role model good nursing practice. Desire to be part of an effective, highly regarded nursing team, reputed to provide high-quality safe nursing care<br>Maintaining positive professional image |
| Other health professionals | Trust in the rest of the clinical team, crossing medical, nursing and allied health disciplines and workgroups<br>Potential to improve team cohesiveness |
| Your supervisor/nursing leaders | Satisfaction that the services under their leadership are providing high-quality and safe care<br>Confident that the resources are being used effectively and efficiently |
| Organisation managers and leaders | Satisfied that the service is meeting its obligations to the funding and performance agreements |

From the nurse's perspective, as the one who works at the clinical coalface, the process will be to your advantage. Table 7.1 offers thoughts regarding the benefits to accreditation.

### CRITICAL THINKING EXERCISE 7.1 Quality

Think about quality nursing care. What does it look like? Of course it will depend on who is doing the looking. Write down your thoughts regarding how the following groups might describe quality nursing care:

- Your community
- The individual and their family
- Your nursing colleagues
- Your nursing professional group
- Your supervisor/manager
- Your organisation

## SAFETY IN HEALTHCARE

*The Inquiry report categorically determined that lack of resources did not cause the tragedy but the 'extra factors were poor teamwork and management, inadequate leadership, a closed "club" culture, an absence of systems to monitor performance, a failure at the centre to listen to concerns, and some people whose behaviour was substandard'.*

**(Smith 2001)**

Safety in healthcare has attracted a great deal of attention in recent decades. The first step is to understand what is meant by the phrase 'safety in healthcare' or '**patient safety**'.

Patient safety means to avoid or reduce harm, either actual or potential, in delivery of healthcare (National Health Performance Committee 2001). Although this definition suggests that harm can be reduced or avoided, it important to understand that not all harm is preventable. Leape (1994), using results from the Harvard Medical Practice Study, suggested 69% of harm was preventable. Current rates of preventable harm are now closer to 20–25%.

In some countries funding may be associated with the provision of safe healthcare. This connection may be by way of penalty or incentive. In the United States in 2014, Medicare funding has been reduced at those hospitals that have unacceptably high rates of preventable hospital-acquired conditions such as pressure injuries, central-line-associated bloodstream infections and catheter-associated infections (Latner 2015). In Australia, the notion of penalising services that have high rates of preventable harm has not taken root. However, the funding model that is increasingly being used to fund public services across the country, activity-based funding (ABF), is reported to reward those services that provide a safe healthcare experience for service users. There are mechanisms built into the system to encourage improvements in safety and quality. The ABF model funds an episode of care based on the cost that same episode of care would require in similar conditions elsewhere in Australia. There is little evidence to date that demonstrates how this funding model impacts on rates of preventable harm to individuals (Eagar et al 2013).

In Australia, of the 10 National Safety and Quality Health Service Standards (see Clinical Interest Box 7.2), eight are focused on areas:

- That commonly cause harm
- Where there is a gap between current and best practice
- Where there exist improvement strategies that are evidence-based and achievable (ACSQHC 2012).

## CLINICAL INTEREST BOX 7.2 National Safety and Quality Health Service Standards

1. **Governance for Safety and Quality in Health Service Organisations** which describes the quality framework required for health service organisations to implement safe systems.
2. **Partnering with Consumers** which describes the systems and strategies to create a consumer-centred health system by including consumers in the development and design of quality healthcare.
3. **Preventing and Controlling Healthcare Associated Infections** which describes the systems and strategies to prevent infection of patients within the healthcare system and to manage infections effectively when they occur to minimise the consequences.
4. **Medication Safety** which describes the systems and strategies to ensure clinicians safely prescribe, dispense and administer appropriate medicines to informed patients.
5. **Patient Identification and Procedure Matching** which describes the systems and strategies to identify patients and correctly match their identity with the correct treatment.
6. **Clinical Handover** which describes the systems and strategies for effective clinical communication whenever accountability and responsibility for a patient's care is transferred.
7. **Blood and Blood Products** which describes the systems and strategies for the safe, effective and appropriate management of blood and blood products so the patients receiving blood are safe.
8. **Preventing and Managing Pressure Injuries** which describes the systems and strategies to prevent patients developing pressure injuries and best practice management when pressure injuries occur.
9. **Recognising and Responding to Clinical Deterioration in Acute Healthcare** which describes the systems and processes to be implemented by health service organisations to respond effectively to patients when their clinical condition deteriorates.
10. **Preventing Falls and Harm from Falls** which describes the systems and strategies to reduce the incidence of patient falls in health service organisations and best practice management when falls do occur.

*(ACSQHC 2012)*

## Preventable patient harm

Leape (1994) challenged medical practitioners to recognise the high level of **preventable patient harm** in the healthcare industry. He cites the socialisation of medical staff to be perfect in all aspects of practice as a barrier to improving the safety of the healthcare. The area of patient safety has been growing at a very fast rate since this was published. Previously most attention was focused on quality in healthcare, assuming that quality processes led to safe patient care. It is clear that this is not true. Having quality systems and processes in place will certainly help, but these systems and processes must facilitate safe care and to do that other factors must be considered. The most common factor, that has many variables impacting on it, is that health professionals are people.

Health professionals are human and, being human, can and will make mistakes. They make mistakes every day; no one is perfect. Despite having been trained well and having developed high-level skills and knowledge in practice, a perfect practitioner does not exist. In all work places, mistakes are made. Some result in damage, some do not. Some damage is considered to be of greater importance than others. Think of the person who cuts your hair—your local hairdresser or barber. Making a mistake such as cutting your hair too short will not commonly end up in a courtroom or in the media. Now consider a surgeon who may remove the wrong ovary and, realising the error, removes the correct one in the same operation, leaving the patient without any ovaries. It is highly likely that both litigation and media scrutiny may become a reality.

*It is important to note that the extent of harm can only be confirmed by the person who has been harmed.*

Thinking about the error made by the hairdresser above, imagine the two possible scenarios:

1. The supermodel whose work relies on her appearance. She may feel extremely damaged by the error. It could cost her some modelling contracts or a photographer may have taken a photo of her with a poor hairstyle.
2. The retired banker, who takes pride in his appearance and values a good haircut may feel annoyed. However, he will most likely vow never to return to that hairdresser or even take the philosophical approach that 'there are only 3 weeks between a good and bad haircut'.

Now think about the woman who had the wrong ovary removed. Imagine the two possible scenarios:

1. She is 60 years old, menopausal, and did not place high value on the need to keep the healthy ovary remaining in place. She may not perceive high-level harm. She may even be pleased as she does not require further surgery to remove the diseased ovary and considered this outcome acceptable.
2. She is 30 years old, recently married and eager to start her family. This will be devastating to this woman and her husband.

It is important for all nurses to understand this key point: the individual's (and family's) perception of the harm in the

context of a preventable **error** in healthcare is the most important element in the determination of the severity of that harm.

Healthcare workers are expected to always focus on the person and their experience of the care provided. Being able to see the harm from their perspective will be very important and is a key element of person-centred care. In this model of care, the healthcare worker tailors their activity to the individual. However, in earlier discussion the notion of standardisation is promoted as a key patient safety strategy. Can these two concepts co-exist? Through strong communication, where listening to and hearing the person is as important as the person listening to the healthcare worker, it is possible.

## Error management

To reduce patient harm or injury from errors, nurses must understand how errors result in the injury; this is known as **error management**. Reason (1990) suggested a simple way of understanding this process; he called it the Swiss cheese model. He asserts that errors occur at every stage of a process. By the time a patient is provided direct care, there have been many activities where one or more errors have occurred, hence the reference to Swiss cheese. The holes represent the errors.

To get to an outcome there are a number of activities that need to occur. Consider each of these activities as a layer of Swiss cheese. A slice of Swiss cheese has holes, some small, some large. Imagine the hole to be an error, either small or large, in that activity. Now lay each slice of cheese on top of one another. If there is a hole seen through all the layers, it is suggested that there will be an error at the patient level. Depending on the error, the patient may be harmed. Figure 7.1 illustrates how harm can occur when a series of errors or mistakes are made. If only one of these errors was not made then the harm would not have occurred.

Errors can be latent or active. Understanding the difference between the two will assist the nurse to focus on how to manage errors in their clinical setting. Latent errors (also referred to as latent conditions) are found in the systems and processes of the work environment. They include workforce factors around staffing (skill mix, rostering etc), equipment (purchasing and maintenance decisions) and environment (temperature, lighting, noise, furniture, workplace design, workplace culture including reporting incidents, attention to documentation and compliance with procedures etc). Basically the workplace and everything in and about it can hold latent errors. Active errors (active failures) are those actions that occur during the patient contact when the result is not what was expected. Active errors are mostly seen arising from activity undertaken by people, and usually result from human error. Figure 7.1 illustrates how seemingly benign lapses or mistakes made along a process can end up in harm for a patient.

When an adverse event causing harm does occur, it is essential to analyse each and every action, process or activity looking for latent or active errors. This process will highlight many errors—one or two may be proven to be the root cause of the adverse event, but many others will be identified as contributing to the problem rather than causing it. These other errors are called contributing factors.

### Human error

**Human error** can be described as an undesired outcome that resulted from a human action or inaction. These errors occur as a failure in the cognitive process. Humans have the ability to have two thinking (cognitive) processes running at once, known as the dual process model. This model incorporates automatic (mostly unconscious, fast, reflexive) and analytic (conscious, slow) thinking. Everyone uses both, switching between the two as the situation demands. However, when

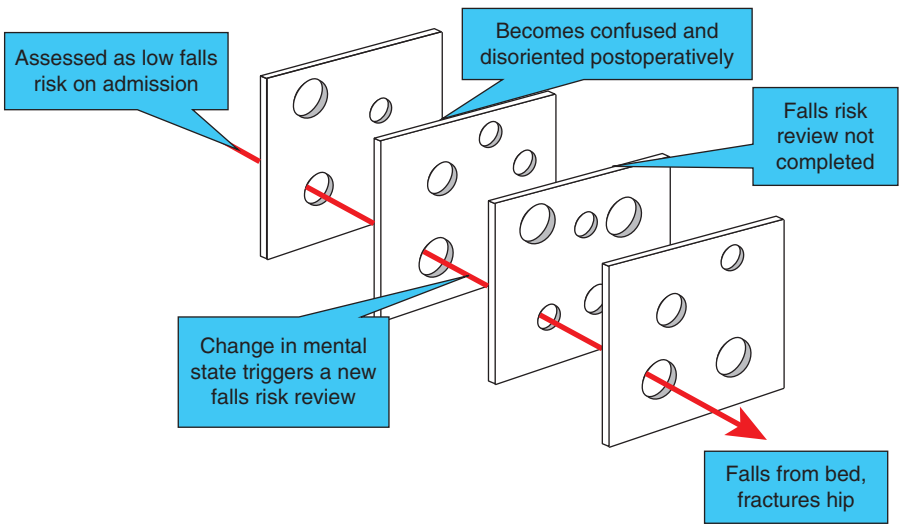

**Figure 7.1** Using the Swiss cheese model to describe an adverse event
*(Adapted from Reason 2000)*

the person is highly emotional or is tired or fatigued, then the person tends to stay on automatic thinking even when analytical thinking is required. Additionally, when there are multiple interruptions, using automatic thinking will be easier than analytical. In these situations, there is a higher likelihood that an error will be made.

Errors made by people are either mistakes (conscious action that was inaccurate from analytical processes) or slips (unconscious errors arising from automatic thinking) and are commonplace in life. On most occasions these errors do not cause harm and are well tolerated. It would be easy to find a nurse who remembers driving home from night duty and, before climbing into bed, put the car keys in the fridge or the rubbish bin, known as a simple slip. Clinical Interest Box 7.3 follows through on each of these slips.

## Human factors engineering

The Agency for Healthcare Research and Quality (AHRQ) defines **human factors engineering** (HFE) as 'the discipline that takes into account human strengths and limitations in the design of interactive systems that involve people, tools and technology, and work environments to ensure safety, effectiveness, and ease of use' (AHRQ 2015).

Applications of HFE can be most commonly seen in healthcare through the standardisation of processes and practices, systems and processes, forcing functions, usability testing and resilience efforts. Using an electronic information-management computerised system to collect information about a patient employs a number of HFE processes. A system like this uses the 'forcing function' to improve safety. The user is forced to input certain types of information in a certain order and the system may not allow the user to save and close until all the information is entered. This system also offers standardised processes and practices.

Standardisation of practices and processes is a key HFE strategy. Having the same system in place across all variations of the practice or product will improve reliability and information flow, and reduce training needs. For example, consider your experiences in driving a car. Many cars have the indicator on the right of the steering wheel. If you find yourself in a vehicle with the indicator on the left side, as it is in many European vehicles, you will find yourself making an error with respect to using the indicator. In a healthcare setting, an electronic information system ensures that all staff know how to access information in any clinical area of that setting, regardless of their usual work area.

Usability testing is used to ensure that new processes and practices are efficient and effective in the workplace. If blocks or barriers occur and create an inefficient or ineffective outcome, inevitably the nurse will find a work-around to suit their needs. Unfortunately, these work-arounds are developed on the fly and can be unsafe. All changes to systems should be tested to ensure the outcome is suitable to the staff that use them.

## Patient safety in the workplace

Many nurses work in settings that will have an established routine that could change in an instant due to an unexpected event, such as two or three new admissions arriving at once or a patient's clinical condition rapidly deteriorating. The nurse needs to be vigilant for the unexpected, but not to the detriment of the expected or routine tasks. Reason (2000) advances the notion that it is the routine tasks that are most subject to human error.

Situation awareness (SA) refers to being aware of things happening around you and being able to identify, analyse and interpret relevant information. You have lost situational awareness when you not only don't know how to fix a problem, but you are not even aware you have a problem. It is important to understand that only those around you can see you have lost SA—you cannot see it for yourself. If you accept this last point, when a colleague raises an issue with you about an unsafe practice or decision it could be because you have lost situational awareness.

It can be tricky for a nurse to point out an unsafe practice to someone higher on the authority gradient. In most clinical situations, when a doctor is present they will have a higher

### CLINICAL INTEREST BOX 7.3 Error scenarios

Consider the following similar scenarios.

Barry is an Enrolled Nurse at the emergency department of a major metropolitan hospital. After a very busy shift Barry arrived home and put the keys to the family car he had used to drive to work:

1. in the fridge instead of on the shelf. The keys were found by his younger sister who had put them on the shelf before anyone had noticed them missing. Later Barry was teased by other members of the family.
2. in a plastic shopping bag, which was then placed in the rubbish bin. Later that day all members of the household were looking for the keys, but they were unable to be found. The bin was emptied and the keys never discovered. Barry was distressed and was required to use some of his savings to replace the keys and was never allowed to drive the family car again.

Scenario 1 would not even be considered an error and would be rationalised away as Barry being tired—after all, the keys were found and no harm occurred. Now consider scenario 2. The keys ended up missing. Most people would consider it an error or serious mistake as harm had occurred, being the cost of replacing the keys as well as inconvenience. Now the misplacement of these keys becomes an issue and the culprit considered careless. The person who lost the keys would feel guilty and distressed at their action and would be punished as a result.

The cause of the error is the same—being tired—but the outcome of the scenarios was very different. It is important to remember that errors happen all the time when humans are involved.

**TABLE 7.2 | Levels of graded assertiveness and examples**

| | | |
|---|---|---|
| Level 1 | Express initial concern with an 'I' statement | *I am concerned about ...* |
| Level 2 | Make an inquiry or offer a solution | *Would you like me to ...* |
| Level 3 | Ask for an explanation | *It would help me to understand ...* |
| Level 4 | A definitive challenge demanding a response | *For the safety of the patient you must listen to me.* |

*(Curtis et al 2011:18)*

authority than the nurse. In situations where those with a higher authority have lost their situational awareness, those at a lower level must have the ability speak up and get the point across. Sometimes the communication needs to be assertive, using a method called graded assertiveness (Curtis et al 2011). Table 7.2 describes graded assertiveness using an example of how the communication may be phrased in the first instance. This type of communication will allow the relationship between the parties to remain professional into the future.

Communication and teamwork are other important mechanisms that play a significant role in patient safety. All healthcare professionals are trained in communication; however, in most programs the focus is on individual technical skills with less focus on cross-discipline communication and teamwork (Dingley et al 2008). A variety of tools have been developed that enhance communication and teamwork that have been found to be useful in healthcare settings (Dingley et al 2008; Curtis et al 2011; ACSQHC 2011). These tools include, but are not limited to:

- A situational briefing guide known as SBAR (Situation, Background, Assessment, Recommendation) or ISBAR (Introduction, Situation, Background, Assessment, Recommendation)
- Team huddles
- Briefing
- Multidisciplinary rounds
- Clinical handover using a variety of information-sharing techniques such as SBAR, ISBAR and SHARED (Situation, History, Assessment, Risk, Expectation, Documentation).

There has been a lot of discussion over the past decade regarding patient safety culture. This term refers to the healthcare workers' shared values and beliefs about and towards safe practice. If a nurse was asked to define safety culture, the response would commonly be 'The way we do things'. The culture of a work setting is impacted by a variety of elements. This will include how the healthcare workers function as a team (including the way they communicate with people inside and outside of the team). The perception of job satisfaction and stress recognition also will impact on safety culture. Importantly, the management and leadership of an organisation must actively create a positive safety culture (Wakefield et al 2008). This is achieved by:

- Being vigilant regarding opportunities to learn from errors using robust reporting systems and patient safety rounds
- Promoting a just culture regarding blame
- Dedicating resources to patient safety activities
- Involving patients and their families in safety initiatives.

Most healthcare services now have a rigorous incident-management system. These systems are commonly electronic, creating a user-friendly approach to understanding issues at a system level rather than at an individual level. Staff are encouraged to report safety concerns and both actual and potential safety events. Reporting the incident is only the beginning of the process. What happens next is what will influence the embedding of a strong safety culture. Analysis is the most important factor in understanding and learning from an incident (also called an **adverse event**) which will further strengthen the patient safety culture of the organisation. The key steps in the analysis of the incident include:

- Have all the information—access all possible sources of information. Avoid jumping to conclusions
- Understand the cause of the event. Track down all parts of the process leading up to the event. Most events have errors occurring in many points along the timeline
- Always look to the system to find the solutions to adverse events.

## WORK HEALTH AND SAFETY ISSUES

There is always potential for injuries in our workplace. The practice of nursing in itself demands a degree of physical, emotional and psychological effort. It is important for each of us to understand that standards and procedures will keep all of us safe while ensuring the care is efficient and effective. A good example of this is the trauma experienced by the people connected to an error that has resulted in serious harm, particularly those who work closely with the person who was harmed, often the nurse or the doctor. This type of harm is known as the **second victim**.

When a patient is harmed, whether it was preventable or not, the direct healthcare provider will also 'feel' the pain and stress. That person will often feel guilty, even though they are often not, and never were, in a position to have prevented the event. This person is also a victim of the adverse event, but often not recognised as being traumatised as a result of the event and subsequently not supported through the issue. Some will feel unworthy of the support, taking on full responsibility for the harm. Unresolved, these feelings will create harm and that person may suffer burnout, stress and anxiety disorders. They are a second victim to the error causing harm. See Case Study 7.1 for an example of a second victim scenario.

## CASE STUDY 7.1A INCIDENT MANAGEMENT

Nurse Dan undertook a course of study to become an Enrolled Nurse. He then further developed his knowledge and skills by working in the clinical setting over a number of years and attending professional development and training activities. He cares for his patients and works really hard. He is considered by his colleagues and other members of the healthcare team to be a 'good' nurse.

Dan is on a shift where a drug error has occurred. As he participated in the administration of a restricted drug (Morphine), excess to what was ordered by the medical officer, he was named as a party to this error. Dan is devastated. He questions his ability as a nurse.

What are your thoughts? Is Dan now incompetent because of this one mistake?

Before you can decide you may ask, was the patient harmed? Patient safety focuses on preventable patient harm after all.

In this circumstance the patient had been in severe pain and hadn't been sleeping well. The effect of the medication on the patient was that he was more heavily sedated than was necessary, and he slept deeply for 12 hours.

1. At this point, do you think the patient suffered harm?

Back to Dan. His confidence is shattered. Before you make your judgment about his level of competence, you will also need to know a little more about Dan and the shift.

- Dan was on his 8th shift in a row and was working this afternoon shift after 7 night duty shifts. This was an overtime shift and he had only an 8-hour break between the shifts. He was to have 4 days off at the end of the 7 night duty shifts.
- The ward is a very busy medical ward with 3 new admissions in the previous 2 hours.
- The patient was under a surgical team and was being cared for in this medical ward as there weren't any beds available in the correct ward.
- The incident occurred when 2 staff (of the rostered 5) were at a compulsory training session.

2. Is Dan incompetent? Explain your answer.

## CASE STUDY 7.1B

Let's follow the patient from the Case Study above. The next morning the patient is in need of going to the toilet. He rings the buzzer for assistance, but before the nurse arrives he feels he is unable to hold on and gets out of bed. On his third step towards the bathroom he falls. He suffers a fractured hip.

With just the information above, you may be tempted to attribute the injury to be a result of the excess drug. However, after analysis of the event, the following information has been identified:

- The patient had been assessed as a high risk of falling. Strategies included wearing hip protectors but he was not wearing them at this time as he had been ordered to 'Rest in bed'.
- The patient has a history of transient periods of confusion.
- The shift had just commenced and the nursing allocation had not been completed as there was a delay of some agency nurses arriving on the ward.

1. Is the drug error the cause of this preventable patient harm—fractured hip? What is your rationale for this answer?
2. What are some possible system issues relating to the drug error in the first part of the scenario?
3. What are some possible system issues relating to the fall in the second part of the scenario?

## Summary

The nursing profession has a long history of seeking out ways to give our best to our patients through monitoring and evaluating our care. Florence Nightingale was known to be one of the early adopters of quality improvement (Malone 2004). Nurses are committed to service based on evidence-based practice, clinical guidelines, professional standards and scope of practice. Nurses practise to the best of their ability. Quality and safety is not an optional extra; it should be what nurses simply do.

Nurses also, on a daily basis, participate at some level in a range of measurement activities such as audits, benchmarking, safety score cards and nursing-sensitive indicators. Their practice setting then seeks accreditation and re-accreditation with a particular accreditation agency, depending on the practice service type, relying upon nurses to collect and collate data as evidence of meeting accreditation standards.

What is the difference between quality and safety? In simple terms healthcare quality is about getting the right service to the right patient at the right time and at the right cost. Patient safety is about protecting the patient from preventable harm. The nurse is a key player in both quality and safety.

Nurses must understand quality and safety and be able to define them, identify them and measure them. The patients depend on it.

## Review Questions

1. What is your understanding of quality in healthcare?
2. What does accreditation mean for a healthcare facility?
3. Explain:
   - Benchmarking
   - Clinical indicators.
4. How is patient safety different from quality?
5. Why is the perspective of the person who was harmed important when measuring severity of harm?
6. What is the difference between active and latent errors?
7. What is meant by 'contributing factors'?
8. Why is standardisation considered a powerful patient safety initiative?

Answer guide for the Review Questions, Critical Thinking Exercises, Decision-Making Framework Exercises and Critical Thinking Questions in Case Studies are hosted on Evolve: http://evolve.elsevier.com/AU/Koutoukidis/Tabbner/

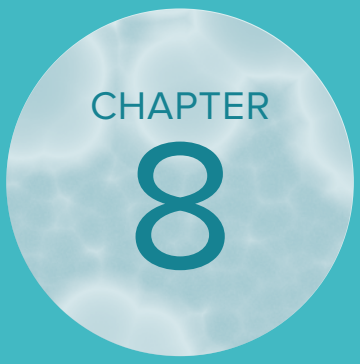
# Communication and nursing practice

*Maree Gault*



## LEARNING OUTCOMES

At the completion of this chapter and with further reading, students should be able to:

- Define the key terms
- Identify the components of the communication process
- State the factors that influence effective communication
- Identify the factors that act as barriers to effective communication
- Identify ways to overcome barriers to communication
- State how culture impacts on communication
- Demonstrate techniques for monitoring how culture impacts on their communication
- Identify and implement communication processes that facilitate individual safety and quality care

## KEY TERMS

assertive communication
barriers to communication
culture
ISOBAR
verbal communication
non-verbal communication

## CHAPTER FOCUS

Communication is an interactive process involving the verbal or non-verbal transference of information between people. Effective communication is essential to the provision of safe, quality care in nursing and vital to the development of a therapeutic relationship between nurse and an individual (Jones 2012). This chapter has a particular emphasis on the crucial communication issues affecting the delivery of safe healthcare to individuals and the importance of health team communication in relation to individual safety.

## LIVED EXPERIENCE

I remember the last time I was in hospital. I was feeling very nervous about the procedure I was having. One of the nurses asked me how I was and I told her that I was very scared. She just told me not be silly and that nothing bad would happen. Then while she was helping me dress she talked the whole time to another nurse about what she did on the weekend. I felt like she didn't care about me and I got more nervous. By the time I got to theatre I had decided that I wouldn't go ahead with the procedure but the next nurse I spoke to was wonderful. She really listened to me and didn't dismiss my concerns. She looked at me while I was talking and asked me questions. I felt she really cared. As it turned out, what I was worried about wasn't really an issue. I was so glad she was there otherwise I probably wouldn't have had the operation.

**Elizabeth, 55 years old**

Effective communication is vital to ensure that nursing care provided to an individual meets their needs and wishes. It is not just about sharing information but should also encourage the person to talk freely about their concerns without fear. Communication is essential for quality healthcare and an individual's safety and is a key component in the Australian Charter of Healthcare Rights (Joanna Briggs Institute 2011; Iedema & Manidis 2013; Jones 2012; Department of Health and Human Services 2014).

*Through their relationships with individuals, nurses express concern, care and commitment. In the absence of interpersonal relationships with nurses, individuals can be viewed as objects, clinical conditions or a set of problems to be solved. Nursing care that is offered without a human connection is impoverished. It lacks a caring connection.*

**(Stein-Parbury 2014)**

Being an effective communicator is a highly desirable skill. It enables individuals to share important information and helps to develop and maintain relationships and friendships (Department of Health 2012). With nurses and midwives accounting for about 58% of the health workforce (AIHW 2015) the need for nurses to be able to communicate effectively with everyone in the healthcare environment, especially the people that they are caring for, becomes critical (Berman et al 2015). The ability of nurses to communicate effectively is an essential factor in ensuring an individual experience in a healthcare encounter is of the highest value and causes no inadvertent harm (Wallis 2011; Kleiner et al 2014). Nurses need to be skilful in what they do for individuals but at the same time they need to communicate with them in ways that are supportive and helpful, and promote feelings of trust (Institute of Medicine 2011).

All these aspects become of the utmost importance when you consider that approximately 10% of all people admitted to healthcare facilities will suffer an adverse event (AIHW 2015). The Joint Commission reported that in a study of over 4000 adverse events, 70% of sentinel events were caused by a communication breakdown (Wheeler 2014). There has been a new focus on individual safety in the past decade and although it is difficult to prove causation, an emerging body of literature suggests that quality of care depends to a large degree on nurses (Institute of Medicine 2011).

The focus of this chapter is to provide knowledge and strategies to enable the development of effective communication skills in nurses to ensure people receive the care that they require, the quality of care that they receive is enhanced and that they do not suffer any harm due to poor communication.

## COMPONENTS OF THE COMMUNICATION PROCESS

All communication is a two-way process in which messages are conveyed by verbal and/or non-verbal means by one person, and received by another (Berman et al 2015). All behaviour conveys some message and is therefore a form of communication. For example, even an individual refusing to speak or acknowledge the presence of a nurse conveys a message that the nurse will attempt to interpret (decode). Non-verbal communication includes the messages sent by facial expression, gestures, body posture and appearance, and has a large impact on the meaning of the message sent (O'Toole 2012). Communication is an ongoing dynamic series of events in which meaning is generated and

transmitted. Communication occurs when a person responds to a message and assigns meaning to it. During interactions people respond to messages they receive and create meanings for those messages. If the intended meaning of a message is misunderstood by the recipient, communication has not occurred effectively (Webb 2011; O'Toole 2012).

Communication takes place at many different levels and to ensure high quality and safe delivery of healthcare nurses need competence in all of them. Communication may occur at the interpersonal, small-group, organisational, public and mass communication levels (Arnold & Boggs 2011).

## ELEMENTS OF THE COMMUNICATION PROCESS

Communication is a multidimensional and complex process in which ideas, thoughts, values, knowledge or feelings are shared and interpreted. During the process people simultaneously send and receive numerous messages at many different levels. Figure 8.1 is a model that depicts the basic elements of communication. It shows that communication is a linear process between sender and receiver. The process of communication involves:

- A sender
- A message
- A channel
- A receiver.

This model depicts the sender as the individual who initiates the communication. The receiver is the person to whom the message is transmitted. The role of sender and receiver may alternate between participants at any time during the period messages are being transmitted.

The message is the information that is transmitted by the sender, and the channel is the means by which the message is conveyed (Arnold & Boggs 2011; Webb 2011; Jones 2012).

Communication between two human beings is far more complex than this in reality and is influenced by many and varied external and internal processes (O'Toole 2012). Communication between two people may comprise both verbal and non-verbal information; for example, through the visual, auditory, olfactory or tactile routes. The sender's facial expressions and body gestures visually convey a message to the receiver; for example, a facial grimace or tense body posture sends a visual message to the nurse that the individual may be in pain. The spoken word is conveyed via the auditory channel and touching a person while communicating uses the tactile channel. A nurse can convey a message of caring and compassion to a distressed individual by a simple touch of the hand. The olfactory route is particularly important in nursing. Distinct odours can indicate a variety of conditions, including incontinence, the onset of a urinary tract or other infection, and sometimes more serious events such as a smell of acetone on an individual's breath which can indicate a serious lack of insulin in the body (diabetic ketoacidosis).

Feedback helps the sender recognise whether the meaning of the message conveyed has been perceived as intended. The receiver's verbal and non-verbal responses convey feedback to the sender to reveal the receiver's understanding of the message. Feedback helps to clarify communication as it guides people in adjusting the messages they send to one another. Effective communicators continuously seek feedback from the people with whom they are communicating, to determine whether the information they are transmitting is being received and understood as intended (that there are no misinterpretations of the meaning of the messages) (Arnold & Boggs 2011).

When communication occurs and information is transmitted from one person to another, two processes must take place: encoding and decoding. Encoding refers to the cognitive processes that occur in the mind of the person who sends

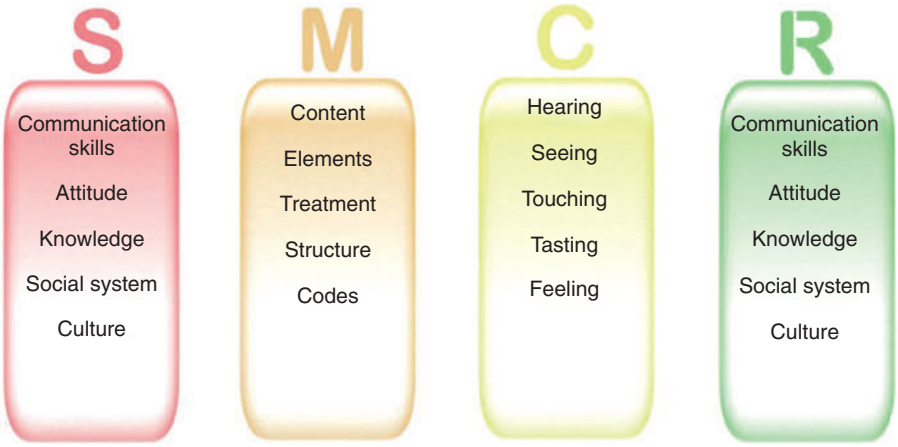


**Figure 8.1** Sender–Message–Channel–Receiver Model

*(JasonSWrench, CC BY 3.0)*

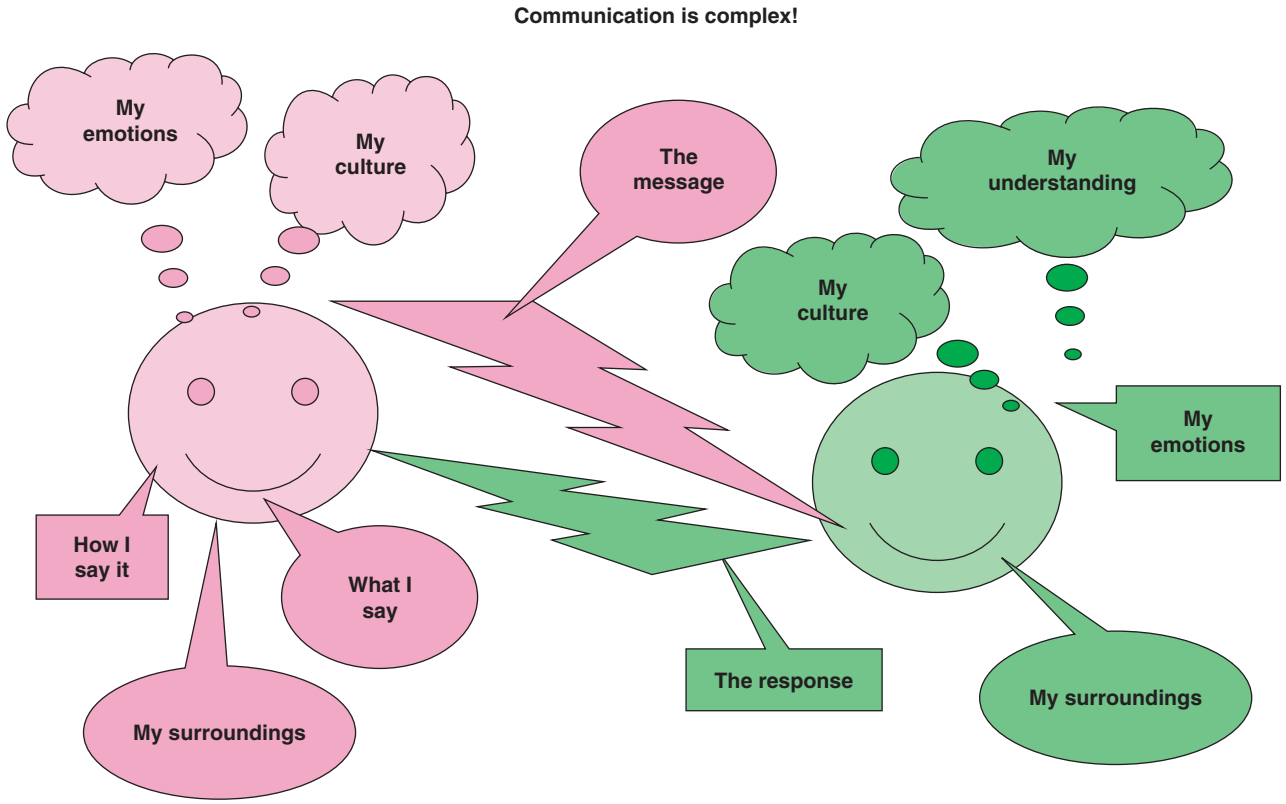

**Figure 8.2** Communication is complex
*(Queensland Health 2009)*

the message. These thoughts must be translated into a code, such as verbal language, to be transmitted to the person who is to receive the message. Decoding refers to the cognitive processes used by the receiver of the message to make sense of what is seen or heard. Generally the sender and the receiver encode and decode messages in a cyclical pattern while communication is taking place (Arnold & Boggs 2011; Jootun & McGhee 2011).

Even during a simple act of interpersonal communication between two people, many factors influence how effectively messages are conveyed and understood (Berman et al 2015). These factors relate to anything that influences or interferes with how the sender transmits a message, how the recipient perceives (interprets) the meaning of the message and the route or channel of communication.

Factors such as the setting in which communication takes place, the presence of distractions such as background noise, and the language, perceptions, values, knowledge, cultural background, role and emotions of each person taking part in the communication can influence the quality and effectiveness of the communication. These factors can enhance the effectiveness of communication between people but they are often barriers. A setting that does not provide adequate privacy such as a shared hospital room may be a significant barrier when a nurse is attempting to communicate with an individual about their personal concerns. Therefore in reality communication is more a transactional exchange as shown by Figure 8.2, which depicts the complexity of factors involved in the communication process (Queensland Health 2009). Clinical Interest Box 8.1 demonstrates the communication process in action.

## CLINICAL INTEREST BOX 8.1 The communication process in action

Mrs Ling has been in hospital for several days and is about to be discharged home. Before she is discharged, the nurse must make certain that she understands she has to attend an appointment with the medical officer in 2 weeks' time. The nurse (the sender) thinks about the best way to pass on the information (the message), and decides (encodes) to write the time and date of the appointment on a card, in addition to telling Mrs Ling. Thus, both spoken and written words (auditory and visual channels) are used to transmit the message. Mrs Ling (receiver) listens to the nurse and looks at the appointment card. Because the words used are familiar to her, she is able to understand (decode) the information. She confirms she has understood the message by asking, 'So I need to come back here and see the medical officer again at 11 o'clock on Tuesday 2nd October?' (feedback to the nurse).

# FACTORS THAT INFLUENCE THE COMMUNICATION PROCESS

## Perception

Perception is a process by which the meanings of messages are interpreted. The way messages are perceived is related to a combination of a person's social and cultural influences, gender, educational background and knowledge, and experiences (O'Toole 2012). This complex mix of influences means that no two people are likely to perceive the same message in exactly the same way. Some of the strongest influences on the way messages are sent and their meanings perceived are the attitudes, values and beliefs that individuals hold (Vorman & Cote 2011; O'Toole 2012).

## Attitudes, values and beliefs

Attitude is the way one person behaves towards another. A person's attitude can be positive or negative and unpleasant. An unpleasant attitude in the workplace makes other people feel uncomfortable and it is detrimental to the wellbeing of individuals (Lux et al 2013; Hanson 2014). Attitude can be influenced by what is happening in a person's life. For example, a fight with a friend may create feelings of anger or distress. Such feelings can be reflected in a negative, even hostile, attitude towards others, which can change the way messages are transmitted and received. Nurses have a professional responsibility to maintain a positive attitude towards people at all times, so every effort must be made to put personal concerns and feelings aside when communicating with others (O'Toole 2012).

Attitude towards others is also related to the values and beliefs that a person holds about the ideas or practices of other people in society, and they are not always consciously recognised. For example, cultural values commonly lie outside conscious awareness and are often simply taken for granted as being the right values (O'Toole 2012). It is natural for people's values and beliefs to differ within and across social and cultural groups. Nurses will encounter many situations in which their own cultural values and beliefs differ from those of the people that they are caring for. Tolerance and understanding of differences in views and cultural practices helps to facilitate these therapeutic relationships. For example, a nurse who holds strong values and beliefs about no sex without marriage will need to demonstrate acceptance that personal views are not shared when caring for a pregnant, single, woman. If the nurse is unable to accept this and put personal views to one side, it will be difficult to communicate with people in a therapeutic manner (Stein-Parbury 2014).

While a nurse's personal values can create interference in therapeutic relationships if they are imposed on people or used in judgment, they can also serve to enhance therapeutic effects. For example, a nurse who holds beliefs that all people have positive qualities and that every individual is a worthwhile person will find that such beliefs enhance the establishment of effective therapeutic relationships (Stein-Parbury 2014; O'Toole 2012).

## Differences in knowledge

When the level of knowledge between two people is different, communication can be difficult. For example, an individual's level of knowledge may be so far above that of the person being spoken to that the meaning of the message may be lost entirely. The nurse must take care to express messages in words and phrases that will be understood. For example, a nurse who is familiar with nursing or medical language, especially jargon, may forget that other people may not be, and if words or phrases are used that are not part of the person's vocabulary the message may be misinterpreted. Studies have shown that when jargon use is minimal there is an increase in comprehension by the individual. The use of specific language that is familiar to members of a subculture or profession may confuse, frighten or alienate people who are not part of that subculture or profession. For example, not every man will know what the nurse means when asked, 'Do you need a bottle?' The word bottle is nursing jargon used to describe a portable male urinal but it could easily be perceived as meaning something entirely different (Lin et al 2014; Al Sayah et al 2014; O'Toole 2012).

## Past experiences

Past experiences can have a powerful effect on a person's perceptions of the meaning of messages. For example, an individual who has had a previous traumatic and painful experience in hospital may discount, distrust or disbelieve messages from the nurse that pain after surgery will be controlled. The nurse can help by talking with the individual about the past experience and explaining fully every measure that will be implemented to ensure adequate pain relief (O'Toole 2012; Stein-Parbury 2014).

## Emotions

Emotions strongly influence how a person relates to other people, and the power of emotion in communication should not be underestimated. Nurses must also be aware that if they become too emotionally involved with the suffering experienced by an individual they may be unable to effectively meet that person's needs. This aspect is one of the most difficult situations faced by nurses, as on the one hand nurses must become emotionally involved to assist people, while on the other hand personal emotions cannot be allowed to adversely affect individual care (Stein-Parbury 2014). All nurses need to be aware of their emotions, and many find it helpful to talk with other experienced nurses about what they are feeling and experiencing (Leavy et al 2011).

It is also important to realise that, if people cultivate 'emotional distance' in an interpersonal interaction, they prevent any deep sharing of meaning and may even arouse animosity. For example, if an individual feels that a nurse is treating them as an 'interesting case' or a 'problem' rather than as a person, they are likely to feel resentful, and therapeutic communication is not likely to occur (Hanson 2014; O'Toole 2012).

People receiving healthcare services can often be anxious or upset, and strong emotions interfere with the ability to absorb the information in messages such as those given by medical officers or nurses. There would be little point, for example, in a medical officer informing a woman about treatment plans immediately after telling her that her breast biopsy revealed a malignant breast tumour. It would not be surprising if her anxiety level increased to such an extent on hearing the diagnosis that it prevented her from absorbing any of the following information about the proposed treatment. The nurse can help in this situation by ensuring the information is repeated when she is less anxious or distressed and by providing the information in written form so that it can be absorbed more effectively at a later time (Renske van Bruinessen et al 2013; Arnold & Boggs 2011; Moola 2014).

### Relationships and roles

There are numerous types of interpersonal relationships, including those between friends, acquaintances, work colleagues, family members and partners. It is usually only when there is enough trust in a relationship that totally honest communication occurs, when ideas, judgments and emotions can be revealed without fear of reprisal, humiliation or rejection.

Trust in the nurse needs to develop quickly and is essential if the relationship is to be therapeutic. People in hospital may not say what they are thinking or feeling if there is a lack of trust in the nurse; often this means that the person has a fear of being judged. A therapeutic relationship means demonstrating unconditional acceptance of all people, without judging. The nurse accepts the person as worthwhile even if the individual's behaviour is challenging. As a nurse's communication skills develop they become increasingly effective and therapeutic, but even when these skills have been learned and practised they may still be difficult to apply in some particularly challenging situations (Stein-Parbury 2014; Arnold & Boggs 2011).

### Environmental setting

Effective communication is more likely to occur if it takes place within a setting that is conducive to listening and concentrating. An area that is at a comfortable temperature, private and free from noise and other distractions is suitable, whereas an area where there is noise or a lack of comfort or privacy may create tension and confusion, making effective communication difficult. For example, background noise and the movements of other people in the environment may distract the listener, and even missing one or two vital words in a sentence can result in the meaning of a whole sentence being lost.

Ideally individuals should be able to communicate with health professionals and other people in a private room, but this is sometimes difficult to achieve in busy healthcare facilities. Nurses should, whenever possible, talk with people about personal issues in a private area such as an interview room or even a quiet garden area to gain privacy. The very least that nurses can do if the person does not have a single room is to close the curtains surrounding the bed, speak quietly and avoid discussing personal details while visitors are in the area (O'Toole 2012).

### Physical discomfort

Communication is likely to be less effective if one or both participants are experiencing fatigue, pain or other physical discomfort. Like its emotional counterpart, physical discomfort can distract a person so that it is not possible to concentrate on what is being said. The nurse who is about to engage in a therapeutic dialogue with an individual is advised to ensure that the person is free of pain, lying or sitting in a comfortable position and not needing to go to the toilet. It is also important to consider that some medications, including those administered for pain relief, can affect an individual's memory and the ability to concentrate or to think clearly (Arnold & Boggs 2011; O'Toole 2012).

### Pressure of time

Because most people have many pressures on their time, the urge to speed up communication is increasing. Nurses often feel the need to complete other tasks while communicating with people and this results in less effective communication (Ghorbani et al 2014). It is not always easy, but even a few minutes of attentive listening can be very therapeutic for an individual. Not all interactions with people need to be lengthy but it does take time to explain, to listen, to reduce fears or anxieties and to assimilate facts. A person who senses the nurse's need to get on with other things is unlikely to raise any issues of concern that need to be talked about. It is one of the major challenges in contemporary nursing practice to prioritise tasks and manage time so that the psychological as well as the physical needs of individuals are met (Arnold & Boggs 2011; O'Toole 2012).

Clinical Interest Box 8.2 provides examples of communicating effectively with individuals.

## FORMS OF COMMUNICATION

Communication is the process of sharing information and understanding, using verbal and non-verbal methods. **Verbal communication** involves the use of words and the way they are delivered. Words can be written or spoken. **Non-verbal communication** involves facial expressions, body posture and gestures, touch and the use of space.

### Verbal communication

In addition to the words used, verbal communication involves the tone and pitch of the voice, the rate and volume of speech, the use of pauses and sounds. These additional components are referred to as paralanguage (Arnold & Boggs 2011).

#### The words

Messages are only understood if the words used are familiar to the sender and the receiver. Nurses in Australia often care for people for whom English is not a first language, and it

## CLINICAL INTEREST BOX 8.2 Guidelines to facilitate effective communication

- Be clear about the message to be conveyed, and how and why it will be conveyed
- Use the most appropriate medium (channel) for conveying a message
- Use language that is appropriate for the recipient's level of intellectual understanding, emotional status and culture
- Choose the right timing and length of message for each occasion
- Use specific skills to gain and interpret feedback from the other person
- Use active listening skills to listen for what is said
- Use keen observation skills to determine what is not being said; for example, be aware of non-verbal communication
- Observe for clues and contradictions in the verbal and non-verbal messages from the other person
- Encourage and wait for questions, and answer them clearly and honestly
- Ask appropriate questions and actively listen to the response
- Be sensitive to individual differences in communication behaviour and, as far as possible, adjust the style of communicating to accommodate these differences
- Identify and minimise the barriers to effective communication.

*(Stein-Parbury 2014)*

may be necessary to get help from an interpreter (Department of Health and Human Services 2014). Even within a cultural or sub-cultural group the meaning of many words can be ambiguous and one word can have two meanings in the same culture, so that remarks can easily be misunderstood. For example, a 5-year-old boy was being prepared for a surgical operation and the nurse told him he would be going to the theatre in 2 hours time. Imagine his distress when he arrived in the operating room to have his tonsils removed, when he thought that he was being taken to see a film.

### Sounds

In addition to words, sounds made by the voice can deliver very strong messages about a person. Sounds can convey pain (groans, moans), distress and sadness (crying, sobs), boredom or despair (sighs), excitement or fear (screeches and screams) or a range of other emotions. The meaning of a sound can easily be misinterpreted, as most sounds can express more than one emotion. A moan might not always express pain—it may be a moan of pleasure or disappointment. The nurse must always validate the meaning of a sound individual; for example, the nurse might ask, 'That sounds like you have pain, Mrs Jacobs. Do you have pain?'

### Tone and pitch

The tone and pitch of the voice can have a powerful effect, sometimes more so than words. No matter what words are being said, a loud aggressive voice will send a strong message. A nurse's tone and pitch of voice and the inflections used add meaning to words. Tone and pitch of voice can display anger, apathy, disgust, enthusiasm, excitement and other emotions. An individual can often determine more about another person from the way in which the words are spoken than from the actual words used. Loud, rapid, forcefully spoken words can intimidate and communicate aggression, a patronising tone can communicate condescension or contempt, and expressionless speech can communicate lack of interest. People can discern much about each other from their respective voices, especially the tone and pitch which can convey messages about emotional feelings and energy levels (Arnold & Boggs 2011; O'Toole 2012).

### Rate and volume

Rate and volume of speech are best kept at a moderate level. Speaking too fast, too slowly or too loudly is not conducive to comfortable conversation, and messages may be lost or misinterpreted. Nurses frequently care for people with hearing and cognitive impairments; these people need to be consulted and assessed to determine the most successful rate and volume of speech to facilitate therapeutic communication (Department of Health 2010; Department of Health 2012).

### The use of pauses

Pauses can provide time for individuals to think about what they want to say, but pauses that are too long (more than 10–15 seconds) may seem awkward or uncomfortable (O'Toole 2012).

In normal conversation the style of communication that individuals use is generally not thought about consciously. When engaged in therapeutic relationships, nurses need to consciously evaluate the way they communicate and develop a conscious awareness of the tone, pitch, rate and volume at which they speak. Other basic aspects of verbal communication that are helpful to be aware of are the need to:

- Be brief: short pieces of information make understanding easier—the fewer words, the less the risk of misinterpretation
- Keep the messages clear, simple and direct: complicated information leads to confusion and unnecessary words detract from clarity; for example, additions such as 'you know', 'OK', 'and that' or 'um' are best avoided
- Enunciate words clearly: make messages clearly heard; mumbling makes them incoherent
- Use examples to clarify meaning: an example often makes it easier for the message to be understood. For example, the nurse might clarify, 'By aids to help you at home I mean things like a seat that fits across the bath, grip rails in the bathroom for you to hold onto and perhaps a ramp instead of steps at your back door.'
- Time the delivery of the message appropriately: timing is important when giving information of any sort.

Trying to tell an individual about what will happen in surgery just as the pathology nurse is taking a blood sample would demonstrate poor timing, as the individual's concentration would not be totally focused on the message (Al Sayah et al 2014; Lin et al 2014; Arnold & Boggs 2011).

## Non-verbal communication

In nearly every interaction, words are accompanied by simultaneous non-verbal messages that the sender may not be consciously aware of. **Non-verbal communication** refers to messages transmitted without using words. They include those transmitted via:

- Facial expressions
- Posture, body movements and gestures
- Eye behaviour
- Touch
- Use of space (proxemics).

(Arnold & Boggs 2011; O'Toole 2012)

Non-verbal messages form the most significant component of communication and together with paralanguage can make up to 80% of the meaning of a message (O'Toole 2012). During interpersonal communication with people it is essential for the nurse to look as well as listen. Concentrating only on words means that much of what could be discerned is being missed. Non-verbal communication comes from many sources and it is easy to miss something significant. For example, while watching a person's foot tapping, a significant hand gesture or eye movement may not be noticed. Generally, non-verbal messages are not received in isolation and they are interpreted subconsciously but nurses need to develop the skills of consciously considering verbal and non-verbal messages, together and in context, and validating the meanings perceived in the messages (Arnold & Boggs 2011).

### Facial expressions

Facial expressions convey emotional states, and therefore a great deal of information can be obtained about individuals' feelings by observing their facial expressions (O'Toole 2012). For example, a frown or an eyebrow raised in disbelief reveals something of how an individual is reacting to what is being said. Some specific facial expressions of emotion seem to be universal across cultures. They are those that convey surprise, fear, disgust, anger, happiness and sadness. Facial expressions provide the nurse with continual non-verbal feedback from most individuals, but some people have expressionless mask-like faces that reveal little or nothing of what they are thinking or feeling. This may be a person's usual demeanour but sometimes it is due to the effects of an illness such as Parkinson's disease, Alzheimer's dementia or severe depression. In such cases the nurse must detect the person's mood from other clues such as body posture, activity level and appetite, or simply by asking how the person is feeling.

Individuals are often very sensitive to the facial expressions of the nurse and it is imperative that, even though it is sometimes difficult to control, nurses make every effort not to facially express feelings of shock, alarm, repulsion or any other negative emotion in front of the individual (Arnold & Boggs 2011). Imagine the effect on an individual with a stoma, an amputation or serious burns who detects repulsion on the face of a nurse. Additionally, nurses need to develop awareness of the effect their facial expressions may have on people during procedures and interactions of any sort. For example, a nurse frowning in concentration while dressing a wound may be interpreted by the individual as the nurse being worried and concerned about the look of the wound.

### Posture, body movements and gestures

The way individuals move, walk, sit or stand communicates information about their mood, attitude, state of mental and physical health and self-esteem (Arnold & Boggs 2011; O'Toole 2012). An upright posture together with decisive, quick and purposeful movements communicates a sense of wellbeing and self-confidence. A slumped posture, hesitant movements and a slow shuffling or stumbling gait may indicate depression, physical illness or impairment or that a person is substance-affected or fatigued.

Some basic communication gestures convey the same message in almost every culture. For example, nodding the head is almost universally used to indicate 'yes', or affirmation.

Conversely, a specific gesture may be meaningless or assume a different meaning in another culture. Even within one culture a meaning may be different according to whether the gesture is made in certain ways. In most European countries the V sign means victory when gestured with the palm facing away from the body, and a rude 'shove it' when the palm is facing towards the body of the person gesticulating (O'Toole 2012). See Chapter 10 for more information on cultural differences.

### Eye behaviour

Eye contact is one of the most crucial aspects of communication. How often people make eye contact or how long they hold a gaze can make a vital difference to the quality of an interaction. Eye contact and behaviour can convey openness and sincerity, and an individual's emotional state and level of interest in a person or what is being said, and a failure to make eye contact can reduce the effectiveness of communication. A commonly held perception is that failure to make eye contact can mean the person is lying; however, there are many reasons why people may avoid making eye contact (Arnold & Boggs 2011). These could include shyness, nervousness, low self-esteem, embarrassment and defensiveness.

The norms about what eye contact means, how often it should occur and with whom, differ in varying degrees from culture to culture and generation to generation. Some Aboriginal or Torres Islander Strait people may avoid eye contact if they are in pain and many cultures have rules about eye contact according to status, age and gender. Nurses therefore need to consider cultural differences when using eye contact themselves or when interpreting eye contact given by people (Arnold & Boggs 2011).

Looking down on a person from a higher position can be intimidating. When people are in bed it is preferable for

the nurse, or any other health professional, to sit down and make eye contact at eye level because communicating at eye level indicates equality and helps develop trust in a relationship (Stickley 2011; Webb 2011).

## Touch

Touch (tactile communication) is one of the most powerful and personal forms of expression. A person's first comfort in life comes from touch, and so, frequently, does their last, as touch may communicate with a dying person when words cannot. There is no way to practise nursing without touching and, in nursing, touch may be the most important of all non-verbal communications. Touch occurs in everyday procedures such as taking vital signs and assisting people with showers or baths. It also occurs at times of joy, fear, stress and loss. How nurses use touch while providing care conveys a great deal about the way they feel towards people and their illnesses.

In nursing, touch can be used therapeutically to transmit positive feelings of understanding, compassion or reassurance. To be effective, tactile communication must be used at the appropriate time and place. Not all people like to be touched and all individuals consider a certain amount of space around them as private. Touch can be seen as an invasion of that privacy unless it is desired. Touch must be used at the right time and in the right way, otherwise the message may be misinterpreted. Nurses always need to assess and be sensitive to how comfortable a person is with being touched (Albardiaz 2014).

## Space

The concept of 'space' is important in communication, as it determines the distance a person usually keeps between themself and other people. The individuals involved, and the context or situation, dictate acceptable distance zones. People surround themselves with their own 'informal' personal space, which is invisible and mobile, and nurses need to be aware not to impinge on another person's personal space (Arnold & Boggs 2011; O'Toole 2012). The categories of personal space or zone are shown in Figure 8.3.

The intimate zone (between 15 cm and 45 cm from the body surface) is the most important to a person, who guards it as if it were personal property. Usually only those who are emotionally close to the person are permitted to enter this zone, such as spouses, partners or lovers, parents, children, close friends and relatives. The personal zone (between 46 cm and 1.2 m) is about the distance individuals keep between them at friendly gatherings and social functions. The social zone (between 1.2 m and 3.6 m) is the distance individuals keep between themselves and strangers or people who are not well known to them (Arnold & Boggs 2011).

The nature of nursing practice means that nurses frequently invade an individual's intimate or personal space. Many people will be uncomfortable with this closeness, and nurses should observe and respond to the person's non-verbal cues to ensure that any discomfort can be identified and dealt with. Conversely, such necessary closeness when handled sensitively may promote rapport between a nurse and an individual.

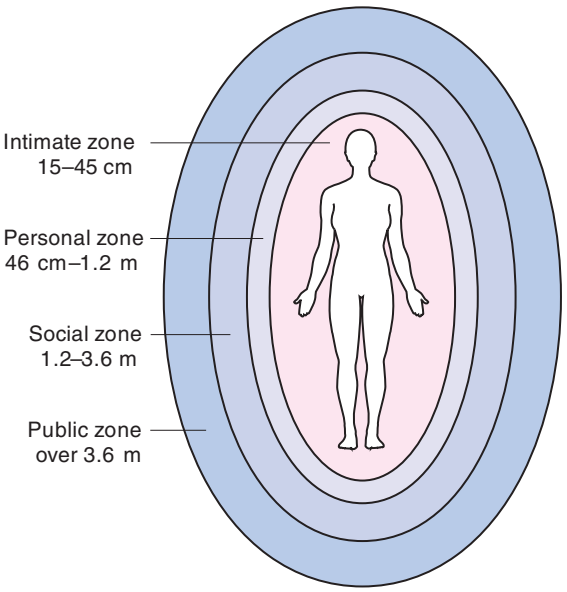

**Figure 8.3** Personal space zones

## Summary

In summary, although non-verbal communication provides information on how a person is feeling, it is a mistake to interpret a single movement, gesture or facial expression in isolation. For example, a person with arms folded across the chest and stomping about might simply be protecting himself from the cold, but if this was accompanied by sobbing, shouting or a facial grimace it may indicate severe pain, distress or anger. All non-verbal clues need to be observed together when considering what is really happening.

When a person's actions or gestures do not match spoken words, the messages are said to be incongruent. This means that the body movements or gestures are conveying one message, while the verbal words are conveying a different message. When an individual conveys incongruent messages it is important that the nurse tries to clarify what is happening even though it may at first feel awkward doing so. Conversely nurses should also ensure that the non-verbal cues that they provide are congruent with what they say. Imagine a nurse asking someone if they have any questions but not looking at them and walking away before the person can answer. The nurse's behaviour indicates disinterest which contradicts the words spoken. When this occurs the non-verbal messages take precedence as they are considered to be more truthful (Arnold & Boggs 2011). Clinical Interest Box 8.3 provides an example of how a nurse can explore incongruence between verbal and non-verbal messages.

# CONFLICT AND COMMUNICATION

The very nature of nursing means that nurses will inevitably have to deal with a situation of conflict. The conflict that nurses may have to deal with could be between themselves

### CLINICAL INTEREST BOX 8.3 Recognising verbal and non-verbal communications

Andrew, 40, was admitted to hospital for overnight observations after being concussed in a motor vehicle accident the day before. The nurse was concerned because, although there seemed to be no problems from his concussion, she had observed Andrew limping and grimacing when he was walking. When she asked if he had any pain he said no. The nurse began exploring the incongruent messages being received by saying, 'I am concerned about you because even though you say you have no pain you seem to have trouble walking.' After talking with Andrew for only a short while he admitted he had considerable pain in his foot, but did not want to tell anyone because he could not afford any more time in hospital and thought it was probably only bruising that would get better without treatment. X-rays revealed that Andrew had broken two bones in his foot which, without correct treatment, could have resulted in permanent disability.

and other nurses or other healthcare professionals, or the people that they are caring for or their relatives. Unresolved conflict between nurses has been identified as a major contributing factor as to why nurses leave the profession and can contribute to the reduced care of an individual. Regardless of the parties involved, a breakdown in communication is the major cause of situations of conflict (Brinkert 2010). In the healthcare setting it can result from people misunderstanding their prognosis or treatment, or being given inconsistent, confusing, too much or too little information. Nurses are often communicating with people during times of high stress or severe physical or mental impairment and all these factors can contribute to ineffective communication and a situation of conflict (Arnold & Boggs 2011; Weissman et al 2010). Often in these situations people's emotions rule their behaviour. They may feel tired, annoyed, irritated, frustrated or angry. Other factors that can lead to a situation of conflict include past experiences (previous negative experience), lack of trust or cultural differences (expectations are different). It is important that situations of conflict are dealt with appropriately to ensure that the relationships between nurses and the people that they are caring for remain therapeutic. Nurses require skills that identify situations where poor communication has led to conflict and must be able to recognise the emotion that the person is feeling so they can use appropriate conflict-resolving strategies (O'Toole 2012).

## PASSIVE, AGGRESSIVE AND ASSERTIVE COMMUNICATION

The style of communication that people adopt in a situation of conflict can be categorised as passive, aggressive or assertive.

### Passive communication

Nurses tend to use a passive style of communication where they avoid conflict and pretend that it is not really occurring (Mahon & Nicotera 2011; Pavlakis et al 2011). Individuals who are passive don't adequately communicate their feelings and needs to others. They tend to fear conflict and let their needs go unmet in order to 'keep the peace'. They let others win while they lose out; consequently the conflict is never resolved and often recurs or leads to resentments. The person who is passive continues to avoid confrontation, becoming increasingly angry until, when they finally do say something, it comes out aggressively. The other party does not know there is a problem until the individual who was formerly passive virtually explodes. This leads to hard feelings, weaker relationships and more passivity (O'Toole 2012; Arnold & Boggs 2011).

### Aggressive communication

In contrast, individuals behaving aggressively will tend to employ tactics that are disrespectful, manipulative, demeaning or abusive. They make negative assumptions about the motives of others and think in retaliatory terms, or they don't think of the other person's point of view at all. They win at the expense of others, and create unnecessary conflict. An aggressive person will shout or impose their opinion on others and insist on having their own way (Ellis & Abbott 2013; O'Toole 2012; Arnold & Boggs 2011). Responding to a person who is aggressive with aggression will only serve to inflate a situation of conflict. Nurses should ensure that they do not get caught up in the emotion of a conflict situation and become defensive, argumentative or abusive themselves (Stein-Parbury 2014; Collopy 2011).

### Assertive communication

**Assertive communication** is the best approach to take when dealing with a situation of conflict. It helps to facilitate beneficial communication outcomes and improves relationships (O'Toole 2012). Assertiveness is the ability to express one's feelings and assert one's rights while respecting the feelings and rights of others. Assertive communication is appropriately direct, open and honest, and clarifies one's needs to the other person (O'Toole 2012; Stein-Parbury 2014). Assertiveness comes naturally to some, but if it doesn't it is a skill that can be learned. People who have mastered the skill of assertiveness are able to greatly reduce the level of interpersonal conflict in their lives, thereby reducing a major source of stress (O'Toole 2012; Ellis & Abbott 2013).

The key to assertive communication is the 'I' message. It sends a different message to the 'you' message. Imagine a nurse saying this to another nurse 'You are so lazy' instead of 'I feel that I am not getting enough help from you'. The 'I' message does not lay blame and the person owns how they are feeling. In contrast the 'you' message does the reverse and tends to inflame situations of conflict (Stein-Parbury 2014). To further explore other assertive communication strategies see Clinical Interest Box 8.4. See Table 8.1.

## CLINICAL INTEREST BOX 8.4
## Assertive communication skills

Use these steps to help you develop an assertive response:

1. Express empathy

*'I can see that ...'*
*'It must be difficult for you ...'*

2. Describe your feelings or the situation

*'I feel upset that ...'*
*'It seems like ...'*

3. State expectations

*'I would like you to ...'*
*'What needs to happen is ...'*

4. List consequences

*'If this happens then ...'*
*'Then we will be able to ...'*
*'If it doesn't happen then ...'*

Example

*'I understand that you are upset because you would like to accompany your wife into the operating theatre but you cannot go in because of the infection risk. I would like you to wait here and I will let you know when you can see her. This will help ensure that she stays healthy.'*

*(Arnold & Boggs 2011)*

# THERAPEUTIC COMMUNICATION

The development of a therapeutic relationship between an individual and a nurse is vital to effective nursing care (Punjani & Bhanji 2014). A therapeutic relationship is about meeting the healthcare needs and wishes of the individual. For a therapeutic relationship to occur there must be mutual understanding and this arises from the development of respect, empathy and trust. Underpinning all therapeutic relationships is therapeutic communication, an essential element of nursing practice (O'Toole 2012; Kleier 2013).

Clinical Interest Box 8.5 provides examples of some techniques for therapeutic communication.

# SKILLS TO FACILITATE THERAPEUTIC COMMUNICATION

## Active listening

Active listening is not an automatic ability. It is a skill that develops with practice and perseverance. Active attentive listening is as important to the process of therapeutic communication as speaking and it could be said that the art of therapeutic conversation lies in the ability to listen with perception.

Active listening requires attention and concentration, to hear not only the words but the feelings or meanings that are often hidden behind the words. Active listening involves being tuned in and ready to receive messages (Arnold & Boggs 2011). Nurses can demonstrate readiness to listen by

**TABLE 8.1 | Assertive behaviour versus aggressive or passive behaviour**

| Aggressive | Passive | Assertive |
|---|---|---|
| Raised voice | Looking away from speaker | Eye contact |
| Blaming | Saying yes reluctantly | Nodding and giving feedback to a speaker |
| Pointing | Turning away from speaker | Showing respect for the other speaker |
| Shouting | Hiding under the desk | Explaining clearly why a suggested deadline might not be possible |
| Standing with hands on hips | Waffling | Taking responsibility for one's own feelings |
| Talking over a speaker | Shuffling feet | Acknowledging the other person's position/ feelings |
| Standing over a seated person | Avoiding confrontation | |
| Constantly 'topping' a person's story | | |
| Public criticism | | |
| Standing too close to a person | | |

*(Arnold & Boggs 2011; Collopy 2011; O'Toole 2012)*

## CLINICAL INTEREST BOX 8.5 Therapeutic communication

Therapeutic communication techniques in nursing are those that:

- Convey respect and acceptance of individuals, no matter what situation they are in or illness they have
- Encourage the expression of the views, feelings and ideas of others
- Demonstrate a non-judgmental attitude towards the situations, views, feelings and ideas of others.

They include the skills of assertive communication, active listening, asking questions, providing feedback, paraphrasing, clarifying, reflecting, using silence and summarising (Arnold & Boggs 2011; Joanna Briggs Institute 2011).

minimising environmental distractions and adopting a posture as detailed below. The acronym SOLER is a useful way to remember these following points:

- **S**itting at a comfortable distance away from the person and facing them
- **O**pen, relaxed posture (arms not folded and legs not crossed)
- **L**eaning slightly forwards
- **E**ye contact
- **R**elaxed posture.

Active listening incorporates simultaneously listening for the content, or facts, of the message, and the feelings in or behind the message. Sometimes feelings are expressed openly, for example, 'I'm really fed up and I am scared that this ulcer on my leg will never heal', but often feelings are only hinted at, implied or talked around. Sometimes it is the way something is said that reveals how an individual is feeling; for example, 'My doctor was here just now; he said everything is going fine, according to plan' might be said in a way that reveals the individual is happy about the news, or in a way that indicates the individual doubts the truth of the news. Sometimes feelings are deliberately concealed or expressed only non-verbally. Active listening requires the nurse to:

- Stay mentally alert
- Focus on the speaker's ideas
- Pay close attention to what is said
- Avoid interrupting the other person's speech or being anxious to butt in
- Avoid thinking about what to say next while listening
- Remain alert for an unexpected remark
- Keep an open mind.

Communication strategies that indicate active listening include eye contact, nodding or smiling to encourage the speaker to continue, prompting the speaker by using expressions such as 'go on' or 'then what?' and asking questions to clarify what has been said (Hayes & Collins 2013; Stickley 2011).

## Asking questions

Nurses ask questions to gain information from individuals. The responses provide the data from which care is planned and implemented. Questions also assist in the development of trust and rapport if they are the right question asked at the right time. The type of questions asked depends on the situation and the type of response required. Some questions call for simple and direct responses, while others are more probing in nature (O'Toole 2012).

### Closed questions

Closed questions are those designed to elicit a simple 'yes' or 'no' or a very short and factual answer. They often start with 'who', 'where' or 'when'. For example, 'When did you last see your medical practitioner?' is a closed question, and the expected response to this question would be merely a date. Closed questions limit options but are useful in emergency situations when the goal is to obtain information quickly; for example, 'How severe is the pain on a scale of 1 to 10 where 10 is the worst pain imaginable?' Closed questions are not designed to elicit extensive detail or to discover or explore feelings or attitudes (Arnold & Boggs 2011; Stein-Parbury 2014).

### Open-ended questions

Open-ended questions are designed to evoke a long answer. They enable a person to choose how much or how little information to reveal and can be seen as less threatening. Open-ended questions often start with 'why', 'what' or 'how'. Open-ended questions are more effective in encouraging a person to elaborate on a topic, as such questions cannot be answered with a simple 'yes' or 'no' (Williams 2008). This style of questioning invites the person to reveal personal perceptions, views, thoughts and feelings (Ellis 2009). For example, 'What were your reasons for choosing to move from Alice Springs to Melbourne?' is an open-ended question. The nurse should always allow the individual to fully answer each question before moving on to a follow-up question or changing the topic. Open questions may also begin with inquiries such as 'Can you tell me more about …' which encourage the individual to elaborate (O'Toole 2012).

### 'Why' questions and leading questions

It may hinder the development of a therapeutic relationship to use questions beginning with 'Why?' because they may seem judgmental. For example, 'Why don't you want a shower?' can sound accusatory to an individual. The 'why' question could make a person feel that they have to justify themselves or that there is something wrong with what they are feeling. It is better to ask, 'I'm concerned that you don't feel up to a shower; how are you feeling?' (Stein-Parbury 2014).

It is also recommended that the use of leading questions be avoided. Leading questions are rhetorical because they have an implied answer and are often used to confirm what nurses think they know (O'Toole 2012). For example, individuals might find it easier to answer 'Yes' to a leading

question such as 'You're all right, aren't you?'; while they might feel obliged to answer 'No' to the question 'You don't need any more pain relief, do you?' Individuals might interpret such leading questions as the nurse not caring or not being interested in how they are really feeling, or not having the time to be concerned.

When individuals are admitted it is usual for the nurse to ask a range of questions. Most interviews comprise a mixture of closed and open-ended questions, but nurses need to be sensitive to the fact that overuse of closed questions can seem like an interrogation. Being bombarded with multiple closed questions as a nurse completes an admission form can feel dehumanising because it does not provide an opportunity for individuals to talk about issues that might be important and of concern to them. It is often a more relaxed and friendly approach to ask questions less directly. A gentle command could be used instead; for example, 'Tell me about your health over the past few years' may elicit most or even all the information needed but gives some control to the individual. Skilful questioning, using mostly open techniques, can be a way of beginning a meaningful relationship with an individual.

## Feedback—paraphrasing, clarifying and reflecting

Other techniques that help the communication process are clarifying, paraphrasing and reflecting. All these are methods of providing feedback. Feedback is a very important component of the communication process. If a listener is not providing any feedback, the sender has no way of knowing whether a message has been received or how well it has been understood (O'Toole 2012).

Facial expression and body language can provide some feedback from the listener to the sender, or the person who is sending the message can obtain feedback by asking the listener to verbally express their understanding of what was said, or to demonstrate understanding. For example, after a nurse has taught an individual how to use an aerosol inhaler, the individual can be asked to demonstrate understanding by showing the nurse that they can use it effectively. Alternatively, the listener can describe their perceptions of a sent message by using the skills of clarifying, paraphrasing and reflecting, all of which give the sender the opportunity to correct any misperceptions.

### Paraphrasing

Paraphrasing is a technique whereby the listener reiterates what the sender has said in their own words, more briefly whenever possible. Paraphrasing is a means of sending feedback to the sender of the message that lets the person know whether or not the meaning of the message was received as intended. Paraphrasing can be very effective for checking understanding of the content of a message, as it gives the individual an opportunity to correct any misunderstandings. It also helps build trust as the person recognises that the nurse is interested in gaining a full understanding of what the individual is trying to communicate (Arnold & Boggs 2011; Stein-Parbury 2014). For example:

*Individual: 'I'm on 10 medications in the morning and two at lunch and then six in the evening. There are two pink ones in the morning and the rest are white. I think there might be a blue one at night. Oh yeah, and some shiny red ones. I don't know what half of them are for.'*

*Nurse: 'You sound like you would like to know a little more about the medication that you are taking.'*

Paraphrasing can also be in the form of a reflective question. For example, 'Didn't you say that you had your heart attack before you were diagnosed as having diabetes?'. Progress Note Example 8.1 illustrates how a nurse might ask an individual to paraphrase to ensure effective understanding.

### Clarification

Clarification is used in situations in which there is a lack of sense about what an individual means, to the degree that it makes the use of paraphrasing impossible. Clarifying reinforces that the nurse is trying to gain an understanding, and the nurse should not continue until clarification has been managed. The nurse must be careful not to put blame for lack of clarification onto the individual; for example, saying, 'You're not being very clear about how this happened' would be unhelpful, might alienate the individual and would not facilitate a therapeutic relationship. It would be better for the nurse to take responsibility and say, 'I'm having some trouble following what you mean'.

When needing to clarify it is possible to ask a direct question such as 'What do you mean?', but this is best avoided because it may sound critical and accusatory to individuals. Whatever way clarification is sought the tone and pitch of

**PROGRESS NOTE EXAMPLE 8.1**

| | |
|---|---|
| 10/09/2016<br>1500 hrs | On admission Mary was not able to explain to me the medical procedure she was having today. She told me she was very frightened and thought she might die. I explained the procedure to her again and answered her questions. She was able to explain it back to me and told me that she didn't feel as anxious anymore. I also contacted her surgeon, who came down to the ward to explain the procedure to her as well. She stated that she will go ahead with the procedure. She informed me that she suffers from anxiety and is very worried about how she will cope when she is discharged.<br>***J. McArdle* (McArdle) EN** |

voice, facial expression and body language used can make a difference to how the individual feels about not being understood (Stein-Parbury 2014).

### Reflecting

Reflecting is another skill that can be used to check that a message received has been correctly interpreted and works particularly well to reiterate the individual's feelings. Reflection is the mirroring of feelings the nurse believes have been expressed by individuals. The feelings are reflected by the nurse's words as a way to check that perception of an individual's feelings is correct. For example, an individual may say 'Just look at me, I've lost so much weight since I've been in hospital.' The nurse might reflect back the feelings perceived by using a reflective question, 'You're anxious about how much weight you have lost?' The individual may confirm with a 'yes' or correct a misperception by saying, 'Oh no, I feel good—I've been trying to get to this weight for years.'

Reflecting feelings is especially important in nursing because it conveys that the nurse recognises and accepts an individual's emotions as a valid part of the illness experience which furthers the trusting relationship (Arnold & Boggs 2011). For example, an individual may say, 'This hip of mine doesn't seem any better now than before the operation.' The nurse may reflect, 'You seem pretty frustrated (anxious/worried) about your lack of progress.' This validates the individual's feelings and at the same time provides permission for the individual to talk more about what is being experienced. Reflected feelings should be stated tentatively, no assumptions should be made about what an individual is feeling unless stated directly, and often they are only implied or hinted at. It is quite difficult to select the right words to describe a feeling and the intensity of it. The nurse should not proceed with dialogue about an individual's feelings until the individual has verified that the nurse's perception of what the individual is feeling is correct. Care is also needed not to underestimate or overestimate the intensity of the feelings that an individual is experiencing (Stein-Parbury 2014).

It is often helpful and therapeutic for an individual to be able to share what they are feeling with the nurse. But not all individuals want to talk about what they are feeling. They may prefer to keep those feelings under control or share them with someone else—a partner, close family member, friend or priest, for example. The nurse must respond sensitively to the messages given out by individuals when they initiate discussion of feelings, and individuals should never feel coerced into talking about feelings they prefer to keep contained.

## The use of silence

Silence, used correctly as a communication tool, can be as effective and as supportive as words (Arnold & Boggs 2011). There are instances where words seem inadequate when a person wishes to convey thoughts and feelings to another person. In such instances, it may be most helpful simply to sit quietly with the person and share the silence. Just to be with another person at moments of grief, sorrow, conflict or joy may be more helpful than trying to fill the silence with useless words or clichés.

In some situations silence is not productive and can cause discomfort. Silence can be used to indicate approval or disapproval of a situation, or it may be used to punish or hurt another person. In such instances silence causes **barriers to communication** and may cause a person to feel inferior or rejected. There are times in nursing when silence is not therapeutic. During interviews with individuals there may be times when the nurse cannot think how to respond to what an individual has said. It is understandably difficult to know how to respond when an individual says something such as 'I don't want this baby' or 'I know I'm going to die' or 'my life will never be the same now'. If what is called 'a stumped silence' ensues after personal information or strong views or feelings have been revealed, the individual may feel awkward and perceive that the nurse is expressing negative judgment or disapproval. Rather than have an uncomfortable stumped silence it is better to use the skill of paraphrasing or reflecting feelings, touching gently or saying something such as 'I wish I knew what to say to help'. Nurses need to develop awareness of stumped silences and practise communication strategies that help avoid them, and ways to use silence therapeutically.

## Summarising

Summarising is a way of briefly highlighting the key aspects of a conversation. It is a skill most often used before terminating an interaction or nurse–individual interview. In addition to clarifying, paraphrasing and reflecting feelings, it is another method of allowing the nurse to check understanding of what has been shared and discussed, and to have that understanding confirmed or corrected by the individual. Summarising is a helpful strategy in that it also informs the individual that the interaction is coming to a close and provides the opportunity for the individual to raise any issues of concern not yet discussed (Stein-Parbury 2014).

Summarising is important because it is not uncommon for individuals or relatives to present the most significant aspect of what has been happening to them just as the interview is about to end. This is probably because the significant aspects are often those that are embarrassing or that elicit the most intense emotions. These things are not easy to share and, as the nurse summarises, individuals realise that the opportunity to do so will soon be gone. The nurse should factor this possibility into the time allocated for interactions. Summarising and permitting the individual to raise issues not previously mentioned enables the individual and the nurse to feel a sense of satisfactory completion at the end of the interaction (Arnold & Boggs 2011).

Summarising can also be useful at the beginning or midway through an interaction. Sometimes it is helpful for the nurse to summarise the content of a previous interaction, for example, 'When we last spoke you told me you were anxious about who was looking after your home and your dog while you were in hospital and that you were going to contact your neighbour about keeping an eye on things. How

have things worked out?' This serves to focus the interaction into the area needing further exploration.

Midway through an interaction it may be helpful to summarise before moving on to a new topic; for example, 'Before we talk about what will happen after your surgery, just let me see if I have things clear. You haven't had anything to eat or drink since 6 o'clock this morning. You haven't taken your medication that was due at lunchtime, and you are worried because you were so unwell after your last anaesthetic. The only other thing is that you want me to make sure the anaesthetist is coming so that you can talk to him about that.'

A summary can take the form of a question or a series of questions and answers to make sure that an accurate understanding has taken place; for example, 'Let me see if I have understood what you have told me. You had a heart attack when you were aged 47, the following year you were diagnosed with diabetes, and now you are having problems keeping your blood sugar levels within the recommended range?'

In addition to confirming or correcting the content of the interaction as perceived by the nurse, this can help individuals recall what has been said so far and prompt questions they might wish to ask while the issues are fresh in their mind. Whether the summary is at the beginning, midway or at the termination of an interaction, sufficient time should be allowed for the individual to expand on a point, clarify misperceptions or add something new (Lin et al 2014). Refer to Clinical Interest Box 8.6.

## Conveying empathy

Empathy refers to the ability to recognise and understand the essence or reality of an individual's experience and to communicate that understanding back to the individual. Empathy is considered to be different from sympathy. Sympathy is seen by some as subjectively sharing the feelings of the other person and thinking 'How would I feel if I was going through this', whereas empathy is seen as 'reaching out' and understanding the other person's experience without equating the intense feelings with past personal experience. In nursing, empathy is often viewed as a more desirable response because the focus is on the other person, not what the nurse is feeling and nurses are encouraged to be empathetic rather than sympathetic (Stein-Parbury 2014).

Empathy can be communicated by touch, by direct, clear and accurate statements that reflect understanding of the core of an individual's experience and by skills such as reflecting feelings. Expressions of empathy foster feelings of trust. If a person is able to demonstrate an understanding of how another person is feeling, rapport is established between them, and this promotes mutual trust. Trust is a belief that a person will respect another's needs and will behave towards them in a responsible and predictable manner. When people trust each other they feel more comfortable in their relationship, and communication is more effective (Joanna Briggs Institute 2011). Empathy also fosters higher patient satisfaction and improved mental health outcomes (Lelorain et al 2012).

## Self-disclosure

Self-disclosure refers to the skill of sharing personal experiences, feelings, thoughts, ideas and views with individuals in a way that is comforting. It can be comforting because it communicates understanding of the individual's situation and feelings and reinforces that the experience is not unique (O'Toole 2012). Self-disclosure should only be used when it is helpful to the individual, the purpose is to benefit the individual and the focus should not remain on the nurse after self-disclosure has occurred. For example, the nurse might say, 'I had a premature baby 2 years ago and was overwhelmed with the constant demands. I was lucky I had a lot of support. What sort of support will you have with your baby?' Self-disclosure can be used as a means of prompting and encouraging individuals to express their own fears, feelings and experiences. It also sends a message that the nurse trusts the individual with personal information, which may help the individual to feel comfortable enough to reciprocate that trust (Stein-Parbury 2014).

## The use of humour

Fun and laughter can be very therapeutic, but humour needs to be used with caution and, initially, tentatively when people are ill or upset and vulnerable, because not all people share or appreciate the same sort of humour. Humour has the potential to:

- Release tension and reduce anxiety
- Reduce embarrassment
- Reduce depression by stimulating the release of endorphins from the hypothalamus
- Stimulate immune system functioning
- Reduce pain by decreasing serum cortisol levels.

The use of humour can promote rapport between nurse and individual and facilitate communication that is relaxed

### CLINICAL INTEREST BOX 8.6 Summarising as an effective communication technique

A community health nurse might summarise an interaction in an individual's home: 'So, to sum up, your mum has now been diagnosed with Alzheimer's dementia. As well as looking after your own home and your two children you are currently doing all the shopping, cooking and cleaning for your mum, and there is no-one else who can help. You agree for me to arrange a visit from the Aged Care Assessment Services to see what help is available.'

After waiting for points to be clarified and the summary to be confirmed or corrected, the nurse might then ask, 'Is there anything else you would like to ask or tell me before I go?'

*(Arnold & Boggs 2011)*

and comfortable. However, it should be used to benefit the individual and never as a mechanism to hide behind when nurses are ill at ease in particular situations (Arnold & Boggs 2011; O'Toole 2012; Tremayne 2014).

## COMMUNICATING WITH CHILDREN, ADOLESCENTS AND OLDER ADULTS

In addition to the skills previously explained, there are further aspects to consider when communicating with children, adolescents, the older person and the individual's relatives and friends.

### Children

Ability with language and the processing of concepts and thoughts differs according to a child's age and developmental level. The nurse needs to adapt the style of communication according to these differences. Table 8.2 presents some basic guidelines for communicating effectively with children.

### Adolescents

As when communicating with anyone, all the skills that enhance effective communication are employed when talking with adolescents. Adolescents may be very sensitive to feelings of being judged or criticised, so it is important to be open minded when listening attentively to their feelings, ideas and opinions. It is helpful for adolescents to have expectations clearly explained and it enhances self-esteem when praise is given appropriately. Chapter 13 provides more information to assist the nurse when interacting with adolescents.

### The older person

Older people may need more time to respond during conversation or to answer questions because they have a large

**TABLE 8.2 | Guidelines for communicating effectively with children**

| Action | Rationale |
|---|---|
| Address parents first at the initial meeting, then the child | It is courteous to address the parents and the child at the start of the interview, but the focus should then move to communicating directly with the child |
| Put children at ease; for example, by asking their name, stating yours and talking about their friends/toys/pets/school | A child who is relaxed generally communicates quite freely |
| Talk directly to children (do not continually direct remarks or questions to the parents) | Demonstrates respect for the child. Sometimes in their anxiety parents tend to answer for their child; talking directly to the child helps to avoid this and demonstrates respect for the child and the child's feelings and opinions |
| Talk at eye level | Standing above a child is intimidating |
| Ask children questions that they can answer on their own. If parents are present, the nurse should look to them for confirmation or reply only when necessary | Establishes a relationship with the child and begins to develop trust |
| Explain any procedures or activity to be performed in terms the child can understand. Include the child in the discussion when a plan of care is being explained to the parents | Children are more likely to accept interventions if they know what to expect |
| Talk with a child as you would an adult; for example, be honest, do not disregard any information the child offers. Provide older children with the chance to speak without the parents present | Demonstrates respect for the child |
| Answer a child's questions honestly whenever possible. For example, if a child asks if a procedure is going to hurt, it is much better to be honest | If a child has been told that a procedure will not hurt, and it does, trust in the nurse will be reduced |
| Respect a child's confidences. If a child reveals information necessary for a parent to know, explain why this is so and suggest the child tells the parent. Otherwise seek the child's permission to talk to the parent about the matter (Arnold & Boggs 2011; Webb 2011) | Failing to respect a confidence destroys trust |

repertoire of experiences to draw on and sorting through them requires time. The process of retrieving a memory of an event and the words needed to express themselves may be slower than in previous years. This may be due to memory impairment associated with normal ageing. It may be mild, and many older people adapt to this change, but at times of stress, tiredness or when situations are demanding, the slowed ability to recall events and words may be much more noticeable. The nurse needs to be patient and allow older individuals adequate time to respond. If sure of a word the individual is searching to remember, it may help, after waiting a few moments, to provide it.

Older adults sometimes find it takes longer to absorb new knowledge, especially if the information does not connect to familiar concepts. Older and younger individuals alike find it more difficult to absorb information while anxiety levels are high. Giving new information to older individuals while they are ill, upset or anxious is likely to mean that they will be unable to recall it Nurses also need to consider that many older individuals will have age-related changes to hearing and vision that also impact on communication. Some older people may require written information with pictures to aid in recall and understanding (O'Toole 2012).

## COMMUNICATING WITH AN INDIVIDUAL'S RELATIVES, FRIENDS AND SIGNIFICANT OTHERS

The loved ones and friends of a sick person will often need support to help them cope with that person's illness. A person's illness can be a very disruptive episode in the lives of their significant others. They may need to discuss their concerns and share the frustrations of the illness. Table 8.3 and Clinical Interest Box 8.7 provide some general guidelines for communicating effectively with relatives, friends or others who are emotionally close to an individual who is unwell or who has died.

**TABLE 8.3 | General guidelines for communicating effectively with relatives and friends**

| Action | Rationale |
|---|---|
| Introduce yourself to the relatives and inform them that you are helping to look after their loved one | It is a common courtesy to greet all visitors regardless of whether or not they need support or information |
| Provide them with opportunities to express any concerns and anxieties | Simply having concerns heard can reduce stress |
| Include them in discussions about the individual's care when appropriate; for example, only when certain that the individual approves | Relatives have often been providing care at home for individuals before their admission to hospital and will often continue care after the individual is discharged from hospital. It is rude and dismissive of their care work to exclude them from care planning decisions |
| Offer opportunities to assist with care activities as appropriate | Often relatives like to feel useful, needed and involved |
| Answer their questions as appropriate (be aware of confidentiality issues) or refer questions to the nurse in charge | The unknown is often very stressful. Information is important in planning for what is still to come |
| Demonstrate warmth; for example, by touch, close proximity, body posture and facial expressions. This is of particular relevance when relatives are confronted with a loved one who is seriously ill or dying | When a loved one is sick or dying it helps to know others empathise |

## BARRIERS THAT INTERFERE WITH THERAPEUTIC COMMUNICATION

Several aspects of communication can impair effective communication, hinder the development of trust in a therapeutic relationship and damage an existing one. In addition to the inappropriate use of humour mentioned earlier, some other communication pitfalls act as barriers to therapeutic relationships that nurses need to be aware of and avoid. They are not hard to fall into inadvertently, but also they are not hard to avoid once aware of them. Using the basic communication skills previously outlined, together with avoiding the pitfalls, will enhance every relationship and facilitate therapeutic relationships between nurses and individuals. Because of the emotional content of many nurse–individual interactions, the potential for nurses to inadvertently put up barriers if they are not aware of them is high. Sometimes nurses unknowingly use communication barriers as a way of protecting themselves from uncomfortable feelings. Examples of these include changing the subject inappropriately, offering false reassurances and using clichés (Arnold & Boggs 2011; Stein-Parbury 2014). A list of barriers that block effective communication is provided in Clinical Interest Box 8.8.

### Changing the subject inappropriately

People sometimes change the subject when they are uncomfortable with, or unwilling to discuss, a specific topic. For example, an individual may say to a nurse, 'I feel so weak, I don't think I am going to be around for much longer.' If the

## CLINICAL INTEREST BOX 8.7 Communicating with family and friends after a loved one has died

- Be aware that people who are grieving will tend to work through five stages: denial, anger, bargaining, depression and acceptance. Each person moves through theses stages at a different rate or sometimes remains in one stage. Provide support regardless of the response.
- Listen and reflect feelings
- Avoid using platitudes or clichés (e.g. 'It will be OK', 'It was for the best')
- Don't give advice (e.g. 'Calm down', 'Don't think about it')
- Give honest and complete answers to questions
- Avoid ambiguous phrases such as 'He has gone to a better place'
- Express empathy (e.g. 'I am so sorry for the loss of your mum', 'It must be such a shock for you')
- Offer practical assistance and accommodate their needs as much as possible (e.g. 'Is there anyone you would like me to call?', 'Would you like me to stay with you?')
- Ensure that your non-verbal signals indicate that you have time to listen and support the grieving person
- Don't change the subject if the grieving person wishes to talk about their loved one.

*(Arnold & Boggs 2011; Dosser & Kennedy 2013; Scott 2013)*

## CLINICAL INTEREST BOX 8.8 Barriers to effective communication

- Stereotyping, labelling or pre-judging the speaker
- Talking, not listening
- Becoming distracted or daydreaming
- Asking leading questions
- Asking 'Why?' questions
- Asking too many probing (perceived as prying) questions
- Listening only to content; not hearing feelings
- Not attending to non-verbal cues
- Overuse of closed questions
- Finishing the other person's sentences
- Offering false reassurance or using clichés
- Criticising and judging
- Preaching or moralising
- Interrupting
- Advice giving
- Jumping to conclusions
- Incongruent body language
- Being defensive
- Changing the subject inappropriately

*(O'Toole 2012; Stein-Parbury 2014; Renske van Bruinessen et al 2013)*

nurse feels unable to deal with the feelings the individual has raised, they may abruptly switch the conversation to a more comfortable area by saying, 'You shouldn't dwell on that. Let's get you washed—where are your things for the shower?' The individual gets the message, accurate or not, that the nurse is not sensitive to their concerns. The nurse misses the opportunity to be helpful because the individual is denied the opportunity to discuss their feelings, and therapeutic communication between the two is blocked.

### False reassurance

A nurse may try to alleviate emotional discomfort with an individual's concerns, or an inability to cope with what an individual is expressing, by giving false reassurance. Such responses are often automatic, trite, and in the form of clichés or platitudes, such as, 'You'll be right' or 'Don't worry, it'll work out'. These do nothing to allay anxiety. In fact, the individual may become more anxious, wondering if the nurse is trying to hide something about their condition. As with inappropriate changes of topic, responses that offer false reassurance can make individuals feel that their anxieties are being dismissed and do not matter, and that as a person they are of no importance to the nurse. Because platitudes and clichés are often automatic, the nurse may need to rescue the situation if one has been uttered without thinking. For example, after saying, 'Don't worry, you'll be right' the nurse might rescue the situation by saying, 'Still that's easy for me to say, isn't it? You sound as though you are really worried that things are not going well'.

It is, of course, appropriate to provide comforting reassurance when it is needed, but reassurance should always be based on honesty, and the individual's feelings should be explored and clarified. It would, for example, be appropriately reassuring to say, 'Don't worry, it is usual to be weak after the operation you have had, and it is usual to get stronger within a few days'. Nurses need to listen for the feelings being expressed by individuals, and respond appropriately to those feelings and anxieties, no matter how disturbing they may be. It is only by doing so that nurses can communicate caring and offer the comfort that individuals need. It is one of the challenges of nursing to develop a range of skills to respond therapeutically to the many intimate and intense emotions expressed by individuals. Many nurses choose to undertake courses specifically designed to develop self-awareness and extend basic counselling skills (Stein-Parbury 2014).

### Being defensive

A defensive response is most often the result of a nurse feeling judged negatively or unfairly when an individual complains, or feeling the need to defend other members of the healthcare team who are being criticised. For example, when an individual says something like, 'I've been waiting ages for someone to redress this leg ulcer, this is the third time I've asked for it to be done', it might be tempting to retaliate and say, 'Well, it's not my fault, we're short-staffed and we've been run off our feet today.' Retaliation such as this is a defensive and

antagonistic response and likely to annoy the individual further. It brings the focus on to the feelings of the nurse rather than those of the individual. By being defensive rather than demonstrating an understanding of the individual's point of view, the nurse becomes an adversary rather than a therapeutic helper. It is more helpful to reflect the individual's feelings with a reply such as, 'Yes, I'm sorry, it's upsetting to have been waiting so long.'

Being defensive when criticised implies that the individual does not have the right to show feelings or state an opinion. When individuals complain, the nurse can defuse negativity and anger by listening uncritically to what the individual has to say. It is often appropriate for the nurse to explore whether or not there are deeper concerns underlying the cause of an individual's complaint. In a therapeutic relationship the nurse might choose to facilitate the individual expressing deeper feelings or concerns by tentatively saying something such as, 'You sound as if you feel you are not getting the care you need.'

In certain situations individuals may not be in control of their angry feelings. (Chapter 39 focuses on mental health and incorporates strategies that can help the nurse to cope with and help individuals who are aggressive or demonstrate other unacceptable ways of communicating.)

### Offering advice or giving an opinion

When an individual asks a nurse for advice such as, 'What would you do?' it is appropriate and therapeutic to share information about available options and provide an opportunity to discuss them. When advice or a personal opinion is offered, the focus moves onto the nurse. This may mean that the individual is swayed to do what the nurse considers best and may not consider all the options effectively in relation to themself and their own life situation. What may be the right decision for one person may not be the right or best decision for another. It is empowering and therefore therapeutic for individuals to have control of decisions and make their own informed choices. Providing information about options and educating individuals are important components of a nurse's role, but providing advice is different and can cause problems. For example, giving advice or a personal view about treatment options may lead to an individual accepting that advice as expert advice and later blaming the nurse for a real or perceived negative outcome.

Using the communication skills of active listening, asking questions, clarifying, paraphrasing and reflecting and avoiding the communication pitfalls are important in all interactions with individuals and others.

## CULTURALLY SAFE COMMUNICATION

Individuals who do not speak the same language as the nurse or who come from a different cultural background also have special requirements, and it may be necessary to communicate through an interpreter (Department of Health and Human Services 2014). Culture influences how each individual perceives and responds to the world, and performs and interacts with others. Although there are many definitions of **culture**, it may be defined as 'a complex social concept that encompasses the entirety of socially transmitted communication styles, family customs, political systems, and ethnic identity held by a particular group of people' (Arnold & Boggs 2011). Nurses must have an understanding of the importance of culture as it relates to communication and be aware of their own beliefs and how this might affect the care given to people from a different culture. It is especially important that nurses are aware of any stereotypes they have about different ethic or cultural groups. This may severely impact the level of care provided. For example, if a nurse believes that a woman complaining of pain is exaggerating because 'this is how people from that country behave' then proper assessment and intervention will not occur. Culturally sensitive nursing skills and knowledge will be necessary to provide competent care to the rapidly changing multicultural population (Stein-Parbury 2014).

To value cultural and ethnic diversity involves the appreciation of variations in culture as well as negotiating skills for effective communication. Communication with individuals from diverse backgrounds is especially complex because of the influence of culture on language and communication. When communicating with individuals, the nurse should be aware of cultural beliefs and behaviours and communicate (both verbally and non-verbally) in a way that meets the individual's cultural needs. Strategies include not assuming English proficiency, taking time, speaking clearly and slowly (avoiding the use of jargon and colloquialisms), observing non-verbal cues and checking for understanding (Department of Health and Human Services 2014; O'Toole 2012). Be aware that checking for understanding involves more than asking a closed question such as 'Do you understand?'. Individuals may lie and say 'yes' because they feel ashamed or do not want the nurse to 'lose face'. See Chapter 10 for further reading on cultural diversity.

### CRITICAL THINKING EXERCISE 8.1

Mrs Jackson, 75, was admitted with anaemia for investigation. She underwent a colonoscopy and a rectal mass was found. Her surgeon has just told her that it is most likely malignant, but that they will need to wait for the biopsy results before a definitive diagnosis can be made. After he leaves she is visibly upset. How can the nurse help to communicate with Mrs Jackson at this time?

## INDIVIDUALS WITH SPECIAL REQUIREMENTS

A variety of conditions can impede the ability to communicate effectively. Individuals with these conditions have special requirements. Some of the more common of these conditions include alterations in vision, hearing and speech ability,

cognitive impairment or a total inability to communicate, generally associated with the individual who is unconscious or dying.

## Alterations to vision

Some individuals will have partial or total inability to see what is in the environment. When individuals have reduced vision it can interfere with the ability to see another person's body language, so verbal communication must be particularly clear, and touch used as effectively as possible. Individuals with vision impairment experience vision loss differently, so careful individual assessment is necessary to determine needs. The aim of care for every individual with reduced vision includes promoting a sense of security, ensuring safety and comfort, and facilitating effective therapeutic communication. Table 8.4 provides advice for facilitating effective communication with individuals who have reduced vision. Entering a new environment for the first time can be a frightening experience, and even more so when vision is reduced, so effective and clear communication explaining who and what is in the environment, especially potential dangers, is vital.

## Alterations to hearing

The individual who is experiencing hearing loss, either temporary or permanent, needs assistance to adjust to the physical and psychosocial implications. The main way to assist the individual with impaired hearing is to maintain and improve the ability to communicate. Table 8.5 provides advice for facilitating effective communication with hearing-impaired individuals. If an individual has a hearing aid it must be maintained in good working condition and used correctly.

## Alterations to speech

Imperfect articulation of speech (dysarthria) is related to neurological damage that causes alterations to the muscles (primarily of the mouth and tongue) involved in the act of forming words. People with a condition called receptive aphasia (often resulting from damage to the temporal lobe of the brain or a central lesion) are unable to understand what someone else is saying. For example, the person may hear the word fork and recognise it as a familiar word but be unable to attach the word to the object it represents. If individuals have expressive aphasia (often caused by damage to the frontal lobe of the brain) it means they are unable to clearly express what they want to say or what they are feeling. For example, the individual may say the word 'yes' when meaning 'no' or may cry instead of laugh. Often individuals have receptive and expressive aphasia together. This is very frustrating for them and the nurse has an important role in communicating in a way that promotes rehabilitation. When caring for individuals experiencing speech difficulties, the nurse usually collaborates closely with a speech therapist. Table 8.6 provides advice about communicating therapeutically with individuals experiencing speech difficulties.

A range of practical communication aids can help individuals with visual, hearing or speech impairments. Some examples are provided in Clinical Interest Box 8.9.

## Alterations to cognitive abilities

The first step in communicating with an individual who is cognitively impaired is to assess the level of impairment. This may range from a minor difficulty in remembering the meaning of words or simple phrases to a total inability to comprehend what is being said, or to express thoughts and ideas. The nurse adjusts communication techniques according to the needs of individual individuals. Depending on the level of impairment it may or may not be necessary to:

- Speak more slowly
- Make gestures more pronounced
- Remind individuals who you are each time you address them
- Use very simple one-step-at-a-time instructions; for example, when assisting individuals to get dressed or clean their teeth

### CLINICAL INTEREST BOX 8.9 Communication aids for individuals with visual, hearing or speech impairments

Communication aids to help visually impaired people:

- Magnifiers
- Talking books (novels as audiobooks, etc)
- Braille books and documents
- Guide dogs
- Enlarged-print books
- Modified telephones
- Canes.

Communication aids to help hearing-impaired people:

- Hearing aids
- Telephone, radio and television amplifying devices
- Telephone typewriter devices
- Picture boards
- Television caption devices
- Shake awake clocks.

Communication aids to help people with impaired speech:

- Call bells and alarms
- Sign language
- Pen and paper or magic slate
- Electronic voice devices
- Communication board with commonly used words, letters or pictures that indicate needs (e.g. a drink, toilet)
- Use of eye blinks for simple responses (e.g. one blink indicating yes, two blinks indicating no)
- Artificial voice box (vibrating device helpful for individuals who have had a laryngectomy).

*(Arnold & Boggs 2011; Department of Health 2012)*

**TABLE 8.4 | Facilitating effective communication with visually impaired individuals**

| Action | Rationale |
|---|---|
| Address the individual by name as you approach | Alerts the individual to your presence |
| Introduce yourself each time you enter the individual's room or area | Reduces stress when individual knows who is there |
| Tell the individual when you are leaving the room or area. If the individual enters an area where you are, alert them to your presence | It is courteous to let the individual know when you are leaving the room or when they have entered the presence of someone unseen |
| Orientate the individual to others who are in the area | Facilitates communication with others, reduces sense of isolation |
| Orientate individual to what items and sounds are in the area | Reduces stress from the unknown |
| Leave things where they are | Reduces risk of injury from trips or spills, increases individual's sense of security |
| Use a normal tone of voice | There is sometimes a tendency to speak loudly to visually impaired people, but it is of no help and can be irritating |
| Address the individual by name when addressing questions or remarks to them. In a group situation, each person should address each other by name as they speak to one another | Alerts the individual to who is being spoken to |
| Give step-by-step explanations of procedures as they are performed | Reduces fear of what is happening and prepares individual for the physical feelings associated with the procedure |
| Ensure the call bell is always within reach | Increases safety and sense of security |
| Do not assume a visually impaired person needs assistance—ask before initiating help | Many visually impaired people have adapted to their condition and function independently. They may resent an assumption that help is needed when it is not |
| If the individual needs assistance moving around an area:<br>• Stand just in front of the individual with your elbow bent at a 90° angle<br>• Have the individual grasp your elbow and follow<br>• Alert individual to potential dangers such as stairs, changes in levels and other barriers<br>• Guide the individual's hand to handrails or other useful aids that might facilitate them moving around more independently | This method of assisting visually impaired individuals is safe because the nurse is looking towards the front. It is respectful because the individual actively follows rather than being pulled by the arm or hand, which might feel degrading<br>Maintains safety; for example, prevents accidental falls<br>Independence promotes a sense of wellbeing |
| To assist the individual to sit in a chair, place one of their hands on the back or arm of the chair and give them time to locate the seat area | Assists the individual to sit down with minimal assistance. Demonstrating understanding of how to communicate information enhances therapeutic relationship |
| Explain the location of food and beverages on the table. The clock face technique can help describe food on the plate; for example, the potato is at nine o'clock | Communicating this information clearly aids independence and enhances mealtime pleasure. Communicating the practical information establishes a trusting relationship that prepares the way for communication of other deeper and more personal issues |

**TABLE 8.5 | Facilitating effective communication with hearing-impaired individuals**

| Action | Rationale |
|---|---|
| Reduce or eliminate background noises | Minimises competing sounds |
| Ensure adequate lighting | The individual can see facial expressions and body language clearly to receive non-verbal messages |
| Approach from the front or the side, not from behind | Approaching from behind can startle the individual |
| If necessary gain the individual's attention by gently waving your hand in their line of vision or lightly tapping their shoulder | Communication is not possible until the individual is actively concentrating on the communicator |
| Face and look directly at the individual when speaking. Allow a clear view of your face by placing yourself near a light source | Clear vision is essential to read facial expressions and body language. Shadows and glares affect the individual's ability to see your face clearly |
| Ensure spectacles, if they are worn, are clean | Individuals who can lip-read need a clear view of the communicator's lips |
| Check hearing aids are in place and working effectively | Individuals do not always wear hearing aids all the time |
| Speak towards the individual's ear that has the greater hearing capacity | This uses remaining hearing ability to advantage |
| Speak clearly and at normal or only slightly higher volume than normal. Speak at normal rate unless the individual indicates that speaking slowly is a help: do not shout or over-exaggerate speech | Louder sounds mean a higher pitch of voice is used. A higher pitch means that vowels are accentuated and consonants become concealed. Therefore a loud voice or shouting does not help. If a louder voice is used, a lower tone and pitch must be used |
| Rephrase if words are not understood | Rephrasing the statement with different words may make lip-reading easier |
| Keep your hands away from your mouth and avoid chewing or smoking while speaking | Covering the mouth reduces the ability to lip-read |
| Clearly state the topic of conversation | Individual can focus on the topic—knowing words likely to be included in the conversation may facilitate easier recognition of words associated with the topic |
| Do not turn or walk away from the individual while still talking | Reduces individual's ability to decipher messages from facial expressions or to lip-read |
| Consciously use gestures and body movements to help clarify meanings | A large proportion of communication occurs via facial expressions and body language |
| If there continues to be difficulty, use written communication or other communication aids | Resorting to other methods of communication is less frustrating for the individual than not receiving messages at all or receiving them inaccurately |

- Ask only very simple closed questions
- Give very clear and basic explanations.

When people cannot comprehend what is being said or cannot find the words to express their own thoughts, it can be very frustrating and embarrassing for them and also challenging for the nurse. It can sometimes take patience and effort to include cognitively impaired individuals in conversations, and nurses should be wary of excluding them, for example, by speaking to each other over or across the individual. Excluding individuals who are cognitively impaired from conversations reinforces feelings of low self-worth; conversely, including them promotes feelings that they are valued and worthwhile. Disorders that cause dementia, such as Alzheimer's disease, are among the most common causes of cognitive impairment.

Table 8.7 provides advice to facilitate communication with individuals who are experiencing some of the more severe symptoms of a dementing illness. These include

**TABLE 8.6 | Communicating therapeutically with individuals experiencing speech difficulties**

| Action | Rationale |
|---|---|
| Face directly and make eye contact. Listen attentively, allow time for responses. Do not take over and complete sentences for the individual | The aim is to help individuals re-learn how to speak—they need to work hard at this and they need to practise. They may give up if nurses deter efforts by pre-empting what they are about to say |
| Use short phrases and simple, closed questions | This encourages progress |
| Let the individual know that you do not understand: never pretend that you do | Honesty demonstrates respect for the individual. The individual can sense when not understood and feels patronised and upset if the nurse is not honest about it |
| Be consistent, use the same words and gestures each time you give an instruction or ask a question | Consistency promotes success in communicating effectively and this encourages further practice |
| Clearly match up items with words | Aids rehabilitation |
| Use a communication picture board only as a back-up resource | The aim is to encourage the individual to practise verbal expression |
| Take care not to exclude individuals from conversations | It takes patience to communicate with and encourage speech-impaired individuals, it may be easier to exclude them but it is not therapeutic and it does not promote rehabilitation |
| Ensure only one person is speaking at a time | The individual will have difficulty focusing on more than one speaker and may become dejected when unable to follow and join in conversation |
| Do not shout or speak loudly | A raised voice does not help and can cause distress |

significant memory loss, decreased sense of personal identity, loss of language and communication skills, disorientation and difficulty with visual perception. Individuals with a dementing illness are most commonly in the older age group and so frequently experience the additional difficulties of reduced hearing and vision associated with the normal ageing process. This means that, in addition to using dementia-specific communication skills, the nurse must use the communication skills specifically relevant to vision and hearing impairment. In particular this means that the nurse must be aware of which individuals need to wear hearing aids or glasses, as the individuals themselves may no longer remember that they need them or how to put them on. Case Study 8.1 explores communicating with people who have dementia.

### Individuals who are unable to respond

Some individuals are unable to communicate at all; for example, those who are not conscious. It may be difficult at first to speak to a person who does not respond, with whom you have no eye contact and from whom you receive no feedback of any sort; however, it becomes easier with only a little practice. Even when individuals are unable to respond it should be assumed that they can hear when spoken to and feel when touched (Arnold & Boggs 2011).

Effective communication with individuals who have special needs involves assessing and responding to the individual needs of each individual. Planning effective measures includes adapting basic therapeutic communication techniques and adding extra communication strategies relevant to the individual's particular impairment. These strategies need to be implemented and other appropriate communication aids accessed, including other health professionals, such as speech therapists. The success of care is evaluated by how well the individual feels able to communicate needs, feelings and thoughts. Signs that the individual is withdrawn, anxious, aggressive or frustrated indicate that therapeutic communication may not be at a high level. When a nurse feels frustrated or irritable with an individual it may indicate the same thing, and that means communication techniques need to be reviewed and improved.

## COMMUNICATION WITHIN THE HEALTHCARE TEAM

There is now much evidence that communication within the healthcare team is essential to the provision of quality care and individual safety (Kleiner et al 2014; Wheeler 2014).

The Australian Commission on Safety and Quality in Health Care (ACSQHC) has placed emphasis on the clinical

## TABLE 8.7 | Facilitating communication with individuals with dementia

| Action | Rationale |
|---|---|
| Ensure that you can be seen and heard before addressing the individual by name. Sit, stand or kneel so you gain eye contact. Touch the individual gently to attract attention if necessary | Individual may not respond if simply called by name without the other cues |
| Minimise distractions | Damage to the brain leaves little ability to screen out extraneous noise |
| Introduce yourself each time you communicate with the individual, if necessary | The individual may not remember who you are from one encounter to the next |
| Be aware of how you present yourself | When words are not understood, facial expression, body language and appearance are what the individual responds to most. A smile rather than a frown is appealing |
| Be aware of the feelings you transmit and the atmosphere you create; for example, keep tone of voice warm and low, move about calmly | Feelings of tension, irritability or a sense of being rushed will upset and may frighten a disoriented and confused individual. A calm, relaxed approach helps the individual remain relaxed. Relaxed individuals are more likely to agree to what the nurse is asking of them. A nurse who is rushed or agitated will create the opposite effect |
| Begin your conversation socially; for example, talk about a reassuring topic such as the weather—don't rush into asking the individual to do things, and always ask, do not order | Helps to gain the individual's trust. Gaining trust before asking the individual to agree to tasks, such as having a shower, facilitates cooperation. The individual is more likely to agree when asked rather than directed to do something |
| Keep messages short, simple and specific. Give one message at a time | The individual may have only minimal understanding of words |
| Use questions that require a yes/no answer, rather than open-ended questions | A question such as, 'Is this the dress you would like to wear today?' is less complicated to understand and answer than, 'What would you like to wear today?' |
| Use statements more than questions | Asking questions that an individual cannot remember how to answer may trigger a negative response and the individual might interpret questions as 'prying' and feel resentful. Statements may be more acceptable and they tend to elicit interest; for example, 'That cat looks hungry.' |
| Back up words with gestures. Show as well as tell; for example, point to clothes that are placed ready to put on | Aids understanding |
| Pause between sentences and allow plenty of time for the information to be understood. Wait for a response | Allows time for a damaged brain to process messages |
| Repeat or rephrase the message if there is no response—several times if necessary | Some words may be recognised when others are not |
| Look and listen for other cues when speech doesn't make sense; for example, facial expressions and gestures can reveal emotions | Detecting the individual's underlying feelings provides clues as to an appropriate response |
| Respond by reflecting feelings | Reflecting feelings; for example, 'That makes you feel angry, doesn't it?' shows understanding even if you are not sure of what caused the emotion. Being understood has a positive effect on self-esteem |

**TABLE 8.7 | Facilitating communication with individuals with dementia—cont'd**

| Action | Rationale |
|---|---|
| Break tasks down into small steps | Everyday tasks are made up of a series of complicated actions stored in the memory. The individual may feel overwhelmed at not being able to remember how to manage a complete task; for example, to get undressed. But may manage independently if prompted what to do at every step; for example, undo buttons, take this arm out of the sleeve, etc. This approach enables tasks to be completed successfully and can be satisfying and pleasurable for nurse and individual |
| Use touch therapeutically, provided that the individual does not indicate a dislike of being touched | Touch is a powerful medium to impart caring and can be reassuring when words are not understood. An arm around the shoulder or a squeeze of the hand can convey more than words. A hand or foot massage can have a calming effect |

## CASE STUDY 8.1

Isabelle is an 87-year-old resident at 'Happy Days' nursing home. She has dementia and is very confused and often agitated. You and another nurse are caring for the residents this morning. Both of you are from a nursing agency and have not cared for Isabelle before. You notice her walking along the corridors with her walking frame. She is trying to open all the doors leading outside but to no avail. She stops whoever walks past her and demands that they help her. You can hear her yelling, 'They've got me prisoner. Please help me get out. I have to get to my children'. The other nurse rushes up to Isabelle and with her face close to hers yells in a loud voice, 'Stop being silly. You are not being kept prisoner!. You are annoying everyone. Get back to your room'. Upon hearing this Isabelle lets out a scream and starts moaning and crying and tells the nurse to leave her alone and becomes more agitated and distressed. Witness to all of this is Isabelle's daughter who has just arrived to visit her mother. She approaches the nurse and looks very angry. She yells, 'You stupid nurse! How dare you speak to mother like that!' The daughter turns to you and says, 'I've had enough of this. You're all incompetent and don't care about anyone!'

1. What are some communication strategies that should be used when communicating with people who have dementia?
2. What could you have said to Isabelle when you initially saw her becoming increasingly distressed as she was trying to leave?
3. What non-verbal strategies would you have used?
4. What resources could you have used to assist you in communicating with Isabelle?
5. What strategies would you use to resolve the situation of conflict with Isabelle's daughter?

handover as the lynch pin to improving inter health team member communication. As such they have produced the 'OSSIE guide to clinical handover' (ACSQHC 2012) as a framework to assist clinicians improve health team communication. OSSIE is a mnemonic which equates to a framework for change management. Each letter in the mnemonic stands for a change phase:

- **O**rganisational leadership
- **S**imple solution development
- **S**takeholder engagement
- **I**mplementation
- **E**valuation and maintenance.

The framework was developed to improve clinical handovers in healthcare. The OSSIE guide states: 'Current handover processes are unreliable and highly variable. Standardisation of handover content and process will improve the safety of handover by ensuring consistency in critical information exchanges.' It defines clinical handover as 'the transfer of professional responsibility and accountability for some or all aspects of care for a patient, or group of patients, to another person or professional group on a temporary or permanent basis'.

The basis of the framework comes from the SBAR communication model. The SBAR acronym stands for **S**ituation **B**ackground **A**ssessment **R**ecommendation.

SBAR is an organised and systematic process to ensure effective communication when relating an individual's condition to other members of the healthcare team.

The OSSIE guide to clinical handover expands further on this technique and has developed the **ISOBAR**:

- **I**dentification
- **S**ituation
- **O**bservations
- **B**ackground
- **A**ssessment and action
- **R**esponsibility.

## CRITICAL THINKING EXERCISE 8.2

Using the SBAR communication tool detailed in Table 8.8, how would you hand over the details of the following situation? What recommendations would you make?

Mr Jones, 48, had a right total knee replacement 2 days ago. About 1 hour ago he started complaining of chest pain. His pulse is 116 and his blood pressure is 126/58. He is restless and short of breath. You have just started oxygen at 4 L/min via the nasal prongs.

See Clinical Interest Box 8.10 for a detailed explanation of ISOBAR.

On completion of this chapter, review Nursing Care Plan 8.1. This sample demonstrates that effective communication was vital to developing appropriate nursing care.

## CLINICAL INTEREST BOX 8.10 ISOBAR

| | |
|---|---|
| I | Identification of individual<br>This step, which ensures individuals are correctly identified, should include three identifiers; for example, individual name, date of birth and medical record number. |
| S | Situation and status<br>This step includes the individual's current clinical status (e.g. stable, deteriorating, improving), advance directives and individual-centred care requirements including the prospect of discharge or transfer. |
| O | Observation<br>This step ensures the incoming team is informed of the latest observations of the individual and when they were taken. It serves as a checking mechanism to identify deteriorating individuals for emergency response assistance. Unit members need to be aware of local emergency response call criteria and process. |
| B | Background and history<br>This step provides the incoming team with a summary of background; history (the presenting problem, background problems and current issues); evaluation (physical examination findings, investigation findings and current diagnosis); as well as management to date and whether it is working. |
| A | Assessment and actions<br>This step is to ensure that all tasks and abnormal or pending results are clearly communicated. Most importantly, there must be an established and agreed management and escalation of care plan, which could include:<br>• A shared understanding of what conditions are being treated or, if the diagnosis is not known, clear communication of this fact to everyone<br>• Tasks to be completed<br>• Abnormal or pending results (must include recommendations, the agreed plan and who to call if there is a problem)<br>• A plan for communication to the senior in charge<br>• Clear accountability for actions. |
| R | Responsibility and risk management<br>Clinical handover must include the transfer of responsibility as staff are leaving the institution.<br>This can only be achieved through acceptance of tasks by the incoming team, which is best ensured by face-to-face handover. Where risks are identified for an individual, clinical risk management strategies (such as for infectious disease alerts or alerts for DVT prophylaxis) should be clearly communicated.<br>Responsibility transfer and task acceptance ideally includes accepting handover sheets or signing of handover sheets.<br>Read back of critical information is helpful, especially in situations where face-to-face handover is not possible.<br>Risks and management plans should be included in handover when required. |

## NURSING CARE PLAN 8.1

Mary was not able to explain to me the medical procedure she was having today. She told me she was very frightened and thought she might die. I explained the procedure to her again and answered her questions. She was able to explain it back to me and told me that she doesn't feel as anxious any more. She stated that she will go ahead with the procedure. She informed me that she suffers from anxiety and is very worried about how she will cope when she is discharged.
**Assessment:** Anxiety due to concerns about ability to cope upon discharge
**Issue/s to be addressed:** Medication review—at present not on anti-anxiolytics or anti-depressants
**Goal/s:** Mary verbalises reduced level of anxiety and is able to state processes which are in place to improve her ability to cope when discharged

| Care/Actions | Rationale |
|---|---|
| Spend time with Mary encouraging her to discuss her worries and concerns | If interest and concern are demonstrated Mary will be more likely to talk about her worries. Verbalising concerns decreases anxiety |
| Explain the role of allied health and the assistance that they will be able to provide | Knowledge of the support services available will provide reassurance to Mary |
| Provide empathy and develop a therapeutic relationship with Mary | Mary will be more willing to discuss her concerns if she feels accepted and trusts the caregiver |
| Collaborate with allied health | Improved health outcomes occur when all healthcare professionals collaborate and share knowledge |
| Provide information regarding the action and side effects if anti-anxiolytics or antidepressants are commenced | Increased knowledge will reduce anxiety |
| Monitor for negative side effects if anti-anxiolytics or antidepressants are commenced | Early intervention will ensure strategies can be implemented such as further education or change of medication |

**Evaluation**

Mary reported a much lower level of anxiety since admission
Mary was able to state the services and support that she will receive at home after discharge

## TABLE 8.8 | SBAR

SBAR is a communication tool that can be used by any/every discipline, and in any situation—routine or emergency.
Routine examples include:
- Ward nurse to pharmacy
- Medical to allied health referral
- Hospital to community referral

| | |
|---|---|
| **S**ituation | I am calling about … (state individual name and location) |
| | The individual's condition is … (code status) |
| | The issue/problem I am calling about is … |
| | I have just assessed the individual personally: Vital signs are: Blood pressure _____/_____, Pulse _____, Respiration _____ and Temperature _____ |
| | I am concerned about the: (state the abnormal findings, e.g.:)<br>• Blood pressure because it is over 180 or less than 90 systolic, or 30 mmHg below usual<br>• Pulse because it is over 140 or less than 40/min<br>• Respiration because it is less than 10 or over 30/min<br>• Temperature because it is less than 35.5°C or over 38°C. |
| **B**ackground | The individual's mental status is: (give examples, e.g.:)<br>• Alert and oriented to person place and time<br>• Confused and cooperative or non-cooperative<br>• Agitated or combative<br>• Lethargic but conversant and able to swallow<br>• Stuporous and not talking clearly and possibly not able to swallow<br>• Comatose, eyes closed, not responding to stimulation. |

*Continued*

**TABLE 8.8 | SBAR—cont'd**

| | |
|---|---|
| | The skin is:<br>• Warm and dry/pale/mottled/diaphoretic<br>• Extremities are cold<br>• Extremities are warm. |
| | • The individual is not or is on oxygen.<br>• The individual has been on _____ (L/min) or _____ (%) oxygen for _____ minutes (hours)<br>• The oximeter is reading _____%<br>• The oximeter does not detect a good pulse and is giving erratic readings. |
| **A**ssessment | This is what I think the problem is: (say what you think is the problem, e.g.:)<br>• The problem seems to be cardiac/infection/neurological/respiratory _____<br>• I am not sure what the problem is but the individual is deteriorating<br>• The individual seems to be unstable and may get worse—we need to do something. |
| **R**ecommendation | I suggest or request that you (say what you would like to see done, e.g.:)<br>• Transfer the individual to critical care<br>• Come to see the individual at this time<br>• Talk to the individual or family about code status<br>• Ask the on-call family practice resident to see the individual now<br>• Ask for a consultant to see the individual now. |

## Summary

Communication is a process of sharing experiences, ideas, attitudes, values and feelings. It occurs at different levels, and communication at the interpersonal level is core to the provision of effective nursing care (Berman et al 2015). Messages between people are communicated via visual, auditory, tactile and olfactory channels, but many other factors or variables come into play. The individual attitudes, values and beliefs, levels of knowledge, past experiences and current physical and emotional status are some of the many variables that influence the effectiveness of communication between people. It is now an accepted fact that communication and individual safety go hand in hand (Kleiner et al 2014; Wheeler 2014), so it is therefore essential for nurses to gain an awareness of their own level of communication competence and the skills necessary to enable effective therapeutic communication (Webb 2011).

Some of the essential skills include interpreting verbal and non-verbal messages, the use of open and closed questions, clarifying, paraphrasing and reflecting feelings to ensure communication with individuals and others in the workplace promotes high-quality, safe care (Thomas et al 2009). Additional skills are needed to communicate effectively with individuals who have special needs, such as those who are experiencing sensory and cognitive impairments. The most effective nurses, as communicators, listen to individuals and are able to explore what the illness experience really means to each individual, facilitate understanding and foster the development of a helpful and therapeutic relationship.

The nurse who has effective communication skills:

- Listens attentively to others
- Assists individuals to communicate their needs
- Clearly communicates information to individuals, their relatives and other members of the healthcare team
- Accurately relays information to personnel in other healthcare agencies
- Responds empathically to feelings experienced by individuals and their relatives
- Considers culture, both theirs and the individual's, as a barrier to effective communication (Jones 2012).

## Review Questions

1. Identify the components of the communication process.
2. List the factors that influence effective communication.
3. What are the factors that act as barriers to effective communication?
4. What communication aids can be used for individuals who have visual, hearing or speech impairments?
5. Why is communication an essential determinant in the success or failure of a nurse–individual relationship?
6. What is the benefit of open questioning?
7. Convert the following to open questions:
   Do you feel angry?
   How many siblings do you have?

Do you love your partner?
Do you agree with your parents often?
Are you sick?
Do you like being in hospital?

8. What is paralanguage and why is it important?
9. Choose which of these responses would be most appropriate. Why? Explain why the other responses act as barriers.

Scenario 1

'I'm just so fed up with being sick and in pain. I'm tired of having to rely on the nurses all the time.'

a. Just relax and let us help you
b. Come on, now. Stop being so negative.
c. Sounds like all of this is really starting to get you down.
d. Well, if you don't want my help I'll go.
e. What is bothering you the most?

Scenario 2

'I never really looked after myself. Now look how I am suffering.'

a. There are lots of people worse off than you.
b. Well, you would have looked after yourself if it mattered to you
c. Sounds like you feel upset that you neglected your health?
d. Seems like you are angry with yourself?
e. Let's get you out of bed and into the shower. That will make you feel better.

Scenario 3

'Don't bother with me. I'm going to die anyway.'

a. You sound really fed up with everything.
b. Don't talk like that. You are not going to die.
c. Tell me more about how you are feeling.
d. The doctor says you could have at least 3 more months. I think you should be more positive and try to enjoy your last days.
e. You're old now so it's natural to want to die.

Scenario 4

'The surgeon explained everything about the operation, but I didn't understand what he said. I didn't even know what to ask.'

a. Let's get your medications organised.
b. So you feel worried because you don't understand what's going on with the operation.
c. What information was confusing to you?
d. If I were you I would tell the surgeon that I want some answers.
e. Don't worry about it. You don't need to know that stuff. It's too complicated for you to understand.

Scenario 5

'I get so tired looking after David day after day. There is all the physical care, but I think the mental strain is the worst. I worry constantly about where he is and what he is doing. I'm sure he is sick of me looking over him. The worst thing is that it's constant. There is no relief.'

a. The constant worry seems to be really getting to you and it is the thing that is wearing you down the most. You feel like you just can't seem to get away from it.
b. Oh, I get tired too. That's life. You'll be OK.
c. Try to put the worry out of your mind at least once each day. Make yourself a cup of tea, sit down and just relax.
d. You sound a bit guilty. Maybe you're thinking about the times that you could have been more supportive of David.
e. It's never-ending for you and you're exhausted.

10. Write down what you might say to this person using assertive communication. Use the 'How to communicate assertively and resolve conflict' handout as a guide. In situations where there is a potential for conflict what else would you do?

a. Your friend is driving too fast and dangerously while you are a passenger in his car and you would like him to slow down.
b. Mr James had a TKR (total knee replacement) 8 days ago. He is waiting for the physiotherapist to assess him before he can be discharged from hospital. He has been pacing up and down the corridor all morning and has yelled at you twice that he's 'sick of this bloody place and hanging around here doing nothing'.
c. A patient (Jess) is very demanding of your time and keeps pressing the buzzer and asking you to do tasks that she can easily do herself. As a consequence you are falling behind with your work and are running out of time to administer medications to all of your patients.

Answer guide for the Review Questions, Critical Thinking Exercises, Decision-Making Framework Exercises and Critical Thinking Questions in Case Studies are hosted on Evolve: http://evolve.elsevier.com/AU/Koutoukidis/Tabbner/

CHAPTER 9

# Models of nursing care, management and leadership

*Gabrielle Koutoukidis*

## KEY TERMS

autocratic (authoritarian) leader
bureaucratic leader
case management
charismatic leader
democratic (participative, consultative) leader
emotional intelligence
executive-level managers
frontline managers
individual allocation or total individual care
laissez-faire (non-directive, permissive) leader
leader
manager
mentor
preceptor
middle-level managers
models of care
primary nursing
shared leadership
task-oriented nursing
team nursing
transactional leader
transformational leader

## LEARNING OUTCOMES

At the completion of this chapter and with further reading, students should be able to:

- Define the key terms
- Compare and contrast leadership and management
- Compare and contrast different leadership styles
- Identify the characteristics of an effective leader
- Discuss the roles and functions of nurse managers
- Identify the skills required for effective nursing management
- Appreciate the nurse's role in managing and coordinating care
- Describe the role of the manager in planning for and implementing change
- Explore the role of the Enrolled Nurse in management and leadership
- Understand the relationship between leadership, management and mentoring
- Develop an understanding of the different models of clinical nursing care
- Discuss the factors that influence an individual's leadership style
- Discuss the competencies required for future nurse leaders

## CHAPTER FOCUS

Nurses in contemporary healthcare organisations are at the forefront of planning and managing care, directing the agenda of healthcare delivery in the policy setting as well as managing and delivering care in the preventative, acute, community and residential care settings (Crisp et al 2013).

As part of the disciplinary team, the nurse is often in a leadership position and frequently delegates aspects of care to others. There are opportunities within the nursing profession to become leaders at various levels and also many situations in which the nurse functions as a manager and as a change agent (Berman et al 2015).

This chapter focuses on the nurse as a leader and manager, leadership and management styles, models of nursing care and the skills and competencies of nurse managers required both today and for future workforce needs. This will assist the Enrolled Nurse to have a greater understanding of leadership and management in the work environment and their role and scope of practice within management and leadership roles, including models of care.

## LIVED EXPERIENCE

I come from a family of nurses, so it was no surprise that I followed in their footsteps and became an Enrolled Nurse. I undertook my nursing education at Caritas Christi Hospice in Kew, Melbourne, where I found it to be both a privilege and an inspiration to assist people as they prepared to depart this world. I am passionate about enrolled nursing because that's where I firmly believe I make a positive contribution to the community and the profession.

I have been a member of the Royal College of Nursing (now ACN) since 1996. When the RCNA established the inaugural Advisory Council I was appointed to represent Enrolled Nurses' interests. During my career I have been the Enrolled Nurse representative on the National Board and the President of the National Enrolled Nurse Association of Australia (NENA). As part of these roles I was asked at both a federal and a state level to give advice regarding Enrolled Nurses in terms of their education and roles in the workforce. When I first commenced my Enrolled Nurse education over 30 years ago, I would never have thought that I would have opportunities to be in national leadership roles for Enrolled Nurses.

**Maryanne Craker, Former President, NENA**

## THE NURSE AS A LEADER AND MANAGER

Often nurses are required to assume the role of leader and manager. Nurses undertake management and leadership roles through directing, delegating and coordinating nursing activities. Nurses need to be knowledgeable about how and when to delegate, as well as the legal requirements of delegation and the acceptance of this delegation. Nurses must also evaluate the quality of care provided (Huber 2014).

Carney (2009) states that nurses are often ill-prepared for their roles as clinical, administrative and academic leaders and at times take on these roles without academic preparation and with a lack of support from their organisation. It is thought that early experience of leadership and support for and in the role are important for future success in the leadership role.

A **leader** is defined as someone who influences others to work together to accomplish a specific goal. They are often visionary, informed, articulate, confident and self-aware. Leaders usually have outstanding interpersonal skills and are excellent listeners and communicators. They have initiative and the ability and the confidence to innovate, motivate and facilitate, and to mentor others. Within their organisations, nurse leaders participate in and guide teams that assess the effectiveness of care, implement evidence-based practice and construct process improvement strategies (Berman et al 2015).

Nurses assume leadership roles to:

- Improve the health status of individuals or families
- Increase the effectiveness and level of satisfaction among professional colleagues
- Improve the attitudes of the general public and legislators towards the nursing profession and their expectations of it.

(Berman et al 2015)

A **manager** is defined as someone who is given authority, power and responsibility for planning, organising, coordinating and directing the work of others and for establishing and evaluating standards. Managers control human, financial and material resources. They set goals, make decisions and solve problems and initiate and implement change (Berman et al 2015).

As managers, nurses are responsible for managing individuals' care. Some nurses assume a position within the organisation as a nurse manager, supervisor or manager of nursing services. As a manager, the nurse is responsible for:

- Efficiently accomplishing the goals of the organisation
- Efficiently using the organisation's resources
- Ensuring individuals receive effective care
- Ensuring compliance with institutional, professional, legal, regulatory and governmental standards.

(Berman et al 2015)

A comparison of the roles of managers and leaders is outlined in Table 9.1.

**TABLE 9.1 | Comparison of the roles of leaders and managers**

| Leaders | Managers |
|---|---|
| Are developers of people and passionate about helping their people to be the best they can be | Generally manage people in the interest of achieving specific performance outcomes |
| Motivate people to generate solutions for the problems they present | Spend the majority of time solving their people's problems for them and focusing on operational issues |
| Embrace and adapt to change | Provide the process for change |
| Gain commitment from their people by ensuring that they regularly take action to fulfil individual values at work | Do not differentiate between individuals and respond to everyone in the same way |
| Focus on strategic outcomes and provide vision | Focus on daily targets |
| Work from an elected base | Are appointed to the position |
| Have confidence in people | Define performance accountability |
| Provide direction | Are concerned with control |
| Are people focused | Are process/systems focused |
| Influence others towards goal setting | Carry out predetermined policies, rules and regulations |
| Are interested in taking risks and exploring new ideas | Manage resources |
| Manage relationships | Maintain an orderly, controlled, rational and equitable structure |

*(Adapted from Berman et al 2015)*

## MODELS OF NURSING CARE DELIVERY

When commencing work in an organisation, nurses should have an understanding of what the model of care delivery is within that organisation, and have an understanding that within the same organisation there could be a variety of models of nursing care in different wards/departments/sections. It is important to know this, so that each nurse is aware of each other's roles and responsibilities when working within the model.

Key goals of nursing **models of care** should be to promote an individual's independence and wellness and incorporate interventions and strategies for:

- Promoting an individual's understanding of their clinical condition, treatment plan and anticipated trajectory of their condition
- Developing an individual's skills and opportunities necessary for negotiating and following a care plan in partnership with their health professionals
- Providing resources and knowledge for monitoring and managing the signs and symptoms of the individual's conditions
- Adopting lifestyles that promote risk factor modification and focus on prevention and early intervention to promote health and wellbeing
- Increasing access to support services including social and financial support (Crisp et al 2013).

Nursing care relates to a set of activities that are performed by nurses for individuals. For example, a nurse on a ward may undertake to assist with all showers and another may do all the medications. Nursing models of care should be flexible and responsive to the needs of individuals and the healthcare system.

Models of care may include:

- Task-oriented nursing
- Team nursing
- Allocation of individual or total individual care
- Primary nursing
- Case management.

(Crisp et al 2013)

**Task-oriented nursing** is a model of care in which nurses undertake specific tasks related to nursing care across a group of individuals.

**Team nursing** occurs when experienced nurses are teamed with less-experienced nurses or casual staff to achieve nursing goals using a group approach. The team leader in each group is responsible for assigning individual care and has overall responsibility for person care by team members. All team members work together, each performing the activities for which they are best prepared.

It is reported that team work is critical in assuring the safety and quality of care of individuals within healthcare organisations (Kalisch & Lee 2010). In addition, nurses stay in jobs where team work is effective, they are more

**TABLE 9.2 | Strengths and limitations of models of care in nursing**

| Model of nursing care | Strengths | Limitations |
|---|---|---|
| Task-oriented nursing | Nurses become proficient in a designated task. Potential for efficiencies in time management | Lack of an integrated approach to care management. Individual needs subsumed in organisational demands |
| Team nursing | Accommodates a range of skill mix and scopes of practice. Allows for a collaborative approach and uses a range of expertise | Less involvement by Registered Nurses may impact adversely on an individual's outcomes. Dependent on high-level organisational, delegation and coordination skills of the Registered Nurse |
| Individual allocation or total individual care | High level of coordination of care. Access to high-level clinical skills and decision making | Increased costs associated with high numbers of Registered Nurses. Decreased capacity for skill development in more junior members of the nursing team |
| Primary nursing | Strong person-centred model of care promoting autonomous decision making. Promotes continuity of care and interdisciplinary communication | Efficacy of the model dependent on the quality of the care plan and communication within the healthcare team. Greater dependence on Registered Nurse models of care. Potential for role burden for the Registered Nurse |
| Case management | Promotes continuity of care. Optimal for individuals with chronic and complex care needs. Creates a point of contact for individuals and the healthcare team | Need for communication structures such as regular team meetings which can be time consuming. Dependent on coordinating and communication skills of case manager |

*(Adapted from Crisp et al 2013:129)*

productive, less stressed and there are fewer errors (Kalisch et al 2009).

**Individual allocation** models were developed because nurses recognised the need for **total individual care**. Rather than caring for individuals as a series of tasks, nurses get to know the whole individual. A nurse is allocated to specific individuals and undertakes all nursing care for these individuals.

**Primary nursing** allows the nurse to provide individualised direct care to a small number of individuals during their entire stay. In primary nursing, the nurse provides care, communicates with individuals, families and other healthcare providers and carries out discharge planning.

**Case management** focuses on the management of a group of individuals. The nurse who is the case manager is usually a clinical specialist, and the caseload consists of individuals with similar healthcare needs. As case manager, the nurse makes appropriate referrals to other healthcare providers and manages the quality of care provided, such quality including accuracy, timeliness and cost. The case manager is also in contact with the individuals after discharge, ensuring continuity of care and health maintenance.

Some models work better when there are sufficient numbers of highly qualified staff to deliver care; others may focus on supporting less experienced staff using a team approach (Crisp et al 2013).

The strengths and limitations of these models of care are summarised in Table 9.2.

## LEADERSHIP STYLES

It is thought that leaders develop a particular leadership style through education, training and life experiences.

An **autocratic (authoritarian) leader** makes decisions for the group, believing that individuals are externally motivated and are incapable of independent decision making. The autocratic leader determines policies, giving directions to the group, which may feel secure under this leadership style because procedures are well defined and activities are predictable; productivity may also be high. This style is effective when urgent decisions are necessary (e.g. during a cardiac arrest), when group members are unable or unwilling to participate in decision making and when a project must be completed quickly.

A **democratic (participative, consultative) leader** encourages discussion and decision making, acting as a catalyst or facilitator, actively guiding towards achievement of group goals. The participative leader focuses on providing constructive feedback, offering information, making suggestions and asking questions; productivity and satisfaction are high as group members contribute to the work effort.

The **laissez-faire (non-directive, permissive) leader** recognises the group's need for autonomy and self-regulation, assuming a 'hands-off' approach. However, group members may act independently and at cross purposes because of a lack of cooperation and coordination. This style is most effective for groups whose members have both personal and professional maturity so that, once a decision has been made, they become committed to it and have the required expertise to implement it.

The **bureaucratic leader** trusts neither self nor others to make decisions and relies instead on the organisation's rules, policies and procedures to direct work efforts.

Effective leaders are those who can adapt their leadership style to the situation. They make a conscious choice between use of directive and supportive behaviours; consider the staff members' abilities; know the nature of the task and are sensitive to the context or environment (Berman et al 2015). Clinical Interest Box 9.1 illustrates the characteristics of effective leaders. Clinical Interest Box 9.2 outlines the factors that can influence a leadership style.

### Leadership styles and emotional intelligence

Vesterinen et al (2009) believe that a leader needs emotional resources and the ability to change when creating an environment that promotes commitment to work. **Emotional intelligence** has been defined as the ability to observe one's own and others' feelings and emotions, to discriminate between them and to use this information to direct one's thinking and actions. Emotional intelligence is composed of both personal competence and social competence.

Nurse leaders who possess emotional intelligence can easily form relationships with others, read employees' feelings and responses accurately and lead successfully. Self-awareness and self-management are reflections of personal competence and influence the way the leader manages themself. Social awareness and relationship management reflect social competence which affects how the leader manages relationships with others.

## CONTEMPORARY LEADERSHIP THEORIES

Contemporary leadership theories are as follows:

A **charismatic leader** creates an emotional relationship between themself and the group members. The powerful personality of the leader evokes strong feelings of commitment to both the leader and the leader's cause and beliefs.

The **transactional leader** has a relationship with followers based on an exchange or some resource valued by the follower. These incentives are used to promote loyalty and performance. For example, the nurse manger entices a nurse to work night duty shift in exchange for a weekend off.

A **transformational leader** fosters creativity, risk taking, commitment and collaboration by empowering the group to share the organisation's vision. The leader inspires others with

### CLINICAL INTEREST BOX 9.1 Characteristics of effective leaders

Effective leaders:

- Use a leadership style appropriate to the task and the members
- Assess the effectiveness of their behaviour on others and the effects of others' behaviours on themselves
- Are sensitive to the forces acting for and against change
- Express an optimistic view about human nature
- Are energetic
- Are open and encourage openness, so that real issues are confronted
- Facilitate personal relationships
- Motivate and inspire
- Are consistent in behaviours towards group members
- Delegate tasks and responsibilities to develop members' abilities
- Involve members in all decisions
- Value and use group members' contributions
- Encourage creativity
- Encourage feedback about their leadership style
- Assess for and promote the use of current technology.

*(Berman et al 2015:574)*

### CLINICAL INTEREST BOX 9.2 Factors that influence leadership style

- Experience with previous managers/supervisors
- Values—individual's own and those of the organisation
- Communication of information—how it is disseminated
- Collaboration—both managerial and collegial support
- Employees—experience, support required
- Education.

*(Vesterinen et al 2009)*

### CRITICAL THINKING EXERCISE 9.1

A nurse leader informs staff that there has been a major road accident and that the hospital needs to prepare for major casualties. The nursing team members begin to display high levels of anxiety and disorganisation.

What would be the most appropriate leadership style for the nurse leader to assume?

### CLINICAL INTEREST BOX 9.3
### Nursing leadership

Reflect on:
- What makes a leader?
- Why do some individuals who do not have a formal leadership position appear to be leaders, while other individuals in leadership positions do not?
- Why are some managers not seen as leaders?
- Who do you respect as a leader and why?

a clear, attractive and attainable goal and enlists them to participate in attaining the goal.

**Shared leadership** recognises that a professional workforce is made up of many leaders. No one person is considered to have knowledge or ability beyond that of other members of the work group (Berman et al 2015).

Clinical Interest Box 9.3 asks you to reflect on nursing leadership.

## MANAGEMENT

A manager's responsibility encompasses planning, organising, coordinating and directing the work of others.

### Levels of management

The three levels of manager are as follows:

**Frontline managers** are responsible for managing the work of non-managerial personnel and the day-to-day activities of a specific work group or groups. This level manager communicates staff issues to upper administration and reports administration messages back to staff. Titles may include nurse unit manager or team leader.

**Middle-level managers** supervise a number of first-level managers and are responsible for the activities in the departments they supervise. They serve as liaison between frontline managers and executive-level managers. They may be called supervisors, nurse unit managers, nurse managers or service managers.

**Executive-level managers** are organisational executives who are primarily responsible for establishing goals and developing strategic plans. Nurse executives, whose titles may include manager of nursing services and manager of clinical services, are Registered Nurses who are responsible for the management and practice of nursing within the organisation (Berman et al 2015).

Clinical Interest Box 9.4 looks at the Enrolled Nurse as leader.

### Management functions

The following management functions help to achieve the goal of quality individual care.

### CLINICAL INTEREST BOX 9.4
### Enrolled Nurse as a leader

Enrolled Nurses can be team leaders in a variety of settings:
- As the leader of a team of unregulated workers in aged care settings
- In wound care. The Enrolled Nurse may have undertaken professional development in a wound care course and may be the leader of a team in wound care

At all times the Enrolled Nurse must work within their scope of practice and within the decision-making framework.

#### Planning

Planning is an ongoing process that involves assessing a situation; establishing goals and objectives based on assessment of a situation or future trends; and developing a plan of action that identifies priorities, delineates who is responsible, determines deadlines and describes how the intended outcome is to be achieved and evaluated. An example of planning is risk management: having in place a system to reduce danger to individuals and staff. The steps of risk management include anticipating and seeking sources of risk; analysing, classifying and prioritising risks; developing a plan to avoid and manage risk; gathering data that indicate success at avoiding or minimising risk; and evaluating and modifying risk reduction programs.

#### Organising

Organising is also an ongoing process. After identifying the work and evaluating human and material resources, the manager arranges the work into smaller units. Organising involves determining responsibilities, communicating expectations and establishing chain of command for authority and communication.

#### Directing

Directing is the process of setting strategic directions for others to follow in order to accomplish the organisation's mission and objectives. This executive function includes establishing a vision, setting goals and managing interfaces with other organisations.

#### Coordinating

Coordinating is the process of ensuring that plans are carried out and outcomes are evaluated. The manager measures results or actions against standards or desired outcomes and then reinforces effective actions or changes ineffective ones (Berman et al 2015).

### Principles of management

A manager has authority, accountability and responsibility.

Authority is an integral component of managing. It is determined largely by the situation and it is always associated with responsibility and accountability.

Accountability is the ability and willingness to assume responsibility for one's actions and to accept the consequences of one's behaviour.

Responsibility is an obligation to complete a task. Managers are responsible for utilisation of resources, communication to subordinates and implementation of organisational goals and objectives (Berman et al 2015).

## Skills and competencies of nurse managers

To be effective managers, nurses need to think critically, communicate well, manage resources effectively, enhance employee performance, build and manage teams, manage conflict, manage time and initiate and manage change (Berman et al 2015).

### Critical thinking

The nurse manager reasons with logic, exploring assumptions, alternatives and the consequences of actions. See Chapter 16 for further discussion of critical thinking.

### Communicating

Good communication is essential, determines the manager's success as a leader and is core to effective nursing practice. Managers use both verbal and written communication skills.

### Managing resources

Budgeting and determining variances between the actual and the budgeted expenses are crucial skills for any manager.

### Enhancing employee performance

Managers are responsible for ensuring that employees develop through appropriate learning opportunities, whether by providing in-service education, facilitating attendance at professional workshops and conferences, or encouraging achievement of advanced education such as diplomas or higher degrees.

Managers can provide day-to-day coaching and act as a **mentor** or **preceptor**. Mentors give their time, energy and material support to teach, guide, assist, counsel and inspire a new graduate nurse.

Mentoring involves a voluntary, mutually beneficial professional relationship. In this relationship, one person is an experienced and knowledgeable leader (mentor) who supports the transition of a less-experienced person (mentee) to a new organisation culture and expectations of role (Bally 2007). Mentoring responsibilities include teaching, counselling, confirmation, accepting, friendship, protection, coaching and sponsorship (Bally 2007).

Mentor programs are thought to stimulate professional growth, career development, staff morale and quality within nursing workplaces, all areas that are thought to assist in recruitment and retention of nurses in the workforce. For mentorship to be effective, positive nursing leadership is required (Bally 2007).

In the clinical area, the term 'preceptor' is used to describe relationships in which the experienced nurse assists the new nurse in improving clinical nursing skills and judgment (Berman et al 2015). Clinical Interest Box 9.5 outlines the models of clinical supervision and support for enrolled nursing students.

### CLINICAL INTEREST BOX 9.5 Models of clinical supervision and support for enrolled nursing students

The type of clinical supervision and support a student Enrolled Nurse may experience may include the following:

- Clinical facilitator
- May be supplied by the education provider or by the host organisation. The clinical facilitator will provide regular checks on how the student is progressing, group debriefing sessions and one-on-one time for skill assessments.
- Mentor
- Will provide a relationship that facilitates a student's personal growth and development. The student needs to be able to communicate their learning needs to help attain goals. The mentor may provide information to the clinical facilitator about the student's performance to assist with completing the student's overall performance on placement.
- Preceptor
- Preceptors work the same shifts as the student. They plan orientation, negotiate learning experiences, monitor students' progress and provide feedback and assessment on performance.

*(Government of Victoria, Department of Health 2010)*

### Building and managing teams

Familiarity with the group processes facilitates the manager's ability to lead the group and enhances development of the group into a work team. A range of factors contribute to developing an effective team and many of these factors are dependent on the aptitudes and capabilities of clinical leaders (Berman et al 2015). Clinical Interest Box 9.6 outlines some of the characteristics of effective teams and leaders and Clinical Interest Box 9.7 lists the factors that can impact on positive practice environment.

In addition, having an understanding of the different attributes of each generation may also assist the manager to delegate and communicate more effectively within a team. Clinical Interest Box 9.8 describes the attributes of the different generations of nurses that could be working together on a team.

### Managing conflict

There are many methods that a manager can use to manage conflict. Compromise, negotiation and collaboration are

## CLINICAL INTEREST BOX 9.6 Some of the characteristics of effective teams and leaders

- Negotiating goals and intended outcomes of nursing interventions
- Leading by inspiring, enabling and motivating rather than dominating
- Communicating strategies and processes for sharing information effectively
- Clarifying roles, responsibilities and accountability of team members
- Collaborating and seeking external opinion and expertise
- Reflecting regularly on team progress and how this relates to the team goals
- Taking the time to celebrate successes and support each other when things are not going well.

*(Crisp et al 2013)*

## CLINICAL INTEREST BOX 9.7 Factors that can create a positive practice environment

- Leadership and support at all levels along the health spectrum
- Effective formal and informal communication processes that are transparent
- Participation in decision making regarding an individual's and organisational decision making in respect of clinical care delivery models
- Promoting a safe work environment that provides adequate education and opportunity for personal and professional development and recognition of achievements
- Implementation and monitoring of equitable and manageable workloads.

*(Crisp et al 2013)*

commonly used. Basic principles for all types of conflict management include demonstrating respect for all parties, avoiding blame, allowing full discussion, using ground rules during meetings to promote fairness, encouraging active listening, identifying the themes in the discussion and exploring alternative solutions (Berman et al 2015).

### Managing time

Strategies that the manager and all nurses can use in order to use time well involve setting goals and priorities, delegating appropriately, examining how time is used, minimising paperwork and using regular schedules that avoid interruptions and set time limits on activities.

## CLINICAL INTEREST BOX 9.8 The generation gap and management

In nursing there may be up to three generations of nurses working together in a particular clinical area. Each generation has its own set of expectations, values, goals and motivators. The different generations are as follows:

- Baby boomers (born 1945–1964). They are often ambitious, loyal and optimistic. They are highly committed to their employer, are regarded as workaholics and are reluctant to change jobs
- Generation X (born 1965–78). They try to balance career, family and leisure activities. They tend to be sceptical, competitive, autonomous, image conscious and in need of regular feedback about their performance. They value fun and humour in the workplace
- Generation Y (born 1978–2000). They are highly aware of their rights and work entitlements. They expect their employers to be flexible and to accommodate individual needs. They are conversant with technology, altruistic, ambitious and independent.

**Implications**

Understanding the differences between each generation can assist the manager to delegate and communicate more effectively.

*(Berman et al 2015:579)*

## CRITICAL THINKING EXERCISE 9.2

You have just received the morning shift handover report on the individuals you will be caring for. You have been assigned the following individuals:

- Stephanie, a 75-year-old woman who is day 2 following a total hip replacement. She has a patient-controlled analgesia infusion
- Bill, a 69-year-old man admitted to hospital for a fractured femur who has new onset shortness of breath and is becoming agitated
- Bec, a 44-year-old woman admitted to hospital with a stress spinal fracture due to metastases. She has a morphine infusion and she has just reported a score of 8/10 for pain.

In what order do you attend to these individuals? Justify your response.

Managers need to consider work–life balance for themselves and staff. Work–life balance requires providing employees with flexible work arrangements to enable them to both participate in the workforce and fulfil their family and lifestyle commitments (Berman et al 2015).

### Cultural needs

There is an increasing recognition that nursing practice and research needs to take into account cultural competence,

## CLINICAL INTEREST BOX 9.9
## Culture, leadership and management in nursing

Indigenous Australians comprise 3% of Australia's population (ABS 2010). Managers must understand and demonstrate sensitivity to cultural issues and promote supports available to their Indigenous staff, such as the Congress of Aboriginal and Torres Strait Islander Nurses (CATSIN).

Managers from Indigenous backgrounds face many challenges adjusting to a leadership role in the nursing profession.

*(Berman et al 2015)*

cultural safety and culturally congruent approaches to ensure that appropriate healthcare interventions and practices are established in healthcare (Berman et al 2015).

Clinical Interest Box 9.9 describes culture, leadership and management in nursing.

### Managing change

Change can involve gaining new knowledge or skills or adapting what is currently known in the light of new information. Change is an integral aspect of nursing and nurses are often change agents; they initiate, motivate and implement change (Berman et al 2015).

## CLINICAL INTEREST BOX 9.10
## Factors for the nurse to consider when delegating to non-nursing staff

- The delegation of care and supervision is lawful
- The individual has been assessed prior to delegation of care
- The individual is medically stable
- The task is considered routine for this individual
- The task does not require a substantial amount of scientific knowledge or technical skill
- The task is considered safe for this individual
- The task has a predictable outcome
- The delegation complies with the employing organisation's procedures and policies about delegation
- The nurse fully understands the scope of practice and the knowledge, skills and job description for each healthcare discipline represented on the team
- The nurse is aware of the diversity in work abilities
- Expectations about performance and reporting are clear
- There is an atmosphere that fosters communication, by encouraging staff to ask questions, listening carefully to their concerns and making use of every opportunity to teach.

*(Berman et al 2015)*

## THE NURSE AS A DELEGATOR

Delegation is the transference of responsibility and authority for an activity to a competent individual. The delegate assumes responsibility for the actual performance of the task and procedure. The delegator retains accountability for the decision to delegate and for monitoring outcomes. The National Framework for the Development of Decision-making Tools for Nursing and Midwifery Practice (2007) was developed to assist nurses and midwives in making decisions about delegation and supervision (NMBA 2013).

Delegation is a tool that allows the delegator to devote more time to strategic initiatives that cannot be delegated. It also enhances the skills and abilities of the delegate, which builds self-esteem, promotes morale and enhances team work and attainment of the organisation's goals. In nursing, delegation refers to indirect care—the intended outcome is achieved through the work of someone supervised by the nurse—and involves defining the task, determining who can perform the task, describing the expectation, seeking agreement, monitoring performance and providing feedback to the delegate regarding performance.

A nurse who delegates a task to another healthcare worker is accountable for selecting an appropriately skilled caregiver and for continued evaluation of the individual's care. The nurse should understand the role and function of the healthcare worker to ensure the tasks being delegated do not exceed the limits of their education, competence, experience and legal authority (Berman et al 2015).

Registered Nurses are accountable for making decisions about who is the most appropriate person to perform an activity that is part of the nursing plan of care. Enrolled Nurses are accountable for making decisions about their own practice and about what is within their own capacity and scope of practice (NMBA 2013). Principles regarding the nurse's decision to delegate ensure the safety and quality of outcomes. Once the decision has been made to delegate, the nurse must communicate clearly to the staff member and verify that the staff member understands:

- The specific tasks to be done for each individual
- When each task is to be completed
- The expected outcomes for each task
- Who is available to serve as a resource if needed
- When and in what format a report on the task is expected (Berman et al 2015).

Clinical Interest Box 9.10 outlines factors to be considered by the nurse when delegating work to non-nursing staff.

*Competency Standards for the Advanced Enrolled Nurse* (ANF 2006) have been developed and describe the role of the advanced Enrolled Nurse as:

- Having post-enrolment training, education and qualifications

- Having a breadth or depth of clinical experience and knowledge
- Undertaking a greater scope of delegated responsibility which may include clinical and management responsibilities
- Being able to practise competently with indirect Registered Nurse supervision
- A role model and resource to others in their area of practice
- An active member of the nursing profession.

The advanced Enrolled Nurse with appropriate additional education and experience may be able to undertake a broader range of responsibilities including overseeing the practice of student Enrolled Nurses and unregulated health workers. These Enrolled Nurses may also assist in evaluating individuals'/residents' needs, develop care plans and provide care for groups, as well as teach individuals, family members and/or carers how to perform simple healthcare procedures. It should be noted that this role exists only in some states and territories in Australia. While Registered Nurse supervision is a legal requirement for Enrolled Nurses in most states and territories, the nature of supervision may vary according to the context of care, level of education and experience of the individual Enrolled Nurses (ANF 2006). See Decision-making Framework Exercise 9.1.

Clinical Interest Box 9.11 outlines how an advanced skill Enrolled Nurse can contribute to the education of others.

## PREPARING NURSE LEADERS FOR THE FUTURE

Huston (2008) states that contemporary nursing and healthcare leaders should identify skill sets that will be needed by nurse leaders in the future and begin now to create the educational models and management development programs necessary to ensure these skills are present. Essential nurse leader competencies for the future are thought to be:

- A global perspective or mindset regarding healthcare and professional nursing issues
- Technology skills
- Evidence-based expert decision-making skills
- The ability to create organisational cultures that provide quality healthcare and individual/worker safety

### CRITICAL THINKING EXERCISE 9.3

Beth, a newly registered Enrolled Nurse, is caring for an individual who has just reported central chest pain and is diaphoretic. Beth takes a full set of vital signs, performs a 12-lead echocardiogram and administers glyceryl trinitrate. Beth believes the individual is suffering from a myocardial infarction and informs the medical officer. The medical officer asks Beth to administer a bolus dose of thrombolytic therapy. This is outside her scope of practice as she has not completed the administration of intravenous medication course. Beth informs the medical officer of this and he becomes irate and argumentative.

1. What should Beth do?
2. Who should she contact to seek support and clarification?
3. How should she communicate with the medical officer?

### CLINICAL INTEREST BOX 9.11 How an advanced skill Enrolled Nurse can contribute to the education of others

An advanced skill Enrolled Nurse is expected to contribute to the education of others. This can be demonstrated through:

- orientating new staff to local practices
- being a preceptor or mentor of new graduate Enrolled Nurses, student Enrolled Nurses and Assistants in Nursing
- assisting with the development of educational material for a ward.

*(Government of Western Australia, Department of Health, Nursing and Midwifery Office 2012)*

### DECISION-MAKING FRAMEWORK EXERCISE 9.1

You have just been employed at a healthcare service as an Enrolled Nurse. The ward you have been assigned to uses individual allocation as the model of nursing care. On this shift there are two (2) Registered Nurses, three (3) Enrolled Nurses and two (2) Assistants in Nursing. A Registered Nurse asks you to look after two (2) individuals who are 3 hours postoperative requiring IV medications, an individual requiring an insertion of an indwelling catheter and another individual requiring a blood transfusion. You have completed the intravenous unit as part of your Diploma of Nursing course, but the healthcare service has a policy stating that Enrolled Nurses are unable to administer IV medications. In addition, you have never looked after an individual with a blood transfusion and have only inserted an IDC in the nursing laboratory during your course.

Using the decision-making framework:

1. Do you accept these individuals as part of allocation?
2. What strategies could you use in this situation?
3. Considering the staff on this shift, is the model of nursing care appropriate?
4. If the model of care is not appropriate, what model would you suggest would work?

- Understanding and appropriately intervening in political processes
- Highly developed collaborative and team building skills
- The ability to balance authenticity and performance expectations
- Being able to envisage and proactively adapt to a healthcare system characterised by rapid change and chaos.
  (Huston 2008)

## Leadership skills for nursing students

A strategy for preparing nurse leaders and managers is to ensure leadership training is included in undergraduate nursing education, for both Registered and Enrolled Nurse. Students can commence developing clinical leadership skills by using critical thinking strategies (see Chapter 16) for making effective clinical decisions through clinical assessment, appraisal of the evidence and assessment of individual needs, learning from their own mistakes and those of others, actively seeking guidance and mentorship, collaborating closely with professional nurses and striving to improve their performance during each individual interaction. A nursing student can learn to use certain leadership skills such as clinical care coordination, team communication, delegation and knowledge building. In addition, seeking feedback from preceptors, facilitators and fellow students can be helpful in developing coordination and communication skills (Crisp et al 2013).

## Summary

Nurse managers have an important role in developing and leading nursing. Their role is changing and they require information and knowledge on budgeting, healthcare legislation, employment conditions and future planning (Vesterinen et al 2009). Nurse managers use a variety of leadership styles, and knowledge of these styles and the factors influencing them is important for nurse managers who provide future leadership and management education. In addition, Enrolled Nurses within their scope of practice have an ability to take on management and leadership roles.

## Review Questions

1. A nurse assigns appropriate work activities to other members of the team. What role is being illustrated?
2. What are the four (4) functions of management?
3. What are the characteristics of an effective leader?
4. How do the characteristics of leaders and managers differ?
5. What factors should be considered by the nurse when delegating work to non-nursing team members?
6. Where do managers add most value to the performance of your organisation?
7. What are the benefits of team nursing as a model of care?
8. Why is it important to have a mentoring culture in nursing?

Answer guide for the Review Questions, Critical Thinking Exercises, Decision-Making Framework Exercises and Critical Thinking Questions in Case Studies are hosted on Evolve: http://evolve.elsevier.com/AU/Koutoukidis/Tabbner/

# Health beliefs, cultural diversity and safety

CHAPTER 10
Cultural competence and safety

CHAPTER 11
Australian Indigenous health

CHAPTER 10

# Cultural competence and safety

*Denise Wilson and Lesley Seaton*

## KEY TERMS

communication
contested knowledges
cultural competence
cultural diversity
cultural relativism
cultural responsiveness
cultural safety
culture
dehumanisation
discrimination
Indigenous
marginalisation
prejudice
racism
stereotypes
trivialisation
world view (values, beliefs, attitudes)

## LEARNING OUTCOMES

At the completion of this chapter and with further reading, students should be able to:

- Define key terms
- Critically reflect on the place of culture in their own personal, community and professional life
- Analyse and appraise the literature related to culture
- Explain structures, practices and relations within a range of nursing and health care professional settings
- Examine the impact of the culture of health systems on individuals, communities and workers
- Develop the capacity to provide a culturally appropriate environment for users of health services
- Critically analyse their own models of intervention within the context of cultural difference

## CHAPTER FOCUS

This chapter assists students to increase their awareness of, and ability to critique the construct of, culture within themselves as individuals, their profession and the communities in which they work. They are encouraged to explore their own culturally embedded values, beliefs and practices and will be expected to develop an understanding of how culture impacts on the way they work and how they can work more appropriately and effectively across cultures.

## LIVED EXPERIENCE

As a student nurse belonging to the 'dominant' cultural group, I struggled to understand my own cultural location when learning about the role and importance of culture and health. I had always yearned to be Māori (the Indigenous peoples of Aotearoa). They always seemed happy—singing, laughing and being together as a whānau (extended family). I liked the thought of eating hangi, the food Māori cooked in the ground and often featured in tourist promotion material.

When the lecturers asked about my own culture, I initially denied having a culture. In fact I said that my family did not have a culture as such. But I was prompted to consider what things I valued in life, what were the beliefs that I learnt growing up and that continued to influence my daily life; how we did things such as having dinner; what food we ate; and what events we celebrated, and when. I slowly came to realise that I valued individual achievement, education, money, family, caring for others and travel, and as a family we celebrated Christmas and Easter and each member's birthday. I also became aware that I believed that people controlled their own destiny and, therefore, were solely responsible as individuals for their health and wellbeing.

I realise now that I held a rather romanticised view about other people's culture, focusing only on the interesting or mysterious aspects of their culture. I realised that all I really understood about the cultures of Māori peoples was what was contained within tourist brochures. Importantly, by examining my own cultural values, beliefs and practices I have come to see how some of my beliefs, like my belief that people are responsible for their own health, could be potentially harmful to people from different cultural backgrounds. For example, I could inadvertently deny people the involvement of their family members in their healthcare experience, or blame those individuals who do not adhere to their treatment regimen.

**Maria, Enrolled Nurse**

## INTRODUCTION

Health beliefs and practices are firmly embedded in people's social and cultural lives and backgrounds, and, therefore, vary between individuals. This chapter focuses on encouraging student nurses to develop an understanding of their own culture and the importance of integrating this knowledge into their nursing practice. Culture, particularly the things that people ordinarily take for granted, varies within and between groups and influences people's health beliefs and how they go about keeping healthy.

It is unrealistic for nurses to believe that they can 'know' every person's culture, especially those aspects important to their health and wellbeing. What is important is that nurses develop an understanding of culture, including their own cultural background. This will enable them to be in a better position to respect the differences impacting on how individuals seek healthcare. Nurses are also prompted to explore how their personal beliefs and professional understandings about culture impact their ability to provide appropriate and effective healthcare for individuals. In addition, the professional cultures of nursing and other health professions, along with healthcare services, are also considered. Students are encouraged to explore their own culturally embedded values, beliefs and practices by turning their gaze from 'others' to look at themselves. This helps students to understand how culture influences the way they work, and consider how they can work more appropriately and effectively within diverse cultures.

All students come with their own personal cultural background, which will be shaped by nursing's professional culture and that of the healthcare system. Understanding what goes into developing nurses' personal and professional identity and how this impacts on their work practice is crucial for working effectively with culturally diverse groups. Learning about your own culture is an interesting activity, albeit challenging, particularly for those belonging to the dominant or largest cultural groups in Australia. It is a common human way of behaving to think that your own way of doing or seeing things is the most obvious, the most right and the most logical.

For most people culture is a challenging concept. Many people see and use the word culture frequently. They use phrases like 'go to the theatre for a "bit of culture"'; individuals may work with other cultural groups; may criticise the culture of their workplace; or hear or read in the media about the so-called self-oriented and materialistic culture of Generation Y. Most commonly, the first thing many people think of when they hear the word culture is to think of somebody different to them, someone who looks physically different, usually racially different, maybe even exotic, but certainly someone who is 'other' (not us).

## VALUES, BELIEFS AND ATTITUDES

Underpinning culture are the values, beliefs and attitudes that are important for understanding individuals' and group's cultures. Prior to discussing what culture is, we will begin by explaining what these are. Values are commonly used to denote worth or goodness of various aspects of life. They are those things in life that are important to individuals and the groups they belong to. They vary from person to person and group to group, and become standards people use to judge their own and other people's actions. Value and belief systems are embedded in people's culture and the meaning that individuals ascribe to these. Values inform how individuals think things ought to be or how people ought to behave, especially in terms of qualities such as honesty, integrity and openness. Beliefs, on the other hand, are individuals' views about themselves and other people, based on the expectations they have about how things should be or are in the world. People's beliefs stem from their own cultural and life experiences and reflect their values.

Attitudes are evident in the manner or disposition individuals display or articulate about people, events or situations and are linked to their values and beliefs. Attitudes are usually established ways of responding to situations, commonly referred to as behaviours. These have been learned from others and through various experiences. They are usually based on the beliefs, values and assumptions individuals hold, whether they are substantiated or not.

Beliefs, values and attitudes are linked. Individuals' beliefs and values influence their attitudes and behaviours. These are moderated by a person's emotional intelligence so their attitude is positive and their behaviour adjusted in particular situations (Taylor & Guerin 2010).

## WHAT IS CULTURE?

When talking about culture, nurses need to be clear about the differences between race, ethnicity and culture because these terms are invariably used interchangeably by many people. Clinical Interest Box 10.1 outlines the differences between race, ethnicity and culture. Race and ethnicity are generally used to classify large numbers of people into groups. These terms are limited, however, because they tell little about what health beliefs and values individuals may have, for instance, or how they carry out their daily life. In Australia, many people are categorised under these broad categories. For example, many immigrants are classified as 'Asian' implying that these people are all the 'same'. This approach ignores the fact that 'Asia' is a large continent made up of many countries, which are made up of people belonging to different ethnicities. In actual fact, many different cultural groups exist within a country.

How is culture defined? While there are many definitions for culture, generally culture:

- Consists of ideas, meanings, values, attitudes and beliefs shared within a group
- Is evident in the behaviours, relationships and other symbolic forms that reflect a person's or group's values and beliefs
- Is learned
- Is dynamic and constantly changing.

It is also widely held that generally there are no valid standards by which cultural principles and practices can be judged.

It is important to recognise that while some cultural groups share similar values, beliefs and characteristics they are not all homogenous or the 'same'. Individuals and groups of people belonging to a cultural group can differ in their beliefs and practices. Viewing cultural groups as homogenous can erroneously lead to stereotyping individuals and making unsubstantiated assumptions that oversimplifies people and their behaviour. Thus, when referring to culture in nursing practice it is important to remember that **cultural diversity** (between people) exists between the many different cultural groups (intercultural) as well as within such groups (intracultural).

An example to illustrate this comes from the **Indigenous** peoples of Australia. There are cultural differences between Indigenous peoples and the degree to which they have been able to retain traditional cultural customs and practices through colonisation; those who live in urban and rural or remote settings and in the different areas of Australia; and the degree to which social and technological changes have influenced changes in cultural beliefs and practices. Culture will vary across and within these different groups. Indigenous peoples speak different languages and dialects, and have varying religious and healing practices, family traditions and

### CLINICAL INTEREST BOX 10.1 The differences between race, ethnicity and culture

*Race* uses broad classifications based on the shared and similar physical traits that people possess, such as skin colour, facial features, hair and body build. Some common racial classifications include people belonging to Caucasian, Micronesian, Melanesian and Polynesian groups, for example.

*Ethnicity* comprises socially determined categories based on common ancestral, social, cultural or country experiences that people feel they either belong to or identify with. People are asked to indicate their ethnicity when they complete Census questionnaires in Australia. It is important to be mindful that ethnicity does not reliably indicate a person's culture.

*Culture* refers to the values, beliefs and customs that people carry out on a daily basis. These are generally learned within families and communities, and are adapted as we encounter other social and technological experiences. Culture is invariably transmitted from one generation to the next through participation and language.

*(Wilson et al 2012)*

## NURSING CARE PLAN 10.1

**Assessment:** Mrs Erueti is a 70-year-old woman who has been admitted for a lower limb amputation on her left leg. She was accompanied by her family (son, daughter-in-law and two grandchildren). Mrs Erueti identifies as Māori and New Zealand European ethnicity, and speaks both te reo Māori (Māori language) and English. When asked about important beliefs and practices to be observed during her stay, she said she wanted to have the opportunity for karakia (prayer) with her family prior to going for her operation, have her amputated limb returned and have her extended family close. She has asked for her family to be present when all important information is shared. It is noted that Mrs Erueti needs clear and simple explanations and prefers to speak te reo Māori.

**Issue/s to be addressed:** Contact the multicultural team and alert them about Mrs Erueti's admission and the possible need for an interpreter when her family are not present.

- Liaison with the operating room/theatre regarding Mrs Erueti's:
  - > Need for karakia with her family prior to going to theatre.
  - > Request to have her amputated limb returned.
- Work with Mrs Erueti's son about a spokesperson for the family to coordinate communication with the various members and to ensure their needs are met.

**Goal/s:** Mrs Erueti will feel that her cultural needs have been responded to, and she feels culturally safe during her stay in hospital.

| Care/Actions | Rationale |
|---|---|
| Promote optimal communication by using clear and simple language, and an interpreter if needed | Optimal communication is essential for Mrs Erueti to understand information and care instructions |
| Ensure Mrs Erueti is able to have: (a) karakia prior to her surgery; (b) a process for the return of her amputated limb | Meeting Mrs Erueti's spiritual needs is an important part of her feeling spiritually and culturally safe |

**Evaluation:** Work with the multidisciplinary health team to ascertain that Mrs Erueti's needs have been met, and any areas for improvement.

community structures (McMurray & Clendon 2011). This is why throughout this chapter there is reference to Indigenous 'peoples and cultures', rather than Indigenous 'people and culture'.

Cultural diversity can also be seen within ethnic groups. Nurses can mistakenly treat all people belonging to an 'immigrant' group the same without recognising that there can be great variations in those who have recently immigrated and those who are second- or third-generation Australian-born. Similarly while Indigenous peoples from Australia have shared histories of colonisation, different tribal groups have different experiences. This means that some Indigenous peoples have retained their cultural traditions and languages, while others have become disconnected from their culture and have lost their languages. These examples highlight the importance of nurses identifying the important cultural beliefs or practices for each individual and including these in their nursing care plan (see the Nursing Care Plan 10.1 example provided and Case Study 10.1 to explore these ideas further).

Culture extends beyond ethnicity. People also belong to groups that are defined by gender, age, sexual orientation, occupation, socioeconomic status, disability, organisation and profession. Each of these groups also have distinct beliefs and customs. Furthermore, people also belong to multiple cultural groups at the same time. For example, a young student nurse may belong to her family of origin that identifies with one or more ethnic groups, while at the same time

### CASE STUDY 10.1

You have been asked to take the initial vital signs for Mr Kumar, a 56-year-old Indian man who is a recent immigrant. This is the first time he has sought healthcare since being in the country. He has come to the healthcare service with his son, Suvir, because he has been feeling unwell for the past 2 weeks. He appears to be nervous and unsure of what is happening, and you observe that he does not have a good command of spoken and written English. You note that it is Suvir, not Mr Kumar, who is completing the forms, and that he is speaking to his father in an Indian language. You realise that you will need to discuss with him whether his son will be acceptable as an interpreter or whether you need to contact one. Based on these observations, you talk to the Registered Nurse about how to proceed with Mr Kumar, particularly with regard to identifying and meeting his cultural needs. However, the Registered Nurse informs you that you should just treat him like all other individuals using the healthcare service; she says flippantly, 'When in Rome do as the Romans do.' She goes on to say, 'Besides, all you need to know is that they eat curries!'

1. What are the key issues confronting Mr Kumar and his son, and you as his nurse?
2. How should you proceed?

identifying as belonging to a youth group, as a woman, and learning the professional cultural norms of nursing.

Professional culture relates to those cultural behaviours and understandings that are developed within the contexts of the nursing profession and the workplace. Evident in healthcare services are distinct cultures, such as the medical culture, hospital culture and nursing culture. These different cultures influence what individuals learn, know and practise, which importantly dictates what constitutes appropriate behaviours in the workplace.

The dominant cultures of Australian health services are rooted in a western biomedical world view, which influences the nature of health service delivery. This world view focuses on individuals and relates to the causation and curing of disease and illness. A key belief is that causes of disease and illness can be found in people's bodies, which can then be by and large cured. Individuals seeking healthcare are often rendered passive and silent; however, Lupton (2003) points out that:

*... most patients do not have free access to biomedical knowledge, they do not necessarily come to the doctor-patient encounter as empty vessels passively awaiting the wisdom of the doctor. People's understandings of illness, disease and good health states are dynamic and sometimes incoherent, changing in response to personal experiences and circumstances such as emotional states. Most individuals develop health beliefs derived from folk-models of illness, alternative forms of medical practice, the mass media and 'common sense' understandings derived from personal experience or from consultation with friends and family and continue to subscribe to these beliefs while consuming orthodox health care. (p. 108)*

While the world view of nursing can vary between the different healthcare settings within which nurses practise, they generally draw on the values such as holism, caring and person-centred care (Dempsey et al 2009). Despite nurses having a professional culture with various values and beliefs, the reality is that most practise within the dominant culture of the health system and with other professions such as medicine, which has its own world view and culture. In this situation, nurses can be forced into conforming to the dominant culture that dictates how healthcare services will be structured and delivered. In doing so, they need to be mindful that practising in a biomedical way tends to reduce people's health to a disease process or illness that ignores their cultural and spiritual needs (Wilson & Barton 2012). For those people belonging to minority cultural groups with different world views that influence their beliefs about health, interactions with health services and professionals can be both stressful and a source of conflict. Cultural conflict can be based in either personal or professional cultures, but if it is left unattended it can impact on nurses' abilities to care for individuals and their families in ways that meet their culturally based needs, and uphold their rights to quality healthcare (LaVeist et al 2013).

A common cause of conflict for nursing staff and individuals and their families is **communication** challenges, because communication patterns are also culturally embedded and determined. A common frustration is an individual's inability to grasp what one is trying to say, leading to others thinking 'they just don't get it'. This usually indicates that the sender's message has been poorly conveyed, and rather than blame the other person it signals the need to explore other options. For example, Australians are known for being 'upfront' and speaking their mind; this differs from Japanese people who, by comparison, are much more formal, reserved and polite in their communication approach, and Indigenous peoples who can use extensive non-verbal patterns of communication. Communication is explored more detail in Chapter 8.

**CRITICAL THINKING EXERCISE 10.1**

What communication strategies can nurses use when they are working with someone from another culture?

## Ethnocentrism

Culture can influence a person's daily life in ways they are unaware of because it is often hidden and taken for granted. It is not unusual for nurses to come across a person or situation that confronts their cultural values and beliefs, which leads them to make judgments and assumptions that are often based on their own or their professional cultural values and beliefs. This process helps us to determine how we see and make sense of the world. It is from individuals' world views and cultural positions that we perceive, interpret and make judgments about situations or the behaviours of others, which may or may not be accurate. Functioning in this way from one's own personal or professional cultural backgrounds is known as **ethnocentrism**. Bizumic et al (2009) state that:

*Ethnocentrism is an attitudinal construct that involves a strong sense of ethnic group self-centeredness and self-importance ... Intergroup expressions involve the central belief or sentiment that one's own ethnic group is more important than other ethnic groups, whereas intragroup expressions involve the central belief or sentiment that one's own ethnic group is more important than its individual members. Intergroup expressions often involve preferring ethnic ingroups over outgroups, a belief in the superiority of one's ethnic group over outgroups, the wish for ethnic purity within the ethnic ingroup, and the acceptance of exploitation of outgroups when this is in ingroup's interests ... (p. 874)*

In this way, ethnocentrism enables people to stereotype and form prejudices about those belonging to different or other cultural groups. It can also contribute to nurses inadvertently or deliberately practising in ways that are either unhelpful or prejudicial, especially when we belong to the dominant cultural group. Ethnocentrism is associated with words such as dominance, superiority, power and authority, and is closely linked to the power and authority held by the dominant group. Such stances immediately put other people belonging to minority cultural groups in positions of inferiority and can render them passive in their healthcare experience.

What a person thinks of other societies and cultures has an impact on their personal and professional self. It is worth keeping in mind that ethnocentrism was one of the key components of European colonisation of Australia, thus setting the tone for interactions with **Indigenous** inhabitants. This has also played out in various ways with the subsequent waves of immigration.

In contrast to ethnocentrism, **cultural relativism** involves attempting to understand an individual's culture from their own standards. It is underpinned by the notion that there is no universal standard to measure cultures—people view and interact with the world differently—no one way is more right or wrong than other ways. Therefore, all cultures are equally valid and must be understood in their own terms, in a respectful manner. Sometimes this can be challenging for nurses, especially when some culturally embedded behaviours appear inexplicable and difficult to comprehend, and are seen to cause distress, disease or death. Clinical Interest Boxes 10.2 and 10.3 provide examples of cultural relativism as it applies to nursing practice.

**CRITICAL THINKING EXERCISE** 10.2

What strategies could a nurse working with a family seeking to have their son circumcised take to resolve the cultural conflict that may arise from not wanting to judge this family or condone a practice unaccepted by the dominant culture?

## Prejudice, discrimination and racism on people's health and wellbeing

When individuals belonging to minority groups and their families access healthcare, some encounter health professional attitudes and actions that result in them being treated differently to others, for no apparent reason. Treating people differently compared to others affects not only their quality of care and treatment, but negatively impacts health outcomes (Johnstone & Kanitsaki 2009; Rumball-Smith & Hider 2013; Ziersch et al 2011). Nurses need to reflect on their own practice, and recognise ways they may be practising that result in differences in the quality of care for some groups of people. Practising in ways that are prejudicial, discriminatory or racist is inappropriate, unprofessional and breaches every person's right to optimal standards of healthcare (Universal Declaration of Human Rights 1948). Clinical Interest Box 10.4 highlights how failing to acknowledge the existence of racism is a false premise or, as Johnstone and Kanitsaki (2009) indicate, an 'illusion'.

**Prejudice** is a process of forming opinions, preconceptions or judgments about other people that are unfounded or unreasonable because they are not based on facts or information that dispute these. In some situations, people form prejudices without any direct or actual experience, facilitated by ethnocentrism. Such opinions are generally negative and serve to disadvantage the group of people they are directed towards. Importantly, when nurses do not attempt to understand the cultural perspectives of individuals seeking healthcare services, they risk prejudices influencing their practice.

### CLINICAL INTEREST BOX 10.2
### Cultural relativism in action

Circumcision of male children for religious and cultural reasons is a practice undertaken by some families who have immigrated to Australia. While once an accepted practice in Australia, debates in the early 1970s that were grounded in human rights, ethical issues and a lack of evidence supporting this practice being beneficial resulted in circumcision becoming unacceptable (Royal Australasian College of Physicians 2010); that is, a shift in culture occurred. Recently in New Zealand, because it is difficult to get their boys circumcised, some people belonging to the Pasifika community have been having this done at home. This has led to boys being hospitalised with infections.

*(Johnston 2015)*

### CLINICAL INTEREST BOX 10.3
### Cultural relativism in action

A continuing source of conflict for nurses is the presence of family members, in the capacity of either visitors or support persons, when an individual attends a healthcare appointment. Most healthcare service cultures tend to restrict the number of people visiting people in hospital settings or acting in the role as support person. This stance is generally enforced by nurses, many of whom support such an approach. However, for families who belong to cultural groups with collective orientations, whereby members have responsibilities and obligations to support an individual who is unwell, the imposition of such practices causes them stress and distress. Nurses can avoid an ethnocentric approach to visiting and support by understanding the cultural positions of those people with obligations to support other family members, and negotiate with the family in a way that facilitates meeting their need to be present.

### CLINICAL INTEREST BOX 10.4

*'Despite the universal right to health, people of minority racial and ethnic backgrounds experience commonplace and significant unjust inequalities in their health and health care. A key reason for this rests on what might be described as "the illusion of non-racism in health care"—an illusion that rests on the frequently articulated belief that "racism is not an issue any more".'*

*(Johnstone & Kanitsaki 2009:63)*

Prejudicial opinions are often evident in the stereotypes we hold about other people who are seen to be different.

**Stereotypes** are permanent and simplistic generalisations about groups of people that are held by a wide range of people. Stereotypes are a way to cognitively process complex information about groups of people in order to simplify our social world by categorising them. However, these categories tend to become fixed and resistant to change, even in the face of contrary evidence or logic; are unproven and negative; and become accepted fact. Stereotypes are usually more than just personal beliefs about a group; they become part of the broader set of dominant cultural beliefs about others (Thompson 2003). It is important to realise that while stereotyped beliefs may apply to some people in a group, generally they do not apply to all people belonging to that group.

### CRITICAL THINKING EXERCISE 10.3

Think about the groups of people who access health services in your area, such as those who are young or old, belonging to different ethnic or occupational groups, and ways in which they are considered. For example, some people shout and talk excessively slowly to older people based on the belief that they are either deaf or cognitively impaired in some way.

What prejudices and stereotypes do you hold about each of these groups? What evidence exists to validate the stereotypes you have identified?

**Discrimination** involves acting on our prejudices and stereotypes that classify people based on factors such as, for example, age, gender or ethnicity. Such actions deny those subject to discriminatory actions full involvement in activities or access to needed services that others in society have. Discrimination involves processes like stereotyping, marginalisation, invisibilisation, dehumanisation and trivialisation (Thompson 2003).

When one or more groups of people are excluded from aspects of society, they are pushed to the margins—this includes accessing and using healthcare services. For example, it is not unusual for the Indigenous peoples of Australia to be marginalised from health services, evident in their lower access to primary healthcare services but over-representation in avoidable hospitalisations (Australian Indigenous Health InfoNet 2012).

**Marginalisation** manifests when nurses and health professionals ignore, push aside or trivialise individuals' concerns and issues; present health-related information in a language or medium that they have difficulty in understanding; and exclude individuals from decision making related to their treatment options.

When individuals who are marginalised present to health services, it is not unusual for them to be blamed or accused of being non-compliant for their poor health status as nurses and health professionals draw on stereotypes to justify their accusations. In addition to being marginalised, people belonging to minority groups are often rendered invisible, particularly when they are seen by those belonging to dominant cultural groups as lacking power, status, reputation and influence.

Another discriminating process used is **dehumanisation**. This occurs when people are treated in detached and objective ways that lack empathy, and are impersonal and disrespectful. Dehumanisation is evident in the language that nurses and health professionals use. For example, rather than referring to a person by his or her name, they may be called 'they' or by their illness or condition (e.g. 'the appendix'); or their use of body language (such as dismissive gestures and facial expressions) that conveys that they are not valued. Such acts are disempowering and highlight the need for nurses to be sensitive to the verbal and non-verbal language they use. Associated with dehumanisation is **trivialisation**, a process whereby nurses can divert attention away from what is important for an individual or the information they are trying to share. Nurses can do this by ridiculing or devaluing what individuals have to say as lacking relevance, validity or importance. This leaves individuals feeling unsupported, isolated and disempowered; for example, when a nurse planning an elderly woman's discharge does not attend to her concern that her medication makes her feel dizzy by dismissing her concern as nothing to worry about.

**Racism** is the enacting of discriminatory practices. It is a system of power that structures and values opportunities according to people's race. It is evident in various ways in healthcare services; that is, institutional, healthcare workers and individuals accessing health services. Jones (2000) describes three levels of racism that nurses need to be aware of.

*Institutional racism* refers to the way in which the government and health service planners ensure equitable distribution of necessary determinants of health, and also plan and deliver healthcare that results in differential access to necessary determinants of health and healthcare services. Critically examining the structure and delivery of healthcare services whereby some people are under-utilising services, for example, can uncover inequities. These forms of racism can be identified in the decision-making processes, the misuse of evidence, deficit in cultural competence and consultation, and the use of dominant cultural lens against which to make judgments and decisions (Came 2014).

*Personally mediated racism* refers to the different assumptions and prejudices held by healthcare professionals, such as nurses, and the discriminatory practices that target people belonging to a particular group. Such practices may include being disrespectful or not asking questions during an assessment, which influences the quality of care that people receive.

*Internalised racism* refers to people belonging to groups whereby they have internalised negative, discriminatory and racist messages evident in society, which result in a sense of hopelessness and helplessness. In some cases, people believe the messages that are conveyed.

It is important to realise that it is not only doing something (commission) that is discriminatory or racist, but not doing something (omission) can be equally damaging. For instance, neglecting to determine an individual's cultural

### CRITICAL THINKING EXERCISE 10.4

Determinants of health are generally those things that people need to lead full and healthy lives, but sit outside the healthcare system.

What are determinants of health? Why are determinants of health important for ensuring people are well and healthy? Who in your country and local health area is less likely to have equitable access to necessary determinants of health?

### CRITICAL THINKING EXERCISE 10.5

Sometimes nurses claim they treat all individuals the same.

What advantages and disadvantages are there in adopting such an approach? What approach is needed to meet individuals' cultural needs?

needs for whatever reasons potentially compromises the quality of care that they receive. Moreover, racism has detrimental effects on individuals' health and wellbeing (Harris 2012; Pauly et al 2009). Health effects include individuals feeling stressed, having raised blood pressure, being anxious, mistrusting healthcare professionals and feeling unsatisfied and that their health needs were unmet. These things can contribute to future avoidance and under-utilisation of healthcare services. Crucially, once an individual's and their family's trust has been breached, it is difficult for healthcare professionals to re-establish it (LaVeist et al 2013). Nurses can play an important role by being aware of prejudices, discrimination and racism, and avoiding engagement in such behaviours.

## Summary

In summary, nurses should engage with each person as an individual—while learning specific aspects of people's cultures may seem alluring, it is potentially dangerous. Labelling or assigning people to boxes compromises the quality of individuals' healthcare, and can negatively impact their health outcomes. While culture involves shared values, ideas and beliefs, cultural groups invariably have subcultures within them as well as their members holding differing perspectives. For example, some of the many subcultures in the dominant cultures of Australia include different social classes, LGBTQI (Lesbian-Gay-Bisexual-Transgender-Queer-Intersex) communities, the elderly, single mothers, IV drug users, teenagers, football players—the list goes on. Furthermore, people generally belong to more than one cultural group at a time, meaning the various cultures they belong to intersect, blurring the boundaries between them. In this way, cultural groups cannot be considered as clearly defined entities. Thus, it is important for nurses to always be mindful of the diversity that exists not only between groups but within cultural groups, and that people invariably belong to more than one cultural group at any one time that can influence the expression of their culture.

# CULTURE AND WELLBEING

Our **world view** relates to how we know about, function in and relate to the 'world' that we live in. Simply it is how we see the world, and depending on where we are in the world

### CLINICAL INTEREST BOX 10.5
### The role of culture in individuals' experiences of pain

Despite pain being a universal, physiological experience, Flaskerud (2015) highlighted the role that individuals' culture has on how they respond. It helps explain why a woman from one cultural background remains silent during labour and childbirth, while another is very vocal during contractions. Flaskerud states:

*Culture affects the pain response in several ways: cultural endorsement of stoicism vs expressivity; cultural conceptualizations and descriptions of pain; cultural beliefs about managing pain; and culturally prescribed roles for patient and healthcare professionals ... Understanding the patient's cultural beliefs and practices will lead to a better assessment of pain, and incorporating the cultural beliefs and practices that are beneficial or neutral into the management plan may enhance pain control. Because culture is such an important part of a person's identity, respecting cultural norms promotes a feeling of being valued. In turn, this improves communication, which will improve pain outcomes.* (p. 76)

influences how we see it. It is linked to our ways of knowing and what constitutes knowledge about health. How individuals view and know their world strongly influences how they will make sense of it. World views influence our beliefs about health and how we understand health, wellbeing, illness, life and death and dying. In this way, people's concepts of health are constructed within the sociocultural contexts that we live in. We begin to learn about health growing up in our families of origin, which is then moderated as we interact with others (such as school teachers, nurses, doctors and friends). Health beliefs and behaviours are embedded as part of our cultural beliefs and practices, and vary among individuals accordingly. World views influence understandings about all aspects of life, including health: how we experience health and illness, what it means to be well, what we do when we get sick, who we talk to and how we understand the cause/s of our conditions. Clinical Interest Box 10.5 provides an example of how individuals' cultural beliefs and practices can influence our experience and expression of pain.

Nevertheless, world view is also tied to the concept of different knowledge systems. As well as there being different

ways of perceiving the world there are also different ways of 'knowing' about the world, which will influence understandings of all aspects of life, including health. Negotiating between different knowledge systems is central to understanding about working in a variety of cultural contexts. However, **contested knowledges** refers to an individual's way of seeing and understanding the world, that they believe constitutes the 'truth'—it is their reality.

The healthcare system in Australia is where contested knowledges are evident. As mentioned earlier, these healthcare systems operate under a Western biomedical world view—one that has come to dominate knowledge in the health arena. Consequently, knowledge is only considered valid if it is generated using objective and systematic observation and scientific processes. Knowledge is then ordered into a hierarchy that reflects the quality of evidence based on the research design used. This way of knowing is promoted by those belonging to dominant cultures, and has become a 'valid' way of knowing. As a result, other forms of knowledge and ways of generating knowledge have been disregarded and viewed as invalid.

This means that people belonging to minority cultures whose healthcare practices are embedded in holistic and eco-spiritual world views can have their cultural beliefs regarding health dismissed. Research has shown that Indigenous peoples who hold holistic and eco-spiritual world views and for whom relationships and obligations to other members are valued highly are marginalised by healthcare professionals (see, for example, Wilson & Barton 2012).

Nurses should be aware of contested knowledges and the need to respect individuals' cultural perspectives on health. In order to do this, it becomes important to develop relationships with individuals and their families in order to understand their world view and health-related understandings, as well as the influences these are likely to have on their health experience. Furthermore, also being aware of their historical, social and cultural contexts is crucial in planning care that will be relevant and achievable.

## Indigenous knowledges

Without question, the colonisation of Australia has been detrimental to the health and wellbeing of their respective Indigenous peoples (i.e. Aboriginal and Torres Strait Islander peoples). Colonisation has negatively impacted their cultural traditions and customs; people's cultural identity and connections; traditional languages; and people's social wellbeing and health status. Similar to other countries that have been colonised, Indigenous peoples of Australia have poorer social and health outcomes compared to others living in their respective countries. While their health status is explained in terms of negative stereotypes, victim blaming and deficit explanations, the evidence shows us that not only do many Indigenous peoples have inequitable access to the necessary determinants of health and to health services themselves, but they are subjected to differences in the quality of care they receive and to discriminatory practices and healthcare professionals. The reality is that Indigenous peoples do not have access to affordable and accessible healthcare services, are more likely than others to have avoidable hospital admissions and to die prematurely of avoidable or preventable health conditions.

All people have the right to quality healthcare under the United Nations Declaration of Human Rights and the Declaration on the Rights of Indigenous Peoples. Advocating for access to timely and appropriate healthcare services and the quality and nature of the care they deliver are areas in which nurses can make a difference for Indigenous peoples. Understanding local Indigenous cultural beliefs and practices (e.g. the importance of tribal lands, known as country, for Aboriginal and Torres Strait Islander peoples) is essential for nurses to improve the quality of healthcare that they deliver to Indigenous individuals and their families.

Dominant health service cultures tend to privilege an individual orientation, which is contrary to Indigenous (and some other minority groups') perspectives whereby relationships are of the utmost importance and individuals are part of the collective group. This is evident in Wilson and Barton's (2012) work, whereby Indigenous people of New Zealand, Māori, stressed the importance of their whānau (extended family) and their wairua (spiritual wellbeing) while in hospital. Indeed, this study showed that because of how individuals were treated by healthcare professionals, they were cared for by their whānau during their hospital stay who concluded it was not a conducive environment for their healing.

Western scientific knowledge has long been held up as the ultimate truth and used as the measuring stick against which to measure every other form of knowledge. However, its dominance has served to objectify, marginalise and silence other ways of knowing, thereby invalidating Indigenous knowledges while perpetuating power imbalances (Chilisa 2012; Smith 2012). However, Indigenous knowledges are legitimate in their own right and this concept needs to be recognised when working in cross-cultural contexts. For example, one of the features of Yolngu theory of knowledge, and the theory of knowledge of Indigenous peoples throughout Australia, is the notion that 'knowledge belongs to people'. It is not an abstract or universal thing. It is tied to people, places and history, and is held by right, as is land, history, ceremony and language. It is constructed by people who have lived in and observed their environment and complemented by knowledges handed down from their ancestors through prayer, song, dance and artworks, for example. It is localised and is collective, and varies between Indigenous groups. By contrast, an objectivist view tends to present knowledge as an abstraction, separated from people. These concepts of knowledge and world view are very important to understand, as they are fundamental to understanding culture.

When thinking or talking about health, people often assume that a shared meaning of the concept exists. On closer examination the term 'health' not only has more than one definition, but its meaning will differ between individuals, both within and across different cultures. This has important implications for nurses and healthcare and services. For example, the *National Strategic Framework for Aboriginal and Torres Strait Islander Health* describes:

*For Aboriginal and Torres Strait Islander peoples, health is not just the physical well-being of the individual, but encompasses social, emotional, spiritual and cultural well-being, community capacity and governance. A holistic approach that also recognises the diversity of Aboriginal and Torres Strait Islander cultures is central to improving Aboriginal and Torres Strait Islander health.*

**(NATSIHC 2013)**

This definition shows that for many Indigenous peoples, health does not focus on the individual, as is usually the case in Western societies. Rather, an individual's health is tied up with the health of the community, which is also inseparable from the health of their country.

Commonly held Indigenous beliefs propose that when factors that influence social wellbeing and harmony within groups are maintained, people are healthy. However, when social, emotional and cultural wellbeing is disrupted, ill health results. Indigenous spirituality was and still is land centred. While this broad definition of health is emphasised by Indigenous people in different ways, they believe that health cannot be disassociated from self-determination, land rights and cultural vitality; and it cannot be neatly divided into mental and physical aspects (NATSIHC 2013).

## EFFECTIVE COMMUNICATION

A nurse working in a healthcare setting needs to be able to use a wide range of communication skills within a variety of relationships. Nurses also need to acknowledge the variables that may impact on the quality of that communication. There is an imperative to deliver effective and appropriate care to the culturally diverse population in most healthcare settings to improve people's health outcomes and their health experiences. Underpinning this is a fundamental need for culturally appropriate methods of obtaining, interpreting and understanding information people share that will be used to determine the most effective and appropriate care to be provided by the nurse.

The relationship between the person (and their family members) and the nurse in any encounter plays a crucial, but often under-acknowledged, role in communication. The nature and quality of communication itself has an important influence on the dynamic between any individual and groups with whom the nurse is interacting. Control of people's interactions in healthcare services is primarily located with its staff, such as nurses. The holder of power, in this instance the nurse (who has knowledge of and access to the healthcare system) has a significant influence on communication, especially in terms of controlling interactions, accessing and sharing information and decision making about actions to be taken.

Problems in the area of cross-cultural communication have long been widely and readily acknowledged (Higgins 2009; Taylor et al 2013; Wilson & Barton 2012), yet they persist. Effective communication requires a shared understanding between a person and the nurse. Difficulties exist not only with language barriers. Many people in Australia are linguistically diverse, meaning they may not understand English well or at all. Language barriers become even more evident in healthcare settings, where there is a heavy usage of medical terminology and increasingly complex therapeutic regimens. In addition, there may be misunderstandings arising from people holding differing beliefs and practices regarding health and illness that may vary from those working in healthcare settings.

But the problems also extend to the nature of the communication between a nurse and an individual. For example, the most common way to gain information about a person and their condition or progress is to ask a series of questions. However, this is often at odds with the way people from different cultural groups might communicate and lead to potential misunderstandings between the nurse and individuals and their families. Such issues related to communication are often amplified because of heavy workloads: nurses not having or taking the time needed for giving individuals a full explanation of a diagnosis and treatment plan, and people not feeling as though they had sufficient opportunity to ask questions of the nurse.

Communication across cultures is recognised as an ongoing issue, often with individuals and healthcare staff talking past one another. Yet, the extent and ongoing impact of communication is not always recognised or addressed, which can lead to low standards of communication becoming the norm. The outcome of ineffective communication between a person and a nurse is likely to be unsatisfactory for both parties. Communication is explored in more detail in Chapter 8.

### Implications of cultural diversity for practice

People with different experiences, values and life ways are likely to have different ways of understanding the world, making judgments and understanding the meaning of statements made. They might hold different ideas about what is more or less important in a conversation. Most lay people will very likely have different ideas to the nurse about what criteria they will use to make a decision or reach a conclusion about what is being said. They will also use different factors when considering what information or evidence to use when making decisions about their health. Given that healthcare professionals will invariably explain the same information in slightly different ways, depending on their own disciplinary background, the challenges for both individuals and professionals when communicating are exacerbated.

When nurses work with individuals receiving care it is important to discover the unique perspective of that person, family and/or community. Therefore, it is important to work in a culturally responsive manner that will enable communication to be meaningful and helpful. Ideally it should take place in a mutual way, and in a 'safe' space for the person. If this is not achieved, most communication with healthcare providers is at risk of being meaningless, and may even place an individual at risk of negative outcomes or potential harm. Nurses must work with individuals, their families and

communities in ways that are inclusive of their diversity, responsive to their wishes and respectful of individuals' preferences and decision making (Taylor & Guerin 2010). When dealing with people from culturally diverse backgrounds, it is crucial to ask who provides care at home, and who is responsible for making decisions within the individual and family context. For example, for most Indigenous peoples, this means taking into consideration the kinship and family structure and what determines acceptable social behaviour (Best & Fredericks 2014).

It is vital that individuals seeking nursing services feel listened to, informed and supported; and that clear, concise and jargon-free language is used. This ensures people feel cared for, and facilitates their fully understanding the information given and received (Taylor et al 2013). Education about the whole healthcare experience is essential as the person and their family may be in an unfamiliar environment and context. They may be feeling uncertain and in doubt about their illness or disease and its physiology, progression and symptoms, along with the treatment options and their potential side effects. It is a universal human reaction to be fearful of the unknown, therefore the more information people have about their situation and the available choices (e.g. understanding their diagnosis, the treatment modalities and pain management available), the more straightforward the decision-making process should be for themselves and staff.

When working with people who have a different ethnicity, cultural background or life way to the nurse, it is crucial to acknowledge that the person's, their family's or community's viewpoint may vary from that of the nurse. It is important to focus on the individual or group you are working with to develop the trust and respect necessary to enable individuals to share the information required to provide individualised and appropriate care that is most relevant for them. It is useful to note that just as there is diversity between cultural groups, there is also diversity within them. Therefore, it is best to avoid using stereotypes or trying to memorise specific and complex cultural mores for any number of different cultural groups that a nurse may work with during their professional lifetime.

The following components of culturally responsive and effective nursing care are essential when working in any healthcare context, and specifically in the increasingly culturally diverse environment seen today:

- Respecting an individual's culture, knowledge, previous experiences and level of healthcare literacy
- Avoiding any assault on a person's identity, including not acknowledging it
- Treating all individuals with respect and dignity, notwithstanding your own personal beliefs.

Clear communication is essential when providing individual care to cultural minority groups for whom the use of English may be a key issue. Clinical Interest Box 10.6 provides an outline of the five key clinical issues that have been identified as most significant in cultural interactions.

## CLINICAL INTEREST BOX 10.6 Common cross-cultural communication issues

### 1. Language barriers

These are the main obstacles in obtaining an accurate health history and pain score, communicating reasons for delays, arranging appointments by telephone, explaining medications and their side effects, or diagnosing and communicating problems. Written instructions and medication labels also present a problem. This is not limited to those with English language difficulties—such problems are experienced by the elderly and those with neurological or perceptual problems.

### 2. Low levels of literacy (general and health) and high levels of anxiety

Anxiety and impaired health literacy means that individuals are not able to accurately articulate problems and require more time for explanations, including frequent repetition. Low literacy, poor vision, dyslexia, arthritis and general frailty exacerbate problems. This contributes to a lack of confidence in individuals with poor English, those belonging to Indigenous or ethnic minority groups, or those who are older or adolescent. People belonging to these groups are likely to delay seeking help until crisis point is reached, and often have greater difficulty coping in the community.

### 3. Lack of understanding

This is a significant issue, especially for individuals who are immigrants. They are unfamiliar with the healthcare system, hospital procedures and the role of healthcare professionals and the expectations they have of individuals accessing a health service. This leads to problems with treatment choices and modalities, waiting to be seen, making appointments and what is interpreted as non-compliance to treatment regimens.

### 4. General attitudes, gender attitudes and health beliefs

Factors such as how gender-based roles are diversely understood, family composition and its impact on decision making, expression of sexuality and lifestyle, age-based differences and differences in religious or other beliefs can lead to misunderstanding and misinterpretation. This in turn can lead to nurses or individuals seeking help failing to interact because of a fear of offending or alienating others.

### 5. Retention of information

Stress and anxiety associated with healthcare encounters affect a person's ability to remember, recall and interpret information. This is compounded if a person's English is acquired or little used. This can lead to an inability to recall instructions given, self-administration medication errors and readmission to the healthcare service.

*(Adapted from Taylor et al 2013)*

## CULTURE, THE INDIVIDUAL AND THEIR PROFESSION

Nurses should keep in mind the different cultures of the various professions that the health professional interacts with and/or belongs to. They should think about what unites professionals and what differences they may have. This will help develop understanding of their own and other professionals' cultures.

Managing cultural diversity in the workforce does not feature prominently in the preparation of professionals for the workforce (Kiely & Main 2011). Yet, Australia is one of the most culturally diverse nations today globally. One-third of Australians identify as being born outside the country, more than 200 languages are spoken and there is a high level of intercultural marriage (Australian Bureau of Statistics 2013). The nursing workforce is undeniably multicultural and the number of immigrant healthcare professionals practising in Australia will continue to rise. An ageing workforce and skills shortages in nursing has led to a continuing reliance on overseas countries to recruit nurses. Australasia is an attractive destination for immigrants, and as families settle and integrate into the community, cultural diversity is increasingly becoming a hallmark of the nursing profession as well as the people accessing healthcare services. Healthcare will become part of the new globalised world, and professionals must adapt accordingly.

### Values, beliefs and attitudes

Nurses need to bear in mind the different cultures of the various professionals and allied healthcare providers that they must interact and work with collaboratively. They should think about what unites professionals as well as what differences they might have. This will help to deepen understanding of nurses' and others' professional cultures.

When beginning in any of the healthcare disciplines, individuals are acculturated into the values, beliefs and understandings of the professional culture. These values are outlined in the relevant codes of practice, ethics and professional conduct that provide individuals with a valuable tool for reflecting on the required professional standards and how best to meet these.

Nurses should make sure they are familiar with and refer to their own codes and regulations and those of other professions they will work closely with. Some of these are listed at the end of this chapter, but they are frequently amended, revised and updated. It must be a part of maintaining professional competency to ensure continued familiarity with them (AHPRA 2013).

### Healthcare in a contemporary context

Nurses and all healthcare professionals want what is the best outcome for individuals, families and communities. Multiculturalism needs to be substantially embedded in the workplace. It is no longer a 'minority' issue, but rather a whole of population concern (Queensland Health 2010). To achieve this, nurses, similar to other health professionals, need to accept the diversity within their own professional group in order to collegially work together to improve outcomes for those people accessing healthcare services.

Increased cultural diversity in healthcare organisations will invariably lead to greater complexity in communication, decision making and workplace relations. These complexities are predominantly evident in the variability in both verbal and non-verbal communication styles, attitudes to decision making, approaches to completing tasks and decision-making processes (Kiely & Main 2011). Difficulties in all these areas can potentially lead to confusion and uncertainty for individuals seeking healthcare.

Moving into the future, the healthcare workforce will need to shift from utilising current mono-cultural organisational practices to those that recognise diversity. This requires input from across the organisation and the people seeking help with their healthcare. Policy and practices that promote strong cultural awareness must be implemented to assure social inclusiveness as well as compliance to legal and ethical responsibilities. It is imperative that nurses know how to work with and across diverse cultures given the demographic changes within our countries, and consequently the healthcare workplace (Hawthorne 2012).

### Multidisciplinary teams

The structure of healthcare teams differs considerably within organisations and across services. Some are hierarchical (or vertical) profession-specific structures, as often seen in urban hospitals. In these structures there is a line of authority descending from the person(s) in charge to the most junior team member. Primary healthcare or community healthcare teams, however, generally have a more horizontal structure, with most or all of the team members at a similar level of responsibility and authority. Leadership in horizontal structures may rotate between members, depending on circumstances and the type of service.

Despite the structures used in healthcare settings, there is always a sense of authority, generally based on the level of professional knowledge held by the various group members. However, the nature of healthcare education and preparation predisposes professionals to authoritative and sometimes autocratic positions being taken by the different team members. This can contribute to cultures that differ from an egalitarian power-sharing ideal, especially in urban tertiary hospitals.

Cultural responsiveness involves all health professionals examining hierarchy or power relationships with individuals and their families, and realising the detrimental effects these can have on health outcomes. Professionals may not be fully aware of the power and authority associated with their role, which may have an adverse cultural effect on others. Clinical Interest Box 10.7 outlines the importance of appropriate communication in a person's care.

## CLINICAL INTEREST BOX 10.7

*'Offering services in a way that is sensitive and respectful is likely to be experienced as "safe" and consequently is more acceptable and effective. It is therefore important to recognise cultural diversity and how treatments need to be culturally appropriate: sometimes the "best" treatment option may not be the most culturally appropriate, e.g. a patient refusing treatment for cancer because of spiritual beliefs. There are many cultural realities and ways of thinking which need to be respected. Openness and engagement of other cultural realities leads to the establishment of trust which results in successful negotiation.'*

*(Skellett 2012:383. © Pharmaceutical Society of Australia Ltd)*

# CULTURAL DIVERSITY AND INDIVIDUALS' EXPERIENCES OF THE SYSTEM

Some of the difficulties individuals, their families and communities experience when accessing healthcare and professional services are primarily the result of differing and often competing world views, language barriers and misunderstandings that arise as a result. Major factors that influence healthcare access and equity in a service are its appropriateness for its user group; individuals' previous experiences, both within wider society and healthcare services; and the degree of cultural responsiveness and safety evident within the service itself.

## Understanding the experiences of another person

It is useful to have an understanding of prejudice and discrimination, as such experiences can have a profound effect on how people see themselves in a social world. This also has the potential for significant impact when individuals seek healthcare from mainstream organisations that are staffed predominantly by persons from the dominant culture.

It is not hard to see how difficult it can be for some members of minority and culturally diverse groups to access mainstream services in Australia (Rumball-Smith & Hider 2013; Thackrah & Thompson 2013; Ware 2013; WHO 2008; Woodland 2011). Most practising nurses have recognised and seen that some of these biases and prejudices exist within all people and groups of people, in both the workplace and broader society. Many individuals are able to identify times when they felt uncomfortable or unsafe in some situations in work, social or service environments.

This discomfort is more likely to occur in situations where an individual is not in the same category as the group of people around them—whether this be by gender, sexuality, ethnicity, class, income or profession—which makes them different. On some of these occasions there will be nothing overt in the behaviour or environment of the group that can be identified or described, only a sense of unease felt by the 'different' individual. At other times that person may feel this discomfort more strongly and that they are, in fact, being discriminated against.

In some cases individuals can choose whether or not to disclose their being 'different'. For example, they can decide not to tell the GP (general practitioner) that they use recreational drugs (for fear of being labelled a 'drug user'); they might not tell their next-door neighbour that they are homosexual (for fear of being judged or subjected to homophobia); they might not tell their workmates that they are a devout Christian (for fear of being discriminated against for their religious beliefs); or a teenager might not disclose that they have had an abortion (for fear of being judged as promiscuous or stupid). These individuals still suffer marginalisation and **discrimination** from dominant group members (or those belonging to other minority groups), but physically they may attempt to 'blend in with the crowd' as much as possible.

Those people who look physically different from the dominant cultural group cannot hide their identity or choose not to disclose their difference. Every time they come in contact with mainstream groups they are made aware of their difference. These experiences, which may begin in childhood or when relocating to another country or social context, contribute strongly to their sense of identity and sense of self. That is, they will feel 'side-lined', may feel excluded, and often express that they feel others view them negatively or demonstrate prejudice towards them. These experiences are built upon and reinforced over time (Meucke et al 2011).

## Interactions with the healthcare system

In Australia, the healthcare system has developed from an allopathic biomedical scientific model. This model is based on an understanding of health and the body derived from a curative, evidence-based and rationalist paradigm. It is not surprising, therefore, that individuals with a different world view or from another type of cultural background face challenges when they interact with such a system. This can, in turn, have a significant impact on the way that individuals utilise the healthcare system, and understand or misunderstand their diagnosis and treatment.

There is increasing recognition in healthcare services that providing services without taking into account individuals' social, cultural and environmental contexts and influences is ineffective. Furthermore, many have argued that the biomedical approach of the healthcare industry is too focused on pathology. That is, disease is viewed as an organic condition, causes of illness or disease can be found within the body or biology and, accordingly, an ill person will respond to prescribed medical treatments. The biomedical model used in mainstream healthcare requires individuals to rely upon and trust 'expert' professionals and their knowledge (Adrian 2009; Thackrah & Thompson 2013). Using this approach, the health professional as the expert determines the individual's needs and offers advice, education and other strategies to address these needs (see Clinical Interest Box 10.8).

### CLINICAL INTEREST BOX 10.8
### Guiding healthcare principles

*'Good health care matters because people matter. Health care and nursing practice must be guided fundamentally by principles that promote, establish and protect human dignity. Protection of dignity is central to all that nurses engage in ... each person and their family have integral value ... their uniqueness and importance must be acknowledged.'*

*(Daly et al 2010:231)*

The expert model has been increasingly challenged, as it fails to recognise or respect the centrality of the individual's role in determining their own health. It also fails to address problems that relate to the cultural, social, historical or environmental contexts and subsequent influences on people's health and wellbeing. In an area as complex as healthcare, the expert model fails to recognise the multiple layers of complexity that influence an individual's or population's health and wellbeing (Thackrah & Thompson 2013).

## CULTURE IN PRACTICE

Many of the problems encountered by individuals, their families and the community with healthcare services are systemic and it is appreciated that individual nurses are limited in their capacity to influence these. However, there are some steps that individual nurses can take to improve services for people from minority or ethnically different groups.

### It's all about you/me and them/us

Attitudes of service providers, such as nurses, and the relationships that are formed between the service provider and individuals seeking healthcare can often be the most influential factor in achieving positive experiences and outcomes for individuals.

Overt discrimination has become increasingly unacceptable and is not tolerated under specific legislation in Australia. Nonetheless, individuals frequently report instances of alienation and social discomfort when using healthcare services (Muecke et al 2011; Wilson & Barton 2012). It is difficult for those who do not experience such discrimination to see it, but many individuals report such instances and nurses have a responsibility to respond to these accounts.

We all have beliefs, biases and prejudices in lesser or greater degrees. Understanding one's own point of view, bias and prejudices enables nurses to take responsibility for how stances might affect their delivery of care to individuals, their families and communities. Being aware of, and revising, our responses to the individuals we care for significantly influences and mediates improving services for individuals and groups who are marginalised within the healthcare system. Most healthcare professionals do not deliberately intend to be discriminatory, but can inadvertently discriminate when confronted with persons who have life ways significantly different to our own. Nevertheless, working with individuals who are very different from ourselves does not require an over-emphasis on the differences—such an emphasis could in fact impede the development of relationships of trust between the nurse and an individual.

### Working in authentic partnerships

An alternative approach lies in the partnership model. Working in partnership requires us to transfer the focus of professional attention away from problems, deficits and weaknesses and towards the strengths or power of the person or community. This orientates the nurse towards developing a collaborative and equal partnership with individuals, focusing on building an individual relationship. A major emphasis of the partnership model is that all individuals have strengths and capabilities and are more likely to respond to interventions that resonate with their belief systems, and build on their innate strengths, than rely on those that identify weaknesses and deficits (Kimpton 2013; Ware 2013).

An important component of the partnership model is that rather than the expertise lying with the professional or nurse, there is an increasing emphasis on the capability of individuals, their families and communities. The assumption is that with support they will discover their own way, rather than learning to adopt the approach of the nurses or learn the 'right way' defined by an expert. Individual or person-centred care involves professionals and individuals and their family working together to achieve common mutually determined goals that are based on shared decision making and responsibility, and mutual trust and respect (Spencer 2012).

Another important feature of the partnership model is to develop rather than threaten the person's self-esteem. Working in a strengths-based partnership does not deny the expertise of the nurse or professional; it merely identifies the complementary expertise of individuals and their families in terms of their own needs. Importantly, it also utilises their capacity and capability in how best to meet their requirements.

The partnership model is particularly important when working with marginalised groups, such as Indigenous peoples, who are historically mistrustful of 'experts' or authority figures (Queensland Health 2010; Thackrah & Thompson 2013). An important component of empowerment, embedded within the partnership model, occurs when the professional identifies and believes in individuals' ability to understand, learn and manage their own situation. The aim is to focus on strengths and increase individuals' capabilities and feelings of self-worth, rather than perceptions of themselves as less competent and dysfunctional, and as such increasingly ostracised within the mainstream healthcare model. The mainstream healthcare system, by its very nature, reinforces the notion that professionals diagnose, treat and cure. This creates dependence and fosters isolation of individuals. It is essential that services based on a partnership model build skills and capacity rather than create dependency.

Nurses and all health professionals should examine their own communication style and biases for their own judgments and prejudices that will impact on their ability to work in partnership. If nurses believe that individuals are unable or unwilling to take part in or manage their own lives, long-term health gains will be difficult to achieve. Healthcare professionals may have a heightened sense of their own authority that is incompatible with respecting individuals as being expert on their own lives and health.

Working in partnership requires that nurses assist individuals with a genuine intent to develop, secure and use strategies and practices that will promote or foster a sense of control and self-efficacy. Shared decision making between nurses and individuals is important and the personal qualities and attitudes of staff are pivotal to ensuring good outcomes and health gains.

### CRITICAL THINKING EXERCISE 10.6

1. How can you ensure that you are a culturally responsive nurse and communicate effectively?
2. List three (3) steps that you could take to ensure that you enhance your communication with individuals and their families who are from a different culture to your own.

## Cultural responsiveness and cultural safety and what they mean for nurses

Cultural responsiveness refers to a way of delivering healthcare that is receptive to and inclusive of individuals' needs. It requires nurses to be culturally competent, and involves responding to people within their own cultural contexts (Gill & Babacan 2012; Werkmeister-Rozas & Klein 2009). It involves nurses establishing relationships with individuals that respect and include their cultural values and beliefs. It also involves their support networks and community.

**Cultural responsiveness**, **cultural safety** and **cultural competence** are all concerned with how to create and maintain contexts for nursing care in which individuals, families and communities can access and experience healthcare provision from healthcare professionals without, in any way, having their cultural identity compromised.

The experience of working as a nurse in culturally diverse environments or with members of marginalised groups is both an interesting and a challenging experience. There are both similarities and differences, and varying degrees of commonalities within any cultural group. Those who work in such contexts, as nurses are increasingly called to do, need to recognise that their own cultural beliefs, values and behaviour will impact the care they provide as a professional.

Cultural safety is a term that has been widely used in nursing and forms a crucial part of nurses being culturally competent. It is a requirement in Australia for a nurse to demonstrate the capacity to work in a culturally competent manner for continued registration as a nurse. Cultural safety, first defined by Irihapeti Ramsden (2002) in the 1990s, has been defined by the Nursing Council of New Zealand (2011) as:

> *the effective nursing practice of a person or family from another culture, and is determined by that person or family. Culture includes, but is not restricted to, age or generation; gender; sexual orientation; occupation and socioeconomic status; ethnic origin or migrant experience; religious or spiritual belief; and disability.*
>
> *The nurse delivering the nursing service will have undertaken a process of reflection on his or her own cultural identity and will recognise the impact that his or her personal culture has on his or her professional practice. Unsafe cultural practice comprises any action which diminishes, demeans or disempowers the cultural identity and well-being of an individual.*
>
> **(Ramsden 2002:7)**

In summary cultural safety means providing an environment in which individuals feel spiritually, socially and emotionally safe, as well as being physically safe. By contrast, unsafe cultural care is any action that diminishes, demeans or disempowers the cultural identity and wellbeing of an individual or group. Culture is also defined as being more than ethnicity; it is wider in intent, embracing individuals from marginalised groups including those different from the nurse in, for example, age, religion, socioeconomic group or intellectual disability.

### DECISION-MAKING FRAMEWORK 10.1

You have been employed as an enrolled nurse in a healthcare service that serves an ethnically diverse population. Two of the goals of the service are to ensure that individuals attending the healthcare service have their cultural needs both identified and attended to, and that they understand the information they receive. The aim is to improve people's health outcomes.

Using the following decision-making framework to assist you:

- What factors do you need to ensure are part of your practice when engaging with individuals who are from a culture that is different to your own?
- What strategies might you use to manage the cultural diversity that you will encounter working as a nurse?
- What information related to individuals and communication do you need to collect and document when undertaking assessments of individuals?
- What strategies and information can you use/access to be responsive to an individual's unique needs?
- If you encounter difficulties in communicating with individuals, what alternative approach(s) can you take?

## The nursing role

A nurse's effectiveness in working with those seeking healthcare depends largely on the manner in which they interact with individuals. This does not mean that they should ignore systemic issues that place constraints on how they practise or how to improve individuals' experiences of the healthcare service. Nor can nurses ignore their professional duty of care to provide high-quality services to all people. This requires practitioners to be mindful of their personal and professional values, beliefs and experiences, and how these impact their interactions with people from cultures different to their own.

The importance of addressing ethnocentrism and ameliorating the impact of prejudices cannot be emphasised enough. There are many aspects of society and mainstream healthcare services that individuals cannot change, but the attitudes of a non-judgmental, caring and empathetic service provider can make a significant impact on the experiences of individuals, their families and communities.

## Summary

This chapter presents a number of complex and challenging topics, ranging from the place of culture in the nurse's own personal and professional life to theories of cross-cultural care, prejudice and marginalisation, as well as discussing the structures, practices and complex relationships within healthcare settings. The broad impact of a healthcare system's culture on individuals, families and communities contributes to not only the behaviour and practices of healthcare professionals but also the access to and quality of services they deliver. Nurses are asked to reflect on their own models of interaction and intervention with minority and marginalised individuals and groups, particularly how they can make changes to improve these.

This chapter aims to assist nurses to increase their awareness of and ability to critique the construct of culture within themselves, their profession and the communities in which they work. Nurses are encouraged to explore their own culturally embedded values, beliefs and practices and to develop an understanding of how culture impacts the way people work and how they can work more appropriately and effectively across cultures.

## Review Questions

1. What does culture mean?
2. How is cultural safety defined?
3. What other terms are used in health when discussing cultural safety?
4. How can ethnocentrism influence nursing practice?
5. Consider how your own nursing practice is culturally responsive. What areas would benefit from further development?

CHAPTER
11

# Australian Indigenous health

*Juanita Sherwood and Jodie Hughson*

## KEY TERMS

Aboriginal and Torres Strait Islander peoples
Closing the Gap
colonisation
country
health
human rights
Indigenous Australians
Indigenous peoples
respect
social determinants
social justice

## LEARNING OUTCOMES

At the completion of this chapter and with further reading, students should be able to:

- Understand the continuing effects of colonisation on Indigenous health and social and emotional wellbeing
- Outline the impact of particular historical, social and political processes on the health and social and emotional wellbeing of Indigenous people in Australia
- Discuss traditional and contemporary Indigenous healthcare knowledge and practices
- Discuss contemporary issues associated with Indigenous health and health service delivery

## CHAPTER FOCUS

This chapter aims to provide some valuable information for making a difference when working with Aboriginal and Torres Strait Islander peoples in and out of the health setting. Indigenous **health** in Australia is most often written about as a bad news story. This can often make the reader feel overwhelmed and unable to anticipate how they can personally make a difference. This chapter aims to deliver a story that you can engage with and that enables you to feel confident about your role in working with Aboriginal and Torres Strait Islander peoples. Working with Australia's First Peoples in achieving improved health outcomes in all dimensions requires health professionals to support the Indigenous person to determine the health partnership that they want and need. An important part of wellbeing for Aboriginal and Torres Strait Islanders is being able to express themselves through music, art and storytelling; this is reflected within this chapter by the presence of a number of works and stories from Indigenous people (see Figures 11.1 and 11.2).

Essentially, Aboriginal and Torres Strait Islander people's current health is very different from that of most Australians. This is because their circumstances historically and today have been significantly impacted by past and present government policies which specifically targeted **Indigenous Australians** in a negative and harmful manner. These policies and a universal lack of access to culturally safe and competent care have contributed to the high burden of morbidity and mortality. Most Australians have had the ability to be in control of their lives and make choices about their lives that ensured that they and their families enjoyed a life of freedom and wellness; this has not been the case for most Indigenous Australians. The reasons for this are not often explored; however, this chapter aims to enlighten you as to the many structural barriers that continue to ensure there is a significant gap and difference between the health and wellbeing of Indigenous Australians and the health and wellbeing of those who inhabit a developed nation.

It is important to know about the health issues that impact on the lives of Aboriginal and Torres Strait Islander peoples; however, this is not enough to make the difference. It is necessary to have:

- positive engagement with Indigenous people
- respect for the ways Indigenous people view health and social and emotional wellbeing
- the building of relationships to ensure effective communication is achieved between yourself and the Indigenous person
- the growing of trust between the health professional and the Indigenous person.

This is a powerful and important working-together strategy that will make a difference for yourself and Aboriginal and Torres Strait Islander peoples or other individuals.

## LIVED EXPERIENCE

I came from Ngarluma country to a hospital in the big city. They told me I had heart disease and gave me lots of pills to take. I call it poison. I believe I have a curse and this is why I am sick. I don't believe in the white man's medicine so I don't take it.

**Tom**

See Figure 11.3.

The land we now call Australia is home to the oldest surviving cultural groups in the world. Before 1788, these comprised over 500 language groups living as separate nations with their own traditions. **Colonisation** saw these peoples and their culturally specific names for themselves dismissed as irrelevant (Smith 1999). These names were replaced with Western terms such as 'Aboriginal' and 'Indigenous', imposed by the colonising forces (Best 2014:8). Appreciating that English and the Western dominant communication modes are and were not those used by Aboriginal and Torres Strait Islander peoples—even down to the names given to these peoples—is a worthy point of consideration when attempting to communicate effectively with Indigenous Australians in the health setting and beyond. Many health professionals are unaware that English is not commonly used in remote Indigenous communities and that interpreters are essentially required to ensure that Australian Indigenous peoples receive a well-informed health account that can be trusted and understood.

Storytelling and yarning is an important form of communication and is used a great deal by **Aboriginal and Torres Strait Islander peoples** and **Indigenous peoples** across the world. It is a way of sharing knowledge and has been used for many thousands of years, pre-dating current English literacy. It is a less direct communication approach, and offers an informal and meaningful way of sharing knowledge about yourself in context with your family and community (Bessarab & Ng'andu 2010; Fredericks 2003; Geia et al 2013; Kovach 2009).

*When strangers visit our country, we observe with a keen interest the way they respond and react to the panoramic view stretched out before them. What are they really seeing and thinking? We reckon they may be thinking about the beautiful scenery or just simply enjoying the peace and quiet or the wide-open spaces. Together we stand gazing at the same scenery. We look beyond the pristine beauty of the bush out in all its glory. The land contains our stories, it's enriching and powerful.*

**(Rose et al 2011:vi)**

**Figure 11.3** Ngarluma Country is located in the West Pilbara region

*(Photographer Sharmila Wood, Courtesy FORM, Ngarluma Ngurra: Aboriginal Culture on the map)*

It is from appreciating their stories and experiences that we hope you will gain further knowledge of the importance of working with, and not on, Australia's Indigenous peoples.

## WORLDVIEWS

The way we view our world is important to how we think about things and reflect on information we have had shared with us. Appreciating that there are many ways of knowing the world is an essential first step in opening up effective communication lines. When we discover through our studies that there is not one right way or one truth we can become concerned. However, when we uncover that there are many ways of knowing and that these many different ways and truths are important to each person, we can start to grasp the value of recognising how worldviews can influence the way we may view and perceive health and health professionals.

## LAND AND COUNTRY

**Country** always was and remains central to Indigenous Australians' health and wellbeing. Indigenous Australians' ways of knowing about land and country are very different from the Western ways of thinking and knowing land. Country is acknowledged as the mother, the source of all resources, a profoundly spiritual essence and framework for living sustainably that requires respect and ceremony to celebrate her gifts and storylines. This way of knowing and talking about country and place is very different from the ways of understanding country and place of non-Indigenous peoples (Burgess & Morrison 2007). 'Place provides the context to relate to other Indigenous peoples and places and to enter dialogue, both nationally and globally' (Burgess & Morrison 2007:180).

*In Aboriginal English, the word 'country' is both a common noun and a proper noun. People talk about country in the same way they talk about a person: they speak to country, sing to country, visit country, worry about country, grieve for country and long for country. Country is a living entity with a yesterday, today and tomorrow, with consciousness, action and a will toward life. Because of this richness of meaning, country is home and peace; nourishment for body, mind and spirit; and heart's ease.*

**(Rose et al 2011:12)**

Living on country and looking after country requires a great deal of knowledge to ensure all aspects of the ecosystems remain in balance to ensure sustainability. The applications of knowledge and actions are sophisticated and are evidence based and so have scientific rigour, and as such these practices require time and respect in relation to the benefits they ensure and provide for all Australians. Some of these vital knowledge applications are fire stick burning and farming; fashioning breeding and harvesting environments; harvesting and growing of plants and tubers; and establishment of sanctuaries for animals (Ranzijn et al 2009:57).

Contrary to ill-informed government ideologies we have learnt through research that living on country is good for Aboriginal people's health. Burgess et al's research evidenced that self-reported involvement in caring for country provided significant positive health outcomes.

*Greater Indigenous participation in caring for country activities is associated with significantly better health ... [O]ur findings suggest that investment in caring for country may be a means to foster economic development and gains for both ecological and Indigenous peoples' health.*

**(Burgess et al 2009:567)**

## Indigenous concepts of 'country' and the importance of caring for country

For Indigenous peoples 'country' encompasses an interdependent relationship between them and their ancestral lands and seas. Country is multidimensional—it consists of people, animals, plants, Dreaming, underground, earth, soils, minerals, waters, air etc. 'People talk about country in the same way that they would talk about a person: they speak to country, sing to country, visit country, worry about country, feel sorry for country, and long for country' (Rose et al 2011:12).

'Caring for country' means participating in interrelated activities on Aboriginal lands and seas with the objective of promoting ecological, spiritual and human health. It is also a community-driven movement towards long-term social, cultural, physical and sustainable economic development in rural and remote locations, simultaneously contributing to the conservation of globally valued environmental and cultural assets.

By combining customary and contemporary knowledge, Aboriginal landowners deliver a broad suite of environmental services of national and global significance, including:

- Border protection
- Quarantine services
- Wildfire abatement/carbon sequestration
- Control of invasive weeds and feral animals
- Biodiversity conservation and fisheries management
- Sustainable commercial use of wildlife
- Cultural maintenance activities (Burgess et al 2009:567).

# DEMOGRAPHICS

The following data has been projected by the Australian Bureau of Statistics (ABS) from the 2011 Census for 30th of June 2013. The Australian Indigenous population was estimated by the ABS to be 698 583 people, being 3.1% of the total Australian population. It was projected that NSW has the largest Indigenous population of all states in 2013, being 216 612 people (Australian Indigenous HealthInfoNet 2014:v). The map in Figure 11.4 demonstrates the percentages of Aboriginal and Torres Strait Islander populations in 2011. Some of the figures are surprising to many as it is often assumed that Aboriginal and Torres Strait Islander populations are found more in the outback areas of Western Australia, South Australia and the Northern Territory than in more heavily populated states like New South Wales. Even more astounding is the fact that Sydney, a highly urban city, has the largest Australian Indigenous population in Australia.

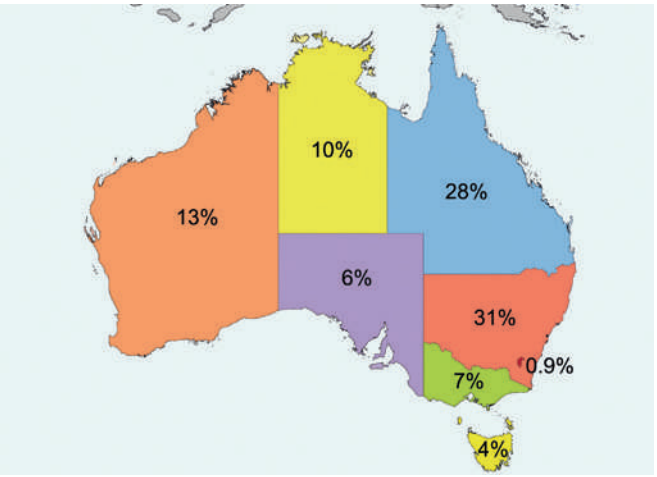

**Figure 11.4** Aboriginal and Torres Strait Islander population by state and territory 2011 (preliminary)

**CRITICAL THINKING EXERCISE 11.1**

Why do you think these figures and demographics could be different from what you thought you knew about Australia's First Nation peoples?

It was further projected for 2013 that the Northern Territory (NT) had the greatest proportion of Indigenous peoples, being some 30% of the total NT population. It was noted that in 2011 approximately 33% of Indigenous Australians lived in cities (Australian Indigenous HealthInfoNet 2014:v).

Figure 11.5 illustrates there were many nations of Aboriginal and Torres Strait Islander peoples who lived in and cared for this continent. Each nation group had and has its own legal, economic, education and health systems, as well as multiple languages. Traditions varied considerably from one nation to the next.

English was a foreign and introduced language to Australia. It has become the dominant language now used in this continent. However, there are many languages spoken in Australia that are not English. These are the First Australians' languages and those of peoples who now live in Australia and came from countries where English was not the dominant voice taught or used.

In healthcare systems we are aware of the essential requirement of ensuring health messages are heard and comprehended. We should always make sure that the individual has understood what we have explained to them. This can be very difficult if the message is in a language that is not their first language.

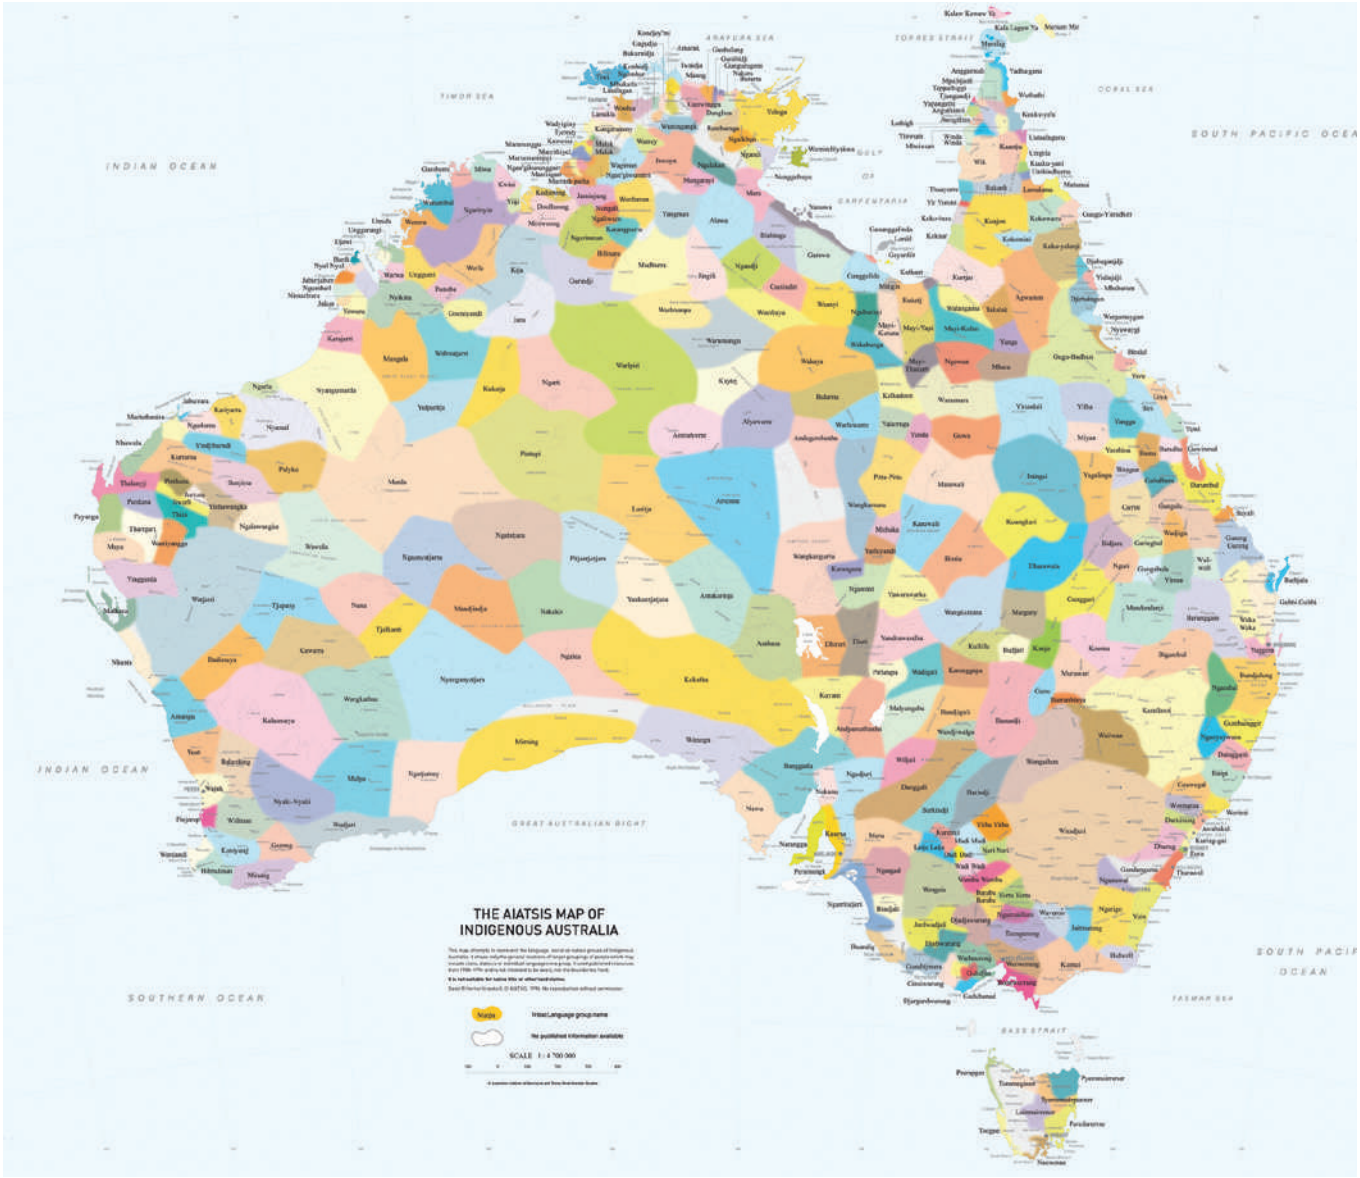

**Figure 11.5** Map of Aboriginal and Torres Strait Islander Australia: nations and language

This map attempts to represent the language, social or nation groups of Aboriginal Australia. It shows only the general locations of larger groupings of people which may include clans, dialects or individual languages in a group. It used published resources from 1988–94 and is not intended to be exact, nor the boundaries fixed. It is not suitable for native title or other land claims. ## DIVERGENT WORLDVIEWS

Unlike the cooperative, collective and holistic natures of Indigenous cultures, Western cultures are considered to be autonomous, self-assured, individualistic and competitive. This results from many centuries of Western religious, political and academic warfare (Ranzijn et al 2009:23).

Western medicine is a paradigm that is newly evolved and has developed its own language and skill sets (Foucault 1994). Western health research has built up many effective ways of dealing with disease, cancers and chronic and acute conditions. It is a way of knowing, being and doing that many

### CRITICAL THINKING EXERCISE 11.2
### Land and country reflective questions

How does Aboriginal and Torres Strait Islander peoples' view of Australia and their own countries differ from your own?

Considering the information provided on 'caring for country', do you need to reflect further on the impact that being off country will have on the wellbeing of an Indigenous person?

How can you make sure that an Aboriginal or Torres Strait Islander person has understood you?

different health professions and their respective professionals undertake to participate in health agency and improving outcomes for their individuals. These many different professions and their particular health focus can make the health story a confusing one for those not trained in its logic and language, especially the focus on separation of body parts and conditions versus the entire holistic body.

It is important to accept that this way of knowing a person may be very foreign to an individual's worldview of health. Richard Trudgen, author of *Why Warriors Lie Down and Die*, has reasoned that many health professionals are not taught that their way of viewing health may elicit a 'communication gap' between themselves and the person they are caring for who does not share the same dominant Western background (Trudgen 2000:76). This is very important as the communication gap works in dual ways.

## Communication and cultural security

The accommodation of health knowledge is designed to shift your ability and capacity to engage in health-improving activities. You may not be aware that you are speaking a foreign language to those you are caring for. This is the skill base you have spent years studying to acquire. This skill base is not shared by other non-health professionals and therefore they may have great difficulty in understanding the way you try and share this knowledge (Best 2014:64–68).

### CRITICAL THINKING EXERCISE 11.3
### Health worldview clash reflective questions

Communication is a tricky thing and there are many ways to improve your communication skills. This chapter is focused on the gaps that you may not be aware you are creating because of your expert knowledge base. Your health worldview will be very different from that of other health professionals you work with or may have worked with. You may have already had experiences where these worldviews and assumptions have clashed.

Recall how you felt in this situation and how you dealt with it. Did you walk away feeling you were heard and understood or did you come away angry, confused and lacking confidence?

These are feelings and experiences you can create for the people you are caring for by not appreciating what they may not know, or know on a different level or through another view of the world.

What can you do to ensure that you do not generate this uncomfortable and unsafe experience for Aboriginal and Torres Strait Islander persons?

Respect is a very powerful word and practice in Aboriginal and Torres Strait Islander peoples' culture. **Respect** is an overarching value and protocol that is central and fundamental to developing a meaningful and ongoing relationship. This relationship process has been laid by Aboriginal law, and this is because '[l]aw belongs to people and to country' (Bird Rose 1996:32). The law and knowledge through respect embody our ways of knowing, being and doing honourable living. Respect is an ethical/moral space and a term we share in being principled.

*Respect, in the Indigenous sense, means to listen and to hear and value what we have to say about ourselves and our experiences, even if what we have to say challenges your ways of knowing. Respect means you're open enough to acknowledge that there are many ways of being in this world, and that they all have their own authority. (Sherwood 2010:261)*

Respect is very important to Indigenous Australians and acts considered to be disrespectful can and do cause harm.

Many people do not access health services because of poor treatment and poor communication experiences. Many do try again to access services and are sent away. There have been many deaths of Indigenous Australians as a result of poor communication and culturally unsafe health service provision (Cox 2007), and people continue to die in Australia for these reasons today.

### CRITICAL THINKING EXERCISE 11.4
### Respect and health reflective questions

Being disrespectful can contribute to the worsening of health outcomes by reducing a person's trust in the system and your partnership.

What do we mean by respect? How you can show it? How are health outcomes for an Indigenous person affected if you are disrespectful?

# CULTURAL RESPECT, SECURITY AND COMPETENCE

The Australian government states that:

*High quality health care must be accessible and appropriate for the needs of Aboriginal and Torres Strait Islander people, acknowledging that those with disability may have additional barriers in accessing health care. Coordinated, culturally appropriate health services across health care, hospital care and aged care will improve the patient journey and health outcomes for Aboriginal and Torres Strait Islander people and their families.*

*A culturally respectful and non-discriminatory health system*

*'Discussion about racism is difficult and highly charged in the Australian community and action should be focused on the development of respectful relationships and non-sanctioning of discriminatory behaviour, policies and practices, including within the health system*[1]*.'*

*Goal*

*All health care, whether government, community or private, is free of racism.*

[1]The Lowitja Institute Submission: The Lowitja Institute 2012, Submission to the Australian Government for the development of a National Aboriginal and Torres Strait Islander Health Plan.

*Context*

*Racism is a key social determinant of health for Aboriginal and Torres Strait Islander people and can deter people from achieving their full capabilities by debilitating confidence and self-worth, which in turn leads to poorer health outcomes. Evidence suggests that racism experienced in the delivery of health services contributes to low levels of access to health services by Aboriginal and Torres Strait Islander people.*[2]

*There are a number of pathways from racism to ill-health—experiences of discrimination, linked with poor self-assessed health status, psychological distress, depression and anxiety, and health risk behaviours such as smoking and substance misuse.*

*Experiences of racism are compounded by the traumatic legacy of colonisation, forced removals and other past government discriminatory policies. The consequences of these events have been profound, creating historical disadvantage that has been passed from one generation to the next.*[3]

**(Australian Government 2013:14–15)**

Many Aboriginal and Torres Strait Islander people and their health professionals and social scientists have argued that **social determinants** are central to the continuing disease encountered by Indigenous Australians (Anderson 2007; Bailie & Myfawny 2001; Behrendt 2012; Saggers & Gray 2007). The Australian Institute of Health and Welfare (AIHW) has further verified this argument through its analysis of data. The AIHW is proposing that the central reason for the gap between the health and wellbeing of Indigenous Australians and those who are non-Indigenous is social determinants rather than health risk behavioural factors. Social determinants are considered responsible for 33% of the gap as opposed to 11% for health risk behaviours (Close the Gap Campaign Steering Committee 2015:37).

Most of these health determinants are out of the control of the health sector and require a holistic or a whole of model of care and management system that engages with and works very closely with Aboriginal and Torres Strait Islander people who have been selected by Aboriginal and Torres Strait Islander peoples to represent them. This is a request made regularly by Indigenous Australians and their organisations, particularly the Aboriginal Community Controlled Health sector. This is because Aboriginal and Torres Strait Islander peoples are the experts in what works for them and what does not. A fundamental barrier to improving health outcomes has been the inability of governments and services to listen to Aboriginal and Torres Strait Islander peoples and follow up with responding to their requests.

## Cultural safety

Cultural safety is a model of care developed by the Nursing Council of New Zealand. It has five principles, which are also used in Australia:

1. Reflect on your practice
2. Seek to minimise power differentials
3. Engage in discourse with the person
4. Undertake a process of decolonisation
5. Ensure that you do not diminish, demean or disempower others through your actions (Best 2014:64–68).

## Cultural competence

The journey towards cultural competence requires both motivation and willingness in order to advance cross-cultural communication and effective practice. The following definition of cultural competence is one that has credence:

*A set of congruent behaviours, attitudes and policies that come together in a system, agency or among professionals and enable that system, agency or those professionals to work effectively in cross-cultural situations.*

**(Cross et al 1989 cited in Walker et al 2014:200)**

Cultural competence is importantly not an end state but rather a continuous process. The process is a lifelong journey that requires the processing of new knowledge, the gaining of skills, the uptake of values and the actioning of attributes.

The following continuum provides a framework for understanding the steps and shifts that are required to be undertaken to improve cross-cultural communication:

- **Cultural incompetence:** lack of knowledge of the cultural implications of health behaviour
- **Cultural knowledge:** learning the elements of culture and their role in shaping and defining health behaviour
- **Cultural awareness:** recognising and understanding the cultural implications of behaviour
- **Cultural sensitivity:** the integration of cultural knowledge and awareness into individual and institutional behaviour
- **Cultural competence:** the routine application of culturally appropriate healthcare interventions and practices
- **Cultural proficiency:** the integration of cultural competence into one's repertoire for scholarship (e.g. practice, teaching, research) (Wells cited in Walker et al 2014:203).

Walker and colleagues recommend that cultural competence is about adopting a particular standpoint—a state of mindfulness, humility, sensitivity, authenticity and a willingness to really listen and learn from others (Walker et al 2014:204).

# INDIGENOUS WAYS OF VIEWING HEALTH

Indigenous peoples universally across the world view health through a holistic lens. This is because of the way they have lived for thousands and thousands of years.

*Indigenous people teach us about the values that have permitted humankinds to live on this planet for many thousands of years without desecrating it. They teach us about holistic approaches to health that seek to strengthen the social*

[2]Awofeso, N 2011, 'Racism: a major impediment to optimal Indigenous health and health care in Australia', *Australian Indigenous Health Bulletin*, vol. 11, no. 3.
[3]Australian Bureau of Statistics 2010, *National Aboriginal and Torres Strait Islander Social Survey*, ABS Cat. No. 4704.0, Canberra.

*networks of individuals and communities, while connecting them to the environment in which they live.*
**(Gro Bruntland 1999 cited in Burgess & Morrison 2007:178)**

The National Aboriginal Health Strategy's Working Party embarked on a far-reaching consultative process to bring forward the first well-informed text on Aboriginal health that became the pivotal agenda for setting guidelines for action to improve the health and wellbeing for Aboriginal and Torres Strait Islander peoples. The strategy brought forward an Aboriginal-informed description of the way Aboriginal health could be explained and viewed. See Clinical Interest Box 11.1.

This social system for living with all other matter living and non-living is known universally across Australia as the Dreaming, although each language group has its own name for this system. Jukurrpa is the language term used by nations in central Australia for Dreaming. The Dreaming was established by creator beings that encrypted the law into the land to ensure the survival of all beings including people, animals, plants and rocks, mountains, rivers, sky, waterholes, etc. This law requires everything to be cared for, to sustain the balance for survival of all.

Swan and Raphael brought forward, in their seminal *Report: Ways Forward*, a number of principles for working with Aboriginal and Torres Strait Islander people with mental health issues. Swan and Raphael are both consummate and experienced mental health professionals who undertook a national consultative project regarding Aboriginal and Torres Strait Islander mental health. The findings of this national process demonstrated that health professionals and specifically mental health workers required a further explanation of the way Aboriginal health was viewed, as they were not effectively working with Aboriginal and Torres Strait Islander peoples and their social and emotional wellbeing health issues. The following first principle of the report delivers a succinct definition of cause and effect:

*Aboriginal concept of health is holistic, encompassing mental health and physical, cultural, and spiritual health. This holistic concept does not merely refer to the 'whole body' but in fact is steeped in the harmonised inter-relations which constitute cultural well-being. These inter-relating factors can be categorised largely as spiritual, environmental, ideological, political, social, economic, mental and physical. Crucially, it can be understood that when the harmony of these interrelations is disrupted, Aboriginal ill health will persist.*
**(Swan & Raphael 1995:19)**

Although these explanations have been provided to inform health action, government policies throughout the past 200 years have ensured that most Indigenous Australians do not have a sense of control over their lives (Carey 2013), a vital determinant of health and wellbeing.

The following section will provide you with some information to assist you in considering the current status of Aboriginal and Torres Strait Islander health and wellbeing with a context of Indigenous Australian history, colonisation and its continuation and problematic policy implications (Saggers & Gray 2007).

## CLINICAL INTEREST BOX 11.1

'Health' to Aboriginal people is a matter of determining all aspects of their life, including control over their physical environment, of dignity, of community self-esteem and of justice. It is not merely a matter of the provision of doctors, hospitals and medicines, or the absence of disease and incapacity.

Prior to colonisation Aboriginal peoples had control over all aspects of their life. They were able to exercise self-determination in the purest form. They were able to determine their 'very being', the nature of which ensured their psychological fulfilment and incorporated the cultural, social and spiritual sense.

In Aboriginal society there was no word, term or expression for 'health' as it is understood in Western society. It would be difficult from the Aboriginal perception to conceptualise 'health' as one aspect of life. The word as it is used in Western society almost defies translation but the nearest translation in an Aboriginal context would probably be a phrase such as 'life is health is life'.

In contemporary terms Aboriginal people are more concerned about the 'quality of life'. Traditional Aboriginal social systems include a three-dimensional model that provides a blueprint for living. Such a social system is based on inter-relationships between people and land, people and creator beings, and between people, which ideally stipulates inter-dependence within and between each set of relationships (NAHSWP 1989:ix).

## HISTORY TAKING: THE CONTEXT

The taking down of the history of an individual is an essential nursing skill. This history offers you vital information that can assist you and your health peers in delivering culturally safe and relevant healthcare to Australia's First Peoples.

Many health professionals have not had access to the history of Australia from an Indigenous perspective. This lack of knowledge is very common and is mainly a result of what most of us were not taught at school. This lack of knowledge, however, has become a stumbling block in improving the health and wellbeing needs of Aboriginal and Torres Strait Islander peoples.

### Considering the context

Having access to this history is important and can assist you in appreciating why there is such a high level of poor health status among Aboriginal and Torres Strait Islander peoples. Australia is the oldest continent in the world and boasts to have the oldest and longest living cultural groups in the world. Aboriginal peoples have looked after country and survived a very harsh environment because of their deep respect for the land/country. This deep respect of country continues today, as it is central to life and wellbeing. Looking after country is and has been always an extension of looking after self and community. Connection to land and country is

central to the wellbeing of Indigenous society. Ensuring country is looked after ensured that country looked after you. Country was and remains ingrained with law. This law is known as the Dreaming and articulates responsibilities that are required of people to maintain a sustainable environment. People were generally healthy and well. There has been no archaeological evidence of the diseases that exist today apart from trachoma. Other diseases came about with the disruption of land tenure and caring for country.

Keeping people off country has resulted in not looking after country and this has ensured that both people and country have suffered. Settlement significantly disturbed tenure to land as the following text illustrates. Aboriginal people's ways of knowing, being and doing, and consequently living were informed by laws laid down by the Dreaming. This way of living has been greatly changed; however, Indigenous Australians continue to have a strong connection with their land, ancestors and matter, living and not living, that can be difficult for those not from this culture and worldview to appreciate or understand.

Australia's colonial story established and enforced Aboriginal and Torres Strait Islander peoples to become refugees in their own country. These acts did not occur overnight; rather they have been rolled out over the past two centuries under many Acts, laws, policies and actions. These were foreign laws from England that were brought to the shores of Australia to sanction the occupation of a country that was not British. Australia had its own laws; these laws are written in the land and were followed by Aboriginal Australians from time immemorial. When the British arrived these laws and principles were largely ignored and broken, resulting in conflict.

A conflict of warfare was maintained from 1788 through to 1838 (Connor 2003) in the east of Australia, although massacres of Aboriginal clans continued widespread up until the 1860s in NSW and the 1890s in Queensland. Tasmania's black war raged from 1804 through to 1832, instigated by a massacre of Aboriginal clansmen; 1000 black and white people were killed (Ryan 2012). Professor Ryan has stated, 'I think people have largely been in denial about frontier violence. There's a lot of puzzlement about it. There's a degree of embarrassment.' 'It would signal a new understanding among Australians in general and Tasmanians in particular that violent bloodshed on home soil has been an important part of our history' (Darby 2012). Western Australia and the Northern Territory were settled later than the eastern seaboard; however, they both suffered many massacres up until 1926 and 1928 respectively.

National warfare and free settlement ensured Aboriginal Australians were uprooted from their countries, their way of living and surviving, and were left as itinerant refugees to survive as best they could manage. The killing of livestock to survive often resulted in reprimands from settlers and the paramilitary, which would often result in large-scale massacres (Reynolds 1987; 1989; 2003). Disease brought to this country and lack of food ensured many Aboriginal Australians died before their time.

In 1838 a Bill was passed in Britain in order to halt the large-scale massacres and 'to protect the natives' (Ella et al 1998:29). The Bill required that each state establish a Protector whose role was to prevent further massacres. This was not enacted until 1882 in NSW when a board was established under the jurisdiction of a Protector. The Protection Board sanctioned and enforced the incarceration of Aboriginal peoples onto reserves and missions throughout NSW and the rest of the country (Ella et al 1998). The missions received minimal government funding for the building and maintenance of housing and/or food, healthcare or education. Housing conditions were subsequently poor and became a significant determinant in relation to Aboriginal Australians' health and wellbeing, as people were forced to live together in close and often overcrowded conditions that enabled contagious diseases to spread easily. Many died from communicable diseases such as TB, measles, influenza and pneumonia. Indigenous housing continues today to be poorly funded and remains a source for infection through overcrowding.

Food was provided through a ration system and those who lived on the reserves and missions were expected to work for their keep. This new diet of white flour, sugar, tea and perhaps some meat was a far cry from the nutrients Aboriginal people were able to consume prior to white settlement. Starvation and poor health due to poor nutrition ensured greater levels of diseases and deaths. Importantly many Aboriginal Australians died as a result of this new dramatically different but enforced lifestyle. This newly prescribed lifestyle would have long-term implications for forthcoming generations. The devastating high rates of chronic disease such as circulatory disease and diabetes, respiratory disease and obesity can be linked back to this dramatic shift in diet and life style (Mitchell 2007).

Poverty resulted directly from being taken off country and being forced to work for rations and not money. The Protection Board had pretended to take care of the wages of Aboriginal people across the country for safe keeping. Instead these stolen wages were used for mainstream services (see Clinical Interest Box 11.2). Aboriginal wages funded hospitals and schools that they were not allowed to access or use (Kidd 2000). Those who were able to continue to work on their lands as drovers and farm hands were equally disadvantaged financially, often being paid in rations that could include tobacco, rather than a wage (Morrissey 2003).

Poverty was entrenched both historically and socially. This was a direct result of government and non-government practice and policy regarding Aboriginal and Torres Strait Islander peoples, not just in Queensland but all over the country.

For families living on the missions and reserves, they also lost their freedom, and were prevented from speaking their languages or maintaining their law, health and educational practices. English became the dominant and enforced language. Requests had to be made to the police and/or the Aboriginal Protector if they wanted to get married, apply for a job, buy a dress or access any form of healthcare. Often healthcare was refused.

## CLINICAL INTEREST BOX 11.2 Excerpt from the Queensland stolen wages fact sheet

Since the 1897 Protection Act the Queensland government could declare any Aboriginal a ward of state and control every aspect of their lives. People were forcibly interned on reserves (1938:7525; 1968:8500).

From 1904 all employment, wages and savings were controlled by government under compulsory labour contracts. From 1904 workers' wages went direct to police protector apart from 'pocket money' retained by employer for distribution during work period. From 1910 government took levies from wages of people living on reserves. From 1919 government took levies from wages of those not living on reserves.

From 1919 government set pastoral wages at 66% of white wage. 'Every Aboriginal on a reserve must work for rations and shelter'. In 1943 government set up Aboriginal Welfare Fund to receive wages, levies and profits from reserve enterprises, to be used to develop enterprises on reserves. From 1950s government pays few shillings to a few key workers on reserves.

In 1968 government starts wage economy on reserves; workers paid 50% state minimum wage. From 1968 equal wages in pastoral industry; forced contracting ceases. From 1971 forced confinement on reserves ceases. 1972 forced control over wages and savings (bank books) ceases, although people have to request to be free from financial management.

From 1979 government knows underpaying reserve workers is illegal; wage 72% of state minimum. In 1986 government paying reserve workers only 75% of award. In 1985 seven Palm Island workers start action in Human Rights Commission for legal wages. From 1987 government hands control of communities to Aboriginal councils; budget insufficient to cover award rates.

In 1996 government loses Human Rights Commission case on under award wages; refuses to pay suggested compensation of $7000 to each of six workers. Workers commence federal court action; government capitulates in 1997.

*(http://www.reconciliation.qut.edu.au/issues/recweek/StolenWagesFactSheet.pdf.)*

The following excerpt from *No more yardin' us up like Cattle* illustrates that country continues to be at the heart of survival and meaning for Aboriginal Australians:

*In the south-west Gulf of Carpentaria in the Northern Territory there are five language groups, Mara, Gudanji, Yanyuwa, Garawa and Waanyi. We are all related through ceremony, culture, land and marriage. We lost control of our country, all of it, in the same way, when white people brought cattle into our country. Our people tried to protect their country, especially the wetlands; many of them were important sacred sites and places where there was always lots of food. When people speared the cattle to protect the sites and the water from being fouled, whole families were shot, men, women and children. Others were flogged and chained up and walked from places, like Wundigalla on Robinson River to Borroloola. Some of them died on the road.*

*We claimed some of our country back in the early days of Land Rights beginning in the late 1970s. We didn't win all our country back; we only managed to get a few of the pastoral stations where white people had failed to make a living and walked off or were looking for a quick sale. In 1984 we won the Nicholson (Waanyi/Garawa Aboriginal Land trust) through a land claim. We got Robinson River (Garawa Aboriginal Land Trust) in 1990 when we managed to get a grant to get the pastoral lease. Once we had the lease we can put a claim over it to change the title to Aboriginal freehold. The Commonwealth's Aboriginal Land Rights (Northern Territory) Act 1976 allows for such claims, but only for Aboriginal owned stations. That's why we could do it. We did it so we wouldn't ever lose it again, as under the Land Rights Act the land becomes inalienable, like it is under our law. These are the two places where the Garawa and Waanyi peoples have started caring for country projects.*

**(Green et al 2012:190)**

The protection policy continued to control the lives of Aboriginal peoples up until the 1970s. Poor health conditions resulting from change of lifestyles enabled health research to promote a 'doomed race theory'. Healthcare was provided to those who were considered infectious with conditions such as TB, leprosy and STDs by way of lock-up hospitals or incarceration. These lock-up hospitals were scattered across the country and those who went off to these hospitals did not come back home (Grant & Wronski 2008).

'High rates of morbidity and mortality mean that most Aboriginal and Torres Strait Islanders experience their own and others' illness and premature death on a painfully regular basis' (Saggers et al 2011:5).

Under the policy of protection and up until today, Aboriginal and Torres Strait Islander children were removed from their families. The government and its agencies argued that was for the children's own good and removed the children in order for them to 'be educated and civilised' (Ella et al 1998). This policy indentured children into labour camps called training homes where they became institutionalised. The impact of child removal on mothers, fathers and children was not considered harmful by government agencies. However, many national reports including *Bringing them Home* have demonstrated the significant damage that was caused and continues to be caused by this government policy and practice of child removal (HREOC 1997; 2007).

The legacy of the stolen generations has resulted in 'an intergenerational cycle of disadvantage, marginalisation and trauma' (Libesman 2014:76). Although the harm has been recorded and acknowledged by Prime Minister Kevin Rudd with a government apology to the stolen generations in 2008, the rate of Aboriginal and Torres Strait Islander child removal remains high. Terry Libesman argues that these high rates continue because of worldview differences held by child welfare agencies and Australian Indigenous communities, in that the agencies use a Western benchmark of effective parenting and neglect to respect or appreciate other parenting models. They also fail to consider poverty is not a form of

negligence but has in fact been constructed through historical experiences of ongoing marginalisation as a result of ongoing dispossession (Libesman 2014). Perhaps most problematic is the removing of children from a parent who was removed themselves, and possibly had a parent who had been removed. This is a cycle that has been established by this government policy and associated services. It ensures that parents do not gain the skills to be the parents they want to be, and prevents families growing. It also has a significant impact on the well-being of the entire community.

Government policies have had significant impacts on the health and wellbeing of Indigenous Australians and continue to do so. The Northern Territory Intervention—now called the Stronger Futures policy—is a bipartisan, agreed government policy with many laws that have once again been enforced on Aboriginal people living in the Northern Territory (see Clinical Interest Box 11.3). We were all told this was a policy to help Aboriginal people, and many believed this. However, the then United Nations Special Rapporteur on the Rights of Indigenous Peoples, Professor James Anya, was perceptive enough to ask the necessary questions of Indigenous and non-Indigenous Australians living in the Northern Territory to find that the Intervention 'overtly discriminates against Aboriginal peoples, infringing their right of self-determination and stigmatizes already stigmatized communities' (Sherwood 2013:36).

The Northern Territory now has the highest rate of youth suicide in the world.

History is a determinant of health. We need to stop repeating these policies that have been designed by those who don't know and don't work with Aboriginal and Torres Strait Islander peoples.

## CLINICAL INTEREST BOX 11.3

The Intervention has had a devastating impact on Aboriginal communities. At the core of this has been the destruction of employment opportunities and municipal and other community services with the closure of the Community Development Employment Projects (CDEP). A recent report by the Council of Australian Governments (COAG) Reform Council found that the NT had the highest level of Indigenous unemployment.

After 6 years of the Intervention, the NT Children's Commissioner Howard Bath says that, 'on the whole, the child well-being indicators in remote communities are getting worse'.

Most disturbing is the huge increase in the rate of suicide and self-harm. A recent Aboriginal and Torres Strait Islander Social Justice Commission report says that between 2001–2005 and 2006–2010, the incidence of Indigenous youth suicide in the NT increased by 160%. In contrast, non-Indigenous youth suicide had declined by one-third. The number of incidents of attempted suicide and self-harm being reported in remote communities has exploded by more than 500%.

The report noted: 'We know that feelings of hopelessness and disempowerment contribute to vulnerability to suicide. These types of feelings are well documented and widely acknowledged symptoms of the local government reforms and the Intervention.'

Aboriginal imprisonment has almost doubled since 2007, giving the NT one of the highest imprisonment rates in the world. The number of Aboriginal women being incarcerated is now more than three times pre-Intervention levels. Conditions in NT prisons resemble concentrations camps, with 15 people in a cell, thin mattresses on the floor and cells which flood when it rains.

(Solidarity.net.au, *Six years of shame: Aboriginal assimilation and the NT Intervention* (13 June 2013). http://www.solidarity.net.au/aboriginal/six-years-of-shame-aboriginal-assimilation-and-the-nt-intervention/.)

## SOME OF THE HARD DATA

Indigenous Australians' life expectancy if born in 2010–2012 was estimated to be 69.1 years for males and 79.7 years for females, around 10–11 years less than the estimates for non-Indigenous males and females.

- In 2008–2012, age-specific death rates were higher for Indigenous people than for non-Indigenous people across all age groups, and were much higher in the young and middle adult years
- For 2010–2012, the infant mortality rate was higher for Indigenous infants than for non-Indigenous infants; the rate for Indigenous infants was highest in the NT
- From 1991 to 2010, there were significant declines in infant mortality rates for Indigenous and non-Indigenous infants in WA, SA and the NT
- From 2006 to 2010, the leading causes of death among Indigenous people were cardiovascular disease, neoplasms (almost entirely cancers) and injury including suicide
- In 2003–2005, maternal mortality ratios were 2.7 times higher for Indigenous women than for non-Indigenous women (Australian Indigenous HealthInfoNet 2014:v)
- Circulatory disease continues to be the most prolific killer of Indigenous Australians and at younger years than in the mainstream population
- 68% of deaths from 2006 to 2010 were a result of chronic disease
- The gap in morbidity and mortality rates for Indigenous Australians is broadening in relation to cancer. Research has demonstrated that there are disparities in the 'stage of diagnosis and treatment (including lower rate of surgery, chemotherapy and radiotherapy)' for Indigenous Australians (AHMAC 2012:2)
- Kidney disease mortality rates have leapt by 89% between 2001 and 2010. This leap is at a faster rate than that of other Australians and, therefore, the gap has widened
- The occurrence of end-stage renal disease has grown by 96%, being 7 times the rate of other Australians (AHMAC 2012:2).

The following statistics on chronic disease are drawn from the 2011 report by the Steering Committee for the Review of Government Service Provision, which tracks federal

government progress in **Closing the Gap** (SCRGSP 2015). When compared to the non-Indigenous population, Aboriginal and Torres Strait Islander people experience the following burdens of disease:

- Deaths attributed to circulatory disease are over 2.5 times more frequent
- Deaths attributed to combined endocrine, nutritional and metabolic diseases are 3.5 times more frequent
- Deaths attributed to diabetes are over 8.5 times more frequent
- Deaths from respiratory illness such as asthma are over 3.5 times more frequent
- Deaths from renal disease are over 5.0 times more frequent.

The SCRGSP report suggests that the rates of diabetes, circulatory disease and renal disease are increasing among Aboriginal and Torres Strait Islander people (SCRGSP, cited in Hellsten 2014:225).

## Closing the gap

The health of Aboriginal and Torres Strait Islander people has continued to be observed within Australia as problematic. However, this view has had no impact in shifting the great disparities or gaps between Indigenous and non-Indigenous Australians' health morbidities and mortalities. These gaps in health and wellbeing within Indigenous populations across the world have required a broader plan of action than simply a health focus. They have required a human-rights-based approach. The United Nations Declaration on the Rights of Indigenous Peoples affirms that health is a right that all humans should enjoy:

*Article 24: Health*

*Indigenous people have the right to their traditional medicines and health practices. The plants, animals and minerals used in medicines shall be protected. Indigenous peoples shall have access to all social and health services without discrimination. Indigenous individuals have an equal right to the highest attainable standard of physical and mental health.*

**(Amnesty International 2009)**

Indigenous Australians' health was far worse than that of people in other English-speaking developed nations such as Canada, the US and New Zealand. The recognition that a different approach had to be made regarding Indigenous Australian health required pressure from the Social Justice Commissioner, who at that time was Tom Calma. Calma challenged the federal, state and territory governments to commit to achieving health equality in health status and life expectation for Indigenous Australians (Calma 2005; Sherwood & Geia 2014).

*The provision of Article 24 will only be realised when Aboriginal peoples and Torres Strait Islanders at the national, regional and local levels have the right to full participation in health service design, delivery, monitoring and evaluation. This is integral to closing the gap in life expectancy within a generation.*

*The network of Aboriginal and Torres Strait Islander Community Controlled Health Services provides frontline, culturally appropriate, primary health care in urban, regional and remote communities across Australia. It also gives Indigenous Australians the chance to set priorities to address needs at the local level.*

*The health sector needs to be properly resourced so we can reach our full potential and provide comprehensive care and improved health outcomes for people in our communities.*

**(Doctor Mick Adams in Amnesty International 2009:14)**

The Aboriginal and Torres Strait Islander Health Performance Framework was set up to measure the outcomes of the National Strategic Framework for Aboriginal and Torres Strait Islander Health (NSFATSIH). Since the National Strategic Framework was signed in 2003, the 17-year disparity in life expectancy between Indigenous and non-Indigenous Australians continues to be the most obvious indicator of overall Indigenous disadvantage. The unacceptable level of health disadvantage still being experienced by Indigenous Australians highlights that there is much still to be done, particularly using a whole-of-government approach, to increase life expectancy and quality of life for Aboriginal and Torres Strait Islander people.

Cuts in health resources by the federal and state governments made it very difficult for the primary health care sector to be able to deliver the changes necessary for closing the life expectancy gap. In 2007 Aboriginal and Torres Strait Islander health concerns were reported to be at alarming proportions, a situation that should not have occurred in a wealthy developed nation such as Australia. This claim was made by the National Aboriginal Community Controlled Health Organisation (NACCHO) and Oxfam, an international aid body that assists those who are living in poverty and injustice, in its report *Close the Gap: Solutions to Indigenous Health Crisis Facing Australia* (NACCHO and Oxfam 2007; Sherwood 2013).

In 2008, the new federal Labor government took up Social Justice Commissioner's challenge and NACCHO and Oxfam's plea to take action and assist in the closing of the gap (see Clinical Interest Box 11.4).

The **social justice** agenda and Closing the Gap form a story that is vital for you to know about and participate in. It is a question of **human rights**. According to the Social Justice Commissioner, Mick Gooda, '[t]he right to health is not to be understood as a right to be healthy. This cannot be guaranteed by governments. A human rights-based approach to health is about providing equal opportunities to be healthy, it's about participation and progressive realisation' (Australian Government 2013:10).

Improving the health status of Aboriginal and Torres Strait Islander people has been an ongoing trial for Australian governments. There have been some improvements over the past 50 years but they have not made Indigenous health commensurate with the non-Indigenous population, who are now enjoying longevity and wellbeing that is unprecedented (Sherwood et al 2014). The National Strategic Framework for Aboriginal and Torres Strait Islander Health has signalled that improving the health outcome for Indigenous Australians requires action beyond the tackling of targets set by COAG. It requires that socially constructed inequalities be addressed—these being the social determinants—and that strategies to

## CLINICAL INTEREST BOX 11.4

In 2008, COAG agreed to six ambitious targets to address the disadvantage faced by Indigenous Australians in life expectancy, child mortality, education and employment.

It aims to:

1. Close the gap in life expectancy within a generation (by 2031)
2. Halve the gap in mortality rates for Indigenous children under 5 by 2018
3. Ensure access to early childhood education for all Indigenous 4-year-olds in remote communities by 2013
4. Halve the gap in reading, writing and numeracy achievements for children by 2018
5. Halve the gap for attainment rates for Indigenous students in Year 12 (or equivalent) by 2020
6. Halve the gap between Indigenous and other Australians in employment outcomes by 2018.

*(Council of Australian Governments 2015:1)*

**Figure 11.6** Gough Whitlam pours soil into the hands of Vincent Lingiari, symbolically handing the Wave Hill station back to the Gurindji people in 1975

*(Fairfaxphotos/Merv Bishop)*

tackle racism in the health care sector be acted upon (Australian Government 2013:3).

## GOOD NEWS STORIES

The news is not all bad. There have been some positive movements to adjust how health services are delivered to Aboriginal and Torres Strait Islanders and to keep them connected to country. Below are some examples of how this is being done in areas across Australia for Aboriginal and Torres Strait Islander peoples. See Figure 11.6.

### The papunya and kintore renal dialysis good news and success story

The Western Desert of Australia is home to many Yanangu communities (Aboriginal peoples of the Western Desert) who are world-renowned Papunya Tula artists. They also have the highest rates of renal disease in Australia, being 30 times the national average.

*Dialysis is one downstream point along a pathway of chronic disease care. Upstream, when kidney function begins to deteriorate, its onset and duration is uncertain but can be delayed by primary health care interventions. Chronic kidney disease is usually symptomless, and reduced kidney function is often identified during routine clinical consultations for other common chronic conditions such as diabetes. End-stage kidney disease is defined when kidney function is reduced to 5 per cent of normal function, and renal replacement therapy, of which dialysis is the most common, is required to sustain life thereafter.*

**(Paul Rivalland, for Western Desert Nganampa Walytja Palyantjaku Tjutaku 2006:4)**

The lifesaving treatment of dialysis was only available for the Western Desert mob in Alice Springs at the renal dialysis unit. For many of those people with end-stage renal disease leaving home, country and family for treatment was very hard. It meant long times away and perhaps even dying in Alice. It was also very hard for family.

*The nurses don't realise why the renal Indigenous peoples die, because people worry for their family, for their Country, and to be there with the family close by. That's why they get worry and stress, they get a lot and they get sick because of thinking, you know.*

**(Smithy Zimran Tjampitjinpa, cited in Paul Rivalland, for Western Desert Nganampa Walytja Palyantjaku Tjutaku 2006:7)**

Many people could not bring themselves to leave country and family and so had to refuse dialysis treatment in Alice Springs, which could be 600 to 1200 km from home. The Yanangu knew that there was a different way that would work for the people and maintain life in a way that was respectful. Their communities are remote and have very little infrastructure to support end-stage treatment. The high rates of chronic and end-stage kidney disease are 'characterised by rapidly changing lifestyles, relative poverty and disadvantage' (Paul Rivalland, for Western Desert Nganampa Walytja Palyantjaku Tjutaku 2006:4).

*With limited infrastructure, which is also of significantly reduced quality, the regional population has extremely poor health, low levels of formal education and little or no employment. Although not all Indigenous groups are affected equally by end-stage kidney disease, Northern Territory rates are now some thirty times higher than the national figure, accelerating over the past few decades in conjunction with the co-existing conditions of type-2 diabetes and ischaemic heart disease.*

*The cause of end-stage kidney disease is not simple but certainly includes such diverse determinants as socio-economic disadvantage, low birth-weight and the institutional racism that has been operating in Australia since colonisation. Yanangu describe how processes that undermine individual and community coherence and wellbeing, including well-intentioned dialysis treatment services, exacerbate and cause ill-health.*

**(Paul Rivalland, for Western Desert Nganampa Walytja Palyantjaku Tjutaku 2006:4)**

Yanangu communities planned a number of ventures and took the initiative to raise money to set up their own renal service (Paul Rivalland, for Western Desert Nganampa Walytja Palyantjaku Tjutaku 2006:4). They were very successful and in their first venture were able to raise $1.1 million. This money was raised at the Art Gallery of New South Wales.

*They can't leave their Country. They think about their spirit and they think about their Dreaming, land and Country. They can't leave their families. Culture is the main one. They can't leave the place where they were born. They want to stay because they have grown up in that Country. Their land is what they think about, because if they go to another place they get sick and weak. Doing that they lose the spirit in their heart, and that is why they need to stay home.*

**(WDNWPT member, cited in Paul Rivalland, for Western Desert Nganampa Walytja Palyantjaku Tjutaku 2006: 4)**

**Figure 11.7** Purple House CEO Sarah Brown with Indigenous artist Patrick Tjungarryi

*(Photo by Justin Brierty)*

**Figure 11.8** The Purple House is the base of the Western Desert's nurses-led community health and renal care service

*(© Western Desert Nganampa Walytja Palyantjaku Tjutaku Aboriginal Corporation)*

In 2001 the Yanangu community set up the return to country services bringing people home from Alice Springs regularly so they did not worry too much about country and family. Additionally, they formed a kidney committee to do research on remote dialysis options, the Western Desert Nganampa Walytja Palyantjaku Tjutaku Aboriginal Corporation (WDNWPT). In 2003, the WDNWPT was officially incorporated.

In 2004, the WDNWPT started dialysis treatment at the Purple House in Alice—importantly out of the hospital grounds—and started home dialysis at Kintore. Figures 11.7 and 11.8 show Purple House CEO Sarah Brown and Indigenous artist Patrick Tjungarryi in front of his artwork on the Purple House.

WDNWPT continued to pursue services for the Western Desert and purchased the Purple Truck, which was funded by Medicines Australia in 2011 to provide dialysis. 2014 saw the celebration of 10 years of dialysis in Kintore (see Figures 11.9 and 11.10).

## Summary

Aboriginal and Torres Strait Islander peoples have been significantly impacted by past and present government policies which specifically targeted Indigenous Australians in a negative and harmful manner. These policies and a universal lack of access to culturally safe and competent care have contributed to the high burden of morbidity and mortality. Most Australians have had the ability to be in control of their lives and make choices about their lives that ensured that they and their families enjoyed a life of freedom and wellness; this has not been the case for most Indigenous Australians. Governments and communities need to keep working with Aboriginal and Torres Strait Islander peoples to ensure the future health of Indigenous peoples is impacted in a positive way. There are some good examples of this in some areas as described in this chapter; however, much more work needs to be done.

## Review Questions

1. Why is it that Aboriginal and Torres Strait Islander peoples' current health is very different from that of most Australians?
2. Discuss the meaning of 'country' to Indigenous peoples.
3. What are the five (5) principles of cultural safety?
4. Name five (5) areas where burden of disease is greater in Indigenous populations than in non-Indigenous populations.
5. What were the six (6) targets set by COAG in relation to Indigenous disadvantage?

Answer guide for the Review Questions, Critical Thinking Exercises, Decision-Making Framework Exercises and Critical Thinking Questions in Case Studies are hosted on Evolve: http://evolve.elsevier.com/AU/Koutoukidis/Tabbner/

# Nursing care throughout the lifespan

CHAPTER 12
Nursing care across the lifespan: conception to late childhood

CHAPTER 13
Nursing care across the lifespan: late childhood to adolescence

CHAPTER 14
Nursing care across the lifespan: younger adulthood to middle adulthood

CHAPTER 15
Nursing care across the lifespan: older adult

CHAPTER
12

# Nursing care across the lifespan: conception to late childhood

*Andree Gamble*

## KEY TERMS

cognitive development
development
embryo
emotional development
extrauterine
fetus
growth
intellectual development
intrauterine
maturation
personality development
social development
social learning

## LEARNING OUTCOMES

At the completion of this chapter and with further reading, students should be able to:

- Define key terms
- Describe the process of conception
- Discuss the growth and development of the placenta
- Explain intrauterine growth and development of the fetus
- Discuss the transition from intrauterine to extrauterine life
- Discuss the growth and development of neonates
- Examine growth and development from early to late childhood
- Compare and discuss the various theories of development
- Compare the theories of Erik Erikson and Jean Piaget
- Recognise the factors that influence growth and development
- Discuss the theories in relation to nursing a child
- State the factors that influence growth and development
- Describe the major physical and psychosocial changes that occur during each stage of development

## CHAPTER FOCUS

Nursing children is challenging at times as their understanding of life changes throughout their growth and development. This chapter looks at various developmental theories which view development as a continuous process. Growth and development are processes that begin at conception and continue through each stage of the life cycle. Human development involves biological and psychosocial components. Biological science is concerned mainly with structure and function, while the psychosocial sciences focus on the behavioural aspects of development. Nursing care of the infant and child is directed at promoting the optimal level of health for the individual and family. It is important for the nurse to understand that both infancy and childhood are unique phases of development and that these phases are accompanied by special needs. To understand these needs the nurse first requires knowledge of normal growth and development, beginning with conception.

## LIVED EXPERIENCE

The first time I cared for a child in hospital, I said, 'I'm going to take your vital signs now.' The child looked distressed and frightened and asked 'What does that mean and where are you taking it?' I realised that I needed to explain what I was going to do, and how and why I was going to do it in a way that a child would understand. It was a good lesson to learn.

**Madeline, Enrolled Nursing Student**

Nurses care for people in different stages of development. A basic understanding of growth and development enables the nurse to recognise individual needs, assess health status and thus provide appropriate care. Human **growth** and **development** are orderly processes that begin at conception and continue until death. Every person progresses through definite phases of growth and development, but the rate and behaviours of this progression vary with each individual.

Each person is a unique individual and, while growth and development are generally categorised into age stages or by using terms describing the features of an age group, categorisation does not take into account individual differences. It does, however, provide a means of describing the characteristics associated with most individuals at stages when comparative developmental changes appear. Growth and development affect the whole person and, although defined separately, overlap and are dependent on each other.

Physical growth results as cells repeatedly divide then synthesise new components, causing an increase in the number and size of cells and, consequently, an increase in the size and weight of the body or any of its parts. Growth can be measured in height and mass or by the changes in physical appearance and body functions that occur as a person grows older (Hockenberry & Wilson 2013).

Development refers to an increase in the complexity of function and skill progression that enables an individual to adapt to the environment.

**Maturation** is the process of attaining complete development and is the unfolding of full physical, emotional and intellectual capabilities. The term maturation is generally used to describe an increase in complexity that enables a person to function at a higher level (Hockenberry & Wilson 2013).

A person's development encompasses a range of dimensions besides the physical; for example, emotional and moral development. There are several theories, or approaches, regarding growth and development of these different dimensions. This chapter discusses these approaches and their implications for nursing practice.

## CONCEPTION

Fertilisation occurs when the chromosomes of a single egg and sperm (gametes) unite to form a fertilised egg (zygote), and is the benchmark of the beginning of a pregnancy. This event does not occur in isolation but as a result of a series of events, including ovulation (release of the egg), union of the gametes and implantation of the embryo into the uterus. Only after all these events are successfully completed can the process of embryonic and fetal development begin (Figure 12.1 and Table 12.1).

Fertilisation of the ovum occurs in the distal third of the uterine (fallopian) tube. The fertilised ovum (zygote) develops by simple cell division and as it travels to the uterus it forms a loose collection of cells called the morula. The morula separates into an outer (ectodermal) and an inner (endodermal) cell mass, fluid forms and fills the space between the two layers; the structure is then referred to as a blastocyst. The outer layer of the blastocyst becomes the trophoblast and will develop into the placenta and outer membrane, while the inner layer will develop into the embryo, cord and inner membrane. Between these two layers a third layer (mesoderm) will form (Marieb & Hoehn 2013).

Implantation (embedding in the endometrium) occurs about 6–7 days after fertilisation and normally occurs in the upper body of the uterus. After implantation, the lining of

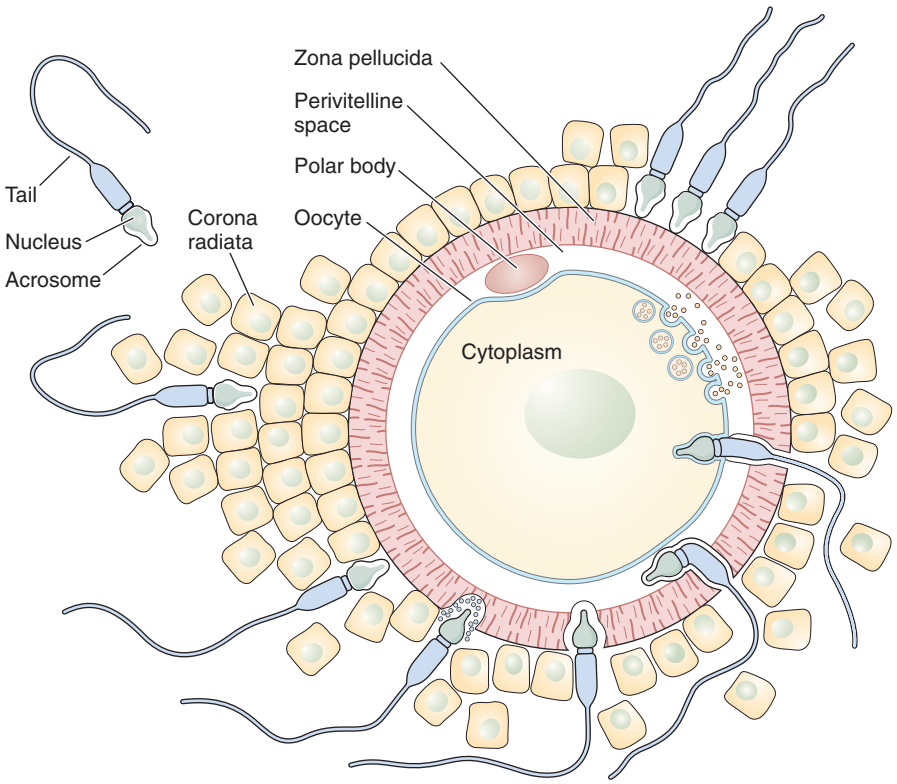

**Figure 12.1** Fertilisation
*(Falcone & Hurd 2007)*

**TABLE 12.1 | Fetal growth terms**

| Term | Time period in fetal development |
|---|---|
| Ovum | From ovulation to conception (fertilisation) |
| Zygote | From conception (fertilisation) to implantation |
| Embryo | From implantation to 8 weeks after conception |
| Fetus | From 8 weeks after conception until term |

the uterus grows over the blastocyst and pregnancy is established. From this stage onwards the lining of the uterus is termed the decidua (Marieb & Hoehn 2013) (Figure 12.2).

During week 3, the inner cell mass of the blastocyst differentiates into three distinct layers:

1. The outer layer (ectoderm), which develops to become the skin, hair, nails, brain and nervous system
2. The middle layer (mesoderm), which develops to become the circulatory, musculoskeletal and urinary systems, and most of the reproductive tract
3. The inner layer (endoderm), which develops to become the intestines, internal organs, respiratory system and the germ cells of the ovaries or testes.

(Marieb & Hoehn 2013)

As development continues, a cavity appears above the ectoderm. The lining of this amniotic cavity becomes the amniotic membrane, which secretes fluid that makes up part of the 'liquor' (the fluid that surrounds the embryo). The amniotic cavity enlarges so that eventually the embryo is suspended by the umbilical cord in a closed sac (membranes) of amniotic fluid.

## DEVELOPMENT OF THE PLACENTA, MEMBRANES, LIQUOR AND CORD

### The placenta

The outer cells of the trophoblast develop projections (villi), which project into the maternal capillaries to allow the exchange of oxygen, nutrients and waste products. The villi eventually join with an area of uterine tissue to form the placenta. The placenta continues to grow throughout the pregnancy, with one surface (maternal surface) attached to the lining of the uterus, and the other (fetal surface) with the umbilical cord arising from its centre. The fully formed placenta is disc-shaped, about 2.5 cm thick in the centre, and weighs about 500 g. The functions of the placenta are nutritional, respiratory, excretory and hormonal (Marieb & Hoehn 2013).

### The membranes

The two fetal membranes—the amnion and the chorion—are derived from part of the trophoblast and attached to the placenta. The inner membrane (amnion) encloses the **fetus**

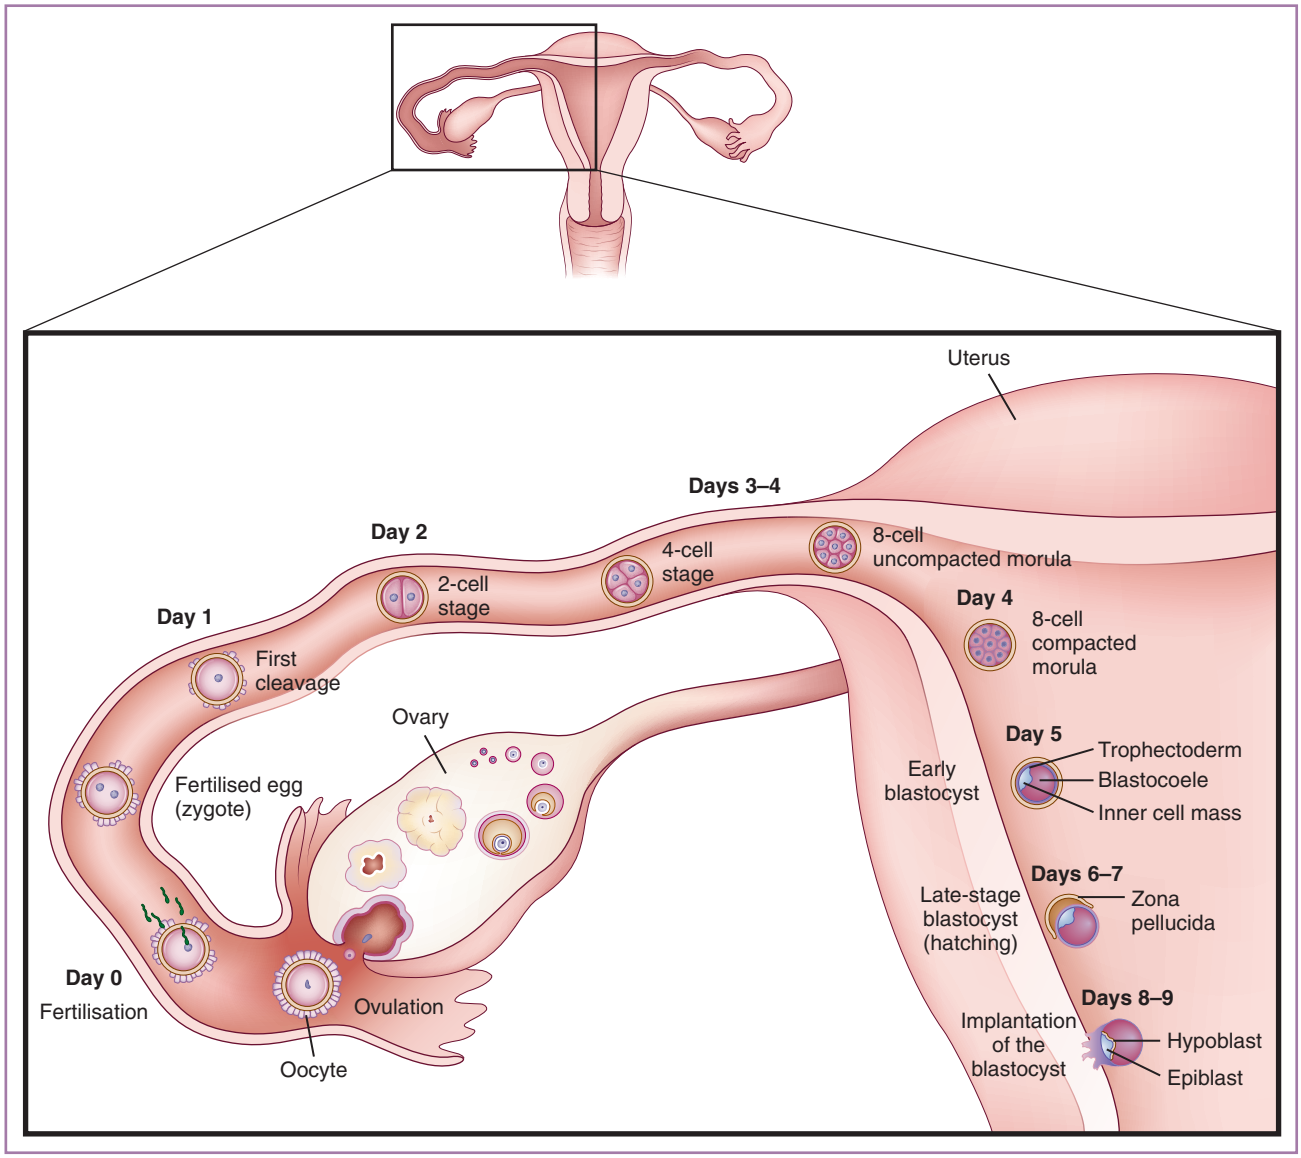

**Figure 12.2** Ovulation and implantation
*(Greene et al 2008)*

and liquor and covers the fetal surface of the placenta and the cord. The outer membrane (chorion) is continuous with the margin of the placenta and adheres to the wall of the uterus (Marieb & Hoehn 2013).

## Liquor

The liquor (amniotic fluid) is the pale straw-coloured liquid that surrounds the fetus in the amniotic sac. Initially derived mainly from maternal blood then combined with fetal urine, liquor is 99% water plus mineral salts. The functions of liquor include protection of the fetus, prevention of embryonic parts fusing together and maintenance of an even intrauterine temperature (Marieb & Hoehn 2013).

## The umbilical cord

The umbilical cord extends from the fetal umbilicus to the fetal surface of the placenta. It contains two umbilical arteries, which transport deoxygenated blood from the fetus, and one umbilical vein, which transports oxygenated and nutrient-rich blood from the placenta to the fetus. The vessels in the cord are embedded in a thick jelly-like substance and the cord is covered by amniotic membrane. At 40 weeks of pregnancy the cord can be up to 3 cm in diameter and 55 cm long (Beall 2014).

## Fetal circulation

The fetal circulation is designed so that the major blood flow bypasses the fetal lungs. The first blood cells arise in the yolk sac and, by the end of the third week, the embryo has a system of paired vessels which remain occluded until birth. Oxygen and nutrients move from the maternal blood into the fetal blood, and fetal wastes move in the opposite direction. As blood from the umbilical vein flows towards the fetal heart, most of it bypasses the fetal liver through the ductus venosus

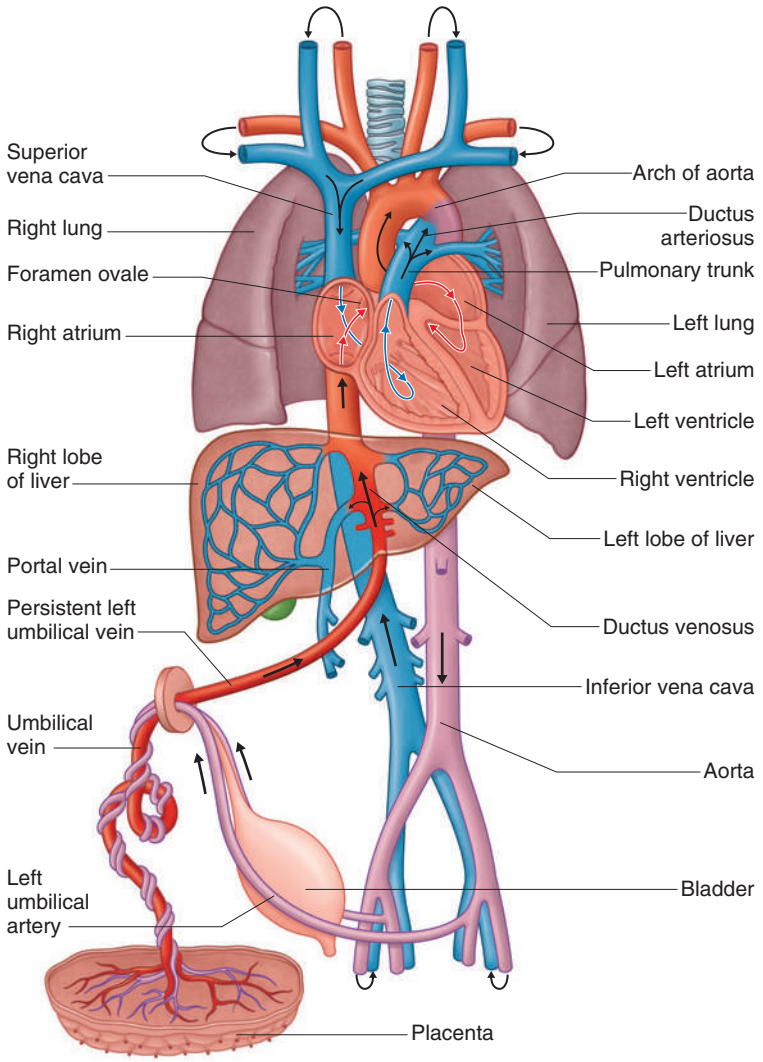

**Figure 12.3** Fetal circulation
*(Standring 2008)*

and enters the inferior vena cava. Some of the blood entering the right atrium is shunted into the left atrium through the foramen ovale, a temporary opening in the septum between the atria. Blood that enters the right ventricle is pumped out through the pulmonary artery, where it meets the ductus arteriosus, a short vessel connecting the pulmonary artery to the aorta. Because the fetal lungs are collapsed, blood enters the systemic circulation through the ductus arteriosus. The aorta transports blood to the fetal tissues and, ultimately, back to the placenta through the umbilical arteries (Marieb & Hoehn 2013) (Figure 12.3).

## INTRAUTERINE DEVELOPMENT AND GROWTH

The prenatal period is the stage of development from conception to birth, normally lasting 40 weeks. As the **embryo** grows, first in a cephalocaudal direction (head to tail), then in a proximodistal direction (from the centre of the body outwards), differentiation of cells gives rise to specific tissues and the shape of the embryo changes to gradually assume a human appearance (Figure 12.4).

The embryo continues to develop and by the end of the 8th week all organ systems are recognisable and the embryo is known as a fetus.

**Intrauterine** growth and development occurs in three main stages, each lasting 3 months (the first, second and third trimesters). Different tissues and regions of the body mature at different rates, while growth in length and mass proceeds at a predetermined rate.

Growth in length and mass depends on factors inherent in the fetus, placenta and mother. Growth and development of the fetus may be impeded by factors such as infectious agents (e.g. the rubella virus), chemical agents (e.g. ionising radiation or certain drugs), immunological factors (e.g. the Rh factor) or by nutritional factors (e.g. maternal mineral deficiency) (Norwitz & Schorge 2013).

The first trimester of intrauterine life is the most crucial for the developing fetus, as it is during this period that the fetal cells differentiate and develop into essential organ

systems. Any factors that cause interference with growth can result in extensive structural or functional alteration or congenital absence of an organ or system (Chiocca 2011). By the end of the second trimester, most organ systems are complete and capable of functioning, and the fetus is considered viable (capable of life outside the uterus). By 26 weeks, although the skin remains transparent, the fetus resembles a small baby. If a fetus is born at this stage, extensive environmental support is necessary to promote survival. From this stage onwards the major activities are growth and organ specialisation. During the third trimester, the fetus grows in length and mass and by the end of 40 weeks is about 50 cm long and weighs between 3.2 and 3.4 kg. When born, the infant is able to make the transition from intrauterine to **extrauterine** life without support (Figure 12.5 and Table 12.2).

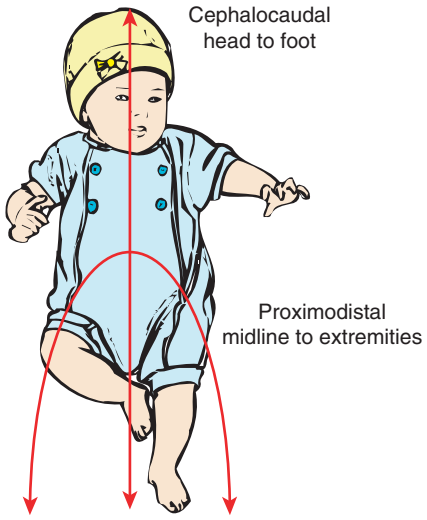

**Figure 12.4** Patterns of development

## TRANSITION TO EXTRAUTERINE LIFE

After the infant is born and begins to breathe, the shunting of blood from the pulmonary artery to the aorta via the ductus arteriosus is no longer needed and blood is circulated to the lungs. The pressure in the right side of the heart falls as the lungs become fully inflated and there is little resistance to blood flow. This causes the foramen ovale to close. The infant's blood oxygen level rises and the ductus arteriosus constricts and is converted to a fibrous ligament. The closure of these structures thus depends on the initiation of respiration. The cardiovascular system adapts so that blood circulation no longer bypasses the lungs, and the lungs are able to inflate, thereby enabling gaseous exchange (Figure 12.6). When blood stops flowing through the umbilical vessels, the circulatory pattern becomes that of an adult (Marieb & Hoehn 2013).

## THEORIES OF DEVELOPMENT

Some theories view development as a continuous process that moves from the simple to the complex, while other theories view development as a process characterised by alternating periods of equilibrium and change. The various developmental theories differ in how the human being is viewed. The following section provides the reader with an introduction to the major theories, or approaches, which are psychoanalytical, cognitive–developmental, maturational, **social learning** and moral. It is not the intent of this section to provide the reader with an in-depth analysis of these theories, rather to provide an overview of each approach.

### Erikson's theory

Using the psychoanalytical framework, Erik Erikson based his (1963) theory of psychosocial development on the process of socialisation. According to Erikson, a person spends their whole life constructing, shaping and reshaping their

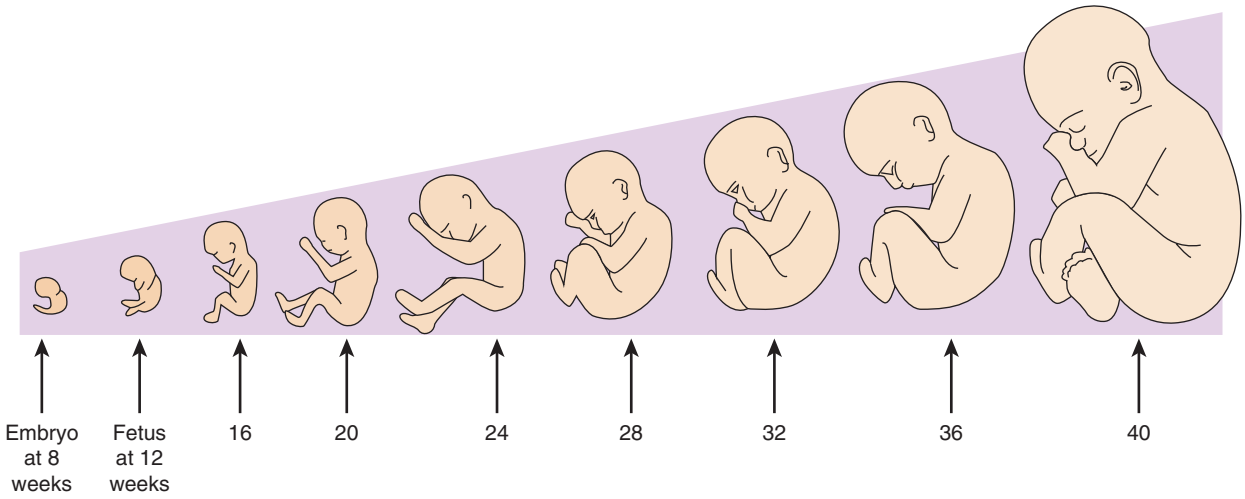

**Figure 12.5** Fetal growth

*(Reproduced from http://nursingcrib.com/wp-content/uploads/fetal-growth.jpg)*

## TABLE 12.2 | Developmental events of the fetal period

| Time | Changes and accomplishments |
|---|---|
| 8 weeks (end of embryonic period)<br> <br>8 weeks | Head nearly as large as body; all major brain regions present; first brain waves in brain stem<br>Liver disproportionately large and begins to form blood cells<br>Limbs present; digits are initially webbed, but fingers and toes are free by the end of this interval<br>Ossification just begun; weak, spontaneous muscle contractions occur<br>Cardiovascular system fully functional (heart has been pumping blood since the fourth week)<br>All body systems present in at least rudimentary form<br>Approximate crown-to-rump length: 22 mm; weight: 2 grams |
| 9–12 weeks (month 3)<br> <br>12 weeks | Head still dominant, but body elongating; brain continues to enlarge, shows its general structural features; cervical and lumbar enlargements apparent in spinal cord; retina of eye is present<br>Skin epidermis and dermis obvious; facial features present in crude form<br>Liver prominent and bile being secreted; palate is fusing; most glands of endodermal origin are developed; walls of hollow visceral organs gaining smooth muscle<br>Blood cell formation begins in bone marrow<br>Notochord degenerating and ossification accelerating; limbs well moulded<br>Sex readily detected from the genitals<br>Approximate crown-to-rump length at end of interval: 90 mm |
| 13–16 weeks (month 4)<br> <br>16 weeks | Cerebellum becoming prominent; general sensory organs differentiated; eyes and ears assume characteristic position and shape; blinking of eyes and sucking motions of lips occur<br>Face looks human and growth of the body beginning to outpace that of the head<br>Glands developed in GI tract; meconium is collecting<br>Kidneys attain typical structure<br>Most bones are now distinct and joint cavities are apparent<br>Approximate crown-to-rump length at end of interval: 140 mm |
| 17–20 weeks (month 5) | Vernix caseosa (fatty secretions of sebaceous glands) covers body; lanugo (silk-like hair) covers skin<br>Fetal position (body flexed anteriorly) assumed because of space restrictions<br>Limbs reach near-final proportions<br>Quickening occurs (mother feels spontaneous muscular activity of fetus)<br>Approximate crown-to-rump length at end of interval: 190 mm |
| 21–30 weeks (months 6 and 7) | Period of substantial increase in weight (may survive if born prematurely at 27–28 weeks, but hypothalamic temperature regulation and lung production of surfactant are still inadequate)<br>Myelination of spinal cord begins; eyes are open<br>Distal limb bones are beginning to ossify<br>Skin is wrinkled and red; fingernails and toenails are present; tooth enamel is forming on deciduous teeth<br>Body is lean and well proportioned<br>Bone marrow becomes sole site of blood cell formation<br>Testes reach scrotum in seventh month (in males)<br>Approximate crown-to-rump length at end of interval: 280 mm |
| 30–40 weeks (term) (months 8 and 9)<br> <br>At birth | Skin whitish pink; fat laid down in subcutaneous tissue (hypodermis)<br>Approximate crown-to-rump length at end of interval: 360 mm; weight: 3.2 kg |

*(Marieb & Hoehn 2013. © 2013, pp. 1087–1089. Reprinted by permission of Pearson Education, Inc., New York, New York)*

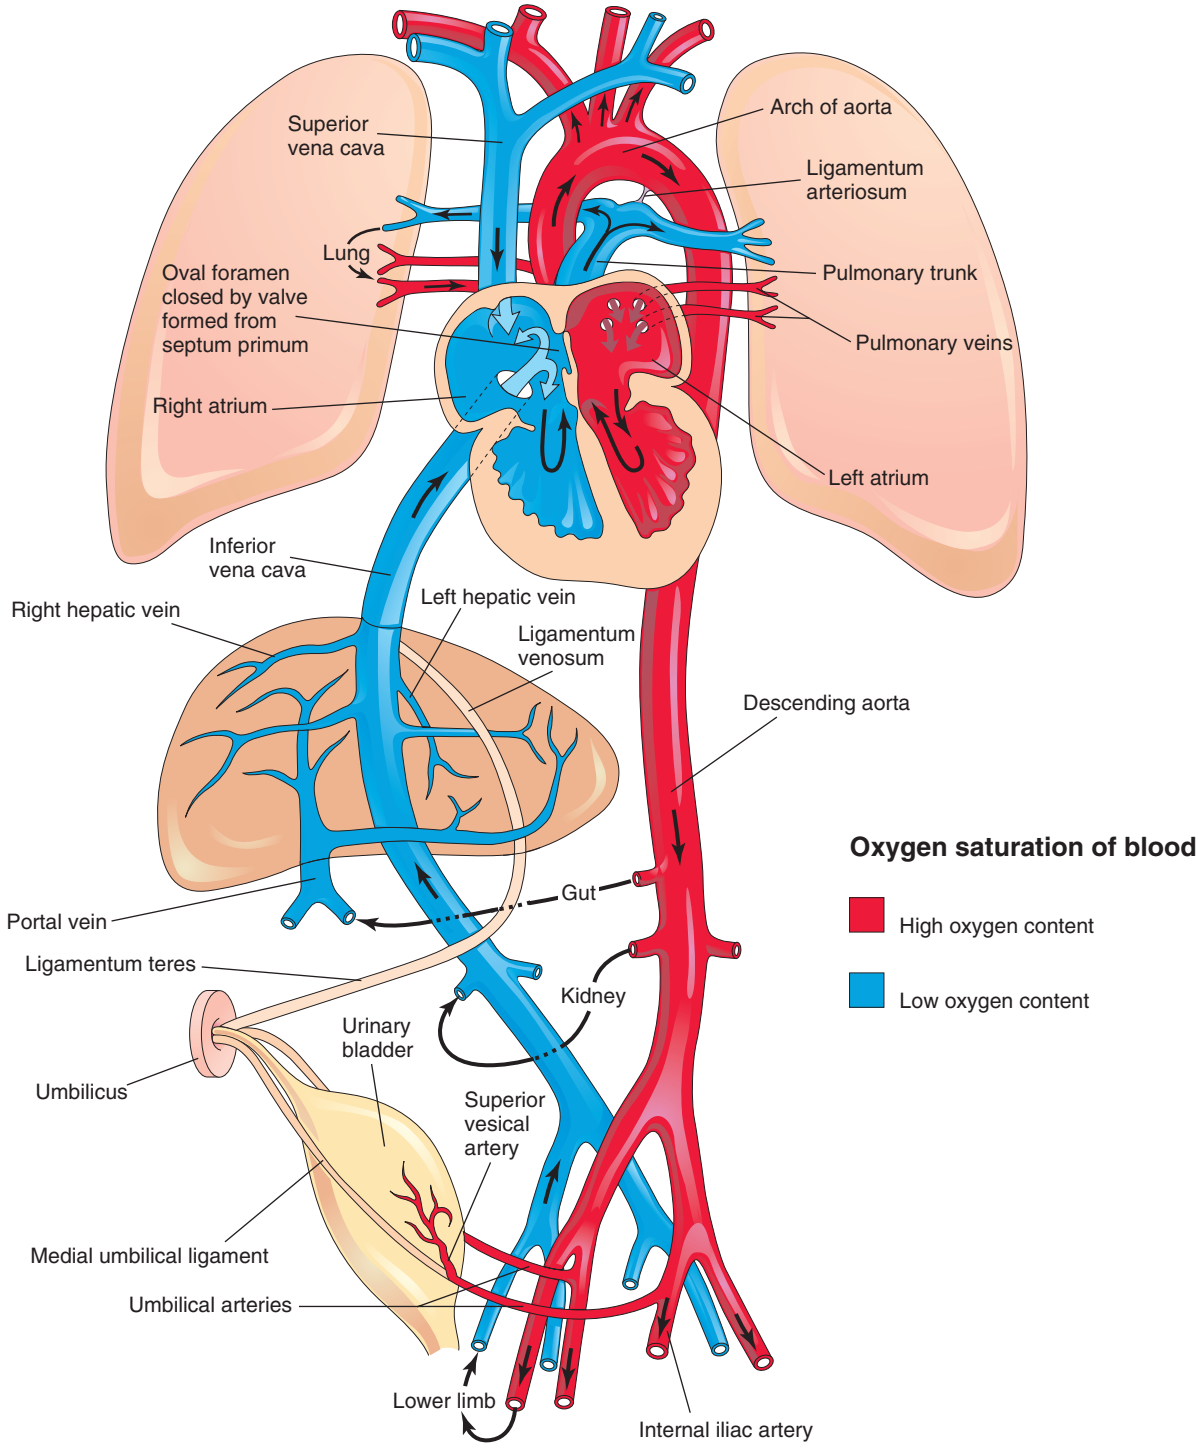

**Figure 12.6** Transition to extrauterine life
*(Moore et al 2012)*

personality, which is influenced by psychological, biological, social and environmental factors. Erikson described key conflicts or problems that the individual seeks to master during critical periods of **personality development**. Successful completion of each conflict is built on satisfactory completion of the previous stage. However, no core problem is ever entirely resolved, as each new situation will present a conflict in a new form (Chiocca 2011). Table 12.3 outlines the stages of development according to Erikson.

## Piaget's theory

The theory of **cognitive development** focuses on the gradual development of cognitive processes, such as problem solving, and intellectual growth. Cognitive development is the process

**TABLE 12.3 | Erikson's stages of development**

| Stage | Age | Conflict | Behaviours |
|---|---|---|---|
| I | 0–1 year | Trust versus mistrust | Develops basic trust in someone who consistently responds to needs. When needs are not met, may develop basic mistrust of others |
| II | 1–4 years | Autonomy versus shame and doubt | Develops a sense of self-control and independence. Feelings of shame and doubt may arise if made to feel self-conscious, or when expected to be independent in areas where not capable |
| III | 4–8 years | Initiative versus guilt | Plans and undertakes tasks and initiates a fantasy life whereby they can work out fears and conflicts. A sense of guilt may arise if a child is made to feel that their activities or imaginings are bad |
| IV | 8–12 years | Industry versus inferiority | Engages in tasks and activities that can be carried through to completion. Needs and wants real achievement. Feelings of inferiority or inadequacy may arise if a child believes that they cannot measure up to the standards set for them by others |
| V | 12–20 years | Identity versus role confusion | Establishes own identity and intimate relationships. Role confusion may result if unable to solve conflicts about role in society |
| VI | 20–30 years | Intimacy and solidarity versus isolation | Enters into intimate relationships by allowing others to share the psychosocial and physical aspects of their personality. May experience a sense of isolation if unable to become close to others |
| VII | 30–60 years | Generativity versus self-absorption and stagnation | Establishes and guides the next generation and strives to ensure the continuation of their work and lifestyle. If unable to assume responsibility for promoting the future, may experience a sense of stagnation. As a result, becomes self-absorbed and experiences difficulty in relating to the world |
| VIII | 60 years–death | Integrity versus despair | Strives to feel a sense of worth. A sense of integrity develops when an individual feels satisfied with past achievements. Despair arises when an individual is unable to recognise or accept their worth, or when they feel remorse for that which might have been |

*(Hockenberry & Wilson 2013)*

by which a child acquires knowledge and the ability to think, learn, reason and abstract.

Jean Piaget's (1969) theory of cognitive development deals with age-related changes in cognition and the way in which a child progressively learns about the world through the development of reasoning skills. It does not take into account all the psychosocial aspects of the personality. Piaget's views are that, for learning to occur, a variety of new experiences or stimuli must exist. He believed that there are four major stages in the development of logical thinking, and that each stage builds on the accomplishments of the previous stage. Table 12.4 outlines Piaget's stages of cognitive development (Chiocca 2011).

For further reading on theories of development, please refer to the Recommended Reading list.

## GROWTH AND DEVELOPMENT

Growth and development are interrelated processes that are influenced by a variety of factors, either modifiable or non-modifiable. The modifiable influences include nutrition, illness and provision of developmentally appropriate activities. Non-modifiable influences include culture and genetics (Chiocca 2011).

It is important for the nurse to understand that childhood incorporates unique phases of development, and that these phases are accompanied by special needs. To care for individuals from infancy to adolescence, the nurse first requires knowledge of normal growth and development. By understanding what is normal, the nurse is more able to recognise departures from normal and, therefore, to plan and implement appropriate nursing actions. Growth and development affect the total person and, although separately defined, growth and development overlap and are interdependent. Both occur from the moment of fertilisation until death. There is a predictable sequence, order and pattern to growth and development where certain developmental tasks must be accomplished during each stage. Although there is an orderly pattern to the processes, the rate of growth and development varies among individuals.

**TABLE 12.4 | Piaget's stages of cognitive development**

| Stage | Age | Intellectual development |
|---|---|---|
| Sensorimotor | Birth–2 years | This stage of intellectual development is governed by sensations in which simple learning takes place. Problem solving is primarily trial and error, as the child progresses from reflex activity, through repetitive behaviours, to imitative behaviour. The child gradually acquires a sense that external objects have a separate and independent existence and that they exist even when they are not visible to them |
| Preoperational | 2–7 years | During this stage the predominant characteristic is egocentricity, wherein the child considers their own viewpoint as the only one possible. Thinking is concrete and tangible and the child lacks the ability to make deductions or generalisations. Problem solving does not usually follow logical thought processes |
| Concrete operational | 7–11 years | Thought becomes increasingly logical and problems are solved in a systematic fashion. The child is able to consider points of view other than their own. Towards the end of this stage, the child demonstrates a greater reasoning ability |
| Formal operational | > 11 years | Thinking is characterised by logical reasoning. The adolescent is able to think in abstract terms, draw logical conclusions and solve problems |

*(Hockenberry & Wilson 2013)*

Development encompasses various aspects—motor, vision and hearing, speech and language, intellectual, emotional, personality, moral and social. A developmental task is a set of skills and competencies specific to each developmental stage, which children must accomplish to deal effectively with their environment. Each stage lays the foundation for the next stage of development (Hockenberry & Wilson 2013). The stages of development are:

- Prenatal (conception to birth)
- Neonatal (birth to 28 days)
- Infancy (1 month to 12 months)
- Early childhood:
  - Toddlerhood (12 months to 3 years)
  - Preschool (3 years to 6 years)
- Late childhood:
  - School age (6 years to 12 years)
- Adolescence (12 years to about 18–20 years)
- Adulthood (18–20 years onwards).

Growth in weight (mass) and height is variable and not uniform throughout life. The maximum rate of growth occurs before birth, in the 4th month of fetal life. Growth in height stops when maturation of the skeleton is complete. Standard growth charts are available on which measurements of growth may be periodically plotted and compared with the norm for that particular age group.

Growth and development occur in specific directions. Development is closely related to maturation of the nervous system, and occurs in the cephalocaudal direction (head to tail), which is logical; for example, an infant's head is disproportionately large. The second direction is from the centre of the body outwards (proximodistal); for example, infants can roll over before they can grasp an object with thumb and second finger (Chiocca 2011). The third pattern is differentiation (simple to complex development), where global patterns of behaviour become more specific and refined (Hockenberry & Wilson 2013).

## GROWTH AND DEVELOPMENT OF THE INFANT

Infancy is the stage of development from birth to 12 months. The first 28 days of extrauterine life are referred to as the neonatal period. (Refer to Table 12.5.)

### Physical development

At birth the spinal cord and lower brain centres are well developed and, while not capable of coordinated movement, the infant exhibits a range of reflexes. A **reflex** is an involuntary muscle reaction to specific stimulation (refer to Table 12.6). The Moro reflex is one example—a sudden loud noise or movement causes the infant to draw up their legs, fan out their arms and then bring them back together towards the midline in an embrace position. The presence and strength of a reflex is an important sign of neurological development and function. Many infant reflexes disappear as the child grows older, although some remain throughout adulthood. The presence of an infant reflex after the age at which the reflex normally disappears can be a sign of brain damage or damage to the nervous system (Hockenberry & Wilson 2013).

### Measurement

During the first 12 months the infant increases in length by more than one-third, and mass almost triples. (Refer to Table 12.7 for measurements at birth.)

As the infant grows in height and mass, internal organs also grow and develop to cope with the increasing demands made on them. Growth is influenced by hormones, especially thyroxine and growth hormone (Dempsey et al 2014).

**TABLE 12.5 | Growth and development—birth to 12 months**

| Age | Motor, communication, manipulative and social skills |
|---|---|
| Birth to 1 month | Primitive reflexes: can suck, grasp and respond to sudden sounds. Crying patterns and 'cooing' noises |
| 1–3 months | Holds head up when prone, holds head erect when held in a sitting position. Begins to vocalise. Smiles responsively. Distinguishes parents from others |
| 3–5 months | Turns head towards sounds. Rolls from prone to supine. Makes sounds when spoken to, may squeal with pleasure. Clasps hands together and can hold a rattle. Begins to watch own hands. Smiles and vocalises |
| 6–9 months | Sits with support and, later, alone. Sits up from a lying position. Crawls. Babbles and vocalises; says words like mum-mum, da-da. Picks objects up between finger and thumb. Reacts to strangers with anxiety |
| 10–12 months | Pulls self into a standing position, may walk with support. Says single words. Obeys simple instructions. Imitates adults (e.g. will scribble with a crayon). Expresses emotion. Can hold a cup to drink |

*(Hockenberry & Wilson 2013)*

**TABLE 12.6 | Development of reflexes**

| | |
|---|---|
| Eye reflex | When a bright light is directed towards the eyes, the pupils contract; blinking is elicited when objects are brought towards the eyes |
| Rooting reflex | Elicited when the infant's cheek contacts the mother's breast and in response to peri-oral touch. This reflex enables the infant to find a nipple in order to feed |
| Moro reflex | Elicited by a sudden loud noise or movement. If this occurs the infant draws the legs up and the arms fan out and then come together towards the midline in an embrace position |
| Grasp reflex | Elicited when the palm is stimulated so that the fingers flex and grip the object |
| Tonic neck reflex | A postural reflex that is sometimes assumed by sleeping infants. The head is turned to one side, the arm and leg of one side are extended, and the opposite arm and leg are flexed in a 'fencing' position |
| Sucking reflex | Sucks when area around mouth stimulated |
| Startle reflex | Legs and arms are pulled inwards after loud noise |
| Stepping reflex | Stepping motions when sole of foot touches hard surface |

*(Hockenberry & Wilson 2013)*

Children under 3 years of age should be weighed naked (ensuring maintenance of privacy), placed in the middle of the scale and must be still to ensure an accurate measurement is attained. Feeding should be considered when weighing an infant and, if possible, infants should be weighed at the same time each day. Length is measured in infants (rather than height), and should be undertaken using an appropriate measuring device if available (Hockenberry & Wilson 2015). (Refer to Figure 12.7 for standard growth charts.)

**TABLE 12.7 | General measurements at birth**

| Parameter | Birth |
|---|---|
| Length | 50–55 cm |
| Weight | 2.8–4 kg |
| Head circumference | 33–38.5 cm |

*(Hockenberry & Wilson 2015; Marieb & Hoehn 2013)*

## Sensory

At birth the infant can follow objects and pupils react to light; binocular vision begins at 6 weeks and is established by 4 months. At about 6 months the infant can move the head and eyes in every direction. By 12 months they are able to recognise familiar people and objects at a distance. Infants can hear at birth and by 1 month they are able to move their eyes towards a sound. The brain is not sufficiently developed initially for any meaning to be attached to sounds, but by 5 to 6 months the infant turns immediately to the sound of their mother's voice even when she is quite a distance away. Speech develops from vocalising at birth and crying as a means of communication. Crying allows the infant to signal displeasure (hunger) but also helps to develop infant–parent relationship. Infants cry between 1 and 4 hours per day until aged 6 weeks. Crying usually decreases by 12 weeks and by 12 months the infant is able to say three to five recognisable words but understand as many as 120. With time the number of words spoken increases and they become clearer. The rate of vocabulary gain varies and is related to factors such as the amount and type of speech the infant hears (Hockenberry & Wilson 2013).

*(Centers for Disease Control and Prevention: www.cdc.gov/nchs—reproduced with permission from the National Center for Health Statistics)*

*Continued*

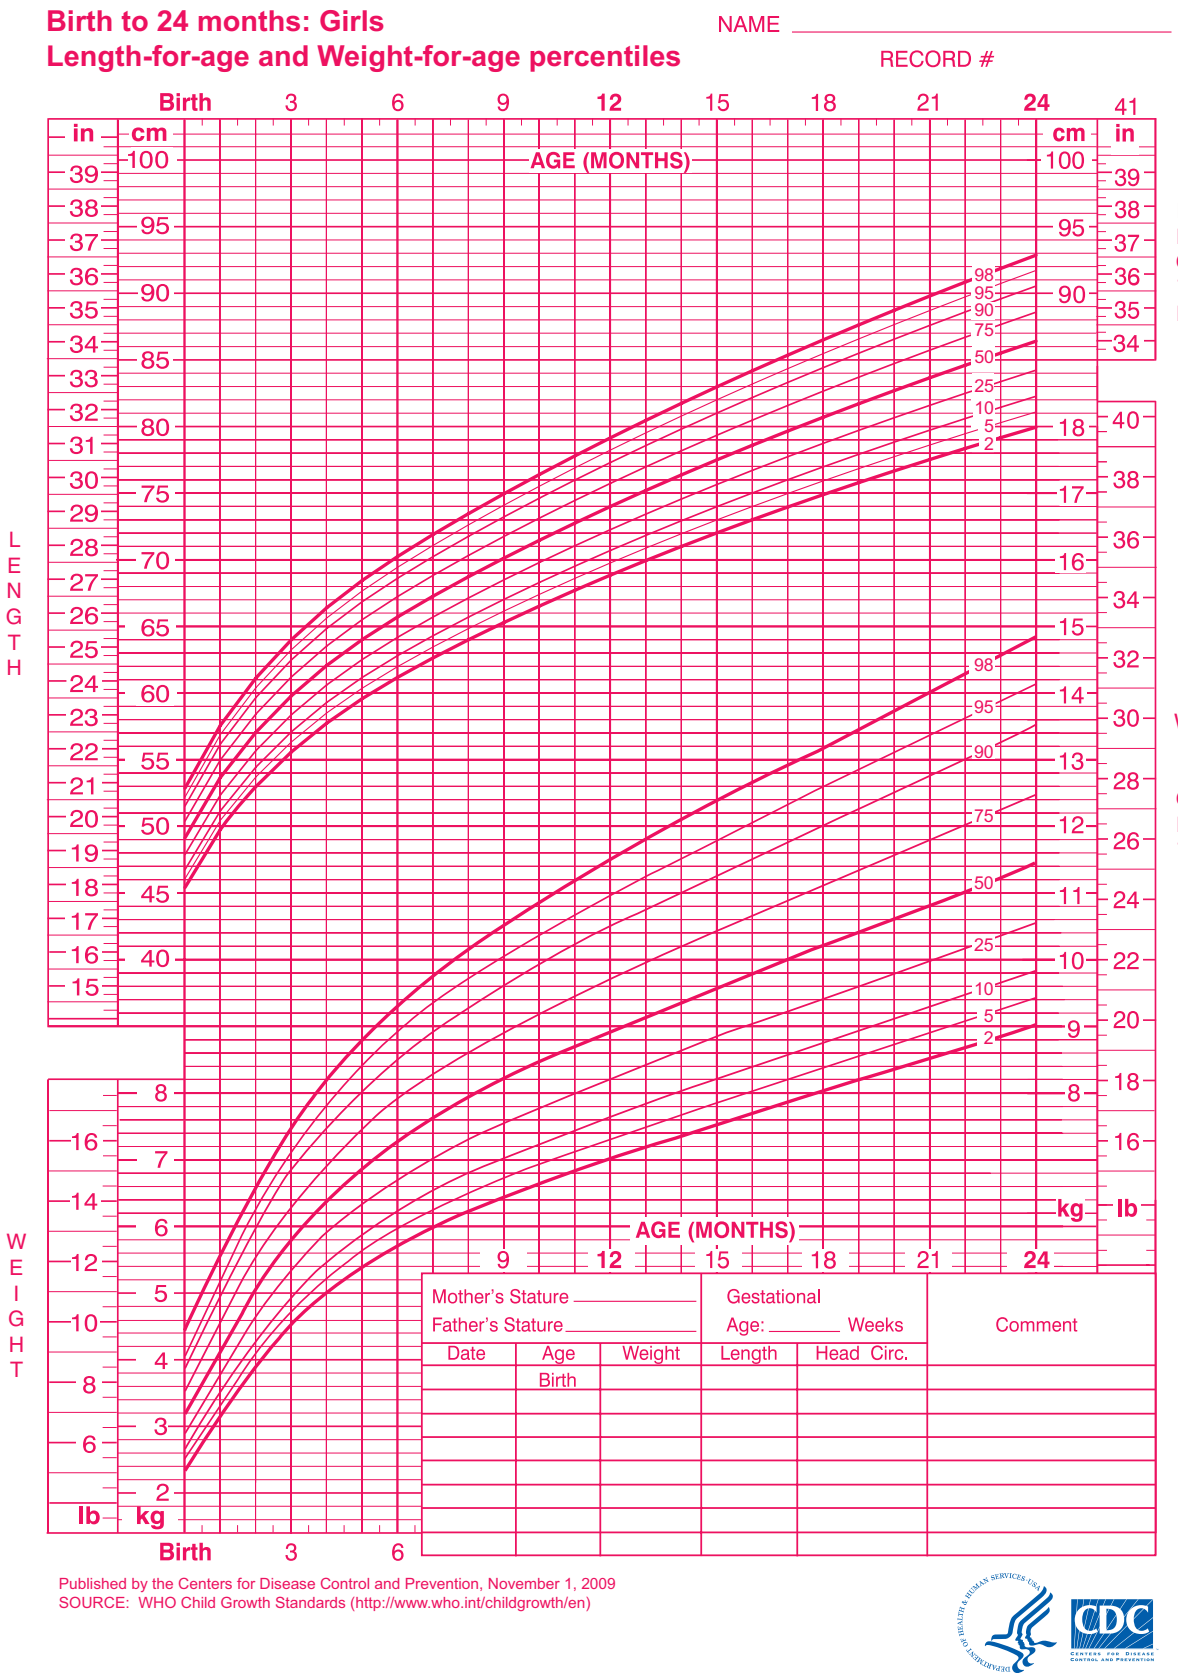

Figure 12.7, cont'd

## Motor

Locomotion proceeds in stages. First, the infant learns to position the head in space, then to crawl on hands and knees, later to move about while sitting upright and, finally, to stand, balance and walk. Thus, motor development occurs in the cephalocaudal direction.

## Psychosocial development

Psychosocial development refers to how a person learns to interact with others and begins early in an infant's life; smiling, for example, can be considered a social response. Initially a smile can be elicited in response to strangers but after about 6 months the infant's smile becomes more selective. As the infant begins to vocalise and later to speak, social interaction is increased.

The family is the first, and most important, social institution for the infant and they begin to develop trust as their parents meet their needs. Social roles such as brother or sister or playmate are gradually acquired during **social development** in infancy. Play provides the opportunity for social development, whereby the infant learns the social expectations that accompany relationships. Infants' play first revolves around their own body, but by age 3 to 6 months the infant exhibits more discriminate interest in stimuli and will play alone. Play becomes more vocal (laughing to demonstrate pleasure) and more sensorimotor between 6 months and 1 year of age and although solitary, infants choose with whom they will interact (Hockenberry & Wilson 2015).

The formation of personality, influenced by a combination of hereditary, psychological, environmental and social influences, includes those stable psychological characteristics that make each human being unique. An individual's personality traits form early in life and encompass many factors including intellectual abilities, motives, emotional reactivity, attitudes, beliefs and moral values. Infants are typically egocentric, or self-centred, and are primarily concerned with satisfying physical desires, such as hunger (Mitchell & Ziegler 2012).

Emotion is the term used to describe a feeling such as anger, fear, joy and sorrow. **Emotional development** depends on a variety of factors such as maturation, heredity, socialisation and the environment. Most emotional expressions appear to be learned, and emotional development is related to age. While some forms of emotional expression appear to be inborn or develop through maturation, learning is important in modifying emotional expression to conform to the patterns approved by a specific culture.

At birth infants are able to exhibit distress and pleasure; by 3 to 6 months they can express anger, distrust and fear; and by about 8 to 10 months they can exhibit anxiety, surprise, dis-satisfaction, obstinacy, anticipation and frustration (Mitchell & Ziegler 2012).

## Cognitive development

### Perception

The process of **intellectual development** skills such as reasoning, thinking and problem solving involves two main processes—perception and conceptualisation. Perception is the sensory process by which a person obtains information about themselves and their environment. Conceptualisation is the process of concept formation and is an intellectual activity that facilitates reasoning, thinking and problem solving. Concepts allow sense to be made of the information received through the senses (Mitchell & Ziegler 2012).

### Cognitive ability

Infants progress from reflexive behaviour to repetitive acts to imitation of activity. The crucial events of cognitive development during infancy include separation, where infants learn to separate from objects in the environment; object permanence, where infants begin to realise that objects outside of the visual field still exist; and mental representation, which is defined as the use of symbols to think about an experience without experiencing it (Hockenberry & Wilson 2015).

### Memory

Various studies have shown that infants as young as several days old are able to recognise significant figures in their life. Evidence has also shown that infants as young as 4 months of age can recall individual actions. It is not until 9 months of age, however, that infants are able to remember the order of actions after long delays. Research suggests that after a 3-minute delay, infants (12 months) can remember about 70% of the way they play with toys. After 1 week, more than 50% is remembered and, after 4 weeks, infants can recall about 50% of the way they initially learned to play with toys (raisingchildren.net.au).

### Learning

Learning starts at birth and is a continuous process; infants learn through imitation, exploration, discovery and play. Infants learn through a variety of mediums including observation, making sounds and stimulation of the senses—including putting things in their mouth. Infants can also remember what they see and copy it at a later time (Boyce 2013).

**CRITICAL THINKING EXERCISE 12.1**

Natalie is 24 and has attended the maternal–child health clinic with her baby for a routine 8-week checkup. Natalie is curious about the stages of infant development and asks, 'How is my baby doing? How long should she be and how much should she weigh now? When will she start smiling and trying to roll onto her back?'

What subjective and objective data do you need before you answer? What will you tell Natalie in response to her questions?

# HEALTH RISKS/PROBLEMS

## Colic

Colic occurs in approximately 15–40% of infants and is defined as abdominal pain that is manifested as loud crying for longer than 3 hours per day, more than 3 days per week

for more than 3 weeks. Infants with colic are also observed to draw their legs up to their abdomen. Episodes usually occur in the late afternoon (Hockenberry & Wilson 2011). There is no known definitive cause, but theories related to rapid or improper feeding, air swallowing and intestinal factors have been identified as potential causes. There is no specific treatment for colic, but infants are treated primarily with changes in formula, environmental or behavioural interventions (Hockenberry & Wilson 2015).

### Failure to thrive

Failure to thrive (FTT) is diagnosed when the infant isn't growing at the expected rate. FTT can be organic (resulting from an acute illness), non-organic (psychological problem such as failure to bond) or a mixture of both. FTT is considered when the infant fails to gain or loses weight, exhibits a decline in growth progress of length and then head circumference. Treatment is directed at the cause—either the underlying disease or the environment (Harari, as cited by Thomson et al 2015).

### Skin disorders

Skin disorders such as nappy rash are relatively common in infancy. Nappy rash is a form of contact dermatitis most prevalent in infants ranging from 9 to 12 months of age. The development of nappy rash is directly related to contact with irritants, such as urine and faeces, which permits constant exposure to moisture leading to breakdown of the skin and an increase in microbial count. Treatment is directed first towards prevention (frequent changes of nappy, ensure thorough drying occurs) followed by application of barrier creams (Hockenberry & Wilson 2015).

### Sudden infant death syndrome (SIDS)

Sudden infant death syndrome is defined as the sudden death of an infant younger than 1 year of age that remains unexplained. Although much research has been carried out over the past 20 years into the mechanism of SIDS, no definitive cause has been identified. The incidence of SIDS peaks between 2 and 4 months of age.

Risk factors may include premature birth, low birth weight, being one of a multiple pregnancy, being exposed to maternal smoking in utero, prone sleeping position, infant overheating or overcooling, or a brainstem abnormality in the control of cardiorespiratory function (Cutz 2014).

The most effective strategy in reducing the incidence of SIDS has been the 'safe sleeping' campaign which aims to educate parents about the importance of putting baby on their back to sleep, keeping their face uncovered, avoiding exposure to cigarette smoke and ensuring the baby sleeps at the end of an uncluttered cot (no toys or bumper) (www.sidsandkids.org).

Sleeping on the back reduces the risk of SIDS. Tummy or side sleeping increases the risk of SIDS. Healthy babies placed to sleep on the back are less likely to choke on vomit than tummy sleeping infants.

Research has shown that sleeping baby in the same room, but not in the same bed, with the parents in the first 6 to 12 months of life is protective. This is thought to be because parents can see the baby and easily check to see that baby is safe. This protective effect does not work if the baby is in the room with other children, probably because the children do not know if the baby is safe or not. Recent evidence from the UK indicates that sharing the same room during baby's daytime sleeps is also protective (Moon 2011).

## GROWTH AND DEVELOPMENT OF THE CHILD

Childhood may be divided into two stages of development: early childhood (from 12 months to about age 5–6), and late childhood (extending from age 6 to adolescence). (See Table 12.8.)

### Physical development

Physical growth slows and steadies during the toddler and preschool years. The average weight gain is 1.8 to 2.7 kg per year and by about 30 months the birth mass has quadrupled. Preschoolers have an increase in weight of 2 to 3 kg per year. The toddler grows approximately 7.5 cm per year which is mainly due to elongation of the legs rather than the trunk. In comparison, the preschool child has a height increase of 6.5 to 9 cm which results in a more slender body appearance (Hockenberry & Wilson 2015) (see Table 12.8).

The rate of increase in head circumference also slows and by 1 to 2 years of age, it is equal to chest circumference. After the second year the chest circumference exceeds the abdominal measurement, the lower extremities grow and the child assumes a taller, leaner appearance. However, the toddler maintains a 'pot-bellied' appearance because of less developed abdominal musculature and short legs. By the end of toddlerhood most of the body systems are relatively mature. The internal structures of the ear and throat continue to be short and straight, and the lymphoid tissue of the tonsils and adenoids remains large. These circumstances account for a high incidence of ear, throat and upper respiratory tract infections during this stage of development (Hockenberry & Wilson 2015).

**TABLE 12.8 | Average height and weight measurements**

| Age | Average weight | Average height |
|---|---|---|
| 2 years | 12 kg | 86.6 cm |
| 5 years | 18.7 kg | 110 cm |
| 12 years | 40 kg | 150 cm |

*(Hockenberry & Wilson 2015)*

Towards the end of childhood, height increases by an average 5 cm/year and mass by about 2 to 3 kg/year. There is little size difference between the genders, although boys tend to be slightly taller and heavier initially but by the end of the school-age years, although both genders increase in size, girls do tend to surpass boys in both height and weight. Body proportions take on a slimmer appearance, as fat gradually diminishes and its distribution patterns change. Development of all body systems continues during middle childhood to become more efficient and adult-like in function. Bones continue to ossify, but ossification of small and long bones is not completed during this stage of development. By about age 12, all temporary teeth have been shed and most permanent teeth have erupted. In later childhood most systems are mature and can adjust to moderate stress and change (Hockenberry & Wilson 2015).

## Measurement

Children until the age of 3 should be weighed naked if possible. Sitting or standing scales are appropriate, depending on the child's condition, ability to stand or willingness to participate in the procedure. If distressed, the child can be weighed with a caregiver, and their weight subtracted from the measurement. Height is measured in children, and can be gained through use of an accurate tool, such as a tape measure on the wall (Hockenberry & Wilson 2015).

## Sensory

Visual acuity of 20/40 exists during toddlerhood, but depth perception continues to develop. Children's vision continues to develop throughout their preschool years. The senses become well developed, coordinated and associated with experiences, and taste/texture preferences become evident as children progress through to late childhood (Hockenberry & Wilson 2015). Reading is important during the early childhood years as young children develop strong visualisation skills as they 'picture' the story in their minds. A child should have their first eye exam by age 3 (sooner if vision problems run in the family) so the optometrist can check if vision is developing normally and catch any problems early. Vision should be checked again when the child enters school (www.childrensvision.com).

## Motor

Motor development continues rapidly during early childhood with the major development being locomotion. By 12 to 13 months toddlers can walk alone and by 18 months they try to run but fall over. Between 2 and 3 years of age, children develop improved coordination and balance, allowing refinement of the upright walking position (Hockenberry & Wilson 2013). Fine motor skills also develop, allowing for increasing manual dexterity.

The school-age child gains increasing control over muscular skills and coordination, allowing for development of skill in games such as football and improved fine motor control for activities such as drawing (Berman et al 2012). (Refer to Table 12.9 for developmental progression.)

## Cognitive

Cognitive processes develop rapidly, and the major achievement of early childhood is the acquisition of language. Reasoning skills remain primitive (and should be considered when managing behaviour) but recognition of causal relationships becomes apparent. Preschool children tend to use words without comprehending meaning while children can use concepts correctly, but usually only in the circumstances in which they were learned. By the time children enter school, events and actions can be transferred into mental representations and expressed verbally (Hockenberry & Wilson 2015).

### Perception

Within the preconceptual phase (2 to 4 years), children become dependent on perception for problem solving (Hockenberry & Wilson 2015). In addition to object permanence, another perceptual milestone of toddlerhood is the capacity to sort objects into categories based on traits such as colour or type. By six years of age, kids can represent the things they perceive with symbols and words.

### Memory

Memory develops in children from as young as 7 months and is enhanced throughout development by acquisition of knowledge, familiarity and repetition. By early preschool years, children can plan and sequence activities based on retained memory (Sheridan 2014).

### Learning

During the ages from 6 to 12 years the ability to think abstractly and to solve problems develops and improves. Verbal language skills are further developed with an increased vocabulary and fluency of speech. The ability to read becomes a valuable means of increasing knowledge. By approximately 18 months, experimentation is used to achieve goals and skills become important for the function they serve. During this phase, there is differentiation of self from others which is reflected in the child's ability to tolerate longer periods of separation from parents. By the beginning of the second year, the child is able to think and reason and the concepts of time, space and causality (cause and effect) begin to have meaning. By about age five, egocentric thinking is replaced partially by intuitive thought. The child begins to acquire the ability to use thought processes to make sense of experiences, events and actions. Piaget describes this stage of development as concrete operational (Hockenberry & Wilson 2015).

## Psychosocial

As a child learns through interaction with others, they become more specific in the expression of emotions, and begin to learn the effects of their own behaviour on others. Behaviour is involved with meeting psychological needs such as security, acceptance, approval and feelings of self-worth. Emotions can activate and direct behaviour in the same way as biological drives.

Relationships with others play an important role in emotional and personality development. As the child interacts

**TABLE 12.9 | Growth chart—infant to younger child**

| Age | Motor, communication, manipulative and social skills |
|---|---|
| 12–15 months | Walks on own, can creep up stairs and climb onto chairs. Can kneel without support, runs clumsily and falls often. Says 4–6 words including names, asks for objects by pointing and understands simple commands. Tolerates separation from parents, begins to imitate parents, less likely to fear strangers |
| 18 months | Assumes standing position, walks up stairs with one hand held, jumps in place with both feet, seats self on chair, throws ball overhead without falling, builds tower of 3–4 cubes, says 10+ words and forms word combinations, expresses emotions and may have temper tantrums, imitates others, beginning awareness of ownership |
| 24 months | Able to run, climb, walk up and down stairs alone. Begins to put two or three words together, begins to use pronouns. Imitates adult activities, can dress themself but not do up buttons. Plays with other children |
| 3 years | Goes up and down steps alone with two feet on each step, runs confidently, jumps, can ride a tricycle. Can say own name and sex. Listens to stories. Vocabulary of 300 words. Thinks egocentrically. Plays constructively, has sustained attention span, increased independence from parents, interacts with peers |
| 4 years | Catches a ball, can hop on one foot. Can lace shoes but not always able to tie knot, uses scissors to cut out picture following outline. Vocabulary of 1500+ words, uses sentences of 4–5 words, knows many letters of the alphabet and can count up to 10. May rebel if parents ask too much and take out aggression on them or siblings |
| 5 years | Recites and sings. Asks lots of 'why' and 'how' questions. Vocabulary of 2100 words, sentences of 6–8 words. Can use scissors. Plays cooperatively with others. Can skip and hop. Can identify colours. Increased vocabulary, enjoys jokes and riddles. Ties shoelaces, does up buttons. More independent. Strongly identifies with parent of the same sex |

*(Hockenberry & Wilson 2013; Marieb & Hoehn 2013)*

with other people they learn to cope more effectively, and an ability to cooperate or compete with others involves a sense of accomplishment. Every small success increases the child's self-image, and a positive self-image makes the child feel likeable and worthwhile. If a child is incapable of, or unprepared for, assuming the responsibilities associated with a sense of accomplishment, they may develop a sense of inadequacy or inferiority. It is generally recognised that if a child's need for love and security is not met they may become insecure and unable to relate effectively to others in later life. Therefore, throughout childhood, emotional and personality development depend largely on having psychological needs met. Emotional deprivation results in developmental retardation. Young children especially do not thrive if their main carer is hostile or indifferent to them and their needs (Mitchell & Ziegler 2012).

With increasing age, social development becomes less family dominant and other people exert an influence on the growing child, which is essential to learning and to developing a healthy personality. Each group the child becomes involved with, such as school friends, provides a social relationship of varying strength and type. One of the most important socialising agents in a child's life is the peer group with whom they explore ideas and the physical environment. Through peer relationships children learn ways in which to relate and deal with others, and such relationships are important factors in gaining independence from parents.

As a child interacts with peers they become aware that there are views other than their own. As a result the child learns to persuade, bargain and cooperate to maintain friendships. The child becomes increasingly sensitive to the social norms and pressures of the peer group, and the need for peer approval becomes a powerful influence towards conformity. Peer relationships in which a child experiences love and closeness from a friend seem to be important as a foundation for close relationships in adulthood (Guan & Fuligni 2015).

Although increased independence is the goal of middle to late childhood, children still feel secure knowing that there is someone, such as the parents, to implement controls and restrictions. With a secure base in a loving family, a child is able to develop self-confidence and independence (Mitchell & Ziegler 2012).

## Moral development

Young children (2 to 4 years) have a limited understanding of moral judgment and judge actions depending on their result (reward or punishment). By 4 to 7 years, children begin to develop a sense of justice and fairness; however, their focus remains on satisfying their own needs rather than the needs of others. During school-age years, children begin to identify with the values and morals of their parents, develop awareness of acceptable behaviour and demonstrate guilt when these are violated. By age 6 to 7, although children are aware of rules and behaviours, they may not know the rationale behind

**TABLE 12.10 | Developmental stages according to Kohlberg**

| Stage | Age | Behaviours |
|---|---|---|
| Preconventional | Infant (birth–12 months) | Amoral stage<br>Punishment and obedience |
| Preconventional | Toddler (1–3 years) | Stage 1: Punishment and obedience<br>Children obey rules to avoid punishment and to obtain reward but they have no understanding of the reasons why they must obey rules<br>Stage 2: Instrumentalist relativist orientation<br>Behaviour fits the child's own needs, sharing and loyalty are not seen |
| Preconventional | Preschool (3–6 years) | Stages 1 and 2<br>Stage 3: 'Good girl or boy, nice girl or boy'<br>Conscience emerges, likes conforming to norms, seeks approval, behaviour is based on avoiding punishment or gaining rewards |
| Preconventional (<9 years) | School age (6–12 years) | Stage 4: Law and order<br>Obeys rules, respects authority |
| Conventional | 9–20 years | Stage 5: Social contract, utilitarian orientation<br>Behaviour and morals based on societal norms, increased desire to please others and 'be good' |

*(Hockenberry & Wilson 2013)*

them but by the older school-age period, an ability to judge behaviour based on intent rather than consequence is observed (Hockenberry & Wilson 2015) (refer to Table 12.10).

### Spiritual development

Spiritual development parallels cognitive development and is strongly influenced by the child's family and environment. Toddlers, unable to distinguish between make-believe and reality, learn about values and beliefs through the actions of those closest to them. By the preschool period, children have a more concrete perception of values and beliefs but remain unable to fully understand religious rituals (Hockenberry & Wilson 2015).

## HEALTH RISKS/PROBLEMS

### Injury

Once the infancy period has passed, deaths from injury emerge as the leading cause of mortality for children. In Australia the age group most likely to sustain injury is the 0–14 years age group, with a reported prevalence of 25% (Australian Bureau of Statistics 2012).

Injuries sustained in childhood include:

- Transport accidents where the child was either an occupant of a motor vehicle or a pedestrian
- Accidental drowning (children < 5 years of age are most vulnerable, more boys than girls)
- Suffocation or choking
- Burns
- Falls
- Poisoning.

The overall decline in injury deaths is partly due to injury prevention and safety promotion factors including speed limit initiatives, improved car safety including car seat installation, improved emergency and medical response and emphasis on safety in the home (childproofing cupboards, safety plugs in electrical outlets, supervision) (www.abs.gov.au).

**CRITICAL THINKING EXERCISE 12.2**

Annabelle is a 13-month-old toddler (see Clinical Interest Box 12.1) admitted to the paediatric ward following a fall sustained in the home. What developmental milestones and theories are related to Annabelle sustaining this injury? What impact could this fall have for Annabelle's family? What is the role of the paediatric nurse in this situation?

**CLINICAL INTEREST BOX 12.1**
**Childhood safety**

Annabelle is 14 months old and curious to explore the world. She is in the care of her grandmother when she attempts to crawl down a flight of stairs when unsupervised. As Annabelle's grandmother is not a regular carer for her granddaughter, the house is not 'toddler proof'.

Because locomotion is the major gross motor skill acquired during toddlerhood and Annabelle is striving to develop autonomy through experiences, safety becomes a high priority.

## Child maltreatment

Child maltreatment refers to any non-accidental behaviour by parents, caregivers, other adults or older adolescents that is outside the norms of conduct and entails a substantial risk of causing physical or emotional harm to a child or young person. Maltreatment may be intentional or unintentional and includes acts of omission (i.e. neglect, where a caregiver fails to provide the child's basic needs and an adequate level of care) or commission (i.e. physical, sexual or emotional abuse) (Hockenberry & Wilson 2015). Maltreatment can occur as a single incident, but usually takes place over time. Maltreatment can prevent children from reaching their growth and development milestones and can have long-lasting effects.

### Physical abuse

Physical abuse occurs when a child is physically hurt and it is *not* an accident. Bruises from being hit, burns, broken bones, babies being shaken and strangulation may be indicative of physical abuse.

### Emotional abuse

Wearing down the child's self-esteem and self-worth by putting the child down, criticising, shaming or rejecting the child, or never showing love or warmth are types of emotional abuse. Exposing a child to a negative environment (abuse between parents) can also affect a child's emotional state (Health Insite 2014).

### Sexual abuse

Sexual abuse is any sexual behaviour imposed on a child. Sexual abuse happens to both boys and girls and includes behaviour such as exhibitionism (purposely showing sexual organs), sexually suggestive comments and behaviour, fondling the child in a sexual way, making the child caress the abuser, oral sex or putting a finger, penis or anything else into the child's vagina or anus (Health Insite 2014).

### Effects of child abuse

Effects of child abuse are many and vary from child to child. A child who has been abused may have any or several of the following characteristics:

- Bruising, broken bones, burns
- Anxiety or low self-esteem
- Malnutrition or poor weight gain
- Poor school attendance
- Physical or intellectual developmental delay
- Dirty body, dirty clothes, unwashed hair
- Sad affect
- Self-destructive behaviour
- Abusive to the next generation of children
- Difficulty trusting others
- Feeling guilty even though it is not their fault
- Fear of having nappy changed or being bathed
- Sudden avoidance of familiar adults or places
- Difficulty dealing with emotions

In some cases they may die.

(Health Insite 2014)

The primary responsibility of the nurse is to identify abusive situations as early as possible and report concerns. All information gained during care of the child and family should be accurately documented in case of legal proceedings. For further information refer to Chapter 2. Care given to the child must be sensitive to their needs and they should be treated as any other child, rather than as a victim of abuse.

### Mandatory reporting

All suspected cases of child maltreatment must be reported under mandatory reporting laws. Reporting is the responsibility of any person who believes, on reasonable grounds, that a child is in need of protection and the child's parents are unable or unwilling to protect the child. In addition, anyone who suspects that a child is being abused and/or neglected or is at risk of being abused and/or neglected may make a report to child protection authorities (SECASA 2015).

### Legally mandated notification

Certain professionals must report to child protection services when, in the course of their duty, they 'form the belief on reasonable grounds that a child is in need of protection because the child has suffered, or is likely to suffer, significant harm as a result of physical injury and the child's parents have not protected or are unlikely to protect the child from harm' (Victorian Government 2015). Legally mandated professions include nursing. Reasonable grounds to report include when a child states they have been physically or sexually abused, a child states they know someone who has been abused, or a relative, friend or acquaintance or sibling of the child states that the child has been abused. Professional observations of the child's behaviour or development that led to the formation of a belief that the child has been abused, or if there are signs of physical or sexual abuse, must also be reported. Mandatory reporting takes precedence over maintenance of confidentiality and should be done without delay when grounds for the existence of abuse exist. A nurse does not have to prove the abuse has occurred (Victorian Government 2015).

## Obesity

The number of overweight children in Australia has doubled in recent years, with a quarter of children considered overweight or obese. Obesity not only causes health problems but can lead to social problems such as being teased by peers and the potential to develop low self-esteem and body image concerns. Being overweight and obese poses risks to the child's long- and short-term health as overweight children are very likely to become overweight adults (Better Health Channel 2015). Risk factors include:

- Poor food choices
- Lack of physical activity
- Increased levels of sedentary activity
- Overweight parents
- Genetics.

## Chronic illness

Improvements in healthcare services and technology, and reduced mortality rates, have led to an increased number of

children in the community living with chronic illness. The most common chronic illnesses experienced by children include cystic fibrosis, asthma, neurological impairment and cancers (Hockenberry & Wilson 2015).

The prevalence of asthma is increasing worldwide. Tobacco use is likely to be a key factor in higher rates of respiratory-related illnesses such as asthma. The principles of caring for children and families experiencing chronic illness include maintaining normalcy, supporting growth and development and promoting family-centred care in either the hospital or the home environment.

## FACTORS INFLUENCING GROWTH AND DEVELOPMENT

A person's development is influenced both by genetic factors and by the environment. Genetic factors are often referred to as the natural forces that influence development, while environmental factors are referred to as the nurturing forces. It is difficult to separate the effects of 'nature' and 'nurture', as individual development is affected by the interaction between these two forces. Another factor that influences development is maturation, which is a genetically programmed sequence of physical changes that is independent of environmental circumstances. Many behavioural changes that occur in the early months of life are related to maturation of the nervous system, muscles and glands. These changes represent a continuation of the growth processes that guide the development of the fetus within the uterus. Although maturation is not controlled by the environment, it can be accelerated or impeded by the quality of the environment and by life experiences.

### Genetic factors

Genetic factors influence many aspects of an individual's physical and psychosocial being. Research indicates that, as well as determining physical characteristics, genetic factors also influence parts of an individual's psychological makeup, such as temperament.

The central structure of a living cell is its complement of genes, which are located on the chromosomes within the cell nucleus. In humans, each cell normally contains 46 chromosomes and when fertilisation occurs the sperm and the ovum unite, each contributing 23 chromosomes to the zygote, which replicate in every cell of the body as the embryo develops (Figure 12.8).

Because of the high number of genes in each chromosome, 'shuffling' during replication and because during cell division each pair of chromosomes sorts randomly into the daughter cells, it is extremely unlikely that any two human beings would ever have identical genetic makeup, even with the same parents. One exception is identical (monozygotic) twins who, having developed from the same ovum, have exactly the same chromosomes and genes (Sigelman & Rider 2011). The single cell formed at fertilisation is capable of multiplying and developing into a fetus, with its sex and other characteristics, such as hair and eye colour, racial

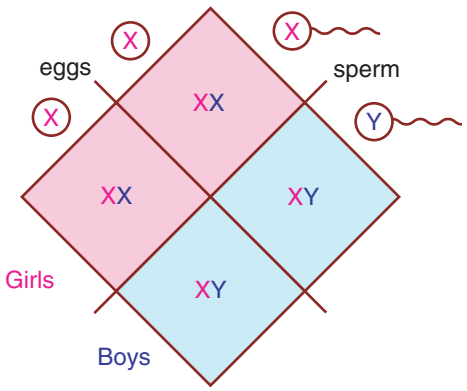

**Figure 12.8** Sex determination
*(Modified from Leifer 2010)*

characteristics and physical stature predetermined. Each person's genetic structure is unique and lifelong, so heredity affects all stages of development. While each person's capacities are inherited, the extent to which they are used in development is influenced by the environment (Marieb & Hoehn 2013).

### Environmental factors

The hereditary potential a person is born with is greatly influenced by the environment they encounter. Therefore, the environmental conditions to which an infant is exposed are a major influence on development. 'Environment' refers to the people with whom an individual has contact, the experiences they have throughout life and the physical surroundings they are exposed to.

Attachment and bonding are the processes by which the parents/carer and infant establish a relationship. Both parents/carer and the infant have a role to play in the attachment process, whereby each establishes emotional ties with the other. As the parent/carer responds to the infant, the infant responds to the parent/carer; for example by cooing or eye contact. Creating a situation in which the parent's/carer's and the infant's eyes meet in visual contact is significant in the formation of emotional ties. Research has suggested that this early social attachment provides the security necessary for infants to explore their environment and that it forms the basis for interpersonal relationships in later years (Hockenberry & Wilson 2015).

Early stimulation is important in providing the background necessary to cope with the environment at a later stage. Stimulation is provided by handling the infant, allowing them to move about freely and assume different positions, and by providing conditions whereby the infant receives visual and auditory stimuli, such as coloured objects, mobiles and the sounds of voices and music. Many studies indicate that a stimulating early environment is important for later intellectual development. Conversely, too much stimulation too soon could be upsetting for an infant, who may exhibit distress at being unable to respond to multiple stimuli (Smith & Hart 2010).

Through its various functions, the family exerts a major influence on development. It is through the family

environment that the individual first learns about self, the world and their place within a society. Initially the individual adopts the family's values and belief systems. Family functions include providing love and security, meeting the basic needs such as food and warmth, facilitating emotional and social development and helping the individual to learn about society, roles and behaviours (Hockenberry & Wilson 2013).

Factors within the everyday environment, such as nutrition, housing and socioeconomic status, have been found to influence development. For example, the adequacy of nutrients in the diet influences how physiological needs are met, and subsequent growth and development. When a diet is lacking in adequate nutrients, deficits in height, weight and developmental progression occur. In comparison, obesity results from a kilojoule intake greater than is required and can be attributed to hereditary, social, cultural or psychological factors. Obesity is rapidly becoming a significant health issue with children as young as 5 years affected. (Refer to Clinical Interest Box 12.2.)

## CLINICAL INTEREST BOX 12.2 Childhood obesity

### Facts about childhood obesity

- Results from the 2011–12 Australian Health Survey show that one-quarter (25%) of children aged 2–17 are overweight or obese, with 18% being overweight and 7% obese. The proportion of boys who are overweight or obese is not significantly different from girls (25% compared with 26%).
- Rates of overweight and obesity are similar across age groups, ranging from 23% for children aged 2–4 to 27% for adolescents aged 12–15. Boys aged 5–7 have the highest obesity rate (9%), and obesity among girls is most common at ages 5–7 and 16–17 (8%).
- The proportion of children and adolescents aged 5–17 who are overweight or obese increased between 1995 and 2007–08 (21% and 25%, respectively) but has remained stable to 2011–12 (26%).
- Obese children have a 25–50% chance of being obese as an adult and this might be as high as 78% in older obese adolescents.
- Children who are overweight or obese are at increased risk of developing certain health conditions, such as cardiovascular conditions and type 2 diabetes, compared with children of normal weight. They also have a higher risk of psychological and social problems, such as discrimination, victimisation and bullying. Obesity, in particular, may continue into adulthood and affect long-term health.

*(Australian Bureau of Statistics 2009; Ministry of Health 2009; AIHW 2012)*

## Demographic factors

Demographic characteristics include age, gender, race, socioeconomic status and education, all of which have the potential to affect health and health risks (Hockenberry & Wilson 2015). Age is considered the most influential factor when considering health promotion and disease prevention (e.g. children under 5 years of age and particularly infants are at higher risk than the rest of the population for respiratory syncytial virus).

## Socioeconomic factors

Socioeconomic status can exert significant impact on a child's growth, development and access to health services. Poverty can lead to inadequate nutrition and poor hygiene, and lack of education in combination with poverty can lead to limited access to healthcare. Lower levels of education can produce an inability to read information, and poor levels of involvement in health prevention (including immunisations and dental care).

### CRITICAL THINKING EXERCISE 12.3

Amy, aged 3, is admitted to your ward for elective surgery to remove her tonsils. Her weight is 25 kg and you notice on admission that she is very pale and doesn't attempt to communicate either verbally or physically with her mother or you. You ask her mother if she is normally very quiet and she tells you 'she never speaks, she just sits and watches television all day'. What physical and psychological factors may be affecting Amy's growth and development? According to developmental theory and milestone development, what would you expect to observe when assessing Amy? As a nurse, how would you educate Amy and her mother on the importance of diet and exercise?

# CULTURAL DIVERSITY

Beliefs related to health, causes of illness and treatments are strongly linked to culture. Nurses involved in the care of children and families from diverse cultures must recognise individual practices and respect family choices without displaying judgment. Examples of cultural practices seen in healthcare include 'coining' which is an Asian practice where a coin is repeatedly rubbed on the skin to rid the body of disease; coining results in welts which may appear as signs of abuse. Traditional herbal remedies can also be utilised by some cultures to treat various ailments; the role of the nurse is to elicit this information from the family and work with the medical team to identify any adverse interactions with prescribed treatment regimens (Hockenberry & Wilson 2015).

## Indigenous children

Indigenous children can have many health problems. Babies are more likely to be underweight, suffer from middle ear infections, malnutrition and exposure to cigarette smoke, all

of which have been linked to problems with mental development and disorders including anaemia and recurring infections. Indigenous people are nearly twice as likely to be admitted to hospital as non-Indigenous people. For children aged 15 years and under, the main reasons for hospitalisation include diseases of the chest and throat, injuries caused by accidents and middle ear infections (Better Health Channel 2015).

Hearing loss during childhood has a significant effect on speech and language development as well as emotional, social and educational development. Otitis media affects up to 40% of the Australian Indigenous population. The prevalence of otitis media can be directly linked to poor living conditions, poor nutrition, lack of hygiene and lack of access to appropriate health services. Primary prevention strategies are aimed at improving the environment and nutrition, increasing breastfeeding, reducing passive smoking and increasing access to health screening and treatments (Levi et al 2013). Perforation of the tympanic membrane occurs in up to 50% of otitis media cases and can result in permanent hearing loss.

**CRITICAL THINKING EXERCISE 12.4**

James is a 7-year-old Indigenous boy. His teacher has noted his poor school performance and apparent reduced hearing capacity and is concerned. She requests a referral to the school nurse. What could be causing James's poor school performance? What socioeconomic and cultural influences could exert an impact on James's situation? What is the role of the school nurse in providing care for James?

## HEALTH PROMOTION

Health promotion enables individuals to determine the influences on their health and identify strategies for how health can be improved. Many hospitals now produce fact sheets that outline potential hazards and strategies to prevent injuries from occurring (such as bicycle helmets). Health promotion must meet the needs of the child and family and be delivered using developmentally appropriate methods such as posters and storybooks for younger children and computer technology for the older population.

## PAEDIATRIC NURSING CARE

Nursing care of infants and children is directed towards promoting the optimal level of health for the individual and family. Knowledge regarding specific health problems and needs of each age/developmental phase is essential to the provision of individually appropriate care. The nursing role involves disease and injury prevention, health promotion, involvement of the family in care provision, health teaching, participating in a team approach to care and implementing measures to meet the physical, emotional, social and cultural needs of each individual in a developmentally appropriate manner. Because children are not 'little adults', their growth, development, reactions to illness, interventions, treatment and separation from family all influence care planning and delivery.

The role of a paediatric nurse can be described as that of carer, coordinator, educator and emotional support and resource person. The nurse involved in paediatric care, together with other members of the paediatric team, needs to adopt a holistic attitude towards caring for the child and parent(s)/carer(s) as a family unit. Many healthcare facilities recognise the need for family-centred care and adopt a philosophy to meet the needs of the family as a unit. Family-centred care recognises the family as the constant in the child's life and its pivotal role in shaping the hospital experience for their child. As such, supporting, respecting, involving and educating the family strengthens the partnership between health professionals and family.

### Nursing children in a hospital setting

Paediatric nursing recognises the role of the family as the constant in the child's life and their primary source of support and strength. As such, nurses should provide care based on principles of collaboration, partnership, sharing of knowledge, negotiation and respect (Hockenberry & Wilson 2015).

Hospitalisation is often the first stressful event in a child's life and they may lack the coping mechanisms to manage stressors. The causes of stress differ across the developmental continuum; however, the most common regardless of age/developmental stage are separation anxiety, loss of control, injury and pain. Responses to stress also differ according to their age, previous experience with illness/hospitalisation, innate or acquired coping skills, seriousness of the diagnosis and availability of support systems (Hockenberry & Wilson 2015). Although negative responses to hospitalisation can occur, there can also be beneficial outcomes such as developing resilience, coping skills, socialisation experiences and recovery from illness.

Practical approaches to caring for the hospitalised child include:

- Preparing the child and family for admission prior to hospitalisation using a pre-admission hospital orientation, multimedia or other developmentally appropriate strategies
- Encouraging family involvement in care delivery
- Minimising separation
- Minimising fear and anxiety through provision of developmentally appropriate explanations
- Allowing children to familiarise themselves with medical equipment if appropriate
- Encouraging involvement in medical play
- Assessing the child in a non-formal manner—during play is an optimal time for assessment
- Referring to developmental play therapists as necessary
- Offering some degree of choice (you have to have the medicine, but do you want the green or the red mixture?)
- Maintaining the child's routine (to the greatest possible extent)
- Encouraging independence.

## CASE STUDY 12.1

Amy is a 3-year-old girl admitted to the paediatric ward for removal of tonsils and adenoids (TandA). She was diagnosed with obstructive sleep apnoea (OSA) (confirmed by overnight oximetry), but has not been admitted to hospital previously. She is the eldest child of parents Michael and Jennifer who also have a baby aged 3 weeks. During admission, Jennifer indicates that Amy is a well child who is having her TandA removed for OSA which is manifested by loud snoring and an average of 10 episodes of apnoea (up to 20 seconds) per night. Jennifer states that Amy has no surgical history, her immunisations are up to date and she has been previously well apart from the 'normal childhood coughs and colds'. Jennifer indicates because of the new baby and keeping a close eye on Amy during the night, she is very tired. Michael works long hours as a bank manager and is rarely home before 8 pm, which means Jennifer is responsible for the majority of the children's care needs.

1. What is the relevant data in this clinical scenario?
2. Relate the significance of the data to the situation.
3. Develop a list of questions for inclusion in your nursing assessment.
4. Identify the rationale for these questions.
5. Discuss how your strategies would change when admitting a child rather than an adult to hospital.
6. What preoperative education would you provide to Amy and her family? How would you deliver this education?
7. How could you involve Jennifer in Amy's care during hospitalisation?
8. What support services/allied health referrals may be needed by this family? Justify your response.
9. What are the potential impacts of hospitalisation on Amy and on her family?

## DECISION-MAKING FRAMEWORK EXERCISE 12.1

Madeleine is a student Enrolled Nurse currently undertaking clinical placement on the paediatric ward of the local hospital. She is caring for 3-year-old Amy who is scheduled to undergo an elective tonsillectomy this afternoon. Amy has been reviewed by the anaesthetist who ordered a pre-medication to be given prior to surgery. Amy has not yet been reviewed by the surgeon and her mother has yet to sign the consent form.

Madeleine has completed the preoperative assessments and has been informed that the operating theatre is now ready for Amy to be transferred to preoperative hold. Madeleine knows that Amy has been ordered a pre-med; however, she also knows that pre-medication should not be given before the consent form is completed. Madeleine also knows that she is not permitted to give paediatric medications until she has achieved 100% in her medication calculations assessment.

1. Should Madeleine give the pre-medication? Consider the following:
   - What is the hospital policy regarding administration of pre-medications?
   - Have staff in preoperative hold been informed that the consent form has yet to be signed?
   - Has Madeleine or the RN informed the surgeon of the situation?
   - Is preparation and administration of medication without direct supervision within Madeleine's scope of practice?
   - Will administration of the pre-medication comply with accepted standards of nursing practice?
   - Have any potential risks of administering the medication been identified?
   - Is her preceptor adequately supporting Madeleine?
   - Does Madeleine have the required level of education and supervision available?

See Case Study 12.1 and Decision-making Framework Exercise 12.1 for exercises about nursing children in a hospital setting. The Progress Note Example 12.1 also shows a sample of an entry in nursing notes.

## PROGRESS NOTE EXAMPLE 12.1

| | |
|---|---|
| 12/01/2016<br>1430 hrs | Nursing: Amy is a 3-year-old girl admitted to the paediatric ward this morning. She has a history of obstructive sleep apnoea (OSA) and is scheduled for removal of tonsils and adenoids this afternoon. Assessment on admission: T: 37.2, HR: 106, RR: 24, weight 14.5 kg, no known allergies, immunisations are up to date. Amy has been fasting since an early breakfast at 0700 this morning. Prepared for theatre, two arm bands in situ, refusing theatre gown so remains in own pyjamas. Awaiting anaesthetist visit, mum yet to sign consent form. Amy and mum orientated to the ward and preoperative education completed.<br>***L. Adams* (Adams) EN** |

## Nursing care of the infant and child

Communication strategies should reflect the developmental stage with the use of appropriate verbal and non-verbal strategies. Developing language ability can cause problems when symptoms need to be described so the focus in the younger age groups should fall to non-verbal cues such as their activity levels and posture. Securing parental/carer involvement is imperative for the younger child; however, as children get older, they should be offered greater choices regarding level of involvement in procedures (where appropriate) and presence of parents/carers. Assessment should follow a least-to-most intervention format as the irritable infant or child can distort assessment findings. If possible, assessment should occur during normal interaction or play. When interacting with a child, the nurse must offer explanations as appropriate,

## CLINICAL INTEREST BOX 12.3 Play

- Children should be given choices regarding some elements of their care, and toys are an ideal way to give them both choice and control.
- Medical play is play with real medical equipment and often dolls, which allows children a non-threatening way to learn about and familiarise themselves with medical procedures, equipment, hospitals, medical officers and nurses.
- Through medical play, children can express fears about their hospital experience that they may be unable to express verbally.
- Infants will look at, handle, mouth and generally become familiar with medical equipment. Preschool children will re-enact medical events on dolls or stuffed animals while school-age children will explore medical equipment, allowing them to gain insight into the procedures and roles of staff and work through feelings within a controlled environment.

## CRITICAL THINKING EXERCISE 12.5

Thomas is a 7-year-old boy who presents to outpatient clinic with his parents for review of a painful left knee. Thomas has been complaining of pain and reduced mobility for approximately two weeks. On examination, his knee is red and swollen; he is unable to full weight bear on this leg. The orthopaedic surgeon diagnoses osteomyelitis which will require surgical incision and washout. He is scheduled for admission to hospital in 2 days.

Thomas has never been hospitalised before and is very anxious. His parents are unsure about how to prepare him for this experience. How should Thomas's parents prepare him for hospitalisation? What resources are available to help prepare Thomas for hospital? What information would you give to Thomas's mother, who would like to stay overnight with him in hospital? How can the concept of pain be explained to Thomas?

be truthful and gain the trust of both child and parent/carer. For further information on caring for the hospitalised child refer to Chapter 21.

Hospitals can be strange and scary places for children. Children are faced with unfamiliar people (the staff), separation from family and their home environment, painful or distressing procedures and different foods, smells and sounds. Negative hospital experiences can interfere with recovery and can inhibit normal growth and development. It is not unusual for a child to react to hospitalisation by crying or having tantrums and they may regress in their behaviour (e.g. revert back to bedwetting) or become withdrawn. Play is a way to help children cope with hospitalisation and reduce their stress levels. Play allows the child to participate in activities 'normal' to them, enables developmental progression and learning and offers a distraction from painful procedures or treatments (The Royal Children's Hospital Melbourne 2016) (refer to Clinical Interest Box 12.3).

Maintaining safety of the infant or child in hospital and promoting safety in the home is an important role for the paediatric nurse. Certain age groups, as their curiosity and mobility increases, are at increased risk of injury or illness. While the child is in hospital, the nurse should ensure they are free from exposure to dangerous situations such as boiling water, slippery floors, medication, chemicals or lack of cot sides which prevent falling from bed.

## CHILD HEALTH SERVICES

There are a variety of child health services whose broad aims are promoting the health of infants and children, providing parental/carer support and caring for the child who is ill. Many of the services are involved in preventing illness, health promotion and monitoring the health of children from birth. Preventative services include maternal–child health clinics and school health services.

Maternal–child health services support parents/carers and provide information on a variety of topics such as hygiene, nutrition, growth and development, and illness prevention strategies such as immunisation. These services play an important role in assessing growth and development and undertake screenings for various disorders (physical, metabolic, neurological). The maternal–child health nurse also consults with paediatricians on health problems, refers to other health professionals as required and offers parents the chance to meet other parents/carers to access information and support. The nurse also keeps comprehensive records that include information on the child's growth and development, immunisations and illnesses. These records are important tools for assessment and for detecting situations that require early intervention and preventive action. Refer to Table 12.11 for general trends in height and weight during childhood.

School health services are directed towards health promotion and early identification of and intervention for health concerns. School nurses provide specific health assessment activities for children at school entry and during school life. They undertake vision screening and hearing testing, immunisation, accident and injury prevention, nutrition assessment and guidance, positive parenting and asthma management, while maintaining regular contact with students, teachers and parents. Secondary school nurses have a key role in reducing negative health outcomes and risk-taking behaviours among young people. The role specifically encompasses individual health counselling, health promotion and planning, and is a resource and referral service to assist young people to make healthy lifestyle choices (www.education.vic.gov.au). (See Nursing Care Plan 12.1.)

Child guidance clinics staffed by educational psychologists, social workers and psychiatrists are available to assess

**TABLE 12.11 | A summary of general trends in height and weight during childhood**

| Age group | Weight | Height |
|---|---|---|
| Birth–6 months | 140–200 g/week<br>Birth weight doubles by 4–7 months | Monthly gain 2.5 cm |
| 6–12 months | 85–140 g/week<br>Birth weight triples by end of first year | Monthly gain 1.25 cm<br>Birth length increases by 50% by end of first year.<br>Height at 2 years is 50% of adult height |
| Toddler | Birth weight quadruples by 2½ years | Gain during second year 12 cm<br>Gain during third year 6–8 cm |
| Preschooler | Yearly gain 2–3 kg | Yearly gain 5–7.5 cm<br>Birth length doubles by age 4 years |
| School age | Yearly gain 2–3 kg | Yearly gain after age 7 is 5 cm<br>Birth length triples by age 13 |
| Females 10–14 years | Weight gain 7–25 kg<br>Average 17.5 kg | Gain is 5–25 cm<br>Average 20.5 cm |
| Males 10–14 years | Weight gain 7–30 kg<br>Average 23.7 kg | Gain is 10–30 cm<br>Average 27.5 cm |

*(Chiocca 2011)*

## NURSING CARE PLAN 12.1

**Assessment:** Suzie and her mother present to the community maternal–child health nurse (MCHN) for her 6-week health and development appointment. During discussion, Suzie's mother indicates that Suzie has not been feeding well, vomits small amounts of undigested milk after every feed and has lost weight since her birth. The MCHN weighs Suzie and finds that she is below the 50th percentile on the growth chart.
**Issue/s to be addressed:** Poor feeding
Weight below 50th percentile on growth chart
Failure to thrive
**Goal/s:** Suzie's mother will receive adequate education in both written and verbal forms to ensure adequate nutrition
Suzie will tolerate small frequent feeds with nil vomiting
Suzie will gain weight by next MCHN visit in 2 weeks

| Care/Actions | Rationale |
|---|---|
| Suzie to be fed with small frequent feeds | Increase caloric intake to assist weight gain |
| Thickener to be added to feeds | Identify change in condition or pattern of vomiting |
| Mother to record episodes of vomiting | To ensure Suzie does not become malnourished or dehydrated |
| Suzie to remain in upright position for feeding and for 20 minutes post feeds | To promptly identify and manage any concerns before condition deteriorates |
| Elevate head of bed | |
| Mother to receive education related to assessment of hydration and nutritional status | |
| Mother to notify MCHN/GP if nil improvement in condition | |

**Evaluation:** Suzie will gain weight before next MCHN visit.
Mother is able to identify correct feeding techniques and signs of malnourishment and dehydration.

children and provide services to help children overcome difficulties. The services assist children who show evidence of emotional instability or psychological disturbance to attain personal, social or educational readjustment. Children with mental or physical impairments are provided for by health, education and social services. Integration in ordinary schools is promoted so that all children can receive education, irrespective of the degree of their disability. In some instances this may not be possible and it may be necessary to provide education at home or in a special school. Every effort is made

to ensure that a mentally or physically impaired child can develop to their fullest potential (Department of Education and Early Childhood Development 2011).

## NEEDS OF INFANTS AND CHILDREN

The needs of children throughout the various stages of development are both physical and psychosocial. Physical needs include the need for food, water, oxygen, elimination, warmth, safety and protection. Meal times should be pleasant unhurried occasions and the environment should be one that enables children to enjoy meals. Psychosocial needs include the need for love and affection, security, dependence and independence and self-development. When physical or psychosocial needs are not met, children experience disruptions to their biological, emotional, social or educational growth and development. When needs are not met there are a variety of effects on the child, such as a greater incidence of disease and accidents, failure to thrive, behavioural problems, delayed language skills, antisocial behaviour such as conflicts with the law or substance use and abuse, learning difficulties and social inadequacy.

## Summary

Growth and development are processes that begin at conception and continue throughout each stage of the life cycle. Growth may be defined as the physical changes that occur in a steady and orderly manner, while development relates to changes in psychological and social functioning. The stages of growth and development are generally described as being prenatal, infancy, childhood, adolescence and adulthood. Characteristic changes occur at each stage, but the pace and behaviours of growth and development vary with each individual.

To care for individuals from infancy to late childhood the nurse first requires knowledge of normal growth and development. Infancy and childhood are unique phases of development accompanied by special needs. The paediatric nurse needs to develop certain skills to provide a high quality of individualised family-centred care to children and their families.

## Review Questions

1. Define fertilisation. Where does it normally occur?
2. Explain the importance of the placenta and umbilical cord to fetal growth.
3. Outline some of the major developmental changes during fetal development.
4. There are several theories about the various stages of growth and development, particularly in regard to infants and children. Name the stages according to Erikson and Piaget.
5. Identify the significant factors that influence growth and development during childhood.
6. List the developmental stages of early childhood and briefly outline the changes that occur during each phase. (Early childhood: toddler and preschool years (12 months–6 years of age).)
7. Identify the role of a children's nurse in various clinical settings.
8. Why are children aged less than 5 years most vulnerable to drowning?

Answer guide for the Review Questions, Critical Thinking Exercises, Decision-Making Framework Exercises and Critical Thinking Questions in Case Studies are hosted on Evolve: http://evolve.elsevier.com/AU/Koutoukidis/Tabbner/

CHAPTER 13

# Nursing care across the lifespan: late childhood to adolescence

*Jean Elizabeth Ross*

## KEY TERMS

adolescence
anorexia nervosa
body image
bulimia nervosa
cognition
concrete operational stage
cultural differences
formal operations
health promotion
hormonal production
identity
menarche
morals and values
peer group
physical development
preadolescence
primary sex characteristics
psychosocial development
puberty
risk-taking behaviours
rite of passage
secondary sex characteristics
sexuality
social relationships
substance abuse
suicide

## LEARNING OUTCOMES

At the completion of this chapter and with further reading, students should be able to:

- Define the key terms
- Describe the physical changes that occur at puberty
- Discuss the changes that occur during adolescence
- Discuss factors influencing the growth and development of the adolescent
- Identify the role that 'others' have during adolescence (peers, family and friends)
- Plan health promotion activities for a group of adolescents

## CHAPTER FOCUS

Adolescence is the transitional stage between being a child and becoming an adult. For the child it is a time marked with many changes, from the most obvious physical ones to the more intrinsic cognitive, emotional and attitudinal changes. It is a time that is packed with milestones and incorporates many rites of passage. Although there are many guides to providing care for the adolescent, the rates of change for the child can vary considerably, so that each adolescent must be cared for individually and according to the stage that they are at. This chapter takes a holistic look at the preadolescent and the adolescent and helps guide the reader through the often complex route between being a child and developing into an adult. While this chapter discusses both the preadolescent and the adolescent experiences, the use of the term adolescent often encompasses all stages of adolescence.

An understanding of preadolescent and adolescent development is essential for nurses in their daily practice. This is the period in the lifespan where the individual, previously reliant on parents and carers for values and identity, becomes independent and, in this move towards independence, attempts to create a new and personal identity. It is a time when group identity is vital, often a time of experimentation with self-image, and a time to question family values and beliefs. It is a period of rapid and complex changes. This chapter highlights the growth and development of the adolescent and helps the nurse to understand how to use this knowledge to provide optimal nursing care for the adolescent when hospitalised or treated within the community.

## LIVED EXPERIENCE

I can't believe that my parents don't understand how busy I am and how annoying they are! With all the things I have to do they still expect me to drop everything when they need me to help out with my sisters. I hold down a part-time job, try to play netball and am expected to get over 80 in all my assessments if I want to get to uni next year. I'm trying to get my Ps and go to some of the gigs that the others seem to have no trouble fitting in. When I try to talk to the parents they end up telling me what I should do, but really I just want them to listen to me. When it suits I'm an adult and other times just a kid.

**Marnie, aged 17**

Having teenagers is much harder than childbirth! No matter what we say or do it's the wrong thing. Marnie is so busy with school, work and play, we hardly see her except to drop off or pick up. She never offers to help and gets annoyed when I ask her to do anything. When we do talk I try to offer advice but none of it is any use to her. I feel like I'm losing my daughter.

**Marnie's mum**

# PREADOLESCENCE

The transitional period between childhood and adolescence is referred to as **preadolescence**. However, it may also be referred to as late childhood, early adolescence or pubescence. Preadolescence is the period of about 2 years before **puberty** when the individual is developing preliminary physical changes that herald sexual maturity. Children during this period of time are often popularly referred to as tweenies or tweenagers—both newly coined terms that have only recently entered the English language. They are heavily targeted by advertisers as children of this age represent an important demographic. Often because they have their own purchasing power, they influence their parents'/carers' buying decisions and they are the adult consumers of the future.

# GROWTH AND DEVELOPMENT OF THE PREADOLESCENT

## Physical development

Preadolescence refers to the beginning of the second skeletal growth spurt, when physical changes such as the development of female breasts and pubic hair also begin. These physical changes occur about 2 years earlier in girls than boys (Tortora & Derricksen 2011). The bones begin to lengthen and broaden. More in-depth descriptions of these changes are included in this chapter under the heading 'Physical development' in the section on adolescence below.

## Cognitive development

**Cognition** is involved with thinking: perception, language, learning, memory and problem solving. According to the theories of the French psychologist Piaget, the preadolescent is in what is termed 'the **concrete operational stage**' of thinking (Atherton 2013). In this stage children think logically as long as they have the object of their thoughts physically present to manipulate. It is difficult for them to understand theories or abstract concepts.

## Emotional development

The preadolescent is better able to describe their feelings than the younger child, especially about developmental changes they are experiencing. They become better at problem solving and achieving their goals. Some experience mood swings,

which develop from the same hormones that contribute to physical changes. They may feel happy one minute and irritable or sad the next. Their feelings may be overpowering. The preadolescent may also give in to impulses, as the parts of the brain that are involved in impulse control have not yet developed fully.

### Psychosocial development

In the preadolescent stage children become more social and their behavioural patterns become much less predictable. Included in this stage are experimentation with make-up by girls and the interest in music and performers that are popular with older adolescents. Typically they have same-sex friends and tend to spend more time with their friends than with their families. Preadolescents often develop friendships with adults other than their parents and use these relationships to gather information about adults. They are no longer totally egocentric and begin to see the importance of others within their social environments.

### Sexual development

During this time most children experience some of the changes of puberty. As their bodies begin to change they tend to develop a natural modesty. They are frequently curious about sex and, provided that there is an environment where sex can be spoken about comfortably, they are likely to ask many questions. Sometimes when children are in hospital and curious about their bodies they ask questions of nurses they trust. This may be an indication that information relating to sexuality or sexual matters is wanted. It is advisable for the nurse to find out what knowledge the child already has to avoid giving inappropriate answers (Carpenito-Moyet 2010). (See Case Study 13.1.)

#### CASE STUDY 13.1

Hope is a 13-year-old girl with insulin-dependent diabetes who has been rushed to her local hospital in an unresponsive state while on holiday with her grandparents.

When recovered she discloses that she had not taken her medication or dietary requirements for the past 2 days.

When questioned about the incident Hope states she hates being a freak and that she doesn't want to be a diabetic anymore.

Hope has voiced her anger at the changes that puberty has brought and wishes to remain a child to escape this diagnosis. Hope states that it is not fair for this to happen to her and she will not inject herself again.

Both the grandparents and the parents are very distressed and are blaming each other for this event.

What could you do to help Hope?

## ADOLESCENCE

**Adolescence** is the period of development from age 12 to 20 and is the stage that marks the transition from childhood to adulthood (Mitchell & Ziegler 2013). Adolescence is a stage of development characterised by sudden physical changes and social and emotional maturing. It begins with the gradual appearance of secondary sex characteristics and ends with the cessation of body growth.

The term 'adolescent' usually refers to psychological maturation of the person, whereas puberty refers to the point at which sexual maturity is achieved and reproduction becomes possible. Puberty mainly refers to the maturational, hormonal and growth process that occurs when the reproductive organs begin to function and the secondary sex characteristics develop.

Adolescence is often described in three distinct subphases: early adolescence (11–14 years), middle adolescence (15–17 years) and late adolescence (18–20 years).

## GROWTH AND DEVELOPMENT OF THE ADOLESCENT

### Physical development

The **physical development** and changes of early adolescence (puberty) are primarily the result of hormonal activity, with the sequence of pubertal growth changes the same in most individuals (Sigelman & Rider 2015). (See Tables 13.1 and 13.2.)

Physical changes occur rapidly in both males and females. Physical distinctions between boys and girls are determined on the basis of distinguishing characteristics: **primary sex**

**TABLE 13.1 | Usual sequence of maturational changes in adolescence**

| Boys | Girls |
|---|---|
| Skeletal growth spurt | Skeletal growth spurt |
| Enlargement of testes and scrotal sac | Beginning of breast development |
| Appearance of pubic hair | Appearance of pubic hair |
| Changes in larynx and voice | Menarche |
| Enlargement of penis and prostate gland | Ovulation and completion of breast growth |
| Nocturnal emissions | Appearance of axillary hair |
| Growth of downy facial hair | Widening of pelvis, deposition of body fat |
| Appearance of axillary hair | Abrupt decrease of linear growth |
| Increase in shoulder width | |
| Deepening of voice, appearance of coarse facial hair | |
| Abrupt decrease of linear growth | |

*(Hockenberry & Wilson 2015)*

## TABLE 13.2 | Growth and development during adolescence

| Early adolescence (11–14 years) | Middle adolescence (14–17 years) | Late adolescence (17–20 years) |
|---|---|---|
| **Growth** | | |
| Rapidly accelerating growth<br>Reaches peak velocity<br>Secondary sex characteristics appear | Growth decelerating in girls<br>Stature reaches 95% of adult height<br>Secondary sex characteristics well advanced | Physically mature<br>Structure and reproductive growth almost complete |
| **Cognition** | | |
| Explores newfound ability for limited abstract thought<br>Clumsy groping for new values and energies<br>Comparison of 'normality' with peers of same sex | Developing capacity for abstract thinking<br>Enjoys intellectual powers, often in idealistic terms<br>Concern with philosophical, political and social problems | Established abstract thought<br>Can perceive and act on long-range operations<br>Able to view problems comprehensively<br>Intellectual and functional identity established |
| **Identity** | | |
| Preoccupied with rapid body changes<br>Trying out of various roles<br>Measurement of attractiveness by acceptance or rejection by peers<br>Conformity to group norms | Modifies body image<br>Very self-centred; increased narcissism<br>Tendency towards inner experience and self-discovery<br>Has a rich fantasy life<br>Idealistic<br>Able to perceive future implications of current behaviours and decisions; variable application | Body image and gender-role definition nearly secured<br>Mature sexual identity<br>Phase of consolidation of identity<br>Stability of self-esteem<br>Comfortable with physical growth<br>Social roles defined and articulated |
| **Relationships with parents** | | |
| Defining independence–dependence boundaries<br>Strong desire to remain dependent on parents while trying to detach<br>No major conflicts over parental control | Major conflicts over independence and control<br>Low point in parent–child relationship<br>Greatest push for emancipation; disengagement<br>Final and irreversible emotional detachment from parents; mourning | Emotional and physical separation from parents completed<br>Independence from family with less conflict<br>Emancipation nearly secured |
| **Relationships with peers** | | |
| Seeks peer affiliations to counter instability generated by rapid change<br>Upsurge in close idealised friendships with members of the same sex<br>Struggle for mastery takes place within peer group | Strong need for identity to affirm self-image<br>Behavioural standards set by peer group<br>Acceptance by peers extremely important—fear of rejection<br>Exploration of ability to attract opposite sex or same sex romantic partners | Peer group recedes in importance in favour of individual friendships<br>Testing of romantic relationships against possibility of permanent alliance<br>Relationships characterised by giving and sharing |
| **Sexuality** | | |
| Self-exploration and evaluation<br>Limited dating, usually group<br>Limited intimacy | Multiple plural relationships<br>Internal identification of heterosexual, homosexual or bisexual attractions<br>Exploration of 'self-appeal'<br>Feeling of 'being in love'<br>Tentative establishment of relationships | Forms stable relationship and attachment to another<br>Growing capacity for mutuality and reciprocity<br>Dating as a romantic pair<br>May publicly identify as gay, lesbian or bisexual<br>Intimacy involves commitment rather than exploration and romanticism |

*Continued*

**TABLE 13.2 | Growth and development during adolescence—cont'd**

| Early adolescence (11–14 years) | Middle adolescence (14–17 years) | Late adolescence (17–20 years) |
|---|---|---|
| **Psychological health** | | |
| Wide mood swings<br>Intense daydreaming<br>Anger outwardly expressed with moodiness, temper outbursts and verbal insults and name calling | Tendency towards inner experiences; more introspective<br>Tendency to withdraw when upset or feelings are hurt<br>Vacillation of emotions in time and range<br>Feelings of inadequacy common; difficulty in asking for help | More constancy of emotion<br>Anger more apt to be concealed |

*(Hockenberry & Wilson 2015)*

**characteristics** are the internal and external organs that carry out reproductive functions (ovaries, breasts, penis, uterus); **secondary sex characteristics** play no direct part in reproduction but are the changes that occur in the body as a result of the hormonal change (development of facial and pubic hair, changes in voice, fat deposits). Secondary sex characteristics externally differentiate males from females.

The main physical changes are:

- Increased growth rate of the skeleton and muscles
- Alteration in the distribution of muscle and fat
- Gender-specific changes, such as changes in shoulder and hip width
- Development of the reproductive system and secondary sex characteristics.

Height and weight usually increase during the prepubertal growth spurt. The final 20% to 25% of height is achieved during puberty, with most of this growth occurring in a 24–36 month period. For girls this usually begins between 8 and 14 years of age. Weight increases by 7–25 kg and height increases by 5–20 cm. Growth in height usually stops 2–2.5 years after menarche in girls. For males this growth spurt occurs between 10 and 16 years of age. Height increases by 10–30 cm and weight increases by 7–30 kg. Growth in length of the limbs and neck precedes growth in other areas. Increases in hip and chest width take place in a few months, followed by an increase in shoulder width several months later (Crisp et al 2013).

Growth in height usually stops at age 18–20 in boys. The individual often appears awkward and clumsy and the sequence of changes is responsible for the long-legged gawky appearance that is often seen. These changes require the adolescent to adjust their perception of their self in space as well as accepting a new body image. Fat becomes redistributed into adult proportions as height and mass increase, and the adolescent gradually assumes an adult appearance. Adolescents who are concerned about physical changes that make them different from their peers should be reassured by the nurse about normal growth curves and that their own growth patterns are normal.

**Figure 13.1** Acne on the cheek of 16-year-old girl
*(Clayton & Tom 2010. © 2010)*

An increase in the secretion of sebum occurs from the skin and frequently results in acne. This development can have significant effects on how the adolescent views their physical image. (See Figure 13.1.)

## Hormonal changes of puberty

**Hormonal production** is controlled by the anterior pituitary gland, which is in turn stimulated by the hypothalamus. The stimulation of the anterior pituitary results in the release of the gonadotrophic hormones that stimulate the gonads. As a result of this stimulation, testicular cells produce testosterone and ovarian cells produce oestrogen. These hormones contribute to the development of secondary sex characteristics and play an essential role in reproduction. The changing concentration of these hormones is also linked to problems of adolescence, such as body odour and acne.

### CRITICAL THINKING EXERCISE 13.1

You are working as an Enrolled Nurse on a ward with a 10-year-old girl admitted with a fractured right arm.

As you are assisting her in the shower she discloses that she doesn't like how her body is changing and asks if you can help her stop it. What might you say to her based on your understanding of changes that occur during puberty?

## Sexual maturation in girls

The initial indication of puberty in most girls is the appearance of breast buds. Breasts begin to develop from about age 10 (development continues until about age 17). (See Figure 13.2.) About 2–6 months later, growth of pubic hair on the mons pubis begins. (See Figure 13.3.) The initial appearance of menstruation (**menarche**) occurs about 2 years after the first pubescent changes. The normal age range of menarche is 10.5–15 years, with ovulation usually beginning 6–14 months after menarche.

Concerns about pubertal delay in girls should be considered if breasts have not started to develop by age 13 or if menarche has not occurred within 4 years of the onset of breast development (Sigelman & Rider 2015). It is important to remember that racial origin and environmental issues can contribute to when puberty begins. Girls from some genetic backgrounds will experience earlier menarche than girls from others. Similarly, girls with nutritional problems such as anorexia or those having to keep a minimal body weight for some activities such as dancing, modelling and gymnastics may also experience delayed menarche. The body requires a set level of fat deposits before menarche can be initiated.

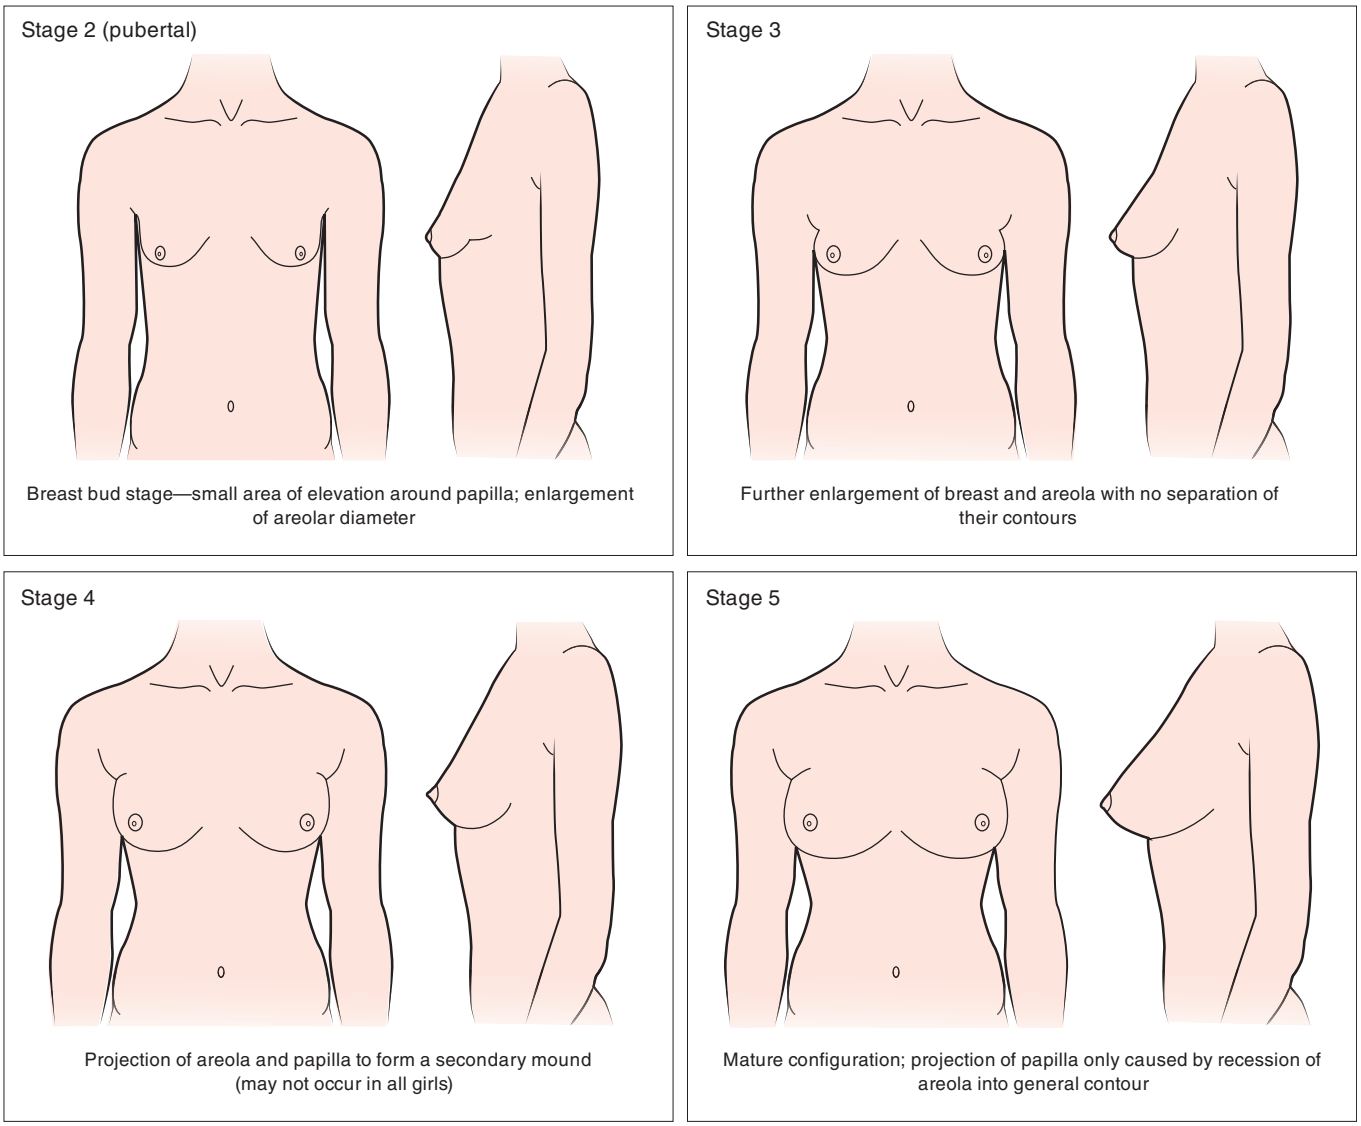

**Figure 13.2** Development of breasts in girls. Stage 1 (prepubertal elevation of papillae only) not shown
*(Adapted from Hockenberry 2005; Daniel et al 1979)*

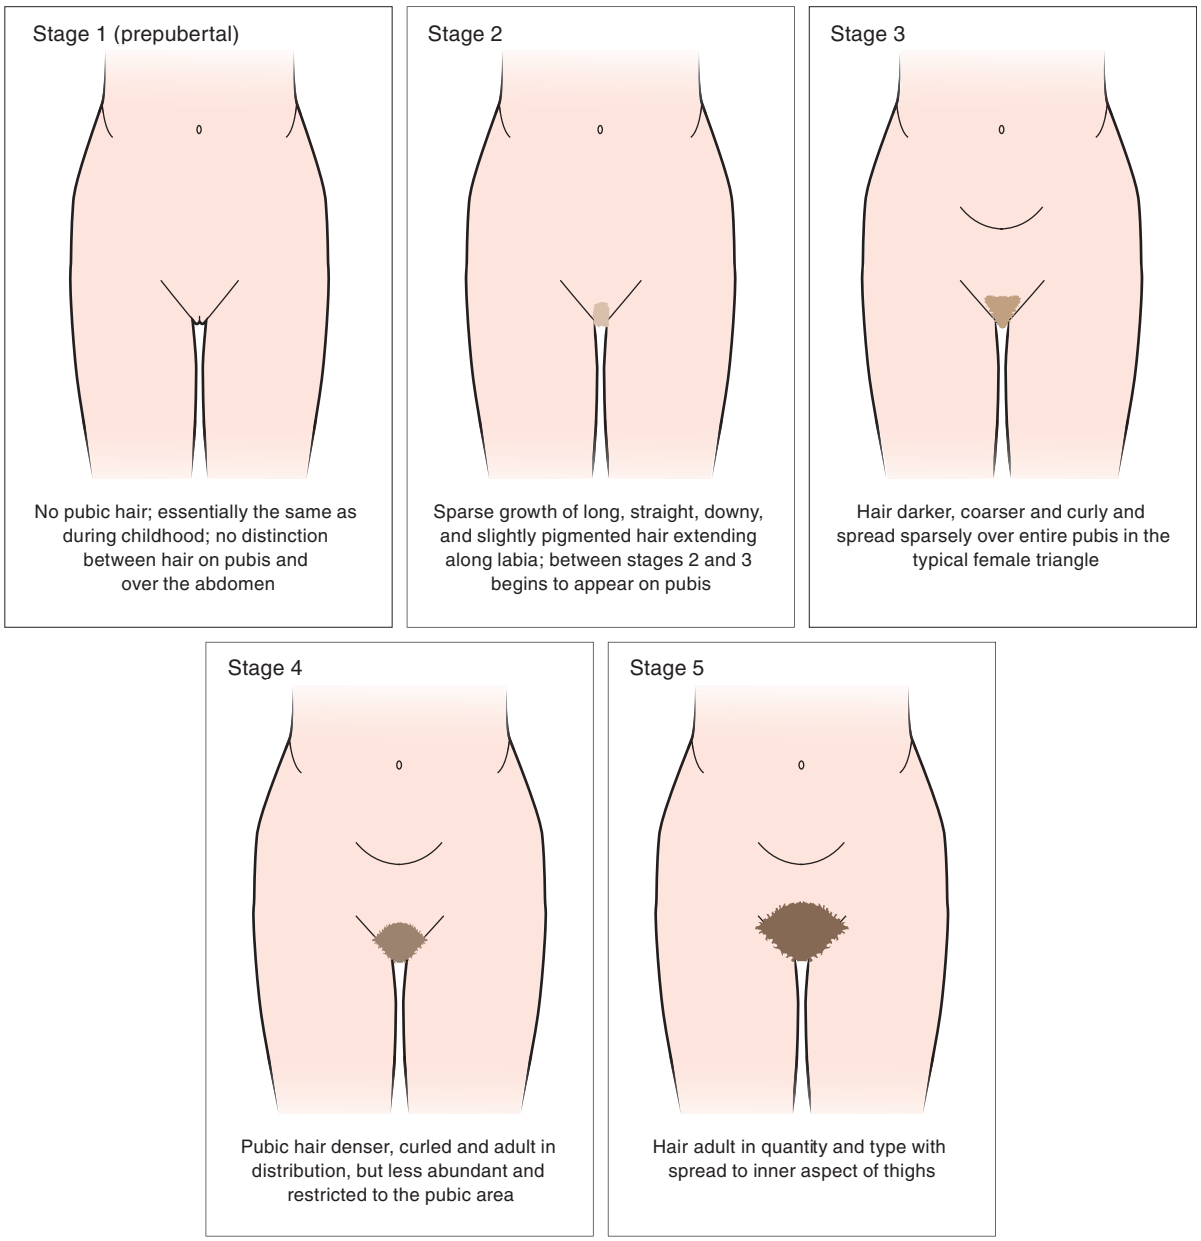

**Figure 13.3** Growth of pubic hair in girls
*(Adapted from Hockenberry 2005; Daniel et al 1979)*

The commencement of menstruation is often seen as a **rite of passage** in many cultures and is frequently heralded with celebrations. In mainstream Australasian and North American culture this time is not celebrated overtly. However, in other cultures it is celebrated by ritual bathing, specific ceremonies or the wearing of special clothing. In some Indigenous communities the practice of female circumcision is still undertaken to celebrate and mark this rite of passage.

## Sexual maturation in boys

Testicular enlargement, accompanied by thinning, reddening and increased looseness of the scrotum, is the first pubescent change in boys and usually occurs between ages 9.5 and 14. Penile enlargement begins, with continuing testicular enlargement and growth of pubic hair. (See Figure 13.4.) Facial hair may develop along with early voice changes. Temporary breast enlargement (gynaecomastia) and tenderness are common during mid-puberty. This breast enlargement usually disappears within 2 years. Height and weight growth occur towards the end of mid-puberty. Nocturnal emissions of seminal fluid are an indication of puberty in the male and occur spontaneously and periodically during sleep. In late puberty the testicles and penis enlarge, and the voice deepens. Axillary hair develops and facial hair extends to cover the

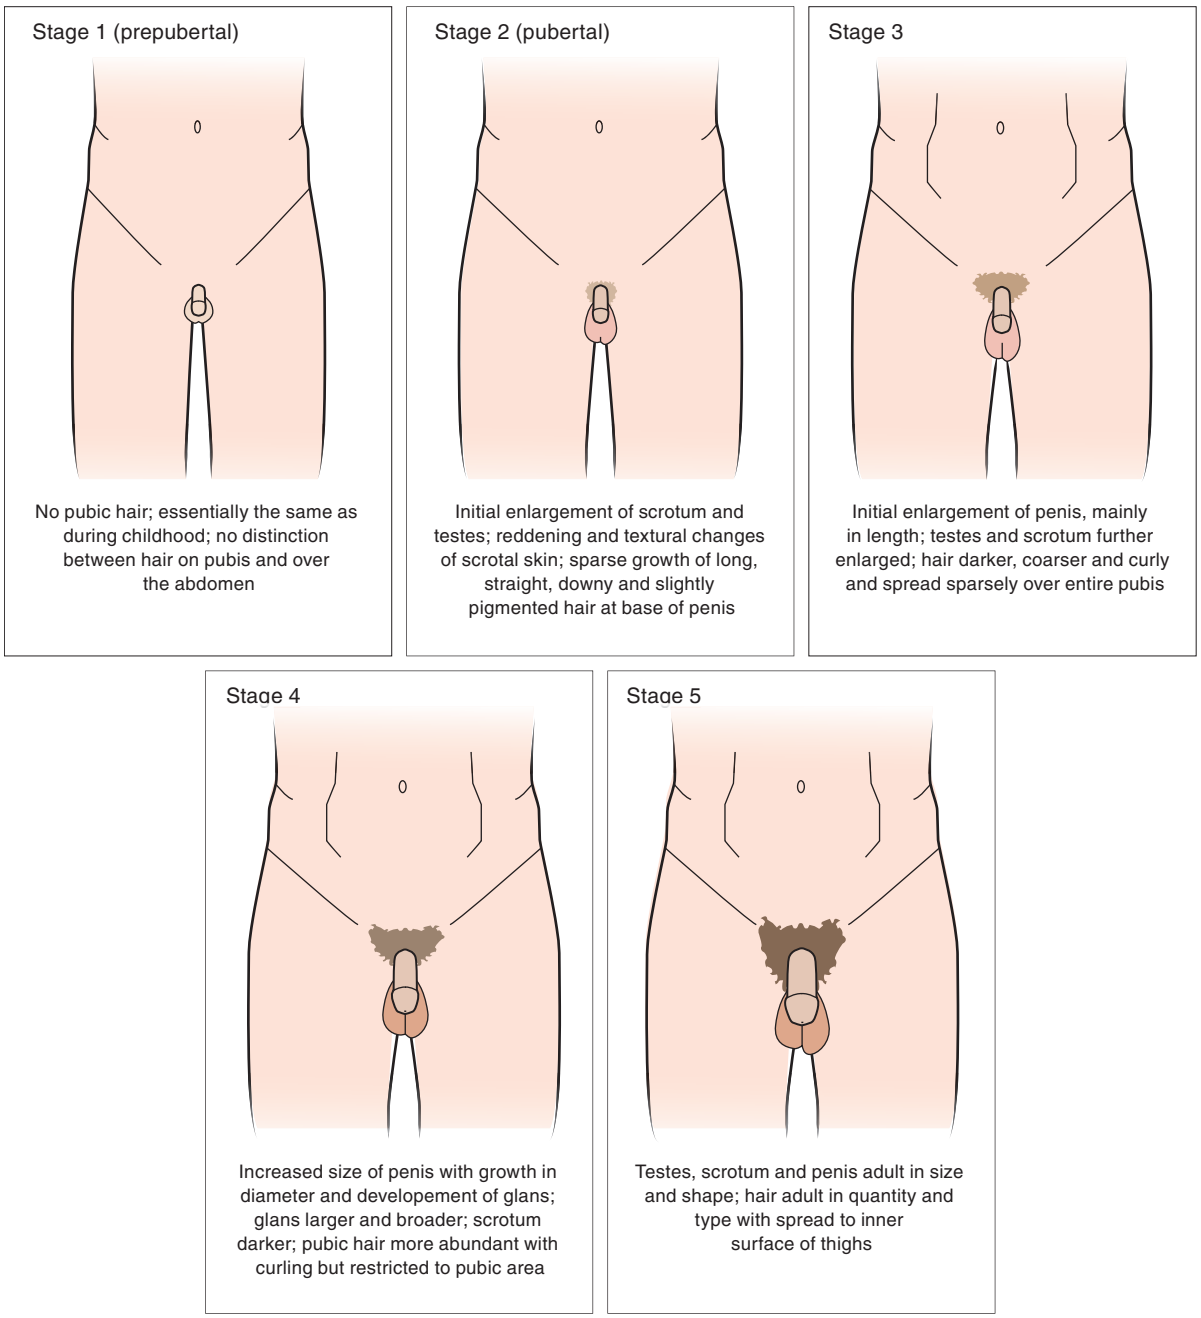

**Figure 13.4** Developmental stages of secondary sex characteristics and genital development in boys
*(Adapted from Hockenberry 2005; Daniel et al 1979)*

neck. During this time the opening of the foreskin in non-circumcised boys becomes larger and enables the foreskin to be retracted to below the head of the glans.

Boys may be considered to have pubertal delay if there is no enlargement of the testes or scrotal changes by age 13.5–14 or if genital growth is not complete 4 years after enlargement of the testicles.

In some cultures sexual maturation in boys is celebrated by routine circumcision or the undertaking of specific ceremonies. These ceremonies are aimed at initiating the boy into manhood. In mainstream Australasian and North American cultures no specific rite of passage is undertaken. Rites of passage for boys are more frequently celebrated at the attaining of a specific age rather than on the attaining of puberty. (See Clinical Interest Box 13.1.)

The physical changes that occur during adolescence are rapid and dramatic and play a significant role in **psychosocial development**. By understanding these changes you are better able to plan appropriate nursing care and to reassure and educate adolescents about their body care needs. The timing of these physical changes depends on factors such as heredity and nutrition and whether the adolescent is a boy or girl. The

## CLINICAL INTEREST BOX 13.1
## Rites of passage

Achieving sexual maturity is often celebrated as a rite of passage in some cultures. These ritual events mark the passage from child to adult. Some of these coming of age traditions include:

- Bar Mitzvah and Bat Mitzvah—Jewish (boys and girls)
- Ritual hair cutting—Cook Islands (boys)
- Quinceañera—parts of Latin America (girls)
- Upanayana—Hindu (boys)
- Debutante balls—western culture (girls)
- Land diving—Vanuatu (boys)
- Circumcision—some African tribes (boys and girls)

sequence of growth changes (Tables 13.1 and 13.2) is the same in most individuals (Sigelman & Rider 2015).

## Physiological needs

The strength and size of the heart and systolic blood pressure and blood volume increase during puberty. The pulse rate and basal heat production decrease. Boys have a higher blood volume than girls, which may be related to boys having a greater muscle mass. All formed elements of the body reach adult levels. Respiratory volume and vital capacity are increased, but respiratory rate and the basal metabolic rate decrease. As a result of increased strength and size of muscles and increased cardiac, respiratory and cardiac functioning, physiological responses to exercise change dramatically.

### Nutritional needs

During adolescence nutritional needs are significantly increased. As the person goes through this time of accelerated physical and emotional development, the body's metabolic rate increases, which intensifies the body's nutritional needs. There is no other time in life except during pregnancy and lactation that nutritional requirements are at this maximum. Both boys and girls are often constantly hungry and may have to eat frequently to meet their needs. Boys may even have to consume up to 16 000 kilojoules per day simply to avoid losing weight. Increased protein, fibre, calcium, iron and phosphorus especially are required to fuel the extra demands of the developing body. The adolescent who does not meet these needs is at high risk of compromising both psychomotor and cognitive development (Murray & Zentner 2014). Conditions such as malnutrition and anorexia are especially harmful at this stage. Chapter 30 of this text provides you with more information about meeting the nutritional needs of the individual.

## Cognitive development

Adolescents are capable of using deductive reasoning and abstract thinking and can consider the logic of a problem. According to Piaget, this stage, known as the period of **formal operations**, is the highest level of intellectual development. Being able to think logically about role behaviours enables adolescents to develop their own thoughts and means of expressing their identity. Intellectual development continues through formal education and the pursuit of personal interests (Atherton 2013). Without an appropriate educational environment, individuals may not reach this stage. The teenager can think abstractly and is no longer restricted to the real and actual, but can deal with the hypothetical. Adolescents are able to manipulate more than two different variables at one time. They think about what might be, whereas primary-school-age children only think about what is. This allows adolescents to have more skill and insight when playing board games or video games, for example.

By mid-adolescence, cognition develops an introspective quality. At this stage adolescents wonder about what others think of them and increasingly imagine the thoughts of others. They question society and its values and, although they have the ability to think as well as an adult, they do not have the experiences that an adult has on which to build. They can think about the consequences of their actions and can detect logical consistency or inconsistency in a set of statements or actions (Crisp et al 2013). For example, they will question a parent/carer who swears but tries to persuade the adolescent not to use bad language.

Language development is relatively complete by adolescence, although vocabulary continues to expand. The main focus becomes the development of communication skills that can be employed effectively in various situations. Adolescents need to share thoughts, facts and feelings to parents, teachers, peers and others. The skills needed are varied. The adolescent must decide whom they will communicate with, the message they wish to share and the way they will transmit the message. For example, the way a teenager tells peers about a new relationship is not the same as the way they tell their parents (Mitchell & Ziegler 2013).

## CRITICAL THINKING EXERCISE 13.2

While you are taking a nursing history of a teenager who is being admitted to the ward, his parent states that 'he eats like a horse and is lazy, sleeping in till 12 on the weekends'.

Understanding the physiological changes that occur in puberty, what could you ask to determine if the teenager's eating and sleeping habits were normal?

## Psychosocial development

Adolescence is a time when the young person is seeking and learning the skills to become independent. It is often a period of emotional turmoil and insecurity, caused by the conflict between the need and desire for independence and the need to retain dependence on others. It is a time when **identity** is consolidated and a time when choices about vocation and lifestyle must be made. Relationships with parents undergo change and the adolescent begins to assert individuality and

a desire for independence, often by resisting adult authority and advice. The adolescent usually displays mood swings and experiences confused emotions. In later adolescence, emotions are better controlled and more mature. However, an older adolescent is still subject to heightened emotion and their expressive behaviour reflects feelings of insecurity and indecision (Crisp et al 2013). As adolescents move into adulthood they normally become less reliant on positive reinforcement from others as their main source of self-esteem-enhancing experiences.

For those working with adolescents, knowledge of the theories of adolescent development is essential to obtain an understanding of the adolescent stage and the ability to recognise the tasks of adolescence. One such theory is Erikson's theory of human development (1963) which encompasses the whole of the lifespan in eight stages, each of which involves opposing crises which must be negotiated to be able to go on to the next stage. This theory recognises the period of adolescence as a time spent searching for identity. Erikson sees identity (or role) confusion as the main danger of this stage. The adolescent's search for identity involves the quest for individual, sex-role, moral and group identity (Mitchell & Ziegler 2013).

### Group identity

The adolescent's need to develop a personal sense of self is strong and an adolescent will often identify with a **peer group** that provides an identity. Adolescents seek to belong to a group to feel that they belong and have status. The pressure to belong to a group intensifies and, as the adolescent moves away from the family, the values of the peer group and their appraisal of them become increasingly important. Peer groups provide a sense of belonging, approval and the opportunity to learn acceptable behaviour. By developing close bonds with peers, adolescents are able to develop a frame of reference for their own identity (Crisp et al 2013).

### Individual identity

A sense of identity is the individual's concept of who they are and where they are going in life. To find out who they are, adolescents must formulate standards of conduct and know what they value as important and worth doing. This fulfils their need for a sense of their own worth and importance. Adolescents need to develop their own ethical systems based on personal values. When parental views and values differ greatly from those of peers and other important figures, the possibility for conflict is great. As a result, the adolescent may experience role diffusion as they try out one role after another and they may have difficulty in synthesising the different roles into a single identity. A positive identity eventually emerges after periods of confusion and adjustment, as the adolescent makes choices about the future.

### Moral development (identity)

Moral development is consolidated in adolescence as the teenager moves from accepting the decisions of adults to gaining their own set of **morals and values**. Kohlberg (1964) explains moral development in terms of stages and, according to his theory of moral development, adolescents begin to question existing moral values and learn to make choices. The development of moral judgment depends on communication, cognitive skills and peer interaction. Not all adolescents reach the same level of moral development. Boys may have more justice-oriented responses to moral problems, while girls have been found to have more caring responses. Table 13.3 summarises the developmental behaviours of adolescents.

## Social development

Social development involves an expansion of the network of **social relationships** and social activities. For many adolescents the peer group remains the most important social group, serving as a strong support providing a sense of belonging. It provides a link between independence and autonomy. Adolescents may move away from family domination and define their identity independently of parental authority. Adolescents may want to separate from parental restraints but at the same time may be fearful of the consequences associated with independence. This process of achieving independence often involves turmoil and ambiguity as both adolescent and parent learn new roles. Conflicts can arise from almost any situation or subject. Adolescents may find themselves argumentative, critical and remote with both parents as they attempt to achieve independence from parental controls. This rejection is usually not consistent and varies with mood changes. Some research shows that parents who provide a more cooperative style of parenting rather than an authoritative style improve the adolescent's ability to be independent and make appropriate decisions (Peterson 2014). Social relationships that develop outside the family help the adolescent identify their role in society.

## Sexual development

Adolescence is a time of acute awareness and sensitivity to emerging **sexuality** and body image, when appearance, personal and sexual attractiveness and peer acceptance are of crucial importance to self-esteem and a sense of belonging (Varcarolis et al 2014; Videbeck 2014).

A positive self-concept and sense of emotional security depends significantly on the support the adolescent receives while coping with the physical and emotional changes experienced during the difficult and sometimes tumultuous transition to adulthood. Support includes allowing for privacy, the freedom to develop personal interests and new relationships and understanding the frequent changes of mood and behaviour that commonly occur.

Particular sensitivity is needed when nursing the ill or hospitalised adolescent, because changes or threats to appearance or functioning can have a profound impact, resulting in anxiety, feelings of vulnerability and a negative impact on self-image. The nurse can help the adolescent, as any other individual, by demonstrating respect, which reinforces self-worth. The nurse can show this in many ways, including by being non-judgmental, reinforcing the belief that the individual is doing their best to cope, to adapt or to change and

## TABLE 13.3 | Developmental behaviours of adolescents

| |
|---|
| **Relationships with parents** |
| Adolescents' desires for increasing independence and autonomy and continuing need for some dependence and limit setting by parents place strain on their relationship. Effective communication and democratic parenting are best tools for meeting this challenge. |
| **Relationships with siblings** |
| Younger siblings rarely understand their adolescent sibling's need for privacy to think, dream and talk with peers. Adolescents often enjoy interacting with and guiding younger brothers and sisters when timing is convenient for them and they can remain in control. |
| **Relationships with peers** |
| Peer group is a factor of critical influence to adolescents, who have increasing need for recognition and acceptance. Companionship offered by peer groups provides a secure environment for individuals to try out new ideas and share similar feelings and attitudes. Adolescents often form cliques with peers from the same socioeconomic group with similar interests. Cliques, which are highly exclusive, help their members, who have strong emotional bonds, develop their identities. The crowd, which is more impersonal than the clique, offers opportunities for heterosexual interaction and social activities. The crowd also maintains rigid membership requirements; clique membership is usually a prerequisite for crowd membership. |
| **Self-concept** |
| Formal and informal peer groups are a primary force in shaping self-concept of group members. Popularity and recognition within the peer group enhance self-esteem and reinforce self-concept. Total immersion in peer group may make it appear that adolescents have no original thoughts and are incapable of making decisions. Adolescents who withdraw from peers into isolation struggle with developing identity. |
| **Fears** |
| Fears in this age group centre on peer group acceptance, body changes, loss of self-control and emerging sexual urges. Adolescents constantly examine their bodies for changes and signs of imperfection. Any defect, real or imagined, is the cause of endless worry. Adolescents' developing awareness of economic and political problems may result in fear of going to war, with its resulting death and destruction. |
| **Coping patterns** |
| Repertoire of coping behaviours has expanded with experiences adolescents have gained from life and from developing cognitive maturity. By age 15, most use full range of defence mechanisms, including rationalisation and intellectualisation. Adolescents' problem-solving abilities have matured, and they can reason through philosophical discussions and complex situations that require abstract thinking and proposition of hypotheses. Some adolescents use avoidance coping strategies in which the problem is denied or repressed and an attempt is made to reduce tension by engaging in chemical abuse or avoiding people. |
| **Morals** |
| According to Kohlberg (1964), as youths approach adolescence they reach conventional level, where internalisation of expectations of their family and society begins. Initially there is considerable conformity to rules to win praise or approval from others and to avoid social disapproval or rejection; later, they seek to avoid criticism from persons of authority in institutions. |
| **Diversional activity** |
| Many adolescents develop special interests in certain sports and concentrate on developing maximal skills therein. Recreational activities are often determined by what is popular with peers and what can provide independence from parents (e.g. computers, cars). |
| **Nutrition** |
| Total nutritional needs become greater during adolescence. Girls' energy needs decrease and their need for protein increases slightly. Iron needed by adolescent boys is almost twice that of adult men, and growth spurts increase calcium demand. |

*(Modified from Crisp et al 2013)*

by demonstrating acceptance of the adolescent individual's own perspective and feelings (Stein-Parbury 2014).

During adolescence there may be a great deal of experimentation in the expression of sexuality. Heterosexual and homosexual liaisons are common and sexual behaviour usually includes masturbation (Makadon 2011). Assurance about what is generally accepted as normal in physical and emotional development is helpful, as is open, honest and accurate information on topics such as body changes, sexual orientation, sexual practices, emotional responses within intimate relationships, sexually transmitted infections (STIs) and contraception. (Information about contraception and reproductive health is provided in Chapter 37.)

There are times when the nurse may feel it appropriate to explore sexuality issues with an adolescent; for example, when working in sexual health clinics, adolescent mental health units and in drug and alcohol clinics.

Experts generally agree that sexual orientation is probably the outcome of complex interactions between biological, cognitive and environmental factors and that it is established at an early age but commonly emerges in adolescence. It is accepted that genetic and hormonal factors play a part in shaping a person's sexuality to the extent that the person has no conscious choice in the matter, but also that there are probably many combining reasons for a person's sexual orientation, which may be different for different people (Makadon 2011; Rathus et al 2013). Often it is difficult for the adolescent to discuss with their family and friends their thoughts in relation to their own sexuality or sexual orientation. Always be aware that the adolescent who is developing their sexual identity may not be ready or willing to discuss this issue with health practitioners either. Huffaker and Calvert (2005) suggested that the use of social media and virtual reality may be one area in which adolescents may feel more comfortable expressing their sexual orientation and exploring their sexual identity beyond social prescriptions. This is mainly due to the anonymity that can be gained by communicating online.

Healthcare professionals should be aware that a recent Australian study identified that mental health problems, particularly depression and anxiety, are experienced in high levels in people who identify as transgender/transsexual (Hyde et al 2014).

Many healthcare providers including nurses feel uncomfortable and unskilled in discussing sexuality with adolescent individuals. It is essential, therefore, that you first examine your own attitudes about sexuality, particularly those that relate to adolescents, and reflect on how these attitudes affect your work with teenagers.

## Issues in adolescence

This is a good question rather than a statement. We need to acknowledge that the issues of adolescence change from year to year as our communities and societies change, ensuring that Australian young people will require healthcare professionals and systems to constantly adjust to respond. The following are some prevalent issues with research that has been captured. There are potentially many others that due to the age group and rapid changes may not be identified or researched but impact on caring for this group.

## Social media

The adolescent of today has always had exposure to electronic media. The computer, the internet and mobile phones have been part of their lives since early childhood. Their use as a tool for communication is an important aspect of the adolescent's life. There is significant discussion about the effects of the use of social media, with some researchers suggesting that heavy use can have negative effects, and others observing the positive influences that social media can have on adolescent development (Valkenburg & Peter 2007). Networking sites like Twitter and Facebook are often used by the adolescent to keep in touch with their friends and can be seen as positive tools in maintaining relationships. However, heavy usage of these sites may have risks for susceptible persons. Cyber bullying, stalking and predatory behaviour are just a few of the issues that can affect the adolescent user. Unfortunately the cyber bully can remain anonymous to the victim, making it difficult to track and/or halt the behaviour. It is suggested that the cyber bully can be motivated to use not only SMS phone text messages but to also use chat rooms and emails as tools of bullying. While research in this area is still fairly limited, it has been suggested that such bullying is widespread. The management of cyber bullying can be difficult due to its covert nature and the difficulty of tracing the offender (Cross et al 2009).

### CRITICAL THINKING EXERCISE 13.3

The mother of a teenager in your care complains that she is worried her daughter has a speech problem. On further discussion she indicates that her daughter rarely talks but is constantly texting on her phone. How would you investigate this issue?

## Body image

How the adolescent responds to the physical changes of puberty depends on their stage of development. In early adolescence some adolescents are preoccupied with the changes in their body and **body image**. Girls find body changes difficult to adjust to and are often concerned with weight increase and associated fat deposits. This may lead them to think they are obese and lead to fad dieting. Frequently they will compare their body with images in the media and their peers. With the increased use of 'photoshopping' of photographs of celebrities to remove evidence of imperfections and fat deposits, and the increasingly slimmer bodies of those portrayed in the media, the adolescent is often using an invalid measure to compare their bodies with. As the average model is 23% thinner than the average person and with the media praising and celebrating this fact, it can be very difficult for the adolescent to be satisfied with their body shape (Derenne & Beresin 2006). The nurse must be

## NURSING CARE PLAN 13.1

**Assessment:** Katie is a 15-year-old girl admitted to your ward with anorexia nervosa. Her weight has dropped to 45 kg, she exercises excessively, takes laxatives and will only eat small amounts of vegetables and fruit. She has recently broken up with her boyfriend and believes this is because she is 'fat'.
**Issue/s to be addressed:** Nutrition less than body requirements
Sensitivity to cold
**Goal/s:** Katie will consume nourishment adequate for weight gain and will reduce energy expenditure
Maintain normal temperature

| Care/Actions | Rationale |
|---|---|
| Start high-calorie diet and explain diet plan | To encourage gradual weight gain and commence healthy dietary education |
| Monitor physical activity | To participate in quiet and planned activities and reduce basic metabolic rate (BMR) |
| Ensure dressed appropriately and environment is warm | Reduce energy expended to maintain temperature |
| Promote a positive sense of self-regard | Encourage positive health behaviours |

**Evaluation**

Katie has been involved in her own care making decisions involving food choices and activity levels.
She has commenced education and understanding of a healthy diet plan and has stated she is less cold.

## PROGRESS NOTE EXAMPLE 13.1

| | |
|---|---|
| 24/07/2015<br>2030 hrs | Nursing: Katie's mother spoke with the dietitian and Katie at 1600 hrs today. Katie has refused all nutrition this afternoon and this evening is sitting quietly with her mother. Attempts from staff to engage with Katie have been declined. Temperature at 1800 was 36.4 with offers of warm blankets declined.<br>***J. Mackenzie* (Mackenzie) EN** |

extremely cautious when working with the adolescent with body image distortions. Always refer to the care plan or seek advice from the RN when you are unsure how to approach an adolescent in your care who has body image issues.

Overeating or under-eating during adolescence is of concern particularly for girls who, when they experience the normal increase in fat deposition and weight associated with the growth spurt, are more likely to resort to dieting.

**Anorexia nervosa** is a clinical syndrome with physical and psychosocial components. People with anorexia nervosa have an intense fear of gaining weight and refuse to maintain their weight at the normal minimal weight for their age and height.

**Bulimia nervosa** involves binge eating followed by behaviours such as induced vomiting, use of laxatives and excessive exercise to prevent weight gain. It is important to take a thorough dietary history when working with these adolescents. Good and appropriate nursing care can make a significant difference in the recovery process of individuals with anorexia nervosa (Ommen et al 2009). Review Nursing Care Plan 13.1 and Progress Note Example 13.1 for samples of documentation in this area.

Obesity is becoming more prevalent in adolescence. American studies refer to 'the childhood obesity crisis' with research identifying that almost one-third of children in the US over the age of 2 years are already overweight or obese (Wojcicki & Heyman 2010). Australian research also identifies similar findings, with up to 25% of all children between the ages of 5 and 17 years identified as being either overweight or obese. There are now more severely obese children than ever before. Poor nutrition and decreased physical activity have been identified as two major risk factors for individuals who are overweight and obese. In the adolescent the most immediate consequence of obesity is social discrimination associated with poor self-esteem and depression. They are also more likely to develop other comorbidities such as diabetes than children within normal weight ranges (Queensland Health 2008). This problem has serious ongoing effects across the health continuum.

## CULTURAL DIVERSITY

With Australia rapidly becoming more multicultural it is important for the nurse to be aware of some of the cultural issues surrounding the development of the adolescent. Not all cultures have the same attitudes or beliefs about adolescence and it is extremely important that the normalised western theories of adolescence are not measured against all adolescent behaviours. While these theories are a sound template, **cultural differences** must always be considered. If you are caring for an adolescent from a culturally diverse background, ensure that the advice and care that you give are culturally appropriate.

Adolescents from diverse cultures and migrant families may have stressors that affect the way they behave. Immigration has its own inherent problems such as dealing with a new life pattern and issues of loss. And at times individuals face discrimination as they adjust to life within a new country. Conflict often occurs between the adolescent and their family in relation to social and gender differences between Australia

and their country of origin (Murray & Zentner 2014). Chapter 10 of this text provides more insight into the cultural issues of Australia.

### Indigenous adolescents

Australian Indigenous adolescents have not only the concerns of all adolescents, but also their own specific set of problems. They may feel alienated from both their traditional cultures and mainstream society. Without a thorough understanding of both the contemporary and the historical issues no appropriate understanding of the health and developmental issues of these adolescents can be gained. Readers are advised to research texts and articles specifically written for these groups to obtain further information.

As a nurse you are also urged to discover more about social determinants and their effects on the Australian Indigenous adolescent before attempting to make assumptions on the health status of the adolescents you are caring for. When developing health promotion and other tools to address these issues, care must be taken to ensure that the literature is culturally sensitive and in the appropriate language. It is essential to adopt a culturally appropriate approach to provide effective individual education. Chapter 11 of this text provides you with a greater insight into Indigenous health in Australia.

## HEALTH RISKS

The major causes of morbidity and mortality in adolescents are not diseases but health-damaging behaviours related to depression, injury, violence and sexually transmitted infections (STIs).

### Risk taking

Adolescents are risk takers. While there are a number of theories that attempt to determine why the adolescent engages in **risk-taking behaviour**, it is often seen as a normal part of the adolescent process. Teenagers are good at weighing up the pros and cons of their decisions but take risks because they enjoy the thrill of a risky situation more than other age groups, especially when they have a 'lucky escape'. Teenagers take risks, not because they do not foresee the consequences, but because they choose to take those risks (Burnett et al 2010). Research with adolescents has revealed that risk-taking behaviour is more prevalent among males, early school leavers and youths with less parental supervision and peers who also actively engage in risk-taking behaviour, have negative attitudes to authority and high alcohol use. Unfortunately, a tendency for risk-taking behaviour together with feelings of indestructibility makes adolescents particularly prone to accidents, especially those involving motor vehicles and sports. Risk behaviours in adolescents are reported to be the primary source of death in adolescents (Fredrickson & Levin 2007). (See Case Study 13.2.)

### Suicide

**Suicide** is a prominent public health concern with 2522 deaths occurring in 2013, or 6.9 deaths by suicide per day in Australia. For young Australians, when considering all deaths, the statistics for suicides in 2013 for those aged 15–19 years old were males 21.9% and females 32.6%.

Data from hospitalisation for self-harm indicates that teens to middle age are the most common group (Australian Bureau of Statistics 2015). This is consistent with the data that between 22% and 38% of adolescents have had thoughts about suicide at some point in their lives and 6–7% have self-harmed in any 12-month period. Understanding self-harm can be challenging but there are some common triggers:

- Disputes with family or friends
- School or workplace issues (i.e. bullying)
- Relationship and or sexual/gender issues
- Physical or mental health (i.e. depression)
- Drug and or alcohol abuse.

(Headspace 2009)

Suicide usually results from a combination of factors. In adolescence it is often used to escape from a situation that adolescents do not feel they can manage and it can be associated with depression. The following warning signs may occur for at least a month before a suicide attempt:

- Withdrawal
- Loss of initiative
- Decreased performance at school
- Crying, sadness and loneliness
- Disturbance in sleep and appetite
- Verbalisation of suicidal thoughts
- Giving away possessions.

Prevention of suicide always involves education. This can be done in major health promotional campaigns or in smaller campaigns run by school and community nurses or even one-on-one sessions with susceptible individuals. As a nurse, you need to be able to identify precipitating events and adolescent suicide risk factors. If assessment suggests that the adolescent is at risk of suicide you need to facilitate referral to mental health professionals while helping the adolescent to focus on the positive aspects of life and develop coping skills such as

### CASE STUDY 13.2

James is a 12-year-old who is admitted for removal of skin lesions on his face and body.

While preparing him for operating theatre (OT) he discloses that he will be ugly after this surgery and that he has grown his hair to cover the scars.

After returning from OT he covers his face with the sheet and turns away from the door.

His 10-year-old brother comes to visit and calls James 'Frankie'—short for Frankenstein. James is furious and grabs his brother, threatening to hurt him. The parents are not concerned at this behaviour and state, 'Boys will be boys!'

Consider if this is a cultural/social phenomenon. How could you assist James and this family?

problem solving, anger management, conflict resolution and assertive communication.

## Substance abuse

**Substance abuse** involves the use of mood-altering substances in an attempt to create a sense of wellbeing or improve levels of performance. The adolescent's peer group can have a significant affect upon the individual's use of illicit or other substances. All adolescents are at risk of substance abuse and have a higher risk of becoming addicted than an adult if abuse continues. The adolescent will use illegal/recreational substances for a number of reasons; these include perceived risk, social approval and availability (Crisp et al 2013). Drug-related health problems vary according to the type of drug, how much is used and the duration of use.

Alcohol is one of the main substances that the adolescent is liable to abuse and although only a small percentage (2.6%) of all adolescents claim to have undertaken risky drinking, the percentage is increasing. Not only is alcohol use by the young person proven to be linked to dependence later in life, it also can have a detrimental effect on the maturing brain (AIHW 2009).

It is important to note that if the adolescent has a substance abuse problem it is not just an individual problem. Their network of family and friends will also be affected in some way.

## Sexual experimentation

Sexual experimentation during adolescence is often seen as behaviour to confirm sexual orientation. Current awareness of issues such as marriage equality has also raised awareness of sexuality and gender identity (e.g. lesbian, gay, bisexual, transgender or intersex (LGBTI) (Headspace 2009)) that many young people can experience.

Some consequences of sexual activity during adolescence are sexually transmitted infections (STIs) and unplanned pregnancy. At least 1 in 4 sexually active teenage American girls has a sexually transmitted disease (Centers for Disease Control and Prevention 2008). While these are American statistics it is reasonable to assume that the figures would be similar in Australasia.

A thorough sexual history should be included in any screening of adolescent health. The nurse can use the interview process to identify risk factors.

Education about the ways STIs are transmitted is recommended, as most adolescents believe they are not at risk. (See Clinical Interest Box 13.2.) The rate of adolescent pregnancy has fallen in Australia. This is a result of education and the availability of contraception and, in most states and territories, access to abortion.

### CLINICAL INTEREST BOX 13.2 Teaching individuals about transmission of sexually transmitted infections

**Objective**

- Individual will identify how sexually transmitted infections are transmitted

**Teaching strategies**

- Provide information on the transmission of sexually transmitted infections (STIs)
- Educate about the symptoms and names of STIs
- Encourage the use of condoms if sexually active
- Inform the adolescent about the consequences of sexual activity

**Evaluation**

- The adolescent is able to identify the common STIs, how they are transmitted and their consequences

# HEALTH PROMOTION

**Health promotion** for adolescents consists mainly of education and guidance to avoid health-damaging behaviours and risk-taking activities. Health professionals who work with adolescents should acknowledge their increasing independence and responsibility, and try to maintain privacy and confidentiality. Health promotion during adolescence is directed towards:

- Establishing healthy habits of daily living in relation to personal care, such as vision, hearing, posture, body piercing and sun tanning
- Education in stress-reducing techniques
- Providing information on nutritional requirements and eating habits and behaviours
- Accident prevention in relation to vehicle-related injuries and sport injuries
- Immunisation
- Exercise and activity
- Education about sexuality and guidance on avoiding STIs and unplanned pregnancies
- Substance abuse.

(See also Table 13.4.)

Nurses need to be aware of the prevalence of adolescent problems affecting healthy habits of daily living and must make assessments accordingly. Community and school-based health programs focus on illness prevention and health promotion. Nurses can play an important role in preventing injuries and deaths related to accidents and substance abuse. You will find more information about health promotion in Chapter 6.

# NURSING IMPLICATIONS

All nurses caring for the adolescent need to understand that this is a lengthy transition period. During this transition from childhood to adulthood, the adolescent undergoes a significant number of changes and these changes are both diverse and complex.

**TABLE 13.4 | Health promotion during the adolescent period**

| Adolescent health concern | Health promotion |
|---|---|
| Accidents | Provide information on proper use of sports equipment<br>Emphasise proper pedestrian behaviour<br>Promote proper behaviour while a passenger in a vehicle<br>Reinforce use of seatbelts<br>Encourage attendance at driver education course, reinforce dangers of drugs when driving<br>Teach basic rules of water safety<br>Promote use of safe sports and recreational facilities<br>Instruct in safe use and respect for firearms |
| Suicide | Be alert for signs of depression<br>Offer suicide prevention education<br>Teach methods to cope with a suicidal peer<br>Promote alternatives to suicide |
| Substance abuse | Educate about the risks of tobacco, alcohol and drug use<br>Screen for substance abuse |
| Sexually transmitted infections | Provide information about mode of transmission and symptoms<br>Encourage use of condoms, abstinence from sexual activity<br>Educate about the consequences of sexual activity |
| Nutrition | Provide information about nutritional requirements during adolescence<br>Educate about the risks of snacking and irregular mealtimes<br>Promote regular consumption of breakfast and a balanced diet |

*(Modified from Crisp et al 2013)*

These changes can cause considerable emotional stress for the adolescent which can manifest in many ways. The adolescent will often rebel against rules and regulations, criticise treatment and be uncooperative. This may be due to a combination of an instinctive negative reaction against authority and hidden anxieties and fears. Much of the behaviour observed in the adolescent is related to the struggle for independence and the external constraints that are placed on this maturation process. It is essential that the nurse has a strong understanding of the issues of adolescence and provides an empathetic and understanding approach to care. More information on care of the hospitalised adolescent can be found in Chapter 21.

### DECISION-MAKING FRAMEWORK EXERCISE 13.1

You are an EN student undertaking placement in a busy surgical ward. The RN asks you to speak to the parents of a child with a concussion prior to discharge about signs and symptoms to be alert for at home.

You have not as yet had the theoretical or practical education about this condition during your course.

Use the decision-making framework to assist you with this issue by asking three questions:

1. Am I educated to complete this task?
2. Am I authorised to complete this task?
3. Am I competent to complete this task?

## Summary

Adolescent behaviour patterns highlight the need for the nurse to understand the expected process through which an adolescent passes. Adolescents cannot be cared for wholly as adults, as they often lack the emotional maturity to cope with independence and still require the emotional support of parents or adult carers. Nurses with an understanding of adolescent phases will be able to develop an environment that provides privacy and protects independence, which will enable the adolescent to feel supported in unfamiliar surroundings.

## Review Questions

1. Under each of the headings list the changes that can occur in puberty.

| Physical | Cognitive | Emotional | Psychosocial | Sexual |
|---|---|---|---|---|
| | | | | |

2. What nursing action would you take if when taking a nursing history you observed the following behaviours in an individual?
   - Withdrawal
   - Loss of initiative
   - Decreased performance at school
   - Crying, sadness and loneliness
   - Disturbance in sleep and appetite
   - Verbalisation of suicidal thoughts.
3. What health promotions are directed at adolescents?
4. True or False quiz

   Select True (T) or False (F) for each of these statements:

| | |
|---|---|
| Changes in puberty are brought about by the effect of hormonal activity. | T/F |
| Puberty decreases metabolic rate. | T/F |
| Sensitivity to emerging sexuality and body image is normal in adolescence. | T/F |
| Growth in height usually stops at age 18–20 in boys. | T/F |
| Depression and suicide are uncommon in adolescence. | T/F |
| Education about STIs is not recommended for adolescence. | T/F |
| Alcohol is the most commonly abused substance in the age group. | T/F |
| Up to 25% of 5–17-year-olds are obese. | T/F |
| Racial origin and environmental issues can contribute to when puberty begins. | T/F |
| Rite of passage is when you first have sex. | T/F |

Answer guide for the Review Questions, Critical Thinking Exercises, Decision-Making Framework Exercises and Critical Thinking Questions in Case Studies are hosted on Evolve: http://evolve.elsevier.com/AU/Koutoukidis/Tabbner/

CHAPTER
14

# Nursing care across the lifespan: younger adulthood to middle adulthood

*Vivienne Therese Decleva*

## KEY TERMS

emerging adulthood
emotional development
menopause
sexual dysfunction
sexual identity
sexual orientation

## LEARNING OUTCOMES

At the completion of this chapter and with further reading, students should be able to:

- Define relevant key terms and concepts
- Identify the factors that influence growth and development
- Describe the major physical and psychological developmental changes that occur during early and middle adulthood
- Discuss the issues related to emerging adulthood
- Discuss the key concepts of sexual development and sexuality
- Discuss nursing interventions to promote sexual health through the lifespan
- Identify relevant nursing management and health promotion requirements
- Apply critical thinking and problem-solving approaches to management of individuals

## CHAPTER FOCUS

The chapter looks at growth and development of the body as it transitions through young adulthood (20 to 40 years) and middle adulthood (40 to 65 years). Adulthood is the period of time spanning from adolescence to death and encompasses three main phases: early adulthood, middle adulthood and older adulthood. This chapter focuses specifically on the first two phases. Early adulthood, which is the period of development from 19–20 years, is the period when a person transitions to maturity, independence and considerable social change. This is followed by middle adulthood occurring between the ages of 40 and 65 years. This phase is a time of stabilisation and physical change. Not only natural growth and development but also environment, social and life choices influence health issues that arise in adult life.

## LIVED EXPERIENCE

Doing a course in health services is something that I had been thinking about for a long time. But because of my age, I thought that no one would want me. Just think, starting my career in my forties. The years of staying home and looking after the kids are behind me. Now I am working towards doing something for myself. I feel good doing the course because I will be contributing to the community, and in turn I am sure that I will get a lot back.

**Trish Boyer, approximately 40 years old. Health services student**

The age spans of early adulthood, middle adulthood and older adulthood feature three very different generations commonly described as: Baby boomers (born between 1945 and 1964), generation X (born between 1965 and 1978) and generation Y (born between 1979 and 2000). Baby boomers are often described as workaholics with an optimistic, driven and team-orientated outlook to their work. In the majority of cases people of generation X have been raised in a two-parent family unit; they strive for a balance between work and personal time and have a slightly sceptical outlook on life. People of generation Y have shown themselves to be ambitious, technologically savvy and enjoy public recognition of their efforts (Berman et al 2015).

## EMERGING ADULTHOOD

**Emerging adulthood** is described as the period of time when an individual is an adolescent but not yet fully adult (Arnett 2014) where the transition to adult roles is delayed until the late teens to mid twenties. This phase is primarily observed in industrialised societies, as the majority of individuals in non-Western countries, because they have fewer economic resources, often live in rural regions and have limited education and typically enter marriage, parenthood and lifelong work earlier than their Western counterparts.

Arnett (2014) identified five main features of emerging adulthood:

1. It is the age of identity exploration, of trying out various possibilities, especially in love and work.
2. It is the age of instability.
3. It is the most self-focused age of life.
4. It is the age of feeling in-between, in transition, neither adolescent nor adult.
5. It is the age of possibilities, when hopes flourish, when people have an unparalleled opportunity to transform their lives.

## GROWTH AND DEVELOPMENT IN EARLY ADULTHOOD

### Physical development

With the exception of the major physical changes that accompany a pregnancy, physical changes are minimal during this stage of development. Females have generally reached their maximum height by the age of 18 years, with males reaching maximum height at approximately 20 years. Muscle continues to develop during the earlier phase in this age span, particularly in males, and both males and females will add body fat with an average weight gain of 6.5 kg (Crisp et al 2013). The main growth and developmental changes occurring in early adulthood are summarised in Table 14.1.

During early adulthood an individual is usually 'at their prime'. It is often a peak time for athletic performance and ability to perform strenuous activity, trouble-free reproduction and childbearing, as well as maximum health status with fewer illness-related deaths reported. The emerging adult may expose their body to extreme risk and serious injury (Nelson & Barry 2005) as they become more interested in extreme sports and activities such as base jumping, abseiling and bungee jumping.

### Cognitive development

Brain growth often continues to develop into the early twenties with changes in the frontal lobe and cerebral cortex. Maximum memory and cognitive speed occur at this stage. Decision-making processes need to be flexible, as the young adult is constantly adjusting to changes in their home, workplace and personal life. Formal and informal educational experiences and life experiences together with occupational opportunities increase the young adult's conceptual and problem-solving skills.

**TABLE 14.1 | Summary of developmental stages in early adulthood**

| | |
|---|---|
| Physical development | Maximum height achieved for both males and females<br>Physical strength peaks<br>Peak physical performance occurs between 25 and 30, then declines 1% per year<br>Male pattern baldness in males occurs<br>Short-sightedness develops during 20 and 30s<br>Peak bone densities reached by 30 years<br>Sexual responsiveness at its peak<br>Testosterone levels begin to drop 1% per year after 30 |
| Cognitive development | Brain development completed between 22 and 25<br>Able to comprehend and balance arguments<br>Creativity tends to peak |
| Psychosocial development | Seek meaningful relationships<br>Women more likely to consider relationships integral to sense of self<br>According to Erikson, enter stage of intimacy versus isolation<br>Exploration of self and separation from parents<br>Undertake high-risk behaviours |

*(Adapted from Levinson 1978; Erikson 1982)*

The young adult is more capable of assimilating a number of complex and sometimes contradictory situations and arguments during this stage. While this could also be said of adolescents, the difference is that the young adult does not tend to focus as critically on the absolute answer and is more comfortable with finding a balance they can be happy with. Most young adult thinking will also reflect strongly on the values and norms of their social group and their behaviours will be consistent with these (Pfaffenberger 2005). Research has also shown that the influence of peer groups can contribute to the either positive or negative choices the young adult makes (Young et al 2015).

## Psychosocial development

**Emotional development** concerns adjustment to independent adult life and centres on the formation of adult relationships. Erik Erikson (1963) described this stage of development as that between 'intimacy and solidarity' and 'isolation'. The young adult often becomes conflicted by the choices between occupation, education, relationships, living arrangements and independence. As they strive to establish life goals and work towards financial and emotional independence they may also need to choose between intimacy and isolation (Crisp et al 2013). Choices may need to be made between entering into close relationships (which may involve marriage and a family and the need to redefine goals and beliefs to accommodate those of a partner) or choosing a successful career or travel. Ultimately, the young adult wants to be able to do all of these things but often at least one 'dream' will need to be sacrificed.

The success of relationships is believed to be linked to the type of relationships the young adult has observed or had in their childhood. Events such as divorce, domestic violence and single-parent relationships impact on the young adult's ability to maintain their relationships (Crisp et al 2013).

## Moral development

As the young adult moves into adulthood, moral development enters what is described as the post-conventional stage whereby they recognise that everyone has a right to their own opinion and this may be based upon age, social group, culture and their life experiences to date. Decisions during this stage in moral development are based on the ability to determine what is right and wrong and may vary depending on the circumstances surrounding the situation.

## Spiritual development

The spirituality of the young adult will be dependent on their experience as a child. Where there has been some exposure to religion or some form of faith, the adult will rationalise the experience and make a decision to either accept or redefine these beliefs. This does not mean that an adult will not seek and develop spiritual beliefs in the absence of similar experiences. Heischman (2010) identifies this stage in development as a time where the young adult often 'struggles to find meaning'.

## Sexual development

In early adulthood many people begin to think of relationships having long-term implications. With the formation of sexual relationships the young adult becomes concerned about what is a 'normal' sexual response and this may involve sexual experimentation. The quality of sexual relations during this time is just as significant as that experienced during puberty and may lead to feelings of inadequacy and confusion. Unless positive outcomes can be achieved, the insecurities established at this point in sexual development can lead to a **sexual dysfunction** which may impact significantly on future relationships, and possibly **sexual orientation**.

### CLINICAL INTEREST BOX 14.1 Boomerang kids

According to the ABS, in 2006–2007, of males and females aged 18–24 years, 49% of males and 45% of females had never left the parental home. This is a slight fall from the 25–34 years age group in which 13% of males and 15% of females had never left home (ABS 2008). In 2009, McCrindle Research found that 8% of Australians between the ages of 30 and 34 years have retuned to live in their parental home—many have returned with their children (McCrindle Research 2009).

During early adulthood the search for **sexual identity** and meaning continues. In the past the trend has been for many young adults to enter into marriage and start a family. This has changed in recent years, with many young adults preferring to cohabit with a partner. Many young adults are also choosing to remain single, be celibate or enter into casual relationships. The availability and variety of contraception also provides more options for young adults to engage in sexual activities and to choose when they will start a family.

## Socioeconomic development

During this stage young adults generally give more attention to occupational and social pursuits and attempt to improve their socioeconomic status. Their network of relationships provides opportunities for fulfilling a variety of social roles and entering a range of different social systems. This stage in adulthood was once marked by lifestyle choices such as marriage, getting a mortgage and starting a family. In the past, most young adults would leave home to establish independence. Today it is not uncommon for children to still live at home into their thirties or to return home for a period after completing tertiary schooling, or even in the first years of marriage. This subset of young adults is referred to as 'Boomerang kids' (Berman et al 2015) (Clinical Interest Box 14.1).

Career is strongly influenced by the educational choices made during early adulthood. The early stages of adulthood may be spent gaining the qualifications that will secure employment stability in later years. Many women are delaying getting married and having a family, preferring to remain in the workforce. Women are also choosing to return to work after childbirth rather than remain at home and raise their children, which was the trend in past years. Young adults are technologically savvy and information empowered and expect diversity, variety and freedom in their jobs. They are likely to change jobs if clear job progression and career pathways are not available.

# HEALTH RISKS/PROBLEMS IN EARLY ADULTHOOD

In the period 2010 to 2012, life expectancy at the age of 25 years for Australian males was 79.7 years and for females was 84.2 years (Australian Bureau of Statistics (ABS) 2013a). (See Clinical Interest Box 14.2.) According to the ABS (2013b), statistics for 2010–12 showed the life expectancy at birth for Indigenous males was 69.1 years and for females 73.7 years, some 10 years less than for non-Indigenous people.

### CLINICAL INTEREST BOX 14.2 Life expectancy

Over the past 120 years in Australia, life expectancy at birth has improved. In 2011–13, life expectancy at birth was 33–34 years longer than it was in the late 1890s (AIHW 2016c). Based on current mortality rates, a boy born from 2011 to 2013 can expect to live 80.1 years, while a girl can expect to live 84.3 years (AIHW 2016c).

According to United Nations estimates for 2005–10, Australia's life expectancy at birth is ranked among the highest in the world.

Over the past 20 years, death rates have declined for both males and females for all age groups (ABS 2013b).

Australian males had the joint fourth-highest life expectancy in the world (along with Switzerland) over the period 2005–10. Only Iceland, Japan and Hong Kong have higher male life expectancy than Australia. Australian females have the joint third-highest female life expectancy.

(AIHW 2010)

While this stage is commonly the healthiest time of life, health problems do occur and are generally related to lifestyle choices. The National Health Survey of 2014–15 estimated that 63.8% of 25- to 34-year-olds rated their health as excellent or very good, with females rating their health as excellent more often than males (ABS 2015a). The ten most common long-term health conditions for 25- to 44-year-olds in Australia are shown in Table 14.2.

A number of factors put the young adult's health at risk. These include lifestyle factors, family history, poor personal hygiene and habits, psychosocial situation, environmental and occupational factors and culture. According to ABS (2015b), in 2013 the main cause of death for adults between ages of 25 and 44 years was suicide, with accidental poisoning being second and land transport accident third. Ischaemic heart disease was the leading cause of death for men and women between the ages of 45 and 64, with lung cancer being the second and breast cancer the third (ABS 2015b). (See Table 14.3.) In 2013 ischaemic heart disease remained the leading cause of death for both males and females.

## Injuries

Injuries associated with lifestyle and the workplace have a significant impact during this period of development. Causes of mortality in young adults include motor vehicle accidents, drowning and workplace injuries (Crisp et al 2013), as well as drug overdose, suicide and injuries due to physical attacks.

## Chronic illness

Hypertension is becoming a significant problem in young adults. While the reason for the increased diagnosis of hypertension in young adults is not well understood, it is thought to be due to lifestyle factors and obesity. Hereditary as well as lifestyle factors such as smoking, obesity and stress are all thought to be contributory factors (Berman et al 2015).

**TABLE 14.2 | Ten most common long-term health conditions, people aged 25–44 years, 2011–2012**

| Age group | Condition | Percentage |
|---|---|---|
| 25–34 | Short-sightedness | 25.1 |
| | Hayfever and allergic rhinitis | 21.9 |
| | Back pain and disc problems | 11.9 |
| | Mood (affective) problems | 10.2 |
| | Chronic sinusitis | 8.2 |
| | Asthma | 11.1 |
| | Long-sightedness | 8.5 |
| | Migraine | 8.4 |
| | Astigmatism | 8.3 |
| | Other mental and behavioural problems | 0.6 |
| 35–44 | Short-sightedness | 25.6 |
| | Hayfever and allergic rhinitis | 22.5 |
| | Back pain and disc problems | 17.6 |
| | Long-sightedness | 14.6 |
| | Chronic sinusitis | 11.2 |
| | Asthma | 9.8 |
| | Migraine | 9.4 |
| | Mood (affective) problems | 12.8 |
| | Arthritis (all types) | 7.6 |
| | Deafness | 7.2 |

*(Adapted from ABS 2012)*

## Cancers

The most common malignancies diagnosed in males during this stage in development include testicular and prostate cancer. The most common malignancies for females include breast and cervical cancer. Breast cancer is the most common cause of cancer deaths among women in Australia (Crisp et al 2013). In addition, individuals may be diagnosed with lung cancer, bowel cancer and skin cancers.

Early diagnosis of cancer is the main method of reducing the incidence of cancer and this involves education of the community and maintenance of national databases and health promotion strategies such as the National Cervical Screening Program. The Australian Cancer Council notes that the improvement in statistics related to the incidence of cancer can be attributed to better diagnosis methods, earlier detection and improved treatment.

## Mental illness

According to ABS, one in nine (11.7%) Australians aged 18 years and over had experienced very high or high level of psychological distress (ABS 2015a). Women between the ages of 18 and 24 years experienced the highest rate (13.0% and 20.0% respectively) of psychological distress than any other group (ABS 2015a). Women between the ages of 45 and 54 years experienced the second highest level (15.4%) (ABS 2015a). For males the incidence of psychological distress was higher between the ages of 18 and 24 years (11.1%) and it decreased between the ages of 45 and 54 years (9.2%) (ABS 2015a). Depression is one of the major concerns in individuals in their twenties to mid-thirties, with a majority of the individuals who are diagnosed with major depression diagnosed in this life stage. In a study completed by Welch et al (2009) a link was found between mild adolescent depression and depression in early and later adulthood. The study followed teenagers with mood, anxiety and eating disorders, disruptive behaviours and substance abuse problems into their twenties and thirties and found they had significant depressive illness with an increased risk of anxiety and eating disorders as adults.

**TABLE 14.3 | Leading causes of death by sex and age group, Australia, 2013**

| | Males | | | Females | | |
|---|---|---|---|---|---|---|
| Age group | Cause of death | Deaths | % of deaths | Cause of death | Deaths | % of deaths |
| 25–34 | Suicide | 300 | 22.3 | Suicide | 73 | 12.5 |
| | Land transport accidents | 206 | 15.3 | Land transport accidents | 45 | 7.7 |
| | Accidental poisoning | 128 | 9.5 | Accidental poisoning | 27 | 4.6 |
| 35–44 | Suicide | 319 | 15.0 | Breast cancer | 167 | 13.6 |
| | Coronary heart disease | 204 | 9.6 | Suicide | 85 | 6.9 |
| | Land transport accidents | 148 | 7.0 | Lung cancer | 47 | 3.8 |

*(AIHW 2016b)*

Depression during this stage is thought to be due to feelings of being trapped in a cycle of dysfunctional thoughts and feelings of powerlessness related to a conflict between intimacy and isolation. Onset may be due to a failure to succeed in relationships, career and lifestyle choices which leads to feelings of despair, inadequacy and eventually depression. The individual often has feelings of helplessness, loss of control, hopelessness and worthlessness, insomnia, fatigue, weight gain, suicidal thoughts, lack of concentration and persistent crying.

Young people from culturally and linguistically diverse (CALD) backgrounds are believed to have an increased risk of developing a depressive illness as their backgrounds may result in young adults experiencing additional challenges with feelings of being torn between cultures, communication difficulties and intergenerational conflict.

Being alert to the symptoms of depression and having an understanding of the disease can ensure the young adult is referred to appropriate health professional support and provided with the resources that will enable the condition to be managed effectively.

Case Study 14.1 explores a scenario involving mental illness.

## Suicide

Over the past decade there has been a decline in the reported incidence of suicide in Australia. Suicide in males continues to be significantly higher than in females and the incidence across different age groups tends to be relatively consistent. Suicide by hanging remains the most common method of suicide, with only a slight decline in its use over the past decade.

Through identification of behaviours and risk factors such as depression, sleep disturbances, weight loss, altered gastrointestinal function, social isolation, mood swings and increased use of alcohol and drugs, the nurse is able to refer their concerns on to the appropriate health professional or support such as a general practitioner (GP) (Berman et al 2015).

## Substance abuse

Substance abuse is another health concern for young adults. The prolonged use of alcohol, marijuana, amphetamines, cocaine and nicotine can lead to ongoing health issues in later life and, depending on the time of use, such as during pregnancy or when driving, it can significantly affect the lives of other individuals. The long-term use of cigarettes can lead to deteriorating health due to chronic respiratory diseases, cardiovascular disease and malignancies affecting the lungs.

The role of the nurse in relation to substance abuse will in some cases be about support and education to help individuals make life choices which do not include the use of these substances and to ensure they have the counselling and help needed to make a change (Berman et al 2015).

### CASE STUDY 14.1

A 21-year-old woman arrives with her mother and older sister to the outpatient clinic where you work. The young woman chooses to be interviewed alone. As you are gathering her history she states that she:

- Lives at home with her mum and dad and two sisters
- Loves her sisters and parents
- Has a few friends and does not socialise much as she spends most of her time studying
- Is doing second year law at university
- Would rather be a primary school teacher than a lawyer and feels that she is not clever enough to be lawyer
- Has just completed her mid-year exams. She has been repeating some modules from last year and feels she has not done well this semester
- Feels very nervous about the results and does not want to bring shame to her family again.

When you ask why she is doing law, she explains that her parents want her to be a lawyer and she feels that it is very important to respect their wishes.

She states that she is experiencing the following symptoms:

- Constant headaches
- Lacking energy and feeling tired
- Sleeping a lot
- Feeling very sad and bad about herself
- Having a very 'grey' down feeling since finishing her exams 2 weeks ago
- Feeling irritable and aggressive one minute and lethargic the next
- Crying often in the last weeks
- Not feeling hungry, but snacking on junk foods
- Drinking a lot of soft drinks, fruit juices and home-made smoothies for energy
- Experiencing constipation
- Had the flu 3 weeks ago and is still not feeling 100%.

1. Discuss how you would approach the care of this person.
2. What referral if any would you make?
3. Would you involve the mother and sister in the care?

## Eating disorders

Eating disorders such as obesity, anorexia and bulimia are an issue for many young adults. It is believed the eating disorders occurring during this stage in development are due to an attempt to manage emotional conflicts through the control of weight and food intake. As the young adult continues to seek their identity as an individual in the community, they can be adversely influenced by media, peer-group pressure and expectations which can result in feelings of inadequacy and a desire to conform to perceived expectations.

The nurse needs to observe and assess the nutritional needs of individuals affected by an eating disorder to ensure

### CLINICAL INTEREST BOX 14.3 Incidence of diabetes in early adulthood

According to the National Diabetes Register (NDR), the incidence rate of type 1 diabetes during 2007 was 15.1 cases per 100 000 population for people aged 15–24 with a further 10.9 cases per 100 000 and 4.6 cases per 100 000 accumulative, for people aged 25–39 years and 40 years and over respectively.

*(AIHW 2010)*

nutritional needs are met. This may involve monitoring dietary intake and education about appropriate dietary choices (Berman et al 2015).

## Diabetes

The recorded incidence of diabetes in Australia is increasing (AIHW 2016a). This increase is believed to be due to the increase in obesity (Colagiuri et al 2015). Of the three main types of diabetes, type 1 diabetes and gestational diabetes affect the young adult. New cases of gestational diabetes in women between the ages of 15 and 49 increased by 15% between 2000–2001 and 2008–2009 (AIHW 2010). (See Clinical Interest Box 14.3.)

Diabetes is the sixth leading cause of disease and injury in Australia, putting a significant burden on healthcare and funding. The role of the health professional in the management of this complex, chronic disease is therefore important and needs to be focused on promoting prevention strategies, self-management and treatment options. Key factors in self-management include making decisions about diet, exercise and treatment which promote a healthier lifestyle.

To be successful in the education of the person with diabetes the nurse must be familiar with the most current methods of screening and diagnosing the disease as well as the treatments and management strategies available (Berman et al 2015).

## Sexually transmitted infections

Common sexually transmitted infections (STIs) affecting the young adult include *Chlamydia*, genital herpes, syphilis, gonorrhoea and AIDS. Chlamydial infections are the most frequently reported sexually transmitted infection in Australia, with 60 000 cases notified in 2008 (Department of Health & Ageing 2010). Genital herpes caused by the herpes simplex virus type 2 (HSV2) affects 12% of Australian adults. The significance of these two conditions is that they often go untreated due to non-specific symptoms. In the case of *Chlamydia*, untreated infection is the main cause of infertility in later life.

There is an opportunity for the nurse when the younger adult is in a healthcare facility to provide educational advice on safe sex techniques and the reduction of the transmission of causative microorganisms. As the management of most STIs involves the use of multiple antibiotics it may also include education on the appropriate use of medications, as well as knowledge on the symptoms associated with each infection.

### CRITICAL THINKING EXERCISE 14.1

Marc Diaz is 24 years old. Four months ago he was involved in a car accident that left him paralysed from the waist down. He is now recovering in the rehabilitation unit. Discuss the tasks of an early adult and how the nurse may assist Marc to carry out some of these tasks.

# GROWTH AND DEVELOPMENT IN MIDDLE-AGED ADULTS

The stage identified as middle age begins at about 40 years and extends to the age of 65 years. This stage is usually considered to be the time of continuity and consolidation. Children are often older or fully grown and may move away from home, which can lead to what is called the empty-nest syndrome. This stage is often also associated with the term midlife crisis which describes a phenomenon that occurs when individuals reflect back on what has been achieved or not achieved. It may also be a time to contemplate stability in life or significant change (Orshan 2006).

## Physical development

Major physiological changes occur between the ages of 40 and 65 years. By the age of 65 years visible signs of ageing are obvious, regardless of race, ethnicity, culture or socioeconomic status. Hair becomes thinner and may be grey, wrinkles develop on the skin's surface, most people need to wear glasses, there may be a level of hearing loss and internally major organ function is reduced. Physical growth is replaced by physical degeneration, bringing about changes such as:

- Skin turgor decreases
- Muscle mass decreases
- Range of joint motion decreases
- Declining oestrogen and progesterone production occurs preceding menopause
- Level of androgen decreases, leading to male and female menopause
- Possible diminished acuity of the senses (Ebersole et al 2008).

Secondary ageing due to a lifetime of unhealthy behaviours—smoking, poor diet, substance abuse, lack of exercise and obesity—also become apparent. The leading causes of death during this stage in development are heart disease and cancer.

## Psychosocial development

Erik Erikson (1963) described middle adulthood as the stage characterised by 'generativity' versus self-absorption. During this stage in development a chosen lifestyle has been

established. For some this will have involved raising a family, and for others this may have involved achieving career goals and travel. For the person who has raised a family, the focus shifts from their children to retirement. This is regarded as the stage when a person is interested in establishing and guiding the next generation, and one in which people strive to ensure continuation of their work and lifestyle.

During middle adulthood most individuals, including those who have divorced and remarried, describe their relationships as meaningful and intimate. Married couples start to have more time for each other and recreational pursuits such as bowling, golf or volunteer work. Relationships with children and parents also tend to improve as the focus shifts from needing to provide for the family.

In middle adulthood there are likely to be many changes in a person's life, such as children moving away from home, change in career and assuming responsibility for the care of ageing parents. Loss of a spouse or partner by divorce or death is not uncommon. Retirement will be a reality for most adults towards the end of this stage, so it is necessary to plan for the future well before the event.

The nurse should be aware of possible life changes that may impact on the individual's health and should include assessment of coping mechanisms and social support (Crisp et al 2013).

Review Nursing Care Plan 14.1 and Progress Note Example 14.1 to see how a presentation in this area might be documented.

## Cognitive development

Changes in intellectual capacity are relatively uncommon, except in the presence of disease or trauma, and the middle-aged adult is able to continue learning. Some people may experience increased difficulty with concentration and retention of information.

While younger generations tend to perform better in IQ tests than older generations, this does not mean that older people have diminished capacity. Recent research suggests

### NURSING CARE PLAN 14.1

John, a 55-year-old male, is admitted to the ward. On arrival he was confused, felt hot and sweaty and complained of headache and leg cramps. Before arriving on the ward John had experienced palpitations and shortness of breath. An ECG done in ER showed no abnormalities.
**Assessment:** During the data gathering you find out that John had just completed a marathon in 35°C heat. Immediately after the run he started to vomit, had cramps to both lower legs and felt dizzy. He also temporarily experienced heaviness and palpitations in his chest. John has type 2 diabetes which is well controlled by diet and exercise. On arrival John's glucose level was 4.4 mmol/L, his vital signs were T 38.5°C, HR 94 (weak), R 32 (shallow), B/P 110/75.
**Issue/s to be addressed:** Dehydration
Confusion and dizziness
Cramps to lower legs
Palpitations and shortness of breath
**Goal/s:** John's hydration will be restored by taking small sips of fluid if tolerated and/or administration of isotonic saline (0.9%) as per IV therapy as prescribed by medical officer
John will rest in bed until headache and dizziness have subsided
John will be kept cool to reduce temperature
Symptoms of hypokalaemia will subside

| Care/Actions | Rationale |
|---|---|
| Measure for signs of dehydration | Poor skin turgor, dry mucous membranes, presence of thirst are all signs of dehydration |
| Assess skin turgor, mucous membrane, thirst | Vomiting may aggravate dehydration |
| Assess nausea or/and vomiting | Compensatory peripheral vasoconstriction will result in a weak pulse and low blood pressure. A reduced heart rate and an increase in blood pressure will indicate decrease in peripheral vasoconstriction. |
| Measure vital signs, first after 30 minutes and then if improving every 60 minutes | Normal depth of level of respiration will indicate hypokalaemia |
| Monitor discomfort, cramps in lower legs, palpitations, headaches | Decrease in severity of cramps, palpitations and headaches will indicate a return to normal potassium level |
| Monitor level of consciousness | Alterations in mental status can be the result of volume depletion and altered sodium levels |
| Monitor IV therapy | Volume replacement is required to restore vital circulation |
| Maintain a fluid balance chart | To measure fluid input and output |

**Evaluation**
Hydration will be restored.
John will become alert and aware, no dizziness will be present.
Cramps to lower legs, palpitations and headache would have completely subsided.

## PROGRESS NOTE EXAMPLE 14.1

| | |
|---|---|
| 25/06/2016<br>1530 hrs | Nursing: John, a 55-year-old man, has been admitted to the ward this afternoon. John ran a marathon earlier in the day. On admission John was confused, appeared very hot, was sweaty, confused and complained of cramp to both lower legs. Prior to arriving on the ward he had also experienced palpitations and shortness of breath. An ECG performed in emergency room showed no cardiac abnormalities. Assessment on admission: glucose level 4.4 mmol/L, T 38.5°C, HR 94 (weak), R 32 (shallow), B/P 110/75. IV therapy 1 L isotonic saline (0.9%) was commenced at 1500 hrs. John able to tolerate small sips of water.<br>***F. Moodie* (Moodie) EN** |

### CRITICAL THINKING EXERCISE 14.2

Emily Jackson is 45 years old. Emily has worked for 20 years as a primary school teacher. At present she is recovering after having a right mastectomy. You are the visiting nurse and see Emily twice a week to check her dressing, vital signs and general wellbeing. During one of your visits you notice that Emily is feeling down. In conversation she conveys that she would like to go back to work, but is not able to do so for a few months. At the moment she feels that she is being unproductive and useless.

Discuss how you as the nurse may be able to assist Emily to have a constructive attitude.

that cognitive performance may be enhanced or maintained in people who regularly stimulate their brain.

Table 14.4 summarises the common physical, cognitive and psychosocial changes of middle adulthood.

## Socioeconomic development

A major lifestyle issue in middle adulthood is the impact of what is referred to as the sandwich generation—when baby boomers and generation X have become sandwiched between the responsibility of caring for their dependent children as well as having to care for their older parents (Crisp et al 2013). This is compounded by the combination of trends such as delayed childbearing, delayed financial independence of children and an increased life expectancy for older adults.

The relationship of middle-aged adults with their children may also be at risk, with alterations to expected roles. Some adults will become grandparents and may still fulfil the traditional role of passing on traditions and stories, helping with the care of grandchildren and providing support to their adult children. Others may have limited involvement, perhaps as a result of distance, which provides the greatest obstacle to relationships between grandparents and grandchildren. Fractured families can leave grandparents without the opportunity to maintain a relationship with the grandchildren. When a marriage breaks down visitation rights of grandparents can be an issue if the relationship between the daughter-in-law or son-in-law is not maintained. Health problems may occur as a result of individuals stretching themselves across two carer roles for their children and for their elderly parents. As the role of the carer becomes more complex there may be implications for health professionals and the healthcare system (Ebersole et al 2008).

**TABLE 14.4 | Summary of developmental stages in middle adulthood**

| | |
|---|---|
| Physical development | Lens of the eye becomes dense and inflexible leading to increased loss of visual acuity<br>Hearing generally remains good<br>Less air intake during strenuous activity<br>Body less efficient at clearing byproducts of metabolism<br>Osteoporosis may develop in women due to decline in oestrogen levels<br>Sexual responsiveness may decline<br>Enter into menopause at approximately 50 years |
| Cognitive development | Reaction time generally remains the same<br>Problem solving and memory remain unchanged<br>Adaptation to stress improves |
| Psychosocial development | Relationships improve with children and each other<br>According to Erikson, enter stage of generativity versus self-absorption<br>Preparing to retire from workforce<br>Feel more comfortable in 'self'<br>Focus shifts from work to social and recreational activities |

*(Adapted from Levinson 1978; Erikson 1982)*

## Sexual development

Middle age is associated with many changes, and people in their middle years may experience doubt or anxiety about their sexual attractiveness or adequacy. The major developmental change influencing sexuality for women is the onset of **menopause**. Some women perceive this in a negative way and view it as a time when maternal potential, feminine

characteristics and sexual attractiveness disappear. Others perceive it as a time of freedom and new challenges (Orshan 2006). The term 'male menopause' is sometimes used to describe the changes that occur in men during this stage of the life cycle. It is not widely accepted as an issue in males.

In these middle years, self-image is less likely to suffer if the person has previously established a positive self-concept in relation to personal appearance and relationships with other people and is generally satisfied with their life achievements (Shives 2007; Varcarolis et al 2006; Videbeck 2007).

The middle-aged person who already has a low self-image is likely to have that esteem further reduced when the physical changes of middle age begin, such as greying hair, wrinkles and alterations to genitalia. Societal and cultural attitudes that value youth and beauty above age and experience may be a cause for anxiety in people approaching older age. If people perceive a loss of attractiveness during these years it may impact negatively on their ability to express their sexuality.

Frequency of sexual activity and the number of sexual partners often decline during middle adulthood. In some cases this may be due to lack of opportunity as individuals continue to juggle balancing a career, relationship pressures and financial burden, often leaving little time or energy for sex. Medications used may also affect sexuality as side effects reduce sexual function (Crisp et al 2013). Sexual activity may also decline due to the effects of disease processes, particularly chronic conditions where long-term effects, treatment and management can limit ability and/or inclination.

## HEALTH RISKS/PROBLEMS IN MIDDLE-AGED ADULTS

According to AIHW (2016c), the life expectancy at 64 years is 84.2 years for males and 87.1 years for females. While the majority of middle-aged adults remain healthy throughout this stage, health issues that were present in early adulthood continue to have an effect and may become more significant. The Australian Health Survey of 2011–12 indicated that most Australians between the ages of 24 and 64 reported their health to be very good or excellent (ABS 2015a). Table 14.5 lists the ten most common health conditions for people aged 45–64 years. Lifestyle, the ageing process, family history and emotional and situational stressors are usually the cause of developing health problems (Berman et al 2015).

The leading causes of death for people over the ages of 45 are ischaemic heart disease followed by cerebrovascular disease, cancers and suicide (AIHW 2016b). Table 14.6 lists the leading cause of death for people aged 45–64 years.

**TABLE 14.5 | Ten most common long-term health conditions, people aged 45–64 years, 2011–2012**

| Age group | Condition | Percentage |
|---|---|---|
| 45–54 | Long-sightedness | 53.0 |
| | Short-sightedness | 30.1 |
| | Back pain and disc problems | 18.6 |
| | Arthritis (all types) | 18.7 |
| | Hayfever and allergic rhinitis | 19.1 |
| | Chronic sinusitis | 11.5 |
| | Deafness | 10.7 |
| | High blood pressure | 11.6 |
| | Mood (affective) problems | 14.0 |
| | Asthma | 9.7 |
| 55–64 | Long-sightedness | 62.3 |
| | Short-sightedness | 35.9 |
| | Arthritis (all types) | 35.5 |
| | High blood pressure | 22.8 |
| | Back pain and disc problems | 19.9 |
| | Deafness | 17.7 |
| | High cholesterol | 22.8 |
| | Hayfever and allergic rhinitis | 14.1 |
| | Chronic sinusitis | 12.3 |
| | Other diseases of circulatory system | 34.5 |

*(Adapted from ABS 2012)*

**TABLE 14.6 | Leading causes of death by sex and age group, 2011–13**

| | MALES | | | FEMALES | | |
|---|---|---|---|---|---|---|
| Age group | Cause of death | Deaths | % of deaths | Cause of death | Deaths | % of deaths |
| 45–54 | Coronary heart disease | 644 | 15.1 | Breast cancer | 376 | 14.3 |
| | Lung cancer | 271 | 6.4 | Lung cancer | 222 | 8.5 |
| | Suicide | 270 | 6.3 | Coronary heart disease | 123 | 4.7 |
| | | | | Colorectal cancer | 123 | 4.7 |
| 55–64 | Coronary heart disease | 1296 | 16.2 | Breast cancer | 581 | 12.0 |
| | Lung cancer | 858 | 10.7 | Lung cancer | 538 | 11.1 |
| | Suicide | 388 | 4.9 | Coronary heart disease | 308 | 6.4 |

*(AIHW 2016b)*

## Chronic conditions

The chronic conditions that may be present in this age group are diabetes, asthma and hypertension. The most common form of diabetes at this stage is type 2, accounting for 85–90% of all cases. Depending on the time of onset, diagnosis and level of control, complications may be minimal or advanced in the person with diabetes.

The prevalence of cardiovascular disease increases markedly with age. Between 2011 and 2012, 10.2% of males and 7.5% of females aged 50–64 years suffered from a cardiovascular disease (ABS 2013c). It was reported that approximately 6.8% of Australians aged 55–64 years had long-term coronary heart disease. Hypertension, stroke, atherosclerosis and myocardial infarction may develop as the result of hyperlipidaemia, obesity, sedentary lifestyle, familial history and diabetes mellitus. Table 14.7 summarises lifestyle issues causing disease in middle adulthood.

**TABLE 14.7 | Lifestyle issues causing disease in middle adulthood**

| Disease | Lifestyle issues |
|---|---|
| Cardiovascular (CHD, stroke) | Dietary intake—high fat, carbohydrates and salt intake<br>Sedentary lifestyle<br>Obesity<br>Stress<br>Long-term alcohol intake |
| Skeletal (osteoporosis) | Dietary intake—inadequate calcium, phosphorus, magnesium, vitamin D<br>Immobility<br>Decreased oestrogen levels in females<br>Lack of exercise |
| Respiratory (emphysema, asthma) | Chronic asthma<br>Long-term nicotine use<br>Air pollution<br>Occupational exposure to chemicals |
| Psychological (depression, dementia) | Long-term diagnosis of disease<br>Loss of spouse, family member<br>Loss of occupation<br>Social isolation |
| Cancer | Familial history<br>Occupational exposure<br>Long-term cigarette and alcohol use<br>Radiation<br>Environmental carcinogens |
| Sexual dysfunction | Loss of partner<br>Long-term abstinence<br>Effects of medications used to treat health issues |

*(Adapted from AIHW 2010)*

The onset of chronic illness and disability and death occurs approximately 20 years earlier in Indigenous Australians than in non-Indigenous Australians. These rates are most significant in Aboriginal and Torres Strait Islander adults living in rural and remote areas.

The burden of chronic disease states and their associated complications has a significant impact on the economy and is the focus of the work of many healthcare providers. The role of the nurse is to provide ongoing education and support by identifying deficits in knowledge and ensuring resources are provided to promote health and ongoing stabilisation of conditions.

### CRITICAL THINKING EXERCISE 14.3

Eric Jones, a 56-year-old train driver, has been admitted to the ward with chest pain. He states he has been experiencing pains for a week and decided he would see his GP only on the advice of his wife. Mr Jones is overweight and admits not exercising as much as he did when he was younger.

1. What questions would you ask Mr Jones to gather a complete history?
2. What health issues may be attributed to Mr Jones's chest pains?
3. How would you phrase questions related to Mr Jones's sexuality?
4. What health promotion education might Mr Jones require?

## Cancer

The National Health Policy Area identifies the common cancers affecting individuals during this stage of the lifespan as colorectal cancer, lung cancer, melanoma of the skin, non-melanoma skin cancer (NMSC), breast and cancer of the cervix in females, prostate cancer in males and non-Hodgkin lymphoma (AIHW 2010). Lifestyle and hereditary factors are thought to be the main cause of their development. The current risk of dying from cancer before the age of 75 years is estimated to be one in eight for males and one in twelve for females.

## Depression

In this mid-life stage many people may be at a crossroad in their life and become depressed because of a perception that goals and dreams identified throughout early adulthood have not been achieved and because of feelings of failure. Depression diagnosed in early adulthood will need continued management and treatment. Lifestyle and psychosocial changes such as loss of job, end of a long-term relationship, onset of menopause, ageing or death of a spouse may trigger the onset of depression during this stage in the lifespan.

# CULTURAL DIVERSITY

Australia's population consists of a diverse range of migrant cultures with a rich combination of values, beliefs, traditions

and languages. According to ABS (2011), in 2010 5.3% of Australia's population was born in the United Kingdom, with 2.4% born in New Zealand, 1.7% born in China, 1.5% born in India and 1.0% born in Italy.

Indigenous Australians make up an increasing percentage of the population with the 2006 census showing an increase of 11% in the number of Indigenous Australians. This increase is believed to be due not only to a higher birth rate but also to better recording of numbers.

For many Indigenous Australians the accumulative effects of poor health during infancy, unstable family and community influences, poor socioeconomic conditions and engagement in antisocial behaviours have led to what is described as 'prejudicial entry into adulthood' (Eckermann et al 2010).

For health professionals the rich tapestry of cultures that makes up Australia's population means they must have a degree of cultural competence that will allow them to develop awareness and positive attitudes in conjunction with the knowledge and skills to live and work effectively in a culturally diverse environment (Thackrah & Scott 2011). (See Clinical Interest Box 14.4.)

**CRITICAL THINKING EXERCISE** 14.4

Refer to Clinical Interest Box 14.4.

What does the ceremony initiating Indigenous males into adulthood involve? Discuss the cultural conflict in this clinical scenario.

## HEALTH PROMOTION

Young adults generally have a minimum of major health problems and are interested in meeting their health needs. However, because of the many changes that occur and the stresses in their lifestyle, they may be at risk of illness. Young adults may also be genetically susceptible to certain chronic diseases such as diabetes. Physiological concerns for the middle-aged adult include stress, level of wellness and the formation of positive health habits. The nurse may wish to discuss some or all of the health promotion topics outlined in Table 14.8.

### CLINICAL INTEREST BOX 14.4
### A young man's cultural dilemma

Mark is a 24-year-old male. His father is a white Australian cattle station owner in remote Australia and his mother is a full-blood Aboriginal woman from a local Aboriginal community. Mark completed most of his secondary schooling at a boarding school in Darwin and wishes to return to Darwin to complete tertiary studies but is feeling conflicted by the need to connect with his Aboriginal heritage and to work on the cattle station with his father.

Mark recalls visits to the community where his mother grew up and being intrigued by the stories and ceremonies. On his last visit Mark overheard one of the elders talking about the fact that it was time for him to prove his courage and transition into 'manhood'. However, Mark is unsure whether taking part in a ceremony would mean he would have to live in the community and give up his dream of studying.

## IMPLEMENTING THE NURSING PROCESS

Assessment and care planning which focuses on the physical, cognitive, psychosocial and cultural elements of care is important if holistic care needs are to be addressed. As a nurse it can sometimes be uncomfortable asking questions about a person's sexuality. It is good to remember that the person may also feel uncomfortable talking about these issues.

### History taking

When nurses take a nursing history, it helps if they ask questions in a matter-of-fact manner and that they are clear about the purpose of those questions. For example, a non-threatening approach to specific issues such as sexuality might be, 'Sometimes people who have this illness experience some changes; have you noticed any changes happening to you?' It is important in such situations for the nurse to establish a relationship and an environment where the person feels safe in talking about their concerns. At the same time the nurse needs to be aware that the person may not reveal the most concerning or personal issues during the initial interview. These may be revealed later, when the person feels that they can trust the nurse (Stein-Parbury 2009).

For trust to develop the nurse must be non-judgmental, put personal values and beliefs aside and be open to the world of the person as construed through their words, feelings and values.

### Care planning

Whenever possible, care planning is a collaborative activity that follows identification of nursing issues. The nurse and person together develop a care plan that responds to individual needs. If appropriate, the person's partner/carer may be included in the planning. This is particularly relevant when the identified individual is in an established relationship, or has alterations to bodily functions or appearance; for example, the individual who has an ostomy (ileostomy or colostomy) as a result of colorectal cancer may respond negatively to the stoma and have concerns about maintaining a physical relationship with their partner.

One aim of care is to facilitate open communication between the nurse and other health professionals as well as the person concerned. It is this open and honest communication which will promote discussion of concerns. The nurse with excellent interpersonal skills such as listening, asking open-ended questions, using silence and summarising the discussion will help individuals to share feelings, concerns and information more openly, which will ensure all care needs are met.

**TABLE 14.8 | Health promotion in adulthood**

| | Early adulthood | Middle adulthood |
|---|---|---|
| Safety | Workplace measures<br>Sun-safe measures<br>Motor vehicle safety | Workplace measures<br>Motor vehicle, especially driving at night<br>Home safety measures (e.g. handrails, non-slip mats, lighting) |
| Routine health screening | Breast screening<br>Vision and hearing<br>Testicular examination<br>Immunisation<br>Dental<br>Smoking<br>Physical examination | Breast screening<br>Vision and hearing, particularly glaucoma, macular degeneration<br>Testicular examination<br>Screening for cardiovascular disease<br>Screening for cancers (e.g. breast, colorectal, prostate)<br>Smoking |
| Nutrition and exercise | Need for regular exercise—assess joint mobility, muscle tone, musculoskeletal<br>Nutrition assessment of risk factors for heart disease (e.g. obesity, cholesterol and fat intake) | Dietary assessment, including fat, calcium, vitamin D<br>Exercise assessment, need for regular exercise<br>Screen for nutritional and exercise risk factors for cardiovascular disease |
| Psychosocial | Assess for job or family stress<br>Encourage setting of short- and long-term goals | Screen for anxiety associated with physiological and psychosocial changes<br>Depression<br>Retirement planning |

*(Berman et al 2015; Crisp et al 2013)*

## Summary

Growth and development are processes that begin at conception and continue throughout each stage of the life cycle. Growth may be defined as the physical changes that occur in a steady and orderly manner, while development relates to the adjustment to the changes in psychological and social functioning. The stages of adult growth and development are: early adulthood, middle adulthood and older adulthood. Characteristic changes occur at each stage, but the pace and behaviours of growth and development vary with each individual. In each stage in the lifespan, disease and injury can impact on continued health and wellbeing.

### DECISION-MAKING FRAMEWORK EXERCISE 14.1

Mary is a student nurse on clinical placement. She has not yet completed her medications and IV therapy education. This afternoon Mary will be caring for John (refer to Nursing Care Plan 14.1).

Using the decision-making framework:

1. Should Mary accept delegation to care for John?
2. What observations would Mary make during the evening shift?
3. What observations would she refer to the RN?
4. If John continues to tolerate fluids, how could hydration be maintained?
5. What changes in John's condition would indicate that he is improving?
6. If John asks the reason for the palpitations and shortness of breath what explanation could Mary give?
7. What other factors may be considered regarding the care of John?
8. What questions regarding John's condition could Mary ask her preceptor?

## Evaluation

Current models of care relate to maintaining a 'person-centred' approach to care which requires the health professional to be responsive to the needs of the individual. This involves consideration of cultural and linguistic backgrounds, lifespan issues, socioeconomic and educational issues, as well as the healthcare setting in which care is provided. To determine if nursing goals have been achieved the nurse has to be observant on how the person responds to the interventions implemented as part of nursing care. If nursing goals are not achieved, the nurse is to modify the care to ensure the person's specific needs are met.

## Review Questions

1. What is meant by the term 'early adulthood'?
2. Under the heading 'early adulthood', identify the main health issues.
3. Discuss the meaning of the phrase 'intimacy and isolation' when applied to early adulthood.
4. Under the heading 'middle adulthood', briefly outline the growth and developmental phases.
5. Under the heading 'middle adulthood', identify the main health issues.

Answer guide for the Review Questions, Critical Thinking Exercises, Decision-Making Framework Exercises and Critical Thinking Questions in Case Studies are hosted on Evolve: http://evolve.elsevier.com/AU/Koutoukidis/Tabbner/

# Nursing care across the lifespan: older adult

*Margaret Webb*

CHAPTER 15

## LEARNING OUTCOMES

At the completion of this chapter and with further reading, students should be able to:

- Define the key terms
- Discuss the key concepts of older adulthood
- Explain the terms ageism, ageing process, age-related adjustments, dementia
- Understand how cultural factors impact on the ageing process
- Outline psychological, physical and social impacts of ageing on older adults
- Understand the impact of disability on lifestyle choices in older adults
- Identify and describe nursing interventions to promote person-centred care in residential care environments
- State primary functions of nurses in promoting quality nursing care in older individuals

## KEY TERMS

ability
abuse

## CHAPTER FOCUS

Ageing is an inevitable part of life. Ageing begins as soon as life begins and ceases only when life is terminated; it is dynamic and extends across the lifespan. Ageing is a process that accumulates changes in organisms or objects over time and involves multidimensional changes on physical, psychological, cultural and social levels. Physiologically, it cannot be avoided or delayed. The physical appearance of an older adult offers only a superficial view of ageing. Although ageing is an inevitability for all, it does not always happen without some health compromises. Nurses, because of their unique work practices and relationships with individuals, are in an ideal situation to recognise age-related health compromise, promote healthy ageing and recognise and reinforce wellness as a desired state of ageing.

## LIVED EXPERIENCE

Some people are born old ... others feel young for their whole lives. It is a state of mind ... you're only as old as you feel and I feel like I did when I was 20!

**Charles, 78 years young**

I do not ask to be young again; all I want is to go on getting older.

**Konrad Adenauer (First Chancellor of West Germany after World War II. Lived to be 91)**

I do not remember becoming old. All of a sudden I was there.

**Elaine M. Brody MSW.DSc(Hons). DOB 1922**

You can't help getting older, but you can help yourself from becoming old and infirm. In mind as well as body.

**Joan Collins**

For the purposes of this chapter we will view ageing from the point in people's lives at which they reach maturity during adulthood and at which **ageing** and development in later adulthood becomes apparent. This occurs around the seventh decade, when people are thinking of, or are actually, retiring from the paid workforce. This is, of course, a generalisation as some people retire in their fifties whereas others are still fully employed or work part time well into their late sixties or seventies. Chronological age for many is not indicative of when and how they enter the later stage of life (see Clinical Interest Box 15.1).

Theories of development in the twentieth century focused predominantly on children, adolescents and young adulthood. However, in recent decades, far more attention has become focused on the older population, using geriatrics (the study of disease process in older adults) and gerontology (the study of healthy ageing) (Crisp et al 2013).

### CLINICAL INTEREST BOX 15.1 Categories of older adulthood

Older adulthood is divided into the following categories:

| | |
|---|---|
| Young Old (Stage I) | 65–74 years |
| Old Old (Stage II) | 75–84 years |
| Oldest Old (Stage III) | 85 years+ |
| Centenarians (Stage IV) | older adults of 100 years or more |

*(Adapted from Crisp & Taylor 2009; AIHW 2007)*

## THE STATE OF AGEING IN AUSTRALIA

The population of Australia is ageing and is considered to be mainly middle aged in terms of the average age of the population (37.3 years) (Thornton 2010). Between 1994 and 2014 the proportion of people aged 65 years and over increased from 11.8% to 14.7%. The Australian Bureau of Statistics (ABS) (2014) has predicted that over the next decade, this increase will be significantly steeper. In 2014, the number of people who were over the age of 85 years was 456 500 and 4080 were over the age of 100 years (ABS 2014).

## AGEISM

**Ageism** refers to a set of ideas and beliefs that are associated with discriminatory attitudes directed towards older adults (Quadagno 2011). It implies negative beliefs and stereotypes about older people collectively. These negative beliefs, attitudes, norms and values are used to justify stereotypical views of the older person (Johnson & Chang 2014).

Ageism is seen in all the categories of ageing, from limitations in employment to life-changing decisions that must be made in regard to living or lifestyle choices. At no time should age be a factor in not empowering an older person to be involved in decision making. With the increasing number

of older people in developed countries, ageism may face some opposition (Crisp et al 2013). Discrimination based on age is deemed to be unlawful by Commonwealth law as outlined in the *Age Discrimination Act 2004* (Australian Government 2014c).

## GROWTH AND DEVELOPMENT

The process of ageing can be viewed from the perspective of physical, social, psychological, functional and emotional ageing. There is no one theory of ageing, but a number of theories have been developed to explain the ageing process. Biological theories look at the physiological and anatomical changes that occur, while psychological theories seek to explain the thought processes and behaviours of older people (Crisp et al 2013).

### Physical changes

The body's organs and systems undergo changes as they age. These changes alter susceptibility to various diseases and will frequently alter the efficiency of the functioning of the organ/organ systems. Changes are often difficult to identify in just one individual system because of the inter-relatedness of the body organs, systems and functions. Understanding these processes is important for nurses because many of the adverse effects of ageing are first noticed in body function.

#### Neurological and sensory systems

The nervous system has some distinctive **age-related changes**, but the origin of these changes may be attributed to other body system variations, such as reduced cerebral circulation attributed to cardiovascular weakening (Eliopoulos 2010). (See Clinical Interest Box 15.2.) What is evident is that there is a decline in brain weight and circulation; however, there is little evidence that thinking and behaviour are affected early in later adulthood. Neurons, nerve fibres and cerebral circulation will decrease. Efficiency of function of the hypothalamus is altered. Lens, pupil size and corneal and retinal changes will affect visual acuity, and atrophy and sclerosis in the tympanic membrane and inner ear structures will impact on hearing.

#### Integumentary system

Ageing affects all aspects of the integumentary system. Flattening of the dermal–epidermal junction, reduced thickness and vascularity of the dermis and loss of collagen and uniformity of fibres make skin less elastic. Skin becomes thinner, and the change in lean-muscle-to-fat ratio means that skin is more at risk from bony prominences underneath it (Berman et al 2015). Skin becomes drier. There is a reduction of melanocytes, the skin's immune system diminishes, sweat glands atrophy and heat receptors that have typically been spread through the dermis are less receptive, resulting in delayed recognition of heat on the skin. Growth rate of hair declines (head, pubis, axillary), but facial, eyebrow, ear and nasal hair becomes more prominent in men (refer to Clinical Interest Box 15.3).

### CLINICAL INTEREST BOX 15.2 Neurological and sensory systems

Vision: inability to focus or accommodate properly (presbyopia), changes in clarity and density to the lens (cataracts), narrowing of visual field (decreased peripheral vision), decreased ability to adjust to dim light, alteration to blood supply to retina (can cause macular degeneration)

Hearing: presbycusis develops (progressive hearing loss, especially high-frequency sounds, progressing to low and mid-range sounds), accumulation of cerumen (ear wax)

Taste/smell: approximately 50% of all older adults experience some loss of their ability to smell. Taste acuity is dependent on smell; decreased saliva production and effects of medication may cause loss of sensitivity to taste and perception of food may be altered

Slower reflexes: delayed responses to multiple stimuli, alterations to balance and coordination may increase the risk of falls

Body temperature: regulation is less effective because of decreased function of hypothalamus, with delayed thirst, atrophy of sweat glands, decreased muscle:fat ratio

Quality of sleep (especially in stages III and IV): sleep is altered due to circadian and homeostatic factors

Tactile sensation: sensation and response to pressure and pain are reduced

*(Crisp et al 2013; Eliopoulos 2010)*

### CLINICAL INTEREST BOX 15.3 Integumentary system

- As the skin becomes less elastic, it becomes drier and more fragile, increasing the risk of tearing
- As subcutaneous tissue is lost, skin sags, wrinkles and becomes more irritated and more at risk of infection
- Nails become brittle and growth decreases
- Thinning and baldness of hair in men, greying of hair due to loss of pigment
- Skin pigmentation due to clumping of melanocytes
- Increased risk of benign and malignant skin lesions

*(Crisp et al 2013; Eliopoulos 2010)*

#### Cardiovascular system

The heart muscles decrease in efficiency and contractile strength with age. Left ventricular hypertrophy is slight, but the aorta thickens and dilates, as do the atrioventricular valves, causing sclerosis and fibrosis. Cardiac output is reduced. Valve closure may become incomplete, causing systolic and diastolic murmurs (Eliopoulos 2010). Arteries

## CLINICAL INTEREST BOX 15.4
## Cardiovascular system

- Blood pressure increases to compensate for increased peripheral resistance and decreased cardiac output (particularly systolic)
- Hypertension predisposes older adults to heart failure and coronary disease, renal disease, peripheral vascular disease, stroke
- Less efficient utilisation of oxygen results in less available energy, especially with strenuous exercise
- Increased heart rate occurs when body is affected by anxiety, excitement, illness or strenuous activity, and there is a longer period until baseline heart rate returns
- Peripheral pulses are weaker and lower extremities may be cooler

*(Crisp et al 2013)*

## CRITICAL THINKING EXERCISE 15.1

George Minnow is a 92-year-old man admitted to an acute care facility following a fall in the residential aged care facility in which he lives. It is expected that he has a fractured right neck of femur (RNOF). You have concerns for his skin integrity while he is on bed rest. What factors could compromise his skin integrity?

stiffen with age, decreasing their properties of stretch and contractility, creating more resistance for the heart to pump blood through them. Veins, conversely, become less rigid and are less resistant; therefore bulging and pooling is experienced. (See Clinical Interest Box 15.4.)

### Respiratory system

As a result of age-related structural changes in the chest (see also 'Musculoskeletal system' below), there is a reduction in respiratory activity and efficiency. Costal cartilage calcification makes the rib cage and trachea more rigid. The anterior and posterior diameter of the chest cavity increases and, with osteoporotic changes, the appearance of kyphosis (sometimes referred to as a dowager's hump) may be seen, particularly in women (Crisp et al 2013). The inspiratory/expiratory muscles are weaker, causing a decrease in lung expansion and vital capacity and there is a decrease in strength of cough and laryngeal reflexes. In the lungs, cilia are reduced in number and effectiveness, and less elastic alveoli result in increased difficulty in clearing secretions. The maximum capacity of the lungs may decrease as much as 40% between the ages of 20 and 70 years. Spontaneous alveoli destruction increases in rate. Available energy is decreased (in conjunction with the cardiovascular system) and exercise/activity tolerance is decreased. There is increased risk of infection because of decreased efficiency in clearing secretions and expelling accumulated material. There is also increased prevalence of shortness of breath because of decreased vital capacity (Crisp et al 2013).

## CLINICAL INTEREST BOX 15.5
## Gastrointestinal system

- Teeth enamel becomes harder and more brittle
- Increasing numbers of cavities; the bones supporting teeth decrease in height and density
- Flattening of chewing cusps occurs
- Taste sensation becomes less acute
- Increased risk of aspiration due to altered gag response
- Risk of pernicious anaemia due to diminished or absent intrinsic factor
- Increased risk of constipation

*(Crisp et al 2013, Eliopoulos 2010)*

### Gastrointestinal system

Changes in the gastrointestinal system are identifiable at most levels and they may create a greater need for adaptation than do some of the other body systems. Changes can be noticed in the mouth. These changes affect the condition and effectiveness of teeth and may cause the tongue to atrophy, a decrease in production of saliva by up to two-thirds and changes to cheek musculature, which can impact on the mechanical breakdown of food and swallowing (Eliopoulos 2010). Gag reflex and oesophageal motility are diminished; in addition there are changes to gastric mucus and production of bicarbonate, which will impact on the pH of the stomach. Abdominal muscles become weaker and there is a decreased tone and peristalsis in the smooth muscle of the intestines. This results in an increased tendency for constipation (Scott et al 2015). The effects of medication may change because of changes in the metabolism capacity of the liver. (Refer to Clinical Interest Box 15.5.)

### Musculoskeletal system

Muscle tissue atrophies and muscle strength and tone diminish in proportion to the decline in muscle mass. Joints become less elastic and flexible with the loss and calcification of cartilage. There is an alteration to the equilibrium between bone deposition and resorption, and in postmenopausal women decreased oestrogen increases bone resorption and decreases calcium deposition (Scott et al 2015). The loss of bone density particularly affects long bones and vertebrae. The curve of the lower back changes, resulting in a change to the centre of gravity (Crisp et al 2013). There is a loss of lean muscle tissue which is converted to fat. Basal metabolic rate (BMR) can decrease during mid to later adulthood; therefore an increase in body weight may be experienced early in later

## CLINICAL INTEREST BOX 15.6 Musculoskeletal system

- Fibrous tissue gradually replaces muscle
- Arm and leg muscles become particularly flabby and weak when the person becomes less active
- Muscle cramps are more prevalent
- Increased brittleness of bones, bone loss and decreased bone density, increasing the risk of fractures and damage from only minor trauma
- Increased risk and prevalence of osteoporosis
- Reduction in height and appearance of kyphosis
- Limitation to joint mobility, appearance of spurs and points on bone ends, limiting motion and activity and increasing joint pain
- Gait changes due to structural and postural changes

*(Crisp et al 2013, Eliopoulos 2010)*

adulthood. Body fat moves deeper in the body with ageing. Body heat is less effectively retained. Muscle activity associated with shivering to increase body temperature is less efficient (Eliopoulos 2010). Thermoregulation is compromised (by the age-related changes in the cardiovascular, integumentary, neurological and musculoskeletal systems). Age-related changes may affect mobility and safety. The older adult is at increased risk of falls and fractures. (Refer to Clinical Interest Box 15.6.)

### Urinary system

Overall, kidney function decreases with age, although even with a 50% reduction the body can function adequately in the absence of disease. Atherosclerosis of the renal vessels may promote atrophy of the kidney, and renal tissue growth decreases (Miller 2008). The total capacity of the bladder declines and tissues may atrophy, causing both functional and structural incontinence. Detrusor overactivity, which is more commonly known as an 'overactive bladder', is also frequently seen as a cause of incontinence occurring in older people. (DeMaagd & Davenport 2012). It is suggested that 68% of older people living in nursing homes require some urinary continence care. Urinary incontinence can be directly attributed to reduced social wellbeing, reduced quality of life and an increase in urinary tract infections and falls (Yu et al 2015).

### Reproductive system

Changes in structure and function are the result of hormone alterations. In men, there is no definite cessation of fertility, but refractory periods may increase. Prostatic hypertrophy can cause incontinence, frequency and nocturia in men. Female breasts become smaller, sag and become more pendulous due to loss of breast tissue mass, elasticity and tone. Incidences of breast cancer will increase for individuals aged over 80 (AIHW 2014a). Lubricating vaginal secretions are reduced (Berman et al 2015). Reduced libido is not usually related to hormonal changes, but decreased sexual activity may be the result of illness, death of sexual partner or decreased socialisation (Elias & Ryan 2011).

### Immune system

T-cell activity declines and T-cells take longer to replenish in older people. More immature T-cells are present in the thymus and are less able to proliferate in response to pathogens; therefore, the immune response to invading antigens is slowed. The immune system is not ineffective; it is just slower and less responsive to invasion. Responses to vaccines (influenza, tetanus) are decreased (Berman et al 2015). Inflammatory response declines; therefore, in the presence of inflammation or infection clinical manifestations such as fever and pain may not be present. Immune system changes may precipitate insulin resistance (Berman et al 2015).

### Endocrine system

The thyroid gland fibroses and becomes more nodular. Despite changes, thyroid activity remains adequate in the absence of disease. Parathyroid activity remains within normal limits. The adrenal cortex, regulated by the pituitary gland, decreases production of adrenocorticotrophic hormone, and there is also a noted decrease in the production of oestrogen, testosterone and androgens (Crisp et al 2013). There is delayed and insufficient release of insulin by the beta cells, and a decreased sensitivity in tissues to insulin. The ability to metabolise glucose due to the reduction in insulin production is reduced, causing increased blood glucose concentrations (Scott et al 2015).

## Psychosocial changes

There are a number of psychosocial **theories of ageing** which are currently used to frame our understanding of the psychosocial ageing process. Where once disengagement theory was seen as a preferred model to shape nursing practice, it is now not so widely accepted. Disengagement theory sees ageing as a process in which the person begins to withdraw from their active roles and activities and becomes increasingly self-occupied. It is assumed that withdrawal from society is a natural aspect of ageing (Johnson & Chang 2014). Within this model the nurse assists the older person to withdraw from aspects of active life.

Conversely, activity theory and continuity theory both propose that the continuation of active involvement in social activities, roles and relationships is essential for successful ageing. It is suggested that the older person is happiest when they can stay active and maintain social interactions (Johnson & Chang 2014). Whereas activity theory proposes the maintenance of regular roles and activities, continuity theory suggests that personality, attitudes and behaviours remain constant across the lifespan. Within these models the nurse assists the older person to not only maintain existing activities and roles but also to help develop them.

Personality development continues even in late adulthood. Late adulthood is the developmental stage during which people clarify and use what they have learned over the years. Older adults can continue to grow and adapt when they are flexible and realistic. Older adults can use their skills to conserve their strength, adjust to change and loss and use these years productively. For some older people there is a new awareness of time and older persons may want to use the time they have left to leave a legacy to their children or to the world, pass on their knowledge and experiences and validate their lives as having been meaningful.

### Older adulthood and the experience of grief

The experience of grief is not limited to the losses experienced when someone close to us dies. For an older adult, there can be many losses that will be grieved:

- Retirement from the paid workforce
- Change of living arrangements
- Change in physical health and wellness
- Loss (of function) of body parts
- Changes to abilities (such as being independent in activities of daily living [ADLs])
- Loss of sensory acuity (failing sight, hearing)
- Loss of mobility (e.g. driving a car)
- Regret at recognition of stage of life (i.e. later adulthood)
- Lack of fulfilment or achievements in life
- Lack of longevity expected in rest of life (own mortality) (Jeffreys 2010).

It is anticipated that those in older adulthood will encounter loss through death of siblings, parents, partners and friends. Some older people become more accepting of death as they age, whereas others grieve for the loss of longevity in their lives in the process of adapting to the ageing process. (See Clinical Interest Box 15.7 for strategies to assist an older person who is grieving.)

**CRITICAL THINKING EXERCISE 15.2**

You are undertaking a home visit to Martha Wells. Martha recently had a major cerebrovascular accident (CVA) and has a significant right-sided paresis. You arrive at her home at 11 am to find her crying and still in her night attire. When you ask her what the problem is she cries more and tells you that she is helpless and feeling sad. What do you do? What might be her problem?

## Cognitive changes

Cognitive changes that impact on everyday life are not a part of normal ageing (Berman et al 2015). Such changes should be considered abnormal. The risk of dementia does increase with age (Clinical Interest Box 15.8) but is not an inevitable condition of ageing.

**CLINICAL INTEREST BOX 15.7**
**Strategies for nurses to assist older people to grieve**

Nurses should be aware of their own attitudes towards dying, death, grief and loss. Death is a taboo topic in many cultures and many people do not think about it or discuss it with others.

Many people are very uncomfortable talking about loss or listening to someone else talk about it. Grieving people often feel alone in their experience and do not want to burden others with discussion of their feelings. Giving a grieving person an opportunity to share personal feelings can be a very powerful experience.

Encourage the expression of feelings, needs and beliefs, and listen closely to what is being expressed. Whether an individual is experiencing denial, anger, confusion, fear or guilt, the nurse should remain calm, even when the emotions of the grieving person are intense.

Do not take anger or irrational outbursts personally. Remember that the individual is grieving. Reacting to anger with anger will only escalate the situation.

Because each person experiences grief very differently, nurses should not tell a grieving person that they know what they are feeling or understand what they are going through. What should be communicated is that they are sorry for their loss and offer sympathy and support.

Do not try to talk individuals out of their feelings. People experience intense emotions following a loss and need a safe place to express them. Use active listening skills, like responding to statements without agreeing, challenging or disputing the other person's perspective. Listen carefully and acknowledge what the person has said.

Allow an individual time to think about the loss. This is especially true for older adults who may be processing information more slowly.

If grief is interfering with daily functioning for more than 2 months after the loss, referral to a grief counsellor may be beneficial.

*(Adapted from Christensen & Kockrow 2011)*

**CLINICAL INTEREST BOX 15.8**
**Dementia**

The incidence of dementia in Australia is projected to rise from the current figure of 257 275 in 2010 to 1 130 700 by 2050 (Access Economics 2009). Its prevalence in older adulthood increases with age:

- 65–69 years: 1 in 100
- 85 years: 25 in 100.

**Dementia** is the term used to describe the symptoms of a group of illnesses that cause a progressive decline in a person's cognition, to a degree that it interferes with intellectual, social and occupational function. Dementia is discussed in more depth later in the chapter.

### Socioeconomic changes

The majority of older adults in Australia continue to make valuable contributions to their families and their community. A substantial proportion of volunteering, both in the community and in the care of younger and older family members, is undertaken by people aged 55 years and over (ABS 2011; Thornton 2010). Formal, paid employment may decrease for many older adults in the population, but immeasurable economic, cultural and social contributions are made to the community through informal care and participation by older adults, often for other older adults and those who are disadvantaged or have disabilities that impact on their **ability** to function independently. The contribution of older adults is often not measurable until it is discontinued as a result of illness or a change in circumstance. The value of volunteering and informal care arrangements impacts on the recipient, but also on the older adult, who is active, engaged and continues to find worth and identifiable roles in the later stages of their life (Crisp et al 2013).

### Sexuality and the older adult

Sexuality is a part of self, regardless of age or disability. As a person ages, the ways in which their sexuality is expressed, and the way they see themselves as sexual beings, may change (Crisp et al 2013). The expression of sexuality and self extends from basic human needs such as the ability to give and receive tactile stimulation (touching, stroking and massage), to the way we present ourselves to the world. If it was important for a woman to always wear a skirt with stockings as a part of how she saw and expressed herself, her choices and expression should be continued for as long as is practicable to ensure that the maintenance of personhood (self) is preserved. Sexuality is not only about sexual intercourse or sexual activity, although both may be part of how a person—older or younger—expresses themselves. Sexual health and/or wellbeing will have a different meaning for individuals. For some it may be in the way they present themselves or feel, but for others it may be the fulfilment of intimate sexual expression.

## HEALTH RISKS/PROBLEMS

Australians' life expectancy at birth continues to rise and is among the highest in the world. For older people, the main causes of death are heart disease, stroke and cancer. At age 65, Australian males can now expect to live a further 19 years to almost 84 years of age, and females a further 22 years to almost 87. Life expectancy, however, is not uniform across all groups of society in Australia. Compared with those who have social and economic advantages, disadvantaged Indigenous populations are more likely to have shorter lives. Indigenous people are recognised as being generally less healthy compared with other cohorts in the community, die at much younger ages and have more disability and a lower quality of life. People living in rural and remote areas tend to have higher levels of disease risk factors and illness than those in major cities (AIHW 2010; Cotter et al 2012).

In taking into account age-related changes, the most common specific health problems of later adulthood are usually related to degenerative changes in body systems. It is often thought that most older people with degenerative changes will experience some loss of function in a body system; therefore, comorbidities increase the complexity of disease processes, treatment and the nursing care that is required.

### Chronic conditions

Although the majority of older people are in good health, chronic medical conditions do become more frequent with age and may cause **disability**. Older people have at least one chronic condition: the most common conditions are arthritis (48%), complete or partial deafness (33%), cardiovascular disease (24%), osteoporosis (16%) and type 2 diabetes (13%) (ABS 2010). Another common problem of late adulthood is dental problems, especially tooth decay. This affects digestion and leads to many other problems. Older people may suffer from a wide variety of functional disorders related to ageing and chronic diseases. With a slowing down in immune system functional ability, the older person is also more susceptible to viral and/or contagious diseases which could further compromise existing chronic conditions (Scott et al 2015).

### Impaired cognition

The three most common conditions affecting cognition in the older adult are dementia, delirium and depression. These three conditions are colloquially referred to as 'The 3Ds' in ageing individuals. The nurse should be able to distinguish between the three in order to select appropriate nursing interventions (Crisp et al 2013). Failure to be able to differentiate between them will result in not only highly inappropriate nursing care being given, but may also further compromise the person's health and wellbeing.

**CRITICAL THINKING EXERCISE 15.3**

Mary Avery is a 78-year-old woman with Alzheimer's disease. She lives at home with her daughter in central Queensland. Recently she has started having conversations with her husband who has been dead for 20 years and her urinary incontinence has worsened. What should initially be done?

#### Dementia

Dementia is not a single disease but a term that is associated with many different diseases. It is a disease process and is progressive in nature. It is not a normal part of ageing, but the incidence and prevalence of this condition increases proportionately with chronological ageing. Dementia interferes with cognitive functioning to the degree that it impacts on

normal social and occupational activity. Dementia is the single greatest cause of disability in older Australians (Alzheimer's Australia 2015b). The areas of function that may be affected in a person living with dementia are:

- Memory
- Insight
- Ability to plan and make decisions
- Ability to reason or learn new ideas
- Language skills
- Filtering systems
- Control mechanisms including emotions
- Tolerance to stress
- Information processing
- Orientation and spatial awareness (Alzheimer's Australia 2015a).

A person living with dementia will not necessarily have disturbance to all intellectual function, but will experience difficulties with abstract thinking and decision making (Christensen & Kockrow 2011).

Risk factors for dementia include hypertension, high cholesterol levels, poor diet, obesity, age (65+), smoking, excessive alcohol consumption, heredity (5–10%) and head injury.

There are more than 160 different types of dementia:

- *Alzheimer's disease*: the most common form of dementia accounting for between 50% and 70% of all dementias. Alzheimer's disease is a physical disease which attacks the brain, resulting in impaired memory, thinking and behaviour. As brain cells die, the substance of the brain shrinks. Abnormal material builds up as 'tangles' in the centre of the brain cells and 'plaques' outside the brain cells, disrupting messages within the brain and damaging connections between brain cells. This leads to the eventual death of the brain cells and prevents the recall of information (Alzheimer's Australia 2015a).
- *Vascular dementia*: the broad term for dementia associated with problems of circulation of blood to the brain. There are a number of different types of vascular dementia, the most common being multi-infarct dementia. Multi-infarct dementia is caused by a number of small strokes called transient ischaemic attacks (TIAs). The strokes cause damage to the cortex of the brain, the area associated with learning, memory and language (Alzheimer's Australia 2015a).
- *Dementia with Lewy bodies*: this is caused by the degeneration and death of nerve cells in the brain. The name comes from the presence of abnormal spherical structures, called Lewy bodies, which develop inside nerve cells. It is thought that these may contribute to the death of the brain cells. People living with dementia with Lewy bodies may experience difficulty with concentration and attention, extreme confusion, difficulties judging distances (often resulting in falls), visual hallucinations, parkinsonism and fluctuations in mental state from lucidity to extreme confusion (Alzheimer's Australia 2015a).
- *Fronto-temporal lobar degeneration*: the name given to dementia when there is degeneration in one or both of the frontal or temporal lobes of the brain. There is considerable difference in symptoms, depending on which parts of the frontal and temporal lobes are affected. The right and left frontal lobes govern mood, behaviour, judgment and self-control. Damage leads to alterations in personality and behaviour, changes in the way a person feels and expresses emotion and loss of judgment. The right and left temporal lobes are involved in the organisation of sensory input such as what is heard or seen. Damage may lead to difficulty placing words or pictures into categories (Alzheimer's Australia 2015a).
- *Parkinson's disease*: dementia with Lewy bodies sometimes co-occurs with Alzheimer's disease and/or vascular dementia. It may also be hard to distinguish dementia with Lewy bodies from Parkinson's disease, which is also associated with Lewy bodies, and some people who have Parkinson's disease develop a similar dementia (Alzheimer's Australia 2015a).

Clinical Interest Box 15.9 discusses the issue of sexuality and dementia.

## Delirium

Delirium is an acute, transient confusional state that often has a reversible physiological cause. It is characterised by impaired cognitive function and reduced ability to focus, sustain or shift attention (Gross et al 2012). The disturbance manifests in a very short time, and fluctuates throughout the day. It may last only a few days or may persist for weeks, depending on the ability to identify and manage the cause of the confusion. Delirium in older people is often overlooked or misdiagnosed. Delirium is usually precipitated by an underlying acute health condition, which in most cases can be identified with careful assessment and investigation. This can include an alteration in sodium or infections such as urinary tract infections. Increasing old age, dementia, visual impairment and severe medical illness are important risk factors for delirium (Paulson et al 2014). It is estimated that significant numbers of older adults admitted to acute health facilities will experience delirium during their admission and about 40% of older adults in residential aged care facilities may be found to be in delirium state. Nurses should place importance on environmental and physiological changes that may impact on the psychosocial presentation of older adults.

## Depression

Depression is not a normal part of ageing. It is under-recognised and inadequately treated in many older people. Misdiagnosis of depression delays treatment, increases the risk of functional decline and slows the rate of recovery. Depression in older adulthood is a serious condition and can be associated with a loss of independent function, cognitive impairment, poor response to rehabilitation and diminished recovery. It also can lead to an increased risk of death. Major depression occurs in 1–3% of the general older population, with a further 8–16% having clinically significant depressive symptoms. The incidence of depression in long-term care

## CLINICAL INTEREST BOX 15.9
## Sexuality and dementia

If behaviour is sexually motivated and inappropriate (e.g. if it is being conducted publicly), the matter may be resolved and the person's dignity maintained by gently discouraging the behaviour or by redirecting the person with dementia to another activity. Some people who are living with dementia may behave in a sexually inappropriate manner that is totally different to behaviour before the onset of their dementia. The underlying cause is the invisible damage to the brain caused by the illness. It can be helpful to remember that the person with dementia does not intentionally seek to embarrass or annoy others (Alzheimer's Australia 2015a). Nurses need to recognise that the desires and needs of older people are not unlike their own. There is no reason to prevent older people, even those who are very old, from forming relationships. This may mean that they simply wish to spend time together, hold hands, hug or kiss. Or it may mean that a couple wish to sit, lie down together or become more intimate. This can be reassuring and comforting for both but can also cause problems in different ways.

Specific problems may arise if:

- One or both has a wife or husband but are no longer aware of their marital status because of memory impairment in dementia
- One or the other is at risk of harm or injury as a result of the relationship
- The new relationship distresses a spouse or other family members
- One individual is exerting power over the other, or in any way coercing the other
- Staff are in conflict about the 'rights and wrongs' of the situation and cannot agree on how it should be managed.

In such cases it is advisable for the healthcare facility to have a clearly formulated policy concerning residents and sexual behaviour. This should guide responses and can be shown to family members in case of conflict about what should happen. A policy may indicate that if there is no evidence of overt sexual activity the rights of the residents to have a relationship will be respected; alternatively, the policy may indicate that such relationships will be discouraged by close monitoring or by moving one individual to another facility.

Ideally, relatives should be alerted to how the pathophysiology of dementia can lead to the possibility of such relationships developing and be made aware of relevant policies before the loved one is admitted to the facility.

settings is three to four times higher than in the general population (Victorian Government Health Information 2010). Sleep disturbances can result in cognitive impairment and depression. Depression can be effectively treated in older people resulting in improved mood, improved function and an increased quality of life.

With the projection of the numbers of people who will be living with dementia in the 21st century, and the assumption that we will live longer in adulthood, nurses must have the knowledge and skills to communicate effectively and provide appropriate care that celebrates the person who is living with a dementing illness. See Table 15.1 for a comparison of dementia, delirium and depression.

## Polypharmacy

As the incidence of disease and chronic ill health increases in the older body, there is an increase in the number of medications that are prescribed. Multiple-drug use is referred to as polypharmacy. For the older person this can be especially hazardous as there can be a slower metabolism rate for the drugs. Drugs that need to be excreted via the kidneys have the potential for developing toxicity due to the slower excretion rate for older persons. (Refer to Chapter 24 for more details.)

## Falls

The World Health Organization defines a **fall** as 'an event which results in a person coming to rest inadvertently on the ground or floor or other lower level'. An *injurious fall* is a fall that causes a fracture to the limbs, hip or shoulders (Australian Commission on Safety and Quality in Health Care 2009). It is recognised that older adults are more at risk of falls related to both physiological (e.g. osteoporosis, decreased exercise, vision impairment) and environmental factors. See Clinical Interest Box 15.10 for general safety measures to prevent falls. These safety measures can be utilised for all hospitalised individuals. See Chapter 19 for falls risk assessment.

In some circumstances even the most careful nursing interventions are unable to avoid the risk of injury or harm to individuals. In such cases, as a last resort, it becomes necessary to consider the use of restraining devices to protect individuals.

### Restraints

**Restraints**, sometimes called protective devices, are used to limit the freedom of movement of an individual of any age, to varying degrees. Restraints may be physical or chemical. Protective or restraining devices are used to prevent individuals from harm or from harming others.

The Department of Health and Ageing (2012) has produced guidelines for the use of restraints in all health and aged care settings. These guidelines state that:

- The least restrictive form of restraint must be used
- A full, documented assessment must be completed prior to using a restraint
- The person must be monitored and observed closely for signs of distress or harm
- A medical officer's order for restraint must state the reason for the restraint, the time period and the type of restraint to be used
- Restraints should only be used after all other possible ways of ensuring safety have been tried and documented as unsuccessful
- Restraints cannot be used for staff convenience.

**TABLE 15.1 | Differentiating the 3Ds—dementia, delirium and depression**

| Feature | Dementia | Delirium | Depression |
|---|---|---|---|
| Onset | Slow and insidious—deterioration over months or years | Sudden—over hours or days | Often abrupt—may coincide with life changes |
| Course | Symptoms are progressive over a long period of time; not reversible | Short and fluctuating—often worse at night and on waking<br>Usually reversible with treatment of the underlying condition | Typically worse in the morning. Usually reversible with treatment |
| Duration | Months to years | Hours to less than 1 month—not often longer | At least 2 weeks—can last for months or years |
| Psychomotor activity | Wandering/exit seeking or agitated or withdrawn (may be related to coexisting depression) | Hyperactive delirium: agitation, restlessness, hallucinations<br>Hypoactive delirium: sleepy, slow moving | Usually withdrawn, apathy |
| Alertness | Generally normal | Fluctuates—may be hypervigilant through to very lethargic | Normal |
| Attention | Generally normal | Impaired—difficulty following conversation, fluctuates | Normal |
| Mood | Depression may be present in early dementia | Fluctuating emotions (e.g. anger, tearful outbursts, fear) | Depressed mood<br>Lack of interest or pleasure in usual activities<br>Change in appetite (increase or decrease) |
| Thinking | Difficulty with word finding and abstraction | Disorganised, distorted, fragmented | Intact—themes of helplessness and hopelessness present |
| Perception | Misperceptions usually absent (can be present in Lewy body dementia) | Distorted—illusions, hallucinations, delusions; difficulty distinguishing between reality and misperceptions | Usually intact (hallucinations and delusions only present in severe cases) |

*(Adapted from Scott et al 2015; Clinical Epidemiology and Health Service Evaluation Unit 2006)*

Protective devices include the use of:

- Side rails on an individual's bed
- Security or safety belt on trolleys or wheelchairs
- Soft material ties (extremity immobilisers) that prevent movement of the hands and feet
- Padded coverings for the hands; for example, hand mitts
- Vest or jacket chest restraint that secures an individual in an upright position in a wheelchair.

***Selecting a restraint*** When selecting a restraint the nurse must consider the following:

- It is the least restrictive possible
- It does not interfere with treatment
- It can be changed easily
- It is the safest restraint for the individual
- It is the least obvious to others.

The use of restraint is always deemed to be the last option for managing challenging behaviours. Challenging behaviours can at times be triggered by an event or sequence of events. The nurse should always try to identify these triggers and amend/remove them where possible. Alternative measures must always be considered before physically or chemically restraining a person. These measures include environmental changes, introduction of or changes to activities and alteration to nursing care (Department of Health and Ageing 2012).

Some suggestions for alternatives to the use of a restraint are identified in Clinical Interest Box 15.11.

## Mistreatment of the older adult

Mistreatment or **abuse** may be directed towards an older person or carer and may involve physical, psychological, financial or sexual neglect (Berman et al 2015).

Physical neglect/mistreatment may involve failure to provide food, fluid, personal care and hygiene. Overmedication may be used to cause sedation. Hitting, slapping and pushing may also occur.

Psychological mistreatment may involve name calling, swearing, threats, humiliation or bullying. Abuse may also

## CLINICAL INTEREST BOX 15.10 Safety measures to prevent falls

General safety measures to prevent falls include:

- Ensuring that floors are free of clutter, slippery substances and loose rugs. Spills should be wiped up immediately, floor coverings should be maintained in good repair and rugs should have a non-slip backing or be removed from the area. Large, clearly worded warning signs should be displayed when floors are wet or slippery
- Installing handrails in corridors, stairways, bathrooms and toilets. These provide support for individuals who are weak or unsteady when walking and also provide support when a individual is sitting down or getting up; for example, sitting on the toilet or getting out of the bath
- Placing a non-slip mat on the floor at the base of the bath or just outside the shower cubicle. A chair should be available in the bathroom for individuals to sit on; for example, during a shower or while dressing or undressing. Floor tiles in any area should be of the non-slip variety
- The nurse remaining with and supporting at-risk individuals during hygiene and toileting procedures and whenever there is a risk of the individual falling
- The nurse frequently checking more independent individuals during hygiene and toileting procedures and ensuring that every individual is aware of the position of the call button in the shower or toilet area
- Adjusting the height of the bed to meet the needs of the individual enabling them to get into and out of the bed safely and independently whenever possible
- Placing any items that the individual might need within easy reach; for example, when the individual is in bed or sitting on a chair. Items required should be on the locker or over-bed table that is positioned close to the individual. This avoids the risk of a fall from the bed caused by the individual stretching while attempting to reach for a needed item
- Ensuring that all walking aids, for example crutches and frames, are fitted with non-slip tips to prevent them skidding on the floor. Individuals who are using walking aids should be supported adequately and supervised until they are able to use the aids safely. All walking aids should be positioned at the correct height for the individual
- Ensuring that clear lighting is available in all areas and that a nightlight is provided in the individual's room
- Placing the signal device within the individual's easy reach so that assistance can be summoned if necessary; for example, to get out of bed
- Keeping all areas free of items that could cause a person to fall; for example, electrical cords, cleaning equipment, linen, dressing or medication trolleys
- Ensuring that ambulant individuals wear shoes or slippers that are well fitting and have non-slip soles. The cord from a dressing gown should not be allowed to trail, as it could cause the person to trip
- Doors should remain fully open or closed, as people are more likely to bump into a door that is ajar.

*(Crisp et al 2013)*

include isolation or confinement. Misappropriation of money or valuables or denying the right to money may also occur (Crisp et al 2013).

The older adult may be mistreated in their own home, an aged care facility or hospital. Abusers may be family members/carers, other relatives and in some cases healthcare providers. Older adults are usually afraid to report abuse or neglect because they are ashamed or fear retaliation. Nurses should be familiar with the laws under which they work in regard to the reporting of suspected or known cases of neglect (Berman et al 2015).

## CULTURAL ASPECTS OF AGEING

In Australia the population of older people from culturally and linguistically diverse populations is increasing (Crisp et al 2013). Based on the 2011 Australian census figures, 30.22% of all Australians were born overseas. As culture includes aspects of life such as language, values, beliefs and customs, an environment that does not support these characteristics can create challenges for the older person, their family and friends, and for the nurses who provide their care. Isolation and feelings of alienation created by a lack of cultural interaction can be compounded by difficulties with communication and acceptance of care strategies. In Australia the introduction of culturally specific residential care services is attempting to address this challenge; however, unless these services are accessible for the older adults requiring them, many culturally diverse older adults will be accommodated within mainstream care services.

For many family members of these culturally diverse older people guilt at not being able to provide care at home for their relative may increase the difficulties experienced by the older adult and the care staff.

To care for the culturally diverse older individual competently, nurses must develop appropriate strategies. These may include:

- Appreciating that all people have diversity in their backgrounds
- Considering own beliefs, attitudes and values
- Refraining from assumptions relating to the thoughts and feelings of the older adults and their families in regard to difficulties experienced. Listening and communication are paramount

## CLINICAL INTEREST BOX 15.11 Suggestions to promote restraint minimisation

- Bed, chair or wrist alarms
- Exit door alarm
- Electronic movement sensors (see Figure 15.1)
- Planned night-time activities for those who wander at night
- Daytime recreational and social activities, provide auditory and visual stimuli such as soothing music, television or radio
- Activity areas at the end of each corridor
- Easy access to safe outdoor areas
- Structural design of units modified to enhance visibility of residents. Assign confused or disoriented individuals to rooms with high visibility
- Rocker and recliner chairs
- Outlets for industrious or anxious behaviour; for example, physical, occupational and recreational therapies
- Ensure regular toileting
- Review medication to ensure it is having the desired therapeutic effect
- Allocate staff to ensure familiarity with individual
- Change position frequently.

*(Adapted from Department of Health and Ageing 2012; Joanna Briggs Institute 2002)*

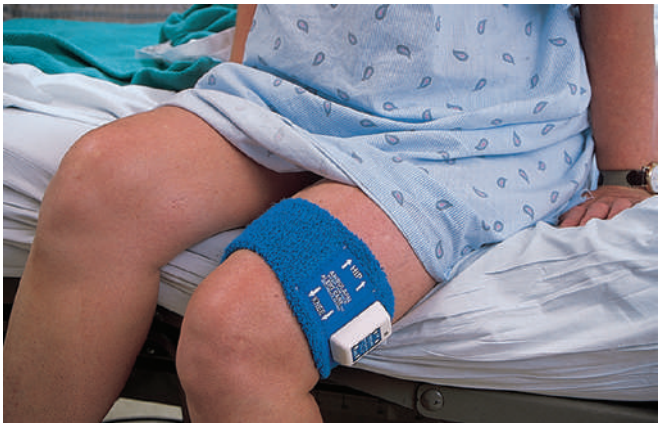

**Figure 15.1** Individual wearing an Ambualarm
*(Fig 27.9 Crisp et al 2013, see Tabbner's 6e Fig 13.2)*

## CLINICAL INTEREST BOX 15.12 Attitudes to ageing

Which of these statements of negative and positive views of ageing do you agree with?

**Negative**

- People have a poor view of turning 60 or 70 and fear getting older
- The older you get the worse your health will become
- Older people will end up in an old age home. Families will put them in a home when they become a burden
- Older people will experience age discrimination (employment, healthcare, etc)
- Women aren't as beautiful as they age
- Older people become more cranky and have wrinkled skin and grey hair
- Many older people are sick, disabled, demented
- Older people have no sexual desire or the thought of them having sex is repulsive
- Older people are a drain on the healthcare system
- Old workers are not as effective as younger workers
- Older people live in poverty or cannot afford their medications
- Older people are a burden to society

**Positive**

- People look forward to the 'golden years'
- Society has different standards that older people are held to in comparison to younger people
- Older people have more free time to spend with friends and family
- Older people have the freedom to do the things that they couldn't do before
- Older people are nice, warm, friendly people
- Older people have lots of knowledge and wisdom and have the time to help others
- Older people are well off financially and don't have career and childcare issues to worry about
- Old age is peaceful and fun
- Older people look forward to the future

- Appreciating the diversity that exists within cultures, language and values (different dialects, religions, practices within an ethnicity)
- Clarifying with the older adult and their family the importance of cultural behaviours and events
- Seeking education and familiarising self and workplace with the specific needs of people from culturally and linguistically diverse backgrounds (Crisp et al 2013)
- Realising that non-verbal cues and indicators can at times be more important than verbal language within cross-cultural communication (Kirov & Webb 2014).

There are times when nurses hold stereotypical views and attitudes towards ageing which will significantly impact upon their own practice. While some of these may be linked to cultural misconceptions, others may be attributed directly to the nurses' own lived experiences. To understand the needs of another person, nurses must look past their own beliefs and values and consider the world view of those in their care (Hofstede 2011).

See also Clinical Interest Box 15.12.

**CRITICAL THINKING EXERCISE 15.4**

Mabel Grainger is a 70-year-old woman who has been admitted to hospital following a fall at home. She has a haematoma on her right arm and on her face, but has not sustained any major injuries. What issues do you think may have led to her fall at home? What aspects of care will you consider in planning her discharge?

## HEALTH ASSESSMENT AND PROMOTION

Assessments and health screening that are undertaken in wellness will assist in identifying adjustments or treatments that are required to manage age-related changes to ensure that function and quality of life are maintained. With an accumulation of age-related changes, disease processes may begin to impact on the person's quality of life and functional ability. This impact may be identified through assessments by healthcare professionals.

The Australian government funds some programs through Medicare and other national health strategies. These may include:

- Vision and hearing tests
- Breast screening (for women over 40 years)
- Prostate checks (for men of all ages)
- Bowel screening (for those over 50 years)
- Medication review
- Older person's health assessment
- Podiatry
- Physiotherapy assessments for falls risk.

The Aged Care Assessment Program is a federally funded program that comprehensively assesses the frail older person in order to identify their care needs and help gain access to appropriate care services (Australian Government 2014b).

## CARE SETTINGS

### Continuum of care—assessment as the basis for care

With the ageing of the baby boomers in Australia (those born after the end of World War II and up to 1964), the number of people within the population who are moving towards the 'young old' category of older adulthood is increasing markedly. With this rise expected to continue over the next decade, changes in care provision will continue to be refined by successive governments. What is becoming clearer is that older adulthood is no longer accepted as a time of only frailty and chronic illness, but that older adults enjoy 'good health and wellness' as they age, and actively pursue their own choice with regard to their finances, health and occupation. Their considerable influence (and power related to numbers) means that political parties are listening more carefully to the needs and wants of older adults. The time of assumptions of knowing what is best for older people has passed.

For nurses to assist older adults in planning effective care, a familiarity with current forms and access to services is necessary.

### Community care

When older people are required to make adjustments in their lives to accommodate assistance with their functionality, community services may provide this assistance. This may be in response to assistance required after an illness, surgery, hospitalisation or as a result of an assessment prompted by a general practitioner (GP) or a relative to identify areas in the ADLs that the older person may not be able to manage independently.

Community care services may assist older people to live independently with informal care for extended or short periods of time. When the decision is made, either willingly or as a necessity for more formalised, continual care, an Aged Care Assessment Team (ACAT) referral will be required.

### Aged Care/Needs Assessment Teams (ACAT)

A formal assessment is required for most government-funded care services (federal, state or local government funded). The multidisciplinary ACAT team operates as a single point of entry to community Home Care Packages and residential aged care services. An ACAT assessment is not required for Home and Community care services. A referral for ACAT assessment may be by self-referral or it may come via family or friends, healthcare practitioners or community services known to the person. Assessment of a person's care needs takes into account physical, medical, psychological and social factors, and facilitates access to appropriate care services.

Care needs will be determined, and an assessment will be made regarding the requirement for care needs. High-level care indicates that the older adult requires frequent care interventions of a complex nature. This care can be delivered in the community or in a residential aged care facility (RACF). Low-level care indicates that the degree and frequency of care is less, and care can also be delivered in the community or in an RACF.

### Community aged care support

Community aged care support allows older adults to receive the care they require without relocating; that is, they are able to remain in their own homes and communities. The services provided vary according to the needs of the individual.

Community care services may include meals, cleaning, transport, home and garden maintenance and assistance with personal care. For older adults with greater needs, home nursing (district nursing), counselling and therapy may also be provided.

There are two main streams of support available:

1. Home Care Packages
2. Home and Community Care Packages.

### Home Care Packages

To be eligible for a Home Care Package the person must have a home care agreement with a service provider following an ACAT assessment. As these packages are consumer directed the person and the home care provider decide together what services the person wishes to receive. Reforms in funding indicate that from 1 July 2015 all applications for a Home Care Package will be means tested and a co-payment required (AIHW 2014b).

There are four levels of Home Care Packages.

1. Level 1 supports people with basis care needs
2. Level 2 supports people with low-level care needs (formerly Community Aged Care Packages)
3. Level 3 supports people with intermediate care needs
4. Level 4 supports people with high-level care needs (formerly Extended Aged Care at Home and Extended Aged Care at Home Dementia Packages).

These packages are consumer directed and aimed at supporting the lifestyle of the person, not aimed at solely providing personal support (AIHW 2014b).

### Home and Community Care Packages (HACC)

HACC is a basic Commonwealth/state-funded home care service and is aimed at supporting the older person who only requires help with daily tasks or basic care to stay within their own home. Assessment for these services is undertaken by the service provider (AIHW 2014b).

This support may include:

- domestic assistance—household jobs like cleaning, clothes washing and ironing
- personal care—help with bathing or showering, dressing, hair care and toileting
- home maintenance—minor general repair and care of the house or yard; for example, changing light bulbs and replacing tap washers or lawn mowing
- home modification—installing safety aids such as alarms, ramps and support rails
- nursing care—for example, wound care, continence advice (Australian Government 2014c).

In 2013, there were over 56 515 older adults using community aged care packages in Australia, with most requiring a relatively low level of care (AIHW 2014b). The aim is to provide options and alternatives for older adults who require assistance to continue to live in their own homes. (See Case Study 15.1.)

## Acute settings

On occasions, assessment, treatment and rehabilitation of a new or existing chronic illness or a surgical or medical intervention may require admission to an acute care setting. Older people are typically more at risk in this setting than those in younger age groups. Nurses will benefit from an awareness of age-related changes to older adults and how risk is increased for this cohort. See Clinical Interest Box 15.13 for a list of risk factors for hospitalised older people.

Discharge planning for older adults in acute settings is imperative to ensure that the older person has the required support for ADLs, as well as service provision for nursing and home care to optimise the highest level of function and independence possible. Refer to the resources in the References and Recommended Reading section at the end of this chapter.

### CASE STUDY 15.1

Alan Porter is 75 years old and has lived alone for the past 10 years. He enjoys living in his neighbourhood and plays cards every Thursday night with some friends up the road. He also lives a suburb away from his niece and goes to church with her and her family on Sundays. His pride and joy is his modest-sized garden, in which he has a variety of fruit trees and a vegetable patch.

Recently, Alan has had trouble with his vision and, as a result, has decided to give up driving. He has also noticed that while he still loves his garden, the work needed to maintain it seems to take twice as much effort. Alan's niece has noticed that the state of his appearance has been deteriorating, as his clothes are often dirty. She also recently visited him at home and found that, while Alan spent a lot of time working on his garden, his house was quite dirty and his cupboards were bare except for some tins of soup and baked beans. Alan feels very connected to his community and wants to stay there, but he has realised that in order to do this he may need help. He is trying to decide what options might be available to him. Alan's neighbour suggested that he should contact his GP and ask for help.

1. What help could the GP offer?
2. Who would assess Alan?
3. What help could Alan potentially receive?
4. Can Alan's niece seek help on Alan's behalf?
5. Will Alan have to pay for any help?

### CLINICAL INTEREST BOX 15.13 Risk factors for hospitalised older people

- Effects of immobility (loss of strength, constipation, stasis)
- Adverse reaction to anaesthetics
- Adverse reaction to medications
- Increased risk of nosocomial infection
- Loss of independence, autonomy
- Response to unfamiliar environment
- Increased risk of falls
- Slower recovery rate due to reduced energy reserve and response
- Slower adaptation and coping mechanisms (physical/emotional)

*(Crisp et al 2013; Eliopoulos 2010)*

## Rehabilitation

To assist an older person to reach and maintain their optimum level of function, a phase or period of rehabilitation may be

necessary. The site for rehabilitation may be in the acute care setting, as an outpatient in the community, in a specific rehabilitation unit or in the residential care setting. Nurses are an important part of the multidisciplinary rehabilitation team, often taking a role in assisting the older person in their ADLs and facilitating adjustment to their independence and ability (Berman et al 2015). See Chapter 40 for more information on rehabilitation nursing.

**CRITICAL THINKING EXERCISE 15.5**

Joseph King is a resident in a RACF. He is not his usual self when you inform him he has a visitor awaiting him in the lounge room, and he says he does not want to leave his room today. What might be your actions to address this change in Joseph?

## Residential aged care facilities (RACF)

When older adults can no longer remain in their own homes, they may decide, or a decision may be made for them, to move into residential aged care facilities where their care needs can be more holistically met. Aged care facilities provide suitable accommodation, as well as services such as meals, laundry and cleaning, personal care, medication assistance and complex nursing care, as assessed by nursing staff once the older adult has taken up residence.

In Australia in 2011, there were 169 000 people (usually referred to as 'residents') in mainstream residential aged care. Seventy-seven per cent of all residents were aged 80 or over and 57% were aged 85 or over. Seventy per cent of all residents were women and 1127 (0.7%) identified as Indigenous (AIHW 2012).

The admission to an RACF has the potential to affect an older person in physical, psychological and emotional ways. Nurses must be aware of this period and the ability of the older person to adjust to this major change in their circumstances and way that they live. Issues of privacy, dignity, self-esteem and maintenance of personhood are all factors that require the older person to undertake a period of adjustment and adaptation. Some older adults find the move to residential care comforting, while others feel isolated and alienated.

### Quality of care in residential aged care

The monitoring of the standards of care is managed by a process called Aged Care Accreditation This process ensures care facilities provide a high quality of care. The Australian Aged Care Quality Agency has the responsibility for the accreditation of all RACFs (Australian Government 2014a).

The standards cover all aspects of residents' needs from health and personal care and safety to a range of lifestyle matters including independence, privacy and dignity. Care facilities (service providers) that meet these standards are accredited/certified. Service providers that do not meet these standards may be subject to sanctions. There are four Standards and 44 expected outcomes that must be met. The Standards are:

1. Standard 1: management systems, staffing and organisational development
2. Standard 2: health and personal care
3. Standard 3: care recipient lifestyle
4. Standard 4: physical environment and safe systems.

The Accreditation Standards are detailed in the Quality of Care Principles 2014 (Australian Government 2014a).

**CLINICAL INTEREST BOX 15.14**
**Adjustments and adaptations to ageing required of older people**

- Retirement/end of paid employment
- Housing/living arrangements
- Health status/changes to capacity
- Loss of partner/friends
- Financial capacity/position
- Changes to self-image/self-esteem
- Accepting self as ageing
- Finding ways to maintain quality of life

*(Adapted from AIHW 2007; Crisp et al 2013)*

# NURSING CARE OF THE AGEING PERSON

Older Australians face challenges and adjustments as they move into later adulthood. (See Clinical Interest Box 15.14.) They contend with the end of employment at whatever age they retire; changes in health status; changes in relationships with family, children and friends; and adjustments to losses. Nurses must listen to older individuals, rather than making assumptions about what they value and aim for in their lives.

As age-related changes and chronic illnesses affect the functioning of older adults, the assistance that they require becomes more complex. This is not to say that all older people will require full assistance with all of their care needs. It is frequently shown that with assistance to meet needs in certain areas (such as mobility or positioning), other ADLs such as nutrition or toileting can be better maintained by the older person themselves. This type of care is called person-centred care—care that is specific and individualised to that unique person. However, within the community the framework of care as discussed earlier is frequently that of consumer-directed care (CDC). CDC gives the person more choices and control over the types of care and services that they choose to receive. (See Progress Note Example 15.1.)

# IMPLEMENTING THE NURSING PROCESS

Nurses must recognise that holistic care needs do not disappear or become inappropriate due to changes in health circumstances. No matter what the illness, injury or disability, care delivery needs to be assessed in conjunction with the

individual's previous attitudes, beliefs, knowledge, experiences and behaviours relating to their expression of self. Assessment and care planning need to incorporate physical, psychological, social and cultural elements. (See Chapter 17 for discussion of these components of the nursing process.)

## Specific nursing assessments for older adults

*Nutrition*: Mini Nutritional Assessments (MNAs) have been developed to allow for a holistic assessment of factors that may impact on nutritional status. Refer to Clinical Interest Box 15.15 for these factors in older adulthood.

*Falls*: falls are the most common cause of injury for older adults in an acute care facility (deWit 2015) but every individual in every care setting should be assessed for the risk of having a fall. Falls risk is a recognised priority in Australian healthcare. There are many different falls risk assessment tools (see Clinical Interest Box 15.16).

*Skin assessment*: relative to the level of dependence and disability in an older adult, the risk of interruptions to skin integrity and the development of pressure ulcers is a risk factor that must be managed. Refer to Table 15.2 for an example of the Norton Scale which is used to assess risk of pressure ulcers.

*Continence*: although incontinence can affect all age groups, assessment of urinary and faecal continence is an important component of the assessment process for the older adult.

*MMSE*: the Mini-Mental State Examination (MMSE) and the Abbreviated Mental Test Score (AMTS) provide quick measures of cognitive impairment (Molloy 2014).

### PROGRESS NOTE EXAMPLE 15.1

| | |
|---|---|
| 18/02/2015<br>1500 hrs | Mrs Jones stated that she had pain over her right knee and that it was causing some difficulties when mobilising. On inspection the area appeared to be slightly swollen. She was observed to be limping slightly. RN advised. RN Mallard completed an assessment of Mrs Jones and administered pain relief as per medication chart at 1330 hrs. At 1430 hrs Mrs Jones stated that her pain was significantly less and she was able to walk better.<br>***M. Myers* (Myers) Student Enrolled Nurse** |

### CRITICAL THINKING EXERCISE 15.6

Barry Whiteley has always been a keen bowls player, but is becoming frustrated with his form and says he is not going to continue with his three-times-a-week sport. When you go to visit him with the district nursing service, he is dishevelled and non-communicative. What might be your actions in addressing Barry's situation?

### CLINICAL INTEREST BOX 15.15 Non-physiological causes of under-nutrition in older people

**Social factors**

- Poverty
- Inability to shop
- Inability to prepare and cook meals
- Inability to feed themself
- Living alone, social isolation or lack of social support network
- Failure to cater to ethnic food preferences

**Psychological factors**

- Alcoholism
- Bereavement
- Depression
- Dementia or Alzheimer's disease

**Medical factors**

Mediated through anorexia, early satiation, malabsorption, increased metabolism and impaired functional status

- Medications

*(Adapted from Ahmed & Haboubi 2010)*

### DECISION-MAKING FRAMEWORK EXERCISE 15.1

You have just commenced working within a unit at the Sunray Residential Aged Care Facility as an Enrolled Nurse. Within this unit there are 25 residents, all with dementia. On this shift apart from you there are two care workers who both hold the Certificate III in Aged Care qualification, a diversional therapist and a volunteer. The aged care workers advise you that they will do the medications administration, and that you only need to do the dressings and assess any of the residents in case they exhibit challenging behaviours. The volunteer advises you that she is great with the residents when they become restless and will let you know so that you can give them their 'calming down' pills. You call your supervisor who advises you that this was the normal practice and task allocation.

Using the decision-making framework address the following:

1. Do you accept this allocation of duties?
2. What (if any) are the issues that could potentially result in you working outside your scope of practice?
3. Identify the potential and/or actual flaws within this scenario.

These tests are useful to assess and document severity of cognitive impairment and to measure changes in cognitive function. Alzheimer's Association Australia provides further explanations of the implications of these tests (refer to Clinical Interest Box 15.17 and References and Recommended Reading).

## CLINICAL INTEREST BOX 15.16 Falls risk-assessment tool

Place a tick in front of the items that apply to the individual.

General information
- Age over 70
- History of falls*
- Confusion at times
- Confused most of the time*
- Impaired memory or judgment
- Unable to follow directions*
- Needs assistance with elimination
- Visual impairment
- Feels physically weak*

Medications
- Receiving central nervous system suppressants (narcotic, sedative, tranquilliser, hypnotic, antidepressant, psychotropic, anticonvulsant)
- Receiving medication that causes orthostatic hypotension (antihypertensive, diuretic)*
- Medication that may cause diarrhoea (cathartic)
- Medication that may alter blood glucose levels (insulin, hypoglycaemics)

Gait and balance
- Poor balance when standing*
- Balance problems when walking*
- Swaying, lurching or slapping gait*
- Unstable when making turns*
- Needs assistive device (walker, cane, holds onto furniture)*

*(deWit 2015)*

**Note: A tick on any starred item indicates a risk for falls. A combination of four or more of the unstarred items indicates a risk for falls.*

## Care planning

The nurse and individual together (or the older person's representative) develop a care plan that responds to individual needs (see Nursing Care Plan 15.1). This is particularly relevant when the older person's partner, family or significant other has been involved in the primary care of the person. The information that the older person and their primary carer can provide will ensure, where appropriate, that this care and preference can be continued, further supporting the value of person-centred care planning and delivery. Honest communication about concerns, wants and needs will assist the older adult to feel positive about their ability to maintain some degree of decision making and independence, even when faced with serious impairment. Refer to Clinical Interest Box 15.18 for strategies to help the older adult face the challenges of ageing.

The nurse with excellent interpersonal skills such as listening, asking open-ended questions, using silence and summarising the discussion will help individuals to share feelings, concerns and information about themselves (Stein-Parbury 2013). See Chapter 8 for more information on communication.

## CLINICAL INTEREST BOX 15.17 Mini-Mental State Exam

The MMSE tests:
- Orientation to time and place
- Short-term memory, registration, retention and recall
- Attention and concentration
- Language
- Information processing
- Word-finding abilities
- Ability to follow three-stage command
- Planning, constructional and spatial abilities.

*(Adapted from Molloy 2014. © Commonwealth of Australia 2014)*

**TABLE 15.2 | Norton scale**

| Physical condition | Mental condition | Activity | Mobility | Incontinence |
|---|---|---|---|---|
| Good 4 | Alert 4 | Ambulant 4 | Full 4 | Not 4 |
| Fair 3 | Apathetic 3 | Walk help 3 | Slightly limited 3 | Occasional 3 |
| Poor 2 | Confused 2 | Chair bound 2 | Very limited 2 | Usually/urine 2 |
| Very bad 1 | Stupor 1 | Bed 1 | Immobile 1 | Doubly 1 |

Each of the five items in the scale is scored from 1 to 4, with a maximum total score of 20. Scores of 14 or less rate the individual as at risk of developing pressure sores; the lower the score, the greater the risk.

*(Kroshinsky & Strazula 2013 adapted from Norton 1989)*

## NURSING CARE PLAN 15.1

Morris Fisher has returned home following a period of time within the Rehabilitation Unit at a local hospital. He confides to you (his community nurse) that his biggest fear is falling as it was a fall that resulted in his recent admission to hospital. He walks with a walker both inside and outside his house. He is waiting for an assessment to be completed by the occupational therapist on his home. You are the first healthcare worker to visit him.
**Assessment:** Potential for falls due to decreased functional mobility and fear of falling
**Goal/s:** To minimise the risk of falls
To improve his confidence in mobilising

| Care/Actions | Rationale |
|---|---|
| Remove all loose mats | Loose mats are a hazard for tripping |
| Endure that all passageways are free from clutter | Clutter from furniture or other areas is a potential trip hazard |
| Instruct Morris on how to get in and out of his bed without falling | Getting out of bed in the morning is potentially hazardous if not undertaken slowly and appropriately |
| Instruct Morris on how to get onto and off the toilet safely | Changing position from standing to sitting and the reverse can result in a fall |
| Encourage Morris to use his walker at all times | Continuous use of a mobility device such as a walker will considerably decrease the risk of falling, plus increase his confidence in mobilising |

**Evaluation**

Morris expresses greater confidence in mobilising.
Morris does not experience any falls until his home has been reviewed and amendments made by the occupational therapist.

## CLINICAL INTEREST BOX 15.18
## Helping older people face the challenge of ageing

- Help older adults maintain roles and relationships
- Offer maximum support to facilitate older people to do or be involved in personal decision making
- Discover and celebrate the uniqueness of older adults' interest, skills and knowledge. Encourage discussion on past accomplishments and experiences to support the maintenance of personhood
- Listen to the concerns of your individual, regardless of their age or ability
- Reminisce with older adults—their experiences can be valuable in promoting and maintaining relationships and self-esteem.

*(Adapted from Crisp et al 2013; Eliopoulos 2010)*

Nurses involved in planning care also require the following:

- Knowledge about ageing, age-related changes and the needs of older adults across this period of their life cycle
- Ability to be non-judgmental and not make assumptions about preferences
- Awareness of their own limitations and knowing when to refer the individual to another healthcare professional.

## Summary

The older adult may access healthcare services in a variety of settings and for a number of reasons. The nurse needs to have an understanding of the ageing process and the physiological and psychological aspects of ageing. It is also important that nurses be aware of their own and others' attitudes towards ageing and how these affect their approach to giving care to the older person. Nursing an older person requires a thorough understanding of all aspects of healthcare in order to ensure that the person receives appropriate holistic care.

## Review Questions

1. What are the main changes that occur to the neurological and sensory systems with ageing?
2. What are the differences between dementia, delirium and depression?
3. What are the risk factors for the hospitalised adult?
4. What strategies can be used to reduce the use of restraints?
5. Define consumer-directed care.
6. What is the difference between the disengagement theory of ageing and the activity theory of ageing?
7. Identify four (4) types of elder abuse.

Answer guide for the Review Questions, Critical Thinking Exercises, Decision-Making Framework Exercises and Critical Thinking Questions in Case Studies are hosted on Evolve: http://evolve.elsevier.com/AU/Koutoukidis/Tabbner/

# Critical thinking and reflective practice

CHAPTER 16
Critical thinking, problem-based learning and reflective practice in nursing care

CHAPTER 17
Nursing process: framework

CHAPTER 18
Health information: nursing documentation and clinical handover

CHAPTER 16

# Critical thinking, problem-based learning and reflective practice in nursing care

*Jennifer Marshall*

## KEY TERMS

clinical reasoning
critical thinking
problem-based learning
professional practice reflective journal
reflection on practice
reflective practice
reflective practitioner

## LEARNING OUTCOMES

At the completion of this chapter and with further reading, students should be able to:

- Define the key terms
- Outline how critical thinking differs from 'thinking'
- Understand the relevance of clinical reasoning to the continued development of practice
- Recognise the role of problem-based learning in practitioner development
- Outline the three phases of reflective practice
- Apply their understanding of 'reflection on practice' in a professional practice reflective journal

## CHAPTER FOCUS

To enhance professional practice in an ever-changing, complex healthcare setting, nurses must have the knowledge and skills to appropriately process a vast amount of information in a timely fashion, ensuring the results reflect contemporary nursing practice. Critical thinking, problem-based learning and reflective practice are learned conceptual processes and practices that assist nurses to process information that will influence the provision of nursing care and enhance professional development. By demystifying these concepts and processes we hope to stimulate nurses' interest in becoming lifelong learners.

## LIVED EXPERIENCE

The first time I walked into a dementia unit, I felt anxious about the behaviour of a couple of residents. I considered them unpredictable, my heart was racing and I avoided them. At the time I had very little knowledge of dementia. Since then, I have gained more knowledge, participated in learning-based role plays in class and engaged in critical thinking under the guidance of my workplace preceptor. I am now more aware of my behaviour and communication approach and consequently more comfortable in supporting people with dementia. I am more skilled at interpreting a person's behaviour as a form of communication.

**Bronwen, Enrolled Nursing Student**

# INTRODUCTION

This chapter introduces students to the conceptual processes of critical thinking, problem-based learning and reflective practice, with the expectation that they will be stimulated to learn and practise these skills in their everyday nursing practice.

# CRITICAL THINKING

## It's more than just 'thinking'

**Critical thinking** is a cognitive skill that with practice in the classroom—using questioning, small group activity, role play, case studies and problem-based learning strategies, along with exposure to the clinical setting—will enable the nurse to incorporate this process into their nursing practice. Critical thinking requires that the nurse exhibits or develops the attributes of habit of mind, confidence, contextual perspective, creativity, flexibility, inquisitiveness, intellectual integrity, intuition, open-mindedness, perseverance and reflection (Niemer et al 2010). (See Clinical Interest Box 16.1.)

The importance in the development and application of critical thinking to nursing practice cannot be overstated. The Australian Nursing and Midwifery Accreditation Council (ANMAC) mandates it as a curriculum requirement and it forms part of the competency standards for the Enrolled Nurse (Industry Skills Council 2012). Critical thinking in nursing is an essential component of professional accountability and quality nursing care (Romeo 2010; Hunter et al 2014). The complex health environment, caring for individuals with high acuity needs and the increasing number of comorbidity presentations demand that nurses deliver competent and appropriate nursing care. Castledine (2010) cautions that failure to develop the skills of a critical thinker 'are not only letting their clients down but also their colleagues in the professional healthcare team'.

### CLINICAL INTEREST BOX 16.1 Critical thinking attributes

- Habit of mind
- Confidence
- Contextual perspective
- Creativity
- Flexibility
- Inquisitiveness
- Intellectual integrity
- Intuition
- Open-mindedness
- Perseverance
- Reflection

*(Asselin 2011; Kim et al 2010)*

The literature contains many definitions for critical thinking, including critical reasoning, critical analysis and critical decision making as elements of the critical thinking process. Peter Facione (Facione et al 1994), internationally known for his work on the definition and measurement of critical thinking for over 40 years, described critical thinking as the process of purposeful, self-regulatory judgment. This process gives reasoned consideration to evidence, context, conceptualisation, methods and criteria. Thus, this definition describes critical thinking as not 'mindless' thinking or 'day dreaming' but as a focused cognitive process of continually assessing information derived from multiple databases, then questioning and sorting that knowledge to initiate sound contemporary nursing practice and learning from the experience. 'Critical thinking is an attribute that enhances one's skills in problem solving and decision making' (Romeo 2010). One element of critical thinking is clinical reasoning. It will be necessary to rehearse this cognitive skill in order for a nurse to apply critical thinking to their everyday nursing practice.

## Clinical reasoning, clinical judgments and clinical decisions

### Clinical reasoning

**Clinical reasoning** can be considered to consist of both 'formal and informal processes involved in making sound professional judgments' (Koharchik et al 2015). Clinical reasoning is the process by which nurses collect cues, process the information, come to an understanding of the individual's problem or situation, plan and implement interventions, evaluate outcomes and reflect and learn from the process.

'Effective clinical reasoning depends upon the nurse's ability to collect the right cues and to take the right action for the right patient at the right time and for the right reason' (Levett-Jones et al 2010). Clinical reasoning often includes 'if–then' statements, such as; if a nurse learns the signs and symptoms (cues) of a disease then they can choose the appropriate action.

### Clinical judgments and decisions

Clinical judgments and decisions are interrelated as both these elements form part of the critical thinking process which can contribute to the appropriateness of a nurse's eventual actions. Using clinical judgment the nurse evaluates alternative courses of action in order to reach an appropriate decision suited to the specific needs of the person (Thompson & Stapley 2011). For example, a nurse who does not apply clinical judgment observes 'the diabetic person is pale, cold and clammy' then chooses an inappropriate action of 'providing extra blankets'. For nurses to make appropriate decisions, exposure to health education practices and professional nursing practice that support the development of clinical reasoning skills is essential. Some methods of health education that may assist the student to develop clinical reasoning and critical thinking skills include utilisation of the nursing process, problem-based learning, role playing, reflective learning, the critical incidence conference, preceptorship, case studies and concept mapping (Rochmawati & Wiechula 2010; Kong et al 2014). (See Clinical Interest Box 16.2.)

**CLINICAL INTEREST BOX 16.2**
**Clinical reasoning and critical thinking learning methods**

- The nursing process
- Problem-based learning
- Role playing
- Reflective practice
- Critical incidence conference
- Videotaped vignettes
- Preceptorship
- Case studies
- Concept mapping

*(Asselin 2011; Kim et al 2010)*

**CRITICAL THINKING EXERCISE 16.1**

Review the attributes required for critical thinking. Which attributes do you think you possess and which attributes require further development?

**CRITICAL THINKING EXERCISE 16.2**

Consider realistic opportunities outside of the classroom where you might practise your critical thinking skills. Who will you collaborate with in these exercises?

# PROBLEM-BASED LEARNING

## Relationship to the nursing process

**Problem-based learning** is a student-centred health education method which is thought to contribute to the development of critical thinking skills. Problem-based learning encourages use of skills that correspond to those used in application of the nursing process such as organising and appraising available data, team-based reasoning and reporting decisions (Martyn et al 2014). As a process, problem-based learning starts by applying currently held knowledge to an identified clinical problem, then building understanding through the attainment of new knowledge (Kong et al 2014). Therefore, problem-based learning can be seen as an inductive process whereas the nursing process is associated with a deductive reasoning approach.

It is important to reaffirm that the nursing process, as discussed in Chapter 17, is an integral element of the critical thinking, problem-solving and decision-making process. Similar to the nursing process, problem solving involves the elements of assessment, planning, implementing and evaluating; the best course of action in a given situation for the best possible outcome.

In the clinical practice setting nurses are continually confronted with complex individualised care problems to solve. Problem-based learning is a teaching method which allows students to practise and develop these skills in the classroom prior to entering the clinical practice setting, so as to be better prepared to solve real-life clinical problems.

## A health education method

Problem-based learning is described as an active educative strategy, providing a framework for the development of self-directed learning, self-evaluation, interpersonal communication, critical thinking and access to and retrieval of information (Chunta & Katrancha 2010). It is a classroom teaching strategy that requires the student to participate actively in the learning process. The instructor facilitates the learning, as a co-learner, to provide clarity, encouragement, feedback and guidance, until the problem is solved.

Often problem-based learning is in the form of a case study simulating a real-life problem which can be conducted in small groups. Collectively, students must actively seek out information, draw from their knowledge base and use clinical practice experience and/or further research to accurately solve the simulated clinical case study. Together students initiate discussions by asking 'what do we know' and 'what do we not know', further analysing the problem by brainstorming ideas from the group members.

As self-directed learners the students seek out the gaps in their knowledge base, form a hypothesis and seek instructor guidance as required, until they solve the presented problem. During this process, the students are productively building on their knowledge base through collective and individual clinical reasoning and critical thinking skills. A study conducted by Vittrup and Davey (2010) found that a group-based learning approach promoted critical thinking, clinical judgment and knowledge-acquisition skills.

Successful implementation of problem-based learning entails designing a learning environment that stimulates constructive, self-directed, collaborative and contextual learning. It should also foster the ability to work as a member of a group and collaborate effectively with others (Kong et al 2014). It is important that students are exposed to, and provided with, many opportunities to develop and practise their clinical reasoning and problem-solving skills in the classroom setting. The problem-solving scenarios should reflect the students' level of theoretical knowledge and clinical exposure and develop from non-complex to more complex case studies.

## CRITICAL THINKING EXERCISE 16.3 A non-complex problem-based learning scenario

Students were given these instructions during class.

In groups of four, read each step carefully. Before moving on, consult with your facilitator at the end of each step.

Step 1: Acute cerebrovascular accident (CVA) assessment

Miss Maureen Smith, a 65-year-old, is admitted to the medical ward at 0700 following an acute right CVA. She has a history of arthritic pain in her knees and both feet. She also lives with myopia. She wears corrective lenses.

1. Explain your understanding of the medical terms.
2. Name four aspects of monitoring that may be required in the acute phase and provide a rationale.
3. Describe why a CVA occurs and list possible complications of a CVA.
4. Formulate a list of questions that you would need to ask Maureen Smith or her family.

Step 2: Rehabilitative assessment

Maureen Smith has remained stable for 72 hours. She has been assessed by the rehabilitation team as stable and therefore will now commence rehabilitation. Maureen has a right-sided hemiparesis with neglect, and is currently prescribed a texture-modified diet for a dysphagia.

1. What are the three standard levels of texture-modified diets and corresponding thickened fluid regimens?
2. What are some of the neurocognitive deficits commonly associated with right-sided CVAs?

Step 3: Nursing care plans

Review Nursing Care Plan 16.1 which provides an example of a nursing diagnosis relevant to the rehabilitative phase. For the nursing diagnosis, planned interventions are listed with rationales. Develop additional nursing care plans for other nursing diagnoses, then list appropriate interventions, rationales and means of evaluation for the following assessments:

1. Assessment: Left-sided hemiparesis with neglect secondary to R CVA, history of myopia.
2. Issues/s to be addressed: Difficulty negotiating environment safely due to stroke-related deficits of hemiparesis and neglect and long-standing myopia.

   Goal/s: Enable Maureen to negotiate immediate environment safely.

1. Assessment: Dysphagia with hemiparesis.
2. Issue/s to be addressed: Risk of aspiration due to impaired swallow reflex and hemiparesis.

   Goal/s: To minimise risk of aspiration while maintaining optimal nutritional and hydration status.

3. Assessment: Hemiparesis, arthritis in knees, feet. Decreased strength and exercise intolerance due to deconditioning associated with period of acute illness.

Goal/s: To improve from current level of strength and deconditioning which will be evident in functional level.

Step 4: Report

Prepare your case study to present to the class for further discussion.

Problem-based learning provides a safe way for students to learn how to make high-risk decisions and teaches them to use and fine tune their critical thinking skills in the new context of clinical reasoning (Russell et al 2011).

The nursing care plan and related progress note entry below provide examples of a care plan developed in the rehabilitative phase following an individual's cerebrovascular accident (CVA). The individual has a right-sided hemiparesis with neglect and they are currently prescribed a texture-modified diet for a dysphagia. The nursing care plan provides a practical example of critical analysis, reasoning, judgment and decision making in action. These skills are applied to the health problems identified following assessment of the individual's needs (see Nursing Care Plan 16.1 and Progress Note Example 16.1).

## NURSING CARE PLAN 16.1

**Assessment:** Arthritis in knees and feet, left-sided hemiparesis with neglect.
**Issue/s to be addressed:** Difficulty mobilising due to painful lower limb joints and muscle weakness of left limbs.
**Goal/s:** Maureen will be able to mobilise with less difficulty.

| Care/Actions | Rationale |
|---|---|
| To implement regular pain charting and report to medical officer in order to optimise current regular analgesia | Analgesic requirements will have changed from usual management regimen due to current immobility of joints. Pain charting supports objective assessment of analgesic need |
| Provide two-person assistance with mobility at all times. Increase occasions of mobility from two to three times per day | Supported mobility will maintain Maureen's safety given current level of dependence. Increase in mobility level will assist to regain previous range of movement in joints and strengthen muscles |
| Assist Maureen with active assisted lower limb exercises as prescribed by physio, while lying down or sitting out | Maintaining movement in the limbs can help prevent muscle contractures and stiffness |

**Evaluation**

Maureen reports more ease in mobilising. Pain charting demonstrates more consistent pain control.

## PROGRESS NOTE EXAMPLE 16.1

| | |
|---|---|
| 25/11/2015<br>1400 hrs | Nursing: Maureen continues to tire quickly after hygiene and assisted walk of 50 metres, refusing opportunity for assisted walk after lunch. Maureen tearful as knocked water jug off bedside table at lunchtime, as a result of neglect. Pain chart indicates pain management regimen is effective at present. Maureen informed me her usual pattern prior to stroke was to always have an afternoon walk. Agreement with Maureen that we shall assist her with her exercises in the morning, then shorter walk after lunch, leaving the longer walk for the afternoon as is her usual pattern. Await physio feedback on goal of moving to three walks per day. Prior to each meal, prompt Maureen to scan the environment in order to: establish routine practice which will reduce risk of accidents, enable movement of required items to the left and aid her independent functioning.<br>***B. Mawhill*** **(Mawhill) RN** |

### CRITICAL THINKING EXERCISE 16.4

Recall recent problem-based learning exercises in class that you have participated in. Have you challenged the assumptions of others in the group? Have you offered alternative perspectives or contradicting knowledge? Consider your level of active participation in the exercises and reflect on the reasons influencing your level of engagement.

# REFLECTIVE PRACTICE

## Becoming a reflective practitioner

There are many occurrences in a person's life that provide potential sources for reflection. **Reflective practice** is a systematic and thoughtful activity that enables individuals to make sense of experiences and phenomena then make changes, if appropriate, for future situations. An integral component of reflection in nursing practice is that it will involve some kind of clinical reasoning to arrive at an outcome or resolution. Reflection is a conscious, dynamic process of thinking about, analysing and learning from a clinical experience, enabling the nurse to gain insight into self and practice (Asselin 2011).

Cognitively, a **reflective practitioner** starts with a 'clean slate' to critically examine the 'when', why', 'what' and 'how' of themself, a situation or clinical problem, which may lead to other questioning styles to elicit further information or understanding. In reflecting on a clinical problem the nurse would consider: 'What was the nature of the problem?', 'When did the problem happen?', 'Who was involved?' and 'Why did the problem occur?'

For self-reflection, the nurse recalls from a personal perspective, asking questions such as: 'What was my reaction to the situation?', 'Why did I react this way?', 'How do I feel about the situation?', 'What do I think about it now?' and 'What can I do to change these feelings?' Reflective practice enhances the nurse's ability to identify their knowledge deficit, generate knowledge from the experience and systematically arrive at new insights, with the potential for improvement and change. Reflective practice is the process of drawing pertinent information from past experiences, then using that knowledge to guide the current practice and related decisions (Walton 2014).

## Barriers to reflection

For beginning practitioners, it is worth acknowledging the barriers to reflection so as to minimise the impact on your

learning. The use of writing to record the account of practice upon which to base the reflection is considered 'gold standard'. Varying written formats have been used, ranging from a narrative account through to mind mapping in conjunction with care plans. There are also several models of reflective practice that can be used. Using a model can assist the practitioner to engage in the practice. The selection of model should be based on individual preference. Individuals may feel drawn more to one than another that assists them to learn. Making time, especially time that is not too disconnected from the event as to interfere with recall, is recognised as important to the usefulness of the activity.

Incorporating the habit of reflective practice into your professional behaviour from an early stage is advantageous. Clinical reasoning skills are also important to the process. Therefore, it is often useful for the practice to be reinforced through supervision, professional development forums and persistence in mastering the practice (Olarerin 2013).

## Types or phases in reflection

Nursing curriculums expose students to a vast array of theoretical knowledge which they must be able to apply to clinical practice if they are to be truly professional nurses. There are different types of knowledge which in turn influence the approach or phases in the reflection process. An understanding of knowledge is taken from Habermas's (1972) critical social theory, which describes knowledge in terms of empirical, interpretive and critical models.

Empirical knowledge, as the name suggests, has been scientifically tested or researched and claims to be predictive or not happening by chance. Interpretive knowledge is the human or personal experiences, values and judgments about how we feel and think and is said to be a true account from that person's lived experience. Critical knowledge is also referred to as emancipatory as it is seen to free individuals or groups from oppressive conditions and give them the consciousness to view the world from a different perspective or understanding.

The phases in reflection are closely aligned to these domains of knowledge and are focused on reflecting on professional practice situations in three phases: descriptive phase, reflective phase and critical (emancipatory) phase. (See Clinical Interest Box 16.3.)

In nursing the first descriptive reflection phase provides an account of actions, thoughts and feelings of the clinical situation. The second reflective phase is analysed at three levels: reflection against standards, reflection on the situation and reflection of intentions. The third and final stage of reflection is the critical phase which is focused on identifying changes that need to be made to correct any gaps in knowledge or competency (Asselin 2011; Kim et al 2010).

## Professional practice reflective journal

A **professional practice reflective journal** is a narrative account of the nurse's experiences and feelings towards those experiences, and is often referred to as a log or a diary. Other methods of recording experiences may be through the media of audio recording, or drawings or other forms of creative expression.

### CLINICAL INTEREST BOX 16.3 Phases of reflection

- Descriptive phase: setting the scene
- Reflective phase: against standards, on situations and intentions
- Critical phase: focused on identifying changes to practice, gaps in knowledge and competency.

*(Asselin 2011; Kim et al 2010)*

Most nursing education programs prescribe the use of recording experiences in the written form and these are used as an educational tool to review students' progress and identify problems they may have in meeting educational requirements. For the individual, the written record provides an opportunity for review at a later date to learn more about themselves and their skills, values, beliefs and attitudes.

The written word, like a camera, captures the 'moment' and yields snapshots which the nurse can interpret and learn from when reviewing what has been written. It is important that the recordings be made as soon as possible and at least daily and that they tell a story of events, situations and feelings.

It is important to encourage nurses to look at both positive and negative feelings, situations and/or outcomes. Reflection on both can promote professional growth, problem solving and development of knowledge from practice, and can potentially improve practice through changed behaviours (Asselin 2011). (See Case Study 16.1.)

The recording of experiences and feelings provides the nurse with an opportunity to be continually asking probing questions and to be prepared to move out of their comfort zone. The questions a nurse asks themself about a clinical practice situation are constructed around the phases in reflection: that is, descriptive, reflective and critical phases which are individually or collectively **reflection on practice**.

The more exposure a nurse has to educative methods of critical thinking, problem-based learning, reflection and clinical practice, the better their skills in reflective writing will become. The nurse should be encouraged to view reflective practice as a journey of discovery until they have gained as much insight as they can from the situation or experience.

In preparing for reflective writing the student commences with the descriptive phase of reflection, a pure description of an event that sets the scene. Some questions that may facilitate reflection include: 'How do you feel about the situation?', 'How do your feelings relate to any action?', 'If you "step back" from this, does it look different?' (Kowalski 2010).

For the reflective and critical phases of reflection Kim and colleagues (2010) provided examples of questions that will assist in the writing of reflection on practice in the professional practice reflective journal. Examples of questions in reflective phase are set out in Clinical Interest Box 16.4 and questions for the critical phase in Clinical Interest Box 16.5.

## CASE STUDY 16.1 Professional practice reflective journal entry

Emma was excited to be working in the cardiac ward. She expected she would be caring for people who were acutely unwell and assisting and learning about the monitoring of cardiac issues.

Saturday entry

For the past week I have been working in the cardiac ward. The individuals there range in age, I have seen some really interesting presentations and have been working closely with the Registered Nurse caring for people who are acutely unwell. Today, we had a busy morning, with one person quite unstable which had been taking a lot of the Registered Nurse's time, another person was recovering from a valve repair surgery earlier in the week and I had been discharging another post angiogram. At the same time, we had admitted another lady on transfer from the oncology unit, she was elderly. Apparently she had experienced some atrial fibrillation over the past 24 hours. When she arrived on the ward she had quite a lot of family in tow as well as the admitting doctor. The RN and I set the lady up on the monitor, raced through the admission paper work and settled her in her room. She seemed anxious and wanted the commode and assistance to use it. Thinking back now, maybe I looked rushed or impatient, because when the lady was finished she apologised to me for being a nuisance. Then the family said to me that she has been experiencing urgency associated with her bowels and she is anxious about being incontinent. They reinforced with me that she can't help this need. I do remember feeling frustrated when the lady had asked for assistance with her personal hygiene. At the time, I was pre-occupied with the other issues and work that had to be done, and I was probably making judgments in my head about the lady being older while we had younger people in need. Also, this is a cardiac ward, so I felt we had more important care to be attending then helping people with their toileting all shift, why was she in the cardiac ward if she has more pressing medical needs? I think I shall speak to my preceptor about this, we are due to touch base on Monday.

Monday entry

Wow, spoke to my preceptor today about the lady and toileting issues on the weekend. We reviewed the lady's file and I realise I wasn't really focusing on the whole picture. Although she had acute cardiac issues, she also had been receiving treatment for a bowel obstruction secondary to her cancer which was also being treated! I now see that I can't really separate one health issue from the whole person! Furthermore, each of those conditions would be impacting on the other. Secondly, I have been reflecting on what attitudes are leading me to think the younger peoples' needs should take priority over older peoples. In future I intend to maintain focus on the rights of each person—if I don't maintain awareness, I could potentially be influenced by other discriminating judgments as well as ageism. Such mindlessness would not support me to be there for those I am caring for. That is what I shall now practise, truly 'being present' with each person at the time I am attending them.

**Emma, Enrolled Nursing Student**

Describe how using a reflective practice journal can enhance individual care.

## CLINICAL INTEREST BOX 16.4 Professional practice reflective journalling

Examples of questions in the reflective phase:

- What did I believe guided my actions (or inactions)?
- What do I think guided my actions as I think back now?
- What knowledge informed my actions?
- Did I possess the knowledge required in this situation?
- What sorts of values or ethical standards guided my actions?
- Were my actions harmonious with the situation? How so?
- What aspects of the situation influenced my actions?
- Were my intentions in agreement with the person's goals?
- Why did I carry out the actions in the way I did?
- Did I get the outcomes I wanted in this situation?

*(Asselin 2011; Kim et al 2010)*

The intended outcomes of reflection are not only that the nurse gains an understanding of gaps in their knowledge but also that they examine their nursing practices to ensure provision of competent contemporary nursing and that they learn from the experience. An example of how a nurse may document reflection on practice is provided in Table 16.1.

## CLINICAL INTEREST BOX 16.5 Professional practice reflective journalling

Examples of questions in the critical phase:

- Did I use this knowledge appropriately?
- Do I need to revise my knowledge base?
- What were the critical factors that got in the way of doing a better job, and why?
- Do I need to rethink my values and attitudes?
- What have I learned from the situation?
- How could I change my practice in the future?

*(Asselin 2011; Kim et al 2010)*

**TABLE 16.1 | The phases of the clinical reasoning process with examples**

| Process | Description | Example |
|---|---|---|
| Consider the person's situation | *Describe* or list facts, context, objects or people | This 60-year-old gentleman is in ICU because he had an abdominal aortic aneurysm (AAA) surgery yesterday |
| Collect cues/ information | *Review* current information (e.g. handover reports, history, charts, results of investigations and nursing/medical assessments previously undertaken) | He has a history of hypertension and he takes beta-blockers<br>His BP was 140/80 an hour ago |
| | Gather new information (e.g. undertake assessment) | I've checked his BP and it is now 110/60, Pulse 110, Temp 38°. Epidural running @ 10 mL/hour |
| | *Recall* knowledge (e.g. physiology, pathophysiology, pharmacology, epidemiology, therapeutics, culture, context of care, ethics, law etc) | BP is related to fluid status<br>Epidurals can drop the BP because they cause vasodilation. In ICU we have standing orders for epidural management |
| Process information | *Interpret*: analyse data to come to an understanding of signs or symptoms. Compare normal vs abnormal | His BP is low, especially for a person who is normally hypertensive |
| | *Discriminate*: distinguish relevant from irrelevant information; recognise inconsistencies, narrow down the information to what is most important and recognise gaps in cues collected | His temp is up a bit but I'm not too worried about it—I'm more concerned about his BP and pulse<br>I'd better check his urine output and his $O_2$ saturation |
| | *Relate*: discover new relationships or patterns; cluster cues together to identify relationships between them | His hypotension, tachycardia and oliguria could be signs of impending shock<br>His BP went down after we increased the epidural |
| | *Infer*: make deductions or form opinions that follow logically by interpreting subjective and objective cues; consider alternatives and consequences | His BP could be low because of blood loss during surgery or because of the epidural |
| | *Match*: current situation to past situations or current experiences to past experiences (usually an expert thought process) | AAAs often have hypotension post op |
| | *Predict*: an outcome (usually an expert thought process) | If I don't give him more fluids he could go into shock |
| Identify problem/ issue | *Synthesise* facts and inferences to make a definitive diagnosis of the person's problem | He is hypovolaemic and the epidural has worsened the BP by causing vasodilation |
| Establish goals | *Describe* what you want to happen—a desired outcome, a time frame | I want to improve his haemodynamic status—get his BP up and urine output back to normal over the next hour |
| Take action | *Select* a course of action between different alternatives available | I will ring the doctor to get an order to increase his IV rate and to give aramine if needed |
| Evaluate | *Evaluate* the effectiveness of outcomes and actions. Ask: 'Has the situation improved now?' | His BP is up for now but we will need to keep an eye on it as he may still need aramine a bit later.<br>His urine output is averaging >30 mL/hour now |
| Reflect on process and new learning | *Contemplate* what you have learnt from this process and what you could have done differently | Next time I would ...<br>I should have ...<br>If I had ...<br>I now understand ... |

*(School of Nursing and Midwifery University of Newcastle 2009)*

### CRITICAL THINKING EXERCISE 16.5

Think about what reflection means to you. How would you define reflection and to what extent do you consider reflection has enhanced your practice?

### CRITICAL THINKING EXERCISE 16.6

Think about any incident that happened while caring for a person, or interacting with a work colleague. Work through the descriptive, reflective and critical phases of reflection of the incident and provide the answers to these questions:

1. What was the nature of the problem?
2. Where did it happen?
3. What were your thoughts, perceptions and feelings?
4. What aspects of the situation influenced your actions?
5. What do you think guided your actions as you think back now?
6. What would you do differently if the problem occurred again, and why?

## Summary

This chapter has introduced the concepts and processes of critical thinking, problem-based learning and reflective practice. The student should now be aware of, and stimulated to pursue, these forms of inquiry in all aspects of everyday learning and nursing practice. The nursing profession and people accessing healthcare deserve and demand excellence in nursing care and healthcare delivery that is critical in its approach and contemporary by nature. This critical and contemporary approach cannot be provided unless the nurse has the attributes, skills and knowledge to reflect on their practice and be prepared to take steps for change to occur.

## Review Questions

1. Discuss your understanding of critical thinking and how it differs from 'thinking'.
2. Outline your understanding of clinical reasoning.
3. Describe the relationship between the nursing process and critical thinking.
4. Provide an example of questions that may be used in the three (3) phases of reflection.
5. List some health education methods that assist in developing critical thinking skills.
6. Discuss your understanding of problem-based learning.
7. Describe the process taken by students during problem-based learning in the class setting.
8. Discuss your understanding of the relevance of critical thinking, problem-based learning and reflection to your nursing practice.
9. Explain what a professional practice reflective journal is.

Answer guide for the Review Questions, Critical Thinking Exercises, Decision-Making Framework Exercises and Critical Thinking Questions in Case Studies are hosted on Evolve: http://evolve.elsevier.com/AU/Koutoukidis/Tabbner/

CHAPTER 17

# Nursing process: framework

*Gillianne Meek*

## KEY TERMS

assessment
clinical judgment
clinical reasoning
critical thinking
evidence-based practices
interventions
nursing care plan
nursing interview
nursing process
objective data
SMART goals
subjective data

## LEARNING OUTCOMES

At completion of this chapter and with further reading, students should be able to:

- Define key terms
- Discuss the five steps used in the nursing process
- Explain the principles of care planning using the nursing process as a framework
- Explain the benefits of involving the individual in planning their care
- Describe the process for carrying out a nursing interview
- Differentiate between subjective data and objective data
- Identify how critical thinking and clinical reasoning are used to identify actual and potential issues
- Use clinical judgment skills to develop and implement care plans that use Specific, Measurable, Achievable, Realistic, Time-bound (SMART) goals
- Incorporate evidence-based practice into nursing interventions

## CHAPTER FOCUS

The nursing process is an organised step-by-step approach that creates a framework for nurses to use as the basis for a person's care plan. It is universally adaptable and can be used in a range of clinical settings such as acute care, long-term care and in the community. Through a process of using critical thinking skills, nurses are able to identify actual or potential issues and to develop a nursing care plan utilising the five dynamic and interrelated components of the nursing process. The use of clinical reasoning skills supports nurses with the process of collecting objective and subjective data about the person, while the use of evidence-based clinical judgment informs the nursing actions and care nurses should implement and evaluate. The components of the nursing process are assessment, identification, planning, implementation and evaluation. This chapter examines the five components of the nursing process and uses real-life examples to illustrate how nurses can use the framework in a systematic and methodical manner.

## LIVED EXPERIENCE

I was really excited when I found out my next practicum placement would be on the surgical admissions unit (SAU). I knew that the SAU admitted people on the day of their surgery. Some people would return post theatre to the SAU if it was minor surgery and would be discharged from there later that day, while others would be transferred to a main ward after their surgery. When I went to the SAU to collect my roster, I met Louise, the RN who I would be working with. She told me that many of the admissions we would be nursing would be for the endoscopy unit and that it would be a good idea to read up on those procedures.

**Una, Enrolled Nurse Student**

## AN OVERVIEW OF THE NURSING PROCESS

The **nursing process** (an organised step-by-step approach that creates a framework for nurses to use as the basis for a person's care plan) provides a structured framework of nursing actions. It is comprised of five interrelated components that follow on in a step-by-step cyclic manner. Each of the components requires the nurse to use **critical thinking** skills (a process-driven way of thinking which uses problem solving techniques and reflective practice to make reasoned judgments that support clinical decision making) to collect, review and validate the amassed data. By using **clinical reasoning** skills (a dynamic process used by nurses to collect the right information to allow them to understand the clinical situation and plan effective nursing actions) and **clinical judgment** (the ability to make an informed decision about nursing actions based on observations, analysis of data, reviewing alternatives and reflection) nurses are able to plan, implement and then evaluate the effectiveness of their nursing interventions. The data collected through the nursing process is used to formulate a nursing care plan. The **nursing care plan** is a legal document which records all pertinent interactions the nurse has with the person and follows the five steps of the nursing process: assessment, identification, planning, implementation and evaluation. Significantly, the care plan is developed, negotiated and evaluated in collaboration with the individual who is receiving the nursing care. This person-centred care approach considers the individual as a whole person and promotes individual autonomy, control and decision making (Fawcett & Rhynas 2012).

The nursing process is both continuous and cyclic, with each step reliant on the step preceding and the step following. At the centre of the process is the person. Figure 17.1 is a diagrammatic representation of the nursing process.

### CRITICAL THINKING EXERCISE 17.1

If you were Una from the Lived Experience feature, how would you research about endoscopic procedures? What different types of endoscopic procedures are there? What is the nursing care required for individuals after undergoing an endoscopic investigation? For a person coming for day surgery, what specific assessment questions related to the admission would you ask?

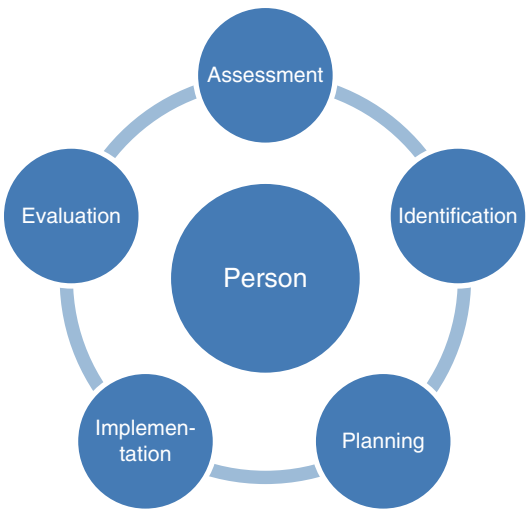

**Figure 17.1** Components of the nursing process

## ASSESSMENT

**Assessment** is the first component of the nursing process and the first step in developing a care plan. Assessment is the process of obtaining data about an individual with the purpose being to:

- create a baseline set of data about the individual
- better understand the condition and circumstances of the individual
- identify actual and potential issues
- identify required nursing interventions
- develop a therapeutic relationship with the individual.

The data may be obtained directly from the person, from others of significance to them, from other members of the health team and from the person's past or present medical and nursing records. This data needs to be actual, factual, complete and relevant in nature. It may be either subjective or objective.

**Subjective data** includes the person's unique perceptions, ideas, experiences and sensations about an issue that they share with the nurse. For example, a person may supply information about their sensations of pain in their lower abdomen; they may say it feels as if it is gripping or burning and that it is increasing in intensity.

**Objective data** consists of information that can be observed or measured directly by the nurse. For example, while a person may report the location and intensity of abdominal pain (subjective data) an increase in blood pressure, pulse and respirations recorded by the nurse provides measurable objective data.

Several different methods can be used to obtain both subjective and objective data, including interviewing the individual, carrying out a physical examination and observations and reviewing laboratory and diagnostic tests. However, the process usually commences with the nurse initiating an interview with the person. A **nursing interview** is the process used by nurses to obtain physical data, along with health and social information from a person in a structured and comprehensive manner. It includes aspects of physical assessment and a health history. If the nurse is able to, they should make themselves as familiar as possible with the person's past and current nursing, social and medical history. The nurse should review the latest laboratory and diagnostic results, as these could help guide the assessment interview and can provide additional prompts for the nurse when talking with the person.

Most importantly, the nurse should work towards establishing an effective therapeutic relationship with the person, which enables them to build trust in the nurse and the healthcare organisation. By adopting a person-centred approach, the nurse works with the person as a partner. This partnership approach is based on mutual respect and a sharing of power. It is underpinned by the person being actively empowered and supported to make informed decisions about their healthcare. Chapter 19 provides further reading on general health assessment.

### CRITICAL THINKING EXERCISE 17.2

Robert is 55 years old and has had a productive cough for several months. An x-ray showed a suspicious area in his left lung that requires a biopsy. In preparing Robert for being admitted to the SAU for a bronchoscopy the following day, Una printed off the latest set of blood test results for him. She notices one of the tests was for an $HbA_{1c}$ test. What does this blood test tell us? How can this information be used by Una as part of carrying out her nursing interview with Robert? What additional factors should Una be considering in nursing Robert?

### The nursing interview

The aim of a nursing interview is to talk with the person and/or their significant other(s) in a structured manner so that a comprehensive nursing history can be obtained. Nurses must obtain consent from the individual for the interview to go ahead and the person must be informed why and how the information is to be gathered and used. Ensuring patient confidentiality is essential, along with their rights to privacy when the interview is taking place and to withhold information they do not wish to share. The nurse must ensure the person gives consent to having a third person present during the interview, as there may be questions of an intimate nature that the person does not want discussed or disclosed in their presence.

The information gained through undertaking a nursing interview enables the nurse to initiate a plan of care, one that can be developed to meet the unique needs of the person. The information gained is documented and used as part of the data collection. Good quality nursing documentation has both legal and practical implications for nurses. The ability to write in a succinct, clear and legible manner reduces the risk of adverse outcomes due to misinterpretation and poor communication (Blair & Smith 2012).

How this data/information is recorded is determined by the individual healthcare facility. For example, it could be through pro forma documentation or direct input into a computer-based patient management system (PMS) or electronic medical record (EMR). (See Chapter 5.)

Through the use of effective interviewing skills, the nurse is able to obtain information about the person's current and past health problems, their lifestyle, activities of living and their psychosocial history. A nursing history centres on the person's description and interpretation of their physical, psychological and emotional reactions to their healthcare needs and on the resultant actual and potential changes to their lifestyle. The answers a person gives may prompt the nurse to ask further exploratory questions so that a complete picture of the person may be obtained. The answers a person provides may also direct the nurse to provide health education information or to make a referral to another health professional (McKenna et al 2011).

A nursing history:

- Requires the nurse to use critical thinking and problem solving skills to ask the right questions to the person
- Requires the nurse to listen closely to the person's responses and to use clinical reasoning skills to guide how the information gained is then used to probe and ask additional questions
- Establishes baseline data from which the nurse can identify actual and potential issues as the foundation for the care plan
- Forms the basis for a therapeutic person-centred relationship with the person
- Allows the nurse to make a holistic assessment of the person that utilises verbal and non-verbal communication perspectives (e.g. the use of the sense of smell or touch)
- Gives individuals an opportunity to talk about any health issues
- Assists the person in revealing any past, present and family issues that may require nursing intervention
- Forms a collection of data and information about the person's physical, functional, social, psychological, spiritual and emotional state
- Identifies environmental and lifestyle factors which influence the person's wellbeing.

A nursing history should be obtained as soon as possible after the person is admitted to the healthcare agency and should be conducted, when feasible, by the nurse with primary responsibility for planning the person's care. A culturally sensitive approach needs to be taken and the nurse should reflect on any cultural considerations; for instance, the person may want to be accompanied by their partner or other family members and have them remain with them throughout their healthcare journey. Chapter 21 of this book covers admission, discharge and transfer processes.

Before beginning the interview the nurse must explain its purpose so the person can understand why certain questions will be asked. The interview setting should be quiet and private for the person to feel comfortable about discussing personal details. If a person is unable to communicate effectively an appropriate aid must be utilised. This may include the use of an interpreter or communication aids such as visual cues and writing pads. If an interpreter is required, this must be arranged prior to the nursing history being obtained; it is not acceptable practice to rely on family or friends to do the interpreting as this may breach confidentiality. It is valuable to record on the nursing assessment form what aids were utilised to obtain the assessment information so that other staff are aware of the need to utilise these in future interviews. It is important to take the time to accurately and comprehensively document all aspects of the nursing history/assessment as this helps to meet legal and professional standards, demonstrates nursing accountability and facilitates quality nursing care (Blair & Smith 2012).

The process of history taking will vary depending on the age of the person. It is usual for a parent or other adult to provide information for a young child, but older children may be able to give their own factual account. It is essential for the nurse to use terminology that the child can easily understand. Additionally, questions about reaching milestones and immunisations should be included. The nurse needs to be mindful of the needs of older people who may have sensory deficits such as loss of hearing or vision. The seating arrangements during the interview should allow the nurse to position themself so that the person can both hear and see clearly what is happening.

It is essential that any information obtained during the interview is documented accurately and concisely, as the nursing assessment form is a legal document that needs to be retained for future reference together with other documentation. The basic information, which should be obtained in a nursing history, includes:

- Personal demographics, age, gender, marital status, next of kin or significant other(s), preferred name of address
- Reason for requiring medical/nursing intervention and the person's understanding of why they are there
- Past and current medical history, including any age-appropriate questions such as immunisation status for children
- Cultural considerations such as dietary requirements, the use of traditional healing practices and specific religious practices
- Current medications and treatments including any allergies
- The use of any aids or prosthetics
- Baseline information regarding their normal level of ability to carry out the physical activities of daily living (breathing, eating and drinking, maintaining a safe environment, communicating, eliminating, personal hygiene and dressing, controlling body temperature, mobilising, expressing sexuality, working and playing, sleeping and concerns about death and dying)
- Social data including accommodation and home circumstances, education, occupation, religion
- Psychological, emotional and spiritual wellbeing
- Personal habits including alcohol usage, smoking or the use of illegal drugs.

## Open and closed questions

Effective communication skills are particularly important in taking a nursing history and consideration must be given to the type of questions being asked (Thornbory 2013). Table 17.1 gives some examples of open and closed questions. Open questions invite the person to divulge a wide range of information and to describe how the person is feeling, why they are there and what happened. They promote the development of a therapeutic relationship. While it is not a direct question, starting a question with the phrase 'Tell me about . . .' is a good way to prompt open discussion. Closed questions often require a single word reply or brief answer. They do not encourage the person to disclose information but can be useful when you need specific information. See Chapter 8 for further reading on communication.

**TABLE 17.1 | Open and closed questions**

| Questions | Expected responses | Open/closed |
|---|---|---|
| Are you in pain? | Yes, I am in pain | Closed |
| | No, I am not in pain | Closed |
| **What** do you mean when you say you are in pain? | I mean I have a dull ache that I can feel in my left shoulder and across my upper back. It has been there for more than a week | Open |
| **How** are you feeling about having your surgery today? | I'm anxious; I just wish it was over with | Open |
| Are you prepared for your surgery? | Yes | Closed |
| | No | Closed |
| Do you take aspirin? | Yes | Closed |
| | No | Closed |
| **What** medications do you take? | I take aspirin every morning when I have my breakfast and medications for my blood pressure. I have a list of my tablets here with me | Open |
| Are you concerned about your health? | Yes | Closed |
| | No | Closed |
| **Why** have you come to the clinic today? | I've been having pain in my knee for several weeks and I am concerned as it is appears to now be swollen | Open |
| **Tell me** about your previous hospital admission | I was admitted last year with abdominal pain and had surgery for appendicitis. This was in July | Open |

## Physical examination and observation

Traditionally medical officers have been the profession who would perform the initial assessment and physical examination of individuals. They would use this information to make a medical diagnosis and to determine the most appropriate course of treatment (Fawcett & Rhynas 2012). As the profession of nursing and nursing practice has evolved, increasingly this is being carried out by nurses (Anderson et al 2013) as part of a holistic person-centred approach to healthcare delivery.

A physical examination uses the techniques of inspection, palpation, percussion and auscultation to detect any abnormalities that may provide information about the person's current or past health history. This information is recorded in the person's nursing notes and may be used in conjunction with the evidence gained in the nursing interview, as the foundation for identifying health issues, developing SMART goals and the planning and implementation of nursing care (see section Creating SMART goals later in this chapter).

As part of the physical assessment of the person, a set of baseline observations or vital signs need to be recorded. Nurses have traditionally carried out observations which include blood pressure, pulse, temperature, respiratory rate and oxygen saturation to assess their patients (Elliot & Coventry 2012); however, depending on the reason for the assessment, the nurse may also record the person's height and weight, test and record urinalysis results and measure blood sugar levels. Having an accurate weight recorded for a baby or young child is especially important as many drug doses are calculated based on body weight. Body weight is also an important factor when a person is having a general anaesthetic, or to achieve a therapeutic dose of some medications.

Observation of the person is performed by the nurse during the interview and requires a head-to-toe assessment. This relies on the nurse using all their senses to pick up information about the person. This could include the sense of smell picking up evidence of urinary incontinence or an infected wound or the sense of touch if a person feels hot, cold or clammy.

### Clinical pathways and standardised care plans

Some healthcare agencies use clinical pathways or standardised care plans as a communication tool between healthcare clinicians. A clinical or care pathway is a document which outlines a standardised, evidence-based multidisciplinary management plan. A standardised care plan is used in much the same way and can be used with people with the same diagnosis, similar treatments or similar nursing issues; however, it can be individualised to meet specific needs (Jakobsson & Wann-Hansson 2013). The purposes of using

standardised documentation are to reduce discrepancies, enhance the quality of care provision, promote safety and user satisfaction, support interdisciplinary integrated care, improve health outcomes and optimise resource utilisation (Beaulieu 2013; Schrijvers et al 2012). A clinical pathway identifies the appropriate sequence of clinical interventions, timeframes, milestones and expected outcomes for people. As there will always be exceptions, the pathway should be followed in accordance with the clinician's assessment of each individual case. A process for charting by exception should be in place. Charting by exception involves the nurse only charting significant findings or exceptions to the standards or norms of the predicted care pathway for the person. See Chapter 42 for further reading.

## Cultural considerations care planning

With an increasingly diverse cultural population for nurses to care for, the ability to deliver care in a culturally safe and appropriate manner becomes vital if successful healthcare engagement is to be achieved. Culture influences all aspects of health and wellness behaviour so that having an understanding and awareness of our own cultural beliefs is vital for every nurse to ensure the best possible healthcare outcomes (Nardi et al 2012). Culture can be defined as the shared values, beliefs, customs and social norms that characterise the everyday structure of a socially defined group. This may be significantly different from the cultural norms of the nurse; however, for nurses to be able to carry out culturally safe nursing care, they need to acknowledge the potential impact of their own culture on their interactions with people from other cultures.

A cultural assessment allows the nurse to ask the person how they would like to be cared for based on their individual cultural beliefs. By doing this, it provides the basis for power sharing between the person and the nurse and acknowledges the value of diversity within the population. Nurses should have an awareness of a wide range of different cultures, but it is equally import that the nurse does not stereotype the person as part of the cultural assessment. For more information on cultural diversity see Chapter 10.

## Laboratory and diagnostic tests

Laboratory and diagnostic tests, which are the most objective forms of assessment data, provide another source of information about the person. Both subjective and objective data are required to create a comprehensive assessment. For example, during the nursing interview the person may reveal that they feel constantly tired (subjective data). The nurse visually observes that the person looks extremely pale (objective data) and the laboratory test results indicate that their haemoglobin level is below normal (objective data). In this situation, the laboratory results (low haemoglobin level) verified the personal feelings of the person (feeling tired) and the visual observations of the nurse (the person looks pale).

While it is usually the role of a medical officer to order laboratory and diagnostic tests, increasingly this is becoming part of advanced practice nursing roles, such as the nurse practitioner. A nursing role is to ensure that the person understands why they are having the test and to prepare and support them for the test. This may be by providing education or preparing them by keeping them nil by mouth for tests such as fasting blood sugar tests or some abdominal ultrasound scans.

Now that you have read through the documentation part of the chapter, review Case Study 17.1 that explores an admission scenario.

### CASE STUDY 17.1

Emma is an Enrolled Nurse working in an aged care facility. She has been asked to prepare for an unexpected admission. Mrs Taylor has had a fall and has fractured her right shoulder. She lives alone and can't manage, especially since she is right handed. She will be admitted for one week until her daughter can come and stay with her. She will be arriving later that morning. Emma has prepared her work plan for that morning and has a very busy morning. When Mrs Taylor arrives she is taken to her room and put into a chair. She is unsure of her surroundings and a little nervous. The room looks messy and the bed is not made. No one orientates her to the facility or the room.

When she arrives it is lunch time and she has not eaten since breakfast; unfortunately there is no lunch prepared for Mrs Taylor and although she is quite hungry she feels too intimidated to alert anyone. Later that afternoon her daughter arrives to find her mother in tears; she has not had any of her medications, she is very hungry and very distressed as she has wet her pants, being unable to find a toilet. Her daughter demands to speak with the manager and arranges transfer to another home the next day. She also lodges a written letter of complaint.

How could this admission have been' handled better to avoid this poor outcome for Mrs Taylor?

# IDENTIFICATION

The second component of the nursing process is the identification of issues related to the health situation. This involves using all the information gained at the assessment stage to identify actual or potential issues. These issues are from the person's perspective and are identified, discussed and constructed in collaboration with the person and the nurse.

Actual issues are those that the person is currently experiencing, whereas a potential issue is one that the person does not currently have but that may occur. By taking preventative actions, nursing staff can reduce the risk of potential problems developing into actual problems. This is especially important when people are unable to make those decisions themselves. This could be due to lack of knowledge about the risks or because the person is dependent on nursing staff. Once actual and potential issues are identified the nurse and the person can work together to plan the care that needs to be implemented.

### CRITICAL THINKING EXERCISE 17.3

Fred is 72 years old. Prior to being in a motor vehicle accident he was fully independent in all activities of daily living. Following orthopaedic surgery to his pelvis and legs he is non-weight-bearing and is being nursed supine in bed. What potential issues should nursing staff observe Fred for, given that Fred is immobile? What nursing action should be implemented to reduce the risk of any potential issues occurring for Fred?

### CLINICAL INTEREST BOX 17.1 SMART framework

One of the frameworks for setting goals is to use the acronym SMART, which stands for:
**S**pecific
**M**easurable
**A**ttainable/Achievable
**R**ealistic/Relevant
**T**ime-bound

## PLANNING

The third component of the nursing process is planning. After the actual and potential issues have been identified, the nurse needs to plan the care that is required to be implemented to achieve the desired outcomes. This is accomplished by setting person-centred goals, prioritising those goals, determining what nursing interventions are required to meet those goals and updating the care plan within a given timeframe.

### Creating SMART goals

Goal setting is a collaborative process in which nurses and the people to whom they are providing care work together to establish a desired outcome and create a workable plan so that this can be achieved in a timely and realistic manner. Goals establish the framework for a nursing care plan and are the stages that need to be met to reach the desired outcome (see Clinical Interest Box 17.1). Hence, for each identified issue the nurse, in conjunction with the person, sets the goals to be achieved. A short-term goal may be one that is expected to be achieved in a relatively short timeframe such as hours or days, while a long-term goal is one to be achieved in the future, perhaps in several weeks or months. Before a person is able to return to their normal state, short-term goals may need to be set to measure their progress towards returning to their normal level of functioning.

**SMART goals** are used to express behaviours that are observable and measurable: in that way it is easy to determine if the goal has been met or not within the given timeframe. By using SMART goals it is easy to establish when these goals are achieved. In a similar way, when goals are not being achieved they can be re-established between the person and the nurse. Goals are not achieved for a number of reasons, which may include the development of complications or unforeseen events.

### CRITICAL THINKING EXERCISE 17.4

After several weeks of being nursed in bed, Fred has been re-assessed by the medical staff and the physiotherapist. Fred can now begin the process of rehabilitation and regaining his mobility. What would be short-term and long-term SMART goals appropriate to Fred and his mobility issues?

### Prioritising goals

Priorities are established after specific goals have been set by grading them in order of importance. Basic physiological needs, such as the need for oxygen, nutrition or water, are given priority over the other needs. However, in using a person-centred approach to prioritising the goals, the nurse works with the person to establish which goals the person perceives as being of most importance and value to them after these most basic of needs. From this discussion, high-priority goals that require immediate attention take precedence over low-priority goals that may not need to be attained as quickly.

In working with people, nurses should always think that managing pain should be considered high priority. Setting a SMART goal to reduce pain to a tolerable level within a given timeframe is very important. This is because pain can have such a profound effect on many other of the activities of daily living, such as impacting on mobility, impairing psychological wellbeing, reducing appetite/nutritional wellbeing and reducing the ability to sleep and rest. Nurses should not underestimate the effect that being in pain has for an individual and should suggest a range of options to manage the pain.

### Determining nursing interventions

This step involves selecting the activities or **interventions** that are expected to help the person achieve the set goals, which in turn create the expected or desired outcomes. All possible options need to be discussed in consultation with the person, and time given for them to be able to make informed decisions about their healthcare needs. Sometimes at the request of the person these discussions need to be made in consultation with family members or significant others, so that they too are involved in the person's care. Critical thinking and good decision-making skills assist the nurse to select the most appropriate nursing activities or interventions to discuss with the people involved. Appropriate nursing interventions must be based on sound clinical judgment using an evidence-based practice approach to problem solving. **Evidence-based practices** are those that have been researched and shown to provide the best possible outcome for people. After a decision has been made by the person, in consultation with the nurse and sometimes with other members of the multidisciplinary team, the proposed actions or interventions to be implemented are formulated into statements and written in the nursing care plan. For example, one selected nursing activity may be for the nurse to assist the person to shower each morning.

All proposed nursing interventions must be written specifically and in adequate detail to enable all nursing personnel to carry them out correctly. Interventions may consist of activities that the nurse will perform or actions to be taken by the person with or without assistance from the nurse; however, all actions should be person- and outcome-focused.

### Nursing care plans

A nursing care plan is a document developed by the healthcare agency to record all aspects of the care the person requires. The structure of the care plan may vary between health agencies. Some agencies use paper records while others have computerised care plans, electronic medical records and patient management systems (PMS). Nurses need to be familiar with the nursing care plan and all other documentation used within the healthcare agency in which they are working. Nursing care plans form part of the person's healthcare records and can be requested and used in legal situations. Nurses need to adhere to the legal and ethical guidelines for documenting and remember that the clinical progress notes and care plan may be the only record of what care was given by the healthcare providers and can be the main source of evidence used in the investigation of complaints (Blair & Smith 2012). (For more information see Chapter 18.)

Nursing care plans may vary in structure but the basic principles remain the same. The nurse should be able to clearly identify:

- The issues relevant to the person
- The goals and expected outcomes
- The specific nursing interventions for each goal
- If the goals are being achieved (evaluation).

Some forms of nursing care plans use the headings of the nursing process and are set out in a table using columns. As mentioned previously, some health agencies are using clinical or care pathways which outline predetermined care plans, interventions and goals for specific plans of treatment and nursing care.

While the structure of a nursing care plan may vary between healthcare settings, the principles of care planning remain the same. A correctly formulated nursing care plan facilitates the coordination and continuity of care for the person. See Nursing Care Plan 17.1.

## IMPLEMENTATION

The fourth component of the nursing process is implementation. Implementation means putting the nursing care plan into operation by using nursing actions and interventions. This is the performance of selected nursing actions/interventions to help the person achieve the goals that have been set. These actions can include providing health education, wound care, catheter management, assisting the person with activities of daily living in which they are not independent, carrying on the work of other health professionals such as physiotherapists and the recording of specific observations (e.g. vital signs, pain score, blood glucose levels). All actions and interventions should utilise the most current evidence-based practices and be based on sound clinical judgment. Nurses need to ensure their clinical practice is up to date with any innovations in nursing care and that it incorporates policies, procedures and guidelines published by the healthcare provider they are employed by. Nurses are accountable for their decision making and clinical actions. They need to ensure that they are able to carry out any actions and interventions in a competent manner so that they do not place the person at risk or work beyond their capabilities or limitations. Quality nursing care is provided by nurses when they intentionally deliver evidence-based nursing care which is person-centred, based on sound clinical judgment and incorporates caring, patient advocacy and respect, while taking responsibility and being accountable for their actions.

The person's needs are reassessed continuously during the implementation stage so that any new needs can be identified and the nursing care plan modified or adapted to take these into account. As the person's condition changes, the nursing actions and interventions need to be reassessed and the care plan reviewed. This may mean that new goals and interventions are added to the nursing care plan and those that are ineffective may need to be modified. The process of implementation is closely linked with the final stage of the nursing process, evaluation.

## EVALUATION

The fifth component of the nursing process is evaluation of care. Once the planned nursing interventions have been implemented, the nurse must evaluate the results to determine whether the interventions were effective or not. Evaluation is the process of determining the extent to which the set goals have been achieved and the desired outcome obtained. It enables the nurse to monitor the effectiveness of the nursing actions, as documented in the care plan, and to determine if the care plan was a success or not. The success of the care plan can be determined by comparing the initial desired outcomes with those outcomes that were eventually achieved.

Evaluation requires an examination of the results of the interventions, assessing the person for possible side effects and adverse reactions to the nursing interventions and analysing the results. Analysis involves determining whether the person has improved, deteriorated or shows no change.

Based on the data obtained from the evaluation of the care plan, nurses use their clinical judgment to determine what actions or interventions are required next. Evaluation allows the nurse to revise and, if necessary, modify or change the plan at any stage. If the set goals have been achieved, the plan is deemed to be successful and the nursing interventions can usually be discontinued. If the goals have not been achieved, the person's needs must be reassessed, new nursing goals formulated and the care plan changed and re-implemented.

While evaluation is proposed as the fifth and final component, it is actually performed continuously throughout the nursing process. It is the most important method of determining the effectiveness of a nursing care plan. The effectiveness of a nursing care plan can also be determined by another

## NURSING CARE PLAN 17.1

**Assessment:** Nancy has commenced compression bandaging on her right leg as treatment for a venous ulcer on her shin. The bandaging will be managed by the Wound Nurse Specialist. It will be changed weekly at the local hospital.
**Issue/s to be addressed:** Potential issues with having compression bandaging can include the dressing becoming loose due to swelling subsiding, pinching caused by increased swelling, loss of sensation in any part of the leg, toes going pale or dusky and increased pain; however, increased pain can be common in the first week.
**Goal/s:** To provide education to Nancy on admission about the potential issues from compression bandaging and ensure that there are no issues arising between her weekly visits to the Wound Nurse Specialist.

| Care/Actions | Rationale |
|---|---|
| Provide education session with Nancy on admission and follow up as required, so that she is aware of any potential issues that can develop and the benefits of compression bandaging (Yarwood-Ross & Haigh 2012) | Providing education to Nancy means she will know what is important to report to the nurse if there are any issues with her bandages |
| Check compression twice daily for signs of slippage/ pinching or excessive exudate and document (Wounds International 2013) | Checking her toes daily for colour, warmth, movement and sensation allows the nurse to have an objective measure of how the circulation is for her foot/leg |
| Document twice daily colour, warmth, movement sensation (CWMS) in Nancy's toes | It is a legal requirement to document nursing actions and care and any changes can be an indicator that problems are developing |
| Encourage a high-protein diet to support wound healing | A high-protein diet encourages wound healing |
| Report any concerns directly to the Wound Nurse Specialist (Todd 2011) | |

**Evaluation**

On third day of admission the bandage was noticeably looser. The Wound Nurse Specialist was contacted and arranged to have the bandaging re-done later that day. The looseness was due to a significant reduction in swelling. By the end of the first week, Nancy thought her leg was much less painful and this was verified with her decreasing pain scores.

Nancy continued to have weekly visits to the Wound Nurse Specialist for the 6 weeks she remained in the care home. The wound documentation showed a decrease in the dimensions of the wound; however, it was anticipated the treatment would need to continue for at least 12 weeks. Nancy was discharged home to her unit after 6 weeks. There had been no further issues with the compression bandaging.

**Assessment:** Nancy states she has pain in her right leg caused by the wound on her right shin and the compression bandaging. Nancy says the pain is worse when sitting and improved when she has her leg elevated.
**Issue/s to be addressed:** Pain in right leg caused by the wound on her right shin, the compression bandaging. The pain is worse when sitting and improved when she has her leg elevated.
**Goal/s:** To reduce pain to a tolerable level within 24 hours of admission.

| Care/Actions | Rationale |
|---|---|
| Give prescribed regular analgesia and monitor the effectiveness (Anderson & Knight 2011) | Giving regular analgesia to Nancy prevents any peaks of pain caused by having no medication, and is a better approach to pain management. Using a pain scale is an objective measure of how much pain Nancy says she is in. It allows the nurse to know how effective the care and the analgesics have been |
| Observe for potential side effects including constipation | Some analgesia can cause constipation and as Nancy is not as mobile this could also add to the problem |
| Use a pain scale to evaluate the effectiveness of the analgesia (Wood 2004) | |
| Encourage Nancy to ask for her PRN medication (as required medication) to keep breakthrough pain to a minimum | |
| Provide Nancy with a recliner chair and encourage her to sit with her legs elevated to promote venous return and to reduce swelling (Anderson & Knight 2011) | Having Nancy sit with her feet elevated helps reduce the swelling in her legs; however, by also encouraging her to gently mobilise it prevents her joints becoming stiff |
| Encourage gentle mobilisation at least four times daily (Wounds International 2013) | Mobilising may also encourage Nancy to socialise which prevents boredom and the risk of depression |
| Encourage Nancy to becoming involved in recreational activities she enjoys (e.g. reading, listening to the radio) so as to be distracted from the pain | |

**Evaluation**

After the first week of admission, Nancy reported a decrease in the pain in her leg. This was evidenced with the pain scale scores. Nancy said she has been reluctant to ask for her PRN medication while in hospital as she did not want to disturb the staff; however, Nancy said she now used the opportunity to exercise by walking along to the nurses' office to ask for her medication. On discharge Nancy was only taking PRN analgesia.

method of evaluation, a nursing audit. A nursing audit is a thorough review of a person's journey to evaluate the overall nursing care received by a person in relation to outcomes achieved. An audit is generally performed by an experienced nurse who is external to the unit carrying out the nursing care, or an external committee. Each healthcare agency develops its own nursing audit form. Another type of audit identifies a specific standard which needs to be attained and a list of criteria which need to be met as part of reaching the required standard. Many healthcare providers carry out monthly scheduled audits which can document patterns of improvement and deterioration in audit results. Ensuring nurses meet these standards is a way of demonstrating quality nursing practices.

## Summary

The nursing process forms the basis for all nursing practice. It is a cyclic process that relies on the five interrelated components of assessment, identification, planning, implementation and evaluation. The nursing process provides nurses with a systematic method of problem solving, which requires the nurse to use critical thinking and clinical reasoning skills to develop a plan of nursing care and interventions based on sound clinical judgment and evidence-based nursing practice.

## Review Questions

1. Explain the benefits of involving the person in planning their care and developing a care plan.
2. Name the five (5) components of the nursing process and give a single sentence definition for each component.
3. Give three (3) examples of open questions you could ask a person at admission about their medication.
4. What are SMART goals?

Answer guide for the Review Questions, Critical Thinking Exercises, Decision-Making Framework Exercises and Critical Thinking Questions in Case Studies are hosted on Evolve: http://evolve.elsevier.com/AU/Koutoukidis/Tabbner/

CHAPTER
18

# Health information: nursing documentation and clinical handover

*Leisa Bishop*

## KEY TERMS

care pathway
clinical handover
computer-assisted documentation
computerised documentation
documentation
incident reports
ISBAR
narrative report
SOAPIE

## LEARNING OUTCOMES

At the completion of this chapter and with further reading, students should be able to:

- Define the key terms
- Define the purpose of nurse documentation and reporting
- Discuss the legal and ethical considerations associated with documentation
- Describe guidelines for documenting individual information
- Identify the types of documentation formats in use
- Review case management and critical pathway systems
- Define the term ‘clinical handover’
- Determine the principles for reporting individual information
- Develop and practise the skills of verbal and written reporting and recording in the delivery of individual care

## CHAPTER FOCUS

The term *documentation* refers to any written or electronically generated information that describes the care or service provided to an individual or group. Health records include paper documents or electronic documents such as faxes, emails, audio or images (including video or digital images).

As defined within the National Safety and Quality Health Service (NSQHS) Standards (2012:5) developed by the Australian Commission on Safety and Quality in Health Care (ACSQHC), clinical handover is defined as 'the transfer of professional responsibility and accountability for some or all aspects of care for an individual, or a group of individuals, to another person or professional group on a temporary or permanent basis'.

Several types of records may be used to communicate information about the individual. These include, but are not limited to:

- Integrated progress notes
- Nursing, medical and allied health admission and discharge formats
- Observation charts
- Incident reports
- Fluid balance charts
- Medication charts and care pathways.

## LIVED EXPERIENCE

I have been a witness in a medical court case in Sydney in 2008 involving a surgeon. The alleged incident occurred in 2002. From this experience, I cannot stress strongly enough the importance of accurate documentation in nursing or midwifery practice. My clinical area was the perioperative environment; however, documentation in any arena is important.

When giving every statement on each of the six patients to detectives who were gathering evidence, I was presented with the relevant patient's history and shown the specific pages, count sheet and perioperative patient care plan involving my documentation. I was then questioned on these notes, being asked what I had written and if it was my writing and signature. In this you are required to answer honestly and are relying on your documentation as your evidence.

In the courtroom I was frequently shown photocopies of schedules from the patient history, being the count sheet and perioperative care plan I had signed. I was questioned and requisitioned from different angles at length on these by barristers for the Office of the Department of Public Prosecutions and the judge. I was also extensively cross-questioned by the defence barrister on these documents.

At the conclusion of my time in the witness stand, the judge commended me on the accuracy and neatness of the writing on these schedules and the importance of this in the legal system.

Following my first appearance to give evidence, the Office of the Department of Public Prosecutions' barrister spoke with me outside the courtroom regarding my documentation. She stressed the importance of the accurateness of documentation, that Nil or N/A had been written and that no space had a line through it, which could have been written by anybody or a mistaken slip of the pen, leaving no opening for misinterpretation.

Due to the duration of this case, from 2002 when the procedure took place until giving evidence in 2008, recollections of the events throughout the operation were non-existent. I had to rely on what I had documented in the notes to provide an accurate statement to detectives.

The intensity of the court case has impacted on my health and it has been a cruel educator; however, I have gained valuable insight into the legal/medical system. Six years is a long timeframe for the memory on a specific perioperative patient. Thankfully my documentation was accurate, concise and complete. The bottom line is your registration is involved, so take the time to provide accurate and legible documentation every day in your clinical practice. Every time you document in a patient's notes you could become a witness in a lawsuit.

**Penny Arnold, Perioperative Nurse**

*(Arnold 2012:28)*

# PURPOSE OF DOCUMENTATION

The primary purpose of **documentation** is to communicate information between the healthcare team members caring for the individual. Nurses provide 24-hour care; therefore, information exchange, whether verbal (clinical handover) or documented, is a significant part of nurse activity and must be reliable (Joanna Briggs Institute 2011). Through documentation nurses communicate to other nurses and the healthcare team their assessment of the status of individuals, nursing interventions that are carried out and the outcome of these interventions. This allows for continuity of care and follow-up from previous care provided.

As noted by Forrester (2011), healthcare records of individuals are not legal documents in their own right; however, they assist with several important functions including:

- An account of care and individual treatment and procedures
- A way of communicating between health professionals
- A source for gaining data for research
- Evidence if required in the event of legal action in the future.

There are a number of other purposes of nursing documentation; these include professional accountability, legislative requirements, quality improvement, research and resource management and funding (Crisp et al 2013).

## Professional accountability

In discussing the importance of nursing documentation, Jefferies and colleagues (2010:113) stated that 'not only is nursing documentation a repository of knowledge about the individual, it is also verifiable evidence showing how decisions are made and records the results of those decisions'. Documentation demonstrates nurse accountability and records professional practice. It may be used to determine responsibility of care providers and to resolve questions or concerns in relation to care required. The nurse's documentation may be used in relation to performance management, internal organisational inquiries and/or legal proceedings (such as civil lawsuits or coronial inquests).

## Legislative requirements

Nurses are required to document in accordance with standards of practice of their profession and local organisational policy and procedure which in Australia are the National Safety and Quality Health Service Standards (2012). The *Enrolled Nurse Standards for Practice* (NMBA 2016) reflect the minimum standard for documentation and reporting. These standards are used to assess the performance of students to determine if the student has met the standard required to gain a licence to practise. These standards are also used to assess the ongoing performance of an Enrolled Nurse in professional practice, specifically in complaint investigation of a professional practice matter.

The *Code of Ethics for Nurses in Australia* and the *Code of Professional Conduct for Nurses in Australia* outline the minimum requirements of documentation which nurses and midwives are to maintain within individual records. Value statement 7 'Nurses value ethical management of information' of the *Code of Ethics for Nurses* (ANMC 2008:5–6) states 'the information being recorded to be accurate, non-judgemental and relevant to the health, care and treatment of a person. All health documentation is a record that cannot be changed or altered other than by the addition of further information'.

Legislation may further identify and require specific information and content to be recorded and maintained. Acts such as failure to keep and maintain certain documentation records as required, falsifying documentation, incomplete or inaccurate documentation, signing or issuing a document that the person knows or suspects to be false or misleading, may be found to constitute unprofessional conduct by a regulatory authority. For an outline of the NMBA *Enrolled Nurse Standards for Practice* that relate to documentation and communication see Clinical Interest Box 18.1.

### CLINICAL INTEREST BOX 18.1 *NMBA Enrolled Nurse Standards for Practice* provision of care domain

Standard 7: Communicates and uses documentation to inform and report care

Indicators:

7.1 Collects data, reviews and documents the health and functional status of the person receiving care accurately and clearly.

7.2 Interprets and reports the health and functional status of people receiving care to the RN and appropriate members of the multidisciplinary healthcare team as soon as practicable.

7.3 Uses a variety of communication methods to engage appropriately with others and documents accordingly.

7.4 Prepares and delivers written and verbal care reports such as clinical handover, as a part of the multidisciplinary healthcare team.

7.5 Provides accurate and appropriate information to enable informed decision making by others.

*(NMBA 2016)*

## Quality improvement and research

Documentation is used by organisations to evaluate professional practice as part of quality improvement processes, including performance reviews, audits, organisational accreditation processes and incident investigations. In addition, health records provide valuable information for medical research in relation to clinical interventions, evaluation of individual outcomes and individual care.

The Australian Council on Healthcare Standards (ACHS) requires hospitals to establish quality improvement programs and imposes standards for information to be included in the healthcare record. The Standards require information be accurate, complete, timely, confidential and specific to the individual (ACHS 2010).

## Resource management and funding

Governments are progressively moving towards systems of activity-based funding, which means that health services are funded on the basis of their expected activity. In residential care, the activity is counted per day and resources are allocated as per the Aged Care Funding Instrument (ACFI) assessment. There are three areas by which funding is allocated: activities of daily living, behaviour supplement and complex health supplement. It is the Registered and Enrolled Nurses' responsibility to conduct clinical assessments and complete accurate documentation so the correct funding can be allocated. Table 18.1 shows the ACFI at a glance.

## TABLE 18.1 | Aged Care Funding Instrument (ACFI) at a glance

| | Question | ACFI appraisal evidence |
|---|---|---|
| Note: the resident's ACCR must be included in the ACFI Appraisal Pack | | |
| | **Mental and Behavioural Diagnosis**<br>**Medical Diagnosis** | • Disorders/diagnosis checklists<br>• Source materials checklists<br>• Copies of source materials e.g. ACCR, GP comprehensive medical assessment, other medical practitioner assessments or notes |

*(Australian Government Department of Social Services 2013. © Commonwealth of Australia)*

In most hospital models, activity is counted by 'episode of care', which refers to the whole time an individual is in hospital from admission to discharge. The healthcare record must contain the correct diagnosis-related grouping (DRG) for the facility to receive payment through Medicare. The DRG is obtained from the documentation in the healthcare record. Nursing documentation contributes to the codable diagnoses. If the individual's length of stay exceeds that allowed, thorough documentation assists in justifying the additional care, treatment or length of stay (Berman et al 2015; Crisp et al 2013). The Royal College of Nursing Australia (2011) raised concerns that 'current models of activity-based funding do not capture the unit price and characteristics of nursing services, and case mix classifications that are predominantly medically based fail to reflect nursing sensitive information'. With this said, nursing documentation is of growing importance to assist determining the most appropriate level of service delivery for the provision of care. Nurses must document all elements of a quality assessment, monitor findings and respond in an appropriate and timely manner.

## LEGAL AND ETHICAL CONSIDERATIONS

The promise of confidentiality encourages open communication between the individual and healthcare team. The nurse has a legislative, professional and ethical obligation to protect individual confidentiality. Legal and ethical considerations relating to documentation and reporting were introduced in Chapter 2. There are Australian legislative provisions to protect individual privacy and confidentiality. The nurse needs to understand the application of the law in the jurisdiction they practise in. The 13 Australian Privacy Principles are listed in Clinical Interest Box 18.2.

### CLINICAL INTEREST BOX 18.2 Australian Privacy Principles January 2014

Australian Privacy Principle 1—open and transparent management of personal information
Australian Privacy Principle 2—anonymity and pseudonymity
Australian Privacy Principle 3—collection of solicited personal information
Australian Privacy Principle 4—dealing with unsolicited personal information
Australian Privacy Principle 5—notification of the collection of personal information
Australian Privacy Principle 6—use or disclosure of personal information
Australian Privacy Principle 7—direct marketing
Australian Privacy Principle 8—cross-border disclosure of personal information
Australian Privacy Principle 9—adoption, use or disclosure of government-related identifiers
Australian Privacy Principle 10—quality of personal information
Australian Privacy Principle 11—security of personal information
Australian Privacy Principle 12—access to personal information
Australian Privacy Principle 13—correction of personal information

*(Australian Government 1988. For the latest information on Australian Government law please go to https://www.legislation.gov.au)*

Legislation also protects individual privacy and confidentiality of individual records that are stored electronically. Health services and departments of health install systems to monitor, protect and recover data that is stored electronically. The nurse assists in this process by using personal passwords

to enter and sign off from electronic records, not sharing passwords with others, never leaving computers unattended when logged on, ensuring that screens displaying individual information are not visible to the public and knowing the health service policy for protecting and reporting potential breaches of confidentiality.

To summarise, the nurse needs to be aware that the healthcare agency owns the healthcare record and the law includes provisions for the individual to access their healthcare record and also provisions for the restriction of access to the individual in specific circumstances.

Matters of privacy, confidentiality and consent must be considered by nurses, students and organisations when using exemplars of practice and journalling of practice experience. With the use of social media and the internet, the world's ability to connect is at an all-time high. This may result in contextual descriptions along with the location of the author(s) enabling identification of person(s) involved in the exemplar.

It is recommended that the nurse obtain consent from those involved in the situation described when using exemplars or journals. This means talking with the individual and staff involved, sharing the story with them and informing them on how it would be used.

### CASE STUDY 18.1

Coroner's investigation into the death of Keiran Daragah Watmore, Albany 2009

'At about 2 am his oxygen saturation rate was 88% on room air. As this was low, I put him on oxygen through nasal prongs and later mentioned I had done so to one of the Registered Nurses. About half an hour after I had connected up the oxygen, I checked his oxygen saturation level and it was up to 98%'.

In evidence Nurse F was asked to which of the Registered Nurses she had mentioned the low oxygen saturation level. She stated that she could not recall which one it was and that it might have been both of them. Nurse F was asked whether or not the nurse she spoke to had said anything to her in response, to which she said, 'I can't recall them saying anything, no.' She stated that she did not make any entry in the notes recording this conversation or recording the observations which she claimed indicated that the oxygen saturation level had gone up to 98%. Coroner Hope stated that, 'In my view Nurse F's account in respect of this matter was inconsistent and unconvincing.'

Provide an example of an appropriate entry into the progress notes that may have been made by Nurse F at the time the initial observations were taken at 0200.

## DOCUMENTATION GUIDELINES AND PRINCIPLES

Forrester (2011) described nursing documentation as a 'fundamental skill that underpins high quality patient care'. Each Australian state health department has policies detailing the standards required for nursing documentation and clinical handover and it is essential that you refer to these state policies as well as your local employer's policy to ensure compliance. Chapter 2 lists the important points to ensure quality documentation is provided while Case Study 18.1 further highlights the importance of accurate documentation within the clinical setting.

### Effective nursing documentation

Jefferies and colleagues (2010) identified seven critical themes for effective nursing documentation:

#### Theme 1

Nursing documentation should be centred on the individual. This means that the individual's own perception of their condition and their response to care should be the basis of nursing documentation.

#### Theme 2

Nursing documentation must contain the actual work of nurses, including education and psychosocial support; for example, the nurse 'supervised performing blood sugar level check. Continues to require instruction to clean finger prior to finger stick'.

#### Theme 3

Nursing documentation is written to reflect the objective clinical judgment of the nurse; for example, do not write 'appears to be asleep', write 'when observed was asleep'. Nurses working within rehabilitation, aged and home care also have the responsibility of documenting activities of daily living as well as the burden of care as legislated by the Australian Aged Care Quality Agency within the Quality of Care Principles 2014. (See Clinical Interest Box 18.3.) The nurse should accurately describe how nursing care has contributed to the outcome for the individual; use of the following words can aid in demonstrating the relevance of nursing care:

- *Assist* can be used when the person is unable to perform a task independently
- *Instruct* can be used when a person is able, but not knowledgeable and needs to be taught how to do something
- *Monitor/supervise* can be used for a person who is impulsive in undertaking a task that is not safe for them to undertake independently.

Phrasing personal cares in this manner also validates Commonwealth government funding as well as the facility's compliance for accreditation from the Aged Care Standards and Accreditation Agency.

## CLINICAL INTEREST BOX 18.3 Examples of documentation of delivery of care in rehabilitation practice

'Nurse provided instruction to ambulate in room to increase activity tolerance.'
'Instructed to call for assistance if feels weak/unbalanced.'
'As recommended by physiotherapist, nurse instructed and supervised Mr Smith in using walker to facilitate and promote independence.'
'Nurse instructed Mr Smith to place feet flat on the ground before attempting transfer.'
'To maintain skin integrity, the individual/family require assistance with turning for pressure relief.'
'Reports fatigue after therapy and has difficulty removing pants independently. Instructed to use the electric bed to sit up and the reacher device to facilitate reaching lower legs. With these instructions, Mr Smith can remove clothing, but it takes him a little longer than normal.'

### Theme 4

Nursing documentation must be presented in a logical and sequential manner.

### Theme 5

Nursing documentation should be written as events occur; this is described as contemporaneous documentation. Documenting events as they occur guarantees that important information about the individual's condition and care is not forgotten as subsequent events take place. In the event of a deposition or trial, your testimony should be based primarily on the information provided in the individual's health record (see Case Study 18.1). You may testify regarding undocumented care provided, but your credibility can be compromised if what you did or said you did is not accurately documented in the healthcare record.

Figure 18.1 illustrates the 24-hour clock.

### Theme 6

Nursing documentation should record variances of care.

### Theme 7

Nursing documentation should fulfil legal requirements. Documentation demonstrates that the nurse has applied nursing knowledge, skills and judgment in their care of the individual or group. The nurse's documentation may be used in evidence in coroners' investigations, disciplinary hearings and lawsuits. A summary of the legal requirements that are necessary for nursing documentation is outlined in Clinical Interest Box 18.4 and Clinical Skill 18.1, with additional explanation within Chapter 2.

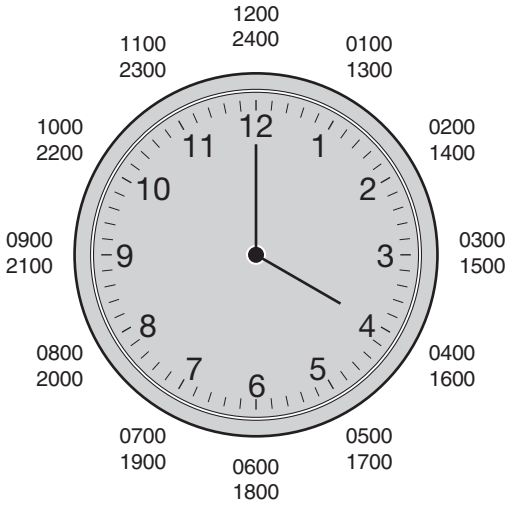

**Figure 18.1** 24-hour clock

## DOCUMENTATION FORMATS AND APPROACHES

The healthcare record includes many documents that are designed to demonstrate the nursing care given. Many of these are discussed in other chapters throughout the text.

The various types of records that may be used by a healthcare agency include:

- Nursing and medical admission histories
- Individual interview forms
- Nursing care plans
- Flow charts
- Progress notes/integrated notes
- Laboratory/diagnostic test reports
- Consent forms
- Incident reports
- Pre-operative anaesthetic records and postoperative surgical reports
- Therapeutic order sheets
- Medication records
- Medication charts
- Discharge summaries
- Medical orders for life-sustaining therapy.

The nurse is most likely to be regularly involved in recording information on individual interview forms, nursing care plans, various flow charts and progress notes. See Table 18.2.

### Types of documentation

Most documentation falls into one of two categories: documentation by inclusion or documentation by exception. Documentation by exception is a system in which only abnormal or significant findings to norms are recorded. When charting by exception it is assumed that all standards are met unless documented otherwise (Guido 2013; CRNBC 2013). When documenting it is important to identify information which is *subjective* and that which is *objective*.

## CRITICAL THINKING EXERCISE 18.1

Mrs A is an 81-year-old female admitted with a diagnosis of a fractured right radius post syncope. Vital signs are as follows: blood pressure 85/60 mmHg, pulse rate 110–145 beats per minute, respirations 24 breaths per minute and temperature 38°C.

During your initial assessment she complains of feeling breathless with only a small amount of exertion and feeling dizzy. Mrs A states that she has fainted a couple of times over the past 2 weeks but this was the worst fall that she has had in weeks. Mrs A is speaking in single words and short sentences, you note that her shoulders rise as she inspires, her lungs have crackles in both bases and she has peripheral oedema. There is no audible wheeze. Mrs A has a history of hypertension, ischaemic heart disease (medically managed) and COPD. Mrs A's right arm is in a cast. Differentiate between objective and subjective data.

## CLINICAL INTEREST BOX 18.4 Standards of documentation

Documentation in healthcare records must comply with the following:

1. Be clear and accurate.
2. Legible and in English.
3. Use approved abbreviations and symbols.
4. Written in dark ink that is readily reproducible, legible and difficult to erase and write over for paper-based records.
5. Time of entry (using a 24-hour clock—hhmm).
6. Date of entry (using dd/mm/yy or dd/mm/yyyy).
7. Signed by the author, and include their printed name and designation. In a computerised system, this will require the use of an appropriate identification system (e.g. electronic signature).
8. Entries by students involved in the care and treatment of an individual must be co-signed by the student's supervising clinician.
9. Entries by different professional groups are integrated (i.e. there are not separate sections for each professional group).
10. Be accurate statements of clinical interactions between the individual and their significant others, and the health service relating to assessment, diagnosis, care planning, management/care/treatment/services provided and response/outcomes, professional advice sought and provided, observation/s taken and results.
11. Be sufficiently clear, structured and detailed to enable other members of the healthcare team to assume care of the individual or to provide ongoing service at any time.
12. Distinguish between what was observed or performed, what was reported by others as happening and/or professional opinion.
13. Made at the time of an event or as soon as possible afterwards. The time of writing must be distinguished from the time of an incident, event or observation being reported.
14. Sequential—where lines are left between entries they must be ruled across to indicate they are not left for later entries and to reflect the sequential and contemporaneous nature of all entries.
15. Be relevant to that individual.
16. Only include personal information about other people when relevant and necessary for the care and treatment of the individual.
17. Addendum—if an entry omits details any additional details must be documented next to the heading 'Addendum', including the date and time of the omitted event and the date and time of the addendum. For hardcopy records, addendums must be appropriately integrated within the record and not documented on additional papers and/or attached to existing forms.
18. Written in error—all errors must be appropriately corrected. No alteration and correction of records is to render information in the records illegible. An original incorrect entry must remain readable (i.e. do not overwrite incorrect entries, do not use correction fluid). An accepted method of correction is to draw a line through the incorrect entry or 'strikethrough' text in electronic records; document 'written in error', followed by the author's printed name, signature, designation and date/time of correction. For electronic records the history of audited changes must be retained and the replacement note linked to the note flagged as 'written in error'. This provides the viewer with both the erroneous record and the corrected record.

*(NSW Health 2012:5–6)*

## CLINICAL SKILL 18.1 Documentation

**Review and carry out the standard steps for all clinical skills/interventions**

| **NMBA Decision-making Framework considerations:** | **Equipment:** |
|---|---|
| 1. Am I educated?<br>2. Am I authorised?<br>3. Am I competent?<br>If you answer 'no' to any of these, do not perform that activity. Seek guidance and support from your teacher/a nurse team leader/clinical facilitator/educator. | Individual care profile/individual history<br>Progress note<br>Pen (blue or black)<br>Computer (If electronic health record) |

| **Skill activity** | **Rationale** |
|---|---|
| **Documenting in progress notes** | |
| Review standard steps for all nursing procedures and interventions | These steps must be performed consistently with each individual to ensure safe nursing care is provided |
| Review individual's assessment data and problems identified (e.g. nursing diagnosis, goals, expected outcomes, interventions and individual's responses during each contact) | Makes it easier to document in an organised manner and decreases errors |
| After contact with the individual identify information that needs to be documented. Consider abnormal findings, changes in individual's status and any new problem identification | Ensures quality; accurate, timely and continuity of information; and completion of documentation in a timely manner; therefore the record is contemporaneous |
| Obtain necessary forms or access appropriate computer for documentation depending on hospital protocol | In accordance with legal requirements for documentation. Charting on the correct form ensures the information can be accessed efficiently by other health professionals |
| Ensure the documentation is correctly identifiable with the individual's details: full name, date of birth and gender. Generally this will be with an identification label attached to the healthcare record | In accordance with legal requirements for documentation and to reduce the risk of errors in documentation |
| Use a blue or black pen. Ensure your writing is legible, free of blank areas, comprehensible and contemporaneous | In accordance with legal requirements for documentation. Makes the reporting more legible and ensures the correct sequence of events and that correct treatment is provided to the individual. Blank spaces should be eliminated to ensure no incorrect information is added into the space. |
| Record date and time using the dd/mm/yy system and 24-hour clock for each entry | In accordance with legal requirements for documentation. This ensures the correct sequence of events is recorded |
| In conjunction with facility/organisation policy and recommended format, document in chronological order the following:<br>• Pertinent, factual, objective data<br>• Selected subjective data that validates and clarifies (avoid subjective statements)<br>• Nursing actions taken<br>• Evaluation of the individual's responses to nursing actions<br>• Any additional nursing actions needed<br>• To whom information has been reported, including name and status | Ensures high-quality documentation is used in order to enhance efficient and individualised care and that documentation is completed to professional standards as for legal requirements |
| Depending on the facility/organisation procedure, make a progress note entry using the SOAP format. The SOAP format consists of subjective data, objective data, assessment and plan and is usually based on a numbered list of problems or nursing diagnoses | Written plans are developed to deal with each problem the individual has. As more problems develop more plans are made, and additionally as more problems are resolved the plans are completed and no longer addressed in the documentation |

| CLINICAL SKILL 18.1 Documentation—cont'd | |
|---|---|
| Depending on the facility/organisation procedure, make a progress note using the PIE format. The PIE format consists of problem, intervention and evaluation. It is a problem-orientated system in which documentation is based on individual problems | This format is used to address problems identified during baseline assessment and monitor during care. This tends to be more nursing focused and flexible with specific information easier to find |
| Depending on the facility/organisation procedure, make a progress note using a basic narrative note format. This is not using a problem list but tells a story on the individual's problem, interventions and outcomes in a chronological order | Narrative documentation can tend to be repetitive, especially in long-term care |
| Depending on facility/organisation procedure, make a progress note using a CBE (charting by exception) format. This progress note will describe any deviations from the individual's normal assessment findings and can sometimes be described as a variance. This is usually completed in addition to care pathways | Reduces the amount of time and documentation required. It relies on the nurses using the established flow sheets, graphic records, standard protocols and care plans or pathways which are already in place to ensure continuous appropriate care is provided |
| Ensure your writing is error free or if you make an error it is crossed out with a single line through it and 'error' plus your initials written above | In accordance with legal requirements for documentation. Chart may become illegible and it can appear you were attempting to hide information. It is important that errors are corrected promptly to ensure no errors in treatment |
| Only care that has been personally delivered is documented, with the exception being in an emergency situation, in which case a designated scribe is in control of all recording of information | In accordance with legal requirements for documentation |
| Record the individual's response to treatment | Allows for ineffective treatment to be ceased and effective interventions to continue |
| Ensure appropriate medical terminology and approved abbreviations and acronyms are used | In accordance with legal requirements for documentation. Reduces the chance of errors and ineffective communication, therefore improving individual safety |
| Sign the progress note with full name or first initial and last name and status according to healthcare organisation policy. If you are a student, you need to indicate your school affiliation and level of education | In accordance with legal requirements for documentation. Documents who is accountable for the information written |
| If documenting a late entry, this must follow the last entry and be noted as such: either 'addit' or 'late entry' written beside the time you actually wrote the notation. The time of the original occurrence must also be documented within the note | In accordance with legal requirements for documentation |
| Review previously documented entries with those that you enter, identifying if there is any significant change in the individual's health status or care and report as needed | Changes in medical, physical, emotional or psychological condition are documented to report and alert other healthcare professionals to potential complications |
| **Use of electronic health records (EHRs)** | |
| Sign on to EHR using your password; never share passwords and keep your password private | For accountability purposes, your user name and password become your signature and therefore you are accepting accountability for your documentation |
| Do not leave individual's information on the monitor where others can view it | The individual's privacy and confidentiality must be maintained |

*Continued*

| CLINICAL SKILL 18.1 Documentation—cont'd | |
|---|---|
| Review assessment data, problems identified (e.g. nursing diagnosis, goals, expected outcomes, interventions and individual's responses during each contact) | Makes it easier to document in an organised manner and decreases errors |
| Follow procedures for entering information in all appropriate program functions | Some programs will not let you enter pages until you have completed other forms or procedures to ensure documentation is complete |
| Review previously documented entries with those that you enter, identifying if there is any significant change in the individual's health status or care and report as needed | Changes in medical, physical, emotional or psychological condition are documented to report and alert other healthcare professionals to potential complications |
| Know and implement procedures to correct documentation errors | This may be different in different computer programs and is important to be done promptly to ensure errors in the individual's treatment do not occur |
| Save information as you complete documentation | Information may be lost if you do not save your documentation |
| Log off when you leave the computer | In accordance with legal requirements for documentation. Ensures no one uses your user name to change data or review individual's health conditions and also ensures individual's privacy and confidentiality are maintained |

Note: Documentation must be completed according to the facility/organisation's guidelines and policy. Therefore, it is important to become familiar with different formats of documentation and their best indications of use.

You need not document information that is already charted on flow charts, unless that information is relevant to other pertinent information you are recording (Tollefson 2016). Content of documentation will depend on the individual and their condition. But whatever the individual's condition there should always be nursing interventions documented and the individual's response to these (Tollefson et al 2016).

When documenting, remember the guidelines for quality documentation:

- Factual
- Accurate
- Complete
- Concise
- Current
- Organised (Perry et al 2012).

*(Rebeiro et al 2013; Perry et al 2012; Tollefson 2016; Tollefson et al 2016)*

## Narrative documentation: SOAPIE, APIE, PIE

For a **narrative report** the nurse charts in chronological order the events that occur, including the gathering of information. The format is generally story-like, and is often repetitive and long.

There are a number of other methodologies that the nurse may apply to construct a logical order to documentation.

## Subjective data, objective data, assessment and plan

SOAP is an acronym for **S**ubjective data, **O**bjective data, **A**ssessment and **P**lan; however, some nurses use an amended format of **SOAPIE** in which **I**mplementation and **E**valuation have been added.

## Assessment, plan, implementation and evaluation (APIE)

APIE is a method in which the nurse will document **A**ssessment, **P**lan, **I**mplementation and **E**valuation. The subjective and objective data have been combined in assessment, while combining what nurses do with the expected outcomes of individual care forms the plan component.

## Problems, intervention and evaluation (PIE)

PIE is an acronym for **P**roblems, **I**ntervention and **E**valuation of nursing care. When the nursing assessment is undertaken, an individual problem list is developed with each individual problem being allocated a number. The charting is documented using the numbering system, by individual

**TABLE 18.2 | Example organisation of traditional source record**

| Sections | Contents |
|---|---|
| Admission sheet | Specific demographic data about client: legal name, identification number, sex, age, birth date, marital status, occupation and employer, health insurance, nearest relative to notify in an emergency, religious preference, name of attending doctor, date and time of admission |
| Doctor's order sheet | Record of doctor's orders for treatment and medications, with date, time and doctor's signature |
| Nurse's admission assessment | Summary of nursing history and physical examination |
| Graphic sheet and flow sheet | Record of repeated observations and measurements such as vital signs, daily weights, and intake and output |
| Medical history and examination | Results of initial examination performed by doctor, including findings, family history, confirmed diagnoses and medical plan of care |
| Nurses' notes | Narrative record of nursing process: assessment, nursing diagnosis, planning, implementation and evaluation of care |
| Medication records | Accurate documentation of all medications administered to client: date, time, dose route and nurse's signature |
| Doctor's progress notes | Ongoing record of client's progress and response to medical therapy and review of disease process |
| Healthcare discipline's records | Entries made into record by all health-related disciplines: radiology, social work and laboratories |
| Discharge summary | Summary of client's condition, progress, prognosis, rehabilitation and teaching needs at time of dismissal from hospital or healthcare agency |

*(Crisp et al 2013:422)*

problem, followed by the nursing intervention that is delivered in relation to the identified problem and the evaluation of nursing care to resolve or improve the individual problem.

## Focus charting: DAR

Focus charting is used when an individual-centred problem is identified. The identified problem will be commented on during each shift until incorporated into routine management. The method of organising the narrative in focus charting is the principle: **D**ata, **A**ction and **R**esponse (DAR). Data reflects a combination of subjective (what the individual states) and objective (what the nurse observes), action is the documentation reflecting what nursing actions were taken to address the problem and response is the individual's response to the nursing action (see Clinical Interest Box 18.5).

## Computerised documentation and charting

In 2005 the National E-Health Transition Authority (NEHTA) was formed. It 'is the lead organisation supporting a national vision for eHealth for Australia' (NEHTA 2015). Its purpose is to lead, support and direct Australian e-health while enhancing healthcare by increasing accessibility 'to the right information, for the right person, at the right time and place' (NEHTA 2015) for individuals and healthcare providers. NEHTA is jointly funded by the Australian Commonwealth and state and territory governments and engages with the ACSQHC and the University

### CRITICAL THINKING EXERCISE 18.2

Mr Q returned from operating theatre at 1600 hrs post a right video assisted thoracotomy (VAT) and wedge biopsy for diagnosis of right lung pathology. He returned to the ward with oxygen 6 L/min via a Hudson mask (HM) maintaining oxygen saturations ($SpO_2$) greater than 94%. Intravenous 1 L 0.9% sodium chloride infusing at 80 mL/hour. Tolerating ice only orally. Fentanyl patient-controlled analgesia (PCA) providing effective pain relief, pain score as per patient 2/10. Indwelling urinary catheter (IDC) output 50 mL–110 mL/hour. Two chest drains (ICC) are combined into one underwater seal drain (UWSD) with 300 mL of haemoserous fluid drained, 10 cm $H_2O$ suction, swing and air leak are present. Cutifilm dressing is intact to right thoracotomy wound, clean and dry. Vital signs, blood pressure 100/84 mmHg, respiratory rate 12 breaths per minute, pulse rate 88 beats per minute.

Use this information to write a nursing progress note using the following formats: SOAPIE, PIE, DAR.

## CLINICAL INTEREST BOX 18.5 Focus reporting

Nursing 20/01/2016 1130 hrs

Mobility: Found sitting up on floor against bedside locker by myself at 1110 hrs. Mrs Smith stated she climbed over the bed rails and fell on the floor, hitting head on bedside table. Disoriented to time and place (normal for Mrs Smith). Swelling to left temporal area of skull, skin remains intact. Painful to touch, complaining of headache rated at 3/10. Vital signs within normal parameters. Not reporting pain elsewhere. Returned to bed by staff, bed rails down. Resident medical officer contacted at 1120 hrs to review Mrs Smith, instructed to commence 4/24 full neurological observations. Falls risk management tool completed. Falls prevention strategies implemented as per nursing care plan. Braden Score reassessed at 15, all strategies implemented and charted as per pressure ulcer risk assessment and minimisation. Glasgow Coma Scale Score (GCS) 14.

Signature, designation and print surname.

Nursing 20/01/2016 1700 hrs

Observations: GCS 12, agitated, confused and incontinent of urine. Resident medical officer informed, full neurological observations now 30 minutely as instructed. After hours nurse manager contacted at 1645 hrs. Behavioural observation form commenced and patient care assistant companion now in place. Awaiting cranial CT. Family notified.

Signature, designation and print surname.

of New South Wales Centre for Health Informatics to ensure the clinical safety and governance of the Personally Controlled Electronic Health Record (PCEHR) and e-Health products and solutions (National E-Health Transition Authority 2015).

**Computerised documentation** is data entry of individual information onto a computerised system. This may occur through keyboard, touch screen or voice-activated data entry. The advantages of computerised documentation include:

- Information is always legible
- Abbreviations can be restricted to agency-approved abbreviations
- Each field of a form needs to be completed before the nurse can progress to the next
- Individual identifying information is automatically generated with each page
- The addition of drop-down boxes creates standardisation and can reduce data entry time for the nurse
- Automatic storing of access numbers to individual staff and logging of date and time assists with information integrity.

To ensure contemporaneous recording of information bedside data entry options are essential. These may be fixed or computers on wheels (COW). Additional confidentiality considerations include orientating the computer screens away from public view; use of automatic timed screen savers and logout mechanisms; assigning individual access numbers and passwords; restricting levels of individual data to authorised groups of staff; automatic storing of date, time and access numbers when individual records are accessed; and encrypting individual information transmitted through the internet.

Some computer programs use predictive text and/or autocorrect which may cause problems if the nurse does not check the entry made (Staunton & Chiarella 2013).

**Computer-assisted documentation** includes the implementation of advanced speech recognition technology (voice recognition programs) to increase the quality and accuracy of transcribed documents and reduce the turnaround for clinical notes and the cost of medical transcription processes (Rozmus 2010). In nursing services voice recognition programs may improve efficiency and access to records, particularly in nurse-led clinic environments and emergency departments when timely discharge of information is required (see also Chapter 5).

### CRITICAL THINKING EXERCISE 18.3

While you are entering into electronic progress notes the nurse call bell rings. At this stage you have entered only half of the required information into the computer. What actions should you undertake to ensure that safe individual care is performed quickly and efficiently and privacy is also maintained?

## Care pathways or individual management guidelines

A **care pathway** (CPW) or individual management guideline is a document outlining a standardised, evidence-based multidisciplinary management plan, which identifies the appropriate sequence of clinical interventions, timeframes, milestones and expected outcomes for a common individual group. These pathways aim to have the most current evidence incorporated into clinical practice and provide recommendations, processes and timeframes for the management of specific medical conditions. CPWs identify the expected course of events for the majority of individuals (approximately 70%) (Zhang & Liu 2011). In a Cochrane review of CPWs it was found that when they were used there was a significant decrease in in-hospital complications (including bleeding and infection) and length of stay, and therefore cost to the hospital. Documentation appeared to improve, which supports the theory that there was an increase in communication (Rotter et al 2010). As there will always be exceptions, the pathway should be followed in accordance with the nurse's assessment of each individual case. A process of charting by exception (CBE) may be adopted when utilising CPWs. Charting by exception involves the nurse charting only

significant findings or exceptions to the standards or norms of the predicted care pathway for the individual, as supported by local and governing policies (Kerr 2013). Often a statement will be made within the individual's medical records such as 'nursed as per care pathway with nil variances'.

### Flow sheets

Flow sheets are records to reflect the individual's condition. They enable the nurse to document routine care such as the individual's vital signs, medications, fluid intake and output. Flow charts have traditionally been utilised in the critical care areas; however, more recently, flow charts have evolved for physiological monitoring into 'track and trigger' charts for general wards. These charts prompt the nurse to graphically chart the individual's observations (track) and when abnormal parameters are reached, a prescribed response or escalation plan is documented and expected of the nurse (trigger) (see Figure 18.2).

## DOCUMENTATION IN AGED CARE

In 2002, the National Framework for Documenting Care in Residential Aged Care Services (NATFRAME) was developed to provide guidance to aged care workers and facilities to provide high-quality care for older people. As previously discussed, accurate documentation is an essential component of quality care.

This framework combines all the necessary components documenting care. At the centre of the conceptual framework is the resident, with the resident being the focus of care and the reason for documentation and accountability to exist. While the care process and accountability process are identified separately they are connected to meet the needs of the individual. NATFRAME lists 'the elements that are fundamental to both processes as:

- The assessment of the resident
- The identification of resident capabilities, needs or problems
- The development of interventions, actions and strategies
- The development of strategies required to meet the needs of the resident
- The ongoing evaluation of the resident's response to the care given' (Commonwealth Department of Health and Ageing 2015).

NATFRAME provides examples of assessment tools which may be adopted by aged care facilities, covering five areas: social, cultural and spiritual; physical; functional; communication; and cognitive and mental health. Clinical Interest Box 18.6 provides information on the steps/timing for effective documentation.

### CLINICAL INTEREST BOX 18.6 NATFRAME steps for effective documentation

**Step 1—On admission**

Initial assessment to determine immediate care needs

*Resident care assessment record*

**Step 2—Ongoing assessment**

Assess the resident according to facility policy and timetable. Complete the ongoing assessment section using further *assessment tools* if indicated.

Not all assessment areas will be required for all residents. Record results of the assessment process in the *care profile* including the results obtained from the tools used.

*Ongoing assessment*
*Assessment tools*
*Care profile*

**Step 3—Analysis**

Analyse the results of the assessment process and identify the care needs for the resident.

**Step 4—Identify and record**

Identify the care interventions and strategies that will meet the resident's capabilities and identified care needs based on evidence and best practice. Record these strategies in summary form on the *care profile* and the relevant *management chart*.

**Step 5—Monitor and record**

Monitor the resident's response to care as indicated by the resident or on a regular basis. Record responses on the relevant *management chart* and if unexpected or different from usual response, record in *progress notes* in accordance with state and territory legislation.

If an incident, error or adverse event occurs these also should be recorded in the *progress notes* and on the facility's incident reporting forms.

**Step 6—Continuous update**

Continuously draw on the *progress notes* and evaluations in the *management charts* to ensure that ongoing update of the *care profile* occurs, as per facility policy.

**Step 7—Continuous assessment and planning**

Use the documents to continue to assess the resident, identify care needs, plan care to meet these needs and evaluate the response to care given.

*(Department of Social Services 2015. © Commonwealth of Australia)*

## CLINICAL HANDOVER

The NSQHS Standards include 'Communicating for safety'. Effective communication is critical at all points where information is transferred. The Standard focuses on ensuring safe care by supporting the principles of coordination and continuity of care (ACSQHC 2015). Errors with communication and **clinical handover** are contributing elements in 70% of hospital events and therefore lead to an increased risk of adverse events. It is pertinent to say that ineffective clinical handover or the absence of clinical handover has serious

Family name:

Given names:

Date of birth: Sex: ☐ M ☐ F

## Other Charts In Use

| | | |
|---|---|---|
| ☐ Alcohol Withdrawal | ☐ Insulin Infusion | ☐ Pain/Epidural/Patient Controlled Analgesia |
| ☐ Anticoagulant | ☐ Neurological | |
| ☐ Fluid Balance | ☐ Neurovascular | |

## General Instructions

- You must record appropriate observations:
  - On admission
  - At a frequency appropriate for the patient's clinical state.
- You must record a full set of observations:
  - If the patient is deteriorating or an observation is in a shaded area
  - Whenever you are concerned about the patient.
- When graphing observations, place a dot (•) in the centre of the box which includes the current observation in its range of values and connect it to the previous dot with a straight line. For blood pressure, use the symbol indicated on the chart.
- Whenever an observation falls within a shaded area, you must initiate the actions required for that colour, unless a modification has been made (see below).
- If observations fall within two or more different coloured areas for the same time period, the actions required for the darker colour apply.

## Modifications

If abnormal observations are to be tolerated for the patient's clinical condition, write the acceptable ranges (where a response will not be triggered) below, and tick the box overleaf. Modifications must be reviewed at least every 48 hours. Further modifications will require a new chart.

## Medical Emergency Response Call

| Response Criteria | Actions Required |
|---|---|
| • **Any observation in a purple area**<br>• Airway threat<br>• Respiratory or cardiac arrest<br>• Sudden fall in level of consciousness<br>• Drop in $O_2$ saturation ≤ 84%<br>• Seizure<br>• A medical review that has not been attended<br>• You are worried about the patient but they do not fit the above criteria | • Place Emergency call<br>• Initiate ALS/BLS protocols |

## Medical Review

| Response Criteria | Actions Required |
|---|---|
| • **Any observation in a red area**<br>• New or unrelenting chest pain<br>• New or unrelenting shortness of breath<br>• Increased or unexpected fluid or blood loss<br>• Pain not relieved by current analgesia<br>• Drop in $O_2$ saturation ≤ 90%<br>• BGL < 3 or > 19<br>• Urine output ≤ 29 mL/hr<br>• You are worried about the patient but they do not fit the above criteria | • Doctor to review patient within 30 minutes (via phone or in person)<br>• Record observations every 15 minutes<br>• If medical review not attended within 30 minutes, initiate MER call |

## Senior Nurse Review

| Response Criteria | Actions Required |
|---|---|
| • **Any observation in an orange area**<br>• You are worried about the patient but they do not fit the above criteria | • Senior Nurse must review patient<br>• Senior Nurse must contact Medical Officer to discuss whether a Clinical Review is required<br>• Record observations at least once every hour<br>• Review $O_2$ requirement<br>• Manage fever, pain, fiuids, blood loss or distress |

## Increased Surveillance

| Response Criteria | Actions Required |
|---|---|
| • **Any observation in a yellow area**<br>• You are worried about the patient but they do not fit the above criteria | • Inform Shift Coordinator<br>• Record observations at least every 2 hours<br>• Carry out appropriate interventions as prescribed<br>• Manage fever, pain, fiuids, blood loss or distress<br>• Review $O_2$ requirement |

**Figure 18.2** Cont'd

## CLINICAL INTEREST BOX 18.7 Principles of handover (ACSQHC 2012)

**Principle 1 Preparing for handover**

- Clearly allocating staff roles is essential to reduce disruptions and ensure safe individual care during handover.
- Ensure all participants, the venue and the time of handover are nominated.
- Prior to handover the clinicians should obtain all relevant documents.

**Principle 2 Organising the relevant members to participate**

- Make sure all participants have arrived before starting the handover.
- Handover of individuals should be supervised by a designated leader.

**Principle 3 Being aware of the clinical contexts and their needs**

- Handover should include notification about individuals who might require significant levels of care or immediate attention; are deteriorating or might deteriorate; or present occupational safety issues.

**Principle 4 Participating in effective handover resulting in transfer of responsibility and accountability of care**

- The handover of individuals must be achieved through a standardised content delivery and should include the transfer of accountability and responsibility.

*(ACSQHC 2012)*

consequences for the individual's safety. Clinical Interest Box 18.7 lists the four principles of clinical handover as per the ACSQHC Standard (ACSQHC 2012; 2015) (see also Chapter 7).

There are many methods that may be utilised to perform safe clinical handover. Figure 18.3 summarises the appropriate methods and situations in which clinical handover should be conducted as per the 'Communicating for safety' Standard. See Clinical Skill 18.2.

## Transfer of care

The two main uses of verbal reporting are when a nurse transfers care to another healthcare provider and when the nurse recognises and responds to changes in the health and functional status of the individual. It is at this time that the nurse provides a summary of the individual's condition, care plan, interventions and response to interventions for the purpose of transferring the accountability of care for the individual to another healthcare provider. Handover record formats can vary slightly, depending on the context of practice. Standardising the process of individual handover is seen as key in improving individual safety (James et al 2013) with

## CRITICAL THINKING EXERCISE 18.4

Mr K is a 76-year-old man admitted with bradycardia. He has a history of ischaemic heart disease (IHD), previous percutaneous coronary interventions (PCI) 6 months ago and was recently diagnosed with non-insulin-dependent diabetes mellitus (NIDDM). You have responded to his call bell and he states that he has severe chest pain, radiating down his left arm. The pain began after he returned from the toilet. Individual is alert but diaphoretic. Vital signs: temperature 36.5°C, blood pressure 170/90 mmHg, respiratory rate 28 breaths per minute, heart rate 50 beats per minute, pain score is 9/10 and oxygen saturations 95% on room air. Document the observations on the observation chart, document your interventions based on the escalation plan outlined in the adult observation and response chart included in this chapter (Figure 18.2) and document the verbal report you would provide to the medical officer.

some organisations adopting a documented clinical handover checklist tool as well as bedside handover to increase individual safety (see Case Study 18.2, Decision-making Exercise 18.1).

The **ISBAR** framework is often used as part of the reporting process. It represents a standardised approach to communication which can be used in any situation. It stands for Introduction, Situation, Background, Assessment and Recommendation (see also Chapter 8).

## Bedside nursing handover

Bedside nursing handover involves the nursing team and the individual and/or their family. Nurses recognise that bedside handover facilitates more accurate information exchange and individuals feel that their care is individualised and personalised as they are included in clinical handover (Tobiano et al 2013). In a study by Maxson et al (2012), bedside nurse-to-nurse shift handover had a positive impact on individuals and nursing staff with individuals noting a significant increase in their perception of being informed of the plan of care for the day and there being an increase in accuracy as individuals were able to contribute to clinical handover. Not only has the introduction of bedside handover not extended the time taken for handover (a commonly cited barrier to implementation), it has improved the comprehensiveness, visualisation and identification of care priorities (Bradley & Mott 2012).

Chaboyer et al (2010) further identify that bedside clinical handover provides the additional benefit of student teaching and mentoring, assists less experienced staff to learn professional goals and values and promotes cohesion within the nursing group. 'In this style of handover, students begin to see nursing as something done with rather than for patients' (Chaboyer et al 2010:28).

Legitimate concerns relating to individual privacy and confidentiality are managed through individual organisation's policies, which outline what information is to be conveyed at the bedside handover. This is particularly important in shared rooms.

| | | | | | | | | |
|---|---|---|---|---|---|---|---|---|
| **WHY** Implement standard key principles? | | Provide the best patient care by improving the transfer of clinical information, responsibility and accountability. | | | | | | |
| **WHAT** Clinical information is handed over? | | Locally defined minimum data set that meets the key principles, ensuring the most imporatant clinical information is handed over.** | | | | | | |
| **WHO** Should attend the handover? | | Key participants is the handover process are identified and available to attend the clinical handover of their patients. | | | | | | |
| **WHEN** Should handover occur? | | **Escalation of deteriorating patient** | **Patient transfers to another ward** | **Shift to shift change over** | **Patient transfers for a test or appointment** | **Patient transfers to another facility** | **Multi-disciplinary team handover** | **Patient transfers to/from the community** |

## CLINICAL SKILL 18.2 Clinical handover

**Review and carry out the standard steps for all clinical skills/interventions**

| **NMBA Decision-making Framework considerations:** | **Equipment:** |
|---|---|
| 1. Am I educated?<br>2. Am I authorised?<br>3. Am I competent?<br>If you answer 'no' to any of these, do not perform that activity. Seek guidance and support from your teacher/a nurse team leader/clinical facilitator/educator. | Handover sheet<br>Individual flow charts as necessary |

| **Skill activity** | **Rationale** |
|---|---|
| **All clinical handover** | |
| Review standard steps for all nursing procedures and interventions | These steps must be performed consistently with each individual to ensure safe nursing care is provided |
| Be interactive in communication | The receiver of the information must be allowed to question the deliverer of the handover for clarification and more extensive information if needed |
| Use medical terminology, clear language and avoid confusing abbreviations and jargon | Allows a report to be complete and concise, demonstrates knowledge of the medical terminology and acknowledges the professional status of the person being handing over to |
| Use effective communication techniques in a timely manner | Effective communication will help decrease the time for handover to be complete and ensures the information is communicated clearly |
| Prepare for handover. Read the individual's medical record and check the individual's bedside chart to ensure accuracy. Plan what you are going to say using a time planner guide or prompts as necessary | Provides consistency and allows those who are receiving the report to listen and assimilate the material more easily |
| Use up-to-date information regarding individual's condition and treatment. Information must be accurate, concise and complete | Inaccurate or incomplete information during handover can jeopardise the individual's comfort and safety. You need to be aware of what information is relevant and what is irrelevant. Missing or incorrect information can impact on the individual's recovery, delay diagnosis, decrease individual satisfaction, increase length of hospital stay and increase the risk of potential complications |
| Limit interruptions during the handover process and conduct the handover in private surroundings | Handover must be conducted in private surroundings to maintain confidentiality. If performing bedside handover and information may be overheard by other individuals or staff, keep voices low and refrain from personal comment other than what is strictly necessary. If appropriate you may ask any uninvolved people to vacate the area |
| **General clinical handover format** | |
| State individual's demographics including name, age, location (room number, or indicate if they are off the ward and where) and attending medical officer's name | Ensures the individual is identified and identifies the multidisciplinary team caring for the individual |
| Describe the individual's history or complaint, treatment, diagnosis and the date of surgery and day post operation if applicable | Gives a general overview of the individual and allows a plan of nursing care to be implemented |

## CLINICAL SKILL 18.2 Clinical handover—cont'd

| | |
|---|---|
| Describe the individual's response to treatment or medications. Include physical, psychological and emotional response to treatment initiated, alterations in medications ordered and response to medications | The individual's response to treatment is imperative in ensuring the treatment is effective or ineffective, and in either continuing or changing the treatment plan |
| State any tubes (IVs, NGT) and include site, fluid, amount, rate and time to change. Also state any drains (IDC, wound) the individual has including location, type and amount of drainage | Any information regarding tubes and drains needs to be accurate to ensure any changes in the individual's condition are identified in a timely manner |
| Describe the individual's physical assessment, vital signs and pain assessment. Note any information that indicates a change in condition | Important for prompt recognition of changes in condition |
| State any laboratory results or imaging | Prompt reporting of results can ensure the individual's treatment is effective, and if ineffective changes can be implemented |
| Discuss the current treatment plan, include procedures scheduled, preparation done or needed, education, treatments, consents required, new orders and any concerns of staff about the individual | Ensures continuity of care provided to the individual |
| State any consultations requested or completed including specialist physicians, physiotherapy, dietitian or occupational therapy | Provides the individual with effective holistic care; different health professionals may be needed to treat the individual |
| Discuss any special needs such as aids (hearing, walking etc), equipment needed, family concerns, spiritual or cultural concerns, anything else important not yet mentioned | Special needs of individuals need to be discussed to ensure the individual receives tailored care |
| Discuss any future plans or concerns about the individual including discharge planning, community referrals, expected date of discharge | Discharge planning should be discussed with the individual throughout their admission to ensure they have continuity of care when they leave the department |
| **Bedside handover using ISBAR format (identify, situation, background, assessment, recommendation)** | |
| Prepare the individual's bedside environment. Determine if the individual wishes family to be present during the handover and ask non-family members to wait outside while handover is completed | Ensures privacy and confidentiality is maintained and allows a quiet area for handover to be completed |
| Introduce the nurses who will be taking over care and call the individual by name, establishing their identity | Ensures individual identification and also allows the individual to know who their care providers will be |
| Exchange the information using the ISBAR format which encompasses the following:<br>• State the individual's condition and severity<br>• Provide background information related to the situation<br>• Include the following information: admitting diagnosis, date of admission, list of current medications, allergies, test results, vital signs, code status and any other pertinent clinical information<br>• Give assessment of the situation during the transfer of care<br>Discuss any recommendations regarding the individual to the oncoming nurse | The use of a standardised communication tool provides a predictable structure for communication between healthcare professionals and improves the individual's safety during handover from one nurse to another. It ensures the quality of the content and simplifies the communication of complex information |
| Involve the individual; ask them if they have any concerns. If the oncoming nurse wishes to clarify information they can do this with both the individual and the nurse who is handing over | Individual-centred care is the basis of nursing and by involving the individual in the handover process they are able to discuss their concerns and priorities, which may be different from that of the healthcare team |

*Continued*

## CLINICAL SKILL 18.2 Clinical handover—cont'd

| | |
|---|---|
| The oncoming nurse will need to perform a safety scan including checking the call bell is within the individual's reach, the suction and oxygen equipment are working and reviewing the bedside chart, ensuring accurate records are maintained | A safety check is important for both the individual's and the nurses' safety within the room. It also ensures all equipment is in working order in case of emergency. By reviewing the bedside chart, the incoming nurse is reviewing the individual's flow charts and ensuring these are completed and they are prepared to take responsibility of the individual |
| If there is sensitive information that needs to be handed over, this can be done outside the room in a private area | Some information may be too sensitive to address within the individual's room; this may be due to their comfort, knowledge or wish to not discuss certain issues. To ensure privacy and confidentiality this must be completed in a private area |
| **Following the handover** | |
| Verify information received, including a read back or repeat back process. This is where a plan of ongoing care for the individual is confirmed | Allows clarification of information and decreases the incidence of communication errors occurring |

Note: Reporting on individual's condition during handover should be completed as per healthcare organisation policy; therefore, it is important for nurses to familiarise themselves with the relevant format before they give the handover. All nursing shift-to-shift handovers should follow a standardised approach to ensure continuity of individual care and effective transfer of accountability and responsibility. The handover process should include a clear transfer of responsibility as this relates to the accountability of care for individuals and the transfer of this accountability of care from one nurse to another.

*(Rebeiro et al 2013; Perry et al 2012; Tollefson 2016; Tollefson et al 2016)*

## CASE STUDY 18.2

Mr X was admitted to hospital with a brainstem stroke. Once there he deteriorated, was intubated and was transferred to ICU where he had a prolonged stay. Mr X was in and out of consciousness and had a tracheostomy which prevented him from speaking. While conscious he was able to do what was instructed of him.

At night time Mr X would become agitated and needed sedating and restraining. During these episodes Mr X removed his nasogastric tube about three times, and even did this on the night before he was transferred to the ward.

Handover from ICU to the acute stroke ward was given verbally, it appeared incomplete and the content was not documented.

On the ward Mr X was not restrained or sedated during the night. Subsequently he removed his nasogastric tube and his tracheostomy tube. When he was found he was unresponsive and unable to be resuscitated.

During investigation it was not clear if information about the individual's night-time agitation, sedating and restraining was communicated.

1. How would a handover using the ISBAR format and a documented handover checklist have helped in this situation?
2. What would be the advantages of a structured clinical handover in this situation?

*(NSW Department of Health 2009)*

## DECISION-MAKING FRAMEWORK EXERCISE 18.1

You are allocated beds 20–25 for your afternoon shift. The person allocated to bed 21 is due to be transferred from ICU. The ICU nurse arrives with the person. The person is settled into the room and you prepare for clinical handover from the ICU nurse. The ICU nurse states, 'This person is routine post left anterior resection. Everything is documented, I'm really busy and need to get back to the ICU, call me if you have any questions.' The ICU nurse prepares to leave.

Using the decision-making framework:

1. Do you accept this handover as a reasonable bedside clinical handover?
2. What strategies could you adopt to gain a sound clinical handover?
3. If a resolution is not made, what would your course of action be?

Individual groups that may not participate in handover include those who are:

- Asleep
- Confused
- Comatose
- In isolation
- Having difficulty communicating in English
- Experiencing other conditions that preclude participation.

Sensitive information that may be shared away from the bedside includes blood tests of a diagnostic nature (e.g. HIV positive, pregnancy); communicable disease information (e.g. hepatitis); psychiatric issues (e.g. thoughts of self-harm, ethanol abuse); not for resuscitation orders; some family issues (e.g. conflicts, domestic violence); other information the individual may wish to be held in confidence.

'With the public expecting more transparency regarding patient safety in health care, it is only logical patients participate in their plans of care' (Maxson et al 2012:144).

Clinical Interest Box 18.8 is a sample of a standard operating protocol for implementing bedside handover in nursing.

## CLINICAL INTEREST BOX 18.8 Bedside handover

| | |
|---|---|
| Preparation | RN Annie is a team leader. She reads the individual's medical record before handover ensuring she is up to date with the medical decisions recorded in the doctor's notes. She checks the bedside chart to ensure everything in the handover is accurate.<br>Towards handover time, RN Annie gets the team members together to update the handover sheet. Annie tells the individual that handover will occur shortly, ascertains whether the individual wishes family to be present during the handover and asks non-family members to wait outside for a short while.<br>All oncoming staff members are given a handover sheet. |
| Introduction | 'Mr Smith, good afternoon, this is Sylvia, an RN, Cindy an EN and Susan, a nursing assistant. They will be taking care of you in the evening shift.' |
| Information exchange<br>S<br>B<br>A<br>R | RN Annie keeps her voice low but ensures that Mr Smith and the oncoming staff can hear her.<br>S: Mr Smith came to the ED complaining of chest pain and shortness of breath. He was placed on oxygen via nasal cannula at 2 L/min. He is on an antihypertensive, aspirin and a beta-blocker (medication chart shown to RN Sylvia).<br>B: Mr Smith has a history of chest pain over the past 2 days, which radiates down his left arm. He has PRN anginine at home. Over the past 6 months he has had several bouts of chest pain, and has been followed up by his GP. Today, prior to being admitted, he developed chest pain but is currently pain free.<br>A: This afternoon, his BP = 130/88, Temp = 38 and heart rate = 76. He is currently pain free.<br>R: Dr Jones has arranged a cardiac echo for him. He has had an ECG today with no significant changes. Blood tests all attended and are waiting on results.<br>RN Sylvia then asks about any treatment for his raised temperature and also asks about mobility. RN Annie replies: 'Dr Jones is aware and has asked to be notified if it goes above 38.5°C. Mr Smith can mobilise with assistance but only toilet and shower privileges.' |
| Individual involvement | RN Annie asks, 'Mr Smith, have you been to cardiac echo?' Mr Smith says 'yes'. RN Annie then asks, 'Did the doctor say anything to you?' Mr Smith says, 'She said, I may need a cardiac catheter.' RN Sylvia then asks, 'Do you have any questions, Mr Smith?' Mr Smith replies, 'Can you find out if I need the cardiac test?' |
| Safety scan | EN Cindy undertakes a safety check of the equipment, including checking that the call bell is within reach, the suction and oxygen equipment are functioning.<br>RN Sylvia and RN Annie review the bedside chart, checking the following: care plan, observation chart, medication chart and the pressure ulcer assessment. RN Sylvia asks, 'Has Mr Smith needed any GTN recently?' RN Annie said, 'Oh, I forgot, Mr Smith had chest pain around 9.30 am and took one GTN sublingually. This was relieved within 5 minutes. Yes. I will sign for the med now.' |
| Handover completed | RN Annie says, 'Mr Smith, we have finished the handover. Do you want to add anything before we leave?' Mr Smith says, 'No, I'll wait to hear about that other heart test.' |
| Confidentiality | After finishing the handover in the four-bed room, all staff went out of the room. In the corridor RN Annie said, 'I have to hand over some sensitive information related to Mr Smith; he has hepatitis C, so make sure that you adhere to universal precautions when undertaking his care.' |

*(Chaboyer et al 2008:15–16)*

## Reporting changes in individual condition

The mechanism for nurses to report changes in the health and functional status of the individual will be determined by the:

- Organisation's policy to activate a clinical review of the individual
- Timelines established by the organisation for the level of deterioration of the individual.

## Telephone reports

Nurses are required to communicate individual information through telephone reporting in a variety of contexts, from conveying a laboratory result to a hospital doctor to conveying complex assessment and treatment information to a medical officer at a remote site. The minimum data set for individual handover includes identification of the nurse and individual, situation and status of the individual, observations, background and history, assessment and actions and responsibility and risk management (ACSQHC 2012) (see Figure 18.4). Documentation must be made relating to the phone call and should include the date and time, the name of the person giving the information and what information was given (Crisp et al 2013).

Most organisational policy and procedure will include the requirement for the nurse to read back and confirm the therapy or plan prescribed by the medical officer. When medications are ordered, this includes a repeating of the medication order to a second nurse, who will also be required to read back to confirm the order. The ACSQHC (2009) provides guidelines for telephone and verbal orders for medications.

## Incident reporting

Healthcare facilities have policies in place that require nurses to complete an incident form following a near miss or an incident such as a medication error or fail. These **incident reports** are confidential documents and are filed separately from the individual's health record. The reports may be written or electronic and are an important part of the quality improvement programs for healthcare facilities. Regardless of whether incident reports are used, nurses have professional accountability to document the facts of the care provided to the individual and the outcome for the individual (see Clinical Interest Box 18.9).

### CLINICAL INTEREST BOX 18.9 Reporting a clinical incident in the health record

A medical officer prescribes morphine 10 mg orally and you mistakenly administer 15 mg. Your medical record documentation should read like this:

| | |
|---|---|
| 08/01/2015 1430 hrs | Nursing: Administered morphine 15 mg orally at 1300 hrs for abdominal pain, which the individual rated at 7/10. Dr Smith notified of above dose at 1315 hrs and gave no additional orders. Observations increased in frequency to every 30 minutes for 4 hours, vital signs have remained within normal parameters at time of report. Mr Jones rates pain as 1/10. Name of nurse, signature, nurse designation. |

## Summary

Nurses provide 24-hour care; therefore, information exchange, whether verbal or documented, is a significant part of nurse activity and must be reliable. Through documentation the nurse communicates to other nurses and the healthcare team their assessment of the status of the individual, the nursing interventions that were carried out and the outcome of these interventions.

Individual records are kept for a number of purposes, including communication, research and quality activities, funding arrangements, legal documentation and healthcare analysis.

Clinical handover is an essential part of the communication of individual care and is practised in numerous ways depending on the clinical setting. It includes both written and verbal information. The two main uses of verbal reporting by a nurse are when a nurse is transferring care to another healthcare provider and when the nurse recognises and responds to changes in the health and functional status of the individual. Research has proven that effective clinical handover is an essential component of ensuring safe and effective care to individuals.

The healthcare record is a legal document. It includes paper documents or electronic documents such as faxes, emails, audio or images (including video or digital images). Legislation governs the privacy and confidentiality of the healthcare record.

All information relating to the individual's healthcare is gathered by subjective or objective methods. Any change in an individual's condition requires immediate documentation of the nurse assessment, nurse actions and the individual's response to the nursing interventions.

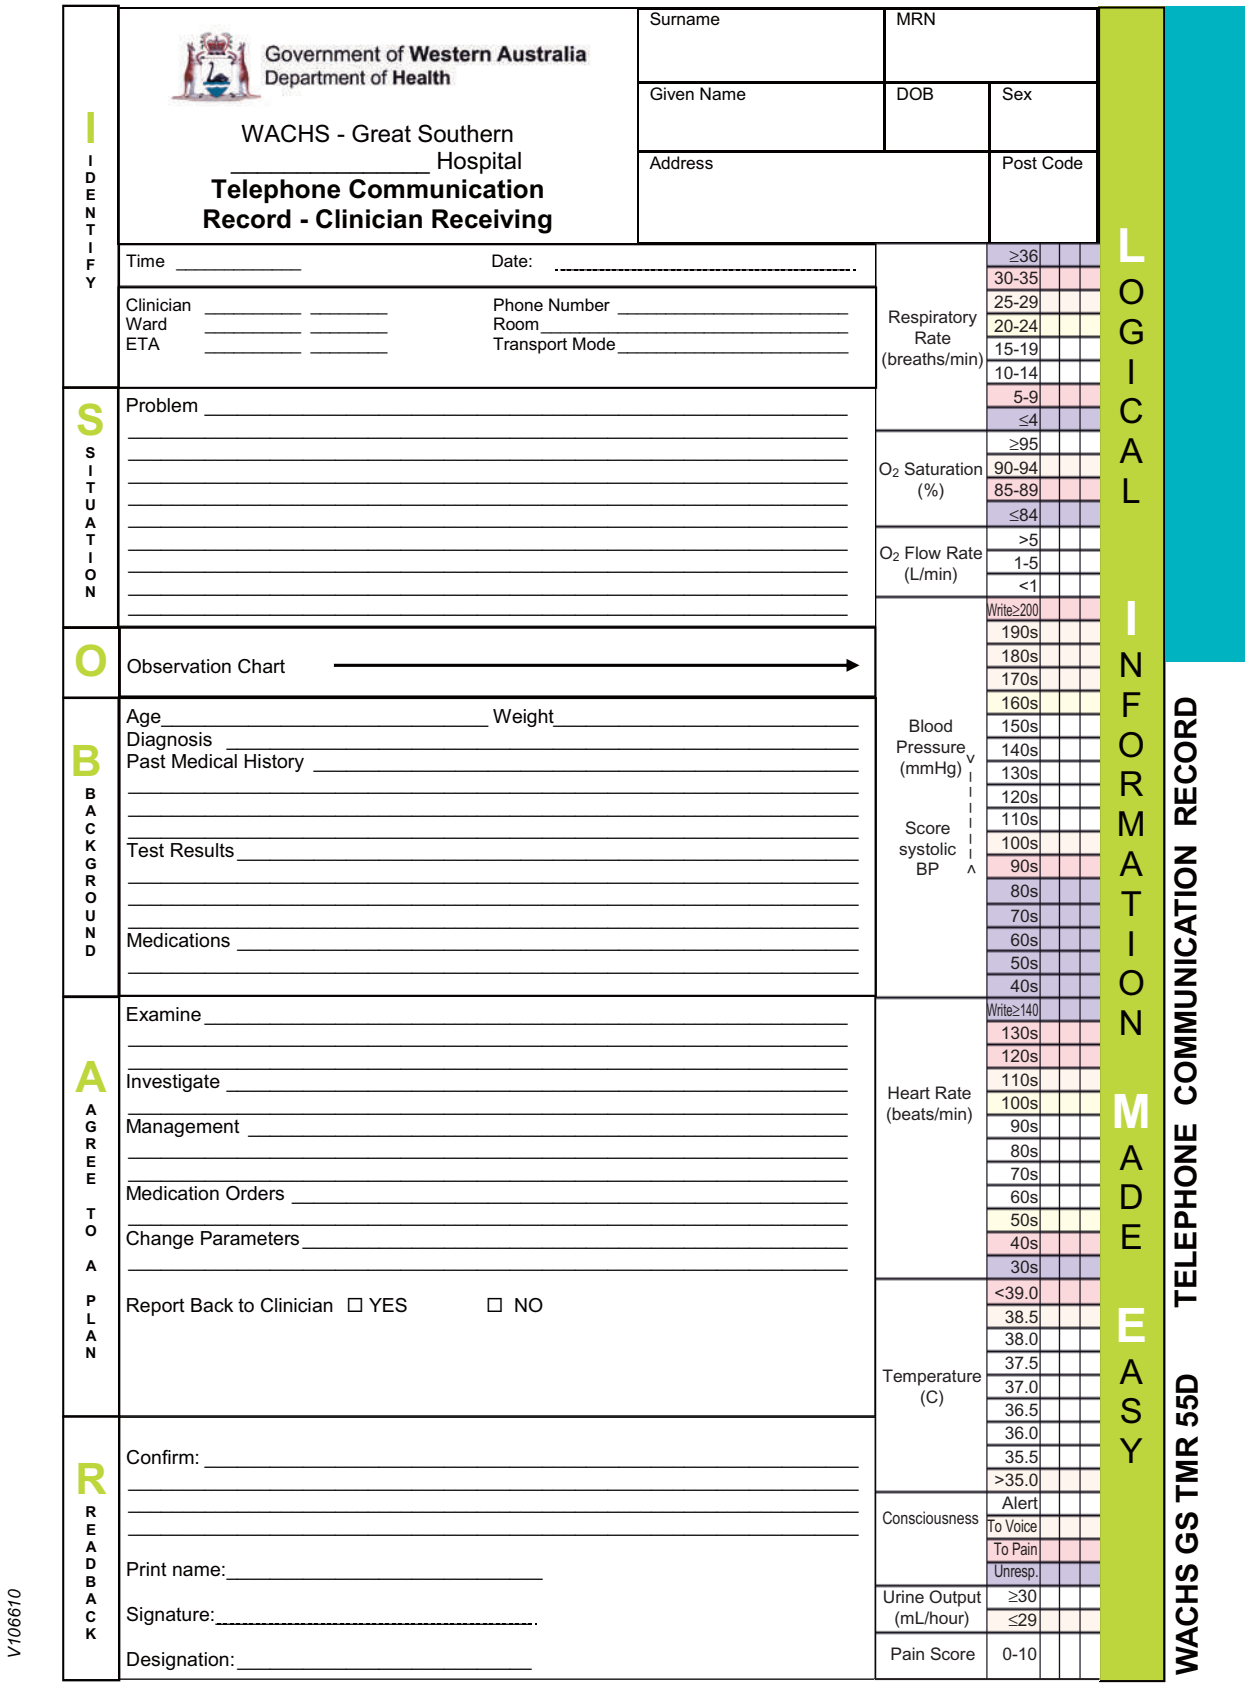

**Figure 18.4** Telephone communication record

*(Sample chart. Telephone Communication Record: Medical Emergency Response Call. WA Country Health Service)*

## Review Questions

1. What is the primary purpose of documentation?
2. Name some other purposes of documentation.
3. Name the seven (7) critical themes for effective nursing documentation.
4. What does the acronym SOAP stand for?
5. What is Standard 6 of the 2012 ACSQHC NSQHS Standards and what is its intention?
6. List the benefits of bedside clinical handover.

Answer guide for the Review Questions, Critical Thinking Exercises, Decision-Making Framework Exercises and Critical Thinking Questions in Case Studies are hosted on Evolve: http://evolve.elsevier.com/AU/Koutoukidis/Tabbner/

# Health assessment frameworks: initial and ongoing

*Kate Stainton and Gabrielle Koutoukidis*

## KEY TERMS

clinical handover
focused assessments
general assessment
nursing health history
objective data
physical assessment
subjective data

## LEARNING OUTCOMES

At completion of this chapter and with further reading, students should be able to:

- Define the key terms
- Identify the purposes of undertaking a health assessment
- Identify the expected outcomes of a health assessment
- Describe the techniques used with each assessment skill
- Identify information from the nursing health history before performing a physical assessment
- Document assessment findings appropriately
- Understand the importance of information gathered during assessment in clinical handover
- Identify assessment tools used as part of the initial and ongoing health assessment

## CHAPTER FOCUS

Obtaining a general health assessment is vital to managing comprehensive nursing care. It is performed at various stages during admission to a healthcare facility. The four basic types of assessment are the initial comprehensive assessment, ongoing assessment, focused assessment and emergency assessment (Lewis et al 2014). The initial assessment involves a detailed review of the individual's condition, with the nurse collecting a **nursing health history** and performing a behavioural and physical examination. Data is collected about the individual's past and current level of wellness, family and sociocultural history and psychosocial responses to illness. These provide a baseline database for ongoing care and against which changes can be evaluated (Crisp et al 2013; Jarvis et al 2012). Periodic assessments are performed on a regular basis throughout the shift and when there is an event that may change the individual's condition. Effective assessment skills can facilitate the identification of new signs and symptoms that indicate complications of an illness or adverse reaction. Standardised assessment forms are used to ensure that regulatory requirements are met, and vary according to the healthcare facility. These forms include initial assessment forms, ongoing assessment forms and specialised and screening assessment forms. One of the main tasks of nurses in the provision of person-centred nursing care is recognition of normal and abnormal signs and symptoms in assessment, intervention and evaluation of individual health and functional status (ANMC 2002). The National Safety and Quality Health Service Standards (NSQHS) provide a framework for an organisational approach to identifying and preventing avoidable risks. Those that form part of the initial and ongoing health assessment are included in this chapter.

## LIVED EXPERIENCE

Ms Cath Kidson, 54 years of age, was 3 days post op after a right hip replacement. Her dressing had become moist and required a dressing change. I was so excited that the Registered Nurse asked me to do this that I did not check that Ms Kidson was actually allergic to the waterproof dressing I was about to place on her wound—until she reminded me. I saw that she had a red allergy band on her wrist but assumed it was related to medications, not dressings and tapes. This was a reminder to me to always assess an individual holistically.

**Stephanie, Enrolled Nursing Student**

## GUIDELINES FOR CONDUCTING A GENERAL HEALTH ASSESSMENT

Conducting a general health assessment allows nurses to be engaged with individuals. By engaging, nurses are able to establish baseline responses of individuals under their care to physical and psychosocial needs such that when there is an altered response or a deviation from the baseline, appropriate nursing measures can be established by applying clinical judgment (Phaneuf 2008). The information gathering as part of the health assessment must be factual and complete as it provides the basis for clinical decision making (Jarvis et al 2012; Lewis et al 2014).

General health assessments need to include overall health status, detailed health history and physical examination, using a holistic approach. When commencing a general health assessment the nurse should:

- Set priorities for assessment based on individual presenting signs and symptoms
- Utilise a framework to collect data as this facilitates an effective assessment. This could be based on functional health patterns, body systems or a head-to-toe approach (Lewis et al 2014). Gordon's 11 functional health patterns framework (see Table 19.1) is a holistic framework that can assist in developing a nursing perspective to health assessment
- Engage the individual by allowing active participation in the assessment process
- Record quick notes to facilitate accurate documentation
- Integrate health promotion and education into physical assessment activities
- Consider the cultural background of the individual (see Table19.2).

Zambas (2010) and Lewis and colleagues (2014) suggest that a systematic approach to assessment does not necessarily involve a formal assessment each time. In fact, every encounter a nurse has with the individual is an opportunity for assessment of physiological functioning and coping. These forms of assessments can be done while the nurse is administering medication; assisting the person to change position in bed; assisting with toileting and shower or at any other times the nurse observes the person during the course of the shift. This type of assessment may also be performed in a hospital, community or home setting. Continued assessments encourage a person-centred approach and thus help to reduce incidences of adverse events. Douglas and colleagues (2014) explored the barriers to nurses undertaking physical assessment and found that inadequate physical assessment by nurses may lead to a failure to recognise individuals at risk of clinical deterioration.

General health assessments conducted at the emergency department are brief so that the information gathered can

**TABLE 19.1 | Functional health patterns health assessment framework**

| Functional health pattern | Focus of health assessment |
|---|---|
| Health perception–health management pattern | *Describes the individual's perceived pattern of health and well-being and how health is managed*<br>Reason for seeking healthcare<br>Description of present illness (onset, course, treatment)<br>Description of health (usual)<br>Relevance of health to activities<br>Preventative measures, general healthcare behaviour<br>Previous hospitalisations, expectations for this episode |
| Nutritional–metabolic pattern | *Describes patterns of food and fluid consumption relative to metabolic needs and pattern indicators of local nutrient supply*<br>Usual food and fluid intake (24-hour dietary recall)<br>Daily eating times<br>Recent weight change and reason<br>Food restrictions or preferences, supplements<br>Swallowing, chewing, eating problems, food allergies<br>Skin lesions and general ability to heal<br>Condition of the skin, hair, nails, mucous membranes and teeth |
| Elimination pattern | *Describes patterns of excretory function (bowel, bladder and skin)*<br>Bowel, bladder and skin excretion<br>Regularity of urination and bowel evacuation<br>Colour, quality and quantity of urine and faeces<br>Aids used to facilitate function, such as routines, devices (laxatives, suppositories, enemas) and methods to control excretion<br>Changes or disturbances in bowel or bladder elimination |
| Activity–exercise pattern | *Describes patterns of exercise, activity, leisure and recreation. The activity–exercise pattern describes three functions that are important to everyone's daily life:*<br>Mobility—movement, posture, balance and gait<br>Independent self-care—ability to perform activities of daily living (ADLs)<br>Exercise and leisure—exercise tolerance, activities requiring energy expenditure |
| Cognitive–perceptual pattern | *Describes sensory-perceptual and cognitive patterns. The ability to collect information from the environment and use it in reasoning and other thought processes*<br>Adequacy of hearing, vision, smell, touch, taste<br>Impact on ADLs and compensation or devices used such as glasses or hearing aids<br>Pain and how it is managed<br>Cognitive functional abilities such as orientation, memory, reasoning, judgment and decision making |
| Sleep–rest pattern | *Describes patterns of sleep, rest and relaxation in a 24-hour period*<br>Usual sleep routine, sleep pattern<br>Perception of quality and quantity of sleep<br>Rest and relaxation or quiet periods during the day<br>Sleep disturbances<br>Use of aids to sleep, such as medications or night-time routines |
| Coping–stress tolerance pattern | *Describes the client's general coping pattern and the effectiveness of the pattern in terms of stress tolerance*<br>Stressors and stress tolerance<br>General coping strategies<br>Support systems<br>Perceived ability to control or manage situations |
| Role–relationship pattern | *Describes the work, family and social roles and relationships of individuals that may be influenced by health-related factors or may offer support during illness*<br>Life roles and responsibilities<br>Satisfaction or dissatisfaction in family, work and social relationships<br>Impact of illness on roles and relationships |

## TABLE 19.1 | Functional health patterns health assessment framework—cont'd

| Functional health pattern | Focus of health assessment |
|---|---|
| Self-perception–self-concept pattern | *Describes the client's self-concept pattern and perceptions of self (e.g. self-identity, esteem and body image, self-efficacy, mood state)*<br>Self-description<br>Effects of illness on self-concept<br>Body image, identity, self-esteem<br>Posture, eye contact, voice and speech patterns |
| Sexuality–reproductive pattern | *Describes the client's patterns of satisfaction and dissatisfaction with sexuality pattern; describes reproductive pattern*<br>Perceived satisfaction or dissatisfaction with sexuality–reproductive pattern<br>Impact of illness or treatments on sexual activity<br>Adequacy of sexual knowledge<br>Reproductive development and state (e.g. menstruation and menopause) |
| Values–beliefs pattern | *Describes patterns of values, beliefs (including spiritual) and goals that guide the client's choices or decisions*<br>Values, goals or beliefs that are basis for decision making<br>Spiritual or religious affiliation<br>Spiritual practices and religious needs |

*(Adapted from Gordon M 2007 Manual of nursing diagnosis, ed 11. Ontario, Jones & Bartlett; Crisp et al 2013, p. 573, Table 27.1)*

## TABLE 19.2 | Cultural considerations in health assessment

| What you need to know | Why you need to know it |
|---|---|
| Ethnicity and country of birth | This information can be an indicator of the individual's culture, traditions, customs, health beliefs and preferred languages.<br>Remember that:<br>Ethnicity may be more significant than country of birth. For example, individuals may have been born in a country where their parents lived briefly. |
| Preferred language | May indicate the need for an interpreter<br>Remember that:<br>Preferred language may not be related to country of birth.<br>It is the health professional's responsibility to ensure that communication is conducted in the preferred language of the individual and can be understood by the individual.<br>This is a Victorian Government requirement at critical points of communication. |
| Literacy | May affect the individual's capacity to respond to written information provided during the assessment.<br>May indicate the individual's social status and education level in their previous country of residence or origin.<br>Remember that:<br>Individuals may rely on family members to read and explain written information.<br>Individuals and their families may not be literate in the language they prefer to speak. |
| Interpreter preferences | Identifying an appropriate interpreter, and ensuring that the individual is comfortable using an interpreter, is essential for clear and appropriate communication.<br>Remember that:<br>The individual may not be familiar with using an interpreter—you may need to explain the process.<br>Individuals may have concerns about the confidentiality of interpreters.<br>There is a small chance that the individual may know the interpreter, which may raise privacy concerns.<br>Consider individual preferences regarding the gender and ethnicity of the interpreter, and whether an on-site or telephone interpreter is preferred.<br>Only qualified interpreters should be used: the individual's family members should not be used as interpreters. |

*Continued*

**TABLE 19.2 | Cultural considerations in health assessment—cont'd**

| What you need to know | Why you need to know it |
|---|---|
| Migration status and experience | Stress and trauma resulting from pre-migration, migration or post-migration experiences can greatly affect an individual's health and wellbeing.<br>Visa status can affect access to subsidised health services. |
| Beliefs about health and illness | Individuals' beliefs and past experience affect the way they view health, causes of illness and treatment.<br>Understanding and acknowledging the individual's health beliefs and practices is an important step in creating a mutually acceptable care plan. |
| Understanding of the health system | Individuals may not be familiar with the structure of the health service system or how to access various services.<br>Individuals may not be familiar with health system processes (e.g. waiting lists for hospitals, Medicare support, etc) |
| Family and social support | The responsibility for care may not lie only with the individual: other people, including extended family, may assume responsibility for care.<br>Remember that:<br>In some cultures, 'family' may include non-related individuals.<br>An individual's social support networks may be limited.<br>An individual may be able to access support through community organisations. |
| Religious practices | Individuals may wish to access spiritual or religious leaders.<br>Particular times for prayer may be important.<br>Religious practices may occasionally conflict with treatment plans.<br>Particular customs may need to be followed during birth, illness and death and dying. |
| Dietary practices | There may be religious restrictions on food consumption.<br>Some foods may have cultural meanings for individuals (e.g. the belief that certain foods are beneficial or harmful to health). |

*(Centre for Culture, Ethnicity & Health 2011)*

effectively rule out differential diagnoses and quickly allow appropriate nursing measures to be taken. On the other hand, assessments performed for an admission need to include a comprehensive set of individuals' information so that nurses can plan for actual as well as potential nursing interventions for the length of the hospitalisation (see Figure 19.1 and Chapter 17).

Enrolled Nurses may undertake assessments under the delegation of the Registered Nurse (NMBA 2016). Abnormal findings must be validated and interpreted by the Registered Nurse and reported to the medical officer.

## General assessment

A **general assessment** includes the following steps (Crisp et al 2013):

- Assess the individual's responses
- Review baseline vital signs (see Chapter 20 for vital signs)
- Review the individual's fluid intake and output
- Assess posture and position and body movements
- Assess speech
- Observe hygiene and grooming:
  - Observe the colour, distribution, quantity, thickness, texture and lubrication of hair
  - Inspect the condition of the nails
  - Assess the presence or absence of body odour
- Assess the eyes:
  - Inspect pupils for size, shape and equality
  - Note the condition of the individual's vision
- Assess hearing
- Inspect the nose externally for shape, skin colour, alignment and presence of deformity or inflammation. Note the colour of the mucosa and any lesions, discharge, swelling or presence of bleeding
- In an individual with nasogastric tubes, inspect the nares for excoriation or inflammation
- Assess the mouth, inspect the oral mucosa, tongue, teeth and gums for hydration; determine whether the individual wears dentures
- Inspect the skin surfaces, comparing the skin colour of symmetrical body parts
- Inspect the character of any secretions: note colour, odour, amount and consistency
- Assess skin turgor
- Assess the condition of the skin for pressure injury (see Clinical Skill 19.1)
- Assess consciousness, feelings and emotional status

## CLINICAL SKILL 19.1 Pressure injury risk assessment

**Review and carry out the standard steps for all clinical skills/interventions**

| **NMBA Decision-making Framework considerations:** | **Equipment:** |
|---|---|
| 1. Am I educated?<br>2. Am I authorised?<br>3. Am I competent?<br>If you answer 'no' to any of these, do not perform that activity. Seek guidance and support from your teacher/a nurse team leader/clinical facilitator/educator. | Assessment tool used in the clinical facility/organisation<br>The individual's nursing care plan and history |
| **Skill activity** | **Rationale** |
| Identify indications and rationale for performing the activity. This may include identifying:<br>• Past history of pressure injuries<br>• Intrinsic and extrinsic factors that may contribute to pressure injuries<br>• Understanding reasons why the pressure injury risk assessment needs to be performed or has been ordered | Reduces unnecessary assessments performed on an individual |
| Identify the individual using three individual identifiers. This may include but is not limited to:<br>• Identification—allocated healthcare number on hospital bracelet/band<br>• Verbal confirmation from the individual of given and family name<br>• Date of birth<br>• Gender<br>• Address<br>• Medical record number | Reduces the incidence of performing an assessment on the incorrect individual |
| Explain and communicate the activity clearly to the individual. This may include but is not limited to explaining to the individual:<br>• Why the procedure has been ordered<br>• Why the procedure will be undertaken and frequency<br>• What is involved in undertaking the procedure<br>• What will be done with the data collected | Reduces anxiety/apprehension and gains an individual's trust and cooperation |
| Ensure therapeutic interaction. This may include but is not limited to:<br>• Introducing oneself<br>• Ensuring privacy before undertaking the assessment<br>• Listening to the individual's concerns or questions about the assessment before it is undertaken<br>• Ensuring the individual is aware of the responsibilities required of them before undertaking the assessment<br>• Maintaining professional boundaries<br>• Assessing any cultural/language barriers | Assists with alleviation of fear prior to the assessment |
| Gain the individual's consent:<br>• By explaining the assessment, reasons for undertaking and risks if not undertaken<br>• By asking the individual for verbal or written consent before undertaking the assessment | Ensures that the individual understands why the assessment needs to be performed, therefore promoting cooperation |
| Perform hand hygiene | Prevents cross-infection |
| Ensure provision of comfort measures prior to the assessment including the removal of restrictive clothing and providing pain relief if required | Promotes an individual's cooperation, removes risk factors with clothing and ensures accurate data is collected |

## CLINICAL SKILL 19.1 Pressure injury risk assessment—cont'd

| | |
|---|---|
| Assess and document the individual's sensory perception in the progress notes and facility/organisational chart:<br>• By assessing the individual's ability to detect pain<br>• In unconscious individuals, the ability to react to pain | Assesses the individual's ability to verbalise pressure-related discomfort that will indicate skin damage<br>Prompts the EN to apply interventions and strategies on how often to replace and clean linen, incontinence aids<br>Assesses the unconscious individual's ability to react to pressure-related discomfort which will indicate skin damage |
| Assess and document the individual's degree of exposure to moisture in the progress notes and organisation chart by direct observation or assessment of turgor, dampness, excessive moisture loss affecting skin<br>Assess continence | Assesses the individual's risk of skin damage and degeneration if exposed to excessive moisture<br>Prompts the EN to apply interventions and strategies on how often to replace and clean linen, incontinence aids |
| Assess and document the individual's activity and mobility status in the progress notes and organisational chart:<br>• By assessing the ability of the individual to move or the ability to be moved<br>• In unconscious individuals, the ability to be moved<br>• Observing for any reddened skin that blanches white under light pressure | Assesses the individual's risk of skin damage and degeneration from the degree of physical mobility<br>Prompts the EN to apply interventions and strategies on how often to assist the individual in changing body position to relieve pressure on the skin<br>Prompts the EN to engage the use and expertise of an occupational therapist and physiotherapist |
| Assess and document the individual's nutritional status in the progress notes and organisational chart<br>Nutritional data collection will include:<br>• Loss of appetite of an individual<br>• Unusual weight loss or gain in an individual<br>• Fluid intake of an individual | Assess the individual's risk of skin damage and degeneration caused by malnutrition or poor nutritional status<br>Prompts the EN to apply interventions and strategies on how often to assist the individual with meals<br>Prompts the EN to engage the use and expertise of a dietitian |
| Assess and document the individual's risk of friction and shear when moving in the progress notes and organisational chart by:<br>• Assessing and identifying any mechanical force that could occur when two surfaces rub together, creating resistance between the skin and a surface<br>• Identifying typical areas where this will occur (e.g. heels and elbows), resulting from repositioning<br>• Assessing and identifying any mechanical force created from parallel loads (e.g. movement on a bed sheet), which can create an occlusion or displacement of tissue | Assesses the individual's risk of skin damage and degeneration from friction or shearing of the skin when moving<br>Prompts the EN to apply interventions and strategies on how often to assist the individual in changing body position to relieve pressure on the skin<br>Prompts the EN to engage the use and expertise of an occupational therapist and physiotherapist<br>Shear forces are a significant risk for pressure injury formation as blood flow is disrupted |
| Undertake a head-to-toe assessment of the skin to identify any existing or new skin tears, especially over bony prominences such as sacrum, elbows, shoulder blades.<br>This includes:<br>• Identifying intact skin or skin loss<br>• Blanchable or non-blanchable skin<br>• Areas that may be painful, warmer, cooler or oedematous<br>If skin breaks have been identified:<br>• Skin break is measured and documented in depth and width on the pressure area risk tool<br>• Colour and/or ooze is documented on the pressure area risk tool<br>• Location is identified on the pressure area risk tool<br>• Treatment plan is documented on the pressure risk tool | Ensures pressure areas are identified early and treated early<br>These are warning signs of impending skin damage |

*Continued*

| CLINICAL SKILL 19.1 Pressure injury risk assessment—cont'd | |
|---|---|
| Ensure provision of comfort measures after the assessment including repositioning of the individual | Promotes an individual's comfort and privacy |
| Identify the individual's need for assistance and comorbidities by accessing the individual's nursing care plan prior to undertaking the assessment | Ensures the nurse has factored into the assessment already-known risk factors prior to the assessment being undertaken |
| Determine the frequency of the pressure risk monitoring by identifying and evaluating the individual's risk status, such as high, medium or low, according to the pressure injury chart | Ensures a range of data is collected over different situations and times. |
| Link theory to practice | An understanding of why the nurse is undertaking the assessment ensures a thorough collection of data and an understanding of the data collected |
| Demonstrate current best practice in the care provided by understanding the current trends in pressure injury management | Ensures quality care is provided to the individual |
| Adhere to the policy and procedures of the facility/ organisation by locating and reading prior to assessment to ensure the delegation is valid | Policies and procedures are written documents that include guidelines and practices developed to address legal, ethical and regulatory requirements<br>Both policies and procedures convey to employees and to other stakeholders the organisation's interests and the vision, mission and methods they intend to use to achieve those goals |
| Work in collaboration with other allied healthcare staff by working with the Registered Nurse and identifying referral to allied health staff if required | Referral to other health professions ensures holistic care with appropriate interventions |
| Demonstrate a structured clinical handover process, either verbal or written, using the identified organisation policy | Ensures current and correct information is relayed to other health professionals for continuity and safety of care |
| Document assessment findings using the correct documentation tools as per the policy of the organisation | Ensures a systematic record for reference by other allied healthcare professionals |
| Record the assessment findings with the date, time and signature on the pressure injury chart | Provides a baseline observation for assessment improvement or deterioration |
| Report abnormal assessment findings to the Registered Nurse | Ensures appropriate strategies and intervention are put in place to encourage positive outcomes |
| *(Adapted from ACSQHC 2012; Jensen 2013; NSW Government 2010; State Government of Victoria 2010; Viljoen & Uys 2001)* | |

- Observe the individual's interaction with their spouse or partner, older adult child or carer
- Observe for signs of abuse:
  - for a child, blood on underclothing, pain in the genital area or difficulty in sitting or walking may be indicative of child sexual abuse
  - for a female individual, injury or trauma inconsistent with a reported cause, or obvious injuries to face or neck, could indicate domestic violence
  - for an older adult, injury or trauma inconsistent with a reported cause, injuries in unusual locations (neck or genitalia), pattern injuries, parallel injuries and burns may suggest abuse.

A general health assessment consists of assessing an individual's physical, mental health, socioeconomic and financial status. The data collected will assist the nurse to focus on the effects that health and illness have on quality of life (Jensen 2013). Different interview styles and approaches to physical examinations are used for individuals of different age groups. See Clinical Interest Box 19.1.

## Focused assessment

Sometimes a more focused assessment may be necessary. **Focused assessments** are used to observe and monitor systems-related complications. A focused assessment is a more detailed assessment of a particular problem (Lewis et al 2014; Brown et al 2015). For example, if a person suddenly presents

## CLINICAL INTEREST BOX 19.1 Assessment of age groups

### 1. Children

The focus of a paediatric assessment is usually on growth and development, sensory screening, dental examination and behavioural assessment, and is normally conducted by an experienced nurse.

> The nursing history will need to be obtained mostly from parents or a guardian
> The examination should be performed in a non-threatening area and provide the child with time to play
> Do not pass judgment on the parents and offer support
> Call children by their given name
> Use open-ended questions to allow parents to describe the child's problems
> Interview older children and observe the parent–child interactions
> Adolescents will respond better if they are treated as adults
> Adolescents have the right to confidentiality.

*(Crisp et al 2013)*

### 2. Older adults

Health assessment of older adults should include an evaluation of mental status, family relationships, group involvement and religious and occupational pursuits. An important part of the assessment will involve analysis of activities of daily living (dressing, bathing, toileting, grooming, feeding and continence) and more complex activities such as preparing meals and managing money (Crisp et al 2013).

> Do not stereotype ageing individuals
> Understand that sensory or physical limitations can affect how quickly you are able to interview older adults
> Perform the examination with adequate space
> Older adults may find giving some health information stressful. Illness may be seen as a threat to independence
> Perform the examination near bathroom facilities
> Be aware of signs of fatigue (e.g. irritability, leaning against objects for support and drooping of the head and shoulders).

*(Crisp et al 2013)*

with lowered conscious status, the nurse needs to pay close attention to the immediate assessment of the neurological status in order to plan appropriate interventions. These assessments are usually initiated by identifying and responding to an acute onset of the individual's symptoms. Even when a focused assessment is performed, it is still important to look at the entire individual presentation. This is because a problem in one body system will affect or be affected by another body system. So it is important to observe from head to toe and note any changes in other body systems.

Comprehensive assessment provides a framework to ensure all areas of potential risk are covered. Assessments commonly performed by nurses include the following.

## Mental health assessment

A comprehensive mental health assessment will involve clinical assessment and information gathering in the following areas:

- Presenting problems
- History of presenting problems (onset, duration, course, severity)
- Current functioning (across domains; e.g. employment/education, family, social)
- Relevant cultural issues (personal and family)
- Previous assessments and interventions
- Psychiatric history (personal and family history)
- Current medications
- Medical history and family history
- Developmental history
- Substance use
- Forensic and legal history
- Risk screen (e.g. suicide, self-harm, aggression, vulnerability; absconding risk, risks to dependent children and risk of disrupted attachment)
- Goals for treatment
- Mental status examination.

This assessment is usually completed by a psychiatrist, psychologist, social worker or mental health nurse (Queensland Health 2010).

See Clinical Skill 19.2.

## Falls risk assessment

A falls risk assessment is used to identify any person who may be at risk of falls. Some of these risks can be classified as personal or environmental. Personal risk factors include age, gender, ability and health conditions. Environmental factors refer to hazards found in and around the home and in public places (e.g. uneven surfaces, lack of hand rails) (Queensland Health 2012). A falls risk assessment can help determine what interventions should be implemented. (See Clinical Skill 19.3 and Nursing Care Plan 19.1.)

## Venous thromboembolism (VTE) assessment

VTE is one of the leading causes of preventable death in Australia. People at risk of forming a VTE are those with medical illnesses including cancer, people who have been involved in a trauma, individuals admitted to intensive care units, women hospitalised during pregnancy and the puerperium and those who have had surgery (NHMRC 2009). See Clinical Skill 19.4.

## Nutrition assessment

Nutritional intake can be affected by disease, genetic disorders, injury and surgical and medical treatments. A subjective assessment will include the person's description of their daily dietary and fluid intake, use of dietary supplements, food

*Text continued on p. 383*

## CLINICAL SKILL 19.2 Mental health assessment

**Review and carry out the standard steps for all clinical skills/interventions**

| **NMBA Decision-making Framework considerations:** | **Equipment:** |
|---|---|
| 1. Am I educated?<br>2. Am I authorised?<br>3. Am I competent?<br>If you answer 'no' to any of these, do not perform that activity. Seek guidance and support from your teacher/a nurse team leader/clinical facilitator/educator. | Assessment tool used in the clinical facility/organisation<br>The individual's nursing care plan and history |

| **Skill activity** | **Rationale** |
|---|---|
| Identify indications and rationale for performing the activity | Reduces unnecessary assessments performed on an individual |
| Identify the individual using three individual identifiers. This may include but is not limited to:<br>• Identification—allocated healthcare number on hospital bracelet/band<br>• Verbal confirmation from the individual of given and family name<br>• Date of birth<br>• Gender<br>• Address<br>• Medical record number | Reduces the incidence of performing an assessment on the incorrect individual |
| Explain and communicate the activity clearly to the individual. This may include but is not limited to explaining to the individual:<br>• Why the procedure has been ordered<br>• Why the procedure will be undertaken and frequency<br>• What is involved in undertaking the procedure<br>• What will be done with the data collected | Reduces anxiety/apprehension and gains an individual's trust and cooperation |
| Gain the individual's consent | Ensures that the individual understands why the assessment needs to be performed therefore promoting cooperation |
| Assess presenting problems<br>Assess history of presenting problems (onset, duration, course, severity)<br>Assess current functioning (across domains e.g. employment/education, family, social)<br>Assess previous assessments and interventions<br>Assess psychiatric history (personal and family history)<br>Assess current medications<br>Assess medical history<br>Assess family history of mental health<br>Assess developmental history<br>Assess substance use<br>Assess forensic and legal history<br>Assess risk screen (e.g. suicide, self-harm, aggression, vulnerability, absconding risk, risks to dependent children) | Provides a baseline data set and possible links to an individual's mental health |
| Assess mental status | Gathers data on the individual's current status and highlights indications of the individual's mental health status |

| CLINICAL SKILL 19.2 Mental health assessment—cont'd | |
|---|---|
| *Appearance:*<br>• Usual and unusual appearance (e.g. statue)<br>• Grooming or any evidence of neglect<br>• Apparent age vs real age<br>• Facial features<br>• Identifying features such as skin marks, moles | Provides a baseline data set and possible links to an individual's mental health |
| *Behaviour:*<br>• Any physical signs of anxiety<br>• Restlessness, relaxed<br>• Hand or facial gestures<br>• Eye contact | Provides a baseline data set and possible links to an individual's mental health |
| *Speech:*<br>• Rate—slow, fast, normal<br>• Logic<br>• Ability to complete sentences<br>• Absence | Provides a baseline data set and possible links to an individual's mental health |
| *Mood and affect:*<br>• Responses to questions<br>• Emotional status—crying, laughing inappropriately<br>• Anger<br>• Anxiety<br>• Irritability | Provides a baseline data set and possible links to an individual's mental health |
| *Form of thought, content of thought:*<br>• Hallucinations—visual or auditory<br>• Hearing of voices<br>• Concerns<br>• Evidence of paranoia | Provides a baseline data set and possible links to an individual's mental health |
| *Insight and cognition:*<br>• Orientation to time, place, person<br>• Understanding of health issues<br>• Understanding of medication therapy and treatment | Provides a baseline data set and possible links to an individual's mental health |
| *Memory:*<br>• Long-term memory<br>• Short-term memory | Provides a baseline data set and possible links to an individual's mental health |
| Identify lifespan, cultural and language barriers | Identifies any considerations required by the nurse when undertaking the assessment, influenced by an individual's past experience, ability to understand and comprehend instructions and age-related considerations |
| Provide privacy | Reduces distraction and reduces the risk of disclosing an individual's information, decreasing embarrassment, and ensures the individual's self-worth is maintained |
| Ensure provision of comfort measures | Promotes an individual's cooperation, removes risk factors with clothing and ensures accurate data is collected |
| Ensure therapeutic interaction | Assists with alleviation of fear prior to the assessment |
| Identify the individual's need for assistance and comorbidities by accessing the individual's nursing care plan prior to undertaking the assessment | Ensures the nurse has factored into the assessment already-known risk factors prior to the assessment being undertaken |

*Continued*

| CLINICAL SKILL 19.2 Mental health assessment—cont'd | |
|---|---|
| Prepare the environment to ensure safety measures are addressed for the individual | Removes risk factors that will interfere with the assessment data collection |
| Demonstrate current best practice in the care provided | Ensures quality care is provided to the individual |
| Adhere to the policy and procedures of the facility/organisation to ensure the delegation is valid | Policies and procedures are written documents that include guidelines and practices developed to address legal, ethical and regulatory requirements<br>Both policies and procedures convey to employees and to other stakeholders the organisation's interests and the vision, mission and methods they intend to use to achieve those goals |
| Ensure the individual's rights are respected<br>Ensure informed consent | Demonstrates quality individual care<br>Demonstrates informed consent |
| Work in collaboration with other allied healthcare staff | Referral to other health professions ensures holistic care with appropriate interventions |
| Demonstrate a structured clinical handover process, either verbal or written | Ensures current and correct information is relayed to other health professionals for continuity and safety of care |
| Document assessment findings using the correct documentation tools | Ensures a systematic record for reference by other allied healthcare professionals |
| Record the assessment findings with the date, time and signature | Provides a baseline observation for assessment improvement or deterioration |
| Report abnormal assessment findings to the Registered Nurse | Ensures appropriate strategies and intervention are put in place to encourage positive outcomes |
| *(Adapted from ACSQHC 2012; Jensen 2013; NSW Government 2010; State Government of Victoria 2010; Viljoen & Uys 2001)* | |

| CLINICAL SKILL 19.3 Falls risk assessment | |
|---|---|
| **Review and carry out the standard steps for all clinical skills/interventions** | |
| **NMBA Decision-making Framework considerations:**<br>1. Am I educated?<br>2. Am I authorised?<br>3. Am I competent?<br>If you answer 'no' to any of these, do not perform that activity. Seek guidance and support from your teacher/a nurse team leader/clinical facilitator/educator. | **Equipment:**<br>Assessment tool used in the clinical facility/organisation<br>Appropriately fitted mobility aids if required<br>The individual's nursing care plan and history |
| **Skill activity** | **Rationale** |
| **Step 1: Preparation for the activity** | |
| Identify indications and rationale for performing the activity. This may include identifying:<br>• Past history of falls<br>• Intrinsic and extrinsic factors that may contribute to falls<br>• Understanding reasons why the falls risk assessment needs to be performed or has been ordered | Reduces unnecessary assessments performed on an individual |

| CLINICAL SKILL 19.3 Falls risk assessment—cont'd | |
|---|---|
| Identify the individual using three individual identifiers. This may include but is not limited to:<br>• Identification—llocated healthcare number on hospital bracelet/band<br>• Verbal confirmation from the individual of given and family name<br>• Date of birth<br>• Gender<br>• Address<br>• Medical record number | Reduces the incidence of performing an assessment on the incorrect individual |
| Explain and communicate the activity clearly to the individual. This may include but is not limited to explaining to the individual:<br>• Why the procedure has been ordered<br>• Why the procedure will be undertaken and frequency<br>• What is involved in undertaking the procedure<br>• What will be done with the data collected | Reduces anxiety/apprehension and gains an individual's trust and cooperation |
| Ensure therapeutic interaction. This may include but is not limited to:<br>• Introducing oneself<br>• Ensuring privacy before undertaking the assessment<br>• Listening to the individual's concerns or questions about the assessment before it is undertaken<br>• Ensuring the individual is aware of the responsibilities required of them before undertaking the assessment<br>• Maintaining professional boundaries<br>• Assessing any cultural/language barriers | Assists with alleviation of fear prior to the assessment |
| Gain the individual's consent:<br>• By explaining the assessment, reasons for undertaking and risks if not undertaken<br>• By asking the individual for verbal or written consent before undertaking the assessment | Ensures that the individual understands why the assessment needs to be performed, therefore promoting cooperation |
| **Step 2: Perform the activity** | |
| Undertake an assessment data collection and document this on the falls risk chart and progress notes by reading and researching the individual's:<br>Medical history:<br>• Past and current health history<br>• Medications<br>Social situation:<br>• Whether the individual lives alone or with family | Provides an understanding of any medical conditions on the individual's falls risk history. This assessment will include relevant medical history including medications<br>This data will provide an understanding of any family members requiring the need for education or assistance when planning care<br>If the individual is alone, this data will provide an insight into the individual's need for assistance or aids. This assessment will include whether an individual lives alone or with a carer and carer/individual difficulty managing at home |
| Identify and document on the falls chart history past or recent falls by talking to the individual or identifying this in the past medical history of the individual:<br>• When<br>• Where<br>• Any underlying cause of fall | This data will provide insight into a pattern of recent or past falls by an individual that can be used in the planning of care |

*Continued*

## CLINICAL SKILL 19.3 Falls risk assessment—cont'd

Collect and document on the falls risk chart and in the individual's progress notes intrinsic assessment data (data collected from the individual, family or by direct observation):

- Past and present medical history
- Past or present vision impairments
- Past or present nutritional impairments
- Past or present mobility impairments including gait, balance and transfer
- Past or present cognitive impairments
- Past or present continence (faecal/urinary) impairments
- Past or present medication history

Medical history includes:

- Past history of the individual
- Relevant history of the individual
- Symptoms of dizziness voiced by an individual
- Any unsteadiness on standing by an individual
- Any visible signs after a head-to-toe assessment of bleeding, bruising or skin breaks

Vision data collection includes:

- Visual aids used by an individual
- Difficulty in seeing obstacles by an individual

Nutritional data collection includes:

- Loss of appetite of an individual
- Unusual weight loss or gain in an individual
- Fluid intake of an individual

Mobility data collection includes:

- Identifying concerns in an individual's gait such as swaying or holding onto furniture to assist with walking
- Identifying an individual's concerns with limb weakness or reduced sensation
- Identifying an individual's incorrect usage of previously prescribed mobility aids
- Identifying ill-fitting footwear

Cognitive data collection includes:

- Identifying difficulties in an individual's ability to follow or interpret instructions

Continence data collection includes:

- Identifying an individual's concerns about urinary or faecal urgency, nocturia or incontinence that may be identified as risk factors in falls management

Medication data collection includes:

- Identifying an individual's emaciation management plan
- Identifying if the individual is prescribed more than two of the following medications, which may be identified as risk factors in falls management:
  - Diuretics
  - Psychotropic medications
  - Parkinson's disease medications
  - Antidepressants
  - Antihypertensives
  - Sedative medication

Intrinsic data collection provides an insight into risk factors that may require invasive actions that will reduce or minimise falls of an individual

| CLINICAL SKILL 19.3 Falls risk assessment—cont'd | |
|---|---|
| Collect and document on the falls risk chart and in the individual's progress notes extrinsic assessment data on past or present environmental hazards by direct observation or talking with the individual or family<br>This will include identifying:<br>• An individual's reporting of difficulty with stairs<br>Observation or reporting of:<br>• Indoor and outdoor hazards<br>• Poor lighting<br>• Restricted traffic ways or cluttering<br>• An individual's reporting of difficulty moving on and off the bed/toilet/chair | Extrinsic data collection provides an insight into risk factors that may require invasive actions that will reduce or minimise falls of an individual |
| Collect and document on the falls risk chart and in the individual's progress notes assessment data on activities of daily living. This can be obtained via direct observation of the individual or by talking to the individual and family<br>This will include identifying:<br>• An individual's reporting of feeling unsafe when performing activity or difficulty in bending down<br>• Observation of an individual's ability to perform the ADL (e.g. showering, cleaning teeth, combing hair safely without rushing)<br>• An understanding of whether the individual already receives assistance with these activities | Activities of daily living collection provides an insight into risk factors that may require invasive actions that will reduce or minimise falls of an individual |
| Collect and document on the falls risk chart and in the individual's progress notes lifespan and cultural and language barriers by direct observation or by talking to the individual and family | Identifies any considerations required by the nurse when undertaking the assessment, influenced by an individual's past experience, ability to understand and comprehend instructions, and age-related considerations |
| Provide privacy by closing bedside curtains or by undertaking the falls risk assessment in a private room | Reduces distraction and reduces the risk of disclosing an individual's information, decreasing embarrassment, and ensures the individual's self-worth is maintained |
| Ensure provision of comfort measures prior to the assessment including the removal of restrictive clothing and providing pain relief if required | Promotes an individual's cooperation, removes risk factors with clothing and ensures accurate data is collected |
| Identify the individual's need for assistance and comorbidities by accessing the individual's nursing care plan prior to undertaking the assessment | Ensures the nurse has factored into the assessment already-known risk factors prior to the assessment being undertaken |
| Prepare the environment to ensure safety measures are addressed for the individual by removing furniture or items such as electrical cords that could cause an individual to fall | Removes risk factors that will interfere with the assessment data collection |
| Determine the frequency of the falls risk monitoring by identifying and evaluating the individual's risk status, such as high, medium or low, according to the falls risk chart | Ensures a range of data is collected over different situations and times. The higher the falls risk the more frequent the individual's monitoring should be |
| **Step 3: Completion of activity** | |
| To link theory to practice, the Enrolled Nurse should understand the pathophysiology of the individual's health conditions and why this activity was undertaken | An understanding of why the nurse is undertaking the assessment ensures a thorough collection of data and an understanding of the data collected |
| Demonstrate current best practice in the care provided by understanding the current trends in falls risk management | Ensures quality care is provided to the individual |

*Continued*

| CLINICAL SKILL 19.3 Falls risk assessment—cont'd | |
|---|---|
| Adhere to the policy and procedures of the facility/ organisation by locating and reading prior to assessment | Policies and procedures are written documents that include guidelines and practices developed to address legal, ethical and regulatory requirements<br>Both policies and procedures convey to employees and to other stakeholders the organisation's interests and the vision, mission and methods they intend to use to achieve those goals |
| Work in collaboration with other allied healthcare staff by working with the Registered Nurse and identifying referral to allied health staff if required | Referral to other health professions ensures holistic care with appropriate interventions |
| Demonstrate a structured clinical handover process, either verbal or written, using the identified organisational policy | Ensures current and correct information is relayed to other health professionals for continuity and safety of care |
| Document assessment findings using the correct documentation tools as per the policy of the organisation | Ensures a systematic record for reference by other allied healthcare professionals |
| Record the assessment findings with the date, time and signature on the falls risk chart and progress notes | Provides a baseline observation for assessment improvement or deterioration |
| Report abnormal assessment findings to the Registered Nurse | Ensures appropriate strategies and intervention are put in place to encourage positive outcomes |
| *(Adapted from ACSQHC 2012; Jensen 2013; NSW Government 2010; State Government of Victoria 2010; Viljoen & Uys 2001)* | |

## NURSING CARE PLAN 19.1

**Assessment:** Mrs Cain, 80 years, is admitted to the ward with cellulitis of her left leg. She is physically immobile and unable to get out of bed. Whilst completing the pressure-risk screening tool as part of your admission assessment you note that she has an area on her buttocks that is reddened and warm to touch. Mrs Cain is incontinent of urine, which leads to moisture on her skin.
**Issue/s to be addressed:** Risk for impaired skin integrity related to immobility and incontinence.
**Goal/s:** Mrs Cain will not develop any further skin breakdown during her stay at the facility.

| Care/Actions | Rationale |
|---|---|
| Obtain and place a pressure relieving device on bed | Redistributes amount of pressure on bony prominences |
| Reposition Mrs Cain at least once every 2 hours | Repositioning redistributes pressure<br>Positioning interventions reduce pressure and shearing force to the skin |
| Maintain the elevation of the head of the bed to 30 degrees or less when supine | Prevents shear<br>Moisture softens the skin and causes a break in the skin integrity |
| Keep the skin clean and dry<br>Complete pressure risk assessment daily | Systematic inspection can identify impending problems early |

**Evaluation**

Mrs Cain's skin is monitored daily and has no signs of worsening or advanced impairment.

## CLINICAL SKILL 19.4 Venous thromboembolism assessment

**Review and carry out the standard steps for all clinical skills/interventions**

| **NMBA Decision-making Framework considerations:** | **Equipment:** |
|---|---|
| 1. Am I educated?<br>2. Am I authorised?<br>3. Am I competent?<br>If you answer 'no' to any of these, do not perform that activity. Seek guidance and support from your teacher/a nurse team leader/clinical facilitator/educator. | Assessment tool used in the clinical facility/organisation<br>The individual's nursing care plan and history |
| **Skill activity** | **Rationale** |
| Identify indications and rationale for performing the activity. This may include identifying the individual's:<br>• Past history of thromboembolisms<br>• Intrinsic and extrinsic factors that may contribute to emboli<br>• Understanding reasons why the venous thromboembolism assessment needs to be performed or has been ordered | Reduces unnecessary assessments performed on an individual<br>Can allow for early intervention |
| Identify the individual using three individual identifiers. This may include but is not limited to:<br>• Identification—allocated healthcare number on hospital bracelet/band<br>• Verbal confirmation from the individual of given and family name<br>• Date of birth<br>• Gender<br>• Address<br>• Medical record number | Reduces the incidence of performing an assessment on the incorrect individual |
| Explain and communicate the activity clearly to the individual. This may include but is not limited to explaining to the individual:<br>• Why the procedure has been ordered<br>• Why the procedure will be undertaken and frequency<br>• What is involved in undertaking the procedure<br>• What will be done with the data collected | Reduces anxiety/apprehension and gains an individual's trust and cooperation |
| Gain the individual's consent:<br>• By explaining the assessment, reasons for undertaking and risks if not undertaken<br>• By asking the individual for verbal or written consent before undertaking the assessment<br>• Assessing any cultural/language barriers | Ensures that the individual understands why the assessment needs to be performed, therefore promoting cooperation |
| Assess individual's level of mobility. Mobility data collection includes:<br>• Identifying concerns in an individual's gait such as swaying or holding onto furniture to assist with walking<br>• Identifying an individual's decrease in mobility<br>• Identifying an individual's concerns with limb weakness or reduced sensation | The indication of VTE risk can be established by identifying if an individual is a medical or surgical patient |

*Continued*

## CLINICAL SKILL 19.4 Venous thromboembolism assessment—cont'd

| | |
|---|---|
| Assess baseline risk (intrinsic factors) from the individual, family or by direct observation:<br>• Past and present medical history<br>• Past or present medication history<br>• Past or present nutritional impairments<br>Medical history includes:<br>• Past history of the individual<br>• Relevant history of the individual<br>• Symptoms of shortness of breath<br>• Medication history<br>Medication data collection includes:<br>• Identifying an individual's emaciation management plan<br>• Identifying if the individual is prescribed more than two of the following medications, which may be identified as risk factors in falls management:<br>> Diuretics<br>> Psychotropic medications<br>> Parkinson's disease medications<br>> Antidepressants<br>> Antihypertensives<br>> Sedative medication<br>Nutritional data collection includes:<br>• Loss of appetite of an individual<br>• Unusual weight loss or gain in an individual<br>• Fluid intake of an individual | The indication of VTE risk can be established by identifying an individual's age, pregnancy status, previous history of VTE, obesity, varicose veins, active malignancy |
| Assess additional risk of VTE (extrinsic) by direct observation or talking with the individual or family:<br>• Dehydration status<br>• Surgical risk by type (pelvic, orthopaedic, joint surgery)<br>• Medical risk by type (stroke, heart failure, myocardial infarction) | The indication of additional VTE risk can allow for early intervention |
| Administer and document in the individual's medication chart pharmacological treatments as ordered by reviewing the individual's medication chart | The administration of prescribed pharmacological treatments will decrease the VTE risk |
| Assess contraindications to pharmacological treatments by reviewing the individual's medication chart. This may include but is not limited to:<br>• Known hypersensitivity to agents used in pharmacological prophylaxis<br>• Active bleeding or risk of bleeding | Understanding the contraindications of administering the pharmacological treatment and drug interactions will decrease the risk of bleeding or reaction. This must be reported to the Registered Nurse before the treatment is withheld |
| Apply and document in the individual's progress notes mechanical VTE inventions as ordered:<br>• Anti-embolic stockings at correct size by measuring length and width of extremity and applying the appropriate size as indicated on the packaging | The application of mechanical compression stockings will decrease the VTE risk. Bunching of the stockings from incorrect fitting could result in leg ulceration, pressure injuries, slipping and falling on mobilisation |
| Assesses any contraindications to mechanical prophylaxis treatment. This may include but is not limited to:<br>• Morbid obesity where correct fitting cannot be achieved<br>• Inflammatory conditions of the lower leg<br>• Severe peripheral arterial disease<br>• Diabetic neuropathy (there is a risk of injury due to decreased sensation and discomfort if there is a problem with the fitting)<br>• Severe oedema of the legs<br>• Unusual leg deformity<br>• Allergy to stocking material<br>• Cardiac failure | Understanding the contraindications of administering mechanical treatment will decrease the risk of reduced blood flow, pressure ulcers or risk of falls. This must be reported to the Registered Nurse if a decision is made to withhold the treatment |

| CLINICAL SKILL 19.4 Venous thromboembolism assessment—cont'd | |
|---|---|
| Discuss overall risk assessment and management with the Registered Nurse before treatment is applied | Ensures that evidence-based decisions have been considered and are appropriately required (e.g. risk vs benefits of treatment) |
| Identify the individual's need for assistance and comorbidities by accessing the individual's nursing care plan prior to undertaking the assessment | Ensures the nurse has factored into the assessment already-known risk factors prior to the assessment being undertaken |
| Prepare the environment to ensure safety measures are addressed for the safety of the individual | Removes risk factors that will interfere with the assessment data collection |
| To link theory to practice, the Enrolled Nurse should understand the pathophysiology of the individual's health conditions and why this activity was undertaken | An understanding of why the nurse is undertaking the assessment ensures a thorough collection of data and an understanding of the data collected |
| Demonstrate current best practice in the care provided by understanding the current trends in VTE risk management | Ensures quality care is provided to the individual |
| Adhere to the policy and procedures of the facility/organisation by locating and reading prior to assessment to ensure the delegation is valid | Policies and procedures are written documents that include guidelines and practices developed to address legal, ethical and regulatory requirements<br>Both policies and procedures convey to employees and to other stakeholders the organisation's interests and the vision, mission and methods they intend to use to achieve those goals |
| Work in collaboration with other allied healthcare staff by working with the Registered Nurse and identifying referral to allied health staff if required | Referral to other health professions ensures holistic care with appropriate interventions |
| Demonstrate a structured clinical handover process, either verbal or written, using the identified organisational policy | Ensures current and correct information is relayed to other health professionals for continuity and safety of care |
| Document assessment findings using the correct documentation tools as per the policy of the organisation | Ensures a systematic record for reference by other allied healthcare professionals |
| Record the assessment findings with the date, time and signature on the clinical tool | Provides a baseline observation for assessment improvement or deterioration |
| Report abnormal assessment findings to the Registered Nurse | Ensures appropriate strategies and intervention are put in place to encourage positive outcomes |
| *(Adapted from ACSQHC 2012; Jensen 2013; NSW Government 2010; State Government of Victoria 2010; Viljoen & Uys 2001)* | |

preferences, eating patterns, ability to chew, nutritional knowledge, activity and exercise. Questions are focussed on recent alterations in weight; appetite; nausea and vomiting; condition of hair, skin and nails; and any medications. Physical assessment will also include examination of the mouth, measurement of height and weight and assessment of abdomen, hair, skin and nails (Crisp et al 2013). See Clinical Skill 19.5.

**CRITICAL THINKING EXERCISE** 19.1

Mr Leonard enters the hospital with a history of weight loss and general fatigue. What questions will you ask to elicit the appropriate responses that will help to establish the nursing assessment?

## Physical assessment

A **physical assessment** or examination of an individual in a healthcare facility is obtained to:

- Gather baseline data about the person's health
- Supplement, confirm or refute data obtained in the nursing history
- Confirm and identify nursing diagnoses
- Make clinical judgments about an individual's changing health status and management
- Identify issues for health promotion
- Evaluate the outcomes of care.

(Crisp et al 2013; Berman et al 2015; Potter et al 2015)

A nurse must learn how to really discern an individual's condition so that, even in passing or without conscious effort, clues to an individual's health or ill health are not missed.

## CLINICAL SKILL 19.5 Nutritional assessment/weight, height and BMI

**Review and carry out the standard steps for all clinical skills/interventions**

| **NMBA Decision-making Framework considerations:** | **Equipment:** |
|---|---|
| 1. Am I educated?<br>2. Am I authorised?<br>3. Am I competent?<br>If you answer 'no' to any of these, do not perform that activity. Seek guidance and support from your teacher/a nurse team leader/clinical facilitator/educator. | Assessment tool used in the clinical facility/organisation<br>The individual's nursing care plan and history |

| **Skill activity** | **Rationale** |
|---|---|
| Identify indications and rationale for performing the activity | Reduces unnecessary assessments performed on an individual |
| Identify the individual using three individual identifiers. This may include but is not limited to:<br>• Identification—allocated healthcare number on hospital bracelet/band<br>• Verbal confirmation from the individual of given and family name<br>• Date of birth<br>• Gender<br>• Address<br>• Medical record number | Reduces the incidence of performing an assessment on the incorrect individual |
| Explain and communicate the activity clearly to the individual. This may include but is not limited to explaining to the individual:<br>• Why the procedure has been ordered<br>• Why the procedure will be undertaken and frequency<br>• What is involved in undertaking the procedure<br>• What will be done with the data collected | Reduces anxiety/apprehension and gains an individual's trust and cooperation |
| Gain the individual's consent:<br>• By explaining the assessment, reasons for undertaking and risks if not undertaken<br>• By asking the individual for verbal or written consent before undertaking the assessment | Ensures that the individual understands why the assessment needs to be performed, therefore promoting cooperation |
| Assess the individual's past and current history:<br>• Past medical and surgical history<br>• Medication history<br>• Alcohol and drug use<br>• Bowel habits | Establishes data on past history which may contribute to weight loss or gain |
| Assess the individual's psychosocial history:<br>• Economic status<br>• Occupation<br>• Education level<br>• Living and cooking arrangements<br>• Education level<br>• Mental status | Establishes a data base that may identify any effects on nutritional status |
| Undertake a nutritional history by asking and/or observing the individual:<br>• Nausea/vomiting (>3 days)<br>• Diarrhoea<br>• Dysphagia<br>• Usual adult weight—refer to normal BMI charts<br>• Current weight by weighing the individual<br>• Recent changes in appetite or food tolerance<br>• Oedema and/or abnormal swelling | Provides data on appetite |

## CLINICAL SKILL 19.5 Nutritional assessment/weight, height and BMI—cont'd

| | |
|---|---|
| Undertake a nutritional intake history by asking and/or observing the individual:<br>• Diet restrictions<br>• Appetite<br>• Eating patterns and intakes<br>• Taste changes<br>• Dentition<br>• Dysphagia<br>• Feeding independence<br>• Vitamin/mineral intake<br>• Abdominal pain<br>• Nausea and vomiting<br>• Changes in bowel pattern (normal or baseline); diarrhoea (consistency, frequency, volume, colour, presence of cramps)<br>• Difficulty swallowing (solids vs liquids, intermittent vs continuous)<br>• Indigestion or heartburn<br>• Mouth sores (ulcers, tooth decay)<br>• Pain in swallowing<br>• Sore tongue or gums | Establishes nutritional assistance and modality |
| Assess unexplained weight loss or gain<br>Undertake a current weight<br>Undertake a height measurement | Collects data for possible undiagnosed medical conditions |
| Assess other factors that may affect nutritional status:<br>• Age<br>• Level of physical activity | Establishes other not-identified risk factors |
| Identify lifespan, cultural and language barriers | Identifies any considerations required by the nurse when undertaking the assessment, influenced by an individual's past experience, ability to understand and comprehend instructions, and age-related considerations |
| Provide privacy | Reduces distraction and reduces the risk of disclosing an individual's information, decreasing embarrassment, and ensures the individual's self-worth is maintained |
| Ensure provision of comfort measures prior to the assessment including the removal of restrictive clothing | Promotes an individual's cooperation, removes risk factors with clothing and ensures accurate data is collected |
| Ensure therapeutic interaction | Assists with alleviation of fear prior to the assessment |
| Identify the individual's need for assistance and comorbidities by accessing the individual's nursing care plan prior to undertaking the assessment | Ensures the nurse has factored into the assessment already-known risk factors prior to the assessment being undertaken |
| Prepare the environment to ensure safety measures are addressed for the individual | Removes risk factors that will interfere with the assessment data collection |
| Adhere to the policy and procedures of the facility/organisation by locating and reading prior to assessment | Policies and procedures are written documents that include guidelines and practices developed to address legal, ethical and regulatory requirements<br>Both policies and procedures convey to employees and to other stakeholders the organisation's interests and the vision, mission and methods they intend to use to achieve those goals |
| Ensure the individual's rights are respected<br>Ensure informed consent | Demonstrates quality patient care<br>Demonstrates informed consent |

## CLINICAL INTEREST BOX 19.2 Purpose of the systematic physical assessment in everyday practice

A less obvious purpose of the physical assessment but one that is no less important is that of enhancing communication and caring opportunities with the individual. The incorporation of physical assessment into the nurse's everyday practice brings the nurse to the bedside—touching, observing and communicating with the individual. Physical assessment can provide an opportunity to take the time to be with the individual, an important component in developing a therapeutic relationship.

*(Zambas 2010; Lewis et al 2014)*

This includes being aware of an individual and their general appearance, colour, expression and body posture. During closer contact with the individual no significant external feature should escape the nurse's notice. The nurse must be able to recognise deviations from what is acceptable and usual for the person. To do this the nurse must know what to look for and what constitutes the acceptable and usual for each individual.

Observation skills are critical to taking a thorough health history, performing a physical assessment and relying on these accumulated skills for the interpretation of clinical data (Pellico et al 2009). (See Clinical Interest Box 19.2.)

Individuals are assessed when they are first admitted to a healthcare institution or when community or home nursing care is initiated. Thereafter, assessment is performed continuously to evaluate the individual's progress and to identify changing needs. Table 19.3 lists the observations to be made during the admission assessment, the acceptable findings and various deviations from the norm.

In addition to the observations listed in this table, the nurse must assess the individual's:

- Degree of independence
- Ability to perform the activities of daily living
- Ability to interact with others
- Reactions and responses to treatment; for example, medications
- Basic needs; for example, for food, water, oxygen, safety, exercise and comfort
- Specific needs; for example, for wound care or pain relief
- Excretions and secretions; for example, urine, faeces, vomitus, wound drainage.

Information on these topics is provided in the relevant chapters; for example, Chapter 23 addresses comfort needs and Chapter 33 addresses the need for freedom from pain.

Subjective and objective data are included in the assessment of the individual. **Subjective data** are collected by interviewing the individual during the nursing history. This includes information that can only be described or verified by the individual. Family members and caregivers can also contribute to subjective data about the individual. Subjective data are also referred to as symptoms. **Objective data** are data that can be observed and measured. These types of data are obtained using inspection, palpation, percussion, auscultation and olfaction during the physical examination. Objective data are also called signs and may be obtained from the healthcare record (Lewis et al 2014). Although subjective data are usually obtained by interview and objective data are obtained by physical examination, it is common for the individual to provide subjective data while the nurse is performing the physical examination, and it is also common for the nurse to observe objective signs while taking the individual's history (Brown et al 2015; Berman et al 2015; Fawcett & Rhynas 2012).

## Before the assessment

Preparing the individual before the assessment involves:

- A full explanation of the type of assessment to be performed
- An opportunity to empty the bladder and/or bowel. The individual will feel more comfortable and the

## TABLE 19.3 | Admission assessment

| Aspect | Normal | Deviations from normal |
|---|---|---|
| General physical appearance | Normal weight for age, sex, height, body build<br>Personal hygiene and grooming satisfactory | Overweight, underweight<br>Appears to be neglected |
| Skin | Normal colour for race<br>Neither dry nor moist<br>Normal temperature<br>Smooth<br>Elastic<br>No lesions | Pallor, cyanosis, jaundice<br>Excessively dry or moist<br>Elevated temperature, localised warmth or coldness<br>Rough, or localised changes or irregularities<br>Diminished by dehydration or oedema<br>Rashes, bruises, scars, abrasions, ulcers, nodules |
| Hair | Normal texture for age, race<br>Normal distribution<br>Scalp clean and healthy<br>Shiny and clean | Brittle, dry, coarse<br>Areas of hair loss<br>Dandruff, lesions, lice<br>Dull, neglected |
| Nails | Transparent<br>Smooth<br>Convex<br>Pink nail beds | Streaks (red or white)<br>Ridged<br>Concave curves<br>Cyanosed, pale |
| Eyes | Sclerae and corneas clear<br>Eyelashes turn out and away<br>Open eyelids do not fall over pupils<br>Pupils equal and reacting to light<br>No discharge<br>Tolerance to light<br>Normal visual acuity | Pale, inflamed, jaundiced<br>Rubbing on eyeball<br>Ptosis (drooping)<br>Dilated, pinpoint, unequal, non-reactive<br>Watery or purulent discharge<br>Photophobia (intolerance to light)<br>Visual impairment |
| Ears | Normal hearing acuity<br>Ear canal clean<br>No discharge | Hearing impairment<br>Inflamed, presence of excessive wax<br>Watery or purulent discharge<br>Itching, pain, tinnitus |
| Mouth | Lips pink, moist, smooth<br>Mucosa pink, moist, glistening<br>Gums pink, moist, smooth<br>Teeth white, straight, smooth<br>Tongue pinky red, moist<br>Breath fresh | Pale, cyanosed, dry, cracked<br>Pale, cyanosed, dry, ulcers, cracks<br>Inflamed, swollen, bleeding, lesions<br>Discoloured, chalky, decayed<br>Coated, cracked<br>Halitosis (bad breath), ketone odour |
| Thorax and lungs | Normal-shaped chest<br>Normal breath sounds | Barrel-shaped chest<br>Wheezing, rales, gurgles, dry or moist cough |
| Abdomen | Slightly convex, symmetrical | Excessively concave, asymmetrical, distended |
| Posture and gait | Able to sit, stand and walk normally | Postural abnormalities (e.g. kyphosis, scoliosis); abnormal gait |
| Mobility | Full range of joint motion | Stiffness or instability of a joint, unusual joint movement, swelling of a joint, pain on movement |
| Muscle tone and strength | Normal tone and strength | Increased or decreased tone, decreased strength |
| Speech | Ability to speak clearly | Speech impairment (e.g. lisp or stammer) |
| Mental and emotional status | Appropriate emotional responses | Responses inappropriate, apprehension, anxiety, depression, hostility |
| Level of consciousness and orientation | Alert, responsive, oriented to time, place, person | Disoriented, unresponsive to stimuli, shortened attention span |
| Presence of prosthesis or aids | None, although aids to sight and hearing are common | Spectacles, contact lenses, artificial eye, hearing aids, walking sticks, frames, wheelchairs, artificial limb, dentures |

assessment will be performed more effectively if the bladder and rectum are empty
- Providing privacy by closing any doors or windows or by drawing the screens around the bed
- Providing a drape for warmth and privacy. The upper bedclothes should be folded to the bottom of the bed
- Allowing for cultural differences and consider cultural or social norms with physical closeness during the assessment, especially if performing an examination of a person of the opposite gender
- Assistance to the required position (information on various positions is provided in Chapter 23). The pillows should be arranged to provide comfort and support. The positions normally used are:
  - for examining the chest and back, the individual is assisted into a sitting position. The nightgown or pyjama top is undone or removed if necessary and a drape positioned to provide privacy
  - for examining the abdomen, the individual is assisted into the recumbent position. The clothing is adjusted to expose the abdomen and a drape is positioned to provide privacy
  - for a rectal examination, the individual is assisted to assume the left lateral position. A drape is positioned so that only the anal area is exposed
  - for a vaginal examination, the individual is assisted to assume either the dorsal or Sims' position, according to the medical officer's instructions. Adequate draping is necessary to ensure that only the vaginal area is exposed.

(Crisp et al 2013; Potter et al 2015)

Before the assessment the nurse may need to assist the medical officer in collecting the equipment required. Check each health facility's protocol for the list of equipment and procedure outline.

### During the assessment

During the assessment the nurse should remain with the individual to provide physical and emotional support and assist when a change of position is required, remembering to provide adequate physical support and privacy (Crisp et al 2013). Emotional support is partially provided by the nurse's presence, and further support may be given in the form of encouragement and explanations of what is to happen. Observe facial expressions for fear and body movements for anxiety. The nurse may also be required to assist the medical officer or receive any specimen obtained.

### After the assessment

The individual is assisted into a position of comfort, clothing is readjusted and the bedclothes are arranged to meet needs. If a rectal or vaginal examination was performed, the person should be provided with tissues to wipe off any excess lubricant (Crisp et al 2013). The equipment is removed and attended to in the appropriate manner. Any specimens are despatched to the laboratory as soon as possible. The assessment and the person's response to it is reported to the nurse in charge and documented.

## ASSESSMENT TECHNIQUES

Inspection, palpation, percussion, auscultation and olfaction are the five basic assessment techniques. Each skill enables the nurse to collect a broad range of physical data about individuals (Brown et al 2015; Potter et al 2015).

### Assessment through inspection

While observation of all the aspects mentioned in this chapter is essential, one of the most important skills a nurse develops is the ability to look at a person and determine whether they are comfortable. A person's comfort depends on many things, the most basic of which are that needs for hygiene, posture, maintenance of body temperature and freedom from pain are met. deWit and Williams (2014) listed the following as items that the nurse observes and assesses when looking at an individual:
- Rest and activity needs: (see Clinical Skill 19.6)
  - Body proportion and appearance
  - Range of motion in joints
  - Muscular strength
  - Balance
  - Ability to perform activities of daily living
  - Sleep pattern
  - Pain
- Nutritional, fluid and electrolyte needs:
  - Height and usual weight (See Clinical Interest Box 19.3)
  - Unusual gain or loss of weight
  - Amount and types of foods eaten
  - Compliance with prescribed diet
  - Fluid intake and output
  - Abnormal loss of body fluid
  - Skin turgor and moistness of mucous membranes

### CLINICAL INTEREST BOX 19.3 Height and weight

Height and weight are performed as part of the initial and ongoing assessment. To measure the height of a weight-bearing person, remove their shoes, have the person stand erect with heels together and the heels, buttocks and back of the head against the measuring device. Eyes should look straight ahead.

Weight should be measured on the same scale each time, at the same time each day and with a similar amount of clothing. If weight bearing, the person may be weighed on a standing scale. People who cannot stand can be weighed on a chair or stretcher/bed scale.

*(Berman et al 2015; Potter et al 2015)*

## CLINICAL SKILL 19.6 Mobility assessment

**Review and carry out the standard steps for all clinical skills/interventions**

| **NMBA Decision-making Framework considerations:** | **Equipment:** |
|---|---|
| 1. Am I educated?<br>2. Am I authorised?<br>3. Am I competent?<br>If you answer 'no' to any of these, do not perform that activity. Seek guidance and support from your teacher/a nurse team leader/clinical facilitator/educator. | Assessment tool used in the clinical facility/organisation<br>The individual's nursing care plan and history<br>Mobility aids |
| **Skill activity** | **Rationale** |
| Identify indications and rationale for performing the activity. This may include identifying:<br>• Past history of falls<br>• Intrinsic and extrinsic factors that may contribute to falls<br>• Understanding reasons why the falls risk assessment needs to be performed or has been ordered | Reduces unnecessary assessments performed on an individual |
| Identify the individual using three individual identifiers. This may include but is not limited to:<br>• Identification—allocated healthcare number on hospital bracelet/band<br>• Verbal confirmation from the individual of given and family name<br>• Date of birth<br>• Gender<br>• Address<br>• Medical record number | Reduces the incidence of performing an assessment on the incorrect individual |
| Explain and communicate the activity clearly to the individual. This may include but is not limited to explaining to the individual:<br>• Why the procedure has been ordered<br>• Why the procedure will be undertaken and frequency<br>• What is involved in undertaking the procedure<br>• What will be done with the data collected | Reduces anxiety/apprehension and gains an individual's trust and cooperation |
| Ensure therapeutic interaction. This may include but is not limited to:<br>• Introducing oneself<br>• Ensuring privacy before undertaking the assessment<br>• Listening to the individual's concerns or questions about the assessment before it is undertaken<br>• Ensuring the individual is aware of the responsibilities required of them before undertaking the assessment<br>• Maintaining professional boundaries<br>• Assessing any cultural/language barriers | Assists with alleviation of fear prior to the assessment |
| Gain the individual's consent:<br>• By explaining the assessment, reasons for undertaking and risks if not undertaken<br>• By asking the individual for verbal or written consent before undertaking the assessment | Ensures that the individual understands why the assessment needs to be performed, therefore promoting cooperation |
| Prepare equipment<br>Identify the correct mechanical aids that will assist in the assessment such as four-prong walking frame, wheelie frame | Ensures that the procedure is conducted appropriately, promptly and efficiently with the tools required<br>Includes timely documentation |

*Continued*

| CLINICAL SKILL 19.6 Mobility assessment—cont'd | |
|---|---|
| Assesses the individual's cognitive status. This may include but is not limited to:<br>• Identifying the individual's conscious state<br>• Identifying if the individual has trouble remembering instructions<br>• Identifying if the individual understands instructions<br>• Identifying if the individual has trouble remembering conversations<br>• Identifying if the individual has difficulty finding the right word or often uses incorrect words | Identifies the individual's ability to understand instructions and ability to mobilise safely |
| Assess the individual's trunk strength. This may include but is not limited to:<br>• Identifying if the individual can stand from a sitting position<br>• Identifying if the individual can stand unsupported<br>• Identifying if the individual can sit from a standing position with or without support<br>• Identifying if an individual can pick up items from the floor safely without falling<br>• Identifying any symptoms or signs of paralysis | Identifies the individual's ability to be seated safely |
| Assess the individual's lower extremity for strength, symmetry and tone. This may include but is not limited to:<br>• Identifying the strength of both limbs as equal—this can be done by having the individual resist your force as you move the body part against the direction of pull<br>• Identifying the muscle bulk of both limbs is equal—this can be done by observation of symmetry of both limbs<br>• Identifying the coordination of both limbs is equal—this can be done by observation of a sequence of movements<br>• Identifying the abnormal movements of the limbs such as tremors, dystonia, weakness<br>• Identifying any symptoms or signs of paralysis | Identifies the individual's lower extremity stability in order to stand |
| Assesses the individual's standing balance and gait. This may include but is not limited to:<br>• Identifying the symmetry of gait<br>• Identifying the length of stride<br>• Identifying walking at normal pace<br>• Identifying the ability to turn at normal pace using the least amount of steps<br>• Identifying the ability to walk in a straight line<br>• Identifying any symptoms or signs of paralysis | Identifies the individual's ability to stand and mobilise safely |
| Adhere to the policy and procedures of the facility/ organisation by locating and reading prior to assessment<br>Ensure the 'no lift' policy is adhered to | Policies and procedures are written documents that include guidelines and practices developed to address legal, ethical and regulatory requirements<br>Both policies and procedures convey to employees and to other stakeholders the organisation's interests and the vision, mission and methods they intend to use to achieve those goals |
| Work in collaboration with other allied healthcare staff by working with the Registered Nurse and identifying referral to allied health staff if required | Referral to other health professions ensures holistic care with appropriate interventions |

| CLINICAL SKILL 19.6 Mobility assessment—cont'd | |
|---|---|
| Demonstrate a structured clinical handover process, either verbal or written, using the identified organisation policy | Ensures current and correct information is relayed to other health professionals for continuity and safety of care |
| Document assessment findings using the correct documentation tools as per the policy of the organisation | Ensures a systematic record for reference by other allied healthcare professionals |
| Record the assessment findings with the date, time and signature on the chart identified by the organisation and progress notes | Provides a baseline observation for assessment improvement or deterioration |
| Report abnormal assessment findings to the Registered Nurse | Ensures appropriate strategies and intervention are put in place to encourage positive outcomes |
| *(Adapted from ACSQHC 2012; Jensen 2013; NSW Government 2010; State Government of Victoria 2010; Viljoen & Uys 2001)* | |

- Safety and security:
  - Potential risks for injury
  - Sensory deficits
  - Ability to speak and understand English
  - Need for side rails or safety devices
- Hygiene and grooming:
  - Ability to bathe, dress and groom self
  - Amount of assistance needed
- Oxygenation and circulation needs:
  - Rate and depth of breathing; breath sounds; cough or sputum production
  - Level of consciousness
  - Blood pressure
  - Pulse rate and characteristics
  - Peripheral pulses
  - Skin colour and temperature
- Psychosocial needs:
  - Desire for spiritual assistance
  - Supports
  - Usual coping mechanisms
  - Financial concerns
  - Fears and concerns
- Elimination:
  - Characteristics and amount of urinary output
  - Characteristics and regularity of bowel movements
  - Alterations in elimination
  - Presence of pain, burning or other discomfort.

As well as observing and assessing the individual and their needs, the nurse must also use the sense of sight to assess the functioning of equipment used in individual care. Nurses assess various items of equipment to determine whether they are functioning correctly when they are in use, for example:

- Intravenous fluid apparatus
- Oxygen apparatus
- Urinary drainage systems
- Wound drainage systems
- Traction apparatus.

While Enrolled Nurses may not be directly responsible for the management of specific items of equipment, they have a responsibility to observe their functioning and report any deviations from normal immediately to the appropriate person so that appropriate measures can be taken.

## Assessment through palpation

Palpation uses the sense of touch. Through palpation the hands make delicate and sensitive measurements of specific physical signs. Palpation detects resistance, resilience, roughness, texture, temperature and mobility. The nurse uses different parts of the hand to detect specific characteristics. For example, the back of the hand is sensitive to temperature variations. The pads of the fingertips detect subtle changes in texture, shape, size, consistency and pulsation of body parts. The palm of the hand is sensitive to vibration. The nurse measures position, consistency and turgor by lightly grasping the body part with fingertips. Assist the individual to relax and position comfortably as muscle tension during palpation impairs the ability to palpate correctly. Asking the individual to take slow, deep breaths enhances muscle relaxation. Palpate tender areas and ask individual to point out areas that are more sensitive and note any non-verbal signs of discomfort (Elkin et al 2012; Potter et al 2015).

The sense of touch should be developed so that a nurse is able to detect abnormalities such as:

- Abnormally hot, cool, moist, dry, inelastic or roughened skin
- An excessively hard or soft peripheral vein
- A rapid, slow, weak or irregular pulse
- Rigid or flaccid muscles
- Swelling of part of the body; for example, a joint.

Touch is also used when examining an individual by palpation or percussion. Palpation, usually performed by a medical officer or a Registered Nurse, is a technique whereby the examiner feels the texture, size, consistency and location of certain parts of the body with the hands. For example, the examiner may palpate the upper abdomen to determine the size of the liver.

## Assessment through percussion

Percussion, usually performed by a medical officer or a Registered Nurse, is a technique in which the examiner strikes

the body surface with a finger, producing vibration and sound. An abnormal sound suggests the presence of a mass or accumulation of fluid within an organ or cavity. For example, the examiner may percuss the posterior chest wall to determine the presence of fluid in the lungs.

### Assessment using the sense of auscultation

It is important that a nurse learns to listen effectively, so that not only what a person says is registered but also the tone of voice, which often conveys a great deal. A nurse must also learn how to recognise abnormal sounds. Information on the art of effective listening in communication is provided in Chapter 8 and emphasises the importance of recognising that listening is an active process that involves much more than just hearing the spoken word. In person-centred care, recognising abnormal sounds involves the ability to detect:

- Abnormalities of breathing; for example, respirations that are wheezing, noisy or distressed
- Abnormalities of heart sounds, blood pressure, bowel sounds or fetal heart sounds when using a stethoscope
- Manifestations of an individual's distress; for example, coughing, expectorating sputum, vomiting, crying or moaning
- Changes in the sound or rhythm of technical equipment such as suction or artificial ventilation apparatus.

Auscultation is listening with a stethoscope to sounds produced by the body. To auscultate correctly, listen in a quiet environment. To be successful, the nurse must first be able to recognise normal sounds from each body structure, including the passage of blood through an artery, heart sounds and movement of air through the lungs (Elkin et al 2012). See Case Study 19.1.

### Assessment using the sense of olfaction (smell)

A well-developed sense of smell enables a nurse to detect odours that are characteristic of certain conditions. Some alterations in body function and certain bacteria create characteristic odours, for example:

- The 'fishy' smell of infected urine
- The ammonia odour associated with concentrated or decomposed urine
- The musty or offensive odour of an infected wound
- The offensive rotting odour associated with gangrene (tissue necrosis)
- The smell of ketones on the breath in ketoacidosis (accumulation of ketones in the body)
- The smell of alcohol on the breath, due to ingestion of alcohol
- Halitosis (offensive breath) accompanying mouth infections; for example, gingivitis or certain disorders of the digestive system such as appendicitis
- The foul odour associated with steatorrhoea (abnormal amount of fat in the faeces)
- The characteristic odour associated with melaena (abnormal black tarry stool containing blood)
- The faecal odour of vomitus associated with a bowel obstruction
- Bromhidrosis (offensive smelling perspiration) caused by bacterial decomposition of perspiration on the skin. (Crisp et al 2013; Potter et al 2015)

### Assessment using equipment

A nurse should acquire proficiency in the correct operation of equipment used to provide information about an individual (Crisp et al 2013); for example:

- Clinical thermometer
- Sphygmomanometer
- Stethoscope
- Weighing scales
- Urine-testing equipment
- Tape measure; for example, to measure head, limb or abdominal circumference
- Auriscope, to visualise the ear canal
- Pen-light torch.

## ROUTINE SHIFT ASSESSMENT

Each person should also be assessed at the beginning of each shift, as this helps the nurse to establish priorities of care and organise the work for the shift (Elkin et al 2012). Clinical Interest Box 19.4 outlines the routine shift assessment. The nurse introduces themself to each person at the start of the shift and observes:

- Skin colour
- Appearance
- Ease of respiration
- How the person is feeling
- Ability to respond to questions
- Ability to communicate
- Level of consciousness
- Vital signs
- Voiding status
- Ability to move easily

### CASE STUDY 19.1

A 58-year-old woman presented at the emergency department with dyspnoea. She claims that she has been having difficulty breathing for the past 3 days. It gets worse when walking up stairs and unloading groceries from the car.

General health assessment:

- Inability to complete sentences, moderately obese
- Physical assessment: BP 145/89 mmHg, RR 22/min with distended neck veins and productive cough.

What does the general health assessment indicate and what should the focused assessment be aimed at?

## CLINICAL INTEREST BOX 19.4 Checklist for routine shift assessment

1. Mental and neurological status
   a. Level of consciousness (LOC)/responsiveness
   b. Alertness/orientation
   c. Pupils equal, round, and reactive to light and accommodation (PERRLA)
   d. Mood
   e. Behaviour
2. Vital signs
   a. Blood pressure
   b. Pulse
   c. Respiration
   d. Temperature
   e. Pain and comfort level
3. Motor sensory function
   a. Range of motion (ROM)
   b. Movement
   c. Strength
   d. Presence of numbness or tingling
4. Integument (skin/mucous membranes)
   a. Colour
   b. Temperature
   c. Turgor
   d. Moisture
   e. Oedema
   f. Integrity
5. Cardiopulmonary system
   a. Heart sounds
   b. Apical rate and rhythm
   c. Lung sounds
   d. Breathing pattern
   e. Peripheral pulses
   f. Capillary refill
6. Gastrointestinal (GI) system
   a. Bowel sounds
   b. Abdominal palpation
   c. Degree of abdominal distension
   d. Bowel elimination problems (e.g. diarrhoea, constipation, flatulence)
7. Wounds
   a. Cleanliness
   b. Presence of swelling, redness, infection or drainage
   c. Bandage/dressing
8. Invasive tubes (e.g. intravenous (IV) lines, nasogastric (NG) tubes, wound drains, catheters)
   a. Device and location
   b. IV line: Correct fluid/medicine infusing
   c. Patency and position
   d. Presence of redness, swelling or tenderness at site
   e. Drainage rate or infusion rate
   f. Date of last tubing change

*(Elkin et al 2012)*

- Skin lesions or pressure areas
- Presence of oedema.

It is important to note that an individual should be assessed whenever the nurse first has contact with that person (Elkin et al 2012; Berman et al 2015). Nurses also need to:

- Ascertain the time of the last bowel movement
- Check tubes and equipment (IV lines, nasogastric tubes, urinary catheters, dressings, wound suction devices, oxygen rates, traction)
- Ensure that call bell, TV control, water and tissues are in reach
- Check that room temperature is suitable
- Determine which supplies will be needed in the room for the remainder of the shift.

## DIAGNOSTIC INVESTIGATIONS

Apart from the physical examination, specific tests may be performed to assist diagnosis or aid in evaluating the individual's condition. Diagnostic procedures include:

- Radiological examination
- Ultrasonography
- Blood tests
- Urine tests
- Histological tests
- Microbiological tests
- Endoscopy
- Recording electrical activity
- CT scanning.

The nurse may be involved in preparing the individual before a diagnostic procedure, assisting throughout the procedure and providing care after the procedure (Crisp et al 2013). To determine the specific preparation and post-test care required for each procedure, the nurse should refer to the healthcare facility's policy manual.

### CRITICAL THINKING EXERCISE 19.2

Melissa is an 88-year-old woman who has been admitted for investigation. When undertaking a nursing history on admission you note that she appears slightly confused and her husband reports that she has been incontinent of urine, which is not usual for Melissa. What assessments will you undertake as an Enrolled Nurse and why?

Preparing the individual before any diagnostic procedure involves both physical and psychological preparation. The nurse should explain the purpose of the test and the procedure. If the person understands what is to happen and why, they may be less anxious about the test. Use an interpreter for individuals who do not speak or understand English. The nurse should ensure that the person is informed of when, where and who will perform the test, and that the individual's informed consent has been obtained. Many tests, especially those of an invasive nature, require that the individual gives informed consent for the test to be performed.

### CRITICAL THINKING EXERCISE 19.3

John Stuart, age 43, complains of increasing symptoms of dyspnoea and cough which worsen upon physical exertion. He also experiences chest tightness with occasional wheezing symptoms. Identify the types of diagnostic investigations that may be carried out to determine the cause(s) of John's condition. Explain the necessary preparation required for each of the investigations.

## RECORDING AND REPORTING

Documentation may occur during the assessment or at the end. Healthcare facilities use specific forms to document the data collected. After conducting a general health assessment the nurse should document the collected data as follows:

- Record the individual's vital signs on the vital signs chart
- Measure and record weight and height (see Clinical Interest Box 19.3)
- Record the description of alterations in the individual's general appearance
- Describe the individual's behaviours using appropriate terminology. Include the individual's description of their own signs and symptoms
- Report abnormalities and acute symptoms to the Registered Nurse or medical officer.
  (Elkin et al 2012)

Documentation of assessment data forms the baseline database for other members of the healthcare team. This information is used to plan care and communicates information to other healthcare staff (Lewis et al 2014). See Progress Note Example 19.1.

## TEACHING CONSIDERATIONS

While conducting the general survey, the nurse should use it as an opportunity to undertake health education with the individual (Crisp et al 2013). The following could be incorporated:

- During the general survey, inform the person of the acceptable ranges for vital signs and normal weight for height
- Discuss the person's dietary intake and discuss any problems the person has in terms of food preparation or food selection
- If the person has been undertaking any high-risk behaviour activity such as smoking, overexposure to the sun or drinking alcohol discuss the health risks of these.
  See Case Study 19.2.

## CLINICAL HANDOVER

Handover is about communicating the individual's relevant information including health assessment, past medical history, current health status and overall management to the healthcare team to establish an effective continuity of care (ACSQHC 2010; 2012; 2015). Nurses have the most contact with each individual. Therefore, they play a significant role in being able to identify the subtle changes that the individuals may be presenting prior to a deteriorating event.

The *OSSIE Guide to Clinical Handover Improvement* has been developed by the Australian Commission on Safety and Quality in Health Care. The document is aimed at improving nursing and medical handover—which include verbal and documented formats—from shift to shift.

### CASE STUDY 19.2

The following are details of Tom's health assessment:
General health assessment:

- A 64-year-old male with 4-year history of type 2 diabetes with non-compliance to medication
- Physical assessment: BMI 32.6 kg/m$^2$, BP 154/96 mmHg, RR 20/minute, Pulse 88/min
- After a physical health assessment was conducted, a pressure sore was identified on one of Tom's right toes. Tom was not aware of this sore.

1. What education considerations may Tom need in relation to his diabetes?
2. What could you do to educate Tom about foot care?

### PROGRESS NOTE EXAMPLE 19.1

| | |
|---|---|
| 10/05/2015<br>1300 hrs | Nursing: Mr Jones is 26 years, admitted to ward at 1230 hrs after sustaining an injury to his left ankle while playing football. His weight is 67 kg and height is 1.68 m. Vital signs were attended on admission and are within normal range. He has tenderness over the posterior aspect of his left tibia and swelling around the lateral malleolus. The area is warm to touch and the skin is intact. Neurovascular observations were attended and no deficits noted. He states that the pain is worse over his ankle and he is unable to weight bear on his left foot. He is awaiting x-ray and review by medical officer.<br>***K. Adams* (Adams) EN** |

According to the guide, **clinical handover** is the transfer of professional responsibility and accountability for some or all aspects of an individual or a group of individuals to another person or professional group on a temporary or permanent basis. It is identified that proper clinical handover can reduce risk of unnecessary delays in diagnosis, treatment and care. See Chapters 8 and 18 for further information on clinical handover.

## ADVANCE HEALTH DIRECTIVES

With advances in medical technology, there has been increasing effort by healthcare professionals to reduce mortality and prolong life through artificial means. When the individual can no longer communicate their own decision, doctors and family can find themselves having to decide for them when to withhold or withdraw life-sustaining treatments (RACGP 2010).

An advance health directive is a document voluntarily completed by an individual which specifies their decisions about future medical treatment (see Chapter 2 and Clinical Interest Box 19.5).

On admission, it is important to find out if the individual has completed an advance health directive prior to admission to the healthcare setting. If there is one, it must be acknowledged, clearly documented and handed over to all members of the healthcare team.

### CLINICAL INTEREST BOX 19.5 Advance health directives

What is an advance health directive?

An advance health directive is a document that contains the individual's decisions about future treatment—including medical, surgical and dental treatment and other healthcare—that they are prepared to accept, or refuse.

Why prepare an advance health directive?

Some people, perhaps because of personal experience, religious beliefs or advice from loved ones, feel it is important to specify the treatments they want, or do not want, to receive in the future. It is not mandatory to complete a directive.

*(Department of Health, Government of Western Australia nd)*

### DECISION-MAKING FRAMEWORK EXERCISE 19.1

You are an enrolled nursing student who is on their first acute care placement for the course. On day 2 in a very busy surgical ward, you are asked to take a full nursing history by the Registered Nurse you are working with, which includes undertaking a general health assessment for William Benjamin, a 44-year-old male who will be having surgery on his lower back and is in a lot of pain. You have only practised taking a nursing history with a friend in the simulation nursing lab at your education provider and are very nervous. Using the decision-making framework, what action are you going to take?

## Summary

The general health assessment is conducted to assess the function and integrity of the individual's body. Baseline assessment findings of an individual provide a basis for comparison with subsequent assessment findings. Ongoing focused assessment of an individual monitors their progress and response to treatments. The health assessment is conducted in a systematic manner that requires the fewest position changes for the individual. In addition, applicable health education should be integrated through assessments to assist individuals learn about health promotion and illness prevention. The data obtained in the physical health examination supplement, confirm or refute data obtained during the nursing history. Physical assessments should be ongoing when the nurse assists the individual with care, including assessing for both mental and emotional status (Crisp et al 2013).

## Review Questions

1. What is the difference between general and focused assessments?
2. What are the four (4) methods of assessment that a medical officer would use when performing a physical examination on an individual?
3. An individual is admitted with a diagnosis of diabetes mellitus and the nurse detects unpleasant, musky odours during the general assessment. What assessment technique is being used?
4. Before undertaking a physical assessment, how can the nurse prepare the individual?
5. List assessments of the skin that you would make as part of your admission and ongoing assessments.
6. Cecilia is a 74-year-old woman who is 1 day postoperative after a right knee replacement. What focused assessments should you undertake?
7. While admitting Mrs Midler, an 84-year-old woman, to the medical ward for investigation of chest pain, you note that she is confused to time and place. Do you assume that this could be due to her age or do you undertake an assessment? Outline the actions you would undertake.

Answer guide for the Review Questions, Critical Thinking Exercises, Decision-Making Framework Exercises and Critical Thinking Questions in Case Studies are hosted on Evolve: http://evolve.elsevier.com/AU/Koutoukidis/Tabbner/

CHAPTER 20

# Vital sign assessment

*Rachel Gilder*

## KEY TERMS

bradycardia
bradypnoea
Cheyne–Stokes breathing
cyanosis
dyspnoea
external respiration
hypertension
hyperthermia
hypotension
hypothermia
hypoxia
internal respiration
Korotkoff sounds
Kussmaul's breathing
oxygen saturation
respiration
tachycardia
tachypnoea
vital signs

## LEARNING OUTCOMES

At the completion of this chapter and with further reading, students should be able to:

- Define the key terms
- Describe factors that affect the vital signs
- Identify the variations in acceptable ranges for body temperature, pulse, respirations and blood pressure that occur from infancy to older adulthood
- Describe advantages and disadvantages of using each body temperature site
- Verbalise the factors involved in the maintenance of the pulse and blood pressure
- Identify the sites commonly used to assess the pulse and state the reasons for their use
- State the factors necessary for an adequate supply of oxygen to the cells
- Identify the characteristics that should be included in a respiratory assessment
- Describe the various methods and sites to measure blood pressure
- Describe the importance of accurate and timely vital sign assessment in recognising a deteriorating individual

## CHAPTER FOCUS

Assessment is an essential part of the nursing process, as a comprehensive assessment of the body, which includes recording vital signs, will gather in-depth information about each body system and establish a baseline measure (Clarke 2014). Enrolled Nurses have a key role in performing vital sign assessments, and it is pivotal that they detect and respond to a changing or deteriorating individual (Chua et al 2013).

Continued, timely and accurate assessment enables the nurse to determine the clinical health of the individual, any change in the individual's clinical condition and the effectiveness of the implemented nursing care plan. These assessments not only assist the medical officer in making a diagnosis and treatment plan, but underpin many care decisions and can predict and prevent adverse events (Yeung et al 2012). (See Nursing Care Plan 20.1 and Progress Notes Example 20.1.) Information on critical thinking and reflective practice is provided in Unit 5, which should be referred to in conjunction with this chapter, as critical thinking and critical reasoning are vital components in the development of accurate clinical judgment (Fisher & King 2013).

Vital signs are a quick and efficient way of monitoring an individual's condition or identifying problems and evaluating the individual's response to interventions. To assess an individual effectively, the nurse requires knowledge of the acceptable ranges in measurements of vital signs in order to identify deviations or abnormalities. Documentation, recognition and action on any changes in an individual's vital signs are essential roles of a nurse (Yeung et al 2012). The nurse must also understand how to use the equipment necessary to complete vital signs assessment to ensure it is accurate. Vital signs, however, are only part of the clinical picture of an individual's assessment and should be interpreted with other factors such as level of consciousness, muscle strength, urine output, diet and bowel actions.

## LIVED EXPERIENCE

The last time I was admitted into hospital I had a young student nurse look after me. The student was very meticulous and looked after all my needs. The only time that I felt uncomfortable and a little scared was the first time he took all my vital signs. He pumped up the cuff to take my blood pressure, with an intense look on his face, and deflated it. He then proceeded to do this three times. He then took my pulse and temperature and then, without telling me what was wrong, left the room with a panicked look on his face, telling me that he would have to go and get his teacher. I was so worried, I thought there was something wrong with me and that I wouldn't be able to go home. As I sat there waiting, thinking the worst, the student came back with the teacher and it turned out that he had placed the stethoscope the wrong way in his ears so he was unable to hear anything for my blood pressure and all my other observations were good.

**Bill, age 70**

## NURSING CARE PLAN 20.1

**Assessment:** Nicholas Peters, a 63-year-old man, has low blood pressure (101/59) and feels dizzy when ambulating.
**Issue/s to be addressed:** Low blood pressure
Feeling dizzy when ambulating
**Goal/s:** Monitor blood pressure
Increase blood pressure
Maintain safety and reduce dizzy feeling when ambulating

| Care/Actions | Rationale |
|---|---|
| Monitor individual's blood pressure 2/24 and report changes appropriately | To evaluate other care actions and monitor the individual's blood pressure |
| Monitor individual's blood pressure before ambulating | To maintain safety of the individual and prevent patient harm |
| Educate the person to ensure there is a nurse present when ambulating | To maintain safety of the individual and prevent patient harm |
| Encourage oral fluid intake | To avoid dehydration, increase circulating volume and increase blood pressure |

**Evaluation**
The individual's safety was maintained through frequency of monitoring and ensuring nurse presence when ambulating.

## GUIDELINES FOR TAKING VITAL SIGNS

**Vital signs** (temperature, respiration rate, heart rate, blood pressure and oxygen saturation) are the key indicators for physiological health status through the indication of the body's ability to regulate body temperature, maintain blood flow and oxygenate body tissues. Pain assessment is also considered an important part of a vital sign assessment, as pain can be accompanied by the body's stress response. This can be indicated by an increased heart rate, blood pressure and sweating and pallor. Therefore pain must be assessed and documented regularly to ensure the individual's entire clinical situation is critically assessed (Gregory 2014) (see Chapter 33). When checking vital signs or 'taking an individual's observations', a nurse must be able to measure the vital signs correctly, understand and interpret the values, document, communicate and action any changes in the individual's physiological health status. An individual's vital signs are taken:

- On admission to a healthcare facility
- On a routine schedule according to your clinical judgment, a medical officer's order or hospital policy
- During a home healthcare visit
- Before and after a surgical procedure or an invasive diagnostic procedure
- Before and after administration of certain medications that affect the cardiovascular, respiratory or temperature control function
- When an individual's general physical condition changes
- Before and after nursing interventions influencing a vital sign
- When an individual reports non-specific symptoms of physical distress; for example, 'feeling funny'
- Before, during and after a transfusion of blood products.

When taking vital signs the nurse should:

- Check that the equipment is functioning and appropriate
- Know the acceptable range for all vital signs
- Have knowledge of the person's medical history and any conditions that could affect this individual's vital signs
- Have knowledge of the individual's ongoing therapies and prescribed medications
- Control or minimise environmental factors that may affect the vital signs
- Use an organised systematic approach
- Use clinical judgment to interpret their significance and make clinical decisions about the individual's care
- Use clinical judgment to alter the frequency of vital sign assessments on the basis of the person's clinical condition
- Recognise and communicate significant changes in vital signs to the Registered Nurse (RN) and the medical officer.

### Recognising and responding to clinical deterioration

To recognise and respond to clinical deterioration appropriate interpretation of an individual's observations must be made. This can be done by:

- Comparison with the acceptable ranges for a given group of people
- Knowledge of the individual's previous results and clinical condition
- Analysing the whole clinical condition of a person.

For example, for a nurse to be able to analyse the significance of an abnormal pulse rate, the entire clinical condition, including blood pressure, temperature, respiration rate, oxygen saturation, level of consciousness and pain, must be considered, as well as the acceptable pulse range, previous results and clinical condition of the individual. Therefore, while a single observation provides some information about a person, all observations must be completed to enable a more accurate assessment of their condition.

The National Safety and Quality Health Service (NSQHS) Standards have ensured the implementation of an observation chart that specifies physiological abnormalities and how they should be escalated; however, it is still the responsibility of the nurse to document, recognise, report and action these abnormalities (ACSQHC 2012).

## BODY TEMPERATURE

Accurate measurement and assessment of the body temperature provides the nurse with an objective evaluation of the body's ability to maintain temperature regulation—a deviation from the normal range is an important clinical indication of altered physiological status requiring further investigation (Grainger 2013).

The human body has inbuilt mechanisms that maintain a balance between heat production and heat loss. This results in the internal or core temperature being stable independent of our environment. However, during ill health or periods of prolonged exposure to extreme temperatures the balance may be upset and considerable stress may be placed on the body's adaptive mechanisms. The temperature range of a normal adult, which is tightly controlled, depends on age, physical activity, status of hydration and state of health, including the presence of infection (Sund-Levander & Grodzinsky 2013). Accurate temperature monitoring is an essential nursing skill and when monitored in combination with other clinical observations can aid in detecting a deteriorating individual (Grainger 2013).

### Regulation of body temperature

The body requires maintenance of its temperature to ensure cellular function can occur, and this is controlled by both voluntary actions and involuntary mechanisms (Grainger 2013). The surface temperature of the body varies with changes in the environmental temperature, and people adjust to these changes by adapting their immediate surroundings;

for example, selecting appropriate clothing, moving away from or towards the source of heat or cold, and altering the temperature of heaters or coolers can help to provide a comfortable environmental temperature.

Core temperature is maintained in the brain by the hypothalamus which acts as an internal thermostat. The hypothalamus processes and reacts to the heat of arterial blood flow while also receiving information from peripheral receptors to maintain the individual's temperature to a set point or range (Sund-Levander & Grodzinsky 2013). If the core temperature is outside this set point the hypothalamus will initiate impulses to the peripheral nervous system to attempt to correct this (Grainger 2013).

## Heat production and heat loss

Heat is continually being produced by the process of cellular metabolism and is constantly being lost to the environment through the following processes.

### Radiation

Body heat is transferred to cooler objects in the environment without physical contact. Loss of heat by radiation means loss in the form of infrared rays. For example, the sun transfers heat to the Earth through radiation.

### Conduction

Body heat is lost through physical contact with another object or person. For example, a cool or ice mat, applied directly to the skin, can be used to reduce an individual's temperature.

### Convection

Convection is the dispersion of heat by air currents across the skin; for example, the air movement of a fan to cool the body.

### Evaporation

Insensible evaporation of water directly through the skin results from continual diffusion of water molecules, regardless of body temperature. However, when the body becomes overheated, large quantities of sweat are secreted onto the surface of the skin to provide rapid evaporative cooling of the body.

### Balancing heat production and heat loss

Through the control of the hypothalamus the body aims to balance the rate of heat production and heat loss. When the body temperature rises, the hypothalamus sends impulses to the peripheral nervous system to dilate the skin arterioles, with loss of heat occurring from radiation, conduction, convection and evaporation of sweat. When the body temperature falls, the impulses from the hypothalamus are increased, causing vasoconstriction of the skin arterioles, reducing heat loss and increasing the flow of blood to vital internal organs. Shivering is an important source of heat, and is initiated by involuntary impulses from the central nervous system travelling to the skeletal muscles. These impulses begin intense physiological work through increased skeletal muscle tone, resulting in increased muscle metabolism and increased rate of heat production (Grainger 2013).

## Factors affecting body temperature

A range of intrinsic processes and activities affect body temperature. These include circadian rhythm, age, exercise and thyroid hormones (McCallum & Higgins 2012). An individual's stress and environment can also contribute. Factors that lower the body temperature include exposure to a cold damp environment, insufficient warm clothing and an under-secretion of the hormone thyroxin. Factors that raise the body temperature include:

- Exposure to a hot humid environment
- Strenuous muscular activity
- Intake of foods high in fat or carbohydrates
- Strong emotions such as anger
- An over-secretion of the hormone thyroxin
- Changes in production of the hormone progesterone (e.g. in menopause or menstrual cycle)
- Insufficient fluid intake.

There are also several actions an individual may undertake to assist the physiological processes of body temperature control. These could include altering their surrounding environment to ensure a comfortable temperature, selecting appropriate clothing to suit the climate, altering their level of physical activity and changing their diet and fluid intake to suit the climate (McCallum & Higgins 2012).

## Assessing body temperature

There are both routine and clinical indicators for measuring an individual's body temperature. They include:

- Obtaining a baseline temperature for future comparisons
- Monitoring and observing an individual for changes from resolving hypothermia/hyperthermia which could indicate infection or the effect of antimicrobial treatment
- Monitoring for signs of a reaction before, during and after the administration of blood products (McCallum & Higgins 2012).

There are several different methods to assess an individual's body temperature, so it is essential the nurse determines the most appropriate technique to ensure it is measured accurately, as inaccurate assessment could compromise individual safety and fail to identify deterioration of an individual (McCallum & Higgins 2012). Measuring the individual's temperature together with assessment of the other vital signs is an important method of determining their general condition. The nurse must also use sense of sight and touch to aid the clinical decision-making process (see Clinical Interest Box 20.1).

## Measuring body temperature

Several types of clinical thermometers, both invasive and non-invasive, are used to measure body temperature. The most commonly used types are electronic, tympanic electronic and infrared devices. Electronic thermometers (Figure 20.1) are most commonly used in healthcare facilities as research shows they are the most accurate (El-Radhi 2014).

## CLINICAL INTEREST BOX 20.1 Measuring temperature in older adults

- As neurological feedback and response in an older person have become slower the temperature of older adults is at the lower end of normal temperature range: 36°C (Grainger 2013)
- Temperatures considered within acceptable range may reflect a fever in an older adult
- Older adults are sensitive to slight changes in temperature

**Figure 20.1** An electronic thermometer

*(photo courtesy of Welch Allyn)*

An electronic thermometer enables an accurate temperature reading to be obtained within a few seconds and may also be used when it is necessary to monitor an individual's temperature continuously.

## Body temperature sites

Body temperature may be measured using the oral, tympanic membrane or axillary sites. The taking of rectal temperature with a rectal thermometer is rarely performed because of the trauma and pain it causes individuals and because of the risk of cross-contamination. Even though some consider rectal temperature assessment as the gold standard for core temperature analysis in neonates, it is no longer performed (El-Radhi 2014).

### Tympanic site

The tympanic membrane is now the most commonly used site for taking temperature. An otoscope-like speculum with an infrared sensor tip detects heat radiated from the tympanic membrane. Within 2–5 seconds of placement in the auditory canal, a reading appears on the display unit (Figure 20.2). The advantages of using this site are that it is easily accessible and minimally invasive; minimal individual repositioning is required; the reading is unaffected by oral intake of food, fluids or smoking; and it can be used with individuals with tachypnoea without affecting breathing. Due to its position situated near the hypothalamus it has also been reported to detect rapid fluctuations in the core temperature (McCallum & Higgins 2012). Disadvantages of using this site are that it can be uncomfortable and it involves the risk of injuring the tympanic membrane if the probe is inserted too far, the presence of cerumen (wax) and purulent discharge can affect the reading and it requires removal of a hearing aid before measurement (McCallum & Higgins 2012). It is imperative to check the manufacturer's guidelines for use of this device, as operator error and poor technique can alter accuracy and reliability.

**Figure 20.2** Measuring temperature with tympanic thermometer

*(R. Gilder 2015)*

### The oral site

The thermometer is placed under the person's tongue, close to the sublingual artery in the sublingual pocket, and the person closes their lips. This ensures changes in core temperature can be monitored (McCallum & Higgins 2012). The advantages of this site are that it is easily accessible, comfortable for the individual, reflects rapid change in core temperature and provides accurate surface temperature reading. Some factors that affect accuracy of this site are recent ingestion of hot/cold fluids or foods, and recent smoking or receiving oxygen by mask or nasal cannula (McCallum & Higgins 2012). Care must also be taken when an individual has dentures as it may be difficult for the individual to keep their mouth closed for the measurement. To obtain an accurate temperature measurement, the person must be:

- Able to close their lips completely and retain the thermometer in the correct position
- Able to breathe comfortably through their nose for the length of time the thermometer is in their mouth

- Have not smoked cigarettes in the previous 15–30 minutes
- Have not consumed cold or hot fluids in the previous 15–30 minutes.

The oral site is unsuitable for people who:

- Have an oral infection or painful mouth
- Have higher than 6 L/min of supplemental oxygen being supplied (McCallum & Higgins 2012)
- Have recently had oral surgery
- Experience any impairment of breathing or obstruction of the nasal passages
- Have a history of seizure activity
- Are children
- Are unconscious.

### The axilla

Using the axilla provides a less accurate measurement of body temperature, but may be used when it is not possible to measure the temperature orally (see Clinical Interest Box 20.2). It is safe and non-invasive and can be used with newborns and unconscious individuals. The thermometer is placed in the axilla in contact with two dry skin surfaces and is kept in place in the axilla by bringing the person's arm over their chest (Figure 20.3). A disadvantage of using this site is that the thermometer must be left in place for a long time to obtain an accurate measurement; it can be affected by exposure to environmental factors and requires continuous positioning by the nurse (Sund-Levander & Grodzinsky 2013).

### The skin

Various types of single-use disposable thermometers are available. A temperature-sensitive strip of tape is placed on the forehead or abdomen to record the heat of the body (Figure 20.4). These are often used in nurseries of newborns. Directions on the package explain how to use these thermometers. Most disposable thermometers will register the temperature within 60 seconds. The advantages of this site are that it is inexpensive, provides continuous reading and is safe and non-invasive. The disadvantages are that measurement lags behind other sites during temperature changes, it is sometimes affected by environmental temperature, diaphoresis or sweat can impair adhesion and due to a newborn's sensitive skin it must be moved frequently (Schafer et al 2014).

### Temporal artery thermometer

The temporal artery thermometer scans across the forehead of the individual in a single direction and senses the infrared emissions that radiate from the skin. One advantage of this device is that there is no need for disposable covers because the device can be cleaned with alcohol swabs between individuals. Another advantage is that the device doesn't actually touch the skin of the individual so can be used on a sleeping child. A disadvantage of this mode is that its reliability and validity have not been tested widely to ensure accuracy (McCallum & Higgins 2012).

## STEPS IN OBTAINING AN ACCURATE MEASUREMENT OF BODY TEMPERATURE

To obtain an accurate measurement of body temperature and to promote the individual's comfort and safety, the nurse should:

- Select the appropriate site
- Check that the thermometer is undamaged, not contaminated and is working properly

**Figure 20.3** Taking temperature from the axilla

*(© Elsevier Australia)*

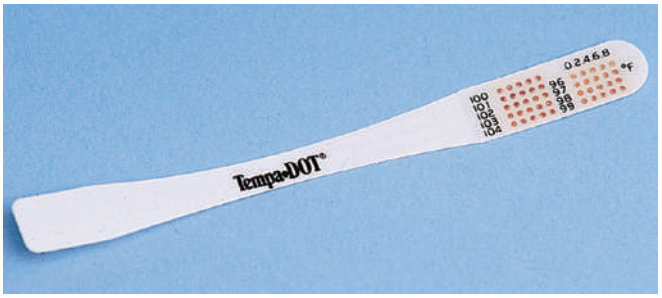

**Figure 20.4** Disposable, single-use thermometer strip

*(Potter & Perry et al 2013)*

### CLINICAL INTEREST BOX 20.2 Axillary temperature in paediatrics

- Axillary temperature cannot be relied on to detect fevers in infants and young children
- Although axillary temperature has a lower sensitivity, it is safe and has no complications. The thermometer must be kept in place for 5 minutes (Sahin et al 2012)
- Infants are sensitive to slight changes in environmental temperatures

**TABLE 20.1 | Measuring body temperature**

| | Oral | Axilla | Skin | Tympanic |
|---|---|---|---|---|
| Time thermometer is left in position | 1 minute | 3 minutes | 60 seconds | 2–5 seconds |
| Normal range of temperature | 36–37.2°C | 36–37°C | 36–37°C | 35.5–37.6°C |
| Position of individual | Lying or sitting | Lying or sitting with arm across the chest | Lying or sitting | Lying or sitting |

*(McCallum & Higgins 2012)*

- Ensure that the person is informed of the procedure
- Position the person according to the site selected
- Wash hands to prevent cross-infection and ensure that the thermometer has been disinfected before the procedure
- Use the correct probe for the site selected when using an electronic thermometer.

Depending on the site being used, some variations occur in the time that the thermometer is left in position, the normal range of temperature and the position in which the person is placed (see Table 20.1). Because of variations between sites it is important to note on the observation or vital signs chart what method was used to take the temperature. For example, if the temperature was taken orally, the temperature would be recorded: 36.7 PO (Latin: *per os* (by mouth)). Temperature measurements are then usually recorded on graph-style charts (Figure 20.5). These enable the pattern of temperature variations to be observed readily. While the actual procedure for measuring temperature may vary slightly in different healthcare settings, the general principles remain the same (see Clinical Skill 20.1).

## Alterations in body temperature

Core body temperature is tightly regulated and reflects body function, and a deviation from the acceptable temperature range is an indication of body dysfunction. An imbalance between the production and the loss of heat results in a rise or fall in normal body temperature. An elevated temperature can be referred to as either hyperthermia or fever, although these two terms have different meanings. A temperature above 41°C is referred to as hyperpyrexia. A temperature below the acceptable range is referred to as hypothermia.

**Hyperthermia** occurs when the heat-loss mechanisms within the hypothalamus fail, resulting in excessive heat production which exceeds the body's adaptive abilities. This can be a manifestation of a metabolic disorder or induced by various medications (Musselman & Saely 2013). **Fever** is generally defined as a temperature above 38 degrees, and occurs when the hypothalamus increases the core body temperature in response to an infection (Musselman & Saely 2013). **Hypothermia** is a body temperature below 35 degrees and is not compatible with life (Grainger 2013). The thermal regulating centre in the hypothalamus is greatly impaired when the temperature of the body falls below 34.4°C and at this level, the activity of the cells is decreased, less heat is produced and sleepiness and coma can develop (Sund-Levander & Grodzinsky 2013). Those at risk of hypothermia include postoperative individuals who have been cooled during surgery, newborn infants, elderly or debilitated individuals and any person who is subjected to prolonged exposure to a cold environment (Grainger 2013). Alterations in body temperature produce certain physiological effects, as shown in Table 20.2.

**TABLE 20.2 | Effects of altered body temperature**

| Hyperthermia | Hypothermia |
|---|---|
| Elevated temperature, pulse and ventilation rates (rigor may occur) | Subnormal temperature, decreased pulse and ventilation rates |
| Warm flushed skin and sweating may be present | Cool, pale or mottled dry skin |
| Restlessness, drowsiness or confusion | Drowsiness, shivering |
| Aching muscles and joints | Muscle weakness |
| Headache | Mental confusion |
| Photophobia | Unconsciousness (if prolonged) |
| Loss of appetite | Hypotension |
| Increased thirst | Frostbite (nose, fingers, toes) |
| Dehydration (if prolonged) | Decreased urinary output |

*(Grainger 2013)*

## Nursing care of an individual with altered body temperature

### Hyperthermia and fever

The first priority for an individual with hyperthermia is to assess their airway, breathing and circulation, and then

## General Instructions

» You must record appropriate observations:
- On admission
- At a frequency appropriate for the patient's clinical state.

» You must calculate a Total ADDS Score:
- If the patient is deteriorating or an observation is in a shaded area
- Whenever you are concerned about the patient.

» When graphing observations, place a dot (•) in the centre of the box which includes the current observation in its range of values and connect it to the previous dot with a straight line. For blood pressure, use the symbols indicated on the chart.

» Whenever an observation falls within a shaded area, you must enter the ADDS Score for that vital sign in the appropriate row of the ADDS Scores table, unless a modification has been made (see below).

## Modifications

- If abnormal observations are to be tolerated for the patient's clinical condition, write the acceptable ranges below (where the ADDS Score will be 0).
- Modifications must be reviewed at least every 72 hours.
- If **any** vital sign needs further modifying, draw two diagonal lines through the entire Modification record in use and write the new acceptable ranges in the next Modification record.

## CLINICAL SKILL 20.1 Assessing body temperature

**Review and carry out the standard steps for all clinical skills/interventions**

| **NMBA Decision-making Framework considerations:** | **Equipment:** |
|---|---|
| 1. Am I educated?<br>2. Am I authorised?<br>3. Am I competent?<br>If you answer 'no' to any of these, do not perform that activity. Seek guidance and support from your teacher/a nurse team leader/clinical facilitator/educator. | Appropriate thermometer<br>Disposable probe cover or sleeve<br>Pen (blue/black) and observation chart |

| **Skill activity** | **Rationale** |
|---|---|
| **Before assessing body temperature** | |
| Assess the individual for temperature alterations and anything that may interfere with the accuracy of temperature measurement<br>Wait 15–20 minutes if the individual has smoked or ingested hot or cold foods or fluids | Physical signs and symptoms of temperature alterations may be present such as the individual being flushed or shivering<br>If using an oral thermometer, intake of some foods can cause inaccurate readings<br>If using a tympanic thermometer, hearing aids can increase temperature readings |
| Determine appropriate temperature site and temperature device for the individual | Different individuals will have different requirements due to their health conditions |
| **Assessing body temperature with a tympanic membrane electronic thermometer** | |
| Assist the individual in assuming a comfortable position, with head turned away from the nurse | Ensures comfort and exposes auditory canal for accurate temperature measurement. Ensures individual safety and comfort |
| Observe for ear wax (cerumen) in individual's ear canal | Lens cover of speculum must not be impeded by earwax (will not obtain an accurate measurement). Switch to other ear or select an alternative measurement site |
| Remove thermometer from charging base and slide disposable speculum cover over otoscope-like tip until it locks into place, being careful not to touch lens cover | Base provides battery power. Soft plastic probe cover prevents transmission of microorganisms |
| If holding handheld unit with right hand, obtain temperature from individual's right ear; left-handed persons should obtain temperature from individual's left ear | The less acute the angle of approach the better the probe will seal inside the auditory canal |
| Insert speculum into ear canal, following manufacturer's instructions for tympanic probe positioning. Pull pinna backwards, up and out for an adult, move thermometer in a figure-eight pattern, fit probe snugly in canal and do not move, point towards the nose | Correct positioning of probe will ensure accurate readings as there will be maximum exposure of the tympanic membrane |
| As soon as probe is in place, depress scan button. Leave thermometer probe in place until an audible signal is given and individual's temperature appears on the digital display | Depression of scan button causes infrared energy to be detected. Otoscope tip must stay in situ until signal occurs to ensure accurate measurement |
| Carefully remove speculum from auditory meatus. Push ejection button on unit to discard plastic probe cover into an appropriate receptacle | Reduces transmission of microorganisms |
| Return handheld unit to charging base | Protects sensor tip from damage and keeps unit charged ready for next use |

*Continued*

| CLINICAL SKILL 20.1 Assessing body temperature—cont'd | |
|---|---|
| Assist individual in reassuming a comfortable position | Restores comfort and sense of wellbeing |
| Perform hand hygiene | Reduces risk of transmission of microorganisms |
| Discuss findings with individual as needed | Promotes participation in care and understanding of health status |
| If this is the first time temperature has been measured, if in normal range establish as baseline | Used to compare future readings |
| If this is not the first time, compare with baseline and acceptable temperature range for individual's age group | Normal body temperature fluctuates within normal range, comparison of readings can reveal presence of abnormality |
| Record the time and temperature on the vital signs chart. Record measurements in the progress notes if the temperature was elevated and report abnormal findings to the relevant Registered Nurse or medical officer | Verifies that temperature was taken and makes measurement data available |
| **Measurement of body temperature with electronic thermometer** | |
| **Oral temperature** | |
| Remove thermometer from charging unit. Slide disposable plastic probe cover over thermometer probe until cover locks in place | Charging provides battery power. Soft plastic cover prevents transmission of microorganisms |
| Ask the individual to open their mouth then gently place thermometer probe under the tongue in posterior sublingual pocket lateral to centre of jaw | Heat from superficial blood vessels in sublingual pocket produces temperature reading |
| Ask individual to hold thermometer probe with lips closed | Maintains proper position of thermometer during recording |
| Leave thermometer probe in place until audible signal occurs and individual's temperature appears on digital display | To ensure accurate reading, probe must stay in place until signal occurs |
| Remove thermometer probe from under individual's tongue, push ejection button and discard plastic probe cover into an appropriate receptacle | Reduces risk of transmission of microorganisms |
| Return thermometer to storage position of thermometer unit and return to charger | Maintains battery charge |
| Discuss findings with individual as needed | Promotes participation in care and understanding of health status |
| If this is the first time temperature has been measured, if in normal range establish as baseline | Used to compare future readings |
| If this is not the first time, compare with baseline and acceptable temperature range for individual's age group | Normal body temperature fluctuates within normal range, comparison of readings can reveal presence of abnormality |
| Record the time and temperature on the vital signs chart. Record measurements in the progress notes if the temperature was elevated and report abnormal findings to the relevant Registered Nurse or medical officer | Verifies that temperature was taken and makes measurement data available |

## CLINICAL SKILL 20.1 Assessing body temperature—cont'd

| | |
|---|---|
| **Measurement of axillary temperature** | |
| Draw curtain around bed and/or close door | Provides privacy |
| Position individual either lying supine or sitting and move clothing away from shoulder and arm | Provides easy access to axilla and exposes area for correct thermometer probe placement |
| Remove thermometer from charging unit. Slide disposable plastic probe cover over thermometer probe until cover locks in place | Charging provides battery power. Soft plastic cover prevents transmission of microorganisms |
| Raise individual's arm away from torso and make sure the axilla is dry | Moisture may interfere with accurate reading and give a false low reading |
| Place thermometer into centre of axilla, lower arm over probe and place arm across individual's chest | Maintains position of thermometer against blood vessels in axilla |
| Hold thermometer in place until audible signal occurs and individual's temperature appears on digital display; remove probe from axilla | Ensures an accurate reading |
| Push ejection button on thermometer probe stem to discard plastic probe cover into an appropriate receptacle | Reduces risk of transmission of microorganisms |
| Return thermometer to storage position of thermometer unit and return to charger | Maintains battery charge |
| Assist individual to assume a comfortable position | Restores comfort and promotes privacy |
| Discuss findings with individual as needed | Promotes participation in care and understanding of health status |
| If this is the first time temperature has been measured, if in normal range establish as baseline | Used to compare future readings |
| If this is not the first time, compare with baseline and acceptable temperature range for individual's age group | Normal body temperature fluctuates within normal range, comparison of readings can reveal presence of abnormality |
| Record the time and temperature on the vital signs chart. Record measurements in the progress notes if the temperature was elevated and report abnormal findings to the relevant Registered Nurse or medical officer | Verifies that temperature was taken and makes measurement data available |
| **Measuring temporal artery temperature** | |
| Ensure the forehead is dry | Moisture may interfere with accurate readings |
| Place sensor flush on individual's forehead | Ensures accurate measurement |
| Press red scan button with your thumb. Then slowly slide the thermometer straight across the forehead while keeping the sensor flush with the skin | Scanning for the highest temperature continues until you release the scan button |
| Keeping the scan button pressed, lift the sensor from the forehead and touch the sensor to the skin on the neck just below the earlobe. Peak temperature occurs when the clicking sound during scanning stops. Then release scan button | Sensor confirms highest temperature behind the ear lobe |
| Clean sensor | Prevents transmission of microorganisms |
| Assist individual to assume a comfortable position | Restores comfort and promotes privacy |

*Continued*

| CLINICAL SKILL 20.1 Assessing body temperature—cont'd | |
|---|---|
| Discuss findings with individual as needed | Promotes participation in care and understanding of health status |

| Record the time and temperature on the vital signs chart. Record measurements in the progress notes if the temperature was elevated and report abnormal findings to the relevant Registered Nurse or medical officer | Verifies that temperature was taken and makes measurement data available |
| Note:<br>• In an infant or young child it may be necessary to hold the arm against the child's side when using axillary method. If infant is in a side-lying position, the lower axilla will record the higher temperature.<br>• Do not use axilla if skin lesions are present because local temperature may be altered and area may be painful to touch. | |
| *(Crisp et al 2013; Perry et al 2012; Rebeiro et al 2012; Tollefson et al 2012)* | |

investigate why they have this condition (Vijay 2014). The nurse should ask the following questions:

- Have I accurately checked this temperature? Did the person recently have a hot drink?
- Can I check this with another device to reduce user or device errors?
- Why is the individual febrile?
- What other clinical information such as tachycardia adds to the clinical picture of the individual?
- Who should I inform of this clinical change in the individual's assessment—the nurse in charge or the medical officer?

These questions need to be answered prior to any care aimed at reducing the temperature, as the medical officer may want to obtain blood cultures while the individual is febrile to identify any microorganisms causing an infection in the individual. Giving medications to reduce an individual's fever prior to obtaining blood cultures can affect the results (Clinical Excellence Commission 2012). The most important question to always ask is 'Why, and what other pieces of assessment data add to the clinical picture?' Is the individual febrile, tachycardic, with burning sensation on urination, or is the individual febrile, tachycardic, tachypnoeic with a productive cough? When coupled with other assessment data the potential reasons the individual is febrile can be identified and treated.

Once the need for collection of blood cultures is assessed or potential reasons for hyperthermia are identified the nurse should focus on the following areas and nursing actions:

- Reducing body temperature to an acceptable range through administration of prescribed medication such as antipyretics and antibiotics. This is very important as it will reduce the individual's metabolic demands and oxygen consumption. The person's vital signs should be measured 30 minutes after completion
- Sponging the individual with tepid water
- Relieving any associated discomfort through regular mouth care and ensuring the individual's bed linen is clean and dry
- Encouraging rest to decrease the production of body heat
- Continually checking the individual's skin colour, temperature and general condition to assess the effectiveness of nursing interventions
- Monitoring renal function and maintaining nutritional and fluid status through providing adequate fluids, which are necessary to prevent dehydration. The individual should be encouraged to drink large amounts of cool or iced fluids. If the person is unable to tolerate fluids orally, intravenous administration of fluids may be necessary. The input and output of all fluids should be closely monitored and the person observed for any signs of dehydration (Vijay 2014).

Information on the signs and symptoms of dehydration is provided in Chapter 26.

A rigor sometimes occurs in response to the physiological processes associated with hyperthermia. The nurse should assess the individual's condition throughout the three typical stages of a rigor, and implement the nursing actions necessary to promote individual comfort:

- Stage 1: As the body temperature begins to rise the individual feels cold and may shiver violently. Comfort should be promoted by keeping the individual warm but avoiding overheating. The intake of fluids should be encouraged

- Stage 2: The temperature rises to approximately 40°C and the individual feels very hot and uncomfortable. Minimal clothing and bed linen should be used and other actions to reduce the body temperature should be implemented; for example, encouraging the individual to drink large amounts of cool fluid
- Stage 3: Profuse sweating occurs and as a result body temperature begins to fall. Actions to reduce temperature should be stopped and any damp clothing or bed linen should be changed to maintain a dry environment. The individual should be encouraged to rest quietly in an attempt to reduce the production of body heat.

### Hypothermia

Hypothermia can occur due to physiological factors such as an impaired hypothalamus and inadequate heat production to counteract heat loss. Hypothermia can occur from other factors such as excessive heat loss. The first priority of any changes to an individual's temperature is to assess their airway, breathing and circulation, as this is compromised during moderate to severe hypothermia, then the cause must be investigated (Kunde 2014). See the section above on hyperthermia for questions to ask prior to treatment of any alteration in temperature.

The aims and nursing actions of caring for an individual with hypothermia include:

- Restoring body temperature to an acceptable range through passive warming, such as additional blankets or a space blanket, or active warming, increasing the ambient temperature or applying forced-air blanket systems (Kunde 2014). Rewarming needs to occur slowly to avoid haemodynamic changes and possible shock (Scaravilli et al 2012).
- Relieving any discomfort associated with hypothermia
- Encouraging mobilisation to increase the production of body heat if the individual is able to stand
- Maintaining nutritional and fluid status through encouragement of warm food or fluid that is high in carbohydrate to aid heat production.
- Continually checking the individual's vital signs and general condition to assess the effectiveness of nursing interventions.

#### CRITICAL THINKING EXERCISE 20.1

1. What is the most appropriate temperature measurement site for a child?
2. What are some other physiological observations that would change if an individual is febrile and why?
3. A colleague suggests that oral thermometers are the only accurate measurement of temperature. How would you respond to this statement?
4. Mr Sam Neugen, a 65-year-old retiree, has been admitted to a medical–surgical ward. Sam is febrile at 38°C with a suspected chest infection. He has non-significant past medical history. Sam is thirsty, tired and short of breath. Identify two nursing diagnoses and at least four interventions for each diagnosis while caring for Sam as an individual.

## PULSE

With each contraction of the heart the increased volume of blood pushed into the arteries can be palpated at certain points on the body (Elliott & Coventry 2012). Measuring the pulse or heart rate, which is one of the measurable characteristics of the pulse, gives the nurse vital information about the health of an individual. The pulse can be affected by a variety of factors including age, medical conditions, medications and fluid status.

As described in Chapter 25, the cardiovascular system transports essential substances to the tissue cells, and waste substances from the tissue cells to various organs for excretion. An adequate supply of blood is necessary for the cells to function effectively, and any disruption to the blood supply may have serious consequences. An adequate flow of blood throughout the body is dependent on the ability of the heart to pump, the ability of the blood vessels to transport the blood and the quantity and quality of the blood.

The most important factor responsible for the transport of substances to the tissues is cardiac output, which is the volume of blood pumped by the heart during each minute. It is the product of the volume of blood pumped at each beat (stroke volume) and the number of beats during one minute (heart rate). A healthy heart in a healthy adult ejects 5–6 litres of blood per minute (Marik 2013). This amount can be increased by an increase in either heart rate and/or stroke volume and can also vary with:

- Body size, as cardiac output increases in proportion to the surface area of the body
- Age, as with increasing age the cardiac output decreases
- Posture, as cardiac output is greater when a person is standing
- Exercise, as the greater the degree of physical activity the greater the cardiac output needs to be. Strenuous physical activity can result in an increased heart rate and a cardiac output of 30 L/min
- A sudden increase in total blood volume; for example, the infusion of fluid intravenously
- Certain disease states—cardiac output is increased in conditions such as pulmonary disease and anaemia, and is decreased in conditions such as shock or myocardial infarction.

The rate at which the heart beats is controlled by the conducting system of the heart and the autonomic nervous system. The sinoatrial node initiates impulses that spread throughout the conducting system and to all areas of the cardiac muscle, resulting in atrial then ventricular contraction. Stimulation of the parasympathetic nerve fibres, primarily the vagus nerves, reduces the heart rate, while stimulation

of the sympathetic nerve fibres increases the heart rate. Various chemicals and ions can also affect heart activity; for example, adrenaline inhibits the parasympathetic nerves, resulting in increased heart rate. An excess of potassium ions in the blood decreases the ability of the heart to contract. Heart, and therefore pulse, rate varies according to age, gender, body build, level of physical activity and emotions.

## Assessing the pulse

Cardiovascular function is assessed by monitoring the pulse and blood pressure as well as observing the general appearance of the individual and detecting the signs and symptoms of dysfunction, such as cyanosis, pallor, cool skin temperature, oedema and dyspnoea. The frequency with which the pulse and blood pressure are assessed depends on the person's condition and how closely it needs to be monitored. Residents in long-term care facilities will generally require pulse and blood pressure measurement infrequently, whereas people who are acutely ill may have continuous monitoring or measurements performed at intervals ranging from every 30 minutes to six times a day.

Assessment of the pulse characteristics, which includes strength, equality and regularity, provides significant information about a person's cardiac function and peripheral perfusion (Elliott & Coventry 2012). The waves of blood that cause pulsation through the arteries can be felt when a superficial artery is partially compressed by the fingers, and is most easily felt over a large artery that lies close to the skin and crosses over a bone or firm tissue (see Clinical Skill 20.2).

## Pulse sites

The pulse sites (Figure 20.6) where the pulse may be palpated are:

- Temporal: the temporal artery is palpated immediately in front of the ear
- Carotid: the carotid artery is palpated at the front of the neck, to the side of the thyroid cartilage
- Apical: the apical pulse is the beat heard at the apex of the heart, and is assessed using a stethoscope. The stethoscope is placed over the apex of the heart, in the left centre of the chest just below nipple level
- Brachial: the brachial artery is palpated in the antecubital fossa at the elbow joint
- Radial: the radial artery is palpated in the wrist just above the thumb
- Femoral: the femoral artery is palpated in the inguinal area
- Popliteal: the popliteal artery is palpated at the back of the knee (Figure 20.7)
- Posterior tibial: the posterior tibial artery is palpated just behind the medial malleolus of the ankle (Figure 20.8)
- Pedal: the dorsalis pedis artery is palpated on the anterior surface of the foot (Figure 20.9).

The radial artery is the most commonly used site, as it is conveniently located and readily accessible (Figure 20.10). The femoral or carotid sites may be used if it is difficult to palpate the radial artery easily; for example, the individual has poor peripheral perfusion. The remaining sites are used when there are specific indications for assessing the flow of blood through a particular artery; for example, the popliteal and pedal pulses are assessed after certain types of surgery to the leg.

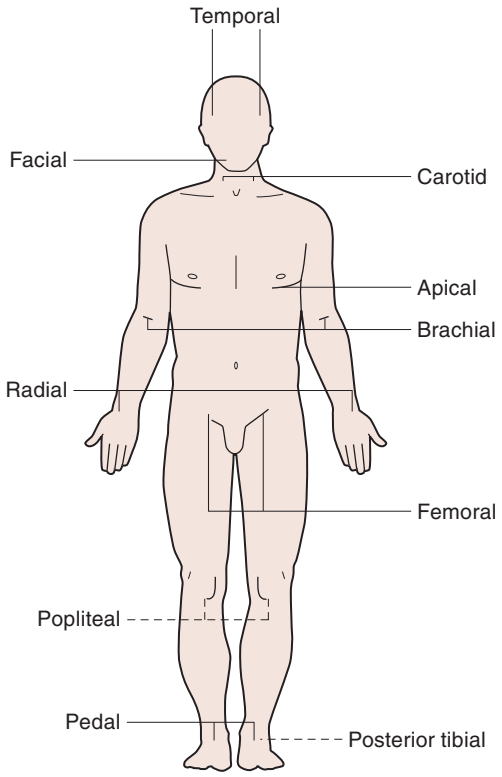

**Figure 20.6** Location of the pulse sites

**Figure 20.7** Measuring the popliteal pulse

*(Potter & Perry et al 2013)*

## CLINICAL SKILL 20.2 Assessing pulse (radial)

**Review and carry out the standard steps for all clinical skills/interventions**

| **NMBA Decision-making Framework considerations:** | **Equipment:** |
|---|---|
| 1. Am I educated?<br>2. Am I authorised?<br>3. Am I competent?<br>If you answer 'no' to any of these, do not perform that activity. Seek guidance and support from your teacher/a nurse team leader/clinical facilitator/educator. | Watch<br>Pen (blue/black)<br>Observation chart |

| **Skill activity** | **Rationale** |
|---|---|
| Check individual's previous baseline resting pulse rate | It is important to know the individual's usual pulse rate to compare changes with that measurement |
| The radial pulse is normally assessed unless indicated. If individual is supine, place individual's forearm straight alongside or across lower chest or upper abdomen with wrist extended straight. If sitting, bend individual's elbow 90 degrees and support lower arm on chair or on nurse's arm. If not using the radial pulse, position individual so appropriate peripheral pulse point is accessible | Relaxed position of lower arm permits full exposure of artery to palpation |
| Place the index and middle fingers over the site and press gently until pulsation can be felt. Obliterate pulse initially and then relax pressure so pulse becomes easily palpable. Slightly extend the wrist with palm down until you note the strongest pulse | The assessor's thumb is not used, as it has a strong pulse and may be felt instead of the individual's pulse. Pressure that is too light will fail to detect the pulse, and firm pressure may obliterate the pulse |
| Determine the strength of the pulse, noting whether it is bounding, strong, weak or thready | Strength reflects volume of blood ejected against arterial wall with each heart contraction. Accurate description of strength improves communication among nurses and other healthcare professionals |
| Using a watch with a second hand, count the pulse for 1 minute. While the rate is being counted, the rhythm and volume are also assessed. If pulse is regular count rate for 30 seconds and multiply total by 2. If pulse is irregular, count rate for 60 seconds. Assess frequency and pattern of irregularity and compare radial pulses bilaterally | Allows sufficient time to detect the rate and any abnormalities. It requires 30 seconds to determine if the pulse is regular in rhythm. Inefficient contraction of heart fails to transmit pulse wave, interfering with cardiac output, resulting in irregular pulse. Longer time period ensures more accurate count. A marked difference between radial pulses may indicate arterial flow is compromised in one extremity and action should be taken immediately |
| When pulse is irregular, compare radial pulses bilaterally | A marked inequality indicates compromised arterial flow to one extremity and you need to take action |
| Assist individual to assume a comfortable position | Restores comfort and promotes privacy |
| Discuss findings with individual as needed | Promotes participation in care and understanding of health status |
| Document the time of assessment and the rate and characteristics of the pulse. Record the pulse measurement | A record provides information about the individual's condition |
| Any abnormalities must be reported immediately, as an apical measurement may be indicated | An apical measurement provides a more accurate assessment of the pulse |

**Note:** If pulse is irregular, assess for a pulse deficit. Count apical pulse while colleague counts radial pulse. Begin apical pulse, initiating counting by a signal to simultaneously assess pulses for a full minute. If pulse count differs by more than 2 beats per minute, a pulse deficit exists, which may indicate alteration in cardiac output.

*(Crisp et al 2013; Perry et al 2012; Tollefson et al 2012)*\

**Figure 20.8** Measuring the posterior tibial pulse
*(R. Gilder 2015)*

**Figure 20.9** Measuring the pedal pulse
*(R. Gilder 2015)*

The apical pulse is assessed when a more accurate estimation of heart rate or regularity is required, or when there is any doubt about the rate or regularity of a peripheral pulse (Figure 20.11). It is routinely used for infants and children up to 3 years of age. Apical–radial pulse assessment may be indicated for an individual with certain cardiovascular disorders. This assessment requires two healthcare workers as one person palpates and assesses the radial pulse while a second person assesses the apical pulse at the same time—the apical and radial rates should be identical. Some heartbeats that can be detected at the apex are not strong enough to be palpated at peripheral sites. Any difference between the two measurements is called the pulse deficit, and should be reported immediately.

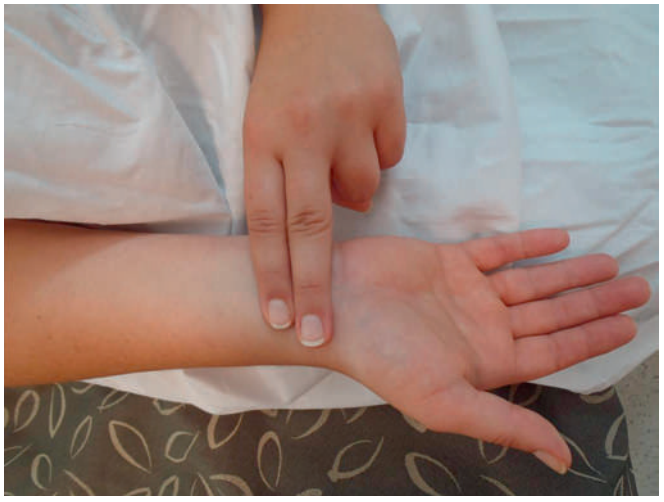

**Figure 20.10** Measuring the radial pulse
*(R. Gilder 2015)*

**Figure 20.11** Counting the apical pulse
*(© Elsevier Australia)*

## Character of the pulse

The pulse is assessed for rate, regularity and strength:

- *Rate*: the pulse rate is the number of beats per minute, and the acceptable rate varies according to age: 120–140 beats/min for an infant, 90–120 beats/min for a child, 60–100 beats/min for an adult. It should be noted that athletes and other physically fit individuals commonly have a pulse rate below 60 beats/min. A large proportion of elderly people also have a pulse rate below 60 beats/min

## CLINICAL INTEREST BOX 20.3
## The pulse in older adults

It is often difficult to palpate the pulse of an older adult or obese individual. A stethoscope provides a more accurate reading.

Once elevated, the pulse rate of an older adult takes longer to return to a normal resting rate.

- *Regularity*: a normal pulse has a regular rhythm, with the same intervals between each beat
- *Strength*: an acceptable pulse is strong and easily palpated.

## Factors affecting pulse characteristics

The pulse characteristics can vary according to age (see Clinical Interest Box 20.3), sex, body build, level of physical activity, fever, medications, haemorrhage, position changes, pregnancy, stress and emotions. The pulse may also be affected during various disease states, which result in alterations to its character.

### Rate

An increase in the pulse rate above 100 beats/min is called **tachycardia** and may result from fear, anxiety, excitement, anger or pain. Tachycardia may also occur in conditions such as haemorrhage, shock, fever, thyrotoxicosis or congestive cardiac failure. A decrease in the pulse rate below 60 beats/min is called **bradycardia** and may occur during absolute relaxation or sleep. Bradycardia may also occur in conditions such as cerebral haemorrhage, heart block, myxoedema or drug toxicity, such as with digitalis.

### Regularity

An irregular rhythm, when the intervals between each beat vary, is called arrhythmia, or dysrhythmia, and may occur in conditions such as electrolyte imbalance or cardiac tissue damage. Examples of irregular rhythm include:

- Ectopic beats, which are premature heartbeats and may be occasional or frequent
- Coupled beats (or bigeminal pulse), in which two beats in close succession are followed by a pause during which no pulse is felt
- Atrial fibrillation, in which fibrillation of the atria results in random ventricular contractions and, consequently, an irregular pulse.

### Strength

An increased strength, when the pulse is referred to as being full and bounding, can result from strenuous physical exercise or strong emotions. An increased strength can also occur in conditions such as hypertension, thyrotoxicosis or aortic valve incompetence. A decreased strength, when the pulse is referred to as being weak and thready, can occur in conditions such as haemorrhage, shock, acute myocardial infarction or cardiac failure. When the pulse is so weak that it cannot be palpated it is referred to as being imperceptible.

When assessing the pulse, any deviations from an individual's acceptable range should be reported immediately and documented. Pulse measurements are recorded and graphed on an Adult Deterioration Detection System chart (see Figure 20.5) which allows healthcare workers to see changes and trends in an individual's measurements.

## Alterations in pulse rate

For an individual with an altered pulse rate, the priority should be ensuring a full vital sign assessment has been completed and documented to ensure that acute deterioration is identified and managed appropriately (Clarke 2014). The nurse should ask the following questions:

- Have I completed the assessment accurately?
- Is this normal for this individual?
- What other clinical information is consistent with an altered pulse rate?
- Do I need to inform the appropriate person of alterations in the individual's condition?

As healthcare becomes more complicated due to individuals with co-morbidities, it is essential that nurses use the decision-making framework and their clinical judgment to ensure a positive outcome for the individual (Purling & King 2012).

Review Case Study 20.1 and apply the above information when answering the questions.

## CRITICAL THINKING EXERCISE 20.2

1. Rita Ryan has been allocated into your care and you conduct a vital sign assessment. The pulse you palpate is irregular and fast at 150 beats per minute. Using Figure 20.5, identify what action you would take next while caring for Rita.
2. Rita asks you what an irregular pulse means. How would you answer her question?
3. A medical officer asks you to palpate bilateral popliteal pulses and document the results. Where do you place your fingers?
4. What are the possible reasons for requesting bilateral pulses be palpated and documented?

# RESPIRATION

Oxygen, a colourless and odourless gas, makes up about 20% of the atmosphere, and is essential for sustaining most forms of life. The respiratory system gives the body the ability to absorb oxygen and excrete waste products, such as carbon dioxide. The capillary alveoli membrane in the lungs allows the exchange of oxygen from the atmosphere to the bloodstream and carbon dioxide to be diffused out. (Further information about the structure and function of the respiratory system is provided in Chapter 25.)

The cardiovascular system and the respiratory system work together to bring about **respiration**, the exchange of

## CASE STUDY 20.1

George Callahan, a 65-year-old male, is admitted to the cardiac ward with atrial fibrillation. This is a new presentation and George has never been admitted to hospital before. George's wife has many questions about what atrial fibrillation is and how it will affect his life. George wants to know why he finds it difficult to breathe when he is walking.

Past history: hypertension, high cholesterol
Allergies: none known
Observations:

- Pulse: 110 beats per minute and irregular
- Blood pressure: 100/55 mmHg
- Temperature: 36.8°C
- Respiratory rate: 14 breaths per minute
- Oxygen saturation: 96% on room air

1. Which observations are abnormal?
2. Why is George's pulse irregular?
3 What advice would you give to George's family about his admission?
4. Why does George become short of breath on exertion?

oxygen and carbon dioxide. **External respiration** is the exchange of oxygen and carbon dioxide between the external environment and the blood by the process of diffusion in the lungs. **Internal respiration** is the exchange of oxygen and carbon dioxide between the blood and the body tissues by the process of diffusion between the capillaries and the cell membrane (Klocke 2014).

The passage of oxygen from the atmosphere to the alveoli in the lungs and the passage of carbon dioxide from the alveoli to the atmosphere require:

- An unobstructed airway
- Adequate oxygen in the atmosphere
- A functioning respiratory tract
- Functioning thoracic muscles and nerves to control the thoracic cage
- Blood to transport the gases
- Capillaries in close proximity to the cells to allow the exchange of gases (Klocke 2014).

## Regulation of breathing and respiration

The automatic control of breathing stems from the respiratory centres located in the brainstem. From these sites, neural networks send impulses along the spinal cord to the nerves that control the diaphragm and intercostal muscles. Reflex responses and chemical signals control these nerve centres and thus the rate of breathing. During actions such as speaking and swallowing, impulses from the throat are conveyed to the respiratory centre and breathing stops temporarily. The chemical control of breathing mainly depends on the level of carbon dioxide in the blood, which is detected by chemoreceptors. The presence of excess carbon dioxide causes the respiratory rate to increase until the excess carbon dioxide is eliminated. Conversely, a decreased carbon dioxide level slows the respiratory rate (Klocke 2014).

## Factors affecting respiratory function

Factors that affect the process of respiration include:

- *Availability of oxygen*. Oxygen makes up 20% of the air and normally this is sufficient to meet the needs of the body, but a decrease in this amount of oxygen can cause problems. Two instances where the available oxygen may be deficient are:
  1. High altitude. The total pressure of all gases, including oxygen, in the air decreases at high altitude. Therefore, people experience difficulty in obtaining adequate oxygen until they become acclimatised. As a result, the respiratory rate is increased in an attempt to supply the body with sufficient oxygen
  2. The presence of noxious gases. Noxious gases in the air displace the oxygen and reduce the amount normally available for inspiration (Klocke 2014).
- *Regulating mechanisms*. Any factor that interferes with the control mechanisms in the respiratory centre of the brain may cause respiratory difficulties; for example, cerebral oedema or medications such as morphine. Respirations increase when the pH of the blood is lowered, as a respiratory response to rid the body of the excess acid.
- *Passage of oxygen and carbon dioxide*. The efficiency of respiration can be affected by any factor that obstructs the patency of the respiratory tract or the actions of the respiratory muscles; for example, an accumulation of secretions resulting from a reduced cough reflex. Respirations may be reduced by factors that affect the actions of the respiratory muscles; for example, injury or disease that restricts the movements of the diaphragm (Klocke 2014).
- *Diffusion of oxygen and carbon dioxide*. Any dysfunction of the lungs (e.g. pulmonary oedema, asthma or chronic obstructive airways disease) may impede the transfer of oxygen and carbon dioxide (Klocke 2014). (Information on these and other respiratory disorders is provided in Chapter 25.)
- *Transport of oxygen and carbon dioxide to and from the cells*. Any condition affecting the efficiency of the heart, the blood vessels or the blood can interfere with the transportation of oxygen to the cells and carbon dioxide away from the cells. Such conditions include congestive cardiac failure, atherosclerosis and anaemia. (Information on these and other cardiovascular disorders is provided in Chapter 25.)
- *Influences on the rate, depth and rhythm of breathing*. Several factors influence the characteristics of breathing; for example, the degree of physical activity. Oxygen requirements are greatest during exertion and least during sleep. The respiratory rate and depth vary in response to the body's demand for oxygen; for example, during strenuous exercise the volume of air drawn into

## CLINICAL INTEREST BOX 20.4
## Respiration in older adults

- Ageing causes ossification of costal cartilage and downward slanting of ribs, resulting in a more rigid rib cage, which reduces chest wall expansion
- Depth of respirations tends to decrease with ageing

*(Cooper & Gosnell 2015)*

the lungs with each breath may be increased from the usual 500 mL to as much as 4000 mL. Changes in mood or emotion may also affect the rate, depth and rhythm of ventilation; for example, the respiration rate is commonly increased during anxiety, pain or anger. Smoking also affects breathing and often causes short-term effects such as coughing and shortness of breath, or long-term effects such as severe dyspnoea, resulting from emphysema.

See Clinical Interest Box 20.4 for the effects of ageing on respirations.

## Assessing respirations

An individual's respiratory status is the first observation that will indicate a deterioration in a person's condition and predict a serious adverse event, such as cardiac arrest (Philip et al 2013). Assessment is not only to ascertain whether the individual is receiving an adequate supply of oxygen to meet their body's needs, but aids in evaluating airway patency, the status of the respiratory muscles and the individual's metabolic state (Elliott & Coventry 2012). Assessment is made by observing the individual for signs and symptoms of an inadequate oxygen supply, assessing their respirations and identifying any deviations from normal. The frequency with which respirations are subsequently assessed depends on how closely the individual's condition needs to be monitored. Residents in long-term care facilities commonly have their respirations assessed less often than acutely ill individuals, whose condition may need to be monitored continuously.

Respirations are assessed without the individual's knowledge by noting the rise and fall of the chest. If a person is aware that their respirations are being assessed they may become conscious of them and may unintentionally change their character. The nurse may assess the respirations by observing the person or by placing a hand on the individual's chest to feel the rise and fall. To avoid making the individual aware that their respirations are being assessed, the nurse may place fingers on the person's radial pulse site and continue as if counting the pulse (Elliott & Coventry 2012). (See Clinical Skill 20.3.)

Respirations are assessed for rate, rhythm, depth and sound:

- *Rate*. The respiratory rate is the number of respirations per minute. One inhalation and one exhalation equal one respiration (Figure 20.12). The rate of respiration varies according to age, level of activity and emotions. The normal respiratory rates according to age are about 20–40 breaths per minute for a 1-year-old, 20–30 in a 3-year-old, 16–22 in a 6-year-old and 12–20 in an adult (Kinney 2014; Van Kuiken & Huth 2013)
- *Rhythm*. The rhythm of respiration is the pattern or regularity of breathing. Normal respirations are evenly spaced, with little variation from one breath to another
- *Depth*. Depth of respirations depends on the volume of air being inhaled and exhaled with each respiration. The depth should be constant with each breath and is assessed by observing the individual's chest movement for adequate expansion. Respirations are described as being normal, shallow or deep
- *Sound*. Normal respirations are inaudible (Klocke 2014).

**Figure 20.12** Measuring respirations

*(© Elsevier Australia)*

Assessing respiratory status and identifying any actual or potential problems are assisted by obtaining information from an individual regarding:

- Allergic reactions, such as coughing, sneezing or shortness of breath, that occur as a result of exposure to allergens such as dust, pet hairs or pollen
- Exposure to environmental air pollutants such as chemical wastes
- Smoking habits
- Presence of a cough and/or the production of sputum
- Chest pain.

## CLINICAL SKILL 20.3 Assessment of respirations

**Review and carry out the standard steps for all clinical skills/interventions**

| **NMBA Decision-making Framework considerations:** | **Equipment:** |
|---|---|
| 1. Am I educated?<br>2. Am I authorised?<br>3. Am I competent?<br>If you answer 'no' to any of these, do not perform that activity. Seek guidance and support from your teacher/a nurse team leader/clinical facilitator/educator. | Watch<br>Pen (blue/black)<br>Observation chart |

| **Skill activity** | **Rationale** |
|---|---|
| Ensure that the individual is resting in a position of comfort, preferably sitting or lying with the head of the bed elevated 45–60 degrees | Exercise or discomfort alters the nature of respirations<br>Sitting erect promotes full ventilator movement |
| Check individual's previous baseline respirations | It is important to know the individual's usual respiration rate to compare with that measurement |
| Assess for signs and symptoms of respiratory alterations such as cyanotic appearance, restlessness, irritability, confusion, reduced level of consciousness, pain, difficulty breathing, production of sputum, presence of a cough | Physical signs and symptoms may indicate alterations in respiratory status related to ventilation |
| Place individual's arm (or your hand) in relaxed position across the abdomen or lower chest, directly over individual's upper abdomen | Individual's or nurse's hand rises and falls during the respiratory cycle, which makes it easier to count the respirations |
| Observe complete respiratory cycle (one inspiration and one expiration) | The nurse determines an accurate rate only after viewing the entire respiratory cycle |
| Using a watch with a second hand, without changing the position of your hand on the pulse and without the individual's knowledge, count the respirations for 1 minute | Maintaining the same position keeps individual from being aware that their respirations are being assessed. Inconspicuous assessment prevents individual from consciously or unintentionally altering rate and depth of breathing. The intervals between respirations may be inconsistent, and counting for a full minute enables an accurate measurement of rate |
| If rhythm is regular, count number of respirations in 30 seconds and multiply by 2. If rhythm is greater than 16 respirations per minute, count for a full minute | Respiratory rate is equivalent to number of respirations per minute. Suspected irregularities require assessment for at least 1 minute |
| While measuring the rate, also observe the rhythm (regular and irregular), depth (shallow, normal or deep) and sound of respirations | A complete assessment of respirations is necessary |
| Observe for evidence of dyspnoea (increased effort to inhale and exhale). Ask individual to describe subjective experience of shortness of breath compared with usual breathing pattern | Individuals with chronic lung disease may experience difficulty breathing all the time and can best describe their own discomfort from shortness of breath |
| Assist individual to assume a comfortable position | Restores comfort and promotes privacy |
| Discuss findings with individual as needed | Promotes participation in care and understanding of health status |
| Perform hand hygiene | Prevents risk of transmission of microorganisms |
| Document the time of measurement and the rate and character of the respirations on the appropriate chart using numbers or dots | A record of the respirations provides information about the individual's condition to members of the healthcare team |
| Report any deviations from usual acceptable ranges | Appropriate care may be planned and implemented |

**Note:** Occasional periods of apnoea are a symptom of underlying disease in the adult and must be reported to the medical officer or relevant Registered Nurse. Irregular respirations and short episodes of apnoea are normal in a newborn. Sighing is not an abnormality and should not be confused with an abnormal rhythm; it is one deep breath that opens up the small airways in the individual.

It is important to observe the skin colour for signs of cyanosis. **Cyanosis** is a bluish discolouration of the skin and mucous membranes due to inadequate oxygenation and can be either peripheral or central. Peripheral cyanosis is caused by local vasoconstriction and is usually visible only in the nail beds and sometimes the lips. Central cyanosis is the result of prolonged **hypoxia** (diminished availability of oxygen to the body tissues) and affects all body organs. It is most visible in highly vascular areas such as the lips, nail beds, tip of the nose, the external ear and the underside of the tongue. In people with naturally dark brown or black skin, cyanosis can be most readily detected by inspecting the mucosa inside the lips.

Hypoxia may result from disorders that limit the volume of air entering the lungs or from obstructive lung diseases such as asthma and emphysema. The signs and symptoms of hypoxia and respiratory distress include:

- Elevated blood pressure and pulse rate
- Shortness of breath and fatigue
- Cyanosis
- Abnormal ventilations
- Use of accessory muscles during breathing and flaring of the nares
- Retraction of the sternum and intercostal muscles
- Apprehension or agitation
- Confusion or reduced level of consciousness
- Visible perspiration.

A person who has a chronic respiratory disorder should also be observed for a barrel-shaped chest, which is a thoracic deformity commonly associated with chronic obstructive airways disease. When chronic hypoxia exists, a person experiences general fatigue and intolerance to exercise and may have clubbing of the fingers (Hill Bailey et al 2013).

## Alterations in respirations

Research suggests that alterations in respiratory rate can be an early sign that the individual is deteriorating. However, research studies have also found that some nurses believe that this observation is not completed as accurately as pulse or blood pressure measurements. It is imperative that accurate measurement of the respirations is done to ensure early signs of clinical deterioration are identified (Philip et al 2013). Many factors may cause alterations to the rate, rhythm, depth or sound of respirations and deviations from the acceptable range and pattern.

### Rate

An increase in the rate above the acceptable range is called **tachypnoea** and may occur as a result of physical exercise; states such as fear, pain, anxiety, excitement or anger; and disease states such as fever, infection, respiratory disorders, thyrotoxicosis and congestive cardiac failure. A decrease in the rate below the acceptable range is called **bradypnoea** and may occur as a result of absolute rest or sleep, trauma to the brain, uraemia, diabetic coma or medications that depress the respiratory centre, such as morphine.

### Rhythm

The normal regular pattern of breathing may be altered by a variety of disease states. In obstructive airways disease, such as asthma, chronic bronchitis or emphysema, there is a prolonged expiratory phase. In heart failure or increased intracranial pressure, **Cheyne–Stokes breathing** may occur. This is an abnormal pattern characterised by periods of apnoea. The cycle of Cheyne–Stokes breathing begins with slow shallow breaths that gradually increase in depth and rate. Breathing then gradually becomes slower and more shallow, culminating in a 10–60 second period without ventilation (apnoea), before the cycle is repeated.

### Depth

If a person inhales and exhales only small amounts of air, the respirations are described as shallow. *Hypoventilation* is the term used to describe a reduced rate and depth of ventilation, and may occur as a result of a decreased response of the respiratory centre to carbon dioxide, or in respiratory disorders such as bronchitis or atelectasis. Unresolved hypoventilation results in hypoxia and increased amounts of carbon dioxide in the blood.

When large amounts of air are inhaled and exhaled the respirations are described as deep. **Kussmaul's breathing** is the term used to describe abnormally deep, very rapid, sighing respirations. This pattern of breathing may occur as a result of disorders such as renal failure or metabolic acidosis.

**Dyspnoea** is the term used to describe shortness of breath or difficulty in breathing and may occur after strenuous exercise (temporarily) or as a result of certain respiratory or cardiac disorders. Dyspnoea is commonly accompanied by hypoventilation or *hyperventilation*, which is rapid deep breathing. Sustained hyperventilation, which is sometimes a consequence of extreme anxiety, causes loss of carbon dioxide and a decrease in carbonic acid concentration in the blood. This alters the acid–base balance causing respiratory alkalosis to occur.

Orthopnoea is the term used to describe the condition in which an individual must sit up or stand to breathe deeply or comfortably. This condition occurs in various respiratory or cardiac disorders, such as emphysema, pulmonary oedema and asthma.

Pursed-lip breathing is a technique commonly employed by people with severe dyspnoea or orthopnoea; for example, as a consequence of emphysema. This technique of breathing funnels expired air through a narrow opening, thus creating a positive back pressure on the airways to keep them open.

### Sound

Abnormal breath sounds can occur when air passes through narrowed airways or moisture, or when there is inflammation of the lungs or pleura.

*Stertorous breathing* is the term used to describe laboured respirations that have a snoring sound, which commonly result from an obstructed airway.

*Wheezing* results from narrowed airways, such as in asthma, and respirations sound high pitched and squeaking.

*Bubbling* refers to gurgling sounds heard as air passes through moist secretions in the respiratory tract.

*Crackles* refer to an abnormal non-musical sound heard on auscultation of the lungs during inspiration when air enters alveoli that contain serous secretions. It sounds like hair rubbed between the fingers next to the ear (Klocke 2014).

*Stridor* results from an obstruction or spasm in the trachea or larynx, as in laryngotracheobronchitis (croup), in which the respirations have a high-pitched musical sound, particularly on inspiration.

When the nurse is assessing an individual's breathing, any deviations from the acceptable range and sound should be reported immediately so that appropriate actions can be planned and implemented. Respiration rates are documented using dots on a chart similar to the one illustrated in Figure 20.5.

In certain circumstances an instrument called a spirometer is used to assess pulmonary function by measuring and recording the volume of inhaled and exhaled air.

### CRITICAL THINKING EXERCISE 20.3

1. Why are unequal bilateral breath sounds clinically significant?
2. A nursing colleague states that she only writes down 12 breaths per minute on an individual's chart when assessing respiratory rate. What does the research suggest about the accuracy of respiratory rate and its importance when detecting clinical deterioration?
3. When auscultating breath sounds what difference would you expect before and after ventolin administration?
4. Mr Lui was admitted to a medical ward with a respiratory infection. What would you expect Mr Lui's respiratory rate and oxygen saturations to be, and why?

## PULSE OXIMETRY—MEASURING OXYGEN SATURATION

Pulse oximetry is the non-invasive measurement of arterial blood **oxygen saturation**; that is, the extent to which haemoglobin is loaded with oxygen and is expressed as a percentage. For example, an $SpO_2$ reading indicates that 96% of the haemoglobin molecules are carrying oxygen molecules. A pulse oximeter is a probe with a light-emitting diode (LED) connected by cable to an oximeter. Light waves emitted by the LED are absorbed then reflected back by oxygenated and deoxygenated haemoglobin molecules. The reflected light is processed by the oximeter, which calculates pulse oxygen saturation ($SpO_2$) (Slade 2014).

$SpO_2$ is a reliable estimate of arterial oxygen saturation and is a simple painless measurement (Figure 20.13). The nurse should attach the non-invasive sensor to the individual's finger when possible; however, a toe, earlobe or bridge of nose can be used (Slade 2014). In addition, sensors for infants and children can be applied to the palm or the sole of the foot. Graphed trends over time provide the best information about the individual's oxygenation. The measurement can be affected by factors that affect light transmission, such as outside light sources or an individual's motion. Conditions that decrease arterial blood flow such as peripheral vascular disease, hypothermia, medications, hypotension or peripheral oedema affect accurate determination of $SpO_2$ (see Clinical Interest Boxes 20.5–20.7) (Slade 2014). Anaemia can also affect the accuracy of the oxygen saturation reading interpretation. An individual with anaemia may have oxygen saturations above 95%; however, as a result of less haemoglobin circulating the individual may still be hypoxic. It is

### CLINICAL INTEREST BOX 20.5 Pulse oximetry in older adults

Identifying an acceptable pulse oximeter probe site may be difficult with older adults because of the likelihood of peripheral vascular disease, decreased carbon dioxide level, cold-induced vasoconstriction and anaemia (Cooper & Gosnell 2015).

### CLINICAL INTEREST BOX 20.6 Factors affecting determination of pulse oxygen saturation

**Interference with light transmission**

- Outside light sources can interfere with the oximeter's ability to process reflected light
- Carbon monoxide (caused by smoke inhalation or poisoning) artificially elevates $SpO_2$ by absorbing light similar to oxygen
- Individual motion can interfere with the oximeter's ability to process reflected light
- Jaundice may interfere with the oximeter's ability to process reflected light
- Intravascular dyes (methylene blue) artificially lower saturation

**Reduction of arterial pulsations**

- Peripheral vascular disease (Raynaud's disease, atherosclerosis) can reduce pulse volume
- Hypothermia at assessment site decreases peripheral blood flow
- Pharmacological vasoconstrictors (adrenaline, phenylephrine, dopamine) will decrease peripheral pulse volume
- Low cardiac output and hypotension decrease blood flow to peripheral arteries
- Peripheral oedema can obscure arterial pulsation

*(Slade 2014)*

## CLINICAL INTEREST BOX 20.7 Inaccuracy in oxygen saturation readings

An individual was admitted to a medical–surgical ward following a right lower lobe lobectomy. The individual was still on oxygen 4 days after the surgery, the individual's respiratory rate was normal and the individual did not appear short of breath; however, he continually had low oxygen saturation readings on room air. A senior nurse was asked to review the individual. When the individual was reviewed the senior nurse noted the poor peripheral circulation. She used instead an ear probe as the colour to the individual's ear appeared pink. The saturation was 95% on room air. This example highlights the importance of knowing what can make the reading of oxygen saturation inaccurate.

essential that the reading is interpreted as part of the clinical picture of an individual (Slade 2014) (see Clinical Skill 20.4).

## BLOOD PRESSURE

Blood pressure is the force exerted by the blood on the walls of the blood vessels as the heart contracts and relaxes. The pressure that the blood exerts against arterial walls during contraction of the left ventricle is called the systolic pressure. Diastolic pressure is the arterial pressure during left ventricular relaxation, and is a measurement of the minimum pressure being exerted on the arterial walls (Elliott & Coventry 2012). Measuring blood pressure provides significant information about the individual's cardiovascular function. A series of blood pressure measurements may show the development of a trend and is therefore more significant than a single measurement.

Blood pressure is maintained by the complex interaction of the body's homeostatic mechanisms and is influenced and related to:

- Cardiac output
- The force of ventricular contractions
- The viscosity (thickness) of the blood
- Peripheral vascular resistance
- Elasticity of blood vessel walls (Elliott & Coventry 2012).

It is generally measured by a non-invasive or indirect method, using a manometer and a stethoscope. It may also be measured directly by the insertion of a probe or catheter into a blood vessel. Blood pressure varies according to age, time of day, body posture and emotions. Blood pressure is not a routine part of assessment in children under age 3.

### Assessing blood pressure

Indirect blood pressure measurement is made using one of several devices (Figure 20.14), which include:

- **The sphygmomanometer**, consisting of a cloth-covered rubber bag (the cuff) from which two rubber tubes extend. One of the tubes is connected to a hand-operated bulb that has a valve which can be tightened and released. The second tube is connected to the manometer that registers millimetre calibrations. Thus, blood pressure is measured in millimetres of mercury (mmHg). Blood pressure cuffs come in various sizes because the bladder must be the correct width and length for the individual's arm (Figure 20.15). If the bladder is too narrow, the blood pressure reading will be erroneously elevated; if it is too wide, the reading will be erroneously low (Flynn Makic et al 2013).
- **The stethoscope**, which is used with the sphygmomanometer to hear the Korotkoff sounds, must be used appropriately for an accurate blood pressure measurement to be obtained. When using a doubled-sided stethoscope, ensure it is placed on the appropriate side for the sound you are listening for, either bell or diaphragm. The bell side is for hearing

## CLINICAL SKILL 20.4 Measuring oxygen saturation (pulse oximetry, $SpO_2$)

**Review and carry out the standard steps for all clinical skills/interventions**

| **NMBA Decision-making Framework considerations:** | **Equipment:** |
|---|---|
| 1. Am I educated?<br>2. Am I authorised?<br>3. Am I competent?<br>If you answer 'no' to any of these, do not perform that activity. Seek guidance and support from your teacher/a nurse team leader/clinical facilitator/educator. | Pulse oximeter monitor<br>Sensor probe and cord<br>Pen (blue/black)<br>Observation chart<br>Nail polish remover if required |

| **Skill activity** | **Rationale** |
|---|---|
| Assess for signs and symptoms of alterations in oxygen saturation such as altered respiratory status, cyanotic appearance, restlessness, irritability, confusion, reduced level of consciousness, laboured or difficulty breathing | Physical signs and symptoms may indicate abnormal oxygen saturation |
| Assess for factors that normally influence measurement of $SpO_2$ including oxygen therapy, haemoglobin level and temperature | Allows for accurate assessment of oxygen saturation variations. Peripheral vasoconstriction related to hypothermia can interfere with $SpO_2$ determination |
| Instruct individual to breathe normally | Prevents large fluctuations in respiration and possible error in reading |
| Assess the site most appropriate for sensor probe placement. Site must have adequate local circulation and be free of moisture. If finger is to be used, remove nail polish | Peripheral vasoconstriction can interfere with $SpO_2$ determination. Opaque coatings such as nail polish decrease light transmission |
| Determine capillary refill at site. If less than 3 seconds, select alternative site | Cool temperature with vasoconstriction or vascular disease may decrease circulation, impede refill and prevent sensor from measuring $SpO_2$ |
| Position individual comfortably. If finger is chosen as monitoring site, support lower arm. Instruct individual to keep sensor probe site still | Movement interferes with $SpO_2$ determination. Pressure of sensor probe's spring tension on finger or earlobe may be uncomfortable |
| Attach sensor probe to monitoring site | Select sensor site based on peripheral circulation and extremity temperature |
| Turn on oximeter by activating power and observe pulse waveform. Correlate oximeter pulse rate with individual's radial pulse | Enables detection of valid pulse |
| Leave probe in place until oximeter readout reaches constant value and pulse display reaches full strength during each cardiac cycle. Read $SpO_2$ on digital display | Pulse waveform and intensity display enables detection of valid pulse or presence of interfering signal. Reading may take from 10 to 30 seconds |
| If continuous $SpO_2$ monitoring is planned, verify $SpO_2$ alarm limits, which are pre-set by the manufacturer at a low of 85% and a high of 100%. Limits for $SpO_2$ and pulse rate should be determined as indicated by individual's condition. Verify that alarms are on, assess skin integrity under sensor every 2 hours. Relocate sensor at least every 4 hours, and more frequently if skin integrity is altered | Spring tension of sensor or sensitivity to disposable sensor adhesive can cause skin irritation and lead to disruption of skin integrity |
| If intermittent or spot-checking $SpO_2$ measurements are planned, remove sensor probe and turn oximeter power off. Store sensor probe in appropriate location | Sensor probes are expensive and vulnerable to damage |

| CLINICAL SKILL 20.4 Measuring oxygen saturation (pulse oximetry, $SpO_2$)—cont'd | |
|---|---|
| Discuss findings with individual as needed | Promotes participation in care and understanding of health status |
| Remove probe and turn oximeter power off. Clean according to manufacturer's instructions | Maintains battery charge, reduces risk of transmission of microorganisms |
| Assist individual in returning to comfortable position | Restores comfort and promotes sense of wellbeing |
| Perform hand hygiene | Reduces risk of transmission of microorganisms |
| Document the time of measurement and the rate and character of the respirations on the appropriate chart using numbers or dots | A record of the respirations provides information about the individual's condition to members of the healthcare team |
| Report any deviations from usual acceptable ranges | Appropriate care may be planned and implemented |

**Note:**
- Do not attach probe to finger, ear or bridge of nose if area is oedematous or skin integrity is compromised.
- Do not attach sensor to fingers that are hypothermic as vasoconstriction will alter the reading.
- Do not place sensor on same extremity as electronic blood pressure cuff. Blood flow to finger will be temporarily interrupted when cuff inflates and cause inaccurate blood pressure reading that triggers alarm.
- Do not place pulse oximeter on a limb that has an arterial or intravenous line in situ as fluid entering the arterial line may dilute the blood to alter the reading, and an intravenous line may reduce the outflow of blood from the limb so there is congestion of the venous blood, also altering the reading.
- If oximeter pulse rate, individual's radial pulse rate and apical pulse rate are different, re-evaluate oximeter sensor placement and reassess pulse rates.

*(Crisp et al 2013; Perry et al 2012; Tollefson et al 2012)*

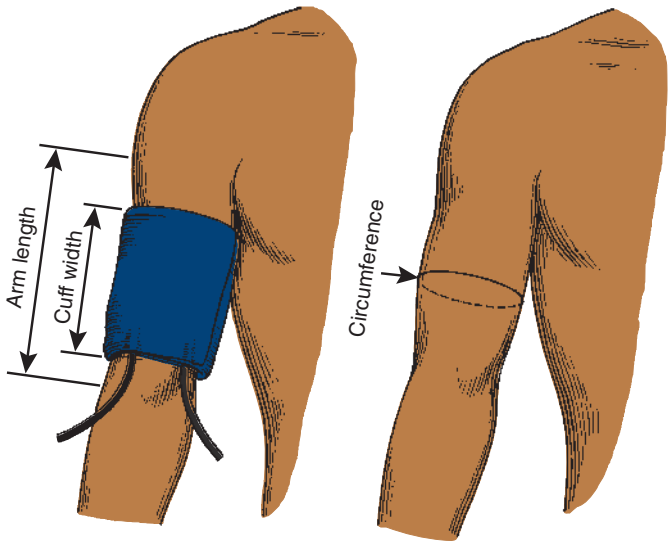

**Figure 20.15** Guidelines for proper blood pressure cuff size

Cuff width = 20% more than upper arm diameter, or 40% of circumference and two-thirds of arm length

*(Potter & Perry et al 2013)*

low-pitched sounds (heart sounds) and the diaphragm side is for high-pitched sounds (lung sounds).

- **An electronic device** where the measurement is displayed on a screen. These devices are sometimes applied when frequent blood pressure assessment is required, such as in the critically ill or potentially unstable individual. The system includes either a microphone or a pressure sensor built into the inflatable cuff. The microphone or acoustic system hears Korotkoff sounds and registers diastolic and systolic readings. The pressure sensor or ultrasonic system responds to the pressure waves generated by the movement of blood through the artery. These devices however should be used with caution on individuals with blood clotting deficiencies, such as a person on a heparin infusion, because the cuff can cause damage to capillaries if it over-inflates.

**Korotkoff sounds** are sounds heard during the taking of blood pressure using a sphygmomanometer and stethoscope. In some individuals, the sounds are clear and distinct, whereas in others only the beginning and ending sounds are heard. As air is released from the cuff, pressure on the brachial artery is decreased and the blood is heard pulsing through the vessel. These sounds are described in phases:

- *Phase I*: systolic pressure indicated by a sharp thump
- *Phase II*: a blowing or whooshing sound that increases as the cuff is deflated
- *Phase III*: crisp intense tapping that occurs with each heartbeat
- *Phase IV*: a softer blowing sound that fades
- *Phase V*: silence (Frese et al 2011).

Blood pressure should be obtained using a sphygmomanometer, manual method, before applying automatic devices and to confirm any abnormal blood pressure readings

## CLINICAL INTEREST BOX 20.8
## Palpating the systolic blood pressure

- Apply blood pressure cuff to the upper arm in the same method as the auscultation method
- Continually palpate the radial artery
- Inflate blood pressure cuff 30 mmHg above the point at which the radial pulse can no longer be palpated
- Release valve and allow mercury to fall by 2 mmHg
- As soon as the radial pulse is palpable, note the manometer reading, which is the systolic blood pressure

*(Flynn Makic et al 2013)*

obtained. The advantages of automatic devices are the ease of use and efficiency when repeated or frequent measurements are indicated. No stethoscope is required. The microphone or pressure sensor must be positioned directly over the artery for proper function.

### Palpation

The indirect palpation technique is useful for individuals whose atrial pulsations are too weak to create Korotkoff sounds, such as with severe blood loss and decreased heart contractility; however, the diastolic pressure is difficult to determine by palpation. When the palpation technique is used, the systolic value and the manner in which it was measured are recorded; for example, RA 90/–, palpated, supine. Clinical Interest Box 20.8 outlines the method for palpating the systolic blood pressure.

## Blood pressure sites

The site commonly used to measure arterial blood pressure indirectly is the brachial artery in the antecubital fossa at the elbow joint (Figure 20.16). If the upper extremities are inaccessible due to dressings, casts, arteriovenous fistulas or shunts, and axillary lymph-node dissection, it may be measured at the popliteal artery behind the knee (Figure 20.17) (see Clinical Skill 20.5).

Blood pressure measurements are recorded using arrows and dots on a graph similar to the one illustrated in Figure 20.5, or in longhand. If the longhand method of recording is used, the systolic pressure is recorded above the diastolic pressure; for example, 120/70 mmHg. If taking an individual's blood pressure for the first time during the current admission, it should be taken in both arms. As the heart is not centrally located, but slightly to the left, there should be a difference of no more than 5–10 mmHg between the arms. The arm found to have the higher pressure should be used for subsequent examinations. Document and record, where appropriate, which arm to use. Figure 20.18 provides the usual site for measuring blood pressure and placement of the stethoscope diaphragm.

## CLINICAL SKILL 20.5 Measuring blood pressure

**Review and carry out the standard steps for all clinical skills/interventions**

| **NMBA Decision-making Framework considerations:** | **Equipment:** |
|---|---|
| 1. Am I educated?<br>2. Am I authorised?<br>3. Am I competent?<br>If you answer 'no' to any of these, do not perform that activity. Seek guidance and support from your teacher/a nurse team leader/clinical facilitator/educator. | Sphygmomanometer—including manometer, an appropriate-sized cuff and bladder, and a bulb and pressure valve<br>Stethoscope<br>Alcohol swab<br>Pen (blue/black)<br>Observation chart<br>For electronic blood pressure:<br>Electronic blood pressure machine<br>Blood pressure cuff of appropriate size as recommended by manufacturer<br>Source of electricity |

| **Skill activity** | **Rationale** |
|---|---|
| Ensure that the individual is rested and in a position of comfort. Encourage individual to avoid exercise, caffeine and smoking for 30 minutes prior to assessment of blood pressure and have them rest at least 5 minutes before measuring. Provide privacy and reduce environmental noise | Activity or discomfort may increase blood pressure. Allows you to hear the blood pressure sounds more accurately and puts the individual at ease |
| Observe for signs and symptoms of blood pressure alterations, either high (headache, face flushing, nosebleed, fatigue) or low (dizziness, mental confusion, restlessness, pale skin, cool and mottled skin over extremities) | Physical signs and symptoms may indicate alterations in blood pressure |
| Determine best site for blood pressure assessment. Avoid applying cuff to extremity when intravenous fluids are infusing; an arteriovenous shunt or fistula is present; breast or axillary surgery has been performed on that side; extremity has been traumatised, is diseased or requires a cast or bulky bandage. The lower extremities may be used when the brachial arteries are inaccessible | Inappropriate site selection may result in poor amplification of sounds causing inaccurate readings. Application of pressure from inflated bladder temporarily impairs blood flow and can further compromise circulation in extremity that already has impaired blood flow |
| Select an appropriate cuff size | A cuff that is too small may result in a false high reading, while a cuff that is too large may result in a false low reading |
| Have the individual assume a sitting position if possible | Sitting is preferred to lying. Diastolic pressure measured while sitting is approximately 5 mmHg higher then when measured supine |
| Remove any constricting clothing from the individual's arm. Support the arm in an extended position with the palm facing up. Position the arm so that the brachial artery is at the level of the heart | Tight clothing may reduce blood flow or create venous congestion in the arm. Correct arm placement enables accurate blood pressure measurement. If arm is extended and not supported, individual may perform isometric exercise that can increase diastolic pressure 10%. Placement of arm above the level of the heart causes false low readings. Placement of arm lower than the level of the heart causes false high readings. Even in the supine position a diastolic increase of as much as 3 to 4 mmHg can occur for each 5 cm the arm is below the level of the heart |
| Check for air leaks in the cuff, tubing and valves of the sphygmomanometer | Leakage of air may result in an inaccurate measurement |
| Squeeze the cuff to expel any air, then tighten the valves | Prepares the cuff for use<br>Inflating bladder directly over artery ensures proper pressure is applied during inflation |

*Continued*

## CLINICAL SKILL 20.5 Measuring blood pressure—cont'd

**Two-step method**

| | |
|---|---|
| Position the sphygmomanometer on a level surface, at eye level | An incorrectly placed, or loosely applied, cuff may result in an inaccurate measurement |
| Palpate the radial pulse and, with the fingers on the pulse, rapidly inflate cuff to 30 mmHg above point at which pulse disappears, slowly deflate cuff and note point when pulse reappears | Errors in measurement can occur if the manometer is not vertical<br>This measurement provides an approximation of the systolic pressure, and prevents the cuff from subsequently being overinflated |
| Deflate the cuff completely and allow 30 seconds for arm to rest before re-inflating the cuff | Releases remaining air. Allows blood trapped in the veins to be returned to circulation |
| Place the disc of the stethoscope over the brachial artery in the antecubital fossa and hold in place with the thumb and index finger of your non-dominant hand. Reflate the cuff 30 mmHg above the palpated systolic pressure reading during the previous inflation | Pulse beat can be heard when the disc is placed directly over the artery, allowing for precise measurement of the systolic pressure |
| Use the valve on the hand pump to release air, and slowly deflate the cuff at 2–3 mmHg per second—no faster than 5 mmHg per second | If the cuff is deflated too rapidly, there will be insufficient time to assess the pressure accurately. Deflating too rapidly or too slowly gives false readings. Avoid contact of the stethoscope tubing with the clothing, cuff or tubing of the sphygmomanometer to decrease the possibility of extraneous noise |
| Note the pressure reading on the manometer as soon as the pulse beat is heard through the stethoscope. The sound slowly increases in intensity | This measurement indicates the systolic pressure |
| Continue to slowly deflate the cuff. Note the pressure reading as soon as the pulse sounds muffled or disappears. Listen for 10–20 mmHg after the last sound then allow the remaining air to escape quickly | This measurement indicates the diastolic pressure, releases remaining air and decreases individual discomfort |
| Remove the cuff and adjust the individual's clothing | Promotes comfort |
| If this is the first assessment of individual, repeat procedure on other extremity | Comparison of blood pressure in both extremities detects circulation problems (normal difference of 5–10 mmHg exists between extremities) |
| Discuss findings with individual as needed | Inform the individual of the blood pressure. If possible, discuss risk factors for high blood pressure. If blood pressure is elevated, inquire as to any factors that may have affected blood pressure, including general health, life stress or diet changes. If individual takes blood pressure medication, determine if anything has interfered with prescribed regimen. Promotes participation in care and understanding of health status |
| Record the measurement immediately | Prevents errors or omissions |
| Perform hand hygiene.<br>Clean earpieces and diaphragm of stethoscope and cuff with alcohol swab | Reduces risk of transmission of microorganisms |
| Report any deviations from normal | Appropriate care can be planned and implemented |

## CLINICAL SKILL 20.5 Measuring blood pressure—cont'd

| | |
|---|---|
| **One-step method** | |
| Place stethoscope earpieces in ears and be sure sounds are clear and not muffled | Ensures each earpiece follows angle of ear canal to facilitate hearing |
| Relocate brachial artery, and place diaphragm of stethoscope over it. Do not allow chest-piece to touch cuff or clothing | Proper stethoscope placement ensures optimal reception |
| Close valve of pressure bulb clockwise until tight | Tightening of valve prevents air leak during inflation |
| Quickly inflate cuff to 30 mmHg above individual's usual systolic pressure | Inflation above systolic level ensures accurate measurement of systolic pressure |
| Slowly release pressure bulb valve, and allow manometer needle to fall at a rate of 2–3 mmHg/sec. Note point on manometer when you hear the first sound. The sound will slowly increase in intensity | Too rapid or slow a decline in pressure release causes inaccurate readings. The first Korotkoff sounds reflect systolic pressure |
| Continue to deflate cuff gradually, noting point at which sound disappears in adults. Note pressure to nearest 2 mmHg. Listen for 20 to 30 mmHg after the last sound, and then allow remaining air to escape quickly | Beginning of the fifth Korotkoff sound is an indicator of diastolic pressure in adults. Fourth Korotkoff sound involves distinct muffling of sounds and is an indication of diastolic pressure in children |
| Remove the cuff and adjust the individual's clothing | Promotes comfort |
| Record the measurement immediately | Prevents errors or omissions |
| Discuss findings with individual as needed | Inform the individual of the blood pressure. If possible, discuss risk factors for high blood pressure. If blood pressure is elevated, inquire as to any factors that may have affected blood pressure, including general health, life stress or diet changes. If individual takes blood pressure medication, determine if anything has interfered with prescribed regimen. Promotes participation in care and understanding of health status |
| Perform hand hygiene.<br>Clean earpieces and diaphragm of stethoscope and cuff with alcohol swab | Reduces risk of transmission of microorganisms |
| Report any deviations from normal and document | Appropriate care can be planned and implemented |
| **Assessing blood pressure electronically** | |
| Determine appropriateness of using electronic blood pressure measurement | Individuals with irregular heart rate, peripheral vascular disease, seizures, tremors and shivering are not candidates for this device |
| Determine best site for blood pressure assessment. Avoid applying cuff to extremity when intravenous fluids are infusing; an arteriovenous shunt or fistula is present; breast or axillary surgery has been performed on that side; extremity has been traumatised, is diseased or requires a cast or bulky bandage. The lower extremities may be used when the brachial arteries are inaccessible | Inappropriate site selection may result in poor amplification of sounds causing inaccurate readings. Application of pressure from inflated bladder temporarily impairs blood flow and can further compromise circulation in extremity that already has impaired blood flow |
| Assist individual to comfortable position, either lying or sitting. Plug in device and place near individual ensuring that connector hose reaches between cuff and machine | Ensures individual comfort and that equipment is prepared and in a good position to use |
| Locate on/off switch and turn on machine to enable device to self-test computer systems | Ensures it is working |

*Continued*

| CLINICAL SKILL 20.5 Measuring blood pressure—cont'd | |
|---|---|
| Select appropriate cuff size for individual extremity and appropriate cuff for machine | Ensures accurate reading. Electronic blood pressure cuff and machine are matched by manufacturer and are not interchangeable |
| Expose extremity for measurement by removing constricting clothing | To ensure proper cuff application, cuff must not be placed over clothing |
| Prepare blood pressure cuff by manually squeezing the air out of the cuff and connecting cuff to connector hose | Prepares the cuff for use |
| Wrap flattened cuff snugly around extremity, verifying that only one finger fits between cuff and individual's skin. Make sure that the 'artery' arrow marked on the outside of the cuff is correctly placed | An incorrectly placed, or loosely applied, cuff may result in an inaccurate measurement |
| Verify that connector hose between cuff and machine is not kinked | Kinking prevents proper inflation and deflation of cuff |
| Following manufacturer's directions, set the frequency control to automatic or manual, and then press start button. The first blood pressure measurement pumps the cuff to a peak pressure of about 180 mmHg. After this pressure is reached, the machine begins a deflation sequence that determines blood pressure. The first reading determines the peak pressure inflation for additional measurements | Following manufacturer's directions is important in obtaining an accurate measure |
| When deflation is complete, digital display provides the most recent values and flashes time in minutes that have elapsed since the measurement occurred | If the individual is having their blood pressure measured at intervals, this function can inform you of when the last measurement was |
| Set frequency of blood pressure measurements and upper and lower alarm limits for systolic, diastolic and mean blood pressure readings. Intervals between blood pressure measurements are set from 1 to 90 minutes | The nurse determines frequency and alarm limits based on individual's acceptable range of blood pressure, nursing judgment, facility/organisation's standards or healthcare provider order |
| Obtain additional readings at any time by pressing the start button. Pressing the cancel button immediately deflates the cuff | Additional readings may be needed if the individual's condition changes |
| If frequent blood pressure measurements are required keep the cuff in place. Remove cuff every 2 hours to assess underlying skin integrity and if possible alternate blood pressure sites | Individuals with abnormal bleeding tendencies are at risk for microvascular rupture from repeated inflations |
| Compare electronic blood pressure readings with auscultated blood pressure measurements to verify accuracy of electronic blood pressure device | Individuals with hypertension, hypotension or an arrhythmia may have inaccurate electronic blood pressure monitor readings |
| Report any deviations from normal and document | Appropriate care can be planned and implemented |
| Discuss findings with individual as needed | Inform the individual of the blood pressure. If possible, discuss risk factors for high blood pressure. If blood pressure is elevated, inquire as to any factors that may have affected blood pressure, including general health, life stress or diet changes. If individual takes blood pressure medication, determine if anything has interfered with prescribed regimen. Promotes participation in care and understanding of health status |
| *(Crisp et al 2013; Perry et al 2012; Tollefson et al 2012)* | |

## Alterations in blood pressure

It is generally considered that an acceptable systolic blood pressure for an adult is 100–120 mmHg, and acceptable diastolic blood pressure ranges from 60–80 mmHg. Commonly, systolic pressure is regarded as being elevated when it is higher than 140 mmHg, and diastolic pressure elevated when it is above 90 mmHg (AIHW 2015) (see Clinical Interest Box 20.9).

The significance of a recorded blood pressure level can only be reliably assessed in the knowledge of previous levels, and in relation to the individual's current health state. For example, a person with a blood pressure of 95/60 mmHg may be perfectly healthy. Conversely, a person displaying signs of clinical shock but with a blood pressure of 135/90 mmHg may normally have a blood pressure exceeding this level.

At times it may be necessary to measure the blood pressure with the individual assuming first a lying then a standing position, particularly if the person is on certain medications and/or has certain cardiovascular problems. It is important to report and document any differences observed between the two measurements.

If the blood pressure is to be measured frequently (e.g. every half hour), the cuff may be left on the person's arm but, after each measurement, the nurse must ensure that the cuff is deflated completely. Care must be taken to avoid inflating the cuff repeatedly within a short time, as this action may result in venous congestion and cause the individual pain.

**Hypertension** is the term used to describe an elevated arterial blood pressure. Hypertension is a feature of many disease states but frequently its cause is unclear—when the cause is unclear it is described as 'essential' hypertension. The potential for onset of hypertension increases with obesity, smoking, a family history of high blood pressure or high serum sodium or cholesterol levels (AIHW 2015). Hypertension is associated with cardiac enlargement, heart failure, coronary artery disease and cerebrovascular accidents. Sustained hypertension is associated with a high mortality rate, so the importance of preventing and controlling hypertension is considerable (Warren 2014).

### CLINICAL INTEREST BOX 20.9
### Hypertension in older adults

Hypertension is common in older adults. An older adult's blood pressure range is usually 140–160/80–90 mmHg. Systolic blood pressure is a better predictor of coronary heart disease, heart failure and stroke than is diastolic blood pressure.

Older adults are instructed to change position slowly and pause after each change to avoid postural hypotension and to prevent injuries.

*(Cooper & Gosnell 2015)*

**Hypotension** is the term used to describe a low blood pressure in relation to an individual's usual pressure. Hypotension is associated with low cardiac output states (e.g. left ventricular failure), and with hypovolaemic and cardiogenic shock. With sustained hypotension the blood pressure is not adequate for normal tissue perfusion and oxygenation and may result in renal failure.

### CRITICAL THINKING EXERCISE 20.4

1. You are working in a nursing home and the Registered Nurse asks you to complete a blood pressure reading on a new admission. The individual is morbidly obese and the cuff only just fits around the individual's arm. How would this affect the accuracy of the reading?
2. You are working in a community health centre and you need to complete a blood pressure reading on a 75-year-old female, Rita Smith. Rita wants to keep her thick woollen jumper on while you complete the blood pressure. How would you respond to Rita's request?
3. You are caring for Renae Polontee, a 30-year-old apprentice chef, who has accidentally cut off her right thumb. There was considerable blood loss prior to first aid administered at the scene. Would you expect Renae to be hypotensive or hypertensive? Justify your answer.
4. Which arm would you assess Renae's blood pressure on and why?

## RECOGNISING AND RESPONDING TO CLINICAL DETERIORATION IN ACUTE HEALTHCARE

The Australian Commission on Safety and Quality in Health Care (ACSQHC) has released the National Safety and Quality Health Service (NSQHS) Standards, in which one of the standards refers to early recognition of clinical deterioration. Recognition of clinical deterioration, when followed by effective action, can minimise the occurrence of adverse events such as a cardiac arrest (ACSQHC 2012). There are guiding principles that build on this standard and revolve around early recognition of deterioration, documentation and communication, appropriate escalation of care with supportive responses from healthcare staff and maintaining a person-centred care approach (ACSQHC 2010). ACSQHC (2010) identified that changes to respiratory rate, oxygen saturation, heart rate, blood pressure, temperature and level of consciousness indicate deterioration of an individual's condition. The ACSQHC Working Party developed a colour-coded observation chart, which all hospitals have adopted and customised for local use, to identify when an individual may be deteriorating and what further assessment and escalation of care the nurse should undertake (see the Adult Deterioration

Detection System (ADDS) chart, Figure 20.5). While the ADDS chart should allow for early recognition of an individual's deterioration through colour coding, it is essential that all nurses have the underpinning clinical knowledge and clinical judgment to respond appropriately (see Clinical Interest Box 20.10).

Communication is extremely important in the event of clinical deterioration, and it is always essential to follow ISBAR handover when escalating the care of an individual. ISBAR handover will ensure that all information is passed on efficiently and correctly so the individual can be managed appropriately (see Chapter 8 on Communication for more information on ISBAR).

## CLINICAL INTEREST BOX 20.10 Clinical deterioration

'Individual admitted with pneumonia. Became short of breath and had low oxygen levels. Staff did not call for assistance in a timely way. The individual died' (ACSQHC 2008). It is imperative that nursing staff identify clinical deteriorations and act accordingly for individual safety.

## DECISION-MAKING FRAMEWORK EXERCISE 20.1

You have just been employed as a graduate Enrolled Nurse at a healthcare facility. You are completing a vital sign assessment on one of your allocated individuals, and you discover her blood pressure is 98/55 and heart rate is 95 bpm; all other vital signs are in normal limits. The individual states she does feel a bit light headed and can't remember the last time she passed urine. After approaching the medical officer and handing over the individual and current situation, the medical officer asks you to insert an IV cannula and orders the commencement of IV therapy.

Using the decision-making framework:

1. From the interventions ordered by the medical officer, are all interventions within your current scope of practice?
2. What actions are required in this situation?
3. How would you document the above situation in your nursing notes?

## PROGRESS NOTE EXAMPLE 20.1

| | |
|---|---|
| 04/06/2016 1300 hrs | Nursing: CNS: pt alert and orientated to person, place and time. Nil complaints of pain. CVS: complained of feeling dizzy when ambulating, vital signs checked—BP 101/59, HR 66, RR 15, $SaO_2$ 99% on RA, Temp 36.5. BP monitored 2/24, oral fluids encouraged and ambulation supervised. BP increased to 115/70. GIT: tolerating diet and fluids. BNO. Renal: pt voiding on sensation. FBC maintained. ADLs: showered independently. Supervision when ambulating with nil mobility aids. Legal: medication given as per medication chart. |

***Zoe Morgan*** **(Morgan) EN**

## Summary

Vital signs reflect changes in body function and therefore provide the nurse with important information about the clinical health status of an individual. Various sites and methods can be used to assess vital signs, and the nurse selects the site and method that is safest for the individual and that will provide the most accurate measurement possible. It is important to note that changes in one vital sign can trigger changes in other vital signs.

Vital signs are generally assessed when an individual is admitted to a healthcare agency, to establish baseline data, when there is a change or possibility of change in the individual's condition and as part of routine care. Data obtained from measurements of vital signs are then used to plan and implement appropriate nursing interventions, as well as to evaluate an individual's response to nursing interventions or prescribed medical therapy. It is important for the nurse to have knowledge of the normal ranges of vital signs and of the factors that regulate and influence vital signs, as this helps them interpret the measurements that deviate from normal. It is also imperative that the nurse has the underpinning clinical knowledge and judgment to recognise and respond to a deteriorating individual and act accordingly to maintain the clinical health status (ACSQHC 2012).

## Review Questions

1. What are the factors that can affect vital signs?
2. What are the advantages and disadvantages of using each body temperature site?
3. What characteristics should be included in a respiratory assessment?
4. What is an early indicator of a clinical deterioration in an individual?
5. Ms Hawdon has just given birth to a healthy baby boy. After the delivery she has a postpartum haemorrhage and loses 1200 mL of blood. Would you expect Ms Hawdon's blood pressure to increase or decrease? State the reason for your answer.
6. Identify two sites for taking blood pressure in an adult. Describe the procedure.
7. What are the three (3) characteristics of a pulse? What characteristic(s) would be altered during atrial fibrillation and why?
8. Mr Ryan, 82 years of age, has just been admitted with shortness of breath. Describe the observation you would conduct.
9. Review the information in the observation chart below, then answer the questions that follow.

| | |
|---|---|
| Admission obs | T—36.7, P—100, R—22, B/P—140/90: 1600 hrs |
| Preoperative obs | T—36.4, P—80, R—18, B/P—130/70: 0800 hrs |
| Postoperative obs | T—35.8, P—60, R—16, B/P—120/70: 1400 hrs |
| | T—36.4, P—80, R—18, B/P—130/70: 1800 hrs |
| | T—36.4, P—76, R—18, B/P—120/70: 2000 hrs |
| Day 1 Post op | T—36.4, P—80, R—20, B/P—130/70: 1000 hrs |
| | T—36.4, P—80, R—20, B/P—130/70: 1800 hrs |
| | T—36.8, P—88, R—20, B/P—130/70: 2200 hrs |
| Day 2 Post op | T—37.0, P—88, R—20, B/P—130/70: 0100 hrs |
| | T—37.8, P—90, R—22, B/P—135/80: 1400 hrs |
| | T—38.5, P—90, R—24, B/P—135/90: 2000 hrs |
| Day 3 Post op | T—37.4, P—88, R—22, B/P—135/70: 0700 hrs |

   a Suggest a reason that, on the day of her admission, Mrs Seagal's vital signs were slightly elevated.
   b Suggest a reason why Mrs Seagal's vital signs had decreased on the preoperative assessment.
   c What could you infer from the overall change in vital signs in the postoperative period?
   d What further objective and subjective data would you need to collect to confirm your assumptions?
10. Chart the above observations (in Q 9) on the Adult Deterioration Detection System chart (Figure 20.5). Identify if an escalation of care is required for this individual. If so, what type of escalation and why?

Answer guide for the Review Questions, Critical Thinking Exercises, Decision-Making Framework Exercises and Critical Thinking Questions in Case Studies are hosted on Evolve: http://evolve.elsevier.com/AU/Koutoukidis/Tabbner/

# Admission, transfer and discharge processes

*Susan Jones*

CHAPTER 21

## LEARNING OUTCOMES

At completion of this chapter and with further reading, students should be able to:

- Define the key terms
- Describe the planning and implementation of care for the individual who requires admission, transfer or discharge
- Describe the means by which a child may be prepared for admission to hospital
- Identify common stressors related to illness and hospitalisation
- Describe the physiological and psychological responses to stress
- Demonstrate a range of nursing skills that alleviate stress in the anxious person

## KEY TERMS

admissions
anxiety
continuity of care
discharge
emergency admissions
guided imagery
health education
play therapy
pre-admission
stress
transfer

## CHAPTER FOCUS

The scenario when an individual is admitted to a healthcare facility such as a hospital can represent a major disruption for the person and their significant others, resulting in anxiety, not only regarding their admission but also the implications and causes of their illness. While all hospitals have subtle variations in the process of admission, the basic protocols generally remain the same. During this time of heightened anxiety and fear, the nurse has a key role in alleviating some of the fears of hospitalisation, not only for the person but also for their loved ones. This chapter focuses on the admission process, the transferring and the discharge of children, adolescents and adults and the nurse's role in ensuring these processes cause minimal disruption.

## LIVED EXPERIENCE

My son was 3 when he was first admitted to hospital. He'd been having continuous ear infections and sinus problems and his specialist decided that he should have grommets inserted and his adenoids removed. We booked a date, and I tried to put it to the back of my mind, and then the day was finally here. I was so nervous and worried for him. I tried to keep replaying what the specialist had said about how 'routine' his surgery was, but when they came to wheel him away, I broke down. The theatre nurse was so warm and caring, but I still felt so silly. It's not easy leaving your child in the care of strangers.

**Eleanor, mother, age 37**

## TYPES OF ADMISSION

**Admissions** are classified as either elective or non-elective. Admissions are deemed elective when they are planned and not emergent and, while acuity is generally not severe, the potential to deteriorate and require intervention is possible (Berman et al 2012). People awaiting an elective admission can often be on waiting lists until such time that a hospital bed becomes vacant. An average wait period can be between 2 and 3 months for an elective procedure in Australian hospitals; some procedures can have a wait time up to and exceeding 12 months. The individual will receive either a letter or a phone call to advise them that their procedure has been scheduled. However, this can change depending on the volume of **emergency admissions**, which can further delay the individual's elective procedure due to cancellation (Johar et al 2013).

Non-elective or emergency admissions occur, by their very nature, suddenly, and may be associated with severe injury or life-threatening disease. They are the cause of about 90% of all hospital admissions (Symons et al 2013). People in emergent situations may be admitted any number of ways, including through referral from their medical practitioner, or the emergency department of a hospital, or perhaps by ambulance.

Healthcare facilities individually have policies regarding the admission and discharge process for elective and emergency admissions. In most cases individuals presenting for elective procedures will report to an admitting department on a prearranged date and time for the purpose of commencing the admission process. Prior to reporting for their procedure the individual should have received some written material with information regarding their diet prior to admission (e.g. fasting for surgery), whether to cease taking particular prescription or over-the-counter medications, what items to bring (e.g. toiletries, clothing) and information regarding visiting hours, the provision of telephones and televisions and location of the cafeteria. An efficient admission process can reduce waiting times for both admitted and discharged persons as well as reducing the stress factors related to admission to hospital (Kang et al 2014; Willis et al 2012).

## REACTIONS TO ADMISSION

With the possible exception of maternity, the majority of individuals facing admission to a hospital do so with apprehension and reluctance. Regardless of the duration of the hospital visit, admission is likely to cause a degree of stress, and reactions to this stress will vary depending on a number of factors including age, gender, past experiences and expectations and comorbidities. The admission nurse must take into consideration the impact of how admission to hospital will further exacerbate the stress for our Indigenous and culturally and linguistically diverse populations, (see Chapters 10 and 11). The principal causes of **anxiety** that hospitalised individuals experience are predominantly related to fears associated with anaesthesia, pain and associated complications (Sveinsdóttir 2010; Davydow et al 2013). While elective procedures are often associated with lower levels of anxiety, the nurse must acknowledge that all individuals will have an individual and valid reaction to the impending stress of hospitalisation in their life. A nurse can reduce a person's potential anxiety by ensuring a well-organised admission process is completed in a respectful and understanding manner. Effective admission procedures are directed towards:

- Confirming the person's identity
- Assessing the individual's physical and psychological status
- Promoting the individual's comfort in an unfamiliar environment

- Providing items needed for care
- Providing the individual with information about various practices and protocols
- Providing the person the opportunity to ask questions
- Ensuring adequate orientation to the hospital, ward and room are conducted as needed (Berman et al 2012; Zator Estes et al 2013).

**Stress** is widely regarded as an aversive state of arousal in which a physiological response occurs in reaction to a demand or stressor (Davydow et al 2013; Kring et al 2013). Stress can be experienced as either psychological or physical and can result in a range of varying responses which require a response or change. The stressful impact of hospitalisation on an individual's self-esteem, self-concept and body image are varying and diverse and include:

- Loss of independence and vulnerability
- Relationship disruptions and fretting about loved ones
- Unfamiliar environment, equipment and personnel
- Potential loss of income and impacts on employment
- The nature and implications of the illness
- Painful and/or embarrassing tests or procedures
- Impacts on activities of daily living (ADLs)
- Loss of privacy and dignity
- Loss of emotional or moral support
- Fear of dying and death.

Reactions to stress and coping mechanisms include:

- Nervousness
- Anxiety
- Irritability
- Emotional lability
- Anger or hostility
- Decreased tolerance towards others
- Forgetfulness
- Confusion
- Indifference
- Withdrawal
- Depression
- Difficulty sleeping.

Physiological manifestations of stress include:

- Palpitations
- Elevated blood pressure, pulse and respirations
- Diaphoresis (perspiration)
- Gastrointestinal upset
- Insomnia
- Muscle tension
- Trembling
- Dry mouth
- Difficulty concentrating (Kring et al 2013; Crisp et al 2013).

It is essential for the benefit of the individual that the nurse acknowledges the distress this anxiety may be causing the person, and demonstrates empathy, warmth and respect while preserving dignity and independence. The nurse should anticipate fluctuations in the person's psychosocial status and offer routine and relaxed socialisation in the clinical setting. The nurse should adopt a collaborative approach to care that is inclusive of the individual's rights and needs, through empowerment and mutual understanding (Crisp et al 2013). Advocating for collaboration in care is fundamental; when individuals are empowered and involved in the decision-making processes of their treatment, improved nursing outcomes ensue (Norman 2010).

### CRITICAL THINKING EXERCISE 21.1

Fifty-year-old Thomas has been admitted to the medical ward with exacerbation COAD. When you are completing his admission it is apparent that Thomas is experiencing a high level of stress and anxiety due to his admission. When you ask what is upsetting him, he tells you that he has two cats at home that cannot get outside, and he been unable to contact any friends to let them know he is being admitted to hospital. What nursing interventions could the nurse develop to decrease Thomas's anxiety and stress?

## Illness and stress

### Hospitalised adults

Hospitalisation means that individuals are not, for the duration of their stay, able to follow their usual daily routines; for example, the diet or exercise they are used to. They often severely miss the lack of home comforts and the presence of family, friends and familiar things. They may also be stressed by an unknown diagnosis and frightened about possible pain and discomfort, potential treatments and outcomes. The nurse can help alleviate some of this anxiety by providing full and timely information. Anxiety can affect concentration and memory, so when a person is anxious it is particularly important to ascertain whether the information has been understood, to repeat it if necessary and provide written information that the person may consider later (Crisp et al 2013).

Hospitalised individuals also have to adapt to stressors such as the lack of privacy, which may include concerns about sharing a room with strangers, strangers finding out about their medical details, having to wear hospital gowns that are open down the back, exposure of private areas during surgery, investigative procedures or treatments and having healthcare workers coming into their room during toileting or bathing. The nurse can help alleviate some of these stressors by introducing newly admitted people to those in the shared room, by being diligent about protecting confidentiality and taking practical steps to prevent unnecessary exposure. Nurses not assisting with personal care should themselves undertake not to enter the room or the area behind closed curtains without first confirming that the individual is not exposed.

Some individuals may be very anxious about the ability to meet religious dietary, worship, modesty or hygiene requirements. Those with limited spoken English are likely to be stressed about the ability to understand or be understood. A nursing assessment that carefully identifies cultural and spiritual needs is the tool that helps the nurse minimise associated stressors. Resolution might include coordinating

care to allow time for prayer, adapting Western-oriented hygiene methods to suit specific modesty needs and involving an interpreter.

Other stressors include worry about family responsibilities, costs of medical treatment and perhaps loss of earnings while ill. Compounding the problem there may be an inability to sleep because of pain, discomfort, noise, a strange bed or missing the usual sleeping partner. Empathic and considerate general nursing care activities can significantly reduce these common anxieties.

A significant aspect of care related to minimising stress is the establishment of a relationship that demonstrates respect and empathy for the person. **Health education** plays a major part in lessening the anxiety and stress levels of the individual. The nurse must ensure the individual has received the correct information surrounding their health issues using evidence-based practice. This includes being prepared to sit and listen to the individual and facilitating the expression of fears and anxieties (Brown et al 2015; Kell 2014; Pèrez & Luquis 2013).

## Children

It is not unusual for children to feel anxiety. Very young children often fear strangers or being left alone; preschoolers often fear imaginary creatures, animals and the dark. School-age children may experience anxiety about their own safety; for example, being very anxious during a storm. As children move towards the middle years of school and head into adolescence, anxieties tend to become more focused on performance at school, appearance and other social and health issues.

It is quite common for children to develop fears about losing their parents (separation anxiety). When this anxiety is strong, children may be diagnosed with separation anxiety disorder. Children who have separation anxiety may experience physical symptoms such as nausea, vomiting, stomach pains, palpitations, respiratory difficulty and dizziness. Separation anxiety can occur at any age. Children may follow parents around the house, needing to be constantly in very close proximity, they may refuse to go to school and may worry about being kidnapped and killed, or their parents being killed. Most children outgrow this fear but some have symptoms that recur periodically and especially when attachments are threatened or disrupted, such as at the time of hospitalisation (Copanitsanou & Valkeapaa 2014). See Chapters 12 and 13 for further reading on this topic.

The nurse who is aiming to reduce stress in children is most therapeutic when able to listen actively and encourage dialogue with open questioning such as, 'Tell me about what you like playing with at home'. It is best to avoid the specific question–answer format because children tend to feel uncomfortable about this and answer with very short, simple responses that give little information. Communicating effectively with children is a specific communication skill. Children are very sensitive to insincere platitudes and fake sentiments and are usually very quick at determining if a nurse is genuine and can be trusted.

Working with emotionally stressed children in the area of mental health is an area of specialty. A variety of therapies are helpful, including play therapy, art therapy and guided imagery. The goals of therapy are to:

- Establish rapport
- Help children reveal feelings they are unable to verbalise
- Enable children to act out feelings, anxieties or tension in a constructive manner
- Understand children's relationships and interactions with others of significance to them in their lives
- Teach adaptive socialisation skills
- Enhance self-esteem.

***Play therapy and children*** **Play therapy** is based on the belief that the relationship between the child and the health-care professional is the primary healing factor for the child. Play therapy recognises play as the child's developmentally appropriate vernacular when the individual is experiencing difficulties arising from circumstantial changes causing internal struggles, such as during hospitalisation. Play therapy can assist the child to:

- Assume greater self-responsibility
- Become more self-directing
- Engage in self-determined decision making
- Experience a feeling of control
- Become sensitive to the process of coping (Crenshaw & Stewart 2014:7).

***Guided imagery and children*** **Guided imagery** is an anxiety-reducing technique that many adults find helpful. It is a form of therapy that helps people consciously visualise positive images to lift their mood, reduce their anxiety, deal with the effects of illness or trauma or prevent illness (Forsner et al 2014). In a simple form it can successfully be used with children to increase their coping skills and enhance their feelings of self-worth. Children usually have strong imaginations and are able to conjure up mental pictures quite easily. Guided imagery begins with a short relaxation exercise followed by general directions for the imagery (visualisation). Children may be gently guided towards mental images of heroes and heroines that help them cope, and may be able to visualise themselves and their families as happy and cheerful. They may also imagine different ways of interacting with others (Crisp et al 2013). For example, Laura, aged 10, had frequent nightmares and was very frightened of the 'dark monster who comes in the night'. She was able to imagine herself a friend to a fire-breathing dragon. Through guided imagery she learned how to call on her dragon friend, whom she called Sheba, to come and stay by her to protect her whenever she felt scared.

## Adolescents

Sometimes high levels of stress during hospitalisation can result in adolescent behaviours that challenge the nurse. The adolescent years are a time of incredible physical and psychological adjustment. The tasks of adolescence include acceptance of a changed body image, establishing independence

from parents, deciding on a career pathway and adjusting to a comfortable sexual role. The adolescent may be supersensitive to recent body changes and may have concerns about body image. The threat of body exposure may be a source of great embarrassment. The nurse can help reduce adolescent stress by respecting individual autonomy and valuing the adolescent as a person, facilitating the verbalisation of fears, demonstrating sensitivity to concerns about body image, exposure and function and providing clear explanations about all care, treatment and procedures (Spurr et al 2013). See Chapter 13 for more reading on adolescents.

Common reasons for hospitalisation in adolescence include vehicle and sporting accidents, unsuccessful suicide attempts, teenage pregnancy, sexually transmitted infections, drug abuse and depression. Anorexia nervosa and bulimia nervosa are also common but are generally treated on an outpatient basis unless severe enough to be life threatening. It is the professional responsibility of the healthcare worker to view and treat the individual objectively (Crisp et al 2013).

Sometimes concerns are overwhelming for the adolescent and may result in emotional responses such as resentment, hostility or guilt. The hospitalised adolescent may become isolative and manipulative, and reject hospital rules or even physical care if feelings such as fear, guilt or embarrassment are unmanageable.

A case study and a corresponding example of an entry into progress notes have been developed on these themes (see Case Study 21.1 and Progress Note Example 21.1).

Stressors may be lessened by supportive peer interactions. Visits from friends are important, especially when adolescents are placed on wards with only adults for company. This may help relieve anxiety about missing school, social activities or losing touch with the peer group. Sometimes the adolescent individual's feelings and fears can be exacerbated because adult persons in a shared room tease or give erroneous advice or information. It should be acknowledged that while the adolescents may strive to demonstrate adult behaviour, they may be struggling with homesickness—hospitalisation is sometimes the first time young teenagers have been separated from parents or family without being with their peers (Yamuna 2013; Crisp et al 2013). Nursing interventions to address adolescent emotional responses and some of the more common behaviours are identified in Table 21.1.

### CRITICAL THINKING EXERCISE 21.2

Thirteen-year-old Jess has been admitted to the adolescent ward for an exacerbation of asthma. It becomes apparent that Jess has not been taking her preventer medications. What is the nurse's role in health education for Jess, and what approach might the nurse take?

## Older adults

People in the older age group frequently experience many losses and changes in a relatively short timeframe. Some older people adapt effectively to the stress this causes. Many are able to plan and implement a successful transition from work to retirement. Many are able to respond positively to the challenges and find exciting and creative activities that provide

### CASE STUDY 21.1

**The link between fears and behaviour**

Melanie, 15, was diagnosed with diabetes. She was resentful and hostile towards the nurse who was encouraging her to self-administer her insulin medication. Melanie stormed away, shouting and refusing the treatment altogether. A little later the nurse sat and talked with Melanie, who eventually disclosed fears about how having diabetes would affect her social life. She also revealed beliefs that the diabetes was her own fault, a punishment for promiscuous behaviour and a termination of pregnancy that she had not told her parents about. The nurse listened without judging Melanie, alleviated some of the guilt by answering questions about the onset of diabetes and helped her to identify some ways that she might cope with the diabetes after discharge.

1. What strategies could you use to encourage Melanie to participate and self-administer her insulin? Think holistically when thinking about strategies.
2. Which allied health members could you involve in Melanie's care to ensure a successful outcome on discharge?

### PROGRESS NOTE EXAMPLE 21.1

| | |
|---|---|
| 03/02/2016<br>1300 hrs | Individual became verbally hostile and would not listen when staff were attempting to educate her regarding her diabetes and injection administration techniques. Staff stopped education at this time.<br>***M. Alexander* (Alexander) RN** |
| 03/02/2016<br>2100 hrs | Staff assessed individual and her ability to comply with her insulin administration. Individual admitted to being afraid that her new diagnosis would affect her social life, as well as having feelings of guilt and blaming herself for becoming diabetic. Staff answered all questions related to her diabetes and medication administration. Diabetic education was completed, which included strategies to assist her with diabetes post discharge. Request for counsellor assessment completed, waiting confirmation of appointment time.<br>***M. Alexander* (Alexander) RN** |

**TABLE 21.1 | Nursing interventions for a selection of common adolescent emotional responses and behaviours**

| Adolescent emotional response/behaviour | Nursing interventions |
|---|---|
| Embarrassment | Reassure and maintain confidentiality. Provide an opportunity to talk about concerns, without family present, if necessary<br>Be alert to feelings regarding body image and need for privacy<br>Encourage as much self-care as possible<br>Provide for personal space and minimal body exposure during care<br>Ensure that individual has received and understood the appropriate health education pertinent to the procedures or surgery, and expected impact on body |
| Homesickness | If possible, provide for home conveniences such as TV, telephone and snacks<br>Facilitate dietary preferences when appropriate<br>Encourage family members to bring in favourite foods, provided that they meet with medical dietary needs<br>Ensure person is kept informed of news from home<br>Encourage family visitation whenever possible |
| Fear | Accept without judgment any defences or behaviour used to retain control<br>Report any concerns to allow the appropriate healthcare professional the ability to discuss the issues with the person in an objective manner<br>Ensure the individual is provided with relevant health information including a detailed explanation regarding treatment, nursing care and progress |
| Resentment | Facilitate exploration of feelings of resentment to help identify underlying cause<br>Encourage visits from peers and siblings, with flexible visiting hours as much as possible<br>Coordinate care so that any school work can be continued when able<br>Do not 'side with' parents/carers in any criticism of the adolescent or their behaviour, even if the individual displays anger or hostility |

a high quality of life well into old age. Others experience difficulty with the transition, the accumulative losses and changes and suffer stress overload. Nurses may be able to observe signs of this, such as unconscious repetitive actions that serve to relieve tension and stress and, sometimes, changes to cognitive abilities. Many physical changes such as those that affect sight and hearing or mobility may occur gradually and this allows time for the process of adaptation. However, such stressors, whether slow or sudden, may compound with social losses and concerns about the future to the point where strong inner resources are needed to avert a stress crisis. Some of the stressors faced by older people include:

- Changes in body image
- Increases in rent or living costs and ability to manage financially now or in the future
- Coping with home maintenance
- Loss of driver's licence or transport independence
- Death of friends, siblings or pets
- Chronic or acute pain
- Concern about care and protection when frail and vulnerable
- Fear of losing, or loss of, mental abilities
- Fear of loneliness, dying alone or not being found
- Fear of institutionalisation and leaving own possessions or pets
- Inheritance conflicts
- Intolerance or negative ageist attitudes demonstrated by others
- Caring for a spouse with dementia (Brown et al 2015).

Anxiety and low self-esteem often occur together and particularly in older people who are ill, hospitalised or living in residential care settings. Hospitalisation for the older adult can have a complexity of ramifications due to the stress pattern response, which can be linked directly to sleep deprivation and is a common occurrence for the older person in hospital (Maffio et al 2013). See Chapter 15 for more reading on the older person.

The way care is provided and the nurse's communication with individuals or residents can have a highly positive effect on reducing anxiety and increasing morale. Two basic principles for minimising stress are:

1. Limiting change as much as possible; for example, when and where possible, have the same people provide services and care (change increases stress)
2. Coordinating care and implementing any essential change during the period when the person is best able

to cope. People frequently have times of the day, month or year when they are functioning better or are less stressed than others; for example, it would not be advisable to discuss changing a person's accommodation arrangements late in the evening if that is when they are most tired; it would be unwise to introduce any major changes near the anniversary of a significant bereavement (Maffio et al 2013).

The nurse can also help to limit the damage from the structural and chemical changes to the body and the risk of an exacerbation of illness caused by prolonged stress by ensuring that, whenever possible, the individual has a highly nutritious diet, and by sustaining an environment and associated nursing strategies that ensure the individual maintains adequate rest and sleep patterns (Brown et al 2015; Maffio et al 2013).

***Preventing and treating stress in the older person*** Preventing and treating stress in the older person includes promoting self-worth, a sense of control, feelings of connectedness and hope. The nurse can facilitate feelings of self-worth by complimenting individuals on their achievements and encouraging reflection on personal strengths. A sense of control can be promoted by allowing individuals to make decisions for themselves. For a person with dementia this may mean offering simple choices that do not confuse; for example, 'Would you like to wear this dress today?' Simple actions such as encouraging participation in group activities, introducing individuals to each other and smiling and speaking to the person that you pass in the corridor helps to foster feelings of connectedness. Providing pleasurable experiences and activities nurtures happiness and hope, even in very difficult circumstances. For example, the individual who has cancer or a degenerative disorder can still enjoy the pleasures of music, a beautiful garden, the smell of roses, the company of pets and children and other social interactions (Whyne & de Fras 2015).

**CRITICAL THINKING EXERCISE 21.3**

Mr Braddon, aged 77, is about to be discharged from the medical ward after a hip replacement. On assessment, you discover that he is single and lives alone in a two-storey townhouse. He has trouble making meals for himself. What do you need to consider before discharging Mr Braddon, and which community and interdisciplinary services might be involved?

# THE ADMISSION PROCESS

## Pre-admission

**Pre-admission** clinics are an important aspect in the provision of holistic and continuous care. They can reduce an individual's anxiety regarding their admission (this is particularly beneficial with children) and provide and obtain useful health history information and assessment of vital signs (McShane & Honeysett 2013). It is during pre-admission that discharge planning should (and does) commence (see Clinical Skill 21.1), as the person's needs are identified for the rehabilitation phase, and provides the individual with opportunities to ask questions, tour the ward (if applicable) and familiarise themselves with staff and routines (Kralik & van Loon 2011; Richardson-Tench et al 2012).

## Admitting an adult to a healthcare facility

When an individual is admitted to a healthcare facility, potential anxiety can be reduced by the efficiency and effective organisation of this process in an empathetic and sensitive manner. Effective admission procedures are directed towards:

- Confirming the person's identity
- Assessing the individual's physical and psychological status
- Promoting the individual's comfort in an unfamiliar environment
- Providing items needed for care
- Providing the individual with information about various practices and protocols
- Providing the person with the opportunity to ask questions (Berman et al 2012; Zator Estes et al 2013).

**CRITICAL THINKING EXERCISE 21.4**

What would you say to make an anxious person and their family more relaxed during admission?

## Day of surgery admission

Many hospitals are admitting elective surgical admissions to a specialty unit designed to facilitate admissions to theatre. This ensures a smoother transition to the operating theatre. Nursing and medical staff work together to ensure each person is prepared for theatre. Individuals are sent home with a friend or relative who can watch them (of particular importance after a general anaesthetic), and a brochure highlighting health education and what signs and symptoms to look for in the event of an emergency, analgesia management and emergency contacts (Concannon et al 2013).

## Admitting department

Medical admissions and many elective surgical admissions are transferred from the admitting department directly to the unit. Clerical staff obtain and clarify the individual's demographics and financial information for registration purposes. This includes scheduling pre-admission testing, room allocation and transfers and discharge. The admission department is responsible for maintaining meticulous census statistics and disseminating data to the relevant units within the hospital. The staff are also responsible for escorting the individual to the allocated unit, where they are received by the nurse (Griffin 2012).

## CLINICAL SKILL 21.1 Admission and discharge process

**Review and carry out the standard steps for all clinical skills/interventions**

| **NMBA decision-making framework considerations:** | **Equipment:** |
|---|---|
| 1. Am I educated?<br>2. Am I authorised?<br>3. Am I competent?<br>If you answer 'no' to any of these, do not perform that activity. Seek guidance and support from your teacher/a nurse team leader/clinical facilitator/educator. | *For admission:*<br>Thermometer<br>Sphygmomanometer<br>Stethoscope<br>Pulse oximeter<br>Penlight torch<br>Digital watch<br>Scales<br>Tape measure<br>Facility/organisation admission forms and charts<br>ID bands<br>Relevant information brochures<br>Pen (blue/black)<br>*For discharge:*<br>Relevant information brochures<br>Discharge medications and instructions for administration<br>Appointment cards and referral letters<br>X-rays and relevant scans and reports<br>Any further discharge supplies (e.g. mobility aids, appliances) |

| **Skill activity** | **Rationale** |
|---|---|
| **For admission** | |
| Ensure the room and environment is ready for the individual. Bed may need to be adapted for the individual, extra items such as oxygen equipment, intravenous poles, suction apparatus need to be placed in room if required. Ensure room is clean and welcoming | Ensures individual's needs will be met and they will be comfortable when entering the room |
| Ensure privacy. Close curtains and door | Protects individual privacy and confidentiality |
| Confirm the individual's identity and place identification band on individual's wrist and ankle as per facility/organisation policy | Safety precaution to ensure individual's identity |
| Introduce self, other staff and their roles to the individual. Inform the individual about mealtimes, visiting hours, ward/hospital facilities, smoking rules and use of mobile phones. Familiarise them with the call bell, bathroom, space for their belongings, TV, how to adjust the bed and introduce them to other people in the room | Allows individual to feel comfortable in the environment. Also gives individuals a sense of security and belonging, therefore decreasing stress and anxiety |
| Check if the individual has brought in any valuables and if they need to be stored and recorded as per facility/organisation policy. An inventory may be made of individual's personal belongings and any prostheses such as dentures, hearing aids or glasses, as per facility/organisation protocol | Decreases the risk of theft and loss of personal belongings while in the facility/organisation |
| Obtain a complete set of vital signs and document findings, reporting on any abnormalities | Acts as baseline individual data and also gives information regarding their current physiological status |
| If indicated, perform a pain assessment on the individual using a pain assessment tool | Adds to baseline data regarding the individual |
| Complete weight and height of individual and document | Some medications and treatments are height and weight dependent. This will also act as a baseline for the individual |

| CLINICAL SKILL 21.1 Admission and discharge process—cont'd | |
|---|---|
| Complete a urinalysis on the individual if indicated according to facility/organisation policy | For a baseline assessment |
| Identify any allergies. If individual has allergies place an alert band around their wrist | Alerts staff that the individual has an allergy and decreases the incidence of potentially adverse events occurring |
| Obtain a complete nursing history, including data about the individual's social and cultural background, surgical and medical history, history of the current illness and reason for admission. Assess any cultural/language barriers | Gains a broader understanding of the individual's health history and ensures accurate and effective treatment is provided to the individual. It can also be used to identify any potential knowledge deficits the individual has regarding their health |
| Throughout the assessment, note the individual's verbal and non-verbal behaviours, determine their conscious state and orientation by observing and talking to the individual | Behaviours may reflect specific physical abnormalities. Note timing of medications, especially analgesics and sedatives, which may cause the individual to be groggy or less responsive |
| Note their affect and mood, whether they are demonstrating appropriate emotional responses | Reflects their mental and emotional status, consciousness and feelings |
| Note individual's ability to communicate and understand English; also their speech and ability to speak clearly | Alterations reflect neurological impairment, injury or impairment of mouth, improperly fitting dentures or differences in dialect and language |
| If uncertain whether the individual has understood a question, rephrase or ask a similar question | Inappropriate response from an individual may be caused by language barriers, deterioration of mental status, preoccupation with illness or decrease in hearing acuity |
| During the admission process, observe how the individual interacts with family/carer. Be alert for any indications of fear, hesitancy to report health status or willingness to let caregiver control interview. Also observe for any signs of abuse and note if the individual has any obvious physical injuries | Suspect abuse in individuals who have suffered obvious physical injury or neglect, show signs of malnutrition or have bruises on the extremities or trunk. Report as per facility/organisation protocol |
| Identify next of kin, contact details and who to contact when the individual is ready for discharge | In case of an emergency and for any notifications needed to be provided to the next of kin |
| List all medications currently being taken by the individual; this should include both prescription and non-prescription. Any medications present should be locked in a medication drawer or ward cupboard as per facility/organisation policy and returned to the individual on discharge | Administration and storage of medications is completed as per the hospital policy. Medications taken prior to admission need to be listed so they can be reviewed by a medical officer and/or a pharmacist to determine their effectiveness, side effects and contraindications with other medications or treatments |
| Note the presence of any additional treatments and invasive tubes on or with the individual; for example, catheters, intravenous cannulas or drain tubes. Check each device and note the following: device and location, patency and position, correct fluid/medication infusing,<br>any presence of redness, swelling or tenderness, drainage rate or infusion rate and date of last tubing change | Ensures continuity of care to the individual. Any invasive tubes present need careful and accurate monitoring and consequently documentation. Any medical orders regarding additional treatments and invasive tubes need to be recognised and documented |
| Review the individual's fluid intake and output. Ask about their appetite, their bowel function, their bladder function and their oral intake. Commence a fluid balance chart if indicated | Important for fluid and electrolyte balance especially if the individual is at risk for imbalance due to electrolyte losses associated with vomiting, diarrhoea, gastrointestinal drainage or wounds such as burns |
| Note the individual's general physical appearance (weight, age, sex, height, body build) and their personal hygiene and any body odour | Grooming may reflect activity level before examination, resources available to purchase grooming supplies, individual's mood and self-care practices. Can also reflect their culture, lifestyle and personal preferences. Body odour can result from, for example, physical exercise or deficient hygiene |

*Continued*

| CLINICAL SKILL 21.1 Admission and discharge process—cont'd | |
|---|---|
| Inspect skin integrity, ensure that it is a normal colour for race with no areas of skin colour variation, neither dry nor moist, normal temperature, smooth, elastic, no lesions. Ask the individual if they have noticed any changes in their skin condition including pruritus, oozing, bleeding, changes in moles. While doing this identify any wounds present and their management. Inspect pressure points observing for signs of any pressure injury | Changes in colour can indicate pathological alterations. Changes in moles can indicate cancer. Itching could be a result from dry skin, oozing could indicate infection and bleeding may indicate a blood disorder |
| Complete a pressure injury risk assessment (Braden, Waterlow or Norton) if indicated | Most facilities/organisations will complete a pressure injury risk assessment on admission to determine if an individual is at risk of developing a pressure injury. If they are at high risk this allows strategies to be implemented immediately to decrease this risk |
| Assess hair, taking note of quality, texture, distribution and cleanliness | Changes in hair can reflect hormone changes, ageing changes, poor nutrition or use of certain hair care products |
| Monitor nails for any deviations from normal (both hands and feet) | Changes in condition of nails can indicate inadequate nutrition or grooming practices, nervous habits or systemic diseases |
| Note visual acuity and if need for any visual aids. Assess pupils for size, shape and equality. Assess eyes, inspect the position of eyes, colour and condition of conjunctivae and movement | If the individual has vision acuity loss, they may need to make adjustments to support self-caring measures. Normal pupils are round, clear and equal in size. If eyes are asymmetrical in position, this can reflect trauma or tumour growth. Changes in colour of conjunctivae can be due to local infection or symptomatic of another abnormality |
| Assess ears for cleanliness and discharge, assess hearing acuity | Hearing impairment can be caused by impacted cerumen, external otitis or swelling; therefore, the ear structure needs to be inspected |
| Assess mouth, look at lips, mucosa, gums, teeth and tongue, noting any abnormalities | Ill-fitting dentures can cause lesions in the mouth. Inadequate oral hygiene or unhealthy teeth may cause bad breath |
| Assess thorax and lungs, listen to breath sounds and note shape of chest, assess respiratory status, determine rate and rhythm of breathing | Abnormal airflow into the lungs can indicate airway obstruction or mucus. A 'barrel chest' (ribs become more horizontal) can be present in chronic lung disease. Individuals with breathing problems can also assume positions that improve ventilation |
| Assess abdomen, listen to bowel sounds if indicated, ask the individual about their current bowel and bladder function | Changes in symmetry or contour of abdomen can reveal underlying masses, fluid collection or gaseous distension. Normal bowel sounds occur in irregular sequence every 5–15 seconds. If absent can indicate cessation of gastric motility. Hyperactive bowel sounds not related to hunger or recent meal can indicate diarrhoea or early intestinal obstruction. Hypoactive bowel sounds can indicate paralytic ileus or peritonitis |
| Note level of consciousness and orientation. If individual's responses are inappropriate ask them short, direct questions regarding information they should know; for example, 'What is your name', 'What is the name of this place?', 'Where do you live', 'What day is it today?', 'What month is it?' | Measures individual's orientation to person, place and time. Document this as oriented x 3. If disoriented in any way, include subjective and objective data rather than documenting 'disoriented' |
| If indicated, perform a focused neurological assessment. This will include using the Glasgow Coma Scale, pupil size and reaction and limb assessment. A mental state examination may be performed if indicated | Gives further focused baseline data regarding the individual and their condition |

| CLINICAL SKILL 21.1 Admission and discharge process—cont'd | |
|---|---|
| Note gait and posture and if the individual is able to sit, stand and walk normally. Assess their body movements: are they purposeful? Do they display tremors? Are movements co-ordinated or uncoordinated? When assessing posture, note the alignment of the shoulders and hips, observe if they appear slumped, erect or bent | Reveals musculoskeletal problems, mood and presence of pain or difficulty breathing in certain positions. Can also indicate neurological or muscular problems |
| Note degree of mobility, level of independence and range of motion (ROM) | Assessment of individual's normal range of motion provides baseline for assessing changes. It also identifies muscle strength and detects limited ROM |
| Note use of prostheses or aids | May affect discharge home and indicates other devices that may be required. It can also indicate any current health deficits |
| Complete a falls risk assessment if indicated | Most hospitals will complete a falls risk assessment on admission to determine if an individual is a falls risk and, if they are, to implement strategies immediately to decrease the risk of falling |
| Ask the individual if there is any information about physical conditions or their health which hasn't been discussed with them | Allows individuals to discuss any health concerns they have. This is important as they may perceive other health concerns as being more important to them than the one that they have presented with; therefore, it is important to address this for provision of person-centred care |
| Identify and provide any relevant individual learning needs and provide teaching and brochures regarding these; for example, pain management or what to expect post surgery | It is important to ensure information is repeated when necessary and provided in written format if available. The individual may be stressed and demonstrating poor concentration and therefore may not remember the information provided to them |
| Conduct a physical assessment of individual if indicated | If the individual needs further physical assessments in any area of concern these need to be completed |
| Discuss findings with individual as needed | Promotes participation in care and understanding of health status |
| Before leaving the individual, ensure they are comfortable, that they have a water jug (if they are not fasting), they have the call bell within reach and that they have no further questions | If unable to answer any questions, it is important to refer the individual to the appropriate person who can |
| Develop nursing care plan suitable for the individual | Allows effective and efficient nursing treatment of the individual to commence in conjunction with a medical treatment plan |
| Perform hand hygiene | Reduces transmission of microorganisms |
| Document and report relevant information and any abnormalities detected | Verifies the information collected and makes this information available to other members of the healthcare team |
| **For discharge** | |
| Identify the following information about the individual's discharge:<br>• Location on discharge<br>• Who will pick up the individual<br>• How they will travel to their discharge location<br>• What time they will be picked up<br>• If there is a need to use a facility/organisation 'transit lounge' to wait to go home (this should be organised the day before discharge) | Ensures the individual and their family/carer are prepared for discharge |

*Continued*

| CLINICAL SKILL 21.1 Admission and discharge process—cont'd | |
|---|---|
| Ensure the individual is confident about performing any self-care activities that have been taught | Ensures compliance on discharge and that the individual will be able to care for themselves on discharge, reducing the risk of re-admission |
| Assess the individual and family/carer needs for health education; for example, self-care actions, use of equipment, changes to lifestyle as a result of the illness, understanding illness or changing personal behaviours that influence health, use of medications | Allows education to be provided to the individual and their family/carer to help them cope more effectively at home and decrease the risk of deterioration and re-admission |
| Check all referrals to community agencies such as Home and Community Care (HACC), Hospital in the Home (HITH) and physiotherapy have been completed and the individual has the relevant follow-up appointment cards | Ensures the individual will not miss any further follow-up care and that they will have continuity of care once they leave the facility/organisation |
| Ensure the individual has in their possession any aids and equipment necessary | Individuals will grow to rely on the facility/organisation's aids during their stay; therefore, it is important that they have aids available to them on discharge if necessary to ensure a smooth transition home |
| Give the individual advice if needed on where they can obtain any long-term supplies or equipment | If the individual is undecided about buying or hiring equipment while in the facility/organisation, it is important to give them options for when they are discharged to obtain anything they may require. Refer them to an occupational therapist to assist in this |
| If wound care is required, identify and teach the person who will be providing that care (unless it is a community nurse) and supply materials if indicated | Ensures wounds heal appropriately prior to and post discharge. Decreases re-admission. It is also important to identify if someone may need community nursing for wound care early in their admission process as there may be a waiting period for these services |
| Ensure any intravenous cannulas, drain tubes etc have been removed | Once they have been removed also educate the individual on signs of infection from the site |
| Ensure individual has received discharge medications with instructions on their administration. They may need verbal instructions along with written | Medication mismanagement can have dire consequences for the individual; therefore, it is important they understand the correct administration of their medications. A pharmacist review may also be necessary and provision of a Webster pack |
| Ensure private x-rays are returned to the individual | These are generally the property of the individual and may be needed for follow-up care in the community |
| Give any paperwork needed by that individual, for example medical certificates, Work Cover certificates or Transport Accident Commission (TAC) forms | Depending on the individual's circumstances, they may need a variety of different forms and certificates filled out; it is important that these are completed while in the facility/organisation (generally a few days before discharge) |
| Give the individual a copy of their discharge summary and explain any further details needed. Ensure individual has all details of discharge, review all discharge advice | Discharge forms include a summary from the multidisciplinary team and are concise and instructive. They are a good tool for the individual on discharge to assist in their ongoing management of their health |
| Provide the individual with any relevant brochures; for example, routine guidelines about postoperative care, cast care, driving etc | Written information is preferred over verbal as the individual may need this on discharge to clarify any doubts or concerns they have |
| Ensure the individual and their family/carer understand potential complications following discharge and what to do if these occur. Also ensure they are provided with contact details in lieu of any problems | Often this information is also provided on the discharge summary. If not, this needs to be supplied to the individual, preferably in written form |

| CLINICAL SKILL 21.1 Admission and discharge process—cont'd | |
|---|---|
| Ensure all belongings, clothing and valuables are returned to the individual. Help the individual collect and pack all their personal belongings. Assist the individual from the area with a wheelchair if needed and assist them to transfer into the vehicle | Ensures a safe transition for the individual |
| Document and report relevant information | Verifies the information given to the individual |
| Note:<br>• During the admission general health survey assessment, the nurse may need to perform more focused specific assessments as indicated by the individual's health condition.<br>• Discharge planning occurs at different points during the individual's admission to a facility/organisation and is an ongoing procedure. Therefore, on the individual's day of discharge the discharge process will consist of ensuring the individual understands and has all information required for their discharge. Key elements needed for effective discharge planning include collaboration with the individual, efficient communication, prompt assessment of potential interventions needed at home and an interdisciplinary approach. The goal is to assist the individual in making a smooth transition from one setting to another. | |

## Room preparation

Prior to the individual's admission to the unit, the nursing team will determine the location of their bed. Depending on the person's individual needs and room availability, they may be admitted into a shared or single room. Prior to the orientation of the person to the unit, the nurse should ensure that the room is in order and that all necessary items are available. The room is likely to contain a bed, bedside locker, over-bed table, chair and wardrobe. The location of showering and toileting facilitates may be located in the individual's room, or communally out on the unit. The bed may need to be adapted to meet specific needs; namely the provision of extra pillows, a bed-cradle, high-low bed, falls mat, padded cot sides or a sheepskin blanket (Berman et al 2012).

Although the items placed in the room may vary slightly in different healthcare facilities, the basic items provided for each individual are two bath towels, two face washers and an information booklet. Information provided in this booklet usually involves aspects such as details of visiting hours; meal times; how to identify various personnel; cafeteria, telephone, television and laundry facilities available; regulations regarding smoking, and the time the individual is expected to vacate the room upon **discharge**. Extra items such as oxygen equipment, suction apparatus or an intravenous pole are placed in the room if required. The top of the bedclothes may be turned back or they may be folded down to receive a person who arrives on a trolley (Berman et al 2012).

## Reception of the person

Chapter 19 provides details of the admission assessment. Unless the admission is emergent, the individual should report to the admitting department of the healthcare facility prior to arrival in the unit. Here a member of the clerical staff obtains and records the demographics including the person's full name; age; gender; marital status; religion; next of kin contact details (name, address, phone number); private insurance details (if any) and Medicare number. A white identification band (Figure 21.1) is placed on the individual's wrist as a basic safety precaution against mistaken identity and treatment. If the individual has any known allergies (medication, food, environmental factors), a red identification band (Figure 21.2) replaces the white wrist band; only one band should be used at any one time (ACSQHC 2015). Some facilities require a wrist *and* ankle identification band. Should the person require an x-ray or pathology test, they will be referred to this department prior to admission to the unit. The individual will then be escorted to the unit where a nurse will receive and orientate them (Berman et al 2012).

**Figure 21.1** Standard (white) identification band
*(Medical Illustration, RMH)*

The nurse who has been allocated the admission of the person should greet them and any accompanying friend or relative in a warm and friendly manner. The nurse should

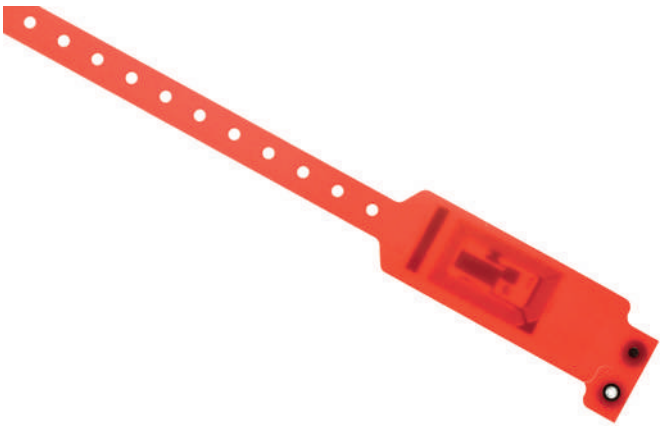

**Figure 21.2** Standard (red) identification band
*(iStockphoto/Mutlu Kurtbas)*

address the individual by their preferred name and introduce themselves, then escort the person to the room and begin the process of admission. Depending on the circumstances, a relative or friend may be present and/or be offered a seat in a waiting area.

The admission procedure is basically the same in most healthcare facilities but will vary in detail in different settings, and in sequence, according to circumstances. The individual is taken to their room and if they are sharing, introduced to any other person in the room. It is important to remember the significance of respecting privacy in a shared room by drawing curtains and lowering your voice in these situations. The individual should be shown the layout of the room, including where to stow personal belongings. It is important that the individual is shown how to use the signal device (call bell), and how to operate the electronic bed, lights, television and radio controls. The individual's identity band should be checked against the bed and or/treatment sheet to ensure they are correct. Depending on the circumstances, the person may remain in day clothes and be able to walk about the unit, or they may be required to change into hospital-provided clothes or personal night attire and get into bed.

Although the person will have been advised not to bring valuable items, an inventory is made of any personal effects. Generally it is not necessary to itemise clothing, but a list compiled of any items of value, such as wristwatch, jewellery, television set, radio and money may be needed. Some healthcare facilities also require that documentation is made of any prosthesis, such as dentures, eye glasses, hearing aids or a prosthetic limb. If the individual has arrived with a large sum of money they are encouraged to either send it home with a relative or to place it in the healthcare facility's safe. A 'valuables' envelope is provided for the safe keeping of money or other valuable items. It is very important to inform the individual that the healthcare facility accepts no responsibility for valuable items, unless they are deposited in their safe. The nurse is advised to follow individual hospital policies regarding the procedures to be followed when individuals' valuables are stored (Crisp et al 2013).

### CRITICAL THINKING EXERCISE 21.5

You are admitting Mrs Smith, a 45-year-old woman, to the surgical unit for a scheduled procedure tomorrow. Mrs Smith understands that she has to be admitted the night before due to the pre-operative preparation that is required. While you are helping Mrs Smith to unpack and settle into her room you notice that she has her purse in the suitcase and she has a jewellery box packed as well. You ask Mrs Smith if there are any valuables that need to be locked up with security. She replies that she always takes her diamonds and precious stones with her so they don't get stolen while she is away. You ask Mrs Smith if she has any money and cards in her purse that need to be locked with security. She opens her purse and you notice that she has a large wad of money plus credit/bank cards in her purse. You advise Mrs Smith that she will need to lock up all the valuables in security. She promptly declines stating that she will look after them. What are the nurse's responsibilities in this situation?

As soon as practicable, assessment is made of vital signs and weight, and this information is documented in the clinical file. A sample of urine may be obtained and urinalysis performed. (Information on vital signs and urinalysis is provided in Chapters 20 and 31.) The individual's height may also be measured and documented (Zator Estes et al 2013). Throughout the admission procedure the nurse should discreetly observe the individual to gain information that will assist in planning care. Nursing assessment is completed (and documented accurately on the relevant documentation (see Figure 21.3)) of the individual's:

- General physical appearance
- Degree of mobility
- Level of independence
- Psychological status
- Skin integrity
- Hearing and visual acuity
- Ability to communicate
- Level of consciousness and orientation
- Gait and posture
- Use of prostheses or aids (Berman et al 2012; Zator Estes et al 2013).

At the time of admission or as soon as practical afterwards, a nursing history is compiled and a nursing care plan developed. (Information on these and other aspects of the nursing process is provided in Chapters 16 and 17.)

Unless the individual is on fluid restriction due to their illness or impending surgery, they should be offered a jug of water and a cup of tea or coffee. Anyone accompanying the person may also be offered a drink, or directed to the cafeteria and telephone areas. This assistance is of particular importance in the event of an emergency admission. It is common for significant others to be very distressed, and it may be appropriate for them to be shown to a private area

*(Broadmeadows Health Service. Modified from the original, with permission)*

where they can rest or contact family. The hospital may also provide accommodation options for relatives if the person is very ill.

Prior to leaving the room the nurse should ensure that the individual and significant others have been given all the information they require, in conjunction with an opportunity to ask any questions. Should the nurse be unable to answer any questions, it is important that the family be referred to the appropriate person who can. When individuals are stressed they may demonstrate poor concentration and may not remember information provided to them; therefore, it is important to ensure that information is repeated whenever necessary and/or provided in written format as available and in the required language (Berman et al 2012; Zator Estes et al 2013).

## ADMITTING THE PERSON TO THE MENTAL HEALTH UNIT

When a person arrives at a mental health unit it can often be under duress, resulting in distress and, more frequently, anger. Individuals presenting to a mental health unit can be scheduled as 'voluntary' or 'involuntary' (see Chapter 39). The initial reception of a person to the mental health unit is an opportunity for the nurse to commence the foundations for developing a therapeutic relationship. The therapeutic relationship in the mental health setting is an imperative aspect of nursing, and its development and maintenance has significant impacts on outcomes (Bingham 2012).

As with the admission of any individual, the nurse should demonstrate an empathetic manner, validate the person's distress at being detained involuntarily and adopt a warm and sensitive approach (McGuinness et al 2013). Care and sensitivity should be taken when discussing the legalities of an involuntary admission; the individual should be informed of their rights and the avenues of appeal. Care should also be taken when liaising with family or significant others. Consent must be obtained by the person prior to sharing information with family, and obviously this can result in significant distress when individuals do not want concerned family members to be informed of their treatment (Ryan et al 2014). Mental health nurses must maintain confidentiality regarding the individual's wishes, while acknowledging the distress of close family and friends who are experiencing exclusion at being uninformed. Mental health nurses must also be cognisant of the potential for the individual to engage in self-harming behaviours, and consequently remove any potentially dangerous items (see Clinical Interest Box 21.1) (Damon et al 2012).

### CLINICAL INTEREST BOX 21.1 Clinical risk factors and associated nursing interventions when admitting the individual to the mental health unit

Nursing goals for the individual include:

1. Safety
2. Stabilisation
3. Engagement
   - > Orientation to room and unit, including communal areas, toileting/showering facilities, kitchen and laundry areas, telephone
   - > Introduction to all other people (particularly those sharing a room)
   - > Introduction to medical, nursing, interdisciplinary staff
   - > Information regarding meal times; medication times; community meetings; group sessions and basic unit routines (including curfew if applicable)
   - > Search and documentation of belongings (for individuals with potential to harm self or others)
   - > Removal and documentation of valuables to units safe
   - > Removal of sharp items (razors, mirror, glass, scissors etc)
   - > Removal of potential other self-harming items (belts, stockings, tracksuit cords/ties, shoe laces, electrical cords)
   - > Assist individual with engaging in treatment on the unit
   - > Introduction to activities to decrease related psychiatric symptoms

*(Damon et al 2012)*

## ADMITTING A CHILD TO A HEALTHCARE FACILITY

When a child has a condition that requires hospitalisation the nurse should understand the effects of this admission on the child and their parents/carers. Admission to hospital for a child may be elective or an emergency and it is important to understand that an emergency admission to hospital for a child and their parents/carers is often a time of high stress and crisis. In the emergency situation it is imperative that the nurse provides a safe environment for the child and their parents, and that the nurse demonstrates good communication skills and adequate procedure explanations (Rudd & Kocisko 2014). Children in crisis situations will often mirror or mimic their parents'/carers' emotional responses, so it is imperative that the nurse reassures and comforts parents to alleviate their distress and ultimately that of the child (Rudd & Kocisko 2014). It is important that parents and healthcare providers are honest about hospitalisation, and that children are never threatened with an admission as a form of punishment or told they are going on a holiday (Hockenberry & Wilson 2015). From an elective admission perspective, research suggests that children and their parents/carers benefit from pre-admission visits and the provision of detailed leaflets on their procedure prior to admission (Glasper 2013).

Many factors influence the way in which a child and the child's family react when illness or an injury makes it necessary for the child to be admitted to hospital. These include:

- The age of the child and their cognitive ability
- The degree of preparation the child has been given by parents/carers prior to admission. Children who are emotionally secure usually adapt well if they are provided with a realistic explanation of hospital life, informed of the reason for their admission and reassured that their parents will spend as much time as possible with them. Parents/carers often fail to adequately inform their child about impending hospitalisation and can unintentionally transfer their own fears and anxieties which can result in the admission to hospital as a very frightening and traumatic experience for the child (Chiocca 2015; Hockenberry & Wilson 2015)
- The condition of the child. An acutely ill or severely injured child may not be totally aware of the situation but the parents/carers will be distressed and apprehensive
- The cultural background of the child. In some cultures there is an extended and very close-knit family pattern and the child who is accustomed to the loving protection and guidance from parents, grandparents, aunts and uncles can be quite devastated and distressed when separated from such an environment (Chiocca 2015). Also, the child who is accustomed to a little companionship or family support may find the noise and company of other children welcome, or completely overwhelming
- The parents'/carers' reactions to the situation can markedly impact the situation. Emotional outbursts, anxiety and tension are likely to increase feelings of anxiety, insecurity and apprehension in the child. On the contrary, emotionally composed, calm and confident parents/carers will allay their child's fears by promoting feelings of security (Chiocca 2015; Hockenberry & Wilson 2015)
- The relationship between the healthcare staff and the child's parents/carers is a very important factor, particularly in the case of an older child, who will relate more readily to nurses who have established rapport with the parents.

It is evident and widely held that the role of the parents/carers during a child's hospitalisation is important, and parents/carers are often provided unrestricted visiting opportunities and accommodation facilities as necessary (Chiocca 2015; Hockenberry & Wilson 2015; Damon et al 2012). Parents/carers are encouraged to participate in the treatment of their child; however, care should be taken as many parents/carers find this experience anxiety provoking and are confused by blurred or ill-defined roles (Damon et al 2012). When a parent/carer is restricted from spending time with their ill child due to home commitments or economic or travelling issues, they should be referred to the hospital's social worker with a view to arranging help.

## Preparation for admission

Research suggests that preparation is the key to children accepting hospitalisation as reality (Higham et al 2013; Damon et al 2012; Hockenberry & Wilson 2015). While difficulty lies in explaining hospitalisation to infants, children from the age of 2 years can be helped to adjust to hospitalisation by means of adequate preparation through use of drawings and role playing with dolls or their favourite soft toy (Chiocca 2015; Hockenberry & Wilson 2015). Many hospitals have independently published posters, books, DVDs and computer games in order to educate children (and their parents) on the likely procedures and processes of their impending hospital stay, and these tools in conjunction with adequate explanations can enhance understanding (The Royal Children's Hospital Melbourne 2015). Preparation is directed towards overcoming fears and anxieties, such as the fear of:

- Separation
- Bodily injury and pain
- Loss of routine and rituals
- Physical restrictions
- Enforced dependency and loss of independence
- Strangers
- Loss of body image (Hockenberry & Wilson 2015).

The process of preparing for admission includes explaining to the child what will happen to them in age-appropriate, meaningful language. Parents/carers should encourage their child to discuss all aspects of hospitalisation to help overcome any fears and anxieties. Many hospitals now encourage visits to the ward before admission so that the child can see the area and meet some of the personnel who will be involved in their care. Many hospitals with children's facilities also offer 'practice' opportunities prior to procedures, for treatments such as CT scans and MRIs where remaining motionless in a noisy area is imperative. Another way of preparing children prior to hospitalisation is to allow them to pack their own belongings such as favourite pyjamas and teddy in readiness for the trip (The Royal Children's Hospital Melbourne 2015).

Parents/carers are likely to also experience fear and anxiety when their child is to be admitted to hospital (Chiocca 2015). They can be helped to overcome this anxiety if they are provided with information about their child's condition, aspects of their hospitalisation and given an opportunity to ventilate any fears that they have. The emphasis on parental involvement and family-centred care can do much to relieve anxiety. Parents/carers should be informed of the facilities available should they wish to stay with their child and be provided with opportunities to participate in their child's care.

In an emergency admission there is no time to prepare the child or parents and the event can therefore be very traumatic for both. Encouraging one or both parents to stay as long as possible can reduce some of the child's fears and anxieties (Chiocca 2015; Hockenberry & Wilson 2015).

Many children go through various phases of disturbance when they are hospitalised, particularly if they are separated from their parents. During the initial phase, that of *protest*, the child may cry or scream for their parents and refuse the

attention of anyone else (Hockenberry & Wilson 2015). It is not unusual for the child to stop protesting only when physically exhausted. During the second stage, that of *despair*, the crying generally subsides and the child may become withdrawn and apathetic (Hockenberry & Wilson 2015). The child may feel abandoned and experience feelings of hopelessness and grief. During the third stage, that of *detachment*, the child appears to have adjusted to the separation but in reality the child is detaching from the parents in an attempt to escape the pain and wishing they were there (Hockenberry & Wilson 2015). When the parents do visit, the child may react with disinterest and, unless the parents understand these reactions, they may become very distressed. In order to provide an appropriate response, it is important that nurses are familiar with separation anxiety issues and accept that a portion of their time will be directed towards settling the child and helping the parents adjust to the reality of hospitalisation (Rudd & Kocisko 2014).

## Admission

Understandably an admission, either emergent or elective, can be frightening and distressing for the child and their family. Given that many children respond to their parents' emotional reactions with fear and apprehension, it is imperative that the nurse develops a rapport with parents/carers and gains their confidence from the time of admission (Lambert et al 2012). This will reassure the child, and likely calm a potentially distressing situation. Research shows that children experience fears and concerns regarding pain, mutilation, parental separation, immobility and loss of control (Rudd & Kocisko 2014). The nurse has a crucial role to play in alleviating some of this distress.

Prior to admission, the nurse in charge of the unit assigns a room based on the child's age and diagnosis. Some hospitals' paediatric units have age-segregated rooms or units (including adolescent units), while others, where possible, keep infants together to ensure older children can rest without interruption. Other children in the unit will be informed of the pending arrival so that they can be welcomed. Like any other admission, the room should be appropriately prepared with any necessary equipment prior to the child's arrival, as this ensures the nurse will not have to leave the child to gather items.

The admission procedure may vary slightly between hospitals, depending on hospital policy and the prevailing circumstances. The child should have their vital signs assessed, height and weight recorded, identity bands placed on their wrist and/or ankle (or pinned on their clothing if they become upset by this) and urinalysis done if required. The child and their family should also be orientated to the facilities on the unit, including call bells, bed controls, television and radio remotes, telephone and toileting facilities. The child and their family should also be shown the playroom and dining areas and the parents should be provided with details about rooming-in facilities (Glasper 2013; Chiocca 2015).

During the admission, the parents/carers are encouraged to remain with the child and to assist with activities such as undressing and settling at night. The functions of equipment should be explained and, where appropriate, the child should be encouraged to handle some equipment with supervision, to allay fears. Children and their parents/carers are likely to adapt better if they are informed in advance of the possibility of treatments involving the use of intravenous therapy equipment, drainage tubes, dressings, plasters or oxygen apparatus. Like adults, children benefit from participating in the decision-making process, and therefore the nurse should adopt a collaborative and inclusive approach to care (Copanitsanou & Valkeapaa 2014; Hockenberry & Wilson 2015).

## General aspects of paediatric nursing

Care of children differs from the care of adults in many ways; for example, the inability of very young children to communicate necessitates special skills of observation and interpretation. While each child must be treated as an individual, there are certain aspects of care which apply to all children:

- Complete honesty is important. Age-appropriate explanations should be given prior to any procedure. The nurse should not tell a child that a procedure will not hurt if, in fact, it is likely to cause pain; however, the nurse should avoid generating gratuitous concern and distress (The Royal Children's Hospital Melbourne 2015; Hockenberry & Wilson 2015). The nurse should be patient and anticipate that, for some children, becoming 'ready' for the procedure may take time
- The nurse should recognise the child's need for love and a feeling of security. Should the parents/carers be unable to be present all the time, the nurse should ensure the child receives extra time and affectionate support
- **Continuity of care** is important; therefore, where possible, the same nurse should care for the child during hospitalisation. Attempts should be made to maintain a routine similar to the one the child is accustomed to at home. A similar routine makes hospital life less bewildering for a child and promotes a feeling of security
- Efforts should be made to minimise a hospital-type environment; for example, by encouraging the child to wear their own clothes, to sit at a table for meals and by parents providing personal effects such as toys, blankets and photographs
- Encourage discussions on family, pets, friends and school in an attempt to lessen feelings of separation. If parents cannot be with the child all the time, it is sometimes helpful if they leave small presents for the child to open each day. School friends and siblings should be encouraged to visit
- Always attempt to maintain the child's dignity and independence after establishing the parameters with their parents. Developmental regression can be distressing for both the child and the parents/carers and can be exacerbated by hospitalisation
- Allow for periods of regression during hospitalisation and recognise that regressive behaviour is a feature of

illness. Given that regression is exacerbated by stress and hospitalisation is a known cause of stress, it is not uncommon for children to experience regression (Rudd & Kocisko 2014; The Royal Children's Hospital Melbourne 2015). For example, a previously toilet-trained child may begin bedwetting while in hospital

- The provision of opportunities for play is very important in paediatric units. 'Play' is a concept whereby children engage in creative activities of an exploratory nature that are fun, where they interact with their environment in a safe and unpredictable manner (The Royal Children's Hospital Melbourne 2015). Within the hospital environment, play can provide opportunities to reduce anxiety, ensure skill retention and enhancement, provide a diversion and therefore reduce feelings of homesickness and increase empowerment (Hockenberry & Wilson 2015). Children should have access to age-appropriate and safe toys and games in an appropriately supervised environment. Many hospitals now provide children opportunities to play with DVDs and game consoles, to be visited by play and music therapists and, for those with longer-term hospitalisations, to be provided with school programs. Some charitable organisations also fund activities such as clowns, and excursions off the hospital site
- Provide an atmosphere and opportunities that encourage free expression of feelings by the child and parents (Rudd & Kocisko 2014; The Royal Children's Hospital Melbourne 2015)
- Discharge preparation involves providing the parents/carers and child with information about medication or other forms of treatment, postoperative or wound care and follow-up appointments with their doctor or community nurse. It is important to explain to parents/carers that children may experience behavioural disruptions upon returning home such as sleep disturbances, difficulties at school or regressive behaviours (Hockenberry & Wilson 2015). The prevalence of home hospital care has seen an increase in the degree of medical technology used to treat ill individuals in the comfort of their home. Should a child be discharged with intravenous medications, oxygen or other medical treatment, parents/carers should be educated to use this equipment, given opportunities to practise and provided with a contact telephone number should they need advice (Hockenberry & Wilson 2015).

**CRITICAL THINKING EXERCISE 21.6**

You are admitting a 7-year-old girl to the paediatric unit with a chest infection. What are nursing responsibilities to ensure the child and parents remain calm during the period of hospitalisation?

## ADMITTING AN ADOLESCENT TO A HEALTHCARE FACILITY

Adolescence is an important stage of development during which the individual transitions from childhood, enhancing their maturity both physically and emotionally; it is characterised by the appearance of secondary sex characteristics and eventually a cessation of body growth (Chiocca 2015; Hockenberry & Wilson 2015). (More information on growth and development during adolescence is provided in Chapters 13 and 14.) When an adolescent requires hospitalisation, the most appropriate and beneficial environment is one that is specifically designed to cater for their needs. Every effort should be made to accommodate hospitalised adolescents in age-appropriate and, where available, gender-specific units and rooms (The Royal Children's Hospital Melbourne 2015).

Collaboration in care is a vital process in empowering the adolescent in decision making, and is adopted in conjunction with promoting independence and autonomy (Chiocca 2015; Hockenberry & Wilson 2015; Rudd & Kocisko 2014).

In Australia, accidents are the leading cause of death and injury in adolescence. They are largely the result of a tendency to risk-taking behaviours in conjunction with feelings of indestructibility (Crisp et al 2013). The nurse has the opportunity to provide health promotion regarding risk-taking behaviours in a non-judgmental and non-authoritarian manner.

## DISCHARGE PLANNING

There are a number of key elements to discharge planning, namely collaboration with the person, efficient communication, prompt assessment of potential interventions needed at home and an interdisciplinary approach (Lees 2012; Shepperd et al 2013) (see Clinical Skill 21.1). Ideally, discharge planning should commence at a pre-admission clinic or as soon as the person is admitted to hospital and may involve carers or significant others who will be involved with the individual after discharge (Lees 2012; Shepperd et al 2013; Kralik & van Loon 2011). The purpose of discharge planning is to assist the individual to make a smooth transition from one setting or level of care to another without impeding the progress already achieved. By adopting a holistic, interdisciplinary approach the nurse can utilise the diversity of skills in the team, resulting in a positive outcome for the person (Shepperd et al 2013; Kralik & van Loon 2011). While many people are discharged to their home, some move onto long-term rehabilitative settings, nursing homes or palliation. Community services such as Meals on Wheels, community day centres, home cleaners and district nurses all allow the transition from hospital to home to flow smoothly. It is important to acknowledge that a person's outcomes are improved when the discharge process is commenced promptly and efficiently, is inclusive of the individual and their wishes and provides appropriate follow-up at home, in the form of telephone support or postoperative counselling (Barkemeyer 2015; Kralik & van Loon 2011). Effective discharge planning is also associated with a decrease in readmission rates, a

reduction in the length of hospital stays and a reduction in the degree of follow-up community care (Barkemeyer 2015; Kralik & van Loon 2011).

Discharge planning should adopt a team approach and should be family inclusive, ensuring the involvement of the person, medical officers, nurses and other member of the interdisciplinary team; for example, occupational therapist, dietitian, psychologist and social worker (Barkemeyer 2015; Kralik & van Loon 2011). Clinical Interest Box 21.2 outlines the elements of a discharge form.

Steps involved in discharge planning are:

- Assessing the person and their significant others
- Interpreting data to identify specific needs and targeting those needs
- Planning to meet those needs
- Psychological preparation
- Implementing the plan
- Evaluating the discharge planning process and the results (Figure 21.4).

## Preparing individuals to go home

Nurses preparing the person to go home need to assess:

- The individual's personal and health data
- The individual's ability to safely perform the activities of daily living
- Any physical, cognitive or other functional limitations the individual may have
- Carers' responses and abilities
- Dependants
- Adequacy of individual's financial resources
- Community supports
- Hazards or barriers that the home environment presents (e.g. stairs, no shower)
- Need for healthcare assistance in the home.

### CLINICAL INTEREST BOX 21.2 Elements of a written discharge summary form

- Mode of discharge: ambulatory, wheelchair, stretcher
- Individual's instructions for self-care activities: medications, diet, food–drug interactions, wound care, self-catheterisation, pain management, tracheostomy care and treatments
- Signs, symptoms and actions to be taken regarding complications or drug reactions
- Permissible activities (e.g. lifting, driving)
- Correct settings for required equipment
- Follow-up instructions and appointments
- Health-promoting education and interventions
- Explanation of emergency procedures in meaningful language and/or print
- Person's signature, acknowledging understanding of instructions

*(Crisp et al 2013; Brown et al 2015)*

The following outcomes must be evaluated for an individual's discharge plan (Figure 21.5):

- Can the person and family, if appropriate, explain the diagnosis and the safe and effective use of discharge medication?
- What specialist instruction or training is required for the individual and family to be able to provide proper care after discharge?
- What community support systems need to be coordinated to enable the individual to return home safely?
- Are there any physical barriers to returning home (e.g. stairs)?
- Are the person and family able to cope with the individual's health status?
- Is relocation of the individual, coordination of support systems or transfer to another healthcare facility needed? (Crisp et al 2013; Brown et al 2015)

Clinical Interest Box 21.3 outlines home assessment parameters that need to be considered before discharging a person home.

## Teaching as a part of discharge planning

The goal is to provide the individual and their family with the knowledge and skills required to meet ongoing health needs. It is difficult to provide a person with information they need the evening before or the morning of discharge. Before beginning to teach you must determine what information has already been given by the medical officer or other carers. A useful way of determining a person's degree of understanding is to ask them to describe what they believe they are to do when they return home. Any discrepancies can then be identified and the nurse can work with the individual to ensure that they are aware of this information prior to discharge. It is important that the nurse be cognisant of any potential barriers to communication or learning issues that may disrupt the person from understanding their discharge needs (see Clinical Interest Box 21.4). In particular, language barriers must be addressed with interpreters and/or written instructions in the required language. It is important that the individual is provided with a medically trained interpreter, and not a family member. There are a number of reasons for this; namely issues pertaining to confidentiality and ensuring medical information is passed on correctly (Burke et al 2013; Barkemeyer 2015). Given that people from ethnically and linguistically diverse backgrounds have a higher likelihood of medication mismanagement than people from the dominant culture, it is very important that they understand messages clearly and that nurses make every effort to ensure this happens (Juckett & Unger 2014).

Learning will be enhanced if spoken instructions are reinforced with materials in other formats such as DVDs, booklets, audio and simulation which can be used in conjunction with community support groups and internet forums. The nurse should document any instruction that is given to an individual. After a family has learned how to perform any

necessary carer skills, have them assume care before the person returns home. Many hospitals require that family members manage care before the person is discharged home to ensure correct understanding of the discharge plan (Crisp et al 2013).

## Day of discharge

When the date and time of discharge have been determined, the individual and significant others are informed, preferably the day before. Transport should be arranged in the form of a taxi, or a transport ambulance, if necessary. Before the person leaves the healthcare facility the nurse should check that:

- The medical officer's discharge orders for prescriptions, changes in treatment or the need for special equipment have been organised
- Dismissal summary containing information pertaining to reason for admission, significant findings and results has been done
