Betty J. Ackley | Gail B. Ladwig
Mary Beth Flynn Makic | Marina Martinez-Kratz | Melody Zanotti

25 YEARS ANNIVERSARY

NURSING DIAGNOSIS HANDBOOK

An Evidence-Based Guide to Planning Care

Twelfth Edition

Look Online! Printable Critical Thinking Care Plans

Interventions and rationales for
Adult, Geriatric, Mental Health, Pediatrics, Maternal/Child Health, Multicultural, Home Care, Client/Family Teaching and Discharge Planning

Evolve® | Student resources on Evolve. Details inside.

ELSEVIER

Nursing Diagnosis Handbook

An Evidence-Based Guide to Planning Care

TWELFTH EDITION

Betty J. Ackley, MSN, EdS, RN

Gail B. Ladwig, MSN, RN

Mary Beth Flynn Makic, PhD, RN, CCNS, FAAN, FNAP

Marina Reyna Martinez-Kratz, MS, RN, CNE

Melody Zanotti, BA, RN, LSW

How to Use *Nursing Diagnosis Handbook: An Evidence-Based Guide to Planning Care*

- Step 1: Assess
- Step 2: Diagnose
- Step 3: Determine Outcomes
- Plan Interventions
- Give Nursing Care
- Evaluate Nursing Care
- Document

Section I Nursing Process, Clinical Reasoning, Nursing Diagnosis, and Evidence-Based

Nursing

Introduction

Part A The Nursing Process

- The “Patient's Story”
- The Nursing Process
- Step 1: Assessment (**A**DPIE)
- Step 2: Nursing Diagnosis (A**D**PIE)
- Step 3: Planning (AD**P**IE)
- Step 4: Implementation (ADP**I**E)
- Step 5: Evaluation (ADPI**E**)

Part B Advanced Nursing Process Concepts

- References

Section II Guide to Nursing Diagnosis

Introduction

List of Nursing Diagnosis by Letter

A

- Abdominal Distention
- Abdominal Hysterectomy
- Abdominal Pain
- Abdominal Surgery
- Abdominal Trauma
- Ablation, Radiofrequency Catheter
- Abortion, Induced
- Abortion, Spontaneous
- Abruptio Placentae <36 Weeks
- Abscess Formation
- Abuse, Child
- Abuse, Spouse, Parent, or Significant Other

Accessory Muscle Use (to Breathe)

Accident Prone

Achalasia

Acid-Base Imbalances

Acidosis, Metabolic

Acidosis, Respiratory

Acne

Acromegaly

Activity Intolerance, Potential to Develop

Acute Abdominal Pain

Acute Alcohol Intoxication

Acute Back Pain

Acute Confusion

Acute Coronary Syndrome

Acute Lymphocytic Leukemia (ALL)

Acute Renal Failure

Acute Respiratory Distress Syndrome

Acute Substance Withdrawal Syndrome

Adams–Stokes Syndrome

Addiction

Addison's Disease

Adenoidectomy

Adhesions, Lysis of

Adjustment Disorder

Adjustment Impairment

Adolescent, Pregnant

Adoption, Giving Child Up for

Adrenocortical Insufficiency

Advance Directives

Affective Disorders

Age-Related Macular Degeneration

Aggressive Behavior

Aging

Agitation

Agoraphobia

Agranulocytosis

AIDS (Acquired Immunodeficiency Syndrome)

AIDS, Child

AIDS Dementia

Airway Obstruction/Secretions

Alcohol Withdrawal

Alcoholism

Alcoholism, Dysfunctional Family Processes

Alkalosis

ALL (Acute Lymphocytic Leukemia)

Allergies

Alopecia

ALS (Amyotrophic Lateral Sclerosis)

Altered Mental Status

Alzheimer's Disease

AMD (Age-Related Macular Degeneration)

Amenorrhea

AMI (Acute Myocardial Infarction)

Amnesia

Amniocentesis

Amnionitis

Amniotic Membrane Rupture

Amputation

Amyotrophic Lateral Sclerosis (ALS)

Anal Fistula

Anaphylactic Shock

Anaphylaxis Prevention

Anasarca

Anemia

Anemia, in Pregnancy

Anemia, Sickle Cell

Anencephaly

Aneurysm, Abdominal Aortic Repair Surgery

Aneurysm, Cerebral

Anger

Angina

Angiocardiography (Cardiac Catheterization)

Angioplasty, Coronary

Anomaly, Fetal/Newborn (Parent Dealing with)

Anorectal Abscess

Anorexia

Anorexia Nervosa

Anosmia (Smell, Loss of Ability to)

Antepartum Period

Anterior Repair, Anterior Colporrhaphy

Anticoagulant Therapy

Antisocial Personality Disorder

Anuria

Anxiety

Anxiety Disorder

Aortic Valvular Stenosis

Aphasia

Aplastic Anemia

Apnea in Infancy

Apneustic Respirations

Appendectomy

Appendicitis

Apprehension

ARDS (Acute Respiratory Distress Syndrome)

Arrhythmia

Arterial Insufficiency

- Arthritis
- Arthrocentesis
- Arthroplasty (Total Hip Replacement)
- Arthroscopy
- Ascites
- Asperger's Syndrome
- Asphyxia, Birth
- Aspiration, Danger of
- Assault Victim
- Assaultive Client
- Asthma
- Ataxia
- Atelectasis
- Atherosclerosis
- Athlete's Foot
- ATN (Acute Tubular Necrosis)
- Atrial Fibrillation
- Atrial Septal Defect
- Attention Deficit Disorder
- Autism
- Autonomic Dysreflexia
- Autonomic Hyperreflexia

List of Nursing Diagnosis by Letter: B

B

- Baby Care
- Bacteremia
- Balanced Energy Field
- Barrel Chest
- Bathing/Hygiene Problems
- Battered Child Syndrome
- Battered Person

Bedbugs, Infestation

Bed Mobility, Impaired

Bed Rest, Prolonged

Bedsores

Bedwetting

Bell's Palsy

Benign Prostatic Hypertrophy

Bereavement

Biliary Atresia

Biliary Calculus

Biliary Obstruction

Bilirubin Elevation in Neonate

Biopsy

Bioterrorism

Bipolar Disorder I (Most Recent Episode, Depressed or Manic)

Birth Asphyxia

Birth Control

Bladder Cancer

Bladder Distention

Bladder Training

Bladder Training, Child

Bleeding Tendency

Blepharoplasty

Blindness

Blood Disorder

Blood Glucose Control

Blood Pressure Alteration

Blood Transfusion

Body Dysmorphic Disorder

Body Image Change

Body Temperature, Altered

Bone Marrow Biopsy

Borderline Personality Disorder

Boredom

Botulism

Bowel Incontinence

Bowel Obstruction

Bowel Resection

Bowel Sounds, Absent or Diminished

Bowel Sounds, Hyperactive

Bowel Training

Bowel Training, Child

BPH (Benign Prostatic Hypertrophy)

Bradycardia

Bradypnea

Brain Injury

Brain Surgery

Brain Tumor

Braxton Hicks Contractions

Breast Biopsy

Breast Cancer

Breast Examination, Self

Breast Lumps

Breast Pumping

Breastfeeding, Effective

Breastfeeding, Ineffective

Breastfeeding, Interrupted

Breast Milk Production, Insufficient

Breath Sounds, Decreased or Absent

Breathing Pattern Alteration

Breech Birth

Bronchitis

Bronchopulmonary Dysplasia

Bronchoscopy

- Bruits, Carotid
- Bryant's Traction
- Buck's Traction
- Buerger's Disease
- Bulimia
- Bullying
- Bunion
- Bunionectomy
- Burn Risk
- Burns
- Bursitis
- Bypass Graft

List of Nursing Diagnosis by Letter: C

C

- CABG (Coronary Artery Bypass Grafting)
- Cachexia
- Calcium Alteration
- Cancer
- Candidiasis, Oral
- Capillary Refill Time, Prolonged
- Carbon Monoxide Poisoning
- Cardiac Arrest
- Cardiac Catheterization
- Cardiac Disorders in Pregnancy
- Cardiac Dysrhythmia
- Cardiac Output, Decreased
- Cardiac Tamponade
- Cardiogenic Shock
- Caregiver Role Strain
- Carious Teeth
- Carotid Endarterectomy

Carpal Tunnel Syndrome

Carpopedal Spasm

Casts

Cataract Extraction

Catatonic Schizophrenia

Catheterization, Urinary

Cavities in Teeth

Celiac Disease

Cellulitis

Cellulitis, Periorbital

Central Line Insertion

Cerebral Aneurysm

Cerebral Palsy

Cerebral Perfusion

Cerebrovascular Accident (CVA)

Cervicitis

Cesarean Delivery

Chemical Dependence

Chemotherapy

Chest Pain

Chest Tubes

Cheyne-Stokes Respiration

Chickenpox

Child Abuse

Childbearing Problems

Child Neglect

Child with Chronic Condition

Childbirth

Childhood Obesity

Chills

Chlamydia Infection

Chloasma

Choking or Coughing with Eating

Cholecystectomy

Cholelithiasis

Chorioamnionitis

Chronic Confusion

Chronic Functional Constipation

Chronic Lymphocytic Leukemia

Chronic Obstructive Pulmonary Disease (COPD)

Chronic Pain

Chronic Renal Failure (Chronic Renal Disease)

Chvostek's Sign

Circumcision

Cirrhosis

Cleft Lip/Cleft Palate

Clotting Disorder

Cocaine Baby

Codependency

Cold, Viral

Colectomy

Colitis

Collagen Disease

Colostomy

Colporrhaphy, Anterior

Coma

Comfort, Loss of

Communicable Diseases, Childhood (e.g., Measles, Mumps, Rubella, Chickenpox, Scabies, Lice, Impetigo)

Communication

Communication Problems

Community Coping

Community Health Problems

Companion Animal

Compartment Syndrome

Compulsion

Conduction Disorders (Cardiac)

Confusion, Acute

Confusion, Chronic

Congenital Heart Disease/Cardiac Anomalies

Congestive Heart Failure (CHF)

Conjunctivitis

Consciousness, Altered Level of

Constipation

Constipation, Chronic Functional

Constipation, Perceived

Constipation, Risk for

Contamination

Continent Ileostomy (Kock Pouch)

Contraceptive Method

Convulsions

COPD (Chronic Obstructive Pulmonary Disease)

Coping

Coping Problems

Corneal Injury

Corneal Reflex, Absent

Corneal Transplant

Coronary Artery Bypass Grafting (CABG)

Costovertebral Angle Tenderness

Cough, Ineffective

Crackles in Lungs, Coarse

Crackles in Lungs, Fine

Craniectomy/Craniotomy

Crepitation, Subcutaneous

Crisis

Crohn's Disease

Croup

- Cryosurgery for Retinal Detachment
- Cushing's Syndrome
- Cuts (Wounds)
- CVA (Cerebrovascular Accident)
- Cyanosis, Central with Cyanosis of Oral Mucous Membranes
- Cyanosis, Peripheral with Cyanosis of Nail Beds
- Cystic Fibrosis
- Cystitis
- Cystocele
- Cystoscopy

List of Nursing Diagnosis by Letter: D

D

- Deafness
- Death
- Death, Oncoming
- Decisions, Difficulty Making
- Decubitus Ulcer
- Deep Vein Thrombosis (DVT)
- Defensive Behavior
- Dehiscence, Abdominal
- Dehydration
- Delirium
- Delirium Tremens (DT)
- Delivery
- Delusions
- Dementia
- Denial of Health Status
- Dental Caries
- Depression (Major Depressive Disorder)
- Dermatitis
- Despondency

Destructive Behavior Toward Others

Developmental Concerns

Diabetes in Pregnancy

Diabetes Insipidus

Diabetes Mellitus

Diabetes Mellitus, Juvenile (Insulin-Dependent Diabetes Mellitus Type 1)

Diabetic Coma

Diabetic Ketoacidosis

Diabetic Neuropathy

Diabetic Retinopathy

Dialysis

Diaphragmatic Hernia

Diarrhea

DIC (Disseminated Intravascular Coagulation)

Digitalis Toxicity

Dignity, Loss of

Dilation and Curettage (D&C)

Dirty Body (for Prolonged Period)

Discharge Planning

Discomforts of Pregnancy

Dislocation of Joint

Dissecting Aneurysm

Disseminated Intravascular Coagulation (DIC)

Dissociative Identity Disorder (Not Otherwise Specified)

Distress

Disuse Syndrome, Potential to Develop

Diversional Activity Engagement, Lack of

Diverticulitis

Dizziness

Domestic Violence

Down Syndrome

Dress Self (Inability to)

- Dribbling of Urine
- Drooling
- Dropout from School
- Drug Abuse
- Drug Withdrawal
- Dry Eye
- Dry Mouth
- DT (Delirium Tremens)
- DVT (Deep Vein Thrombosis)
- Dying Client
- Dysfunctional Eating Pattern
- Dysfunctional Family Unit
- Dysfunctional Ventilatory Weaning
- Dysmenorrhea
- Dyspareunia
- Dyspepsia
- Dysphagia
- Dysphasia
- Dyspnea
- Dysrhythmia
- Dysthymic Disorder
- Dystocia
- Dysuria

List of Nursing Diagnosis by Letter: E

E

- Ear Surgery
- Earache
- Eating Dynamics, Adolescent
- Eating Dynamics, Child
- Eating Dynamics, Infant
- Eclampsia

ECMO (Extracorporeal Membrane Oxygenator)

ECT (Electroconvulsive Therapy)

Ectopic Pregnancy

Eczema

ED (Erectile Dysfunction)

Edema

Elder Abuse

Elderly

Electroconvulsive Therapy

Electrolyte Imbalance

Emaciated Person

Emancipated Decision-Making, Impaired

Embolectomy

Emboli

Embolism in Leg or Arm

Emesis

Emotional Problems

Empathy

Emphysema

Emptiness

Encephalitis

Endocardial Cushion Defect

Endocarditis

Endometriosis

Endometritis

Enuresis

Environmental Interpretation Problems

Epididymitis

Epiglottitis

Epilepsy

Episiotomy

Epistaxis

- Epstein-Barr Virus
- Erectile Dysfunction (ED)
- *Escherichia coli* Infection
- Esophageal Varices
- Esophagitis
- Evisceration
- Exhaustion
- Exposure to Hot or Cold Environment
- External Fixation
- Extracorporeal Membrane Oxygenator (ECMO)
- Eye Discomfort
- Eye Surgery

List of Nursing Diagnosis by Letter: F

F

- Failure to Thrive, Child
- Falls, Risk for
- Family Problems
- Family Process
- Fatigue
- Fear
- Febrile Seizures
- Fecal Impaction
- Fecal Incontinence
- Feeding Dynamics, Infant
- Feeding Problems, Newborn
- Female Genital Mutilation
- Femoral Popliteal Bypass
- Fetal Alcohol Syndrome
- Fetal Distress/Nonreassuring Fetal Heart Rate Pattern
- Fever
- Fibrocystic Breast Disease

- Filthy Home Environment
- Financial Crisis in the Home Environment
- Fistulectomy
- Flail Chest
- Flashbacks
- Flat Affect
- Fluid Volume Deficit
- Fluid Volume Excess
- Fluid Volume Imbalance, Risk for
- Food Allergies
- Foodborne Illness
- Food Intolerance
- Foreign Body Aspiration
- Formula Feeding of Infant
- Fracture
- Fractured Hip
- Frail Elderly Syndrome
- Frequency of Urination
- Friendship
- Frostbite
- Frothy Sputum
- Fusion, Lumbar

List of Nursing Diagnosis by Letter: G

G

- Gag Reflex, Depressed or Absent
- Gallop Rhythm
- Gallstones
- Gang Member
- Gangrene
- Gas Exchange, Impaired
- Gastric Ulcer

Gastritis

Gastroenteritis

Gastroenteritis, Child

Gastroesophageal Reflux (GERD)

Gastroesophageal Reflux, Child

Gastrointestinal Bleeding (GI Bleed)

Gastrointestinal Hemorrhage

Gastrointestinal Surgery

Gastroschisis/Omphalocele

Gastrostomy

Gender Dysphoria

Genital Herpes

Genital Warts

GERD

Gestational Diabetes (Diabetes in Pregnancy)

GI Bleed (Gastrointestinal Bleeding)

Gingivitis

Glaucoma

Glomerulonephritis

Gluten Allergy

Gonorrhea

Gout

Grandiosity

Grand Mal Seizure

Grandparents Raising Grandchildren

Graves' Disease

Grieving

Grieving, Complicated

Groom Self (Inability to)

Growth and Development Lag

Guillain-Barré Syndrome

Guilt

List of Nursing Diagnosis by Letter: H

H

- Hair Loss
- Halitosis
- Hallucinations
- Headache
- Head Injury
- Health Behavior, Risk-Prone
- Health Maintenance Problems
- Health-Seeking Person
- Hearing Impairment
- Heart Attack
- Heartburn
- Heart Failure
- Heart Surgery
- Heat Stroke
- Hematemesis
- Hematuria
- Hemianopia
- Hemiplegia
- Hemodialysis
- Hemodynamic Monitoring
- Hemolytic Uremic Syndrome
- Hemophilia
- Hemoptysis
- Hemorrhage
- Hemorrhoidectomy
- Hemorrhoids
- Hemothorax
- Hepatitis
- Hernia

Herniated Disk

Herniorrhaphy

Herpes in Pregnancy

Herpes Simplex I

Herpes Simplex II

Herpes Zoster

HHNS (Hyperosmolar Hyperglycemic Nonketotic Syndrome)

Hiatal Hernia

Hip Fracture

Hip Replacement

Hirschsprung's Disease

Hirsutism

Hitting Behavior

HIV (Human Immunodeficiency Virus)

Hodgkin's Disease

Homelessness

Home Maintenance Problems

Hope

Hopelessness

Hospitalized Child

Hostile Behavior

HTN (Hypertension)

Human Energy Field

Humiliating Experience

Huntington's Disease

Hydrocele

Hydrocephalus

Hygiene, Inability to Provide Own

Hyperactive Syndrome

Hyperbilirubinemia, Neonatal

Hypercalcemia

Hypercapnia

- Hyperemesis Gravidarum
- Hyperglycemia
- Hyperkalemia
- Hypernatremia
- Hyperosmolar Hyperglycemic Nonketotic Syndrome (HHNS)
- Hyperphosphatemia
- Hypersensitivity to Slight Criticism
- Hypertension (HTN)
- Hyperthermia
- Hyperthyroidism
- Hyperventilation
- Hypocalcemia
- Hypoglycemia
- Hypokalemia
- Hypomagnesemia
- Hypomania
- Hyponatremia
- Hypoplastic Left Lung
- Hypotension
- Hypothermia
- Hypothyroidism
- Hypovolemic Shock
- Hypoxia
- Hysterectomy

List of Nursing Diagnosis by Letter: I

I

- IBS (Irritable Bowel Syndrome)
- ICD (Implantable Cardioverter/Defibrillator)
- IDDM (Insulin-Dependent Diabetes)
- Identity Disturbance/Problems
- Idiopathic Thrombocytopenic Purpura (ITP)

Ileal Conduit

Ileostomy

Ileus

Immigration Transition, Risk for Complicated

Immobility

Immunization

Immunosuppression

Impaction of Stool

Impaired Sitting

Impaired Standing

Imperforate Anus

Impetigo

Implantable Cardioverter/Defibrillator (ICD)

Impotence

Impulsiveness

Inactivity

Incompetent Cervix

Incontinence of Stool

Incontinence of Urine

Indigestion

Induction of Labor

Infant Apnea

Infant Behavior

Infant Care

Infant Feeding Pattern, Ineffective

Infant of Diabetic Mother

Infant of Substance-Abusing Mother

Infantile Polyarteritis

Infection, Potential for

Infectious Processes

Infertility

Inflammatory Bowel Disease (Child and Adult)

- Influenza
- Inguinal Hernia Repair
- Injury
- Insomnia
- Insulin Shock
- Intellectual Disability
- Intermittent Claudication
- Internal Cardioverter/Defibrillator (ICD)
- Internal Fixation
- Interstitial Cystitis
- Intervertebral Disk Excision
- Intestinal Obstruction
- Intestinal Perforation
- Intoxication
- Intraaortic Balloon Counterpulsation
- Intracranial Pressure, Increased
- Intrauterine Growth Retardation
- Intravenous Therapy
- Intubation, Endotracheal or Nasogastric
- Iodine Reaction with Diagnostic Testing
- Irregular Pulse
- Irritable Bowel Syndrome (IBS)
- Isolation
- Itching
- ITP (Idiopathic Thrombocytopenic Purpura)

List of Nursing Diagnosis by Letter: J

J

- Jaundice
- Jaundice, Neonatal
- Jaw Pain and Heart Attacks
- Jaw Surgery

- Jittery
- Jock Itch
- Joint Dislocation
- Joint Pain
- Joint Replacement
- JRA (Juvenile Rheumatoid Arthritis)

List of Nursing Diagnosis by Letter: K

K

- Kaposi's Sarcoma
- Kawasaki Disease
- Keloids
- Keratoconjunctivitis Sicca (Dry Eye Syndrome)
- Keratoplasty
- Ketoacidosis, Alcoholic
- Ketoacidosis, Diabetic
- Keyhole Heart Surgery
- Kidney Disease Screening
- Kidney Failure
- Kidney Failure Acute/Chronic, Child
- Kidney Failure, Nonoliguric
- Kidney Stone
- Kidney Transplant
- Kidney Transplantation, Donor
- Kidney Transplantation, Recipient
- Kidney Tumor
- Kissing Disease
- Knee Replacement
- Knowledge
- Knowledge, Deficient
- Kock Pouch
- Korsakoff's Syndrome

List of Nursing Diagnosis by Letter: L

L

- Labor, Induction of
- Labor, Normal
- Labor Pain
- Labyrinthitis
- Lacerations
- Lactation
- Lactic Acidosis
- Lactose Intolerance
- Laminectomy
- Language Impairment
- Laparoscopic Laser Cholecystectomy
- Laparoscopy
- Laparotomy
- Large Bowel Resection
- Laryngectomy
- Laser Surgery
- LASIK Eye Surgery (Laser-Assisted in Situ Keratomileusis)
- Latex Allergic Reaction
- Laxative Abuse
- Lead Poisoning
- Left Heart Catheterization
- Legionnaires' Disease
- Lens Implant
- Lethargy/Listlessness
- Leukemia
- Leukopenia
- Level of Consciousness, Decreased
- Lice
- Lifestyle, Sedentary

- Lightheadedness
- Limb Reattachment Procedures
- Liposuction
- Lithotripsy
- Liver Biopsy
- Liver Cancer
- Liver Disease
- Liver Function
- Liver Transplant
- Living Will
- Lobectomy
- Loneliness
- Loose Stools (Bowel Movements)
- Loss of Bladder Control
- Loss of Bowel Control
- Lou Gehrig's Disease
- Low Back Pain
- Low Blood Glucose
- Low Blood Pressure
- Lower GI Bleeding
- Lumbar Puncture
- Lumpectomy
- Lung Cancer
- Lung Surgery
- Lupus Erythematosus
- Lyme Disease
- Lymphedema
- Lymphoma

List of Nursing Diagnosis by Letter: M

M

- Macular Degeneration

Magnetic Resonance Imaging (MRI)

Major Depressive Disorder

Malabsorption Syndrome

Maladaptive Behavior

Malaise

Malaria

Male Infertility

Malignancy

Malignant Hypertension (Arteriolar Nephrosclerosis)

Malignant Hyperthermia

Malnutrition

Mammography

Manic Disorder, Bipolar I

Manipulative Behavior

Marfan Syndrome

Mastectomy

Mastitis

Maternal Infection

Maturational Issues, Adolescent

Maze III Procedure

MD (Muscular Dystrophy)

Measles (Rubeola)

Meconium Aspiration

Meconium Delayed

Medical Marijuana

Melanoma

Melena

Memory Deficit

Ménière's Disease

Meningitis/Encephalitis

Meningocele

Menopause

Menorrhagia

Mental Illness

Metabolic Acidosis

Metabolic Alkalosis

Metabolic Imbalance Syndrome

Metastasis

Methicillin-Resistant *Staphylococcus aureus* (MRSA)

MI (Myocardial Infarction)

MIDCAB (Minimally Invasive Direct Coronary Artery Bypass)

Midlife Crisis

Migraine Headache

Military Families, Personnel

Milk Intolerance

Minimally Invasive Direct Coronary Bypass (MIDCAB)

Miscarriage

Mitral Stenosis

Mitral Valve Prolapse

Mobility, Impaired Bed

Mobility, Impaired Physical

Mobility, Impaired Wheelchair

Modified Radical Mastectomy

Mononucleosis

Mood Disorders

Moon Face

Moral/Ethical Dilemmas

Morning Sickness

Motion Sickness

Mottling of Peripheral Skin

Mourning

Mouth Lesions

MRI (Magnetic Resonance Imaging)

MRSA (Methicillin-Resistant *Staphylococcus aureus*)

- MS (Multiple Sclerosis)
- Mucocutaneous Lymph Node Syndrome
- Mucous Membrane Integrity, Impaired Oral
- Multi-Infarct Dementia
- Multiple Gestations
- Multiple Personality Disorder (Dissociative Identity Disorder)
- Multiple Sclerosis (MS)
- Mumps
- Murmurs
- Muscular Atrophy/Weakness
- Muscular Dystrophy (MD)
- MVC (Motor Vehicle Crash)
- Myasthenia Gravis
- Mycoplasma Pneumonia
- Myelocele
- Myelomeningocele
- Myocardial Infarction (MI)
- Myocarditis
- Myringotomy
- Myxedema

List of Nursing Diagnosis by Letter: N

N

- Narcissistic Personality Disorder
- Narcolepsy
- Narcotic Use
- Nasogastric Suction
- Nausea
- Near-Drowning
- Nearsightedness
- Nearsightedness; Corneal Surgery
- Neck Vein Distention

Necrosis, Kidney Tubular; Necrosis, Acute Tubular

Necrotizing Enterocolitis

Negative Feelings About Self

Neglect, Unilateral

Neglectful Care of Family Member

Neonatal Abstinence Syndrome

Neonatal Hyperbilirubinemia

Neonate

Neoplasm

Nephrectomy

Nephrostomy, Percutaneous

Nephrotic Syndrome

Neural Tube Defects (Meningocele, Myelomeningocele, Spina Bifida, Anencephaly)

Neuralgia

Neuritis (Peripheral Neuropathy)

Neurogenic Bladder

Neurologic Disorders

Neuropathy, Peripheral

Neurosurgery

Newborn, Normal

Newborn, Postmature

Newborn, Small for Gestational Age (SGA)

Nicotine Addiction

NIDDM (Non–Insulin-Dependent Diabetes Mellitus)

Nightmares

Nipple Soreness

Nocturia

Nocturnal Myoclonus

Nocturnal Paroxysmal Dyspnea

Non–Insulin-Dependent Diabetes Mellitus (NIDDM)

Normal Pressure Hydrocephalus (NPH)

NSTEMI (non–ST-elevation myocardial infarction)

- Nursing
- Nutrition
- Nutrition, Imbalanced

List of Nursing Diagnosis by Letter: O

O

- Obesity
- OBS (Organic Brain Syndrome)
- Obsessive-Compulsive Disorder (OCD)
- Obstruction, Bowel
- Obstructive Sleep Apnea
- OCD (Obsessive-Compulsive Disorder)
- Occupational Injury
- ODD (Oppositional Defiant Disorder)
- Older Adult
- Oliguria
- Omphalocele
- Oophorectomy
- OPCAB (Off-Pump Coronary Artery Bypass)
- Open Heart Surgery
- Open Reduction of Fracture with Internal Fixation (Femur)
- Opioid Addiction
- Opioid Use
- Opportunistic Infection
- Oppositional Defiant Disorder (ODD)
- Oral Mucous Membrane Integrity, Impaired
- Oral Thrush
- Orchitis
- Organic Mental Disorders
- Orthopedic Traction
- Orthopnea
- Orthostatic Hypotension

- Osteoarthritis
- Osteomyelitis
- Osteoporosis
- Ostomy
- Otitis Media
- Ovarian Carcinoma

NANDA-I Diagnoses

Activity intolerance, 122
Risk for **Activity** intolerance, 127
Ineffective **Activity** planning, 127
Risk for Ineffective **Activity** Planning, 130
Ineffective **Airway** clearance, 131
Risk for **Allergy** reaction, 136
Anxiety, 140
Death **Anxiety**, 144
Risk for **Aspiration**, 147
Risk for Impaired **Attachment**, 153
Autonomic Dysreflexia, 159
Risk for **Autonomic Dysreflexia**, 163
Risk for **Bleeding**, 163
Risk for unstable **Blood Pressure**, 168
Disturbed **Body Image**, 171
Insufficient **Breast Milk** production, 174
Ineffective **Breastfeeding**, 176
Interrupted **Breastfeeding**, 179
Readiness for enhanced **Breastfeeding**, 182
Ineffective **Breathing** pattern, 185
Decreased **Cardiac** output, 190
Risk for decreased **Cardiac** output, 198
Risk for decreased **Cardiac** tissue perfusion, 198
Caregiver Role Strain, 203
Risk for **Caregiver Role Strain**, 210
Risk for ineffective **Cerebral** tissue perfusion, 211
Ineffective **Childbearing** process, 214
Readiness for enhanced **Childbearing** process, 218
Risk for ineffective **Childbearing** process, 224
Impaired **Comfort**, 225
Readiness for enhanced **Comfort**, 228
Readiness for enhanced **Communication**, 233
Impaired verbal **Communication**, 236
Acute **Confusion**, 241
Chronic **Confusion**, 249
Risk for acute **Confusion**, 254
Constipation, 254
Risk for **Constipation**, 261
Perceived **Constipation**, 261
Chronic functional **Constipation**, 265
Risk for chronic functional **Constipation**, 269
Contamination, 270
Risk for **Contamination**, 274
Risk for adverse reaction to iodinated **Contrast Media**, 275
Readiness for enhanced community **Coping**, 278
Defensive **Coping**, 281
Ineffective **Coping**, 284
Readiness for enhanced **Coping**, 291
Ineffective community **Coping**, 295
Compromised family **Coping**, 298
Disabled family **Coping**, 304
Readiness for enhanced family **Coping**, 306

Readiness for enhanced **Decision-Making**, 309
Decisional Conflict, 311
Impaired emancipated **Decision-Making**, 314
Readiness for enhanced emancipated **Decision-Making**, 318
Risk for impaired emancipated **Decision-Making**, 321
Ineffective **Denial**, 324
Impaired **Dentition**, 327
Risk for delayed **Development**, 334
Diarrhea, 336
Risk for **Disuse** syndrome, 342
Decreased **Diversional** acitivity engagement, 346
Ineffective adolescent **Eating** dynamics, 351
Ineffective child **Eating** dynamics, 354
Ineffective infant **Eating** dynamics, 357
Risk for **Electrolyte** imbalance, 360
Imbalanced **Energy Field**, 363
Risk for dry **Eye**, 365
Labile **Emotional Control**, 368
Risk for **Falls**, 371
Dysfunctional **Family** processes, 377
Interrupted **Family** processes, 381
Readiness for enhanced **Family** processes, 384
Fatigue, 387
Fear, 392
Ineffective infant **Feeding** pattern, 396
Risk for **Female Genital Mutilation**, 399
Risk for imbalanced **Fluid** volume, 402
Deficient **Fluid** volume, 406
Excess **Fluid** volume, 412
Risk for deficient **Fluid** volume, 417
Frail Elderly syndrome, 417
Risk for **Frail Elderly** syndrome, 420
Impaired **Gas** exchange, 420
Risk for dysfunctional **Gastrointestinal** motility, 426
Dysfunctional **Gastrointestinal** motility, 426
Risk for unstable blood **Glucose** level, 430
Grieving, 434
Complicated **Grieving**, 441
Risk for complicated **Grieving**, 444
Deficient community **Health**, 445
Risk-prone **Health** behavior, 447
Ineffective **Health** management, 452
Readiness for enhanced **Health** management, 457
Ineffective family **Health** management, 461
Ineffective **Health** maintenance, 464
Impaired **Home** maintenance, 468
Readiness for enhanced **Hope**, 472
Hopelessness, 474
Risk for compromised **Human Dignity**, 478
Neonatal **Hyperbilirubinemia**, 480
Risk for neonatal **Hyperbilirubinemia**, 485
Hyperthermia, 487
Hypothermia, 492
Risk for **Hypothermia**, 498
Risk for **Perioperative Hypothermia**, 499
Disturbed personal **Identity**, 503
Risk for disturbed personal **Identity**, 510
Risk for complicated **Immigration Transition**, 510
Ineffective **Impulse** control, 513
Functional urinary **Incontinence**, 516
Overflow urinary **Incontinence**, 520
Reflex urinary **Incontinence**, 520
Stress urinary **Incontinence**, 524
Urge urinary **Incontinence**, 529

Risk for urge urinary **Incontinence**, 534
Bowel **Incontinence**, 535
Disorganized **Infant** behavior, 540
Readiness for enhanced organized **Infant** behavior, 545
Risk for disorganized **Infant** behavior, 546
Risk for **Infection**, 546
Risk for surgical site **Infection**, 552
Risk for **Injury**, 558
Risk for corneal **Injury**, 562
Risk for occupational **Injury**, 565
Risk for urinary tract **Injury**, 574
Insomnia, 577
Decreased **Intracranial** adaptive capacity, 581
Deficient **Knowledge**, 584
Readiness for enhanced **Knowledge**, 587
Latex Allergy reaction, 590
Risk for **Latex Allergy** reaction, 593
Readiness for enhanced health **Literacy**, 595
Risk for impaired **Liver** function, 598
Risk for **Loneliness**, 601
Risk for disturbed **Maternal–Fetal** dyad, 605
Impaired **Memory**, 608
Risk for **Metabolic Imbalance** syndrome, 611
Impaired bed **Mobility**, 615
Impaired physical **Mobility**, 620
Impaired wheelchair **Mobility**, 624
Impaired **Mood** regulation, 628
Moral Distress, 630
Risk for dry **Mouth**, 634
Nausea, 639
Neonatal Abstinence syndrome, 644
Readiness for enhanced **Nutrition**, 648
Imbalanced **Nutrition:** less than body requirements, 651
Impaired **Oral Mucous Membrane** integrity, 657
Risk for impaired **Oral Mucous Membrane** integrity, 663
Obesity, 663
Overweight, 667
Risk for **Overweight**, 671
Acute **Pain**, 676
Chronic **Pain**, 683
Chronic **Pain** syndrome, 691
Labor **Pain**, 692
Impaired **Parenting**, 695
Readiness for enhanced **Parenting**, 699
Risk for impaired **Parenting**, 702
Risk for **Perioperative Positioning** injury, 703
Risk for **Peripheral Neurovascular** dysfunction, 707
Risk for **Poisoning**, 709
Post-Trauma syndrome, 715
Risk for **Post-Trauma** syndrome, 719
Readiness for enhanced **Power**, 722
Powerlessness, 724
Risk for **Powerlessness**, 727
Risk for **Pressure Ulcer**, 728
Ineffective **Protection**, 733
Rape-Trauma syndrome, 738
Ineffective **Relationship**, 742
Readiness for enhanced **Relationship**, 742
Risk for ineffective **Relationship**, 745
Impaired **Religiosity**, 745
Readiness for enhanced **Religiosity**, 748
Risk for impaired **Religiosity**, 750
Relocation stress syndrome, 751
Risk for **Relocation** stress syndrome, 755

Impaired **Resilience**, 756
Readiness for enhanced **Resilience**, 759
Risk for impaired **Resilience**, 761
Parental **Role** conflict, 763
Ineffective **Role** performance, 766
Sedentary lifestyle, 770
Readiness for enhanced **Self-Care**, 774
Bathing **Self-Care** deficit, 781
Dressing **Self-Care** deficit, 785
Feeding **Self-Care** deficit, 787
Toileting **Self-Care** deficit, 791
Readiness for enhanced **Self-Concept**, 793
Chronic low **Self-Esteem**, 797
Situational low **Self-Esteem**, 801
Risk for chronic low **Self-Esteem**, 803
Risk for situational low **Self-Esteem**, 804
Risk for **Self-Mutilation**, 806
Self-Mutilation, 811
Self-Neglect, 814
Sexual Dysfunction, 817
Ineffective **Sexuality** pattern, 822
Risk for **Shock**, 828
Impaired **Sitting**, 832
Impaired **Skin** integrity, 836
Risk for impaired **Skin** integrity, 840
Sleep deprivation, 843
Readiness for enhanced **Sleep**, 847
Disturbed **Sleep** pattern, 850
Impaired **Social** interaction, 854
Social isolation, 857
Chronic **Sorrow**, 861
Spiritual distress, 865
Risk for **Spiritual** distress, 868
Readiness for enhanced **Spiritual** well-being, 869
Impaired **Standing**, 873
Stress overload, 875
Acute **Substance Withdrawal** syndrome, 880
Risk for acute **Substance Withdrawal** syndrome, 885
Risk for **Sudden Infant Death**, 889
Risk for **Suffocation**, 892
Risk for **Suicide**, 896
Delayed **Surgical** recovery, 906
Risk for delayed **Surgical** recovery, 910
Impaired **Swallowing**, 911
Risk for **Thermal** injury, 916
Ineffective **Thermoregulation**, 919
Risk for ineffective **Thermoregulation**, 923
Impaired **Tissue** integrity, 924
Risk for impaired **Tissue** integrity, 928
Ineffective peripheral **Tissue Perfusion**, 929
Risk for ineffective peripheral **Tissue Perfusion**, 933
Impaired **Transfer** ability, 933
Risk for **Physical** Trauma, 938
Unilateral Neglect, 942
Impaired **Urinary** elimination, 944
Urinary Retention, 948
Risk for **Vascular Trauma**, 953
Risk for **Venous Thrombosis**, 957
Impaired spontaneous **Ventilation**, 960
Dysfunctional **Ventilatory** weaning response, 966
Risk for other-directed **Violence**, 972
Risk for self-directed **Violence**, 982
Impaired **Walking**, 983
Wandering, 986

Dedication

To Jerry Ladwig, my wonderful husband who, after 54 years, is still supportive and helpful; he has been my "right-hand man" in every revision of this book. Also, to my very special children, their spouses, and all of my grandchildren ... Jerry, Kathy, Alexandra, Elizabeth, and Benjamin Ladwig; Christine, John, Sean, Ciara, and Bridget McMahon; Jennifer, Jim, Abby, Katelyn, Blake, and Connor Martin; Amy, Scott, Ford, and Vaughn Bertram ... the greatest family anyone could ever hope for. A special thank you to my grandson Sean for his work on checking and incorporating the correct/new NANDA language for the diagnoses that I worked on.

Gail B. Ladwig

Thank you to my husband, Zlatko, and children, Alexander and Erik, whose unconditional love and support are ever present in my life. To my parents and sisters for always encouraging me to follow my passion. To Gail, for her incredible leadership and mentorship throughout the rigorous process of revising this essential text. And finally, to Betty, for her unwavering commitment to the profession of nursing through her roles as an expert teacher and prolific author. You are missed but your spirit continues to inform nursing practice excellence.

Mary Beth Flynn Makic

To my best friend and the love of my life, Kent Martinez-Kratz. To my children, Maxwell, Jesse, and Sierra, whose love, inspiration, and wit make my life complete. To my first fans, my parents and siblings. To Gail, for being the absolute best nursing professor, mentor, and comadre. And finally, to Betty's memory, for inspiring excellence in nursing education and practice.

Marina Reyna Martinez-Kratz

Thank you to my husband Marty for his infinite patience and encouragement in all my endeavors. Thank you to my amazing children, their spouses, and my grandchildren ... Rachael, Frank, Corey, Zak, Dominic, and Dylan ... for their unconditional love and inspiration. Thank you to my friend and mentor Gail Ladwig for offering me the opportunity to contribute to this incredible textbook. Your gifts of friendship, knowledge, and positivity will stay with me forever. Your lifelong dedication and commitment to the field of nursing are truly inspiring.

Melody Zanotti

About the Authors

Betty Ackley was co-author of *Nursing Diagnosis: Guide to Planning Care,* which has been a successful text for 20 years, and co-author for four editions of *Mosby's Guide to Nursing Diagnosis*. She was also a lead co-author/editor of *Evidence-Based Nursing Care Guidelines: Medical-Surgical Interventions*. This text is designed to help nurses easily find and use evidence to provide excellence in nursing care. The text was published in 2008 and was named AJN book of the year.

Gail B. Ladwig has a long career in teaching and practicing nursing. Gail is co-author of *Nursing Diagnosis: Guide to Planning Care,* which has been a very successful text for more than 25 years, and she has been co-author for all editions of *Mosby's Guide to Nursing Diagnosis,* now in its fifth edition. She is also a co-author/editor of *Evidence-Based Nursing Care Guidelines: Medical-Surgical Interventions*. This text was published in 2008 and was named AJN book of the year. Gail has been an active member and supporter of NANDA-I for many, many years. Gail is the mother of 4 children and grandmother of 12 and loves to spend time with her grandchildren. She has been married to her husband Jerry for 54 years and is passionate about her family and the profession of nursing.

Mary Beth Flynn Makic is a Professor at the University of Colorado, College of Nursing, Aurora, Colorado, where she teaches in the undergraduate, graduate, and doctoral programs. She is the director of the Clinical Nurse Specialist graduate program at the College of Nursing. She has worked predominately in critical care for 30 years. Mary Beth is best known for her publications and presentations, regionally and nationally, as an expert

on evidence-based practice in nursing. Her practice expertise and research focus on the care of the trauma, general surgical, and burn-injured patient populations; acute wound healing; pressure ulcer prevention; and hospital-acquired conditions (HACs). She is passionate about nurses' understanding and translating current best evidence into practice to optimize patient and family outcomes. She is co-author of *Trauma Nursing: from Resuscitation through Rehabilitation* and a section editor of *American Association of Critical Care Nurses Procedure Manual for Critical Care.* She is actively involved in several professional nursing and interprofessional organizations.

Marina Reyna Martinez-Kratz is a professor of nursing at Jackson College, Jackson, Michigan. She is a registered nurse with 30 years of experience and is a Certified Nurse Educator. She received her nursing degrees from Jackson Community College and the University of Michigan. Her expertise in nursing practice has focused on psychiatric nursing, professional issues, and nutrition. In 1998, Marina joined the faculty at Jackson Community College and currently teaches nursing courses in Behavioral Health, Leadership, and Nutrition. In addition, Marina serves on the Nursing Assessment and Professional Development Committees and is a Mandated Reporter Trainer. She has served as a behavioral health consultant for several health care facilities, contributes to and reviews many academic publications, and has presented at the state and national level. Marina belongs to many professional organizations and serves as Board Secretary for the Jackson Council for the Prevention of Child Abuse and Child Neglect and the NLN Ambassador for Jackson College. Marina's passion is helping students learn to think like nurses! Marina is the proud mother of 3 children and has been married to her partner and best friend Kent for 28 years.

Melody Zanotti has enjoyed a diverse career in health care and education for over 30 years. She worked as a staff nurse in MICU, SICU and stepdown units for many years. She was instrumental in establishing a nurse triage and resource call center for a major health care system in Ohio. She worked as a school nurse before pursuing a degree in Social Work. Melody received a BA in Social Work and worked as a school social worker for over 10 years. While working as an LSW, she co-developed a truancy prevention program, partnering the school district with local municipalities. Melody currently volunteers her time for many causes. She has done medical missionary work in Africa and is working on a health education program empowering young women in Uganda.

Preface

Nursing Diagnosis Handbook: An Evidence-Based Guide to Planning Care is a convenient reference to help the practicing nurse or nursing student make a nursing diagnosis and write a care plan with ease and confidence. This handbook helps nurses correlate nursing diagnoses with known information about clients on the basis of assessment findings; established medical, surgical, or psychiatric diagnoses; and the current treatment plan.

Making a nursing diagnosis and planning care are complex processes that involve diagnostic reasoning and critical thinking skills. Nursing students and practicing nurses cannot possibly memorize the extensive list of defining characteristics, related factors, and risk factors for the 244 diagnoses approved by NANDA-International (NANDA-I). There are also two additional diagnoses that the authors think are significant: Hearing Loss and Vision Loss. These diagnoses are contained in Appendix E. This book correlates suggested nursing diagnoses with what nurses know about clients and offers a care plan for each nursing diagnosis.

Section I, Nursing Process, Clinical Reasoning, Nursing Diagnosis, and Evidence-Based Nursing, is divided into two parts. Part A includes an overview of the nursing process. This section provides information on how to make a nursing diagnosis and directions on how to plan nursing care. It also includes information on using clinical reasoning skills and eliciting the "client's story." Part B includes advanced nursing concepts: concept mapping, QSEN (quality and safety education for nurses), evidence-based nursing care, quality nursing care, patient-centered care, safety, informatics in nursing, and team/collaborative work with an interprofessional team.

In **Section II, Guide to Nursing Diagnoses,** the nurse can look up symptoms and problems and their suggested nursing diagnoses for more than 1450 client symptoms; medical, surgical, and psychiatric diagnoses; diagnostic procedures; surgical interventions; and clinical states.

In **Section III, Guide to Planning Care,** the nurse can find care plans for all nursing diagnoses suggested in Section II. We have included the suggested nursing outcomes from the Nursing Outcomes Classification (NOC) and interventions from the Nursing Interventions Classification (NIC) by the Iowa Intervention Project. We believe this work is a significant addition to the nursing process to further define nursing practice with standardized language.

Scientific rationales based on research are included for most of the interventions. This is done to make the evidence base of nursing practice apparent to the nursing student and practicing nurse.

New special features of the twelfth edition of *Nursing Diagnosis Handbook: An Evidence-Based Guide to Planning Care* include the following:

- Labeling of classic older research studies that are still relevant as Classic Evidence-Based (CEB)
- Seventy-two revised nursing diagnoses approved by NANDA-I
- Addition of the terms At-Risk Populations and Associated Conditions to the diagnostic indicators as approved by NANDA-I
- NANDA-I approved change for the definition of the Health Promotion Diagnoses
- Seventeen new nursing diagnoses recently approved by NANDA-I, along with retiring eight nursing diagnoses: Risk for disproportionate growth, Noncompliance, Readiness for enhanced fluid balance, Readiness for enhanced urinary elimination, Risk for impaired cardiovascular function, Risk for ineffective gastrointestinal perfusion, Risk for ineffective renal perfusion, and Risk for imbalanced body temperature
- Eleven revisions of nursing diagnoses made by NANDA-I in existing nursing diagnoses
    - **Old diagnosis:** Deficient diversional activity
      Revised diagnosis: Decreased diversional activity engagement
    - **Old diagnosis:** Insufficient breast milk

Revised diagnosis: Insufficient breast milk production
- **Old diagnosis:** Neonatal jaundice
  Revised diagnosis: Neonatal hyperbilirubinemia
- **Old diagnosis:** Risk for neonatal jaundice
  Revised diagnosis: Risk for hyperbilirubinemia
- **Old diagnosis:** Impaired oral mucous membrane
  Revised diagnosis: Impaired oral mucous membrane integrity
- **Old diagnosis**: Risk for impaired oral mucous membrane
  Revised diagnosis: Risk for impaired oral mucous membrane integrity
- **Old diagnosis**: Risk for sudden infant death syndrome
  Revised diagnosis: Risk for sudden infant death
- **Old diagnosis**: Risk for trauma
  Revised diagnosis: Risk for physical trauma
- **Old diagnosis**: Risk for allergy response
  Revised diagnosis: Risk for allergic reaction
- **Old diagnosis**: Latex allergy response
  Revised diagnosis: Latex allergic reaction
- **Old diagnosis**: Risk for latex allergy response
  Revised diagnosis: Risk for latex allergic reaction

• Further addition of pediatric and critical care interventions to appropriate care plans
• An associated Evolve Online Course Management System that includes a care plan constructor, critical thinking case studies, Nursing Interventions Classification (NIC) and Nursing Outcomes Classification (NOC) labels, PowerPoint slides, review questions for the NCLEX-RN® exam, and appendixes for Nursing Diagnoses Arranged by Maslow's Hierarchy of Needs, Nursing Diagnoses Arranged by Gordon's Functional Health Patterns, Motivational Interviewing for Nurses, Wellness-Oriented Diagnostic Categories, and Nursing Care Plans for Hearing Loss and Vision Loss

The following features of *Nursing Diagnosis Handbook: A Guide to Planning Care* are also available:

• Suggested nursing diagnoses for more than 1450 clinical entities, including signs and symptoms, medical diagnoses, surgeries, maternal-child disorders, mental health disorders, and geriatric disorders
• Labeling of nursing research as EBN (Evidence-Based Nursing) and clinical research as EB (Evidence-Based) to identify the source of evidence-based rationales
• An Evolve Online Courseware System with a Care Plan Constructor that helps the student or nurse write a nursing care plan
• Rationales for nursing interventions that are (for the most part) based on nursing research
• Nursing references identified for each care plan
• A complete list of NOC Outcomes on the Evolve website
• A complete list of NIC Interventions on the Evolve website
• Nursing care plans that contain many holistic interventions
• Care plans written by leading national nursing experts from throughout the United States, along with international contributors, who together represent all of the major nursing specialties and have extensive experience with nursing diagnoses, the nursing process, and evidence-based practice. Several contributors are the original submitters/authors of the nursing diagnoses established by NANDA-I.

- A format that facilitates analyzing signs and symptoms by the process already known by nurses, which involves using defining characteristics of nursing diagnoses to make a diagnosis
- Use of NANDA-I terminology and approved diagnoses
- An alphabetical format for Sections II and III, which allows rapid access to information
- Nursing care plans for all nursing diagnoses listed in Section II
- Specific geriatric interventions in appropriate plans of care
- Specific client/family teaching interventions in each plan of care
- Information on culturally competent nursing care included where appropriate
- Inclusion of commonly used abbreviations (e.g., AIDS, MI, HF) and cross-references to complete terms in Section II

We acknowledge the work of NANDA-I, which is used extensively throughout this text. The original NANDA-I work can be found in *NANDA-I Nursing Diagnoses: Definitions & Classification 2018-2020*, eleventh edition.

We and the consultants and contributors trust that nurses will find this twelfth edition of *Nursing Diagnosis Handbook: An Evidence-Based Guide to Planning Care* a valuable tool that simplifies the process of identifying appropriate nursing diagnoses for clients and planning for their care, thus allowing nurses more time to provide evidence-based care that speeds each client's recovery.

Acknowledgments

We would like to thank the following people at Elsevier: Sandy E. Clark, Senior Content Strategist, who supported us with this twelfth edition of the text with intelligence and kindness; Jennifer Wade, Senior Content Development Specialist, who was a continual source of support; and a special thank you to Clay Broeker for the project management of this edition.

With gratitude, we acknowledge nurses and student nurses, who are always an inspiration for us to provide fresh and accurate material. We are honored that they continue to value this text and to use it in their studies and practice.

We would like to thank all of the dedicated contributors who are experts in their fields of nursing. We appreciate all of their hard work.

Care has been taken to confirm the accuracy of information presented in this book. However, the authors, editors, and publisher cannot accept any responsibility for consequences resulting from errors or omissions of the information in this book and make no warranty, express or implied, with respect to its contents. The reader should use practices suggested in this book in accordance with agency policies and professional standards. Every effort has been made to ensure the accuracy of the information presented in this text.

We hope you find this text useful in your nursing practice.

How to Use *Nursing Diagnosis Handbook: An Evidence-Based Guide to Planning Care*

Step 1: Assess

Following the guidelines in Section I, begin to formulate your nursing diagnosis by gathering and documenting the objective and subjective information about the client.

Nursing Process, Clinical Reasoning, Nursing Diagnosis, and Evidence-Based Nursing 3

Figure 1.1
Nursing process.

STEP 1: ASSESSMENT (ADPIE)

STEP 2: NURSING DIAGNOSIS (ADPIE)

Step 2: Diagnose

Turn to Section II, Guide to Nursing Diagnoses, and locate the client's symptoms, clinical state, medical or psychiatric diagnoses, and anticipated or prescribed diagnostic studies or surgical interventions (listed in alphabetical order). Note suggestions for appropriate nursing diagnoses.

Then use Section III, Guide to Planning Care, to evaluate each suggested nursing diagnosis and "related to" (r/t) etiology statement. Section III is a listing of care plans according to NANDA-I, arranged alphabetically by diagnostic concept, for each nursing diagnosis referred to in Section II. Determine the appropriateness of each nursing diagnosis by comparing the Defining Characteristics and/or Risk Factors to the client data collected.

Step 3: Determine Outcomes

Use Section III, Guide to Planning Care, to find appropriate outcomes for the client. Use either the NOC Outcomes with the associated rating scales or Client Outcomes as desired.

Plan Interventions

Use Section III, Guide to Planning Care, to find appropriate interventions for the client. Use the Nursing Interventions as found in that section.

Give Nursing Care

Administer nursing care following the plan of care based on the interventions.

Evaluate Nursing Care

Evaluate nursing care administered using either the NOC Outcomes or Client Outcomes. If the outcomes were not met and the nursing interventions were not effective, reassess the client and determine if the appropriate nursing diagnoses were made.

Document

Document all of the previous steps using the format provided in the clinical setting.

SECTION I

Nursing Process, Clinical Reasoning, Nursing Diagnosis, and Evidence-Based Nursing

OUTLINE

Introduction

Part A The Nursing Process Using Clinical Reasoning Skills to Determine Nursing Diagnoses and Plan Care

Part B Advanced Nursing Process Concepts

Introduction

Section I is divided into two parts. Part A includes an overview of the nursing process. This section provides information on how to make a nursing diagnosis and directions on how to plan nursing care. It also includes information on using clinical reasoning skills and eliciting the "patient's story." Part B includes advanced nursing concepts.

Part A: The Nursing Process: Using Clinical Reasoning Skills to Determine Nursing Diagnosis and Plan Care

1. **A**ssessing: performing a nursing assessment
2. **D**iagnosing: making nursing diagnoses
3. **P**lanning: formulating and writing outcome statements and determining appropriate nursing interventions based on appropriate best evidence (research)
4. **I**mplementing care
5. **E**valuating the outcomes and the nursing care that has been implemented. Make necessary revisions in care interventions as needed

Part B: Advanced Nursing Concepts

- Concept mapping
- Quality and Safety Education for Nurses (QSEN)
- Evidence-based nursing care
- Quality nursing care
- Patient-centered care
- Safety
- Informatics in nursing
- Team/collaborative work with interprofessional team

PART A

The Nursing Process

Using Clinical Reasoning Skills to Determine Nursing Diagnoses and Plan Care

The primary goals of nursing are to (1) determine client/family responses to human problems, level of wellness, and need for assistance; (2) provide physical care, emotional care, teaching, guidance, and counseling; and (3) implement interventions aimed at prevention and assisting the client to meet his or her own needs and health-related goals. The nurse must always focus on assisting clients and families to their highest level of functioning and self-care. The care that is provided should be structured in a way that allows clients the ability to influence their health care and accomplish their self-efficacy goals. The nursing process, which is a problem-solving approach to the identification and treatment of client problems, provides a framework for assisting clients and families to their optimal level of functioning. The nursing process involves five dynamic and fluid phases: **assessment, diagnosis, planning, implementation,** and **evaluation.** Within each of these phases, the client and family story is embedded and is used as a foundation for knowledge, judgment, and actions brought to the client care experience. A description of the "patient's story" and each aspect of the nursing process follow.

The "Patient's Story"

The "patient's story" is a term used to describe objective and subjective information about the client that describes who the client is as a person in addition to their usual medical history. Specific aspects of the story include physiological, psychological, and family characteristics; available resources; environmental and social context; knowledge; and motivation. Care is influenced, and often driven, by what the client states—verbally or through their physiological state. The "patient's story" is fluid and must be shared and understood throughout the client's health care experience.

There are multiple sources for obtaining the patient's story. The primary source for eliciting this story is through communicating directly with the client and the client's family. It is important to understand how the illness (or wellness) state has affected the client physiologically, psychologically, and spiritually. The client's perception of his or her health state is important to understand and may have an impact on subsequent interventions. At times, clients will be unable to tell their story verbally, but there is still much they can communicate through their physical state. The client's family (as the client defines them) is a valuable source of information and can provide a rich perspective on the client. Other valuable sources of the "patient's story" include the client's health record. Every time a piece of information is added to the health record, it becomes a part of the "patient's story." All nursing care is driven by the client's story. The nurse must have a clear understanding of the story to effectively complete the nursing process. Understanding the full story also provides an avenue for identifying mutual goals with the client and family aimed at improving client outcomes and goals.

Note: The "patient's story" is terminology that is used to describe a holistic assessment of information about the client, including the client's and the family's input as much as possible. In this text, we use the term "patient's story" in quotes whenever we refer to the specific process. In all other places, we use the term *client* in place of the word *patient*; we think labeling the person as a client is more respectful and empowering for the person. *Client* is also the term that is used in the National Council Licensure Examination (NCLEX-RN) test plan (National Council of State Boards of Nursing, 2016).

Understanding the "patient's story" is critically important, in that psychological, socioeconomic, and spiritual characteristics play a significant role in the client's ability and desire to access health care. Also knowing and understanding the "patient's story" is an integral first step in giving client-centered care. In today's health care world, the focus is on the client, which leads to increased satisfaction with care. Improving the client's health care experience is tied to reimbursement through value-based purchasing of care to reward providers for the quality of care they provide (Centers for Medicare and Medicaid Services, 2018).

The Nursing Process

The nursing process is an organizing framework for professional nursing practice, which is a critical thinking process for the nurse to use to give the best care possible to the client. It is very similar to the steps used in scientific reasoning and problem solving. This section is designed to help the nursing student learn how to use this thinking process, or the nursing process. Key components of the process include the steps listed subsequently. An easy, convenient way to remember the steps of the nursing process is to use an acronym, **ADPIE** (Figure I.1):

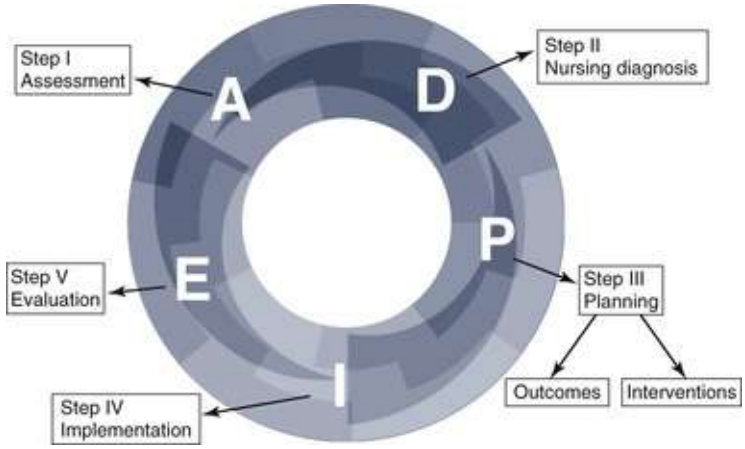

FIGURE I.1 Nursing process.

1. **A**ssess: perform a nursing assessment.
2. **D**iagnose: make nursing diagnoses.
3. **P**lan: formulate and write outcome/goal statements and determine appropriate nursing interventions based on the client's reality and evidence (research).
4. **I**mplement care.
5. **E**valuate the outcomes and the nursing care that has been implemented. Make necessary revisions in care interventions as needed.

The next section is an overview and practical application of the steps of the nursing process. The steps are listed in the usual order in which they are performed.

Step 1: Assessment (ADPIE)

The assessment phase of the nursing process is foundational for appropriate diagnosis, planning, and intervention. Data on all dimensions of the "patient's story," including biophysical, psychological, sociocultural, spiritual, and environmental characteristics, are embedded in the assessment, which involves performing a thorough holistic nursing assessment of the client. This is the first step needed to make an appropriate nursing diagnosis, and it is done using the assessment format adopted by the facility or educational institution in which the practice is situated.

The nurse assesses components of the "patient's story" every time an assessment is performed. Often, nurses focus on the physical component of the story (e.g., temperature, blood pressure, breath sounds). This component is certainly critical, but it is only one piece. Indeed, one of the unique and wonderful aspects of nursing is the holistic theory that is applied to clients and families. Clients are active partners in the healing process. Nurses must increasingly develop the skills and systems to incorporate client preferences into care (Feo et al, 2017). Assessment information is obtained first by completing a thorough health and medical history, and by listening to and observing the client. To elicit as much information as possible, the nurse should use open-ended questions, rather than questions that can be answered with a simple "yes" or "no." The nurse should assess for the client's gender identity choice when appropriate. That choice should be respected when caring for the client. Most care plans are written for "traditional " gender identity; the caregiver will be responsible for adapting the care accordingly.

In screening for depression in older clients, the following open-ended questions are useful (Lusk & Fater, 2013):

- What made you come here today?
- What do you think your problem is?
- What do you think caused your problem?
- Are you worried about anything in particular?
- What have you tried to do about the problem so far?
- What would you like me to do about your problem?
- Is there anything else you would like to discuss today?

These types of questions will encourage the client to give more information about his or her situation. Listen carefully for cues and record relevant information that the client shares. Even when the client's physical condition or developmental age makes it impossible for them to verbally communicate with the health care team, nurses may be able to communicate with the client's family or significant other to learn more about the client. The information that is obtained verbally from the client is considered *subjective* information.

Information is also obtained by performing a physical assessment, taking vital signs, and noting diagnostic test results. This information is considered *objective* information.

The information from all of these sources is used to formulate a nursing diagnosis. All of this information needs to be carefully documented on the forms provided by the agency or school of nursing. When recording information, the Health Insurance Portability and Accountability Act (HIPAA) (Tovino, 2017) regulations need to be followed carefully. To protect client confidentiality, the client's name should *not* be used on the student care plan. When the assessment is complete, proceed to the next step.

Step 2: Nursing Diagnosis (ADPIE)

In the diagnosis phase of the nursing process, the nurse begins clustering the information within the client story and formulates an evaluative judgment about a client's health status. Only after a thorough analysis—which includes recognizing cues, sorting through and organizing or clustering the information, and determining client strengths and unmet needs—can an appropriate diagnosis be made. This process of thinking is called *clinical reasoning*. Clinical reasoning is a cognitive process that uses formal and informal thinking strategies to gather and analyze client information, evaluate the significance of this information, and determine the value of alternative actions (Benner, 2010). Benner (2010) described this cognitive process as "thinking like a nurse." Watson and Rebair (2014) referred to "noticing" as a precursor to clinical reasoning. By noticing the nurse can preempt possible risks or support subtle changes toward recovery. Noticing can be the activity that stimulates nursing action before words are exchanged, preempting need. The nurse synthesizes the evidence while also knowing the client as part of clinical reasoning that informs client-specific diagnoses (Cappelletti, Engel, & Prentice, 2014).

The nursing diagnoses that are used throughout this book are taken from North American Nursing Diagnosis Association—International (Herdman & Kamitsuru, 2017). The complete nursing diagnosis list is on the inside front cover of this text, and it can also be found on the Evolve website that accompanies this text. The diagnoses used throughout this text are listed in alphabetical order by the **diagnostic concept.** For example, *impaired wheelchair mobility* is found under *mobility,* not under *wheelchair* or *impaired* (Herdman & Kamitsuru, 2018).

The holistic assessment of the client helps determine the type of diagnosis that follows. For example, if during the assessment a client is noted to have unsteady gait and balance disturbance and states, "I'm concerned I will fall while walking down my stairs," but has not fallen previously, then the client would be identified as having a "risk" nursing diagnosis.

Once the diagnosis is determined, the next step is to determine related factors and defining characteristics. The process for formulating a nursing diagnosis with related factors and defining characteristics is found in the next section. A client may have many nursing and medical diagnoses, and determining the priority with which each should be addressed requires clinical reasoning and application of knowledge.

Formulating a Nursing Diagnosis With Related Factors and Defining Characteristics

A working nursing diagnosis may have two or three parts. The two-part system consists of the nursing diagnosis and the "related to" (r/t) statement: "Related factors are etiologies, circumstances, facts, or influences that have some type of relationship with the nursing diagnosis (e.g., cause, contributed factor)." (Herdman & Kamitsuru, 2018).

The two-part system is often used when the defining characteristics, or signs and symptoms identified in the assessment, may be obvious to those caring for the client.

The three-part system consists of the nursing diagnosis, the r/t statement, and the defining characteristics, which are "observable cues/inferences that cluster as manifestations of an actual or wellness nursing diagnosis"

(Herdman & Kamitsuru, 2018).

Some nurses refer to the three-part diagnostic statement as the **PES system**:

P (problem)—The nursing diagnosis label: a concise term or phrase that represents a pattern of related cues. The nursing diagnosis is taken from the official NANDA-I list.
E (etiology)—"Related to" (r/t) phrase or etiology: related cause or contributor to the problem.
S (symptoms)—Defining characteristics phrase: symptoms that the nurse identified in the assessment.

Here we use the example of a beginning nursing student who is attempting to understand the nursing process and how to make a nursing diagnosis:

Problem: Use the nursing diagnosis label deficient **Knowledge** from the NANDA-I list. Remember to check the definition: "Absence or deficiency of cognitive information related to a specific topic" (Herdman & Kamitsuru, 2018).
Etiology: r/t unfamiliarity with information about the nursing process and nursing diagnosis. At this point the beginning nurse would not be familiar with available resources regarding the nursing process.
Symptoms: Defining characteristics, as evidenced by (aeb) verbalization of lack of understanding: "I don't understand this, and I really don't know how to make a nursing diagnosis."

When using the **PES** system, look at the **S** first, and then formulate the three-part statement. (You would have gotten the **S**, symptoms, which are defining characteristics, from your assessment.)

Therefore, the three-part nursing diagnosis is: deficient **Knowledge** r/t unfamiliarity with information about the nursing process and nursing diagnosis aeb verbalization of lack of understanding.

Types of Nursing Diagnoses

There are three different types of nursing diagnoses.

Problem-Focused Diagnosis.

"A clinical judgment concerning an undesirable human response to a health condition/life process that exists in an individual, family, group or community" (Herdman & Kamitsuru, 2018, p 35).

"Related factors are an integral part of all problem-focused diagnoses. Related factors are etiologies, circumstances, facts or influences that have some type of relationship with the nursing diagnosis (e.g., cause, contributed factor)" (Herdman & Kamitsuru, 2018, p 39).

Example of a Problem-Focused Nursing Diagnosis.

Overweight related to excessive intake in relation to metabolic needs, concentrating food intake at the end of the day aeb weight 20% over ideal for height and frame. Note: This is a three-part nursing diagnosis.

Risk Nursing Diagnosis.

Risk nursing diagnosis is a "clinical judgment concerning the susceptibility of an individual, family, group, or community for developing an undesirable human response to health conditions/life processes" (Herdman & Kamitsuru, 2018, p 35). "Risk factors are influences that increase the vulnerability of an individual, family, group, or community to an unhealthy event" (Herdman & Kamitsuru, 2018, p 39). Defining characteristics and related factors are observable cues and circumstances or influences that have some type of relationship with the nursing diagnosis that may contribute to a health problem. Identification of related factors allows nursing interventions to be implemented to address the underlying cause of a nursing diagnosis (Herdman & Kamitsuru, 2018, p 39).

Example of a Risk Nursing Diagnosis.

Risk for **Overweight:** Risk factor: concentrating food at the end of the day. Note: This is a two-part nursing diagnosis.

Health Promotion Nursing Diagnosis.

A clinical judgment concerning motivation and desire to increase well-being and to actualize health potential. These responses are expressed by a readiness to enhance specific health behaviors, and can be used in any health state. Health promotion responses may exist in an individual, family, group, or community (Herdman & Kamitsuru, 2018, p 35). Health promotion is different from prevention in that health promotion focuses on being as healthy as possible, as opposed to preventing a disease or problem. The difference between health promotion and disease prevention is that the reason for the health behavior should always be a positive one. *With a health*

promotion diagnosis, the outcomes and interventions should be focused on enhancing health.

Example of a Health Promotion Nursing Diagnosis.

Readiness for enhanced **Nutrition** aeb willingness to change eating pattern and eat healthier foods. Note: This is a two-part nursing diagnosis.

Application and Examples of Making a Nursing Diagnosis

When the assessment is complete, identify common patterns/symptoms of response *to actual or potential health problems from the assessment* and select an appropriate nursing diagnosis label using clinical reasoning skills. Use the steps with Case Study 1. (The same steps can be followed using an actual client assessment in the clinical setting or in a student assessment.)

A. Highlight or underline the relevant symptoms (defining characteristics). As you review your assessment information, ask: Is this normal? Is this an ideal situation? Is this a problem for the client? You may go back and validate information with the client.
B. Make a list of the symptoms (underlined or highlighted information).
C. Cluster similar symptoms.
D. Analyze/interpret the symptoms. (What do these symptoms mean or represent when they are together?)
E. Select a nursing diagnosis label from the NANDA-I list that fits the appropriate defining characteristics and nursing diagnosis definition.

Case Study 1—Older Client with Breathing Problems

A Underline the Symptoms (Defining Characteristics)

A 73-year-old man has been admitted to the unit with a diagnosis of chronic obstructive pulmonary disease (COPD). He states that he has "difficulty breathing when walking short distances." He also states that his "heart feels like it is racing" (heart rate is 110 beats per minute) at the same time. He states that he is "tired all the time," and while talking to you about his story, he is continually wringing his hands and looking out the window.

B List the Symptoms (Subjective and Objective)

"Difficulty breathing when walking short distances"; "heart feels like it is racing"; heart rate is 110 beats per minute; "tired all the time"; continually wringing his hands and looking out the window.

C Cluster Similar Symptoms

"Difficulty breathing when walking short distances"
"Heart feels like it is racing"; heart rate = 110 beats per minute
"Tired all the time"
Continually wringing his hands
Looking out the window

D Analyze

Interpret the Subjective Symptoms (What the Client Has Stated)

- "Difficulty breathing when walking short distances" = exertional discomfort: a defining characteristic of **Activity** intolerance
- "Heart feels like it is racing" = abnormal heart rate response to activity: a defining characteristic of **Activity** intolerance
- "Tired all the time" = verbal report of weakness: a defining characteristic of **Activity** intolerance

Interpret the Objective Symptoms (Observable Information)

- Continually wringing his hands = extraneous movement, hand/arm movements: a defining characteristic of **Anxiety**
- Looking out the window = poor eye contact, glancing about: a defining characteristic of **Anxiety**
- Heart rate = 110 beats per minute

E Select the Nursing Diagnosis Label

In Section II, look up *dyspnea (difficulty breathing)* or *dysrhythmia (abnormal heart rate or rhythm)*, which are chosen because they are high priority, and you will find the nursing diagnosis **Activity** intolerance listed with these symptoms. Is this diagnosis appropriate for this client?

To validate that the diagnosis **Activity** intolerance is appropriate for the client, turn to Section III and read the NANDA-I definition of the nursing diagnosis **Activity** intolerance: "Insufficient physiological or psychological energy to endure or complete required or desired daily activities" (Herdman & Kamitsuru, 2018, p 228). When reading the definition, ask, "Does this definition describe the symptoms demonstrated by the client?" "Is any more assessment information needed?" "Should I take his blood pressure or take an apical pulse rate?" If the appropriate nursing diagnosis has been selected, the definition should describe the condition that has been observed.

The client may also have defining characteristics for this particular diagnosis. Are the client's symptoms that you identified in the list of defining characteristics (e.g., verbal report of fatigue, abnormal heart rate response to activity, exertional dyspnea)?

Another way to use this text and to help validate the diagnosis is to look up the client's medical diagnosis in Section II. This client has a medical diagnosis of COPD. Is **Activity** intolerance listed with this medical diagnosis? Consider whether the nursing diagnosis makes sense given the client's medical diagnosis (in this case, COPD). There may be times when a nursing diagnosis is not directly linked to a medical diagnosis (e.g., ineffective **Coping**) but is nevertheless appropriate given nursing's holistic approach to the client/family.

The process of identifying significant symptoms, clustering or grouping them into logical patterns, and then choosing an appropriate nursing diagnosis involves diagnostic reasoning (critical thinking) skills that must be learned in the process of becoming a nurse. This text serves as a tool to help the learner in this process.

"Related to" Phrase or Etiology

The second part of the nursing diagnosis is the "related to" (r/t) phrase. Related factors are those that appear to show some type of patterned relationship with the nursing diagnosis. Such factors may be described as antecedent to, associated with, related to, contributing to, or abetting. Pathophysiological and psychosocial changes, such as developmental age and cultural and environmental situations, may be causative or contributing factors.

Often, a nursing diagnosis is complementary to a medical diagnosis and vice versa. Ideally the etiology (r/t statement), or cause, of the nursing diagnosis is something that can be treated independently by a nurse. When this is the case, the diagnosis is identified as an independent nursing diagnosis.

If medical intervention is also necessary, it might be identified as a collaborative nursing diagnosis. A carefully written, individualized r/t statement enables the nurse to plan nursing interventions and refer for diagnostic procedures, medical treatments, pharmaceutical interventions, and other interventions that will assist the client/family in accomplishing goals and return to a state of optimum health. Diagnoses and treatments provided by the multidisciplinary team all contribute to the client/family outcome. The coordinated effort of the team can only improve outcomes for the client/family and decrease duplication of effort and frustration among the health care team and the client/family.

The etiology is *not* the medical diagnosis. It may be the underlying issue contributing to the nursing diagnosis, but a medical diagnosis is *not* something the nurse can treat independently, without health care provider orders. In the case of the man with COPD, think about what happens when someone has COPD. How does this affect the client? What is happening to him because of this diagnosis?

For each suggested nursing diagnosis, the nurse should refer to the statements listed under the heading Related Factors (r/t) in Section III. These r/t factors may or may not be appropriate for the individual client. If they are not appropriate, the nurse should develop and write an r/t statement that is appropriate for the client. For the client from Case Study 1, a two-part statement could be made here:

Problem = Activity intolerance
Etiology = r/t imbalance between oxygen supply and demand

It was already determined that the client had **Activity** intolerance. With the respiratory symptoms identified from the assessment, imbalance between oxygen supply and demand is appropriate.

Defining Characteristics Phrase

The defining characteristics phrase is the third part of the three-part diagnostic system, and it consists of the signs and symptoms that have been gathered during the assessment phase. The phrase "as evidenced by" (aeb) may be used to connect the etiology (r/t) with the defining characteristics. The use of identifying defining characteristics is similar to the process that the health care provider uses when making a medical diagnosis. For example, the health care provider who observes the following signs and symptoms—diminished inspiratory and expiratory capacity of the lungs, complaints of dyspnea on exertion, difficulty in inhaling and exhaling deeply, and sometimes chronic cough—may make the medical diagnosis of COPD. This same process is used to identify the nursing diagnosis of **Activity** intolerance.

Put It All Together: Writing the Three-Part Nursing Diagnosis Statement

Problem—Choose the label (nursing diagnosis) using the guidelines explained previously. A list of nursing diagnosis labels can be found in Section II and on the inside front cover.
Etiology—Write an r/t phrase (etiology). These can be found in Section II.
Symptoms—Write the defining characteristics (signs and symptoms), or the "as evidenced by" (aeb) list. A list of the signs and symptoms associated with each nursing diagnosis can be found in Section III.

Case Study 1—73-Year-Old Male Client with Chronic Obstructive Pulmonary Disease (Continued)

Using the information from the earlier case study/example, the nursing diagnostic statement would be as follows:

Problem—**Activity** intolerance.
Etiology—r/t imbalance between oxygen supply and demand.
Symptoms—Verbal reports of fatigue, exertional dyspnea ("difficulty breathing when walking"), and abnormal heart rate response to activity ("racing heart"), heart rate 110 beats per minute.

Therefore, the nursing diagnostic statement for the client with COPD is **Activity** intolerance r/t imbalance between oxygen supply and demand aeb verbal reports of fatigue, exertional dyspnea, and abnormal heart rate in response to activity.

Consider a second case study:

Case Study 2—Woman with Insomnia

As before, the nurse always begins with an assessment. To make the nursing diagnosis, the nurse follows the steps below.

A Underline the Symptoms

A 45-year-old woman comes to the clinic and asks for medication to help her sleep. She states that she is worrying too much and adds, "It takes me about an hour to get to sleep, and it is very hard to fall asleep. I feel like I can't do anything because I am so tired. My job has become very stressful because of a new boss and too much work."

B List the Symptoms (Subjective and Objective)

Asks for medication to help her sleep; states she is worrying about too much; "It takes me about an hour to get to sleep"; "it is very hard to fall asleep"; "I feel like I can't do anything because I am so tired"; "My job has become very stressful because of a new boss and too much work."

C Cluster Similar Symptoms

Asks for medication to help her sleep
"It takes me about an hour to get to sleep."
"It is very hard to fall asleep."
"I feel like I can't do anything because I am so tired."
"I am worrying too much."
"My job is stressful."
"Too much work."

D Analyze/Interpret the Symptoms

Subjective Symptoms

- Asks for medication to help her sleep; "It takes me about an hour to get to sleep"; "it is very hard to fall asleep"; "I feel like I can't do anything because I am so tired." (All defining characteristics = verbal complaints of difficulty with sleeping.)
- States she is worrying too much (anxiety): "My job is stressful."

Objective Symptoms

- None

E Select a Nursing Diagnosis with Related Factors and Defining Characteristics

Look up "sleep" in Section II. Listed under the heading "**Sleep** pattern, disturbed" in Section II is the following information:

> **Insomnia** (nursing diagnosis) r/t anxiety and stress

This client states she is worrying too much, which may indicate anxiety; she also recently has increased job stress.

Look up **Insomnia** in Section III. Check the definition: "A disruption in amount and quality of sleep that impairs functioning" (Herdman & Kamitsuru, 2017, p 213). Does this describe the client in the case study? What are the related factors? What are the symptoms? Write the diagnostic statement:

> Problem—**Insomnia**
> Etiology—r/t anxiety, stress
> Symptoms—Difficulty falling asleep, "I am so tired, I can't do anything."

The nursing diagnostic statement is written in this format: **Insomnia** r/t anxiety and stress aeb difficulty falling asleep.

Note: There are more than 30 case studies available for both student and faculty use on the Evolve website that accompanies this text.

After the diagnostic statement is written, proceed to the next step: planning.

Step 3: Planning (ADPIE)

The planning phase of the nursing process includes the identification of priorities and determination of appropriate client-specific outcomes and interventions. The nurse in collaboration with the client and family (as applicable) and the rest of the health care team must determine the urgency of the identified problems and prioritize client needs. *Mutual goal setting,* along with s*ymptom pattern recognition* and *triggers,* helps prioritize interventions and determine which interventions are going to provide the greatest impact. *Symptom pattern recognition* and/or *triggers* is a process of identifying symptoms that clients have related to their illness, understanding which symptom patterns require intervention, and identifying the associated time frame to intervene effectively. For example, a client with heart failure is noted to gain 5 pounds overnight. Coupling this symptom with other symptoms of edema and shortness of breath while walking can be referred to as "symptom pattern recognition"—in this case, that the client is retaining fluid. The nurse, and often the client/family, recognize these symptoms as an immediate *cause* and that more action/intervention is needed to avoid a potential adverse outcome.

Nursing diagnoses should be prioritized based on urgent needs, diagnoses with high level of congruence with defining characteristics, related factors, or risk factors (Herdman & Kamitsuru, 2018, p 41). Use of ABC (airway, breathing, and circulation) and safety is a method to rank threats to the client's immediate survival or safety. The highest priority can also be determined by using Maslow's hierarchy of needs. In this hierarchy, priority is given to immediate problems that may be life-threatening (thus ABC). For example, ineffective **Airway** clearance, aeb the symptoms of increased secretions and increased use of inhaler related to asthma, creates an immediate cause compared to the nursing diagnosis of **Anxiety,** a love and belonging or security need, which makes it a lesser priority than ineffective **Airway** clearance. Refer to Appendix A on Evolve for assistance in prioritizing nursing diagnoses.

The planning phase should be done, whenever possible, with the client/family and the multidisciplinary team to maximize efforts and understanding, and increase compliance with the proposed plan and outcomes. For a

successful plan of care, measurable goals and outcomes, including nursing interventions, must be identified.

SMART Outcomes

When writing outcome statements, it can be helpful to use the acronym SMART, which means the outcome must be:

Specific
Measurable
Attainable
Realistic
Timed

The SMART acronym is used in business, education, and health care settings. This method assists the nurse in identifying patient outcomes more effectively.

Once priorities are established, outcomes for the client can be easily identified. Client-specific outcomes are determined based on the mutually set goals. Outcomes refer to the measurable degree of the client's response. The client's response/outcome may be intentional and favorable, such as leaving the hospital 2 days after surgery without any complications. The client's outcome can be negative and unintentional, such as demonstrating a surgical site infection. Generally, outcomes are described in relation to the client's response to interventions; for example, the client's cough becomes more productive after the client begins using the controlled coughing technique.

Based on the "patient's story," the nursing assessment, the mutual goals and outcomes identified by the caregiving team and the client/family, and the clinical reasoning that the nurse uses to prioritize his or her work, the nurse then decides what interventions to use. Based on the nurse's clinical judgment and knowledge, nursing interventions are defined as *all treatments that a nurse performs to enhance client outcomes*.

The selection of appropriate, effective interventions can be individualized to meet the mutual goals established by the client/family. It is then the nurses' education, experiences, and skills that allow them to select and carry out interventions to meet that mutual goal.

Outcomes

After the appropriate priority setting of the nursing diagnoses and interventions is determined, outcomes are developed or examined and decided on. This text includes standardized Nursing Outcomes Classification (NOC) outcomes written by a large team of University of Iowa College of Nursing faculty and students in conjunction with clinicians from a variety of settings (Moorhead et al, 2018). "Nursing-sensitive outcome (NOC) is an individual, family or community state, behavior or perception that is measured along a continuum in response to nursing interventions. The outcomes are stated as concepts that reflect a client, caregiver, family, or community state, perception of behavior rather than as expected goals" (Moorhead et al, 2018).

It is very important for the nurse to *involve* the client and/or family in determining appropriate outcomes. The use of outcomes information creates a continuous feedback loop that is essential to improve nursing quality, ensure patient safety, and secure the best possible client outcomes (Sim et al, 2018). The minimum requirements for rating an outcome are when the outcome is selected (i.e., the baseline measure) and when care is completed (i.e., the discharge summary). This may be sufficient in short-stay, acute-care settings. Depending on how rapidly the client's condition is expected to change, some settings may evaluate once a day or once a shift. Community agencies may evaluate every visit or every other visit, for example. Because measurement times are not standardized, they can be individualized for the client and the setting (Moorhead et al, 2018).

Development of appropriate outcomes can be done one of two ways: using the NOC list or developing an appropriate outcome statement, both of which are included in Section III. There are suggested outcome statements for each nursing diagnosis in this text that can be used as written or modified as necessary to meet the needs of the client.

The Evolve website includes a list of additional NOC outcomes. The use of NOC outcomes can be helpful to the nurse because they contain a five-point, Likert-type rating scale that can be used to evaluate progress toward achieving the outcome. In this text, the rating scale is listed, along with some of the more common indicators; for example, see the rating scale for the outcome **Sleep** (Table I.1).

TABLE I.1

Example NOC Outcome

				Sleep—0004			
Domain—Functional Health (I)				Care Recipient			
Class—Energy Maintenance (A)				Data Source:			
Scale(s)—Severely Compromised to Not Compromised (a) and Severe to None (n) **Definition:** Natural periodic suspension of consciousness during which the body is restored. Outcome Target Rating: Maintain at_____ Increase to _____							
	Sleep Overall Rating	**Severely Compromised**	**Substantially Compromised**	**Moderately Compromised**	**Mildly Compromised**	**Not Compromised**	
		1	2	3	4	5	
INDICATORS:							
000401	Hours of sleep	1	2	3	4	5	NA
000402	Observed hours of sleep	1	2	3	4	5	
000403	Sleep pattern	1	2	3	4	5	NA
000404	Sleep quality	1	2	3	4	5	NA
000405	Sleep efficiency	1	2	3	4	5	NA
000407	Sleep routine	1	2	3	4	5	NA
000418	Sleeps through the night consistently	1	2	3	4	5	NA
000408	Feelings of rejuvenation after sleep	1	2	3	4	5	NA
000410	Wakeful at appropriate times	1	2	3	4	5	NA
000419	Comfortable bed	1	2	3	4	5	NA
000420	Comfortable temperature in room	1	2	3	4	5	NA
000411	Electroencephalogram findings	1	2	3	4	5	NA

000425	Pain	1	2	3	4	5	NA

Adapted from Moorhead, S., Johnson, M., Maas, M. L., et al. (Eds.). (2018). *Nursing outcomes classification (NOC)* (6th ed.). St Louis: Elsevier.

Because the NOC outcomes are specific, they enhance the nursing process by helping the nurse measure and record the outcomes before and after interventions have been performed. The nurse can choose to have clients rate their own progress using the Likert-type rating scale. This involvement can help increase client motivation to progress *toward* outcomes.

After client outcomes are selected or written, and *discussed* with a client, the nurse plans nursing care with the client and establishes a means that will help the client achieve the selected outcomes. The usual means are nursing interventions.

Interventions

Interventions are like road maps directing the best ways to provide nursing care. The more clearly a nurse writes an intervention, the easier it will be to complete the journey and arrive at the destination of desired client outcomes.

Section III includes suggested interventions for each nursing diagnosis. The interventions are identified as independent (autonomous actions that are initiated by the nurse in response to a nursing diagnosis) or collaborative (actions that the nurse performs in collaboration with other health care professionals, and that may require a health care provider's order and may be in response to both medical and nursing diagnoses). The nurse may choose the interventions appropriate for the client and individualize them accordingly, or determine additional interventions.

This text also contains several suggested Nursing Interventions Classification (NIC) interventions for each

nursing diagnosis to help the reader see how NIC is used along with NOC and nursing diagnoses. The NIC interventions are a comprehensive, standardized classification of treatments that nurses perform. The classification includes both physiological and psychosocial interventions, and covers all nursing specialties. A list of NIC interventions is included on the Evolve website. For more information about NIC interventions, refer to the NIC text (Butcher & Bulechek, 2018).

Putting It All Together—Recording the Care Plan

The nurse must document the actual care plan, including prioritized nursing diagnostic statements, outcomes, and interventions. This may be done electronically or in writing. To ensure continuity of care, the plan must be documented and shared with all health care personnel caring for the client. This text provides rationales, most of which are research based, to validate that the interventions are appropriate and workable.

The Evolve website includes an electronic care plan constructor that can be easily accessed, updated, and individualized. Many agencies are using electronic records, and this is an ideal resource. See the inside front cover of this text for information regarding access to the Evolve website, or go to http://evolve.elsevier.com/Ackley/NDH.

Step 4: Implementation (ADPIE)

The implementation phase includes the "carrying out" of the specific, individualized, jointly agreed on interventions in the plan of care. Often, the interventions implemented are focused on *symptom management*, which is alleviating symptoms. Typically, nursing care does not involve "curing" the medical condition causing the symptom; rather, nursing care focuses on caring for the client/family so they can function at their highest level.

The implementation phase of the nursing process is the point at which you actually give nursing care. You perform the interventions that have been individualized to the client. All the hard work you put into the previous steps (ADP) can now be actualized to assist the client. As the interventions are performed, make sure that they are appropriate for the client. Consider that the client who was having difficulty breathing was also older. He may need extra time to carry out any activity. Check the rationale or research that is provided to determine why the intervention is being used. The evidence should support the individualized actions that you are implementing.

Client outcomes are achieved by the performance of the nursing interventions in collaboration with other disciplines and the client/family. During this phase, the nurse continues to assess the client to determine whether the interventions are effective and the desired outcomes are met.

Step 5: Evaluation (ADPIE)

The final phase of the nursing process is evaluation. Evaluation occurs not only at the end of the nursing process, but throughout the process. Evaluation of an intervention is, in essence, another nursing assessment; hence, the dynamic feature of the nursing process. The nurse reassesses the client, taking into consideration where the client was before the intervention (i.e., baseline) and where the client is after the intervention. Nurses are also in a great place (at the bedside) to evaluate how clients respond to other, multidisciplinary interventions, and their assessment of the client's response is valuable to determine whether the client's plan of care needs to be altered or not. For example, the client may receive 2 mg of morphine intravenously for pain (a pharmaceutical intervention to treat pain), and the nurse is the member of the health care team who can best assess how the client responded to that medication. Did the client receive relief from pain? Did the client develop any side effects? The nurse's documented evaluation of the client's response will be very helpful to the entire health care team.

The client/family can often tell the nurse how the intervention helped or did not help. This reassessment requires the nurse to revisit the mutual outcomes/goals set earlier and ask, "Are we moving toward that goal, or does the goal seem unreachable after the intervention?" If the outcomes were not met, the nurse begins again with assessment and determines the reason they were not met. Consider the **SMART** acronym and Case Study 1. Were the outcomes **S**pecific? Were the outcomes **M**easurable? Did the client's heart rate decrease? Did the client indicate that it was easier to breathe when walking from his bed to the bathroom? Were the outcomes **A**ttainable and **R**ealistic? Did he still report "being tired"? Did you allow adequate **T**ime for a positive outcome? Also ask yourself whether you identified the correct nursing diagnosis. Should the interventions be changed? At this point, the nurse can look up any new symptoms or conditions that have been identified and adjust the care plan as needed. Decisions about implementing additional interventions may be necessary; if so, they should be made in collaboration with the client/family if possible.

In some instances, the client/family/nurse triad will establish new, achievable goals and continue to cycle through the nursing process until the mutual goals are achieved.

Another important part of the evaluation phase is documentation. The nurse should use the facility's tool for

documentation and record the nursing activity that was performed as well as the results of the nursing interventions. Many facilities use problem-oriented charting, in which the nurse evaluates the care and client outcomes as part of charting. Documentation is also necessary for legal reasons, because in a legal dispute, *if it wasn't charted/recorded, it wasn't done*.

Many health care providers use critical pathways or care maps to plan nursing care. The use of nursing diagnoses should be an integral part of any critical pathway/care map to ensure that nursing care needs are being assessed and appropriate nursing interventions are planned and implemented.

PART B

Advanced Nursing Process Concepts

Conceptual Mapping and the Nursing Process

Conceptual mapping is an active learning strategy that promotes critical thinking and clinical judgment, and helps increase clinical competency (George et al, 2014; Jamison & Lis, 2014; Kaddoura, Van-Dyke, & Yang, 2016). Nurses identify complex client problems that require critical thinking to identify priority interventions based on current best evidence to impact client outcomes. (Kaddoura, Van-Dyke, & Yang, 2016). Concept mapping facilitates critical thinking and encourages deeper understanding of the complexity of concepts that influence nursing practice interventions (Lee et al, 2013). The process involves developing a diagram or pictorial representation of newly generated ideas. A concept map begins with a central theme or concept, and then related information is diagrammed radiating from the center theme. A concept map can be used to diagram the critical thinking strategy involved in applying the nursing process in practice.

Start with a blank sheet of paper; the client should be at the center of the paper. The next step involves linking to the person, via lines, the symptoms (defining characteristics) from the assessment to help determine the appropriate nursing diagnosis.

Figure I.2 is an example of how a concept map can be used to begin the nursing diagnostic process.

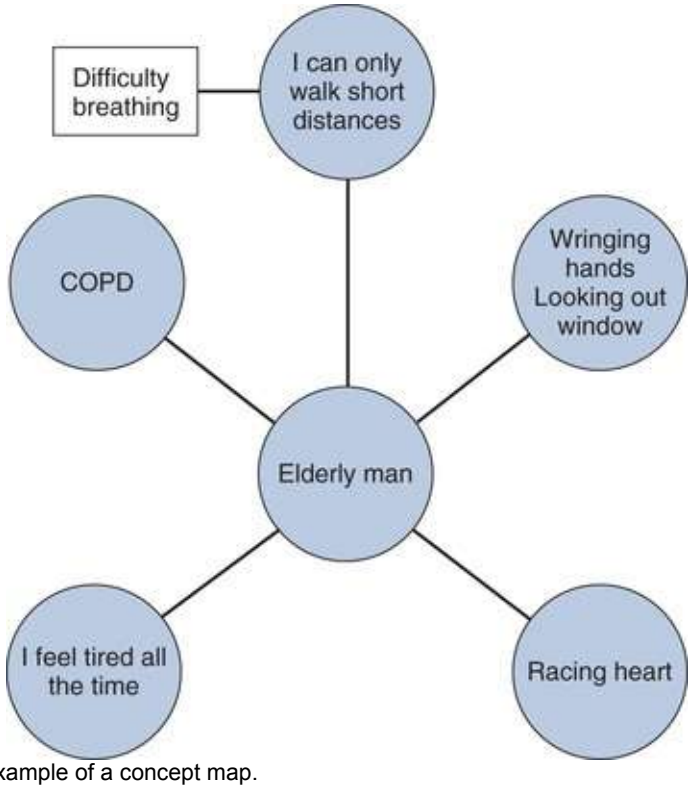

FIGURE I.2 Example of a concept map.

After the symptoms are visualized, similar ones can be put together to formulate a nursing diagnosis using another concept map (Figure I.3).

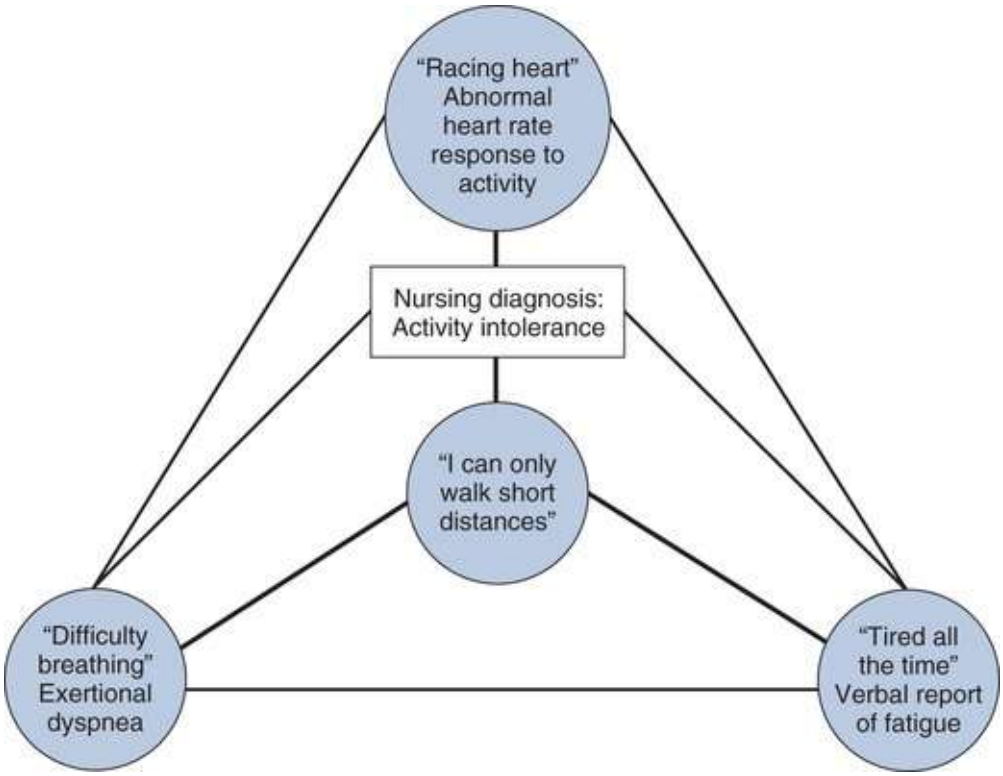

FIGURE I.3 Formulating a nursing diagnosis using a concept map.

The central theme in this concept map is the nursing diagnosis: **Activity** intolerance, with the defining characteristics/client symptoms as concepts that lead to and support the nursing diagnosis. The conceptual map can then be used as a method for determining outcomes and interventions as desired. The nursing process is a thinking process. Using conceptual mapping is a method to help the nurse or nursing student think more effectively about the client.

Quality and Safety Education for Nurses

The QSEN (2018) project represents the nursing profession's response to the five health care competencies articulated by the Institute of Medicine (now called the National Academy of Medicine) (2003). These competencies were adopted by nursing leaders to guide nursing education to better meet the evolving needs of clients and the health care system. (Cronenwett et al, 2007). The QSEN project defined the six competencies for nursing: patient-centered care, teamwork and collaboration, evidence-based practice (EBP), quality improvement, safety, and informatics (Cronenwett et al, 2007). The objective of the QSEN project is to provide nurses with the knowledge, skills, and attitudes critical for improving the quality and safety of health care systems. Initially, QSEN was developed to enhance nursing education, but it has since been incorporated into practice settings (Lyle-Edrosolo & Waxman, 2016). Additionally, the core elements of QSEN map to key practice initiatives identified by The Joint Commission (TJC) and The American Nurses Credentialing Center Magnet (Magnet) recognition program (The Joint Commission, 2018). A crosswalk of the similarities of the QSEN competencies to TJC and Magnet demonstrates the alignment of the QSEN competencies to guide nursing practice excellence to improve the quality and safety of health care (Lyle-Edrosolo & Waxman, 2016; QSEN, 2018). The following are the competencies that were identified.

Patient-Centered Care

Patient-centered care is the ability to "recognize the patient or designee as the source of control and full partner in providing compassionate and coordinated care based on respect for patient's preferences, values, and needs" (QSEN, 2018). Patient-centered care begins with the nurse learning as much as possible about the client, including their "client's story" as explained in Part A of this text. The nursing process, using nursing diagnosis, is intrinsically all about patient-centered care when the nurse engages the client/family as a full partner in the entire process: assessment, nursing diagnosis selection, outcomes, interventions, and evaluation. This competency is about providing care in partnership with the client and family. The client, family, nurse, health care provider, and other health care workers form a team to collaborate with the client and family in every way

possible to achieve health.

Client education needs to be centered on the needs of the client, addressing behavior-changing techniques to accomplish the defined goals. At present, too often new health information is given to clients in the form of a lecture, handout, admonishment, or direction where the client is powerless. Conversations need to occur between the client and nurse to understand behavioral changes that can be implemented to achieve goals. Motivational interviewing is a technique based on reinforcement of the client's present thoughts and motivations on behavior change, and based on respect for the client as an individual (Miller & Rollnick, 2013). This technique has been used for almost 30 years and has an extensive research base showing effectiveness by engaging in conversations to empower clients to identify strategies and tools to achieve health care goals. To learn more about motivational interviewing, refer to Appendix C on Evolve.

Addressing the unique cultural needs of clients is another example of patient-centered care. Nurses who are culturally competent base care planning on cultural awareness and assessments, which enables them to identify client values, beliefs, and preferences. Cultural awareness can ensure safe and quality outcomes for all clients by assisting clients to become "safety allies" who can alert professionals to their preferences and deviations from their usual routines (Sherwood & Zomorodi, 2014). This text provides the addition of multicultural interventions that reflect the client's cultural preferences, values, and needs.

Patient-centered care can help nurses change attitudes toward clients, especially when caring for older clients (Pope, 2012). Caring for the retired school teacher who raised four children can be different from just caring for the client woman in Room 234 who has her call light on frequently and is incontinent of urine at too-frequent intervals. Including the client and family in the bedside report and care decisions is key to patient satisfaction and enhances overall quality of care (Flagg, 2015).

Teamwork and Collaboration

Teamwork and collaboration are defined as the ability to "function effectively within nursing and interprofessional teams, fostering open communication, mutual respect, and shared decision-making to achieve quality client care" (QSEN, 2018). Interprofessional collaboration has the potential to shift the attitudes and perceptions of health care providers so there is an increased awareness of each other's roles, values, and disciplinary knowledge (Wilson et al, 2014). The need for collaboration by health care professionals is a reality of contemporary health care practice and is identified within each nursing diagnosis in this text. Many nursing interventions are referrals to other health care personnel to best meet the client's needs; thus collaborative interventions are designated with a triangular symbol ▲.

Evidence-Based Practice

QSEN defines EBP as the integration of best current evidence with clinical expertise and client/family preferences and values for delivery of optimal health care (QSEN, 2018). It is well established that EBP results in higher quality care for clients than care that is based on traditional nursing knowledge (Makic et al, 2014; Buccheri et al, 2017). It is imperative that each nurse and nursing student develops clinical inquiry skills, which means the nurse continually questions whether care is being given in the best way possible based on a review of the quality and strength of the evidence (Buccheri et al, 2017). Basing nursing practice on evidence, inclusive of research and other forms of evidence, is a concept that is incorporated throughout this text. EBP is a systematic process that uses current evidence in making decisions about the care of clients, including evaluation of quality and applicability of existing research, client preferences, clinical expertise, and available health care resources (Melnyk & Fineout-Overholt, 2015). To determine the best way of giving care, the use of EBP is needed. To make this happen, nurses need ready access to the evidence.

This text includes evidence-based rationales whenever possible. An effort is made to provide research-based rationales. The evidence ranges along a continuum from a case study about a single client to a systematic review performed by experts to quality improvement reports that provide information to guide nursing care. Every attempt has been made to supply the most current evidence for the nursing interventions. In Section III, the abbreviation **EBN** is used when interventions have a scientific rationale supported by nursing research. The abbreviation **EB** is used when interventions have a scientific rationale supported by research that has been obtained from disciplines other than nursing. **CEB** is used as a heading for classic research that has not been replicated or is older. It may be either nursing research or research from other disciplines. Many times the **CEB**-labeled research will be the seminal studies that were conducted addressing client concern or nursing care intervention.

When using **EBP,** it is vitally important that the client's concerns and individual situations be taken into consideration. The nurse must always use critical thinking when applying evidence-based guidelines to any particular nursing situation. Each client is unique in his or her needs and capabilities. To improve outcomes, clinicians and clients should collaborate to formulate a treatment plan that incorporates both evidence-based data and client preferences within the context of each client's specific clinical situation (Mackey and Bassendowski, 2017). This text integrates current best evidence and the nursing process, and it assists the nurse in increasing the use of evidence-based interventions in the clinical setting.

Quality Improvement

Quality improvement has been used for many years, with processes in place to ensure that the client receives appropriate care. The QSEN quality improvement competency is defined as the ability of the nurse to use data to monitor the outcomes of care processes and use improvement methods to design and test changes to continuously improve the quality and safety of health care systems (QSEN, 2018). QSEN resources supporting quality improvement initiatives are available at their website http://qsen.org/competencies/quality-improvement-resources-2/. As with EBP, quality improvement initiatives need to critically examine research and other forms of strong evidence in supporting process changes. Research is the basis on which best practice should be supported (Odom-Forren, 2013) Research in addition to other forms of evidence, such as quality improvement studies, provide a growing body of evidence to guide practice.

It is essential for nurses to participate in the work of quality and performance improvement to attain and sustain excellence in nursing care. As nurses are educated about performance and quality measures, they are more likely to value these activities and make quality improvement part of their nursing practice (Nelson, 2014). Although there is potential overlap of work in quality departments and EBP/research departments, the hope is that quality departments collaborate closely with EBP/research departments to improve the practice of nursing. Best evidence should be used to guide nursing practice interventions, and quality improvement critically evaluates and enhances the process of care to ensure effective delivery of high quality, evidence-based care to clients.

Safety

Safety is defined as minimizing risk of harm to clients and providers through both system effectiveness and individual performance (QSEN, 2018). Client safety is a priority when health care is delivered. Nurses are required to adhere to established standards of care as a guideline for providing safe client care. Internal organizational policies and procedures established by health care institutions should be based on the most relevant and current evidence to guide safe practice standards. External standards of care are established by regulatory agencies (e.g., TJC), professional organizations (e.g., the American Nurses Association), and health care organizations. QSEN competencies align well with external agencies guiding safe practice expectations (Lyle-Edrosolo & Waxman, 2016).

Client safety was identified as a priority of care by TJC through the launch of National Patient Safety Goals in 2002. TJC continually reviews and establishes standards for improving client safety that include the need for increased handwashing, better client identification before receiving medications or treatments, and protection of suicidal clients from self-harm. Many of the safety standards have been incorporated into the care plans in this text.

Informatics

QSEN defines informatics as the nurse's ability to use information and technology to communicate, manage knowledge, mitigate error, and support decision-making (QSEN, 2018). The use of information technology is a critical part of the nurse's professional role, and every nurse must be computer literate (Technology Informatics Guiding Education Reform [TIGER], 2018). Key technology and computer proficiencies for nursing practice should include basic computer system and desktop skills; the ability to search for client information; communication using email; ability to search electronic health care databases; and use of technology for client education, client documentation, and client monitoring (Hubner et al, 2017; TIGER, 2018).

In addition to computer literacy, nurses must also acquire informatic knowledge that addresses client privacy and the security of health care information as it applies to the use of technology (Hubner et al, 2017; TIGER, 2018). Because nurses document on the electronic medical record and use smartphones for access to information on medications, diagnoses, and treatments, there are constant threats to client confidentiality, which needs to be maintained through secure access systems. Nurses also use clinical decision support systems in many facilities that contain order sets tailored for conditions or types of clients. These systems include information vital to nurses and also may provide alerts about potentially dangerous situations when giving client care.

Nurses need access to technology to effectively bring evidence to the client bedside because evidence is constantly evolving. Use of informatics is integral in the use of EBP. As evidence changes, practice should also change. Moving best evidence consistently into practice requires behavior changes by the clinician and system to effectively implement best evidence into practice. Similarly, habits in practice that result in unnecessary care need to be deimplemented. (van Bodegrom-Vos, Dvidoff, & Marang-van de Mheen, 2017). The Choosing Wisely campaign primarily focused on deimplementing unnecessary medical tests or treatments that were found to not provide benefit to patients (Levinson et al, 2015). Similarly, there are interventions that nurses should question because these interventions may not be beneficial for clients. The American Academy of Nursing maintains a list of nursing interventions that should be questioned as to client benefit. Continually reviewing the evidence to implement best practice while deimplementing interventions that are no longer supported by evidence or may no longer be truly necessary requires the nurses to remain actively engaged in EBP as a practice norm (American Academy of Nursing, 2015).

EBP, safety initiatives, informatics, patient-centered care, teamwork, and quality work together in a synergistic manner lead to excellence in nursing care. Quality care needs to be more than safe; the care should result in the best outcome possible for the client. For this to happen, the client should receive care that is based on evidence of

the effectiveness of the nursing care interventions.

The nursing process is continually evolving. This text is all about *thinking* for the nurse to help the client in any way possible. Our goal is to present state-of-the art information to help the nurse and nursing student provide the best care possible.

Introduction

Section II is an alphabetical listing of client symptoms, client problems, medical diagnoses, psychosocial diagnoses, and clinical states. Each of these will have a list of possible nursing diagnoses. You may use this section to find suggestions for nursing diagnoses for your client.

- Assess the client using the format provided by the clinical setting.
- Locate the client's symptoms, problems, clinical state, diagnoses, surgeries, and diagnostic testing in the alphabetical listing contained in this section.
- Note suggestions given for appropriate nursing diagnoses.
- Evaluate the suggested nursing diagnoses to determine whether they are appropriate for the client and have information that was found in the assessment.
- Use Section III (which contains an alphabetized list of all NANDA-I approved nursing diagnoses) to validate this information and check the definition, related factors, and defining characteristics. Determine whether the nursing diagnosis you have selected is appropriate for the client.

List of Nursing Diagnosis by Letter

A

Abdominal Distention	Abdominal Hysterectomy	Abdominal Pain
Abdominal Surgery	Abdominal Trauma	Ablation, Radiofrequency Catheter
Abortion, Induced	Abortion, Spontaneous	Abruptio Placentae <36 Weeks
Abscess Formation	Abuse, Child	Abuse, Spouse, Parent, or Significant Other
Accessory Muscle Use (to Breathe)	Accident Prone	Achalasia
Acid-Base Imbalances	Acidosis, Metabolic	Acidosis, Respiratory
Acne	Acromegaly	Activity Intolerance, Potential to Develop
Acute Abdominal Pain	Acute Alcohol Intoxication	Acute Back Pain
Acute Confusion	Acute Coronary Syndrome	Acute Lymphocytic Leukemia (ALL)
Acute Renal Failure	Acute Respiratory Distress Syndrome	Acute Substance Withdrawal Syndrome
Adams–Stokes Syndrome	Addiction	Addison's Disease
Adenoidectomy	Adhesions, Lysis of	Adjustment Disorder
Adjustment Impairment	Adolescent, Pregnant	Adoption, Giving Child Up for
Adrenocortical Insufficiency	Advance Directives	Affective Disorders
Age-Related Macular Degeneration	Aggressive Behavior	Aging
Agitation	Agoraphobia	Agranulocytosis
AIDS (Acquired Immunodeficiency Syndrome)	AIDS, Child	AIDS Dementia
Airway Obstruction/Secretions	Alcohol Withdrawal	Alcoholism
Alcoholism, Dysfunctional Family Processes	Alkalosis	ALL (Acute Lymphocytic Leukemia)
Allergies	Alopecia	ALS (Amyotrophic Lateral Sclerosis)
Altered Mental Status	Alzheimer's Disease	AMD (Age-Related Macular Degeneration)
Amenorrhea	AMI (Acute Myocardial Infarction)	Amnesia
Amniocentesis	Amnionitis	Amniotic Membrane Rupture
Amputation	Amyotrophic Lateral Sclerosis (ALS)	Anal Fistula
Anaphylactic Shock	Anaphylaxis Prevention	Anasarca
Anemia	Anemia, in Pregnancy	Anemia, Sickle Cell
Anencephaly	Aneurysm, Abdominal Aortic	Aneurysm, Cerebral

	Repair Surgery	
Anger	Angina	Angiocardiography (Cardiac Catheterization)
Angioplasty, Coronary	Anomaly, Fetal/Newborn (Parent Dealing with)	Anorectal Abscess
Anorexia	Anorexia Nervosa	Anosmia (Smell, Loss of Ability to)
Antepartum Period	Anterior Repair, Anterior Colporrhaphy	Anticoagulant Therapy
Antisocial Personality Disorder	Anuria	Anxiety
Anxiety Disorder	Aortic Valvular Stenosis	Aphasia
Aplastic Anemia	Apnea in Infancy	Apneustic Respirations
Appendectomy	Appendicitis	Apprehension
ARDS (Acute Respiratory Distress Syndrome)	Arrhythmia	Arterial Insufficiency
Arthritis	Arthrocentesis	Arthroplasty (Total Hip Replacement)
Arthroscopy	Ascites	Asperger's Syndrome
Asphyxia, Birth	Aspiration, Danger of	Assault Victim
Assaultive Client	Asthma	Ataxia
Atelectasis	Atherosclerosis	Athlete's Foot
ATN (Acute Tubular Necrosis)	Atrial Fibrillation	Atrial Septal Defect
Attention Deficit Disorder	Autism	Autonomic Dysreflexia
Autonomic Hyperreflexia		

A

Abdominal Distention

Constipation r/t decreased activity, decreased fluid intake, decreased fiber intake, pathological process
Dysfunctional Gastrointestinal motility r/t decreased perfusion of intestines, medication effect
Nausea r/t irritation of gastrointestinal tract
Imbalanced Nutrition: less than body requirements r/t nausea, vomiting
Acute Pain r/t retention of air, gastrointestinal secretions
Delayed Surgical recovery r/t retention of gas, secretions

Abdominal Hysterectomy

See Hysterectomy

Abdominal Pain

Dysfunctional Gastrointestinal motility r/t decreased perfusion, medication effect
Acute Pain r/t injury, pathological process

Abdominal Surgery

Constipation r/t decreased activity, decreased fluid intake, anesthesia, opioids
Dysfunctional Gastrointestinal motility r/t medication or anesthesia effect, trauma from surgery
Imbalanced Nutrition: less than body requirements r/t high metabolic needs, decreased ability to ingest or digest food
Acute Pain r/t surgical procedure
Ineffective peripheral Tissue Perfusion r/t immobility, abdominal surgery
Risk for delayed Surgical recovery: Risk factor: extensive surgical procedure
Risk for Surgical Site Infection: Risk factor: invasive procedure
Risk for Venous Thromboembolism: Risk factor: immobility, surgery
Readiness for enhanced Knowledge: expresses an interest in learning
See Surgery, Perioperative Care; Surgery, Postoperative Care; Surgery, Preoperative Care

Abdominal Trauma

Disturbed Body Image r/t scarring, change in body function, need for temporary colostomy
Ineffective Breathing pattern r/t abdominal distention, pain
Deficient Fluid volume r/t hemorrhage, active fluid volume loss
Dysfunctional Gastrointestinal motility r/t decreased perfusion
Acute Pain r/t abdominal trauma
Risk for Bleeding: Risk factor: trauma and possible contusion/rupture of abdominal organs
Risk for Infection: Risk factor: possible perforation of abdominal structures

Ablation, Radiofrequency Catheter

Fear r/t invasive procedure

Risk for decreased Cardiac tissue perfusion: Risk factor: catheterization of heart

Abortion, Induced

Compromised family Coping r/t unresolved feelings about decision
Acute Pain r/t surgical intervention
Chronic low Self-Esteem r/t feelings of guilt
Chronic Sorrow r/t loss of potential child
Risk for Bleeding: Risk factor: trauma from abortion
Risk for delayed Development: Risk factors: unplanned or unwanted pregnancy
Risk for Infection: Risk factors: open uterine blood vessels, dilated cervix
Risk for Post-Trauma syndrome: Risk factor: psychological trauma of abortion
Risk for Spiritual distress: Risk factor: perceived moral implications of decision
Readiness for enhanced Health literacy: expresses desire to enhance personal health care decisions
Readiness for enhanced Knowledge: expresses an interest in learning

Abortion, Spontaneous

Disturbed Body Image r/t perceived inability to carry pregnancy, produce child
Disabled family Coping r/t unresolved feelings about loss
Ineffective Coping r/t personal vulnerability
Interrupted Family processes r/t unmet expectations for pregnancy and childbirth
Fear r/t implications for future pregnancies
Grieving r/t loss of fetus
Acute Pain r/t uterine contractions, surgical intervention
Situational low Self-Esteem r/t feelings about loss of fetus
Chronic Sorrow r/t loss of potential child
Risk for Bleeding: Risk factor: trauma from abortion
Risk for Infection: Risk factors: septic or incomplete abortion of products of conception, open uterine blood vessels, dilated cervix
Risk for Post-Trauma syndrome: Risk factor: psychological trauma of abortion
Risk for Spiritual distress: Risk factor: loss of fetus
Readiness for enhanced Knowledge: expresses an interest in learning

Abruptio Placentae <36 Weeks

Anxiety r/t unknown outcome, change in birth plans
Death Anxiety r/t unknown outcome, hemorrhage, or pain
Interrupted Family processes r/t unmet expectations for pregnancy and childbirth
Fear r/t threat to well-being of self and fetus
Impaired Gas exchange: **placental** r/t decreased uteroplacental area
Acute Pain r/t irritable uterus, hypertonic uterus
Impaired Tissue integrity: **maternal** r/t possible uterine rupture
Risk for Bleeding: Risk factor: separation of placenta from uterus causing bleeding
Risk for Infection: Risk factor: partial separation of placenta
Risk for disturbed Maternal–Fetal dyad: Risk factors: trauma of process, lack of energy of mother
Risk for Shock: Risk factor: separation of placenta from uterus
Readiness for enhanced Knowledge: expresses an interest in learning

Abscess Formation

Ineffective Protection r/t inadequate nutrition, abnormal blood profile, drug therapy, depressed immune function
Impaired Tissue integrity r/t altered circulation, nutritional deficit or excess
Readiness for enhanced Knowledge: expresses an interest in learning

Abuse, Child

See Child Abuse

Abuse, Spouse, Parent, or Significant Other

Anxiety r/t threat to self-concept, situational crisis of abuse
Caregiver Role Strain r/t chronic illness, self-care deficits, lack of respite care, extent of caregiving required
Impaired verbal Communication r/t psychological barriers of fear
Compromised family Coping r/t abusive patterns
Defensive Coping r/t low self-esteem
Dysfunctional Family processes r/t inadequate coping skills
Insomnia r/t psychological stress
Post-Trauma syndrome r/t history of abuse
Powerlessness r/t lifestyle of helplessness
Chronic low Self-Esteem r/t negative family interactions
Risk for impaired emancipated Decision-Making: Risk factor: inability to verbalize needs and wants
Risk for Female Genital Mutilation: Risk factor: lack of family knowledge about impact of practice on physical health
Risk for self-directed Violence: Risk factor: history of abuse

Accessory Muscle Use (to Breathe)

Ineffective Breathing pattern (See **Breathing** pattern, ineffective, Section III)
See Asthma; Bronchitis; COPD (Chronic Obstructive Pulmonary Disease); Respiratory Infections, Acute Childhood (Croup, Epiglottis, Pertussis, Pneumonia, Respiratory Syncytial Virus)

Accident Prone

Frail Elderly syndrome r/t history of falls
Acute Confusion r/t altered level of consciousness
Ineffective Coping r/t personal vulnerability, situational crises
Ineffective Impulse control (See **Impulse** control, ineffective, Section III)
Risk for Injury: Risk factor: history of accidents

Achalasia

Ineffective Coping r/t chronic disease
Acute Pain r/t stasis of food in esophagus
Impaired Swallowing r/t neuromuscular impairment
Risk for Aspiration: Risk factor: nocturnal regurgitation

Acid-Base Imbalances

Risk for Electrolyte imbalance: Risk factors: renal dysfunction, diarrhea, treatment-related side effects (e.g., medications, drains)

Acidosis, Metabolic

Acute Confusion r/t acid-base imbalance, associated electrolyte imbalance
Impaired Memory r/t effect of metabolic acidosis on brain function
Imbalanced Nutrition: **less than body requirements** r/t inability to ingest, absorb nutrients
Risk for Electrolyte imbalance: Risk factor: effect of metabolic acidosis on renal function
Risk for Injury: Risk factors: disorientation, weakness, stupor
Risk for decreased Cardiac tissue perfusion: Risk factor: dysrhythmias from hyperkalemia
Risk for Shock: Risk factors: abnormal metabolic state, presence of acid state impairing function,

decreased tissue perfusion

Acidosis, Respiratory

Activity intolerance r/t imbalance between oxygen supply and demand
Impaired Gas exchange r/t ventilation-perfusion imbalance
Impaired Memory r/t hypoxia
Risk for decreased Cardiac tissue perfusion: Risk factor: dysrhythmias associated with respiratory acidosis

Acne

Disturbed Body Image r/t biophysical changes associated with skin disorder
Ineffective Health management r/t insufficient knowledge of therapeutic regimen
Impaired Skin integrity r/t hormonal changes (adolescence, menstrual cycle)

Acromegaly

Activity intolerance (See **Activity** intolerance, Section III)
Ineffective Airway clearance r/t airway obstruction by enlarged tongue
Disturbed Body Image r/t changes in body function and appearance
Impaired physical Mobility r/t joint pain
Risk for decreased Cardiac tissue perfusion: Risk factor: increased atherosclerosis from abnormal health status
Risk for unstable blood Glucose level: Risk factor: abnormal physical health status
Sexual dysfunction r/t changes in hormonal secretions
Risk for Overweight: Risk factor: energy expenditure less than energy intake

Activity Intolerance, Potential to Develop

Activity intolerance (See **Activity** intolerance, Section III)

Acute Abdominal Pain

Deficient Fluid volume r/t air and fluids trapped in bowel, inability to drink
Acute Pain r/t pathological process
Risk for dysfunctional Gastrointestinal motility: Risk factor: ineffective gastrointestinal tissue perfusion
See Abdominal Pain

Acute Alcohol Intoxication

Ineffective Breathing pattern r/t depression of the respiratory center from excessive alcohol intake
Acute Confusion r/t central nervous system depression
Dysfunctional Family processes r/t abuse of alcohol
Risk for Aspiration: Risk factor: depressed reflexes with acute vomiting
Risk for Infection: Risk factor: impaired immune system from malnutrition associated with chronic excessive alcohol intake
Risk for Injury: Risk factor: chemical (alcohol)

Acute Back Pain

Anxiety r/t situational crisis, back injury
Constipation r/t decreased activity, effect of pain medication

Ineffective Coping r/t situational crisis, back injury
Impaired physical Mobility r/t pain
Acute Pain r/t back injury
Readiness for enhanced Knowledge: expresses an interest in learning

Acute Confusion

See Confusion, Acute

Acute Coronary Syndrome

Decreased Cardiac output r/t cardiac disorder
Risk for decreased Cardiac tissue perfusion (See **Cardiac** tissue perfusion, risk for decreased, Section III)
See Angina; Myocardial Infarction (MI)

Acute Lymphocytic Leukemia (ALL)

See Cancer; Chemotherapy; Child with Chronic Condition; Leukemia

Acute Renal Failure

See Renal Failure

Acute Respiratory Distress Syndrome

See ARDS (Acute Respiratory Distress Syndrome)

Acute Substance Withdrawal Syndrome

Anxiety r/t unknown outcome of withdrawal sequence, physiological effects
Imbalanced Energy Field r/t hyperactivity of energy flow
Impaired Comfort r/t restlessness and agitation
Acute Confusion r/t effects of substance withdrawal
Ineffective Coping r/t situational crisis, withdrawal
Labile Emotional Control r/t lack of control over the progression of withdrawal process
Fear r/t threat to well-being of self
Insomnia r/t physical and psychological effects of substance withdrawal
Imbalanced Nutrition: **less than body requirements** r/t nausea, anxiety
Powerlessness r/t loss of ability to control withdrawal process
Risk for acute Confusion: Risk factor: possible alteration in level of consciousness
Risk for Injury: Risk factor: alteration in sensory perceptual functioning
Risk for Suicide: Risk factor: psychic pain
Risk for other-directed Violence: Risk factors: poor impulse control, hallucinations
Risk for self-directed Violence: Risk factors: poor impulse control, hallucinations

Adams–Stokes Syndrome

See Dysrhythmia

Addiction

See Alcoholism; Substance Abuse

Addison's Disease

Activity intolerance r/t weakness, fatigue
Disturbed Body Image r/t increased skin pigmentation
Deficient Fluid volume r/t failure of regulatory mechanisms
Imbalanced Nutrition: **less than body requirements** r/t chronic illness
Risk for Injury: Risk factor: weakness
Readiness for enhanced Knowledge: expresses an interest in learning

Adenoidectomy

Acute Pain r/t surgical incision
Ineffective Airway clearance r/t hesitation or reluctance to cough as a result of pain, fear
Nausea r/t anesthesia effects, drainage from surgery
Acute Pain r/t surgical incision
Risk for Aspiration: Risk factors: postoperative drainage, impaired swallowing
Risk for Bleeding: Risk factor: surgical incision
Risk for deficient Fluid volume: Risk factors: decreased intake as a result of painful swallowing, effects of anesthesia
Risk for Dry Mouth: Risk factor: mouth breathing due to nasal congestion
Risk for imbalanced Nutrition: **less than body requirements**: Risk factor: reluctance to swallow
Readiness for enhanced Knowledge: expresses an interest in learning

Adhesions, Lysis of

See Abdominal Surgery

Adjustment Disorder

Anxiety r/t inability to cope with psychosocial stressor
Labile Emotional Control r/t emotional disturbance
Risk-prone Health behavior r/t assault to self-esteem
Disturbed personal Identity r/t psychosocial stressor (specific to individual)
Situational low Self-Esteem r/t change in role function
Impaired Social interaction r/t absence of significant others or peers

Adjustment Impairment

Risk-prone Health behavior (See **Health** behavior, risk-prone, Section III)

Adolescent, Pregnant

Anxiety r/t situational and maturational crisis, pregnancy
Disturbed Body Image r/t pregnancy superimposed on developing body
Decisional Conflict: **keeping child versus giving up child versus abortion** r/t lack of experience with decision-making, interference with decision-making, multiple or divergent sources of information, lack of support system
Disabled family Coping r/t highly ambivalent family relationships, chronically unresolved feelings of guilt, anger, despair
Ineffective Coping r/t situational and maturational crisis, personal vulnerability
Ineffective Denial r/t fear of consequences of pregnancy becoming known
Ineffective adolescent Eating dynamics r/t lack of knowledge of nutritional needs during pregnancy
Interrupted Family processes r/t unmet expectations for adolescent, situational crisis

Fear r/t labor and delivery
Deficient Knowledge r/t pregnancy, infant growth and development, parenting
Imbalanced Nutrition: **less than body requirements** r/t lack of knowledge of nutritional needs during pregnancy and as growing adolescent
Ineffective Role performance r/t pregnancy
Situational low Self-Esteem r/t feelings of shame and guilt about becoming or being pregnant
Impaired Social interaction r/t self-concept disturbance
Social isolation r/t absence of supportive significant others
Risk for impaired Attachment: Risk factor: anxiety associated with the parent role
Risk for delayed Development: Risk factor: unplanned or unwanted pregnancy
Risk for urge urinary Incontinence: Risk factor: pressure on bladder by growing uterus
Risk for disturbed Maternal–Fetal dyad: Risk factors: immaturity, substance use
Risk for impaired Parenting: Risk factors: adolescent parent, unplanned or unwanted pregnancy, single parent
Readiness for enhanced Childbearing process: reports appropriate prenatal lifestyle
Readiness for enhanced Health literacy: expresses desire to enhance social support for health
Readiness for enhanced Knowledge: expresses an interest in learning

Adoption, Giving Child Up for

Decisional Conflict r/t unclear personal values or beliefs, perceived threat to value system, support system deficit
Ineffective Coping r/t stress of loss of child
Interrupted Family processes r/t conflict within family regarding relinquishment of child
Grieving r/t loss of child, loss of role of parent
Insomnia r/t depression or trauma of relinquishment of child
Social isolation r/t making choice that goes against values of significant others
Chronic Sorrow r/t loss of relationship with child
Risk for Spiritual distress: Risk factor: perceived moral implications of decision
Readiness for enhanced Spiritual well-being: harmony with self-regarding final decision

Adrenocortical Insufficiency

Deficient Fluid volume r/t insufficient ability to reabsorb water
Ineffective Protection r/t inability to tolerate stress
Delayed Surgical recovery r/t inability to respond to stress
Risk for Shock: Risk factors: deficient fluid volume, decreased cortisol to initiate stress response to insult to body
See Addison's Disease; Shock, Hypovolemic

Advance Directives

Death Anxiety r/t planning for end-of-life health decisions
Decisional Conflict r/t unclear personal values or beliefs, perceived threat to value system, support system deficit
Grieving r/t possible loss of self, significant other
Readiness for enhanced Spiritual well-being: harmonious interconnectedness with self, others, higher power, God

Affective Disorders

See Depression (Major Depressive Disorder); Dysthymic Disorder; Manic Disorder, Bipolar I; SAD (Seasonal Affective Disorder)

Age-Related Macular Degeneration

See Macular Degeneration

Aggressive Behavior

Fear r/t real or imagined threat to own well-being
Risk for other-directed Violence (See **Violence,** other-directed, risk for, Section III)

Aging

Death Anxiety r/t fear of unknown, loss of self, impact on significant others
Impaired Dentition r/t ineffective oral hygiene
Risk for Frail Elderly syndrome: Risk factors: >70 years, activity intolerance, impaired vision
Grieving r/t multiple losses, impending death
Ineffective Health maintenance r/t powerlessness
Hearing Loss r/t exposure to loud noises, aging
Functional urinary Incontinence r/t impaired vision, impaired cognition, neuromuscular limitations, altered environmental factors
Impaired Resilience r/t aging, multiple losses
Sleep deprivation r/t aging-related sleep-stage shifts
Risk for Caregiver Role Strain: Risk factor: inability to handle increasing needs of significant other
Risk for Impaired emancipated Decision-Making: Risk factor: inability to process information regarding health care decisions
Risk for Injury: Risk factors: vision loss, hearing loss, decreased balance, decreased sensation in feet
Risk for Loneliness: Risk factors: inadequate support system, role transition, health alterations, depression, fatigue
Risk for Ineffective Thermoregulation: Risk factor: aging
Readiness for enhanced community Coping: providing social support and other resources identified as needed for elderly client
Readiness for enhanced family Coping: ability to gratify needs, address adaptive tasks
Readiness for enhanced Health management: knowledge about medication, nutrition, exercise, coping strategies
Readiness for enhanced Knowledge: specify need to improve health
Readiness for enhanced Nutrition: need to improve health
Readiness for enhanced Relationship: demonstrates understanding of partner's insufficient function
Readiness for enhanced Sleep: need to improve sleep
Readiness for enhanced Spiritual well-being: one's experience of life's meaning, harmony with self, others, higher power, God, environment

Agitation

Acute Confusion r/t side effects of medication, hypoxia, decreased cerebral perfusion, alcohol abuse or withdrawal, substance abuse or withdrawal, sensory deprivation or overload
Sleep deprivation r/t sustained inadequate sleep hygiene, sundown syndrome

Agoraphobia

Anxiety r/t real or perceived threat to physical integrity
Ineffective Coping r/t inadequate support systems
Fear r/t leaving home, going out in public places
Impaired Social interaction r/t disturbance in self-concept
Social isolation r/t altered thought process

Agranulocytosis

Delayed Surgical recovery r/t abnormal blood profile
Risk for Infection: Risk factor: abnormal blood profile
Readiness for enhanced Knowledge: expresses an interest in learning

AIDS (Acquired Immunodeficiency Syndrome)

Death Anxiety r/t fear of premature death
Disturbed Body Image r/t chronic contagious illness, cachexia
Caregiver Role Strain r/t unpredictable illness course, presence of situation stressors
Diarrhea r/t inflammatory bowel changes
Interrupted Family processes r/t distress about diagnosis of human immunodeficiency virus (HIV) infection
Fatigue r/t disease process, stress, decreased nutritional intake
Fear r/t powerlessness, threat to well-being
Grieving: **family/parental** r/t potential or impending death of loved one
Grieving: **individual** r/t loss of physical and psychosocial well-being
Hopelessness r/t deteriorating physical condition
Imbalanced Nutrition: **less than body requirements** r/t decreased ability to eat and absorb nutrients as a result of anorexia, nausea, diarrhea; oral candidiasis
Chronic Pain r/t tissue inflammation and destruction
Impaired Resilience r/t chronic illness
Situational low Self-Esteem r/t crisis of chronic contagious illness
Ineffective Sexuality pattern r/t possible transmission of disease
Social isolation r/t self-concept disturbance, therapeutic isolation
Chronic Sorrow r/t chronic illness
Spiritual distress r/t challenged beliefs or moral system
Risk for deficient Fluid volume: Risk factors: diarrhea, vomiting, fever, bleeding
Risk for Infection: Risk factor: inadequate immune system
Risk for Loneliness: Risk factor: social isolation
Risk for impaired Oral Mucous Membrane integrity: Risk factor: immunological deficit
Risk for impaired Skin integrity: Risk factors: immunological deficit, diarrhea
Risk for Spiritual distress: Risk factor: physical illness
Readiness for enhanced Health literacy: expresses desire to enhance understanding of health information to make health care choices
Readiness for enhanced Knowledge: expresses an interest in learning
See AIDS, Child; Cancer; Pneumonia

AIDS, Child

Impaired Parenting r/t congenital acquisition of infection secondary to intravenous (IV) drug use, multiple sexual partners, history of contaminated blood transfusion
See AIDS (Acquired Immunodeficiency Syndrome); Child with Chronic Condition; Hospitalized Child; Terminally Ill Child, Adolescent; Terminally Ill Child, Infant/Toddler; Terminally Ill Child, Preschool Child; Terminally Ill Child, School-Age Child/Preadolescent; Terminally Ill Child/Death of Child, Parent

AIDS Dementia

Chronic Confusion r/t viral invasion of nervous system
See Dementia

Airway Obstruction/Secretions

Ineffective Airway clearance (See **Airway** clearance, ineffective, Section III)

Alcohol Withdrawal

Anxiety r/t situational crisis, withdrawal
Acute Confusion r/t effects of alcohol withdrawal
Ineffective Coping r/t personal vulnerability
Dysfunctional Family processes r/t abuse of alcohol
Insomnia r/t effect of alcohol withdrawal, anxiety

Imbalanced Nutrition: **less than body requirements** r/t poor dietary habits
Chronic low Self-Esteem r/t repeated unmet expectations
Acute Substance Withdrawal syndrome: Risk factor: developed dependence to alcohol
Risk for deficient Fluid volume: Risk factors: excessive diaphoresis, agitation, decreased fluid intake
Risk for other-directed Violence: Risk factor: substance withdrawal
Risk for self-directed Violence: Risk factor: substance withdrawal
Readiness for enhanced Knowledge: expresses an interest in learning

Alcoholism

Anxiety r/t loss of control
Risk-prone Health behavior r/t lack of motivation to change behaviors, addiction
Acute Confusion r/t alcohol abuse
Chronic Confusion r/t neurological effects of chronic alcohol intake
Defensive Coping r/t denial of reality of addiction
Disabled family Coping r/t codependency issues due to alcoholism
Ineffective Coping r/t use of alcohol to cope with life events
Labile Emotional Control r/t substance abuse
Ineffective Denial r/t refusal to acknowledge addiction
Dysfunctional Family processes r/t alcohol abuse
Impaired Home maintenance r/t memory deficits, fatigue
Insomnia r/t irritability, nightmares, tremors
Impaired Memory r/t alcohol abuse
Self-Neglect r/t effects of alcohol abuse
Imbalanced Nutrition: **less than body requirements** r/t anorexia, inappropriate diet with increased carbohydrates
Powerlessness r/t alcohol addiction
Ineffective Protection r/t malnutrition, sleep deprivation
Chronic low Self-Esteem r/t failure at life events
Social isolation r/t unacceptable social behavior, values
Acute Substance Withdrawal syndrome: Risk factor: developed dependence to alcohol
Risk for Injury: Risk factor: alteration in sensory or perceptual function
Risk for Loneliness: Risk factor: unacceptable social behavior
Risk for Acute Substance Withdrawal syndrome: Risk factor: developed dependence to alcohol
Risk for other-directed Violence: Risk factors: reactions to substances used, impulsive behavior, disorientation, impaired judgment
Risk for self-directed Violence: Risk factors: reactions to substances used, impulsive behavior, disorientation, impaired judgment

Alcoholism, Dysfunctional Family Processes

Dysfunctional Family processes (See **Family** processes, dysfunctional, Section III)

Alkalosis

See Metabolic Alkalosis

ALL (Acute Lymphocytic Leukemia)

See Cancer; Chemotherapy; Child with Chronic Condition; Leukemia

Allergies

Latex Allergic reaction r/t hypersensitivity to natural rubber latex
Risk for Allergic reaction: Risk factors: chemical factors, dander, environmental substances, foods, insect stings, medications
Risk for Latex Allergic reaction: Risk factor: repeated exposure to products containing latex

Readiness for enhanced Knowledge: expresses an interest in learning

Alopecia

Disturbed Body Image r/t loss of hair, change in appearance
Readiness for enhanced Knowledge: expresses an interest in learning

ALS (Amyotrophic Lateral Sclerosis)

See Amyotrophic Lateral Sclerosis (ALS)

Altered Mental Status

See Confusion, Acute; Confusion, Chronic; Memory Deficit

Alzheimer's Disease

Caregiver role strain r/t duration and extent of caregiving required
Chronic Confusion r/t loss of cognitive function
Compromised family Coping r/t interrupted family processes
Frail Elderly syndrome r/t alteration in cognitive functioning
Impaired Home maintenance r/t impaired cognitive function, inadequate support systems
Hopelessness r/t deteriorating condition
Insomnia r/t neurological impairment, daytime naps
Impaired Memory r/t neurological disturbance
Impaired physical Mobility r/t severe neurological dysfunction
Self-Neglect r/t loss of cognitive function
Powerlessness r/t deteriorating condition
Self-Care deficit: **specify** r/t loss of cognitive function, psychological impairment
Social isolation r/t fear of disclosure of memory loss
Wandering r/t cognitive impairment, frustration, physiological state
Risk for chronic functional Constipation: Risk factor: impaired cognitive functioning
Risk for Injury: Risk factor: confusion
Risk for Loneliness: Risk factor: potential social isolation
Risk for Relocation stress syndrome: Risk factors: impaired psychosocial health, decreased health status
Risk for other-directed Violence: Risk factors: frustration, fear, anger, loss of cognitive function
Readiness for enhanced Knowledge: Caregiver: expresses an interest in learning
See Dementia

AMD (Age-Related Macular Degeneration)

See Macular Degeneration

Amenorrhea

Imbalanced Nutrition: **less than body requirements** r/t inadequate food intake
See Sexuality, Adolescent

AMI (Acute Myocardial Infarction)

See MI (Myocardial Infarction)

Amnesia

Acute Confusion r/t alcohol abuse, delirium, dementia, drug abuse
Dysfunctional Family processes r/t alcohol abuse, inadequate coping skills
Impaired Memory r/t excessive environmental disturbance, neurological disturbance
Post-Trauma syndrome r/t history of abuse, catastrophic illness, disaster, accident

Amniocentesis

Anxiety r/t threat to self and fetus, unknown future
Decisional Conflict r/t choice of treatment pending results of test
Risk for Infection: Risk factor: invasive procedure

Amnionitis

See Chorioamnionitis

Amniotic Membrane Rupture

See Premature Rupture of Membranes

Amputation

Disturbed Body Image r/t negative effects of amputation, response from others
Grieving r/t loss of body part, future lifestyle changes
Impaired physical Mobility r/t musculoskeletal impairment, limited movement
Acute Pain r/t surgery, phantom limb sensation
Chronic Pain r/t surgery, phantom limb sensation
Ineffective peripheral Tissue Perfusion r/t impaired arterial circulation
Impaired Skin integrity r/t poor healing, prosthesis rubbing
Risk for Bleeding: Risk factor: vulnerable surgical site
Risk for Impaired Tissue integrity: Risk factor: mechanical factors impacting site
Readiness for enhanced Knowledge: expresses an interest in learning

Amyotrophic Lateral Sclerosis (ALS)

Death Anxiety r/t impending progressive loss of function leading to death
Ineffective Breathing pattern r/t compromised muscles of respiration
Impaired verbal Communication r/t weakness of muscles of speech, deficient knowledge of ways to compensate and alternative communication devices
Decisional Conflict: **ventilator therapy** r/t unclear personal values or beliefs, lack of relevant information
Impaired Resilience r/t perceived vulnerability
Chronic Sorrow r/t chronic illness
Impaired Swallowing r/t weakness of muscles involved in swallowing
Impaired spontaneous Ventilation r/t weakness of muscles of respiration
Risk for Aspiration: Risk factor: impaired swallowing
Risk for Spiritual distress: Risk factor: chronic debilitating condition
See Neurological Disorders

Anal Fistula

See Hemorrhoidectomy

Anaphylactic Shock

Deficient Fluid volume r/t compromised regulatory mechanism
Ineffective Airway clearance r/t laryngeal edema, bronchospasm
Latex Allergic reaction r/t abnormal immune mechanism response
Impaired spontaneous Ventilation r/t acute airway obstruction from anaphylaxis process

Anaphylaxis Prevention

Risk for Allergic reaction (See **Allergic reaction**, risk for, Section III)

Anasarca

Excess Fluid volume r/t excessive fluid intake, cardiac/renal dysfunction, loss of plasma proteins
Risk for decreased Cardiac Output: Risk factor: imbalanced fluid volume
Risk for impaired Skin integrity: Risk factor: impaired circulation to skin from edema

Anemia

Anxiety r/t cause of disease
Impaired Comfort r/t feelings of always being cold from decreased hemoglobin and decreased metabolism
Fatigue r/t decreased oxygen supply to the body, increased cardiac workload
Impaired Memory r/t change in cognition from decreased oxygen supply to the body
Delayed Surgical recovery r/t decreased oxygen supply to body, increased cardiac workload
Risk for Bleeding (See **Bleeding,** risk for, Section III)
Risk for Injury: Risk factor: alteration in peripheral sensory perception
Readiness for enhanced Knowledge: expresses an interest in learning

Anemia, in Pregnancy

Anxiety r/t concerns about health of self and fetus
Fatigue r/t decreased oxygen supply to the body, increased cardiac workload
Risk for delayed Development: Risk factor: reduction in the oxygen-carrying capacity of blood
Risk for Infection: Risk factor: reduction in oxygen-carrying capacity of blood
Risk for disturbed Maternal–Fetal dyad: Risk factor: compromised oxygen transport
Readiness for enhanced Knowledge: expresses an interest in learning

Anemia, Sickle Cell

See Anemia; Sickle Cell Anemia/Crisis

Anencephaly

See Neural Tube Defects (Meningocele, myelomeningocele, Spina Bifida, Anencephaly)

Aneurysm, Abdominal Aortic Repair Surgery

Risk for deficient Fluid volume: Risk factor: hemorrhage r/t potential abnormal blood loss
Risk for Surgical Site Infection: Risk factor: invasive procedure
See Abdominal Surgery

Aneurysm, Cerebral

See Craniectomy/Craniotomy; Subarachnoid Hemorrhage

Anger

Anxiety r/t situational crisis
Defensive Coping r/t inability to acknowledge responsibility for actions and results of actions
Labile Emotional Control r/t stressors
Fear r/t environmental stressor, hospitalization
Grieving r/t significant loss
Risk-prone Health behavior r/t assault to self-esteem, disability requiring change in lifestyle, inadequate support system
Powerlessness r/t health care environment
Risk for compromised Human Dignity: Risk factors: inadequate participation in decision-making, perceived dehumanizing treatment, perceived humiliation, exposure of the body, cultural incongruity
Risk for Post-Trauma syndrome: Risk factor: inadequate social support
Risk for other-directed Violence: Risk factors: history of violence, rage reaction
Risk for self-directed Violence: Risk factors: history of violence, history of abuse, rage reaction

Angina

Activity intolerance r/t acute pain, dysrhythmias
Anxiety r/t situational crisis
Decreased Cardiac output r/t myocardial ischemia, medication effect, dysrhythmia
Ineffective Coping r/t personal vulnerability to situational crisis of new diagnosis, deteriorating health
Ineffective Denial r/t deficient knowledge of need to seek help with symptoms
Grieving r/t pain, loss of health
Acute Pain r/t myocardial ischemia
Ineffective Sexuality pattern r/t disease process, medications, loss of libido
Readiness for enhanced Knowledge: expresses an interest in learning
See MI (Myocardial Infarction)

Angiocardiography (Cardiac Catheterization)

See Cardiac Catheterization

Angioplasty, Coronary

Fear r/t possible outcome of interventional procedure
Ineffective peripheral Tissue Perfusion r/t vasospasm, hematoma formation
Risk for Bleeding: Risk factors: possible damage to coronary artery, hematoma formation
Risk for decreased Cardiac tissue perfusion: Risk factors: ventricular ischemia, dysrhythmias
Readiness for enhanced Knowledge: expresses an interest in learning

Anomaly, Fetal/Newborn (Parent Dealing with)

Anxiety r/t threat to role functioning, situational crisis
Decisional Conflict: **interventions for fetus or newborn** r/t lack of relevant information, spiritual distress, threat to value system
Disabled family Coping r/t chronically unresolved feelings about loss of perfect baby
Ineffective Coping r/t personal vulnerability in situational crisis
Interrupted Family processes r/t unmet expectations for perfect baby, lack of adequate support systems
Fear r/t real or imagined threat to baby, implications for future pregnancies, powerlessness
Grieving r/t loss of ideal child
Hopelessness r/t long-term stress, deteriorating physical condition of child, lost spiritual belief
Deficient Knowledge r/t limited exposure to situation
Impaired Parenting r/t interruption of bonding process
Powerlessness r/t complication threatening fetus or newborn

Parental Role conflict r/t separation from newborn, intimidation with invasive or restrictive modalities, specialized care center policies
Situational low Self-Esteem r/t perceived inability to produce a perfect child
Social isolation r/t alterations in child's physical appearance, altered state of wellness
Chronic Sorrow r/t loss of ideal child, inadequate bereavement support
Spiritual distress r/t test of spiritual beliefs
Risk for impaired Attachment: Risk factor: ill infant unable to effectively initiate parental contact as result of altered behavioral organization
Risk for disorganized Infant behavior: Risk factor: congenital disorder
Risk for impaired Parenting: Risk factors: interruption of bonding process; unrealistic expectations for self, infant, or partner; perceived threat to own emotional survival; severe stress; lack of knowledge
Risk for Spiritual distress: Risk factor: lack of normal child to raise and carry on family name

Anorectal Abscess

Disturbed Body Image r/t odor and drainage from rectal area
Acute Pain r/t inflammation of perirectal area
Risk for Constipation: Risk factor: fear of painful elimination
Readiness for enhanced Knowledge: expresses an interest in learning

Anorexia

Deficient Fluid volume r/t inability to drink
Imbalanced Nutrition: **less than body requirements** r/t loss of appetite, nausea, vomiting, laxative abuse
Delayed Surgical recovery r/t inadequate nutritional intake
Risk for delayed Surgical recovery: Risk factor: inadequate nutritional intake

Anorexia Nervosa

Activity intolerance r/t fatigue, weakness
Disturbed Body Image r/t misconception of actual body appearance
Constipation r/t lack of adequate food, fiber, and fluid intake
Defensive Coping r/t psychological impairment, eating disorder
Disabled family Coping r/t highly ambivalent family relationships
Ineffective Denial r/t fear of consequences of therapy, possible weight gain
Diarrhea r/t laxative abuse
Interrupted Family processes r/t situational crisis
Ineffective adolescent Eating dynamics r/t food refusal
Ineffective family Health management r/t family conflict, excessive demands on family associated with complexity of condition and treatment
Imbalanced Nutrition: **less than body requirements** r/t inadequate food intake, excessive exercise
Chronic low Self-Esteem r/t repeated unmet expectations
Ineffective Sexuality pattern r/t loss of libido from malnutrition
Risk for Infection: Risk factor: malnutrition resulting in depressed immune system
Risk for Spiritual distress: Risk factor: low self-esteem
See Maturational Issues, Adolescent

Anosmia (Smell, Loss of Ability to)

Imbalanced Nutrition: **less than body requirements** r/t loss of appetite associated with loss of smell

Antepartum Period

See Pregnancy, Normal; Prenatal Care, Normal

Anterior Repair, Anterior Colporrhaphy

Urinary Retention r/t edema of urinary structures
Risk for urge urinary Incontinence: Risk factor: trauma to bladder
Readiness for enhanced Knowledge: expresses an interest in learning
See Vaginal Hysterectomy

Anticoagulant Therapy

Risk for Bleeding: Risk factor: altered clotting function from anticoagulant
Risk for deficient Fluid volume: **hemorrhage**: Risk factor: altered clotting mechanism
Readiness for enhanced Knowledge: expresses an interest in learning

Antisocial Personality Disorder

Defensive Coping r/t excessive use of projection
Ineffective Coping r/t frequently violating the norms and rules of society
Labile Emotional Control r/t psychiatric disorder
Hopelessness r/t abandonment
Impaired Social interaction r/t sociocultural conflict, chemical dependence, inability to form relationships
Spiritual distress r/t separation from religious or cultural ties
Ineffective Health management r/t excessive demands on family
Risk for Loneliness: Risk factor: inability to interact appropriately with others
Risk for impaired Parenting: Risk factors: inability to function as parent or guardian, emotional instability
Risk for Self-Mutilation: Risk factors: self-hatred, depersonalization
Risk for other-directed Violence: Risk factor: history of violence, altered thought patterns

Anuria

See Renal Failure

Anxiety

See **Anxiety**, Section III

Anxiety Disorder

Ineffective Activity planning r/t unrealistic perception of events
Anxiety r/t unmet security and safety needs
Death Anxiety r/t fears of unknown, powerlessness
Decisional Conflict r/t low self-esteem, fear of making a mistake
Defensive Coping r/t overwhelming feelings of dread
Disabled family Coping r/t ritualistic behavior, actions
Imbalanced Energy Field r/t feelings of restlessness and apprehension
Impaired Mood Regulation r/t functional impairment, impaired social functioning, alteration in sleep pattern
Ineffective Coping r/t inability to express feelings appropriately
Ineffective Denial r/t overwhelming feelings of hopelessness, fear, threat to self
Insomnia r/t psychological impairment, emotional instability
Labile Emotional Control r/t emotional instability
Powerlessness r/t lifestyle of helplessness
Self-Care deficit r/t ritualistic behavior, activities
Sleep deprivation r/t prolonged psychological discomfort
Risk for Spiritual distress: Risk factor: psychological distress

Readiness for enhanced Knowledge: expresses an interest in learning

Aortic Valvular Stenosis

See Congenital Heart Disease/Cardiac Anomalies

Aphasia

Anxiety r/t situational crisis of aphasia
Impaired verbal Communication r/t decrease in circulation to brain
Ineffective Coping r/t loss of speech
Ineffective Health maintenance r/t deficient knowledge regarding information on aphasia and alternative communication techniques

Aplastic Anemia

Activity intolerance r/t imbalance between oxygen supply and demand
Fear r/t ability to live with serious disease
Risk for Bleeding: Risk factor: inadequate clotting factors
Risk for Infection: Risk factor: inadequate immune function
Readiness for enhanced Knowledge: expresses an interest in learning

Apnea in Infancy

See Premature Infant (Child); Premature Infant (Parent); SIDS (Sudden Infant Death)

Apneustic Respirations

Ineffective Breathing pattern r/t perception or cognitive impairment, neurological impairment

Appendectomy

Deficient Fluid volume r/t fluid restriction, hypermetabolic state, nausea, vomiting
Acute Pain r/t surgical incision
Delayed Surgical recovery r/t rupture of appendix
Risk for Infection: Risk factors: perforation or rupture of appendix, peritonitis
Risk for Surgical Site Infection: Risk factor: surgical incision
Readiness for enhanced Knowledge: expresses an interest in learning
See Hospitalized Child; Surgery, Postoperative Care

Appendicitis

Deficient Fluid volume r/t anorexia, nausea, vomiting
Acute Pain r/t inflammation
Risk for Infection: Risk factor: possible perforation of appendix
Readiness for enhanced Knowledge: expresses an interest in learning

Apprehension

Anxiety r/t threat to self-concept, threat to health status, situational crisis
Death Anxiety r/t apprehension over loss of self, consequences to significant others

ARDS (Acute Respiratory Distress Syndrome)

Ineffective Airway clearance r/t excessive tracheobronchial secretions
Death Anxiety r/t seriousness of physical disease
Impaired Gas exchange r/t damage to alveolar capillary membrane, change in lung compliance
Impaired spontaneous Ventilation r/t damage to alveolar capillary membrane
See Ventilated Client, Mechanically

Arrhythmia

See Dysrhythmia

Arterial Insufficiency

Ineffective peripheral Tissue Perfusion r/t interruption of arterial flow
Delayed Surgical recovery r/t ineffective tissue perfusion

Arthritis

Activity intolerance r/t chronic pain, fatigue, weakness
Disturbed Body Image r/t ineffective coping with joint abnormalities
Impaired physical Mobility r/t joint impairment
Chronic Pain r/t progression of joint deterioration
Self-Care deficit: **specify** r/t pain with movement, damage to joints
Readiness for enhanced Knowledge: expresses an interest in learning
See JRA (Juvenile Rheumatoid Arthritis)

Arthrocentesis

Acute Pain r/t invasive procedure

Arthroplasty (Total Hip Replacement)

See Total Joint Replacement (Total Hip/Total Knee/Shoulder); Surgery, Perioperative Care; Surgery, Postoperative Care; Surgery, Preoperative Care

Arthroscopy

Impaired physical Mobility r/t surgical trauma of knee
Readiness for enhanced Knowledge: expresses an interest in learning

Ascites

Ineffective Breathing pattern r/t increased abdominal girth
Imbalanced Nutrition: **less than body requirements** r/t loss of appetite
Chronic Pain r/t altered body function
Readiness for enhanced Knowledge: expresses an interest in learning
See Ascites; Cancer; Cirrhosis

Asperger's Syndrome

Ineffective Relationship r/t poor communication skills, lack of empathy

See Autism

Asphyxia, Birth

Ineffective Breathing pattern r/t depression of breathing reflex secondary to anoxia
Ineffective Coping r/t uncertainty of child outcome
Fear (parental) r/t concern over safety of infant
Impaired Gas exchange r/t poor placental perfusion, lack of initiation of breathing by newborn
Grieving r/t loss of perfect child, concern of loss of future abilities
Impaired spontaneous Ventilation r/t brain injury
Risk for impaired Attachment: Risk factors: ill infant who is unable to initiate parental contact, hospitalization in critical care environment
Risk for delayed Development: Risk factor: lack of oxygen to brain
Risk for disorganized Infant behavior: Risk factor: lack of oxygen to brain
Risk for Injury: Risk factor: lack of oxygen to brain
Risk for ineffective Cerebral tissue perfusion: Risk factor: poor placental perfusion or cord compression resulting in lack of oxygen to brain

Aspiration, Danger of

Risk for Aspiration (See **Aspiration,** risk for, Section III)

Assault Victim

Post-Trauma syndrome r/t assault
Rape-Trauma syndrome r/t rape
Impaired Resilience r/t frightening experience, post-trauma stress response
Risk for Post-Trauma syndrome: Risk factors: perception of event, inadequate social support, unsupportive environment, diminished ego strength, duration of event
Risk for Spiritual distress: Risk factors: physical, psychological stress

Assaultive Client

Risk for Injury: Risk factors: confused thought process, impaired judgment
Risk for other-directed Violence: Risk factors: paranoid ideation, anger

Asthma

Activity intolerance r/t fatigue, energy shift to meet muscle needs for breathing to overcome airway obstruction
Ineffective Airway clearance r/t tracheobronchial narrowing, excessive secretions
Anxiety r/t inability to breathe effectively, fear of suffocation
Disturbed Body Image r/t decreased participation in physical activities
Ineffective Breathing pattern r/t anxiety
Ineffective Coping r/t personal vulnerability to situational crisis
Ineffective Health management (See **Health** management, ineffective, in Section III)
Impaired Home maintenance r/t deficient knowledge regarding control of environmental triggers
Sleep deprivation r/t ineffective breathing pattern, cough
Readiness for enhanced Health management (See **Health** management, readiness for enhanced, in Section III)
Readiness for enhanced Knowledge: expresses an interest in learning
See Child with Chronic Condition; Hospitalized Child

Ataxia

Anxiety r/t change in health status
Disturbed Body Image r/t staggering gait
Impaired physical Mobility r/t neuromuscular impairment
Risk for Falls: Risk factors: gait alteration, instability

Atelectasis

Ineffective Breathing pattern r/t loss of functional lung tissue, depression of respiratory function or hypoventilation because of pain
Impaired Gas exchange r/t decreased alveolar-capillary surface
Anxiety r/t alteration in respiratory pattern
See Atelectasis

Atherosclerosis

See MI (Myocardial Infarction); CVA (Cerebrovascular Accident); Peripheral Vascular Disease (PVD)

Athlete's Foot

Impaired Skin integrity r/t effects of fungal agent
Readiness for enhanced Knowledge: expresses an interest in learning
See Pruritus

ATN (Acute Tubular Necrosis)

See Renal Failure

Atrial Fibrillation

See Dysrhythmia

Atrial Septal Defect

See Congenital Heart Disease/Cardiac Anomalies

Attention Deficit Disorder

Risk-prone Health behavior r/t intense emotional state
Disabled family Coping r/t significant person with chronically unexpressed feelings of guilt, anxiety, hostility, and despair
Ineffective Impulse control r/t (See **Impulse** control, ineffective, Section III)
Chronic low Self-Esteem r/t difficulty in participating in expected activities, poor school performance
Social isolation r/t unacceptable social behavior
Risk for delayed Development: Risk factor: behavior disorders
Risk for Falls: Risk factor: rapid non-thinking behavior
Risk for Loneliness: Risk factor: social isolation
Risk for impaired Parenting: Risk factor: lack of knowledge of factors contributing to child's behavior
Risk for Spiritual distress: Risk factor: poor relationships

Autism

Impaired verbal Communication r/t speech and language delays

Compromised family Coping r/t parental guilt over etiology of disease, inability to accept or adapt to child's condition, inability to help child and other family members seek treatment
Disturbed personal Identity r/t inability to distinguish between self and environment, inability to identify own body as separate from those of other people, inability to integrate concept of self
Self-Neglect r/t impaired socialization
Impaired Social interaction r/t communication barriers, inability to relate to others, failure to develop peer relationships
Risk for delayed Development: Risk factor: autism
Risk for Loneliness: Risk factor: difficulty developing relationships with other people
Risk for Self-Mutilation: Risk factor: autistic state
Risk for other-directed Violence: Risk factors: frequent destructive rages toward others secondary to extreme response to changes in routine, fear of harmless things
Risk for self-directed Violence: Risk factors: frequent destructive rages toward self, secondary to extreme response to changes in routine, fear of harmless things
See Child with Chronic Condition

Autonomic Dysreflexia

Autonomic Dysreflexia r/t bladder distention, bowel distention, noxious stimuli
Risk for Autonomic Dysreflexia: Risk factors: bladder distention, bowel distention, noxious stimuli

Autonomic Hyperreflexia

See Autonomic Dysreflexia

List of Nursing Diagnosis by Letter: B

Baby Care	Bacteremia	Balanced Energy Field
Barrel Chest	Bathing/Hygiene Problems	Battered Child Syndrome
Battered Person	Bedbugs, Infestation	Bed Mobility, Impaired
Bed Rest, Prolonged	Bedsores	Bedwetting
Bell's Palsy	Benign Prostatic Hypertrophy	Bereavement
Biliary Atresia	Biliary Calculus	Biliary Obstruction
Bilirubin Elevation in Neonate	Biopsy	Bioterrorism
Bipolar Disorder I (Most Recent Episode, Depressed or Manic)	Birth Asphyxia	Birth Control
Bladder Cancer	Bladder Distention	Bladder Training
Bladder Training, Child	Bleeding Tendency	Blepharoplasty
Blindness	Blood Disorder	Blood Glucose Control
Blood Pressure Alteration	Blood Transfusion	Body Dysmorphic Disorder
Body Image Change	Body Temperature, Altered	Bone Marrow Biopsy
Borderline Personality Disorder	Boredom	Botulism
Bowel Incontinence	Bowel Obstruction	Bowel Resection
Bowel Sounds, Absent or Diminished	Bowel Sounds, Hyperactive	Bowel Training
Bowel Training, Child	BPH (Benign Prostatic Hypertrophy)	Bradycardia
Bradypnea	Brain Injury	Brain Surgery
Brain Tumor	Braxton Hicks Contractions	Breast Biopsy
Breast Cancer	Breast Examination, Self	Breast Lumps
Breast Pumping	Breastfeeding, Effective	Breastfeeding, Ineffective
Breastfeeding, Interrupted	Breast Milk Production, Insufficient	Breath Sounds, Decreased or Absent
Breathing Pattern Alteration	Breech Birth	Bronchitis
Bronchopulmonary Dysplasia	Bronchoscopy	Bruits, Carotid
Bryant's Traction	Buck's Traction	Buerger's Disease
Bulimia	Bullying	Bunion
Bunionectomy	Burn Risk	Burns
Bursitis	Bypass Graft	

B

Baby Care

Readiness for enhanced Childbearing process: demonstrates appropriate feeding and baby care techniques, along with attachment to infant and providing a safe environment
Anxiety r/t situational crisis, back injury
Ineffective Coping r/t situational crisis, back injury
Impaired physical Mobility r/t pain
Acute Pain r/t back injury
Chronic Pain r/t back injury
Risk for Constipation: Risk factors: decreased activity, side effect of pain medication
Risk for Disuse syndrome: Risk factor: severe pain
Readiness for enhanced Knowledge: expresses an interest in learning

Bacteremia

Risk for Infection: Risk factor: compromised immune system
Risk for Shock: Risk factor: development of systemic inflammatory response from presence of bacteria in bloodstream

Balanced Energy Field

Imbalanced Energy Field (See **Energy Field**, imbalanced, Section III)

Barrel Chest

See Aging (if appropriate); COPD (Chronic Obstructive Pulmonary Disease)

Bathing/Hygiene Problems

Impaired Mobility r/t chronic physically limiting condition
Self-Neglect (See **Self-Neglect**, Section III)
Bathing Self-Care deficit (See **Self-Care** deficit, bathing, Section III)

Battered Child Syndrome

Dysfunctional Family processes r/t inadequate coping skills
Sleep deprivation r/t prolonged psychological discomfort
Chronic Sorrow r/t situational crises
Risk for Post-Trauma syndrome: Risk factors: physical abuse, incest, rape, molestation
Risk for Self-Mutilation: Risk factors: feelings of rejection, dysfunctional family
Risk for Suicide: Risk factor: childhood abuse
See Child Abuse

Battered Person

See Abuse, Spouse, Parent, or Significant Other

Bedbugs, Infestation

Impaired Home maintenance r/t deficient knowledge regarding prevention of bedbug infestation
Impaired Skin integrity r/t bites of bedbugs
See Pruritus

Bed Mobility, Impaired

Impaired bed Mobility (See **Mobility,** bed, impaired, Section III)

Bed Rest, Prolonged

Decreased Diversional activity engagement r/t prolonged bed rest
Impaired bed Mobility r/t neuromuscular impairment
Social isolation r/t prolonged bed rest
Risk for chronic functional Constipation: Risk factor: insufficient physical activity
Risk for Disuse syndrome: Risk factor: prolonged immobility
Risk for Frail Elderly syndrome: Risk factor: prolonged immobility
Risk for Loneliness: Risk factor: prolonged bed rest
Risk for Overweight: Risk factor: energy expenditure below energy intake
Risk for Pressure ulcer: Risk factor: prolonged immobility
Risk for Venous Thromboembolism: Risk factor: prolonged immobility

Bedsores

See Pressure Ulcer

Bedwetting

Ineffective Health maintenance r/t unachieved developmental level, neuromuscular immaturity, diseases of the urinary system

Bell's Palsy

Disturbed Body Image r/t loss of motor control on one side of face
Imbalanced Nutrition: **less than body requirements** r/t difficulty with chewing
Acute Pain r/t inflammation of facial nerve
Risk for Injury (eye): Risk factors: decreased tears, decreased blinking of eye
Readiness for enhanced Knowledge: expresses an interest in learning

Benign Prostatic Hypertrophy

See BPH (Benign Prostatic Hypertrophy); Prostatic Hypertrophy

Bereavement

Grieving r/t loss of significant person
Insomnia r/t grief

Risk for complicated Grieving: Risk factor: emotional instability, lack of social support
Risk for Spiritual distress: Risk factor: death of a loved one

Biliary Atresia

Anxiety r/t surgical intervention, possible liver transplantation
Impaired Comfort r/t inflammation of skin, itching
Imbalanced Nutrition: **less than body requirements** r/t decreased absorption of fat and fat-soluble vitamins, poor feeding
Risk for Bleeding: Risk factors: vitamin K deficiency, altered clotting mechanisms
Risk for ineffective Breathing pattern: Risk factors: enlarged liver, development of ascites
Risk for impaired Skin integrity: Risk factor: pruritus
See Child with Chronic Condition; Cirrhosis; Hospitalized Child

Biliary Calculus

See Cholelithiasis

Biliary Obstruction

See Jaundice

Bilirubin Elevation in Neonate

See Hyperbilirubinemia, Neonatal

Biopsy

Fear r/t outcome of biopsy
Readiness for enhanced Knowledge: expresses an interest in learning

Bioterrorism

Contamination r/t exposure to bioterrorism
Risk for Infection: Risk factor: exposure to harmful biological agent
Risk for Post-Trauma syndrome: Risk factor: perception of event of bioterrorism

Bipolar Disorder I (Most Recent Episode, Depressed or Manic)

Ineffective Activity planning r/t unrealistic perception of events
Fatigue r/t psychological demands
Risk-prone Health behavior: Risk factor: low state of optimism
Ineffective Health maintenance r/t lack of ability to make good judgments regarding ways to obtain help
Self-Care deficit: **specify** r/t depression, cognitive impairment
Chronic low Self-Esteem r/t repeated unmet expectations
Social isolation r/t ineffective coping
Risk for complicated Grieving: Risk factor: lack of previous resolution of former grieving response
Risk for Loneliness: Risk factors: stress, conflict
Risk for Spiritual distress: Risk factor: mental illness
Risk for Suicide: Risk factors: psychiatric disorder, poor support system
See Depression (Major Depressive Disorder); Manic Disorder, Bipolar I

Birth Asphyxia

See Asphyxia, Birth

Birth Control

See Contraceptive Method

Bladder Cancer

Urinary Retention r/t clots obstructing urethra
See Cancer; TURP (Transurethral Resection of the Prostate)

Bladder Distention

Urinary Retention r/t high urethral pressure caused by weak detrusor, inhibition of reflex arc, blockage, strong sphincter

Bladder Training

Disturbed Body Image r/t difficulty maintaining control of urinary elimination
Functional urinary Incontinence r/t altered environment; sensory, cognitive, mobility deficit
Stress urinary Incontinence r/t degenerative change in pelvic muscles and structural supports
Urge urinary Incontinence r/t decreased bladder capacity, increased urine concentration, overdistension of bladder
Readiness for enhanced Knowledge: expresses an interest in learning

Bladder Training, Child

See Toilet Training

Bleeding Tendency

Risk for Bleeding (See **Bleeding,** risk for, Section III)
Risk for delayed Surgical recovery: Risk factor: bleeding tendency

Blepharoplasty

Disturbed Body Image r/t effects of surgery
Readiness for enhanced Knowledge: expresses an interest in learning

Blindness

Interrupted Family processes r/t shift in health status of family member (change in visual acuity)
Impaired Home maintenance r/t decreased vision
Ineffective Role performance r/t alteration in health status (change in visual acuity)
Self-Care deficit: **specify** r/t inability to see to be able to perform activities of daily living
Risk for delayed Development: Risk factor: vision impairment
Risk for Injury: Risk factor: sensory dysfunction
Readiness for enhanced Knowledge: expresses an interest in learning

Blood Disorder

Ineffective Protection r/t abnormal blood profile
Risk for Bleeding: Risk factor: abnormal blood profile
See ITP (Idiopathic Thrombocytopenic Purpura); Hemophilia; Lacerations; Shock, Hypovolemic

Blood Glucose Control

Risk for unstable blood Glucose level (See **Glucose** level, blood, unstable, risk for, Section III)

Blood Pressure Alteration

See Hypotension; HTN (Hypertension)
See **Unstable Blood Pressure,** Risk for, Section III)

Blood Transfusion

Anxiety r/t possibility of harm from transfusion
See Anemia

Body Dysmorphic Disorder

Anxiety r/t perceived defect of body
Disturbed Body Image r/t over involvement in physical appearance
Chronic low Self-Esteem r/t lack of self-valuing because of perceived body defects
Social isolation r/t distancing self from others because of perceived self-body defects
Risk for Suicide: Risk factor: perceived defects of body affecting self-valuing and hopes

Body Image Change

Disturbed Body Image (See **Body Image,** disturbed, Section III)

Body Temperature, Altered

Ineffective Thermoregulation (See **Thermoregulation**, ineffective, Section III)

Bone Marrow Biopsy

Fear r/t unknown outcome of results of biopsy
Acute Pain r/t bone marrow aspiration
Readiness for enhanced Knowledge: expresses an interest in learning
See Disease necessitating bone marrow biopsy (e.g., Leukemia)

Borderline Personality Disorder

Ineffective Activity planning r/t unrealistic perception of events
Anxiety r/t perceived threat to self-concept
Defensive Coping r/t difficulty with relationships, inability to accept blame for own behavior
Ineffective Coping r/t use of maladjusted defense mechanisms (e.g., projection, denial)
Powerlessness r/t lifestyle of helplessness
Social isolation r/t immature interests
Ineffective family Health management r/t manipulative behavior of client

Risk for Caregiver Role Strain: Risk factors: inability of care receiver to accept criticism, care receiver taking advantage of others to meet own needs or having unreasonable expectations
Risk for Self-Mutilation: Risk factors: ineffective coping, feelings of self-hatred
Risk for Spiritual distress: Risk factor: poor relationships associated with abnormal behaviors
Risk for self-directed Violence: Risk factors: feelings of need to punish self, manipulative behavior

Boredom

Decreased Diversional activity engagement r/t environmental lack of diversional activity
Impaired Mood regulation r/t emotional instability
Social isolation r/t altered state of wellness

Botulism

Deficient Fluid volume r/t profuse diarrhea
Readiness for enhanced Knowledge: expresses an interest in learning

Bowel Incontinence

Bowel Incontinence r/t decreased awareness of need to defecate, loss of sphincter control, fecal impaction
Readiness for enhanced Knowledge: expresses an interest in learning

Bowel Obstruction

Constipation r/t decreased motility, intestinal obstruction
Deficient Fluid volume r/t inadequate fluid volume intake, fluid loss in bowel
Imbalanced Nutrition: **less than body requirements** r/t nausea, vomiting
Acute Pain r/t pressure from distended abdomen

Bowel Resection

See Abdominal Surgery

Bowel Sounds, Absent or Diminished

Constipation r/t decreased or absent peristalsis
Deficient Fluid volume r/t inability to ingest fluids, loss of fluids in bowel
Delayed Surgical recovery r/t inability to obtain adequate nutritional status
Risk for dysfunctional Gastrointestinal motility (See **Gastrointestinal** motility, dysfunctional, risk for, Section III)

Bowel Sounds, Hyperactive

Diarrhea r/t increased gastrointestinal motility

Bowel Training

Bowel Incontinence r/t loss of control of rectal sphincter
Readiness for enhanced Knowledge: expresses an interest in learning

Bowel Training, Child

See Toilet Training

BPH (Benign Prostatic Hypertrophy)

Ineffective Health maintenance r/t deficient knowledge regarding self-care with prostatic hypertrophy
Insomnia r/t nocturia
Urinary Retention r/t obstruction of urethra
Risk for urge urinary Incontinence: Risk factors: detrusor muscle instability with impaired contractility, involuntary sphincter relaxation
Risk for Infection: Risk factors: urinary residual after voiding, bacterial invasion of bladder
Readiness for enhanced Knowledge: expresses an interest in learning
See Prostatic Hypertrophy

Bradycardia

Decreased Cardiac output r/t slow heart rate supplying inadequate amount of blood for body function
Risk for ineffective Cerebral tissue perfusion: Risk factors: decreased cardiac output secondary to bradycardia, vagal response
Readiness for enhanced Knowledge: expresses an interest in learning

Bradypnea

Ineffective Breathing pattern r/t neuromuscular impairment, pain, musculoskeletal impairment, perception or cognitive impairment, anxiety, fatigue or decreased energy, effects of drugs
See Sleep apnea (See **Airway** clearance, ineffective, Section III)

Brain Injury

See Intracranial Pressure, Increased
Risk for ineffective Thermoregulation: Risk factor: post traumatic inflammation or infection

Brain Surgery

See Craniectomy/Craniotomy

Brain Tumor

Acute Confusion r/t pressure from tumor
Fear r/t threat to well-being
Grieving r/t potential loss of physiosocial-psychosocial well-being
Decreased Intracranial adaptive capacity r/t presence of brain tumor
Acute Pain r/t pressure from tumor
Vision Loss r/t tumor growth compressing optic nerve and/or brain tissue
Risk for Injury: Risk factors: sensory-perceptual alterations, weakness
Risk for ineffective Thermoregulation: Risk factor: changes in metabolic activity of the brain
See Cancer; Chemotherapy; Child with Chronic Condition; Craniectomy/Craniotomy; Hospitalized Child; Radiation Therapy; Terminally Ill Child, Adolescent; Terminally Ill Child, Infant/Toddler; Terminally Ill Child, Preschool Child; Terminally Ill Child, School-Age Child/Preadolescent; Terminally Ill Child/Death of Child, Parent

Braxton Hicks Contractions

Activity intolerance r/t increased contractions with increased gestation
Anxiety r/t uncertainty about beginning labor
Fatigue r/t lack of sleep
Stress urinary Incontinence r/t increased pressure on bladder with contractions
Insomnia r/t contractions when lying down
Ineffective Sexuality pattern r/t fear of contractions associated with loss of infant

Breast Biopsy

Fear r/t potential for diagnosis of cancer
Risk for Spiritual distress: Risk factor: fear of diagnosis of cancer
Readiness for enhanced Knowledge: expresses an interest in learning

Breast Cancer

Death Anxiety r/t diagnosis of cancer
Ineffective Coping r/t treatment, prognosis
Fear r/t diagnosis of cancer
Sexual dysfunction r/t loss of body part, partner's reaction to loss
Chronic Sorrow r/t diagnosis of cancer, loss of body integrity
Risk for Spiritual distress: Risk factor: fear of diagnosis of cancer
Readiness for enhanced Health literacy: expresses desire to enhance understanding of health information to make health care choices
Readiness for enhanced Knowledge: expresses an interest in learning
See Cancer; Chemotherapy; Mastectomy; Radiation Therapy

Breast Examination, Self

See SBE (Self-Breast Examination)

Breast Lumps

Fear r/t potential for diagnosis of cancer
Readiness for enhanced Knowledge: expresses an interest in learning

Breast Pumping

Risk for Infection: Risk factors: possible contaminated breast pump, incomplete emptying of breast
Risk for impaired Skin integrity: Risk factor: high suction
Readiness for enhanced Knowledge: expresses an interest in learning

Breastfeeding, Effective

Readiness for enhanced Breastfeeding (See **Breastfeeding,** readiness for enhanced, Section III)

Breastfeeding, Ineffective

Ineffective Breastfeeding (See **Breastfeeding,** ineffective, Section III)
See Infant Feeding Pattern, Ineffective; Painful Breasts, Engorgement; Painful Breasts, Sore Nipples

Breastfeeding, Interrupted

Interrupted Breastfeeding (See **Breastfeeding,** interrupted, Section III)

Breast Milk Production, Insufficient

Insufficient Breast Milk Production (See **Breast Milk Production,** insufficient, Section III)

Breath Sounds, Decreased or Absent

See Atelectasis; Pneumothorax

Breathing Pattern Alteration

Ineffective Breathing pattern r/t neuromuscular impairment, pain, musculoskeletal impairment, perception or cognitive impairment, anxiety, decreased energy or fatigue

Breech Birth

Fear: **maternal** r/t danger to infant, self
Impaired Gas exchange: **fetal** r/t compressed umbilical cord
Risk for Aspiration: **fetal**: Risk factor: birth of body before head
Risk for delayed Development: Risk factor: compressed umbilical cord
Risk for impaired Tissue integrity: **fetal**: Risk factor: difficult birth
Risk for impaired Tissue integrity: **maternal**: Risk factor: difficult birth

Bronchitis

Ineffective Airway clearance r/t excessive thickened mucus secretion
Readiness for enhanced Health management: wishes to stop smoking
Readiness for enhanced Knowledge: expresses an interest in learning

Bronchopulmonary Dysplasia

Activity intolerance r/t imbalance between oxygen supply and demand
Excess Fluid volume r/t sodium and water retention
Imbalanced Nutrition: **less than body requirements** r/t poor feeding, increased caloric needs as a result of increased work of breathing
See Child with Chronic Condition; Hospitalized Child; Respiratory Conditions of the Neonate

Bronchoscopy

Risk for Aspiration: Risk factor: temporary loss of gag reflex
Risk for Injury: Risk factors: complication of pneumothorax, laryngeal edema, hemorrhage (if biopsy done)

Bruits, Carotid

Risk for ineffective Cerebral tissue perfusion: Risk factors: interruption of carotid blood flow to brain

Bryant's Traction

See Traction and Casts

Buck's Traction

See Traction and Casts

Buerger's Disease

See Peripheral Vascular Disease (PVD)

Bulimia

Disturbed Body Image r/t misperception about actual appearance, body weight
Compromised family Coping r/t chronically unresolved feelings of guilt, anger, hostility
Defensive Coping r/t eating disorder
Diarrhea r/t laxative abuse
Fear r/t food ingestion, weight gain
Imbalanced Nutrition: **less than body requirements** r/t induced vomiting, excessive exercise, laxative abuse
Ineffective adolescent Eating dynamics r/t overeating, leading to purge
Powerlessness r/t urge to purge self after eating
Chronic low Self-Esteem r/t lack of positive feedback
See Maturational Issues, Adolescent

Bullying

Anxiety r/t specific or nonspecific threat to self
Impaired Social interaction r/t dysfunctional interactions with others
Fear r/t perceived threat to self
Risk for compromised Human Dignity: Risk factors: dehumanizing treatment, humiliation
Risk for other-directed Violence: Risk factors: social isolation, unresolved interpersonal conflicts
Risk for Powerlessness: Risk factor: ineffective coping strategies
Risk for impaired Resilience: Risk factor: insufficient familial and social support
Risk for self-directed violence: Risk factors: unresolved interpersonal conflicts, social isolation
Risk for chronic low Self-Esteem: Risk factors: ineffective coping strategies, absence of sense of belonging, inadequate respect from others

Bunion

Readiness for enhanced Knowledge: expresses an interest in learning

Bunionectomy

Impaired physical Mobility r/t sore foot
Impaired Walking r/t pain associated with surgery
Risk for Surgical Site Infection: Risk factors: surgical incision
Readiness for enhanced Knowledge: expresses an interest in learning

Burn Risk

Risk for Thermal injury (See **Thermal** injury, risk for, Section III)

Burns

Anxiety r/t burn injury, treatments

Disturbed Body Image r/t altered physical appearance
Decreased Diversional activity engagement r/t long-term hospitalization
Fear r/t pain from treatments, possible permanent disfigurement
Deficient Fluid volume r/t loss of protective skin
Grieving r/t loss of bodily function, loss of future hopes and plans
Hypothermia r/t impaired skin integrity
Impaired physical Mobility r/t pain, musculoskeletal impairment, contracture formation
Imbalanced Nutrition: **less than body requirements** r/t increased metabolic needs, anorexia, protein and fluid loss
Acute Pain r/t burn injury, treatments
Chronic Pain r/t burn injury, treatments
Ineffective peripheral Tissue Perfusion r/t circumferential burns, impaired arterial/venous circulation
Post-Trauma syndrome r/t life-threatening event
Impaired Skin integrity r/t injury of skin
Delayed Surgical recovery r/t ineffective tissue perfusion
Risk for ineffective Airway clearance: Risk factors: potential tracheobronchial obstruction, edema
Risk for deficient Fluid volume: Risk factors: loss from skin surface, fluid shift
Risk for Infection: Risk factors: loss of intact skin, trauma, invasive sites
Risk for Peripheral Neurovascular dysfunction: Risk factor: eschar formation with circumferential burn
Risk for Post-Trauma syndrome: Risk factors: perception, duration of event that caused burns
Risk for ineffective Thermoregulation: Risk factor: disruption of skin integrity
Readiness for enhanced Knowledge: expresses an interest in learning
See Hospitalized Child; Safety, Childhood

Bursitis

Impaired physical Mobility r/t inflammation in joint
Acute Pain r/t inflammation in joint

Bypass Graft

See Coronary Artery Bypass Grafting (CABG)

List of Nursing Diagnosis by Letter: C

CABG (Coronary Artery Bypass Grafting)	Cachexia	Calcium Alteration
Cancer	Candidiasis, Oral	Capillary Refill Time, Prolonged
Carbon Monoxide Poisoning	Cardiac Arrest	Cardiac Catheterization
Cardiac Disorders in Pregnancy	Cardiac Dysrhythmia	Cardiac Output, Decreased
Cardiac Tamponade	Cardiogenic Shock	Caregiver Role Strain
Carious Teeth	Carotid Endarterectomy	Carpal Tunnel Syndrome
Carpopedal Spasm	Casts	Cataract Extraction
Catatonic Schizophrenia	Catheterization, Urinary	Cavities in Teeth
Celiac Disease	Cellulitis	Cellulitis, Periorbital
Central Line Insertion	Cerebral Aneurysm	Cerebral Palsy
Cerebral Perfusion	Cerebrovascular Accident (CVA)	Cervicitis
Cesarean Delivery	Chemical Dependence	Chemotherapy
Chest Pain	Chest Tubes	Cheyne-Stokes Respiration
Chickenpox	Child Abuse	Childbearing Problems
Child Neglect	Child with Chronic Condition	Childbirth
Childhood Obesity	Chills	Chlamydia Infection
Chloasma	Choking or Coughing with Eating	Cholecystectomy
Cholelithiasis	Chorioamnionitis	Chronic Confusion
Chronic Functional Constipation	Chronic Lymphocytic Leukemia	Chronic Obstructive Pulmonary Disease (COPD)
Chronic Pain	Chronic Renal Failure (Chronic Renal Disease)	Chvostek's Sign
Circumcision	Cirrhosis	Cleft Lip/Cleft Palate
Clotting Disorder	Cocaine Baby	Codependency
Cold, Viral	Colectomy	Colitis
Collagen Disease	Colostomy	Colporrhaphy, Anterior
Coma	Comfort, Loss of	Communicable Diseases, Childhood (e.g., Measles, Mumps, Rubella, Chickenpox, Scabies, Lice, Impetigo)
Communication	Communication Problems	Community Coping
Community Health Problems	Companion Animal	Compartment Syndrome

Compulsion	Conduction Disorders (Cardiac)	Confusion, Acute
Confusion, Chronic	Congenital Heart Disease/Cardiac Anomalies	Congestive Heart Failure (CHF)
Conjunctivitis	Consciousness, Altered Level of	Constipation
Constipation, Chronic Functional	Constipation, Perceived	Constipation, Risk for
Contamination	Continent Ileostomy (Kock Pouch)	Contraceptive Method
Convulsions	COPD (Chronic Obstructive Pulmonary Disease)	Coping
Coping Problems	Corneal Injury	Corneal Reflex, Absent
Corneal Transplant	Coronary Artery Bypass Grafting (CABG)	Costovertebral Angle Tenderness
Cough, Ineffective	Crackles in Lungs, Coarse	Crackles in Lungs, Fine
Craniectomy/Craniotomy	Crepitation, Subcutaneous	Crisis
Crohn's Disease	Croup	Cryosurgery for Retinal Detachment
Cushing's Syndrome	Cuts (Wounds)	CVA (Cerebrovascular Accident)
Cyanosis, Central with Cyanosis of Oral Mucous Membranes	Cyanosis, Peripheral with Cyanosis of Nail Beds	Cystic Fibrosis
Cystitis	Cystocele	Cystoscopy

C

CABG (Coronary Artery Bypass Grafting)

See Coronary Artery Bypass Grafting (CABG)

Cachexia

Frail Elderly syndrome r/t fatigue, feeding self-care deficit
Imbalanced Nutrition: less than body requirements r/t inability to ingest food because of physiological factors
Risk for Infection: Risk factor: inadequate nutrition

Calcium Alteration

See Hypercalcemia; Hypocalcemia

Cancer

Activity intolerance r/t side effects of treatment, weakness from cancer
Death Anxiety r/t unresolved issues regarding dying
Disturbed Body Image r/t side effects of treatment, cachexia
Decisional Conflict r/t selection of treatment choices, continuation or discontinuation of treatment, "do not resuscitate" decision
Constipation r/t side effects of medication, altered nutrition, decreased activity
Compromised family Coping r/t prolonged disease or disability progression that exhausts supportive ability of significant others
Ineffective Coping r/t personal vulnerability in situational crisis, terminal illness
Ineffective Denial r/t complicated grieving process
Fear r/t serious threat to well-being
Grieving r/t potential loss of significant others, high risk for infertility
Ineffective Health maintenance r/t deficient knowledge regarding prescribed treatment
Hopelessness r/t loss of control, terminal illness
Insomnia r/t anxiety, pain
Impaired physical Mobility r/t weakness, neuromusculoskeletal impairment, pain
Imbalanced Nutrition: less than body requirements r/t loss of appetite, difficulty swallowing, side effects of chemotherapy, obstruction by tumor
Impaired Oral Mucous Membrane integrity r/t chemotherapy, effects of radiation, oral pH changes, decreased oral secretions
Chronic Pain r/t metastatic cancer
Powerlessness r/t treatment, progression of disease
Ineffective Protection r/t cancer suppressing immune system
Ineffective Role performance r/t change in physical capacity, inability to resume prior role
Self-Care deficit: specify r/t pain, intolerance to activity, decreased strength
Impaired Skin integrity r/t immunological deficit, immobility
Social isolation r/t hospitalization, lifestyle changes
Chronic Sorrow r/t chronic illness of cancer
Spiritual distress r/t test of spiritual beliefs
Risk for Bleeding: Risk factor: bone marrow depression from chemotherapy

Risk for Disuse syndrome: Risk factors: immobility, fatigue
Risk for impaired Home maintenance: Risk factor: lack of familiarity with community resources
Risk for Infection: Risk factor: inadequate immune system
Risk for compromised Resilience: Risk factors: multiple stressors, pain, chronic illness
Risk for Spiritual distress: Risk factor: physical illness of cancer
Readiness for enhanced Knowledge: expresses an interest in learning
Readiness for enhanced Spiritual well-being: desire for harmony with self, others, higher power, God, when faced with serious illness
See Chemotherapy; Child with Chronic Condition; Hospitalized Child; Leukemia; Radiation Therapy; Terminally Ill Child, Adolescent; Terminally Ill Child, Infant/Toddler; Terminally Ill Child, Preschool Child; Terminally Ill Child, School-Age Child/Preadolescent; Terminally Ill Child/Death of Child, Parent

Candidiasis, Oral

Readiness for enhanced Knowledge: expresses an interest in learning
Impaired Oral Mucous Membrane integrity r/t overgrowth of infectious agent, depressed immune function
Acute Pain r/t oral condition

Capillary Refill Time, Prolonged

Impaired Gas exchange r/t ventilation perfusion imbalance
Ineffective peripheral Tissue Perfusion r/t interruption of arterial flow
See Shock, Hypovolemic

Carbon Monoxide Poisoning

See Smoke Inhalation

Cardiac Arrest

Post-Trauma syndrome r/t experiencing serious life event
See Dysrhythmia; MI (Myocardial Infarction)

Cardiac Catheterization

Fear r/t invasive procedure, uncertainty of outcome of procedure
Risk for Injury: hematoma: Risk factor: invasive procedure
Risk for decreased Cardiac tissue perfusion: Risk factors: ventricular ischemia, dysrhythmia
Risk for Peripheral Neurovascular dysfunction: Risk factor: vascular obstruction
Risk for Impaired Tissue integrity: Risk factor: invasive procedure
Readiness for enhanced Knowledge: expresses an interest in learning postprocedure care, treatment, and prevention of coronary artery disease

Cardiac Disorders in Pregnancy

Activity intolerance r/t cardiac pathophysiology, increased demand for cardiac output because of pregnancy, weakness, fatigue
Death Anxiety r/t potential danger of condition
Compromised family Coping r/t prolonged hospitalization or maternal incapacitation that exhausts supportive capacity of significant others
Ineffective Coping r/t personal vulnerability
Interrupted Family processes r/t hospitalization, maternal incapacitation, changes in roles
Fatigue r/t physiological, psychological, and emotional demands
Fear r/t potential maternal effects, potential poor fetal or maternal outcome

Powerlessness r/t illness-related regimen
Ineffective Role performance r/t changes in lifestyle, expectations from disease process with superimposed pregnancy
Situational low Self-Esteem r/t situational crisis, pregnancy
Social isolation r/t limitations of activity, bed rest or hospitalization, separation from family and friends
Risk for decreased Cardiac tissue perfusion: Risk factor: strain on compromised heart from work of pregnancy, delivery
Risk for delayed Development: Risk factor: poor maternal oxygenation
Risk for deficient Fluid volume: Risk factor: sudden changes in circulation after delivery of placenta
Risk for excess Fluid volume: Risk factors: compromised regulatory mechanism with increased afterload, preload, circulating blood volume
Risk for impaired Gas exchange: Risk factor: pulmonary edema
Risk for disturbed Maternal–Fetal dyad: Risk factor: compromised oxygen transport
Risk for compromised Resilience: Risk factors: multiple stressors, fear
Risk for Spiritual distress: Risk factor: fear of diagnosis for self and infant
Readiness for enhanced Knowledge: expresses an interest in learning

Cardiac Dysrhythmia

See Dysrhythmia

Cardiac Output, Decreased

Decreased Cardiac output r/t cardiac dysfunction
Decreased Cardiac output (See **Cardiac** output, decreased, Section III)
Oliguria r/t cardiac dysfunction
Risk for decreased Cardiac output (See **Cardiac** output, risk for decreased, Section III)

Cardiac Tamponade

Decreased Cardiac output r/t fluid in pericardial sac
See Pericarditis

Cardiogenic Shock

See Shock, Cardiogenic

Caregiver Role Strain

Caregiver Role Strain (See **Caregiver Role Strain**, Section III)
Risk for compromised Resilience: Risk factor: stress of prolonged caregiving

Carious Teeth

See Cavities in Teeth

Carotid Endarterectomy

Fear r/t surgery in vital area
Risk for ineffective Airway clearance: Risk factor: hematoma compressing trachea
Risk for Bleeding: Risk factor: possible hematoma formation, trauma to region
Risk for ineffective Cerebral tissue perfusion: Risk factors: hemorrhage, clot formation
Readiness for enhanced Knowledge: expresses an interest in learning

Carpal Tunnel Syndrome

Impaired physical Mobility r/t neuromuscular impairment
Chronic Pain r/t unrelieved pressure on median nerve
Self-Care deficit: bathing, dressing, feeding r/t pain

Carpopedal Spasm

See Hypocalcemia

Casts

Decreased Diversional activity engagement r/t physical limitations from cast
Impaired physical Mobility r/t limb immobilization
Self-Care deficit: **bathing, dressing, feeding** r/t presence of cast(s) on upper extremities
Self-Care deficit: toileting r/t presence of cast(s) on lower extremities
Impaired Walking r/t cast(s) on lower extremities, fracture of bones
Risk for Peripheral Neurovascular dysfunction: Risk factors: mechanical compression from cast, trauma from fracture
Risk for impaired Skin integrity: Risk factor: unrelieved pressure on skin from cast
Readiness for enhanced Knowledge: expresses an interest in learning
See Traction and Casts

Cataract Extraction

Anxiety r/t threat of permanent vision loss, surgical procedure
Vision Loss r/t edema from surgery (*see Appendix E on Evolve*)
Risk for Injury: Risk factors: increased intraocular pressure, accommodation to new visual field
Readiness for enhanced Knowledge: expresses an interest in learning

Catatonic Schizophrenia

Impaired verbal Communication r/t cognitive impairment
Impaired Memory r/t cognitive impairment
Impaired physical Mobility r/t cognitive impairment, maintenance of rigid posture, inappropriate or bizarre postures
Imbalanced Nutrition: **less than body requirements** r/t decrease in outside stimulation, loss of perception of hunger, resistance to instructions to eat
Social isolation r/t inability to communicate, immobility
See Schizophrenia

Catheterization, Urinary

Risk for Infection: Risk factor: invasive procedure
Readiness for enhanced Knowledge: expresses an interest in learning

Cavities in Teeth

Impaired Dentition r/t ineffective oral hygiene, barriers to self-care, economic barriers to professional care, nutritional deficits, dietary habits

Celiac Disease

Diarrhea r/t malabsorption of food, immune effects of gluten on gastrointestinal system
Imbalanced Nutrition: less than body requirements r/t malabsorption caused by immune effects of gluten
Readiness for enhanced Knowledge: expresses an interest in learning

Cellulitis

Acute Pain r/t inflammatory changes in tissues from infection
Impaired Tissue integrity r/t inflammatory process damaging skin and underlying tissue
Ineffective peripheral Tissue Perfusion r/t edema of extremities
Risk for Vascular Trauma: Risk factor: infusion of antibiotics
Readiness for enhanced Knowledge: expresses an interest in learning

Cellulitis, Periorbital

Acute Pain r/t edema and inflammation of skin/tissues
Impaired Skin integrity r/t inflammation or infection of skin, tissues
Vision Loss r/t decreased visual field secondary to edema of eyelids (*see Appendix E on Evolve*)
Readiness for enhanced Knowledge: expresses an interest in learning
See Hospitalized Child

Central Line Insertion

Risk for Infection: Risk factor: invasive procedure
Risk for Vascular Trauma (See **Vascular Trauma**, risk for, Section III)
Readiness for enhanced Knowledge: expresses an interest in learning

Cerebral Aneurysm

See Craniectomy/Craniotomy; Intracranial Pressure, Increased; Subarachnoid Hemorrhage

Cerebral Palsy

Impaired verbal Communication r/t impaired ability to articulate or speak words because of facial muscle involvement
Decreased Diversional activity engagement r/t physical impairments, limitations on ability to participate in recreational activities
Impaired physical Mobility r/t spasticity, neuromuscular impairment or weakness
Imbalanced Nutrition: **less than body requirements** r/t spasticity, feeding or swallowing difficulties
Self-Care deficit: **specify** r/t neuromuscular impairments, sensory deficits
Impaired Social interaction r/t impaired communication skills, limited physical activity, perceived differences from peers
Chronic Sorrow r/t presence of chronic disability
Risk for Falls: Risk factor: impaired physical mobility
Risk for Injury: Risk factors: muscle weakness, inability to control spasticity
Risk for impaired Parenting: Risk factor: caring for child with overwhelming needs resulting from chronic change in health status
Risk for Spiritual distress: Risk factor: psychological stress associated with chronic illness
See Child with Chronic Condition

Cerebral Perfusion

Risk for ineffective Cerebral tissue perfusion (See **Cerebral** tissue perfusion, ineffective, risk for, Section III)

Cerebrovascular Accident (CVA)

See CVA (Cerebrovascular Accident)

Cervicitis

Ineffective Health maintenance r/t deficient knowledge regarding care and prevention of condition
Ineffective Sexuality pattern r/t abstinence during acute stage
Risk for Infection: Risk factors: spread of infection, recurrence of infection

Cesarean Delivery

Disturbed Body Image r/t surgery, unmet expectations for childbirth
Interrupted Family processes r/t unmet expectations for childbirth
Fear r/t perceived threat to own well-being, outcome of birth
Impaired physical Mobility r/t pain
Acute Pain r/t surgical incision
Ineffective Role performance r/t unmet expectations for childbirth
Situational low Self-Esteem r/t inability to deliver child vaginally
Risk for Bleeding: Risk factor: surgery
Risk for imbalanced Fluid volume: Risk factors: loss of blood, fluid shifts
Risk for Surgical Site Infection: Risk factor: surgical incision
Risk for Urinary Retention: Risk factor: regional anesthesia
Readiness for enhanced Childbearing process: a pattern of preparing for, maintaining, and strengthening care of newborn
Readiness for enhanced Knowledge: expresses an interest in learning

Chemical Dependence

See Alcoholism; Substance Abuse

Chemotherapy

Death Anxiety r/t chemotherapy not accomplishing desired results
Disturbed Body Image r/t loss of weight, loss of hair
Fatigue r/t disease process, anemia, drug effects
Nausea r/t effects of chemotherapy
Imbalanced Nutrition: less than body requirements r/t side effects of chemotherapy
Impaired Oral Mucous Membrane integrity r/t effects of chemotherapy
Ineffective Protection r/t suppressed immune system, decreased platelets
Risk for Bleeding: Risk factors: tumor eroding blood vessel, stress effects on gastrointestinal system
Risk for Infection: Risk factor: immunosuppression
Risk for Vascular Trauma: Risk factor: infusion of irritating medications
Readiness for enhanced Knowledge: expresses an interest in learning
See Cancer

Chest Pain

Fear r/t potential threat of death
Acute Pain r/t myocardial injury, ischemia
Risk for decreased Cardiac tissue perfusion: Risk factor: ventricular ischemia
See Angina; MI (Myocardial Infarction)

Chest Tubes

Ineffective Breathing pattern r/t asymmetrical lung expansion secondary to pain
Impaired Gas exchange r/t decreased functional lung tissue
Acute Pain r/t presence of chest tubes, injury
Risk for Injury: Risk factor: presence of invasive chest tube

Cheyne-Stokes Respiration

Ineffective Breathing pattern r/t critical illness

Chickenpox

See Communicable Diseases, Childhood

Child Abuse

Interrupted Family processes r/t inadequate coping skills
Fear r/t threat of punishment for perceived wrongdoing
Insomnia r/t hypervigilance, fear
Imbalanced Nutrition: **less than body requirements** r/t inadequate caretaking
Acute Pain r/t physical injuries
Impaired Parenting r/t psychological impairment, physical or emotional abuse of parent, substance abuse, unrealistic expectations of child
Ineffective child Eating dynamics r/t hostile parental relationship
Post-Trauma syndrome r/t physical abuse, incest, rape, molestation
Chronic low Self-Esteem r/t lack of positive feedback, excessive negative feedback
Impaired Skin integrity r/t altered nutritional state, physical abuse
Social isolation: **family imposed** r/t fear of disclosure of family dysfunction and abuse
Risk for delayed Development: Risk factors: shaken baby syndrome, abuse
Risk for Poisoning: Risk factors: inadequate safeguards, lack of proper safety precautions, accessibility of illicit substances because of impaired home maintenance
Risk for Suffocation: Risk factors: unattended child, unsafe environment
Risk for Physical Trauma: Risk factors: inadequate precautions, cognitive or emotional difficulties

Childbearing Problems

Ineffective Childbearing process (See **Childbearing** process, ineffective, Section III)
Risk for ineffective Childbearing process: (See **Childbearing** process, risk for ineffective, Section III)

Child Neglect

See Child Abuse; Failure to Thrive

Child with Chronic Condition

Activity intolerance r/t fatigue associated with chronic illness
Compromised family Coping r/t prolonged overconcern for child; distortion of reality regarding child's health problem, including extreme denial about its existence or severity
Disabled family Coping r/t prolonged disease or disability progression that exhausts supportive capacity of significant others
Ineffective Coping: **child** r/t situational or maturational crises
Decisional Conflict r/t treatment options, conflicting values
Decreased Diversional activity engagement r/t immobility, monotonous environment, frequent or lengthy treatments, reluctance to participate, self-imposed social isolation
Interrupted Family processes r/t intermittent situational crisis of illness, disease, hospitalization
Ineffective Health maintenance r/t exhausting family resources (finances, physical energy, support

systems)
Impaired Home maintenance r/t overtaxed family members (e.g., exhausted, anxious)
Hopelessness: **child** r/t prolonged activity restriction, long-term stress, lack of involvement in or passively allowing care as a result of parental overprotection
Insomnia: **child or parent** r/t time-intensive treatments, exacerbation of condition, 24-hour care needs
Deficient Knowledge r/t knowledge or skill acquisition regarding health practices, acceptance of limitations, promotion of maximal potential of child, self-actualization of rest of family
Imbalanced Nutrition: **less than body requirements** r/t anorexia, fatigue from physical exertion
Risk for Overweight r/t effects of steroid medications on appetite
Chronic Pain r/t physical, biological, chemical, or psychological factors
Powerlessness: **child** r/t health care environment, illness-related regimen, lifestyle of learned helplessness
Parental Role conflict r/t separation from child as a result of chronic illness, home care of child with special needs, interruptions of family life resulting from home care regimen
Chronic low Self-Esteem r/t actual or perceived differences; peer acceptance; decreased ability to participate in physical, school, and social activities
Ineffective Sexuality pattern: **parental** r/t disrupted relationship with sexual partner
Impaired Social interaction r/t developmental lag or delay, perceived differences
Social isolation: **family** r/t actual or perceived social stigmatization, complex care requirements
Chronic Sorrow r/t developmental stages and missed opportunities or milestones that bring comparisons with social or personal norms, unending caregiving as reminder of loss
Risk for delayed Development: Risk factor: chronic illness
Risk for Infection: Risk factor: debilitating physical condition
Risk for impaired Parenting: Risk factors: impaired or disrupted bonding, caring for child with perceived overwhelming care needs
Readiness for enhanced family Coping: impact of crisis on family values, priorities, goals, or relationships; changes in family choices to optimize wellness

Childbirth

Readiness for enhanced Childbearing process (See **Childbearing** process, readiness for enhanced, Section III)
See Labor, Normal; Postpartum, Normal Care

Childhood Obesity

Obesity r/t disordered eating behaviors
Risk for Activity intolerance: Risk factors: sedentary lifestyle, exertional discomfort
Risk for unstable blood Glucose Level: Risk factor: excessive weight gain
Risk for Metabolic Imbalance syndrome: Risk factors: obesity, sedentary lifestyle
Readiness for enhanced Knowledge: expresses desire to make healthier nutrition choices

Chills

Hyperthermia r/t infectious process

Chlamydia Infection

See STD (Sexually Transmitted Disease)

Chloasma

Disturbed Body Image r/t change in skin color

Choking or Coughing with Eating

Impaired Swallowing r/t neuromuscular impairment
Risk for Aspiration: Risk factors: depressed cough and gag reflexes

Cholecystectomy

Imbalanced Nutrition: **less than body requirements** r/t high metabolic needs, decreased ability to digest fatty foods
Acute Pain r/t trauma from surgery
Risk for deficient Fluid volume: Risk factors: restricted intake, nausea, vomiting
Risk for Surgical Site Infection: Risk factor: invasive procedure
Readiness for enhanced Knowledge: expresses an interest in learning
See Abdominal Surgery

Cholelithiasis

Nausea r/t obstruction of bile
Imbalanced Nutrition: **less than body requirements** r/t anorexia, nausea, vomiting
Acute Pain r/t obstruction of bile flow, inflammation in gallbladder
Readiness for enhanced Knowledge: expresses an interest in learning

Chorioamnionitis

Anxiety r/t threat to self and infant
Grieving r/t guilt about potential loss of ideal pregnancy and birth
Hyperthermia r/t infectious process
Situational low Self-Esteem r/t guilt about threat to infant's health
Risk for Infection: Risk factors: infection transmission from mother to fetus; infection in fetal environment

Chronic Confusion

See Confusion, Chronic

Chronic Functional Constipation

(See **Constipation**, chronic functional, section III)
(See **Constipation**, chronic functional, risk for, section III)

Chronic Lymphocytic Leukemia

See Cancer; Chemotherapy; Leukemia

Chronic Obstructive Pulmonary Disease (COPD)

See COPD (Chronic Obstructive Pulmonary Disease)

Chronic Pain

See Pain Management, Chronic

Chronic Renal Failure (Chronic Renal Disease)

See Renal Failure

Chvostek's Sign

See Hypocalcemia

Circumcision

Acute Pain r/t surgical intervention
Risk for Bleeding: Risk factor: surgical trauma
Risk for Infection: Risk factor: surgical wound
Readiness for enhanced Knowledge: **parent:** expresses an interest in learning

Cirrhosis

Chronic Confusion r/t chronic organic disorder with increased ammonia levels, substance abuse
Defensive Coping r/t inability to accept responsibility to stop substance abuse
Fatigue r/t malnutrition
Ineffective Health maintenance r/t deficient knowledge regarding correlation between lifestyle habits and disease process
Nausea r/t irritation to gastrointestinal system
Imbalanced Nutrition: **less than body requirements** r/t loss of appetite, nausea, vomiting
Chronic Pain r/t liver enlargement
Chronic low Self-Esteem r/t chronic illness
Chronic Sorrow r/t presence of chronic illness
Risk for Bleeding: Risk factors: impaired blood coagulation, bleeding from portal hypertension
Risk for Injury: Risk factors: substance intoxication, potential delirium tremens
Risk for impaired Oral Mucous Membrane integrity: Risk factors: altered nutrition, inadequate oral care
Risk for impaired Skin integrity: Risk factors: altered nutritional state, altered metabolic state

Cleft Lip/Cleft Palate

Ineffective Airway clearance r/t common feeding and breathing passage, postoperative laryngeal, incisional edema
Ineffective Breastfeeding r/t infant anomaly
Impaired verbal Communication r/t inadequate palate function, possible hearing loss from infected eustachian tubes
Fear: **parental** r/t special care needs, surgery
Grieving r/t loss of perfect child
Ineffective infant Feeding dynamic r/t fear resulting in inadequate feeding
Ineffective infant Feeding pattern r/t cleft lip, cleft palate
Impaired physical Mobility r/t imposed restricted activity, use of elbow restraints
Impaired Oral Mucous Membrane integrity r/t surgical correction
Acute Pain r/t surgical correction, elbow restraints
Impaired Skin integrity r/t incomplete joining of lip, palate ridges
Chronic Sorrow r/t birth of child with congenital defect
Risk for Aspiration: Risk factor: common feeding and breathing passage
Risk for disturbed Body Image: Risk factors: disfigurement, speech impediment
Risk for delayed Development: Risk factor: inadequate nutrition resulting from difficulty feeding
Risk for deficient Fluid volume: Risk factor: inability to take liquids in usual manner
Risk for Infection: Risk factors: invasive procedure, disruption of eustachian tube development, aspiration
Readiness for enhanced Knowledge: **parent:** expresses an interest in learning

Clotting Disorder

Fear r/t threat to well-being
Risk for Bleeding: Risk factor: impaired clotting
Readiness for enhanced Knowledge: expresses an interest in learning
See Anticoagulant Therapy; DIC (Disseminated Intravascular Coagulation); Hemophilia

Cocaine Baby

See Neonatal Abstinence Syndrome

Codependency

Caregiver Role Strain r/t codependency
Impaired verbal Communication r/t psychological barriers
Ineffective Coping r/t inadequate support systems
Decisional Conflict r/t support system deficit
Ineffective Denial r/t unmet self-needs
Powerlessness r/t lifestyle of helplessness

Cold, Viral

See Infectious Processes

Colectomy

Constipation r/t decreased activity, decreased fluid intake
Imbalanced Nutrition: **less than body requirements** r/t high metabolic needs, decreased ability to ingest or digest food
Acute Pain r/t recent surgery
Risk for Surgical Site Infection: Risk factor: invasive procedure
Readiness for enhanced Knowledge: expresses an interest in learning
See Abdominal Surgery

Colitis

Diarrhea r/t inflammation in colon
Deficient Fluid volume r/t frequent stools
Acute Pain r/t inflammation in colon
Readiness for enhanced Knowledge: expresses an interest in learning
See Crohn's Disease; Inflammatory Bowel Disease (Child and Adult)

Collagen Disease

See specific disease (e.g., Lupus erythematosus; JRA [juvenile rheumatoid arthritis]); Congenital Heart Disease/Cardiac Anomalies

Colostomy

Disturbed Body Image r/t presence of stoma, daily care of fecal material
Ineffective Sexuality pattern r/t altered body image, self-concept
Social isolation r/t anxiety about appearance of stoma and possible leakage of stool
Risk for Constipation: Risk factor: inappropriate diet
Risk for Diarrhea: Risk factor: inappropriate diet
Risk for impaired Skin integrity: Risk factor: irritation from bowel contents
Readiness for enhanced Knowledge: expresses an interest in learning

Colporrhaphy, Anterior

See Vaginal Hysterectomy

Coma

Death Anxiety: **significant others** r/t unknown outcome of coma state
Interrupted Family processes r/t illness or disability of family member
Functional urinary Incontinence r/t presence of comatose state
Self-Care deficit: r/t neuromuscular impairment
Ineffective family Health management r/t complexity of therapeutic regimen
Risk for Aspiration: Risk factors: impaired swallowing, loss of cough or gag reflex
Risk for Disuse syndrome: Risk factor: altered level of consciousness impairing mobility
Risk for Dry Mouth: Risk factor: inability to perform own oral care
Risk for Hypothermia: Risk factors: inactivity, possible pharmaceutical agents, possible hypothalamic injury
Risk for Injury: Risk factor: potential seizure activity
Risk for corneal Injury: Risk factor: suppressed corneal reflex
Risk for urinary tract Injury: Risk factor: long-term use of urinary catheter
Risk for impaired Oral Mucous Membrane integrity: Risk factors: dry mouth, inability to do own mouth care
Risk for Pressure ulcer: Risk factor: prolonged immobility
Risk for impaired Skin integrity: Risk factor: immobility
Risk for Spiritual distress: **significant others**: Risk factors: loss of ability to relate to loved one, unknown outcome of coma
Risk for impaired Tissue integrity: Risk factor: impaired physical mobility
See Head Injury; Subarachnoid Hemorrhage; Intracranial Pressure, Increased

Comfort, Loss of

Impaired Comfort (See **Comfort**, impaired, Section III)
Readiness for enhanced Comfort (See **Comfort**, readiness for enhanced, Section III)

Communicable Diseases, Childhood (e.g., Measles, Mumps, Rubella, Chickenpox, Scabies, Lice, Impetigo)

Impaired Comfort r/t pruritus, inflammation or infection of skin, subdermal organisms
Decreased Diversional activity engagement r/t imposed isolation from peers, disruption in usual play activities, fatigue, activity intolerance
Ineffective Health maintenance r/t nonadherence to appropriate immunization schedules, lack of prevention of transmission of infection
Acute Pain r/t impaired skin integrity, edema
Risk for Infection: **transmission to others**: Risk factor: contagious organisms
See Meningitis/Encephalitis; Respiratory Infections, Acute Childhood

Communication

Readiness for enhanced Communication (See **Communication**, readiness for enhanced, Section III)

Communication Problems

Impaired verbal Communication (See **Communication**, verbal, impaired, Section III)

Community Coping

Ineffective community Coping (See **Coping**, community, ineffective, Section III)
Readiness for enhanced community Coping: community sense of power to manage stressors, social supports available, resources available for problem solving

Community Health Problems

Deficient community Health (See **Health**, deficient, community, Section III)

Companion Animal

Anxiety r/t environmental and personal stressors
Impaired Comfort r/t insufficient environmental control

Compartment Syndrome

Fear r/t possible loss of limb, damage to limb
Acute Pain r/t pressure in compromised body part
Ineffective peripheral Tissue Perfusion r/t increased pressure within compartment

Compulsion

See OCD (Obsessive-Compulsive Disorder)

Conduction Disorders (Cardiac)

See Dysrhythmia

Confusion, Acute

Acute Confusion r/t older than 70 years of age with hospitalization, alcohol abuse, delirium, dementia, substance abuse
Frail Elderly syndrome r/t impaired memory
Risk for acute Confusion: Risk factor: alteration in level of consciousness

Confusion, Chronic

Chronic Confusion r/t dementia, Korsakoff's psychosis, multi-infarct dementia, cerebrovascular accident, head injury
Frail Elderly syndrome r/t impaired memory
Impaired Memory r/t fluid and electrolyte imbalance, neurological disturbances, excessive environmental disturbances, anemia, acute or chronic hypoxia, decreased cardiac output
Impaired Mood regulation r/t emotional instability
See Alzheimer's Disease; Dementia

Congenital Heart Disease/Cardiac Anomalies

Activity intolerance r/t fatigue, generalized weakness, lack of adequate oxygenation
Ineffective Breathing pattern r/t pulmonary vascular disease
Decreased Cardiac output r/t cardiac dysfunction
Excess Fluid volume r/t cardiac dysfunction, side effects of medication
Impaired Gas exchange r/t cardiac dysfunction, pulmonary congestion
Imbalanced Nutrition: **less than body requirements** r/t fatigue, generalized weakness, inability of

infant to suck and feed, increased caloric requirements
Risk for delayed Development: Risk factor: inadequate oxygen and nutrients to tissues
Risk for deficient Fluid volume: Risk factor: side effects of diuretics
Risk for disorganized Infant behavior: Risk factor: invasive procedures
Risk for Poisoning: Risk factor: potential toxicity of cardiac medications
Risk for ineffective Thermoregulation: Risk factor: neonatal age
See Child with Chronic Condition; Hospitalized Child

Congestive Heart Failure (CHF)

See Heart Failure

Conjunctivitis

Acute Pain r/t inflammatory process
Vision Loss r/t change in visual acuity resulting from inflammation

Consciousness, Altered Level of

Acute Confusion r/t alcohol abuse, delirium, dementia, drug abuse, head injury
Chronic Confusion r/t multi-infarct dementia, Korsakoff's psychosis, head injury, cerebrovascular accident, neurological deficit
Functional urinary Incontinence r/t neurological dysfunction
Decreased Intracranial adaptive capacity r/t brain injury
Impaired Memory r/t neurological disturbances
Self-Care deficit: **specify** r/t neuromuscular impairment
Risk for Aspiration: Risk factors: impaired swallowing, loss of cough or gag reflex
Risk for Disuse syndrome: Risk factor: impaired mobility resulting from altered level of consciousness
Risk for Dry Mouth: Risk factor: inability to perform own oral care
Risk for Falls: Risk factor: diminished mental status
Risk for impaired Oral Mucous Membrane integrity: Risk factors: dry mouth, interrupted oral care
Risk for ineffective Cerebral tissue perfusion: Risk factors: increased intracranial pressure, altered cerebral perfusion
Risk for impaired Skin integrity: Risk factor: immobility
See Coma; Head Injury; Subarachnoid Hemorrhage; Intracranial Pressure, Increased

Constipation

Constipation (See **Constipation**, Section III)

Constipation, Chronic Functional

Constipation (See **Constipation**, chronic functional, Section III)

Constipation, Perceived

Perceived Constipation (See perceived **Constipation**, Section III)

Constipation, Risk for

Risk for Constipation (See **Constipation**, risk for, Section III)
Risk for chronic functional Constipation (See **Constipation**, chronic functional, risk for, Section III)

Contamination

Contamination (See **Contamination**, Section III)
Risk for Contamination (See **Contamination**, risk for, Section III)

Continent Ileostomy (Kock Pouch)

Ineffective Coping r/t stress of disease, exacerbations caused by stress
Imbalanced Nutrition: **less than body requirements** r/t malabsorption from disease process
Risk for Injury: Risk factors: failure of valve, stomal cyanosis, intestinal obstruction
Readiness for enhanced Knowledge: expresses an interest in learning
See Abdominal Surgery; Crohn's Disease

Contraceptive Method

Decisional Conflict: **method of contraception** r/t unclear personal values or beliefs, lack of experience or interference with decision-making, lack of relevant information, support system deficit
Ineffective Sexuality pattern r/t fear of pregnancy
Readiness for enhanced Health management: requesting information about available and appropriate birth control methods

Convulsions

Anxiety r/t concern over controlling convulsions
Impaired Memory r/t neurological disturbance
Risk for Aspiration: Risk factor: impaired swallowing
Risk for delayed Development: Risk factor: seizures
Risk for Injury: Risk factor: seizure activity
Readiness for enhanced Knowledge: expresses an interest in learning
See Seizure Disorders, Adult; Seizure Disorders, Childhood

COPD (Chronic Obstructive Pulmonary Disease)

Activity intolerance r/t imbalance between oxygen supply and demand
Ineffective Airway clearance r/t bronchoconstriction, increased mucus, ineffective cough, infection
Anxiety r/t breathlessness, change in health status
Death Anxiety r/t seriousness of medical condition, difficulty being able to "catch breath," feeling of suffocation
Interrupted Family processes r/t role changes
Impaired Gas exchange r/t ventilation-perfusion inequality
Ineffective Health management (See **Health** management, ineffective, Section III)
Imbalanced Nutrition: **less than body requirements** r/t decreased intake because of dyspnea, unpleasant taste in mouth left by medications, increased need for calories from work of breathing
Powerlessness r/t progressive nature of disease
Self-Care deficit: r/t fatigue from the increased work of breathing
Chronic low Self-Esteem r/t chronic illness
Sleep deprivation r/t breathing difficulties when lying down
Impaired Social interaction r/t social isolation because of oxygen use, activity intolerance
Chronic Sorrow r/t presence of chronic illness
Risk for Infection: Risk factor: stasis of respiratory secretions
Readiness for enhanced Health management (See **Health** management, readiness for enhanced, Section III)

Coping

Readiness for enhanced Coping (See **Coping**, readiness for enhanced, Section III)

Risk for Complicated Immigration Transition: Risk factors: insufficient knowledge about the process to access resources in the host country, insufficient social support in the host country, overt discrimination

Coping Problems

Compromised family Coping (see **Coping**, compromised family, Section III)
Defensive Coping (See **Coping**, defensive, Section III)
Disabled family Coping (See **Coping**, disabled family, Section III)
Ineffective Coping (See **Coping**, ineffective, Section III)
Ineffective community Coping (see **Coping**, ineffective community, Section III)

Corneal Injury

Risk for corneal Injury (See corneal **Injury**, risk for, Section III)

Corneal Reflex, Absent

Risk for Injury: Risk factors: accidental corneal abrasion, drying of cornea

Corneal Transplant

Risk for Surgical Site Infection: Risk factors: invasive procedure, surgery
Readiness for enhanced Health management: describes need to rest and avoid strenuous activities during healing phase

Coronary Artery Bypass Grafting (CABG)

Decreased Cardiac output r/t dysrhythmia, depressed cardiac function, change in preload, contractility or afterload
Fear r/t outcome of surgical procedure
Deficient Fluid volume r/t intraoperative blood loss, use of diuretics in surgery
Acute Pain r/t traumatic surgery
Risk for Perioperative Positioning injury: Risk factors: hypothermia, extended supine position
Risk for Surgical Site Infection: Risk factor: surgical incision
Risk for Impaired Tissue integrity: Risk factor: surgical procedure
Readiness for enhanced Knowledge: expresses an interest in learning

Costovertebral Angle Tenderness

See Kidney Stone; Pyelonephritis

Cough, Ineffective

Ineffective Airway clearance r/t decreased energy, fatigue, normal aging changes
See Bronchitis; COPD (Chronic Obstructive Pulmonary Disease); Pulmonary Edema

Crackles in Lungs, Coarse

Ineffective Airway clearance r/t excessive secretions in airways, ineffective cough
See Heart Failure; Pneumonia; Pulmonary Edema

Crackles in Lungs, Fine

Ineffective Breathing pattern r/t fatigue, surgery, decreased energy
See Bronchitis or Pneumonia (if from pulmonary infection); Congestive Heart Failure (CHF) (if cardiac in origin); Infection, potential for

Craniectomy/Craniotomy

Frail Elderly syndrome r/t alteration in cognition
Fear r/t threat to well-being
Decreased Intracranial adaptive capacity r/t brain injury, intracranial hypertension
Impaired Memory r/t neurological surgery
Acute Pain r/t recent brain surgery, increased intracranial pressure
Risk for ineffective Cerebral tissue perfusion: Risk factors: cerebral edema, increased intracranial pressure
Risk for Injury: Risk factor: potential confusion
See Coma (if relevant)

Crepitation, Subcutaneous

See Pneumothorax

Crisis

Anxiety r/t threat to or change in environment, health status, interaction patterns, situation, self-concept, or role functioning; threat of death of self or significant other
Death Anxiety r/t feelings of hopelessness associated with crisis
Compromised family Coping r/t situational or developmental crisis
Ineffective Coping r/t situational or maturational crisis
Fear r/t crisis situation
Grieving r/t potential significant loss
Impaired individual Resilience r/t onset of crisis
Situational low Self-Esteem r/t perception of inability to handle crisis
Stress overload (See **Stress** overload, Section III)
Risk for Spiritual distress: Risk factors: physical or psychological stress, natural disasters, situational losses, maturational losses

Crohn's Disease

Anxiety r/t change in health status
Ineffective Coping r/t repeated episodes of diarrhea
Diarrhea r/t inflammatory process
Ineffective Health maintenance r/t deficient knowledge regarding management of disease
Imbalanced Nutrition: **less than body requirements** r/t diarrhea, altered ability to digest and absorb food
Acute Pain r/t increased peristalsis
Powerlessness r/t chronic disease
Risk for deficient Fluid volume: Risk factor: abnormal fluid loss with diarrhea

Croup

See Respiratory Infections, Acute Childhood (Croup, Epiglottitis, Pertussis, Pneumonia, Respiratory)

Cryosurgery for Retinal Detachment

See Retinal Detachment

Cushing's Syndrome

Activity intolerance r/t fatigue, weakness
Disturbed Body Image r/t change in appearance from disease process
Excess Fluid volume r/t failure of regulatory mechanisms
Sexual dysfunction r/t loss of libido
Impaired Skin integrity r/t thin vulnerable skin from effects of increased cortisol
Risk for Infection: Risk factor: suppression of immune system caused by increased cortisol levels
Risk for Injury: Risk factors: decreased muscle strength, brittle bones
Readiness for enhanced Knowledge: expresses an interest in learning

Cuts (Wounds)

See Lacerations

CVA (Cerebrovascular Accident)

Anxiety r/t situational crisis, change in physical or emotional condition
Disturbed Body Image r/t chronic illness, paralysis
Caregiver Role Strain r/t cognitive problems of care receiver, need for significant home care
Impaired verbal Communication r/t pressure damage, decreased circulation to brain in speech center informational sources
Chronic Confusion r/t neurological changes
Constipation r/t decreased activity
Ineffective Coping r/t disability
Interrupted Family processes r/t illness, disability of family member
Frail Elderly syndrome r/t alteration in cognitive functioning
Grieving r/t loss of health
Impaired Home maintenance r/t neurological disease affecting ability to perform activities of daily living
Functional urinary Incontinence r/t neurological dysfunction
Reflex urinary Incontinence r/t loss of feeling to void
Impaired Memory r/t neurological disturbances
Impaired physical Mobility r/t loss of balance and coordination
Unilateral Neglect r/t disturbed perception from neurological damage
Self-Care deficit: **specify** r/t decreased strength and endurance, paralysis
Impaired Social interaction r/t limited physical mobility, limited ability to communicate
Impaired Swallowing r/t neuromuscular dysfunction
Impaired Transfer Ability r/t limited physical mobility
Vision Loss r/t pressure damage to visual centers in the brain (*see Appendix E on Evolve*)
Impaired Walking r/t loss of balance and coordination
Risk for Aspiration: Risk factors: impaired swallowing, loss of gag reflex
Risk for chronic functional Constipation: Risk factor: immobility
Risk for Disuse syndrome: Risk factor: paralysis
Risk for Falls: Risk factor: paralysis, decreased balance
Risk for Injury: Risk factors: vision loss, decreased tissue perfusion with loss of sensation
Risk for ineffective Cerebral tissue perfusion: Risk factor: clot, emboli, or hemorrhage from cerebral vessel
Risk for impaired Skin integrity: Risk factor: immobility
Readiness for enhanced Knowledge: expresses an interest in learning

Cyanosis, Central with Cyanosis of Oral Mucous Membranes

Impaired Gas exchange r/t alveolar-capillary membrane changes

Cyanosis, Peripheral with Cyanosis of Nail Beds

Ineffective peripheral Tissue Perfusion r/t interruption of arterial flow, severe vasoconstriction, cold temperatures

Cystic Fibrosis

Activity intolerance r/t imbalance between oxygen supply and demand
Ineffective Airway clearance r/t increased production of thick mucus
Anxiety r/t dyspnea, oxygen deprivation
Disturbed Body Image r/t changes in physical appearance, treatment of chronic lung disease (clubbing, barrel chest, home oxygen therapy)
Impaired Gas exchange r/t ventilation-perfusion imbalance
Impaired Home maintenance r/t extensive daily treatment, medications necessary for health
Imbalanced Nutrition: **less than body requirements** r/t anorexia; decreased absorption of nutrients, fat; increased work of breathing
Chronic Sorrow r/t presence of chronic disease
Risk for Caregiver Role Strain: Risk factors: illness severity of care receiver, unpredictable course of illness
Risk for deficient Fluid volume: Risk factors: decreased fluid intake, increased work of breathing
Risk for Infection: Risk factors: thick, tenacious mucus; harboring of bacterial organisms; immunocompromised state
Risk for Spiritual distress: Risk factor: presence of chronic disease
See Child with Chronic Condition; Hospitalized Child; Terminally Ill Child, Adolescent; Terminally Ill Child, Infant/Toddler; Terminally Ill Child, Preschool Child; Terminally Ill Child, School-Age Child/Preadolescent; Terminally Ill Child/Death of Child, Parent

Cystitis

Acute Pain: **dysuria** r/t inflammatory process in bladder and urethra
Impaired Urinary elimination: **frequency** r/t urinary tract infection
Urge urinary Incontinence: Risk factor: infection in bladder
Readiness for enhanced Knowledge: expresses an interest in learning

Cystocele

Stress urinary Incontinence r/t prolapsed bladder
Readiness for enhanced Knowledge: expresses an interest in learning

Cystoscopy

Urinary Retention r/t edema in urethra obstructing flow of urine
Risk for Infection: Risk factor: invasive procedure
Readiness for enhanced Knowledge: expresses an interest in learning

List of Nursing Diagnosis by Letter: D

Deafness	Death	Death, Oncoming
Decisions, Difficulty Making	Decubitus Ulcer	Deep Vein Thrombosis (DVT)
Defensive Behavior	Dehiscence, Abdominal	Dehydration
Delirium	Delirium Tremens (DT)	Delivery
Delusions	Dementia	Denial of Health Status
Dental Caries	Depression (Major Depressive Disorder)	Dermatitis
Despondency	Destructive Behavior Toward Others	Developmental Concerns
Diabetes in Pregnancy	Diabetes Insipidus	Diabetes Mellitus
Diabetes Mellitus, Juvenile (Insulin-Dependent Diabetes Mellitus Type 1)	Diabetic Coma	Diabetic Ketoacidosis
Diabetic Neuropathy	Diabetic Retinopathy	Dialysis
Diaphragmatic Hernia	Diarrhea	DIC (Disseminated Intravascular Coagulation)
Digitalis Toxicity	Dignity, Loss of	Dilation and Curettage (D&C)
Dirty Body (for Prolonged Period)	Discharge Planning	Discomforts of Pregnancy
Dislocation of Joint	Dissecting Aneurysm	Disseminated Intravascular Coagulation (DIC)
Dissociative Identity Disorder (Not Otherwise Specified)	Distress	Disuse Syndrome, Potential to Develop
Diversional Activity Engagement, Lack of	Diverticulitis	Dizziness
Domestic Violence	Down Syndrome	Dress Self (Inability to)
Dribbling of Urine	Drooling	Dropout from School
Drug Abuse	Drug Withdrawal	Dry Eye
Dry Mouth	DT (Delirium Tremens)	DVT (Deep Vein Thrombosis)
Dying Client	Dysfunctional Eating Pattern	Dysfunctional Family Unit
Dysfunctional Ventilatory Weaning	Dysmenorrhea	Dyspareunia
Dyspepsia	Dysphagia	Dysphasia
Dyspnea	Dysrhythmia	Dysthymic Disorder
Dystocia	Dysuria	

D

Deafness

Impaired verbal Communication r/t impaired hearing
Hearing Loss r/t alteration in sensory reception, transmission, integration
Risk for delayed Development: Risk factor: impaired hearing
Risk for Injury: Risk factor: alteration in sensory perception

Death

Risk for Sudden Infant Death (See **Sudden Infant Death**, risk for, Section III)

Death, Oncoming

Death Anxiety r/t unresolved issues surrounding dying
Compromised family Coping r/t client's inability to provide support to family
Ineffective Coping r/t personal vulnerability
Fear r/t threat of death
Grieving r/t loss of significant other
Powerlessness r/t effects of illness, oncoming death
Social isolation r/t altered state of wellness
Spiritual distress r/t intense suffering
Readiness for enhanced Spiritual well-being: desire of client and family to be in harmony with each other and higher power, God
See Terminally Ill Child, Adolescent; *Terminally Ill Child, Infant/Toddler*; *Terminally Ill Child, Preschool Child*; *Terminally Ill Child, School-Age Child/Preadolescent*; *Terminally Ill Child/Death of Child, Parent*

Decisions, Difficulty Making

Decisional Conflict r/t support system deficit, perceived threat to value system, multiple or divergent sources of information, lack of relevant information, unclear personal values or beliefs
Risk for impaired Emancipated Decision-Making: Risk factor: insufficient self-confidence in decision-making
Readiness for enhanced Decision-Making (See **Decision-Making**, readiness for enhanced, Section III)

Decubitus Ulcer

See Pressure Ulcer

Deep Vein Thrombosis (DVT)

See DVT (Deep Vein Thrombosis); *Venous Thromboembolism*

Defensive Behavior

Defensive Coping r/t nonacceptance of blame, denial of problems or weakness
Ineffective Denial r/t inability to face situation realistically

Dehiscence, Abdominal

Fear r/t threat of death, severe dysfunction
Acute Pain r/t stretching of abdominal wall
Impaired Skin integrity r/t altered circulation, malnutrition, opening in incision
Delayed Surgical recovery r/t altered circulation, malnutrition, opening in incision
Impaired Tissue integrity r/t exposure of abdominal contents to external environment
Risk for deficient Fluid volume: Risk factor: altered circulation associated with opening of wound and exposure of abdominal contents
Risk for Surgical Site Infection: Risk factors: loss of skin integrity, open surgical wound

Dehydration

Deficient Fluid volume r/t active fluid volume loss
Impaired Oral Mucous Membrane integrity r/t decreased salivation, fluid deficit
Risk for chronic functional Constipation: Risk factor: decreased fluid volume
Risk for Dry Mouth: Risk factor: decreased fluid volume
Risk for ineffective Thermoregulation: Risk factor: decreased fluid volume
Risk for unstable Blood Pressure: Risk factor: hypotension caused by insufficient fluid volume
See Burns; Heat Stroke; Vomiting; Diarrhea

Delirium

Acute Confusion r/t effects of medication, response to hospitalization, alcohol abuse, substance abuse, sensory deprivation or overload, infection, polypharmacy
Impaired Memory r/t delirium
Sleep deprivation r/t sustained inadequate sleep hygiene
Risk for Injury: Risk factor: altered level of consciousness

Delirium Tremens (DT)

See Alcohol Withdrawal

Delivery

See Labor, Normal

Delusions

Impaired verbal Communication r/t psychological impairment, delusional thinking
Acute Confusion r/t alcohol abuse, delirium, dementia, substance abuse
Ineffective Coping r/t distortion and insecurity of life events
Fear r/t content of intrusive thoughts
Risk for other-directed Violence: Risk factor: delusional thinking
Risk for self-directed Violence: Risk factor: delusional thinking

Dementia

Chronic Confusion r/t neurological dysfunction
Interrupted Family processes r/t disability of family member
Frail Elderly syndrome r/t alteration in cognitive functioning

Impaired Home maintenance r/t inadequate support system, neurological dysfunction
Imbalanced Nutrition: **less than body requirements** r/t neurological impairment
Functional urinary Incontinence r/t neurological dysfunction
Insomnia r/t neurological impairment, naps during the day
Impaired physical Mobility r/t alteration in cognitive function
Self-Neglect r/t cognitive impairment
Self-Care deficit: **specify** r/t psychological or neuromuscular impairment
Chronic Sorrow: **Significant other** r/t chronic long-standing disability, loss of mental function
Impaired Swallowing r/t neuromuscular changes associated with long-standing dementia
Risk for Caregiver Role Strain: Risk factors: number of caregiving tasks, duration of caregiving required
Risk for Chronic Functional Constipation: Risk factor: decreased fluid intake
Risk for Falls: Risk factor: diminished mental status
Risk for Frail Elderly syndrome: Risk factors: cognitive impairment
Risk for Injury: Risk factors: confusion, decreased muscle coordination
Risk for impaired Skin integrity: Risk factors: altered nutritional status, immobility

Denial of Health Status

Ineffective Denial r/t lack of perception about the health status effects of illness
Ineffective Health management r/t denial of seriousness of health situation

Dental Caries

Impaired Dentition r/t ineffective oral hygiene, barriers to self-care, economic barriers to professional care, nutritional deficits, dietary habits
Ineffective Health maintenance r/t lack of knowledge regarding prevention of dental disease

Depression (Major Depressive Disorder)

Death Anxiety r/t feelings of lack of self-worth
Constipation r/t inactivity, decreased fluid intake
Fatigue r/t psychological demands
Ineffective Health maintenance r/t lack of ability to make good judgments regarding ways to obtain help
Hopelessness r/t feeling of abandonment, long-term stress
Impaired Mood Regulation r/t emotional instability
Insomnia r/t inactivity
Self-Neglect r/t depression, cognitive impairment
Powerlessness r/t pattern of helplessness
Chronic low Self-Esteem r/t repeated unmet expectations
Sexual dysfunction r/t loss of sexual desire
Social isolation r/t ineffective coping
Chronic Sorrow r/t unresolved grief
Risk for complicated Grieving: Risk factor: lack of previous resolution of former grieving response
Risk for Suicide: Risk factor: grieving, hopelessness

Dermatitis

Anxiety r/t situational crisis imposed by illness
Impaired Comfort r/t itching
Impaired Skin integrity r/t side effect of medication, allergic reaction
Readiness for enhanced Knowledge: expresses an interest in learning
See Itching

Despondency

Hopelessness r/t long-term stress

See Depression (Major Depressive Disorder)

Destructive Behavior Toward Others

Risk-prone Health behavior r/t intense emotional state
Ineffective Coping r/t situational crises, maturational crises, disturbance in pattern of appraisal of threat
Risk for other-directed Violence (See **Violence**, other-directed, risk for, Section III)

Developmental Concerns

Risk for delayed Development (See **Development**, delayed, risk for, Section III)
See Growth and Development Lag

Diabetes in Pregnancy

See Gestational Diabetes (Diabetes in Pregnancy)

Diabetes Insipidus

Deficient Fluid volume r/t inability to conserve fluid
Ineffective Health maintenance r/t deficient knowledge regarding care of disease, importance of medications

Diabetes Mellitus

Ineffective Health maintenance r/t complexity of therapeutic regimen
Ineffective Health management (See **Health** management, ineffective, Section III)
Imbalanced Nutrition: **less than body requirements** r/t inability to use glucose (type 1 [insulin-dependent] diabetes)
Risk for Overweight: Risk factor: excessive intake of nutrients (type 2 diabetes)
Ineffective peripheral Tissue perfusion r/t impaired arterial circulation
Powerlessness r/t perceived lack of personal control
Sexual dysfunction r/t neuropathy associated with disease
Vision Loss r/t ineffective tissue perfusion of retina
Risk for unstable blood Glucose level (See **Glucose** level, blood, unstable, risk for, Section III)
Risk for Infection: Risk factors: hyperglycemia, impaired healing, circulatory changes
Risk for Injury: Risk factors: hypoglycemia or hyperglycemia from failure to consume adequate calories, failure to take insulin
Risk for dysfunctional Gastrointestinal motility: Risk factor: complication of diabetes
Risk for Metabolic Imbalance syndrome: Risk factor: complication of diabetes
Risk for impaired Skin integrity: Risk factor: loss of pain perception in extremities
Risk for delayed Surgical recovery: Risk factor: impaired healing due to circulatory changes
Readiness for enhanced Health literacy: expresses desire to enhance understanding of health information to make health care choices
Readiness for enhanced Health management (See **Health** management, readiness for enhanced, Section III)
Readiness for enhanced Knowledge: expresses an interest in learning
See Hyperglycemia; Hypoglycemia

Diabetes Mellitus, Juvenile (Insulin-Dependent Diabetes Mellitus Type 1)

Risk-prone Health behavior r/t inadequate comprehension, inadequate social support, low self-efficacy, impaired adjustment attributable to adolescent maturational crises

Disturbed Body Image r/t imposed deviations from biophysical and psychosocial norm, perceived differences from peers
Impaired Comfort r/t insulin injections, peripheral blood glucose testing
Ineffective Health maintenance r/t (See **Health** maintenance, ineffective, Section III)
Imbalanced Nutrition: **less than body requirements** r/t inability of body to adequately metabolize and use glucose and nutrients, increased caloric needs of child to promote growth and physical activity participation with peers
Risk for Metabolic Imbalance syndrome: Risk factor: complication of diabetes
Readiness for enhanced Knowledge: expresses an interest in learning
See Diabetes Mellitus; Child with Chronic Condition; Hospitalized Child

Diabetic Coma

Acute Confusion r/t hyperglycemia, presence of excessive metabolic acids
Deficient Fluid volume r/t hyperglycemia resulting in polyuria
Ineffective Health management r/t lack of understanding of preventive measures, adequate blood glucose control
Risk for unstable blood Glucose level (See **Glucose** level, blood, unstable, risk for, Section III)
Risk for Infection: Risk factors: hyperglycemia, changes in vascular system
See Diabetes Mellitus

Diabetic Ketoacidosis

See Ketoacidosis, Diabetic

Diabetic Neuropathy

See Neuropathy, Peripheral

Diabetic Retinopathy

Grieving r/t loss of vision
Ineffective Health maintenance r/t deficient knowledge regarding preserving vision with treatment if possible, use of low-vision aids
See Vision Impairment; Blindness

Dialysis

See Hemodialysis; Peritoneal Dialysis

Diaphragmatic Hernia

See Hiatal Hernia

Diarrhea

Diarrhea r/t infection, change in diet, gastrointestinal disorders, stress, medication effect, impaction
Deficient Fluid volume r/t excessive loss of fluids in liquid stools
Risk for Electrolyte imbalance: Risk factor: effect of loss of electrolytes from frequent stools

DIC (Disseminated Intravascular Coagulation)

Fear r/t threat to well-being
Deficient Fluid volume: **hemorrhage** r/t depletion of clotting factors
Risk for Bleeding: Risk factors: microclotting within vascular system, depleted clotting factors

Digitalis Toxicity

Decreased Cardiac output r/t drug toxicity affecting cardiac rhythm, rate
Ineffective Health management r/t deficient knowledge regarding action, appropriate method of administration of digitalis

Dignity, Loss of

Risk for compromised Human Dignity (See **Human Dignity**, compromised, risk for, Section III)

Dilation and Curettage (D&C)

Acute Pain r/t uterine contractions
Risk for Bleeding: Risk factor: surgical procedure
Risk for Surgical Site Infection: Risk factor: surgical procedure
Risk for ineffective Sexuality pattern: Risk factors: painful coitus, fear associated with surgery on genital area
Readiness for enhanced Knowledge: expresses an interest in learning

Dirty Body (for Prolonged Period)

Self-Neglect r/t mental illness, substance abuse, cognitive impairment

Discharge Planning

Impaired Home Maintenance r/t family member's disease or injury interfering with home maintenance
Deficient Knowledge r/t lack of exposure to information for home care
Relocation stress syndrome: Risk factors: insufficient predeparture counseling, insufficient support system, unpredictability of experience
Readiness for enhanced Health literacy: expresses desire to enhance understanding of health information to make health care choices
Readiness for enhanced Knowledge: expresses an interest in learning

Discomforts of Pregnancy

Disturbed Body Image r/t pregnancy-induced body changes
Impaired Comfort r/t enlarged abdomen, swollen feet
Fatigue r/t hormonal, metabolic, body changes
Stress urinary Incontinence r/t enlarged uterus, fetal movement
Insomnia r/t psychological stress, fetal movement, muscular cramping, urinary frequency, shortness of breath
Nausea r/t hormone effect
Acute Pain: **headache** r/t hormonal changes of pregnancy
Acute Pain: **leg cramps** r/t nerve compression, calcium/phosphorus/potassium imbalance
Risk for Constipation: Risk factors: decreased intestinal motility, inadequate fiber in diet
Risk for Injury: Risk factors: faintness and/or syncope caused by vasomotor lability or postural hypotension, venous stasis in lower extremities

Dislocation of Joint

Acute Pain r/t dislocation of a joint
Self-Care deficit: r/t inability to use a joint
Risk for Injury: Risk factor: unstable joint

Dissecting Aneurysm

Fear r/t threat to well-being
See Abdominal Surgery; Aneurysm, Abdominal Aortic Repair

Disseminated Intravascular Coagulation (DIC)

See DIC (Disseminated Intravascular Coagulation)

Dissociative Identity Disorder (Not Otherwise Specified)

Anxiety r/t psychosocial stress
Ineffective Coping r/t personal vulnerability in crisis of accurate self-perception
Disturbed personal Identity r/t inability to distinguish self-caused by multiple personality disorder, depersonalization, disturbance in memory
Impaired Memory r/t altered state of consciousness
See Multiple Personality Disorder (Dissociative Identity Disorder)

Distress

Anxiety r/t situational crises, maturational crises
Death Anxiety r/t denial of one's own mortality or impending death

Disuse Syndrome, Potential to Develop

Risk for Disuse syndrome: Risk factors: paralysis, mechanical immobilization, prescribed immobilization, severe pain, altered level of consciousness

Diversional Activity Engagement, Lack of

Decreased Diversional activity engagement r/t environmental lack of diversional activity as in frequent hospitalizations, lengthy treatments

Diverticulitis

Constipation r/t dietary deficiency of fiber and roughage
Diarrhea r/t increased intestinal motility caused by inflammation
Deficient Knowledge r/t diet needed to control disease, medication regimen
Imbalanced Nutrition: **less than body requirements** r/t loss of appetite
Acute Pain r/t inflammation of bowel
Risk for deficient Fluid Volume: Risk factor: diarrhea

Dizziness

Decreased Cardiac output r/t alteration in heart rate and rhythm, altered stroke volume
Deficient Knowledge r/t actions to take to prevent or modify dizziness and prevent falls
Impaired physical Mobility r/t dizziness
Risk for Falls: Risk factor: difficulty maintaining balance

Risk for ineffective Cerebral tissue perfusion: Risk factor: interruption of cerebral arterial blood flow

Domestic Violence

Impaired verbal Communication r/t psychological barriers of fear
Compromised family Coping r/t abusive patterns
Defensive Coping r/t low self-esteem
Dysfunctional Family processes r/t inadequate coping skills
Fear r/t threat to self-concept, situational crisis of abuse
Insomnia r/t psychological stress
Post-Trauma syndrome r/t history of abuse
Powerlessness r/t lifestyle of helplessness
Situational low Self-Esteem r/t negative family interactions
Risk for compromised Resilience: Risk factor: effects of abuse
Risk for other-directed Violence: Risk factor: history of abuse

Down Syndrome

See Child with Chronic Condition; Intellectual Disability

Dress Self (Inability to)

Dressing Self-Care deficit r/t intolerance to activity, decreased strength and endurance, pain, discomfort, perceptual or cognitive impairment, neuromuscular impairment, musculoskeletal impairment, depression, severe anxiety

Dribbling of Urine

Overflow urinary Incontinence r/t degenerative changes in pelvic muscles and urinary structures
Stress urinary Incontinence r/t degenerative changes in pelvic muscles and urinary structures

Drooling

Impaired Swallowing r/t neuromuscular impairment, mechanical obstruction
Risk for Aspiration: Risk factor: impaired swallowing

Dropout from School

Impaired individual Resilience (See **Resilience**, individual, impaired, Section III)
Anxiety r/t conflict about life goals
Ineffective Coping r/t inadequate resources

Drug Abuse

See Substance Abuse

Drug Withdrawal

See Acute Substance Withdrawal Syndrome

Dry Eye

Risk for dry Eye: Risk factors: (See dry **Eye**, risk for, Section III)
Risk for Corneal Injury: Risk factor: suppressed corneal reflex
Readiness for enhanced Knowledge: expresses an interest in learning
See Conjunctivitis; Keratoconjunctivitis Sicca (Dry Eye Syndrome)

Dry Mouth

Risk for Dry Mouth: Risk factors: (See **Dry Mouth**, risk for, Section III)
Risk for impaired Oral Mucous Membrane integrity: Risk factor: reduced quality or quantity of saliva caused by decreased fluid volume

DT (Delirium Tremens)

See Alcohol Withdrawal

DVT (Deep Vein Thrombosis)

Constipation r/t inactivity, bed rest
Impaired physical Mobility r/t pain in extremity
Acute Pain r/t vascular inflammation, edema
Ineffective peripheral Tissue perfusion r/t deficient knowledge of aggravating factors
Delayed Surgical recovery r/t impaired physical mobility
Readiness for enhanced Knowledge: expresses an interest in learning
Risk for ineffective Thermoregulation: Risk factor: inactivity
See Anticoagulant Therapy; Venous Thromboembolism, risk for (See Section III)

Dying Client

See Terminally Ill Adult; Terminally Ill Adolescent; Terminally Ill Child, Infant/Toddler; Terminally Ill Child, Preschool Child; Terminally Ill Child, School-Age Child/Preadolescent; Terminally Ill Child/Death of Child, Parent

Dysfunctional Eating Pattern

Imbalanced Nutrition: **less than body requirements** r/t psychological factors
Risk for Overweight: Risk factor: psychological factors
See Anorexia Nervosa; Bulimia; Maturational Issues, Adolescent; Obesity

Dysfunctional Family Unit

See Family Problems

Dysfunctional Ventilatory Weaning

Dysfunctional Ventilatory weaning response r/t physical, psychological, situational factors

Dysmenorrhea

Nausea r/t prostaglandin effect
Acute Pain r/t cramping from hormonal effects
Readiness for enhanced Knowledge: expresses an interest in learning

Dyspareunia

Sexual Dysfunction r/t lack of lubrication during intercourse, alteration in reproductive organ function

Dyspepsia

Anxiety r/t pressures of personal role
Acute Pain r/t gastrointestinal disease, consumption of irritating foods
Readiness for enhanced Knowledge: expresses an interest in learning

Dysphagia

Impaired Swallowing r/t neuromuscular impairment
Risk for Aspiration: Risk factor: loss of gag or cough reflex

Dysphasia

Impaired verbal Communication r/t decrease in circulation to brain
Impaired Social interaction r/t difficulty in communicating

Dyspnea

Activity intolerance r/t imbalance between oxygen supply and demand
Ineffective Breathing pattern r/t compromised cardiac or pulmonary function, decreased lung expansion, neurological impairment affecting respiratory center, extreme anxiety
Fear r/t threat to state of well-being, potential death
Impaired Gas exchange r/t alveolar-capillary damage
Insomnia r/t difficulty breathing, positioning required for effective breathing
Sleep deprivation r/t ineffective breathing pattern

Dysrhythmia

Activity intolerance r/t decreased cardiac output
Decreased Cardiac output r/t alteration in heart rate, rhythm
Fear r/t threat of death, change in health status
Risk for ineffective Cerebral tissue perfusion: Risk factor: decreased blood supply to the brain from dysrhythmia
Risk for unstable Blood Pressure r/t cardiac arrhythmia and electrolyte imbalance
Readiness for enhanced Knowledge: expresses an interest in learning

Dysthymic Disorder

Ineffective Coping r/t impaired social interaction
Ineffective Health maintenance r/t inability to make good judgments regarding ways to obtain help
Insomnia r/t anxious thoughts
Chronic low Self-Esteem r/t repeated unmet expectations
Ineffective Sexuality pattern r/t loss of sexual desire
Social Isolation r/t ineffective coping
See Depression (Major Depressive Disorder)

Dystocia

Anxiety r/t difficult labor, deficient knowledge regarding normal labor pattern

Ineffective Coping r/t situational crisis
Fatigue r/t prolonged labor
Grieving r/t loss of ideal labor experience
Acute Pain r/t difficult labor, medical interventions
Powerlessness r/t perceived inability to control outcome of labor
Risk for Bleeding: Risk factor: hemorrhage secondary to uterine atony
Risk for ineffective Cerebral tissue perfusion (fetal): Risk factor: difficult labor and birth
Risk for delayed Development: infant: Risk factor: difficult labor and birth
Risk for Infection: Risk factor: prolonged rupture of membranes
Risk for impaired Tissue integrity (maternal and fetal): Risk factor: difficult labor

Dysuria

Impaired Urinary elimination r/t infection/inflammation of the urinary tract
Risk for urge urinary Incontinence: Risk factor: detrusor hyperreflexia from infection in the urinary tract
Acute Pain r/t infection/inflammation of the urinary tract

List of Nursing Diagnosis by Letter: E

Ear Surgery	Earache	Eating Dynamics, Adolescent
Eating Dynamics, Child	Eating Dynamics, Infant	Eclampsia
ECMO (Extracorporeal Membrane Oxygenator)	ECT (Electroconvulsive Therapy)	Ectopic Pregnancy
Eczema	ED (Erectile Dysfunction)	Edema
Elder Abuse	Elderly	Electroconvulsive Therapy
Electrolyte Imbalance	Emaciated Person	Emancipated Decision-Making, Impaired
Embolectomy	Emboli	Embolism in Leg or Arm
Emesis	Emotional Problems	Empathy
Emphysema	Emptiness	Encephalitis
Endocardial Cushion Defect	Endocarditis	Endometriosis
Endometritis	Enuresis	Environmental Interpretation Problems
Epididymitis	Epiglottitis	Epilepsy
Episiotomy	Epistaxis	Epstein-Barr Virus
Erectile Dysfunction (ED)	*Escherichia coli* Infection	Esophageal Varices
Esophagitis	Evisceration	Exhaustion
Exposure to Hot or Cold Environment	External Fixation	Extracorporeal Membrane Oxygenator (ECMO)
Eye Discomfort	Eye Surgery	

E

Ear Surgery

Acute Pain r/t edema in ears from surgery
Hearing Loss r/t invasive surgery of ears, dressings
Risk for delayed Development: Risk factor: hearing impairment
Risk for Falls: Risk factor: dizziness from excessive stimuli to vestibular apparatus
Readiness for enhanced Knowledge: expresses an interest in learning
See Hospitalized Child

Earache

Acute Pain r/t trauma, edema, infection
Hearing Loss r/t altered sensory reception, transmission

Eating Dynamics, Adolescent

Imbalanced Nutrition: **less than body requirements** r/t negative perception of one's body
Ineffective Adolescent Eating Dynamics r/t altered family dynamics, eating disorder, excessive stress
Risk for Overweight: Risk factor: Media influence resulting in unhealthy choices, insufficient interest in physical activity
Readiness for enhanced Health literacy: expresses desire to learn to make healthy food choices

Eating Dynamics, Child

Imbalanced Nutrition: **less than body requirements** r/t excessive of parental control over quantity and choices of foods
Ineffective Child Eating Dynamics r/t bribing child to eat, forcing child to eat
Risk for delayed Development: Risk factor: inadequate nutrition to meet metabolic needs for normal development
Risk for Overweight: Risk factors: unhealthy choices, frequent snacking, low physical activity

Eating Dynamics, Infant

See Feeding Dynamics, Infant

Eclampsia

Interrupted Family processes r/t unmet expectations for pregnancy and childbirth
Fear r/t threat of well-being to self and fetus
Risk for Aspiration: Risk factor: seizure activity
Risk for ineffective Cerebral tissue perfusion: **fetal**: Risk factor: uteroplacental insufficiency
Risk for delayed Development: Risk factor: uteroplacental insufficiency
Risk for excess Fluid volume: Risk factor: decreased urine output as a result of renal dysfunction
Risk for unstable Blood Pressure: Risk factor: hypertension caused by excess fluid volume

ECMO (Extracorporeal Membrane Oxygenator)

Death Anxiety r/t emergency condition, hemorrhage
Decreased Cardiac output r/t altered contractility of the heart
Impaired Gas exchange (See **Gas** exchange, impaired, Section III)
See Respiratory Conditions of the Neonate

ECT (Electroconvulsive Therapy)

Decisional Conflict r/t lack of relevant information
Fear r/t real or imagined threat to well-being
Impaired Memory r/t effects of treatment
See Depression (Major Depressive Disorder)

Ectopic Pregnancy

Death Anxiety r/t emergency condition, hemorrhage
Disturbed Body Image r/t negative feelings about body and reproductive functioning
Fear r/t threat to self, surgery, implications for future pregnancy
Acute Pain r/t stretching or rupture of implantation site
Ineffective Role performance r/t loss of pregnancy
Situational low Self-Esteem r/t loss of pregnancy, inability to carry pregnancy to term
Chronic Sorrow r/t loss of pregnancy, potential loss of fertility
Risk for Bleeding: Risk factor: possible rupture of implantation site, surgical trauma
Risk for ineffective Coping: Risk factor: loss of pregnancy
Risk for interrupted Family processes: Risk factor: situational crisis
Risk for Infection: Risk factors: traumatized tissue, surgical procedure
Risk for Spiritual distress: Risk factor: grief process

Eczema

Disturbed Body Image r/t change in appearance from inflamed skin
Impaired Comfort: **pruritus** r/t inflammation of skin
Impaired Skin integrity r/t side effect of medication, allergic reaction
Readiness for enhanced Knowledge: expresses an interest in learning

ED (Erectile Dysfunction)

See Erectile Dysfunction (ED); Impotence

Edema

Excess Fluid volume r/t excessive fluid intake, cardiac dysfunction, renal dysfunction, loss of plasma proteins
Ineffective Health maintenance r/t deficient knowledge regarding treatment of edema
Risk for impaired Skin integrity: Risk factors: impaired circulation, fragility of skin
See Heart Failure; Renal Failure

Elder Abuse

See Abuse, Spouse, Parent, or Significant Other

Elderly

See Aging; Frail Elderly Syndrome

Electroconvulsive Therapy

See ECT (Electroconvulsive Therapy)

Electrolyte Imbalance

Risk for Electrolyte imbalance (See **Electrolyte imbalance**, risk for, Section III)
Risk for unstable Blood Pressure: Risk factor: fluid volume changes

Emaciated Person

Frail Elderly syndrome r/t living alone, malnutrition, alteration in cognitive functioning
Imbalanced Nutrition: less than body requirements r/t inability to ingest food, digest food, absorb nutrients because of biological, psychological, economic factors

Emancipated Decision-Making, Impaired

Risk for impaired emancipated Decision-Making: Risk factor: inability or unwillingness to verbalize needs and wants
Readiness for enhanced emancipated Decision-Making: expresses desire to enhance decision-making process

Embolectomy

Fear r/t threat of great bodily harm from embolus
Ineffective peripheral Tissue Perfusion r/t presence of embolus
Risk for Bleeding: Risk factors: postoperative complication, surgical area
See Surgery, Postoperative Care

Emboli

See Pulmonary Embolism (PE)

Embolism in Leg or Arm

Ineffective peripheral Tissue Perfusion r/t arterial/venous obstruction from clot
See DVT (Deep Vein Thrombosis)

Emesis

Nausea (See **Nausea**, Section III)
See Vomiting

Emotional Problems

See Coping Problems

Empathy

Readiness for enhanced community Coping: social supports, being available for problem solving
Readiness for enhanced family Coping: basic needs met, desire to move to higher level of health
Readiness for enhanced Spiritual Well-Being: desire to establish interconnectedness through spirituality

Emphysema

See COPD (Chronic Obstructive Pulmonary Disease)

Emptiness

Social isolation r/t inability to engage in satisfying personal relationships
Chronic Sorrow r/t unresolved grief
Spiritual distress r/t separation from religious or cultural ties

Encephalitis

See Meningitis/Encephalitis

Endocardial Cushion Defect

See Congenital Heart Disease/Cardiac Anomalies

Endocarditis

Activity intolerance r/t reduced cardiac reserve, prescribed bed rest
Decreased Cardiac output r/t inflammation of lining of heart and change in structure of valve leaflets, increased myocardial workload
Risk for imbalanced Nutrition: less than body requirements: Risk factors: fever, hypermetabolic state associated with fever
Risk for ineffective Cerebral tissue perfusion: Risk factor: possible presence of emboli in cerebral circulation
Risk for ineffective peripheral Tissue perfusion: Risk factor: possible presence of emboli in peripheral circulation
Readiness for enhanced Knowledge: expresses an interest in learning

Endometriosis

Grieving r/t possible infertility
Nausea r/t prostaglandin effect
Acute Pain r/t onset of menses with distention of endometrial tissue
Sexual dysfunction r/t painful intercourse
Readiness for enhanced Knowledge: expresses an interest in learning

Endometritis

Anxiety r/t, fear of unknown
Ineffective Thermoregulation r/t infectious process
Acute Pain r/t infectious process in reproductive tract
Readiness for enhanced Knowledge: expresses an interest in learning

Enuresis

Ineffective Health maintenance r/t unachieved developmental task, neuromuscular immaturity, diseases of urinary system
See Toilet Training

Environmental Interpretation Problems

See Chronic Confusion

Epididymitis

Anxiety r/t situational crisis, pain, threat to future fertility
Acute Pain r/t inflammation in scrotal sac
Ineffective Sexuality pattern r/t edema of epididymis and testes
Readiness for enhanced Knowledge: expresses an interest in learning

Epiglottitis

See Respiratory Infections, Acute Childhood (Croup, Epiglottitis, Pertussis, Pneumonia, Respiratory Syncytial Virus)

Epilepsy

Anxiety r/t threat to role functioning
Ineffective Health management r/t deficient knowledge regarding seizure control
Impaired Memory r/t seizure activity
Risk for Aspiration: Risk factors: impaired swallowing, excessive secretions
Risk for delayed Development: Risk factor: seizure disorder
Risk for Injury: Risk factor: environmental factors during seizure
Readiness for enhanced Knowledge: expresses an interest in learning
See Seizure Disorders, Adult; Seizure Disorders, Childhood (Epilepsy, Febrile Seizures, Infantile Spasms)

Episiotomy

Anxiety r/t fear of pain
Disturbed Body Image r/t fear of resuming sexual relations
Impaired physical Mobility r/t pain, swelling, tissue trauma
Acute Pain r/t tissue trauma
Sexual dysfunction r/t altered body structure, tissue trauma
Impaired Skin integrity r/t perineal incision
Risk for Infection: Risk factor: tissue trauma

Epistaxis

Fear r/t large amount of blood loss
Risk for deficient Fluid volume: Risk factor: excessive blood loss

Epstein-Barr Virus

See Mononucleosis

Erectile Dysfunction (ED)

Situational low Self-Esteem r/t physiological crisis, inability to practice usual sexual activity
Sexual dysfunction r/t altered body function
Readiness for enhanced Knowledge: information regarding treatment for erectile dysfunction
See Impotence

Escherichia coli Infection

Fear r/t serious illness, unknown outcome
Deficient Knowledge r/t how to prevent disease; care of self with serious illness
See Gastroenteritis; Gastroenteritis, Child; Hospitalized Child

Esophageal Varices

Fear r/t threat of death from hematemesis
Risk for Bleeding: Risk factors: portal hypertension, distended variceal vessels that can easily rupture
See Cirrhosis

Esophagitis

Acute Pain r/t inflammation of esophagus
Readiness for enhanced Knowledge: expresses an interest in learning

Evisceration

See Dehiscence, Abdominal

Exhaustion

Impaired individual Resilience (See **Resilience**, individual, impaired, Section III)
Disturbed Sleep pattern (See **Sleep** pattern, disturbed, Section III)

Exposure to Hot or Cold Environment

Hyperthermia r/t exposure to hot environment, abnormal reaction to anesthetics
Hypothermia r/t exposure to cold environment
Risk for ineffective Thermoregulation: Risk factors: extremes of environmental temperature, inappropriate clothing for environmental temperature

External Fixation

Disturbed Body Image r/t trauma, change to affected part
Risk for Infection: Risk factor: presence of pins inserted into bone
See Fracture

Extracorporeal Membrane Oxygenator (ECMO)

See ECMO (Extracorporeal Membrane Oxygenator)

Eye Discomfort

Risk for dry Eye (See **Eye**, dry, risk for, Section III)

Risk for corneal Injury: Risk factors: exposure of the eyeball, blinking less than five times per minute

Eye Surgery

Anxiety r/t possible loss of vision
Self-Care deficit: **specify** r/t impaired vision
Vision Loss r/t surgical procedure, eye pathology
Risk for Injury: Risk factor: impaired vision
Readiness for enhanced Knowledge: expresses an interest in learning
See Hospitalized Child

List of Nursing Diagnosis by Letter: F

Failure to Thrive, Child	Falls, Risk for	Family Problems
Family Process	Fatigue	Fear
Febrile Seizures	Fecal Impaction	Fecal Incontinence
Feeding Dynamics, Infant	Feeding Problems, Newborn	Female Genital Mutilation
Femoral Popliteal Bypass	Fetal Alcohol Syndrome	Fetal Distress/Nonreassuring Fetal Heart Rate Pattern
Fever	Fibrocystic Breast Disease	Filthy Home Environment
Financial Crisis in the Home Environment	Fistulectomy	Flail Chest
Flashbacks	Flat Affect	Fluid Volume Deficit
Fluid Volume Excess	Fluid Volume Imbalance, Risk for	Food Allergies
Foodborne Illness	Food Intolerance	Foreign Body Aspiration
Formula Feeding of Infant	Fracture	Fractured Hip
Frail Elderly Syndrome	Frequency of Urination	Friendship
Frostbite	Frothy Sputum	Fusion, Lumbar

F

Failure to Thrive, Child

Disorganized Infant behavior (See **Infant** behavior, disorganized, Section III)
Ineffective Child Eating dynamics r/t lack of knowledge or resources regarding nutritional needs of child
Ineffective Infant Feeding dynamics r/t lack of knowledge regarding nutritional needs of infant
Insomnia r/t inconsistency of caretaker; lack of quiet, consistent environment
Imbalanced Nutrition: less than body requirements r/t inadequate type or amounts of food for infant or child, inappropriate feeding techniques
Impaired Parenting r/t lack of parenting skills, inadequate role modeling
Chronic low Self-Esteem: parental r/t feelings of inadequacy, support system deficiencies, inadequate role model
Social isolation r/t limited support systems, self-imposed situation
Risk for impaired Attachment: Risk factor: inability of parents to meet infant's needs
Risk for delayed Development (See **Development**, delayed, risk for, Section III)
Readiness for enhanced Knowledge: parent expresses willingness to learn how to meet **infant/child nutritional needs**

Falls, Risk for

Risk for Falls (See **Falls,** risk for, Section III)

Family Problems

Compromised family Coping (See **Coping,** family, compromised, Section III)
Disabled family Coping (See **Coping,** family, disabled, Section III)
Interrupted Family processes r/t situation transition and/or crises, developmental transition and/or crises
Ineffective family Health management (See family **Health** management, ineffective, Section III)
Readiness for enhanced family Coping: needs sufficiently gratified, adaptive tasks effectively addressed to enable goals of self-actualization to surface

Family Process

Dysfunctional Family processes (See **Family** processes, dysfunctional, Section III)
Interrupted Family processes (See **Family** processes, interrupted, Section III)
Readiness for enhanced Family processes (See **Family** processes, readiness for enhanced, Section III)
Readiness for enhanced Relationship (See **Relationship,** readiness for enhanced, Section III)

Fatigue

Fatigue (See **Fatigue,** Section III)

Fear

Death Anxiety r/t fear of death
Fear r/t identifiable physical or psychological threat to person

Febrile Seizures

See Seizure Disorders, Childhood (Epilepsy, Febrile Seizures, Infantile Spasms)

Fecal Impaction

See Impaction of Stool
(See **Constipation**, Section III)
(See **Constipation**, chronic functional, Section III)

Fecal Incontinence

Bowel Incontinence r/t neurological impairment, gastrointestinal disorders, anorectal trauma, weakened perineal muscles

Feeding Dynamics, Infant

Ineffective Infant Eating Dynamics r/t inappropriate transition to sold foods
Risk for Caregiver Role Strain: Risk factor: fatigue leading to ineffective or insufficient feeding
Risk for impaired Attachment: Risk factor: inability physically or psychologically to meet nutritional needs of newborn
Risk for impaired Parenting: Risk factors: stress, sleep deprivation, insufficient knowledge, and/or social isolation
Readiness for enhanced Health literacy: expresses a desire to enhance knowledge of appropriate feeding dynamics for each developmental stage (See **Ineffective Feeding Dynamics,** Infant, Section III)

Feeding Problems, Newborn

Ineffective Breastfeeding (See **Breastfeeding**, ineffective, Section III)
Ineffective Infant Feeding Dynamics r/t attachment issues, lack of knowledge of appropriate methods of feeding infant for each stage of development
Insufficient Breast Milk Production (See **Breast Milk Production**, insufficient, Section III)
Disorganized Infant behavior r/t prematurity, immature neurological system
Ineffective Infant Feeding dynamics r/t parental lack of knowledge of appropriate feeding methods for each stage of development
Ineffective infant Feeding pattern r/t prematurity, neurological impairment or delay, oral hypersensitivity, prolonged nothing-by-mouth status
Impaired Swallowing r/t prematurity
Neonatal Abstinence syndrome: At-risk population: in utero substance exposure secondary to maternal substance use
Risk for delayed Development: Risk factor: inadequate nutrition
Risk for deficient Fluid volume: Risk factor: inability to take in adequate amount of fluids

Female Genital Mutilation

Acute Pain r/t traumatic surgical procedure
Anxiety r/t situational crisis
Disturbed Body Image r/t scarring, changes in body function
Fear r/t threat to well-being
Powerlessness r/t absence of control of decision-making
Impaired Skin Integrity r/t traumatic surgical procedure

Impaired Tissue Integrity r/t wound, potential for infection
Risk for compromised Human Dignity: Risk factor**:** dehumanizing treatment
Risk for Infection: Risk factor: invasive procedure
Risk for Post-Trauma Syndrome: Risk factor: experiencing traumatic surgery
Risk for chronic low Self-Esteem: Risk factor: cultural incongruence (See **Female Genital Mutilation,** Risk for, Section III)

Femoral Popliteal Bypass

Anxiety r/t threat to or change in health status
Acute Pain r/t surgical trauma, edema in surgical area
Ineffective peripheral Tissue Perfusion r/t impaired arterial circulation
Risk for Bleeding: Risk factor: surgery on arteries
Risk for Surgical Site Infection: Risk factor: invasive procedure

Fetal Alcohol Syndrome

See Neonatal Abstinence Syndrome

Fetal Distress/Nonreassuring Fetal Heart Rate Pattern

Fear r/t threat to fetus
Ineffective peripheral Tissue Perfusion: fetal r/t interruption of umbilical cord blood flow

Fever

Ineffective Thermoregulation r/t infectious process

Fibrocystic Breast Disease

See Breast Lumps

Filthy Home Environment

Impaired Home maintenance (See **Home** maintenance**,** impaired, Section III)
Self-Neglect r/t mental illness, substance abuse, cognitive impairment

Financial Crisis in the Home Environment

Impaired Home maintenance r/t insufficient finances

Fistulectomy

See Hemorrhoidectomy

Flail Chest

Ineffective Breathing pattern r/t chest trauma
Fear r/t difficulty breathing
Impaired Gas exchange r/t loss of effective lung function
Impaired spontaneous Ventilation r/t paradoxical respirations

Flashbacks

Post-Trauma syndrome r/t catastrophic event

Flat Affect

Hopelessness r/t prolonged activity restriction creating isolation, failing or deteriorating physiological condition, long-term stress, abandonment, lost belief in transcendent values or higher power or God
Risk for Loneliness: Risk factors: social isolation, lack of interest in surroundings
See Depression (Major Depressive Disorder); Dysthymic Disorder

Fluid Volume Deficit

Deficient Fluid volume r/t active fluid loss, vomiting, diarrhea, failure of regulatory mechanisms
Risk for Shock: Risk factors: hypovolemia, sepsis, systemic inflammatory response syndrome (SIRS)
Risk for unstable Blood Pressure: Risk factor: hypotension, excessive loss or insufficient intake of fluid

Fluid Volume Excess

Excess Fluid volume r/t compromised regulatory mechanism, excess sodium intake
Risk for unstable Blood Pressure: Risk factor: hypertension, excessive intake or retention of fluid

Fluid Volume Imbalance, Risk for

Risk for imbalanced Fluid volume: Risk factor: major invasive surgeries

Food Allergies

Diarrhea r/t immune effects of offending food on gastrointestinal system
Risk for Allergic reaction: Risk factor: specific foods
Readiness for enhanced Knowledge: expresses an interest in learning
See Anaphylactic Shock

Foodborne Illness

Diarrhea r/t infectious material in gastrointestinal tract
Deficient Fluid volume r/t active fluid loss from vomiting and diarrhea
Deficient Knowledge r/t care of self with serious illness, prevention of further incidences of foodborne illness
Nausea r/t contamination irritating stomach
Risk for dysfunctional Gastrointestinal motility: Risk factor: contaminated food
See Gastroenteritis; Gastroenteritis, Child; Hospitalized Child; Escherichia coli *Infection*

Food Intolerance

Risk for dysfunctional Gastrointestinal motility: Risk factor: food intolerance

Foreign Body Aspiration

Ineffective Airway clearance r/t obstruction of airway
Ineffective Health maintenance r/t parental deficient knowledge regarding high-risk items
Risk for Suffocation: Risk factor: inhalation of small objects

See Safety, Childhood

Formula Feeding of Infant

Grieving: maternal r/t loss of desired breastfeeding experience
Ineffective Infant Feeding Dynamics r/t lack of knowledge of appropriate methods of feeding infant for each stage of development
Risk for Constipation: infant: Risk factor: iron-fortified formula
Risk for Infection: infant: Risk factors: lack of passive maternal immunity, supine feeding position, contamination of formula
Readiness for enhanced Knowledge: expresses an interest in learning

Fracture

Decreased Diversional activity engagement r/t immobility
Impaired physical Mobility r/t limb immobilization
Acute Pain r/t muscle spasm, edema, trauma
Post-Trauma syndrome r/t catastrophic event
Impaired Walking r/t limb immobility
Risk for ineffective peripheral Tissue Perfusion: Risk factors: immobility, presence of cast
Risk for Peripheral Neurovascular dysfunction: Risk factors: mechanical compression, treatment of fracture
Risk for impaired Skin integrity: Risk factors: immobility, presence of cast
Risk for Venous Thromboembolism: Risk factors: trauma, immobility
Readiness for enhanced Knowledge: expresses an interest in learning

Fractured Hip

See Hip Fracture

Frail Elderly Syndrome

Activity intolerance r/t sensory changes
Risk for Frail Elderly syndrome (see **Frail Elderly** syndrome, risk for, Section III)
Risk for Injury: Risk factors: impaired vision, impaired gait
Risk for Powerlessness: Risk factor: inability to maintain independence

Frequency of Urination

Stress urinary Incontinence r/t degenerative change in pelvic muscles and structural support
Urge urinary Incontinence r/t decreased bladder capacity, irritation of bladder stretch receptors causing spasm, alcohol, caffeine, increased fluids, increased urine concentration, overdistended bladder
Impaired Urinary elimination r/t urinary tract infection
Urinary retention r/t high urethral pressure caused by weak detrusor, inhibition of reflex arc, strong sphincter, blockage

Friendship

Readiness for enhanced Relationship: expresses desire to enhance communication between partners

Frostbite

Acute Pain r/t decreased circulation from prolonged exposure to cold
Ineffective peripheral Tissue Perfusion r/t damage to extremities from prolonged exposure to cold

Impaired Tissue integrity r/t freezing of skin and tissues
Risk for ineffective Thermoregulation: Risk factor: prolonged exposure to cold
See Hypothermia

Frothy Sputum

See CHF (Congestive Heart Failure); Pulmonary Edema; Seizure Disorders, Adult; Seizure Disorders, Childhood (Epilepsy, Febrile Seizures, Infantile Spasms)

Fusion, Lumbar

Anxiety r/t fear of surgical procedure, possible recurring problems
Impaired physical Mobility r/t limitations from surgical procedure, presence of brace
Acute Pain r/t discomfort at bone donor site, surgical operation
Risk for Injury: Risk factor: improper body mechanics
Risk for Perioperative Positioning injury: Risk factor: immobilization during surgery
Readiness for enhanced Knowledge: expresses an interest in learning

List of Nursing Diagnosis by Letter: G

Gag Reflex, Depressed or Absent	Gallop Rhythm	Gallstones
Gang Member	Gangrene	Gas Exchange, Impaired
Gastric Ulcer	Gastritis	Gastroenteritis
Gastroenteritis, Child	Gastroesophageal Reflux (GERD)	Gastroesophageal Reflux, Child
Gastrointestinal Bleeding (GI Bleed)	Gastrointestinal Hemorrhage	Gastrointestinal Surgery
Gastroschisis/Omphalocele	Gastrostomy	Gender Dysphoria
Genital Herpes	Genital Warts	GERD
Gestational Diabetes (Diabetes in Pregnancy)	GI Bleed (Gastrointestinal Bleeding)	Gingivitis
Glaucoma	Glomerulonephritis	Gluten Allergy
Gonorrhea	Gout	Grandiosity
Grand Mal Seizure	Grandparents Raising Grandchildren	Graves' Disease
Grieving	Grieving, Complicated	Groom Self (Inability to)
Growth and Development Lag	Guillain-Barré Syndrome	Guilt

G

Gag Reflex, Depressed or Absent

Impaired Swallowing r/t neuromuscular impairment
Risk for Aspiration: Risk factors: depressed cough or gag reflex

Gallop Rhythm

Decreased Cardiac output r/t decreased contractility of heart

Gallstones

See Cholelithiasis

Gang Member

Impaired individual Resilience (See **Resilience**, individual, impaired, Section III)

Gangrene

Fear r/t possible loss of extremity
Ineffective peripheral Tissue perfusion r/t obstruction of arterial flow
See Diabetes Mellitus; Peripheral Vascular Disease

Gas Exchange, Impaired

Impaired Gas exchange r/t ventilation-perfusion imbalance

Gastric Ulcer

See GI Bleed (Gastrointestinal Bleeding); Ulcer, Peptic (Duodenal or Gastric)

Gastritis

Imbalanced Nutrition: less than body requirements r/t vomiting, inadequate intestinal absorption of nutrients, restricted dietary regimen
Acute Pain r/t inflammation of gastric mucosa
Risk for deficient Fluid volume: Risk factors: excessive loss from gastrointestinal tract from vomiting, decreased intake

Gastroenteritis

Diarrhea r/t infectious process involving intestinal tract
Deficient Fluid volume r/t excessive loss from gastrointestinal tract from diarrhea, vomiting
Nausea r/t irritation to gastrointestinal system
Imbalanced Nutrition: **less than body requirements** r/t vomiting, inadequate intestinal absorption of nutrients, restricted dietary intake
Acute Pain r/t increased peristalsis causing cramping
Risk for Electrolyte imbalance: Risk factor: loss of gastrointestinal fluids high in electrolytes
Readiness for enhanced Knowledge: expresses an interest in learning
See Gastroenteritis, Child

Gastroenteritis, Child

Impaired Skin integrity: **diaper rash** r/t acidic excretions on perineal tissues
Readiness for enhanced Knowledge: expresses an interest in learning
Acute Pain r/t increased peristalsis causing cramping
See Gastroenteritis; Hospitalized Child

Gastroesophageal Reflux (GERD)

Ineffective Airway clearance r/t reflux of gastric contents into esophagus and tracheal or bronchial tree
Ineffective Health maintenance r/t deficient knowledge regarding anti-reflux regimen (e.g., positioning, change in diet)
Acute Pain r/t irritation of esophagus from gastric acids
Risk for Aspiration: Risk factor: entry of gastric contents in tracheal or bronchial tree

Gastroesophageal Reflux, Child

Ineffective Airway clearance r/t reflux of gastric contents into esophagus and tracheal or bronchial tree
Anxiety: **parental** r/t possible need for surgical intervention
Deficient Fluid volume r/t persistent vomiting
Imbalanced Nutrition: **less than body requirements** r/t poor feeding, vomiting
Risk for Aspiration: Risk factor: entry of gastric contents in tracheal or bronchial tree
Risk for impaired Parenting: Risk factors: disruption in bonding as a result of irritable or inconsolable infant; lack of sleep for parents
Readiness for enhanced Knowledge: expresses an interest in learning
See Child with Chronic Condition; Hospitalized Child

Gastrointestinal Bleeding (GI Bleed)

See GI Bleed (Gastrointestinal Bleeding)

Gastrointestinal Hemorrhage

See GI Bleed (Gastrointestinal Bleeding)

Gastrointestinal Surgery

Risk for Injury: Risk factor: inadvertent insertion of nasogastric tube through gastric incision line
See Abdominal Surgery

Gastroschisis/Omphalocele

Ineffective Airway clearance r/t complications of anesthetic effects
Impaired Gas exchange r/t effects of anesthesia, subsequent atelectasis

Grieving r/t threatened loss of infant, loss of perfect birth or infant because of serious medical condition
Risk for deficient Fluid volume: Risk factors: inability to feed because of condition, subsequent electrolyte imbalance
Risk for Infection: Risk factor: disrupted skin integrity with exposure of abdominal contents
Risk for Injury: Risk factors: disrupted skin integrity, ineffective protection

Gastrostomy

Risk for impaired Skin integrity: Risk factor: presence of gastric contents on skin
See Tube Feeding

Gender Dysphoria

Anxiety r/t conflict between physical (assigned) gender and gender they identify with
Decisional Conflict r/t uncertainty about choices regarding gender reassignment
Disturbed Body Image r/t alteration in self-perception, inability to identify with own body
Ineffective Denial r/t insufficient emotional support
Fear r/t victimization
Disturbed Personal Identity r/t gender confusion
Ineffective Sexuality Pattern r/t conflict surrounding gender identity
Risk for Compromised Human Dignity: Risk factor: cultural incongruence, humiliation
Readiness for enhanced Decision-Making: expresses desire to enhance understanding of choices for decision-making

Genital Herpes

See Herpes Simplex II

Genital Warts

See STD (Sexually Transmitted Disease)

GERD

See Gastroesophageal Reflux (GERD)

Gestational Diabetes (Diabetes in Pregnancy)

Anxiety r/t threat to self and/or fetus
Impaired Nutrition: **less than body requirements** r/t decreased insulin production and glucose uptake in cells
Risk for Overweight: fetal: r/t excessive glucose uptake
Impaired Nutrition: **more than body requirements**: **fetal** r/t excessive glucose uptake
Risk for delayed Development: **fetal:** Risk factor: endocrine disorder of mother
Risk for unstable blood Glucose: Risk factor: excessive intake of carbohydrates
Risk for disturbed Maternal–Fetal dyad: Risk factor: impaired glucose metabolism
Risk for impaired Tissue integrity: **fetal:** Risk factors: large infant, congenital defects, birth injury
Risk for impaired Tissue integrity: **maternal:** Risk factor: delivery of large infant
Readiness for enhanced Knowledge: expresses an interest in learning
See Diabetes Mellitus

GI Bleed (Gastrointestinal Bleeding)

Fatigue r/t loss of circulating blood volume, decreased ability to transport oxygen

Fear r/t threat to well-being, potential death
Deficient Fluid volume r/t gastrointestinal bleeding, hemorrhage
Imbalanced Nutrition: **less than body requirements** r/t nausea, vomiting
Acute Pain r/t irritated mucosa from acid secretion
Risk for ineffective Coping: Risk factors: personal vulnerability in crisis, bleeding, hospitalization
Readiness for enhanced Knowledge: expresses an interest in learning

Gingivitis

Impaired Oral Mucous Membrane integrity r/t ineffective oral hygiene

Glaucoma

Deficient Knowledge r/t treatment and self-care for disease
See Vision Impairment

Glomerulonephritis

Excess Fluid volume r/t renal impairment
Imbalanced Nutrition: **less than body requirements** r/t anorexia, restrictive diet
Acute Pain r/t edema of kidney
Readiness for enhanced Knowledge: expresses an interest in learning

Gluten Allergy

See Celiac Disease

Gonorrhea

Acute Pain r/t inflammation of reproductive organs
Risk for Infection: Risk factor: spread of organism throughout reproductive organs
Readiness for enhanced Knowledge: expresses an interest in learning
See STD (Sexually Transmitted Disease)

Gout

Impaired physical Mobility r/t musculoskeletal impairment
Chronic Pain r/t inflammation of affected joint
Readiness for enhanced Knowledge: expresses an interest in learning

Grandiosity

Defensive Coping r/t inaccurate perception of self and abilities

Grand Mal Seizure

See Seizure Disorders, Adult; Seizure Disorders, Childhood (Epilepsy, Febrile Seizures, Infantile Spasms)

Grandparents Raising Grandchildren

Anxiety r/t change in role status

Decisional Conflict r/t support system deficit
Parental Role conflict r/t change in parental role
Compromised family Coping r/t family role changes
Interrupted Family processes r/t family roles shift
Ineffective Role performance r/t role transition, aging
Ineffective family Health management r/t excessive demands on individual or family
Risk for impaired Parenting: Risk factor: role strain
Risk for Powerlessness: Risk factors: role strain, situational crisis, aging
Risk for Spiritual distress: Risk factor: life change
Readiness for enhanced Parenting: physical and emotional needs of children are met

Graves' Disease

See Hyperthyroidism

Grieving

Grieving r/t anticipated or actual significant loss, change in life status, style, or function
Imbalanced Energy Field r/t blockage of the energy flow

Grieving, Complicated

Complicated Grieving r/t expected or sudden death of a significant other with whom there was a volatile relationship, emotional instability, lack of social support
Risk for complicated Grieving: Risk factors: death of a significant other with whom there was a volatile relationship, emotional instability, lack of social support

Groom Self (Inability to)

Bathing Self-Care deficit (See **Self-Care** deficit, bathing, Section III)
Dressing Self-Care deficit (See **Self-Care** deficit, dressing, Section III)

Growth and Development Lag

See Failure to Thrive, Child

Guillain-Barré Syndrome

Impaired Spontaneous Ventilation r/t weak respiratory muscles
Risk for Aspiration: Risk factors: ineffective cough; depressed gag reflex
See Neurologic Disorders

Guilt

Grieving r/t potential loss of significant person, animal, prized material possession, change in life role
Impaired individual Resilience (See **Resilience,** individual, impaired, Section III)
Situational low Self-Esteem r/t unmet expectations of self
Risk for complicated Grieving: Risk factors: actual loss of significant person, animal, prized material possession, change in life role
Risk for Post-Trauma syndrome: Risk factor: exaggerated sense of responsibility for traumatic event
Readiness for enhanced Spiritual well-being: desire to be in harmony with self, others, higher power or God

List of Nursing Diagnosis by Letter: H

Hair Loss	Halitosis	Hallucinations
Headache	Head Injury	Health Behavior, Risk-Prone
Health Maintenance Problems	Health-Seeking Person	Hearing Impairment
Heart Attack	Heartburn	Heart Failure
Heart Surgery	Heat Stroke	Hematemesis
Hematuria	Hemianopia	Hemiplegia
Hemodialysis	Hemodynamic Monitoring	Hemolytic Uremic Syndrome
Hemophilia	Hemoptysis	Hemorrhage
Hemorrhoidectomy	Hemorrhoids	Hemothorax
Hepatitis	Hernia	Herniated Disk
Herniorrhaphy	Herpes in Pregnancy	Herpes Simplex I
Herpes Simplex II	Herpes Zoster	HHNS (Hyperosmolar Hyperglycemic Nonketotic Syndrome)
Hiatal Hernia	Hip Fracture	Hip Replacement
Hirschsprung's Disease	Hirsutism	Hitting Behavior
HIV (Human Immunodeficiency Virus)	Hodgkin's Disease	Homelessness
Home Maintenance Problems	Hope	Hopelessness
Hospitalized Child	Hostile Behavior	HTN (Hypertension)
Human Energy Field	Humiliating Experience	Huntington's Disease
Hydrocele	Hydrocephalus	Hygiene, Inability to Provide Own
Hyperactive Syndrome	Hyperbilirubinemia, Neonatal	HypercalcemiaHypercapnia
Hyperemesis Gravidarum	Hyperglycemia	Hyperkalemia
Hypernatremia	Hyperosmolar Hyperglycemic Nonketotic Syndrome (HHNS)	Hyperphosphatemia
Hypersensitivity to Slight Criticism	Hypertension (HTN)	Hyperthermia
Hyperthyroidism	Hyperventilation	Hypocalcemia
Hypoglycemia	Hypokalemia	Hypomagnesemia
Hypomania	Hyponatremia	Hypoplastic Left Lung
Hypotension	Hypothermia	Hypothyroidism
Hypovolemic Shock	Hypoxia	Hysterectomy

H

Hair Loss

Disturbed Body Image r/t psychological reaction to loss of hair
Imbalanced Nutrition: **less than body requirements** r/t inability to ingest food because of biological, psychological, economic factors

Halitosis

Impaired Dentition r/t ineffective oral hygiene
Impaired Oral Mucous Membrane integrity r/t ineffective oral hygiene

Hallucinations

Anxiety r/t threat to self-concept
Acute Confusion r/t alcohol abuse, delirium, dementia, mental illness, substance abuse
Ineffective Coping r/t distortion and insecurity of life events
Risk for Self-Mutilation: Risk factor: command hallucinations
Risk for other-directed Violence: Risk factors: catatonic excitement, manic excitement, rage or panic reactions, response to violent internal stimuli
Risk for self-directed Violence: Risk factors: catatonic excitement, manic excitement, rage or panic reactions, response to violent internal stimuli

Headache

Acute Pain r/t lack of knowledge of pain control techniques or methods to prevent headaches
Ineffective Health management r/t lack of knowledge, identification, elimination of aggravating factors

Head Injury

Ineffective Breathing pattern r/t pressure damage to breathing center in brainstem
Acute Confusion r/t increased intracranial pressure
Decreased Intracranial adaptive capacity r/t increased intracranial pressure
Risk for ineffective Cerebral tissue perfusion: Risk factors: effects of increased intracranial pressure, trauma to brain
See Neurologic Disorders

Health Behavior, Risk-Prone

Risk-prone Health behavior: Risk factors (See **Health** behavior, risk-prone, Section III)
Risk for Metabolic Imbalance syndrome r/t obesity

Health Maintenance Problems

Ineffective Health maintenance (See **Health** maintenance, ineffective, Section III)
Ineffective Health management (See **Health** management, ineffective, Section III)

Health-Seeking Person

Readiness for enhanced Health literacy (See **Health** literacy, readiness for enhanced, Section III)
Readiness for enhanced Health management (See **Health** management, readiness for enhanced, Section III)

Hearing Impairment

Impaired verbal Communication r/t inability to hear own voice
Hearing Loss *(see Appendix E on Evolve)*
Social isolation r/t difficulty with communication

Heart Attack

See MI (Myocardial Infarction)

Heartburn

Nausea r/t gastrointestinal irritation
Acute Pain: **heartburn** r/t inflammation of stomach and esophagus
Risk for imbalanced Nutrition: **less than body requirements:** Risk factor: pain after eating
Readiness for enhanced Knowledge: expresses an interest in learning
See Gastroesophageal Reflux (GERD)

Heart Failure

Activity intolerance r/t weakness, fatigue, shortness of breath
Decreased Cardiac output r/t impaired cardiac function, increased preload, decreased contractility, increased afterload
Constipation r/t activity intolerance
Fatigue r/t disease process with decreased cardiac output
Fear r/t threat to one's own well-being
Excess Fluid volume r/t impaired excretion of sodium and water
Impaired Gas exchange r/t excessive fluid in interstitial space of lungs
Powerlessness r/t illness-related regimen
Risk for Shock (cardiogenic): Risk factors: decreased contractility of heart, increased afterload
Readiness for enhanced Health management (See **Health** management, readiness for enhanced, Section III)
See Child with Chronic Condition; Congenital Heart Disease/Cardiac Anomalies; Hospitalized Child

Heart Surgery

See Coronary Artery Bypass Grafting (CABG)

Heat Stroke

Deficient Fluid volume r/t profuse diaphoresis from high environmental temperature
Hyperthermia r/t vigorous activity, high environmental temperature, inappropriate clothing

Hematemesis

See GI Bleed (Gastrointestinal Bleeding)

Hematuria

See Kidney Stone; UTI (Urinary Tract Infection)

Hemianopia

Anxiety r/t change in vision
Unilateral Neglect r/t effects of disturbed perceptual abilities
Risk for Injury: Risk factor: disturbed sensory perception

Hemiplegia

Anxiety r/t change in health status
Disturbed Body Image r/t functional loss of one side of body
Impaired physical Mobility r/t loss of neurological control of involved extremities
Self-Care deficit: **specify:** r/t neuromuscular impairment
Impaired Sitting r/t partial paralysis
Impaired Standing r/t partial paralysis
Impaired Transfer ability r/t partial paralysis
Unilateral Neglect r/t effects of disturbed perceptual abilities
Impaired Walking r/t loss of neurological control of involved extremities
Risk for Falls: Risk factor: impaired mobility
Risk for impaired Skin integrity: Risk factors: alteration in sensation, immobility; pressure over bony prominence
See CVA (Cerebrovascular Accident)

Hemodialysis

Ineffective Coping r/t situational crisis
Interrupted Family processes r/t changes in role responsibilities as a result of therapy regimen
Excess Fluid volume r/t renal disease with minimal urine output
Powerlessness r/t treatment regimen
Risk for Caregiver Role Strain: Risk factor: complexity of care receiver treatment
Risk for Electrolyte imbalance: Risk factor: effect of metabolic state on renal function
Risk for deficient Fluid volume: Risk factor: excessive removal of fluid during dialysis
Risk for Infection: Risk factors: exposure to blood products, risk for developing hepatitis B or C, impaired immune system
Risk for Injury: Risk factors: clotting of blood access, abnormal surface for blood flow
Risk for impaired Tissue integrity: Risk factor: mechanical factor associated with fistula formation
Readiness for enhanced Knowledge: expresses an interest in learning
See Renal Failure; Renal Failure, Child with Chronic Condition

Hemodynamic Monitoring

Risk for Infection: Risk factor: invasive procedure
Risk for Injury: Risk factors: inadvertent wedging of catheter, dislodgment of catheter, disconnection of catheter
Risk for impaired Tissue integrity: Risk factor: invasive procedure
See Shock, Cardiogenic; Shock, Hypovolemic; Shock, Septic

Hemolytic Uremic Syndrome

Fatigue r/t decreased red blood cells

Fear r/t serious condition with unknown outcome
Deficient Fluid volume r/t vomiting, diarrhea
Nausea r/t effects of uremia
Risk for Injury: Risk factors: decreased platelet count, seizure activity
Risk for impaired Skin integrity: Risk factor: diarrhea
See Hospitalized Child; Renal Failure, Acute/Chronic, Child

Hemophilia

Fear r/t high risk for AIDS infection from contaminated blood products
Impaired physical Mobility r/t pain from acute bleeds, imposed activity restrictions, joint pain
Acute Pain r/t bleeding into body tissues
Risk for Bleeding: Risk factors: deficient clotting factors, child's developmental level, age-appropriate play, inappropriate use of toys or sports equipment
Readiness for enhanced Knowledge: expresses an interest in learning
See Child with Chronic Condition; Hospitalized Child; Maturational Issues, Adolescent

Hemoptysis

Fear r/t serious threat to well-being
Risk for ineffective Airway clearance: Risk factor: obstruction of airway with blood and mucus
Risk for deficient Fluid volume: Risk factor: excessive loss of blood

Hemorrhage

Fear r/t threat to well-being
Deficient Fluid volume r/t massive blood loss
See Hypovolemic Shock

Hemorrhoidectomy

Anxiety r/t embarrassment, need for privacy
Constipation r/t fear of pain with defecation
Acute Pain r/t surgical procedure
Urinary retention r/t pain, anesthetic effect
Risk for Bleeding: Risk factors: inadequate clotting, trauma from surgery
Readiness for enhanced Knowledge: expresses an interest in learning

Hemorrhoids

Impaired Comfort r/t itching in rectal area
Constipation r/t painful defecation, poor bowel habits
Impaired Sitting r/t pain and pressure
Readiness for enhanced Knowledge: expresses an interest in learning

Hemothorax

Deficient Fluid volume r/t blood in pleural space
See Pneumothorax

Hepatitis

Activity intolerance r/t weakness or fatigue caused by infection
Decreased Diversional activity engagement r/t isolation

Fatigue r/t infectious process, altered body chemistry
Imbalanced Nutrition: **less than body requirements** r/t anorexia, impaired use of proteins and carbohydrates
Acute Pain r/t edema of liver, bile irritating skin
Social isolation r/t treatment-imposed isolation
Risk for deficient Fluid volume: Risk factor: excessive loss of fluids from vomiting and diarrhea
Readiness for enhanced Knowledge: expresses an interest in learning

Hernia

See Hiatal Hernia; Inguinal Hernia Repair

Herniated Disk

See Low Back Pain

Herniorrhaphy

See Inguinal Hernia Repair

Herpes in Pregnancy

Fear r/t threat to fetus, impending surgery
Situational low Self-Esteem r/t threat to fetus as a result of disease process
Risk for Infection: infant: Risk factors: transplacental transfer during primary herpes, exposure to active herpes during birth process
See Herpes Simplex II

Herpes Simplex I

Impaired Oral Mucous Membrane integrity r/t inflammatory changes in mouth

Herpes Simplex II

Ineffective Health maintenance r/t deficient knowledge regarding treatment, prevention, spread of disease
Acute Pain r/t active herpes lesion
Situational low Self-Esteem r/t expressions of shame or guilt
Sexual dysfunction r/t disease process
Impaired Tissue integrity r/t active herpes lesion
Impaired Urinary elimination r/t pain with urination

Herpes Zoster

See Shingles

HHNS (Hyperosmolar Hyperglycemic Nonketotic Syndrome)

See Hyperosmolar Hyperglycemic Nonketotic Syndrome (HHNS)

Hiatal Hernia

Ineffective Health maintenance r/t deficient knowledge regarding care of disease
Nausea r/t effects of gastric contents in esophagus
Imbalanced Nutrition: **less than body requirements** r/t pain after eating
Acute Pain r/t gastroesophageal reflux

Hip Fracture

Acute Confusion r/t sensory overload, sensory deprivation, medication side effects, advanced age, pain
Constipation r/t immobility, opioids, anesthesia
Fear r/t outcome of treatment, future mobility, present helplessness
Impaired physical Mobility r/t surgical incision, temporary absence of weight bearing, pain when walking
Acute Pain r/t injury, surgical procedure, movement
Powerlessness r/t health care environment
Self-Care deficit: specify r/t musculoskeletal impairment
Impaired Transfer ability r/t immobilization of hip
Impaired Walking r/t temporary absence of weight bearing
Risk for Bleeding: Risk factors: postoperative complication, surgical blood loss
Risk for Surgical Site Infection: Risk factor: invasive procedure
Risk for Injury: Risk factors: activities such as greater than 90-degree flexion of hips that can result in dislodged prosthesis, unsteadiness when ambulating
Risk for Perioperative Positioning injury: Risk factors: immobilization, muscle weakness, emaciation
Risk for Peripheral Neurovascular dysfunction: Risk factors: trauma, vascular obstruction, fracture
Risk for impaired Skin integrity: Risk factor: immobility
Risk for Venous Thromboembolism: Risk factors: immobility, trauma

Hip Replacement

See Total Joint Replacement (Total Hip/Total Knee/Shoulder)

Hirschsprung's Disease

Constipation: **bowel obstruction** r/t inhibited peristalsis as a result of congenital absence of parasympathetic ganglion cells in distal colon
Grieving r/t loss of perfect child, birth of child with congenital defect even though child expected to be normal within 2 years
Imbalanced Nutrition: **less than body requirements** r/t anorexia, pain from distended colon
Acute Pain r/t distended colon, incisional postoperative pain
Impaired Skin integrity r/t stoma, potential skin care problems associated with stoma
Readiness for enhanced Knowledge: expresses an interest in learning
See Hospitalized Child

Hirsutism

Disturbed Body Image r/t excessive hair

Hitting Behavior

Acute Confusion r/t dementia, alcohol abuse, drug abuse, delirium
Risk for other-directed Violence (See **Violence,** other-directed, risk for, Section III)

HIV (Human Immunodeficiency Virus)

Fear r/t possible death
Ineffective Protection r/t depressed immune system

Readiness for enhanced Health literacy: expresses desire to enhance understanding of health information to make health care choices
See AIDS (Acquired Immunodeficiency Syndrome)

Hodgkin's Disease

See Anemia; Cancer; Chemotherapy

Homelessness

Impaired Home maintenance r/t impaired cognitive or emotional functioning, inadequate support system, insufficient finances

Home Maintenance Problems

Impaired Home maintenance (See **Home** maintenance, impaired, Section III)
Self-Neglect r/t mental illness, substance abuse, cognitive impairment
Powerlessness r/t interpersonal interactions
Risk for Physical Trauma: Risk factor: being in high-crime neighborhood

Hope

Readiness for enhanced Hope (See **Hope,** readiness for enhanced, Section III)

Hopelessness

Hopelessness (See **Hopelessness,** Section III)

Hospitalized Child

Activity intolerance r/t fatigue associated with acute illness
Anxiety: **separation (child)** r/t familiar surroundings and separation from family and friends
Compromised family Coping r/t possible prolonged hospitalization that exhausts supportive capacity of significant people
Ineffective Coping: **parent** r/t possible guilt regarding hospitalization of child, parental inadequacies
Decreased Diversional activity engagement r/t immobility, monotonous environment, frequent or lengthy treatments, reluctance to participate, therapeutic isolation, separation from peers
Interrupted Family processes r/t situational crisis of illness, disease, hospitalization
Fear r/t deficient knowledge or maturational level with fear of unknown, mutilation, painful procedures, surgery
Hopelessness: **child** r/t prolonged activity restriction, uncertain prognosis
Insomnia: **child or parent** r/t 24-hour care needs of hospitalization
Acute Pain r/t treatments, diagnostic or therapeutic procedures, disease process
Powerlessness: child r/t health care environment, illness-related regimen
Risk for impaired Attachment: Risk factor: separation
Risk for delayed Development: **regression**: Risk factors: disruption of normal routine, unfamiliar environment or caregivers, developmental vulnerability of young children
Risk for Injury: Risk factors: unfamiliar environment, developmental age, lack of parental knowledge regarding safety (e.g., side rails, IV site/pole)
Risk for imbalanced Nutrition: less than body requirements: Risk factors: anorexia, absence of familiar foods, cultural preferences
Readiness for enhanced family Coping: impact of crisis on family values, priorities, goals, relationships in family
See Child with Chronic Condition

Hostile Behavior

Risk for other-directed Violence: Risk factor: antisocial personality disorder

HTN (Hypertension)

Ineffective Health management (See **Health** management, ineffective, Section III)
Readiness for enhanced Health management (See **Health** management, readiness for enhanced, Section III)
Risk for Overweight: Risk factor: lack of knowledge of relationship between diet and disease process

Human Energy Field

Energy Field, Imbalanced (See **Imbalanced Energy Field,** Section III)

Humiliating Experience

Risk for compromised Human Dignity (See **Human Dignity,** compromised, risk for, Section III)

Huntington's Disease

Decisional Conflict r/t whether to have children
See Neurologic Disorders

Hydrocele

Acute Pain r/t severely enlarged hydrocele
Ineffective Sexuality pattern r/t recent surgery on area of scrotum

Hydrocephalus

Decisional Conflict r/t unclear or conflicting values regarding selection of treatment modality
Interrupted Family processes r/t situational crisis
Imbalanced Nutrition: **less than body requirements** r/t inadequate intake as a result of anorexia, nausea, vomiting, feeding difficulties
Risk for delayed Development: Risk factor: sequelae of increased intracranial pressure
Risk for Infection: Risk factor: sequelae of invasive procedure (shunt placement)
Risk for ineffective Cerebral tissue perfusion: Risk factors: interrupted flow, hypervolemia of cerebral ventricles
Risk for Falls: Risk factors: acute illness, alteration in cognitive functioning
See Normal Pressure Hydrocephalus (NPH); Child with Chronic Condition; Hospitalized Child; Premature Infant (Child); Premature Infant (Parent)

Hygiene, Inability to Provide Own

Frail Elderly syndrome r/t living alone
Self-Neglect (See **Self-Neglect,** Section III)
Bathing Self-Care deficit (See **Self-Care** deficit, bathing, Section III)

Hyperactive Syndrome

Decisional Conflict r/t multiple or divergent sources of information regarding education, nutrition,

medication regimens; willingness to change own food habits; limited resources
Parental Role conflict: **when siblings present** r/t increased attention toward hyperactive child
Compromised family Coping r/t unsuccessful strategies to control excessive activity, behaviors, frustration, anger
Ineffective Impulse control r/t disorder of development, environment that might cause frustration or irritation
Ineffective Role performance: **parent** r/t stressors associated with dealing with hyperactive child, perceived or projected blame for causes of child's behavior, unmet needs for support or care, lack of energy to provide for those needs
Chronic low Self-Esteem r/t inability to achieve socially acceptable behaviors; frustration; frequent reprimands, punishment, or scolding for uncontrolled activity and behaviors; mood fluctuations and restlessness; inability to succeed academically; lack of peer support
Impaired Social interaction r/t impulsive and overactive behaviors, concomitant emotional difficulties, distractibility and excitability
Risk for delayed Development: Risk factor: behavior disorders
Risk for impaired Parenting: Risk factor: disruptive or uncontrollable behaviors of child
Risk for other-directed Violence: **parent or child:** Risk factors: frustration with disruptive behavior, anger, unsuccessful relationships

Hyperbilirubinemia, Neonatal

Anxiety: **parent** r/t threat to infant, unknown future
Parental Role conflict r/t interruption of family life because of care regimen
Neonatal Hyperbilirubinemia r/t abnormal breakdown of red blood cells following birth
Imbalanced Nutrition: **less than body requirements (infant)** r/t disinterest in feeding because of jaundice-related lethargy
Risk for Injury: infant: Risk factors: kernicterus, phototherapy lights
Risk for ineffective Thermoregulation: Risk factor: phototherapy
Readiness for enhanced Health management (parents): expresses desire to manage treatment: assessment of jaundice when infant is discharged from the hospital, when to call the physician, and possible preventive measures such as frequent breastfeeding
(See Neonatal **Hyperbilirubinemia,** Risk for, Section III)

Hypercalcemia

Decreased Cardiac output r/t bradydysrhythmia
Impaired physical Mobility r/t decreased muscle tone
Imbalanced Nutrition: less than body requirements r/t gastrointestinal manifestations of hypercalcemia (nausea, anorexia, ileus)
Risk for Disuse syndrome: Risk factor: comatose state impairing mobility

Hypercapnia

Fear r/t difficulty breathing
Impaired Gas exchange r/t ventilation-perfusion imbalance, retention of carbon dioxide
See ARDS (Adult Respiratory Distress Syndrome); COPD (Chronic Obstructive Pulmonary Disorder); Sleep Apnea

Hyperemesis Gravidarum

Anxiety r/t threat to self and infant, hospitalization
Deficient Fluid volume r/t excessive vomiting
Impaired Home maintenance r/t chronic nausea, inability to function
Nausea r/t hormonal changes of pregnancy
Imbalanced Nutrition: **less than body requirements** r/t excessive vomiting
Powerlessness r/t health care regimen
Social isolation r/t hospitalization
Risk for Electrolyte imbalance: Risk factor: vomiting

Hyperglycemia

Ineffective Health management r/t complexity of therapeutic regimen, decisional conflicts, economic difficulties, unsupportive family, insufficient cues to action, deficient knowledge, mistrust, lack of acknowledgment of seriousness of condition
Risk for unstable blood Glucose level (See **Glucose** level, blood, unstable, risk for, Section III)
See Diabetes Mellitus

Hyperkalemia

Risk for Activity intolerance: Risk factor: muscle weakness
Risk for decreased Cardiac tissue perfusion: Risk factor: abnormal electrolyte level affecting heart rate and rhythm
Risk for excess Fluid volume: Risk factor: untreated renal failure

Hypernatremia

Risk for deficient Fluid volume: Risk factors: abnormal water loss, inadequate water intake

Hyperosmolar Hyperglycemic Nonketotic Syndrome (HHNS)

Acute Confusion r/t dehydration, electrolyte imbalance
Deficient Fluid volume r/t polyuria, hyperglycemia, inadequate fluid intake
Risk for Electrolyte imbalance: Risk factor: effect of metabolic state on kidney function
Risk for Injury: **seizures:** Risk factors: hyperosmolar state, electrolyte imbalance
See Diabetes Mellitus; Diabetes Mellitus, Juvenile (Insulin-Dependent Diabetes Mellitus Type 1)

Hyperphosphatemia

Deficient Knowledge r/t dietary changes needed to control phosphate levels
See Renal Failure

Hypersensitivity to Slight Criticism

Defensive Coping r/t situational crisis, psychological impairment, substance abuse

Hypertension (HTN)

See HTN (Hypertension)
Risk for decreased Cardiac output: Risk factors: decreased contractility and altered conductivity associated with myocardial damage
Risk for unstable Blood Pressure: (See **Unstable Blood Pressure,** Risk for, Section III)

Hyperthermia

Hyperthermia (See **Hyperthermia,** Section III)

Hyperthyroidism

Anxiety r/t increased stimulation, loss of control
Diarrhea r/t increased gastric motility
Insomnia r/t anxiety, excessive sympathetic discharge

Imbalanced Nutrition: less than body requirements r/t increased metabolic rate, increased gastrointestinal activity
Risk for Injury: **eye damage:** Risk factor: protruding eyes without sufficient lubrication
Risk for unstable Blood Pressure r/t hyperthyroidism
Readiness for enhanced Knowledge: expresses an interest in learning

Hyperventilation

Ineffective Breathing pattern r/t anxiety, acid-base imbalance
See Anxiety Disorder; Dyspnea; Heart Failure

Hypocalcemia

Activity intolerance r/t neuromuscular irritability
Ineffective Breathing pattern r/t laryngospasm
Imbalanced Nutrition: less than body requirements r/t effects of vitamin D deficiency, renal failure, malabsorption, laxative use

Hypoglycemia

Acute Confusion r/t insufficient blood glucose to brain
Ineffective Health management r/t deficient knowledge regarding disease process, self-care
Imbalanced Nutrition: **less than body requirements** r/t imbalance of glucose and insulin level
Risk for unstable blood Glucose level (See **Glucose** level, blood, unstable, risk for, Section III)
See Diabetes Mellitus; Diabetes Mellitus, Juvenile (IDDM Type 1)

Hypokalemia

Activity intolerance r/t muscle weakness
Risk for decreased Cardiac tissue perfusion: Risk factor: possible dysrhythmia from electrolyte imbalance

Hypomagnesemia

Imbalanced Nutrition: **less than body requirements** r/t deficient knowledge of nutrition, alcoholism
See Alcoholism

Hypomania

Insomnia r/t psychological stimulus
See Manic Disorder, Bipolar I

Hyponatremia

Acute Confusion r/t electrolyte imbalance
Excess Fluid volume r/t excessive intake of hypotonic fluids
Risk for Injury: Risk factors: seizures, new onset of confusion

Hypoplastic Left Lung

See Congenital Heart Disease/Cardiac Anomalies

Hypotension

Decreased Cardiac output r/t decreased preload, decreased contractility
Risk for deficient Fluid volume: Risk factor: excessive fluid loss
Risk for ineffective Cerebral tissue perfusion: Risk factors: hypovolemia, decreased contractility, decreased afterload
Risk for Shock (See **Shock,** risk for, Section III)
Risk for unstable Blood Pressure (See **Unstable Blood Pressure,** Risk for, Section III)
See Dehydration; Heart Failure; MI (Myocardial Infarction)

Hypothermia

Hypothermia (See **Hypothermia,** Section III)
Risk for Hypothermia (see **Hypothermia,** risk for, Section III)

Hypothyroidism

Activity intolerance r/t muscular stiffness, shortness of breath on exertion
Constipation r/t decreased gastric motility
Impaired Gas exchange r/t respiratory depression
Impaired Skin integrity r/t edema, dry or scaly skin
Risk for Overweight: Risk factor: decreased metabolic process

Hypovolemic Shock

See Shock, Hypovolemic

Hypoxia

Acute Confusion r/t decreased oxygen supply to brain
Fear r/t breathlessness
Impaired Gas exchange r/t altered oxygen supply, inability to transport oxygen
Risk for Shock (See **Shock,** risk for, Section III)

Hysterectomy

Constipation r/t opioids, anesthesia, bowel manipulation during surgery
Ineffective Coping r/t situational crisis of surgery
Grieving r/t change in body image, loss of reproductive status
Acute Pain r/t surgical injury
Sexual dysfunction r/t disturbance in self-concept
Urinary retention r/t edema in area, anesthesia, opioids, pain
Risk for Bleeding: Risk factor: surgical procedure
Risk for Constipation: Risk factors: opioids, anesthesia, bowel manipulation during surgery
Risk for ineffective peripheral Tissue perfusion: Risk factor: deficient knowledge of aggravating factors
Risk for Surgical Site Infection: Risk factor: invasive procedure
Readiness for enhanced Knowledge: Expresses an interest in learning
See Surgery, Perioperative Care; Surgery, Preoperative Care; Surgery, Postoperative Care

List of Nursing Diagnosis by Letter: I

IBS (Irritable Bowel Syndrome)	ICD (Implantable Cardioverter/Defibrillator)	IDDM (Insulin-Dependent Diabetes)
Identity Disturbance/Problems	Idiopathic Thrombocytopenic Purpura (ITP)	Ileal Conduit
Ileostomy	Ileus	Immigration Transition, Risk for Complicated
Immobility	Immunization	Immunosuppression
Impaction of Stool	Impaired Sitting	Impaired Standing
Imperforate Anus	Impetigo	Implantable Cardioverter/Defibrillator (ICD)
Impotence	Impulsiveness	Inactivity
Incompetent Cervix	Incontinence of Stool	Incontinence of Urine
Indigestion	Induction of Labor	Infant Apnea
Infant Behavior	Infant Care	Infant Feeding Pattern, Ineffective
Infant of Diabetic Mother	Infant of Substance-Abusing Mother	Infantile Polyarteritis
Infection, Potential for	Infectious Processes	Infertility
Inflammatory Bowel Disease (Child and Adult)	Influenza	Inguinal Hernia Repair
Injury	Insomnia	Insulin Shock
Intellectual Disability	Intermittent Claudication	Internal Cardioverter/Defibrillator (ICD)
Internal Fixation	Interstitial Cystitis	Intervertebral Disk Excision
Intestinal Obstruction	Intestinal Perforation	Intoxication
Intraaortic Balloon Counterpulsation	Intracranial Pressure, Increased	Intrauterine Growth Retardation
Intravenous Therapy	Intubation, Endotracheal or Nasogastric	Iodine Reaction with Diagnostic Testing
Irregular Pulse	Irritable Bowel Syndrome (IBS)	Isolation
Itching	ITP (Idiopathic Thrombocytopenic Purpura)	

I

IBS (Irritable Bowel Syndrome)

Constipation r/t low-residue diet, stress
Diarrhea r/t increased motility of intestines associated with disease process, stress
Ineffective Health management r/t deficient knowledge, powerlessness
Chronic Pain r/t spasms, increased motility of bowel
Risk for Electrolyte imbalance: Risk factor: diarrhea
Readiness for enhanced Health management: expresses desire to manage illness and prevent onset of symptoms

ICD (Implantable Cardioverter/Defibrillator)

Anxiety r/t possible dysrhythmia, threat of death
Decreased Cardiac output r/t possible dysrhythmia
Readiness for enhanced Knowledge: expresses an interest in learning

IDDM (Insulin-Dependent Diabetes)

See Diabetes Mellitus

Identity Disturbance/Problems

Disturbed personal Identity r/t situational crisis, psychological impairment, chronic illness, pain
Risk for disturbed personal Identity (See **Identity**, personal, risk for disturbed in Section III)

Idiopathic Thrombocytopenic Purpura (ITP)

See ITP (Idiopathic Thrombocytopenic Purpura)

Ileal Conduit

Disturbed Body Image r/t presence of stoma
Ineffective Health management r/t new skills required to care for appliance and self
Ineffective Sexuality pattern r/t altered body function and structure
Social isolation r/t alteration in physical appearance, fear of accidental spill of urine
Risk for Latex Allergic reaction: Risk factor: repeated exposures to latex associated with treatment and management of disease
Risk for impaired Skin integrity: Risk factor: difficulty obtaining tight seal of appliance
Readiness for enhanced Knowledge: expresses an interest in learning

Ileostomy

Disturbed Body Image r/t presence of stoma

Diarrhea r/t dietary changes, alteration in intestinal motility
Deficient Knowledge r/t limited practice of stoma care, dietary modifications
Ineffective Sexuality pattern r/t altered body function and structure
Social isolation r/t alteration in physical appearance, fear of accidental spill of ostomy contents
Risk for impaired Skin integrity: Risk factors: difficulty obtaining tight seal of appliance, caustic drainage
Readiness for enhanced Knowledge: expresses an interest in learning

Ileus

Deficient Fluid volume r/t loss of fluids from vomiting, fluids trapped in bowel
Dysfunctional Gastrointestinal motility r/t effects of surgery, decreased perfusion of intestines, medication effect, immobility
Nausea r/t gastrointestinal irritation
Acute Pain r/t pressure, abdominal distention
Readiness for enhanced Knowledge: expresses an interest in learning

Immigration Transition, Risk for Complicated

Anxiety r/t changes in safety and security needs
Fear r/t unfamiliar environment, separation from support system, possible language barrier
Impaired Social interaction r/t possible communication or sociocultural barriers
Risk for Loneliness: Risk factor: separation from support system
Risk for Powerlessness: Risk factor: insufficient social support
Risk for Relocation stress syndrome: Risk factors: insufficient support system, social isolation, and potential communication barriers
Risk for Impaired Resilience: Risk factor: decreased ability to adapt to adverse or changing situations
Readiness for enhanced Coping: expresses desire to enhance social support
Readiness for enhanced Knowledge: expresses a desire to become familiar with resources within their environment

Immobility

Ineffective Breathing pattern r/t inability to deep breathe in supine position
Acute Confusion: elderly r/t sensory deprivation from immobility
Constipation r/t immobility
Risk for Frail Elderly syndrome: Risk factors: low physical activity, bed rest
Impaired physical Mobility r/t medically imposed bed rest
Ineffective peripheral Tissue Perfusion r/t interruption of venous flow
Powerlessness r/t forced immobility from health care environment
Impaired Walking r/t limited physical mobility, deconditioning of body
Risk for Disuse syndrome: Risk factor: immobilization
Risk for impaired Skin integrity: Risk factors: pressure over bony prominences, shearing forces when moved; pressure from devices
Risk for Impaired Tissue Integrity: Risk factors: mechanical factors from pressure over bony prominences, shearing forces when moved; pressure from devices
Risk for Overweight: Risk factor: energy expenditure less than energy intake
Risk for Venous Thromboembolism: Risk factor: lack of physical activity
Readiness for enhanced Knowledge: expresses an interest in learning

Immunization

See **Readiness for enhanced Health literacy**, Section III
See **Readiness for enhanced Health management**, Section III

Immunosuppression

Risk for Infection: Risk factors: immunosuppression; exposure to disease outbreak
Impaired Social interaction r/t therapeutic isolation

Impaction of Stool

Constipation r/t decreased fluid intake, less than adequate amounts of fiber and bulk-forming foods in diet, medication effect, or immobility

Impaired Sitting

Impaired physical Mobility r/t musculoskeletal, cognitive, or neuromuscular disorder

Impaired Standing

Activity intolerance r/t insufficient physiological or psychological energy
Powerlessness r/t loss of function

Imperforate Anus

Anxiety r/t ability to care for newborn
Deficient Knowledge r/t home care for newborn
Impaired Skin integrity r/t pruritus

Impetigo

Impaired Skin integrity r/t infectious disease
Readiness for enhanced Knowledge: expresses an interest in learning
See Communicable Diseases, Childhood (e.g., Measles, Mumps, Rubella, Chickenpox, Scabies, Lice)

Implantable Cardioverter/Defibrillator (ICD)

See ICD (Implantable Cardioverter/Defibrillator)

Impotence

Situational low Self-Esteem r/t physiological crisis, inability to practice usual sexual activity
Sexual dysfunction r/t altered body function
Readiness for enhanced Knowledge: treatment information for erectile dysfunction
See Erectile Dysfunction (ED)

Impulsiveness

Ineffective Impulse control r/t (See **Impulse** control, ineffective in Section III)

Inactivity

Activity intolerance r/t imbalance between oxygen supply and demand, sedentary lifestyle, weakness, immobility
Hopelessness r/t deteriorating physiological condition, long-term stress, social isolation
Impaired physical Mobility r/t intolerance to activity, decreased strength and endurance, depression, severe anxiety, musculoskeletal impairment, perceptual or cognitive impairment, neuromuscular

impairment, pain, discomfort
Risk for Constipation: Risk factor: insufficient physical activity

Incompetent Cervix

See Premature Dilation of the Cervix (Incompetent Cervix)

Incontinence of Stool

Disturbed Body Image r/t inability to control elimination of stool
Bowel Incontinence r/t decreased awareness of need to defecate, loss of sphincter control
Toileting Self-Care deficit r/t cognitive impairment, neuromuscular impairment, perceptual impairment, weakness
Situational low Self-Esteem r/t inability to control elimination of stool
Risk for impaired Skin integrity: Risk factor: presence of stool

Incontinence of Urine

Functional urinary Incontinence r/t altered environment; sensory, cognitive, or mobility deficits
Overflow urinary Incontinence r/t relaxation of pelvic muscles and changes in urinary structures
Reflex urinary Incontinence r/t neurological impairment
Stress urinary Incontinence (See **Incontinence**, urinary, stress, Section III)
Urge urinary Incontinence (See **Incontinence**, urinary, urge, Section III)
Toileting Self-Care deficit r/t cognitive impairment
Situational low Self-Esteem r/t inability to control passage of urine
Risk for impaired Skin integrity: Risk factor: presence of urine on perineal skin

Indigestion

Nausea r/t gastrointestinal irritation
Imbalanced Nutrition: less than body requirements r/t discomfort when eating

Induction of Labor

Anxiety r/t medical interventions, powerlessness
Decisional Conflict r/t perceived threat to idealized birth
Ineffective Coping r/t situational crisis of medical intervention in birthing process
Acute Pain r/t contractions
Situational low Self-Esteem r/t inability to carry out normal labor
Risk for Injury: **maternal and fetal:** Risk factors: hypertonic uterus, potential prematurity of newborn
Readiness for enhanced Family processes: family support during induction of labor

Infant Apnea

See Premature Infant (Child); Respiratory Conditions of the Neonate; Sudden Infant Death Syndrome (SIDS)

Infant Behavior

Disorganized Infant behavior r/t pain, oral/motor problems, feeding intolerance, environmental overstimulation, lack of containment or boundaries, prematurity, invasive or painful procedures
Risk for disorganized Infant behavior: Risk factors: pain, oral/motor problems, environmental overstimulation, lack of containment or boundaries
Readiness for enhanced organized Infant behavior: stable physiologic measures, use of some self-regulatory measures

Infant Care

Readiness for enhanced Childbearing process: a pattern of preparing for, maintaining, and strengthening care of newborn infant

Infant Feeding Pattern, Ineffective

Ineffective infant Feeding pattern r/t prematurity, neurological impairment or delay, oral hypersensitivity, prolonged nothing-by-mouth order

Infant of Diabetic Mother

Decreased Cardiac output r/t cardiomegaly
Deficient Fluid volume r/t increased urinary excretion and osmotic diuresis
Imbalanced Nutrition: **less than body requirements** r/t hypotonia, lethargy, poor sucking, postnatal metabolic changes from hyperglycemia to hypoglycemia and hyperinsulinism
Risk for delayed Development: Risk factor: prolonged and severe postnatal hypoglycemia
Risk for impaired Gas exchange: Risk factors: increased incidence of cardiomegaly, prematurity
Risk for unstable blood Glucose level: Risk factor: metabolic change from hyperglycemia to hypoglycemia and hyperinsulinism
Risk for disturbed Maternal–Fetal dyad: Risk factor: impaired glucose metabolism
See Premature Infant (Child); Respiratory Conditions of the Neonate

Infant of Substance-Abusing Mother

See Neonatal Abstinence Syndrome

Infantile Polyarteritis

See Kawasaki Disease

Infection, Potential for

Risk for Infection (See **Infection,** risk for, Section III)

Infectious Processes

Impaired Comfort r/t distressing symptoms
Diarrhea r/t gastrointestinal inflammation
Ineffective Health maintenance r/t knowledge deficit regarding transmission, symptoms, and treatment
Ineffective Health Management r/t lack of knowledge regarding preventative immunizations
Ineffective Protection r/t inadequate nutrition, abnormal blood profiles, drug therapies, treatments
Impaired Social interaction r/t therapeutic isolation
Risk for Electrolyte Imbalance: Risk factors: vomiting, diarrhea
Risk for deficient Fluid Volume: Risk factors: vomiting, diarrhea, inadequate fluid intake
Risk for Infection: Risk factor: increased environmental exposure when in close proximity to infected persons
Risk for Surgical Site Infection r/t immunosuppression
Risk for ineffective Thermoregulation: Risk factor: infectious process
Readiness for enhanced Knowledge: expresses desire for information regarding prevention and treatment

Infertility

Ineffective Health management r/t deficient knowledge about infertility
Powerlessness r/t infertility
Chronic Sorrow r/t inability to conceive a child
Spiritual distress r/t inability to conceive a child

Inflammatory Bowel Disease (Child and Adult)

Ineffective Coping r/t repeated episodes of diarrhea
Diarrhea r/t effects of inflammatory changes of the bowel
Deficient Fluid volume r/t frequent and loose stools
Imbalanced Nutrition: less than body requirements r/t anorexia, decreased absorption of nutrients from gastrointestinal tract
Acute Pain r/t abdominal cramping and anal irritation
Impaired Skin integrity r/t frequent stools, development of anal fissures
Social isolation r/t diarrhea
See Child with Chronic Condition; Crohn's Disease; Hospitalized Child; Maturational Issues, Adolescent

Influenza

See Infectious Processes

Inguinal Hernia Repair

Impaired physical Mobility r/t pain at surgical site and fear of causing hernia to rupture
Acute Pain r/t surgical procedure
Urinary retention r/t possible edema at surgical site
Risk for Surgical Site Infection: Risk factor: surgical procedure

Injury

Risk for Falls: Risk factors: orthostatic hypotension, impaired physical mobility, diminished mental status
Risk for Injury: Risk factor: environmental conditions interacting with client's adaptive and defensive resources
Risk for corneal Injury: Risk factors: blinking less than five times per minute, mechanical ventilation, pharmaceutical agent, prolonged hospitalization
Risk for Thermal injury: Risk factors: cognitive impairment, inadequate supervision, developmental level
Risk for urinary tract Injury: Risk factor: inflammation and/or infection from long-term use of urinary catheter

Insomnia

(See **Insomnia**, Section III)

Insulin Shock

See Hypoglycemia

Intellectual Disability

Impaired verbal Communication r/t developmental delay
Interrupted Family processes r/t crisis of diagnosis and situational transition
Grieving r/t loss of perfect child, birth of child with congenital defect or subsequent head injury
Deficient community Health r/t lack of programs to address developmental deficiencies
Impaired Home maintenance r/t insufficient support systems
Self-Neglect r/t learning disability
Self-Care deficit: **bathing, dressing, feeding, toileting** r/t perceptual or cognitive impairment
Self-Mutilation r/t inability to express tension verbally
Social isolation r/t delay in accomplishing developmental tasks
Spiritual distress r/t chronic condition of child with special needs
Stress overload r/t intense, repeated stressor (chronic condition)
Impaired Swallowing r/t neuromuscular impairment
Risk for ineffective Activity planning r/t inability to process information
Risk for delayed Development: Risk factor: cognitive or perceptual impairment
Risk for impaired Religiosity: Risk factor: social isolation
Risk for Self-Mutilation: Risk factors: separation anxiety, depersonalization
Readiness for enhanced family Coping: adaptation and acceptance of child's condition and needs
See Child with Chronic Condition; Safety, Childhood

Intermittent Claudication

Deficient Knowledge r/t lack of knowledge of cause and treatment of peripheral vascular diseases
Acute Pain r/t decreased circulation to extremities with activity
Ineffective peripheral Tissue Perfusion r/t interruption of arterial flow
Risk for Injury: Risk factor: tissue hypoxia
Readiness for enhanced Knowledge: prevention of pain and impaired circulation
See Peripheral Vascular Disease (PVD)

Internal Cardioverter/Defibrillator (ICD)

See ICD (Implantable Cardioverter/Defibrillator)

Internal Fixation

Impaired Walking r/t repair of fracture
Risk for Infection: Risk factors: traumatized tissue, broken skin
See Fracture

Interstitial Cystitis

Acute Pain r/t inflammatory process
Impaired Urinary elimination r/t inflammation of bladder
Risk for Infection: Risk factor: suppressed inflammatory response
Readiness for enhanced Knowledge: expresses an interest in learning

Intervertebral Disk Excision

See Laminectomy

Intestinal Obstruction

See Ileus; Bowel Obstruction

Intestinal Perforation

See Peritonitis

Intoxication

Anxiety r/t loss of control of actions
Acute Confusion r/t alcohol abuse
Ineffective Coping r/t use of mind-altering substances as a means of coping
Impaired Memory r/t effects of alcohol on mind
Risk for Aspiration: Risk factors: diminished mental status, vomiting
Risk for Falls: Risk factor: diminished mental status
Risk for other-directed Violence: Risk factor: inability to control thoughts and actions

Intraaortic Balloon Counterpulsation

Anxiety r/t device providing cardiovascular assistance
Decreased Cardiac output r/t heart dysfunction needing counterpulsation
Compromised family Coping r/t seriousness of significant other's medical condition
Impaired physical Mobility r/t restriction of movement because of mechanical device
Risk for Peripheral Neurovascular dysfunction: Risk factors: vascular obstruction of balloon catheter, thrombus formation, emboli, edema
Risk for Infection: Risk factor: invasive procedure
Risk for impaired Tissue integrity: Risk factor: invasive procedure

Intracranial Pressure, Increased

Ineffective Breathing pattern r/t pressure damage to breathing center in brainstem
Acute Confusion r/t increased intracranial pressure
Decreased Intracranial adaptive capacity r/t sustained increase in intracranial pressure
Impaired Memory r/t neurological disturbance
Vision Loss r/t pressure damage to sensory centers in brain
Risk for ineffective Cerebral tissue perfusion: Risk factors: body position, cerebral vessel circulation deficits
See Head Injury; Subarachnoid Hemorrhage

Intrauterine Growth Retardation

Anxiety: **maternal** r/t threat to fetus
Ineffective Coping: **maternal** r/t situational crisis, threat to fetus
Impaired Gas exchange r/t insufficient placental perfusion
Imbalanced Nutrition: **less than body requirements** r/t insufficient placenta
Situational low Self-Esteem: **maternal** r/t guilt about threat to fetus
Spiritual distress r/t unknown outcome of fetus
Risk for Powerlessness: Risk factor: unknown outcome of fetus

Intravenous Therapy

Risk for Vascular Trauma: Risk factor: infusion of irritating chemicals

Intubation, Endotracheal or Nasogastric

Disturbed Body Image r/t altered appearance with mechanical devices
Impaired verbal Communication r/t endotracheal tube
Imbalanced Nutrition: **less than body requirements** r/t inability to ingest food because of the presence of tubes
Impaired Oral Mucous Membrane r/t presence of tubes

Acute Pain r/t presence of tube

Iodine Reaction with Diagnostic Testing

Risk for adverse reaction to iodinated Contrast Media (See Reaction to iodinated **Contrast Media**, risk for adverse, Section III)

Irregular Pulse

See Dysrhythmia

Irritable Bowel Syndrome (IBS)

See IBS (Irritable Bowel Syndrome)

Isolation

Impaired individual Resilience (See **Resilience**, individual, impaired, Section III)
Social isolation (See **Social** isolation, Section III)

Itching

See Pruritus

ITP (Idiopathic Thrombocytopenic Purpura)

Decreased Diversional activity engagement r/t activity restrictions, safety precautions
Ineffective Protection r/t decreased platelet count
Risk for Bleeding: Risk factors: decreased platelet count, developmental level, age-appropriate play
See Hospitalized Child

List of Nursing Diagnosis by Letter: J

Jaundice	Jaundice, Neonatal	Jaw Pain and Heart Attacks
Jaw Surgery	Jittery	Jock Itch
Joint Dislocation	Joint Pain	Joint Replacement
JRA (Juvenile Rheumatoid Arthritis)		

J

Jaundice

Imbalanced Nutrition: less than body requirements r/t decreased appetite with liver disorder
Risk for Bleeding: Risk factor: impaired liver function
Risk for impaired Liver function: Risk factors: possible viral infection, medication effect
Risk for impaired Skin integrity: Risk factors: pruritus, itching
See Cirrhosis; Hepatitis

Jaundice, Neonatal

See Hyperbilirubinemia, Neonatal

Jaw Pain and Heart Attacks

See Angina; Chest Pain; MI (Myocardial Infarction)

Jaw Surgery

Deficient Knowledge r/t emergency care for wired jaws (e.g., cutting bands and wires), oral care
Imbalanced Nutrition: less than body requirements r/t jaws wired closed, difficulty eating
Acute Pain r/t surgical procedure
Impaired Swallowing r/t edema from surgery
Risk for Aspiration: Risk factor: wired jaws

Jittery

Anxiety r/t unconscious conflict about essential values and goals, threat to or change in health status
Death Anxiety r/t unresolved issues relating to end of life
Risk for Post-Trauma syndrome: Risk factors: occupation, survivor's role in event, inadequate social support

Jock Itch

Ineffective Health management r/t prevention and treatment of disorder
Impaired Skin integrity r/t moisture and irritating or tight-fitting clothing
See Pruritus

Joint Dislocation

See Dislocation of Joint

Joint Pain

See Arthritis; Bursitis; JRA (Juvenile Rheumatoid Arthritis); Osteoarthritis; Rheumatoid Arthritis (RA)

Joint Replacement

Risk for Peripheral Neurovascular dysfunction: Risk factor: orthopedic surgery
Risk for impaired Tissue integrity: Risk factor: invasive procedure
See Total Joint Replacement (Total Hip/Total Knee/Shoulder)

JRA (Juvenile Rheumatoid Arthritis)

Impaired Comfort r/t altered health status
Fatigue r/t chronic inflammatory disease
Impaired physical Mobility r/t pain, restricted joint movement
Acute Pain r/t swollen or inflamed joints, restricted movement, physical therapy
Self-Care deficit: feeding, bathing, dressing, toileting r/t restricted joint movement, pain
Risk for compromised Human Dignity: Risk factors: perceived intrusion by clinicians, invasion of privacy
Risk for Injury: Risk factors: impaired physical mobility, splints, adaptive devices, increased bleeding potential from antiinflammatory medications
Risk for compromised Resilience: Risk factor: chronic condition
Risk for situational low Self-Esteem: Risk factor: disturbed body image
Risk for impaired Skin integrity: Risk factors: splints, adaptive devices
See Child with Chronic Condition; Hospitalized Child

List of Nursing Diagnosis by Letter: K

Kaposi's Sarcoma	Kawasaki Disease	Keloids
Keratoconjunctivitis Sicca (Dry Eye Syndrome)	Keratoplasty	Ketoacidosis, Alcoholic
Ketoacidosis, Diabetic	Keyhole Heart Surgery	Kidney Disease Screening
Kidney Failure	Kidney Failure Acute/Chronic, Child	Kidney Failure, Nonoliguric
Kidney Stone	Kidney Transplant	Kidney Transplantation, Donor
Kidney Transplantation, Recipient	Kidney Tumor	Kissing Disease
Knee Replacement	Knowledge	Knowledge, Deficient
Kock Pouch	Korsakoff's Syndrome	

K

Kaposi's Sarcoma

Risk for complicated Grieving: Risk factor: loss of social support
Risk for impaired Religiosity: Risk factors: illness/hospitalization, ineffective coping
Risk for impaired Resilience: Risk factor: serious illness
See AIDS (Acquired Immunodeficiency Syndrome)

Kawasaki Disease

Anxiety: **parental** r/t progression of disease, complications of arthritis, and cardiac involvement
Impaired Comfort r/t altered health status
Hyperthermia r/t inflammatory disease process
Imbalanced Nutrition: **less than body requirements** r/t impaired oral mucous membrane integrity
Impaired Oral Mucous Membrane integrity r/t inflamed mouth and pharynx; swollen lips that become dry, cracked, fissured
Acute Pain r/t enlarged lymph nodes; erythematous skin rash that progresses to desquamation, peeling, denuding of skin
Impaired Skin integrity r/t inflammatory skin changes
Risk for imbalanced Fluid volume: Risk factor: hypovolemia
Risk for decreased Cardiac tissue perfusion: Risk factor: cardiac involvement
Risk for Dry Mouth: Risk factor: decreased fluid intake
See Hospitalized Child

Keloids

Disturbed Body Image r/t presence of scar tissue at site of a healed skin injury
Readiness for enhanced Health management: desire to have information to manage condition

Keratoconjunctivitis Sicca (Dry Eye Syndrome)

Risk for dry Eye: Risk factors: aging, staring at a computer screen for long intervals
Risk for Infection: Risk factor: dry eyes that are more vulnerable to infection
Risk for corneal Injury: Risk factors: dry eye, exposure of the eyeball
See Conjunctivitis

Keratoplasty

See Corneal Transplant

Ketoacidosis, Alcoholic

See Alcohol Withdrawal; Alcoholism

Ketoacidosis, Diabetic

Deficient Fluid volume r/t excess excretion of urine, nausea, vomiting, increased respiration
Impaired Memory r/t fluid and electrolyte imbalance
Imbalanced Nutrition: l**ess than body requirements** r/t body's inability to use nutrients
Risk for unstable blood Glucose level: Risk factor: deficient knowledge of diabetes management (e.g., action plan)
Risk for Powerlessness: Risk factor: illness-related regimen
Risk for impaired Resilience: Risk factor: complications of disease
See Diabetes Mellitus

Keyhole Heart Surgery

See MIDCAB (Minimally Invasive Direct Coronary Artery Bypass)

Kidney Disease Screening

Readiness for enhanced Health management: seeks information for screening

Kidney Failure

See Renal Failure

Kidney Failure Acute/Chronic, Child

See Renal Failure, Acute/Chronic, Child

Kidney Failure, Nonoliguric

See Renal Failure, Nonoliguric

Kidney Stone

Acute Pain r/t obstruction from kidney calculi
Impaired Urinary elimination: **urgency and frequency** r/t anatomical obstruction, irritation caused by stone
Risk for Infection: Risk factor: obstruction of urinary tract with stasis of urine
Readiness for enhanced Knowledge: expresses an interest in learning about prevention of stones

Kidney Transplant

Ineffective Protection r/t immunosuppressive therapy
Readiness for enhanced Decision-Making: expresses desire to enhance understanding of choices
Readiness for enhanced Family processes: adapting to life without dialysis
Readiness for enhanced Health management: desire to manage the treatment and prevention of complications after transplantation
Readiness for enhanced Spiritual well-being: heightened coping, living without dialysis
See Renal Failure, Kidney Transplantation, Donor; Kidney Transplantation, Recipient; Nephrectomy; Surgery, Perioperative Care; Surgery, Postoperative Care; Surgery, Preoperative Care

Kidney Transplantation, Donor

Impaired emancipated Decision-Making r/t harvesting of kidney from traumatized donor
Moral Distress r/t conflict among decision makers, end-of-life decisions, time constraints for decision-making
Spiritual distress r/t grieving from loss of significant person
Risk for Surgical Site Infection: Risk factor: surgical procedure
Readiness for enhanced Communication: expressing thoughts and feelings about situation
Readiness for enhanced family Coping: decision to allow organ donation
Readiness for enhanced emancipated Decision-Making: expresses desire to enhance understanding and meaning of choices
Readiness for enhanced Resilience: decision to donate organs
Readiness for enhanced Spirituality: inner peace resulting from allowance of organ donation
See Nephrectomy

Kidney Transplantation, Recipient

Anxiety r/t possible rejection, procedure
Ineffective Health maintenance r/t long-term home treatment after transplantation, diet, signs of rejection, use of medications
Deficient Knowledge r/t specific nutritional needs, possible paralytic ileus, fluid or sodium restrictions
Impaired Urinary elimination r/t possible impaired renal function
Risk for Bleeding: Risk factor: surgical procedure
Risk for Infection: Risk factor: use of immunosuppressive therapy to control rejection
Risk for Surgical Site Infection: Risk factor: surgical procedure
Risk for Shock: Risk factor: possible hypovolemia
Risk for Spiritual distress: Risk factor: obtaining transplanted kidney from someone's traumatic loss
Readiness for enhanced Spiritual well-being: acceptance of situation

Kidney Tumor

See Wilms' Tumor

Kissing Disease

See Mononucleosis

Knee Replacement

See Total Joint Replacement (Total Hip/Total Knee/Shoulder)

Knowledge

Readiness for enhanced Knowledge (See **Knowledge,** readiness for enhanced, Section III)

Knowledge, Deficient

Ineffective Health maintenance r/t lack of or significant alteration in communication skills (written, verbal, and/or gestural)
Deficient Knowledge (See **Knowledge,** deficient, Section III)
Readiness for enhanced Knowledge (See **Knowledge,** readiness for enhanced, Section III)

Kock Pouch

See Continent Ileostomy (Kock Pouch)

Korsakoff's Syndrome

Acute Confusion r/t alcohol abuse
Dysfunctional Family processes r/t alcoholism as possible cause of syndrome
Impaired Memory r/t neurological changes associated with excessive alcohol intake
Self-Neglect r/t cognitive impairment from chronic alcohol abuse
Risk for Falls: Risk factor: cognitive impairment from chronic alcohol abuse
Risk for Injury: Risk factors: sensory dysfunction, lack of coordination when ambulating from chronic alcohol abuse
Risk for impaired Liver function: Risk factor: substance abuse (alcohol)
Risk for imbalanced Nutrition: **less than body requirements:** Risk factor: lack of adequate balanced intake from chronic alcohol abuse

List of Nursing Diagnosis by Letter: L

Labor, Induction of	Labor, Normal	Labor Pain
Labyrinthitis	Lacerations	Lactation
Lactic Acidosis	Lactose Intolerance	Laminectomy
Language Impairment	Laparoscopic Laser Cholecystectomy	Laparoscopy
Laparotomy	Large Bowel Resection	Laryngectomy
Laser Surgery	LASIK Eye Surgery (Laser-Assisted in Situ Keratomileusis)	Latex Allergic Reaction
Laxative Abuse	Lead Poisoning	Left Heart Catheterization
Legionnaires' Disease	Lens Implant	Lethargy/Listlessness
Leukemia	Leukopenia	Level of Consciousness, Decreased
Lice	Lifestyle, Sedentary	Lightheadedness
Limb Reattachment Procedures	Liposuction	Lithotripsy
Liver Biopsy	Liver Cancer	Liver Disease
Liver Function	Liver Transplant	Living Will
Lobectomy	Loneliness	Loose Stools (Bowel Movements)
Loss of Bladder Control	Loss of Bowel Control	Lou Gehrig's Disease
Low Back Pain	Low Blood Glucose	Low Blood Pressure
Lower GI Bleeding	Lumbar Puncture	Lumpectomy
Lung Cancer	Lung Surgery	Lupus Erythematosus
Lyme Disease	Lymphedema	Lymphoma

L

Labor, Induction of

See Induction of Labor

Labor, Normal

Anxiety r/t fear of the unknown, situational crisis
Impaired Comfort r/t labor
Fatigue r/t childbirth
Deficient Knowledge r/t lack of preparation for labor
Labor Pain r/t uterine contractions, stretching of cervix and birth canal
Impaired Tissue integrity r/t passage of infant through birth canal, episiotomy
Risk for ineffective Childbearing process (See **Childbearing** process, Section III)
Risk for Falls: Risk factors: excessive loss or shift in intravascular fluid volume, orthostatic hypotension
Risk for deficient Fluid volume: Risk factor: excessive loss of blood
Risk for Infection: Risk factors: multiple vaginal examinations, tissue trauma, prolonged rupture of membranes
Risk for Injury: **fetal:** Risk factor: hypoxia
Risk for Post-Trauma syndrome: Risk factors: trauma or violence associated with labor pains, medical or surgical interventions, history of sexual abuse
Readiness for enhanced Childbearing process: responds appropriately, is proactive, bonds with infant, uses support systems
Readiness for enhanced family Coping: significant other provides support during labor
Readiness for enhanced Health management: prenatal care and childbirth education birth process
Readiness for enhanced Power: expresses readiness to enhance participation in choices regarding treatment during labor

Labor Pain

Labor Pain r/t uterine contractions, stretching of cervix and birth canal

Labyrinthitis

Ineffective Health management r/t delay in seeking treatment for respiratory and ear infections
Risk for Injury r/t dizziness
Readiness for enhanced Health management: management of episodes
See Ménière's Disease

Lacerations

Readiness for enhanced Health management: appropriate care of injury
Risk for Infection: Risk factor: broken skin
Risk for Physical Trauma: Risk factor: children playing with dangerous objects

Lactation

See Breastfeeding, Ineffective; Breastfeeding, Interrupted

Lactic Acidosis

Decreased Cardiac output r/t altered heart rate/rhythm, preload, and contractility
Risk for Electrolyte imbalance: Risk factor: impaired regulatory mechanism
Risk for decreased Cardiac tissue perfusion: Risk factor: hypoxia
See Ketoacidosis, Diabetic

Lactose Intolerance

Readiness for enhanced Knowledge: interest in identifying lactose intolerance, treatment, and substitutes for milk products
See Abdominal Distention; Diarrhea

Laminectomy

Anxiety r/t change in health status, surgical procedure
Impaired Comfort r/t surgical procedure
Deficient Knowledge r/t appropriate postoperative and postdischarge activities
Impaired physical Mobility r/t neuromuscular impairment
Acute Pain r/t localized inflammation and edema
Urinary retention r/t competing sensory impulses, effects of opioids or anesthesia
Risk for Bleeding: Risk factor: surgery
Risk for Surgical Site Infection: Risk factor: invasive procedure, surgery
Risk for Perioperative Positioning injury: Risk factor: prone position
See Surgery, Perioperative Care; Surgery, Postoperative Care; Surgery, Preoperative Care

Language Impairment

See Speech Disorders

Laparoscopic Laser Cholecystectomy

See Cholecystectomy; Laser Surgery

Laparoscopy

Urge urinary Incontinence r/t pressure on the bladder from gas
Acute Pain: shoulder r/t gas irritating the diaphragm

Laparotomy

See Abdominal Surgery

Large Bowel Resection

See Abdominal Surgery

Laryngectomy

Ineffective Airway clearance r/t surgical removal of glottis, decreased humidification
Death Anxiety r/t unknown results of surgery
Disturbed Body Image r/t change in body structure and function
Impaired Comfort r/t surgery
Impaired verbal Communication r/t removal of larynx
Interrupted Family processes r/t surgery, serious condition of family member, difficulty communicating
Grieving r/t loss of voice, fear of death
Ineffective Health management r/t deficient knowledge regarding self-care with laryngectomy
Imbalanced Nutrition: **less than body requirements** r/t absence of oral feeding, difficulty swallowing, increased need for fluids
Impaired Oral Mucous Membrane r/t absence of oral feeding
Chronic Sorrow r/t change in body image
Impaired Swallowing r/t edema, laryngectomy tube
Risk for Electrolyte imbalance: Risk factor: fluid imbalance
Risk for complicated Grieving: Risk factors: loss, major life event
Risk for compromised Human Dignity: Risk factor: inability to communicate
Risk for Surgical Site Infection: Risk factors: invasive procedure, surgery
Risk for Powerlessness: Risk factors: chronic illness, change in communication
Risk for impaired Resilience: Risk factor: change in health status
Risk for situational low Self-Esteem: Risk factor: disturbed body image

Laser Surgery

Impaired Comfort r/t surgery
Constipation r/t laser intervention in vulval and perianal areas
Deficient Knowledge r/t preoperative and postoperative care associated with laser procedure
Acute Pain r/t heat from laser
Risk for Bleeding: Risk factor: surgery
Risk for Infection: Risk factor: delayed heating reaction of tissue exposed to laser
Risk for Injury: Risk factor: accidental exposure to laser beam

LASIK Eye Surgery (Laser-Assisted in Situ Keratomileusis)

Impaired Comfort r/t surgery
Decisional Conflict r/t decision to have surgery
Risk for Infection: Risk factor: invasive procedure/surgery
Readiness for enhanced Health management: surgical procedure preoperative and postoperative teaching and expectations

Latex Allergic Reaction

Latex Allergic reaction (See **Latex Allergic** reaction, Section III)
Risk for Latex Allergic reaction (See **Latex Allergic** reaction, risk for, Section III)
Readiness for enhanced Knowledge: prevention and treatment of exposure to latex products

Laxative Abuse

Perceived Constipation r/t health belief, faulty appraisal, impaired thought processes

Lead Poisoning

Contamination r/t flaking, peeling paint in presence of young children
Impaired Home maintenance r/t presence of lead paint
Risk for delayed Development: Risk factor: lead poisoning

Left Heart Catheterization

See Cardiac Catheterization

Legionnaires' Disease

Contamination r/t contaminated water in air-conditioning systems
See Pneumonia

Lens Implant

See Cataract Extraction; Vision Impairment

Lethargy/Listlessness

Frail Elderly syndrome r/t alteration in cognitive function
Fatigue r/t decreased metabolic energy production
Insomnia r/t internal or external stressors
Risk for ineffective Cerebral tissue perfusion: Risk factor: carbon dioxide retention and/or lack of oxygen supply to brain

Leukemia

Ineffective Protection r/t abnormal blood profile
Fatigue r/t abnormal blood profile and/or side effects of chemotherapy treatment
Risk for imbalanced Fluid volume: Risk factors: nausea, vomiting, bleeding, side effects of treatment
Risk for Infection: Risk factor: ineffective immune system
Risk for impaired Resilience: Risk factor: serious illness
See Cancer; Chemotherapy

Leukopenia

Ineffective Protection r/t leukopenia
Risk for Infection: Risk factor: low white blood cell count

Level of Consciousness, Decreased

See Confusion, Acute; Confusion, Chronic

Lice

Impaired Comfort r/t inflammation, pruritus
Readiness for enhanced Health management: preventing and treating infestation
Impaired Home maintenance r/t close unsanitary, overcrowded conditions
Self-Neglect r/t lifestyle
See Communicable Diseases, Childhood (e.g., Measles, Mumps, Rubella, Chickenpox, Scabies, Lice)

Lifestyle, Sedentary

Sedentary lifestyle (See **Sedentary** lifestyle, Section III)
Risk for ineffective peripheral Tissue Perfusion: Risk factor: lack of movement

Lightheadedness

See Dizziness; Vertigo

Limb Reattachment Procedures

Anxiety r/t unknown outcome of reattachment procedure, use and appearance of limb
Disturbed Body Image r/t unpredictability of function and appearance of reattached body part
Grieving r/t unknown outcome of reattachment procedure
Spiritual distress r/t anxiety about condition
Stress overload r/t multiple coexisting stressors, physical demands
Risk for Bleeding: Risk factor: severed vessels
Risk for Perioperative Positioning injury: Risk factor: immobilization
Risk for Peripheral Neurovascular dysfunction: Risk factors: trauma, orthopedic and neurovascular surgery, compression of nerves and blood vessels
Risk for Powerlessness: Risk factor: unknown outcome of procedure
Risk for impaired Religiosity: Risk factors: suffering, hospitalization
See Surgery, Postoperative Care

Liposuction

Disturbed Body Image r/t dissatisfaction with unwanted fat deposits in body
Risk for impaired Resilience: Risk factor: body image disturbance
Readiness for enhanced Decision-Making: expresses desire to make decision regarding liposuction
Readiness for enhanced Self-Concept: satisfaction with new body image
See Surgery, Perioperative Care; Surgery, Postoperative Care; Surgery, Preoperative Care

Lithotripsy

Readiness for enhanced Health management: expresses desire for information related to procedure and aftercare and prevention of stones
See Kidney Stone

Liver Biopsy

Anxiety r/t procedure and results
Risk for deficient Fluid volume: Risk factor: hemorrhage from biopsy site
Risk for Infection: Risk factor: invasive procedure
Risk for Powerlessness: Risk factor: inability to control outcome of procedure

Liver Cancer

Risk for Bleeding: Risk factor: liver dysfunction
Risk for Falls: Risk factor: confusion associated with liver dysfunction
Risk for impaired Liver function: Risk factor: disease process
Risk for impaired Resilience: Risk factor: serious illness
See Cancer; Chemotherapy; Radiation Therapy

Liver Disease

See Cirrhosis; Hepatitis

Liver Function

Risk for impaired Liver function (See **Liver** function, impaired, risk for, Section III)

Liver Transplant

Impaired Comfort r/t surgical pain
Decisional Conflict r/t acceptance of donor liver
Ineffective Protection r/t immunosuppressive therapy
Risk for impaired Liver function: Risk factors: possible rejection, infection
Readiness for enhanced Family processes: change in physical needs of family member
Readiness for enhanced Health management: desire to manage the treatment and prevention of complications after transplantation
Readiness for enhanced Spiritual well-being: heightened coping
See Surgery, Perioperative Care; Surgery, Postoperative Care; Surgery, Preoperative Care

Living Will

Moral Distress r/t end-of-life decisions
Readiness for enhanced Decision-Making: expresses desire to enhance understanding of choices for decision-making
Readiness for enhanced Relationship: shares information with others
Readiness for enhanced Religiosity: request to meet with religious leaders or facilitators
Readiness for enhanced Resilience: uses effective communication
Readiness for enhanced Spiritual well-being: acceptance of and preparation for end of life
See Advance Directives

Lobectomy

See Thoracotomy

Loneliness

Spiritual distress r/t loneliness, social alienation
Risk for Loneliness (See **Loneliness,** risk for, Section III)
Risk for impaired Religiosity: Risk factor: lack of social interaction
Readiness for enhanced Hope: expresses desire to enhance interconnectedness with others
Readiness for enhanced Relationship: expresses satisfaction with complementary relationship between partners

Loose Stools (Bowel Movements)

Diarrhea r/t increased gastric motility
Risk for dysfunctional Gastrointestinal motility (See **Gastrointestinal** motility, dysfunctional, risk for, Section III)
See Diarrhea

Loss of Bladder Control

See Incontinence of Urine

Loss of Bowel Control

See Incontinence of Stool

Lou Gehrig's Disease

See Amyotrophic Lateral Sclerosis (ALS)

Low Back Pain

Impaired Comfort r/t back pain
Ineffective Health maintenance r/t deficient knowledge regarding self-care with back pain
Impaired physical Mobility r/t back pain
Chronic Pain r/t degenerative processes, musculotendinous strain, injury, inflammation, congenital deformities
Urinary Retention r/t possible spinal cord compression
Risk for Powerlessness: Risk factor: living with chronic pain
Readiness for enhanced Health management: expresses desire for information to manage pain

Low Blood Glucose

See Hypoglycemia

Low Blood Pressure

See Hypotension

Lower GI Bleeding

See GI Bleed (Gastrointestinal Bleeding)

Lumbar Puncture

Anxiety r/t invasive procedure and unknown results
Deficient Knowledge r/t information about procedure
Acute Pain r/t possible loss of cerebrospinal fluid
Risk for ineffective Cerebral tissue perfusion: Risk factor: treatment-related side effects
Risk for Infection: Risk factor: invasive procedure

Lumpectomy

Decisional Conflict r/t treatment choices
Readiness for enhanced Knowledge: preoperative and postoperative care
Readiness for enhanced Spiritual well-being: hope of benign diagnosis
See Cancer

Lung Cancer

See Cancer; Chemotherapy; Radiation Therapy; Thoracotomy

Lung Surgery

See Thoracotomy

Lupus Erythematosus

Disturbed Body Image r/t change in skin, rash, lesions, ulcers, mottled erythema
Fatigue r/t increased metabolic requirements
Ineffective Health maintenance r/t deficient knowledge regarding medication, diet, activity
Acute Pain r/t inflammatory process
Powerlessness r/t unpredictability of course of disease
Impaired Religiosity r/t ineffective coping with disease
Chronic Sorrow r/t presence of chronic illness
Spiritual distress r/t chronicity of disease, unknown etiology
Risk for decreased Cardiac tissue perfusion: Risk factor: altered circulation
Risk for impaired Resilience: Risk factor: chronic disease
Risk for impaired Skin integrity: Risk factors: chronic inflammation, edema, altered circulation

Lyme Disease

Impaired Comfort r/t inflammation
Fatigue r/t increased energy requirements
Deficient Knowledge r/t lack of information concerning disease, prevention, treatment
Acute Pain r/t inflammation of joints, urticaria, rash
Risk for decreased Cardiac output: Risk factor: dysrhythmia
Risk for Powerlessness: Risk factor: possible chronic condition

Lymphedema

Disturbed Body Image r/t change in appearance of body part with edema
Excess Fluid volume r/t compromised regulatory system; inflammation, obstruction, or removal of lymph glands
Deficient Knowledge r/t management of condition
Risk for Infection: Risk factors: abnormal lymphatic system allowing stasis of fluids with decreased resistance to infection
Risk for situational low Self-Esteem: Risk factor: disturbed body image

Lymphoma

See Cancer

List of Nursing Diagnosis by Letter: M

Macular Degeneration	Magnetic Resonance Imaging (MRI)	Major Depressive Disorder
Malabsorption Syndrome	Maladaptive Behavior	Malaise
Malaria	Male Infertility	Malignancy
Malignant Hypertension (Arteriolar Nephrosclerosis)	Malignant Hyperthermia	Malnutrition
Mammography	Manic Disorder, Bipolar I	Manipulative Behavior
Marfan Syndrome	Mastectomy	Mastitis
Maternal Infection	Maturational Issues, Adolescent	Maze III Procedure
MD (Muscular Dystrophy)	Measles (Rubeola)	Meconium Aspiration
Meconium Delayed	Medical Marijuana	Melanoma
Melena	Memory Deficit	Ménière's Disease
Meningitis/Encephalitis	Meningocele	Menopause
Menorrhagia	Mental Illness	Metabolic Acidosis
Metabolic Alkalosis	Metabolic Imbalance Syndrome	Metastasis
Methicillin-Resistant *Staphylococcus aureus* (MRSA)	MI (Myocardial Infarction)	MIDCAB (Minimally Invasive Direct Coronary Artery Bypass)
Midlife Crisis	Migraine Headache	Military Families, Personnel
Milk Intolerance	Minimally Invasive Direct Coronary Bypass (MIDCAB)	Miscarriage
Mitral Stenosis	Mitral Valve Prolapse	Mobility, Impaired Bed
Mobility, Impaired Physical	Mobility, Impaired Wheelchair	Modified Radical Mastectomy
Mononucleosis	Mood Disorders	Moon Face
Moral/Ethical Dilemmas	Morning Sickness	Motion Sickness
Mottling of Peripheral Skin	Mourning	Mouth Lesions
MRI (Magnetic Resonance Imaging)	MRSA (Methicillin-Resistant *Staphylococcus aureus*)	MS (Multiple Sclerosis)
Mucocutaneous Lymph Node Syndrome	Mucous Membrane Integrity, Impaired Oral	Multi-Infarct Dementia
Multiple Gestations	Multiple Personality Disorder (Dissociative Identity Disorder)	Multiple Sclerosis (MS)
Mumps	Murmurs	Muscular Atrophy/Weakness
Muscular Dystrophy (MD)	MVC (Motor Vehicle Crash)	Myasthenia Gravis
Mycoplasma Pneumonia	Myelocele	Myelomeningocele
Myocardial Infarction (MI)	Myocarditis	Myringotomy
Myxedema		

M

Macular Degeneration

Ineffective Coping r/t visual loss
Compromised family Coping r/t deteriorating vision of family member
Risk-prone Health behavior r/t deteriorating vision while trying to maintain usual lifestyle
Hopelessness r/t deteriorating vision
Sedentary lifestyle r/t visual loss
Self-Neglect r/t change in vision
Social isolation r/t inability to drive because of visual changes
Risk for Falls: Risk factor: visual difficulties
Risk for Injury: Risk factor: inability to distinguish traffic lights and safety signs
Risk for Powerlessness: Risk factor: deteriorating vision
Risk for impaired Religiosity: Risk factor: possible lack of transportation to church
Risk for impaired Resilience: Risk factor: changing vision
Readiness for enhanced Health management: appropriate choices of daily activities for meeting the goals of a treatment program

Magnetic Resonance Imaging (MRI)

See MRI (Magnetic Resonance Imaging)

Major Depressive Disorder

See Depression (Major Depressive Disorder)

Malabsorption Syndrome

Diarrhea r/t lactose intolerance, gluten sensitivity, resection of small bowel
Dysfunctional Gastrointestinal motility r/t disease state
Deficient Knowledge r/t lack of information about diet and nutrition
Imbalanced Nutrition: less than body requirements r/t inability of body to absorb nutrients because of physiological factors
Risk for Electrolyte imbalance: Risk factors: hypovolemia, hyponatremia, hypokalemia
Risk for imbalanced Fluid volume: Risk factors: diarrhea, hypovolemia
See Abdominal Distention

Maladaptive Behavior

See Crisis; Post-Trauma Syndrome; Suicide Attempt

Malaise

See Fatigue

Malaria

Contamination r/t geographic area
Risk for Contamination: Risk factors: increased environmental exposure (not wearing protective clothing, not using insecticide or repellant on skin, clothing, and in room in areas in which infected mosquitoes are present); inadequate defense mechanisms (inappropriate use of prophylactic regimen)
Risk for impaired Liver function: Risk factor: complications of disease
Readiness for enhanced community Coping: uses resources available for problem-solving
Readiness for enhanced Health management: expresses desire to enhance immunization status/vaccination status
Readiness for enhanced Resilience: immunization status
See Anemia

Male Infertility

See Erectile Dysfunction (ED); Infertility

Malignancy

See Cancer

Malignant Hypertension (Arteriolar Nephrosclerosis)

Decreased Cardiac output r/t altered afterload, altered contractility
Fatigue r/t disease state, increased blood pressure
Excess Fluid volume r/t decreased kidney function
Risk for ineffective Cerebral tissue perfusion: Risk factor: elevated blood pressure damaging cerebral vessels
Risk for acute Confusion: Risk factors: increased blood urea nitrogen or creatinine levels
Risk for imbalanced Fluid volume: Risk factors: hypertension, altered kidney function
Risk for unstable Blood Pressure: Risk factor: damaged vessels due to disease process
Readiness for enhanced Health management: expresses desire to manage the illness, high blood pressure

Malignant Hyperthermia

Hyperthermia r/t anesthesia reaction associated with inherited condition
Readiness for enhanced Health management: knowledge of risk factors

Malnutrition

Insufficient Breast Milk Production r/t (See **Breast Milk,** insufficient production, Section III)
Frail Elderly syndrome r/t undetected malnutrition
Deficient Knowledge r/t misinformation about normal nutrition, social isolation, lack of food preparation facilities
Imbalanced Nutrition: less than body requirements r/t inability to ingest food, digest food, or absorb nutrients because of biological, psychological, or economic factors; institutionalization (i.e., lack of menu choices)
Ineffective Protection r/t inadequate nutrition
Ineffective Health management r/t inadequate nutrition
Self-Neglect r/t inadequate nutrition
Risk for Powerlessness: Risk factor: possible inability to provide adequate nutrition

Mammography

Readiness for enhanced Health management: follows guidelines for screening
Readiness for enhanced Resilience: responsibility for self-care

Manic Disorder, Bipolar I

Anxiety r/t change in role function
Ineffective Coping r/t situational crisis
Ineffective Denial r/t fear of inability to control behavior
Interrupted Family processes r/t family member's illness
Risk-prone Health behavior r/t low self-efficacy
Ineffective Health management r/t unpredictability of client, excessive demands on family, chronic illness, social support deficit
Impaired Home maintenance r/t altered psychological state, inability to concentrate
Disturbed personal Identity r/t manic state
Insomnia r/t constant anxious thoughts
Imbalanced Nutrition: less than body requirements r/t lack of time and motivation to eat, constant movement
Impaired individual Resilience r/t psychological disorder
Ineffective Role performance r/t impaired social interactions
Self-Neglect r/t manic state
Sleep deprivation r/t hyperagitated state
Risk for ineffective Activity planning r/t inability to process information
Risk for Caregiver Role Strain: Risk factor: unpredictability of condition
Risk for imbalanced Fluid volume: Risk factor: hypovolemia
Risk for Powerlessness: Risk factor: inability to control changes in mood
Risk for Spiritual distress: Risk factor: depression
Risk for Suicide: Risk factor: bipolar disorder
Risk for self-directed Violence: Risk factors: hallucinations, delusions
Risk for other-directed Violence: Risk factor: pathologic intoxication
Readiness for enhanced Hope: expresses desire to enhance problem-solving goals

Manipulative Behavior

Defensive Coping r/t superior attitude toward others
Ineffective Coping r/t inappropriate use of defense mechanisms
Self-Mutilation r/t use of manipulation to obtain nurturing relationship with others
Self-Neglect r/t maintaining control
Impaired Social interaction r/t self-concept disturbance
Risk for Loneliness: Risk factor: inability to interact appropriately with others
Risk for situational low Self-Esteem: Risk factor: history of learned helplessness
Risk for Self-Mutilation: Risk factor: inability to cope with increased psychological or physiological tension in healthy manner

Marfan Syndrome

Decreased Cardiac output r/t dilation of the aortic root, dissection or rupture of the aorta
Risk for decreased Cardiac tissue perfusion: Risk factor: heart-related complications from Marfan syndrome
Readiness for enhanced Health management: describes reduction of risk factors
See Mitral Valve Prolapse; Scoliosis

Mastectomy

Disturbed Body Image r/t loss of sexually significant body part
Impaired Comfort r/t altered body image; difficult diagnosis
Death Anxiety r/t threat of mortality associated with breast cancer
Fatigue r/t increased metabolic requirements
Fear r/t change in body image, prognosis

Deficient Knowledge r/t self-care activities
Nausea r/t chemotherapy
Acute Pain r/t surgical procedure
Sexual dysfunction r/t change in body image, fear of loss of femininity
Chronic Sorrow r/t disturbed body image, unknown long-term health status
Spiritual distress r/t change in body image
Risk for Surgical Site Infection: Risk factors: surgical procedure, broken skin
Risk for impaired physical Mobility: Risk factors: nerve or muscle damage, pain
Risk for Post-Trauma syndrome: Risk factors: loss of body part, surgical wounds
Risk for Powerlessness: Risk factor: fear of unknown outcome of procedure
Risk for impaired Resilience: Risk factor: altered body image
See Cancer; Modified Radical Mastectomy; Surgery, Perioperative Care; Surgery, Postoperative Care; Surgery, Preoperative Care

Mastitis

Anxiety r/t threat to self, concern over safety of milk for infant
Ineffective Breastfeeding r/t breast pain, conflicting advice from health care providers
Deficient Knowledge r/t antibiotic regimen, comfort measures
Acute Pain r/t infectious disease process, swelling of breast tissue
Ineffective Role performance r/t change in capacity to function in expected role

Maternal Infection

Ineffective Protection r/t invasive procedures, traumatized tissue
See Postpartum, Normal Care

Maturational Issues, Adolescent

Ineffective Coping r/t maturational crises
Risk-prone Health behavior r/t inadequate comprehension, negative attitude toward health care
Interrupted Family processes r/t developmental crises of adolescence resulting from challenge of parental authority and values, situational crises from change in parental marital status
Deficient Knowledge: potential for enhanced health maintenance r/t information misinterpretation, lack of education regarding age-related factors
Impaired Social interaction r/t ineffective, unsuccessful, or dysfunctional interaction with peers
Social isolation r/t perceived alteration in physical appearance, social values not accepted by dominant peer group
Risk for Ineffective Activity planning: Risk factor: unrealistic perception of personal competencies
Risk for disturbed personal Identity: Risk factor: maturational issues
Risk for Injury: Risk factor: thrill-seeking behaviors
Risk for chronic low Self-Esteem: Risk factor: lack of sense of belonging in peer group
Risk for situational low Self-Esteem: Risk factor: developmental changes
Readiness for enhanced Communication: expressing willingness to communicate with parental figures
Readiness for enhanced Relationship: expresses desire to enhance communication with parental figures
See Sexuality, Adolescent; Substance Abuse (if relevant)

Maze III Procedure

See Dysrhythmia; Open Heart Surgery

MD (Muscular Dystrophy)

See Muscular Dystrophy (MD)

Measles (Rubeola)

See Communicable Diseases, Childhood (e.g., Measles, Mumps, Rubella, Chickenpox, Scabies, Lice)

Meconium Aspiration

See Respiratory Conditions of the Neonate

Meconium Delayed

Risk for neonatal hyperbilirubinemia: Risk factor: delayed meconium

Medical Marijuana

Imbalanced Nutrition: less than body requirements r/t eating disorder, appetite loss, effects of chemotherapy
Chronic Pain Syndrome r/t persistence of pain as a result of physical injury or condition
Nausea r/t effects of chemotherapy

Melanoma

Disturbed Body Image r/t altered pigmentation, surgical incision
Fear r/t threat to well-being
Ineffective Health maintenance r/t deficient knowledge regarding self-care and treatment of melanoma
Acute Pain r/t surgical incision
Chronic Sorrow r/t disturbed body image, unknown long-term health status
Readiness for enhanced Health management: describes reduction of risk factors; protection from sunlight's ultraviolet rays
See Cancer

Melena

Fear r/t presence of blood in feces
Risk for imbalanced Fluid volume: Risk factor: hemorrhage
See GI Bleed (Gastrointestinal Bleeding)

Memory Deficit

Impaired Memory (See **Memory,** impaired, Section III)

Ménière's Disease

Risk for Injury: Risk factor: symptoms of disease
Readiness for enhanced Health management: expresses desire to manage illness
See Dizziness; Nausea; Vertigo

Meningitis/Encephalitis

Ineffective Airway clearance r/t seizure activity
Impaired Comfort r/t altered health status
Excess Fluid volume r/t increased intracranial pressure, syndrome of inappropriate secretion of antidiuretic hormone

Decreased Intracranial adaptive capacity r/t sustained increase in intracranial pressure
Impaired Mobility r/t neuromuscular or central nervous system insult
Acute Pain r/t biological injury
Risk for Aspiration: Risk factor: seizure activity
Risk for acute Confusion: Risk factor: infection of brain
Risk for Falls: Risk factors: neuromuscular dysfunction and confusion
Risk for Injury: Risk factor: seizure activity
Risk for impaired Resilience: Risk factor: illness
Risk for Shock: Risk factor: infectious process
Risk for ineffective Cerebral tissue perfusion: Risk factors: cerebral tissue edema and inflammation of meninges, increased intracranial pressure; infection
Risk for ineffective Thermoregulation: Risk factor: infectious process
See Hospitalized Child

Meningocele

See Neural Tube Defects

Menopause

Impaired Comfort r/t symptoms associated with menopause
Insomnia r/t hormonal shifts
Impaired Memory r/t change in hormonal levels
Sexual dysfunction r/t menopausal changes
Ineffective Sexuality pattern r/t altered body structure, lack of lubrication, lack of knowledge of artificial lubrication
Ineffective Thermoregulation r/t changes in hormonal levels
Risk for urge urinary Incontinence: Risk factor: changes in hormonal levels affecting bladder function
Risk for Overweight: Risk factor: change in metabolic rate caused by fluctuating hormone levels
Risk for Powerlessness: Risk factor: changes associated with menopause
Risk for impaired Resilience: Risk factor: menopause
Risk for situational low Self-Esteem: Risk factors: developmental changes, menopause
Readiness for enhanced Health management: verbalized desire to manage menopause
Readiness for enhanced Self-Care: expresses satisfaction with body image
Readiness for enhanced Spiritual well-being: desire for harmony of mind, body, and spirit

Menorrhagia

Fear r/t loss of large amounts of blood
Risk for deficient Fluid volume: Risk factor: excessive loss of menstrual blood

Mental Illness

Defensive Coping r/t psychological impairment, substance abuse
Ineffective Coping r/t situational crisis, coping with mental illness
Compromised family Coping r/t lack of available support from client
Disabled family Coping r/t chronically unexpressed feelings of guilt, anxiety, hostility, or despair
Ineffective Denial r/t refusal to acknowledge abuse problem, fear of the social stigma of disease
Risk-prone Health behavior r/t low self-efficacy
Disturbed personal Identity r/t psychoses
Ineffective Relationship r/t effects of mental illness in partner relationship
Chronic Sorrow r/t presence of mental illness
Stress overload r/t multiple coexisting stressors
Ineffective family Health management r/t chronicity of condition, unpredictability of client, unknown prognosis
Risk for Loneliness: Risk factor: social isolation
Risk for Powerlessness: Risk factor: lifestyle of helplessness
Risk for impaired Resilience: Risk factor: chronic illness

Risk for chronic low Self-Esteem: Risk factor: presence of mental illness/repeated negative reinforcement

Metabolic Acidosis

See Ketoacidosis, Alcoholic; Ketoacidosis, Diabetic

Metabolic Alkalosis

Deficient Fluid volume r/t fluid volume loss, vomiting, gastric suctioning, failure of regulatory mechanisms

Metabolic Imbalance Syndrome

Ineffective Health Maintenance r/t deficient knowledge regarding basic health practice
Obesity r/t energy expenditure below energy intake
Risk for unstable blood Glucose level: Risk factor: variations in serum glucose levels

Metastasis

See Cancer

Methicillin-Resistant *Staphylococcus aureus* (MRSA)

See MRSA (Methicillin-Resistant Staphylococcus aureus)

MI (Myocardial Infarction)

Activity intolerance r/t imbalance between oxygen supply and demand
Anxiety r/t threat of death, possible change in role status
Death Anxiety r/t seriousness of medical condition
Constipation r/t decreased peristalsis from decreased physical activity, medication effect, change in diet
Ineffective family Coping r/t spouse or significant other's fear of partner loss
Ineffective Denial r/t fear, deficient knowledge about heart disease
Interrupted Family processes r/t crisis, role change
Fear r/t threat to well-being
Ineffective Health maintenance r/t deficient knowledge regarding self-care and treatment
Acute Pain r/t myocardial tissue damage from inadequate blood supply
Situational low Self-Esteem r/t crisis of MI
Ineffective Sexuality pattern r/t fear of chest pain, possibility of heart damage
Risk for Powerlessness: Risk factor: acute illness
Risk for Shock: Risk factors: hypotension, myocardial dysfunction, hypoxia
Risk for Spiritual distress: Risk factor: physical illness
Risk for decreased Cardiac output: Risk factors: alteration in heart rate, rhythm, and contractility
Risk for decreased Cardiac tissue perfusion: Risk factors: coronary artery spasm, hypertension, hypotension, hypoxia
Readiness for enhanced Knowledge: expresses an interest in learning about condition
See Angioplasty, Coronary; Coronary Artery Bypass Grafting (CABG)

MIDCAB (Minimally Invasive Direct Coronary Artery Bypass)

Risk for Bleeding: Risk factor: surgery
Readiness for enhanced Health management: preoperative and postoperative care associated with surgery

Risk for Surgical Site Infection: Risk factor: surgical procedure
See Angioplasty, Coronary; Coronary Artery Bypass Grafting (CABG)

Midlife Crisis

Ineffective Coping r/t inability to deal with changes associated with aging
Powerlessness r/t lack of control over life situation
Spiritual distress r/t questioning beliefs or value system
Risk for disturbed personal Identity: Risk factor: alteration in social roles
Risk for chronic low Self-Esteem: Risk factor: ineffective coping with loss
Readiness for enhanced Relationship: meets goals for lifestyle change
Readiness for enhanced Spiritual well-being: desire to find purpose and meaning to life

Migraine Headache

Ineffective Health maintenance r/t deficient knowledge regarding prevention and treatment of headaches
Readiness for enhanced Health management: expresses desire to manage illness
Acute Pain: headache r/t vasodilation of cerebral and extracerebral vessels
Risk for impaired Resilience: Risk factors: chronic illness, disabling pain

Military Families, Personnel

Anxiety r/t apprehension and helplessness caused by uncertainty of family members' situation
Interrupted Family Processes r/t possible change in family roles, decrease in available emotional support
Relocation stress syndrome r/t unpredictability of experience, powerlessness, significant environmental change

Milk Intolerance

See Lactose Intolerance

Minimally Invasive Direct Coronary Bypass (MIDCAB)

See MIDCAB (Minimally Invasive Direct Coronary Artery Bypass)

Miscarriage

See Pregnancy Loss

Mitral Stenosis

Activity intolerance r/t imbalance between oxygen supply and demand
Anxiety r/t possible worsening of symptoms, activity intolerance, fatigue
Decreased Cardiac output r/t incompetent heart valves, abnormal forward or backward blood flow, flow into a dilated chamber, flow through an abnormal passage between chambers
Fatigue r/t reduced cardiac output
Ineffective Health maintenance r/t deficient knowledge regarding self-care with disorder
Risk for decreased Cardiac tissue perfusion: Risk factor: incompetent heart valve
Risk for Infection: Risk factors: invasive procedure, risk for endocarditis

Mitral Valve Prolapse

Anxiety r/t symptoms of condition: palpitations, chest pain
Fatigue r/t abnormal catecholamine regulation, decreased intravascular volume
Fear r/t lack of knowledge about mitral valve prolapse, feelings of having heart attack
Ineffective Health maintenance r/t deficient knowledge regarding methods to relieve pain and treat dysrhythmia and shortness of breath, need for prophylactic antibiotics before invasive procedures
Acute Pain r/t mitral valve regurgitation
Risk for ineffective Cerebral tissue perfusion: Risk factor: postural hypotension
Risk for Infection: Risk factor: invasive procedures
Risk for Powerlessness: Risk factor: unpredictability of onset of symptoms
Readiness for enhanced Knowledge: expresses interest in learning about condition

Mobility, Impaired Bed

Impaired bed Mobility (See **Mobility,** bed, impaired, Section III)

Mobility, Impaired Physical

Impaired physical Mobility (See **Mobility,** physical, impaired, Section III)
Risk for Falls: Risk factor: impaired physical mobility

Mobility, Impaired Wheelchair

Impaired wheelchair Mobility (See **Mobility,** wheelchair, impaired, Section III)

Modified Radical Mastectomy

Readiness for enhanced Communication: willingness to enhance communication
See Mastectomy

Mononucleosis

Activity intolerance r/t generalized weakness
Impaired Comfort r/t sore throat, muscle aches
Fatigue r/t disease state, stress
Ineffective Health maintenance r/t deficient knowledge concerning transmission and treatment of disease
Acute Pain r/t enlargement of lymph nodes, oropharyngeal edema
Impaired Swallowing r/t enlargement of lymph nodes, oropharyngeal edema
Risk for Injury: Risk factor: possible rupture of spleen
Risk for Loneliness: Risk factor: social isolation

Mood Disorders

Caregiver Role Strain r/t overwhelming needs of care receiver, unpredictability of mood alterations
Labile Emotional Control r/t (See Labile **Emotional Control**, Section III)
Risk-prone Health behavior r/t hopelessness, altered locus of control
Impaired Mood regulation r/t (See **Mood** regulation, impaired, Section III)
Self-Neglect r/t inability to care for self
Social isolation r/t alterations in mental status
Risk for situational low Self-Esteem: Risk factor: unpredictable changes in mood
Readiness for enhanced Communication: expresses feelings
See specific disorder: Depression (Major Depressive Disorder); Dysthymic Disorder; Hypomania; Manic Disorder, Bipolar I

Moon Face

Disturbed Body Image r/t change in appearance from disease and medication(s)
Risk for situational low Self-Esteem: Risk factor: change in body image
See Cushing's Syndrome

Moral/Ethical Dilemmas

Impaired emancipated Decision-Making r/t questioning personal values and belief, which alter decision
Moral Distress r/t conflicting information guiding moral or ethical decision-making
Risk for Powerlessness: Risk factor: lack of knowledge to make a decision
Risk for Spiritual distress: Risk factor: moral or ethical crisis
Readiness for enhanced emancipated Decision-Making: expresses desire to enhance congruency of decisions with personal values and goals
Readiness for enhanced Religiosity: requests assistance in expanding religious options
Readiness for enhanced Resilience: vulnerable state
Readiness for enhanced Spiritual well-being: request for interaction with others regarding difficult decisions

Morning Sickness

See Hyperemesis Gravidarum; Pregnancy, Normal

Motion Sickness

See Labyrinthitis

Mottling of Peripheral Skin

Ineffective peripheral Tissue Perfusion r/t interruption of arterial flow, decreased circulating blood volume
Risk for Shock: Risk factor: inadequate circulation to perfuse body

Mourning

See Grieving

Mouth Lesions

See Mucous Membrane Integrity, Impaired Oral

MRI (Magnetic Resonance Imaging)

Anxiety r/t fear of being in closed spaces
Readiness for enhanced Health management: describes reduction of risk factors associated with exam
Deficient Knowledge r/t unfamiliarity with information resources; exam information
Readiness for enhanced Knowledge: expresses interest in learning about exam

MRSA (Methicillin-Resistant *Staphylococcus aureus*)

Impaired Skin integrity r/t infection

Delayed Surgical recovery r/t infection
Ineffective Thermoregulation r/t severe infection stimulating immune system
Impaired Tissue integrity r/t wound, infection
Risk for Loneliness: Risk factor: physical isolation
Risk for impaired Resilience: Risk factor: illness
Risk for Shock: Risk factor: sepsis

MS (Multiple Sclerosis)

See Multiple Sclerosis

Mucocutaneous Lymph Node Syndrome

See Kawasaki Disease

Mucous Membrane Integrity, Impaired Oral

Impaired Oral Mucous Membrane integrity (See **Oral Mucous Membrane** integrity, impaired, Section III)

Multi-Infarct Dementia

See Dementia

Multiple Gestations

Anxiety r/t uncertain outcome of pregnancy
Death Anxiety r/t maternal complications associated with multiple gestations
Insufficient Breast Milk Production r/t multiple births
Ineffective Childbearing process r/t unavailable support system
Fatigue r/t physiological demands of a multifetal pregnancy and/or care of more than one infant
Impaired Home maintenance r/t fatigue
Stress urinary Incontinence r/t increased pelvic pressure
Insomnia r/t impairment of normal sleep pattern; parental responsibilities
Deficient Knowledge r/t caring for more than one infant
Neonatal Hyperbilirubinemia r/t feeding pattern not well established
Deficient Knowledge r/t caring for more than one infant
Imbalanced Nutrition: less than body requirements r/t physiological demands of a multifetal pregnancy
Stress overload r/t multiple coexisting stressors, family demands
Impaired Walking r/t increased uterine size
Risk for ineffective Breastfeeding: Risk factors: lack of support, physical demands of feeding more than one infant
Risk for delayed Development: fetus: Risk factor: multiple gestations
Risk for neonatal hyperbilirubinemia: Risk factors: abnormal weight loss, prematurity, feeding pattern not well-established
Readiness for enhanced Childbearing process: demonstrates appropriate care for infants and mother
Readiness for enhanced Family processes: family adapting to change with more than one infant

Multiple Personality Disorder (Dissociative Identity Disorder)

Anxiety r/t loss of control of behavior and feelings
Disturbed Body Image r/t psychosocial changes
Defensive Coping r/t unresolved past traumatic events, severe anxiety
Ineffective Coping r/t history of abuse

Hopelessness r/t long-term stress
Disturbed personal Identity r/t severe child abuse
Chronic low Self-Esteem r/t rejection, failure
Risk for Self-Mutilation: Risk factor: need to act out to relieve stress
Readiness for enhanced Communication: willingness to discuss problems associated with condition
See Dissociative Identity Disorder (Not Otherwise Specified)

Multiple Sclerosis (MS)

Ineffective Activity planning r/t unrealistic perception of personal competence
Ineffective Airway clearance r/t decreased energy or fatigue
Impaired physical Mobility r/t neuromuscular impairment
Self-Neglect r/t functional impairment
Powerlessness r/t progressive nature of disease
Self-Care deficit: specify r/t neuromuscular impairment
Sexual dysfunction r/t biopsychosocial alteration of sexuality
Chronic Sorrow r/t loss of physical ability
Spiritual distress r/t perceived hopelessness of diagnosis
Urinary Retention r/t inhibition of the reflex arc
Risk for Disuse syndrome: Risk factor: physical immobility
Risk for Injury: Risk factors: altered mobility, sensory dysfunction
Risk for imbalanced Nutrition: less than body requirements: Risk factors: impaired swallowing, depression
Risk for Powerlessness: Risk factor: chronic illness
Risk for impaired Religiosity: Risk factor: illness
Risk for Thermal Injury: Risk factor: neuromuscular impairment
Readiness for enhanced Health management: expresses a desire to manage condition
Readiness for enhanced Self-Care: expresses desire to enhance knowledge of strategies and responsibility for self-care
Readiness for enhanced Spiritual well-being: struggling with chronic debilitating condition
See Neurologic Disorders

Mumps

See Communicable Diseases, Childhood (e.g., Measles, Mumps, Rubella, Chickenpox, Scabies, Lice)

Murmurs

Decreased Cardiac output r/t altered preload/afterload
Risk for decreased Cardiac tissue perfusion: Risk factor: incompetent valve
Risk for Fatigue: Risk factor: decreased cardiac output

Muscular Atrophy/Weakness

Risk for Disuse syndrome: Risk factor: impaired physical mobility
Risk for Falls: Risk factor: impaired physical mobility

Muscular Dystrophy (MD)

Activity intolerance r/t fatigue, muscle weakness
Ineffective Activity planning r/t unrealistic perception of personal competence
Ineffective Airway clearance r/t muscle weakness and decreased ability to cough
Constipation r/t immobility
Fatigue r/t increased energy requirements to perform activities of daily living
Impaired physical Mobility r/t muscle weakness and development of contractures
Imbalanced Nutrition: less than body requirements r/t impaired swallowing or chewing
Self-Care deficit: feeding, bathing, dressing, toileting r/t muscle weakness and fatigue

Self-Neglect r/t functional impairment
Impaired Transfer ability r/t muscle weakness
Impaired Swallowing r/t neuromuscular impairment
Impaired Walking r/t muscle weakness
Risk for Aspiration: Risk factor: impaired swallowing
Risk for decreased Cardiac tissue perfusion: Risk factor: hypoxia associated with cardiomyopathy
Risk for Disuse syndrome: Risk factor: complications of immobility
Risk for Falls: Risk factor: muscle weakness
Risk for Infection: Risk factor: pooling of pulmonary secretions as a result of immobility and muscle weakness
Risk for Injury: Risk factors: muscle weakness and unsteady gait
Risk for Overweight: Risk factor: inactivity
Risk for Powerlessness: Risk factor: chronic condition
Risk for impaired Religiosity: Risk factor: illness
Risk for impaired Resilience: Risk factor: chronic illness
Risk for situational low Self-Esteem: Risk factor: presence of chronic condition
Readiness for enhanced Self-Concept: acceptance of strength and abilities
Risk for impaired Skin integrity: Risk factors: immobility, braces, or adaptive devices
See Child with Chronic Condition; Hospitalized Child

MVC (Motor Vehicle Crash)

See Fracture; Head Injury; Injury; Pneumothorax

Myasthenia Gravis

Ineffective Airway clearance r/t decreased ability to cough and swallow
Interrupted Family processes r/t crisis of dealing with diagnosis
Fatigue r/t paresthesia, aching muscles, weakness of muscles
Impaired physical Mobility r/t defective transmission of nerve impulses at the neuromuscular junction
Imbalanced Nutrition: less than body requirements r/t difficulty eating and swallowing
Impaired Swallowing r/t neuromuscular impairment
Risk for Caregiver Role Strain: Risk factors: severity of illness of client, overwhelming needs of client
Risk for impaired Religiosity: Risk factor: illness
Risk for impaired Resilience: Risk factor: new diagnosis of chronic, serious illness
Readiness for enhanced Spiritual well-being: heightened coping with serious illness
See Neurologic Disorders

Mycoplasma Pneumonia

See Pneumonia

Myelocele

See Neural Tube Defects

Myelomeningocele

See Neural Tube Defects

Myocardial Infarction (MI)

See MI (Myocardial Infarction)

Myocarditis

Activity intolerance r/t reduced cardiac reserve and prescribed bed rest
Decreased Cardiac output r/t altered preload/afterload
Deficient Knowledge r/t treatment of disease
Risk for decreased Cardiac tissue perfusion: Risk factors: hypoxia, hypovolemia, cardiac tamponade
Readiness for enhanced Knowledge: treatment of disease
See Heart Failure, if appropriate

Myringotomy

Fear r/t hospitalization, surgical procedure
Ineffective Health maintenance r/t deficient knowledge regarding care after surgery
Acute Pain r/t surgical procedure
Risk for Surgical Site Infection: Risk factor: invasive procedure
See Ear Surgery

Myxedema

See Hypothyroidism

List of Nursing Diagnosis by Letter: N

Narcissistic Personality Disorder	Narcolepsy	Narcotic Use
Nasogastric Suction	Nausea	Near-Drowning
Nearsightedness	Nearsightedness; Corneal Surgery	Neck Vein Distention
Necrosis, Kidney Tubular; Necrosis, Acute Tubular	Necrotizing Enterocolitis	Negative Feelings About Self
Neglect, Unilateral	Neglectful Care of Family Member	Neonatal Abstinence Syndrome
Neonatal Hyperbilirubinemia	Neonate	Neoplasm
Nephrectomy	Nephrostomy, Percutaneous	Nephrotic Syndrome
Neural Tube Defects (Meningocele, Myelomeningocele, Spina Bifida, Anencephaly)	Neuralgia	Neuritis (Peripheral Neuropathy)
Neurogenic Bladder	Neurologic Disorders	Neuropathy, Peripheral
Neurosurgery	Newborn, Normal	Newborn, Postmature
Newborn, Small for Gestational Age (SGA)	Nicotine Addiction	NIDDM (Non–Insulin-Dependent Diabetes Mellitus)
Nightmares	Nipple Soreness	Nocturia
Nocturnal Myoclonus	Nocturnal Paroxysmal Dyspnea	Non–Insulin-Dependent Diabetes Mellitus (NIDDM)
Normal Pressure Hydrocephalus (NPH)	NSTEMI (non–ST-elevation myocardial infarction)	Nursing
Nutrition	Nutrition, Imbalanced	

N

Narcissistic Personality Disorder

Defensive Coping r/t grandiose sense of self
Impaired emancipated Decision-Making r/t lack of realistic problem-solving skills
Interrupted Family processes r/t taking advantage of others to achieve own goals
Risk-prone Health behavior r/t low self-efficacy
Disturbed personal Identity r/t psychological impairment
Ineffective Relationship r/t lack of mutual support/respect between partners
Impaired individual Resilience r/t psychological disorders
Impaired Social interaction r/t self-concept disturbance
Risk for Loneliness: Risk factors: emotional deprivation, social isolation

Narcolepsy

Anxiety r/t fear of lack of control over falling asleep
Disturbed Sleep pattern r/t uncontrollable desire to sleep
Risk for Physical Trauma: Risk factor: falling asleep during potentially dangerous activity
Readiness for enhanced Sleep: expresses willingness to enhance sleep

Narcotic Use

See Opioid Use (preferred terminology)

Nasogastric Suction

Impaired Oral Mucous Membrane integrity r/t presence of nasogastric tube
Risk for Electrolyte imbalance: Risk factor: loss of gastrointestinal fluids that contain electrolytes
Risk for imbalanced Fluid volume: Risk factor: loss of gastrointestinal fluids without adequate replacement
Risk for dysfunctional Gastrointestinal motility: Risk factor: decreased intestinal motility

Nausea

Nausea (See **Nausea,** Section III)

Near-Drowning

Ineffective Airway clearance r/t aspiration of fluid
Aspiration r/t aspiration of fluid into lungs
Fear: parental r/t possible death of child, possible permanent and debilitating sequelae
Impaired Gas exchange r/t laryngospasm, holding breath, aspiration, inflammation
Grieving r/t potential death of child, unknown sequelae, guilt about accident
Ineffective Health maintenance r/t parental deficient knowledge regarding safety measures appropriate for age
Hypothermia r/t central nervous system injury, prolonged submersion in cold water

Risk for delayed Development: Risk factors: hypoxemia, cerebral anoxia
Risk for complicated Grieving: Risk factors: potential death of child, unknown sequelae, guilt about accident
Risk for Infection: Risk factors: aspiration, invasive monitoring
Risk for ineffective Cerebral tissue perfusion: Risk factor: hypoxia
Readiness for enhanced Spiritual well-being: struggle with survival of life-threatening situation
See Child with Chronic Condition; Hospitalized Child; Safety, Childhood; Terminally Ill Child/Death of Child, Parent

Nearsightedness

Readiness for enhanced Health management: need for correction of myopia

Nearsightedness; Corneal Surgery

See LASIK Eye Surgery (Laser-Assisted in Situ Keratomileusis)

Neck Vein Distention

Decreased Cardiac output r/t decreased contractility of heart resulting in increased preload
Excess Fluid volume r/t excess fluid intake, compromised regulatory mechanisms
See Congestive Heart Failure (CHF); Heart Failure

Necrosis, Kidney Tubular; Necrosis, Acute Tubular

See Renal Failure

Necrotizing Enterocolitis

Ineffective Breathing pattern r/t abdominal distention, hypoxia
Diarrhea r/t infection
Deficient Fluid volume r/t vomiting, gastrointestinal bleeding
Neonatal Hyperbilirubinemia r/t feeding pattern not well established
Imbalanced Nutrition: less than body requirements r/t decreased ability to absorb nutrients, decreased perfusion to gastrointestinal tract
Risk for dysfunctional Gastrointestinal motility: Risk factor: infection
Risk for Infection: Risk factors: bacterial invasion of gastrointestinal tract, invasive procedures
See Hospitalized Child; Premature Infant (Child)

Negative Feelings About Self

Chronic low Self-Esteem r/t long-standing negative self-evaluation
Self-Neglect r/t negative feelings
Readiness for enhanced Self-Concept: expresses willingness to enhance self-concept

Neglect, Unilateral

Unilateral Neglect (See **Unilateral Neglect,** Section III)

Neglectful Care of Family Member

Caregiver Role Strain r/t overwhelming care demands of family member, lack of social or financial

support
Disabled family Coping r/t highly ambivalent family relationships, lack of respite care
Interrupted Family processes r/t situational transition or crisis
Deficient Knowledge r/t care needs
Impaired individual Resilience r/t vulnerability from neglect
Risk for compromised Human Dignity: Risk factor: inadequate participation in decision-making

Neonatal Abstinence Syndrome

Ineffective Airway clearance r/t pooling of secretions from lack of adequate cough reflex, effects of viral or bacterial lower airway infection as a result of altered protective state
Interrupted Breastfeeding r/t use of drugs or alcohol by mother
Ineffective Childbearing process r/t inconsistent prenatal health visits, suboptimal maternal nutrition, substance abuse
Impaired Comfort r/t irritability and inability to relax
Diarrhea r/t effects of withdrawal, increased peristalsis from hyperirritability
Disorganized infant Behavior r/t exposure and/or withdrawal from toxic substances (alcohol or drugs), lack of attachment
Ineffective infant Feeding pattern r/t uncoordinated or ineffective sucking reflex
Imbalanced Nutrition: less than body requirements r/t feeding problems; uncoordinated or ineffective suck and swallow; effects of diarrhea, vomiting, or colic associated with maternal substance abuse
Impaired Parenting r/t impaired or absent attachment behaviors, inadequate support systems
Ineffective infant Feeding Pattern r/t neurological delay
Disturbed Sleep Pattern r/t hyperirritability or hypersensitivity to environmental stimuli
Risk for impaired Attachment: Risk factor: (parent) substance misuse, inability to meet infant's needs
Risk for delayed Development: Risk factor: effects of prenatal substance abuse
Risk for Infection: Risk factor: stress effects of withdrawal
Risk for Disturbed Maternal–Fetal Dyad: Risk factor: substance abuse
Risk for Sudden Infant Death: Risk factor: prenatal illicit drug exposure
Risk for ineffective Thermoregulation: Risk factor: immature nervous system
See Anomaly, Fetal/Newborn (Parent Dealing with); Cerebral Palsy; Child with Chronic Condition; Failure to Thrive; Hospitalized Child; Hyperactive Syndrome; Premature Infant/Child; Sudden Infant Death, Risk for

Neonatal Hyperbilirubinemia

Neonatal Hyperbilirubinemia (See neonatal **Hyperbilirubinemia,** Section III)

Neonate

Readiness for enhanced Childbearing process: appropriate care of newborn
See Newborn, Normal; Newborn, Postmature; Newborn, Small for Gestational Age (SGA)

Neoplasm

Fear r/t possible malignancy
See Cancer

Nephrectomy

Anxiety r/t surgical recovery, prognosis
Ineffective Breathing pattern r/t location of surgical incision
Constipation r/t lack of return of peristalsis
Acute Pain r/t incisional discomfort
Spiritual distress r/t chronic illness
Risk for Bleeding: Risk factor: surgery
Risk for imbalanced Fluid volume: Risk factors: vascular losses, decreased intake
Risk for Surgical Site Infection: Risk factor: surgical procedure

Nephrostomy, Percutaneous

Acute Pain r/t invasive procedure
Impaired Urinary elimination r/t nephrostomy tube
Risk for Infection: Risk factor: invasive procedure

Nephrotic Syndrome

Activity intolerance r/t generalized edema
Disturbed Body Image r/t edematous appearance and side effects of steroid therapy
Excess Fluid volume r/t edema resulting from oncotic fluid shift caused by serum protein loss and kidney retention of salt and water
Imbalanced Nutrition: less than body requirements r/t anorexia, protein loss
Imbalanced Nutrition: more than body requirements r/t increased appetite attributable to steroid therapy
Social isolation r/t edematous appearance
Risk for Infection: Risk factor: altered immune mechanisms caused by disease and effects of steroids
Risk for impaired Skin integrity: Risk factor: edema
See Child with Chronic Condition; Hospitalized Child

Neural Tube Defects (Meningocele, Myelomeningocele, Spina Bifida, Anencephaly)

Chronic functional Constipation r/t immobility or less than adequate mobility
Grieving r/t loss of perfect child, birth of child with congenital defect
Reflex urinary Incontinence r/t neurogenic impairment
Total urinary Incontinence r/t neurogenic impairment
Urge urinary Incontinence r/t neurogenic impairment
Impaired Mobility r/t neuromuscular impairment
Chronic low Self-Esteem r/t perceived differences, decreased ability to participate in physical and social activities at school
Impaired Skin integrity r/t incontinence
Risk for delayed Development: Risk factor: inadequate nutrition
Risk for Latex Allergic reaction: Risk factor: multiple exposures to latex products
Risk for imbalanced Nutrition: more than body requirements: Risk factors: diminished, limited, or impaired physical activity
Risk for Powerlessness: Risk factor: debilitating disease
Risk for impaired Skin integrity: lower extremities: Risk factor: decreased sensory perception
Readiness for enhanced family Coping: effective adaptive response by family members
Readiness for enhanced Family processes: family supports each other
See Child with Chronic Condition; Premature Infant (Child)

Neuralgia

See Trigeminal Neuralgia

Neuritis (Peripheral Neuropathy)

Activity intolerance r/t pain with movement
Ineffective Health maintenance r/t deficient knowledge regarding self-care with neuritis
Acute Pain r/t stimulation of affected nerve endings, inflammation of sensory nerves
See Neuropathy, Peripheral

Neurogenic Bladder

Reflex urinary Incontinence r/t neurological impairment
Urinary Retention r/t interruption in the lateral spinal tracts
Risk for Latex Allergic reaction: Risk factor: repeated exposures to latex associated with possible repeated catheterizations

Neurologic Disorders

Ineffective Airway clearance r/t perceptual or cognitive impairment, decreased energy, fatigue
Acute Confusion r/t dementia, alcohol abuse, drug abuse, delirium
Ineffective Coping r/t disability requiring change in lifestyle
Interrupted Family processes r/t situational crisis, illness, or disability of family member
Grieving r/t loss of usual body functioning
Impaired Home maintenance r/t client's or family member's disease
Risk for corneal Injury: Risk factor: lack of spontaneous blink reflex
Impaired Memory r/t neurological disturbance
Impaired physical Mobility r/t neuromuscular impairment
Imbalanced Nutrition: less than body requirements r/t impaired swallowing, depression, difficulty feeding self
Powerlessness r/t progressive nature of disease
Self-Care deficit: specify r/t neuromuscular dysfunction
Sexual dysfunction r/t biopsychosocial alteration of sexuality
Social isolation r/t altered state of wellness
Impaired Swallowing r/t neuromuscular dysfunction
Risk for Disuse syndrome: Risk factors: physical immobility, neuromuscular dysfunction
Risk for Injury: Risk factors: altered mobility, sensory dysfunction, cognitive impairment
Risk for ineffective Cerebral tissue perfusion: Risk factor: cerebral disease/injury
Risk for impaired Religiosity: Risk factor: life transition
Risk for impaired Skin integrity: Risk factors: altered sensation, altered mental status, paralysis
See specific condition: Alcohol Withdrawal; Amyotrophic Lateral Sclerosis (ALS); CVA (Cerebrovascular Accident); Delirium; Dementia; Guillain-Barré Syndrome; Head Injury; Huntington's Disease; Spinal Cord Injury; Myasthenia Gravis; Muscular Dystrophy (MD); Parkinson's Disease

Neuropathy, Peripheral

Chronic Pain r/t damage to nerves in the peripheral nervous system as a result of medication side effects, vitamin deficiency, or diabetes
Ineffective Thermoregulation r/t decreased ability to regulate body temperature
Risk for Injury: Risk factors: lack of muscle control, decreased sensation
Risk for impaired Skin integrity: Risk factor: poor perfusion
Risk for Thermal Injury: Risk factor: nerve damage
See Peripheral Vascular Disease (PVD)

Neurosurgery

See Craniectomy/Craniotomy

Newborn, Normal

Breastfeeding r/t normal oral structure and gestational age greater than 34 weeks
Ineffective Thermoregulation r/t immaturity of neuroendocrine system
Risk for Sudden Infant Death: Risk factors: lack of knowledge regarding infant sleeping in prone or side-lying position, prenatal or postnatal infant smoke exposure, infant overheating or overwrapping, loose articles in the sleep environment
Risk for Infection: Risk factors: open umbilical stump, immature immune system
Risk for Injury: Risk factors: immaturity, need for caretaking
Readiness for enhanced Childbearing process: appropriate care of newborn
Readiness for enhanced organized Infant behavior: demonstrates adaptive response to pain
Readiness for enhanced Parenting: providing emotional and physical needs of infant

Newborn, Postmature

Hypothermia r/t depleted stores of subcutaneous fat
Impaired Skin integrity r/t cracked and peeling skin as a result of decreased vernix
Risk for ineffective Airway clearance: Risk factor: meconium aspiration
Risk for unstable blood Glucose level: Risk factor: depleted glycogen stores

Newborn, Small for Gestational Age (SGA)

Neonatal Hyperbilirubinemia r/t neonate age and difficulty feeding
Imbalanced Nutrition: less than body requirements r/t history of placental insufficiency
Ineffective Thermoregulation r/t decreased brown fat, subcutaneous fat
Risk for delayed Development: Risk factor: history of placental insufficiency
Risk for Injury: Risk factors: hypoglycemia, perinatal asphyxia, meconium aspiration
Risk for Sudden Infant Death: Risk factor: low birth weight

Nicotine Addiction

Risk-prone Health behavior r/t smoking
Ineffective Health maintenance r/t lack of ability to make a judgment about smoking cessation
Risk for impaired Skin integrity: Risk factor: poor tissue perfusion associated with nicotine
Powerlessness r/t perceived lack of control over ability to give up nicotine
Readiness for enhanced emancipated Decision-Making: expresses desire to enhance understanding and meaning of choices
Readiness for enhanced Health literacy: expresses desire to enhance understanding of health information to make health care choices
Readiness for enhanced Health management: expresses desire to learn measures to stop smoking

NIDDM (Non–Insulin-Dependent Diabetes Mellitus)

Readiness for enhanced Health management: expresses desire for information on exercise and diet to manage diabetes
See Diabetes Mellitus

Nightmares

Post-Trauma syndrome r/t disaster, war, epidemic, rape, assault, torture, catastrophic illness, or accident

Nipple Soreness

Impaired Comfort r/t physical condition
See Painful Breasts, Sore Nipples; Sore Nipples, Breastfeeding

Nocturia

Urge urinary Incontinence r/t decreased bladder capacity, irritation of bladder stretch receptors causing spasm, alcohol, caffeine, increased fluids, increased urine concentration, overdistention of bladder
Impaired Urinary elimination r/t sensory motor impairment, urinary tract infection
Risk for Powerlessness: Risk factor: inability to control nighttime voiding

Nocturnal Myoclonus

See Restless Leg Syndrome; Stress

Nocturnal Paroxysmal Dyspnea

See PND (Paroxysmal Nocturnal Dyspnea)

Non–Insulin-Dependent Diabetes Mellitus (NIDDM)

See Diabetes Mellitus

Normal Pressure Hydrocephalus (NPH)

Impaired verbal Communication r/t obstruction of flow of cerebrospinal fluid affecting speech
Acute Confusion r/t increased intracranial pressure caused by obstruction to flow of cerebrospinal fluid
Impaired Memory r/t neurological disturbance
Risk for ineffective Cerebral tissue perfusion: Risk factor: fluid pressing on the brain
Risk for Falls: Risk factor: unsteady gait as a result of obstruction of cerebrospinal fluid

NSTEMI (non–ST-elevation myocardial infarction)

See MI (Myocardial Infarction)

Nursing

See Breastfeeding, Effective; Breastfeeding, Ineffective; Breastfeeding, Interrupted

Nutrition

Readiness for enhanced Nutrition (See **Nutrition,** readiness for enhanced, Section III)

Nutrition, Imbalanced

Imbalanced Nutrition: less than body requirements (See **Nutrition:** less than body requirements, imbalanced, Section III)
Obesity (See **Obesity,** Section III)
Overweight (See **Overweight,** Section III)
Risk for Dry Mouth r/t depression
Risk for Overweight (See **Overweight,** risk for, Section III)

List of Nursing Diagnosis by Letter: O

Obesity	OBS (Organic Brain Syndrome)	Obsessive-Compulsive Disorder (OCD)
Obstruction, Bowel	Obstructive Sleep Apnea	OCD (Obsessive-Compulsive Disorder)
Occupational Injury	ODD (Oppositional Defiant Disorder)	Older Adult
Oliguria	Omphalocele	Oophorectomy
OPCAB (Off-Pump Coronary Artery Bypass)	Open Heart Surgery	Open Reduction of Fracture with Internal Fixation (Femur)
Opioid Addiction	Opioid Use	Opportunistic Infection
Oppositional Defiant Disorder (ODD)	Oral Mucous Membrane Integrity, Impaired	Oral Thrush
Orchitis	Organic Mental Disorders	Orthopedic Traction
Orthopnea	Orthostatic Hypotension	Osteoarthritis
Osteomyelitis	Osteoporosis	Ostomy
Otitis Media	Ovarian Carcinoma	

O

Obesity

Disturbed Body Image r/t eating disorder, excess weight
Risk-prone Health behavior: r/t negative attitude toward health care
Obesity (See **Obesity,** Section III)
Chronic low Self-Esteem r/t ineffective coping, overeating
Risk for Metabolic Imbalance syndrome: Risk factor: obesity
Risk for ineffective peripheral Tissue Perfusion: Risk factor: sedentary lifestyle
Readiness for enhanced Nutrition: expresses willingness to enhance nutrition

OBS (Organic Brain Syndrome)

See Organic Mental Disorders; Dementia

Obsessive-Compulsive Disorder (OCD)

See OCD (Obsessive-Compulsive Disorder)

Obstruction, Bowel

See Bowel Obstruction

Obstructive Sleep Apnea

Insomnia r/t blocked airway
Obesity r/t excessive intake related to metabolic need
See PND (Paroxysmal Nocturnal Dyspnea)

OCD (Obsessive-Compulsive Disorder)

Ineffective Activity planning r/t unrealistic perception of events
Anxiety r/t threat to self-concept, unmet needs
Impaired emancipated Decision-Making r/t inability to make a decision for fear of reprisal
Disabled family Coping r/t family process being disrupted by client's ritualistic activities
Ineffective Coping r/t expression of feelings in an unacceptable way, ritualistic behavior
Risk-prone Health behavior r/t inadequate comprehension associated with repetitive thoughts
Powerlessness r/t unrelenting repetitive thoughts to perform irrational activities
Impaired individual Resilience r/t psychological disorder
Risk for situational low Self-Esteem: Risk factor: inability to control repetitive thoughts and actions

Occupational Injury

Fatigue r/t lack of sleep

Deficient Knowledge r/t inadequate training, improper use of equipment
Stress Overload r/t feelings of pressure
Risk for Occupational Injury (See **Risk for Occupational Injury,** Section III)

ODD (Oppositional Defiant Disorder)

Anxiety r/t feelings of anger and hostility toward authority figures
Ineffective Coping r/t lack of self-control or perceived lack of self-control
Disabled Family coping r/t feelings of anger, hostility; defiant behavior toward authority figures
Risk-prone Health behavior r/t multiple stressors associated with condition
Ineffective Impulse control r/t anger/compunction to engage in disruptive behaviors
Chronic or situational low Self-Esteem r/t poor self-control and disruptive behaviors
Impaired Social interaction r/t being touchy or easily annoyed, blaming others for own mistakes, constant trouble in school
Social isolation r/t unaccepted social behavior
Ineffective family Health management r/t difficulty in limit setting and managing oppositional behaviors
Risk for ineffective Activity planning: Risk factors: unrealistic perception of events, hedonism, insufficient social support
Risk for impaired Parenting: Risk factors: children's difficult behaviors and inability to set limits
Risk for Powerlessness: Risk factor: inability to deal with difficult behaviors
Risk for Spiritual distress: Risk factors: anxiety and stress in dealing with difficult behaviors
Risk for other-directed Violence: Risk factors: history of violence, threats of violence against others, history of antisocial behavior, history of indirect violence

Older Adult

See Aging

Oliguria

Deficient Fluid volume r/t active fluid loss, failure of regulatory mechanism, inadequate intake
See Cardiac Output, Decreased; Renal Failure; Shock, Hypovolemic

Omphalocele

See Gastroschisis/Omphalocele

Oophorectomy

Risk for ineffective Sexuality pattern: Risk factor: altered body function
See Surgery, Perioperative Care; Surgery, Postoperative Care; Surgery, Preoperative Care

OPCAB (Off-Pump Coronary Artery Bypass)

See Angioplasty, Coronary; Coronary Artery Bypass Grafting (CABG)

Open Heart Surgery

Risk for decreased Cardiac tissue perfusion: Risk factor: cardiac surgery
See Coronary Artery Bypass Grafting (CABG); Dysrhythmia

Open Reduction of Fracture with Internal Fixation (Femur)

Anxiety r/t outcome of corrective procedure
Impaired physical Mobility r/t postoperative position, abduction of leg, avoidance of acute flexion
Powerlessness r/t loss of control, unanticipated change in lifestyle
Risk for Surgical Site Infection: Risk factor: surgical procedure
Risk for Perioperative Positioning injury: Risk factor: immobilization
Risk for peripheral neurovascular dysfunction: Risk factors: mechanical compression, orthopedic surgery, immobilization
Risk for venous thromboembolism: Risk factor: impaired mobility
See Surgery, Postoperative Care

Opioid Addiction

See Substance Abuse

Opioid Use

Acute Pain r/t physical injury or surgical procedure
Chronic Pain syndrome r/t prolonged use of opioids
Risk for Constipation: Risk factor: effects of opioids on peristalsis
See Substance Abuse; Substance Withdrawal; Pain Management, Acute; Pain Management, Chronic

Opportunistic Infection

Delayed Surgical recovery r/t abnormal blood profiles, impaired healing
Risk for Infection: Risk factor: abnormal blood profiles
See AIDS (Acquired Immunodeficiency Syndrome); HIV (Human Immunodeficiency Virus)

Oppositional Defiant Disorder (ODD)

See ODD (Oppositional Defiant Disorder)

Oral Mucous Membrane Integrity, Impaired

Impaired Oral Mucous Membrane integrity (See **Oral Mucous Membrane** integrity, impaired, Section III)

Oral Thrush

See Candidiasis, Oral

Orchitis

Readiness for enhanced Health management: follows recommendations for mumps vaccination
See Epididymitis

Organic Mental Disorders

Chronic Confusion r/t progressive impairment in cognitive functioning
Frail Elderly syndrome r/t alteration in cognitive function
Impaired Social interaction r/t disturbed thought processes
Risk for disturbed personal Identity: Risk factor: delusions/fluctuating perceptions of stimuli
See Dementia

Orthopedic Traction

Ineffective Role performance r/t limited physical mobility
Impaired Social interaction r/t limited physical mobility
Impaired Transfer ability r/t limited physical mobility
Risk for impaired Religiosity: Risk factor: immobility
See Traction and Casts

Orthopnea

Ineffective Breathing pattern r/t inability to breathe with head of bed flat
Decreased Cardiac output r/t inability of heart to meet demands of body

Orthostatic Hypotension

See Dizziness

Osteoarthritis

Acute Pain r/t movement
Impaired Walking r/t inflammation and damage to joints
See Arthritis

Osteomyelitis

Decreased Diversional activity engagement r/t prolonged immobilization, hospitalization
Fear: parental r/t concern regarding possible growth plate damage caused by infection, concern that infection may become chronic
Ineffective Health maintenance r/t continued immobility at home, possible extensive casts, continued antibiotics
Impaired physical Mobility r/t imposed immobility as a result of infected area
Acute Pain r/t inflammation in affected extremity
Ineffective Thermoregulation r/t infectious process
Risk for Constipation: Risk factor: immobility
Risk for Infection: Risk factor: inadequate primary and secondary defenses
Risk for impaired Skin integrity: Risk factor: irritation from splint or cast
See Hospitalized Child

Osteoporosis

Deficient Knowledge r/t diet, exercise, need to abstain from alcohol and nicotine
Impaired physical Mobility r/t pain, skeletal changes
Imbalanced Nutrition: **less than body requirements** r/t inadequate intake of calcium and vitamin D
Acute Pain r/t fracture, muscle spasms
Risk for Injury: **fracture:** Risk factors: lack of activity, risk of falling resulting from environmental hazards, neuromuscular disorders, diminished senses, cardiovascular responses to drugs
Risk for Powerlessness: Risk factor: debilitating disease
Readiness for enhanced Health management: expresses desire to manage the treatment of illness and prevent complications

Ostomy

See Child with Chronic Condition; Colostomy; Ileal Conduit; Ileostomy

Otitis Media

Acute Pain r/t inflammation, infectious process
Risk for delayed Development: **speech and language:** Risk factor: frequent otitis media
Risk for Infection: Risk factors: eustachian tube obstruction, traumatic eardrum perforation, infectious process
Readiness for enhanced Knowledge: information on treatment and prevention of disease

Ovarian Carcinoma

Death Anxiety r/t unknown outcome, possible poor prognosis
Fear r/t unknown outcome, possible poor prognosis
Ineffective Health Maintenance r/t deficient knowledge regarding self-care, treatment of condition
Readiness for enhanced Family Processes: family functioning meets needs of client
Readiness for enhanced Resilience: participates in support groups
See Chemotherapy; Hysterectomy; Radiation Therapy

List of Nursing Diagnosis by Letter

P

Pacemaker	Paget's Disease	Pain Management, Acute
Pain Management, Chronic	Painful Breasts, Engorgement	Painful Breasts, Sore Nipples
Pallor of Extremities	Palpitations (Heart Palpitations)	Pancreatic Cancer
Pancreatitis	Panic Disorder (Panic Attacks)	Paralysis
Paralytic Ileus	Paranoid Personality Disorder	Paraplegia
Parathyroidectomy	Parent Attachment	Parental Role Conflict
Parenting	Parenting, Impaired	Parenting, Risk for Impaired
Paresthesia	Parkinson's Disease	Paroxysmal Nocturnal Dyspnea (PND)
Patent Ductus Arteriosus (PDA)	Patient-Controlled Analgesia (PCA)	Patient Education
PCA (Patient-Controlled Analgesia)	Pectus Excavatum	Pediculosis
PEG (Percutaneous Endoscopic Gastrostomy)	Pelvic Inflammatory Disease (PID)	Penile Prosthesis
Peptic Ulcer	Percutaneous Transluminal Coronary Angioplasty (PTCA)	Pericardial Friction Rub
Pericarditis	Periodontal Disease	Perioperative Hypothermia
Perioperative Positioning	Peripheral Neuropathy	Peripheral Neurovascular Dysfunction
Peripheral Vascular Disease (PVD)	Peritoneal Dialysis	Peritonitis
Pernicious Anemia	Persistent Fetal Circulation	Personal Identity Problems
Personality Disorder	Pertussis (Whooping Cough)	Pesticide Contamination
Petechiae	Petit Mal Seizure	Pharyngitis
Phenylketonuria (PKU)	Pheochromocytoma	Phlebitis
Phobia (Specific)	Photosensitivity	Physical Abuse
Pica	PID (Pelvic Inflammatory Disease)	PIH (Pregnancy-Induced Hypertension/Preeclampsia)
Piloerection	Pink Eye	Pinworms
Pituitary Tumor, Benign	PKU (Phenylketonuria)	Placenta Abruptio
Placenta Previa	Plantar Fasciitis	Pleural Effusion
Pleural Friction Rub	Pleural Tap	Pleurisy
PMS (Premenstrual Syndrome)	PND (Paroxysmal Nocturnal Dyspnea)	Pneumonectomy
Pneumonia	Pneumothorax	Poisoning, Risk for
Poliomyelitis	Polydipsia	Polyphagia

Polyuria	Postoperative Care	Postpartum Depression
Postpartum Hemorrhage	Postpartum, Normal Care	Post-Trauma Syndrome
Post-Trauma Syndrome, Risk for	Post-Traumatic Stress Disorder (PTSD)	Potassium, Increase/Decrease
Power/Powerlessness	Preeclampsia	Pregnancy, Cardiac Disorders
Pregnancy-Induced Hypertension/Preeclampsia (PIH)	Pregnancy Loss	Pregnancy, Normal
Premature Dilation of the Cervix (Incompetent Cervix)	Premature Infant (Child)	Premature Infant (Parent)
Premature Rupture of Membranes	Premenstrual Tension Syndrome (PMS)	Prenatal Care, Normal
Prenatal Testing	Preoperative Teaching	Pressure Ulcer
Preterm Labor	Problem-Solving Dysfunction	Projection
Prolapsed Umbilical Cord	Prostatic Hypertrophy	Prostatitis
Pruritus	Psoriasis	Psychosis
PTCA (Percutaneous Transluminal Coronary Angioplasty)	PTSD (Posttraumatic Stress Disorder)	Pulmonary Edema
Pulmonary Embolism (PE)	Pulmonary Stenosis	Pulse Deficit
Pulse Oximetry	Pulse Pressure, Increased	Pulse Pressure, Narrowed
Pulses, Absent or Diminished Peripheral	Purpura	Pyelonephritis
Pyloric Stenosis	Pyloromyotomy (Pyloric Stenosis Repair)	

P

Pacemaker

Anxiety r/t change in health status, presence of pacemaker
Death Anxiety r/t worry over possible malfunction of pacemaker
Deficient Knowledge r/t self-care program, when to seek medical attention
Acute Pain r/t surgical procedure
Risk for Bleeding: Risk factor: surgery
Risk for decreased Cardiac tissue perfusion: Risk factor: pacemaker malfunction
Risk for Infection: Risk factors: invasive procedure, presence of foreign body (catheter and generator)
Risk for Powerlessness: Risk factor: presence of electronic device to stimulate heart
Readiness for enhanced Health management: appropriate health care management of pacemaker

Paget's Disease

Disturbed Body Image r/t possible enlarged head, bowed tibias, kyphosis
Deficient Knowledge r/t appropriate diet high in protein and calcium, mild exercise
Chronic Sorrow r/t chronic condition with altered body image
Risk for Physical Trauma: fracture: Risk factor: excessive bone destruction

Pain Management, Acute

Acute Pain r/t injury or surgical procedure
Imbalanced Energy Field r/t unpleasant sensory and emotional feelings

Pain Management, Chronic

Chronic Pain (See **Pain,** chronic, Section III)
Chronic Pain Syndrome r/t persistent pain affecting daily living
Risk for Constipation: Risk factor: effects of meds on peristalsis
Readiness for enhanced Knowledge: expresses a desire to learn alternative methods of non-pharmaceutical pain control
See Substance Abuse

Painful Breasts, Engorgement

Acute Pain r/t distention of breast tissue
Ineffective Role performance r/t change in physical capacity to assume role of breastfeeding mother
Impaired Tissue integrity r/t excessive fluid in breast tissues
Risk for ineffective Breastfeeding: Risk factors: pain, infant's inability to latch on to engorged breast
Risk for Infection: Risk factor: milk stasis

Painful Breasts, Sore Nipples

Insufficient Breast Milk Production r/t long breastfeeding time/pain response
Ineffective Breastfeeding r/t pain

Acute Pain r/t cracked nipples
Ineffective Role performance r/t change in physical capacity to assume role of breastfeeding mother
Impaired Skin integrity r/t mechanical factors involved in suckling, breastfeeding management
Risk for Infection: Risk factor: break in skin

Pallor of Extremities

Ineffective peripheral Tissue Perfusion r/t interruption of vascular flow
See Shock; Peripheral Vascular disease (PVD)

Palpitations (Heart Palpitations)

See Dysrhythmia

Pancreatic Cancer

Death Anxiety r/t possible poor prognosis of disease process
Ineffective family Coping r/t poor prognosis
Fear r/t poor prognosis of the disease
Grieving r/t shortened life span
Deficient Knowledge r/t disease-induced diabetes, home management
Spiritual distress r/t poor prognosis
Risk for impaired Liver function: Risk factor: complications from underlying disease
See Cancer; Chemotherapy; Radiation Therapy; Surgery, Perioperative Care; Surgery, Postoperative Care; Surgery, Preoperative Care

Pancreatitis

Ineffective Breathing pattern r/t splinting from severe pain, disease process and inflammation
Ineffective Denial r/t ineffective coping, alcohol use
Diarrhea r/t decrease in pancreatic secretions resulting in steatorrhea
Deficient Fluid volume r/t vomiting, decreased fluid intake, fever, diaphoresis, fluid shifts
Ineffective Health maintenance r/t deficient knowledge concerning diet, alcohol use, medication
Nausea r/t irritation of gastrointestinal system
Imbalanced Nutrition: less than body requirements r/t inadequate dietary intake, increased nutritional needs as a result of acute illness, increased metabolic needs caused by increased body temperature, disease process
Acute Pain r/t irritation and edema of the inflamed pancreas
Chronic Sorrow r/t chronic illness
Readiness for enhanced Comfort: expresses desire to enhance comfort

Panic Disorder (Panic Attacks)

Ineffective Activity planning r/t unrealistic perception of events
Anxiety r/t situational crisis
Ineffective Coping r/t personal vulnerability
Risk-prone Health behavior r/t low self-efficacy
Disturbed personal Identity r/t situational crisis
Post-Trauma syndrome r/t previous catastrophic event
Social isolation r/t fear of lack of control
Risk for Loneliness: Risk factor: inability to socially interact because of fear of losing control
Risk for Post-Trauma syndrome: Risk factors: perception of the event, diminished ego strength
Risk for Powerlessness: Risk factor: ineffective coping skills
Readiness for enhanced Coping: seeks problem-oriented and emotion-oriented strategies to manage condition
See Anxiety; Anxiety Disorder

Paralysis

Disturbed Body Image r/t biophysical changes, loss of movement, immobility
Impaired Comfort r/t prolonged immobility
Constipation r/t effects of spinal cord disruption, inadequate fiber in diet
Ineffective Health maintenance r/t deficient knowledge regarding self-care with paralysis
Impaired Home maintenance r/t physical disability
Reflex urinary Incontinence r/t neurological impairment
Impaired physical Mobility r/t neuromuscular impairment
Impaired wheelchair Mobility r/t neuromuscular impairment
Self-Neglect r/t functional impairment
Powerlessness r/t illness-related regimen
Self-Care deficit: specify r/t neuromuscular impairment
Sexual dysfunction r/t loss of sensation, biopsychosocial alteration
Chronic Sorrow r/t loss of physical mobility
Impaired Transfer ability r/t paralysis
Risk for Autonomic Dysreflexia: Risk factor: cause of paralysis
Risk for Disuse syndrome: Risk factor: paralysis
Risk for Falls: Risk factor: paralysis
Risk for Injury: Risk factors: altered mobility, sensory dysfunction
Risk for Latex Allergic reaction: Risk factor: possible repeated urinary catheterizations
Risk for Post-Trauma syndrome: Risk factor: event causing paralysis
Risk for impaired Religiosity: Risk factors: immobility, possible lack of transportation
Risk for impaired Resilience: Risk factor: chronic disability
Risk for situational low Self-Esteem: Risk factor: change in body image and function
Risk for impaired Skin integrity: Risk factors: altered circulation, altered sensation, immobility
Risk for Venous Thromboembolism: Risk factor: prolonged immobility
Readiness for enhanced Self-Care: expresses desire to enhance knowledge and responsibility for strategies for self-care
See Child with Chronic Condition; Hemiplegia; Hospitalized Child; Neural Tube Defects (Meningocele, Myelomeningocele, Spina Bifida, Anencephaly); Spinal Cord Injury

Paralytic Ileus

Constipation r/t decreased gastrointestinal motility
Deficient Fluid volume r/t loss of fluids from vomiting, retention of fluid in bowel
Dysfunctional Gastrointestinal motility r/t recent abdominal surgery, electrolyte imbalance
Nausea r/t gastrointestinal irritation
Acute Pain r/t pressure, abdominal distention, presence of nasogastric tube
See Bowel Obstruction

Paranoid Personality Disorder

Ineffective Activity planning r/t unrealistic perception of events
Anxiety r/t uncontrollable intrusive, suspicious thoughts
Risk-prone Health behavior r/t intense emotional state
Disturbed personal Identity r/t difficulty with reality testing
Impaired individual Resilience r/t psychological disorder
Chronic low Self-Esteem r/t inability to trust others
Social isolation r/t inappropriate social skills
Risk for Loneliness: Risk factor: social isolation
Risk for other-directed Violence: Risk factor: being suspicious of others and their actions

Paraplegia

See Spinal Cord Injury

Parathyroidectomy

Anxiety r/t surgery
Risk for ineffective Airway clearance: Risk factors: edema or hematoma formation, airway obstruction
Risk for Bleeding: Risk factor: surgery
Risk for impaired verbal Communication: Risk factors: possible laryngeal damage, edema
Risk for Infection: Risk factor: surgical procedure
See Hypocalcemia

Parent Attachment

Risk for impaired Attachment (See **Attachment,** impaired, risk for, Section III)
Readiness for enhanced Childbearing process: demonstrates appropriate care of newborn
See Parental Role Conflict

Parental Role Conflict

Parental Role conflict (See **Role** conflict, parental, Section III)
Ineffective Relationship r/t unrealistic expectations
Chronic Sorrow r/t difficult parent–child relationship
Risk for Spiritual distress: Risk factor: altered relationships
Readiness for enhanced Parenting: willingness to enhance parenting

Parenting

Readiness for enhanced Parenting (See **Parenting,** readiness for enhanced, Section III)

Parenting, Impaired

Impaired Parenting (See **Parenting,** impaired, Section III)
Chronic Sorrow r/t difficult parent–child relationship
Risk for Spiritual distress: Risk factor: altered relationships

Parenting, Risk for Impaired

Risk for impaired Parenting (See **Parenting,** impaired, risk for, Section III)
See Parenting, Impaired

Paresthesia

Risk for Injury: Risk factors: inability to feel temperature changes, pain
Risk for impaired Skin integrity: Risk factor: impaired sensation
Risk for Thermal injury: Risk factor: neuromuscular impairment

Parkinson's Disease

Impaired verbal Communication r/t decreased speech volume, slowness of speech, impaired facial muscles
Constipation r/t weakness of muscles, lack of exercise, inadequate fluid intake, decreased autonomic nervous system activity
Frail Elderly syndrome r/t chronic illness
Imbalanced Nutrition: less than body requirements r/t tremor, slowness in eating, difficulty in chewing and swallowing

Chronic Sorrow r/t loss of physical capacity
Risk for Injury: Risk factors: tremors, slow reactions, altered gait
See Neurologic Disorders

Paroxysmal Nocturnal Dyspnea (PND)

See PND (Paroxysmal Nocturnal Dyspnea)

Patent Ductus Arteriosus (PDA)

See Congenital Heart Disease/Cardiac Anomalies

Patient-Controlled Analgesia (PCA)

See PCA (Patient-Controlled Analgesia)

Patient Education

Deficient Knowledge r/t lack of exposure to information misinterpretation, unfamiliarity with information resources to manage illness
Readiness for enhanced emancipated Decision-Making: expresses desire to enhance understanding of choices for decision-making
Readiness for enhanced Knowledge (specify): interest in learning
Readiness for enhanced Health management: expresses desire for information to manage the illness

PCA (Patient-Controlled Analgesia)

Deficient Knowledge r/t self-care of pain control
Nausea r/t side effects of medication
Risk for Injury: Risk factors: possible complications associated with PCA
Risk for Vascular Trauma: Risk factors: insertion site and length of insertion time
Readiness for enhanced Knowledge: appropriate management of PCA

Pectus Excavatum

See Marfan Syndrome

Pediculosis

See Lice

PEG (Percutaneous Endoscopic Gastrostomy)

See Tube Feeding

Pelvic Inflammatory Disease (PID)

See PID (Pelvic Inflammatory Disease)

Penile Prosthesis

Ineffective Sexuality pattern r/t use of penile prosthesis
Risk for Surgical Site Infection: Risk factor: invasive surgical procedure
Risk for situational low Self-Esteem: Risk factor: ineffective sexuality pattern
Readiness for enhanced Health management: seeks information regarding care and use of prosthesis
See Erectile Dysfunction (ED); Impotence

Peptic Ulcer

See Ulcer, Peptic (Duodenal or Gastric)

Percutaneous Transluminal Coronary Angioplasty (PTCA)

See Angioplasty, Coronary

Pericardial Friction Rub

Decreased **Cardiac** output
Acute Pain r/t inflammation, effusion
Risk for decreased Cardiac tissue perfusion: Risk factors: inflammation in pericardial sac, fluid accumulation compressing heart

Pericarditis

Activity intolerance r/t reduced cardiac reserve, prescribed bed rest
Decreased Cardiac output r/t impaired cardiac function from inflammation of pericardial sac
Risk for decreased Cardiac tissue perfusion: Risk factor: inflammation in pericardial sac
Deficient Knowledge r/t unfamiliarity with information sources
Risk for imbalanced Nutrition: less than body requirements: Risk factors: fever, hypermetabolic state associated with fever
Acute Pain r/t biological injury, inflammation

Periodontal Disease

Risk for impaired Oral Mucous Membrane integrity (See **Oral Mucous Membrane** integrity, impaired, risk for, Section III)

Perioperative Hypothermia

Risk for Perioperative Hypothermia (See **Perioperative Hypothermia,** risk for, Section III)

Perioperative Positioning

Risk for Perioperative Positioning injury (See **Perioperative Positioning** injury, risk for, Section III)

Peripheral Neuropathy

See Neuropathy, Peripheral

Peripheral Neurovascular Dysfunction

Risk for Peripheral Neurovascular dysfunction (See **Peripheral Neurovascular** dysfunction, risk for,

Section III)
See Neuropathy, Peripheral; Peripheral Vascular disease (PVD)

Peripheral Vascular Disease (PVD)

Ineffective Health maintenance r/t deficient knowledge regarding self-care and treatment of disease
Chronic Pain: intermittent claudication r/t ischemia
Ineffective peripheral Tissue Perfusion r/t disease process
Risk for Falls: Risk factor: altered mobility
Risk for Injury: Risk factors: tissue hypoxia, altered mobility, altered sensation
Risk for Peripheral Neurovascular dysfunction: Risk factor: possible vascular obstruction
Risk for impaired Tissue integrity: Risk factor: altered circulation or sensation
Readiness for enhanced Health management: self-care and treatment of disease
See Neuropathy, Peripheral; Peripheral Neurovascular Dysfunction

Peritoneal Dialysis

Ineffective Breathing pattern r/t pressure from dialysate
Impaired Comfort r/t instillation of dialysate, temperature of dialysate
Impaired Home maintenance r/t complex home treatment of client
Deficient Knowledge r/t treatment procedure, self-care with peritoneal dialysis
Chronic Sorrow r/t chronic disability
Risk for ineffective Coping: Risk factor: disability requiring change in lifestyle
Risk for unstable blood Glucose level: Risk factors: increased concentrations of glucose in dialysate, ineffective medication management
Risk for imbalanced Fluid volume: Risk factor: medical procedure
Risk for Infection: peritoneal: Risk factors: invasive procedure, presence of catheter, dialysate
Risk for Powerlessness: Risk factors: chronic condition and care involved
See Child with Chronic Condition; Hemodialysis; Hospitalized Child; Renal Failure; Renal Failure, Acute/Chronic, Child

Peritonitis

Ineffective Breathing pattern r/t pain, increased abdominal pressure
Constipation r/t decreased oral intake, decrease of peristalsis
Deficient Fluid volume r/t retention of fluid in bowel with loss of circulating blood volume
Nausea r/t gastrointestinal irritation
Imbalanced Nutrition: less than body requirements r/t nausea, vomiting
Acute Pain r/t inflammation and infection of gastrointestinal system
Risk for dysfunctional Gastrointestinal motility: Risk factor: gastrointestinal disease

Pernicious Anemia

Diarrhea r/t malabsorption of nutrients
Fatigue r/t imbalanced nutrition: less than body requirements
Impaired Memory r/t lack of adequate red blood cells
Nausea r/t altered oral mucous membrane; sore tongue, bleeding gums
Imbalanced Nutrition: less than body requirements r/t lack of appetite associated with nausea and altered oral mucous membrane
Impaired Oral Mucous Membrane integrity r/t vitamin deficiency; inability to absorb vitamin B_{12} associated with lack of intrinsic factor
Risk for Falls: Risk factors: dizziness, lightheadedness
Risk for Peripheral Neurovascular dysfunction: Risk factor: anemia

Persistent Fetal Circulation

See Congenital Heart Disease/Cardiac Anomalies

Personal Identity Problems

Disturbed personal Identity (See **Identity,** personal, disturbed, Section III)
Risk for disturbed personal Identity (See disturbed personal **Identity,** risk for, Section III)

Personality Disorder

Ineffective Activity planning r/t unrealistic perception of events
Impaired individual Resilience r/t psychological disorder
See specific disorder: Antisocial Personality Disorder; Borderline Personality Disorder; OCD (Obsessive-Compulsive Disorder); Paranoid Personality Disorder

Pertussis (Whooping Cough)

Risk for impaired emancipated Decision-Making: Risk factor: indecision regarding administration of usual childhood vaccinations
See Respiratory Infections, Acute Childhood

Pesticide Contamination

Contamination r/t use of environmental contaminants; pesticides
Risk for Allergic reaction: Risk factor: repeated exposure to pesticides

Petechiae

See Anticoagulant Therapy; Clotting Disorder; DIC (Disseminated Intravascular Coagulation); Hemophilia

Petit Mal Seizure

Readiness for enhanced Health management: wears medical alert bracelet; limits hazardous activities such as driving, swimming, working at heights, operating equipment
See Epilepsy

Pharyngitis

See Sore Throat

Phenylketonuria (PKU)

See PKU (Phenylketonuria)

Pheochromocytoma

Anxiety r/t symptoms from increased catecholamines—headache, palpitations, sweating, nervousness, nausea, vomiting, syncope
Ineffective Health maintenance r/t deficient knowledge regarding treatment and self-care
Insomnia r/t high levels of catecholamines
Nausea r/t increased catecholamines
Risk for decreased Cardiac tissue perfusion: Risk factor: hypertension

See Surgery, Perioperative Care; Surgery, Postoperative Care; Surgery, Preoperative Care

Phlebitis

See Thrombophlebitis

Phobia (Specific)

Fear r/t presence or anticipation of specific object or situation
Powerlessness r/t anxiety about encountering unknown or known entity
Impaired individual Resilience r/t psychological disorder
Readiness for enhanced Power: expresses readiness to enhance identification of choices that can be made for change
See Anxiety; Anxiety Disorder; Panic Disorder (Panic Attacks)

Photosensitivity

Ineffective Health maintenance r/t deficient knowledge regarding medications inducing photosensitivity
Risk for dry Eye: Risk factors: pharmaceutical agents, sunlight exposure
Risk for impaired Skin integrity: Risk factor: exposure to sun

Physical Abuse

See Abuse, Child; Abuse, Spouse, Parent, or Significant Other

Pica

Anxiety r/t stress
Imbalanced Nutrition: less than body requirements r/t eating nonnutritive substances
Impaired Parenting r/t lack of supervision, food deprivation
Risk for Constipation: Risk factor: presence of undigestible materials in gastrointestinal tract
Risk for dysfunctional Gastrointestinal motility: Risk factor: abnormal eating behavior
Risk for Infection: Risk factor: ingestion of infectious agents via contaminated substances
Risk for Poisoning: Risk factor: ingestion of substances containing lead
See Anemia

PID (Pelvic Inflammatory Disease)

Ineffective Health maintenance r/t deficient knowledge regarding self-care, treatment of disease
Acute Pain r/t biological injury; inflammation, edema, congestion of pelvic tissues
Ineffective Sexuality pattern r/t medically imposed abstinence from sexual activities until acute infection subsides, change in reproductive potential
Risk for Infection: Risk factors: insufficient knowledge to avoid exposure to pathogens; proper hygiene, nutrition, other health habits
See Maturational Issues, Adolescent; STD (Sexually Transmitted Disease)

PIH (Pregnancy-Induced Hypertension/Preeclampsia)

Anxiety r/t fear of the unknown, threat to self and infant, change in role functioning
Death Anxiety r/t threat of preeclampsia
Decreased Diversional activity engagement r/t bed rest
Interrupted Family processes r/t situational crisis
Impaired Home maintenance r/t bed rest

Deficient Knowledge r/t lack of experience with situation
Impaired physical Mobility r/t medically prescribed limitations
Impaired Parenting r/t prescribed bed rest
Powerlessness r/t complication threatening pregnancy, medically prescribed limitations
Ineffective Role performance r/t change in physical capacity to assume role of pregnant woman or resume other roles
Situational low Self-Esteem r/t loss of idealized pregnancy
Impaired Social interaction r/t imposed bed rest
Risk for imbalanced Fluid volume: Risk factors: hypertension, altered kidney function
Risk for Injury: fetal: Risk factors: decreased uteroplacental perfusion, seizures
Risk for Injury: maternal: Risk factors: vasospasm, high blood pressure
Risk for unstable Blood Pressure: Risk factor: hypertension, imbalanced fluid volume
Readiness for enhanced Knowledge: exhibits desire for information on managing condition

Piloerection

Hypothermia r/t exposure to cold environment

Pink Eye

See Conjunctivitis

Pinworms

Impaired Comfort r/t itching
Impaired Home maintenance r/t inadequate cleaning of bed linen and toilet seats
Insomnia r/t discomfort
Readiness for enhanced Health management: proper handwashing; short, clean fingernails; avoiding hand, mouth, nose contact with unwashed hands; appropriate cleaning of bed linen and toilet seats

Pituitary Tumor, Benign

See Cushing's Disease

PKU (Phenylketonuria)

Risk for delayed Development: Risk factors: not following strict dietary program; eating foods extremely low in phenylalanine; avoiding eggs, milk, any foods containing aspartame (e.g., NutraSweet)
Readiness for enhanced Health management: testing for PKU and following prescribed dietary regimen

Placenta Abruptio

Death Anxiety r/t threat of mortality associated with bleeding
Fear r/t threat to self and fetus
Ineffective Health maintenance r/t deficient knowledge regarding treatment and control of hypertension associated with placenta abruptio
Acute Pain: abdominal/back r/t premature separation of placenta before delivery
Risk for Bleeding: Risk factor: placenta abruptio
Risk for deficient Fluid volume: Risk factor: maternal blood loss
Risk for Powerlessness: Risk factors: complications of pregnancy and unknown outcome
Risk for Shock: Risk factor: hypovolemia
Risk for Spiritual distress: Risk factor: fear from unknown outcome of pregnancy

Placenta Previa

Death Anxiety r/t threat of mortality associated with bleeding
Disturbed Body Image r/t negative feelings about body and reproductive ability, feelings of helplessness
Ineffective Coping r/t threat to self and fetus
Decreased Diversional activity engagement r/t long-term hospitalization
Interrupted Family processes r/t maternal bed rest, hospitalization
Fear r/t threat to self and fetus, unknown future
Impaired Home maintenance r/t maternal bed rest, hospitalization
Impaired physical Mobility r/t medical protocol, maternal bed rest
Ineffective Role performance r/t maternal bed rest, hospitalization
Situational low Self-Esteem r/t situational crisis
Spiritual distress r/t inability to participate in usual religious rituals, situational crisis
Risk for Bleeding: Risk factor: placenta previa
Risk for Constipation: Risk factors: bed rest, pregnancy
Risk for deficient Fluid volume: Risk factor: maternal blood loss
Risk for imbalanced Fluid volume: Risk factor: maternal blood loss
Risk for Injury: fetal and maternal: Risk factors: threat to uteroplacental perfusion, hemorrhage
Risk for disturbed Maternal–Fetal dyad: Risk factor: complication of pregnancy
Risk for impaired Parenting: Risk factors: maternal bed rest, hospitalization
Risk for ineffective peripheral Tissue Perfusion: placental: Risk factors: dilation of cervix, loss of placental implantation site
Risk for Powerlessness: Risk factors: complications of pregnancy, unknown outcome
Risk for Shock: Risk factor: hypovolemia

Plantar Fasciitis

Impaired Comfort r/t inflamed structures of feet
Impaired physical Mobility r/t discomfort
Acute Pain r/t inflammation
Chronic Pain r/t inflammation

Pleural Effusion

Ineffective Breathing pattern r/t pain
Excess Fluid volume r/t compromised regulatory mechanisms; heart, liver, or kidney failure
Acute Pain r/t inflammation, fluid accumulation

Pleural Friction Rub

Ineffective Breathing pattern r/t pain
Acute Pain r/t inflammation, fluid accumulation

Pleural Tap

See Pleural Effusion

Pleurisy

Ineffective Breathing pattern r/t pain
Impaired Gas exchange r/t ventilation perfusion imbalance
Acute Pain r/t pressure on pleural nerve endings associated with fluid accumulation or inflammation
Impaired Walking r/t activity intolerance, inability to "catch breath"
Risk for ineffective Airway clearance: Risk factors: increased secretions, ineffective cough because of pain

Risk for Infection: Risk factor: exposure to pathogens

PMS (Premenstrual Syndrome)

Fatigue r/t hormonal changes
Excess Fluid volume r/t alterations of hormonal levels inducing fluid retention
Deficient Knowledge r/t methods to deal with and prevent syndrome
Acute Pain r/t hormonal stimulation of gastrointestinal structures
Risk for Powerlessness: Risk factors: lack of knowledge and ability to deal with symptoms
Risk for impaired Resilience: Risk factor: PMS symptoms
Readiness for enhanced Communication: willingness to express thoughts and feelings about PMS
Readiness for enhanced Health management: desire for information to manage and prevent symptoms

PND (Paroxysmal Nocturnal Dyspnea)

Anxiety r/t inability to breathe during sleep
Ineffective Breathing pattern r/t increase in carbon dioxide levels, decrease in oxygen levels
Insomnia r/t suffocating feeling from fluid in lungs on awakening from sleep
Sleep deprivation r/t inability to breathe during sleep
Risk for decreased Cardiac tissue perfusion: Risk factor: hypoxia
Risk for Powerlessness: Risk factor: inability to control nocturnal dyspnea
Readiness for enhanced Sleep: expresses willingness to learn measures to enhance sleep

Pneumonectomy

See Thoracotomy

Pneumonia

Activity intolerance r/t imbalance between oxygen supply and demand
Ineffective Airway clearance r/t inflammation and presence of secretions
Impaired Gas exchange r/t decreased functional lung tissue
Ineffective Health management r/t deficient knowledge regarding self-care and treatment of disease
Imbalanced Nutrition: less than body requirements r/t loss of appetite
Impaired Oral Mucous Membrane integrity r/t dry mouth from mouth breathing, decreased fluid intake
Ineffective Thermoregulation r/t infectious process
Risk for acute Confusion: Risk factors: underlying illness, hypoxia
Risk for deficient Fluid volume: Risk factor: inadequate intake of fluids
Risk for Vascular Trauma: Risk factor: irritation from intravenous antibiotics
See Respiratory Infections, Acute Childhood

Pneumothorax

Fear r/t threat to own well-being, difficulty breathing
Impaired Gas exchange r/t ventilation-perfusion imbalance, decreased functional lung tissue
Acute Pain r/t recent injury, coughing, deep breathing
Risk for Injury: Risk factor: possible complications associated with closed chest drainage system
See Chest Tubes

Poisoning, Risk for

Risk for Poisoning (See **Poisoning,** risk for, Section III)

Poliomyelitis

See Paralysis

Polydipsia

See Diabetes Mellitus

Polyphagia

Readiness for enhanced Nutrition: knowledge of appropriate diet for diabetes
See Diabetes Mellitus

Polyuria

See Diabetes Mellitus

Postoperative Care

See Surgery, Postoperative Care

Postpartum Depression

Anxiety r/t new responsibilities of parenting
Disturbed Body Image r/t normal postpartum recovery
Ineffective Childbearing process r/t depression/lack of support system
Ineffective Coping r/t hormonal changes
Fatigue r/t childbirth, postpartum state, crying child
Risk-prone Health behavior r/t lack of support systems
Impaired Home maintenance r/t fatigue, care of newborn
Hopelessness r/t stress, exhaustion
Deficient Knowledge r/t lifestyle changes
Impaired Parenting r/t hormone-induced depression
Ineffective Role performance r/t new responsibilities of parenting
Sexual dysfunction r/t fear of another pregnancy, postpartum pain, lochia flow
Sleep deprivation r/t environmental stimulation of newborn
Impaired Social interaction r/t change in role functioning
Risk for disturbed personal Identity: Risk factor: role change/depression/inability to cope
Risk for situational low Self-Esteem: Risk factor: decreased power over feelings of sadness
Risk for Spiritual distress: Risk factors: altered relationships, social isolation
Readiness for enhanced Hope: expresses desire to enhance hope and interconnectedness with others
See Depression (Major Depressive Disorder)

Postpartum Hemorrhage

Activity intolerance r/t anemia from loss of blood
Death Anxiety r/t threat of mortality associated with bleeding
Disturbed Body Image r/t loss of ideal childbirth
Insufficient Breast Milk Production r/t fluid volume depletion
Interrupted Breastfeeding r/t separation from infant for medical treatment
Decreased Cardiac output r/t hypovolemia
Fear r/t threat to self, unknown future
Deficient Fluid volume r/t uterine atony, loss of blood
Impaired Home maintenance r/t lack of stamina

Deficient Knowledge r/t lack of exposure to situation
Acute Pain r/t nursing and medical interventions to control bleeding
Ineffective peripheral Tissue Perfusion r/t hypovolemia
Risk for Bleeding: Risk factor: postpartum complications
Risk for impaired Childbearing: Risk factor: postpartum complication
Risk for imbalanced Fluid volume: Risk factor: maternal blood loss
Risk for Infection: Risk factors: loss of blood, depressed immunity
Risk for impaired Parenting: Risk factor: weakened maternal condition
Risk for Powerlessness: Risk factor: acute illness
Risk for Shock: Risk factor: hypovolemia

Postpartum, Normal Care

Anxiety r/t change in role functioning, parenting
Effective Breastfeeding r/t basic breastfeeding knowledge, support of partner and health care provider
Fatigue r/t childbirth, new responsibilities of parenting, body changes
Acute Pain r/t episiotomy, lacerations, bruising, breast engorgement, headache, sore nipples, epidural or intravenous site, hemorrhoids
Sexual dysfunction r/t recent childbirth
Impaired Tissue integrity r/t episiotomy, lacerations
Sleep deprivation r/t care of infant
Impaired Urinary elimination r/t effects of anesthesia, tissue trauma
Risk for Constipation: Risk factors: hormonal effects on smooth muscles, fear of straining with defecation, effects of anesthesia
Risk for Infection: Risk factors: tissue trauma, blood loss
Readiness for enhanced family Coping: adaptation to new family member
Readiness for enhanced Hope: desire to increase hope
Readiness for enhanced Parenting: expresses willingness to enhance parenting skills

Post-Trauma Syndrome

Post-Trauma syndrome (See **Post-Trauma** syndrome, Section III)

Post-Trauma Syndrome, Risk for

Risk for Post-Trauma syndrome (See **Post-Trauma** syndrome, risk for, Section III)

Post-Traumatic Stress Disorder (PTSD)

See PTSD (Post-Traumatic Stress Disorder)

Potassium, Increase/Decrease

See Hyperkalemia; Hypokalemia

Power/Powerlessness

Powerlessness (See **Powerlessness,** Section III)
Risk for Powerlessness (See **Powerlessness,** risk for, Section III)
Readiness for enhanced Power (See **Power,** readiness for enhanced, Section III)

Preeclampsia

See PIH (Pregnancy-Induced Hypertension/Preeclampsia)

Pregnancy, Cardiac Disorders

See Cardiac Disorders in Pregnancy

Pregnancy-Induced Hypertension/Preeclampsia (PIH)

See PIH (Pregnancy-Induced Hypertension/Preeclampsia)

Pregnancy Loss

Anxiety r/t threat to role functioning, health status, situational crisis
Compromised family Coping r/t lack of support by significant other because of personal suffering
Ineffective Coping r/t situational crisis
Grieving r/t loss of pregnancy, fetus, or child
Acute Pain r/t surgical intervention
Ineffective Role performance r/t inability to assume parenting role
Ineffective Sexuality pattern r/t self-esteem disturbance resulting from pregnancy loss and anxiety about future pregnancies
Chronic Sorrow r/t loss of a fetus or child
Spiritual distress r/t intense suffering from loss of child
Risk for deficient Fluid volume: Risk factor: blood loss
Risk for complicated Grieving: Risk factor: loss of pregnancy
Risk for Infection: Risk factor: retained products of conception
Risk for Powerlessness: Risk factor: situational crisis
Risk for ineffective Relationship: Risk factor: poor communication skills in dealing with the loss
Risk for Spiritual distress: Risk factor: intense suffering
Readiness for enhanced Communication: willingness to express feelings and thoughts about loss
Readiness for enhanced Hope: expresses desire to enhance hope
Readiness for enhanced Spiritual well-being: desire for acceptance of loss

Pregnancy, Normal

Anxiety r/t unknown future, threat to self secondary to pain of labor
Disturbed Body Image r/t altered body function and appearance
Interrupted Family processes r/t developmental transition of pregnancy
Fatigue r/t increased energy demands
Fear r/t labor and delivery
Deficient Knowledge r/t primiparity
Nausea r/t hormonal changes of pregnancy
Imbalanced Nutrition: less than body requirements r/t growing fetus, nausea
Imbalanced Nutrition: more than body requirements r/t deficient knowledge regarding nutritional needs of pregnancy
Sleep deprivation r/t uncomfortable pregnancy state
Impaired Urinary elimination r/t frequency caused by increased pelvic pressure and hormonal stimulation
Risk for Constipation: Risk factor: pregnancy
Risk for Sexual dysfunction: Risk factors: altered body function, self-concept, body image with pregnancy
Readiness for enhanced Childbearing process: appropriate prenatal care
Readiness for enhanced family Coping: satisfying partner relationship, attention to gratification of needs, effective adaptation to developmental tasks of pregnancy
Readiness for enhanced Family processes: family adapts to change
Readiness for enhanced Health management: seeks information for prenatal self-care
Readiness for enhanced Nutrition: desire for knowledge of appropriate nutrition during pregnancy
Readiness for enhanced Parenting: expresses willingness to enhance parenting skills
Readiness for enhanced Relationship: meeting developmental goals associated with pregnancy
Readiness for enhanced Spiritual well-being: new role as parent
See Discomforts of Pregnancy

Premature Dilation of the Cervix (Incompetent Cervix)

Ineffective Activity planning r/t unrealistic perception of events
Ineffective Coping r/t bed rest, threat to fetus
Decreased Diversional activity engagement r/t bed rest
Fear r/t potential loss of infant
Grieving r/t potential loss of infant
Deficient Knowledge r/t treatment regimen, prognosis for pregnancy
Impaired physical Mobility r/t imposed bed rest to prevent preterm birth
Powerlessness r/t inability to control outcome of pregnancy
Ineffective Role performance r/t inability to continue usual patterns of responsibility
Situational low Self-Esteem r/t inability to complete normal pregnancy
Sexual dysfunction r/t fear of harm to fetus
Impaired Social interaction r/t bed rest
Risk for Infection: Risk factor: invasive procedures to prevent preterm birth
Risk for Injury: fetal: Risk factors: preterm birth, use of anesthetics
Risk for Injury: maternal: Risk factor: surgical procedures to prevent preterm birth (e.g., cerclage)
Risk for impaired Resilience: Risk factor: complication of pregnancy
Risk for Spiritual distress: Risk factors: physical/psychological stress

Premature Infant (Child)

Insufficient Breast Milk Production r/t ineffective sucking, latching on of the infant
Impaired Gas exchange r/t effects of cardiopulmonary insufficiency
Disorganized Infant behavior r/t prematurity
Insomnia r/t noisy and noxious intensive care environment
Neonatal Hyperbilirubinemia r/t infant experiences difficulty making transition to extrauterine life
Imbalanced Nutrition: less than body requirements r/t delayed or understimulated rooting reflex, easy fatigue during feeding, diminished endurance
Impaired Swallowing r/t decreased or absent gag reflex, fatigue
Ineffective Thermoregulation r/t large body surface/weight ratio, immaturity of thermal regulation, state of prematurity
Risk for delayed Development: Risk factor: prematurity
Risk for Infection: Risk factors: inadequate, immature, or undeveloped acquired immune response
Risk for Injury: Risk factor: prolonged mechanical ventilation, retinopathy of prematurity (ROP) secondary to 100% oxygen environment
Risk for Neonatal Hyperbilirubinemia: Risk factor: late preterm birth
Readiness for enhanced organized Infant behavior: use of some self-regulatory measures

Premature Infant (Parent)

Ineffective Breastfeeding r/t disrupted establishment of effective pattern secondary to prematurity or insufficient opportunities
Decisional Conflict r/t support system deficit, multiple sources of information
Compromised family Coping r/t disrupted family roles and disorganization, prolonged condition exhausting supportive capacity of significant persons
Ineffective infant Feeding dynamics r/t insufficient knowledge of nutritional needs
Grieving r/t loss of perfect child possibly leading to complicated grieving
Complicated Grieving (prolonged) r/t unresolved conflicts
Parental Role conflict r/t expressed concerns, expressed inability to care for child's physical, emotional, or developmental needs
Chronic Sorrow r/t threat of loss of a child, prolonged hospitalization
Spiritual distress r/t challenged belief or value systems regarding moral or ethical implications of treatment plans
Risk for impaired Attachment: Risk factors: separation, physical barriers, lack of privacy
Risk for disturbed Maternal–Fetal dyad: Risk factor: complication of pregnancy
Risk for Powerlessness: Risk factor: inability to control situation
Risk for impaired Resilience: Risk factor: premature infant
Risk for Spiritual distress: Risk factor: challenged belief or value systems regarding moral or ethical implications of treatment plans

Readiness for enhanced Family process: adaptation to change associated with premature infant
See Child with Chronic Condition; Hospitalized Child

Premature Rupture of Membranes

Anxiety r/t threat to infant's health status
Disturbed Body Image r/t inability to carry pregnancy to term
Ineffective Coping r/t situational crisis
Grieving r/t potential loss of infant
Situational low Self-Esteem r/t inability to carry pregnancy to term
Risk for ineffective Childbearing process: Risk factor: complication of pregnancy
Risk for Infection: Risk factor: rupture of membranes
Risk for Injury: fetal: Risk factor: risk of premature birth

Premenstrual Tension Syndrome (PMS)

See PMS (Premenstrual Tension Syndrome)

Prenatal Care, Normal

Readiness for enhanced Childbearing process: appropriate prenatal lifestyle
Readiness for enhanced Knowledge: appropriate prenatal care
Readiness for enhanced Spiritual well-being: new role as parent
See Pregnancy, Normal

Prenatal Testing

Anxiety r/t unknown outcome, delayed test results
Acute Pain r/t invasive procedures
Risk for Infection: Risk factor: invasive procedures during amniocentesis or chorionic villus sampling
Risk for Injury: Risk factor: invasive procedures

Preoperative Teaching

See Surgery, Preoperative Care

Pressure Ulcer

Impaired bed Mobility r/t intolerance to activity, pain, cognitive impairment, depression, severe anxiety, severity of illness
Imbalanced Nutrition: less than body requirements r/t limited access to food, inability to absorb nutrients because of biological factors, anorexia
Acute Pain r/t tissue destruction, exposure of nerves
Impaired Skin integrity: stage I or II pressure ulcer r/t physical immobility, mechanical factors, altered circulation, skin irritants, excessive moisture
Impaired Tissue integrity: stage III or IV pressure ulcer r/t altered circulation, impaired physical mobility, excessive moisture
Risk for Infection: Risk factors: physical immobility, mechanical factors (shearing forces, pressure, restraint, altered circulation, skin irritants, excessive moisture, open wound)
Risk for Pressure ulcer (See **Pressure** ulcer, risk for, Section III)

Preterm Labor

Anxiety r/t threat to fetus, change in role functioning, change in environment and interaction patterns,

use of tocolytic drugs
Ineffective Coping r/t situational crisis, preterm labor
Decreased Diversional activity engagement r/t long-term hospitalization
Grieving r/t loss of idealized pregnancy, potential loss of fetus
Impaired Home maintenance r/t medical restrictions
Impaired physical Mobility r/t medically imposed restrictions
Ineffective Role performance r/t inability to carry out normal roles secondary to bed rest or hospitalization, change in expected course of pregnancy
Situational low Self-Esteem r/t threatened ability to carry pregnancy to term
Sexual dysfunction r/t actual or perceived limitation imposed by preterm labor and/or prescribed treatment, separation from partner because of hospitalization
Sleep deprivation r/t change in usual pattern secondary to contractions, hospitalization, treatment regimen
Impaired Social interaction r/t prolonged bed rest or hospitalization
Risk for Injury: fetal: Risk factors: premature birth, immature body systems
Risk for Injury: maternal: Risk factor: use of tocolytic drugs
Risk for Powerlessness: Risk factor: lack of control over preterm labor
Risk for Vascular Trauma: Risk factor: intravenous medication
Readiness for enhanced Childbearing process: appropriate prenatal lifestyle
Readiness for enhanced Comfort: expresses desire to enhance relaxation
Readiness for enhanced Communication: willingness to discuss thoughts and feelings about situation

Problem-Solving Dysfunction

Defensive Coping r/t situational crisis
Impaired Emancipated Decision-Making r/t problem-solving dysfunction
Risk for chronic low Self-Esteem: Risk factor: repeated failures
Readiness for enhanced Communication: willing to share ideas with others
Readiness for enhanced Relationship: shares information and ideas between partners
Readiness for enhanced Resilience: identifies available resources
Readiness for enhanced Spiritual well-being: desires to draw on inner strength and find meaning and purpose to life

Projection

Anxiety r/t threat to self-concept
Defensive Coping r/t inability to acknowledge that own behavior may be a problem, blaming others
Chronic low Self-Esteem r/t failure
Impaired Social interaction r/t self-concept disturbance, confrontational communication style
Risk for Loneliness: Risk factor: blaming others for problems
See Paranoid Personality Disorder

Prolapsed Umbilical Cord

Fear r/t threat to fetus, impending surgery
Ineffective peripheral Tissue Perfusion: fetal r/t interruption in umbilical blood flow
Risk for ineffective Cerebral tissue perfusion: fetal: Risk factor: cord compression
Risk for Injury: Risk factor: (maternal) emergency surgery
See TURP (Transurethral Resection of the Prostate)

Prostatic Hypertrophy

Ineffective Health maintenance r/t deficient knowledge regarding self-care and prevention of complications
Sleep deprivation r/t nocturia
Urinary Retention r/t obstruction
Risk for Infection: Risk factors: urinary residual after voiding, bacterial invasion of bladder
See BPH (Benign Prostatic Hypertrophy)

Prostatitis

Impaired Comfort r/t inflammation
Ineffective Health maintenance r/t deficient knowledge regarding treatment
Urge urinary Incontinence r/t irritation of bladder
Ineffective Protection r/t depressed immune system

Pruritus

Impaired Comfort r/t inflammation of skin causing itching
Deficient Knowledge r/t methods to treat and prevent itching
Risk for impaired Skin integrity: Risk factors: scratching, dry skin

Psoriasis

Disturbed Body Image r/t lesions on body
Impaired Comfort r/t irritated skin
Ineffective Health maintenance r/t deficient knowledge regarding treatment modalities
Powerlessness r/t lack of control over condition with frequent exacerbations and remissions
Impaired Skin integrity r/t lesions on body

Psychosis

Ineffective Activity planning r/t compromised ability to process information
Ineffective Health maintenance r/t cognitive impairment, ineffective individual and family coping
Self-Neglect r/t mental disorder
Impaired individual Resilience r/t psychological disorder
Situational low Self-Esteem r/t excessive use of defense mechanisms (e.g., projection, denial, rationalization)
Risk for disturbed personal Identity: Risk factor: psychosis
Impaired Mood regulation r/t psychosis
Risk for Post-Trauma syndrome: Risk factor: diminished ego strength
See Schizophrenia

PTCA (Percutaneous Transluminal Coronary Angioplasty)

See Angioplasty, Coronary

PTSD (Posttraumatic Stress Disorder)

Anxiety r/t exposure to internal or external cues that symbolize or resemble an aspect of the traumatic event
Chronic Sorrow r/t chronic disability (e.g., physical, mental)
Death Anxiety r/t psychological stress associated with traumatic event
Ineffective Breathing pattern r/t hyperventilation associated with anxiety
Ineffective Coping r/t extreme anxiety
Ineffective Impulse control r/t thinking of initial trauma experience
Insomnia r/t recurring nightmares
Post-Trauma syndrome r/t exposure to a traumatic event
Sleep deprivation r/t nightmares interrupting sleep associated with traumatic event
Spiritual distress r/t feelings of detachment or estrangement from others
Risk for impaired Resilience: Risk factor: chronicity of existing crisis
Risk for Powerlessness: Risk factors: flashbacks, reliving event
Risk for ineffective Relationship: Risk factor: stressful life events
Risk for self- or other-directed Violence: Risk factors: fear of self or others
Readiness for enhanced Comfort: expresses desire to enhance relaxation

Readiness for enhanced Communication: willingness to express feelings and thoughts
Readiness for enhanced Spiritual well-being: desire for harmony after stressful event

Pulmonary Edema

Anxiety r/t fear of suffocation
Ineffective Airway clearance r/t presence of tracheobronchial secretions
Decreased Cardiac output r/t increased preload, infective forward perfusion
Impaired Gas exchange r/t extravasation of extravascular fluid in lung tissues and alveoli
Ineffective Health maintenance r/t deficient knowledge regarding treatment regimen
Sleep deprivation r/t inability to breathe
Risk for acute Confusion: Risk factor: hypoxia
See Heart Failure

Pulmonary Embolism (PE)

Anxiety r/t fear of suffocation
Decreased Cardiac output r/t right ventricular failure secondary to obstructed pulmonary artery
Fear r/t severe pain, possible death
Impaired Gas exchange r/t altered blood flow to alveoli secondary to embolus
Deficient Knowledge r/t activities to prevent embolism, self-care after diagnosis of embolism
Acute Pain r/t biological injury, lack of oxygen to cells
Ineffective peripheral Tissue Perfusion r/t deep vein thrombus formation
See Anticoagulant Therapy

Pulmonary Stenosis

See Congenital Heart Disease/Cardiac Anomalies

Pulse Deficit

Risk for Decreased Cardiac output r/t dysrhythmia
See Dysrhythmia

Pulse Oximetry

Readiness for enhanced Knowledge: information about treatment regimen
See Hypoxia

Pulse Pressure, Increased

See Intracranial Pressure, Increased

Pulse Pressure, Narrowed

See Shock, Hypovolemic

Pulses, Absent or Diminished Peripheral

Ineffective peripheral Tissue Perfusion r/t interruption of arterial flow
Risk for Peripheral Neurovascular dysfunction: Risk factors: fractures, mechanical compression, orthopedic surgery trauma, immobilization, burns, vascular obstruction

Purpura

See Clotting Disorder

Pyelonephritis

Ineffective Health maintenance r/t deficient knowledge regarding self-care, treatment of disease, prevention of further urinary tract infections
Acute Pain r/t inflammation and irritation of urinary tract
Disturbed Sleep pattern r/t urinary frequency
Impaired Urinary elimination r/t irritation of urinary tract

Pyloric Stenosis

Imbalanced Nutrition: less than body requirements r/t vomiting secondary to pyloric sphincter obstruction
Acute Pain r/t abdominal fullness
Risk for decreased Fluid volume: Risk factors: vomiting, dehydration
See Hospitalized Child

Pyloromyotomy (Pyloric Stenosis Repair)

See Surgery Preoperative Care, Perioperative Care, Postoperative Care

List of Nursing Diagnosis by Letter

R

RA (Rheumatoid Arthritis)	Rabies	Radial Nerve Dysfunction
Radiation Therapy	Radical Neck Dissection	Rage
Rape-Trauma Syndrome	Rash	Rationalization
Rats, Rodents in Home	Raynaud's Disease	RDS (Respiratory Distress Syndrome)
Rectal Fullness	Rectal Lump	Rectal Pain/Bleeding
Rectal Surgery	Rectocele Repair	Reflex Incontinence
Regression	Regretful	Rehabilitation
Relationship	Relaxation Techniques	Religiosity
Religious Concerns	Relocation Stress Syndrome	Renal Failure
Renal Failure Acute/Chronic, Child	Renal Failure, Nonoliguric	Respiratory Acidosis
Respiratory Conditions of the Neonate (Respiratory Distress Syndrome [RDS], Meconium Aspiration, Diaphragmatic Hernia)	Respiratory Distress	Respiratory Distress Syndrome (RDS)
Respiratory Infections, Acute Childhood (Croup, Epiglottitis, Pertussis, Pneumonia, Respiratory Syncytial Virus)	Respiratory Syncytial Virus	Restless Leg Syndrome
Retinal Detachment	Retinopathy, Diabetic	Retinopathy of Prematurity (ROP)
Rh Factor Incompatibility	Rhabdomyolysis	Rheumatic Fever
Rheumatoid Arthritis (RA)	Rib Fracture	Ridicule of Others
Ringworm of Body	Ringworm of Nails	Ringworm of Scalp
Roaches, Invasion of Home with	Role Performance, Altered	ROP (Retinopathy of Prematurity)
RSV (Respiratory Syncytial Virus)	Rubella	Rubor of Extremities
Ruptured Disk		

R

RA (Rheumatoid Arthritis)

See Rheumatoid Arthritis (RA)

Rabies

Ineffective Health maintenance r/t deficient knowledge regarding care of wound, isolation, and observation of infected animal
Acute Pain r/t multiple immunization injections
Risk for ineffective Cerebral tissue perfusion: Risk factor: rabies virus

Radial Nerve Dysfunction

Acute Pain r/t trauma to hand or arm
See Neuropathy, Peripheral

Radiation Therapy

Activity intolerance r/t fatigue from possible anemia
Disturbed Body Image r/t change in appearance, hair loss
Diarrhea r/t irradiation effects
Fatigue r/t malnutrition from lack of appetite, nausea, and vomiting; side effect of radiation
Deficient Knowledge r/t what to expect with radiation therapy, how to do self-care
Nausea r/t side effects of radiation
Imbalanced Nutrition: **less than body requirements** r/t anorexia, nausea, vomiting, irradiation of areas of pharynx and esophagus
Impaired Oral Mucous Membrane integrity r/t irradiation effects
Ineffective Protection r/t suppression of bone marrow
Risk for Dry Mouth: Risk factor: possible side effect of radiation treatments
Risk for impaired Oral Mucous Membrane integrity: Risk factor: radiation treatments
Risk for Powerlessness: Risk factors: medical treatment and possible side effects
Risk for impaired Resilience: Risk factor: radiation treatment
Risk for impaired Skin integrity: Risk factor: irradiation effects
Risk for Spiritual distress: Risk factors: radiation treatment, prognosis

Radical Neck Dissection

See Laryngectomy

Rage

Risk-prone Health behavior r/t multiple stressors
Labile Emotional Control r/t psychiatric disorders and mood disorders
Impaired individual Resilience r/t poor impulse control
Stress overload r/t multiple coexisting stressors

Risk for Self-Mutilation: Risk factor: command hallucinations
Risk for Suicide: Risk factor: desire to kill self
Risk for other-directed Violence: Risk factors: panic state, manic excitement, organic brain syndrome

Rape-Trauma Syndrome

Rape-Trauma syndrome (See **Rape-Trauma** syndrome, Section III)
Chronic Sorrow r/t forced loss of virginity
Risk for ineffective Childbearing process r/t to trauma and violence
Risk for Post-Trauma syndrome: Risk factor: trauma or violence associated with rape
Risk for Powerlessness: Risk factor: inability to control thoughts about incident
Risk for ineffective Relationship: Risk factor: trauma and violence
Risk for chronic low Self-Esteem: Risk factors: perceived lack of respect from others, feeling violated
Risk for Spiritual distress: Risk factor: forced loss of virginity

Rash

Impaired Comfort r/t pruritus
Impaired Skin integrity r/t mechanical trauma
Risk for Infection: Risk factors: traumatized tissue, broken skin
Risk for Latex Allergic reaction: Risk factor: allergy to products associated with latex

Rationalization

Defensive Coping r/t situational crisis, inability to accept blame for consequences of own behavior
Ineffective Denial r/t fear of consequences, actual or perceived loss
Impaired individual Resilience r/t psychological disturbance
Risk for Post-Trauma syndrome: Risk factor: survivor's role in event
Readiness for enhanced Communication: expresses desire to share thoughts and feelings
Readiness for enhanced Spiritual well-being: possibility of seeking harmony with self, others, higher power, God

Rats, Rodents in Home

Impaired Home maintenance r/t lack of knowledge, insufficient finances
Risk for Allergic reaction: Risk factor: repeated exposure to environmental contamination
See Filthy Home Environment

Raynaud's Disease

Deficient Knowledge r/t lack of information about disease process, possible complications, self-care needs regarding disease process and medication
Ineffective peripheral Tissue Perfusion r/t transient reduction of blood flow
Acute Pain r/t transient reduction in blood flow

RDS (Respiratory Distress Syndrome)

See Respiratory Conditions of the Neonate

Rectal Fullness

Chronic functional Constipation r/t decreased activity level, decreased fluid intake, inadequate fiber in diet, decreased peristalsis, side effects of antidepressant or antipsychotic therapy
Risk for chronic functional Constipation: Risk factor: habitual denial of or ignoring urge to defecate

Rectal Lump

See Hemorrhoids

Rectal Pain/Bleeding

Chronic functional Constipation r/t pain on defecation
Deficient Knowledge r/t possible causes of rectal bleeding, pain, treatment modalities
Acute Pain r/t pressure of defecation
Risk for Bleeding: Risk factor: rectal disease

Rectal Surgery

See Hemorrhoidectomy

Rectocele Repair

Chronic functional Constipation r/t painful defecation
Ineffective Health maintenance r/t deficient knowledge of postoperative care of surgical site, dietary measures, exercise to prevent constipation
Acute Pain r/t surgical procedure
Urinary retention r/t edema from surgery
Risk for Bleeding: Risk factor: surgery
Risk for Surgical Site Infection: Risk factors: surgical procedure, possible contamination of area with feces

Reflex Incontinence

Reflex urinary Incontinence (See **Incontinence,** urinary, reflex, Section III)

Regression

Anxiety r/t threat to or change in health status
Defensive Coping r/t denial of obvious problems, weaknesses
Self-Neglect r/t functional impairment
Powerlessness r/t health care environment
Impaired individual Resilience r/t psychological disturbance
Ineffective Role performance r/t powerlessness over health status
See Hospitalized Child; Separation Anxiety

Regretful

Anxiety r/t situational or maturational crises
Death Anxiety r/t feelings of not having accomplished goals in life
Risk for Spiritual distress: Risk factor: inability to forgive

Rehabilitation

Ineffective Coping r/t loss of normal function
Impaired physical Mobility r/t injury, surgery, psychosocial condition warranting rehabilitation
Self-Care deficit: **specify** r/t impaired physical mobility
Risk for Falls: Risk factor: physical deconditioning
Readiness for enhanced Comfort: expresses desire to enhance feeling of comfort

Readiness for enhanced Self-Concept: accepts strengths and limitations
Readiness for enhanced Health Management: expresses desire to manage rehabilitation

Relationship

Ineffective Relationship (See ineffective **Relationship,** Section III)
Readiness for enhanced Relationship (See Risk for enhanced **Relationship**, Section III)

Relaxation Techniques

Anxiety r/t situational crisis
Readiness for enhanced Comfort: expresses desire to enhance relaxation
Readiness for enhanced Health management: desire to manage illness
Readiness for enhanced Religiosity: requests religious materials or experiences
Readiness for enhanced Resilience: desire to enhance resilience
Readiness for enhanced Self-Concept: willingness to enhance self-concept
Readiness for enhanced Spiritual well-being: seeking comfort from higher power

Religiosity

Impaired Religiosity (See **Religiosity,** impaired, Section III)
Risk for impaired Religiosity (See **Religiosity,** impaired, risk for, Section III)
Readiness for enhanced Religiosity (See **Religiosity,** readiness for enhanced, Section III)

Religious Concerns

Spiritual distress r/t separation from religious or cultural ties
Risk for impaired Religiosity: Risk factors: ineffective support, coping, caregiving
Risk for Spiritual distress: Risk factors: physical or psychological stress
Readiness for enhanced Spiritual well-being: desire for increased spirituality

Relocation Stress Syndrome

Relocation stress syndrome (See **Relocation** stress syndrome, Section III)
Risk for Relocation stress syndrome (See **Relocation** stress syndrome, risk for, Section III)

Renal Failure

Activity intolerance r/t effects of anemia, heart failure
Death Anxiety r/t unknown outcome of disease
Decreased Cardiac output r/t effects of heart failure, elevated potassium levels interfering with conduction system
Impaired Comfort r/t pruritus
Ineffective Coping r/t depression resulting from chronic disease
Fatigue r/t effects of chronic uremia and anemia
Excessive Fluid volume r/t decreased urine output, sodium retention, inappropriate fluid Intake
Ineffective Health management r/t complexity of health care regimen, inadequate number of cues to action, perceived barriers, powerlessness
Imbalanced Nutrition: less than body requirements r/t anorexia, nausea, vomiting, altered taste sensation, dietary restrictions
Impaired Oral Mucous Membrane integrity r/t irritation from nitrogenous waste products
Chronic Sorrow r/t chronic illness
Spiritual distress r/t dealing with chronic illness
Impaired urinary Elimination r/t effects of disease, need for dialysis
Risk for Electrolyte imbalance: Risk factor: renal dysfunction

Risk for Infection: Risk factor: altered immune functioning
Risk for Injury: Risk factors: bone changes, neuropathy, muscle weakness
Risk for impaired Oral Mucous Membrane integrity: Risk factors: dehydration, effects of uremia
Risk for Powerlessness: Risk factor: chronic illness
Risk for Sepsis: Risk factor: infection

Renal Failure Acute/Chronic, Child

Disturbed Body Image r/t growth retardation, bone changes, visibility of dialysis access devices (shunt, fistula), edema
Decreased Diversional acitivity engagement r/t immobility during dialysis
See Child with Chronic Condition; Hospitalized Child

Renal Failure, Nonoliguric

Anxiety r/t change in health status
Risk for deficient Fluid volume: Risk factor: loss of large volumes of urine
See Renal Failure

Respiratory Acidosis

See Acidosis, Respiratory

Respiratory Conditions of the Neonate (Respiratory Distress Syndrome [RDS], Meconium Aspiration, Diaphragmatic Hernia)

Ineffective Airway clearance r/t sequelae of attempts to breathe in utero resulting in meconium aspiration
Fatigue r/t increased energy requirements and metabolic demands
Impaired Gas exchange r/t decreased surfactant, immature lung tissue
Dysfunctional Ventilator weaning response r/t immature respiratory system
Risk for Infection: Risk factors: tissue destruction or irritation as a result of aspiration of meconium fluid
See Bronchopulmonary Dysplasia; Hospitalized Child; Premature Infant, Child

Respiratory Distress

See Dyspnea

Respiratory Distress Syndrome (RDS)

See Respiratory Conditions of the Neonate

Respiratory Infections, Acute Childhood (Croup, Epiglottitis, Pertussis, Pneumonia, Respiratory Syncytial Virus)

Activity intolerance r/t generalized weakness, dyspnea, fatigue, poor oxygenation
Ineffective Airway clearance r/t excess tracheobronchial secretions
Ineffective Breathing pattern r/t inflamed bronchial passages, coughing
Fear r/t oxygen deprivation, difficulty breathing
Deficient Fluid volume r/t insensible losses (fever, diaphoresis), inadequate oral fluid intake
Impaired Gas exchange r/t insufficient oxygenation as a result of inflammation or edema of epiglottis,

larynx, bronchial passages
Imbalanced Nutrition: less than body requirements r/t anorexia, fatigue, generalized weakness, poor sucking and breathing coordination, dyspnea
Ineffective Thermoregulation r/t infectious process
Risk for Aspiration: Risk factors: inability to coordinate breathing, coughing, sucking
Risk for Infection: **transmission to others:** Risk factor: virulent infectious organisms
Risk for Injury (to pregnant others): Risk factors: exposure to aerosolized medications (e.g., ribavirin, pentamidine), resultant potential fetal toxicity
Risk for Suffocation: Risk factors: inflammation of larynx, epiglottis
See Hospitalized Child

Respiratory Syncytial Virus

See Respiratory Infections, Acute Childhood

Restless Leg Syndrome

Disturbed Sleep pattern r/t leg discomfort during sleep relieved by frequent leg movement
Chronic Pain r/t leg discomfort
See Stress

Retinal Detachment

Anxiety r/t change in vision, threat of loss of vision
Deficient Knowledge r/t symptoms, need for early intervention to prevent permanent damage
Vision Loss r/t impaired visual acuity
Risk for impaired Home maintenance: Risk factors: postoperative care, activity limitations, care of affected eye
Risk for impaired Resilience: Risk factor: possible loss of vision
See Vision Impairment

Retinopathy, Diabetic

See Diabetic Retinopathy

Retinopathy of Prematurity (ROP)

Risk for Injury: Risk factors: prolonged mechanical ventilation, ROP secondary to 100% oxygen environment
See Retinal Detachment

Rh Factor Incompatibility

Anxiety r/t unknown outcome of pregnancy
Neonatal Hyperbilirubinemia r/t Rh factor incompatibility
Deficient Knowledge r/t treatment regimen from lack of experience with situation
Powerlessness r/t perceived lack of control over outcome of pregnancy
Risk for Injury: **fetal:** Risk factors: intrauterine destruction of red blood cells, transfusions
Risk for neonatal Hyperbilirubinemia: Risk factor: Rh factor incompatibility
Readiness for enhanced Health management: prenatal care, compliance with diagnostic and treatment regimen

Rhabdomyolysis

Ineffective Coping r/t seriousness of condition
Impaired physical Mobility r/t myalgia and muscle weakness
Risk for deficient Fluid volume: Risk factor: reduced blood flow to kidneys
Risk for Shock: Risk factor: hypovolemia
Readiness for enhanced Health management: seeks information to avoid condition
See Kidney Failure

Rheumatic Fever

See Endocarditis

Rheumatoid Arthritis (RA)

Imbalanced Nutrition: **less than body requirements** r/t loss of appetite
Chronic Pain r/t joint inflammation
Disturbed Body Image r/t joint deformity and muscle atrophy
Impaired Physical Mobility r/t pain, impaired joints
Risk for impaired Resilience: Risk factor: chronic, painful, progressive disease
See Arthritis; JRA (Juvenile Rheumatoid Arthritis)

Rib Fracture

Ineffective Breathing pattern r/t fractured ribs
Acute Pain r/t movement, deep breathing
Impaired Gas exchange r/t ventilation-perfusion imbalance, decreased depth of ventilation

Ridicule of Others

Defensive Coping r/t situational crisis, psychological impairment, substance abuse
Risk for Post-Trauma syndrome: Risk factor: perception of event

Ringworm of Body

Impaired Comfort r/t pruritus
Impaired Skin integrity r/t presence of macules associated with fungus
See Itching; Pruritus

Ringworm of Nails

Disturbed Body Image r/t appearance of nails, removed nails

Ringworm of Scalp

Disturbed Body Image r/t possible hair loss (alopecia)
See Itching; Pruritus

Roaches, Invasion of Home with

Impaired Home maintenance r/t lack of knowledge, insufficient finances
See Filthy Home Environment

Role Performance, Altered

Ineffective Role performance (See **Role** performance, ineffective, Section III)

ROP (Retinopathy of Prematurity)

See Retinopathy of Prematurity (ROP)

RSV (Respiratory Syncytial Virus)

See Respiratory Infection, Acute Childhood

Rubella

See Communicable Diseases, Childhood (e.g., Measles, Mumps, Rubella, Chickenpox, Scabies, Lice, Impetigo)

Rubor of Extremities

Ineffective peripheral Tissue Perfusion r/t interruption of arterial flow
See Peripheral Vascular Disease (PVD)

Ruptured Disk

See Low Back Pain

List of Nursing Diagnosis by Letter

S

SAD (Seasonal Affective Disorder)	Sadness	Safe Sex
Safety, Childhood	Salmonella	Salpingectomy
Sarcoidosis	SBE (Self-Breast Examination)	Scabies
Scared	Schizophrenia	Sciatica
Scoliosis	Sedentary Lifestyle	Seizure Disorders, Adult
Seizure Disorders, Childhood (Epilepsy, Febrile Seizures, Infantile Spasms)	Self-Breast Examination (SBE)	Self-Care
Self-Care Deficit, Bathing	Self-Care Deficit, Dressing	Self-Care Deficit, Feeding
Self-Care Deficit, Toileting	Self-Concept	Self-Destructive Behavior
Self-Esteem, Chronic Low	Self-Esteem, Situational Low	Self-Mutilation
Senile Dementia	Separation Anxiety	Sepsis, Child
Septicemia	Service Animal	Severe Acute Respiratory Syndrome (SARS)
Sexual Dysfunction	Sexual Harassment Victim	Sexuality, Adolescent
Sexuality Pattern, Ineffective	Sexually Transmitted Disease (STD)	Shaken Baby Syndrome
Shakiness	Shame	Shingles
Shivering	Shock, Cardiogenic	Shock, Hypovolemic
Shock, Septic	Shoulder Repair	Sickle Cell Anemia/Crisis
SIDS (Sudden Infant Death Syndrome)	Sitting Problems	Situational Crisis
SJS (Stevens-Johnson Syndrome)	Skin Cancer	Skin Disorders
Skin Turgor, Change in Elasticity	Sleep	Sleep Apnea
Sleep Deprivation	Sleep Problems	Sleep Pattern, Disturbed, Parent/Child
Slurring of Speech	Small Bowel Resection	Smell, Loss of Ability to
Smoke Inhalation	Smoking Behavior	Social Interaction, Impaired
Social Isolation	Sociopathic Personality	Sodium, Decrease/Increase
Somatization Disorder	Sore Nipples, Breastfeeding	Sore Throat
Sorrow	Spastic Colon	Speech Disorders
Spina Bifida	Spinal Cord Injury	Spinal Fusion

Spiritual Distress	Spiritual Well-Being	Splenectomy
Sprains	Stable Blood Pressure, Risk for Unstable	Standing Problems
Stapedectomy	Stasis Ulcer	STD (Sexually Transmitted Disease)
STEMI (ST-Elevation Myocardial Infarction)	Stent (Coronary Artery Stent)	Sterilization Surgery
Stertorous Respirations	Stevens-Johnson Syndrome (SJS)	Stillbirth
Stoma	Stomatitis	Stool, Hard/Dry
Straining with Defecation	Strep Throat	Stress
Stress Urinary Incontinence	Stridor	Stroke
Stuttering	Subarachnoid Hemorrhage	Substance Abuse
Substance Abuse, Adolescent	Substance Abuse in Pregnancy	Substance Withdrawal
Sucking Reflex	Sudden Infant Death Syndrome (SIDS)	Suffocation, Risk for
Suicide Attempt	Support System, Inadequate	Suppression of Labor
Surgery, Perioperative Care	Surgery, Postoperative Care	Surgery, Preoperative Care
Surgical Recovery, Delayed	Surgical Site Infection	Suspected Child Abuse and Neglect (SCAN), Child
Suspected Child Abuse and Neglect (SCAN), Parent	Suspicion	Swallowing Difficulties
Syncope	Syphilis	Systemic Lupus Erythematosus

S

SAD (Seasonal Affective Disorder)

Readiness for enhanced Resilience: uses SAD lights during winter months
See Depression (Major Depressive Disorder)

Sadness

Complicated Grieving r/t actual or perceived loss
Impaired Mood regulation r/t chronic illness (See **Mood** regulation, impaired, Section III)
Spiritual distress r/t intense suffering
Risk for Powerlessness: Risk factor: actual or perceived loss
Risk for Spiritual distress: Risk factor: loss of loved one
Readiness for enhanced Communication: willingness to share feelings and thoughts
Readiness for enhanced Spiritual well-being: desire for harmony after actual or perceived loss
See Depression (Major Depressive Disorder); Major Depressive Disorder

Safe Sex

Readiness for enhanced Health management: takes appropriate precautions during sexual activity to keep from contracting sexually transmitted disease
See Sexuality, Adolescent; STD (Sexually Transmitted Disease)

Safety, Childhood

Deficient Knowledge: potential for enhanced health maintenance r/t parental knowledge and skill acquisition regarding appropriate safety measures
Risk for Aspiration (See **Aspiration,** risk for, Section III)
Risk for Injury: Risk factors: developmental age, altered home maintenance
Risk for impaired Parenting: Risk factors: lack of available and effective role model, lack of knowledge, misinformation from other family members (old wives' tales)
Risk for Poisoning: Risk factors: use of lead-based paint; presence of asbestos or radon gas; drugs not locked in cabinet; household products left in accessible area (bleach, detergent, drain cleaners, household cleaners); alcohol and perfume within reach of child; presence of poisonous plants; atmospheric pollutants
Risk for Thermal injury: Risk factor: inadequate supervision
Readiness for enhanced Childbearing process: expresses appropriate knowledge for care of child

Salmonella

Impaired Home maintenance r/t improper preparation or storage of food, lack of safety measures when caring for pet reptile
Risk for Shock: Risk factors: hypovolemia, diarrhea, sepsis
Readiness for enhanced Health management: avoiding improperly prepared or stored food, wearing gloves when handling pet reptiles or their feces
See Gastroenteritis; Gastroenteritis, Child

Salpingectomy

Decisional Conflict r/t sterilization procedure
Grieving r/t possible loss from tubal pregnancy
Risk for impaired Urinary elimination: Risk factor: trauma to ureter during surgery
See Hysterectomy; Surgery, Perioperative Care; Surgery, Postoperative Care; Surgery, Preoperative Care

Sarcoidosis

Anxiety r/t change in health status
Impaired Gas exchange r/t ventilation-perfusion imbalance
Ineffective Health maintenance r/t deficient knowledge regarding home care and medication regimen
Acute Pain r/t possible disease affecting joints
Ineffective Protection r/t immune disorder
Risk for decreased Cardiac tissue perfusion: Risk factor: dysrhythmias
Risk for impaired Skin integrity: Risk factor: immunological disorder

SBE (Self-Breast Examination)

Readiness for enhanced Health management: desires to have information about SBE
Readiness for enhanced Knowledge: SBE

Scabies

See Communicable Diseases, Childhood (e.g., Measles, Mumps, Rubella, Chickenpox, Scabies, Lice, Impetigo)

Scared

Anxiety r/t threat of death, threat to or change in health status
Death Anxiety r/t unresolved issues surrounding end-of-life decisions
Fear r/t hospitalization, real or imagined threat to own well-being
Impaired individual Resilience r/t violence
Readiness for enhanced Communication: willingness to share thoughts and feelings

Schizophrenia

Ineffective Activity planning r/t compromised ability to process information
Anxiety r/t unconscious conflict with reality
Impaired verbal Communication r/t psychosis, disorientation, inaccurate perception, hallucinations, delusions
Ineffective Coping r/t inadequate support systems, unrealistic perceptions, inadequate coping skills, disturbed thought processes, impaired communication
Decreased Diversional activity engagement r/t social isolation, possible regression
Interrupted Family processes r/t inability to express feelings, impaired communication
Fear r/t altered contact with reality
Ineffective Health maintenance r/t cognitive impairment, ineffective individual and family coping, lack of material resources
Ineffective family Health management r/t chronicity and unpredictability of condition
Impaired Home maintenance r/t impaired cognitive or emotional functioning, insufficient finances, inadequate support systems
Hopelessness r/t long-term stress from chronic mental illness
Disturbed personal Identity r/t psychiatric disorder
Impaired Memory r/t psychosocial condition
Imbalanced Nutrition: less than body requirements r/t fear of eating, lack of awareness of hunger, disinterest toward food
Impaired individual Resilience r/t psychological disorder

Self-Care deficit: **specify** r/t loss of contact with reality, impairment of perception
Self-Neglect r/t psychosis
Sleep deprivation r/t intrusive thoughts, nightmares
Impaired Social interaction r/t impaired communication patterns, self-concept disturbance, disturbed thought processes
Social isolation r/t lack of trust, regression, delusional thinking, repressed fears
Chronic Sorrow r/t chronic mental illness
Spiritual distress r/t loneliness, social alienation
Risk for Caregiver Role Strain: Risk factors: bizarre behavior of client, chronicity of condition
Risk for compromised Human Dignity: Risk factor: stigmatizing label
Risk for Loneliness: Risk factor: inability to interact socially
Risk for Post-Trauma syndrome: Risk factor: diminished ego strength
Risk for Powerlessness: Risk factor: intrusive, distorted thinking
Risk for impaired Religiosity: Risk factors: ineffective coping, lack of security
Risk for Suicide: Risk factor: psychiatric illness
Risk for self-directed Violence: Risk factors: lack of trust, panic, hallucinations, delusional thinking
Risk for other-directed Violence: Risk factor: psychotic disorder
Readiness for enhanced Hope: expresses desire to enhance interconnectedness with others and problem-solve to meet goals
Readiness for enhanced Power: expresses willingness to enhance participation in choices for daily living and health and enhance knowledge for participation in change

Sciatica

See Neuropathy, Peripheral

Scoliosis

Risk-prone Health behavior r/t lack of developmental maturity to comprehend long-term consequences of noncompliance with treatment procedures
Disturbed Body Image r/t use of therapeutic braces, postsurgery scars, restricted physical activity
Impaired Comfort r/t altered health status and body image
Impaired Gas exchange r/t restricted lung expansion as a result of severe presurgery curvature of spine, immobilization
Ineffective Health maintenance r/t deficient knowledge regarding treatment modalities, restrictions, home care, postoperative activities
Impaired physical Mobility r/t restricted movement, dyspnea caused by severe curvature of spine
Acute Pain r/t musculoskeletal restrictions, surgery, reambulation with cast or spinal rod
Impaired Skin integrity r/t braces, casts, surgical correction
Chronic Sorrow r/t chronic disability
Risk for Perioperative Positioning injury: Risk factor: prone position
Risk for impaired Resilience: Risk factor: chronic condition
Readiness for enhanced Health management: desires knowledge regarding treatment for condition
See Hospitalized Child; Maturational Issues, Adolescent

Sedentary Lifestyle

Activity intolerance r/t sedentary lifestyle
Sedentary lifestyle (See **Sedentary** lifestyle, Section III)
Obesity (See **Obesity**, Section III)
Overweight (See **Overweight**, Section III)
Risk for Overweight (See **Overweight**, Section III)
Risk for ineffective peripheral Tissue Perfusion: Risk factor: insufficient knowledge of aggravating factors (e.g., immobility, obesity)
Readiness for enhanced Coping: seeking knowledge of new strategies to adjust to sedentary lifestyle

Seizure Disorders, Adult

Acute Confusion r/t postseizure state
Social isolation r/t unpredictability of seizures, community-imposed stigma
Risk for ineffective Airway clearance: Risk factor: accumulation of secretions during seizure
Risk for Falls: Risk factor: uncontrolled seizure activity
Risk for Powerlessness: Risk factor: possible seizure
Risk for impaired Resilience: Risk factor: chronic illness
Readiness for enhanced Knowledge: anticonvulsive therapy
Readiness for enhanced Self-Care: expresses desire to enhance knowledge and responsibility for self-care
See Epilepsy

Seizure Disorders, Childhood (Epilepsy, Febrile Seizures, Infantile Spasms)

Ineffective Health maintenance r/t lack of knowledge regarding anticonvulsive therapy, fever reduction (febrile seizures)
Social isolation r/t unpredictability of seizures, community-imposed stigma
Risk for ineffective Airway clearance: Risk factor: accumulation of secretions during seizure
Risk for delayed Development: Risk factors: effects of seizure disorder, parental overprotection
Risk for Falls: Risk factor: possible seizure
Risk for Injury: Risk factors: uncontrolled movements during seizure, falls, drowsiness caused by anticonvulsants
See Epilepsy

Self-Breast Examination (SBE)

See SBE (Self-Breast Examination)

Self-Care

Readiness for enhanced Self-Care (See **Self-Care,** readiness for enhanced, Section III)

Self-Care Deficit, Bathing

Bathing Self-Care deficit (See **Self-Care** deficit, bathing, Section III)

Self-Care Deficit, Dressing

Dressing Self-Care deficit (See **Self-Care** deficit, dressing, Section III)

Self-Care Deficit, Feeding

Feeding Self-Care deficit (See **Self-Care** deficit, feeding, Section III)

Self-Care Deficit, Toileting

Toileting Self-Care deficit (See **Self-Care** deficit, toileting, Section III)

Self-Concept

Readiness for enhanced Self-Concept (See **Self-Concept,** readiness for enhanced, Section III)

Self-Destructive Behavior

Post-Trauma syndrome r/t unresolved feelings from traumatic event
Risk for Self-Mutilation: Risk factors: feelings of depression, rejection, self-hatred, depersonalization; command hallucinations
Risk for Suicide: Risk factor: history of self-destructive behavior
Risk for self-directed Violence: Risk factors: panic state, history of child abuse, toxic reaction to medication

Self-Esteem, Chronic Low

Chronic low Self-Esteem (See **Self-Esteem,** low, chronic, Section III)
Risk for disturbed personal Identity: Risk factor: chronic low self-esteem

Self-Esteem, Situational Low

Situational low Self-Esteem (See **Self-Esteem,** low, situational, Section III)
Risk for situational low Self-Esteem (See **Self-Esteem,** low, situational, risk for, Section III)

Self-Mutilation

Ineffective Impulse control r/t ineffective management of anxiety
Self-Mutilation (See **Self-Mutilation,** Section III)
Risk for Self-Mutilation (See **Self-Mutilation,** risk for, Section III)

Senile Dementia

Ineffective Relationship r/t cognitive changes in one partner
Sedentary lifestyle r/t lack of interest in movement
See Dementia

Separation Anxiety

Ineffective Coping r/t maturational and situational crises, vulnerability related to developmental age, hospitalization, separation from family and familiar surroundings, multiple caregivers
Insomnia r/t separation for significant others
Risk for impaired Attachment: Risk factor: separation
See Hospitalized Child

Sepsis, Child

Impaired Gas exchange r/t pulmonary inflammation associated with disease process
Imbalanced Nutrition: **less than body requirements** r/t anorexia, generalized weakness, poor sucking reflex
Delayed Surgical recovery r/t presence of infection
Ineffective Thermoregulation r/t infectious process, septic shock
Ineffective peripheral Tissue Perfusion r/t arterial or venous blood flow exchange problems, septic shock
Risk for deficient Fluid volume: Risk factor: inflammation leading to decreased systemic vascular resistance
Risk for impaired Skin integrity: Risk factor: desquamation caused by disseminated intravascular coagulation
See Hospitalized Child; *Premature Infant, Child*

Septicemia

Imbalanced Nutrition: less than body requirements r/t anorexia, generalized weakness
Ineffective peripheral Tissue Perfusion r/t decreased systemic vascular resistance
Risk for deficient Fluid volume: Risk factors: vasodilation of peripheral vessels, leaking of capillaries
Risk for Shock: Risk factors: hypotension, hypovolemia
Risk for unstable Blood Pressure: Risk factor: hypovolemia
See Sepsis, Child; Shock, Septic

Service Animal

Readiness for enhanced Power: expresses desire to enhance independence with actions for change
Readiness for enhanced Resilience: expresses desire to enhance involvement in activities, desire to enhance environmental safety

Severe Acute Respiratory Syndrome (SARS)

See Pneumonia

Sexual Dysfunction

Sexual Dysfunction r/t insufficient knowledge about sexual function
Ineffective Relationship r/t reported sexual dissatisfaction between partners
Chronic Sorrow r/t loss of ideal sexual experience, altered relationships
Risk for situational low Self-Esteem: Risk factor: alteration in body function
See Erectile Dysfunction (ED)

Sexual Harassment Victim

Anxiety r/t situational crisis
Risk for Compromised Human Dignity: Risk factors: humiliation, dehumanizing treatment
Risk for Post-Trauma syndrome: Risk factors: perceived traumatic event, insufficient social support
Risk for Spiritual Distress: Risk factors: physical, psychological stress
See Assault Victim

Sexuality, Adolescent

Disturbed Body Image r/t anxiety caused by unachieved developmental milestone (puberty) or deficient knowledge regarding reproductive maturation with expressed concerns regarding lack of growth of secondary sex characteristics
Impaired emancipated Decision-Making: sexual activity r/t undefined personal values or beliefs, multiple or divergent sources of information, lack of relevant information
Ineffective Impulse control r/t denial of consequences of actions
Deficient Knowledge: potential for enhanced health maintenance r/t multiple or divergent sources of information or lack of relevant information regarding sexual transmission of disease, contraception, prevention of toxic shock syndrome
See Maturational Issues, Adolescent

Sexuality Pattern, Ineffective

Ineffective Sexuality pattern (See **Sexuality** pattern, ineffective, Section III)

Sexually Transmitted Disease (STD)

See STD (Sexually Transmitted Disease)

Shaken Baby Syndrome

Decreased intracranial Adaptive capacity r/t brain injury
Impaired Parenting r/t stress, history of being abusive
Impaired individual Resilience r/t poor impulse control
Stress overload r/t intense repeated family stressors, family violence
Risk for other-directed Violence: Risk factors: history of violence against others, perinatal complications
See Child Abuse; Suspected Child Abuse and Neglect (SCAN), Child; Suspected Child Abuse and Neglect (SCAN), Parent

Shakiness

Anxiety r/t situational or maturational crisis, threat of death

Shame

Situational low Self-Esteem r/t inability to deal with past traumatic events, blaming of self for events not in one's control

Shingles

Acute Pain r/t vesicular eruption along the nerves
Ineffective Protection r/t abnormal blood profiles
Social isolation r/t altered state of wellness, contagiousness of disease
Risk for Infection: Risk factor: tissue destruction
See Itching

Shivering

Impaired Comfort r/t altered health status
Fear r/t serious threat to health status
Hypothermia r/t exposure to cool environment
Ineffective Thermoregulation r/t serious infectious process resulting in immune response of fever
See Shock, Septic

Shock, Cardiogenic

Decreased Cardiac output r/t decreased myocardial contractility, dysrhythmia

Shock, Hypovolemic

Deficient Fluid volume r/t abnormal loss of fluid, trauma, third spacing

Shock, Septic

Deficient Fluid volume r/t abnormal loss of intravascular fluid, pooling of blood in peripheral circulation, overwhelming inflammatory response
Ineffective Protection r/t inadequately functioning immune system
See Sepsis, Child; Septicemia

Shoulder Repair

Self-Care deficit: **bathing, dressing, feeding** r/t immobilization of affected shoulder
Risk for Perioperative Positioning injury: Risk factor: immobility
See Surgery, Preoperative Care; *Surgery, Perioperative Care*; *Surgery, Postoperative Care*; *Total Joint Replacement (Total Hip/Total Knee/Shoulder)*

Sickle Cell Anemia/Crisis

Activity intolerance r/t fatigue, effects of chronic anemia
Deficient Fluid volume r/t decreased intake, increased fluid requirements during sickle cell crisis, decreased ability of kidneys to concentrate urine
Impaired physical Mobility r/t pain, fatigue
Acute Pain r/t viscous blood, tissue hypoxia
Ineffective peripheral Tissue Perfusion r/t effects of red cell sickling, infarction of tissues
Risk for decreased Cardiac tissue perfusion: Risk factors: effects of red cell sickling, infarction of tissues
Risk for Infection: Risk factor: alterations in splenic function
Risk for impaired Resilience: Risk factor: chronic illness
Risk for ineffective cerebral Tissue perfusion: Risk factors: effects of red cell sickling, infarction of tissues
See Child with Chronic Condition; *Hospitalized Child*

SIDS (Sudden Infant Death Syndrome)

Anxiety: parental worry r/t life-threatening event
Interrupted Family processes r/t stress as a result of special care needs of infant with apnea
Grieving r/t potential loss of infant
Insomnia: parental/infant r/t home apnea monitoring
Deficient Knowledge: potential for enhanced health maintenance r/t knowledge or skill acquisition of cardiopulmonary resuscitation and home apnea monitoring
Impaired Resilience r/t sudden loss
Risk for Sudden Infant Death (See **Sudden Infant Death**, risk for, Section III)
Risk for Powerlessness: Risk factor: unanticipated life-threatening event
See Terminally Ill Child/Death of Child, Parent

Sitting Problems

Impaired Sitting (See **Sitting,** impaired, Section III)

Situational Crisis

Imbalanced Energy Field r/t hyperactivity of the energy flow
Ineffective Coping r/t situational crisis
Interrupted Family processes r/t situational crisis
Risk for ineffective Activity planning: Risk factor: inability to process information
Risk for disturbed personal Identity: Risk factor: situational crisis
Readiness for enhanced Communication: willingness to share feelings and thoughts
Readiness for enhanced Religiosity: requests religious material and/or experiences
Readiness for enhanced Resilience: desire to enhance resilience
Readiness for enhanced Spiritual well-being: desire for harmony following crisis

SJS (Stevens-Johnson Syndrome)

See Stevens-Johnson Syndrome (SJS)

Skin Cancer

Ineffective Health maintenance r/t deficient knowledge regarding self-care with skin cancer
Ineffective Protection r/t weakened immune system
Impaired Tissue integrity r/t abnormal cell growth in skin, treatment of skin cancer
Readiness for enhanced Health management: follows preventive measures
Readiness for enhanced Knowledge: self-care to prevent and treat skin cancer

Skin Disorders

Impaired Skin integrity (See **Skin** integrity, impaired, Section III)

Skin Turgor, Change in Elasticity

Deficient Fluid volume r/t active fluid loss

Sleep

Readiness for enhanced Sleep (See **Sleep,** readiness for enhanced, Section III)

Sleep Apnea

Ineffective Breathing pattern r/t obesity, substance abuse, enlarged tonsils, smoking, or neurological pathology such as a brain tumor
Impaired Comfort r/t use of bilevel positive airway pressure (BiPAP)/continuous positive airway pressure (CPAP) machine

Sleep Deprivation

Fatigue r/t lack of sleep
Sleep deprivation (See **Sleep** deprivation, Section III)

Sleep Problems

Insomnia (See **Insomnia,** Section III)

Sleep Pattern, Disturbed, Parent/Child

Insomnia: **child** r/t anxiety or fear
Insomnia: **parent** r/t parental responsibilities, stress
See Suspected Child Abuse and Neglect (SCAN), Child; Suspected Child Abuse and Neglect (SCAN), Parent

Slurring of Speech

Impaired verbal Communication r/t decrease in circulation to brain, brain tumor, anatomical defect, cleft palate
Situational low Self-Esteem r/t speech impairment
See Communication Problems

Small Bowel Resection

See Abdominal Surgery

Smell, Loss of Ability to

Risk for Injury: Risk factors: inability to detect gas fumes, smoke smells
See Anosmia (Smell, Loss of Ability to)

Smoke Inhalation

Ineffective Airway clearance r/t smoke inhalation
Impaired Gas exchange r/t ventilation-perfusion imbalance
Risk for acute Confusion: Risk factor: decreased oxygen supply
Risk for Infection: Risk factors: inflammation, ineffective airway clearance, pneumonia
Risk for Poisoning: Risk factor: exposure to carbon monoxide
Readiness for enhanced Health management: functioning smoke detectors and carbon monoxide detectors in home and work, escape route planned and reviewed
See Atelectasis; Burns; Pneumonia

Smoking Behavior

Insufficient Breast Milk Production r/t smoking
Risk-prone Health behavior Risk factor: smoking
Ineffective Health maintenance r/t denial of effects of smoking, lack of effective support for smoking withdrawal
Readiness for enhanced Knowledge: expresses interest in smoking cessation
Risk for dry Eye: Risk factor: smoking
Risk for ineffective peripheral Tissue Perfusion: Risk factor: effect of nicotine
Risk for Thermal injury: Risk factor: unsafe smoking behavior
Readiness for enhanced Health literacy: verbalizes desire to enhance understanding of health information to make health care choices

Social Interaction, Impaired

Impaired Social interaction (See **Social** interaction, impaired, Section III)

Social Isolation

Social isolation (See **Social isolation**, Section III)

Sociopathic Personality

See Antisocial Personality Disorder

Sodium, Decrease/Increase

See Hyponatremia; Hypernatremia

Somatization Disorder

Anxiety r/t unresolved conflicts channeled into physical complaints or conditions
Ineffective Coping r/t lack of insight into underlying conflicts
Ineffective Denial r/t displaced psychological stress to physical symptoms

Nausea r/t anxiety
Chronic Pain r/t unexpressed anger, multiple physical disorders, depression
Impaired individual Resilience r/t possible psychological disorders

Sore Nipples, Breastfeeding

Ineffective Breastfeeding r/t deficient knowledge regarding correct feeding procedure
See Painful Breasts, Sore Nipples

Sore Throat

Impaired Comfort r/t sore throat
Deficient Knowledge r/t treatment, relief of discomfort
Impaired Oral Mucous Membrane integrity r/t inflammation or infection of oral cavity
Impaired Swallowing r/t irritation of oropharyngeal cavity
Risk for Dry Mouth: Risk factor: painful swallowing

Sorrow

Grieving r/t loss of significant person, object, or role
Chronic Sorrow (See **Sorrow,** chronic, Section III)
Readiness for enhanced Communication: expresses thoughts and feelings
Readiness for enhanced Spiritual well-being: desire to find purpose and meaning of loss

Spastic Colon

See IBS (Irritable Bowel Syndrome)

Speech Disorders

Anxiety r/t difficulty with communication
Impaired verbal Communication r/t anatomical defect, cleft palate, psychological barriers, decrease in circulation to brain

Spina Bifida

See Neural Tube Defects (Meningocele, Myelomeningocele, Spina Bifida, Anencephaly)

Spinal Cord Injury

Decreased Diversional activity engagement r/t long-term hospitalization, frequent lengthy treatments
Fear r/t powerlessness over loss of body function
Disturbed Body Image r/t alteration in body function
Chronic functional Constipation r/t inhibition of reflex arc
Complicated Grieving r/t loss of usual body function
Ineffective Coping r/t inability to meet basic needs and insufficient sense of control
Sedentary Lifestyle r/t lack of resources or interest
Impaired physical Mobility r/t neuromuscular impairment
Impaired wheelchair Mobility r/t neuromuscular impairment
Impaired Standing r/t spinal cord injury
Urinary Retention r/t inhibition of reflex arc
Risk for Latex Allergy reaction: Risk factor: continuous or intermittent catheterization
Risk for Autonomic Dysreflexia: Risk factors: bladder or bowel distention, skin irritation, deficient knowledge of patient and caregiver

Risk for ineffective Breathing pattern: Risk factor: neuromuscular impairment
Risk for Infection: Risk factors: chronic disease, stasis of body fluids
Risk for Loneliness: Risk factor: physical immobility
Risk for Powerlessness: Risk factor: loss of function
Risk for Pressure ulcer: Risk factor: immobility and decreased sensation
Risk for Thermal Injury: Risk factor: physical immobility
Risk for Venous Thromboembolism: Risk factor: physical immobility
See Child with Chronic Condition; Hospitalized Child; Neural Tube Defects (Meningocele, Myelomeningocele, Spina Bifida, Anencephaly); Paralysis

Spinal Fusion

Impaired bed Mobility r/t impaired ability to turn side to side while keeping spine in proper alignment
Impaired physical Mobility r/t musculoskeletal impairment associated with surgery, possible back brace
Readiness for enhanced Knowledge: expresses interest in information associated with surgery
See Acute Back Pain; Scoliosis; Surgery, Preoperative Care; Surgery, Perioperative Care; Surgery, Postoperative Care

Spiritual Distress

Spiritual distress (See **Spiritual** distress, Section III)
Risk for chronic low Self-Esteem: Risk factor: unresolved spiritual issues
Risk for Spiritual distress (See **Spiritual** distress, risk for, Section III)

Spiritual Well-Being

Readiness for enhanced Spiritual well-being (See **Spiritual** well-being, readiness for enhanced, Section III)

Splenectomy

See Abdominal Surgery

Sprains

Acute Pain r/t physical injury
Impaired physical Mobility r/t injury
Impaired Walking r/t injury

Stable Blood Pressure, Risk for Unstable

Deficient Knowledge r/t inconsistency with medication regiment
(See **Unstable Blood Pressure,** Risk for, Section III)

Standing Problems

Impaired Standing (see Impaired **Standing,** Section III)

Stapedectomy

Hearing Loss r/t edema from surgery

Acute Pain r/t headache
Risk for Falls: Risk factor: dizziness
Risk for Infection: Risk factor: invasive procedure

Stasis Ulcer

Impaired Tissue integrity r/t chronic venous congestion
Risk for Infection: Risk factor: open wound
See CHF (Congestive Heart Failure); Varicose Veins

STD (Sexually Transmitted Disease)

Impaired Comfort r/t infection
Fear r/t altered body function, risk for social isolation, fear of incurable illness
Ineffective Health maintenance r/t deficient knowledge regarding transmission, symptoms, treatment of STD
Ineffective Sexuality pattern r/t illness, altered body function, need for abstinence to heal
Social isolation r/t fear of contracting or spreading disease
Risk for Infection: spread of infection: Risk factor: lack of knowledge concerning transmission of disease
Readiness for enhanced Knowledge: seeks information regarding prevention and treatment of STDs
See Maturational Issues, Adolescent; PID (Pelvic Inflammatory Disease)

STEMI (ST-Elevation Myocardial Infarction)

See MI (Myocardial Infarction)

Stent (Coronary Artery Stent)

Risk for Injury: Risk factor: complications associated with stent placement
Risk for decreased Cardiac tissue perfusion: Risk factor: possible restenosis
Risk for Vascular Trauma: Risk factors: insertion site, catheter width
Readiness for enhanced Decision-Making: expresses desire to enhance risk-benefit analysis, understanding and meaning of choices, and decisions regarding treatment
See Angioplasty, Coronary; Cardiac Catheterization

Sterilization Surgery

Decisional Conflict r/t multiple or divergent sources of information, unclear personal values or beliefs
See Surgery, Preoperative Care; Surgery, Perioperative Care; Surgery, Postoperative Care; Tubal Ligation; Vasectomy

Stertorous Respirations

Ineffective Airway clearance r/t pharyngeal obstruction

Stevens-Johnson Syndrome (SJS)

Impaired Oral Mucous Membrane integrity r/t immunocompromised condition associated with allergic medication reaction
Acute Pain r/t painful skin lesions and painful mucosa lesions
Impaired Skin integrity r/t allergic medication reaction
Risk for deficient Fluid volume: Risk factors: factors affecting fluid needs (hypermetabolic state, fever), excessive losses through normal routes (vomiting and diarrhea)

Risk for Infection: Risk factor: sloughing skin
Risk for impaired Liver function: Risk factor: impaired immune response

Stillbirth

See Pregnancy Loss

Stoma

See Colostomy; Ileostomy

Stomatitis

Impaired Oral Mucous Membrane integrity r/t pathological conditions of oral cavity; side effects of chemotherapy
Risk for impaired Oral Mucous Membrane integrity (See impaired **Oral Mucous Membrane** integrity, risk for, Section III)

Stool, Hard/Dry

Chronic functional Constipation r/t inadequate fluid intake, inadequate fiber intake, decreased activity level, decreased gastric motility

Straining with Defecation

Chronic functional Constipation r/t less than adequate fluid intake, less than adequate dietary intake
Risk for decreased Cardiac output: Risk factor: vagal stimulation with dysrhythmia resulting from Valsalva maneuver

Strep Throat

Risk for Infection: Risk factor: exposure to pathogen
See Sore Throat

Stress

Anxiety r/t feelings of helplessness, feelings of being threatened
Ineffective Coping r/t ineffective use of problem-solving process, feelings of apprehension or helplessness
Fear r/t powerlessness over feelings
Stress overload r/t intense or multiple stressors
Readiness for enhanced Communication: shows willingness to share thoughts and feelings
Readiness for enhanced Spiritual well-being: expresses desire for harmony and peace in stressful situation
See Anxiety

Stress Urinary Incontinence

Stress urinary Incontinence r/t degenerative change in pelvic muscles

Stridor

Ineffective Airway clearance r/t obstruction, tracheobronchial infection, trauma

Stroke

See CVA (Cerebrovascular Accident)

Stuttering

Anxiety r/t impaired verbal communication
Impaired verbal Communication r/t anxiety, psychological problems

Subarachnoid Hemorrhage

Acute Pain: headache r/t irritation of meninges from blood, increased intracranial pressure
Risk for ineffective Cerebral tissue perfusion: Risk factor: bleeding from cerebral vessel
See Intracranial Pressure, Increased

Substance Abuse

Acute Substance Withdrawal syndrome: Risk factor: developed dependence to alcohol or other addictive substances
Anxiety r/t threat to self-concept, lack of control of drug use
Compromised family Coping r/t codependency issues
Defensive Coping r/t substance abuse
Disabled family Coping r/t differing coping styles between support persons
Ineffective Coping r/t use of substances to cope with life events
Ineffective Denial r/t refusal to acknowledge substance abuse problem
Dysfunctional Family processes r/t substance abuse
Risk-prone Health behavior r/t addiction
Deficient community Health r/t prevention and control of illegal substances in community
Ineffective Impulse control r/t addictive process
Insomnia r/t irritability, nightmares, tremors
Imbalanced Nutrition: less than body requirements r/t poor eating habits
Powerlessness r/t feeling unable to change patterns of drug abuse
Ineffective Relationship r/t inability for well-balanced collaboration between partners
Sexual Dysfunction r/t actions and side effects of drugs
Sleep deprivation r/t prolonged psychological discomfort
Impaired Social interaction r/t disturbed thought processes from drug abuse
Risk for Acute Substance Withdrawal syndrome: Risk factor: developed dependence to alcohol or other addictive substances
Risk for impaired Attachment: Risk factor: substance abuse
Risk for Injury: Risk factors: hallucinations, drug effects
Risk for disturbed personal Identity: Risk factor: ingestion/inhalation of toxic chemicals
Risk for chronic low Self-Esteem: Risk factors: perceived lack of respect from others, repeated failures, repeated negative reinforcement
Risk for Thermal injury: Risk factor: intoxication with drugs or alcohol
Risk for unstable Blood Pressure: Risk factor: vasoconstriction of cardiac arteries
Risk for Vascular Trauma: Risk factor: chemical irritant self injected into veins
Risk for self-directed Violence: Risk factors: reactions to substances used, impulsive behavior, disorientation, impaired judgment
Risk for other-directed Violence: Risk factor: poor impulse control
Readiness for enhanced Coping: seeking social support and knowledge of new strategies
Readiness for enhanced Self-Concept: accepting strengths and limitations
See Alcoholism

Substance Abuse, Adolescent

See Alcoholism; Maturational Issues, Adolescent; Substance Abuse

Substance Abuse in Pregnancy

Ineffective Childbearing process r/t substance abuse
Defensive Coping r/t denial of situation, differing value system
Ineffective Health management r/t addiction
Deficient Knowledge r/t lack of exposure to information regarding effects of substance abuse in pregnancy
Neonatal Abstinence syndrome r/t in utero substance exposure secondary to maternal substance use
Risk for impaired Attachment: Risk factors: substance abuse, inability of parent to meet infant's or own personal needs
Risk for Infection: Risk factors: intravenous drug use, lifestyle
Risk for Injury: **fetal:** Risk factor: effects of drugs on fetal growth and development
Risk for Injury: **maternal:** Risk factor: drug or alcohol use
Risk for impaired Parenting: Risk factor: lack of ability to meet infant's needs due to addiction with use of alcohol or drugs
See Alcoholism; Substance Abuse

Substance Withdrawal

See Acute Substance Withdrawal Syndrome

Sucking Reflex

Effective Breastfeeding r/t regular and sustained sucking and swallowing at breast

Sudden Infant Death Syndrome (SIDS)

See SIDS (Sudden Infant Death Syndrome)

Suffocation, Risk for

Risk for Suffocation (See **Suffocation,** risk for, Section III)

Suicide Attempt

Risk-prone Health behavior r/t low self-efficacy
Ineffective Coping r/t anger, complicated grieving
Hopelessness r/t perceived or actual loss, substance abuse, low self-concept, inadequate support systems
Ineffective Impulse control r/t inability to modulate stress, anxiety
Post-Trauma syndrome r/t history of traumatic events, abuse, rape, incest, war, torture
Impaired individual Resilience r/t poor impulse control
Situational low Self-Esteem r/t guilt, inability to trust, feelings of worthlessness or rejection
Social isolation r/t inability to engage in satisfying personal relationships
Spiritual distress r/t hopelessness, despair
Risk for Post-Trauma syndrome: Risk factor: survivor's role in suicide attempt
Risk for Suicide (See **Suicide,** risk for, Section III)
Readiness for enhanced Communication: willingness to share thoughts and feelings
Readiness for enhanced Spiritual well-being: desire for harmony and inner strength to help redefine purpose for life
See Violent Behavior

Support System, Inadequate

Readiness for enhanced family Coping: ability to adapt to tasks associated with care, support of significant other during health crisis
Readiness for enhanced Family processes: activities support the growth of family members
Readiness for enhanced Parenting: children or other dependent person(s) expressing satisfaction with home environment

Suppression of Labor

See Preterm Labor

Surgery, Perioperative Care

Risk for imbalanced Fluid volume: Risk factor: surgery
Risk for Perioperative Hypothermia: Risk factors: inadequate covering of client, cold surgical room
Risk for Perioperative Positioning injury: Risk factors: predisposing condition, prolonged surgery

Surgery, Postoperative Care

Activity intolerance r/t pain, surgical procedure
Anxiety r/t change in health status, hospital environment
Deficient Knowledge r/t postoperative expectations, lifestyle changes
Nausea r/t manipulation of gastrointestinal tract, postsurgical anesthesia
Imbalanced Nutrition: less than body requirements r/t anorexia, nausea, vomiting, decreased peristalsis
Ineffective peripheral Tissue Perfusion r/t hypovolemia, circulatory stasis, obesity, prolonged immobility, decreased coughing, decreased deep breathing
Acute Pain r/t inflammation or injury in surgical area
Delayed Surgical recovery r/t extensive surgical procedure, postoperative surgical infection
Urinary retention r/t anesthesia, pain, fear, unfamiliar surroundings, client's position
Risk for Bleeding: Risk factor: surgical procedure
Risk for ineffective Breathing pattern: Risk factors: pain, location of incision, effects of anesthesia or opioids
Risk for Constipation: Risk factors: decreased activity, decreased food or fluid intake, anesthesia, pain medication
Risk for imbalanced Fluid volume: Risk factors: hypermetabolic state, fluid loss during surgery, presence of indwelling tubes, fluids used to distend organ structures being absorbed into body
Risk for Surgical Site Infection: Risk factors: invasive procedure, pain, anesthesia, location of incision, weakened cough as a result of aging

Surgery, Preoperative Care

Anxiety r/t threat to or change in health status, situational crisis, fear of the unknown
Insomnia r/t anxiety about upcoming surgery
Deficient Knowledge r/t preoperative procedures, postoperative expectations
Readiness for enhanced Knowledge: shows understanding of preoperative and postoperative expectations for self-care

Surgical Recovery, Delayed

Delayed Surgical recovery (See **Surgical** recovery, delayed, Section III)
Risk for delayed Surgical recovery (See **Surgical** recovery, delayed, risk for, Section III)

Surgical Site Infection

Anxiety r/t unforeseen result of surgery
Impaired Comfort r/t surgical site pain
Risk for ineffective Thermoregulation: Risk factor: infectious process
Risk for delayed Surgical Recovery: Risk factor: interrupted healing of surgical site
Readiness for enhanced Knowledge: expresses desire for knowledge of prevention and symptoms of infection

Suspected Child Abuse and Neglect (SCAN), Child

Ineffective Activity planning r/t lack of family support
Anxiety: **child** r/t threat of punishment for perceived wrongdoing
Deficient community Health r/t inadequate reporting and follow-up of SCAN
Disturbed personal Identity r/t dysfunctional family processes
Rape-Trauma syndrome r/t altered lifestyle because of abuse, changes in residence
Risk for impaired Resilience: Risk factor: adverse situation
Readiness for enhanced community Coping: obtaining resources to prevent child abuse, neglect
See Child Abuse; Hospitalized Child; Maturational Issues, Adolescent

Suspected Child Abuse and Neglect (SCAN), Parent

Disabled family Coping r/t dysfunctional family, underdeveloped nurturing parental role, lack of parental support systems or role models
Dysfunctional Family processes r/t inadequate coping skills
Ineffective Health maintenance r/t deficient knowledge of parenting skills as result of unachieved developmental tasks
Impaired Home maintenance r/t disorganization, parental dysfunction, neglect of safe and nurturing environment
Ineffective Impulse control r/t projection of anger, frustration onto child
Impaired Parenting r/t unrealistic expectations of child; lack of effective role model; unmet social, emotional, or maturational needs of parents; interruption in bonding process
Impaired individual Resilience r/t poor impulse control
Chronic low Self-Esteem r/t lack of successful parenting experiences
Risk for other-directed Violence: parent to child: Risk factors: inadequate coping mechanisms, unresolved stressors, unachieved maturational level by parent

Suspicion

Disturbed personal Identity r/t psychiatric disorder
Powerlessness r/t repetitive paranoid thinking
Impaired Social interaction r/t disturbed thought processes, paranoid delusions, hallucinations
Risk for self-directed Violence: Risk factor: inability to trust
Risk for other-directed Violence: Risk factor: impulsiveness

Swallowing Difficulties

Impaired Swallowing (See **Swallowing,** impaired, Section III)

Syncope

Anxiety r/t fear of falling
Impaired physical Mobility r/t fear of falling
Ineffective Health management r/t lack of knowledge in how to prevent syncope
Social isolation r/t fear of falling
Risk for decreased Cardiac output: Risk factor**:** dysrhythmia
Risk for Falls: Risk factor: syncope
Risk for Injury: Risk factors: altered sensory perception, transient loss of consciousness, risk for falls
Risk for ineffective Cerebral tissue perfusion: Risk factor: interruption of blood flow

Syphilis

See STD (Sexually Transmitted Disease)

Systemic Lupus Erythematosus

See Lupus Erythematosus

List of Nursing Diagnosis by Letter

T

T & A (Tonsillectomy and Adenoidectomy)	Tachycardia	Tachypnea
Tardive Dyskinesia	Taste Abnormality	TB (Pulmonary Tuberculosis)
TBI (Traumatic Brain Injury)	TD (Traveler's Diarrhea)	Technology Addiction
Temperature, Decreased	Temperature, High	Temperature Regulation, Impaired
TEN (Toxic Epidermal Necrolysis)	TENS Unit (Transcutaneous Electrical Nerve Stimulation)	Tension
Terminally Ill Adult	Terminally Ill Child, Adolescent	Terminally Ill Child, Infant/Toddler
Terminally Ill Child, Preschool Child	Terminally Ill Child, School-Age Child/Preadolescent	Terminally Ill Child/Death of Child, Parent
Tetralogy of Fallot	Tetraplegia	Thermoregulation, Ineffective
Thoracentesis	Thoracotomy	Thought Disorders
Thrombocytopenic Purpura	Thrombophlebitis	Thyroidectomy
TIA (Transient Ischemic Attack)	Tic Disorder	Tinea Capitis
Tinea Corporis	Tinea Cruris	Tinea Pedis
Tinea Unguium (Onychomycosis)	Tinnitus	Tissue Damage, Integumentary
Tissue Perfusion, Peripheral	Toileting Problems	Toilet Training
Tonsillectomy and Adenoidectomy (T & A)	Toothache	Total Anomalous Pulmonary Venous Return
Total Joint Replacement (Total Hip/Total Knee/Shoulder)	Total Parenteral Nutrition (TPN)	Tourette's Syndrome (TS)
Toxemia	Toxic Epidermal Necrolysis (TEN) (Erythema Multiforme)	TPN (Total Parenteral Nutrition)
Tracheoesophageal Fistula	Tracheostomy	Traction and Casts
Transfer Ability	Transient Ischemic Attack (TIA)	Transposition of Great Vessels
Transurethral Resection of the Prostate (TURP)	Trauma in Pregnancy	Trauma, Physical, Risk for
Traumatic Brain Injury (TBI)	Traumatic Event	Traveler's Diarrhea (TD)
Trembling of Hands	Tricuspid Atresia	Trigeminal Neuralgia
Truncus Arteriosus	TS (Tourette's Syndrome)	TSE (Testicular Self-Examination)
Tubal Ligation	Tube Feeding	Tuberculosis (TB)

TURP (Transurethral Resection of the Prostate)		

T

T & A (Tonsillectomy and Adenoidectomy)

Ineffective Airway clearance r/t hesitation or reluctance to cough because of pain
Deficient Knowledge: potential for enhanced health maintenance r/t insufficient knowledge regarding postoperative nutritional and rest requirements, signs and symptoms of complications, positioning
Nausea r/t gastric irritation, pharmaceuticals, anesthesia
Acute Pain r/t surgical incision
Risk for Aspiration: Risk factors: postoperative drainage and impaired swallowing
Risk for deficient Fluid volume: Risk factors: decreased intake because of painful swallowing, effects of anesthesia (nausea, vomiting), hemorrhage
Risk for imbalanced Nutrition: **less than body requirements:** Risk factors: hesitation or reluctance to swallow

Tachycardia

See Dysrhythmia

Tachypnea

Ineffective Breathing pattern r/t pain, anxiety, hypoxia
See cause of Tachypnea

Tardive Dyskinesia

Ineffective Health management r/t complexity of therapeutic regimen or medication
Deficient Knowledge r/t cognitive limitation in assimilating information relating to side effects associated with neuroleptic medications
Risk for Injury: Risk factor: drug-induced abnormal body movements

Taste Abnormality

Frail Elderly syndrome r/t chronic illness

TB (Pulmonary Tuberculosis)

Ineffective Airway clearance r/t increased secretions, excessive mucus
Ineffective Breathing pattern r/t decreased energy, fatigue
Fatigue r/t disease state
Impaired Gas exchange r/t disease process
Ineffective Health management r/t deficient knowledge of prevention and treatment regimen
Impaired Home maintenance management r/t client or family member with disease
Ineffective Thermoregulation r/t presence of infection
Risk for Infection: Risk factor: insufficient knowledge regarding avoidance of exposure to pathogens
Readiness for enhanced Health management: takes medications according to prescribed protocol for

prevention and treatment

TBI (Traumatic Brain Injury)

Interrupted Family processes r/t traumatic injury to family member
Chronic Sorrow r/t change in health status and functional ability
Risk for Post-Trauma syndrome: Risk factor: perception of event causing TBI
Risk for impaired Religiosity: Risk factor: impaired physical mobility
Risk for impaired Resilience: Risk factor: crisis of injury
See Head Injury; Neurologic Disorders

TD (Traveler's Diarrhea)

See Traveler's Diarrhea

Technology Addiction

Decreased Diversional activity engagement r/t insufficient motivation to separate from electronic devices
Impaired Social interaction r/t lack of desire to engage in personal face-to-face contact with others
Risk for impaired Attachment: Risk factor: preoccupation with electronic devices
Risk for impaired Parenting: Risk factor: insufficient uninterrupted meaningful interaction between parent and child as the result of preoccupation with electronic devices
Risk for ineffective Relationship: Risk factor: ineffective face-to-face communication skills

Temperature, Decreased

Hypothermia r/t exposure to cold environment

Temperature, High

Hyperthermia r/t neurological damage, disease condition with high temperature, excessive heat, inflammatory response

Temperature Regulation, Impaired

Ineffective Thermoregulation r/t trauma, illness, cerebral injury

TEN (Toxic Epidermal Necrolysis)

See Toxic Epidermal Necrolysis (TEN)

TENS Unit (Transcutaneous Electrical Nerve Stimulation)

Risk for unstable Blood Pressure: Risk factor: improper use of TENS unit (front of neck)
Readiness for enhanced Comfort: expresses desire to enhance resolution of complaints

Tension

Anxiety r/t threat to or change in health status, situational crisis
Readiness for enhanced Communication: expresses willingness to share feelings and thoughts

See Stress

Terminally Ill Adult

Death Anxiety r/t unresolved issues relating to death and dying
Imbalanced Energy Field r/t weak energy field patterns
Risk for Spiritual distress: Risk factor: impending death
Readiness for enhanced Religiosity: requests religious material and/or experiences
Readiness for enhanced Spiritual well-being: desire to achieve harmony of mind, body, spirit
See Terminally Ill Child/Death of Child, Parent

Terminally Ill Child, Adolescent

Disturbed Body Image r/t effects of terminal disease, already critical feelings of group identity and self-image
Ineffective Coping r/t inability to establish personal and peer identity because of the threat of being different or not being healthy, inability to achieve maturational tasks
Impaired Social interaction r/t forced separation from peers
See Child with Chronic Condition; Hospitalized Child, Terminally Ill Child/Death of Child, Parent

Terminally Ill Child, Infant/Toddler

Ineffective Coping r/t separation from parents and familiar environment from inability to understand dying process
See Child with Chronic Condition, Terminally Ill Child/Death of Child, Parent

Terminally Ill Child, Preschool Child

Fear r/t perceived punishment, bodily harm, feelings of guilt caused by magical thinking (i.e., believing that thoughts cause events)
See Child with Chronic Condition, Terminally Ill Child/Death of Child, Parent

Terminally Ill Child, School-Age Child/Preadolescent

Fear r/t perceived punishment, body mutilation, feelings of guilt
See Child with Chronic Condition, Terminally Ill Child/Death of Child, Parent

Terminally Ill Child/Death of Child, Parent

Compromised family Coping r/t inability or unwillingness to discuss impending death and feelings with child or support child through terminal stages of illness
Decisional Conflict r/t continuation or discontinuation of treatment, do-not-resuscitate decision, ethical issues regarding organ donation
Ineffective Denial r/t complicated grieving
Interrupted Family processes r/t situational crisis
Grieving r/t death of child
Hopelessness r/t overwhelming stresses caused by terminal illness
Insomnia r/t grieving process
Impaired Parenting r/t risk for overprotection of surviving siblings
Powerlessness r/t inability to alter course of events
Impaired Social interaction r/t complicated grieving
Social isolation: **imposed by others** r/t feelings of inadequacy in providing support to grieving parents
Social isolation: **self-imposed** r/t unresolved grief, perceived inadequate parenting skills
Spiritual distress r/t sudden and unexpected death, prolonged suffering before death, questioning the death of youth, questioning the meaning of one's own existence

Risk for complicated Grieving: Risk factors: prolonged, unresolved, obstructed progression through stages of grief and mourning
Risk for impaired Resilience: Risk factor: impending death
Readiness for enhanced family Coping: impact of crisis on family values, priorities, goals, or relationships; expressed interest or desire to attach meaning to child's life and death

Tetralogy of Fallot

See Congenital Heart Disease/Cardiac Anomalies

Tetraplegia

Autonomic dysreflexia r/t bladder or bowel distention, skin irritation, infection, deficient knowledge of patient and caregiver
Grieving r/t loss of previous functioning
Powerlessness r/t inability to perform previous activities
Impaired Sitting r/t paralysis of extremities
Impaired spontaneous Ventilation r/t loss of innervation of respiratory muscles, respiratory muscle fatigue
Risk for Aspiration: Risk factor: inadequate ability to protect airway from neurological damage
Risk for Infection: Risk factor: urinary stasis
Risk for impaired Skin integrity: Risk factor: physical immobilization and decreased sensation
Risk for ineffective Thermoregulation: Risk factors: inability to move to increase temperature, possible presence of infection to increase temperature

Thermoregulation, Ineffective

Ineffective Thermoregulation (See **Thermoregulation**, ineffective, Section III)
Risk for Ineffective Thermoregulation, (See **Ineffective Thermoregulation**, risk for, Section III)

Thoracentesis

See Pleural Effusion

Thoracotomy

Activity intolerance r/t pain, imbalance between oxygen supply and demand, presence of chest tubes
Ineffective Airway clearance r/t drowsiness, pain with breathing and coughing
Ineffective Breathing pattern r/t decreased energy, fatigue, pain
Deficient Knowledge r/t self-care, effective breathing exercises, pain relief
Acute Pain r/t surgical procedure, coughing, deep breathing
Risk for Bleeding: Risk factor: surgery
Risk for Surgical Site Infection: Risk factor: invasive procedure
Risk for Injury: Risk factor: disruption of closed-chest drainage system
Risk for Perioperative Positioning injury: Risk factors: lateral positioning, immobility
Risk for Vascular Trauma: Risk factors: chemical irritant; antibiotics

Thought Disorders

See Schizophrenia

Thrombocytopenic Purpura

See ITP (Idiopathic Thrombocytopenic Purpura)

Thrombophlebitis

See Deep Vein Thrombosis (DVT)

Thyroidectomy

Risk for ineffective Airway clearance: Risk factor: edema or hematoma formation, airway obstruction
Risk for impaired verbal Communication: Risk factors: edema, pain, vocal cord or laryngeal nerve damage
Risk for Injury: Risk factor: possible parathyroid damage or removal
See Surgery, Preoperative Care; Surgery, Perioperative Care; Surgery, Postoperative Care

TIA (Transient Ischemic Attack)

Acute Confusion r/t hypoxia
Readiness for enhanced Health management: obtains knowledge regarding treatment prevention of inadequate oxygenation
See Syncope

Tic Disorder

See Tourette's Syndrome (TS)

Tinea Capitis

Impaired Comfort r/t inflammation from skin irritation
See Ringworm of Scalp

Tinea Corporis

See Ringworm of Body

Tinea Cruris

See Jock Itch; Itching; Pruritus

Tinea Pedis

See Athlete's Foot; Itching; Pruritus

Tinea Unguium (Onychomycosis)

See Ringworm of Nails

Tinnitus

Ineffective Health maintenance r/t deficient knowledge regarding self-care with tinnitus
Hearing Loss r/t ringing in ears obscuring hearing

Tissue Damage, Integumentary

Impaired Tissue integrity (See **Tissue** integrity, impaired, Section III)
Risk for impaired Tissue integrity (See **Tissue** integrity, impaired, risk for, Section III)

Tissue Perfusion, Peripheral

Ineffective peripheral Tissue Perfusion (See **Tissue Perfusion**, peripheral, ineffective, Section III)
Risk for ineffective peripheral Tissue Perfusion (See **Tissue Perfusion**, peripheral, ineffective, risk for, Section III)

Toileting Problems

Toileting Self-Care deficit r/t impaired transfer ability, impaired mobility status, intolerance of activity, neuromuscular impairment, cognitive impairment
Impaired Transfer ability r/t neuromuscular deficits

Toilet Training

Deficient Knowledge: **parent** r/t signs of child's readiness for training
Risk for Constipation: Risk factor: withholding stool
Risk for Infection: Risk factor: withholding urination

Tonsillectomy and Adenoidectomy (T & A)

See T & A (Tonsillectomy and Adenoidectomy)

Toothache

Impaired Dentition r/t ineffective oral hygiene, barriers to self-care, economic barriers to professional care, nutritional deficits, lack of knowledge regarding dental health
Acute Pain r/t inflammation, infection

Total Anomalous Pulmonary Venous Return

See Congenital Heart Disease/Cardiac Anomalies

Total Joint Replacement (Total Hip/Total Knee/Shoulder)

Disturbed Body Image r/t large scar, presence of prosthesis
Impaired physical Mobility r/t musculoskeletal impairment, surgery, prosthesis
Risk for Injury: neurovascular: Risk factors: altered peripheral tissue perfusion, impaired mobility, prosthesis
Risk for Peripheral Neurovascular dysfunction: Risk factors: immobilization, surgical procedure
Ineffective peripheral Tissue perfusion r/t surgery
See Surgery, Preoperative Care; Surgery, Perioperative Care; Surgery, Postoperative Care

Total Parenteral Nutrition (TPN)

See TPN (Total Parenteral Nutrition)

Tourette's Syndrome (TS)

Hopelessness r/t inability to control behavior
Impaired individual Resilience r/t uncontrollable behavior
Risk for situational low Self-Esteem: Risk factors: uncontrollable behavior, motor and phonic tics
See Attention Deficit Disorder

Toxemia

See PIH (Pregnancy-Induced Hypertension/Preeclampsia)

Toxic Epidermal Necrolysis (TEN) (Erythema Multiforme)

Death Anxiety r/t uncertainty of prognosis

TPN (Total Parenteral Nutrition)

Imbalanced Nutrition: less than body requirements r/t inability to digest food or absorb nutrients as a result of biological or psychological factors
Risk for Electrolyte imbalance: Risk factor: need for regulation of electrolytes in TPN fluids
Risk for excess Fluid volume: Risk factor: rapid administration of TPN
Risk for unstable blood Glucose level: Risk factor: high glucose levels in TPN to be regulated according to blood glucose levels
Risk for Infection: Risk factors: concentrated glucose solution, invasive administration of fluids
Risk for Vascular Trauma: Risk factors: insertion site, length of treatment time

Tracheoesophageal Fistula

Ineffective Airway clearance r/t aspiration of feeding because of inability to swallow
Imbalanced Nutrition: less than body requirements r/t difficulties swallowing
Risk for Aspiration: Risk factor: common passage of air and food
Risk for Vascular Trauma: Risk factors: venous medications and site
See Respiratory Conditions of the Neonate; Hospitalized Child

Tracheostomy

Ineffective Airway clearance r/t increased secretions, mucous plugs
Anxiety r/t impaired verbal communication, ineffective airway clearance
Disturbed Body Image r/t abnormal opening in neck
Impaired verbal Communication r/t presence of mechanical airway
Deficient Knowledge r/t self-care, home maintenance management
Acute Pain r/t edema, surgical procedure
Risk for Aspiration: Risk factor: presence of tracheostomy
Risk for Bleeding: Risk factor: surgical incision
Risk for Surgical Site Infection: Risk factors: invasive procedure, pooling of secretions

Traction and Casts

Constipation r/t immobility
Decreased Diversional activity engagement r/t immobility
Impaired physical Mobility r/t imposed restrictions on activity because of bone or joint disease injury
Acute Pain r/t immobility, injury, or disease
Self-Care deficit: feeding, dressing, bathing, toileting r/t degree of impaired physical mobility, body area affected by traction or cast

Impaired Transfer ability r/t presence of traction, casts
Risk for Disuse syndrome: Risk factor: mechanical immobilization
See Casts

Transfer Ability

Impaired Transfer ability (See **Transfer** ability, impaired, Section III)

Transient Ischemic Attack (TIA)

See TIA (Transient Ischemic Attack)

Transposition of Great Vessels

See Congenital Heart Disease/Cardiac Anomalies

Transurethral Resection of the Prostate (TURP)

See TURP (Transurethral Resection of the Prostate)

Trauma in Pregnancy

Anxiety r/t threat to self or fetus, unknown outcome
Deficient Knowledge r/t lack of exposure to situation
Acute Pain r/t trauma
Impaired Skin integrity r/t trauma
Risk for Bleeding: Risk factor: trauma
Risk for deficient Fluid volume: Risk factor: fluid loss
Risk for Infection: Risk factor: traumatized tissue
Risk for Injury: fetal: Risk factor: premature separation of placenta
Risk for disturbed Maternal–Fetal dyad: Risk factor: complication of pregnancy

Trauma, Physical, Risk for

Risk for Physical Trauma (See **Physical Trauma,** risk for, Section III)

Traumatic Brain Injury (TBI)

See TBI (Traumatic Brain Injury); Intracranial Pressure, Increased

Traumatic Event

Post-Trauma syndrome r/t previously experienced trauma

Traveler's Diarrhea (TD)

Diarrhea r/t travel with exposure to different bacteria, viruses
Risk for deficient Fluid Volume: Risk factor: excessive loss of fluids
Risk for Infection: Risk factors: insufficient knowledge regarding avoidance of exposure to pathogens (water supply, iced drinks, local cheese, ice cream, undercooked meat, fish and shellfish, uncooked vegetables, unclean eating utensils, improper handwashing

Trembling of Hands

Fear r/t threat to or change in health status, threat of death, situational crisis

Tricuspid Atresia

See Congenital Heart Disease/Cardiac Anomalies

Trigeminal Neuralgia

Ineffective Health management r/t deficient knowledge regarding prevention of stimuli that trigger pain
Imbalanced Nutrition: less than body requirements r/t pain when chewing
Acute Pain r/t irritation of trigeminal nerve

Risk for corneal Injury: Risk factor: possible decreased corneal sensation

Truncus Arteriosus

See Congenital Heart Disease/Cardiac Anomalies

TS (Tourette's Syndrome)

See Tourette's Syndrome (TS)

TSE (Testicular Self-Examination)

Readiness for enhanced Health management: seeks information regarding self-examination

Tubal Ligation

Decisional Conflict r/t tubal sterilization
See Laparoscopy

Tube Feeding

Risk for Aspiration: Risk factors: improper placement of feeding tube, improper positioning of client during and after feeding, excessive residual feeding or lack of digestion, altered gag reflex
Risk for deficient Fluid volume: Risk factor: inadequate water administration with concentrated feeding
Risk for imbalanced Nutrition: **less than body requirements:** Risk factors: intolerance to tube feeding, inadequate calorie replacement to meet metabolic needs

Tuberculosis (TB)

See TB (Pulmonary Tuberculosis)

TURP (Transurethral Resection of the Prostate)

Deficient Knowledge r/t postoperative self-care, home maintenance management
Acute Pain r/t incision, irritation from catheter, bladder spasms, kidney infection
Urinary retention r/t obstruction of urethra or catheter with clots
Risk for Bleeding: Risk factor: surgery
Risk for deficient Fluid volume: Risk factors: fluid loss, possible bleeding
Risk for urge urinary Incontinence: Risk factor: edema from surgical procedure
Risk for Infection: Risk factors: invasive procedure, route for bacteria entry

List of Nursing Diagnosis by Letter

U

Ulcer, Peptic (Duodenal or Gastric)	Ulcerative Colitis	Ulcers, Stasis
Unilateral Neglect of One Side of Body	Unsanitary Living Conditions	Upper Respiratory Infection
Urgency to Urinate	Urinary Catheter	Urinary Diversion
Urinary Elimination, Impaired	Urinary Incontinence	Urinary Retention
Urinary Tract Infection (UTI)	Urolithiasis	Uterine Atony in Labor
Uterine Atony in Postpartum	Uterine Bleeding	UTI (Urinary Tract Infection)

U

Ulcer, Peptic (Duodenal or Gastric)

Fatigue r/t loss of blood, chronic illness
Ineffective Health maintenance r/t lack of knowledge regarding health practices to prevent ulcer formation
Nausea r/t gastrointestinal irritation
Acute Pain r/t irritated mucosa from acid secretion
See GI Bleed (Gastrointestinal Bleeding)

Ulcerative Colitis

See Inflammatory Bowel Disease (Child and Adult)

Ulcers, Stasis

See Stasis Ulcer

Unilateral Neglect of One Side of Body

Unilateral Neglect (See **Unilateral Neglect,** Section III)

Unsanitary Living Conditions

Impaired Home maintenance r/t impaired cognitive or emotional functioning, lack of knowledge, insufficient finances, addiction
Risk for Allergic reaction: Risk factor: exposure to environmental contaminants

Upper Respiratory Infection

See Cold, Viral

Urgency to Urinate

Urge urinary Incontinence (See **Incontinence,** urinary, urge, Section III)
Risk for urge urinary Incontinence (See **Incontinence,** urinary, urge, risk for, Section III)

Urinary Catheter

Risk for urinary tract Injury: Risk factors: confused client, long-term use of catheter, large retention balloon or catheter, perirectal burn injured client

Urinary Diversion

See Ileal Conduit

Urinary Elimination, Impaired

Impaired Urinary elimination (See **Urinary** elimination, impaired, Section III)

Urinary Incontinence

See Incontinence of Urine

Urinary Retention

Urinary Retention (See **Urinary Retention,** Section III)

Urinary Tract Infection (UTI)

See UTI (Urinary Tract Infection)

Urolithiasis

See Kidney Stone

Uterine Atony in Labor

See Dystocia

Uterine Atony in Postpartum

See Postpartum Hemorrhage

Uterine Bleeding

See Hemorrhage; Postpartum Hemorrhage; Shock, Hypovolemic

UTI (Urinary Tract Infection)

Ineffective Health maintenance r/t deficient knowledge regarding methods to treat and prevent UTIs, prolonged use of indwelling urinary catheter
Acute Pain: dysuria r/t inflammatory process in bladder
Impaired Urinary elimination: frequency r/t urinary tract infection
Risk for acute Confusion: Risk factor: infectious process
Risk for urge urinary Incontinence: Risk factor: hyperreflexia from cystitis

List of Nursing Diagnosis by Letter: V

VAD (Ventricular Assist Device)	Vaginal Hysterectomy	Vaginitis
Vagotomy	Value System Conflict	Varicose Veins
Vascular Dementia (Formerly Called Multi-Infarct Dementia)	Vasectomy	Venereal Disease
Venous Thromboembolism (VTE)	Ventilated Client, Mechanically	Ventricular Assist Device (VAD)
Ventricular Fibrillation	Veterans	Vertigo
Violent Behavior	Viral Gastroenteritis	Vision Impairment
Vomiting	VTE (Venous Thromboembolism)	

V

VAD (Ventricular Assist Device)

See Ventricular Assist Device (VAD)

Vaginal Hysterectomy

Urinary retention r/t edema at surgical site
Risk for urge urinary Incontinence: Risk factors: edema, congestion of pelvic tissues
Risk for Infection: Risk factor: surgical site
Risk for Perioperative Positioning injury: Risk factor: lithotomy position

Vaginitis

Impaired Comfort r/t pruritus, itching
Ineffective Health maintenance r/t deficient knowledge regarding self-care with vaginitis
Ineffective Sexuality pattern r/t abstinence during acute stage, pain

Vagotomy

See Abdominal Surgery

Value System Conflict

Decisional Conflict r/t unclear personal values or beliefs
Spiritual distress r/t challenged value system
Readiness for enhanced Spiritual well-being: desire for harmony with self, others, higher power, God

Varicose Veins

Ineffective Health maintenance r/t deficient knowledge regarding health care practices, prevention, treatment regimen
Chronic Pain r/t impaired circulation
Ineffective peripheral Tissue Perfusion r/t venous stasis
Risk for impaired Tissue integrity: Risk factor: altered peripheral tissue perfusion

Vascular Dementia (Formerly Called Multi-Infarct Dementia)

See Dementia

Vasectomy

Decisional Conflict r/t surgery as method of permanent sterilization

Venereal Disease

See STD (Sexually Transmitted Disease

Venous Thromboembolism (VTE)

Anxiety r/t lack of circulation to body part
Acute Pain r/t vascular obstruction
Ineffective peripheral Tissue Perfusion r/t interruption of circulatory flow
Risk for Peripheral Neurovascular dysfunction: Risk factor: vascular obstruction

Ventilated Client, Mechanically

Ineffective Airway clearance r/t increased secretions, decreased cough and gag reflex
Ineffective Breathing pattern r/t decreased energy and fatigue as a result of possible altered nutrition: less than body requirements, neurological disease or damage
Impaired verbal Communication r/t presence of endotracheal tube, inability to phonate
Fear r/t inability to breathe on own, difficulty communicating
Impaired Gas exchange r/t ventilation-perfusion imbalance
Powerlessness r/t health treatment regimen
Social isolation r/t impaired mobility, ventilator dependence
Impaired spontaneous Ventilation r/t metabolic factors, respiratory muscle fatigue
Dysfunctional Ventilatory weaning response r/t psychological, situational, physiological factors
Risk for Falls: Risk factors: impaired mobility, decreased muscle strength
Risk for Infection: Risk factors: presence of endotracheal tube, pooled secretions
Risk for pressure Ulcer: Risk factor: decreased mobility
Risk for impaired Resilience: Risk factor: illness
See Child with Chronic Condition; Hospitalized Child; Respiratory Conditions of the Neonate

Ventricular Assist Device (VAD)

Anxiety r/t possible failure of device
Risk for Infection: Risk factor: device insertion site
Risk for Vascular Trauma: Risk factor: insertion site
Readiness for enhanced Decision-Making: expresses desire to enhance the understanding of the meaning of choices regarding implanting a VAD
See Open Heart Surgery

Ventricular Fibrillation

See Dysrhythmia

Veterans

Anxiety r/t possible unmet needs, both physical and psychological
Risk for Post-Trauma Syndrome: Risk factors: witnessing death, survivor role, guilt, environment not conducive to needs
Risk for Suicide: Risk factors: substance abuse, insufficient social support, physical injury, psychiatric disorder

Vertigo

See Syncope

Violent Behavior

Risk for other-directed Violence (See **Violence,** other-directed, risk for, Section III)
Risk for self-directed Violence (See **Violence,** self-directed, risk for, Section III)

Viral Gastroenteritis

Diarrhea r/t infectious process, Norovirus
Deficient Fluid volume r/t vomiting, diarrhea
Ineffective Health management r/t inadequate handwashing
See Gastroenteritis, Child

Vision Impairment

Fear r/t loss of sight
Social isolation r/t altered state of wellness, inability to see
Risk for impaired Resilience: Risk factor: presence of new crisis
See Blindness; Cataracts; Glaucoma

Vomiting

Nausea r/t infectious processes, chemotherapy, postsurgical anesthesia, irritation to the gastrointestinal system, stimulation of neuropharmacological mechanisms
Imbalanced Nutrition: less than body requirements r/t inability to ingest food
Risk for Electrolyte imbalance: Risk factor: vomiting

VTE (Venous Thromboembolism)

See Venous Thromboembolism, Risk for, Section III

List of Nursing Diagnosis by Letter: W

Walking Impairment	Wandering	Weakness
Weight Gain	Weight Loss	Wellness-Seeking Behavior
Wernicke-Korsakoff Syndrome	West Nile Virus	Wheelchair Use Problems
Wheezing	Wilms' Tumor	Withdrawal from Alcohol
Withdrawal from Drugs	Wound Debridement	Wound Dehiscence, Evisceration
Wound Infection	Wounds, Open	

W

Walking Impairment

Impaired Walking (See **Walking,** impaired, Section III)

Wandering

Wandering (See **Wandering,** Section III)

Weakness

Fatigue r/t decreased or increased metabolic energy production
Risk for Falls: Risk factor: weakness

Weight Gain

Overweight (See **Overweight,** Section III)

Weight Loss

Imbalanced Nutrition: **less than body requirements** r/t inability to ingest food because of biological, psychological, economic factors

Wellness-Seeking Behavior

Readiness for enhanced Health management: expresses desire for increased control of health practice

Wernicke-Korsakoff Syndrome

See Korsakoff's Syndrome

West Nile Virus

See Meningitis/Encephalitis

Wheelchair Use Problems

Impaired wheelchair Mobility (See **Mobility,** wheelchair, impaired, Section III)

Wheezing

Ineffective Airway clearance r/t tracheobronchial obstructions, secretions

Wilms' Tumor

Chronic functional Constipation r/t obstruction associated with presence of tumor
Acute Pain r/t pressure from tumor
See Chemotherapy; Hospitalized Child; Radiation Therapy; Surgery, Preoperative Care; Surgery, Perioperative Care; Surgery, Postoperative Care

Withdrawal from Alcohol

See Alcohol Withdrawal

Withdrawal from Drugs

See Acute Substance Withdrawal Syndrome

Wound Debridement

Acute Pain r/t debridement of wound
Impaired Tissue integrity r/t debridement, open wound
Risk for Infection: Risk factors: open wound, presence of bacteria

Wound Dehiscence, Evisceration

Fear r/t client fear of body parts "falling out," surgical procedure not going as planned
Disturbed Body Image r/t change in body structure and wound appearance
Imbalanced Nutrition: **less than body requirements** r/t inability to digest nutrients, need for increased protein for healing
Risk for deficient Fluid volume: Risk factors: inability to ingest nutrients, obstruction, fluid loss
Risk for Injury: Risk factor: exposed abdominal contents
Risk for delayed Surgical recovery: Risk factors: separation of wound, exposure of abdominal contents
Risk for Surgical Site Infection: Risk factor: open wound after surgical procedure

Wound Infection

Disturbed Body Image r/t open wound
Imbalanced Nutrition: **less than body requirements** r/t biological factors, infection, fever
Ineffective Thermoregulation r/t infection in wound resulting in fever
Impaired Tissue integrity r/t wound, presence of infection
Risk for imbalanced Fluid volume: Risk factor: increased metabolic rate
Risk for Infection: spread of: Risk factor: imbalanced nutrition: less than body requirements
Risk for delayed Surgical recovery: Risk factor: presence of infection

Wounds, Open

See Lacerations

SECTION III

W

Introduction

Section III is a collection of NANDA-I nursing diagnosis care plans. The care plans are arranged alphabetically by diagnostic concept. They contain definitions, defining characteristics, and related factors if appropriate. Risk diagnoses, however, only contain "risk factors." Care plans include suggested outcomes and interventions for all nursing diagnoses.

MAKING AN ACCURATE NURSING DIAGNOSIS

Verify the accuracy of the previously suggested nursing diagnoses (from Section II) or from alphabetized list (front of the book) for the client.

STEPS

- Read the definition for the suggested nursing diagnosis and determine if it is appropriate.
- Compare the Defining Characteristics with the symptoms that were identified from the client data collected.

or

- Compare the Risk Factors with the factors that were identified from the client data collected.

WRITING OUTCOMES STATEMENTS AND NURSING INTERVENTIONS

After selecting the appropriate nursing diagnosis, use this section to write outcomes and interventions.

STEPS

- Use the Client Outcomes/Nursing Interventions as written by the authors and contributors (select ones that are appropriate for your client).

or

- Use the NOC/NIC outcomes and interventions (as appropriate for your client).
- Read the rationales; the majority of rationales are based on nursing or clinical research that validates the efficacy of the interventions. Every attempt has been made to utilize current references; however, some significant research has not been replicated. Important research studies that are older than 5 years are included because they are the only evidence available. They are designated as **CEB** (Classic Evidence-Based).

Following these steps, you will be able to write an evidence-based nursing care plan.

- Follow this care plan to administer nursing care to the client.
- Document all steps and evaluate and update the care plan as needed.

List of Planning Care by Letter: A

Activity intolerance	Risk for Activity intolerance	Ineffective Activity planning
Risk for Ineffective Activity planning	Ineffective Airway clearance	Risk for Allergy reaction
Anxiety	Death Anxiety	Risk for Aspiration
Risk for impaired Attachment	Autonomic Dysreflexia	Risk for Autonomic Dysreflexia

A

• = Independent; ▲ = Collaborative; **EBN** = Evidence-Based Nursing **EB** = Evidence-Based

Activity intolerance

Lorraine Duggan MSN, ACNP-BC

NANDA-I

Definition

Insufficient physiological or psychological energy to endure or complete required or desired daily activities.

Defining Characteristics

Abnormal blood pressure response to activity; abnormal heart rate response to activity; electrocardiogram (ECG) change; exertional discomfort; exertional dyspnea; fatigue; generalized weakness

Related Factors

Imbalance between oxygen supply/demand; immobility; inexperience with an activity; physical deconditioning; sedentary lifestyle

At-Risk Population

History of previous activity intolerance

Associated Condition

Circulatory problem; respiratory condition

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Activity Tolerance; Endurance; Energy Conservation; Self-Care: Instrumental Activities of Daily Living (IADLs)

Example NOC Outcome with Indicators

Activity Tolerance as evidenced by the following indicators: Oxygen saturation with activity/Pulse rate with activity/Respiratory rate with activity/Blood pressure with activity/Electrocardiogram findings/Skin color/Walking distance. (Rate the outcome and indicators of **Activity Tolerance:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Participate in prescribed physical activity with appropriate changes in heart rate, blood pressure, and breathing rate; maintain monitor patterns (rhythm and ST segment) within normal limits

• State symptoms of adverse effects of exercise and report onset of symptoms immediately
• Maintain normal skin color; skin is warm and dry with activity
• Verbalize an understanding of the need to gradually increase activity based on testing, tolerance, and symptoms
• Demonstrate increased tolerance to activity

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Activity Therapy; Energy Management; Exercise Therapy: Ambulation

Example NIC Activities—Energy Management

Monitor cardiorespiratory response to activity; Monitor location and nature of discomfort or pain during movement/activity

Nursing Interventions and *Rationales*

• Determine cause of Activity intolerance (see Related Factors) and determine whether cause is physical, psychological, or motivational. **QSEN:** *As nurses we are called on to ensure higher levels of safety and quality for our clients by our governments, professional organizations, and hospital administrations. It is essential that we implement evidence-based nursing care strategies to reduce avoidable errors in care so that clinical outcomes improve (Vollman, 2013).*
• If mainly on bed rest, minimize cardiovascular, neuromuscular, and skeletal deconditioning by positioning the client in an upright position several times daily if possible and performing simple range-of-motion (ROM) techniques (passive or active). **EB:** *Physical inactivity leads to a deconditioning of the skeletal, neuromuscular, and cardiovascular systems. It can lead to impaired quality of life, loss of autonomy, falls, and fractures (Kramer et al, 2017).*
• Assess the client daily for appropriateness of activity and bed rest orders. Mobilize the client as soon as possible. **EB:** *Mobilization is a cost-effective and simple method of maintaining stable cardiovascular parameters (i.e., blood pressure, heart rate), countering orthostatic intolerance, and reducing the risk of secondary problems in clients during long-term immobilization (Wieser et al., 2014).*
• If the client is mostly immobile, consider use of a transfer chair or a chair that becomes a stretcher. **EB:** *The use of simple shifting aids can optimize the patient transfer by avoiding heavy lifting situations and possible back injury to the caregivers. It reduces the effort of the caregivers and makes sure that the patient is not hurt during the process of conversion (Ahmed et al, 2015).*
• When appropriate, gradually increase activity, allowing the client to assist with positioning, transferring, and self-care as able. Progress the client from sitting in bed to dangling, to standing, to ambulation. Always have the client dangle at the bedside before standing to evaluate for postural hypotension. **EB:** *A reduction in plasma volume associated with bed rest impacts the physiological responses of autonomic control of circulation (Dorantes-Mendez et al, 2013; Tibaldi et al, 2014).*
▲ When getting a client up, observe for symptoms of intolerance such as nausea, pallor, dizziness, visual dimming, and impaired consciousness, as well as changes in vital signs; manual blood pressure monitoring is best. *When an adult rises to the standing position, blood pools in the lower extremities; symptoms of central nervous system*

hypoperfusion may occur, including feelings of weakness, nausea, headache, lightheadedness, dizziness, blurred vision, fatigue, tremulousness, palpitations, and impaired cognition. **EB:** *Impaired orthostatic blood pressure recovery, delayed recovery, and/or sustained orthostatic hypotension are independent risk factors for future falls, unexplained falls, and injurious falls (Ciaren et al, 2017).*

• If the client has symptoms of postural hypotension, such as dizziness, lightheadedness, or pallor, take precautions, such as dangling the client and applying leg compression stockings before the client stands. **EB:** *Put graduated compression stockings on the client or use lower limb compression bandaging, if ordered, to return blood to the heart and brain. Have the client dangle at the side of the bed with legs hanging over the edge of the bed, flexing and extending the feet several times after sitting up, then standing slowly with someone holding the client. If the client becomes lightheaded or dizzy, return him or her to bed immediately (Tibaldi et al, 2014).*

• Perform ROM exercises if the client is unable to tolerate activity or is mostly immobile. See care plan for Risk for **Disuse** syndrome.

• Monitor and record the client's ability to tolerate activity: note pulse rate, blood pressure, respiratory pattern, dyspnea, use of accessory muscles, and skin color before, during, and after the activity. If the following signs and symptoms of cardiac decompensation develop, activity should be stopped immediately:

- ❍ Onset of chest discomfort or pain
- ❍ Dyspnea
- ❍ Palpitations
- ❍ Excessive fatigue
- ❍ Lightheadedness, confusion, ataxia, pallor, cyanosis, nausea, or any peripheral circulatory insufficiency
- ❍ Dysrhythmia
- ❍ Exercise hypotension
- ❍ Excessive rise in blood pressure
- ❍ Inappropriate bradycardia
- ❍ Increased heart rate
- ❍ Decreased oxygen saturation

▲ Instruct the client to stop the activity immediately and report to the health care provider if the client is experiencing the following symptoms: new or worsened intensity or increased frequency of discomfort; tightness or pressure in chest, back, neck, jaw, shoulders, and/or arms; palpitations; dizziness; weakness; unusual and extreme fatigue; or excessive air hunger**.** **EB:** *Cardiovascular deconditioning has long been recognized as a characteristic of the physiological adaptation to long-term bed rest in patients. The process is thought to contribute to orthostatic intolerance and enhance secondary complications in a significant way (Wieser et al, 2014).*

• Observe and document skin integrity several times a day. ***Activity*** *intolerance, if resulting in immobility, may lead to pressure ulcers. Mechanical pressure, moisture, friction, and shearing forces all predispose to their development.* Refer to the care plan Risk for impaired **Skin** integrity.

• Assess for constipation. If present, refer to care plan for **Constipation.** ***Activity*** *intolerance is associated with increased risk of* ***Constipation.***

▲ Refer the client to physical therapy to help increase activity levels and strength.

▲ Consider a dietitian referral to assess nutritional needs related to **Activity** intolerance; provide nutrition as indicated. If the client is unable to eat food, use enteral or parenteral feedings as needed.

• Recognize that malnutrition causes significant morbidity because of the loss of lean

body mass.
• Provide emotional support and encouragement to the client to gradually increase activity. Work with the client to set mutual goals that increase activity levels. Fear of breathlessness, pain, or falling may decrease willingness to increase activity.
▲ Observe for pain before activity. If possible, treat pain before activity and ensure that the client is not heavily sedated. *Pain restricts the client from achieving a maximal activity level and is often exacerbated by movement.*
▲ Obtain any necessary assistive devices or equipment needed before ambulating the client (e.g., walkers, canes, crutches, portable oxygen).
▲ Use a gait-walking belt when ambulating the client. **EBN:** *Use of gait belts is a nurse-driven intervention and encouraged to be used to assist in ambulation and transfer (Walker et al, 2014).*
▲ *Use evidence-based practices for safe client handling to reduce the risk of injury for both clients and health care workers (Elnitsky et al, 2014).*

Activity Intolerance Due to Respiratory Disease

• If the client is able to walk and has chronic obstructive pulmonary disease (COPD), use the traditional 6-minute walk distance to evaluate ability to walk.
▲ Ensure that the chronic pulmonary client has oxygen saturation testing with exercise. Use supplemental oxygen to keep oxygen saturation 90% or above or as prescribed with activity. **EB:** *Oxygen therapy can prolong life (Apps et al, 2016).*
• Monitor a respiratory client's response to activity by observing for symptoms of respiratory intolerance, such as increased dyspnea, loss of ability to control breathing rhythmically, use of accessory muscles, nasal flaring, appearance of facial distress, and skin tone changes such as pallor and cyanosis.
• Instruct and assist the client with COPD in using conscious, controlled breathing techniques during exercise, including pursed-lip breathing, and inspiratory muscle use.
▲ Evaluate the client's nutritional status. Refer to a dietitian if indicated. Use nutritional supplements to increase nutritional level if needed.
▲ For the client in the intensive care unit, consider mobilizing the client with passive exercise. **EBN:** *Nurses should consider incorporating at least 20 minutes of passive exercise early in the plan of care for critically ill clients treated with mechanical ventilation so that opportunities to improve client outcomes are not missed (Amidei & Sole, 2013).*
▲ *Refer the COPD client to a pulmonary rehabilitation program.* **EB:** *Pulmonary rehabilitation improves patient's functionality and decreases hospital admissions (Apps et al, 2016).*

Activity Intolerance Due to Cardiovascular Disease

• If the client is able to walk and has heart failure, consider use of the 6-minute walk test to determine physical ability.
• Allow for periods of rest before and after planned exertion periods such as meals, baths, treatments, and physical activity.
▲ Refer to a heart failure program or cardiac rehabilitation program for education, evaluation, and guided support to increase activity and rebuild life. **EB:** *Exercise training improves functional capacity, the ability to perform activities of daily living (ADLs), and quality of life, and it reduces the risk for subsequent cardiovascular events (Billinger et al, 2014).*

▲ Refer to a community support program that includes support of significant others.
▲ **EB:** *Contemporary studies now suggest that behavior change and multifactorial risk factor modification—especially smoking cessation and more intensive measures to control hyperlipidemia with diet, drugs, and exercise—may slow, halt, or even reverse (albeit modestly) the otherwise inexorable progression of atherosclerotic coronary artery disease (CAD) (Spring, 2013).*
• See care plan for Decreased **Cardiac** output for further interventions.

Pediatric

• Focus interview questions toward exercise tolerance specifically including any history of asthma exacerbations. **EB:** *Cardiopulmonary deconditioning should be considered as an important differential diagnosis for breathlessness among obese adolescents. Some of these children may need pulmonary rehabilitation if difficulty breathing is the perceived reason for not exercising (Shim et al, 2013).*

Geriatric

• Slow the pace of care. Allow the client extra time to perform physical activities. *Slow gait in older adults may be related to fear of falling, decreased strength in muscles, reduced balance or visual acuity, knee flexion contractures, and foot pain.* **QSEN:** *Older patients with chronic cardiac conditions are more vulnerable to falls and injuries. Cardiovascular conditions, prevalent in older people, are also the frequent cause of potentially harmful fall injuries in this group. The need to identify the fall risk-related factors that cluster with arrhythmia and syncope is relevant, in that it will potentially reduce patients' risk for falls and fall injuries (Belita et al, 2013).*
• Encourage families to help/allow an older client to be independent in whatever activities possible. **EB:** *Longitudinal observational studies show an association between higher levels of physical activity and a reduced risk of cognitive decline and dementia (Blondell et al, 2014). Older adults can engage in a variety of physical activities to advance health ranging from walking, gardening, to household chores, and/or planned group exercise (World Health Organization, 2017).*
▲ Assess for swaying, poor balance, weakness, and fear of falling while older clients stand/walk. Refer to physical therapy if appropriate. **EB:** *A home exercise program was beneficial to improve the balance of community-dwelling frail older adults (Light et al, 2016).*
• Refer to the care plan for Risk for **Falls** and Impaired **Walking.**
▲ Initiate ambulation by simply ambulating a patient a few steps from bed to chair, once a health care provider's out-of-bed order is obtained. **EBN:** *Lack of ambulation and deconditioning effects of bed rest are one of the most predictable causes of loss of independent ambulation in hospitalized older persons. Nurses have been identified as the professional most capable of promoting walking independence in the hospital setting (Doherty-King & Bowers, 2013).*
▲ Evaluate medications the client is taking to see if they could be causing **Activity** intolerance. **EB:** *Antihypertensive medications were associated with an increased risk of serious fall injuries, particularly among those with previous fall-related injuries. The potential harms versus benefits of antihypertensive medications should be weighed in deciding to continue treatment with antihypertensive medications in older adults with multiple chronic conditions (Tinetti et al, 2014).*
▲ If heart disease is causing **Activity** intolerance, refer the client for cardiac rehabilitation.

▲ Refer the disabled older client to physical therapy for functional training including gait training, stepping, and sit-to-stand exercises, or for strength training. **EBN:** *Older adults often experience functional losses during hospitalization. Clinical care activities have been increasingly promoted as a way to help older hospitalized patients offset these losses and recover from acute illness (Casey et al, 2016).*

Home Care

▲ Begin discharge planning as soon as possible with the case manager or social worker to assess the need for home support systems and the need for community or home health services. **EB:** *A structured, moderate-intensity physical activity program compared with a health education program reduced major mobility disability over 2.6 years among older adults at risk for disability. These findings suggest mobility benefit from such a program in vulnerable older adults (Pahor et al, 2014).*
▲ Assess the home environment for factors that contribute to decreased activity tolerance such as stairs or distance to the bathroom. Refer the client for occupational therapy, if needed, and to assist the client in restructuring the home and ADL patterns. *During hospitalization, clients and families often estimate energy requirements at home inaccurately because the hospital's availability of staff support distorts the level of care that will be needed.*
▲ Refer the client for physical therapy for strength training and possible weight training to regain strength, increase endurance, and improve balance. If the client is homebound, the physical therapist can also initiate cardiac rehabilitation. **EB:** *The older and frailer the individual, the greater the rationale for the addition of progressive resistance and balance training to aerobic exercise programs, given the prevalence of sarcopenia, mobility impairment, and functional dependency in this group. Frailty is not a contraindication to exercise, but conversely, one of the most important reasons to prescribe it (Bauman et al, 2016).*
• Encourage progress with positive feedback. The client's experience should be validated within expected norms. Recognition of progress enhances motivation.
• Teach the client/family the importance of and methods for setting priorities for activities, especially those having a high energy demand (e.g., home/family events). Instruct in realistic expectations.
• Encourage routine low-level exercise periods such as a daily short walk or chair exercises.
• Provide the client/family with resources such as senior centers, exercise classes, educational and recreational programs, and volunteer opportunities that can aid in promoting socialization and appropriate activity. Social isolation can be an outcome of and contribute to **Activity** intolerance.
• Instruct the client and family in the importance of maintaining proper nutrition.
• Instruct the client in use of dietary supplements as indicated. Illness may suppress appetite, leading to inadequate nutrition.
▲ Refer to medical social services as necessary to assist the family in adjusting to major changes in patterns of living because of **Activity** intolerance.
▲ Assess the need for long-term supports for optimal activity tolerance of priority activities (e.g., assistive devices, oxygen, medication, catheters, massage), especially for a hospice client. Evaluate intermittently.
▲ Refer to home health aide services to support the client and family through changing levels of activity tolerance. Introduce aide support early. Instruct the aide to promote independence in activity as tolerated.

• Allow terminally ill clients and their families to guide care. Control by the client or family respects their autonomy and promotes effective coping.
• Provide increased attention to comfort and dignity of the terminally ill client in care planning. *Interventions should be provided as much for psychological effect as for physiological support. For example, oxygen may be more valuable as a support to the client's psychological comfort than as a booster of oxygen saturation.*
▲ Institute case management of frail elderly to support continued independent living.

Client/Family Teaching and Discharge Planning

• Instruct the client on techniques for avoiding **Activity** intolerance, such as controlled breathing techniques.
• Teach the client techniques to decrease dizziness from postural hypotension when standing up.
• Help client with energy conservation and work simplification techniques in ADLs.
• Describe to the client the symptoms of **Activity** intolerance, including which symptoms to report to the physician.
• Explain to the client how to use assistive devices, oxygen, or medications before or during activity.
• Help the client set up an activity log to record exercise and exercise tolerance.

Risk for Activity intolerance

Mary Beth Flynn Makic PhD, RN, CCNS, FAAN, FNAP

NANDA-I

Definition

Susceptible to experiencing insufficient physiological or psychological energy to endure or complete required or desired daily activities, which may compromise health.

Risk Factors

Imbalance between oxygen supply/demand; immobility; inexperience with an activity; physical deconditioning; sedentary lifestyle

At-Risk Population

History of previous activity intolerance

Associated Condition

Circulatory problem; respiratory condition

NIC, NOC, Client Outcomes, Nursing Interventions and *Rationales*, Client/Family Teaching and Discharge Planning, and References

Refer to care plan for **Activity** intolerance.

Ineffective Activity planning

Annie Muller DNP, APRN-BC, Gail B. Ladwig MSN, RN

NANDA-I

Definition

Inability to prepare for a set of actions fixed in time and under certain conditions.

Defining Characteristics

Absence of plan; excessive anxiety about a task to be undertaken; fear about task to be undertaken; insufficient organizational skills; insufficient resources; pattern of failure; pattern of procrastination; unmet goals for chosen

activity; worried about a task to be undertaken

Related Factors

Flight behavior when faced with proposed solution; hedonism; insufficient information processing ability; insufficient social support; pattern of procrastination; unrealistic perception of event; unrealistic perception of personal abilities

NOC Outcomes (Nursing Outcomes Classification)

Suggested NOC Outcomes

Cognition; Cognition Orientation; Concentration; Decision-Making; Information Processing; Memory

Example NOC Outcome with Indicators

Cognition as evidenced by the following indicators: Communication clear and appropriate for age/Comprehension of the meaning of situations/Information processing/Alternatives weighed when making decisions. (Rate the outcome and indicators of **Cognition:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Patient Outcomes

Patient Will (Specify Time Frame)

- Verbalize need for self-directed activity
- Choose the health care option that fits his or her lifestyle within an appropriate amount of time that allows enactment of the choice
- Describe how the chosen option fits into current lifestyle before or after the decision has been made
- Verbalize the need for a behavioral change to improve physical activity
- Offer alternative options to those with barriers to participating in physical activity

NIC Interventions (Nursing Interventions Classification)

Suggested NIC Interventions

Activity Therapy; Anxiety Reduction; Behavior Management; Behavior Modification; Calming Technique; Coping Enhancement; Cognitive Restructuring; Decision-Making Support; Life Skills Enhancement

Example NIC Activities—Coping Enhancement

Assist client in developing an objective appraisal of the event; Explore with client previous methods of dealing with life problems

Nursing Interventions and *Rationales*

- Ask clients how they perceive the situation to gather their personal vision of the problem and how they envisage their self-involvement. Specify the goals. *Clients and caregivers may have different priorities on what is important (Junius-Walker et al, 2011).*
    - ❍ Identify the informational needs of the client: understanding of the client's state of health, supervision of client's treatment if he or she is receiving treatment, diet, and important telephone numbers. **EBN:** *This study of clients with stage 4 chronic kidney disease validated the need for an individual assessment to determine the unique informational needs of each person (Lewis et al, 2010).*
    - ❍ Tackle the client's fears and worries and encourage him or her to make a cognitive reconstruction. Use "desire thinking." Drill and repeat: "I can

change false ideas that make me believe that I am unable to carry out (achieve) my plan." **EBN:** *Desire thinking is a voluntary cognitive process involving verbal and imaginal elaboration of a desired target. Recent research has highlighted the role of desire thinking in the maintenance of addictive, eating, and impulse control disorders (Caselli & Spada, 2011).*

• Client verbalizes need for behavioral change for improved physical activity. **EB:** *This study reflects how combining planning and coping planning of a client's self-worth can be beneficial in promoting an exercise program for those individuals who lack self-esteem (Kroon et al, 2014).*

• Encourage clients to verbalize the need for physical activity to help reduce role overload. **EB:** *This study demonstrated the need for planning activities for those individuals who were experiencing a role overload in life to allow them time for leisure activities (Lovell & Butler, 2015).*

▲ Determine as fairly as possible the success factors needed for the planning and success of the project: financial resources; the family situation; prior medical, psychiatric, and psychosocial conditions; material resources; and the ability to manage stress. **EBN:** *Discussions identifying resources help to handle past resources, the functional solutions of everyday life, favorable changes, exceptions and differences in everyday life, the availability of support, and the prospects of future. By noting and providing feedback to families, the nurse offers families a new perspective on themselves (Häggman-Laitila et al, 2010).*

▲ *Older adult patients may be able to delay or prevent problems of chronic diseases by engaging in physical activity (Watson et al, 2016).*

Pediatric

• Begin activity planning in preschool-aged children of working parents. **EB:** *This study focused on the inactivity of migrant workers' preschool-aged children and the need to have a more structured and planned activity for the migrant worker. The focus was on the child because not much is known and very little research has been done. Also, there is a wide disparity of health in this population. The results showed very little physical activity was encouraged by parents and there was a great need for intervention to help with developing a future healthy lifestyle for reducing potential long-term health problems (Grzywacz et al, 2014).*

• Establish a contract. **EBN:** *This study of adolescents with type 1 diabetes indicated that behavioral contracts may be an important adjunct to reduce nagging and improve outcomes with behavioral changes (Carroll et al, 2011).*

• Provide support to the schools for physical activities in all school venues. **EB:** *Depending on the location of the school and the available resources, schools may promote a physical activity program that is beneficial and available to the student. Schools with few resources have limited staff available, which can be a barrier to promoting a healthy lifestyle to the adolescent student (Hobin et al, 2013).*

• Support safe neighborhood activity programs. **EB:** *Children who immigrate to the United States are at higher risk for inactivity than those from the United States. Safety issues in the neighborhoods could be an issue that causes a barrier and prevents them from engaging in outside physical activity (Brewer & Kimbro, 2014).*

Geriatric

• Plan activities for older clients. **EB:** *In a study of stroke clients, it was found that physical*

activity may improve quality of life, physical function, and self-worth (Walter et al, 2015).
• Plan activities for older clients with impaired mental function. **EB:** *In this study, it was found that clients with impaired mental function are often limited in their ability to become involved with planned physical activity; therefore staff is needed to intervene and assist with the planned activity (Koring et al, 2012).*
• Community-based activities for older adults. **EB:** *A study for group exercises demonstrated improved mobility of the older adults who attended twice weekly exercises and mobility classes (Brach et al, 2017).*

Multicultural

• Provide literature and information in the appropriate language for the client who speaks little to no English. **EB:** *This study was able to show that those clients who did not speak English fluently were not adequately prepared for or educated on the need for physical activity, and they were not well represented in the study to show that culture was represented in understanding about cognitive health and risks of Alzheimer's disease (Rose et al, 2013).*
• Preplanning educational programs for the culturally diverse population needs to be developed. **EB:** *A low level of preplanning and poor organization of physical activities for the culturally diverse causes a loss of participation by those involved because of a lack of understanding of the concepts involved (Jeong et al, 2015).*
• Education with support from the physician and family to provide teaching on how exercise can help reduce and/or prevent falls of older adults. **EB:** *A study done on how culture influences exercise participation showed cultural values and social support to be positively instrumental in helping to reduce falls in the older population (Jang et al, 2016).*

Home Care

• Have a preplanned activity exercise for the home client with a debilitating musculoskeletal disease to help improve functional status. **EB:** *This study showed an improvement for those clients who were homebound because of a musculoskeletal disorder, which improved their personal commitment to exercise to increase their functional ability by gaining some muscle strength and range of motion (Hideyuki & Hitoshi, 2014).*
• Assess the home environment for barriers that can impact the client's motivation to be a participant in the activity planned. **EB:** *The research study done on homebound older adults showed that the client knew and understood the need for planned physical activity, but they were not motivated to participate because they thought their age was a barrier. The idea is to teach the older client that although age may be a factor in some types of activity planning or exercise, there are many ways to adapt to the activity that can be accommodating to the client's ability (Burton et al, 2013).*
• Home care for the cardiac rehabilitation patient: **EB:** *Providing a daily exercise plan for the home care cardiac rehabilitation patient did show improvement in the cardiorespiratory function of the patient (Noites et al, 2017).*
• For additional interventions, refer to care plans **Anxiety,** Readiness for enhanced family **Coping,** Readiness for enhanced **Decision-Making, Fear,** Readiness for enhanced **Hope,** Readiness for enhanced **Power,** Readiness for enhanced **Spiritual** well-being, and Readiness for enhanced **Health** management.

Risk for Ineffective Activity planning

Gail B. Ladwig MSN, RN

NANDA-I

Definition

Susceptible to an inability to prepare for a set of actions fixed in time and under certain conditions, which may compromise health.

Risk Factors

Flight behavior when faced with proposed solution; hedonism; insufficient information processing ability; insufficient social support; pattern of procrastination; unrealistic perception of event; unrealistic perception of personal abilities

NOC, NIC, Client Outcomes, Nursing Interventions and *Rationales*, Client/Family Teaching and Discharge Planning, and References

Refer to ineffective **Activity** planning.

Ineffective Airway clearance

Debra Siela PhD, RN, CCNS, ACNS-BC, CCRN-K, CNE, RRT

NANDA-I

Definition

Inability to clear secretions or obstructions from the respiratory tract to maintain a clear airway.

Defining Characteristics

Absence of cough; adventitious breath sounds; alteration in respiratory pattern; alteration in respiratory rate; cyanosis; difficulty verbalizing; diminished breath sounds; dyspnea; excessive sputum; ineffective cough; orthopnea; restlessness; wide-eyed look

Related Factors

Excessive mucus; exposure to smoke; foreign body in airway; retained secretions; secondhand smoke; smoking

Associated Condition

Airway spasm; allergic airway; asthma; chronic obstructive pulmonary disease; exudate in the alveoli; hyperplasia of the bronchial walls; infection; neuromuscular impairment; presence of artificial airway

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Aspiration Prevention; Respiratory Status: Airway Patency, Gas Exchange, Ventilation

Example NOC Outcome with Indicators

Respiratory Status: Ventilation as evidenced by the following indicators: Respiratory rate/Respiratory rhythm/Depth of inspiration/Chest expansion symmetrical/Ease of breathing/Tidal volume/Vital capacity. (Rate each indicator of **Respiratory Status: Ventilation:** 1 = severe deviation from normal range, 2 = substantial deviation from normal range, 3 = moderate deviation from normal range, 4 = mild deviation from normal range, 5 = no deviation from normal range [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Demonstrate effective coughing and clear breath sounds
- Maintain a patent airway at all times
- Explain methods useful to enhance secretion removal
- Explain the significance of changes in sputum to include color, character, amount, and odor
- Identify and avoid specific factors that inhibit effective airway clearance

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Airway Management; Airway Suctioning; Cough Enhancement

Example NIC Activities—Airway Management

Instruct how to cough effectively; Auscultate breath sounds, noting areas of decreased or absent ventilation and presence of adventitious sounds

Nursing Interventions and *Rationales*

• Auscultate breath sounds every 1 to 4 hours. The presence of crackles and wheezes may alert the nurse to airway obstruction, which may lead to or exacerbate existing hypoxia. *In severe exacerbations of chronic obstructive pulmonary disease (COPD), lung sounds may be diminished or distant with air trapping (Bickley & Szilagyi, 2017).*

• Monitor respiratory patterns, including rate, depth, and effort. *A normal respiratory rate for an adult without dyspnea is 12 to 16 breaths per minute (Bickley & Szilagyi, 2017). With secretions in the airway, the respiratory rate will increase.*

• Monitor blood gas values and pulse oxygen saturation levels as available. An oxygen saturation of less than 90% (normal: 95%–100%) or a partial pressure of oxygen of less than 80 mm Hg (normal: 80–100 mm Hg) indicates significant oxygenation problems (*Bickley & Szilagyi, 2017*; *Siela & Kidd, 2017*; *Lee 2017*).

▲ Administer oxygen as ordered. *Oxygen administration has been shown to correct hypoxemia. Administer humidified oxygen through an appropriate device (e.g., nasal cannula or Venturi mask per the health care provider's order); aim for an oxygen (O_2) saturation level of 90% or above. Oxygen should be titrated to target an SpO_2 of 94% to 98%, except with carbon monoxide poisoning (100% oxygen), acute respiratory distress syndrome (ARDS) (88%–95%), those at risk for hypercapnia (88%–92%), and premature infants (88%–94%).*

• Position the client in a semirecumbent position with the head of the bed at a 30- to 45-degree angle to decrease the aspiration of gastric, oral, and nasal secretions (American Association of Critical Care Nurses, 2016, 2017; Grap, 2009; Siela, 2010; Vollman et al, 2017). **CEB/EB:** *In a mechanically ventilated client, there is a decreased incidence of ventilator-associated pneumonia (VAP)/ventilator-associated event if the client is positioned at a 30- to 45-degree semirecumbent position rather than a supine position (American Association of Critical Care Nurses, 2017*; *Vollman et al, 2017*; *Siela, 2010).*

• Help the client deep breathe and perform controlled coughing. Have the client inhale deeply, hold breath for several seconds, and cough two or three times with mouth open while tightening the upper abdominal muscles. **CEB:** *Controlled coughing uses the diaphragmatic muscles, making the cough more forceful and effective (Gosselink et al, 2008*; *GOLD, 2017).*

• If the client has obstructive lung disease, such as COPD, cystic fibrosis, or bronchiectasis, consider helping the client use the forced expiratory technique called the "huff cough." The client does a series of coughs while saying the word "huff." *This technique prevents the glottis from closing during the cough and is effective in clearing secretions (Gosselink et al, 2008*; *GOLD, 2017).*

▲ Encourage the client to use an incentive spirometer. Recognize that controlled coughing and deep breathing may be just as effective as incentive spirometry (Gosselink et al, 2008; GOLD, 2017).

• Encourage activity and ambulation as tolerated. If the client cannot be ambulated, turn the client from side to side at least every 2 hours. *Body movement helps mobilize secretions.* (See interventions for impaired **Gas** exchange for further information on positioning a respiratory client.)

• Encourage fluid intake of up to 2500 mL/day within cardiac or renal reserve. *Fluids help minimize mucosal drying and maximize ciliary action to move secretions.*

▲ Administer medications such as bronchodilators or inhaled steroids as ordered. Watch for side effects such as tachycardia or anxiety with bronchodilators, or inflamed pharynx with inhaled steroids. *Bronchodilators decrease airway resistance, improve the efficiency of respiratory movements, improve exercise tolerance, and can reduce symptoms of dyspnea on exertion (O'Donnell et al, 2014). Pharmacologic therapy in COPD is used to reduce symptoms, reduce the frequency and severity of exacerbation, and improve health strategies and exercise tolerance (GOLD, 2017).*
▲ Provide percussion, vibration, and oscillation as appropriate for individual client needs. *Airway clearance techniques for clients with acute exacerbations of COPD may have a small but important positive effect on the need for and duration of ventilatory assistance, and may reduce hospital length of stay (Osadnik et al, 2013). Mucoregulators such as N-acetylcysteine and carbocysteine are recommended to reduce the frequency of COPD acute exacerbations (GOLD, 2017).*
• Observe sputum, noting color, odor, and volume. Normal sputum is clear or gray and minimal, whereas abnormal sputum is green, yellow, or bloody; malodorous; and often copious. The presence of purulent sputum during a COPD exacerbation can be a sufficient indication for starting empirical antibiotic treatment. Notify health care provider of purulent sputum (GOLD, 2017).

Critical Care

▲ In intubated clients, body positioning and mobilization may optimize airway secretion clearance. *Lateral rotational movement provides continuous postural drainage and mobilization of secretions (Wanless & Aldridge, 2011; St. Clair & MacDermott, 2017).* Reposition the client as needed. Use rotational or kinetic bed therapy in clients for whom side-to-side turning is contraindicated or difficult. **EBN:** *Changing position frequently decreases the incidence of atelectasis, pooling of secretions, and resultant pneumonia. Continuous, lateral rotational therapy has been shown to improve oxygenation and decrease the incidence of VAP (St. Clair & MacDermott, 2017; Nino & Makic, 2017).*
• If the client is intubated, consider use of kinetic therapy. Using a kinetic therapy bed slowly moves the client with 40-degree turns. *Kinetic therapy, or rotational therapy, may decrease the incidence of pulmonary complications in high-risk clients with increasing ventilator support requirements who are at risk for VAP, and with clinical indications for acute lung injury or ARDS with worsening PaO_2:FiO_2 ratio, presence of fluffy infiltrates via chest radiograph concomitant with pulmonary edema, and refractory hypoxemia (Bein et al, 2012; St. Clair & MacDermott, 2017; Nino et al, 2017).*
▲ *Early mobility and physical rehabilitation can reduce muscle weakness, mechanical ventilation duration, intensive care unit stay, and hospital stay (Costa et al, 2017; Spruit et al, 2013). The Awakening and Breathing Coordination, Delirium Monitoring and Management, and Early Mobility (ABCDE) bundle has criteria to determine when clients are candidates for early mobility (Balas et al, 2012; Costa et al, 2017).* An early mobility and walking program can promote weaning from ventilator support as a client's overall strength and endurance improve (Gosselink et al, 2008; Perme et al, 2014).
• If the client is intubated and is stable, consider getting the client up to sit at the edge of the bed, transfer to a chair, or walk as appropriate, if an effective interdisciplinary team is developed to keep the client safe (Balas et al, 2012; Costa et al, 2017). *For every week of bed rest, muscle strength can decrease 20%; early ambulation also helped clients develop a positive outlook (Perme et al, 2014).*
• When suctioning an endotracheal tube or tracheostomy tube for a client on a ventilator, do the following:

- ❍ Explain the process of suctioning beforehand and ensure the client is not in pain or overly anxious. Suctioning can be a frightening experience; an explanation along with adequate pain relief or needed sedation can reduce stress, anxiety, and pain (Seckel, 2017).
- ❍ Hyperoxygenate before and between endotracheal suction sessions. Studies have demonstrated that hyperoxygenation may help prevent oxygen desaturation in a suctioned client (Seckel, 2017; Vollman et al, 2017; Siela, 2010).
- ❍ Suction for less than 15 seconds. Studies demonstrated that because of a drop in the partial pressure of oxygen with suctioning preferably there should be no more than 10 seconds of actual suctioning, with the entire procedure taking 15 seconds (Seckel, 2017).
- ❍ Use a closed, in-line suction system. Closed in-line suctioning has minimal effects on heart rate, respiratory rate, tidal volume, and oxygen saturation and may reduce contamination (Seckel, 2017).
- ❍ Avoid saline instillation during suctioning. **CEBN/EBN:** *Repeated studies have demonstrated that saline instillation before suctioning has an adverse effect on oxygen saturation in both adults and children (Seckel, 2017; Caparros, 2014; Rauen et al, 2008; Siela, 2010).*
- ❍ Use of a subglottic suctioning endotracheal tube reduces the incidence of VAP or ventilator-associated complications (Vollman et al, 2017; Haas et al, 2014).
- ❍ Use of nonstick endotracheal tubes can reduce the formation of biofilm and hence VAP (Haas et al, 2014).
- ❍ Document results of coughing and suctioning, particularly client tolerance and secretion characteristics such as color, odor, and volume (Seckel, 2017).

Pediatric

• Educate parents about the risk factors for ineffective airway clearance such as foreign body ingestion and passive smoke exposure.
• See the care plan Risk for **Suffocation** for more interventions on choking. **EB:** *Passive smoke exposure significantly increases the risk of asthma and respiratory infections in children (Farber et al, 2016). A recent study found maternal smoking increased childhood visits to the emergency department for exacerbated respiratory conditions to include asthma (Farber et al, 2016).*
• Educate children and parents on the importance of adherence to peak expiratory flow monitoring for asthma self-management.
• Educate parents and other caregivers that cough and cold medication bought over the counter are not safe for a child younger than 2 years unless specifically ordered by a health care provider.

Geriatric

• Encourage ambulation as tolerated without causing exhaustion. Immobility is often harmful to older adults because it decreases ventilation and increases stasis of secretions, leading to atelectasis or pneumonia.
• Actively encourage older adults to deep breathe and cough. Cough reflexes are blunted, and coughing is decreased in older adults.
• Ensure adequate hydration within cardiac and renal reserves. Older adults are

prone to dehydration and therefore more viscous secretions because they frequently use diuretics or laxatives and forget to drink adequate amounts of water.

Home Care

• Some of the previously mentioned interventions may be adapted for home care use.
▲ Begin discharge planning as soon as possible with the case manager or social worker to assess need for home support systems, assistive devices, and community or home health services.
• Assess home environment for factors that exacerbate airway clearance problems (e.g., presence of allergens, lack of adequate humidity in air, poor air flow, stressful family relationships).
• Assess affective climate within family and family support system. *Problems with respiratory function and resulting anxiety can provoke anger and frustration in the client. Feelings may be displaced onto caregiver and require intervention to ensure continued caregiver support.* Refer to care plan for **Caregiver Role Strain.**
• Refer to GOLD guidelines for management of home care and indications of hospital admission criteria (see http://www.goldcopd.org/).
• When respiratory procedures are being implemented, explain equipment and procedures to family members and caregivers and provide needed emotional support. *Family members assuming responsibility for respiratory monitoring often find this stressful. They may not have been able to assimilate fully any instructions provided by hospital staff.*
• When electrically based equipment for respiratory support is being implemented, evaluate home environment for electrical safety, proper grounding, and so on. Ensure that notification is sent to the local utility company, the emergency medical team, and police and fire departments.
• Provide family with support for care of a client with chronic or terminal illness. *Breathing difficulty can provoke extreme anxiety, which can interfere with the client's ability or willingness to adhere to the treatment plan.*
• Refer to care plan for **Anxiety.** *Witnessing breathing difficulties and facing concerns of dealing with chronic or terminal illness can create fear in the caregiver. Fear inhibits effective coping.* Refer to care plan for **Powerlessness.**
• Instruct the client to avoid exposure to persons with upper respiratory infections, to avoid crowds of people, and wash hands after each exposure to groups of people or public places.
▲ Determine client adherence to medical regimen. Instruct the client and family in importance of reporting effectiveness of current medications to health care provider. *Inappropriate use of medications (too much or too little) can influence the amount of respiratory secretions.*
• Teach the client when and how to use inhalant or nebulizer treatments at home.
• Teach the client/family the importance of maintaining regimen and having "as-needed" drugs easily accessible at all times. *Success in avoiding emergency or institutional care may rest solely on medication compliance or availability.*
• Instruct the client and family in the importance of maintaining proper nutrition, adequate fluids, rest, and behavioral pacing for energy conservation and rehabilitation.
• Instruct in use of dietary supplements as indicated. *Illness may suppress appetite, leading to inadequate nutrition. Supplements will allow clients to eat with minimal energy consumption.*
• Identify an emergency plan, including criteria for use. *Ineffective airway clearance can*

be life-threatening.

▲ Refer for home health aide services for assistance with activities of daily living (ADLs). *Clients with decreased oxygenation and copious respiratory secretions are often unable to maintain energy for ADLs.*

▲ Assess family for role changes and coping skills. Refer to medical social services as necessary. *Clients with decreased oxygenation are unable to maintain role activities and therefore experience frustration and anger, which may pose a threat to family integrity. Family counseling to adapt to role changes may be needed.*

▲ For the client dying at home with a terminal illness, if the "death rattle" is present with gurgling, rattling, or crackling sounds in the airway with each breath, recognize that anticholinergic medications can often help control symptoms, if given early in the process. *Anticholinergic medications can help decrease the accumulation of secretions, but do not decrease existing secretions. This medication must be administered early in the process to be effective (Twomey & Dowling, 2013; Fielding & Long, 2014).*

▲ For the client with a death rattle, nursing care includes turning to mobilize secretions, keeping the head of the bed elevated for postural drainage of secretions, and avoiding suctioning. *Suctioning is a distressing and painful event for clients and families, and it is rarely effective in decreasing the death rattle (Twomey & Dowling, 2013; Fielding & Long, 2014).*

Client/Family Teaching and Discharge Planning

▲ Teach the importance of not smoking. Refer to a smoking cessation program, and encourage clients who relapse to keep trying to quit. Ensure that the client receives appropriate medications to support smoking cessation from the primary health care provider. *A Cochrane review found that use of the antidepressant medications increased the rate of smoking withdrawal two to three times more than smoking withdrawal without use of medications (Hughes et al, 2014).*

▲ Teach the client how to use a flutter clearance device if ordered, which vibrates to loosen mucus and gives positive pressure to keep airways open (Gosselink et al, 2008). **CEB:** *A study demonstrated that use of the mucus clearance device had improved exercise performance compared with COPD clients who use a sham device (Osadnik et al, 2013; Morrison & Agnew, 2009).*

▲ Teach the client how to use the peak expiratory flow rate (PEFR) meter if ordered and when to seek medical attention if the PEFR reading drops. Also teach the client how to use metered-dose inhalers and self-administer inhaled corticosteroids as ordered following precautions to decrease side effects.

• Teach the client how to deep breathe and cough effectively. *Controlled coughing uses the diaphragmatic muscles, making the cough more forceful and effective (Gosselink et al, 2008; GOLD, 2017).*

• Teach the client/family to identify and avoid specific factors that exacerbate ineffective airway clearance, including known allergens and especially smoking (if relevant) or exposure to secondhand smoke.

• Educate the client and family about the significance of changes in sputum characteristics, including color, character, amount, and odor. *With this knowledge, the client and family can identify early the signs of infection and seek treatment before acute illness occurs.*

• Teach the client/family the importance of taking antibiotics as prescribed and consuming all tablets until the prescription has run out. *Taking the entire course of antibiotics helps eradicate bacterial infection, which decreases lingering, chronic infection.*

• Teach the family of the dying client in hospice with a death rattle that rarely are clients aware of the fluid that has accumulated, and help them find evidence of comfort in the client's nonverbal behavior (*Twomey & Dowling, 2013*; *Fielding & Long, 2014*).

Risk for Allergy reaction

Julianne E. Doubet BSN, RN, EMT-B

NANDA-I

Definition

Susceptible to an exaggerated immune response or reaction to substances, which may compromise health.

Risk Factors

Exposure to allergen; exposure to environmental allergen; exposure to toxic chemical

At-Risk Population

History of food allergy; history of insect sting allergy; repeated exposure to allergen-producing environmental substance

NOC Outcomes (Nursing Outcomes Classification)

Suggested NOC Outcomes

Allergic Response: Systemic; Immune Hypersensitivity Response; Knowledge: Health Behavior, Risk Control, Risk Detection; Tissue Integrity: Skin and Mucous Membranes

Example NOC Outcome with Indicators

Immune Hypersensitivity Response as evidenced by the following indicators: Respiratory, cardiac, gastrointestinal, renal and neurological function status IER/Free of allergic reactions. (Rate each indicator of **Immune Hypersensitivity Response:** 1 = not controlled, 2 = slightly controlled, 3 = moderately controlled, 4 = well controlled, 5 = very well controlled [see Section I].)
IER, In expected range.

Client Outcomes

Client Will (Specify Time Frame)

- State risk factors for allergies
- Demonstrate knowledge of plan to treat allergic reaction

NIC Interventions (Nursing Interventions Classification)

Suggested NIC Interventions

Allergy Management; Environmental Risk Protection

Example NIC Activity

Place an allergy band on client

Nursing Interventions and *Rationales*

- A careful history is important in detecting allergens and avoidance of these allergens. **EB:** *In a review of the National Institute for Health and Care Excellence (NICE) recommendations, Walsh (2017) agreed that food allergies may be identified by using an "allergy-focused clinical history."*
- Obtain a precise history of allergies, as well as medications taken and foods ingested before surgery. **EB:** *In their study of perioperative anaphylaxis, Meng et al (2017) confirmed that antibiotics and neuromuscular blocking agents are common producers of anaphylaxis.*
- ▲ Teach the client about the correct use of the injectable epinephrine and have the client do a return demonstration. **EB:** *Recent research on the correct use of the injectable epinephrine showed that 84% of the patients were unable to do it correctly (Bonds et al, 2015).*
- ▲ Carefully assess the client for allergies. Below is information that is important for clients with allergies. Refer for immediate treatment if anaphylaxis is suspected.

Causes

Common allergens include animal dander; bee stings or stings from other insects; foods, especially nuts, fish, and shellfish; insect bites; medications; plants; pollens

Symptoms

Common symptoms of a mild allergic reaction include hives (especially over the neck and face), itching, nasal congestion, rashes, watery, red eyes

Symptoms of a moderate or severe reaction include cramps or pain in the abdomen; chest discomfort or tightness; diarrhea; difficulty breathing; difficulty swallowing; dizziness or lightheadedness; fear or feeling of apprehension or anxiety; flushing or redness of the face; nausea and vomiting; palpitations; swelling of the face, eyes, or tongue; weakness; wheezing; unconsciousness

First Aid

For a mild to moderate reaction: calm and reassure the person having the reaction because anxiety can worsen symptoms.

1. Try to identify the allergen and have the person avoid further contact with it. If the allergic reaction is from a bee sting, scrape the stinger off the skin with something firm (e.g., fingernail or plastic credit card). Do not use tweezers; squeezing the stinger will release more venom.
2. Apply cool compresses and over-the-counter hydrocortisone cream for itchy rash.
3. Watch for signs of increasing distress.
4. Get medical help. For a mild reaction, a health care provider may recommend over-the-counter medications (e.g., antihistamines).

For a Severe Allergic Reaction (Anaphylaxis)

1. Check the person's airway, breathing, and circulation (the ABCs of Basic Life Support). A warning sign of dangerous throat swelling is a very hoarse or whispered voice or coarse sounds when the person is breathing in air. If necessary, begin rescue breathing and cardiopulmonary resuscitation.
2. Call 911.
3. Calm and reassure the person.
4. If the allergic reaction is from a bee sting, scrape the stinger off the skin with something firm (e.g., fingernail or plastic credit card). Do not use tweezers; squeezing the stinger will release more venom.
5. If the person has emergency allergy medication on hand, help the person take or inject the medication. Avoid oral medication if the person is having difficulty breathing.
6. Take steps to prevent shock. Have the person lie flat, raise the person's feet about 12 inches, and cover him or her with a coat or blanket. Do NOT place the person in this position if a head, neck, back, or leg injury is suspected or if it causes discomfort.

Do NOT

- Do NOT assume that any allergy shots the person has already received will provide complete protection.
- Do NOT place a pillow under the person's head if he or she is having trouble breathing. This can block the airways.
- Do NOT give the person anything by mouth if the person is having trouble breathing.

When to Contact a Medical Professional

Call for immediate medical emergency assistance if:

- The person is having a severe allergic reaction—always call 911. Do not wait to see if the reaction is getting worse.
- The person has a history of severe allergic reactions (check for a medical ID tag).

Prevention

- Avoid triggers such as foods and medications that have caused an allergic reaction (even a mild one) in the past. Ask detailed questions about ingredients when you are eating away from home. Carefully examine ingredient labels. **EB:** *Education concerning allergen vulnerability will help patients to prevent most accidental exposures to known allergic triggers (Mahr & Hernandez-Trujillo, 2017).*
- If you have a child who is allergic to certain foods, introduce one new food at a time in limited amounts so you can recognize an allergic reaction. **EB:** *There is a decrease in the threat for the evolution of food allergies in patients who are at risk with the early introduction of known allergy-producing foods: abstaining from these types of foods, without a clear history of allergic reactions, may increase the chances of developing an allergy (Schroer et al, 2017).*
- People who know that they have had serious allergic reactions should wear a medical ID tag. **EBN:** *Anaphylaxis is a dangerous, unpredictable, and usually rapid hypersensitivity response to an allergen and is generally caused by a known irritant; it is advised then, that those who have had a severe allergic reaction wear medical alert jewelry (Hunt, 2016).*
- Preoperative patients should be closely assessed for allergies. **EB:** *According to Kuric et al (2017), general anesthesia may mask the classic, initial signs of allergy, which would be seen in the conscious patient.*
- ▲ If you have a history of serious allergic reactions, carry emergency medications (e.g., a chewable form of diphenhydramine and injectable epinephrine or a bee sting kit) according to your health care provider's instructions. *The initial intervention for anaphylaxis should be epinephrine; medical providers across the board agree that its quick administration is vital to prevent progression of the reaction, improve patient outcomes, and that epinephrine use will contribute to a decrease in hospitalizations and fatalities (Fromer, 2016).*
- Do not give your injectable epinephrine (or any other personal medication), to anyone else. They may have a condition (e.g., a heart problem) that could be negatively affected by this drug. **EB:** *Negative effects of medicine sharing include adverse events, complications, and a delay in seeking professional help; medicine sharing could also be motivated by ill-advised self-treatment options (Beyene et al, 2014).*
- ▲ Refer the client for skin testing to confirm IgE-mediated allergic response. **EB:** *Stylianou et al (2016) stated that allergen-specific immunotherapy (SIT) is thought to be the*

most effective remedy for immunoglobulin E (IgE)-mediated allergies.

- See care plans for **Latex Allergy** response and Risk for **Latex Allergy** response.

Pediatric

- ▲ Teach parents and children with allergies to peanuts and tree nuts to avoid them and to identify them. **EBN:** *Nut allergies can have an undesirable impact on both the individual and their family; the key responsibilities of the nurse is ongoing support of those affected and to aid in creating a management plan to control allergen response (Proudfoot & Saul, 2016).*
- ▲ Teach parents and children with asthma about modifiable risk factors, which include allergy triggers. **EBN:** *Proudfoot & Saul (2016) recommended that those who care for asthmatic children have a "Risk Assessment Management Plan" that includes avoidance of the allergen (nuts, etc.), rescue medication, diabetic referral as needed, and continued support for both child and family.*
- ▲ Counsel parents to limit infant exposure to traffic and cigarette carbon monoxide pollution**. EB:** *Early childhood exposure to traffic-related air pollution (TRAP) was linked with the evolution of asthma in childhood (Bowatte et al, 2015).* **EBN:** *Children exposed to secondhand smoke (SHS) have an elevated rate of respiratory infections, ear infections, SHS-triggered asthma attacks, and sudden infant death syndrome (Kleier et al, 2017).*
- ▲ Suspect food protein-induced enterocolitis syndrome (FPIES) in formula-fed infants with repetitive emesis, diarrhea, dehydration, and lethargy 1 to 5 hours after ingesting the offending food (the most common are cow's milk, soy, and rice). Remove the offending food. **EB:** *If FPIES becomes chronic, it may lead to an infant's failure to thrive (Nowak-Wegrzyn et al, 2015).*
- ▲ Children should be screened for seafood allergies and if an allergy is detected, avoid seafood and any foods containing seafood. **EB:** *According to a study by Presler (2016), fish and shellfish are powerful allergens that cause grave IgE antibody-mediated untoward reactions in those who are sensitive.*

Anxiety

Gail B. Ladwig MSN, RN, Julianne E. Doubet BSN, RN, EMT-B

NANDA-I

Definition

Vague, uneasy feeling of discomfort or dread accompanied by an autonomic response (the source often nonspecific or unknown to the individual); a feeling of apprehension caused by anticipation of danger. It is an alerting sign that warns of impending danger and enables the individual to take measures to deal with threat.

Defining Characteristics

Behavioral

Decrease in productivity; extraneous movement; fidgeting; glancing about; hypervigilance; insomnia; poor eye contact; restlessness; scanning behavior; worried about change in life event

Affective

Anguish; apprehensiveness; distress; fear; feelings of inadequacy; helplessness; increase in wariness; irritability; nervousness; overexcitement; rattled; regretful; self-focused; uncertainty

Physiological

Facial tension; hand tremors; increase in perspiration; increase in tension; trembling; tremor; voice quivering

Sympathetic

Alteration in respiratory pattern; anorexia; brisk reflexes; cardiovascular excitation; diarrhea; dry mouth; facial flushing; heart palpitations; increase in blood pressure; increase in heart rate; increase in respiratory rate; pupil dilation; superficial vasoconstriction; twitching; weakness

Parasympathetic

Abdominal pain; alteration in sleep pattern; decreased blood pressure; decrease in heart rate; diarrhea; faintness; fatigue; nausea; tingling in extremities; urinary frequency; urinary hesitancy; urinary urgency

Cognitive

Alteration in attention; alteration in concentration; awareness of physiological symptoms; blocking of thoughts; confusion; decrease in perceptual field; diminished ability to learn; diminished ability to problem solve; forgetfulness; fear; preoccupation; rumination; tendency to blame others

Related Factors

Conflict about life goals; interpersonal contagion; interpersonal transmission; stressors; substance misuse; threat of death; threat to current status; unmet needs; value conflict

At-Risk Population

Exposure to toxin; family history of anxiety; heredity; major change; maturational crisis; situational crisis

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Anxiety Level; Anxiety Self-Control; Coping; Impulse Self-Control Fear level; Fear Self-Control; Mood Equilibrium

Example NOC Outcome with Indicators

Anxiety Self-Control as evidenced by the following indicators: Eliminates precursors of anxiety/Monitors physical manifestations of anxiety/Controls anxiety response. (Rate the outcome and indicators of **Anxiety Self-Control:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often

demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Identify and verbalize symptoms of anxiety
- Identify, verbalize, and demonstrate techniques to control anxiety
- Verbalize absence of or decrease in subjective distress
- Have vital signs that reflect baseline or decreased sympathetic stimulation
- Have posture, facial expressions, gestures, and activity levels that reflect decreased distress
- Demonstrate improved concentration and accuracy of thoughts
- Demonstrate return of basic problem-solving skills
- Demonstrate increased external focus
- Demonstrate some ability to reassure self

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Anxiety Reduction; Calming Technique; Coping Enhancement; Impulse Control Training; Relaxation Therapy

Example NIC Activities—Anxiety Reduction

Use calm, reassuring approach; Explain all procedures, including sensations likely to be experienced during the procedure

Nursing Interventions and *Rationales*

- Assess the client's level of anxiety and physical reactions to anxiety (e.g., tachycardia, tachypnea, irritability, restlessness). **EBN:** *Barley & Lawson (2016) stated in their study of health psychology's effects on common mental disorders that for nurses to deliver holistic care, they must be alert to the possibility that the patient may be undergoing psychological anxiety and then use appropriate communication skills to identify and manage this issue.*
- Rule out withdrawal from alcohol, sedatives, or smoking as the cause of anxiety. **EBN:** *Signs and symptoms of alcohol withdrawal syndrome (AWS) are many times indistinguishable from other illnesses, especially those seen in the acute care setting (Skinner, 2014).*
- Use empathy to encourage the client to interpret the anxiety symptoms as normal. **CEB:** *The way a nurse interacts with a client influences his or her quality of life. Providing psychological and social support can reduce the symptoms and problems associated with anxiety (Wagner & Bear, 2009).*
- If irrational thoughts or fears are present, offer the client accurate information and encourage him or her to talk about the meaning of the events contributing to the anxiety. **EBN:** *In one study providing cancer patients with accurate information about their disease, prognosis and outcomes significantly reduced their anxiety and increased empowerment (Lauzier et al, 2014).*
- Encourage the client to use positive self-talk. **EBN:** *One research study showed that self-talk strengthens both actual behavior performance and prospective behavioral intentions (Dolcos & Albarracin, 2014).*
- Intervene when possible to remove sources of anxiety. **EBN:** *Aiding in the reduction*

of anxiety is an essential nursing intervention in patient care state (Elham et al, 2015).
• Explain all activities, procedures, and issues that involve the client; use nonmedical terms and calm, slow speech then validate the client's understanding. **EBN:** *In a study of the needs of anxious and/or depressed patients, Kim (2016) found that nursing care must include patient-centered undertakings to form a bond between patient and nurse, therefore reassuring and empowering these patients.*
▲ Use massage therapy to reduce anxiety. **EBN:** *The use of massage therapy has been shown to markedly reduce psychological stress and anxiety (Kim et al, 2016).*
▲ Consider massage therapy for preoperative clients. **EBN:** *Complementary therapies, including massage, have been shown to aid patient relaxation prior to surgery (Hansen, 2015).*
• Use therapeutic touch and healing touch techniques. **EBN:** *One study showed that Reiki therapeutic touch reduced anxiety and pain (Sagkal et al, 2013).*
• Use guided imagery to decrease anxiety. **EBN:** *Guided imagery can be utilized to aid patients in handling undesirable emotions connected with the symptoms of their illness (Nooner et al, 2016).*
• Suggest yoga to the client. **EBN:** *In a study by Centrella-Negro (2017), it was noted that the practice of yoga was beneficial to the welfare and comfort of cardiac patients.*
• Provide clients with a means to listen to music of their choice or audiotapes. **EBN:** *According to Quach (2017), nurses and other providers should recognize the value of music therapies and use them in patient care when appropriate.*

Pediatric

• The previously mentioned interventions may be adapted for the pediatric client.

Geriatric

▲ Monitor the client for depression. Use appropriate interventions and referrals. **EBN/EB:** *Gould et al (2016) stated that "Anxiety disorders are common and debilitating in older individuals" and further noted that simple tests used to recognize anxiety symptoms in the older patient are beneficial because they can begin discussions about current treatments.*
• Observe for adverse changes if antianxiety drugs are taken. **EB:** *Because of changes in pharmacodynamics and pharmacokinetics in older patients, those who take antianxiety drugs should be watched for potential side effects (Jacobson, 2013).*
• Mindfulness meditation is successful in mediating anxiety. **EB:** *The use of mindfulness has become an accepted clinical treatment in reducing anxiety and stress (Grecucci et al, 2015).*

Multicultural

• Assess for the presence of culture-bound anxiety states. **EBN:** *When assessing people with culturally and linguistically diverse (CALD) histories, it is imperative that any special cultural practices, requirements, or beliefs, such as prayers or alternative medicines, are acknowledged and appreciated when planning nursing interventions (Baker et al, 2016).*
• Identify how anxiety is manifested in the culturally diverse client. **EB:** *People of non-Western ethnocultural origins many times have diverse ideas and contrasting perceptions of mental health and illness as opposed to those from Western societies (Balkir Neftci & Barnow, 2016).*
• For diverse clients experiencing preoperative anxiety, provide music of their choice. **EBN:** *According to Quach (2017), music, as a complimentary intervention, has been shown to notably improve both patient anxiety and patient physical well-being and should be used in*

nursing care.

Home Care

- The previously mentioned interventions may be adapted for home care use.
- ▲ Assess for suicidal ideation. **EBN:** *Developing a protective setting for patients who are suicidal first necessitates recognizing those patients who are at risk; The Nurses' Global Assessment of Suicide Risk is an assessment tool that is an accepted evidence-based suicide risk evaluation (Adams, 2013).*
- Assess for influence of anxiety on medical regimen. **CEB:** *Anxiety can affect a patient's ability to complete their medical regimen as prescribed, including taking medications, exercise, diet, and follow-up therapies (Hynninen et al, 2010).*
- Assess for presence of depression. **EBN:** *Clinician report generally had the most favorable sensitivity and specificity for measuring depressive symptoms and treatment recommendations, respectively (Henry et al, 2014).*
- Assist family to be supportive of the client in the face of anxiety symptoms. **EBN:** *Vieira et al (2015) surmised in a study that both patient and caregiver/family must realize and accept that medical conditions will bring a change of lifestyle for each and they should adapt as best they can.*
- ▲ Consider referral for the prescription of antianxiety or antidepressant medications for clients who have panic disorder (PD) or other anxiety-related psychiatric disorders. **EBN:** *Pharmacotherapy is an effective intervention for anxiety disorders because it decreases symptoms and enhances a sense of well-being for the patient (da Cruz et al, 2016).*
- ▲ Assist the client/family to institute the medication regimen appropriately. Instruct in side effects and the importance of taking medications as ordered. **EBN:** *Instruct the patient and/or caregivers concerning possible drug side effects and interactions that could have detrimental results (sleepiness, nausea, etc.) on the patient and be certain the patient/caregiver understands how the medication is to be given (Creed, 2017).*
- ▲ Refer for psychiatric home health care services. **CEB:** *Providing home health services for patients with anxiety increases self-efficacy and reduces symptoms of anxiety, stress, and depression (Shelby et al, 2009).* **EB:** *A mixture of mental health services is provided in some aging services networks that incorporates screenings, telephone reassurance, individual counseling, and support groups (Roberts et al, 2014).*

Client/Family Teaching and Discharge Planning

- ▲ Teach use of appropriate community resources in emergency situations (e.g., suicidal thoughts), such as hotlines, emergency departments, law enforcement, and judicial systems. **EB:** *Boudreaux et al (2016) suggested that community mental health services, delivered in conjunction with community emergency departments, may improve patient commitment to aftercare and as a result reduce future behavioral health crises as well as decrease return visits to the emergency department.*
- Teach the client/family the symptoms of anxiety.
- Teach the client techniques to self-manage anxiety. **EB:** *Guided Internet-based cognitive-behavioral therapy (ICBT) has been found to be valuable for social anxiety disorder (SAD) by some research groups (Boettcher et al, 2013).*
- Teach the client to visualize or fantasize about the absence of anxiety or pain, successful experience of the situation, resolution of conflict, or outcome of procedure. **EB:** *Guided imagery has been shown to augment comfort and can be used as a psychosupportive intervention (Satija & Bhatnagar, 2017).*

• Teach the relationship between a healthy physical and emotional lifestyle and a realistic mental attitude. **EBN:** *Jiwani (2016) stated that "anxiety leads to physiological and psychological changes in the human body" and can be controlled with various learned self-help techniques.*

Death Anxiety

Gail B. Ladwig MSN, RN, Julianne E. Doubet BSN, RN, EMT-B

NANDA-I

Definition

Vague, uneasy feeling of discomfort or dread generated by perceptions of a real or imagined threat to one's existence.

Defining Characteristics

Concern about strain on the caregiver; deep sadness; fear of developing terminal illness; fear of loss of mental abilities when dying; fear of pain related to dying; fear of premature death; fear of prolonged dying process; fear of suffering related to dying; fear of the dying process; negative thoughts related to death and dying; powerlessness; worried about the impact of one's death on significant other

Related Factors

Anticipation of adverse consequences of anesthesia; anticipation of impact of death on others; anticipation of pain; anticipation of suffering; discussions on topic of death; nonacceptance of own mortality; observations related to death; perceived imminence of death; uncertainty about encountering a higher power; uncertainty about life after death; uncertainty about the existence of a higher power; uncertainty of prognosis

At-Risk Population

Discussions on the topic of death; experiencing the dying process; near-death experience; observations related to dying process

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Acceptance: Health Status; Anxiety Self-Control; Comfort Status: Psychospiritual; Comfortable Death; Coping; Dignified Life Closure; Family Coping; Fear Self-Control; Grief Resolution; Health Beliefs: Perceived Threat: Hope; Personal Resiliency; Psychosocial Adjustment; Life Change; Quality of Life

Example NOC Outcome with Indicators

Dignified Life Closure as evidenced by the following indicators: Expresses readiness for death/Resolves important issues/Shares feelings about dying/Discusses spiritual concerns. (Rate the outcome and indicators of **Dignified Life Closure:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- State concerns about impact of death on others
- Express feelings associated with dying
- Seek help in dealing with feelings
- Discuss realistic goals
- Use prayer or other religious practice for comfort

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Active Listening; Animal Assisted Therapy; Anticipatory Guidance; Anxiety Reduction; Aromatherapy; Coping Enhancement; Dying Care; Emotional Support; Grief Work Facilitation; Journaling; Respite Care; Spiritual Support; Support System Enhancement

Example NIC Activities—Dying Care

Communicate willingness to discuss death; Support client and family through stages of grief

Nursing Interventions and *Rationales*

- ▲ Assess the psychosocial maturity of the individual. **EB:** *In a large study, females scored higher on death anxiety than males. Additional tests reported that life satisfaction, an altering consciousness coping style, and avoidance coping was significantly related to risk for developing a stress-related illness when faced with the death of a loved one (Moore, 2013).*
- ▲ Assess clients for pain and provide pain relief measures. **EB:** *Pain can be a significant problem that has important ramifications on patients' quality of life and the management of pain can be obstructed by poor patient–provider communication (Johnsen et al, 2016).* **EBN:** *Nurses have a fundamental responsibility for the assessment and alleviation of patient's pain (Brorson et al, 2014).*
- Assess client for fears related to death. **EB:** *In their study of chronic obstructive pulmonary disease (COPD) patients with end-of-life issues, Stenzel et al (2015) found that patient care should not be limited to managing just the physical manifestation of the disease, but also the need to address psychological anxiety and disease-specific concerns.*
- Assist clients with life planning: consider and redefine main life goals, focus on areas of strength and/or goals that will provide satisfaction, adopt realistic goals, and recognize those that are impossible to achieve. **EBN:** *Nurses have an obligation in communicating with those under their care, which should include the discussion of life preferences and relating pertinent, personal information (Coyle et al, 2015).*
- Assist clients with life review and reminiscence. **EBN:** *Chen et al (2017) found in their studies of life review, for those suffering life-threatening illnesses, that this practice aided in diminishing depression and augmenting self-esteem.*
- Provide music of the client's choosing. **EB:** *There is convincing evidence that music effectively assists those facing end-of-life concerns (Clement-Cortis, 2016).*
- Provide social support for families: understanding what is most important to families who are caring for clients at the end of life. **EBN:** *Nurses, who deal not only with technical and resuscitative aspects of critical patient care, are now developing their expertise to include "advocating for, communicating with, teaching, and guiding patients and families through end-of-life issues" (Banjar, 2017).*
- Encourage clients to pray. **EBN:** *The Society of Critical Care Medicine recommends that the spiritual needs of patients facing a critical end-of-life illness should be recognized and managed by the health care team (Fournier, 2017).*

• Carefully assess older adults for issues regarding death anxiety. **EB:** *This study by Bonnewyn et al (2016) proposed that the way older adults perceive dying, in part, affects whether they have a desire to die: it could be advantageous to explore the subject of death with your patient.*
• Provide back massage for clients who have anxiety regarding issues such as death. **EBN:** *Back massage significantly reduced anxiety in the study population. Systolic blood pressure (BP) decreased to a greater degree in the male participants, particularly in those with greater levels of anxiety and higher systolic BP (Chen et al, 2013).*
• Refer to care plan for **Grieving.**

Multicultural

• Assist clients to identify with their culture and its values. **EBN:** *Cultures stand apart in their approach to how death is framed, viewed, and accepted (MacCloud et al, 2016).*
• Refer to care plans for **Anxiety** and **Grieving.**

Home Care

• The previously mentioned interventions may be adapted for home care.
• Identify times and places when anxiety is greatest. Provide for psychological support at those times, using such strategies as personal contact, telephone contact, diversionary activities, or therapeutic self. **EBN:** *Participants across conditions reported similar levels of anxiety, suggesting that promoting an interest in sustained contact can be accomplished without reducing anxiety, but rather by shielding individuals from the negative effects of anxiety during social interactions (Stern & West, 2014).*
• Support religious beliefs; encourage the client to participate in services and activities of choice. **EBN:** *Enhancing the psychosocial and spiritual well-being of cancer patients can reduce their death anxiety and promote better quality of life (Shukla & Rishi, 2014).*
▲ Refer to appropriate medical services, social services, and/or mental health services, as needed. **EBN:** *The union between physical health and mental health needs requires added awareness and acknowledgement in the contemporary nursing care of palliative patients (Hayes, 2017).*
▲ Identify the client's preferences for end-of-life care; aid in honoring preferences as much as practicable. **EBN:** *To engage in patient-centered care at end of life requires the entire health care team to enlist patients and families in communication and decision-making, especially about the clients' preferences and decisions concerning the use of life-extending technologies (Nouvet et al, 2016).*
▲ Assist the client in making contact with death-related planning organizations, if appropriate, such as the Cremation Society and funeral homes. **EB:** *Advanced care planning is important to older clients. However, when clients are not accepting of death or if death is outside of the client's understanding, it can be difficult to work on advanced care planning. Nurses should explore whether the client accepts dying as a likely outcome and assess the client's fears of dying and need for control before attempting any planning (Piers et al, 2013).*
• Refer to care plan for **Powerlessness.**

Client/Family Teaching and Discharge Planning

• Promote more effective communication to family members engaged in the caregiving role. **CEB:** *Encouraging loved ones to discuss their wishes and areas of concern*

will assist the family during the grieving process; they will know the wishes of the dying family member and can carry them out as much as possible (Webb & Guarino, 2011).

• Allow family members to be physically close to their dying loved one, giving them permission, instruction, and opportunities to touch. Keep family members informed.

EBN: *Dosser & Kennedy (2014) maintained that care giver support is an integral part of nursing care and essential to improved outcomes.*

Risk for Aspiration

Debra Siela PhD, RN, CCNS, ACNS-BC, CCRN-K, CNE, RRT

NANDA-I

Definition

Susceptible to entry of gastrointestinal secretions, oropharyngeal secretions, solids, or fluids to the tracheobronchial passages, which may compromise health.

Risk Factors

Barrier to elevating upper body; decrease in gastrointestinal motility; ineffective cough; insufficient knowledge of modifiable factors

Associated Condition

Decrease in level of consciousness; delayed gastric emptying; depressed gag reflex; enteral feedings; facial surgery; facial trauma; impaired ability to swallow; incompetent lower esophageal sphincter; increase in gastric residual; increase in intragastric pressure; neck surgery; neck trauma; oral surgery; oral trauma; presence of oral/nasal tube; treatment regimen; wired jaw

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Aspiration Prevention; Respiratory Status: Ventilation; Swallowing Status

Example NOC Outcome with Indicators

Aspiration Prevention as evidenced by the following indicators: Avoids risk factors/Maintains oral hygiene/Positions self upright for eating and drinking/Selects foods according to swallowing ability/Selects foods and fluid of proper consistency/Remains upright for 30 minutes after eating. (Rate the outcome and indicators of **Aspiration Prevention:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = continually demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Maintain patent airway and clear lung sounds
- Swallow and digest oral, nasogastric, or gastric feeding without aspiration

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Aspiration Precautions

Example NIC Activities—Airway Management

Monitor level of consciousness, cough reflex, gag reflex, and swallowing ability; Check nasogastric or gastrostomy residual before feeding

Nursing Interventions and *Rationales*

- Monitor respiratory rate, depth, and effort. Note any signs of aspiration such as dyspnea, cough, cyanosis, wheezing, hoarseness, foul-smelling sputum, or fever. If new onset of symptoms, then perform oral suction and notify provider immediately. **CEB/EB:** *Signs of aspiration should be detected as soon as possible to prevent further aspiration and to initiate treatment that can be lifesaving (Swaminathan et al, 2017). Clients with dysphagia may experience silent aspiration because of laryngeal pooling and residue (Metheny, 2011b).*
- Auscultate lung sounds frequently and before and after feedings; note any new onset of crackles or wheezing. **CEB:** *With decreased symptoms of pneumonia, an increased respiratory rate and/or crackles may be the first sign of pneumonia (Metheny, 2011b).*

• Take vital signs frequently, noting onset of a fever, increased respiratory rate, and increased heart rate.
• Before initiating oral feeding, check client's gag reflex and ability to swallow by feeling the laryngeal prominence as the client attempts to swallow (Rees, 2013; American Association of Critical Care Nurses, 2016a). If client is having problems swallowing, see nursing interventions for Impaired **Swallowing.**
• If client needs to be fed, feed slowly and allow adequate time for chewing and swallowing. **EB:** *Slowed feeding allows time for more deliberate swallowing, reducing aspiration (Rees, 2013).*
• When feeding client, watch for signs of impaired swallowing or aspiration, including coughing, choking, and spitting food.
• Have suction machine available when feeding high-risk clients. If aspiration does occur, suction immediately. *A client with aspiration needs immediate suctioning and may need further lifesaving interventions such as intubation and mechanical ventilation (Rees, 2013).*
• Keep the head of the bed (HOB) elevated at 30 to 45 degrees, preferably with the client sitting up in a chair at 90 degrees when feeding. Keep head elevated for an hour after eating. **EBP:** *Decreased gastric reflux occurs at both 30- and 45-degree HOB elevation. Thus gastric-fed patients should be maintained at the highest HOB elevation that is comfortable to prevent aspiration (Metheny & Frantz, 2013).*
• Note presence of nausea, vomiting, or diarrhea. Treat nausea promptly with antiemetics.
• If the client shows symptoms of nausea and vomiting, position on side. *The side-lying position can help the client expel the vomitus and decrease the risk for aspiration (Chard, 2013).*
• Assess the abdomen and listen to bowel sounds frequently, noting if they are decreased, absent, or hyperactive. *Decreased or absent bowel sounds can indicate an ileus with possible vomiting and aspiration; increased high-pitched bowel sounds can indicate a mechanical bowel obstruction with possible vomiting and aspiration (Kasper et al, 2015).*
• Note new onset of abdominal distention or increased rigidity of abdomen. **EB:** *Abdominal distention or rigidity can be associated with paralytic or mechanical obstruction and an increased likelihood of vomiting and aspiration (Kasper et al, 2015).*
• If client has a tracheostomy, ask for referral to speech pathologist for swallowing studies before attempting to feed. **EB:** *There is an increased risk for aspiration when tracheostomy tubes are in place, and inflating the cuff does not prevent aspiration (Rees, 2013).*
• Provide meticulous oral care including brushing of teeth at least two times per day. *Good oral care can prevent bacterial or fungal contamination of the mouth, which can be aspirated (American Association of Critical Care Nurses, 2017a).* **EB:** *Research has shown that excellent dental care/oral care can be effective in preventing hospital-acquired (or extended care–acquired) pneumonia (Munro, 2014).*
• Sedation agents can reduce cough and gag reflexes as well as interfere with the client's ability to manage oropharyngeal secretions. **EB:** *Using the smallest effective level of sedation may help reduce risk of aspiration (American Association of Critical Care Nurses, 2016a; Barr et al, 2013).*

Enteral Feedings

▲ Insert nasogastric feeding tube using the internal nares to distal lower esophageal sphincter distance. The ear-to-nose-to-xiphoid-process is often inaccurate. **EB:** *An*

integrative review of the evidence found the ear-to-nose-to-xiphoid-process to be less accurate than the method using gender, weight, and nose to the umbilicus with the adult's head flat on the bed (GWNUF) (Santos et al, 2016).

▲ *Verification of gastric tube placement should initially be obtained by radiography. Other methods of assessing proper gastric tube placement include capnography, aspirate assessment, tube markings, and pH tests. Auscultation should not be used to assess gastric tube placement (American Association of Critical Care Nurses, 2016b; Amirlak et al, 2012; Williams et al, 2014).*

• Tape the feeding tube securely to the nose using a skin protectant under the tape. **CEBN:** *A research study found that insertion of the feeding tube into the small intestine and keeping the HOB position elevated to at least 30 degrees reduced the incidence of aspiration and aspiration-related pneumonia drastically in critically ill clients (Metheny et al, 2010). Another study found that aspiration and pneumonia were reduced by feeding the clients in the mid-duodenum or farther in the small intestine (Metheny et al, 2011).*

• Check to make sure the initial nasogastric feeding tube placement was confirmed by x-ray, with the openings of the tube in the stomach, not the esophagus or lungs. This is especially important if a small-bore feeding tube is used, although larger tubes used for feedings or medication administration also should be verified by radiography. *Radiographic verification of placement remains the gold standard for determining safe placement of feeding tubes (American Association of Critical Care Nurses, 2016b; Guenter, 2010; Metheny et al, 2012b; Williams et al, 2014).*

• After radiographic verification of correct placement of the tube in the intestines, mark the tube's exit site clearly with tape or a permanent marker (Simons & Abdallah, 2012).

• Measure and record the length of the tube that is outside of the body at defined intervals to help ensure correct placement. *Note the length of the tube outside of the body; it is possible for a tube to slide out and be in the esophagus, without obvious disruption of the tape (American Association of Critical Care Nurses, 2016b; McClave et al, 2016).*

• Note the placement of the tube on any chest or abdominal radiographs that are obtained for the client. *Acutely ill clients receive frequent x-ray examinations. These are available for the nurse to determine continued correct placement of the nasogastric tube (American Association of Critical Care Nurses, 2016b; McClave et al, 2016; Simons & Abdallah, 2012). When using electromagnetic feed tube placement, radiographic confirmation of tube position is preferred because of the variance of the ability of clinicians to place the tube (Metheny & Meert, 2014).*

• Check the pH of the aspirate. *If the pH reading is 4 or less, the tube is probably in the stomach. Recognize that the pH may not indicate correct placement if the client is receiving continuous tube feedings, is receiving a hydrogen ion blocker or proton pump inhibitor, has blood in the aspirate, or is receiving antacids (American Association of Critical Care Nurses, 2016b; Simons & Abdallah, 2012).*

• Use a number of determinants for verification of correct placement before each feeding or every 4 hours if the client is on continuous feeding. Measure length of tube outside the body, and review recent x-ray results and check pH of the aspirate if relevant and its characteristic appearance. If findings do not ensure correct placement of the tube, obtain a radiograph to verify placement. Do not rely on the air insufflation method to assess correct tube placement. **EBN:** *The auscultatory air insufflation method is not reliable for differentiating between gastric or respiratory placement; the "whooshing" sound can be heard even if the tube is incorrectly placed in the lung (American Association of Critical Care Nurses, 2016b; Simons & Abdallah, 2012; Williams et al, 2014).*

• *Capnography (CO_2 sensor) may be used to assess proper tube placement (American Association of Critical Care Nurses, 2016b; Gilbert & Burns, 2012; Williams et al, 2014).*
• Follow unit policy regarding checking for gastric residual volume during continuous feedings or before feedings, and holding feedings if increased residual is present. **CEB/EBN:** *There is little evidence to support the use of measuring gastric residual volume, and the practice may or may not be effective in preventing aspiration (Makic et al, 2011; McClave et al, 2016). It is still done at intervals (American Association of Critical Care Nurses, 2016b; Metheny et al, 2012a), especially if there is a question of tube feeding intolerance. The practice of holding tube feedings if there is increased residual reduces the amount of calories given to the client. If the client has a small-bore feeding tube, it is difficult to check gastric residual volume and it may be inaccurate. It is unclear if aspiration for residual volumes helps reduce the risk of aspiration (Metheny et al, 2012a); practice guidelines suggest continuing to feed the client until the residual is greater than 500 mL (Canadian Clinical Practice Guidelines, 2013; Elke et al, 2015).*
• Follow unit protocol regarding returning or discarding gastric residual volume. At this time there is no definitive research base to guide practice. **CEBN:** *A study of the effectiveness of either returning gastric residual volumes to the client or discarding them resulted in inconclusive findings, and more research is needed in the area (Williams & Leslie, 2010).*
• Do not use glucose testing to determine correct placement of enteral tube or to identify aspirated enteral feeding. *Glucose was found in tracheal secretions of clients who were not receiving enteral feedings (Guenter, 2010).*
• Do not use blue dye to tint enteral feedings (Guenter, 2010). *The presence of blue and green skin and urine and serum discoloration from the use of blue dye has been associated with the death of clients. The US Food and Drug Administration (2009) has reported at least 12 deaths from the use of blue dye in enteral feedings.*
• During enteral feedings, position client with HOB elevated 30 to 45 degrees (American Association of Critical Care Nurses, 2016a; Schallom et al, 2015). **CEB:** *HOB elevation greater than 30 degrees is feasible and preferred to 30 degrees for reducing oral secretion volume, reflux, and aspiration without pressure ulcer development in gastric-fed clients receiving mechanical ventilation (American Association of Critical Care Nurses, 2017b; Schallom et al, 2015). A study of mechanically ventilated clients receiving tube feedings demonstrated that there was an increase of the presence of pepsin (from gastric contents) in pulmonary secretions if the client was in a flat position versus being positioned with the head elevated (Metheny & Frantz, 2013). Generally, do not turn off the tube feeding when repositioning clients. Stopping the tube feeding during repositioning is counterproductive because the client receives less nutrition and the rate of emptying of the stomach is slow. If it is imperative to keep the HOB elevated, consider use of reverse Trendelenburg (head higher than feet) when repositioning (Metheny, 2011a) Precautionary withholding of enteral feedings during repositioning does not reduce the incidence of aspiration in critically ill clients (DiLibero et al, 2015).*
• Take actions to prevent inadvertent misconnections with enteral feeding tubes into intravenous (IV) lines or other harmful connections. Safety actions that should be taken to prevent misconnections include:
    - ❍ Trace tubing back to origin. Recheck connections at time of client transfer and at change of shift.
    - ❍ Label all tubing.
    - ❍ Use oral syringes for medications through the enteral feeding; *do not use IV syringes.*

❍ Teach nonprofessional personnel to "do not reconnect" if a line becomes dislodged; rather, find the nurse instead of taking the chance of plugging the tube into the wrong place. *Enteral feeding tube lines have been inadvertently plugged into IV peripheral catheters, peritoneal dialysis catheters, central lines, medical gas tubing, and tracheostomies, resulting in death in some cases (Guenter, 2010).*

Critical Care

• Recognize that critically ill clients are at an increased risk for aspiration because of severe illness and interventions that compromise the gag reflex. *Predisposing causes of aspiration include sedation, endotracheal intubation and mechanical ventilation, neurological disorders, altered level of consciousness, hemodynamic instability, and sepsis (American Association of Critical Care Nurses, 2016a; Makic et al, 2011).*
• Recognize that intolerance to feeding as defined by increased gastric residual is more common early in the feeding process. **EB:** *A study found that feeding intolerance in critical care clients was common in the first 5 days of feeding, and feeding intolerance was associated with increased length of both critical care and hospital length of stay (O'Connor et al, 2011). For clients receiving gastric tube feedings, assess for gastrointestinal intolerance to the feedings at 4-hour intervals (American Association of Critical Care Nurses, 2016a).*
• *Avoid bolus feedings in tube-fed clients who are at high risk for aspiration (American Association of Critical Care Nurses, 2016a).*
• *Maintain endotracheal cuff pressures at an appropriate level to prevent leakage of secretions around the cuff (American Association of Critical Care Nurses, 2016a).*
• *Pepsin and amylase are biomarkers of microaspiration of gastric contents in tracheal aspirate. Amylase presence is a better biomarker of aspiration of oral contents in the tracheal aspirate. Both pepsin and amylase were present in tracheal aspirate of critically ill clients even with backrest elevation of 30 degrees. HOB elevation is inversely related to the presence of pepsin (Sole et al, 2014). For a desired positive predictive value of 100%, a pH cut point of less than 5.0 provides the best negative predictive values, regardless of gastric acid inhibitor administration and feeding status. The pepsin assay is promising as an additional marker to distinguish gastric from tracheal aspirates (Metheny et al, 2017). Although reflux of gastric juice into the oropharynx must precede its aspiration into the lungs, individual reflux events do not necessarily lead to aspiration. Increased pepsin in oral secretions suggests that the client is at risk for aspiration (Schallom et al, 2013).*

Geriatric

• Carefully check older client's gag reflex and ability to swallow before feeding. *A slowed rate of swallowing is common in older adults (Rees, 2013).*
• Watch for signs of aspiration pneumonia in older adults with cerebrovascular accidents, even if there are no apparent signs of difficulty swallowing or of aspiration. *Bedside evaluation for swallow and aspiration can be inaccurate.* **EB:** *Silent aspiration can occur in the older population (Metheny, 2011b).*
• Recognize that older adults with aspiration pneumonia have fewer symptoms than younger people; repeat cases of pneumonia in older adults are generally associated with aspiration (Eisenstadt, 2010). *Aspiration pneumonia can be undiagnosed in older adults because of decreased symptoms; sometimes the only obvious symptom may be new onset of delirium (Metheny, 2011b).*
• Use central nervous system depressants cautiously; older clients may have an

increased incidence of aspiration with altered levels of consciousness. *Older clients have altered metabolism, distribution, and excretion of drugs. Many medications can interfere with the swallowing reflex, including antipsychotic drugs, proton pump inhibitors, and angiotensin-converting enzyme inhibitors (van der Maarel-Wierink et al, 2011).*
• Keep older, mostly bedridden clients sitting upright for 45 minutes to 1 hour after meals.
• Recommend to families that enteral feedings may or may not be indicated for clients with advanced dementia. Instead, if possible use hand-feeding assistance, modified food consistency as needed, and feeding favorite foods for comfort (Sorrell, 2010).
EB/CEB: *Research has demonstrated that tube feedings in this population do not prevent malnutrition or aspiration, improve survival, reduce infections, or result in other positive outcomes (Teno et al, 2010).*

Home Care

• The previously mentioned interventions may be adapted for home care use.
• For clients at high risk for aspiration, obtain complete information from the discharging institution regarding institutional management.
• Assess the client and family for willingness and cognitive ability to learn and cope with swallowing, feeding, and related disorders.
• Assess caregiver understanding and reinforce teaching regarding positioning and assessment of the client for possible aspiration.
• Provide the client with emotional support in dealing with fears of aspiration. *Fear of choking can provoke extreme anxiety, which can interfere with the client's ability or willingness to adhere to the treatment plan.* Refer to care plan for **Anxiety.**
• Establish emergency and contingency plans for care of the client. *Clinical safety of the client between visits is a primary goal of home care nursing.*
• Have a speech and occupational therapist assess the client's swallowing ability and other physiological factors and recommend strategies for working with the client in the home (e.g., pureeing foods served to the client; providing adequate adaptive equipment for independence in eating). *Successful strategies allow the client to remain part of the family.*
• Obtain suction equipment for the home as necessary.
• Teach caregivers safe, effective use of suctioning devices. Inform the client and family that only individuals instructed in suctioning should perform the procedure.
• Institute case management of frail elderly to support continued independent living.

Client/Family Teaching and Discharge Planning

• Teach the client and family signs of aspiration and precautions to prevent aspiration.
• Teach the client and family how to safely administer tube feeding.
• Teach the family about proper client positioning to facilitate feeding and reduce risk of aspiration.
• Verify client family/caregiver knowledge about feeding, aspiration precautions, and signs of aspiration.

Risk for impaired Attachment

Mary Alice DeWys RN, BS, CIMI, Margaret Elizabeth Padnos RN, AB, BSN, MA

NANDA-I

Definition

Susceptible to disruption of the interactive process between parent or significant other and child that fosters the development of a protective and nurturing reciprocal relationship.

Risk Factors

Anxiety; child's illness prevents effective initiation of parental contact; disorganized infant behavior; inability of parent to meet personal needs; insufficient privacy; parental conflict resulting from disorganized infant behavior; parent-child separation; physical barrier; substance misuse

At-Risk Population

Premature infant

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Parent-Infant Attachment; Parenting Performance: Psychosocial Adjustment: Life Change

Example NOC Outcomes with Indicators

Holds infant close, touches, strokes, pats infant, responds to infant cues, holds infant for feeding, vocalizes to infant. (Rate the outcome and indicators of appropriate parent and infant behaviors that demonstrate an enduring affectionate bond: 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Parent(s)/Caregiver(s) Will (Specify Time Frame)

• Be willing to consider pumping breast milk (and storing appropriately) or breastfeeding, if feasible
• Demonstrate behaviors that indicate secure attachment to infant/child
• Provide a safe environment, free of physical hazards
• Provide nurturing environment sensitive to infant/child's need for nutrition/feeding, sleeping, comfort, and social play
• Read and respond contingently to infant/child's distress
• Support infant's self-regulation capabilities, intervening when needed
• Engage in mutually satisfying interactions that provide opportunities for attachment
• Give infant nurturing sensory experiences (e.g., holding, cuddling, stroking, rocking)
• Demonstrate an awareness of developmentally appropriate activities that are pleasurable, emotionally supportive, and growth fostering
• Avoid physical and emotional abuse and/or neglect as retribution for parent's perception of infant/child's misbehavior
• State appropriate community resources and support services

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Anticipatory Guidance; Attachment Promotion; Coping Enhancement; Counseling; Developmental Enhancement: Infant; Family Involvement Promotion; Parent Education: Infant; Parenting Promotion

Example NIC Activities—Anticipatory Guidance

Instruct about normal development and behavior, as appropriate; Provide a ready reference for the client (e.g., educational materials, pamphlets) as appropriate

Nursing Interventions and *Rationales*

• Establish a trusting relationship with parent/caregiver. **EBN:** *"Overall, the research indicates that health care professionals urgently need to address the concerns of parents (N = 600) and their emotional reactions, be positive with communication exchanges, encourage parents to seek help, enhance parents' capability to positively explore the sources of social support and fully mobilize all social forces to ease psychological pressure" (Kong et al, 2013).*
• Support mothers of preterm infants in providing pumped breast milk for their babies until they are ready for oral feedings and transitioning from gavage to breast. **EBN:** *The Spatz Ten Steps model (Spatz, 2004) is associated with "significant improvements in parents' perception of nurses' support for mothers' efforts to breastfeed and [improvement] in the odds of the VLBW [very-low-birth-weight] infant receiving MOM [mother's own milk] at the time of hospital discharge" (Fugate et al, 2015).*
• Identify factors related to postpartum depression (PPD)/major depression and offer appropriate interventions/referrals. **EB:** *An Australian study of nulliparous women (N = 1507) highlights the need to "integrate concern for physical health with initiatives to address psychological well-being" for extreme tiredness, lower back pain, breast problems, urinary incontinence, perineal pain, constipation, hemorrhoids, and cesarean wound pain (Woolhouse et al, 2014).* **EBN:** *Because a mother's unpreparedness for premature childbirth may predispose her to "multiple and continuous waves of emotional responses, which will consequently lead to decline in performance … and mental irritation," more attention should be given to support these mothers as the main caregivers of their infants (Valizadeh et al,*

2014).

• Identify eating disorders/comorbid factors related to depression and offer appropriate interventions/referrals. **CEB:** *Combined psychological stressors of new motherhood and body image concerns of pregnancy may predispose exacerbation of eating disorder symptoms and development of postpartum mood disorders, in which mothers can be nonresponsive, inconsistent, or rejecting of the infant (Astrachan-Fletcher et al, 2008).* **EBN:** *Even though they may have prioritized food before their children's need—or in the words of one participant (N = 9), "food comes before anything," overall, mothers juggled the competing demands of their eating disorder with their children's needs" (Stitt & Reupert, 2014).*

Additional relevant research: (Emerson et al, 2017).

• Nurture parents so that they in turn can nurture their infant/child. **EB:** *Family-centered developmental care (FCDC) is designed to meet the needs of all babies, healthy newborns as well as hospitalized infants, and the needs of families coping with the crisis of the neonatal intensive care unit (NICU) experience (Craig et al, 2015).*

• Offer parents opportunities to verbalize their childhood fears associated with attachment. **CEB:** *"Parental lack of resolution concerning loss or trauma has been proposed to result in atypical parenting behaviors, which may have a disorganizing effect on the parent–child relationship" (Bernier & Meins, 2008).*

• Suggest journaling or scrapbooking as a way for parents of hospitalized infants to cope with stress and emotions. **EB:** *Narrative writing provides opportunities to remember and organize events in a meaningful and sensible manner. It helps create a feeling of problem-solving, stops unpleasant feelings, and gradually leads to the fading of negative experiences (Kadivar et al, 2015).*

• Offer parent-to-parent support to parents of infants in the NICU. **EBN:** *In one neonatal unit, parent-support volunteers collaborated with staff to create an innovative educational and psychosocial support program specifically targeting teen parents to help them increase engagement with their hospitalized infants and their caregiving confidence (Walsh & Goser, 2013).*

• Encourage parents of hospitalized infants to "personalize the baby" by bringing in clothing, pictures of themselves, toys, and tapes of their voices. **CEB:** *These actions help parents claim the infant as their own and support families' confidence/competence in caring for their infants at their own pace (Lawhon, 2002).*

• Encourage physical closeness using skin-to-skin experiences as appropriate. **EB:** *Because kangaroo mother care (KMC) provides proven health benefits to high-risk infants, involves parents in their care, and humanizes the NICU experience/environment, it is a commonly recognized model of care for very preterm (VP) infants as well as infants who "are not so preterm and not so tiny babies who are transferred from or admitted to the NICU" (Davanzo et al, 2013).*

• Plan ways for parents and their support system to interact/assist with infant/child caregiving. **EB:** *As "full participatory, essential, healing partners with the NICU caregiving team," parents should provide "hands-on care to their baby, including early frequent and prolonged skin-to-skin contact as is medically appropriate, participate in medical rounds and nursing shift change reports, and have full access and input to written and electronic medical records" (Craig et al, 2015).*

• Educate parents about the importance of the infant–caregiver relationship as a foundation for the development of the infant's self-regulation capacities. **EB:** *By showing the "calming and regulating effect" of moderate pressure massage, this study contributes to a greater understanding of the influence of self-regulation on the development of play and playfulness in preterm babies and on mothers' participation in such interventions with their infants (Hendel, 2017).*

• Assist parents in developing new caregiving competencies and/or revising/extending old ones. **CEB:** *Five caregiving domains are identified: (1) being with infant, (2) knowing infant as a person, (3) giving care, (4) communicating/engaging with others regarding infant/parent needs, (5) problem-solving/decision-making/learning (Pridham et al, 1998).* **EB:** *A Canadian study of Family Integrated Care programs in 20 level 3 NICUs gives evidence of parents' empowerment by providing "as much of their infant's care as they are able"; benefits include reduced length of stay, decreased readmission, and improved rate of breastfeeding and weight gain (Lee & O'Brien, 2014).*
• Educate parents in reading/responding sensitively to their infant's unique "body language" (behavior cues), which communicates approach ("I'm ready to play"), avoidance/stress ("I'm unhappy. I need a change."), and self-calming ("I'm helping myself"). **CEBN:** *Mothers with lower competence and more technology-dependent children may perceive their children as more vulnerable and their cues as harder to read (Holditch-Davis et al, 2011).* **EB:** *"Learning the principles of neurodevelopment and understanding the meaning of preterm behavioral cues make it possible for NICU caregivers and parents to provide individualized developmentally appropriate, neuroprotective care to each infant" (Altimier & Phillips, 2016).*
• Educate and support parents' ability to relieve the infant/child's stress/distress/pain. **CEBN:** *In facilitated tucking by parents (FTP), a parent holds the infant in a side-lying, fetal position and offers skin-to-skin contact (SSC) with the hands during a stressful/painful situation (Axelin et al, 2010).* **EBN:** *Various studies demonstrate the efficacy of facilitated tucking as a nonpharmacological pain intervention in premature infants as young as 23 weeks' gestational age during such painful procedures as heel sticks, endotracheal suctioning, and venipuncture (Hartley et al, 2015).*
• Guide parents in adapting their behaviors/activities with infant/child cues and changing needs. **EB:** *Parents' emotional closeness to their preterm NICU infant "may be crucial to the well-being of the newborn, the development of mutual regulation, the establishment of a functioning parent–infant affective relationship and the parents' confidence in their ability to provide care for their baby" (Stefana & Lavelli, 2017).*
• Attend to both parents and infant/child to strengthen high-quality interactions. **CEB:** *A mother's behavioral and brain responses to her infant's cues may be important predictors of infant development; in cases of maternal depression or substance abuse, an infant's smiling face may fail to elicit positive caregiving (Strathearn et al, 2008).* **EBN:** *NICU fathers of preterm infants have been found to exhibit coping strategies and needs different from NICU mothers. As a result, nursing support and intervention need to be tailored to parents individually to sustain caregiving engagement and the transition to postdischarge parenting (Provenzi & Santoro, 2015).* **Additional relevant research:** (Strathearn & Kim, 2013).
• Assist parents with providing pleasurable sensory learning experiences (i.e., sight, sound, movement, touch, body awareness). **EB:** *Therapeutic use of "parent-preferred lullabies" has been shown to improve feeding behaviors and sucking patterns, may increase prolonged periods of quiet-alert states, and enhance bonding, thus decreasing the stress parents associate with premature infant care" (Loewy et al, 2013).*
• Encourage physical closeness using skin-to-skin experiences as appropriate. **EB:** *When intermittent KMC is not deemed appropriate, parents must be taught alternative ways to minimize negative effects of separation from their baby (e.g., gentle containing touch, proprioceptive sense stimulation, face-to-face visual contact, talking, reading, singing soothing lullabies, and olfactory stimulation (Davanzo et al, 2013).*
• Encourage parents and caregivers to massage their infants and children. **CEB:** *Preliminary studies suggest that infant massage combined with kinesthetic stimulation may have positive effects on preterm infants: greater weight gain, improved bone mineralization,*

earlier hospital discharge, and more optimal behavioral and motor responses compared with controls (Massaro et al, 2009). **EB:** *A study of preterm and low-birth-weight infants who received massage reported greater alert and daytime activity in the first month of life; less awakening during sleep, and less crying in the second and third months; and significantly greater weight gain at 2 and 3 months of age compared with infants who did not receive massage (Karbasi et al, 2014).*

• Identify mothers who may need assistance in enhancing maternal role attainment (MRA). **CEBN:** *"Mothers with more illness-related distress and less alert infants, and unmarried and less educated mothers may need interventions to enhance MRA" (Miles et al, 2011).* **EBN:** *"Peer support and role modeling by NICU-based breastfeeding peer counselors helped mothers throughout every stage of their infants' hospitalizations, from giving them hope to helping them begin to develop maternal identity, to providing anticipatory guidance about taking their infants home" (Rossman et al, 2015).*

• Recognize that fathers, compared with mothers, may have different starting points in the attachment process in the NICU because nurses encourage parents to have early SSC. **CEB:** *One study showed that after giving birth prematurely, mothers felt powerless, experiencing the immediate postnatal period as surreal and strange, whereas fathers experienced the birth as a shock but were ready to become immediately involved (Fegran et al, 2008). Results of this Taiwanese study confirm the positive effects of father–infant SSC "in terms of exploring, talking, touching, and caring" as well as the enhancing of the relationship at 3 days postpartum (Chen et al, 2017).* **Additional relevant research:** (Arockisamy et al, 2008).

Pediatric

• Recognize and support infant/child's capacity for self-regulation and intervene when appropriate. **CEB:** *Infants must learn to take in sensory information while simultaneously managing not to become overaroused and overwhelmed by stimuli (DeGangi & Breinbauer, 1997; Greenspan, 1992).*

• Provide lyrical, soothing music in the nursery and at home that is age appropriate (i.e., corrected, in the case of premature infants) and contingent with state/behavioral cues. **EB**: *A study using pacifier-activated lullabies (PALs) sung by the infants' mothers showed improvement in oral feeding skills in preterm infants, including those with brain injuries (Chorna et al, 2014).*

• Recognize and support infant/child's attention capabilities. **CEB:** *"The ability to take an interest in the sights, sounds, and sensations of the world" is a significant developmental milestone (Greenspan & Wieder, 1998).*

• Encourage opportunities for mutually satisfying interactions between infant and parent. **CEB:** *The process of attachment involves communication and synchronous and rhythmic patterns of interaction (Rossetti, 1999).*

• Encourage opportunities for physical closeness. **CEB:** *Despite overwhelming evidence provided by this comprehensive literature review regarding benefits of infant massage (e.g., increased weight gain and bone density), "preterm infant massage is only practiced in 38% of NICUs (Field et al, 2010).* **EB:** *A study evaluating 11 NICUs in 6 European countries concluded that units providing facilities for parents to stay overnight had a higher level of parental presence, with younger mothers, in particular, staying close to their infants (Raisklia et al, 2017).*

Multicultural

• Provide culturally sensitive parent support to new immigrant families and other non–native-English-speaking mothers and families. **CEBN:** *In a study contrasting NICU norms in Christchurch, New Zealand, and Tokyo, Japan, areas of difference in parental support needs included (1) establishment of oral feeding, (2) nursing care–related decision-making, (3) parental information/involvement early in hospitalization, (4) visiting regulations, and (5) Western-based interventions (Ichijima, 2009; Ichijima et al, 2011).* **EB:** *"Within the premise of providing family-centered care is the concept of honoring cultural, ethnic, and socioeconomic diversity; it is imperative that culturally competent care be considered and implemented as a separate stand-alone aspect when caring for new immigrant families" (Hendson et al, 2015).*
• Discuss cultural norms with families to provide care that is appropriate for enhancing attachment with the infant/child. **EB:** *It is important to consider factors such as who makes decisions on the child's behalf, how the family prefers to communicate and interact with the medical and nursing team, and roles of family members in the home country (Langer et al, 2015).*
• Promote the attachment process in women who have abused substances by providing a culturally based, women-centered treatment environment. **CEB:** *Pregnant/postpartum Asian/Pacific Islander women identified provisions for the newborn, infant health care, parent education, and infant–mother bonding as conducive to their treatment (Morelli et al, 2001).* **EBN:** *In a study of the experiences of mothers of NICU infants with neonatal abstinence syndrome (NAS), participants said that feeling judged for having used illicit drugs during pregnancy interfered with their ability to trust their nurses; these findings "may lead to more customized nursing care for this high-risk population of mothers and infants" (Cleveland & Bonugli, 2014).*
• Promote attachment process/development of maternal sensitivity in incarcerated women. **CEB:** *By creating a simple and uncomplicated plan for an incarcerated mother to pump and store her breast milk, "nurses have the opportunity to change the mothering experience" as they promote maternal–infant attachment and improve health for mother and infant (Allen & Baker, 2013).*
• Empower family members to draw on personal strengths in which multiple worldviews/values are recognized, incorporated, and negotiated. **CEBN:** *According to a Thai study of NICU parents, the need to be strong, to be there, and to care for infants emerged as main themes in parents' stories (Sitanon, 2009).* **EBN:** *A study conducted in Taiwan concluded that designing an intervention that provides informational, emotional, instrumental, and esteem support for fathers can empower their parenting abilities as well as reduce their stress (Lee et al, 2013).*
• Encourage positive involvement and relationship development between children and fathers. **EB:** *Using the HUG Your Baby DVD and family-friendly instructional programs with NICU fathers increased their knowledge of infant behavior and is likely to boost their confidence, promote the parent–child relationship, and strengthen the family unit (Kadivar & Mozafarinia, 2013).*

Home Care

• The previously mentioned interventions may be adapted for home care use.
• Assess quality of interaction between parent and infant/child. **CEB:** *In a study examining effectiveness of home visiting by paraprofessionals/nurses, outcomes of nurse visitations in particular included more responsive mother–child interaction, less emotional vulnerability in response to fear stimuli among infants, greater infant emotional vitality in response to joy/anger stimuli, and less likelihood of language delays (Olds et al, 2002).*

• Use "interaction coaching" (i.e., teaching mother to let the infant lead) so that the mother will match her interaction style to the baby's cues. **EB:** *During a feeding interaction, when the infant is thought to have "communicative intent," the focus changes from the volume of milk consumed to a coregulated, cue-based approach through which the infant guides the caregiver (Shaker, 2013).* **EBN:** *The coregulated feeding intervention (CoReg) "aims to prevent stress during the feeing and ease the challenge VP infants experience coordinating breathing and swallowing during the early months" (Thoyre et al, 2016).*

▲ Provide supportive care for infants and children whose parents have been deployed during wartime. **CEB:** *Given the stressful task facing returning service members (i.e., reintegrating themselves into families "whose internal rhythms have changed and where children have taken on new roles"), the authors advocate for strengthening community support services and adopting public health education measures that reduce the stigma of seeking treatment for posttraumatic stress disorder (Lester & Flake, 2013).*

• Encourage custodial grandparents to use support groups available for caregivers of children. *Although custodial grandparents are disproportionately poor, female, African American or Latino, and isolated from important resources, a growing body of work on resilience suggests that these grandparents may be supported in successfully coping with the challenges of raising their grandchildren (Dolbin-MacNab & Hayslip, 2014).*

Autonomic Dysreflexia

Ellen MacKinnon MS, RN, CNRN, AGCNS-BC

NANDA-I

Definition

Life-threatening, uninhibited sympathetic response of the nervous system to a noxious stimulus after a spinal cord injury at the 7th thoracic vertebra (T7) or above.

Defining Characteristics

Blurred vision; bradycardia; chest pain; chilling; conjunctival congestion; diaphoresis above the injury; diffuse pain in different areas of the head; Horner's syndrome; metallic taste in mouth; nasal congestion; pallor below injury; paresthesia; paroxysmal hypertension; pilomotor reflex; red blotches on skin above the injury; tachycardia

Related Factors

Gastrointestinal Stimuli

Constipation; difficult passage of feces; digital stimulation; enemas; fecal impaction; suppositories

Integumentary Stimuli

Cutaneous stimulation; skin irritation

Musculoskeletal-Neurological Stimuli

Irritating stimuli below level of injury; painful stimuli below level of injury; pressure over bony prominence; pressure over genitalia; range of motion exercises; spasm

Regulatory-Situational Stimuli

Constrictive clothing; environmental temperature fluctuations; positioning

Reproductive-Urological Stimuli

Bladder distention; bladder spasm; instrumentation; sexual intercourse

Other
Insufficient caregiver knowledge of disease process; insufficient knowledge of disease process

At-Risk Population
Ejaculation; extremes of environmental temperature; menstruation

Associated Condition
Bowel distention; cystitis; deep vein thrombosis; detrusor sphincter dyssynergia; epididymitis; esophageal reflux disease; fracture; gallstones; gastric ulcer; gastrointestinal system pathology; hemorrhoids; heterotopic bone; labor and delivery period; ovarian cyst; pharmaceutical agent; pregnancy; pulmonary emboli; renal calculi; substance withdrawal; sunburn; surgical procedure; urethritis; urinary catheterization; urinary tract infection; wound

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes
Neurological Status; Neurological Status: Autonomic; Vital Signs

Example NOC Outcome with Indicators
Neurological Status: Autonomic as evidenced by the following indicators: Systolic blood pressure/Diastolic blood pressure/Apical heart rate/Perspiration response pattern/Goose bumps response pattern/Pupil reactivity/Peripheral tissue perfusion. (Rate each indicator of **Neurological Status: Autonomic:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Maintain baseline blood pressure
- Remain free of dysreflexia symptoms
- Explain symptoms, treatment, and prevention of dysreflexia

NIC (Nursing Interventions Classification)

Suggested NIC Intervention
Dysreflexia Management

Example NIC Activities—Dysreflexia Management
Identify and minimize stimuli that may precipitate dysreflexia; Monitor for signs and symptoms of autonomic dysreflexia

Nursing Interventions and *Rationales*

- Teach spinal cord injury (SCI) patients about potential causes, symptoms, treatment, and prevention of autonomic dysreflexia (AD). **EB:** *The nurse should inform the individual and his or her family about the signs and symptoms of AD. Written material about AD treatment should be given to the client as well. The nurse should emphasize the importance of keeping a dysreflexia diary and encourage patients to carry an AD card at all times (Vatansever, 2015).*
- Monitor the client for symptoms of dysreflexia, particularly those with high-level and more complete spinal cord injuries. See Defining Characteristics. **EB:** *This condition most commonly occurs in individuals with lesions at or above the level of sympathetic splanchnic outflow (T6), with incidence increasing with more clinically complete*

SCI (Solinsky et al, 2016). The most common signs and symptoms of AD are a sudden increase in systolic blood pressure (SBP) of at least 20 mm Hg from baseline, bradycardia, pounding headache, diaphoresis, flushing, and piloerection above the level of injury. Symptoms of AD are observed in about 85% of patients with injuries at T6 and above (Liepvre et al, 2017; Vatansever, 2015).

▲ Collaborate with providers and caregivers to identify the cause of dysreflexia. AD is triggered by a stimulus from below the level of injury, leading to systemic vasoconstriction. The most common triggers are bladder distension, kidney stones, kink in urinary catheter, urinary tract infection, fecal impaction, pressure ulcer, ingrown toenail, menstruation, hemorrhoids, tight clothing, invasive testing, and sexual intercourse (*Caruso et al, 2015*; *Wan & Krassioukov, 2014*). **EB:** *Medical personnel, caregivers, and individuals with SCI should be aware about the timely diagnosis and management of this life-threatening condition that can result in a variety of significant complications including stroke, seizures, myocardial ischemia, and death (Wan & Krassioukov, 2014).*

• If dysreflexia symptoms are present, immediately place client in high Fowler's position, remove all support hoses or binders, loosen clothing, check the urinary catheter for kinks, and attempt to determine the noxious stimulus causing the response. Check the patient's blood pressure every 3 to 5 minutes. If blood pressure cannot be decreased following these initial interventions, notify the provider emergently (i.e., STAT). **EB:** *Sitting allows some gravitational pooling of blood in the lower extremities. Survey the person for instigating causes beginning with the most common cause, the urinary system. To determine the stimulus for dysreflexia:*

- ❍ First, assess bladder function. Check for distention, and if present catheterize the client using an anesthetic jelly as a lubricant. Do not use the Valsalva maneuver or Crede's method to empty the bladder because this form of reflex voiding could worsen AD. Ensure existing catheter patency and irrigate if necessary. Also assess for signs of urinary tract infection. **EB:** *Bladder distension or irritation is responsible for up to 90% of AD cases (O'Stephenson & Berliner, 2017; Vatansever, 2015).*
- ❍ Second, assess bowel function. Numb the bowel area with a topical anesthetic as ordered and gently check for impaction. **EB:** *Check the rectal vault. Instill lidocaine gel into the rectum, pause 2 minutes, and gently remove any stool (Solinsky et al, 2016). For clients who require manual removal of stool, pretreatment with lidocaine cream may decrease the flow of impulses from the bowel and lower blood pressure during removal (Faaborg et al, 2014).*
- ❍ Third, assess the skin. Look for any pressure points, wounds, and ingrown toenails. **EB:** *Any noxious stimuli can cause AD. Although bladder and intestinal problems are most common, approximately 2% of AD cases are attributed to skin issues (Vatansever, 2015).*

▲ Initiate antihypertensive therapy as soon as ordered and monitor for cardiac dysrhythmias. **EB:** *Because of the large amount of sympathetic discharge following AD, clients in hypertensive crisis are at risk for arrhythmias, myocardial infarction, cerebral hemorrhage, seizures, and death (Furlan, 2013; Wan & Krassioukov, 2014). Antihypertensives should be administered when SBP remains at 150 mm Hg. Nitrates and nifedipine are most commonly used for acute episodes of AD, whereas clonidine is most effective for recurrent AD (Biering-Sorensen et al, 2018; Caruso et al, 2015; O'Stephenson & Berliner, 2017).*

• Monitor vital signs every 3 to 5 minutes during an acute event; continue to monitor vital signs after event is resolved (e.g., symptoms resolve and vital signs return to baseline, usually up to 2 hours postevent). **EB:** *Monitor pulse and blood pressure every 2*

to 5 minutes during an episode of AD, keeping in mind that impaired autonomic function can lead to labile blood pressure. Monitor for rebound hypotension following antihypertensive administration (O'Stephenson & Berliner, 2017).

- Watch for complications of dysreflexia, including signs of cerebral hemorrhage, seizures, cardiac dysfunction, or intraocular hemorrhage. **EB:** *Extremely high blood pressure can cause intracranial hemorrhage, myocardial injury and dysfunction, and death (Wan & Krassioukov, 2014).*
- Accurately and completely record any incidences of dysreflexia; especially note the precipitating stimuli. *It is imperative to determine the noxious stimuli that precipitated AD and whether the condition is recurrent, requiring the client to take medications routinely or to implement different interventions to prevent repeat incidences (Wan & Krassioukov, 2014).*
- Use the following interventions to prevent dysreflexia:
    - Ensure catheter patency and empty urinary catheter bags frequently. Assess the client for signs and symptoms of urinary tract infection during every shift. **EB:** *Approximately 90% of AD episodes are caused by genitourinary issues (Vatansever, 2015).*
    - Ensure a regular pattern of defecation to prevent fecal impaction. **EB:** *Approximately 8% of AD episodes can be attributed to the gastrointestinal system (Vatansever, 2015). A regular bowel program is essential in preventing constipation, impaction, or ileus. Topical lidocaine is useful in preventing dysreflexia from occurring during a bowel program (O'Stephenson & Berliner, 2017).*
    - Frequently change position of client to relieve pressure and prevent formation of pressure injuries. **EB:** *Routine weight shifts while sitting and frequent skin checks are imperative in preventing pressure injury. Any skin breakdown should be addressed by a physician or wound care personnel (O'Stephenson & Berliner, 2017).*
- Notify all health care team members of recurrent AD episodes. **EB:** *Recurrent dysreflexia may be caused by an occult or insidious pathophysiological process, which requires a more comprehensive workup (Biering-Sorensen et al, 2018).*
- For female clients with SCI, assess the client for AD during menstrual cycle. If the client becomes pregnant, collaborate with obstetrical health care practitioners to monitor for signs and symptoms of dysreflexia. **EB:** *In a recent cohort study, 60% of pregnant women with a spinal cord lesion above T6 experienced AD, with two cases resulting in cerebral hemorrhage during labor. Pregnancy in the female SCI population must be preceded by preconceptional consultation with a multidisciplinary team including both prenatal and neurological specialists (Liepvre et al, 2017).*

Home Care

- The previously mentioned interventions may be adapted for home care use.
- Provide the client and caregiver with written information on common causes of AD and initial treatment. **EB:** *Despite the availability of consensus-based resources, first responders and emergency room (ER) health care professionals (HCPs) have limited knowledge regarding AD (Krassioukov et al, 2016). An AD card is available from the Craig Hospital Autonomic Dysreflexia Resources page (see https://craighospital.org/uploads/Educational-PDFs/624.CRADEnglishWalletID.pdf) as well as from the Christopher and Dana Reeve Foundation (see https://www.christopherreeve.org/living-with-paralysis/free-resources-and-downloads/wallet-cards) (Craig, 2015; Christopher and Dana Reeve Foundation, 2015).*
- Provide resources to clients with any known proclivity toward dysreflexia. Advise

them to wear a medical alert bracelet and carry a medical alert wallet card when not accompanied by knowledgeable caregivers. **EB:** *Always keep an AD emergency kit on hand. Include the following items: blood pressure cuff, lubricating jelly (for rectal check), spare urinary catheter and insertion kit, bladder irrigation kit, and prescribed antihypertensives (Craig, 2015).*

▲ Establish an emergency plan: maintain a current prescription of antihypertensive medication, and administer antihypertensives when dysreflexia is refractory to nonmedicinal interventions. If SBP remains over 150 mm Hg following the previously mentioned interventions, go to the nearest ER and present the AD wallet card on arrival. **EB:** *A paucity of knowledge regarding AD diagnosis and treatment still exists among ER HCPs; therefore it is important to present the wallet card on arrival to ensure safe and effective care (Krassioukov et al, 2016).*

• When an episode of dysreflexia has resolved, continue to monitor blood pressure every 30 to 60 minutes for the next 2 hours or admit to an institution for observation. **EB:** *AD may resolve following administration of antihypertensive medication; however, if the underlying cause is not corrected, recurrence should be expected (O'Stephenson & Berliner, 2017).*

Client/Family Teaching and Discharge Planning

• Teach recognition of early dysreflexia symptoms, appropriate interventions, and the need to obtain help immediately. Give client a written card describing signs and symptoms of AD and initial actions. **EB:** *Clients and caregivers at risk for not understanding the key elements of AD occurrence and management are clients with nontraumatic etiologies, those with T5 or lower injuries, those in the youngest age group at injury, and those who had a shorter duration of injury (Schottler et al, 2009). Clients have reported knowledge gaps regarding AD and experiencing symptoms of AD, but not recognizing the condition (McGillivray et al, 2009).*

• Teach steps to prevent dysreflexia episodes: routine bladder and bowel care, pressure injury prevention, and preventing other forms of noxious stimuli (e.g., not wearing clothing that is too tight, nail care). Discuss the potential impact of sexual intercourse and pregnancy on AD. **EB:** *Sperm retrieval methods used in men with SCI lesions at T6 and above can stimulate an episode of AD (Ibrahim et al, 2016).*

Risk for Autonomic Dysreflexia

Mary Beth Flynn Makic PhD, RN, CCNS, FAAN, FNAP

NANDA-I

Definition

Susceptible to life-threatening, uninhibited response of the sympathetic nervous system post-spinal shock, in an individual with spinal cord injury or lesion at the 6th thoracic vertebra (T6) or above (has been demonstrated in patients with injuries at the 7th thoracic vertebra [T7] and the 8th thoracic vertebra [T8]), which may compromise health.

Risk Factors

Gastrointestinal Stimuli

Bowel distention; constipation; difficult passage of feces; digital stimulation; enemas; fecal impaction; suppositories

Integumentary Stimuli

Cutaneous stimulations; skin irritation; sunburn; wound

Musculoskeletal-Neurological Stimuli

Irritating stimuli below level of injury; painful stimuli below level of injury; pressure over bony prominence; pressure over genitalia; range of motion exercises; spasm

Regulatory-Situational Stimuli

Constrictive clothing; environmental temperature fluctuations; positioning

Reproductive-Urological Stimuli

Bladder distention; bladder spasm; instrumentation; sexual intercourse

Other

Insufficient caregiver knowledge of disease process; insufficient knowledge of disease process

At-Risk Population

Ejaculation; extremes of environmental temperature; menstruation

Associated Condition

Bowel distention; cystitis; deep vein thrombosis; detrusor sphincter dyssynergia; epididymitis; esophageal reflux disease; fracture; gallstones; gastric ulcer; gastrointestinal system pathology; hemorrhoids; heterotopic bone; labor and delivery period; ovarian cyst; pharmaceutical agent; pregnancy; pulmonary emboli; renal calculi; substance withdrawal; sunburn; surgical procedure; urethritis; urinary catheterization; urinary tract infection; wound

NIC, NOC, Client Outcomes, Nursing Interventions and *Rationales,* Client/Family Teaching and Discharge Planning, and References

Refer to care plan for **Autonomic Dysreflexia.**

List of Planning Care by Letter: B

Risk for Bleeding	Risk for unstable Blood Pressure	Disturbed Body Image
Insufficient Breast Milk production	Ineffective Breastfeeding	Interrupted Breastfeeding
Readiness for enhanced Breastfeeding	Ineffective Breathing pattern	

B

• = Independent; ▲ = Collaborative; **EBN** = Evidence-Based Nursing; **EB** = Evidence-Based

Risk for Bleeding

Tara Cuccinelli RN, MS, ACCNS-BC

NANDA-I

Definition

Susceptible to a decrease in blood volume, which may compromise health.

Risk Factors

Insufficient knowledge of bleeding precautions

At-Risk Population

History of falls

Associated Condition

Aneurysm; circumcision; disseminated intravascular coagulopathy; gastrointestinal condition; impaired liver function; inherent coagulopathy; postpartum complication; pregnancy complication; trauma; treatment regimen

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Blood Coagulation; Blood Loss Severity; Circulation Status; Fall Prevention Behavior; Gastrointestinal Function; Knowledge: Personal Safety, Maternal Status, Physical Injury Severity, Risk Control, Safe Home Environment, Vital Signs

Example NOC Outcome with Indicators

Blood Coagulation as evidenced by the following indicators: Clot formation/International normalized ratio (INR)/Hemoglobin (HGB)/Platelet Count/Bleeding/Bruising/Hematuria/Hematemesis. (Rate the outcome and indicators of **Blood Coagulation:** 1 = severe deviation from normal range, 2 = substantial deviation from normal range, 3 = moderate deviation from normal range, 4 = mild deviation from normal range, 5 = no deviation from normal range.)

Client Outcomes

Client Will (Specify Time Frame)

- Discuss precautions to prevent bleeding complications
- Explain actions that should be taken if bleeding happens
- Maintain adherence to agreed on anticoagulant medication and laboratory work regimens
- Monitor for signs and symptoms of bleeding

• Maintain a mean arterial pressure above 70 mm Hg, a heart rate between 60 and 100 beats per minute with a normal rhythm, and urine output greater than 0.5 mL/kg/hr
• Maintain warm, dry skin

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Admission Care; Bleeding Precautions; Bleeding Reduction; Blood Product Administration; Circumcision Care; Fluid Management; Health Screening; Hemorrhage Control; Neurologic Monitoring; Postpartum Care; Risk Identification; Teaching: Disease Process; Teaching: Prescribed Medication; Oxygen Therapy; Shock Prevention; Surveillance; Vital Signs Monitoring

Example NIC Activities—Bleeding Precautions

Monitor the client closely for hemorrhage; Monitor coagulation studies; Monitor orthostatic vital signs, including blood pressure; Instruct the client and/or family on signs of bleeding and appropriate actions in case bleeding occurs

Nursing Interventions and *Rationales*

• Perform admission fall risk assessment. Safety precautions should be implemented for all at-risk clients. **EBN:** *On client admission to any health care facility, nurses should assess for fall risk factors that could increase the risk of bleeding (Kampfen et al, 2014).*
• Monitor the client closely for hemorrhage, especially in those at increased risk for bleeding. Watch for any signs of bleeding, including bleeding of the gums, nosebleed, blood in sputum, emesis, urine or stool, bleeding from a wound, bleeding into the skin with petechiae, and purpura. **EB:** *Clients at increased risk for bleeding may include older individuals (>60 years of age) and individuals with active gastroduodenal ulcer, anemia, intrapartum and postpartum women, previous bleeding episode, hypertension, labile INRs or INR greater than 3.0, low platelet count, active malignancy, renal or liver failure, intensive care unit stay, drug or alcohol use, coadministration of antiplatelets and nonsteroidal antiinflammatory drugs (NSAIDs), and antithrombotic and anticoagulant therapies (Hastings-Tolsma et al, 2013; Shoeb & Fang, 2013).*
• If bleeding develops, apply pressure over the site or appropriate artery as needed. Apply pressure dressing; if unable to stop the bleeding, then consider a tourniquet if indicated. **EB:** *Nonpharmacological means, such as application of pressure, may reduce bleeding (Makris et al, 2013; Raval et al, 2017).*
▲ Collaborate on an appropriate bleeding management plan, including nonpharmacological and pharmacological measures to stop bleeding based on the antithrombotic used. **EB:** *Recommendations for bleeding risk prevention and management carefully weigh the risks and benefits of nonpharmacological and pharmacological interventions (Makris et al, 2013).*
▲ Monitor coagulation studies, including prothrombin time, INR, activated partial thromboplastin time (aPTT), fibrinogen, fibrin degradation/split products, and platelet counts as appropriate. **EB:** *New direct oral anticoagulants (DOACs) often have no requirement for routine coagulation studies; however, vigilance is still warranted because the risk for bleeding without benefit of reversal agents exists, except for dabigatran (Pradaxa), which can be reversed with intravenous (IV) idarucizumab (Praxbind) (Siegal & Crowther, 2013; Levy, 2014; Burnett et al, 2016; Raval et al, 2017). INR is the preferred method to evaluate warfarin therapy, typically at least 16 hours after the last dose is administered. Dose adjustments will not result in a steady-state INR value for up to 3 weeks (Witt et al, 2016).*

CEB: *Assess vital signs at frequent intervals to assess for physiological evidence of bleeding, such as tachycardia, tachypnea, and hypotension. Symptoms may include dizziness, shortness of breath, altered mental status, and fatigue.* **EB:** *Carefully assess for compensatory changes associated with bleeding, including increased heart rate and respiratory rate. Initially blood pressure may be stable, before beginning to decrease. Assess for orthostatic blood pressure changes (drop in systolic by >20 mm Hg and/or a drop in diastolic by >10 mm Hg in 3 minutes) by taking blood pressure with the client in lying, sitting, and standing positions (Emergency Nurses Association, 2017).*

▲ Monitor all medications for potential to increase bleeding, including antiplatelets, NSAIDs, selective serotonin reuptake inhibitors (SSRIs), and complementary and alternative therapies such as coenzyme Q10 and ginger. **EB:** *Antiplatelet medications can increase the risk of bleeding in high-risk clients (ginger, when taken with medicines that slow clotting, may increase the chances for bruising and bleeding).* **CEB:** *There are a multitude of medications including over-the-counter medications and herbs/natural supplements that can interact with anticoagulants. When any of these medications are stopped or started, closer monitoring of INR may be warranted (Burnett et al, 2016; Witt et al, 2016; Harter, Levine, Henderson, 2015).*

Safety Guidelines for Anticoagulant Administration: Joint Commission National Patient Safety Goals

Follow approved protocol for anticoagulant administration:

- Use prepackaged medications and prefilled or premixed parenteral therapy as ordered
- Check laboratory tests (i.e., INR) before administration
- Use programmable pumps when using parenteral administration
- Ensure appropriate education for client/family and all staff concerning anticoagulants used
- Notify dietary services when warfarin is prescribed (to provide consistent vitamin K in diet)
- Monitor for any symptoms of bleeding before administration. **EB:** *Standard defined protocols can decrease errors in administration (Joint Commission, 2016; Witt et al, 2016).*
- Anticoagulation therapy is complex. **EBN:** *Nurses have an integral role in medication management through the education of clients.* **EB:** *Medication reconciliation techniques and predischarge education used by pharmacists in an emergency department setting demonstrated enhanced accuracy of preadmission medication listings, resulting in a reduction in readmission rates (Gardella, Cardwell, & Nnadi, 2012; Nutescu et al, 2013).* **CEB:** *Risk of bleeding is reduced in clients who receive appropriate education in anticoagulant therapy use (Joint Commission, 2016).*

▲ Before administering anticoagulants, assess the clotting profile of the client. If the client is on warfarin, assess the INR. If the INR is outside of the recommended parameters, then notify the provider. **EB:** *Target INR for warfarin is between 2 and 3 for nonvalvular atrial fibrillation and between 2.5 and 3.5 for valvular atrial fibrillation. Risk for bleeding is increased when INR is >4 and risk for thromboembolism increases when INR is <1.7. A single slightly out of range INR <0.3 units above or below therapeutic range may just be monitored. It is not recommended to skip or boost doses for a slightly out of range INR in the absence of bleeding (Witt et al, 2016).*

▲ Recognize that vitamin K for vitamin K antagonists (e.g., warfarin, phenprocoumon, Sinthrome, and phenindione) may be given orally or IV as ordered for INR levels greater than 4.5 without signs of bleeding. In the case of major bleeding, prohemostatic therapies may be warranted for the rapid reversal of vitamin

K antagonists (tranexamic acid, fresh frozen plasma, cryoprecipitate, platelet transfusion, fibrinogen concentrate, factor IV prothrombin complex concentrate [KCentra], and activated prothrombin complex concentrate) (Makris et al, 2013; Witt et al, 2016). **EB:** *With INR levels above 4.5, it is recommended to give vitamin K rather than withholding the warfarin; administration of vitamin K is by oral or IV route, because subcutaneous and intramuscular routes result in erratic absorption (Christos & Naples, 2016).*

▲ Manage fluid resuscitation and volume expansion as ordered. **EB:** *A Cochrane systematic review including 86 trials and more than 5000 subjects suggested that there is no evidence that any one colloidal solution is safer or more effective than any other (Bunn & Trivedi, 2012).* **CEB:** *Blood products (including human albumin), nonblood products, or combinations can be used to restore circulating blood volume in individuals at risk for blood losses from trauma, burns, or surgery. Administration of albumin over normal sterile saline does not alter survival rates (Alderson et al, 2004).*

▲ Consider use of permissive hypotension and restrictive transfusion strategies when treating bleeding episodes. **EB:** *Hypotensive resuscitation (permissive hypotension), which maintains effective although low mean arterial pressures, may allow adequate perfusion without disruption of coagulation mechanisms, although additional research is warranted (Gourgiotis et al, 2013). A study of 921 subjects with upper gastrointestinal bleeding suggested that restrictive strategies (transfusing when HGB levels fell to below 7 g/dL) improved survival (P = .02) and resulted in fewer adverse events (P = .02) (Villanueva, 2013).*

▲ Consider discussing the coadministration of a proton-pump inhibitor alongside traditional NSAIDs, or with the use of a cyclooxygenase 2 inhibitor with the prescriber. **EB:** *Risk of NSAID-related bleeding may be reduced with the use of a proton-pump inhibitor or cyclooxygenase 2 inhibitor (Burnett et al, 2016; Witt et al, 2016).*

• Ensure adequate nurse staffing to provide a high level of surveillance capability. **EBN/QSEN:** *A key component in surveillance is monitoring; additional research is warranted in this area to identify new technologies and processes to optimize surveillance (Gardella et al, 2012).* **EB:** *The number and skill of nurses staffed in hospitals has been demonstrated to have a direct effect on client outcomes. Lower levels of nurse staffing have been associated with higher rates of poor client outcomes* (Cho et al, 2016)

Pediatric

▲ Recognize that prophylactic vitamin K administration should be used in neonates for vitamin K deficiency bleeding (VKDB). **EB:** *A dose of 0.5 to 1 mg vitamin K remains a standard administration for neonates to avoid VKDB and associated problems (Lippi & Franchini, 2011).*

▲ Recognize warning signs of VKDB, including minimal bleeds, evidence of cholestasis (icteric sclera, dark urine, and irritability), and failure to thrive. **EB:** *Signs of classic VKDB may be mild and include delayed or difficulty feeding or bruising in 24 hours to 1 week, whereas late VKDB associated with breastfeeding may occur at 2 to 12 weeks (Lippi & Franchini, 2011).*

▲ *Use caution in administering NSAIDs in children.* **CEB:** *A study of children aged 2 months to 16 years found that although upper gastrointestinal bleeding is rare, one-third of the cases seen were attributable to exposure to NSAIDs at doses used for analgesia or antipyretic purposes.* **EB:** *A Cochrane review of 15 trials including approximately 1000 children found insufficient evidence to exclude an increase in bleeding risk after using NSAIDs, although the findings supported use of NSAIDs to reduce emesis (Lewis et al, 2013).*

▲ Monitor children and adolescents for potential bleeding after trauma. **EB:** *Trauma*

in children aged 1 through 12 years has been associated with early coagulopathy and subsequent bleeding (Christiaans et al, 2014). **CEB:** *Children and adolescents who take SSRIs need to be closely monitored because the potential for bleeding exists across age groups (Andrade et al, 2010).*

▲ Closely monitor children after cardiac surgery for excessive blood loss. **EB:** *In a study of 182 children aged from neonate to older than 3 years, postoperative blood loss was found to be significantly associated with age (P = .003) and the presence of cyanotic disease (P = .01) (Faraoni & Van der Linden, 2014).*

Client/Family Teaching and Discharge Planning

• Teach client and family or significant others about any anticoagulant medications prescribed, including when to take, how often to have laboratory tests done, signs of bleeding to report, dietary consistency, and need to wear medic alert bracelet and precautions to be followed. Instruct the client to report any adverse side effects to his or her health care provider. *Medication teaching includes the drug name, purpose, administration instructions (e.g., with or without food), necessary laboratory tests, and any side effects. Provision of such information using clear communication principles and an understanding of the client's health literacy level may facilitate appropriate adherence to the therapeutic regimen by enhancing knowledge base (Joint Commission, 2016; National Institutes of Health [NIH] 2016).*

• Instruct the client and family on the disease process and rationale for care. When clients and their family members have sufficient understanding of their disease process they can participate more fully in care and healthy behaviors. Knowledge empowers clients and family members, allowing them to be active participants in their care. **EB/CEBN:** *Use of written, verbal, and/or video education enhances client retention of information needed when managing potent medications. Patients actively engaged in their health care report better experiences, improved outcomes, and lower health care costs (Burnett et al, 2016; Joint Commission, 2016).*

• Provide client and family or significant others with both oral and written educational materials that meet the standards of client education and health literacy. **EB:** *The use of clear communication, materials written at a fifth-grade level, and the teach-back method enhance the client's ability to understand important health-related information and improves self-care safety (Burnett, 2016; NIH, 2016; Hull & Garcia, 2017).*

Risk for unstable Blood Pressure

Mary Beth Flynn Makic PhD, RN, CCNS, FAAN, FNAP

NANDA-I

Definition

Susceptible to fluctuating forces of blood flowing through arterial vessels, which may compromise health.

Risk Factors

Inconsistency with medication regimen; orthostasis

Associated Condition

Adverse effects of cocaine; adverse effects of nonsteroidal anti-inflammatory drugs (NSAIDs); adverse effects of steroids; cardiac dysrhythmia; Cushing Syndrome; electrolyte imbalance; fluid retention; fluid shifts; hormonal change; hyperosmolar solutions; hyperparathyroidism; hyperthyroidism; hypothyroidism; increased intracranial pressure; rapid absorption and distribution of anti-arrhythmia agent; rapid absorption and distribution of

diuretic agent; rapid absorption and distribution of vasodilator agents; sympathetic responses; use of antidepressant agents

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Fatigue; Arrhythmia; Dizziness; Confusion; Blurred Vision; Circulation Status; Tissue Perfusion: Cardiac; Tissue Perfusion: Cellular; Vital Signs

Example NOC Outcome with Indicators

Tissue Perfusion: Cardiac as evidenced by the following indicators: Heart rate/Arrhythmia/Profuse diaphoresis/Nausea/Vomiting. (Rate the outcome and indicators of **Tissue Perfusion: Cardiac:** 1 = severe, 2 = substantial, 3 = moderate, 4 = mild, 5 = none [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Maintain vital signs within normal range
- Remain asymptomatic with cardiac rhythm (have absence of arrhythmias, tachycardia, or bradycardia)
- Be free from dizziness with changes in positions (lying to standing)
- Deny fatigue, nausea, vomiting
- Deny chest pain

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Cardiac Care; Cardiac Precautions; Hypertension Management; Hypotension Management; Dysrhythmia Management; Vital Signs Monitoring

Example NIC Activity—Vital Signs Monitoring

Note trends and wide fluctuations in blood pressure; Monitor blood pressure while client is lying, sitting, and standing before and after position change as appropriate; Monitor blood pressure after patient has taken medications if possible; Monitor for central and peripheral cyanosis

Nursing Interventions and *Rationales*

▲ Hypertension (HTN) is a major risk factor for cardiovascular disease placing the client at increased risk of myocardial infarction and stroke (Whelton et al, 2017). **EB:** *The 2017 clinical practice guidelines for the management of adults with HTN now defines HTN as a blood pressure above 130/80 mm Hg for anyone at risk of a myocardial infarction or stroke. Significant emphasis is placed on ensuring the client understands the importance of lifestyle modifications to include regular exercise and dietary changes (Whelton et al, 2017).*

- Provide client-specific education about the importance of a healthy lifestyle to reduce complications associated with HTN. **EB:** *A heart-healthy diet with low-sodium content, maintaining a normal weight, limiting alcohol consumption, and a regular exercise program can lower the client's blood pressure and associated risk of cardiovascular disease (Whelton et al, 2017).*
- Provide drug and client-specific education if medications are prescribed to manage

the client's HTN. Blood pressure medications may cause hypotension or secondary complications such as electrolyte imbalances, dehydration, and orthostasis (Whelton et al, 2017).

▲ Screen clients for secondary causes of HTN with abrupt onset or age <30 years. **EB:** *Secondary HTN should be explored so that the primary cause of the HTN is treated. The client should be evaluated for undetected renal disease, primary aldosteronism, obstructive sleep apnea (OSA), thyroid disease, and alcohol-induced HTN (Grossman & Messerli, 2012; Whelton et al, 2017; Wolf et al, 2018).*

▲ Review the client's past medical history. **EB:** *Understanding the client's risk for secondary causes of HTN is important to establishing a proper plan of care and follow-up treatments (Wolf et al, 2018).*

• Explore the client's subjective statements concerning poor sleep, report of snoring, and daytime fatigue. **EB:** *OSA compromises cardiovascular health. Assessment of OSA can be easily incorporated into practice using valid and reliable assessment tools such as STOP Bang (Nagappa et al, 2015; Miller & Berger 2016). If OSA is assessed, the nurse should notify the provider for additional monitoring to address OSA and HTN management.*

• Review the client's history of arrhythmias, especially a history of atrial fibrillation. **EB:** *Atrial fibrillation alters cardiac output and can cause hypotension and HTN episodes that result in client falls and/or altered mentation, or chest pain (Rapsomaniki et al, 2014).*

• Review the client's current medications both prescribed and over the counter. **EB:** *Many medications and over-the-counter agents can cause HTN and interfere with antihypertension treatments (Grossman & Messerli, 2012).*

• Steroid agents, administered at higher doses, (e.g., 80–200 mg/day) can trigger HTN (Grossman & Messerli, 2012). Teach the client to monitor blood pressure and report changes to their prescribing provider.

• Ask the client if they are prescribed antidepressant agents. Several antidepressant agents cause an elevation in blood pressure that may be progressively clinically significant if the diastolic blood pressure rises >90 mm Hg (Grossman & Messerli, 2012; Whelton et al, 2017).

• NSAIDs can induce HTN and/or interfere with antihypertensive therapy. **EB:** *Ask the client if they use NSAIDS to include dose and frequency of consuming these over-the-counter drugs (Grossman & Messerli, 2012; Whelton et al, 2017).*

• Over consumption of caffeine stimulates sympathetic activity, which causes a rise in blood pressure that can be followed by a decrease in blood pressure once the effects of the caffeine have worn off. **EB:** *Ask the client to describe their caffeine consumption to include frequency, dose, and physical effects when consuming products containing caffeine (Grossman & Messerli, 2012; Turnbull et al, 2017).*

• Licorice consumption may trigger HTN in some patients. **EB:** *Licorice consumption can prolong cortisol metabolism associated with an 11β-hydroxysteroid dehydrogenase deficiency leading to HTN. Ask the client about typical consumption of licorice (Ferrari, 2010; Grossman & Messerli, 2012).*

• Some herbal products may induce HTN and/or interfere with antihypertensive treatment. **EB:** *Over-the counter herbal agents are poorly regulated; however, some agents such as arnica, bitter orange, blue-cohosh, dong quai, ephedra, ginkgo, ginseng, guarana, licorice, pennyroyal oil, Scotch broom, senna, southern bayberry, St. John's wort, and yohimbine are known stimulants that may elevate blood pressure (Jalili et al, 2013). Ask the client about herbal agents to include dose, frequency, and reason for taking the herbal agent.*

• Alcohol is known to elevate blood pressure and increases the client's risk of HTN. **EB:** *Inquire about the client's typical alcohol consumption. Current recommendations suggest men should be limited to no more than two drinks per day and women to no more than one*

standard alcohol drink per day (Whelton et al, 2017).

• Blood pressure may be unstable with substance abuse disorders (SUDs). *Certain drugs have specific effects on the cardiovascular system. Clients may experience tachycardia along with severe hypotension or HTN with an overdose of opioid, cocaine, and synthetic cannabinoids (Akerele & Olupona, 2017).*

• Cocaine use causes increased alertness and feelings of euphoria, along with dilated pupils, increased body temperature, tachycardia, and increased blood pressure. Tachyarrhythmias and marked elevated blood pressure can be life-threatening. *Cocaine overdose can present as a myocardial infarction or arterial dissection (Hoffman, 2010; Akerele & Olupona, 2017).*

• Cocaine overdose is a medical emergency because of the risk of cardiac toxicity. *Treatment is focused on lowering body temperature with external cooling devices and antipyretic medications, administering sedation agents to treat hyperactivity, oxygen to address increased myocardial oxygen needs, and possible administration of antithrombotic agents if a myocardial infarction is suspected (Hoffman, 2010; Akerele & Olupona, 2017).*

• Opioid intoxication results in changes in heart rate, slowed breathing, and decrease in blood pressure leading to loss of alertness. *Opioid intoxication and overdose lead to primarily respiratory arrest with subsequent cardiovascular arrest (Jones et al, 2015; Akerele & Olupona, 2017).*

• Synthetic cannabinoids are man-made, mind-altering chemicals that may be added to foods or inhaled. There is a growing availability of these designer drugs in which adverse effects are not well known. **EB:** *The primary effect of synthetic cannabinoid intoxication results in severe anxiety, paranoia, nausea, vomiting, and cardiovascular symptoms to include slurred speech, HTN, chest pain, skin pallor, muscle twitches, and hypokalemia that may lead to arrhythmias (Weaver, Hooper, & Gunderson, 2015; Akerele & Olupona, 2017).*

Critical Care

• Monitor the client for symptoms associated with chest pain, myocardial infarction, acute HTN, and hypotension. **EB:** *Alterations in blood pressure, HTN, and hypotension adversely affect cardiac function and myocardial oxygen consumption that can result in myocardial muscle injury. Nursing interventions to monitor cardiac function and reduce oxygen needs should be implemented along with continuous cardiac function monitoring (Habib, 2018).*

• Clients with hypertensive crisis will require close monitoring for signs and symptoms consistent with acute renal failure, stroke, myocardial infarction, and acute heart failure. *Many conditions may cause hypertensive crisis; however, uncontrolled HTN is the most common cause. Subjective symptoms include severe headache, shortness of breath, faintness, and severe anxiety (Habib, 2018).*

• Myxedema coma is an acute emergency associated with hypothyroidism that manifests with severe hypotension, bradycardia, hypothermia, seizures, and coma. *Treatment focuses on supporting the client's blood pressure and restoring thyroid function by administering levothyroxine as prescribed, and supporting other organ systems (Njoku, 2013).*

• Thyroid storm (thyrotoxicosis) is an acute, life-threatening, hypermetabolic state induced by excessive release of thyroid stimulating hormone (TSH). Symptoms are severe and include fever, tachycardia, HTN, congestive heart failure leading to hypotension and shock, profuse sweating, respiratory distress, nausea and vomiting, diarrhea, abdominal pain, jaundice, anxiety, seizures, and coma. **EB:** *Nursing care focuses on symptom management to include reducing fever and cardiovascular support*

(Njoku, 2013).

Pediatric

• HTN is an underrecognized disease in children. Current recommendations include annual blood pressure monitoring with more focused monitoring in high-risk children. **EB:** *Blood pressure monitoring should be initiated starting at age 3. Client risk factors that include obesity and inactivity should be addressed during well child visits to reduce the cardiovascular risks associated with childhood HTN (Dionne, 2017).*
▲ Secondary causes of HTN should be explored in the absence of childhood obesity, known cardiovascular disease, family history. *Kidney disease should be explored as a possible etiology of unexplained HTN (Dionne, 2017).*
• Normal ranges for child and adolescent blood pressure measurements were recently updated to reflect age, gender, and weight considerations. *Revisions to the blood pressure table are intended to facilitate earlier detection of abnormal blood pressure allowing for earlier intervention to reduce the risk of end-organ injury (Flynn et al, 2017).*

Geriatric

• Risk of cardiac arrhythmias increases with advanced age placing the client at increased risk of HTN and hypotension. **EB:** *Ask the client about a history of arrhythmias, feeling his or heart "skip beats," history of falls, and lightheadedness (Rapsomaniki et al, 2014).*
• Comorbid cardiovascular disease risks increase with advanced age. **EB:** *Clients, regardless of age, should be encouraged to engage in daily physical activity, consuming a heart-healthy diet, maintaining ideal body weight, and monitoring effects of prescribed cardiovascular medications (Whelton et al, 2017).*
• Polypharmacy is a risk for both hypotension and HTN in older clients. *Review the client's medications frequently to include prescribed and over-the-counter medications and herbal agents.*

Client/Family Teaching and Discharge Planning

• Nutritional education has been found to be an important variable in an individual maintaining cardiovascular health. **EB:** *Assumptions have been made that individuals understand what a healthy diet means. Current guidelines suggest using props such as a plate and food types/portions along with practicing reading food labels are essential to client nutritional education/learning (Allison, 2017).*
• Teach the client to monitor blood pressure and to report changes in blood pressure to the provider and with each health care visit. **EB:** *A recent systematic review and meta-analysis found that teaching the client to properly self-monitor blood pressure along with other cardiovascular treatments (i.e., diet, exercise, medications) has been found to clinically lower blood pressure for up to a year (Tucker et al, 2017).*

Disturbed Body Image

Gail B. Ladwig MSN, RN, Marsha McKenzie MA Ed, BSN, RN

NANDA-I

Definition

Confusion in mental picture of one's physical self.

Defining Characteristics

Absence of body part; alteration in body function; alteration in body structure; alteration in view of one's body; avoids looking at one's body; avoids touching one's body; behavior of acknowledging one's body; behavior of monitoring one's body; change in ability to estimate spatial relationship of body to environment; change in lifestyle; change in social involvement; depersonalization of body part by use of impersonal pronouns; depersonalization of loss by use of impersonal pronouns; emphasis on remaining strengths; extension of body boundary; fear of reaction by others; focus on past appearance; focus on past function; focus on previous strength; heightened achievement; hiding of body part; negative feeling about body; nonverbal response to change in body; nonverbal response to perceived change in body; overexposure of body part; perceptions that

reflect an altered view of one's body appearance; personalization of body part by name; personalization of loss by name; preoccupation with change; preoccupation with loss; refusal to acknowledge change; trauma to nonfunctioning body part

Related Factors

Alteration in self-perception; cultural incongruence; spiritual incongruence

At-Risk Population

Developmental transition

Associated Condition

Alteration in body function; alteration in cognitive functioning; illness; impaired psychosocial functioning; injury; surgical procedure; trauma; treatment regimen

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Body Image; Self-Esteem; Acceptance Health Status: Coping, Personal Identity

Example NOC Outcome with Indicators

Body Image as evidenced by the following indicators: Congruence between body reality, body ideal, and body presentation/Satisfaction with body appearance/Adjustment to changes in physical appearance. (Rate the outcome and indicators of **Body Image:** 1 = never positive, 2 = rarely positive, 3 = sometimes positive, 4 = often positive, 5 = consistently positive [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Demonstrate adaptation to changes in physical appearance or body function as evidenced by adjustment to lifestyle change
- Identify and change irrational beliefs and expectations regarding body size or function
- Recognize health-destructive behaviors and demonstrate willingness to adhere to treatments or methods that will promote health
- Verbalize congruence between body reality and body perception
- Describe, touch, or observe affected body part
- Demonstrate social involvement rather than avoidance and use adaptive coping and/or social skills
- Use cognitive strategies or other coping skills to improve perception of body image and enhance functioning
- Use strategies to enhance appearance (e.g., wig, clothing)

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Body Image Enhancement; Counseling; Eating Disorders Management; Referral; Self-Awareness Enhancement; Self-Esteem Enhancement; Support Group; Therapy Group; Weight Gain Assistance

Example NIC Activities—Body Image Enhancement

Determine client's body image expectations based on developmental stage; Assist client to identify actions that will enhance appearance

Nursing Interventions and *Rationales*

• Incorporate psychosocial questions related to body image as part of nursing assessment to identify clients at risk for body image disturbance.
• Maintain awareness of conditions or changes that are likely to cause a disturbed body image: removal of a body part or change/loss of body function such as blindness or hearing loss, cancer survivors, clients with eating disorders, burns, skin disorders, or those with stomas or other disfiguring conditions, or a loss of perceived attractiveness such as hair loss.
• Be aware of the impact of treatments and surgeries that involve the face and neck and be prepared to address the client's psychosocial needs. **EB:** *A cross-sectional survey of 150 patients with head and neck cancer demonstrated that radical neck surgery has a significant impact on their body image (Tsung-Min et al, 2017)*
• Maintain understanding that age, gender, and other demographic identifiers may be associated with higher degrees of body image disturbance. **EB:** *A study of body image disturbance in clients with stomas was demonstrated to be higher in males, younger adults, and overweight clients* (*Jayarajah & Samarasekera, 2017).*
• Consideration should be given to providing counseling for women with breast cancer to assist with acceptance of the reality of the disease and to increase their resilience against breast surgery **EB:** *Current research supports previous findings regarding the change in body image satisfaction following breast surgery (Mushtaq & Naz, 2017).*
• Discuss treatment options and outcomes for women diagnosed with breast cancer. Be prepared to explore options of lumpectomy versus mastectomy and the potential for reconstructive surgery. Include cosmetic and appliance options available to mitigate effects of mastectomy and/or chemotherapy, such as wigs and customized mastectomy bras. **EB:** *Disturbance of body image has a relationship to the extent of the surgical procedure and the perceived ability to mitigate these body alterations (Rosenberg et al, 2013).*
• Nurses and other health professionals should support clients with stomas in problem-focused coping strategies. **EBN:** *It is also important for nurses to encourage patients to have contact with their friends and family, as well as stoma support groups (Burch, 2017).*

Pediatric

• Many of the previously mentioned interventions are appropriate for the pediatric client.
• Educate parents on the role their own attitudes play in a child's body perception and acceptance. **EB:** *A recent study confirms previous research demonstrating body dissatisfaction is related to internalization of a socially acceptable body size and the pressure to change body shape among parents. There is an elevated risk that parents can model negative body attitudes to their children (Kościcka et al, 2016).*
• When caring for teenagers, be aware of the impact of acne vulgaris on quality of life. The impact was proportional to the severity of acne. Assess for symptoms of social

withdrawal, limited eye contact, and expressions of low self-esteem. Educate teens on skin care and hygiene, and assist with referrals to a dermatologist when needed. **EB:** *Research performed by Tasoula et al (2012) showed that feelings of unworthiness attributable to negative appraisal by peers were present in half of the subjects with acne in their study.*

Geriatric

• Encourage regular exercise for older adults. **EB:** *Research done by Mortensen et al (2012) supports the importance of physical activity to preserve functioning in older adults.*

Multicultural

• Acknowledge that body image disturbances can affect all individuals regardless of culture, race, or ethnicity. Assess for the influence of cultural beliefs, regional norms, and values on the client's body image. **EB:** *A study of Indian college students found that males were slightly more at risk for eating disorders than female students (Chaudhari et al, 2017), and another study found some discrepancies in body image perception correlated to ethnicity (Goldzak-Kunik & Leshem, 2017). A study of Brazilian women found a significant number of those studied reported having a worse quality of life associated with being overweight or underweight (Medeiros De Morais et al, 2017).*

Home Care

• The previously mentioned interventions may be adapted for home care use.
• Assess client's level of social support. Social support is one of the determinants of the client's recovery and emotional health.
• Assess family/caregiver level of acceptance of the client's body changes.
• Encourage clients to discuss concerns related to sexuality and provide support or information as indicated. Many conditions that affect body image also affect sexuality.
• Teach all aspects of care. Involve clients and caregivers in self-care as soon as possible. Do this in stages if clients still have difficulty looking at or touching a changed body part.

Client/Family Teaching and Discharge Planning

• Advise clients with a stoma about the support available to them. **EBN:** *Proper discharge preparation for clients with a stoma involves the anticipation of psychological issues and depression and support to manage these issues (Burch, 2017).*

Insufficient Breast Milk production

Kerstin West-Wilson BS, MS, BSN, RN, IBCLC

NANDA-I

Definition

Inadequate supply of maternal breast milk to support nutritional state of an infant or child.

Defining Characteristics

Absence of milk production with nipple stimulation; breast milk expressed is less than prescribed volume for infant; delay in milk production; infant constipation; infant frequently crying; infant frequently seeks to suckle at breast; infant refuses to suckle at breast; infant voids small amounts of concentrated urine; infant weight gain <500 g in a month; prolonged breastfeeding time; unsustained suckling at breast

Related Factors

Ineffective latching on to breast; ineffective sucking reflex; insufficient opportunity for suckling at the breast; insufficient suckling time at breast; maternal alcohol consumption; maternal insufficient fluid volume; maternal malnutrition; maternal smoking; maternal treatment regimen; rejection of breast

Associated Condition

Pregnancy

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Breastfeeding Establishment: Infant, Maternal; Breastfeeding Maintenance; Anxiety Self-Control; Parent-Infant Attachment

Example NOC Outcome with Indicators

Breastfeeding Establishment: as evidenced by the following indicators: Proper alignment/Latch on/Areolar compression/Suck reflex/Nursing minimum of 15 minutes per breast/Urinations and stools appropriate for age/Weight gain appropriated for age. (Rate the outcome and indicators of **Breastfeeding Establishment:** 1 = not adequate, 2 = slightly adequate, 3 = moderately adequate, 4 = substantially adequate, 5 = totally adequate [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- State knowledge of indicators of adequate milk supply
- State and demonstrate measures to ensure adequate milk supply

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Lactation Counseling; Lactation Suppression; Kangaroo Care; Parent Education: Infant

Example NIC Activities—Lactation Counseling

Correct misconceptions, misinformation, and inaccuracies about breastfeeding; Provide educational material, as needed; Encourage attendance at breastfeeding classes and support groups for "perceived insufficient milk supply" (Gatti, 2008)

Nursing Interventions and *Rationales*

- Provide lactation support at all phases of lactation (Neifert & Bunick, 2013; Nielsen et al, 2011).
- *Communicate routine advice to mothers without making them feel pressured or guilty, and nurses should be aware of "how" they give routine instructions (Flaherman et al, 2012).*
- Initiate skin-to-skin contact at birth and undisturbed contact for the first hour following birth; the mother should be encouraged to watch the baby, not the clock. *These behaviors are associated with an abundant milk supply (Noonan, 2011; Parker et al, 2013).*
- Encourage postpartum women to start breastfeeding based on infant need as early as possible and reduce formula use to increase breastfeeding frequency. Use nonnarcotic analgesics as early as possible. **EBN:** *These interventions are suggested to decrease early weaning in this study of women who had cesarean deliveries and perceived insufficient milk supply (Chantry, 2014; Gatti, 2008; Kent et al, 2013; Lin et al, 2011; Lou et al, 2014; Nielsen et al, 2011).*
- Provide suggestions for mothers on how to increase milk production and how to determine whether there is insufficient milk supply. **EBN:** *Teach mothers how to determine low intake of breast milk by checking baby's wet diapers (fewer than 6–8) and monitoring the frequency and amount of the baby's bowel movements. Provide suggestions to women on how to increase milk production, such as improving latch-on, increasing frequency of feedings, offering both breasts during each breastfeeding session, and drinking enough fluids (Gatti, 2008; Ndikom et al, 2014; Yen-Ju & McGrath, 2011).*
- Instruct mothers that breastfeeding frequency, sucking times, and amounts are variable and normal. Assist mothers in optimal milk removal frequency. **EBN:** *Breastfeeding rates may be affected by a maternal perception of insufficient milk production and less than optimal milk removal frequency (Kent et al, 2012, 2013).*

▲ Consider the use of medication for mothers of preterm infants with insufficient expressed breast milk. **EBN:** *Breast milk remains the optimal form of enteral nutrition for term and preterm infants until up to 6 months postnatal age. In these studies there was modest improvement in expressing breast milk (EBM) values with the use of a galactagogue medication (Donovan & Buchanan, 2012).*

▲ *Need to be more cautious with recommending galactagogues.*
▲ *Not in the scope of practice for International Board of Lactation Consultants (IBLC) to recommend galactagogues (Academy of Breastfeeding Medicine Protocol Committee, 2011; Donovan & Buchanan, 2012).*

Pediatric

• Provide individualized follow-up with extra home visits or outpatient visits for teen mothers within the first few days after hospital discharge and encourage schools to be more compatible with breastfeeding. *Adolescent mothers in the United States are much less likely to imitate breastfeeding than older mothers. This study indicated that these interventions may be helpful for teens who desire to breastfeed (Tucker et al, 2011).*

Multicultural

• Provide information and support to mothers on benefits of breastfeeding at antenatal visits. **EB:** *A study of mothers of infants in Bhaktapur, Nepal, found that, although proper breastfeeding is the most cost-effective intervention for reducing childhood morbidity and mortality, adherence to breastfeeding recommendations in developing countries is not satisfactory. Although many mothers instituted breastfeeding within 1 hour of delivery, continuation for up to 6 months was not common. Very few mothers received any information on breastfeeding during the antenatal visit (Neifert & Bunik, 2013; Sultana et al, 2013; Ulak et al, 2012).*
• Refer to care plans Interrupted **Breastfeeding** and Readiness for enhanced **Breastfeeding** for additional interventions.

Ineffective Breastfeeding

Barbara J. Wheeler RN, BN, MN, IBCLC

NANDA-I

Definition

Difficulty feeding milk from the breasts, which may compromise nutritional status of the infant/child.

Defining Characteristics

Inadequate infant stooling; infant arching at breast; infant crying at the breast; infant crying within the first hour after breastfeeding; infant fussing within 1 hour of breastfeeding; infant inability to latch on to maternal breast correctly; infant resisting latching on to breast; infant unresponsive to other comfort measures; insufficient emptying of each breast per feeding; insufficient infant weight gain; insufficient signs of oxytocin release; perceived inadequate milk supply; sore nipples persisting beyond first week; sustained infant weight loss; unsustained suckling at the breast

Related Factors

Delayed stage II lactogenesis; inadequate milk supply; insufficient family support; insufficient opportunity for suckling at breast; insufficient parental knowledge regarding breastfeeding techniques; insufficient parental knowledge regarding importance of breastfeeding; interrupted breastfeeding; maternal ambivalence; maternal anxiety; maternal breast anomaly; maternal fatigue; maternal obesity; maternal pain; pacifier use; poor infant sucking reflex; supplemental feedings with artificial nipple

At-Risk Population

Prematurity; previous breast surgery; previous history of breastfeeding failure; short maternity leave

Associated Condition

Oropharyngeal defect

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes and Example

Breastfeeding Establishment: Infant/Maternal; Breastfeeding Maintenance; Knowledge: Breastfeeding; Refer to care plan for Readiness for enhanced **Breastfeeding**

Client Outcomes

Client Will (Specify Time Frame)

- Achieve effective milk transfer (dyad)

• Verbalize/demonstrate techniques to manage breastfeeding problems (mother)
• Manifest signs of adequate intake at the breast (infant)
• Manifest positive self-esteem in relation to the infant feeding process (mother)
• Explain alternative method of infant feeding if unable to continue exclusive breastfeeding (mother)

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Referral; Lactation Counseling; Teaching Infant Nutrition 0-3 Months

Nursing Interventions and *Rationales*

• Identify women with risk factors for lower breastfeeding initiation and continuation rates, as well as factors contributing to ineffective breastfeeding (see conditions listed in the section Related Factors) as early as possible in the perinatal experience. **EB:** *Health care professionals are well positioned to identify mothers at risk for breastfeeding challenges, and to provide accurate information and support the development of breastfeeding skills, which facilitates breastfeeding confidence and success (Balogun et al, 2016; Ogbo et al, 2017).*
• Provide time for clients to express expectations and concerns, and provide emotional support as needed. **EB:** *Lactation consultants, nurses, and peers play a key role in the establishment and continuation of breastfeeding (Balogun et al, 2016; McFadden et al, 2017).*
• Encourage skin-to-skin holding, beginning immediately after delivery. **EB:** *Skin-to-skin holding is associated with improved milk supply, early initiation of breastfeeding, and improved breastfeeding duration (Moore et al, 2016).*
• Use valid and reliable tools to measure breastfeeding performance and to predict early discontinuance of breastfeeding whenever possible/feasible. **EB:** *Casal et al (2017) examined the purpose, theoretical underpinnings, and psychometric properties of 16 instruments measuring breastfeeding attitudes, knowledge, and social support.* **CEB:** *The Breastfeeding Self-Efficacy Scale (BSES) has been used in many settings and with diverse patient populations, and it has consistently demonstrated an ability to accurately predict breastfeeding success or failure, thus providing opportunity for focused education and support for mothers who need it (Dennis, 2003).*
• Promote comfort and relaxation to reduce pain and anxiety. **EB:** *Discomfort and increased tension are factors associated with reduced likelihood to initiate breastfeeding, reduced let-down reflex, increased use of formula supplements, and premature discontinuance of breastfeeding (Fallon et al, 2016).*
• Avoid supplemental feedings. **EB:** *A correlation exists between formula and/or water supplements and failure to succeed with exclusive breastfeeding (Tarrant et al, 2015).*
• Teach mother to observe for infant behavioral cues and responses to breastfeeding. **EB:** *Providing support and education to mother will build her confidence and knowledge base, and is associated with improved breastfeeding duration and exclusivity (McFadden et al, 2017).*
▲ Provide necessary equipment/instruction/assistance for milk expression as needed. **EB:** *Expressing breast milk by hand may be more effective in the removal of milk, particularly in the immediate postpartum period, than the use of electric pumps (Becker et al, 2016).*

▲ Provide referrals and resources: lactation consultants, nurse and peer support programs, community organizations, and written and electronic sources of information. **EB:** *Systematic reviews support the use of professionals with special skills in breastfeeding, peer support programs, and written and electronic information to promote continued breastfeeding (McFadden et al, 2017). Novel approaches to education, such as text messages to mothers and interactive online education programs for fathers/partners, have demonstrated improved breastfeeding knowledge base and self-efficacy (Abbass-Dick et al, 2017) and improved breastfeeding exclusivity rates (Harari et al, 2017).*
• See care plan for Readiness for enhanced **Breastfeeding**.

Multicultural

• Assess whether the client's cultural beliefs about breastfeeding are contributing to ineffective breastfeeding. **EB:** *Women from different cultures, such as Chinese, Somali, and Hispanic women, may add formula as a result of concerns that the infant is not getting enough to eat and the perception that "big is healthy" (Kuswara et al, 2016; Waldrop, 2013; Wandel et al, 2016).* **EB:** *Some traditional cultures, including mothers from Asia, Latin America, and sub-Saharan Africa, consider colostrum unsuitable to feed the newborn, thus liquids such as tea, juice, water, or water sweetened with sugar or honey may be given. These feedings may significantly increase the risk of infection, particularly in developing countries in which sanitation may be poor. In addition, failure to empty the breasts regularly in the early hours and days after delivery may result in suboptimal milk supply (Agho et al, 2016).*
• Assess the influence of family support on the decision to continue or discontinue breastfeeding. **EB:** *Family members' impressions and ideas about breastfeeding influence breastfeeding initiation and duration (Lok et al, 2017).*
• See care plan for Readiness for enhanced **Breastfeeding**.

Home Care

• The previously mentioned interventions may be adapted for home care use.
• Provide anticipatory guidance in relation to home management of breastfeeding. **EB:** *The two most common problems experienced by breastfeeding women are nipple and/or breast pain and low (or perceived low) milk supply; these problems may be preventable with anticipatory guidance (Cleugh & Langseth, 2017; Wood & Sanders, 2017). For mothers returning to the workforce, longer maternity leaves and regularly pumping milk during the workday are associated with enhanced work–life balance and longer breastfeeding duration (Jantzer et al, 2017).*
▲ Investigate availability of and refer to public health department, hospital home follow-up breastfeeding program, or other postdischarge support. **EBN:** *Postdischarge follow-up has been associated with improved breastfeeding duration (Wood & Sanders, 2017).*
• See care plan for Risk for impaired **Attachment**.

Client/Family Teaching and Discharge Planning

• Instruct the client on maternal breastfeeding behaviors/techniques (preparation for, positioning, initiation of/promoting latch-on, burping, completion of session, and frequency of feeding) using a variety of strategies such as written materials, videos, and online resources. **EB:** *Assess breastfeeding mothers to determine knowledge deficits and providing individualized teaching facilitates breastfeeding success (Cleugh & Langseth, 2017; Nilsson et al, 2017).*
• Teach the mother self-care measures (e.g., breast care, management of breast/nipple

discomfort, nutrition/fluid, rest/activity). **EB:** *Painful nipples, mastitis, inadequate hydration, and fatigue are some potentially modifiable problems a breastfeeding woman may experience (Cleugh & Langseth, 2017; McFadden et al, 2017).*

• Provide information regarding infant feeding cues and behaviors and appropriate maternal responses, as well as measures of infant feeding adequacy. **EB:** *Improved knowledge base and ongoing support to learn psychomotor skills facilitates effective breastfeeding (Cleugh & Langseth, 2017; McFadden et al, 2017).*

• Provide education to partner/family/significant others as needed. **EB:** *Family members' impressions and ideas about breastfeeding influence breastfeeding initiation and duration (Lok et al, 2017).*

Interrupted Breastfeeding

Barbara J. Wheeler RN, BN, MN, IBCLC

NANDA-I

Definition

Break in the continuity of feeding milk from the breasts, which may compromise breastfeeding success and/or nutritional status of the infant/child.

Defining Characteristics

Nonexclusive breastfeeding

Related Factors

Maternal employment; maternal-infant separation; needing abruptly to wean infant

At-Risk Population

Hospitalization of child; prematurity

Associated Condition

Contraindications to breastfeeding; infant illness; maternal illness

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Breastfeeding Maintenance; Knowledge: Breastfeeding; Parent-Infant Attachment

Example NOC Outcome with Indicators

Breastfeeding Maintenance as evidenced by the following indicators: Infant's growth and development in normal range/Ability to safely collect and store breast milk/Awareness that breastfeeding can continue beyond infancy/Knowledge of benefits from continued breastfeeding. (Rate the outcome and indicators of **Breastfeeding Maintenance: Infant:** 1 = not adequate, 2 = slightly adequate, 3 = moderately adequate, 4 = substantially adequate, 5 = totally adequate [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

Infant

- Receive mother's breast milk if not contraindicated by maternal conditions (e.g., certain drugs, infections) or infant conditions (e.g., galactosemia)

Maternal

- Maintain lactation

- Achieve effective breastfeeding or satisfaction with the breastfeeding experience
- Demonstrate effective methods of breast milk collection and storage

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Bottle Feeding; Cup Feeding: Newborn; Emotional Support; Lactation Counseling

Example NIC Activities—Lactation Counseling

Instruct patient to contact health care provider (lactation consultant, nurse, midwife, or physician) to assist in determining status of milk supply (i.e., whether insufficiency is perceived or actual); Encourage employers to provide opportunities and private facilities for lactating mothers to pump and store breast milk during the workday

Nursing Interventions and *Rationales*

- Provide information and support to mother and partner/family regarding mother's desire/intention to begin or resume breastfeeding. **EB:** *Mothers who perceived that care providers, partners, and other family members favored exclusive breastfeeding achieved significantly higher rates of breastfeeding compared with those who perceived care providers and family were neutral about the method of infant feeding (Lok et al, 2017; Ramakrishnan et al, 2014).*
- Clarify that interruption in breastfeeding is truly necessary. (Expert recommendation): *Mothers are sometimes inappropriately advised to discontinue breastfeeding (ACOG, 2017; CDC, 2016; Ngoh & Ng, 2016).*
- Provide anticipatory guidance to the mother/family regarding potential duration of the interruption when possible/feasible, ensuring that measures to sustain or restart lactation and promote parent–infant attachment can make it possible to resume breastfeeding when the condition/situation requiring interruption is resolved. **EB:** *Mothers who had never breastfed, and those who had stopped, were successful in establishing or reestablishing breastfeeding with the help of a lactation support (Nyati et al, 2014).*
- Reassure the mother/family that the infant will benefit from any amount of breast milk provided. **EBN:** *One of the most common reasons mothers supplement or stop breastfeeding is their perception of the baby not getting milk and/or enough milk (Wood & Sanders, 2017).*
- Assess mother's concerns, and observe mother performing psychomotor skills (expression, storage, alternative feeding, skin-to-skin care, and/or breastfeeding) and assist as needed. **EBN:** *Individualized support and instruction improves likelihood of breastfeeding success (Becker et al, 2016; McFadden et al, 2017).*
- Collaborate with mother/family/health care providers (as needed) to develop a plan for skin-to-skin contact. **EBN:** *Skin-to-skin contact between mothers and newborns results in improved rates of exclusive breastfeeding (McFadden et al, 2017).*
- Collaborate with the mother/family/health care provider/employer (as needed) to develop a plan for expression/pumping of breast milk and/or infant feeding. **EB:** *Individualized education focused on evidence-based strategies to optimize milk production and extraction enhances milk quality and quantity (Becker et al, 2016)*
- Monitor for signs indicating infant's ability to breastfeed and interest in breastfeeding. **EBN:** *Teach the mother to recognize and respond to her baby's feeding cues and signs that her breasts are filling (McFadden et al, 2017).*

▲ Use supplementation only as medically indicated. **EB:** *Reducing the number of formula supplements given to infants in the hospital is associated with increased rates of exclusive breastfeeding and breastfeeding duration (Tarrant et al, 2015).*
• Provide anticipatory guidance for common problems associated with interrupted breastfeeding (e.g., incomplete emptying of milk glands, diminishing milk supply, infant difficulty with resuming breastfeeding, or infant refusal of alternative feeding method). **EBN** and **expert recommendation:** *Emotional support, as well as information regarding how to prevent and respond to breastfeeding problems, contributes to promotion of exclusive breastfeeding (Cleugh & Langseth, 2017; Wood & Sanders, 2017).*
▲ Initiate follow-up and make appropriate referrals.
• Assist the client to accept and learn an alternative method of infant feeding if effective breastfeeding is not achieved. **CEB:** *If it is clear that breastfeeding cannot be achieved after the interruption and an alternative feeding method must be instituted, the mother needs support and education (Mozingo et al, 2000).*
• See care plans for Readiness for enhanced **Breastfeeding** and Ineffective **Breastfeeding.**

Multicultural

• Teach culturally appropriate techniques for maintaining lactation. **CEB:** *The Oketani method of breast massage is used by Japanese and other Asian women. Oketani breast massage improves the quality of human milk by increasing total solids, lipids, casein concentration, and gross energy (Foda et al, 2004). Some traditional cultures, including Asian, Latin American, and sub-Saharan African, consider colostrum unsuitable to feed the newborn; thus formula is required to prevent hypoglycemia and dehydration, and breast expression/pumping is needed to ensure breasts are regularly emptied, which facilitates an optimal milk supply (Agho et al, 2016).*
• See care plans for Readiness for enhanced **Breastfeeding** and Ineffective **Breastfeeding.**

Home Care

• The previously mentioned interventions may be adapted for home care use.

Client/Family Teaching and Discharge Planning

• Teach mother effective methods to express breast milk. **EBN:** *Expressing breast milk by hand may be more effective in the removal of milk, particularly in the immediate postpartum period, than the use of electric pumps (Becker et al, 2016).*
• Teach mother/parents about skin-to-skin care. **EBN:** *Skin-to-skin care promotes attachment, facilitates improved milk production, and contributes to improved rate and duration of breastfeeding (Brown et al, 2014).*
• Instruct mother on safe breast milk handling techniques. **EB:** *Breastfeeding mothers can retain the high quality of breast milk and the health of their infant by using safe preparation guidelines and storage methods (CDC, 2017).*
• See care plans for Readiness for enhanced **Breastfeeding** and Ineffective **Breastfeeding.**

Readiness for enhanced Breastfeeding

Barbara J. Wheeler RN, BN, MN, IBCLC

NANDA-I

Definition

A pattern of providing milk to an infant or young child directly from the breasts, which may be strengthened.

Defining Characteristics

Mother expresses desire to enhance ability to provide breast milk for child's nutritional needs; mother expresses desire to enhance ability to exclusively breastfeed

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Breastfeeding Establishment: Infant, Maternal; Breastfeeding Maintenance

Example NOC Outcome with Indicators

Breastfeeding Establishment: Infant as evidenced by the following indicators: Proper alignment and latch-on/Proper areolar grasp/Effective areolar compression/Correct suck and tongue placement/Audible swallow/Breastfeeding a minimum of 5 to 10 minutes per breast/Minimum eight feedings per day/Urinations per day appropriate for age/Weight gain appropriate for age. (Rate the outcome and indicators of **Breastfeeding Establishment: Infant:** 1 = not adequate, 2 = slightly adequate, 3 = moderately adequate, 4 = substantially adequate, 5 = totally adequate [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Maintain effective breastfeeding
- Maintain normal growth patterns (infant)
- Verbalize satisfaction with breastfeeding process (mother)

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Lactation Counseling

Example NIC Activities—Lactation Counseling

Provide information about psychological and physiological benefits of breastfeeding; Provide mother the opportunity to breastfeed after birth, when possible

Nursing Interventions and *Rationales*

- Encourage expectant mothers to learn about breastfeeding before and during pregnancy. **EB:** *Systematic reviews have identified that health education, particularly individualized education, significantly increases breastfeeding initiation rates (Balogun et al, 2016).*
- Encourage and facilitate early skin-to-skin contact. **EB:** *Skin-to-skin holding is associated with improved milk supply, early initiation of breastfeeding, and improved breastfeeding duration (Moore et al, 2016).*
- Encourage rooming-in and breastfeeding on demand. **EBN:** *Mothers who room-in with their infants have greater percentages of exclusive breastfeeding when released from the hospital (Neifert & Bunik, 2013).*
- Monitor the breastfeeding process, identify opportunities to enhance knowledge and experience, and provide direction as needed. **EB:** *Individualized education focused on evidence-based strategies improves breastfeeding duration and exclusivity (McFadden et al, 2017).*
- Give encouragement and positive feedback to mothers as they learn to breastfeed. **CEB:** *Positive feedback builds confidence. The Breastfeeding Self-Efficacy Scale, which measures maternal breastfeeding confidence, has demonstrated that higher self-efficacy (confidence) is associated with longer duration of breastfeeding (Dennis, 2003).*
- Discuss prevention and treatment of common breastfeeding problems, such as nipple pain and/or trauma. **EB & Expert Recommendation:** *Common problems experienced by breastfeeding women may be preventable with anticipatory guidance, or*

successfully managed with prompt assistance from a health care provider (Amir, 2014; Cleugh & Langseth, 2017).

• Teach mother to observe for infant behavioral cues and responses to breastfeeding. **EB & Expert Recommendation:** *Awareness and recognition of infant cues facilitate successful breastfeeding (Cleugh & Langseth, 2017; McFadden et al, 2017).*

• Identify current support-person network and opportunities for continued breastfeeding support. **EB:** *Family members' impressions and ideas about breastfeeding influence breastfeeding initiation and duration (Lok et al, 2017).*

• Use supplementation only as medically indicated, and do not provide samples of formula on discharge from hospital. **EB:** *Reducing the number of formula supplements given to infants in hospital, and refraining from sending formula samples home, is associated with increased rates of exclusive breastfeeding and increased breastfeeding duration (Tarrant et al, 2015).*

▲ Provide follow-up contact; as available provide home visits and/or peer counseling. **EB:** *Systematic reviews support the use of professionals with special skills in breastfeeding and peer support programs to promote continued breastfeeding (McFadden et al, 2017; Wood & Sanders 2017).*

Multicultural

• Assess for the influence of cultural beliefs, norms, and values on current breastfeeding practices. **EB:** *Women from different cultures, such as Chinese, Somali, and Hispanic women, may add formula as a result of concerns that the infant is not getting enough to eat and the perception that "big is healthy" (Kuswara et al, 2016; Waldrop, 2013; Wandel et al, 2016).* **EB:** *Some traditional cultures, including Asian, Latin American, and sub-Saharan African, consider colostrum unsuitable to feed the newborn; thus formula may be required to prevent hypoglycemia and dehydration, and breast expression/pumping is needed to ensure breasts are regularly emptied to facilitate an optimal milk supply (Agho et al, 2016).*

Home Care

• The previously mentioned interventions may be adapted for home care use.

Client/Family Teaching and Discharge Planning

• Include the partner and other family members in education about breastfeeding. **EB:** *Family members' impressions and ideas about breastfeeding influence breastfeeding initiation and duration (Lok et al, 2017).*

• Teach the client the importance of maternal nutrition. **CEB:** *Breastfeeding mothers should consume about 500 calories more per day than nonpregnant, nonnursing women, with a focus on nutrient-dense foods, including 200 to 300 mg docosahexaenoic acid (DHA) (the amount ingested with consumption of one to two portions of fish per week) recommended (AAP, 2012).*

• Teach mother about the infant's subtle hunger cues (e.g., rooting, sucking, mouthing, hand-to-mouth and hand-to-hand activity) and encourage her to breastfeed whenever signs are apparent. **EB:** *Evidence-based practice guidelines support the teaching/reinforcement of these skills as important to effective breastfeeding (McFadden et al, 2017).*

• Review guidelines for frequency (at least every 2–3 hours, or 8–12 feedings per 24 hours) and duration (until suckling and swallowing slow down and satiety is reached) of feeding times. **EB:** *In the first few days, frequent and regular stimulation of the*

breasts is important to establish an adequate milk supply; after breastfeeding is established, feeding lasts until the breasts are drained (McFadden et al, 2017).

• Provide information about common infant behaviors related to breastfeeding, and appropriate maternal responses. **EBN:** *Improved knowledge base and ongoing support to learn psychomotor skills facilitates effective breastfeeding (Cleugh & Langseth, 2017; McFadden et al, 2017).*

▲ Provide referrals and resources: lactation consultants, nurse and peer support programs, community organizations, and written and electronic sources of information. **EB:** *Systematic reviews support the use of professionals with special skills in breastfeeding, peer support programs, and written and electronic information to promote continued breastfeeding (McFadden et al, 2017).*

Ineffective Breathing pattern

Debra Siela PhD, RN, CCNS, ACNS-BC, CCRN-K, CNE, RRT

NANDA-I

Definition

Inspiration and/or expiration that does not provide adequate ventilation.

Defining Characteristics

Abnormal breathing pattern; altered chest excursion; bradypnea; decrease in expiratory pressure; decrease in inspiratory pressure; decrease in minute ventilation; decrease in vital capacity; dyspnea; increase in anterior-posterior chest diameter; nasal flaring; orthopnea; prolonged expiration phase; pursed-lip breathing; tachypnea; use of accessory muscles to breathe; use of three-point position

Related Factors

Anxiety; body position that inhibits lung expansion; fatigue; hyperventilation; obesity; pain; respiratory muscle fatigue

Associated Condition

Bony deformity; chest wall deformity; hypoventilation syndrome; musculoskeletal impairment; neurological immaturity; neurological impairment; neuromuscular impairment; spinal cord injury

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Respiratory Status: Airway Patency, Ventilation; Vital Signs

Example NOC Outcome with Indicators

Respiratory Status: Ventilation as evidenced by the following indicators: Respiratory rate/Moves sputum out of airway/Adventitious breath sounds not present/Shortness of breath not present/Auscultated breath sounds/Auscultated vocalization/Chest x-ray findings. (Rate each indicator of **Respiratory Status: Ventilation:** 1 = severe deviation from normal range, 2 = substantial deviation from normal range, 3 = moderate deviation from normal range, 4 = mild deviation from normal range, 5 = no deviation from normal range [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Demonstrate a breathing pattern that supports blood gas results within the client's normal parameters
- Report ability to breathe comfortably
- Demonstrate ability to perform pursed-lip breathing and controlled breathing
- Identify and avoid specific factors that exacerbate episodes of ineffective breathing patterns

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Airway Management; Respiratory Monitoring

Example NIC Activities—Airway Management

Encourage slow, deep breathing, turning, and coughing; Monitor respiratory and oxygenation status as appropriate

Nursing Interventions and *Rationales*

• Monitor respiratory rate, depth, and ease of respiration. *Normal respiratory rate is 10 to 20 breaths per minute in the adult (Jarvis, 2015).*
• Note pattern of respiration. If client is dyspneic, note what seems to cause the dyspnea, the way in which the client deals with the condition, and how the dyspnea resolves or gets worse. **EB:** *Ask the client if they are short of breath (Campbell, 2017; Mahler & O'Donnell, 2015). Use dyspnea rating tools such as the dyspnea fatigue index, multidimensional dyspnea profile (Kjellstrom & van der Wal, 2013), or for nonverbal clients the Respiratory Distress Observation Scale is a behavioral scale that can be used to evaluate dyspnea (Campbell, 2017).*
• Note amount of anxiety associated with the dyspnea. **EBN:** *A normal respiratory pattern is regular in a healthy adult. To assess dyspnea, it is important to consider all of its dimensions, including antecedents, mediators, reactions, and outcomes. Dyspnea is a subjective experience of breathing discomfort that is best understood by asking the client about dimensions and triggers of the symptom experience (Campbell, 2017).*
• Attempt to determine if client's dyspnea is physiological or psychological in cause. *The evaluation of a client with dyspnea continues to be dependent on a thorough history and physical examination. In the client with acute worsening of chronic breathlessness, the health care provider must be attuned to the possibility of a new pathophysiological derangement superimposed on a known disorder. Instruments or sections of instruments pertaining to dyspnea should be classified as addressing domains of the sensory-perceptual experience, affective distress, or symptom/disease impact or burden (Kjellstrom & van der Wal, 2013; Mahler & O'Donnell, 2015; Parshall et al, 2012).*
• The rapidity of which the onset of dyspnea is noted is also an indicator of the severity of the pathological condition (Croucher, 2014)

Psychological Dyspnea—Hyperventilation

• Monitor for symptoms of hyperventilation including rapid respiratory rate, sighing breaths, lightheadedness, numbness and tingling of hands and feet, palpitations, and sometimes chest pain (Bickley & Szilagyi, 2016).
• Assess cause of hyperventilation by asking client about current emotions and psychological state.
    ❍ Pulmonary rehabilitation programs that contain elements of behavioral, cognitive, or psychosocial components have been shown to improve dyspnea and reduce anxiety and depression, particularly in clients with chronic obstructive pulmonary disease (COPD) (von Leupoldt et al, 2014).
    ❍ Pharmacological treatment to reduce anxiety and panic that likely increase dyspnea are not recommended for clients with asthma and COPD (von Leupoldt et al, 2014).
• Ask the client to breathe with you to slow down their respiratory rate. *Maintain eye contact and give reassurance. By making the client aware of respirations and giving support, the client may gain control of the breathing rate.*
▲ Consider having the client breathe in and out of a paper bag as tolerated. *This simple treatment helps associated symptoms of hyperventilation including helping to retain carbon dioxide, which will decrease associated symptoms of hyperventilation (Bickley & Szilagyi, 2016).*
▲ If the client has chronic problems with hyperventilation, numbness and tingling in extremities, dizziness, and other signs of panic attacks, refer for counseling or pulmonary rehabilitation (Lareau et al, 2014).

Physiological Dyspnea

▲ Ensure that client in acute dyspneic state has received any ordered medications, oxygen, and any other treatment needed.

• *Determine intensity, unpleasantness, or distress of dyspnea using a rating scale such as an intensity focused modified Borg scale or visual analog scale (Campbell, 2017; Hareendran & Leidy, 2014; Lareau et al, 2014; Parshall and Schwartzstein, 2014; Parshall et al, 2012).*

• *Note client description of the quality of breathing discomfort, such as chest tightness, air hunger, inability to breathe deeply, urge to breathe, starved for air, and feeling of suffocation are different types of dyspnea sensation reported by individuals with breathlessness (Campbell, 2017; Kjellstrom & van der Wal, 2013; Parshall and Schwartzstein, 2014).*

• Acute onset of dyspnea is often accompanied by signs of respiratory distress, which include tachypnea, cough, stridor, wheezing, cyanosis, impaired speech, tachycardia, hypotension, peripheral edema, frothy sputum, pursed lip breathing, accessory respiratory muscle use, crackles, tripod positioning, and other signs (Croucher, 2014)

• Observe color of tongue, oral mucosa, and skin for signs of cyanosis. *In central cyanosis, both the skin and mucous membranes are affected because of seriously impaired pulmonary function from unventilated or underventilated alveoli. Peripheral cyanosis (skin only) usually indicates vasoconstriction or obstruction to blood flow (Loscalzo, 2013).*

• Auscultate breath sounds, noting decreased or absent sounds, crackles, or wheezes. *These abnormal lung sounds can indicate a respiratory pathology associated with an altered breathing pattern (Croucher, 2014).*

• *Assess for hemodynamic stability for the client with acute dyspnea. Rapid evaluation for impending respiratory failure is essential and includes fragmented speech, tripod positioning, diaphoresis, cyanosis, PaO_2 less than 50 mm Hg, $PaCO_2$ greater than 70, and use of accessory muscles. Hypotension along with dyspnea indicates threat of cardiopulmonary collapse (Croucher, 2014).*

▲ Monitor oxygen saturation continuously using pulse oximetry. Note blood gas results as available. *An oxygen saturation of less than 90% (normal: 95%–100%) or a partial pressure of oxygen of less than 80 mm Hg (normal: 80–100 mm Hg) indicates significant oxygenation problems.*

- ❍ If a client is both dyspneic and hypoxemic, high-flow oxygen may be more beneficial to relieve the dyspnea. **EB:** *Significant differences were found between low-flow and high-flow oxygen in reduction of dyspnea perceptions, reduction in respiratory rate, and increase in SaO_2. (Lenglet et al, 2012).*
- ❍ For clients with chronic breathlessness but no hypoxemia, oxygen therapy does not affect the sensation of dyspnea (Siela & Kidd, 2017).

• Using touch on the shoulder, coach the client to slow respiratory rate, demonstrating slower respirations; making eye contact with the client; and communicating in a calm, supportive fashion. *The nurse's presence, reassurance, and help in controlling the client's breathing can be beneficial in decreasing anxiety.* **EB:** *Anxiety is an important indicator of the severity of the client's COPD (Campbell, 2017).*

• Support the client in using pursed-lip and controlled breathing techniques. *Pursed-lip breathing may relieve dyspnea in advanced COPD (Lareau et al, 2014; Mahler, 2014; Parshall et al, 2012). Pursed-lip breathing results in increased use of intercostal muscles, decreased respiratory rate, increased tidal volume, and improved oxygen saturation levels (Mahler, 2014).*

• If the client is acutely dyspneic, consider having the client lean forward over a bedside table, resting elbows on the table if tolerated (Mahler, 2014). *Leaning forward*

can help decrease dyspnea, possibly because gastric pressure allows better contraction of the diaphragm (Mahler, 2014). This is called the tripod position and is used during times of distress, including when walking.

• Position the client in an upright or semi-Fowler's position. *Most clients will have optimal vital capacity, oxygenation, and reduced dyspnea when upright with arms elevated on pillows or a bedside table (Campbell, 2017; Mahler, 2014).* See Nursing Interventions and *Rationales* for Impaired **Gas** exchange for further information on positioning.

• Increased respiratory drive is one of the causes of dyspnea. Pulmonary rehabilitation reduces respiratory drive through endurance exercise training, strength training, restorative therapy with calories and anabolic agents, pacing strategies and pursed lip breathing techniques, and optimizing bronchodilator therapy (Lareau et al, 2014).

▲ Administer oxygen as ordered. Supplemental oxygen may not relieve all dyspnea (Parshall et al, 2012). *Supplemental oxygen during exertion can result in marked reductions in exercise-induced breathlessness and improvements in exercise endurance in clients with COPD (Casey & Goldstein, 2014). Palliative oxygen therapy is not superior to medical air for breathlessness in palliative care clients (Casey & Goldstein, 2014). Reducing the effect of impaired ventilatory mechanics through reducing dynamic hyperinflation in COPD and strengthening respiratory muscles can reduce breathlessness. Interventions include exercise training with supplemental oxygen along with bronchodilators and inspiratory muscle training (Lareau et al, 2014).*

• *Mechanical ventilation, invasive or noninvasive, is a reliable means of reducing dyspnea associated with respiratory failure (Campbell, 2017).*

• *Opioids may be used for both acute and terminal dyspnea, considering careful safe dosing for relief and the side effect of constipation (Campbell, 2017; Parshall et al, 2012).*

• Altering the central perception of dyspnea may reduce breathlessness through exercise training, reduction in anxiety and fear of dyspnea, and self-management strategies and promotion of self-efficacy (Lareau et al, 2014).

• Use of music as a distraction may reduce the perception of dyspnea (Mahler, 2014).

• Inspiratory muscle training likely improves breathlessness during exercise and/or with activities of daily living in clients with COPD and congestive heart failure (CHF) who exhibit inspiratory muscle weakness (Lareau et al, 2014; Mahler, 2014).

• Increase client's activity to walking three times per day as tolerated. Assist the client to use oxygen during activity as needed. See Nursing Interventions and *Rationales* for **Activity** intolerance. Walking 20 minutes per day is recommended for those unable to be in a structured program (GOLD, 2017). *Supervised exercise has been shown to decrease dyspnea and increase tolerance to activity (GOLD, 2017; Lareau et al, 2014).*

• Schedule rest periods before and after activity. *Respiratory clients with dyspnea are easily exhausted and need additional rest. Nurses coordinate all client care and are integral to ensuring spacing of activity to minimize or prevent dyspnea (Campbell, 2017).*

▲ Evaluate the client's nutritional status. Refer to a dietitian if needed. Use nutritional supplements to increase nutritional level if needed. *Improved nutrition may help increase inspiratory muscle function and decrease dyspnea.*

• Provide small, frequent feedings. *Small feedings are given to avoid compromising ventilatory effort and to conserve energy. Clients with dyspnea often do not eat sufficient amounts of food because their priority is breathing.*

• Offer a fan to move the air in the environment. **CEB/EB:** *Handheld fans can significantly reduce dyspnea in clients with chronic breathlessness (Galbraith et al, 2010; Mahler, 2014). A small portable handheld fan provides an effective self-management strategy for clients with dyspnea (Swan & Booth, 2015).*

• Encourage the client to take deep breaths at prescribed intervals and do controlled coughing.
• Help the client with chronic respiratory disease to evaluate dyspnea experience to determine whether previous incidences of dyspnea were similar and to recognize that the client survived those incidences. Encourage the client to be self-reliant if possible, use problem-solving skills, and maximize use of social support. *The focus of attention on sensations of breathlessness has an impact on judgment used to determine the intensity of the sensation (Campbell, 2017).*
• See Ineffective **Airway** clearance if client has a problem with increased respiratory secretions.
▲ Refer the client with COPD for pulmonary rehabilitation. **EB:** *Clients receiving pulmonary rehabilitation have a significant and clinically meaningful improvement in dyspnea discomfort and an impact in improving the effect of dyspnea on activities of daily living and overall quality of life* (*Lareau et al, 2014). Among the beneficial effects of pulmonary rehabilitation are a reduction in exertional dyspnea during exercise and improved exercise tolerance, as well as decreases in self-reported dyspnea with activity (Parshall et al, 2012). Appropriately resourced home-based exercise training has proven effective in reducing dyspnea and increasing exercise performance activity in the context of pulmonary rehabilitation (Spruit et al, 2013). Pulmonary rehabilitation benefits for COPD clients include reduction of the perceived intensity of breathlessness (GOLD, 2017).*

Geriatric

• Assess respiratory systems in older adults with the understanding that inspiratory muscles weaken, resulting in a slight barrel chest. Expiratory muscles work harder with the use of accessory muscles (Martin-Plank, 2014).
• Encourage ambulation as tolerated. *Encourage movement because immobility is harmful to older adults and it decreases ventilation and increases stasis of secretions (Frederick, 2017).*
• Encourage older clients to sit upright or stand and to avoid lying down for prolonged periods during the day. *Thoracic aging results in decreased lung expansion; an erect position fosters maximal lung expansion (Frederick, 2017).*

Home Care

• The previously mentioned interventions may be adapted for home care use.
• Work with the client to determine what strategies are most helpful during times of dyspnea. Provide education to empower the client to self-manage the disease associated with impaired gas exchange.
• Assist the client and family in identifying other factors that precipitate or exacerbate episodes of ineffective breathing patterns (i.e., stress, allergens, stairs, activities that have high energy requirements). *Awareness of precipitating factors helps clients avoid them and decreases the risk of ineffective breathing episodes (Campbell, 2017).*
• Assess client knowledge of and compliance with medication regimen. *Client/family may need repetition of instructions received at hospital discharge and may require reiteration as fear of a recent crisis decreases. Fear interferes with the ability to assimilate new information.*
▲ Refer the client for telemonitoring with a pulmonologist as appropriate, with use of an electronic spirometer or an electronic peak flowmeter**. EB:** *A growing body of evidence shows that telemonitoring is both time and cost effective for the provider and client providing more timely continuity of care (Di Cerbo et al, 2015).*

• Teach the client and family the importance of maintaining the therapeutic regimen and having as-needed drugs easily accessible at all times. *Appropriate and timely use of medications can decrease the risk of exacerbating ineffective breathing. The 2017 GOLD Report states that bronchodilator medications are central to management of dyspnea (GOLD, 2017).*
• Provide the client with emotional support in dealing with symptoms of respiratory difficulty. Provide family with support for care of a client with chronic or terminal illness. Refer to care plan for **Anxiety.** Witnessing breathing difficulties and facing concerns of dealing with chronic or terminal illness can create fear in the caregiver. Fear inhibits effective coping (Campbell, 2017).
• When respiratory procedures (e.g., apneic monitoring for an infant) are being implemented, explain equipment and procedures to family members, and provide needed emotional support. *Family members assuming responsibility for respiratory monitoring often find this stressful. They may not have been able to assimilate fully any instructions provided by hospital staff (Martin-Plank, 2014).*
• When electrically based equipment for respiratory support is being implemented, evaluate home environment for electrical safety, such as proper grounding. Ensure that notification is sent to the local utility company, the emergency medical team, and police and fire departments. *Notification is important to provide for priority service.*
• Refer to GOLD guidelines for management of home care and indications of hospital admission criteria.
• Support clients' efforts at self-care. Ensure they have all the information they need to participate in care.
• Identify an emergency plan including when to call your health care provider or 911. *Having a ready emergency plan reassures the client and promotes client safety.*
▲ Refer to occupational therapy for evaluation and teaching of energy conservation techniques.
▲ Refer to home health aide services as needed to support energy conservation. *Energy conservation decreases the risk of exacerbating ineffective breathing*.
▲ Institute case management of frail elderly to support continued independent living (Martin-Plank, 2014).

Client/Family Teaching and Discharge Planning

• Teach pursed-lip and controlled breathing techniques. **EB:** *Studies have demonstrated that pursed-lip breathing was effective in decreasing breathlessness and improving respiratory function (Lareau et al, 2014; Mahler, 2014). Pursed-lip breathing may relieve dyspnea in advanced COPD (Parshall et al, 2012).*
• Teach about dosage, actions, and side effects of medications. *Inhaled steroids and bronchodilators can have undesirable side effects, especially when taken in inappropriate doses.*
• Teach client progressive muscle relaxation techniques. **EB:** *Relaxation therapy may help reduce dyspnea and anxiety (von Leupoldt et al, 2014). Benefits of pulmonary rehabilitation include reduction of anxiety and depression associated with COPD (GOLD, 2017).*
• Teach the client to identify and avoid specific factors that exacerbate ineffective breathing patterns, such as exposure to other sources of air pollution, especially smoking. If client smokes, refer to the smoking cessation section in the impaired **Gas** exchange care plan.

Decreased Cardiac output

Ann Will Poteet MS, RN, CNS, AGNP-C

NANDA-I

Definition

Inadequate blood pumped by the heart to meet the metabolic demands of the body.

Defining Characteristics

Altered Heart Rate/Rhythm

Bradycardia, electrocardiogram (ECG) change; heart palpitations; tachycardia

Altered Preload

Decrease in central venous pressure (CVP); decrease in pulmonary artery wedge pressure (PAWP); edema; fatigue; heart murmur; increase in central venous pressure (CVP); increase in pulmonary artery wedge pressure (PAWP); jugular vein distention; weight gain

Altered Afterload

Abnormal skin color; alteration in blood pressure; clammy skin; decrease in peripheral pulses; decrease in pulmonary vascular resistance (PVR); decrease in systemic vascular resistance (SVR); dyspnea; increase in pulmonary vascular resistance (PVR); increase in systemic vascular resistance (SVR); oliguria; prolonged capillary refill

Altered Contractility

Adventitious breath sounds; coughing; decreased cardiac index; decrease in ejection fraction; decrease in left ventricular stroke work index (LVSWI); decrease in stroke volume index (SVI); orthopnea; paroxysmal nocturnal dyspnea; presence of S3 heart sound; presence of S4 heart sound

Behavioral/Emotional

Anxiety; restlessness

Related Factors

To be developed

Associated Condition

Alteration in afterload, alteration in contractility; alteration in heart rate; alteration in heart rhythm; alteration in preload; alteration in stroke volume

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Cardiac Pump Effectiveness; Circulation Status; Tissue Perfusion: Abdominal Organs, Peripheral; Vital Signs

Example NOC Outcome with Indicators

Cardiac Pump Effectiveness as evidenced by the following indicators: Blood pressure/Heart rate/Cardiac index/Ejection fraction/Activity tolerance/Peripheral pulses/Neck vein distention not present/Heart rhythm/Heart sounds/Angina not present/Peripheral edema not present/Pulmonary edema not present. (Rate the outcome and indicators of **Cardiac Pump Effectiveness:** 1 = severe deviation from normal range, 2 = substantial deviation from normal range, 3 = moderate deviation from normal range, 4 = mild deviation from normal range, 5 = no deviation from normal range [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Demonstrate adequate cardiac output as evidenced by blood pressure, pulse rate, and rhythm within normal parameters for client; strong peripheral pulses; maintained level of mentation, lack of chest discomfort or dyspnea, and adequate urinary output; an ability to tolerate activity without symptoms of dyspnea, syncope, or chest pain
- Remain free of side effects from the medications used to achieve adequate cardiac output
- Explain actions and precautions to prevent primary or secondary cardiac disease

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Cardiac Care; Cardiac Care: Acute

Example NIC Activities—Cardiac Care

Evaluate chest pain (e.g., intensity, location, radiation, duration, precipitating and alleviating factors); Document cardiac dysrhythmias

Nursing Interventions and *Rationales*

- Recognize characteristics of decreased cardiac output including, but not limited to, fatigue, dyspnea, edema, orthopnea, paroxysmal nocturnal dyspnea, chest pain, decreased exercise capacity, weight gain, hepatomegaly, jugular venous distension, palpitations, lung rhonchi, cough, clammy skin, skin color changes, dysuria, altered mental status, anemia, and hemodynamic changes.
- Monitor and report presence and degree of symptoms including dyspnea at rest, reduced exercise capacity, difficulty with activities of daily living, orthopnea, paroxysmal nocturnal dyspnea, cough, palpitations, chest pain, distended abdomen, fatigue, presyncope/syncope, or weakness. Monitor and report signs including jugular vein distention, peripheral edema, S3 gallop, rales, positive hepatojugular reflux, ascites, laterally displaced or pronounced point of maximal impact, heart murmur, narrow pulse pressure, cool extremities, tachycardia with pulsus alternans, and irregular heartbeat. **EB:** *These are symptoms and signs consistent with heart failure (HF) and decreased cardiac output (Yancy et al, 2013).*
- Monitor orthostatic blood pressures, oxygenation, hemodynamic values, and daily weights. **EB:** *These interventions assess for fluid volume status. Peripheral edema or the lack of peripheral edema is not always indicative of hypervolemia or decreased cardiac output (Yancy et al, 2013).*
- Recognize that decreased cardiac output can occur in a number of noncardiac disorders such as septic shock and hypovolemia. Expect variation in orders for differential diagnoses related to decreased cardiac output, because orders will be

distinct to address the primary cause of the altered cardiac output.
• Obtain a thorough client-specific and familial history. **EB:** *It is important to assess for cardiac and noncardiac disorders and/or behaviors that might accelerate the progression of HF symptoms, such as high-sodium diet, excess fluid intake, substance abuse, missed medication doses, hypertension, diabetes mellitus, metabolic syndrome, obesity, hyperlipidemia, hormonal abnormalities, genetic disorders, coronary artery disease, sleep disordered breathing, congenital heart disease, cancer, immune disorders, and pregnancy (Bozkurt et al, 2016; Yancy et al, 2013, 2017).*
▲ Monitor pulse oximetry and administer oxygen as needed per health care provider's order. Supplemental oxygen increases oxygen availability to the myocardium and can relieve symptoms of hypoxemia. Resting hypoxia or oxygen desaturation may indicate fluid overload or concurrent pulmonary disease.
• Place client in semi-Fowler's or high Fowler's position with legs down or in a position of comfort. Elevating the head of the bed and legs in the down position may decrease the work of breathing and may also decrease venous return and preload.
• During acute events, ensure client remains on short-term bed rest or maintains activity level that does not compromise cardiac output.
• Provide a restful environment by minimizing controllable stressors and unnecessary disturbances. Reducing stressors decreases cardiac workload and oxygen demand.
▲ Apply graduated compression stockings or intermittent sequential pneumatic compression (ISPC) leg sleeves as ordered. Ensure proper fit by measuring accurately. Remove stockings at least twice a day, and then reapply. Assess the condition of the extremities frequently. Graduated compression stockings may be contraindicated in clients with peripheral arterial disease (Kahn et al, 2012). **EB:** *A Cochrane review that assessed use of knee-length graduated compression stockings versus thigh-length graduated compression stockings found no difference in effectiveness. Type of stocking should be determined by client preference, cost, and ease of use (Sajid et al, 2012).* **EB:** *Graduated compression stockings, alone or used in conjunction with other prevention modalities, help promote venous return and reduce the risk of deep vein thrombosis in hospitalized clients (Sachdeva et al, 2014).*
▲ Check blood pressure, pulse, and condition before administering cardiac medications (e.g., angiotensin-converting enzyme inhibitors, angiotensin receptor blockers, calcium channel blockers, diuretics, digoxin, and beta-blockers). Notify health care provider if heart rate or blood pressure is low before holding medications. It is important that the nurse evaluate how well the client is tolerating current medications before administering cardiac medications; do not hold medications without health care provider input. The health care provider may decide to have medications administered even though the blood pressure or pulse rate has lowered. **EB:** *Clients with preserved ejection heart failure (HFpEF) or reduced ejection fraction heart failure (HFrEF) and persistent hypertension, and those with HF and increased cardiovascular risk (age >75 years old, established vascular disease, chronic renal disease, or Framingham risk score >15%) should receive guideline-directed medical therapy (GDMT) to maintain a systolic blood pressure less than 130 mm Hg (Yancy et al, 2017).*
• Observe for and report chest pain or discomfort; note location, radiation, severity, quality, duration, and associated manifestations such as nausea, indigestion, or diaphoresis; also note precipitating and relieving factors. Chest pain/discomfort may indicate an inadequate blood supply to the heart, which can further compromise cardiac output. **EB:** *Clients with decreased cardiac output may present with myocardial ischemia. Those with myocardial ischemia may present with decreased cardiac output and HF*

(Amsterdam et al, 2014; Yancy et al, 2013).
▲ If chest pain is present, then refer to the interventions in risk for Decreased **Cardiac** tissue perfusion care plan.
• Recognize the effect of sleep-disordered breathing in HF and that sleep disorders are common in clients with HF (Yancy et al, 2013, 2017). **EB:** *Central sleep apnea is recognized as an independent risk factor for worsening HF and reduced survival in clients with HF. The pathological effects of sleep apnea that contribute to worsening cardiac function include sympathetic nervous system stimulation, systemic inflammation, oxidative stress, and endothelial dysfunction (Costanzo et al, 2015).* **EB:** *For obstructive sleep apnea, continuous positive airway pressure (CPAP) can reduce apneic events, improve nocturnal oxygenation, and improve sleep quality (Yancy et al, 2017).*
• Administer CPAP or supplemental oxygen at night as ordered for management of suspected or diagnosed sleep disordered breathing. **EB:** *Both CPAP and nocturnal oxygen supplementation have been shown to reduce episodes of sleep apnea, reduce sympathetic nervous system stimulation, and improve cardiac function (Costanzo et al, 2015).*
▲ Closely monitor fluid intake, including intravenous lines. Maintain fluid restriction if ordered. In clients with decreased cardiac output, poorly functioning ventricles may not tolerate increased fluid volumes. **EB:** *Fluid restriction along with sodium restriction can enhance volume management with diuretics, and in some clients can improve outcomes (Yancy et al, 2013).*
• Monitor intake and output (I&O). If client is acutely ill, measure hourly urine output and note decreases in output. Decreased cardiac output results in decreased perfusion of the kidneys, with a resulting decrease in urine output. **EB:** *Clinical practice guidelines cite that monitoring I&Os is useful for monitoring effects of HF treatment, including diuretic therapy (Yancy et al, 2013).*
▲ Note results of initial diagnostic studies, including electrocardiography, echocardiography, and chest radiography. **EB:** *Clinical practice guidelines suggest that chest radiography, echocardiography, and electrocardiogram are recommended in the initial assessment of HF (Yancy et al, 2013).*
▲ Note results of further diagnostic imaging studies such as radionuclide imaging, stress echocardiography, cardiac catheterization, or magnetic resonance imaging (MRI). **EB:** *Clinical practice guidelines state that radionuclide and MRI are useful studies when assessing left ventricular ejection fraction and volume if echocardiography is not sufficient (Yancy et al, 2013).*
▲ Review laboratory data as needed including arterial blood gases, complete blood count, serum electrolytes (sodium, potassium, magnesium, and calcium), blood urea nitrogen, creatinine, iron studies, urinalysis, glucose, fasting lipid profile, liver function tests, thyroid-stimulating hormone, B-type natriuretic peptide (BNP assay), or N-terminal pro-B-type natriuretic peptide (NTpro-BNP). Routine blood work can provide insight into the etiology of HF and extent of decompensation. **EB:** *Clinical practice guidelines recommend that BNP or NTpro-BNP assay should be measured in clients to determine prognosis or disease severity in chronic or acute decompensated HF, guide treatment during hospitalization, and establish a baseline at time of hospital discharge. BNP can also be evaluated in at-risk clients for prevention in the outpatient setting (Yancy et al, 2017).* **EB:** *Iron-deficiency anemia is related to decreased exercise capacity, and anemia is a strong indication of HF severity (Yancy et al, 2017).*
• Gradually increase activity when the client's condition is stabilized by encouraging slower paced activities, or shorter periods of activity, with frequent rest periods after exercise prescription; observe for symptoms of intolerance. Take blood pressure and pulse before and after activity and note changes. Activity of the cardiac client should

be closely monitored. See **Activity** intolerance.

▲ Encourage a diet that promotes cardiovascular health and reduces risk of hypertension, atherosclerotic disease, renal impairment, insulin resistance, and hypervolemia, within the context of an individual's cultural preferences (Eckel et al, 2013; Van Horn et al, 2016; Whelton et al, 2017). **EB:** *Reduced sodium intake, weight loss, healthy diet (low sugar, whole grains, fruits and vegetables, low saturated and total fat), and avoidance of excess caloric intake is recommended for individuals with elevated blood pressure and for prevention of cardiovascular disease (Van Horn et al, 2016; Whelton et al, 2017).*

▲ Monitor bowel function. Provide stool softeners as ordered. Caution client not to strain when defecating. Decreased activity, pain medication, and diuretics can cause constipation. **EBN:** *Clients with HF have autonomic dysfunction, which places them at risk for reduced mean arterial blood pressure and reduced cerebral blood flow. Autonomic challenges, such as the Valsalva maneuver, can put the HF client at risk for hypoperfusion, ischemia, and stroke (Serber et al, 2014).*

• Weigh the client at the same time daily (after voiding). Daily weight is a good indicator of fluid balance. Use the same scale if possible when weighing clients for consistency. Increased weight and severity of symptoms can signal decreased cardiac function with retention of fluids. **EB:** *Clinical practice guidelines state that weighing at the same time daily is useful to assess effects of diuretic therapy (Yancy et al, 2013).*

▲ Provide influenza and pneumococcal vaccines as needed before client discharge for those who have yet to receive those inoculations (Centers for Disease Control, 2017).

• Assess for presence of depression and/or anxiety and refer for treatment if present. See Nursing Interventions and *Rationales* for **Anxiety** to facilitate reduction of anxiety in clients and family. **EB:** *Depression is common in clients with HF, and it has been found that individuals with depressive symptoms have poorer quality of life, use health care services more frequently, have poorer self-care, and have worse clinical outcomes (Yancy et al, 2013).*

▲ Refer to a cardiac rehabilitation program for education and monitored exercise. **EB:** *Exercise training or regular physical activity is recommended for HF clients. Cardiac rehabilitation can improve quality of life and functional capacity, and decrease mortality (Anderson & Taylor, 2014; Yancy et al, 2013). A systematic review of outcomes of exercise-based interventions in clients with systolic HF found that hospitalizations and those for systolic HF were reduced for clients in an exercise program and quality of life was improved (Taylor et al, 2014).*

▲ Refer to an HF program for education, evaluation, and guided support to increase activity and rebuild quality of life. Support for the HF client should be client centered, culturally sensitive, and include family and social support. **EB:** *Multidisciplinary systems of care that are designed to support clients with HF can improve outcomes (Yancy et al, 2013).*

Critically Ill

▲ Observe for symptoms of cardiogenic shock, including impaired mentation, hypotension, decreased peripheral pulses, cold clammy skin, signs of pulmonary congestion, and decreased organ function. If present, notify the health care provider immediately. Cardiogenic shock is a state of circulatory failure from loss of cardiac function associated with inadequate organ perfusion and a high mortality rate. **EB:** *Critical cardiogenic shock presents with severe hypotension, increasing inotropic and vasopressor support, organ hypoperfusion, and worsening acidosis and lactate levels (Yancy et al, 2013).*

▲ If shock is present, monitor hemodynamic parameters for an increase in pulmonary

wedge pressure, an increase in SVR, or a decrease in stroke volume, cardiac output, and cardiac index. **EB:** *Hemodynamic monitoring with a pulmonary artery catheter can be beneficial in clients with respiratory distress, impaired systemic perfusion, and dependence on intravenous inotropic support, and when clinical assessment is inadequate or severe symptoms persist despite recommended therapies (Yancy et al, 2013).*

▲ Titrate inotropic and vasoactive medications within defined parameters to maintain contractility, preload, and afterload per health care provider's order. By following parameters, the nurse ensures maintenance of a delicate balance of medications that stimulate the heart to increase contractility, while maintaining adequate perfusion of the body. **EB:** *Clinical practice guidelines recommend that intravenous inotropic drugs might be reasonable for HF clients presenting with low blood pressure and low cardiac output to maintain systemic perfusion and preserve end-organ performance (Yancy et al, 2013).*

▲ Identify significant fluid overload and initiate intravenous diuretics as ordered. Monitor I&Os, daily weight, and vital signs, as well as signs and symptoms of congestion. Watch laboratory data, including serum electrolytes, creatinine, and urea nitrogen. **EB:** *Intravenous loop diuretics should be initiated in the HF client who presents with significant fluid overload as either intermittent boluses or continuous infusion to reduce morbidity (Yancy et al, 2013).*

▲ When using pulmonary arterial catheter technology, be sure to appropriately level and zero the equipment, use minimal tubing, maintain system patency, perform square wave testing, position the client appropriately, and consider correlation to respiratory and cardiac cycles when assessing waveforms and integrating data into client assessment. **EB:** *Clinical practice guidelines recommend that invasive hemodynamic monitoring can be useful in acute HF with persistent symptoms when therapy is refractory, fluid status is unclear, systolic pressures are low, renal function is worsening, vasoactive agents are required, or when considering advanced device therapy or transplantation (Yancy et al, 2013).*

▲ Observe for worsening signs and symptoms of respiratory compromise. Recognize that invasive or noninvasive ventilation may be required for clients with acute cardiogenic pulmonary edema. **EB:** *Clinical practice guidelines for an HF state that CPAP improves daily functional capacity and quality of life for those with HF and obstructive sleep apnea and is reasonable for clients with refractory HF not responding to other medical therapies (Costanzo et al, 2015; Yancy et al, 2013).* **EB:** *Noninvasive positive pressure ventilation (NPPV), including CPAP and bilevel NPPV, can reduce hospital mortality, intensive care unit (ICU) length of stay, and intubation rate, and result in faster client improvement (Vital et al, 2013).*

▲ Monitor client for signs and symptoms of fluid and electrolyte imbalance when clients are receiving ultrafiltration or continuous renal replacement therapy (CRRT). Clients with refractory HF may have ultrafiltration or CRRT ordered as a mechanical method to remove excess fluid volume. **EB:** *Clinical practice guidelines cite that ultrafiltration is reasonable for clients with obvious volume overload and congestion, and refractory congestion not responsive to medical therapy (Yancy et al, 2013).*

• Recognize that hypoperfusion from low cardiac output can lead to altered mental status and decreased cognition. **CEB:** *A study that assessed an association among cardiac index and neuropsychological ischemia found that decreased cardiac function, even with normal cardiac index, was associated with accelerated brain aging (Jefferson et al, 2010).*

• Recognize that clients with severe HF may undergo additional therapies, such as internal pacemaker or defibrillator placement, and/or placement of a ventricular assist device (VAD). **EB:** *The use of VADs is a reasonable treatment as a bridge to recovery, transplant, or decision-making in selected HF clients with reduced ejection fraction and*

profound hemodynamic compromise (Yancy et al, 2013).

Geriatric

• Recognize that older clients may demonstrate fatigue and depression as signs of HF and decreased cardiac output.
▲ If the client has heart disease causing activity intolerance, refer for cardiac rehabilitation. **EB:** *Cardiac rehabilitation can positively affect an individual's quality of life and reduce hospitalizations regardless of age (Anderson & Taylor, 2014; Taylor et al, 2014).*
▲ Recognize that edema can present differently in the older population. **EB:** *In the older population, lower extremity edema is often related to peripheral causes, such as dependency, rather than cardiac causes (Yancy et al, 2013).*
▲ Recognize that blood pressure control is beneficial for older clients to reduce the risk of worsening HF. **EB:** *Hypertension treatment is particularly beneficial in the older population, and control of both systolic and diastolic hypertension has been shown to reduce the risk of incident HF (Yancy et al, 2013).* **EB:** *Clients with stage A HF and hypertension, with increased cardiovascular risk (age >75 years old, established vascular disease, chronic renal disease, or Framingham risk score >15%) should have a target systolic blood pressure less than 130 mm Hg (Yancy et al, 2017).*
▲ Recognize that renal function is not always accurately represented by serum creatinine in the older population because of less muscle mass (Yancy et al, 2013).
▲ Observe for side effects from cardiac medications. Older adults can have difficulty with metabolism and excretion of medications because of decreased function of the liver and kidneys; therefore toxic side effects are more common. **EB:** *Older adults are at increased risk for digoxin toxicity, especially at larger doses, because of lower body mass and impaired renal function (Yancy et al, 2013).*
▲ Older adults may require more frequent visits, closer monitoring of medication dose changes, and more gradual increases in medications, because of changes in the metabolism of medications and impaired renal function (Yancy et al, 2013).
▲ As older adults approach end of life, clinicians should help to facilitate a comprehensive plan of care that incorporates the client and family's values, goals, and preferences (Allen et al, 2012; National Consensus Project for Quality Palliative Care, 2013). **EB:** *For older adults (>65 years old) with multiple comorbidities and limited life expectancy, it is reasonable to use a team-based approach to weigh the risks and benefits of tight blood pressure control and choice of antihypertensive medication (Whelton et al, 2017).*

Home Care

• Some of the previously mentioned interventions may be adapted for home care use. Home care agencies may use specialized staff and methods to care for chronic HF clients. **CEB:** *A study assessing HF outcomes over a 10-year period between a multidisciplinary home care intervention and usual care found significantly improved survival and prolonged event-free survival and was both cost and time effective (Ingles et al, 2006).*
• Assess for fatigue and weakness frequently. Assess home environment for safety, as well as resources/obstacles to energy conservation.
• Help family adapt daily living patterns to establish life changes that will maintain improved cardiac functioning in the client. Take the client's perspective into consideration and use a holistic approach in assessing and responding to client planning for the future.
• Assist client to recognize and exercise power in using self-care management to

adjust to health change. Refer to care plan for **Powerlessness.**

▲ Refer to medical social services, cardiac rehabilitation, telemonitoring, and case management as necessary for assistance with home care, access to resources, and counseling about the impact of severe or chronic cardiac diseases. **EB:** *Access to systems that promote care coordination is essential for successful care of the HF client. Good communication and documentation between services, health care providers, and transitions of care is essential to ensure improved outcomes in HF clients (Albert et al, 2015; Yancy et al, 2013).*

▲ As the client chooses, refer to palliative care for care, which can begin earlier in the care of the HF client. Palliative care can be used to increase comfort and quality of life in the HF client before end-of-life care. **EB:** *Palliative care should address quality of life, ongoing symptom control, preferences about end of life, psychosocial distress, and caregiver support (National Consensus Project for Quality Palliative Care, 2013; Yancy et al, 2013).*

▲ If the client's condition warrants, refer to hospice. **EB:** *The palliative care and HF teams are best suited to determine when end-of-life care is appropriate for the client and family (Yancy et al, 2013).* **CEB:** *The multidisciplinary hospice team can reduce hospital readmission, increase functional capacity, and improve quality of life in end-stage HF (Coviello et al, 2002).*

Client/Family Teaching and Discharge Planning

• Begin discharge planning as soon as possible on admission to the emergency department (ED) if appropriate with a case manager or social worker to assess home support systems and the need for community or home health services. **EB:** *Discharge planning should include adherence to the treatment plan, medication management, follow-up with health care providers and care coordination, dietary and physical activities, cardiac rehabilitation, and secondary prevention recommendations (Albert et al, 2015; Yancy et al, 2013).*

• Discharge education should be comprehensive, evidence based, culturally sensitive, and include both the client and family (Yancy et al, 2013).

• Teach the client about any medications prescribed. Medication teaching includes the drug name; its purpose, administration instructions, such as taking it with or without food; and any side effects. Instruct the client to report any adverse side effects to his or her health care provider.

• Teach the importance of performing and recording daily weights on arising for the day, and to report weight gain. Ask if client has a scale at home; if not, assist in getting one. **EB:** *Clinical practice guidelines suggest that daily weight monitoring leads to early recognition of excess fluid retention, which, when reported, can be offset with additional medication to avoid hospitalization from HF decompensation (Yancy et al, 2013).*

• Teach the types and progression patterns of worsening HF symptoms, when to call a health care provider for help, and when to go to the hospital for urgent care (Yancy et al, 2013).

• Stress the importance of ceasing tobacco use (Whelton et al, 2017). **EB:** *Tobacco use can cause or worsen decreased blood flow in the coronaries, as well as cause vasoconstriction, which can lead to atherosclerotic disease. Effects of nicotine include increasing pulse and blood pressure and constricting of blood vessels. Tobacco use is a primary factor in heart disease (American Heart Association, 2014).*

▲ Individuals should be screened for electronic cigarette use (e-cigarette). **EB:** *Although more studies are needed regarding the health effects of e-cigarette use, the American Heart Association recommends that all health care providers educate their clients regarding the long-term use of e-cigarettes given the known toxicities present in e-cigarettes, as well as the*

presence of nicotine in most types of e-cigarettes (Bhatnagar et al, 2014).

• On hospital discharge, educate clients about low-sodium, low–saturated fat diet, with consideration of client education, literacy, and health literacy level.

• Educate clients that comorbidities, including obesity, hypertension, metabolic syndrome, diabetes mellitus, and hyperlipidemia, are common in individuals with HF and can affect clinical outcomes related to HF if not controlled (Bozkurt et al, 2016).

• For clients with diabetes mellitus, educate about the importance of glycemic control. **EB:** *Individuals with diabetes mellitus are at increased risk for HF, and should be managed according to recommended guidelines. Thiazolidinediones should be avoided in individuals with class III or IV HF because of increased fluid retention (Bozkurt et al, 2016).*

• Instruct client and family on the importance of regular follow-up care with health care providers. **EB:** *Post discharge support can significantly reduce hospital readmissions and improve health care outcomes, quality of life, and costs (Yancy et al, 2013).*

▲ Teach stress reduction (e.g., meditation, imagery, controlled breathing, muscle relaxation techniques). **CEB:** *A study that assessed effects of relaxation or exercise in HF clients versus controls found that those who participated in regular relaxation therapy or exercise training reported greater improvements in psychological outcomes, with the relaxation group significantly improving depression and the exercise training group improving fatigue (Yu et al, 2007).* **EB:** *Meditation is a reasonable adjunct to GDMT for reduction of cardiovascular risk and lifestyle modification (Levine et al, 2017).*

• Discuss advance directives with the HF client, including resuscitation preferences. **EB:** Evidence suggests that advance directives can help to reduce overall health care costs, reduce in-hospital deaths, and increase hospice use (National Consensus Project for Quality Palliative Care, 2013; Yancy et al, 2013).

• Clients should be provided with education regarding the influenza vaccine and pneumococcal vaccine prior to discharge. **EB:** *The influenza vaccine is recommended for all adults, and the pneumococcal vaccine is recommended for individuals more than 65 years old and for individuals who are at high risk for cardiovascular disease (Centers for Disease Control, 2017).*

• Teach the importance of physical activity as tolerated. **EB:** *Exercise helps control blood pressure and weight, which are the most important controlled risk factors for cardiovascular disease. Individuals should engage in aerobic physical activity of varying intensity as tolerated and incorporate variable anaerobic activities such as resistance training (Bozkurt et al, 2016; Eckel et al, 2013).* **EB:** *Exercise is beneficial in the prevention of cardiovascular disease and HF (Bozkurt et al, 2016).* **EB:** *Clients with arrhythmias or advanced HF may require supervision or monitoring during exercise (Bozkurt et al, 2016).*

Risk for decreased Cardiac output

Mary Beth Flynn Makic PhD, RN, CCNS, FAAN, FNAP

NANDA-I

Definition
Susceptible to inadequate blood pumped by the heart to meet metabolic demands of the body, which may compromise health.

Risk Factors
To be developed

Associated Condition
Alteration in afterload; alteration in contractility; alteration in heart rate; alteration in heart rhythm; alteration in preload; alteration in stroke volume

NIC, NOC, Client Outcomes, Nursing Interventions and *Rationales*, Client/Family Teaching and Discharge Planning, and References
Refer to care plan for Decreased **Cardiac output**.

Risk for decreased Cardiac tissue perfusion

Ann Will Poteet MS, RN, CNS, AGNP-C

NANDA-I

Definition
Susceptible to a decrease in cardiac (coronary) circulation, which may compromise health.

Risk Factors
Insufficient knowledge of modifiable factors; substance misuse

At-Risk Population
Family history of cardiovascular disease

Associated Condition
Cardiac tamponade; cardiovascular surgery; coronary artery spasm; diabetes mellitus; hyperlipidemia; hypertension; hypovolemia; hypoxemia; hypoxia; increase in C-reactive protein; pharmaceutical agent

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes
Cardiac Pump Effectiveness; Circulation Status; Tissue Perfusion: Cardiac; Tissue Perfusion: Cellular; Vital Signs

Example NOC Outcome with Indicators

Tissue Perfusion: Cardiac as evidenced by the following indicators: Angina/Arrhythmia/Tachycardia/Bradycardia/Nausea/Vomiting/Profuse diaphoresis. (Rate the outcome and indicators of **Tissue Perfusion: Cardiac:** 1 = severe, 2 = substantial, 3 = moderate, 4 = mild, 5 = none [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Maintain vital signs within normal range
- Retain an asymptomatic cardiac rhythm (have absence of arrhythmias, tachycardia, or bradycardia)

• Be free from chest and radiated discomfort as well as associated symptoms related to acute coronary syndromes (ACSs)
• Deny nausea and be free of vomiting
• Have skin that is dry and of normal temperature

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Cardiac Care; Cardiac Precautions; Embolus Precautions; Dysrhythmia Management; Vital Signs Monitoring; Shock Management: Cardiac

Example NIC Activity—Cardiac Precautions

Avoid causing intense emotional situations; Avoid overheating or chilling the client; Provide small frequent meals; Substitute artificial salt and limit sodium intake if appropriate; Promote effective techniques for reducing stress; Restrict smoking

Nursing Interventions and *Rationales*

• Be aware that the primary cause of ACS, which include unstable angina (UA), non–ST-elevation myocardial infarction (NSTEMI), and ST-elevation myocardial infarction (STEMI), is an imbalance between myocardial oxygen consumption and demand that is associated with partially or fully occlusive thrombus development in coronary arteries (Amsterdam et al, 2014).
• Assess for symptoms of coronary hypoperfusion and possible ACS, including chest discomfort (pressure, tightness, crushing, squeezing, dullness, or achiness), with or without radiation (or originating) in the retrosternum, back, neck, jaw, shoulder, or arm discomfort or numbness; shortness of breath (SOB); associated diaphoresis; abdominal pain; dizziness, lightheadedness, loss of consciousness, or unexplained fatigue; nausea or vomiting with chest discomfort, heartburn, or indigestion; and associated anxiety. **EB:** *These symptoms are signs of decreased cardiac perfusion and ACSs, such as UA, NSTEMI, or STEMI, as well as other cardiovascular disorders such as aortic aneurysm, valve disorders, and pericarditis. A physical assessment will aid in the assessment of the extent, location, and presence of, and complications resulting from a myocardial infarction (MI). It will promote rapid triage and treatment. It is also important to assess whether the client had a prior stroke, heart failure, or other cardiovascular disorder. It is important to note that certain psychiatric disorders (somatoform disorders, panic attack, and anxiety disorders) can mimic ACS, but they are typically noncardiac causes of chest pain (Amsterdam et al, 2014; Mehta et al, 2016).*
• Consider atypical presentations of ACS for women, older adults, and individuals with diabetes mellitus, impaired renal function, and dementia. **EB/CEB:** *Women, older adults, and individuals with diabetes mellitus, impaired renal function, and dementia may present with atypical findings (Amsterdam et al, 2014; McSweeney et al, 2016; Mehta et al, 2016; Mieres et al, 2014). A systematic review of differences showed that women had significantly less chest discomfort and were more likely to present with fatigue, neck pain, syncope, nausea, right arm pain, dizziness, and jaw pain (Coventry et al, 2011). Delaying identification of atypical presentations can have negative effects on timely intervention and management of ACS, resulting in poorer outcomes and higher mortality (Mehta et al, 2016).*
• Review the client's medical, surgical, social, and familial history. **EB:** *A medical history must be concise and detailed to determine the possibility of ACSs and to help determine the possible cause of cardiac symptoms and pathology (Amsterdam et al, 2014).*
• Perform physical assessments for both coronary artery disease (CAD) and

noncoronary findings related to decreased coronary perfusion, including vital signs, pulse oximetry, equal blood pressure in both arms, heart rate, respiratory rate, and pulse oximetry. Check bilateral pulses for quality and regularity. Report tachycardia, bradycardia, hypotension or hypertension, pulsus alternans or pulsus paradoxus, tachypnea, or abnormal pulse oximetry reading. Assess cardiac rhythm for arrhythmias; skin and mucous membrane color, temperature, and dryness; and capillary refill. Assess neck veins for elevated central venous pressure, cyanosis, and pericardial or pleural friction rub. Examine client for cardiac S4 gallop, new heart murmur, lung crackles, altered mentation, pain on abdominal palpation, decreased bowel sounds, or decreased urinary output. **EB:** *These indicators help assess for cardiac and noncardiac etiologies of symptoms and differential diagnoses (Amsterdam et al, 2014).*

▲ Administer supplemental oxygen as ordered and needed for clients presenting with ACS, respiratory distress, or other high-risk features of hypoxemia to maintain a P_{O_2} of at least 90%. **EB:** *American Heart Association guidelines for emergency cardiovascular care during ACS recommend administering oxygen for breathlessness, hypoxemia, signs of heart failure, or if signs of shock are present, and the need for oxygen should be guided by noninvasive monitoring of oxygen saturation. There is limited evidence to support or refute the use of high-flow or low-flow supplemental oxygen if a normal oxygen level (>90%) is present, but it is reasonable to withhold supplemental oxygen in normoxic individuals (O'Connor et al, 2015).* **EB:** *A Cochrane review found there was limited evidence to support or refute the use of routine supplemental oxygen with acute MI, and that harm from excess supplemental oxygen cannot be ruled out, recommending further studies (Cabello et al, 2016).*

▲ Use continuous pulse oximetry as ordered. **EB:** *Prevention and treatment of hypoxemia includes maintaining arterial oxygen saturation over 90% (Amsterdam et al, 2014).*

▲ Insert one or more large-bore intravenous catheters to keep the vein open. Routinely assess saline locks for patency. Clients who come to the hospital with possible decrease in coronary perfusion or ACS may have intravenous fluids and medications ordered routinely or emergently to maintain or restore adequate cardiac function and rhythm.

▲ Observe the cardiac monitor for hemodynamically significant arrhythmias, ST depressions or elevations, T-wave inversions and/or Q-waves as signs of ischemia or injury. Report abnormal findings. **EB:** *Arrhythmias and electrocardiogram (ECG) changes indicate myocardial ischemia, injury, and/or infarction. Note that left ventricular hypertrophy, ventricular pacing, and bundle branch blocks can mask signs of ischemia or injury (Amsterdam et al, 2014).*

• Have emergency equipment and defibrillation capability nearby and be prepared to defibrillate immediately if ventricular tachycardia with clinical deterioration or ventricular fibrillation occurs.

▲ Perform a 12-lead ECG as ordered to be interpreted within 10 minutes of emergency department arrival and during episodes of chest discomfort or angina equivalent. **EB:** *A 12-lead ECG should be performed within 10 minutes of emergency department arrival for all clients who are having chest discomfort. ECGs are used to identify the area of ischemia or injury, such as ST depressions or elevations, new left-bundle branch block, T-wave inversions, and/or Q-waves, and to guide treatment (Amsterdam et al, 2014; O'Gara et al, 2013).*

▲ Administer nonenteric-coated aspirin as ordered, as soon as possible after presentation and for maintenance. **EB:** *Aspirin has been shown to prevent platelet clumping, aggregation, and activation that leads to thrombus formation, which in coronary arteries leads to ACSs. Contraindications include active peptic ulcer disease, bleeding disorders, and aspirin allergy (Amsterdam et al, 2014; O'Gara et al, 2013).*

▲ Administer nitroglycerin tablets sublingually as ordered, every 5 minutes until the chest pain is resolved while monitoring the blood pressure for hypotension, for a maximum of three doses as ordered. Administer nitroglycerin paste or intravenous preparations as ordered. **EB:** *Nitroglycerin causes coronary arterial and venous dilation, and at higher doses peripheral arterial dilation, reducing preload and afterload and decreasing myocardial oxygen demand while increasing oxygen delivery (Amsterdam et al, 2014).*

• Do not administer nitroglycerin preparations to individuals with hypotension, or individuals who have received phosphodiesterase type 5 inhibitors, such as sildenafil, tadalafil, or vardenafil, in the last 24 hours (48 hours for long-acting preparations). **EB:** *Synergistic effect causes marked exaggerated and prolonged vasodilation/hypotension (Amsterdam et al, 2014).*

▲ Administer morphine intravenously as ordered, every 5 to 30 minutes until pain is relieved while monitoring blood pressure when nitroglycerin alone does not relieve chest discomfort. **EB:** *Morphine has potent analgesic and antianxiolytic effects and causes mild reductions in blood pressure and heart rate that reduce myocardial oxygen consumption. Hypotension and respiratory depression are the most serious complications of morphine use, and naloxone may be administered as ordered for morphine overdose (Amsterdam et al, 2014).*

▲ Assess and report abnormal laboratory work results of cardiac enzymes, specifically troponin I or T, B-type natriuretic peptide, chemistries, hematology, coagulation studies, arterial blood gases, finger stick blood sugar, elevated C-reactive protein, or drug screen. **EB:** *Abnormalities can identify the cause of the decreased perfusion and identify complications related to the decreased perfusion such as anemia, hypovolemia, coagulopathy, drug abuse, hyperglycemia, kidney (renal) failure, and heart failure. Markedly elevated cardiac enzymes are usually indicative of an MI, and the cardiac enzymes can also help determine short- and long-term prognosis (Amsterdam et al, 2014).*

• Assess for individual risk factors for CAD, such as hypertension, dyslipidemia, cigarette smoking, diabetes mellitus, metabolic syndrome, obesity, or family history of heart disease. Other risk factors including sedentary lifestyle, obesity, or cocaine or amphetamine use. Note age and gender as risk factors. **EB:** *Certain conditions place clients at higher risk for decreased cardiac tissue perfusion (Amsterdam et al, 2014; Mehta et al, 2016; Mieres et al, 2014).*

▲ Administer additional heart medications as ordered, including beta-blockers, calcium channel blockers, angiotensin-converting enzyme inhibitors, angiotensin II receptor blockers, aldosterone antagonists, antiplatelet agents, and anticoagulants. Always check blood pressure and pulse rate before administering these medications. If the blood pressure or pulse rate is low, contact the health care provider to establish whether the medication should be withheld. Also check platelet counts, renal function, and coagulation studies as ordered to assess proper effects of these agents. **EB:** *These medications are useful to optimize cardiac and kidney function, including blood pressure, heart rate, myocardial oxygen demand, intravascular fluid volume, and cardiac rhythm (Amsterdam et al, 2014).*

▲ Administer lipid-lowering therapy as ordered. **EB:** *Use of statin drugs has been shown to reduce an individual's risk of recurrent MI, stroke, and coronary heart disease mortality, especially with high-intensity statins that lower low-density lipoprotein cholesterol levels (Amsterdam et al, 2014; Stone et al, 2013). A systematic review of statin use in primary prevention of cardiovascular disease showed reductions in all-cause mortality, major vascular events, and revascularizations (*Taylor et al, 2013*).*

▲ Prepare client with education, withholding of meals and/or medications, and intravenous access for early invasive therapy with cardiac catheterization, reperfusion therapy, and possible percutaneous coronary intervention in individuals with

refractory angina or hemodynamic or electrical instability, and first medical contact to device time of less than 90 minutes if STEMI is suspected. **EB:** *First medical contact to device time of less than 90 minutes was associated with improved client outcomes (Amsterdam et al, 2014; O'Gara et al, 2013).*

▲ Prepare clients with education, withholding of meals and/or medications, and intravenous access for noninvasive cardiac diagnostic procedures such as echocardiogram, exercise, or pharmacological stress test, and cardiac computed tomography scan as ordered. **EB:** *Clients suspected of decreased coronary perfusion should receive these diagnostic procedures as appropriate to evaluate for CAD (Amsterdam et al, 2014; Fletcher et al, 2013; Mieres et al, 2014).*

▲ Request a referral to a cardiac rehabilitation program. **EB:** *Cardiac rehabilitation programs are designed to limit the physiological and psychological effects of cardiac disease, reduce the risk for sudden cardiac death and reinfarction, control symptoms and stabilize or reverse the process of plaque formation, and enhance psychosocial and vocational status of clients (Amsterdam et al, 2014).* **EB:** *Cardiac rehabilitation can improve quality of life and functional capacity, and decrease mortality (Anderson & Taylor, 2014).*

Geriatric

• Consider atypical presentations of possible ACS in older adults. **CEB:** *Older adults may present with atypical signs and symptoms such as weakness, stroke, syncope, or change in mental status (Amsterdam et al, 2014; McSweeney et al, 2016; Mehta et al, 2016).*

▲ Ask the prescriber about possible reduced dosage of medications for older clients, considering weight, creatinine clearance, and glomerular filtration rate. **EB:** *Older clients can have reduced pharmacokinetics and pharmacodynamics, including reduced muscle mass, reduced renal and hepatic function, and reduced volume of distribution, which can alter drug dosing, efficacy, and safety, as well as some drug–drug interactions (Amsterdam et al, 2014; Stone et al, 2013).*

• Consider issues such as quality of life, palliative care, end-of-life care, and differences in sociocultural aspects for clients and families when supporting them in decisions regarding aggressiveness of care. Ask about living wills, as well as medical and durable power of attorney. **EB:** *Management decisions, including decisions regarding invasive treatment, should be client-centered and take into account client preferences and goals, comorbidities, cognitive and functional status, and life expectancy (Amsterdam et al, 2014; McSweeney et al, 2016; Mehta et al, 2016; National Consensus Project for Quality Palliative Care, 2013).*

Client/Family Teaching and Discharge Planning

▲ Client and family education regarding a multidisciplinary plan of care should start early. Special attention to client and family education should occur during transitions of care. **EB:** *It is important to provide the client and family with a comprehensive plan of care and education materials that are evidence based to assist with client compliance and to potentially reduce hospital readmissions related to ACS. The plan of care should take into consideration the client's psychosocial and socioeconomic status, access to care, risk for depression and/or social isolation, and health care disparities (Amsterdam et al, 2014).*

• Teach the client and family to call 911 for symptoms of new angina, existing angina unresponsive to rest and sublingual nitroglycerin tablets, or heart attack, or if an individual becomes unresponsive.

• On discharge, instruct clients about symptoms of ischemia, when to cease activity,

when to use sublingual nitroglycerin, and when to call 911.
• Teach client about any medications prescribed. Medication teaching includes the drug name, its purpose, administration instructions such as taking it with or without food, and any side effects to be aware of. Instruct the client to report any adverse side effects to the health care provider.
• On hospital discharge, educate clients and significant others about discharge medications, including nitroglycerin sublingual tablets or spray, with written, easy to understand, culturally sensitive information. **EB:** *Clients and significant others need to be prepared to act quickly and decisively to relieve ischemic discomfort (Amsterdam et al, 2014).*
• Provide client education related to risk factors for decreased cardiac tissue perfusion, such as hypertension, hyperlipidemia, metabolic syndrome, diabetes mellitus, tobacco use, obesity, advanced age, and gender (female). **EB:** *Those with two or more risk factors should have a 10-year risk screening for development of symptomatic coronary heart disease. Client education is a vital part of nursing care for the client. Start with the client's base level of understanding and use that as a foundation for further education. It is important to factor in cultural and/or religious beliefs in the education provided (Amsterdam et al, 2014; Barnason et al, 2017; Eckel et al, 2013; Goff et al, 2013).*
• Instruct the client on antiplatelet and anticoagulation therapy, and about signs of bleeding, need for ongoing medication compliance, and international normalized ratio monitoring. **EB:** *Special attention and education should be provided to older individuals, because they are at greater risk for bleeding (Amsterdam et al, 2014).*
• After discharge, continue education and support for client blood pressure and diabetes control, weight management, and resumption of physical activity. **EB:** *Reducing risk factors acts as secondary prevention of CAD (Amsterdam et al, 2014; Eckel et al, 2013).*
▲ Clients should be provided with education regarding the influenza vaccine and pneumococcal vaccine before hospital discharge. **EB:** *The influenza vaccine is recommended for all adults, and the pneumococcal vaccine is recommended for individuals older than 65 years and for individuals who are at high risk for cardiovascular disease (Amsterdam et al, 2014; Centers for Disease Control, 2017).*
▲ Stress the importance of ceasing tobacco use (Whelton et al, 2017). **EB:** *Tobacco use can cause or worsen decreased blood flow in the coronaries, as well as cause vasoconstriction, which can lead to atherosclerotic disease. Effects of nicotine include increasing pulse and blood pressure and constricting blood vessels. Tobacco use is a primary factor in heart disease (American Heart Association, 2014; Amsterdam et al, 2014).*
▲ Individuals should be screened for electronic cigarette use (e-cigarette). **EB:** *Although more studies are needed regarding the health effects of e-cigarette use, the American Heart Association recommends that all health care providers educate their clients regarding the long-term use of e-cigarettes given the known toxicities present in e-cigarettes, as well as the presence of nicotine in most types of e-cigarettes (Bhatnagar et al, 2014).*
▲ On hospital discharge, educate clients about a low-sodium, low-saturated fat diet, with consideration to client education, literacy, and health literacy level. **EB:** *Reducing risk factors acts as secondary prevention of CAD (Amsterdam et al, 2014; Eckel et al, 2013).*
• Teach the importance of physical activity as tolerated. **EB:** *Exercise helps control blood pressure and weight, which are the most important controlled risk factors for cardiovascular disease. Individuals should engage in aerobic physical activity of varying intensity as tolerated and incorporate variable anaerobic activities such as resistance training (Amsterdam et al, 2014; Bozkurt et al, 2016; Eckel et al, 2013).* **EB:** *Exercise is beneficial in the prevention of cardiovascular disease and heart failure (Bozkurt et al, 2016).* **EB:** *Clients with arrhythmias or advanced heart failure may require supervision or monitoring during exercise (Bozkurt et al,*

2016).

Caregiver Role Strain

Barbara A. Given PhD, RN, FAAN

NANDA-I

Definition

Difficulty in fulfilling care responsibilities, expectations, and/or behaviors for family or significant others.

Defining Characteristics

Caregiving Activities

Apprehensiveness about future ability to provide care; apprehensiveness about the future health of care receiver; apprehensiveness about possible institutionalization of care receiver; apprehensiveness about well-being of care receiver if unable to provide care; difficulty completing required tasks; difficulty performing required tasks; dysfunctional change in caregiving activities; preoccupation with care routine

Caregiver Health Status

Physiological

Fatigue; gastrointestinal distress; headache; hypertension; rash; weight change

Emotional

Alteration in sleep pattern; anger; depression; emotional vacillation; frustration; impatience; ineffective coping strategies; insufficient time to meet personal needs; nervousness; somatization; stressors

Socioeconomic

Changes in leisure activities; low work productivity; refusal of career advancement; social isolation

Caregiver-Care Receiver Relationship

Difficulty watching care receiver with illness; grieving of changes in relationship with care recipient; uncertainty about changes in relationship with care receiver

Family Processes

Concerns about family member(s); family conflict

Related Factors

Care Receiver

Condition inhibits conversation; dependency; discharged home with significant needs; increase in care needs; problematic behavior; substance misuse; unpredictability of illness trajectory; unstable health condition

Caregiver

Physical conditions; substance misuse; unrealistic self-expectations; competing role commitments; ineffective coping strategies; inexperience with caregiving; insufficient emotional resilience; insufficient energy; insufficient fulfillment of others' expectations; insufficient fulfillment of self-expectations; insufficient knowledge about community resources; insufficient privacy; insufficient recreation; isolation; not developmentally ready for caregiver role; stressors

Caregiver-Care Receiver Relationship

Abusive relationship; codependency; pattern of ineffective relationships; presence of abuse; conflictual relationships; unrealistic care receiver expectations; violent relationship

Caregiving Activities

Around-the-clock care responsibilities; change in nature care of activities; complexity of care activities; excessive caregiving activities; extended duration of caregiving required; inadequate physical environment for providing care; insufficient assistance; insufficient equipment for providing care; insufficient respite for caregiver; insufficient time; unpredictability of care situation

Family Processes

Family isolation; ineffective family adaptation; pattern of family dysfunction; pattern of family dysfunction prior to the caregiving situation; pattern of ineffective family coping

Socioeconomic

Alienation; difficulty accessing assistance; difficulty accessing community resources; difficulty accessing support; insufficient community resources; insufficient social support; insufficient transportation; social isolation

At-Risk Population

Care receiver's condition inhibits conversation; developmental delay of care receiver; developmental delay of caregiver; exposure to violence; female caregiver; financial crisis; partner as caregiver; prematurity

Associated Condition

Care Receiver

Alteration in cognitive functioning; chronic illness; congenital disorder; illness severity; psychiatric disorder; psychological disorder

Caregiver

Alteration in cognitive functioning; health impairment; psychological disorder

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Caregiver Adaptation to Patient Institutionalization; Caregiver Emotional Health; Caregiver Home Care Readiness; Caregiver Lifestyle Disruption; Caregiver-Patient Relationship; Caregiver Performance: Direct Care; Caregiver Performance: Indirect Care; Caregiver Physical Health; Caregiver Role Endurance; Caregiver Stressors; Caregiver Well-Being; Family Resiliency; Family Coping

Example NOC Outcome with Indicators

Caregiver Emotional Health with plans for a positive future as evidenced by the following indicators: Satisfaction with life/Sense of control/Self-esteem/Certainty about future/Perceived social connectedness/Perceived spiritual well-being/Perceived adequacy of resources. (Rate the outcome and indicators of **Caregiver Emotional Health:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Throughout the Care Situation, the Caregiver Will

- Be able to express feelings of strain
- Feel supported by health care professionals, family, and friends; feel they have adequate information to provide care
- Report reduced or acceptable feelings of burden or distress
- Take part in self-care activities to maintain own physical and psychological/emotional health; identify resources (family and community) available to help in giving care
- Verbalize mastery of the care activities; feel confident and competent to provide care; have the skills to provide care
- Identify resources to obtain social support
- Ask for help when needed or when feeling comprised in ability to provide care

- Not refuse help when needed and offered; ask for help when needed

Throughout the Care Situation, the Care Recipient Will

- Obtain quality and safe physical care and emotional care
- Be treated with respect and dignity

NIC (Nursing Interventions Classification)

Suggested NIC Intervention
Caregiver Support

Example NIC Activities—Caregiver Support
Determine caregiver's acceptance of role; Accept expressions of negative emotion

Nursing Interventions and *Rationales*

- Mood management. Regularly monitor signs of depression, anxiety, burden, and deteriorating physical health in the caregiver throughout the care situation if the care demands change frequently, especially if the relationship is poor, the care recipient has cognitive or neuropsychiatric symptoms, there is little social support available, the caregiver becomes enmeshed in the care situation, the caregiver has multiple comorbidities, or has poor preexisting physical or emotional health. Refer to the care plan for **Hopelessness** when appropriate. **EBN:** *High levels of distress in caregivers are linked to multiple variables (van der Lee et al, 2014) and may include worse quality of life (QoL), sleep disturbance, depressive symptoms, and overall physical health decline (Shaffer et al, 2017; Trevino et al, 2017). Other factors contributing to distress include cognitive and motor function of the care recipient and duration of the disease and caregiving activities (de Wit et al, 2017).* **EB:** *Caregiving may weaken the immune system and predispose the caregiver to illness (Vitlic et al, 2015). Caregiver depressive symptoms may lead to physical health decline (Shaffer et al, 2017; Trevino et al, 2017).*
- The impact of providing care on the caregiver's emotional health should be assessed at regular intervals using a reliable and valid instrument such as the Caregiver Strain Risk Index (which was validated with caregivers of clients with diagnosed Parkinson's disease), Caregiver Burden Inventory, Caregiver Reaction Assessment, Screen for Caregiver Burden, Subjective and Objective Scale, and Family Caregiver Self Expectations. **EBN:** *Family caregivers face potential strain in caring for persons with Parkinson's disease and amyotrophic lateral sclerosis (ALS) because of the unpredictability of symptom presentation and greater physical and behavioral impairment (de Wit et al, 2017). The Caregiver Strain Risk Screen (CSRS) was developed and tested for initial validation. The 28-item CSRS demonstrated acceptable validity and reliability in measuring caregiver strain (Abendroth, 2015). Research has validated the effectiveness of a number of evaluation tools for caregiver stress including Caregiver Reaction Assessment (Given et al, 1992), Burden Interview, the Caregiver Strain Index, and the Caregiver Burden Inventory. Caregiver assessment should be done at regular intervals throughout the care trajectory (Adelman et al, 2014) noting changes that require action. Another tool is called the Positive Aspects of Caregiving Questionnaire (Abdollahpour et al, 2017).*
- Identify potential caregiver personal resources such as mastery, benefit funding, social support, optimism, and positive aspects of care and resilience. Good outcomes can be achieved through resources (Joling et al, 2017). **EB/EBN:** *Research has shown that*

caregivers can have simultaneous positive and negative responses to providing care (Roth et al, 2015). Positive responses may help buffer the negative effects of providing care on caregivers' emotional health and may also increase the effectiveness of interventions to reduce strain. Caregiver resilience can be observed as caregivers feel competent to provide care (Joling et al, 2017).

• Screen for caregiver role strain at the onset of the care situation, at regular intervals throughout the care situation, at care transitions, and with changes in care recipient status. **EB/EBN:** *Improvement in patient physical function resulted in both patient and caregiver physical and psychological QoL. Decreases in caregiver burden can be associated with improvement in caregiver physical and psychological QoL (Pucciarelli et al, 2017). Changes in the care recipient's health status necessitate new skills and monitoring from the caregiver and affect the caregiver's ability to continue to provide care and may affect caregiver health (Trevino et al, 2017).*

• Assist the client to identify spiritual beliefs and engage in spiritual practices. **EB:** *Spiritual beliefs and practices may help caregivers cope because it protects them from depression (Penman, 2017).*

• Regularly monitor social support for the caregiver and help the caregiver identify and use appropriate support systems for varying times in the care situation. **EBN:** *For heart failure patients Evangelista et al (2016) found in an integrated review that support group interventions affected caregiver burden, depressive symptoms, confidence, and preparedness. Positive effects on empowerment, coping, and resilience can result (Brand et al, 2016; MacCourt et al, 2017).*

• Help the caregiver learn mindfulness stress management techniques, which can reduce psychological distress. **EB:** *Mindfulness stress reduction interventions can result in improvement in QoL, self-compassion, caregiver burden, and relationship satisfaction (Schellekens et al, 2017).*

• Encourage the caregiver to share feelings, concerns, uncertainties, and fears. Support groups, even Internet-based ones, can be used to gain support. **EBN:** *For the isolated caregiver support groups can improve feelings of support and self-efficacy.* **EB:** *Internet social support groups can be an effective form of support (Evangelista et al, 2016; MacCourt et al, 2017; Parker et al, 2017).*

• Observe for any evidence of caregiver or care recipient violence or abuse, particularly verbal abuse and emotional abuse; if evidence is present, identify the conflict and seek help to manage. **EB/CEB:** *Caregiver abuse is possible, and screening should be done at regular intervals (Hoover & Polson, 2014; Liu et al, 2017).*

▲ Encourage regular and open communication with the care recipient and with the health care team. Care transitions are a critical point to ensure that caregivers have adequate information for patient safety and efficient and effective care. **EB:** *High-quality communication and patient and family engagement facilitate excellent care by families and reduce barriers to care transitions (Scott et al, 2017).*

• Assist caregiver to secure and manage finances to meet care recipient's needs. **EB:** *Caregivers with financial difficulty were more likely to have depressive symptoms* (*Nam, 2016*).

• Help the caregiver identify competing occupational demands and potential benefits to maintaining work as a way of providing normalcy. Guide caregivers to seek ways to maintain employment through mechanisms such as working remotely, job sharing, or decreasing hours at work. **EB:** *Adult children caregivers reported more stress and partner strain, whereas elder caregivers received greater psychological stress. Sandwiched generation caregivers reported poorer overall psychosocial functioning. Adult children female caregivers had more family-to-work conflicts and less partner support than males (de Moor*

et al, 2017; *DePasquale et al, 2017*).
• Help the caregiver problem solve to meet the care recipient's needs. **EBN:** *Interventions that teach caregivers problem-solving skills have been shown to positively influence caregivers' psychosocial well-being (Cheng et al, 2014).*

Geriatric

• Monitor the caregiver for psychological distress and signs of depression, especially if there was an unsatisfactory family relationship before caregiving. **EBN:** *Family caregivers' relationship satisfaction is linked with caregiver role burden, anxiety, and depression (Kruithof et al, 2016).*
• Assess the health of caregivers, particularly their control over chronic diseases and comorbid conditions, at regular intervals. **CEB:** *Caregivers with high levels of depressive symptoms have demonstrated poor health and increased health care utilization and cost (Shaffer et al, 2017; Trevino et al, 2017).*
• Implement a telephone-based collaborative care program to provide support. **EBN:** *Social support has been shown to be an integral part of maintaining caregiver emotional health (Kruithof et al, 2016; Mavandadi et al, 2017).*
• Provide medication management to facilitate safe and effective use of medications for self and care recipient by medication reconciliation and education. **EB:** *Polypharmacy should be avoided and communicated to providers (Koronkowski et al, 2016).*
• To improve the ability to provide safe care: provide skills training related to direct care, perform complex monitoring tasks, supervise and interpret client symptoms, assist with decision-making, assist with medication adherence.
• Provide emotional support and comfort, and coordinate care. Family members need the resources and support to provide care to the care recipient. **CEB:** *Each task demands different skills and knowledge, and caregivers need to be assisted to care (Polenick et al, 2017). Complex tasks are associated with emotional difficulties, thus caregivers need the training to gain the needed skills (Petruzzo et al, 2017; Toye et al, 2016).*
• Insurance authorization: health professionals, such as social workers, assist care recipients to obtain the needed referrals to gain payment for needed health and community services.
• Teach symptom management techniques (assessment, potential causes, aggravating factors, potential alleviating factors, and reassessment), particularly for fatigue, dyspnea, constipation, anorexia, and pain. **EBN:** *Well-prepared caregivers are important for older care recipients. Caregivers require and desire training in care recipient monitoring symptom management and interpretation, and they can benefit from a problem-solving approach (Cheng et al, 2014).*

Multicultural

• Assess for the influence of cultural beliefs, ethnic and racial norms, and values on the caregiver's ability to provide care as well as the response to care. **EBN:** *What the client considers normal and abnormal may be based on cultural perceptions (Itty et al, 2014).* **EBN:** *Each caregiver should be assessed for the response to care. African American caregivers of dementia patients had decreased positive affect and less physical activity (Cothran et al, 2017). Despite the importance of cultural differences in perceptions of caregiver role strain, there are common characteristics that are distressing to caregivers across multiple cultures and they may experience burden and depression. African American and Hispanic caregivers received less professional intervention support than their white counterparts (Graham-Phillips*

et al, 2016). **EBN:** *Social support and care recipients' behavioral differences have been shown to be an important factor in caregiver distress across multiple cultures (Han et al, 2014). Persons with different cultural backgrounds may not perceive the demands of care with equal degrees of distress (Cothran et al, 2017; Graham-Phillips et al, 2016).*

• *Tailoring interventions for caregivers based on racial, ethnic, and cultural characteristics may affect caregiver outcomes* (*Jessup et al, 2015*).

• Recognize and understand that culture often plays a role in identifying who will be recognized as a family caregiver. **EB:** *In a study of Native Americans, 49% reported stress as a major difficulty; males reported financial difficulty and they desired training in patient care. Gender played a role in differences in activity of caregivers in some tribes (Cordova et al, 2016).*

• Encourage spirituality as a source of support for coping. **EBN:** *Spirituality and spiritual engagement may protect caregiver from depression (Penman, 2017). Spiritual care can reduce care strain in caregivers of elderly patients with Alzheimer's (Mahdavi et al, 2017).*

Home Care

• Assess the client and caregiver at every visit for the quality of their relationship, and for the quality and safety of the care provided. **EB:** *Quality of the caregiver-care recipient relationship and the impact of the care situation on that relationship can be an important source of distress or support for the caregiver (van der Lee et al, 2014). Education, social support, and behavioral management are the most effective support for caregivers of dementia patients (Clarkson et al, 2017).*

• Encourage use of respite care if it seems appropriate to support the caregiver. Allow the caregiver to gain confidence in the respite provider. **EB:** *Respite care provides time away from the care situation and may help alleviate some caregiver distress (Vandepitte et al, 2016); others may be too fearful.*

▲ Refer the client to home health aide services for assistance with activities of daily living and light housekeeping. Home health aide services can provide physical relief and respite for the caregiver. **EB:** *Barriers to community social services may be related to minority and ethnic carer satisfaction (Greenwood et al, 2015).*

• Assess preexisting strengths and weaknesses that the caregiver brings to the situation. **EB/EBN:** *Caregivers' personality type, mastery, self-efficacy, optimism, and social support have all been linked to the amount of distress the caregiver will perceive as a result of providing care (Adelman et al, 2014). Improving caregiver sense of competency to deal with neuropsychiatric symptoms of dementia patients can prevent or reduce caregiver burden (van der Lee et al, 2014).*

Client/Family Teaching and Discharge Planning

• Identify client and caregiver factors that necessitate the use of formal home care services, that may affect provision of care, or that need to be addressed before the client can be safely discharged from home care. **EBN:** *Health care practitioners should assess needs for support resources, home care or community assistance prior to discharge, and at routine intervals throughout the care situation.(Greenwood et al, 2015). Interventions to be considered needed at discharge may include medication management, medication reconciliation, symptom monitoring, identification of community-based resources, and specific caregiver concerns about home care. Skills training is needed for many caregiving situations (Mollica et al, 2017).*

• Collaborate with the caregiver and discuss the care needs of the client, disease

processes, medications, and what to expect as part of discharge planning and transition care.
Use a variety of instructional techniques (e.g., explanations, demonstrations, visual aids) until the caregiver is able to express a degree of comfort with needed care. **EB:** *Knowledge and confidence are separate concepts and both are needed for caregiving. Self-assurance in caregiving will decrease the amount of distress the caregiver perceives as a result of providing care (Jessup et al, 2015; Mollica et al, 2017) and may improve the quality of care provided.*
• Assess family caregiving skill. The identification of caregiver difficulty with any of a core set of processes highlights areas for intervention. **EB:** *Caregiver skills training has been shown to improve caregiver knowledge and skills (Mollica et al, 2017).*
• Discharge care should be individualized to specific caregiver needs and care situations, and enable them to be prepared. **EBN:** *Interventions implemented by advance practice nurses have been successful in preventing negative outcomes (Naylor et al, 2017; Stone, 2014; Toles et al, 2017).*
• Assess the caregiver's need for information such as information on symptom management, disease progression, specific skills, and available support. **EBN:** *Caregiver interventions should be individualized to meet specific caregiver needs (Naylor et al, 2017). Multicomponent strategies to provide education, support, counseling, care continuity, and linkage to community resources to ease transitions can improve caregiver health and coping (Naylor et al, 2017; Ostwald et al, 2014).*
▲ Involve the family caregiver in care transitions and discharge from institutions; use a multidisciplinary team to provide medical and social services for detailed instruction and planning specific to the care need. The CARE Act, available in 39 states, requires caregiver instruction at hospital discharge. **EB:** *Family members need education specific to their situation at discharge, and this educational approach should be based on patient's needs. The postdischarge visit serves as an important vehicle to prevent readmissions and improve quality of care for patients (Rodakowski et al, 2017; Soufer et al, 2017).*
▲ Refer to counseling or support groups to assist in adjusting to the caregiver role and periodically evaluate not only the caregiver's emotional response to care but the safety of the care delivered to the care recipient.

Risk for Caregiver Role Strain

Marina Martinez-Kratz MS, RN, CNE

NANDA-I

Definition

Susceptible to difficulty in fulfilling care responsibilities, expectations, and/or behaviors for family or significant others, which may compromise health.

Risk Factors

Care Receiver

Dependency; discharged home with significant needs; increase in care needs; problematic behavior; substance misuse; unpredictability of illness trajectory; unstable health condition

Caregiver

Substance misuse; unrealistic self-expectations; competing role commitments; ineffective coping strategies; inexperience with caregiving; insufficient emotional resilience; insufficient energy; insufficient fulfillment of

others' expectations; insufficient fulfillment of self-expectations; insufficient knowledge about community resources; insufficient privacy; insufficient recreation; isolation; not developmentally ready for caregiver role; physical conditions; stressors

Caregiver-Care Receiver Relationship

Abusive relationship; codependency; pattern of ineffective relationships; presence of abuse; unrealistic care receiver expectations; violent relationship

Caregiving Activities

Around-the-clock care responsibilities; change in nature of care activities; complexity of care activities; excessive caregiving activities; extended duration of caregiving required; inadequate physical environment for providing care; insufficient assistance; insufficient equipment for providing care; insufficient respite for caregiver; insufficient time; unpredictability of care situation

Family Processes

Family isolation; ineffective family adaptation; pattern of family dysfunction; pattern of family dysfunction prior to the caregiving situation; pattern of ineffective family coping

Socioeconomic

Alienation; difficulty accessing assistance; difficulty accessing community resources; difficulty accessing support; insufficient community resources; insufficient social support; insufficient transportation; social isolation

At-Risk Population

Care receiver's condition inhibits conversation; developmental delay of care receiver; developmental delay of caregiver; exposure to violence; female caregiver; financial crisis; partner as caregiver; prematurity

Associated Condition

Care Receiver

Alteration in cognitive functioning; chronic illness; congenital disorder; illness severity; psychological disorder; psychiatric disorder

Caregiver

Alteration in cognitive functioning; health impairment; psychological disorder

NIC, NOC, Client Outcomes, Nursing Interventions and *Rationales,* Client/Family Teaching, and References

Refer to care plan for **Caregiver Role Strain**.

Risk for ineffective Cerebral tissue perfusion

Kimberly S. Meyer PhD, ACNP-BC, CNRN

NANDA-I

Definition

Susceptible to a decrease in cerebral tissue circulation, which may compromise health.

Risk Factors

Substance misuse

At-Risk Population

Recent myocardial infarction

Associated Condition

Abnormal partial thromboplastin time (PTT); abnormal prothrombin time (PT); akinetic left ventricular wall segment; aortic atherosclerosis; arterial dissection; atrial fibrillation; atrial myxoma; brain injury; brain neoplasm;

carotid stenosis; cerebral aneurysm; coagulopathy; dilated cardiomyopathy; disseminated intravascular coagulopathy; embolism; hypercholesterolemia; hypertension; infective endocarditis; mechanical prosthetic valve; mitral stenosis; pharmaceutical agent; sick sinus syndrome; treatment regimen

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Acute Confusion Level; Tissue Perfusion: Cerebral; Agitation Level; Neurological Status; Cognition; Seizure Control; Motor Strength

Example NOC Outcome with Indicators

Tissue Perfusion: Cerebral as evidenced by the following indicators: Headache/Restlessness/Listlessness/Agitation/Vomiting/Fever/Impaired cognition/Decreased level of consciousness/Motor weakness/Dysphagia/Slurred speech. (Rate the outcome and indicators of **Tissue Perfusion: Cerebral:** 1 = severe, 2 = substantial, 3 = moderate, 4 = mild, 5 = none [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- State absence of headache
- Demonstrate appropriate orientation to person, place, time, and situation
- Demonstrate ability to follow simple commands
- Demonstrate equal bilateral motor strength
- Demonstrate adequate swallowing ability
- Maintain (or improve) neurological exam

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Medication Management; Neurologic Monitoring; Positioning: Neurologic; Cerebral Perfusion Promotion; Fall Prevention; Cognitive Stimulation; Environmental Management: Safety

Example NIC Activities—Neurologic Monitoring

Monitor pupillary size, shape, symmetry, and reactivity; Monitor level of consciousness; Monitor level of orientation; Monitor trend of Glasgow Coma Scale; Monitor facial symmetry; Note complaint of headache; Monitor blood pressure (BP) and heart rate; Monitor respiratory function

Nursing Interventions and *Rationales*

- To decrease risk of reduced cerebral perfusion related to stroke or transient ischemic attack (TIA):
    - ❍ Obtain a family history of hypertension, diabetes, and stroke to identify persons who may be at increased risk of stroke. **EB:** *A positive family history of stroke increases risk of stroke by approximately 30% (Goldstein et al, 2011).*
    - ❍ Monitor BP regularly, because hypertension is a major risk factor for both ischemic and hemorrhagic stroke. **EB:** *Systolic BP should be treated to a goal of less than 140 mm Hg and diastolic BP to less than 90 mm Hg, whereas clients with diabetes or renal disease have a BP goal of less than 130/80 mm Hg (Boan et al, 2014).*
    - ❍ Teach hypertensive clients the importance of taking their health care provider-ordered antihypertensive agent to prevent stroke. **EB:** *Treatment of hypertension in adults with diabetes with a calcium channel blocker may be useful*

(James et al, 2014).

- ❍ Stress smoking cessation at every encounter with clients, using multimodal techniques to aid in quitting, such as counseling, nicotine replacement, and oral smoking cessation medications. Provide client and family education to reduce lifestyle-associated risk factors for stroke. **EB:** *Studies show that a consistent and overwhelming relationship between lifestyle risk factors such as smoking, physical inactivity, and poor diet associated with obesity, increase the client risk of both ischemic and hemorrhagic stroke (Meschia, 2014; Sarikaya et al, 2015).*
- ❍ Teach clients who experience a transient TIA that they are at increased risk for a stroke. **EB:** *The 90-day risk for stroke after a TIA is as high as 17%, with the greatest risk occurring in the first week (Heron, 2016).*
- ❍ Screen clients 65 years of age and older for atrial fibrillation with pulse assessment. **EB:** *Atrial fibrillation is associated with a fivefold increase in stroke. Systematic pulse assessment in a primary care setting resulted in a 60% increase in the detection of atrial fibrillation (Proietti et al, 2016; Goldstein et al, 2011; Meschia, 2014).*
- ❍ Call 911 or activate the rapid response team of a hospital immediately when clients display symptoms of stroke as determined by the Cincinnati Stroke Scale (F: facial drooping; A: arm drift on one side; S: speech slurred) being careful to note the time of symptom appearance. Additional symptoms of stroke include sudden numbness/weakness of face, arm, or leg, especially on one side; sudden confusion; trouble speaking or understanding; sudden difficulty seeing with one or both eyes; sudden trouble walking, dizziness, loss of balance, or coordination; or sudden severe headache (Jauch et al, 2013). **EB:** *The Cincinnati Stroke Scale (derived from the National Institutes of Health [NIH] Stroke Scale) is used to identify clients having a stroke who may be candidates for thrombolytic therapy (Jauch et al, 2013). Emergency medical services (EMS) activation results in faster health care provider assessment, computed tomography, and neurological evaluation, which facilitates administering thrombolytics to eligible stroke victims within the required 3-hour time period (Jauch et al, 2013).*
- ❍ Use clinical practice guidelines for glycemic control and BP targets to guide the care of clients with diabetes who have had a stroke or TIA. **EB:** *The American Stroke Association recommends that evidence-based guidelines be used in the care of clients with diabetes. Good glycemic control has been associated with decreased incidence of strokes (Meschia, 2014).* **EB:** *Hypoglycemia (blood sugar < 60 mg/dL) should be corrected immediately to improve stroke outcomes (Jauch et al, 2013).* **EB:** *Persistent hyperglycemia (blood sugar >180 mg/dL) should be avoided because hyperglycemia is associated with worse stroke outcomes (Jauch et al, 2013).*
- ❍ Maintain head of bed less than 30 degrees in the acute phase (<72 hours of symptom onset) of ischemic stroke. **EB:** *Cortical cerebral blood flow is decreased when head of bed is elevated from 0 to 30 degrees in clients with acute ischemic stroke (Favilla et al, 2014).*
- ❍ Head of bed may be elevated to sitting position without detrimental effect to cerebral blood flow in clients with ischemic stroke or subarachnoid hemorrhagic at 72 hours after symptom onset. **EB:** *Head of bed elevation of 45 and 70 degrees in the subacute phase of ischemic stroke resulted in minor changes in cerebral blood flow velocities (Aries et al, 2013).* **EB:** *Cerebral blood flow had no significant changes in head of bed elevations from 0 to 90 degrees in clients with*

subarachnoid hemorrhage at days 3, 7, and 10 (Kung et al, 2013).

- ❍ Administer oral nimodipine as prescribed by the health care provider after subarachnoid hemorrhagic strokes for 21 days. **EB:** *Nimodipine, a calcium channel blocker, has been shown by multiple randomized clinical trials to improve outcome by limiting delayed cerebral ischemia after subarachnoid hemorrhage strokes (Raya et al, 2014).*
- ❍ Monitor neurological function frequently in the first 2 weeks after subarachnoid hemorrhage because subtle declines may be related to cerebral vasospasm. **EB:** *Cerebral vasospasm occurs in up to 70% of patients with subarachnoid hemorrhage and can lead to delayed cerebral ischemia (Grasso et al, 2017).*
- ❍ Maintain cerebral perfusion pressure (CPP) 60 to 70 mm Hg in patients with traumatic brain injury. **EB:** *When injury-related impaired autoregulation is present, CPP less than 60 is associated with worse outcomes (Carney et al, 2016; Guiza et al, 2017).*

▲ To decrease risk of reduced CPP: CPP = Mean arterial pressure − intracranial pressure (CPP = MAP − ICP): See care plan for Decreased **Intracranial** adaptive capacity.

- ❍ Maintain euvolemia. **EB:** *Infusing isotonic intravenous fluids to sustain normal circulating volume helps maintain normal cerebral blood flow (Hemphill et al, 2015).*

▲ To treat decreased CPP:

- ❍ Clients with subarachnoid hemorrhagic stroke experiencing delayed cerebral ischemia, as evidenced by declining neurological exam, should undergo a trial of induced hypertension. **EB:** *Medically managed hypertension increased cerebral blood flow and produced neurological improvement in the majority of clients (Raya et al, 2014).*
- ❍ Administer norepinephrine infusion to raise MAP per collaborative protocol. **EB:** *Patients with delayed cerebral ischemia treated with norepinephrine have better BP augmentation and better clinical outcomes than patients treated with other vasopressors (Roy et al, 2017; Sookplung et al, 2011).*
- ❍ Mobilize patients with subarachnoid hemorrhage as early as 1 day after aneurysm is secured. **EB:** *Patients undergoing early mobilization are less likely to develop severe cerebral vasospasm (Karic et al, 2017).*

Ineffective Childbearing process

Dianne F. Hayward RN, MSN, WHNP

NANDA-I

Definition

Inability to prepare for and/or maintain a healthy pregnancy, childbirth process, and care of the newborn for ensuring well-being.

Defining Characteristics

During Pregnancy

Inadequate prenatal care; inadequate prenatal lifestyle; inadequate preparation of newborn care items; inadequate preparation of the home environment; ineffective management of unpleasant symptoms in pregnancy; insufficient access of support system; insufficient respect for unborn baby; unrealistic birth plan

During Labor and Delivery

Decrease in proactivity during labor and delivery; inadequate lifestyle for stage of labor; inappropriate response to onset of labor; insufficient access of support system; insufficient attachment behavior

After Birth

Inadequate baby care techniques; inadequate postpartum lifestyle; inappropriate baby feeding techniques; inappropriate breast care; insufficient access of support system; insufficient attachment behavior; unsafe environment for an infant

Related Factors

Domestic violence; inadequate maternal nutrition; inconsistent prenatal health visits; insufficient cognitive readiness for parenting; insufficient knowledge of child-bearing process; insufficient parental role model; insufficient prenatal care; insufficient support system; low maternal confidence; maternal powerlessness; maternal psychological distress; substance misuse; unrealistic birth plan; unsafe environment

At-Risk Population

Unplanned pregnancy; unwanted pregnancy

NOC Nursing Outcomes Classification

Suggested NOC Outcomes

Fetal Status: Antepartum, Intrapartum; Maternal Status: Antepartum, Intrapartum; Depression Level; Family Resiliency; Knowledge: Substance Use Control; Social Support; Spiritual Support

Example NOC Outcome with Indicators

Maternal Status: Antepartum as evidenced by the following indicators: Emotional attachment to fetus/Coping with discomforts of pregnancy/Mood lability/Has realistic birth plan/Has support system. (Rate each indicator of **Maternal Status: Antepartum:** 1 = severe deviation from normal range, 2 = substantial deviation from normal range, 3 = moderate deviation from normal range, 4 = mild deviation from normal range, 5 = no deviation from normal range [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

Antepartum

- Obtain early prenatal care in the first trimester and maintain regular visits
- Demonstrate appropriate care of oneself during pregnancy including good nutrition and psychological health
- Understand the risks of substance abuse and resources available
- Feel empowered to seek social and spiritual support for emotional well-being during pregnancy
- Prepare home for baby (e.g., crib, diapers, infant car seat, outfits, blankets)
- Use support systems for labor and emotional support
- Develop a realistic birth plan, taking into account any high-risk pregnancy issues
- Understand the labor and delivery process and comfort measures to manage labor pain

Postpartum

- Provide a safe environment for self and infant
- Demonstrate appropriate newborn care and postpartum care of self
- Demonstrate appropriate bonding and parenting skills

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

High-Risk Pregnancy Care; Intrapartal Care; Infant Care: Newborn

Example NIC Activities—High-Risk Pregnancy Care

Instruct client in self-care techniques to increase the chance of a healthy outcome (e.g., hydration, diet, activity modifications, importance of regular prenatal checkups, normalization of blood sugars, and sexual precautions, including abstinence).

Monitor physical and psychosocial status closely throughout pregnancy. Refer as appropriate for specific programs (e.g., smoking cessation, substance abuse treatment, diabetes education, preterm birth prevention education, abuse shelter as needed).

Nursing Interventions and *Rationales*

• Encourage early prenatal care and regular prenatal visits. **EB:** *There are a multitude of comorbidities and prior and current pregnancy complications that may deem a pregnancy high risk (Carter et al, 2016). A small Canadian study of a high-risk obstetric population found that most women who presented with no prenatal care did so late in pregnancy and had high rates of adverse outcomes (Knight et al, 2014). The World Health Organization (WHO) guidelines for antenatal care include a minimum of eight contacts to reduce perinatal mortality and improve women's experience of care, counselling about healthy eating, and keeping physically active during pregnancy (World Health Organization, 2016).*

▲ Identify any high-risk factors that may require additional surveillance, such as preterm labor, hypertensive disorders of pregnancy, diabetes, depression, other chronic medical conditions, presence of fetal anomalies, homelessness, or other high-risk factors. **EB:** *Timely and accurate antenatal screening is believed to be an important factor in preventing preterm birth, screening for gestational diabetes, preeclampsia, intrauterine growth restriction, and depression. Finding and treating problems early improves outcome (Beeckman et al, 2013). Health care providers should include disaster preparedness to displaced pregnant women as a part of their care. The displaced women who perceived high levels of social support gave birth to infants with higher birth weights (Sanguanklin et al, 2014).*

▲ Assess and screen for signs and symptoms of depression during pregnancy and in the postpartum period including history of depression or postpartum depression, poor prenatal care, poor weight gain, hygiene issues, sleep problems, substance abuse, and preterm labor. If depression is present, refer for behavioral-cognitive counseling and/or medication. **EB:** *Susser et al (2016) reported that nearly 20% of women in pregnancy and in the postpartum period are affected with depression. There is a high risk of morbidity and mortality when a woman is affected with perinatal depression and this may have long-term consequences on child development. Depression may also affect the maternal infant bond.*

▲ Observe for signs of alcohol use and counsel women to stop drinking during pregnancy. Give appropriate referral for treatment if needed. **EB:** *There is no known safe amount or safe time to drink alcohol during pregnancy or while trying to get pregnant. The sooner a pregnant woman stops drinking, the better it will be for both her baby and herself (Centers for Disease Control and Prevention, 2016).*

▲ Obtain a smoking history and counsel women to stop smoking for the safety of the baby. Give appropriate referral to a smoking cessation program if needed. **EB:** *"Psychosocial interventions to support women to stop smoking in pregnancy can increase the proportion of women who stop smoking in late pregnancy, and reduce low birthweight and preterm births" (Chamberlain et al, 2013).* **EBN:** *A recent study described the development of an iPad application to promote knowledge of tobacco risk and cessation resources for pregnant women and the evaluation of women's acceptance and perceptions regarding the application (Walsh Dotson et al, 2017).*

▲ Monitor for substance abuse with recreational drugs. Refer to a drug treatment program as needed. Refer opiate-dependent women to methadone clinics to improve maternal and fetal pregnancy outcomes. **EBN:** *It is important to involve a pregnant woman in a methadone treatment program because methadone prevents withdrawal symptoms and eliminates drug craving. Methadone blocks the euphoric effects of illegal self-administered narcotics. It also supports stable maternal opioid levels to protect the fetus from repeated occurrences of withdrawal and decreases the risk for sexually transmitted infections by decreasing drug-seeking behaviors such as prostitution. When a woman makes the decision to enroll in a methadone treatment program, she is taking a significant step toward recovery (Maguire, 2014).*

▲ Monitor for psychosocial issues including lack of social support system, loneliness,

depression, lack of confidence, maternal powerlessness, and socioeconomic problems. **EBN:** *"To maximize detection of at-risk women, screening must be expanded to include significant risk factors other than depression and anxiety symptoms" (Ruyak et al, 2017).*

▲ Monitor for signs of domestic violence. Refer to a community program for abused women that provides safe shelter as needed. **EB:** *Women who were involved in intimate partner violence were more likely to experience negative outcomes such as preterm delivery and delivery of low-birth-weight infants (Shneyderman & Kiely, 2013).* **EBN:** *The woman who suffers from abuse needs to formulate a safety plan with a professional trained to guide her in the planning The components of a safety plan include: (1) an escape plan; (2) a place for the woman to go should she decide to leave the abuser; (3) a secure place for essential items such as birth certificates, photo identification, welfare card, green card, marriage certificate, custody papers, health insurance, medical prescriptions, bank statements, car titles, deed to the house, or any reports filed to the police; and (4) other items such as extra sets of clothes, an extra set of keys to the house and car, cash, and jewelry. Organizations, such as the Family Violence Prevention Fund, provide information on safety planning that can be shared with women (Bianchi et al, 2016).*

• Provide antenatal education to increase the woman's knowledge needed to make informed choices during pregnancy, labor, and delivery and to promote a healthy lifestyle. **EB:** *Antenatal classes must be interesting enough to maintain attention, relevant to the attendees, and understandable. The parents should feel empowered that the decisions they make about maternity care and parenthood are made with up-to-date evidence-based information and fit into their lifestyle. O'Sullivan et al (2014) found that class sizes tended to be too large to include class participation. They also reported educators sometimes just focused on maternity care and not on parenthood, healthy lifestyle, and changing relationships. Although resources are available, the educators reported their facility had limited educational resources.*

• Encourage expectant parents to prepare a realistic birth plan or "birth preferences" to prepare for the physical and emotional aspects of the birth process and to plan ahead for how they want various situations handled. **EB/EBN:** *The birth plan allows the woman to communicate her expectations and needs (Biescas et al, 2017). A flexible approach to the birth plan is necessary, including the consideration of using alternative approaches and allowing for unexpected circumstances (Divall et al, 2017). The term "birth plan" has been considered by some midwives to be inappropriate, especially requests for an intervention-free birth. They suggested that the term "birth preferences" may be a better term. These plans must be flexible or they may lead to disappointment for the woman and her partner when there is a necessary deviation from their birth plan (Welsh & Syman, 2014).*

• Encourage good nutritional intake during pregnancy to facilitate proper growth and development of the fetus. Women should consume an additional 300 calories per day during pregnancy, take a multi-micronutrient supplement containing at least 400 µg folic acid, and achieve a total weight gain of 25 to 30 lb. **EB:** *A healthy, varied diet (e.g., Choosemyplate.gov) is of vital importance for optimal birth outcome, including taking a multivitamin with folic acid from before conception to at least the twelfth week of pregnancy, as well as a vitamin D supplement throughout pregnancy. Many women are not following the guidelines and there are concerns for these vulnerable groups (US Department of Agriculture, 2014; Williamson & Wyness, 2013). Inadequate levels of key nutrients during crucial periods of fetal development may lead to changes within fetal tissues, predisposing the infant to chronic illnesses and conditions in later life (Procter & Campbell, 2014).*

Multicultural

▲ Provide for a translator if needed. In some cultures a woman prefers to have a female translator. **EB:** *The health care industry must recognize that providing translators for language assistance is an important tool for improving quality of care, saving lives, and avoiding costly and dangerous medical errors. Although costly, the American health care industry needs to comply with federal and state laws as well as accreditation standards by being prepared to provide care in at least 100 different languages (Rivers & Rivers, 2013).* **EBN:** *In the Arab and most Middle Eastern cultures female translators would be necessary because they are reluctant or sometimes forbidden to discuss female concerns with men (Meyer et al, 2016).*

▲ Provide depression screening for clients of all ethnicities. **EB:** *Race and ethnicity are important risk factors for antenatal depression. A 2015 study found that Mexican American women exhibit higher prenatal maternal depressive symptoms relative to the general population. Depressive symptoms increased when the women tried to mesh American and Mexican cultural values, and incorporation of the Anglo value of self-reliance and independence was a risk factor for depression (D'Anna-Hernandez et al, 2015).* **EB:** *Santiago and Figueiredo (2015) conducted a systematic literature review to investigate the relationship between sociodemographic characteristics of immigrant women and its impact on factors influencing prenatal and postpartum care and the incidence of postpartum depression. Factors identified were the socioeconomic status of migrant women participants, language barriers, and health care professionals' lack of cultural sensitivity, leading to women's hesitancy in using health services.*

• Perform a cultural assessment and provide obstetrical care that is culturally appropriate to ensure a safe and satisfying childbearing experience. **EBN:** *Providing nonjudgmental care that promotes equality can be accomplished through the appropriate use of translation services and good communication skills to make certain that women feel heard and have the opportunity to make choices (Rowland-Neve, 2017).*

Readiness for enhanced Childbearing process

Gail B. Ladwig MSN, RN, Dianne F. Hayward RN, MSN, WHNP

NANDA-I

Definition

A pattern of preparing for and maintaining a healthy pregnancy, childbirth process, and care of newborn for ensuring well-being, which can be strengthened.

Defining Characteristics

During Pregnancy

Expresses desire to enhance knowledge of childbearing process; expresses desire to enhance management of unpleasant pregnancy symptoms; expresses desire to enhance prenatal lifestyle; expresses desire to enhance preparation for newborn

During Labor and Delivery

Expresses desire to enhance lifestyle appropriate for stage of labor; expresses desire to enhance proactivity during labor and delivery

After Birth

Expresses desire to enhance attachment behavior; expresses desire to enhance baby care techniques; expresses desire to enhance baby feeding techniques; expresses desire to enhance breast care; expresses desire to enhance environmental safety for the baby; expresses desire to enhance postpartum lifestyle; expresses desire to enhance use of support system

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Knowledge: Pregnancy; Knowledge: Infant Care; Knowledge: Postpartum Maternal Health; Knowledge: Breastfeeding, Parent-Infant Attachment

Example NOC Outcome with Indicators

Knowledge: Pregnancy as evidenced by client conveying understanding of the following indicators: Importance of frequent prenatal care/Importance of prenatal education/Benefits of regular exercise/Healthy nutritional practices/Anatomic and physiological changes of pregnancy/Psychological changes associated with pregnancy/Birthing options/Effective labor techniques/Signs and symptoms of labor. (Rate the outcome and indicators of **Knowledge: Pregnancy:** 1 = no knowledge, 2 = limited knowledge, 3 = moderate knowledge, 4 = substantial knowledge, 5 = extensive knowledge [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

During Pregnancy

- Attend all scheduled prenatal visits and attend prenatal education with her significant other or involved family member
- Use appropriate self-care for discomforts of pregnancy
- Make healthy lifestyle choices prenatally: activity and exercise/healthy nutritional practices
- Use strategies to balance activity and rest

During Labor and Delivery

- Demonstrate appropriate lifestyle choices during labor
- State knowledge of birthing options, signs and symptoms of labor
- Demonstrate effective labor techniques

After Birth

- Demonstrate appropriate lifestyle choices postpartum
- Report normal physical sensations after delivery
- State understanding of recommended nutrient intake, strategies to balance activity and rest, appropriate exercise, time frame for resumption of sexual activity, strategies to manage stress
- Demonstrate bonding with infant
- Demonstrate proper handling and positioning of infant/infant safety
- Demonstrate feeding technique and bathing of infant

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Prenatal Care; Intrapartal Care; Postpartal Care; Attachment Promotion; Infant Care: Newborn; Lactation Counseling; Family Support

Example NIC Activities—Prenatal Care

Encourage prenatal class attendance and encourage involvement of client's partner or involved family member; Discuss nutritional needs and concerns (e.g., balanced diet, folic acid, food safety, and supplements); Discuss activity level with client (e.g., appropriate exercise, activities to avoid, and importance of rest); Discuss importance of participating in prenatal care throughout entire pregnancy

Nursing Interventions and *Rationales*

- Refer to care plans Risk for impaired **Attachment;** Readiness for enhanced **Breastfeeding;** Readiness for enhanced family **Coping;** Readiness for enhanced **Family** processes; **Growth;** Readiness for enhanced **Nutrition;** and Readiness for enhanced **Parenting;** Ineffective **Role** performance.

Prenatal Care

- Ensure that pregnant clients have an adequate diet and take multimicronutrient supplements containing at least 400 µg of folic acid, especially during early pregnancy. **EB:** *Cawley et al (2015) recommended taking 400 µg of folic acid 12 weeks before conception, and all childbearing age women should be taking a folic acid supplementation daily to reduce the risk of neural tube defects.* **EB:** *A healthy, varied diet (i.e., Choosemyplate.gov) is of vital importance for optimal birth outcome, and this includes taking a folic acid supplement from before conception to the 12th week of pregnancy, as well as a vitamin D supplement, throughout pregnancy (United States Department of Agriculture [USDA], 2014).* **EB:** *Fortified cereal is no longer recommended as the only source of folic acid because levels vary by consumption (Viswanathan et al, 2017).*
- Assess smoking status of pregnant clients and offer effective smoking-cessation interventions. **EB:** *Smoking is the leading cause of preventable death and disease in the United States. Exposure to nicotine during pregnancy adversely affects both maternal and fetal health and contributes to multiple adverse outcomes such as preterm birth and stillbirth*

and doubles the risk of placenta previa and placenta abruption. When infants are exposed to smoking, either directly or secondhand, their risk for sudden infant death syndrome is increased (United States Department of Health and Human Services [HHS], 2014). "Psychosocial interventions to support women to stop smoking in pregnancy can increase the proportion of women who stop smoking in late pregnancy, and reduce low birthweight and preterm births" (Chamberlain et al, 2013). **EBN:** *A recent study described the development of an iPad application to promote knowledge of tobacco risk and cessation resources for pregnant women (Walsh Dotson et al, 2017).*

• See HHS for quitting smoking guidelines (https://betobaccofree.hhs.gov/quit-now/index.html).

▲ Assess all pregnant clients for signs of depression and make appropriate referral for inadequate weight gain, underutilization of prenatal care, increased substance abuse, and premature birth. Assess past personal or family history of depression, being single, poor health functioning, and alcohol use. **EBN:** *Social and emotional health problems associated with depression in the perinatal period can lead to poor outcomes for women, their infants, and their families (Rollans et al, 2013).*

• Discuss breastfeeding with a pregnant client, including all the benefits both to the infant and the mother. **EB:** *A government-funded nursing study done by Bass, Rodgers, and Baker (2014) placed a lactation consultant in an obstetrics (OB) office providing breastfeeding education throughout pregnancy. This offered the new mothers an opportunity to make an informed decision regarding the feeding choice for their newborns. The theory was that as the mother begins to breastfeed her newborn, her confidence is bolstered. Bass, Rodgers and Baker (2014) found exclusive breastfeeding rates increased from 33% to 60% in 8 months. They proposed that if frontline antenatal, intrapartum, and postpartum nurses begin to increase the mother's breastfeeding knowledge base, and continue to support and promote her feeding efforts, exclusive breastfeeding could increase.*

Intrapartal Care

• Encourage psychosocial support during labor, especially by the father of the baby or the woman's mother if possible. **EBN:** *When a husband provides continuous support during his wife's labor, his presence is considered effective in reducing her dissatisfaction with the childbirth process. According to de Lacerda, da Silva, and Davim (2014), the ideal companion is someone with whom the client has a bond and is trusted. The father of the child ranked first, followed by the mother of the postpartum woman.* **EBN:** *The key to promoting a normal birth and reducing medical interventions is high-quality continuous support. This support increases a woman's perception of a positive birth experience, fosters a positive adaptation to motherhood, and reduces the risk for posttraumatic stress disorder and other postpartum mental health problems (Sapkota, Kobayashi, & Takase, 2013; Ross-Davie & Cheyne, 2014).*

• Provide a calm, relaxing, and supportive birth environment. **EBN:** *The patient's outcome and safety are affected by the birth environment and culture. The care providers, whether midwives, doulas, and/or the nursing staff, must be knowledgeable and committed to providing labor support (Stark, Remynse, & Zwelling, 2016).* **EB:** *A birth environment that is calming and reduces stress supports physiological birth. Low levels of stress hormones during labor and birth promote uterine blood flow and support neonatal well-being, whereas greater levels of stress hormones can lengthen labor and impede the neonatal transition (Buckley, 2015).*

• Offer the client in labor a clear liquid diet and water if allowed. **EB:** *There is insufficient evidence to make conclusions about the relationship between fasting times for clear*

liquids and the risk for emesis, reflux, or pulmonary aspiration during labor. Although there is some disagreement, the majority of experts agree that oral intake of clear liquids during labor does not lead to increased maternal complications (American Congress of Obstetricians and Gynecologists [ACOG], 2013).

Multicultural

Prenatal

▲ Provide for a translator if needed. In some cultures a women prefers to have a female translator. **EB:** *The health care industry must recognize that providing translators for language assistance is an important tool for improving quality of care, saving lives, and avoiding costly and dangerous medical errors. Although costly, the American health care industry needs to comply with federal and state laws and accreditation standards by being prepared to provide care in at least 100 different languages (Rivers & Rivers, 2013).* **EBN:** *In the Arab and most Middle Eastern cultures female translators would be necessary because they are reluctant or sometimes forbidden to discuss female concerns with men (Meyer et al, 2016).*
• Assess the client's beliefs and concerns about prenatal care. Provide culturally appropriate prenatal care for clients. **EBN:** *When caring for a woman of a different culture recognize the danger of making assumptions about the health care needs of the group to which she belongs. Explore the specific needs of the individual. It is fundamental that women need to feel safe and supported, which sometimes involves challenging societal prejudices and providing nonjudgmental care that promotes equality. During this important and vulnerable time, caregivers need to ensure that women feel involved in their care, especially when there are language barriers. This can be accomplished through appropriate use of translation services and good communication skills to make certain that women are listened to and have the opportunity to make choices (Rowland-Neve, 2017).*
▲ Refer the client to a centering pregnancy group (8–10 women of similar gestational age receive group prenatal care after initial obstetrical visit) or group prenatal care. **EB:** *Group prenatal care appears to have created a benefit to the women, not just with their birth experiences, but also with the psychological and social aspects of this life change (Risisky, Asghar, & Chaffee, 2013).*

Intrapartal

• Assess client's beliefs and concerns about labor. Consider the client's culture when assisting in labor and delivery. **EB:** *There is a strong need to avert misunderstandings in today's multicultural society, and perhaps harm, through facilitating cultural awareness and competency of care rather than misinterpretations of opposition to care. Religious and traditional beliefs about childbearing practices can be very diverse among women with varied sociocultural backgrounds. Migrating women may not feel comfortable with the highly medicalized maternity care. Adherence to culturally specific traditional belief systems may produce a very different belief about maternity care and health care. They may regard the processes of pregnancy and delivery as normal events; therefore they may not seek maternity care. African women in Australia are not comfortable with pain relief injections. They think that pain relief disrupts normal events and using pain relief interrupts the natural birthing process. They also believe it to be harmful for the baby. Immigrants to a new country are often confronted with language barriers, lack of social supports, and lack of knowledge regarding the availability of conventional and alternative health care service (Higginbottom et al, 2013). According to van Dijk et al (2013) most clients receiving maternity services desired the option of culturally appropriate care but typically did not receive it.*

Postpartal

• Assess client's beliefs and concerns about the postpartum period. Provide culturally appropriate health and nutrition information and guidance on contemporary postpartum practices and take away common misconceptions about traditional dietary and health behaviors (e.g., fruit and vegetables should be restricted because of cold nature). Encourage a balanced diet and discourage unhealthy hygiene taboos. **EB:** *Many cultures practice food taboos surrounding pregnancy with consequent depletion of vital nutrients, which can be detrimental to both the mother and fetus (Oni & Tukur, 2012).* **EBN:** *When caring for a woman of a different culture recognize the danger of making assumptions about the health care needs of the group to which she belongs. Explore the specific needs of the individual. It is fundamental that women need to feel safe and supported, which sometimes involves challenging societal prejudices and providing nonjudgmental care that promotes equality (Rowland-Neve, 2017). Our Western ways are not the norm for many other cultures. A new Muslim mother rests for 40 days after giving birth so she may not want to ambulate after giving birth. She also may not want to breastfeed right away. She is considered unclean during this time so others prepare the food and do housework. The new mother in Japan returns to her childhood home to be "mothered" by her mother. There are rules in China that a new mother has to follow to restore balance. The balance of opposites, such as hot and cold, is part of a belief system of many cultural groups such as Filipinos and Hispanics. Many in these groups believe there are natural external factors that must be kept in balance to maintain health (Littleton-Gibbs & Engelbretson, 2013).*

Home Care

Prenatal

▲ Involve pregnant drug users in drug treatment programs that include coordinated interventions in several areas, such as drug use, infectious diseases, mental health, personal and social welfare, and gynecological/obstetric care. **EBN:** *The drug addict is obsessed by the drug of choice because of a change in the pathophysiology of the brain. Treating addiction as a chronic disease instead of a moral weakness will be more supportive to women who abuse drugs. It is important to involve a pregnant woman in a treatment program such as a methadone clinic to help stabilize the maternal–fetal dyad. Methadone prevents withdrawal symptoms and eliminates drug craving. Methadone blocks the euphoric effects of illegal self-administered narcotics. It also supports stable maternal opioid levels to protect the fetus from repeated occurrences of withdrawal and decreases the risk for sexually transmitted infections (STIs) by decreasing drug-seeking behaviors such as prostitution. When a woman makes the decision to enroll in a methadone treatment program, she is taking a significant step toward recovery (Maguire, 2014).*

Postpartal

• Suggest parenting websites approved by the medical provider to support new parents with postpartum advice, newborn care, and breastfeeding. **EBN:** *Digital technology is being used to provide innovative family support services via websites. Online family support websites afford parents an alternative, cost-effective service that can be accessed from anywhere, increasing opportunities for parents to become active in their own support. They are, however, largely unfiltered and they raise unique challenges in identifying and managing child safeguarding concerns (Lamberton, Devaney, & Bunting, 2016).*

Client/Family Teaching and Discharge Planning

Prenatal

• Provide dietary and lifestyle counseling as part of prenatal care to pregnant women. **EB:** *A healthy prepregnancy weight, appropriate weight gain, physical activity during pregnancy, intake of a wide variety of foods, appropriate vitamin and mineral supplementation, avoidance of alcohol and other harmful substances, regular prenatal visits, and safe food handling are all components leading to a healthy pregnancy outcome. Pregnancy is a crucial period, and maternal nutrition and lifestyle choices are major influences on mother and infant/child health. Healthy lifestyle changes are the key to the health of the next generation (Procter & Campbell, 2014).*

• Provide group prenatal care to low-risk pregnant women belonging to high-risk demographic groups. **EB:** *The average pregnant woman who delivers at 40 weeks spends about 2 hours with her health care provider over the course of her entire pregnancy. Women who take part in group care have about 20 hours with their health care provider and have the opportunity to learn and encourage one another. Group prenatal care seems to lead to less low-birth-weight babies and fewer adverse perinatal outcomes compared with women in traditional care. The Carter et al (2017) study findings, together with data from earlier studies, proposed that group prenatal care may be a new and innovative way to provide prenatal care to low-risk individuals belonging to high-risk demographic groups to improve perinatal outcomes (Carter et al, 2017).*

Postpartal

• Encourage physical activity in postpartum women, after being cleared by the health care provider; teach postpartum women that exercise may reduce anxiety and depression, and encourage downloading phone apps that help track exercise like Fitbit or Pedometer Master. **EB:** *Research on anxiety, depression, and exercise shows that the psychological and physical benefits of exercise can help reduce anxiety and improve mood (Mayo Clinic Staff, 2014).*

▲ Provide breastfeeding mothers contact information for a lactation consultant, phone numbers, and website information for the La Leche League (http://www.lalecheleague.org), and local breastfeeding support groups. **EBN:** *The Joint Commission in 2014 made the rates of exclusive breastfeeding a perinatal core measure. In 2015 The Association of Women's Health, Obstetric and Neonatal Nurses (AWHONN) published its position statement on breastfeeding: it "supports, protects, and promotes breastfeeding as the ideal and most normal method for feeding infants" (Henry et al, 2017).* **EBN:** *The World Health Organization (WHO) recommended exclusive breastfeeding for the first 6 months of life for up to 2 years or more. Optimally, breastfeeding should begin within 1 hour of birth even after a C-section; breastfeeding should be "on demand," as often as the infant wants day and night; and bottles or pacifiers should not be used. Breast milk production is essential to long-term breastfeeding, and necessitates early, frequent and successful removal of colostrum. To remove as much milk as possible from the breasts, hand expression is recommended. This is a simple and risk-free method to stimulate milk production and can alleviate the pressure of achieving perfect attachment. The expressed colostrum can be spoonfed or cupfed to the infant. Hand expression and spoon- or cup-feeding also can be used when there is a problem such as sore breasts or difficulty latching. There is a new breastfeeding policy approved by the Centers for Disease Control and Prevention (CDC), United States Breastfeeding Committee (USBC), and the Joint Commission. The policy is called "Ten Steps to Successful Breastfeeding" (Baby-Friendly USA, n.d.). The policy is aimed at the hospital's*

commitment to breastfeeding and steps to achieve the Baby Friendly Initiative (Morton, Hall, & Pessl, 2014). **EB:** *In a French study, polyunsaturated fatty acids (PUFAs) in colostrum and duration of breastfeeding were associated with an increase in children's IQs. The results supported breastfeeding and added evidence for the role of early PUFA exposure on childhood cognition (Bernard et al, 2017).*

- Teach mothers of young children principles of a healthy lifestyle: Substitute foods high in saturated fat with foods moderate in PUFAs such as avocados, tuna, walnuts, and olive oil. Include lean protein, fruits and vegetables, and complex carbohydrates. It is also important to increase physical activity. **EB:** *In a French study, PUFAs in colostrum and duration of breastfeeding were associated with an increase in children's IQs. The results support breastfeeding and added evidence for the role of early PUFA exposure on childhood cognition (Bernard et al, 2017).* **EB:** *PUFAs are the chief components of the brain and retina, and are the essential fatty acids with significant physiologically active functions. PUFAs should be provided to children, and they are vital in the brain growth and development for fetuses, newborn infants, and children (Lee, 2013).* **EB:** *Food preferences are important determinants of children's food intakes. Parental feeding behavior has a significant influence on the development of children's food preferences (Russell, Worsley, & Campbell, 2015).* **EBN:** *Omega 3 PUFAs are required for very early brain development, and that need continues throughout life. These essential fatty acids are crucial in cell functioning. Humans are not able to synthesize omega 3 PUFAs; therefore they must be included in the daily diet (Helvig & Decker, 2014).*

Risk for ineffective Childbearing process

Dianne F. Hayward RN, MSN, WHNP

NANDA-I

Definition

Susceptible to an inability to prepare for and/or maintain a healthy pregnancy, childbirth process, and care of the newborn for ensuring well-being.

Risk Factors

Domestic violence; inadequate maternal nutrition; inconsistent prenatal health visits; insufficient cognitive readiness for parenting; insufficient knowledge of childbearing process; insufficient parental role model; insufficient prenatal care; insufficient support system; low maternal confidence; maternal powerlessness; maternal psychological distress; substance misuse; unrealistic birth plan; unsafe environment

At-Risk Population

Unplanned pregnancy; unwanted pregnancy

NOC, NIC, Client Outcomes, Nursing Interventions and *Rationales*, Client/Family Teaching, and References

Refer to care plan for Ineffective **Childbearing** process.

Impaired Comfort

Gail B. Ladwig MSN, RN, Julianne E. Doubet BSN, RN, EMT-B

NANDA-I

Definition

Perceived lack of ease, relief, and transcendence in physical, psychospiritual, environmental, cultural, and/or social dimensions.

Defining Characteristics

Alteration in sleep pattern; anxiety; crying; discontent with situation; distressing symptoms; fear; feeling cold; feeling of discomfort; feeling of hunger; feeling warm; inability to relax; irritability; itching; moaning; restlessness; sighing; uneasy in situation

Related Factors

Insufficient environmental control; insufficient privacy; insufficient resources; insufficient situational control; noxious environmental stimuli

Associated Conditions

Illness-related symptoms; treatment regimen

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Client Satisfaction; Symptom Control; Comfort Status; Coping; Hope; Pain Control; Anxiety Level Personal Well-Being; Spiritual Health

Example NOC Outcomes with Indicators

Comfort Status as evidenced by the following indicators: Physical and psychological well-being/Symptom control/Enhanced comfort. (Rate the outcome and indicators of **Comfort Status:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Provide evidence for improved comfort compared to baseline
- Identify strategies, with or without significant others, to improve and/or maintain acceptable comfort level
- Perform appropriate interventions, with or without significant others, as needed to

improve and/or maintain acceptable comfort level
• Evaluate the effectiveness of strategies to maintain/and or reach an acceptable comfort level
• Maintain an acceptable level of comfort when possible

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Calming Techniques; Massage; Healing Touch; Heat/Cold Application; Hope Inspiration; Humor; Meditation Facilitation; Music Therapy; Pain Management; Acute/Chronic; Presence; Progressive Muscle Relaxation; Spiritual Growth Facilitation; Distraction

Example NIC Activities—Hope Inspiration

Assist the client/significant others to identify areas of hope in life; Help expand spiritual self; Involve the client actively in own care

Nursing Interventions and *Rationales*

• Assess client's understanding of ranking his or her comfort level. **CEB:** *Performing accurate comfort measurements is essential for providing evidence about which strategies and interventions are effective (Kolcaba, 2003).* **EB:** *Teachings are easily understood (as well as patient participation in discussions prior to discharge), which target patient comprehension of instructions, have the potential to increase patient knowledge, and strengthen the ability to self-manage (Flink & Ekstedt, 2016).*
• Ask about client's current level of comfort. This is the first step in helping clients achieve improved comfort. **EBN:** *Sources of assessment data to determine level of comfort can be subjective, objective, primary, or secondary (Kolcaba, 2014).*
• Comfort is a holistic state under which pain management is included. **EBN:** *Nurses, have a responsibility to promote optimal comfort for patients and to intercede in certain situations to protect the patient's level of comfort, including pain (Karabulut et al, 2015).* **EBN:** *One randomized study (N = 53) found that female breast cancer clients undergoing radiation therapy rated their overall comfort as being greater than the sum of the hypothesized components of comfort, which provided evidence for the theory of the holistic nature of comfort (Kolcaba, 2014).*
• Assist clients to understand how to rate their current state of holistic comfort, using the institution's preferred method of documentation. **EBN:** *Documentation of comfort prenursing and postnursing interactions is essential to demonstrate efficacy of nursing activities (Kolcaba, 2014).*
• Enhance feelings of trust between the client and the health care provider. To attain the highest comfort level, clients must be able to trust their nurse. **EBN:** *This randomized design (N = 31) demonstrated the importance of promoting open relationships with clients, which helps to acknowledge their individuality. Knowing the client/significant others is essential in the provision of optimum palliative and terminal care (Kolcaba, 2014).*
• Manipulate the environment as necessary to improve comfort. **CEB:** *Addressing clients' environmental preferences or needs enhances holistic comfort (Kolcaba, 2003).* **EBN:** *The theoretical foundation of holistic comfort, which consists of relief, ease, and transcendence, in the settings of physical, psychological, social, and environmental experiences, enables the nurse to meet the individual comfort needs of a patient (Ng, 2017).*
• Encourage early mobilization and provide routine position changes. Range of motion and weight bearing decrease physical discomforts and disability associated with bed rest. **EBN:** *It has been shown that immobility is linked to many unacceptable*

patient outcomes in critical care units. Mobility takes many forms (passive and active range of motion exercises, sitting up, dangling legs on side of bed, etc.) along with walking, and these should be included in patient care (Crowe et al, 2017).

• Provide simple massage. Massage has many therapeutic effects, including improved relaxation, circulation, and well-being. **EBN:** *Several quantitative studies support the efficacy of simple massage for enhancing holistic comfort (Townsend et al, 2014).*

• Provide a healing touch, which is well suited for clients who cannot tolerate more stimulating interventions. **EBN:** *According to Anderson et al (2017), providing nurses with the knowledge of healing touch and demonstrating its use in acute patient care gives the nurse another means of ensuring positive patient outcomes.*

• Encourage clients to use relaxation techniques to reduce pain, anxiety, depression, and fatigue. **EBN:** *In a quantitative study with 22 participants, the effects of traditional massage and cranial still point induction were statistically significant in improving comfort and decreasing chronic pain (Townsend et al, 2014).*

Geriatric

• Use hand massage for older adults. Most older adults respond well to touch and the health care provider's presence. Lines of communication open naturally during hand massage. **CEB:** *In an experiment (N = 60), the effects of hand massage on the comfort of nursing home residents was found to be significant immediately after the massage compared with residents who did not receive hand massage* (*Kolcaba, 2014*).

• Discomfort from cold can be treated with warmed blankets. There are physiological dangers associated with hypothermia. **EBN:** *A study (N = 126) found significantly increased comfort and decreased anxiety in clients who used self-controlled warming gowns* (*Kolcaba, 2014*).

• Use complementary therapies such as doll therapy in clients with dementia to increase comfort and reduce stress. **EBN:** *In a review of the literature, doll therapy reduced panic, anxiety, and aggression while improving the dining experience and social interaction (Mitchell & O'Donnell, 2013).*

• Address any unmet physical, psychological, emotional, spiritual, and environmental needs when attempting to mediate the behavior of an older client with dementia. **EBN:** *As nursing and health care adjust to serve an aging population, there is a renewed interest in providing holistic nursing care appropriate to the patient's mental and physical conditions (Pryor & Clarke, 2017).*

Multicultural

• Identify and clarify cultural language used to describe pain and other discomforts. Expressions of pain and discomfort vary across cultures. **CEB:** *Clients may interchange words meaning discomfort and pain, may not admit to having pain, may refer to minor discomforts as pain, or may not discuss nonpainful discomforts at all (Kolcaba, 2003).* **EBN:** *Nurses today are challenged to find means to facilitate culturally harmonious care for all patients: according to Jeffreys and Zoucha (2017), this can be accomplished "through ongoing assessment, education, research, and practice initiatives."*

• Assess skin for ashy or yellow-brown appearance. **CEB:** *Black skin appears ashy and brown skin appears yellow-brown when clients have pallor sometimes associated with discomfort (Peters, 2007).*

• Use soap sparingly if the skin is dry. Black skin tends to be dry, and soap exacerbates this condition.

• Encourage and allow clients to practice their own cultural beliefs and recognize the impact that diverse cultures have on a client's belief about health care, comforting measures, and decision-making. **EBN:** *Cultural competence is a necessary element of complete nursing care and is achieved by establishing good communication, having skill in making the correct diagnosis, and by recognition of clients' language and beliefs as it relates to health and illness (Debiasi & Selleck, 2017).*
• Assess for cultural and religious beliefs when providing care. **EB:** *According to Schweda et al (2017), in their study of cultural stereotyping, it was found that there is not just one perspective on culture and/or religion, but each individual's stance is formed by political, social, and situation beliefs.*

Client/Family Teaching and Discharge Planning

• Teach techniques to use when the client is uncomfortable, including relaxation techniques, guided imagery, hand massage, and music therapy. **CEB:** *Interventions such as progressive muscle relaxation training, guided imagery, and music therapy can effectively decrease the perception of uncomfortable sensations, including pain (Kolcaba, 2003).* **EBN:** *Families want to learn how to provide comfort measures to their loved ones who are uncomfortable* (*Kolcaba, 2014).*
• At end of life, the dying client is comforted by having a companion. **EBN:** *In a study of literature concerning death and dying while in palliative care, Dobrina et al (2014) found that the nurse's presence alone made the patient's end-of-life journey more comfortable and peaceful.*
• Instruct the client and family about prescribed medications and complementary therapies that improve comfort.
• Teach the client to follow-up with the health care provider if discomfort persists. There are many avenues for enhancing comfort.
• Encourage clients to use the Internet as a means of providing education to complement medical care for those who may be homebound or unable to attend face-to-face education. **EB:** *Jones et al (2015) surmised that Internet usage by the older population benefits them in many ways (reduces social isolation, access to services, etc.) and especially serves to improve health and give the client a sense of well-being.*

Mental Health

• Encourage clients to use guided imagery techniques. Guided imagery helps distract clients from stressful situations and facilitates relaxation. **EBN:** *A quasi-experimental study (N = 60) found that clients who listened to a guided imagery compact disk once a day for 10 days had improved comfort and decreased depression, anxiety, and stress over time* (*Kolcaba, 2014).*
• Provide psychospiritual support and a comforting environment to enhance comfort during emotional crises. **EBN:** *As health care professionals, nurses should intervene and provide care that recognizes and reduces strain for the patient, caregiver, and family during a mental health crisis (Naseimento et al, 2016).*
• When nurses attend to the comfort of perioperative clients, the clients' sense of hope for a full recovery increases. **EBN:** *In a quantitative study with 191 participants, direct and significant relationships were observed between comfort and hope (Seyedfatemi et al, 2014).*
• Providing music and verbal relaxation therapy enhances holistic comfort by reducing anxiety. **EBN:** *In her review of studies using music as a nursing intervention, Eells (2014) found that music is an effective tool in relieving anxiety.*

- Caregivers should not hesitate to use humor when caring for their clients. **EB:** *Humor is seen as a health-promoting means of handling life's stress (Roaldsen et al, 2015).*

Readiness for enhanced Comfort

Gail B. Ladwig MSN, RN, Julianne E. Doubet BSN, RN, EMT-B

NANDA-I

Definition

A pattern of ease, relief, and transcendence in physical, psychospiritual, environmental, and/or social dimensions that is sufficient for well-being and can be strengthened.

Defining Characteristics

Expresses desire to enhance comfort; expresses desire to enhance feelings of contentment; expresses desire to enhance relaxation; expresses desire to enhance resolution of complaints

NOC Outcomes (Nursing Outcomes Classification)

Suggested NOC Outcomes

Client Satisfaction: Caring; Symptom Control; Comfort Status; Coping; Hope; Motivation; Pain Control; Participation in Health Care Decisions; Spiritual Health

Example NOC Outcomes with Indicators

Comfort Status as evidenced by the following indicators: Physical well-being/Symptom control/Psychological well-being. (Rate the outcome and indicators of **Comfort Level:** 1 = not at all satisfied, 2 = somewhat satisfied, 3 = moderately satisfied, 4 = very satisfied, 5 = completely satisfied [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Assess current level of comfort as acceptable
- Express the need to achieve an enhanced level of comfort
- Identify strategies to enhance comfort
- Perform appropriate interventions as needed for increased comfort
- Evaluate the effectiveness of interventions at regular intervals
- Maintain an enhanced level of comfort when possible

NIC Interventions (Nursing Interventions Classification)

Suggested NIC Interventions

Calming Technique; Cutaneous Stimulation; Environmental Management: Comfort; Heat/Cold Application; Hope Inspiration; Humor; Meditation Facilitation; Music Therapy; Pain Management: Acute and Chronic; Presence; Guided Imagery; Massage; Relaxation Therapy; Spiritual Growth Facilitation; Therapeutic Play; Therapeutic Touch; Touch; Distraction

Example NIC Activities—Spiritual Growth Facilitation

Assist the client with identifying barriers and attitudes that hinder growth or self-discovery; Assist the client to explore beliefs as related to healing of the body, mind, and spirit; Model healthy relating and reasoning skills

Nursing Interventions and *Rationales*

- Assess clients' comfort needs and current level of comfort in various contexts, as outlined in Kolcaba's (2003) comfort theory and practice: physical, psychospiritual, sociocultural, and environmental. **CEB:** *Assessing comfort needs helps develop holistic, client-centered comfort interventions, whereas establishing a baseline helps evaluate their effectiveness by comparing comfort levels after each intervention to the previous baseline (Kolcaba, 2003).* **EBN:** *By using the comfort theory's framework, the nurse can recognize the patient's physical, psychosocial, sociocultural, and environmental needs; bringing these aspects into play will aid in identifying nursing problems and the necessary interventions that can be implemented to enrich the patient's environment (Ng, 2017).*
- Educate clients about the various contexts of comfort and help them understand that enhanced comfort is a desirable, positive, and achievable goal. **CEB:** *Human beings strive to have their basic comfort needs met, with comfort being more than just the absence of pain (Kolcaba, 2003).* **EBN:** *According to Silveira Mendes et al (2016), nursing care*

should incorporate all aspects of the patient's comfort needs and not just the physical, which are both expressed and unexpressed.

- Enhance feelings of trust between the client and the health care provider to maintain an effective and therapeutic relationship. **EBN:** *Trust is an essential element in the nurse-client relationship that is fostered through caring attitudes, availability, respect, empathy, sensitivity to client needs, competence, and effective communication (Dinç & Gastmans, 2013).*
- Maintain an open and effective communication with clients and keep them informed about their health, their plan of care, and their environment. **EBN:** *Communicating to hospitalized cardiothoracic clients the source of sounds heard or expected to be heard around the unit, such as alarms, staff conversations, and rolling carts, alleviated their anxiety and enhanced relaxation (Mackrill et al, 2013), hence, promoting their environmental comfort.*
- Implement comfort rounds that regularly assess for clients' comfort needs. **EBN:** *Regular 1-hour or 2-hour rounds that address pain, positioning, personal needs, and environment were found to increase client satisfaction, decrease call light usage, and promote safety by decreasing fall rates (Chu, 2014; Ciccu-Moore et al, 2014).*
- Collaborate with other health care professionals, such as health care providers, pharmacists, social workers, chaplains, occupational and physical therapists, and dietitians, among others, in planning interventions that address comfort needs in various contexts: physical, psychospiritual, sociocultural, and environmental. **EBN:** *Kolcaba's comfort theory can be used as a guide for patient care in offering uncomplicated and holistic standards that assist the nurse in recognizing patient's needs, developing interventions to satisfy those needs, assessing the outcomes of these interventions, and meeting goals of quality patient and family care. These goals may also encompass discharge planning and follow-up with various health and spiritual providers (Boudiab & Kolcaba, 2015).*
- Educate clients about and encourage the use of various integrative therapies and modalities to provide options that enhance comfort, beyond the traditional plan of care. Institute of Medicine (IOM) and Pain examples of such modalities are listed below:
    - Therapeutic massage and touch therapy. **EBN:** *Massage and touch therapy have been found to promote comfort in clients with dementia by decreasing anxiety and agitation (Battaglini, 2014). There is evidence to support recommending massage to clients with subacute and chronic back pain, mechanical neck pain, and labor pain, as well as to decrease anxiety and blood pressure and to improve quality of life in clients with HIV/AIDS (D'Arcy, 2014)*
    - Guided imagery. **EBN:** *Guided imagery was also effective in improving chronic tension headaches and body pain, as well as promoting overall mental health and energy level (Read, 2013).*
    - Mindfulness and mindfulness-based interventions such as mindfulness-based stress reduction (MBSR), mantra repetition (silent repetition of a sacred word), mindfulness meditation, and mindful breathing and walking, among others. **EB:** *A study of MBSR in cancer clients concluded that mindfulness promotes a sense of calmness, inner peace, and personal and spiritual growth (Labellea et al, 2014).* **EBN:** *Mantra repetition is found to decrease posttraumatic stress disorder (PTSD) symptoms and increase sense of well-being in veterans when added to their traditional PTSD treatment plan (Bormann et al, 2014).*
    - Energy therapy or biofield therapy such as healing touch, therapeutic touch, and Reiki. Biofield therapy seems to be promising in promoting

comfort and relaxation, but more sound and systematic research is needed to build a strong body of evidence. **EBN:** *Healing touch has been found effective as an adjunct therapy in relieving anxiety and depression (Harlow, 2013).* **EBN:** *Biofield therapy strengthens the immune system, decreases stress, and allows the body to heal. It can be integrated in the care of cancer clients in various settings for relaxation and symptom management, as well as in those with musculoskeletal and joint pain, agitation and dementia, and other chronic conditions (Gonella et al, 2014).*

- ❍ Acupuncture and auricular acupuncture. **EBN:** *Faircloth (2015) stated that acupuncture and acupressure have been found to decrease apprehension preoperatively, reduce intraoperative anesthetic requirements, diminish postoperative discomfort, lower the occurrence of postoperative nausea and vomiting, and fortify the treatment of chronic pain management.*
- ❍ Aromatherapy. **EB:** *In their study of individuals exposed to the lemon grass scent, Costa Goes et al (2015) found that there was a reduction in anxiety and subjective stress within minutes of the aroma's administration.*
- ❍ Music. **EBN:** *Music, as a nursing intervention, has been shown to be beneficial in relieving patients' discomfort, apprehension, and distress (Waterworth & Rickson, 2017).*
- ❍ Other mind–body therapies such as meditation, yoga, etc. **EB:** *Meditation is a strategy of self-care that offers potential usefulness in mental health situations, in behavioral self-regulation, and integrative medical care (Burke et al, 2017).*

• Foster and instill hope in clients whenever possible. **EBN:** *A study of clients undergoing surgery in the preanesthesia stage found a strong correlation between hope and comfort (Seyedfatemi et al, 2014). See the care plan for* ***Hopelessness.***

• Provide opportunities for and enhance spiritual care activities. **EBN:** *Recognizing and satisfying patients' spiritual needs is essential to nursing care; now, with the acceptance of integrative medicine, nurses play a key role in promoting spiritual comfort for their patients (Chan, 2014).*

▲ Enhance social support and family involvement. **EBN:** *In their survey (based on Kolcaba's enhanced comfort theory) addressing family experiences, when a loved one is hospitalized in an intensive care unit, Twohig et al (2015) found that there was an elevated level of satisfaction among family members in all aspects of patient care, including communication and the opportunity to be involved in decision-making.*

▲ Promote participation in creative arts and activity programs. **EB:** *Adult education classes in creative arts were found to improve well-being by boosting mood and providing a feeling of belonging. It also supported members in developing self-confidence, in the development of new relationships, and in general it encouraged more active lives (Pearce, 2017).*

▲ Encourage clients to use health information technology (HIT) as needed). **EB:** *In a European Union study, Internet users in the United Kingdom validated the concept that the Internet was a good option in gaining knowledge of self-care and care of others and was valuable in positive health care outcomes (Marton, 2015).*

• Evaluate the effectiveness of all comfort interventions at regular intervals and adjust therapies as necessary. **EBN:** *In a study by Coelho et al (2016), patients were asked how they sensed a feeling of comfort, and their responses included: individualized care, symptom containment, need for a comfortable environment, and hope and relationships. Recognition of these needs gives the nurse the opportunity to construct personalized interventions that meet these needs as well as to evaluate and revise them as needed.*

Geriatric

- Refer to previously mentioned interventions for geriatric interventions.

Pediatric

- Assess and evaluate the child's level of comfort at frequent intervals. With assessment of pain in children, it is best to use input from the parents or a primary care giver. **EBN:** *According to Shaw et al (2017), skillful communication with patients and families is necessary for proficient, personalized comfort care in the pediatric environment.* **EBN:** *Continued research is necessary to establish the most useful and valid methods in assessment of pediatric pain and/or discomfort, and may incorporate technology as a viable assessment tool (Quinn et al, 2014).*
- Skin-to-skin contact (SSC) in the comfort of newborns, especially those at risk. **EBN:** *Newborn SSC practice is natural and instinctive and has been found to have positive effects on health outcomes and comfort, especially for at-risk newborns in low-support environments (Hubbard et al, 2017).*
- Adjust the environment as needed to enhance comfort. **CEB:** *Environmental comfort measures include maintaining orderliness; quiet; minimizing furniture; and special attention to temperature, light and sound, color, and landscape (Kolcaba & DeMarco, 2005).*
- Encourage parental presence whenever possible. **EBN:** *In a study done by Carnevale and Gaudreault (2013) of seriously ill pediatric patients in a university-connected children's hospital, they found that the presence of parents was the most important source of the child's comfort.*
- Promote use of alternative comforting strategies such as positioning, presence, massage, spiritual care, music therapy, art therapy, and story-telling to enhance comfort when needed. **EB:** *In their study of comfort measures and sedation/analgesics used in pediatric intensive care units (PICUs), Guerra et al (2016) found that enhanced comfort care is offered through music, swaddling, pacifiers, television, and sucrose solutions.*
- Support the child's spirituality. **EB:** *A child's spiritual growth is recognized along with moral, mental, and social development as an important part of children's lives and is deserving of preservation and development (Karlsen et al, 2014).*

Multicultural

- Identify cultural beliefs, values, lifestyles, practices, and problem-solving strategies when assessing a client's comfort. **EB:** *The responsibility of providing cultural health care to those in our multicultural society continues to prove challenging; it is good to remember that cultural traditions are powerful forces and should not be generalized in caring for clients of diverse cultures (Wiener et al, 2013).*
- Enhance cultural knowledge by actively seeking out information regarding different cultural and ethnic groups **EBN:** *As the multicultural population of the United States continues to expand, there is a growing need for outreach and culturally sensitive education that will better serve these communities (Elminowski, 2015).*
- Recognize the impact of culture on communication styles and techniques **EBN:** *Livesay et al (2017) surmised that growing diversification of societies places increasing emphasis on the demand for culturally suitable communication, which both addresses the needs of the health care consumer and the provider.*
- Provide culturally competent care to clients from different cultural groups. **EBN:** *It is crucial that nurses, as an important part of the health care team, are cognizant and perceptive concerning the distinctive problems related to providing care and treatment to*

people from different cultures (Michigan Nurse, 2015).

Home Care

- The nursing interventions described for Readiness for enhanced **Comfort** may be used with clients in the home care setting. When needed, adaptations can be made to meet the needs of specific clients, families, and communities.
  - ▲ Make appropriate referrals to other organizations or health care providers as needed to enhance comfort. **EBN:** *Parker et al (2013) submitted that a palliative care referral that encompasses pain assessment and management, transition and coordination of levels of care, and advanced care planning can enhance outcomes and increase patient satisfaction.* **EBN:** *Unnecessary referrals for older patients may lead to poorer health, decreased feeling of well-being, and magnified confusion (Kihlgren et al, 2016).*
  - ▲ Promote an interdisciplinary (home care nurses, physicians, pharmacy, etc.) approach to home care. **EBN:** *Imhoff (2016), in his study of nurse-led interdisciplinary team approach to palliative care, found that the nurse specialist was an important player in establishing and sustaining an interdisciplinary complex system of care.*
- Evaluate regularly if enhanced comfort is attainable in the home care setting. **EB:** *A study by Seow et al (2016) found that home care nurses provided comfort and support to cancer patients who wished to die at home and not in the hospital.*

Client/Family Teaching and Discharge Planning

- Teach client how to regularly assess levels of comfort.
- Instruct client that a variety of interventions may be needed at any given time to enhance comfort. **EBN:** *Health care professionals involved in home care should be proficient in medical technology to preserve a feeling of safety and allay fears in both patients and their care givers (Munck & Sandgren, 2017).*
- Help clients understand that enhanced comfort is an achievable goal.
- Teach techniques to enhance comfort as needed.
  - ▲ When needed, empower clients to seek out other health professionals as members of the interdisciplinary team to assist with comforting measures and techniques.
- Encourage self-care activities and continued self-evaluation of achieved comfort levels to ensure enhanced comfort is maintained.

Readiness for enhanced Communication

Stacey M. Carroll PhD, APRN-BC, Suzanne White MSN, RN, PHCNS, BC

NANDA-I

Definition

A pattern of exchanging information and ideas with others, which can be strengthened.

Defining Characteristics

Expresses desire to enhance communication

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Communication; Communication: Expressive, Receptive

Example NOC Outcome with Indicators

Communication as evidenced by the following indicators: Use of spoken language/Use of written language/Acknowledgment of messages received/Exchanges messages accurately with others. (Rate the outcome and indicators of **Communication:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Express willingness to enhance communication
- Demonstrate ability to speak or write a language
- Form words, phrases, and language
- Express thoughts and feelings
- Use and interpret nonverbal cues appropriately
- Express satisfaction with ability to share information and ideas with others

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Active Listening; Communication Enhancement: Hearing Deficit; Communication Enhancement: Speech Deficit

Example NIC Activities—Communication Enhancement

Hearing Deficit
Listen attentively; Allow patient adequate time to process communication and respond; Verify what was said or written using patient's response before continuing

Nursing Interventions and *Rationales*

- Establish a therapeutic nurse–client relationship: provide appropriate education for the client, demonstrate caring by being present to the client. **CEB:** *Clients who were*

nonvocal and ventilated appreciated nursing care that was delivered in an individualized, caring manner (Carroll, 2007).

• Assess the client's readiness to communicate, using an individualized creative approach, and avoid making assumptions regarding the client's preferred communication method. **EB:** *Creative methodologies such as life history projects, photography, drawing, music, and poetry enhanced communication in those with learning disabilities (Kennedy & Brewer, 2014).*

• Assess the client's literacy level so information can be tailored accordingly. *The Rapid Estimate of Adult Literacy in Medicine–Short Form (REALM-SF) provides a quick valid assessment (Agency for Healthcare Research and Quality, 2014).*

• Use these practical guidelines to assist in communication: Listen attentively and provide a comfortable environment for communicating; slow down and listen to the client's story; use augmentative and alternative communication methods (e.g., lip reading, communication boards, writing, body language, computer/electronic communication devices) as appropriate; repeat instructions if necessary; limit the amount of information given; have the client "teach back" to confirm understanding; avoid asking, "Do you understand?"; and be respectful, caring, and sensitive. **CEB:** *Multiple augmentative and alternative communication methods, applied with an individualized and creative approach, aided in facilitating communication (Radtke et al, 2011).*

▲ Use interdisciplinary collaboration to ensure continuity of enhanced communication. **EB:** *Effective interdisciplinary collaboration and follow-up was recommended when working with clients with significant communication impairments after having a stroke (Jones et al, 2013).*

▲ Refer couples in maladjusted relationships for psychosocial intervention and social support to strengthen communication; consider nurse specialists. **EB:** *Emotionally focused therapy for couples is an effective evidence-based treatment (Wiebe & Johnson, 2016).*

• Consider using music to enhance communication between a client who is dying and his or her family. **CEB:** *In clients with communication difficulties, music therapy resulted in improvement in communication (Leow et al, 2010).*

• Use social media as a means to facilitate communication. **EB:** *Individuals who use augmentative and alternative communication methods may benefit from integration of social media to further enhance communication (Caron, 2016).*

• Teach clients mindfulness meditation. **EB:** *Mindfulness meditation enhanced language production in clients with aphasia (Dickinson et al, 2017).*

• Use photographs as a communication aid. **EB:** *Use of photographs during conversation resulted in people with aphasia talking more about the topic and staying on that topic (Ulmer, 2017).*

• Encourage clients with aphasia to sing. **EB:** *Participation in a community choir led by a neurologic music therapist resulted in qualitatively identified improvement/changes in communication among clients with aphasia (Tamplin et al, 2013).*

• See care plan for Impaired verbal **Communication.**

Pediatric

• All individuals involved in the care and everyday life of children with learning difficulties need to have a collaborative approach to communication. **EBN:** *Collaboration in tasks requires the formation of personal relationships based on mutual trust and respect (Callery & Milnes, 2012).*

• See care plan for Impaired verbal **Communication.**

Geriatric

▲ Assess for hearing and vision impairments, and make appropriate referrals for hearing aids. **EB:** *Healthy People 2020 recommended early identification of people with hearing and vision loss (Healthy People 2020, 2014).*
• Use touch if culturally acceptable when communicating with older clients and their families. **CEBN:** *Touch has a calming effect on a client who may be frightened because of difficulty with communication (Grossbach et al, 2011).*
• Encourage group singing activities and music therapy interventions in clients with dementia. **EB:** *"Singing for the Brain" is a group singing activity developed by the Alzheimer's Society and the program resulted in increased social inclusiveness and improvements in relationships (Osman et al, 2016).* **EB:** *Music therapy with a client with dementia facilitated engagement in communication (Mette Ridder & Gummesen, 2015).*
• Encourage drawing by caregivers of clients with dementia. **EBN:** *Drawing by caregivers of clients with dementia enhanced the communication experience (McEvoy & Bellass, 2017).*
• See care plan for Impaired verbal **Communication.**

Multicultural

• See care plan for Impaired verbal **Communication.**

Home Care

• The interventions described previously may be used in home care.
• See care plan for Impaired verbal **Communication.**

Client/Family Teaching and Discharge Planning

• See care plan for Impaired verbal **Communication.**

Impaired verbal Communication

Stacey M. Carroll PhD, APRN-BC, Suzanne White MSN, RN, PHCNS, BC

NANDA-I

Definition

Decreased, delayed, or absent ability to receive, process, transmit, and/or use a system of symbols.

Defining Characteristics

Absence of eye contact; difficulty comprehending communication; difficulty expressing thoughts verbally; difficulty forming sentences; difficulty forming; difficulty in selective attending; difficulty in use of body expressions; difficulty in use of facial expressions; difficulty maintaining communication; difficulty speaking; difficulty verbalizing; disoriented to person; disoriented to place; disoriented to time; dyspnea; inability to speak; inability to speak language of caregiver; inability to use body expressions; inability to use facial expressions; inappropriate verbalization; partial visual deficit; slurred speech; stuttering; total visual deficit

Related Factors

Alteration in self-concept; cultural incongruence; emotional disturbance; environmental barrier; insufficient information; insufficient stimuli; low self-esteem; vulnerability

At-Risk Population

Absence of significant other

Associated Condition

Alteration in development; alteration in perception; central nervous system impairment; oropharyngeal defect; physical barrier; physiological condition; psychotic disorder; treatment regimen

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Communication; Communication: Expressive, Receptive

Example NOC Outcome with Indicators

Communication as evidenced by the following indicators: Use of spoken and written language/Acknowledgment of messages received/Exchanges messages accurately with others. (Rate the outcome and indicators of **Communication:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Use effective communication techniques
- Use alternative methods of communication effectively
- Demonstrate congruency of verbal and nonverbal behavior
- Demonstrate understanding even if not able to speak
- Express desire for social interactions

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Active Listening; Communication Enhancement: Hearing Deficit; Communication Enhancement: Speech Deficit; Presence; Touch

Example NIC Activities—Communication Enhancement

Hearing Deficit

Listen attentively; Allow client adequate time to process communication and respond; Verify what was said or written using client's response before continuing

Nursing Interventions and *Rationales*

- Use a comprehensive nursing assessment to determine the language spoken, cultural considerations, literacy level, cognitive level, and use of glasses and/or hearing aids. **EBN:** *Language barriers, low literacy, and lack of understanding are barriers to effective communication (Taylor et al, 2013).*
- Determine client's own perception of communication difficulties and potential solutions when possible. **CEB:** *The Communication Confidence Rating Scale for Aphasia (CCRSA) was found to be an effective tool for assessment of the self-report of communication confidence among clients with aphasia (Babbitt et al, 2011).*
- Involve a familiar person when attempting to communicate with a client who has difficulty with communication, if accepted by the client. **EB:** *Training communication partners of clients with traumatic brain injury improved the communication experience of the client and family member (Togher et al, 2016).* **EB:** *Retaining valued relationships facilitated communication in people with dementia (Alsawy et al, 2017).*
- Listen carefully. Validate verbal and nonverbal expressions particularly when dealing with pain and use appropriate scales for pain when appropriate. **EBN:** *The Critical Care Pain Observation Tool and the Behavioral Pain Scale are valid and reliable options for use in clients who are nonverbal (Makic, 2013).* **EB:** *The Revised Nonverbal Pain Scale and the Original Nonverbal Pain Scale both demonstrated reliability and validity for assessing pain in clients who are nonverbal and ventilated (Chookalayi et al, 2017).*
- Use appropriate scales to assess communication and behavior in clients who are nonvocal and mechanically ventilated. **EBN:** *Preliminary research shows that the revised Communication Interaction Behavior Instrument scale has good face validity and shows good interrater reliability for use with older adults who are ventilated and nonvocal (Nilsen et al, 2014).*
- Use therapeutic communication techniques: speak in a well-modulated voice, use simple communication, maintain eye contact at the client's level, get the client's attention before speaking, and show concern for the client. **EBN:** *Effective communication entails involving clients, being sensitive to client needs, and ensuring client*

understanding (O'Hagan et al, 2014).

• Avoid ignoring the client with verbal impairment; be engaged and provide meaningful responses to client concerns. Place call light within reach of client who cannot verbally call for help. **EBN:** *Ignoring clients was found to be a negative communication strategy (O'Hagan et al, 2014).*

• Validate clients' feelings, focus on their strengths, and assist them in gaining confidence in identifying needs. **EBN:** *Viewing patients with communicative difficulties in a holistic manner cultivates empowering communication (Parsloe & Carroll, 2018)*

• Use touch as appropriate. **EBN:** *Gentle touch is a therapeutic communication strategy for clients, such as those with dementia who may be frightened because of difficulty with communication (Veselinova, 2014).*

• Use presence: spend time with the client and allow time for responses. *Client-centered care involves respect, communication, and comfort (Bechtold & Fredericks, 2014).*

• Explain all health care procedures, be persistent in deciphering what the client is saying, and do not pretend to understand when the message is unclear. **CEBN:** *Persons who were nonvocal and ventilated appreciated persistence on the nurses' part with respect to being understood, found it bothersome when others pretended to understand them, and appreciated explanations from the nurse (Carroll, 2007).*

• Use an individualized and creative multidisciplinary approach to augmentative and alternative communication (AAC) assistance and other communication interventions. *Ensure the choice of AAC is driven by client' communication needs rather than by the device (Light & McNaughton, 2013).* **EB:** *AAC improved communication among those with intellectual disabilities (Hagan & Thompson, 2014).* ***EB:*** *A specialized communication intervention resulted in improved communication between nurses and intensive care unit (ICU) clients who were nonvocal (Happ et al, 2014).*

• Use consistent nursing staff for those with communication impairments. **CEBN:** *Consistent nursing care increased client–nurse communication and decreased client powerlessness (Carroll, 2007).* **EB:** *Among linguistically and culturally diverse clients with dementia, other communication methods (body language, etc.) along with spoken language can develop over time, indicating the importance of the continuity of providers (Strandroos & Antelius, 2017).*

▲ Consult communication specialists from various disciplines as appropriate. Speech language pathologists, audiologists, and interpreters provide comprehensive communication assistance for those with impaired communication. *Lip reading translators (LRTs) are proficient lip readers who determine what a nonvocal client is mouthing and then verbalize the client's words verbatim to others to facilitate communication* (Carroll, 2003). **CEB:** *Lip reading translators can assist in meeting nonvocal clients' communication needs (Meltzer et al, 2012).*

▲ When the client is having difficulty communicating, assess and refer for audiology consultation for hearing loss. Suspect hearing loss when:

- ❍ Client frequently complains that people mumble, claims that others' speech is not clear, or client hears only parts of conversations.
- ❍ Client often asks people to repeat what they said.
- ❍ Client's friends or relatives state that the client does not seem to hear very well, or plays the television or radio too loudly.
- ❍ Client does not laugh at jokes because of missing too much of the story.
- ❍ Client needs to ask others about the details of a meeting that the client attended.
- ❍ Client cannot hear the doorbell or the telephone.
- ❍ Client finds it easier to understand others when facing them, especially in a

noisy environment.

• People with hearing loss do not hear sounds clearly. The loss may range from hearing speech sounds faintly or in a distorted way to profound deafness (American Academy of Audiology, 2017).

• When communicating with a client with a hearing loss:

  ❍ Obtain client's attention before speaking and face toward his or her unaffected side or better ear while allowing client to see the speaker's face at a reasonably close distance, use gestures as appropriate to aid in communication, do not raise voice or over enunciate, and minimize extraneous noise. *Correct positioning and an optimal listening environment increase the client's awareness of the interaction and enhance the client's ability to communicate (University of California San Francisco, 2017).*

  ❍ Provide sufficient light and do not stand in front of a window. *Light illuminates the speaker's face, making expressions and lip movements clearer; standing in front of a window causes glare, which impedes the client's ability to clearly see the speaker (University of California San Francisco, 2017).*

  ❍ Remove masks if safe to do so, or use see-through masks. *Removing the mask barrier allows for visibility of the mouth which enhances communication. For information on see-through masks, see* www.amphl.org.

  ❍ Avoid making assumptions about the communication choice of those with hearing loss or voice impairments. **CEBN:** *After seeking client input, communication rounds or communication care plans can be completed (Happ et al, 2010).*

Pediatric

• Observe behavioral communication cues in infants. **EB:** *Reissland et al (2012) studied mothers and infants (N = 50) and found that preverbal infants express pain by crying and with facial and body behaviors, which have to be interpreted by the caregiver.*

• Identify and define at least two new forms of socially acceptable communication alternatives that may be used by children with significant disabilities. **EB:** *Pasco and Tohill (2011) conducted a study of nonverbal children with autism spectrum disorder (N = 23) and found that the Picture Exchange Communication System (PECS) may provide valuable predictive information regarding social communication skills.* **EB:** *Brady et al (2013) investigated a model of language development for nonverbal school-aged children (N = 93) and found the importance of enriching social communication input across home and school environments, as well as assessments of and interventions aimed at improving comprehension, play, visual discrimination, and communication complexity.*

• Teach children with severe disabilities functional communication skills. **EB:** *Allen and Marshall (2011) conducted a study involving parent–child interaction therapy (PCIT) (N = 16) for school-aged children with specific language impairment and found that PCIT offered a single block of therapy in which the parents' communication and interaction skills are developed to provide the child with an appropriate language-rich environment.*

▲ Refer children with primary speech and language delay/disorder for speech and language therapy interventions. **EB:** *Pasco and Tohill (2011) conducted a study of nonverbal children with autism spectrum disorder (N = 23) and found the assessment of the developmental level of potential PECS users may provide valuable predictive information for speech-and-language therapists and other professionals in relation to the likely degree of progress and in setting realistic and achievable targets.*

Geriatric

- Carefully assess all clients for hearing difficulty using an audiometer. Healthy People 2020 encouraged early identification of people with hearing loss (Healthy People 2020, 2014).
- Avoid use of "elderspeak," which is a speech style similar to baby talk. **EB:** *A brief communication training intervention resulted in lower use of elderspeak by staff and less resistiveness to care among clients with dementia (Williams et al, 2017b).*
- Initiate communication with the client with dementia, and give client time to respond. Use eye contact, gentle touch as appropriate, and shorter sentences. *The responsibility to use a creative approach and take the time to listen and understand clients who have dementia lies with the clinician (Veselinova, 2014).* **EBN:** *The Verbal and Nonverbal Interaction Scale is valid and reliable and can assess sociable and unsociable communication in clients with dementia (Williams et al, 2017a).*
- Encourage the client to wear hearing aids, if appropriate. **EBN:** *Hearing aids assist with communication and hearing aid storage boxes can prevent loss or damage (Holmes, 2014).*
- Facilitate communication through reminiscing with memory boxes that contain objects, photographs, and writings that have meaning for the client. *Reminiscence stimulates memories, thus improving communication (Swann, 2013).* **EB:** *Memory boxes encouraged reminiscence in clients with dementia, facilitating communication (Gulwadi, 2013).*
- Continue to find means to communicate even with those who are completely nonverbal. **EB:** *Spontaneous reciprocal interaction promoted family harmony among nonvocal clients with severe dementia (Walmsley & McCormack, 2014).*

Multicultural

- Attend to the meaning of a culture's nonverbal communication modes, such as eye contact, facial expression, touching, and body language. **EB:** *Attending to nonverbal interactions facilitated communication among culturally and linguistically diverse clients with dementia (Strandroos & Antelius, 2017).*
- Assess for the influence of cultural beliefs, norms, and values on the client's communication process. **EBN:** *Misunderstandings and conflicts can arise when there is a difference in language and/or culture of the provider and client (Crawford et al, 2017).*
- Assess personal space needs, acceptable communication styles, acceptable body language, interpretation of eye contact, perception of touch, and use of paraverbal modes when communicating with the client. **EB:** *When caring for clients of varied ethnicities and languages, nurses used nonverbal means such as pointing, smiling, modeling, and touch to convey information and calm clients in long-term care (Small et al, 2015).*
- Assess how language barriers contribute to health disparities among ethnic and racial minorities. **EBN:** *Language barriers were the main obstacle in eliciting an accurate medical history, explaining and gaining pain scores, communicating reasons for client transport delays, arranging appointments by telephone, explaining medication and side effects, or diagnosing and communicating problems (Taylor et al, 2013).* **EBN:** *Patient safety was compromised when language barriers were present (van Rosse et al, 2016).*
- Although touch is generally beneficial, it is culturally defined and there may be times when it may not be advisable because of cultural considerations. **EB:** *Touch conveys various meanings depending on the client's culture and the situation (Albardiaz, 2014).*

• The Office of Minority Health of the US Department of Health and Human Services national standards on culturally and linguistically appropriate services (CLAS) in health care should be used as needed. **EB:** *These standards aim to improve health care quality and advance health equity by establishing a framework for organizations to serve the nation's increasingly diverse communities (CLAS, 2014).*

Home Care

The interventions described previously may be adapted for home care use.

Client/Family Teaching and Discharge Planning

▲ Refer the client to a speech-language pathologist (SLP) or audiologist. Audiological assessment quantifies and qualifies hearing in terms of the degree of hearing loss, the type of hearing loss, and the configuration of the hearing loss. Once a particular hearing loss has been identified, a treatment and management plan can be put into place by an SLP. *Audiological services can improve communication in clients with dementia and hearing loss (Mamo et al, 2017). SLPs can provide strategies for communication partners of adults with communication impairments (Ball & Lasker, 2013).*

▲ Teach the client and family techniques to increase communication, including the use of communication devices and tactile touch. Incorporate multidisciplinary recommendations. **CEBN:** *The nurse plays a critical role in individualized communication assessment as clients transition from hospital to home (Cerantola & Happ, 2012).* **CEB:** *Clients who are mechanically ventilated at home have a long struggle to find effective communication methods (Laasko et al, 2011).*

NANDA-I

Definition
Reversible disturbances of consciousness, attention, cognition, and perception that develop over a short period of time, and which last less than 3 months.

Defining Characteristics
Agitation; alteration in cognitive functioning; alteration in level of consciousness; alteration in psychomotor functioning; hallucinations; inability to initiate goal-directed behavior; inability to initiate purposeful behavior; insufficient follow-through with goal-directed behavior; insufficient follow-through with purposeful behavior; misperception; restlessness

Related Factors
Alteration in sleep-wake cycle; dehydration; impaired mobility, inappropriate use of restraints; malnutrition, pain, sensory deprivation; substance misuse; urinary retention

At-Risk Population
Age ≥60 years; history of cerebral vascular accident; male gender

Associated Condition
Alteration in cognitive functioning; delirium; dementia; impaired metabolic functioning; infection; pharmaceutical agent

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes
Improved Cognitive Function; Improved Sensory Perception; Improved Thought Processes

Example NOC Outcome with Indicators
Cognition as evidenced by the following indicators: Communication clear for age/Comprehension of the meaning of situations/Attentiveness/Concentration/Cognitive orientation. (Rate the outcome and indicators of **Cognition:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Demonstrate restoration of cognitive status to baseline
- Be oriented to time, place, and person
- Demonstrate appropriate motor behavior
- Maintain functional capacity
- Remain free from injury

NIC (Nursing Interventions Classification)

Suggested NIC Interventions
Delirium Management; Delusion Management

Example NIC Activities—Delirium Management
Inform client of time, place, and person as needed; Provide information slowly and in small doses with frequent rest periods; Ensure client has appropriate assistive sensory devices (e.g., glasses, hearing aids)

Nursing Interventions and *Rationales*

- Recognize that delirium is characterized by an acute onset, a fluctuating course,

inattention, and disordered thinking. **EBN:** *Delirium is often under recognized and can have significant adverse consequences for clients to include increase in length of hospitalization, cognitive deficits, and increased mortality risk. Common conditions that place clients at risk for delirium include advanced age, pain, dehydration, infections, metabolic disturbances, and surgery. It is important for nurses to assess for delirium and implement interventions. (Faught 2014; Davidson et al, 2015).*

- Identify the three distinct types of delirium: hyperactive (easy to recognize), hypoactive (commonly missed), and mixed (the most commonly occurring) (Downing et al, 2013).
    - ❍ Hyperactive: delirium characterized by restlessness, agitation, irritability, hypervigilance, hallucinations, and delusions; client may be combative or may attempt to remove tubes, lines.
    - ❍ Hypoactive: delirium characterized by decreased motor activity, decreased vocalization, detachment, apathy, lethargy, somnolence, reduced awareness of surroundings, and confusion.
    - ❍ Mixed: delirium characterized by the client fluctuating between periods of hyperactivity and agitation and hypoactivity and sedation. **EBN:** *Delirium is under recognized by both medical and nursing staff, particularly the hypoactive form (Davidson et al, 2015; Faught 2014).*
- Obtain an accurate history and perform a mental status examination that includes the following assessment:
    - ❍ History from a reliable source that documents an acute and fluctuating change in cognitive function, attention, and behavior from baseline.
    - ❍ Cognition as evidenced by level of consciousness; orientation to time, person, and place; thought process (thinking may be disorganized, distorted, fragmented, slow, or accelerated with delirium; conversation may be irrelevant or rambling); and content (perceptual disturbances such as visual, auditory, or tactile delusions or hallucinations).
    - ❍ Level of attention (may be decreased or may fluctuate with delirium; may be unable to focus, shift, or sustain attention; may be easily distracted or may be hypervigilant).
    - ❍ Behavior characteristics and level of psychomotor behavior (activity may be increased or decreased and may include restlessness, finger tapping, picking at bedclothes, changing position frequently, spastic movements or tremors, or decreased psychomotor activity such as sluggishness, staring into space, remaining in the same position for prolonged periods).
    - ❍ Level of consciousness (may be easily aroused, lethargic, drowsy, difficult to arouse, unarousable, hyperalert, easily startled, and overly sensitive to stimuli).
    - ❍ Mood and affect (may be paranoid or fearful with delirium; may have rapid mood swings).
    - ❍ Insight and judgment (may be impaired).
    - ❍ Memory (recent and immediate memory is impaired with delirium; unable to register new information).
    - ❍ Language (may have rapid, rambling, slurred, incoherent speech).
    - ❍ Altered sleep-wake cycle (insomnia, excessive daytime sleepiness).
    - ❍ **EB:** *Establishing the client's baseline mental status by obtaining an accurate history and performing a brief cognitive assessment observing for key diagnostic criteria are important in the diagnosis of delirium (Davidson et al, 2015; Inouye et al, 2014). Encouraging family to be present will facilitate assessment of subtle*

changes in cognition (Devlin et al, 2018).

- Assess the client's behavior and cognition systematically and continually throughout the day and night; use a validated tool to assess presence of delirium, such as the Confusion Assessment Method (CAM) or Delirium Observation Screening Scale (DOS). **CEB:** *The CAM is accurate, brief, and easy to use (Davidson et al, 2015; Grover & Kate, 2012); the DOS was found to be a useful screening tool in a small study of verbally active palliative care clients (Detroyer et al, 2014).*
- Recognize that delirium may be superimposed on dementia; the nurse must be aware of the client's baseline cognitive function. **EB:** *Dementia increases the risk and severity of delirium, and current research suggests delirium is an independent risk for subsequent dementia (Fong et al, 2015); delirium superimposed on dementia was a strong predictor of decline in function and resultant institutionalization of older adults admitted to a rehabilitation facility (Morandi et al, 2014).*
- Identify predisposing factors that may precede the development of delirium: dementia, cognitive impairment, functional impairment, visual impairment, alcohol misuse, multiple comorbidities, severe illness, history of transient ischemic attack or stroke, depression, history of delirium, and advanced age (older than 65). **EB:** *Delirium is a multifactorial syndrome most commonly seen in the intensive care unit (ICU), palliative care, and postoperative settings; identification of risk factors is important for prevention (Inouye et al, 2014; Devlin et al, 2018).*
- Surgical procedures increase the risk of delirium post operatively. **EB:** *Assess the client for risk factors and implement interventions to re-orient patient post operatively. Effectively treat pain and anxiety with the lowest effective dose. Avoid benzodiazepine agents if possible (Leigh et al, 2016; Devlin et al, 2018).*
- Identify precipitating factors that may precede the development of delirium, especially for individuals with predisposing factors: use of restraints, indwelling bladder catheter, metabolic disturbances, polypharmacy, pain, infection, dehydration, blood loss, constipation, electrolyte imbalances, immobility, general anesthesia, mechanical ventilation, hospital admission for fractures or hip surgery, anticholinergic medications, anxiety, sleep deprivation, lack of use of vision and/or hearing aids, and environmental factors. **EB:** *Awareness of risk factors for development of delirium helps identify clients at risk for developing delirium (Ahmed et al, 2014).* **EB:** *Prevention of delirium needs to remain a high priority in light of frequency of occurrence, high treatment costs, longer hospital length of stay, higher rates of functional decline and resultant institutional care, and greater mortality; delirium may persist and lead to long-term cognitive decline (Davidson et al, 2015; Faught, 2014; Fong et al, 2015).* **EB:** *Interventions to prevent or lessen the length and severity of delirium may be developed when early identification of delirium risk is instituted (Davidson et al, 2015).*
- Facilitate appropriate extended visitation for clients at risk of delirium. **EB:** *Extended visitation is associated with decreased incidence of delirium and shorter length of stay (Rosa et al, 2017).*

▲ Assess for and report possible physiological alterations (e.g., sepsis, hypoglycemia, hypoxia, hypotension, infection, changes in temperature, fluid and electrolyte imbalance, use of medications with known cognitive and psychotropic side effects). **EB:** *Systemic disturbances, including immunological, metabolic, neuroinflammatory, endocrinological, and neurological factors lead to alterations in neurotransmitter synthesis and availability, which leads to delirium (Maldonado, 2013).*

❍ Treat the underlying risk factors or the causes of delirium in collaboration with the health care team: establish/maintain normal fluid and electrolyte balance, normal body temperature, normal oxygenation (if the client

experiences low oxygen saturation, deliver supplemental oxygen), normal blood glucose levels, and normal blood pressure, and address malnutrition and anemia. **EB:** *Early recognition of risk factors may help to prevent the negative sequelae of delirium (Fineberg et al, 2013).*

▲ Conduct a medication review and eliminate unnecessary medications; potentially inappropriate medications for older adults at risk for delirium include anticholinergics, benzodiazepines, corticosteroids, H_2 receptor antagonists, sedative hypnotics, and tricyclic antidepressants (American Geriatrics Society, 2015). **EB:** *A software-based program that identified potential delirium-causing medications and triggered a medication review and monitoring plan by pharmacists led to a decreased incidence of delirium in long-term care (Clegg et al, 2014); polypharmacy is associated with delirium, and a reduction of polypharmacy improves cognition (van der Cammen et al, 2014).*

- ❍ Communicate client status, cognition, and behavioral manifestations to all necessary health care providers.
- ❍ Monitor for any trends occurring in these manifestations, including laboratory tests. **EB:** *Careful monitoring of laboratory tests assessing for metabolic abnormities is important to identify the potential etiological factors for delirium (Davidson et al, 2015; Faught, 2014).*

• Identify, evaluate, and treat pain quickly and adequately (see care plans for Acute **Pain** or Chronic **Pain**). **CEB:** *Untreated pain is a potential cause of delirium, as is excessive opioid administration (Clegg & Young, 2011).*

• Facilitate sleep hygiene. Establish day/night routines. **EB:** *Improved sleep is associated with decreased risk of delirium (Patel et al, 2014; Devlin et al, 2018).*

• Promote regulation of bowel and bladder function; use bladder scanning to identify retention, avoid prolonged insertion of urinary catheters, and remove catheters as soon as possible. **EB:** *Stool impaction may cause urinary retention, which is associated with delirium (Boddaert et al, 2014).* **CEB & EBP:** *Constipation may precipitate delirium (O'Mahoney et al, 2011); constipation has been found to be an independent risk factor of delirium with clients who are critically ill and mechanically ventilated (Smonig et al, 2016). Urinary catheterization is associated with delirium (Ahmed et al, 2014).*

• Ensure adequate nutritional and fluid intake. **EB:** *Malnutrition is significantly associated with delirium (Ahmed et al, 2014); attending to correct levels of B vitamins, antioxidants, glucose, water, and lipids may lead to resolution of delirium (Sanford & Flaherty, 2014).*

• Promote early mobilization and rehabilitation in a progressive manner. **EB:** *Avoiding immobility and promoting early mobilization postoperatively reduces delirium (Butler et al, 2013).* **EBN:** *Standardized early mobilization protocols promote functional status, prevent complications associated with functional decline, and contribute to greater well-being and/or decreased length of stay for medical-surgical inpatients (Drolet et al, 2013; Pashikanti & Von Ah, 2012).*

• Promote continuity of care; avoid frequent changes in staff and surroundings. **EB:** *Changes may contribute to feelings of disorientation and confusion (O'Mahoney et al, 2011).*

• Plan care that allows for an appropriate sleep-wake cycle. Refer to the care plan for **Sleep** deprivation. **EB:** *Interventions to promote sleep were associated with a decreased incidence of delirium (Patel et al, 2014).*

• Facilitate appropriate sensory input by having clients use aids (e.g., glasses, hearing aids, dentures) as needed; check for impacted ear wax. **EB:** *Delirium can be addressed with nonpharmacological interventions, such as decreasing sensory impairment (Javedan & Tulebaev, 2014) or avoiding sensory overload for clients with agitation.* **EB:** *A systematic*

review of interventions to help reduce delirium risk included multicomponent interventions, such as encouraging use of vision and hearing aids, and may assist in the prevention of delirium in individuals who are not cognitively impaired (Trogrlić et al, 2015).

- Modulate sensory exposure; eliminate excessive noise, use appropriate lighting based on the time of day, and establish a calm environment. **EB:** *Noise levels in the hospital, often from staff conversation and other avoidable sources, are higher than recommended and lead to significant sleep loss (Makic et al, 2014).*
- Provide cognitive stimulation through conversation about current events, viewpoints, and relationships and encourage reminiscence or word games. **EBN:** *Daily cognitive stimulation can prevent cognitive decline and promote cognitive recovery (Trogrlić et al, 2015).*
- Allow appropriate visitation.
- Provide reality orientation, including identifying self by name at each encounter with the client, calling the client by their preferred name, and the gentle use of orientation techniques; when reorientation is not effective, use distraction. **EB:** *Efforts to reorient may agitate some clients; changing the subject may help calm the client (Davidson et al, 2015; Faught 2014; Trogrlić et al, 2015).*
- Provide clocks and calendars, update dry erase white boards each shift, encourage family to visit regularly and to bring familiar objects from home, such as family photos or an afghan, and gently correct misperceptions. **EB:** *Persons at risk for delirium should be provided clocks and calendars that are easily visible; family and friends may help with reorientation (O'Mahoney et al, 2011).*
- Use gentle, caring communication; provide reassurance of safety; and give simple explanations of procedures.
- Provide supportive nursing care, including meeting basic needs, such as feeding, regular toileting, and ensuring adequate hydration; closely observe behaviors that provide clues as to what might be distressing the client. Delirious clients are unable to care for themselves because of their confusion (Rubin et al, 2011). **EB:** *Understanding and anticipating behaviors promotes client comfort and safety (Faught 2014).*
- ▲ Recognize that delirium is frequently treated with antipsychotic medications or sedatives; if there is no other way to keep the client safe, administer these medications cautiously, as ordered, while monitoring for medication side effects. **EB:** *Reducing unnecessary medications, pain, stress, sleep deprivation, inflammation, and other neurological insults is crucial because antipsychotics and sedatives may actually prolong the duration of delirium and worsen outcomes (Inouye et al, 2014).*
    - ❍ For clients nearing the end of life, for whom delirium may be irreversible, focus on relief of symptoms by increasing supervision, reducing invasive lines and devices that restrict movement, keeping the bed in low position, and placing mats on the floor; support of family, caregivers, and the health care team is also of prime importance. **EB:** *Nonpharmacological means should always be used to ameliorate delirium and may be used in conjunction with medication; delirium is distressing to those caring for the client (Irwin et al, 2013).*
    - ❍ Choose the appropriate medication and consider the type and reversibility of the delirium; titrate the medication to control the symptoms and minimize side effects. **EB:** *Pharmacological means can be rapid, safe, and effective using the lowest effective dose of the appropriate medication based on the type of delirium (Irwin et al, 2013).*

• Recognize admission risk factors for delirium. **EB:** *ICU clients are at increased risk for delirium because of greater use of sedatives, analgesics, severity of illness, age, infection, multiorgan failure, sleep deprivation, surgery, fracture, restraint use, immobility, tubes, catheters, hypovolemia, polypharmacy, malnutrition, electrolyte imbalance, and stroke (Barr et al, 2013; Devlin et al, 2018).*
• Obtain an accurate history regarding cognitive impairment and mental health, including history of anxiety and depression, alcohol use, medication use, chronic pain, and use of benzodiazepines. **EBN:** *An accurate history guides appropriate interventions to maximize neurocognitive status of older adults with complex illnesses in the ICU (Tate & Happ, 2011).*
• Assess level of arousal using the Richmond Agitation Sedation Scale; clients receiving a score of −5 to −4 are comatose and unable to be assessed for delirium. **EB:** *Establishing level of arousal before using the CAM for the ICU (CAM-ICU) decreases the incidence of inappropriate "unable to assess" (UTA) ratings on the CAM-ICU; it was found that noncomatose clients were inappropriately determined to be UTA (Swan, 2014).*
• Assess for pain every 2 to 3 hours or more frequently as needed with a standardized assessment tool, which includes either a numerical rating scale or one with behavioral indicators, such as the Behavioral Pain Scale (BPS) or Critical Care Pain Observation Tool (CPOT). **EB:** *The self-report is the gold standard for pain assessment (Barr & Pandharipande, 2013); the BPS and CPOT are the most valid and reliable tools to use for adult ICU clients (excluding brain injured) with intact motor function and observable behaviors who are unable to self-report (Barr et al, 2013).* **EBN:** *Uncontrolled pain is common in the ICU and can contribute to delirium; routine assessment of pain may decrease duration of ventilation and ICU length of stay and increase client satisfaction (Stites, 2013). Clients are less likely to communicate symptoms such as pain when delirious (Tate et al, 2013).*
‣ Incorporate the Awakening and Breathing Coordination, Delirium Monitoring and Management, and Early Mobility (ABCDE) ICU delirium and weakness prevention bundle in conjunction with the interdisciplinary team. **EB:** *Interdisciplinary communication and daily rounds and staff education facilitate optimal ABCDE bundle implementation (Balas et al, 2013); bundle implementation leads to less delirium, reduced ventilator time, and more time out of bed (Balas et al, 2014).*
    ❍ Assess safety and implementation of a spontaneous awakening trial (SAT) using an established protocol. **EB:** *Daily interruption of sedation may be beneficial when it results in a reduced total dose of sedative administered; minimizing the depth and duration of sedation is beneficial for reducing delirium (Reade & Finfer, 2014).*
    ❍ Assess safety and implementation of a spontaneous breathing trial (SBT). **EBN:** *Implementing SAT/SBT protocols reduces the duration and use of mechanical ventilation, which may lead to decreased complications and does not increase self-extubation (Jones et al, 2014).*
    ❍ Assess sedation and agitation level using a valid and reliable tool; titrate sedation to target sedation level. **EB:** *Sedatives and analgesics prescribed to improve client–ventilator dyssynchrony and treat anxiety and pain may precipitate delirium (Barr et al, 2013; Davidson et al, 2015); for most clients being ventilated in the ICU, a score of 3 to 4 on the Riker or a score of −2 to 0 on the Richmond are appropriate targets (Reade & Finfer, 2014).*
    ❍ Screen for delirium using a reliable and valid monitoring tool once per shift or more often if delirium is present, and recognize that hypoactive delirium is the form most often present in the ICU; communicate and discuss results with the interdisciplinary team. **EB:** *The CAM-ICU and the Intensive Care*

Delirium Screening Checklist are the most valid and reliable tools for adult ICU clients (Barr et al, 2013); staff education, discussion of delirium during bedside rounds, and documentation promote successful screening and treatment (Brummel et al, 2013). **EBN:** *The hypoactive form of delirium is the most common form seen in the ICU and contributes to the under recognition of delirium by clinicians (Tate et al, 2013).*

- ❍ Assess safety to begin mobilization; collaborate with physical therapy (PT), occupational therapy (OT), and respiratory therapy (RT) to implement an early mobility plan using a progressive approach. **EB:** *Early mobilization of stable ICU clients may significantly reduce the length of delirium and length of stay and prevent other complications related to immobility (Hunter et al, 2014).*

• Encourage visits from families and educate families about delirium if it occurs. **EB:** *Delirium is distressing to clients and families; providing education can alleviate distress (Irwin et al, 2013).* **EBN:** *Families are most familiar with the client's baseline behavior, so they can assist in the diagnosis of delirium. Just by their presence, family may help to prevent and ameliorate delirium (Keyser et al, 2012; Devlin et al, 2018).*

• Promote uninterrupted sleep by grouping cares at night to avoid sleep interruption, offering eye mask, soft music, and earplugs; optimizing room temperature; by reducing noise and light after 10 p.m.; and by avoiding excessive daytime napping. **EB:** *Sleep deprivation and delirium in the ICU may be iatrogenic; engaging clients to keep them more awake during the day may ensure better outcomes (Weinhouse, 2014).* **EBN:** *Multifaceted approaches are required to promote sleep in the ICU to avoid the negative consequences of disrupted sleep (Kamdar et al, 2014; Patel et al, 2014).*

Geriatric

• The interventions described previously are relevant to the geriatric client.

• Reorient high-risk clients frequently, answer questions, and discuss concerns; use a white board, clock, watch, and calendar, and encourage family members to bring familiar objects from home such as family photos or afghan to assist with orientation. **EB:** *Environmental factors may be modified to improve outcomes for clients with delirium (McCusker et al, 2013).*

• Provide cognitive stimulation by discussing current events, reading the newspaper, promoting reminiscence, or using games. **EB:** *Therapeutic activities can minimize cognitive decline (Zaubler et al, 2013).*

• Promote use of glasses, assistive hearing devices, hearing aids, and dentures. **CEB:** *Sensory impairment is a modifiable risk factor for delirium.*

• Provide feeding assistance as needed. See care plan for Imbalanced **Nutrition:** less than body requirements.

- ▲ Determine whether the client is adequately nourished; watch for protein–calorie malnutrition. Consult with health care provider or dietitian as needed. **EB:** *Malnutrition is significantly associated with delirium (Ahmed et al, 2014); attending to correct levels of B vitamins, antioxidants, glucose, water, and lipids may lead to resolution of delirium (Sanford & Flaherty, 2014).*

• Promote adequate hydration; keep a glass of water within easy reach of the client and offer fluids frequently. **EB:** *Keeping a glass of water within reach abated dehydration and delirium in the long-term care population (McCusker et al, 2013).*

• Avoid use of restraints; remove all nonessential equipment such as telemetry, blood pressure cuffs, catheters, and intravenous lines as soon as possible. **CEBN:** *In a study of long-term care residents with dementia, the use of physical restraints was the factor most*

associated with delirium; initiate alternative interventions (Voyer et al, 2011). **EB:** *A study that implemented care programs incorporating gentle persuasive approaches in dementia care was found to reduce adverse events in the care of clients with dementia to include fewer violent client interactions, reduced restraint and sitter use, and fewer client safety events (e.g., falls) (Gillies et al, 2015).*

• Consider use of music to decrease the development of delirium, especially in surgical patients. **EB:** *Listening to music has been found to decrease delirium during acute hospitalization of older clients (Abraha et al, 2015; Cheong et al, 2016).* **CEB:** *Listening to music before and after surgery has been shown to decrease delirium in geriatric patients undergoing elective surgery (McCaffrey & Locsin, 2004).*

• Evaluate all medications for potential to cause or exacerbate delirium; potentially inappropriate medications for older adults at risk for delirium include tricyclic antidepressants, anticholinergics, antipsychotics, benzodiazepines, corticosteroids, H_2 receptor antagonists, and sedative hypnotics. **EB:** *To enhance client safety, medications used for older adults should be routinely assessed for inappropriateness (Beers list) (American Geriatrics Society, 2015).*

• Assess pain frequently and treat pain with the lowest dose of regularly scheduled medication as well as with nonpharmacological approaches; use client self-report or a validated behavioral pain scale to assess pain accurately. **EB:** *Uncontrolled pain can lead to delirium (Stites, 2013).*

▲ Assess risk for falls and implement fall prevention strategies. **EB:** *Geriatric syndromes are more common in older adults with delirium discharged to postacute care facilities; proactively addressing risk factors may improve outcomes (Anderson et al, 2012).*

• Recognize that delirium may be superimposed on dementia; determine client's baseline cognitive status. **EB:** *Dementia increases the risk and severity of delirium (Fong et al, 2015); delirium superimposed on dementia was a strong predictor of decline in function and resultant institutionalization of older adults admitted to a rehabilitation facility (Morandi et al, 2014).*

▲ Determine whether the client is nourished; watch for protein–calorie malnutrition. Consult with health care provider or dietitian as needed. **EB:** *Malnutrition is significantly associated with delirium (Ahmed et al, 2014); attending to correct levels of B vitamins, antioxidants, glucose, water, and lipids may lead to resolution of delirium (Sanford & Flaherty, 2014).*

• Explain hospital routines and procedures slowly and in simple terms; repeat information as necessary.

• Provide continuity of care when possible, avoid room changes, and encourage frequent visits from family members or significant others. **EB:** *Frequent changes may contribute to confusion (O'Mahoney et al, 2011).*

• Educate family members about delirium assessment and strategies to use to prevent and lessen delirium; use the Family Confusion Assessment Method (FAM-CAM) assessment tool to solicit accurate information from caregivers regarding the presence of delirium. **EBN:** *A small pilot study found that forming a trusting and respectful partnership with family caregivers in delirium prevention impacts family and nurse satisfaction (Rosenbloom & Fick, 2013). The FAM-CAM is a sensitive screening tool to assist in the early diagnosis of delirium in individuals with preexisting dementia (Steis et al, 2012).*

• If clients know that they are not thinking clearly, acknowledge the concern. Fear is frequently experienced by people with delirium. **EB:** *Confusion is frightening; the memory of the delirium can be distressing to clients and families (Partridge et al, 2013).*

• The interventions described previously are relevant to home care use. Assess and monitor for acute changes in cognition and behavior. **EB:** *Delirium has an acute onset and fluctuating course, and it is characterized by disordered thinking and a change in behavior (Downing et al, 2013).*
• Recognize that delirium is reversible but can become chronic if untreated in a multidisciplinary fashion; the client may be discharged from the hospital to home care in a state of undiagnosed delirium. **EB:** *Complete recovery may be possible with appropriate multidisciplinary care (Wakefield et al, 2014).*
• Avoid preconceptions about the source of acute confusion; assess each occurrence on the basis of available evidence.
▲ Institute case management of frail elderly clients to support continued independent living if possible once delirium has resolved.

Client/Family Teaching and Discharge Planning

▲ Teach the family to recognize signs of early confusion and seek medical help.
• Counsel the client and family regarding the management of delirium and its sequelae. Increased care requirements at discharge may be needed for clients who have experienced delirium; frailty and delirium can lead to functional decline and institutionalization (Quinlan et al, 2011).

Chronic Confusion

Olga F. Jarrín PhD, RN

NANDA-I

Definition

Irreversible, progressive, insidious, and long-term alteration of intellect, behavior, and personality, manifested by impairment in cognitive functions (memory, speech, language, decision making, and executive function), and dependency in execution of daily activities.

Defining Characteristics

Adequate alertness to surroundings; alteration in at least one cognitive function other than memory; alteration in behavior; alteration in long-term memory; alteration in personality; alteration in short-term memory; alteration in short term functioning; inability to perform at least one daily activity; insidious and irreversible onset in cognitive impairment; long-term cognitive impairment; progressive impairment in cognitive functioning

Associated Condition

Cerebrovascular accident; dementia

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Cognition; Cognitive Orientation; Distorted Thought Self-Control

Example NOC Outcome with Indicators

Cognition as evidenced by the following indicators: Cognitive orientation/Communicates clearly for age/Comprehends the meaning of situations/Attentiveness/Concentration. (Rate the outcome and indicators of **Cognition:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Remain content and free from harm
- Function at maximal cognitive level
- Participate in activities of daily living at the maximum of functional ability
- Have minimal episodes of agitation (agitation occurs in up to 70% of clients with dementia)

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Dementia Management; Environmental Management; Surveillance: Safety; Validation Therapy

Example NIC Activities—Dementia Management

Use distraction rather than confrontation to manage behavior; Give one simple direction at a time

Nursing Interventions and *Rationales*

Note: Nursing science has a rich history of conceptualizing behavioral and psychological symptoms of dementia (including agitation and vocalizations) as expressions of unmet pathophysiological and psychological needs

related to environmental and caregiver factors (Kolanowski et al, 2017).

- Assess the client for delirium (physiological causes of delirium include acute hypoxia, pain, medication effects, malnutrition, and infections such as urinary tract infection, fatigue, electrolyte disturbances, constipation, and urinary retention). **EB:** *Delirium superimposed on dementia (presenting as inattention, and impaired arousal or vigilance) is a common clinical syndrome in hospital and institutional settings that often results in poor outcomes (Morandi et al, 2017).*
- Assess for pain using a method appropriate to the level of cognition. **EBN:** *Pain assessment should include the use of a valid and reliable observer-rated tool such as the Pain Assessment in Advanced Dementia Scale (PAINAD) (Warden et al, 2003) or Rotterdam Elderly Pain Observation Scale (REPOS) (Masman et al, 2018).*
- Assess the client for signs of depression and anxiety (including sadness, irritability, agitation, somatic complaints, tension, loss of concentration, insomnia, poor appetite, apathy, flat affect, and withdrawn behavior) with an instrument appropriate for the cognitive level. **EB:** *The Cornell Scale for Depression in Dementia (CSDD) and Hamilton Depression Rating Scale (HDRS) have the highest sensitivity for screening patients with dementia (Goodarzi et al, 2017). The Geriatric Anxiety Inventory (GAI), Hospital Anxiety and Depression Scale (HADS-A), and Rating Anxiety in Dementia (RAID) scale are reliable and valid instruments for identifying and measuring anxiety in dementia (Creighton et al, 2018).*
- Assess the for psychological stressors, including changes in the environment, caregiver, or routine; demands to perform beyond capacity; or multiple competing stimuli, including discomfort; and encourage communication by addressing the client in a calm, gentle tone of voice, using appropriate body language, facial expressions, and gestures. **EBN:** *Agitated behaviors can be an expression of a need that is not being met; needs assessment is facilitated through methods to enhance communication so that needs may be expressed (Kolanowski et al, 2017).*
- Promote person-centered care through supporting, encouraging, educating, and supervising staff and other caregivers. **EBN:** *Strong evidence supports person-centered approaches; to improve person-centered care nursing managers should target organizational and environmental factors, including a shared philosophy of care, staff use of time, the physical environment, interprofessional support, and support from leaders and colleagues (Jensen & Padilla, 2017; Sjögren et al, 2017).*
- Begin each interaction with the client by gaining and maintaining eye contact, identifying yourself, and calling the client by name. Approach the client with a caring, accepting, and empathetic attitude, and speak calmly and slowly. **CEB:** *Specific communication skills training for caregivers improves the well-being and quality of life in individuals with dementia and increases positive interactions (Eggenberger et al, 2013).*
- Enhance communication with a calm approach; avoid distractions; show interest; keep communication simple; give clear choices and one-step instructions; give the client time with word finding; use repetition and rephrasing; and use gestures, prompts, and cues or visual aids. **CEB:** *These communication techniques assist in focusing attention, incorporate nonverbal means of communication, simplify memory demands, compensate for cognitive slowing, and assist with retrieval and comprehension (Eggenberger et al, 2013).*
- Facilitate the use of music therapy; identify the client's music preferences and interview family members if necessary. **EB:** *Music therapy is beneficial and improves behavior disorders, anxiety, depression, and agitation in people living with dementia (Abraha et al, 2017; Gómez-Romero et al, 2017).*

• Promote regular, supervised physical activity and exercise. **EB:** *The beneficial effect of physical activity on cognitive function is driven by interventions that include aerobic exercise, are independent of the clinical diagnosis, and the frequency of the intervention (Groot et al, 2016).* **EB:** *Physical exercise for 1 hour, 2 to 3 days a week improves strength, balance, mobility, and endurance in people with cognitive impairment and dementia (Lam et al, 2018).*
• Facilitate the use of doll therapy for patients with advanced dementia and challenging behaviors. **EB:** *Doll therapy is associated with reducing cognitive, behavioral, and emotional symptoms of dementia; improving overall well-being; and the ability to relate with an external environment (Ng et al, 2017).*
• Obtain information about the client's life history, interests, routines, needs, and preferences from the family or significant others; collaborate with family members to engage in reminiscence. **EBN:** *Understanding the individual's past and sharing memories enhances communication and client and staff satisfaction (Scales et al, 2018).*
• Provide opportunities for contact with nature gardens or nature-based stimuli, such as facilitating time spent outdoors or indoor gardening. **EBN:** *Improvements in mood among clients with dementia were associated with exposures to nature of relatively short duration (Scales et al, 2018; White et al, 2017).*
• Provide animal-assisted activities when possible. **EBN:** *Animal-assisted activities and interventions (including use of centrally located aquariums) showed a strong positive effect on social behaviors, physical activity, and dietary intake in dementia patients and a positive effect on agitation/aggression and quality of life (Scales et al, 2018; Yakimicki et al, 2018).*
• Use individual or group reminiscence therapy. **EBN:** *Reminiscence therapy can positively affect quality of life, attitudes towards old age, and symptoms of depression in elderly adults with cognitive impairment (Scales et al, 2018; Siverova & Buzgova, 2018).*
• Use the Environmental Audit Tool to evaluate and optimize living environment (provide unobtrusive safety features, reduce unnecessary stimulation, enhance useful stimulation, provide for wandering, etc.). **EB:** *Higher quality of life for people living with dementia is associated with a living environment that is familiar and that provides opportunities for engagement with objects and activities, privacy, and social contact, along with the amenities and opportunities to take part in domestic activities (Fleming et al, 2016; Jensen & Padilla, 2017).*
• Use lighting to support regulation of sleep-wake patterns and associated behavioral issues. **EBN:** *An ambient lighting intervention designed to increase daytime circadian stimulation can be used to increase sleep efficiency in persons with dementia and their caregivers (Abraha et al, 2017; Figueiro et al, 2015).*
• Engage volunteers and family caregivers in one-on-one activities with the client, such as folding, sorting, or stacking activities; arranging flowers; or other hobbies or routines the individual enjoyed before the onset of dementia. **EB:** *Volunteers may be trained to engage clients in meaningful individualized activities to enhance quality of life (Van der Ploeg et al, 2014).*
• Provide information to the patient/resident/client and family regarding advance directives, palliative and hospice care options, and discuss/document goals of care. **EB:** *Discussion of delicate and important end-of-life issues should be discussed with patients early in the course of their illness, when analytic capacity is less likely to be impaired, and decisions regarding goals of care may more accurately reflect their true personal preferences (Abu Snineh et al, 2017).* **EBN:** *Advantages of advanced care planning with dementia include increased communication and documentation about end-of-life care preferences; increased concordance between care preferences documented and provided; and lower rates of unwanted, burdensome treatments at end-of-life (Kim et al, 2015).*
• For clients with memory impairment concerns, refer to the Impaired **Memory** care

plan.
• For clients who wander, refer to the **Wandering** care plan.
• For care of clients with self-care deficits, see the appropriate care plan (Feeding **Self-Care** deficit; Dressing **Self-Care** deficit; Toileting **Self-Care** deficit; Bathing **Self-Care** deficit, etc.).

Geriatric

Note: All interventions are appropriate for geriatric clients.

Multicultural

• Provide culturally and linguistically appropriate care. **EB:** *Linguistic and cultural isolation may cause or worsen agitation in people living with dementia (Cooper et al, 2018).*
• Assess for the influence of cultural beliefs, norms, and values on the client and the family's understanding of chronic confusion or dementia; assist the family or caregiver in identifying and accessing available social services or other supportive services. **EBN:** *In a study of six ethnic groups in the United States, all expressed concern and fear about memory loss, losing independence, and becoming "a burden." American Indians, Chinese Americans, Latinos, and Vietnamese Americans expected memory loss. American Indians, Chinese Americans, and Vietnamese Americans were concerned about the stigma associated with Alzheimer's disease. African Americans, Chinese, and whites expressed concern about genetic risks. African Americans and whites expressed concern about behavior changes (Laditka et al, 2011).* **EB:** *As in many other cultures, in Eastern Mediterranean countries (i.e., Afghanistan, Bahrain, Egypt, Iran, Iraq, Jordan, Kuwait, Lebanon, Morocco, Pakistan, Saudi Arabia, Somalia, Tunisia, United Arab Emirates, Yemen), the older adult is highly respected, and placement outside of the family home is considered an abandonment of family duty. The term dementia carries stigma, and it is widely believed that dementia is caused by "fate" (Yaghmour et al, in press).*

Home Care

Note: Because community-based care is usually less structured than institutional care, in the home setting the goal of maintaining safety for the client takes on primary importance.

• The interventions described previously may be adapted for home care use.
• Assess the home for safety features and client needs for assistive devices. Refer to the care plans for Feeding **Self-Care** deficit; Dressing **Self-Care** deficit; Toileting **Self-Care** deficit; Bathing **Self-Care** deficit, etc., as needed.
• Provide education and support to the family regarding effective communication, home safety, fall prevention, engagement in meaningful activities, ways to manage cognitive and behavioral changes, and comprehensive health care including screening for depression. Be prepared to offer support and information to family members who also live at a distance. **EB:** *The need for care, services, and support for individuals in the community with dementia and their caregivers is often unmet; evaluation and diagnosis of dementia, personal and home safety, physical and mental health care, advanced care planning, and legal issues are needs that should be addressed (Poirier et al, 2018; Roberts & Struckmeyer, 2018).*
• Provide information about respite care to family caregivers. **EB:** *Although many caregivers report that they derive significant emotional and spiritual rewards from their caregiving role, many also experience physical and emotional problems directly related to the stress and demands of daily care. Caregiver resilience can be enhanced through the use of respite programs, including day care, overnight respite, support groups, and counseling*

services (Roberts & Struckmeyer, 2018).

• Reinforce the use of therapeutic communication guidelines. *Home-based behavioral management techniques, caregiver-based interventions in communication skills, and person-centered care with supervision during implementation were found to be effective for symptomatic and severe agitation (Abraha et al, 2017).*

• Assess family caregivers for caregiver stress, loneliness, and depression. Refer to the care plan for **Caregiver Role Strain.**

Client/Family Teaching and Discharge Planning

• In the client's early stages of dementia, provide the caregiver with information on illness processes, needed care, available services, role changes, and importance of advance directives discussion; facilitate family cohesion. **EBN:** *Education provided to caregivers early in the disease trajectory may assist them to anticipate care needs and role changes and to facilitate involving the individual with dementia in care decisions (Abu Snineh et al, 2017; Kim et al, 2015).*

• Provide education and support to the family regarding effective communication, home safety, fall prevention, engagement in meaningful activities, ways to manage cognitive and behavioral changes, and comprehensive health care including screening for depression. Be prepared to offer support and information to family members who also live at a distance. **EB:** *The need for care, services, and support for individuals in the community with dementia and their caregivers is often unmet; evaluation and diagnosis of dementia, personal and home safety, physical and mental health care, advanced care planning, and legal issues are needs that should be addressed (Poirier et al, 2018; Roberts & Struckmeyer, 2018).*

Risk for acute Confusion

Marina Martinez-Kratz MS, RN, CNE

NANDA-I

Definition

Susceptible to reversible disturbances of consciousness, attention, cognition, and perception that develop over a short period of time, which may compromise health.

Risk Factors
Alteration in sleep-wake cycle; dehydration; impaired mobility; inappropriate use of restraints; malnutrition; pain; sensory deprivation; substance misuse; urinary retention

At-Risk Population
Age ≥60 years; history of cerebral vascular accident; male gender

Associated Condition
Alteration in cognitive functioning; delirium; dementia; impaired metabolic functioning; infection; pharmaceutical agent

NIC, NOC, Client Outcomes, Nursing Interventions and *Rationales*, Client/Family Teaching, and References
Refer to care plan for Acute **Confusion**.

Constipation

Amanda Andrews BSc (Hons), MA, Bernie St. Aubyn BSc (Hons), MSc

NANDA-I

Definition
Decrease in normal frequency of defecation accompanied by difficult or incomplete passage of stool and/or passage of excessively hard, dry stool.

Defining Characteristics
Abdominal pain; abdominal tenderness with palpable muscle resistance; abdominal tenderness without palpable muscle resistance; anorexia; atypical presentations in older adults; borborygmi; bright red blood with stool; change in bowel pattern; decrease in stool frequency; decrease in stool volume; distended abdomen; fatigue; hard, formed stool; headache; hyperactive bowel sounds; hypoactive bowl sounds; inability to defecate; increase in intra-abdominal pressure; indigestion; liquid stool; pain with defecation; palpable abdominal mass; palpable rectal mass; percussed abdominal dullness; rectal fullness; rectal pressure; severe flatus; soft, paste-like stool in rectum; straining with defecation; vomiting

Related Factors
Abdominal muscle weakness; average daily physical activity is less than recommended for gender and age; confusion; decrease in gastrointestinal motility; dehydration; depression; eating habit change; emotional disturbance; habitually suppresses urge to defecate; inadequate dietary habits; inadequate oral hygiene; inadequate toileting habits; insufficient fiber intake; insufficient fluid intake; irregular defecation habits; laxative abuse; obesity; recent environmental change

Associated Condition
Electrolyte imbalance; hemorrhoids; Hirschsprung's disease; inadequate dentation; iron salts; neurological impairment; postsurgical bowel obstruction; pregnancy; prostate enlargement; rectal abscess; rectal anal fissure; rectal anal stricture; rectal prolapse; rectal ulcer; rectocele; tumor.

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes
Bowel Elimination; Hydration

Example NOC Outcome with Indicators
Bowel Elimination as evidenced by the following indicators: Elimination pattern/Stool soft and

formed/Passage of stool without aids/Ease of stool passage. (Rate each indicator of **Bowel Elimination:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

Maintain passage of soft, formed stool every 1 to 3 days without straining; State relief from discomfort of constipation; Identify measures that prevent or treat constipation

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Constipation/Impaction Management

Example NIC Activities—Constipation/Impaction Management

Identify factors (e.g., medications, bed rest, diet) that may cause or contribute to constipation/impaction; Institute a toileting schedule, as appropriate

Nursing Interventions and *Rationales*

- Introduce yourself to the client and any companions and inform them of your role. Introducing yourself to a client helps establish and develop a therapeutic relationship that recognizes the person within the client and forms the basis for building trust on which to base the provision of care (Howatson-Jones et al, 2012).
- Gain consent to perform care before proceeding further with the assessment. Clients have the right of autonomy both legally and morally and therefore should be fully involved in the decision-making process (Avery, 2013).
- Wash hands using a recognized technique. **EB:** *Performing strict hand-hygiene regimens significantly reduces the incidence of infection with methicillin-resistant* Staphylococcus aureus *and* Clostridium difficile *infection (Goldberg, 2017).*
- Assess usual pattern of defecation and establish the extent of the constipation problem. **EB:** *A detailed and accurate assessment of the client enables the nurse to plan interventions, monitor outcomes, and evaluate care, ensuring no unnecessary treatment is rendered (Noiesen et al, 2013).*
- Assess the client's bowel habits:
    - ❍ Time of day of bowel evacuation
    - ❍ Amount and frequency of stool
    - ❍ Consistency of stool (using the Bristol Stool Scale)
    - ❍ Bleeding/passing mucus on defecation
    - ❍ History of bowel habits and/or laxative use

Assess usual pattern of defecation, including time of day; amount and frequency of stool; consistency of stool; history of bowel habits or laxative use; and diet, including fiber and fluid intake. A nursing assessment that identifies the client's usual bowel habits will assist in the identification and management of their constipation (Lee, 2015).

- Assess the client's lifestyle factors that may influence constipation:
    - ❍ Fiber content in diet
    - ❍ Daily fluid intake
    - ❍ Exercise patterns
    - ❍ Personal remedies for constipation
    - ❍ Recently stopped smoking

- ❍ Alcohol consumption/recreational drug use

Assess the client's lifestyle factors that may influence or exacerbate constipation (Lee, 2015).

- Review the client's past medical history:
  - ❍ Obstetrical/gynecological/urological history and surgeries
  - ❍ Diseases that affect bowel motility
  - ❍ Bleeding/passing mucous on defecation
  - ❍ Current medications

Review the client's past medical history for conditions that may contribute to constipation, obstetrical/gynecological history, surgeries, diseases that affect bowel motility, alterations in perianal sensation, and the present bowel regimen. It is imperative to establish a nursing history that identifies the client's bowel habits because this will assist in the identification and management of their constipation (Lee, 2015).

- Assess the client for emotional influences that may be contributing to constipation:
  - ❍ Anxiety and depression
  - ❍ Long-term defecation issues
  - ❍ Stress

Consider emotional influences (e.g., depression and anxiety) on defecation. Emotions influence gastrointestinal function, possibly because control of both emotions and gastrointestinal function is located in the limbic system of the brain. Difficulties with defecation often begin in childhood (e.g., during toilet training), and constipation is also associated with sexual and physical abuse, depression, and anxiety. **CEBN:** *In a study, clients with functional constipation were compared with normal controls; subjects with functional constipation had significantly higher anxiety and depression scores (Zhou et al, 2010).*

- Complete a physical examination (palpation for abdominal distention, percussion for dullness, and auscultation for bowel sounds). *A physical examination provides positive and negative findings and may provide the diagnosis without the need for further testing. It may also reveal unsuspected findings or confirm normality (Rhoads & Murphy-Jensen, 2014).*
- Encourage the client or family to keep a 7-day diary of bowel habits to include time of day, length of time spent on the toilet, consistency, amount and frequency of stool, and any straining (using the Bristol Stool Scale). **EB:** *Keeping a diary helps establish a client's bowel pattern and may contribute to the client's adherence to the proposed care plan (Andrews & Morgan, 2013).*
- Encourage the client or family to keep a 7-day diary of lifestyle issues in relation to bowel habits to include fluid consumption, fiber content in diet, usual bowel stimulus, and exercise regimen. **EB:** *Enabling clients to present their condition in their own words ensures that they feel the health care professionals understand their concerns (Smith, 2012).*
- Use the Bristol Stool Scale to assess stool consistency. *The Bristol Stool Scale is widely used as a more objective measure to describe stool consistency (Tack et al, 2011; DerSarkissian, 2017).*
- ▲ Review the client's current medications. *A review of current medication should be requested to include recently started medications and any over-the-counter or herbal medications the client is taking. Medications associated with chronic constipation include opioid analgesics, anticholinergics, antipsychotics, antispasmodics, and calcium channel blockers (Joint Formulary Committee, 2016). This baseline information is key to gaining a comprehensive client assessment (Bardsley, 2017).*
- Discuss with clients already taking opioids (temporarily or long term) that constipation is a common side effect. Advise them to contact their health care

provider for a prescription of an appropriate laxative. *The thorough and comprehensive assessment of clients on opioids experiencing constipation will also allow for a bowel function approach for laxative prescribing rather than one based on the opioid dose alone (Andrews & Morgan, 2012).*

▲ Recognize that opioids cause constipation. If the client is receiving temporary opioids (e.g., for acute postoperative pain), request an order for routine stool softeners from the primary care provider, monitor bowel movements, and request a laxative for the client if constipation develops. If the client is receiving around-the-clock opiates (e.g., for palliative care), laxatives, then softeners, stimulants, or osmotics should be requested. **EB:** *Opioids cause constipation because they decrease propulsive movement in the colon and enhance sphincter tone, making it difficult to defecate. Laxatives are the most common first-line management strategy for opioid-induced constipation because they are low cost and high efficacy (Szigethy et al, 2014).*

▲ If the client is terminally ill and is receiving around-the-clock opioids for palliative care, speak with the prescribing health care provider about ordering low-dose naloxone, which is a drug that blocks opioid effects on the gastrointestinal tract without interfering with analgesia *(Sanders et al, 2015).*

• If new onset of constipation, determine whether the client has recently stopped smoking. **CEB/EB:** *Constipation is common, but usually transient, when people stop smoking (Wilcox et al, 2010). A recent study surveyed 16,840 individuals between 45 and 75 years of age and found that smoking was associated with abdominal pain, bloating, and constipation (Lundstrome et al, 2016).*

• Palpate for abdominal distention, percuss for dullness, and auscultate bowel sounds. *In clients with constipation the abdomen is often distended and tender, and stool in the colon produces a dull percussion sound; however, bowel sounds will be present.*

▲ Check for impaction; if present, then use a combination of oral laxatives and enemas initially to remove fecal loading and impaction (National Institute for Health and Care Excellence, 2015). Clients with neurogenic bowel dysfunction (e.g., spinal cord injury) commonly require manual evacuation of stool (McClurg & Norton, 2016).

▲ Advise a fiber intake of 18 to 25 g daily and suggest foodstuffs high in fiber (e.g., prune juice, leafy green vegetables, whole meal bread and pasta). *Fiber creates bulky feces and stretches the bowel wall to stimulate peristalsis, thus shortening bowel transit time (Bardsley, 2017).*

• Add fiber gradually to the diet to decrease bloating and flatus. *Larger stools move through the colon faster than smaller stools, and dietary fiber makes stools bigger because it is undigested in the upper intestinal tract. A study by Lawton et al (2013) looked into whether increasing insoluble fiber improved digestive feelings, well-being, and bowel function. The study found significant improvement in ease of defecation, bloating and digestive discomfort, and the client's perception of general well-being.*

• Provide prunes or prune juice daily. Each 100 g of prunes contains about 6 g of fiber, 15 g of sorbitol, and 184 mg of polyphenol, which all have laxative effects (Attaluri et al, 2011). **CEB:** *In a randomized study, dried prunes produced significantly more complete spontaneous bowel movements per week than psyllium, and both treatments produced significantly more complete spontaneous bowel movements than at baseline (Attaluri et al, 2011).*

• Advise a fluid intake of 1.5 to 2 L of fluid per day (ideally, 6–8 glasses of water), unless contraindicated by comorbidities, such as kidney or heart disease. *Water passes into the gut to promote the formation of a softer fecal mass and provides lubrication to prevent a blockage of the gut (Boyle, 2013).*

▲ If the client is uncomfortable or in pain because of constipation or has acute or

chronic constipation that does not respond to increased fiber, fluid, activity, and appropriate toileting, refer the client to the primary care provider for an evaluation of bowel function and health status. *The main aim of referral is to rule out any serious causes of changes in bowel habits, e.g., the presence of tumors, old scarring, and megacolon. The use of red flags (anemia, rectal bleeding, and a family history of bowel cancer or inflammatory bowel disease) are commonly used in general practice to identify the need for further referral (Lee, 2015).*

• Encourage physical activity within the client's current ability to mobilize. Encourage turning and changing position in bed if immobile. For clients with reduced mobility, encourage knee to chest raises, waist twists, and stretching the arms away from the body. For fully mobile clients, encourage walking and swimming. *Physical activity can help stimulate peristaltic waves in the colon and encourage the transit of feces to the rectum (Rogers, 2013).*

• Demonstrate the use of gentle external abdominal massage, using aroma therapy oils, following the direction of colon activity. *Abdominal massage encourages rectal loading by increasing intraabdominal pressure and, in some cases, it may elicit rectal waves, which may stimulate the somatoautonomic reflex and enhance bowel sensation (McClurg et al, 2011).*

• Recommend that clients establish a regular elimination routine. If required assist clients to the bathroom at the same time every day; always be mindful of the need for privacy (closing of bathroom doors). *Establishing a routine allows for the use of the gastrocolic reflex, especially in the morning, which aids defecation (Rogers, 2013).*

• Provide privacy for defecation. If not contraindicated, help the client to the bathroom and close the door. *Bowel elimination is a private act in Western cultures, and a lack of privacy can hinder the defecation urge, thus contributing to constipation.*

• Help clients onto a bedside commode or toilet so they can either squat or lean forward while sitting. Recognize that it is difficult to impossible to defecate in the lying supine position. Sitting upright allows gravity to aid defecation. **CEB/EB:** *A study of men found that flexing the hip to 90 degrees or more straightens the angle between the anus and the rectum and pulls the anal canal open, decreasing the resistance to the movement of feces from the rectum and the amount of pressure needed to empty the rectum. Hip flexion is greatest when squatting or when leaning forward while sitting (Tagart, 1966; Clark & Currow 2014).*

• Educate the client about how to adopt the best posture for defecation. Keep knees slightly higher than hips, keep feet flat on the floor, and lean forward putting elbows onto knees. **EB:** *Adopting the correct position to open one's bowels allows the angle of the rectum and anal canal to straighten out. This facilitates an increase in abdominal pressure, which makes defecation more effective (Rogers, 2013).*

• Teach clients about the importance of responding promptly to the urge to defecate. **EB:** *The body's natural "call to stool" should be heeded in that it is a response to the stimulation of nerve endings in the rectum when a stool is present. Ignoring this urge will result in the rectum becoming desensitized to a stool in situ (Coggrave et al, 2014).*

• Consider the use of laxatives, suppositories, enemas, and bowel irrigation as required if other more natural interventions are not effective. *Laxative therapies can be used in conjunction with lifestyle changes (while waiting for the lifestyle changes to take effect or if the change is not sufficient in itself) (Marples, 2011).*

• Discourage the use of long-term laxatives and enemas and advise clients to gradually reduce their use if taken regularly. *Long-term use or overuse of laxatives can cause health problems (e.g., electrolyte imbalance) or hide symptoms that may be from a serious medical condition, such as cardiac arrhythmias (Aschenbrenner, 2014).*

Geriatric

- Assess older adults for the presence of factors that contribute to constipation, including dietary fiber and fluid intake (less than 1.5 L/day), physical activity, use of constipating medications, and diseases that are associated with constipation.
- Explain the importance of adequate fiber intake, fluid intake, activity, and established toileting routines to ensure soft, formed stool. **EB:** *Strong evidence exists for the efficacy of adequate hydration (Gandell et al, 2013) and dietary fiber (Bardsley, 2017) in the prevention of constipation in older adults. Evidence suggests that the majority of clients would respond to lifestyle modifications reinforced by bowel training measures (De Giorgio et al, 2015).*
- Determine the client's perception of normal bowel elimination and laxative use; promote adherence to a regular schedule. **EB:** *A systematic review on older people's experiences of living with constipation showed that older people had individual and personal strategies relative to their own beliefs. Clients reported bodily experiences of everyday life shadowed by constipation and adverse psychological effects, which need to be explored to prevent and treat constipation (Tvistholm et al, 2017).*
- Explain why straining (Valsalva maneuver) should be avoided. *Excessive straining can cause syncope or cardiac dysrhythmias in susceptible people (Pstras et al, 2016).*
- Respond quickly to the client's call for assistance with toileting.
- Offer food, fluids, activity, and toileting opportunities to older clients who are cognitively impaired. *Even cognitively impaired individuals who are unable to initiate a request for food, fluids, and so forth may respond when opportunities are offered.* **CEB:** *In a randomized controlled trial (RCT) involving nursing home residents, subjects who received the treatment protocol (offering of food, fluid, activity, and toileting opportunities) had significantly more bowel movements than the control group. Both cognitively intact and cognitively impaired subjects benefited from the treatment (Schnelle et al, 2010).*
- Avoid regular use of enemas in older adults. *Enemas can cause fluid and electrolyte imbalances and damage to the colonic mucosa. However, judicious enema use may help prevent impactions (De Giorgio et al, 2015).*
- Advise the client against attempting to remove impacted feces on his or her own. *Older or confused clients in particular may attempt to remove feces and cause rectal damage.*
- ▲ Use opioids cautiously. Opioids cause constipation (Andrews & Morgan, 2013).
- Position the client on the toilet or commode and place a small footstool under the feet. Placing a small footstool helps the client assume a squatting posture to facilitate defecation.

Home Care

- The interventions described previously may be adapted for home care use.
- Take complaints seriously and evaluate claims of constipation in a matter-of-fact manner. *Continued constipation can lead to bowel obstruction, which is a medical emergency. Use of a matter-of-fact manner will limit positive reinforcement of the behavior if actual constipation does not exist. Refer to the care plan for Perceived **Constipation**.*
- Assess the self-care management activities the client is already using. **EB:** *Many older adults seek solutions to constipation, with laxative use a frequent remedy that creates its own problems (Tvistholm et al, 2017).*
- Offer the following treatment recommendations:
    - ❍ Acknowledge the client's lifelong experience of bowel function; respect

beliefs, attitudes, and preferences, and avoid patronizing responses.
- ❍ Make available comprehensive, useful written information about constipation and possible solutions.
- ❍ Make available empathetic and accessible professional care to provide treatment and advice; a multidisciplinary approach (including health care provider, nurse, and pharmacist) should be used.
- ❍ Institute a bowel management program.
- ❍ Consider affordability when suggesting solutions to constipation; discuss cost-effective strategies.
- ❍ Discuss a range of solutions to constipation and allow the client to choose the preferred options.
- ❍ Have orders in place for a suppository and enema as needed. As part of a bowel management program, suppositories or enemas may become necessary.

• Although the use of a bedside commode may be necessitated by the client's condition, allow the client to use the toilet in the bathroom when possible and provide assistance. *Bowel elimination is a private act, and a lack of privacy can contribute to constipation.*
• In older clients, routinely advise consumption of fluids, fruits, and vegetables as part of the diet, and ambulation if the client is able. *Introduce a bowel management program at the first sign of constipation. Constipation is a major problem for terminally ill or hospice clients who may need very high doses of opioids for pain management.*
▲ Refer for consideration of the use of polyethylene glycol 3350 (PEG-3350) for constipation. *There is good evidence to support the use of PEG-3350 for both chronic constipation and constipation associated with irritable bowel syndrome (Chapman et al, 2013).*
• When using a bowel program, establish a pattern that is very regular and allows the client to be part of the family unit. *Regularity of the program promotes psychological and/or physiological readiness to evacuate stool. Families of home care clients often cannot proceed with normal daily activities until bowel programs are complete.*

Client/Family Teaching and Discharge Planning

• Instruct the client on normal bowel function and the need for adequate fluid and fiber intake, activity, and a defined toileting pattern in a bowel program.
• Encourage the client to heed defecation warning signs and develop a regular schedule of defecation by using a stimulus such as a warm drink or prune juice. *Most cases of constipation are mechanical and result from habitual neglect of impulses that signal the appropriate time for defecation.*
• Encourage the client to avoid long-term use of laxatives and enemas and to gradually withdraw from their use if they are used regularly. *Use of stimulant laxatives should be avoided; long-term use can result in dependence on laxative for defecation (Roerig et al, 2010).*
• If not contraindicated, teach the client how to do bent-leg sit-ups to increase abdominal tone; also encourage the client to contract the abdominal muscles frequently throughout the day. Help the client develop a daily exercise program to increase peristalsis.
• Provide client with comprehensive written information about constipation and its management. **EB:** *Providing clients with well-written, evidence-based information about their condition and treatment can have a beneficial effect on the outcomes of treatment. In addition, clients are more likely to retain important information that will assist them in*

making informed decisions about their care (Coulter, 2011).

▲ Collaborate with members of the interprofessional team to provide treatment and advice to clients and caregivers. Teamwork is a central process in health care organizations. It increases the capacity of teams to absorb and develop new knowledge, which will improve client health and well-being (Ortega et al, 2013).

• Formalize all advice by providing a bowel management program reiterating the mechanism of normal bowel function and the need for adequate fluid and fiber intake, physical activity, and a defined toileting pattern in an agreed bowel program. **EB:** *The implementation of an organized bowel management program is effective and significantly reduces hospital admissions in clients with severe idiopathic constipation (Russell et al, 2013).*

• Document all care and advice given in a factual and comprehensive manner. *Good record keeping is an integral part of nursing practice and is essential to the provision of safe and effective care (St. Aubyn & Andrews, 2015).*

Risk for Constipation

Mary Beth Flynn Makic PhD, RN, CCNS, FAAN, FNAP

NANDA-I

Definition

Susceptible to a decrease in normal frequency of defecation accompanied by difficult or incomplete passage of stool, which may compromise health.

Risk Factors

Abdominal muscle weakness; average daily physical activity is less than recommended for gender and age; confusion; decrease in gastrointestinal motility; dehydration; depression; eating habit change; emotional disturbance; habitually suppresses urge to defecate; inadequate dietary habits; inadequate oral hygiene; inadequate toileting habits; insufficient fiber intake; insufficient fluid intake; irregular defecation habits; laxative abuse; obesity; recent environmental change

Associated Condition

Electrolyte imbalance; hemorrhoids; Hirschsprung's disease; inadequate dentition; iron salts; neurological impairment; postsurgical obstruction; pregnancy; prostate enlargement; rectal abscess; rectal anal fissure; rectal

anal stricture; rectal prolapse; rectal ulcer; rectocele; tumor

NIC, NOC, Client Outcomes, Nursing Interventions and *Rationales*, Client/Family Teaching, and References

Refer to care plan for **Constipation**.

Perceived Constipation

Amanda Andrews BSc (Hons), MA, Bernie St. Aubyn BSc (Hons), MSc

NANDA-I

Definition

Self-diagnosis of constipation combined with abuse of laxatives, enemas, and/or suppositories to ensure a daily bowel movement.

Defining Characteristics

Enema abuse; expects a daily bowel movement; expects daily bowel movement at same time every day; laxative abuse; suppository abuse

Related Factors

Cultural health beliefs; family health beliefs; impaired thought process

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Bowel Elimination; Health Beliefs; Health Beliefs: Perceived Threat

Example NOC Outcome with Indicators

Bowel Elimination as evidenced by the following indicators: Elimination pattern/Stool soft and formed/Passage of stool without aids/Ease of stool passage. (Rate each indicator of **Bowel Elimination:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Regularly defecate soft, formed stool without use of aids
- Explain the need to decrease or eliminate the use of stimulant laxatives, suppositories, and enemas
- Identify alternatives to stimulant laxatives, enemas, and suppositories for ensuring defecation
- Explain that defecation does not have to occur every day

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Bowel Management; Medication Management

Example NIC Activities—Bowel Management

Note preexistent bowel problems, bowel routine, and use of laxatives; Initiate a bowel training program, as appropriate

Nursing Interventions and *Rationales*

- Introduce yourself to the client and any companions, and inform them of your role. *Introducing yourself to a client helps establish and develop a therapeutic relationship that recognizes the person within the client and forms the bases for building trust on which to base the provision of care (Howatson-Jones et al, 2012).*
- Gain consent before proceeding further with the assessment. *Clients have the right of autonomy both legally and morally and therefore should be fully involved in the decision-making process (Avery, 2013).*
- Wash hands using a recognized technique. **EB:** *Performing strict hand-hygiene regimens significantly reduces the incidence of infection with methicillin-resistant* Staphylococcus aureus *and* Clostridium difficile *infections (Goldberg, 2017).*
- Assess usual pattern of defecation and establish the extent of the perceived constipation problem to include:
  - Assess the client's bowel habits
    - Time of day
    - Amount and frequency of stool
    - Consistency of stool (using the Bristol Stool Scale)
    - Bleeding/passing mucus on defecation
    - Patient history of bowel habits and/or laxative use
    - Family history of bowel habits and/or laxative use

EB: *A detailed and accurate assessment of the patient enables the nurse to plan interventions, monitor outcomes, and evaluate care, ensuring no unnecessary treatment is rendered (Noiesen et al, 2013).*

  - Assess the client's lifestyle that may impact bowel function
    - Fiber content in diet
    - Daily fluid intake
    - Exercise patterns
    - Personal remedies for constipation
    - Cultural remedies for constipation
    - Recently stopped smoking
    - Alcohol consumption/recreational drug use

EB: *One of the key causes of constipation is dehydration of stools. A lack of water in the bowel leads to hard fecal matter, which is difficult to pass (Bardsley, 2017). Alcohol has a dehydrating effect on the body.*

  - Review the client's past medical history
    - Obstetrical/gynecological/urological history and surgeries
    - Diseases that affect bowel motility
    - Bleeding/passing mucus on defecation
    - Current medications

EB: *Review the client's past medical history for conditions that may contribute to constipation, obstetrical/gynecological history, surgeries, diseases that affect bowel motility, alterations in perianal sensation, and the present bowel regimen (Lee, 2015).*

  - Emotional influences
    - Anxiety and depression/psychological disorders
    - History of eating disorders
    - History of physical/or sexual abuse
    - Long-term defecation issues

❍ Stress

EB: *Clients' psychological reactions to the experience of constipation change over time. Anxiety and fear about the anticipated health-related consequences of constipation are often expressed. The absence of a bowel movement or the failure of constipation treatment can lead to anxiety and depression (Dhingra et al, 2012).* **EB:** *Stress can alter the mucosal immune function of the central nervous system. This causes afferent signals to the gut to be reduced, causing constipation (Drossman, 2016).*

• Encourage the client or family to keep a 7-day diary of bowel habits to include time of day, length of time spent on the toilet, consistency, amount and frequency of stool, and any straining (using the Bristol Stool Scale). **EB:** *Keeping a diary helps establish a patient's bowel pattern and may contribute to the patient's adherence to the proposed care plan (Andrews & Morgan, 2013).*
• Encourage the client or family to keep a 7-day diary of lifestyle issues in relation to bowel habits to include fluid consumption, fiber content in diet, usual bowel stimulus, and exercise regimen. **EB:** *Enabling patients to present their condition in their own words ensures that they feel the health care professionals understand their concerns (Smith, 2012).*
• Educate the client that it is not necessary to have a daily bowel movement. **EB:** *A healthy bowel function can vary from three stools each day to three stools each week. The criteria of choice used for establishing a diagnosis of constipation are often the Rome IV criteria. The criteria-based definition calls for the presence of two or more of the symptoms for at least 3 months for a definition of constipation (Drossman, 2016).*
• Encourage the client to record use of laxatives, suppositories, or enemas, and suggest replacing them with an increase in fluid and fiber intake. **EB:** *Overtreatment with laxatives can result in iatrogenic diarrhea, which can lead to dehydration, delirium, and the false-positive labeling and unnecessary treatment of* C. difficile *carriers. This can result in increased morbidity and mortality, and a longer stay in hospital. By improving the assessment and treatment of constipation, patient outcomes should improve, resulting in significant hospital cost savings (Linton, 2014).*
• Advise a fiber intake of 18 to 30 g daily in adults and suggest foodstuffs high in fiber (e.g., prune juice, leafy green vegetables, whole meal bread and pasta). *Fiber creates bulky feces and stretches the bowel wall to stimulate peristalsis, thus shortening bowel transit time (Bardsley, 2017). For further information on use of fiber, please refer to the care plan for* ***Constipation.***
• Advise a fluid intake of 1.5 to 2 L of fluid per day (ideally, 6–8 glasses of water), unless contraindicated by comorbidities, such as kidney or heart disease. *Water passes into the gut to promote the formation of a softer fecal mass and provides lubrication to prevent a blockage of the gut (Boyle, 2013).*
• Obtain a referral to a dietitian for analysis of the client's diet and fluid intake to provide strategies to improve diet and nutrition.
• Encourage physical activity within the client's current ability to mobilize. Encourage turning and changing position in bed if immobile. For clients with reduced mobility, encourage knee to chest raises, waist twists, and stretching the arms away from the body. For fully mobile clients, encourage walking and swimming. *Physical activity can help stimulate peristaltic waves in the colon and encourage the transit of feces to the rectum (Rogers, 2013).*
• Demonstrate the use of gentle external abdominal massage, using aroma therapy oils, following the direction of colon activity. *Abdominal massage encourages rectal loading by increasing intraabdominal pressure and in some cases it may elicit rectal waves, which may stimulate the somatoautonomic reflex and enhance bowel sensation (Turan and*

Atabek Aşt, 2016).

• Recommend clients establish a regular elimination routine. If required assist clients to the bathroom at the same time every day being mindful of the need for privacy (closing of bathroom doors). *Establishing a routine allows for the use of the gastrocolic reflex, especially in the morning, which aids in defecation (Rogers, 2013).*

• Observe for the presence of an eating disorder by using laxatives to control or decrease weight; refer for counseling if needed. *People with eating disorders suffer from constipation and other gastrointestinal symptoms, or use laxatives as part of inducing weight loss (Sato & Fukudo, 2015).*

• Observe family cultural patterns related to eating and bowel habits. Cultural patterns may control bowel habits.

Client/Family Teaching and Discharge Planning

• Provide education to the client on ways to adopt the best posture for defecation. Keep knees slightly higher than hips, keep feet flat on the floor and lean forward putting elbows onto knees. *Adopting the correct position to open one's bowels allows the angle of the rectum and anal canal to straighten out. This facilitates an increase in abdominal pressure, which makes defecation more effective (Rogers, 2013).*

• Teach clients the importance of responding promptly to the urge to defecate. **EB:** *The body's natural "call to stool" should be heeded in that it is a response to the stimulation of nerve endings in the rectum when a stool is present. Ignoring this urge will result in the rectum becoming desensitized to a stool in situ (Coggrave et al, 2014).*

• Discourage the use of long-term laxatives and enemas and explain the potential harmful effects of the continual use of defecation aids such as laxatives and enemas. **EB:** *"Lazy bowel syndrome" may occur if laxatives are used too frequently, causing the bowel to become dependent on laxatives to stimulate a bowel movement. Overuse of laxatives can also lead to poor absorption of vitamins and other nutrients, and to damage of the gastrointestinal tract (Elran-Barak et al, 2017).*

• Advise clients to gradually reduce their use of laxatives, if taken regularly, which may take months to achieve. *Long-term use or overuse of laxatives can cause health problems (e.g., electrolyte imbalance) or hide symptoms that may be from a serious medical condition, such as cardiac arrhythmias (Aschenbrenner, 2014).*

• Provide client with comprehensive written information about constipation and its management. **EB:** *Providing patients with well-written, evidence-based information about their condition and treatment can have a beneficial effect on the outcomes of treatment. In addition, patients are more likely to retain important information that will assist them in making informed decisions about their care (Coulter, 2011).*

• Collaborate with members of the interprofessional team to provide treatment and advice to clients and caregivers. *Teamwork is a central process in health care organizations. It increases the capacity of teams to absorb and develop new knowledge, which will improve patient health and well-being (Ortega et al, 2013).*

• Formalize all advice by providing a bowel management program reiterating the mechanism of normal bowel function and the need for adequate fluid and fiber intake, physical activity, and a defined toileting pattern in an agreed bowel program. **EB:** *The implementation of an organized bowel management program is effective and significantly reduces hospital admissions in patients with severe idiopathic constipation (Russell et al, 2013).*

• Document all care and advice given in a factual and comprehensive manner. *Good record keeping is an integral part of nursing practice and is essential to the provision of safe*

and effective care (St. Aubyn & Andrews, 2015).

Chronic functional Constipation

Amanda Andrews BSc (Hons), MA, Bernie St. Aubyn BSc (Hons), MSc

NANDA-I

Definition

Infrequent or difficult evacuation of feces, which has been present for at least three of the prior 12 months.

Defining Characteristics

Adult: Presence of ≥2 of the following symptoms on Rome III classification system:

Lumpy or hard stools in ≥25% defecations; straining during ≥25% of defecations; sensation of incomplete evacuation for ≥25% of defecations; sensation of anorectal obstruction/blockage for ≥25% of defecations; manual maneuvers to facilitate ≥25% of defecations (digital manipulation, pelvic floor support); ≤3 evacuations per week

Child >4 years; Presence of ≥2 criteria on the Rome III Pediatric classification system for ≥2 months:

≤2 defecations per week; ≥1 episode of fecal incontinence per week; stool retentive posturing; painful or hard bowel movements; presence of large fecal mass in the rectum; large diameter stools that may obstruct the toilet

Child ≤4 years; Presence of ≥2 criteria on the Rome III Pediatric classification system for ≥1 month:

≤2 defecations per week; ≥1 episode of fecal incontinence per week; stool retentive posturing; painful or hard bowel movements; presence of large fecal mass in the rectum; large diameter stools that may obstruct the toilet

General

Distended abdomen; fecal impaction; leakage of stool with digital stimulation; pain with defecation; palpable abdominal mass; positive fecal occult blood test; prolonged straining; type 1 or 2 on Bristol Stool Chart

Related Factors

Decrease in food intake; dehydration; depression; diet disproportionally high in fat; diet disproportionally high in protein; frail elderly syndrome; habitually suppresses urge to defecate; impaired mobility; insufficient dietary intake; insufficient fluid intake; insufficient knowledge of modifiable factors; low caloric intake; low-fiber diet; sedentary lifestyle

Associated Condition

Amyloidosis; anal fissure; anal stricture; autonomic neuropathy; cerebral vascular accident; chronic intestinal pseudoobstruction; chronic renal insufficiency; colorectal cancer; dementia; dermatomyositis; diabetes mellitus; extra intestinal mass; hemorrhoids; Hirschsprung's disease; hypercalcemia; hypothyroidism; inflammatory bowel disease; ischemic stenosis; multiple sclerosis; myotonic dystrophy; panhypopituitarism; paraplegia; Parkinson's disease; pelvic floor dysfunction; perineal damage; pharmaceutical agent; polypharmacy; porphyria; postinflammatory stenosis; pregnancy; proctitis; scleroderma; slow colon transit time; spinal cord injury; surgical stenosis

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Bowel Elimination; Symptom Severity

Example NOC Outcome with Indicators

Bowel Elimination as evidenced by the following indicators: Elimination pattern/Stool soft and formed/Passage of stool without aids/Ease of stool passage. (Rate each indicator of **Bowel Elimination:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Maintain passage of soft, formed stool every 1 to 3 days without straining
- State relief from discomfort of constipation
- Identify measures that prevent or treat constipation

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Constipation/Impaction Management

Example NIC Activities—Constipation/Impaction Management

Identify factors (e.g., medications, bed rest, diet) that may cause or contribute to constipation/impaction; Institute a toileting schedule, as appropriate

Nursing Interventions and *Rationales*

All Client Ages

- Introduce yourself to the client and anyone accompanying him or her and inform them of your role. Introducing yourself to a client helps establish and develop a therapeutic relationship that recognizes the person within the client and forms the basis for building trust on which to base the provision of care (Howatson-Jones et al, 2012).
- Gain consent to provide care before proceeding further with the assessment. Clients have the right of autonomy both legally and morally and therefore should be fully involved in the decision-making process (Avery, 2013).
- Wash hands using a recognized technique. Strict hand-hygiene regimens significantly reduce the incidence of methicillin-resistant *Staphylococcus aureus* and *Clostridium difficile* infection (Goldberg, 2017).
- Assess usual pattern of defecation and establish the extent of the constipation problem to include:
  - Assess bowel habits
    - Time of day
    - Amount and frequency of stool
    - Consistency of stool (using the Bristol Stool Scale)
    - Bleeding/passing mucus on defecation
    - History of bowel habits and/or laxative use
    - Assess children younger than 4 years using the Rome III pediatric classification (for at least 1 month)
    - Assess children older than age 4 years using the Rome III pediatric classification (for at least 2 months)

EB: *Assess adults using the Rome IV classification. The Rome Foundation updated the criteria with the release of Rome IV criteria, devised in 2016, which specify that clients must be symptomatic with at least two or more of the criteria that are relevant to their specific age range (Drossman, 2016).*

  - Assess the client's lifestyle that may impact bowel function
    - Fiber content in diet
    - Daily fluid intake
    - Exercise patterns
    - Personal remedies for constipation
    - Recently stopped smoking
    - Alcohol consumption/recreational drug use
    - Personal habits related to defecation

EB: *Alcohol has a dehydrating effect on the body. One of the key causes of constipation is dehydration of stools. A lack of water in the bowel leads to hard fecal matter, which is difficult to pass (Bardsley, 2017). A detailed and accurate assessment of the patient enables the nurse to plan interventions, monitor outcomes, and evaluate care, ensuring no unnecessary treatment is rendered (Noiesen et al, 2013).*

  - Review the client's past medical history
    - Obstetrical/gynecological/urological history and surgeries
    - Existing anatomical anomalies (e.g., anal fissures, anal strictures and hemorrhoids)
    - Diseases that affect bowel motility (e.g., colorectal cancer, chronic intestinal pseudoobstruction and Hirschsprung's disease)

- ❍ Bleeding/passing mucus on defecation
- ❍ Current medications

EB: *Established algorithms and guidelines recommend that secondary pathology and causes of constipation are identified and first excluded before moving on to assessment of diet and lifestyle issues (Tack et al, 2011).*

- ▲ Emotional influences
  - ❍ Anxiety and depression
  - ❍ Long-term defecation issues
  - ❍ Stress

EB: *A detailed and accurate assessment of the client enables the nurse to plan interventions, monitor outcomes, and evaluate care, ensuring no unnecessary treatment is performed (Noiesen et al, 2013). Stress can alter the mucosal immune function of the central nervous system. This causes afferent signals to the gut to be reduced, causing constipation (Drossman, 2016).*

• Complete a physical assessment (palpation for abdominal distention; percussion for dullness; auscultation for bowel sounds; and observation for anal fissures, anal strictures, and hemorrhoids). *A physical examination provides positive and negative findings and may provide the diagnosis without the need for further testing. It may also reveal unsuspected findings or confirm normality (Rhoads & Murphy-Jensen, 2014).*
• Encourage the client or family to keep a 7-day diary of bowel habits to include time of day, length of time spent on the toilet, consistency, amount and frequency of stool, and any straining (using the Bristol Stool Scale). *Keeping a diary helps establish a client's bowel pattern and may contribute to the client's adherence to the proposed care plan (Andrews & Morgan, 2013).*
• Encourage the client or family to keep a 7-day diary of lifestyle issues in relation to bowel habits to include fluid consumption, fiber content in diet, usual bowel stimulus, and exercise regime. *Enabling clients to present their condition in their own words ensures that they feel the health care professionals understand their concerns (Smith, 2012).*
• Actively encourage the use of reward/star charts with children when establishing regular bowel routines. *Research highlights that children respond better to positive enforcement when learning to manage constipation with regular toileting rather than confrontation about the problem (Afzal et al, 2011).*
• Discuss with clients already taking opioids (temporarily or long term) that constipation is a common side effect. Advise the client to contact their primary health care provider for a prescription of an appropriate laxative. *The thorough and comprehensive assessment of clients on opioids experiencing constipation will also allow for a bowel function approach for laxative prescribing rather than one based on the opioid dose alone (Andrews & Morgan, 2012).*
• Advise a fiber intake of 18 to 30 g of fiber daily in adults and suggest foodstuffs to facilitate this diet (e.g., prune juice, leafy green vegetables, whole meal bread and pasta). *Fiber creates bulky feces and stretches the bowel wall to stimulate peristalsis, thus shortening bowel transit time (Bardsley, 2017).*
• Advise a fluid intake of 1.5 to 2 L of fluid per day (ideally, 6–8 glasses of water), unless this is contraindicated by comorbidities such as renal or heart disease. *Water passes into the gut to promote the formation of a softer fecal mass and provides lubrication to prevent a blockage of the gut (Boyle, 2013).*
• Encourage physical activity within the client's current ability to mobilize. Encourage turning and changing position in bed if immobile. For reduced mobility clients,

encourage knee to chest raises, waist twists, and stretching the arms away from the body. For fully mobile clients, encourage walking and swimming. *Physical activity can help stimulate peristaltic waves in the colon and encourage the transit of feces to the rectum (Rogers, 2013).*

• Demonstrate the use of gentle external abdominal massage, following the direction of colon activity. **EB:** *A random control trial established that patients who received abdominal massage experienced reduced symptoms of constipation and an improved quality of life (Turan & Atabek Aşt, 2016).*

• Recommend clients establish a regular elimination routine. If required, assist clients to the bathroom at the same time every day, being mindful of the need for privacy (closing of bathroom doors). *Establishing a routine allows for the use of the gastrocolic reflex, especially in the morning, which aids defecation (Rogers, 2013).*

• Educate the client in how to adopt the best posture for defecation: keep knees slightly higher than hips, keep feet flat on the floor and lean forward, putting elbows onto knees. *Adopting the correct position to open one's bowels allows the angle of the rectum and anal canal to straighten. This facilitates an increase in abdominal pressure, which makes defecation more effective (Rogers, 2013).*

• Consider the teaching of biofeedback therapy to encourage a "new normal" bowel routine for clients to adopt. **EB:** *A recent literature review concluded that the use of biofeedback therapy in chronic constipation was successful and remains the safest option to successfully manage chronic constipation (Chiarioni, 2016).*

• Teach clients about the need to respond promptly to the defecation urge. **EB:** *The body's natural "call to stool" should be heeded because it is a response to the stimulation of nerve endings in the rectum when a stool is present. Ignoring this urge results in the rectum becoming desensitized to a stool in situ (Coggrave et al, 2014).*

• Consider the use of laxatives, suppositories, enemas, and bowel irrigation as required when other more natural interventions are not effective. **EB:** *Laxative therapies can be used in conjunction with lifestyle changes (while waiting for the lifestyle changes to take effect or if the change is not sufficient in itself) (Bardsley, 2017). Bowel irrigation is thought to both stimulate colonic reflex and act as a mechanical bowel washout. It has been acknowledged as a minimally invasive technique with proven clinical benefit to the patient (Holroyd, 2014).*

• Discourage the use of long-term laxatives and enemas and advise clients to gradually reduce their use if taken regularly. *Long-term use or overuse of laxatives can cause health problems (e.g., electrolyte imbalance) or hide symptoms of a serious medical condition, such as cardiac arrhythmias (Aschenbrenner, 2014).*

• Provide client with comprehensive written information about constipation and its management. **EB:** *Research shows that providing clients with well-written evidence-based information about their condition and treatment can have a beneficial effect on the outcomes of treatment. In addition, clients are more likely to retain important information that will assist them in making informed decisions about their care (Coulter, 2011).*

• Provide written instructions for children about taking their medication and about how the bowel works. *Written clear information provided to children with chronic functional constipation will help them understand and therefore recognize when they are at risk for constipation recurrence (National Institute for Health and Care Excellence, 2017).*

• Liaise with members of the interprofessional team as appropriate to provide treatment and advice to clients and caregivers. *Teamwork is a central process in health care organizations. It increases the capacity of teams to absorb and develop new knowledge, which will improve clients' health and well-being (Ortega et al, 2013).*

• Educate the client on the mechanism of normal bowel function and the need for

adequate fluid and fiber intake, physical activity, and a defined toileting pattern in an agreed-on bowel management program. *The implementation of an organized bowel management program is effective and significantly reduces hospital admissions in clients with severe idiopathic constipation (Russell et al, 2013).*

• Document all care and advice given in a factual and comprehensive manner. *Good record keeping is an integral part of nursing practice and is essential to the provision of safe and effective care (St. Aubyn & Andrews, 2015).*

Risk for chronic functional Constipation

Mary Beth Flynn Makic PhD, RN, CCNS, FAAN, FNAP

NANDA-I

Definition

Susceptible to infrequent or difficult evacuation of feces, which has been present nearly 3 of the prior 12 months, which may compromise health.

Risk Factors

Decrease in food intake; dehydration; depression; diet proportionally high in fat; diet disproportionally high in protein; frail elderly syndrome; habitually suppresses urge to defecate; impaired mobility; insufficient dietary intake; insufficient fluid intake; insufficient knowledge of modifiable factors; low caloric intake; low-fiber diet; sedentary lifestyle

Associated Condition

Amyloidosis; anal fissure; anal stricture; autonomic neuropathy; cerebral vascular accident; chronic intestinal pseudoobstruction; chronic renal insufficiency; colorectal cancer; dementia; dermatomyositis; diabetes mellitus; extra intestinal mass; hemorrhoids; Hirschsprung's disease; hypercalcemia; hypothyroidism; inflammatory bowel disease; ischemic stenosis; multiple sclerosis; myotonic dystrophy; panhypopituitarism; paraplegia; Parkinson's disease; pelvic floor dysfunction; perineal damage; pharmaceutical agent; polypharmacy; porphyria; postinflammatory stenosis; pregnancy; proctitis; scleroderma; slow colon transit time; spinal cord injury; surgical stenosis

NIC, NOC, Client Outcomes, Nursing Interventions and *Rationales,* Client/Family Teaching and Discharge Planning, and References

Refer to care plan for Chronic functional **Constipation.**

Contamination

Pauline McKinney Green PhD, RN, CNE

NANDA-I

Definition

Exposure to environmental contaminants in doses sufficient to cause adverse health effects.

Defining Characteristics

Pesticides

Dermatological effects of pesticide exposure; gastrointestinal effects of pesticide exposure; neurological effects of pesticide exposure; pulmonary effects of pesticide exposure; renal effects of pesticide exposure

Chemicals

Dermatological effects of chemical exposure; gastrointestinal effects of chemical exposure; immunological effects of chemical exposure; neurological effects of chemical exposure; pulmonary effects of chemical exposure; renal effects of chemical exposure

Biologics

Dermatological effects of biologic exposure; gastrointestinal effects of biologic exposure; neurological effects of biologic exposure; pulmonary effects of biologic exposure; renal effects of biologic exposure

Pollution

Neurological effects of pollution exposure; pulmonary effects of pollution exposure

Waste

Dermatological effects of waste exposure; gastrointestinal effects of waste exposure; hepatic effects of waste exposure; pulmonary effects of waste exposure

Radiation

Genetic effects of radiation exposure; immunological effects of radiation exposure; neurological effects of radiation exposure; oncological effects of radiation exposure

Related Factors

External

Carpeted flooring; chemical contamination of food; chemical contamination of water; flaking, peeling surface in presence of young children; inadequate breakdown of contaminant; inadequate household hygiene practices; inadequate municipal services; inadequate personal hygiene practices; inadequate protective clothing; inappropriate use of protective clothing; ingestion of contaminated material; playing where environmental contaminants are used; unprotected exposure to chemical; unprotected exposure to heavy metal; unprotected exposure to radioactive material; use of environmental contaminant in the home; use of noxious material in insufficiently ventilated area; use of noxious material without effective protection

Internal

Concomitant exposure; inadequate nutrition; smoking

At-Risk Population

Children <5 years; economically disadvantaged; exposure to areas with high concomitant level; exposure to atmospheric pollutants; exposure to bioterrorism; exposure to disaster; exposure to radiation; female gender; gestational age during exposure; older adults; previous exposure to contaminant

Associated Condition

Pre-existing disease; pregnancy

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Community Health Status; Family Physical Environment; Anxiety Level; Fear Level

Example NOC Outcome with Indicators

Community Health Status as evidenced by the following indicators: Evidence of health protection measures/Compliance with environmental health standards/Health status of population. (Rate the outcome and indicators of **Community Health Status:** 1 = poor, 2 = fair, 3 = good, 4 = very good, 5 = excellent [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Have minimal health effects associated with contamination
- Cooperate with appropriate decontamination protocol
- Participate in appropriate isolation precautions

Community Will (Specify Time Frame)

- Use health surveillance data system to monitor for contamination incidents
- Use disaster plan to evacuate and triage affected members
- Have minimal health effects associated with contamination
- Use measures to reduce household environmental risks

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Triage: Disaster; Infection Control; Anxiety Reduction; Crisis Intervention; Health Education

Example NIC Activities—Triage: Disaster

Initiate appropriate emergency measures, as indicated; Monitor for and treat life-threatening injuries or acute needs

Nursing Interventions and *Rationales*

- ▲ Help individuals cope with contamination incident by doing the following:
  - ❍ Use groups that have survived terrorist attacks as a useful resource for victims
  - ❍ Provide accurate information on risks involved, preventive measures, use of antibiotics and vaccines
  - ❍ Assist to deal with feelings of fear, vulnerability, and grief
  - ❍ Encourage individuals to talk to others about their fears
  - ❍ Assist victims to think positively and to move toward the future

▲ *In a crisis situation, interventions aimed at supporting an individual's cope help the person deal with feelings of fear, helplessness, and loss of control that are normal reactions in a crisis situation.*

• Triage, stabilize, transport, and treat affected community members. **EB:** *Accurate triage and early treatment provide the best chance of survival to affected persons (Veenema, 2013).*

• Prioritize mental health care for highly vulnerable risk groups or those with special needs (deeply affected groups, women, older persons, children and adolescents, displaced persons—especially those living in shelters, persons with preexisting mental health disorders including those living in institutions) (Pan American Health Organization, 2012).

• Collaborate with members of the health care delivery system and outside agencies (local health department, emergency medical services [EMS], state and federal agencies). *Communication among agencies increases the ability to handle a crisis efficiently (Veenema, 2013; CDC, 2015).*

• Use approved procedures for decontamination of persons, clothing, and equipment. Victims may first require decontamination before entering health facility to receive care to prevent the spread of contamination (US Army Medical Research Institute of Infectious Diseases, 2014).

• Use appropriate isolation precautions: universal, airborne, droplet, and contact isolation to prevent cross-contamination by contaminating agents (US Army Medical Research Institute of Infectious Diseases, 2014). **CEB:** *The World Health Organization (WHO) recommends strict guidelines for handwashing at five moments in time: before touching a patient, before clean/aseptic procedures, after body fluid exposure/risk, after touching a patient, and after touching patient surroundings (WHO, 2009).*

• Monitor individuals for therapeutic effects, side effects, and compliance with postexposure drug therapy that may extend over a long period of time and require monitoring for compliance and for therapeutic and side effects (Veenema, 2013; Adalja et al, 2015).

• Perform effective handwashing before and after handling medical charts, entering case notes, touching clients, and performing procedures, especially in intensive care unit environments. **EB:** *A prospective study to identify and compare the incidence of bacterial contamination of hospital charts found the plastic chart covers to be contaminated*

(63.5% for general wards and 83.2% for special units); chart covers can act as vectors and potential sources of infection (Chen, Chen, & Wang, 2014).

• Prevent cross-contamination by systematically disinfecting stethoscopes (diaphragm and tubing) after each use. **EB:** *A study of the contamination level of health care providers' hands and stethoscopes found that the contamination level of the stethoscope is substantial after a single health care provider examination and is comparable to the contamination of parts of the provider's hand (Longtin, Schneider, & Tschopp, 2014).*

• Minimize occupational exposure to antineoplastic agents by following National Institute of Occupational Safety and Health (NIOSH) guidelines regarding personal protective equipment and correct handling of hazardous drugs. **EB:** *Nurse safety is directly related to knowledge of hazard assessment, decontamination, and proper use of personal protective equipment (NIOSH, 2009; Crickman & Finnell, 2017).*

Geriatric

• Help the client identify age-related factors that may affect response to contamination incidents.

• Advise older adults to follow public notices related to drinking water. *Contaminated water can harm the health of older persons and those with chronic conditions (CDC, 2014a).*

• Encourage older adults to receive influenza vaccination when it is available, beginning as early as late August and continuing through the end of February. *Flu vaccination protects against influenza and protects those in proximity who are more vulnerable to serious flu illness (CDC, 2017a).*

• Instruct older adults with special needs or chronic conditions to create and share a plan with family and friends for emergencies and keep medications, prescriptions, and special devices on hand. *Sharing a plan for emergencies helps older adults create a social network that will be available for support and assistance* (*Federal Emergency Management Agency, 2017).*

Pediatric

• Provide environmental health hazard information. *Developing children are more vulnerable to environmental toxicants because of greater and longer exposure and particular susceptibility windows (Children's Environmental Health Network, 2017).*

• Reduce risks from exposure to environmental contaminants by identifying the ages and life stages of children. **EB:** *Coordinate hazard and exposure assessment using children's ages and life stages to accommodate for children's physiology and developmental stage, which contribute to opportunities for environmental exposure and contamination (Hubal, de Wet, & Du Toit, 2014).*

• Screen newly arrived immigrant and refugee children for elevated blood lead levels secondary to lead hazards in older housing. **EB:** *Resettlement in areas with older housing stock increases risk for lead poisoning (CDC, 2013a).*

• Be aware that the risk for lead exposure is much higher in many countries from which children are adopted than in the United States; screening should then be conducted for those identified from 6 months and up to 16 years of age *(CDC, 2014b).*

• The current reference level of 5 μg/dL is used to identify children and environments associated with lead-exposure hazards. **EB:** *The Centers for Disease Control and Prevention (CDC) currently recommends using 5 μg/dL as the reference value in place of the previously recommended level of 10 μg/dL; reference values are updated every 4 years based on the most recent population-based blood lead surveys among children (CDC, 2017b).*

Multicultural

- Ask about use of imported or culture-specific products that contain lead, such as greta and azarcon (Hispanic folk medicine for upset stomach and diarrhea), ghasard (Indian folk medicine tonic), ba-baw-san (Chinese herbal remedy), and daw-tay (Thai and Myanmar remedy). *Immigrant children are at increased risk for contamination, particularly from lead related to exposure to imported culture-specific products (CDC, 2013b).*
- Nurses need to consider the cultural and social factors that impact access to and understanding of the health care system, particularly for groups such as migrant workers who do not have consistent health care providers. **EB:** *Subtle cultural biases in how nurses approach care can affect outcomes (Holmes, 2012; Hubal, de Wet, & Du Toit, 2014).*

Home Care

- Assess current environmental stressors and identify community resources. *Accessing resources decreases stress and increases ability to cope.*
- Recognize that relocated and unemployed individuals/families are at risk for psychological distress. **EB:** *People who lose their social network are at a very high risk for postevent psychological distress and require appropriate care (Oyama et al, 2012).*
- Support policy and program initiatives that provide emergency mental health services following large-scale contamination events. **EB:** *A study of the utilization of mental health services following a major disaster found community mental health service use increased in the period following the event and that brief interventions were more effective than conventional, multisession interventions (Boscarino, Adams, & Figley, 2011).*
- Instruct community members concerned about lead in drinking water from plumbing pipes and fixtures to have the water tested by calling the Environmental Protection Agency (EPA) drinking water hotline at 800-426-4791.
- Educate community members to reduce exposure to lead by inquiring about lead-based paint before buying a home or renting an apartment built before 1978; federal law requires disclosure of known information about lead-based paint *(EPA, 2017).*
- Instruct individuals and families that food contamination occurs through a variety of mechanisms and that food safety is associated with proper washing of hands, surfaces, and utensils; prompt refrigeration of food; and cooking foods at the correct temperature. **EB:** *Pathogens can be introduced into food from infected humans who handle food without thoroughly washing their hands, from food that touches surfaces or utensils contaminated by pathogens in raw food, and improper refrigeration or heating of food (CDC, 2016).*

Client/Family Teaching and Discharge Planning

- Provide truthful information to the person or family affected.
- Discuss signs and symptoms of contamination.
- Explain decontamination protocols.
- Explain need for isolation procedures.
- *Well-managed efforts at communication of contamination information ensure messages are correctly formulated, transmitted, and received and result in meaningful actions.*
- Emphasize the importance of preexposure and postexposure treatment of contamination. *Early treatment decreases associated complications related to contamination (ATSDR, 2014).*
- Provide parents with actionable information to reduce environmental

contamination in the home. **EBN:** *A randomized educational intervention to reduce contamination in the home demonstrated significant reduction in biomarker levels and improved environmental health self-efficacy and precaution adoption (Butterfield et al, 2011).*

Risk for Contamination

Mary Beth Flynn Makic PhD, RN, CCNS, FAAN, FNAP

NANDA-I

Definition
Susceptible to exposure to environmental contaminants, which may compromise health.

Risk Factors

External
Carpeted flooring; chemical contamination of food; chemical contamination of water; flaking, peeling surface in presence of young children; inadequate breakdown of contaminant; inadequate household hygiene practices; inadequate municipal services; inadequate personal hygiene practices; inadequate protective clothing; inappropriate use of protective clothing; ingestion of contaminated material; playing where environmental contaminants are used; unprotected exposure to chemical; unprotected exposure to heavy metal; unprotected exposure to radioactive material; use of environmental contaminant in the home; use of noxious material in insufficiently ventilated area; use of noxious material without effective protection

Internal
Concomitant exposure; inadequate nutrition; smoking

At-Risk Population
Children <5 years; economically disadvantaged; exposure to areas with high contaminant level; exposure to atmospheric pollutants; exposure to bioterrorism; exposure to disaster; exposure to radiation; female gender; gestational age during exposure; older adults; previous exposure to contaminant

Associated Condition
Preexisting disease; pregnancy

NIC, NOC, Client Outcomes, Nursing Interventions and *Rationales*, Client/Family Teaching, and References
Refer to care plan for **Contamination**.

Risk for adverse reaction to iodinated Contrast Media

Pauline McKinney Green PhD, RN, CNE

NANDA-I

Definition
Susceptible to noxious or unintended reaction associated with the use of iodinated contrast media that can occur within seven days after contrast agent injection, which may compromise health.

Risk Factors
Dehydration; generalized weakness

At-Risk Population
Extremes of age; history of allergy; history of previous adverse effect from iodinated contrast media

Associated Condition
Chronic illness; concurrent use of pharmaceutical agents; contrast media precipitates adverse event; fragile vein; unconsciousness

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes
Tissue Perfusion: Renal; Kidney Function

Example NOC Outcome with Indicators
Kidney Function as evidenced by 24-hour intake and output balance/Blood urea nitrogen/Serum creatinine/Urine color/Serum electrolytes. (Rate the outcome and indicators of **Kidney Function:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Maintain normal blood urea nitrogen and serum creatinine levels
- Maintain urine output of 0.5 mL/kg/hr
- Maintain serum electrolytes (K^+, PO_4, Na^+) within normal limits

NIC (Nursing Interventions Classification)

Suggested NIC Interventions
Fluid/Electrolyte Management; Laboratory Data Interpretation

Example NIC Activities—Fluid/Electrolyte Management
Monitor for serum electrolytes levels, as available; Weigh daily and monitor trends; Monitor vital signs, as appropriate

Nursing Interventions and *Rationales*
Recognize that iodinated contrast media can be harmful to clients in a number of ways, including onset of contrast-induced nephropathy (CIN), allergic reactions to the dye, and damage to veins and vascular access devices.

Contrast-Induced Nephropathy
Protect clients from contrast media-induced nephropathy by taking the following actions:

- ▲ Assess clients for low body mass index (BMI), history of heart failure, or repeated administration of contrast material. *Low BMI and heart failure are risk factors for CIN (Balemans et al, 2012).*
- ▲ In nondiabetic clients with acute coronary syndrome, assess for presence of hyperglycemia on admission and report to health care provider. *High blood glucose in acute coronary syndrome patients not known to be diabetic is associated with increased incidence of CIN after percutaneous coronary intervention (Islam et al, 2013).*
- Identify clients who have had multiple doses of iodinated contrast media in less than 24 hours and report to health care provider. *Repeat administration of contrast material may be a risk factor for CIN (American College of Radiology, 2017a).*

• Communicate information about at-risk clients to provider and procedure team in the hand-off report and electronic medical record. **EBN:** *A study of patients undergoing percutaneous coronary interventions with contrast media demonstrated significant reduction in acute kidney injury rates when evidence-based practices in nursing were introduced/standardized (Lambert et al, 2017).*

▲ Ensure that clients having diagnostic testing with contrast are well hydrated with isotonic intravenous (IV) fluids as ordered before and after the examination. **EB:** *Incidence of CIN is reduced by IV hydration with isotonic fluids (lactated Ringer's or 0.9% normal saline) before and after IV contrast administration (American College of Radiology, 2017a). Low incidence of CIN is associated with the use of hydration (Balemans et al, 2012).*

▲ *Assess patients with symptoms of heart failure on an individual basis to determine tolerance for IV fluids used for hydration in the periprocedure period (Lambert et al, 2017).*

▲ Verify that a baseline serum creatinine has been drawn from clients at risk for CIN. *A baseline value is important for comparison after the contrast injection; estimated glomerular filtration rate is considered a biomarker for CIN risk (American College of Radiology, 2017a).*

• Be vigilant for signs of CIN in clients who have cancer. *Clients with cancer are vulnerable to CIN, especially within 45 days of chemotherapy and in those with hypertension (Cicin et al, 2014).*

▲ Monitor for and report signs of acute kidney injury for 48 hours after iodinated contrast administration in clients at risk: absolute serum creatinine increase ≥0.3 mg/dL, percentage increase in serum creatinine ≥50%, or urine output reduced to ≤0.5 mL/kg/hr for at least 6 hours. (Refer to your institution policy for specific clinical parameters.) *These clinical parameters are suggestive of acute kidney injury (American College of Radiology, 2017a).*

▲ Clients taking metformin may increase client risk of developing lactic acidosis should CIN develop after contrast administration. *Review medications with the provider as metformin may be at the time of the procedure and held for up to 48 hours. Renal function tests should be evaluated prior to restarting metformin (Rose & Choi, 2015).*

Allergic Reaction to Contrast Media

▲ Previous allergic reactions to contrast material, history of asthma, and other allergies are factors that may increase the client's risk of developing an adverse reaction. Discuss premedication with methylprednisolone or diphenhydramine with the provider for clients who have had previous reactions to contrast media or known asthma or allergies. *Premedication may reduce the incidence of allergic reaction in some clients (Rose & Choi, 2015; American College of Radiology, 2017b).*

▲ Monitor carefully for symptoms of a reaction, which can be mild, moderate, or severe. Report all symptoms to the provider because symptoms can advance rapidly from mild to severe.

- ❍ *Mild reactions*: Nausea, vomiting, headache, itching, flushing, mild skin rash, or hives
- ❍ *Moderate reactions*: Severe skin rash or hives, wheezing, abnormal heart rhythms, high or low blood pressure, shortness of breath, or difficulty breathing
- ❍ *Severe reactions*: Difficulty breathing, cardiac arrest, swelling of throat or other parts of the body, convulsion, or profound low blood pressure
- ❍ *Both allergic and allergic-like (anaphylactoid) reactions can occur. Life-threatening events usually occur within 20 minutes after injection. Delayed reactions may occur with rash that appears hours or days afterward (American College of*

Radiology, 2017b).

Vein Damage and Damage to Vascular Access Devices

- Recognize that *only* vascular access devices labeled "power injectable" can be used to administer power injected contrast media. These include a power port, a power peripherally inserted central catheter (PICC) line, and a power central venous catheter (*Radiology and Biomedical Imaging, 2017a). A regular vascular access device used for administration of contrast media can rupture from the high pressures used to administer the contrast media.* **EB:** *A retrospective study of the function of 204 power ports found that they are safe for use with power injections of contrast media (Goltz et al, 2012).*
- Reduce the risk of vein and vascular access device damage with the following:
  - ❍ Maintain constant communication with the client during the injection and monitor client for report of pain or swelling at the injection site. *These are signs of complications that require the injection to be discontinued (American College of Radiology, 2017a).*
  - ❍ Monitor access site for extravasation during and after the procedure; be vigilant for clients at increased risk of extravasation. *Clients at increased risk include those who cannot communicate such as infants, older adults, or those with altered consciousness; severely ill or debilitated clients; clients with abnormal circulation in the affected limb; clients receiving the injection via a peripheral IV line that has been in place for more than 24 hours or into a vein that has been punctured multiple times; and clients with arterial insufficiency or compromised venous or lymphatic drainage in the affected extremity (American College of Radiology, 2017a).*
  - ❍ Assess for venous backflow before injecting contrast. *If backflow is not obtained, the catheter may need adjustment (American College of Radiology, 2017a).*
  - ❍ Directly monitor and palpate the venipuncture site during the first 15 seconds of injection. *A critical step in preventing significant extravasation is direct monitoring of the venipuncture site (American College of Radiology, 2017a).*

Geriatric

- Screen the older client thoroughly before diagnostic testing using contrast media. *Adults over 60 years of age are considered at risk for acute adverse reactions to contrast media (Beckett, Moriority, & Langer, 2015).*

Pediatric

"When the proper technique is used, contrast medium can be safely administered intravenously by power injector at high flow rates of up to 2 mls/second (depending on size of patient). A short peripheral IV catheter in the antecubital or forearm is the preferred route for intravenous contrast administration" (Radiology and Biomedical Imaging, 2017b).

Client/Family Teaching and Discharge Teaching

Provide patient/family teaching on the importance of keeping appointments with provider for monitoring kidney status, reporting symptoms of fluid retention or decrease in urine output, and awareness of increased risk for CIN with repeat exposure to contrast media (Jorgensen, 2013).

Readiness for enhanced community Coping

Marina Martinez-Kratz MS, RN, CNE

NANDA-I

Definition

A pattern of community activities for adaptation and problem-solving for meeting the demands or needs of the community, which can be strengthened.

Defining Characteristics

Expresses desire to enhance availability of community recreation programs; expresses desire to enhance availability of community relaxation programs; expresses desire to enhance communication among community members; expresses desire to enhance communication between aggregates and larger community; expresses desire to enhance community planning for predictable stressors; expresses desire to enhance community resources for managing stressors; expresses desire to enhance community responsibility for stress management; expresses desire to enhance problem-solving for identified issue

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Community Competence; Community Health Status

Example NOC Outcome with Indicators

Community Health Status as evidenced by the following indicators: Prevalence of health promotion programs, health status of infants, children, adolescents, adults, elders, participation rates in community health programs. (Rate the outcome and indicators of **Community Health Status:** 1 = poor, 2 = fair, 3 = good, 4 = very good, 5 = excellent [see Section I].)

Community Outcomes

Community Will (Specify Time Frame)

- Develop enhanced coping strategies
- Maintain effective coping strategies for management of stress

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Environmental Management: Community; Health Policy Monitoring: Program Development

Example NIC Activities—Program Development

Assist the group or community in identifying significant health needs or problems; Identify alternative approaches to address the need(s) or problem(s)

Nursing Interventions and *Rationales*

Note: Interventions depend on the specific aspects of community coping that can be enhanced (e.g., planning for stress management, communication, development of community power, community perceptions of stress, community coping strategies). *Nursing interventions are conducted in collaboration with key members of the community, community/public health nurses, and members of other disciplines (Anderson & McFarlane, 2011).*

- Establish a collaborative partnership with the community. **EB:** *A recent study found*

that counties whose Area Agencies for the Aging (AAAs) maintained informal partnerships with a broad range of organizations in health care and other sectors had significantly lower hospital readmission rates compared with counties whose AAAs had informal partnerships with fewer types of organizations (Brewster et al, 2018).

• Assess community needs with the use of concept mapping methodology. **EB:** *The findings of a recent study showed that an integration of several concept mapping methods into a community engagement process was able to increase the input from a wide range of populations (Velonis et al, 2018).*

• Encourage participation in faith-based organizations that want to improve community stress management. **EBN:** *A recent study showed that coaching by faith community nurses created an environment of sustained support that promoted improved lifestyles and blood pressure changes over time (Cooper & Zimmerman, 2017).*

▲ Identify the health services and information resources that are currently available in the community through network analysis. **EB:** *A study found that network analysis served as a useful tool to evaluate community partnerships and facilitate coalition building (Ruopeng et al, 2017).*

• Work with community members to increase problem-solving abilities. **EBN:** *Problem-solving is essential for effective coping. Findings from a recent study showed positive outcomes from a direct and tailored problem-solving training program (Easom et al, 2018).*

• Provide support to the community and help community members identify and mobilize additional supports. **EB:** *A community mobilization project demonstrated how cross-sector, coordinated efforts focused on vulnerable populations can leverage local strengths to establish and enhance breastfeeding support services customized to local needs (Colchamiro et al, 2015).*

• Advocate for the community in multiple arenas (e.g., multimedia, social media, and governmental agencies). **EB:** *A recent study explored how social media can help community organizations engage in advocacy work (Guo et al, 2017).*

• Work with communities to ensure that vulnerable individuals with access and functional needs are included in preparations for, response to, and recovery from disasters. **EB:** *Analysis of recent disasters has identified that a combination of strategic and operational methods, appropriate planning tools, and planning for the entire community will prevent individuals with access and functional needs from being disproportionately and negatively affected by disasters (Franks & Seaton, 2017).*

• Write grant proposals to help community members obtain funds for programs that reduce stress or improve coping (Anderson & McFarlane, 2011).

• Work with members of the community to identify and develop coping strategies that promote a sense of power (e.g., obtaining sources for funding, collaborating with other communities) (Anderson & McFarlane, 2011).

Pediatric

• Protect children and adolescents from exposure to community violence. **EB:** *A systematic review found evidence for a positive association between community violence exposure and cardiovascular and sleep problems in children and adolescents (Wright et al, 2017).*

• Assess children and adolescents for the effects of direct and indirect crime exposure rather than only focusing solely on violent victimization. **EB:** *A study found poor behavioral health outcomes for adolescents with self-reported crime exposure (Grinshteyn et al, 2018).*

Multicultural

- Acknowledge the stressors unique to racial/ethnic communities. **EB:** *A recent study of Hispanic and African American women found that neighborhood context was an important factor in examining the determinants of health, survivorship, and quality of life outcomes among cancer patients (Wu et al, 2018).*
- Identify community strengths with community members. **EBN:** *A community-based participatory research approach was used to obtain Native American community input and identify strengths to address youth suicide and substance abuse. The results led to the development of a strengths-based intervention incorporating the Gathering of Native American's curriculum (Holliday et al, 2018).*
- Use an empowerment approach to address health behaviors in diverse communities. An empowerment approach includes increasing clients' self-efficacy and capacity to make informed decisions about their health care. **EB:** *A recent study found use of an empowerment approach was effective in changing nonadherent Latinas' breast screening behaviors and promoting them to become agents of change in their communities (Molina et al, 2018). The empowerment intervention has three sessions focused on early detection, sharing information with family/friends, and health volunteerism.*
- Work with members of the community to prioritize and target health goals specific to the community. **EB:** *Recent research found that members of underserved communities, in informed deliberations, prioritized research on quality of life, patient-doctor, special needs, access, and compare approaches (Goold et al, 2017).*
- Establish and sustain partnerships with key individuals within communities when developing and implementing programs. **EB:** *A study of community engagement strategies found the following techniques to be effective: proactively engaging stakeholders in informational meetings, webinars, social media, the promising practice process, and community advisory council meetings (D'Angelo et al, 2017).*
- Use mentoring strategies for community members. **EB:** *A recent study showed parent mentors are highly effective in insuring uninsured Latino children and eliminating disparities (Flores et al, 2018).*
- Use community church settings as a forum for advocacy, teaching, and program implementation. **EBN:** *A recent study found that trust, respect, open dialog with participants, and commitment to address community health needs contributed to successful engagement and recruitment of African American churches to serve as participants in cancer research projects (Slade et al, 2018).*

Client/Family Teaching and Discharge Planning

- Review coping skills, power for coping, and the use of power resources.

Defensive Coping

Marina Martinez-Kratz MS, RN, CNE

NANDA-I

Definition

Repeated projection of falsely positive self-evaluation based on a self-protective pattern that defends against underlying perceived threats to positive self-regard.

Defining Characteristics

Alteration in reality testing; denial of problems; denial of weaknesses; difficulty establishing relationships; difficulty maintaining relationships; grandiosity; hostile laughter; hypersensitivity to a discourtesy; hypersensitivity to criticism; insufficient follow through with treatment; insufficient participation in treatment; projection of blame; projection of responsibility; rationalization of failures; reality distortion; ridicule of others; superior attitude toward others

Related Factors

Conflict between self-perception and value system; fear of failure; fear of humiliation; fear of repercussions; insufficient confidence in others; insufficient resilience; insufficient self-confidence; insufficient support system; uncertainty; unrealistic self-expectations

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Coping; Decision-Making; Impulse Self-Control; Information Processing

Example NOC Outcome with Indicators

Coping as evidenced by the following indicators: Identifies effective and ineffective coping patterns/Modifies lifestyle to reduce stress. (Rate the outcome and indicators of **Coping:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Acknowledge need for change in coping style
- Accept responsibility for own behavior
- Establish realistic goals with validation from caregivers
- Solicit caregiver validation in decision-making

NIC (Nursing Interventions Classification)

Suggested Nursing Interventions

Body Image Enhancement; Complex Relationship Building; Coping Enhancement; Patient Contracting; Resiliency Promotion; Self-Awareness Enhancement; Self-Esteem Enhancement; Socialization Enhancement; Surveillance

Example NIC Activities—Self-Awareness Enhancement

Encourage client to recognize and discuss thoughts and feelings; Assist client in identifying behaviors that are self-destructive

Nursing Interventions and *Rationales*

- Assess for possible symptoms associated with defensive coping: depressive symptoms, excessive self-focused attention, negativism and anxiety, hypertension, posttraumatic stress disorder (e.g., exposure to terrorism), substance use symptoms, unjust world beliefs. **EB:** *A study of the features of defensive coping behaviors found that alcohol-dependent women use coping avoidance, impulsive actions, and reactive formations more often than alcohol-dependent men, whereas alcohol-dependent men use intellectualization. Overall, alcohol-dependent men and women express higher levels of aggressive actions, compensation, and substitution (Chkhikvadze et al, 2018).*
  - Use cognitive behavioral interventions. **EBN:** *In a randomized control trial (N = 240), 120 in each group (experimental and control), a nurse-led cognitive behavioral intervention addressed inaccurate thinking and promoted more positive self-regard; the experimental group had improved quality of life, which included physical and psychological health, relief of symptom, and social functioning (Zhuang et al, 2013).*
- Ask appropriate questions to assess whether denial (defensive coping) is being used in association with health problems including alcoholism, myocardial infarction (MI), or rheumatoid arthritis. **EBN:** *In a case-based article, Wilson (2013) demonstrated a nurse-*

provided approach to screening, brief intervention, and referral to treatment (SBIRT), which is an approach recommended by the Substance Abuse and Mental Health Services Administration (2015), in a client requiring a peripherally inserted central catheter for a man with liver disease caused by alcoholism. **EB:** *In a 5-year prospective study of adults with rheumatoid arthritis (N = 74), researchers found that defensive coping impacted responses to pain and overall health, leading to poorer outcomes (Goulia et al, 2015).*

• Promote interventions with multisensory stimulation environments. **EB:** *In a review of the literature regarding sharing multisensory body space with others for those with altered bodies, such as amputations or congenital limb absence, researchers concluded that sharing multisensory body space is pertinent and may close the gap between neurology and psychiatry in the treatment of persons with altered bodies (Brugger & Lenggenhager, 2014).*

• Empower the client/caregiver's self-knowledge. **EB:** *In a qualitative study of adults receiving highly active antiretroviral treatment for HIV and methadone maintenance, participants described tension between negative feelings such as denial and positive feelings of empowerment (Batchelder et al, 2013).*

Geriatric

▲ Identify problems with alcohol in older adults with the appropriate tools and make suitable referrals. **EB:** *Community-dwelling older adults (N = 370) completed the Drinking Motives Questionnaire (DMQ); findings indicated that the most frequent motivation for drinking was social, with enhancement and coping motives, respectively, as the top three motivations (Gilson et al, 2013).* **CEB:** *Tools such as the Alcohol Use Disorders Identification Test (AUDIT), Michigan Alcohol Screening Test-Geriatric Version (MAST-G), and the Alcohol-Related Problems Survey (ARPS) may have additional use in this population. Brief interventions have been shown to be effective in producing sustained abstinence or reducing levels of consumption, decreasing hazardous and harmful drinking (Culberson, 2006).*

• Encourage exercise for positive coping. **EBN:** *One research group identified that exercise is known to facilitate maintenance of functional abilities in older adults and tested an intervention to encourage older adults (N = 106) to engage in physical activity (PA)/exercise using peer mentors. The researchers found high participation and retention and improved fitness scores in all mentored groups (Dorgo et al, 2013).* **EB:** *Researchers performed a secondary analysis of data to examine the use of PA in middle-aged and older adults during a smoking cessation attempt (N = 799). The researchers found that PA, primarily walking, was used by only a small percentage of participants (11.6%); women were more likely to use PA as a coping strategy than men. The researchers recommended further study and approaches that encourage older adults to engage in PA for general health and quality of life (Treviño et al, 2014).*

• Stimulate individual reminiscence therapy. **EBN:** *Structured reminiscence is an evidence-based, independent nursing intervention that is used with individuals and groups and is used to increase emotional awareness and enhance social interactions in older adults (Stinson & Long, 2014).*

• Stimulate group reminiscence therapy. **EBN:** *Stinson's structured group reminiscence is a multisession evidence-based approach used with older adults (Stinson & Long, 2014).* ***EB:*** *A multimedia intergenerational reminiscence program was tested in a small (N = 26) group of community-dwelling older adults; qualitative data from stories and focus groups indicated that the intervention showed promise as a group intergenerational intervention (Chonody & Wang, 2013).*

Multicultural

• Acknowledge racial/ethnic differences at the onset of care. **EB:** *In a qualitative study of white professionals working with racial minority immigrant clients, researchers found that although some professionals reported being comfortable discussing race and cultural differences, some expressed discomfort and difficulty, and others did not perceive race and culture to be a priority. The researchers recommended further attention to cultural competence training in clinical programs (Singer & Tummala-Narra, 2013).*
• Assess an individual's sociocultural backgrounds in teaching self-management and self-regulation. **EBN:** *A systematic review of qualitative evidence related to women's coping with type 2 diabetes indicated that in multiple countries self-management is challenged by the complexities of regimens and women's multiple caregiving roles. Researchers recommended recognition of the coping and emotional factors by health care providers, families, and friends; psychoeducation programs for clients and families; and enhanced support of family and friends (Li, Drury, & Taylor, 2014).* **EB:** *In a study of the Cellie Coping Kit for Sickle Cell Disease, researchers provided the intervention to 15 black/African American children aged 6 to 14 years and their health care provider. Although the researchers reported strong acceptability, some sociocultural issues like living situation and health literacy did provide challenges to the use of the tool (Marsac et al, 2014).*
• Encourage the client to use spiritual coping mechanisms such as faith and prayer. **CEB/EBN:** *In a qualitative study of Thai Buddhist and Muslim women's (N = 48) use of religion and spiritual practices related to self-management of type 2 diabetes, researchers found four themes that related to cultural or spiritual practices, including prayer, which helped them cope, despite poor glycemic control (Lundberg & Thrakul, 2013).* **EB:** *In a study of religion and coping with racial discrimination among African American (N = 2032) and Caribbean blacks (N = 857), researchers found that both groups were similar in their likelihood of using prayer for coping with discrimination (Hayward & Krause, 2015).*
• Encourage spirituality as a source of support for coping. **EBN:** *In a small (N = 17) pilot study of African American women with breast cancer, women reported high levels of spiritual and positive religious coping (sense of purpose in life) strategies such as prayer. Researchers recommended that although the findings of the pilot are not generalizable, spirituality and religious coping need to be explored as core coping mechanisms for African American women with breast cancer (Gaston-Johansson et al, 2013).*

Home Care

▲ Refer the client for programs that teach coping skills. **EB:** *Researchers examining bullying and the association with cultural/family factors, substance use, and depressive symptoms in ninth and tenth grade Hispanic youth (N = 1167) found the stress of acculturation was associated with substance use and depressive symptoms and the need for the development of coping skills in youth. Recommendations included school-based programs to teach coping skills (Forster et al, 2013).*

Client/Family Teaching and Discharge Planning

• Teach coping skills to clients and caregivers. **EBN:** *In a trial of a culturally adapted cognitive behavioral therapy intervention to promote coping skills among Chinese Americans with type 2 diabetes, strategies and coping skills that addressed personal, family, and illness-specific topics were included; researchers reported enhanced efficacy for self-management (Chesla et al, 2013).*
• Teach reflexive and expressive writing to address emotions. **EBN:** *Journaling was used in an intervention study to enhance civility among nursing students; researchers found*

coping improvements in self-controlling and positive reappraisal (Jenkins et al, 2013). **EB:** *In a randomized trial of expressive writing in the third person, 44 undergraduates wrote about their deepest thoughts and feelings about a traumatic or very stressful life event; findings included less intrusive thinking in both groups, but third-person writers had better outcomes in overall health than did the first-person writers. Researchers recommend third-person expressive writing for those recovering from traumatic or highly stressful events (Andersson & Conley, 2013).*

Ineffective Coping

Arlene T. Farren PhD, RN, AOCN, CTN-A, CNE

NANDA-I

Definition

A pattern of invalid appraisal of stressors, with cognitive and/or behavioral efforts, that fails to manage demands related to well-being.

Defining Characteristics

Alteration in concentration; alteration in sleep pattern; change in communication pattern; destructive behavior toward others; destructive behavior toward self; difficulty organizing information; fatigue; frequent illness; inability to ask for help; inability to attend to information; inability to deal with a situation; inability to meet basic needs; inability to meet role expectation; ineffective coping strategies; insufficient access of social support; insufficient goal directed behavior; insufficient problem resolution; insufficient problem-solving skills; risk taking behavior; substance misuse

Related Factors

High degree of threat; inability to conserve adaptive energies; inaccurate threat appraisal; inadequate confidence in ability to deal with a situation; inadequate opportunity to prepare for stressor; inadequate resources; ineffective tension release strategies; insufficient sense of control; insufficient social support

At-Risk Population

Maturational crisis; situational crisis

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Coping; Decision-Making; Impulse Self-Control; Information Processing

Example NOC Outcome with Indicators

Coping as evidenced by the following indicators: Identifies effective and ineffective coping patterns/Modifies lifestyle to reduce stress. (Rate the outcome and indicators of **Coping:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Use effective coping strategies
- Use behaviors to decrease stress
- Remain free of destructive behavior toward self or others
- Report decrease in physical symptoms of stress
- Report increase in psychological comfort
- Seek help from a health care professional as appropriate

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Coping Enhancement; Decision-Making Support

Example NIC Activities—Coping Enhancement

Assist the client in developing an objective appraisal of the event; Explore with the client previous methods of dealing with life problems

Nursing Interventions and *Rationales*

- Observe for contributing factors of ineffective coping such as poor self-concept, grief, lack of problem-solving skills, lack of support, recent change in life situation, maturational or situational crises. **EBN:** *Factors predicting maladaptive coping in a small sample of sexual minority men (N = 89) included experiences of intimate partner sexual victimization and intimate partner violence resulting in injury (Goldberg-Looney et al, 2016).* **EBN:** *Following infant hospitalization in the neonatal intensive care, researchers identified that mothers experienced greater stress than the fathers with previous miscarriages and the presence of chronic diseases being statistically significant risks for posttraumatic stress disorder in this sample (Aftyka et al, 2017).* **EB:** *In a longitudinal study of children and their parents (N = 1064), children living in homes with parental violence were at risk for developing ineffective coping strategies in early adulthood (Jester et al, 2015).*
- Use verbal and nonverbal therapeutic communication approaches including empathy, active listening, and confrontation to encourage the client and family to express emotions such as sadness, guilt, and anger (within appropriate limits); verbalize fears and concerns; and set goals. **EBN:** *In a qualitative study using focus groups to understand nurses' (N = 27) experiences of presence, researchers found empathy, active listening, and use of silence were among the therapeutic communication approaches that were required to implement presence and improve client outcomes (Stockmann et al, 2016).* **EB:** *A survey of people living with spasticity (N = 281) about their experiences and expectations, concluded that there were unmet needs regarding communication and therapeutic relationships with health care providers (Barnes et al, 2017).*
- Collaborate with the client to identify strengths such as the ability to relate the facts and to recognize the source of stressors. **EBN:** *Strength-based nursing (SBN) is a philosophical approach that includes eight values including a collaborative partnership with clients and families (Gottlieb & Gottlieb, 2017).*
- Encourage the client to describe previous stressors and the coping mechanisms used. **EB:** *A review examining endometriosis and behavioral, cognitive, and emotional coping strategies found that despite mixed results, clinician should engage in an evaluation of women's coping strategies to promote well-being and minimize poor mental health outcomes (Zarbo et al, 2018).*
- Provide opportunities for the client to discuss the meaning the situation might have for the client. **EBN:** *A qualitative study of the coping experiences of spouses of people with dementia found that spouses search each day for meaning while experiencing stress and using coping strategies (Myhre et al, 2018).* **EBN:** *A phenomenological study of adults living with diabetes (N = 13) found that the meanings of trigger situations were an opportunity for learning (Kneck et al, 2016).*
- Assist the client to set realistic goals and identify personal skills and knowledge. **EBN:** *Multiple interviews with 33 nonmetastatic breast cancer clients revealed that some experienced personal goal interference and required goal-based psychosocial support from oncology nurses and other professionals to overcome interference, which can lead to clinical depression (Stefanic et al, 2015).* **EBN:** *Setting realistic goals is recommended as part of the*

support needed during weight loss programs (Fruh, 2017). **EB:** *In a quantitative study of 272 university students, researchers learned that positive affective states and autonomous goal motivation predicted positive coping (Blouin-Hudon, Gaudreau, & Gareau, 2016).*

• Provide information regarding care before care is given. **EBN:** *Researchers surveyed 45 family members with a client in the intensive care unit and found that one of the most important needs was related to information about the client and the care provided (Jacob et al, 2016).*

• Discuss changes with the client before making them. **EBN:** *In a review of evidence about minimally invasive, robotic-assisted cancer surgery, researchers recommended that nursing care should focus on providing information and preparation to patients and families for shorter hospital stays (Sun & Fong, 2017).* **EN:** *In a study (N = 451) about transfer of patients from an intensive care unit to inpatient unit, researchers learned that informing the client/family in advance about impending transfers would contribute to improving the process (Stelfox et al, 2017).*

• Provide mental and physical activities within the client's ability (e.g., reading, television, radio, crafts, outings, movies, dinners out, social gatherings, exercise, sports, games). **EB:** *Physical activity contributes indirectly to coping efficacy in middle-aged women (N = 103) experiencing menopausal symptoms (Kishida & Elavsky, 2015).*

• Discuss the power of the client and family to change a situation or the need to accept a situation. **EB:** *Cox et al (2016) conducted a secondary analysis of data from participants (N = 1189) in the Childhood Cancer Survivor Study to examine selected unmet needs and found that 51% of participants reported unmet information needs related to cancer/treatment.*

• Offer instruction regarding alternative coping strategies. **EBN:** *Motivational interviewing is a supportive strategy that helps elicit client perspectives and can promote coping (Carr, 2016).* **EBN:** *Mills, Wong-Anuchit, and Poogpan (2017) conducted a concept analysis of Thum-jai, a Thai coping strategy, and discussed the consequences or outcomes, which include emotional stability, positive thought, and productive change. It is recommended as an alternate coping strategy.*

• Encourage use of spiritual resources as desired. **EBN:** *Researchers found that in bereaved parents (N = 165) black mothers and Protestant and Catholic parents commonly used religious coping practices, and mothers were more likely to use spiritual and religious coping than fathers (Hawthorne, Youngblut, & Brooten, 2017).* **EBN:** *Clark and Hunter (2018) conducted a literature review (N = 30) regarding spiritual coping in clients with advanced heart failure and recommend Reed's Theory of Self-Transcendence as a foundation for examining individual's perspectives of their vulnerability and understanding how it affects one's sense of meaning.*

• Encourage use of social support resources. **EBN:** *Aftyka et al (2017) found mothers (N = 72) of infants in the neonatal intensive care unit (NICU) were more likely than fathers (N = 53) to engage in coping strategies such as venting of emotions and instrumental support.*

▲ Refer for additional or more intensive therapies as needed. **EB:** *More complex interventions are available to assist with coping; for example, a randomized controlled trial of older adults in the community found that mindfulness and a self-compassion program consisting of 10, 2-hour sessions were successful in improving coping strategies (Perez-Blasco et al, 2016).*

Pediatric

• Monitor the client's risk of harming self or others and intervene appropriately. **QSEN:** See care plan for Risk for **Suicide**. **EBN:** *In a study of 140 Taiwanese secondary*

school students, resourcefulness as a coping strategy was associated with depressive symptoms (r = −0.35, P < .001) and self-harm (r = −0.29, P ≤ .001) (Yang et al, 2017).

• Monitor adolescents for exposure to community violence. **EB:** *Researchers found support that active coping mediates exposure to violence and externalizing symptoms in a predominately low-income African American and Latino sample (Carothers et al, 2016).* **EB:** *A group intervention (five, 1-hour sessions) modeled after the "Listen to the Children" approach was delivered to 74 African American children and adolescents aged 5 to 19. Chosen discussion topics included bullying, community violence, loss of a loved one, incarceration of a loved one, and conflict. Participants liked the discussion and reported improved feelings, behaviors, and increased hope; parents reported improved behaviors in their children (Allen et al, 2016).* **EB:** *In a sample of LGBTQ adolescents aged 13 to 20 attending a HATCH Youth Program, those with longer attendance reported greater social support and improved coping ability. The HATCH program is a series of group sessions. Participants attending 1 to 6 months did have benefits, whereas participants attending 1 month or less did not (Wilkerson et al, 2017).*

Geriatric

▲ Assess and report possible physiological alterations (e.g., sepsis, hypoglycemia, hypotension, infection, changes in temperature, fluid and electrolyte imbalances, use of medications with known cognitive and psychotropic side effects). **EBN:** *Researchers supported the idea that caregivers of older stroke survivors have significant physical and mental comorbidities after conducting a prospective, exploratory study of uncertainty in caregivers of older adults poststroke (Eeseung et al, 2016).* **EBN:** *Researchers examined stressful life events in adults aged 55 to 99 and found that health problems were among the most stressful for older adults (Rubio et al, 2016).*

• Screen for elder neglect or other forms of elder mistreatment. **EBN/EB:** *There is no gold standard for assessment of elder neglect, abuse, or mistreatment. There are several literature reviews exploring best practices for assessment and intervention (Fearing et al, 2017; Hirst et al, 2016; Moore & Browne, 2017) and several studies examining potential screening tools (Cannell et al, 2016; Friedman et al, 2017; Pickering et al, 2017).*

• Encourage the client to make choices (as appropriate) and participate in planning care and scheduled activities. **EB:** *Researchers found older adults preferred active engagement in making health care decisions, but the preference may be different for those with more comorbidities (four or more) (Chi et al, 2017).*

• Target selected coping mechanisms for older persons based on client features, use, and preferences. **EB:** *In a small qualitative study of older adults with mild dementia, researchers found three themes related to psychological support, one of which was coping mechanisms. The mechanisms included were asserting control, engaging in new activities, and using humor (Birtwell & Dubrow-Marshal, 2018).*

• Increase and mobilize support available to older persons by encouraging a variety of mechanisms involving family, friends, peers, and health care providers. **CEBN:** *A trial of a nursing intervention to facilitate older adult access to community resources and remain at home found that the older adults accepted that the intervention had improved health empowerment, purposeful participation in goal attainment, and well-being (Shearer, Fleury, & Belyea, 2010).* **EB:** *Families give older adults important psychological support for coping with functional disabilities, pain, and other health issues (Honn Quails, 2016).*

• Actively listen to complaints and concerns. **EBN:** *During the working phase of Peplau's theory, holistic communication includes the use of active listening to promote the older adult patient's development of a deeper connection with the nurse; active listening and focusing are*

essential holistic communication skills (Deane & Fain, 2016). **EB:** *A focus on active listening and not interrupting the patient are among key features of patient-centered communication skills (Hashim, 2017).*

• Engage the client in reminiscence. **EBN:** *A study of older adults with dementia living in a nursing home implemented a combined intervention of music reminiscence therapy with reality orientation techniques. Researchers found positive improvements in depression in the intervention group and recommended further research of the efficacy of the intervention (Onieva-Zafra et al, 2018).*

Multicultural

• Assess for the influence of cultural beliefs, norms, and values on the client's perceptions of effective coping. **EB:** *Researchers found that in a sample of African American college students (N = 191), a variety of past messages regarding racial socialization may predict race-specific coping in AA college students (Blackmon et al, 2016).*

• Assess for intergenerational family problems that can overwhelm coping abilities. **EBN:** *A study of Chinese family caregivers revealed family expectations to provide care, but family resources contributed to coping, and a sense of self-sacrifice by the caregivers (Qiu, Sit, & Koo, 2018).* **EB:** *A study conducted in South Pacific and Asian cultures found a relationship between problem gambling between parents and participants; the researchers suggested that expectancies and motives about gambling may help to target interventions for offspring of problem gamblers (Dowling et al, 2018).*

• Negotiate with the client regarding aspects of coping behavior that will need to be modified. **QSEN/EBN:** *Adolescents are less likely to engage in help-seeking behaviors, which places them at greater risk for self-harm and suicide; resourcefulness has been found to be negatively and significantly related to self-harm in Taiwanese adolescents (Yang et al, 2017). Likewise, a study of rural American adolescents found that life events and use of positive coping strategies can make a significant difference toward positive outcomes (Rew et al, 2016).*

• Encourage moderate aerobic exercise or other forms of physical activity (as appropriate). **EB:** *Black and Kashikar-Zuck (2017) proposed a novel intervention for juvenile fibromyalgia that combined neuromuscular training and cognitive-behavioral therapy to aid in coping with pain. The training is called the Fibromyalgia Integrative Training for Teens Program or FIT Teens.*

• Identify which family members the client can count on for support. **EBN:** *In Madurai women who underwent hysterectomy (N = 60), researchers found that family support was associated with coping and quality of life and concluded that support from the partner is especially important to both coping and quality of life (Shanthi & Jeyapal, 2016).*

• Support the inner resources that clients use for coping. **EBN:** *Researchers in the United States and Asia have found evidence that supports that self-transcendence is an inner resource for coping and well-being in a variety of populations and situations; the effects of inner resources, such as resilience, self-adjustments, and getting out of oneself for the interest of others, are ways to enhance self-transcendence and meaning in life (Ho et al, 2016; Haase et al, 2017).*

• Use an empowerment framework to redefine coping strategies. **EBN:** *Canadian researchers tested an intervention based on a Caregiver Grief Model that enhanced empowerment and coping in caregivers of people with dementia (MacCourt et al, 2017).*

Home Care

• The interventions described previously may be adapted for home care use.

▲ **QSEN:** Assess for suicidal tendencies. Refer for mental health care immediately if indicated.
▲ **QSEN:** Identify an emergency plan should the client become suicidal. Ineffective coping can occur in a crisis situation and can lead to suicidal ideation if the client sees no hope for a solution. A suicidal client is not safe in the home environment unless supported by professional help. Refer to the care plan for Risk for **Suicide.**
• Discuss preferred coping strategies of family caregivers. **EBN:** *Coping style and strategies may differ from individual to individual. Gender has been identified as one variant. For example, in family member caregivers (N = 308) of terminally ill cancer patients in Austria, women are more likely to prefer and benefit from adaptive coping strategies that deal with the demands of caregiving and working outside the home (Schrank et al, 2016).*
• Encourage the client to participate knowingly in their care. Refer to the care plan for **Powerlessness.** **EBN:** *Caregivers of school-age female children in Haiti participated in a health patterning modality that included storytelling, goal identification, educational session, and distribution of needed resources to enhance the caregivers' knowing participation in change. The researcher concluded that people can participate knowingly in their care and that knowing participation can be enhanced by relating with clients in a variety of ways (Leveille-Tulce, 2017).* **EBN:** *In a study of obstetric nurses, Heelan-Francher (2016) found that power as knowing participation in change had the greatest impact on patient advocacy.*
▲ Refer the client and family to support groups. **EB:** *A study of adolescents and adults with neurofibromatosis type 1 (NF1), a genetic, progressive disorder, explored knowledge of the disease, self-esteem, and the impact of support groups. Researchers found that participation in support groups had an influence on self-esteem and recommended that health care professionals inform clients about support groups (Rosnau et al, 2017).*
▲ If monitoring medication use, contract with the client or solicit assistance from a responsible caregiver. **EBN:** *Spoelstra et al (2016) have developed a clinical trial to test a multipronged approach to enhance adherence to oral anticancer medication regimens for both patients and caregivers; it involves education about self-management and medication teaching, motivational interviewing, and cognitive behavioral approaches.*
▲ Institute case management for frail elderly clients to support continued independent living. **EBN:** *Nurse-led community care for the oldest old that includes care coordination and follow-up could preserve functioning in the oldest-old in the community (Bleijenberg et al, 2017).* **EB:** *A study examining tablet and Skype use in a case management program for frail older adults found that the participants had positive experiences with the technology as a means of communicating with case managers (Berner et al, 2016).*

Client/Family Teaching and Discharge Planning

• Teach the client to problem solve. Have the client define the problem and cause, and list the advantages and disadvantages of the options. **EB:** *A problem-solving intervention that included defining the problem and goals, listing multiple solutions, and selecting a solution found improved task-oriented coping, avoidant coping, and generic health-related quality of life (Visser et al, 2016).*
• Teach relaxation techniques. **EBN:** *Nurses in Turkey provided relaxation exercise training to postmenopausal women with insomnia (N = 81 in intervention group and 80 in control group) once per week for 8 weeks in addition to teaching sleep hygiene measures. The researchers concluded that the statistically significant reduction in insomnia suggested that nurses' teaching of progressive relaxation techniques coupled with sleep hygiene training was an effective approach to improving insomnia in postmenopausal women (Duman & Taşhan, 2018).*

• Work closely with the client to develop appropriate educational tools that address individualized needs. **EB:** *A participatory project to develop patient education materials for older adults about lung stereotactic body radiotherapy (SBRT) involved patients at each step of the process. Participants had high health literacy and home Internet access, but researchers found that the participants had a preference for written and verbal teaching about the SBRT procedure (Jewitt et al, 2016).*

▲ Teach the client about available community resources (e.g., therapists, ministers, counselors, self-help groups). **EBN:** *Easom, Cotter, and Ramos (2018) conducted a postparticipation examination of the Resources for Enhancing Alzheimer's Caregiver Health (REACH II) program provided to African American and Caucasian caregivers of people with Alzheimer's disease and found it to be a culturally appropriate and effective program.*

Readiness for enhanced Coping

Marina Martinez-Kratz MS, RN, CNE

NANDA-I

Definition

A pattern of valid appraisal of stressors with cognitive and behavioral efforts to manage demands related to well-being, which can be strengthened.

Defining Characteristics

Awareness of possible environmental change; expresses desire to enhance knowledge of stress management strategies; expresses desire to enhance management of stressors; expresses desire to enhance social support; expresses desire to enhance use of emotion-oriented strategies; expresses desire to enhanced use of problem-oriented strategies; expresses desire to enhance use of spiritual resource

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Coping; Personal Well-Being; Social Interaction Skills; Quality of life

Example NOC Outcome with Indicators

Coping as evidenced by the following indicators: Identifies effective coping patterns/Uses effective coping strategies. (Rate the outcome and indicators of **Coping:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Acknowledge personal power
- State awareness of possible environmental changes that may contribute to decreased coping
- State that stressors are manageable
- Seek new effective coping strategies
- Seek social support for problems associated with coping
- Demonstrate ability to cope, using a broad range of coping strategies
- Use spiritual support of personal choice

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Coping Enhancement; Health Education; Decision-Making Support

Example NIC Activities—Coping Enhancement

Assist client in developing an objective appraisal of the event; Explore with client previous methods of dealing with life problems

Nursing Interventions and *Rationales*

- Assess and support positive psychological strengths, that is, hope, optimism, self-efficacy, resiliency, and social support. **EBN:** *Based on a systematic review (N = 57 studies) covering the phases of the cancer experience, researchers found resilience and optimism are protective characteristics that contribute to coping and well-being (Molina et al, 2014).*
- Be physically and emotionally present for the client while using a variety of therapeutic communication techniques. **EBN:** *A qualitative study using focus groups to understand nurses' (N = 27) experiences of presence, found empathy, active listening, and use of silence were among the therapeutic communication approaches that were required to implement presence and improve client outcomes (Stockmann et al, 2016).* **EBN:** *Adult primary care clients (N = 251) receiving early cancer care identified nurses' use of active listening, providing information, and being present for client-centered care as critical behaviors of oncology nurse navigators (Horner et al, 2013).*
- Empower the client to set realistic goals and to engage in problem-solving. **EBN:** *In a randomized control trial testing the effectiveness of a 16-week Oncology Nurse Navigator (ONN) program compared with standard care to support clients with cancer (N = 251) during early treatment, researchers described the intervention, which included the use of using problem-solving and motivational interviewing in the provision of psychosocial support (Horner et al, 2013).*
- Encourage expression of positive thoughts and emotions. **EBN:** *In an intervention study of Turkish family caregivers of adults with mental illness, a family-to-family support intervention resulted in improvements in self-confidence and optimism in the experimental*

group (N = 34) after the intervention from baseline and at 3 months, whereas there was no change in the control group (N = 34) at any measurement period (Bademli & Duman, 2014).
• Encourage the client to use spiritual coping mechanisms such as faith and prayer. **EBN:** *In a qualitative study of the lived spiritual experiences of those receiving outpatient surgery, clients (N = 7) described their use of spiritual coping and that spiritual care at a time of vulnerability contributed to their well-being (Griffin, 2013).* **EBN:** *Use of spiritual coping such as praying has been associated with increased psychological well-being and decreased psychological distress in samples of Caucasian and African American early breast cancer survivors (Gaston-Johansson et al, 2013b).*
• Help the client with serious and chronic conditions such as depression, cancer diagnosis, and chemotherapy treatment to maintain social support networks or assist in building new ones. **EBN:** *Women with advanced breast cancer (N = 35) receiving high-dose chemotherapy were treated with a comprehensive coping strategy program that included the use of social support and other coping enhancement skills; the treatment group had improved quality of life at 1 year posttreatment (Gaston-Johansson et al, 2013a).*
▲ Refer for cognitive-behavioral therapy (CBT) to enhance coping skills. **EBN:** *Gaston-Johansson et al (2013a) from the Johns Hopkins School of Nursing conducted an intervention study that included cognitive restructuring as part of a comprehensive coping strategies program and found that women with breast cancer in the intervention group (N = 38) had improved well-being and quality of life compared with the control group (N = 35) at 1 year postintervention. Refer to the care plans for Readiness for enhanced **Communication** and Readiness for enhanced **Spiritual** well-being.*

Pediatric

• Encourage children and adolescents to engage in diversional activities and exercise to promote self-esteem, enhance coping, and prevent behavioral and other physical and psychosocial problems. **EBN:** *Researchers examining physical activity in children attending school (N = 133) found that enjoyment and self-efficacy were important influences in promoting physical activity in children (Ling et al, 2015).* **EBN:** *In a qualitative study of hospitalized children (N = 10) receiving chemotherapy for cancer, researchers found that engaging children in entertaining activities and having fun were among positive coping strategies (Sposito et al, 2015).*
• Provide families of children with chronic illness with education, transitional assistance, and psychosocial support to enhance coping. **EBN:** *An integrative literature review found that interventions should be directed toward education and psychosocial support for patients and families dealing with a new diagnosis of chronic illnesses (Gunter & Duke, 2018).*

Geriatric

• Encourage active, meaning-based coping strategies for older adults with chronic illness. **EBN:** *In a qualitative study of older adults living with HIV (N = 40) residing in an urban environment, researchers uncovered four themes: accessing support, helping one's self and others, and tapping into their own spirituality. These address successful coping for the participants (DeGrezia & Scrandis, 2015).*
• Consider the use of Web-based and technological resources for older adults in the community. **EB:** *The results of a mixed method systematic review of 112 articles indicated that approximately 24% of the articles addressed Web-based packages and assistive information technology that assists older adults and their family caregivers with health*

information, resources for performing tasks safely, engaging in self-management, increasing coping strategies, and other types of support; studies indicated client satisfaction as an outcome (Vedel et al, 2013).

• Refer the older client to self-help support groups that address health, psychosocial, and/or social support. **EB:** *In a mixed age sample with more than 50% of the participants older than age 50 years (range 19–83 years), Internet-based self-help groups for persons who experienced cancer (N = 350) have been associated with perceived increased coping and improved satisfaction with perceived health status (Seckin, 2013).* **EB:** *Greysen et al (2013) studied social isolation in older veterans and recommended the use of in-person and Internet-based self-help support groups.*

Multicultural

• Assess an individual's sociocultural backgrounds to identify factors that support coping. **EB:** *Researchers found that in a sample of African American college students (N = 191), a variety of past messages regarding racial socialization may predict race-specific coping in AA college students. (Blackmon et al, 2016).* **EB:** *In a study comparing coping strategies used by Caucasian, Korean, and African American older women (N = 343), researchers found there are differences in preferred coping strategies used by the three ethnic groups; the most common strategy used by all three groups was religious/spiritual belief systems (Lee & Mason, 2013).*

• Encourage spirituality as a source of support for coping. **EBN:** *Religion and spiritual practices were used by Buddhist and Muslim Thai women to cope with type 2 diabetes self-management (Lundberg & Thrakul, 2013).*

• Facilitate positive ethnocultural identity to enhance coping. **EB:** *Ojeda and Liang (2014) examined coping in Mexican American adolescent men (N = 93) and found that ethnocultural factors such as positive affirmation and view of one's ethnic identity, as well as culture bound characteristics, such as caballerismo (positive Latino masculinity), was associated with more effective coping strategies, such as positive reframing, planning, and the use of humor.* **EB:** *In African American women who self-reported experience with trauma (N = 161), higher self-esteem and well-being were associated with more effective, active coping strategies (Stevens-Watkins et al, 2014).*

• Foster family support. **EBN:** *In Madurai women who underwent hysterectomy (N = 60), researchers found that family support was associated with coping and quality of life and concluded that support from the partner is especially important to both coping and quality of life (Shanthi & Jeyapal, 2016). Refer to the care plan for Ineffective* ***Coping*****.**

Home Care

• The interventions described previously may be adapted for home care use.

• Engage both clients and their caregivers as a dyad. **CEBN:** *In a review of a program of research about helping clients and family caregivers cope with cancer, Northouse (2012) related lessons learned about caring for client and family caregiver dyad; recommendations included identifying strengths; three-way, open communication and alliances; and promoting active coping (versus avoidant coping).*

▲ Institute case management for frail elderly clients to support continued independent living. **EBN:** *Nurse-led community care for the oldest-old that includes care coordination and follow-up could preserve functioning in the oldest-old in the community (Bleijenberg et al, 2017).* **EB:** *A study examining tablet and Skype use in a case management program for frail older adults found that the participants had positive experiences with the technology as a*

means of communicating with case managers (Berner et al, 2016).

• Refer the client and family to support groups. **EB:** *A study of adolescents and adults with neurofibromatosis type 1 (NF1), a genetic, progressive disorder, explored knowledge of the disease, self-esteem, and the effect of support groups. Researchers found that participation in support groups had an influence on self-esteem and recommended that health care professionals inform clients about support groups (Rosnau et al, 2017).*

• Refer prostate cancer clients and their spouses to family programs that include family-based interventions of communication, hope, coping, uncertainty, and symptom management. **EBN:** *Researchers conducted a qualitative study of prostate cancer survivors and their spouses (N = 95) to determine the long-term quality of life effects of treatment at 36 months after treatment; the recommendations included offering counseling to couples after treatment to improve quality of life and assist with managing relationship intimacy (Harden et al, 2013).*

▲ Refer military members, veterans, and family members for appropriate health services. **EB:** *Research found veterans with and without posttraumatic stress disorder (PTSD) enrolled in the Veterans Administration Program of Comprehensive Assistance for Family Caregivers (PCAFC) accessed more mental health, primary, and specialty care services than weighted comparisons (Shepherd-Banigan et al, 2018).*

Client/Family Teaching and Discharge Planning

• Teach the client about available community resources (e.g., therapists, ministers, counselors, self-help groups, family education groups). **EBN:** *Easom, Cotter, and Ramos (2018) conducted a postparticipation examination of the Resources for Enhancing Alzheimer's Caregiver Health (REACH II) program provided to African American and Caucasian caregivers of people with Alzheimer's disease and found it to be a culturally appropriate and effective program.*

• Teach caregivers using a variety of interventions that contribute to coping. **EBN:** *Researchers conducting a systematic review of 17 articles regarding couples-based intervention for coping with cancer recommended interventions that include skills training, psychoeducational interventions, and client/family support (Li & Loke, 2014).*

• Teach expressive writing, journaling, and education about emotions. **EBN:** *Journaling was one of the components of an intervention study aimed to promote civility among nursing students; there were improvements in coping in the areas of self-controlling, seeking social support, and positive reappraisal after the intervention (Jenkins et al, 2013).*

Ineffective community Coping

Marina Martinez-Kratz MS, RN, CNE

NANDA-I

Definition

A pattern of community activities for adaptation and problem-solving that is unsatisfactory for meeting the demands or needs of the community.

Defining Characteristics

Community does not meet expectations of its members; deficient community participation; elevated community illness rate; excessive community conflict; excessive stress; high incidence of community problems; perceived community powerlessness; perceived community vulnerability

Related Factors

Inadequate resources for problem-solving; insufficient community resources; nonexistent community systems

At-Risk Population

Exposure to disaster; history of disaster

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Community Competence; Community Health Status; Community Violence Level

Example NOC Outcome with Indicators

Community Competence as evidenced by the following indicators: Participation rates in community activities/Consideration of common and competing interests among groups when solving community problems/Representation of all segments of the community in problem-solving/Effective use of conflict management strategies. (Rate the outcome and indicators of **Community Competence:** 1 = poor, 2 = fair, 3 = good, 4 = very good, 5 = excellent [see Section I].)

Community Outcomes

A Broad Range of Community Members Will (Specify Time Frame)

- Participate in community actions to improve power resources
- Develop improved communication among community members
- Participate in problem-solving
- Demonstrate cohesiveness in problem-solving
- Develop new strategies for problem-solving
- Express power to deal with change and manage problems

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Community Health Development; Program Development

Example NIC Activities—Community Health Development

Enhance community support networks; Identify and develop potential community leaders; Unify community members behind a common mission; Ensure that community members maintain control over decision-making

Nursing Interventions and *Rationales*

Note: The diagnosis of Ineffective **Coping** does not apply and should not be used when stress is being imposed by external sources or circumstance. If the community is a victim of circumstances, using the nursing diagnosis Ineffective **Coping** is equivalent to blaming the victim. See the care plan for Readiness for enhanced community **Coping**.

▲ Establish a collaborative partnership with the community (see the care plan for Readiness for enhanced community **Coping** for additional references). **EB:** *A recent study found that counties whose Area Agencies for the Aging (AAAs) maintained informal partnerships with a broad range of organizations in health care and other sectors had significantly lower hospital readmission rates compared with counties whose AAAs had informal partnerships with fewer types of organizations (Brewster et al, 2018).*
• Assess community needs with the use of concept mapping methodology. **EB:** *The findings of a recent study showed that an integration of several concept mapping methods into a community engagement process was able to increase the input from a wide range of populations (Velonis et al, 2018).*
• Encourage participation in faith-based organizations that want to improve community stress management. **EBN:** *A recent study showed that coaching by faith community nurses created an environment of sustained support that promoted improved lifestyles and blood pressure changes over time (Cooper & Zimmerman, 2017).*
▲ Identify the health services and information resources that are currently available in the community through network analysis. **EB:** *A study found that network analysis served as a useful tool to evaluate community partnerships and facilitate coalition building (Ruopeng et al, 2017).*
• Work with community members to increase problem-solving abilities. **EBN:** *Problem-solving is essential for effective coping. Findings from a recent study showed positive outcomes from a direct and tailored problem-solving training program (Easom et al, 2018).*
• Provide support to the community and help community members identify and mobilize additional supports. **EB:** *A community mobilization project demonstrated how cross-sector, coordinated efforts focused on vulnerable populations can leverage local strengths to establish and enhance breastfeeding support services customized to local needs (Colchamiro et al, 2015).*
• Advocate for the community in multiple arenas (e.g., multimedia, social media, governmental agencies). **EB:** *A recent study explored how social media can help community organizations engage in advocacy work (Guo et al, 2017).*
• Work with communities to ensure that vulnerable individuals with access and functional needs are included in preparations for, response to, and recovery from disasters. **EB:** *Analysis of recent disasters has identified that a combination of strategic and operational methods, appropriate planning tools, and planning for the entire community will prevent individuals with access and functional needs from being disproportionately and negatively affected by disasters (Franks & Seaton, 2017).*
• Write grant proposals to help community members obtain funds for programs that reduce stress or improve coping (Anderson & McFarlane, 2011).
• Work with members of the community to identify and develop coping strategies that promote a sense of power (e.g., obtaining sources for funding, collaborating with other communities) (Anderson & McFarlane, 2011).

Pediatric

• Protect children and adolescents from exposure to community violence. **EB:** *A systematic review found evidence for a positive association between community violence exposure and cardiovascular and sleep problems in children and adolescents (Wright et al, 2017).*
• Assess children and adolescents for the effects of direct and indirect crime exposure rather than only focusing solely on violent victimization. **EB:** *A study found poor behavioral health outcomes for adolescents with self-reported crime exposure (Grinshteyn et al,*

2018).

Multicultural

- Acknowledge the stressors unique to racial/ethnic communities. **EB:** *A recent study of Hispanic and African American women found that neighborhood context was an important factor in examining the determinants of health, survivorship, and quality of life outcomes among cancer patients (Wu et al, 2018).*
- Identify community strengths with community members. **EBN:** *A community-based participatory research approach was used to obtain Native American community input and identify strengths to address youth suicide and substance abuse. The results led to the development of a strengths-based intervention incorporating the Gathering of Native American's curriculum (Holliday et al, 2018).*
- Use an empowerment approach to address health behaviors in diverse communities. An empowerment approach includes increasing clients' self-efficacy and capacity to make informed decisions about their health care. **EB:** *A recent study found use of an empowerment approach was effective in changing nonadherent Latinas' breast screening behaviors and promoting them to become agents of change in their communities (Molina et al, 2018). The empowerment intervention has three sessions focused on early detection, sharing information with family/friends, and health volunteerism.*
- Work with members of the community to prioritize and target health goals specific to the community. **EB:** *Recent research found that members of underserved communities, in informed deliberations, prioritized research on quality of life, patient-doctor, special needs, access, and compare approaches (Goold et al, 2017).*
- Establish and sustain partnerships with key individuals within communities when developing and implementing programs. **EB:** *A study of community engagement strategies found the following techniques to be effective: proactively engaging stakeholders in informational meetings, webinars, social media, the promising practice process, and community advisory council meetings (D'Angelo et al, 2017).*
- Use mentoring strategies for community members. **EB:** *A recent study showed parent mentors are highly effective in insuring uninsured Latino children and eliminating disparities (Flores et al, 2018).*
- Use community church settings as a forum for advocacy, teaching, and program implementation. **EBN:** *A recent study found that trust, respect, open dialog with participants, and commitment to address community health needs contributed to successful engagement and recruitment of African American churches to serve as participants in cancer research projects (Slade et al, 2018).*

Community Teaching

- Teach strategies for stress management.
- Explain the relationship between enhancing power resources and coping.

Compromised family Coping

Katherina Nikzad-Terhune PhD, MSW

NANDA-I

Definition

A usually supportive primary person (family member, significant other, or close friend) provides insufficient, ineffective, or compromised support, comfort, assistance, or encouragement that may be needed by the client to manage or master adaptive tasks related to his or her health challenge.

Defining Characteristics

Assistive behaviors by support person produce unsatisfactory results; client complaint about support person's response to health problems; client concern about support person's response to health problem; limitation in communication between support person and client; protective behavior by support person incongruent with

client's abilities; protective behavior by support person incongruent with client's need for autonomy; support person reports inadequate understanding that interferes with effective behaviors; support person reports insufficient knowledge that interferes with effective behaviors; support person reports preoccupation with own reaction to client's need; support person withdraws from client

Related Factors

Coexisting situations affecting the support person; exhaustion of support person's capacity; family disorganization; insufficient information available to support person; insufficient reciprocal support; insufficient support given by client to support person; insufficient understanding of information by support person; misinformation obtained by support person; preoccupation by support person with concern outside of family

At-Risk Population

Developmental crisis experienced by support person; family role change; prolonged disease that exhausts capacity of support person; situational crisis faced by support person

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Caregiver Emotional Health; Caregiver-Client Relationship; Family Coping; Family Participation in Professional Care; Family Support During Treatment

Example NOC Outcome with Indicators

Family Coping as evidenced by the following indicators: Confronts family problems/Manages family problems/Reports needs for family assistance. (Rate each indicator of **Family Coping:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Family/Significant Person Will (Specify Time Frame)

- Verbalize internal resources to help deal with the situation
- Verbalize knowledge and understanding of illness, disability, or disease
- Provide support and assistance as needed
- Identify need for and seek outside support

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Caregiver Support; Coping Enhancement; Family Involvement Promotion; Family Mobilization; Family Support; Mutual Goal Setting; Normalization Promotion; Sibling Support

Example NIC Activities—Family Support

Appraise family's emotional reaction to client's condition; Promote trusting relationship with family

Nursing Interventions and *Rationales*

- Assess the strengths and deficiencies of the family system. Consider using Family Systems Nursing to focus on the entire family as a unit of care. **EBN:** *A systematic review of the Family Systems Nursing literature found that when the focus was on both the individual and the family as a unit, improvements across cognitive, emotional, and behavioral domains were found, including enhanced understanding and coping, improved emotional well-being for the family and the individual, and improved interactions among family members (Östlund & Persson, 2014).*
- Establish rapport with families by providing accurate communication.

• Assist family members to recognize the need for help and teach them how to ask for it.
• Encourage family members to verbalize feelings. Spend time with them, sit down and make eye contact, and offer coffee and other nourishment.
• Provide family support interventions in situations in which caregiving is involved in the family. **EB:** *A comprehensive review of caregiving literature in both the fields of aging and developmental disabilities revealed that family-support interventions improved participant well-being, improved service access and satisfaction, reduced caregiver burden, and delayed institutional placement (Heller, Gibbons, & Fisher, 2015).*
• Provide privacy during family visits. If possible, maintain flexible visiting hours to accommodate more frequent family visits. If possible, arrange staff assignments so the same staff members have contact with the family. Familiarize other staff members with the situation in the absence of the usual staff member. Providing privacy, maintaining flexible hours, and arranging consistent staff assignments reduces stress, enhances communication, and facilitates the building of trust.
• Provide education to clients regarding active coping strategies to use in situations involving chronic illnesses. **EB:** *Mindfulness-based activities and cognitive behavioral therapy strategies can improve emotional, behavioral, and cognitive functioning in individuals experiencing various stressors (Gu et al, 2015).*
• Provide psychoeducation interventions and support for families providing palliative care to help reduce caregiver stress and burden. **EB:** *Brief psychoeducation interventions helped reduce stress in caregivers caring for a dying relative (Hudson et al, 2015).*
• Refer the family with ill family members to appropriate resources for assistance as indicated (e.g., counseling, psychotherapy, financial assistance, spiritual support).

Pediatric

• Provide screening for postpartum depression (PPD) during the prenatal period and during the 6-week postpartum checkup to identify symptoms of depression in mothers. **CEB:** *The Edinburgh Postnatal Depression Scale (EPDS) is the most widely used screening tool for detecting PPD and has been shown to be effective both prenatally and postnatally for detecting symptoms of depression in women (Cox, Holden, & Sagovsky, 1987; Zhong et al, 2014).*
▲ Consider medication management and psychosocial interventions, including individual therapy, group therapy, support groups, and brief psychotherapy. **EB:** *These are effective treatment strategies for managing PPD (Kleiman & Raskin, 2013; Miniati et al, 2014).*
▲ Use preventive strategies, such as screening, psychoeducation, postpartum debriefing, and companionship in the delivery room (e.g., community volunteer). **EBN:** *These strategies play an important role in the prevention of and recovery from PPD (Dennis & Dowswell, 2013).*
• Use technology-based education to help increase knowledge and support for parents performing care procedures for their children. **EBN:** *Research suggests that smartphone-based education should be considered as an effective educational intervention in providing nursing support for parents of children with respiratory disease (Lee, Kim, & Min, 2017).*
• Make communication and environmental adaptations when interacting with children with autism spectrum disorder (ASD) to enhance communication, improve quality of care, and reduce frustration. **EBN:** *Feasible adaptations in communication style*

can help enhance the nurse–patient relationship with children with ASD. Adaptations include reducing environmental sensory stimuli, recognizing that behavioral outbursts are often a sign of frustration in the child, and allowing for extra time when interacting with children with ASD (Brown & Elder, 2014).

• Effectively engaging and collaborating with parents is essential for supporting parents of children with long-term health conditions, and it may enhance the parent–professional relationship and communication. **EBN:** *Smith, Swallow, and Coyne (2015) provided a framework for involving parents in the care of a child with long-term health conditions, which includes valuing the parent's knowledge and expertise of their child, supporting parents in their role, establishing rapport, mutually exchanging information with parents, sharing decisions, collaborating during care planning, and designing services around both the needs of the child and the family.*

• Provide evidence-based psychological therapies for parents with children with chronic conditions. **EB:** *Psychological therapies, such as cognitive behavioral therapy, can lead to improvements in mood and behavior in parents of children diagnosed with attention-deficit hyperactivity disorder (ADHD) (Wong et al, 2017).*

• When performing pediatric diabetes care, be attentive to the mother's experience, including burnout experienced as a result of caregiving for the child. **EBN:** *The well-being of the mother has the potential to impact the well-being of the child and the well-being of the family unit. Focusing on the well-being of mothers of children with pediatric diabetes may lead to improvements in overall family functioning, and referrals for appropriate interventions (Lindström et al, 2017).*

• Provide options for home-based interventions when severe childhood illnesses make it difficult for children and families to participate in interventions. In-home visits, assessments, and interventions may help improve self-management among the patient and family, and reduce emergency room (ER) visits and inpatient hospitalizations. **EBN:** *The delivery of a home visit program for pediatric asthma patients enhanced early communication, reduced response time between problem identification and resolution, and reduced inpatient care over the course of 1 year (McClure et al, 2017).*

Geriatric

▲ Perform a holistic assessment of all needs of informal family caregivers. **EB:** *A systematic review of dementia caregivers revealed that caregivers often experience unmet needs regarding their own physical and psychological well-being (McCabe, You, & Tatangelo, 2016).* **EBN:** *Nurse-led caregiver-centered intervention may help prevent decompensation in caregiver well-being. Results from a recent study reveal that caregivers view a trusting relationship with mental health nurses as being crucial, and that collaboration with nurses can lead to increased well-being in both care recipients and caregivers (Zegwaard et al, 2017).*

▲ Provide caregivers with options for Internet-based support strategies to enhance coping. **EB:** *Research reveals that more than half of caregivers use the Internet to obtain caregiving information, including conditions or treatments, service availability, and care facilities (Li, 2015).*

• In situations in which familial caregiving is being provided, assess current coping strategies utilized within the family. Provide interventions for family caregivers that are designed specifically to enhance coping skills, including problem-solving strategies and emotional support. **EB:** *Psychosocial interventions that incorporated problem-solving skills, emotional support, knowledge of dementia, and social resources helped caregivers develop more effective coping strategies, which have the potential to reduce caregiver burden (Chen et al, 2015).*

• Assist informal caregivers with reducing unmet needs by helping them obtain the information and education necessary for caring for an older adult with a chronic health condition. **EB:** *Internet interventions can help meet the educational and support needs of informal dementia caregivers. Results from a systematic review demonstrate that Internet interventions for informal caregivers of individuals with dementia may lead to improvements in caregiver well-being, including improvements in confidence, depression, and self-efficacy (Boots et al, 2014).*

Multicultural

• Acknowledge sociocultural differences and health care disparities at the onset of care. **EBN:** *Consider using Almutairi's critical cultural competence (CCC) model as a comprehensive approach for addressing challenges that may arise from sociocultural and linguistic issues during cross-cultural interactions. Research support use of the Critical Cultural Competence Scale (CCCS) to measure health care providers' perceptions of their CCC (Almutairi, Dahinten, & Rodney, 2015; Almutairi & Dahinten, 2017).*
• Use valid and culturally competent assessment tools and procedures when working with families with different racial/ethnic backgrounds. **EBN:** *The cultural information in nursing models and assessments should encompass health beliefs and practices, communication styles, religious orientation, and the degree of acculturation among others (Shen, 2015).*
• Assess for the influence of cultural beliefs, norms, and values on the individual/family/community's perceptions of coping. **EB:** *A comprehensive review of the coping literature reveals that there are culturally preferred coping patterns among acculturating migrants, and that these patterns vary with acculturation levels. Nurses and other health care professionals should educate themselves on their patients' culturally preferred coping patterns (Kuo, 2014).*
• Provide opportunities for families to discuss spirituality. **EBN:** *African American women with breast cancer use more positive religious coping and experience less distress and greater spiritual well-being (Gaston-Johansson et al, 2013).*
• Ensure culturally responsive approaches to end-of-life care. **EBN:** *Providing culturally informed nursing care allows elderly immigrants the opportunity to make choices during their end-of-life care that are congruent with their cultural beliefs and expectations (Johnstone et al, 2016).*

Home Care

• The interventions described previously may be adapted for home care use.
• Assess the reason behind the breakdown of family coping. *Knowledge of the reasons behind compromised coping will assist in identification of appropriate interventions. Refer to the care plan for* **Caregiver Role Strain**.
▲ During the time of compromised coping, increase visits to ensure the safety of the client, support of the family, and reassurance regarding expectations for prognosis as appropriate.
▲ Assess the needs of the caregiver in the home, and intervene to meet needs as appropriate; explore all available resources that may be used to provide adequate home care (e.g., parish nursing as an effective adjunct, home health aide services to relieve the caregiver's fatigue).
▲ Encourage caregivers to attend to their own physical, mental, and spiritual health, and give more specific information about the client's needs and ways to meet them.

▲ Refer the family to medical social services for evaluation and supportive counseling. Serve as an advocate, mentor, and role model for caregiving; provide written information for the care needed by the client.
▲ A positive approach and caring by the nurse and concrete task definition and assignment reinforce positive coping strategies and allow caregivers to feel less guilty when tasks are delegated to multiple caregivers.
▲ When a terminal illness is the precipitating factor for ineffective coping, offer hospice services and support groups as possible resources. **EB:** *Research suggests that clients and their families value home hospice care services and report experiencing beneficial outcomes as a result of using hospice services (Ong et al, 2016).*
• Encourage the client and family to discuss changes in daily functioning and routines created by the client's illness, and validate discomfort resulting from changes. *Individuals who live together for a long period tend to become familiar with each other's patterns; for example, meals are expected at certain times or a spouse becomes accustomed to the client's sleep habits.*
• Support positive individual and family coping efforts. *Positive feedback reinforces desired behaviors and supports the family unit.*
• Screen for mental health disorders (MHDs) in the elderly home care population. **EBN:** *Approximately one-third of elderly patients with MHDs received mental health services during a 60-day home care episode. Regular screening and intervention protocols can improve psychiatric care for the homebound elderly (Wang et al, 2016).*
• During home care visits and assessments, provide individuals and families with information for Internet-based interventions, including information on using social media as a health communications tool. **EB:** *Social media is now a new dimension to health care that provides a platform for patients and health care providers to communicate about health, and potentially improve health outcomes. A systematic review of the literature revealed various benefits of using social media for health communication, including increased interactions with others, increased accessibility to information, more available shared information, and social support (Moorhead et al, 2013).*

Client/Family Teaching and Discharge Planning

• Assess grief in parents who have lost a child to help determine parental needs, especially in the first year after the death of a child. **EB:** *The presentation of grief may differ in mothers and fathers, resulting in different needs during the first year after a child's death (Youngblut et al, 2017).*
▲ Refer women with breast cancer and their family caregivers to support groups (including social network sites and online communities), and to other services that provide assistance with daily coping. **EB:** *Positive interventions applied to patients and survivors of breast cancer helped enhance quality of life, well-being, feelings of hope, and optimism (Casellas-Grau, Font, & Vives, 2014).*
▲ For families dealing with childhood illnesses or other psychosocial stressors, refer parents to support and education groups to provide opportunities for parents to access support, learn new parenting skills, and obtain additional coping resources. **EB:** *Childhood cancer support organizations and parent support groups are effective forms of support for families who have children with cancer (Dollman, Bekele, & Watanabe, 2014).* **EBN:** *Parents report satisfaction with Internet-based peer support, which can be used to supplement support offered by professionals (Niela-Vilén et al, 2014).*
• Provide comprehensive discharge planning for individuals with a mental health diagnosis to help improve quality of life at home. **EBN:** *During the discharge process,*

communication between health professionals, patients with a mental health diagnosis, and their families can result in quality of life improvements and reduced hospital readmissions (Nurjannah et al, 2014).

- Children of parents with dual diagnoses (e.g., psychiatric illness and addiction) require more extensive support and resources. **EB:** *Preventative support groups for children with parents with comorbidity can help support emotional, social, and cognitive coping skills, and may help reduce the risk of these children developing subsequent problems (van Santvoort et al, 2014a,b).*
- Nurses can help type II diabetes patients with self-management education and support (DSME/S), which includes the facilitation of knowledge, skills, and abilities necessary to manage diabetes, as well as obtaining the support necessary for executing and maintaining the coping and behavioral skills needed for self-management. **EB:** *Self-management education and support has been shown to improve health outcomes in patients with type II diabetes (Powers et al, 2017).*
- Involve informal caregivers of older adults in the discharge process. **EB:** *For older adults being discharged to a community setting, integrating informal caregivers into the discharge planning process reduced the risk of hospital readmission (Rodakowski et al, 2017).*

Disabled family Coping

Marsha McKenzie MA Ed, BSN, RN

NANDA-I

Definition

Behavior of primary person (family member, significant other, or close friend) that disables his or her capacities

and the client's capacities to effectively address tasks essential to either person's adaptation to the health challenge.

Defining Characteristics

Abandonment; adopts illness symptoms of client; aggression; agitation; client dependence; depression; desertion; disregard for client's needs; distortion of reality about client's health problem; family behaviors detrimental to well-being; hostility; impaired ability to structure a meaningful life; impaired individualization, intolerance; neglect of basic needs of client; neglect of relationship with family member; neglect of treatment regimen; performing routines without regard for client needs; prolonged hyperfocus on client; psychosomatic symptoms; rejection

Related Factors

Ambivalent family relationships; chronically unexpressed feelings by support person; differing coping styles between support person and client; differing coping styles between support persons; inconsistent management of family's resistance to treatment

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Caregiver Well-Being; Family Coping; Family Normalization; Neglect Recovery

Example NOC Outcome with Indicators

Family Normalization as evidenced by the following indicators: Adapts family routines to accommodate needs of affected member/Meets physical and psychosocial needs of family members/Provides activities appropriate to age and ability for affected family member/Uses community support groups. (Rate the outcome and indicators of **Family Normalization:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Family/Significant Person Will (Specify Time Frame)

- Identify normal family routines that will need to be adapted
- Participate positively in the client's care within the limits of his or her abilities
- Identify responses that may be harmful
- Acknowledge and accept the need for assistance with circumstances
- Identify appropriate activities for affected family member

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Family Process Maintenance; Caregiver Support; Family Support; Family Therapy; Respite Care

Example NIC Activities—Family Process Maintenance

Determine typical family processes; Minimize family routine disruption by facilitating family routines and rituals such as private meals together or family discussions for communication and decision-making; Design schedules of home care activities that minimize disruption of family routine

Nursing Interventions and *Rationales*

- Families dealing with acute trauma are susceptible to mild to very severe levels of anxiety. Support should be offered through necessary channels, which are appropriate to the situation, such as providing frequent information, offering social services, or counseling. **EB:** *Findings from one study suggest that a large percentage of caregivers of patients with trauma suffered from mild to very severe levels of anxiety*

(Rahnama et al, 2017).

• Assess coping strategies of both the patient and the spouse when managing women with breast cancer and men with prostate cancer. **EB:** *A study conducted by Lambert et al (2012) concluded that coping with prostate cancer was more effective when both the patient and spouse were assisted with management of the illness.*

• Cancer caregiving interventions should include communication skill building, including strategies for self-care. **EB:** *Findings from this study confirmed that caregiver quality of life is impacted by stress about communication across all domains (Wittenberg et al, 2017).*

• Provide ideas for positive child coping and consider collaboration with mental health providers for children with chronic illnesses who are facing emotional problems. **EBN:** *One study suggested that negative child coping may have deleterious effects on the family (Woodson et al, 2015).*

• Assess social support of family members caring for survivors of traumatic brain injuries (TBIs). Facilitate realistic expectations about caregiving. **EB:** *TBI survivors and caregivers had multiple self-reported unaddressed needs after their discharge from facility-based treatment. They expressed the need for further education regarding potential post-TBI challenges and strategies for addressing them, including a need for community and mental health resources (Adams & Dahdah, 2016).*

• Respect and promote the spiritual needs of the client and family. **EB:** *Spiritual well-being is associated with better mental health and positive coping skills of family caregivers (Kelley & Morrison, 2015).*

Pediatric

• Assist parents and children suffering from chronic illness to develop accommodative coping skills (adapting to stressors rather than attempting to change the stressors). **EB:** *Compas et al (2012) found considerable evidence across chronic childhood illnesses and medical conditions that suggests that secondary control coping, or accommodative coping, is related to better adjustment in children and adolescents.*

• Assess educational level of parents of ill children and construct parent teaching to address educational attainment. **EB:** *Gage-Bouchard, Devine, and Heckler (2013) found programs that address educational gaps and teach caregivers planning and active coping skills may be beneficial for parents with lower educational attainment, particularly men.*

Geriatric

• Assess the emotional well-being of family members who are caring for clients with long-term illnesses, such as stroke. **EB:** *A study by Ali and Kausar (2016) studied levels of psychological distress experienced by the caregivers of stroke patients concluding that distress can be reduced by providing greater social support.*

• Be aware of age-related deterioration in coping skills. **EB:** *Diehl et al (2014) found that the defense mechanisms of doubt, displacement, and regression increased after the age of 65 years. Linear age-related decreases were found for the coping mechanism of ego regression and the defense mechanisms of isolation and rationalization.*

Multicultural

• Be sensitive to the stigma attached to particular illness in various cultures. **EB:** *Iseselo, Kajula, and Yahya-Malima (2016) studied families coping with mental illness in Tanzania and concluded that the psychosocial challenges of families and caregivers require a*

collaborative approach.

Home Care

The interventions described previously may be adapted for home care use:

- Assess for strain in family caregivers.
- Assess for "caregiver fatigue" and provide information related to available respite care.
- Consult social services for available home resources related to the client's age and illness.

Client/Family Teaching and Discharge Planning

- Involve the client and family in the planning of care as often as possible.
- Recognize that family decision makers may need additional psychosocial support services.
- Educate family members regarding stress management techniques including massage and alternative therapies.

Readiness for enhanced family Coping

Keith A. Anderson PhD, MSW

NANDA-I

Definition

A pattern of management of adaptive tasks by primary person (family member, significant other, or close friend) involved with the client's health challenge, which can be strengthened.

Defining Characteristics

Expresses desire to acknowledge growth impact of crisis; expresses desire to choose experiences that optimize wellness; expresses desire to enhance connection with others who have experienced a similar situation; expresses desire to enhance enrichment of lifestyle; expresses desire to enhance health promotion

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Family Coping; Health-Seeking Behavior; Participation in Health Care Decisions

Example NOC Outcome with Indicators

Family Coping as evidenced by the following indicators: Confronts and manages family problems/Cares for needs of all family members. (Rate the outcome and indicators of **Family Coping:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

State a plan indicating coping strengths, abilities, and resources, as well as areas for growth and change; Perform tasks and engage resources needed for growth and change; Evaluate changes and continually reevaluate plan for continued growth

NIC Interventions (Nursing Interventions Classification)

Suggested NIC Interventions

Family Integration Promotion; Family Involvement Promotion; Family Support; Mutual Goal Setting

Example NIC Activities—Family Coping

Facilitate communication of concerns and feelings between clients and family or among family members; Provide resources that support and encourage adaptive family coping; Respect and support adaptive coping mechanisms used by family

Nursing Interventions and *Rationales*

- Assess the structure, resources, and coping abilities of families and use these assessments in selecting interventions and formulating care plans. **EB/EBN:** *It is critical to understand the resiliency and coping capabilities of families; the use of established assessment instruments (e.g., Family Assessment Device, Family Assessment Measure) can provide insight into family dynamics, coping styles, and resources of family systems (Mansfield, Keitner, & Dealy, 2014; Sawin, 2016).*
- Acknowledge, assess, and support the spiritual needs and resources of families and clients. **EB/EBN:** *Spirituality has been found to be an important, yet often overlooked, coping resource for families and clients during illness and recovery (O'Brien, 2014; Hodge, 2015; Prouty et al, 2016).*
- Establish rapport with families and empower their decision-making through effective communication and patient/family-centered care. **EBN:** *Effective communication and patient/family-centered care approaches can help to establish rapport, personalize treatment plans, and empower families in their caregiving activities and decision-making capacities (Mitchell et al, 2016; Coombs et al, 2017).*
- Provide family members with educational and skill-building interventions to

alleviate caregiving stress and to facilitate adherence to prescribed plans of care. **EBN:** *The provision of psychoeducational and supportive interventions may enable family members to gain a sense of control in the caregiving role and to become more comfortable in providing care and making informed decisions (Ostlund & Persson, 2014; Dockham et al, 2016).*

▲ Develop, provide, and encourage family members to use counseling services and interventions. **EB/EBN:** *Family-centered counseling interventions have been shown to be effective, particularly in situations regarding serious illness and difficult family decisions (Cheng, Chair, & Chow et al, 2014; Creasy et al, 2015).*

▲ Identify and refer to support programs that discuss experiences and challenges similar to those faced by the family (e.g., cancer support groups). **EB:** *Although there is wide diversity in the format of support programs, couples and family support approaches can be beneficial and enhance coping (Ostlund & Persson, 2014; Inhestern et al, 2016).*

▲ Incorporate the use of emerging technologies to increase the reach of interventions to support family coping. **EBN:** *Emerging computer and Internet-based supportive and educational interventions may hold promise in enhancing family members' well-being and informational needs (Risling, Risling, & Holtslander, 2017; Salem et al, 2017).*

▲ Refer to Compromised family **Coping** for additional interventions.

Pediatric

▲ Identify and assess the management styles of families and facilitate the use of more effective ways of coping with childhood illness. **EB:** *Understanding the dominant characteristics of each family's coping styles and resources and helping them to use more effective management styles can result in better family functioning and treatment outcomes (Ketelaar et al, 2016; McCarthy et al, 2016).*

▲ Provide educational and supportive interventions for families caring for children with illness and disability. **EBN:** *Providing information, training parents in care management, and offering supportive programs can reduce stress levels in parents and lead to better outcomes for children (Golfenshtein, Srulovici, & Deatrick, 2016).*

Geriatric

▲ Encourage family caregivers to participate in counseling and support groups. **EB/EBN:** *Although a wide variety of programs exist, certain counseling and support group programs have been found to be effective in increasing family resourcefulness and lowering caregiver burden, anxiety, depression, and family conflict (Dam et al, 2016; Muller et al, 2017).*

▲ Provide educational and therapeutic interventions to family caregivers that focus on knowledge and skill building. **EBN:** *Psychoeducational interventions that are accessible and tailored to individual needs can be highly valued and useful to family caregivers (Bakas et al, 2014; Bakas, McCarthy, & Miller, 2017).*

Multicultural

▲ Acknowledge and understand the importance of cultural influences in families and ensure that assessments and assessment tools account for such cultural differences. **EB:** *Family coping tends to vary across cultures and may affect the fit, reliability, and validity of existing family functioning and coping assessment tools (Desai, Rivera, & Backes, 2016).*

▲ Understand and incorporate cultural differences into interventions to enhance the impact of family interventions. **EB/EBN:** *Tailoring interventions to the customs, beliefs, preferences, and strengths of specific groups may increase effectiveness (Dayer-Berenson,*

2014; *McCalman et al, 2017*).

Readiness for enhanced Decision-Making

Dawn Fairlie PhD, NP

NANDA-I

Definition

A pattern of choosing a course of action for meeting short- and long-term health-related goals, which can be strengthened.

Defining Characteristics

Expresses desire to enhance congruency of decisions with sociocultural goal; expresses desire to enhance congruency of decisions with sociocultural value; expresses desire to enhance congruency of decisions with goal; expresses desire to enhance congruency of decisions with values; expresses desire to enhance decision-making; expresses desire to enhance risk-benefit analysis of decisions; expresses desire to enhance understanding of choices for decision-making; expresses desire to enhance understanding of meaning of choices; expresses desire to enhance use of reliable evidence for decisions

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Decision-Making; Participation in Health Care Decisions; Personal Autonomy

Example NOC Outcome with Indicators

Participation in Health Care Decisions as evidenced by the following indicators: Claims decision-making responsibility/Exhibits self-direction in decision-making/Seeks reputable information/Specifies health outcome preferences. (Rate the outcome and indicators of **Participation in Health Care Decisions:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Review treatment options with providers
- Ask questions about the benefits and risks of treatment options
- Communicate decisions about treatment options to providers in relation to personal preferences, values, and goals

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Decision-Making Support; Mutual Goal Setting; Support System Enhancement; Values Clarification

Example NIC Activities—Decision-Making Support

Help client identify the advantages and disadvantages of each alternative; Facilitate collaborative decision-making; Help client explain decisions to others, as needed

Nursing Interventions and *Rationales*

- Support and encourage clients and their representatives to engage in health care decisions. **EB:** *Decisional conflict was assessed using the Decisional Conflict Scale among 186 Dutch mental health patients. They concluded that patient participation in decision-making and measuring decisional conflict and knowledge about influencing factors could improve adherence to treatment and clinical outcomes (Metz et al, 2018).* **EBN:** *Decision aids are intended to help people participate in decisions that involve weighing the benefits and harms of treatment options, often with scientific uncertainty. Hart, Tofthagen, and Hsiao-Lan (2016) developed a decision aid that could be adapted and used in a variety of settings with a focus on initiating a conversation between the patient and provider on lung cancer screening. Respect personal preferences, values, needs, and rights.* **EBN:** *"Clarifying values can be a rewarding exercise, as it not only ensures the best possible decision but demonstrates to patients that we are genuinely interested in incorporating their views and how they value the outcomes from screening options" (Lang et al, 2018, p 29).*
- Provide information that is appropriate, relevant, and timely. **EBN:** *Decisional conflict was assessed using the Decisional Conflict Scale (DCS) among surrogate decision-makers to compare end-of-life terminologies "Do Not Resuscitate" (DNR) and "Allow Natural Death" (AND). Findings included that the framing of the decision influenced decision satisfaction and decision-making. Additionally, prior experience with end-of-life decision-making demonstrated lower mean total DCS scores and lower mean subscores, indicating that prior experience is an important aspect of end-of-life decision-making (Fairlie, 2017).*
- Determine the health literacy of clients and their representatives before helping with decision-making. **EB:** *An online decision aid for a low health literacy population will be pilot tested with 30 women diagnosed with early breast cancer with the anticipation that the low health literacy decision aid will be useful and acceptable to young women with low health literacy who have been diagnosed with breast cancer and it will be preferred over the high literacy decision aid (Peate et al, 2017).*
- Tailor information to the specific needs of individual clients, according to principles of health literacy. **EB:** *Altin and Stock (2016) sampled 1125 German adults to examine the contributions of health literacy, shared decision-making, patient-centered communication, and satisfaction with care received by the general practitioner. Respondents with sufficient health literacy skills were 2.06 times as likely to be satisfied with their care.*
- Motivate clients to be as independent as possible in decision-making. **EB:** *A study of shared decision-making and autonomy among patients with multiple sclerosis revealed that patient-centered decision-making was most commonly preferred by study participants, followed by shared decision-making (Cofield et al, 2017).*
- Facilitate communication between the client and family members regarding the final decision; offer support to the person actually making the decision. **EBN:** *A study of surrogate decision-makers' decisional conflict with end-of-life decision-making found that surrogates who had discussed end-of-life preferences with their loved one experienced less decisional conflict than those who had not discussed preferences (Fairlie, 2017).*
- Design educational interventions for decision support. **EBN:** *The goal of patient decision aids is to engage patients in health care decisions by providing evidence-based*

information in plain language. The goal is to assist patients in understanding the risks and benefits of all available treatment/diagnosis options and engage patients in health care decisions to improve alignment of treatment choices with patients' preferences (Madden & Kleinlugtenbelt, 2017).

Geriatric

- The previously mentioned interventions may be adapted for geriatric use.
- Facilitate collaborative decision-making. **EB:** *A systematic review of randomized controlled trials evaluating the efficacy of decision aids compared with the usual care for older adults facing treatment, screening, or care decisions found that decision aids improve older adults' knowledge, increase their risk perception, decrease decisional conflict, and seem to enhance participation in shared decision-making (van Weert et al, 2016).*

Multicultural

- Use existing decision aids for particular types of decisions or develop decision aids as indicated. **EB:** *Hoffman et al (2017) measured decisional conflict as a primary measure of decision quality and an intermediate measure in the process of screening uptake in a sample of 88 African American males. The purpose of patient decision was to prepare patients for a consultation with their doctor. The entertainment–education decision aid significantly improved African American patients' knowledge, reduced their decisional conflict, and increased their sense of self-advocacy regarding colorectal cancer screening.*

Home Care

- The previously mentioned interventions may be adapted for home care use.
- Develop clinical practice guidelines that include shared decision-making. **EBN:** *Thoma-Lurken et al (2018) reported that people with dementia who wish to age in place are susceptible to nursing home admission. Nurses can intervene by detecting practical problems people with dementia and caregivers face. They identified three domains, decreased self-reliance, safety-related problems, and informal caregiver/social network-related problems, and proposed addressing these domains to facilitate aging in place.*

Client/Family Teaching and Discharge Planning

- Instruct the client and family members to provide advance directives in the following areas:
    - ❍ Person to contact in an emergency
    - ❍ Preference (if any) to die at home or in the hospital
    - ❍ Desire to initiate advanced directives, such as a living will or medical power of attorney
    - ❍ Desire to donate an organ
    - ❍ Funeral arrangements (i.e., burial, cremation)

▲ **EBN:** *Shared decision-makers experienced less decisional conflict when they had discussed end-of-life preferences with the client (Fairlie, 2017).*

Decisional Conflict

Dawn Fairlie PhD, APRN-BC

NANDA-I

Definition

Uncertainty about course of action to be taken when choice among competing actions involves risk, loss, or challenge to values and beliefs.

Defining Characteristics

Delay in decision-making; distress while attempting a decision; physical sign of distress (e.g., increase in heart rate, restlessness); physical sign of tension; questioning of moral principle while attempting a decision; questioning of moral rule while attempting a decision; questioning of moral values while attempting a decision; questioning of personal beliefs while attempting a decision; questioning of personal values while attempting a decision; recognizes undesired consequences of actions being considered; self-focused; uncertainty about choices; vacillating among choices

Related Factors

Conflict with moral obligation; conflicting information sources; inexperience with decision-making; insufficient information; insufficient support system; interference in making decision-making; moral principle supports mutually inconsistent actions; moral rule supports mutually inconsistent actions; moral value supports mutually inconsistent actions; perceived threat to value system; unclear personal beliefs unclear personal values

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Decision-Making; Information Processing; Participation in Health Care Decisions; Personal Autonomy

Example NOC Outcome with Indicators

Decision-Making as evidenced by the following indicators: Identifies relevant information/Identifies alternatives/Identifies potential consequences of each alternative/Identifies needed resources to support each alternative. (Rate the outcome and indicators of **Decision-Making:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised

[see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- State the advantages and disadvantages of choices
- Share fears and concerns regarding choices and responses of others
- Seek resources and information necessary for making an informed choice
- Make an informed choice

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Decision-Making Support

Example NIC Activities—Decision-Making Support

Inform client of alternative views or solutions in a clear and supportive manner; Provide information requested by client

Nursing Interventions and *Rationales*

- Observe for factors causing or contributing to conflict (e.g., value conflicts, fear of outcome, poor problem-solving skills). **EB:** *When studying clients with prostate cancer, Hoffman et al (2018) assessed differences across four treatment groups and asked about decision-making.*
- Decisional conflict was associated with anxiety. Findings suggested a potential role for early use of validated decision aids.
- Provide emotional support. **EB:** *O'Neill et al (2018) assessed the information needs and levels of distress and correlates of this distress of young women with breast cancer. They reported lower distress and significantly lower decisional conflict and greater endorsement of an array of healthy coping strategies and suggested that young adult women have unmet cancer genetic information and support needs.*
- Use decision aids or computer-based decision aids to assist clients in making decisions. **EB:** *Baptista et al (2018) found that Web-based decision aids performed similarly to alternative formats for decision-quality outcomes. Additionally, because of anonymity Web-based decision aids increased access to decision aids that support prostate cancer screening decisions among men. Initiate health teaching and referrals when needed.* **EB:** *Lopez-Olivo et al (2018) developed and tested multimedia patient education tools (video tools) for patients with knee osteoarthritis (OA), osteoporosis (OP), and rheumatoid arthritis (RA). They found that multimedia educational tools that incorporate videos increase patient understanding and management of their disease.*
- Facilitate communication between the client and family members regarding the final decision; offer support to the person actually making the decision. **EBN:** *A study of surrogate decision makers' decisional conflict with end-of-life decision-making found that surrogates who had discussed end-of-life preferences with their loved ones experienced less decisional conflict than those who had not discussed their preferences (Fairlie, 2018).*

Geriatric

- Carefully assess clients with dementia regarding ability to make decisions. **EBN:** *A*

study of the shared decision-making process of persons with dementia identified a broad spectrum of the shared decision-making process. Results indicated that not all persons with dementia are excluded from participating in the decision-making process. Loizeau et al (2018) tested the effect of fact box decision support tools on decisional conflict and preferences in advanced dementia. They found that fact boxes reduced decisional conflict, increased knowledge, and promoted preferences to forego antibiotics in advanced dementia in decision makers.

• Discuss the purpose of advance directives such as a living well or medical power of attorney. **EB:** *Basile et al (2018) studied a Web-based decision aid in patients with severe chronic obstructive pulmonary disease to assist in preparation for decision-making about invasive mechanical ventilation for respiratory failure. Increased knowledge and opportunity to deliberate and discuss treatment choices after using the decision aid improved decision-making at the time of critical illness.*

Multicultural

• Assess for the influence of cultural beliefs, norms, and values on the client's decision-making conflict. **EB:** *A study of couples undergoing genetic counseling found that factors associated with conflict during decision-making included cultural customs, age, emotional state, religious beliefs, and being forced to attend counseling. Provide support for client's decision-making (Schoeffel et al, 2018).*

Home Care

• The interventions described previously may be adapted for home care use.
▲ **EB:** *Torke et al (2018) conducted a feasibility study of the Physician Orders for Life-Sustaining Treatment (POLST) with community-dwelling adults aged 65 and older enrolled in a complex care management program. They found that 87.5% of decision makers agreed or strongly agreed that "talking about the (POLST) form helped me think about what I really want."*

Client/Family Teaching and Discharge Planning

• Instruct the client and family members to provide advance directives in the following areas:
- ❍ Person to contact in an emergency
- ❍ Preference (if any) to die at home or in the hospital
- ❍ Desire to initiate advanced directives, such as a living will or medical power of attorney
- ❍ Desire to donate an organ
- ❍ Funeral arrangements (i.e., burial, cremation)

▲ **EBN:** *Shared decision makers experienced less decisional conflict when they had discussed the client's preferences with the client (Fairlie, 2018).*

• Inform the family of treatment options; encourage and defend self-determination. **EB:** *Hwang et al (2018) surveyed patients seeking treatment for a lumbar herniated disc and measured decisional conflict using the SURE questionnaire. They found that participants with decisional conflict were less satisfied with their treatment decision and found a high level of decisional conflict when choosing a treatment option. They concluded that there is a need to implement tools and strategies to improve decisional quality, such as decision aids before consultation.*

• Recognize and allow the client to discuss the selection of complementary therapies

available, such as spiritual support, relaxation, imagery, exercise, lifestyle changes, diet (e.g., macrobiotic, vegetarian), and nutritional supplementation. **EB:** *Hippman and Balneaves (2018) studied women's decision-making for treatment of depression during pregnancy and found that women require a nonjudgmental environment when choosing between medications, psychotherapy, electroconvulsive therapy, deep brain stimulation, and complementary and alternative medicine options.*

▲ Provide the POLST form for clients and families faced with end-of-life choices across the health care continuum. **EB:** *Torke et al (2018) found that a large majority of decision makers agreed or strongly agreed that talking about the (POLST) form helped with decision-making.*

Impaired emancipated Decision-Making

Ruth A. Wittmann-Price PhD, RN, CNS, CNE, CHSE, ANEF, FAAN

NANDA-I

Definition

A process of choosing a health care decision that does not include personal knowledge and/or consideration of social norms, or does not occur in a flexible environment, resulting in decisional dissatisfaction.

Defining Characteristics

Delay in enacting chosen health care option; distress when listening to other's opinion; excessive concern about what others think is the best decision; excessive fear of what others think about a decision; feeling constrained in

describing own opinion; inability to choose a health care option that best fits current lifestyle; inability to describe how option will fit into current lifestyle; limited verbalization about health care options in others' presence

Related Factors

Decrease in understanding of all available health care options; inability to adequately verbalize perceptions about health care options; inadequate time to discuss health care options; insufficient confidence to openly discuss health care options; insufficient information regarding health care options; insufficient privacy to openly discuss health care options; insufficient self-confidence in decision-making

At-Risk Population

Limited decision-making experience; traditional hierarchical family; traditional hierarchical health care system

NOC Outcomes (Nursing Outcomes Classification)

Suggested NOC Outcomes

Decision-Making; Self-Esteem; Coping; Health Promoting Behavior; Stress Level; Communication; Self-Care Status; Participation in Health Care Decisions; Health-Seeking Processing; Personal Autonomy; Psychosocial Adjustment: Life Change

Example NOC Outcome with Indicators

Participation in Health Care Decisions as evidenced by the following indicator: Claims decision making responsibility. (Rate the outcome and indicators of **Participation in Health Care Decisions:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Verbalize option outcomes freely before making a health care decision
- Freely verbalize own opinion with health care providers before making a health care decision
- Choose the health care option that fits his or her lifestyle within an appropriate amount of time that allows enactment of the choice
- Describe how the chosen option fits into his or her current lifestyle before or after the decision has been made
- Verbalizes appropriate concern about others' opinions before making the health care choice
- Remains stress-free when listening to others' opinions before making the health care choice
- Arrives at a decision in a timely manner

NIC Interventions (Nursing Interventions Classification)

Suggested NIC Interventions

Decision-Making Support; Health Coaching; Cognitive Restructuring; Self-Awareness Enhancement

Example NIC Activities—Emancipated Decision-Making

Assist client in making an emancipated decision about health care options by discussing social norms with the client; Provide a flexible environment; Encourage the client to use personal knowledge

Nursing Interventions and *Rationales*

- Assess client's readiness to openly discussing the decision-making process. **EB:**

DenOuden, Vos, and Guy (2017) studied shared decision-making with diabetic patients (N = 72) and found that in a randomized control trial those patients who chose to be involved in the decision-making process achieved better goals (lower A1C levels and lower blood pressures) than those diabetic patients who did not openly participate in health care decision-making. **EB:** *Chen (2017) conducted a study with 15 cancer patients about the decision-making process within three stages of cancer treatment and found that different decision-making approaches to provided information was taken by patients and ranged from informed, to paternalistic, to shared. This study demonstrates that increased attention is needed to open a discussion about treatment options and more provider education on the shared decision-making process.*

• Use active listening in a nonjudgmental manner to provide the client with a flexible decision-making environment. **EB:** *A study done retrospectively with spinal cord injury patients (N = 22) demonstrated that decision-making was easier in the nonacute stage and that the environment affected the patient's decision-making ability. Along with the environment the communication of information was important and assisted patients to "personalize" their decisions (Schelle-Sailer et al, 2017).* **EB:** *In a randomized control trial, Perestelo-Perez et al (2017) studied patients with depression using a shared decision-making aid (N = 68) with those not using (N = 70) an aid and found that patients using the tool perceived their goals and concerns were better met.*

• Use anticipatory guidance by proactively providing the client with information. **EB:** *Brom et al (2017) studied shared decision-making with end-of-life patients and found that practitioners need to have ongoing communication to understand patients' expectations and concern to guide patients through the last stages of life.* **CEB:** *Wittmann-Price, Fliszar, and Bhattacharya (2011) found in a mixed method study that the majority of pregnant clients (N = 50) reported they had been provided with information prenatally, but not all clients felt they were given enough information at the time of delivery to make an informed choice.*

• *Establish a purposeful provider–client relationship.* **EB:** *A mixed methods study with Parkinson's patients (N = 65) demonstrated that the provider–patient relationship was important for the patient in the decision-making process. Establishing a relationship affected patients' ability to enact decisions based on their own preference (Zizzo et al, 2017).* **EB:** *In a study involving oncologists it was found that patient preferences (N = 60) were most commonly initiated by the patient and not the provider. The student suggests additional education for providers in eliciting patients' preferences would enhance communication and treatment (Henselmans et al, 2017).*

▲ Refer to counseling as needed. **EB:** *Klausen et al (2017) qualitatively studied patients in the outpatient setting (N = 25) who were referred for mental health issues and found four key components to shared decision-making: (1) during admission, (2) in individualized treatment, (3) in different treatment contexts, and (4) in user–professional relationships.* **CEB:** *Wittmann-Price (2006) demonstrated in a quantitative correlational study that women's (N = 97) decision-making was empowered when they were provided resources and information to arrive at an emancipated choice.*

• Provide decision-making support. **EBN:** *A case study of a pregnant patient whose decision-making abilities were deficit highlights the need for ethical consideration of the patient's values in the decision-making process (Mabel, Rose, & Kodish, 2017).* **EBN:** *Lazenby et al (2017) studied 15 physicians and 5 nurses about their involvement in end-of-life conversations and decisions with hemodialysis patients and found that advanced decision-making planning was deficit and needed attention to accommodate patients' wishes.*

• Provide a flexible environment by encouraging others to accept the client's choice. **EBN:** *A qualitative study with 11 women with breast cancer demonstrated that decision-making on treatment was enhanced by practitioners recognizing three aspects of decision-making: (1) issues caused by the health care problem, (2) understanding the societal burden*

related to gender, and (3) evaluating the patient's support system (Kkotbong & Jinhyang, 2017). **CEB:** *Wittmann-Price and Bhattacharya (2008) quantitatively studied pain management decisions for clients in labor (N = 92) and found that a flexible environment was needed for the client to make a supported and emancipated decision.*

• Encourage the client to use personal knowledge as part of the decision-making process to increase decisional satisfaction. **CEB:** *Women can make health care decisions that are right for them if they can use personal knowledge to overcome oppressive social forces (Stepanuk et al, 2013).* **CEB:** *Using personal knowledge is the best indicator to making an emancipated decision and correlates strongly and positively with satisfaction with the decision (Wittmann-Price, 2006).*

Pediatric

• When able, involve the client in health care decision-making when possible. **EBN:** *Adams and Levy (2017) found that a shared decision-making process with families who care for disabled children should include families' values and priorities to make the best decision for the child.* **EBN:** *Craske et al (2017) studied qualitatively how 12 nurses decide on withdrawal of pediatric sedation using vignettes to understand nurses' cognitive process and found in complex pediatric cases that there is a variation in assessing patient behavior and response to treatment. Provide parental information in the decision-making process.* **EBN:** *Delaney et al (2017) studied the use of a tool to assist practitioners to make caring decisions around pediatric end of life and found that it enhanced family empowerment and provided a professional resource.* **EBN:** *Richards et al (2017) performed an integrative review of family-centered behaviors that were experienced in the intensive care unit and found that there were five salient themes needed to engage parents in decision making: (1) sharing information, (2) hearing parental voices, (3) making decisions for or with parents, (4) negotiating roles, and (5) individualizing communication.*

• Enhance client decision-making in critical care setting. **EBN:** *Petrinec (2017) studied the family decision makers (N = 30) for patients in long-term critical care situations and found they had post intensive care syndrome, which warrants nursing awareness and interventions to support family decision makers.* **EBN:** *Stinson (2017) performed a descriptive correlational study with nurses that work in the intensive care unit and compared years of experience with their ability to engage in clinical decision-making. This may support separate education for decisional science in nursing education as practitioners and as patient advocates.*

Geriatric

• Include geriatric clients in the decisional process. **EB:** *Communication and decision-making go hand-in-hand for end-of-life care. Brooks, Manias, and Nicholson (2017) studied nurses (N = 17) and physicians (N = 11) in an intensive care unit about interprofessional end-of-life care and found that timing and conducting difficult conversations were better implemented with a team approach.* **EB:** *Paillaud et al (2017) studied older (over 70 years) patients' (N = 133) decision-making processes who did and did not have cancer and found that those with cancer had a strong desire for information and to be part of their health care decision-making process.*

Multicultural

• Consider cultural influences on decision-making. **EBN:** *A qualitative study of Korean women (N = 32) and their decision to get Pap smears was conducted by Kim et al (2017). The women who made a decision to receive a Pap smear desired to make the decision and were*

satisfied with their decision. **EBN:** *Adefris et al (2017) studied women (N = 384) who delayed treatment for uterine prolapse in sub-Saharan Africa and found that it was the "social stigma" within the culture and additional open communication about the problem is needed.*

Home Care

- Use open communication to assist clients to develop health care plans to which they can adhere. **EBN:** *An integrative review of the literature by Bayless et al (2017) found that men who choose active surveillance rather than surgical intervention for prostate cancer take a more active, communicative role in the decision-making process.* **EBN:** *Talley, Davis, and Wyman (2017) presented a case study about ethical decision-making and the concepts that need to be considered in all environments. They used a four-concept approach to decision-making that included health care indications, patient preference, quality of life, and contextual features.*

Readiness for enhanced emancipated Decision-Making

Ruth A. Wittmann-Price PhD, RN, CNS, CNE, CHSE, ANEF, FAAN

NANDA-I

Definition

A process of choosing a health care decision that includes personal knowledge and/or consideration of social norms, which can be strengthened.

Defining Characteristics

Expresses desire to enhance ability to choose health care options that best fit current lifestyle; expresses desire to enhance ability to enact chosen health care option; expresses desire to enhance ability to understand all available health care options; expresses desire to enhance ability to verbalize own opinion without constraint; expresses desire to enhance comfort to verbalize health care options in the presence of others; expresses desire to enhance confidence in decision-making; expresses desire to enhance confidence to discuss health care options openly; expresses desire to enhance decision-making; expresses desire to enhance privacy to discuss health care options

NOC Outcomes (Nursing Outcomes Classification)

Suggested NOC Outcomes

Decision-Making; Self-Esteem; Coping; Health Promotion Behavior; Stress Level; Communication; Self-Care; Participation in Health Care Decisions; Health-Seeking Behavior; Knowledge: Treatment Options; Psychosocial Adjustment

Example NOC Outcome with Indicators

Participation in Health Care Decisions as evidenced by the following indicator: Claims decision-making responsibility. (Rate the outcome and indicators of **Participation in Health Care Decisions:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Verbalize option of outcomes freely before making a health care decision
- Freely verbalize own opinion with health care providers before making a health care decision
- Choose the health care option that best fits his or her lifestyle within an appropriate amount of time that allows enactment of the choice
- Describe how the chosen option fits into his or her current lifestyle before or after the decision has been made
- Verbalizes appropriate concern about others' opinions before making the health care choice
- Remains stress-free when listening to others' opinions before making the health care choice
- Arrives at a decision in a timely manner

NIC Interventions (Nursing Interventions Classification)

Suggested NIC Intervention

Decision-Making Support

Example NIC Activities—Emancipated Decision-Making

Assist client in making an emancipated decision about health care options by discussing social norms with the client; Provide a flexible environment; Encourage the client to use personal knowledge

Nursing Interventions and *Rationales*

- Assess client's readiness to choose through active listening. **EB:** *Hadrych-Rosier (2017) explored the concepts of truly listening to patients by observations of using nonverbal communication, proper eye contact, body language to connect with patients, and avoiding internal thoughts while interacting.* **EBN:** *Chen et al (2017) applied a home-based, individually tailored intervention, which included nursing education, skills training, listening/counseling, and resources for family caregivers of cognitively impaired individuals. Listening skills and interventions improved caregiving skills and increased the family's quality of life.*
- Use anticipatory guidance by proactively providing the client with information. (Refer to Impaired emancipated **Decision-Making.**)
- Establish a purposeful provider–client relationship. **EB:** *Researchers examined the quality of the patient–provider relationship and its effect on attachment and self-management of patients with multiple chronic diseases (N = 209). The study results demonstrated that*

patient–provider relationships with attachment and communication provide that patient with information and improve decisions about self-management (Brenk-Franz et al, 2017). **EB:** *Chien-Ching et al (2017) studied the relationship of patient–provider communication variable on the physical health quality of life and mental health quality of life of cancer patients (N = 479) and found that reducing communication barriers increased patients' satisfaction in both quality of life indicators. Patients had high mental health quality of life scores if they were comfortable asking their provider questions.*

▲ Include interdisciplinary health care professionals as needed to increase knowledge of chosen option. **EB:** *Researchers designed a pilot study to measure patients' and staffs' perception of teamwork. The results revealed that coordination among nurses scored the highest and were positively correlated with patients' perceptions (Cottingham et al, 2017).* **EB:** *Wong et al (2017) studied the lived experience of emergency department (ED) staff (N = 31) members caring for agitated patients and found three themes from the focus groups: (1) ED staff provide high-quality care to marginalized patients, (2) teamwork is critical to safely managing patients and hierarchy and professional silos hinder care, and (3) environmental challenges increase threats to staff safety.*

• Provide decision-making support. (Refer to Impaired emancipated **Decision-Making.**)

• Continue to provide a flexible environment for client to enact choice. **EB:** *Investigators studied shared decision-making about health care options with spinal cord injury (SCI) patients (N = 22) during the patients' first rehabilitation experience and found using interviews that decision-making capabilities were reduced in the first few days of hospitalizations because of physical, psychological, and environmental factors. Additionally, they stated that understandable, personalized information was necessary to participate in decision-making (Scheek-Sailer et al, 2017).* **EB:** *Den Ouden, Vos, and Rutten (2017) completed a 5-year clinical trial with type 2 diabetic patients (N = 35) and found that using a shared decision-making model benefited both prioritizing and reaching treatment goals with improved patient outcomes.*

• Encourage the client to use personal knowledge as part of the decision-making process to increase decisional satisfaction. **EB:** *Hultberg and Rudebeck (2017) explored patient agency and resistance in decision-making about cardiovascular treatments in primary care settings. The study described patient resistance as part of the decision-making process and it can be passive or aggressive. Health care providers need to allow patient agency and open communication to establish a working relationship in shared decision-making.*

Pediatric

• Understand interventions that parents prefer when in the decision-making process. **EBN:** *Craske et al (2017) studied withdrawal syndrome in children and how nurses (N = 12) make decisions about treatment and qualitatively found each stage of decision-making described as noticing, interpreting, and responding.* **EB:** *Bekken (2017) explored the distinction that professionals make between difficult and less difficult decisions in pediatric rehabilitation and the child's right to participate in health care decisions concerning their own body and life and found that professional reasoning can work negatively against children's involvement in decisions.*

Multicultural

• Use open communication to assist clients to develop health care plans to which they can adhere. **EBN:** *Rodrigo, Cais, and Monforte-Rovo (2017) qualitatively studied using*

grounded theory nurses' participation in decision-making in Spain and found that the health care system still functions mainly from a disease-focused view making it difficult for nurses to take responsibility for decision-making. **EBN:** *Kim et al (2017) studied how immigrant women (N = 32) make decisions about Pap tests (screenings) using interviews and found that most women with positive decisions made their own decisions and considered the positive and negative aspects of having a Pap smear. Women who deferred decisions perceived Pap tests as negative and sometimes deferred to the provider or significant other.*

Home Care/Nursing Home Care

- Optimize self-care personal knowledge for home care. **EB:** *Mariani et al (2017) studied shared decision-making in patients with dementia and allowing the patient to take part in making choices to promote social health and found the following themes: team collaboration and communication skills assisted shared decision-making. Lack of funding and lack of family involvement hindered shared decision-making in nursing home care, but findings can be applicable to home care.* **EB:** *Reinhardt et al (2017) studied end-of-life care communication between family and providers and found that documentation was in place for nursing home residents and these should be available and done well in advance.*
- Refer to care plan Impaired emancipated **Decision-Making** for additional interventions for pediatric, critical care, geriatric, and multicultural care.

Risk for impaired emancipated Decision-Making

Ruth A. Wittmann-Price PhD, RN, CNS, CNE, CHSE, ANEF, FAAN

NANDA-I

Definition

Susceptible to a process of choosing a health care decision that does not include personal knowledge and/or consideration of social norms, or does not occur in a flexible environment, resulting in decisional satisfaction.

Risk Factors

Decrease in understanding of all available health care options; inability to adequately verbalize perceptions about health care options; Inadequate time to discuss health care options; insufficient confidence to openly discuss health care options; insufficient information regarding health care options; insufficient privacy to openly discuss health care options; insufficient self-confidence in decision-making

At-Risk Population

Limited decision-making experience; traditional hierarchical family; traditional hierarchical health care systems

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Decision-Making; Self-Confidence; Coping; Health Promotion Behavior; Stress Level; Communication; Self-Care; Participation in Health Care Decisions; Health-Seeking Behavior; Knowledge; Treatment Options; Psychosocial Adjustment

Example NOC Outcome with Indicators

Participation in Health Care Decisions as evidenced by the following indicator: Claims decision-making responsibility. (Rate the outcome and indicators of **Participation in Health Care Decisions:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Verbalize option outcomes freely before making a health care decision in a private setting with in which he or she feels comfortable
- Freely verbalize own opinion with health care providers before making a health care decision
- Discuss how options fit or hinder his or her lifestyle within an appropriate amount of time that allows enactment of the choice

• Discuss concerns about others' opinions before making the health care choice
• Decrease stress about others' opinions by placing options in perspective through informational resources
• Discuss the time frame in which the decision needs to be made

NIC Interventions (Nursing Interventions Classification)

Suggested NIC Interventions

Establish Rapport; Decision-Making Support

Example NIC Activities—Emancipated Decision-Making

Assist client to verbalize and discuss barriers that she or he perceives in making an emancipated decision about health care options; Acknowledge social norms about decision options; Provide a flexible environment that is safe and private for the discussions; Use empathy to understand the client's personal point of view about the options

Nursing Interventions and *Rationales*

• Assess client's vulnerability for an impaired decision-making process. **EBN:** *Scheepmans et al (2017) studied the decision-making process of placing older adults (N = 5) in restraints at home and found through a cross-sectional survey that the main decision-making variables were safety, keeping the patient home longer, and to provide respite for the caregiver.* **EB:** *Researchers studied the variables related to continuous observation and decisions about safety and privacy in psychiatric patients. Study results indicated that patients struggled with lack of privacy, but they did say they felt safe with the staff. The staff interviewed revealed that decisions were based on patient–staff collaboration (Barnicot et al, 2017).*
• Assess the client's experience with decision-making. **EB:** *Talley (2017) presented a case study regarding the treatment decision-making process for an older adult with urinary incontinence that was dependent on a family caregiver. The study found that care can be complicated by conflicting ethical principles between the patient and caregiver and the principles may account for the decisions made.* **EBN:** *Smith et al (2017) studied cancer patients' (N = 21) perceptions of their involvement in treatment decisions and found that most patients just consented to radiation because of oncologist recommendations. The study recommends that patients be provided with more opportunities to ask questions to be empowered in decisions about their uncertainties and concerns.*
• Recognize the traditional hierarchical family and health care system. **EB:** *Siouta et al (2017) studied how patients with atrial fibrillation were involved in their care and how they were communicated with through a physician perspective. Physician participants revealed that by encouraging patients to be actively involved they increased communication and adherence to treatment options.* **EBN:** *Petrinec (2017) studied the effect of patients' long-term care experiences on the family decision-maker (N = 30) and found, using a qualitative descriptive study method, that family decision-makers need support and often have post intensive care syndrome caused by the stress.*
• Provide privacy to discuss health care options. **EBN:** *Chang et al (2017) studied the decision-making of nurses that triage patients in an emergency department and what factors were considered in their decision-making. The study results indicated that the patients' privacy was an important consideration in choosing care options and prioritizing during a triage situation.* **EB:** *Ng et al (2017) studied patients (N = 11) who use hearing aids and found though qualitative analysis using the constant comparative method that important concepts to the patients were getting to know their clinician and providing privacy when using adaptive smartphones for communication. This study highlighted the concern about privacy in relation*

to smartphone application and tracking features.

• Allow the client time to choose. **EB:** *Simmons et al (2017) studied an online decision aid for youth (N = 66) with depression and their ability to make decisions and found that it assisted patients to feel involved in their decision and providing them with time to make the decision and accessibility.* **EB:** *Researchers studied decision-making and leadership over time and found that participation in decision-making shifts over time, and the value of decision-making is perceived higher earlier in the process (D'Aunno, Alexander, & Lan, 2017).*

▲ Understand the primary care providers' role in the decision-making process. **EB:** *Hyde et al (2017) did a systematic review about shared decision-making and prescribing analgesia by primary care practitioners for musculoskeletal pain and identified important factors in shared decision-making that mainly focus on patient emotions and conditions that required analgesics.* **EB:** *Researchers completed a literature review on decision-making by women who had ductal carcinoma in situ breast cancer and found that decisions are influenced by understanding risks, the clinical features of the cancer, and the benefits and harms of treatment. The conclusion was that informed and shared decision-making requires clear communication of and support from clinicians (Wu et al, 2017).*

• Provide informational resources. **EBN:** *Asiodu et al (2017) completed a critical ethnographic research study to describe breastfeeding perceptions of African American mothers (N = 21) and key themes that were identified about the high percentage of early weaning, which were expressed as guilt and shame for not breastfeeding, stressors, lack of breastfeeding role models, limited experiences, and changes to the family dynamics.* **EB:** *Paillaud et al (2017) studied older patients (N = 113) with cancer in relation to information, decision-making, and surrogate designation and compared patients with a group without cancer and found increasingly that the cancer patients wanted to receive information and participate in decisions about their care.*

• Provide encouragement so clients increase their confidence in the decision-making process. **EB:** *Researchers studied patients' (N = 22) perceptions about decision-making involvement and communication with nurses and physicians and found that patients felt involved when obtaining clarifications about their disease and its treatment. Communication with providers built up the patients' confidence in decision-making (Siouta et al, 2017).* **EB:** *Knox, Douglas, and Bigby (2017) studied how patients with traumatic brain injury (TBI) participated in decision-making and by using grounded theory discovered that self-conceptualization was a theme and that TBI patients wanted a sense of autonomy.*

Pediatric

• Understand the parent/guardian's vulnerability when making health care decisions for their children. **EB:** *O'Hare et al (2017) studied a tool to evaluate children and young patient's (N = 151) participation in decision-making. The pilot demonstrated that the reliability and validity of the Child and Adolescent Participation in Decision-Making Questionnaire (CAP-DMQ) showed promise as a useful tool to evaluate decision-making participation, which can assist the family when decisions need to be made.* **EB:** *Researchers from Johns Hopkins studied sleep-disordered breathing (SDB) in children to understand social and communication factors that influence decision-making for treatment. Researchers surveyed practitioners (N = 10) and found that three main themes were considered during SDB decision-making: (1) approach to treatment and alternatives, (2) communication with families, and (3) sociocultural factors (Boss et al, 2017).*

• Understand the adolescent decision-making processes. **EB:** *Bernhardt et al (2017) studied impulsive and value-based decision-making in young adults (N = 198) who socially drank alcohol and found that actually chronic alcohol consumption itself is implicated in*

impulsive behavior rather than innate personality traits. **EB:** *Mosner et al (2017) investigated vicarious effort-based decision-making in adolescents (N = 50) with autism spectrum disorders (ASDs) in a comparison study. Group comparisons demonstrated that adolescents with ASD were better choosing for themselves than making choices that involved other people, indicating the participants had decreased sensitivity toward others.*

- Refer to care plan Impaired emancipated **Decision-Making** for additional interventions for critical care, geriatric, multicultural care, and home care.

Ineffective Denial

Julianne E. Doubet BSN, RN, EMT-B

NANDA-I

Definition

Conscious or unconscious attempt to disavow the knowledge or meaning of an event to reduce anxiety and/or fear, leading to the detriment of health.

Defining Characteristics

Delay in seeking health care; denies fear of death; denies fear of invalidism; displaces fear of impact of the condition; displaces source of symptoms; does not admit impact of disease on life; does not perceive relevance of danger; does not perceive relevance of symptoms; inappropriate affect; minimizes symptoms; refusal of health care; use of dismissive comments when speaking of distressing event; use of dismissive gestures when speaking of distressing event; use of treatment not advised by health care professional

Related Factors

Anxiety; excessive stress; fear of death; fear of losing autonomy; fear of separation; ineffective coping strategies; insufficient emotional support; insufficient sense of control; perceived inadequacy in dealing with strong emotions; threat of unpleasant reality

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Acceptance: Health Status; Anxiety Self-Control; Health Beliefs: Perceived Threat; Symptom Control

Example NOC Outcome with Indicators

Anxiety Self-Control as evidenced by the following indicators: Eliminates precursors of anxiety/Monitors physical manifestations of anxiety/Controls anxiety response. (Rate the outcome and indicators of **Anxiety Self-Control:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Outcomes

Client Will (Specify Time Frame)

- Seek out appropriate health care attention when needed
- Use home remedies only when appropriate
- Display appropriate affect and verbalize fears
- Actively engage in treatment program related to identified “substance” of abuse
- Remain substance free
- Demonstrate alternate adaptive coping mechanism

NIC (Nursing Interventions Classification)

Suggested NIC Intervention
Anxiety Reduction

Example NIC—Activities Anxiety Reduction

Use a calm, reassuring approach; Stay with the patient to promote safety and reduce fear

Nursing Interventions and *Rationales*

- Assess the client's and family's understanding of the illness, the treatments, and expected outcomes. **CBN:** *Effective communication between client and health care provider in relation to health promotion, disease prevention, and disease management is key to optimal health outcomes (Heinrich & Karner, 2011).*
- Allow client time for adjustment to his or her situation. **EBN:** *Thoughtful contemplation of life expectancy and end-of-life care are vital for clients to ensure their continued optimum quality of life (Walczak et al, 2014).*
- Aid the client in making choices regarding treatment and actively involve him or her in the decision-making process. **EBN:** *Nurses must encourage a client's participation in shared decision-making by providing the client with balanced, evidence-based treatment alternatives, and endeavor to identify what is most important to the client and then support their choices (Stacey & Legare, 2015).*
- Allow the client to express and use denial as a coping mechanism if appropriate to treatment. **EB:** *According to Werner and Steihaug (2017), it is important for the health care provider to respect the client's autonomy and realize that the client has the right to refuse information regarding his or her condition.*
- Support the client's spiritual coping measures. **EBN:** *According to Baldacchino et al (2013), spiritual, although not necessarily religious, coping may enhance adjustment of clients to their chronic illnesses.*
- Develop a trusting, therapeutic relationship with the client/family. **EBN:** *According to Dinc and Gastmans (2013), in their study of the literature focusing on nurse–patient relationships, nurses' professional expertise and interpersonal caring qualities were essential in developing trust.*
- Assist the client in using existing and additional sources of support. **EBN:** *In their study of men with brain tumors who did not access social services, Longbecker, Eckberg, and Yates (2017) opined that there is a divide between patients' needs and utilization of services; this may be a result of the client's expectancy of what the medical system would offer, alternations in standards for well-being, changes in cognition, and difficulties accessing services.*
- Refer to care plans for Defensive **Coping** and Dysfunctional **Family** processes.

Geriatric

- Allow the client to explain his or her concepts of health care needs, and then use reality-focused techniques whenever possible to provide feedback. **EB:** *Clients should be made conscious of the fact that primary medical treatment, even when associated with a positive prognosis, does not in and of itself predict how well clients will fare during their lifetime (Linden et al, 2015).*
- Encourage communication among family members. **EB:** *According to Hays, Maliski, and Warner (2017), family can be the most important means of support for those diagnosed with health problems, if they are made aware of the client's medical issues.*
- Recognize denial and be aware that grieving may prolong denial. **EBN:** *In her study*

of dying children in palliative care, Smith (2014) stated that denial can be an effective coping technique, and that it allows parents and families the time to gather emotional strength with which to support their child.

Multicultural

• Assess for the influence of cultural beliefs, norms, and values involved in the client's understanding of and ability to acknowledge health status. **EB:** *Lee and Mason (2014) suggested that health care practitioners should develop programs that include ethnic- and gender-specific components, which, in turn, will aid older adults in coping with the stress caused by illness.*
• Discuss with the client those aspects of his or her health behavior/lifestyle that will remain unchanged by health status and those aspects of health behavior that need to be modified to improve health status. **EBN:** *"Culturally sensitive interventions are required to ensure people of culturally and linguistically diverse backgrounds have the appropriate skills to self-manage their complex medical conditions" (Williams et al, 2015).*
• Assess the role of fatalism in the client's ability to acknowledge health status. **EB:** *Some minorities, because of cultural factors (e.g., fatalism, medical mistrust), have negative attitudes toward health care interventions: targeting these cultural issues may help reduce undertreatment of minorities (Lin et al, 2014).*

Home Care

• Previously mentioned interventions may be adapted for home care utilization.
• Observe family interaction and roles. Refer the client/family for follow-up if prolonged denial is a risk. **EBN:** *Nurses are mentors and guides who can support caregivers of dying family members with coordination of care, symptom management education, and in making referrals to other agencies as needed (Hartnett, Thom, & Kline, 2016).*
Encourage communication between family members, particularly when dealing with the loss of a significant person. **EBN:** *Ineffectual family communication, especially after the loss of a significant loved one, lessens the capacity to cope, leaving those who are grieving more susceptible to complicated grief (Brownhill et al, 2013).*

Client/Family Teaching and Discharge Planning

• Instruct client and family to recognize the signs and symptoms of recurring illness and the appropriate responses to alterations in client's health status. **EBN:** *According to Bagdan and Raines (2016), using interactive communication and literacy screening allows the giver (and receiver)of written and oral discharge instructions to question and strengthen the client's and his or her family's comprehension of vital interventions that may be needed, relieving anxiety related to the client's care.*
• Consider the client's belief in and use of complementary therapies in self-managing his or her disease. **EBN:** *No matter what other care is provided, nurses should support any program type that genuinely makes a difference for the client and his or her family (Madden, 2014).*
• Teach family members that denial may continue throughout the adjustment to treatment and they should not be confrontational. **EB:** *Losses come with progressing years and may dictate interpersonal and selfish readjustments to relationships, occupations, and avocations: the use of denial as a defense mechanism may play a significant role in these situations (Clemens, 2014).*
▲ Inform family of available community support resources. **EBN:** *According to study*

findings by Mendes and Palmer (2016), nurses, especially those involved with the community, can play a pivotal part in aiding caregivers by furnishing useful information, connecting caregivers to community resources, and contributing essential emotional support.

Impaired Dentition

Morgan Nestingen MS, AGCNS, ONS

NANDA-I

Definition
Disruption in tooth development/eruption pattern or structural integrity of individual teeth.

Defining Characteristics
Absence of teeth; abraded teeth; dental caries; enamel discoloration; erosion of enamel; excessive oral calculus; excessive oral plaque; facial asymmetry; halitosis; incomplete tooth eruption for age; loose tooth; malocclusion; premature loss of primary teeth; root caries; tooth fracture; tooth misalignment; toothache

Related Factors
Barrier to self-care; difficulty accessing dental care; excessive intake of fluoride; excessive use of abrasive oral cleaning agents; habitual use of staining substance; inadequate dietary habits; inadequate oral hygiene; insufficient knowledge of dental health; malnutrition

At-Risk Population
Economically disadvantaged; genetic predisposition

Associated Condition
Bruxism; chronic vomiting; oral temperature sensitivity; pharmaceutical agent

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes
Oral Health

Example NOC Outcome with Indicators
Oral Health as evidenced by the following indicators: Cleanliness of teeth/Cleanliness of gums/Cleanliness of dentures/Tongue integrity/Gum integrity. (Rate the outcome and indicators of **Oral Health:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Have clean teeth, healthy pink gums
- Be free of halitosis
- Explain and demonstrate how to perform oral care
- Demonstrate ability to masticate foods without difficulty
- State absence of pain in mouth

NIC (Nursing Interventions Classification)

Suggested NIC Interventions
Oral Health Maintenance; Oral Health Promotion; Oral Health Restoration

Example NIC Activities—Oral Health Maintenance

Establish a mouth care routine; Arrange for dental care and check-ups as needed

Nursing Interventions and *Rationales*

▲ Inspect oral cavity/teeth/gingiva at least once daily and note any discoloration, presence of debris, amount of plaque buildup, presence of lesions such as white lesions or patches, edema, or bleeding, and intactness of teeth. Refer to a dentist or periodontist as appropriate. **EB:** *Inspection is a critical diagnostic tool; observations can identify impending problems. Leukoplakia is the presence of uncharacterized white lesions, which can be a precursor to squamous cell carcinoma. If leukoplakia is observed, prompt referral for diagnosis and potential biopsy is indicated (van Der Waal, 2015; ADA, 2017b).*

• If the client is free of bleeding disorders and able to swallow, encourage toothbrushing with a soft toothbrush using fluoride-containing toothpaste at least two times per day. Do not use foam swabs or lemon glycerin swabs to clean the teeth. **EB:** *Oral bacteria cause caries and periodontal disease. Plaque is a biofilm of bacteria, which often becomes contaminated with antibiotic-resistant bacteria in the hospitalized client (Olsen, 2015).* **CEB/EB:** *The toothbrush is the most important tool for oral care. Twice daily mechanical toothbrushing is the most effective method of reducing plaque and controlling periodontal disease (ADA, 2017f). Historically, foam swabs have been found ineffective in the removal of plaque (Pearson & Hutton, 2002). Recently, evidence suggested that with trained technique, foam swabs are equivalent to toothbrushing in the mechanically ventilated patient (Marino et al, 2016). Lemon glycerin swabs dry the oral mucosa and can erode the tooth enamel (Poland, 1987; Meurman et al, 1996; Foss-Durant & McAffee, 1997). Normal gums should be pink and firm. Gingivitis is characterized by changes in gingival tissue including redness, sponginess, bleeding, and changes in contour (Fiorellini & Stathopoulou, 2015).*

• Encourage the client to perform interdental hygiene by flossing or cleaning between teeth with interdental brushes, woodsticks, or oral irrigation at least once per day if free of a bleeding disorder. If the client is unable to floss, assist with flossing or encourage the use of an oral irrigator (i.e., "water flossing"). **EB:** *A meta-review determined that all forms of interdental cleaning performed in addition to toothbrushing are associated with decreased gingivitis. Interdental cleaning may also be effective at plaque removal, but current findings are inconsistent (Sälzer et al, 2015). Oral irrigators have been shown to be superior to flossing at reducing plaque, but they remain less accepted by users (Stauff et al, 2017).*

• Use a rotation-oscillation power toothbrush for removal of dental plaque. **EB:** *Use of a rotation-oscillation power toothbrush more effectively removes plaque versus manual toothbrushing (Kurtz et al, 2016). Multiple studies have found rotation-oscillation power toothbrushes more effective than ultrasonic power toothbrushes (He et al, 2008; Williams et al, 2008; Grender et al, 2013). Studies have consistently demonstrated that rotation-oscillation powered toothbrushes are safe to use on both hard and soft dental tissues (Robinson, 2011; Dörfer, Staehle, & Wolff, 2016).*

• Determine the client's mental status and manual dexterity; if the client is unable to care for self, nursing personnel must provide dental hygiene. The nursing diagnosis Bathing **Self-Care** deficit is then applicable.

• If the client is unable to brush his or her own teeth, follow this procedure:
  - ❍ Position the client sitting upright or on side.
  - ❍ Use a soft bristle baby toothbrush.
  - ❍ Use fluoride toothpaste and tap water or saline as a solution.
  - ❍ Brush teeth in an up-and-down manner.
  - ❍ Suction as needed.

Each client must receive oral care including toothbrushing twice daily to maintain healthy teeth and oral tissues and to prevent complications associated with periodontitis (the advanced form of gum disease that can cause tooth loss), which is associated with health problems such as cardiovascular disease, stroke, and bacterial pneumonia (ADA, 2017f,g).

• Monitor the client's nutritional and fluid status to determine if adequate. Recommend the client eat a balanced diet and limit between-meal snacks. *Poor nutrition predisposes clients to dental disease (Hujoel & Lingström, 2017).*
• Recommend that the client maintain a healthy diet with limited sugar intake; in particular, the client should limit sugary beverages and snacks. *Diets high in sugar are strongly associated with formation of caries (ADA, 2017e).* **EB:** *A study demonstrated a much higher incidence of caries in children who drank soft drinks and had increased intake of processed foods (Evans et al, 2013).*
• Instruct the client with halitosis to clean the tongue when performing oral hygiene. Brush tongue with a tongue scraper or toothbrush and follow with a mouth rinse. **EB:** *A Cochrane review found that tongue cleaning was effective for short-term control of halitosis (Mehmet Mustafa, 2015).*
• Determine the client's usual method of oral care. Whenever possible, build on the client's existing knowledge base and current practices to develop an individualized plan of care.
• Instruct the client to use a soft-bristled toothbrush, which should be replaced every 3 to 4 months. Angle the toothbrush at a 45-degree angle to the gums and use short lateral strokes. Brush all surfaces of each tooth. Use short, vertical strokes to clean inner tooth surfaces *(ADA, 2017c).*
• Therapeutic mouthwashes help prevent or reduce periodontal disease symptoms including plaque, gingivitis, and caries. Cosmetic mouthwashes can provide comfort and reduce halitosis, but are otherwise ineffective *(ADA, 2017d).* Avoid the use of hydrogen peroxide, or alcohol-based mouthwashes. **CEB/EB:** *Hydrogen peroxide can cause mucosal damage and is extremely foul tasting to clients (Tombes & Gallucci, 1993). Use of hydrogen peroxide in mouthwash has been linked with chemical gastritis and colitis (Zanelli, Ragazzi, & De Marco, 2017).*
▲ Recommend client see a dentist at prescribed intervals, generally two times per year if teeth are in satisfactory condition. *It is important to see a dentist at regular intervals for preventive dental care and treatment of symptoms (ADA, 2017f).*
▲ If there are any signs of bleeding when the teeth are brushed, refer the client to a dentist. If bleeding accompanies apparently inflamed gums, refer client to a periodontist. Bleeding in the presence of halitosis is associated with gingivitis. *Early gingivitis can often be reversed with good oral hygiene. Advanced cases may require treatment by a periodontist.* If platelet numbers are decreased, or if the client is edentulous, use moistened Toothettes or a customized extra soft toothbrush for oral care. *Use of a regular toothbrush can cause soft tissue injury and stimulate bleeding in clients with low platelet counts.*
• Recognize that meticulous dental care/oral care can be effective in preventing hospital-acquired (or extended care-acquired) pneumonia. **CEB/EB:** *Numerous references have found oral care effective in preventing new-onset pneumonia (Ishikawa et al, 2008; van Der Maarel-Wierink et al, 2013; Quinn et al, 2014).*
• Provide scrupulous dental care to critically ill clients, including ventilated clients to prevent ventilator-associated pneumonia. **EB/EBN:** *Numerous studies have demonstrated decreased incidence of ventilator-associated pneumonia with good oral care. Germicides (i.e., chlorhexidine gluconate) may further reduce risk of ventilator-associated pneumonia in addition to toothbrushing (Hennequin-Hoenderdos, Slot, & Van Der Weijden, 2016; de*

Lacerda Vidal et al, 2017).
• If teeth are nonfunctional for chewing, modification of oral intake (e.g., edentulous diet, soft diet) may be necessary. The nursing diagnosis **Imbalanced Nutrition:** less than body requirements may apply.
• If the client is unable to swallow, keep suction nearby when providing oral care.
• See care plan for Impaired **Oral Mucous Membrane.**

Pregnant Client

• Encourage the expectant mother to eat a healthy, balanced diet that is rich in calcium. The teeth usually start to form in the gums during the second trimester of pregnancy. *To encourage the development of good, strong teeth, expectant mothers should eat a healthy, balanced diet that is rich in calcium (ADA, 2017h).*
• Pregnancy is associated with increased risk of oral health complications including gingivitis, caries, erosion, and granulomas. Meticulous, twice daily oral care is critical to maternal health and pregnancy outcomes. Pregnancy complications may be associated with the presence of maternal periodontal disease arising from poor oral hygiene and pregnancy-related hormones (ADA, 2017h).
• Advise the pregnant mother not to smoke. **CEB:** *Maternal smoking during pregnancy has been associated with increased caries in the teeth of the child (Majorana et al, 2014).*
• Advise the expectant mother to practice good care of her teeth, and to protect her child's teeth once born. Dental caries in children are associated with high levels of Streptococcus mutans. This bacterium is commonly spread from the mother with infected teeth to the infant by tasting of food and sharing of utensils once the child is born (Çolak et al, 2013; Chaffee et al, 2014).

Infant Oral Hygiene

• Gently wipe the infant's gums with a clean washcloth or sterile gauze at least once a day. *Wiping gums prevents bacterial buildup in the mouth.*
• Never allow the infant to fall asleep with a bottle containing milk, formula, fruit juice, or sweetened liquids. If the infant needs a comforter between regular feedings, at night, or during naps, fill a bottle with cool water or provide a clean pacifier recommended by the dentist or health care provider. Never give an infant a pacifier dipped in any sweet liquid. Avoid filling the infant's bottle with liquids such as sugar water and soft drinks. *Decay occurs when sweetened liquids such as milk, formula, and fruit juice are given and are left clinging to an infant's teeth for long periods. Bacteria in the mouth use these sugars as food to produce acids that attack the teeth (Çolak et al, 2013; Majorana et al, 2014).*
▲ When multiple teeth appear, brush the child's teeth with a small toothbrush with a small (pea-size) amount of fluoride toothpaste. Application of either a fluoride gel or fluoride varnish is recommended. *Parental toothbrushing and topical fluoride applications (i.e., varnish) have been shown to be effective in reducing the formation of early childhood caries (Jiang et al, 2014).*
• Advise parents to begin dental visits at 1 year of age. *Pediatric periodontal disease has been associated with problems of alignment of permanent teeth; difficulty chewing; and problems speaking, sleeping, concentrating, learning, and with self-esteem (Chaffee et al, 2014).*

Older Children

▲ Encourage the family to talk with the dentist about dental sealants, which can help prevent cavities in permanent teeth. **EB:** *A Cochrane review found that use of dental sealants on the molars of children was effective in preventing caries (Wright et al, 2016).*
• Teach to brush teeth twice a day. **EB:** *Twice daily tooth brushing is a low-cost, effective strategy to reduce the risk of childhood caries (Huebner & Milgrom, 2015).*
• Recommend the child use dental floss to help prevent gum disease. The dentist will give guidelines on when to start using floss.
• Recommend that parents should not allow the child to smoke or chew tobacco, and stress the importance of setting a good example by not using tobacco products themselves.
• Recommend the child drink fluoridated water when possible. Fluoride in drinking water is one of several available fluoride resources. *The American Dental Association (ADA) strongly endorses use of fluoridated water, based on scientific research that validates the effectiveness in preventing cavities (ADA, 2017a).* **EB:** *Community water fluoridation remains an effective public health strategy for delivering fluoride to prevent tooth decay and is the most feasible and cost-effective strategy for reaching entire communities (US Department of Health & Human Services Federal Panel on Community Water Fluoridation, 2015).*
• Recommend the child use toothpaste containing fluoride. **EB:** *Studies demonstrate that fluoride toothpaste is effective in caries prevention and is safe for children of all ages (Wright et al, 2014).*

Geriatric

• Provide dentists with accurate medication history to avoid drug interactions and client harm. If the client is taking anticoagulants, laboratory values should be reviewed before providing dental care.
• Help clients brush their own teeth, or provide dental care after breakfast and before bed every day. *If the client lacks dexterity in hands, consider the use of modified dental equipment, including large-handled, powered toothbrushes or interdental cleaning devices (Bissett, 2011; Balzer, 2012).*
• If the client has dementia or delirium and exhibits care-resistant behavior such as fighting, biting, or refusing care, then use the following method:
  - ❍ Ensure client is in a quiet environment such as his or her own bathroom, and sitting or standing at the sink to prime memory for appropriate actions.
  - ❍ Approach the client at eye level within his or her range of vision.
  - ❍ Approach with a smile, and begin conversation with a touch of the hand and gradually move up.
  - ❍ Use mirror–mirror technique, standing behind the client, and brush and floss teeth.
  - ❍ Use respectful adult speech. Do not use "elderspeak," which is a sing-song voice, or diminutive terms such as "deary" or "honey." *Elderspeak is a documented trigger for care-resistant behavior (Williams et al, 2017).*
  - ❍ Promote self-care when client brushes own teeth if possible.
  - ❍ Use distractors when needed: talking, reminiscing, singing.

▲ **EBN:** *Use of specific techniques can decrease resistance to nursing care and increase the effectiveness of nurses providing oral care to clients. Additional research is needed to examine oral care in the client with dementia (Mohammadi, Franks, & Hines, 2015; Rozas, Sadowsky, & Jeter, 2017).*
▲ Ensure that dentures are removed and cleaned regularly, after each meal and before bedtime. Brush and rinse dentures to remove debris and soak overnight in a

peroxide-based cleaning solution. Dentures left in the mouth at night impede circulation to the palate and predispose the client to oral lesions. **EB:** *A study found that brushing combined with immersion in a peroxide-based cleaning solution reduce the number of microorganisms surviving on the surface of dentures (Nishi et al, 2014).*
▲ Support other caregivers providing oral hygiene. Physical and cognitive impairment in older adults can interfere with the client's ability to perform oral hygiene, and oral hygiene should be provided by a caregiver. If no caregiver is available, the client is prone to dental problems such as dental caries, tooth abscess, tooth fracture, and gingival and periodontal disease.

Multicultural

• Assess for the influence of cultural beliefs, norms, and values on the client's understanding of dental care. **EBN:** *What the client considers normal and abnormal dental health and appropriate care may be based on cultural perceptions (Lo & Tan, 2014).*
• Assess for barriers to access to dental care, such as lack of insurance. Minority groups may have limited access to dental care (Da Fonseca & Avenetti, 2017). **EB:** *Social determinants of health including ethnic minority, low socioeconomic status, impaired family structure, and low health literacy are associated with limited access to care and poor oral health outcomes, including caries and tooth loss (Tellez, Zini, & Estupiñan-Day, 2014; Da Fonseca & Avenetti, 2017).*

Home Care

• Assess client patterns for daily and professional dental care and related patterns (e.g., smoking, nail biting). Assess for environmental influences on dental status (e.g., fluoride).
• Assess client facilities and financial resources for providing dental care. *Lack of appropriate facilities or financial resources is a barrier to positive dental care patterns. Provision for dental care may be missing from health care plans or unavailable to the uninsured.*
• Request dietary log from the client, adding column for type of food (i.e., soft, pureed, regular).
• Observe a typical meal to assess first-hand the effect of impaired dentition on nutrition. *Clients, especially older adults, are often hesitant to admit nutritional changes that may be embarrassing because of poor dentition.*
• Assist the client with accessing financial or other resources to support optimum dental and nutritional status.

Client/Family Teaching and Discharge Planning

• Teach how to inspect the oral cavity and monitor for problems with the teeth and gums.
• Teach how to implement a personal plan of dental hygiene, including appropriate brushing of teeth and tongue and use of dental floss. Use motivational interviewing sessions to facilitate increased compliance in dental care (Stenman et al, 2017). **EB:** *A systematic review demonstrated improved dental hygiene, including interdental cleaning, when motivational interviewing was applied to teaching oral hygiene techniques (Kopp et al, 2017). See Appendix C, Motivational Interviewing, on Evolve.*
• Advise the clients to change their toothbrush every 3 to 4 months, because after that toothbrushes are less effective in removing plaque and are a source of bacterial

contamination of the mouth and teeth *(ADA, 2017c)*.

- Teach the client the value of having an optimal fluoride concentration in drinking water, and to brush teeth twice daily with toothpaste containing fluoride.
- Teach clients of all ages about the need to decrease intake of sugary foods and to brush teeth regularly.
- Inform individuals who are considering tongue piercing of the potential complications such as chipping and cracking of teeth and possible trauma to the gingiva. If piercing is done, teach the client how to care for the wound and prevent complications. **EB:** *Oral piercings are associated with increased risk of gingival recession and tooth injuries (Hennequin-Hoenderdos, Slot, & Van Der Weijden, 2016).*

Risk for delayed Development

Marsha McKenzie MA Ed, BSN, RN

NANDA-I

Definition

Susceptible to delay of 25% or more in one or more of the areas of social or self-regulatory behavior, or in cognitive, language, gross, or fine motor skills, which may compromise health.

Risk Factors

Inadequate nutrition; presence of abuse; substance misuse; technology dependence

At-Risk Population

Behavioral disorder; economically disadvantaged; exposure to natural disaster; exposure to violence; history of adoption; inadequate maternal nutrition; insufficient parental care; involvement with the foster care system; late-term parental care; maternal age ≤15; maternal age ≥35; maternal function illiteracy; maternal substance misuse; positive drug screen; prematurity; unplanned pregnancy; unwanted pregnancy

Associated Condition

Brain injury; caregiver learning disability; caregiver mental health issue; chronic illness; congenital disorder; endocrine disorder; failure to thrive; genetic disorder; hearing impairment; impaired vision; lead poisoning; parental infection; recurrent otitis media; seizure disorder; treatment regimen

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Abuse Recovery; Child Development: 1 Month, 2 Months, 4 Months, 6 Months, 12 Months, 2 Years, 3 Years, 4 Years, 5 Years, Middle Childhood, Adolescence; Development: Late Adulthood, Middle Adulthood, Young Adulthood; Knowledge: Parenting, Neglect Recovery

Example NOC Outcome with Indicators

Child Development as evidenced by the following indicators: Appropriate milestones of physical, cognitive, and psychosocial age-appropriate progression. (Rate the outcome and indicators of **Child Development:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client/Parents/Primary Caregiver Will (Specify Time Frame)

- Infant/child/adolescent will achieve expected milestones in all areas of

development (physical, cognitive, and psychosocial)
• Parent/caregiver will verbalize understanding of potential impediments to normal development and demonstrate actions or environmental/lifestyle changes necessary to provide appropriate care in a safe, nurturing environment

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Abuse Protection Support: Child; Caregiver Support; Developmental Enhancement: Child/Adolescent; Home Maintenance Assistance; Immunization/Vaccination Management; Infant Care; Kangaroo Care; Lactation Counseling; Learning Facilitation; Newborn Care; Newborn Monitoring; Nonnutritive Sucking; Normalization Promotion; Nutrition Management; Parent Education: Infant/Adolescent/Childbearing Family; Parenting Promotion; Referral; Risk Identification: Childbearing Family; Teaching: (Infant) Nutrition/Safety/Stimulation; (Toddler) Nutrition/Safety; Temperature Regulation (Infant); Therapeutic Play

Example NIC Activities—Parent Education

Instruct parent on normal physiological, emotional, and behavioral characteristics of child

Nursing Interventions and *Rationales*

Preconception/Pregnancy

• Assess for alcohol/drug use during pregnancy. Expectant mothers should be instructed that no amount of alcohol consumption is safe during pregnancy. **EB:** *Alcohol is a well-established teratogen that can cause variable physical and behavioral effects on the fetus. Increased fetal exposure to alcohol and sustained alcohol intake during any trimester of pregnancy is associated with an increased risk of fetal alcohol syndrome (FAS) (Gupta, Gupta, & Shirasaka, 2016).*
• Be aware of state legislation requiring mandatory reporting of maternal prenatal drug use. Be aware that mandatory reporting may further hamper prenatal care in that drug addicted mothers may delay or defer care for fear of legal action. **EB:** *Wu et al (2013) noted that fear of reporting drug use to authorities can create a "flight from care" environment rather than promote improved prenatal care among drug addicted mothers.*
• Advise expectant mothers to stop smoking and assist with methods of smoking cessation. Smoking is a known precursor to low birth weight and other significant prenatal issues. **EB:** *Reese et al (2017) noted that pregnant women disproportionately under report smoking and smokers tend to have lower follow-up rates to repeat questionnaires.*
• Recommend that women of childbearing age take 400 μg of folic acid daily to reduce the risk of neural tube defects. **CEB:** *Taking 400 mcg of folic acid daily, at least 3 months before conception and continuing throughout pregnancy, can prevent as many as 70% of neural tube defects (Greener, 2011).* **EB:** *Additionally, a comprehensive meta-analysis suggested that maternal use of folic acid supplements during pregnancy could significantly reduce the risk of autism spectrum disorders in children regardless of ethnicity compared with those women who did not supplement with folic acid (Wang et al, 2017).*

Neonate/Infant

• Encourage mother/baby interactions when caring for premature infants.
• Encourage caution regarding use of glucocorticoids in premature and term infants. **EB:** *Vázquez et al (2012) noted that administration of glucocorticoids in infancy has the potential of causing neurological developmental difficulties, including anxiety and depressive disorders, later in life.*

• Provide support and education to parents of toddlers with developmental disabilities (i.e., Down's syndrome [DS], cerebral palsy). **EB:** *A recent study of infants with DS affirmed previous findings showing that the rate of attainment of motor skills is delayed in children with DS compared with children with typical development; however, the developmental sequence is the same. The delayed development is more prominent in more complex skills (Beqaj, Jusaj, & Živković, 2017).*
• Be aware of the role maternal eating disorders plays in childhood development. **EB:** *Sadeh-Sharvit, Levy-Shiff, and Lock (2016) found that children of mothers with eating disorders showed delayed mental and psychomotor development. Severity of maternal eating disorder symptoms emerged as a significant predictor of child development, but other maternal psychopathology did not. Findings suggest that maternal eating disorder history may play a unique role in the development of neurodevelopmental functions in their children. The children of mothers with eating disorders showed delayed mental and psychomotor development. Severity of maternal eating disorder symptoms appeared as a significant predictor of child development.*
• Encourage parents of toddlers to obtain age-appropriate developmental screenings to detect early problems.
• Toddlers who are underweight should be offered solid foods first rather than juices. *Excessive juice and milk consumption may interfere with nutritional absorption.*
• Teach parents the importance of avoiding lead-based paints in the home and other sources of lead in the environment. **EB:** *Hou et al (2013) confirmed previous research indicating that when the blood lead level reaches about 50 µg/L in the body of children, it can impair growth, memory, intelligence, and behavior, even when there is no obvious clinical manifestation.*
• Understand the role premature birth plays in the development of speech. **EB:** *Data suggest that very preterm born children retain atypical bilateral language organization longer than term born controls, which may be explained by a delay in neural language organization caused by very premature birth (Mürner-Lavanchy, 2014).*
• Teach new mothers the importance of breastfeeding. **EB:** *Moss and Yeaton (2014) found that breastfeeding along with delaying complementary foods yielded consistently and substantially lower the likelihood of obesity and greater probability of healthy weight in infants and toddlers*. **EB:** *Jäger et al (2014) discovered an inverse association between breastfeeding duration and risk of diabetes.*

Diarrhea

Rosemary Koehl Lee DNP, ARNP, ACNP-BC, CCNS, CCRN

NANDA-I

Definition

Passage of loose, unformed stools.

Defining Characteristics

Abdominal pain; bowel urgency; cramping; hyperactive bowel sounds; loose liquid stools, >3 in 24 hours

Related Factors

Anxiety; increase in stress level; laxative abuse; substance misuse

At-Risk Population

Exposure to contaminant; exposure to toxin; exposure to unsanitary food preparation

Associated Condition

Enteral feedings; gastrointestinal inflammation; gastrointestinal irritation; infection; malabsorption; parasite; treatment regimen

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Bowel Elimination; Electrolyte and Acid-Base Balance; Fluid Balance; Hydration; Risk Control: Environmental Hazards; Community Risk Control: Communicable Disease

Example NOC Outcome with Indicators

Bowel Elimination as evidenced by the following indicators: Elimination pattern/Stool soft and formed/Bowel sounds/Liquid stool. (Rate each indicator of **Bowel Elimination:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Defecate formed, soft stool every 1 to 3 days
- Maintain the perirectal area free of irritation
- State relief from cramping and less or no diarrhea

- Explain cause of diarrhea and rationale for treatment
- Maintain good skin turgor and weight at usual level
- Have negative stool cultures

NIC (Nursing Interventions Classification)

Suggested NIC Intervention
Diarrhea Management

Example NIC Activities—Diarrhea Management
Evaluate medication profile for gastrointestinal side effects; Suggest trial elimination of foods containing lactose

Nursing Interventions and *Rationales*

• Assess pattern of defecation or have the client keep a diary that includes the following: time of day defecation occurs; usual stimulus for defecation; consistency, amount, and frequency of stool; type of, amount of, and time food consumed; fluid intake; history of bowel habits and laxative use; diet; exercise patterns; obstetrical/gynecological, medical, and surgical histories; medications; alterations in perianal sensations; and present bowel regimen. *Assessment of defecation pattern and factors surrounding diarrhea episode to include changes in diet, medications, exercise, and health history will help direct interventions and treatment (Gale & Wilson, 2016).*
• Recommend use of standardized tool to consistently assess, quantify, and then treat diarrhea. **EB:** *Stool classification systems include the Hart and Dobb Diarrhea Scale, the Guenther and Sweed Stool Output Assessment Tool, the Bristol Stool Scale, and the Diarrhea Grading Scale (Dag et al, 2015; Ford & Talley, 2016).*
• Inspect, auscultate, palpate, and percuss the abdomen, in that order. *Expect increased frequency of bowel sounds with diarrhea (Lattimer, Chandler, & Borum, 2017).*
▲ Use an evidence-based bowel management protocol that includes identifying and treating the cause of the diarrhea, obtaining a stool specimen if infectious etiology is suspected, evaluate current medications and osmolality of enteral feedings, assess and treat hydration status of client, review and stop ordered and/or over-the-counter (OTC) laxatives, assess food preparation practices, assess home environment, provide good skin care and apply barrier creams to prevent skin irritation from diarrhea, and evaluate need for antidiarrheal agents and possible fecal containment device with provider. **EB:** *The possible cause of the diarrhea needs to be assessed and client hydration and skin protective interventions put into place rapidly to prevent secondary complications associated with the client's diarrhea episodes (DuPont 2016; Gale & Wilson, 2016).*
▲ Identify the cause of diarrhea if possible based on history (e.g., infection, gastrointestinal inflammation, medication effect, malnutrition or malabsorption, laxative abuse, osmotic enteral feedings, anxiety, stress). See Related Factors: *Identification of the underlying cause is important, because the treatment is determined based on the cause of diarrhea.*
▲ Testing for diarrhea may consist of laboratory work such as a complete blood count with differential and blood cultures if the client is febrile. Also obtain stool specimens as ordered, to either rule out or diagnose an infectious process (e.g., ova and parasites, *Clostridium difficile* infection, bacterial cultures for food poisoning). *Assessing for signs of systemic infection and inflammatory response as well as evaluation of the stool for infection are important first steps in identifying the cause of diarrhea (Schiller &*

Sellin, 2016).

▲ Consider the possibility of *C. difficile* infection if the client has any of the following: watery diarrhea, low-grade fever, abdominal cramps, history of antibiotic therapy, history of gastrointestinal tract surgery, and if the client is taking medications that reduce gastric acid, including proton-pump inhibitors (PPIs). *Any antibiotic can cause* C. difficile *infection, but clindamycin, cephalosporins, and fluoroquinolones pose the greatest risk, as do multiple antibiotics and longer duration of antibiotics (Dunne, Hayes, & Marsh, 2016; Schiller & Sellin, 2016; Tariq et al, 2017).* **EB:** C. difficile *infections have become increasingly common because of the frequent use of broad-spectrum antibiotics, and now there is a hypervirulent form of* C. difficile *causing increased morbidity and mortality. Antibiotics and gastric acid reducing medications can change normal gut flora, increasing the risk for development of* C. difficile *infection, diarrhea, and colitis) (Dunne, Hays, & Marsh, 2016; Schiller & Sellin, 2016).*

• Use standard precautions when caring for clients with diarrhea to prevent spread of infectious diarrhea; use gloves and handwashing. *C. difficile* and viruses causing diarrhea have been shown to be highly contagious. C. difficile *is difficult to eradicate because of spore formation (Martin et al, 2014).* **EB:** *A review of client care related to* C. difficile *summarizes care to include full contact isolation, soap and water handwashing (alcohol rubs are not effective), use of disposable equipment, and environmental room decontamination (Dubberke et al, 2014; Martin et al, 2014; Centers for Disease Control and Prevention [CDC], 2017).* C. difficile *can survive for at least 24 hours on inanimate surfaces, and spores can survive for months on objects such as toilets, sinks, and bed rails (Martin et al, 2014; CDC, 2017).*

▲ Antibiotic stewardship is an important aspect in the prevention of *C. difficile* infections. *Antibiotics should be used judiciously (Vardakas, Trigkidis, & Boukouvala, 2016; CDC, 2017).* If the client has diarrhea associated with antibiotic therapy, consult with the health care provider regarding the use of probiotics, such as yogurt with active cultures, to treat diarrhea, or probiotic dietary supplements, or preferably use probiotics to prevent diarrhea when first beginning antibiotic therapy. **EB:** *Although conclusive evidence on the effectiveness of probiotic in treating and preventing* C. difficile *and diarrhea is lacking, evidence suggests that probiotics may be helpful for some clients. Probiotics may be used in an attempt to balance intestinal flora and restrict the colonization of* C. difficile *(Clauson & Crawford, 2015; Patro-Golab, Shamir, & Szajewska, 2015; Wilkins & Sequoia, 2017).*

▲ If a probiotic is ordered, administer it with food. Recommend that it be taken through the antibiotic course and 10 to 14 days afterward. *Food tends to buffer the stomach acids, allowing more of the probiotic ingredients to pass through the stomach for absorption in the intestines. Beginning this therapy early helps prevent antibiotic-associated diarrhea (Clauson & Crawford, 2015).*

▲ Recognize that *C. difficile* can commonly recur and that reculturing of stool is often required before initiating retreatment. **EB:** *High reinfection rates have been reported within the first 2 months of initial diagnosis. Repeat courses of antibiotics, usually metronidazole or vancomycin, are necessary to treat repeat* C. difficile *infections. Evidence is evolving to support fecal transplant for clients with severe recurrent* C. difficile *infections (Liubakka & Vaughn, 2016).*

• Have the client complete a diet diary for 7 days and monitor the intake of high fructose corn syrup and fructose sweeteners in relation to onset of diarrhea symptoms. If diarrhea is associated with fructose ingestion, intake should be limited or eliminated. **EB:** *High fructose corn syrup or fructose sweeteners from fruit juices can cause gastrointestinal symptoms of bloating, rumbling, flatulence, and diarrhea at amounts of*

25 to 50 g. Malabsorption is demonstrated in clients after 25 g fructose, and most clients develop symptoms with 50 g fructose (Schiller & Sellin, 2016).

▲ If the client has infectious diarrhea, consider avoiding use of medications that slow peristalsis. **EB:** *If an infectious process is occurring, such as* C. difficile *infection or food poisoning, medication to slow peristalsis should generally not be given. The increase in gut motility helps eliminate the causative factor, and use of antidiarrheal medication could result in a toxic megacolon (Schiller & Sellin, 2016).*

• Assess for dehydration by observing skin turgor over sternum and inspecting for longitudinal furrows of the tongue. Watch for excessive thirst, fever, dizziness, lightheadedness, palpitations, excessive cramping, bloody stools, hypotension, and symptoms of shock. *Severe diarrhea can cause deficient fluid volume, electrolyte imbalance, extreme weakness, and a possible shock state (Gale & Wilson, 2016; Schiller & Sellin, 2016).*

• Refer to care plans for Deficient **Fluid** volume and Risk for **Electrolyte** imbalance if appropriate.

▲ If the client has frequent or chronic diarrhea, consider suggesting use of dietary fiber after consultation with a nutritionist and/or provider. **EB:** *Use of a fiber supplement decreases the number of incontinent stools and improves stool consistency (Schiller & Sellin, 2016).*

▲ If diarrhea is chronic and there is evidence of malnutrition, consult with the provider for a dietary consult and possible nutrition supplementation to maintain nutrition while the gastrointestinal system heals (Schiller & Sellin, 2016).

• Encourage the client to eat small, frequent meals, eating foods that are easy to digest at first (e.g., bananas, crackers, pretzels, rice, potatoes, clear soups, applesauce), but switch to a regular diet as soon as tolerated. Also recommend avoiding milk products, foods high in fiber, and caffeine (dark sodas, tea, coffee, chocolate). *The bananas, rice, applesauce, toast (BRAT) diet has been traditionally recommended but may be nutritionally incomplete (International Foundation for Functional Gastrointestinal Disorders, 2014; Schiller, Pardi, & Sellin, 2017).*

• Provide a readily available bathroom, commode, or bedpan.

• Thoroughly cleanse and dry the perianal and perineal skin daily as needed using a cleanser capable of stool removal. Apply skin moisture barrier cream as needed. Refer to perirectal skin care in the care plan for Bowel **Incontinence.**

▲ If the client has enteral tube feedings and diarrhea, consider infusion rate; position of feeding tube; tonicity of formula; possible formula contamination; and excessive intake of hyperosmolar medications, such as sorbitol commonly found in the liquid version of medications (Taylor et al, 2016). Consider changing the formula to a lower osmolarity, lactose-free, or high-fiber feeding. *Determination of the cause of diarrhea should include an abdominal examination, fecal leukocytes, quantification of stool, stool culture for* C. difficile *(and/or toxin assay), serum electrolyte panel, and review of medications (Schiller & Sellin, 2016).*

• Avoid administering bolus enteral feedings into the small bowel. The stomach has a larger capacity for large fluid volumes, whereas the small bowel can usually only tolerate up to 150 mL/hr (Taylor et al, 2016).

▲ Dilute liquid medications before administration through the enteral tube and flush the enteral feeding tube with sufficient water before and after medication administration. *Because many liquid medications contain sorbitol or are hyperosmotic, diluting the medication may help decrease occurrence of diarrhea (Joos et al, 2015).*

• Teach clients with cancer the types of diarrhea they may encounter, emphasizing not only chemotherapy- and radiation-induced diarrhea, but also *C. difficile,* along with associated signs and symptoms, and treatments. **EB:** *Diarrhea in cancer patients is*

a common complication that causes dehydration, electrolyte imbalances, nutritional deficits, and hospitalization for treatment. Providing the client education focusing on early recognition of diarrhea necessitating early interventions is important in preventing adverse client outcomes (Tarricone et al, 2016; Escalante et al, 2017; Schiller, Pardi, & Sellin, 2017).

▲ For chemotherapy-induced diarrhea (CID) and radiation-induced diarrhea (RID), review rationale for pharmacological interventions, along with soluble fiber and probiotic supplements. Consult a registered dietitian to assist with recommendations to alleviate diarrhea, decrease dehydration, and maintain nutritional status. **EBN:** *Both CID and RID can occur as often as or more than 50% of the time, depending on the chemotherapy regimen or combination with radiation (Escalante et al, 2017; Schiller, Pardi, & Sellin, 2017).*

▲ Acute traveler's diarrhea is the most common illness affecting individuals traveling to, usually, low-income regions of the world. **EB:** *Improved hygiene and avoidance of foods for which preparation methods are unknown (e.g., street food) can mitigate the severity of gastric distress. Clients should be counseled about precautions they can take while traveling to reduce the severity of the diarrhea, and a self-treatment antibiotic series may be prescribed by the health care provider for at-risk clients (Steffen, Hill, & DuPont, 2015; Porter et al, 2017).*

Pediatric

▲ Assess for mild or moderate signs of dehydration with both acute and persistent diarrhea: mild (increased thirst and dry mouth or tongue) and moderate (decreased urination; no wet diapers for 3+ hours; feeling of weakness/lightheadedness, irritability, or listlessness; few or no tears when crying) (Gupta, 2016). Refer to primary care provider for treatment.

▲ Recommend that parents give the child oral rehydration fluids to drink in the amounts specified by the health care provider, especially during the first 4 to 6 hours to replace lost fluid. Once the child is rehydrated, an orally administered maintenance solution should be used along with food. Continue even if child vomits. **EB:** *Treatment with oral rehydration fluids for children is generally as effective as intravenous fluids (Carson, Mudd, & Madati, 2017). Oral rehydration therapy (ORT) is an isoosmolar, glucose-electrolyte solution that has been recognized for more than 40 years to be effective in treating children with dehydration caused by acute infectious diarrhea). Vomiting is not a contraindication to ORT. Adequate ORT is absorbed by most clients during vomiting (Rehydration Project, 2014).*

• Recommend the mother resumes breastfeeding as soon as possible.

• Recommend parents avoid giving the child flat soda, fruit juices, gelatin dessert, or instant fruit drink. *These fluids have a high osmolality from carbohydrate contents and can exacerbate diarrhea. In addition they have low sodium concentrations that can aggravate existing hyponatremia (Rehydration Project, 2014).*

• Recommend parents give children foods with complex carbohydrates, such as potatoes, rice, bread, cereal, yogurt, fruits, and vegetables. Avoid fatty foods, foods high in simple sugars, and milk products.

▲ Recommend rotavirus vaccine within the child's vaccination schedule. **EB:** *Two vaccines, Rotarix and Rotateq, have undergone comprehensive studies with findings that they can significantly prevent severe rotavirus diarrhea and death caused by dehydration in children; (Glass et al, 2014; Mwenda et al, 2017).*

Geriatric

▲ Evaluate medications the client is taking. Recognize that many medications can result in diarrhea, including digitalis, propranolol, angiotensin-converting enzyme inhibitors, histamine-receptor antagonists, nonsteroidal antiinflammatory drugs, anticholinergic agents, oral hypoglycemia agents, antibiotics, and so forth. **EB:** *Numerous medications can cause diarrhea. Evaluate changes in the client's medications as a possible cause of the diarrhea (DuPont, 2016; Schiller, Pardi, & Sellin, 2017).*
▲ Monitor the client closely to detect whether an impaction is causing diarrhea; remove impaction as ordered. Clients with fecal impaction commonly experience leakage of mucus or liquid stool from the rectum, rectal irritation, distention, and impaired anal sensation (Schiller, Pardi, & Sellin, 2017; Schiller & Sellin, 2016).
▲ Seek medical attention if diarrhea is severe or persists for more than 24 hours, or if the client has a history of dehydration or electrolyte disturbances, such as lassitude, weakness, or prostration. *Older adult clients can dehydrate rapidly; especially serious is the development of hypokalemia with dysrhythmias.* C. difficile *is a common cause of diarrhea in older clients when they have been subjected to long-term antibiotic therapy (Gale & Wilson, 2016; Vardakas, Trigkidis, & Boukouvala, 2016).*
• Provide emotional support for clients who are having trouble controlling unpredictable episodes of diarrhea. Diarrhea can be a great source of embarrassment to older clients and can lead to social isolation and a feeling of powerlessness.

Home Care

Previously mentioned interventions may be adapted for home care use to keep the client well hydrated.

• Assess the home for general sanitation and methods of food preparation. Reinforce principles of sanitation for food handling. *Poor sanitation or mishandling of food may cause bacterial infection or transmission of dangerous organisms from utensils to food.*
• Assess for methods of handling soiled laundry if the client is bed bound or has been incontinent. Instruct or reinforce universal precautions with family and bloodborne pathogen precautions with agency caregivers. *The Bloodborne Pathogen Regulations of the Occupational Safety and Health Administration (OSHA) identify legal guidelines for caregivers.*
• When assessing medication history, include OTC drugs, both general and those currently being used to treat the diarrhea. Instruct clients not to mix OTC medications when self-treating. *Mixing OTC medications can further irritate the gastrointestinal system, intensifying the diarrhea or causing nausea and vomiting.*
• Evaluate current medications for indications that specific interventions are warranted. *Blood levels of medications may increase during prolonged episodes of diarrhea, indicating the need for close monitoring of the client or direct intervention.*
▲ Evaluate the need for a home health aide or homemaker service referral. Caregiver may need support for maintaining client cleanliness to prevent skin breakdown.
• Evaluate the need for durable medical equipment in the home. The client may need a bedside commode, call bell, or raised toilet seat to facilitate prompt toileting.

Client/Family Teaching and Discharge Planning

• Encourage avoidance of coffee, spices, milk products, and foods that irritate or stimulate the gastrointestinal tract.
• Teach the appropriate method of taking ordered antidiarrheal medications; explain side effects.
• Explain how to prevent the spread of infectious diarrhea (e.g., careful handwashing,

appropriate handling and storage of food, and thoroughly cleaning the bathroom and kitchen). **EB:** *Good hand hygiene has repeatedly been found to be the first step in preventing the spread of infectious diarrhea (Dickinson & Surawicz, 2014; CDC, 2017).*

• Help the client to determine stressors and set up an appropriate stress reduction plan, if stress is the cause of diarrhea.

• Teach signs and symptoms of dehydration and electrolyte imbalance.

• Teach perirectal skin care.

▲ Consider teaching clients about complementary therapies, such as probiotics, after consultation with primary care provider.

Risk for Disuse syndrome

Darcy O'Banion RN, MS, ACCNS-AG

NANDA-I

Definition

Susceptible to deterioration of body systems as the result of prescribed or unavoidable musculoskeletal inactivity, which may compromise health.

Risk Factors

Pain

Associated Condition

Alteration in level of consciousness; mechanical immobility; paralysis; prescribed immobility

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Pain Level; Endurance; Immobility Consequences: Physiological; Mobility; Neurological Status: Consciousness; Progressive Mobility

Example NOC Outcome with Indicators

Immobility Consequences: Physiological as evidenced by the following indicators: Pressure injury/Constipation/Compromised nutrition status/Urinary calculi/Compromised muscle strength. (Rate the outcome and indicators of **Immobility Consequences: Physiological:** 1 = severe, 2 = substantial, 3 = moderate, 4 = mild, 5 = none [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Express pain level that is tolerable to allow for desired mobility

- Maintain full range of motion in joints
- Maintain intact skin, good peripheral blood flow, and normal pulmonary function
- Maintain normal bowel and bladder function
- Express feelings about imposed immobility
- Explain methods to prevent complications of immobility

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Energy Management; Exercise Therapy: Joint Mobility; Muscle Control; Positioning; Pain management

Example NIC Activities—Energy Management

Determine the client's significant other's perception of causes of fatigue; Use valid instruments to measure fatigue, as indicated

Nursing Interventions and *Rationales*

• Screen for mobility skills in the following order: (1) bed mobility; (2) supported and unsupported sitting; (3) transitional movements such as sit to stand, stand to sit, and transfers to chair from bed, from chair to bed, and so forth; and (4) standing and walking activities. Use a mobility assessment tool such as the Banner Mobility Assessment Tool (Boynton et al, 2014) or the Perme ICU Mobility Score (Perme et al, 2014). **EB:** *A systematic review showed that early mobilization lead to a greater probability of walking without assistance at time of discharge, and more days alive and out of hospital (Tipping et al, 2017).* **EB:** *Mobilization of stable, critically ill patients can be done safely with minimal risk (Boynton et al, 2014).*

• Assess the level of assistance needed by the client and express in terms of amount of effort expended by the person assisting the client. The range is as follows: total assist, meaning client performs 0% to 25% of task and, if client requires the help of more than one caregiver, it is referred to as a dependent transfer; maximum assist, meaning client gives 25% of effort while the caregiver performs the majority of the work; moderate assist, meaning client gives 50% of effort; minimal assist, meaning client gives 75% of effort; contact guard assist, meaning no physical assist is given but caregiver is physically touching client for steadying, guiding, or in case of loss of balance; stand by assist, meaning caregiver's hands are up and ready in case needed; supervision, meaning supervision of task is needed even if at a distance; modified independent, meaning client needs assistive device or extra time to accomplish task; and independent, meaning client is able to complete task safely without instruction or assistance. **EB:** Functional status is often based on rating from the Functional Independence Measure, which is an instrument that includes 18 items covering 6 domains of self-care, sphincter control, transfer, locomotion, communication, and social cognition (Graham et al, 2014; Granger, 2015).

▲ Request a referral to a physical therapist (PT) as needed so that client's range of motion, muscle strength, balance, coordination, endurance, and early mobilization can be part of the initial evaluation. The PT may provide the client with bed exercises, including stretching, flexing/extending muscle groups, or using bands to maintain muscle strength and tone. Collaboration with nursing staff, therapy, and respiratory therapy as needed to mobilize patients as early and as safely possible. **EB:** *Muscle atrophy from disuse is associated with disability, functional decline, metabolic derangements, and early mortality (Atherton et al, 2016).*

• Passive range of motion can be done as the client tolerates. **EBN:** *Although there is evidence to support early mobility in reducing complications, recent literature shows that passive range of motion and stretching does not prevent or treat muscle contracture (Prabhu, Swaminathan, & Harvey, 2013; Harvey et al, 2017).*
• Use specialized boots to prevent pressure injury on the heels and foot drop; remove boots twice daily to assess the skin and to provide foot care as needed. Elevate heels off the bed as the client tolerates when boots are not in place. *Boots help keep the foot in normal anatomical alignment to prevent foot drop and off-loading prevents pressure injury formation on the heel.* **EB:** *A Cochrane review found that there is no good evidence base to determine which boots or pressure redistribution system is most effective in preventing heel pressure injury (McInnes et al, 2015).*
• When positioning a client on the side, tilt client 30 degrees or less while lying on the side. *Full (versus tilt) side-lying position places higher pressure on the trochanter, predisposing to skin breakdown; however, more evidence is needed to fully determine the effect of full versus tilted positioning on pressure injury (Gillespie et al, 2014; National Pressure Ulcer Advisory Panel, 2014).*
• Assess skin condition every shift and more frequently if needed. Use a risk assessment tool such the Braden Scale or the Norton Scale to predict the risk of developing pressure ulcers (now referred to as pressure injury). **EBN:** *Use of a risk assessment tool is possibly effective to predict the risk of developing a pressure injury (National Pressure Ulcer Advisory Panel, 2014). Refer to care plan for* risk for Impaired **Skin** integrity.
• Discuss with staff and management a "safe patient handling" policy that may include a "no lift" policy to prevent staff injury. *Lifting equipment can reduce risk of injury; however, the equipment should be an integral part of nursing practice because lifting equipment is not regularly used even when available (Boynton et al, 2014; Lee & Lee, 2017).*
• Turn clients at high risk for pressure/shear/friction frequently. Turn clients at least every 2 to 4 hours on a pressure-reducing mattress and every 2 hours on standard foam mattress. *These are general guidelines for turning, but there is no robust evidence to support frequency of repositioning. Preferably base the turning schedule on close assessment of the client's condition and predisposing conditions (Gillespie et al, 2014; Makic, 2014; National Pressure Ulcer Advisory Panel, 2014).*
• Provide the client with a pressure-relieving horizontal support surface. For further interventions on skin care, refer to the care plan for Impaired **Skin** integrity.
• Help the client out of bed as soon as able. **EB:** *Prolonged immobilization leads to harmful consequences on musculoskeletal, cardiovascular, respiratory, integumentary systems, as well as cognition (Atherton et al, 2016; Parry & Puthucheary, 2015). Early mobilization reduces risk of atelectasis, pneumonia, venous thromboembolism (VTE), and pulmonary embolism, and decreases orthostatic hypotension (Makic, 2014), as well as reducing the risk of skeletal muscle atrophy, joint contractures, insulin resistance, microvascular dysfunction, systemic inflammation, and pressure injury (Parry& Puthucheary, 2015).*
• When getting the client up after bed rest, do so slowly and watch for signs and symptoms of postural (orthostatic) hypotension, including dizziness, tachycardia, nausea, diaphoresis, or syncope. *To assess orthostatic vital signs, take the first blood pressure and heart rate measurements once the client has been lying supine for 5 minutes. Then have the client stand and check blood pressure and heart rate 1 and 3 minutes after standing. A decrease in systolic blood pressure by 20 mm Hg, a decrease in diastolic pressure of 10 mm Hg or more, or an increase in heart rate by 20 beats per minute or more are indicative of intravascular volume loss (Emergency Nurses Association, 2015; CDC, 2017). Compression wraps to abdomen and/or lower limbs can facilitate venous return if hypotension*

is an issue (Logan et al, 2017).
• Obtain assistive devices such as braces, crutches, or canes to help the client reach and maintain as much mobility as possible. *Assistive devices can help increase mobility (Boynton et al, 2014).*
▲ Apply graduated compression stockings as ordered, if indicated for orthostatic hypotension. Ensure proper fit by measuring accurately. Remove the stockings at least twice a day, in the morning with the bath and in the evening to assess the condition of the extremity, and then reapply. Knee length is preferred rather than thigh length. **EB:** *The American College of Chest Physicians (AACP, 2016) does not recommend graduated compression stockings to prevent deep vein thrombosis (DVT). Based on recent evidence, compression stockings did not reduce the rate of DVTs. However, intermittent pneumatic compression devices are associated with significantly lower incidences of VTE compared with graduated compression devices (Arabi et al, 2013). Please refer to the ACCP guidelines for use of mechanical prophylaxis for specific client situations.*
• Observe for signs of DVT, including pain, tenderness, redness, and swelling in the calf and thigh. Also observe for signs and symptoms of pulmonary embolism, including sudden onset of dyspnea, chest pain, syncope, dizziness, tachycardia, or tachypnea. *Because of poor specificity of signs and symptoms of VTE, the diagnosis based on clinical manifestation alone is unreliable (Nisio, van Es, & Butler, 2017).*
• Have the client cough and deep breathe or use incentive spirometry every 2 hours while awake. Bed rest compromises breathing and can lead to atelectasis and pneumonia because of decreased chest expansion, decreased cilia activity, pooling of mucus, and the effects of organ shift (such as the diaphragm and heart and pressure on the esophagus when in the supine position) and leads to partial or complete atelectasis usually of the left lower lobe (Parry & Puthucheary, 2015).
• Monitor respiratory functions, noting breath sounds, work of breathing, and respiratory rate. Percuss for new onset of dullness in lungs.
• Note bowel function daily. Provide fluids, fiber, and natural laxatives such as prune juice as needed. Constipation is common in immobilized clients because of decreased activity and reduced fluid and food intake. Refer to care plan for **Constipation.**
• Increase fluid intake to 2000 mL/day within the client's cardiac and renal reserve. Adequate fluids help prevent kidney stones and constipation, both of which are associated with bed rest.
• Encourage intake of a balanced diet with adequate amounts of fiber and protein. Consider recommending Practical Interventions to Achieve Therapeutic Lifestyle Changes (TLC), which includes monounsaturated and polyunsaturated fats, oils, margarines, beans, peas, lentils, soy, skinless poultry, lean fish, trimmed cuts of meat, fat-free and low-fat daily foods, omega-3 polyunsaturated fat sources, and whole grains, including soluble fiber sources such as oats, oat bran, and barley (Osborn et al, 2013).

Critical Care

▲ Recognize that the client who has been in an intensive care environment may develop a neuromuscular dysfunction acquired in the absence of causative factors other than the underlying critical illness and its treatment, resulting in intensive care unit-acquired weakness, with an approximate incidence of 40% requiring more than 1 week of mechanical ventilation (Appleton, Kinsella, & Quasim, 2015). The client may need a workup to determine the cause before satisfactory ambulation can begin. *Critical care clients can develop neuromuscular weakness, polyneuropathy, and delirium*

(Appleton, Kinsella, & Quasim, 2015; Wintermann et al, 2015).
▲ Consider the use of a continuous lateral rotation therapy bed. **EB:** *A systematic review demonstrated limited evidence on the effects of routine lateral repositioning for critically ill patients, although mostly because of poor quality studies (Hewitt, Bucknall, & Faraone, 2016).*
▲ For the stable client in the intensive care unit, consider mobilizing the client in a four-phase method from dangling at the side of the bed to walking if there is sufficient knowledgeable staff available to protect the client from harm. Even intensive care unit clients receiving mechanical ventilation can be mobilized safely if a multidisciplinary team is present to support, protect, and monitor the client for intolerance to activity (Kalisch, Lee, & Dabney, 2013; Boynton et al, 2014; Agency for Healthcare Research and Quality, 2017). **EBN:** *Critical care clients are at high risk for complications related to immobility such as ventilator-associated pneumonia (VAP), atelectasis, and long-lasting functional limitations. Early mobility has been associated with reduced length of stay and reduced cognitive and physical impairment; therefore once the client is hemodynamically stable, use progressive mobilization to dangle legs, sit in a chair, stand and bear weight, and walk (Engel et al, 2013; Makic, 2014; Wahab et al, 2016).*

Geriatric

• Get the client out of bed as early as possible and ambulate frequently after consultation with the health care provider. *Immobility is a risk factor for VTE; early ambulation can help prevent clot formation (AACP, 2016; Makic, 2014). Functional decline from hospital-associated deconditioning is common in older adults, particularly because they are already more deconditioned and less fit, and early rehabilitation can be effective in preventing this condition in addition to other comorbidities (Menezes et al, 2014; Wood et al, 2014).*
• Consider physical and occupational therapy referrals to guide with environmental safety assessment and home exercise program.
• Monitor nutrition status in the elderly to prevent malnutrition. **EB:** *Malnutrition related to chronic disease is associated with poor rehabilitation outcomes in hospital-associated deconditioning, and most elderly hospitalized patients with deconditioning are malnourished (Wakabayashi & Sashika, 2014).*
• Monitor for signs of depression: flat affect, poor appetite, insomnia, and many somatic complaints. *Depression can commonly accompany decreased mobility and function in older adults, and mobilization has a positive effect on depressive mood and enhances independence (Kalisch et al, 2013).*
• Keep careful track of bowel function in older adults; do not allow the client to become constipated. *Older adults can easily develop impactions as a result of immobility. Refer to* ***Constipation*** *care plan.*

Home Care

• Some of the previous interventions may be adapted for home care use.
▲ Begin discharge planning at time of admission with case manager or social worker and input from physical and occupational therapy as appropriate to assess need for home support systems and community or home health services.
▲ Become oriented to all programs of care for the client before discharge from institutional care.
▲ Confirm the immediate availability of all necessary assistive devices for home.

• Perform complete physical assessment and recent history at initial home visit.
▲ Refer to physical and occupational therapies for immediate evaluations of the client's potential for independence and functioning in the home setting and for follow-up care.
• Allow the client to have as much input and control of the plan of care as possible. Client perception of control increases self-esteem and motivation to follow medical plan of care.
• Assess knowledge of all care with caregivers. Review as necessary. Having the necessary knowledge and skills to perform care decreases caregiver role strain and supports safety of the client.
▲ Support the family of the client in the assumption of caregiver activities. Refer for home health aide services for assistance and respite as appropriate. Refer to medical social services as appropriate.
▲ Institute case management of frail elderly to support continued independent living, if possible in the home environment.

Client/Family Teaching and Discharge Planning

• Teach client/family how to perform range-of-motion exercises in bed if not contraindicated; this is referred to as a home exercise program.
• Teach the family how to turn and position the client and provide all care necessary.

Note: Nursing diagnoses that are commonly relevant when the client is on bed rest include **Constipation,** risk for Impaired **Skin** integrity, Disturbed **Sleep** pattern, **Frail Elderly** syndrome, and **Powerlessness.**

Decreased Diversional activity engagement

Nadia Charania PhD, RN

NANDA-I

Definition

Reduceded stimulation, interest, or participation in recreational or leisure activities.

Defining Characteristics

Alteration in mood; boredom; discontent with situation; flat affect; frequent naps; physical deconditioning

Related Factors

Current setting does not allow engagement in activity; impaired mobility; environmental barrier; insufficient energy; insufficient motivation; physical discomfort; insufficient diversional activity

At-Risk Population
Extremes of age; prolonged hospitalization; prolonged institutionalization

Associated Condition
Prescribed immobility; psychological stress; therapeutic isolation

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes
Leisure Participation; Play Participation; Social Involvement

Example NOC Outcome with Indicators
Leisure Participation as evidenced by the following indicators: Expresses satisfaction with leisure activities/Feels relaxed from leisure activities/Enjoys leisure activities. (Rate the outcome and indicators of **Leisure Participation:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Engage in personally satisfying diversional activities

NIC (Nursing Interventions Classification)

Suggested NIC Interventions
Recreation Therapy; Self-Responsibility Facilitation

Example NIC Activities—Recreation Therapy
Assist the client to identify meaningful recreational activities; Provide safe recreational equipment

Nursing Interventions and *Rationales*

- Observe ability to engage in activities that require good vision and use of hands. *Diversional activities must be tailored to the client's capabilities.*
- Discuss activities with clients that are interesting and feasible in the present environment.
- Encourage the client to share feelings about situation of inactivity. *Work and hobbies provide structure and continuity to life; the client may feel a sense of loss.*
- Encourage the client to participate in any available social or recreational opportunities in the health care environment. **EB:** *Social engagement is associated with self-reported physical health in older adults (Cherry et al, 2013).*
- Encourage a mix of physical and mental activities if possible (e.g., crafts, crossword puzzles).
- Provide videos and/or DVDs of movies for recreation and distraction.
- Provide magazines and books of interest.
- Provide books on CD and CD player, and electronic versions of books for listening or reading as available.
- Set up a puzzle in a community space, or provide individual puzzles as desired.
- Provide access to a portable computer so that the client can access email and the Internet. Give client a list of interesting websites, including games and directions on how to perform Web searches if needed.

• Encourage the client to schedule visitors so that they are not all present at once or at inconvenient times. *A schedule prevents the client from becoming exhausted from frequent company.*
▲ Request recreational or art therapist to assist with activities. **EB:** *Art therapy can assist individuals undergoing stroke rehabilitation to reduce anxiety and feelings of isolation (Ali et al, 2014).*
▲ Refer to occupational therapy. **EB:** *Occupational therapists are professionals with expertise in the use of activities as therapeutic instruments (Potasz et al, 2014).*
• Provide a change in scenery; get the client out of the room as much as possible. *A lack of sensory stimulation has significant adverse effects on clients.*
• Help the client to experience nature through looking at a nature scene from a window, or walking through a garden if possible. **EB:** *Physical activity in the natural environment can promote emotional well-being (Pasanen, Tyrväinen, & Korpela, 2014).*
• Structure the environment as needed to promote optimal comfort and sensory diversity (e.g., have family bring in posters, banners, or photos; change lighting; change arrangement of furniture). **CEBN:** *For hospitalized clients needing close observation, consider the use of a S.A.F.E. unit that uses trained "diversional partners" rather than sitters; diversional activities were promoted through the use of TVs and VCRs on rolling carts, radios and CD players with music from various genres, movies, rocking chairs, a storage cabinet stocked with games and art supplies, stuffed animals, soft balls, and towels for folding (Nadler-Moodie et al, 2009).*
• Work with family or music therapist to provide music that is enjoyable to the client. **EB:** *Hospitalized patients who received an individualized music therapy session and who were provided with a CD for listening demonstrated marginally better quality of life pain scores after hospitalization and were more likely to recommend the hospital to others (Mandel, Davis, & Secic, 2014).*
• Use art making and music listening. **EBN:** *A randomized trial did not show a significant difference among the control, art making, and diversional music groups in reducing symptoms related to blood and marrow transplantation. It was asserted that art making and music listening are safe and desirable diversional activities for clients undergoing blood and marrow transplant in an outpatient clinic (Lawson et al, 2016).*
• Structure the client's schedule around personal wishes for time of care, relaxation, and participation in fun activities. *Increased client control fosters increased client self-esteem.*
• Spend time with the client when possible, giving the client full attention and being present in the moment, or arrange for a friendly visitor.
• Be creative, for example, use of the activity pillowcases with soft fabric pieces, plastic zipper, and a pouch to hold a picture as a diversional intervention that could be used in inpatient and hospice care settings. **EBN:** *Considered to be helpful aid for adult clients who have intellectual and developmental disabilities and are in need of distraction and sensory input or modulation (Bahle et al, 2016).*
• Engage clients in physical activity or exercise programs as an adjunct treatment modality for a variety of mental illnesses; for example, depression, schizophrenia, anxiety, disorders, posttraumatic stress disorders, and substance abuse. **EB:** *The narrative synthesis of systematic reviews and clinical trials endorsed the integration of physical activity programs as part of the mental health treatment plan (Rosenbaum et al, 2016).*

▲ Request an order for a child life specialist or, if not available, a play therapist for children. Child life therapists provide opportunities for self-expression and play for hospitalized children and may help to normalize the environment.
• Engage preschool children in play therapy. **EBN:** *The result of a prospective randomized controlled study supported the role of play therapy among preschoolers in promoting their social, emotional, and behavioral skills. Moreover, play therapy might be beneficial in reducing fear and anxiety and promoting communication, coping skills, and self-esteem (Sezici, Ocakci, & Kadioglu, 2017).*
• Engage school-age children in play activities during hospitalization. **EB:** *A randomized control trial results indicated a decrease in cortisol levels after children engaged in play activities (Potasz et al, 2014).*
• Promote a referral to a music therapist. **EBN:** *Music therapy may lead to a decrease in self-reported pain and anxiety in hospitalized children, and it may lead to improved patient and family satisfaction (Colwell et al, 2013).*
• Consider art therapy for children living with chronic illness who have activity restrictions. **CEB:** *In a study of children with persistent asthma, those who engaged in art therapy demonstrated a reduction in anxiety and an improvement in emotional health (Beebe, Gelfand, & Bender, 2010).*
• Provide opportunities for children to connect with family and friends through technology. **EBN:** *Children desire to feel connected to the world outside the hospital environment; technology can reduce isolation as well as support educational needs (Lambert et al, 2014).*
• Provide animal-assisted therapy for hospitalized children. **CEBN:** *Animal-assisted therapy produces a number of therapeutic benefits for hospitalized children, including a reduction in pain (Braun et al, 2009).*
• Provide computer games and virtual reality experiences for children, which can be used as distraction techniques during venipuncture, wound care, or other procedures. **EBN:** *Actively engaging children in serious gaming resulted in lower observed behavioral pain scores and distress for children undergoing wound dressing changes (Nilsson et al, 2013).*

Geriatric

• Assess the interests of older adults and the types of activities that they enjoy; encourage creative expression such as storytelling, drama, dance, art, writing, or music. **EB:** *Art therapy was shown to be effective in reducing anxiety and negative emotions, and improving self-esteem in a group of Korean American older adults (Kim, 2013). Participating in music making with others may improve quality of life, well-being, and physical and mental health in older adults (Creech et al, 2013).*
• If the client is able, arrange for him or her to attend group senior citizen activities. **EB:** *Social connectedness may assist with older adults' perception that they are aging well (Hodge et al, 2013).*
• Promote activity for older adults through the use of exergames (video games combined with exercise). **EB:** *A pilot study demonstrated that Wii interactive videogaming is feasible for use with older adults with mild cognitive impairment. Participants enjoyed physical, mental, and social stimulation from the intervention (Hughes et al, 2014).*
• Encourage involvement in dance. **EB:** *Active participation in dance may enhance healthy aging (Noice, Noice, & Kramer, 2013).*
• Encourage clients to use their ability to help others by volunteering. **EB:** *Volunteering is associated with better self-reported health, fewer functional limitations, reduced depressive symptoms, and lower mortality (Anderson et al, 2014).*

• Provide an environment that promotes activity (e.g., one that has adequate lighting for crafts, large-print books, and adequate acoustics).
• Provide opportunities for storytelling and life review. **EBN:** *Reflection on one's life assists individuals to discover meaning and purpose. A pilot study demonstrated a significant reduction in depressive symptoms after the creation of life story books (Chan et al, 2014).*
• For clients who love gardening but who may have difficulty being outside, bring in seeds, soil, and pots for indoor gardening experiences. Use seeds such as sunflower, pumpkin, and zinnia that grow rapidly. **EB:** *Gardening may foster socialization, fitness, flexibility, cognitive ability, health, and quality of life (Wang & Macmillan, 2013).*
• For hospitalized clients with cognitive impairment, engage the assistance of volunteers to provide diversional activities. **EBN:** *A small pilot study demonstrated that patients, caregivers, staff, and volunteers were satisfied with a volunteer program that engaged hospitalized patients in a variety of activities during hospitalization (Shee, Phillips, & Hill, 2014).*
• For clients in assisted-living facilities, provide leisure educational programs and pleasant dining experiences. **EB:** *Opportunities for social engagement lead to psychological benefits for older adults in assisted living (Jang et al, 2014).*
• For clients who are interested in reading and writing, promote book or writing groups or journaling, and creative or expressive writing. **EB:** *Participation in reading and writing activities positively influenced quality of life in a group of older adults (Sampaio & Ito, 2013).*
• Prescribe activities to engage passive dementia clients based on their former interests and hobbies. **EB:** *Residents of long-term care facilities who have dementia spend the majority of their time engaged in no activity at all, and inactivity has been linked to agitated behavior; stimuli such as looking at and sorting pictures, arranging flowers, folding towels, making puzzles, planting seeds, screwing nuts and bolts together, and listening to and singing along with favorite music led to positive affect and a decrease in agitated behavior (Van der Ploeg et al, 2013).*
• Initiate opportunities for creative expression such as a TimeSlips storytelling group or Memories in the Making project to foster meaningful activities for clients with dementia. **EB:** *A creative storytelling program for clients with dementia, TimeSlips, resulted in increased creativity, quality of life, and involvement in meaningful activity, and positively altered resident behavior while allowing staff to develop a deeper understanding of residents (George & Singer, 2011).*

Home Care

• Many of the previously listed interventions may be administered in the home setting.
• Explore with the client previous interests; consider related activities that are within the client's capabilities.
▲ Assess the client for depression. Refer for mental health services as indicated. **EB:** *Lack of interest in previously enjoyed activities is part of the syndrome of depression (American Psychiatric Association, 2013).*
• Assess the family's ability to respond to the client's psychosocial needs for stimulation. Assist as able.
▲ Refer to occupational therapy. **EB:** *Clients with low vision who received adequate training in the use of low vision devices tailored to individual goals were able to improve independence at home (Liu et al, 2013).*
• Introduce (or continue) friendly volunteer visitors if the client is willing and able to

have the company. If transportation is an issue or if the client does not want visitors in the home, consider alternatives (e.g., telephone contacts, computer messaging).
• If the client is approaching the end of life, and is interested, assist in making a videotape, audiotape, or memory book for family members with treasured stories, memoirs, pictures, and video clips. **CEB:** *Leaving a legacy entails passing on the essence of one's self; passing on values and beliefs is important to older adults (Hunter, 2007–2008).*

Client/Family Teaching and Discharge Planning

• Work with the client and family on learning diversional activities in which the client is interested (e.g., knitting, hooking rugs, writing memoirs).
• If the client is in isolation, give the client complete information on why isolation is needed and how it should be accomplished, especially guidelines for visitors; provide diversional activities and encourage visitation. **EBN:** *Children in isolation feel lonely and bored; access to play, social connections, and education may be helpful (Austin, Prieto, & Rushforth, 2013).*

Ineffective adolescent Eating dynamics

Marina Martinez-Kratz MS, RN, CNE

NANDA-I

Definition

Altered eating attitudes and behaviors resulting in over or under eating patterns that compromise nutritional health.

Defining Characteristics

Avoids participation in regular mealtimes; complains of hunger between meals, food refusal, frequent snacking; frequently eating from fast food restaurants; frequently eating poor quality food; frequently eating processed food; overeating; poor appetite; undereating

Related Factors

Altered family dynamics; anxiety; changes to self-esteem on entering puberty; depression; eating disorder; eating in isolation; excessive family mealtime control; excessive stress; inadequate choice of food; irregular mealtime; media influence on eating behaviors of high caloric unhealthy foods; media influence on knowledge of high caloric unhealthy foods; negative parental influences on eating behaviors; psychological abuse; psychological neglect; stressful mealtimes

Associated Condition

Physical challenge with eating; physical challenge with feeding; physical health issue of parents; psychological health issues of parents

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Nutritional Status; Nutritional Status: Food and Fluid Intake; Nutrient Intake; Weight Control; Knowledge: Healthy Diet; Knowledge: Weight Management; Eating Disorder Self-Control; Body Image

Example NOC Outcome with Indicators

Knowledge Healthy Diet as evidenced by the following indicators: Caloric intake appropriate for metabolic needs/Nutrient intake appropriate for individual needs/Guidelines for food portions/Importance of eating breakfast/Strategies to avoid foods with high caloric value. (Rate the outcome and indicators of **Nutritional Status:** 1 = no knowledge, 2 = limited knowledge, 3 = moderate knowledge, 4 = substantial knowledge, 5 = extensive knowledge [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Maintain weight within normal range for height and age
- Eat breakfast daily
- Participate in meal planning and preparation
- Consume healthy and nutritious foods

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Nutrition Counseling; Nutrition Monitoring; Family Involvement Promotion; Parenting Promotion

Example NIC Activities—Nutritional Counseling

Establish a therapeutic relationship based on trust and respect; Facilitate identification of eating behaviors to be changed; Discuss the meaning of food to patient

Nursing Interventions and *Rationales*

- Assess for goals and motives related to eating behaviors. **EB:** *A recent study found that appearance-focused goals and controlled eating regulation were positively related to disordered eating symptoms (Verstuyf et al, 2016).*

▲ Assess the adolescent client for comorbid psychological disorders and make appropriate referrals for treatment. **EB:** *A long-term evolution study's findings suggested a reciprocal relationship between depressive symptoms and unhealthy eating behaviors (Wu et al, 2016). A cross-sectional study found that binge eating was associated with trait anxiety in Korean adolescent girls (Jung et al, 2017).*

- Assess the adolescent for experiences of cyberbullying and the strength of friendship dynamics. **EB:** *A study found that adolescents who were cyberbullied were almost twice as likely to consider themselves too fat. Stronger friendship dynamics were associated with decreased levels of body dissatisfaction with friendship dynamics partially mediating the relationship between cyberbullying and body dissatisfaction (Kenny et al, 2017).*
- Offer obese or overweight adolescents healthy methods for weight loss. **EB:** *A recent study showed statistically significant health behavior improvements after implementing a developmentally informed intervention to increase positive health diet and exercise behaviors (Issner et al, 2017).*
- Offer families of obese or overweight children prejudice-free, individually accepting, and supportive interventions to address weight loss. **EBN:** *Obese children treated with motivational interviewing showed significant improvement in their weight-related behavior and obesity-related anthropometric measures (Wong & Cheng, 2013).*
- Recommend that families eat together for at least one meal per day. **EB:** *Findings from a review provide clear evidence that family meals (among youth) and shared meals (among adults) are associated with better dietary intake and that these findings transcend the life span (Fulkerson et al, 2014).*
- Recommend involving the adolescents in planning family meals and food preparation. **EB:** *Results suggested that involving adolescents in food preparation for the family is related to better adolescent dietary quality and eating patterns (Berge et al, 2016).*
- Assist parents at being good role models of healthy eating. **EB:** *The Healthy Home Offerings via the Mealtime Environment Plus program showed significantly improved parental self-efficacy for identifying appropriate portion sizes (Fulkerson et al, 2018).*
- Recommend that the family try new foods, such as either a new food or recipe every week. **EB:** *The Healthy Home Offerings via the Mealtime Environment Plus program showed*

decreasing child neophobia scores over time that were developmentally appropriate (Fulkerson et al, 2018).

• Frame healthy eating as consistent with the adolescent values of autonomy from adult control and the pursuit of social justice. **EB:** *A study with eighth-graders framed healthy eating as a way to take a stand against manipulative practices of the food industry, such as engineering addictive junk food and marketing to young children. These youth would forgo unhealthy foods for healthier options after associating healthy eating with autonomy-assertive and social justice-oriented behavior (Bryan et al, 2016).*

• Explore the adolescent's friendship dynamics. **EB:** *Findings from a recent study indicated that adolescent friendships play an integral role in the development of unhealthy weight control and are a useful method to identify adolescents at risk (Simone, Long, & Lockhart, 2018).*

Multicultural

• Assess racial-ethnic minority overweight adolescents for disordered eating behaviors. **EB:** *A study found that across diverse cultural groups, overweight adolescents are at risk for disordered eating (Rodgers et al, 2017).*

• Assess racial-ethnic minority adolescents for experiences of harassment. **EB:** *A study found that any type of harassment experienced by racial-ethnic adolescents was significantly associated with poor self-esteem, depressive symptoms, low body satisfaction, substance use, and self-harm behaviors (Bucchianeri et al, 2014).*

Home Care

• The interventions previously described may be adapted for home care use.

Client/Family Teaching and Discharge Planning

▲ Refer the adolescent and family to family treatment-behavior (FT-B) for treatment of eating disorders. **EB:** *A review found that FT-B is the only well-established treatment for adolescent eating disorders (Lock, 2015).*

▲ Teach the family that hospitalization of the adolescent may be indicated for medical stabilization of serious physical complications and refer as needed. **EB:** *A study found that inpatient medical stabilization for adolescent eating disorders addresses acute medical complications and also appears to activate the patient and family regarding the need for ongoing treatment (Bravender, Elkus, & Lange, 2017).*

Ineffective child Eating dynamics

Marina Martinez-Kratz MS, RN, CNE

NANDA-I

Definition

Altered attitudes, behaviors, and influences on child eating patterns resulting in compromised nutritional health.

Defining Characteristics

Avoids participation in regular mealtimes; complains of hunger between meals, food refusal, frequent snacking; frequently eating from fast food restaurants; frequently eating poor quality food; frequently eating processed food; overeating; poor appetite; undereating

Related Factors

Eating Habit

Bribing child to eat; consumption of large volumes of food in a short period of time; disordered eating habits; eating in isolation; excessive parental control over child's eating experience; excessive parental control over family mealtime; forcing child to eat; inadequate choice of food; lack of regular mealtimes; limiting child's eating; rewarding child to eat; stressful mealtimes; unpredictable eating patterns; unstructured eating of snacks between meals

Family Process

Abusive relationship; anxious parent–child relationship; disengaged parenting style; hostile parent–child relationship; insecure parent–child relationship; over involved parenting style; tense parent–child relationship; under involved parenting style

Parental

Anorexia; depression; inability to divide eating responsibility between parent and child; inability to divide feeding responsibility between parent and child; inability to support healthy eating patterns; ineffective coping strategies; lack of confidence in child to develop healthy eating habits; lack of confidence in child to grow

appropriately; substance misuse

Environmental

Media influence on eating behaviors of high caloric unhealthy foods; media influence on knowledge of high caloric unhealthy foods

At-Risk Population

Economically disadvantaged; homeless; involvement with the foster care system; life transition; parental obesity

Associated Condition

Physical challenge with eating; physical challenge with feeding; physical health issue of parents; psychological health issues of parents

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Appetite; Parenting Performance; Knowledge: Healthy Diet; Health Beliefs; Nutritional Status

Example NOC Outcome with Indicators

Appetite as evidenced by the following indicators: Desire to eat/Food intake/Nutrient intake/Fluid intake/Stimulus to eat. (Rate the outcome and indicators of **Appetite:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Will (Specify Time Frame)

Client Outcomes

- Identify hunger and satiety cues
- Consume healthy and nutritious foods
- Consume adequate calories to support growth and development
- Engage in positive interactions with caregiver during meals

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Nutrition management; Nutrition Counseling; Nutritional Monitoring

Example NIC Activities—Nutritional Counseling

Establish a therapeutic relationship based on trust and respect; Determine attitudes and beliefs of significant others about food, eating, and the patient's needed nutritional change

Nursing Interventions and *Rationales*

▲ Use a nutritional screening tool designed for nurses such as Subjective Global Nutrition Assessment (SGNA), and refer to a dietician for scores of moderate or severe. **EB:** *A study found that SGNA can be a reliable tool for assessing nutritional status in children (Minocho et al, 2017).*

• Assess parents for food or eating concerns, aberrant feeding behavior, or inappropriate feeding practices. **EB:** *Caregiver concerns about food or child eating warrants additional assessment (Kerzner et al, 2015).*

• Assess child for type of eating difficulty. Children can present with limited appetite, food selectivity, and fear of feeding. **EB:** *Identifying the eating issue will enable*

appropriate intervention (Kerzner et al, 2015).
• Assess the caregivers feeding style by asking three questions: How anxious are you about your child's eating? How would you describe what happens during mealtime? What do you do when your child will not eat? **EB:** *Kerzner et al (2015) identify three feeding styles that have negative consequences: neglectful, controlling, and indulgent. Responses from neglectful parents will be vague, and controlling parents will describe pressuring/forcing their child to eat. Indulgent parents will describe pleading, begging, and preparing special foods.*
• Assess the child for persistent picky eating with three questions/answers: Is your child a picky eater? (yes). Does she or he have strong likes with regard to food? (yes). Does your child accept new foods readily? (no). **EB:** *A study found that 3 of 18 feeding behavior questions were significantly associated with persistent picky eaters (Toyama & Agras, 2016). Early identification of picky eating will allow early intervention.*
• Assess child for symptoms of malnutrition including short stature, thin arms and legs, poor condition of skin and hair, visible vertebrae and rib cage, wasted buttocks, wasted facial appearance, lethargy, and in extreme cases, edema.
• Assess weight and height of the child and use a growth chart to help determine growth pattern, which reflects nutrition. Age-related growth charts are available from www.cdc.gov/growthcharts/ (Centers for Disease Control and Prevention, 2016).
• Recommend that families eat together for at least one meal per day. **EB:** *Findings from a review provide unmistakable evidence that family meals (among youth) and shared meals (among adults) are associated with better dietary intake and that these findings transcend the life span (Fulkerson et al, 2014).*
• Encourage parent–child interactions that promote attachment. **EB:** *A study found that insecure attachment was significantly associated with higher body mass index (Maras et al, 2016).*
• Recommend that the child eats an appropriate size breakfast daily. **EB:** *A study of urban children found higher mean body mass index percentiles among children who did not consume any breakfast and those who consumed greater than or equal to three breakfasts daily (Lawman et al, 2014).*
• Recommend involving the family in planning meals and food preparation. Children can learn about nutrition as they help plan and make meals. **EB:** *The Healthy Home Offerings via the Mealtime Environment Plus program showed increased cooking skills among the children participating (Fulkerson et al, 2018).*
• Assist parents at being good role models of healthy eating. **EB:** *The Healthy Home Offerings via the Mealtime Environment Plus program showed significantly improved parental self-efficacy for identifying appropriate portion sizes (Fulkerson et al, 2018).*
• Recommend that the family try new foods, either a new food or recipe every week. **EB:** *The Healthy Home Offerings via the Mealtime Environment Plus program showed decreasing child neophobia scores over time that were developmentally appropriate (Fulkerson et al, 2018).*
▲ Refer children with highly selective food behaviors and sensory food aversion to a nutritional specialist. **EB:** *Refusal to eat entire categories of foods related to their taste, texture, smell, temperature, and/or appearance can interrupt normal development and have negative health consequences (Kerzner et al, 2015).*
▲ Refer children with feeding difficulties caused by a medical condition to the appropriate specialist. **EB:** *Organic conditions may contribute to feeding difficulties and express as food aversions, fear of feeding, and selective eating (Kerzner et al, 2015).*

• Assess for the meanings, attitudes, and behaviors related to feeding practices in culturally diverse families. **EB:** *A qualitative study of Hispanic mothers found feeding attitudes were central to the maternal responsibility of having well-fed children, and feeding practices included the use of coercive/negative reinforcement strategies (Martinez et al, 2015).*
• Assess the feeding styles of Hispanic and African American mothers for congruence with current child feeding recommendations. **EB:** *A recent study showed that Hispanic and African American mothers seldom spoke to their children about food characteristics, rarely referred to feelings of hunger and fullness, encouraged more eating, and made more attempts to enforce table manners than to teach eating skills (Power et al, 2015).*

Home Care

• The interventions previously described may be adapted for home care use.

Client/Family Teaching and Discharge Planning

• Provide parents with the following guidelines: avoid distractions during mealtimes (television, cell phones, etc.), maintain a pleasant neutral attitude throughout meal, feed to encourage appetite, limit meal duration (20–30 minutes), 4 to 6 meals/snacks a day with only water in between, serve age-appropriate foods, systematically introduce new foods (up to 8–15 times), encourage self-feeding, and tolerate age-appropriate mess. **EB:** *Guidelines will prevent and/or resolve feeding difficulties, whether mild or severe (Kerzner et al, 2015).*
• Teach families to use positive family- and parent-level interpersonal dynamics (i.e., warmth, group enjoyment, parental positive reinforcement) and positive family- and parent-level food-related dynamics (i.e., food warmth, food communication, parental food positive reinforcement) at family meals. **EB:** *A reduced risk of childhood obesity was significantly associated with positive family- and parent-level interpersonal dynamics and positive family- and parent-level food-related dynamics (Berge et al, 2014).*
• Teach parents to recognize the difference between hunger and satiety in their children. **EB:** *Parents may misperceive the child's appetite despite normal growth and need encouragement to accept the child's interpretation of their hunger and satiety (Kerzner et al, 2015).*
• Teach parents of children with limited appetites to establish a feeding schedule with a maximum of five meals per day and nothing but water in between. Parents must be taught to model healthy eating, adhere to the established feeding schedule, and set limits/consequences for mealtime behavior. **EB:** *A feeding schedule will provide adequate nutrition and assist the child with recognizing and responding appropriately to hunger and satiety (Kerzner et al, 2015).*
• Teach parents of children with food selectivity to refrain from coercive and indulgent feeding practices. **EB:** *Coercive and indulgent feeding practices may create family discord and subsequent child behavioral problems (Kerzner et al, 2015).*
• Teach parents the concept of being a responsive feeder, in which the parent determines where, when, and what the child is fed and the child determines how much to eat. Responsive feeders guide the child's eating, set limits, model appropriate eating, talk positively about food, and respond appropriately to the child's feeding cues. **EB:** *Research has reported that a responsive feeding style has resulted in children developing a lower risk of being overweight through consumption of more fruits, vegetables, and dairy products and less unhealthy foods (Kerzner et al, 2015).*

Ineffective infant Eating dynamics

Marina Martinez-Kratz MS, RN, CNE

NANDA-I

Definition

Altered parental feeding behaviors resulting in over or under eating patterns.

Defining Characteristics

Food refusal; inappropriate transition to solid foods; overeating; poor appetite; undereating

Related Factors

Abusive relationship; attachment issues; disengaged parenting style; lack of confidence in child to develop healthy eating habits; lack of confidence in child to grow appropriately; lack of knowledge of appropriate methods of feeding infant for each stage of development; lack of knowledge of infant's developmental stages; lack of knowledge of parent's responsibility in infant feeding; media influence on feeding infant high caloric, unhealthy foods; media influence on knowledge of high caloric, unhealthy foods; multiple caregivers; over involved parenting style; under involved parenting style

At-Risk Population

Abandonment; economically disadvantaged; history of unsafe eating and feeding experiences; homeless; involvement with the foster care system; life transition; neonatal intensive care experiences; prematurity; prolonged hospitalization; small for gestational age

Associated Condition

Chromosomal disorders; cleft lip; cleft palate; congenital heart disease; genetic disorder; neural tube defects;

physical challenge with eating; physical health issues of parents; prolonged enteral feedings; psychological health issues of parents; sensory integration problems

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Bottle Feeding Establishment: Infant; Bottle Feeding Performance; Breastfeeding Establishment: Infant; Breastfeeding Maintenance; Breastfeeding Weaning; Parenting Performance: Infant; Knowledge: Parenting

Example NOC Outcome with Indicators

Parenting Performance Infant as evidenced by the following indicators: Exhibits a loving relationship/Interacts with infant to promote trust/Provides age-appropriate nutrition/Provides appropriate weaning. (Rate the outcome and indicators of **Nutritional Status:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Infant will consume adequate calories to support growth and development
- Caregiver will follow healthy infant feeding practices
- Caregiver will identify infant behavioral cues related to hunger and satiety
- Caregiver and infant will engage in positive interactions during feeding

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Infant Care; Bottle Feeding; Teaching: Infant Nutrition

Example NIC Activities—Teaching: Infant Nutrition

Provide parents with written materials appropriate to identified knowledge needs; Instruct parent/caregiver to feed only breast milk or formula for first year (no solids before 4 months)

Nursing Interventions and *Rationales*

- Assess weight and height of the infant and use a growth chart to help determine growth pattern, which reflects nutrition. Age-related growth charts are available from www.cdc.gov/growthcharts/ (Centers for Disease Control and Prevention, 2016).
- Assess mothers for symptoms of postpartum depression. **EB:** *A study found an association between postpartum depression and poor infant nutritional status (Madeghe et al, 2016).*
- Encourage parent–child interactions that promote attachment. **EB:** *A study found that insecure attachment was significantly associated with higher body mass index (Maras et al, 2016).*
- Encourage overweight and obese mothers to follow current infant feeding guidelines. **EB:** *Research indicated that compared with normal weight mothers, overweight/obese mothers were less likely to breastfeed exclusively at infant age 2 months age; they were more likely to breastfeed at low intensity during the first 2 months, and more likely to initiate early introduction of solid foods (Kisantas et al, 2015).*
- Encourage breastfeeding as appropriate. **EB:** *A study found that adolescents with a history of shorter breastfeeding duration in infancy had poorer satiety response and higher food*

consumption during an eating in absence of hunger procedure (Reyes et al, 2014).

• Teach infant caregivers to recognize the following infant communication: infants signal appetite through interest or disinterest in food; infants use rapid and transient facial expressions to signal liking; and they use subtle or potent gestures, body movements, and vocalizations to express wanting. **EB:** *Research demonstrated the bidirectionality and interdependence of infant communication feeding, with more responsive feeding associated with more proficient communication by the infant (Hetherington, 2017).*

• Provide teaching and resources during pregnancy about recommended infant feeding practices. **EB:** *The results of a clinical trial testing a prenatal–postpartum individual nutrition/breastfeeding counseling program with follow-up nutrition and parenting support groups showed increased exclusive breastfeeding and reduced complementary foods and liquids in 3-month-old infants (Gross, 2016).*

• Provide caregivers of infants with teaching to encourage the early development of healthy eating patterns. **EB:** *A cross-sectional analysis of 24-hour dietary recall data from the 2008 Feeding Infants and Toddlers Study found that feeding and dietary issues started during infancy continue in toddler and preschool stages (Deming et al, 2014).*

• Provide caregivers of infants with teaching about the strong association between sugar-sweetened beverages, obesity, and related chronic diseases. **EB:** *A cross-sectional analysis of Special Supplemental Nutrition Program for Women, Infants, and Children (WIC) participants found that compared with nonparticipants, fewer WIC infants were breastfed and consumed any vegetable, but more consumed 100% juice. Fewer WIC toddlers and preschoolers consumed any fruit versus nonparticipants and were more likely to consume sugar-sweetened beverages (Deming et al, 2014).*

• Assist mothers to identify infant engagement and disengagement cues during breastfeeding or formula feeding. **EB:** *A study found breastfeeding and formula-fed infants exhibited engagement and disengagement during feeding. Supporting a mother's ability to identify engagement and disengagement cues may promote more responsive feeding strategies (Shloim et al, 2017).*

• Provide mothers with unconditional positive regard in their choice of breast, formula, or mixed feeding of their infant. **EB:** *A study of breastfeeding woman found women experienced feelings of pressure and judgment around their infant feeding decisions (Hunt & Thomson, 2016).*

Multicultural

• Assess for cultural beliefs, values, and practices related to the feeding of infants. **EB:** *Education and supportive efforts to enhance healthy infant feeding practices should be culturally tailored for success (Fischer & Olson, 2014).*

• Identify the support persons of the infant caregiver and extend healthy infant feeding education and information to those support persons. **EB:** *A study of first-time African American mothers and breastfeeding indicated that over half of the mothers intended to exclusively breastfeed but were unable to because of life stressors and experiences. An informed support person could promote healthy infant feeding practices (Asiodu et al, 2017).*

Home Care

• The interventions previously described may be adapted for home care use.

Client/Family Teaching and Discharge Planning

• Many of the interventions previously described involve teaching.

Risk for Electrolyte imbalance

Susan M. Dirkes BSN, MSA

NANDA-I

Definition

Susceptible to changes in serum electrolyte levels, which may compromise health.

Risk Factors

Diarrhea; excessive fluid volume; insufficient fluid volume; insufficient knowledge of modifiable factors; vomiting

Associated Condition

Compromised regulatory mechanism; endocrine regulatory dysfunction; renal dysfunction; treatment regimen

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Electrolyte and Acid-Base Balance; Fluid Balance; Hydration; Nutritional Status: Biochemical Measures; Nutritional Status: Food and Fluid Intake; Nutritional Status: Nutrient Intake; Kidney Function

Example NOC Outcome with Indicators

Electrolyte and Acid-Base Balance as evidenced by the following indicators: Apical heart rate/Apical heart rhythm/Serum potassium/Serum sodium/Serum calcium, serum magnesium, serum phosphorus. (Rate the outcome and indicators of **Electrolyte and Acid-Base Balance:** 1 = severe deviation from normal range, 2 = substantial deviation from normal range, 3 = moderate deviation from normal range, 4 = mild deviation from normal range, 5 = no deviation from normal range [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Maintain a normal sinus heart rhythm with a regular rate
- Have a decrease in edema
- Maintain an absence of muscle cramping
- Maintain normal serum potassium, sodium, calcium, magnesium and phosphorus
- Maintain normal serum pH

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Electrolyte Monitoring; Electrolyte Management: Hypokalemia, Hyperkalemia, Hypocalcemia, Hypercalcemia, Hyponatremia, Hypernatremia, Hypomagnesemia, Hypermagnesemia, Hypophosphatemia, and Hyperphosphatemia; Electrolyte Management: Hyponatremia; Fluid/Electrolyte Management; Laboratory Data Interpretation

Example NIC Activities—Electrolyte Monitoring

Identify possible causes of electrolyte imbalances; Monitor the serum level of electrolytes

Nursing Interventions and *Rationales*

▲ Monitor vital signs at least three times a day, or more frequently as needed. Notify health care provider of significant deviation from baseline. *Electrolyte imbalance can lead to clinical manifestations such as respiratory failure, arrhythmias, edema, muscle weakness, and altered mental status (Wagner & Hardin-Pierce, 2014).*

▲ Monitor cardiac rate and rhythm. Report changes to provider. *Hypokalemia and hyperkalemia can result in electrocardiogram (ECG) changes that can lead to cardiac arrest, and ventricular dysrhythmias.* **EB:** *Hypophosphatemia can cause ventricular arrhythmias, derangements of cardiac and respiratory function, and death. It can also cause cardiomyopathy (Ariyoshi et al, 2016; Christopoulou et al, 2017). Magnesium and calcium imbalances also can cause cardiac arrhythmias. Low serum magnesium (≤2 mEq/L) is associated with hypokalemia and ECG changes, and high phosphate may indicate kidney injury (Wagner & Hardin-Pierce, 2014). Low magnesium also may impair respiratory function. It has been associated with higher mortality, the need for mechanical ventilation, and increased length of stay (Upala et al, 2016). Low magnesium also is common in heart failure patients (Gonzales et al, 2013).*

• Monitor intake and output and daily weights using a consistent scale. *Weight gain is a sensitive and consistent sign of fluid volume excess (Wagner & Hardin-Pierce, 2014).*

• *Monitor for abdominal distention and discomfort. A focused assessment should be done on any patient presenting with hepatic, gastrointestinal, or pancreatic dysfunction (Wagner & Hardin-Pierce, 2014).* **EB:** *Abdominal distension and intraabdominal swelling can lead to compression of the abdominal contents and acute kidney injury, especially in the postoperative period (Raghavendra et al, 2017).*

• Monitor the client's respiratory status and muscle strength. *Phosphorus is an essential element in cell structure, metabolism, and maintenance of acid-base processes. Consequences of hypophosphatemia include cardiac failure, respiratory failure, and alterations in sensorium (Wagner & Hardin-Pierce, 2014; Diringer, 2017).*

• Assess cardiac status and neurological alterations. **EB:** *Hypophosphatemia can cause myocardial dysfunction, hematological dysfunction, respiratory depression, and neurological*

changes (Diringer, 2017).
• *Imbalances of sodium, potassium, calcium, and magnesium all can cause neurological disturbances (Gardner & Gardner, 2014). Hyperphosphatemia is associated with hypocalcemia (because it is inversely related to calcium), causing tetany, muscle spasms, and cardiac arrhythmias, as well as vascular mineralization (Wagner & Hardin-Pierce, 2014; Marcuccilini, Chonchol, & Jovanovich, 2017).*
▲ Review laboratory data as ordered and report deviations to provider. *Laboratory studies may include serum electrolytes potassium, chloride, sodium, bicarbonate, magnesium, phosphate, calcium; serum pH; comprehensive metabolic panel; and arterial blood gases.*
• Review the client's medical and surgical history for possible causes of altered electrolytes. *Periods of excess fluid loss can lead to dehydration and resulting loss of electrolytes; fluid can be lost through gastrointestinal illness, renal failure, hyperthermia, blood loss, and perspiration caused by strenuous exercise (Chlibkova et al, 2014; Wagner & Hardin-Pierce, 2014; Hew-Butler et al, 2017). Additional causes of electrolyte imbalances include excessive use of antacids, burns, trauma, sepsis, diabetic ketoacidosis, extensive surgeries, and changes in acid-base balance (Nykamp & Krause, 2013).*
▲ Complete pain assessment. Assess and document the onset, intensity, character, location, duration, aggravating factors, and relieving factors. Notify the provider for any increase in pain or discomfort or if comfort measures are not effective. *Symptoms of electrolyte imbalance and dehydration can include muscle cramps, paresthesias, abdominal cramps, skin manifestations, cardiac arrhythmias, and tetany (Wagner & Hardin-Pierce, 2014).*
▲ Monitor the effects of ordered medications such as diuretics and heart medications. **EB:** *Medications can have adverse effects on kidney function and electrolyte balance, particularly contrast agents, chemotherapeutic agents, amphotericin B, aminoglycosides, phosphate ingestion, loop diuretics, and vitamin D (Calazza, 2014; Wagner & Hardin-Pierce, 2014).*
▲ Administer parenteral fluids as ordered and monitor their effects. *Rapid resuscitation with fluids can cause adverse effects such as electrolyte imbalance, increased bleeding, and coagulopathies (Wang et al, 2014). Administration of fluids should be done to impact the plasma electrolytes and pH and hemodynamic improvement (Vassalos & Rooney, 2013).*

Geriatric

• Monitor electrolyte levels carefully, including sodium levels and potassium levels, with both increased and decreased levels possible. **EB:** *Older adults are prone to electrolyte abnormalities because of failure of regulatory mechanisms associated with heart and kidney disease, a decrease in the ability to reabsorb sodium, and a loss of diluting capacity in the kidneys (Bolignano, 2014). Dehydration in the elderly is attributable to inadequate water intake caused by dysfunction of the central nervous system controlling thirst. Data also suggest that sodium appetite is reduced in aged rats and therefore also in elderly (Begg, 2017). Many older clients receive selective serotonin reuptake inhibitors for treatment of depression, which can result in hyponatremia (Varela-Piñón & Adán-Manes, 2017).*

Client/Family Teaching and Discharge Planning

• Teach client/family the signs of low potassium and the risk factors. *Signs and symptoms of low potassium include muscle weakness, nausea, vomiting, constipation, and irregular pulse (Wagner & Hardin-Pierce, 2014).*

• Teach client/family the signs of high potassium and the risk factors. *Signs and symptoms of high potassium include restlessness, muscle weakness, slow heart rate, diarrhea, and cramping (Wagner & Hardin-Pierce, 2014).*
• Teach client/family the signs of low sodium and the risk factors. *Early signs of low sodium include nausea, muscle cramps, disorientation, and mental status changes (Wagner & Hardin-Pierce, 2014).*
• Teach client/family the signs of high sodium and the risk factors. *Signs of high sodium include thirst, dry mucous membranes, rapid heartbeat, low blood pressure, and mental status changes; symptoms can progress to confusion, delirium, and seizures (Wagner & Hardin-Pierce, 2014).*
• Teach client/family the importance of hydration during exercise. Dehydration occurs when the amount of water leaving the body is greater than the amount consumed. *The body can lose large amounts of fluid when it tries to cool itself by sweating (Begg, 2017).*
• Teach client/family the warning signs of dehydration. Early signs of dehydration include thirst and decreased urine output. As dehydration increases, symptoms may include dry mouth, muscle cramps, nausea and vomiting, lightheadedness, and orthostatic hypotension. *Severe dehydration can cause confusion, weakness, coma, and organ failure (Wagner & Hardin-Pierce, 2014).*
• Teach client about any medications prescribed. Medication teaching includes the drug name, its purpose, administration instructions such as taking it with or without food, and any side effects. **EB:** *Studies have shown that insufficient and ineffective patient education leading to poor treatment adherence, and suboptimal use of guideline-recommended drug regimens have been identified as contributing factors to patient nonadherence to antiplatelet therapy and high hospital acute coronary syndrome (ACS) readmission rates (Larkin et al, 2017). Patients on a diuretic should understand side effects such as those for low potassium. Diuretic use remains a primary cause of low serum potassium levels (Arampatzis et al, 2013). Patients on warfarin should also be educated on dietary interactions to improve medication efficacy (Jenner et al, 2015).*
▲ Instruct the client to report any adverse medication side effects to his or her health care provider. Assessing and instructing clients about medications and focusing on important details can help prevent client medication errors. **EB:** *Pharmacist involvement with patient education can improve medication efficacy and decrease hospital readmissions (Phatak et al, 2016).*

Imbalanced Energy Field

Gail B. Ladwig MSN, RN, Julianne E. Doubet BSN, RN, EMT-B

NANDA-I

Definition

A disruption in the vital flow of human energy that is normally a continuous whole and is unique, dynamic, creative, and nonlinear.

Defining Characteristics

Arrhythmic energy field patterns; blockage of energy flow; congested energy field patterns; congestion of the energy flow; dissonant rhythms of the energy field patterns; energy deficit of the energy flow; expression of the need to regain the experience of the whole; hyperactivity of the energy flow; irregular energy field patterns; magnetic pull to an area of the energy field; pulsating to pounding frequency of the energy field patterns; pulsations sensed in the energy flow; random energy field patterns; rapid energy field patterns; slow energy field patterns; strong energy field patterns; temperature differentials of cold in the energy flow; temperature differentials of heat in the energy flow; tingling sensed in the energy flow; tumultuous energy field patterns; unsynchronized rhythms sensed in the energy flow; weak energy field patterns

Related Factors

Anxiety; discomfort; excessive stress; interventions that disrupt the energetic pattern or flow; pain

At-Risk Population

Crisis states; life transition

Associated Condition
Illness; injury

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes
Personal Well-Being, Personal Health Status; Psychomotor Energy; Quality of Life

Example NOC Outcome with Indicators

Personal Well-Being as evidenced by the following indicators: Psychological health/Spiritual life/Ability to relax/Level of happiness. (Rate the outcome and indicators of **Personal Well-Being:** 1 = not all satisfied, 2 = somewhat satisfied, 3 = moderately satisfied, 4 = very satisfied, 5 = completely satisfied [see Section I].)

NIC (Nursing Interventions Classification)

Suggested NIC Interventions
Therapeutic Touch (TT); Hope Inspiration; Reiki

Nursing Interventions and *Rationales*

- Consider using complimentary health approaches (CHAs)–energy medicine (TT/healing touch, hope inspiration, and reiki) for clients with anxiety, tension, pain, or other conditions that indicate a disruption in the flow of energy. **EBN:** *According to Papathanassoglou (2016), the sense of touch has the potential of evoking and balancing human emotions; interpersonal touch then may perform an influential part in the emotional well-being of the client and family.* **EBN:** *"The goal of Healing Touch is to restore harmony and balance in the energy system, placing the client in a position to self-heal" (Drozdowicz & Dillard, 2014).* **EBN:** *Developing evidence suggested that there is biological support for the lessening of pain and anxiety for patients who receive CHAs in acute care settings (Kramlich, 2017).* **EBN:** *Reiki can contribute to changes in mindfulness from conflict and confusion to harmony and well-being (Jamison & Grohman, 2015).*
- Refer to care plans for **Anxiety,** Acute **Pain,** and Chronic **Pain**.

Guidelines for Complimentary Health Approaches

- CHA may be practiced by anyone with the requisite preparation, desire, and commitment. **EBN:** *Acute and critical care nurses who are certified to practice CHA in the acute care setting must adhere to their scope of practice, be conscious of their role, and recognize their professional boundaries (Kramlich, 2017).*
- Volunteers who are not licensed health care professionals may practice in the home, but not in the health care setting unless they undertake a rigorous training program. **EBN:** *Because patient safety is of utmost concern in the acute and critical care settings, volunteer complimentary health professionals (CHPs) must support infection control, patient privacy, and patient security (Kramlich, 2017).*

Pediatric

- Consider using CHAs for pediatric clients with adjunct therapies to decrease stress, anxiety, and pain. **EB:** *McClafferty et al (2017) encouraged medical professionals who care*

for children to foster the utilization of "relevant, safe, effective, and age-appropriate health services and therapies," whether conventional or complementary. **EB:** *In pediatric cases of pain and chronic conditions, the successful use of complementary alternative medicine (CAM) has markedly increased (Adams et al, 2014).*

Geriatric

• Consider CHAs for elderly with pain. **EB:** *Overall, CAM therapies are valuable to the geriatric population, especially for those who cope with chronic conditions and suffer from constant pain, therefore enhancing their quality of life. CAM nurtures good health practices and bolsters the body's defenses, its natural healing ability, and promotion of self-care and patient empowerment (Siddiqui et al, 2014).* **EB:** *The use of patient-centered communication about the risks/benefits of CAM is necessary to promote effective management of chronic illnesses and pain among an aging population (Ho et al, 2014).*

Multicultural

• Assess for the influence of cultural beliefs, norms, and values on the client's use of CAM. **EB:** *CAMs cover a wide range of methodologies (herbal medicine, manual healing techniques, traditional therapies, and mind–body interventions) and are used globally to treat a wide-range of illnesses and to support good health (Mathew et al, 2013).*

Home Care

• Help the client and family accept CAMS as natural healing interventions. **EB:** *Because homeopathy is one of the most commonly used methods of CAM, Schmacke, Muller, and Stamer (2014), in their survey of homeopathic use, found that the initial homeopathic consultation and the search for appropriate medication was seen by patients as an endorsement of personalized homeopathic treatment.*
▲ In the presence of a psychiatric disorder, refer for psychiatric home health care services for client reassurance and implementation of therapeutic regimens. **EB:** *It has been shown that a home visit intervention (HoVI) of psychiatric clients generates positive outcomes shown by the documented decrease in rehospitalization rates and number of days hospitalized, leading to health care cost savings (Chang & Chou, 2015).*

Client/Family Teaching and Discharge Planning

• Teach the client how to use guided imagery. **EBN:** *Urge your client to use guided imagery and relaxation. This nonpharmacological technique has proven valuable in treating sleep deprivation and the promotion of relaxation to reduce pain (Adeola et al, 2015).*
• Consider the use of progressive muscle relaxation, autogenic training, relaxation response, biofeedback, emotional freedom technique, guided imagery, diaphragmatic breathing, transcendental meditation, cognitive behavioral therapy, mindfulness-based stress reduction, and emotional freedom technique. **CEB:** *These are all evidence-based techniques that are easy to learn and practice and have good results in individuals with good health or with a disease (Varvogli & Darviri, 2011).* **EB:** *"CAM routines and rituals constitute key elements in cancer patients' regular and satisfied CAM use, and they promote familial strengthening" (Klafke et al, 2014).*

Nurses/Staff

- The practice of CAMs, both giving and receiving, can improve well-being. **EBN:** *The patient–CAM practitioner connection is vital because it embodies healing intent, which in turn produces substantial influence on positive outcomes (Dunning, 2014).*
- See the EVOLVE website for Weblinks for client education resources.

Risk for dry Eye

Mary Beth Flynn Makic PhD, RN, CCNS, FAAN, FNAP

NANDA-I

Definition

Susceptible to eye discomfort or damage to the cornea and conjunctiva due to reduced quantity or quality of tears to moisten the eye, which may compromise health.

Risk Factors

Air conditioning; air pollution; caffeine intake; excessive wind; insufficient knowledge of modifiable factors; low humidity; prolonged reading; smoking; sunlight exposure; vitamin A deficiency

At-Risk Population

Aging; contact lens wearer; female gender; history of allergy

Associated Condition

Autoimmune disease; hormonal change; mechanical ventilation; neurological lesion with sensory or motor reflex loss; ocular surface damage; treatment regime

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes (Visual)

Dry Eye Severity; Sensory Function: Vision; Vision Compensation Behavior

Example NOC Outcome with Indicators

Dry Eye Severity as evidenced by the following indicators: Decreased tear production/Redness of conjunctiva/Burning eye sensation/Itchy eye sensation/Eye pain/Excessive watering/Blurred vision. (Rate each indicator of **Dry Eye Severity:** 1 = severe, 2 = substantial, 3 = moderate, 4 = mild, 5 = none [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- State eyes are comfortable with no itching, burning, or dryness
- Have corneal surface that is intact and without injury
- Demonstrate self-administration of eye drops if ordered
- State vision is clear

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Communication Enhancement: Visual Deficit; Environmental Management

Example NIC Activities—Communication Enhancement: Visual Deficit

Identify yourself when you enter the client's space; Provide adequate room lighting

Nursing Interventions and *Rationales*

▲ Assess for symptoms of dry eyes, such as "irritation, tearing, burning, stinging, dry or foreign body sensation, mild itching, photophobia, blurry vision, contact lens intolerance, redness, mucus discharge, increased frequency of blinking, eye fatigue, diurnal fluctuation, symptoms that worsen later in the day" (American Academy of Ophthalmology [AAO], 2015, 2018).

▲ If symptoms are present, then refer client to an ophthalmologist for diagnosis and treatment. **EB:** *Clients with dry eye who are evaluated by nonophthalmologist health care providers should be referred promptly to the ophthalmologist if moderate or severe pain, lack of response to therapy, corneal infiltration or ulceration, or vision loss occurs (AAO, 2018).*

▲ Administer ordered eye drops. *As the severity of the dry eye increases, aqueous enhancement of the eye using topical agents is appropriate. Emulsions, gels, and ointments can be used (AAO, 2015, 2018).*

• Consider use of eyeglass side shields or moisture chambers. **EB:** *Eyeglass side shields can protect the eyes from drafts. Moisture chambers are a type of eyeglasses that are frequently worn by motorcyclists and mountain climbers and can be purchased at stores or online (AAO,*

2015, *2018*; *American Optometric Association [AOA], 2018*).
▲ Watch for symptoms of blepharitis including crusting and irritation at the base of the lashes and adjacent redness of the eyelid, which may accompany dry eye; refer for treatment as needed. **EB:** *Contributing ocular factors such as blepharitis should be treated. Particularly effective treatments for evaporative tear deficiency include eyelid therapy for conditions such as blepharitis (AAO, 2015).*
▲ Discuss use of caffeine with client's health care provider. **EB:** *Arita et al (2012) and Wachler (2017) found that use of caffeine capsules increased tear volume.*
• Provide education to the client about limiting screen time, computers, smart devices, and television can assist with eyestrain and dry eyes. **EB:** *Eye discomfort is associated with screen time, and digital eyestrain because most people blink less when looking at screens causing eyestrain and dryness (Vimont & Khurana, 2017). Encourage the client to use natural tears if prolonged or frequent digital eye strain is anticipated.*

Geriatric

• Recognize that symptoms of dry eye are more common in menopausal women and geriatric clients. *Hormonal changes after menopause can disrupt tear production. It is estimated that one in three individuals older than 65 years experiences dry eyes (National Health Service [NHS], 2014).*

Critical Care

▲ Provide regular cleaning of the eyes, lubricating eye drops and ointments, and consultation with an ophthalmologist if infection is suspected in clients in the intensive care unit (ICU). *ICU staff may miss ocular complications while caring for life-threatening conditions. Ocular complications can seriously impair vision and quality of life.* **EB:** *"As ICU patients are more susceptible to develop dry eye, keratopathy, and ocular infections, they should be consulted by an ophthalmologist for early diagnosis of ocular surface disorders" (Saritas et al, 2013).*
• Avoid using adhesive tape to keep eyes closed in sedated patients. **EBN:** *In an audit of eye dryness and corneal abrasions of patients in four ICUs in Iran, patients receiving adhesive tape as an eye care method were twice as likely to develop corneal abrasion (Masoudi et al, 2014).*

Client/Family Teaching and Discharge Planning

• Teach client conditions that can exacerbate dry eye symptoms. *Exacerbating conditions include wind, air travel, decreased humidity, air conditioning or heating, and prolonged activities that reduce blink rate such as reading and computer use (AAO, 2015, 2018; AOA, 2018).*
• Teach client good eye hygiene:
  - ❍ Apply warm compresses for 10-minute intervals using a clean cloth and water that has been boiled and cooled (or sterile water).
  - ❍ Gently massage around eyelids.
  - ❍ Gently clean eyelids to remove excess oil, crusts, and bacteria. Use a few drops of baby shampoo in water that has been boiled and cooled, or in sterile water.
  - ❍ Good hygiene can help improve dry eyes, especially dry eye associated with blepharitis (NHS, 2014).
• Teach clients methods to decrease problems with dry eye including the following:

❍ Avoid drafty (e.g., ceiling fans) and low-humidity environments.
❍ Avoid smoking and exposure to secondhand smoke.

▲ Discuss avoidance of offending medications with health care provider.

• Drink plenty of water to keep well hydrated. **EB:** *For patients with a clinical diagnosis of mild dry eye, potentially exacerbating exogenous factors such as antihistamine or diuretic use, cigarette smoking, and exposure to secondhand smoke, and environmental factors such as air drafts and low-humidity environments should be addressed (AAO, 2015, 2018). Symptoms of dry eye may be exacerbated by the use of medications such as diuretics, antihistamines, anticholinergics, antidepressants, and systemic retinoids (AAO, 2015, 2018). Self-care includes drinking plenty of water to stay hydrated (AOA, 2018).*

• Teach client to lower the computer screen to below eye level and to blink more frequently. *Measures such as lowering the computer screen to below eye level to decrease lid aperture, scheduling regular breaks, and increasing blink frequency may decrease the discomfort associated with computer and reading activities (AAO, 2015, 2018).*

▲ Teach client to consult with the health care provider regarding use of omega-3 supplements to decrease dry eye. **EB:** *Omega-3 fatty acid products without ethyl esters may be beneficial in the treatment of dry eye, although they may increase the risk of prostate cancer (AAO, 2015, 2018).*

• Teach client how to self-administer eye drops.

• Warn clients with dry eyes that driving at night can be dangerous. *Clients with dry eyes have light sensitivity and decreased refraction.*

Labile Emotional Control

Marina Martinez-Kratz MS, RN, CNE

NANDA-I

Definition

Uncontrollable outbursts of exaggerated and involuntary emotional expression.

Defining Characteristics

Absence of eye contact; crying; difficulty in use of facial expressions; embarrassment regarding emotional expression; excessive crying without feeling sadness; excessive laughing without feeling happiness; expression of emotion incongruent with triggering factor; involuntary crying; involuntary laughing; uncontrollable crying; uncontrollable laughing; withdrawal from occupational situation; withdrawal from social situation

Related Factors

Alteration in self-esteem; emotional disturbance; fatigue; insufficient knowledge about symptom control; insufficient knowledge of disease; insufficient muscle strength; social distress; stressors; substance misuse

Associated Condition

Brain injury; functional impairment; mood disorder; musculoskeletal impairment; pharmaceutical agent; physical disability; psychiatric disorder

NOC Outcomes (Nursing Outcomes Classification)

Suggested NOC Outcomes

Coping; Knowledge: Disease Process; Impulse; Self-Control; Self-Esteem; Quality of Life; Personal Well-Being; Stress Level

Example NOC Outcomes with Indicators

Knowledge: Disease Process as evidenced by the following indicator: Specific disease process. (Rate the outcome and indicators of **Knowledge: Disease Process:** 1 = no knowledge, 2 = limited knowledge, 3= moderate knowledge, 4 = substantial knowledge, 5 = extensive knowledge [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Improve coping strategies
- Improve knowledge about disease process, signs and symptoms, triggers, symptom control
- Use mechanisms to control impulses and ask for help when feeling impulses
- Improve feelings of dignity
- Enhance and improve response to social and environmental stimuli

NIC Interventions (Nursing Interventions Classification)

Suggested NIC Interventions

Coping Enhancement; Teaching: Disease Process; Enhance Self-Esteem; Improved Quality of Life; Improved Well-Being

Example NIC Activities—Labile Emotional Control

Coping Enhancement: Assist the patient to solve problems in a constructive manner; Instruct the patient on the use of relaxation techniques, as needed; Assist the patient to identify positive strategies to deal with limitations and manage needed lifestyle or role changes

Nursing Interventions and *Rationales*

- Identify clients at risk of having labile emotional control. **EB:** *Clients with traumatic brain injury (TBI), Parkinson's disease (PD), multiple sclerosis (MS), amyotrophic lateral sclerosis (ALS), stroke, and schizophrenia (including schizoaffective and schizophreniform disorders) were most closely associated with pseudobulbar affect (PBA) diagnosis, which is associated with emotional lability (Allen et al, 2017).*
- Assess clients with the Pathological Laughter and Crying Scale (PLACS) to identify

pathological laughing and crying or related disorders (e.g., involuntary emotional expression disorder [IEED], PBA). **EBN:** *PLACS is an interviewer-administered instrument that has been validated in clients with acute stroke. It has shown excellent interrater and test–retest reliability (Ahmed & Simmons, 2013).*

• Assess clients for use of experiential avoidance, which is the process of negatively evaluating, escaping, or avoiding unwanted thoughts, emotions, or sensations. **EB:** *A recent study found experiential avoidance was associated with both higher levels of negative affect ($P < .001$) and increased emotional lability ($P = .021$) (Gerhart et al, 2018).*

• Offer the client choices when possible in emotional situations. **EB:** *A study found that choice appears to be a powerful tool that permits regulation of negative emotions in an adaptive fashion (Thuillard & Dan-Glauser, 2017).*

• Provide progressive muscle relaxation (PMR) exercise and guided imagery (GI) techniques. **EBN:** *A nursing study found that PMR and GI were effective in reducing anxiety and improving mood states in parents of children with malignancy (Tsitsi et al, 2016).*

• Offer instruction regarding alternative coping strategies such as mindfulness and breath awareness. **EB:** *Increased breath awareness (a fundamental component of mindfulness meditation) has been shown to reduce autonomic and psychological arousal, and this increased capacity to remain calm can help individuals to respond more adaptively to internal and external stressors (Compare et al, 2014).* **EB:** *Studies have demonstrated the effects of mindfulness and yoga on well-being, somatic effects of stress, immune system, and physical symptoms and chronic conditions (Lazaridou, Philbrook, & Tzika, 2013).*

• Consider using cognitive-behavioral therapy (CBT). **EB:** *A current study of youth with anxiety disorders found that CBT resulted in decreased sadness and anger dysregulation and increases in adaptive coping with anger (Suveg et al, 2017).*

• Provide music therapy. **EB:** *The use of music therapy can improve mental well-being, social functioning, quality of life, anxiety, pain, mood, relaxation, and comfort in persons with several disorders/diseases such as cancer, schizophrenia, mood disorders, and autism (Kamioka et al, 2014).*

Pediatric

• Assess adolescents with high emotional dysregulation for substance use disorders. **EB:** *Study results indicated that adolescents scoring high on emotional dysregulation are at risk for substance dependence because of more externalizing and internalizing symptomatology (Wills et al, 2016).*

• Teach parents that their reactions to their children's emotions play a critical role in teaching children effective emotion regulation. **EB:** *A recent study suggested that supportive parent emotion socialization practices are associated with parent-rated emotion regulation skills (Breaux et al, 2018).*

• Provide parents with emotion coaching strategies to manage their children's emotional outbursts. Emotion coaching includes fostering parental awareness and acceptance of their children's emotions with behaviors that acknowledge their children's emotions, and teaches understanding, coping with, and appropriately expressing emotion. **EB:** *Study results suggested that when children with oppositional defiant disorder (ODD) experience more frequent, intense, and unstable emotions, families are better able to benefit from treatment and reduce children's behavior problems when mothers begin treatment or are already engaging in emotion coaching (Dunsmore et al, 2016).*

▲ Refer adolescent clients to a dialectical behavior therapy (DBT) group. **EB:** *Research shows DBT is an effective means of assisting adolescents to learn to enhance their emotion regulation skills (Gill et al, 2018).*

Geriatric

- Many of the previous interventions may be adapted for geriatric use.
- Evaluate geriatric clients suspected of PBA with the following three-step model: (1) crying inconsistent with environment/stimuli; (2) diagnosis of any of the following neurological disorders, such as TBI, PD, MS, ALS; or (3) at least two of the following disorders, such as stroke, schizophrenia (including schizoaffective and schizophreniform disorders), or documentation of spinal cord injury (SCI) as most closely associated with the PBA diagnosis. **EB:** *Based on analysis, this three-item checklist to facilitate PBA risk assessment in the nursing home setting was developed (Allen et al, 2017).*

Multicultural and Home Care

- The previous interventions may be adapted for multicultural and home care.

Client/Family Teaching and Discharge Planning

- Inform client and family about the emotional lability and talk with them about how to cope with the situation. **EBN:** *Clients and families need more information about this syndrome so they can recognize the signs and symptoms, get a diagnosis, and obtain treatment (Schneider & Schneider, 2017).*
- Use verbal and nonverbal therapeutic communication approaches including empathy, active listening, and confrontation to encourage the client and family to express emotions such as sadness, guilt, and anger (within appropriate limits); verbalize fears and concerns; and set goals. *Solution-focused communication with clients helps focus on goals and helps find solutions*
- Provide psychoeducation for stress-related variables to client and family. **EB:** *Psychoeducation was conducted in seven studies, six of which had positive outcomes on depression, anxiety, or knowledge levels (Bte Iskhandar Shah et al, 2013).*

List of Planning Care by Letter: F

Risk for Falls	Dysfunctional Family processes	Interrupted Family processes
Readiness for enhanced Family processes	Fatigue	Fear
Ineffective infant Feeding pattern	Risk for Female Genital Mutilation	Risk for imbalanced Fluid volume
Deficient Fluid volume	Excess Fluid volume	Risk for deficient Fluid volume
Frail Elderly syndrome	Risk for Frail Elderly syndrome	

F

• = Independent; ▲ = Collaborative; **EBN** = Evidence-Based Nursing; **EB** = Evidence-Based

Risk for Falls

Sherry A. Greenberg PhD, RN, GNP-BC

NANDA-I

Definition

Susceptible to increased susceptibility to falling, which may cause physical harm and compromise health.

Risk Factors

Children

Absence of stairway gate; absence of window guard; inadequate supervision; insufficient automobile restraints

Environment

Cluttered environment; exposure to unsafe weather-related condition; insufficient anti-slip material in bathroom; insufficient lighting; unfamiliar setting; use of restraints; use of throw rugs

Physiological

Alteration in blood glucose level; decrease in lower extremity strength; diarrhea; difficulty with gait; faintness when extending neck; faintness when turning neck; impaired mobility; incontinence; sleeplessness; urinary urgency

Other

Alcohol consumption; insufficient knowledge of modifiable factors

At-Risk Population

Age ≥65 years; age ≤2 years; history of falls; living alone; male gender when <1 year of age

Associated Condition

Acute illness; alteration in cognitive functioning; anemia; arthritis; condition affecting the foot; hearing impairment; impaired balance; impaired vision; lower limb prosthesis; neoplasm; neuropathy; orthostatic hypotension; pharmaceutical agent; postoperative recovery period; proprioceptive deficit; use of assistive device; vascular disease

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Fall Prevention Behavior; Knowledge: Child Physical Safety; Knowledge: Fall Prevention; Risk Control: Falls

Example NOC Outcome with Indicators

Fall Prevention Behavior as evidenced by the following indicators: Uses assistive devices correctly/Eliminates clutter, spills, glare from floors/Uses safe transfer procedures. (Rate each indicator of **Fall Prevention Behavior:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4

= often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Remain free of falls
- Have a decreased risk of injury if sustains a fall
- Adapt environment to minimize the incidence of falls
- Explain methods to prevent injury

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Dementia Management; Fall Prevention; Post-Fall Assessment; Surveillance: Safety

Example NIC Activities—Fall Prevention

Assist unsteady individual with ambulation; Monitor gait, balance, and fatigue level with ambulation

Nursing Interventions and *Rationales*

- Safety Guidelines. Complete a fall-risk assessment for older adults in any health care setting with national guidelines and action plans such as the Falls Free: 2015 National Falls Prevention Action Plan (National Council on Aging, 2015).
- Use a valid and reliable fall risk assessment tool to assess the client risk for falling, for example, in the acute care setting the Hendrich II Model (Hendrich, Bender, & Nyhuis, 2016). Recognize that risk factors for falling include recent history of falls, fear of falling, confusion, depression, altered elimination patterns, cardiovascular/respiratory disease impairing perfusion or oxygenation, postural hypotension, dizziness or vertigo, primary cancer diagnosis, and altered mobility (National Council on Aging, 2015; Gray-Miceli, 2016). **EB:** *The Hendrich II Fall Risk Model is quick to administer and provides a determination of risk for falling based on gender, mental and emotional status, symptoms of dizziness, and known categories of medications increasing risk (Hendrich, Bender, & Nyhuis, 2016). This tool screens for primary prevention of falls and is integral in a postfall assessment for the secondary prevention of falls (Hendrich, Bender, & Nyhuis, 2016).*
- Screen all clients for balance and mobility skills (i.e., supine to sit, sitting supported and unsupported, sit to stand, standing, walking and turning around, transferring, stooping to floor and recovering, and sitting down). Use tools such as the Balance Scale by Tinetti or the Timed Up & Go Test. **CEB/EB:** *It is helpful to determine the client's functional abilities and then plan for ways to improve problem areas or determine methods to ensure safety (Podsiadlo & Richardson, 1991; National Council on Aging, 2015; Gray-Miceli, 2016).*
- Carefully assist a mostly immobile client up. Be sure to lock the bed and wheelchair and have sufficient personnel to protect the client from falls. When rising from a lying position, have the client change positions slowly, dangle legs, and stand next to the bed before walking to prevent orthostatic hypotension. *Encourage client engagement in a monitored exercise program that will strengthen core and lower extremities to reduce fall risk (Grabiner, 2013; Hirase et al, 2014; National Institute of Neurological Disorders and Stroke [NINDS], 2018).*
- Use a "high-risk fall" armband/bracelet and fall risk room sign to alert staff for

increased vigilance and mobility assistance. *These steps alert the nursing staff of the increased risk of falls (McCarter-Bayer, Bayer, & Hall, 2005; Goodwin et al, 2014).*

▲ Evaluate the client's medications to determine whether medications increase the risk of falling. Consult with health care provider regarding the client's need for medication if appropriate. **EB:** *Polypharmacy, or taking more than four medications, has been associated with increased falls. Medications such as benzodiazepines, as well as antipsychotic and antidepressant medications given to promote sleep, actually increase the rate of falls (Goodwin et al, 2014; National Council on Aging, 2015; The American Geriatrics Society Beers Criteria Update Expert Panel, 2015).* **EB:** *Short- to intermediate-acting benzodiazepine and tricyclic antidepressants may produce ataxia, impaired psychomotor function, syncope, and additional falls (Greenberg, 2016; The American Geriatrics Society Beers Criteria Update Expert Panel, 2015).*

• Orient the client to the environment. Place the call light within reach and show how to call for assistance; answer call light promptly.

• Use one-fourth to one-half length side rails only, and maintain bed in a low position. Ensure that wheels are locked on the bed and commode. Keep dim light in the room at night. *Use of full side rails can result in the client climbing over the rails, leading with the head, and sustaining a head injury. Side rails with widely spaced vertical bars and side rails not situated flush with the mattress have been associated with asphyxiation deaths because of rail and in-bed entrapment and should not be used (Capezuti, 2004; Goodwin et al, 2014).*

• *Routinely assist the client with toileting on his or her own schedule. Take the client to the bathroom on awakening and before bedtime (McCarter-Bayer, Bayer, & Hall, 2005; Goodwin et al, 2014).*

• Keep the path to the bathroom clear, label the bathroom, and leave the door open.

▲ Avoid use of restraints if possible. Obtain health care provider's order if restraints are deemed necessary, and use the least restrictive device. **EB:** *The use of restraints has been associated with serious injuries including rhabdomyolysis, brachial plexus injury, neuropathy, and dysrhythmias, as well as strangulation, asphyxiation, traumatic brain injuries, and all the consequences of immobility (Evans & Cotter, 2008; Cotter & Evans, 2012).* **CEB:** *A study demonstrated that there was no increase in falls or injuries in a group of clients who were not restrained versus a similar group that was restrained in a nursing home (Capezuti et al, 2004). A study in two acute care hospitals demonstrated that when restraints were not used, there was no increase in client falls, injuries, or therapy disruptions (Mion et al, 2001).*

• In place of restraints, use the following:
  - ❍ Well-staffed and educated nursing personnel with frequent client contact with careful consideration during shift changes
  - ❍ Nursing units designed to care for clients with cognitive and/or functional impairments
  - ❍ Nonskid footwear, sneakers preferable
  - ❍ Glasses and/or hearing aids, as needed
  - ❍ Adequate lighting, night-light in bathroom
  - ❍ Frequent toileting
  - ❍ Frequently assess need for invasive devices, tubes, intravenous (IV) access
  - ❍ Hide tubes with bandages to prevent pulling of tubes
  - ❍ Consider alternative IV placement site to prevent pulling out IV line
  - ❍ Alarm systems with ankle, above-the-knee, or wrist sensors
  - ❍ Bed or wheelchair alarms
  - ❍ Wedge cushions on chairs to prevent slipping

- ❍ Increased observation of the client
- ❍ Locked doors to unit
- ❍ Low or very low height beds
- ❍ Border-defining pillow/mattress to cue the client to stay in bed

• *These alternatives to restraints can be helpful to prevent falls (McCarter-Bayer, Bayer, & Hall, 2005; Cotter & Evans, 2012; Grabiner, 2013).*
• If the client has an acute change in mental status (delirium), recognize that the cause is usually physiological and is a medical emergency. Consider possible causes for delirium. Consult with the health care provider immediately. See interventions for Acute **Confusion.**
• If the client has chronic confusion caused by dementia, implement individualized strategies to enhance communication. *Assessment of specific receptive and expressive language abilities is needed to understand the client's communication difficulties and facilitate communication. See interventions for Chronic* ***Confusion.***
• Ask family to stay with the client to assist with activities of daily living and prevent the client from accidentally falling or pulling out tubes.
▲ If the client is unsteady on his or her feet, have two nursing staff members alongside when walking the client. Use facility-approved mobility devices to assist with client ambulation (e.g., gait belts, walkers). Consider referral to physical therapy for gait training and strengthening. *The client can walk independently, but the nurse can rapidly ensure safety if the client becomes weak or unsteady. Interprofessional care is most comprehensive and beneficial to the client (Grabiner, 2013).*
• Place a fall-prone client in a room that is near the nurses' station. *Such placement allows more frequent observation of the client.*
• Help clients sit in a stable chair with armrests. Avoid use of wheelchairs except for transportation as needed. *Clients are likely to fall when left in a wheelchair because they may stand up without locking the wheels or removing the footrests.*
▲ Refer to physical therapy or other programs for exercise programs that target strength, balance, flexibility, or endurance. **EB:** *Programs with at least two of these components have been shown to decrease the rate of falling and number of people falling (Gillespie et al, 2009; National Council on Aging, 2015).*

Geriatric

• Assess mobility and gait speed using the Timed Up & Go Test. Ask the client to stand up from a standard arm chair, walk 10 feet (or 3 meters), turn around, walk back to the chair, and sit down (Podsiadlo & Richardson, 1991). This should be done with the client wearing usual footwear. *Performance on this screening exam demonstrates the client's mobility. If the client completes the test in less than 10 seconds, he or she is considered freely mobile. If completing the test takes 10 to 19 seconds, then the client is considered to be mostly independent in mobility. If the client takes 20 to 29 seconds, then the client is considered to have variable mobility. If the client takes 30 or more seconds, he or she is considered to have impaired mobility, and is more likely to be dependent on others and more likely to sustain a fall (Podsiadlo & Richardson, 1991).*
• Complete a fall risk assessment for older adults in acute care using a valid and reliable tool such as the Hendrich II Fall Risk Model. *It is quick to administer and provides a determination of risk for falling based on gender, mental and emotional status, symptoms of dizziness, and known categories of medications increasing risk (Hendrich, Bender, & Nyhuis, 2003; Hendrich, 2016). This tool screens for primary prevention of falls and is integral in a postfall assessment for the secondary prevention of falls (Goodwin et al,*

2014; *Hendrich, 2016*).

▲ If there is new onset of falling, assess for laboratory abnormalities, and signs and symptoms of infection and dehydration, blood glucose level for diabetics, and check blood pressure and pulse rate with client in supine, sitting, and standing positions for hypotension and orthostatic hypotension. If the client has borderline high blood pressure, the risk of falling because of the administration of antihypertensives may outweigh the benefits of the antihypertensive medication. Discuss with the health care provider on a client-to-client basis. *If orthostatic hypotension is present and there is minimal change in the heart rate, most likely the baroreceptors are not working to maintain blood pressure on arising. This is common in older adults and may be caused by hypovolemia resulting from the excessive use of diuretics, vasodilators, or other types of drugs; dehydration; or prolonged bed rest as well as cardiovascular disease, neurological disease, or the adverse effects of another medication (NINDS, 2018). Insertion of a pacemaker can reduce falls in people with frequent falls associated with carotid sinus hypersensitivity, which is a condition that may cause changes in heart rate and blood pressure (Gillespie et al, 2009).*

• Complete a fear of falling assessment for older adults. This includes measuring fear of falling, or the level of concern about falling, and falls self-efficacy, which is the degree of confidence a person has in performing common activities of daily living without falling. Fear of falling may be measured by a single-item question asking about the presence of fear of falling or rating severity of fear of falling on a 1 to 4 Likert scale as is commonly done in studies. Falls self-efficacy may be measured using a valid and reliable tool such as the Falls Efficacy Scale-International (Yardley et al, 2005; Greenberg, 2011, 2012; Greenberg et al, 2016).

• Encourage the client to wear glasses and use walking aids when ambulating.

• If the client experiences dizziness because of orthostatic hypotension when getting up, teach methods to decrease dizziness, such as rising slowly, remaining seated several minutes before standing, flexing feet upward several times while sitting, sitting down immediately if feeling dizzy, and trying to have someone present when standing. **CEB/EB:** *Always have the client dangle at the bedside before standing to evaluate for postural hypotension. Watch the client closely for dizziness during increased activity. Postural hypotension can be detected in up to 30% of older clients. These methods can help prevent falls and maintain adequate fluid intake (Tinetti, 2003; Goodwin et al, 2014).*

▲ If the client is experiencing syncope, determine symptoms that occur before syncope, and note medications that the client is taking. Refer for medical care. The circumstances surrounding syncope often suggest the cause. *Use of many medications, including diuretics, antihypertensives, digoxin, beta-blockers, and calcium channel blockers, can cause syncope. Use of the tilt table can be diagnostic in incidences of syncope (Fick & Mion, 2013; Goodwin et al, 2014).*

▲ Observe client for signs of anemia, and refer to health care provider for testing if appropriate.

• Evaluate client for chronic alcohol intake and mental health and neurological function.

▲ Refer to physical therapy for strength training, using free weights or machines, and suggest participation in exercise programs. *Exercise can prevent falls in older people. Greater relative effects are seen in programs that include exercises that challenge balance, use a higher dose of exercise, and do not include a walking program. Service providers can use these findings to design and implement exercise programs for falls prevention (Grabiner, 2013; Hirase et al, 2014; National Council on Aging, 2015).*

▲ Evidence-based guidelines for preventing falls in older adults were published by the American Geriatrics Society (AGS) and British Geriatrics Society (BGS)

collaboratively and specify recommendations for all clinical settings. These recommendations include screening and assessment and interventions. Examples of interventions include (1) exercise for balance and for gait and strength training, such as tai chi or physical therapy; (2) environmental adaptation to reduce fall risk factors in the home and in daily activities; (3) cataract surgery when indicated; (4) medication reduction with particular attention to medications that affect the brain such as sleeping medications and antidepressants; (5) assessment and treatment of postural hypotension; (6) identification and appropriate treatment of foot problems; (7) vitamin D supplementation for those with vitamin D deficiency (The American Geriatrics Society [AGS], 2011).

Home Care

- Some of the previously mentioned interventions may be adapted for home care use.
- Implement evidence-based fall prevention practices in community settings and home health care programs for older adults (National Council on Aging, 2015).

▲ If delirium is present, assess for cause of delirium and/or falls with the use of an interprofessional team. Consult with the health care provider immediately. Assess and monitor for acute changes in cognition and behavior. *An acute and fluctuating change in cognition and behavior is the classic presentation of delirium. Delirium is reversible and should be considered a medical emergency. Delirium can become chronic if untreated, and clients may be discharged from hospitals to home care in states of undiagnosed delirium.* **EB:** *Falls may be a precipitating event or an indication of frailty consistent with delirium (Goodwin et al, 2014).*

- Assess home environment for threats to safety including clutter, slippery floors, scatter rugs, and other potential hazards. Additionally, assess external environment (e.g., uneven pavement, unleveled stairs/steps). *Clients suffering from impaired mobility, impaired visual acuity, and neurological dysfunction, including dementia and other cognitive functional deficits, are all at risk for injury from common hazards. These recommendations were shown to be effective to reduce falls (Tinetti, 2003; AGS, 2011; Goodwin et al, 2014; National Council on Aging, 2015).*

▲ Institute a home-based, nurse-delivered exercise program to reduce falls or refer to physical therapy services for client and family education of safe transfers and ambulation and for strengthening exercises for the client (Grabiner, 2013; National Council on Aging, 2015).

▲ Instruct the client and family or caregivers on how to correct identified hazards for those with visual impairment. Refer to physical and occupational therapy services for assistance if needed. **EB:** *Interventions to improve home safety were shown to be effective in people at high risk, such as those with severe visual impairment (Gillespie et al, 2009; National Council on Aging, 2015).*

▲ Use a multifactorial assessment along with interventions targeted to the identified risk factors. Key components of the interventions include evaluating need for all medications, balance, gait and strength training, use of strategies to deal with postural hypotension if present, home safety evaluation with needed modifications, and any needed cardiovascular treatment. **EB:** *As people age, they may fall more often for multiple reasons including problems with balance, poor vision, and dementia. Fear of falling can result in self-restricted activity levels (Gillespie et al, 2009; National Council on Aging, 2015).*

- If the client lives alone or spends a great deal of time alone, teach the client what to do if he or she falls and cannot get up, and make sure he or she has a personal emergency response system or a mobile phone that is available from the floor (Tinetti,

2003; AGS, 2011; National Council on Aging, 2015).

• Ensure appropriate nonglare lighting in the home. Ask the client to install indoor strip or "runway" type of lighting to baseboards to help clients balance. Install motion-sensitive lighting that turns on automatically when the client gets out of bed to go to the bathroom.

• Have the client wear supportive, low-heeled shoes with good traction when ambulating. Avoid use of slip-on footwear. Wear appropriate footwear in inclement weather. *Supportive shoes provide the client with better balance and protect the client from instability on uneven surfaces. Anti-slip shoe devices worn in icy conditions have been shown to reduce falls (Gillespie et al, 2009; AGS, 2011; National Council on Aging, 2015).*

• Provide a signaling device for clients who wander or are at risk for falls. *Orienting a vulnerable client to a safety net relieves the anxiety of the client and caregiver and allows for rapid response to a crisis situation.*

• Provide medical identification bracelet for clients at risk for injury from dementia, diabetes, seizures, or other medical disorders.

• Suggest a tai chi class designed for older adults and selected clients who have sufficient balance to participate. **EB:** *Participation in once per week tai chi classes for 16 weeks can prevent falls in relatively healthy community-dwelling older people (Voukelatos et al, 2007; AGS, 2011).*

Client/Family Teaching and Discharge Planning

• Safety Guidelines. Teach the client and the family about the fall reduction measures that are being used to prevent falls (The Joint Commission, 2017).

• Teach the client how to safely ambulate at home, including using safety measures such as handrails in bathroom, reaching for items on high shelves, and avoiding carrying things or performing other tasks while walking.

• Teach the client the importance of maintaining a regular exercise program. If the client is afraid of falling while walking outside, suggest that he or she walk the length of a local mall. *Exercise can prevent falls in older people. Greater relative effects are seen in programs that include exercises that challenge balance and use a higher dose of exercise than just walking programs (Sherrington et al, 2008; AGS, 2011; Grabiner, 2013; Hirase et al, 2014).*

Dysfunctional Family processes

Shelley Sadler BSN, MSN, APRN, WHNP-BC

NANDA-I

Definition

Family functioning which fails to support the well-being of its members.

Defining Characteristics

Behavioral

Agitation; alteration in concentration; blaming; broken promises; chaos; complicated grieving; conflict avoidance; contradictory communication pattern; controlling communication pattern; criticizing; decrease in physical contact; denial of problems; dependency; difficulty having fun; difficulty with intimate relationships; difficulty with life cycle transitions; disturbances in academic performance in children; enabling substance use pattern; escalating conflict; failure to accomplish developmental tasks; harsh self-judgment; immaturity; inability to accept a wide range of feelings; inability to accept help; inability to adapt to change; inability to deal constructively with traumatic experiences; inability to express wide range of feelings; inability to meet the emotional needs of its members; inability to meet the security needs of its members; inability to meet the spiritual needs of its members; inability to receive help appropriately; inappropriate anger expression; ineffective communication skills; insufficient knowledge about substance abuse; insufficient problem solving skills; lying; manipulation; nicotine addiction; orientation favors tension relief rather than goal attainment; paradoxical communication pattern; power struggles; rationalization; refusal to get help; seeking of affirmation; seeking of approval; self-blame; social isolation; special occasions centered on substance use; stress-related physical illnesses; substance abuse; unreliable behavior; verbal abuse of children; verbal abuse of parent; verbal abuse of partner

Feelings

Abandonment; anger; anxiety; confuses love and pity; confusion; depression; dissatisfaction; distress; embarrassment; emotional isolation; emotionally controlled by others; failure; fear; feeling different from others; feeling misunderstood; feeling unloved; frustration; guilt; hopelessness; hostility; hurt; insecurity; lack of identity; lingering resentment; loneliness; loss; loss of identity; low self-esteem; mistrust; moodiness; powerlessness; rejection; repressed emotions; shame; taking responsibility for substance misuser's behavior; tension; unhappiness; vulnerability; worthlessness

Roles and Relationships

Change in role function; chronic family problems; closed communication systems; conflict between partners; deterioration in family relationships; diminished ability of family members to relate to each other for mutual growth and maturation; disruption in family rituals; disruption in family roles; disturbance in family dynamics; family denial; inconsistent parenting; ineffective communication with partner; insufficient cohesiveness; insufficient family respect for autonomy of its members; insufficient family respect for individuality of its members; insufficient relationship skills; neglect of obligation to family member; pattern of rejection; perceived insufficient parental support; triangulating family relationships

Related Factors

Addictive personality; ineffective coping skills; insufficient problem-solving skills; substance misuse

At-Risk Population

Economically disadvantaged; family history of resistance to treatment; family history of substance misuse; genetic predisposition to substance misuse

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Family Coping; Family Functioning; Family Health Status; Substance Addiction Consequences

Example NOC Outcome with Indicators

Family Coping as evidenced by the following indicators: Confronts/manages family problems/Involves family members in decision-making. (Rate the outcome and indicators of **Family Coping:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Family/Client Will (Specify Time Frame)

• State one way that alcoholism has affected the health of the family
• Identify three healthy coping behaviors that family members can use to facilitate a shift toward improved family functioning
• Identify one Al-Anon meeting from the Al-Anon meeting schedule that family members express a desire to attend
• Attend different types of meetings (lead, big book, discussion, beginner's meeting) to find a good match and commit to attending that group regularly

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Family Process Maintenance; Substance Use Treatment

Example Activities—Family Process Maintenance

Identify effects of role changes on family process; Assist family members to use existing support mechanisms

Nursing Interventions and *Rationales*

• Refer to care plans for Ineffective **Denial** and Defensive **Coping** for additional interventions.
▲ Behavioral screening and intervention (BSI) should be integrated into all health care settings. Different terminology has evolved for screening, intervention, and referral for various behavioral issues. The five As—ask, advise, assess, assist, and arrange—apply to tobacco use. Screening, brief intervention, and referral to treatment (SBIRT) pertains to alcohol and drug use. **EB:** *The US Preventive Services Task Force recommends universal screening and intervention for tobacco use, excessive drinking, and depression. These services improve health outcomes, decrease health care costs, enhance public safety, and generate substantial return on investment (Moyer, 2013; Babor, Del Boca, & Bray, 2017).*
• Screen clients for at-risk drinking during routine primary care visits and before surgery using the Alcohol Use Disorders Identification Test (AUDIT). **EB:** *Complications after total joint arthroplasty were significantly related to alcohol misuse in this group of male patients treated at a Veteran Health Administration (VHA) facility. The AUDIT-C has three simple questions that can be incorporated into a preoperative evaluation and can alert the treatment team to patients with increased postoperative risk (Moyer, 2013).*
• Provide brief education and individual counsel as a routine part of primary care. **EB:** *Brief interventions may be effective in helping patients engage in nonharmful drinking. The objective of the current study tested the implementation of a telephone-based brief intervention (telephone care management [TCM]) with heavy drinkers in primary care. The addition of TCM to primary care provider standard care (screening and brief advice) was compared with standard care alone. Both groups significantly decreased their drinking over time, with 40% of participants no longer engaging in heavy drinking at follow-up. Both groups decreased the number of drinking days and the average number of drinks per day over the follow-up period. Participants reported a decrease in alcohol use frequency and alcohol-related problems (Helstrom et al, 2014).*
• Refer for family therapy and other family-oriented resources. **EB:** *Evidence-based interventions targeting affected family members have been shown to improve health outcomes for all family members, result in better addiction treatment outcomes, and prevent adolescent substance use (Ventura & Bagley, 2017).*
▲ Refer for possible use of medication-assisted treatment to address substance use.

EB: *The Food and Drug Administration has approved three medications for treating alcohol dependence. Naltrexone can help people reduce heavy drinking; acamprosate makes it easier to maintain abstinence; and disulfiram blocks the breakdown (metabolism) of alcohol by the body, causing unpleasant symptoms such as nausea and flushing of the skin. Those unpleasant effects can help some people avoid drinking while taking disulfiram. It is important to remember that not all people will respond to medications, but for a subset of individuals, they can be an important tool in overcoming alcohol dependence (NIH, 2014).*

Pediatric

▲ Encourage early intervention. When parental depression, childhood exposure to conflict and violence, and childhood experience with abuse and neglect coexist with parental substance abuse their children are more likely to engage in increased teacher-rated unfavorable student behavioral problems. **EB:** *Early intervention with children of substance abusers (COSA) is necessary to reach children while they are more receptive to treatment (Usher, McShane, & Dwyer, 2015).*

• Encourage parent communication about alcohol use with adolescents. **EB:** *NIH (2017) identified parent–adolescent communication as important in delaying the onset and escalation of alcohol use.*

▲ Consider the Community Reinforcement Approach (CRA), which encourages clients to become progressively involved in alternative non–substance-related pleasant social activities and to work on enhancing the enjoyment they receive within the "community" of their family and job. **EB:** *CRA, originally developed for individuals with alcohol use disorders, has been successfully used to treat a variety of substance use disorders for more than 35 years. Based on operant conditioning, CRA helps adolescents rearrange their lifestyles so that healthy, drug-free living becomes rewarding and thereby competes with alcohol and drug use (Godley et al, 2014).*

▲ Educate family members about available educational and support programs and encourage no/limited alcohol use in the home. **EBN:** *Both individual and multiperson interventions exert an influential role in family-based therapy for treatment of adolescent drug abuse (Gilligan et al, 2016).*

• Encourage adolescents to attend a 12-step program. **EB:** *Wendt et al (2017) demonstrated that adolescents who attend 12-step groups after alcohol and other drug (AOD) treatment are more likely to remain abstinent and to avoid relapse.*

• Provide interactive school-based drug-prevention program to middle school students. **EB:** *A meta-analysis found support for the use of interactive school-based programs to prevent cannabis use among middle school students in North America (Lize et al, 2017).*

Geriatric

• Include the assessment of possible alcohol abuse when assessing older family members. **EB:** *Alcohol abuse and dependence in older people are important problems that frequently remain undetected by health services (Draper et al, 2015). The majority of older alcoholics are married, have low education levels, and do not belong to high social classes (Draper et al, 2015).*

Multicultural

• Acknowledge racial/ethnic differences at the onset of care. **EBN:** *Acknowledgment of race/ethnicity issues will enhance communication, establish rapport, and promote treatment outcomes (Giger & Davidhizar, 2013).*

• Use a family-centered approach when working with Latino, Asian American, African American, and Native American clients. **EBN:** *American Indian families may be extended structures that could exert powerful influences over functioning (George, Duran, & Norris, 2014). Family therapy is important in addressing the needs of Hispanic families with adolescent substance abusers (George, Duran, & Norris, 2014).*
• Some less acculturated Latino families may be unwilling to discuss family issues with health care providers until they perceive a close personal relationship with the provider. **EBN:** *Some Latino families may believe that personal problems should be kept private and may not respond to the health care provider until there is an established personal relationship (George, Duran, & Norris, 2014).*
• Work with families in a way that incorporates cultural elements. **CEB:** *Activities such as tundra walks and time with older adults supported in treatment were used successfully for substance abuse treatment with Yup'ik and Cup'ik Eskimos (Mills, 2003).*

Home Care

Note: In the community setting, alcoholism as a cause of dysfunctional family processes must be considered in two categories: (1) when the client suffers personally from the illness, and (2) when a significant other suffers from the illness, that is, the client is not the active alcoholic but may depend on the alcoholic for caregiving. The following considerations apply to both situations with appropriate adaptation for the circumstances.

• The previous interventions may be adapted for home care use.
• Work with family members to support a sense of valued fit on their part; include them in treatment planning and identify the importance of their roles in the client's care. At the same time, encourage the pursuit of positive outside activities that enhance their sense of belonging. **CEBN:** *Sense of belonging (valued fit) has been identified as a buffer to depression among both depressed and nondepressed individuals with a family history of alcoholism. A buffering effect was not found for individuals with a family history of drug abuse (Sargent et al, 2002).*
• Educate client and family regarding the interactions of alcohol use with medications and the therapeutic regimen. *Increased awareness of drug interactions decreases the chance of relapse caused by over-the-counter and other medications (Shapiro, 2015).*
▲ Refer for psychiatric home health care services for client reassurance and implementation of therapeutic regimen. **CEB:** *Twelve studies (five randomized controlled trials, one quasi-experimental study, and six uncontrolled cohort studies) found that home and community-based treatment of psychiatric symptoms of socially isolated older adults with mental illness was associated with improved or maintained psychiatric status. All randomized controlled trials reported improved depressive symptoms, and one reported improved overall psychiatric symptoms (Van Citters & Bartells, 2004).*
▲ Consider the use of a smartphone-based intervention for alcohol use disorders. *Participants in a pilot study indicated the smartphone provided numerous features for addressing ongoing drinking, craving, connection with supportive others, managing life problems, high-risk location alerting, and activity scheduling. These intervention modules were helpful in highlighting alcohol use patterns. Tools related to managing alcohol craving, monitoring consumption, and identifying triggers to drink were rated by participants as particularly helpful. Participants also demonstrated significant reductions in hazardous alcohol use while using the system (Dulin, Gonzalez, & Campbell, 2014).*

Client/Family Teaching and Discharge Planning

• Suggest that the client complete a confidential Internet self-screening test for identification of problems and suggestions for treatment if a problem with alcohol is

suspected. Many tools are available. *These screenings help individuals to assess their own alcohol consumption patterns to determine whether their drinking is likely harming their health or increasing their risk for future harm. Education and referrals urge those whose drinking is harmful or hazardous to take positive action and informs all adults who consume alcohol about guidelines and caveats for lower risk drinking (Donoghue et al, 2014).*

• Provide education for the family. **EB:** *Family education facilitates understanding of the disease and its causes, effects, and treatment (US Department of Health and Human Services, 2014).*

• Facilitate participation in mutual help groups (MHGs). **EB:** *MHGs appear to mobilize the same change processes, such as coping, motivation, and self-efficacy, which are mobilized by many different types of professionally led groups (Kelly et al, 2013).*

Interrupted Family processes

Marina Martinez-Kratz MS, RN, CNE

NANDA-I

Definition

Break in the continuity of family functioning which fails to support the well-being of its members.

Defining Characteristics

Change in availability for affective responsiveness; change in family conflict resolution; change in family satisfaction; change in intimacy; change in participation for problem-solving; assigned tasks change; change in communication pattern; change in somatization; change in stress reduction behavior; changes in expressions of conflict with community resources; changes in expressions of isolation from community resources; changes in participation for decision-making; changes in relationship pattern; decrease in available emotional support; decrease in mutual support; ineffective task completion; power alliance change; ritual change

Related Factors

Changes in interaction with community; power shift among family members; shift in family roles

At-Risk Population

Change in family finances; change in family social status; developmental crisis; developmental transition; situational crisis

Associated Condition

Shift in health status of a family member

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Family Coping; Family Functioning; Family Normalization; Psychosocial Adjustment: Life Change, Role Performance

Example NOC Outcome with Indicators

Family Coping as evidenced by the following indicators: Confronts/manages family problems/Involves family members in decision-making. (Rate the outcome and indicators of **Family Coping:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Family/Client Will (Specify Time Frame)

- Express feelings (family)
- Identify ways to cope effectively and use appropriate support systems (family)
- Treat impaired family member as normally as possible to avoid overdependence (family)
- Meet physical, psychosocial, and spiritual needs of members or seek appropriate assistance (family)
- Demonstrate knowledge of illness or injury, treatment modalities, and prognosis (family)
- Participate in the development of the plan of care to the best of ability (significant person)

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Family Integrity Promotion; Family Process Maintenance; Normalization Promotion

Example NIC Activities—Family Integrity Promotion

Collaborate with family in problem-solving and decision-making; Counsel family members on additional effective coping skills for their own use

Nursing Interventions and *Rationales*

- Recognize informal roles in medical decision-making by family members. **EBN:** *Informal roles emerge in critical situations to help fill the gaps in how family members respond to the challenge of end-of-life decision-making (Connor & Chase, 2015).*
- Acknowledge the range of emotions and feelings that may be experienced when the health status of a family member changes. **EBN:** *Nurses can better support caregivers regarding their perception of family support and expressive family functioning (Svavarsdottir & Sigurdardottir, 2013).*
- Encourage family members to list their personal strengths and available resources. **EBN:** *Families provide the main support network, and family strengths are closely associated with the family use of resources (Coym, 2013).*
- Establish relationships among clients, their families, and health care professionals. **EBN:** *A progressively engaging approach to relationships with clients and their families emphasizes trust and reciprocity, which supports joint decision-making with nurses in acute care settings (Segaric & Hall, 2015).*
- Encourage family to visit the client; adjust visiting hours to accommodate the family's schedule. **EBN:** *Incorporating visiting family members in the plan of care is complex and requires balancing the visitor's needs for information and access to a loved one with the nurse's need to safely manage the care of a critically ill individual (Alves et al, 2013).*
- Allow and encourage family members to assist in the client's treatment. **EBN:** *Support for family members is an essential part of quality end-of-life care for residents, and health care facilities should embrace the opportunity to demonstrate the value of family participation in care (Oliver et al, 2014).*
- Support family members during emotional and conflict type situations in the clinical setting. **EBN:** *A study found that bereaved parents identified nurses as "good" if the nurses looked out for the parents by providing emotional support, comfort, and using presence*

(Butler et al, 2018).
• Anticipate and implement family reunification efforts after a disaster. **EBN:** *Family reunification after disasters should be prioritized and included in plans at all emergency response levels (Chung & Blake, 2014).*
• Refer to the care plan Readiness for enhanced **Family** processes for additional interventions.

Pediatric

• Carefully assess potential for reunifying children placed in foster care with their birth parents. **EB:** *Reunifying children placed in foster care with their birth parents is a primary goal of the child welfare system (Orsi et al, 2018).*
• Provide prebirth risk assessments to identify prebirth and postbirth supports for high-risk pregnant women. **EB:** *Prebirth risk assessment is a process by which circumstances affecting an unborn child can be identified and support for mother and infant embedded into care (Harnett et al, 2018).*
• Provide parents with both general information and professional support by family-centered early childhood intervention services to their families. **EB:** *Providing families with general information in addition to specialized information about their children is most important to empower parents and increase family resiliency (Frantz et al, 2018).*
• Encourage and support parents/family to assist in client's care. **EBN:** *Parents need to be able to negotiate with health staff as to what this participation will involve and negotiate new roles for themselves in sharing care of their sick child (Kelly & Kelly, 2013).*
• Assess military families for the influence of deployment on family functioning. **EB:** *A study of families with a service member concurrently deployed at the time of a child neglect incident were at higher risk for failure to provide physical needs, lack of supervision, and educational neglect (Cozza et al, 2018).*
▲ Refer parents and other primary caregivers to a mindfulness-based stress reduction (MBSR) program. **EBN:** *Community-based MBSR programs can be an effective intervention to reduce stress and improve psychological well-being for parents and caregivers of children, especially those with developmental disabilities (Bazzano et al, 2013).*

Geriatric

• Encourage family members to be involved in the care of relatives who are in residential care settings. **EBN:** *Family involvement in residential long-term care is important especially when preparing for end-of-life care (Oliver et al, 2014).*
• Support group problem-solving among family caregivers and include the older member. **EBN:** *Health personnel must be aware that family caregiving undergoes a transition, shifting both how and when family members mobilize to meet the needs of the older adult (Wongsawang et al, 2013).*
▲ Refer family for counseling with a psychotherapist who is knowledgeable about gerontology.
• Refer to care plan for Readiness for Enhanced **Family** processes for additional interventions.

Multicultural

• Motivate family members to speak openly about illnesses, keeping in mind the importance of ethnic origin. **EBN:** *Recognizing ethnic origin to caregivers' open communication can improve the quality of life to allow family members to derive solutions and*

face challenges (Bachner et al, 2014).

• Assess LGBTQ youth for factors that contribute to family rejection. **EB:** *A recent study found that poverty and family instability are often precursors to family rejection and ultimately homelessness for LGBTQ youth (Robinson, 2018a).*

• Refer to the care plan Readiness for Enhanced **Family** processes for additional interventions.

Home Care

• The nursing interventions described in the care plan for Compromised family **Coping** should be used in the home environment with adaptations as necessary.

• Encourage family members to find meaning in life with a serious illness. **EB:** *A study found that families dealing with chronic illness move through the process of healing and eventually shift the focus away from illness and toward living (Robinson, 2018b).*

Client/Family Teaching and Discharge Planning

• Refer to Client/Family Teaching and Discharge Planning in Compromised family **Coping** and Readiness for enhanced family **Coping** for suggestions that may be used with minor adaptations.

Readiness for enhanced Family processes

Kimberly Silvey MSN, RN, RAC-CT

NANDA-I

A pattern of family functioning to support the well-being of family members, which can be strengthened.

Defining Characteristics

Expresses desire to enhance balance between autonomy and cohesiveness; expresses desire to enhance communication pattern; expresses desire to enhance energy level of family to support activities of daily living; expresses desire to enhance family adaptation to change; expresses desire to enhance family dynamics; expresses desire to enhance family resilience; expresses desire to enhance growth of family members; expresses desire to enhance interdependence with community; expresses desire to enhance maintenance of boundaries between family members; expresses desire to enhance respect for family members; expresses desire to enhance safety of family members.

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Family Coping; Health-Promoting Behavior; Health-Seeking Behavior; Parent-Infant Attachment; Parenting Performance

Example NOC Outcome with Indicators

Family Coping as evidenced by the following indicators: Confronts/Manages family problems/Obtains family assistance. (Rate the outcome and indicators of **Family Coping:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Family/Client Will (Specify Time Frame)

- Identify ways to cope effectively and use appropriate support systems (family)
- Meet physical, psychosocial, and spiritual needs of members or seek appropriate assistance (family)
- Demonstrate knowledge of potential environmental, lifestyle, and genetic risks to health and use appropriate measures to decrease possibility of risk (family)
- Focus on wellness, disease prevention, and maintenance (family and individual)
- Seek balance among exercise, work, leisure, rest, and nutrition (family and individual)

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Coping Enhancement; Decision-Making Support; Family Integrity Promotion; Family Involvement Promotion; Family Mobilization; Family Process Maintenance; Parent Education: Adolescent; Childrearing Family; Risk Identification; Role Enhancement

Example NIC Activities—Risk Identification

Determine availability and quality of resources (e.g., psychological, financial, education level, family and other social, and community)

Nursing Interventions and *Rationales*

- Assess the family's stress level and coping abilities during the initial nursing assessment. **EB:** *Assessing parental stress level will help the nurse to plan interventions to better care for the child and their parents (Burke et al, 2014).*
- Consider the use of family-centered theory as the conceptual foundation to help guide interventions. **EBN:** *Working closely with pediatric patients and their families helps the nurse to plan care with the family in mind (Cady et al, 2015).*
- Use family-centered care and role modeling for holistic care of families. **EB:** *A holistic approach to care enhances the family's well-being and respects the family's beliefs (Krishna, 2013).*
- Discuss with family members and identify the perceptions of the health care experience. **EBN:** *Nurses and parents may perceive the care the child receives differently, and it is important to help identify the differences to better care for the child and family (Stuart & Melling, 2014).*
- Support family needs, strengths, and resourcefulness through family interviews. **EBN:** *Family interviews can give the nurse an understanding of the family's understanding and expectations (Alsem et al, 2014).*
- Spend time with family members; allow them to verbalize their feelings. **EB:** *Listening to what the family is saying can help the nurse understand how they are feeling (SmithBattle et al, 2013).*
- Encourage family members to find meaning in a serious illness. **EBN:** *Just because parents have hope for their child does not mean they do not understand their child's prognosis (O'Brien, 2014).*
- Provide family-centered care to explore and use all available resources appropriate for the situation (e.g., counseling, social services, self-help groups, pastoral care). **EB:** *Family-centered care includes multiple members of the health care team (Hodgetts et al, 2013).*
- Consider focus groups to provide insight into family perceptions of illness and/or disease prevention. **EBN:** *Focus groups provide insight into the perception of care that is received by the client (Pozzar et al, 2014).*

Pediatric

- Provide a parenting class series based on individual and couple changes in meaning and identity, roles, and relationships and interaction during the transition to parenthood. Address mother and father roles, infant communication abilities, and patterns of the first 3 months of life in a mutually enjoyable, possibility focused manner. **EB:** *Parenting classes can improve parenting and coping skills to enhance quality of life (Okamoto et al, 2013).*

• Encourage families with children and adolescents to have family meals. **EB:** *Family meals help strengthen a family and provide structure for better development (Utter et al, 2013). Research found that dinnertime rituals can potentially moderate the effects of parenting stress on child outcomes (Yoon et al, 2015).*

Geriatric

• Carefully listen to residents and family members in the long-term care facility. **EBN:** *Nurses can improve life and dignity for residents by listening to residents and family members (Nayer et al, 2014).*
• Support caregivers' awareness of the positive effects of their contribution to the well-being of parents. **EBN:** *Children caring for their elderly parents can have a positive effect on the child and the parent (Lin et al, 2013).*
• Teach family members about the effect of developmental events (e.g., retirement, death, change in health status, and household composition). **EBN:** *Knowledge helps the family to better cope with health care and the care of the client (Nigolian & Miller, 2011).*
• Encourage social networks; social integration; social engagement and Internet social networking with friends, children, and relatives of older adults. **EB:** *Social networking enables older adults to be more engaged (Cornejo et al, 2013).*

Multicultural

• Assess for the influence of cultural beliefs, norms, and values on the family's perceptions of normal functioning. **EBN:** *Cultural beliefs will have a considerable effect on a client's functioning (Mutair et al, 2014).*
• Identify and acknowledge the stresses unique to racial/ethnic families. **EBN:** *Understanding a client's unique racial/ethnic background may help the nurse identify stressors that the client and the family may be experiencing (Balaam et al, 2013).*
• Assess and support spiritual needs of families. **EB:** *Assessing and supporting the spiritual needs of the client and the family can enhance the understanding of the family's perception of care and the care that was actually received (Bernstein et al, 2013).*
• With the client's consent, facilitate a group meeting for family members to discuss how the family is functioning. **EBN:** *Communication with the patient and the family encourages discussion about the wants and needs of each individual and keeps each informed of what is occurring with the patient (Kisvetrová et al, 2016).*
• Facilitate modeling and role playing for the client and family regarding healthy ways to start a discussion about the client's prognosis. **EBN:** *It is helpful to practice communication skills in a safe environment before trying them in a real-life situation (Waite & McKinney 2016).*
• Encourage family mealtimes. **EB:** *Encouraging family mealtimes enhances the health and well-being* and can decrease parental stress (*Yoon et al, 2015).*

Home Care

• The previous nursing interventions should be used in the home environment with adaptations as necessary.
▲ Encourage virtual support groups to family caregivers. **EB:** *Use of online support groups gives the caregiver a forum for giving and receiving guidance and support (Diefenbeck et al, 2014).*

Client/Family Teaching and Discharge Planning

• Refer to Client/Family Teaching and Discharge Planning for readiness for enhanced family **Coping** for suggestions that may be used with minor adaptations.

Fatigue

Barbara A. Given PhD, RN, FAAN

NANDA-I

Definition

An overwhelming sustained sense of exhaustion and decreased capacity for physical and mental work at the usual level.

Defining Characteristics

Alteration in concentration; alteration in libido; apathy; disinterest in surroundings; drowsiness; guilt about difficulty maintaining responsibilities; impaired ability to maintain usual physical activity; impaired ability to maintain usual routines; increase in physical symptoms; increase in rest requirement; ineffective role performance; insufficient energy; introspection; lethargy; nonrestorative sleep pattern; tiredness

Related Factors

Anxiety; depression; environmental barrier; increase in physical exertion; malnutrition; nonstimulating lifestyle; demanding occupation; physical deconditioning; sleep deprivation; stressors

At-Risk Population

Demanding occupation; exposure to negative life event

Associated Condition

Anemia; illness; pregnancy

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Concentration; Endurance; Energy Conservation/Restoration; Nutritional Status; Energy; Vitality

Example NOC Outcome with Indicators

Endurance as evidenced by the following indicators: Performance of daily activities/Energy restored after rest/Blood oxygen level with activity/Muscle endurance. (Rate the outcome and indicators of **Endurance:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Identify potential etiology of fatigue
- Identify potential factors that aggravate and relieve fatigue
- Describe ways to assess and track patterns of fatigue over set periods of time (e.g., within a day, a few days, a week, a month)
- Describe ways in which fatigue affects the ability to accomplish activities of daily living (ADLs)
- Verbalize increased energy and improved vitality
- Explain energy conservation plan to offset fatigue
- Explain energy restoration plan to offset fatigue
- Verbalize ability and capacity to concentrate
- Verbalize strategies for restorative activities

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Energy management, including both conservation and restoration; conservation interventions are targeted at preserving an individual's energy, whereas restorative interventions are intended to reestablish vitality and energy

Example NIC Activities—Energy Management

Assess client's physiological and psychological status for deficits resulting in fatigue within the context of age, development, and stage of disease or illness; Determine client/significant other's perception of causes of client's fatigue and factors that contribute to the relief. Assessing the pattern within a 24-hour period can be used to recommend usual daily activity.

Nursing Interventions and *Rationales*

• Assess severity of fatigue on a scale of 0 to 10 (average fatigue, worst and best levels); assess frequency of fatigue (number of days per week and time of day), activities and symptoms associated with increased fatigue (e.g., pain), activities that relieve, ability to perform ADLs and instrumental ADLs, interference with social and role function, times of the day for increased energy, ability to concentrate, mood, usual pattern of physical activity, and interference with sleep cycles. Consider use of instruments such as the Profile of Mood State Short Form Fatigue Subscale, the Multidimensional Assessment of Fatigue, the Lee Fatigue Scale, the Multidimensional Fatigue Inventory, the HIV-Related Fatigue Scale, or the Brief Fatigue Inventory, Short Form Vitality Subscale, Piper Fatigue Scale, Chalder Fatigue Scale, or Nottingham of Chronic Illness Therapy Fatigue Scale, and Fatigue Severity Scale. **EBN/CEB:** *These assessments have all been shown to have good internal reliability. The Fatigue Severity Scale, Fatigue Impact Scale, and Brief Fatigue Inventory are relatively short with good psychometric properties, making them clinically useful. These measures, along with the Multidimensional Assessment of Fatigue, have shown the ability to detect changes in fatigue over time (Whitehead, 2009). The European Organization for Research and Treatment of Cancer Quality of Life Core Questionnaire (EORTC QLQ-FA 13) (Schuler et al, 2016) was proven reliable. Varying populations may respond differently to instruments and there are a number of scales for specific diseases such as stroke, multiple sclerosis, Parkinson's disease, and sleep disorders. The Fatigue Scale for Motor and Cognitive functions and the Unidimensional Fatigue Impact Scale demonstrate good applicability in clients with multiple sclerosis; the Functional Assessment of Chronic Illness Therapy Fatigue subscale and the Fatigue Severity Scale demonstrate good applicability in clients with Parkinson's disease (Elbers, Berendse, & Kwakkel, 2016). Poststroke clients may have severe fatigue without depression (Drummond et al, 2017).*

• Evaluate adequacy of nutrition and sleep hygiene (napping throughout the day, inability to fall asleep or stay asleep). Encourage the client to get adequate rest; limit naps (particularly in the late afternoon or evening); use a routine sleep/wake schedule; plan and prioritize for daily activities as tolerated; allow exposure to sunlight during daytime hours by going outside or opening shades and curtains in the home; use relaxation techniques before bedtime such as meditation, music therapy, or guided imagery (Kwekkeboom & Bratzke, 2016); avoid caffeine in the late afternoon or evening; and eat a well-balanced diet that includes fresh fruits, vegetables, and lean meats. Mindfulness interventions also result in improved sleep quality (Black et al, 2015). Refer to Imbalanced **Nutrition:** less than body requirements

or **Insomnia** if appropriate. **EBN:** *Dysfunction in sleep (too much, too little, or too many interruptions) can aggravate fatigue (Black et al, 2015).*

• Evaluate fluid status and assess for dehydration. Encourage at least eight glasses of water a day. Avoid caffeine, which can cause further dehydration. **EB:** *Dehydration has been shown to cause fatigue in conditions such as multiple sclerosis (Malkki, 2016). Older adults, and those with other medical conditions, are more susceptible to dehydration often because of symptoms such as diarrhea and vomiting or from treatments such as diuretics.*

▲ Collaborate with the primary care provider to identify physiological and/or psychological causes of fatigue that could be treated, such as anemia, pain, electrolyte imbalance (e.g., altered potassium levels), dehydration, thyroid disorders, anemia, arthritis, depression, anxiety, sleep disturbances (insomnia/sleep deprivation), acute or chronic infection, medication use or side effects, alcohol use/abuse, metabolic disorders (diabetes), or a preexisting comorbidity or disease (multiple sclerosis, cancer or cancer treatment, respiratory disease, fibromyalgia, cardiac disease, renal disease, Parkinson's disease) (Berger et al, 2015). **EB/EBN:** *If an etiology for fatigue can be determined, the condition should be treated according to the underlying cause. Fatigue is also related to psychological distress, nausea/vomiting (Oh & Seo, 2011), medication side effects, and nutritional deficit (caused by change in taste or cancer affecting swallowing or the digestive tract) (Berger et al, 2015), and from chemotherapy and radiotherapy in cancer (Kolak et al, 2017). Fatigue also negatively affects a client's quality of life (Bower et al, 2014). Tumor necrosis and cytokines, especially proinflammatory ones, have recently been identified (Kolak et al, 2017).*

▲ Work with the primary care provider to determine if the client has chronic fatigue syndrome. *Chronic fatigue syndrome is unexplained fatigue lasting 6 months or longer that is not associated with a diagnosed physical or psychological condition but may include muscle pain, memory problems, headaches, sleep problems, joint pain, and diarrhea (Milrad et al, 2017).* **EB:** *Proinflammatory cytokines may contribute to these symptoms (Montoya et al, 2017). Studies also suggest there is a genetic component to chronic fatigue syndrome (Pihur, Datta, & Datta, 2011).*

• Encourage the client to express feelings, attribution of cause and behaviors about fatigue, including potential causes of fatigue, and possible interventions to alleviate fatigue. Such interventions could include setting small, easily achieved short-term goals and developing energy management and energy conservation techniques; use active listening techniques to help identify sources of hope. Retroactive activities should be considered. Assess client's level of motivation and willingness to adopt new behaviors that can improve symptoms of fatigue. **EBN/EB:** *Cognitive behavioral therapy and self-efficacy interventions have been shown to be effective in reducing fatigue (Hoffman et al, 2017). Education, counseling, and expressive therapy have also been shown to be effective for managing fatigue (Bower et al, 2014).*

• Encourage the client to keep a journal of activities (or record using one of the many apps available) that contribute to symptoms of fatigue, patterns of symptoms across days/weeks/months, and feelings, including how fatigue affects the client's normal daily activities and roles. **EBN:** *Clients may have physical activity promoted by using information and communication technology (Zhang et al, 2017) that results in lower levels of fatigue (Kolak et al, 2017).*

• Help the client identify sources of support and prioritize essential and nonessential tasks to determine which tasks need to be completed and which can be delegated and to whom. Give the client permission to limit or change social and role demands if needed (e.g., switch to part-time employment, give up activities for a short period, hire cleaning service). **EBN:** *Psychoeducational interventions that include fatigue education,*

priority setting, self-care, coping techniques, and activity management have been shown to be effective in reducing cancer-related fatigue (Bower et al, 2014). Emotional support has been linked to decreased level of physical symptoms, including fatigue, for heart failure clients (Heo et al, 2017).

▲ Collaborate with the primary care provider regarding the appropriateness of referrals to physical therapy for carefully monitored aerobic exercise program and possible physical aids, such as a walker or cane if client has a disability. **EBN:** *Physical activity, exercise, particularly aerobic exercise and yoga, can reduce cancer-related fatigue (Berger et al, 2015).*

• Encourage the client to try complementary and alternative therapy such as guided imagery, massage therapy, relaxation, mediation, mindfulness, and acupressure (Heo et al, 2017). **EB:** *Mindfulness-cognitive behavioral therapy has exhibited improved outcomes for those experiencing cancer-related fatigue (Berger et al, 2015).*

▲ Refer the client to diagnosis-appropriate support groups such as the National Chronic Fatigue Syndrome Association, National Parkinson Foundation, PatientsLikeMe, Multiple Sclerosis Association, American Cancer Society, or the National Comprehensive Cancer Network.

▲ For a person with cardiac disease, recognize that fatigue is common with myocardial infarction, congestive heart failure (CHF), or chronic cardiac insufficiency. Refer to cardiac rehabilitation for a carefully prescribed and monitored exercise and rehabilitation program.

• If fatigue is associated with cancer or cancer-related treatment, assess for other symptoms that may enhance fatigue (e.g., pain, insomnia, anemia, emotional distress, electrolyte imbalance [nausea, vomiting, diarrhea], or depression). **EBN:** *Clients with cancer who reported both pain and fatigue may have more symptoms than clients who reported neither pain nor fatigue (Berger et al, 2015).*

• *Fatigue associated with rheumatoid arthritis can affect a client's quality of life and coping. Group cognitive behavior therapy (CBT) has been shown to be effective in improving fatigue self-management, coping, and fatigue severity. CBT involves using self-management skills such as problem-solving and goal setting to improve self-efficacy while achieving a sense of balance, priority planning, and pacing of activities (Berger et al, 2015).*

▲ Collaborate with the primary care provider to identify attentional fatigue, which may manifest itself as the inability to direct attention necessary to perform usual activities. Attentional fatigue is associated with sleep disturbances, depressive symptoms, anxiety, and psychosocial stressors, which can lead to inability concentrate, inability to plan goals, and inability to control emotions or social interactions. **EBN:** *A meta-analysis reported that persons with chronic fatigue syndrome had deficits in the areas of attention, memory, and reaction time (Geraghty, Hann, & Kurtez, 2017).*

▲ Collaborate with primary care providers to identify potential pharmacological treatment for fatigue. **EBN:** *Pharmacological therapy has not been shown to be effective in reducing fatigue, although treatment of comorbidities may be effective (Berger et al, 2015). Psychostimulants, erythropoiesis-stimulating agents (ESAs) for cancer-related fatigue, cytokine blockers, and nutritional supplements have all been shown to have limited improvement of symptoms of fatigue (Berger et al, 2015).*

Geriatric

• Evaluate fatigue in geriatric clients routinely, particularly in clients with limited physical function and lower levels of social support. Chronic conditions related to age

can contribute to fatigue in the geriatric client, such as cancer, dyspnea, anemia, multiple medication usage and side effects from medication, depression, insomnia (Keles et al, 2016), nutritional deficiencies, electrolyte imbalance, and comorbidities such as chronic obstructive pulmonary disease (COPD) (Kentson et al, 2016) and cardiac disease (Nasiri et al, 2016). *Older adults report fatigue that limits physical function, sleep, and social ability, which can aggravate comorbid conditions. Fatigue is one of the most common and debilitating symptoms experienced by clients living with chronic conditions.*

• Review medications to determine possible side effects or interaction effects that could cause fatigue. **EB:** *The aging process changes the way an individual absorbs, metabolizes, and eliminates medications, leaving the geriatric client susceptible to medication side effects and medication-to-medication interactions that can cause fatigue and other conditions.*

• Review comorbid conditions that may contribute to fatigue, such as CHF, pulmonary disease, cardiac disease, multiple sclerosis, arthritis, obesity, anemia, depression, Parkinson's disease, insomnia, and cancer.

• Identify recent losses and even loss of function; monitor for depression or loneliness as a possible contributing factor to fatigue. **EB:** *There is a strong correlation between depression and fatigue in clients after a stroke (Galligan et al, 2016) and other chronic conditions.*

• Review other symptoms the client may be experiencing. Fatigue is often associated with other symptom clusters such as depression and sleep disturbances *(Mänty et al, 2014; National Comprehensive Cancer Network, 2014).Clusters may be independent of age (Agasi-Idenburg et al, 2017).*

▲ Review medications for side effects. Certain medications (e.g., diuretics with associated loss of potassium, antihypertensives, antihistamines, pain medications [Rich & Nienaber, 2014], anticonvulsants, chemotherapeutic agents, psychiatric medications, and corticosteroids) may cause fatigue in older adults. Fatigue is a major component of FRAILTY Scales (Gleason et al, 2017).

Home Care

The previously mentioned interventions may be adapted for home care use as well.

• Assess the client's history and current patterns of fatigue as they relate to the home environment and environmental and behavioral triggers of increased fatigue. **CEB:** *Fatigue may be more pronounced in specific settings for physical, environmental (e.g., stairs required to reach bathroom, patterns of movement around home, cleaning activities that require high energy), or psychological reasons (Wahl et al, 2009). Frailty may be related for the elderly.*

▲ Encourage planned exercise regimens or physical activities such as walking or light aerobic exercises. This activity can be organized in the home or in a setting such as senior centers or wellness facilities. **EB:** *Continued physical activity after cancer treatment has been associated with improved functioning in both physical and social realms (Hoffman et al, 2017). After a stroke frail elderly also responded to an individualized exercise program; they also had increased physical endurance and self-efficacy (Liu et al, 2017).*

▲ Refer to occupational and/or physical therapy if substantial intervention is needed to assist the client in adapting to home and daily patterns. **EB:** *Interventions in older adults led by occupational and physical therapists have been associated with less difficulty in ADLs and instrumental ADLs, which may lead to lower levels of fatigue (Murphy & Niemiec, 2014). Occupational and physical therapy rehabilitation have also been shown to decrease fatigue in cancer survivors (Dalzell et al, 2017). Home-based exercise in stage IV lung and*

colorectal clients has shown improvement in levels of fatigue (Hoffman et al, 2017).

- For clients receiving chemotherapy, intervene to:
    - ❍ Relieve symptom distress (anxiety, nausea and vomiting, diarrhea, lack of appetite, emotional distress, difficulty sleeping).
    - ❍ Encourage as much physical activity as possible with a specific recommendation (Hoffman et al, 2017).
- Teach the client and family the importance of and methods for setting priorities for activities, especially those with high energy demand (e.g., home or family events). Instruct in realistic expectations and behavioral pacing. **EBN:** *Prioritization of activities can be effective in restoring energy (Poort et al, 2017).*
    - ❍ Identify with the client ways in which he or she continues to be a valued part of his or her social environment.
    - ❍ Identify with the client ways in which he or she continues to participate in preferred daily activity or social activities.
    - ❍ Encourage the client to maintain regular family routines (e.g., meals, sleep patterns) as much as possible.

Client/Family Teaching and Discharge Planning

- Help the client to reframe cognitively; share information about fatigue and how to live with it, including need for positive self-talk. **EBN:** *Cognitive behavioral approaches to managing fatigue have been shown to have a positive effect with multiple sclerosis (Wendebourg et al, 2017).*
- Teach strategies for energy conservation (e.g., sitting instead of standing during showering, storing items at waist level). **EB:** *Energy conservation strategies can decrease the amount of energy used (Blikman et al, 2017).*
- Teach the client to carry a pocket calendar, make lists of required activities, and post reminders around the house.
- Teach the importance of following a healthy lifestyle with adequate nutrition, fluids, and rest; pain relief; insomnia correction; and appropriate exercise to decrease fatigue (i.e., energy restoration).
- See **Hopelessness** care plan if appropriate.

Fear

Nadia Charania PhD, RN

NANDA-I

Definition

Response to perceived threat that is consciously recognized as a danger.

Defining Characteristics

Apprehensiveness; decrease in self-assurance; excitedness; feeling of alarm; feeling of dread; feeling of fear; feeling of panic; feeling of terror; fidgeting; increase in blood pressure; increase in tension; muscle tension; nausea; pallor; pupil dilation; vomiting

Cognitive

Decrease in learning ability; decrease in problem-solving ability; decrease in productivity; identifies object of fear; stimulus believed to be a threat

Behaviors

Attack behaviors; avoidance behaviors; focus narrowed to the source of fear; impulsiveness; increase in alertness

Physiological

Anorexia; change in physiological response; diarrhea; dry mouth; dyspnea; fatigue; increase in perspiration

Related Factors

Language barrier; learned response to threat; response to phobic stimulus; separation from support system; unfamiliar setting

NOC (Nursing Outcomes Classification)

Suggested NOC Outcome

Fear Self-Control

Example NOC Outcome with Indicators

Fear Self-Control as evidenced by the following indicators: Eliminates precursors of fear/Seeks information to reduce fear/Plans coping strategies for fearful situations. (Rate the outcome and indicators of **Fear Self-Control:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Verbalize known fears
- State accurate information about the situation
- Identify, verbalize, and demonstrate those coping behaviors that reduce own fear
- Report and demonstrate reduced fear

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Anxiety Reduction; Coping Enhancement; Security Enhancement

Example NIC Activities—Anxiety Reduction

Use a calm, reassuring approach; Stay with the client to promote safety and reduce fear

Nursing Interventions and *Rationales*

- Assess source of fear with the client. *Many clients with chronic diseases such as multiple sclerosis or those with mobility issues have a fear of falling (Topuz et al, 2014).*
- Assess for a history of anxiety. **EB:** *Clients experiencing posttraumatic stress disorder often fear uncertainty, which can exacerbate symptoms (Boswell et al, 2013).*
- Assess for presence of fear avoidance beliefs. **EB:** *A systematic review found that fear avoidance beliefs were associated with poor treatment outcome in patients with lower back pain of less than 6 months (Wertli et al, 2014).*
- Have the client draw the object of his or her fear. **EBN:** *In a study of older adults with a fear of falling, a community-based art program helped them overcome fears and anxiety (Beauvais & Beauvais, 2014).*
- Stay with clients when they express fear; provide verbal and nonverbal (touch and hug with permission and if culturally acceptable) reassurances of safety if safety is within control. **EBN:** *One study in which nurses stayed with ventilated clients to provide support and reassurance reduced anxiety levels in these clients. Clients' ability to interact with the environment served as a basis for identification and management of anxiety or agitation. Health care providers' attributions about anxiety or agitation, and "knowing the patient," contributed to their assessment of client response (Tate et al, 2013).*
- Explore coping skills previously used by the client to deal with fear; reinforce these skills and explore other outlets. Provide backrubs and massage for clients to decrease anxiety. **EB:** *A study of 87 children who received massage prior to a painful treatment had lower levels of fear and anxiety then those who did not receive massage (Celebiogiu et al, 2014). In a group of older adults, those who received massage had less pain after hip or knee surgery (Büyükyılmaz & Aştı, 2013).*
- ▲ Refer for cognitive behavior therapy. **EB:** *Therapeutic touch and harp music reduced fear and anxiety in a group of postoperative clients (Lincoln et al, 2014).*
- ▲ Animal-assisted therapy can be incorporated into the care of clients in hospice situations.
- Encourage clients to express their fears in narrative form. *Refer to care plans for **Anxiety** and Death **Anxiety**.*
- Enhance client's self-efficacy when a client is experiencing initial fear of disease progression. **EBP:** *A research indicated the positive effect of self-efficacy in initial progression of fear of disease progression (Melchior et al, 2013).*
- Engage client in a mindfulness-based stress reduction program. **EBP:** *Mindfulness-based stress reduction significantly reduced fear of illness recurrence and improved physical functioning (Lengacher et al, 2014).*
- Provide brief psychoeducation to client who has fear about surgery. **EBP:** *A randomized trial supported that brief psychoeducation significantly lowered fear scores prior to surgery. Although the exact mechanism of action is not fully known, it could be that brief psychoeducation modifies beliefs (Shahmansouri et al, 2014).*

Pediatric

• Incorporate play therapy as an intervention to reduce fears. **EBN:** *A study concluded that play therapy helped children lower their fear and anxiety levels, improve their communication and coping skills, and promote their self-esteem (Sezici et al, 2014).*

Geriatric

• Provide a protective and safe environment, use consistent caregivers, and maintain the accustomed environmental structure. **CEBN:** *Providing an environment that included safety equipment and balance training reduced the fear of falling among older adults (Gusi et al, 2011).*
• Assess for fear of falls in hospitalized clients with hip fractures to determine risk of poor health outcomes. **EBN:** *Fear of falling can increase risk of depression and isolation, and further decrease physical performance in older clients (Park et al, 2014).*
• Pair cognitive-behavioral strategies with exercises to improve physical skills and mobility to decrease fear of falling. **EBN:** *A study found that the combination of cognitive-behavioral strategies with exercises decreased fear of falling while increasing mobility and muscle strength (Huang et al, 2016).*
• Assist the client in identifying and reducing risk factors for falls, including environmental hazards in and out of the home, the importance of good nutrition and activity, proper footwear, and how to stand up after a fall. **EB:** *Clients receiving education focused on identifying and reducing risk factors for falls were found to have a significant reduction in their fear of falling (Park et al, 2014).*

Multicultural

• Identify what triggers fear response. **EB:** *Culture plays a role in how people perceive themselves in fearful situations. Fear, fatalism, and current and historical relationships influence how people perceive themselves (Somayaji & Cloyes, 2014).*
• Assess for fears of racism in culturally diverse clients.
• Explore client's meaning of illness including a fear of illness. **EBN:** *Research shows that the meaning of illness guides the type of coping strategies used by the client (Obeidat et al, 2013).*
• Provide education, support, and guidance. **EBN:** *Research shows that engagement of the health care providers could help client reframe the negative meaning attached to the fear of an illness to a more positive one (Obeidat et al, 2013).*

Home Care

• The previous interventions may be adapted for home care use.
• Refer to care plan for **Anxiety.**
▲ Encourage the client to seek or continue appropriate counseling to reduce fear associated with stress or resolve alterations in irrational thought processes. *Correcting mistaken beliefs reduces anxiety. Creating a fear appeal that helps the client see that the fear is out of proportion to the situation can reduce fear in some clients (Sandkuhler & Lee, 2013).*
▲ Offer to sit quietly with a terminally ill client as needed by the client or family, or provide hospice volunteers to do the same. **EB:** *Skill in communicating and being with dying clients and their families is an important aspect of health care (Curtis, Back, & Ford, 2013).*

Client/Family Teaching and Discharge Planning

- Teach the client the difference between warranted and excessive fear. *Different interventions are indicated for rational and irrational fears. Creating a fear appeal that helps the client see that the fear is out of proportion to the situation can reduce fear in some clients (Sandkuhler & Lee, 2013).*
- Teach clients to use guided imagery when they are fearful; have them use all senses to visualize a place that is "comfortable and safe" for them. *Imagery makes use of subjective symbolism, bypassing the rational mind and making the areas "safe" that the client may otherwise be reluctant to face (Milad, Rosenblum, & Simon, 2014).*
- Teach use of appropriate community resources in emergency situations (e.g., hotlines, emergency departments, law enforcement, judicial systems). *Serious emergencies need immediate assistance to ensure the client's safety. Social media has a profound impact on society and affects many aspects of human life. Its applications in combating crises are unanticipated results of social media inventors, and many lessons could be learned from its applications in combating real crises (Chen, Ractham, & Kaewkitipong, 2014).*
- If fear is associated with bioterrorism, provide accurate information and ensure that health care personnel have appropriate training and preparation. *Clear, consistent, accessible, reliable, and redundant information (received from trusted sources) will diminish public uncertainty about the cause of symptoms that might otherwise prompt persons to seek unnecessary treatment. Training for providers is essential.* **EB:** *Using a diverse group of experts and providing a transparent and open line of communication can reduce fear in communities and the nation regarding bioterrorism (Siegrist & Zingg, 2014).*

Ineffective infant Feeding pattern

Shelley Sadler BSN, MSN, APRN, WHNP-BC

NANDA-I

Definition

Impaired ability of an infant to suck or coordinate the suck-swallow response resulting in inadequate oral nutrition for metabolic needs.

Defining Characteristics

Inability to coordinate sucking, swallowing, and breathing; inability to initiate an effective suck; inability to sustain an effective suck

Related Factors

Oral hypersensitivity; prolonged nil per os (NPO) status

At-Risk Population

Prematurity

Associated Conditions

Neurological delay; neurological impairment; oral hypersensitivity

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Bottle Feeding Establishment: Infant; Bottle Feeding Performance; Breastfeeding Establishment: Infant, Maternal; Breastfeeding: Maintenance; Hydration; Nutritional Status: Food and Fluid Intake

Example NOC Outcome with Indicators

Breastfeeding Establishment: Infant as evidenced by the following indicators: Proper alignment and latch-on/Correct suck and tongue placement/Urinations per day appropriate for age/Weight gain appropriate for age. (Rate the outcome and indicators of **Breastfeeding Establishment: Infant:** 1 = not adequate, 2 = slightly adequate, 3 = moderately adequate, 4 = substantially adequate, 5 = totally adequate [see Section I].)

Client Outcomes

Infant Will (Specify Time Frame)

- Consume adequate calories that will result in appropriate weight gain and optimal growth and development
- Have opportunities for skin-to-skin (kangaroo care) experiences
- Have opportunities for "trophic" (i.e., small volume of breast milk/formula) enteral feedings prior to full oral feedings
- Progress to stable, neurobehavioral organization (i.e., motor, state, self-regulation, attention-interaction)
- Demonstrate presence of mature oral reflexes that are necessary for safe feeding
- Progress to safe, self-regulated oral feedings
- Coordinate the suck-swallow-breathe sequence while nippling
- Display clear behavioral cues related to hunger and satiety
- Display approach/engagement cues, with minimal avoidance/disengagement cues
- Have opportunities to pace own feeding, taking breaks as needed
- Display evidence of being in the "quiet-alert" state while nippling
- Progress to and engage in mutually positive parent/caregiver–infant/child interactions during feedings

Parent/Family Will (Specify Time Frame)

- Recognize necessity of adequate calories for appropriate weight gain and optimal growth and development
- Learn to read and respond contingently to infant's behavioral cues (e.g., hunger, satiety, approach/engagement, stress/avoidance/disengagement)
- Learn strategies that promote organized infant behavior
- Learn appropriate positioning and handling techniques
- Learn effective ways to relieve stress behaviors during nippling
- Learn ways to help infant coordinate suck-swallow-breathe sequence (i.e., external pacing techniques)
- Engage in mutually positive interactions with infant during feeding
- Recognize ways to facilitate effective feedings: feed in quiet-alert state; keep length of feeding appropriate; burp; prepare/structure environment; recognize signs of sensory overload; encourage self-regulation; respect need for breaks and breathing pauses; avoid pulling and twisting nipple during pauses; allow infant to resume sucking when ready; provide oral support (cheek and/or jaw) as needed; use appropriate nipple hole size and flow rate

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Bottle Feeding; Fluid Monitoring; Kangaroo Care; Lactation Counseling; Nutritional Monitoring; Teaching:

Example NIC Activities—Lactation Counseling

Provide information about psychological and physiological benefits of breastfeeding; Refer to a lactation consultant

Nursing Interventions and *Rationales*

• Refer to care plans for Disorganized **Infant** behavior, Risk for disorganized **Infant** behavior, Ineffective and Interrupted **Breastfeeding,** and Insufficient **Breast Milk** and assess as needed.
• Interventions follow a sequential pattern of implementation that can be adapted as appropriate.
• Assess coordination of infant's suck, swallow, and gag reflex. **EBN:** *During this first hour when the infant starts seeking the breast, the rooting reflex becomes successively more mature and distinct (Svensson et al, 2013).*
▲ Provide developmentally supportive neonatal intensive care for preterm infants. **EBN:** *Decrease barriers for mothers to optimize breast milk feedings during infants' first weeks of life (Purdy et al, 2012).*
• Provide opportunities for kangaroo (i.e., skin-to-skin) care. **EBN:** *Use of kangaroo care increases the interval of breastfeeding and reduces the risk of mortality, infection/sepsis, hypothermia, and length of hospital stay (Gregson & Blacker, 2011).*
▲ Before the infant is ready for oral feedings, implement gavage feedings (or other alternative) as ordered, using breast milk whenever possible. **EBN:** *Gavage feeding is the method used to feed preterm infants or infants with inadequate suck/swallow during feeding (Pineda, 2011).*
• Provide a naturalistic environment for tube feedings (nasoorogastric, gavage, or other) that approximates a pleasurable oral feeding experience: hold infant in semiupright/flexed position; offer nonnutritive sucking; pace feedings; allow for semidemand feedings contingent with infant cues; offer rest breaks; burp, as appropriate. **EBN:** *Nonnutritive sucking during gavage feeding is comforting for the infant and significantly supports breastfeeding ability (Garpiel, 2012).*
• Foster direct breastfeeding as early as possible and enable the first oral feed to be at the breast in the neonatal intensive care unit (NICU). **EBN:** *Research demonstrated a link between direct breastfeeding behaviors in the NICU and success with provision of milk at discharge (Pineda, 2011).*
• Allow parents to feed the infant when possible. **EBN:** *Parents who feed effectively early on develop positive feeding relationships with their infants and promote infant feeding self-regulation and normative growth patterns (Horodynski et al, 2011).*
• Position infant in semiupright position, with head, shoulders, and hips in a straight line facing the mother with the infant's nose level with the mother's nipple. **EBN:** *Good positioning of the baby during breastfeeding is crucial to encourage oxytocin and prolactin release (Hughes, 2011).*
• Feed infant in the quiet-alert state. **EBN:** *Preterm infants who are in awake states at the beginning of nipple feedings are more successful at ingesting their feeding volumes (McCain et al, 2012).*
• Determine the appropriate shape, size, and hole of nipple to provide flow rate for preterm infants. **EBN:** *The coordination of rhythmic sucking, swallowing, and breathing patterns during feeding is disorganized in preterm infants with bronchopulmonary dysplasia*

(McCain et al, 2012).
• Implement pacing for infants having difficulty coordinating breathing with sucking and swallowing. **EBN:** *Paced feedings decrease risk of fatigue and oxygen desaturation of the infant (McCain et al, 2012).*
• Provide infants with jaw and/or cheek support, as needed. **EBN:** *Breastfeeding difficulties can be avoided if good attachment and positioning are achieved at the first and early feeds (Goyal et al, 2011).*
• Allow the stable newborn to breastfeed within the first half hour after birth. **EBN:** *Mothers of infants who were breastfed within 1 to 2 hours were almost three times more likely to experience breastfeeding problems in the postpartum period than those mothers who breastfed within 30 minutes of birth (Demirtas, 2012).*
• Allow appropriate time for nipple feeding to ensure infant's safety, limiting to 15 to 20 minutes for bottle feeding. **EBN:** *Bottle feeding mothers need to develop responsive behavior to their infants' hunger and satiety cues (Horodynski et al, 2011).*
• Monitor length of breastfeeding so that it does not exceed 30 minutes. Breast milk transfer may last from as little as 5 to 20 minutes during breastfeeding depending on variations in milk supply during a 24-hour day (Flaherman et al, 2012).
• Encourage transitioning from scheduled to semidemand feedings, contingent with infant behavior cues. *Flexible feeding schedules allow infants to feed during awake and alert periods in response to infant's readiness and tolerance of nipple feedings (McCain et al, 2012).*
▲ Refer to a multidisciplinary team (e.g., neonatal/pediatric nutritionist, physical or occupational therapist, speech pathologist, lactation specialist) as needed. **EB:** *Follow-up visits with lactation consultants, nurses, and health care providers are beneficial for breastfeeding mothers (Henry & Britz, 2011).*

Home Care

• The previously mentioned appropriate interventions may be adapted for home care use.
▲ Infants with risk factors and clinical indicators of feeding problems present before hospital discharge should be referred to appropriate community early-intervention service providers (e.g., community health nurses, early learning programs [individualized per states], occupational therapy, speech pathologists, feeding specialists) to facilitate adequate weight gain for optimal growth and development. **EBN:** *Late preterm infants are susceptible to multiple complications including feeding and sucking problems (Henry & Britz, 2011).*

Client/Family Teaching and Discharge Planning

• Provide anticipatory guidance for infant's expected feeding course. *Providing written information and education on breastfeeding with culturally sensitive awareness helps guide parents after early discharge (Wiener & Wiener, 2011).*
• Teach various effective feeding methods and strategies to parents. **EBN:** *Mothers need to be given evidence-based information and support before discharge, giving mothers a sense of security and providing understanding care (Demirtas, 2015).*
• Teach parents how to read, interpret, and respond contingently to infant cues. **EBN:** *Parents' ability to recognize and react quickly and consistently to their infant's state or cues leads to parental confidence in providing care, promotes parent–child relationship, and strengthens the family unit (Kadivar & Maryam Mozafarinia, 2013).*
• Help parents identify support systems before hospital discharge. *Nurses need to*

assess the support system of the family and collaborate with other health care team members to meet the mother's needs for successful breastfeeding (Feldman-Winter, 2013).

• Provide anticipatory guidance for the infant's discharge. *Providing written information and education on breastfeeding with culturally sensitive awareness helps guide parents after early discharge (Wiener & Wiener, 2011).*

Risk for Female Genital Mutilation

Marina Martinez-Kratz MS, RN, CNE

NANDA-I

Definition

Susceptible to full or partial ablation of the female external genitalia and other lesions of the genitalia, whether for cultural, religious, or any other nontherapeutic reasons, which may compromise health.

Risk Factors

Lack of family knowledge about impact of practice on physical health; lack of family knowledge about impact of practice on reproductive health; lack of family knowledge about impact of practice on psychosocial health

At-Risk Population

Residing in country in which the practice is accepted; family leaders belong to ethnic group in which practice is accepted; belonging to family in which any female member has been subjected to the practice; favorable attitude of family toward the practice; female gender; belonging to ethnic group in which the practice is accepted; planning to visit family's country of origin

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Abuse Cessation; Abuse Protection; Abuse Recovery; Abuse Recovery: Emotional; Abuse Recovery: Physical

Example NOC Outcome with Indicators

Abuse Protection as evidenced by the following indicators: Plan for avoiding abuse/Implementation of plan to avoid abuse/Safety of self/Safety of child/Self-advocacy. (Rate the outcome and indicators of **Abuse Protection:** 1 = not adequate, 2 = slightly adequate, 3 = moderately adequate, 4 = substantially adequate, 5 = totally adequate [see Section I].)

Client/Family Outcomes

Client Will (Specify Time Frame)

- Express effects of family/culture on beliefs about female genital mutilation (FGM)
- Demonstrate evidence that FGM has not occurred
- Express/implement a plan for avoiding FGM
- Maintain safety of female children
- Demonstrate the ability to make decisions independent of cultural group
- Demonstrate self-advocacy skills

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Abuse Protection Support; Abuse Protection Support: Child; Abuse Protection Support: Religious

Example NIC Activities—Abuse Protection Support: Child

Identify parents who demonstrate an increased need for parent education; Determine whether a child demonstrates signs of physical abuse; Report suspected abuse or neglect to proper authorities; Refer families to human services and counseling professionals as needed

Nursing Interventions and *Rationales*

- Identify the decision-making process related to the practice of FGM. **EB:** *The decision to undergo FGM is often a community decision and not an individual or family decision. Some survivors of FGM report that relatives or other community members performed FGM on them without their consent or the consent of their parents (Burrage, 2016).*
- Identify the type of FGM for which the female client is at risk. **EB:** *The World Health Organization (WHO) classifies types of FGM as follows.* ***Type 1:*** *Clitoridectomy, which is partial or total removal of the clitoris (a small sensitive and erectile part of the female genitals)*

and, in rare cases, removal of the prepuce only (the fold of skin surrounding the clitoris). ***Type 2:*** *Excision, which is partial or total removal of the clitoris and labia minora with or without removal of the labia majora (the labia are "the lips" that surround the vagina).* ***Type 3:*** *Infibulation, which is narrowing of the vaginal opening through the creation of a covering seal. The seal is formed by cutting and repositioning the labia minora or majora with or without removal of the clitoris.* ***Type 4:*** *Other, which includes all other harmful procedures to the genitals for nonmedical reasons, for example, pricking, piercing, incision, scraping, and cauterizing the genital area (WHO, 2016). WHO best practice standards indicated that nurses and health care providers are knowledgeable and aware of the types of FGM (WHO, 2016).*

• Assess and identify geographic, environmental, familial, religious, and/or other cultural factors that increase risk for FGM. **EB:** *Research indicated that the following are risk factors identified with FGM: older mothers, rural mothers, less educated mothers, maternal fears of social stigma, and mothers who have had FGM (Pashaei et al, 2016). FGM is most common in 30 countries of the western, eastern, and northeastern regions of Africa, in some countries in Asia and the Middle East, and among migrants from these areas. Countries with the highest rates of FGM are Egypt, Ethiopia, and Somalia (WHO, 2016).*

• Encourage the mothers of at-risk daughters to express their beliefs and attitudes toward FGM. **EB:** *Nurses and health care providers have to first understand the beliefs and attitudes toward FGM before implementing interventions to address the beliefs and attitudes. Among the beliefs for FGM are female cleanliness, beauty, safeguarding virginity, and as a rite of passage to adult womanhood (Pashaei et al, 2016).*

• Assess the mothers of at-risk daughters for positive affect (expression of feelings) and attitudes toward FGM. **EB:** *A recent Iranian study concluded that mothers' attitudes were the strongest predictor of their intention to allow their daughters to undergo FGM, suggesting that mothers with a more favorable attitude toward FGM are more likely to show the intention of mutilating their daughters (Pashaei et al, 2016).*

• In a respectful and nonjudgmental manner, convey accurate and clear information about FGM, using language and methods that can be readily understood by clients. **EB:** *Best practices indicated that individuals have the right to be fully informed by appropriately trained personnel with the assistance of an interpreter, if necessary (WHO, 2016).*

• In a respectful and nonjudgmental manner, provide the client, client's parents, and family with information that FGM is not a universal practice and that it is an illegal practice in many parts of the world. **EB:** *Women from countries that practice FGM may have inadequate knowledge of their bodies and biological facts and be shocked or angry to learn that FGM is not a universal practice and is illegal in the United States (Costello, 2015).*

• In a respectful and nonjudgmental manner, provide the client, client's parents, and family with health education to address false beliefs about female and clitoral anatomy and the physiology of women. **EB:** *Women from countries that practice FGM may have inadequate knowledge of their bodies and biological facts. Health education needs to convey that there are no known health benefits from FGM, and that women and children who experience FGM have lifelong health complications (WHO, 2016).*

• In a respectful and nonjudgmental manner, provide the client, client's parents, and family with health education to inform about the negative health outcomes associated with FMG. **EB:** *The negative health outcomes are both immediate and long-term. Immediate complications include bleeding, urinary retention, wound infection, sepsis, and death. Long-term complications include dysmenorrhea, dyspareunia, recurrent vaginal and urinary tract infections, infertility, difficult labor and delivery, and sexual dysfunction (Craven et al, 2016).*

• In a respectful and nonjudgmental manner, provide the client, client's parents, and family with health education to inform about the negative birth outcomes associated

with mothers who have had FMG. **EB:** *A study found that mothers with FGM experienced the following obstetric complications: increased risk of neonatal resuscitation, low birthrate, stillbirth, and early neonatal death (Reisel & Creighton, 2015).*

• Use therapeutic and culturally competent communication to focus on the current and future safety of the female child at risk for FGM. **EB:** *Therapeutic and culturally competent communication will acknowledge cultural practices without blame or judgment and will leverage parental love and concern to prevent harm to the child (Costello, 2015).*

• Utilize a cultural mediator to interpret cross-cultural norms about FGM. **EB:** *Cultural mediators are community leaders who are respected and known in their community for their opposition to FGM (Costello, 2015).*

• In a respectful and nonjudgmental manner, provide fathers with health education to address beliefs about FGM and provide information about the negative health outcomes associated with FGM. **EB:** *A systematic review found that the level of education of men was one of the most important indicators for men's support for the abandonment of FGM practices (Varol et al, 2015).*

▲ Refer families to counseling services **EB:** *Family counseling will ensure that the family understands the reasons for the health care interventions and legislative/legal response and facilitate support of each other through the transition (Costello, 2015).*

• See care plans for **Post-Trauma** syndrome**, Impaired Parenting,** and **Social Isolation.**

Pediatric

• Identify a system for assessment and referral of female infants at risk of FGM born to mothers who have undergone FGM. **EB:** *A British study assessed the effectiveness of a questionnaire to examine the level of risk of FGM if a girl is born to a mother who has undergone FGM. Study results indicated that the questionnaire formalized the referral process; identified infants at high risk; and helped to stratify risk into low, medium, and high. The questionnaire also indicated the demographics of those at highest risk (Flower et al, 2015).*

• For female children that may be victims of FGM, or are at risk of FGM, notify Child Protective Services and other law enforcement authorities. **EB:** *FGM is child abuse. Nurses are mandated reporters and are legally obligated to report all instances of suspected child abuse and neglect. Notification of Child Protective Services and law enforcement allows appropriate health care intervention and may provide protection for siblings and other girls in the family against FGM (Creighton et al, 2016). All individuals have the right to the highest attainable standard of health and the right to life and physical integrity, including freedom from violence and the right to freedom from torture or cruel, inhumane, or degrading treatment (WHO, 2016).*

Risk for imbalanced Fluid volume

Susan M. Dirkes BSN, MSA

NANDA-I

Definition

Susceptible to a decrease, increase, or rapid shift from one to the other of intravascular, interstitial, and/or intracellular fluid, which may compromise health. This refers to body fluid loss, gain, or both.

Risk Factors

To be developed

Associated Condition

Apheresis; ascites; burn injury; intestinal obstruction; pancreatitis; sepsis; trauma; treatment regimen

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Fluid Balance; Electrolyte and Acid-Base Balance; Hydration

Example NOC Outcome with Indicators

Fluid Balance as evidenced by the following indicators: Blood pressure/Peripheral pulses palpable/Skin turgor/Moist mucous membranes/Serum electrolytes/Hematocrit/Body weight stable/24-hour intake and output balanced/Urine specific gravity. (Rate each indicator of **Fluid Balance:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

- Lung sounds clear, respiratory rate 12 to 20 and free of dyspnea
- Urine output greater than 0.5 mL/kg/hr
- Blood pressure, pulse rate, temperature, and oxygen saturation within expected range
- Laboratory values within expected range, that is, normal serum sodium, hematocrit, and osmolarity
- Extremities and dependent areas free of edema
- Mental orientation appropriate based on previous condition

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Autotransfusion; Bleeding Precautions; Bleeding Reduction: Wound; Electrolyte Management; Fluid Management; Fluid Monitoring; Hemodynamic Regulation; Hypervolemia Management; Hypovolemia Management; Intravenous Therapy; Invasive Hemodynamic Monitoring; Shock Management: Volume; Vital Signs Monitoring

Example NIC Activities—Fluid Management

Maintain accurate intake and output record; Monitor vital signs

Nursing Interventions and *Rationales*

Surgical Clients

- Monitor the fluid balance. If there are symptoms of hypovolemia, refer to the interventions in the care plan for Deficient **Fluid** volume. If there are symptoms of hypervolemia, refer to the interventions in the care plan for Excess **Fluid** volume.

Preoperative

- Collect a thorough history and perform a preoperative assessment to identify clients with increased risk for hemorrhage or hypovolemia, that is, clients who take herbal supplements, those with recent traumatic injury, abnormal bleeding or altered clotting times, complicated kidney or liver disease, diabetes, cardiovascular disease, major organ transplant, history of aspirin and/or nonsteroidal antiinflammatory drug (NSAID) use, anticoagulant therapy, or history of hemophilia, von Willebrand's disease, or disseminated intravascular coagulation. Assess the client's use of over-the-counter agents to include herbal products. **EB:** *Use of dietary herbal supplements (DHS) causes the potential for DHS–drug interactions, which may lead to serious adverse events. Although drug-induced adverse events are thought to be responsible for up to 12% of hospitalizations, drug–drug interactions are estimated to be the direct cause of up to 2.8% of hospital admissions. Descriptions of adverse DHS–drug interactions in the surgical setting are found mostly in case reports and animal studies. These interactions mainly affected bleeding tendencies and level of sedation (Levy et al, 2017).*
- Recognize that nothing per mouth (NPO) at midnight may or may not be appropriate for each surgical client. Guidelines from the American Society of Anesthesiologists (2011) recommended that healthy clients having elective surgery should be allowed to have clear liquids up to 2 hours before surgery. **CEB:** *Research has shown the value of allowing healthy clients to consume clear liquids up to 2 hours before surgery, but the practice is not consistent (Crenshaw, 2011).* **EB:** *Many clients are unnecessarily dehydrated from lack of fluid for an extended period, which can complicate postoperative recovery. It is important to provide clear communication to the client that only clear liquids can be safely consumed up to 2 hours before surgery (Allison & George, 2014).*
- Determine length of time the client has been without normal intake, been NPO, or experienced fluid loss (e.g., vomiting, diarrhea, bleeding). *The length of time and severity of these factors, along with the presence of a fluid deficit, allow the health care provider to determine a general estimate of preoperative fluid loss, which can affect intraoperative fluid management. However, laboratory testing of hemoglobin, hematocrit, blood urea nitrogen (BUN), and creatinine should be used to corroborate the assessment (Allison & George, 2014).*

• Assess and document the client's mental status. *A baseline assessment is important so that changes in mental status during the postoperative period can be easily identified.*
• Recognize that there is conflicting evidence regarding liberal intraoperative fluid management versus restrictive fluid management. Fluid administration during surgery is more restrictive to prevent pulmonary complications associated with excessive fluid administration (*Assaad, Popescu, & Perrino, 2013*). **CEB:** *Hypovolemia and hypervolemia decrease tissue perfusion and may result in organ failure. Measurements to assess volume status include measuring mean arterial pressure (MAP), central venous pressure (CVP), and by observing urine output. However, CVP shows a poor correlation to blood volume, is inadequate to detect hypovolemia reliably, and most notably cannot sense a decreased cardiac output (CO) and tissue oxygen debt in an early state. Furthermore, changes in CVP after volume administration do not allow any conclusions to changes in stroke volume (SV) or CO. Other signs such as hypotension and tachycardia may be more reliable indicators of volume assessment (Strunden et al, 2011). Urine output is a measure of glomerular filtration and can be an effective indicator of fluid status (Macedo et al, 2011; Strunden et al, 2011).*
• *To reduce fluid administration volume, colloids rather than crystalloid fluids may be administered during surgery (Cortes et al, 2015).*
• Recognize that an individualized fluid management plan would be developed incorporating client-specific assessment parameters (e.g., existing comorbid diseases, age) and type of surgical procedure (Allison & George, 2014). **EB:** *Perioperative hemodynamic and fluid management that is goal directed improved both short- and long-term outcomes and can be achieved easily (Cecconi et al, 2015).*
• Recognize the effects of general anesthetics, inhalational agents, and regional anesthesia on perfusion in the body and the potential for decreasing the blood pressure. **EB:** *In humans undergoing general anesthesia there is almost no relationship between mean arterial blood pressure and delivery of oxygen (DO_2), presumably because of widely varying systemic vascular resistance. Control of blood pressure requires measurement, an algorithm of action, and an intervention, such as medications or fluid administration (Bartels, Esper, & Thiele, 2016).*
• Monitor for signs of intraoperative hypovolemia such as dry skin, dry mucous membranes, tachycardia, decreased urinary output, decreased CVP, hypotension, increased pulse, and/or deep rapid respirations.
• Monitor for signs of intraoperative hypervolemia such as dyspnea, coarse crackles, increased pulse and respirations, decreased oxygenation, and decreased urinary output, all of which could progress to pulmonary edema.
• In the critically ill surgical client a pulmonary artery catheter or other minimally invasive CO monitoring device may be used to determine fluid balance and guide fluid and vasoactive intravenous (IV) drip administration. **EB:** *Devices that directly (pulmonary artery catheter, or arterial liner) or indirectly (minimally or noninvasive such as ongoing blood pressure monitoring) assess the client's cardiac status and fluid volume status may be used to "optimize" cardiac function by allowing better fluid regimens. Fluids must be individually titrated based on each client's changes in monitored variables (Cecconi et al, 2015; Bartels, Esper, & Thiele, 2016).*
• Monitor the client for hyponatremia with symptoms such as headache, anorexia, nausea and vomiting, diarrhea, tachycardia, general malaise, muscle cramps, weakness, lethargy, change in mental status, disorientation, seizures, and death. *Many pathologies can predispose the client to hyponatremia, including adrenal insufficiency, brain tumor, cirrhosis, hypothyroidism, lung cancer, meningitis, renal disease, tuberculosis, use of*

complementary therapies, and head trauma (Allison & George, 2014).

• Monitor clients undergoing laparoscopic or hysteroscopic procedures for the development of hyponatremia, hypervolemia, and pulmonary edema when an irrigation fluid is used. **EB:** *Use of local or spinal anesthesia for these operations can cause the client to develop symptoms of hyponatremia and hypervolemia sooner than with other anesthetics (Silva et al, 2013).*

• Monitor clients undergoing transurethral resection of the prostate (TURP) procedures for development of hyponatremia and hypervolemia with symptoms of TURP syndrome including headache, visual changes, agitation, lethargy, vomiting, muscle twitching, bradycardia, diminished pupillary reflexes, hypertension, and respiratory distress. *Considerable fluid absorption occurs during TURP procedures and gynecological procedures, which can result in hyponatremia and/or hypervolemia (Pasha et al, 2015).*

• Measure the irrigation fluid used during urological and gynecological procedures accurately for volume deficit such as amount of irrigation used minus amount of irrigation recovered via suction. *Absorption of large amounts of fluid can cause complications for the client (Silva et al, 2013).*

• Monitor intraoperative intake and output including blood loss, urine output, and third-space losses to provide an estimate of fluid volume. **EBN:** *Weighing used sponges can provide an estimate of blood loss (Blanchard & Burlingam, 2012).* **EB:** *Weighing fluid used and returned provides a more accurate measurement of fluid deficit than measuring the fluids (Silva et al, 2013). The use of balanced electrolyte IV solutions has been shown to be safer than the use of isotonic saline alone (Shaw et al, 2012).*

• Observe the surgical client for hyperkalemia with symptoms including dysrhythmias, heart block, asystole, abdominal distention, and weakness. *Hyperkalemia can occur intraoperatively because of massive blood transfusions, tissue breakdown from surgery, shifting of potassium from the cells into the extracellular fluid, decreased potassium excretion caused by renal failure or hypovolemia, crush injuries, or burns (El-Sharkawy et al, 2014).*

• Maintain the client's core temperature at normal levels, using warming devices as needed. **EB:** Hypothermia (body temperature <36°C) is present in the postoperative period in 26% to 90% of all patients who have undergone elective surgery. The risk of hypothermia is particularly high in patients over 60 years of age with poor nutritional status and preexisting disease, which impairs thermoregulation (e.g., diabetes mellitus with polyneuropathy), and in those who have had major or lengthy surgery. Lower temperatures in the operating room also increase the risk of hypothermia: the lower the temperature, the higher the risk (Torossian et al, 2015).

• Fluids administration during surgery can increase risk of hypothermia. **EB:** *Research has shown that perioperative hypothermia can adversely affect the cardiopulmonary system (Giuliano & Hendricks, 2017).*

Postoperative

• Continue to monitor fluids postoperatively. **EB:** *Restrictive fluid therapy and liberal conventional therapy were associated with similar rates of overall and cardiopulmonary complications; however, restrictive fluid therapy was associated with a more rapid recovery and a shorter length of hospital stay (Jia et al, 2017). Also, fluid overload is an independent risk factor for the development of acute kidney injury (Salhuddin et al, 2017).*

• Assess the client for development of tissue edema, especially after cataract surgery in patients with comorbidities such as diabetes. **EB:** *A history of diabetes mellitus has*

been found to be an independent risk factor for the development of postoperative cystoid macular edema in patients undergoing cataract surgery (Ovewole et al, 2017).

• Recognize that IV fluid replacement decisions incorporate multiple assessment parameters such as hourly urine output, blood pressure, heart rate, respiratory rate, lung sounds, output from drains, and changes in laboratory results (e.g., hemoglobin/hematocrit, serum electrolytes).

Geriatric

• Check skin turgor of older clients on the forehead, subclavian area, or inner thigh; also look for the presence of longitudinal furrows on the tongue and dry mucous membranes. *Older people commonly have decreased skin turgor from normal age-related loss of elasticity, and checking skin turgor on the arm is not reflective of fluid volume (El-Sharkawy et al, 2014).*

• Closely monitor urine output, concentration of urine, and serum BUN/creatinine results. **EB:** *Reduced renal perfusion and altered renal function as a normal or abnormal change in physiological aging can compromise the client's fluid volume status (El-Sharkawy et al, 2014).*

• Monitor older clients for excess fluid volume during the treatment of deficient fluid volume: auscultate lung sounds, assess for edema, and trend vital signs.

• Assess the older client's cognitive status. **EB:** *Cognitive impairment is a risk factor associated with dehydration, especially in the older adult (El-Sharkawy et al, 2014).*

Pediatric

• Assess the pediatric client's weight, length of NPO status, underlying illness, and the surgical procedure to be performed.

• Recognize that newborns require very little fluid replacement when undergoing major surgical procedures during the first few days of life.

• Monitor pediatric surgical clients closely for signs of fluid loss.

• Administer fluids preoperatively until NPO status must be initiated so that fluid deficit is decreased.

• Perform an assessment for signs of fluid responsiveness in the pediatric client. **EB:** *A systematic review found that respiratory variation was the only assessment parameter to most reliably predict a pediatric client's responsiveness for fluid administration (Gan et al, 2013).* **EB:** *Rehydration solutions such as low osmolality solutions have been shown to be safe and effective for correcting dehydration in children (Kumar et al, 2015).*

Deficient Fluid volume

Susan M. Dirkes RN, MS, CCRN

NANDA-I

Definition

Decreased intravascular, interstitial, and/or intracellular fluid. This refers to dehydration, water loss alone without change in sodium.

Defining Characteristics

Alteration in mental status; alteration in skin turgor; decrease in blood pressure; decrease in pulse pressure; decrease in pulse volume; decrease in tongue turgor; decrease in urine output; decreased venous filling; dry mucous membranes; dry skin; increase in body temperature; increase in heart rate; increase in hematocrit; increase in urine concentration; sudden weight loss; thirst; weakness

Related Factors

Barrier to accessing fluid; insufficient fluid intake; insufficient knowledge about fluid needs

At-Risk Population

Extremes of age; extremes of weight; factors influencing fluid needs

Associated Condition

Active fluid volume loss; compromised regulatory mechanism; deviations affecting fluid absorption; deviations affecting fluid intake; excessive fluid loss through normal route; fluid loss through abnormal route; pharmaceutical agent

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Fluid Balance; Hydration; Nutritional Status: Food and Fluid Intake

Example NOC Outcome with Indicators

Fluid Balance as evidenced by the following indicators: Elastic skin turgor/Moist mucous membranes/Orthostatic hypotension not present/24-hour intake and output balance/Urine specific gravity. (Rate each indicator of **Fluid Balance:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Maintain urine output of 0.5 to 1.5 mL/kg/hr or at least more than 1300 mL/day
- Maintain normal blood pressure, heart rate, and body temperature
- Maintain elastic skin turgor; moist tongue and mucous membranes; and orientation to person, place, and time
- Explain measures that can be taken to treat or prevent fluid volume loss
- Describe symptoms that indicate the need to consult with health care provider

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Fluid Management; Hypovolemia Management; Shock Management: Volume

Example NIC Activities—Fluid Management

Monitor hydration status (e.g., moist mucous membranes, adequacy of pulses, and orthostatic blood pressure) as appropriate; Administer intravenous (IV) therapy, as prescribed

Nursing Interventions and *Rationales*

- Watch for early signs of hypovolemia, including thirst, restlessness, headaches, and inability to concentrate. *Thirst is often the first sign of dehydration (Wagner & Hardin-Pierce, 2014).* **EB:** *A study of healthy women showed heart rate was increased by fluid restriction along with increased urine specific gravity, darker urine color, and increased thirst. They also experienced decreased alertness and increased sleepiness, fatigue, and confusion (Pross et al, 2013).*
- Recognize symptoms of cyanosis, cold clammy skin, weak thready pulse, confusion,

and oliguria as late signs of hypovolemia. *These symptoms occur after the body has compensated for fluid loss by moving fluid from the interstitial space into the vascular compartment (Wagner & Hardin-Pierce, 2014).*
• Monitor pulse, respiration, and blood pressure of clients with deficient fluid volume every 15 minutes to 1 hour for the unstable client and every 4 hours for the stable client. *Vital sign changes seen with fluid volume deficit include tachycardia, tachypnea, decreased pulse pressure first, then hypotension, decreased pulse volume, and increased or decreased body temperature (Wagner & Hardin-Pierce, 2014).* **CEB:** *A systematic review demonstrated that hypotension and tachycardia, and occasionally fever, are clinical signs of dehydration (Jequier & Constant, 2010).*
• Check orthostatic blood pressures with the client lying, sitting, and standing. *A decrease in systolic blood pressure of 20 mm Hg or a decrease in diastolic blood pressure of 10 mm Hg within 3 minutes of standing when compared with blood pressure from the sitting position is considered orthostatic hypotension. This can occur with dehydration or cardiovascular disorders (Wedro & Stoppler, 2017).*
• Note skin turgor over bony prominences such as the hand or shin.
• Monitor for the existence of factors causing deficient fluid volume (e.g., hypovolemia from vomiting, diarrhea, difficulty maintaining oral intake, fever, uncontrolled type 2 diabetes, diuretic therapy). *Early identification of risk factors and early intervention can decrease the occurrence and severity of complications from deficient fluid volume and acute kidney injury (Ftouh & Lewington, 2014).*
• Observe for dry tongue and mucous membranes, and longitudinal tongue furrows. *These are symptoms of decreased body fluids (Wagner & Hardin-Pierce, 2014).*
• Recognize that checking capillary refill may not be helpful in identifying fluid volume deficit. *Capillary refill can be normal in clients with sepsis because increased body temperature dilates peripheral blood vessels and capillary return may be immediate (Wagner & Hardin-Pierce, 2014). A quick test is compression of the nail bed. If there is good blood flow to the nail bed, a pink color should return in less than 2 seconds after pressure is removed. Slow return to pink color can indicate dehydration (White, 2016).* **CBN:** *Capillary refill has been shown to be a good clinical indicator to detect dehydration with good specificity but poor sensitivity (Shimizu et al, 2012).*
• Weigh client daily and watch for sudden decreases, especially in the presence of decreasing urine output or active fluid loss. *Body weight changes of 1 kg (2.2 pounds) represent a fluid loss of 1 L (Wagner & Hardin-Pierce, 2014).*
• Monitor total fluid intake and output every 4 hours (or every hour for the unstable client or the client who has urine output equal to or less than 0.5 mL/kg/hr). *Recognize that urine output is an indicator of fluid balance. However, urine output alone does not differentiate between volume-sensitive reductions in glomerular filtration rate and structural kidney injury (Schrezenmeier et al, 2017)*
• A urine output of less than 0.5 mL/kg/hr may be indicative of acute kidney injury (Prowle et al, 2011). Nevertheless, in any condition of hypovolemia, renal perfusion pressure falls. If it falls below the level of autoregulation (blood pressure [BP] <80 mm Hg), then renal blood flow and glomerular filtration will fall (Andeucchi et al, 2017). **EB:** *The RIFLE criteria define oliguria as urine output less than 0.5 mL/kg/hr for each of six or more consecutive hours, which is thought to confer "risk" of kidney injury; when urine output less than 0.5 mL/kg/hr and persists for 12 or more consecutive hours, the kidneys are considered to be "in injury" (James et al, 2016). The Kidney Disease: Improving Global Outcomes (KDIGO) guidelines indicate that acute kidney injury is an increase in creatinine 1.5 to 1.9 times baseline and urine output <0.5 mL/kg/hr for 6 to 12 hours (Alseiari, 2016).*
• Note the color of urine, urine osmolality, and specific gravity. *Normal urine is straw*

colored or amber. Dark-colored urine with a specific gravity greater than 1.030 and a high urine osmolality reflects fluid volume deficit (Perrier et al, 2013; Wagner & Hardin-Pierce, 2014). Although these tools for dehydration screening have been advocated for use in the elderly, their diagnostic accuracy is low and may not be useful (Hooper et al, 2016).

• Provide fresh water and oral fluids preferred by the client (distribute over 24 hours [e.g., 1200 mL during days, 800 mL during evenings, and 200 mL during nights]), provide prescribed diet, offer snacks (e.g., frequent drinks, fresh fruits, fruit juice), and instruct significant other to assist the client with feedings as appropriate. *Distributing the intake over the entire 24-hour period and providing snacks, specifically those with creatine and carnitine, and beverages including caffeine may improve muscular ability, endurance, and alertness (Cherniack, 2012).*

▲ Provide oral replacement therapy as ordered and tolerated with a hypotonic glucose-electrolyte solution when the client has acute diarrhea or nausea/vomiting. Provide small, frequent quantities of slightly chilled solutions. *Maintenance of oral intake stabilizes the ability of the intestines to absorb nutrients and promote gastric emptying (Keller & Layer, 2014); glucose-electrolyte solutions increase net fluid absorption while correcting deficient fluid volume. Use diluted carbohydrate-electrolyte solutions, such as sports replacement drinks, and ginger ale (Deshpande, Lever, & Soffer, 2013). The use of diluted oral replacement fluids has been found to reduce the need for IV hydration (Keller & Layer, 2014).*

▲ Administer antidiarrheals and antiemetics as ordered and appropriate. Consider what the client is eating to prevent further diarrhea (Bolen, 2018). *The goal is to stop the loss that results from vomiting or diarrhea. Refer to care plan for **Diarrhea** or **Nausea**.*

• If the client is on enteral feedings, research has shown either continuous or intermittent feedings had similar results regarding diarrhea and nausea (deAraujo et al, 2014). **EB:** *Evaluate the rate of enteral feeding formula administration and other medications to address diarrhea and nausea (Scott & Bowling, 2015).*

▲ Hydrate the client with isotonic IV solutions as prescribed. *For clients with mild to moderate fluid deficit, crystalloids such as 0.9 saline or lactated Ringer's should be used for fluid volume replacement (Peng & Kellum, 2013).*

• Assist with ambulation if the client has postural hypotension. Hypovolemia causes orthostatic hypotension, which can result in syncope when the client goes from a sitting to standing position (Wagner & Hardin-Pierce, 2014).

Critically Ill

▲ Monitor stroke volume, passive leg lift, and ultrasound as trends for more accurate fluid volume status. *Hemodynamic pressures such as central venous pressure (CVP) and pulmonary artery pressures have been demonstrated to be less predictive and specific of fluid volume responsiveness (Kalantari et al, 2013), whereas changes in stroke volume measured by a number of noninvasive methods including passive leg lift may more accurately predict fluid volume responsiveness of a client (Marik, Monnet, & Teboul, 2011; Angappan, 2015; Duus et al, 2015).*

▲ Monitor serum and urine osmolality blood urea nitrogen (BUN)/creatinine ratio and hematocrit for elevations. *These are all measures of concentration and will be elevated with decreased intravascular volume (Wagner & Hardin-Pierce, 2014).*

▲ Insert an indwelling urinary catheter if ordered and measure urine output hourly. Notify health care provider if urine output is less than 0.5 mL/kg/hr. **EB:** *A decrease in urine output is seen with poorly perfused kidneys and a drop in the glomerular filtration rate in the client with normal kidney function, and action, if taken early, can prevent further*

deterioration (Zheng et al, 2014). Intensive monitoring of urine output is associated with increased detection of acute kidney injury and improved outcomes (Jin et al, 2017).

▲ When ordered, initiate a fluid challenge of crystalloids (e.g., 0.9% normal saline or lactated Ringer's) for replacement of intravascular volume. **EB:** *Guidelines for early goal-directed therapy (EGDT) have been developed by the Surviving Sepsis campaign; however, EGDT in one study did not significantly decrease mortality (Zhang et al, 2017).*

▲ Monitor the client's response to prescribed fluid therapy and fluid challenge, especially noting vital signs (mean arterial pressure [MAP] >65 mm Hg in the first 6 hours of treatment, systolic blood pressure >100 mm Hg) (Singer et al, 2016; Rhodes et al, 2017), urine output, blood lactate concentrations, and lung sounds. *A fluid challenge can help the client with deficient fluid volume regain intravascular volume quickly, but the client must be carefully observed to ensure that he or she does not go into fluid volume overload because excess fluid volume can lead to organ edema and increased mortality (Peng & Kellum, 2013; Wang et al, 2014).*

• Position the client flat with legs elevated when hypotensive, if not contraindicated. *This position enhances venous return, and, coupled with stroke volume measurement, is a simple noninvasive technique to determine fluid responsiveness (Assadi, 2017).*

▲ Monitor trends in serum lactic acid levels and base deficit obtained from blood gases as ordered. **EB:** *A trend of increasing lactic acid levels >2.0 has been shown to increase mortality than levels less than 2.0 (Seymour et al, 2016; Rhodes et al, 2017).*

▲ Consult provider if signs and symptoms of deficient fluid volume persist or worsen. *Prolonged deficient fluid volume increases the risk for development of complications, including decrease in cognitive function, weakness, tachycardia, hemodynamic instability, and kidney injury (Singer et al, 2016).*

Pediatric

• Monitor the child for signs of deficient fluid volume, including sunken eyes, decreased tears, dry mucous membranes, poor skin turgor, and decreased urine output (Graves, 2013). **EB:** *These assessment factors are more significant in identifying dehydration, but a combination of physical examination findings is a much better predictor than individual signs (Falszewska, Dziechciarz, & Szajewska, 2014).*

▲ Reinforce the health care provider recommendation for the parents to give the child oral rehydration fluids to drink in the amounts specified, especially during the first 4 to 6 hours to replace fluid losses. Consider using diluted oral rehydration fluids. Once the child is rehydrated, an orally administered maintenance solution should be used along with food. **EB:** *A study demonstrated that treatment with oral rehydration fluids for children was generally as effective as IV fluids, and IV fluids did not shorten the duration of gastroenteritis and are more likely to cause adverse effects than oral rehydration therapy (Ciccarelli, Stolfi, & Caramia, 2013).* **EB:** *Many studies have shown that diluted oral replacement fluids and some drugs resulted in reductions in stool output, decreased vomiting, and less need for IV hydration (Ciccarelli, Stolfi, & Caramia, 2013).*

• Recommend that the mother resume breastfeeding as soon as possible.

• Recommend that parents not give the child carbonated soda, fruit juices, gelatin dessert, or instant fruit drink mix; instead, give the child oral rehydration fluids ordered and, when tolerated, food. *Rehydration solutions such as low osmolality solutions have been shown to be safe and effective for correcting dehydration in children (Kumar et al, 2015). Antiemetic, antidiarrheal agents and probiotics have been shown to reduce the duration and severity of infectious diarrhea (Ciccarelli, Stolfi, & Caramia, 2013).*

• Once the child has been rehydrated, begin feeding regular food, but avoid milk

products *(Guandalini et al, 2017).*

Geriatric

• Monitor older clients for deficient fluid volume carefully, noting new onset of headache, weakness, dizziness, and postural hypotension. *Older people are thought to be at greater risk of dehydration because thirst sensation and urinary concentrating ability frequently decline with age. Many older people use diuretics or laxatives, which encourage fluid loss, and reduced muscle volume leads to a smaller fluid reserve. Oral fluid intake may fall in older people for a variety of reasons including reduced enjoyment of drinks, physical limitations, unmet activities of daily living needs, acute and chronic health problems, and decisions aimed at controlling continence (Oates & Price, 2017). Additionally those with dementia may forget to drink as daily routines are lost and social contact diminishes.*
• Implement fall precautions for clients experiencing weakness, dizziness, and/or postural hypotension. *Falls are a serious risk in the elderly, especially those with hyponatremia (Kuo, 2017*).
• Evaluate the risk for dehydration using the Dehydration Risk Appraisal Checklist. **CEB:** *A study demonstrated that the checklist has potential to predict the onset of dehydration in nursing home clients (Mentes & Wang, 2011).*
• Check skin turgor of older clients on the forehead and axilla; check for dry mucous membranes and dry tongue. **EB:** *A Cochrane review recommended in clinical practice to avoid the reliance on one clinical symptom as a sign of water-loss dehydration in older people* (*Hooper et al, 2016a*). *Older adults are susceptible to dehydration because of acute and chronic health problems, which impair thirst; reduce the ability to drink sufficiently; and/or increase urinary, skin, and respiratory fluid loss (Oates et al, 2017; Hooper et al, 2016b). Older adults present with a constellation of signs and symptoms that need to be further evaluated for connection to dehydration. Signs and symptoms include fatigue, pallor, sunken periorbital area, chapped lips, hypotension, tachycardia, fever, orthostatic blood pressure, weight loss >4%, poor skin turgor over the sternum, and change in mental status (Miller, 2015).*
• Encourage fluid intake by offering fluids regularly to cognitively impaired clients. **EB:** *The single most common risk factor reported associated with dehydration in cognitively impaired clients was a worsening or change in mental state (Oates et al, 2017).*
• Because older clients have low water reserves, they should be encouraged to drink regularly even when not thirsty. Frequent and varied beverage offerings should be made available by hydration assistants to routinely offer increased beverages to clients in extended care. **EB:** *Strategies to improve fluid intake include making healthy drinks and water easily available and accessible at all times and reminding and encouraging older adults to consume these fluids. Older people should not be encouraged to consume large amounts of fluids at once but rather small amounts throughout the day (Oates et al, 2017).*
• Flag the food tray of clients with chronic dehydration to indicate if the client is identified as having chronic dehydration and indicate that they should finish 75% to 100% of their food and fluids. Offering beverages in brightly colored cups may improve fluid intake. *Older clients often have a combination of both malnutrition and fluid deficit and may not have good taste sensation (Hooper et al, 2014).*
• Recognize that lower blood pressures and monitoring of an intake record over 24 hours is recommended to track oral intake and possible dehydration (*Oates et al, 2015*).
• A higher BUN/creatinine ratio can be significant signs of dehydration in older adults. *Structural changes of the kidney include alterations of renal blood flow of up to 50% from age 20 to 80. As people age, the kidney undergoes age-related changes, which translate in an inexorable and progressive decline in renal function.*

• *In the United States, renal dysfunction has a 15% prevalence in persons older than 70 years (Bolignano et al, 2014).*
• Monitor older clients for excess fluid volume during the treatment of deficient fluid volume: auscultate lung sounds, assess for edema, and note vital signs. *The older client has a decreased ability to adapt to rapid increases in intravascular volume and can quickly develop fluid overload.*

Home Care

• Teach family members how to monitor output in the home (e.g., use of commode "hat" in the toilet, urinal, or bedpan, or use of catheter and closed drainage system). Instruct them to monitor both intake and output. Use common terms such as "cups" or "glasses of water a day" when providing education.
• When weighing the client, use same scale each day. Be sure scale is on a flat, not cushioned, surface. Do not weigh the client with a scale placed on any type of rug because scales provide more accurate readings when used on a hard surface.
• Teach family about complications of deficient fluid volume and when to call the health care provider.
• Teach the family the signs of hypovolemia, especially in older adults, and how to monitor for dizziness or unsteady gait.
• If the client is receiving IV fluids, there must be a responsible caregiver in the home. Teach caregiver about administration of fluids, complications of IV administration (e.g., fluid volume overload, development of phlebitis, speed of medication reactions), and when to call for assistance. Assist caregiver with administration for as long as necessary to maintain client safety. *Administration of IV fluids in the home is a high-technology procedure and requires sufficient professional support to ensure safety of the client.*
• Identify an emergency plan, including when to call 911. *Some complications of deficient fluid volume cannot be reversed in the home and are life-threatening. Clients progressing toward hypovolemic shock will need emergency care.*
• Deficient fluid volume may be a symptom of impending death in terminally ill clients. In palliative care situations, treatment of deficient fluid volume should be determined based on client/family goals. Information and support should be provided to assist the client/family in this decision. Support the family/client in a palliative care situation to decide if it is appropriate to intervene for deficient fluid volume or to allow the client to die without fluids. *Deficient fluid volume may be a symptom of impending death in terminally ill clients. There is no defined gold standard for hydrating dying clients, and hydration and nutrition are considered basic acts for care of a dying client (Ong, Yee, & Lee, 2012).*

Client/Family Teaching and Discharge Planning

• Instruct the client to avoid rapid position changes, especially from supine to sitting or standing.
• Teach the client and family about appropriate diet and fluid intake.
• Teach the client and family how to measure and record intake and output accurately.
• Teach the client and family about measures instituted to treat hypovolemia and to prevent or treat fluid volume loss.
• Instruct the client and family about signs of deficient fluid volume that indicate they should contact health care provider.

Excess Fluid volume

Susan M. Dirkes RN, MS, CCRN

NANDA-I

Definition

Surplus intake and/or retention of fluid.

Defining Characteristics

Adventitious breath sounds; alteration in blood pressure; alteration in mental status; alteration in pulmonary artery pressure (PAP); alteration in respiratory pattern; alteration in urine specific gravity; anasarca; anxiety; azotemia; decrease in hematocrit; decrease in hemoglobin; dyspnea; edema; electrolyte imbalance; hepatomegaly; increased central venous pressure (CVP); intake exceeds output; jugular vein distention; oliguria; orthopnea; paroxysmal nocturnal dyspnea; pleural effusion; positive hepatojugular reflex; presence of S3 heart sound; pulmonary congestion; restlessness; weight gain over short period of time

Related Factors

Excessive fluid intake; excessive sodium intake

Associated Condition

Compromised regulatory mechanism

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Electrolyte and Acid-Base Balance; Fluid Balance; Fluid Overload Severity; Hydration

Example NOC Outcome with Indicators

Fluid Balance as evidenced by the following indicators: Peripheral edema/Neck vein distention/Adventitious breath sounds/Body weight increase. (Rate each indicator of **Fluid Balance:** 1 = severe, 2 = substantial, 3 = moderate, 4 = mild, 5 = none [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Remain free of edema, effusion, anasarca
- Maintain body weight appropriate for the client
- Maintain clear lung sounds; no evidence of dyspnea or orthopnea
- Remain free of jugular vein distention, positive hepatojugular reflex, and S3 heart sound
- Maintain normal CVP, PAP, cardiac output, and vital signs
- Maintain urine output of 0.5 mL/kg/hr or more with normal urine osmolality and specific gravity
- Explain actions that are needed to treat or prevent excess fluid volume including fluid and dietary restrictions, and medications
- Describe symptoms that indicate the need to consult with health care provider

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Fluid Management; Fluid Monitoring

Example NIC Activities—Fluid Monitoring

Monitor weight; Monitor intake and output

Nursing Interventions and *Rationales*

- Monitor location and extent of edema using the 1+ to 4+ scale to quantify edema; also measure the legs using a millimeter tape in the same area at the same time each day. Note differences in measurement between extremities. **EBN:** *Numerous studies in patients and in experimental models of congestive heart failure (CHF) have established the important role of the renin–angiotensin–aldosterone system (RAAS) and the sympathetic*

nervous system (SNS) in the progression of cardiovascular and renal dysfunction in CHF. It is now accepted that excessive neurohormonal activation may adversely affect cardiac function and the hemodynamic condition by enhancement of systemic vasoconstriction and promoting salt and water retention by the kidney (Zaher et al, 2017).

• Monitor daily weight for sudden increases; use same scale and type of clothing at same time each day, preferably before breakfast. *Body weight changes reflect changes in body fluid volume.* **EB:** *Body weight is commonly used to monitor for fluid overload (Wagner & Hardin-Pierce, 2014).*

• Monitor intake and output; note trends reflecting decreasing urine output in relation to fluid intake. **EB:** *Abnormally low urine output (oliguria) is a leading indicator of acute kidney injury (AKI), which increases mortality, cost of care, and length of stay (Yong et al, 2013). The volume of all fluids should be measured. If the family is measuring, instruct them on common conversions between household measurements and metric.* **EBN:** *Chronic heart failure (HF) is characterized by neurohumoral activation and sodium retention that leads to excessive fluid accumulation in the systemic and pulmonary circulations. Lung congestion increases dyspnea and impairs gas transfer (Melenovsky et al, 2015).*

• Chronic HF is characterized by neurohormonal activation and sodium retention that leads to excessive fluid accumulation in the systemic and pulmonary circulations. *Monitor vital signs; note decreasing blood pressure, tachycardia, and tachypnea. Monitor for S3 heart sounds. If signs of HF are present, see the care plan for Decreased **Cardiac** output.*

• Auscultate lung sounds for crackles, monitor respiration effort, and determine the presence and severity of orthopnea. *The pulmonary system adapts to the increased post CVP, which is believed to be caused by reduced capillary filtration from pulmonary basal membrane thickening, enhanced alveolar fluid clearance, and increased lymphatic drainage (Melenovsky, 2015).*

• Monitor serum and urine osmolality, serum sodium, blood urea nitrogen (BUN)/creatinine ratio, and hematocrit for abnormalities. **EB:** *Fluid overload is a causative factor for the occurrence of AKI. Volume overload leads to organ congestion and a resultant decrease in renal blood flow (Salahuddin, 2017).*

• BUN and creatinine are monitored currently as biomarkers of kidney injury and failure. **EB:** *Serum creatinine is an imperfect marker because its levels reflect delayed functional consequences of the injury rather than direct cell injury and is not sensitive and specific in the early diagnosis of AKI (TRIBE-AKI Consortium Investigators, 2017). BUN and creatinine is affected by fluid volume status and medications (Andreucci et al, 2016).*

• With head of bed elevated 30 to 45 degrees, monitor jugular veins for distention with the client in the upright position; assess for positive hepatojugular reflex. *Increased intravascular volume results in jugular vein distention as a result of backflow through the vena cava (Wagner & Hardin-Pierce, 2014).*

• Monitor the client's behavior for restlessness, anxiety, or confusion; use safety precautions if symptoms are present. *When excess fluid volume compromises cardiac output, the client may experience confusion, decreased consciousness, delirium, and HF (Wagner & Hardin-Pierce, 2014).*

▲ Monitor for the development of conditions that increase the client's risk for excess fluid volume, including HF, kidney failure, and liver failure, all of which result in decreased glomerular filtration rate and fluid retention. **EB:** *Other causes are increased intake of oral or intravenous (IV) fluids in excess of the client's cardiac and renal reserve levels, and increased levels of antidiuretic hormone (Ronco et al, 2012). Many clients with fluid overload have AKI, and fluid balance is an important indicator of outcomes. One study of end-stage renal disease patients with chronic fluid overload showed a strong risk factor for death (Zoccali et al, 2017).*

▲ Provide a restricted-sodium diet as appropriate if ordered. *Restricting the sodium in the diet will favor the renal excretion of excess fluid. Take care to avoid hyponatremia, which can cause serious complications including nausea, seizures, coma, and death (Rudge & Kim, 2014).*
▲ Monitor serum albumin level and provide protein intake as appropriate. *When plasma proteins, especially albumin, no longer sustain sufficient colloid osmotic pressure to counterbalance hydrostatic pressure, edema develops (Wagner & Hardin-Pierce, 2014).*
▲ Administer prescribed diuretics as appropriate; ensure adequate blood pressure before administration. If diuretic is administered intravenously, note and record the blood pressure and urine output after the dose. Monitor serum sodium for hyponatremia. **EBN:** *Increased arginine vasopressin (AVP) levels in HF patients lead to fluid retention by its actions on vasopressin receptors. Hyponatremia is one of the commonly encountered clinical problems among HF patients with a prevalence of about 20% on hospitalization and has been associated with increased length of stay and in-hospital and postdischarge mortality rates. Hyponatremia in HF is mainly dilutional secondary to neurohormonal activation, especially AVP resulting in free water retention and volume overload (Vinod et al, 2017).* **EB:** *Clinical practice guidelines on HF state that daily weight along with monitoring input and output is useful for monitoring effects of diuretic therapy (Wagner & Hardin-Pierce, 2014).*
• Monitor for side effects of diuretic therapy including orthostatic hypotension (especially if the client is also receiving angiotensin-converting enzyme [ACE] inhibitors), hypovolemia, and electrolyte imbalances (hypokalemia and hyponatremia). *Observe for hyperkalemia in clients receiving a potassium-sparing diuretic and in those on beta-blockers and ACE inhibitors (Rudge & Kim, 2014; Wagner & Hardin-Pierce, 2014).*
▲ Implement fluid restriction as ordered, especially when serum sodium is low; include all routes of intake. Schedule limited intake of fluids around the clock, and include the type of fluids preferred by the client. *Fluid restriction may decrease intravascular volume and myocardial workload. Overzealous fluid restriction should not be used because hypovolemia can worsen HF. Client involvement in planning will enhance participation in the necessary fluid restriction.*
• Maintain the rate of all IV infusions, using an IV pump. *This is done to prevent inadvertent exacerbation of excess fluid volume and to more accurately monitor fluid intake.*
• Turn clients with dependent edema at least every 2 hours and monitor for areas that may develop pressure ulcers. *Decreased oncotic pressure caused by low levels of albumin affects distribution of total body fluids. The association between low levels of albumin and increased risk for pressure ulcers may be caused by a change in tissue tolerance, with redistribution of fluid and formation of edema (Serra et al, 2014).*
▲ Provide ordered care for edematous extremities including compression, elevation, and muscle exercises. **EB:** *Treatments for clients with peripheral edema include elevation of the extremities above heart level, use of a specialty bed, and offloading of the extremity by repositioning or the use of pressure-offloading devices (Bly, 2016).*
• Promote a positive body image and good self-esteem. *Visible edema may alter the client's body image.* Refer to the care plan for Disturbed **Body Image.**
▲ Consult with the health care provider if signs and symptoms of excess fluid volume persist or worsen. *Pulmonary edema requires prompt treatment such as preload reducers, afterload reducers, and morphine to relieve anxiety (Mayo Foundation for Medical Education and Research, 2014).*

• Insert an indwelling urinary catheter if ordered and measure urine output hourly. Notify health care provider if output is less than 0.5 mL/kg/hr. *Urine output of less than 0.5 mL/kg/hr for 6 or more hours is defined as oliguria (Schetz et al, 2017).*
▲ Monitor blood pressure, heart rate, passive leg lift, mean arterial pressure, CVP, PAP, and cardiac output/index; note and report trends of increasing or decreasing pressures over time. *Alterations in these parameters may indicate that the client is going into shock. Hemodynamic criteria for cardiogenic shock are sustained hypotension (systolic blood pressure less than 90 mm Hg for at least 30 minutes) and a reduced cardiac index (less than 2.2 L/min/m^2) in the presence of elevated pulmonary capillary occlusion pressure (greater than 15 mm Hg), pulmonary congestion, dyspnea, and hypoxemia (Wagner & Hardin-Pierce, 2014; Van Diepen et al, 2017).*
▲ Monitor the effects of infusion of diuretic drips. Perform continuous renal replacement therapy (CRRT) as ordered if the client is critically ill and hemodynamically unstable and excessive fluid must be removed. **EBN:** *CRRT is indicated for hypervolemia, metabolic acidosis, and hyperkalemia (Dirkes, 2014).*

Geriatric

• Recognize that the presence of fluid volume excess is particularly serious in older adults. **EB:** The kidney undergoes age-related changes that include structural and functional changes, which may increase the incidence of AKI (Bolignano et al, 2014).
• Monitor electrolyte levels carefully, including sodium levels and potassium levels, with both increased and decreased levels possible. *Older adults are prone to electrolyte abnormalities caused by aging, decreased muscle mass, and decreased total body water (Mannesse et al, 2013). Also, the large number of medications that are taken can affect electrolyte levels. Many older clients receive selective serotonin reuptake inhibitors (SSRIs) for treatment of depression, which can result in hyponatremia (Varela Piñón & Adán-Manes, 2017). SSRIs are also known to be responsible for many sexual side effects such as altered libido, erectile dysfunction, vaginal dryness, ejaculatory disorders, and orgasmic problems, which are frequently reported by patients (Reisman, 2017).*
• Refer to the care plan for Risk for **Electrolyte** imbalance and the care plan for **Sexual Dysfunction.**

Home Care

• Assess client and family knowledge of disease processes causing excess fluid volume.
▲ Teach about disease process and complications of excess fluid volume, including when to contact the health care provider.
• Assess client and family knowledge and compliance with medical regimen, including medications, diet, rest, and exercise. Assist family with integrating restrictions into daily living. *Assistance with integration of cultural values, especially those related to foods, with medical regimen promotes compliance and decreased risk of complications.*
▲ Teach and reinforce knowledge of medications. Instruct the client not to use over-the-counter (OTC) medications (e.g., diet medications) without first consulting the provider.
▲ Instruct the client to make the primary health care provider aware of medications ordered by other health care providers.
• Identify emergency plan for rapidly developing or critical levels of excess fluid

volume when diuresing is not safe at home. *Excess fluid volume can be life-threatening.*
▲ Teach about signs and symptoms of both excess and deficient fluid volume, such as darker urine, dry mouth, and peripheral edema, and when to call the health care provider. *Urine color may be a simple indicator of hydration (Wagner & Hardin-Pierce, 2014).*

Client/Family Teaching and Discharge Planning

• Describe signs and symptoms of excess fluid volume and actions to take if they occur.
▲ Teach client on diuretics to weigh self daily in the morning and to notify the health care provider if there is a 2.2 pound (1 kg) or more weight gain (Wagner & Hardin-Pierce, 2014). **EB:** *Clinical practice guidelines on HF suggest that daily weight monitoring leads to early recognition of excess fluid retention, which, when reported, can be offset with additional medication to avoid hospitalization caused by HF decompensation (Wagner & Hardin-Pierce, 2014).*
▲ Teach the importance of fluid and sodium restrictions. Help the client and family devise a schedule for intake of fluids throughout the entire day. Refer to a dietitian concerning implementation of a low-sodium diet.
• Teach clients how to measure and document intake and output with common household measurements, such as cups.
▲ Teach how to take diuretics correctly: take one dose in the morning and second dose (if taken) no later than 4 p.m. Adjust potassium intake as appropriate for potassium-losing or potassium-sparing diuretics. Note the appearance of side effects such as weakness, muscle cramps, hypertension, or palpitations (Wagner & Hardin-Pierce, 2014).
• For the client undergoing hemodialysis, teach client the required restrictions in dietary electrolytes, protein, and fluid. Spend time with the client to detect any factors that may interfere with the client's compliance with the fluid restriction or restrictive diet. **EBN:** *Nonadherence to fluid restrictions, especially in patients undergoing hemodialysis, has been linked to numerous deleterious outcomes, including patient and provider frustration, treatment failure, illness complications and relapse, and mortality (Howren et al, 2016).*

Risk for deficient Fluid volume

Mary Beth Flynn Makic PhD, RN, CCNS, FAAN, FNAP

NANDA-I

Definition

Susceptible to experiencing decreased intravascular, interstitial, and/or intracellular fluid volumes, which may compromise health.

Risk Factors

Barrier to accessing fluid; insufficient fluid intake; insufficient knowledge about fluid needs

At-Risk Population

Extremes of age; extremes of weight; factors influencing fluid needs

Associated Condition

Active fluid volume loss; compromised regulatory mechanism; deviations affecting fluid absorption; deviations affecting fluid intake; excessive fluid loss through normal route; fluid loss through abnormal route; pharmaceutical agent

NIC, NOC, Client Outcomes, Nursing Interventions and *Rationales,* Client/Family Teaching, and References

Refer to care plan for Deficient **Fluid** volume

Frail Elderly syndrome

Cynthia DeLeon Thelen MSN, BSN, RN

NANDA-I

Definition

Dynamic state of unstable equilibrium that affects the older individual experiencing deterioration in one or more domains of health (physical, functional, psychological, or social) and leads to increased susceptibility to adverse health effects, in particular disability.

Defining Characteristics

Activity intolerance (00092), bathing self-care deficit (00108), decreased cardiac output (00029), fatigue (00093), feeding self-care deficit (00102), hopelessness (00124), imbalanced nutrition: less than body requirements (00002), impaired memory (00131), impaired physical mobility (00085), impaired walking (00088), social isolation (00053), toileting self-care deficit (00110)

Related Factors

Activity intolerance, anxiety, average daily physical activity is less than recommended for gender and age, decrease in energy, decrease in muscle strength, depression, exhaustion, fear of falling, immobility, impaired balance, impaired mobility, insufficient social support, malnutrition, muscle weakness, obesity, sadness, sedentary lifestyle, social isolation

At-Risk Population

Age >70 years, constricted living space, economically disadvantaged, ethnicity other than Caucasian, female gender, history of falls, living alone, low educational level, prolonged hospitalization, social vulnerability

NOC Outcomes (Nursing Outcomes Classification)

Suggested NOC Outcomes

Activity Tolerance; Balance; Exercise Participation; Hope; Physical Aging; Psychosocial Adjustment: Life Change; Client Satisfaction: Functional Assistance

Example NOC Outcomes with Indicators

Client Satisfaction: Functional Assistance as evidenced by the following indicators: Included in planning for optimal mobility and self-care/Encouraged to be as active as possible/Assistance with physical activity/Allowed to choose food for meals. (Rate the outcome and indicators of **Client Satisfaction: Functional Assistance:** 1 = not at all satisfied, 2 = somewhat satisfied, 3 = moderately satisfied, 4 = very satisfied, 5 = completely satisfied [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Remain living as independently as possible in the home or care setting of his or her choice
- Maintain safety when engaging in activities of daily living and ambulation
- Increase exercise and/or daily physical activity to build muscle strength
- Maintain a healthy weight

NIC Interventions (Nursing Interventions Classification)

Suggested NIC Interventions

Exercise Promotion; Exercise Promotion: Balance; Exercise Promotion: Strength Training; Hope Inspiration; Nutrition Therapy

Example NIC Activities—Frail Elderly Syndrome

Promote physical activities that build strength and improve balance and endurance

Nursing Interventions and *Rationales*

• Assess frailty with a tool such as the Frailty Index or the Edmonton Frail Scale. **EB:** *Apóstolo et al (2017) did a systematic review on diagnostic accuracy and predictive ability of frailty measures and found that the Frailty Index had good predictive reliability.* **EB:** *The Edmonton Frail Scale is a tool designed to identify frail older adults in clinical settings (Perna & Francis, 2017).*
• Recognize that balance and gait impairment are features of frailty and are risk factors for falls. **EB:** *Cadore et al (2013) did a systematic review of the literature and found that exercise interventions composed of strength, endurance, and balance training improve the rate of falls in frail older adults.* **EB:** *By reversing frailty through exercise interventions that engender fitness, older adults will remain physically independent longer (Bray et al, 2016).*
• Preserve physical functioning through individualized physical activity plans. **EB:** *Results from the LIFE-P study found that regular physical activity may reduce frailty, especially in individuals at higher risk of disability (Cesari et al, 2014).* **EB:** *de Labra et al (2015) did a systematic review of the literature and found that low physical activity has been shown to be one of the most common components of frailty.*
• Assess falls using a falls risk assessment tool such as the Hendrich II Fall Risk Model. **EBN:** *Falls are an important measure of nursing quality and patient safety (Swartzell, Fulton, & Friesth, 2013).*
• Assess risk of fracture using tools such as the Cardiovascular Health Study (CHS) or Study of Osteoporotic Fracture (SOF) indicators. **EBN:** *Chen et al (2017) did a systematic review of the literature and in total five studies included 103,783 older people and recorded 2960 fractures.*
• Evaluate the client's medications to determine whether medications increase the risk of frailty and/or are potentially inappropriate mediations (PIM), and if appropriate, consult with the client's health care provider regarding the client's medications. **EB:** *Polypharmacy is associated with increased risk of mortality in elderly people (Gómez et al, 2015).* **EB:** *The number of medications prescribed can be useful to help physicians be aware of the high risk for PIM (Tsao et al, 2016).*
▲ Refer to a dietitian for an individualized therapeutic diet. **EB:** *Micronutrient supplementation was associated with a significant increase in the Mini Nutritional Assessment score in persons at risk for malnutrition (von Arnim et al, 2013).* **EB:** *Malafarina et al (2013) did a systematic review of the literature about nutritional supplements in older adults and found that nutritional supplements are effective in the treatment of muscle mass loss, particularly in conjunction with physical exercise.*
• Refer to care plan for Readiness for enhanced **Nutrition** for additional interventions.
• Monitor weight loss. **EB:** *Weight loss is considered a main component of frailty syndrome (Yannakoulia et al, 2017).* **CEB:** *Milne et al (2009) did a systematic literature review and*

found that when given to older adults, nutritional supplements containing protein and energy result in weight gain.

• Encourage clients to engage in active lifestyles. **CEB:** *Peterson et al (2009) studied 2964 older adults for 5 years and found that sedentary older individuals had a greater likelihood of developing frailty than individuals who were engaged in exercise.*

• Provide an exercise-training program. **EB:** *Physical exercise training leads to improved cognitive functioning as well as psychological well-being in older adults who are frail (Langlois et al, 2013).*

• Promote the benefits of home-based exercise to older clients who are frail. **EB:** *Clegg et al (2014) conducted a study of 49 frail older adults and found evidence that the deterioration in mobility may be reduced through a 12-week home-based exercise intervention.*

• Use an interprofessional and person-centered approach for supporting frail older adults. **EBN:** *The focus of caring for frail older adults should not only be on medical problems but also on providing supportive services to help individuals maintain their independence and manage their lives despite frailty (Ebrahimi et al, 2014).* **EBN:** *Engaging patients, their family members, or care givers in care planning and goal setting during transitions is essential (Jeffs et al, 2017).*

• Develop a trusting and responsive relationship with frail clients. **EBN:** *Bindels et al (2013) qualitatively interviewed nurses (N = 23) and found that building a trusting relationship, along with competence, responsiveness, and attentiveness were important for providing frail older adults with good care.*

Multicultural, Home Care, and Client/Family Teaching

• The previously mentioned interventions may be adapted for multicultural, home care, and client family teaching.

Risk for Frail Elderly syndrome

Cynthia DeLeon Thelen MSN, BSN, RN

NANDA-I

Definition

Susceptible to a dynamic of unstable equilibrium that affects the older individual experiencing deterioration in one or more domain of health (physical, functional, psychological, or social) and leads to increased susceptibility to adverse health effects, in particular disability.

Risk Factors

Activity intolerance, anxiety, average daily physical activity is less than recommended for gender and age, decrease in energy, decrease in muscle strength, depression, exhaustion, fear of falling, immobility, impaired balance, impaired mobility, insufficient knowledge of modifiable factors, insufficient social support, malnutrition, muscle weakness, obesity, sadness, sedentary lifestyle, social isolation

At-Risk Population

Age >70 years, contrasted living space, economically disadvantaged, ethnicity other than Caucasian, female gender, history of falls, living alone, low educational level, prolonged hospitalization, social vulnerability

Associated Condition

Alteration in cognitive functioning, altered clotting process, anorexia, chronic illness, decrease in serum 25-hydroxyvitamin D concentration, endocrine, regulatory dysfunction, psychiatric disorder, sarcopenia, sarcopenic obesity, sensory deficit, suppressed inflammatory response, unintentional loss of 25% of body weight over one year, unintentional weight loss >10 pounds (>4.5 kg) in one year, walking 15 feet requires >6 seconds (4 meters > 5 seconds)

NIC, NOC, Client Outcomes, Nursing Interventions and *Rationales,* and References

Refer to care plan for **Frail Elderly** syndrome.

List of Planning Care by Letter: G

Impaired Gas exchange	Risk for dysfunctional Gastrointestinal motility	Dysfunctional Gastrointestinal motility
Risk for unstable blood Glucose level	Grieving	Complicated Grieving
Risk for complicated Grieving		

G

● = Independent; ▲ = Collaborative; **EBN** = Evidence-Based Nursing; **EB** = Evidence-Based

Impaired Gas exchange

Debra Siela PhD, RN, CCNS, ACNS-BC, CCRN-K, CNE, RRT

NANDA-I

Definition

Excess or deficit in oxygenation and/or carbon dioxide elimination at the alveolar-capillary membrane.

Defining Characteristics

Abnormal arterial blood gases; abnormal arterial pH; abnormal breathing pattern; abnormal skin color; confusion; decrease in carbon dioxide (CO_2) level; diaphoresis; dyspnea; headache on awakening; hypercapnia; hypoxemia; hypoxia; irritability; nasal flaring; restlessness, somnolence; tachycardia; visual disturbances

Related Factors

To be developed

Associated Condition

Alveolar-capillary membrane changes; ventilation-perfusion imbalance

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Respiratory Status: Gas Exchange, Ventilation

Example NOC Outcome with Indicators

Achieves appropriate **Respiratory Status: Gas Exchange** as evidenced by the following indicators: Cognitive status/Partial pressure of oxygen/Partial pressure of carbon dioxide/Arterial pH/Oxygen saturation. (Rate each indicator of **Respiratory Status: Gas Exchange:** 1 = severe deviation from normal range, 2 = substantial deviation from normal range, 3 = moderate deviation from normal range, 4 = mild deviation from normal range, 5 = no deviation from normal range [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Demonstrate improved ventilation and adequate oxygenation as evidenced by blood gas levels within normal parameters for that client
- Maintain clear lung fields and remain free of signs of respiratory distress
- Verbalize understanding of oxygen supplementation and other therapeutic interventions

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Acid-Base Management; Airway Management

Example NIC Activities—Acid-Base Management

Monitor for symptoms of respiratory failure (e.g., low PaO_2 and elevated $PaCO_2$ levels and respiratory muscle fatigue); Monitor determinants of tissue oxygen delivery (e.g., PaO_2, SaO_2, and hemoglobin levels, and cardiac output) if available

Nursing Interventions and *Rationales*

- Monitor respiratory rate, depth, and ease of respiration. Watch for use of accessory muscles and nasal flaring. *Normal respiratory rate is 14 to 16 breaths per minute in the adult (Bickley & Szilagyi, 2017). When the respiratory rate exceeds 30 breaths per minute, along with other physiological measures, a significant cardiovascular or respiratory alteration exists.*
- Auscultate breath sounds every 1 to 2 hours. The presence of crackles and wheezes may alert the nurse to airway obstruction, which may lead to or exacerbate existing hypoxia. *In severe exacerbations of chronic obstructive pulmonary disease (COPD), lung sounds may be diminished or distant with air trapping (Bickley & Szilagyi, 2017).*
- The nurse should consider respiratory rate, work of breathing, and lung sounds along with PaO_2 values, arterial oxygen saturation (SaO_2), oxygen saturation continuously using pulse oximetry (SpO_2), patient tidal volume, and minute ventilation. Presence of dyspnea, asynchronous chest and abdominal movements, accessory muscles, and agitation indicate potential oxygenation problems (Barton, Vanderspank-Wright, & Shea, 2016).
- Monitor the client's behavior and mental status for the onset of restlessness, agitation, confusion, and (in the late stages) extreme lethargy. *Changes in behavior and mental status can be early signs of impaired gas exchange. In the late stages the client becomes lethargic and somnolent (Lee, 2017).*
- ▲ Monitor oxygen saturation continuously using pulse oximetry (SpO_2) (Lee, 2017). Note blood gas results as available. *An oxygen saturation of less than 88% (normal is 95%–100%) or a partial pressure of oxygen of less than 55 mm Hg (normal is 80–100 mm Hg) indicates significant oxygenation problems (Bein et al, 2016; Siela & Kidd, 2017). Pulse oximetry is useful for tracking and/or adjusting supplemental oxygen therapy for clients with COPD (GOLD, 2017).*
- Monitor venous oxygen saturation to determine an index of oxygen balance to reflect between oxygen delivery and oxygen consumption (Dirks, 2017).
- Measurements of oxygenation supply in the macrocirculation include those made upstream from the tissue level. The parameters measured are arterial partial pressure of oxygen (PaO_2), arterial oxygen content (CaO_2), arterial oxygen saturation (SaO_2) determined on the basis of arterial blood gas (ABG) analysis and pulse oximetry (SpO_2), and ratio of PaO_2 to fraction of inspired oxygen (FiO_2) or the PF ratio. Measurements of oxygenation or oxygen extraction or consumption in the macrocirculation made downstream from tissues include tissue oxygen consumption, mixed venous oxygen saturation (SvO_2) or central venous oxygen saturation ($ScvO_2$), and blood levels of lactate (Siela & Kidd, 2017).
- Observe for cyanosis of the skin, and especially note color of the tongue and oral

mucous membranes. **EB:** *In central cyanosis both the skin and mucous membranes are affected because of seriously impaired pulmonary function from unventilated or underventilated alveoli. Peripheral cyanosis (skin only) usually indicates vasoconstriction or obstruction to blood flow (Loscalzo, 2016). Central cyanosis of the tongue and oral mucosa is indicative of serious hypoxia and is a medical emergency. Peripheral cyanosis in the extremities may be caused by activation of the central nervous system or exposure to cold and may or may not be serious (Bickley & Szilagyi, 2017).*

• Position the client in a semirecumbent position with the head of the bed at a 30- to 45-degree angle to decrease the aspiration of gastric, oral, and nasal secretions (Grap, 2009; Siela, 2010; American Association of Critical Care Nurses, 2016, 2017; Vollman, Dickinson, & Powers, 2017). *Evidence shows that mechanically ventilated clients have a decreased incidence of aspiration pneumonia if the client is placed in a 30- to 45-degree semirecumbent position as opposed to a supine position.*

• If the client has unilateral lung disease, position with head of bed at 30 to 45 degrees with "good lung down" in a side-lying position and affected lung up (Barton, Vanderspank-Wright, & Shea, 2016).

▲ If the client is acutely dyspneic, consider having the client lean forward over a bedside table, resting elbows on the table if tolerated. *Leaning forward can help decrease dyspnea, possibly because gastric pressure allows better contraction of the diaphragm (Langer et al, 2009; Mahler, 2014). This is called the tripod position and is used during times of distress, including when walking, leaning forward on the walker.*

• Help the client deep breathe and perform controlled coughing. Have the client inhale deeply, hold the breath for several seconds, and cough two or three times with the mouth open while tightening the upper abdominal muscles as tolerated. *Controlled coughing uses the diaphragmatic muscles, which makes the cough more forceful and effective.* If the client has excessive fluid in the respiratory system, see the interventions for Ineffective **Airway** clearance.

▲ Monitor the effects of sedation and analgesics on the client's respiratory pattern; use judiciously (Barton, Vanderspank-Wright, & Shea, 2016). *Both analgesics and medications that cause sedation can depress respiration at times. However, these medications can be very helpful for decreasing the sympathetic nervous system discharge that accompanies hypoxia (Spruit et al, 2013).*

• Schedule nursing care to provide rest and minimize fatigue. *The hypoxic client has limited reserves; inappropriate activity can increase hypoxia (Spruit et al, 2013).*

▲ Administer humidified oxygen through an appropriate device (e.g., nasal cannula or Venturi mask per the health care provider's order); aim for an oxygen (O_2) saturation level of 90% or above. Oxygen should be titrated to target an SpO_2 of 94% to 98%, except with carbon monoxide poisoning (100% oxygen), acute respiratory distress syndrome (ARDS) (88%–95%), those at risk for hypercapnia (88%–92%), and premature infants (88%–94%) (Blakeman, 2013). Watch for onset of hypoventilation as evidenced by increased somnolence. *There is a fine line between ideal and excessive oxygen therapy; increasing somnolence is caused by retention of CO_2 leading to CO_2 narcosis (Wong & Elliott, 2009). Promote oxygen therapy during a COPD exacerbation. Supplemental oxygen should be titrated to improve the client's hypoxemia with a target of 88% to 92% (GOLD, 2017).*

• Once oxygen is started, ABGs should be checked 30 to 60 minutes later to ensure satisfactory oxygenation without CO_2 retention or acidosis (GOLD, 2017). **EBN:** *Use of high-flow nasal cannula oxygen therapy may improve gas exchange and oxygenation in acute hypoxemic respiratory failure (Lenglet et al, 2012; Sztrymf et al, 2012; Rittayamai,*

Tscheikuna, & Rujiwit, 2014; Siela & Kidd, 2017).

• *Supplemental oxygen can cause toxicity and should be administered at the lowest level that achieves an arterial saturation appropriate for a given patient (Budinger & Mutlu, 2013; Helmerhorst et al, 2015). Conservative oxygen strategies that target a goal of 88% to 92% SpO_2 levels in patients receiving invasive mechanical ventilation appear justified (Panwar et al, 2016).*

• Assess nutritional status including serum albumin level and body mass index (BMI). *Malnourishment in a client with COPD has a negative effect on the course of the disease; it can result in loss of muscle mass in the respiratory muscles, including the diaphragm, which can lead to respiratory failure (GOLD, 2017).*

▲ Assist the client to eat small meals frequently and use dietary supplements as necessary. Engage dietary issues by evaluating and creating an optimal nutrition plan. For some clients, drinking 30 mL of a supplement every hour while awake can be helpful.

• If the client is severely debilitated from chronic respiratory disease, consider the use of a wheeled walker to help in ambulation.

▲ Watch for signs of psychological distress including anxiety, agitation, and insomnia.

▲ Refer the COPD client to a pulmonary rehabilitation program. *Pulmonary rehabilitation is now considered a standard of care for the client with COPD (Nici et al, 2009; Spruit et al, 2013; GOLD, 2017).*

Critical Care

▲ Assess and monitor oxygen indices such as the PF ratio (FiO_2:PO_2) and venous oxygen saturation/oxygen consumption (SvO_2 or $ScvO_2$) (Headley & Giuliano, 2011; Dirks, 2017; Siela & Kidd, 2017; Lough, 2018).

▲ Turn the client every 2 hours. Monitor mixed venous oxygen saturation closely after turning. If it drops below 10% or fails to return to baseline promptly, turn the client back into the supine position and evaluate oxygen status. If the client does not tolerate turning, consider use of a kinetic bed that rotates the client from side to side in a turn of at least 40 degrees (St. Clair & MacDermott, 2017).

▲ If the client has ARDS with difficulty maintaining oxygenation, then consider positioning the client prone with the upper thorax and pelvis supported. Monitor oxygen saturation and turn the client back to supine position if desaturation occurs.

EB: *Oxygenation levels have been shown to improve in the prone position, probably because of decreased shunting and better perfusion of the lungs (Gattinoni et al, 2013; Drahnak & Custer, 2015; Barton, Vanderspank-Wright, & Shea, 2016; Bein et al, 2016; Vollman, Dickinson, & Powers, 2017; Vollman, Sole, Quinn, 2017). Prone ventilation significantly reduced mortality in clients with severe acute hypoxemic respiratory failure, but not in clients with less severe hypoxemia (Sud et al, 2010; Gattinoni et al, 2013).* A PaO_2 lower than 150 mm Hg measured on at least 5 cm H_2O positive end-expiratory pressure (PEEP) is a recommended threshold for the application of proning (Gattinoni et al, 2013). Note: If the client becomes ventilator dependent, see the care plan for Impaired spontaneous **Ventilation.**

▲ High levels of PEEP likely improve oxygenation and gas exchange (Suzumura et al, 2014; Barton, Vanderspank-Wright, & Shea, 2016).

Geriatric

▲ Use central nervous system depressants and other sedating agents carefully to avoid decreasing respiration effort (rate and depth of breathing).
▲ Maintain appropriate levels of supplemental oxygen therapy for clients with impaired gas exchange and hypoxemia (GOLD, 2017).

Home Care

• Work with the client to determine what strategies are most helpful during times of dyspnea. Educate and empower the client to self-manage the disease associated with impaired gas exchange. **EBN/EB:** *A study found that use of oxygen, self-use of medication, and getting some fresh air were most helpful in dealing with dyspnea (Thomas, 2009). Evidence-based reviews have found that self-management offers COPD clients effective options for managing the illness, leading to more positive outcomes (Spruit et al, 2013; GOLD, 2017).*
• Collaborate with health care providers regarding long-term oxygen administration for chronic respiratory failure clients with severe resting hypoxemia. Administer long-term oxygen therapy greater than 15 hours daily for P_{O_2} less than 55 or SaO_2 at or below 88% (GOLD, 2017).
• Assess the home environment for irritants that impair gas exchange. Help the client adjust the home environment as necessary (e.g., install an air filter to decrease the level of dust).
▲ Refer the client to occupational therapy as necessary to assist the client in adapting to the home and environment and in energy conservation (GOLD, 2017).
• Assist the client with identifying and avoiding situations that exacerbate impairment of gas exchange (e.g., stress-related situations, exposure to pollution of any kind, proximity to noxious gas fumes such as chlorine bleach). *Irritants in the environment decrease the client's effectiveness in accessing oxygen during breathing.*
• Refer to GOLD guidelines for management of home care and indications of hospital admission criteria (GOLD, 2017).
• Instruct the client to keep the home temperature above 68°F (20°C) and to avoid cold weather. *Cold air temperatures cause constriction of the blood vessels, which impairs the client's ability to absorb oxygen (Bickley* & Szilagyi, *2017).*
• Instruct the client to limit exposure to persons with respiratory infections. *Viruses, bacteria, and environmental pollutants are the main causes of exacerbations of COPD (GOLD, 2017).*
• Instruct the family in the complications of the disease and the importance of maintaining the medical regimen, including when to call a health care provider.
▲ Refer the client for home health aide services as necessary for assistance with activities of daily living. *Clients with decreased oxygenation have decreased energy to perform personal and role-related activities.*
• When respiratory procedures are implemented, explain equipment and procedures to family members and provide needed emotional support. *Family members assuming responsibility for respiratory monitoring often find this stressful (Langer et al, 2009).*
• When electrically based equipment for respiratory support is implemented, evaluate home environment for electrical safety, proper grounding, and so on. Ensure that notification is sent to the local utility company, the emergency medical team, and police and fire departments. *Notification is important to provide for priority service.*
▲ Assess family role changes and coping ability. Refer the client to medical social services as appropriate for assistance in adjusting to chronic illness. **CEB:** *Inability to maintain the level of social involvement experienced before illness leads to frustration and anger in the client and may create a threat to the family unit (Langer et al, 2009).*

• Support the family of the client with chronic illness. *Severely compromised respiratory functioning causes fear and anxiety in clients and their families. Reassurance from the nurse can be helpful (Rose et al, 2014).*

Client/Family Teaching and Discharge Planning

• Teach the client how to perform pursed-lip breathing and inspiratory muscle training, and how to use the tripod position. Have the client watch the pulse oximeter to note improvement in oxygenation with these breathing techniques. **CEB:** *Pursed lip breathing results in increased use of intercostal muscles, decreased respiratory rate, and improved oxygen saturation levels (Mahler, 2014). Pursed-lip breathing may relieve dyspnea in advanced COPD (Mahler, 2014). A systematic review found that inspiratory muscle training was effective in increasing endurance of the client and decreasing dyspnea (Langer et al, 2009). Inspiratory muscle training likely improves breathlessness during exercise and/or with activities of daily living in patients with COPD and congestive heart failure (CHF) who exhibit inspiratory muscle weakness (Mahler, 2014).*
• Teach the client energy conservation techniques and the importance of alternating rest periods with activity. See nursing interventions for **Fatigue.**
▲ Teach the importance of not smoking. Refer to smoking cessation programs, and encourage clients who relapse to keep trying to quit. Ensure that clients receive appropriate medications to support smoking cessation from the primary health care provider. **EB:** *Patients should be referred to a comprehensive smoking cessation program, incorporating behavior change techniques that focus on enhancing patient motivation and confidence, patient education, and pharmacological and nonpharmacological interventions (GOLD, 2017).*
▲ Instruct the family regarding home oxygen therapy if ordered (e.g., delivery system, liter flow, safety precautions). *Long-term oxygen therapy can improve survival, exercise ability, sleep, and ability to think in hypoxemic clients. Client education improves compliance with prescribed use of oxygen (GOLD, 2017).*
▲ Teach the client the need to receive a yearly influenza vaccine. *Receiving a yearly influenza vaccine is helpful to prevent exacerbations of COPD (GOLD, 2017).*
• Teach the client relaxation techniques to help reduce stress responses and panic attacks resulting from dyspnea. **EB:** *Relaxation therapy can help reduce dyspnea and anxiety (Langer et al, 2009).*
• Teach the client to use music, along with a rest period, to decrease dyspnea and anxiety (Mahler, 2014; Loscalzo, 2016).

Risk for dysfunctional Gastrointestinal motility

Mary Beth Flynn Makic PhD, RN, CCNS, FAAN, FNAP

NANDA-I

Definition

Susceptible to increased, decreased, ineffective, or lack of peristaltic activity within the gastrointestinal system, which may compromise health.

Risk Factors

Anxiety; change in water source; eating habit change; immobility; malnutrition; sedentary lifestyle; stressors; unsanitary food preparation

At-Risk Population

Aging; ingestion of contaminated material; prematurity

Associated Condition

Decrease in gastrointestinal circulation; diabetes mellitus; enteral feedings; food intolerance; gastroesophageal reflux disease; infection; pharmaceutical agent; treatment regimen

NIC, NOC, Client Outcomes, Nursing Interventions and *Rationales*, Client/Family Teaching and Discharge Planning, and References

Refer to care plan for Dysfunctional **Gastrointestinal** motility.

Dysfunctional Gastrointestinal motility

Rosemary Koehl Lee DNP, ARNP, ACNP-BC, CCNS, CCRN

NANDA-I

Definition

Increased, decreased, ineffective, or lack of peristaltic activity within the gastrointestinal system.

Defining Characteristics

Abdominal cramping; abdominal pain; absence of flatus; acceleration of gastric emptying; bile-colored gastric residual; change in bowel sounds; diarrhea; difficulty with defecation; distended abdomen; hard, formed stool; increase in gastric residual; nausea; regurgitation; vomiting.

Related Factors

Anxiety; change in water source; eating habit change; immobility; malnutrition; sedentary lifestyle; stressors; unsanitary food preparation

At-Risk Population

Aging; ingestion of contaminated material; prematurity

Associated Condition

Decrease in gastrointestinal circulation; diabetes mellitus; enteral feedings; food intolerance; gastroesophageal reflux disease; infection; pharmaceutical agent; treatment regimen

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Gastrointestinal Function; Electrolyte and Acid-Base Balance; Fluid Balance; Hydration; Nausea and Vomiting Control

Example NOC Outcome with Indicators

Gastrointestinal Function as evidenced by the following indicators: Bowel sounds/Stool soft and formed/Appetite present without evidence of reflux, nausea, or vomiting/Reported normal abdominal comfort/Abdomen soft to palpation without evidence of distention. (Rate the outcome and indicators of **Gastrointestinal Function:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Be free of abdominal distention and pain
- Have normal bowel sounds
- Pass flatus rectally at intervals
- Defecate formed, soft stool every day to every third day
- State has an appetite
- Be able to eat food without nausea and vomiting

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Gastric Motility Management

Example NIC Activities—Gastric Motility Management

Evaluate use of prokinetics for delayed gastric motility; Suggest change in dietary habits to either increase or decrease gastric motility, depending on the presenting complaint

Nursing Interventions and *Rationales*

- Monitor for abdominal distention, and presence of abdominal pain, weight loss, nausea, vomiting, obstipation, or diarrhea. *The acute onset of abdominal distention in conjunction with symptoms of cramping pain, weight loss, nausea, vomiting, constipation, or diarrhea warrants further evaluation for disorders that cause intestinal obstruction (Nagarwala, Dev, & Markin, 2016).*
- Inspect, auscultate for bowel sounds noting characteristics and frequency; palpate and percuss the abdomen. *Hypoactive bowel sounds are found with decreased motility as with peritonitis from paralytic ileus or from late bowel obstruction. Hyperactive bowel sounds are associated with increased motility (Nagarwala, Dev, & Markin, 2016).*
- Review history noting any anorexia or nausea/vomiting. Other symptoms may include relation of symptoms to meals, especially if aggravated by food, satiety, postprandial fullness/bloating, and weight loss or weight loss with severe gastroparesis. *These are signs of abnormal gastric motility (Camilleri, 2016).*
- Monitor for fluid deficits by checking skin turgor and moisture of tongue, daily weights, input and output, and electrolyte values. Refer to care plan for Deficient **Fluid** volume if relevant.
- Monitor for nutritional deficits by keeping close track of food intake. Review laboratory studies that affirm nutritional deficits, such as decreased albumin and

serum protein levels, liver profile, glucose, fecal analysis, and an electrolyte panel. Refer to care plan for Imbalanced **Nutrition:** less than body requirements or Risk for **Electrolyte** imbalance as appropriate.

Slowed Gastric Motility

• *Monitor the client for signs and symptoms of decreased gastric motility, which may include nausea after meals, vomiting, feeling full quickly while eating, abdominal bloating, and abdominal pain (Camilleri, 2016).*
▲ Monitor daily laboratory studies and point of care testing blood glucose levels ensuring ordered glucose levels are performed and evaluated. **EB:** *Elevated blood glucose levels can cause delayed gastric emptying; therefore it is important to normalize blood glucose levels (Wall, 2018).*
• Obtain a thorough gastrointestinal history if the client has diabetes, because he or she is at high risk for gastroparesis and gastric reflux. *Gastroparesis with delayed emptying of the stomach is a well-known complication of diabetes (Camilleri, 2016).*
▲ If client has nausea and vomiting, then provide an antiemetic and intravenous fluids as ordered. Offer or perform oral hygiene after vomiting. Refer to the care plan for **Nausea.**
▲ Evaluate medications the client is taking. Recognize that vasopressors, opioids, or anticholinergic medications can cause gastric slowing (Magidson & Martinez, 2016).
▲ Review laboratory and other diagnostic tools, including complete blood count, amylase, and thyroid-stimulating hormone level, glucose with other metabolic studies, upper endoscopy, and gastric-emptying scintigraphy. *The diagnosis of diabetic gastroparesis is made when other causes are excluded and postprandial gastric stasis is confirmed by gastric emptying scintigraphy, which is considered the gold standard for diagnosing gastroparesis (Camilleri, 2016).*
▲ Consider abdominal massage for relief of constipation. **EB:** *Two small randomized controlled studies identified that abdominal massage may relieve constipation and improve quality of life (Kassolik et al, 2015; Turan & Turkinaz, 2016).*
▲ Obtain a nutritional consult, considering a small particle size diet or diets lower or higher in liquids or solids, depending on gastric motility. **EB:** *A small (N = 45) randomized controlled trial found that diets with smaller particle size reduced the symptoms of gastroparesis in diabetic clients (Olausson et al, 2014).*
▲ If the client is unable to eat or retain food, consult with the registered dietitian and health care provider, considering further nutritional support in the form of enteral or parenteral feedings for the client with gastroparesis. *Some clients require supplementation with either enteral or parenteral nutrition for survival.*
▲ If the client is receiving gastric enteral nutrition, see the care plan Risk for **Aspiration.**
▲ Administer medications that increase gastrointestinal motility as ordered (Nagarwala, Dev, & Markin, 2016).

Postoperative Ileus

• Observe for complications of delayed intestinal motility. Symptoms include vague abdominal pain and distention, nausea, vomiting, anorexia, sometimes bloating, and tympany to percussion. Clients may or may not pass flatus and some stool (Van Bree et al, 2014).
▲ Recommend chewing gum for the abdominal surgery client who is experiencing an

ileus, is not at risk for aspiration, and has normal dentition. **EB:** *Gum chewing may decrease postoperative ileus because it acts as a sham feeding, potentially stimulating gastric and bowel motility. A meta-analysis found that using chewing gum reduces the time of postoperative ileus (Sundsted, Liton, & Bundrick, 2016).*

• Help the client out of bed to walk at least two times per day. Assist client to sit in a rocking chair to rock back and forth. *Exercise may increase gastrointestinal motility.*

▲ If postoperative ileus is associated with opioid pain medication, ensure opioids are decreased or ideally discontinued. Use nonsteroidal antiinflammatory drugs for pain as feasible and if not contraindicated (Cagir, 2016).

▲ Note serum electrolyte levels, especially potassium and magnesium. *A low potassium level decreases the function of intestinal smooth muscle and can result in an ileus. A low magnesium level makes the body refractory to potassium replacement (Viera & Wouk, 2015; Nagarwala, Dev, & Markin, 2016).*

Increased Gastrointestinal Motility

▲ Observe for complications of gastric surgeries such as dumping syndrome. *This syndrome is the effect of changes in size and function of the stomach, with rapid dumping of hyperosmolar food into the intestines (Schattner & Grossman, 2016).*

• Watch for nausea, vomiting, bloating, cramping, diarrhea, dizziness, and fatigue. *These are common signs and symptoms of early rapid gastric emptying (Schattner & Grossman, 2016).*

• Monitor for low blood sugar, weakness, sweating, and dizziness 1 to 3 hours after eating because this is when late rapid gastric emptying may occur. Late rapid gastric emptying is associated with low blood sugar (Schattner & Grossman, 2016).

▲ Order a nutritional consult to discuss diet changes. The diet may vary depending on the kind of surgery causing dumping syndrome. *Encourage small meals that are low in carbohydrates and fats. Space fluids around meal times (Schattner & Grossman, 2016).*

▲ Give intravenous fluids as ordered for the client complaining of diarrhea with weakness and dizziness. Monitor electrolyte panel and acid-base balance. *Severe diarrhea can cause deficient fluid volume with extreme weakness and metabolic acidosis.*

- ❍ Offer bathroom, commode, or bedpan assistance, depending on frequency, amount of diarrhea, and condition of client.
- ❍ Monitor rectal area for decreased skin integrity, and apply barrier creams as needed to protect and treat skin.
- ❍ Consider a bowel management system for bed-bound patients with frequent loose stools. This will protect the perineal skin and minimize spread of infection.

• Refer to the care plans for the nursing diagnoses of Deficient **Fluid** volume, **Nausea,** Impaired **Skin** integrity, and **Diarrhea** as relevant.

Pediatric

• Assess infants and children with suspected delayed gastric emptying for fullness and vomiting. Babies and children with delayed gastric emptying take longer to get hungry again and throw up undigested or partially digested food several hours after feeding (Westfal & Goldstein, 2017).

▲ Observe for nutritional and fluid deficits with assessment of skin turgor, mucous membranes, fontanels, furrows of the tongue, electrolyte panel, fluid status, input and output, and daily weights (Islam, 2015).

▲ Recommend gentle massage for preterm infants as appropriate. **EB:** *With massage, there was increased vagal activity. This was then associated with increased gastric motility and greater weight gain (Field, Diego, & Hernandez-Reif, 2011).*

Geriatric

• Closely monitor diet and medication use/side effects because they affect the gastrointestinal system. Watch for constipation. *Many gastrointestinal functions are slowed in older adults (Baker & Blakely, 2017).*
▲ Watch for symptoms of dysphagia, gastroesophageal reflux disease, dyspepsia, irritable bowel syndrome, maldigestion, and reduced absorption of nutrients. *These are common gastrointestinal disorders in older adults (Baker & Blakely, 2017).*

Client/Family Teaching and Discharge Planning

• Teach the client and caregivers about medications, reinforcing side effects as they relate to gastrointestinal function.
• Teach client and caregivers to report signs and symptoms that may indicate further complications including increased abdominal girth, projectile vomiting, and unrelieved acute cramping pain (bowel obstruction).
• Review signs and symptoms of dehydration with client and caregivers.

Risk for unstable blood Glucose level

Paula D. Hopper MSN, RN, CNE

NANDA-I

Definition

Susceptible to variation in serum levels of glucose from the normal range, which may compromise health.

Risk Factors

Average daily physical activity is less than recommended for gender and age; does not accept diagnosis; excessive stress; excessive weight gain; excessive weight loss; inadequate blood glucose monitoring; ineffective medication management; insufficient diabetes management; insufficient dietary intake; insufficient knowledge of disease management; insufficient knowledge of modifiable factors; nonadherence to diabetes management plan

At-Risk Population

Alteration in mental status; compromised physical health status; delay in cognitive development; rapid growth period

Associated Condition

Pregnancy

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Compliance Behavior: Prescribed Diet; Compliance Behavior: Prescribed Medication; Coping; Endurance; Knowledge: Diabetes Management; Knowledge: Treatment Regimen; Nutritional Status; Personal Health Status; Self-Management: Diabetes; Weight Maintenance Behavior

Example NOC Outcome with Indicators

Blood Glucose Level as evidenced by the following indicators: Blood glucose/Glycosylated hemoglobin/Fructosamine/Urine glucose/Urine ketones. (Rate the outcome and indicators of **Blood Glucose Level:** 1 = severe deviation from normal range, 2 = substantial deviation from normal range, 3 = moderate deviation from normal range, 4 = mild deviation from normal range, 5 = no deviation from normal range [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- For most adults, maintain the following glucose targets (American Diabetes Association [ADA], 2017, S52); consult primary care provider for client-specific goals
  - A_{1C} less than 7% (normal level <5.7%)
  - Preprandial blood glucose between 80 and 130 mg/dL
  - Peak postprandial (1–2 hours after beginning of meal) glucose below 180 mg/dL
- For children and adolescents with type 1 diabetes, maintain the following glucose targets (ADA, 2017, S107):
  - A_{1C} less than 7.5%; a goal of less than 7% is appropriate if it can be achieved without excessive hypoglycemia
- Maintain blood glucose for children and adolescents as follows (ADA, 2017, S107):

    - Preprandial between 90 and 130 mg/dL
    - Bedtime/overnight between 90 and 150 mg/dL
- In pregnant women, maintain blood glucose as follows (ADA, 2017, S116):
    - Preprandial ≤95 mg/dL
    - One-hour postprandial level at or below 140 mg/dL
    - Two-hour postprandial at or below 120 mg/dL
- In pregnant mothers with preexisting type 1 or 2 diabetes blood glucose as follows (ADA, 2017, S115):
    - Fasting ≤95 mg/dL
    - One-hour postprandial ≤140 mg/dL
    - Two-hour postprandial glucose at ≤120 mg/dL
- In older adults, maintain blood glucose values as follows (ADA, 2017, S101):
    - Healthy older adults: preprandial blood glucose 90 to 130 mg/dL; bedtime 90 to 150 mg/dL
    - Older adults with complex coexisting chronic illness: preprandial blood glucose 90 to 150 mg/dL; bedtime 100 to 180 mg/dL
