    - Older adult end-stage chronic illness or moderate to severe cognitive impairment: preprandial blood glucose 100 to 180 mg/dL; bedtime 110 to 200 mg/dL
- Maintain blood glucose in critically ill hospitalized clients between 140 and 180 mg/dL (ADA, 2017, S121)

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Hypoglycemia Management; Hyperglycemia Management

Example NIC Activities—Hypoglycemia Management

Monitor blood glucose levels, as indicated; Provide simple carbohydrate, as indicated

Nursing Interventions and *Rationales*

▲ Monitor blood glucose in hospitalized patients who are eating, before meals; who are not eating, every 4 to 6 hours; and who are receiving intravenous (IV) insulin, every 30 minutes to 2 hours. **EB:** *Hypoglycemia and hyperglycemia in the hospitalized patient are associated with adverse outcomes, including death (ADA, 2017, S120).*

▲ In patients receiving multiple-dose insulin (MDI) or insulin pump therapy, obtain blood glucose before meals and snacks, at bedtime, occasionally after meals, before exercise or critical tasks such as driving, if low blood glucose is suspected, and after treatment for low blood glucose until normoglycemic. **EB:** *Self-monitoring of blood glucose (SMBG) helps guide treatment and self-management decisions (ADA, 2017, S48).* **EB:** *Evidence supports a correlation between SMBG frequency and lower A_{1C} in patients with type 1 diabetes (ADA, 2017, S48).*

▲ Consider continuous glucose monitoring (CGM) in clients with type 1 diabetes on intensive insulin regimens. **EB:** *"When used properly, continuous glucose monitoring (CGM) in conjunction with intensive insulin regimens is a useful tool to lower A_{1C} in selected adults (aged ≥25 years) with type 1 diabetes" (ADA, 2017).*

▲ Evaluate A_{1C} level for glucose control over previous 3 months. **EB:** *"A_{1C} reflects average glycemia over approximately 3 months and has a strong predictive value for diabetes*

complications… A reasonable A_{1C} goal for many nonpregnant adults is 7% (53 mmol/mol)" (ADA, 2017, S50).

▲ Consider monitoring 2 hours after the start of meals in individuals who have premeal glucose values within target but have A_{1C} values above target. **EB:** *"It is clear that postprandial hyperglycemia, like preprandial hyperglycemia, contributes to elevated A_{1C} levels" (ADA, 2017, S52).*

• Monitor for signs and symptoms of hypoglycemia, such as shakiness, dizziness, sweating, hunger, headache, pallor, behavior changes, confusion, or seizures. **EB:** *"Mild hypoglycemia may be inconvenient or frightening to patients with diabetes. Severe hypoglycemia … can progress to loss of consciousness, seizure, coma, or death" (ADA, 2017, S53).*

• If the client is experiencing signs and symptoms of hypoglycemia, test glucose; if the result is below 70 mg/dL, administer 15 to 20 g glucose. Pure glucose is the preferred treatment, but any form of carbohydrate that contains glucose will suffice (a cup of fruit juice or regular [not diet] soda, one cup of milk, a small piece of fruit, or three to four glucose tablets). Avoid treating with foods that contain fat. Repeat test in 15 minutes and repeat treatment if indicated. Once blood glucose returns to normal, the individual should consume a meal or snack to prevent recurrence of hypoglycemia. **EB:** *"Treatment of hypoglycemia (plasma glucose <70 mg/dL) requires ingestion of glucose-containing or carbohydrate-containing foods. The acute glycemic response correlates better with the glucose content than with the carbohydrate content of the food. Although pure glucose is the preferred treatment, any form of carbohydrate that contains glucose will raise blood glucose. Added fat may retard and then prolong the acute glycemic response" (ADA, 2017, S53–S54).*

▲ Clients who experience asymptomatic hypoglycemia should raise their glucose targets to avoid hypoglycemia for several weeks. **EB:** *"Several weeks of avoidance of hypoglycemia has been demonstrated to improve counterregulation and hypoglycemia awareness in many patients" (ADA, 2017, S54).*

• Avoid carbohydrate foods that are also high in protein to prevent or treat hypoglycemia. **EB:** *"In individuals with type 2 diabetes, ingested protein appears to increase insulin response without increasing plasma glucose concentrations. Therefore, carbohydrate sources high in protein should not be used to treat or prevent hypoglycemia" (ADA, 2017, S35).*

• Monitor for signs and symptoms of hyperglycemia, such as increased thirst or urination, or high blood or urine glucose levels. **EB:** *"Better glycemic control is associated with significantly decreased rates of development and progression of microvascular (retinopathy and diabetic kidney disease) and neuropathic complications" (ADA, 2017, S50).*

▲ Monitor fluid balance and replace fluids in clients with diabetic ketoacidosis. **EB:** *Prompt rehydration is vital to restore circulating volume and tissue perfusion, clear ketones, and correct electrolyte imbalances … hydration alone restores circulatory volume and tissue perfusion; improves glycaemic control and acid base balance, and reduces counterregulatory hormones" (Tran et al, 2017).*

▲ Avoid use of sliding scale insulin alone in hospitalized patients. **EB:** *"An insulin regimen including basal, bolus, and correction (sliding scale) insulin is preferred, to prevent hyperglycemia. Sliding scale insulin only corrects blood sugar that is already high" (ADA, 2017, S122).*

• Prime IV tubing with 20 mL of diluted insulin solution before initiating insulin drip. **CEB:** *Glucose adsorbs to some IV tubing; priming with 20 mL is enough to minimize this effect (Goldberg et al, 2006; Zahid et al, 2008).*

▲ Evaluate the client's medication regimen for medications that can alter blood glucose. Some asthma medications, some antipsychotic and antidepressant agents, thiazide diuretics, and glucocorticoids, among others, can cause hyperglycemia. Aspirin and beta-blockers are among agents that can cause hypoglycemia (National Prescribing Service [NPS], 2017).
▲ Refer client to a dietitian for individualized medical nutrition therapy (MNT) instruction. **EB:** *"MNT delivered by a registered dietitian is associated with A_{1C} decreases of 0.3% to 1% for people with type 1 diabetes (38–40) and 0.5% to 2% for people with type 2 diabetes" (ADA, 2017, S34).*
▲ Refer people with type 1 diabetes and those with type 2 diabetes who are prescribed a flexible insulin therapy program for education on how to use carbohydrate counting (and in some cases fat and protein gram estimation) to determine mealtime insulin dosing. **EB:** *Education regarding the carbohydrate-counting approach to meal planning can assist with effectively modifying insulin dosing from meal to meal and improve glycemic control (ADA, 2017, S36).*
▲ Refer overweight and obese clients with type 2 diabetes for diet, activity, and behavioral therapy. **EB:** *"Modest weight loss, defined as sustained reduction of 5% of initial body weight, has been shown to improve glycemic control and to reduce the need for glucose-lowering medications" (ADA, 2017, S36). Structured exercise programs over 8 weeks have been shown to reduce A_{1C} by 0.66% (ADA, 2017, S37).*
• For interventions regarding foot care, refer to the care plan Ineffective peripheral **Tissue Perfusion.**

Geriatric

• Watch for age-related cognitive changes that can impair self-management of diabetes. **EBN:** *"Advanced age is associated with higher rates of cognitive dysfunction, causing difficulty in carrying out complex care activities such as glucose monitoring and adjustment of insulin doses" (Munshi et al, 2016).*
▲ Consider relaxing glucose targets for older adults. **EB:** *"Hypoglycemia is the leading limiting factor in the glycemic management of type 1 and insulin-treated type 2 diabetes. Multiple factors increase the risk of hypoglycemia in older adults, including impaired renal function, slowed hormonal regulation and counterregulation, variable appetite and nutritional intake, polypharmacy, and slowed intestinal absorption. The strongest predictors of severe hypoglycemia have been found to be advanced age, recent hospitalization, and polypharmacy, all of which are common in the (long term care) population" (Munshi et al, 2016).*
▲ In clients with diabetes who require tube feedings, use a diabetes-specific formulation such as Glucerna or Glytrol. **EB:** *"Randomized controlled trials have found diabetes specific formulas for blood glucose management" (Munshi et al, 2016).*

Pediatric

▲ Treat hypoglycemia in newborn infants with 0.5 mL/kg oral (buccal) dextrose gel. **EB:** *"Neonatal hypoglycaemia … can be associated with brain injury." "Treatment of infants with neonatal hypoglycaemia with 40% dextrose gel reduces the incidence of mother-infant separation for treatment"* (*Weston et al, 2016*).
• Teach children and adolescents (and their parents) with type 1 diabetes or on intensive insulin regimens (MDI or insulin pump therapy) to perform SMBG before meals and snacks, occasionally postprandially, at bedtime, before exercise, when they suspect low blood glucose, after treating low blood glucose until they are

normoglycemic, and before critical tasks such as driving. **EB:** *"A database study of almost 27,000 children and adolescents with type 1 diabetes showed that … increased daily frequency of SMBG was significantly associated with lower A_{1C} (−0.2% per additional test per day, leveling off at five tests per day) and with fewer acute complications" (ADA, 2017, S49).*

• Teach parents and children that children and adolescents with type 1 and 2 diabetes should spend 60 minutes daily in moderate to vigorous aerobic activity, and at least 3 days/week in muscle/bone strengthening activity. *"Research is limited on children and activity in diabetes, therefore they should follow general Centers for Disease Control recommendations for children" (ADA, 2017, S37).*

Home Care

▲ Teach family and others having close contact with the person with diabetes how to use an emergency glucagon kit (as prescribed). **EB:** *If the patient is unable to swallow or is unresponsive, subcutaneous or intramuscular glucagon or intravenous glucose should be given by a trained family member or medical personnel (Handelsman et al, 2015).*

Multicultural

• Provide culturally appropriate diabetes health education. **EB:** *"Structured interventions that are developed for diverse populations and that integrate culture, language, finance, religion, and literacy and numeracy skills positively influence patient outcomes" (ADA, 2017, S8).*

• Involve community health workers, peers, and lay leaders in diabetes education and support in underserved communities. **EB:** *"Strong social support leads to improved clinical outcomes, a reduction in psychosocial issues, and adoption of healthier lifestyles" (ADA, 2017, S8).*

Client/Family Teaching and Discharge Planning

• Provide "survival skills" education or review for hospitalized clients, including information about (1) identification of the health care provider who will provide diabetes care after discharge; (2) diagnosis of diabetes, SMBG, explanation of home blood glucose goals, and when to call provider; (3) information on consistent nutrition habits; (4) when and how to take medications including insulin administration; (5) proper use and disposal of needles and syringes if applicable; (6) definition, recognition, treatment, and prevention of hyperglycemia and hypoglycemia; and (7) sick-day management. **EB:** *Appropriate education at the time of discharge can help prevent a potentially dangerous gap in care (ADA, 2017, S125).*

• Refer clients for individual or group Diabetes Self-Management Education (DSME) and Diabetes Self-Management Support (DSMS) of at least 10 hours' duration. **EB:** *"Studies have found that DSME is associated with improved diabetes knowledge and self-care behaviors, lower A_{1C}, lower self-reported weight, improved quality of life, healthy coping, and reduced health care costs. Better outcomes were reported for DSME interventions that were over 10 hours in total duration, included follow-up with DSMS, were culturally and age appropriate, were tailored to individual needs and preferences, and addressed psychosocial issues and incorporated behavioral strategies" (ADA, 2017, S34).*

• Evaluate clients' monitoring technique initially and at regular intervals. *Accuracy of SMBG is instrument and user dependent (ADA, 2017, S48).*

• Teach patients with type 2 diabetes the importance of avoiding sedentary behavior, to move around briefly at least every 20 to 30 minutes, and to walk for 15 minutes after meals. **EB:** *These activities can improve glycemic control (Colberg et al, 2016).*
• Teach clients the importance of at least 150 minutes/week of aerobic physical activity spread over at least 3 days/week. **EB:** *"In type 1 diabetes, aerobic training increases cardiorespiratory fitness, decreases insulin resistance, and improves lipid levels and endothelial function. In individuals with type 2 diabetes, regular training reduces A_{1C}, triglycerides, blood pressure, and insulin resistance" (Colberg et al, 2016).*
▲ Discuss recommending resistance training with the client's provider. **EB:** *"Resistance exercise (free weights or weight machines) increases strength in adults with type 2 diabetes by about 50% and improves A_{1C} by 0.57%" (Colberg et al, 2016).*
• Teach clients with type 1 diabetes to test for blood ketones before exercise if they have unexplained hyperglycemia (≥250 mg/dL). **EB:** *"Exercise should be postponed or suspended if blood ketone levels are elevated (≥1.5 mmol/L) as blood glucose levels and ketones may rise further with even mild activity" (Colberg et al, 2016).*
▲ Teach clients with type 1 diabetes to check blood glucose prior to exercise. Blood glucose levels prior to exercise should ideally be between 90 and 250 mg/dL (5.0 and 13.9 mmol/L). Discuss carbohydrate use prior to exercise with physician. **EB:** *Exercise can increase risk of hypoglycemia during and for up to 48 hours after exercise (Colberg et al, 2016).*
• Teach clients to use alcohol with caution. **EB:** *Alcohol consumption may place people with diabetes at increased risk for delayed hypoglycemia, especially if taking insulin or insulin secretagogues (ADA, 2017, S35).*

Grieving

Ruth A. Wittmann-Price PhD, RN, CNS, CNE, CHSE, ANEF, FAAN

NANDA-I

Definition

A normal complex process that includes emotional, physical, spiritual, social, and intellectual responses and behaviors by which individuals, families, and communities incorporate an actual, anticipated, or perceived loss into their daily lives.

Defining Characteristics

Alteration in activity level; alteration in dream pattern; alteration in immune functioning; alteration in neuroendocrine functioning; alteration in sleep pattern; anger; blaming; despair; detachment; disorganization; distress; finding meaning in a loss; guilt about feeling relieved; maintaining a connection to the deceased; pain; panic behavior; personal growth; psychological distress

Related Factors

To be developed

At-Risk Population

Anticipatory loss of significant object; anticipatory loss of significant other; death of significant other; loss of significant other

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Grief Resolution; Dignified Life Closure; Hope; Psychosocial Adjustment: Life Change

Example NOC Outcome with Indicators

Grief Resolution as evidenced by the following indicators: Resolves feelings about the loss/Verbalizes reality and acceptance of loss/Maintains living environment/Seeks social support. (Rate the outcome and indicators of **Grief Resolution:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client/Family Outcomes

Client/Family Will (Specify Time Frame)

- Discuss meaning of the loss to his or her life and the functioning of the family
- Identify ways to support family members and articulate methods of support he or she requires from family and friends
- Accept assistance in meeting the needs of the family from friends and/or extended family

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Grief Work Facilitation; Dying Care; Emotional Support: Perinatal Death; Hope Instillation; Support System Enhancement; Family Support; Family Integrity Promotion

Example NIC Activities—Grief Work Facilitation

Identify the loss; Encourage expression of feelings about the loss; Assist to identify personal coping strategies; Identify sources of community support

Nursing Interventions and *Rationales*

Anticipatory Grieving Interventions

- Grieving of a critically ill or dying client and clients' family/relatives for the losses experienced during the deteriorating illness, and the future that will be filled with

loss. **EBN:** *Johnson et al (2017) qualitatively studied anticipatory grieving associated with patients at the end of life and their families and found that less than 50% of the dying patients and their families were given an anticipatory grieving nursing diagnosis and met the nursing outcomes at the time of death (such as the spiritual health outcome), demonstrating that expected outcomes need additional nursing attention.*

• Develop a trusting relationship both with the client and with the family by using presence and therapeutic communication techniques. **EB:** *Researchers developed a Relationship Tree as an experiential approach to grief counseling. It includes narrative theory and art therapy, and the therapists asked questions that assisted clients in reinterpreting the death experience and grow from it in the future (Peterson & Goldberg, 2016).*

• Keep the family apprised of the client's ongoing condition as much as possible. Consult with the family for decision-making as appropriate. **EBN:** *Bao-Huan (2016) qualitatively studied anticipatory parents' (N = 19) grieving related to impending loss of school-age children with type I or type II spinal muscular atrophy and found that family members often feel physically and mentally exhausted. The four themes identified in the study included; enduring the helplessness and pressure, suffering caused by the child's rare condition, loss of hope and a reinforcement of the parent–child attachment, and avoiding the pressure of death and enriching the child's life. The study supported nurses recognizing family reactions and in an ongoing fashion to assist them in the grieving process.*

• Keep the family informed of client's needs for physical care and support in symptom control, and inform them about health care options at the end of life, including palliative care, hospice care, and home care. **EB:** *Brooks (2017) completed an interpretative qualitative study about communication and shared decision-making about end-of-life care in a 24-bed intensive care unit (ICU) using focus groups with 17 nurses and 11 physicians. Findings indicated that improvement was needed in initiating and communicating end-of-life care among health care professionals and with the families. Recommendations include that end-of-life care leaders should be properly introduced and processes clearly followed by all health professionals.*

• Discuss preferred place of death (PPD) with client. **EB:** *Costa et al (2016) completed a meta-analysis (N = 26 articles) about patients' PPD because many patients express a preference to die at home. The analysis found that variables that increased the patient being home to die include multidisciplinary home palliative care, preference for home death, cancer diagnoses, early referral to palliative care, not living alone, having a caregiver, and the caregiver's coping skills.*

• Ask family members if they are receiving sufficient sleep. If a family member desires to be in the room for sleep, provide a reclining chair or portable bed if possible, and bedding to keep the family member comfortable. If needed, find housing for family member from out of town with the support of a case manager or social worker. **EB:** *Manheim et al (2016) studied family members (N = 8) of patients in a long-term care program until the end of life who were provided community caregivers 24/7. The qualitative study identified the following themes: the program supported families and families as caregivers, the patients' social and cultural needs at the end of life were better met, and the changing needs of the patients and families were addressed.*

• Ask family members about having adequate resources to care for themselves and the critically ill family member. **EBN:** *Eskola et al (2017) used a mixed-method study on parents' experiences and needs during a child's (N = 47) end-of-life care at home and found that parents created a sense of normality for the child, which caused parental exhaustion. Parents needed practical help with housekeeping and dealing with insurance.*

• Listen to the family member's story. **EB:** *Harrop et al (2016) surveyed family caregivers who experienced a loved one in end-of-life care; results included participants sharing feelings*

of guilt, need for communication and support, and the experience of a "void" created by the withdrawal of professional support after death.

• Encourage family members to show their caring feelings and talk to the client. **EBN:** *The researchers completed a literature review about using transitional objects with parents for perinatal loss such as taking photographs for parents. The objects provide parents a brief sense of healing, but long-term effects of transitional objects need further investigation (LeDuff et al, 2017).*

• Recognize and respect different feelings and wishes from both the family members and the client. **EBN:** *Chevrier et al (2016) studied the use of multidisciplinary care for end-of-life patients in the ICU environment and found that using the values of holism, patient-centeredness, and healing supports family members in complicated and emotionally challenging situations.*

• If necessary, refer a family member for counseling or to a minister/priest to help him or her cope with the existential questions and current overwhelming reality. **EBN:** *Tan and Cheang (2016) completed a retrospective investigation of interventions provided to patients (N = 50) receiving end-of-life care and their families and found that education of nurses and doctors was needed so that they could identify prompt symptoms of pain and the need for spiritual and religious care and then notify the appropriate ministers.*

• Recognize that one family member may be in a state of caregiver role strain from a long caregiving situation. **EBN:** *Church, Schumacher, and Thompson (2016) completed a mixed-methods study about the strain experienced by family caregivers of nursing home patients. The study results uncovered less recognized sources of caregiver strain including the loss of the older adult's dignity, lack of communication from staff, instances of poor-quality care, residents' symptom distress, and hospice care not offered.*

• Promote mutual goal setting in which decisions are made together that affect the family. **EBN:** *Kim et al (2017) descriptively studied the extent to which the patient caregiver (N = 44) used the advanced directives and agreed on end-of-life care decisions for cancer patient. They found 50% of caregivers did not agree on advanced directives, and the overall recommendation is to better include caregivers in end-of-life decisions to decrease disagreement.*

Grieving Interventions When Death of a Loved One Occurs

Use the following activities when interacting with the bereaved person:

❍ Be present and attentive, use active empathetic listening. **EBN:** *Rodgers, Calmes, and Grotts (2016) descriptively explored family members' (N = 13) experience of a bathing and honoring practice after a loved one's death in the acute care setting, and all family members stated that the bathing and honoring practice was a positive experience and supported the grieving process.*

❍ Validate the client's feelings of grief and feeling hurt, stressful, anxious, out of control, and further symptoms of grieving. **EB:** *Vollenbroich et al (2016) retrospectively studied symptom perception by parents (N = 38) and health care professionals for pediatric palliative home care and found that parents who cared for their dying child at home could successfully identify what the child needed by symptoms, and this produced a satisfaction for the parents.*

❍ Provide time and space for the person to tell their story of loss. **EB:** *Lawrence (2017) completed a case study analysis with individuals that experienced catastrophic events as first responders of lost patients or victims. Telling their story assisted in the grieving process.*

❍ *Offer condolences: "I am sorry that you lost your husband."* **EB:** *Librizzi, Isle, and*

Coyle (2016) investigated how to provide bad news to perinatal patients and what to say, and they found that it is a challenge for health care providers to say "I am sorry" to mothers experiencing a loss. It also shows empathy and does not indicate liability. Explain that feelings will oscillate as the person does grief work, from coping to accepting the loss to coping to build a new life without the loved one. **EB:** *Levi-Belz (2017) investigated the role of the ongoing relationship with the deceased family member comparing 58 suicide-loss survivors and 48 sudden-death and 53 natural-death bereaved individuals, and the suicide-loss family reported a lower positive ongoing relationship with the deceased.*

- ❍ Intentionally schedule meetings with family members to provide support during grieving. **EB:** *Parravicini (2017) completed a literature review about the protocols for newborns with life-limiting or life-threatening conditions and found a variety of neonatal palliative care programs without standardization. The review concluded that a multidisciplinary team is needed to address the infant's needs, parental grieving process, and providers' distress.*

• Refer to mental health providers as needed. **EBN:** *Palmer, Saviet, and Tourish (2016) explored adolescent and young adults who experienced a loss in their families because it affects social functioning, physical and mental health, and development, and they found that young adults need support and guidance to decrease the intensity of grief and distress. Therefore the recommendations for nurses are to develop individual patient guidance, support, and referrals.*

• Help the client use a method to give voice to his or her unique story of loss. Methods include keeping a personal journal to record feelings and insights; retelling of the loss narrative to a caring person; music therapy techniques with a trained therapist or listening to music that has significance to the relationship; and use of the "virtual dream," which is a dreamlike short story written by the grieving person to tell the narrative of the loss. **EBN:** *Beiermann (2017) studied families' (N = 50) bereavement reactions related to patients dying in the ICU and found that the majority of families responded positively to receiving an ECG Memento, which is a monitor strip of the patients' heart rhythm. Discuss coping methods with the grieving person. Common coping techniques include exercise, telling the story of grief to a caring person, journaling, pets, and developing a legacy for the deceased.* **EB:** *The researchers used kinetic sculpturing as a grief intervention in case studies to create visual examples of family equilibrium before, in the midst of, and after the deaths of family members. Family members found the creative expression beneficial (Brandon & Goldberg, 2017).*

• Encourage the family to create a quiet and comfortable healing environment, and follow comforting grief rituals such as prayer, interacting with nature, or lighting votive candles. **EBN:** *Barrett (2017) reviewed a case study related to how health care professionals provide empathy to grieving parents who lost a child and suggested nursing implications including being present and listening.*

• Refer the family members for spiritual counseling if desired. **EBN:** *Broadhurst and Harrington (2016) completed a literature review to investigate the correlation between transcendent phenomena and peaceful death and identified four themes: spiritual comfort; peaceful, calm death; spiritual transformation; and unfinished business. The results encouraged nurses to recognize the phenomenon and its importance in spiritual care.*

• Help the family determine the best way and place to find social support. Encourage family members to continue to use support for as long as needed. **EB:** *Researchers studied spouses (N = 1224) whose partners died to examine (a) how life satisfaction changed; (b) whether sociodemographic factors and social and health resources moderate effect life satisfaction; and (c) whether anticipation, reaction, and adaptation are related to mortality. Life satisfaction decreases for about 2.5 years and older age was associated with more intense*

declines (Infurna et al, 2017).
• Identify available community resources, including bereavement groups at local hospitals and hospice centers. Volunteers who provide bereavement support can also be effective. **EB:** *Gibson (2017) investigated the use of Second Life to symbolically bury and memorialize the real-life biological deaths of people. It was shown to not decrease the loss in real life; instead it provides a method to remember the person.*
• Refer to complicated **Grieving** if grieving fails to follow normative (or cultural) expectations and manifests in functional impairment.

Pediatric/Parent

• Treat the child / parents with respect, give him or her the opportunity to talk about concerns and answer questions honestly. **EB:** *Care providers can give anticipatory guidance to caregivers to support children who are grieving; to assist children to better understand what has happened; and to address any misinformation, misinterpretations, or misconceptions (Schonfeld & Demaria, 2017).*
• Listen to the child's expression of grief. **EBN:** *Halliwell and Franken (2016) studied online stories (N = 70) from bereaved siblings about their losses, and discussions supported two main struggles: (1) grieving as deviant behavior versus grieving as a normal process and (2) the deceased as gone forever versus the deceased as still present.*
• Help parents recognize that the grieving child does not have to be "fixed"; instead, they need support going through an experience of grieving just like adults. **EB:** *Templeton et al (2016) studied bereavement in family members who lost a loved one associated with alcohol and/or drugs and found that the stigma associated with the death decreased support for the surviving children and adults. The research uncovered five themes: possibility of death, official processes, stigma, grief, and support. This study demonstrated that this is a marginalized group of bereaved people that includes children that may grieve differently because of lack of social support.*
• Consider the use of art for children in hospice care who are dying or dealing with the death of a parent, sibling, or other family member. **EB:** *Hill and Lineweaver (2016) used art to study the positive and negative affect of grieving children and compared the intervention with another visuospatial task. They found that children who created art individually experienced a significant decrease in negative affect.*
▲ Refer grieving children and parents to a program to help facilitate grieving if desired, especially if the death was traumatic. **EB:** *Koblenz (2016) studied adults (N = 19) who were grieving children, and the qualitative descriptions produced five themes: adjustment to catastrophe, support, therapy, continuing a connection with the deceased parent, and reinvestment. The adults stated that these were the most helpful elements in the years after they experienced a death of a loved one.*
• Help the adolescent determine sources of support and how to use them effectively. **EB:** *DeDiego, Wheat, and Fletcher (2017) explored Adventure Based Counseling (ABC) camps for grieving adolescents and children with positive results. This is just one alternative support system for grieving adolescents and children.*
• Encourage grieving parents to take good care of their own health. **EB:** *Albuquerque et al (2017) studied parental relationships (N = 17) after the death of a child by grounded theory method and identified three themes: search for meaning, communication with the partner, and care-in-relation that assisted couples to maintain a healthy relationship.*
▲ Encourage grieving parents to seek mental health services as needed. The death of a child is regarded as among the most traumatic, incomprehensible, and devastating of losses, with the potential to precipitate a crisis of meaning for the bereaved parent.

EB: *Researchers qualitatively studied meaning reconstruction using a life-story interview with a Japanese woman who lost her son to suicide. The analysis revealed three themes: (1) making sense of her son's death and life, (2) relationships with other people, and (3) reconstruction of a bond with the deceased (Daisuke & Kenji, 2017).*

• Recognize that men and women often grieve differently, and explain this to parents if it becomes an issue. **EB:** *Researchers used a mixed-method approach to investigate mothers' (N = 60) grief after losing a child, forgiveness, and posttraumatic growth. There was a negative correlation between forgiveness and grief and a positive correlation between forgiveness and posttraumatic growth (posttraumatic growth was viewed as changes in life) (Martincekova & Klatt, 2017). Steen (2015) studied multicultural perinatal bereavement interventions (N = 59) by using a cross-sectional method and found differences in interventions by nurses/midwives in different countries regarding knowledge, communication skills, and management of personal feelings, indicating that consistent bereavement information is needed.*

• Recognize that mothers who have a miscarriage/stillbirth grieve and experience sorrow because of the loss of the child. **EBN:** *Rocha et al (2017) performed a literature (N = 29) review about prenatal palliative care for parents carrying a fetus with malformations and found no long-term studies about the effects of prenatal palliative care.*

Geriatric

• Monitor an older adult who has been treated for bereavement-related depression for relapse or recurrence. **EB:** *Tanimukai et al (2017) studied the relationship between depression and insomnia in bereaved families (N = 561) and found that insomnia was highly correlated with depression.*

• Provide support for the family when the loss is associated with dementia of the family member. **EB:** *Researchers studied an intervention with caregivers of veterans with dementia. Caregivers were divided into groups of Internet or telephone intervention and found that in rural populations the Internet was effective if the caregiver was comfortable with technology (Hicken et al, 2017).*

• Determine the social supports of older adults. **EBN:** *Durham, Allmark, and Collins (2017) investigated the experience of cancer pain in elderly patients (N = 9) and by qualitative analysis identified four themes for nursing consideration: better to be old than to be dying, maintaining independence, grieving for a former self, and denial of pain.*

Multicultural

• See interventions and rationales in care plans for complicated **Grieving** and Chronic **Sorrow.**

Home Care

• The interventions previously described may be adapted for home care use.

• Assessment of activities of daily living (ADLs) and instrumental ADLs is essential as part of comprehensive care after a home care client has suffered the loss of a loved one. **EB:** *Raitio, Kaunonen, and Aho (2017) explored parental grief intervention and its effects on maternal grief with health care provider intervention in one group compared with a control group. Results did not demonstrate a significant difference in the grief reactions between groups and support from the health care professionals was positively correlated with stronger personal growth at 6 months post death.*

• Actively listen as the client grieves for his or her own death or for real or perceived

loss. Normalize the client's expressions of grief for self. Demonstrate a caring and hopeful approach. **EB:** *Vergo et al (2017) measured the grief reactions of patients (N = 53) with advanced cancer using the Preparatory Grief in Advanced Cancer (PGAC) instrument and found that preparatory grief was common and 25% of participations had significant grief, and all patients demonstrated distress.*

▲ Refer the client to social services as necessary for losses not related to death. Support is helpful to grief work for all types of losses. Social workers can help the client plan for financial changes as a result of job losses and help with community referrals as appropriate. **EB:** *A study by social work researchers about women who experienced a miscarriage, stillbirth, or child's death compared self-esteem to maternal identity and found that stillbirth and death of a child negatively affected self-esteem, and that self-esteem levels were increased by stronger maternal identity (Wonch et al, 2017).*

▲ Refer the bereaved to hospice bereavement programs or an Internet self-help group. Relief of the suffering of clients and families (physical, emotional, and spiritual) is the goal of hospice care. **EB:** *A ethnographic study was completed to understand the motivation for grieving mothers to start and maintain a blog. After reviewing 140 blogs the researchers identified themes such as sharing the loss and challenges, creating a network to support and comfort other, guaranteeing a space to express feelings, honoring and perpetuating the image of the child lost, and engaging in social activism (Figueiredo et al, 2017).*

Complicated Grieving

Ruth A. Wittmann-Price PhD, RN, CNS, CNE, CHSE, ANEF, FAAN

NANDA-I

Definition

A disorder that occurs after the death of a significant other, in which the experience of distress accompanying bereavement fails to follow normative expectations and manifests in functional impairment.

Defining Characteristics

Anger; anxiety; avoidance of grieving; decrease in functioning in life roles; depression; disbelief; distress about the deceased person; excessive stress; experiencing symptoms the deceased experienced; fatigue; feeling dazed; feeling of detachment from others; feeling of emptiness; feeling of shock; feeling stunned; insufficient sense of well-being; longing for the deceased person; low levels of intimacy; mistrust; non-acceptance of a death; persistent painful memories; preoccupation with thoughts about a deceased person; rumination; searching for a deceased person; self-blame; separation distress; traumatic distress

Related Factors

Emotional disturbance; insufficient social support

At-Risk Population

Death of significant other

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Anxiety Level; Coping; Depression; Grief Resolution; Mood Equilibrium; Personal Well-Being; Psychosocial Adjustment: Life Change; Sleep

Example NOC Outcome with Indicators

See care plan for **Grieving**.

Client Outcomes

Client Will (Specify Time Frame)

- Express appropriate feelings of guilt, fear, anger, or sadness
- Identify somatic distress associated with grief (e.g., anxiety, changes in appetite, insomnia, nightmares, loss of libido, decreased energy, altered activity levels)
- Seek support in dealing with grief-associated issues
- Identify personal strengths and effective coping strategies
- Function at a normal developmental level and begin to successfully and increasingly perform activities of daily living

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Grief Work Facilitation; Grief Work Facilitation: Perinatal Death; Guilt Work Facilitation; Hope Installation

Example NIC Activities—Grief Work Facilitation

See care plan for **Grieving**.

Nursing Interventions and *Rationales*

- Assess for signs of complicated grieving that include symptoms that persist at least 6 months after the death and are experienced at least daily or to a disabling degree. Symptoms include feeling emotionally numb, stunned, shocked, and that life is meaningless; dysfunctional thoughts and maladaptive behaviors; experiencing mistrust and estrangement from others; anger and bitterness over the loss; identity confusion; avoidance of the reality of the loss, or excessive proximity seeking to try to feel closer to the deceased, sometimes focused on wishes to die or suicidal statements and behavior; or difficulty moving on with life. *Symptoms must be associated with psychosocial and physical impairments (Kokou-Kpolou et al, 2017).* **EB:** *Brown (2017) studied the recurrent grief in mothers caring for a child with intellectual disability and found that recurrent grief is correlated with coping and challenging behaviors of the child.* **EB:** *Masferrer, Garre-Olmo, and Caparros (2016) studied complicated grief in the substance-abuse population (N = 196) compared with those who did not abuse drugs (N = 100). Complicated grief was significantly higher among the population who abused drugs (34.2% compared with 5% in the control group).*
  - ▲ Determine the client's state of grieving. Use a tool such as the Prolonged Grief Disorder (PGD) scale (Jordan & Litz, 2014), the Grief Support in Health Care Scale (Anderson et al, 2010), the Hogan Grief Reaction Checklist (Hogan, Worden, & Schmidt, 2004), and the Beck Depression Inventory. **EBN:** *Researchers studied the grief of mothers (N = 130) and fathers (N = 52) after infant or child neonatal or pediatric intensive care unit death by completing the Hogan Grief Reaction Checklist at 1, 3, 6, and 13 months post death, and found initial grief reactions decreased from 3 to 13 months for mothers and from 3 to 6 months for fathers (Youngblut et al, 2017).*
  - ▲ Determine whether the client is experiencing depression, suicidal tendencies, or other emotional disorders. Refer the client for counseling or therapy as appropriate. **EB:** *Researchers studied the effect bereavement services have on depression and grief after a person experiences a significant loss, and patients reported that some of the services provided that were most helpful included time alone with the deceased, a quiet room to be alone after the death, sympathy cards from hospital staff, memorial services, chaplain support, an educational grief booklet, grief book recommendations, a check-in phone call, individual counseling, and a*

relationship-specific support group. The study also found that participants experiencing depression and complicated grief used the services at a more frequent rate than participants who were not clinically depressed (Banyasz et al, 2017).

• Educate the client and his or her support systems that grief resolution is not a sequential process and that the positive outcome of grief resolution is the integration of the deceased into the ongoing life of the griever. **EB:** *Mowll (2017) studied the ways health care professionals can best support family members (N = 48) who needed to view the body of their relative after a traumatic death, and the study identified qualitative themes. Things that assisted the family members included support during interactions, giving permissions and possibilities, providing information and preparation, being caring, timing experiences appropriately, and tuning into family needs.*

▲ Assess caregivers, particularly younger caregivers, for pessimistic thinking and additional stressful life events. Refer for appropriate support. **EB:** *Researchers studied African American caregivers (family members) (N = 108) of persons with dementia and found that negative thoughts increase depression and physical suffering (Schulz et al, 2017).*

• See the interventions and rationales in the care plans for **Grieving** and Chronic **Sorrow.**

Pediatric/Parent

▲ Refer grieving children and parents to a program to help facilitate grieving if desired, especially if the death was traumatic. **EB:** *Schreiber, Sands, and Jordan (2017) studied children whose parents died of suicide and found that children felt isolated, abandoned, and responsible. Suggestions for nursing included developmentally appropriate education about suicide grief, depression, and normalizing.*

• Encourage grieving parents to take part in activities that are supportive, such as faith based activities. **EB:** *Nuzum, Meaney, and O'Donoghue (2017) qualitatively studied parents who experienced the loss of a stillborn child, and study results indicated that stillbirth challenges parents' faith, usually one parent more than the other, indicating that all parents should be offered spiritual care after a stillbirth.*

• Encourage grieving parents to seek mental health services as needed. **EBN:** *Morris et al (2017) noted that bereaved parents are an "at-risk" group, and through anecdotal experiences they developed a hospital-wide, preventative model, bereavement program using education, guidance, and support. The model has been received by participants and staff with good results.*

• Help the adolescent determine sources of support and how to use them effectively. If the client is an adolescent exposed to a peer's suicide, watch for symptoms of traumatic grief and posttraumatic stress disorder, which include numbness, preoccupation with the deceased, functional impairment, and poor adjustment to the loss. **EB:** *Woollett et al (2017) qualitatively studied HIV-positive adolescents in Africa and their ability to disclose the disease and the bereavement process that accompanies the diagnosis. The study found that most participants (N = 25) were orphaned and were really experiencing complicated grief and that was related negatively to mental health and the ability to accept their HIV status and adhere to treatment.*

Geriatric

• Assess for deterioration in bereaved older adults' self-care. **EBN:** *Skritskaya et al (2017) investigated maladaptive cognitions and their relationship to complicated grief by developing a questionnaire called the Typical Beliefs Questionnaire (TBQ) and piloted the tool*

on bereaved adults (N = 394) with complicated grief. The new tool was effective in identifying specific maladaptive cognitions related to complicated grief.

• Those who have lived with older adults with dementia and experienced significant feelings of loss before the loved one's death may be at risk for more intense feelings of grief after the death of the client with dementia. **EB:** *Berenbaum, Tziraki, and Cohen-Mansfield (2017) studied how people with dementia are told about the death of a peer. Adult daycare staff (N = 52) was qualitatively interviewed and felt that their patients have the emotional capacity to mourn despite their cognitive impairments.*

• Monitor the older client for complicated grieving manifesting in physical and mental health problems. **EB:** *Boer et al (2017) studied patients with chronic obstructive pulmonary disease (COPD) who have a grieving process because of loss of functioning and found COPD patients experience four stages of grief including denial, resistance, sorrow, and acceptance.*

Multicultural

• Assess for the influence of cultural beliefs, norms, and values on the client's grief and mourning practices. **EBN:** *Bravo (2017) studied undocumented Latino migrants (N = 12) living in the United States and who have experienced coping with deaths of loved ones in their home countries. The participants experienced sadness and guilt, and communication with those in the home country was an important mechanism for coping.* **EB:** *Kokou-Kpolou et al (2017) studied European refugees (N = 74) and their experiences of losing a family member to death, which is complicated by immigration status. The study found participants reported a deterioration of their social life and profound feelings of guilt.*

• Encourage discussion of the grief process. **EB:** *Granek and Peleg-Sagy (2017) completed a literature review about complicated and pathological grief reactions in the US African American population and found 13 articles, but many of the articles were validated using white populations, indicating the need for grief research for African Americans and other ethnic minorities.* **EBN:** *Mun and Ow (2017) studied the grief process of mothers who lost a child in Singapore and found that qualitatively four themes were identified: (1) meaning to the child's life and death, (2) quality and assurance of an afterlife, (3) the function of crying, and (4) a continuing bond.*

• Identify whether the client had been notified of the health status of the deceased and was able to be present during illness and death. **EB:** *Young (2017) discussed cases related to people with profound intellectual and multiple disabilities (PIMD) that are bereaved and experience social, emotional, and physical constraints. Young found that people with PIMD are a high-risk group and at greater risk of complicated grieving.*

Home Care

• Consider providing support via the Internet. **EB:** *Researchers studied an intervention with caregivers of veterans with dementia. Caregivers were divided into groups of Internet or telephone interventions and found that in rural populations the Internet was effective if the caregiver was comfortable with technology (Hicken et al, 2017).*

Risk for complicated Grieving

Gail B. Ladwig MSN, RN

NANDA-I

Definition

Susceptible to a disorder that occurs after death of a significant other in which the experience of distress accompanying bereavement fails to follow normative expectations and manifests in functional impairment, which may compromise health.

Risk Factors

Emotional disturbance; death of a significant other; insufficient social support

At-Risk Population

Death of significant other

NIC, NOC, Client Outcomes, Nursing Interventions and *Rationales,* Client/Family Teaching and Discharge Planning, and References

Refer to care plan for Complicated **Grieving.**

List of Planning Care by Letter: H

Deficient community Health	Risk-prone Health behavior	Ineffective Health management
Readiness for enhanced Health management	Ineffective family Health management	Ineffective Health maintenance
Impaired Home maintenance	Readiness for enhanced Hope	Hopelessness
Risk for compromised Human Dignity	Neonatal Hyperbilirubinemia	Risk for neonatal Hyperbilirubinemia
Hyperthermia	Hypothermia	Risk for Hypothermia
Risk for Perioperative Hypothermia		

H

• = Independent; ▲ = Collaborative; **EBN** = Evidence-Based Nursing; **EB** = Evidence-Based

Deficient community Health

Marina Martinez-Kratz MS, RN, CNE

NANDA-I

Definition

Presence of one or more health problems or factors that deter wellness or increase the risk of health problems experienced by an aggregate.

Defining Characteristics

Health problem experienced by aggregates or populations; program unavailable to eliminate health problems of an aggregate or population; program unavailable to enhance wellness of an aggregate or population; program unavailable to prevent health problems of an aggregate or population; program unavailable to reduce health problems of an aggregate or population; risk of hospitalization experienced by aggregates or population; risk of physiological states experienced by aggregates or populations; risk of psychological states experienced by aggregates or population

Related Factors

Inadequate consumer satisfaction with program; inadequate program budget; inadequate program evaluation plan; inadequate program outcome data; inadequate social support for program; insufficient access to health care provider; insufficient community experts; insufficient resources; program incompletely addresses health problem

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Community Grief Response; Community Health Screening Effectiveness; Community Health Status Community Program Effectiveness; Community Resiliency; Community Risk Control: Obesity; Community Risk Control: Unhealthy Cultural Traditions

Example NOC Outcome with Indicators

Community Health Status as evidenced by the following indicators: Health status of infants/Children/Adolescents/Adults/Elders/Minority populations/Prevalence of health promotion programs. (Rate the outcome and indicators of **Community Health Status:** 1 = poor, 2 = fair, 3 = good, 4 = very good, 5 = excellent, NA [see Section I].)

Client Outcomes

Community/Adolescents/Minority Clients Will (Specify Time Frame)

- Provide programs for healthy behaviors
- Demonstrate goal setting

• Describe and comply with healthy behaviors
• Describe and demonstrate compliance with hepatitis B virus (HBV) education and testing

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Community health development: Identify health concerns, strengths, and priorities with community partners; Assist community members in raising awareness of health problems and concerns

Nursing Interventions and *Rationales*

Refer to care plans: Readiness for Enhanced community **Coping,** Ineffective Community **Coping,** Ineffective **Health** maintenance, Impaired **Home** maintenance, and Risk for other-directed **Violence**.

• Assess for the presence of demographic variables that predict community mortality. **EB:** *The following demographic variables were associated with increased community mortality: age 65 years or older, poverty, and a high concentration of construction and service workers (Chan et al, 2014).*
• Assess for needs related to the community's priority health concerns. **EB:** *Research results generated from the first study of the National Institutes of Health Sentinel Network identified the top five health concerns of respondents as hypertension, diabetes, cancer, weight, and heart problems (Cottler et al, 2013).*
• Assess patients accessing health services for a history of military service and provide the necessary referrals and information. **EBN:** *Many veterans eligible for Veteran's Administration (VA) health benefits seek health care from community emergency departments and will benefit from information about VA resources (Merkl et al, 2016).*
• Implement community engagement techniques for collaboration with stakeholders to design, develop, and adapt relevant health interventions. **EBN:** *In this study's findings, improved nutrition and physical activity behavior were the result of community engagement techniques used to develop culturally relevant obesity prevention interventions for low-income Hispanic mothers with preschool children (Bender, Clark, & Gahagan, 2014).*
• Encourage attendance at community-based exercise programs. **EBN:** *In this study community-based exercise groups were perceived by pregnant women as a satisfactory and motivating form of exercise engagement (Ette, 2017).*
• Implement community engagement techniques in conjunction with tailored interventions to address health deficiencies. **EB:** *In this study, community engagement techniques were essential in coordinating interventions and engaging patients, the public, and local practitioners in delivery of mental health care (Lamb et al, 2015).*
• Collaborate with other community-based programs to use the Short Message Service (SMS) to broadcast targeted health messages to reach large numbers of community members. **EB:** *A study using SMS broadcasting at a metropolitan sexual health clinic to promote the awareness of influenza vaccinations in HIV-positive patients resulted in a significant increase in the number of patients contacted and vaccinated by the clinic (Stowers, Healey, & O'Connor, 2014).*

Pediatric

▲ Consider use of a clinical-community collaborative to address health deficiencies in underserved populations with children. **EB:** *A clinical-community collaborative enabled pediatric providers to implement a food insecurity-focused intervention that was associated with improved preventive care outcomes for the infants served (Beck et al, 2014).*

▲ Screen at-risk pediatric populations for lead exposure. **EB:** This study showed under testing for lead exposure and no mandatory lead test screening in one-third of eligible children during the study period (Knighton, Payne, & Speedie, 2016).

Geriatric

▲ Assess community-dwelling older individuals for cognitive impairment using the Brief Cognitive Assessment Tool-Short Form (BCAT-SF). **EBN:** *In this study, the BCAT-SF demonstrated sensitivity in differentiating between dementia and nondementia (Mace, Mansbach, & Clark, 2016).*

▲ Assess community-dwelling older individuals with the Identification of Seniors at Risk (ISAR) screening tool when they present for treatment in the emergency department. **EBN:** *In this study, using the ISAR tool predicted adverse outcomes in elderly patients (Asomaning & Loftus, 2014).*

▲ Screen community-dwelling older individuals for fall risk with the Timed Up and Go Test (TUG) or the Functional Gait Assessment (FGA). **EB:** *A clinical review of research recommended the use of the TUG and FGA to identify fall risk in community-dwelling older individuals (Lee, Geller, & Strasser, 2013).*

Multicultural

• Provide culturally and linguistically appropriate risk reduction programs to individuals living in rural and border regions of the country. **EBN:** *Culturally appropriate risk reduction programs will reduce sexual health disparities (Hernandez et al, 2014).*

• Use decision aids (DAs) (personal counseling, multimedia, and print materials) to facilitate communication between patients and health care providers to determine a plan for health care. **EB:** A systematic review found 18 studies illustrating the effectiveness of DAs in improving patient–provider communication and decision quality outcomes in minority populations (Nathan et al, 2016).

Home Care and Client/Family Teaching and Discharge Planning

• The previously mentioned interventions may be adapted for home care and client/family teaching.

Risk-prone Health behavior

Marina Martinez-Kratz MS, RN, CNE

NANDA-I

Definition

Impaired ability to modify lifestyle and/or actions in a manner that improves the level of wellness.

Defining Characteristics

Failure to achieve optimal sense of control; failure to take action that prevents health problem; minimizes health status change; nonacceptance of health status change; smoking; substance misuse

Related Factors

Inadequate comprehension; insufficient social support; low self-efficacy; negative perception of health care provider; negative perception of recommended health care strategy; social anxiety; stressors

At-Risk Population

Family history of alcoholism; economically disadvantaged

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Participation in Health Care Decisions; Psychosocial Adjustment: Life Change; Risk Detection

Example NOC Outcome with Indicators

Risk Detection as evidenced by the following indicators: Recognizes signs and symptoms that indicate risks/Identifies potential health risks/Participates in screening at recommended intervals/Obtains information about changes in health recommendations. (Rate the outcome and indicators of **Risk Detection:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

• State acceptance of change in health status
• Request assistance in altering behaviors to adapt to change
• State personal goals for dealing with change in health status and means to prevent further health problems
• State experience of a period of grief that is proportional to the actual or perceived effect of the loss
• Report and/or demonstrate behavior changes mutually agreed upon with nurse as evidence of positive adaptation

NIC (Nursing Interventions Classification)

Suggested NIC Intervention
Self-Efficacy Enhancement

Example NIC Activities—Self-Efficacy Enhancement
Explore individual's perception of his or her capability to perform the desired behavior; Reinforce confidence in making behavior changes and taking action

Nursing Interventions and *Rationales*

• Assess the client's perceptions of health, wellness, disability, and major barriers to health and wellness. **EB:** *Understanding the differences in perceptions can direct how a provider talks to clients about their health, but it could also provide insight into how clients value and perceive their own disability and wellness (Morris et al, 2018).*
• Use motivational interviewing to help the client identify and change unhealthy behaviors. **EBN:** *In these studies, motivational interviewing helped clients identify and examine their high-risk health behaviors (Wong & Cheng, 2013).*
• Encourage mindfulness and meditation to help the client cope with changes in health status. **EBN:** *Mindfulness and meditation can reduce stress, leading to increased quality of life and self-efficacy (Robins et al, 2014).*
• Allow the client adequate time to express feelings about the change in health status. **EB:** *A longitudinal study of clients with newly diagnosed diabetes found that there was a perception of time pressure, and considerable time was spent with patients by health professionals repeating information that may not be relevant to patient need (Dowell et al, 2018).*
• Use open-ended questions to allow the client free expression (e.g., "Tell me about your last hospitalization" or "How does this time compare?"). **CEB:** *Using open-ended questions generates more objective responses with less bias, leading to a more genuine qualitative understanding (Alemi & Harry, 2014).*
• Help the client work through the stages of grief that occur as part of a psychological adaptation to illness or life change. Assess for signs of nonacceptance to illness or change. **CEB:** *Clients who exhibit nonacceptance are at higher risk for stronger, delayed grief reactions. Identifying these clients and making appropriate referrals for counseling and support groups may prevent future adverse outcomes (Holland et al, 2013).*
• Assess the client for depression and refer for counseling or medical follow-up, as appropriate. **CEB:** *Depression is often a response to and a comorbid condition of chronic disease. Depression is associated with poorer client outcomes and higher risk behavior (Di Benedetto et al, 2014).*
• Discuss the client's current goals and assist in modification as needed. Use a goal attainment scaling (GAS) approach, which is a therapeutic method that refers to the

development of a written follow-up guide between the client and the nurse and is used for monitoring client progress. **EB:** *A study of clients enrolled in a geriatric day hospital (GDH) demonstrated short- and long-term effectiveness of GDHs in helping patients achieve individualized outcome measures using GAS (Moorhous et al, 2017).*

▲ Encourage participation in appropriate wellness programs associated with health changes. **EBN:** *Studies of clients with multiple sclerosis and chronic obstructive pulmonary disease found that wellness programs facilitating positive health choices and self-management demonstrated gains in functional status and decreased anxiety and depression (Simpson & Jones, 2013).*

• Give the client positive feedback for accomplishments, no matter how small. Support the client and family and promote their strengths and coping skills. **EB:** *Support is necessary to help the client and family throughout the illness. Support leads to hopefulness and is associated with improved outcomes (Soundy et al, 2014).*

▲ Promote use of positive spiritual influences, as appropriate. **EBN:** *Faith- and spiritual-based resources may promote an atmosphere of forgiveness and stress personal resilience. These resources may also provide a sense of community and belonging and provide an additional support network (Brewer-Smith & Koenig, 2014).*

▲ Refer to community resources. Provide general and contact information for ease of use. **EBN:** *A study of oncology navigators identified that common barriers for clients obtaining assistance included lack of resources (50%), lack of knowledge about resources (46%), and complex/duplicative paperwork (20%) (Spencer et al, 2018).*

Pediatric

• Include social history in client assessment to help identify past abuse and traumatic experiences. **EBN:** *A systematic review found that only 28% of abuse or neglect cases identified by researchers are found in clients' files. This information is considered essential for developing comprehensive formulations and effective treatment plans (Read et al, 2018).*

• Encourage parents to process and express grief, uncertainty, and discouragement after learning about their child's diagnosis, prognosis, and treatments. Provide parents with resources and tools to help further their understanding of the illness. **EB:** *A study assessed the effectiveness of an intervention called the Nurturing Program for Parents and Their Children with Special Needs and Health Challenges (SNHC) and found that after the intervention families showed an increase in empathy toward their children's needs and an increase in empowerment as measured by the family empowerment scale (Burton et al, 2018).*

- ❍ Provide parents of critically ill children with individualized coping resources. **EBN:** *Research findings indicated that a range of diverse coping strategies are used by neonatal intensive care unit parents. The most common are acceptance emotional support, active coping, positive reframing, religion, planning, and instrumental support. Despite this, 91% of participants indicated they would likely attend at least one type of parent support program, if offered according to their preferences (Huenink & Porterfield, 2017).*

• Use distraction with children undergoing procedures or treatment with unpleasant side effects. **EB:** *This review found that there was strong support for the use of distraction techniques with older children (Ali, McGrath, & Drendel, 2016).*

Geriatric

▲ Assess for signs of depression resulting from illness-associated changes and make appropriate referrals. **EB:** *A review of evidence related to depression in older individuals*

found major depressive disorder (MDD) is less common in late life, but has a more chronic course compared with younger adults with MDD. A significant finding was that older adults with subclinical forms of depression report functional impairment similar to MDD (Haigh et al, 2018).

• Support activities that promote a sense of purpose for older adults. **CEB:** *Purpose in life (PIL) is strongly associated with improved mental and physical health outcomes among older adults. Thus interventions to improve and/or maintain higher levels of PIL over time may promote successful aging (Musich et al, 2018).*

- ❍ Encourage social support. **EB:** *In this study, social support was a prerequisite for success of the health-promoting intervention and perceived well-being in older adults (von Berens et al, 2018).*

Multicultural

• Assess for the influence of cultural beliefs, norms, and values on the client's ability to modify health behavior. **CEB:** *What the client considers normal and abnormal health behavior may be based on cultural perceptions (Leininger & McFarland, 2002).*

• Assess the role of fatalism on the client's ability to modify health behavior. Fatalistic perspectives, which involve the belief that you cannot control your own fate, may influence health behaviors in some cultures. **EB:** *A study found that patients with type 2 diabetes who exhibited more fatalistic attitudes were younger, of lower education levels, had higher body mass index (BMI), and had fewer diabetes comorbidities. It is crucial for health care practitioners to identify fatalistic patients and to tailor culturally appropriate strategies in diabetes management (Sukkarieh-Haraty et al, 2018).*

• Encourage spirituality as a source of support for coping. **EBN:** *Findings from a study provided data to support an understanding of how African American women define spirituality, the role it plays, the purpose it serves, the function of spirituality in their lives, and the implications for breast health behaviors (Conway-Phillips & Janusek, 2018).*

• Negotiate with the client regarding the aspects of health behavior that will need to be modified. **CEB:** *Give-and-take with the client will lead to culturally congruent care (Leininger & McFarland, 2002).*

• Acknowledge client's identified gender and sexual orientation and refer client and family members to support networks that have experience with lesbian, gay, bisexual, or transgender (LGBT) issues, as appropriate. **EBN:** *Disclosure and support systems are associated with better self-help perception; creating safe and accepting environments for LGBT patients has been shown to improve overall care in this underserved population (Kamen et al, 2015).*

Home Care

• The previously mentioned interventions may be adapted for home care use.

• Take the client's perspective into consideration and use a holistic approach in assessing and responding to client planning for the future. **EB:** *A recent qualitative study described the experience of the client with both type 1 diabetes and an eating disorder and that of their health care providers. Results demonstrated the need for interprofessional, collaborative approaches to treatment (Macdonald et al, 2018).*

• Assist the client/family to adapt to his or her diagnosis and to live with their disease. **EBN:** *Research suggested time-sensitive interventions directed toward education and psychosocial support for all patients and families dealing with a new diagnosis of chronic illnesses are needed (Gunter & Duke, 2018).*

• Ensure that evaluations of the client's ability to perform activities of daily living are age appropriate and consider existing, as well as new, diagnoses. **EB:** *This study used a geriatric-designed functional evaluation that took into account the age-related decrease in flexibility and strength by identifying additional areas for potential loss of function (Adamo, Talley, & Goldberg, 2015).*
• Refer to care plan for **Powerlessness.**

Client/Family Teaching and Discharge Planning

• Assess family/caregivers for coping and teaching/learning styles. **EBN:** *Recommendations for teaching family or caregivers include providing realistic expectations and nurturing psychological safety so caregivers feel comfortable asking questions, expressing their thoughts, and discussing mistakes (Lindauer, Sexson, & Harvath, 2017).*
• Foster communication between the client/family and medical staff. **EBN:** A study of caregiver communication indicated that oncology nurses must be able to address questions posed by family caregivers and support family communication challenges (Wittenberg et al, 2017).
• Educate and prepare families regarding the appearance and function of the client and the environment before initial exposure. **EBN:** A study of mother-caregivers found that health care providers can help anchor family management by recognizing caregiver expectations and facilitating communication about realistic expectations (Barakat et al, 2016).
• Teach a client and his or her family relaxation techniques (controlled breathing, guided imagery) and help them practice. **EBN:** Guided imagery with relaxation may be an easy-to-use self-management intervention to improve the quality of life of older adults with osteoarthritis (Helgadottir & Wilson, 2014).
• Allow the client to proceed at his or her own pace in learning; provide time for return demonstrations (e.g., self-injection of insulin). Tailor teaching and learning materials as appropriate for client and caregiver literacy level. **EBN:** Use clear and distinct language free of medical jargon and meaningless values. Be sensitive to education levels and cultural environments that may hinder effective communication (Protheroe & Rowlands, 2013).

Ineffective Health management

Ruth A. Wittmann-Price PhD, RN, CNS, CNE, CHSE, ANEF, FAAN

NANDA-I

Definition

Pattern of regulating and integrating into daily living a therapeutic regimen for the treatment of illness and its sequelae that is unsatisfactory for meeting specific health goals.

Defining Characteristics

Difficulty with prescribed regimen; failure to include treatment regimen in daily living; failure to take action to reduce risk factor; ineffective choices in daily living for meeting health goal

Related Factors

Decisional conflict; difficulty managing complex treatment regimen; difficulty navigating complex health care systems; excessive demands; family conflict; family pattern of health care; inadequate number of cues to action; insufficient knowledge of therapeutic regimen; insufficient social support; perceived barrier; perceived benefit; perceived seriousness of condition; perceived susceptibility; powerlessness

At-Risk Population

Economically disadvantaged

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Health Beliefs: Perceived Control, Perceived Threat; Knowledge: Disease Process; Knowledge: Treatment Regimen; Participation in Health Care Decisions

Example NOC Outcome with Indicators

Knowledge: Treatment Regimen as evidenced by the following indicators: Extent of understanding of prescribed medication, activity, exercise, and specific disease process. (Rate the outcome and indicators of **Knowledge: Treatment Regimen:** 1 = no knowledge, 2 = limited knowledge, 3 = moderate knowledge, 4 = substantial knowledge, 5 = extensive knowledge [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Describe daily food and fluid intake that meets therapeutic goals
- Describe activity/exercise patterns that meet therapeutic goals
- Describe scheduling of medications that meets therapeutic goals
- Verbalize ability to manage therapeutic regimens
- Collaborate with health professionals to decide on a therapeutic regimen that is congruent with health goals and lifestyle

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Adherence Behavior; Health Education; Health System Guidance; Learning Facilitation; Learning Readiness Enhancement; Teaching: Prescribed Diet, Prescribed Exercise, Prescribed Medication

Example NIC Activities—Learning Facilitation

Present the information in a stimulating manner; Encourage the client's active participation

Nursing Interventions and *Rationales*

Note: This diagnosis does not have the same meaning as the diagnosis **Noncompliance.** This diagnosis is made with the client, so if the client does not agree with the diagnosis, it should not be made. The emphasis is on helping the client direct his or her own life and health, not on the client's compliance with the provider's instructions.

- Establish a collaborative partnership with the client for purposes of meeting health-related goals. **EBN:** *Nurse researchers explored ways that nurses and patients can better understand postoperative pain management needs, and the results of a qualitative study revealed the following helpful interventions: (1) communication and knowledge and the*

patients' ability to communicate, (2) pain assessment using a numerical rating scale, and (3) patient–nurse relationship consisting of frequent and direct contact (Kaptain, Bregnballe, & Dreyer, 2017). **EBN:** *Bennett (2017) studied patients who experienced a stroke and nurses' roles in the rehabilitation process using an ethnographic approach with 10 cases. Data revealed that the relationships built and sustained between nurses and patients were important in demonstrating caring, which in turn promoted emotional well-being and assisted stroke recovery.*

• Explore the client's perception of their illness experience and identify uncertainties and needs through open-ended questions. **EBN:** *A research team qualitatively explored perceptions and preferences of older adults (N = 13) and their family members about a fall risk assessment system when aging in place and to develop better technology to promote safety. Results demonstrated an acceptance of the technology after participants adapted, and acceptance was a process that grew in stages as the patient became used to technology (Galambos et al, 2017).* **EB:** *Lee and Chen (2017) studied perceptions about smoking after distributing a humorous antitobacco video on health-related social medial. After viewing the video respondents reported a higher level of risk perception of smoking, less positive attitude toward smokers, and a higher level of intention to avoid smoking in the future than others who viewed it on non–health-related social media sites.*

• Assist the client to enhance self-efficacy or confidence in his or her own ability to manage the illness. **EBN:** *Banman and Sawatzky (2017) completed a literature review on cardiovascular disease prevention and uncovered several reasons women are not as active as men in preventative health management: (1) lower self-efficacy beliefs, (2) lack of social support and confidence in their ability to care for themselves, and (3) any findings of depression negatively correlated with women's self-efficacy beliefs related to health behavior.* **EBN:** *Yu-Jie (2017) explored self-efficacy assessment instruments for patients with chronic kidney disease (CKD). Instruments were studied for reliability and validity, and the implication for nursing is the importance of approximately assessing self-efficacy in CKD patients to properly implement health management strategies. Involve family members in knowledge development, planning for self-management, and shared decision-making (SDM).* **EBN:** *Researchers studied the effects of an educational program developed for heart failure patients and their families (N = 100). They compared the results with patients who received the traditional education and found that the patients and families had better self-care maintenance, confidence, and quality of life (QoL) scores (Srisuk et al, 2017).* **EB:** *Adams and Levy (2017) explored the collaboration established by using SDM with children with disabilities and family and found that it promotes discussion of treatment plans, identifying gaps between the values of the child and the family, priorities, and better understanding of patient and family choices.*

• Review factors of the health belief model (HBM) (individual perceptions of seriousness and susceptibility, demographic and other modifying factors, and perceived benefits and barriers) with the client. **EB:** *Vandyke and Shell (2017) explored the role of the HBM in predicting breast cancer screening among women (N = 170) in rural Appalachia and found women perceived mammography more important if they viewed themselves at risk and though the mammogram was easy to obtain. This is consistent with the HBM, but the frequency of obtaining a mammography did not support the HBM.* **EB:** *Researchers studied the variables for nonadherence to immunosuppressive medication of kidney transplant patients (N = 120) based on the HBM. The results were consistent with the HBM because perceived susceptibility to rejection and perceived benefits were variables that predicted better adherence rates (Pen-Chen et al, 2017).*

• Help the client identify and modify barriers to effective self-management. **EB:** *Researchers examined patients (N = 14) with type 2 diabetes and severe mental illness because*

this group of patients experiences significantly poorer health outcomes than type 2 diabetic patients without diabetes. Participants were aware of the risks and stated that family and health care provider support was important in their self-maintenance (Mulligan et al, 2017).
EB: *Bovenkamp and Dwarswaard (2017) performed a qualitative study to gain insight into patients' self-maintenance or self-management practices and found after intervening with patients (N = 20) with chronic conditions that the practice is dependent on personal and social dynamics, patients' ideas of the good life, and their interactions with care professionals.*
• Help the client self-manage his or her own health through education about strategies for changing habits such as overeating, sedentary lifestyle, and smoking.
EB: *Pappa (2017) investigated the activity behavior and analyzed the message content participants (N = 107,886) in LoseIt (r/loseit), an online weight management community of the online social network Reddit, over 30 days and found that the most discussed topics were healthy food, clothing, calorie counting, workouts, looks, habits, support, and unhealthy food.*
EB: *Cruz et al (2017) performed a prospective, cross-sectional, and correlational study with teenagers (N = 150), aged 15 to 17, to determine whether weight, age, and gender have an influence on physical fitness and found that the participants who had normal weight had regular physical fitness and women had more obesity than men.*
• Develop a contract with the client to maintain motivation for changes in behavior.
EB: *Researchers adapted an existing interprofessional asthma program to fit a smaller practice to promote asthma management and provided a weekly asthma-management clinical for pediatric patients and their families. The results included a 69% and 92% reduction in emergency department (ED)/urgent care visits and hospitalizations, indicating that consistent intervention motivated behavioral changes to improve health (Kwong et al, 2017).* **EBN:** *Leine et al (2017) studied patients (N = 6) with chronic obstructive pulmonary disease (COPD) and their understanding and treatment adherence using a partnership-based nursing practice program. Interviews revealed two themes: feeling safe and comforted, and motivation to take better care of themselves.*
• Use focus groups to evaluate the implementation of self-management programs.
EB: *Serwe et al (2017) used focus groups (N = 4) to study caregivers' implementation of a telehealth self-maintenance program; the themes suggested that it promoted relationships, promoted positive interactions, and better explained the role.*
• Refer to the care plan Ineffective Family **Health** management.

Geriatric

• Identify the reasons for behaviors that are not therapeutic and discuss alternatives.
EBN: *Lee et al (2017) used the Theory of Planned Behavior with older adults to affect diabetes maintenance and found that older adults need adequate social support to sustain diabetes self-management practices.* **EB:** *Akmatov et al (2017) studied why patients do not participate in health initiatives. They surveyed participants between 65 and 80 years of age (N = 5582) and found that nonparticipation was associated with a low interest, a preference for less invasive information, and lack of time.*

Multicultural

• Assess the influence of cultural beliefs, norms, and values on the individual's perceptions of the therapeutic regimen. **EBN:** *Mou (2017) explored traditional Chinese medicine (TCM) as a method for promoting health and found through an online survey in China with 800 responses that cultural orientation and spirituality predicted use of TCM to promote health.* **EB:** *Doede et al (2017) studied the increase of noncommunicable diseases*

(NCDs) in South Africa, and qualitative interviews revealed common themes including resource scarcity, clinic–patient partnerships, management of NCDs, and collaboration between professionals. Discuss all strategies with the client in the context of the client's culture. **EB:** *Bach et al (2017) investigated access to health care for Vietnamese patients (N = 1003) who are on methadone maintenance treatment (MMT) and found that nearly 80% were not currently enrolled in health insurance, participants from rural regions were significantly more likely than urban participants to report poor care access, and 37% of participants reported a lack of information about health insurance and health care options.*

• Provide health information that is consistent with the health literacy of clients. **EB:** *Sainato et al (2017) studied US adolescents with chronic conditions and found that this high-risk group was twice as likely not to receive routine vaccinations, indicating additional education is needed in families with adolescents 16 to 18 years old with chronic illnesses.* **EB:** *Researchers used qualitative methods to study how individuals (N = 26) experienced accessing, understanding, appraising, and applying health information and identified four themes from interviews: using health literacy capacities, psychological and structural factors that affect these capacities, and the relationship quality with the health care providers (McKenna, Sixsmith, & Barry, 2017).*

• Assess for barriers that may interfere with client follow-up of treatment recommendations. **EB:** *Jena et al (2017) studied the effect of eliminating cost sharing for screening mammography on rates for 53,188 women with individual health insurance compared with those with employer-based health insurance. Findings demonstrated that there was a decline for both groups, indicating that other factors are present that deter health management.*

• Use electronic monitoring and dosing to improve management of medications. **EB:** *Rogers et al (2017) developed a system and studied individual discharge medication lists for 3 months in an automated medication system to assess errors that effected patients after discharge from the hospital. The most common error was lack of indication for medications; thus the patients did not know why to take them. The system developed reduced errors from 74% to 26%.* **EBN:** *Riley and Kruger (2017) examined the use of inhalers in patients with COPD and found that it is imperative to assess and teach patients about using a correct inhalation technique, assessing adequate dexterity to use the prescribed inhaler, if there is sufficient inspiratory flow rate to achieve adequate lung deposition, and if the inhaler is used by the patient at all.*

• Validate the client's feelings regarding the ability to manage his or her own care and the impact on lifestyle. **EBN:** *Lee et al (2017) qualitatively studied patients' perceptions of brisk walking as a method to reduce chronic disease symptomology in the community. Six focus groups were conducted (N = 48) ages 48 to 81, and five themes were identified: (1) health promotion and maintenance, (2) relationship building and social interactions, (3) leaders' enthusiasm and peer pressure, (4) the nature of brisk walking, and (5) becoming part of one's daily life.*

Home Care

• Prepare and instruct clients and family members in the use of a medication box. Set up an appropriate schedule for filling the medication box, and post medication times and doses in an accessible area (e.g., attached by a magnet to the refrigerator). **EBN:** *Milner and Bonaventura (2017) used self-management for patients on anticoagulants at home and it increased patient engagement in anticoagulant management, which resulted in better clinical outcomes.* **EB:** *Flood, Hawkins, and Rohloff (2017) studied diabetes self-management education (DSME) as a home-based intervention in a rural setting with 90 participants*

implementing six home visits, and hemoglobin (Hb)A1C decreased and systolic blood pressure improved significantly. Monitor self-management of the medical regimen. **EB:** *Shor et al (2017) studied 1-year medication therapy adherence rates among patients with fibromyalgia (FM) and found that in over 3000 patients 60% did not adhere to their medication regimen, warranting further investigation of intervening factors.*

• Refer to health care professionals for questions and self-care management. **EB:** *Homsted, Magee, and Nesin (2017) studied the use of a comprehensive, medical-home approach to controlling patients' (N = 1300) use of controlled substances. By using a program researchers decreased the use of controlled substances by 67.2% and 65.6%, with fewer patients receiving benzodiazepines.* **EB:** *Researchers studied the effects of a chronic disease self-management program on empowering hemodialysis patients (N = 53) and their QoL. Self-management increased the patients' QoL in 3 months (Ahmadzadeh et al, 2017).*

Client/Family Teaching and Discharge Planning

• Identify the client and/or family's current knowledge and adjust teaching accordingly. Teach the client and family about all aspects of the therapeutic regimen, providing as much knowledge as the client and family will accept, in a culturally congruent manner. **EBN:** *Sugiharto et al (2017) studied the patient outcome of improving nurses' skills and confidence in delivering DSME among type 2 diabetes patients and found that the diabetes training program for community health center nurses increased their skills and confidence in delivering DSME to patients.*

• Teach ways to adjust activities of daily living (ADLs) for inclusion in therapeutic regimens. **EBN:** *Jansons et al (2017) completed a randomized, controlled trial of patients with chronic conditions using a gym-based exercise program for health management and found improved health outcomes in the group that exercised when compared with the control group.* **EBN:** *Nestler et al (2017) performed a literature review (N = 12) related to women's muscle strength and work health issues and found weight training reduced patina and improved outcomes for women working in strenuous and nonstrenuous environments.*

• Teach safety in taking medications. **EB:** *Jones et al (2017) performed a 16-year longitudinal study of patients who were having chronic diseases and had their medication regimen followed and regulated by a specifically designed program. The results show decreased ED use and hospitalization by 18% compared with patients who were not in the program. Teach the client to act as a self-advocate with health providers who prescribe therapeutic regimens.* **EBN:** *Suijn and Hubert (2017) studied three groups with different levels of technology knowledge about accessing personal health information management (PHIM) by online survey and found that advanced PHIM users were significantly more likely to engage in emailing with providers, viewing test results online, and receiving summaries of hospital visits indicating that technology knowledge is important for self-advocating.*

Readiness for enhanced Health management

Ruth A. Wittmann-Price PhD, RN, CNS, CNE, CHSE, ANEF, FAAN

NANDA-I

Definition

A pattern of regulating and integrating into daily living a therapeutic regimen for treatment of illness and its sequelae, which can be strengthened.

Defining Characteristics

Expresses desire to enhance choices of daily living for meeting goals; expresses desire to enhance immunization/vaccination status; expresses desire to enhance management of illness; expresses desire to enhance management of prescribed regimens; expresses desire to enhance management of risk factors; expresses desire to enhance management of symptoms

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Health-Promoting Behavior; Health-Seeking Behavior; Knowledge: Health Behavior; Health Promotion; Health Resources; Illness Care; Medication; Prescribed Activity; Treatment Regimen

Example NOC Outcome with Indicators

Health-Promoting Behavior as evidenced by the following indicators: Monitors personal behavior for risks/Seeks balance activity and rest/Performs healthy behaviors routinely/Uses financial and social support resources to promote health. (Rate each indicator of **Health-Promoting Behavior:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Describe integration of therapeutic regimen into daily living
- Demonstrate continued commitment to integration of therapeutic regimen into daily living routines

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Anticipatory Guidance; Mutual Goal Setting; Client Contracting; Self-Modification Assistance; Self-Responsibility Facilitation; Support System Enhancement

Example NIC Activities—Mutual Goal Setting

Assist client and significant others to develop realistic expectations of themselves in performance of their roles; Clarify with the client the roles of the health care provider and the client, respectively

Nursing Interventions and *Rationales*

• Acknowledge the expertise that the client and family bring to health management. **EBN:** *nurse researchers compared the perceptions of patients (N = 50) with nurses (N = 100) of hospitalized patient care needs and found that surveyed patients and nurses agreed on needed areas such as communication and basic care. Slightly lower agreement scores between nurses and patients were identified for care planning and organization (Fernanades & Galan, 2017).* **EBN:** *Jeyathevan, Lemonde, and Cooper (2017) qualitatively explored the role of oncology nurse navigators (ONNs) (N = 4) with adult lung cancer patients (N = 4) in the community, and the results demonstrated that the patients' perceptions of the ONN role was that it assisted with patient-focused care, needs assessments, accessibility, and eliminating care barriers.*

• Review factors that contribute to the likelihood of health promotion and health protection. Use Pender's Health Promotion Model and Becker's Health Belief Model to identify contributing factors (Pender et al, 2015). **EBN:** *Researchers used a quasi-experimental designed study with women (N =108) who were placed in two groups to examine nutritional behavior, and the nurse researchers found that Pender's Health Promotion Model-based nutritional training improved behavior better in the experimental group (Khodaveisi et al, 2017).* **EBN:** *Acikgoz and Kitis (2017) investigated university students' (N = 572) healthy lifestyle behaviors and their health locus of control and health-specific self-efficacy by Internet survey and found that health-specific self-efficacy is an important factor in changing lifestyle behaviors. The health locus of control had varied effects on healthy lifestyle behaviors. The study results supported Pender's model.*

• Further develop and reinforce contributing factors that might change with ongoing management of the therapeutic regimen (e.g., knowledge, self-efficacy, self-esteem, and perceived benefits). **EB:** *Jiao et al (2017) studied the relationship between methadone maintenance treatment patients with mental health illnesses and resilience and found resilience to be negatively correlated with depression and anxiety, indicating that resilience in this population is important for mental health.*

• Review the client's strengths in the management of the therapeutic regimen. **EBN:** *Tao, Chow, and Wong (2017) investigated the effects of a home exercise program on hemodialysis patients' (N = 113) perceptions about exercise and adherence. Patients were divided into two groups, one of which was a nurse-led exercise program. Patients in the nurse-led group did significantly better in meeting their exercise goals then those afforded traditional care modalities.* **EB:** *Researchers studied the results of womens' (N = 4247) glucose challenge tests (GCTs) longitudinally for 9 years and found that 10% of women who had a high-normal result of 126 to 140 mg% had significantly more diabetes than those women whose GCTs were under 125 mg% (Yoles et al, 2017).*

• Collaborate with the client to identify strategies to maintain strengths and develop additional strengths as indicated. **EB:** *Researchers studied patient-centered care (PCC) by surveying and interviewing older patients (N = 56) in relation to being malnourished patients*

and found themes that effected dietary intake of older adults (>81 years): (1) dietetic follow-up, (2) interdisciplinary coordination, and (3) and high-quality hospital food services. The nutritional recommendations from this study may facilitate evidence-based PCC for older malnourished patients (Hazzard et al, 2017). **EB:** *Schmidt and Rizzolo (2017) explored the role of health care providers in the health and wellness of transgender and gender-diverse adults by investigating hormone therapy. Better results occurred with the individualization of treatment that was agreed on by the patient.*

• Identify contributing factors that may need to be improved now or in the future. **EB:** *Baill and Castiglioni (2017) examined the screenings women should receive post menopause and found that a woman's cardiovascular risk should be assessed every 5 to 10 years; breast cancer screening every other year; colorectal cancer screening; cervical cancer screening every 3 to 5 years; screening for high-risk women for sexually transmitted infections; and routine screening for depression, alcohol abuse, and intimate partner violence. The authors found that patient education was paramount in follow-through with any or all of the screenings. Provide knowledge as needed related to the pathophysiology of the disease or illness, prescribed activities, prescribed medications, and nutrition.* **EBN:** *Hovsepian, McGah, and O'Brien (2017) studied patient teaching postoperatively and learning retention with postoperative outcomes and found that better outcomes were realized when postoperative teaching was done preoperatively.* **EBN:** *Schneider and Howard (2017) investigated the differences in discharge readiness and postdischarge coping in stroke patients (N = 128) using education provided via a technology package (including patient online portal access, email/secure messaging) compared with current standard discharge teaching methods and found that there was no statistically significant difference between the groups in discharge readiness, but there was a significant increase in coping scores in the technology group.*

• Help the client maintain existing support and seek additional supports as needed. **EBN:** *Westcott and Welding (2017) documented case studies that support continuously reassessing home-bound patients' support surfaces in the house, educating patients, and providing appropriate resources to decrease pressure ulcers in community long-term care patients.* **EB:** *Researchers qualitatively explored the needs of patients (N = 41) who underwent bariatric surgery and found that support was needed from health professionals, significant others, peers, and the general community. Lack of support negatively affected surgical outcomes (Sharman et al, 2017).*

Geriatric

• Facilitate the client and family to obtain health insurance and drug payment plans whenever needed and possible. **EBN:** *Researchers used an interprofessional approach to explore the needs of geriatric patients (N = 293) and found through surveys and interviews that the patients' needs included guidance around falls prevention, improved nutrition, medication management, referrals to available community, and social service supports (Hansen et al, 2017).* **EBN:** *Lewis, Samperi, and Boyd-Skiner (2017) conducted telephone follow-up calls to elderly patients or bereaved family members after hospital admission, and patients and family reported feeling lonely and isolated. The patients and families were provided with community social support services with good response from patients and families.*

Multicultural

• Assess client's cultural perspectives on health management. **EB:** *Abbasalizad et al (2017) studied the relationship between Mediterranean diets and cardiovascular disease in*

patients with coronary artery bypass graft (CABG) surgery (N = 454) and found high dietary intakes of saturated fatty acids and cholesterol correlated with lower serum albumin and hemoglobin (Hb) A1C levels.

• Assess health literacy in clients of diverse backgrounds. **EBN:** *Eun, Hee, and Soondool (2017) investigated the level of health literacy in different age groups of South Koreans (N = 1000) and found that for the 45 through 64 and the 65 and over age groups education was positively associated with health literacy. Additionally, the oldest age group and gender also had a positive association with health literacy. Depression was negatively associated with health literacy.* **EB:** *Almaleh et al (2017) studied the factors that effected inadequate health literacy on patients (N = 805) using outpatient clinics and found that 81% of the patients had limited comprehensive health literacy, 18.9% had sufficient health literacy, and females had lower health literacy than males.*

• Validate the client's feelings regarding the ability to manage his or her own care and the impact on current lifestyle. **EBN:** *Araujo do Reis and de Oliva Menezes (2017) qualitatively studied religiosity and spirituality as a resilience strategy for improved lifestyles and health in aging patients (N = 14) and found those patients who revealed they participated in religious or spiritual habits achieved increased well-being and resiliency and were better able to cope with health and social problems.*

• Facilitate the client and family to obtain financial assistance in the form of health insurance and drug payment plans whenever needed and possible. **EB:** *Tumin et al (2017) studied the change in health insurance after heart transplantation among adolescents (N = 366) and found through statistical analysis that changes in health insurance predicted a greater mortality risk compared with patients with continuous private insurance. Therefore assisting with insurance coverage maintenance may provide better health outcomes.*

• Use electronic monitoring to improve medication adherence. **EB:** *Madrasi et al (2017) studied medication adherence for preexposure prophylaxis for patients (N = 1147) using electronic adherence records recording the date and time of medication bottle cap opening and found that female patients and older patients had better adherence.* **EB:** *Researchers completed a literature review focused on asthma controller medication adherence using electronics including text messaging, smart phone applications, and electronic monitoring devices and found that electronics that remind patients improve adherence controller adherence (Anderson & Anderson, 2017). Discuss with clients their beliefs about medication and treatment to enhance medication and treatment adherence.* **EB:** *Cook et al (2017) studied motivational interviewing (MI) and reminders related to adherence of glaucoma treatment for patients (N = 201), and the results demonstrated that reminder calls increased adherence when compared with usual care, but MI did not increase adherence.* **EBN:** *Low et al (2017) studied medication adherence with post kidney transplantation patients (N = 25) in a descriptive exploratory study, and the themes identified were causes of distress, and coping resources. Researchers concluded that regular reminders, such as alarms to take medications, will reduce the stress of managing a kidney transplant.*

Client/Family Teaching and Discharge Planning

• Review therapeutic regimens and their optimal integration with daily living routines. **EB:** *Zelle et al (2017) studied exercise in patients with chronic kidney disease and found that behavioral approaches need to be better integrated into the care of renal patients along with nutrition to ensure better outcomes and quality of life.* **EBN:** *Nurse researchers evaluated a family-based heart failure education program and performed a randomized control trial with patients (N = 50) and caretakers (N = 50) in a rural community and found that patients and family members who received the education program had higher knowledge scores*

at 3 and 6 months than those who received traditional outpatient education (Srisuk et al, 2017).

• Teach disease processes and therapeutic regimens to clients and peer supporters for management of disease processes. **EB:** *Inauen et al (2017) investigated patients (N = 84) with chronic conditions to assess overall multimedication adherence using self-reporting tools. The researchers recommended further study about multimedication adherence because most reports and tools refer to a single treatment or medication adherence.* **EB:** *Goethals et al (2017) longitudinally studied the role of parental responsiveness and control in relation to treatment adherence in diabetic children (N = 521) and found that lower psychological control and higher parental responsiveness were associated with better treatment adherence.*

Ineffective family Health management

Gail B. Ladwig MSN, RN, Julianne E. Doubet BSN, RN, EMT-B

NANDA-I

Definition

A pattern of regulating and integrating, into family processes a program for the treatment of illness and its sequelae that is unsatisfactory for meeting specific health goals of the family unit.

Defining Characteristics

Acceleration of illness symptoms of a family member; decrease in attention to illness; difficulty with prescribed regimen; failure to take action to reduce risk factors; inappropriate family activities for meeting health goals

Related Factors

Decisional conflict; difficulty managing complex treatment regimen;; difficulty navigating complex of healthcare systems; family conflict

At-Risk Population

Economically disadvantaged

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Family Health-Status; Knowledge: Treatment Regimen; Family Participation in Professional Care

Example NOC Outcome with Indicators

Knowledge: Treatment Regimen as evidenced by the following indicator: Understanding conveyed about prescribed medication, activity, exercise, and specific disease process. (Rate the outcome and indicators of **Knowledge: Treatment Regimen:** 1 = no knowledge, 2 = limited knowledge, 3 = moderate knowledge, 4 = substantial knowledge, 5 = extensive knowledge [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Make adjustments in usual activities (e.g., diet, activity, stress management) to incorporate therapeutic regimens of its members
- Reduce illness symptoms of family members
- Desire to manage therapeutic regimens of its members
- Describe a decrease in the difficulties of managing therapeutic regimens
- Describe actions to reduce risk factors

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Family Involvement Promotion; Family Mobilization; Teaching: Disease Process

Example NIC Activities—Family Involvement Promotion

Identify and respect coping mechanisms used by family members; Provide crucial information to family members about the patient in accordance with client's preference

Nursing Interventions and *Rationales*

- Base family interventions on knowledge of the family, family context, family dynamics, family structure, and family function. **EBN:** *Family research has established that families differ widely from one another, even within cultures (Wright & Leahey, 2013).*
- Use a family approach when helping an individual with a health problem that requires therapeutic management. **EB:** *Cwik et al (2013) suggested that a family meeting, which includes the family member who needs medical accommodation, is the first step in planning coordinated care and its integration into everyday life.*
- Review with family members the congruence and incongruence of family behaviors and health-related goals. **EBN:** *To attain the motivation needed for changes in health habits, family members should understand the relation of daily habits to health-related goals (Wright & Leahey, 2013).*
- Acknowledge the challenge of integrating therapeutic regimens with family behaviors. **EBN:** *Therapeutic regimens require modifications of daily activities that have already been established based on family values and beliefs. Acknowledging the difficulty of changing family habits supports families through the process (Wright & Leahey, 2013).*
- Review the symptoms of specific illnesses and work with the family toward development of greater self-efficacy in relation to these symptoms. **EBN:** *Knowledge of symptoms improves the ability of family members to adjust behaviors to prevent and manage symptoms (Larsen, 2014).*
- Support family decisions to adjust therapeutic regimens as indicated. **EB:** *The National Institute of Neurological Disorders and Stroke (2018) published findings that concluded a woman suffering from epilepsy can have a healthy pregnancy and deliver a healthy child with planned adjustments in medication and the addition of certain supplements.*

• Advocate for the family in negotiating therapeutic regimens with health providers. **CEB:** *Illness regimens generally are neither arbitrary nor absolute; therefore modifications can be discussed as needed to fit with the family lifestyle (Wright & Leahey, 2013).*
• Help the family mobilize social supports. **EBN:** *Nurses in any capacity may detect a family/individual in crisis and will be obliged to provide crisis intervention while connecting the family/individual to other needed support services (Parsons, 2016).*
• Help family members modify perceptions as indicated. **EB:** *Illness perception, family adaptability, and coping mechanisms are key factors for the quality of life of a patient with a chronic disease (Postolica et al, 2017).*
• Use one or more theories of family dynamics to describe, explain, or predict family behaviors (e.g., theories of Bowen, Satir, and Minuchin). **EBN:** *Family systems may not be understood by the nurse without adequate knowledge of family theory (Wright & Leahey, 2013).*
▲ Collaborate with expert nurses or other consultants regarding strategies for working with families. **EBN:** *The findings underscore the need for researchers and health care professionals to engage in collaborative discussions and make cooperative efforts to help alleviate treatment burden and tailor treatment regimens to the realities of people's daily lives (Sav et al, 2015).*
• Coaching methods can be used to help families improve their health. **CEB:** *Coaching processes were shown to improve family outcomes related to improved nutrition and physical activity (Heimendinger et al, 2007).* **EB:** *Connecting to Internet sites and online resources that included communication and support from peers; contact with experts, clinicians, and coaches; and those sites offering means of support to the caregiver, improved symptom control in cancer patients (Griffin et al, 2013).*

Pediatric

• Support kangaroo care for infants at risk at birth. Keep infants in an upright position in skin-to-skin contact until they no longer tolerate it. **EBN:** *According to ten Ham-Baloyi, Ricks, and van Rooyen (2017), some of the benefits derived from kangaroo mother care (KMC) are improving mother–infant attachment; encouraging the continuance of breastfeeding; and helping to reduce mortality of preterm neonates.*

Geriatric

• Recommend that clients use the "Ask Me 3" program when communicating with their health providers (What is my main problem? What do I need to do? Why is it important for me to do this?). **EBN:** *The Ask Me 3 program is an effective means of affirming patients' knowledge and understanding of their conditions and treatments. The program also serves to increase "buy in" to their plan of care, thus promoting healthier outcomes (Marben, 2013).*

Multicultural

• Acknowledge racial and ethnic differences at the onset of care. **CEB:** *Acknowledgment of race and ethnicity issues enhances communication, establishes rapport, and promotes treatment outcomes (Giger & Davidhizar, 2008).*
• Ensure that all strategies for working with the family are congruent with the culture of the family. **CEB:** Many nursing studies among people of a variety of cultures show that cultural variations exist in the management of therapeutic regimens, and these differences should be taken into account when working with families (Hanley, 2008).

• Facilitate modeling and role playing for the family regarding healthy ways to communicate and interact. **EBN:** It is helpful for families and the client to practice communication skills in a safe environment before trying them in a real-life situation (Wright & Leahey, 2013).
• Use the nursing intervention of cultural brokerage to help families deal with the health care system. **CEB:** In a study based on 24 in-depth interviews, four empirical mechanisms of cultural brokerage were identified: translating between health systems, bridging divergent images of medicine, establishing long-term relationships, and working with patients' relational networks (Lo, 2010). **EBN:** Culture brokerage is a type of developing care that can be used in various manners when applied to the community and/or hospital environments. This approach benefits the progression of the nursing discipline (Arias-Murcia & Lopez-Dias, 2013).

Client/Family Teaching and Discharge Planning

• Teach about all aspects of therapeutic regimens. Provide as much knowledge as family members will accept, adjust instruction to account for what the family already knows, and directions provide information in a culturally congruent manner. **EBN:** *Use "tailored to the client" instructions, which may include medical and disease education, skills training, and resource connection (Chin et al, 2017).*
• Teach ways to adjust family behaviors to include therapeutic regimens, such as safety in taking medications and teaching family members to act as self-advocates with health providers who prescribe therapeutic regimens. **EBN:** By using continuous care interventions, a trusting relationship can be established with the family caregiver (Chin et al, 2017).

Ineffective Health maintenance

Kathaleen C. Bloom PhD, CNM, Lauren McAlister MSN, FNP, DNP Candidate

NANDA-I

Definition

Inability to identify, manage, and/or seek out help to maintain well-being.

Defining Characteristics

Absence of adaptive behaviors to environmental changes; absence of interest in improving health behaviors; inability to take responsibility for meeting basic health practices; insufficient knowledge about basic health practices; insufficient social support; pattern of lack of health-seeking behavior

Related Factors

Complicated grieving; impaired decision-making; ineffective communication skills; ineffective coping strategies; insufficient resources; spiritual distress

At-Risk Population

Developmental delay

Associated Condition

Alteration in cognitive functioning; decrease in fine motor skills; decrease in gross motor skills; perceptual disorders

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Health Orientation; Health Beliefs: Perceived Resources; Health-Promoting Behavior; Health-Seeking Behavior

Example NOC Outcome with Indicators

Health-Seeking Behavior as evidenced by the following indicators: Completes health-related tasks/Performs self-screening/Obtains assistance from health professional. (Rate the outcome and indicators of **Health-Seeking Behavior:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Discuss fear of or blocks to implementing health regimen
- Follow mutually agreed on health care maintenance plan
- Meet goals for health care maintenance

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Health Education; Health System Guidance; Support System Enhancement

Example NIC Activities—Health Education

Prioritize identified learner needs based on client preference, skills of nurse, resources available, and likelihood of successful goal attainment; Emphasize immediate or short-term positive health benefits to be received by positive lifestyle behaviors, rather than long-term benefits or negative effects of noncompliance

Nursing Interventions and *Rationales*

• Assess the client's feelings, values, and reasons for not following the prescribed plan of care. See Related Factors. **EBN:** *A systematic review of 80 studies determined that personal beliefs and values, decisional control preferences, and perception of the decision-making process affect treatment decision-making in older adults diagnosed with cancer (Tariman et al, 2012).*
• Assess for family patterns, economic issues, and spiritual and cultural patterns that influence compliance with a given medical regimen. **CEB:** *A qualitative study (N = 14) found that critical challenges to increasing physical activity among low-income African American women included financial constraints (Harley et al, 2014).*
• Involve the client in shared decision-making regarding health maintenance. **CEB:** *A meta-analysis of 32 clinical trials revealed that assessing client preferences and involving them in shared decision-making had higher adherence, higher satisfaction, and better clinical outcomes (Lindhiem et al, 2014).*
• Show genuine interest in the client's individual needs. **EBN:** *A systematic review of 24 qualitative studies concluded that clients' perceptions of the health care professional's responsiveness, interest in their individual needs, and shared information positively influence self-care for heart failure (Currie et al, 2014).*
• Assist the client in finding methods to reduce stress. **EBN:** *In a survey of 1257 university students, those who had high levels of perceived stress also engaged in high-risk behaviors such as alcohol consumption, unhealthy diet, physical inactivity, and tobacco and drug use (Deasy et al, 2014).*
• Help the client determine how to manage complex medication schedules (e.g., HIV/AIDS regimens or polypharmacy). **EBN:** *In a pilot study with 20 older adults taking an average of 13.2 prescription medications, providing an illustrated daily medication schedule improved both self-efficacy and adherence (Martin, Kripalani, & Durapau, 2012).*
• Identify complementary healing modalities, such as herbal remedies, acupuncture, healing touch, yoga, or cultural shamans that the client uses in addition to or instead of the prescribed allopathic regimen along with the client's perception of the complementary healing modalities. **CEB:** *Use of complementary healing modalities among clients with chronic disease is relatively high. In an exploratory study with 217 Mexican immigrants, a person's beliefs about complementary and alternative therapies may negatively influence medical adherence (Villagran et al, 2012).*
▲ Refer the client to appropriate medical and social services as needed, providing adequate information on details about the service, including scheduling. **EBN:** *A metasynthesis of 62 qualitative studies concluded that client participation in services such as cardiac rehabilitation is most strongly associated with perceptions of the nature, suitability, and scheduling, but not the benefits of the rehabilitation program (Clark et al, 2013).*
• Identify support groups related to the disease process. **EBN:** *Individuals who attend support groups demonstrate improved disease management and enhanced quality of life. A systematic review of 84 studies of group visits for chronic illness found client benefits to include greater satisfaction and improved clinical outcomes (Jones et al, 2014).*

• Use social media such as text messaging to remind clients of scheduled appointments. **CEB:** *A Cochrane review of eight randomized controlled trials concluded that text messaging reminders increase attendance at health care appointments similar to telephone reminders but better than no reminders or postal reminders (Gurol-Urganci et al, 2013). Additional relevant research is done by Farmer et al (2014) and McInnes et al (2014).*
• Use telehealth interventions to facilitate self-care. **EBN:** *A systematic review of 14 studies supports telehealth as a positive factor in enabling self-care behaviors related to daily weighing, medication management, exercise adherence, fluid and alcohol restriction, salt restriction, and stress reduction in clients with heart failure (Radhakrishnan & Jacelon, 2012).*

Geriatric

• Assess the client's perception of health and health maintenance. **CEB:** *A study of 681 older clients with diabetes or metabolic syndrome found that they often underestimate their cardiovascular risk, with as many as 42% perceiving themselves to be in good or excellent health (Martell-Claros et al, 2013).*
• Assist client to identify both life- and health-related goals. **CEB:** *A study of 308 women demonstrated beginning evidence that when the health goals of older individuals are congruent with their life goals, they are more likely to participate in health-related activities (Saajanaho et al, 2014).*
• Provide information that supports informed decision-making. **CEB:** *In a modified grounded theory study (N = 59), participants endorsed the elements of informed decision-making, including discussion of the role of the client, the clinical issue, the alternatives, and benefits/risks/uncertainties; assessment of client understanding and preference; soliciting input from trusted others; and discussion of the effect on clients' daily lives (Price et al, 2012).*
• Discuss realistic goal setting for changes in health maintenance with the client and support person. **EBN:** *An integrative review of 13 studies revealed that mutual goal-setting between the client and the health care provider improves overall health behaviors and outcomes for older adults with chronic conditions (Anuruang et al, 2014).*
• Educate the client about the symptoms of life-threatening illness, such as myocardial infarction (MI), and the need for timeliness in seeking care. **EBN:** *A qualitative study with 42 persons with an MI found that misinformation regarding the symptoms of MI is common; many believe sudden, intense chest pain is the only indication of MI, resulting in delay in seeking treatment (O'Donnell & Moser, 2012).*

Multicultural

• Assess influence of cultural beliefs, norms, and values on the client's ability to modify health behavior. **EBN:** *A descriptive qualitative study of 30 Thai Buddhists revealed that understanding the cultural and religious traditions, understanding the influence of family and economics when choosing interventions to help them cope with their illness, and empowering them to control their disease are essential for effective care (Lundberg & Thrakul, 2012).*
• Assess the effect of fatalism on the client's ability to modify health behavior. **CEB:** *A population-based study of 2018 adults found that fatalistic beliefs about cancer may hamper screening and delay help-seeking for symptoms (Beeken et al, 2011).*
• Clarify culturally related health beliefs and practices. **EBN:** *Language, culture, and ethnicity influence the choice of a health care provider and participation in health management strategies. An exploratory descriptive study with 23 women found that health/illness beliefs affect both self-care and care seeking (Hjelm, Berntorp, & Apelqvist, 2012).*

• Provide culturally appropriate education and health care services. **CEB:** *In a randomized controlled trial involving 223 Hispanic women, a culturally tailored lifestyle behavior intervention was shown to significantly influence dietary habits, weight, and waist circumference (Koniak-Griffin et al, 2014).* **CEB:** *In a systematic review of 28 studies of culturally adapted strategies to improve diet and weight outcomes of African American women, strategies that reflected the group's values and beliefs and that drew from the group's experiences were the most successful (Kong et al, 2014).*

Home Care

• The interventions described previously may be adapted for home care use.
▲ Provide nurse-led case management. **EBN:** *A review of relevant research concluded that individualized, systematic, and guideline-based nurse case management promotes cardiovascular risk reduction in home-based, primary care, and community settings (Berra, 2011).*
• Provide a health promotion focus for the client with disabilities, with the goals of reducing secondary conditions (e.g., obesity, hypertension, pressure sores), maintaining functional independence, providing opportunities for leisure and enjoyment, and enhancing overall quality of life. **CEB:** *A retrospective analysis of data from a national survey comparing the health of adults with and without physical or cognitive disabilities found that individuals living with physical disabilities or cognitive impairment receive fewer preventive services and have higher rates of chronic illness (Reichard, Stolzle, & Fox, 2011). A systematic review of 11 studies found that community-based physical activity and educational programs provide fitness and psychosocial benefits for individuals with intellectual disabilities (Heller et al, 2011).*
• Provide support and individual training for caregivers before the client is discharged from the hospital. **EBN:** *Caregivers are very interested in receiving instruction and hands-on practice of procedures they would need to perform at home. In a study of hospital-to-home transition of older veterans, caregivers (N = 40) reported increased confidence in their ability to provide such care and to help their loved ones manage symptoms at home (Hendrix et al, 2011).*
• Assist the client to develop confidence in the ability to manage the health condition. **CEB:** *A clinical trial of self-management education targeted at self-efficacy (N = 57) improved physiological outcomes, enhanced coping techniques, and reduced health care use (Labrecque et al, 2011).*

Client/Family Teaching and Discharge Planning

• Provide the family with credible sources in which information can be obtained from social media. (Most libraries have Internet access with printing capabilities.) **CEB:** *In an experimental study (N = 197), researchers concluded that websites containing credible and evidence-based medical information positively affected users seeking health information. General, non–evidence-based sites were perceived positively by the user, independent of the site's credibility, often negatively influencing opinions about health practices (Allam, Schulz, & Nakamoto, 2014).*
▲ Develop collaborative multidisciplinary partnerships. **CEB:** *Multidisciplinary and multifactorial interventions are likely to be more effective in achieving desired outcomes. In a quality improvement study of readmission rates for 463 clients with pneumonia, the clients whose in-hospital and postdischarge diagnosis and care were managed by a multidisciplinary team consisting of health care providers, nurses, and social workers had significantly fewer all-*

cause readmissions and readmissions for pneumonia (Hussein, Golden, & Hahn, 2014).

- Tailor both the information provided and the method of delivery of information to the specific client and/or family. **CEB:** *A systematic review of 27 studies related to medication adherence and diabetes outcomes was not able to identify a specific intervention, but it emphasized the need to tailor interventions to optimize management and improve outcomes (Williams et al, 2014).*
- Explain nonthreatening qualities before introducing more anxiety-producing information regarding possible side effects of the disease or medical regimen. **EBN:** *In a laboratory study of anxiety and task interference (N = 157), anxiety was found to interfere with concentration and the ability to understand and remember (Lachman & Agrigoroaei, 2012).*

Impaired Home maintenance

Kathaleen C. Bloom PhD, CNM, Lauren McAlister MSN, FNP, DNP Candidate

NANDA-I

Definition

Inability to independently maintain a safe growth-promoting immediate environment.

Defining Characteristics

Difficulty maintaining a comfortable environment; excessive family responsibilities; impaired ability to maintain home; insufficient clothing; insufficient cooking equipment; insufficient equipment for maintaining home; insufficient linen; pattern of disease caused by unhygienic conditions; pattern of infection caused by unhygienic conditions; request for assistance with home maintenance; unsanitary environment

Related Factors

Inadequate role model; insufficient family organization; insufficient family planning; insufficient knowledge of home maintenance; insufficient knowledge of neighborhood resources; insufficient support system

At-Risk Population

Financial crisis

Associated Condition

Alteration in cognitive functioning

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Safe Home Environment; Self-Care: Activities of Daily Living (ADLs)

Example NOC Outcome with Indicators

Safe Home Environment as evidenced by the following indicators: Elimination of pests/Smoke detector maintenance/Accessibility of assistive devices/Elimination of tobacco smoke. (Rate the outcome and indicators of **Safe Home Environment:** 1 = not adequate, 2 = slightly adequate, 3 = moderately adequate, 4 = substantially adequate, 5 = totally adequate [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Maintain a healthy home environment
- Use community resources to assist with home care needs
- Maintain a safe home environment

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Home Maintenance Assistance

Example NIC Activities—Home Maintenance Assistance

Involve client/family in deciding home maintenance requirements; Provide information on how to make home environment safe and clean; Help family use social support network

Nursing Interventions and *Rationales*

- Assess the concerns of family members, especially the primary caregiver, about home care for a long time. **EBN:** *A cross-sectional study of 515 caregiver/client dyads found that caregiver confidence in the ability to contribute to their family member's self-care was a significant determinant of how much they were involved in self-care maintenance and management (Vellone et al, 2014).*
- Provide home safety education and, safety equipment when possible. **CEB:** *A Cochrane review of 98 studies (with meta-analysis of 54 studies) concluded that home safety interventions, especially those delivered in the home, were effective in reducing injury and in increasing uptake of home safety measures, including safe water temperature, functional smoke alarms, a fire escape plan, and storing hazardous items out of reach (Kendrick et al, 2013).*

▲ Consider a predischarge home assessment referral to determine the need for accessibility and safety-related environmental changes. **EB:** *A randomized controlled trial (RCT) (N = 842 households, 1848 individual occupants) found significantly fewer falls and fall-related injuries in those households that had specific low-cost home modifications such as alterations in steps inside and outside the house, grab rails and nonslip bath mats in bathrooms, outside lighting, and alterations in carpeting (Keall et al, 2014).*

- Use an assessment tool to identify environmental safety hazards in the home. **EBN:** *In a study of 130 persons receiving discharge teaching, those who received targeted education and practice using a mock-up of their home regarding home safety modifications had significantly fewer overall and in-home falls 1 year after discharge (Kamei et al, 2015).*
- Establish an individualized plan of care for improved home maintenance with the client and family based on the client's needs and the caregiver's capabilities. **EBN:** *In a study involving 116 households with 170 children with asthma, an in-home assessment followed by targeted changes in the home environment resulted in a decrease in all measures of*

asthma severity and health care utilization (Turcotte et al, 2014).
• Set up a system of relief for the main caregiver in the home and a plan for sharing household duties and/or outside assistance. **EBN:** *In a qualitative study, 34 parents providing care to children with disabilities or complex health care needs identified the need for help and support, indicating that respite care was a significant unmet need (Whiting, 2014).*
▲ Provide a multidisciplinary approach to target the home environment and the client's ability to function in the home. **EBN:** *The Community Aging in Place: Advancing Better Living for Elders (CAPABLE), a program involving teams of nurses, occupational therapists, and handymen, targets the home environment and individual physical function (Szanton et al, 2014). An evaluation study of the effectiveness of the program found that 75% of the participants significantly improved their performance of ADLs and had improved ability to do their own shopping and manage their medications (Szanton et al, 2016).*
• Assess the quality of relationships among family members. **CEB:** *In a cross-sectional study of fifth graders (N = 3218), unintentional injuries requiring medical attention were associated with parental marital discord (Schwebel et al, 2012).*

Geriatric

• All of the previously mentioned interventions are applicable for the geriatric population.
• Assess injury prevention knowledge and practices of the client and caregivers and provide information as appropriate. **EBN:** *A survey of 84 older adults showed that only 36% had a working smoke alarm, 22% had a working carbon monoxide alarm, and 36% had water that was hotter than recommended (Shields et al, 2013).*
• Assess functional ability to manage safely after hospital discharge. **EB:** *A validation study of The Assessment of Motor and Process Skills and Cognitive Performance Test were found to reliably predict time to incident of harm post discharge (Douglas et al, 2013).*
• Explore community resources to assist with home maintenance (e.g., senior centers, Department of Aging, hospital case managers, friends and relatives, the Internet, or church parish nurse). **EB:** *In a qualitative study with 43 older adults living at home, participants perceived they were both capable and willing to manage many home maintenance tasks. They reported using compensatory means, such as tools and technologies and to do home maintenance and repairs themselves or hiring someone or having friends, neighbors, or family do the task (Kelly et al, 2014).*
• Provide education related to home modification. **EBN:** *An RCT with 130 community-dwelling older adults found that a home hazard modification program that included education and practice about home safety and specific guidance on how to modify the home to improve safety significantly decreased falls, both indoors and outdoors (Kamei et al, 2015).*
• Focus on the interaction between the older client and the technology, assisting the client to be an active participant in choices of and uses for technology. **EB:** *A qualitative study used focus groups with older adults, care professionals, home care or social work managers, and technology designers and suppliers to identify parameters for technology for aging in place. The researchers found that all groups believed success was enhanced when the older adult's needs and wishes are prioritized and that the technology is accepted by the older adults and perceived as beneficial (Peek et al, 2016).*
• See the care plans for Risk for **Injury** and Risk for **Falls.**

Multicultural

• Acknowledge the stresses unique to racial/ethnic communities. **CEB:** *A systematic*

review of 57 studies revealed that cultural factors, including distrust of home visits, language barriers and lifestyle, were barriers to home injury prevention interventions (Ingram et al, 2012).

Home Care

- The previously mentioned interventions incorporate these resources.
- See care plans **Contamination** and Risk for **Contamination.**

Client/Family Teaching and Discharge Planning

- Identify support groups within the community to assist families in the caregiver role. **CEB:** *Community-based participatory research using focus groups with 39 family caregivers found that caregivers are most in need of effective communication, emotional support, education, and advocacy (Macleod, Skinner, & Low, 2012).*
- Provide counseling and support for clients and for caregivers of clients. **EB:** *A systematic review of 28 studies found that education, counseling, and support of caregivers to individuals with disabilities improved the caregivers' quality of life and decreased their perceived stress of the caregivers (Lawang et al, 2013).* Focus teaching on environmental hazards identified in the nursing assessment. Areas may include, but are not limited to the following:
    - **Home Safety.** Identify the need for and use of common safety measures in the home. **EB:** *An RCT of an injury prevention briefing designed to improve fire safety found numerous risk factors for falls, poisonings, and scalds. Families in the intervention arm were less likely to report match play and more likely to report bedtime fire safety routines (Kendrick et al, 2017).*
    - **Food Safety.** Instruct client to avoid microbial foodborne illness by storing and cooking food at the proper temperature; regularly washing hands, food contact surfaces, and fruits and vegetables; and monitoring expiration dates. **EBN:** *A qualitative study of 10 households found that all took risks in terms of not following recommended practices with respect to best practices and that the logic behind food practices was often faulty (Dickinson et al, 2014).*
- Teach clients to assess their homes for potential environmental health hazards in the home, including risks related to structure, moisture/mold, fire, pets, electrical, ventilation, pests, and lifestyle. **CEB:** *The housing-based hazard index (HHI) is a measure of overall home hazards with good reliability and validity and the ability to discriminate between healthy and nonhealthy homes (N = 643) (Nriagu et al, 2012).*
- See care plans **Contamination,** Risk for **Contamination,** Risk for **Falls,** Risk for **Infection,** and Risk for **Injury.**

Readiness for enhanced Hope

Marina Martinez-Kratz MS, RN, CNE

NANDA-I

Definition

A pattern of expectations and desires for mobilizing energy on one's own behalf, which can be strengthened.

Defining Characteristics

Expresses desire to enhance ability to set achievable goals; expresses desire to enhance belief in possibilities; expresses desire to enhance congruency of expectations with goal; expresses desire to enhance connectedness with others; expresses desire to enhance hope; expresses desire to enhance problem solving to meet goal; expresses desire to enhance sense of meaning in life; expresses desire to enhance spirituality

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Hope; Quality of Life

Example NOC Outcome with Indicators

Hope as evidenced by the following indicators: Expresses expectation of a positive future/Expresses faith/Expresses meaning in life/Exhibits a zest for life/Sets goals. (Rate the outcome and indicators of **Hope:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Describe values, expectations, and meanings
- Set achievable goals that are consistent with values
- Design strategies to achieve goals
- Express belief in possibilities

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Emotional Support; Hope Inspiration; Presence; Support System Enhancement

Example NIC Activities—Hope Inspiration

Assist client and family to identify areas of hope in life; Demonstrate hope by recognizing the client's intrinsic worth; Encourage therapeutic relationships; Help the person expand spiritual self

Nursing Interventions and *Rationales*

- Spend one-on-one time with the client. Use empathy; try to understand what the client is saying and communicate this understanding to the client to create a nonjudgmental trusting environment to develop therapeutic relationships with the client. **EB:** *Patient ratings of the therapeutic relationship predicted social inclusion through hopefulness (Berry & Greenwood, 2015).*

• Assist clients to identify sources of gratitude in their lives using a future-oriented focus. **CEB:** *Research shows that clients with a regulatory focus of promotion were more likely to express gratitude, which inspired them to strengthen their relationships with helpful and responsive partners (Mathews & Shook, 2013).*
• Assist families to identify sources of gratitude in their lives. **CEB:** *Research showed that gratitude fostered all facets of posttraumatic growth, such as relationships, personal strengths, and awareness of meaningful possibilities (Ruini & Vescovelli, 2013).*
• Screen the client for hope using a valid and reliable instrument as indicated. **CEB:** *The HHI is a brief instrument with good psychometric properties that has been developed for clinical use. It has been designed to facilitate the examination of hope at various intervals so that changes in levels of hope can be identified (Hunsaker et al, 2016).*
• Focus on the positive aspects of hope. **EBN:** *An integrative study found that when an institution provides a positive context, it promotes hope (e.g., sets goals, generates pathways, sustains motivation) in attaining educational objectives for college students (Griggs, 2017).*
• Assist the client to develop positive expectations outcomes and recognize the pathways to achieve the positive outcomes. **EB:** *Research findings suggest that lack of positive expectations account for the relationship between hopelessness and future depression and suicidal behavior among adolescents (Horwitz et al, 2017).*
• Explore the meanings, functions, objects, sources, and nature of hope with patients as relates to their current situation. **EBN:** *A better understanding of the patient's meaning of hope can assist nurses to foster hope and provide better support (Marco, Pérez, & García-Alandete, 2016).*
• Teach individuals how to become aware of attention that is focused on unwanted aspects of life and how to redirect attention toward things that feel more wanted or desired by using a future-directed approach. **CEB:** *Future-directed therapy is effective at decreasing hopelessness and increases positive future expectations (Vilhauer et al, 2013).*
• Review the client's strengths and resources in conjunction with the client. **EBN:** *A strengths-based perspective support group intervention reduced the participants' level of depressive symptoms and improved the pathway component of hope (Hou, Ko, & Shu, 2016).*
• Assist the client to consider alternatives and set long- and short-term goals that are important to him or her. **EBN:** *A mixed-method thematic review found that setting and achieving goals was a theme that increased hope (Broadhurst & Harrington, 2016).*
• Encourage engagement in positive and pleasant events. **EB:** *This study found that targeting both hopelessness and engagement in pleasant events may be helpful in improving the quality of life of vulnerable, rural, older adults (Scogin et al, 2015).*
• Facilitate sources of the client's resilience. **CEB:** *Higher levels of resilience were associated with lower levels of hopelessness in children of HIV-positive parents (Mo et al, 2014).*
• Implement social supports and reintegration programs for postdeployment soldiers and veterans in a timely fashion. **EB:** *Research determined that hopelessness was moderated by timely implementation of postdeployment support and reintegration programs (Martin et al, 2016).*
• Encourage the client to adopt active coping strategies. **EB:** *In the current study, proactive coping predicted hope regardless of severity of spinal cord injury (Phillips et al, 2016).*
• Identify spiritual beliefs and practices. **CEB:** *Spirituality was identified as a factor in increasing hope in clients with mental illness (Schrank et al, 2012).*

• The previously mentioned interventions may be adapted for home care use.

Client/Family Teaching and Discharge Planning

• Teach alternative coping strategies such as physical activity. **CEB:** *Clients with severe mental illness showed decreased hopelessness after participation in an adjunct exercise program (Sylvia et al, 2013).*
▲ Refer the client to self-help groups. **EB:** *Support groups provided an experience of community in which hope was encouraged (Behler et al, 2017).*
• Use a family-centered approach to provide information regarding the client's condition, treatment plan, and progress. **EBN:** *Clients reported increased hope after a planned family-centered discharge process (Ingram et al, 2017).*
• Offer emotional support, active listening, and coping assistance to client families. **EBN:** *Family hopelessness is addressed when nurses offer emotional support (Coco et al, 2013).*

Hopelessness

Marina Martinez-Kratz MS, RN, CNE

NANDA-I

Definition

Subjective state in which an individual sees limited or no alternatives or personal choices available and is unable to mobilize energy on own behalf.

Defining Characteristics

Alteration in sleep pattern; decrease in affect; decrease in appetite; decrease in initiative; decrease in response to stimuli; decrease in verbalization; despondent verbal cue; inadequate involvement in care; passivity; poor eye contact; shrugging in response to speaker; turning away from speaker

Related Factors

Chronic stress; loss of belief in spiritual power; loss of belief in transcendent values; prolonged activity restriction; social isolation

At-Risk Population

History of abandonment

Associated Condition

Deterioration in physiological condition

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Decision-Making; Hope; Mood Equilibrium; Nutritional Status: Food and Fluid Intake; Quality of Life; Sleep

Example NOC Outcome with Indicators

Has a presence of **Hope** as evidenced by the following indicators: Expresses expectation of a positive future/Expresses faith/Expresses will to live. (Rate the outcome and indicators of **Hope:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Verbalize feelings
- Participate in care
- Make positive statements (e.g., “I can” or “I will try”)
- Set goals
- Make eye contact, focus on speaker
- Maintain appropriate appetite for age and physical health

- Sleep appropriate length of time for age and physical health
- Express concern for another
- Initiate activity

NIC (Nursing Interventions Classification)

Suggested NIC Intervention
Hope Inspiration

Example NIC Activities—Hope Inspiration
Assist client/family to identify areas of hope in life; Demonstrate hope by recognizing client's intrinsic worth and viewing client's illness as only one facet of the individual; Expand the client's repertoire of coping mechanisms

Nursing Interventions and *Rationales*

▲ Assess for, monitor, and document the potential for suicide. (Refer the client for appropriate treatment if a potential for suicide is identified.) Refer to the care plan Risk for **Suicide** for specific interventions. **CEB:** *In this study of men who had attempted suicide, hopelessness was identified as an important risk factor; thus it is important that it is identified by nurses (Hinkkurinen, Isola, & Kylmä, 2011).*
▲ Assess and monitor potential for depression. (Refer the client for appropriate treatment if depression is identified.) **CEB:** *Hopelessness is a potential predictor for depressive and suicidal symptoms (Wang et al, 2013).*
▲ Assess for hopelessness with the modified Beck Hopelessness Scale. **CEB:** *The modified Beck Hopelessness Scale is a valid and reliable tool to measure hopelessness (Fisher & Overholser, 2013).*
• Assess and monitor family caregivers for symptoms of hopelessness. **EBN:** *Adult daughter caregivers experience hopelessness as part of compassion fatigue (Day, Anderson, & Davis, 2014). Significant correlations were found between hopelessness and coping strategies with a positive correlation between hopelessness and the helpless approaches (Tokem, Ozcelik, & Cicik, 2015).*
• Assess for pain and respond with appropriate measures for pain relief. **EB:** *In the present study, hopelessness played a central role in the relationship between pain and depression with pain intensity positively related to hopelessness (Hülsebusch, Hasenbring, & Rusu, 2016).*
• Facilitate sources of the client's resilience. **CEB:** *Higher levels of resilience were associated with lower levels of hopelessness in children of HIV-positive parents (Mo et al, 2014).*
• Assist the adolescent client to develop positive expectations. **EB:** *Research findings suggest that lack of positive expectations account for the relationship between hopelessness and future depression and suicidal behavior among adolescents (Horwitz et al, 2017).*
• Assist the client to explore the meaning of his or her life, satisfaction with his or her life, and life goals. **EB:** *Research shows that a higher meaning of life buffers the association between suicide risk factors and hopelessness (Marco, Pérez, & García-Alandete, 2016).*
• Encourage adolescent clients to get 9 to 10 hours of sleep nightly. **EB:** *Research shows that among adolescents, as little as 1 hour less of weekday sleep was associated with significantly greater odds of feeling hopeless (Winsler et al, 2015).*
• Assist the client in looking at alternatives and setting long- and short-term goals that are important to him or her. **EBN:** *A mixed-method thematic review found that setting*

and achieving goals was a theme that increased hope (Broadhurst & Harrington, 2016).
• Explore the meanings, functions, objects, sources, and nature of hope with patients as relates to their current situation. **EBN:** *A better understanding of the patient's meaning of hope can assist nurses to foster hope and provide better support (Marco et al, 2016).*
• Spend one-on-one time with the client. Use empathy; try to understand what the client is saying and communicate this understanding to the client to create a nonjudgmental trusting environment to develop therapeutic relationships with the client. **EB:** *Patient ratings of the therapeutic relationship predicted social inclusion through hopefulness (Berry & Greenwood, 2015).*
• Teach alternative coping strategies such as physical activity. **CEB:** *Clients with severe mental illness showed decreased hopelessness after participation in an adjunct exercise program (Sylvia et al, 2013).*
• Use a future-directed approach that teaches individuals how to become aware of attention that is focused on unwanted aspects of life and how to redirect attention toward things that feel more wanted or desired. **CEB:** *Future-directed therapy is effective at decreasing hopelessness and increases positive future expectations (Vilhauer et al, 2013).*
• Review the client's strengths and resources in conjunction with the client. **EBN:** *A strengths-based perspective support group intervention reduced the participants' level of depressive symptoms and improved the pathway component of hope (Hou, Ko, & Shu, 2016).*
• Encourage the client to adopt active coping strategies. **EB:** *In a current study, proactive coping predicted hope regardless of severity of spinal cord injury (Phillips et al, 2016).*
• Offer emotional support, active listening, and coping assistance to client families. **EBN:** *Family hopelessness is addressed when nurses offer emotional support (Coco et al, 2013).*
• Implement social supports and reintegration programs for postdeployment soldiers and veterans in a timely fashion. **EB:** *Research determined that hopelessness was moderated by timely implementation of postdeployment support and reintegration programs (Martin et al, 2016).*
• For additional interventions, see the care plans for Readiness for enhanced **Hope**, **Spiritual** distress, Readiness for enhanced **Spiritual** well-being, and Disturbed **Sleep** pattern.

Geriatric

• Previous interventions may be adapted for geriatric clients.
▲ If depression is suspected, confer with the primary health care provider regarding referral for mental health services. **EB:** *This study of older adults found that hopelessness was a significant predictor of death ideation (Guidry & Cukrowicz, 2016).*
• Take threats of self-harm or suicide seriously and intervene as needed. **EB:** *This study of older adults identified hopelessness as a significant predictor of death ideation (Guidry & Cukrowicz, 2016). Older adults have the highest risk of death by suicide in the United States (Fond et al, 2016).*
• Encourage engagement in positive and pleasant events. **EB:** *This study found that targeting both hopelessness and engagement in pleasant events may be helpful in improving the quality of life of vulnerable, rural older adults (Scogin et al, 2015).*

Multicultural

• Assess for the influence of cultural beliefs, norms, and values on the client's feelings

of hopelessness. **CEB:** *In some Latino cultures, talking about depression* (depresión) *may be taboo. Hopelessness* (desanimo) *may be understood differently by clients of various cultural backgrounds and may have a more normative and culturally specific, comfortable sound for clients (Marsiglia et al, 2011).*

• Assess for the effect of fatalism on the client's expression of hopelessness. **EBN:** A systemic review of qualitative studies found that fatalistic perspectives were common among the cancer beliefs held by ethnic minority populations (Licqurish et al, 2017).

• Use caution when highlighting health disparities of multicultural populations through public health campaigns and media broadcasts. **EB:** This study found that media campaigns that broadcasted health disparities resulted in the targeted population feeling less hopeful about the future (Lee et al, 2017).

• Encourage spirituality as a source of support for hopelessness. **EB:** Structural equation modeling indicated that Malaysian adolescent students were high in hopelessness and depression, but were also high in spirituality and had less suicidal behavior than others (Talib & Abdollahi, 2017).

Home Care

• Previously mentioned interventions may be adapted for home care use.

• Use in-person problem-solving therapy (PST) to address depressive symptoms and hopelessness. **EB:** In-person PST reduced depressive symptoms and alleviated hopelessness in older homebound adults. PST focused on the participants' appraisal of specific problems, identification of the best possible solutions, and the practical implementation of those solutions (Choi, Marti, & Conwell, 2016).

Client/Family Teaching and Discharge Planning

• Provide information regarding the client's condition, treatment plan, and progress. **EBN:** *Clients reported increased hope after a planned family-centered discharge process(Ingram et al, 2017).*

▲ Refer the client to self-help groups. **EB:** *Support groups provided an experience of community in which hope was encouraged (Behler et al, 2017).*

Risk for compromised Human Dignity

Shari D. Froelich DNP, MSN, MSBA, ANP-BC, ACHPN, PMHNP-BC

NANDA-I

Definition

Susceptible for perceived loss of respect and honor, which may compromise health.

Risk Factors

Cultural incongruence; dehumanizing treatment; disclosure of confidential information; exposure of the body; humiliation; insufficient comprehension of health information; intrusion by clinician; invasion of privacy; limited decision-making experience; loss of control over body function; stigmatization

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Health Beliefs: Perceived Control; Decision-Making; Spiritual Control; Perceived Social Support

Example NOC Outcome with Indicators

Health Beliefs: Perceived Control as evidenced by the following indicators: Perceived responsibility for health decisions/Requested involvement in health decisions/Efforts at gathering information/Belief that own decisions control health outcomes/Willingness to designate surrogate decision maker. (Rate the outcome and indicators of **Health Beliefs: Perceived Control:** 1 = very weak, 2 = weak, 3 = moderate, 4 = strong, 5 = very strong [see Section I].)

Client-Based Outcome

Client/Caregiver Will (Specify Time Frame)

- Perceive that dignity is maintained throughout hospitalization/encounter
- Consistently call client by name of choice
- Maintain client's privacy

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Presence; Decision-Making Support; Spiritual Support; Hope Instillation

Example NIC Activities—Presence

Demonstrate accepting attitude; Listen to client's concerns

Nursing Interventions and *Rationales*

- Be authentically present when with the client, try to limit extraneous thoughts of self or others, and concentrate on the well-being of the client. **EBN:** *Human presence never leaves one unaffected. Expressed as compassion and caring, it is not only the words that are spoken or the eyes that notice, leading to action (Manookian, Cheraghi, & Nasrabadi, 2014).*
- Enter into and stay within the other's frame of reference. Connect with the inner life world of meaning and spirit of the other. Join in a mutual search for meaning and wholeness of being and becoming to potentiate comfort measures, pain control, a sense of well-being, wholeness, or even spiritual transcendence of suffering. **EBN:** *Human dignity is a central concept within nursing and the caring professions because it communicates the shared humanity. A shared humanity is evident anywhere in which humans interact, and because nurses are eager to actualize the healing relationship with clients, they have the opportunity to share their humanity (Manookian, Cheraghi, & Nasrabadi, 2014).*

• Determine the client's perspective about his or her health. Example questions include "Tell me about your health." "What is it like to be in your situation?" "Tell me how you perceive yourself in this situation." "What meaning are you giving to this situation?" "Tell me about your health priorities." "Tell me about the harmony you wish to reach." **CEB:** *Such questions usually contribute to helping people find meaning to the crisis in their life (Watson, 2008).* **CEB:** *Confirm the person's worthiness and sense of self. A genuine respect for the person as a unique human being, with an inherent desire or right to make choices according to his or her subjective needs, was found to be fundamental in advocating autonomy and integrity. Confirming the person's worthiness and sense of self in this way was identified as crucial in dignity preservation. To preserve personal dignity and reduce the experienced loss of freedom, autonomy, and integrity, going for frequent walks was given high priority (Tranvag, Petersen, & Naden, 2013).*
• Determine the client's preferences for when and how nursing care is needed and follow the client's guidelines if possible. *The client's autonomy must be recognized as part of dignified nursing care.* **CEB:** *A summary of older adults' perceptions of the most important nurse caring behaviors include knowing what they are doing, know when it's necessary to call the medical provider, treat me as an individual, give my treatments and medications on time, check my condition very closely, give my pain medication on time, know how to handle equipment, keep my family informed of my progress, and don't give up on me when I am difficult to get along with (Marini, 1999).*
• Include the client in all decision-making; if the client does not choose to be part of the decision or is no longer capable of making a decision, then use the named surrogate decision maker. *The Patient Self-Determination Act, effective in 1991, requires that all individuals receiving medical care also receive written information about their right to accept or refuse medical or surgical treatment and their right to initiate advance directives (Dossey & Keegan, 2009).*
• Maintain client's privacy at all times.
• Actively listen to what the client is saying both verbally and nonverbally. **CEB:** *We must quiet our "inner dialogue" so that we may hear more clearly, allow others to tell the entire story, listen without judgment or advice, and bear witness to the experience. Attentive silence is a communicative act in its own right; it is an act of compassion. It signifies respect, legitimizes what is said, and creates an atmosphere in which self-discovery can occur (Stanley, 2002).*
• Encourage the client to share thoughts about spirituality as desired. **CEB:** *The care of the soul remains the most powerful aspect of the art of caring in nursing. The caring occasion becomes "transpersonal" when "it allows for the presence of the spirit of both—then the event of the moment expands the limits of openness and has the ability to expand human capabilities" (Watson, 2008).*
• Use interventions to instill increased hope; see the care plan for Readiness for enhanced **Hope**. **CEB:** *When hope for a cure is no longer possible, help clients recognize that the relationships change between clients, families, and caregivers but do not end. Hope continues, but it has a different focus (Erlen, 2003). Caring does not end but is transformed when intensive treatment ends.*
• For further interventions on spirituality, see the care plan for Readiness for enhanced **Spiritual** well-being.

Geriatric

• Always ask the client how he or she would like to be addressed. Avoid calling older clients "sweetie," "honey," "Gramps," or other terms that can be demeaning unless

this is acceptable in the client's culture or requested by the client. *Appropriate forms of address must be used with older adults to maintain dignity.* **CEB:** *A respectful form of address has positive effects, whereas overfamiliarity tends to have a negative effect on self-respect, physical and mental health, and recovery from disease, particularly in older adults and those with dementia (Woolhead et al, 2006; Williams et al, 2008).*

• Treat the older client with the utmost respect, even if delirium or dementia is present with confusion. *Confused clients respond positively to caregivers who approach gently, with positive regard, and treat the confused client with respect and dignity.*

Multicultural

• Assess for the influence of cultural beliefs, norms, and values on the client's way of communicating, and follow the client's lead in communicating in matters of eye contact, amount of personal space, voice tones, and amount of touching. If in doubt, ask the client. *What the client considers normal and appropriate communication that maintains and facilitates dignity is based on cultural perceptions.* **CEB:** *Client dignity is promoted when staff provide privacy and use interactions that help clients feel comfortable, in control, and valued. Individual staff behavior has a major effect on whether threats to client dignity actually lead to its loss (Baillie, 2009).*

Home Care

• Most of the interventions described previously may be adapted for home care use.

• Recognize that the client with the caregiver has complete autonomy in the home. *The nurse's role is to provide the care needed and desired. The client and caregiver determine whether the care offered is acceptable.*

Client/Family Teaching and Discharge Planning

• Teach family and caregivers the need for the dignity of the client to be maintained at all times. How an individual cognitively perceives and emotionally deals with the illness can depend on the person's family and social relationships, and ultimately can affect the ability to heal. Note: Caring is integral to maintaining dignity. **CEB:** *According to Watson (2008), a caring occasion is the moment (focal point in space and time) when the nurse and another person come together in such a way that an occasion for human caring is created. Both the one cared for and the one caring can be influenced by the caring moment through the choices and actions decided within the relationship, influencing and becoming part of their own life history.*

Neonatal Hyperbilirubinemia

Original author, David Wilson MS, RNC, revised by, Barbara J. Wheeler RN, BN, MN, IBCLC

NANDA-I

Definition

The accumulation of unconjugated bilirubin in the circulation (<15 mL/dL; <257 μmol/L) that occurs after 24 hours of life.

Defining Characteristics

Abnormal blood profile; bruised skin; yellow mucous membranes; yellow sclera; yellow-orange skin color

Related Factors

Deficient feeding pattern; delay in meconium passage; infants with inadequate nutrition

At-Risk Population

ABO incompatibility; age ≤7 days; American Indian ethnicity; blood type incompatibility between mother and infant; East Asian ethnicity; infant who is breastfed; infant with low birthweight; maternal diabetes mellitus; population living at high altitudes; premature infant; previous sibling with jaundice; rhesus (Rh) incompatibility; significant bruising during birth

Associated Condition

Bacterial infection; infant with liver malfunction; infant with enzyme deficiency; internal bleeding; prenatal infection; sepsis; viral infection

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Breastfeeding Establishment: Infant; Breastfeeding Maintenance; Bowel Elimination; Parent: Knowledge: Parenting/Infant Care; Risk Detection/Control

Example NOC Outcome with Indicators

Breastfeeding Establishment: Infant as evidenced by the following indicators: Proper alignment and latch-on/Proper areolar grasp/Proper areolar compression/Correct suck and tongue placement/Audible swallow/Minimum eight feedings per day/Urinations per day appropriate for age/Weight gain appropriate for age. (Rate the outcome and indicators of **Breastfeeding Establishment: Infant:** 1 = not adequate, 2 = slightly adequate, 3 = moderately adequate, 4 = substantially adequate, 5 = totally adequate [see Section I].)

Client Outcomes

Client (Infant) Will (Specify Time Frame)

- Establish effective feeding pattern (breast or bottle)
- Receive bilirubin assessment and screening within the first few days of life to identify potentially harmful levels of serum bilirubin
- Receive appropriate therapy to enhance indirect bilirubin excretion
- Receive nursing assessments to determine risk for severity of jaundice
- Maintain hydration: moist buccal membranes, four to six wet diapers in a 24-hour

period, weight loss no greater than 10% of birth weight
• Evacuate stool within 48 hours of birth, and pass three or four stools per 24 hours by day 4 of life

Client (Parent[s]) Will (Specify Time Frame)

• Receive information on neonatal jaundice prior to discharge from birth hospital
• Verbalize understanding of physical signs of jaundice prior to discharge
• Verbalize signs requiring immediate health practitioner notification: sleepy infant who does not awaken easily for feedings, fewer than four to six wet diapers in 24-hour period by day 4, fewer than three to four stools in 24 hours by day 4, breastfeeds fewer than eight times per day
• Demonstrate ability to operate home phototherapy unit if prescribed

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Parent Education: Infant; Phototherapy: Neonate

Example NIC Activities—Phototherapy: Neonate

Review maternal and infant history for risk factors for hyperbilirubinemia (e.g., Rh or ABO incompatibility, polycythemia, sepsis, prematurity, malpresentation); Observe for signs of jaundice

Nursing Interventions and *Rationales*

• Evaluate maternal and delivery history for risk factors for neonatal jaundice (RhD, ABO, G6PD deficiency, direct Coombs). **EB:** *Assessment of maternal and neonatal risk factors that may cause jaundice is important in the detection of neonatal jaundice (Barrington & Sankaran, 2018).*
• Perform neonatal gestational age assessment once the newborn has had an initial period of interaction with mother and father. **EB:** *Infants who are born late preterm (34 to* $36\frac{6}{7}$ *weeks at birth) and early term (37 and* $38\frac{6}{7}$ *weeks at birth) are at significantly increased risk for problems related to hyperbilirubinemia, feeding problems, and hospital readmission (Reichman et al, 2015).*
• Encourage breastfeeding within the first hour of the neonate's life. **EB:** *Early feedings increase neonatal intestinal activity, and infant begins establishing intestinal flora; in addition, early breastfeeding promotes enhanced maternal confidence in breastfeeding (Flaherman & Maisels, 2017).*
• Encourage skin-to-skin mother–newborn contact shortly after delivery. **EB:** *Early skin-to-skin mother–baby contact helps promote maternal confidence in nurturing abilities, and it is correlated with improved milk supply and milk transfer (Flaherman & Maisels, 2017).*
• Assess infant's skin color at birth and every 8 hours thereafter until birth hospital discharge for the appearance of jaundice. **EB:** *Initial and ongoing neonatal skin assessment is important in the detection of jaundice (Hockenberry, Wilson, & Rodgers, 2017).* **CEB:** *Jaundice is visible when bilirubin levels reach 5 to 6 mg/dL (Blackburn, 2013), and it appears first on the face and head, then slowly advances to the trunk, arms, and lower extremities.* **CEB:** *Skin color alone is not a reliable assessment for neonatal jaundice; therefore it is important that such assessments are supported with empirical serum bilirubin measurements or transcutaneous bilirubin measurements when jaundice is suspected*

(American Academy of Pediatrics, 2004).

• Encourage and assist mother with frequent breastfeeding. **EB:** *Increased frequency of* breastfeeding *accelerates weight gain and increases defecation frequency, reducing the severity of neonatal* hyperbilirubinemia *(Hassan, Zakerihamidi, & Boskabadi, 2018). Exclusive breastfeeding is recommended for neonatal feedings yet is associated with the development of hyperbilirubinemia and not directly as a result of the feeding substrate; perhaps, it is caused by decreased caloric intake in the first week of life and a substance in breast milk that may interfere with bilirubin excretion (Flaherman & Miasels, 2017).*

• Assist parents who choose to bottle feed their neonate. **EB:** *Adequate caloric intake is essential for the promotion of stooling and the subsequent elimination of bilirubin from the intestine; bottle-feeding parents must be helped to optimize feedings (Hockenberry & Wilson, 2015).*

• Avoid feeding supplements such as water, dextrose water, or any other milk substitutes in breastfeeding neonate. **EB:** *Supplements may act to decrease the effective establishment of breastfeeding (Flaherman & Maisels, 2017).*

• Assess neonate's stooling pattern in first 48 hours of life. *Delayed stooling may indicate inadequate breast milk intake and may further increase reabsorption of bilirubin from neonate's intestine (Hockenberry, Wilson, & Rodgers, 2017).*

▲ Collect and evaluate laboratory blood specimens as prescribed or per unit protocol. **EB:** *Because visual assessments of skin color alone are inadequate to determine rising levels of bilirubin, serum bilirubin measurement may be gathered to evaluate risk for pathology (Hockenberry, Wilson, & Rodgers, 2017). The purpose of monitoring, evaluating, and implementing treatment in moderate to severe cases of neonatal hyperbilirubinemia is to prevent acute bilirubin encephalopathy, which is an early acute central nervous system bilirubin toxicity that is related to the amount of unbound (indirect) bilirubin. Kernicterus describes the yellow staining of brain cells and subsequent necrosis that occurs secondary to exposure to high levels of unconjugated (indirect) bilirubin; kernicterus involves long-term, permanent central nervous system changes (Hockenberry, Wilson, & Rodgers, 2017).* **CEB:** *Bilirubin-induced neurologic dysfunction is a term used to describe the spectrum of symptoms associated with acute bilirubin encephalopathy and kernicterus (Johnson & Bhutani, 2011).*

▲ Monitor transcutaneous bilirubin level in jaundiced neonate per unit protocol. **EB:** *Noninvasive bilirubin monitoring is a safe and effective means for monitoring bilirubin levels and determining risk for increasing serum bilirubin levels in infants who are NOT treated with phototherapy (van den Esker-Jonker et al, 2016; Jain et al, 2017).*

• Perform hour-specific total serum bilirubin (TSB) risk assessment before discharge from hospital or birth center and document the results. **CEB:** *The use of an hour-specific nomogram for designation of risk in healthy, late preterm, early term, and term infants, as well as clinical risk factors, may be used to determine the relative risk of rapidly increasing bilirubin levels requiring medical intervention such as phototherapy (American Academy of Pediatrics, 2004; Maisels et al, 2009). The hour-specific nomogram estimates the TSB in one of four risk zones: low risk, low intermediate risk, high intermediate risk (75th to 94th percentile), and high risk (95th percentile or greater). Infants with TSB values at or above the 75th percentile in addition to risk factors, such as preterm birth, may require medical intervention such as phototherapy (Maisels et al, 2009).*

• Monitor newborn for signs of inadequate breast milk or formula intake: dry oral mucous membranes, fewer than 4 to 6 wet diapers per 24 hours, no stool in 24 hours, and body weight loss greater than 10%. **EB:** Inadequate intake of breast milk or formula in the neonatal period has been identified as a risk factor for the development of hyperbilirubinemia (Flaherman & Maisels, 2017).

• Assess late preterm infant (born between 34 weeks and $36\frac{6}{7}$ weeks' gestation) for ability to breastfeed successfully and adequate intake of breast milk. **EB:** Late preterm infants are at higher risk for difficulty breastfeeding and suboptimal milk intake caused by physiological immaturity; thus such infants are also at a much higher risk for severe jaundice than term counterparts (Reichman et al, 2015; Barrington & Sakaran, 2018).
• Assist mother with breastfeeding and assess latch-on. **EB:** Successful breastfeeding in the first few weeks of life is associated with decreased levels of serum bilirubin (Flaherman & Maisels, 2017).
• Encourage alternate methods for providing expressed breast milk if maternal health status is compromised, and assist mother with collection of breast milk via use of breast pump or hand expression. **EB:** Alternate feeding methods for the ingestion of breast milk may be used to enhance milk intake necessary to promote stooling and enhance bilirubin excretion (Flaherman & Maisels, 2017).
• Encourage father's participation in newborn care by changing diapers, helping position newborn for breastfeeding, and holding newborn while mother rests. **EB:** Paternal involvement in the care of the newborn helps solidify the father's role as a parent and strengthens the paternal–infant attachment process; paternal participation also helps the mother rest during the recovery from labor and delivery (Hockenberry & Wilson, 2015).
• Weigh newborn daily. **EB:** Daily weights assist in the detection of excess weight loss, which is often indicative of inadequate caloric intake (Flaherman & Maisels, 2017).
▲ When phototherapy is ordered, place seminude infant (diaper only) under prescribed amount of phototherapy lights. **EB:** *Phototherapy is the primary therapy used to treat mild to moderate neonatal indirect (unconjugated) hyperbilirubinemia; the infant must have a large skin surface area exposed to the light source for optimal effectiveness (Stokowski, 2011; Hockenberry, Wilson, & Rodgers, 2017).* **CEB:** *Turning the infant periodically has not been shown to reduce circulating bilirubin levels (Stokowski, 2011).*
• Protect infant's eyes from phototherapy light source with eye shields; remove eye shields periodically when infant is removed from light source for feeding and parent–infant interaction. **EB:** *Retinal damage may occur from light exposure (Bhutani, Committee on Fetus and Newborn, & American Academy of Pediatrics, 2014; Hockenberry, Wilson, & Rodgers, 2017); however, there is no evidence that removing the infant for parent–infant interaction during feedings and for brief caregiving activities prevents the effectiveness of phototherapy when the infant has mild to moderate hyperbilirubinemia (Hockenberry, Wilson, & Rodgers, 2017).*
• Monitor infant's hydration status, fluid intake, skin status, and body temperature while undergoing phototherapy. **EB:** *Transient side effects of phototherapy include increased body temperature, increased insensible water loss, increased gastrointestinal water loss (loose stools), lethargy, irritability, and poor feeding (Hockenberry, Wilson, & Rodgers, 2017).*
▲ Collect and evaluate laboratory blood specimens (TSB) while infant is undergoing phototherapy. **CEB:** *Transcutaneous bilirubin measurements do not provide an adequate estimate of serum bilirubin level and are not effective once phototherapy has been initiated (American Academy of Pediatrics, 2004; Hockenberry, Wilson, & Rodgers, 2017).*
• Encourage continuation of breastfeeding and brief infant care activities such as changing diapers while the infant is being treated with phototherapy; phototherapy may be interrupted for breastfeeding. **EB:** *In most cases breastfeeding is not interrupted*

for phototherapy; the benefits of breastfeeding exceed any potential harm (Muchowski, 2014). If the infant's oral intake with breastfeeding is inadequate, supplementation with expressed breast milk or infant formula may be recommended (Flaherman & Maisels, 2017).

• Provide emotional support for parents of infants undergoing phototherapy. **EB:** *Separation of the infant from the mother for phototherapy disrupts parent–infant interaction and may promote parental stress and decrease the effective establishment of breastfeeding (Hockenberry, Wilson, & Rodgers, 2017).*

Multicultural

• Assess infants of Asian or American Indian ethnicity for early rising bilirubin levels, especially when breastfeeding. **EB:** *Studies have shown Asian and American Indian newborns to have higher peak serum bilirubin levels than Caucasian and African American newborns (Hockenberry, Wilson, & Rodgers, 2017).*

• Encourage early and exclusive breastfeeding among Asian and American Indian newborns. **EB:** *Early and exclusive breastfeeding may increase elimination of bilirubin in stool (Flaherman & Maisels, 2017).*

Client/Family Teaching and Discharge Planning

• Teach the breastfeeding mother and support persons about the appearance of jaundice (yellow or orange color of skin) after hospital or birth center discharge, and provide health care resource telephone number for parents to call for concerns related to newborn's care. **CEB:** *Follow-up for evaluation of jaundice and feeding may be recommended as early as within the first 48 hours of discharge, depending on newborn's age at discharge and individual risk assessment (Maisels et al, 2009).*

• Teach parents the signs of inadequate milk intake: fewer than three to four stools per day by day 4, fewer than four to six wet diapers in 24 hours, and dry oral mucous membranes; additional danger signs include a sleepy baby that does not awaken for breastfeeding or appears lethargic (decreased activity level from usual newborn pattern). **EB:** *Providing information about jaundice and effective breastfeeding may serve to decrease risk factors associated with increasing bilirubin levels (Flaherman & Maisels, 2017).*

▲ Teach parents about the importance of medical follow-up in the first several days of life for the evaluation of jaundice. **CEB:** *With early postpartum hospital discharge, follow-up visits may be needed as early as 48 hours post discharge for the evaluation of breastfeeding, stooling and voiding pattern (hydration), and jaundice (American Academy of Pediatrics, 2004).*

• Teach parents about the use of phototherapy (hospital or home, as prescribed), the proper use of the phototherapy equipment; feedings; and assessment of hydration, body temperature, skin status, and urine and stool output. *Provide information to the parents of the infant undergoing phototherapy to prevent misinformation about the infant's condition and treatment and to decrease parental anxiety and stress (Hockenberry & Wilson, 2015).*

Quality and Safety in Nursing

• **Client safety:** Minimizes risk of harm to client

• Knowledge: Nurses continually assess newborns for risk factors associated with the development of jaundice

• Skills: Nurses use transcutaneous and serum bilirubin measurements to determine the newborn's bilirubin risk according to the hour-specific nomogram

• Attitudes: Nurses appreciate their role as one of promoting safety for the newborn at risk for developing jaundice
• Knowledge: Nurses implement client-focused strategies to promote serum bilirubin reduction; these include but are not limited to placing the newborn to mother's breast in first hours of life and encouraging frequent breastfeeding of no less than 10 to 12 feedings per 24 hours
• Skills: Nurses identify individual clinical risk factors in the neonate that place him or her at risk for jaundice
• Attitudes: Nurses value their role as a health care team member to promote the safe care of the newborn at discharge from the birth center and beyond
• Knowledge: Nurses understand use of phototherapy to reduce levels of indirect bilirubin
• Skills: Nurses use phototherapy lights appropriately
• Skills: Nurses assess infant for untoward effects of phototherapy
• Attitudes: Nurses appreciate the role of phototherapy as a treatment
• Attitudes: Nurses value their role in the promotion of safety with the use of phototherapy
• Quality and safety education for nurses at www.qsen.org

Risk for neonatal Hyperbilirubinemia

Original author, David Wilson MS, RNC, revised by, Barbara. J. Wheeler RN, BN, MN, IBCLC

NANDA-I

Definition

Susceptible to the accumulation of unconjugated bilirubin in the circulation (less than 15 mL/dL; less than 257 μmol/L) that occurs after 24 hours of life, which may compromise health.

Risk Factors

Deficient feeding pattern; delay in meconium passage; infants with inadequate nutrition

At-Risk Population

ABO incompatibility; age ≤7 days; American Indian ethnicity; blood type incompatibility between mother and infant; East Asian ethnicity; infant who is breastfed; infant with low birthweight; maternal diabetes mellitus; population living at high altitudes; premature infant; previous sibling with jaundice; rhesus (Rh) incompatibility; significant bruising during birth

Associated Condition

Bacterial infection; infant with liver malfunction; infant with enzyme deficiency; internal bleeding; prenatal infection; sepsis; viral infection

NOC (Nursing Outcomes Classification)

See care plan for Neonatal **Hyperbilirubinemia** for suggested NOC outcomes.

Client Outcomes

- Neonatal total serum bilirubin (TSB) will be monitored and there will be no undetected TSB values in the high-risk (95th percentile or greater) or high-intermediate risk (75th to 94th percentile) zones (as determined by the hour-specific nomogram)
- Newborn will receive appropriate therapies to enhance bilirubin excretion
- Newborn will remain free of undetected signs of acute bilirubin neurotoxicity
- Establish effective feeding pattern (breast or bottle)
- Receive bilirubin assessment and screening within the first few days of life to detect increasing levels of serum bilirubin
- Receive nursing assessments to determine risk for severity of jaundice prior to discharge from birth hospital
- Maintain hydration: moist buccal membranes, four to six wet diapers in a 24-hour period, weight loss no greater than 10% of birth weight
- Evacuate stool within 48 hours of birth, and pass three to four stools per 24 hours by day 4 of life

NIC (Nursing Interventions Classification)

See the care plan for Neonatal **Hyperbilirubinemia** for suggested NIC interventions.

Nursing Interventions and *Rationales*

- Identify clinical risk factors that place the infant at greater risk for development of neonatal jaundice: exclusive breastfeeding, isoimmune or hemolytic disease, preterm birth 38⅞ weeks' gestation or less), weight loss of 10% or more from birth weight, maternal diabetes, maternal obesity, previous sibling with jaundice, East Asian

ethnicity, and significant bruising or cephalhematoma. **EB:** *Exclusive breastfeeding that is not going well (suboptimal intake) and preterm birth have been identified as the most predictive of neonatal jaundice (Flaherman & Maisels, 2017). The other risk factors listed may also play a significant role in the development of neonatal jaundice and should be considered in the overall assessment.*

• Measure transcutaneous bilirubin (TcB) of all newborns in the first 24 to 48 hours of life, using a noninvasive transcutaneous bilirubinometer. Plot TcB on a nomogram standardized for the appropriate patient population; determine newborn's risk of subsequent significant hyperbilirubinemia. **EB:** *Transcutaneous measurement of bilirubin, in conjunction with use of a nomogram standardized for the appropriate patient population, has been demonstrated to be an accurate predictor of subsequent hyperbilirubinemia (Jain et al, 2017). The use of TcB in jaundiced neonates is safe and results in a significant reduction of phlebotomy for serum bilirubin measurement (van den Esker-Jonker et al, 2016).*

Refer to care plan for Neonatal **Hyperbilirubinemia** for additional interventions for multicultural and discharge planning.

Client/Family Teaching and Discharge Planning

▲ Teach parents about the importance of medical follow-up in the first several days of life for the evaluation of jaundice, especially in the late preterm infant. **EB:** *Late preterm infants (34–36 weeks' gestation) are at much greater risk for hyperbilirubinemia than infants born at term (37–41 weeks' gestation) and should be followed closely in the first few weeks of life (Reichman et al, 2015).*

Refer to care plan for Neonatal **Hyperbilirubinemia** for additional interventions.

Quality and Safety in Nursing

Refer to care plan for Neonatal **Hyperbilirubinemia** for additional interventions.

Hyperthermia

Rosemary Timmerman DNP, APRN, CCNS, CCRN-CSC-CMC

NANDA-I

Definition

Core body temperature above the normal diurnal range due to failure of thermoregulation.

Defining Characteristics

Abnormal posturing; apnea; coma; flushed skin; hypotension; infant does not maintain suck; irritability; lethargy; seizure; skin warm to touch; stupor; tachycardia; tachypnea; vasodilation

Related Factors
Dehydration; inappropriate clothing; increase in metabolic rate; vigorous activity

At-Risk Population
Exposure to high environmental temperature

Associated Condition
Decrease in sweat response; illness; ischemia; pharmaceutical agent; sepsis; trauma

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes
Thermoregulation; Thermoregulation: Newborn

Example NOC Outcome with Indicators
Thermoregulation as evidenced by the following indicators: Increased skin temperature/Decreased skin temperature/Skin color changes/Dehydration/Hyperthermia. (Rate the outcome and indicators of **Thermoregulation:** 1 = severe, 2 = substantial, 3 = moderate, 4 = mild, 5 = none [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Maintain core body temperature within adaptive levels (less than 104°F, 40°C)
- Remain free of complications of malignant hyperthermia
- Remain free of complication of neuroleptic malignant syndrome
- Remain free of dehydration
- Remain free from infection
- Verbalize signs and symptoms of heat stroke and actions to prevent heat stroke
- Verbalize personal risks for malignant hyperthermia and neuroleptic malignant syndrome to be reported during health history reviews to all health care professionals, including pharmacists

NIC (Nursing Interventions Classification)

Suggested NIC Interventions
Fever Treatment; Malignant Hyperthermia Precautions; Temperature Regulation

Example NIC Activities—Hyperthermia Treatment
Monitor core body temperature using appropriate device; Monitor for abnormalities in mental status

Nursing Interventions and *Rationales*

Temperature Measurement

- Recognize that hyperthermia is a rise in body temperature above 40°C (104°F) that is not regulated by the hypothalamus, resulting in an uncontrolled increase in body temperature exceeding the body's ability to lose heat. It is a medical emergency (Leon & Bouchama, 2015; Gaudio & Grissom, 2016).
- Continually measure a client's core temperature with a distal esophageal probe or obtain near core body temperature measurements with a rectal or bladder

temperature probe and verify with a second method. **EBN:** *Obtaining an accurate core body temperature is essential for detecting heat stroke and monitoring the client's response to treatment; if a core temperature reading is not available or practical, a rectal or bladder temperature measurement provides a closer approximation of the core body temperature than temporal, axillary, oral, aural, or skin measurements* (Lipman et al, 2013; Leon & Bouchama, 2015). **CEB:** *Research is limited on the accuracy of temporal artery measurements outside normal ranges; axillary temperature is accurate in neonates but is not well supported in adults, and tympanic membrane measurements and chemical dot thermometers are least accurate and should be avoided in caring for the acutely ill adult client (Hooper et al, 2010; Makic et al, 2011).*

• Use the same site and method (device) for temperature measurement for a given client so that temperature trends are assessed accurately; record site of temperature measurement. **EBN/CEB:** *There are differences in temperature depending on the site from which temperature measurement is obtained; however, differences between sites should not be greater than 0.3°C to 0.5°C (Bridges & Thomas, 2009; Makic et al, 2011).*

▲ Work with the health care provider to help determine the cause of the temperature increase (hyperthermia), which will often help direct appropriate treatment. *It is important to treat the underlying cause of the temperature to preserve neurologic function of the client as well as implement interventions to rapidly lower the core temperature (Bohman & Levine, 2014; Gaudio & Grissom, 2016).*

• Refer to care plan for Ineffective **Thermoregulation** for interventions managing fever (pyrexia).

Heat Stroke

• Recognize that heat stroke may be separated into two categories: classic and exertional. *Classic heat stroke usually involves the very young and older client during environmental heat waves. Exertional heat stroke occurs in young adults performing strenuous physical activity in hot climates (Leon & Bouchama, 2015; Gaudio & Grissom, 2016).*

• Watch for risk factors for classic heat stroke, which include (Leon & Bouchama, 2015; Gaudio & Grissom, 2016):

- ❍ Medications, especially diuretics, anticholinergic agents, beta-blockers, anti-Parkinson's medications, antidepressants, and antihistamines
- ❍ Alcoholism
- ❍ Mental illness
- ❍ Obesity
- ❍ Heart disease

▲ **EB:** *Physiologic effects of aging include lower onset of sweating and rate of sweating needed to help with dissipation of body heat; medications can dehydrate the client and blunt the physiologic responses necessary to assist with heat dissipation, increasing the risk of heat stroke in older clients (Leon & Bouchama, 2015; Gaudio & Grissom, 2016).*

• Risk factors of exertional heat stroke include (Gaudio & Grissom, 2016; Lipman et al, 2013):

- ❍ Preexisting illness
- ❍ Drug use (e.g., alcohol, amphetamines, ecstasy)
- ❍ Wearing protective clothing (uniforms and athletic gear) that limits heat dissipation

• Recognize signs and symptoms of hyperthermia: core body temperature greater than 40°C (104°F), exercise-associated muscle cramps, tachycardia, tachypnea,

orthostatic dizziness, weakness, vomiting, headache, confusion, delirium, seizures, coma, acute kidney injury (rhabdomyolysis), and hot dry skin (classic heat stroke) (Pryor et al, 2013; Gaudio & Grissom, 2016).

• Recognize that antipyretic agents are of little use in treatment of hyperthermia. **EB:** *Because the cause of the hyperthermia does not involve the hypothalamus, antipyretic agents are ineffective and not indicated in treatment of clients with hyperthermia (Lipman et al, 2013; Gaudio & Grissom, 2016).*

▲ Assess fluid loss and facilitate oral intake or administer intravenous fluids as ordered to accomplish fluid replacement and support the cardiovascular system. *Increased metabolic rate, diuresis, and diaphoresis-associated exertional hyperthermia cause loss of body fluids (Lipman et al, 2013; Leon & Bouchama, 2015).* Refer to the care plan for Deficient **Fluid** volume.

▲ Recognize use of alpha-adrenergic agents should be avoided if possible. *Alpha-adrenergic agonist agents cause cutaneous vasoconstriction, which impairs cooling (Gaudio & Grissom, 2016).*

• Remove clothing and immerse young and healthy clients who have suffered exertional heat stroke in a cold water bath ensuring the head does not go underwater, or continuously douse the client with cold water. **EB:** *Cold water immersion rapidly cools the core temperature because of the high thermal conductivity of water but may not be practical because of client agitation and limited access for cardiovascular monitoring (Leon & Bouchama, 2015; Gaudio & Grissom, 2016).* For clients with classic heat stroke, remove clothes and spray or douse the skin with water and provide continual airflow over the body with a fan. **EB:** *Wetting the skin and directing airflow over the body promotes evaporative and convective cooling; this method is less effective for clients with exertional heat stroke (Leon & Bouchama, 2015; Gaudio & Grissom, 2016).*

▲ Recognize adjunctive cooling measures include administering cold (4°C) intravenous fluids, water circulating hydrogel coated pads placed over the chest and legs, ice packs over the entire body, intravascular cooling catheter, and cooling blankets. **EB:** *There is insufficient evidence to recommend using adjunctive measures as a primary cooling method (Leon & Bouchama, 2015; Gaudio & Grissom, 2016).*

▲ Continuously monitor the effects of cooling measures, stop cooling interventions once the body temperature is less than 39°C, and benzodiazepines may be administered to control shivering. **EB/EBN:** *Hyperthermia must be treated aggressively to lower the body temperature; however, overshooting of the cooling process with resultant hypothermia must be prevented and avoidance of shivering is essential because of the associated increase in heat production, oxygen consumption, and cardiorespiratory effort (Leon & Bouchama, 2015; Gaudio & Grissom, 2016).*

▲ Continually assess the client's neurologic and other organ function, especially kidney function (i.e., signs of rhabdomyolysis), for signs of injury from hyperthermia. **EB/EBN:** *Hyperthermia can cause permanent neurologic injury, acute kidney injury, electrolyte imbalances, and coagulation disorders so continuous assessment of neurologic and other organ function is essential (Leon & Bouchama, 2015; Gaudio & Grissom, 2016).*

Malignant Hyperthermia

▲ If the client has just received general anesthesia, especially halothane, sevoflurane, desflurane, enflurane, isoflurane, or succinylcholine, recognize that the hyperthermia may be caused by malignant hyperthermia and requires immediate treatment to prevent death. *Malignant hyperthermia is often a fatal disease and must be treated promptly with rapid administration of the medication dantrolene, increasing oxygenation, assisting*

ventilation, initiating external cooling measures, and treating acid-base (e.g., metabolic acidosis) and electrolyte disorders (Rosenberg et al, 2015; Safety Committee of Japanese Society of Anesthesiologists [SCJSA], 2017).

• Monitor core temperature for all clients receiving general anesthetic agents for longer than 30 minutes. **EB/EBN:** *Hyperthermia typically occurs 30 minutes after induction of anesthesia and is associated with a higher mortality rate (Larach et al, 2014; Rosenberg et al, 2015).*

• Recognize that signs and symptoms of malignant hyperthermia typically occur suddenly after exposure to the anesthetic agent and include rapid rise in core body temperature, hypercarbia (increase in end tidal carbon dioxide), muscle rigidity, masseter muscle spasm, dysrhythmias, tachycardia, tachypnea, rhabdomyolysis, acute kidney injury, and elevated serum calcium and potassium, progressing to disseminated intravascular coagulation and cardiac arrest (Rosenberg et al, 2015; SCJSA, 2017).

▲ If the client has malignant hyperthermia, begin treatment as ordered, including cessation of the anesthetic agent and intravenous administration of dantrolene sodium, STAT, along with cooling measures, hyperventilation with 100% oxygen, antidysrhythmics, and continued support of the cardiovascular system. *Dantrolene helps decrease the increased muscle activity associated with malignant hyperthermia and can be life-saving (Rosenberg et al, 2015; SCJSA, 2017).*

▲ Recognize that dysrhythmias must not be treated with calcium channel blockers (e.g., verapamil) when the client has malignant hyperthermia. *Calcium channel blockers in combination with dantrolene can lead to cardiac arrest (Rosenberg et al, 2015; SCJSA, 2017).*

• Provide client and family education when malignant hyperthermia occurs because it is an inherited muscle disorder. *Obtaining a thorough health history to include family history of adverse experiences with anesthesia or muscle disorders is important in identifying clients at risk for malignant hyperthermia. Genetic counseling may also be indicated (Malignant Hyperthermia Association of the United States [MHAUS], 2015).*

Neuroleptic Malignant Syndrome

▲ Recognize that neuroleptic malignant syndrome is a rare condition associated with clients who are taking typical and atypical antipsychotic agents or after abrupt discontinuation of dopaminergic agonist agents used for Parkinson's disorder (Paden, Franjic, & Halcomb, 2013; Pileggi & Cook, 2016). **EB/EBN:** *The most common agents associated with the condition are dopamine-2 inhibiting antipsychotic agents (e.g., haloperidol, fluphenazine, chlorpromazine, quetiapine, risperidone, olanzapine) and dopamine antagonists (e.g., metoclopramide, promethazine, prochlorperazine, droperidol); sudden cessation of dopamine agonists (amantadine, levodopa, lithium, and bromocriptine) have also been associated with neuroleptic malignant syndrome (Paden, Franjic, & Halcomb, 2013; Pileggi & Cook, 2016).*

• Watch for signs and symptoms that can range from mild to severe and include a sudden change in mental status, rapid rise in body temperature, muscle rigidity, tachycardia, tachypnea, elevated or labile blood pressure, diaphoresis, rhabdomyolysis, and acute kidney injury (Paden, Franjic, & Halcomb, 2013; Pileggi & Cook, 2016).

▲ Begin treatment when diagnosed, including cessation of the neuroleptic or dopamine antagonist agent or resumption of dopamine agonist agent that may have been abruptly discontinued; order administration of dantrolene, bromocriptine,

amantadine, or benzodiazepine; and continue support of the cardiovascular, pulmonary, and renal systems (Paden, Franjic, & Halcomb, 2013; Pileggi & Cook, 2016).
• A client health history that reports extrapyramidal reaction to any medication should be further explored for risk of neuroleptic malignant syndrome because this syndrome can occur at any time during a client's treatment with typical and atypical antipsychotic agents (Paden, Franjic, & Halcomb, 2013; Pileggi & Cook, 2016).
• Recognize that clients receiving rapid dose escalation of antipsychotic agents (e.g., haloperidol) intramuscularly for acute treatment of delirium may be at increased risk for neuroleptic malignant syndrome (Paden, Franjic, & Halcomb, 2013; Pileggi & Cook, 2016).

Pediatric

• Assess risk factors of malignant hyperthermia including a personal or family history of anesthesia-related complications or death or a history of muscle disorders. *There is an increased prevalence of malignant hyperthermia in the pediatric population, and the administration of inhalation anesthesia and succinylcholine is common in this age group (MHAUS, 2015; Pileggi & Cook, 2016).*
▲ Administer dantrolene, provide oxygen and assist with ventilation, monitor heart rate and rhythm, and treat electrolyte and acid-base disorders (i.e., metabolic acidosis) as ordered if malignant hyperthermia is present. *Dantrolene and airway management/support are necessary during emergent treatment of malignant hyperthermia (Nelson & Litman, 2014).*

Geriatric

• Help the client seek medical attention immediately if elevated core temperature is present. To diagnose the hyperthermia, assess for possible precipitating factors, including changes in medication, environmental changes, and recent medical interventions or infectious exposures. *Older adults are more susceptible to environmentally and medication-induced hyperthermia, because of the greater incidence of underlying chronic medical conditions that impair thermal regulation or prevent removal from a hot environment (Leon & Bouchama, 2015).*
• In hot weather, encourage the client to wear lightweight cotton clothing (Leon & Bouchama, 2015).
• Provide education on the importance of drinking eight glasses of fluid per day (within their cardiac and renal reserves) regardless of whether they are thirsty and wearing appropriate clothing for the environmental temperature; assess for the need for and presence of fans or air conditioning. *Older adults are more susceptible to a hot environment than younger adults because of a decreased sensitivity to heat, decreased sweat gland function, decreased thirst, and decreased mobility (Leon & Bouchama, 2015).*
• In hot weather, monitor the older client for signs of heat stroke such as rising temperature, orthostatic blood pressure drop, weakness, restlessness, mental status changes, faintness, thirst, nausea, and vomiting. If signs are present, move the client to a cool place, have the client lie down, give sips of water, check orthostatic blood pressure, spray with lukewarm water, cool with a fan, and seek medical assistance immediately. *Older adults are predisposed to heat exhaustion and should be watched carefully for occurrence; if present, it should be treated promptly (Leon & Bouchama, 2015).*
• During warm weather, help the client obtain a fan or an air conditioner to increase

evaporation, as needed. Help the older client locate a cool environment to which they can go for safety in hot weather.
• Take the temperature of the older client in hot weather. *Older clients may not be able to tell that they are hot because of decreased sensation.*

Home Care

• Some of the interventions described previously may be adapted for home care use.
• Determine whether the client or family has a functioning thermometer, and know how to use it. Refer to the previous interventions on taking a temperature.
• Help the client and caregivers prevent and monitor for heat stroke/hyperthermia during times of high outdoor temperatures. *Preventive measures include minimizing time spent outdoors, use of air conditioning or fans, increasing fluid intake, and taking frequent rest periods (Centers for Disease Control and Prevention [CDC], 2017).*
• To prevent heat-related injury in athletes, laborers, and military personnel, instruct them to acclimate gradually to the higher temperatures, increase fluid intake, wear vapor-permeable clothing, and take frequent rests (Leon & Bouchama, 2015; CDC, 2017).
• In the event of temperature elevation above the adaptive range, institute measures to decrease temperature (e.g., get the client out of the sun and into a cool place, remove excess clothing, have the client drink fluids, spray the client with lukewarm water, fan with cool air, initiate emergency transport). *Hyperthermia is an acute and possibly life-threatening situation (Kerr et al, 2014; CDC, 2017).*

Client/Family Teaching and Discharge Planning

▲ Instruct to increase fluids to prevent heat-induced hyperthermia and dehydration in the presence of fever. *Liberal fluid intake replaces fluid lost through perspiration and respiration (Lipman et al, 2013).*
• Teach the client to stay in a cooler environment during periods of excessive outdoor heat or humidity. If the client does go out, instruct him or her to avoid vigorous physical activity; wear lightweight, loose-fitting clothing; and wear a hat to minimize sun exposure. *Such methods reduce exposure to high environmental temperatures, which can cause heat stroke and hyperthermia (Kerr et al, 2014; CDC, 2017).*

Hypothermia

Rosemary Timmerman DNP, APRN, CCNS, CCRN-CSC-CMC

NANDA-I

Definition

Core body temperature below normal diurnal range due to failure of thermoregulation.

Defining Characteristics

Acrocyanosis; bradycardia; cyanotic nail beds; decrease in blood glucose level; decrease in ventilation; hypertension; hypoglycemia; hypoxia; increase in metabolic rate; increase in oxygen consumption; peripheral vasoconstriction; piloerection; shivering; skin cool to touch; slow capillary refill; tachycardia

Neonates

Infant with insufficient energy to maintain sucking; infant with insufficient weight gain (<30 g/day); irritability; jaundice; metabolic acidosis; pallor; respiratory distress

Related Factors

Alcohol consumption; decrease in metabolic rate; excessive conductive heat transfer; excessive convective heat transfer; excessive evaporative heat transfer; excessive radiative heat transfer; inactivity; insufficient caregiver knowledge of hypothermia prevention; insufficient clothing; low environmental temperature; malnutrition

Neonates

Delay in breastfeeding; early bathing of newborn; increase in oxygen demand

At-Risk Population

Economically disadvantaged; extremes of age; extremes of weight; high-risk out-of- hospital birth; increased body surface area to weight ratio; insufficient supply of subcutaneous fat; unplanned out-of-hospital birth

Associated Condition

Damage to hypothalamus; immature stratum corneum; increase in pulmonary vascular resistance (PVR); ineffective vascular control; inefficient nonshivering thermogenesis; pharmaceutical agent; radiation therapy; trauma

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Thermoregulation; Thermoregulation: Newborn

Example NOC Outcome with Indicators

Thermoregulation as evidenced by the following indicators: Increased skin temperature/Decreased skin temperature/Skin color changes/Dehydration/Hypothermia. (Rate the outcome and indicators of **Thermoregulation:** 1 = severe, 2 = substantial, 3 = moderate, 4 = mild, 5 = none [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Maintain body temperature within normal range
- Identify risk factors of hypothermia
- State measures to prevent hypothermia
- Identify symptoms of hypothermia and actions to take when hypothermia is present
- If hypothermia is medically induced client/family will state goals for hypothermia treatment

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Hypothermia Treatment; Temperature Regulation; Temperature Regulation: Intraoperative; Vital Signs Monitoring

Example NIC Activities—Temperature Regulation

Institute use of a continuous core temperature-monitoring device, as appropriate; Promote adequate fluid and nutritional intake

Nursing Interventions and *Rationales*

Temperature Measurement

- Recognize hypothermia as a drop in core body temperature below 35°C (95°F) (Paal et al, 2016; Zafren, 2017).
- Measure and record the client's temperature hourly, or if the client's temperature is less than 35°C (95°F), continuously. **EB:** *Ongoing temperature measurements are needed for timely treatment decisions (Paal et al, 2016; Zafren, 2017).*
- Select a core or a near core measurement site based on the clinical situation and ability to obtain an accurate measurement; verify the temperature reading with a second monitoring device as needed. **EB:** *Hypothermia can be a life-threatening crisis and obtaining an accurate temperature measurement is essential for detecting hypothermia and monitoring the client's response to treatment. A core temperature measurement from a pulmonary artery catheter is considered the gold standard, but it is often not practical and may precipitate dysrhythmias in hypothermic clients. A probe placed in the distal esophagus correlates with the pulmonary artery temperature and can be used when the client has a decreased level of consciousness and the upper airway is secured. An indwelling urinary catheter with a temperature probe allows for simultaneous measurement of bladder temperatures and urine output but may not be accurate with a low urine output. Rectal and bladder probes provide near core temperature readings but may lag behind core temperatures during rapid cooling and rewarming. Tympanic measurements may give falsely low readings*

in clients with unstable or absent circulation; oral, skin, and temporal artery temperatures are inaccurate in hypothermic states (Soreide, 2014; Paal et al, 2016; Zafren, 2017).
• Use the same site and method (device) for a given client so that temperature trends are accurately assessed. **CEB:** *There are differences in temperature measurements depending on the site from which the temperature measurement is obtained; however, differences between sites should not be more than 0.3°C to 0.5°C (Makic et al, 2011).*
• See the care plan for Ineffective **Thermoregulation** as appropriate.

Accidental Hypothermia

• Recognize that there are three types of accidental hypothermia (environmental causes):
    ❍ Acute hypothermia, also called immersion hypothermia, often from sudden exposure to cold through immersion in cold water or snow
    ❍ Exhaustion hypothermia, caused by exposure to cold in association with lack of food and exhaustion
    ❍ Chronic hypothermia that occurs over days or weeks and primarily affects older adults (Petrone, 2014)
• Remove the client from the cause of the hypothermic episode (e.g., cold environment, cold or wet clothing), bring into a warm environment, cover the client with warm blankets, and apply a covering to the head and neck to conserve body heat. *Layering of dry clothing, including wearing a hat, can be effective in warming a client with mild hypothermia; the goal is also to prevent any further heat loss (Soreide, 2014; Rischall & Rowland-Fisher, 2016; Zafren, 2017).*
• Keep the moderately and severely hypothermic client horizontal and handle gently during movements. **EB:** *Because cold myocardial tissue is irritable, rough or sudden movements of hypothermic clients can precipitate lethal ventricular dysrhythmias; a vertical position may cause severe cardiovascular stress (Paal et al, 2016; Zafren, 2017).*
• Monitor the client for signs of hypothermia: shivering, slurred speech, confusion, clumsy movements, fatigue progressing to a further decrease in level of consciousness, bradycardia, hypoventilation, hypotension, ventricular fibrillation, and asystole (*Rischall & Rowland-Fisher, 2016*; *Zafren, 2017*). Hypothermic patients have decreased oxygen needs and generally do not need supplemental oxygen (Zafren & Giesbrecht, 2014).
• Monitor the client's vital signs every hour and as appropriate, noting changes associated with hypothermia, such as increased pulse rate, respiratory rate, and blood pressure, as well as diuresis with mild hypothermia, progressing to a decreased pulse rate, respiratory rate and blood pressure, and oliguria with moderate to severe hypothermia. **EB:** *With mild hypothermia, the sympathetic nervous system is activated, which increases the heart rate and respiratory rate; as hypothermia progresses, decreased circulating volume develops, which results in decreased cardiac output and decreased oxygen delivery. Hypoxia, metabolic acidosis, and intrinsic irritability of a cold myocardium result in dysrhythmias (Petrone, 2014; Zafren, 2017).*
▲ Attach electrodes and a cardiac monitor and monitor for dysrhythmias. **EB:** *With hypothermia, the client is prone to dysrhythmias because of the cold myocardium; dysrhythmias may include atrial fibrillation, ventricular fibrillation, or asystole (Paal et al, 2016; Zafren, 2017).*
▲ Recognize that clients with a core temperature less than 30°C are at a higher risk for cardiac arrest; if the client arrests:
    ❍ Check the pulse for up to 1 minute because the pulse may be slow and

weak.
    - ❍ Provide chest compressions and ventilations at the same rate as for a normothermic client.
    - ❍ Limit defibrillations to one attempt at maximal power for clients with ventricular fibrillation or pulseless ventricular tachycardia until the client's core temperature is at least 30°C.
    - ❍ Medications may be withheld until the client has a core temperature greater than 30°C; double the interval between doses once the temperature is above 30°C; resume normal doses of medications once the temperature reaches 35°C.
    - ❍ Recognize prolonged cardiopulmonary resuscitation may be necessary as the client is rewarmed.
    - ❍ **EB:** *Defibrillation and medications are less effective in the moderately or severely hypothermic client (Zafren & Griesbrecht, 2014).*

▲ Monitor for signs of coagulopathy (e.g., oozing of blood from any open areas or from intravascular catheter sites or mucous membranes) and note the results of clotting studies as available. **EB:** *Coagulopathy is a common occurrence during hypothermia because of reduced platelet function and coagulation enzymatic activity (Paal et al, 2016; Rischall & Rowland-Fisher, 2016).*

• For mild hypothermia (core temperature of 32.2°C–35°C [90°F–95°F]), rewarm client passively:
    - ❍ Set room temperature to 21°C to 24°C (70°F–75°F).
    - ❍ Keep the client dry; remove any damp or wet clothing.
    - ❍ Layer clothing and blankets and cover the client's head.
    - ❍ Offer warm fluids, particularly beverages high in carbohydrates for clients who are shivering and able to safely swallow; avoid alcohol or caffeine (Zafren & Giesbrecht, 2014; Zafren, 2017).

• For mild hypothermia, allow the client to rewarm at his or her own pace as heat is generated through the normal metabolism; warm fluids help reduce further heat loss and carbohydrates help fuel metabolic processes (Rischall & Rowland-Fisher, 2016; Zafren, 2017).

▲ For moderate hypothermia (core temperature 28°C–32.1°C [82.4°F–90°F]) or any client with a decreased level of consciousness, use active external rewarming methods, not exceeding an increase of more than 0.5°C to 1°C (1.8°F) per hour. **EB:** *Passive rewarming is not recommended for clients with temperatures lower than 32.2°C (90°F) because it is a slow process, requires sufficient glycogen stores to be used by the client's body, and may increase oxygen consumption, increasing the risk of adverse cardiac events (Rischall & Rowland-Fisher, 2016; Zafren, 2017).*

• Methods to rewarm the client include the following (Paal et al, 2016; Zafren, 2017):
    - ❍ Forced-air warming blankets
    - ❍ Circulation of warm water through external pads
    - ❍ Heated and humidified oxygen (42°C–46°C) through the ventilator circuit as ordered
    - ❍ Warmed (40°C–42°C) intravenous (IV) fluids and blood products using a commercial IV fluid warmer
    - ❍ Radiant heat sources

▲ For severe hypothermia (core temperature below 28°C [82.4°F]), use active core rewarming techniques as ordered (Paal et al, 2016; Rischall & Rowland-Fisher, 2016):
    - ❍ Hemodialysis
    - ❍ Intravascular temperature management catheter

- ❍ Body cavity (thorax, peritoneal, stomach, and bladder) lavage with warmed fluid
- ❍ Recognize that warming by extracorporeal life support (ECLS) using venoarterial extracorporeal membrane oxygenation (ECMO) or cardiopulmonary bypass is essential for clients experiencing hemodynamic instability or hypothermic cardiac arrest

• Rewarm clients slowly, generally at a rate of 0.5°C to 1°C every hour. **EB:** *Slow rewarming helps prevent a phenomenon called "afterdrop," in which cold, hyperkalemic blood from the periphery returns to the heart, resulting in a biochemical injury, leading to dysrhythmias and severe hypotension (Rischall & Rowland-Fisher, 2016; Zafren, 2017).*

• Measure the blood pressure frequently when rewarming and monitor for hypotension. **EB:** *As the body warms, formerly vasoconstricted vessels dilate, resulting in hypotension; dehydration from cold diuresis worsens hypotension (Petrone, 2014; Zafren, 2017).*

▲ Administer isotonic IV fluids warmed to 40°C to 42°C as prescribed. **EB:** *Significant amounts of IV fluids are often needed to maintain adequate perfusion to vital tissues and organs because of hypovolemia from cold diuresis and vasodilation from rewarming; warmed IV fluid does not significantly raise the body temperature but does help prevent further heat loss (Rischall & Rowland-Fisher, 2016; Zafren, 2017).*

• Place a barrier between the patient and the heating blanket and monitor the client's skin. **EB:** *Cold skin is susceptible to pressure and thermal injury (Rischall & Rowland-Fisher, 2016; Zafren, 2017).*

• Determine the factors leading to the hypothermic episode, particularly if the client fails to rewarm, and treat the underlying condition; see Related Factors. *It is important to assess risk factors and precipitating events to prevent another incident of hypothermia and detect and treat underlying disease processes that impede thermoregulation (Rischall & Rowland-Fisher, 2016).*

▲ Request a social service referral to help the client obtain the heat, shelter, and food needed to maintain body temperature. *A preventive approach that includes adequate food and fluid intake, shelter, heat, and clothing decreases the risk of hypothermia.*

▲ Encourage proper nutrition and hydration. *Request a referral to a dietitian to identify appropriate dietary needs; insufficient calorie and fluid intake predisposes the client to hypothermia, especially in older adults (Rischall & Rowland-Fisher, 2016).*

Targeted Temperature Hypothermia

• Recognize that targeted temperature management, also called therapeutic hypothermia, is the active lowering of the client's body temperature, in a controlled manner, to preserve neurological function after a cardiac arrest; targeted temperature management may also be considered for clients who have refractory intracranial hypertension. **EB:** *In the event the client is successfully resuscitated after a cardiac arrest, recognize that medically induced targeted temperature management has been shown to provide neurological protection against ischemic neuronal injury after cardiac arrest (Donnino et al, 2016; Cook, 2017).*

• Recognize that controlled cooling of clients should be considered for all unconscious survivors of in-hospital or out-of-hospital cardiac arrest with an initial shockable (ventricular fibrillation or pulseless ventricular tachycardia) or nonshockable (asystole or pulseless electrical activity) rhythm; achieve and maintain a constant target temperature between 32°C and 36°C for at least 24 hours. **EB:** *The American Heart Association and the International Liaison Committee on Resuscitation have*

included therapeutic hypothermia as an intervention to be considered in the management of cardiac arrest patients to optimize neurological outcomes after return of spontaneous circulation (Donnino et al, 2016; Geocadin et al, 2017).

• Monitor core or near core temperatures continuously using two methods of temperature monitoring. *To ensure that the targeted temperature is achieved and maintained closely within the prescribed temperature range, two methods of core or near core temperature monitoring are recommended (Avery et al, 2015; Cook, 2017).*

• Recognize that cooling may be achieved noninvasively, using fluid-filled cooling pads, or invasively, with an intravascular cooling catheter. **EB/EBN:** *Invasive cooling and surface cooling pads provide a more predictable and rapid cooling, minimizing adverse electrolyte shifts and shivering. Less optimal methods of cooling include the use of fans, ice packs, or blankets, which do not provide temperature regulation feedback between the machine and client (Olson & Hoffman, 2016; Wilson & Penna, 2016).*

• Monitor for signs of infection and implement measures to prevent hospital-acquired infections. *Hypothermia places the client at higher risk for infection because of immunosuppression (Beseda, Smith, & Veenstra, 2014; Cook, 2017).*

• Obtain vital signs hourly (or via continuous monitoring) to include continuous electrocardiogram monitoring, and observe for signs of hypotension, bradycardia, and dysrhythmias. Mechanical ventilation is required to protect the client's airway and breathing during treatment. **EB:** *Diuresis is more pronounced during the induction of hypothermia; hypotension may be more prominent as the client is rewarmed because of vasodilatation, requiring close monitoring and interventions to support blood pressure. Bradycardia associated with hypothermia is often not responsive to atropine but does not need to be treated unless the client is hemodynamically unstable. If the client is overcooled (temperature drops below 32°C), the risk of dysrhythmias will increase and ventricular fibrillation refractory to defibrillation may occur at temperatures below 30°C (Olson & Hoffman, 2016; Cook, 2017).*

▲ Observe for shivering and implement skin counterwarming with blankets; administer sedatives, opioids, neuromuscular blocking agents, buspirone, acetaminophen, or magnesium sulfate as prescribed. **EB:** *Shivering typically occurs as the client transitions between 37°C and 35°C and significantly increases the body's metabolic rate and oxygen consumption (Nakajima, 2016; Cook, 2017).*

▲ Closely inspect the skin before and throughout the cooling intervention and implement frequent turning and other pressure reduction interventions as indicated. *Lowering the body temperature causes vasoconstriction and can compromise perfusion to the skin, increasing the client's risk of skin breakdown and impaired wound healing (Olson & Hoffman, 2016; Cook, 2017).*

▲ Monitor and treat serum electrolytes (e.g., potassium, magnesium, calcium, phosphorus) and serum glucose closely during targeted hypothermia and during rewarming of the client; electrolytes will fluctuate as the client is rewarmed. **EB/EBN:** *Hypokalemia can occur during the induction phase of targeted temperature management as potassium moves intracellularly and is also lost through diuresis; as the client is rewarmed, electrolyte replacements, especially potassium replacements, should be closely monitored to prevent rebound hyperkalemia that may occur as the body temperature rises (Petrone, 2014; Cook, 2017).*

▲ Monitor blood cell counts and observe for signs and symptoms of coagulopathy during targeted hypothermia treatment. **EB:** *For every 1°C decline in temperature, the hematocrit may increase by approximately 2%, requiring monitoring but not treatment. Platelet counts decrease during hypothermic states, but research has not found a significant risk of bleeding during targeted hypothermia treatment* (*Petrone, 2014; Olson & Hoffman,*

2016).

• Rewarming should occur in a controlled manner, with a rise in body temperature of 0.25°C to 0.5°C per hour and a targeted goal of normothermia, 37°C for 36 hours. **EB:** *Aggressive rewarming may cause rebound hyperthermia, cerebral edema, seizures, hypotension, and ventricular fibrillation; hyperthermia during the 36 hours after a cardiac arrest is associated with worse neurological outcomes and a higher mortality rate (Beseda et al, 2014; Kim, Bravo, & Nichol, 2015).*

▲ Neurological and cognitive function should be assessed during targeted temperature treatment and after rewarming. **EB:** *The goal of targeted temperature treatment is neurological protection; close monitoring of neurological function after intervention and serial assessments are indicated (Donnino et al, 2016; Geocadin et al, 2017).*

Pediatric

• Recognize that pediatric clients have a decreased ability to adapt to temperature extremes; take the following actions to maintain body temperature in the infant/child:

- ❍ Keep the head covered.
- ❍ Use blankets to keep the client warm.
- ❍ Keep the client covered during procedures, transport, and diagnostic testing.
- ❍ Keep the room temperature at 22.2°C (72°F).

• *The combination of a relatively smaller body surface area, smaller body fluid volume, less well-developed temperature control mechanisms, and smaller amount of protective body fat limits the infant's and child's ability to maintain normal temperatures (Wyckoff, 2014).*

• For the preterm or low-birth-weight newborn, set the room temperature to 25°C (77°F) before the delivery; cover the infant's head with a wool or polyethylene cap; and use specially designed bags, skin-to-skin care, transwarmer mattresses, radiant warmers, and thermal blankets to keep the infant warm. **EB/EBN:** *These methods can help keep the vulnerable newborn warm in the delivery room (Wyckoff, 2014; Hsu et al, 2015).*

• Avoid bathing neonates for at least 6 hours after birth or until physiological stability is achieved; avoid removing the vernix caseosa and allow it to wear off with normal activity and handling; grossly contaminated vernix caseosa may be gently removed. **EBN:** *Early bathing of a neonate can result in hypothermia; the vernix caseosa protects and moisturizes the skin (Colwell, 2015).*

• Targeted hypothermia to 34°C for 72 hours may be implemented in the treatment of neonates with hypoxic-ischemic encephalopathy (HIE). **EB:** *Cooling may be achieved by selective head cooling or passively, to the entire body, by withholding external heat sources, which requires frequent monitoring of the neonate's temperature to prevent severe hypothermia (Wyckoff, 2014; Douglas-Escobar & Weiss, 2015).*

• Measure the temperature of the neonate undergoing therapeutic hypothermia for HIE with a rectal or nasopharyngeal probe. **EB:** *Although rectal and nasopharyngeal temperature accurately reflect the core body temperature of neonates undergoing targeted hypothermia, axillary temperature measurements do not (Landry et al, 2013; Hine et al, 2017).*

Geriatric

• Normal aging often includes changes in touch-related sensations, making it harder to differentiate cool and cold. *Decreased temperature sensitivity increases the risk of hypothermia in the older adult (Martin, 2016).*

• Recognize that older adults can develop hypothermia even from exposure to mildly

cold temperatures of 60°F to 65°F (15.5°C–18.3°C). *Clients present with vague complaints of mental and/or other skill deterioration (Hypothermia and Older Adults, 2016).*

- ❍ Set the room temperature to 68°C to 70°C (20°C–21.1°C).
- ❍ Instruct client to wear warm clothes as appropriate (long underwear, socks, slippers, and a cap or hat) and to use a blanket to keep shoulders and legs warm while indoors.
- ❍ Instruct client to dress in layers and wear a hat, scarf, and gloves or mittens when going outside during cold weather.
- ❍ Instruct client to maintain adequate calorie intake.

• Assess neurological signs frequently, watching for confusion and decreased level of consciousness. **CEB:** *Mechanisms to control body temperature decrease with age, coupled with a slower counterregulatory response, lower rate of metabolism, and less effective vascular response, making hypothermia less obvious (Danzl et al, 2011).*

Home Care

• Hypothermia is not a symptom that appears in the normal course of home care, but when it occurs it is a clinical emergency, and the client/family should access emergency medical services immediately.
• Some of the interventions described earlier may be adapted for home care use.
• Before a medical crisis occurs, confirm that the client or family has a thermometer that registers accurately and the client or family can read it.
• Instruct the client or family to take the temperature when the client displays cyanosis, pallor, or shivering.
▲ Monitor temperature every hour, as noted previously; if the temperature of the client begins dropping below the normal range, apply layers of clothing or blankets, or adjust environmental heat to the comfort level, being careful to not overheat the client. *Passive rewarming is the only method of rewarming that is appropriate for home care under normal circumstances.*
▲ If temperature continues to drop, activate the emergency system and notify a health care provider. *Hypothermia is a clinically acute condition that cannot be managed safely in the home.*
▲ If the client is in hospice care or is terminally ill, follow advance directives, client wishes, and the health care provider's orders; keep the client free of pain. *The goal of terminal care is to provide dignity and comfort during the dying process.*

Client/Family Teaching and Discharge Planning

• Teach the client and family signs of hypothermia and the method of taking the temperature (age appropriate).
• Teach the client methods to prevent hypothermia: wearing adequate clothing, including a hat and mittens; heating the environment to a minimum of 20°C (68°F); and ingesting adequate food and fluid. *Simple measures such as layering clothes, wearing a hat, and avoiding extremes in temperature prevent significant heat loss (Petrone, 2014).*
• Teach clients who engage in cold weather outdoor activities the importance of appropriate clothing, survival skills, and emergency planning.
▲ Teach the client and family about medications such as sedatives, opioids, and anxiolytics that predispose the client to hypothermia (as appropriate). *If the client has had hypothermia in the past, using alternative medications is an option if there is no contraindication (Danzl et al, 2011).*

Risk for Hypothermia

Rosemary Timmerman DNP, APRN, CCNS, CCRN-CSC-CMC

NANDA-I

Definition

Susceptible to a failure of thermoregulation that may result in a core body temperature below the normal diurnal range, which may compromise health.

Risk Factors

Alcohol consumption; excessive conductive heat transfer, excessive convective heat transfer; excessive evaporative heat transfer; excessive radiative heat transfer; inactivity; insufficient caregiver knowledge of hypothermia prevention; insufficient clothing; low environmental temperature; malnutrition

Neonates

Decrease in metabolic rate; delay in breastfeeding; early bathing of newborn; increase in oxygen demand

At-Risk Population

Economically disadvantaged; extremes of age; extremes of weight; high-risk out-of-hospital birth; increased body surface area to weight ratio; insufficient supply of subcutaneous fat; unplanned out-of-hospital birth

Associated Condition

Damage to hypothalamus; immature stratum corneum; increased in pulmonary vascular resistance (PVR); ineffective vascular control; inefficient nonshivering thermogenesis; pharmaceutical agent; radiation therapy; trauma

NIC, NOC, Client Outcomes, Nursing Interventions and *Rationales,* Client/Family Teaching and Discharge Planning, and References

Refer to care plan for **Hypothermia**

Risk for Perioperative Hypothermia

Catherine Kleiner PhD, MSN, BSN

NANDA-I

Definition

Susceptible to an inadvertent drop in core body temperature below 36°C/96.8°F occurring one hour before to 24 hours after surgery, which may compromise health.

Risk Factors

Excessive conductive heat transfer; excessive convective heat transfer; excessive radiative heat transfer; low environmental temperature

At-Risk Population

American Society of Anesthesiologist (ASA) Physical Status classification score >1; low body weight; low preoperative temperature (<36°C/96.8°F)

Associated Condition

Cardiovascular complications; combined regional and general anesthesia; diabetic neuropathy; surgical procedure

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Thermoregulation

Example NOC Outcome with Indicators

Thermoregulation as evidenced by the following indicators: Increased skin temperature/Decreased skin temperature/Skin color changes/Dehydration/Hypothermia. (Rate the outcome and indicators of Thermoregulation: 1 = severe, 2 = substantial, 3 = moderate, 4 = mild, 5 = none [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Maintain body temperature within normal range
- Identify risk factors of hypothermia
- State measures to prevent hypothermia
- Identify symptoms of hypothermia and actions to take when hypothermia is present
- Client will be free of surgical site infection

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Hypothermia Treatment; Temperature Regulation; Temperature Regulation: Intraoperative; Vital Signs Monitoring

Example NIC Activities—Temperature Regulation

Institute use of a continuous core temperature-monitoring device, as appropriate; Promote adequate fluid and nutritional intake

Nursing Interventions and *Rationales*

Temperature Measurement

- Recognize perioperative hypothermia as a drop in core body temperature below 36°C (96.8°F) (Campbell et al, 2015; Centers for Disease Control and Prevention [CDC], 2018).
- Measure the client's temperature frequently, at least every 15 minutes, while the patient is undergoing general anesthesia and with changes in client condition (e.g., chills, change in mental status); if more than mild hypothermia is present (temperature lower than 36°C/96.85°F), use a continuous temperature-monitoring device. Two modes of temperature monitoring may be indicated. Continuous temperature monitoring using an indwelling method of temperature measurement is usually indicated to monitor effectiveness of treating body alterations in core body temperature. **EBN:** *Hypothermia can be a life-threatening crisis that requires accurate temperature measurement. Core temperature is obtained by a pulmonary artery catheter or less invasive from sublingual, the distal esophagus, nasopharyngeal, or direct tympanic sites (Torossian et al, 2016). Near core temperature measurement sites include oral, bladder, rectal,*

and temporal artery, and peripheral measurements are obtained by skin surface measurements and in the axilla (Barnason et al, 2012). Research is limited on the accuracy of temporal artery, carotid artery, and "zero heat flux" measurements outside normal ranges; however, recent research is demonstrating improved accuracy and reliability (Iden et al, 2015; Imani et al, 2016; Evron et al, 2017). Axillary temperature is accurate in neonates, but it is not well supported in adults; tympanic membrane measurements and chemical dot thermometers are least accurate and should be avoided in caring for the acutely ill adult client (Barnason et al, 2012; Winslow et al, 2012). As technology improves the accuracy and reliability of noninvasive temperature monitoring will make the use of these measures an acceptable choice.

- Use the same site and method (device) for temperature measurement for a given client so that temperature trends are assessed accurately, and record site of temperature measurement. **EB:** *There are differences in temperature depending on the site (esophageal, oral, bladder, rectal, axillary, or temporal artery); however, differences should not be greater than 0.3°C to 0.5°C (Barnason et al, 2012; Torossian et al, 2016).*
- Bladder temperature may be used because an indwelling urinary catheter is often inserted in the management of hypothermia to monitor diuresis. **EBN:** *Bladder temperature probes have been shown to be accurate during states of increased diuresis, but measurements may be less accurate when urine volume is low (low rate of diuresis). Temperatures obtained by this method may lag up to 20 minutes during targeted temperature hypothermia interventions (Burlingame & Conner, 2015).*

Unintentional Perioperative Hypothermia

- Keep the client warm throughout the perioperative period (preoperative, intraoperatively, and postoperatively) to prevent unintentional perioperative hypothermia. **EB:** *Initiating warming interventions preoperatively has been found to assist with normothermia and client comfort (Horosz & Malec-Milewska, 2014).*
- Factors that increase the risk of perioperative hypothermia include anesthetic agents, ambient room air temperature, intravenous (IV) fluid infusion, cavity solution irrigation, blood product administration, duration and type of surgical procedure, anemia, extremes of age, neurological disorders, cachexia, and preexisting conditions (e.g., peripheral vascular disease, endocrine disease, pregnancy, burns, open wounds) (Billeter et al, 2014; American Society of PeriAnesthesia Nurses [ASPAN], 2015).
- Closely monitoring and preventing unintentional perioperative hypothermia is necessary to prevent adverse patient outcomes. **CEB:** *Adverse outcomes include client discomfort, shivering, cardiac events (e.g., arrhythmias), increased catecholamine release, impaired coagulation, altered drug metabolism, impaired wound healing, and impaired immune function (Winslow et al, 2012; Horosz & Malec-Milewska, 2014; Kuchena, Merkel, & Hutches, 2014; ASPAN, 2015).*
- Several interventions should be implemented to prevent unintentional perioperative hypothermia:
    - ❍ Use warming booties perioperatively
    - ❍ Use warming blankets over and under the client perioperatively
    - ❍ Use warming blankets under the client on the operating table
    - ❍ Use of reflective blankets
    - ❍ Adjust environmental room controls to maintain ambient room temperature between 68°F and 77°F
    - ❍ Use humidified heated breathing circuit
    - ❍ Use warmed forced-air blankets preoperatively, during surgery, and in the postanesthesia care unit

❍ Use circulating-water mattress
❍ Use warmed IV fluids and irrigation solutions
❍ Designate responsibility and accountability for thermoregulation

▲ **EBN/EB:** *Maintaining the client's temperature during the surgical procedure has been found to be essential in preventing surgical complications, especially surgical site infections. Maintaining normothermia also enhances client comfort (Institute for Healthcare Improvement [IHI], 2012a; ASPAN, 2015; CDC, 2018). Preoperative warming should be initiated for any patient with a core temperature below 36°C prior to induction of anesthesia, whereas preoperative warming for at least 10 minutes for any patient may prevent the patient from developing hypothermia (Horn et al, 2016; Wetz et al, 2016; Connelly et al, 2017). One study found that clients who experienced unintentional perioperative hypothermia during elective operations experienced a fourfold increase in mortality and stroke (Billeter et al, 2014).*

• Using warmed IV fluids and irrigation solutions during the operative period may assist with reducing the client's risk of unintentional perioperative hypothermia. **EB:** *Researchers found that warmed IV fluids and irrigation solutions kept the core temperatures of study participants warmer than those in clients receiving room temperature fluids (Campbell et al, 2015; Torossian et al, 2016).*

• Active warming interventions include the use of warm blankets and forced-air warming devices. **EBN:** *Blankets used for warming clients quickly lose heat. To prevent rapid heat loss from blankets, warming cabinets should be set at 200°F, and reapply blankets frequently (Kelly et al, 2013).* **EBN:** *Actively warming clients with forced-air warming is the most effective method to prevent hypothermia and offers a clinically important reduction in time to achieve normothermia in postoperative clients (Warttig et al, 2014; Connelly et al, 2017).*

❍ A heated humidified breathing circuit can be used intraoperatively to decrease hypothermia. **EB:** *Heated humidified breathing circuits have decreased the severity of hypothermia in patients undergoing thyroid surgery (Park et al, 2017).*

• Watch the client for signs of hypothermia: shivering, slurred speech, confusion, clumsy movements, fatigue, and dehydration. Shivering increases oxygen consumption by about 40%. As hypothermia progresses, the skin becomes pale, muscles are tense, fatigue and weakness progress, breathing is decreased, and pulmonary congestion is present, compromising oxygenation. Pulses are decreased and blood pressure and heart rate decrease, progressing to lethal arrhythmias (e.g., ventricular fibrillation) (Danzl, 2012; Petrone, 2014; Torossian et al, 2016).

▲ Administer oxygen as ordered. Oxygenation is hampered by the change in the oxyhemoglobin curve caused by hypothermia (Danzl, 2012).

▲ Attach electrodes and a cardiac monitor. Watch for dysrhythmias. With hypothermia, the client is prone to dysrhythmias because of the cold myocardium; dysrhythmias may include atrial fibrillation, ventricular fibrillation, or asystole (Danzl, 2012; Petrone, 2014).

▲ Monitor for signs of coagulopathy (e.g., oozing of blood from any open areas or from intravascular catheter sites or mucous membranes). Also note results of clotting studies as available. Coagulopathy is a common occurrence during hypothermia (Petrone, 2014; Soreide, 2014; ASPAN, 2015).

▲ Monitor for signs of surgical site infection (e.g., increased incisional pain, drainage, poor healing, poor incision approximation). Unintentional perioperative hypothermia has been associated with increased risk of surgical site infections (IHI, 2012a; ASPAN, 2015; CDC, 2018).

• See care plans for **Ineffective Thermoregulation** and **Hypothermia** as appropriate.

Pediatric

• Interventions implemented in the care of adult clients are similar when providing care to pediatric clients to prevent hypothermia. **EB:** *Keep the head covered, use warm blankets, or force warm air to keep the client warm; maintain normal ambient room temperature in the perioperative units and use warmed IV fluids (IHI, 2012b).* **EBN:** *Children with a lower preoperative body temperature are more likely to develop hypothermia during the intraoperative and postoperative period (Beedle et al, 2017).*

Home Care

▲ Hypothermia is not a symptom that appears in the normal course of postoperative home care. If the client continues to complain of chills or feeling cold after discharge home from a surgical procedure, provide the client with warm blankets and if the client is allowed to drink, provide warm fluids by mouth.
▲ Monitor temperature every hour, as noted previously. If the temperature of the client begins dropping below the normal range, apply layers of clothing or blankets, or adjust environmental heat to the comfort level. Do not overheat. Contact a health care provider. Passive rewarming is the only method of rewarming that is appropriate for home care under normal circumstances.
▲ If temperature continues to drop, activate the emergency system and notify a health care provider. Hypothermia is a clinically acute condition that cannot be managed safely in the home.

Client/Family Teaching and Discharge Planning

• Teach the client/family signs of hypothermia and the method of taking the temperature (age appropriate).
▲ Teach the client and family about medications such as sedatives, opioids, and anxiolytics that predispose the client to hypothermia (as appropriate). If the client has had hypothermia in the past, using alternative medications is an option if there is no contraindication (Danzl, 2012).

List of Planning Care by Letter: I

Disturbed personal Identity	Risk for disturbed personal Identity	Risk for complicated Immigration Transition
Ineffective Impulse control	Functional urinary Incontinence	Overflow urinary Incontinence
Reflex urinary Incontinence	Stress urinary Incontinence	Urge urinary Incontinence
Risk for urge urinary Incontinence	Bowel Incontinence	Disorganized Infant behavior
Readiness for enhanced organized Infant behavior	Risk for disorganized Infant behavior	Risk for Infection
Risk for surgical site Infection	Risk for Injury	Risk for corneal Injury
Risk for occupational Injury	Risk for urinary tract Injury	Insomnia
Decreased Intracranial adaptive capacity		

I

• = Independent; ▲ = Collaborative; **EBN** = Evidence-Based Nursing **EB** = Evidence-Based

Disturbed personal Identity

Ruth A. Wittmann-Price PhD, RN, CNS, CNE, CHSE, ANEF, FAAN

NANDA-I

Definition

Inability to maintain an integrated and complete perception of self.

Defining Characteristics

Alteration in body image; confusion about cultural values; confusion about goals; confusion about ideological values; delusional description of self; feeling of emptiness; feeling of strangeness; fluctuating feelings about self; gender confusion; inability to distinguish between internal and external stimuli; inconsistent behavior; ineffective coping strategies; ineffective relationships; ineffective role performance

Related Factors

Alteration in social role; cult indoctrination; cultural incongruence; discrimination; dysfunctional family processes; low self-esteem; manic states; perceived prejudice; stages of growth

At-Risk Population

Developmental transition; situational crisis; exposure to toxic chemical

Associated Condition

Dissociative identity disorder; organic brain disorder; pharmaceutical agent; psychiatric disorder

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Anxiety Self-Control; Abuse Recovery (Emotional, Physical, Sexual); Body Image; Decision-Making; Distorted Thought Self-Control; Identity; Mutilation; Suicide/Self-Restraint

Example NOC Outcome with Indicators

Identity as evidenced by the following indicators: Verbalizes affirmations of personal identity/Exhibits congruent verbal and nonverbal behavior about self/Differentiates self from environment and other human beings. (Rate the outcome and indicators of **Identity:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Demonstrate new purposes for life
- Show interests in surroundings

- Perform self-care and self-control activities appropriate for age
- Acknowledge personal strengths
- Engage in interpersonal relationships

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Decision-Making Support; Mutual Goal Setting; Self-Awareness Enhancement; Self-Esteem Enhancement; Sexual Counseling; Substance Use Prevention

Example NIC Activities—Self-Esteem Enhancement

Monitor client's statements of self-worth; Encourage client to identify strengths

Nursing Interventions and *Rationales*

- Assess and support family strengths of commitment, appreciation, and affection toward each other; positive communication; time together; a sense of spiritual well-being; and the ability to cope with stress and crisis. **EB:** *Hayes, Maliski, and Warner (2017) discovered through a qualitative study that family is an important support for patients, but found that patients are less likely to disclose sensitive health issues when family members are present.* **EB:** *Hoffman et al (2017) studied African American youths (N = 380) longitudinally over 7 years and found that racial identity grew over time and was influenced in a positive way by their mothers.*
- ▲ Assess for suicidal ideation and make appropriate referral for clients dealing with diversity or mental or chronic somatic illness. **EB:** *Lesbian, gay, and bisexual (LGB) individuals (N = 356) were studied for their mechanisms of coping with discrimination and researchers found that the combination of education and advocacy predicted self-awareness and personal growth for LGB people (Szymanski, Mikorski, & Carretta, 2017).* **EB:** *Dutta et al (2017) completed a large quantitative study about the genetics of suicidal ideation with twins (N = 3906 twins) and nontwins (N = 2016) and found that suicidal ideation was 13.0% for men, 21.8% for women, and no difference between twins and nontwins.*
- ▲ Assess clients with mood disorders and make appropriate referrals for treatment. **EB:** *Verhoeven et al (2017) compared the Mini International Neuropsychiatric Interview (MINI) with clinical diagnosis for mood disorders and anxiety differentiation and found that agreement between the MINI and clinical diagnoses was moderate but increased for patients with just one diagnosis.* **EB:** *A study using cognitive behavior therapy (CBT) and an active social control (befriending) on depression and anxiety symptoms in people (N = 110) with chronic obstructive pulmonary disease (COPD) demonstrated improvement in anxiety and depression for the befriending group and improved depression for the CBT group (Doyle et al, 2017), indicating that telephone contact is useful.*
- ▲ Assess and make appropriate referrals for clients with physical or mental disabilities. **EB:** *Gonzalez-Garcia et al (2017) used a sample of children 6 to 18 years old (N = 1216) in residential care and found that 4 of 10 children identified as within the clinical range of abnormal child behavior were not receiving any kind of treatment.* **EB:** *A study compared mental health and physical health participants (N = 701) attending an exercise referral program over a 12-month period and found that mental health participants were more likely to drop out than those with physical health problems, indicating that better referral decisions can be made (Tobi, Kemp, & Schmidt, 2017).*
- ▲ Assess clients for substance abuse and make appropriate referrals. **EB:** *Nandrino and Gandolphe (2017) studied patients with alcohol disorder (N = 27), and their self-defining*

memories (SDMs) and their relationship to personal identity disrupts positive memories and negatively effects personal identity and personal goals. **EB:** *Moshtagh et al (2017) completed 31 in-depth interviews with women who were sexually addicted and found that painful emotional experiences created an inner conflict and disrupted their personal identity.*

• Use empathetic communication and encourage the client and family to verbalize fears, express emotions, and set goals. **EBN:** *Families (N = 612) were provided interventions with emphasis on five positive psychology themes, such as gratitude, flow, happiness, health, and savoring, in a "kitchen project" and results demonstrated that family communication time and frequency of family meal preparation increased with sustainable effects (Ho et al, 2017).* **EBN:** *Nurse researchers studied mothers and children with HIV (N = 102 pairs) and found the relationship between parenting stress and child perceptions of family functioning demonstrated greater maternal parenting stress associated with poorer family functioning outcomes (reported by both the child and the mother) (Schulte et al, 2017).*

• Be present for clients physically or by telephone. **EBN:** *Barrett (2017) completed a grounded theory study about the use of teleconsultation by nurses (N = 17) using video in health care and found that nursing presence was the core category identified and subcategories of nursing presence were operational, clinical, therapeutic, and social, indicating that nurses provided presence during teleconsultation.*

▲ **EBN:** *A qualitative study by Costello (2017) looked at what patients perceived as qualities that increased nurses' presence and identified the following four characteristics: looking for commonalities, sharing personal experiences, use of humor, and caring for spiritual needs.*

• Encourage expression of positive thoughts and emotions. **EB:** *Researchers studied discrimination of lesbian, gay, bisexual, transgender, and queer (LGBTQ) students and its negative affect on academic performance and personal identity development and identified three major themes: (1) the need for programs to better promote LGBTQ identity, (2) a lack of LGBTQ content in curriculums, and (3) lack of support in schools (Craig et al, 2017).* **EBN:** *Hughes, Williams, and Shaw (2017) did a literature review (N = 6) about psychological issues faced by teenagers and young adults during cancer treatment, and analysis identified the following themes: anxieties about treatment, concerns regarding the impact on life (feeling restricted and different, the benefits of being sick, facing uncertainty), and coping strategies (positive thinking and problem-solving, support).*

• Encourage the client to use coping mechanisms. **EBN:** Nursing researchers used a cross-sectional study to better understand family satisfaction with health care of their child by measuring support, family quality of life, expressive family functioning, coping strategies, and health care satisfaction in parents (159 mothers and 60 fathers). Results for mothers demonstrated that satisfaction with health care was predicted by family support and their coping strategies, whereas for fathers, satisfaction was predicted by perceived family support, family quality of life, and whether the child had been hospitalized before (Sigurdardottir, Garwick, & Svavarsdottir, 2017). **EBN:** Rossman et al (2017) completed a narrative qualitative study to understand maternal role attainment of mothers with neonatal intensive care unit (NICU) infants. They found resilience in advocating for their infants, and NICU nurses can assist mothers' health-promoting strengths with resources and coping strategies to decrease their stress.

• Help clients with serious and chronic conditions to maintain social support networks or assist in building new ones. **EB:** A mixed-method (qualitative and quantitative) study was done to evaluate person-centered care for skilled nursing patients (N = 40). The person-centered care included (1) biweekly interdisciplinary care plan meetings with the patient, (2) patient selection of health-related goals that guide team discussions, (3) use of lay language, (4) team accountability to the patient,

and (5) monthly care-team meetings. A significant ($P < .01$) improvement was noted on the Care for Chronic Conditions and Patient Activation Measure surveys. Members viewed the person-centered care experience positively (Abrahamson, Myers, & Nazir, 2017). **EBN:** Hagedoom et al (2017) descriptively studied family caregiving of elderly patients (N = 62) with one or more chronic conditions, and themes identified were addressing the patients' social network, which included "social network structure" and "social network support," and addressing coordination of care issues.

▲ Refer women facing diagnostic and curative breast cancer surgery for psychosocial support. **EBN:** *Wilson (2017) studied exercise for quality of life improvement for breast cancer patients postsurgery and found that it decreased the side effects of surgery.* **EB:** *Literature review (N = 190) about breast cancer treatment for African women found that breast tumors are diagnosed at earlier ages and later stages than in high-income countries, and there is a higher prevalence of triple-negative cancers. Lack of nursing care, inadequate access to radiotherapy and surgery, and poor availability of systemic therapies produces poor survival rates (Vanderpuve et al, 2017).*

• Refer for CBT. **EBN:** *Burn and Lee (2017) used CBT in palliative care (PC) and demonstrated that the CBT tools increased nurses' knowledge and confidence in caring for patients.* **EBN:** *Choi, Lee, and Cho (2017) used CBT with patients (N = 76) who had panic disorder and found it useful and produced greater positive effects in the acute treatment phase than those they experience when receiving only routine treatment.*

▲ Refer clients with borderline personality disorder (BPD) and dual-diagnosed BPD and substance-dependent female clients for dialectical behavior therapy (DBT) and psychoanalytical-orientated day-hospital therapy. **EB:** *Perry, Bond, and Bekes (2017) followed patients with BPD (N = 16) and 35 with non-BPD for 3 to 5 years and found psychotherapy did not always provide faster rates of improvement of the condition.* **EB:** *Stepp and Lazarus (2017) did a study to identify dimensions of children (N = 2450) with temperament and psychopathology symptoms that predict future BPD. Researchers found that parent and teacher ratings of emotionality predicted BPD; therefore early detection may increase care for children with BPD.*

▲ Refer to the care plans for Readiness for enhanced **Communication** and Readiness for enhanced **Spiritual** well-being.

Pediatric

• Encourage adolescents to promote positive self-esteem, to enhance coping, and to prevent behavioral and psychological problems. **EB:** *Thomas et al (2017) studied group identification (N = 369) longitudinally related to sports teams and found three motivators: (1) individuals' personal feelings of self-esteem, (2) social identity, and (3) one collective identity motive. All of these helped meet personal needs.* **EBN:** *Ruhl and Lordly (2017) found that students who are a part of a competitive educational program display a negative effect on personal identity, learning motivation, student collaboration, participation in academic opportunities, and student relationships with faculty.*

• Evaluate and refer children and adolescents for eating disorder prevention programs to include medical care, nutritional intervention, and mental health treatment and care coordination. **EBN:** *Kendal et al (2017) qualitatively studied eating disorders and social media (400 messages) and found the following online discussion themes: taking on the role of mentor, the online discussion forum as a safe space, friendship within the online forum, flexible help, and peer support for recovery and relapse prevention.* **EB:** *Darrow et al (2017) studied the family types of children (N = 123) with eating disorders and*

categorized them into types that assisted the child to get treatment: (1) control-oriented, (2) system maintenance-oriented, and (3) conflict-oriented.

• Use computer-mediated support groups to enhance identity formation. **EBN:** *Jackson and Mixer (2017) used Apple iPads in a pilot study for pediatric patients and families who spoke Spanish and found it assisted in bedside communication, and the results assisted in developing a larger scale communication interface.* **EB:** *Sundstrom, Blankers, and Khadjesari (2017) studied computer-based alcohol interventions by completing a systematic review and found supporting evidence for continuing their use.*

Geriatric

• Evaluate the effectiveness of nursing interventions used to promote positive self-identify in older adults. **EBN:** *A descriptive study about applying a therapeutic relationship to people (N = 112) with a common mental disorder and the results were gathered using frequency statistics and found that the nursing therapeutic relationship in mental health transcends the area of specialty and builds patient coping strategies and helps them make changes in daily life (Nobrega et al, 2017).* **EB:** *Researchers used the international classification of functioning, disability, and health to develop a tool to assess functioning in elderly patients (N = 251). The tool was reliable in assessing the needs of elderly patients and can be studied further for use and to devise care (Ahsberg et al, 2017).*

• Encourage clients to discuss their "life histories." Life history-based interventions and self-esteem and life-satisfaction questionnaires may be used to reinforce personal identity and foster hope. **EBN:** *Tamura-Lis (2017) used reminiscing as an effective evidence-based tool in understanding and treating older adults. Reminiscing has demonstrated that it improves communication and socialization.* **EB:** *Researchers found that health care providers can better understand the needs of PC patients by using storytelling. Storytelling was described in two themes, the living–dying dialect and the practicing–advocating dialog. Understanding the perspective of PC patients can assist caregivers in providing better communication and end-of-life care (Omilion-Hodges & Swords, 2017).*

▲ Refer the older client to self-help support groups. **EB:** *Ilha et al (2017) completed a qualitative study of elderly people (N = 13) with Alzheimer's disease and their caregivers participating in support groups and found the experience positively influenced education by building knowledge that was applied in practice.* **EB:** *Canata et al (2017) studied telephone support for diabetic control in elderly patients compared with patients in a group with written materials and found the telephone group had better metabolic results in glucose level and blood pressure.*

▲ Refer the client with Alzheimer's disease who is terminally ill to hospice. **EBN:** *Schaustz, Chaves, and Serejo (2017) studied overload in caregivers (N = 53) of the elderly and found that 45.3% of the caregivers presented moderate overload, 13.2% presented with moderate to severe overload, 3.8% presented with severe overload, and 32.1% presented with no overload, indicating the need for supportive care.* **EBN:** *Goldsborough and Matzo (2017) discussed the need for PC based on experience and observation within the acute care setting and promoting education of acute care nurses to understand the implications of end-of-life care for elderly patients.*

Multicultural

• Assess an individual's sociocultural background in teaching self-management and self-regulation as a means of supporting hope and coping. **EB:** *Meca et al (2017) qualitatively studied recent Hispanic adolescent immigrants (N = 302) in the United States*

and found that personal identity associated with the US-predicted positivism and decreased antisocial behavior. **EB:** *Sica et al (2017) studied the identity formation of Italian university students through narrative accounts of five identify dimensions: achievement, foreclosure, moratorium, diffused diffusion, carefree diffusion, and undifferentiated. The connections between dimensions reflected a particular personal identity.* **EB:** *Ozer et al (2017) qualitatively studied the globalization-based acculturation process of Ladakhi youth (N = 8) and found participants reported negotiating their cultural identity through discussion of culture, religion, and social issues within social constraints and that researchers found that the acculturation process is complex and ongoing for the young participants.*

• Decrease discrimination to promote positive ethnic identity. **EB:** *Baldwin-White et al (2017) studied the relationship among acculturation, discrimination, and ethnic–racial identity (ERI) in Latino youths (N = 830) and found higher levels of acculturation were associated with lower levels of searching and affirmation, and higher perceived discrimination was associated with higher affirmation.* **EB:** *Researchers studied ethnic identity development of East Asian adolescents (N = 13) and found that five themes emerged in their qualitative study: ethnic/cultural identity and socialization, bicultural living, racial context-racism and stereotypes, family context-parental expectation, and peer context-friendship/dating. Participants' experienced hurtful racial discrimination, but experienced ethnic identity at home (Eunju et al, 2017).*

• Refer to care plan for Ineffective **Coping.**

Home Care

• The interventions described previously may be adapted for home care use.

• Provide an Internet-based health coach to encourage self-management for clients with chronic conditions such as depression, impaired mobility, and chronic pain. Use computer-mediated support groups to enhance identify formation. **EB:** *Phelan et al (2017) tested using the Internet for women receiving* the *Special Supplemental Nutrition Program for Women, Infants, and Children (WIC) postpartum (N = 371) compared with a nonintervention group. The intervention group lost more weight in 12 months.* **EB:** *Researchers studied using the Internet to treat social anxiety disorder (SAD) in participants (N = 42) randomized into two groups. One group had therapy support. Both groups decreased symptoms of SAD, and the group with the therapist interventions had a lower attrition rate (Gershkovich et al, 2017).*

▲ Refer the client to mutual health support groups. Participating in mutual health support groups led to enhanced coping by improving psychological and social functioning. **EB:** *Urbanoski, Mierlo, and Cunningham (2017) used social network analysis to examine online support groups for patients with drinking addictions (N = 711) and found active members were older and after 5 years the online support group was cohesive and stable.* **EB:** *Bossy et al (2017) studied self-management of patients (N = 16) with type 2 diabetes who participated in a support group, and the findings supported group-based self-management support assisted with decreasing self-blame and assisted identity building.*

▲ Refer cancer clients and their spouses to family programs that include family-based interventions for communication, hope, coping, uncertainty, and symptom management. **EB:** *A qualitative study explored the role of family members (N = 41) with cancer patients in the communication process, and all patients and family members preferred open communication with physicians. The study discussed the importance of family for physical and psychological care and discovered that there needed to be a balance between patient autonomy and relative's desire to be protective (Datta et al, 2017).* **EB:** *Prioli et al (2017) evaluated the direct costs and effectiveness of the mindfulness-based art therapy*

(MBAT) compared with the cost and effectiveness of a breast cancer support group (BCSG); both methods worked effectively, but BCSG was more cost-efficient than MBAT.

• Refer combat veterans and service members directly involved in combat, as well as those providing support to combatants, including nurses, for mental health services. **EB:** *Stana, Flynn, and Almeida (2017) conducted a thematic analysis of 466 Internet discussion posts by veterans (N = 623) and partners to understand the type of social support that was available, and most was informational support and network/community support. There was little emotional support.* **EB:** *Gould et al (2017) developed a telephone-based program for older veterans to reduce loneliness and qualitatively found that it benefited socialization, which included connectedness, learning from others, being active despite limitations, and distraction from limitations.*

Client/Family Teaching and Discharge Planning

• Teach the client about available community resources (e.g., therapists, ministers, counselors, self-help groups, family education groups). **EB:** *A 5-year longitudinal study compared participation in pleasant leisure activities and blood pressure in caregivers of Alzheimer's patients (N = 126) and found that greater engagement in pleasant leisure reduced mean arterial blood pressure (Mausbach et al, 2017).* **EBN:** *Kangovi et al (2017) examined if community health worker (CHW) interventions improved outcomes in a low-income population (N = 302) with multiple chronic conditions. They found that using a standardized intervention improved chronic disease control, mental health, and quality of care.*

• Teach coping skills to family caregivers of cancer clients. **EB:** *Blanco et al (2017) studied family environment (N = 50) in relation to childhood and found that families with obese children had higher trait anxiety, criticism and overprotectiveness, and maladaptive coping skills.* **EB:** *Takizawa et al (2017) evaluated the job stress and coping style of caregivers (N = 134) of dementia patients before and after they have completed training. They found that educating caregivers increases coping skills.*

• Refer to Ineffective **Coping** for additional references.

Risk for disturbed personal Identity

Marina Martinez-Kratz MS, RN, CNE

NANDA-I

Definition

Susceptible to the inability to maintain an integrated and complete perception of self, which may compromise health.

Risk Factors

Alteration in social role; cult indoctrination; cultural incongruence; discrimination; dysfunctional family processes; low self-esteem; manic states; perceived prejudice; stages of growth

At-Risk Population

Developmental transition; exposure to toxic chemical; situational crisis

Associated Condition

Dissociative identity disorder; organic brain disorder; pharmaceutical agent; psychiatric disorder

NOC, NIC, Client Outcomes, Nursing Interventions and *Rationales,* Client/Family Teaching and Discharge Planning, and References

Refer to care plan for Disturbed personal **Identity.**

Risk for complicated Immigration Transition

Nadia Charania PhD, RN

NANDA-I

Definition

Susceptibility to experiencing negative feelings (loneliness, fear, anxiety) in response to unsatisfactory consequences and cultural barriers to one's immigration transition, which may compromise health.

Related Factors

Available work is below educational preparation; cultural barriers in host country; unsanitary housing; insufficient knowledge about the process to access resources in the host country; insufficient social support in host country; language barriers in host country; multiple nonrelated persons in household; overcrowded housing; overt discrimination; parent–child conflicts related to enculturation in the host country; and abusive landlord

At-Risk Population

Forced migration; hazardous work conditions with inadequate training; illegal status in host country; labor exploitation; precarious economic situation; separation from family in home country; separation from friends in home country; unfulfilled expectations of immigration

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Relocation Adaptation, Anxiety Level; Fear Level; Loneliness Severity; Coping

Example NOC Outcome with Indicators

Relocation Adaptation as evidenced by the following indicators: Participates in decision-making in new environment/Expresses satisfaction with daily routine/Fear/Loneliness/Anxiety/. (Rate the outcome and indicators of **Relocation Adaptation**: 1 = never demonstrated; 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Participates in community activities
- State satisfaction with social relationships, living arrangements, and social integration
- State satisfaction with health status and access to health care
- Demonstrate actions that are congruent with expressed feelings and thoughts
- State sense of belonging
- Accept strengths and limitations of new environment

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Support System Enhancement; Socialization Enhancement; Values Clarification

Example NIC Activities—Risk for Complicated Immigration Transition

Encourage patience in developing relationships; Encourage social and community activities

Nursing Interventions and *Rationales*

• Understand immigrants' personal perspectives/stories about their health maintenance and illness management. **CEBN:** *Nurses are concerned with the life experiences of people and how these life experiences may affect their health and responses to illness. Furthermore, to diagnose and treat immigrants who are ill, we must be able to put their responses within the context of their lives; otherwise, our understanding and interpretation of their responses to illness will be limited (Meleis, 2010).*
• Focus on providing holistic (physical, emotional, psychological, social, and spiritual) care while caring for immigrants. When appropriate, integrate use of spirituality and connection with ethnic faith institutions. **CEB:** Ethnic faith institutions could be a valuable resource for immigrants and their families because these institutions provide support and relevant services to help immigrants balance their transition, such as providing a valuable link to the home culture and values, providing services in the areas of language acquisition, job training, and child care services (Slessarev-Jamir, 2008).
• Acknowledge the reciprocal relationship of immigrant and his and her cultural context. **EB:** Cultural context shapes the ways in which immigrants conceptualize, express, and cope with distress, resilience, and help-seeking (American Psychological Association [APA], 2013).
• Identify immigrant's sociocultural context, particularly to identify his or her unique perspectives with respect to cultural assimilation and cultural distinctiveness and whether or not he or she considers there is a possibility of combining both perspectives. **EB:** Recognize the role of sociocultural context and assist in providing ethical and appropriate care. Use an approach of combining both perspectives of cultural assimilation and cultural distinctiveness, in which an immigrant preserves his or her cultural distinctiveness yet simultaneously works toward developing a shared identity with those who were born in the country to which the individual immigrated (APA, 2013).
• Consider exploring the following factors in planning and providing care to immigrants: (1) premigration factors; (2) migration experience; (3) reception into new environment and trauma; (4) language/communication; (5) symptom expression; (6) changes in gender roles and intergenerational issues, economic stress, and marginalization; (7) resilience; and (8) multiplicity of identity need. **EB:** The understanding of such factors and how they interact in promoting or preventing the immigrant's health assists in providing culturally competent care (APA, 2013).
• Ensure that immigrants' cultural identities, rights, and needs are respected in the delivery of health care. **CEBN:** Sensitivity in integrating cultural safety when caring for a socially disadvantaged cultural minority group is imperative because cultural safety affects how health care is delivered to them (Baker, 2007).
• Assist immigrants in their transition toward health and a perception of well-being. **CEBN:** Nurses are an integral part of the health care team working with the immigrant population because nurses have a unique perspective on transition, which focuses on facilitating transitions to enhance a sense of well-being (Meleis & Trangestein, 2010).
• Be aware of the benefits and risks of involving an interpreter in providing care to immigrants. **EBN:** In a qualitative research study, nurses shared their perceptions of working with immigrant patients and interpreters and indicated that the interpreter supports the communication between the nurse and the patient but also increases the amount of work undertaken by nurses, complicates the nurse–patient relationship, and/or creates ethical problems (Eklöf, Hupli, & Leino-Kilpi, 2014).

Pediatric

- Explore current barriers and facilitators that are faced by children of immigrants to assimilate into the immigrated country's educational system. **EB:** *Such knowledge plays a significant role in the future of the immigrants' children on many fronts, including addressing barriers to seeking health care and acculturation (APA, 2013).*
- Invest effort in understanding the unique experiences of immigrant children, their health insurance status, and access to care. **CEB:** *The value of such understanding is critical in planning and promoting health care of immigrant children. Low rates of health insurance and limited access to care compounds the risk for deteriorating health (Perreira & Ornelas, 2011).*
- Explore the actual or perceived discrimination experienced by immigrant youth. **CEB:** *Evidence supports the relationship between racial discrimination and health such that they report more anxiety, depression, and risky health behaviors; low levels of self-esteem; and decreased academic motivation and expectations (Gonzales, Fabrett, & Knight, 2009).*
- Health care providers and school personnel need to encourage involvement of immigrant parents in their children's school-based activities. **EB:** *Parents involvement in school-based activities affects behavioral well-being of children of immigrants. Understanding parents' perceptions of parental involvement is important because parent involvement may mean something different in different cultures (Beauregard, Petrakos, & Dupont, 2014).*
- Identify the dynamics between immigrant children and their parents, including intergenerational conflict. **EB:** *Evidence supports that intergenerational conflict (a differing degree of acculturation between parents and children) contributes to acculturative stress (Rogers-Sirin, Ryce, & Sirin, 2014).*
- Encourage children to verbalize their understanding of being separated from their parent(s) or loved ones because of migration. **CEB:** *The process family or loved ones uses to prepare the child for separation plays a central role in how the child makes meaning of and responds to the challenge of separation, for example, feeling abandoned when separation is not framed as temporary and needed versus feeling resilient when separation is framed otherwise (Suarez-Orozco, Todorova, & Louie, 2002).*
- Explore acculturation process-related stress, social support, and ethnic identity of youth. **EB:** *Evidence supports that the increase in acculturative stress over time increases the internalizing of mental health symptoms; however, the presence of social support and ethnic identity plays a protective role against acculturative stress among youth and prevents the internalizing of mental health symptoms (Rogers-Sirin, Ryce, & Sirin, 2014).*
- Focus on assisting adolescent immigrants in their transition to developing bicultural competencies. **CEB:** *Bicultural competencies serve as a protective factor in lowering the chances of developing problematic mental health symptoms in adolescents (Smokowski, Chapman, & Bacallao, 2007).*

Geriatric

Note: All interventions are relevant and appropriate for geriatric immigrants.

Multicultural

Note: All interventions are relevant and appropriate for geriatric immigrants.

Home Care

- Encourage family members of immigrants to engage in home care tasks. Cultures with collective societal values are strongly expected to participate in the meeting of

home care tasks for the elderly and needy. **CEB:** *Elderly who reside with relatives and family members usually fulfill home care tasks. At the same time, there is a strong expectation, for example, within the Chinese community, that children or the younger generation are meeting the elderly's daily needs (Lai, 2004).*

- Educate and encourage immigrants' family members to use available home care-specific support services as needed. **EB:** It is critical to recognize that the immigrated family is faced with both health care system barriers (e.g., discrimination within the health care system and complex bureaucracies) and individual barriers (e.g., limited communication ability, lack of financial resources, and the experience of shame or stigma) when in need of accessing care (Hacker, Anies, Folb, & Zallman, 2015).

Ineffective Impulse control

Marina Martinez-Kratz MS, RN, CNE

NANDA-I

Definition

A pattern of performing rapid, unplanned reactions to internal or external stimuli without regard for the negative consequences of these reactions to the impulsive individual or to others.

Defining Characteristics

Acting without thinking; asking personal questions despite the discomfort of others; gambling addiction; inability to save money or regulate finances; inappropriate sharing of personal details; irritability; overly familiar with strangers; sensation seeking; sexual promiscuity; temper outbursts; violent behavior

Related Factors

Hopelessness; mood disorder; smoking; substance misuse

Associated Condition

Alteration in cognitive functioning; alteration in development; organic brain disorder; personality disorder

NOC (Nursing Outcomes Classification)

Suggested NOC Outcome

Impulse Self-Control

Example NOC Outcome with Indicators

Impulse Self-Control as evidenced by the following indicators: Identifies harmful impulsive behaviors/Identifies feelings that lead to impulsive actions/Avoids high-risk situations/Controls impulses/Maintains self-control without supervision. (Rate the outcome and indicators of **Impulse Self-Control:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = continually demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Be free from harm
- Cooperate with behavioral modification plan
- Verbalize adaptive ways to cope with stress by means other than impulsive behaviors
- Delay gratification and use adaptive coping strategies in response to stress
- Verbalize understanding that behavior is unacceptable
- Accept responsibility for own behavior

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Impulse Control Training

Example NIC Activities—Impulse Control Training

Use a behavior modification plan, as appropriate, to reinforce the problem-solving strategy that is being taught; Teach client to cue himself/herself to "stop and think" before acting impulsively

Nursing Interventions and *Rationales*

• Refer to mental health treatment for cognitive behavioral therapy (CBT). **EB:** *CBT has been beneficial in treating substance use disorders and impulse control disorders (Okai et al, 2013).*
• Assess the circumstances that led the client to seek help for their impulse control disorder. **EB:** *Clients may seek help because they continue to struggle with the desire to engage in the behavior because of the impact of their mounting social, occupational, financial, or legal problems (Grant, Schreiber, & Odlaug, 2013).*
• Assess individuals with impulsive behaviors for exposure to trauma and referral for mental health evaluation. **EB:** *Research indicates that impulsivity is associated with trauma exposure and posttraumatic stress disorder (PTSD) (Netto et al, 2016).*
• Implement motivational interviewing for clients with impulse control disorders. **EB:** *This research review found motivational interviewing helps individuals with gambling addictions work through ambivalence and commit to change (Choi et al, 2017).*
• Teach client mindfulness meditation techniques. Mindfulness meditation includes observing experiences in the present moment, describing those experiences without judgments or evaluations, and participating fully in one's current context. **EB:** *This study showed developing mindfulness was an effective way of diminishing binge eating, eating psychopathology, and depression, and increasing quality of life in women with obesity (Pinto-Gouveia et al, 2016).*
• Refer to self-help groups such as Gambler's Anonymous. **EB:** *This research review found that Gambler's Anonymous is helpful as an adjunct therapy for individuals with gambling addictions (Choi et al, 2017).*
• Use a brief intervention model to screen and provide information and referral to services for clients that may experience at-risk gambling. **EB:** *A pilot study found that when trained, primary care staff were able to screen clients at routine visits for at-risk gambling behavior by using the brief intervention model (Nehlin et al, 2016).*
• Teach clients to use urge surfing techniques when impulses or urges are triggered. **EB:** *This study demonstrated that the mindfulness coping skill of urge surfing was an effective intervention when used by teens experiencing urges to use alcohol (Harris, Stewart, & Stanton, 2017).*
• Teach client to use cue avoidance techniques to reduce impulsive behaviors. **EB:** *This study shows that cue avoidance techniques were successful in reducing alcohol consumption (Di Lemma & Field, 2017).*
• Implement strategies to engage a high-level construal mindset by asking "why" abstaining from the targeted behavior will benefit the client. **EB:** *Questions of why are effective in priming a high-level construal mindset, which then is effective at reducing the targeted behavior (Chiou et al, 2013).*

Pediatric

• Assess children for environmental lead exposure. **EB:** *This research shows that a 1-µg/dL increase in average childhood blood lead level significantly predicts a 0.37 (95% confidence interval [CI] = 0.11, 0.64) point increase in adolescent impulsivity (Winter & Sampson, 2017).*
• Assess the risk-taking and impulsive behaviors of the peer group. **EB:** *Research found an increase in impulsivity in the presence of peers (Weigard et al, 2014).*
• Refer to mental health treatment for CBT. **EB:** *CBT has been beneficial in treating impulse control disorders in pediatric populations (Farrell et al, 2016).*

Geriatric

• Assess for impulsive symptoms and maintain increased surveillance of the client whenever the use of dopamine agonists has been initiated. **EB:** *Dopamine agonist therapy is related to the development of impulse control disorders in clients with Parkinson's disease (Voon et al, 2017).*
• Implement fall risk screening and precautions for geriatric clients with inattention and impulse control symptoms. **EBN:** *The Marianjoy Fall Risk Assessment tool has internal validity and reliability and includes impulsive behavior as one of the fall risk indicators (Ruroede, Pilkington, & Guernon, 2016).*
• Monitor caregivers for evidence of caregiver burden. **EB:** *Recent research shows that significantly greater burden was seen in caregivers of Parkinson's disease clients with impulse control disorders (Marechal et al, 2014).*

Client/Family Teaching and Discharge Planning

• Families should be encouraged to use practical measures to manage behavior such as limiting access to credit cards and restricting and monitoring Internet access gambling and casino websites, checking medication compliance, reporting behavior typical of impulse control disorders (ICDs), and transferring control of financial affairs to a partner or other family members. **EB:** *This recent review showed effective management of impulsive behaviors through patient and caregiver education (Zhang et al, 2016).*

Functional urinary Incontinence

Amanda Andrews BSc (Hons), MA, Bernie St. Aubyn BSc (hons), MSc

NANDA-I

Definition

Inability of a usually continent person to reach the toilet in time to avoid unintentional loss of urine.

Defining Characteristics

Completely empties bladder; early morning urinary incontinence; sensation of need to void; time required to reach toilet is too long after sensation of urge; voiding prior to reaching toilet

Related Factors

Alteration in environmental factor; weakened supporting pelvic structure

Associated Condition

Alteration in cognitive functioning; impaired vision; neuromuscular impairment; psychological disorder

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Urinary Continence; Urinary Elimination

Example NOC Outcome with Indicators

Urinary Continence as evidenced by the following indicators: Recognizes urge to void/Responds to urge in timely manner/Voids in appropriate receptacle/Underclothing remains dry during day/Underclothing or bedding remains dry during night. (Rate the outcome and indicators of **Urinary Continence:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Eliminate or reduce incontinent episodes
- Eliminate or overcome environmental barriers to toileting
- Use adaptive equipment to reduce or eliminate incontinence related to impaired mobility or dexterity

• Use portable urinary collection devices or urine containment devices when access to the toilet is not feasible

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Urinary Habit Training; Urinary Incontinence Care

Example NIC Activities—Urinary Habit Training

Keep a continence-specification record for 3 days to establish voiding pattern; Establish interval for toileting of preferably not less than 2 hours

Nursing Interventions and *Rationales*

• Introduce yourself to the client and anyone accompanying him or her and inform them of your role. *Introducing yourself to a client helps establish and develop a therapeutic relationship that recognizes the person within the client and forms the bases for building trust on which to base the provision of care (Howatson-Jones, Standing, & Roberts, 2012).*
• Gain consent to provide care before proceeding further with the assessment. For clients unable to give consent, discuss permission with relevant health care professionals and/or family members. *Clients have the right of autonomy both legally and morally; therefore they should be fully involved in the decision-making process (Avery, 2013).*
• Wash hands using a recognized technique. *Evidence shows that strict hand hygiene regimens significantly reduce the incidence of methicillin-resistant* Staphylococcus aureus *and* Clostridium difficile *infection (Goldberg, 2017).*
• Assess usual pattern of bladder management and establish the extent of the problem to include a detailed and accurate assessment of the client. *This assessment enables the nurse to plan interventions, monitor outcomes, and evaluate care, ensuring no unnecessary treatment is implemented (NICE, 2015).*
• Evaluate the client's bladder habits:
  - ❍ Episodes of incontinence during the day and night
  - ❍ Alleviating and aggravating factors
  - ❍ Current management strategies to include containing/collection devices, restriction of fluid intake, and avoidance of fluid/food groups that cause bladder irritation
• Complete a Lifestyle and Risk Assessment: Toilet facility access and ability to use, including:
  - ❍ Distance of the toilet from the bed, chair, and living quarters
  - ❍ Characteristics of the bed, including presence of side rails and distance of the bed from the floor
  - ❍ Characteristics of the pathway to the toilet, including barriers such as stairs, loose rugs on the floor, and inadequate lighting
  - ❍ Characteristics of the bathroom, including patterns of use, lighting, height of the toilet from the floor, the presence of handrails to assist transfers to the toilet, and breadth of the door and its accessibility for a wheelchair, walker, or other assistive device

For older adults who may have limited mobility, the nurse must assess environmental barriers that may restrict access to the toilet (Nazarko, 2013).

- Assess the client's physical and mental abilities:
    - Ability to rise from chair and bed, transfer to the toilet, and ambulate, and the need for physical assistive devices such as a cane, walker, or wheelchair. *Urinary incontinence can occur as a direct consequence of the inability to reach and use the toilet either independently or with the assistance of aids or caregivers (Ostaszkiewicz et al, 2013).*
    - Ability to manipulate buttons, hooks, snaps, loop and pile closures, and zippers as needed to remove clothing. *Functional continence requires the ability to remove clothing to urinate; individuals with compromised visual acuity, dexterity, and mobility will need specific interventions to assist with these challenges to continence (Abrams, Andersson, & Birder, 2010).*
    - Functional and cognitive status assessment should be done using a tool such as the Mini Mental Status Examination for the older client with functional incontinence. *A dementia diagnosis (or severe cognitive impairment) is associated with a higher prevalence of incontinence compared with people without such a diagnosis (Gove et al, 2017). An association has also been observed between incontinence and more severe cognitive impairment and mobility problems (Jerez-Roig et al, 2016).*
    - Daily fluid intake included amount of types of fluids drank.
    - Risk of falls caused by dizziness, impaired vision, and hearing.
    - Functional ability declines secondary to comorbidities (cerebral vascular incidents, amputation).
- Discuss quality of life issues relating to socialization and family events. A comprehensive assessment enables the problem to be identified, generating a baseline of information from which to accurately diagnose and plan treatment and care (Reid, 2014).
- Review the client's past medical history:
    - Obstetrical/gynecological/urological history and surgeries
    - Relevant comorbidities such as cardiac, respiratory, renal, or neurological
    - Recurrent urinary tract infections

Reviewing the client's past medical history to identify conditions that may affect an individual's ability to maintain continence is an important step in assessing the client's primary problem (Nazarko, 2013).

- Teach the client, the client's care providers, or the family to complete a bladder diary. Each 24-hour period should be subdivided into 1- to 2-hour periods and include number of urinations occurring in the toilet, actual episodes of incontinence and amount of urine leaked, reasons for episode of incontinence, type and amount of liquid intake, number of bowel movements, and incontinence pads or other products used. **EB:** *Bladder diaries provide accurate data and are more reliable than patients' recollections of symptoms. In addition to being inexpensive and low risk, patients view diaries as easy to complete and helpful for their care (Dixon & Nakib, 2016).*
- Consult with the health care provider and complete a medication review relating to side effects and contraindications. NICE (2015) recommended that a holistic continence assessment should include a medication history to ascertain whether side effects of the medication are contributing to the continence issues.
- Ensure that an appropriate, safe urinary receptacle such as a three-in-one commode, female or male handheld urinal, no-spill urinal, or containment device when toileting access is limited by immobility or environmental barriers is available to assist the client with elimination needs while other interventions are being implemented. **EB:**

Toileting aids should be generally considered as a short-term strategy and/or an addition to ongoing treatment. It is recommended that long-term management with such items should only be considered when all other options have been excluded (NICE, 2015).

▲ Refer to occupational therapy for help in obtaining assistive devices and adapting the home for optimal toilet accessibility. *Occupational therapists are needed to assist patients with dexterity and mobility issues that may be contributing to incontinence (Spencer, McManus, & Sabourin, 2017).*

• Provide advice to clients relating to loose-fitting clothing with stretch waistbands rather than buttoned or zippered waist; minimize buttons, snaps, and multilayered clothing; and substitute a loop-and-pile closure or other easily loosened systems such as Velcro for buttons, hooks, and zippers in existing clothing. *Clients with impaired dexterity or weakness may benefit from clothing that has been modified or is without buttons and zippers (Leaver, 2017).*

• Work with the client on retraining the bladder by regular timed toileting regimens (every 2 hours). For the older client in the home or a long-term care facility who has functional incontinence and dementia:

- ❍ Determine the frequency of current urination using an alarm system or check-and-change device.
- ❍ Record urinary elimination and incontinent patterns in a bladder log to use as a baseline for assessment and evaluation of treatment efficacy.
- ❍ Begin a prompted toileting program based on the results of this program; toileting frequency may vary from every 1.5 to 2 hours to every 4 hours.
- ❍ Provide positive reinforcement.

EB: *Based on a systematic review of 14 clinical trials, prompted voiding has been shown to improve daytime incontinence and the percentage of appropriate toileting episodes in clients with dementia and functional incontinence (Flanagan et al, 2012).*

• Monitor older clients in a long-term care facility, acute care facility, or home for dehydration. **EB:** *Dehydration can exacerbate urine loss, and it is essential to consider it a factor when managing incontinence, particularly in care home settings (Flanagan et al, 2014).*

• Inspect the perineal and perianal skin for evidence of incontinence-associated dermatitis, including inflammation, vesicles in skin exposed to urinary leakage, and especially skinfolds or denudation of the skin, particularly when incontinence is managed by absorptive pads or containment briefs. **EB:** *Skinfolds and the perineal skin are at risk for dermatitis and fungal or bacterial infections (Beeckman, 2017).*

• Begin a preventive skin care regimen for all clients with urinary incontinence and treat clients with incontinence-associated dermatitis or related skin damage. **EB:** *Minimizing exposure to urine; gentle cleansing; moisture protection, preferably with an emollient; and application of a skin protectant are the necessary components of a skin protection program (Beekman, 2017).*

• Advise the client about the advantages of using disposable or reusable insert pads, pad-pant systems, or replacement briefs specifically designed for urinary incontinence as indicated for short-term/long-term use, including social events. *A systematic review identified that the use of incontinence pads are the main conservative behavioral approach to managing continence. They are preferred to invasive management strategies (e.g., catheterization) (Roe, Flanagan, & Maden 2015).*

• Consider the use of an indwelling catheter for continuous drainage in the client who is both homebound and bedbound and is receiving palliative or end-of-life care

(requires a health care provider's order). **EB:** *Indwelling catheters may be used for clients who are at the end of life, when repositioning adds to discomfort or pain (Talley et al, 2014).*

• When an indwelling urinary catheter is in place, follow prescribed maintenance protocols for managing the catheter, taping and replacing the catheter, the drainage bag, and care of perineal skin and urethral meatus. Teach infection control measures adapted to the home care setting. *Proper care reduces the risk of catheter-associated urinary tract infection (Centers for Disease Control and Prevention, 2018).*

• Assist the client in adapting to the catheter. Encourage discussion of the client's response to the catheter. *Research has consistently shown that indwelling catheter users need to be given more information, but some patients still feel poorly informed. Nurses are in a good position to find out what people know, what they need, and to ensure that patients have contact phone numbers for further information and details of reliable websites and support organizations (Prinjha et al, 2016).*

• Provide client with comprehensive written information about bladder care. *Providing clients with well-written, evidence-based information about their condition and treatment can have a beneficial effect on the outcomes of treatment. In addition, clients are more likely to retain important information that will assist them in making informed decisions about their care (Coulter, 2011).*

• Document all care and advice given in a factual and comprehensive manner. *Good record keeping is an integral part of nursing practice and is essential to the provision of safe and effective care (St. Aubyn & Andrews, 2015).*

Overflow urinary Incontinence

Gail Ladwig RN, MSN

NANDA-I

Definition

Involuntary loss of urine associated with overdistention of the bladder.

Defining Characteristics

Bladder distention; high postvoid residual volume; involuntary leakage of small volume of urine; nocturia

Related Factors

Fecal impaction

Associated Condition

Bladder outlet obstruction; detrusor external sphincter dyssynergia; detrusor hypocontractility; severe pelvic organ prolapse; treatment regimen; urethral obstruction

NOC, NIC, Client Outcomes, Nursing Interventions and *Rationales,* Client/Family Teaching and Discharge Planning, and References

Refer to care plan for **Urinary Retention.**

Reflex urinary Incontinence

Amanda Andrews BSc (Hons), MA, Bernie St. Aubyn BSc (hons), MSc

NANDA-I

Definition

Involuntary loss of urine at somewhat predictable intervals when a specific bladder volume is reached.

Defining Characteristics

Absence of voiding sensation; absence of urge to void; inability to voluntarily inhibit voiding; inability to voluntarily initiate voiding; incomplete emptying of bladder with lesion above pontine micturition center; predictable pattern of voiding; sensation of urgency to void without voluntary inhibition of bladder contraction; sensations associated with full bladder

Related Factors

To be developed

Associated Condition

Neurological impairment above level of pontine micturition center; neurological impairment above level of sacral micturition center; tissue damage

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Urinary Continence; Urinary Elimination

Example NOC Outcome with Indicators

Urinary Continence as evidenced by the following indicators: Absence of urinary leakage between catheterizations or containment of micturition by condom catheter and drainage bag/Absence of symptomatic urinary tract infection (absence of leukocytes and absence of bacterial growth or >100,000 colony-forming units/mL)/Underclothing dry during day/Underclothing or bedding dry during night. (Rate the outcome and indicators of **Urinary Continence:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Follow prescribed schedule for bladder emptying
- Have intact perineal skin
- Remain clear of symptomatic urinary tract infection
- Demonstrate how to apply containment device or insert intermittent catheter or be able to provide caregiver with instructions for performing these procedures

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Urinary Catheterization: Intermittent; Urinary Elimination Management; Urinary Incontinence Care

Example NIC Activities—Urinary Elimination Management

Monitor urinary elimination including frequency, consistency, odor, volume, and color as appropriate; Teach client signs and symptoms of urinary tract infection

Nursing Interventions and *Rationales*

• Introduce yourself to the client and anyone accompanying him or her and inform them of your role. *Introducing yourself to a client helps establish and develop a therapeutic relationship that recognizes the person within the client and forms the bases for building trust on which to base the provision of care (Howatson-Jones, Standing, & Roberts, 2012).*
• Gain consent to provide care before proceeding further with the assessment. *Clients have the right of autonomy both legally and morally; therefore they should be fully involved in the decision-making process (Avery, 2013).*
• Wash hands using a recognized technique. **EB:** *Evidence shows that strict hand hygiene regimens significantly reduce the incidence of methicillin-resistant* Staphylococcus aureus *and* Clostridium difficile *infection (Goldberg, 2017).*
• Assess the usual pattern of bladder management and establish the extent of the problem. **EB:** *A detailed and accurate assessment of the client enables the nurse to plan interventions, monitor outcomes, and evaluate care, ensuring no unnecessary treatment is performed (NICE, 2015) (refer to Functional urinary* ***Incontinence*** *care plan).*
• Ask the client to complete a bladder diary/log to determine the pattern of urine elimination, any incontinence episodes, and current bladder management program. An electronic voiding diary may be kept whenever feasible. **EB:** *Bladder diaries provide accurate data and are more reliable than clients' recollections of symptoms. In addition to being inexpensive and low risk, clients view diaries as easy to complete and helpful for their care (Dixon & Nakib, 2016).*
▲ Consult with the health care provider concerning current bladder function and the potential of the bladder to produce hydronephrosis, vesicoureteral reflux, febrile urinary tract infection, or compromised renal function. *Whether the client has urinary retention directs the method of urine management to prevent damage to the renal system from unrelieved obstruction (Dorsher & McIntosh, 2012).*
▲ Consult with the health care provider and physical therapist concerning the neuromuscular ability to perform bladder management. The type of neurological disorder, as well as the level of neurological impairment and the ability to use the hands effectively, determines the method of urine management in reflex incontinence. *Continence assessment needs to be an active process and as such should be undertaken as often as the client's progressive neurological condition dictates (Mangnall, 2011).*
• Inspect the perineal and perigenital skin for signs of incontinence-associated dermatitis and pressure ulcers (Beeckman, 2017). **EB:** *Standardizing skin care routines and making them an integrated part of essential care for incontinence clients will improve client care in specialized areas, which helps reduce the incidence of incontinence-associated dermatitis.*
▲ In consultation with the rehabilitation team, counsel the client and family concerning the merits and potential risks associated with each possible bladder management program, including spontaneous voiding, intermittent self-catheterization (ISC), and reflex voiding with condom catheter containment and in some cases, indwelling suprapubic catheterization. *All bladder management programs carry some risk of urinary incontinence or serious urinary system complications (Newman & Willson, 2011).* **CEB:** *Spontaneous voiding and intermittent catheterization carry greater risk of urine loss than condom catheter containment or indwelling catheter. A study demonstrated increased rates of complications and a high rate of infection with indwelling catheter use compared with other modes of management (Singh et al, 2011). Some studies support the use of suprapubic catheters for long-term treatment of reflex incontinence in spinal cord injury*

clients (Colli & Lloyd, 2011; Böthig, Hirschfeld, & Thietje, 2012).

Intermittent Self-Catheterization

- Begin intermittent catheterization as ordered using sterile technique; the client may be taught to use clean technique in the home situation. **EB:** *Intermittent catheterization is considered the preferred long-term management for a neurogenic bladder. Sterile intermittent catheterization should be used in hospitals, rehabilitation centers, and extended care facilities (Newman & Willson, 2011). There is an associated risk of urinary tract infection with any type of bladder management; however, by performing ISC the risk of urinary tract infections is reduced because the residual volume in the bladder is resolved (Winder, 2012).*
- Schedule the frequency of intermittent catheterization based on the frequency/volume records of previous catheterizations, functional bladder capacity, and the impact of catheterization on the quality of the client's life. *Bladder volumes must be kept lower to prevent development of urinary tract infection from retention of urine, and draining the urine regularly helps prevent movement of bacteria into the bladder long enough to produce symptomatic infection (Newman & Willson, 2011; Dorsher & McIntosh, 2012).*
- Teach the client to recognize signs of symptomatic urinary tract infection and to seek care promptly when these signs occur. The signs of symptomatic infection include the following:
    - ❍ Discomfort over the bladder or during urination
    - ❍ Acute onset of urinary incontinence
    - ❍ Fever
    - ❍ Markedly increased spasticity of muscles below the level of the spinal lesion
    - ❍ Malaise, lethargy
    - ❍ Hematuria
    - ❍ Autonomic dysreflexia (hyperreflexia) symptoms

Signs of symptomatic urinary tract infection as indicated previously should be treated promptly with antimicrobial therapy, whereas asymptomatic bacteriuria should not generally be treated (Matthews, 2011).

- Recognize that intermittent catheterization is typically associated with asymptomatic bacteriuria, and the indwelling catheter is routinely associated with asymptomatic colonization. **EB:** *There is a clinical need to refine the management of asymptomatic infection in association with bacteriuria. Effective strategies should include minimizing inappropriate antimicrobial use unless a symptomatic infection is detected (Nicolle, 2016).*
- Teach intermittent catheterization as the client approaches discharge as per operational guidelines and best practice. Instruct the client and at least one family member in the performance of catheterization. Teach the client with quadriplegia how to instruct others to perform this procedure. **EB:** Intermittent catheterization is a safe and effective bladder management strategy for persons with reflex urinary incontinence. More and more patients are advised to perform intermittent catheterization. Quality-of-life studies show that intermittent catheterization has a great impact on daily life (Cobussen-Boekhorst et al, 2016).
- Teach the client managed by intermittent catheterization to self-administer antispasmodic (parasympatholytic) medications as prescribed by the consulting health care provider and to recognize and manage potential side effects as needed. Antimuscarinic medications should be considered in patients when urodynamic

investigations show impaired bladder storage. It is important to consider the potential central nervous system-related side effects when prescribing to clients with multiple sclerosis (e.g., confusion). Clients also should be aware of the increased risk of constipation with the use of these medications (NICE, 2012).

Condom Catheter/Sheath System

- For a male client with reflex incontinence who does not have urinary retention and cannot manage the condition effectively with spontaneous voiding, who does not choose to perform intermittent catheterization, or who cannot perform catheterization, teach the client and his family to obtain, select, and apply an external collective device and urinary drainage system. Assist the client and family to choose a product that adheres to the glans penis or penile shaft without allowing seepage of urine onto surrounding skin or clothing, which avoids provoking hypersensitivity reactions on the skin, and that includes a urinary drainage reservoir that is easily concealed under the clothing and does not cause irritation to the skin of the thigh. **EB:** *When considering the use of an external continence device it is vital that the correct size is measured and fitted to eliminate many of the problems associated with leakage and the sheath falling off (Woodward, 2015). National Institute for Health and Care Excellence (NICE) guidance (NICE, 2012) advocates that all risks and benefits are discussed relating to the available sheath system options.*
- Teach the client whose incontinence is managed by a condom catheter to routinely inspect the skin with each catheter change for evidence of lesions caused by pressure from the containment device or by exposure to urine, to cleanse the penis thoroughly, and to reapply a new device daily or every other day. **EB:** *A well fitted sheath reduces the risk of skin irritation or ulceration. The sheath should always be fitted leaving a space between the tip of the penis and the shaft allowing urine to flow without the sheath "ballooning" (Woodward, 2015).*
- Ensure the client is aware of when and how to report any problems and/or complications of reflex incontinence care when at home. *Early detection allows for rapid diagnosis and treatment. Information about this should be individually presented to the clients and specifically tailored to their physical condition and cognitive abilities to encourage self-management (Swain, 2012).*
- Encourage a program of self-care management. **EB:** *Addressing self-care activities through exercise, diet, fluid intake, and protective devices helps the client to exercise control over incontinence and may reduce the substantial burden affecting a significant proportion of spouse, partner, or familial care providers.*
- Assist the family with arranging care in a way that allows the client to participate in family or favorite activities without embarrassment. Elicit discussion of the client's concerns about the social or emotional burden of incontinence. **EB:** *Urinary incontinence has a substantial negative effect on the quality of life for clients, both socially and financially. Further studies are needed to determine the true extent of the problem and to address it (Tapia et al, 2013).*
- Teach the client to ensure good hydration. Total daily fluid intake should be approximately 2.7 L/day for women and 3.7 L/day for men. *Adequate fluid helps wash out bacteria from the urethra to prevent urinary tract infections, helps prevent kidney stones, and potentially protects the client from development of cancer of the bladder from exposure to carcinogens concentrated in the urine (Newman & Willson, 2011).*
- Teach the client with a spinal injury the signs of autonomic dysreflexia, its relationship to bladder fullness, and management of the condition. Refer to the care

plan for **Autonomic Dysreflexia.**

• Provide the client with comprehensive written information about bladder care. **EB:** *Providing clients with well-written, evidence-based information about their condition and treatment can have a beneficial effect on the outcomes of treatment. In addition, clients are more likely to retain important information that will assist them in making informed decisions about their care (Coulter, 2011).*

• Document all care and advice given in a factual and comprehensive manner. *Good record keeping is an integral part of nursing practice and is essential to the provision of safe and effective care (St. Aubyn & Andrews, 2015).*

Stress urinary Incontinence

Amanda Andrews BSc (Hons), MA, Bernie St. Aubyn BSc (hons), MSc

NANDA-I

Definition

Sudden leakage of urine with activities that increase intra-abdominal pressure.

Defining Characteristics

Involuntary leakage of small volume of urine; involuntary leakage of small volume of urine in the absence of detrusor contraction; involuntary leakage of small volume of urine in the absence of overdistended bladder

Related Factors

Weak pelvic floor muscles

Associated Condition

Degenerative changes in pelvic floor muscles; increase in intra-abdominal pressure; intrinsic urethral sphincter deficiency

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Urinary Continence; Urinary Elimination

Example NOC Outcome with Indicators

Urinary Continence as evidenced by the following indicators: Experiences no urine leakage with increased abdominal pressure (e.g., sneezing, laughing, lifting)/Voids in appropriate receptacle/Able to move to toilet after strong desire to urinate is perceived/Underclothing remains dry during day/Underclothing or bedding remains dry during night. (Rate the outcome and indicators of **Urinary Continence:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Report fewer stress incontinence episodes and/or a decrease in the severity of urine loss
- Experience reduction in frequency of urinary incontinence episodes as recorded on voiding diary (bladder log)
- Identify containment devices that assist in management of stress incontinence

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Pelvic Muscle Exercises; Urinary Incontinence Care

Example NIC Activities—Urinary Incontinence Care

Explain etiology of problem and rationale for actions; Modify clothing and environment to provide easy access to toilet

Nursing Interventions and *Rationales*

• Introduce yourself to the client and anyone accompanying him or her and inform them of your role. *Introducing yourself to a client helps establish and develop a therapeutic relationship that recognizes the person within the client and forms the bases for building trust on which to base the provision of care (Howatson-Jones, Standing, & Roberts, 2012).*
• Gain consent to provide care before proceeding further with the assessment. In clients unable to give consent, discuss permission with relevant health care professionals and/or family members. *Clients have the right of autonomy both legally and morally; therefore they should be fully involved in the decision-making process (Avery, 2013).*
• Wash hands using a recognized technique. *Evidence shows that strict hand hygiene regimens significantly reduce the incidence of methicillin-resistant* Staphylococcus aureus *and* Clostridium difficile *infection (Goldberg, 2017).*
• Assess usual pattern of bladder management to understand the extent of the problem and establish pattern of bladder management. **EB:** *A detailed and accurate assessment of the client enables the nurse to plan interventions, monitor outcomes, and evaluate care, ensuring no unnecessary treatment is performed (NICE, 2015). Refer to the Functional urinary* ***Incontinence*** *care plan.*

- ❍ Review the client's past medical history to identify possible risk factors for stress incontinence (i.e., pregnancy, parity, large babies, forceps or breech deliveries, obesity, chronic cough, physical activity, previous urinary tract or gynecological surgery, smoking history). *Nazarko (2013) identified the importance of considering other conditions that will affect an individual's ability to maintain continence.* **EB:** *The most common types of urinary incontinence in adult women are stress, urge, or a combination of both (Knarr et al, 2014). Many women are reluctant to initiate a discussion regarding incontinence; identifying women at risk is essential for effective screening (Keyock & Newman, 2011).*
- ❍ Review the client's medication list (e.g., diuretics, lithium, adrenergic blockers, diabetes medications) to see what may exacerbate the client's urinary urgency.

• *Stress urinary incontinence may be caused by anatomical defects in the supporting structures of the bladder and the urethra. This results in suboptimal positioning of these structures leading to involuntary urine leakage on physical exertion (Dumoulin, Hay-Smith, & Mac Habbe-Seguin, 2014).*
• Review the client's bladder habits:

- ❍ Onset and duration of urinary leakage
- ❍ Related lower urinary tract symptoms, including voiding frequency (day/night) and urgency, severity (small, moderate, large amounts) of urinary leakage
- ❍ Factors provoking urine loss (diuretics, bladder irritants, alcohol), focusing on the differential diagnosis of stress, urge or mixed stress, and urge urinary symptoms; consider using a symptom questionnaire that elicits relevant lower urinary tract symptoms and provides differentiation between stress and urge incontinence symptoms

• Stress urinary incontinence is more common in young and middle-aged women, is characterized by incontinence in small amounts (drops, spurts), no nocturia or incontinence at night, and incontinence without sensation of urine loss (Strothers & Friedman, 2011).
• Assess for mixed urinary incontinence (a combination of stress and urge

incontinence) by asking the client:

- ❍ Can you delay urination for a 2-hour movie or car ride?
- ❍ How often do you wake/arise at night to urinate?
- ❍ When you have the urge to urinate, can you reach the toilet without leaking?

EB: *Farrell et al (2013) established that by using a questionnaire for urinary tract diagnosis, the client's ability to assess their own incontinence type was improved. To further enhance this assessment the questionnaire needs to be a validated incontinence-specific quality of life questionnaire (Bardsley, 2016).*

• Complete a lifestyle assessment to understand the effect of stress urinary incontinence on an individual's lifestyle. Inquire about incontinence pad use and change in daily, social, or recreational activities, as well as emotional impact. **EB:** *The impact of urinary incontinence on the quality of life is well recognized and includes a negative effect on psychological well-being, social interactions and activities, and sexual and interpersonal relationships (Minassian et al, 2015).*

• Inspect the perineal skin for evidence of incontinence-associated dermatitis, including inflammation, vesicles in skin exposed to urinary leakage, and especially skinfolds or denudation of the skin, particularly when incontinence is managed by absorptive pads or containment briefs. **CEB/EB:** Ammonia produced from the breakdown of urea in urine causes an increase in skin pH, which increases the permeability of the skin; excess moisture and damage to the acid mantle further increases permeability and vulnerability to bacterial and fungal infections (Langemo et al, 2011; Beeckman, 2017). Skin exposed to urine or stool will become bright red, and the surface may appear shiny because of serous exudate; inflamed areas of individuals with darker skin tones may be a duller red or hypopigmented when compared with adjacent skin. Inspect the skin for a maculopapular red rash typical of candidiasis (Gray, 2010; Beeckman, 2017).

▲ Refer client for specific testing to confirm etiology of incontinence etiology and diagnosis. If trained to do so, perform the cough stress test, and request 24-hour pad test (if appropriate) and urodynamic studies (to include urine speed and flow, postvoid residual measurement, leak point pressure, and pressure flow study). **EB:** *A greater agreement rating was found between cough stress test and urodynamics than between 24-hour pad test and urodynamics in the assessment of stress incontinence (Price & Noblett, 2012; Minassian, et al, 2015).*

• Establish with the client the current use of containment devices; evaluate the devices for their ability to adequately contain urine loss, protect clothing, and control odor. Assist the client in identifying containment devices specifically designed to contain urinary leakage. **EB:** *Recommend that the client buy incontinent products specifically designed to contain urine using hydrogel to contain fluid, and to not use sanitary pads. Using a combination of products may be more effective and economical (Roem Flanagan, & Maden, 2014).* **EB:** *Recognize that incontinence products may present a significant financial burden to clients. Chong, Khan, and Anger (2011) reported that approximately 70% of expenditures attributed to containment devices, laundry, and dry cleaning expenses were paid by the clients themselves.*

• Teach the client to complete a bladder diary by recording voiding frequency, the frequency and degree of urinary incontinence episodes, association with urgency (a sudden and strong desire to urinate that is difficult to defer), fluid intake, and pad usage over a 3- to 7-day period. An electronic voiding diary may be kept whenever feasible. **EB:** *Use of a bladder diary may reduce client discrepancies in recall and is a valuable*

tool for assessment; the short (24-hour) duration of the bladder diary may yield inadequate data, and excessive diary duration reduces compliance (Dixon and Nakib, 2016).

▲ With the client and in close consultation with the health care provider, review treatment options, including behavioral management; drug therapy; use of a pessary, vaginal device, or urethral insert; and surgery. Outline the potential benefits, efficacy, and side effects of each treatment option. **CEB:** *A 10-year review of the literature identified that there are two common conservative treatments recommended to treat stress urinary incontinence in women: strengthening pelvic floor muscles including biofeedback and weighted vaginal cones, and the use of intravaginal devices such as pessaries (McIntosh, Andersen, & Reekie, 2015).*

• Teach the client undergoing pelvic floor muscle training to identify, contract, and relax the pelvic floor muscles without contracting distal muscle groups (e.g., abdominal muscles or gluteus muscles) using verbal feedback based on vaginal or anal palpation, biofeedback, or electrical stimulation and the assistance of an incontinence specialist or health care provider as necessary. **EB:** *Pelvic floor muscle training is effective in the treatment of stress, urge, and mixed urinary incontinence; participation in a supervised program for at least 3 months may yield improved outcomes (Dumoulin, Hay-Smith, & Mac Habbe-Seguin, 2014).*

• **CEB:** To find the proper muscles, the client may be instructed to think about trying to control the urge to pass gas; women will feel a lifting sensation in the vaginal area and a pulling in of the rectum (Keyock & Newman, 2011). When learning to control pelvic floor muscles, clients may recruit other muscles such as the rectus abdominis or gluteal muscles, which may be counterproductive; these muscles must be relaxed to avoid increasing pressure on the bladder or pelvic floor (Burgio et al, 2009).

• Incorporate principles of exercise physiology into a pelvic muscle training program using the following strategies:

- ❍ Begin a graded exercise program, usually starting with 5 to 10 repetitions and advancing gradually to no more than 35 to 50 repetitions every day or every other day based on baseline and ongoing evaluation of maximal strength and endurance.
- ❍ Continue exercise sessions over a period of 3 to 6 months.
- ❍ Integrate muscle training into activities of daily living.
- ❍ Assess progress every 2 weeks during the first month and every 4 to 6 weeks thereafter.

CEB/EB: *Pelvic floor muscle training strengthens urethral sphincter tone (Chong, Khan, & Anger, 2011) and is the first-line conservative approach for all types of incontinence and in particular for stress and mixed urinary incontinence. Women report an improvement in symptoms and quality of life after undergoing this training (Dumoulin, Hay-Smith, & Mac Habbe-Seguin, 2014).*

• Implement a bladder training program with the client. Assist the client in completing a bladder diary over a period of a minimum of 3 days or up to 7 days.

- ❍ Review the results of the diary with the client, determining typical voiding frequency and establishing goals for voiding frequency.
- ❍ Using baseline voiding frequency, as determined by the diary, teach the client to urinate by the clock when awake, typically every 30 to 120 minutes.
- ❍ Encourage adherence to the program with timing devices, as well as verbal encouragement and support, and address individual reasons for schedule interruption.
- ❍ Gradually increase the time between urinations to the negotiated goal. Time intervals between voiding are typically increased in increments of 15

to 30 minutes for clients with a baseline frequency of less than every 60 minutes and increments of 25 to 30 minutes for clients with a baseline frequency of more than every 60 minutes.

EB: *Bladder training reduces the frequency and severity of urinary leakage in women with stress incontinence, urge incontinence, and mixed incontinence.*

- Combining pelvic floor muscle training with bladder training is more effective than bladder training alone in the short term for treating stress urinary incontinence (Kaya et al, 2015).

▲ Teach the client to self-administer duloxetine and imipramine as ordered by the consulting health care provider, and to monitor for adverse side effects. **CEB/EB:** *There are no prescriptive drugs approved for use in stress urinary incontinence in the United States. Nevertheless, several agents are sometimes prescribed to highly selected clients with stress urinary incontinence. They include duloxetine (Schagen van Leeuwen et al, 2008) and imipramine (Andersson, 2000). A systematic review and meta-analysis (Li et al, 2013) concluded that duloxetine decreased incontinence episodes by 50% in more than 56% of clients; however, adverse effects were experienced by 83% of the subjects.*

▲ Teach the client to self-administer topical (vaginal) estrogens as directed, and to monitor for adverse side effects. **EB:** *Intravaginal estrogen has an effect on the bladder and urethral epithelium and can help to relieve symptoms of urinary frequency, particularly in postmenopausal women with vaginal atrophy (Panay et al, 2013).*

- Refer the female client with stress urinary incontinence and pelvic organ prolapse who wishes to use a pessary to manage stress incontinence to a nurse specialist or gynecologist with expertise in the placement and maintenance of these devices. **CEB:** *The use of pessaries can help resolve stress urinary incontinence, with the common types being the dish or the ring. These differ from other pessaries because the ring or dish is placed at the level of the urethral vesical junction to provide additional support to the urethra (Keyock and Newman, 2011).*
- Discuss potentially reversible or controllable risk factors, such as weight loss, with the client with stress incontinence, and assist the client to formulate a strategy to eliminate these conditions. *Although research supports a strong familial predisposition to stress incontinence among women, other risk factors, including obesity, smoking, and chronic coughing from smoking, are reversible.* **CEB:** *Being obese may increase pressure on the pelvic floor and doubles the risk for incontinence (Strothers & Friedman, 2011).*
- Provide information about support resources such as the National Association for Continence, the Simon Foundation for Continence, or the Total Control Program.
- Refer the client with persistent stress incontinence to a continence service, health care provider, or nurse who specializes in the management of this condition. *All clients presenting with incontinence should be offered an initial assessment by an individual who specializes in management of continence disorders.*
- Teach the client to ensure good hydration. Total daily fluid intake should be approximately 2.7 L/day for women and 3.7 L/day for men. **EB:** *Adequate fluid helps wash out bacteria from the urethra to prevent urinary tract infections, helps prevent kidney stones, and potentially protects the client from development of cancer of the bladder from exposure to carcinogens concentrated in the urine (Newman & Willson, 2011).*
- Provide client with comprehensive written information about bladder care. **EB:** *Providing clients with well-written, evidence-based information about their condition and treatment can have a beneficial effect on the outcomes of treatment. In addition, clients are more likely to retain important information that will assist them in making informed decisions*

about their care (Coulter, 2011).

• Encourage a program of self-care management. Addressing self-care activities through exercise, diet, fluid intake, and protective devices helps the client exercise control over incontinence and may reduce the substantial care provider burden affecting a significant proportion of spouse, partner, or familial care providers.

• Assist the family with arranging care in a way that allows the client to participate in family or favorite activities without embarrassment. Elicit discussion of the client's concerns about the social or emotional burden of incontinence. **EB:** Urinary incontinence has a substantial negative effect on the quality of life for clients, both socially and financially. Further studies are needed to determine the true extent of the problem and to address it (Tapia et al, 2013).

• Document all care and advice given in a factual and comprehensive manner. Good record keeping is an integral part of nursing practice and is essential to the provision of safe and effective care (St. Aubyn and Andrews, 2015).

Urge urinary Incontinence

Amanda Andrews BSc (Hons), MA, Bernie St. Aubyn BSc (hons), MSc

NANDA-I

Definition

Involuntary passage of urine occurring soon after a strong sensation or urgency to void.

Defining Characteristics

Inability to reach toilet in time to avoid urine loss; involuntary loss of urine with bladder contractions; involuntary loss of urine with bladder spasms; urinary urgency

Related Factors

Alcohol consumption; caffeine intake; fecal impaction; ineffective toileting habits; involuntary sphincter relaxation

Associated Condition

Atrophic urethritis; atrophic vaginitis; bladder infection; decrease in bladder capacity; detrusor hyperactivity with impaired bladder contractility; impaired bladder contractility; treatment regimen

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Tissue Integrity: Skin and Mucous Membranes; Urinary Continence; Urinary Elimination

Example NOC Outcome with Indicators

Urinary Continence as evidenced by the following indicators: Responds in timely manner to urge/Voids in appropriate receptacle/Has adequate time to reach toilet between urge and evacuation of urine/Underclothing remains dry during day/Underclothing or bedding remains dry during night. (Rate the outcome and indicators of **Urinary Continence:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Report relief from urge urinary incontinence or a decrease in the frequency of incontinent episodes
- Identify containment devices that assist in the management of urge urinary incontinence

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Urinary Habit Training; Urinary Incontinence Care

Example NIC Activities—Urinary Habit Training

Keep a continence specification record for 3 days to establish voiding pattern; Establish interval for toileting of preferably not less than 2 hours

Nursing Interventions and *Rationales*

- Introduce yourself to the client and anyone accompanying him or her and inform them of your role. *Introducing yourself to a client helps establish and develop a therapeutic relationship that recognizes the person within the client and forms the bases for building trust on which to base the provision of care (Howatson-Jones, Standing, & Roberts, 2012).*
- Gain consent to perform care before proceeding further with the assessment. *Clients have the right to autonomy both legally and morally; therefore should be fully involved in the decision-making process (Avery, 2013).*
- Wash hands using a recognized technique. *Evidence shows that strict hand hygiene regimens significantly reduce the incidence of methicillin-resistant* Staphylococcus aureus *and* Clostridium difficile *infection (Goldberg, 2017).*
- Assess the usual pattern of bladder management and establish the pattern of bladder management and extent of the problem. *A detailed and accurate assessment of the client enables the nurse to plan interventions, monitor outcomes, and evaluate care, ensuring no unnecessary treatment is performed (Matthews, 2011).* Refer to Functional urinary **Incontinence** care plan.
- Assess bladder habits and quality of life issues:
    - Diurnal frequency (voiding more than once every 2 hours while awake)
    - Urgency, daytime frequency and nocturia
    - Involuntary leakage and leakage accompanied by or preceded by urgency
    - Amount of urine loss, moderate or large volume
    - Severity of symptoms
    - Alleviating and aggravating factors
    - Effect on quality of life

▲ **EB:** *Incontinence is distressing and may contribute to decreased quality of life. This includes a negative effect on psychological well-being, social interactions and activities, and sexual and interpersonal relationships (Minassian et al, 2015).*

▲ Urge urinary incontinence occurs when involuntary leakage of urine is accompanied by or immediately preceded by urgency; overactive bladder is characterized by the storage symptoms of urgency with or without incontinence and

is usually accompanied by frequency and nocturia (Abrams et al, 2010).

- Ask specific questions relating to urge presentation:
  - Can you delay urination for a 2-hour movie or car ride?
  - How often do you wake at night to urinate?
  - When you have the urge to urinate, can you reach the toilet without leaking?

▲ **EB:** *A history of urine loss associated with urgency is the most helpful criterion for diagnosing urge urinary incontinence (Holroyd-Leduc et al, 2011). To further enhance this assessment the questionnaire needs to be a validated incontinence-specific quality of life questionnaire (Bardsley, 2016).*

▲ In close consultation with a health care practitioner or advanced practice nurse, consider administering a symptom questionnaire that elicits relevant lower urinary tract symptoms and differentiates stress and urge incontinence symptoms. **CEB:** *The Urogenital Distress Inventory short form (UDI-6) is a reliable and valid tool for identifying types of urinary incontinence (Dowling-Castronovo, 2008).*

- Assess the severity of incontinence and the effect on the individual's lifestyle; inquire about incontinence pad use and change in daily, social, or recreational activities, and emotional impact. **EB:** *Incontinence is distressing and may contribute to decreased quality of life, especially for women with mixed incontinence (Bardsley, 2016).*

▲ Perform a focused physical assessment, in close consultation with a health care practitioner or advanced practice nurse including:

  - Bladder palpation after voiding to check for retention
  - Bladder scanning for postvoid residual
  - Inspection of the perineal skin
  - Vaginal examination to determine hypoestrogenic changes in the mucosa (may contribute to urge incontinence)
  - Pelvic examination to determine the presence, location, and severity of vaginal wall prolapse, and reproduction of stress urinary incontinence with the cough test

- Anal tone and constipation should be assessed. *A thorough abdominal and pelvic examination must be completed to accurately assess incontinence. Identification of "red flag" symptoms (e.g., nocturia, hematuria) needs referral to the appropriate consultant (NICE, 2015).*
- Inspect the perineal and perianal skin for evidence of incontinence-associated dermatitis, including inflammation, vesicles in skin exposed to urinary leakage, and especially skinfolds or denudation of the skin, particularly when incontinence is managed by absorptive pads or containment briefs. **EB:** *Ammonia produced from the breakdown of urea in urine causes an increase in skin pH, which increases the permeability of the skin; excess moisture and damage to the acid mantle further increases permeability and vulnerability to bacterial and fungal infections (Beeckman, 2017). Skin exposed to urine or stool will become bright red, and the surface may appear shiny because of serous exudate; inflamed areas of individuals with darker skin tones may be a duller red or hypopigmented when compared with adjacent skin. Inspect the skin for a maculopapular red rash typical of candidiasis (Beeckman, 2017).*
- Teach the client to complete a bladder diary by recording voiding frequency, the frequency and degree of urinary incontinence episodes, their association with urgency (a sudden and strong desire to urinate that is difficult to defer), fluid intake, and pad usage over a 3- to 7-day period. An electronic voiding diary may be kept whenever feasible. In addition to these parameters, the client may be asked to record voided volume and fluid intake. **EB:** *Use of a bladder diary may reduce client discrepancies*

in recall and is a valuable tool for assessment; short (24-hour) duration of the bladder diary may yield inadequate data, and excessive diary duration reduces compliance (Dixon & Nakib, 2016).

• Review all medications the client is receiving, paying particular attention to sedatives, opioid analgesics, diuretics, antidepressants, psychotropic drugs, and cholinergics. Consult the health care practitioner or nurse practitioner about altering or eliminating these medications if they are suspected of affecting incontinence. **EB:** *All medications should be reviewed to determine whether they are contributing to incontinence (Abrams et al, 2010).*

• Assess the client for urinary retention (see the care plan for **Urinary Retention**).

• Assess the client for functional limitations (environmental barriers, limited mobility or dexterity, and impaired cognitive function). Clients with impaired dexterity or weakness may benefit from clothing that has been modified or is without buttons and zippers (Leaver, 2017). Refer to the care plan for Functional urinary **Incontinence.**

• Consult the health care practitioner concerning diabetic management or pharmacotherapy for urinary tract infection when indicated. In specific cases, urgency and an increased risk of urge incontinence may be related to bacteriuria or urinary tract infection (Gupta & Trautner, 2011).

▲ Assess for signs and symptoms of atrophic vaginal changes in the perimenopausal or postmenopausal woman, including vaginal dryness, tenderness to touch, mucosal dryness, friability, and discomfort with gentle palpation. Specifically query the woman with atrophic vaginitis concerning associated lower urinary tract symptoms (usually voiding frequency, urgency, and dysuria). Refer the woman with atrophic vaginal changes and bothersome lower urinary tract symptoms to a gynecologist, urologist, or women's health nurse practitioner for further evaluation and management. *Vaginal topical estrogens may reduce urge incontinence, prevent urogenital atrophy, and prevent recurrent urinary tract infections. Intravaginal estrogen has an effect on the bladder and urethral epithelium and can help to relieve symptoms of urinary frequency, particularly in postmenopausal women with vaginal atrophy (Panay et al, 2013).*

Pelvic Floor Training Program

• Pelvic floor muscle training is effective in the treatment of stress, urge, and mixed urinary incontinence; participation in a supervised program for at least 3 months may yield improved outcomes (Dumoulin, Hay-Smith, & Mac Habbe-Seguin, 2014).

• Teach the client undergoing pelvic floor muscle training to identify, contract, and relax the pelvic floor muscles without contracting distal muscle groups (e.g., abdominal muscles or gluteus muscles) using verbal feedback based on vaginal or anal palpation, biofeedback, or electrical stimulation, using the assistance of an incontinence specialist or health care provider as necessary. **EB:** *To find the proper muscles, the client may be instructed to think about trying to control the urge to pass gas; women will feel a lifting sensation in the vaginal area and a pulling in of the rectum (Keyock & Newman, 2011).* **CEB:** *When learning to control pelvic floor muscles, clients may recruit other muscles such as the rectus abdominis or gluteal muscles, which may be counterproductive; these muscles must be relaxed to avoid increasing pressure on the bladder or pelvic floor (Burgio, 2009; Burgio et al., 2010).*

• Incorporate principles of exercise physiology into a pelvic muscle training program using the following strategies:

  ❍ Begin a graded exercise program, usually starting with 5 to 10 repetitions and advancing gradually to no more than 35 to 50 repetitions every day or

every other day based on baseline and ongoing evaluation of maximal strength and endurance.
- ❍ Continue exercise sessions over a period of 3 to 6 months.
- ❍ Integrate muscle training into activities of daily living.
- ❍ Assess progress every 2 weeks during the first month and every 4 to 6 weeks thereafter.

Pelvic floor muscle training strengthens urethral sphincter tone (Chong, Khan, & Anger, 2011) and is the first-line conservative approach for all types of incontinence, particularly for stress and mixed urinary incontinence; women report an improvement in symptoms and quality of life after undergoing this training (Dumoulin, Hay-Smith, & Mac Habbe Seguin, 2014).

Bladder Training Program

- Assist the client in completing a voiding diary over a period of a minimum of 3 days or up to 7 days.
- Review the results with the client, determining typical voiding frequency and establishing goals for voiding frequency based on the longest time interval between voids that is comfortable for the client.
- Using baseline voiding frequency, as determined by the diary, teach the client to void first thing in the morning, every time the predetermined voiding interval passes, and before going to bed at night.
- Encourage adherence to the program with timing devices and verbal encouragement and support, and address individual reasons for schedule interruption.
- Teach distraction and urge suppression techniques (see later discussion) to control urgency while the client postpones urination.
- Gradually increase the time between urinations to the negotiated goal. Time intervals between voiding are typically increased in increments of 15 to 30 minutes for clients with a baseline frequency of less than every 60 minutes and increments of 25 to 30 minutes for clients with a baseline frequency of more than every 60 minutes. The voiding interval should be increased by 15 to 30 minutes each week (based on the client's tolerance) until a voiding interval of 3 to 4 hours is achieved. Use a bladder diary to monitor progress. **EB:** *Bladder training involves adjusting your habits and developing a schedule to void even if the client does not have an urge to void. Gradually increase the time intervals between urination allowing the bladder to fill more fully and providing more control over the urge to urinate (Mayo Clinic, 2017).*
- Review with the client the types of beverages consumed, focusing on the intake of caffeine, which is associated with a transient effect on lower urinary tract symptoms. Advise all clients to reduce or eliminate intake of caffeinated beverages or over-the-counter medications of dietary aids containing caffeine. Identify and counsel the client to eliminate other bladder irritants that may exacerbate incontinence, such as smoking, carbonated beverages, citrus, sugar substitutes, and tomato products. **CEB/EB:** *Caffeine is a diuretic, a bladder irritant, increases detrusor pressure, and is a risk factor for detrusor instability; reducing caffeine may decrease both stress and urge incontinence. Decrease caffeine gradually to avoid caffeine withdrawal. Carbonated beverages, citrus fruits, sugar substitutes, and tomato products may be bladder irritants (Burgio, 2009; Mayo Clinic, 2017).*
- Review with the client the volume of fluids consumed; fluids may be reduced with caution, *particularly in clients who do not drink more than 1500 mL during the day*, to alleviate urinary frequency, especially in the evening after 6 p.m. or 3 to 4 hours

before bedtime to reduce nocturia. **EB:** *Be aware that adequate fluid intake is essential; six 8-ounce glasses per 24 hours, 1500 mL, or 30 mL/kg body weight is recommended. The type and amount of fluid intake is associated with frequency and urge urinary incontinence (Segal, Saks, & Arya, 2011).*

• Teach the client methods to avoid constipation such as increasing dietary fiber, moderately increasing fluid intake, exercising, and establishing a routine defecation schedule.

• Refer to **Constipation** care plans.

Urge Suppression

• *Urge suppression skills are essential in helping clients learn a new way of responding to the sense of urgency. Rushing to the toilet increases physical pressure on the bladder, enhances the sensation of fullness, exposes the client to visual cues that can trigger incontinence, and exacerbates urgency (Burgio, 2009).*

• Teach the client the following techniques:

- ❍ When a strong or precipitous urge to urinate is perceived, teach the client to avoid running to the toilet.
- ❍ Pause, sit down, and relax the entire body.
- ❍ Perform repeated, rapid pelvic muscle contractions until the urge is relieved.
- ❍ Use distraction: count backward from 100 by sevens; recite a poem; write a letter; balance a checkbook; do handwork such as knitting; and take five deep breaths, focusing on breathing.
- ❍ Relief is followed by micturition within 5 to 15 minutes, using nonhurried movements when locating a toilet and voiding.
- ❍ Use urge suppression strategies on waking during the night. If the urge subsides, the client should be encouraged to go back to sleep. If after a minute or two the urge does not subside, clients should be instructed to get up to void to avoid sleep interruption. **EB:** *Behavioral training for urge incontinence can reduce nocturia (Burgio, 2009).*

• Teach the client to self-administer antimuscarinic (anticholinergic) drugs as directed. Teach dosage side effects and administration of the medication and the importance of combining pharmacotherapy with scheduled voiding, adequate fluid intake, restriction of bladder irritants, and urge suppression techniques. **EB:** *Antimuscarinic drugs increase bladder capacity, reduce the frequency of incontinence episodes, and diminish voiding frequency. However, they do not cure bladder dysfunction or reduce the time between perception of a strong urge and onset of an overactive detrusor contraction. Approximately two-thirds of clients treated with antimuscarinic medication discontinue use within 3 to 4 months; the efficacy of pharmacotherapy for urge incontinence is enhanced when combined with behavioral interventions (Burgio et al, 2010).*

• Assist the client in selecting, obtaining, and applying a containment device for urine loss as indicated. *The use of containment devices can be useful as "stop gap" strategies used alongside long-term management options (Reid, 2014).*

• Provide the client with information about incontinence support groups such as the National Association for Continence and the Simon Foundation for Continence. A helpful website titled Total Control (http://www.totalcontrolprogram.com/Pelvic+Health/Bladder+Health) can be accessed to give support and information to women with incontinence. **EB:** *Knowledge contributes to effective self-management; women with incontinence often do not seek help from*

others and prefer to self-manage their incontinence (Holroyd-Leduc et al, 2011).

- Assess the functional and cognitive status of all clients with urge incontinence; use interventions to improve mobility. **EB:** *Clients with severe cognitive impairments (dementia) and functional mobility problems have an increased likelihood of developing urge incontinence (Jerez-Roig, 2016).*
- Refer client for occupational therapy for help in obtaining assistive devices and adapting the home for optimal toilet accessibility. *Occupational therapists are needed to assist patients with dexterity and mobility issues that may be contributing to incontinence (Spencer, McManus, & Sabourin, 2017).*
- Encourage the client to develop an action plan for self-care management of incontinence. *Making an action plan facilitates behavior change*
- Provide client with comprehensive written information about bladder care. **EB:** *Providing clients with well-written, evidence-based information about their condition and treatment can have a beneficial effect on the outcomes of treatment. In addition, clients are more likely to retain important information that will assist them in making informed decisions about their care (Coulter, 2011).*
- Document all care and advice given in a factual and comprehensive manner. *Good record keeping is an integral part of nursing practice and is essential to the provision of safe and effective care (St. Aubyn & Andrews, 2015).*

Risk for urge urinary Incontinence

Mary Beth Flynn Makic PhD, RN, CCNS, FAAN

NANDA-I

Definition

Susceptible to involuntary passage of urine occurring soon after a strong sensation or urgency to void, which may compromise health.

Risk Factors

Alcohol consumption; caffeine intake; fecal impaction; ineffective toileting habits; involuntary sphincter relaxation

Associated Condition

Atrophic urethritis; atrophic vaginitis; bladder infection; decrease in bladder capacity; detrusor hyperactivity with impaired bladder contractility; impaired bladder contractility; treatment regimen

NIC, NOC, Client Outcomes, Nursing Interventions and *Rationales,* Client/Family Teaching and Discharge Planning, and References

Refer to care plan for Urge urinary **Incontinence.**

Bowel Incontinence

Kim L. Paxton DNP, APRN, ANP-BC, LHIT-C

NANDA-I

Definition

Involuntary passage of stool.

Defining Characteristics

Bowel urgency; constant passage of soft stool; does not recognize urge to defecate; fecal staining; inability to delay defecation; inability to expel formed stool despite recognition of rectal fullness; inability to recognize rectal fullness; inattentive to urge to defecate

Related Factors

Difficulty with toileting self-care; environmental factor; generalized decline in muscle tone; immobility; inadequate dietary habits; incomplete emptying of bowel; laxative abuse; stressors

Associated Condition

Abnormal increase in abdominal pressure; abnormal increase in intestinal pressure; alteration in cognitive functioning; chronic diarrhea; colorectal lesion; dysfunctional rectal sphincter; impaction; impaired reservoir capacity; lower motor nerve damage; pharmaceutical agent; rectal sphincter abnormality; upper motor nerve damage

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Bowel Continence; Bowel Elimination

Example NOC Outcome with Indicators

Bowel Continence as evidenced by the following indicators: Maintains predictable pattern of stool evacuation/Maintains control of stool passage/Evacuates stool at least every 3 days. (Rate the outcome and indicators of **Bowel Continence:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Have regular, complete evacuation of fecal contents from the rectal vault (pattern may vary from every day to every 3 days)
- Have regulation of stool consistency (soft, formed stools)
- Reduce or eliminate frequency of incontinent episodes
- Exhibit intact skin in the perianal/perineal area
- Demonstrate the ability to isolate, contract, and relax pelvic muscles (when incontinence related to sphincter incompetence or high-tone pelvic floor dysfunction)
- Increase pelvic muscle strength (when incontinence related to sphincter incompetence)
- Identify triggers that precipitate change in bowel continence

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Bowel Incontinence Care; Bowel Incontinence Care: Encopresis; Bowel Training

Example NIC Interventions—Bowel Incontinence Care

Determine physical or psychological cause of fecal incontinence; Instruct client/family to record fecal output, as appropriate

Nursing Interventions and *Rationales*

• In a private setting, directly question client about the presence of fecal incontinence. If the client reports altered bowel elimination patterns, problems with bowel control, or "uncontrollable diarrhea," complete a focused nursing history including previous and present bowel elimination routines, dietary history, frequency and volume of uncontrolled stool loss, and aggravating and alleviating factors. **EB:** *Unless questioned directly or the client is experiencing bothersome fecal incontinence, clients are often hesitant to report the presence of fecal incontinence (Spiegel et al, 2014). The nursing history determines the patterns of stool elimination, to characterize involuntary stool loss and the likely etiology of the incontinence (Willson et al, 2014).*

• Recognize that risk factors for fecal incontinence include older individuals, female sex, impaired mobility, cognitive impairment, obesity, individuals who have undergone pelvic surgery, diabetes, and structural or functional impairment of bowel function (Ditah et al, 2014; Willson et al, 2014, Young et al, 2017). *Although fecal incontinence is more common in women, it is also a problem for men and should not be overlooked when obtaining a health history (Young et al, 2017). Physiological changes of the female pelvis that occur with aging, along with those that occur with childbirth increase the risk of elimination problems, both constipation and incontinence (Mannella et al, 2013; Young et al, 2017).* **EBN:** *The prevalence of double incontinence, defined as urinary and fecal incontinence, is nationally estimated to be 10.6% for noninstitutionalized persons 65 and over who reported an occurrence of urinary leakage along with accidental bowel leakage as recorded from the face-to-face National Health and Nutrition Examination Survey (2007–2010) (Gorina et al, 2014).*

• Recognize that additional risk factors for bowel incontinence in hospitalized clients include antibiotic therapy, medications, enteral feeding, indwelling urinary catheter placement, immobility, inability to communicate elimination needs, acute disease processes and procedures (e.g., cancer, abdominal surgery), sedation, and mechanical ventilation (Chang & Huang, 2013; Gorina et al, 2014; Eman & Lohrmann, 2015).

▲ Conduct a health history assessment that includes a review of current bowel patterns/habits to include constipation and use of laxatives; diarrhea; pelvic floor injury with childbirth; acute trauma to organs, muscles, or nerves involved in defecation; gastrointestinal inflammatory disorders; functional disability; and medications (Kaiser et al, 2014; Whitehead, Palsson, & Simren, 2016).

▲ Closely inspect the perineal skin and skinfolds for evidence of skin breakdown in clients with incontinence. **EBN:** *An expert consensus statement defined moisture-associated skin damage as inflammation and erosion of the skin caused by prolonged exposure to various sources of moisture (Coyer, Gardner, & Doubrovsky, 2017). Incontinence-associated dermatitis (IAD) is a form of skin irritation that develops from chronic exposure to urine or liquid stool (Bliss et al, 2015; Coyer, Gardner, & Doubrovsky, 2017). A recent meta-analysis found a strong association between IAD and a client developing a pressure ulcer (Beeckman et al, 2014).*

▲ Use a validated tool that focuses on bowel elimination patterns to help provide a clearer understanding of the client's individual challenges and perceptions of symptoms associated with fecal incontinence (Gillibrand, 2012; Jelovsek et al, 2014).

▲ Complete a focused physical assessment, including inspection of perineal skin, pelvic muscle strength assessment, digital examination of the rectum for the presence of impaction and anal sphincter strength, and evaluation of functional status (mobility, dexterity, and visual acuity).
• Complete an assessment of cognitive function; explore for a history of dementia, delirium, or acute confusion (Bliss et al, 2015; Drennan, Greenwood, & Cole, 2014). **EBN:** *A study found that critically ill clients who were less cognitively aware were 50% more likely to develop IAD than clients who were more cognitively aware (Bliss et al, 2015).*
• Document patterns of stool elimination and incontinent episodes through a bowel record, including frequency of bowel movements, stool consistency, frequency and severity of incontinent episodes, precipitating factors, and dietary and fluid intake. *Documented patterns of elimination are used to narrow the likely etiology of stool incontinence and serve as a baseline to evaluate treatment efficacy (Willson et al, 2014; Rao et al, 2016).*
• Assess stool consistency and its influence on risk for stool loss. *Several classification systems for stool exist and may assist the nurse and client to differentiate among normal soft, formed stool, hardened stools associated with constipation, and liquid stools associated with diarrhea.* **EBN:** *A study of stool consistency found good reliability when evaluated by nurses and clients. Word-only descriptors yielded equivocal consistency when assessed by subjects, as did tools that combined words with illustrations of various stool consistencies (Bliss et al, 2015). Less well-formed (loose or liquid) stool is associated with an increased severity and frequency of fecal incontinence episodes and potential for compromised skin integrity (Bliss et al, 2015; Willson et al, 2014; Beeckman, 2017; Coyer, Gardner, & Doubrovsky, 2017).*
• Identify conditions contributing to or causing fecal incontinence. *Fecal incontinence is frequently multifactorial. Accurate assessment of the probable etiology of fecal incontinence is necessary to select a treatment plan likely to control or eliminate the condition (Unger, Goldman, & Jelovesk, 2014; Willson et al, 2014).*
• Improve access to toileting:
    ❍ Identify usual toileting patterns and plan opportunities for toileting accordingly.
    ❍ Provide assistance with toileting for clients with limited access or impaired functional status (mobility, dexterity, and access).
    ❍ Institute a prompted toileting program for persons with impaired cognitive status.
    ❍ Provide adequate privacy for toileting.
    ❍ Respond promptly to requests for assistance with toileting.

▲ **EB:** *Acute or transient fecal incontinence frequently occurs in the acute care or long-term care facility secondary to mentation changes associated with environment change, inadequate access to toileting facilities, insufficient assistance with toileting, or inadequate privacy when attempting to toilet (Jelovsek et al, 2014; Park & Kim, 2014; Blekken et al, 2016).*
• Review the client's nutritional history and evaluate methods to normalize stool consistency with dietary adjustments (e.g., avoiding high-fat content foods) and use of fiber along with assessing for use of caffeine, lactose, and sugar replacements (*International Foundation for Functional Gastrointestinal Disorders [IFFGD], 2018; Willson et al, 2014; Paquette et al, 2017*). **EB:** *Diet modifications have been found to be helpful in the management of fecal incontinence, including restrictions of some foods, adding fiber to the diet, and establishing consistent eating patterns (National Institute for Diabetes and Digestive and Kidney Diseases, 2013; Willson et al, 2014).*
• Encourage the client to keep a nutrition log to track foods that irritate the bowel *(Paquette et al, 2017).*
• For hospitalized clients with tube feeding–associated fecal incontinence, involve the

nutrition specialist to evaluate the formula composition, osmolality, and fiber content.
• For the client with intermittent episodes of fecal incontinence related to acute changes in stool consistency, begin a bowel reeducation program consisting of the following:
  - ❍ Cleansing the bowel of impacted stool if indicated
  - ❍ Normalizing stool consistency by adequate intake of fluids (30 mL/kg of body weight per day) and dietary or supplemental fiber
  - ❍ Establishing a regular routine of fecal elimination based on established patterns of bowel elimination (patterns established before onset of incontinence)

Education on bowel patterns and strategies to establish normal defecation patterns and stool consistency to reduce or eliminate the risk of recurring fecal incontinence have been found to be beneficial in controlling fecal incontinence associated with changes in stool consistency (IFFGD, 2018; NHS Choices Information, 2018).

▲ Implement a scheduled stimulation defecation program for persons with neurological conditions causing fecal incontinence:
  - ❍ Cleanse the bowel of impacted fecal material before beginning the program.
  - ❍ Implement strategies to normalize stool consistency, including adequate intake of fluid and fiber and avoidance of foods associated with diarrhea.
  - ❍ Determine a regular schedule for bowel elimination (typically every day or every other day) based on prior patterns of bowel elimination.
  - ❍ Provide a stimulus before assisting the client to a position on the toilet; digital stimulation, a stimulating suppository, "mini-enema," or pulsed evacuation enema may be used for stimulation.

The scheduled, stimulated program relies on consistency of stool and a mechanical or chemical stimulus to produce a bolus contraction of the rectum with evacuation of fecal material (Duelund-Jakobsen et al, 2016; Paquette et al, 2017).

▲ Begin a reeducation or pelvic floor muscle exercise program for the person with sphincter incompetence or high-tone pelvic floor muscle dysfunction of the pelvic muscles, or refer persons with fecal incontinence related to sphincter dysfunction to a nurse specialist or other therapist with clinical expertise in these techniques of care. **EB:** *Although evidence of overall effectiveness of pelvic floor muscle exercise programs is inconclusive as a treatment strategy for fecal incontinence, the programs are not harmful (Mannella et al, 2013; Unger, Goldman, & Jelovesk, 2014).*
▲ Consider a sacral nerve stimulation program in clients with urgency to defecate and fecal incontinence related to weakened sphincter muscles or sphincter defect. **EB:** *Sacral nerve stimulation has been found to significantly reduce incontinence for some clients (Van Koughnett & Wexner, 2013; Kaiser et al, 2014).*
• Institute a structured skin care regimen that incorporates three essential steps: cleanse, moisturize, and protect:
  - ❍ Select a cleanser with a pH range comparable to that of normal skin (usually labeled "pH balanced").
  - ❍ Moisturize with an emollient to replace lipids removed with cleansing and protect with a skin. Products containing petrolatum, dimethicone, or zinc oxide base or a no-sting skin barrier should be used.
  - ❍ Routine incontinence care should include daily perineal skin cleansing and after each episode of incontinence.
  - ❍ When feasible, select a product that combines two or all three of these

processes into a single step. Ensure that products are available at the bedside when caring for a client with total incontinence in an inpatient facility.

▲ Use of absorptive pads or adult containment briefs that are applied next to the client's skin increases the risk of IAD. Absorbent underpads that wick moisture away from skin may be used with immobile clients. **EBN:** *A structured skin care regimen based on a three-step process (cleanse, moisturize, and protect) is effective for the prevention of IAD (Willson et al, 2014; Gray, McNickol, & Nix, 2016; Beeckman, 2017; Beeckman et al, 2014; Coyer, Gardner, & Doubrovsky, 2017).*

▲ Consult the provider if a fungal infection is suspected. An antifungal cream or powder beneath a protective ointment may be indicated (*Willson et al, 2014;Gray, McNickol, &* Nix *et al., 2016; Coyer, Gardner, & Doubrovsky, 2017*).

• Assist the client to select and apply a containment device for occasional episodes of fecal incontinence. A fecal containment device will prevent soiling of clothing and reduce odors in the client with uncontrolled stool loss. **EBN:** *A study of community persons with fecal incontinence who used an absorptive dressing to contain mucus and stool leakage after surgery revealed that the device was preferred over traditional pads in 92% (Bliss et al, 2015).*

• In the client with frequent episodes of fecal incontinence and limited mobility, monitor the sacrum and perineal area for pressure ulcerations. **EBN:** *Limited mobility, particularly when combined with fecal incontinence and increased moisture, increases the risk of pressure ulceration. Routine cleansing, pressure reduction techniques, and management of fecal and urinary incontinence reduce this risk (Beeckman et al, 2014; Willson et al, 2014; Beeckman, 2017).*

• With acutely ill clients, anticipate and evaluate the cause of acute diarrhea. Anticipate diarrhea associated with treatment or specific interventions (e.g., medications, initiation of tube feedings). *Interventions to manage acute diarrhea include use of absorbent pads and skin protectant moisturizers or fecal collector/pouch (Willson et al, 2014; Beeckman, 2017; Pather et al, 2017).*

▲ Consult a provider about insertion of a bowel management system (BMS) in the critically ill client when conservative measures have failed and fecal incontinence is excessive and/or produces perianal skin injury or IAD. *Indwelling BMSs, also called fecal management systems (FMSs), are commercially available and designed to direct, collect, and contain liquid stool in immobile clients. BMS devices are approved by the Food and Drug Administration for up to 29 days for management of liquid stool.(Whitely et al., 2014)* **EBN:** *Devices other than BMSs should not be used for indwelling bowel/feces diversion (Munhall & Jindal, 2013; Whitely et al, 2014; Willson et al, 2014).*

Geriatric

• Evaluate all older clients for established or acute fecal incontinence when the older client enters the acute or long-term care facility and intervene as indicated. **EB:** *Fecal incontinence often coexists with urinary incontinence, necessitating evidence-based interventions to prevent skin breakdown and/or pressure ulcer development in the older client (National Pressure Ulcer Advisory Panel, 2014; Willson et al, 2014; Shahin & Lohrmann, 2015).*

• Determine the client's cognitive level using a screening tool such as the Mini-Mental State Exam (MMSE), Montreal Cognitive Assessment (MoCA), the Confusion Assessment Method (CAM), or Mini-Cog. **EB:** *Use of a standard evaluation tool such as the MMSE or MoCA can help determine the client's abilities and assist in planning*

appropriate nursing interventions. Acute or established dementias increase the risk of fecal incontinence among older adults (Jerez-Roig et al, 2015; Trzepacz et al, 2015).

- ❍ Teach nursing colleagues, nonprofessional care providers, family, and clients the importance of providing toileting opportunities and adequate privacy for the client in an acute or long-term care facility.

Home Care

- The preceding interventions may be adapted for home care use.
- Assess and teach a bowel management program to support continence. Address timing, diet, fluids, and actions taken independently to deal with bowel incontinence. *Identifying factors that change level of incontinence may guide interventions. If the client has been taking over-the-counter medications or home remedies, it is important to consider their influence.*
- Instruct the caregiver to provide clothing that is nonrestrictive, can be manipulated easily for toileting, and can be changed with ease. *Avoidance of complicated maneuvers increases the chance of success in toileting programs and decreases the client's risk for embarrassing incontinent episodes.*
- Evaluate self-care strategies of community-dwelling older adults, strengthen adaptive behaviors, and counsel older adults about altering strategies that compromise general health.
- Assist the family in arranging care in a way that allows the client to participate in family or favorite activities without embarrassment. *Careful planning can both help the client retain dignity and maintain integrity of family patterns.*
- ▲ If the client is limited to bed (or bed and chair), provide a commode or bedpan that can be easily accessed. Involve occupational and physical therapy services as indicated to promote safe transfers.
- ▲ If the client is frequently incontinent, refer for home health aide services to assist with hygiene and skin care.
- ▲ Refer the family to support services to assist with in-home management of fecal incontinence as indicated.

Note: Refer to nursing diagnoses **Diarrhea** and **Constipation** for detailed management of these related conditions.

Disorganized Infant behavior

Mary Alice DeWys RN, BS, CIMI, Margaret Elizabeth Padnos RN, AB, BSN, MA

NANDA-I

Definition

Disintegration of the physiological and neurobehavioral systems of functioning.

Defining Characteristics

Attention-Interaction System

Impaired response to sensory stimuli

Motor System

Alteration in primitive reflexes; exaggerated startle response; fidgeting; finger splaying; fisting; hands to face; hyperextension of extremities; impaired motor tone; tremor; twitching; uncoordinated movement

Physiological

Abnormal skin color; arrhythmia; bradycardia; feeding intolerance; oxygen desaturation; tachycardia; time-out signals

Regulatory Problems

Inability to inhibit startle reflex; irritability

State-Organization System

Active-awake; diffuse alpha electroencephalogram (EEG) activity with eyes closed; irritable crying; quiet-awake; state oscillation

Related Factors

Caregiver cue misreading; environmental overstimulation; feeding intolerance; inadequate physical environment; infant malnutrition; insufficient caregiver knowledge of behavioral cures; insufficient containment within environment; insufficient environmental sensory stimulation; pain; sensory deprivation; sensory overstimulation

At-Risk Population

Low postconceptual age; prematurity; parental exposure to teratogen

Associated Condition

Congenital disorder; genetic disorder; infant illness; immature neurological functioning; impaired infant motor functioning; invasive procedure; infant oral impairment

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Child Development; Neurological Status; Newborn Adaptation; Preterm Infant Organization; Sleep; Thermoregulation: Newborn; Infant Nutritional Status

Example NOC Outcome with Indicators

Preterm Infant Organization as evidenced by the following indicators: O_2 saturation >85%/Thermoregulation/Sleep-awake state organization/Smooth transition between states/Ability to attend to visual and auditory stimuli/Habituation. (Rate the outcome and indicators of **Preterm Infant Organization:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

Infant/Child

- Display physiological/autonomic stability: cardiopulmonary, digestive functioning
- Display signs of organized motor system (Wyngarden, DeWys, & Padnos, 1999)
- Display signs of organized state system: ability to achieve and maintain a state, and transition smoothly between states (Wyngarden, DeWys, & Padnos, 1999)
- Demonstrate progress toward effective self-regulation (Wyngarden, DeWys, & Padnos, 1999)
- Demonstrate progress toward or ability to maintain calm attention
- Demonstrate progress or ability to engage in positive interactions
- Demonstrate ability to respond to sensory information (visual, auditory, tactile) in an adaptive way

Parent/Significant Other

- Recognize infant/child behaviors as a complex communication system that expresses specific needs and wants (e.g., hunger, pain, stress, desire to engage or disengage)
- Educate parents/caregivers to recognize infant's avenues of neurobehavioral communication: autonomic/physiological, motor, state, attention/interaction
- Recognize how infants respond to environmental sensory input through stress/avoidance and approach/engagement behaviors
- Recognize and support infant's self-regulatory, coping behaviors used to regain or maintain homeostasis
- Teach parents to “tune in” to their own interactive style and how that affects their infant's behavior
- Teach parents ways to adapt their interactive style in response to infant's style of communication appropriate for developmental stage and gestational age
- Identify appropriate positioning and handling techniques that will enhance normal motor development (Wyngarden, DeWys, & Padnos, 1999)
- Promote infant/child's attention capabilities that support visual and auditory development (Wyngarden, DeWys, & Padnos, 1999)
- Engage parents in pleasurable parent–infant interactions that encourage bonding and attachment (Wyngarden, DeWys, & Padnos, 1999)
- Structure and modify the environment in response to infant/child's behavior and personal needs; personalize their bed space (Wyngarden, DeWys, & Padnos, 1999)
- Identify available community resources that provide early intervention services, emotional support, community health nursing, and parenting classes (Wyngarden, DeWys, & Padnos, 1999)
- Communicate the infant's medical, nursing and developmental needs to the family

in a culturally sensitive and appropriate way that is understandable (DeWys et al, 2016)

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Physiological and Autonomic Stability; Developmental Enhancement; Infant Care; Environmental Management; Kangaroo Care; Nonnutritive Sucking; Parent Education: Infant; Positioning and Handling; Sleep and Awake Stability; Teaching: Infant Stimulation 0-4 months; Bonding and Attachment

Example NIC Activities—Developmental Enhancement, Infant

Provide information to parent about child development and child rearing; Promote and facilitate family bonding and attachment with infant

Nursing Interventions and *Rationales*

• Sensitive nursing care must be implemented at the infant's admission to the neonatal intensive care unit (NICU), continued stay, and continue past discharge as the family adjusts to transitioning home and into the community. **EBN:** *"Learning the principles of neurodevelopment and understanding the meaning of preterm behavioral cues make it possible for NICU caregivers and parents to provide individualized developmentally appropriate, neuroprotective care to each infant" (Altimier & Phillips, 2016).*
• Recognize the neurobehavior systems through which infants communicate organized and/or disorganized/stress behaviors within the subsystems of functioning (i.e., physiological/autonomic, motor, states, attention/interactional, self-regulatory). **CEB:** The Assessment of Preterm Infants' Behavior (APIB) is based on the theory that each subsystem functions independently and interactively with the other subsystems. Infant's physiological/autonomic subsystem has to be stable/organized, enabling infant to attend and/or interact with animate and inanimate environment (Als et al, 2005).
• Recognize and educate parents to recognize the behavior cues infants use to communicate stress/avoidance and approach/engagement. **CEB:** The neurobehavior system theory provides a framework for reading, interpreting, and responding to cues that value the infant's importance and ability to affect the environment (Als et al, 2005).
• Provide high-quality individualized developmental care for low-birth-weight preterm infants in a family-centered care environment that promotes normal neurological, physical, and emotional developmental and prevents disabilities. **EBN:** A study focused on changing NICU "to family-integrated care where parents are intimately involved in baby's care for as many hours a day" and changed the unit's name to newborn intensive parenting unit (NIPU), leading to improved outcomes for NIPU babies (Hall et al, 2017).
• Identify and manage pain using appropriate pain management techniques during invasive procedures (e.g., tube insertion, heel sticks, intravenous lines). **EB:** A combination of oral sucrose and nonnutritive sucking reduces pain during procedures (Liu et al, 2017). **EB:** Kangaroo care is an effective way parents can decrease infant pain during invasive procedures (Bailey & Committee on Fetus and Newborn, 2015). **EBN:** The skin-to-skin method reduces procedural pain (Johnson et al, 2017). **EB:** Odor of breast milk has an analgesic effect and can be used as a safe method for pain

relief and calming (Karbandi et al, 2015).
• Provide developmentally correct positioning and handling to facilitate optimal tone, normal neurodevelopmental outcomes that promote physiological stability, and sleep, and to reduce stress (King & Norton, 2017). Availability of positioning tool at bedside (integrated practice assessment tool [IPAT]) for nurses and parent education are important (Spilker, Hill, & Rosenblum, 2016).
• Provide care that supports development state organization, such as the ability to achieve and maintain quiet sleep and awake states and transition smoothly between states. **EBN:** Promote sleep by timing care and avoiding unnecessary procedures that disrupts sleep (Altimier & Phillips, 2016). **EB:** Recommended NICU noise level between 44 and 45 decibels (Bonan et al, 2014). **EBN:** A study found methods to reduce NICU noise are necessary and achievable (Reeves-Messner & Spilker, 2017).
• **EB:** Supine swaddling decreases restlessness and promotes quiet for sleep for NICU infants (Pease et al, 2016).
• Encourage parents to speak slowly and/or sing to their babies during visits **EB:** Maternal voice demonstrates increased stability in preterm infants (Filippa et al, 2017).
• Provide infants several opportunities for nonnutritive sucking (NNS). **EB:** Infants receiving NNS during tube feedings showed reduced time transitioning to full oral feedings and decreased the length of hospital stay (Foster, Psaila, & Patterson, 2016).
• Provide parents opportunities to experience physical closeness through loving touch, massage, cuddling, and skin-to-skin (kangaroo care), which enhances parent–infant attachment **EBN:** Kangaroo care positively affects mother–infant relationship, sleep, and brain maturation (Ludington-Hoe, 2013).
• Provide an environment that helps infants learn to self-regulate by encouraging self-calming behaviors (e.g., curing up, sucking fingers/fists)**.** A study found that teaching parents ways to calm fussy infants and support good sleep patterns decreased regulatory problems at 12 months of age (Sidor et al, 2013).
• Parental engagement and early interactions in the NICU set the foundation for parent–infant attachment and social relationships. **EB:** Parents emotional closeness to NICU infants may be crucial for developing an affective parent–infant relationship (Stefana & Lavelli, 2017).
• Support effective and pleasurable feeding practices, such as breast, bottle, or combination, as essential for healthy nutrition/calories, for mother-baby bonding and attachment, and for setting the foundation for successful feeding/eating patterns. **EBN:** Support breastfeeding for successful oral feedings (Altimier & Phillips, 2016). **EB:** Full or partial breastfeeding for the first few months lowers sudden infant death syndrome (SIDS) risk (National Institutes of Health, US National Library of Medicine, 2017).
• Provide infants with positive sensory experiences (i.e., visual, auditory, tactile, olfactory, vestibular, proprioceptive) to enhance development of sensory pathways and avoid overstimulation of sensory systems. **Auditory EB:** Music as medicine by Novotney (2013) showed that the maternal voice demonstrates increased physiological stability in preterm infants (Filippa et al, 2017). **Gustatory EBN:** Position infant allowing finger/fist sucking. **Tactile EBN:** Skin-to-skin is a positive sensory experience for both mothers and babies (Baily et al, 2015). **Olfactory EB:** Exposure of breast milk odor can reduce need for O2 therapy (Karbandi et al, 2015). **Visual EBN:** Provide stable lighting, shield eyes from bright lights, and monitor visual stimulation until 37 weeks' gestation (Altimier & Phillips, 2016). **Vestibular EBN:** Change position every 4 hours (Altimier & Phillips, 2016).

• Incorporate parents as coparticipants of infant care by communicating daily progress of their infants' condition. **EBN:** Parents would rather speak with a physician or nurse they are already familiar with versus outside sources for education and support (Wigert & Bry, 2017). **EB:** Parents are an integral partner in the NICU staff (Altimier & Phillips, 2016).

EBN: *"The ultimate goal of NICU nurses is to provide caring environment for parents that supports infant development, and physical and emotional closeness (Freeley et al, 2016).*

• Provide social support to parents including all members of the family. **EB:** *Implement parent-to-parent support as an effective way for NICU parents to gain confidence, improve mental health, and prepare for discharge (Hall et al, 2017).*

Multicultural

• Identify cultural beliefs, norms, and values of family's perceptions of infant/child behavior.
• **EB:** *Health care providers need to deliver appropriate care that supports the culture of American Indian mothers and their premature infants (Brooks et al, 2016).*
• Recognize and support positive mother–infant interactive behaviors and be sensitive to cultural and ethnic backgrounds. **CBN:** *A study identified similar and yet different mother–infant interactive behaviors between American Indian and African American mother–infant dyads. It is important for nurses who work with different ethnic groups to know the different interactive behaviors (Brooks et al, 2013).*

Client/Family Teaching and Discharge Planning

▲ Provide information or refer to community-based follow-up programs for preterm/at-risk infants and their families. **EB:** *"Working together, the care teams can help families build bridges from NICU to community" (Purdy, Craig, & Zennah, 2015).* **CEB:** *Request that parents ask the primary health care provider to implement Ages & Stages Questionnaires (ASQ) at regular follow-up visits to monitor developmental milestones (Bricker & Squires, 2009).* **EB:** *Parents of late-term premature infants are recommended to have developmental monitoring for their babies (Tripathni & Dusing, 2015).*
• Educate parents on safe "back-to-sleep" practice before NICU discharge. **EB:** *Studies found educating parents before NICU discharge on safe-to-sleep practices improved parental compliance of supine positioning from 39% to 83% (Gelfer et al, 2013).*
• Educate and demonstrate to parents prior to NICU discharge a variety of development positions and handling that encourages free body movement, hand-to-mouth and eye–hand coordination, visual scanning, and auditory localizing, and to avoid overuse of infant swings/carriers/bouncy seats. **CEB:** *Support parent education using a variety of different positions during play that increase free movement and tummy time and engage promoting pleasurable parent–infant interaction (Waitzman, 2007).*

Home Care

• NICU discharge is a vulnerable time for parents, and nurses have a key role in increasing parents' confidence by listening to fears, answering questions, and giving time to practice new skills before discharge. **EB: "***To make parents confident and prepared for taking their infant home, giving tailored information, guidance and hands-on experience caring for their infant before discharge is crucial" (Aagaard et al, 2015).*

• Encourage parents to use home visitation whenever possible because it enhances neonatal progress and parental support. **EB:** *Home visitation is effective for education and support for infant and families after NICU discharge (Parker, Warmuskerken, & Sinclair, 2015).*
• Encourage families to teach extended family and support persons to recognize and respond appropriately to the infant's behavioral cues; supportive help may be most appreciated doing physical tasks. **CEB:** *A study found families need to feel comfortable with persons supporting them and need to communicate what support they needed (Als et al, 2005).*
• Provide education on positioning and handling that supports optimal infant growth and development. **EB:** *Encourage the importance of tummy time when awake and supervised (National Institute of Child Health and Development, 2017*). **CEB:** *Support developmental play activities (Waitzman, 2007).*
• Home visitors to need to recognize maternal depression resulting from the NICU experience. **EB:** *A study found maternal depression can have a negative effect on infant health and development (Laszewski et al, 2016). Infant mental health services should be infused with at-risk families struggling with a multitude of factors (Tomlin, Deloian, & Woolesen, 2016).* **EB:** *Home visitation by trained paraprofessionals and nurses is cost-effective and can benefit low-resource mothers by improving the language, behavior, and attention of their children (Olds et al, 2014).*
• Provide families with information about community resources, developmental follow-up services, parent-to-parent support programs, and request primary health care providers to follow developmental progress with parent friendly developmental questionnaires. **EB:** *The ASQ can detect severe developmental delay in preterm children regardless of maternal education. Researchers found that successful follow-up programs included mental health services (Tomlin, Veihweg, & Weatherston, 2016). The newly validated "Premature and Young Infant Development Assessment Tool (PYIDAT)" is designed for premature infants from 34 weeks' gestation to 5 months adjusted age, and is a validated tool that offers a comprehensive assessment of premature infants (DeWys et al, 2016).*

Readiness for enhanced organized Infant

behavior

Gail B. Ladwig MSN, RN

NANDA-I

Definition

An integrated pattern of modulation of the physiological and neurobehavioral systems of functioning, which can be strengthened.

Defining Characteristics

Parent expresses desire to enhance cue recognition; parent expresses desire to enhance environmental conditions; parent expresses desire to enhance recognition of infant's self-regulatory behaviors

NOC, NIC, Client Outcomes, Nursing Interventions and *Rationales,* Client/Family Teaching and Discharge Planning and References

Refer to care plans for Disorganized **Infant** behavior and Risk for disorganized **Infant** behavior.

Risk for disorganized Infant behavior

Gail B. Ladwig MSN, RN

NANDA-I

Definition

Susceptible to disintegration in the pattern of modulation of the physiological and neurobehavioral systems of functioning, which may compromise health.

Risk Factors

Caregiver cue misreading; environmental overstimulation; feeding intolerance; inadequate physical environment; infant malnutrition; insufficient caregiver knowledge of behavioral cues; insufficient containment within environment; insufficient environmental sensory stimulation; pain; sensory deprivation; sensory overstimulation

At-Risk Population

Low postconceptual age; prematurity; prenatal exposure to teratogen

Associated Condition

Congenital disorder; genetic disorder; infant illness; immature neurological functioning; impaired infant motor functioning; invasive procedure; infant oral impairment

NOC, NIC, Client Outcomes, Nursing Interventions and *Rationales,* Client/Family Teaching and Discharge Planning, and References

Refer to Disorganized **Infant** behavior.

Risk for Infection

Ruth M. Curchoe RN, BSN, MSN, CIC

NANDA-I

Definition

Susceptible to invasion and multiplication of pathogenic organisms, which may compromise health.

Risk Factors

Alteration in peristalsis; alteration in skin integrity; inadequate vaccination; insufficient knowledge to avoid exposure to pathogens; malnutrition; obesity; smoking; stasis of body fluid

At-Risk Population

Exposure to disease outbreak

Associated Condition

Alteration in pH of secretion; chronic illness; decrease in ciliary action; decrease in hemoglobin; immunosuppression; invasive procedure; leukopenia; premature rupture of amniotic membrane; prolonged rupture of amniotic membrane; suppressed inflammatory response

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Risk Control: Infectious Process; Immune Status

Example NOC Outcome with Indicators

Risk Control: Infectious Process: Identifies signs and symptoms of infection/Maintains a clean environment/Practices infection control strategies: universal precautions, hand sanitization. (Rate the outcome and indicators of **Risk Control: Infectious Process:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Remain free from symptoms of infection during contact with health care providers
- State symptoms of infection before initiating a health care–related procedure
- Demonstrate appropriate care of infection-prone sites within 48 hours of instruction
- Maintain white blood cell count and differential within normal limits within 48

hours of treatment initiation
• Demonstrate appropriate hygienic measures such as handwashing, oral care, and perineal care within 24 hours of instruction

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Immunization/Vaccination Management; Infection Control; Infection Protection

Example NIC Activities—Infection Protection and Control

Wash hands before and after each client contact; Ensure aseptic handling of all intravenous lines; Ensure appropriate wound care technique; Teach client and family members how to avoid infections

Nursing Interventions and *Rationales*

• Implement targeted surveillance for methicillin-resistant *Staphylococcus aureus* (MRSA) (screen clients at risk for MRSA on admission) and other multidrug-resistant organisms (MDROs). **EB:** *Universal screening for MRSA increased screenings and costs but resulted in few additional cases being detected. Where MRSA is endemic, targeted screening remains the most efficient strategy for early identification of MRSA-positive clients (National Strategy for Combating Antibiotic-Resistant Bacteria, 2014).*
• Obtain a travel history from clients presenting to the health care site (e.g., emergency department, clinic). **EB:** *Outbreaks, such as Ebola and avian flu identified in foreign countries, often present with fever and flu-like symptoms (Centers for Disease Control and Prevention [CDC], 2014a).*
• Observe and report as redness, warmth, discharge, and increased body temperature. **CEB:** *Change in mental status, fever, shaking, chills, and hypotension are indicators of sepsis (Perry, Potter, & Ostendurr, 2014).*
• Assess temperature of neutropenic clients; report a single temperature of greater than 100.5°F. **CEB:** *Fever is often the first sign of an infection (National Guideline Clearing House [NGC], 2015; Klastersky et al, 2016).* **CEBN:** *The immunocompromised host may present with a very different clinical picture compared with an immunocompetent host. The progress of the infection may be more rapid, and the infection may quickly become life-threatening; repeat temperature measurement if significant changes occur and report temperature changes from baseline (EB Medicine, 2013).*
• Oral, rectal, tympanic, temporal artery, or axillary thermometers may be used to assess temperature in adults and infants. **EBN:** *The use of axillary in addition to oral, tympanic, and temporal artery temperature measurement is supported (Bland, Conner, & Messenger, 2017) Rectal and oral temperature measurements are more accurate than other methods of temperature measurement, such as temporal or axillary measurement (Bland, Conner, and Messenger, 2017).*
▲ Note and report laboratory values (e.g., white blood cell count and differential, serum protein, serum albumin, cultures). **EBN:** *Although the white blood cell count may be in the normal range, an increased number of immature bands may be present (Versalovic et al, 2011).* **CEBN:** *A neutropenic client with fever represents an absolute medical emergency (EB Medicine, 2013).*
• Assess skin for color, moisture, texture, and turgor (elasticity). Keep accurate, ongoing documentation of changes. **EB:** *A number of instruments have been developed to assess for risk of pressure ulcers, including the Braden, Norton, and Waterlow scales. All three*

scales include items related to activity mobility, nutritional status, incontinence, and cognition (Balzar & Kottner, 2015; Goldberg, 2015).

• Carefully wash and pat dry skin, including skinfold areas. Use hydration and moisturization on all at-risk surfaces. **EBN:** *Moisturizers result in an increase of skin hydration and restoration of the skin barrier function and play a prominent role in the long-term management of atopic dermatitis (Healthbeat, 2016).* **EB:** *Application of moisturizers containing humectants is clearly effective in enhancing skin barrier function (Kottner, Lichterfelo, & Blume-Peytavi, 2013).*

• Refer to care plan for Risk for impaired **Skin** integrity.

▲ Monitor client's vitamin D level. **EB:** *Vitamin D deficiency has been correlated with increased risk and greater severity of infection, particularly of the respiratory tract. Vitamin D influences the body's immune system by influencing the production of endogenous antimicrobial peptides and regulating the inflammatory cascade (Dankers et al, 2016).*

• Refer to care plan Readiness for enhanced **Nutrition** for additional interventions.

• Use strategies to prevent health care–acquired pneumonia, assess lung sounds and sputum color and characteristics, provide daily oral care with chlorhexidine, use sterile technique when suctioning, suction secretions above tracheal tube before suctioning, drain accumulated condensation in ventilator tubing into a fluid trap or other collection device before repositioning the client, assess patency and placement of nasogastric tubes, and elevate the client's head to 30 degrees or higher to prevent gastric reflux of organisms in the lung (Peyrani, 2014). **EB:** *Hospital mortality of ventilated clients who develop ventilator-associated pneumonia (VAP) is 46% compared with 32% of those ventilated clients without VAP. VAP also adds an estimated cost of $40,000 to a typical hospital admission (CDC, 2005, updated 2014).*

• Encourage fluid intake. **EB:** *Fluid intake helps thin secretions and replace fluid lost during fever (Ackley & Ladwig, 2014; Mayo Clinic Staff, 2016).*

• Use appropriate hand hygiene (i.e., handwashing or use of alcohol-based hand rubs). **EBN:** *Meticulous infection prevention precautions are required to prevent health care–associated infection, with particular attention to hand hygiene and standard precautions (CDC, 2011a).* **EB:** *Handwashing is currently the recommended strategy for reducing transmission of* Clostridium difficile. *Alcohol gels do not inactivate* C. difficile *spores (World Health Organization [WHO], 2009; Edmonds et al, 2013).*

• When using an alcohol-based hand rub, apply an ample amount of product to the palm of one hand and rub hands together, covering all surfaces of hands and fingers, until hands are dry. Note that the volume needed to reduce the number of bacteria on hands varies by product. **EBN:** *Adequate hand antisepsis reduces infection rates. The use of alcohol-based hand rubs is particularly effective; in contrast to handwashing, hand rubs kill susceptible bacteria more rapidly and to a greater extent, and are less time-consuming. Also, skin health is better preserved when moisturizers are added (Hass, 2014).*

• Follow standard precautions and wear gloves during any contact with blood, mucous membranes, nonintact skin, or any body substance except sweat. Use goggles and gowns when appropriate. Standard precautions apply to all clients. You must assume all clients are carrying blood-borne pathogens (CDC, 2007). **EBN:** *Hands of health care workers are the most common cause of health care–associated infections (Hass, 2014).*

• Implement respiratory hygiene/cough etiquette. **CEB:** *Providing control measures (tissues and masks) and accessibility to hand hygiene materials reduces risks of transmission of respiratory illness (CDC, 2007).*

• Follow transmission-based precautions for airborne-, droplet-, and contact-transmitted microorganisms:

- ❍ **Airborne:** Isolate the client in a room with monitored negative air pressure, with the room door closed and the client remaining in the room. Always wear appropriate respiratory protection when you enter the room. Limit the movement and transport of the client from the room to essential purposes only. Have the client wear a surgical mask during transport.
- ❍ **Droplet:** Keep the client in a private room, if possible. If not possible, maintain a spatial separation of 3 feet from other beds or visitors. The door may remain open. Wear a surgical mask when you must come within 3 feet of the client. Some hospitals may choose to implement a mask requirement for droplet precautions for anyone entering the room. Limit transport to essential purposes and have the client wear a mask, if possible.
- ❍ **Contact:** Place the client in a private room, if possible, or with someone (cohorting) who has an active infection from the same microorganism. Wear clean, nonsterile gloves when entering the room. When providing care, change gloves after contact with any infective material such as wound drainage. Remove the gloves and clean your hands before leaving the room and take care not to touch any potentially infectious items or surfaces on the way out. Wear a gown if you anticipate your clothing may have substantial contact with the client or other potentially infectious items. Remove the gown before leaving the room. Limit transport of the client to essential purposes and take care that the client does not contact other environmental surfaces along the way. Dedicate the use of noncritical client care equipment to a single client. **CEB:** *If use of common equipment is unavoidable, adequately clean and disinfect equipment before use with other clients (CDC, 2007).*

▲ Use alternatives to indwelling catheters whenever possible (external catheters, incontinence pads, and bladder control techniques). **EB:** *It is estimated that catheter-associated urinary tract infections (CAUTIs) increase length of stay by 0.5 to 1 day and increase costs between $1200 and $4700 (2009 dollars) (Brusch et al, 2015).*

• If a urinary catheter is necessary, follow catheter management practices. All indwelling catheters should be connected to a sterile, closed drainage system (i.e., not broken), except for good clinical reasons. Cleanse the perineum and meatus twice daily using soap and water. **EBN:** *A nurse-driven protocol achieved a 27.7% reduction in the use of catheters (mean dwell time was 3.46 days) and a CAUTI rate of 0.35% (Mori, 2014).* **EB:** *Significant rates of inappropriate urinary catheter use underscore the importance of establishing guidelines and implementing policy for appropriate use of urinary catheters (Agency for Healthcare Quality and Research [AHRQ], 2015).*

• Use evidence-based practices and educate personnel in care of peripheral catheters: use aseptic technique for insertion and care, label insertion sites and all tubing with date and time of insertion, inspect every 8 hours for signs of infection, record, and report. **EB:** *Use of chlorhexidine gluconate for vascular catheter site care reduces catheter-related bloodstream infections and catheter colonization (CDC, 2011b).*

• Use sterile technique wherever there is a loss of skin integrity. **EBN:** *Skin and soft tissue infections arise when skin integrity is broken by treatments associated with trauma, surgery, burns, and so forth (Apisaranthanara & Mundy, 2014).*

• Ensure the client's appropriate hygienic care with handwashing; bathing; oral care; and hair, nail, and perineal care performed by either the nurse or the client. **CEBN:** *Daily showers or baths can help to reduce the number of bacteria on the client's skin. The oral cavity is a common site for infection (Perry, Potter, & Ostendurr, 2014).*

• Recommend responsible use of antibiotics; use antibiotics sparingly. **EB:** *Use and*

misuse of antibiotics diminishes their therapeutic benefit and facilitates the development of MDROs and C. difficile*-associated disease, and increases health care costs. Antibiotic stewardship is essential in reducing current and future resistance in bacteria (CDC, 2017).*
EB: *The rate of damage to the fallopian tubes increases with subsequent pelvic inflammatory disease episodes, from 34% for the first episode to 54% in women with second and third episodes (Puscheck, Scott-Lucidi, & Woodard, 2013).*

Pediatric

Note: Many of the preceding interventions are appropriate for the pediatric client.

- Follow meticulous hand hygiene when working with children. **EB:** *Keep nails short; prohibit false fingernails, and limit wearing jewelry because it interferes with effective hand hygiene (AAPeds, 2016). Parents recognize the importance of hand hygiene, but in a study only 67% would definitely remind health care workers of its importance (Buser et al, 2012; James, Nelson, & Ashwill, 2014).*
- Cluster nursing procedures to decrease number of contacts with infants, allowing time for appropriate hand hygiene. **EBN:** *Audit programs to track compliance with hand hygiene identified a drop in the incidence of health care–associated infections in very low-birth-weight infants in the neonatal intensive care unit (Mendicino, Morrell, & Hernandez, 2014).*
- Avoid the prophylactic use of topical cream in premature infants. **CEB:** *Prophylactic application of topical ointment increases the risk of coagulase-negative staphylococcal infection and any health care–acquired infection. A trend toward increased risk of any bacterial infection was noted in infants treated prophylactically (Ackley & Ladwig, 2014).*
- Encourage early enteral feeding with human milk. *Human milk enhances immune defenses of the infant (Praveen et al, 2015).*
- ▲ Monitor recurrent antibiotic use in children.
- Instruct parents on appropriate indicators for medical visits and the risks associated with overuse of antibiotics. **EB:** *Guidelines addressing treatment of asthma in children state that antibiotics should not be used as part of chronic asthma therapy or for acute exacerbations, with the exception of clients with comorbid bacterial infections such as pneumonia or sinusitis (Leung, Szefler, & Akdis, 2015).*

Geriatric

- ▲ Suspect pneumonia when the client has symptoms of lethargy or confusion. Assess response to treatment, especially antibiotic therapy. **EB:** *Leading causes of illness and death among older adults are both community and health care–associated respiratory infections. In long-term care facilities, the risk for pneumonia ranges from 0.3 to 2.5 events per 1000 resident-days (Montoya & Moody, 2011).*
- Most clients develop health care–associated pneumonia (HCAP) by either aspirating contaminated substances or inhaling airborne particles. Refer to care plan for Risk for **Aspiration.**
- ▲ *Carefully screen older women with incontinence for urinary tract infections.* **CEB:** *Consider alternatives to chronic indwelling catheters, such as intermittent catheterization. CAUTI has been associated with increased morbidity, mortality, hospital cost, and length of stay (CDC, 2009).*
- Observe and report if the client has a low-grade fever or new onset of confusion. **EB:** *Those caring for older clients must be alerted to the potential presence of infection when even low-grade temperature elevations appear for short periods (Arinzon et al, 2012).*
- Recommend that the geriatric client receive an annual influenza immunization and

one-time pneumococcal vaccine. **EB:** *Immunization against influenza is an effective intervention that reduces serologically confirmed cases (CDC, 2014b,c).*
• Recognize that chronically ill geriatric clients have an increased susceptibility to *C. difficile* infection; practice meticulous hand hygiene and monitor antibiotic response to antibiotics. **EB:** *The incidence of* C. difficile *illness (CDI) is increasing with the greatest impact in persons older than 65 years. More than 90% of deaths from CDI have occurred in this population (CDC, 2012; Kelly & LaMont, 2013; CDC, 2017).*

Home Care

• Adapt the previously mentioned interventions for home care as needed.
• Assess and treat wounds in the home. **EBN:** *Promotion of wound healing is a nursing priority. Specific wound care regimens administered depend on the type, size, and location of the wound and overall treatment goals (Colwell, 2013).*
• Review standards for surveillance of infections in home care. **EB:** *Challenges to surveillance in the home care setting include loss of clients to follow-up, lack of laboratory data, and difficulty in obtaining accurate numerator and denominator data (Yeung, 2014).*
• Maintain infection-prevention policies. **EBN:** *The complexity of clients' conditions is frequently high because the incidence of chronic disease and MDROs is increasing (Yeung, 2014).*
• Refer for nutritional evaluation; implement dietary changes to support recovery and maintain health. **EB:** *Medical nutrition therapy (MNT) is important in preventing diabetes; managing existing diabetes; and preventing, or at least slowing, the rate of development of diabetes complications. Therefore it is important at all levels of diabetes prevention. MNT is also an integral component of diabetes self-management education (or training) Administration on Aging [AOA], 2012).*

Client/Family Teaching and Discharge Planning

• Teach the client risk factors contributing to surgical wound infection. **EB:** *The risk of infection is influenced by characteristics of the client such as age, obesity, and nutritional status (Murphy, 2014).*
• Teach the client and family the importance of hand hygiene in preventing postoperative infections. **EB:** *Two-thirds of wound infections occur after discharge. Using good hand hygiene practices is effective for preventing these infections (CDC, 2011a).*
▲ Encourage high-risk persons, including health care workers, to get vaccinated (CDC, 2011c).
▲ Influenza: Teach symptoms of influenza and the importance of vaccination for influenza. **EB:** *Everyone 6 months of age and older should get the flu vaccine. Seasonal flu vaccine is effective and has a very good safety track record (CDC, 2014b,c).* Teach the client and family how to take a temperature. Encourage the family to take the client's temperature between 4 p.m. and 10 p.m. at least once daily. **CEBN:** *The lowest body temperature usually occurs between 4 a.m. and 5 a.m., with highest readings recorded between 4 p.m. and 8 p.m. (Peate & Wild, 2012).*

Risk for surgical site Infection

Teri Hulett RN, BSN, CIC, FAPIC

NANDA-I

Definition

Susceptible to invasion of pathogenic organisms at surgical site, which may compromise health.

Risk Factors

Alcoholism, Obesity, Smoking

At-Risk Population

Cold temperature of operating room; excessive number of personnel present during the surgical procedure; increased environmental exposure to pathogens; sub-optimal American Society of Anesthesiologists (ASA) physical health status score; surgical wound contamination

Associated Condition

Comorbidity; Diabetes mellitus; duration of surgery; hypertension; immunosuppression; inadequate antibiotic prophylaxis; ineffective antibiotic prophylaxis; infections at other surgical sites; invasive procedure; post-traumatic osteoarthritis; Rheumatoid arthritis; type of anesthesia; type of surgical procedure; use of implants and/or prostheses

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Risk Control: Infectious Process, Immune Status

Example NOC Outcome with Indicators

Risk Control: Infectious Process. Personal actions to understand, prevent, eliminate, or reduce the threat of acquiring an infection as evidenced by client demonstrating the following indicators: Identifies risk factors for infection/Acknowledges personal risk factors for infection/Acknowledges behaviors associated with risk for infection/Monitors personal behaviors for factors associated with infection/Maintains a clean environment/Practices hand sanitization. (Rate the outcome and indicators of **Risk Control: Infectious Process:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Remain free from symptoms of surgical site infections (SSIs)
- Identify personal risk factors associated with increased SSI risk
- Modify personal behaviors that increase SSI risk
- Demonstrate appropriate hygienic practices to reduce infection risk such as handwashing

NIC (Nursing Interventions Classification)

Infection Control, Infection Control: Intraoperative, Infection Protection, Teaching: Individual, Preoperative

Example NIC—Risk for Surgical Site Infection

Verify that prophylactic antibiotics have been ordered and administered as appropriate; Monitor and maintain client normothermia (temperature of 35.5°C [95.9°F] or above) during the perioperative period

Nursing Interventions and *Rationales*

▲ The number of surgical procedures performed in the United States continues to rise, and surgical clients often have comorbidities that increase the complexity. It is estimated that approximately half of SSIs are deemed preventable using evidence-based strategies (World Health Organization [WHO], 2017). SSIs are a complication of surgical care and are associated with significant morbidity, mortality, and cost (Preas, O'Hara, & Thom, 2017).

▲ Optimizing the client's medical condition prior to surgery and eliminating or even diminishing modifiable risk factors for infection can lower the risk of SSIs (Hutzler & Williams, 2017). **EB:** *Modifiable risk factors include current or history of orthopedic infection, rheumatoid arthritis, poor oral health, urinary tract infection, obesity, methicillin-resistant* Staphylococcus aureus *(MRSA), preoperative and anticipated postoperative anemia,*

smoking, malnutrition, diabetes, and HIV (Hutzler & Williams, 2017). The American College of Surgeons (ACS) identifies additional modifiable risk factors as poor glycemic control and diabetic status, dyspnea, alcohol and smoking history, preoperative albumin level (<3.5 mg/dL), total bilirubin >1.0 mg/dL, obesity, and immunosuppression (Ban et al, 2016).

▲ SSI prevention, known as surgical care bundles, are evidence-based interventions that when implemented together can reduce the risk of infection. There are different surgical care bundles for specific high-risk surgical procedures, for example, colorectal surgery bundle, pediatric spinal surgery bundle, total joint arthroplasty surgery bundle, and cardiothoracic surgery bundle. **EB:** *Aspects of each surgical care bundle that are universal for all surgical procedures include: prehospital preoperative bathing, smoking cessation, and glucose control. Hospital-focused bundle interventions include perioperative blood glucose monitoring, surgical site hair-removal technique, surgical site skin preparation, surgical hand scrub, antibiotic prophylaxis, intraoperative normothermia, and supplemental oxygen delivery for patients undergoing general anesthesia (intubated patients) (Ban et al, 2016).*

▲ SSIs can occur because of either client-related (endogenous) or procedure-related (exogenous) risk factors. Risk factors are further stratified into preoperative, intraoperative, and postoperative risk.

• Endogenous client-related risk factors: **EBN:** *Review client history with client prior to surgical procedure to identify modifiable risk factors that can be addressed preoperatively (Smith & Dahlen, 2013).*

Compromised Host Defenses

• Age: Extremes of ages and advanced age increase client risk. **EB:** *Relationship to increased risk of SSI may be secondary to comorbidities or immunosenescence associated with age (Smith & Dahlen, 2013; Singh, Singla, & Chaudhary, 2014).*

• Wound: A wound classification scoring system is used to identify the degree of surgical site skin integrity at the time of surgery. Assess and document skin integrity during the preoperative period to identify classification of surgical site. **EB:** The Centers for Disease Control and Prevention (CDC) recommends assessing surgical wounds and determining the probability of SSI by using a classification that consists of four types of surgical wounds: clean (sterile body site), clean-contaminated, contaminated, and dirty (heavily contaminated site) wounds (Smith & Dahlen, 2013). **EB:** The method of wound classification has been adopted by the ACS and has been effectively used for more than 40 years to stratify the client's risk for SSI. The traditional wound classification system of categorizing procedures into risk groups is based on the degree of microbial contamination (Allen, Apisarnthanarak, & Archer, 2017).

• Smoking: The nicotine in tobacco products results in microvascular vasoconstriction, in addition to tissue hypoxia, which can contribute to the development of SSI (Smith & Dahlen, 2013). **EB:** The increased risk of SSI in clients who smoke is partially related to vasoconstriction of vessels in the surgical bed, which leads to tissue hypovolemia and hypoxia. Poor tissue perfusion affects the transport of nutrients and alters the immune response, which affects healing (Ban et al, 2016).

▲ Assess client's smoking status and offer smoking cessation information to the receptive client. Seek nicotine patch order for client use during hospital admission.

▲ Educate the client on smoking risks using the CDC Fact Sheet on Health Effects of Cigarette Smoking (CDC, 2018).

• Nutrition status: Assess the client's nutrition status. Preoperative risk factors include albumin <3.5 mg/dL or total bilirubin >1.0 mg/dL (Ban et al, 2016). Malnutrition leads to less competent immune response and increased risk of acquiring infections (Singh, Singla, & Chaudhary, 2014). **EBN:** *Clients who are malnourished and have low albumin levels are more likely to develop SSIs (Smith & Dahlen, 2013). Review preoperative laboratory tests and monitor postoperative laboratory values to assess for malnourishment. Provide nutritional consult and support as needed. Anticipate the malnourished client to receive total parenteral nutrition (TPN) in addition to oral nutrition during the initial postoperative period. Consider the administration of oral nutritional supplements (i.e., protein shakes, high-protein snacks) as recommended by the registered dietician after dietary consult.*
• Immunocompromised/immunosuppression: Clients who are immunocompromised or who have immunosuppression are at increased risk of developing infection because of their weakened immune system and inability to mount a defense against pathogenic organisms. Clients who may be immunocompromised or immunosuppressed are clients receiving cancer treatment, organ transplant recipients, clients taking steroids, and clients with HIV. **EBN:** *Determine the use of chronic medications such as steroids and immunosuppressives. These medications have been shown to increase SSI rates and negatively affect wound healing. There is no recommendation to taper or discontinue systemic steroid use (when medically permissible) before elective surgery (Smith & Dahlen, 2013).*
• Review the client's medical history and current medications. Medications that compromise the client's immune response may increase the risk of SSI.
• Diabetes mellitus: Monitor blood glucose levels with the goal to maintain normoglycemia in the perioperative period. Educate the client of the increased risk for SSI with episodes of hyperglycemia. When available, coordinate referral to a diabetic educator as part of the discharge education. **EB:** *Clients with diabetes have a 2.7-fold increase in the risk of developing a wound infection. Postoperative hyperglycemia and previously undiagnosed diabetes are associated with SSIs among cardiothoracic, general, and vascular surgery patients. Hyperglycemia in the postoperative period was identified as an independent risk factor for developing infection that correlated with a 30% increased risk of infection for every 40 mg/dL increase in postoperative glucose level. Improved glycemic management can restore white blood cell function and reduce risk of infection (Shaw, Saleem, & Gahtan, 2014).*
• Preexisting infection: Be aware of all preoperative laboratory work, positive cultures, and actions taken to treat the infection (i.e., was the client started on oral antibiotics). **EBN:** *Remote infections should be identified and treated following evidence-based guidelines prior to surgical procedure (Smith & Dahlen, 2013).*
• Obesity: Obesity is defined as a body mass index (BMI) >30 kg/m^2. Obese clients are at a significant risk factor for SSI, more surgical blood loss, and experience a longer operation time. **EB:** *Obese clients have excessive subcutaneous fat tissue, which predisposes these clients to impaired healing, low regional perfusion, and low oxygen tension at the surgical site. Longer operation times and increased blood loss >1 L are significant predictors of postoperative wound infections. The obese client is also likely to have more comorbidities, such as diabetes, than nonobese clients, increasing the risk of SSI (Tjeertes et al, 2015). Provide discharge teaching for signs and symptoms of poor wound healing and SSI.*

Procedure-Related Risk Factors—Exogenous

• Observe clients identified as being at increased risk for SSI because of modifiable

risk factors for signs and/or symptoms of postoperative SSI (Smith & Dahlen, 2013).
• Extended procedure time. **EB:** Prolonged operations that increase the length of time that tissues are exposed increases the risk of exogenous contamination of the surgical site (Smith & Dahlen, 2013; Singh, Singla, & Chaudhary, 2014; Ban et al, 2016).
• Estimated blood loss greater than 1 L requiring blood transfusion increases the risk of SSI **EB:** *Blood transfusions increase the risk of SSI by decreasing macrophage function (Anderson et al, 2014). The use of allogenic(donor) blood transfusions is associated with increased length of stay and induces immunomodulation that can lead to increased risk for infection at the surgical site (Huntzler & William, 2017).*
• Suboptimal timing of prophylactic antibiotic places the client at increased risk of SSI. **EB:** Administer preoperative prophylactic antimicrobial agent(s) as prescribed (*Berríos-Torres et al, 2017). Surgical antibiotic prophylaxis (SAP) should be administered within 1 hour before incision or within 2 hours for vancomycin or fluoroquinolones. This allows for maximal antibiotic concentration circulating in the blood serum and tissue at the time of surgical incision (Ban et al, 2016). Evidence shows that the administration of SAP after the incision causes a significant increase of SSI risk compared with administration of the SAP prior to incision (WHO, 2016).*
• Preoperative infections place the client at increased risk of SSI prior to elective surgery. **EB:** Identify and treat infections (i.e., urinary tract infection) prior to surgical procedure. Do not routinely treat urinary tract colonization or contamination in the absence of clinical urinary tract infection symptoms (urgency, costovertebral angle [CVA] pain, flank pain, pain with urination, and fever) (Anderson et al, 2014).
• Preoperative interventions: Establish a protocol for procedure-specific preoperative testing to detect medical conditions that increase the risk of SSI. The protocol should focus on nutritional counseling, smoking cessation, preadmission infections, and reconciling mediations with adjustments prior to surgery as indicated (Anderson et al, 2014).
    - ❍ Identify high-risk clients: Clients at high risk for developing SSIs have diabetics, history of transplant, are receiving chemotherapy, are immunosuppressed and immunocompromised, are elderly, have poor dentition, are obese, and are malnourished. Clients having a high-risk procedure with an extended surgical procedure time (i.e., cardiac surgery, joint replacement, major abdominal surgery) are at increased risk of SSI. **EB:** *Identifying high-risk patients through screening and electronic medical record alerts should be used to inform all members of the perioperative team of the client's high-risk condition(s) (Anderson et al, 2014).*
    - ❍ Maintain glycemic control for both diabetic and nondiabetic clients. **EB:** *Elevated blood glucose levels >200 mg/dl cause the release of proinflammatory cytokines that depress the immune system, increasing susceptibility to SSIs (Singh, Singla, & Chaudhary, 2014). Hyperglycemia in the immediate preoperative period is associated with an increased risk of SSI (Ban et al, 2016).*
    - ❍ Staphylococcus aureus (SA) is the most common pathogen causing SSIs. Colonization with SA, primarily in the nares, occurs in roughly one in four persons and increases the risk of SSI by 2- to 14-fold. Perform SA intranasal decolonization by using cotton-tipped applicators to apply a 2% mupirocin ointment in each nostril for up to 5 days prior to surgery, when appropriate and according to evidence-based guidelines (Bratzler et al, 2013). **EB:** *Screen for SA (methicillin-sensitive SA [MSSA] and MRSA) colonization and decolonize surgical patients prior to high-risk procedures, including some orthopedic and cardiothoracic procedures (Anderson et al, 2014).*

- ❍ Provide education on preoperative bathing with soap (antimicrobial or nonantimicrobial) or an antiseptic agent on at least the night before and morning of the day of surgical intervention. **EB:** *It is good clinical practice for the client to bathe or shower before surgery to ensure that the skin is as clean as possible and to reduce the bacterial load, especially at the site of incision (WHO, 2016). Instruct the client to bathe, at a minimum, the night before and morning of the surgical procedure using liquid soap, clean washcloth, and clean towel each time. Instruct the client to wear freshly laundered pajamas after showering the night before the surgical procedure, and freshly laundered clothes the morning of the procedure. This process of using liquid soap and clean washcloths, towels, and clothes prevents recontamination with shed epithelial cells from previously used bar soap, washcloths/towels, and clothes.*
- ❍ Address preexisting dental and nutritional status. **EBN:** *Preoperative dental screenings are needed to evaluate for the presence of tooth decay, inflammatory gum disease/gingivitis, periodontitis, or dental abscesses, which lead to seeding of bacteria and a deep joint infection (Smith & Dahlen, 2013). Educate the client on the need for good oral hygiene to decrease the risk of developing SSI. Provide the client with oral hygiene products while in the hospital. Perform oral hygiene for the client if unable to perform independently.*
- ❍ Nutrition consult as needed.
- ❍ Prepare the surgical site using an alcohol-based antiseptic agent unless contraindicated to reduce SSI risk. **EB:** *Alcohol-based antiseptic solutions for surgical site skin preparation are more effective compared with aqueous solutions in reducing SSIs (WHO, 2016; Berríos-Torres et al, 2017).* **EB:** *Overall, there is evidence that alcohol-based preparations are more effective in reducing SSIs than aqueous preparations and should be used unless contraindications exist (Ban et al, 2016).*
- ❍ Proper hair removal: When hair removal at the operative site is necessary, removal should be done using clippers. **EB:** *Do not remove hair at the operative site unless the presence of hair will interfere with the operation. Do not use razors. If hair removal is necessary, remove hair outside the operating room using clippers or a depilatory agent (Anderson et al, 2014). Shaving causes microscopic cuts and abrasions, resulting in disruption of the skin's barrier defense against microorganisms (Ban et al, 2016).*

• If possible, educate the client preoperatively on the risk of shaving the surgical site, or the area near in which the surgical incision will be, because of the risk for microscopic cuts and abrasions. These cuts and abrasions increase the risk of developing an SSI. For example, for breast surgery, instruct the client not to shave underarms because the underarm is potentially in close proximity to the surgical site. Another example is instructing the client having a total knee replacement not to shave the leg involved in the surgery.

• Intraoperative interventions:

- ❍ Maintain glycemic control: **EB:** *Implement perioperative glycemic control and use blood glucose target levels <200 mg/dL in diabetic and nondiabetic clients (Berríos-Torres et al, 2017). Short-term glucose control can be more impactful in decreasing SSIs than long-term control of hemoglobin (Hgb) A1C (Ban et al, 2016).*
- ❍ Maintain normothermia (temperature of 35.5°C [95.9°F] or above) during the perioperative period in surgical clients who have an anesthesia duration of at least 60 minutes (Anderson et al, 2014). WHO defines hypothermia as a core temperature <36°C (WHO, 2016). **EB:** *Hypothermia can trigger*

subcutaneous vasoconstriction and subsequent tissue hypoxia and increase blood loss that may lead to wound hematomas or need for transfusion, both of which can increase SSI rates (Anderson et al, 2014).

- ❍ Provide supplemental oxygenation, during surgery for intubated clients and in the immediate postoperative period for 2 to 6 hours via a nonrebreathing mask for procedures performed under general anesthesia to ensure a Hgb saturation of >95% is maintained. **EB:** Studies have found that perioperative hyperoxygenation led to a 25% decrease in SSIs (Anderson et al, 2014; WHO, 2016). **EB:** *For patients with normal pulmonary function undergoing general anesthesia with endotracheal intubation, administer increased FiO_2 intraoperatively and postextubation in the immediate postoperative period (Berríos-Torres et al, 2017). The administration of supplemental oxygen is recommended in the immediate postoperative period after surgery performed under general anesthesia (Ban et al, 2016).*

- Postoperative interventions:
  - ❍ Discharge instructions: Teach the client postoperative self-care after discharge. Provide written instructions that include information on how and when to contact the provider, date and time for the scheduled follow-up visit, and signs and symptoms of infection. **EB:** *Educational materials should be provided in multiple languages based on the population served (Anderson et al, 2014).*
  - ❍ Wound care: Wound care instructions will be based on the type of surgical wound closure. **EB:** *Protect primarily closed incisions with a sterile dressing for 24 to 48 hours postoperatively (Berríos-Torres et al, 2017). Instruct the client to keep their surgical wound clean and dry. Teach the client signs and symptoms that would indicate an SSI, such as fever, redness, drainage, swelling, pain, and foul odor at the surgical site. Stress to the client and family that any of these signs and symptoms should be promptly reported to their provider. Assess whether the client and family know how to read a thermometer and provide instructions as necessary. Provide written wound care instructions on the prevention of SSI.*
  - ❍ Nutrition follow-up: For the malnourished and obese clients, provide written dietary instructions by the registered dietician, if appropriate. Encourage a diet that supports wound healing (high protein) and glycemic control. If appropriate, provide written information on community nutrition support group options and contact information.
  - ❍ Bathing/showering instructions: Review instructions with client and family on timing to shower and if/when the client can take a bath. Explain to the client that taking a bath is generally discouraged, at a minimum, for the first week after surgery. Submerging a fresh surgical wound in warm bath water and allowing it to soak is not advised because this provides an environment that potentially exposes the surgical wound to pathogenic organisms, increasing the risk for surgical wound infection.
  - ❍ Physical therapy (PT): For clients prescribed PT after discharge, review options to access services, provide contact phone numbers to call and schedule therapy, and review options for transportation to PT appointments (e.g., spouse, family, friend, senior center transport, cab, Uber, Lyft). Work with the discharge coordinator for client assistance with transport options as needed.
  - ❍ Medications: Review discharge medication prescription(s). Provide written

instructions on medication(s) ordered, how often to take them, and side effects of the prescribed medication(s). Reinforce with client and family that client should not be driving if taking prescription narcotic medications. Review with client and family pain relief expectations, explaining that 100% postoperative pain relief is not realistic, but adequate pain relief should allow the client to function, to ambulate, and to perform activities of daily living (ADLs) with minimal pain.

Pediatric

SSI prevention measures deemed effective in adults are also indicated in the pediatric surgical population (Berríos-Torres et al, 2017).

Geriatric

- The most common cause of postoperative complication in the frail elderly is delirium (Ersan & Schwer, 2015). *Delirium will affect the ability to provide postoperative education in this population.*
- For the frail, elder client who lived independently in a private home prior to surgical procedure, work with the discharge coordinator to assess appropriate client placement in the immediate postoperative period. Explore independent living, acute rehabilitation facility, or skilled nursing facility.
- For the cognitively impaired client being discharged back to independent living (private home or home with a family member), identify a key contact person who will participate in discharge education. Assess for any need of community services (food assistance, meal prep, transport, home health care, etc.) at time of discharge.
- Nutritional deficiencies can be common in elderly clients. Monitor laboratory tests; an albumin <3.2 mg/dL and a cholesterol level of <160mg/dL in the frail elderly are indicators for increased mortality. A BMI of <20 kg/m^2 is a marker for increased risk of wound healing. A dietary consult should be initiated, and nutritional supplements should be provided (Ersan & Schwer. 2015).
- As part of the discharge process, ask the client how they will be obtaining groceries: Will they be cooking? Will they need assistance with meal prep? Do they have someone (friend or family member) who can come into the home to assist with cooking? Does the client need to have a food service (i.e., Meals on Wheels) set up for the immediate postdischarge period? Refer client to community services as necessary.

Multicultural

- Consider race and ethnicity as a key factor when developing the client's plan of care. **EBN:** *Nurses should use culturally competent verbal and nonverbal communication skills to identify clients' values, beliefs, practices, perceptions, and unique health care needs. Effective cultural communication demonstrates respect, dignity, and the preservation of human rights.*
- In the case of a language barrier, use a qualified interpreter rather than family members, unless as a last resort, to communicate with the non–English-speaking client. The use of family members to translate health care-specific information may risk patient privacy issues and interpretation bias. Nurses must be attentive to nonverbal cues, such as effective listening, attentive body language, and use of eye contact.
- Cultural nonverbal communication may also include values of modesty, touch, silence, and provider gender (Douglas et al, 2014). Identify the need for an interpreter

at time of admission and schedule an interpreter to be available, either by phone or in person, for discussions with providers and for education sessions.
• Identify and accommodate the client that prefers same-gender providers. Effective communication may be affected in the client assigned opposite-gender caregivers, which may negatively affect recovery.

Home Care

• Previously listed interventions appropriately pertain to the home care.
• Coordinate with discharge planner, as necessary, for assessment of the client's home care situation that suggests potential safety and mobility concerns.
• Clients discharged back to independent living with new use of walker, crutches, wheelchair, oxygen, and so forth, should have egress access evaluated, and bathing/showering options and potential need for grab bars.

Risk for Injury

Julianne E. Doubet BSN, RN, EMT-B

NANDA-I

Definition

Susceptible to physical damage due to environmental conditions interacting with the individual's adaptive and defensive resources, which may compromise health.

Risk Factors

Compromised nutritional source; exposure to pathogen; exposure to toxic chemical; immunization level with community; insufficient knowledge of modifiable factors; malnutrition; nosocomial agent; physical barrier; unsafe mode of transport

At-Risk Population

Extremes of age; impaired primary defense mechanisms

Associated Condition

Abnormal blood profile; alteration in cognitive functioning; alteration in psychomotor functioning; alteration in sensation; autoimmune dysfunction; biochemical dysfunction; effector dysfunction; immune dysfunction; sensory integration dysfunction; tissue hypoxia

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Personal Safety Behavior; Risk Control; Safe Home Environment; Knowledge: Fall Prevention

Example NOC Outcome with Indicators

Risk Control as evidenced by the following indicators: Monitors environmental risk factors/Develops effective risk control strategies/Follows selected risk control strategies. (Rate the outcome and indicators of **Risk Control:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Remain free of injuries
- Explain methods to prevent injuries
- Demonstrate behaviors that decrease the risk for injury

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Health Education; Environmental Management; Fall Prevention

Example NIC Activities—Health Education

Identify internal or external factors that may enhance or reduce motivation for healthy behavior; Determine current health knowledge and lifestyle behaviors of individual, family, or target group

Nursing Interventions and *Rationales*

Prevent iatrogenic harm to the hospitalized client by following the National Patient Safety goals.

- Accuracy of Client Identification:
  - ❍ Use at least two methods (e.g., client's name and medical record number or birth date) to identify the client on initial entrance to a client's room and before administering medications, blood products, treatments, or procedures.
  - ❍ Before beginning any invasive or surgical procedure, have a final verification to confirm the correct client, the correct procedure, and the correct site for the procedure using active communication techniques.
  - ❍ Label containers used for blood and other specimens in the presence of the client.
- Effectiveness of Communication Among Care Staff:
  - ❍ Verbal or telephone orders should be written and then read back for verification to the individual giving the order. Avoid verbal or telephone orders whenever possible.
  - ❍ Standardize use of abbreviations, acronyms, symbols, and dose designations that are used in the institution.
  - ❍ Ensure that critical test results and values are recorded and reported in a timely manner.
  - ❍ Use a standardized approach of "handing off" communications, including opportunities to ask and answer questions.
  - ❍ Use only approved abbreviations.
  - ❍ Staff should always wear hospital nametags.
- Medication Safety:
  - ❍ Standardize and limit the number of drug concentrations used by the institution (e.g., concentrations of medications such as morphine in client-controlled analgesia pumps).
  - ❍ Label all medications and medication containers (e.g., syringes, medication cups, or other solutions on or off the surgical field).
  - ❍ Identify all of the client's current medications on admission to a health care facility, and ensure that all health care staff has access to the information.
  - ❍ Ensure that accurate medicine information is sent with the client throughout their care.
  - ❍ Reconcile all medication at admission and discharge, and provide list to the client.
  - ❍ Improve the effectiveness of alarm systems in the clinical area.
  - ❍ Standardize a list of medications that look alike or sound alike. This list needs to be updated yearly.
  - ❍ Identify and take extra care with clients who are on anticoagulants.
- Infection Control:
  - ❍ Reduce the risk of infections by following Centers for Disease Control and Prevention (CDC, 2017) hand hygiene guidelines.
  - ❍ Document clearly when clients obtain injuries or die of infectious disease.

    - ❍ Use proven guidelines to prevent infections that are difficult to treat.
    - ❍ Use proven guidelines to prevent infection of the blood from central lines.
    - ❍ Use safe practices to treat the surgical site of the client.
    - ❍ Use proven guidelines to prevent catheter-associated urinary tract infections.
- Fall Prevention:
    - ❍ Evaluate all clients for fall risk daily and take appropriate actions to prevent falls.
- Client Involvement in Care:
    - ❍ Educate the client and family on how to recognize and report concerns about safety issues.
- Identify Clients with Safety Risks:
    - ❍ Identify which clients are at risk for harming themselves.
- Identify Clients Who Are Susceptible to Changes in Health Status:
    - ❍ Educate staff on how to recognize changes in client condition, how to respond quickly, and how to alert specially trained staff to intervene if needed.
    - ❍ Prevent errors in surgery by following established protocols. Update protocols yearly.
    - ❍ Standardize steps to educate staff so documents for surgery are ready before surgery.
    - ❍ Educate staff to mark the body part scheduled for surgery and engage the client in this process as well.

These actions have been shown to increase client safety and are required actions for accreditation by The Joint Commission (2017).

- See care plan for Risk for **Falls.**
- Avoid use of physical and chemical restraints, if at all possible. Restraint free is now the standard of care for hospitals and long-term care facilities. Obtain a health care provider's order if restraints are necessary. **EBN:** *The use of restraints has been associated with serious patient injuries and at present there is no satisfactory evidence to confirm that the use of restraints is beneficial in reducing falls and preventing injuries (Park & Tang, 2007; Rahn et al, 2017).* **EBN:** *Along with physical restraints, other nonpharmaceutical measures can be used to promote safe mobility in client-centered care (Gulpers et al, 2013).*
- Consider providing individualized music of the client's choice if a client is agitated. **EBN:** *Blackburn and Bradshaw (2014) found that music therapy is not only promising in the reduction of agitation in older adults with dementia, but it also helps lessen anxiety and depression, while seemingly improving cognitive function.*
- Review drug profile for potential side effects and interactions that may increase risk of injury. **EB:** *The use of polypharmacy, as prescribed to older adults, is the most significant factor in risk injury in those same adults (Scott et al, 2014).*
- Provide a safe environment:
    - ❍ Use one-fourth– to one-half–length side rails only, and maintain bed in a low position. Ensure that wheels are locked on bed and commode. Keep dim light in room at night.
    - ❍ Remove all possible hazards in environment such as razors, medications, room clutter, wet floors, and matches.
- Place an "at risk for injury" client in a room that is near the nurse's station. **EBN:** *According to Wang et al (2014), when clients' safety culture is improved, there is a decrease in*

client adverse events.

- ❍ If the client has a new onset of confusion (delirium), refer to the care plan for Acute **Confusion.** If the client has chronic confusion, see the care plan for Chronic **Confusion.**

• Involve family in helping to provide a culture of safety. **EBN:** *A client-centered approach to care should include the family, in both planning and decision-making (Wrobleski et al, 2014).*

• Refer the client for physical therapy for strengthening as needed.

▲ Use nonphysical forms of behavior management for the agitated psychotic client. **EB:** *Okumura, Togo, and Fujita (2014) stated that there is a call for approaches to client agitation that focus on psychosocial interventions, antipsychotic withdrawal, and the need to moderate the overall incidence of antipsychotics use.*

Pediatric

• Teach parents the need for close supervision of young children playing near water. **EB:** *Semple-Hess and Campwala (2014) stated that drowning and submersion injuries are one of the most common, yet avoidable, causes of childhood mortality and morbidity.*

• If the child has an underlying medical problem that puts him or her at risk for drowning, it is recommended that the child be given showers, not tub baths. No unsupervised swimming is ever allowed. **EB:** *Caregivers should understand the necessity for constant supervision while children are bathing, especially if the child has an underlying condition such as epilepsy (Bamber et al, 2014).*

• Assess the client's socioeconomic status because financial hardship may correlate with increased rates of injury. **EB:** *According to Anderson, Pomerantz, and Gittelman (2014), there may be a relationship between intentional injury rates and those children in families living below poverty level and experiencing financial hardship.*

• Never leave young children unsupervised around cooking or open flames. **EB:** *Risks for children's thermal injuries can be modified by caregiver awareness of hazards (Jamshidi & Sato, 2013).*

• Teach parents and children the need to maintain safety for the exercising child, including wearing helmets when biking. **EB:** *Parents should be educated in the use of bicycle helmets for their children and set a good example by wearing helmets themselves (Baeseman & Corden, 2014).* **EB:** *It has been proven that the use of bicycle helmets helps prevent or reduce severe head injuries in bicycle riders (Basch et al, 2014).*

• Encourage parents to insist on safety precautions in all phases of participation sports involving children. **EB:** *Parents and youth athletes should be aware that there are increased risks of injury caused by sports specialization and the intense volume of participation the child is subject to when involved in many sports (Post et al, 2017).*

• Provide parents of children with traumatic brain injury with written instruction and emergency phone numbers. Ensure that instructions are understood before the child is discharged from a health care setting. Instruct parents to observe for the following symptoms: nausea, mild headache, dizziness, irritability, lethargy, poor concentration, loss of appetite, and insomnia.

▲ **EBN:** *The nurse plays a pivotal part in educating the patient, family, school, and perhaps coaches on the necessity of lifestyle modifications based on the patient's condition (Gillooly, 2016).*

• Teach both parents and children the need for gun safety; refer to hunting safety courses. **EBN:** *Barton and Kologi (2014), in their study, found that thousands of children are killed or injured every year in the United States because of access to loaded and not safely*

stored firearms.

• Educate parents regarding proper car safety seat use. **EB:** *Deaths among children, who are occupants in automobiles, has decreased over the last 10 years, but many more could be prevented with the consistent use of child safety restraints (Sauber-Schatz et al, 2014).*

Geriatric

• Encourage the client to wear glasses and hearing aids and to use walking aids, including nonslip footwear when ambulating. **EB:** *It has been observed that gait and balance problems lead to falls and injuries in older people; the use of walking aids is meant to augment gait safety and prevent falls (Hardi et al, 2014).*

• Assess for orthostatic hypotension when getting up, teach methods to decrease dizziness, such as rising slowly, remaining seated several minutes before standing, flexing feet upward several times while sitting, sitting down immediately if feeling dizzy, and trying to have someone present when standing. **EBN:** *In a study by Nazarko (2015), it was found that addressing physiological risk factors for falls improves functional capability, a feeling of well-being, and improvement in the quality of life.*

• Discourage driving at night. **EB:** *Older adult drivers who drive at night are at heightened risk for injury because of age-related changes in the amount of light reaching the retina, weaker contrast sensitivity, and variations in dark and light adaptation (Boot, Stothart, & Charness, 2014).*

Multicultural

• Acknowledge racial/ethnic differences at the onset of care. **EBN:** *Alpers and Hanssen (2014) noted that experience in and of itself does not provide nurses with sufficient knowledge for intercultural symptom assessment and culturally competent treatment and care; access to appropriate information is needed along with their perception of clinical practice.*

• Evaluate the influence of culture on the client's perceptions of risk for injury. **EB:** *More African American and Hispanic children, compared with Caucasian children, are dying in automobile crashes because they are unrestrained; effective interventions and education would increase proper restraint use (Sauber-Schatz et al, 2014).*

• Evaluate whether exposure to community violence is a contributor to a client's risk for injury. **EB:** *Exposure to violence can result in many negative consequences for youth, including use of tobacco, alcohol, marijuana, and persistence in neighborhood violence (Fagan, Wright, & Pinchevsky, 2014).*

• Use culturally relevant injury prevention programs when possible. Validate the client's feelings and concerns related to environmental risks. **EB:** *According to research supported by the findings of Richardson, Van Brakle, and St. Vil (2014), parents of adolescent African American males are tested daily in attempting to keep their children safe in high-risk neighborhoods.*

Home Care and Client/Family Teaching and Discharge Planning

Risk for corneal Injury

Michelle Acorn DNP, NP PHC/Adult, BA, BScN/PHCNP, MN/ACNP, GNC(C), CGP

NANDA-I

Definition

Susceptible to infection or inflammatory lesion in the corneal tissue that can affect superficial or deep layers, which may compromise visual health.

Risk Factors

Exposure of the eyeball; insufficient knowledge of modifiable factors

At-Risk Population

Prolonged hospitalization

Associated Condition

Blinking <5 times per minute; Glasgow Coma Scale score <6; intubation; mechanical ventilation; oxygen therapy; periorbital edema; pharmaceutical agent; tracheostomy

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes (Visual)

Sensory Function: Vision; Vision Compensation Behavior

Example NOC Outcome with Indicators

Vision Compensation Behavior as evidenced by the following indicators: Wears protective eye wear for prevention/Eye discomfort improves daily with healing. (Rate each indicator of **Vision Compensation Behavior:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Demonstrate relaxed facial expressions and grimacing reduction
- Remain as independent as possible
- Remain free of physical harm resulting from vision injury risk
- Demonstrate improvement in visual acuity

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Visual Deficit; Environmental Management

Example NIC Activities—Communication Enhancement: Visual Deficit

Clearly identify yourself when you enter the client's space; Build on client's remaining vision, as appropriate

Nursing Interventions and *Rationales*

Emergency Department Visits or Primary Care Office Visit

- Perform a standard ophthalmic exam or examine eye with a slit lamp using fluorescein stain to optimize visualization of the abrasion injury if available.

• Attempt visual acuity measuring using the Snellen eye chart (corrected with glasses).
• Ensure immunization status is current, namely tetanus-diphtheria-pertussis status (every 10 years).
• Teach the client that fingernail-induced corneal abrasions are one of the most common eye injuries and are at risk for complications (Lin & Gardiner, 2014). **EB:** *The Cochrane systematic review of 12 randomized controlled trials (RCTs) with 1080 participants suggested that treating simple corneal abrasions with a patch may not improve healing or reduce pain. This is important because patching the eye probably does not speed up healing and may not have an important effect on pain relief. Furthermore, people receiving an eye patch may be less likely to have a healed corneal abrasion after 24 to 72 hours. Additionally, corneal abrasions in people patched probably take slightly longer to heal. Last, using eye patches may lead to more pain at 24 hours (Lim, Turner, & Lim, 2016).*
• Provide analgesia as needed. Clients with all but the most minor abrasions usually require a strong oral narcotic analgesic initially (Verma & Khan, 2014).
• **EB:** *According to the Cochrane systematic review of nine RCTs with 637 participants. The findings of the studies do not provide strong evidence to support the use of topical nonsteroidal antiinflammatory drugs (NSAIDS) in traumatic corneal abrasions. This is important because NSAIDS are associated with higher costs compared with oral analgesia (Wakai et al, 2017).*
• Injuries that penetrate the cornea are more serious. The outcome depends on the specific injury. Corneal abrasions usually heal quickly and without vision concerns. Even after the original injury is healed, however, the surface of the cornea is sometimes not as smooth as before. *Clients who have had a corneal abrasion may notice that the eye feels irritated for a while after the abrasion heals (Cleveland Clinic, 2015).*

Hospitalization

• Traumatic corneal abrasions are very common ophthalmic injuries accounting for 6% of emergency department visits and 65% trauma related of which 24% were corneal abrasions (Wakai et al, 2017; Menghini et al, 2013).
• Perioperative corneal abrasions typically heal within 72 hours. Risk factors include advanced age, prominent eyes (proptosis, exophthalmos), ocular surface abnormalities (dry eye, recurrent erosion syndrome), surgery greater than 60 to 90 minutes, prone/lateral and Trendelenburg positions, operations on the head and neck body regions, intraoperative hypotension, and preoperative anemia. Potential sources of corneal injury in the surgical patient are after induction (laryngoscope, name badge, watch band), before incision (surgical preparation, gauze/sponges/drapes), during the procedure (instruments, chemical solutions, heat sources, pressure on globe, eye shields), and awakening/recovery (oxygen face mask, fingernails) (Segal et al, 2014; Malafa et al, 2016).
▲ All surgical patients should have eyelids secured in the closed position immediately after induction. A strip of tape is generally sufficient; however, in high-risk cases with Trendelenburg position patients may benefit from use of transparent bioocclusive dressing, which can span the entire lid and provide strong uniform closure, minimizing tear evaporation and acting as a barrier to trauma (Malafa et al, 2016). **EB:** *Clients receiving adhesive tape as an eye care method were twice as likely to develop corneal abrasions (Masoudi et al, 2013).*
• Ocular lubricants support surface moisture, but studies comparing different types of lubricants fail to demonstrate differences in efficacy. However, preservative-free methylcellulose-based ointments are preferred because they are retained in the eye

longer than aqueous solutions. Paraffin-based (petroleum) ointments disrupt tear film stability, carrying a higher risk of eye irritation, and are flammable (Malafa, 2016).
• Assess for corneal abrasion and eye dryness, which are common problems in clients in the intensive care unit. Eye dryness is the main risk factor for the development of corneal abrasions. **EB:** *Sedated clients or clients in induced comas may experience ineffective eye closure, presenting higher risk for corneal injury (Werli-Alvarenga et al, 2013). Consider a humidity chamber with polyethylene fill for best practice (Werli-Alvarenga et al, 2013).*
• **EBN:** *Eye care and eye assessment should be essential parts of nursing care for clients in intensive care. To prevent corneal abrasions, use eye lubricants, which are more effective than closing eyes by adhesive tapes (Masoudi et al, 2013).*

Client/Family Teaching and Discharge Planning

▲ First-aid principles should be reinforced in the event of an eye injury. Clients should not attempt to remove any object in the eye; reserve this for the provider. A referral to an ophthalmologist may be required (Jacobs, 2017).
• Teach clients to use caution when using household cleaners. Many household products contain strong acids, alkalis, or other chemicals. Drain and oven cleaners are particularly dangerous, and can lead to blindness if not used correctly (Vorvick, 2014).
• If chemical exposure has occurred, flush the eye immediately with clean water for 10 minutes. Seek prompt health care attention.
• Wear safety goggles at all times when using hand or power tools or chemicals, during high-impact sports, or in other situations when eye injury is more likely.
• Wear sunglasses that screen ultraviolet light when outdoors, even in winter.
• Pain is usually improved within 3 days. If pain becomes intolerable, an analgesic may be prescribed short term. Seek medical attention if pain is not resolving.
• Driving should be restricted for safety until client's visual acuity is evaluated.

Risk for occupational Injury

Kathleen Buckheit MPH, BSN, RN, CEN, COHN-S/CM, CCM, FAAOHN

NANDA-I

Definition

Susceptible to sustain a work-related accident or illness, which may compromise health.

Risk Factors

Individual

Excessive stress; improper use of personal protective equipment; inadequate role performance; inadequate time management; ineffective coping strategies; insufficient knowledge; misinterpretation of information; psychological distress; unsafe acts of overconfidence; unsafe acts of unhealthy negative habits

Environmental

Distraction from social relationships; exposure to biological agents; exposure to chemical agents; exposure to extremes of temperature; exposure to noise; exposure to radiation; exposure to teratogenic agents; exposure to vibration; inadequate physical environment; labor relationships; lack of personal protective equipment; night shift work rotating to day shift work; occupational burnout; physical workload; shift work

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Personal Health and Safety Behaviors; Risk Control; Adequate Training

Example NOC Outcome with Indicators

Occupational Health as evidence by Knowledge and compliance with health and safety policies and procedures/Demonstration of personal health-promoting behaviors/Knowledge and self-management of a healthy lifestyle. (Rate the outcome and indicators of **Occupational Health:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Attend and participate in all required health and safety training activities
- Demonstrate safe and healthy work behaviors to reduce the risk of occupational injuries and illnesses
- Comply with the organization's health and safety policies and procedures
- Inspect all equipment and tools before use
- Report to management any work hazards, such as facility, tools, and equipment that needs to be repaired
- Demonstrate healthy personal habits, such as healthy nutritional choices, regular exercise, smoking cessation, and effective sleep patterns

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Health Coaching; Health Education; Health Screening; Risk Identification

Example NIC Activities—Risk for Occupational Injury

Encourage early reporting of signs and symptoms related to health and safety hazard exposures

Nursing Interventions and *Rationales*

- Interventions to reduce the risks of occupational injury focus on providing resources for safe work and education to the individual to know safety rules and procedures. Occupational safety requires the individual to engage in safe acts, proper use of equipment to include personal protective equipment (PPE), cognitive focus during work, and self-identification of stressors that may adversely impact the individual's personal safety during work.
- Environmental risks that need to be addressed to ensure a safe work environment focus on elements such as excessive noise, poorly maintained equipment or lack of PPE, uneven or poorly designed work spaces, inadequate lighting, and lack of safety training.
- Alternating shift work or night shift work provides an additional risk related to reduced strength and chronic fatigue. **EB:** *A study looked at nurses' strength and fatigue relative to day or night shift work. A compressed nursing work schedule was found to result in decreased strength and fatigue placing the individual at increased risk for occupational injury (Thompson, Stock, & Banuelas, 2017). A study by Larsen et al (2017) found that individuals exposed to night work were more likely to have accidental injuries compared with nonnight shift workers.*
- Assist the client in reduction of personal and work stress and distractions to increase coping skills, improve interpersonal relationships, and increase personal job performance and satisfaction. Emphasize paying attention to work activities and environment in hazardous and normal work situations. **EB:** *A variety of studies have examined the relationship between job stress and job performance. Job performance has been viewed as an activity in which an individual is able to successfully accomplish the tasks assigned, dependent on the normal constraints of reasonable utilization of the available resources. According to a study by Dar (2011), job stress had a negative relationship with job performance so that when stress occurs it negatively effects the employee's performance, and when stress is lowered, the performance increases.*
- The stress in the work environment negatively effects the intention of employees to perform better in their jobs. **EB:** *When considering work stress, evidence showed that job stress results in employees feeling undervalued and workplace victimization/bullying, unclear role/errands, and fear of joblessness increases. Recommendations included that organizations should reduce psychological strain, work overload, and role ambiguity through the adoption of job redesign techniques and organizational support of counseling and stress reduction workshops (Dar, 2011).*
- Maintaining good interpersonal relationships and communications with management and coworkers can be achieved by leaders who encourage high-quality relationships among employees in the workplace. Strong interpersonal relationships assist in developing trust, respect, and a willingness to share information, resources, and perspectives (Phillips, Rothbard, & Dumas, 2009).

• Cognitive distractions tend to decrease productivity and increase the number of errors workers make (Ratwani, Trafton, & Myers, 2006). **CEB:** *Disruptive behaviors, interruptions, and nonoccupational activities, such as use of cell phones and radio headsets, might need to be prohibited while on duty to reduce distractions* (Ratwani, Trafton, & Myers, 2006).
• Visual deprivation occurs when pedestrians elect to look at the cell phone screen, reducing the available skills necessary to see features in the walking environment. **EB:** *The Ohio State University reports that an estimate of more than 1500 pedestrians were treated in emergency rooms in 2010 for injuries related to using a cell phone while walking, which is more than double the number of cases seen in 2005, according to their nationwide study. According to the researcher, "The role of cell phones in distracted driving injuries and deaths gets a lot of attention and rightly so, but we need to also consider the danger cell phone use poses to pedestrians." The study found that those ages 16 to 25 were most likely to be injured as distracted pedestrians, and most were hurt while talking rather than texting (Nasar & Troyer, 2013).*
• Assist in the integration of personal health behaviors that promote total worker health and safety for the employee, which translates to a more productive worker generating better quality products, resulting in less occupational injuries and illnesses for the workers**. EB:** *Studies have shown that health education activities and materials should address prevention topics for modifiable behaviors observed to be injury risk factors, such as overuse of alcohol and drugs, stress, tobacco use, and poor sleep habits (Schuh-Renner et al, 2017).*
• A community-based study found that gender, young age, regular psychotropic drug use, and diseases influence the occupational injuries. Smokers, overweight subjects, and excess alcohol use also had increased risk for occupational injury. **CEB:** *Preventive measures concerning work conditions, risk assessment, and job knowledge should be conducted. A campaign should be implemented to address concerns with this group of workers that are exposed to higher risk to prevent occupational injury (Bhattacherjee et al, 2003).*
• Sleep is an active process enabling the body to restore and regenerate. Adequate sleep is essential to health and cognitive function. It is critical for cell repair, immune system health, and regulation of hormones, and it critically aids in learning, memory, and emotion. **EB:** *Long-term inadequate sleep can result in many chronic health and mental conditions. The two common sleep disorders affecting the workplace are insomnia and obstructive sleep apnea, which can negatively affect quality of life and increase work-related injuries (Judd, 2017).*
• Maintaining good sleep hygiene promotes alertness and results in decreased occupational injuries and illnesses. However, good sleep hygiene may be difficult in employees without consistent sleep patterns. **CEB:** *A study by Dembe et al (2005) found that working schedules routinely involving overtime work or extended hours increased the risk of injury or illness. Overtime schedules had the greatest relative risk, followed by long daily shifts (>12 hours) or long work weeks (>60 hours). These results indicate that long working hours indirectly precipitate workplace accidents from fatigue or stress (Dembe et al, 2005).*
• Sensory deprivation, also called environmental isolation, occurs when the use of cell phones and other electronics results in limited hearing and peripheral vision. **EB:** *When pedestrians are wearing headphones or are engaged in conversation on a cell phone, the inability to hear sounds emanating from the local surroundings may present unique problems in walking environments in which auditory cues can be more important than visual ones, such as around trains (Lichenstein et al, 2012).*
• Fatigue has been associated with negative safety outcomes. Poor-quality or

decreased sleep has been associated with obesity (higher body mass index [BMI]), and higher BMI rates are related to increased injury risk. Sleep is an active process; the body undergoes restoration and regeneration. According to Judd (2017), adequate sleep is essential to health and cognitive function. Sleep is critical for cell repair, a healthy immune system, and hormonal regulation, and aids in the process of learning, memory, and emotion. Inadequate sleep can lead to multiple chronic health and mental conditions over time. The occupational health nurse can be instrumental in screening for two of the most common sleep disorders, insomnia and obstructive sleep apnea, by asking workers key questions and using simple screening tools to prevent the negative effects of sleep disorders on quality of life and increase in work-related injuries (Judd, 2017). **EB:** *Results from a large sample of US workers found an increase in injury risk for reduced sleep habits, regardless of body mass, but also shows an increase in injury risk for higher BMI, regardless of usual daily sleep duration (Lombardi et al, 2012).*

• When the Occupational Safety and Health Administration (OSHA) professionals understand potential interruptions and adopt a task-design–oriented approach founded in ergonomics and human factors principles and methods, they can focus on aspects of the work environment that can be observed, measured, and controlled. **EB:** *Using signs, a no-interruptions zone, personal electronics policies, and available technologies to promote attention-keeping and interruption recovery can be implemented by organizations to maintain safe environments (Cohen, LaRue, & Cohen, 2017).*

• Provide medical screening, surveillance, and postexposure testing for symptomatic employees to identify and provide the focus on the exposure to control effects that can lead to illness and injury. **EB:** *OSHA requires that exposures to specific hazards require a medical surveillance program to identify adverse effects related to those exposures. OSHA Standards provide the opportunity to monitor exposure to health hazards from inhalation, ingestion, or skin absorption from chemical, biological agent, or radiological exposures. The fundamental purpose of screening is early diagnosis and treatment with a* clinical focus, whereas *surveillance is to detect and eliminate the underlying causes providing a* prevention focus*. Although both contribute to worksite health and safety programs, OSHA "medical surveillance" is generally clinically focused to include medical and work histories, physical assessment, and biological testing, which is used in the monitoring and analysis elements of medical surveillance* (*United States Department of Labor, OSHA, 2000*). *According to OSHA, "Medical surveillance is the analysis of health information to look for problems that may be occurring in the workplace that require targeted prevention. Thus, surveillance serves as a feedback loop to the employer. OSHA Surveillance may be based on a single case or sentinel event, but more typically uses screening results from the group of employees being evaluated to look for abnormal trends in health status"* (*United States Department of Labor, OSHA, 2000).*

• Although compliance with health and safety policies and procedures must be encouraged and enforced, when the employee becomes ill or injured, the occupational health nurse must provide assessment and treatment**. EB:** *Occupational health nursing focuses on promotion and restoration of health, prevention of illness and injury, protection from work-related and environmental hazards, and corporate profitability (McCullagh & Berry, 2015). The roles of today's occupational health nurses are diverse, and their position responsibilities cover an ever-expanding range of tasks. Occupational health nurses can assist employers in controlling their health care costs and maintaining business health by developing, implementing, and evaluating health promotion and disease and injury prevention programs and services for specific workers (Thompson & Wachs, 2012).*

• Many workers have comorbidities (e.g., hypertension, diabetes, hyperlipidemia,

asthma), some of which are related to lifestyle choices or the environment. **EB:** *In a study by Duffy et al (2011) operating engineers were found to have many health behavior risk factors, including smoking, drinking alcohol, diet, exercise, sleep, and sun exposure.*

• Implementing programs that assist overweight and obese workers to increase both strengthening and cardiovascular exercise can result in weight loss and also reduce employees' risk of injury and chronic diseases and improve their mobility and quality of life. Health coaching is the use of evidence-based skillful conversation, clinical strategies, and interventions to actively and safely engage clients in health behavior change to better self-manage their health, health risk(s), and acute or chronic health conditions, resulting in optimal wellness, improved health outcomes, lowered health risk, and decreased health care costs (Huffman, 2016). **EB:** *Rather than focusing on health education, nurses and other health care professionals are now using health coaching based on motivational interviewing to assist workers in changing health-related behaviors (Huffman, 2016).*

• Encourage early reporting of signs and symptoms related to health hazard exposures to provide early recognition and treatment, which is aimed at reducing disability, pain, and workers' compensation costs; absence; and retraining and replacement workers. *Work accommodations may be necessary to keep the employee working.*

• Case management to ensure appropriate referrals and communication is necessary to achieve safe work environment goals and include follow-up assessment to ensure that the worker is not further injured or ill by the accommodated work situation. *Providing appropriate medical referrals and interdisciplinary collaboration can reduce occupational risks to health and safety.*

• OSHA requires a mechanism that identifies to whom the employees report injuries and illnesses and that they are encouraged to do so as early as possible. One of OSHA's strategies is to be proactive and reduce injuries and illnesses by implementing a reporting system that would develop and communicate a simple procedure for workers to report any injuries, illnesses, incidents (including near misses/close calls), hazards, or safety and health concerns without fear of retaliation. This also includes an option for reporting hazards or concerns anonymously (United States Department of Labor, OSHA, 2016a). *Educating the employees on the signs and symptoms of occupational disease is critical to stop and reverse the process before disability results. Early reporting of signs and symptoms related to health hazard exposures provides for the best outcomes of treatment (United States Department of Labor, OSHA, 2016a).*

• Occupational back pain is a multifactorial condition commonly encountered in the workforce. It is very costly for the health care system and industry but can be prevented or limited in its severity**. EB:** *Discouraging bed rest and promoting early return to work with modified job tasks in which accommodations avoid back injury risk factors, individualized interventions, and with follow-up monitoring for assurance is encouraged as part of the rehabilitation program (Al-Otaibi, 2015).*

• Enforce compliance with organizational and regulatory health and safety policies and procedures, demonstrating at least adequate training and the proper use of appropriate tools, equipment, and PPE to reduce risk of injury and illness and ensure that the client receives appropriate training and education on occupational tasks and equipment. *Health education activities and materials should address prevention topics for modifiable behaviors observed to be injury risk factors, such as overuse of alcohol and drugs, stress, tobacco use, and poor sleep habits (Farnacio et al, 2017).*

• *Ensuring that workers are following policies can reduce exposure and illness when exposed to chemicals.* **EB:** *Studies have been done focusing on chemical exposures among agricultural*

workers and their families, using community-based participatory research methods to work with vulnerable, difficult to access working populations. Research has documented the effects of low levels of pesticide exposures on neurobehavioral performance in adults and children of agricultural workers (McCauley, 2012).

• Ensure workers have access to and wear PPE to reduce noise exposure. Engineering and administrative controls should be considered before the use of PPE. **EB:** *A United Auto Workers–General Motors–funded study assessed the effects of noise on blood pressure and heart rate that demonstrated a significant positive relationship between acute noise exposure and both diastolic and systolic blood pressure and heart rate. In assessing the effect of chronic noise exposure, workers who used hearing protection had lower blood pressure and heart rate than workers without hearing protection (McCauley, 2012).*

• A critical component in safety risk management is to adequately identify hazards and mitigate its associated risk using safety program elements (Yorio & Wachter, 2014). **EB:** *An American Society of Safety Engineers (ASSE) published a study identifying quality measures of occupational health and safety management system (OHSMS) activities as important performance variables. Quality measures to consider include safety training test scores, correction rates of inspection nonconformance findings, and perception survey results on the state of the organizational culture and its conduciveness to safe operations (Haight et al, 2014).*

• Employees are at risk when exposed to welding fumes, dust, or chemicals. Continued exposure to these substances can place employees at risk for permanent lung changes. **EB:** *Research illustrates that the health of workers is affected by continued exposure to welding fumes released by the cutting or connecting of metal using a welding technique (Roach, 2017). Exposure to welding fumes is completely preventable. Provide resources to the client to guide ways to address organizational policies and procedures to prevent exposure to fumes during welding work (United States Department of Labor, OSHA, 2016b).*

• Noise in health care varies according to the type of facility and patient care rendered. Mechanical noise from equipment (i.e., from alarms, monitors) can be disruptive to concentration, especially if it is loud and unexpected; patient vocalization depending on the cause (i.e., from pain, fear, disorientation) and amount, volume, and length of time can be considered another type of stressor. Published studies indicate that noise levels in hospitals, particularly in intensive care units (ICUs), are above those recommended by OSHA and have been measured at 90 dB-A, the Action level of the OSHA Noise Standard. Staff exposed to excessive noise experience anxiety and stress and can cause other psychological effects associated with annoyance. The Joint Commission on Accreditation of Healthcare Organizations has identified noise as a potential risk factor for medical and nursing errors, stating that ambient sound should not exceed the level that would prohibit clinicians from clearly understanding each other, so that nurses are not at risk of error when the noise level is 40 dB-A or greater. **EB:** *In a study by Kol et al (2015), rearranging the nurses' station and treatment area, providing staff education, displaying a sign to remind staff and visitors that noise is constantly monitored in the ICU setting, and implementing repairs to ICU equipment were effective noise reduction measures that resulted in a statistically significant decrease ($P < .05$) in noise levels (Kol et al, 2015).*

• Ensure that infection prevention and control policies and procedures are enforced. Blood-borne pathogen risks are inherent when providing nursing care in health care facilities of for injured or ill employees, and appropriate measures must be taken to avoid contact with and spread of infectious organisms.

• Ensure appropriate protection is initiated when workers are exposed to those

considered contagious through airborne exposure. Respiratory protection is required when airborne or droplet exposure to disease agents is suspected. Appropriate selection, training, and fit-testing is required before use of respirators is allowed.
• Provide resources to assist with smoking/vaping cessation. According to the American Lung Association (2018), smoking is the leading cause of preventable death in the United States, causing more than 438,000 deaths per year, and worsening preexisting conditions including cardiovascular disease. Cigars have many of the same health risks as cigarettes, including causing certain cancers. Marijuana smoke contains many of the same toxins, irritants, and carcinogens as tobacco smoke. Smokeless tobacco products are a known cause of cancer and are not a safe alternative to cigarettes. Secondhand smoke is a serious health hazard for people of all ages, causing more than 41,000 deaths each year (American Lung Association, 2018). Electronic cigarettes are a new tobacco product, and the potential health consequences and safety of these products are unknown. The process of using an e-cigarette is called "vaping" rather than smoking. The US Food and Drug Administration (FDA) describes an e-cigarette as a battery-operated device that turns nicotine, formaldehyde, flavorings (diacetyl that causes popcorn lung), and other chemicals into a vapor that can be inhaled. WebMD.com (2018) provides information about smoking and smoking cessation programs that can be helpful when counseling employees as to the adverse effects of smoking (https://www.webmd.com/smoking-cessation/default.htm).
• Provide interdisciplinary collaboration to reduce occupational risks to health and safety. According to Wachs (2005), teamwork is beneficial to American business and industry because of its strength through diversity when a variety of interdisciplinary health and safety professionals offer solutions to complex problems. Teamwork among occupational health and safety professionals, management, and employees is vital to solving complex problems cost-effectively. No single discipline can meet all the needs of workers and the workplace (Wachs, 2005). OSHA has identified that an effective occupational safety and health program involves many components and recommended practices (United States Department of Labor, OSHA, 2016a).
• Maintain a drug-free workplace through the identification of abuse of prescription and illegal drugs, which includes any substance that inhibits the mental, emotional, and physical functioning of the worker.
• Provide accurate and legal documentation for medical and exposure records with adverse health effects from health and safety exposures, maintaining confidentiality of personal medical issues. Legal requirements for documentation ensure correct communication of all aspects of the injury or illness and protects the nurse in case of litigation.
• Documentation communicates information about the employee and confirms that care was provided using the NANDA nursing diagnoses, the NIC, and the NOC as the basis for documentation. **EB:** *All charting should be accurate, complete, objective, and timely. There are several charting guidelines related to vocabulary, descriptions, legibility, errors, and omissions to ensure that charting meets legal requirements and provides an accurate unbiased record of client care. There are many different types of documentation and very little consistency from one organization to another. Each state has its own Nurse Practice Act, but all establish guidelines for documentation and accountability. These include the nursing process of assessment, diagnosis, planning, implementation, and evaluation. The Nurse Practice Act provides for standardized vocabulary, a list of approved abbreviations and symbols, and using legible writing in blue or black ink. Errors require a line to delete with "Error" and a signature; errors cannot be erased, whited-out, or otherwise made illegible*

(Lockwood, 2017).

• OSHA *documentation specifics* include medical, exposure, and training records that must be retained for a period of time, usually at least 30 years. The documentation provides a history of the employee's exposure to hazards, assessment and treatment received, and any worksite hazard abatements or reduction to exposures, and any outcomes of exposure and treatments (United States Department of Labor, OSHA, 2011).

• The Health Insurance Portability and Accountability Act (HIPAA) and Privacy Rule provide the right of privacy to the client, and this extends to all forms of documentation related to the client. *HIPAA of 1996 documents the rights of the individual in relation to privacy regarding health information. The final Privacy Rule, issued in 2000 and modified in 2002, provides for the right to decide who can have access to private health information and requires health care providers to provide confidentiality. Personal employee information is considered protected health information (PHI), which includes any identifying or personal information about the health history, condition, or treatments in any form, including electronic, verbal, or written documentation. Some areas provide extra confidentiality, including assessment and treatment of HIV, substance abuse, rape, pregnancy, and psychiatric disorders (Lockwood, 2017; United States Department of Labor, OSHA, 2013).*

• Considerations for nursing practice include the following:
    - ❍ Identify high-risk work areas and processes for developing occupational injuries and illnesses through (1) auditing of injury and illness reports and insurance claims and (2) conducting periodic walkthroughs of the workplace for unsafe acts and conditions.
    - ❍ Encourage employee compliance with safety policies and procedures to reduce the opportunity for (1) slips, trips, and falls; (2) breaks in skin integrity through chemical exposure, mechanical means (trauma, friction, pressure), physical exposure (heat, cold, radiation), and exposure to biological elements (viruses, bacteria, fungi); (3) musculoskeletal injuries; and (4) misuse of equipment and tools.
    - ❍ Ensure appropriate training through medical, exposure, and training records and notify management to correct when necessary.
    - ❍ Ensure employee availability and understanding of accurate and current Safety Data Sheets for all personnel.
    - ❍ Encourage early reporting of signs and symptoms related to health and safety hazard exposures.
    - ❍ Provide appropriate primary, secondary, and tertiary prevention strategies to ensure the health and safety of the workforce.
    - ❍ For adverse effects of workplace exposures, counsel employees, notify management, and follow OSHA standards (and other regulatory requirements) and company policies and procedures to reduce exposure and reverse the adverse effects to workers.
    - ❍ Promote and assist employees in integrating personal health behaviors that lead to total worker health and safety, such as not smoking or using vapes; exercise; weight loss; stress reduction; hypertension reduction; drug and alcohol-controlled use; and managing personal health issues, such as blood sugar levels.
    - ❍ Monitor employees for an adverse health status through medical surveillance and physical assessment examinations required for workplace

exposures, such as chemicals, noise, ergonomic issues, pulmonary stressors, and radiation.
- ❍ Provide employee counseling specific to employee, health status, and work processes.
- ❍ Encourage compliance with health and safety policies and procedures that reduces opportunity exposure to health hazards from inhalation; ingestion; or skin absorption from chemical, biological agent, or radiological exposure.
- ❍ Encourage early reporting of signs and symptoms related to health hazard exposures.
- ❍ Provide postexposure testing for symptomatic employees or per specific organizational policies and procedures.
- ❍ Provide interdisciplinary collaboration to reduce occupational risks to health and safety.
- ❍ Provide appropriate medical referrals as needed.
- ❍ Provide accurate and legal documentation for medical and exposure records with adverse health effects from health and safety exposures.
- ❍ Maintain confidentiality of personal medical issues.

Geriatric

• Consider the physiological changes in the aging population. *The aging workforce typically has experienced changes in their physical systems that require attention to physical needs. These changes may include slower reaction times, predisposing factors to developing musculoskeletal disorders, a compromised cardiovascular system, less acute hearing and vision, and impaired cognition (Algarni et al, 2015).*
• Although older clients may experience less occupational injuries and illnesses, the aging workforce may take longer to heal injuries and return to work and normal functioning. **EB:** *A review of current best practices by Delloiacono (2015) found that the extent of age-related physical changes in older workers is significantly influenced by chronic illnesses. However, improving lifestyles could reduce organizational costs, and reducing costs is important because although older worker statistics report lower work-related injury rates, their recovery is slower and lost work time is longer. Also, identifying ergonomic risk factors will assist in workplace design improvements in workplace to reduce risks of musculoskeletal disorders for the aging population (Delloiacono, 2015).*

Multicultural

• Address differences in cultures that affect attitudes toward health care professionals and treatment modalities. *Understanding the written and verbal language can significantly affect the instructions and training given to workers.*
• According to the Centers for Disease Control and Prevention (CDC, 2018), young workers have high rates of job-related injury. These injuries are often the result of the many hazards present in the places they typically work, such as sharp knives and slippery floors in restaurants. Limited or no prior work experience and a lack of safety training also contribute to high injury rates. Middle and high school workers may be at increased risk for injury because they may not have the strength or cognitive ability needed to perform certain job duties. *In 2016, there were about 19.3 million workers under the age of 24. These workers represented 13% of the total workforce, and in 2015, 403 workers under the age of 24 died from work-related injuries (CDC, 2018).*
• The US workforce is becoming more diverse (National Center for Public Policy

Research, 2005). Baby boomers are remaining in the workforce past traditional retirement age because their health is better, and they need or want additional income (Bureau of Labor Statistics, 2008). Physical changes occur with the aging workforce that need to be addressed, such as decreased visual acuity that requires increased lighting, decreased hearing from presbycusis, difficulty with balance, and increase in healing time from musculoskeletal injuries. **EB:** *According to a study by Loeppke et al (2013), issues were explored related to the aging workforce, including barriers to integrating health promotion and protection programs to provide recommendations for best practices to maximize contributions of that worker population. Reducing injury costs is important because although older worker statistics report lower work-related injury rates, their recovery is slower and lost work time is longer. The conclusion was a national dialog on this topic was needed, and the result will be that workers will benefit from improved health and job performance, employers will have more productive and engaged workers, and the United States will have a more competitive workforce (Loeppke et al, 2013).*

- The size of the minority workforce is growing, and more women are entering the workforce (Thompson and Wachs, 2012). There is greater diversity in the workplace, and people from different backgrounds and cultures are working alongside each other, often speaking different languages with different educational and literacy backgrounds. **EB:** *As the minority workforce continues to grow, especially the Hispanic workforce, businesses must recognize the unique needs and contributions of this workforce in terms of language, customs, culture, and values* (Thompson and Wachs, 2012). *According to Burgel, Nelson, and White (2015), results of a study on Latino day workers add to the growing body of research documenting the higher prevalence of work-related health complaints or injuries among those workers with work-related health complaints or injuries who were older, reporting poor or fair general physical and mental health, and more likely than those without health complaints or injury, to work in pain during the prior work week without work breaks. Most health complaints or injuries were unreported. Those that occurred within the prior year experienced a higher prevalence of depression and arthritis compared with their counterparts without work-related health complaints or injuries in the prior year. Recommendations were that occupational health nurses should promote the health of and prevent injuries among this group of vulnerable workers at both the individual and system levels.*
- Depending on the setting, comprehensive health care, including, for example, smoking cessation and early diagnosis and treatment of depression, could be provided to this high-risk population using culturally sensitive outreach and motivational interviewing strategies. **EB:** *Because of underreporting, active case findings for occupational injuries are needed when day laborers access any health care system. To ensure the provision of health and safety training and PPE for day laborers at the system level, occupational health nurses can advocate for comprehensive occupational health and safety legal protections for all contingent workers. Reporting health complaints and injuries, in addition to providing rest breaks, deserves further study in this population. In addition to targeted hearing conservation and respiratory protection programs for this high-risk group, the risk of falls from heights is a serious hazard facing day laborers, and this phenomenon also deserves further investigation (Burgel, Nelson, & White, 2015).*
- As women continue to earn significantly less than their male counterparts, they may believe that they need to work harder to prove themselves to earn the promotions and higher pay scales. *The nurse may recognize these situational stressors and need to refer female employees more than the male employees for counseling, such as initiating assistance offered by employee assistance programs or community resources for family support.*
- The Americans with Disabilities Act (ADA) requires that public buildings be

designed to accommodate wheelchairs and other accommodations and that jobs be modified if accommodation is reasonable, so more challenged individuals gain access to buildings and jobs (see https://www.ada.gov/ada_req_ta.htm [ADA]).

Risk for urinary tract Injury

Tammy Spencer DNP, RN, CNE, AGCNS-BC, CCNS

NANDA-I

Definition

Susceptible to damage of the urinary tract structures from use of catheters, which may compromise health.

Risk Factors

Confusion; deficient patient or caregiver knowledge regarding care of urinary catheter; obesity

At-Risk Population

Extremes of age

Associated Condition

Anatomical variation in the pelvic organs; condition preventing ability to secure catheter; detrusor sphincter dyssynergia; impaired cognition; latex allergy; long-term use of urinary catheter; medullary injury; multiple catheterizations; retention balloon inflated to ≥30 mL; use of large caliber urinary catheter

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Urinary Elimination; Knowledge: Infection Management; Treatment Regimen; Treatment Procedure, Tissue Integrity: Skin and Mucous Membranes, Risk Control: Infectious Process, Risk Detection

Example NOC Outcome with Indicators

Urinary Elimination as evidenced by the following indicators: Urine clarity/Urine odor, Urine volume, fluid intake, pain with urination. (Rate the outcome and indicators of **Urinary Elimination:** 1 = severely compromised 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Remain free of urinary tract injury
- State absence of pain with catheter care and during urination
- Experience unobstructed urination after removal of catheter
- Identify interventions to prevent catheter-associated urinary tract infection (CAUTI)
- Maintain adequate urine volume (0.5–1.0 mL/kg/hr for adult); urine without odor; urine clear
- Maintain adequate fluid intake considering client age and comorbidities

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Urinary Elimination Management

Example NIC Activities—Urinary Elimination Management

Monitor urinary elimination, including frequency, consistency, odor, volume, and color, as appropriate; Assess client for pain and increased temperature associated with catheter

Nursing Interventions and *Rationales*

- Monitor urinary elimination, including frequency, consistency, odor, volume, and color, as appropriate.
- Teach the client and caregiver signs and symptoms of urinary tract infection and CAUTI. *Clients may be asymptomatic or have a range of symptoms that may include a persistent urge to urinate, burning sensation during urination, cloudy and/or strong-smelling urine, blood tinged urine, and fatigue.*

• Assess for appropriate use of an indwelling urinary catheter. Insert urinary catheters only when indicated and leave in only as long as clinically necessary. **EB:** *To prevent trauma to the urinary tract structure as well as infections (e.g., CAUTI and urosepsis), use urinary catheters only as indicated (Yokoe et al, 2014; Centers for Disease Control and Prevention [CDC], 2017). Approximately 80% of all health care–associated urinary tract infections are caused by urinary catheterization; infection represents the most significant adverse event following urinary catheter use (Lo et al, 2014; CDC, 2017). CAUTIs are linked to increased mortality, morbidity, hospital cost, antibiotic use, and length of stay (CDC, 2017). Health care providers need to have written guidelines for the use, insertion, and maintenance of urinary catheters (Lo et al, 2014; Yokoe et al, 2014).*

▲ To prevent injury, educate the client and family and/or caregiver regarding the use of an indwelling urinary catheter (Lo et al, 2014; Scott et al, 2014). **EB:** *Accidental or improper removal of catheter can cause urethral injury. Urinary catheters are used in up to 16% of adult hospital inpatients (Lo et al, 2014).*

• Assess clinical indication for urinary catheter daily. **EB:** *Studies found that 21% to 63% of all indwelling urinary catheters are inappropriately placed and are not medically indicated (Meddings et al, 2014). Minimize urinary catheter use in all clients, especially those at risk for CAUTI such as women, the elderly, and immunocompromised clients (Lo et al, 2014; CDC, 2017). Urinary catheter use is inappropriate when used as a substitute for nursing care of the incontinent client, when obtaining a urine culture for the client who can void, and for prolonged periods after surgery without appropriate indications (CDC, 2017). There is a 3% to 7% daily risk of bacteriuria when an indwelling urinary catheter remains in place (Lo et al, 2014). Decreasing the number of days the catheter is in place and avoiding unnecessary catheterization are the primary interventions to decrease CAUTI and unintended client harm (Lo et al, 2014; Meddings et al, 2014).*

• To avoid catheterizations, evaluate alternative strategies for managing urine output for the client. **EB:** *Developing toileting schedules, providing assistance with toileting, and incorporating toileting activities into frequent, scheduled nursing staff rounding can reduce urgency and incontinence episodes. For clients with limited mobility, use a bedside commode with a toileting schedule (Uberoi et al, 2013). Use moisture wicking incontinence pads to reduce moisture-associated skin injury (Oman et al, 2012). Consider using external catheters or intermittent catheterization in appropriate clients (CDC, 2017; Yokoe et al, 2014).*

• If an indwelling urinary catheter is determined to be clinically indicated in the care of a client, proper selection of the right catheter, technique during insertion, and evidence-based care management are needed to reduce infection and injury to the urinary tract structures.

- ❍ Perform hand hygiene and use Standard Precautions before and after insertion of the urinary catheter and any time the catheter, catheter site, or collection system is accessed (Yokoe et al, 2014; CDC, 2017).
- ❍ Ensure that only properly trained personnel familiar with appropriate catheter care techniques are used for inserting and maintaining the catheter (Yokoe et al, 2014; CDC, 2017). *Periodic in-service training helps personnel to maintain proper catheter care techniques (CDC, 2017).*

• Selecting the smallest catheter size (e.g., smaller than 18 French) reduces irritation and inflammation of the urethra and reduces infection risk (Yokoe et al, 2014; CDC, 2017).

• Insert the catheter using aseptic technique in the acute care setting. Wash hands and use sterile technique when opening the catheterization kit and cleansing the urethral meatus and perineal area with an antiseptic solution. Insert the catheter using a no-touch technique (Yokoe et al, 2014; CDC, 2017). In the nonacute care setting,

nonsterile technique may be used for intermittent catheterization (CDC, 2017). *Using a no-touch technique may reduce the risk of infection.*

• Provide routine hygiene care; once a urinary catheter is placed, optimal management includes care of the urethral meatus according to "routine hygiene" (e.g., daily cleansing of the meatal surface during bathing with soap and water and as needed, such as following a bowel movement) (Yokoe et al, 2014; CDC, 2017). Do not clean the periurethral area with antiseptics while the catheter is in place (CDC, 2017).

• Secure the catheter after placement to reduce friction and pain from movement (Clarke et al, 2013; Yokoe et al, 2014).

- ❍ Disruptions in aseptic technique, disconnection, or leakage require the catheter and collection system to be replaced using aseptic technique and sterile equipment(Yokoe et al, 2014; CDC, 2017). *Risk factors for CAUTI include not maintaining a closed drainage system (Lo et al, 2014).*
- ❍ Maintain unobstructed urine flow; maintain the catheter and collecting tube below the level of the bladder and free of kinks. Do not rest the collection bag on the floor. *Keeping the collection bag off the floor prevents contamination. Maintaining the urine collection bag below the level of the bladder and the catheter without kinks minimizes reflux into the catheter itself, preventing retrograde flow of urine and risk for infection (Lo et al, 2014; CDC, 2017).*

• Establish workflow protocols to routinely empty the drainage bag frequently and before transport to reduce urine reflux and opportunities for infection. *Use a separate, clean collecting container for each client when emptying the collection bag; avoid splashing, and prevent contact of the drainage spout with a nonsterile container* (Lo et al, 2014; CDC, 2017). *The collection bag of a bacteriuric client is a reservoir for organisms that may be transmitted by the hands of health care personnel to other clients (Lo et al, 2014).*

• Change urinary catheters and drainage systems based on clinical indications such as infection, obstruction, or when the drainage system is not adequately maintained. Changing indwelling catheters or drainage bags at a routine time interval is not recommended because it opens a closed drainage system and predisposes the client to infection (Lo et al, 2014; CDC, 2017).

• Monitor the client with an indwelling urinary catheter for increased temperature (>38°C), suprapubic pain, frequency, urgency, and flank pain; monitor the skin around the catheter for redness, drainage, or swelling. **EB:** The most common clinical presentation for CAUTI is fever with a positive urine culture (Lo et al, 2014). **EBN:** Monitor the client for CAUTI symptoms caused by localized or systemic inflammatory response (Blodgett et al, 2015).

• Consider an ultrasound scanner for clients who require intermittent catheterization to assess urine volume and reduce unnecessary catheter insertion (CDC, 2017).

▲ Implement systemwide quality improvement programs to include the following interventions to decrease CAUTI:

- ❍ Establish health care provider alerts or reminders for all clients with catheters regarding the need for continued catheterization. **EB/EBN:** *Healthcare providers frequently forget that the catheter is in place, increasing the risk for CAUTI. Studies have shown the rate of CAUTI was decreased with the use of daily checklists, catheter reminders, and stop orders (Halm & O'Connor, 2014; CDC, 2017).*
- ❍ Provide performance feedback and education to personnel responsible for catheter care (CDC 2017; Yokoe et al, 2014).
- ❍ Establish evidence-based "bladder bundles" as part of a multimodal approach to preventing CAUTI. "Bladder bundles" may include

educational interventions aimed at health care providers for appropriate use of urinary catheters, use of appropriately trained personnel to insert and care for the catheter, catheter restriction and removal protocols, and the use of bladder ultrasound to assess urine volume (Lo et al, 2014; Meddings et al, 2014). **EB/EBN:** *Evidence-based "bundles" of interventions, when implemented simultaneously, decrease the risk of CAUTI (**EB:** Lo et al, 2014; **EBN:** Halm & O'Connor, 2014).*

Home Care and Client/Family Teaching and Discharge Planning

- Teach the client and family discharged with an indwelling urinary catheter or performing intermittent catheterization at home techniques for care of urinary catheter and collection bag using the interventions listed above. (Clarke et al, 2013; Yokoe et al, 2014; CDC, 2017)
- Ensure client has adequate supplies at home for catheter insertion and care.
- Teach the client and family to contact the health care provider regarding symptoms of CAUTI including increased temperature (>38°C), suprapubic pain, frequency, urgency, and flank pain; no drainage of urine in the collection bag; and foul smelling, cloudy, or bloody urine (Medline Plus, 2017).
- Teach the client and family methods to keep the urinary tract healthy. Refer to Client/Family Teaching in the care plan for Readiness for enhanced **Urinary** elimination.

Insomnia

Judith Ann Floyd PhD, RN, FNAP, FAAN

NANDA-I

Definition

A disruption in amount and quality of sleep that impairs functioning.

Defining Characteristics

Alteration in affect; alteration in concentration; alteration in mood; alteration in sleep pattern; compromised health status; decrease in quality of life; difficulty initiating sleep; difficulty maintaining sleep state; dissatisfaction with sleep; early awakening; increase in absenteeism; increase in accidents; insufficient energy; nonrestorative sleep pattern; sleep disturbance producing next-day consequences

Related Factors

Alcohol consumption; anxiety, average daily physical activity is less than recommended for gender and age; depression; environmental barrier; fear; frequent naps; grieving; inadequate sleep hygiene; physical discomfort; stressors

Associated Condition

Hormonal change; pharmaceutical agent

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Comfort Level; Pain Level; Personal Well-Being; Psychosocial Adjustment: Life Change; Quality of Life; Rest; Sleep

Example NOC Outcome with Indicators

Sleep as evidenced by the following indicators: Hours of sleep/Sleep pattern/Sleep quality/Sleep efficiency/Feels rejuvenated after sleep/Sleeps consistently through the night. (Rate the outcome and indicators of **Sleep:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Verbalize plan to implement sleep-promoting routines
- Fall asleep with less difficulty a minimum of four nights out of seven
- Wake up less frequently during night a minimum of four nights out of seven
- Sleep a minimum of 6 hours most nights and more if needed to meet next stated outcome
- Awaken refreshed and not be fatigued during day most of the time

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Sleep Enhancement

Example NIC Activities—Sleep Enhancement

Monitor/record client's sleep pattern and number of sleep hours; Encourage client to establish a bedtime

routine to facilitate transition from wakefulness to sleep

Nursing Interventions and *Rationales*

- Obtain a sleep history including amount of time needed to initiate sleep, duration of any awakenings after sleep onset, total nighttime sleep amounts, and dissatisfaction with daytime energy levels and alertness. *Inability to drift off to sleep at bedtime or during the night if awakened can lead to short sleep and poor daytime functioning, as well as negatively affect physical and mental health (Khurshid, 2015).*
- From the history, assess client's current ability to initiate and maintain sleep and the short-term versus chronic nature of inability to initiate and maintain sleep. *Adults can be considered to have insomnia if their daytime tiredness and sleepiness is accompanied by shortened nighttime caused by (1) inability to initiate sleep and/or (2) awakening during the night with inability to reinitiate sleep 3+ nights/week. Insomnia is considered chronic if the inability to initiate sleep continues beyond three months (Khurshid, 2015).*

For short-term insomnia:

- For clients historically able to initiate and maintain sleep, but unable to do so in the current situation (1) minimize sleep disruptions (see Nursing Interventions and *Rationales* for Disturbed **Sleep** pattern), and (2) promote sleep hygiene practices (see Nursing Interventions and *Rationales* for Readiness for enhanced **Sleep**). *Inability to initiate and maintain sleep is common in new sleep environments, especially during times of stress or worry (Dambrosio & Maxanec, 2013).*
- Also attend to the following factors often associated with short-term insomnia:
    - ❍ Assess pain medication use and, when feasible, advocate for pain medications that promote rather than interfere with sleep. (See Nursing Interventions and *Rationales* for Acute **Pain** and Chronic **Pain.**) *Some pain medications also promote sleep, whereas others promote alertness and thus interfere with falling and staying asleep (Laudon & Frydman-Marom, 2014).*
    - ❍ Assess level of tension and encourage use of relaxation techniques as needed. **EBN:** *A review of evidence from nine intervention studies suggested relaxation, meditation, guided imagery, or combinations of these strategies resulted in better sleep and less fatigue in heart-failure patients (Kwekkeboom & Bratzke, 2016).* **EBN:** *A well-controlled clinical pilot study (N = 12) found that patient-controlled relaxation and/or imagery interventions may improve sleep for hospitalized patients (Nooneret et al, 2016).*
    - ❍ Assess level of distress and use therapeutic communication to increase comfort. (See further Nursing Interventions and *Rationales* for Readiness for Enhanced **Comfort**.) **EBN:** *A qualitative study of 10 patients' experiences with sleep during hospitalization identified several themes that promote patients' comfort, increase patients' ability to initiate and maintain sleep and support the nurse's ability to co-create a safe sleep environment with the patient (Gellerstedt, Medin, & Karlsson, 2014).* **EBN:** *A qualitative study of how experienced nurses promote sleep in hospitals (N = 8) identified caring conversation as one of four sleep-promoting nursing strategies (Salzmann-Erikson, Lagerqvist, & Pousette, 2016).*
    - ❍ Assess for signs of overactive bladder. **EB:** *A descriptive study (N = 24) found subjects with overactive bladder syndrome (OAB), but no formal insomnia*

diagnosis, awakened during sleep as often as insomniacs; however, waking durations were shorter in OAB subjects than those with diagnosed insomnia (Preud'homme et al, 2013).

For chronic insomnia:

▲ Rule-out/address any disorders and syndromes associated with chronic insomnia (e.g., addiction to alcohol or other psychoactive substances, anxiety and depressive disorders, chronic pain syndrome, restless leg syndrome, or other sleep disorders). *Coexisting medical conditions, mental disorders, and sleep disorders are interactive and bidirectional (Khurshid, 2015).* **EB:** *In a study of 39 older insomnia patients, those with higher anxiety and depression responded better to treatments for chronic insomnia when anxiety and depression were also treated (Troxel et al, 2013).*

• Encourage practices that calm the mind and body prior to bedtime.

❍ Introduce music into bedtime routines if client finds music relaxing. **EB:** *A meta-analysis of six experimental studies showed that listening to music led to insomnia patients reporting better sleep, although no objective evidence was found of shorter sleep latencies, less waking after sleep onset, or increased total sleep time (Jespersen et al, 2015).*

❍ Teach progressive muscle relaxation as a way to relax at bedtime. **EB:** *An experimental study found that multicomponent treatment programs that included progressive muscle relaxation were effective for decreasing insomnia patients' reports of insomnia severity and increasing self-reported sleep quality (Pech & O'Kearney, 2013).*

❍ Support client's meditation or prayer practices as part of bedtime rituals if client finds them relaxing. **EB:** *A 7-week randomized controlled trial of 54 adults with chronic insomnia that used a treatment of mindfulness meditation reported that improved sleep was found, especially at the 3-month follow-up on both objective and subjective measures of sleep (Ong et al, 2014).*

• Encourage use of the following stimulus control strategies in addition to relaxation and sleep hygiene interventions recommended for short-term insomnia; (1) if feasible, have client arise from bed to participate in calming activities whenever anxious about failure to fall asleep; (2) if not feasible for client to get out of bed when unable to sleep, encourage sitting up in bed to engage in calming activities or simply resting in bed without attempting to fall asleep; (3) avoid a focus on what time it is and subsequent worry about amount of sleep time lost to sleeplessness; and (4) distract from sleeplessness with a focus on positive aspects of life. **EB:** *A meta-analysis of 37 comparative effectiveness studies found medium to large improvements in the ability to initiate and maintain sleep when a combination of stimulus control, relaxation, and sleep hygiene strategies were used to treat insomnia in patients with comorbid medical and psychiatric conditions (Wu et al, 2015).*

• Consider use of foot baths. **CEB:** Small manipulations of core body and skin temperature were found to affect sleep onset in adults, including normal older sleepers and older insomniacs (Raymann & Van Someren, 2008). **EBN:** A review of evidence from 31 papers found that passive body heating via foot baths often relaxed and improved quality of sleep in insomnia patients (Talebi, Heydari-Gorji, & Hadinejad, 2016).

• Be aware that clients diagnosed with chronic insomnia may have a low pain threshold. **CEB:** In a laboratory study (N = 34), subjects with shortened sleep caused by chronic insomnia, were twice as likely to report experiencing spontaneous pain as

healthy controls with no sleep loss; they also had lower pain thresholds during applications of heat and pressure than healthy controls (Haack et al, 2012).
• For clients whose chronic inability to initiate and maintain sleep has led to sleep deprivation, see Nursing Interventions and *Rationales* for **Sleep** deprivation.
▲ For clients with unremitting chronic insomnia, refer to a nurse practitioner trained in cognitive behavioral therapies for insomnia (CBT-I). **EB:** *A meta-analysis of 37 comparative effectiveness studies found chronic insomnia patients with comorbid medical and psychiatric conditions improved their ability to initiate and maintain sleep after completion of multicomponent CBT-I programs (Wu et al, 2015).*
▲ Assist clients diagnosed with chronic insomnia who have been treated with CBT-I to limit use of sleeping agents and to select intermittent nights for sleeping pill use if complete discontinuance of sleeping pills is not feasible. *One option to reduce the risk of habituation or dependence on sleeping medication is to adopt an intermittent dosing approach in which patients are given 10 to 15 tablets for the entire month and are allowed to use them on an as-needed basis (Gooneratne & Vitiello, 2014).* **EB:** *An updated review of evidence supported the ability of patients treated with CBT-I to reduce or even eliminate their dependence on sleeping pills (Bonnet & Arand, 2017).*
• Supplement other interventions with teaching about sleep and sleep promotion. (See further Nursing Interventions and *Rationales* for Readiness for enhanced **Sleep.**)

Geriatric

• Most interventions discussed previously may be used with geriatric clients. In addition, see the Geriatric section of Nursing Interventions and *Rationales* for (1) Readiness for enhanced **Sleep** and (2) Disturbed **Sleep**, and **Sleep** deprivation**.**
• Especially helpful for the elderly client is routine exercise unless contraindicated. **EB:** *In an evidence review of 34 research reports, exercise increased sleep efficiency and duration in healthy older adults regardless of the mode and intensity of activity, and even more so in the elderly with sleep disorders (Dolezal et al, 2017).*
▲ Monitor for uncomfortable sensations in legs and involuntary leg movements during sleep. **EB:** *An observational study of 2872 older community-dwelling men, using home polysomnography, reported that periodic limb movements were common in this population and resulted in more fragmented sleep (Claman et al, 2013).*

Home Care

• Assessments and interventions discussed previously can all be adapted for use in home care.
• In addition, see the Home Care section of Nursing Interventions and *Rationales* for Readiness for enhanced **Sleep.**

Client/Family Teaching

• Teach family about normal sleep and promote adoption of behaviors that enhance it. See Nursing Interventions and *Rationales* for Readiness for enhanced **Sleep.**
• Teach family about sleep deprivation and how to avoid it. See Nursing Interventions and *Rationales* for **Sleep** deprivation.
• Advise family of importance of not disrupting sleep of others unnecessarily. See Nursing Interventions and *Rationales* for Disturbed **Sleep** pattern.
• Advise family of importance of minimizing noise and light, including light from electronic devices in the sleep environment. See Nursing Interventions and *Rationales*

for Disturbed **Sleep** pattern.

• Help family members understand the difference between insomnia and externally caused sleep disruption/resultant sleep deprivation. *Insomnia is generally a stress-related, medication-related, or disease-related psychophysiological activation that interferes with the person's ability to calm the mind and body adequately for initiation and maintenance of sleep (Gooneratne & Vitiello, 2014).*

Decreased Intracranial adaptive capacity

NANDA-I

Definition

Compromise in intracranial fluid dynamic mechanisms that normally compensate for increases in intracranial volumes, resulting in repeated disproportionate increases in intracranial pressure (ICP) in response to a variety of noxious and nonnoxious stimuli.

Defining Characteristics

Baseline intracranial pressure (ICP) ≥10 mm Hg; disproportionate increase in intracranial pressure (ICP) following stimuli; elevated tidal wave intracranial pressure (P2 ICP) waveform; repeated increase in intracranial pressure (ICP) ≥10 mm Hg for ≥5 minutes following external stimuli; volume-pressure response test variation (volume: pressure ratio 2, pressure-volume index <10); wide-amplitude intracranial pressure (ICP) waveform

Related Factors

To be developed

Associated Condition

Brain injury; decrease in cerebral perfusion ≤50 to 60 mm Hg; sustained increase in intracranial pressure (ICP) of 10 to 15 mm Hg; systemic hypotension with intracranial hypertension

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Neurological Status; Neurological Status: Consciousness

Example NOC Outcome with Indicators

Neurological Status as evidenced by the following indicators: Consciousness/Intracranial pressure/Vital signs/Central motor control/Cranial sensory-motor function/Spinal sensory-motor function. (Rate the outcome and indicators of **Neurological Status:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Experience fewer than five episodes of DIICP in 24 hours
- Avoid neurological status changes that are triggered by episodes of disproportionate increases in intracranial pressure (DIICP)
- Have cerebral perfusion pressure (CPP) remaining greater than 60 to 70 mm Hg in adults

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Cerebral Edema Management; Cerebral Perfusion Promotion; Intracranial Pressure Monitoring; Neurological Monitoring

Example NIC Activities—Cerebral Edema Management

Monitor for confusion, changes in mentation, complaints of dizziness, syncope; Allow ICP to return to baseline between nursing activities

Nursing Interventions and *Rationales*

- To assess ICP and CPP effectively:
  - Monitor and display ICP and CPP in clients with severe traumatic brain injury (TBI) and spontaneous intracranial hemorrhage (ICH). **EB:** *Lack of ICP/CPP monitoring in severe TBI increases mortality (Heck 2016; Carney et al, 2017).*
  - Maintain systolic blood pressure (SBP) >110 mm Hg in patients 15 to 49 years of age or over 70 years of age and SBP >100 mm Hg in patients 50 to 69 years of age to improve outcomes. **EB:** *Targeted blood pressure supports adequate CPP, especially in cases of elevated ICP (Carney et al, 2017).*
  - Monitor jugular bulb oxygenation (SjO_2) in select patients with severe TBI. **EB:** *SjO_2 monitoring may provide information for management decisions that can reduce morbidity and mortality associated with elevated ICP (Carney et al, 2017).*
  - Maintain ICP less than 22 mm Hg and CPP greater than 60 mm Hg. **EB:** *The Guidelines for the Management of Severe Brain Injury established the treatment threshold for ICP as greater than 22 mm Hg and CPP less than 60 mm Hg (Carney et al, 2017).*
  - Monitor neurological status frequently (hourly in acute situations) determining both pupillary size and reaction to light and the Glasgow Coma Scale (GCS) score, noting changes in eye opening; motor response to painful stimuli; and awareness of self, time, and place. **EB:** *The combination of a GCS score and the pupil size and reactivity are predictive of outcome and aid in discussions of prognosis with family (Hoffmann et al, 2012).* **EB:** *Research exploring the reliability of automated pupillometers may help reduce the subjective error of estimating client pupil size, allowing for more accurate trending of ICP concerns (Olson et al, 2017).*
  - Monitor brain tissue oxygen ($PbtO_2$). **CEB/EB:** *Low brain $PbtO_2$ is predictive of increased mortality in clients with severe TBI and worse 6-month outcomes (Bohman et al, 2011; Eriksson et al, 2012; Okonkwo et al, 2017).*
- To prevent harmful increases in ICP:
  - Elevate head of bed 30 to 45 degrees with head in midline position. **CEB/EB:** *Elevating the head of the bed allows for increased venous drainage that decreases ICP (Fan, 2004; Ledwith et al, 2010; McNett & Olson, 2013).* **EB:** *If client is suffering acute stroke, CPP may be compromised with head elevation during the first 72 hours after injury (Favilla et al, 2014). See care plan for Risk for ineffective **Cerebral** tissue perfusion.*
  - *Administer sedation per collaborative protocol.* **EB:** *Sedatives including propofol, morphine, and midazolam are effective in controlling ICP (Carney et al, 2017). Sedation was effective in 66% of episodes of decreased $PbtO_2$ (Bohman et al, 2011).*
  - *Maintain glycemic control per collaborative protocol.* **CEB:** *Maintain glucose levels between 110 and 180 mg/dL using insulin therapy in critically ill brain-injured clients (Kramer, Roberts, & Zygun, 2012).*
  - Maintain optimal oxygenation and ventilation, applying positive end-

expiratory pressure (PEEP) as needed and avoiding hyperventilation. **CEB/EB:** *PEEP levels of 10 cm H_2O have been found to produce no significant changes in ICP, especially when combined with head of bed elevation of 30 degrees. Hyperventilation has been found to worsen outcomes in TBI clients and should be avoided, especially in the first 24 hours after injury (Videtta et al, 2002; Carney et al, 2017).*

- ❍ Provide hyperbaric oxygen/normobaric hyperoxia if available during the acute phase of severe TBI. **EB:** *Sixty minutes of hyperbaric oxygen at 1.5 ATA followed by 3 hours of an FiO_2 of 100% every 24 hours during the first 72 hours of severe TBI lowered ICP for the entire 3-day study period in severe TBI clients (Rockswold et al, 2013).*

- ▲ To prevent and treat harmful decreases in CPP:
  - ❍ See care plan for Risk for ineffective **Cerebral** tissue perfusion.
- ▲ To treat sustained ICP (>22 mm Hg):
  - ❍ Remove or loosen rigid cervical collars. **CEB/EB:** *Loosening or removing these collars allows for unrestricted venous drainage that lowers ICP (Mobbs, Stoodley, & Fuller, 2002; McNett & Olson, 2013).*
  - ❍ Administer hypertonic saline (bolus or continuous infusion) per collaborative protocol. **EB:** *Hyperosmolar therapy reduces brain water content. A comparison of mannitol and hypertonic saline found that multiple studies, including randomized controlled trials (RCTs), demonstrated superior effectiveness of hypertonic saline in decreasing ICP (Mortazavi et al, 2012). Alternatively, administer mannitol boluses for increased ICP.* **EB:** *Mannitol controls elevated ICP when given in bolus doses of 0.25 to 1 g/kg as long as hypotension is avoided (Carney et al, 2017).*
  - ❍ Drain cerebrospinal fluid (CSF) from an intraventricular catheter system per collaborative protocol. **EB:** *CSF drainage has been found to be effective in decreasing ICP (Bhargava et al, 2013; Srinivasan et al, 2014).*
  - ❍ Use targeted temperature management to facilitate control of ICP. **EB:** *Target temperatures vary according to intracranial pathology with temperatures 35°C to 37°C associated with lower ICP and temperatures as low as 32°C offering neuroprotection after cardiac arrest (Cariou et al, 2017).*

Deficient Knowledge	Readiness for enhanced Knowledge	

K

• = Independent; ▲ = Collaborative; **EBN** = Evidence-Based Nursing; **EB** = Evidence-Based

Deficient Knowledge

Lauren McAlister MSN, FNP, DNP Candidate, Kathaleen C. Bloom PhD, CNM

NANDA-I

Definition

Absence or deficiency of cognitive information related to a specific topic or its acquisition.

Defining Characteristics

Inaccurate follow-through of instruction; inaccurate performance on a test; inappropriate behavior; insufficient knowledge

Related Factors

Insufficient information; insufficient interest in learning; insufficient knowledge of resources; misinformation presented by others

Associated Condition

Alteration in cognitive functioning; alteration in memory

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Knowledge: Disease Process; Energy Conservation; Health Behavior; Health Resources; Healthy Diet; Infection Management; Medication; Personal Safety; Prescribed Activity; Substance Use Control; Treatment Procedure(s); Treatment Regimen

Example NOC Outcome with Indicators

Knowledge: Health Behavior as evidenced by the following indicators: Healthy nutritional practices/Benefits of regular exercise/Safe use of prescribed and nonprescribed medication. (Rate the outcome and indicators of **Knowledge: Health Behavior:** 1 = no knowledge, 2 = limited knowledge, 3 = moderate knowledge, 4 = substantial knowledge, 5 = extensive knowledge [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Explain disease state, recognize need for medications, and understand treatments
- Describe the rationale for therapy/treatment options
- Incorporate knowledge of health regimen into lifestyle
- State confidence in one's ability to manage health situation and remain in control of life

- Demonstrate how to perform health-related procedure(s) satisfactorily
- Identify resources that can be used for more information or support after discharge

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Teaching: Disease Process, Individual; Learning Facilitation

Example NIC Activities—Teaching: Disease Process

Discuss therapy/treatment options; Describe rationale behind management/therapy/treatment recommendations

Nursing Interventions and Rationales

- Consider the health literacy and the readiness to learn for all clients and caregivers (e.g., mental acuity, ability to see or hear, existing pain, emotional readiness, motivation, previous knowledge). **EBN:** *A new study looking at a new tool, the Newest Vital Sign (NVS), was used to measure the patient's health literacy. Findings showed that this tool is efficient to administer and could help identify low health literacy patients (McCune, Hynha, & Pohl, 2016).*
- Focus on the nature of spoken and written communication when teaching clients and caregivers, especially those who may have health literacy needs. **EBN:** *Lambert and Keogh (2014) provided an overview of tools for effective teaching communication including providing feedback, actively seeking questions, using a teach-back method, and providing age-appropriate client education materials that are in are written in everyday layman's language.* **EBN:** *A recent qualitative study explored the relationship between health literacy and effective communication. One of the overarching themes was that building trust and relationships with the older adults to achieve effective communication can then be applied to meet the individual health literacy needs of the patient (Brooks et al, 2017).*
- Consider the context, timing, and order of how information is presented. **CEB:** *A systematic review of 56 studies on educational interventions found that presenting the most important information first and the use of simplifying, "chunking," and grouping information presented in short sessions were effective (Berkman et al, 2011).*
- Use client-centered approaches that engage clients and caregivers as active versus passive learners. **EB:** *A systematic review of 38 trials with clients with asthma found that using empathy-building strategies within a framework of person-centered counseling would maximize the effectiveness of self-care interventions for those with poorly controlled asthma (Denford et al, 2014).*
- Reinforce learning through frequent repetition and follow-up sessions. **EBN:** *A systematic review of six studies found that frequent and regular educational sessions, including "boost" sessions, improved medication and self-care management outcomes for those with a chronic condition, including stroke clients (Chapman & Bogle, 2014).* **EBN:** *In a qualitative study with semistructured interviews, it was discovered that patients who were in the intensive care unit (ICU) and who attended a follow-up session were better able to process their feelings and emotions. The findings from this study supported the hypothesis that the follow-up session for an ICU patient can aid in processing the illness after the fact (Haraldsson et al, 2015).*
- Use electronic methods for delivery of information when appropriate. **EB:** *A Cochrane review of 24 studies with 8112 participants found that the use of multimedia education (video, audio, and self-paced computer programs) as an adjunct with current*

programs was most effective (Ciciriello et al, 2013). **EB:** *In a Cochrane review of 16 trials with 3478 participants, the use of computer programs and the use of mobile phone interventions helped clients with diabetes type 2 improve blood glucose control, although not all clients have access (Pal et al, 2013).*

• Help the client and caregivers locate appropriate postdischarge groups and resources. **EBN:** *A recent systematic review concluded that the utilization of postdischarge support for patients with chronic obstructive pulmonary disease (COPD) significantly reduced the readmission rates within 30 days and had an effect up to 180 days (Pedersen et al, 2017).*

• Encourage clients and caregivers to maintain and/or expand supportive social networks as self-care learning resources when appropriate. **EB:** *In a longitudinal study of 300 patients with long-term chronic health conditions, those who had sustained or expanded community networks were more likely to sustain self-care management, maintain behavioral change and treatment regimens, and access voluntary caregiving over formal caregiving (Reeves et al, 2014).*

Pediatric

• Use family-centered approaches when teaching children and adolescents. **EBN:** *According to Manente (2017), when families are educated about the patient and know what to expect during the transition out of the ICU, their fears and anxieties are decreased, which can promote healing for the patient.*

• Guide children and adolescents to credible information about their condition. **EBN:** *A recent mixed methods study showed that the best way to inform adolescents about HIV and sexual/reproductive health is via the radio, television, mass media, and social media (Adams et al, 2017).*

Geriatric

• Educate all older clients on safety issues, including fall prevention and medication management. **QSEN:** *In a meta-analysis of 19 studies, clients receiving targeted fall prevention education face to face or through multimedia methods had decrease in falls from those either receiving no formal education or written education (Lee et al, 2014).*

• Use multidisciplinary teams to enhance patient education. **EBN:** *A qualitative study exploring medication management in people with dementia showed potential positive benefits of a community pharmacist working in a multidisciplinary environment outside the pharmacy and can improve medication management (Maidment et al, 2016).*

• Consider using teaching methods and materials appropriate for older adults, especially those with cognitive challenges. **EBN:** *A recent study concluded that screening for cognitive impairment in the elderly population and including the family and caregivers in the discharge education has the potential to minimize the risk of readmission (Agarwal et al, 2016).*

• Assess readiness of older adults for use of technological resources. **EBN:** *Health care providers need to assess the experience and willingness of older adults to use the Internet as a source of health information, and Internet sites need to be assessed for readability, large fonts, and simple structure (Chang & Im, 2014).*

Multicultural

• Use educational interventions that are culturally tailored to the health literacy needs of the client. A Cochrane review of 33 randomized controlled trials focusing on

diabetes type 2 found that culturally appropriate health education improved blood sugar control among participants, compared with those receiving the "usual" care, at 3, 6, 12, and 24 months after the intervention (Attridge et al, 2014).

- Assess for cultural/ethnic self-care practices. **CEB:** *The knowledge of patients' cultural practices can be used by health care providers to help design more culturally competent care for the patient (Theroux, Klar, & Messenger, 2013).*
- Consider the potential influence of medical interpreters in information sharing and decision-making and of the possible difficulties for clients when using medical interpreters. **EBN:** *The use of medical interpreters can help bridge the culture and language gap, allowing patients to feel more comfortable expressing themselves (Rorie, 2015).*
- Consider involving bilingual members of a community who are considered outside the traditional health care system who may assist in the teaching of community health issues. **EBN:** *A recent cross-sectional design study examined challenges associated with migrant and English-speaking cancer patients and found that the majority of participants in all migrant groups reported difficulty communicating with the health care providers and team in English (Hyatt et al, 2016).*

Home Care

- All of the previously mentioned interventions are applicable to the home setting.
- Use telehealth and technology-enhanced practices as appropriate. **EBN:** *Findings from a literature review of 48 papers supported previous findings that technology is desired by consumers and can be effective, but the appropriateness for use should take into consideration the abilities of the clients, as well as the credibility of software applications and the accessibility of the type of technology, including computers and mobile devices (Fitzner & Moss, 2013).* **EBN:** *A recent review of 11 studies looking at the role of telehealth in diabetic foot ulcer management found that telehealth was well received by patients and providers; assessments via the telehealth modalities were congruent with face-to-face assessment (Singh et al, 2016).*

Readiness for enhanced Knowledge

Lauren McAlister MSN, FNP, DNP Candidate, Kathaleen C. Bloom PhD, CNM

NANDA-I

Definition

A pattern of cognitive information related to a specific topic or its acquisition, which can be strengthened.

Defining Characteristics

Expresses desire to enhance learning

NOC (Nursing Outcomes Classification)

Suggested NOC Outcome

Knowledge: Health Promotion

Example NOC Outcome with Indicators

Knowledge: Health Promotion as evidenced by the following indicators: Behaviors that promote health/Reputable health care resources. (Rate the outcome and indicators of **Knowledge: Health Promotion:** 1 = no knowledge, 2 = limited knowledge, 3 = moderate knowledge, 4 = substantial knowledge, 5 = extensive knowledge [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Meet personal health-related goals
- Explain how to incorporate new health regimen into lifestyle
- List sources to obtain information

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Health Education; Health System Guidance

Example NIC Activities—Health Education

Prioritize identified learner needs based on client preference, skills of nurse, resources available, and likelihood of successful goal attainment

Nursing Interventions and Rationales

- Assume a facilitator role versus authority role when engaging clients seeking health-related knowledge. **EBN:** *According to Stacey and Legare (2015), by assuming a facilitator role, nurses are able to provide balanced evidence on options, understand what is most important to the patient, and advocate for the patient's preferences. All of this facilitates shared decision-making and enables the opportunity to determine best practice.* **EBN:** *A descriptive survey (N = 312) found that nurses may make inaccurate assumptions about the willingness and abilities of clients to become engaged in self-care learning (Wu et al, 2014).*
- Consider "health coaching" and motivational interviewing techniques when focusing on health-related goals, priorities, and preferences. **EBN:** *In a randomized controlled trial (RCT) by Benzo et al (2017), health coaching, using motivational interviewing, significantly improved disease-specific quality of life compared with the control group.*
- Seek teachable moments for those with chronic conditions to enhance their knowledge of health promotion. **EB:** *Findings from a recent study indicated that using cancer diagnosis as the teachable moment for health promotion efforts should be tailored and targeted at specific comorbidities (Highland et al, 2015).*
- Refer clients to lifestyle and health promotion resources delivered in the workplace or community sites outside traditional health care environments. **EB:** *In a compilation of literature addressing the outcomes of workplace health promotion programs (WHPPs), Goetzel et al (2014) found success in programs focusing on areas of wellness, especially in*

organizations that had a "culture of health." **EB:** *A meta-analysis of 18 studies found that WHPPs with younger populations and that had weekly contacts were the most effective. Positive effects were seen in self-perceived health and in absences caused by illness (Rongen et al, 2013).*

- Refer clients to interactive and Web-based technological resources as appropriate. **EB:** *In a recent qualitative study by van der Gugten et al (2016), 70% of adults report that they seek health-related information through Internet resources.*
- Refer to Deficient **Knowledge** care plan.

Pediatric

- Consider the use of mobile text messaging as a resource for delivery of health promotion information. **EB:** *A systematic review of 16 studies indicated that the use of multimedia technologies and mobile messaging are viable adjuncts that can help engage adolescents in disease prevention and health promotion (Geckle, 2016).*
- Incorporate health promotion education that reflects the unique cultural interests and values of diverse groups. **EB:** *In a systematic review of 80 papers, Suarez-Balcazar, Friesema, and Lukyanova (2013) found that adapting physical activities, ethnic dancing, and playing games that are culturally relevant were most effective for promoting health and addressing obesity in African American and Latino youth.*
- Involve children and especially adolescents in designing health promotion programs and teaching methods. **EBN:** *In a recent systematic review of eight qualitative studies, when the health care professional ensures children receive education and information appropriate to their health literacy, children are apt to be more involved in their decision-making (Davies & Randall, 2015).*
- Consider settings outside traditional health care centers and interdisciplinary approaches for engaging children and adolescents in preventive health care. **EB:** *A systematic review of 55 studies found that schools may be the best place to implement health-related prevention programs to reduce health risk because of the accessibility of youth and the importance of school and peer learning (Hale, Fitzgerald-Yau, & Viner, 2014).*
- Refer to Deficient **Knowledge** care plan.

Geriatric

- Discuss healthy lifestyle changes that promote safety, health promotion, and health maintenance for older clients. **EB:** *A recent study by Hsu et al (2016) indicated that the elderly individuals with poor health status were more apt to receive a health examination for their diseases. Early detection via health promotion and disease prevention of the potential health risks would reduce the severity of diseases in the prognosis.*
- Consider involving bilingual members of a community who are considered outside the traditional health care system who may assist in the teaching of community health issues. **EB:** *A systematic review of 39 studies found that the use of multicultural health care workers improved chronic disease prevention and self-management (Goris et al, 2013).*

Multicultural

- Refer to Geriatric.
- Refer to Deficient **Knowledge** care plan.

Latex Allergy reaction

Gail B. Ladwig MSN, RN, Julianne E. Doubet BSN, RN, EMT-A

NANDA-I

Definition

A hypersensitive reaction to natural latex rubber products.

Defining Characteristics

Life-Threatening Reactions Within 1 Hour of Exposure

Bronchospasm; chest tightness; contact urticaria progressing to generalized symptoms; dyspnea; edema; hypotension; myocardial infraction; respiratory arrest; syncope; wheezing

Type IV Reactions Occurring ≥ 1 Hour After Exposure

Discomfort reaction to additives; eczema; skin irritation; skin redness

Generalized Characteristics

Generalized discomfort; generalized edema; reports total body warmth; restlessness; skin flushing

Gastrointestinal Characteristics

Abdominal pain; nausea

Orofacial Characteristics

Erythema; itching; nasal congestion; periorbital edema; rhinorrhea; tearing of the eyes

Related Factors

To be developed

At-Risk Population

Frequent exposure to latex product; history of allergy; history of asthma; history of food allergy; history of latex reaction; history of poinsettia plant allergy; history of surgery during infancy

Associated Condition

Hypersensitivity to natural latex rubber protein; multiple surgical procedures

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Allergic Response: Localized, Systemic; Immune Hypersensitivity Response; Symptom Severity; Tissue Integrity: Skin and Mucous Membranes

Example NOC Outcome with Indicators

Immune Hypersensitivity Response as evidenced by the following indicators: Respiratory, cardiac, gastrointestinal, renal, and neurological function status IER/Free of allergic reactions. (Rate the outcome indicators of **Immune Hypersensitivity Response:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)
IER, In expected range.

Client Outcomes

Client Will (Specify Time Frame)

- Identify presence of natural rubber latex (NRL) allergy
- List history of risk factors
- Identify type of reaction
- State reasons not to use or to have anyone use latex products
- Experience a latex-safe environment for all health care procedures
- Avoid areas in which there is powder from NRL gloves
- State the importance of wearing a medical alert bracelet and wear one
- State the importance of carrying an emergency kit with a supply of nonlatex gloves, antihistamines, and an autoinjectable epinephrine syringe (EpiPen), and carry one

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Allergy Management; Latex Precautions

Example NIC Activities—Latex Precautions

Question client or appropriate other about history of systemic reaction or sensitization to NRL (e.g., facial or scleral edema, tearing eyes, urticaria, rhinitis, and wheezing); Place an allergy band on client

Nursing Interventions and *Rationales*

- Identify clients at risk as those persons who are most likely to exhibit sensitivity to NRL, which may result in varying degrees of reactivity. Consider the following client groups:
- Persons with neural tube defects including spina bifida and myelomeningocele/meningocele. **EB:** *In their research, Moroz, Flanagan, and Zaretsky (2017) found that as many as 50% of those who have spina bifida may have a latex allergy, which is probably caused by their multiple surgeries, intermittent catheterization, and condition-related susceptibility.*
- Children with spinal cord injuries. **CEB:** *The frequency of daily bladder catheterizations with latex catheters has been correlated with latex sensitivity (Venkata & Lerman, 2011).*
    - ❍ Clients with a history of multiple surgeries or other latex-exposing procedures. **EB:** *Patients who have experienced multiple surgeries have an elevated risk for latex allergy (Werfel et al, 2015).*
    - ❍ Children who have experienced three or more surgeries, particularly as neonates. **CEB:** *A significant correlation between the total number of surgeries, particularly during the first year of life, and degree of sensitization has been established (Venkata & Lerman, 2011).*
- Atopic individuals (persons with a tendency to have multiple allergic conditions including allergies to certain food products). **EB:** *A report by Werfel et al (2015) stated that 86% of patients with a positive history of fruit allergy, but having no risk factors for latex*

sensitization, showed latex-specific IgE antibodies.

- Persons who have an ongoing occupational exposure to NRL, including health care workers, rubber industry workers, bakers, laboratory personnel, food handlers, hairdressers, janitors, policemen, and firefighters. **EB:** *Products manufactured with latex and the environmental allergen exposure that occurs in the work place are risk factors for the development of occupational latex allergy, especially among health care workers, followed by hairdressers, cleaners, food handlers, and those producing NRL (Caballero & Quirce, 2015).*
    - Latex sensitization is also prevalent in older adults, but they are often overlooked as a high-risk population. **EB:** *Latex allergy has not been studied extensively among older adults, but a recent study demonstrated that approximately 11.4% of the older adults in the study had latex sensitization (Grieco et al, 2014).*
- Take a thorough history of the client at risk. **EB:** *It is of immense importance to recognize allergic disorders in their primary phase so that avoidance and treatment plans can be implemented (Caballero & Quirce, 2015).*
- Have management protocols in place for treating anaphylaxis. **EB:** *Prompt initial treatment is essential in anaphylaxis because a few minutes' delay can lead to hypoxic-ischemic brain damage or death (Simons et al, 2013).* **EB:** *A report from the World Allergy Organization (Kowalski et al, 2016) advised that safety measures such as continuous supervision, specific emergency equipment, and quick access to emergency services should be readily available during at-risk testing procedures.*
- Question the client about associated symptoms of itching, swelling, and redness after contact with rubber products such as rubber gloves, balloons, and barrier contraceptives, or swelling of the tongue and lips after dental examinations. **EB:** *Latex allergy is an IgE-mediated hypersensitivity to NRL and can feasibly cause symptoms in a sensitized person ranging from urticaria to anaphylaxis (German, 2016).* **CEB:** *The range of clinical allergy-induced symptoms may include localized or generalized urticaria, rhinitis, conjunctivitis, bronchospasm, laryngospasm, hypotension, and full-blown anaphylaxis (Behrman, 2013).*
- Consider a blood test to measure serum IgE levels. **CEB:** *In theory, allergy blood testing may be safer because it does not expose the client to any allergens (Siles & Hsieh, 2011).*
- All latex-sensitive clients are treated as if they have NRL allergy. **EB:** *The prevention of further episodes of untoward reactions to the allergen is based on the client's removal from exposure (Siracusa et al, 2014).*
- Clients with spina bifida and others with a positive history of NRL sensitivity or NRL allergy should have all medical/surgical/dental procedures performed in a latex-controlled environment. **EB:** *The institution of primary and secondary prevention latex-safety policies has contributed to the decrease in latex allergy reactions (Mertes et al, 2016).* **CEB:** *Clients who are latex allergic should have a surgical procedure performed as the first case in the morning, when the levels of latex aeroallergens in the environment are the lowest (Siles & Hsieh, 2011).*
- In select high-risk atopic individuals, a specific immunotherapy regimen should be discussed with their health care provider. **EB:** *The initiation of a molecular-based diagnosis supports a continuing focus on allergen immune therapy (AIT) (Passalacqua & Canonica, 2016).* **EB:** *Raulf (2016) stated that molecular allergy diagnosis based on the discovery and quantity of specific IgE to single allergens is quickly developing in importance.*
    - The most effective approach to preventing NRL anaphylaxis is complete latex avoidance. **EB:** *According to Quirce and Fladur (2016), the client must be removed from exposure to a known allergen to avert another reactive event.*

▲ Materials and items that contain NRL must be identified and latex-free alternatives must be found. **EBN:** *It is of upmost importance for patient safety to create a latex-free environment for those sensitive to the allergen (Doenges, Moorhouse, & Murr, 2016).* **EB:** *The substitution of nonlatex materials and the identification of latex-derived products are valuable in the successful control of health risks linked to NRL (Quirce & Fladur, 2016).*
▲ If latex gloves are chosen for protection from blood or body fluids, a reduced-protein, powder-free glove should be selected. **EB:** *According to a study by Baid and Agarwal (2017), powdered gloves have been shown to have greater NRL proteins compared with nonpowdered gloves: these substances could cause life-threatening reactions in sensitized patients and present a risk to health care workers.*

Home Care

• Assess the home environment for presence of NRL products (e.g., balloons, condoms, gloves, and products of related allergies, such as bananas, avocados, and poinsettia plants). **EB:** *According to Wu et al (2016), latex-derived products are still in use universally and latex allergy remains a widespread health risk for many occupations and for the general populace.*
• At onset of care, assess client history and status of NRL allergy response. **EBN:** *A meticulous history must be taken to ascertain the origin and effects of the client's exposure to NRL (Doenges et al, 2016).*
▲ Seek medical care as necessary.
• Assist the client in identifying and obtaining alternatives to NRL products. **EBN:** *If possible, provide a list of latex-free products to the client/caregiver (Doenges et al, 2016).*

Client/Family Teaching and Discharge Planning

• Provide written information about NRL allergy and sensitivity. **EB:** *Clients at risk for a severe allergic reaction/anaphylaxis should be provided with a written action plan that includes education concerning the avoidance of allergic triggers and the self-administration of epinephrine when needed (Lieberman et al, 2015).*
▲ Instruct the client to inform health care professionals if he or she has an NRL allergy, particularly if the client is scheduled for surgery. **EB:** *Anaphylaxis caused by an allergic response in the course of general anesthesia (GA) is uncommon, but it is a life-threatening event that may lead to cardiorespiratory compromise (Krishna et al, 2014).*
• Teach the client what products contain NRL and to avoid direct contact with all latex products and foods that trigger allergic reactions. **EB:** *Patients who are affected by a latex allergy could also develop allergies to avocados, bananas, kiwifruit, chestnuts, and other foods (Werfel et al, 2015).*
• Teach the client to avoid areas in which powdered latex gloves are used and in which latex balloons are inflated or deflated. **CEB:** *Powdered gloves have been shown to increase airborne NRL antigens compared with nonpowdered gloves (Palosuo et al, 2011).*
• Instruct the client with an NRL allergy to wear a medical identification bracelet and/or carry a medical identification card. **EB:** *ID jewelry, such as those provided by Medic Alert, should be suggested (Lieberman et al, 2015).*
• Instruct the client to carry an emergency kit with a supply of nonlatex gloves, antihistamines, and an autoinjectable epinephrine syringe (EpiPen). **EB:** *Clients at risk for a severe allergic reaction/anaphylaxis should be provided with a written action plan that includes education concerning the avoidance of allergic triggers and the self-administration of epinephrine when needed (Lieberman et al, 2015).*

Risk for Latex Allergy reaction

Gail B. Ladwig MSN, RN, Julianne E. Doubet BSN, RN, EMT-A

NANDA-I

Definition

Susceptible to a hypersensitive reaction to natural latex rubber products, which may compromise health.

Risk Factors
To be developed

At-Risk Population
Frequent exposure to latex product; history of allergy; history of asthma; history of food allergy; history of latex reaction; history of poinsettia plant allergy; history of surgery during infancy

Associated Condition
Hypersensitivity to natural latex rubber protein; multiple surgical procedures

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes
Allergic Response: Systemic; Immune Hypersensitivity Response; Risk Control; Risk Detection; Tissue Integrity: Skin and Mucous Membranes

Example NOC Outcome with Indicators
Immune Hypersensitivity Response as evidenced by the following indicators: Respiratory, cardiac, gastrointestinal, renal, and neurological function status IER/Free of allergic reactions. (Rate the outcome and indicators of **Immune Hypersensitivity Response:** 1 = not controlled, 2 = slightly controlled, 3 = moderately controlled, 4 = well controlled, 5 = very well controlled [see Section I].)
IER, In expected range.

Client Outcomes

Client Will (Specify Time Frame)

- State risk factors for natural rubber latex (NRL) allergy
- Request latex-free environment
- Demonstrate knowledge of plan to treat NRL allergic reaction

NIC Interventions (Nursing Interventions Classification)

Suggested NIC Interventions
Allergy Management; Latex Precautions; Environmental Risk Protection

Example NIC Activities—Latex Precautions
Question client or appropriate other about history of systemic reaction to NRL (e.g., facial or scleral edema, tearing eyes, urticaria, rhinitis, and wheezing); Place an allergy band on client

Nursing Interventions and *Rationales*

- Clients at high-risk for NRL allergy need to be identified. **EB:** *Products manufactured with latex and the environmental allergen exposure that occurs in the work place are risk factors for the development of occupational latex allergy; especially among health care workers, followed by hairdressers, cleaners, food handlers, and those making NRL (Caballero & Quirce, 2015).*
- Clients with spina bifida are a high-risk group for NRL allergy and should remain latex free from the first day of life. **EB:** *In their research, Moroz et al (2017) found that as many as 50% of those who have spina bifida may have a latex allergy probably caused by their multiple surgeries, intermittent catheterization, and condition-related susceptibility.*
- Children who require regular medical treatments at home (e.g., catheterization,

home ventilation) should be assessed for NRL allergy. **CEB:** *The frequency of daily bladder catheterizations with latex catheters has been correlated with latex sensitivity (Venkata & Lerman, 2011).*
• Assess for NRL allergy in clients who are exposed to "hidden" latex. **EB:** *According to Wu, McIntosh, and Liu (2016), latex-derived products are still in use universally and latex allergy remains a widespread health risk for many occupations and for the general populace as well.*
• See care plan for **Latex Allergy** reaction.

Home Care

• Ensure that the client has a medical plan if a response develops. **EB:** *Prompt treatment of anaphylactic symptoms decreases the probability of a life-threatening situation. Authors of this report (Sicherer & Simons, 2017) stress the importance of patient, family, and community education in the recognition and immediate management of anaphylaxis.*
• See care plan for **Latex Allergy** reaction. Note client history and environmental assessment.

Client/Family Teaching and Discharge Planning

▲ A client who has had symptoms of NRL allergy or who suspects he or she is allergic to latex needs to give this information to health care providers. **EB:** *Clients should be made aware of any agents that would place them at risk for a serious reaction/anaphylaxis (Liebermann et al, 2015).*
• Provide written information about latex allergy and sensitivity. **EB:** *Client's at risk for a severe allergic reaction/anaphylaxis should be provided with a written action plan that includes education concerning the avoidance of allergic triggers and the self-administration of epinephrine when needed; ID jewelry, such as those provided by Medic Alert, could also be suggested (Liebermann et al, 2015).*
• Health care workers should avoid the use of latex gloves and seek alternatives such as unpowdered gloves made from nitrile. **EB:** *According to a study by Baid and Agarwal (2017), powdered gloves have been shown to have greater NRL proteins in contrast to unpowdered gloves: these substances could cause life-threatening reactions in sensitized patients and they present a risk to health care workers a well.*
• Health care institutions should develop prevention programs and establish latex-safe areas in their facilities. **EBN:** *According to Doenges, Moorhouse, and Murr (2016), the creation of latex-free environments will support client and staff safety.*
• Institute measures that reduce or completely avoid any latex exposure to clients. **EB:** *It is of immense importance to recognize allergic disorders in their primary phase to implement avoidance plans (Cabellero & Quirce, 2015).*

Readiness for enhanced health Literacy

Kathaleen C. Bloom PhD, CNM

NANDA-I

Definition

A pattern of using and developing a set of skills and competencies (literacy, knowledge, motivation, culture, and language) to find, comprehend, evaluate and use health information and concepts to make daily health decisions to promote and maintain health, decrease health risks, and improve overall quality of life, which can be strengthened.

Defining Characteristics

Expresses desire to enhance ability to read, write, speak, and interpret numbers for every day health needs; expresses desire to enhance awareness of civic and/or government processes that impact public health; expresses desire to enhance health communication with health care providers; expresses desire to enhance knowledge of current determinants of health on social and physical environments; expresses desire to enhance personal health care decision-making; expresses desire to enhance social support for health; expresses desire to enhance understanding of customs and beliefs to make health care decisions; expresses desire to enhance understanding of health information to make health care choices; expresses desire to obtain sufficient information to navigate the health care system

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Health Beliefs: Perceived Resources; Health-Promoting Behavior; Health-Seeking Behavior

Example NOC Outcome with Indicators

Health-Seeking Behavior as evidenced by the following indicators: Completes health-related tasks/Performs self-screening/Obtains assistance from health professional/Uses reputable heath information. (Rate the outcome and indicators of **Health-Seeking Behavior:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Use reputable information sources
- Seek information from health care providers
- Communicate with health care provider about understanding of information provided

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Health Literacy Enhancement; Health Education; Health System Guidance

Example NIC Activities—Health Literacy Enhancement

Create a health care environment in which a patient with impaired literacy can seek help without feeling ashamed or stigmatized; Provide understandable health information; Use strategies to enhance understanding

Nursing Interventions and *Rationales*

- Use a standard tool to identify the level of health literacy. *A variety of tools have been developed to measure individuals' health-related reading comprehension (Health Literacy Measurement Tools, 2016).*
- Identify and take into consideration factors affecting health literacy such as age, ethnicity, education, and cognitive function **EBN:** *Improved health literacy is associated with positive outcomes including decreased recidivism (Cloonan, Wood, & Riley, 2013), increased patient satisfaction with nurse communication (Stikes, Arterberry, & Logsdon, 2015), and increased health promotion (Chahardah-Cherik et al, 2018).*
- Implement health literacy universal precautions: assume that all patients may have difficulty understanding health information. *Less than 15% of adults possess the level of health literacy needed to navigate the health care system (AHRQ Health Literacy Toolkit, 2017). All patients need health information that is accurate, accessible, and understandable (French, 2015).*
- Determine readiness for increased health literacy. **EB:** *Assessing motivation and readiness to learn and change has the potential to allow identification of obstacles and overcoming resistance (Ceccarini et al, 2015).*
- Tailor health teaching and educational materials to accommodate the needs of those with low health literacy. **EBN:** *A systematic review and meta-analysis of diabetes self-management interventions (N = 13 studies) found that health literacy–sensitive interventions focused on communication (both written and spoken) and empowerment in the context of language and cultural considerations were the most effective for self-care and health outcomes, including reduction of hemoglobin (Hb)A1C (Kim & Lee, 2016).*
- Modify health teaching and educational materials to patient preferences. **EB:** *Individuals who have lower health literacy prefer, understand, and correctly interpret pictures and icons that are familiar, contextual, and less complex (van Beusekom et al, 2015, 2017; Arcia et al, 2016).*
- Use empowerment to enhance health literacy and improve patient outcomes. **EBN:** *A study with 295 individuals with type 2 diabetes found empowerment directly leading to health literacy, which then influenced self-efficacy, self-care behaviors, and finally HbA1C levels (Lee et al, 2016).*
- Use individual or group interventions as preferred by the patient and appropriate to the topic. **EB:** *A systematic review of 52 studies of interventions examining health literacy and smoking, nutrition, alcohol, physical activity, and/or weight found 73% of the studies with positive associations between improved health literacy and improved outcome (Taggart et al, 2012).*

Geriatric

- The above interventions may be adapted for geriatric use.
- Use simple educational materials targeted at health-promoting behaviors. **EB:** *Older adults with good health literacy are more likely to have mammography, to exercise, and to eat nutritiously and are less likely to perform monthly breast exams or to smoke (Fernandez, Larson, & Zikmund-Fisher, 2016; Geboers et al, 2016).*

Multicultural

- Take the patient's culture into account when designing teaching and education materials. **EB:** *Higher levels of health literacy challenge are associated with being from a culturally diverse background and/or not speaking English (Jessup et al, 2017).* **EB:** *A scoping review of 27 studies revealed three consistent barriers to health care services access: cultural differences between providers and patients, language barriers, and information barriers (Kalich, Heinemann, & Ghahari, 2016).*

Client/Family Teaching and Discharge Planning

- Promote shared decision-making. **EB:** *A systematic review of 19 studies revealed that shared decision-making strategies targeted to low-literacy individuals increased knowledge, informed choice, and participation in decision-making (Durand et al, 2014).*

Risk for impaired Liver function

Janelle M. Tipton MSN, RN, AOCN

NANDA-I

Definition
Susceptible to a decrease in liver function, which may compromise health.

Risk Factors
Substance misuse

Associated Condition
Human immunodeficiency virus (HIV) coinfection; pharmaceutical agent; viral infection

NOC (Nursing Outcomes Classification)

Suggested NOC Outcome
Knowledge: Health Behavior; Liver Function

Example NOC Outcome with Indicators
Knowledge: Health Behavior as evidenced by the following indicators: Safe use of prescription drugs/Adverse health effects of alcohol misuse/Adverse health effects of recreational drug use/Healthy nutritional practices/Self-screening techniques. (Rate the outcome and indicators of **Knowledge: Health Behavior:** 1 = no knowledge, 2 = limited knowledge, 3 = moderate knowledge, 4 = substantial knowledge, 5 = extensive knowledge [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- State the upper limit of the amount of acetaminophen safely taken per day
- Verbalize understanding that over-the-counter (OTC) medications may contain acetaminophen (e.g., OTC cold medicines)
- Have normal liver enzymes, serum and urinary bilirubin levels, white blood cell count, and red blood cell count
- Be free of unexplained weight loss, jaundice, pruritus, bruising, petechiae, gastrointestinal bleeding, and hemorrhage
- Be free of abdominal tenderness/pain, increased abdominal girth, and have normal-colored stool and urine
- Be able to eat frequent small meals per day without nausea and/or vomiting
- If alcohol abuse is factor, state relationship between abuse and worsening

gastrointestinal and liver disease

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Teaching: Disease Process; Substance Use Treatment

Example NIC Activities—Teaching Disease Process

Appraise the client's current level of knowledge related to specific disease process; Discuss lifestyle changes that may be required to prevent future complications and/or control the disease process

Nursing Interventions and *Rationales*

▲ Assess for signs of liver dysfunction including fatigue, nausea, jaundice of the eyes or skin, pruritus, gastrointestinal bleeding, coagulopathy, infections, increasing abdominal girth, fluid overload, shortness of breath, mental status changes, light-colored stools, dark urine, and increased serum and urinary bilirubin levels. *These are symptoms and laboratory results associated with liver disorders (Ghany et al, 2015; Lee, Divens, & Fowler, 2017).*

▲ Evaluate liver function tests. Standard liver panels include the serum enzymes aspartate transaminase (AST), alanine transaminase (ALT), alkaline phosphatase, and γ-glutamyl transferase; total, direct, and indirect serum bilirubin; and serum albumin. **EB:** *Hepatitis C is often asymptomatic early in the disease state (Kwo, Cohen, & Lim, 2017) and may be found during a routine examination when liver function test results are elevated (Ferguson, 2014).*

▲ Discuss with the client/family preparations for other diagnostic studies, such as ultrasound, computed tomography, and magnetic resonance imaging (MRI) exams. *Although costly, MRI has the best quantification of steatosis (Cassard, Gerard, & Perlemuter, 2017).*

▲ Evaluate coagulation studies such as international normalized ratio, prothrombin time, and partial thromboplastin time, especially when there is bleeding of the mouth or gums. *Prolonged prothrombin time and decreased production of clotting factors can result in bleeding.*

• Monitor for signs of hemorrhage, especially in the upper gastrointestinal tract, because it is the most frequent site. *Synthesis of coagulation factors is affected with liver impairment (Lopez & Hendrickson, 2014).*

• Obtain a list of all medications, including OTC nonsteroidal antiinflammatory drugs, acetaminophen, herbal remedies, and dietary supplements. Review risk of drug-induced liver disease. The list includes some antibiotics, anticonvulsants, antidepressants, antiinflammatory drugs, antiplatelets, antihypertensives, calcium channel blockers, cyclosporine, lipid-lowering drugs, chemotherapy drugs, oral hypoglycemics, proton pump inhibitors, inhaled anesthetics, and tranquilizers, among others (Hamilton, Collins-Yoder, & Collins, 2016). If client is taking either OTC medications or herbals, discuss signs and symptoms of toxic hepatitis. *Toxic hepatitis is caused by direct toxins, drugs, herbs, and industrial chemicals. The risk of toxicity with aspirin, ibuprofen, naproxen sodium, and acetaminophen increases with frequency and in combination with use of alcohol (Lopez & Hendrickson, 2014).*

▲ For clients receiving drugs associated with liver injury, review risk factors to prevent potentially severe drug reactions. *Drug-induced liver disease accounts for about 50% of hepatitis cases. The most common risk factors are advanced age, female gender, alcohol*

use with associated infection, and genetic predisposition (Hamilton, Collins-Yoder, & Collins, 2016).

▲ Determine the total amount of acetaminophen the client is taking per day. The amount of acetaminophen ingested should not exceed 3.25 g/day, or even lower in the client with chronic alcohol intake (Hamilton, Collins-Yoder, & Collins, 2016). *It is common for clients to take multiple pain medications, all containing acetaminophen. Acetaminophen is the most common cause of drug-induced liver injury, and approximately 46% of all people with acute liver failure in the United States have liver damage caused by acetaminophen (Ortega-Alonso et al, 2016).*

▲ Evaluation of acetaminophen-associated drug-induced liver injury is done by patient history of ingestion, time, and doses of the medication per weight calculation and serum level of acetaminophen. **EB:** *One of the tools most commonly used for decision-making in the use of N-acetylcysteine is the Rumack-Matthew nomogram for drug overdose. Prompt intervention with N-acetylcysteine has reduced mortality to 0.7% for those patients who overdosed on acetaminophen (Hamilton, Collins-Yoder, & Collins, 2016).*

▲ If the client is on statin medications, ensure that liver enzyme testing is done at intervals. Liver enzymes can become elevated from taking statin medications; it is rare, but possible for statins to cause actual liver damage (Hamilton, Collins-Yoder, & Collins, 2016).

▲ If the client is an alcoholic, refer to a cessation program. It is essential the client stop drinking as soon as possible to allow the liver to heal. Alcoholism is associated with malnutrition, which is harmful to the liver (Fabrellas, 2017). Alcoholism is also associated with increased plasma endotoxins and disruption of the gut barrier, which cause inflammation and resultant damage to the liver (Cassard, Gerard, & Perlemuter, 2017). See care plans for Ineffective **Denial** and Dysfunctional **Family** processes.

▲ Provide frequent smaller meals for easier digestion. Provide diet with optimal carbohydrates, proteins, and fats. Consult with a registered dietitian to discuss best nutritional support. *Proteins can be increased as tolerated and serum protein, albumin levels, and bilirubin levels indicate improved liver function. The goals of nutrition therapy are to provide adequate nutrition, support growth, preserve lean body mass, and prevent micronutrient deficiencies (Leon & Lerret, 2017).*

▲ Recognize that severe malnutrition may result in acute liver failure, which is reversible with improved nutrition.

▲ Review medical history with the client, recognizing that obesity and type 2 diabetes, along with hypertriglyceridemia and polycystic ovarian syndrome, are major risk factors in the development of liver disease, specifically nonalcoholic fatty liver disease. *For those clients showing signs of fatty liver involvement, sound nutritional support can reduce the severity and mitigate the already existing secondary malnutrition (Kunutsor et al, 2014).*

• Encourage vaccinations for hepatitis A and B for all ages. *Hepatitis A can affect anyone in the United States. Vaccination can prevent hepatitis A and B, which at times can cause liver failure (Centers for Disease Control and Prevention [CDC], 2016).*

• Measure abdominal girth if individual presents with abdominal distention and pain. *Increasing abdominal distention and pain are signs of impending portal hypertension with the presence of fluid shifts, resulting in ascites (Ghany et al, 2015).*

• Assess for tenderness and/or pain level in the right upper quadrant. Tenderness in this area is a symptom of biliary, liver, and/or pancreatic problems. *This pain, along with a palpable mass and weight loss, are a classic triad for malignancies (Ferguson 2014; Kunutsor et al, 2014).*

• Use standard precautions for handling of blood and body fluids. Review sterile

techniques when giving intravenous solution and/or medications. **EB:** *This is imperative to decrease the incidence of infection with hepatitis B and hepatitis C viruses. The viruses have been spread in health care settings when injection equipment and intravenous solutions were mishandled and became contaminated (CDC, 2016).*

▲ Observe for signs and symptoms of mental status changes such as confusion from encephalopathy. *The symptoms can fluctuate in severity within hours. Blood concentration of ammonia is not correlated with the severity of hepatic encephalopathy. The most commonly used medical treatment is lactulose because it has a prebiotic effect, lowers the pH in the colon, binds to ammonia, and excretion is promoted by this laxative effect (Bager, 2017).*

Pediatric/Parents

▲ Prescreen pregnant women for hepatitis B surface antigens. If found, recommend nursing case management during pregnancy. **EB:** *Despite advances in prevention of hepatitis B transmission, approximately half of the infections are caused by mother-to-child transmission. Efforts to prevent transmission are an essential element of perinatal maternal and infant care (Ma et al, 2014).*

▲ Recommend implementation of postexposure prophylaxis, including the hepatitis B virus vaccine for an infant born to a hepatitis B surface antigen–positive woman (CDC, 2016).

• Encourage vaccinations for hepatitis A and B for all ages. *Children should be vaccinated between ages 12 and 23 months for hepatitis A (CDC, 2016).*

▲ Recognize that children can develop fatty liver disease, which can result in liver failure. Most children are asymptomatic, but others complain of malaise, fatigue, or vague recurrent abdominal pain (Marzuillo, del Guidice, & Santoro, 2014).

▲ During a well-baby visit, assess for signs of potential liver problems. Observe for prolonged jaundice, pale stools, and urine that is anything other than colorless. Consult with health care provider to order a split bilirubin as needed (CDC, 2016).

Home Care

• Encourage rest, optimal nutrition (high carbohydrates, sufficient protein, and essential vitamins and minerals) during initial inflammatory processes of the liver.

Client/Family Teaching and Discharge Planning

• Teach the client and family to examine all medications the client is taking, looking for acetaminophen as an ingredient, and reinforce the 3.25-g upper limit of intake of acetaminophen to protect liver function (Hamilton, Collins-Yoder, & Collins, 2016).

• For the caregiver or client with hepatitis A, B, or C, teach the need for careful handwashing, use of gloves, and other precautions to prevent spread of any of these diseases.

• Teach avoidance of high-risk behaviors that cause hepatitis and ways to avoid those behaviors.

• Educate clients and their caregivers about treatment options and interventions for hepatitis. Recommend other informational support: risk factors, side effects of the different treatment options, and dietary advice.

• Recommend psychological support if possible during education sessions. **EBN:** *Hepatitis can result in liver inflammation and chronic liver disease and is a common reason for a liver transplant. The client may not have an understanding of liver disease or its complications, may be elderly, or may have mental health issues or additions that affect the*

need for nursing intervention. Developing a plan and/or services to support and to give patient-centered care can provide better support to the client in dealing with liver disease (Greenslade, 2017).

- Assess for adherence to antiviral therapies for the treatment of hepatitis and institute nursing interventions such as client education, communication, and reminder tools to assist patients in medication adherence. *Adherence to antiviral therapies is imperative to help suppress viral load and to reduce progressive liver disease (Polis et al, 2017).*
- For those clients with mental health problems, collaborate with outreach programs to teach signs/symptoms of hepatitis, risk factors, and factors that increase transmission. **EBN:** *These clients have higher potential for substance use and injected-drug use, and increased chances of transmission because of homelessness and living conditions in night shelters. Protocols have proven to be successful in developing an effective approach to meeting the needs of clients with or at risk for infection with hepatitis A, B, and C virus and severe mental health problems. Culturally sensitive, nurse-led interventions, such as counseling and bringing vaccinations to the community through mobile services, are valuable health promotion strategies in high-risk populations (Nyamathi et al, 2015; Fabrellas, 2017).*

Risk for Loneliness

Julianne E. Doubet BSN, RN, EMT-B

NANDA-I

Definition

Susceptible to experiencing discomfort associated with a desire or need for more contact with others, which may compromise health.

Risk Factors

Affectional deprivation; emotional deprivation; physical isolation; social isolation

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Loneliness Severity; Social Interaction Skills; Social Involvement; Social Support

Example NOC Outcome with Indicators

Loneliness Severity as evidenced by the following indicators: Sense of social isolation/Difficulty in establishing contact with others. (Rate the outcome and indicators of **Loneliness Severity:** 1 = severe, 2 = substantial, 3 = moderate, 4 = mild, 5 = none [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Maintain one or more meaningful relationships (growth-enhancing versus codependent or abusive in nature)
- Sustain relationships that allow self-disclosure and demonstrate a balance between emotional dependence and independence
- Participate in personally meaningful activities and interactions that are ongoing, positive, and relevant socially
- Demonstrate positive use of time alone when socialization is not possible

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Family Integrity Promotion; Socialization Enhancement; Visitation Facilitation

Example NIC Activities—Socialization Enhancement

Encourage enhanced involvement in already established relationships; Help client increase awareness of strengths and limitations in communicating with others

Nursing Interventions and *Rationales*

- Assess the client's perception of loneliness. (Is the person alone by choice, or are there other factors that contribute to the feelings of loneliness? Is the client in one of the at-risk populations for loneliness?) **EBN:** *Nyatanga (2017) stated that loneliness can*

be a consequence of hardship, discrimination, inequality, loss of control, decrease in independence, and lack of options.

• Use active listening skills. Establish a therapeutic relationship and spend quality time with the client. **EB:** *In their study of clients and families involved in palliative health care, Ciemins et al (2014) found that one of the client's expectations of health care providers included skillful listening abilities.*

• Assess how unmet needs challenge the client. Note: See care plan for Disturbed **Body Image** if loneliness is associated with chronic illness and/or afflictions (e.g., multiple sclerosis, skin disturbance, mental illness). **EB:** *Unmet needs may exceed what is customary for those clients who are minority, low-income community residents; caregivers with lower education; clients with early-stage dementia; and those with depression (Black et al, 2013).*

▲ Assess the bereaved client for risk of suicide and make appropriate referrals as necessary. **EB:** *A study by Stickley and Koyanago (2016) found that there is a connection between loneliness and suicidal ideation; therefore efforts to reduce loneliness may play a significant part in decreasing its detrimental effects on the client's health and well-being.*

• Assess the client who is alone for substance abuse and make appropriate referrals. **EBN:** *Murdoch's (2014) article emphasized that all health care professionals are responsible for raising the issue of substance misuse/abuse and referring the client to specialized services if needed.*

• Evaluate the client's desire for social interaction. **EB:** *Nurses and other health professionals must have an awareness of the client's social disconnectedness so that they can offer assistance in making and perpetuating social connections (Dinkins, 2017).*

• Assess the client for feelings of loneliness. **EB:** *According to Pikhartova, Bowling, and Victor (2014), the report of loneliness is contingent on sociodemographic factors, such as gender, household income, household living arrangements, and health status.*

• Explore ways to increase the client's support systems. **EBN:** *Nurses must recognize those who need help in dealing with their loneliness and provide direction and support (Kirkevoid et al, 2013).*

• Show respect for the client's personal attributes. **EB:** *Grover (2014) characterized respect as an expression of trust that another person has value.*

Adolescents

• Assess the client's social support system. **EB:** *According to Rowe et al (2014), relationship impediments and a lack of knowledge about where to go for support may hold back an adolescent from seeking help.*

• Evaluate the family stability of adolescent clients. **EBN:** *In their review of literature, Kao, Luplya, and Clemen-Stone (2014) found that family efficacy, characterized as a family's confidence in its ability to manage varied situations and to realize a desired outcome, is associated with the decreased likelihood of adolescents engaging in risky health behaviors.*

• Evaluate peer relationships. **EB:** *Peer relationships have been shown to play a significant role in self-esteem development across adolescence and also to remain influential throughout adulthood (Gruenenfelder-Steiger, Harris, & Fend, 2016).*

• **EBN:** *Encourage social support for clients with disabilities.* **EB:** *In their revisit of a 2006 study involving young adults who suffer from chronic health disorders, Sattoe et al (2014) found that social participation was strongly connected to the client's feelings of independence and self-efficacy.*

• Encourage relationships with peers and involvement with groups and organizations. **EB:** *According to Choukas-Bradley et al (2015), researchers have reported that*

peer influence is not intrinsically detrimental and that attempts to fashion one's own attitude to match that of peers could be seen as a healthy, constructive growth pattern.

Geriatric

• Evaluate the client for any health deviations that may limit or decrease his or her ability to interact with others. **EB:** *A study by Kvaal, Halding, and Kvigne (2014) made the point that loneliness is extensive among older people suffering from chronic physical illness.*
• Assess family caregivers of older persons with chronic conditions for depression related to loneliness. **EBN:** *Caregivers of loved ones many times are subjected to physical, psychological, emotional, social, and financial effects that can be called "caregiver burden" (Sorrell, 2014).*
• Identify support systems for older adults. **EB:** *Senior centers are ideal settings for providing evidence-based health programs to the fast-growing population of older adults and to help facilitate their continued good health and independence (Felix et al, 2014).*
• When relocation is necessary for older adults, evaluate relocation stress as a contributing factor to loneliness. **EB:** *A preliminary study by Theurer et al (2014) suggested that mutual support groups have the potential to offset loneliness, helplessness, and depression among clients in extended care facilities.* **EBN:** *(Sprinks, 2014).*
• Identify risk factors for loneliness in older persons. **EB:** *In their study of aging and loneliness, Brittain et al (2017) stated that recognized risks factors for loneliness include widowhood, living alone, depression, and being female.*
• Encourage support for the client when the decision to stop driving must be made. **EB:** *The nurse should direct the client toward community support systems and alternate methods of transportation when it is no longer feasible for them to continue driving (Pachana, 2015).*
• Provide activities that are pleasurable to the client. **EB:** *In their review of one of the results of the English Longitudinal Study on Aging, Gale et al (2014) found that older people who take pleasure in life tend to live longer, indicating that psychological well-being could be a promising resource for healthier aging. Refer to the care plan for* ***Social*** *isolation for additional interventions.*

Multicultural

• Refer to the care plan for **Social** isolation.

Home Care

▲ The preceding interventions may be adapted for home care use.
▲ Assess for depression with the lonely older client and make appropriate referrals. **EBN:** *The heightened prevalence of depressive symptoms and their relationship to the associated factors (gender, age group, schooling, marital status, and place of residence) of depression in the elderly affirm the necessity to implement means for the advancement of public policies and prioritize strategies that can best guarantee health care for the elderly population (Cambo Leal et al, 2015).*
• If the client has unexplained somatic complaints, evaluate these complaints to ensure that his or her physical needs are being met, and assess for a possible relationship between somatic complaints and loneliness. **EB:** *"Our bodies manifest emotions physically when we cannot effectively express them" (Spencer, 2016).* **EBN:** *In their study, Zimmerman et al (2016) confirmed that the nurse can, in collaboration with the client's physician, competently support self-management of patients with psychosomatic symptoms*

and their psychosocial needs.

• Evaluate alternatives to being alone. **EB:** *O'Connor, Arizmendi, and Kaszniak (2014) conducted a preliminary study of an online support group for those isolated while caring for clients with dementia; the study established the viability of interactive groups in virtual environments to connect members in significant interaction.*

• Refer to the care plan for **Social** isolation.

Client/Family Teaching and Discharge Planning

• Identify the type of loneliness that the client is experiencing as emotional and/or social. **EB:** *If both emotional and social loneliness are to be reduced in older people, strategies should be directed to widening the ranges of interventions (Dahlberg & McKee, 2014).*

• Encourage family members' involvement, if possible, in helping alleviate client's loneliness. **EBN:** *Decreased satisfaction with family support was one of the important predictors of depression levels in older people: this is a factor that should be considered when planning care (Tanner, Martinez, & Harris, 2014).*

• Include the family, if possible, in all client-teaching activities, and give them accurate information. **EBN:** *One of the nurse's central roles is to ensure continuity of care applied to all the client's health care settings; therefore patient and family education is of utmost importance (Marshall et al, 2015).*

• Provide appropriate education for clients and their support persons about disease transmission and treatment if applicable. **EBN:** *Home health patients are cared for in a totally unconstrained environment innate with infection possibilities, so concluded Pandur (2015) in her study of infections in home care settings.*

• Refer to the care plan for **Social** isolation for additional interventions.

List of Planning Care by Letter: M

Risk for disturbed Maternal–Fetal dyad	Impaired Memory	Risk for Metabolic Imbalance syndrome
Impaired bed Mobility	Impaired physical Mobility	Impaired wheelchair Mobility
Impaired Mood regulation	Moral Distress	Risk for dry Mouth

M

• = Independent; ▲ = Collaborative; **EBN** = Evidence-Based Nursing; **EB** = Evidence-Based

Risk for disturbed Maternal–Fetal dyad

Dianne F. Hayward RN, MSN, WHNP

NANDA-I

Definition

Susceptible to a disruption of the mother-fetal relationship as a result of comorbid or pregnancy-related conditions, which may compromise health.

Risk Factors

Inadequate prenatal care; presence of abuse; substance misuse

Associated Condition

Alteration in glucose metabolism; compromised fetal oxygen transport; pregnancy complication; treatment regimen

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Fetal Status: Antepartum; Maternal Status: Antepartum, Intrapartum; Depression Level; Blood Glucose Level; Family Resiliency; Knowledge: Self-Management; Nausea and Vomiting Severity; Social Support; Spiritual Support, Parent-Infant Attachment

Example NOC Outcome with Indicators

Maternal Status: Antepartum as evidenced by the following indicators: Emotional attachment to fetus/Coping with discomforts of pregnancy/Mood lability/Blood pressure/Blood glucose/Hemoglobin. (Rate the outcome and indicators of **Maternal Status: Antepartum:** 1 = Severe deviation from normal range, 2 = Substantial deviation from normal range, 3 = Moderate deviation from normal range, 4 = Mild deviation from normal range, 5 = No deviation from normal range [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Cope with discomforts of high-risk pregnancy until delivery of baby
- Demonstrate emotional attachment to fetus
- Adhere to prescribed regimens to maintain homeostasis during pregnancy

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Example NIC Activities—High-Risk Pregnancy Care

Determine the presence of medical factors that are related to poor pregnancy outcome (e.g., diabetes, hypertension, lupus erythematosus, herpes, hepatitis, HIV, multiple gestation, substance abuse, epilepsy); Provide educational materials that address the risk factors and usual surveillance tests and procedures

Nursing Interventions and *Rationales*

- Standardize internal and external transport forms using the situation, background, assessment, and recommendation (SBAR) format to provide safe and efficient care of a high-risk pregnant client. **EBN:** *SBAR is a powerful tool that is used to improve the effectiveness of communication between individuals. It is an easy-to-use protocol that provides a concise and prioritized structure, which supports consistent, comprehensive, and client-centered reports (Cornell et al, 2013).*
- Assess the antenatal client for fear related to high-risk pregnancy and fetal outcomes. Encourage verbalization of feelings, beliefs, and concerns about fetal well-being, maternal health, and family functioning. Include family when possible. Refer for treatment as needed. **EBN:** *An Istanbul study found that pregnant women with a poor level of psychosocial adaptation showed more depressive manifestations (Fiskin, Kaydirak, & Oskay, 2017).* **EB:** *When a pregnant woman exhibits symptoms of anxiety, she might need counseling and/or treatment to decrease her anxiety (Rubertsson et al, 2014).*
- Assess antepartum clients for depression using a culturally competent tool that evaluates the bio-psycho-social-spiritual dimensions. **EBN:** *Screening and appropriate management is essential to prevent adverse consequences to both the woman and her unborn infant (Anderson & Lieser, 2015).*
- Offer flexible visiting hours, private space for families, and nursing support for management of family stressors; provide distractors such as music, TV, and laptops with Internet access during hospitalization for high-risk pregnancy. **EB:** *Assisting high-risk antepartum hospitalized women should include a focus on family function, liberal visiting hours, a "child-friendly" family visitation room, and education. Understanding the situation can help women accept the responsibility of remaining pregnant and in labor and delivery (Lederman et al, 2013).*
- Focus on the abilities of a pregnant woman with disabilities by encouraging identification of support systems, resources, and need for environmental modification. **EBN:** *In a recent study of pregnant women with disabilities, the women reported a lack of knowledge, awareness, sensitivity, and respect, as well as stereotyping, as issues that contributed to compromised perinatal care (Smeltzer et al, 2016).*
- Assess for lack of social support system, loneliness, depression, lack of confidence, maternal powerlessness, domestic violence, and socioeconomic problems. **EBN:** *Screening should include significant risk factors to detect at-risk women (Ruyak, Flores-Montoya, & Boursaw, 2017).*
- Recognize patterns of physical abuse in all pregnant and postpartum women, regardless of age, race, and socioeconomic status. **EBN:** *Abuse during pregnancy can result in poor maternal, neonatal, and early childhood outcomes; routine screening and assessment may interrupt further abuse and promote positive outcomes (Bianchi, Cesario, & McFarlane, 2016).*
- Perform accurate blood pressure readings at each client's clinic encounter. **EB:** *Elevated blood pressure during pregnancy, regardless of etiology or known risk factors, indicates high risk for preeclampsia and for later cardiovascular disease, chronic kidney*

disease, and diabetes mellitus (Mannisto et al, 2013).

• Provide educational materials and support for personal autonomy about genetic counseling and testing options before pregnancy with preimplantation genetic testing or during pregnancy with fetal nuchal translucency ultrasound, quadruple screen, and cystic fibrosis screening. **EBN:** *Health care providers are presented with several challenges now that consumers have direct access to genetic tests that they may not fully comprehend, which may lead them to act on the results inappropriately (Beery, 2014). Nurses can advocate, understand the perceptions of, and assist patients in their reproductive decision-making (Shiroff & Nemeth, 2015).*

• Identify adherence barriers and assist with meal selections to maintain optimal nutrition and safe pregnancy weight gain (25–35 pounds; 15–25 pounds if overweight). Identify cultural beliefs and nutritional patterns. A prenatal vitamin with 400 mcg of folate should also be strongly recommended. **EB:** *A British task force showed that many women are not following nutritional guidelines. Pregnancy provides an opportunity for health care professionals to encourage women to make dietary improvements (e.g., following "myplate.com") because they tend to be more motivated to change aspects of their diet and lifestyle during this time (Williamson & Wyness, 2013). All women in the reproductive years should consume at least 400 mcg of folic acid per day to reduce risk for neural tube defects (Littleton-Gibbs & Engebretson, 2013).*

• Teach pregnant women diagnosed with gestational diabetes about management and treatment. **EBN:** *To reduce morbidity related to gestational diabetes, clients need education to manage blood glucose levels during pregnancy. When diet and exercise are not enough to control blood glucose levels, drug therapy is the next option. Although insulin remains the treatment of choice, insulin therapy requires sufficient education and skills on the part of the woman with gestational diabetes to be properly managed and may cause hypoglycemia, fear, and anxiety (Mnatsakanyan, Rosario-Sim, & Caboral-Stevens, 2014). Good control of blood glucose is important during delivery to reduce the risk of neonatal hypoglycemia (King, 2017).*

• Assess use of tobacco and, if positive for use, offer a tobacco cessation program and explain the health risks to the unborn fetus and mother. **EB:** *Depressive symptoms were a predictor of tobacco consumption but not of spontaneous quitting; spontaneous quitting was better predicted by anxiety symptoms. Therefore anxious symptoms should be targeted in interventions for smoking cessation during pregnancy (Miguez, Pereira, & Figueiredo, 2017). See US Department of Health and Human Services (USDHHS, 2017) for quitting smoking guidelines at https://betobaccofree.hhs.gov/quit-now/index.html.*

• Assess for alcohol use and counsel women to stop drinking during pregnancy. Give appropriate referral for treatment if needed. **EB:** *There is no known safe amount or safe time to drink alcohol during pregnancy. Drinking alcohol during pregnancy can cause miscarriage; stillbirth; and a range of permanent physical, behavioral, and fetal alcohol spectrum disorders (FASDs) (Centers for Disease Control and Prevention, 2016).*

• Screen for current illicit drug use. Emphasize the risks or drug exposure to the fetus/newborn and the potential for withdrawal. Offer nonjudgmental compassionate care. **EBN:** *"All nurses, regardless of their beliefs about perinatal addiction, must provide nonjudgmental compassionate care that is person-centered" (McKeever, Spaeth-Brayton, & Sheerin, 2014).*

• Refer clients who self-report drug abuse or have positive toxicology screens to a comprehensive addiction program designed for the pregnant woman. Children born to addicted mothers often have poor neonatal outcomes. **EBN:** *It is important to involve a pregnant woman in treatment programs like methadone clinics to stabilize the maternal–fetal dyad. When a woman makes the decision to enroll in a methadone treatment program, she is*

taking a significant step toward recovery (Maguire, 2014).

• Encourage pregnant women to use digital resources, such as Text4Baby (see https://www.text4baby.org) or https://www.whattoexpect.com, to track pregnancy progress and provide education and motivation to make healthy lifestyle choices (abstinence from poor nutrition, smoking, and alcohol). **EBN:** *A recent study described the development of an iPad application to promote knowledge of tobacco risk and cessation resources for pregnant women and the evaluation of women's acceptance and perceptions regarding the application (Walsh Dotson et al, 2017).*

Impaired Memory

NANDA-I

Definition

Persistent inability to remember or recall bits of information or skills.

Defining Characteristics

Consistently forgets to perform a behavior at the scheduled time; persistent forgetfulness; persistent inability to learn a new skill; persistent inability to learn new information; persistent inability to perform a previously learned skill; persistent inability to recall factual information or events; persistent inability to recall familiar names, words, or objects; persistent inability to recall if a behavior was performed; persistent inability to retain a new skill; persistent inability to retain new information; preserved capacity to perform daily activities independently

Related Factors

Alterations in fluid volume

Associated Condition

Anemia; brain injury; decrease in cardiac output; electrolyte imbalance; hypoxia; mild cognitive impairment; neurological impairment; Parkinson's disease

NOC Outcomes (Nursing Outcomes Classification)

Suggested NOC Outcomes

Cognitive Orientation; Memory; Neurological Status: Consciousness

Example NOC Outcome with Indicators

Memory as evidenced by the following indicators: Recalls immediate information accurately/Recalls recent information accurately/Recalls remote information accurately. (Rate each indicator of **Memory:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Demonstrate use of techniques to help with memory loss
- State he or she has improved memory for everyday concerns

NIC Interventions (Nursing Interventions Classification)

Suggested NIC Interventions

Memory Training; Dementia Management; Reality Orientation

Example NIC Activities—Memory Training

Discuss with patient/family any practical memory problems experienced; Implement appropriate memory techniques, such as visual imagery, mnemonic devices, memory games, memory cues, association techniques, making lists, using computers, using name tags, or rehearsing information; Structure the teaching methods according to patient's organization of information; Refer to occupational therapy, as appropriate; Monitor changes in memory with training

Nursing Interventions and *Rationales*

• Determine whether onset of memory loss is gradual or sudden. **EB:** *Acute onset of memory loss may be associated with neurological disease, medication effect, electrolyte disturbances, hypoxia, hypothyroidism, mental illness, posttraumatic stress disorder, drug addiction, or many other physiological factors (Schwabe, Nader, & Pruessner, 2014).*
• Assess overall cognitive function and memory. A brief screening instrument such as the Montreal Cognitive Assessment (s-MoCA) is useful as a first level of evaluation. **EB:** *The s-MoCA is valid across neurological disorders and can be administered in approximately 5 minutes to determine whether the client has cognitive impairment and needs to be referred for further evaluation and treatment (Roalf et al, 2016, 2017).*
• Assess risk of malnutrition, including risk for thiamine (B_1) associated with chronic alcohol abuse, cancer, bariatric surgery, and risk of vitamin D deficiency–associated history of inadequate exposure to sunlight. **EB:** *Wernicke–Korsakoff syndrome is a disorder of the brain that is the result of vitamin B_1 deficiency associated with chronic abuse of alcohol, cancer, and bariatric surgery (Manzo et al, 2014). Vitamin D insufficiency is associated with cognitive impairment (Goodwill & Szoeke, 2017).*
• Determine the client's sleep quality and patterns. If sleep quantity and quality are insufficient, or symptoms of obstructive sleep apnea are reported, refer to the care plan for Disturbed **Sleep** pattern. **EB:** *Sleep disordered breathing is associated with an increased risk of cognitive impairment and a small worsening of executive function (Leng et al, 2017).*
• Teach clients, including those with cognitive disorders, to use memory techniques such as concentrating and attending, repeating information, making mental associations, and placing items in strategic places so that they will not be forgotten. **EBN:** *A meta-analysis of memory-focused interventions found they effectively improved memory-related performance in people with cognitive disorders (Yang et al, 2017).*
• Encourage the client to participate in a multicomponent cognitive rehabilitation program that includes stress and relaxation training, physical activity, structured learning, and social interaction. **EB:** *Mind–body practice, arts-based activities, structured arithmetic, reading aloud, and writing have been shown to improve working memory and cognitive function (Kawashima et al, 2015; Young, Camic, & Tischler, 2016; Chan et al, 2017a,b).*
• Encourage the client to develop an aerobic exercise program. **EB:** *Reviews demonstrated that diet and lifestyle may prevent the onset of age-related problems and can lead to improvements in cognition and memory (Meeusen, 2014; Wang et al, 2014).*
• For clients with memory impairments associated with dementia, also see care plan for Chronic **Confusion**.

Geriatric

• Assess for signs and symptoms of depression. **EBN:** *Depression is often associated with memory loss in older adults; however, cognitive behavior therapy, competitive memory training, reminiscence group therapy, problem-adaptation therapy, and problem-solving therapy are all effective interventions to reduce depressive symptoms (Apóstolo et al, 2016).*
• Teach older adults that they can improve their memory and learn strategies to compensate for memory loss. **EBN:** *Octogenarians were able to improve their memory performance when they challenged their limits, used appropriate strategies, practiced yoga, and invested the energy and time in learning novel memory techniques (McDougall et al, 2015).*

▲ Refer the client for cognitive training. **EB:** *Cognition training has been shown to improve verbal recall, face–name memory, and processing speed (Tak & Hong, 2014; Chan et al, 2016).*

Multicultural

• When using cognitive assessments that have been translated into other languages, refer to translation-specific scoring instructions and any recommended adjustment for low-levels of education. **EB:** *Although cognitive assessments like the MoCA and Mini-Mental State Examination (MMSE) have been translated and validated in many languages, there is wide variation in published cutoff scores, and not correcting for educational bias may result in inappropriate referral or diagnosis (Rosli et al, 2016; Delgado, Araneda, & Behrens, 2017).*
• Assess for the influence of cultural beliefs, norms, and values on the family or caregiver's understanding of impaired memory. **CEB:** American Indians, Chinese Americans, Latino Americans, and Vietnamese Americans may believe serious cognitive decline is a normal part of aging. American Indian, Chinese, and Vietnamese older adults may have great concerns about stigma associated with cognitive impairment (Laditka et al, 2011).
• Visitation facilitation: stigma may result in social isolation, and older adults with memory impairment may need assistance to rebuild and strengthen their social network. **EB:** Social network quality and emotional closeness are positively associated with cognitive functioning among older Chinese adults (Li & Dong, 2017).

Home Care

• The previously mentioned interventions may be adapted for home care use.
• Assist clients to select and use cuing strategies or assistive technology, such as a smart watch, smart phone, pill box, calendar, alarm clock, microwave oven, whistling tea kettle, sign, or written list to cue behaviors at designated times. **EB:** *Cues and assistive technology are positively associated with individuals' abilities to perform daily tasks regardless of age or cognitive disease (Leopold et al, 2015).*

Client/Family Teaching and Discharge Planning

• When teaching the client, determine what the client knows about memory techniques and then build on that knowledge. **EBN:** *New material is organized in terms of what knowledge already exists, and efficient teaching should attempt to take advantage of what is already known to graft on new material (McDougall et al, 2014).*
• When teaching a skill to the client, set up a series of practice attempts that will enhance motivation. Begin with simple tasks so the client can be positively reinforced and progress to more difficult concepts. **EB:** *Distributed practice with correct recall attempts can be a very effective teaching strategy, especially when used over time (Gross et al, 2014).*
▲ Refer for care coordination if family caregiver is unavailable or unable to assist. **EB:** *Home-based dementia care coordination delivered by nonclinical community workers trained and overseen by geriatric clinicians reduced unmet needs, improved self-reported quality of life, and led to delays in nursing home admission (Samus et al, 2014).*

Risk for Metabolic Imbalance syndrome

Marina Martinez-Kratz MS, RN, CNE

NANDA-I

Definition

Susceptible to a toxic cluster of biochemical and physiological factors associated with the development of cardiovascular disease arising from obesity and type 2 diabetes, which may compromise health.

Risk Factors

Ineffective health maintenance (00099), obesity (00232), overweight (00233), risk for unstable blood glucose level (00179), risk-prone health behavior (00188), sedentary lifestyle (00168), stress overload (00177)

At-Risk Population

Age >30 years, family history of diabetes mellitus, family history of dyslipidemia, family history of hypertension, family history of obesity

Associated Condition

Excessive endogenous or exogenous glucocorticoids >25 g/dL, microalbuminuria >30 mg/dL, polycystic ovary syndrome, unstable blood pressure, uric acid >7 mg/dL

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Weight Loss Behavior; Blood Glucose Level; Circulation Status; Exercise Participation; Hypertension Severity; Knowledge: Lipid Disorder Management; Knowledge: Hypertension Management; Knowledge: Prescribed Diet; Knowledge: Prescribed Activity; Knowledge: Weight Management; Metabolic Function; Nutritional Status: Nutrient Intake; Risk Control: Obesity; Risk Control: Lipid Disorder; Risk Control: Hypertension

Example NOC Outcome with Indicators

Risk Control: Lipid Disorder as evidenced by the following indicators: Seeks current information about lipid disorders/Identifies risk factors for lipid disorders/Modifies lifestyle to reduce risk/Develops effective risk control strategies/Maintains recommended body weight. (Rate the outcome and indicators of **Risk Control: Lipid Disorder**: 1 = severe deviation from normal range, 2 = substantial deviation from normal range, 3 = moderate deviation from normal range, 4 = mild deviation from normal range, 5 = no deviation from normal range [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Maintain blood glucose within normal limits
- Explain actions and precautions to decrease cardiovascular risk
- Maintain waist circumference of less than 102 cm/40 inches in men, or less than 88 cm/35 inches in women

• Explain the risk factors associated with lipid disorders
• Maintain normal laboratory results, specifically high-sensitivity C-reactive protein, triglycerides, fasting blood glucose, and high-density lipoprotein (HDL) cholesterol
• Design lifestyle modifications to meet individual long-term goal of health, using effective risk control strategies
• Maintain weight within normal range for height and age
• Develop a system of self-management, for improved dietary intake and physical activity

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Cardiac Risk Management; Exercise Promotion; Health Screening; Hyperglycemia Management; Hyperlipidemia Management; Nutritional Counseling; Teaching: Disease Process

Example NIC Activities—Cardiac Risk Management

Screen patient for risk behaviors associated with adverse cardiac events; Prioritize areas for risk reduction in collaboration with patient and family

Nursing Interventions and *Rationales*

• Assess for risk factors associated with metabolic syndrome. Risk factors for metabolic syndrome include central obesity, dyslipidemia, insulin resistance, and increased blood pressure. **CEB:** *Metabolic syndrome is a clustering of metabolic abnormalities associated with subsequent cardiovascular disease and mortality (Grundy et al, 2005).*
• Assess clients for elevated waist circumference measures; greater than 102 cm/40 inches or more in men, or greater than 88 cm/35 inches or more in women. **EB:** *An elevated waist circumference reflects central obesity and metabolic syndrome screening is recommended in the effort to combat cardiovascular disease and type II diabetes mellitus (Cheong et al, 2015).*
• Examine the client's skin for acanthosis nigricans, acrochordons, keratosis pilaris, hyperandrogenism, and hirsutism, which are skin diseases associated with insulin resistance and obesity. **EB:** *Early recognition of insulin resistance and obesity-associated skin diseases may facilitate an earlier metabolic syndrome diagnoses and therapy initiation (Uzuncakmak et al, 2018).*
• Assess the effect of psychosocial risk factors on cardiovascular risk. **EBN:** *A study found that metabolic syndrome among blue collar workers is closely related to psychosocial factors, such as job stress, social support, and risk perception, with the effect of job stress a point of difference between men and women (Hwang & Lee, 2014).*
• Assess and report abnormal laboratory results, specifically high-sensitivity C-reactive protein, triglycerides, fasting blood glucose, and HDL cholesterol. **EB:** *A recent study found that high-sensitivity C-reactive protein, triglycerides, fasting blood glucose, and HDL cholesterol were factors associated with metabolic syndrome (Tayefi et al, 2018).*
• Screen clients who are prescribed antipsychotic medications for metabolic syndrome during routine health treatment. **EBN:** *A recent study found that despite an increased awareness of comorbid physical health issues among mental health consumers, guidelines and policy directives to clinical practice to address this disparity remains low (Ward*

et al, 2018).
• Screen clients with a family history of polycystic ovary syndrome for metabolic syndrome. **EB:** *A recent meta-analysis suggests that mothers, fathers, sisters, and brothers of women with polycystic ovary syndrome have an increased risk of metabolic syndrome, hypertension, and dyslipidemia when compared with parents and siblings of women without polycystic ovary syndrome (Yilmaz et al, 2018).*
• Assist obese clients to develop a system of self-management, which may include self-monitoring of weight, body mass index (BMI), realistic goal setting, planning, and action planning for improved dietary intake and physical activity; problem-solving; and tracking dietary intake and exercise. **EB:** *A key component of successful weight loss and maintenance is regular self-monitoring (Thomason et al, 2016).*
• Encourage strength training for the client to address modifiable risk factors of metabolic syndrome. **EBN:** *A recent study of a 12-week strength training protocol demonstrated a significant reduction in C-reactive protein level, a positive trend in other biomarkers, and increased functional outcomes of premenopausal women with moderate cardiovascular risk (Flandez et al, 2017).*
• Provide nutritional teaching targeted at reducing daily energy, fat intakes, sugar intakes, and increasing the frequency of eating two portions of vegetables during each meal. **EB:** *A randomized controlled trial demonstrated a reduction in metabolic syndrome risk factors after the implementation of lifestyle modifications focused on dietary intake and physical activity (Watanabe et al, 2016). A study of clients with metabolic syndrome showed that consumption of added sugar decreased after 1 year with American Heart Association dietary counselling (Zhang et al, 2018).*
• Encourage the client to engage in vigorous-intensity physical activity for at least 150 minutes weekly or moderate-intensity physical activity for at least 300 minutes weekly to improve cardiorespiratory fitness and influence body shape and weight. **EB:** *A recent study indicated that being highly fit increased the likelihood of lower metabolic risk approximately 2 and 2.5 times independently of central adiposity compared with average and low fitness, respectively (Lätt et al, 2018).*
• Counsel clients to slow the pace of their eating during meals. **EB:** *A Japanese study found that a fast eating speed was associated with obesity and future prevalence of metabolic syndrome (Yamaji et al, 2018).*
• Provide teaching about reducing intake of ultra-processed foods and increasing intake of minimally processed foods. **EB:** *A study divided foods into ultra-processed, processed, and minimally processed. Ultra-processed foods consisted mainly of fast foods, snacks, sausage, nuts, sweets, and liquor, whereas minimally processed foods consisted mostly of fruits, vegetables, legumes, breads, cheeses, and eggs. Participants in the highest quartile of the "minimally processed/processed" pattern had significantly lower odds for metabolic syndrome (Nasreddine et al, 2018).*
• Encourage once or more weekly consumption of lean fish. **EB:** *A Norwegian study found lean fish consumption once a week or more was significantly associated with decreased future metabolic score, decreased triglycerides, and increased HDL cholesterol in both men and women. In addition, men also showed decreased waist circumference and decreased blood pressure (Torris et al, 2017).*
• Use social media for communication with clients to implement social support and share information about lifestyle modifications. **EB:** *A study using social media to augment the delivery of, and provide support for, a weight management program delivered to overweight and obese individuals during a 24-week intervention found the Facebook group reported a 4.8% reduction in initial weight and numerically greater improvements in BMI, waist circumference, fat mass, lean mass, and energy intake (Monica et al, 2017).*

• Refer clients with Class II and III obesity and diabetes for bariatric surgery consideration. **EB:** *A recent review found that metabolic surgery is highly effective in obtaining significant and durable weight loss, enhancing glycemic control, and achieving diabetes remission (Pareek et al, 2018).*

Pediatric

• Assess adolescent clients for vitamin D deficiency with additional screening for prediabetes if deficiencies are found. **EBN:** *A recent study found an association of vitamin D deficiency with an increased risk of elevated fasting blood glucose levels (Kim et al, 2018).*
• Provide preventive interventions for obesity during early childhood. **EBN:** A meta-analysis found that overweight or obesity in early childhood was associated with a higher risk of adult metabolic syndrome compared with the controls (Kim et al, 2017).

Geriatric

Note: Many of the preceding interventions also apply.

• Encourage strength training for older women. **EB:** *A recent study found that women who participated in a 12-week resistance training program showed decreased C-reactive protein concentrations, reduced blood glucose levels, decreased waist circumference, and lowered systolic blood pressure regardless of diet (Tomeleri et al, 2018).*
• Encourage Tai chi training for older adults. **EB:** *Recent research found that the practice of Tai chi exercise was associated with a statistically significant decrease in hemoglobin (Hb)A1C concentration and oxidative stress score in a group of older adults (Mendoza-Núñez et al, 2018).*

Multicultural

• Use criteria in addition to overweight and obesity when screening for cardiometabolic abnormalities in racial/ethnic minority populations. **EB:** *A cross-sectional study with participants from several US racial/ethnic groups found that nearly a third of the participants with normal weight had cardiometabolic abnormalities (Gujral et al, 2017).*
• Provide African American women with community-based prevention education targeted toward improving knowledge, reducing clinical risk profiles, adoption of heart-healthy lifestyles, reducing inflammatory burden, and decreasing cardiometabolic risk. **EB:** *A 4-month precardiovascular/postcardiovascular disease preventive educational intervention found that compared with baseline, there was a 60% reduction ($P < 0.05$) in the number of participants who met diagnostic criteria for metabolic syndrome (Villablanca et al, 2016).*

Home Care

• Previously discussed interventions may be adapted for home care use.

Client/Family Teaching and Discharge Planning

• Many of the preceding interventions involve teaching.
• Work with the family members regarding information on how to identify and reduce risk factors related to metabolic syndrome.

Impaired bed Mobility

NANDA-I

Definition
Limitation of independent movement from one bed position to another.

Defining Characteristics
Impaired ability to move between long sitting and supine positions; impaired ability to move between prone and supine positions; impaired ability to move between sitting and supine positions; impaired ability to reposition self in bed; impaired ability to turn from side to side

Related Factors
Environmental barrier; insufficient knowledge of mobility strategies; insufficient muscle strength; obesity; pain; physical deconditioning

Associated Condition
Alteration in cognitive functioning; musculoskeletal impairment; neuromuscular impairment; pharmaceutical agent

NOC Outcomes (Nursing Outcomes Classification)

Suggested NOC Outcomes
Immobility Consequences: Physiological; Mobility; Self-Care: Activities of Daily Living (ADLs)

Example NOC Outcome with Indicators
Immobility Consequences: Physiological as evidenced by the following indicators: Pressure sores/Constipation/Hypoactive bowel/Paralytic ileus/Urinary calculi/Contracted joints/Venous thrombosis/Pneumonia. (Rate the outcome and indicators of **Immobility Consequences: Physiological:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Demonstrate optimal independence in positioning, exercising, and performing functional activities in bed
- Demonstrate ability to direct others on how to do bed positioning, exercising, and functional activities

NIC Interventions (Nursing Interventions Classification)

Suggested NIC Intervention
Bed Rest Care

Example NIC Activities—Best Rest Care
Position in proper body alignment; Teach bed exercises, as appropriate

Nursing Interventions and *Rationales*

▲ Recognize that components of normal bed mobility include rolling, bridging, scooting, long sitting, and sitting upright. Activity starts with the client supine, flat in

bed, and promotes normal movements that are bilateral, segmental, well timed, and involve set positions such as weight bearing and trunk centering. Refer to a physical therapist (PT) for individualized instructions and mobility strategies.
• Choose therapeutic beds and positions based on client's history and risk profile.
    ❍ Advocate for specialty beds for bedbound patients incorporating low-airloss pressure relief, shear-reduction with position changes, and turn assist.
    ❍ Use devices such as a trapeze, friction-reducing slide sheets, mechanical lateral transfer aids, and ceiling-mounted or floor lifts to move (rather than drag) clients in bed to prevent injury to staff.
    ❍ Use special beds and equipment to move clients, such as mattress overlay, sliding/roller board, trapeze, stirrup, and pulley attached to overhead traction system (holds one leg up during pericare).
• Place clients in free-standing or ceiling-mounted lifts with padded slings while changing bed linen. **EB:** *Turn-assist features in beds greatly decreased spine loading and pull forces for nurses turning and lateral repositioning in patients of both normal and obese weight, thus decreasing injury potential to staff (Wiggerman, 2016; D'Arcy, Sasai, & Stearns, 2012). Staff should use lifting/transfer equipment and devices, ergonomic assessments, no-lift policies, and education to decrease risk of injury (Choi and Brings, 2016). Only about one-third of nurses with available lifting equipment use it (Lee et al, 2017). A sliding sheet is preferable over a regular cotton sheet to decrease musculoskeletal load for caregivers (Weiner et al, 2016).*
• All patients can benefit from a high sitting position to potentially minimize orthostatic intolerance (Khan et al, 2002).
• Assess to determine whether positioning for one condition may negatively affect another; use critical thinking skills for risk–benefit analysis. **EB:** *Elevation of head of bed (HOB) to a semirecumbent position (at least 30 degrees) is an effective, low-cost, and low-risk intervention associated with a decreased incidence of aspiration and ventilator-associated pneumonia (Agency for Healthcare Research and Quality [AHRQ], 2017). Use critical thinking to determine when specialty bed surfaces will help protect patients from tissue injury if frequent turning is contraindicated by patient instability.*
• Elevate HOB to 30 to 45 degrees unless contraindicated, and elevate HOB to 90 degrees during oral intake of fluids, solids, and oral medications.
• Raise HOB to 30 degrees for clients with acute increased intracranial pressure and brain injury. Refer to care plan for Decreased **Intracranial** adaptive capacity.
▲ Consult health care provider for HOB elevation for acute stroke and monitor response. Refer to care plan for Decreased **Intracranial** adaptive capacity.
• Raise HOB as close to 45 degrees as possible for critically ill ventilated clients to prevent pneumonia (this height may place clients at higher risk for pressure ulcers). Elevating the HOB decreases regurgitation and risk for aspiration of gastric contents.
• Assist client with dysphagia to sit as upright as possible for oral intake, including solids, fluids, and oral medications. Refer to care plan for Impaired **Swallowing**.
• Periodically sit client upright as tolerated in bed; dangle client, if vital signs and oxygen saturation levels remain stable. *Placing a client who is generally immobilized in an upright position is beneficial, using adaptive equipment if necessary (Green et al, 2016). Being vertical has many physiological and psychological benefits (Green et al, 2016)*
• To decrease risk of pressure injury, maintain HOB at lowest elevation that is medically possible and raise the foot of the bed to prevent shear-related injury. Assess the client's sacrum, ischial tuberosities, and heels at least every 2 hours. **EB:** *Shear results when external friction stretches the top layers of the skin as it slides against underlying*

layers and as internal tissues slide over deeper muscle and bone. These forces increase over the ischial tuberosities and sacrum when the backrest of the bed is elevated and result in tissue damage. Raising the foot of the bed in proportion to the HOB to distribute weight brings the body into maximum contact with the supporting surface, helping to eliminate shear. Placing a client who is generally immobilized in a recliner is a good alternative to the bed only if shear- and pressure-reducing bed surfaces cannot be obtained (Guerin et al, 2013; Martin et al, 2017). Use critical thinking and consult with nurse specialist in pressure injury harm reduction to determine when advocating for specialty bed surfaces will help protect patients from tissue injury.

• Try periods of prone positioning for clients and monitor their tolerance/response. **EB/CEB:** *Prone positioning after both above the knee and below the knee amputations promotes extension, preventing flexor contractions in lower extremity residual joints (Wright & Flynn, 2011; Gattinoni et al, 2013; Gosselin & Smith, 2014).*

• Assess client's risk for falls using a valid fall risk assessment tool, such as the Morse Fall Scale (Morse, Tylko, & Dixon, 1987) and implement specific measures to mitigate identified risk factors. **CEB:** *Establish individualized fall prevention strategies and perform postfall assessment to further refine fall prevention interventions.*

• Beds should be kept locked and in the lowest position when occupied. Specialty low beds in which mattresses are approximately 8 to 12 inches from the floor are helpful for clients at risk for falls. Cushioned mats, 2 to 3 inches thick, with beveled edges lined with reflective tape and covered by a rubberized material are also helpful. *Mats seemed to provide "a protective effect" for the pelvis during head-first falls and for the thorax during feet-first falls (Hill & Fauerbach, 2014).*

▲ Bed rails and restraints must be prescribed by a health care provider.

▲ While placing all four bed rails up is considered a form of restraint and requires a health care provider's prescription, two and even three rails up can be a support for bed mobility. *Nursing staff can work with physical and occupational therapists to determine the most effective techniques for bed mobility, including recommendations on the number of bedrails (Hill & Fauerbach, 2014).*

• Place frequently used items within client's reach; demonstrate use of call bell (Hill & Fauerbach, 2014).

• Use a formalized screening tool to identify clients who are at high risk for deep venous thrombosis (e.g., obesity, cancer diagnosis, pelvic surgery, immobility, prior history of deep vein thrombosis [DVT]). **EB:** *Best clinical practice encourages the use of a clinical decision tool that determines deep venous thrombosis risk based on predisposing factors and certain clinical signs and symptoms (Anthony, 2013).*

▲ Assess for injury associated with thromboembolism prophylaxis and other prescribed treatment (e.g., anticoagulants, compression stockings, elastic leg wraps, sequential compression devices, feet/ankle exercises, and hydration). Refer to care plan for Ineffective peripheral **Tissue Perfusion.**

• Use a valid and reliable tool to assess a client's risk for pressure injury. **EB:** *Routine assessment of risk factors is crucial in planning individualized interventions to diminish the risk of hospital-acquired pressure injury occurrences (Braden and Bergstrom, 1989; Moyses et al, 2017).*

• Implement the following interventions to prevent pressure ulcers and complications of immobility:

- ❍ Position sitting clients with special attention to the individual's anatomy, postural alignment, distribution of weight, and foot support.
- ❍ Use static/dynamic bed surfaces and assess for "bottoming out" under susceptible bony areas (body sinks into mattress, thus the recommended 1

inch between mattress/bones is absent). Refer to care plan for Risk for impaired **Skin** integrity.
    - ❍ Use heel protection devices that completely float or offload heels (National Pressure Ulcer Advisory Panel et al, 2014).
    - ❍ Implement a 2-hour on/off schedule for heel protector boots or high-top tennis shoes with socks underneath in clients with paralyzed feet, and check condition of heels when removed.
    - ❍ Strictly maintain leg abduction in persons with a surgical hip pinning or replacement by placing an abductor splint/pillow between legs if prescribed.
    - ❍ Place bariatric beds along a corner wall, which helps keep the bed from moving during repositioning.
- Identify/modify hospital beds with large gaps between bed rail/mattress that create an entrapment hazard. Ensure that mattresses fit the bed; install gap fillers/rail inserts, then monitor effectiveness.
- Apply elbow pads to comatose and/or restrained clients and to those who use their elbows to prop or scoot up in bed. Apply nocturnal elbow splint as prescribed if ulnar nerve palsy exists or if painful elbow with paresthesia in ulnar side of fourth/fifth fingers develops. Reassess sensation every 2 to 4 hours. *The use of pads assists with preventing prolonged compression or flexion pressure on the ulnar nerve, causing neuropathy/nerve damage. Consider obtaining prescription for an enclosure bed for agitated clients to alleviate restraints, preventing arm abrasions, nerve damage, and pain.*
- Explain importance of exhaling versus holding one's breath (Valsalva maneuver) and straining during bed activities.
- Reassess pain level, especially before movement and/or exercising, and accept clients' pain ratings and levels they think is appropriate for comfort. Administer analgesics based on clients' pain rating. Refer to Acute **Pain** or Chronic **Pain.**

Exercise

- Test strength in bilateral grips, arms at elbow flexion and extension, bilateral arm abduction and adduction, bilateral leg or thigh raise (one at a time in bed or chair), and quadriceps and hamstring strength to extend and flex at knee to assess baseline and interval strength gains.
- Perform passive range of motion (ROM) of three repetitions, at least twice a day, to immobile joints. *Perform ROM slowly and rhythmically. Do not range beyond point of pain. Range only to point of resistance in those with loss of sensation and mentation. Fast, jerky ROM increases pain and tone. Slow, rhythmical movements relax/lengthen spastic muscles so they can be ranged further. For clients with neuromuscular conditions, consult with physical therapy for ROM exercises.*
- Range or move a hemiplegic arm with the shoulder slightly externally rotated (hand up).

▲ Encourage client's practice of exercises taught by therapists (muscle setting, strengthening, contraction against resistance, and weight lifting). *Exercises and weight lifting help maintain muscle tone, strength, and lengthening.*

Bed Positioning

- Incorporate the following measures to promote normal tone and prevent complications in clients with neurological impairment:

- ❍ Use a flat head pillow when clients are supine. Use a small pillow behind the head and/or between shoulder blades if neck extension occurs to prevent contractures of the cervical spine and abnormal tone of the neck.
- ❍ Abduct the shoulders of clients with high paraplegia or quadriplegia horizontally to 90 degrees briefly two to three times a day while client is supine.
- ❍ Position a hemiplegic shoulder fairly close to the client's body.

• Tilt hemiplegics onto both unaffected and affected sides with the affected shoulder slightly forward (e.g., move/lift the affected shoulder, not the forearm/hand).
▲ Elevate a client's paralyzed forearms on a pillow when client is supine. Elevate edematous legs on a pillow supporting the knees to prevent hyperextension. Apply resting wrist, hand, and foot/ankle splints and pressure garments or other devices as prescribed. Range joints before applying splints. Adhere to on/off schedule as prescribed by the PT. Remove splints and compression garments or devices to check *underlying tissues for signs of pressure/poor circulation every 2 hours or more often if client resists or manipulates them.*

Geriatric

• Assess caregiver's strength, health history, and cognitive status to predict ability/risk for assisting bedbound clients at home. *Explore alternatives if risk is too high. Caregivers are often frail older adults with chronic health problems who cannot physically help loved ones*. Refer to care plan for **Caregiver Role Strain.**
• Assess the client's stamina and energy level during bed activities/exercises; if limited, spread out activities and allow rest breaks.

Home Care

▲ Collaborate with nurse case managers, care coordinators, social workers, and physical/occupational therapists to assess home support systems and needs, and to provide for home modifications, durable medical equipment, assistive technology, and home health services.
• Encourage use of the client's own bed unless contraindicated. Raise HOB with commercial blocks or grooved-out pieces of wood under legs; set bed against walls in a corner. Emotionally, clients may benefit from sleeping in their own beds with familiar partners.
• Stress psychological/physical benefits of clients being as self-sufficient as possible with bed mobility/care even though it may be time-consuming. Allowing independence and autonomy may help prevent disuse syndromes and feelings of helplessness and low self-esteem.
• Offer emotional support and help client identify usual coping responses to help with adjustment and loss issues. The home environment may trigger the reality of lost function and disability.
• Discuss support systems available for caregivers to help them cope. Refer to care plan for **Caregiver Role Strain.**
▲ In the presence of medical disorders, institute case management for frail older adults to support continued independent living as much as possible or desired by the client.
• Refer to the home care interventions in the care plan for Impaired physical **Mobility.**

Client/Family Teaching and Discharge Planning

• Use various sensory modalities to teach client/caregivers correct ROM, exercises, positioning, self-care activities, and use of devices. Readiness and learning styles vary but may be enhanced with visual/auditory/tactile/cognitive stimulus as follows:

- ❍ Provide demonstrations, sketches, instructional videos, and written directions/schedules, notes.
- ❍ Provide verbal instructions, recorded audiotapes, timers, reading aloud written directions, and self-talk during activities.
- ❍ Use motor task practice/repetition, return demonstrations, note taking, manual guidance, or staff's hand-on-client's-hand technique.

▲ Schedule time with family/caregivers for education and practice for nursing, physical therapy, and occupational therapy. Suggest family come prepared with questions and wear comfortable, safe clothing/shoes. Practice provides opportunity for learning; repetition helps memory retention.

▲ Implement safe approaches for caregivers/home care staff and reinforce an adequate number of people and handling equipment (e.g., friction pads, slide boards, lifts) during bed mobility, exercise, toileting, and bathing to decrease risk of injury.

▲ Coordinate evaluations for bariatric equipment for home use before discharge, including a weight-rated bed, a wheelchair or mobility device (scooter), and lift device. Doorways may need to be widened, floors reinforced, and ramps added for safety.

Impaired physical Mobility

Wendie A. Howland MN, RN-BC, CRRN, CCM, CNLCP, LNCC

NANDA-I

Definition

Limitation in independent, purposeful physical movement of the body or of one or more extremities.

Defining Characteristics

Alteration in gait; decrease in fine motor skills; decrease in gross motor skills; decrease in range of motion; decrease in reaction time; difficulty turning; discomfort; engages in substitutions for movement; exertional dyspnea; movement-induced tremor; postural instability; slowed movement; spastic movement; uncoordinated movement

Related Factors

Activity intolerance; anxiety; body mass index (BMI) >75th percentile appropriate for age and gender; cultural belief regarding acceptable activity; decrease in endurance; decrease in muscle control; decrease in muscle mass; decrease in muscle strength; depression; disuse; insufficient environmental support; insufficient knowledge of value of physical activity; joint stiffness; malnutrition; pain; physical deconditioning; reluctance to initiate movement; sedentary lifestyle

Associated Condition

Alteration in bone structure integrity; alteration in cognitive functioning; alteration in metabolism; contractures; developmental delay; musculoskeletal impairment; neuromuscular impairment; pharmaceutical agent; prescribed movement restrictions; sensory-perceptual impairment

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Ambulation; Ambulation: Wheelchair; Mobility; Self-Care: Activities of Daily Living (ADLs); Instrumental Activities of Daily Living (IADLs); Transfer Performance

Example NOC Outcome with Indicators

Ambulation as evidenced by the following indicators: Walks with effective gait/Walks at moderate pace/Walks up and down steps/Walks moderate distance. (Rate the outcome and indicators of **Ambulation:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Meet mutually defined goals of increased ambulation and exercise that include individual choice, preference, and enjoyment in the exercise prescription
- Describe feeling stronger and more mobile
- Describe less fear of falling and pain with physical activity
- Demonstrate use of adaptive equipment (e.g., wheelchairs, walkers, gait belts, weighted walking vests) to increase mobility
- Increase exercise to 20 minutes/day for those who were previously sedentary (less than 150 minutes/week). Note: Light to moderate intensity exercise may be beneficial in deconditioned persons. In very deconditioned individuals exercise bouts of less than 10 minutes are beneficial
- Increase pedometer step counts by 1000 steps per day every 2 weeks to reach a daily step count of at least 7000 steps per day, with a daily goal for most healthy adults of 10,000 steps per day (approximately 5 miles)
- Perform resistance exercises that involve all major muscle groups (legs, hips, back, chest, abdomen, shoulders, and arms) performed 2 or 3 days/week
- Perform flexibility exercise (stretching) for each of the major muscle-tendon groups 2 days/week for 10 to 60 seconds to improve joint range of motion (ROM); greatest gains occur with daily exercise
- Engage in neuromotor exercise 20 to 30 minutes/day including motor skills (e.g., balance, agility, coordination, gait), proprioceptive exercise training, and multifaceted activities (e.g., Tai chi, yoga) to improve and maintain physical function and reduce falls in those at risk for falling (older persons)
- Engage in purposeful moderate-intensity cardiorespiratory (aerobic) exercise for 30 to 60 minutes/day at least 5 days/week for a total of 2 hours and 30 minutes (150 minutes) per week

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Exercise Therapy: Ambulation; Joint Mobility; Positioning

Example NIC Activities—Exercise Therapy

Assist the client to use footwear that facilitates walking and prevents injury; Instruct in use of assistive devices, if appropriate

Nursing Interventions and *Rationales*

- Adults with disabilities should follow the adult guidelines. If this is not possible, they should be as physically active as their abilities allow and avoid inactivity (US Department of Labor, 2008). Use "start low and go slow" approach for intensity and duration of physical activity if client is highly deconditioned, functionally limited, or has chronic conditions affecting performance of physical tasks. When progressing client's activities, use an individualized and tailored approach based on client's tolerance and preferences (Riebe et al, 2015).
- Assess for fear of falling. **EBN:** *Self-reported fear of falling has been shown to be a*

significantly more sensitive predictor for fall risk than the STRATIFY fall risk assessment tool (Strupeit, Buss, & Wolf-Ostermann, 2016).

• Screen for mobility skills in the following order: (1) bed mobility; (2) dangling and supported and unsupported sitting; (3) weight-bearing for sit to stand, transfer to chair; (4) standing and walking with assistance; and (5) walking independently. **EBN:** *Use a structured tool to assess and determine the patient's highest activity level and guide planning exercise progression toward independence (Jackman et al, 2016).*

• Assess muscle strength and other factors affecting balance, mobility, and endurance. Immobility can affect tissue perfusion and increase risk of postural hypotension; shortness of breath decreases endurance and increases fear; bowel or bladder incontinence can decrease motivation to be mobile; cognitive and neuromuscular deficits, including side effects of medication, can affect balance, coordination, and movement; and pain, fear, or sick role expectations can decrease willingness to be mobile. **EBN:** *Assess for mobility impairment, hazards of limited mobility, and plan care to mitigate complications (Crawford and Harris, 2016).*

• Refer to care plans for Risk for **Falls,** Acute **Pain,** Chronic **Pain,** Ineffective **Coping,** or **Hopelessness.**

• Increase activity tolerance with graded increases in self-care (function-focused care [FFC]), such as bathing, walking to the bathroom instead of using a bedpan/urinal, and ROM. **EBN:** *A study of FFC in older adults hospitalized after trauma found greater improvement in function, less fear of falling, and better physical resilience than controls at discharge and 30 days after (Resnick, Galik, & Vigne 2016).*

• Consider patient's self-reported fear of falling. **EBN:** *Self-reported fear of falling has been shown to be a sensitive predictor for fall risk (Strupeit, Buss, & Wolf-Ostermann, 2016).*

▲ Before activity, observe for and, if possible, treat pain with massage, heat pack to affected area, or medication. Ensure that the client is not oversedated. *Pain limits mobility and if exacerbated by specific movements should be temporarily avoided (American College of Sports Medicine [ACSM], 2018).*

• Obtain any assistive devices needed for activity, such as gait belt, weighted vest, walker, cane, crutches, or wheelchair, ergonomic shower chairs; ceiling and floor-based lifts; and air-assisted lateral transfer devices.

• Monitor and record the client's response to activity, such as pulse rate, blood pressure, dyspnea, skin color, subjective report. Refer to the care plan for **Activity** intolerance. **EB:** *Use valid and reliable screening procedures and tools to assess the client's preparticipation in exercise health screening and risk stratification for exercise testing (low, moderate, or high risk) (ACSM, 2018).*

Special Considerations: Immobility

• Perform passive ROM exercises at least twice a day unless contraindicated; repeat each maneuver three times. **EB:** *Physical rehabilitation interventions were found to be safe, reduced disability, and resulted in few adverse events (Crocker et al, 2013).*

▲ Consult with health care provider for a safety evaluation before beginning an exercise program; if program is approved, begin with the following exercises:

- ❍ Active ROM exercises using both upper and lower extremities (e.g., flexing and extending at ankles, knees, hips)
- ❍ Chin-ups and pull-ups using a trapeze in bed (may be contraindicated in clients with cardiac conditions)
- ❍ Strengthening exercises such as gluteal or quadriceps sitting exercises

• Use assistive technology for mobilizing bedbound patients. Refer to the care plan

for Impaired bed **Mobility**.
• Help the client achieve mobility and start walking as soon as possible if not contraindicated. **EBN:** *To prevent hospital-acquired disability, organizational values should consider both safety (e.g., fall prevention) and injury protection in concert with a philosophy that enables older adults to be self-directed and independent (Boltz et al, 2014).* **EB:** *Early mobilization after hip replacement surgery resulted in decreased time until readiness for discharge (Okamoto et al, 2016).*
• Initiate a "no lift" policy where appropriate assistive devices are used for manual lifting. **EBN:** *Relevance of manual client handling policies that may promote overuse of equipment should be openly discussed among nurse managers and direct care providers to avoid hospital-related loss of mobility among clients (Kneafsey, Clifford, & Greenfield, 2015).*
See care plan for Impaired bed **Mobility**.

Other Clinical Conditions:

▲ If the client has osteoarthritis or rheumatoid arthritis, consult with a physical therapist to on ways to integrate aerobic exercise, resistance exercise, and flexibility exercise (stretching) into care.
▲ If client has had a cerebrovascular accident (CVA) with hemiparesis, consult with physical therapist on constraint-induced movement therapy, in which the functional extremity is purposely constrained and the client is forced to use the involved extremity. **EB:** *Use of this therapeutic approach produced significant positive effects in improving arm function after stroke (Wattchow, McDonnell, & Hillier, 2018).*
• If the client does not feed or groom self, sit side by side with the client, put your hand over the client's hand, support the client's elbow with your other hand, and help the client feed self; use the same technique to help the client comb hair. **EBN:** *Hospitalized older adults who received a family-centered intervention to promote functional and cognitive recovery (family-centered FFC) had improved ADLs and walking ability and less severe and shorter duration of delirium (Boltz et al, 2014).*

Geriatric

• Assess ability to move using valid and reliable criterion-referenced standards for fitness testing that can predict the level of capacity associated with maintaining physical independence into later years of life (e.g., Get Up and Go test).
• Help the mostly immobile client achieve mobility as soon as possible, depending on physical condition. **EB:** A meta-analysis found exercise beneficial in increasing gait speed and improving balance and ADL performance (Lipardo et al, 2017). Mobilization should occur at least three times daily, mobilization should be progressive and scaled, and assessment should take place within 24 hours of admission (Liu et al, 2017).
• Use the FFC rehabilitative philosophy of care in older adults to prevent avoidable functional decline. **EBN:** Mood, satisfaction with staff and activities, and social support for exercise were directly associated with time spent in physical activity (Holmes, Galik, & Resnick, 2017; Resnick & Galik, 2013).
• If the client is scheduled for an elective surgery that will result in admission into the intensive care unit and immobility, or recovery from a joint replacement, for example, initiate a prehabilitation program that includes warm-up, aerobic activity, strength, flexibility, neuromotor, and functional task work. **EBN:** The risk of declines in functional status when older adults are hospitalized requires using evidence-based

strategies to reduce the incidence and effect of decreased mobility, pressure ulcers, pain, dehydration, malnutrition, and sequelae of invasive treatments (Resnick et al, 2016).
• Use gestures and nonverbal cues when helping clients move if they are anxious or have difficulty understanding and following verbal instructions. Nonverbal gestures are part of a universal language that can be understood when the client is having difficulty with communication.
• Recognize that wheelchairs are not a good mobility device and often serve as a mobility restraint.
• Ensure that chairs fit clients. Chair seat should be 3 inches above the height of the knee. Provide a raised toilet seat if needed. Raising the height of a chair can dramatically improve the ability of many older clients to stand up. Low, deep, soft seats with armrests that are far apart reduce a person's ability to get up and down without help.
• If the client is mainly immobile, provide opportunities for socialization and sensory stimulation (e.g., television and visits). Refer to the care plan for Deficient **Diversional** activity.
• Recognize that immobility and a lack of social support and sensory input may result in confusion or depression in older adults. Refer to nursing interventions for Acute **Confusion** or **Hopelessness** as appropriate.

Home Care

• The preceding interventions may be adapted for home care use.
▲ Begin discharge planning as soon as possible with a personal health navigator (e.g., nurse care coordinator or case manager) to assess need for and arrange home support systems, assistive devices, and community or home health services. Nurses are often the first health care providers to assess the patient on admission; this creates the opportunity for early discharge planning (McNeil, 2016).
▲ Assess home environment for factors that create barriers to physical mobility. Refer to occupational therapy services if needed to assist the client in restructuring home environment and daily living patterns. **EB:** *Use the Home Safety Self-Assessment Tool to identify fall risk, prevent falls, and improve mobility and function (Horowitz, Almonte, & Vasil, 2016).*
▲ Refer to home health aide services to support the client and family through changing levels of mobility. Reinforce need to promote independence in mobility as tolerated. *Providing unnecessary assistance with transfers, bathing, and dressing activities may promote dependence and a loss of mobility rather than optimizing a person's underlying physical capability. Such attentive care may actually prevent older adults from using their remaining abilities (Resnick et al, 2016).*
▲ Refer to physical therapy for gait training, strengthening, and balance training. Physical therapists can provide direct interventions and assess need for assistive devices (e.g., cane, walker) (Miller, Sabol, & Pastva, 2017).
• Assess skin condition at every visit. Establish a skin care program that enhances circulation and maximizes position changes. *Impaired mobility decreases circulation to dependent areas. Decreased circulation and shearing place the client at risk for skin breakdown.*
• Once the client is able to walk independently, suggest that the client enter an exercise program, or walk with a friend. **CEB:** *Nurse practitioners providing primary care should prescribe regular physical activity to minimize progressive impaired mobility* (*Miller,*

Sabol, & Pastva, 2017).

• Provide support to the client and family/caregivers during long-term impaired mobility. *Long-term impaired mobility may necessitate role changes within the family and precipitate caregiver stress*. Refer to the care plan for **Caregiver Role Strain.**

Client/Family Teaching and Discharge Planning

• Consider using motivational interviewing techniques when working with both children and adult clients to increase their activity. Refer to the care plan for **Sedentary** lifestyle or *Rationales* for motivational interviewing.

• Teach the client and caregivers processes and tools used during care to use at home to assess fall risk and promote progressive mobility. Involve them in planning for these activities at home. **EBN:** *Few studies have investigated the point of view of older patients on prevention of this decline. Within the framework of a descriptive qualitative study, the perceptions of 30 hospitalized older adults were collected regarding their personal prevention strategies, the barriers to implementing these, and nursing staff interventions deemed useful. Results show that participants are sensitive to the risk of functional decline and use various preventive strategies particularly to maintain their physical abilities, maintain good spirits, keep a clear mind, and foster nutrition and sleep. Their strategies are difficult to implement because of internal and external barriers. Nursing interventions deemed useful are good relational approach, strong basic care, appropriate assessment, and respect for level of autonomy. The study underscores that older hospitalized patients are applying strategies to prevent functional decline, but some nursing interventions may thwart their efforts (Lafreniere et al, 2017).*

Impaired wheelchair Mobility

Wendie A. Howland MN, RN-BC, CRRN, CCM, CNLCP, LNCC

NANDA-I

Definition

Limitation of independent operation of wheelchair within environment.

Defining Characteristics

Impaired ability to operate power wheelchair on a decline; impaired ability to operate power wheelchair on an incline; impaired ability to operative power wheelchair on curbs; impaired ability to operative power wheelchair on even surface; impaired ability to operate power wheelchair on uneven surface; impaired ability to operate wheelchair on a decline; impaired ability to operate wheelchair on an incline; impaired ability to operate wheelchair on curbs; impaired ability to operate wheelchair on even surface; impaired ability to operate wheelchair on uneven surface

Related Factors

Alteration in mood; decrease in endurance; environmental barrier; insufficient knowledge of wheelchair use; insufficient muscle strength; obesity; pain; physical deconditioning

Associated Condition

Alteration in cognitive functioning; impaired vision; musculoskeletal impairment; neuromuscular impairment

NOC (Nursing Outcomes Classification)

Suggested NOC Outcome

Ambulation: Wheelchair

Example NOC Outcome with Indicators

Ambulation: Wheelchair as evidenced by the following indicators: Propels wheelchair safely/Transfers to and from wheelchair/Maneuvers curbs, doorways, ramps. (Rate the outcome and indicators of **Ambulation: Wheelchair:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Demonstrate independence in operating and moving a wheelchair or other wheeled device
- Demonstrate ability to direct others in operating and moving a wheelchair or other device
- Demonstrate therapeutic positioning, pressure relief, and safety principles while operating and moving a wheelchair or other wheeled device

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Exercise Therapy: Muscle Control; Positioning: Wheelchair

Example NIC Activities—Positioning

Wheelchair

Collaborate with occupational therapist [OT]/physical therapist [PT] to select the appropriate wheelchair for the client: standard adult, semireclining, fully reclining, amputees; Monitor client's ability to maintain correct positioning in wheelchair

Nursing Interventions and *Rationales*

▲ Refer to physical and occupational therapy or wheelchair seating clinic. *Seating for wheelchair-dependent clients should be assessed by health care specialists in conjunction with client/caregiver education on weight shift maneuvers (Sprigle & Sonenblum, 2011).*

▲ Recognize that support surfaces on chairs and beds redistribute pressure and should be used for at-risk clients as an adjunct to reduce risk of pressure injury (Sprigle & Sonenblum, 2011; Requejo, Furumasu, & Mulroy, 2015). **EB:** *Sitting-acquired pressure injuries occur primarily over the ischial tuberosities; sacral injuries primarily result from shear and excessive loading in bed (Gefen, Farid, & Shaywitz, 2013; Agency for Healthcare Research and Quality [AHRQ], 2014). Foam cushions increased pressure in seating and should not be relied on for pressure relief (Slayton, Morris, & Brinkley, 2017). There are many pressure-relieving cushions. Several that are commonly used are the ROHO cushion, Varilite Evolution, and Invacare Matrix cushions.* Refer to care plan for Risk for **Pressure Ulcer.**

- Optimize nutrition and hydration for skin and tissue health.
- Intervene to maintain continence or use absorbent underpads or diapers to help prevent skin breakdown caused by excessive moisture and macerated skin. Some wheelchair cushions have moisture-wicking characteristics. *Use air-permeable underpads to decrease maceration (National Pressure Ulcer Advisory Panel, 2014).*
- Assess client's sitting posture frequently and reposition for alignment. Document specific measures to allow for reproducibility. **EB:** *Pressure mapping alone insufficiently describes tissue health (National Pressure Ulcer Advisory Panel, 2014).*
- Implement use of friction-coated projection hand rims and leather gloves for clients to propel manual wheelchairs. *Friction-coated projection rims are less invasive and slippery than aluminum rims; gloves absorb forces of propulsion and help prevent nerve damage/carpal tunnel injury.*

• Manually guide or explain to the client to push forward on both wheel rims to move ahead, push the right rim to turn left and vice versa, and pull backward on both wheel rims to back up.
• Recommend that clients back wheelchair into an elevator. If entering face first, instruct them to turn chairs around to face the elevator doors and controls.
▲ In conjunction with physical therapy for teaching and assessment, reinforce principle of descending a curb backward ("popping a wheelie") if balance, trunk control, strength, and timing are adequate. *Backward descent carries less risk of clients losing control and falling forward out of the wheelchair.*
• Ascend curbs in a forward position by popping a wheelie or having someone aid in tilting the chair back, place front wheels over curb, and roll chair up. If surface is muddy or sandy, ascend backward. *Front casters will not roll on soft surfaces; a backward approach requires less energy and prevents getting stuck or falling forward.*
• During assisted wheelies, helper must hold wheelchair until all four wheels are back on the ground and client has control of wheelchair. *Releasing one's grip too soon may alter client's balance and cause injury.*
▲ Follow therapist's recommendations for how clients should propel manual wheelchairs to prevent upper extremity pain and joint degeneration.
• Recognize that ultra-lightweight, push rim–activated, power-assisted, or powered wheelchairs may be indicated. Striking the balance between optimum independence and preventing injury (e.g., rotator cuff injury from years of manual propulsion) is a consideration. *Consider push rim–activated power-assisted wheelchairs (manual wheelchairs with a motor linked to the push rim in each rear hub) because they reduce energy needed for propulsion and reserve energy for uneven terrain or obstacle negotiation. Recommend antirollback devices for inclined planes to decrease stress on shoulders.* **EB:** *Full-time manual wheelchair users are at high risk for developing shoulder injury (Rice and Rice, 2017). If the client does not have sufficient strength or motor control of the extremities to propel a standard wheelchair, then the client should be evaluated for a power chair.*
▲ Reduce floor clutter and establish safety rules for drivers of electric/power mobility devices; make referrals to physical or occupational therapy for driver reevaluations if accidents occur or client's health deteriorates.
• Request and receive client's permission before moving an unoccupied wheelchair in the room or out to hallway. *Wheelchair-dependent clients may view the chair as part of their identity and independence.*
• Reinforce compensatory strategies for unilateral neglect and agnosia (e.g., visual scanning, self-talk, self-questioning as to what could be wrong) as clients propel wheelchair through doorways and around obstacles. *Too often nurses physically move the wheelchair or obstacle instead of cueing the client to detect and solve problems.* Refer to care plan for **Unilateral Neglect.**
• Offer support to help clients cope with issues related to physical disability. *Depression and anxiety may occur with physical loss.* Refer to care plan for Ineffective **Role** performance.
• Provide information on support group and reliable Internet resource options.
• Provide information about advocacy, accessibility, assistive technology, and issues under the Americans with Disabilities Act as Amended (2008) (Jackson, 2017).
▲ Make social service or wheelchair clinic referral to educate clients on financial coverage/regulations of third-party payers and Health Care Financing Association for wheelchairs. *It is wise to recognize cost, advantages, and durability of different wheelchair models before purchasing one.*
• Recommend that clients test-drive wheelchairs and try out cushions/postural

supports with the advice of a qualified seating professional, not a vendor, before purchasing. If a specialty chair is indicated, for example, for sports or outdoor use, having clients test-drive the wheelchair is especially important. *Equipment is expensive, and different models have different advantages and disadvantages.*

Pediatric

▲ **EB:** *Consult physical or occupational therapist for special considerations for wheelchair fitting and positioning for pediatric client. In children with cerebral palsy, poor trunk control can lead to spinal deformity and pulmonary compromise. Evidence links posture and pulmonary function; special techniques for measuring these may be necessary (Barks & Shaw, 2011).*
▲ Help client/family transition from a manual to a powered wheelchair/scooter if disability is severe. **EB:** *Wheelchairs are essential for maximizing mobility and function. Power wheelchairs can enhance independence for children who are able to use them with hand, head, or mouth mechanisms (Hoon & Tolley, 2013).*

Geriatric

• Avoid using restraints on fidgeting clients who slide down in a wheelchair. Instead, assess for deformities; spinal curvatures; abnormal tone; limited joint range; discomfort from clothing, pressure, or constriction areas; social isolation, and toileting needs.
• Ensure proper seat depth/leg positioning and use custom footrests (not elevated leg rests) to prevent older adults from sliding down in wheelchairs.
▲ Assess for side effects of medications and potential need for dosage readjustments to increase wheelchair tolerance. Give prescribed hydration and medications to treat orthostatic hypotension. Consider leg wraps. Assist client to perform warm-up bed exercises if possible. *Cerebral hypoperfusion and prolonged bedrest are common causes of orthostatic intolerance and hypotension; see care plan for Impaired Bed **Mobility**.*
• Allow client to control speed to propel wheelchair independently if possible. *Older adults may move slowly because of diminished range of motion/strength, stiff/sore joints, and cardiopulmonary compromise. Observe carefully for fatigue, shoulder pain, or other signs of activity intolerance.*
• Assess the client's ability to safely maneuver independently using a wheelchair. **EB:** *Use an evidence-based tool to assess the client's skill and physical ability to safely use a wheelchair (AHRQ, 2017).*

Home Care

▲ Establish a support system for emergency and contingency care (e.g., remote monitoring, emergency call system, alert local emergency medical system). *Wheelchair dependence may be life-threatening during a crisis (e.g., fall, fire, or other environmental emergency).*
• Recommend the following changes to the home to accommodate the use of a wheelchair:
    ❍ Arrange traffic patterns so they are wide enough to maneuver a wheelchair.
    ❍ Recognize that a 5-foot turning space is necessary to maneuver wheelchairs, doorways need to have 32 to 36 inches clear width, and entrance ramps/path slope should be assessed before permanent ramps are installed because standardized slopes may not be appropriate. Temporary

ramps are cost-effective and easier to adjust (Sofka, 2011).
- ❍ Replace door hardware with fold-back hinges, remove doorway encasements (if too narrow), remove/replace thresholds (if too high), hang wall-mounted sinks/handrails, grade floors in showers for roll-in chairs, and use nonskid/nonslip floor coverings (e.g., nonwaxed wood, linoleum, or Berber carpet).
- ❍ Rearrange room functions, furniture, and storage so that toileting, sleeping, bathing, and preparing/eating meals can safely take place on one level of the home.
- ❍ *Refer to the Easter Seals Summary on Home Accessibility for further details* (see http://www.easterseals.com/shared-components/document-library/easy_access_housing.pdf).

▲ Request physical and occupational therapy referrals to evaluate wheelchair fitting, skills, safety, and maintenance. Suggest community resources for servicing and tuning up wheelchairs and/or locating parts so clients can service their own chairs; an annual tune-up is recommended.

Client/Family Teaching and Discharge Planning

▲ Assess pain levels of long-term wheelchair users and make referrals to therapists or wheelchair clinics for modifications as needed.

• Instruct and have client return demonstrate reinflation of pneumatic tires; encourage client to monitor tire pressure every 2 to 3 weeks.

• Instruct family/clients to remove large wheelchair parts (leg rests, armrests) when lifting wheelchair into car for transport; when reassembling, check that all parts are fastened securely and temperature is tepid. *This reduces weight that needs to be lifted; locked parts and a safe temperature prevent injury/thermal injury.*

• Teach the critical importance of using seatbelts and secure chair tie-downs when riding in motor vehicles in a wheelchair. Never transport a client in an unsecured wheelchair in any kind of vehicle.

• For further information, refer to care plan for Impaired **Transfer** ability.

Impaired Mood regulation

Wolter Paans MSc, PhD, Anna van der Woude BSN, Carolien van der Velde, Marloes Harkema BA, Milou Zemering BN

NANDA-I

Definition

A mental state characterized by shifts in mood or affect, which is comprised of a constellation of affective, cognitive, somatic, and/or physiological manifestations varying from mild to severe.

Defining Characteristics

Change in verbal behavior; disinhibition; dysphoria; excessive guilt; excessive self-awareness; excessive self-blame; flight of thoughts; hopelessness; impaired concentration; influenced self-esteem; irritability; psychomotor agitation; psychomotor retardation; sad affect; withdrawal

Related Factors

Alteration in sleep pattern; anxiety; appetite change; hypervigilance; impaired social functioning; loneliness; pain; recurrent thoughts of death; recurrent thoughts of suicide; social isolation; substance misuse; weight change

Associated Condition

Chronic illness; functional impairment; psychosis

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Agitation Level; Hope; Symptom Control; Mood Equilibrium; Comfort Status: Psychospiritual; Concentration; Symptom Severity; Self-Esteem

Example NOC Outcome with Indicators

Mood Equilibrium as evidenced by the following indicators: Exhibits affect that fits situation/Exhibits impulse control/Shows interest in surroundings. (Rate the outcome and indicators of **Mood Equilibrium:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- State feelings related to changes in mood
- Eat appropriate diet for height and weight
- Follow exercise plan
- Have no attempts at self-harm

- Attention during activities

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Activity Therapy; Aromatherapy; Art Therapy; Cognitive Restructuring; Emotional Support; Environmental Management; Forgiveness Facilitation; Hope Inspiration; Milieu Therapy; Presence; Mood Management; Suicide Prevention; Exercise Promotion; Health Education

Nursing Interventions and *Rationales*

- Provide nutritional intake for a client who is unable to feed self. **EB:** *This study aimed to define the role of nutritional interventions in the prevention and treatment of malnutrition in head and neck cancer clients undergoing chemoradiotherapy (CRT) and their effect on CRT-related toxicity and survival. Head and neck cancer clients are frequently malnourished at the time of diagnosis and prior to the beginning of treatment. In addition, CRT causes or exacerbates symptoms, such as alteration or loss of taste, mucositis, xerostomia, fatigue, and nausea and vomiting, with consequent worsening of malnutrition. Nutritional counseling and oral nutritional supplements should be used to increase dietary intake and prevent therapy-associated weight loss and interruption of radiation therapy (Bossola, 2015). Some of the symptoms (e.g., fatigue, loss of taste) are also present in clients with the diagnostic concept "impaired mood regulation." This study clearly demonstrates that nutritional counseling should be used to increase dietary intake and to prevent weight loss.*
- Encourage regular physical exercise to maintain or advance to a higher level of fitness and health. **EB:** Negative affective states such as anxiety, depression, and stress are significant risk factors for cardiovascular disease, particularly in cardiac and postcardiac rehabilitation populations. In this study, yoga is used as physical exercise. Breathing control and meditation can reduce psychosocial symptoms and improve cardiovascular and cognitive function (Yeung et al, 2014). This study showed the interest of physical exercise to advance a higher level of health.
- This intervention can be substantiated by Brett, Traynor, and Stapley (2016) and Carter et al (2016).
- Reduce the risk of self-inflicted harm for a client in crisis or severe depression with a planned treatment program. **CEB/EBN:** This study is about childhood suicidal behavior. This is a complex symptom that requires a carefully planned treatment program that includes multiple modalities of care. Treatment requires a long-term approach that constantly reassesses potential for serious suicidal risk. Psychiatric hospitalization may be required to protect the child from self-inflicted harm and to allow evaluation and appropriate intervention (Pfeffer, 1984). This study is not recent, but it confirms that the risk of self-inflicted harm for a client in crisis should be reduced.
- Advise the client to listen to music in a negative mood (Gold, 2013; Aalbers et al, 2017).
- Try to perceive possible suicidal thoughts on time (Sohn et al, 2017).
- Enable the client to express his or her feelings and try to support the client emotionally if necessary (Kim et al, 2017).
- When possible, use (aromatherapy) massage when in a negative mood (Babaee et al, 2012; Ho et al, 2017).
- Consider recommending cognitive behavior therapy (Whitten & Stanik-Huff, 2011;

Cajanding, 2016; Andersen et al, 2017).
• Consider recommending psychotherapy (Szczepanska-Gieracha et al, 2013).
• Give the client hope, for example, about regaining his or her health (Svensson, Nilsson, & Svantesson, 2016).
• If necessary, emphasize the importance of daily activity and routine (Crowe, Beaglehole, & Inder, 2016).
• Signal and treat pain on time (Husebo et al, 2014).
• Promote the self-efficacy of the client (Madueno Caro et al, 2017).
• In case of a persistent negative mood, recommend meditation to theclient (Yuichi et al, 2015).
• The use of a doll in people with dementia can contribute to a better mood (Shin, 2015).

Client Family Teaching and Discharge Planning

• Provide a treatment involving the cooperation of several aid workers in neighborhood teams and providing customized treatment at the place in which the client resides. **EB/EBN:** *The use of teams is a well-known approach in a variety of settings, including health care, in both developed and developing countries. Team performance comprises teamwork and task work, and ascertaining whether a team is performing as expected to achieve the desired outcome has rarely been done in health care settings in resource-limited countries (Yeboah-Antwi et al, 2013). This article shows that this intervention is still used.*

Moral Distress

Ruth A. Wittmann-Price PhD, RN, CNS, CNE, CHSE, ANEF, FAAN

NANDA-I

Definition

Response to the inability to carry out one's chosen ethical or moral decision and/or action.

Defining Characteristics

Anguish about acting on one's moral choice

Related Factors

Conflict among decision makers; conflicting information available for ethical decision-making; conflicting information available for moral decision-making; cultural incongruence; difficulty reaching end of life decisions; difficulty reaching treatment decision; time constraint for decision-making

At-Risk Population

Loss of autonomy; physical distance of decision maker

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Personal Autonomy; Client Satisfaction; Protection of Rights

Example NOC Outcomes with Indicators

Client Satisfaction: Protection of Rights as evidenced by the following indicators: Requests respected/Included in decisions about care/Care consistent with religious and spiritual needs. (Rate the

outcome and indicators of **Client Satisfaction: Protection of Rights**: 1 = not at all satisfied, 2 = somewhat satisfied, 3 = moderately satisfied, 4 = very satisfied, 5 = completely satisfied [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Be able to act in accordance with values, goals, and beliefs
- Regain confidence in the ability to make decisions and/or act in accord with values, goals, and beliefs
- Express satisfaction with the ability to make decisions consistent with values, goals, and beliefs
- Have choices respected

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Patient Rights Protection; Emotional Support

Example NIC Activities—Patient Rights Protection

Provide environment conducive for private conversations between client, family, and health care professionals

Nursing Interventions and *Rationales*

- Assess if moral distress is present and its relationship to intrinsic or extrinsic factors. **EB:** *Researchers investigated the role of intrinsic motivation (IM) in regimen adherence and glycemic control in type 1 diabetic youths (N = 51) using a new tool to measure IM and found that higher IM was positively correlated with better glycemic control. The 12-item tool is called the Intrinsic Motivation Inventory for Diabetes Management (IMI-DM) (Delamater et al, 2017).* **EB:** *Cannizzaro et al (2017) studied patients' readiness to change by using the Treatment Motivation Questionnaire in substance-abusing patients (N = 145) to examine intrinsic and extrinsic motivation, and results supported that intrinsic and extrinsic motivation can be used to predict treatment outcome. Additionally, extrinsic motivation might play an important role in the initial stages of treatment, whereas IM plays a role in the later stages of treatment.*
- Affirm the distress, commitment "to take care of yourself," and your obligations. Validate feelings and perceptions with others. **EB:** *Hjelle et al (2017) qualitatively studied reablement (a home-based, intensive, goal-oriented rehabilitation intervention for older adults) using semistructured interviews with eight patients, and four main themes emerged: "My willpower is needed," "Being with my stuff and my people," "The home-trainers are essential," and " 'Training is physical exercises, not everyday activities."* **EB:** *Blank et al (2017) reviewed research that supports exercise as an IM for adolescents to quit smoking.*
- Implement strategies to change situations causing moral distress. **EB:** *Sabin (2017) studied moral distress in organizations and deduced moral distress in individuals can be reduced when their reports are given attention and crucial data are extracted on an organization level. Individuals must be able to articulate their concerns without fear of retribution, and leaders must be committed to quality improvement.* **EBN:** *Karagozoglu et al (2017) studied the use of a moral distress tool in another country to evaluate the moral distress*

of nurses (N = 200) in an intensive care unit (ICU) by descriptive and cross-sectional design. The results concluded that the tool was reliable and valid, and the study identified communication as key to decreasing moral distress.

• Assess sources and severity of distress. **EBN:** *Henrich et al (2017) qualitatively examined the effects of moral distress in ICUs using focus groups and found that frustration was the most common emotion associated with moral distress. Specific adverse patient care incidences were also correlated with moral distress.* **EBN:** *Young, Froggatt, & Brearley (2017) studied moral distress in nursing home clinicians (N = 16) with patients who are near the end of life using an interpretive descriptive design and found participants described holding "good dying" values, which influenced their practice including advocating, caring, communicating, and relating with residents and were found to influence interactions with residents, relatives, general practitioners, and colleagues. Moral distress was described when the right thing could not be done and a "bad death" incurred because of a feeling of powerlessness.*

• Give voice/recognition to moral distress and express concerns about constraints to supportive individuals. **EBN:** *Schroter (2017) discussed the differences between moral distress and moral resiliency and advocates assisting others to turn negatives into solutions and positive future outlooks to decrease moral distress.* **EBN:** *Researchers explored moral distress in Chief Nursing Officers (CNOs) (N = 20) using interviews and found six themes emerged including lacking psychological safety, feeling a sense of powerlessness, seeking to maintain moral compass, drawing strength from networking, moral residue, and living with the consequences. This research demonstrated that CNOs experience moral distress but are pressed to show moral courage (Prestia, Sherman, & Demezier, 2017).*

• Engage in healthy problem-solving. **EBN:** *Authors studied strategies to decrease nurses' moral distress and provide better patient care and strategies including legitimizing the experience, mentoring and empowering one another, allocating a safe haven, and improving the ethical climate of organizations (Forozeiya et al, 2017).* **EBN:** *Lachance (2017) completed a review of moral courage and how it emerges to offset moral distress and found that it encompasses building safe, collaborative patient- and family-centered teams. Engage in interdisciplinary problem-solving forums including family meeting and/or interdisciplinary rounds.* **EB:** *Researchers studied the Family Group Decision Making (FGDM) as a strategy to involve family members and social services to make decisions for children and families and found that family participation in family meetings predict planning to ensure services are obtained and reaching family goals (Xu, Ahn, & Bright, 2017).* **EBN:** *Anderson and Puntillo (2017) studied the integration of palliative care in ICUs and provided nurses (N = 428) with professional development, which resulted in increased communication skills and better provision of palliative care needs to patients and families.*

• Identify/use a support system. **EBN:** *Ramdinmawii (2017) completed a descriptive study to understand the level of stress, social support, and life satisfaction among parents (N = 60) who have a child with autism spectrum disorder (ASD). Results showed that parents have moderate stress, moderate social support, and a neutral life satisfaction, and social support is correlated inversely to stress and positively with life satisfaction.* **EB:** *Barimani et al (2017) qualitatively studied the transition to parenthood to discover, describe, and understand transitional conditions that parents perceive as facilitating and inhibiting during the transition to parenthood and to use that knowledge to develop recommendations for professional interventions that support and facilitate the transition to parenthood. The elements that helped the transition to parenthood included perceiving parenthood as normal, enjoying the child's growth, being prepared, having knowledge, and having social support.*

Initiate an ethics consult or ethics committee review. ***EBN:*** *Kuis & Goossensen (2017) investigated whether the emotional touchpoint method (significant moments when patients were effected physically or emotionally by care) interviews of patients (N = 31) met*

appropriate ethical standards when used for evaluating care. The study results demonstrated that the touchpoint method was ethical and valuable in evaluating patient care. ***EBN:*** *Crigger et al (2017) used qualitative research to understand the basic process of ethics consultation services by investigating perceptions of health care professionals and found three stages, moral questioning, seeing the big picture, and coming together, which assisted professionals in ethical decision-making.*

Pediatric

- Consider the developmental age of children when evaluating decisions and conflict. **EB:** *Malas et al (2017) studied somatic symptom disorder (SSD) in children who present disproportionate or inconsistent physical manifestations with history, physical examination, laboratory, and other assessment findings and made recommendations on how to evaluate and assist parents and children who exhibit manifestations and their underlying cause.* **EB:** *Wocial et al (2017) completed a pilot project that included formal weekly discussions about prolonged-stay pediatric ICU (PICU) patients to reduce health care providers' moral distress and decrease length of stay (LOS) and found that the intervention had a positive effect on some factors that contribute to moral distress and shortened the LOS for some patients.*

Multicultural

- Acknowledge and understand cultural differences that may influence a client's moral choices. **EBN:** *Bressler, Hanna, and Smith (2017) qualitatively studied moral distress in a nursing care unit with elderly Orthodox Jewish patients at the end of life to better understand the cultural complexity and differences in expectations for patient care between nurses and families. Interviews revealed the incongruence of perspectives indicating there is needed educational strategies, clinical interventions, and research to address moral distress and cultural complexity.* **EB:** *Howe (2017) discussed observations related to moral distress not only among professionals but also patients and families with a professional-cultural view to view moral distress as a challenge to provide better care.*

Geriatric and Home Care

- Previous interventions may be adapted for geriatric or home care use. **EB:** *Harigane et al (2017) explored the relationship between psychological distress and degree of functional independence among elderly adults (N = 20,282) and found that psychological distress was significantly associated with decreased independence in all activities of daily living.* **EB:** *Knight and Alarie (2017) studied the outcomes of a 10-week multimodal mental health day treatment program for elderly patients (N = 255) with mood and anxiety disorders and found that the program improved anxiety and depression.*

Risk for dry Mouth

Katherine Foss MSN, RN

NANDA-I

Definition

Susceptible to discomfort or damage to the oral mucosa due to reduced quality or quality of saliva to moisten the mucosa, which may compromise health.

Risk Factors

Dehydration; depression; excessive stress; excitement; smoking

Associated Condition

Chemotherapy; fluid restriction; inability to feed orally; oxygen therapy; pharmaceutical agent; pregnancy; radiation therapy to the head and neck; systemic diseases

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Oral Health; Self-Care: Oral Hygiene; Tissue Integrity: Skin and Mucous Membranes

Example NOC Outcome with Indicators

Oral Health as evidenced by the following indicators: Cleanliness of mouth and teeth/Moisture of oral mucosa and tongue/Color of mucous membranes/Oral mucosa/Tongue/Gum integrity. (Rate the outcome and indicators of **Oral Health:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Maintain intact, moist oral mucous membranes that are free of ulceration, inflammation, infection, and debris
- Demonstrate measures to maintain or regain oral health
- Demonstrate oral hygiene knowledge and skills to maintain moisture within the mouth
- Be free of halitosis and oral discomfort
- State tolerable to no changes in taste sensation (dysgeusia)

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Oral Health Restoration

Example NIC Activities—Oral Health Restoration

Monitor condition of client's mouth including character of abnormalities; Instruct client to perform regular oral hygiene measures

Nursing Interventions and *Rationales*

- Perform a comprehensive extraoral and intraoral examination for associated

conditions and risk factors that reduce quantity or quality of saliva and patient complaints of oral dryness and difficulty speaking, eating, or swallowing. *Inspection is a critical assessment and diagnostic tool that can lead to identification of current oral health and impending problems (van Der Waal, 2015).*

• Assess for symptoms of dry mouth. **EB:** Observe for atrophic and erythematous oral mucosa, loss of papillae on the tongue, and lips that peel and crack. Traumatic lesions may be visible on the buccal mucosa and the lateral borders of the tongue (American Dental Association [ADA], 2015).

• Inspect and palpate major salivary glands and lymph nodes for masses, enlargement, tenderness, purulent discharge, or absence of salivary pooling/secretions are components of a comprehensive head and neck examination to differentiate between salivary and nonsalivary causes of dry mouth (ADA, 2015).

• Inspect nasal turbinates for enlargement, swelling, polyps, and nasal flow because nasal blockages increase mouth breathing, which may exacerbate oral dryness symptoms.

• Assess patient for oral candidiasis, dental caries, and gingival recession (ADA, 2015). Oral candidiasis may suggest the client is immunocompromised or on treatment that increases the risk of fungal infection, which can lead to additional health care concerns.

• Assess patient for dental caries and gingival recession because clinical signs of hyposalivation also include increased incidence of tooth decay at the gingival margin and nonspecific gingival inflammation (Plemons, Al-Hashimi, & Marek, 2014; ADA, 2015).

• Assess patient for difficulty chewing, swallowing (dysphagia), or speaking. Dry mouth may cause difficulties with chewing and swallowing, which may place the client at risk of choking and or malnutrition (ADA, 2015; American Academy of Oral Medicine [AAOM], 2016).

• Assess patient for mouth breathing caused by functional impairment of the upper airway and/or presence of nasal, endotracheal, or orogastric tubes that may prevent mouth closure or irritate oral mucosa, which may contribute to an increase in dry mouth symptoms experienced by clients.

• Assess patient hydration status. **EB:** A dry tongue and mucous membranes are symptoms of decreased hydration status (Wagner & Hardin-Pierce, 2014). Decreased hydration status can worsen symptom of dry mouth.

• Assess fluid status because dehydration will also affect salivary flow (Plemons, Al-Hashimi, & Marek, 2014). Consider fluid loss associated with fever, cachexia, vomiting, or diarrhea. Recognize that dehydration is prevalent in older adults and may affect salivary flow (ADA, 2015).

▲ Dry mouth, mouth dryness, or oral dryness (xerostomia) is a dryness of the oral cavity resulting from insufficient or complete lack of saliva secretion. Although dry mouth is a common symptom of salivary gland hyposecretion, there is a distinction between dryness caused by malfunction of the salivary glands and the patient's subjective report of oral dryness despite normal salivary gland function (Tanasiewicz, Hildebrandt, & Obersztyn, 2016). **EB:** *In a review summary of 90 articles, clinical application to the etiology, diagnosis, and treatment of dry mouth requires an interdisciplinary approach to symptom assessment, clinical examination, functional and cognitive assessment, and identifying goals of care. The management of dry mouth begins with a thorough history of symptoms; review of medical, dental, and medication use history; clinical exam; salivary flow rate measurements; salivary imaging studies; and biopsies and laboratory analysis (Han, Suarez-Durall, & Mulligan, 2015).* **CEB:** *In a literature review of dry mouth diagnosis and*

treatment, measurement of salivary output is required to differentiate between salivary and nonsalivary causes of xerostomia (Napeñas, Brennan, & Fox, 2009).

▲ The client may require a dental referral to evaluate salivary flow rate as a tool to monitor dry mouth symptoms (Plemons, Al-Hashimi, & Marek, 2014; ADA, 2015).

▲ Consider use of oral screening, patient self-report tool, and/or subjective questioning regarding dry mouth symptoms to assess client oral health and to predict need for dental intervention and degree of salivary hypofunction. **EB:** *One validated screening tool, for use by nondental professionals, to assess client oral health and identification of need for a dental exam is the Oral Health Assessment Tool (OHAT) and can be used to monitor client progress during an oral hygiene plan of care (Australian Department of Health and Aging, 2009).*

▲ Use client self-report to measure symptoms of dry mouth. **EB:** *The Xerostomia Inventory (XI) questionnaire, developed in Australia during the 1990s and validated in international studies, provided a summative rating of client's xerostomia symptoms (Thomson, 2015).* **EB:** *A Cochrane review found that a change in XI core of 6 or more points is likely to be meaningful, and the tools measure the severity of dry mouth and act as a responsive measure to interventions for dry mouth (Furness et al. 2013).*

• Ask the client about symptoms of hyposalivation. **CEB/EB:** A study of subjective oral dryness compared with salivary flow reports that certain complaints were highly predictive of impaired salivary flow. Positive responses to any of the following complaints are associated with significant hyposalivation: oral dryness when eating, need to sip fluids to swallow dry foods, difficulty swallowing, and the perception of too little saliva (Fox, Busch, & Baum, 1987; Napeñas, Brennan, & Fox, 2009).

▲ Review client medication usage for dry mouth as a side effect of medication. If symptoms are present consult with provider, or refer client to see a dentist or specialist. **EB:** *Assess the client's use of xerostomic medications or medications that are known to directly inhibit saliva flow (ADA, 2015). Anticholinergic and antihypertensive drugs (angiotensin-converting enzyme inhibitors, angiotensin receptor blockers, α- and β-adrenergic blockers, and diuretics) antihistamines, opioids, antidepressants, immunostimulants, and antipsychotic and skeletal muscle relaxant drugs are identified as common causes of dry mouth.* **EBN:** *Consult with a pharmacist regarding timing of medications and possible drug substitutions. Most medications do not cause damage to salivary glands but can reduce salivary flow (Plemons, Al-Hashimi, & Marek, 2014; Tanasiewicz, Hildebrandt, & Obersztyn, 2016).*

▲ Administer pilocarpine and cevimeline as prescribed because these medications are considered first-line therapy in Sjögren's syndrome and head and neck cancer clients with radiotherapy-induced dry mouth and hyposalivation. **EB:** *A systematic review and meta-analysis of 1732 patients in 20 studies indicated that both cevimeline and pilocarpine can reduce dry mouth symptoms and increase salivary flow compared with placebo (Mercadante et al, 2017).*

▲ ADA council on scientific affairs report identifies that pilocarpine and cevimeline have US Food and Drug Administration approval for treating dry mouth caused by Sjögren's syndrome or radiation therapy (ADA, 2015).

▲ Administer amifostine as prescribed to reduce the incidence of acute and late xerostomia for clients treated with standard fractionated radiation and gland-sparing radiation technique to the head and neck. **EB:** *A systematic review of the cytoprotectant amifostine has been shown to reduce the acute and late incidence of xerostomia in head and neck cancer patients treated with conventional radiation therapy (Shiboski et al, 2007).*

• Teach clients about conditions that can exacerbate dry mouth symptoms, including:
    - ❍ Avoidance of low-humidity environments

- ❍ Avoidance of oral irritants: acidic fluids such as carbonated beverages and juices, caffeine, alcohol, tobacco
- ❍ Avoidance of salty, spicy, acidic, or high-sucrose content foods
- ❍ Avoidance of dry, hard, and sticky foods
- ❍ Referral of patient to smoking and/or alcohol cessation program

EB: *Avoiding conditions that can worsen dry mouth can facilitate client self-management of the symptom severity (ADA, 2015; Agency for Healthcare Research and Quality [AHRQ], 2016).*

- Teach the client good oral hygiene:
  - ❍ Twice daily toothbrushing with regular topical fluoride toothpaste.
  - ❍ Use of soft bristle toothbrush. **EB:** *Twice daily use of a soft bristle toothbrush is an accepted standard of care by the ADA to maintain and promote oral health and dentition (ADA, 2017a).*
  - ❍ Daily use of dental floss or another interdental cleaner. **EB:** *Daily use of dental floss or interdental cleaner is an accepted standard of care to maintain and promote oral health and dentition (ADA, 2017a).*
  - ❍ Daily use of alcohol-free mouth rinse. **EB:** *Systematic review by an expert panel recommends regular use of fluoride toothpastes or mouth rinses as highly effective in preventing caries in dry mouth (Zero et al, 2016).*
  - ❍ Recommend use of prescription-strength fluoride toothpastes for severe salivary hypofunction. **EB:** *The use of 1.1% neutral sodium fluoride, or fluoride gel in custom-fit oral tray, or 0.09% fluoride mouth rinse daily (Plemons, Al-Hashimi, & Marek, 2014; ADA, 2017b).*
- Provide instruction regarding cleaning, and assist with care of dental prosthesis as needed. Daily cleansing of a dental prosthetic is an accepted standard of care to maintain and promote oral health and dentition (ADA, 2017a).

▲ Provide instruction on candidiasis prevention and control. Administer antifungal topical treatments as prescribed using available suspensions, pastilles, and lozenges for uncomplicated oral candidiasis. Systemic antifungal agents may be prescribed for complicated candidiasis mucosal infection (*Baer et al, 2017*).

▲ Soak partial or complete dental prosthesis overnight in 0.2% chlorhexidine HCL. **EB:** *A literature review of treatment of dry mouth and other nonocular sicca symptoms in Sjögren's syndrome identified that oral candidiasis mucosal infection is common in clients with salivary gland hypofunction. Administer prescribed antifungal rinses, ointments, or lozenges. Include daily partial or complete denture antifungal treatment; soak dentures overnight in 0.2% chlorhexidine HCL (Baer et al, 2017).*

▲ Recommend professional dental oral examination every 3 to 6 months. Recommend professional teeth cleaning at least every 6 months. **EB:** *ADA Council of Scientific Affairs identifies preventative oral health care for patients with hyposalivation as essential. This includes more frequent dental visits and associated management of secondary infections (ADA, 2015).*

- Discuss selection and use of salivary substitutes with patient and health care provider to assist in maintaining mouth moisture. **EB:** *A Cochrane review of nonpharmacological topical treatments for dry mouth that included salivary substitutes of sugar-free gums, mints, lozenges, sprays, gels, oils, and toothpastes indicated lack of strong evidence that topical therapies are effective in improving salivary flow. Many saliva substitutes are available without prescription and contain a mix of components such as carboxymethylcellulose, polyethylene glycol, sorbitol, and electrolytes. These products typically provide more viscosity and lubrication than water. A saliva spray that contains oxygenated*

glycerol trimester (OGT) is more effective than a water-based electrolyte spray (McMillan, 2016).

• Teach the client that any topical product that is acidic or contains sugar, or noted as sugarless with high fructose, should be avoided. **EB:** *Citrus-flavored sugar-free tablets or oral drops with malic acid may stimulate salivary flow. Additional nonpharmacological management of dry mouth using gel-releasing devices worn in the mouth requires more research. Patient preference also appears to have significant affect in the acceptance and attribution of topical agent efficacy (Furness et al, 2011; Treister, Villa, & Thompson, 2017).* **EB:** *A predesign and postdesign study of 118 elderly patients using an edible oral moisturizing jelly (OMJ) examined the efficacy of OMJ with results of reduced symptoms of dry mouth and prevention of decline of saliva pH, but further study is needed with a larger population and randomized-controlled study design (Dalodom et al, 2016).*

• Encourage the client to try several products, based on client preference, to find a suitable saliva substitute. Clients reported that use of saliva substitutes may be more helpful before sleep because of diurnal variation on reduction in salivary flow at night. It is also suggested that patients mix and match salivary agents based on their daily schedules or activities such as eating or public speaking (Baer et al, 2017). **CEB/EB:** *A literature review through September 2017 of treatment of dry mouth and other nonocular sicca symptoms in Sjögren's syndrome that use saliva substitutes is supported by several randomized trials and studies that show benefit when compared with placebo in relieving symptoms of dry mouth, burning tongue, and difficulties with chewing and swallowing (Wu, 2008; National Institute of Dental and Craniofacial Research, 2016).*

• Lubricate lips every 2 hours, while awake, and as needed. Apply moisturizer (e.g., lanolin) to dry lips every 2 hours, as needed to assist with dryness.

• Teach patients preventative measures to reduce oral dryness:
  - ❍ Maintain adequate oral hydration by sipping water regularly and/or sucking on ice chips (AAOM, 2016)
  - ❍ While eating, drink fluids carefully.
  - ❍ Maintain an oral intake log.
  - ❍ Rinse with normal saline or clean water as a part of daily oral care to prevent dry mouth, or sodium bicarbonate solution (1 teaspoon salt and 1 teaspoon baking soda to 1 L of water). **EB:** *Oral rinses with clean water or normal saline every 2 hours while awake promote a moist oral mucosa, neutralize oral pH, and are readily available with minimal side effects and are inexpensive (AAOM, 2016; ADA, 2017).*

• Encourage the client to use sugar-free gum or sugar-free candy to promote salivary flow. **EB:** *A Cochrane review of nonpharmacological topical treatments for dry mouth included salivary substitutes of sugar-free gum and candy. Although mastication increases saliva production, the evidence is not conclusive that sugar-free chewing gum is better or worse than other saliva substitutes for symptom management of dry mouth, but the use of these interventions also was supported by extensive clinical experience (Furness et al, 2011).*

• Encourage the client to use saline nasal sprays to maintain open nasal passages. *Maintenance of open nasal passage to avoid mouth breathing include saline nasal sprays or gentle nasal lavage to remove dried secretions (AAOM, 2016; Baer, 2017).*

• The client may find the use of a humidifier during sleep at night helpful in reducing symptoms.

▲ Discuss with the client the use of acupuncture, electrical nerve stimulation, and powered versus manual toothbrushes to assist in maintaining mouth moisture. **EB:** *In a systematic review, nonpharmacological therapies using acupuncture, transcutaneous electrical nerve stimulation, and powered versus manual toothbrushing were reported as*

insufficient or low-quality evidence to determine effects of these interventions on dry mouth or saliva production but continued to be studied as alternatives for symptom relief (Simcock et al, 2012; Furness et al, 2013).

▲ Encourage the client to discuss the use of emerging preventative treatments with the health care provider such as gene therapy, tissue engineering, stem cell therapy, and growth factors for etiologies associated with dry mouth. **EB:** *Current research of Sjögren syndrome and head and neck radiation etiologies associated with salivary hypofunction reported that future approaches to treatment and/or prevention of the feeling of dry mouth includes gene therapy, stem cell therapy, and tissue engineering (Quock, 2016).* **EB:** *In a review of 90 articles with clinical application, there are emerging therapies for radiation-induced salivary hypofunction, but the most efficacious with cost-effectiveness are not identified (Han, Suarez-Durall, & Mulligan, 2015).*

▲ Discuss use of Bethanechol HCL saliva stimulant in head and neck cancer patients with radiotherapy-induced dry mouth and hyposalivation with the client and health care provider. **EB:** *Clinical application of Bethanechol HCL to treat dry mouth in clients with radiation therapy-induced dry mouth and salivation is not supported because further research is needed to determine optimal dosing, frequency of use, long-term efficacy, and safety (Han, Suarez-Durall, & Mulligan, 2015; McMillan, 2016).*

Geriatric

• Recognize that symptoms of dry mouth are more common in menopausal women and geriatric patients. *Symptoms of dry mouth are more common in menopausal women and almost 50% of the elderly population because of an age-related increase of systemic disease occurrence and disease treatment, including medications (Turner & Ship, 2007; Thompson, 2015; Dalodom, 2016).*

• Age-associated increase of systemic disease and subsequent disease treatment is the primary cause of dry mouth. **EB:** *Systematic review of the literature from 1980 to 2010 indicates a high prevalence of xerostomia and salivary gland hypofunction in the very elderly population with associated factors of polypharmacy, poor general health, and old age (Liu et al, 2012).*

• Older adults are at risk of xerostomia from a variety of etiologies. **EB:** *In a narrative review of systemic disease in older adults and review of the literature of xerostomia caused by various etiologies, it is recommended to assess the patient for dehydration, nutritional alteration manifested by weight loss, decreased appetite, increased thirst, and any changes in food or beverage preferences. Oral symptoms of malnutrition, such as sore tongue, burning mouth, and gingivitis, may be caused by iron, vitamin B_1, B_2, B_6, and B_{12} or vitamin C deficiencies (Tanasiewicz, Hildebrandt, & Obersztyn, 2016; Critchlow, 2017).*

• Review client medication list routinely. **EB:** *In a cross-sectional study to examine the relationship between nutrition, oral health, and drug use among adults aged 75 and older, it was found that excessive polypharmacy, the use of particular drug groups, and depressive symptoms were associated with xerostomia, supporting the need for a multidisciplinary approach to care (Thompson 2015; Viljakainen et al, 2016).*

Multicultural and Home Care Considerations

• The previously mentioned nursing interventions and client teaching may be adapted for multicultural and home care considerations. See care plan on Impaired **Oral Mucous Membrane** integrity.

Nausea

Janelle M. Tipton MSN, RN, AOCN

NANDA-I

Definition

A subjective, phenomenon of an unpleasant feeling in the back of the throat and stomach, which may or may not result in vomiting.

Defining Characteristics

Aversion toward food; gagging sensation; increase in salivation; increase in swallowing; sour taste

Related Factors

Anxiety; exposure to toxin; fear; noxious environmental stimuli; noxious taste; unpleasant visual stimuli

Associated Condition

Biochemical dysfunction; esophageal disease; gastric distention; gastrointestinal irritation; increase in intracranial pressure (ICP); intra-abdominal tumors; labyrinthitis; liver capsule stretch; localized tumors; Ménière's disease; meningitis; motion sickness; pancreatic disease; pregnancy; psychological disorder; splenetic capsule stretch; treatment regimen

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Comfort Level; Hydration; Nausea and Vomiting Severity; Nutritional Status: Food and Fluid Intake; Nutrient Intake

Example NOC Outcome with Indicators

Nausea and Vomiting Severity as evidenced by the following indicators: Frequency of nausea/Intensity of nausea/Distress of nausea. (Rate the outcome and indicators of **Nausea and Vomiting Severity:** 1 = severe, 2 = substantial, 3 = moderate, 4 = mild, 5 = none [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- State relief of nausea
- Explain methods clients can use to decrease nausea and vomiting (N&V)

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Distraction; Medication Administration; Progressive Muscle Relaxation; Simple Guided Imagery; Therapeutic Touch

Example NIC Activities—Distraction

Encourage the individual to choose the distraction techniques desired, such as music, engaging in conversation or telling a detailed account of event or story, guided imagery, or humor; Advise client to practice the distraction technique before the time needed, if possible

Nursing Interventions and *Rationales*

▲ Determine cause or risk for N&V (e.g., medication effects, infectious causes [viral and bacterial gastroenteritis], disorders of the gut and peritoneum [mechanical obstruction, motility disorders, or other intraabdominal causes], central nervous system causes [including anxiety], endocrine and metabolic causes [including pregnancy], postoperative-related status). *Because N&V are clinically identifiable symptoms, it is important for the cause to be determined and appropriate plan and interventions to be developed. Review the client's medication record, alcohol history, and electrolytes as appropriate for early identification of cause of nausea (Goel & Wilkinson, 2013; Koth & Kolesar, 2017).* **EB:** *Prophylactic interventions given before chemotherapy have proven to be most successful in preventing N&V. Client expectancy of nausea after chemotherapy is predictive of that treatment-related side effect (Kamen et al, 2014; Oncology Nursing Society, 2017).*

▲ Evaluate and document the client's history of N&V, with attention to onset, duration, timing, volume of emesis, frequency of pattern, setting, associated factors, aggravating factors, and past medical and social histories. *The onset and duration of N&V may be distinctly associated with specific events and may be treated differently (Irwin & Johnson, 2014; Tipton, 2014).*

• Document each episode of nausea and/or vomiting separately and the effectiveness of interventions. Consider an assessment tool for consistency of evaluation. **EB:** *A systematic approach can provide consistency, accuracy, and measurement needed to direct care. It is important to recognize that nausea is a subjective experience (Irwin & Johnson, 2014).*

• Identify and eliminate contributing causative factors. This may include eliminating unpleasant odors or medications that may be contributing to nausea. *These interventions are theory based; however, there is no research evidence to support these interventions outside of expert opinion.*

▲ Implement appropriate dietary measures such as nothing by mouth (NPO) status as appropriate; small, frequent meals; and low-fat meals. It may be helpful to avoid foods that are spicy, fatty, or highly salty. Reverting to previous practices when ill in the past and consuming "comfort foods" may also be helpful at this time. *Expert opinion consensus recommends these interventions, with no research data available (Irwin & Johnson, 2014).*

▲ Recognize and implement interventions and monitor complications associated with N&V. This may include administration of intravenous fluids and electrolytes. *Recognition of complications of N&V is critical to prevent and manage complications of dehydration, electrolyte imbalance, and malnourishment. Adequate hydration corrects imbalances and reduces further emesis (Gan et al, 2014).*

▲ Administer appropriate antiemetics, according to emetic cause, by most effective route, considering the side effects of the medication, with attention to and coverage for the time frames in which the nausea is anticipated. **EB:** *Antiemetic medications are*

effective at different receptor sites and treat different causes of N&V. A combination of agents may be more effective than single agents (Jordan et al, 2014; Koth & Kolesar, 2017).

• Consider nonpharmacological interventions such as acupressure, acupuncture, music therapy, distraction, and slow, deliberate movements. **EB:** *Nonpharmacological interventions can augment pharmacological interventions because they predominantly affect the higher cortical centers that trigger N&V. Nonpharmacological interventions are often low cost, relatively easy to use, and have few adverse events. The nonpharmacological interventions most likely to be effective include progressive muscle relaxation, hypnosis for anticipatory chemotherapy-induced N&V (CINV), and managing client expectations. Effectiveness has not been established for several other nonpharmacological interventions, primarily because of study limitations, lack of effect in small studies, and inconsistent results (Irwin & Johnson, 2014; Oncology Nursing Society, 2017).*

• Provide oral care after the client vomits. Oral care helps remove the taste and smell of vomitus, reducing the stimulus for further vomiting.

Nausea in Pregnancy

• Early recognition and conservative measures are recommended to successfully manage nausea in pregnancy, and to prevent progression to hyperemesis gravidarum. Dietary and lifestyle modifications should be implemented before pharmacological interventions. Avoidance of any aversive odors or foods is recommended. Eating multiple small meals per day is also recommended to have some food in the stomach at all times, avoiding hypoglycemia and gastric overdistention. Foods with higher protein (before bedtime) and carbohydrate and lower fat content are helpful (between meals and before getting out of bed early in the morning). Drinking smaller volumes of liquids at multiple times throughout the day is recommended. *These are traditional strategies for alleviating nausea during pregnancy, and there is limited evidence supporting the effectiveness of dietary changes on minimizing N&V with pregnancy symptoms (Clark, Dutta, & Hankins, 2014; Campbell et al, 2016; Argenbright, 2017).*

▲ Because of the high incidence of coexisting gastroesophageal reflux disease (GERD), it is important to assess and manage these symptoms of heartburn, belching, and indigestion. **EB:** *Dietary and lifestyle factors are recommended first, with the use of calcium or aluminum-containing antacids. H_2 receptor blockers or proton pump inhibitors (PPIs) may be needed if antacids have failed (Clark, Dutta, & Hankins, 2014).*

▲ It is well-established that *Helicobacter pylori* infection is associated with hyperemesis gravidarum. *It may also be recommended to test for* H. pylori *if there are persistent symptoms of nausea with pregnancy, prolonged symptoms of GERD, or a previous history of* H. pylori *infection.* H. pylori *is an independent risk factor for vomiting in pregnancy, and in women with daily vomiting, there is an association of adverse birth outcomes such as reduced birth weight (Clark, Dutta, & Hankins, 2014; Grooten et al, 2017).*

▲ Coexisting psychosocial factors may also influence the severity of N&V with pregnancy. Symptoms of anxiety and depression can occur in early pregnancy, especially when N&V is severe and can make the treatment of the N&V more challenging and even ineffective. *Timely diagnosis and treatment is recommended (Clark, Dutta, & Hankins, 2014).*

▲ The American College of Obstetricians and Gynecologists (ACOG) currently recommends converting the prenatal vitamin to folic acid only if nausea persists. Pharmacological options include a combination of oral pyridoxine hydrochloride (vitamin B_6, 10–25 mg) and doxylamine succinate (antihistamine 12.5 mg) to be used

three to four times a day as first-line treatment for N&V of pregnancy after failure of pyridoxine alone. This combination agent of pyridoxine and doxylamine (Diclegis) is the only US Food and Drug Administration pregnancy Category A approved therapy for N&V of pregnancy. There are, however, several pharmacological treatments outlined by the ACOG. *A stepwise, cost-effective strategy may be helpful in approaching N&V. Considerable N&V with associated dehydration may require intravenous antiemetics, hydration, and/or parenteral nutrition (Clark, Dutta, & Hankins, 2014; Campbell et al, 2016; ACOG, 2018).*

▲ Nonpharmacological interventions that are recommended include P6 acupressure with wrist bands and ginger capsules, 250 mg four times a day. **EB:** *These interventions have been shown to be safe and beneficial for the treatment of N&V with pregnancy (Campbell et al, 2016; ACOG, 2018). Mindfulness-based cognitive therapy may also be a helpful adjunct to pyridoxine therapy (Campbell et al, 2016).*

Nausea After Surgery

▲ Evaluate for risk factors for postoperative N&V (PONV). **EB:** *Strong evidence suggests that client-related risk factors such as female gender, age group (<50 years), history of PONV, history of motion sickness, nonsmoking behavior, and environmental risk factors such as postoperative opioid use, emetogenic surgery (type and duration), and volatile anesthetics may increase the risk for PONV. It is important to determine this risk in the preoperative period to better plan strategies to reduce baseline risk (Kovac, 2013; Gan et al, 2014; Smith & Ruth-Sahd, 2016). Childhood risk factors include surgery duration of more than 30 minutes, age older than 3 years, strabismus surgery, and a history of postoperative vomiting or a relative with PONV (Gan, 2014). PONV in children is twice as common as it is in adults, with the occurrence of 13% to 42% in all pediatric cases (Matthews, 2017).*

▲ Reduction of risk factors associated with PONV is beneficial for both adults and children. **EB:** *Avoidance of the use of general anesthesia by the use of regional anesthesia has been associated with a decreased incidence of PONV. The avoidance of both nitrous oxide and volatile anesthetics has also minimized PONV. Decreased and minimal use of intraoperative and postoperative opioids has demonstrated reduction in PONV. Adequate hydration is also an intervention to decrease the risk of PONV (Gan et al, 2014; Skolnik & Gan, 2014; Matthews, 2017).*

▲ Medicate the client prophylactically for nausea as ordered, throughout the period of risk. **EB:** *Antiemetic medications can reduce the incidence of PONV and use of combination treatment such as 5-HT3 antagonist plus dexamethasone is more effective than monotherapy. This recommendation is for clients at moderate or high risk for PONV. Other antiemetics, such as the neurokinin (NK-1) receptor antagonists, may have a role, particularly in preventing vomiting and severity 24 to 48 hours after surgery (Kovac, 2013; Gan et al, 2014). Antihistamines may be helpful in those with previous motion sickness or after ear surgery (Matthews, 2017).*

▲ Alleviate postoperative pain using ordered analgesic agents (refer to care plan for Acute **Pain**). *Pain is known to be a factor in the development of PONV (Bruderer et al, 2017).*

• Consider the use of nonpharmacological techniques, such as P6 acupoint stimulation, as an adjunct for controlling PONV, which has been shown to be effective in reducing PONV by 30%. Acupoint pressure is noninvasive, inexpensive, and has no side effects; thus it is part of a combined approach with antiemetic medication. **EB:** *Acupuncture and acustimulation have been studied with the most consistent results, similarly effective across methods of stimulation (acupuncture or acupressure or wristlike electrical stimulation) (Gan et al, 2014; Matthews, 2017).*

• Include client education on the management of PONV for all outpatients and discuss key assessment criteria (Odom-Forren et al, 2014).

Nausea After Chemotherapy

• Perform risk assessment before chemotherapy administration. Risk factors include female gender, younger age, history of low alcohol consumption, history of morning sickness during pregnancy, anxiety, previous history of chemotherapy, client expectancy of nausea, and emetic potential of the regimen. *It is important to recognize the many risk factors individual clients may have and tailor the antiemetic strategy accordingly. N&V continues to be among the most feared side effects of cancer treatment and can significantly affect quality of life and other complications. Poor control of N&V also has an economic impact, with increased costs related to increased emergency room visits, hospitalizations, and outpatient visits (Koth & Kolesar, 2017).*
▲ Initiate antiemetic strategy prophylactically or when N&V occurs in accordance with evidence-based guidelines. *Preventing N&V is important; one failure in antiemetic therapy can result in anticipatory nausea for the remainder of the client's treatments, and interventions are less likely to be effective (Tageja & Groninger, 2016).*
▲ Drug classes that are recommended for practice include the serotonin receptor antagonists, the NK-1 receptor antagonists, and cannabinoids. *Triple-drug regimens including serotonin receptor antagonists, NK-1 receptor antagonists, and dexamethasone are recommended for adults receiving highly emetogenic chemotherapy (Tageja & Groninger, 2016; Koth & Kolesar, 2017).*
▲ Consider the use of the following integrative therapies that are likely to be effective in reducing N&V: hypnosis with anticipatory N&V, and progressive muscle relaxation and guided imagery with antiemetics. **EB:** *There has been benefit associated with these interventions; however, further data are warranted (Irwin & Johnson, 2014; Oncology Nursing Society, 2017).*
• Consider managing client expectations about CINV. **EBN:** *Education and discussion are interventions that may minimize negative expectations. This intervention is based on the idea that if a patient expects to experience a problem, he or she is more likely to do so. If a patient believes that an intervention will be effective for symptoms, it is more likely to be effective (Irwin & Johnson, 2014; Oncology Nursing Society, 2017).*

Geriatric

• There are no specific guidelines that address the prophylaxis of CINV specifically in older adults. Risk still needs to be assessed, although many older clients are often treated with less emetic chemotherapy. Chemotherapy, however, can cause increased toxicity caused by age-related decreases in organ function, comorbidities, and drug–drug interactions secondary to polypharmacy. Additionally, adherence may be an issue because of cognitive decline, impaired senses, and economic issues. *Increased caution is warranted in this population because of increased safety concerns (Naeim et al, 2014).*

Pediatric

• Interventions for CINV should be implemented before and after chemotherapy. *Despite the extensive use of antiemetics, it is estimated that nausea occurs 40% to 70% in children treated for cancer (Hockenberry & Rodgers, 2015).*
• Relatively few systematic reviews exist examining the antiemetic medications used

for CINV in children. It appears that 5-HT3 antagonists, with palonosetron preferred, combined with dexamethasone and aprepitant (in children 6 months of age or older) are recommended in children receiving highly emetogenic chemotherapy (Dupuis et al, 2017; Patel et al, 2017).

• Integrative therapies for control of nausea in children with cancer have not yet been studied as adequately as they have with adults. Some integrative therapies with potential include cognitive distraction, hypnosis, and acupressure (Momani & Berry, 2017).

Home Care

• Previously mentioned interventions may be adapted for home care use.

▲ In hospice care clients, N&V is common, and can considerably affect quality of life. Assessment is relevant in the management of N&V, and should include history, physical exam, and evaluation of reversible causes. *There can be multiple causes of nausea in clients with advanced cancer, and the causes may be treatment related, or nontreatment related. The causes may be obstructive; examples include increased ICP and bowel obstruction. Metabolic causes may be related to hypercalcemia, hyponatremia, or opioids (Walsh et al, 2017).* **EBN:** *Nausea can effectively be controlled if a cause can be identified. An N&V protocol (e.g., Horvitz Center for Palliative Medicine N&V Protocol) can be used to identify and resolve any reversible causes of nausea, such as metabolic abnormalities or medications (Gupta et al, 2013). If none are found and symptoms persist, a flat-plate radiograph of the abdomen is done to evaluate for obstruction or constipation. Appropriate medications can then be used to treat central nervous system causes and obstructive or nonobstructive causes (Gordon, LeGrand, & Walsh, 2014).*

• Assist the client and family with identifying and avoiding irritants in the home that exacerbate nausea (e.g., strong odors from food, plants, perfume, and room deodorizers). All medications except antiemetics should be given after meals to minimize the risk of nausea. **EB:** *Nausea triggered by odors is related to altered chemoreceptors and pathology (Tipton, 2014).*

Client/Family Teaching and Discharge Planning

• Teach the client techniques to use before and after chemotherapy, including antiemetics/medication management schedules and dietary approaches, such as eating smaller meals, avoiding spicy and fatty foods, and avoiding an empty stomach before chemotherapy (Irwin & Johnson, 2014).

Neonatal Abstinence syndrome

Patricia Hindin PhD, CNM

NANDA-I

Definition

A constellation of withdrawal symptoms observed in newborns as a result of in-utero exposure to addicting substances, or as a consequence of postnatal pharmacological pain management.

Defining Characteristics

Diarrhea (00013); disorganized infant behavior (00116); disturbed sleep pattern (00198); impaired comfort (00214); ineffective feeding pattern (00107); neurobehavioral stress; risk for aspiration (00039); risk for imbalanced body temperature (00005); risk for impaired attachment (00058); risk for impaired skin integrity (00047); risk for injury (00035)

Related Factors

To be developed

At-Risk Population

Iatrogenic substance exposure for pain control following a critical illness or surgery; in utero substance exposure secondary to material substance use

NOC Outcomes (Nursing Outcomes Classification)

Suggested NOC Outcomes

Comfort Status: Physical; Breastfeeding Establishment: Infant; Bottle Feeding Establishment: Infant; Parent-Infant Attachment; Stress Level; Sleep; Thermoregulation: Newborn; Tissue Integrity: Skin and Mucous Membranes; Newborn Adaptation; Risk Control; Bowel Elimination; Risk Control: Aspiration

Example NOC Outcome with Indicators

Parent-Infant Attachment as evidenced by the following indicators: Holds infant close/Uses eye contact/Infant looks at parent/Consoles infant/Responds to infant cues. (Rate the outcome and indicators of **Parent-Infant Attachment:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated range [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Tolerate small frequent formula feedings or frequent breast feedings
- Maintain weight and readjust feedings frequency as necessary for appropriate growth
- Provide calorie-dense formula, which is appropriate for weight gain
- Maintain proper hydration with elastic skin turgor and moist mucus membranes
- Maintain adequate nutrition which will promote adequate growth
- Preserve skin integrity in perianal area

NIC Intervention (Nursing Interventions Classification)

Suggested NIC Interventions

Diarrhea Management; Bottle Feeding; Infant Care: Newborn; Developmental Enhancement: Infant; Feeding

Example NIC Activities—Diarrhea Management

Monitor for signs and symptoms of diarrhea; Observe skin turgor regularly; Monitor skin in perianal area for irritation and ulceration, weigh patient regularly

Nursing Interventions and *Rationales*

- Provide supportive nonpharmacological care with formula feeding as prescribed. **EBN:** *A randomized controlled trial (N = 49) assessed the early initiation of feeding infants with a high-calorie formula compared with feeding with standard-calorie formula. The authors concluded that high-calorie feeding might be advantageous for weight gain (Bogen et al, 2018).*
- Encourage breastfeeding for nutrition and nonpharmacological supportive care. **EB:**

A retrospective cohort study of neonatal abstinence syndrome (NAS) neonates (N = 3725) indicated that there is an association between breastfeeding and a 9.4% decrease in length of stay when compared with nonbreastfed neonates (Short, Gannon, & Abatemarco, 2016). **EB:** *Breastfeeding may decrease the incidence of NAS and the need for pharmacological treatment while reducing the hospital length of stay (Kocherlakota, 2014).*

• Use nursing skills to provide supportive nonpharmacological care. **EBN:** *An ethnographic study described the culture of care provided by 12 full-time registered nurses to infants with NAS in an intensive care unit (ICU). The six themes point to the direction for the culture of care practice: learn the baby, team relationships, role satisfaction, grief, making a difference, and educate and care for the mother (Nelson, 2016).*

• Use vibrotactile stimulation (VS) as a nonpharmacological supportive care option. **EB:** *A prospective study was conducted on 26 opioid-exposed newborns to determine whether exposure to a specially constructed mattress that delivered a dose of stochastic (randomly determined) VS would affect symptoms. The results indicated a 35% reduction in movement with a significant increase in normal breathing and heart rate (Zuzarte et al, 2017).*

• Practice supportive nursing interventions with an understanding of the levels of evidence. **EB:** *Ryan et al (2018) reviewed research papers on NAS from the years 2000 and 2017. The author's goal was to substantiate the efficacy of supportive interventions for the treatment of NAS. The authors determined that level I to III evidence (experimental studies) exists for breastfeeding, swaddling, rooming-in, skin to skin, and environmental control for NAS infants.* **EBN:** *A systematic review performed by MacMullen, Dulski, and Blobaum (2014) evaluated supportive nursing care with NAS infants. The authors found level IV evidence (expert opinion, case reports, and descriptive studies) for interventions such as swaddling, gentle awaking, quiet environment, and nonnutritive sucking.*

• Provide pharmacological treatment as indicated for symptoms. **EB:** *A double-blind, randomized control trial assigned term infants who had been exposed to opioids in utero to either a sublingual buprenorphine treatment group or an oral morphine treatment group. The authors noted that the infants treated with sublingual buprenorphine experienced a shorter duration of treatment (15 days versus 28 days) and a shorter length of hospital stay (21 days versus 33 days) (Kraft et al, 2017).* **EB:** *Streetz, Gildon, and Thompson (2016) engaged in a systematic review of clonidine as treatment for NAS. There is limited evidence that clonidine as a single therapy or in combination with other therapies can be effective with limited adverse reactions and a shorter treatment time.*

• Use of nonpharmacological and complementary therapy to comfort infants and provide relief of symptoms. **EB:** *A prospective, cohort, pilot study was conducted with a sample of infants who were given a one-dose, 30-minute Reiki massage session. The authors found the treatment to be safe for the infants and acceptable to the mothers (Radziewicz et al, 2018).*

• Use of rooming-in and promotion of maternal–infant bonding for mother–infant dyad. **EB:** *A systematic review and meta-analysis were conducted on 549 infants with NAS. MacMillan et al (2018) concluded that rooming-in was associated with a reduction in pharmacological treatment and earlier discharge when compared with infants treated in the ICU.* **EB:** *Schiff et al (2017) performed a retrospective, single cohort study with 86 mother–infant dyads. Infants with NAS were treated with pharmacological modalities and the rooming-in model of care. The presence of the parents was associated with decreased NAS scores and reduction in opioid treatment days.* **EB:** *Boucher (2017) reviewed eight studies on the rooming-in model of care and the use of acupuncture for NAS infants. The author established that the rooming-in model might decrease use of opioids and length of stay, and that acupuncture is safe for infants.*

• Provide compassionate care, free of judgement to substance-abusing mothers. **EBN:**

A qualitative study was conducted with 15 mothers with substance abuse disorders. The judgmental attitudes and behaviors of health care professionals served to retraumatize them during their hospitalization. The importance of nursing care with the empathic approach is essential in the care of these women (Cleveland, Bonugli, & McGlothen, 2016). **EBN:** *The use of a structured communication tool based on the organization of the concepts of knowledge creates circumstances for reflection, teaching, and support (ACTS) script. The ACTS was an implementation to assist neonatal ICU (NICU) nurses in developing positive strategies to change negative attitudes among their peer toward substance-abusing mothers (Marcellus & Poag, 2016).*

Pediatric

- When available consider professional, supportive programs for infants with a history of NAS. **EB:** *Beckwith and Burke (2015) followed the development of 28 infants exposed to prenatal drugs over a 3-year period and determined the exposed infants have a limitation in language and cognition.*

Multicultural

- Specific rural areas are high risk for NAS. **EB:** *Brown, Goodin, and Talbert (2018) reviewed data in Kentucky and determined that rural Appalachian counties in Kentucky experienced NAS rate per 1000 births that are 2 to 2.5 times greater than urban and non-Appalachian counties in the state.* **EB:** *The authors evaluated NAS admissions from the Uniform Billing data form the West Virginia Health Care Authority. They found the NAS rate in rural West Virginia increased from 7.74 to 31.5 per live births per year, indicating an increased need for services for this growing health problem (Stabler et al, 2017).*

Home Care

- Consider alternative models of care for treatment for infants with NAS. **EB:** *Smirk et al (2014) reviewed the treatment of 118 infants with NAS. Thirty-eight infants were managed at home and compared with the rest of the infant population treated in the hospital. The authors found home-based detoxification care reduced length of hospital stay and increased breastfeeding.* **EB:** *Seventy-five patients were weaned from methadone in the hospital, and 46 were treated as outpatients. The combined in-hospital and outpatient management of methadone treatment decreased length of hospital stay and reduced cost. There was more breastfeeding (24 versus 8% $P < .05$) in the combined group (Backes et al, 2012).* **EP:** *Belcher et al (2005) reported on three community programs implemented in Baltimore to provide services to substance-abusing mothers and their infants. The Early Transition Center provided 24-hour on-call services for newly discharged mother and infant dyads. The Home-U-Go-Safely program used community nurses to provide supportive care, health monitoring of the infant, and education to mothers.*

Readiness for enhanced Nutrition

Marina Martinez-Kratz MS, RN, CNE

NANDA-I

Definition

A pattern of nutrient intake, which can be strengthened.

Defining Characteristics

Expresses desire to enhance nutrition

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Nutritional Status; Nutritional Status: Food and Fluid Intake; Nutrient Intake; Weight Control

Example NOC Outcome with Indicators

Nutritional Status as evidenced by the following indicators: Food and fluid intake/Hydration/Body mass index/Weight-height ratio/Hematocrit. (Rate the outcome and indicators of **Nutritional Status:** 1 = severe deviation from normal range, 2 = substantial deviation from normal range, 3 = moderate deviation from normal range, 4 = mild deviation from normal range, 5 = no deviation from normal range [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Explain how to eat according to the US Dietary Guidelines
- Design dietary modifications to meet individual long-term goal of health, using principles of variety, balance, and moderation
- Maintain weight within normal range for height and age

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Nutrition Management; Nutritional Counseling; Weight Reduction Assistance

Example NIC Activities—Nutrition Management

Determine the client's motivation for changing eating habits; Develop with the client a method to keep a daily record of intake

Nursing Interventions and *Rationales*

- Assess the meaning and importance of food in the client's life. **EB:** *Recent research found strong associations between the different domains of food meanings and behavioral outcomes (Arbit et al, 2017).*
- Assess client readiness to determine whether he or she is ready to discuss enhanced nutrition and/or would like nutrition information. **EB:** *Client motivation is a key component of success in a weight loss program and a prerequisite for weight loss therapy (Raynor & Champagne, 2016).*
- Use a motivational interviewing technique when working with clients to promote healthy eating and improved nutrition. **EB:** *Research shows significant weight loss for clients when motivational interviewing techniques were used (Barnes et al, 2018).*
- Counsel the client to measure regularly consumed foods periodically. Help the client learn usual portion sizes. Measuring food alerts the client to normal portion sizes. Estimating amounts can be extremely inaccurate. **EB:** *A randomized controlled trial of 278 overweight and obese participants was conducted to increase portion size awareness with results that demonstrated that the intervention improved portion control behavior and in turn influenced body mass index (BMI) (Poelman et al, 2015).*
- Assist the client to develop a system of self-management, which may include self-monitoring of weight and BMI; realistic goal setting, planning, and action planning for improved dietary intake and physical activity; problem-solving; and tracking dietary intake and exercise. **EB:** *A key component of successful weight loss and maintenance is regular self-monitoring (Thomason et al, 2016).*
- Document the client's height and weight and teach the significance of his or her BMI in relation to current nutritional health. Use a chart or a website such as http://www.cdc.gov/healthyweight/assessing/bmi/index.html (Centers for Disease Control and Prevention [CDC], 2015). **EB:** *Successful enhancement of nutrition in adults*

requires adoption and maintenance of effective self-monitoring (Raynor & Champagne, 2016).

- Encourage the client to engage in vigorous-intensity physical activity for at least 150 minutes weekly or moderate-intensity physical activity for at least 300 minutes weekly. **EB:** *Research evidence suggests that regular physical activity is critical for weight maintenance (Ostendorf et al, 2018).*
- Recommend that the client avoids eating in fast-food restaurants. **CEB:** *A 15-year study demonstrated that people who frequently eat fast foods gain an average of 10 pounds more than those who eat fast food less often, and were two times more likely to develop insulin resistance, which can lead to diabetes (Pereira et al, 2005).*
- Assist the client to reframe slips in nutrition or physical activity behavior as lapses that are a single event and not a full return to previous unhealthy behaviors. Relapse prevention strategies include managing lapses in healthy behavior, identifying high-risk situations for relapses, self-monitoring, providing social support, enhancing skills for coping, and increasing self-efficacy for avoiding relapse. **EB:** *A study of a weight maintenance intervention, delivered primarily by telephone, modestly slowed the rate of weight regain (Voils et al, 2017).*
- Assist clients to engage their social support systems either digitally or face to face in ways that facilitate healthy eating and physical activity behavior change. **EB:** *Significant others, family, friends, and coworkers can facilitate or hinder weight loss success (Romo, 2018).*
- Assist the client to implement informal and formal mindfulness-based interventions (MBIs). Informal MBIs include mindful eating, increasing awareness of hunger and satiety cues, taste satisfaction, and decreasing impulsive tendencies to overeat when experiencing negative emotions. Meditation practice is a formal MBI. **EB:** *Results of a research review suggest that a combination of formal and informal MBIs are effective in reducing weight and improving obesity-related eating behaviors among individuals with overweight and obesity (Carrière et al, 2018).*
- Assist the client to develop stimulus control techniques designed to reduce environmental cues associated with eating behaviors. Specifically clients should be taught to limit the presence of high-calorie/high-fat foods in the home; to reduce the visibility of unhealthy food choices in the home; to limit where and when they eat; to avoid distractions like reading, using the computer, or watching television when eating; and to eat more slowly. **EB:** *Stimulus control strategies are the keys to healthy eating (Butryn et al, 2017).*
- Encourage 7.5 to 8.5 hours of sleep nightly. **EB:** *Recent evidence suggests weight management is hindered when attempted in the context of sleep restriction because there is an upregulation of reward, pleasure, and salience networks in response to food stimuli (St-Onge, 2017).*
- Recommend that clients use dietary supplements such as vitamins and minerals after consulting with their primary health care provider. **EB:** *Research shows micronutrient deficits are prevalent in weight-loss plans, especially vitamin B_{12}, calcium, and vitamin D (Engel et al, 2018).*
- Incorporate the following recommendations from the Academy of Nutrition and Dietetics: Interventions for the Treatment of Overweight and Obesity in Adults (Raynor & Champagne, 2016):
    - ❍ Assess food and nutrition-related history; anthropometric measures; biochemical data, medical tests, and procedures; nutrition-focused physical findings; and client history.
    - ❍ Assess the energy intake and nutrient content of the diet.

- ❍ Use height and weight to calculate BMI, and waist circumference to determine risk of cardiovascular disease (CVD), type 2 diabetes, and all-cause mortality.
- ❍ Use a measured resting metabolic rate (RMR) to determine energy needs.
- ❍ Set a realistic weight-loss goal, such as one of the following: up to 2 pounds/week, up to 10% of baseline body weight, or a total of 3% to 5% of baseline weight if cardiovascular risk factors (hypertension, hyperlipidemia, and hyperglycemia) are present.
- ❍ To achieve weight loss, use an individualized diet, including patient preferences and health status, to achieve and maintain nutrient adequacy and reduce caloric intake, based on one of the following caloric reduction strategies: 1200 to 1500 kcal/day for women and 1500 to 1800 kcal/day for men, with an energy deficit of approximately 500 kcal/day or 750 kcal/day.

Pediatric

• Offer obese or overweight adolescents healthy methods for weight loss. **EB:** *A recent study showed statistically significant health behavior improvements after implementing a developmentally informed intervention to increase positive health diet and exercise behaviors (Issner et al, 2017).*

• Offer families of obese or overweight children prejudice-free, individually accepting, and supportive interventions to address weight loss. **EBN:** *Obese children treated with motivational interviewing showed significant improvement in their weight-related behavior and obesity-related anthropometric measures (Wong & Cheng, 2013).*

• Recommend that families eat together for at least one meal per day. **EB:** *Findings from a review provide clear evidence that family meals (among youth) and shared meals (among adults) are associated with better dietary intake and that these findings transcend the life span (Fulkerson et al, 2014).*

• Recommend involving the family in planning meals and food preparation. Children can learn about nutrition as they help plan and make meals. **EB:** *The Healthy Home Offerings via the Mealtime Environment Plus program showed increased cooking skills among the children participating (Fulkerson et al, 2018).*

• Assist parents at being good role models of healthy eating. **EB:** *The Healthy Home Offerings via the Mealtime Environment Plus program showed significantly improved parental self-efficacy for identifying appropriate portion sizes (Fulkerson et al, 2018).*

• Recommend that the family try new foods, either a new food or recipe every week. **EB:** *The Healthy Home Offerings via the Mealtime Environment Plus program showed decreasing child neophobia scores over time that were developmentally appropriate (Fulkerson et al, 2018).*

Geriatric

• Determine the risks and benefits of weight loss in the older client. A BMI greater than 30 in the older client suggests a moderate weight loss approach. **EB:** *Recommendations for treating obesity in the elderly include ensuring a balanced and appropriately distributed intake of high-quality nutrients, particularly of high-quality protein (i.e., 1.2 to 1.5 g/kg of body weight), limiting the intake of simple carbohydrates and saturated fats, and providing sufficient intake of calcium and vitamin D_3 (Blaz, 2016).*

• Observe for social, psychological, and economic factors that influence diet quality. **EB:** *An exploratory study of diet quality influences in community-dwelling older individuals*

revealed the following influences: food experiences, retirement, bereavement, medical conditions, food environment, food-related habits, social engagement, personal/psychological factors, and transportation (Bloom et al, 2017).

Multicultural

- Tailor nutritional interventions to be consistent with cultural beliefs, norms, and values. **EB:** *A systemic review of culturally tailored interventions for Hispanic women included literacy modification, Hispanic foods/recipes, cultural diabetes beliefs, family/friend participation, structured community input, and innovative experiential learning (McCurley et al, 2016).*
- Offer tailored lifestyle counseling via the telephone. **EBN:** *Investigators have included biweekly and/or monthly health coach calls for African American participants with significant weight gain prevention (Goode et al, 2017).*
- Integrate weight loss and weight maintenance interventions with church faith-based concepts for cultural congruence with African American clients. **EB:** *Recent research suggested that integrating faith themes into a weight loss maintenance program may increase its long-term effect on participants' health behavior change (Seale et al, 2013).*

Client/Family Teaching and Discharge Planning

- The majority of the preceding interventions involve teaching.
- Work with the family members regarding information on how to support and promote enhanced nutritional choices and healthy intakes.

Imbalanced Nutrition: less than body requirements

Jacqueline A. Hogan RD, CSO, LD

NANDA-I

Definition

Intake of nutrients insufficient to meet metabolic needs.

Defining Characteristics

Abdominal cramping; abdominal pain; alteration in taste sensation; body weight 20% or more below ideal weight range; capillary fragility; diarrhea; excessive hair loss; food aversion; food intake less than recommended daily allowance (RDA); hyperactive bowel sounds; insufficient information; insufficient interest in food; insufficient muscle tone; misinformation; misperception; pale mucous membranes; perceived inability to ingest food; satiety immediately on ingesting food; sore buccal cavity; weakness of muscles required for mastication; weakness of muscles required for swallowing; weight loss with adequate food intake

Related Factors

Insufficient dietary intake

At-Risk Population

Biological factors; economically disadvantaged

Associated Condition

Inability to absorb nutrients; inability to digest food; inability to ingest food; psychological disorder

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Nutritional Status; Food and Fluid Intake; Nutrient Intake; Weight Control

Example NOC Outcome with Indicators

Nutritional Status as evidenced by the following indicators: Food and fluid intake/Body mass index/Weight-height ratio/Hematocrit. (Rate the outcome and indicators of **Nutritional Status:** 1 = severe deviation from normal range, 2 = substantial deviation from normal range, 3 = moderate deviation from normal range, 4 = mild deviation from normal range, 5 = no deviation from normal range [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Progressively gain weight toward desired goal
- Weigh within normal range for height and age
- Recognize factors contributing to being underweight
- Identify nutritional requirements
- Consume adequate nourishment
- Be free of signs of malnutrition

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Feeding; Nutrition Management; Nutrition Therapy; Weight Gain Assistance

Example NIC Activities—Nutrition Management

Ascertain the client's food preferences; Provide the client with high-protein, high-calorie, nutritious finger foods and drinks that can be readily consumed, as appropriate

Nursing Interventions and *Rationales*

- Conduct a nutrition screen on all clients within 24 hours of admission and refer to a dietitian as deemed necessary. **EB:** *A study showed that malnutrition at admission and poor food intake early during hospitalization were associated with prolonged length of stay (LOS), suggesting that prompt nutrition intervention and monitoring should be performed when patients are admitted to the hospital (Allard et al, 2016).*
- The screening tool should be based on the client population and the validity and reliability of the screening tool. The Malnutrition Universal Screening Tool (MUST), for example, is considered a quick easy-to-use tool to assess body mass index (BMI), unintentional weight loss, acuity of illness, and nutritional intake. **EB:** *A study demonstrated the validity of MUST compared with a reference nutrition assessment using a patient-generated subjective global assessment-(PG-SGA) in elderly acutely unwell patients. The MUST tool was shown to be reasonably effective in identifying patients at risk of malnutrition when compared with PG-SGA with a sensitivity of 69.7% (Sharma et al, 2017).*
- Recognize the importance of rescreening and monitoring oral intake in hospitalized individuals to help facilitate the early identification and prevention of nutritional decline.
- Recognize the characteristics that classify individuals as malnourished and refer to a dietitian for a complex nutritional assessment and intervention. **CEB:** *According to the Academy of Nutrition and Dietetics and the American Society of Parenteral and Enteral Nutrition, two or more of the following characteristics are recommended to support the diagnosis of malnutrition: insufficient energy intake, weight loss, loss of muscle mass, loss of subcutaneous fat, localized or generalized fluid accumulation, and/or decreased functional status (White, Guenter, & Gordon, 2012).*

• Recognize clients who are likely to experience malnutrition in the context of social or environmental circumstances, characterized by pure chronic starvation and anorexia nervosa without the presence of an inflammatory process (White, Guenter, & Gordon, 2012).
    - ❍ Chronic disease-related malnutrition: those with organ failure, pancreatic cancer, rheumatoid arthritis, sarcopenic obesity
    - ❍ Acute disease or injury-related malnutrition: those with major infection, burns, trauma, closed-head injuries accompanied by a marked inflammatory response (White, Guenter, & Gordon, 2012)

▲ Note laboratory values cautiously; decrease in albumin and prealbumin may be indicators of the inflammatory response that often accompanies acute malnutrition, but it should not be used to diagnose malnutrition. Other potential indicators of inflammatory response include C-reactive protein, white blood cell count, and blood glucose values.

• Weigh the client daily in acute care and weekly to monthly in extended care at the same time (usually before breakfast) with same amount of clothing.

• Observe for potential barriers to eating such as willingness, ability, and appetite. **EB:** *Depression, impaired function, and poor oral intake are associated with increased likelihood of weight loss, low BMI, and poor nutrition in nursing home residents (Tamura et al, 2013).*

Note: If the client is unable to feed self, refer to Nursing Interventions for Feeding **Self-Care** deficit. If the client has difficulty swallowing, refer to Nursing Interventions for Impaired **Swallowing.** If the client is receiving tube feedings, refer to the Nursing Interventions for Risk for **Aspiration.**

• Advocate for the implementation of a feeding protocol, if not already in place, to avoid unnecessary and/or prolonged nothing by mouth (mouth)/clear liquid diet (NPO/CLD) status in hospitalized clients. **EB:** *A study found that on average, patients with unjustified NPO or CLD orders spent 3 days on an NPO or CLD diet, which corresponded to a mean of 10 missed meals (Gallinger et al, 2017).*

• For the client with anorexia nervosa, consider offering high-calorie foods and snacks often. **EB:** *A study found that higher calorie diets led to faster weight gain in hospitalized adolescents with anorexia nervosa compared with lower calorie diets (Garber et al, 2013).*

• For the client who is able to eat but has a decreased appetite, try the following activities:
    - ❍ Offer oral nutritional supplements (ONS) early after admission and continue to encourage intake of ONS throughout the hospital stay. **EB:** *A study found that use of ONS in the inpatient population decreased LOS, episode cost, and 30-day readmission risk (Philipson et al, 2013). A meta-analysis found that use of ONS significantly reduced hospital readmissions, particularly in older adults (Stratton, Hebuterne, & Elia, 2013).*
    - ❍ Avoid interruptions during mealtimes and offer companionship; meals should be eaten in a calm and peaceful environment. **EB:** *A study found that the implementation of protected mealtimes and use of additional assistant-in-nursing assistance alone and in combination improved nutritional intake of hospitalized clients (Young et al, 2013).*
    - ❍ Allow for access to meals or snacks during "off times" if the client is not available at time of meal delivery, monitor food and ONS intake, and communicate with dietitian/health care provider. **EB:** *The Alliance Nutrition*

Care Recommendations include a multidisciplinary approach to address adult hospital malnutrition, which included the rapid implementation of nutrition intervention and continued monitoring (Tappenden et al, 2013).

❍ If the client lacks endurance, schedule rest periods before meals, and open packages and cut up food for the client. *Nursing assistance will conserve the client's energy for eating.*

• Vitamin D deficiency has been shown to be associated with greater risk of falls and fractures in older people. For the client with fracture caused by a fall, consider the need for vitamin D supplementation. **EB:** *A study found that vitamin D without exercise was associated with less injurious falls (Uusi-Rasi et al, 2017).*

• For the client who has had a stroke, repeat nutritional screenings weekly and provide timely interventions for those at risk or who may already be malnourished. **EB:** *According to a recent study, the prevalence of malnutrition and risk of malnutrition in clients with acute stroke increases significantly during the first 10 days of admission (Mosselman et al, 2013). A separate study found that stroke patients identified as having a risk of malnutrition using the nutrition screening tool MUST had a highly significant increase in mortality (Gomes et al, 2016).*

• Recognize the importance of offering high-protein foods and beverages to most hospitalized individuals (use caution with those with compromised renal/liver function). **EB:** *A study found that maintaining adequate dietary protein aids in muscle mass preservation during periods of muscle disuse. Such strategies are of particular relevance to the older patient who is at risk of developing sarcopenia (Wall & van Loon, 2013).*

• Monitor state of oral cavity (gums, tongue, mucosa, and teeth). Provide good oral hygiene before each meal. *Good oral hygiene enhances appetite; the condition of the oral mucosa is critical to the ability to eat. The oral mucosa must be moist, with adequate saliva production to facilitate and aid in the digestion of food.*

▲ Administer antiemetics and pain medications as ordered and needed before meals. *The presence of nausea or pain decreases the appetite.*

• If client is nauseated, remove cover of food tray before bringing it into the client's room. The sudden, concentrated food odors that come when the cover is removed in front of the client can trigger nausea.

• Work with the client to develop a plan for increased activity. Immobility leads to negative nitrogen balance, which fosters anorexia.

Critical Care

• Recognize the need to begin enteral feeding within 24 to 48 hours of admission to the critical care environment, once the client is free of hemodynamic compromise, if the client is unable to eat. **CEB:** *The guidelines for the provision and assessment of nutrition support therapy in the adult critically ill client call for early enteral feeding (McClave et al, 2009).* **EB:** *Per a meta-analysis of randomized controlled trials, provision of early enteral nutrition was associated with a significant reduction in mortality and infectious morbidity, compared with withholding early enteral nutrition (delayed enteral nutrition or standard therapy) (McClave et al, 2016).*

• Recognize that it is important to administer feedings to the client and that frequently checking for gastric residual and fasting clients for procedures can be a limiting factor to adequate nutrition in the tube-fed client. **EBN:** *A study found that implementing a protocol for managing gastric residual volumes, not fasting clients for procedures, and reducing fasting times when weaning clients for extubation reduced the number of interruptions to enteral feeding (Williams et al, 2013). Refer to care plan* for *Risk*

*for **Aspiration.***

Pediatric

▲ Use a nutritional screening tool designed for nurses such as the Subjective Global Nutrition Assessment (SGNA), and if the child's malnutrition is identified as moderate or severe, refer to a dietitian. **EB:** *A study found that SGNA can be a reliable tool for assessing the nutritional status in children (Minocho et al, 2018).*
• Watch for symptoms of malnutrition in the child including short stature; thin arms and legs; poor condition of skin and hair; visible vertebrae and rib cage; wasted buttocks; wasted facial appearance; lethargy; and in extreme cases, edema.
• Weigh and measure the length (height) of the child and use a growth chart to help determine growth pattern, which reflects nutrition. *Age-related growth charts are available from* www.cdc.gov/growthcharts/.
▲ Refer to a health care provider and a dietitian a child who is underweight for any reason. *Good nutrition is extremely important for children to ensure sufficient growth and development of all body systems.*
• Work with the child and parent to develop an appropriate weight gain plan. *The goal for a child is sometimes to maintain existing weight as the body grows taller.*
• Recognize that a large percentage of girls and teenagers are dieting, which can result in nutritional problems.

Geriatric

• Screen for malnutrition in older clients. **EB:** *A study found that the following screening tools were accurate in identifying malnutrition and can be recommended for use in the older adults who are hospitalized: the Malnutrition Screening Tool (MST), the Mini Nutritional Assessment–Short Form (MNA-SF), MUST, the Short Nutritional Assessment Questionnaire (SNAQ), and the Simplified Nutritional Appetite Questionnaire (Young et al, 2013).*
• Screen for dysphagia in all older clients. **EB:** *A study found that prevalence of dysphagia was higher than malnutrition in older patients. Dysphagia was also an independent risk factor for malnutrition and both conditions were related to poor outcomes (Carron et al, 2015). See care plan for Impaired **Swallowing**.*
• Recognize that geriatric clients with moderate or severe cognition impairment have a significant risk for developing malnutrition. **EBN:** *Dementia is one of the factors most consistently associated with poor nutrition (Tamura et al, 2013).*
▲ Interpret laboratory findings cautiously. Watch the color of urine for an indication of fluid balance; darker urine demonstrates dehydration. Low axillary moisture could indicate mild to moderate dehydration. **CEB/EB:** *Because urine color is correlated with urine specific gravity and urine osmolality, observing urine color is a low-cost method of monitoring dehydration (Wakefield et al, 2002). Compromised kidney function makes reliance on blood and urine samples for nutrient analyses less reliable in older adults than in younger persons. Findings of a small pilot study suggest that measuring the axillary moisture of older adults has the potential as a simple tool for detecting dehydration at home and in nursing homes (Kinoshita et al, 2013).*
• Consider using dining assistants and trained nonnursing staff, to provide feeding assistance care in extended care facilities to ensure adequate time for feeding clients as needed. **EB:** *A study found that when trained volunteers were able to deliver mealtime assistance on a large scale nursing staff could complete clinical tasks (Roberts et al, 2017).*

• Consider offering healthy snacks such as yogurt, which is a good source of protein, calcium, zinc, B vitamins, and probiotics. **EB:** *Observational studies suggest that yogurt could play an important role in improving the nutritional health of older adults when combined with a healthy diet (El-Abbadi et al, 2014).*
• Encourage high-protein foods for the older client, unless medically contraindicated by organ failure. **EB:** *A study found protective effects against weight loss in healthy older adults who had protein intakes greater than 1 g/kg per day (Gray-Donald et al, 2014). Anorexia of aging has been found to have an independent association with sarcopenia (Landi et al, 2013). A study showed that an intervention of a vitamin D- and leucine-enriched whey protein ONS resulted in improvements in muscle mass and lower extremity function among sarcopenic older adults. This study shows proof of principle that specific nutritional supplementation alone might benefit geriatric patients, which is especially relevant for those who are unable to exercise (Bauer et al, 2015).*
• Encourage physical activity throughout the day as tolerated. **EB:** *A systemic review found that nutritional supplementation is effective in the treatment of sarcopenia in old age, and its positive effects increase when associated with physical exercise (Malafarina et al, 2013).*
• Recognize the implications of malnutrition on client strength and mobility. **EB:** *Malnutrition is associated with an increased risk of falling and impaired activity in older long-term care residents; malnourished residents were able to decrease their risk for fall after receiving nutritional intervention (Neyens et al, 2013).*
• Monitor for onset of depression. **EB:** *A systematic review of the literature found that depression, impaired function, and poor oral intake were factors consistently associated with increased likelihood of weight loss, low BMI, and poor nutrition (Tamura et al, 2013).*
• Consider offering nutritional supplement drinks served in a glass rather than with a straw inserted directly into the container. **EBN:** *A study found that among people with dementia who are able to feed themselves, they drank statistically significantly more when a nutritional supplement was served in a glass than when consumed directly from the container (Allen et al, 2014).*
• Advise families that enteral nutrition may not be indicated for clients with dementia. **EB:** *A study found that insertions of a percutaneous endoscopic gastrostomy (PEG) tube for enteral nutrition did not improve short-term or long-term mortality (Ayman et al, 2016).* For strategies for feeding clients with dementia, please refer to the ESPEN Guidelines on nutrition in dementia (Volkert et al, 2015). Note: If the client is unable to feed self, refer to Nursing Interventions and *Rationales* for Feeding **Self-Care** deficit. If client has impaired physical function, malnutrition, depression, or cognitive impairment, refer to care plan for **Frail Elderly** syndrome.
• Emphasize the importance of good oral care in the older client. **EB:** *Poor oral health was found to be strongly associated with malnutrition in older hospitalized clients (Poisson et al, 2016).*
• Consult the dietitian if the client has pressure ulcers. **EBN:** *A study found that an interdisciplinary approach including nutrition intervention improved pressure ulcer wound healing and decreased both hospital LOS for treatment of pressure ulcer and total hospital LOS in geriatric clients who were admitted with or developed a pressure ulcer from stage 2 to 3 during hospitalization (Allen, 2013).*

Home Care

• The preceding interventions may be adapted for home care use.
• Screen for malnutrition using the MUST, which is easy and simple. Recognize that the client may also use MUST as a self-screening tool in the home setting. **EB:** *A study*

demonstrated a high percentage of patients with unrecognized malnutrition risk using the MUST screening tool. The patient-directed nutrition screening using the MUST screening tool is a reliable approach. Almost all patients reported self-screening as either very easy or easy to use, and all patients were able to self-screen (Sandhu et al, 2016).

• Monitor food intake. Instruct the client in the intake of small frequent meals of foods with increased calories and protein.

• Assess the client's willingness and ability to eat. **EB:** *Poor intake among older adults has been found to be associated with lack of self-feeding ability, poor dining environment, inadequate time to eat, poor sensory properties of the food, and lack of choice and variety of the food (Keller, 2015).*

• Consider social factors that may interfere with nutrition (e.g., lack of transportation, inadequate income, lack of social support).

• Continue to encourage intake of oral nutritional support to help optimize oral intake. **EB:** *A meta-analysis of randomized controlled trials suggested that oral nutritional support may be considered for older malnourished medical and surgical clients after discharge from the hospital (Beck et al, 2013).*

▲ Recognize that the client on home parenteral nutrition requires regularly scheduled lab work for electrolyte monitoring, increased risk of catheter-related complication, parenteral nutrition-associated liver disease (PNALD), and metabolic bone disease. *Clients should also be educated regarding home parenteral nutrition before discharge from the hospital (Winkler & Smith, 2014).*

Client/Family Teaching and Discharge Planning

• Help the client/family identify the area to change that will make the greatest contribution to improved nutrition.

• Build on the strengths in the client/family's food habits. Adapt changes to their current practices.

• Select appropriate teaching aids for the client/family's background.

• Implement instructional follow-up to answer the client/family's questions.

• Recommend that clients discuss with their primary health care provider before taking any supplements such as vitamins and minerals.

• Suggest community resources, such as Meals on Wheels and community centers as suitable food sources.

• Teach the client and family how to manage tube feedings or parenteral therapy at home as needed.

Impaired Oral Mucous Membrane integrity

Morgan Nestingen MS, AGCNS, ONS

NANDA-I

Definition

Injury to the lips, soft tissue, buccal cavity, and/or oropharynx.

Defining Characteristics

Bad taste in mouth; bleeding; cheilitis; coated tongue; decrease in taste sensation; desquamation; difficulty eating; difficulty speaking; enlarged tonsils; exposure to pathogen; geographic tongue; gingival hyperplasia; gingival pallor; gingival pocketing deeper than 4 mm; gingival recession; halitosis; hyperemia; impaired ability to swallow; macroplasia; mucosal denudation; oral discomfort; oral edema; oral fissure; oral lesion; oral mucosal pallor; oral nodule; oral pain; oral papule; oral ulcer; oral vesicles; presence of mass; purulent oral-nasal drainage; purulent oral–nasal exudates; smooth atrophic tongue; spongy patches in mouth; stomatitis; white patches in mouth; white plaque in mouth; white, curdlike oral exudate; xerostomia

Related Factors

Alcohol consumption; barrier to dental care; barrier to oral self-care; chemical injury agent; decrease in salivation; dehydration; depression; inadequate nutrition; inadequate oral hygiene; insufficient knowledge of oral hygiene; malnutrition; mouth breathing; smoking; stressors

At-Risk Population

Economically disadvantaged

Associated Condition

Allergy; alteration in cognitive functioning; autoimmune disease; autosomal disorder; behavioral disorder; chemotherapy; cleft lip; cleft palate; decrease in hormone level in women; decrease in platelets; immunodeficiency; immunosuppression; infection; loss of oral support structure; mechanical factor; nil per os (NPO) >24 hours; oral trauma; radiation therapy; Sjogren's syndrome; surgical procedure; trauma; treatment regimen

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Oral Health; Oral Hygiene; Tissue Integrity: Skin and Mucous Membranes

Example NOC Outcome with Indicators

Oral Health as evidenced by the following indicators: Cleanliness of mouth and teeth/Moisture of oral mucosa and tongue/Color of mucous membranes/Oral mucosa/tongue/gum integrity. (Rate the outcome and indicators of **Oral Health:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Maintain intact, moist oral mucous membranes that are free of ulceration, inflammation, infection, and debris
- Demonstrate measures to maintain or regain intact oral mucous membranes
- Demonstrate oral hygiene knowledge and skills

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Oral Health Restoration

Example NIC Activities—Oral Health Restoration

Monitor condition of client's mouth including character of abnormalities; Instruct client to avoid commercial mouthwashes

Nursing Interventions and *Rationales*

- Inspect the oral cavity/teeth/gingiva at least once daily and note any discoloration; presence of debris; amount of plaque buildup; presence of lesions such as white lesions or patches, edema, or bleeding; and intactness of teeth. Refer to a dentist or periodontist as appropriate. *Inspection is a critical diagnostic tool; observations can identify impending problems. Leukoplakia is the presence of uncharacterized white lesions, which can be a precursor to squamous cell carcinoma. If leukoplakia is observed, prompt referral for diagnosis and potential biopsy is indicated (van Der Waal, 2015; American Dental Association [ADA], 2017b).*
- If the client is free of bleeding disorders and able to swallow, encourage toothbrushing with a soft toothbrush using fluoride-containing toothpaste at least two times per day. **EB:** *The toothbrush is the most effective method for reducing plaque and controlling periodontal disease (Barnes, 2014; ADA, 2017a).*
- Recommend the use of a power, rotation-oscillation toothbrush for removal of dental plaque and prevention of gingivitis. **EB:** *Two systematic reviews found the powered/oscillating toothbrush to be safe for use on both hard and soft dental tissues and more effective in cleaning teeth (Grender et al, 2013; Slade, 2013; Yaacob et al, 2014).*
- Use foam sticks to moisten the oral mucous membranes, clean out debris, and swab out the mouth of the edentulous client. **Do not use foam sticks to clean the teeth** unless the platelet count is very low and the client is prone to bleeding gums. Foam sticks are useful for cleansing the oral cavity of a client who is edentulous. **EB:** *Foam sticks are not effective for removing plaque. The toothbrush is much more effective at mechanically removing plaque (Chen, 2014a).*
- If the client does not have a bleeding disorder, encourage the client to floss once per day or use an interdental cleaner. **EB:** *Floss is useful to remove plaque buildup between the teeth and prevent gingivitis (ADA, 2017a). Removal of existing plaque buildup is critical to resolving gingivitis (Fiorellini & Stathopoulou, 2015).*
- Use an antimicrobial mouthwash as ordered or tap water or saline only for a mouth rinse. Do not use commercial mouthwashes containing alcohol or hydrogen peroxide. Also, do not use lemon-glycerin swabs. *Some antimicrobial mouthwashes have demonstrated effective action in decreasing bacterial counts in plaque and decreasing gingivitis (ADA, 2017a).* **CEB/EB:** *Hydrogen peroxide can cause mucosal damage and is*

extremely foul-tasting to clients (Tombes & Gallucci, 1993; Zanelli, Ragazzi, & De Marco, 2017). Use of lemon-glycerin swabs can result in decreased salivary amylase and oral moisture, as well as erosion of tooth enamel; instead ice-cold water sprays/swabs and menthol moisturizers may be effective at decreasing thirst without damaging tissue (Puntillo et al, 2014). Chlorhexidine mouthwash and sodium bicarbonate appropriately diluted may be used during oral care (Chen, 2014b).

• Provide oral hygiene if the client is unable to care for himself or herself. The nursing diagnosis Bathing **Self-Care** deficit is then applicable.

• If the client is unable to brush own teeth, follow this procedure:

- ❍ Position the client sitting upright or on side.
- ❍ Use a soft bristle toothbrush.
- ❍ Use fluoride toothpaste and tap water or saline as a solution.
- ❍ Brush teeth in an up-and-down manner.
- ❍ Suction as needed.

Each client must receive oral care including toothbrushing two times every day to maintain healthy teeth and mouth and to prevent complications associated with periodontitis (the advanced form of gum disease that can cause tooth loss), which is associated with health problems, such as cardiovascular disease, stroke, and bacterial pneumonia (ADA, 2017d).

• Monitor the client's nutritional and fluid status to determine whether it is adequate. Refer to the care plan for Deficient **Fluid** volume or Imbalanced **Nutrition:** less than body requirements if applicable. *Dehydration and malnutrition predispose clients to impaired oral mucous membranes.*

• Encourage fluid intake of up to 3000 mL/day if not contraindicated by the client's medical condition. *Fluids help increase moisture in the mouth, which protects the mucous membranes from damage.*

▲ Determine the client's usual method of oral care and address any concerns regarding oral hygiene. If the client has a dry mouth (xerostomia):

- ❍ Recognize that more than 50 classes of medications may cause xerostomia, which is often exacerbated by polypharmacy. When feasible, medications can be discontinued or replaced to increase the client's comfort (Villa et al, 2015).
- ❍ Provide saliva substitutes as ordered. *Saliva substitutes are helpful to decrease the discomfort of dry mouth and may help prevent stomatitis (ADA, 2017c).*
- ❍ Suggest the client chew sugarless gum or sugarless sour candy to promote salivary flow. *Both sugarless gum and candy stimulate the formation of saliva (ADA, 2017c).*
- ❍ Examine the oral cavity for signs of caries, dental plaque, infection, mucositis ulceration, and oral candidiasis. *Untreated xerostomia may result in these conditions (Gil-Montoya et al, 2016).*

• Recommend that the client decrease or preferably stop intake of soft drinks. Sugar-containing soft drinks can cause cavities, and the low pH of the drink can cause erosion in teeth (*ADA, 2017a*).

• If client has halitosis, review good oral care with the client including brushing teeth, using floss, and brushing the tongue. Halitosis can be a beginning sign of gingivitis and can be eradicated by a good program of dental hygiene (*ADA, 2017b*).

• Instruct the client with halitosis to clean the tongue when performing oral hygiene; brush tongue with tongue scraper or toothbrush and follow with a mouth rinse. **EB:** A meta-analysis found that tongue cleaning in addition to toothbrushing was effective for short-term control of halitosis (*Kuo et al, 2013; ADA 2017b*).

▲ Assess the client for underlying medical condition that may be causing halitosis. *Causes of halitosis can be subdivided into three categories: oral origin in which good mouth care can help prevent halitosis; halitosis from the upper respiratory tract including the sinuses and nose; and halitosis from systemic diseases that are blood-borne, volatilized in the lungs, and expelled from the lower respiratory tract. Potential sources of blood-borne halitosis are some systemic diseases, metabolic disorders, medication, and certain foods such as onions and garlic (ADA, 2017b).*

• Keep the lips well lubricated using a water based or aloe based lip balm. *This is a comfort measure (Radvansky, Pace, & Siddiqui, 2013; Puntillo et al, 2014).*

Client Receiving Chemotherapy/Radiation

• Ensure that the client receives a comprehensive oral examination before initiation of chemotherapy or radiation, with aggressive preventive dental care given as needed (Radvansky, Pace, & Siddiqui, 2013; Maria, Eliopoulos, & Muanza, 2017).

• Provide both verbal and written instruction about the need for and method of providing frequent oral care to the client before radiation therapy or chemotherapy. Assess the condition of the oral cavity daily in the client receiving radiation or chemotherapy (Radvansky, Pace, & Siddiqui, 2013).

• For measurement of presence or severity of mucositis, use the Oral Mucositis Assessment Scale (OMAS). **EBN:** *This is an instrument that has two components: clinician's assessment of presence and severity of mucositis and client report about pain, difficulty swallowing, and ability to eat. Scores indicating the presence of a more severe oral mucositis are associated with decreased quality of life (Franco et al, 2017).*

• Use a protocol to prevent/treat mucositis that includes the following:

- ❍ Use a soft toothbrush that is replaced on a regular basis; brush teeth at least two times a day and for at least 90 seconds.
- ❍ Continue to floss teeth daily.
- ❍ Use a bland, alcohol-free rinse to remove debris and moisten the oral cavity. Rinse the mouth often (every 2 hours while awake) if the client has mouth sores.
- ❍ Avoid tobacco, alcohol, and irritating foods (hot, rough, acidic, or spicy).
- ❍ Use a valid and reliable pain assessment tool and treatment of pain as needed.

EB: *Use of an oral care protocol helps to decrease oral mucositis in clients receiving treatment for cancer (Radvansky, Pace, & Siddiqui, 2013; Eilers et al, 2014; Maria, Eliopoulos, & Muanza, 2017).*

• Help the client use a mouth rinse of normal saline or salt and soda every 1 to 2 hours for prevention and treatment of stomatitis. A typical mixture is 1 teaspoon of salt or sodium bicarbonate per pint of water. Clients are directed to take a tablespoon of the rinse and swish it in the mouth for 30 seconds, then expectorate. **EB:** *Rinses are helpful to remove debris and hydrate the oral mucous membranes; sodium bicarbonate can discourage yeast colonization (Maria, Eliopoulos, & Muanza, 2017).*

▲ If the mouth is severely inflamed and it is painful to swallow, contact the health care provider for a topical anesthetic or analgesic order. Modification of oral intake (e.g., soft or liquid diet) may also be necessary to prevent friction trauma. *The nursing diagnosis Imbalanced* ***Nutrition:*** *less than body requirements may apply.*

• If the client's platelet count is lower than 50,000/mm^3 or the client has a bleeding disorder, use a specially made toothbrush designed for sensitive or diseased tissue, or

a toothette that is not soaked in glycerin or flavorings; if the client cannot tolerate a toothbrush or a toothette, a piece of gauze wrapped around a finger can be used to remove plaque and debris (Radvansky, Pace, & Siddiqui, 2013).

Critical Care—Client on a Ventilator

• Use a soft toothbrush to brush teeth to clean the client's teeth at least every 12 hours; use suction to remove secretions. Provide oral moisturizer to oral mucosa and lips every 4 hours. Recognize that good oral care is paramount in the prevention of ventilator-associated events (VAE) and ventilator-associated pneumonia (VAP). **EBN:** *Increased plaque on the teeth is associated with increased contamination of the mouth and incidence of VAP (de Lacerda et al, 2017). An integrative review of the literature found that consistently performing frequent oral care along with other interventions (e.g., head of bed >30 degrees, adequate endotracheal tube cuff pressure to reduce aspiration, daily evaluation of client's readiness for extubation) and oral moisturizing reduced VAP and decreased overall health care expenses (Alhazzani et al, 2013; Hillier et al, 2013; Parsons et al, 2013; Chu, 2014).*
▲ Apply chlorhexidine gluconate mouthwash or gel in the oral cavity after performing tooth brushing, which may reduce the risk of the client developing VAE and VAP. **EB:** *The use of chlorhexidine gluconate has been associated with a 40% reduction in the odds of a client developing VAP (Shi et al, 2013). Routine oral care with chlorhexidine gluconate in the care of the mechanically ventilated cardiac surgery clients reduces the risk of VAP (Klompas et al, 2014; Xue, 2015; de Lacerda et al, 2017).*

Geriatric

• Determine the functional ability of the client to provide his or her own oral care. Refer to Bathing **Self-Care** deficit. *Interventions must be directed toward both treatment of the functional loss and care of oral health.*
• Provide appropriate oral care to older adults with a self-care deficit, brushing the teeth after breakfast and in the evening. **EBN:** *Oral care is often poor for older clients and clients with dementia.* **EB:** *Several studies have shown that the rate of pneumonia was decreased by providing oral care (van Der Maarel-Wierink et al, 2013; Le, 2015).*
• If the client has dementia or delirium and exhibits care-resistant behavior, such as fighting, biting, or refusing care, then use the following method:
- ❍ Ensure client is in a quiet environment such as own bathroom, sitting or standing at the sink to prime memory for appropriate actions.
- ❍ Approach the client at eye level within his or her range of vision.
- ❍ Approach with a smile and begin conversation with a touch of the hand and gradually move up.
- ❍ Use mirror–mirror technique, standing behind the client, and brush and floss teeth.
- ❍ Use respectful adult speech, not "elder speak" (sing-song voice, or diminutive terms such as "dearie" or "honey"). *Elder speak is a documented trigger for care-resistant behavior (Williams et al, 2017).*
- ❍ Promote self-care in which client brushes own teeth if possible.
- ❍ Use distractors when needed: talking, reminiscing, singing. **EBN:** *Use of specific techniques can decrease resistance to nursing care and increase the effectiveness of nurses providing oral care to clients. Additional research is needed to examine oral care in the client with dementia (Mohammadi, Franks, & Hines, 2015; Rozas, Sadowsky, & Jeter, 2017).*

• Carefully observe the oral cavity and lips for abnormal lesions such as white or red patches, masses, ulcerations with an indurated margin, or a raised granular lesion. *Malignant lesions are more common in older adults than in younger persons, especially if there is a history of smoking or alcohol use (Le, 2015; ADA, 2017e).*
• Ensure that dentures are removed and cleaned regularly, preferably after every meal and before bedtime. *Dentures left in the mouth at night may impede circulation to the palate and predispose the client to oral lesions.*

Home Care

• The interventions described previously may be adapted for home care use.
• Instruct the client in ways to soothe the oral cavity (e.g., cool beverages, popsicles, viscous lidocaine).
▲ If necessary, refer for home health aide services to support the family in oral care and observation of the oral cavity.

Client/Family Teaching and Discharge Planning

• Teach the client how to inspect the oral cavity and monitor for signs and symptoms of infection or complications, and when to call the health care provider (Radvansky, Pace, & Siddiqui, 2013; Eilers et al, 2014).
• Recommend the client not smoke, use chewing tobacco, or drink excessive amounts of alcohol. *Tobacco use, either smoking or chewing, is a common cause of leukoplakia. Also, alcohol and human papillomavirus have been associated with squamous cell carcinoma in the oral cavity (van Der Waal, 2015; ADA, 2017e).*
• Teach the client and family, if necessary, how to perform appropriate mouth care. Use the motivational interviewing technique. **EB:** *A systematic review demonstrated improved dental hygiene, including interdental cleaning, when motivational interviewing compared with the usual teaching session on oral hygiene techniques (Kopp et al, 2017). See Appendix C on Evolve for motivational interviewing.*

Risk for impaired Oral Mucous Membrane integrity

Mary Beth Flynn Makic PhD, RN, CCNS, FAAN, FNAP

NANDA-I

Definition
Susceptible to injury to the lips, soft tissues, buccal cavity, and/or oropharynx, which may compromise health.

Risk Factors
Alcohol consumption; barrier to dental care; barrier to oral self-care; chemical injury agent; decrease in salivation; dehydration; depression; inadequate nutrition; inadequate oral hygiene; insufficient knowledge of oral hygiene; malnutrition; mouth breathing; smoking; stressors

At-Risk Population
Economically disadvantaged

Associated Condition
Allergy; alteration in cognitive functioning; autoimmune disease; autosomal disorder; behavioral disorder; chemotherapy; cleft lip; cleft palate; decrease in hormone level in women; decrease in platelets; immunodeficiency; immunosuppression; infection; loss of oral support structure; mechanical factor; Nil per os (NPO) >24 hours; oral trauma; radiation therapy; surgical procedure; Sjogren's syndrome; trauma; treatment regimen

NIC, Client Outcomes, Nursing Interventions and *Rationales*, Client/Family Teaching, and References
Refer to care plan for Impaired **Oral Mucous Membrane** integrity.

Obesity

Marina Martinez-Kratz MS, RN, CNE

NANDA-I

Definition
A condition in which an individual accumulates excessive fat for age and gender that exceeds overweight.

Defining Characteristics
Adult: Body mass index (BMI) >30 kg/m^2; Child <2 years: term not used with children at this age; Child 2 to 18 years: BMI >30 kg/m^2 or >95th percentile or 30 kg/m^2 for age and gender

Related Factors
Average daily physical activity is less than recommended for gender and age; consumption of sugar-sweetened beverages; disordered eating behaviors; disordered eating perceptions; energy expenditure below energy intake based on standard assessment; excessive alcohol consumption; fear regarding lack of food supply; frequent snacking; high frequency of eating restaurant or fried food; low dietary calcium intake in children; portion sizes larger than recommended; sedentary behavior occurring for ≥2 hours/day; shortened sleep time; sleep disorder; solid foods as major food source at >5 months of age

At-Risk Population
Economically disadvantaged; formula- or mixed-fed infants; heritability of interrelated factors; high disinhibition and restraint eating behavior score; maternal diabetes mellitus; maternal smoking; overweight in infancy; paternal obesity; premature pubarche; rapid weight gain during childhood; rapid weight gain during infancy, including the first week, first 4 months, and first year

Associated Condition
Genetic disorder

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Nutritional Status; Nutritional Status: Food and Fluid Intake; Nutrient Intake; Weight Control

Example NOC Outcome with Indicators

Nutritional Status as evidenced by the following indicators: Food and fluid intake/Hydration/Body mass index/Weight-height ratio/Hematocrit. (Rate the outcome and indicators of **Nutritional Status:** 1 = severe deviation from normal range, 2 = substantial deviation from normal range, 3 = moderate deviation from normal range, 4 = mild deviation from normal range, 5 = no deviation from normal range [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Explain how to eat according to the US Dietary Guidelines
- Design dietary modifications to meet individual long-term goal of health, using principles of variety, balance, and moderation
- Maintain weight within normal range for height and age

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Nutrition Management; Nutritional Counseling; Weight Reduction Assistance

Example NIC Activities—Nutrition Management

Determine the client's motivation for changing eating habits; Develop with the client a method to keep a daily record of intake

Nursing Interventions and *Rationales*

- Assess the meaning and importance of food in the client's life. **EB:** *Recent research found strong associations between the different domains of food meanings and behavioral outcomes (Arbit et al, 2017).*
- Assess client readiness to determine whether the client is ready to discuss weight loss and/or would like weight loss information. **EB:** *Client motivation is a key component of success in a weight loss program and a prerequisite for weight loss therapy (Raynor & Champagne, 2016).*
- Use a motivational interviewing technique when working with clients to promote healthy eating and weight loss. **EB:** *Research shows significant weight loss for clients when motivational interviewing techniques were used (Barnes et al, 2018).*
- Counsel the client to measure regularly consumed foods periodically. Help the client learn usual portion sizes. Measuring food alerts the client to normal portion sizes. Estimating amounts can be extremely inaccurate. **EB:** *A randomized controlled trial of 278 overweight and obese participants was conducted to increase portion size awareness with results that demonstrated the intervention improved portion control behavior and in turn influenced BMI (Poelman et al, 2015).*
- Assist the client to develop a system of self-management, which may include self-monitoring of weight and BMI; realistic goal setting, planning, and action planning for improved dietary intake and physical activity; problem-solving; and tracking dietary intake and exercise. **EB:** *A key component of successful weight loss and maintenance is regular self-monitoring (Thomason et al, 2016).*

• Document the client's height and weight and teach the significance of his or her BMI in relationship to current health. Use a chart or a website such as http://www.cdc.gov/healthyweight/assessing/bmi/index.html (Centers for Disease Control and Prevention [CDC], 2015). **EB:** *Successful treatment of overweight and obesity in adults requires adoption and maintenance of effective self-monitoring (Raynor & Champagne, 2016).*
• Encourage the client to engage in vigorous-intensity physical activity for at least 150 minutes weekly or moderate-intensity physical activity for at least 300 minutes weekly. **EB:** *Research evidence suggested that regular physical activity is critical for weight loss and weight loss maintenance (Ostendorf et al, 2018).*
• Recommend that the client avoid eating in fast-food restaurants. **CEB:** *A 15-year study demonstrated that people who frequently eat fast foods gain an average of 10 pounds more than those who eat fast food less often and were two times more likely to develop insulin resistance, which can lead to diabetes (Pereira et al, 2005).*
• Assist the client to reframe slips in weight loss or physical activity behavior as lapses that are a single event and not a full return to previous unhealthy behaviors. Relapse prevention strategies include managing lapses in healthy behavior, identifying high-risk situations for relapses, self-monitoring, providing social support, enhancing skills for coping, and increasing self-efficacy for avoiding relapse. **EB:** *A study of a weight maintenance intervention, delivered primarily by telephone, modestly slowed the rate of weight regain (Voils et al, 2017).*
• Assist clients to engage their social support systems either digitally or face to face in ways that facilitate weight loss, healthy eating, and physical activity behavior change. **EB:** Significant others, family, friends, and coworkers can facilitate or hinder weight loss success (Romo, 2018).
• Assist the client to reframe the goal from a focus on outcome (weight loss) to a focus on process (eating behaviors) for weight loss. **EB:** *A study showed that there were self-regulatory benefits from mental simulations used in the weight loss process (Marszał-Wiśniewska & Jarczewska-Gerc, 2014).*
• Assist the client to implement informal and formal mindfulness-based interventions (MBIs). Informal MBIs include mindful eating, increasing awareness of hunger and satiety cues, taste satisfaction, and decreasing impulsive tendencies to overeat when experiencing negative emotions. Meditation practice is a formal MBI. **EB:** Results of a research review suggested that a combination of formal and informal MBIs are effective in reducing weight and improving obesity-related eating behaviors among individuals with overweight and obesity (Carrière et al, 2018).
• Assist the client to develop stimulus control techniques designed to reduce environmental cues associated with eating behaviors. Specifically clients should be taught to limit the presence of high-calorie/high-fat foods in the home; to reduce the visibility of unhealthy food choices in the home; to limit where and when they eat; to avoid distractions like reading, using the computer, or watching television when eating; and to eat more slowly. **EB:** *Stimulus control strategies are a key to successful weight loss and weight maintenance in conjunction with other weight loss strategies (Butryn et al, 2017).*
• Encourage 7.5 to 8.5 hours of sleep nightly. **EB:** *Recent evidence suggested weight management is hindered when attempted in the context of sleep restriction because there is an upregulation of reward, pleasure, and salience networks in response to food stimuli (St-Onge, 2017).*
• Refer the client to a weight-loss–related therapy group. **EBN:** *A study found there were significant changes in BMI, waist circumference, body fat percentage, and strength of the*

lower limbs for weight-loss group therapy participants (Ferrari et al, 2017).

• *Recommend that clients use dietary supplements such as vitamins and minerals after consulting with their primary health care provider.* **EB:** *Research shows micronutrient deficits are prevalent in weight-loss plans, especially vitamin B_{12}, calcium, and vitamin D (Engel et al, 2018).*

• Incorporate the following recommendations from the Academy of Nutrition and Dietetics: Interventions for the Treatment of Overweight and Obesity in Adults (Raynor & Champagne, 2016):

- ❍ Assess food- and nutrition-related history; anthropometric measures; biochemical data, medical tests, and procedures; nutrition-focused physical findings; and client history.
- ❍ Assess the energy intake and nutrient content of the diet.
- ❍ Use height and weight to calculate BMI; and waist circumference to determine risk of cardiovascular disease (CVD), type 2 diabetes, and all-cause mortality.
- ❍ Use a measured resting metabolic rate (RMR) to determine energy needs.
- ❍ Set a realistic weight-loss goal such as one of the following: up to 2 pounds/week, up to 10% of baseline body weight, or a total of 3% to 5% of baseline weight if cardiovascular risk factors (hypertension, hyperlipidemia, and hyperglycemia) are present.
- ❍ To achieve weight loss, use an individualized diet, including patient preferences and health status, to achieve and maintain nutrient adequacy and reduce caloric intake, based on one of the following caloric reduction strategies: 1200 to 1500 kcal/day for women and 1500 to 1800 kcal/day for men, with an energy deficit of approximately 500 or 750 kcal/day.

Pediatric

• Offer obese or overweight adolescents healthy methods for weight loss. **EB:** *A recent study showed statistically significant health behavior improvements after implementing a developmentally informed intervention to increase positive health diet and exercise behaviors (Issner et al, 2017).*

• Offer families of obese or overweight children prejudice-free, individually accepting, and supportive interventions to address weight loss. **EBN:** *Obese children treated with motivational interviewing showed significant improvement in their weight-related behavior and obesity-related anthropometric measures (Wong & Cheng, 2013).*

• Recommend that families eat together for at least one meal per day. **EB:** *Findings from a review provide clear evidence that family meals (among youth) and shared meals (among adults) are associated with better dietary intake, and that these findings transcend the life span (Fulkerson et al, 2014).*

• Recommend involving the family in planning meals and food preparation. Children can learn about nutrition as they help plan and make meals. **EB:** *The Healthy Home Offerings via the Mealtime Environment Plus program showed increased cooking skills among the children participating (Fulkerson et al, 2018).*

• Assist parents at being good role models of healthy eating. **EB:** *The Healthy Home Offerings via the Mealtime Environment Plus program showed significantly improved parental self-efficacy for identifying appropriate portion sizes (Fulkerson et al, 2018).*

• Recommend that the family try new foods, either a new food or recipe every week. **EB:** *The Healthy Home Offerings via the Mealtime Environment Plus program showed decreasing child neophobia scores over time that were developmentally appropriate (Fulkerson*

et al, 2018).

Geriatric

- Determine the risks and benefits of weight loss in the older client. A BMI greater than 30 in the older client suggests a moderate weight loss approach. **EB:** *Recommendations for treating obesity in the elderly include ensuring a balanced and appropriately distributed intake of high-quality nutrients, particularly of high-quality protein (i.e., 1.2 to 1.5 g/kg of body weight), limiting the intake of simple carbohydrates and saturated fats, providing sufficient intake of calcium and vitamin D_3 (Blaz, 2016).*
- Observe for social, psychological, and economic factors that influence diet quality. **EB:** *An exploratory study of diet quality influences in community-dwelling older individuals revealed the following influences: food experiences, retirement, bereavement, medical conditions, food environment, food-related habits, social engagement, personal/psychological factors, and transportation (Bloom et al, 2017).*

Multicultural

- Tailor nutritional interventions to be consistent with cultural beliefs, norms, and values. **EB:** *A systemic review of culturally tailored interventions for Hispanic women included literacy modification, Hispanic foods/recipes, cultural diabetes beliefs, family/friend participation, structured community input, and innovative experiential learning (McCurley et al, 2016).*
- Offer tailored lifestyle counseling via the telephone. **EBN:** *Investigators have included biweekly and/or monthly health coach calls for African American participants with significant weight gain prevention (Goode et al, 2017).*
- Integrate weight loss and weight maintenance interventions with church faith-based concepts for cultural congruence with African American clients. **EB:** *Recent research suggested that integrating faith themes into a weight loss maintenance program may increase its long-term effect on participants' health behavior change (Seale et al, 2013).*

Client/Family Teaching and Discharge Planning

- The majority of the preceding interventions involve teaching.
- Work with the family members regarding information on how to support and promote weight loss and healthy intakes.

Overweight

Marina Martinez-Kratz MS, RN, CNE

NANDA-I

Definition

A condition in which an individual accumulates abnormal or excessive fat for age and gender.

Defining Characteristics

Adult: Body mass index (BMI) >25 kg/m^2; Child <2 years: Weight-for-length >95th percentile; Child 2 to 18 years: BMI >85th percentile or 25 kg/m^2 but <95th percentile or 30 kg/m^2 for age and gender

Related Factors

Average daily physical activity is less than recommended for gender and age; consumption of sugar-sweetened beverages; disordered eating behaviors disordered eating perceptions; energy expenditure below energy intake based on standard assessment; excessive alcohol consumption; fear regarding lack of food supply; frequent snacking; high frequency of restaurant or fried food; insufficient knowledge of modifiable factors; low dietary calcium intake in children; portion sizes larger than recommended; sedentary behavior occurring for >2 hours/day; shortened sleep time; sleep disorder; solid foods as major food source of <5 months of age

At-Risk Population

Adult: BMI approaching 25 kg/m^2; Child <2 years: Weight-for-length approaching 95th percentile; Child 2 to 18 years: BMI approaching 85th percentile or 25 kg/m^2; children who are crossing BMI percentiles upward; children with high BMI percentiles; economically disadvantaged; formula-fed or mixed-fed infants; heritability of interrelated factors; high disinhibition and restraint eating behavior score; maternal diabetes mellitus; maternal smoking; obesity in childhood; paternal obesity; premature pubarche; rapid weight gain during childhood; rapid weight gain during infancy, including the first week, first 4 months, and first year

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Nutritional Status; Nutritional Status: Food and Fluid Intake; Nutrient Intake; Weight Control

Example NOC Outcome with Indicators

Nutritional Status as evidenced by the following indicators: Food and fluid intake/Hydration/Body mass index/Weight-height ratio/Hematocrit. (Rate the outcome and indicators of **Nutritional Status:** 1 = severe deviation from normal range, 2 = substantial deviation from normal range, 3 = moderate deviation from normal range, 4 = mild deviation from normal range, 5 = no deviation from normal range [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Explain how to eat according to the US Dietary Guidelines
- Design dietary modifications to meet individual long-term goal of health, using principles of variety, balance, and moderation
- Maintain weight within normal range for height and age

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Nutrition Management; Nutritional Counseling; Weight Reduction Assistance

Example NIC Activities—Nutrition Management

Determine the client's motivation for changing eating habits; Develop with the client a method to keep a daily record of intake

Nursing Interventions and *Rationales*

- Assess the meaning and importance of food in the client's life. **EB:** *Recent research found strong associations between the different domains of food meanings and behavioral outcomes (Arbit et al, 2017).*
- Assess client readiness to determine whether the client is ready to discuss weight loss and/or would like weight-loss information. **EB:** *Client motivation is a key*

component of success in a weight-loss program and a prerequisite for weight-loss therapy (Raynor & Champagne, 2016).

• Use a motivational interviewing technique when working with clients to promote healthy eating and weight loss. **EB:** *Research shows significant weight loss for clients when motivational interviewing techniques were used (Barnes et al, 2018).*

• Counsel the client to measure regularly consumed foods periodically. Help the client learn usual portion sizes. Measuring food alerts the client to normal portion sizes. Estimating amounts can be extremely inaccurate. **EB:** *A randomized controlled trial of 278 overweight and obese participants was conducted to increase portion size awareness with results that demonstrated the intervention improved portion control behavior and in turn influenced BMI (Poelman et al, 2015).*

• Assist the client to develop a system of self-management, which may include self-monitoring of weight and BMI; realistic goal setting, planning, and action planning for improved dietary intake and physical activity; problem-solving; and tracking dietary intake and exercise. **EB:** *A key component of successful weight loss and maintenance is regular self-monitoring (Thomason et al, 2016).*

• Document the client's height and weight and teach the significance of his or her BMI in relationship to current health. Use a chart or a website such as http://www.cdc.gov/healthyweight/assessing/bmi/index.html (Centers for Disease Control and Prevention [CDC], 2015). **EB:** *Successful treatment of overweight and obesity in adults requires the adoption and maintenance of effective self-monitoring (Raynor & Champagne, 2016).*

• Encourage the client to engage in vigorous-intensity physical activity for at least 150 minutes weekly or moderate-intensity physical activity for at least 300 minutes weekly. **EB:** *Research evidence suggests that regular physical activity is critical for weight loss and weight-loss maintenance (Ostendorf et al, 2018).*

• Recommend the client avoid eating in fast-food restaurants. **CEB:** *A 15-year study demonstrated that people who frequently eat fast foods gain an average of 10 pounds more than those who eat fast food less often and were two times more likely to develop insulin resistance, which can lead to diabetes (Pereira et al, 2005).*

• Assist the client to reframe slips in weight loss or physical activity behavior as lapses that are a single event and not a full return to previous unhealthy behaviors. Relapse prevention strategies include managing lapses in healthy behavior, identifying high-risk situations for relapses, self-monitoring, providing social support, enhancing skills for coping, and increasing self-efficacy for avoiding relapse. **EB:** *A study of a weight maintenance intervention, delivered primarily by telephone, modestly slowed the rate of weight regain (Voils et al, 2017).*

• Assist clients to engage their social support systems either digitally or face to face in ways that facilitate weight loss, healthy eating, and physical activity behavior change. **EB:** *Significant others, family, friends, and coworkers can facilitate or hinder weight-loss success (Romo, 2018).*

• Assist the client to reframe the goal from a focus on outcome (weight loss) to a focus on process (eating behaviors) for weight loss. **EB:** *A study showed that there were self-regulatory benefits from mental simulations used in the weight-loss process (Marszał-Wiśniewska & Jarczewska-Gerc, 2014).*

• Assist the client to implement informal and formal mindfulness-based interventions (MBIs). Informal MBIs include mindful eating, increasing awareness of hunger and satiety cues, taste satisfaction, and decreasing impulsive tendencies to overeat when experiencing negative emotions. Meditation practice is a formal MBI. **EB:** *Results of a research review suggest that a combination of formal and informal MBIs are effective in*

reducing weight and improving obesity-related eating behaviors among individuals with overweight and obesity (Carrière et al, 2018).

• Assist the client to develop stimulus control techniques designed to reduce environmental cues associated with eating behaviors. Specifically clients should be taught to limit the presence of high-calorie/high-fat foods in the home; to reduce the visibility of unhealthy food choices in the home; to limit where and when they eat; to avoid distractions like reading, using the computer, or watching television when eating; and to eat more slowly. **EB:** *Stimulus control strategies are the key to successful weight loss and weight maintenance in conjunction with other weight-loss strategies (Butryn et al, 2017.*

• Encourage 7.5 to 8.5 hours of sleep nightly. **EB:** *Recent evidence suggests weight management is hindered when attempted in the context of sleep restriction because there is an upregulation of reward, pleasure, and salience networks in response to food stimuli (St-Onge, 2017).*

• Refer the client to a weight-loss–related therapy group. **EBN:** *A study found there were significant changes in BMI, waist circumference, body fat percentage, and strength of the lower limbs for weight-loss group therapy participants (Ferrari et al, 2017).*

• Recommend that clients use dietary supplements such as vitamins and minerals after consulting with their primary health care provider. **EB:** *Research shows micronutrient deficits are prevalent in weight-loss plans, especially vitamin B_{12}, calcium, and vitamin D (Engel et al, 2018).*

• Incorporate the following recommendations from the Academy of Nutrition and Dietetics: Interventions for the Treatment of Overweight and Obesity in Adults (Raynor & Champagne, 2016):

- ❍ Assess food- and nutrition-related history; anthropometric measures; biochemical data, medical tests, and procedures; nutrition-focused physical findings; and client history.
- ❍ Assess the energy intake and nutrient content of the diet.
- ❍ Use height and weight to calculate BMI and waist circumference to determine risk of cardiovascular disease (CVD), type 2 diabetes, and all-cause mortality.
- ❍ Use a measured resting metabolic rate (RMR) to determine energy needs.
- ❍ Set a realistic weight-loss goal such as one of the following: up to 2 pounds/week, up to 10% of baseline body weight, or a total of 3% to 5% of baseline weight if cardiovascular risk factors (hypertension, hyperlipidemia, and hyperglycemia) are present.
- ❍ To achieve weight loss, use an individualized diet, including patient preferences and health status, to achieve and maintain nutrient adequacy and reduce caloric intake, based on one of the following caloric reduction strategies: 1200 to 1500 kcal/day for women and 1500 to 1800 kcal/day for men, and energy deficit of approximately 500 or 750 kcal/day.

Pediatric

• Offer obese or overweight adolescents healthy methods for weight loss. **EB:** A recent study showed statistically significant health behavior improvements after implementing a developmentally informed intervention to increase positive health diet and exercise behaviors (Issner et al, 2017).

• Offer families of obese or overweight children prejudice-free, individually accepting, and supportive interventions to address weight loss. **EBN:** *Obese children*

treated with motivational interviewing showed significant improvement in their weight-related behavior and obesity-related anthropometric measures (Wong & Cheng, 2013).

• Recommend that families eat together for at least one meal per day. **EB:** *Findings from a review provide clear evidence that family meals (among youth) and shared meals (among adults) are associated with better dietary intake and that these findings transcend the life span (Fulkerson et al, 2014).*

• Recommend involving the family in planning meals and food preparation. Children can learn about nutrition as they help plan and make meals. **EB:** *The Healthy Home Offerings via the Mealtime Environment Plus program showed increased cooking skills among the children participating (Fulkerson et al, 2018).*

• Assist parents at being good role models of healthy eating. **EB:** The Healthy Home Offerings via the Mealtime Environment Plus program showed significantly improved parental self-efficacy for identifying appropriate portion sizes *(Fulkerson et al, 2018).*

• Recommend that the family try new foods, either a new food or recipe every week. **EB:** *The Healthy Home Offerings via the Mealtime Environment Plus program showed decreasing child neophobia scores over time that were developmentally appropriate (Fulkerson et al, 2018).*

Geriatric

• Determine the risks and benefits of weight loss in the older client. A BMI greater than 30 in the older client suggests a moderate weight-loss approach. **EB:** *Recommendations for treating obesity in the elderly include ensuring a balanced and appropriately distributed intake of high-quality nutrients, particularly of high-quality protein (i.e., 1.2 to 1.5 g/kg of body weight), limiting the intake of simple carbohydrates and saturated fats, and providing sufficient intake of calcium and vitamin D_3 (Blaz, 2016).*

• Observe for social, psychological, and economic factors that influence diet quality. **EB:** *An exploratory study of diet quality influences in community-dwelling older individuals revealed the following influences: food experiences, retirement, bereavement, medical conditions, food environment, food-related habits, social engagement, personal/psychological factors, and transportation (Bloom et al, 2017).*

Multicultural

• Tailor nutritional interventions to be consistent with cultural beliefs, norms, and values. **EB:** *A systemic review of culturally tailored interventions for Hispanic women included literacy modification, Hispanic foods/recipes, cultural diabetes beliefs, family/friend participation, structured community input, and innovative experiential learning (McCurley et al, 2016).*

• Offer tailored lifestyle counseling via the telephone. **EBN:** *Investigators have included biweekly and/or monthly health coach calls for African American participants with significant weight gain prevention (Goode et al, 2017).*

• Integrate weight loss and weight maintenance interventions with church faith-based concepts for cultural congruence with African American clients. **EB:** *Recent research suggested that integrating faith themes into a weight-loss maintenance program may increase its long-term effect on participants' health behavior change (Seale et al, 2013).*

Client/Family Teaching and Discharge Planning

• The majority of the preceding interventions involve teaching.

- Work with the family members regarding information on how to support and promote weight loss and healthy intakes.

Risk for Overweight*

Marina Martinez-Kratz MS, RN, CNE

NANDA-I

Definition

Susceptible to excessive fat accumulation for age and gender, which may compromise health.

Risk Factors

Average daily physical activity is less than recommended for gender and age; consumption of sugar-sweetened beverages; disordered eating behaviors; disordered eating perceptions; energy expenditure below energy intake based on standard assessment; excessive alcohol consumption; fear regarding lack of food supply; frequent snacking; high frequency of eating restaurant or fried food; insufficient knowledge of modifiable factors; low dietary calcium intake in children; portion sizes larger than recommended; sedentary behavior occurring for more than 2 hours/day; shortened sleep time; sleep disorder; solid foods as major food sources of less than 5 months of age

At-Risk Population

Adult: Body mass index (BMI) approaching 25 kg/m^2; Child <2 years: Weight for length approaching 95th percentile; Child: 2 to 18 years: BMI approaching 85th percentile, or 25 kg/m^2 (whichever is smaller); children who are crossing BMI percentiles upward; children with high BMI percentiles; economically disadvantaged; formula or mixed-fed infants; heritability of interrelated factors; high disinhibition and restraint eating behavior score; maternal diabetes mellitus; maternal smoking; obesity in childhood; parental obesity; premature pubarche; rapid weight gain during childhood; rapid weight gain during infancy, including the first week, first 4 months, and the first year

Associated Condition

Genetic disorder

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Nutritional Status; Nutritional Status: Food and Fluid Intake; Nutrient Intake; Weight Control

Example NOC Outcome with Indicators

Nutritional Status as evidenced by the following indicators: Food and fluid intake/Hydration/Body mass index/Weight-height ratio/Hematocrit. (Rate the outcome and indicators of **Nutritional Status:** 1 = severe deviation from normal range, 2 = substantial deviation from normal range, 3 = moderate deviation from normal range, 4 = mild deviation from normal range, 5 = no deviation from normal range [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Explain how to eat according to the US Dietary Guidelines
- Design dietary modifications to meet individual long-term goal of health, using principles of variety, balance, and moderation

- Maintain weight within normal range for height and age

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Nutrition Management; Nutritional Counseling; Weight Reduction Assistance

Example NIC Activities—Nutrition Management

Determine the client's motivation for changing eating habits; Develop with the client a method to keep a daily record of intake

Nursing Interventions and *Rationales*

- Assess the meaning and importance of food in the client's life. **EB:** *Recent research found strong associations between the different domains of food meanings and behavioral outcomes (Arbit et al, 2017).*
- Assess client readiness to determine whether the client is ready to discuss weight loss and/or would like weight-loss information. **EB:** *Client motivation is a key component of success in a weight-loss program and a prerequisite for weight-loss therapy (Raynor & Champagne, 2016).*
- Use a motivational interviewing technique when working with clients to promote healthy eating and weight loss. **EB:** *Research shows significant weight loss for clients when motivational interviewing techniques were used (Barnes et al, 2018).*
- Counsel the client to measure regularly consumed foods periodically. Help the client learn usual portion sizes. Measuring food alerts the client to normal portion sizes. Estimating amounts can be extremely inaccurate. **EB:** *A randomized controlled trial of 278 overweight and obese participants was conducted to increase portion size awareness with results that demonstrated the intervention improved portion control behavior and in turn influenced BMI (Poelman et al, 2015).*
- Assist the client to develop a system of self-management, which may include self-monitoring of weight and BMI; realistic goal setting, planning, and action planning for improved dietary intake and physical activity; problem-solving; and tracking dietary intake and exercise. **EB:** *A key component of successful weight loss and maintenance is regular self-monitoring (Thomason et al, 2016).*
- Document the client's height and weight and teach significance of his or her BMI in relationship to current health. Use a chart or a website such as http://www.cdc.gov/healthyweight/assessing/bmi/index.html (Centers for Disease Control and Prevention [CDC], 2015). **EB:** *Successful treatment of overweight and obesity in adults requires adoption and maintenance of effective self-monitoring (Raynor & Champagne, 2016).*
- Encourage the client to engage in vigorous-intensity physical activity for at least 150 minutes weekly or moderate-intensity physical activity for at least 300 minutes weekly. **EB:** *Research evidence suggested that regular physical activity is critical for weight loss and weight-loss maintenance (Ostendorf et al, 2018).*
- Recommend that the client avoid eating in fast-food restaurants. **CEB:** *A 15-year study demonstrated that people who frequently eat fast foods gain an average of 10 pounds more than those who eat fast food less often and were two times more likely to develop insulin resistance, which can lead to diabetes (Pereira et al, 2005).*
- Assist the client to reframe slips in weight loss or physical activity behavior as lapses that are a single event and not a full return to previous unhealthy behaviors.

Relapse prevention strategies include managing lapses in healthy behavior, identifying high-risk situations for relapses, self-monitoring, providing social support, enhancing skills for coping, and increasing self-efficacy for avoiding relapse. **EB:** *A study of a weight maintenance intervention, delivered primarily by telephone, modestly slowed the rate of weight regain (Voils et al, 2017).*

- Assist clients to engage their social support systems either digitally or face to face in ways that facilitate weight loss, healthy eating, and physical activity behavior change. **EB:** *Significant others, family, friends, and coworkers can facilitate or hinder weight-loss success (Romo, 2018).*
- Assist the client to reframe the goal from a focus on outcome (weight loss) to a focus on process (eating behaviors) for weight loss. **EB:** *A study showed that there were self-regulatory benefits from mental simulations used in the weight-loss process (Marszał-Wiśniewska & Jarczewska-Gerc, 2014).*
- Assist the client to implement informal and formal mindfulness-based interventions (MBIs). Informal MBIs include mindful eating, increasing awareness of hunger and satiety cues, taste satisfaction, and decreasing impulsive tendencies to overeat when experiencing negative emotions. Meditation practice is a formal MBI. **EB:** *Results of a research review suggested that a combination of formal and informal MBIs are effective in reducing weight and improving obesity-related eating behaviors among individuals with overweight and obesity (Carrière et al, 2018).*
- Assist the client to develop stimulus control techniques designed to reduce environmental cues associated with eating behaviors. Specifically, clients should be taught to limit the presence of high-calorie/high-fat foods in the home; to reduce the visibility of unhealthy food choices in the home; to limit where and when they eat; to avoid distractions like reading, using the computer, or watching television when eating; and to eat more slowly. **EB:** *Stimulus control strategies are a key to successful weight loss and weight maintenance in conjunction with other weight-loss strategies (Butryn et al, 2017).*
- Encourage 7.5 to 8.5 hours of sleep nightly. **EB:** *Recent evidence suggested weight management is hindered when attempted in the context of sleep restriction because there is an upregulation of reward, pleasure, and salience networks in response to food stimuli (St-Onge, 2017).*
- Refer the client to a weight-loss–related therapy group. **EBN:** *A study found there were significant changes in BMI, waist circumference, body fat percentage, and strength of the lower limbs for weight-loss group therapy participants (Ferrari et al, 2017).*
- Recommend that clients use dietary supplements such as vitamins and minerals after consulting with their primary health care provider. **EB:** *Research shows micronutrient deficits are prevalent in weight-loss plans, especially vitamin B_{12}, calcium, and vitamin D (Engel et al, 2018).*
- Incorporate the following recommendations from the Academy of Nutrition and Dietetics: Interventions for the Treatment of Overweight and Obesity in Adults (Raynor & Champagne, 2016):
    - ❍ Assess food- and nutrition-related history; anthropometric measures; biochemical data, medical tests, and procedures; nutrition-focused physical findings; and client history.
    - ❍ Assess the energy intake and nutrient content of the diet.
    - ❍ Use height and weight to calculate BMI and waist circumference to determine risk of cardiovascular disease (CVD), type 2 diabetes, and all-cause mortality.

- ❍ Use a measured resting metabolic rate (RMR) to determine energy needs.
- ❍ Set a realistic weight-loss goal such as one of the following: up to 2 pounds/week, up to 10% of baseline body weight, or a total of 3% to 5% of baseline weight if cardiovascular risk factors (hypertension, hyperlipidemia, and hyperglycemia) are present.
- ❍ To achieve weight loss, use an individualized diet, including patient preferences and health status, to achieve and maintain nutrient adequacy and reduce caloric intake, based on one of the following caloric reduction strategies: 1200 to 1500 kcal/day for women and 1500 to 1800 kcal/day for men and energy deficit of approximately 500 or 750 kcal/day.

Pediatric

- Offer obese or overweight adolescents healthy methods for weight loss. **EB:** *A recent study showed statistically significant health behavior improvements after implementing a developmentally informed intervention to increase positive health diet and exercise behaviors (Issner et al, 2017).*
- Offer families of obese or overweight children prejudice-free, individually accepting, and supportive interventions to address weight loss. **EBN:** *Obese children treated with motivational interviewing showed significant improvement in their weight-related behavior and obesity-related anthropometric measures (Wong & Cheng, 2013).*
- Recommend that families eat together for at least one meal per day. **EB:** *Findings from a review provided clear evidence that family meals (among youth) and shared meals (among adults) are associated with better dietary intake and that these findings transcend the life span (Fulkerson et al, 2014).*
- Recommend involving the family in planning meals and food preparation. Children can learn about nutrition as they help plan and make meals. **EB:** *The Healthy Home Offerings via the Mealtime Environment Plus program showed increased cooking skills among the children participating (Fulkerson et al, 2018).*
- Assist parents at being good role models of healthy eating. **EB:** *The Healthy Home Offerings via the Mealtime Environment Plus program showed significantly improved parental self-efficacy for identifying appropriate portion sizes (Fulkerson et al, 2018).*
- Recommend that the family try new foods, either a new food or recipe every week. **EB:** *The Healthy Home Offerings via the Mealtime Environment Plus program showed decreasing child neophobia scores over time that were developmentally appropriate (Fulkerson et al, 2018).*

Geriatric

- Determine the risks and benefits of weight loss in the older client. A BMI greater than 30 in the older client suggests a moderate weight-loss approach. **EB:** *Recommendations for treating obesity in the elderly include ensuring a balanced and appropriately distributed intake of high-quality nutrients, particularly of high-quality protein (i.e., 1.2 to 1.5 g/kg of body weight), limiting the intake of simple carbohydrates and saturated fats, and providing sufficient intake of calcium and vitamin D_3 (Blaz, 2016).*
- Observe for social, psychological, and economic factors that influence diet quality. **EB:** *An exploratory study of diet quality influences in community-dwelling older individuals revealed the following influences: food experiences, retirement, bereavement, medical conditions, food environment, food-related habits, social engagement, personal/psychological factors, and transportation (Bloom et al, 2017).*

Multicultural

- Tailor nutritional interventions to be consistent with cultural beliefs, norms, and values. **EB:** *A systemic review of culturally tailored interventions for Hispanic women included literacy modification, Hispanic foods/recipes, cultural diabetes beliefs, family/friend participation, structured community input, and innovative experiential learning (McCurley et al, 2016).*
- Offer tailored lifestyle counseling via the telephone. **EBN:** *Investigators have included biweekly and/or monthly health coach calls for African American participants with significant weight gain prevention (Goode et al, 2017).*
- Integrate weight loss and weight maintenance interventions with church faith-based concepts for cultural congruence with African American clients. **EB:** *Recent research suggested that integrating faith themes into a weight-loss maintenance program may increase its long-term effect on participants' health behavior change (Seale et al, 2013).*

Client/Family Teaching and Discharge Planning

- The majority of the preceding interventions involve teaching.
- Work with the family members regarding information on how to support and promote weight loss and healthy intakes.

Acute Pain

Denise Sullivan MSN, ANP-BC, Maureen F. Cooney DNP, FNP-BC

NANDA-I

Definition

Unpleasant sensory and emotional experience associated with actual or potential tissue damage, or described in terms of such damage (International Association for the Study of Pain); sudden or slow onset of any intensity from mild to severe with an anticipated or predictable end, and with a duration of less than 3 months.

Defining Characteristics

Appetite change; change in physiological parameter; diaphoresis; distraction behavior; evidence of pain using standardized pain behavior checklist for those unable to communicate verbally; expressive behavior; facial expression of pain; guarding behavior; hopelessness; narrowed focus; positioning to ease pain; protective behavior; proxy report of pain behavior/activity changes; pupil dilation; self-focused; self-report of intensity using standardized pain scale; self-report of pain characteristics using standardized pain instrument

Related Factors

Biological injury agent; chemical injury agent; physical injury agent

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Pain Control; Pain Level; Pain: Adverse Psychological Response

Example NOC Outcome

Pain Level as evidenced by severity of observed or reported pain

Note: **Pain Level** is the NOC Outcome label; this text recommends use of the self-report numerical pain rating scale in place of the NOC indicator scales because of the amount of research supporting its use.

Client Outcomes

Client Will (Specify Time Frame)

For the Client Who Is Able to Provide a Self-Report

- Use a self-report pain tool to identify current pain intensity level and establish a comfort-function goal
- Report that the pain management regimen achieves comfort-function goal without side effects
- Describe nonpharmacological methods that can be used to help achieve comfort-

function goal
• Perform activities of recovery or activities of daily living (ADLs) easily
• Describe how unrelieved pain will be managed
• State ability to obtain sufficient amounts of rest and sleep
• Notify member of the health care team promptly for pain intensity level that is consistently greater than the comfort-function goal, or occurrence of side effects

For the Client Who Is Unable to Provide a Self-Report

• Decrease in pain-related behaviors
• Perform activities of recovery or ADLs easily as determined by client condition
• Demonstrate the absence of side effects of analgesics
• No pain-related behaviors will be evident in the client who is completely unresponsive; a reasonable outcome is to demonstrate the absence of side effects related to the prescribed pain treatment plan

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Analgesic Administration; Pain Management; Patient-Controlled Analgesia (PCA) Assistance

Example NIC Activities—Pain Management

Ensure client-attentive analgesic care; Perform a comprehensive assessment of pain to include location, characteristics, onset/duration, frequency, quality, intensity or severity of pain, and precipitating factors

Nursing Interventions and *Rationales*

• During the initial assessment and interview if the client is experiencing pain, or when pain first occurs, conduct and document a comprehensive pain assessment, using appropriate pain assessment tools. **CEB/EBN:** *Determining location, temporal aspects, pain intensity, characteristics, and the effect of pain on function and quality of life are critical to determine the underlying cause of pain and effectiveness of treatment (McCaffery, 1968; Drew & Peltier, 2018). The initial assessment includes all pain information that the client can provide for the development of the individualized pain management plan (Drew & Peltier, 2018).*
• Implement or request orders to implement pain management interventions to achieve a satisfactory level of comfort. Components of this initial assessment include location, quality, onset/duration, temporal profile, intensity, aggravating and alleviating factors, and effects of pain on function and quality of life.
• Assess if the client is able to provide a self-report of pain intensity, and if so, assess pain intensity level using a valid and reliable self-report pain tool, such as the 0 to 10 numerical pain rating scale. **EBN:** *Self-report is considered the single most reliable indicator of pain presence and intensity, and single-dimension pain ratings are valid and reliable as measures of pain intensity level (Drew & Peltier, 2018).* **EB:** *Regularly and routinely assess the client for pain presence during activity and rest and with interventions or procedures likely to cause pain.* **EB:** *Acute pain should be reliably assessed both at rest (important for comfort) and during movement (important for function and decreased client risk for cardiopulmonary and thromboembolic events) (Chou et al, 2016; Drew & Peltier, 2018).*
• Ask the client to describe prior experiences with pain, effectiveness of pain management interventions, responses to analgesic medications including occurrence of side effects, and concerns about pain and its treatment (e.g., fear about addiction,

worries, anxiety) and informational needs. **EBN:** *Obtaining an individualized pain history helps identify potential factors that may influence the client's willingness to report pain, as well as factors that may influence pain intensity, the client's response to pain, anxiety, and pharmacokinetics of analgesics (Drew & Peltier, 2018).* **EB:** *Anxiety and fear may intensify pain, and pain may trigger emotional responses such as fear and anxiety (Zhuo, 2016).*

• Using a self-report pain tool, ask the client to identify a comfort-function goal that will allow the client to perform necessary or desired activities easily. **EBN:** *The comfort-function goal provides the basis for individualized pain management plans and assists in determining effectiveness of pain management interventions (Drew & Peltier, 2018).*

• Use the Hierarchy of Pain Measures as a framework for pain assessment (Herr et al, 2011; Drew & Peltier, 2018): (1) attempt to obtain the client's self-report of pain; (2) consider the client's condition and search for possible causes of pain (e.g., presence of tissue injury, pathological conditions, exposure to procedures/interventions that are thought to result in pain); (3) observe for behaviors that may indicate pain presence (e.g., facial expressions, crying, restlessness, changes in activity); (4) evaluate physiological indicators, with the understanding that these are the least sensitive indicators of pain and may be related to conditions other than pain (e.g., shock, hypovolemia, anxiety); and (5) conduct an analgesic trial. **EBN:** *When a client is unable to use a self-report tool (e.g., cognitively impaired, critically ill, anesthetized or sedated), the presence of pain may be assessed by observing specific client behaviors using a valid and reliable behavioral tool (e.g., Critical Care Observation Tool in the critically ill or Checklist of Nonverbal Pain Indicators in cognitively impaired older adults) (Puntillo et al, 2014; Drew & Peltier, 2018). In a study involving turning of neurocritically ill clients after elective brain surgery, self-report was obtained when possible, behaviors were found to be valid indicators of pain, and fluctuations in vital signs suggested the presence of pain, but their validity for such use was not supported, suggesting they should only be used in combination with other validated pain assessment tools (Kapoustina, Echegaray-Benites, & Gelinas, 2014).*

• Assume that pain is present if the client is unable to provide a self-report and has tissue injury, a pathological condition, or has undergone a procedure that is thought to produce pain, and conduct an analgesic trial. **EBN:** *Pain is associated with actual or potential tissue damage such as pathological conditions (e.g., cancer) and procedures (e.g., surgery or trauma, fractures). In the absence of self-report (e.g., anesthetized, critically ill, or cognitively impaired client), the health care provider should use clinical judgment and assume pain is present, and then implement pain management interventions accordingly (Drew & Peltier, 2018).*

▲ Obtain and review an accurate and complete list of medications the client is taking or has taken. **EB:** *Accurate medication reconciliation can guide analgesic plan development and prevent errors associated with incorrect medications, dosages, omission of components of the home medication regimen, drug–drug interactions, and toxicity that can occur when incompatible drugs are combined or when allergies are present (Ignatavicius, 2013).*

▲ Describe the adverse effects of unrelieved pain. **EBN:** *Unrelieved acute pain can have physiological and psychological consequences that facilitate negative client outcomes. Ineffective management of acute pain has the potential for neurohumoral changes; neuronal remodeling; an impact on immune function; and long-lasting physiological, psychological, and emotional distress, and it may lead to persistent pain syndromes (Eksterowicz & DiMaggio, 2018).*

▲ Explain to the client the pain management approach, including pharmacological and nonpharmacological interventions, the assessment and reassessment process, potential side effects, and the importance of prompt reporting of unrelieved pain. **EB:**

One of the most important steps toward improved control of pain is a better client understanding of the nature of pain, its treatment, and the role the client needs to play in pain control (Ignatavicius, 2013).

▲ Discuss the client's fears of undertreated pain, side effects, and opioid use disorder (OUD), and reassure the client that there will be regular assessment and treatment of pain, and assessment for side effects and signs of OUD. **EBN:** *Cogan et al (2014) reported that among 379 clients scheduled for cardiac surgery, 31% stated that it is easy to become addicted to pain medication, 20% report that "good patients" do not talk about their pain, and 35% believe that pain medication should be "saved in case the pain worsens."*

• Teach the client about pain and pharmacological and nonpharmacological interventions when pain is relatively well controlled. **EB:** *Pain causes cognitive impairment* (*Baker et al, 2017*).

▲ Regularly reassess the client for the presence of pain and response to pain management interventions, including effectiveness and the presence of adverse effects related to pain management interventions. Review the client's pain flow sheet and medication administration record to evaluate effectiveness of pain relief, previous 24-hour opioid requirements, and occurrence of side effects. **EBN:** *Systematic tracking of pain is an important factor in improving pain management and making adjustments to the pain management regimen (Eksterowicz & DiMaggio, 2018).*

▲ Advocate for and manage acute pain using a multimodal, opioid-sparing approach. **EB:** *A multimodal approach (combining two or more drugs that act by different mechanisms for providing analgesia) enhances pain relief and allows the lowest effective dose of each drug to be administered, resulting in fewer or less severe side effects, such as nausea, sedation, and respiratory depression (The Joint Commission [TJC], 2012; Chou et al, 2016; Jungquist et al, 2016; Behm, Leinum, & Peltier, 2018).*

▲ Select the route for administration of analgesics based on client condition and pain characteristics. **EB:** *Routes have different rates of onset and duration. The oral route is preferred because of its convenience and the resulting relatively steady blood levels, the rectal route may be used when the oral route is not feasible, the intravenous (IV) route is preferred for rapid control of severe pain and would therefore not generally be used for chronic pain, and intramuscular injections are avoided because of variable absorption and the potential for nerve injury and tissue damage (American Pain Society [APS], 2016; Chou et al, 2016).*

▲ Provide perineural infusions and intraspinal analgesia when appropriate and available. **CEBN:** Superior analgesia can be provided through regional analgesic techniques compared with systemic opioids (Nishimori et al, 2012). **EB:** *Use of preoperative continuous femoral nerve blockade reduced morphine side effects in patients with hip fracture (Chaudet et al, 2016).*

▲ Use diverse analgesic delivery methods such as PCA to increase client's satisfaction with pain management, to lower cost, and to decrease occurrence of adverse reactions. **EBN:** *IV PCA provides superior analgesia compared with IV injection in the first 12 hours after total hysterectomy (Hong & Lee, 2014).*

▲ Administer a nonopioid analgesic for mild to moderate pain and add an opioid analgesic if indicated for moderate to severe acute pain. **EB:** *Nonopioids, such as acetaminophen and nonsteroidal antiinflammatory drugs, are first-line analgesics for the treatment of mild and some moderate acute pain, whereas opioids are included for the treatment of moderate to severe acute pain (American Society of Anesthesiologists [ASA], 2012; APS, 2016; Chou et al, 2016).*

• Avoid administering analgesics based solely on a client's pain intensity rating. **EB:** Administering opioid doses based solely on pain intensity disregards the other essential elements of the pain assessment and may contribute to adverse patient

outcomes such as excessive sedation and respiratory depression as a result of overmedication, or result in poorly controlled pain from undermedication (Pasero et al, 2016).

• Administer analgesics around the clock for continuous pain (expected to be present approximately 50% of the day, such as postoperative pain) and as needed (PRN) for intermittent or breakthrough pain. **EB:** *If pain is present most of the day, the use of PRN medications alone will lead to periods of undermedication and poor pain control and periods of excessive medication and adverse effects (APS, 2016).*

• Prevent pain by administering analgesia before painful procedures whenever possible (e.g., endotracheal suctioning, wound care, heel puncture, venipunctures, and peripherally inserted IV catheters). **EB:** *Adult clients in the intensive care setting experience numerous sources of procedural pain, and chest tube removal, wound drain removal, and arterial line insertion are identified as the most painful procedures (Puntillo et al, 2014). The use of topical lidocaine 1% before removal of extremity vacuum-assisted closure wound dressings results in reduced pain and opioid use (Christensen, Thorum, & Kubiak, 2013).*

• Perform nursing care during the peak effect of analgesics to optimize client comfort and participation in care. **EB:** *Providing care such as mobilization and bathing should be performed when analgesics have reached peak effect: oral medications peak in 60 minutes, subcutaneous opioids in 30 minutes, and IV analgesics in 15 to 30 minutes (APS, 2016; Eksterowicz & DiMaggio, 2018).*

• Advocate for the use of "as needed" opioid range orders to provide effective and appropriate pain relief. **EB:** *Correctly prescribed range orders for the delivery of IV opioids give nurses the flexibility needed to treat clients' pain in a timely manner while allowing for differences in client response to pain and to analgesia (Drew et al, 2014; APS, 2016).*

• Choose analgesic and dose based on orders that reflect the client's report of pain severity and response to the previous dose in terms of pain relief, occurrence of side effects, and ability to perform the activities of recovery or ADLs. **EB:** *Safe and effective pain management requires opioid dose adjustment based on individualized adequate pain and sedation assessment, opioid administration, and evaluation of the response to treatment (Ignatavicius, 2013).*

▲ When converting opioids from parenteral doses to oral doses (the preferred route when the client can tolerate and absorb oral medications), use equianalgesic dosing charts and carefully monitor the client's response to the new medication route and dose. **EB:** *Equianalgesic dosing calculations should be used cautiously to guide dose conversion of an opioid from one route to another to avoid the toxicity associated with overdosing and the inadequate pain control caused by under dosing (APS, 2016).*

▲ Clients who are receiving opioids for acute pain require frequent assessment for effectiveness of opioids and assessment for serious opioid-related adverse effects. This includes respiratory assessment (rate, rhythm, noisiness, and depth) and systematic assessment of sedation level using a sedation scale (Eksterowicz & DiMaggio, 2018). **EB:** *Opioid-induced respiratory depression occurs with the greatest frequency in postoperative clients during the first 24 hours after surgery, and factors contributing to postoperative respiratory depression include the intervention of multiple prescribers (33%), concurrent administration of nonopioid sedating medications (34%), and inadequate nursing assessments or response (31%) (Jarzyna et al, 2011; ASA, 2012; Lee et al, 2015; Jungquist et al, 2016).*

▲ When opioids are included in the multimodal analgesic plan, clients need regular assessment for common side effects such as constipation, nausea, pruritus, lack of appetite, and changes in rest and sleep, and preventive measures are implemented when possible.

• Monitor frequency of bowel movements and provide the client with adequate hydration, a stool softener, and stimulant to prevent/treat opioid-related constipation. **EB:** *Opioid-induced constipation significantly affects quality of life. First-line treatment includes lifestyle changes such as increasing activity and the administration of stool softeners and laxatives (Dorn, Lembo, & Cremonini, 2014).*

▲ Support the client's use of nonpharmacological methods to supplement pharmacological analgesic approaches to help control pain, such as distraction, imagery, music therapy, simple massage, relaxation, and application of heat and cold. **EBN:** *Although more evidence is needed to conclude effectiveness, nonpharmacological methods (which are low cost and low risk) can be used to complement pharmacological treatment of pain (Ignatavicius, 2013). The use of structured touch and guided imagery has shown reduction in pain and anxiety among adults who underwent elective joint replacements (Forward et al, 2015). Evidence suggests efficacy and satisfaction when complementary therapies are integrated into pain treatment plans of older adults (Bruckenthal, Marino, & Snelling, 2016).*

▲ Assist client to identify resources for coping with psychological impact of pain. **EB:** *Cognitive behavioral (mind–body) strategies can restore the client's sense of self-control, personal efficacy, and active participation in his or her own care (Broderick et al, 2014).* **EB:** *Nurses should advocate for cognitive behavioral therapy as first-line therapy and especially when medications are contraindicated, not well tolerated, or refused and when patients are exhibiting ineffective coping skills (O'Connor-Von & Heck, 2018).*

Pediatric

• Assess for the presence of pain using a valid and reliable pain scale based on age, cognitive development, and the child's ability to provide a self-report. **EBN:** *Scales that depict faces at various levels of pain intensity are commonly used in young children and have been shown to be reliable and valid in children as young as 3 years old (Tobias, 2014).* **EB:** *Behavioral tools such as the Face, Legs, Activity, Cry, Consolability (FLACC) Scale may be used to assess pain in infants and children who cannot provide a self-report (Crellin et al, 2015).*

▲ Administer prescribed analgesics using a multimodal approach to treat pain in children, infants, and neonates. **EB:** *Multimodal analgesia improves pain control and reduces side effects in postoperative pediatric patients (Jitpakdee & Mandee, 2014).*

• Prevent procedural pain in neonates, infants, and children by using opioid analgesics and anesthetics, as indicated, in appropriate dosages. **EBN:** *Czarnecki et al (2014) found that several barriers exist to the treatment of procedural pain in children including insufficient medication orders before procedures, insufficient time to premedicate children before procedures, the perception of low priority given to pain management by medical staff, and parents' reluctance to have their children medicated.*

• Use a topical local anesthetic treatment or other nonpharmacologic treatment before performing venipuncture in neonates, infants, and children. **EBN:** *Mechanical vibration with use of Buzzy, a US Food and Drug Administration (FDA)-approved device shaped like a bee that vibrates and has removable "wings" that can be frozen placed proximally to the expected IV insertion site has been shown to be as effective as topical lidocaine (Bahorski et al, 2015).*

• For the neonate, use oral sucrose and nonnutritional sucking (NNS) or human milk for pain of short duration such as heel stick or venipuncture. Neonates, especially preterm neonates, are more sensitive to pain than older children. **EBN:** *In an integrated literature review, Naughton (2013) found that the combination of oral sucrose and NNS is a*

safe and effective method of relieving pain in neonates and increases the calming effect in infants undergoing painful procedures.

• Recognize that breastfeeding has been shown to reduce behavioral indicators of pain. **EB:** *Breastfeeding has not been shown to have a better analgesic effect than sucrose in late preterm infants (Simonse, Mulder, & Van Beek, 2012).*

• As with adults, use nonpharmacological analgesic interventions to supplement, not replace, pharmacological interventions in pediatric clients. **EB:** *Infants who underwent upper limb massage prior to venipuncture had significantly less pain with venipuncture than when massage was not used (Chik, Ip, & Choi, 2017). Pain and distress in children receiving immunizations were significantly reduced when live music therapy was used during the immunization procedure (Sundar et al, 2016).*

Geriatric

• Refer to the Nursing Interventions and *Rationales* in the care plan for Chronic **Pain.**

Multicultural

• Refer to the Nursing Interventions and *Rationales* in the care plan for Chronic **Pain.**

Home Care

▲ Develop the treatment plan with the client and caregivers. **EB:** *Client education and motivation play important roles in self-management of clients with pain. Self-management is influenced by client–provider communication (Dorflinger, Kerns, & Auerbach, 2013).*

▲ Assess the client's full medication profile, including medications prescribed by all health care providers and all over-the-counter medications for drug interactions, and instruct the client to refrain from mixing medications without health care provider approval. **EB:** *Pain medications may significantly affect or be affected by other medications and may cause severe side effects; in a study of diabetic pregabalin and duloxetine users, potential duloxetine drug–drug interactions and drug–condition interactions were associated with significant increases in mean health care costs (Johnston et al, 2013).*

▲ Assess the client/family's knowledge of side effects and safety precautions associated with pain medications. **EB:** *Educational activities related to pain medications are necessary to ensure that clients are knowledgeable about opioid side effects and safety. McCarthy et al (2015) found that clients who read and a one-page information sheet they were given about hydrocodone-acetaminophen safety had better knowledge of precautions related to acetaminophen dosing, and they were less likely to drive a car within 6 hours of taking the medication than those who did not receive this educational intervention.*

• If medication is administered using highly technological methods, assess the home for the necessary resources (e.g., electricity) and ensure that there will be responsible caregivers available to assist the client with administration. **EB:** *With appropriate assessment of home resources, it is possible to provide home management of clients with complex pain management technologies as demonstrated in a study of children with cleft palate repair who received home infusion of local anesthetic via peripheral nerve block catheter (Visoiu, 2014).*

• Assess the knowledge base of the client and family regarding highly technological medication administration and provide necessary education, including the procedure to follow if analgesia is unsatisfactory. **EB:** *With appropriate education and training, outpatient families can successfully manage infusions of local anesthetics through peripheral nerve catheters for analgesia in clients recovering from cleft palate surgery (Visoiu, 2014).*

Client/Family Teaching and Discharge Planning

Note: To avoid the negative connotations associated with the words "drugs" and "narcotics," use the term "pain medicine" when teaching clients.

- Discuss the various discomforts encompassed by the word "pain" and ask the client to give examples of previously experienced pain. Explain the pain assessment process and the purpose of the pain rating scale. **EB:** *It is often difficult for clients to understand the concept of pain and describe their pain experience. Using alternative words and providing a complete description of the assessment process, including the use of scales, ensures that an accurate treatment plan is developed (Drew & Peltier, 2018).*
- Teach the client to use the self-report pain tool to rate the intensity of past or current pain. Ask the client to set a comfort-function goal by selecting a pain level on the self-report tool that will allow performance of desired or necessary activities of recovery with relative ease (e.g., turn, cough, deep breathe, ambulate, participate in physical therapy). If the pain level is consistently above the comfort-function goal, the client should take action that decreases pain or notify a member of the health care team so that effective pain management interventions may be implemented promptly. **EB:** *The use of comfort-function goals provides the basis for the direction and modification of the treatment plan (Eksterowicz & DiMaggio, 2018).*
- Provide written educational materials on various aspects of pain control to improve client understanding of pain and pain-related interventions. **EB:** *Written materials and other educational tools assist in improving clients' knowledge related to pain management. In knee replacement clients, the use of an educational pamphlet and a compact disc was associated with decreased postoperative pain and increased participation in physical rehabilitation (Chen et al, 2014).*
- Discuss and evaluate the client's understanding about the total plan for pharmacological and nonpharmacological treatment, including the medications prescribed and their indication, proper dosing schedule, and adverse events and what to do should they occur. **EB:** *Appropriate instruction increases the accuracy and safety of medication administration (Drew & Peltier, 2018).*
- Teach basic principles of pain management using a variety of educational strategies, and evaluate learning. **EB:** *Client educational strategies that have been shown to increase knowledge, decrease anxiety, and increase satisfaction include the use of computer technology, audiotapes and videotapes, written materials, and demonstrations, or combinations of these strategies (Curtiss & Wrona, 2018).*
- ▲ Reinforce the importance of taking pain medications to maintain the comfort-function goal. **EB:** *Teaching clients to stay on top of their pain and prevent it from getting out of control will improve the ability to accomplish the goals of recovery (APS, 2016; Eksterowicz & DiMaggio, 2018).*
- ▲ Reinforce that short-term use of opioids for acute pain relief is an appropriate part of their multimodal pain treatment plan. **EB:** *Taking opioids only as directed, avoiding alcohol, and talking with the health care provider when pain is poorly controlled are strategies that will lessen the risks for OUD or major opioid-related adverse effects such as respiratory depression and arrest (Costello, 2015).*
- ▲ Reinforce the importance of safe storage of opioid medications out of the reach of others, and to responsibly dispose of any unused opioids. **EB:** *Community medication "take back" days and drop boxes are becoming increasingly popular. Encourage clients/families to check community resources.*
- ▲ Demonstrate the use of appropriate nonpharmacological approaches in addition to pharmacological approaches to help control pain, such as application of heat and/or

cold, distraction techniques, relaxation breathing, visualization, rocking, stroking, listening to music, and watching television. **EB:** *Nonpharmacological interventions are used to complement, not replace, pharmacological interventions (Bruckenthal, Marino, & Snelling, 2016).*

Chronic Pain

Denise Sullivan MSN, ANP-BC, Maureen F. Cooney DNP, FNP-BC

NANDA-I

Definition

Unpleasant sensory and emotional experience associated with actual or potential tissue damage, or described in terms of such damage (International Association for the Study of Pain); sudden or slow onset of any intensity from mild to severe, constant or recurring without an anticipated or predictable end, and a duration of greater than 3 months.

Defining Characteristics

Alteration in ability to continue previous activities; alteration in sleep pattern; anorexia; evidence of pain using standardized pain behavior checklist for those unable to communicate verbally; facial expression of pain; proxy report of pain behavior/activity changes; self-focused; self-report of intensity using standardized pain scale; self-report of pain characteristics using standardized pain instrument

Related Factors

Alteration in sleep pattern; emotional distress; fatigue; increase in body mass index; ineffective sexuality pattern; injury agent; malnutrition; nerve compression; prolonged computer use; repeated handling of heavy loads; social isolation; whole-body vibration

At-Risk Population

Age >50 years; female gender; history of abuse; history of genital mutilation; history of over indebtedness; history of static work postures; history of substance misuse; history of vigorous exercise

Associated Condition

Chronic musculoskeletal condition; contusion; crush injury; damage to the nervous system; fracture; genetic disorder; imbalance of neurotransmitters, neuromodulators, and receptors; immune disorder; impaired metabolic functioning; ischemic condition; muscle injury; post-trauma related condition; prolonged increase in cortisol level; spinal cord injury; tumor infiltration

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Comfort Level; Pain Control; Pain: Disruptive Effects; Pain Level

Example NOC Outcome with Indicators

Pain Level as evidenced by use of a numerical pain rating scale (NRS), asking the client to rate the level of pain from 0 to 10. Self-report is considered the single most reliable indicator of pain presence and intensity (American Pain Society [APS], 2016)

Note: **Pain Level** is the NOC Outcome label; this text recommends use of the self-report NRS in place of the NOC indicator scales because of the amount of research supporting its use.

Client Outcomes

Client Will (Specify Time Frame)

For the Client Who Is Able to Provide a Self-Report

- Provide a description of the pain experience including physical, social, emotional, and spiritual aspects
- Use a self-report pain tool to identify current pain level and establish a comfort-function goal
- Report that the pain management regimen achieves comfort-function goal without the occurrence of side effects
- Describe nonpharmacological methods that can be used to supplement, or enhance, pharmacological interventions and help achieve the comfort-function goal
- Perform necessary or desired activities at a pain level less than or equal to the comfort-function goal
- Demonstrate the ability to pace activity, taking rest breaks before they are needed
- Describe how unrelieved pain will be managed

- State the ability to obtain sufficient amounts of rest and sleep
- Notify a member of the health care team for pain level consistently greater than the comfort-function goal or occurrence of side effect

For the Client Who Is Unable to Provide a Self-Report

- Demonstrate decrease or resolved pain-related behaviors
- Perform desired activities as determined by client condition
- Demonstrate the absence of side effects
- No pain-related behaviors will be evident in the client who is completely unresponsive; a reasonable outcome is to demonstrate the absence of side effects related to the prescribed pain treatment plan

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Analgesic Administration; Pain Management

Example NIC Activities—Pain Management

Ensure that the client receives attentive analgesic care; Perform comprehensive assessment of pain, including location, characteristics, onset and duration, frequency, quality, intensity or severity, and precipitating factors

Nursing Interventions and *Rationales*

- During the initial assessment and interview, if the client is experiencing pain, conduct and document a comprehensive pain assessment, using appropriate pain assessment tools. **EBN:** *Determining location, temporal aspects, pain intensity, characteristics, and the effect of pain on function and quality of life are critical to determine the underlying cause of pain and effectiveness of treatment (McCaffery, 1968; Drew & Peltier, 2018). The initial assessment includes all pain information that the client can provide for the development of the individualized pain management plan (Drew & Peltier, 2018).*
- Determine the quality of the pain and whether the pain has persisted beyond the usual duration for tissue healing. **EB:** *Chronic pain is persistent, lasting beyond the expected time or usual time of tissue healing (usually 3 months). Descriptors such as "sharp," "shooting," or "burning" assist in discriminating neuropathic pain from nociceptive pain (APS, 2016; Elliot, Simpson, & DiMaggio, 2018).* Please refer to the Acute **Pain** section for the Hierarchy of Pain Measures for assessment approach in clients who are unable to provide self-report of pain.
- Perform a pain assessment using a reliable self-report pain tool. **EB:** *Tools such as the 0 to 10 NRS or faces pain scale (FPS) assess pain intensity. Multidimensional tools such as the Brief Pain Inventory (BPI), McGill Pain Questionnaire (MPQ), the Pain Relief Scale (PRS), or the Chronic Pain Grade Scale (CPGS) provide a comprehensive evaluation of the client with persistent pain assessing the characteristics and quality of pain; satisfaction with pain control; and how pain affects mood, activity, sleep, and diet (Fillingim et al, 2016; Drew & Peltier, 2018). Lee et al (2014) reported that the NRS together with the PRS increased the objectivity of pain assessment in chronic spinal pain compared with the use of either scale alone.*
- Ask the client to describe prior experiences with pain, effectiveness of pain management interventions, responses to analgesic medications including occurrence of side effects, and concerns about pain and its treatment (e.g., fear about addiction, worries, anxiety) and informational needs. **EBN:** *Obtaining an individualized pain*

history helps identify potential factors that may influence the client's willingness to report pain, as well as factors that may influence pain intensity, the client's response to pain, anxiety, and pharmacokinetics of analgesics (Drew & Peltier, 2018).

• Using a self-report tool, ask the client to identify a comfort-function goal that will allow the client to perform necessary or desired activities easily. **EBN:** *The comfort-function goal provides the basis for individualized pain management plans and assists in determining effectiveness of pain management interventions (Drew & Peltier, 2018).* Assess the client for the presence of acute pain (see care plan for Acute **Pain**).

▲ Assess chronic pain regularly including the impact of chronic pain on activity; sleep; eating habits; and social conditions including relationships, finances, and employment. **CEB:** *Regular assessment of clients with chronic pain is critical because changes in the underlying pain condition, presence of comorbidities, and changes in psychosocial circumstances can affect pain intensity and characteristics and require revision of the pain management plan (Turk et al, 2016).* **EB:** *Sleep disturbance and decreased physical activity are adverse effects of people with chronic pain. Tang and Sanborn (2014) found clients with chronic pain who had a better night's sleep spontaneously engaged in more physical activity the following day.*

▲ Assess the client for the presence of psychiatric conditions, including anxiety and depression. **EB:** *Among chronic pain clients, 30% to 50% have been found to have depression as a comorbidity, and there is a fourfold higher risk of suicide attempt than in the general population (Breivik et al, 2014). Anxiety and fear may intensify pain, and pain may trigger emotional responses such as fear and anxiety (Turk et al, 2016; Zhuo, 2016). The coexistence of major depressive disorder and persistent pain has been reported to be 30% to 60% (Maletic & DeMuri, 2016).*

▲ If opioid therapy is considered, assist the provider with aspects of an opioid risk assessment, which includes a comprehensive client interview and examination with a pain focus, mental health screening, use of an opioid risk assessment tool, examination of prescription drug monitoring program results, and urine drug screening. **EB:** *Although prevalence rates vary, there is evidence of opioid misuse and substance use disorder (SUD) among those who are prescribed opioids, thus to reduce risk and optimize safe opioid use, risk assessment and stratification are recommended (APS, 2016; Dowell, Haegerich, & Chou, 2016; Hudspeth, 2016).*

▲ For the client who is receiving outpatient opioid therapy, at each visit, assess effect of opioids on pain status, function, goal achievement, and presence of side effects including sleep disturbance and sexual dysfunction; assessment for signs of misuse and SUD should be included, which may involve the use of random urine drug toxicology screening, pill counts, and review of prescription monitoring database. **EB:** *Opioid therapy is associated with risk for misuse and SUD and overdose, whereas the evidence for the long-term use of opioid therapy in chronic pain is inconclusive. To minimize risk, a number of risk mitigation practices, including careful assessment of the client response to opioid therapy, are recommended (APS, 2016; Dowell, Haegerich, & Chou, 2016).*

• Ask the client to maintain a diary (if able) of pain ratings, timing, precipitating events, medications, and effectiveness of pain management interventions. **EBN:** *Systematic tracking of pain has been demonstrated to be an important factor in improving pain management (Fillingim et al, 2016). In a study of smartphone-based interventions with diaries among women with chronic widespread pain, it was found that the use of the smartphone intervention with diaries and personalized feedback reduced catastrophizing and prevented increases in functional impairment and symptoms (Kristjánsdóttir et al, 2013). Franco et al (2015) suggested the use of a smartphone-based electronic pain diary via telemedicine may be a reliable method for conducting remote assessments of chronic pain clients over time, thus*

improving clinical monitoring, differential diagnosis, and treatment of pain.

▲ Obtain and review an accurate and complete list of medications the client is taking or has taken. **CEB:** *Accurate medication reconciliation can guide analgesic plan development and prevent errors associated with incorrect medications, dosages, omission of components of the home medication regimen, drug–drug interactions, and toxicity that can occur when incompatible drugs are combined or when allergies are present (Ignatavicius, 2013).* **EBN:** *Young et al (2015), in an examination of transition-related medication discrepancies in a rural community, found that 55% of the medication discrepancies involved medications for pain control.*

▲ Explain to the client the pain management approach that has been ordered or revised, including therapies, medication administration, side effects, and complications. **EB:** *One of the most important steps toward improved control of pain is a better client understanding of the nature of pain, its treatment, pain management goals, and the role the client needs to play in pain control (Curtiss & Wrona, 2018).*

• Discuss the client's fears of undertreated pain, side effects, opioid use disorder (OUD), and overdose and reassure the client that there will be regular assessment and treatment of pain and assessment for side effects and signs of OUD. **EBN:** *Cogan et al (2014) reported that among 379 clients scheduled for cardiac surgery, 31% stated that it is easy to become addicted to pain medication, 20% report that "good patients" do not talk about their pain, and 35% believe that pain medication should be "saved in case the pain worsens."*

▲ Manage chronic pain using an individualized, multimodal nonopioid or opioid-sparing approach. **EB:** *A multimodal approach (combining two or more drugs that act by different mechanisms for providing analgesia) such as acetaminophen, an anticonvulsant, antidepressant, and opioid in chronic pain enhances pain relief and allows the lowest effective dose of each drug to be administered, resulting in fewer or less severe side effects such as nausea, sedation, and respiratory depression. Nonopioid therapy is the treatment of choice in chronic noncancer pain. Opioids may be considered when all other reasonable attempts at analgesia have failed; however, evidence for long-term effectiveness is not clear (The Joint Commission [TJC], 2012; Dowell, Haegerich, & Chou, 2016; Jungquist et al, 2016; Elliot, Simpson, & DiMaggio, 2018).*

▲ Select the route of administration of analgesics based on client condition and pain characteristics. **CEB:** *The least invasive route of administration capable of providing adequate pain control is recommended. The oral route is preferred because of its convenience and the resulting relatively steady blood levels; the rectal route or transdermal route may be used when the oral route is not feasible; the intravenous route is preferred for rapid control of severe pain, and would therefore not generally be used for chronic pain; and intramuscular injections are avoided because of variable absorption and the potential for nerve injury and tissue damage (APS, 2016; Behm, Leinum, & Peltier, 2018).*

▲ When chronic pain has a neuropathic component, treat with adjuvant analgesics, such as anticonvulsants, antidepressants, and topical local anesthetics. **EB:** *First-line analgesics for neuropathic pain belong to the adjuvant analgesic group and include anticonvulsants, antidepressants, and some topical local anesthetics. Analgesic efficacy with opioids in chronic neuropathic pain is inconclusive (Gilron, Baron, & Jensen, 2015; Dowell, Haegerich, & Chou, 2016; Elliot, Simpson, & DiMaggio, 2018).*

▲ Administer a nonopioid analgesic for mild to moderate chronic pain and as a component of the treatment for all levels of pain for clients with cancer pain. **CEB:** *Nonopioids, such as acetaminophen and nonsteroidal antiinflammatory drugs (NSAIDs), are first-line analgesics for the treatment of mild and moderate pain conditions (e.g., osteoarthritis pain) (Dowell, Haegerich, & Chou, 2016). Consider adding nonopioid analgesics such as acetaminophen and NSAIDs for cancer pain, provided comorbidities and other risks do not*

prevent the use of these analgesics; NSAIDs are used cautiously, especially when used chronically, because many cancer patients may be at high risk for renal, gastrointestinal (GI), or cardiac toxicities; thrombocytopenia; or bleeding problems (National Comprehensive Cancer Network [NCCN], 2017).

- Recognize that opioid therapy may be indicated for some clients experiencing chronic pain. **EB:** *Opioids are often used in the management of moderate to severe chronic cancer pain. Opioid initiation for chronic, noncancer pain is controversial because of the limited data on long-term efficacy and safety. Opioid therapy may be considered with careful client selection when the benefits for pain control and function outweigh client risk (Chou et al, 2015; APS, 2016; Dowell, Haegerich, & Chou, 2016; Pasero et al, 2016).*
- Administer analgesics around the clock for continuous pain and as needed (PRN) for intermittent or breakthrough pain as may be experienced by clients with cancer pain. **EB:** *More than one in two clients with cancer pain also experience breakthrough cancer pain, and if pain is present most of the day, the use of PRN medications alone will lead to periods of undermedication and poor pain control and to periods of excessive medication and adverse effects (Deandrea et al, 2014; APS, 2016).*
- Long-acting or extended release opioids may be indicated for patients with cancer or with chronic non-cancer pain if patients require the regular use of short-acting opioids, and receive adequate relief with them. **EB:** *Controlled-release preparations are helpful because the long duration lessens the severity of end-of-dose pain, decreases analgesic gaps, and allows patients to sleep during the night (APS, 2016).*
- At regular intervals, assess inpatient clients with chronic pain for opioid-related adverse events and include frequent assessment of pain level, assessment of respiratory status (including rate, rhythm, noisiness, and depth), and systematic assessment of sedation level using a sedation scale. **EB:** *Tolerance to opioid-induced respiratory depression usually develops within a week of regular daily opioid dosing, making this side effect less likely to occur in those who are opioid tolerant than those who are not tolerant; however, opioid-tolerant clients are at similar risk for respiratory depression when they misuse opioids, are admitted to the hospital for surgery, or receive more than their usual opioid dose to treat an acute condition, or receive concomitant sedating medications (APS, 2016; Jungquist et al, 2016).*
- During outpatient follow-up, assess clients receiving opioids for risk factors that may increase opioid-related harm. **EB:** *Clients who are receiving higher opioid doses, prescribed concurrent benzodiazepines, have cognitive impairment that could lead to accidental ingestion of excess opioids, mental health disorders that place a client at greater risk for suicide, or a history of SUD are at greater risk for opioid overdose. Take-home naloxone for the treatment of opioid-induced respiratory depression is recommended by numerous federal, state, and professional organizations (Coe & Walsh, 2015).*
- Provide the client with a stool softener and stimulant to prevent/treat opioid-related constipation. Ask about other opioid-related side effects including nausea, pruritus, lack of appetite, and changes in rest and sleep. **EB:** *Although clients may develop tolerance to nausea, pruritus, and other opioid side effects, they do not develop tolerance to opioid-induced constipation. A study of 489 people on long-term opioids revealed varying utilization and responses to laxatives continues to add to the burden of chronic pain (Coyne et al, 2015; Coyne, Bobb, & DiMaggio, 2018).*
- In addition to administering analgesics, support the client's use of nonpharmacological methods to help control pain, such as distraction, imagery, relaxation, and application of heat and cold. **EBN:** *Evidence suggested efficacy and satisfaction when complementary therapies are integrated into pain treatment plans of older adults (Bruckenthal, Marino, & Snelling, 2016).*

▲ **EB:** Cognitive behavioral (mind–body) strategies can restore the client's sense of self-control, personal efficacy, and active participation in his or her own care (Broderick et al, 2014). **EB:** *Motivational interviewing, a counseling method that aims to resolve a client's ambivalence about behavior change, may improve chronic pain treatment adherence, but more study is needed to determine whether it will improve pain intensity and function (Alperstein & Sharpe, 2016).* **EB:** *Interdisciplinary outpatient rehabilitation using physical therapy, occupational therapy, and cognitive behavioral therapy can significantly improve function in people with chronic pain (Kurklinsky et al, 2016).*

• Teach and implement nonpharmacological interventions when pain is relatively well controlled with pharmacological interventions. **EB:** *Pain causes cognitive impairment (Baker et al, 2017).*

▲ Encourage the client to plan activities around periods of greatest comfort whenever possible. **EB:** *Some literature supported the use of pacing (a cognitive behavioral therapy strategy), which is an active self-management strategy in which individuals learn to balance activity and rest for the purpose of increasing function (Andrews et al, 2015).*

▲ Explore appropriate resources for management of pain on a long-term basis (e.g., hospice, pain care center). **EB:** *Outpatient pain management resources must be identified to ensure appropriate chronic pain management. A telecare collaborative management study demonstrated that participants with chronic musculoskeletal pain who received telecare management monthly for 1 year experienced at least 30% improvement in pain scores after 12 months and improved secondary pain (Kroenke et al, 2014).*

▲ If the client has progressive cancer pain, assist the client and family with handling issues related to death and dying and provide access to palliative care programs and hospice services. **CEB:** *In a study by Temel et al (2010), clients with non-small cell lung cancer who received early palliative care intervention had significant improvements in quality of life and mood, less aggressive care at the end of life, and longer survival.* **EB:** *Hui et al (2014) reported that in a study of advanced cancer clients, those who were referred to outpatient palliative care had improved end-of-life care compared with those who received inpatient palliative care.*

Pediatric

• Assess for the presence of pain using a valid and reliable pain scale based on age, cognitive development, and the child's ability to provide a self-report. **EBN:** *Scales that depict faces at various levels of pain intensity are commonly used in young children and have been shown to be reliable and valid in children as young as 3 years old (Tobias, 2014).* **CEB:** *Behavioral tools such as the Face, Legs, Activity, Cry, Consolability (FLACC) Scale may be used to assess pain in infants and children who cannot provide a self-report (Crellin et al, 2015).*

▲ Manage chronic pain children, infants, and neonates with an interdisciplinary and multimodal approach. **EB:** *There is a lack of randomized controlled trials among pediatric patients to identify the best approach to the treatment of pain in this age group. Expert consensus recommends treatment using an interdisciplinary approach, including physical therapies and cognitive behavioral therapy, and when pharmacological approaches are needed, a multimodal pharmacological approach, using medications from a variety of classes, is recommended (Mathew, Kim, & Zempsky, 2016; Bruce et al, 2017).*

• Use a variety of nonpharmacological analgesic interventions to address chronic pain in pediatric clients. **EBN:** *Complementary therapies such as cognitive behavioral strategies, mindfulness-based approaches, and other nonpharmacological approaches may play an important role in chronic pain management in children and adolescents (van der Veek et al,*

2013; Song et al, 2014; Bruce et al, 2017).

Geriatric

▲ An older client's report of pain should be taken seriously and assessed and treated. **EB:** *Chronic pain decreases quality of life, and elderly people with chronic pain report poorer health and decreased mobility and feel more sadness, loneliness, and fatigue, than those without chronic pain (Rapo-Pylkkö, Haanpää, & Liira, 2016). Chronic pain in the elderly is associated with an increase in physical, social, and psychological frailty (Coelho et al, 2017).* **EBN:** *Among the elderly, the presence of severe daily pain is positively correlated with the presence of depression and the frequency of falls and fatigue (Crowe et al, 2017).*

• When assessing pain, speak clearly, slowly, and loudly enough for the client to hear, ensure hearing aids and glasses are in place as appropriate; enlarge pain scales and written materials, and repeat information as needed. **EB:** *Older clients often have multiple sensory deficits, including vision and hearing difficulties, which can affect cognition, lead to loneliness and isolation, and contribute to declines in social interactions and relationships (Correia et al, 2016; Humes & Young, 2016; Stephan et al, 2017).*

• Handle the client's body gently and allow the client to move at his or her own speed. **EB:** *Older adults are particularly susceptible to injury during care activities. Age-related skeletal muscle changes result in weakness and muscle loss, placing patients at risk for injuries. Slow walking and turns may preserve muscle mass and strength in the trunk and limbs, which may enable continued independence (Araki et al, 2017).*

▲ Use nonpharmacological approaches including physical therapy, exercise, or other movement-based programs as the core components to persistent pain management in the older adult. **EB:** *Physical and occupational rehabilitation, behavioral approaches, and movement-based interventions tailored to the older person's needs and capabilities have been shown to be effective and should be used to treat chronic pain when possible (Makris et al, 2014; Reid, Eccleston, & Pillemer, 2015).*

▲ When pharmacological measures are needed to address chronic pain in the elderly, use a multimodal approach, including nonopioid analgesics for mild to moderate pain. **CEB:** *Acetaminophen (maximum dosage 3000 mg/day) is preferred and recommended, unless contraindicated, as first-line therapy for older persons with persistent pain; NSAIDs (preferably in topical form because there is less system absorption than in the oral form) should be used short term and with extreme caution because of the higher GI, cardiovascular, and renal adverse effects; if a systemic NSAID is needed, naproxen has the safest cardiac profile (Makris et al, 2014; Reid, Eccleston, & Pillemer, 2015).*

▲ Use opioids cautiously in the older client with moderate to severe pain. **CEB:** *When pain is not responsive to other treatment modalities, or when persistent pain is associated with increased functional impairment or decreased quality of life, an opioid trial may be initiated, starting with a short-acting low-dose opioid, carefully and slowly titrating to attain therapeutic goal, with assessment of response and effectiveness (Makris et al, 2014; Reid, Eccleston, & Pillemer, 2015).*

▲ Monitor for signs of depression in older clients and refer to specialists with relevant expertise. **EB:** *Depression is often associated with pain and decreased levels of independence with activities of daily living in the older client. Treatment has been demonstrated to decrease pain and improve functional abilities (Tarakci, Zenginler, & Kaya Mutlu, 2015).*

Multicultural

▲ Assess for pain disparities among racial and ethnic minorities. **EB:** *Individuals of*

ethnic and racial minorities often receive fewer treatment options and less effective pain treatment than others because of barriers imposed by health care professionals and health care systems (Tait & Chibnall, 2014).

▲ Assess for the influence of cultural beliefs, norms, and values on the client's perception and experience of pain. **EB:** *The large variations in chronic back pain prevalence and prognosis across different countries may be influenced by culturally determined health beliefs (Henschke et al, 2016).*

▲ Use a family-centered approach to care. **EB:** *Involving the family in care through early regular communication and decision-making may reduce anxiety, alleviate uncertainty, and improve coping strategies (Michael et al, 2014).*

▲ Use culturally relevant pain scales to assess pain in the client. **CEB:** *Clients from minority cultures may express pain differently than clients from the majority culture. The FPS-Revised was shown to be preferred over other self-report pain rating tools in older minority adults (Ware et al, 2006) and in Chinese adults (Li, Herr, & Chen, 2009). A later study demonstrated that the Iowa Pain Thermometer was the preferred tool in older Chinese adults (Li, Herr, & Chen, 2009).*

Home Care

• The interventions previously described may be adapted for home care use. Refer to the Nursing Interventions and *Rationales* in the care plan for Acute **Pain.**

Client/Family Teaching and Discharge Planning

Note: To avoid the negative connotations associated with the words "drugs" and "narcotics," use the term "pain medicine" when teaching clients.

• Discuss the various discomforts encompassed by the word "pain" and ask the client to give examples of previously experienced pain. Explain the pain assessment process and the purpose of the pain rating scale. **EB:** *It is often difficult for clients to understand the concept of pain and describe their pain experience. In a survey, must participants were able to recognize the term narcotic, but very few recognized or understood the term "opioid"(Wallace et al, 2013).*

• Teach the client that if the pain level is consistently above the comfort-function goal, the client should take action that decreases pain or should notify a member of the health care team so that effective pain management interventions may be implemented promptly. (See information on teaching clients to use the pain rating scale.) **EB:** *The use of comfort-function goals provides direction for the treatment plan. Changes are made according to the client's response and achievement of the goals of recovery or rehabilitation (Boswell & Hall, 2017).*

• Provide educational materials on various aspects of pain control to improve client understanding of pain and pain-related interventions. **EB:** *Written materials and other educational tools assist in improving clients' knowledge related to pain management. In knee replacement clients, the use of an educational pamphlet and a compact disc was associated with decreased postoperative pain and increased participation in physical rehabilitation (Chen et al, 2014).*

• Discuss and evaluate the client's understanding about the total plan for pharmacological and nonpharmacological treatment, including the medication plan, the maintenance of a pain diary, and the use of supplies and equipment. **CEB:** *Appropriate instruction increases the accuracy and safety of medication administration (Vaismoradi, Jordan, & Kangasniemi, 2015).*

• Reinforce the importance of taking pain medications to maintain the comfort-

function goal. **EBN:** *Teaching clients to stay on top of their pain and prevent it from getting out of control will improve the ability to accomplish the goals of recovery (APS, 2016; Eksterowicz & DiMaggio, 2018).*

▲ Reinforce that when prescribed, opioids for pain relief are an appropriate part of their multimodal pain treatment plan. **EB:** *Taking opioids only as directed, avoiding alcohol, and talking with the health care provider when pain is poorly controlled are strategies that will lessen the risks for OUD or major opioid-related adverse effects such as respiratory depression and arrest (Costello, 2015).*

▲ Reinforce the importance of safe storage of opioid medications out of the reach of others, and to responsibly dispose of any unused opioids. **EB:** *Community medication "take back" days and drop boxes are becoming increasingly popular. Encourage clients/families to check community resources (Hawk, Vaca, & D'Onofrio, 2015).*

• Demonstrate the use of appropriate nonpharmacological approaches in addition to pharmacological approaches for helping control pain, such as application of heat and/or cold, distraction techniques, relaxation breathing, visualization, rocking, stroking, listening to music, and watching television. Teach these methods when pain is relatively well controlled, because pain interferes with cognition. **EB:** *Nonpharmacological interventions are used to complement pharmacological interventions (Bruckenthal, Marino, & Snelling, 2016).*

▲ Emphasize to the client the importance of participating in a structured, individualized pacing activity and taking rest breaks before they are needed. **EB:** *In a study of adults with chronic pain and overactive behavior, a two-week inpatient program involving education on pain neurophysiology, pacing, activity scheduling, and gym sessions showed that tailored activity pacing intervention provides more pain relief and less fatigue (Andrews et al, 2015).*

• Teach nonpharmacological methods when pain is relatively well controlled. **EB:** *Pain interferes with cognition (Baker et al, 2017).*

Chronic Pain syndrome

Mary Beth Flynn Makic PhD, RN, CCNS, FAAN, FNAP

NANDA-I

Definition

Recurrent or persistent pain that has lasted at least 3 months and that significantly affects daily functioning or well-being.

Defining Characteristics

Anxiety (00146); constipation (00011); deficient knowledge (00126); disturbed sleep pattern (00198); fatigue (00093); fear (00148); impaired mood regulation (00241); impaired physical mobility (00085); insomnia (00095); obesity (00232); social isolation (00053); stress overload (00177)

Related Factors

To be developed

NIC, NOC, Client Outcomes, Nursing Interventions and *Rationales,* Client/Family Teaching and Discharge Planning, and References

Refer to care plan for Acute **Pain** and Chronic **Pain.**

Labor Pain

Nichol Chesser RN, CNM, DNP

NANDA-I

Definition

Sensory and emotional experience that varies from pleasant to unpleasant, associated with labor and childbirth.

Defining Characteristics

Alteration in blood pressure; alteration in heart rate; alteration in muscle tension; alteration in neuroendocrine functioning; alteration in respiratory rate; alteration in sleep pattern; alteration in urinary functioning; decrease in appetite; diaphoresis; distraction behavior; expressive behavior; facial expression of pain; increase in appetite; narrowed focus; nausea; pain; perineal pressure; positioning to ease pain; protective behavior; pupil dilation; self-focused; uterine contraction; vomiting

Related Factors

To be developed

Associated Condition

Cervical dilation; fetal expulsion

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Client Satisfaction: Pain Management, Comfort Status; Knowledge: Pain Management, Pain Control, Pain Level

Example NOC Outcomes with Indicators

Labor pain management as evidenced by the following indicators: recognizes pain onset, discusses pain treatment options with health care professional, monitors therapeutic effects of analgesic, uses effective coping strategies, reports changes in pain symptoms to health care provider. (Rate the outcome and indicators of **Labor Pain:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

• Recognize pharmacological and nonpharmacological interventions to address labor pain
• Demonstrate coping strategies to address labor pain
• Verbalize pain relief effectiveness throughout the labor process

NIC (Nursing Intervention Classification)

Suggested NIC Outcomes

Acute, Analgesic Administration: Intraspinal, Analgesic Administration, Aromatherapy, Dance Therapy, Distraction, Environmental Management: Comfort, Guided Imagery, Massage, Medication Administration: Intraspinal, Meditation Facilitation, Relaxation Therapy, Transcutaneous Electrical Nerve Stimulation

Example NIC Activity—Acute Pain Management

Explore the client's knowledge and beliefs about labor pain including cultural influences; monitor pain using a valid and reliable rating tool

Nursing Intervention and *Rationales*

• Initial assessment and interview, if the client is experiencing pain, conduct and document a comprehensive pain assessment, using appropriate pain assessment tools. **EB/CEB:** *A pain assessment tool consists of obtaining all the information that a client can provide to help individualize a pain management plan of care. Information includes location, intensity, characteristics, coping, and desire for pharmacological or nonpharmacological interventions. Pain level, as evidenced by client self-report of coping or not coping with pain from labor contractions, is considered the best indicator of pain presence and intensity (McCaffery, Herr, & Pasero, 2011; Merskey 1979). Use an evidence-based coping algorithm to help the client find the best means available to cope well with labor pain (Roberts et al, 2010).*
• *Observe for nonverbal pain assessment such as grimacing, lackluster eyes, and fixed or scattered movements.*
• Assess pain on pain level tool such as the 0 to 10 numerical pain rating scale (NRS) if appropriate or alternatively use the Coping with Labor Algorithm (Roberts et al, 2010). Discuss with client the desire for pain management for this labor, past experiences with labor and effectiveness of pain management techniques employed at that time, concerns about pain and its treatment, and information needs (e.g., pain coping techniques that are both analgesic and nonpharmaceutical). **EBN:** *Obtaining individualized history and goals for coping with pain during labor and birth helps identify how to better guide a client through childbirth and increase client satisfaction with the process. Women's satisfaction with the childbirth process is not directly correlated with pharmacological pain relief, but it is greatly enhanced by continuity of care and care provider presence (Van der Gucht & Lewis, 2015).*
• Goal is for the client to manage labor pain from admission until delivery of infant with either natural childbirth and associated pain management techniques, or pharmaceutical measures to reduce pain experience. **EB:** *For the client who is able to self-report, when using a self-report pain tool, caution must be used because a high or low score is not always associated with lack of coping or suffering when used for labor pain (Simkin & Klein, 2017).*
• Based on the client's ability to cope with labor pain, discuss with client pain management options, including pharmacological and nonpharmacological interventions. **EB:** *Implement strategies or request orders to help client cope with labor pain. This may include massage, movement (such as rocking or swaying, sitting on birthing ball, and position changes), rhythmic breathing, relaxation techniques, aromatherapy, intradermal*

water blocks, intravenous (IV) narcotics, transcutaneous electrical nerve stimulus (TENS), nitrous oxide, hydrotherapy, and neuraxial anesthesia (Gilbert, 2017). **CEBN:** *A study found patients self-identified nonpharmacological coping strategies, such as relaxation techniques, distraction, imagery, and breathing techniques, to assist with labor pain (Niven & Gijsbers, 1996).*

- Based on the client's ability to cope, assess the physiological-natural process of labor, physical environment, and emotional/psychosocial dynamics (Roberts et al, 2010). **CBE:** *Labor pain is a physical sensation of pain but also psychoemotional and spiritual (Simkin & Bolding, 2004). Determining the best way to help a laboring woman cope encompasses physiological, physical, emotional, spiritual, and psychosocial assessments (Roberts et al, 2010).*
- Based on the client's ability to cope, offer intervention (either nonpharmacological or pharmacological). **EBN:** *Nonpharmacological pain interventions are low cost and low risk. They are also directed at increasing comfort during labor, preventing suffering, and allowing women to cope with labor pain (Simkin & Klein, 2017). Nonpharmacological pain measures can be used by themselves or in combination with pharmacological intervention during labor. If the client is unable to cope with labor by using nonpharmacological pain relief measures, offering pharmacological pain relief measures is appropriate. A client may be able to proceed through labor and delivery without pain medication but should never be denied medication if she requests it (Simkin & Klein, 2017).*
- Nonpharmacological pain relief measures are low-risk and low-resource interventions (Simkin & Klein, 2017). These approaches can encompass the physical sensation of pain and the psychoemotional and spiritual components of care. By addressing all aspects of client needs (physical, emotional, and spiritual), suffering can be reduced during labor (Simkin & Klein, 2017).
    - Ambulation/rocking/swaying is a safe and effective coping measure for labor pain. This is usually a client-initiated response to labor pain; however, caregivers can encourage women to ambulate or change position to ease pain or allow clients to cope better with labor pain.
    - Hydrotherapy either as immersion in water or bathing can be used to promote relaxation, decrease anxiety, help client cope with pain, and to possibly correct uterine contraction dystocia (Benfield et al, 2010). **CEBN/EBN:** *Water labor may be indicated for women to help with relaxation during labor. This may enable the client to proceed through labor without pharmacological intervention because it may reduce anxiety around labor and contraction pain (Benfield et al, 2010; Nutter et al, 2014). Water temperature must be regulated to stay between 34°C and 45°C and ideally be at 37°C to have the least effect on the maternal cardiovascular and endocrine system (Benfield et al, 2010).*
    - TENS is a small, handheld device that transmits low-voltage electrical impulses to the skin (Simkin & Klein, 2017). The device suppresses the conduction of pain through pain fibers by using small electrical impulses (Shahoei et al, 2017). **EBN:** *The use of this device is controlled by the client herself and can vary the pattern and intensity of the cutaneous electrical impulse depending on the contraction pattern and pain (Simkin & Klein, 2017). The use of TENS has no adverse side effects and can improve overall satisfaction with the labor and birth experience when used correctly (Shahoei et al, 2017).*
- Pharmacological measures for pain relief are high resource and high risk; they require professional training for administration, incur cost, and have a greater risk to mother and baby (Simkin & Klein, 2017).
- Nitrous oxide is a blend of 50% nitrous oxide with 50% oxygen. The use of nitrous

oxide may not alleviate pain, but it may help with satisfaction of the birth experience (American College of Nurse-Midwives [ACNM], 2010). **EBN:** *Nitrous should be avoided in clients with vitamin B_{12} deficiency or MHFR mutation/deficiency (Hays, 2017). Most common side effects of nitrous oxide are nausea and vomiting and respiratory depression (Likis et al, 2014). Correct usage of nitrous is needed for optimum efficacy; it must be initiated prior to contraction pain because the peak onset is 50 seconds from initial inhalation (Collins et al, 2018).*

- IV medications for pain management are an alternative for some women who do not desire an epidural; IV medications are generally opioids. These are advantageous because they are easy to administer, are widely available, and are less invasive than neuraxial techniques of pain relief (i.e., an epidural) *(Collins et al, 2018).* **EBN:** *Side effects are common and include nausea, vomiting, and drowsiness (Collins et al, 2018).*
- Epidural, combined spinal-epidural (CSE), and dural puncture epidural (DPE) are appropriate for laboring women when requested by the client (unless there is a contraindication). **CBE:** *Contraindications to neuraxial anesthesia include coagulopathy, infection of the lower back, and increased intracranial pressure (Leffert, Lee, & Schweamm, 2013).* **EBN:** *During placement of neuraxial anesthesia maternal oxygen saturation and heart rate should be measured continuously. Blood pressure should be measured every 5 minutes, and fetal heart rate should be monitored at least before and after administration according to institution guidelines. Continue to monitor maternal blood pressure, pain control, motor function, and sensory levels at regular intervals to make sure the anesthesia is working properly. Also, continue to document patient's vital signs and pain assessment (Collins et al, 2018).*
- Account for clients' abilities to cope with labor pain regarding their psychosocial, cultural, and spiritual backgrounds. A woman's positive perceptions of how she will be able to cope with labor are associated with reduced anxiety, pain, and intervention during labor (Van der Gucht & Lewis, 2015; Simkin & Klein, 2017). **CBE:** *Coping has many facets, including cognitive, behavioral, and emotional aspects (Abushaikha, 2007). How a woman copes with pain during labor includes factors such as personality traits, type of stress, and personal preference; coping methods encompass physiological, psychological, cognitive, and spiritual methods (Abushaikha, 2007). Each method of coping is an individual decision. Culturally learned values and attitudes may greatly influence how women cope with acute labor pain (Lowe, 2002).*
- *Document pain assessment and interventions and coping assessment and interventions to facilitate labor pain management through the continuum of the women's labor experience (Chajut et al, 2014).*

Impaired Parenting

Kimberly Silvey MSN, RN, RAC-CT

NANDA-I

Definition

Inability of the primary caregiver to create, maintain, or regain an environment that promotes the optimum growth and development of the child.

Defining Characteristics

Infant or Child

Behavioral disorders; delay in cognitive development; diminished separation anxiety; failure to thrive; frequent accidents; frequent illness; history of abuse; history of trauma; impaired social functioning; insufficient attachment behavior; low academic performance; run away from home

Parental

Abandonment of child; failure to provide safe home environment; decrease in ability to manage child; decrease in cuddling; deficient parent-child interaction; frustration with child; hostility; inadequate child health maintenance; inappropriate care-taking skills; inappropriate child care arrangements; inappropriate stimulation; inconsistent behavior management; inconsistent care; inflexibility in meeting needs of child; neglects needs of child; perceived inability to meet child's needs; perceived role inadequacy; punitive; rejection of child; speaks negatively about child

Related Factors

Infant or Child

Prolonged separation from parent; temperament conflicts with parental expectations

Parental

Alteration in sleep pattern; conflict between partners; depression; failure to provide safe home environment; father of child uninvolved; inability to put child's needs before own; inadequate child care arrangements; ineffective communication skills; ineffective coping strategies; insufficient access to resources; insufficient family cohesiveness; insufficient knowledge about child development; insufficient knowledge about child health maintenance; insufficient knowledge about parenting skills; insufficient parental role model; insufficient prenatal care; insufficient problem-solving skills; insufficient resources; insufficient response to infant cues; insufficient social support; insufficient transportation; insufficient valuing of parenthood; late-term prenatal care; low self-esteem; mother of child uninvolved; nonrestorative sleep pattern; preference for physical punishment; role strain; sleep deprivation; social isolation; stressors; unrealistic expectations

At-Risk Population

Infant or Child

Developmental delay; difficult temperament; gender other than desired; prematurity

Parental

Change in family unit; closely spaced pregnancies; difficult birthing process; economically disadvantaged; high number of pregnancies; history of abuse; history of being abusive; history of mental illness; history of substance misuse; insufficient cognitive readiness for parenting; legal difficulty; low education level; multiple births; relocation; single parent; unemployment; unplanned pregnancy; work difficulty; young parental age

Associated Condition

Infant or Child

Alteration in perceptual abilities; behavioral disorder; chronic illness; disabling condition

Parental

Alteration in cognitive functioning; disabling condition; physical illness

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Abuse Cessation; Abuse Protection; Abuse Recovery: Abusive Behavior Self-Restraint; Child Development (all); Coping; Family Functioning; Family Social Climate; Knowledge: Child Physical Safety; Neglect Recovery; Parent-Infant Attachment; Parenting Performance; Psychosocial Safety; Role Performance; Social Support

Example NOC Outcome with Indicators

Parenting Performance: Psychosocial Safety as evidenced by the following indicators: Fosters open communication/Recognizes risks for abuse/Uses strategies to eliminate risks for abuse/Selects appropriate supplemental caregivers/Uses strategies to prevent high-risk social behaviors/Provides required level of supervision/Sets clear rules for behavior/Maintains structure and daily routine in child's life. (Rate the outcome and indicators of **Parenting Performance: Psychosocial Safety:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Initiate appropriate measures to develop a safe, nurturing environment
- Acquire and display attentive, supportive parenting behaviors and child supervision
- Identify appropriate strategies to manage a child's inappropriate behaviors
- Identify strategies to protect child from harm and/or neglect and initiate action when indicated

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Abuse Protection Support: Child; Attachment Promotion; Caregiver Support; Developmental Enhancement: Adolescent, Child; Environmental Management: Family Integrity Promotion; Impulse Control Training; Infant Care; Parent Education: Adolescent, Childrearing Family, Infant; Parenting Promotion; Role Enhancement; Substance Use Prevention, Treatment; Teaching: Infant Stimulation; Toddler Nutrition; Toddler Safety

Example NIC Activities—Family Integrity Promotion

Identify typical family coping mechanisms; Determine typical family relationships for each family; Counsel family members on additional effective coping skills for their own use; Assist family with conflict resolution; Monitor current family relationships; Facilitate a tone of togetherness within and among the family; Encourage family to maintain positive relationships; Refer for family therapy, as indicated

Nursing Interventions and *Rationales*

- Use the Parenting Sense of Competence (PSOC) scale to measure parental self-efficacy. **EB:** *The PSOC contains three useful factors that reflect satisfaction with the parental role, parenting efficacy, and interest in parenting. Mothers and fathers will differ in parenting of their children and their sense of competence (Karp et al, 2015).*
- Examine the characteristics of parenting style and behaviors. Consider dysfunctional child-centered and parent-centered cognitions as potentially critical correlates of abusive behavior. **EBN:** *Identifying possible risk factors for abuse can help nursing and parents reduce the risk of abusive behavior (Ben-Natan et al, 2014).*
- ▲ Institute abuse/neglect protection measures if evidence exists of an inability to cope with family stressors or crisis, signs of parental substance abuse are observed, or a significant level of social isolation is apparent. **EBN:** *Encouraging parents to be involved with social networking can help reduce stressors and assist with coping in a crisis (Bennett et al, 2017).*
- ▲ For a mother with a toddler, assess maternal depression. Make the appropriate referral. **EB:** *Helping mothers identify systems of depression through self-assessment or home visits is beneficial for both mother and toddler (Suplee et al, 2014).*
- Appraise the parent's resources and the availability of social support systems. Determine the single mother's particular sources of support, especially the availability of her own mother and partner. Encourage the use of healthy, strong support systems. **EB:** *Clinicians should help mothers evaluate what resources and support they have and encourage healthy relationships (Letourneau et al, 2013). Provide education to at-risk parents on behavioral management techniques such as looking ahead, giving good instructions, providing positive reinforcement, redirecting, planned ignoring, and instituting time-outs.* **EB:** *Parents with mental health issues need education to help them better care for their children (Houlihan et al, 2013).*
- Promotion of better quality relationships between parents and children is an effective strategy that can lead to enhanced learning. Good quality parenting leads to improved cognitive and social skills for children. **EB:** *Promoting quality relationships promotes optimal health and development (Titze et al, 2014).*
- Support parents' competence in appraising their infant's behavior and responses and aim supportive interventions to minimize parents' experiences of strain or stress. **EBN:** *Encourage and support the presence of the parents with the care of the infant (Ottosson & Lantz, 2017).*
- Model age-appropriate and cognitively appropriate caregiver skills by doing the following: communicating with the child at an appropriate cognitive level of development, giving the child tasks and responsibilities appropriate for age or

functional age/level, instituting safety considerations such as the use of assistive equipment, and encouraging the child to perform activities of daily living as appropriate. **EBN:** *Children learn from the interactions with family, parents, and even medical staff (Rich et al, 2014).*

• Encourage mothers to understand and capitalize on their infant's capacity to interact, particularly in the early months of life. **EBN:** *Mother–infant bonding is very important during the first months of life (Lee et al, 2013).*

▲ Provide programs for homeless mothers with severe mental illness who have lost physical custody of their children. **EB:** *Providing education and support to homeless mothers helps empower them (Sleed et al, 2013).*

▲ Provide a recovery program that includes instruction in parenting skills and child development for mothers who are addicted to cocaine. **EB:** *Women need additional assistance for recovery from substance abuse and need to understand the effect that it will have on their child (McKeever et al, 2014).*

• Refer to Readiness for enhanced **Parenting** for additional interventions.

Multicultural

• Acknowledge that value conflicts from acculturation stresses may contribute to increased anxiety and significant conflict with children. **CEBN:** *Help parents develop a plan to address conflicts within the family (Kim, 2011).*

• Clarify parents' feelings, expectations, perceptions, and availability regarding participation in the care of their sick child. **EBN:** *Cultural differences regarding parent participation in the care of ill or hospitalized children should be considered (Mutair et al, 2014).*

• Carefully assess the meaning of terms used to describe health status when working with Native Americans. **EB:** *Health care providers should allow clients to participate in spiritual care according to their beliefs (Hodge & Wolosin, 2014).*

• Provide support for Chinese families caring for children with disabilities. **EBN:** *The care of the sick in China is based on Old World beliefs. It is important to ensure that all aspects of cultural beliefs are included in care (Zhang et al, 2014).*

• Facilitate modeling and role playing to help the family improve parenting skills. **EB:** *Families need to be able to practice parenting in a safe setting (Franks et al, 2013).*

Home Care

• The interventions previously described may be adapted for home care use.

• Assess parenting stress at each home visit to provide appropriate support and anticipatory guidance to families of children with a chronic disease. **EB:** *Assessing parental stress in the home assists the health care provider in identifying interventions that can be implemented at home (Gabler et al, 2014).*

▲ Assess the single mother's history regarding childhood and partner abuse and current status regarding depressive symptoms, abusive parenting attitudes (lack of empathy, favorable opinion of corporal punishment, parent–child role reversal, and inappropriate expectations). Refer for mental health services as indicated. **EB:** *A mother's history can contribute to the stress and the care of her children (Boeckel et al, 2014).*

Client/Family Teaching and Discharge Planning

• Consider individual and/or group-based parenting programs for teenaged mothers. **EB:** *Offering parenting programs to teenaged parents helps them to better care for*

their child (Mills et al, 2013).

• Consider group-based parenting programs for parents of children younger than 3 years with emotional and behavioral problems. **EBN:** *A study shows that group-based parenting programs assist both the parent and the children (Kendall et al, 2013).*

• Consider group-based parenting programs for parents with anxiety, depression, and/or low self-esteem. **EBN:** *Parenting programs assist parents in identifying issues they may have and learn through others about goals they can set and ways to achieve them (Roose et al, 2014).*

▲ Refer adolescent parents for comprehensive psychoeducational parenting classes. **EBN:** *Adolescent parenting class helps teens to learn the best ways to care for their infant (Allen et al, 2014).*

• Parent training is one of the most effective interventions for behavior problems in young children. **EBN:** *Parent training programs assist with improving family functioning and interactions (Arkan et al, 2013). Encourage positive parenting: respect for children, understanding of normal development, and creative and loving approaches to meet parenting challenges rather than using anger, manipulation, punishment, and rewards.* **EBN:** *Parenting programs assist parents in identifying issues they may have and learn through others about goals they can set and ways to achieve them (Roose et al, 2014).*

▲ Initiate referrals to community agencies, parent education programs, stress management training, and social support groups. Consider the use of technology and the media. **EB:** *Family use of technology to interact with health care providers can broaden the support that the family can receive (Hanlon-Dearman et al, 2014).*

• Provide information regarding available telephone counseling services and Internet support. **EBN:** *Using the Internet allows parents to communicate with and gain support from others all over the world (Niela-Vilén et al, 2014). Refer to the care plans for Risk for disproportionate **Growth**, Risk for delayed **Development**, Risk for impaired **Attachment**, and Readiness for enhanced **Parenting** for additional teaching interventions.*

Readiness for enhanced Parenting

Kimberly Silvey MSN, RN, RAC-CT

NANDA-I

Definition

A pattern of providing an environment for children to nurture growth and development, which can be strengthened.

Defining Characteristics

Children express desire to enhance home environment; parent expresses desire to enhance parenting; parent expresses desire to enhance emotional support of children; parent expresses desire to enhance emotional support of other dependent person

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Child Development; Knowledge: Child Physical Safety; Parenting Performance; Parenting: Psychosocial Safety

Example NOC Outcome with Indicators

Parenting Performance as evidenced by the following indicators: Provides preventive and episodic health care/Stimulates cognitive and social development/Stimulates emotional and spiritual growth/Empathizes with child/Expresses satisfaction with parental role/Expresses positive self-esteem. (Rate the outcome and indicators of **Parenting Performance:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes

demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client/Family Will (Specify Time Frame)

- Affirm desire to improve parenting skills to further support growth and development of children
- Demonstrate loving relationship with children
- Provide a safe, nurturing environment
- Assess risks in home/environment and take steps to prevent possibility of harm to children
- Meet physical, psychosocial, and spiritual needs or seek appropriate assistance

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Anticipatory Guidance; Attachment Promotion; Developmental Enhancement: Adolescent; Child; Family Integrity Promotion: Childbearing Family; Infant Care; Newborn Care; Parent Education: Adolescent, Childrearing Family, Infant; Parenting Promotion; Teaching: Infant Stimulation

Example NIC Activities—Parenting Promotion

Assist parents to have realistic expectations appropriate to developmental and ability level of child; Assist parents with role transition and expectations of parenthood

Nursing Interventions and *Rationales*

- Use family-centered care and role modeling for holistic care of families. **EBN:** *Incorporating family-centered care helps enhance the parents' role in caring for their child (Cady et al, 2015).*
- Assess parents' feelings when dealing with a child who has a chronic illness. **EB:** *Nursing should assist parents (Byczkowski et al, 2014) in identifying their feelings about their child to help the parents develop coping mechanisms.*
- Promote low-technology interventions, such as massage and multisensory interventions (maternal voice, eye-to-eye contact, and rocking) and music to reduce maternal and infant stress and improve mother–infant relationship. **EB:** *When mother sing to their infants it can calm the infant and make them feel safe (de l'Etoile et al, 2017). Support kangaroo care for infants at risk at birth; keep infants in an upright position in skin-to-skin contact.* **EB:** *Kangaroo care helps the mother and infant to not only start bonding but also assist in the infant's growth and development (Shourangiz Beiranvand et al, 2014; Gavhane, Eklare, & Mohammad, 2016).*
- When the person who is ill is the parent, use family-centered assessment skills to determine the effect of an adult's illness on the child, and then guide the parent through those topics that are most likely to be of concern. **EB:** *Ill parents can have a negative effect on the life of a child. It is important to help the parent to continue in their role as parent the best way possible (Razaz et al, 2014). Provide practical and psychological assistance for parents of clients with psychiatric diagnoses, such as schizophrenia.* **EBN:** *Help parents understand the diagnosis of mental illness and the things they can do to help their child and also help themselves. Parents need to know that they do not have to deal with this alone (Hsiao & Tsai, 2014).*
- Refer to the care plan for Impaired **Parenting** for additional interventions.

Multicultural

• Assess the influence of cultural beliefs, norms, and values on the client's perception of parenting. **EB:** *Understanding the cultural beliefs of the family will assist in parental satisfaction with care (Hamilton et al, 2013).*
• Acknowledge racial and ethnic differences at the onset of care and provide appropriate health information and social support. **EB:** *Acknowledgment of racial and ethnicity issues enhances communication, establishes rapport, and promotes treatment outcomes (Tavallali et al, 2014).*
• Support programs for parents of young children in specific cultural communities. **EBN:** *Parents and children benefit when a support group is incorporated in the care (Thomson-Salo et al, 2017). Clarify parents' feelings, expectations, perceptions, and availability regarding participation in the care of their sick child.* **EBN:** *Cultural differences regarding parent participation in the care of ill or hospitalized children should be considered and incorporated into the care of the child and their parents (Majdalani et al, 2014).*
• Acknowledge and praise parenting strengths noted. **EBN:** *Parents see what they are doing right and are encouraged to continue the behavior (Ludmer et al, 2017).*

Home Care

• The nursing interventions previously described should be used in the home environment with adaptations as necessary. **EB:** *Clinicians should help educate parents on the care the child will need at home and modify to meet the family's needs (Thrasher et al, 2017).*
▲ Refer to a parenting program to facilitate learning of parenting skills. **EBN:** *The study shows that parenting programs can increase parental knowledge and confidence (Kendall et al, 2013).*

Client/Family Teaching and Discharge Planning

• Refer to Client/Family Teaching and Discharge Planning for Impaired **Parenting** for suggestions that may be used with minor adaptations.
• Teach parents home safety: reduction of hot water temperature, proper poison storage, use of smoke alarms, and installation of safety gates for stairs. **EB:** *Education may reduce injury and promote children's home safety (Lehna et al, 2014).*
• Teach parents and young teens conflict resolution by using a hypothetical conflict solution with and without a structured conflict resolution guide. Support self-direction of the families with minimal therapist intervention. **EB:** *Encouraging parent participation in positive-parenting programs can decrease the conflict for parents and teens (Salari et al, 2013).*
• Refer mothers of children with type 1 diabetes for community support in babysitting, child care, or respite. **EB:** *Families raising children with diabetes need to have support and interventions to assist with the care of the child to help reduce the burden of care on the parents (Kobos & Imiela, 2015).*
• Teach families the importance of monitoring television viewing, social media, video gaming, and so forth to limit exposure to violence. **EBN:** *Media violence can be hazardous to children's health, and studies overwhelmingly point to a causal connection between media violence and aggressive attitudes, values, and behaviors in some children (Aragon Neely et al, 2013).* Promotion of better quality relationships between parents and children is an effective strategy that can lead to enhanced learning. Good quality parenting leads to improved cognitive and social skills for children. **EBN:** *Parents have*

a positive effect on their children, which can lead to improved self-confidence and a stronger parent–child relationship (Kim et al, 2015).

- See Impaired **Parenting** for additional references.

Risk for impaired Parenting

Gail B. Ladwig MSN, RN

NANDA-I

Definition

Susceptible to primary caregiver difficulty in creating, maintaining, or regaining an environment that promotes the optimum growth and development of the child, which may compromise the well-being of the child.

Risk Factors

Infant or Child

Prolonged separation from parent; Temperament conflicts with parental expectations

Parental

Alteration in sleep pattern; conflict between partners; depression; failure to provide safe home environment; father of child uninvolved; inability to put child's needs before own; inadequate child care arrangements; ineffective communication skills; ineffective coping strategies; insufficient access to resources; insufficient family cohesiveness; insufficient knowledge about child development; insufficient knowledge about child health maintenance; insufficient knowledge about parenting skills; insufficient parental role model; insufficient parental care; insufficient problem-solving skills; insufficient resources; insufficient response to infant cues; insufficient social support; insufficient transportation; insufficient valuing of parenthood; late-term parental care; low self-esteem; mother of child uninvolved; nonrestorative sleep pattern; preference for physical punishment; role strain; sleep deprivation; social isolation; stressors; unrealistic expectations

At-Risk Population

Infant or Child

Developmental delay; difficult temperament; gender other than desired; prematurity

Parental

Change in family unit; closely spaced pregnancies; difficult birthing process; economically disadvantaged; high number of pregnancies; history of abuse; history of being abusive; history of mental illness; history of substance misuse; insufficient cognitive readiness for parenting; legal difficulty; low educational level; multiple births; relocation; single parent; unemployment; unplanned pregnancy; unwanted pregnancy; work difficulty; young parental age

Associated Condition

Infant or Child

Alteration in perceptual abilities; behavioral disorder; chronic illness; disabling condition

Parental

Alteration in cognitive functioning; disabling condition; physical illness

NOC, NIC, Client Outcomes, Nursing Interventions and *Rationales,* Client/Family Teaching and Discharge Planning, and References

Refer to care plans for Readiness for enhanced **Parenting** and Impaired **Parenting**

Risk for Perioperative Positioning injury

Catherine Kleiner PhD, MSN, BSN

NANDA-I

Definition

Susceptible to inadvertent anatomical and physical changes as a result of posture or positioning equipment used during an invasive/surgical procedure, which may compromise health.

Risk Factors

Immobilization

Associated Condition

Disorientation; edema; emaciation; muscle weakness; obesity; sensoriperceptual disturbance from anesthesia

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Circulation Status; Immobility Consequences: Physiological; Joint Movement; Neurological Status; Respiratory Status; Risk Control; Sensory Function; Skeletal Function; Tissue Integrity: Skin and Mucous Membranes; Tissue Perfusion: Peripheral

Example NOC Outcome with Indicators

Tissue Perfusion: Peripheral as evidenced by the following indicators: Peripheral edema/Localized extremity pain/Skin breakdown/Muscle cramps/Peripheral pulses/Numbness/Tingling/Necrosis. (Rate the outcome and indicators of **Tissue Perfusion: Peripheral:** 1 = severe, 2 = substantial, 3 = moderate, 4 = mild, 5 = none [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Demonstrate unchanged skin condition, with exception of the incision, throughout the perioperative experience
- Demonstrate resolution of redness of the skin at points of pressure within 30 minutes after pressure is eliminated
- Remain injury-free related to surgical positioning, including intact skin and absence of pain and/or numbness associated with surgical positioning
- Demonstrate unchanged or improved physical mobility from preoperative status
- Demonstrate unchanged or improved peripheral sensory integrity from preoperative status

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Circulatory Precautions; Fall Prevention; Neurological Monitoring; Peripheral Sensation Management; Positioning: Intraoperative; Pressure Ulcer Prevention; Risk Identification; Skin Surveillance; Surgical Precautions

Example NIC Activities—Positioning: Intraoperative

Use an adequate number of personnel to transfer client; Maintain client's proper body alignment

Nursing Interventions and *Rationales*

General Interventions for Any Surgical Client

- Assess the client's skin integrity throughout the perioperative process to avoid skin breakdown during surgical/invasive procedures. **EB:** *Developing skin breakdown manifested as a skin tear, pressure ulcer, deep tissue injury, or burn is a significant client complication affected by the duration of surgery and client positioning (National Pressure Ulcer Advisory Panel [NPUAP] and European Pressure Ulcer Advisory Panel [EPUAP], 2014; Van Wicklin, 2017).*
- Recognize that surgery increases a patients risk for skin injury because of the time the patient is immobile for the procedure (Spruce, 2017).

Prevention of Pressure Injuries

- Complete a preoperative assessment to identify patient factors that will increase a patients risk for pressure injuries. This includes physical alterations that may require additional precautions for procedure-specific positioning and to identify specific procedural positioning needs, type of anesthesia, and so on. **EBN:** *Factors to consider when assessing the surgical client to plan for proper positioning are preexisting conditions such as vascular disease or diabetes, range of motion, presence of prostheses and/or fractures, skin condition, advanced age, nutritional status, weight, American Society of Anesthesiologists (ASA) physical status classification, and the presence of moisture (Spruce, 2017; Van Wicklin, 2017). Use resources (e.g., positioning aids, padding, transfer devices) to reduce the risk of tissue injury in the care of the older client (Association of periOperative Registered Nurses [AORN], 2015).*
- Identify procedure risk factors such as length and type of surgery, potential for intraoperative hypotensive episodes, low core temperatures, and decreased mobility on postoperative day 1. **EB:** *Assess the client for additional risk factors to include the duration of immobilization before and during the surgical procedure, client severity of illness, preoperative nutritional status, position for the procedure, and type of anesthesia (NPUAP & EPUAP, 2014; Van Wicklin, 2017). Surgeries lasting more than 4 hours provide a significant risk for pressure ulcer development (Sterner et al, 2011).* **CEBN:** *A recent study showed that vasopressor use is a significant risk factor for pressure ulcer development. The study also showed that the number of surgeries a client has during his or her inpatient stay and the length of surgery (over 1 hour), body mass index, Braden score, mortality risk, and history of diabetes are also risk factors for pressure ulcer development. This study did not show that age was related to pressure ulcer development (Tschannen et al, 2012).*
- Recognize that all surgical clients should be considered at high risk for pressure ulcer development, because pressure ulcers can develop in as little as 20 minutes in the operating room. **EBN:** *Operating room mattresses, the patient support surface, should be chosen for its pressure redistribution (Spruce, 2017). Support surfaces that redistribute pressure are recommended; however, which type is most effective is not clear (de Oliveira et al, 2017).*
- Remove all patient jewelry and accessories. **EBN:** *Jewelry and accessories, such as body piercings and hair devices, can get caught and torn out causing skin injury and the patient can lie on them and develop a pressure injury or the patient can experience a burn from cautery equipment (Van Wicklin, 2017).*
- Protect the heels during surgery by elevating the heels completely. **EB:** *Ensure the*

heels are free of the surface of the operating table (NPUAP & EPUAP, 2014). Heel pressure ulcers are one of the most common sites for pressure injury during surgery. Traditional devices such as egg crates, booties, and heel pads do not decrease the pressure. It is recommended that a device is used to elevate the heels and distribute the weight of the patient's leg along the calf (Van Wicklin, 2017).

• Use pressure-reducing devices and pressure-relieving mattresses as necessary to prevent pressure injury. **EB:** *Use a high-specification reactive or alternating pressure support surface on the operating table for all individuals identified as being at risk for pressure ulcer development (NPUAP & EPUAP, 2014). Additional support surfaces may be indicated to offload pressure points on the face and body when the client is placed in a prone position (NPUAP & EPUAP, 2014; Van Wicklin, 2017). Support surfaces may be made of foam, gel, air, fluid, or a combination of these surfaces. The goal is to have pressure distributed over the largest area possible. This is accomplished by having the surface envelope the patient (de Oliveira et al, 2017; Van Wicklin, 2017). Assess for shearing forces that may cause tissue injury when placing the client in the Trendelenburg position for selected robotic surgical procedures (Sutton, Link, & Makic, 2013).*

• Avoid using rolled sheets and towels as positioning devices because they tend to produce high and inconsistent pressures. Special positioning devices are available that redistribute pressure. **EBN:** *Towels and rolled sheets contribute to friction injuries and increase pressure on the patient. Pillows are an acceptable alternative when other positioning devices are unavailable (Van Wicklin, 2017).*

• Avoid covering positioning devices or placing extra blankets on top of a pressure-reducing surface. **EB/CEB:** *Adding material to a pressure reduction surface actually increases the pressure, producing a negative result (Van Wicklin, 2017). Use of rolled sheets and towels beneath overlays decreases the overlay's effectiveness and causes pressure (Van Wicklin, 2017).*

• The nurse should demonstrate knowledge not only of the equipment but also of anatomy and the application of physiological principles to properly position the client. **EBN:** *Preplanning ensures that the correct positioning devices are available and in good working condition, and that appropriate numbers of personnel are available to position the client safely and appropriately. High-specification reactive foam mattresses should be used for patients at high risk for pressure injury (Van Wicklin, 2017).*

• Monitor patient position and pressure being applied to the client intraoperatively by staff, equipment, and/or instruments. *Patients may move slightly or shift during surgery, especially during long procedures or when new equipment is introduced, requiring that the patient be repositioned to avoid pressure or nerve injury (Van Wicklin, 2017).*

• Use additional pressure-redistributing padding on all bony prominences. **EB:** *Additional padding increases patient comfort, helps redistribute pressure, and decreases the chance for development of pressure or nerve injuries (Van Wicklin, 2017). Some positioning devices are solid and can increase pressure over bony prominences (Sutton, Link, & Makic, 2013).*

• Recognize that reddened areas or areas injured by pressure should not be massaged. **EB:** *Rubbing causes friction that can lead to damage to skin/tissue (NPUAP & EPUAP, 2014; Van Wicklin, 2017).*

• Implement measures to prevent inadvertent hypothermia. *Anesthesia can compromise perfusion by causing hypotension and hypothermia. When coupled with the client being immobile on a noncompliant surface for an extended time period, hypothermia increases vulnerability for pressure ulcer development during surgery.*

• Many surgical clients have medical devices placed as a part of the surgical procedure. Avoid positioning the client on the medical device and perform frequent

assessments of the skin under and around the device (Apold & Rydrych, 2012; NPUAP & EPUAP, 2014).

Positioning the Perioperative Client

- Ensure that linens on the operating room table are free of wrinkles. *Wrinkles may cause pressure/injury to the skin if the client is unable to move for prolonged periods of time. Layers of linens or blankets between the patient and the support surface decrease the pressure-redistributing effect of the support surface (Van Wicklin, 2017).*
- Lock the operating room table, cart, or bed and stabilize the mattress before transfer/positioning the client. Monitor the client while on the operating room table at all times. **EB:** *Studies showed that a lack of clear communication about who should be watching the client has contributed to falls (Van Wicklin, 2017).*
- Lift rather than pull or slide the client when positioning to reduce the incidence of skin injury from shearing and/or friction. **EB:** *Sliding or pulling the client can cause shearing force and/or friction (NPUAP & EPUAP, 2014; Van Wicklin, 2017).*
- Ensure that appropriate numbers of personnel are present to assist in positioning the client. **EBN:** *A minimum of two people should assist an awake client to transfer from a cart/bed to the operating room table: one person on the stretcher side to assist the client onto the table and a second person on the far side of the table to prevent the client from falling off (Van Wicklin, 2017). A minimum of four persons are necessary when transferring/positioning an anesthetized, unconscious, obese, or weak client (Van Wicklin, 2017).*
- Recognize that, optimally, clients (especially those with limited range of motion/mobility) should be asked to position themselves under the nurse's guidance before induction of anesthesia so that he or she can verify that a position of comfort has been obtained.
- Ensure that nerves are protected by positioning extremities carefully. **EB:** *Nerves can be injured by stretching and compression, which is caused by a loss of protective muscle tone and pressure between two fixed points. Careful attention to proper body alignment and padding is necessary to prevent peripheral nerve injury (Bouyer-Ferullo, 2013; Van Wicklin, 2017).*
- Use slow and smooth movements during positioning to allow the circulatory system to readjust.
- Reassess the client after positioning and periodically during the procedure to maintain proper alignment and skin integrity. **EBN:** *Changes in position can expose or injure body parts (e.g., shearing, friction, compression) that were originally protected, and the safety strap can shift and apply increased pressure. If possible, after 3 or 4 hours of surgery the patient should be checked, under the drapes, to make sure the patient remains in alignment (Van Wicklin, 2017).*
- Frequently assess the eyes and/or monitor intraocular pressure, especially when client is in the prone, Trendelenburg, or knee-chest position. **CEB/EB:** *The cornea can easily be injured during surgery because of a decrease in lacrimation, failure of the eyes to fully close and/or improperly applied face masks, or prolonged prone positioning (Spruce & Van Wicklin, 2014; Van Wicklin, 2017).*
- Position hips in proper alignment with knees flexed. Unaligned hips can cause pressure to the low back and hip joints. **EB:** *Proper body alignment needs to be maintained to prevent nerve and pressure injuries (Van Wicklin, 2017).*
- Position the arms extended on arm boards so that they do not extend beyond a 90-degree angle. The arms should be at the level of the bed and should not be allowed to hang off the bed. Do not position arms at sides unless surgically necessary. **EB:**

Positioning at less than a 90-degree angle, with elbows slightly flexed and hands supine, decreases the risk of a stretching injury to the brachial plexus and possible compression or occlusion injury to the subclavian and axillary arteries (de Oliveira et al, 2017; Van Wicklin, 2017). When positioning arms at the sides is necessary, place the arms beneath the sheet and bring the sheet over the top of the arm and then tuck the sheet beneath the mattress so that the arm cannot fall off the mattress and hang over the metal edge of the table, where the surgical team could lean against it (Van Wicklin, 2017).

- Protect the client's skin surfaces from injury by preventing pooling of preparative solutions, blood, irrigation, urine, and feces. **EBN:** *Prep solutions may change the pH of the skin and remove protective oils, making the skin more susceptible to pressure and friction. Pooling also increases the risk of maceration (Van Wicklin, 2017).*
- Keep the client appropriately covered and limit traffic in the room during the procedure. Reducing unnecessary exposure provides privacy and dignity for the client during positioning and helps prevent hypothermia (Van Wicklin, 2017).
- When positioning the client prone, care should be taken to ensure the head and neck are properly positioned. In addition, 5- to 10-degree reverse Trendelenburg should be used, if possible, to reduce intraocular pressure and decrease facial edema. **EB:** *Inappropriate positioning of the head and neck in the prone position can lead to vertebral artery obstruction and possible stroke. Standard foam prone pillows should be used because they stabilize the neck in neutral, and the endotracheal tube can be positioned away from the face to decrease excessive pressure (Spruce & Van Wicklin, 2014; Spruce, 2017; Van Wicklin, 2017).*
- Recognize that clients positioned in the lithotomy position should be kept in this position for as short a time as possible. **EB:** *One research review suggested that the client's legs be removed from lithotomy positioning devices every 2 hours when the procedure is expected to last 4 hours or longer. Reported complications from extended time in this position include muscle contusion, compartment syndrome, and acute renal failure (Van Wicklin, 2017).*
- The lowest heel position should be used in the lithotomy position. **EB:** *When possible the legs should be at or lower than the level of the heart to prevent complications (Van Wicklin, 2017).*
- Maintain normal body alignment. *Misalignment, flexion, extension, and rotation may cause muscle and nerve damage and airway interference; pressure on the carotid sinus can cause arrhythmias; and restricted venous outflow can occur with extreme rotation of the head (Van Wicklin, 2017).*
- When applying body supports and restraint straps (safety belt), apply loosely and secure over waist or midthigh at least 2 inches above the knees, avoiding bony prominences by placing a blanket between the strap and the client. **EB:** *Belts positioned directly over the knees cause compression of the peroneal nerve against the fibula (Van Wicklin, 2017).*
- Assess the client's skin integrity immediately postoperatively. **EB:** *Assess and document postoperative skin/tissue integrity focusing on areas with constant pressure during the procedure and limb function for nerve damage (Sutton, Link, & Makic, 2013; NPUAP & EPUAP, 2014).*
- Ensure that complete, concise, accurate documentation of client assessment and use of positioning devices is in the client's medical record.

Risk for Peripheral Neurovascular dysfunction

Krystal Chamberlain BSN, RN, CCRN

NANDA-I

Definition

Susceptible to disruption in the circulation, sensation, and motion of an extremity, which may compromise health.

Risk Factors

To be developed

Associated Condition

Burns injury; fracture; immobilization; mechanical compression; orthopedic surgery; trauma; vascular obstruction

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Circulation Status; Neurological Status: Spinal Sensorimotor Function; Tissue Perfusion: Peripheral

Example NOC Outcome with Indicators

Tissue Perfusion: Peripheral as evidenced by the following indicators: Radial or pedal pulse strength/Capillary refill in fingers or toes/Extremity skin temperature/Localized extremity pain/Numbness/Tingling/Skin color/Muscle strength/Skin integrity/Peripheral edema. (Rate the outcome and indicators of **Tissue Perfusion: Peripheral:** 1 = severe deviation from normal range, 2 = substantial deviation from normal range, 3 = moderate deviation from normal range, 4 = mild deviation from normal range, 5 = no deviation from normal range [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Maintain circulation, sensation, and movement of an extremity within client's own

normal limits
• Explain signs of neurovascular compromise

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Exercise Therapy: Joint Mobility; Peripheral Sensation Management

Example NIC Activities—Peripheral Sensation Management

Monitor for paresthesia: numbness, tingling, hyperesthesia, and hypoesthesia; Monitor for thrombophlebitis and deep vein thrombosis

Nursing Interventions and *Rationales*

• Recognize the risk factors that may result in peripheral neurovascular dysfunction. **EB:** *Conditions that diminish limb perfusion from excessive pressure (e.g., tight-fitting cast, brace, restrictive dressing, compression stockings, prolonged immobility, intraoperative positioning, edema) can result in peripheral neurovascular dysfunction with wide-ranging effects on overall functional ability (Peters, 2017). Compartment syndrome also can occur and is an elevation of pressure within a compartment, which impairs circulation (Garner et al, 2014).*

• Assess for the early onset of compartment syndrome, and report to provider promptly. Perform neurovascular assessment as ordered or as needed based on client's condition. Use the "five Ps" of assessment as outlined in the following list. *The goal is to prevent ischemia and necrosis (cell death). Delay in recognizing compartment syndrome can lead to chronic pain, paralysis, rhabdomyolysis, contracture, amputation of the limb, and death. Compartment syndrome is primarily diagnosed by physical examination, and because of the devastating consequences of a missed compartment syndrome, a fasciotomy should be considered. Assess for the presence of any of the five Ps (Donaldson, Haddad, & Khan, 2014; Garner et al, 2014; Peters, 2017).*

- ❍ Pain: Assess severity (using an appropriate pain scale), quality, radiation, and relief by medications. *Pain "out of proportion" to the injury, requiring strong opiates, often described as burning, feeling deep in the muscle or structure, and elicited with passive stretching of the compartment are the most reliable signs of compartment syndrome and peripheral neurovascular dysfunction (Donaldson, Haddad & Khan, 2014).*
- ❍ Pulses: Check the pulses distal to the injury and compare with the unaffected limb. *Pulselessness is a late sign of compartment syndrome (Garner et al, 2014).*
- ❍ Pallor: Check color and temperature changes below the injury site and compare with unaffected limb. Check capillary refill. *A cold, pale, or bluish extremity indicates poor arterial perfusion or venous congestion. If pallor, cyanosis, mottling, or changes in temperature are present, report to provider promptly and record your assessment findings (Garner et al, 2014; Le, 2016).*
- ❍ Paresthesia (change in sensation): Check by lightly touching the skin proximal and distal to the injury. Ask if the client has any unusual sensations such as hypersensitivity, tingling, prickling, decreased feeling, or numbness. Check nerve function (e.g., whether the client can feel a touch to the area of concern, such as the first web space of the foot [deep peroneal nerve] with tibial fracture). *Paresthesia may occur as an early sign of*

compartment syndrome caused by ischemia of peripheral nerves (Garner et al, 2014).

- ❍ Paralysis: Ask the client to perform appropriate range-of-motion exercises in the unaffected and then the affected extremity. *Loss of movement (paralysis) is a late symptom of compartment syndrome. Decreased range of motion and loss of movement can indicate impending muscle, nerve, and cellular death (Donaldson et al, 2014).*
- ❍ In addition to the five Ps, assess for swelling or increase in compartment pressure by feeling the extremity; note new onset of firmness or swelling of the extremity, and a firm "wooden" feeling on deep palpation. Intercompartmental pressures may also be measured with proprietary monitoring devices. *Internal pressure or external confinement or restriction can proceed to the point at which cellular exchange is diminished. Swelling and tightness of the involved compartment are indications of increased pressure. Not only are surgical or trauma clients at risk for neurovascular compromise, but they also are clients on bed rest because of changes in blood flow through the cardiovascular system (Donaldson et al, 2014).*

▲ All the Ps may not be present, and they are not specific for compartment syndrome. Have a high index of suspicion for any of the Ps. Noting two or more of the Ps increases the probability of compartment syndrome. Monitor the client for compartment syndrome of the nonoperative leg and the operative leg. *Cases of compartment syndrome to the nonoperative side related to patient positioning during surgical procedure, resulting in compression and hypoperfusion, have been reported (Garner et al, 2014).*

• Monitor appropriate application and function of corrective device (e.g., cast, splint, traction) as needed. *Compartment syndrome can result from restrictive pressure from the device or swelling of injured tissue (The Joanna Briggs Institute, 2016). After immobilization (casting or splinting), if pain worsens or there is any tingling or numbness, swelling, delayed capillary refill, or change in color of exposed digits, immediate evaluation is needed.*

• For prevention of deep vein thrombosis (DVT), nursing care of DVT, and pulmonary embolism, refer to the interventions on DVT prevention and treatment in the care plan for Ineffective peripheral **Tissue Perfusion.**

Risk for Poisoning

Melodie Cannon DNP, MSc/FNP, BHScN, RN (EC), NP-PHC, CEN, GNC(C)

NANDA-I

Definition

Susceptible to accidental exposure to, or ingestion of, drugs or dangerous products in sufficient doses, which may compromise health.

Risk Factors

External

Access to dangerous product; access to illicit drugs potentially contaminated by poisonous additives; access to pharmaceutical agent; occupational setting without adequate safeguards

Internal

Emotional disturbance; inadequate precautions against poisoning; insufficient knowledge of pharmacological agents; insufficient knowledge of poisoning prevention; insufficient vision

Associated Condition

Alteration in cognitive functioning

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Knowledge: Child Physical Safety, Medication, Personal Safety; Parenting Performance; Risk Control; Risk Control: Alcohol Use, Drug Use; Risk Detection; Safe Home Environment

Example NOC Outcome with Indicators

Knowledge: Child Physical Safety as evidenced by the following indicators: Appropriate activities for child's developmental level/Strategies to prevent medication misuse/Strategies to prevent exposure to toxic chemicals or substances. (Rate the outcome and indicators of **Knowledge: Child Physical Safety:** 1 = no knowledge, 2 = limited knowledge, 3 = moderate knowledge, 4 = substantial knowledge, 5 = extensive knowledge [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Prevent inadvertent ingestion of or exposure to toxins or poisonous substances
- Explain and undertake appropriate safety measures to prevent ingestion of or exposure to toxins or poisonous substances
- Verbalize appropriate response to apparent or suspected toxic ingestion or poisoning

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Environmental Management: Safety, First Aid; Health Education; Medication Management; Surveillance; Surveillance: Safety

Example NIC Activities—Environmental Management: Safety

Identify safety hazards in the environment (i.e., physical, biological, chemical); Remove hazards from the environment, when possible

Nursing Interventions and *Rationales*

- When a client comes to the hospital with possible poisoning, begin care following the ABCs (airway, breathing and circulation) and administer oxygen if needed. **EB:** *Poisoning is a major cause of morbidity/mortality worldwide. Initial evaluation should include vital signs, mental status, pupil size, oxygenation, finger-stick glucose, and cardiac monitoring. Management is geared to supportive care, prevention of poison absorption, antidote use, and elimination techniques (Rhyee, 2013).*
  - It is important for the triage nurse to call the poison control center. *The poison control hotline is 1-800-222-1222. Poison centers are a valuable tool for medical consultations. They are staffed by nurses, pharmacists, toxicologists, and other specialists in poisons and toxins who can recommend treatment advice (American Association of Poison Control Centers, 2018).*
- Obtain a thorough history of what was ingested, how much, and when, and ask to look at the containers. Note the client's age, weight, medications, medical conditions, and any history of vomiting, choking, coughing, or change in mental status. Also take note of any interventions performed before seeking treatment. **EB:** *The history is important to confirm the diagnosis and is often unreliable when provided by clients with intentional ingestion. Additional information should be obtained from paramedics, police, family, and friends when possible (Rhyee, 2013).*
  - Note results of toxicology screens, arterial blood gases, blood glucose levels, and any other ordered laboratory tests. *If information about what was ingested is incomplete or inaccurate, laboratory tests may be needed to determine treatment. The poison control center will provide valuable information regarding appropriate laboratory tests and investigations specific to the suspected toxin.*
  - Initiate any ordered treatment for poisoning quickly. The poison control center will specify any treatment or medications that need to be administered. **EB:** *Some poisoning deaths may be preventable. Substances ingested in preventable deaths have delayed gastrointestinal (GI) absorption or require metabolic activation to produce severe toxicity. This allows a time frame for recognition and successful intervention. Early poison center consultation may improve outcomes and decrease deaths (Srisuma et al, 2016).*
  - *Ensure that recommendations from the poison control center are clearly documented and readily accessible in the client's chart.*
  - *If the client's condition deteriorates, contact the poison control center again for further direction and notify the most responsible provider.*

Safety Guidelines for Medication Administration

- Prevent iatrogenic harm to the hospitalized client by following these guidelines for administering medications:
  - Use at least two methods to identify the client before administering medications or blood products, such as the client's name and medical record number or birth date. Do not use the client's room number. Use the bar code scanning system for client identification if used by your facility.
  - When taking verbal or telephone orders, the orders should be written down and read back for verification to the individual giving the order. The health care provider who gave the orders for the medication then needs to confirm the information that was read back.
- Standardize use of abbreviations, acronyms, symbols, and dose designations and eliminate those that are prone to cause errors. (Refer to The Joint Commission, Critical

Access Hospital National Patient Safety Goals for list of abbreviations, acronyms, symbols, and dose designations that should not be used [The Joint Commission, 2014].)

- ❍ Be aware of the medications that look/sound alike and ensure that the correct medication is ordered and administered.
- ❍ Use the eight rights of medication administration to decrease the potential for error: right client, right medication, right reason, right dose, right frequency, right route, right site, and right time (College of Nurses of Ontario, 2014).
- ❍ Take high-alert medications off the nursing unit, such as potassium chloride. Standardize concentrations of medications such as morphine in patient-controlled analgesia pumps.
- ❍ Follow agency policy/procedures for medications that require a two-person check and co-signature.
- ❍ Label all medications and medication containers or other solutions that are on or off a sterile field for a procedure. Label them when they are first taken out of the original packaging to another container. Label with medication name, strength, amount, and expiration date/time. Review the labels whenever there is a change of personnel.
- ❍ Use only intravenous (IV) pumps that prevent free flow of IV solution when the tubing is taken out of the pump.

• Identify all the client's current medications on admission to a health care facility and compare the list with the current ordered medications. Reconcile any differences in medications. Use the expertise of the pharmacy department if there is any uncertainty regarding the accuracy of the client's medications. Reconcile the list of medications if the client is transferred from one unit to another, when there is a hand off to the next provider of care, and when the client is discharged.

• *Adverse drug events occur with disturbing frequency in health care settings. These events can be reduced by comparing the patient's medication list to any admission, transfer, or discharge orders, and identifying and bringing forward any discrepancies to the prescribers' attention for clarification. Document any discussions and resulting changes (Canadian Patient Safety Institute, 2016).*

• Detect possible interactions and cumulative or other adverse effects among prescribed medications, self-administered over-the-counter products, culturally based home treatments, herbal remedies, and foods. Medication reconciliation is an important safety issue because of the number of people taking multiple medications and involves determining what medications the person should be taking, medications they are actually taking, and resolving discrepancies (Aronson, 2017).

Pediatric

▲ Evaluate lead exposure risk and consult the health care provider regarding lead screening measures as indicated (public/ambulatory health). **EB:** *High levels of lead can cause anemia, multiorgan damage, seizures, and death in children. Chronic low lead levels can result in physical, cognitive, and neurobehavioral impairment. Sources of lead exposure include lead industries, leaded petrol, lead-based paint, water pipes, paint, dust, soil, and water. Children at risk for lead exposure include those living in deteriorating or renovated older homes with lead-based paint, living in areas with lead-based industry, and socioeconomic disadvantage (Nussbaumer-Streit et al, 2016).*

• Provide guidance for parents and caregivers regarding age-related safety measures,

including the following:

- ❍ Store prescription and over-the-counter medications, vitamins, herbs, and alcohol in a locked cabinet far from children's reach.
- ❍ Do not take medications in front of children (Rodgers et al, 2012).
- ❍ Store cleaning products including things like dishwashing liquids in a high cabinet, out of children's reach.
- ❍ Use safety latches on cabinets that contain poisonous substances.
- ❍ Store potentially harmful substances in the original containers with safety closures intact.
- ❍ Recognize that no container is completely childproof.
- ❍ Do not store medications or toxic substances in food containers or near or with food products.
- ❍ Do not leave alcoholic drinks, cosmetics, or toiletries where children can reach them.
- ❍ Remove poisonous houseplants from the home. Teach children not to put leaves or berries in their mouths (Oerther, 2011).
- ❍ Do not suggest that medications are candy.
- ❍ If interrupted when using a harmful product, take it with you; children can get into it within seconds.
- ❍ Store poisonous automotive or gardening supplies in a locked area.
- ❍ Use extreme caution with pesticides and gardening materials close to children's play areas.
- ❍ When visitors enter the home, place their handbags or backpacks up high where children are unable to reach them, and ask about any potential poisonous substances.

• *Pediatric poisoning deaths most commonly come from ingestion of opioids, other analgesics, cardiovascular medications, antihistamines, and sedatives (Tadros et al, 2016).*

EB: *A multicenter case-control study found that there were increased odds of poisoning in children aged 0 to 4 years when medicines were not locked away or stored out of reach and household products and medicines were not put away immediately after use (Kendrick et al, 2017).*

• Advise families that syrup of ipecac is no longer recommended to be kept and used in the home. *If potential poisoning occurs, contact emergency services or a poison control center (Theurer & Bhavsar, 2013).* Advise families that over-the-counter cough and cold suppressant medications are not recommended and are no longer considered safe for children 2 or younger (US Food and Drug Administration, 2014). *Colds are self-limiting and improve on their own; over-the-counter medications may help relieve symptoms in older children, but they will not change the natural course of the illness (US Food and Drug Administration, 2014).* **EB:** *Since the US Food and Drug Administration advised against the use of cough/cold medicines in children younger than 2 in 2008, there has been a decline in childhood poisonings in this category and a decrease in infant emergency department (ED) visits with adverse events caused by cough/cold medications (Spiller et al, 2013).*

• Recognize that some children may have been exposed to methamphetamines or the components used to make methamphetamines. *Home-based methamphetamine manufacturing may represent significant hazards and exposures to those who manufacture the drug but also to others living in the home. Children are most susceptible to these hazards and these exposures may result in immediate and long-term adverse health effects (Wright, Edwards, & Walker, 2016).*

• *Advise families to contact state or local government agencies or pharmacies to ask about safe*

disposal programs for used, excess, or expired medications (US Food and Drug Administration, 2014).

Geriatric

• Caution the client and family to avoid storing medications with similar appearances close to one another (e.g., nitroglycerin ointment near toothpaste or denture creams). *Confusion and visual impairment can place the older person at risk of incorrectly identifying the contents. Place medications in a medication organizer that indicates when they are to be taken. Failing eyesight, the use of multiple drugs, and difficulty in remembering whether a medication was taken are among the causes of accidental poisoning in older persons.* **EB:** *For both sexes, poisoning is a common, self-inflicted injury in patients admitted to hospital. Among seniors, there is concern regarding the recognition of intentional harm by self-induced poisoning (Skinner et al, 2016). Remind older clients to store medications out of reach when young children come to visit. Childhood poisonings are common events that involve exposure to both prescription and nonprescription pharmaceuticals in the home, resulting in an increased number of serious outcomes (Spiller et al, 2013).*
• Perform medication reconciliation in all older clients entering the health care system and on discharge. *Older clients do not compare drugs that they have at home with new prescriptions and often take multiple drugs with the same indications, leading to toxicity. Encourage older clients to speak with their pharmacist to ensure their medications are reviewed whenever a change occurs. Pharmacists can assist clients with strategies to differentiate medications such as visual, tactile, or audible labeling (Smith & Bailey, 2014). Encourage the consistent use of a pharmacy to promote understanding of medications and any changes. Advise clients who use dosettes or prepackaged medications that the appropriate changes will need to be made before continuing to use the current administration method.*

Home Care

• The interventions previously described may be adapted for home care use.
• Provide the client and/or family with a poison control poster to be kept on the refrigerator or a bulletin board. Ensure that the telephone number for local poison control information is readily available and/or preprogrammed into household telephones.
• Prepour medications for a client who is at risk for ingesting too much of a given medication because of mistakes in preparation. Delegate this task to the family or caregivers if possible. *Older clients who live alone are at greatest risk of poisoning.*
• Identify poisonous substances in the immediate surroundings of the home, such as a garage or barn, including paints and thinners, fertilizers, rodent and bug control substances, animal medications, gasoline, and oil. Label with the name, a poison warning sign, and a poison control center number. Lock out of the reach of children. *Dangerous poisonous substances can be found in areas other than the internal home setting. Curious children are at risk for ingestion when exploring.*
• Identify the risk of toxicity from environmental activities such as spraying trees or roadside shrubs. Contact local departments of agriculture or transportation to obtain material safety data sheets or to prevent the activity in desired areas. *Very young children, women who are of childbearing age or who are pregnant, and older adults are at greatest risk of poisoning.*
• To prevent carbon monoxide poisoning, instruct the client and family in the importance of using a carbon monoxide detector in the home and changing it every 6

months, having the home heating system serviced every year by a qualified technician, and ensuring proper installation and venting of all combustion equipment. Carbon monoxide results from fumes produced by portable generators, stoves, lanterns, gas ranges, running vehicles, or burning charcoal and wood, which can build up in enclosed or partially enclosed spaces and result in harm or death for people and animals exposed. **EB:** *Carbon monoxide poisoning may be not be readily identified because many of the effects are similar to various childhood illnesses (Chang et al, 2017).*

Multicultural

- Prompt caregivers to take action to prevent lead poisoning. **EB:** *Lead knowledge in urban youth is limited and includes misinformation. Some youth demonstrated awareness of specific sources including paint, dust, and water but had limited awareness of prevention strategies (Bogar et al, 2017).*
- If children live in a high-lead environment, teach the need for handwashing before each meal, annual blood testing for lead levels, and avoidance of high-lead areas. **EB:** *Lead industries, leaded petrol, lead-based paint, water pipes, paint, dust, soil, and water are all sources of lead exposure for children (Nussbaumer-Streit et al, 2016).*

Client/Family Teaching and Discharge Planning

- Teach parents that any substance that is absorbed by the body by a variety of means and can affect health and cause mortality is considered a poison. The increasing use of medications and home cleaning products puts children at risk for poison because of the potential for access in the home environment. **EB:** *Research has shown that 94% of children who were poisoned accessed the agent in their own home or another home (Nalliah et al, 2014).*

Safety Guidelines

- Counsel the client and family members regarding the following points of medication safety:
    - Avoid sharing prescriptions.
    - Always use good light when preparing medication. Do not dispense medication during the night without a light on.
    - Read the label before you open the bottle, after you remove a dose, and again before you give it.
    - Always use child-resistant caps and lock all medications away from your child or confused older adult.
    - Give the correct dose. *Never* guess.
    - Do not increase or decrease the dose without calling the health care provider.
    - Always follow the weight and age recommendations on the label.
    - Avoid making conversions. If the label calls for 2 teaspoons and you have a dosing cup labeled only with ounces, do not use it.
    - Be sure the health care provider knows if you are taking more than one medication at a time.
    - Never let young children take medication by themselves.
    - Read and follow labeling instructions on all products; adjust dosage for age.

- ❍ Avoid excessive amounts and/or frequency of doses. ("If a little does some good, a lot should do more.")

• **EB:** *Data from the Nationwide Emergency Department Sample (NEDS) from 2006 to 2012 show there were 21,928 pediatric ED visits for prescription opioid poisonings. An increase in adult prescription opioid abuse contributes to unintentional ingestion of medications in children (Tadros et al, 2016).*

• **EB:** *Unintentional poisoning is the fastest growing cause of childhood fatal injury. As per the Centers for Disease and Prevention (CDC), most of this increase is linked to the inappropriate use of prescription opioids (Johnston & Ebel, 2013; CDC, 2018).*

• **EB:** *Poisoning in children is common and places a significant burden on health care. Parents of poisoned children were more likely to not have safely stored or locked medicines (Kendrick et al, 2017).*

• Advise the family to post first-aid charts and poison control center instructions in an accessible location. Poison control center telephone numbers should be posted close to each telephone and the number programmed into cell phones. *A poison control center should always be called immediately before initiating any first-aid measures. The national toll-free number is (800) 222-1222.*

• Advise family when calling the poison control center to do the following:

- ❍ Give as much information as possible, including your name, location, and telephone number, so that the poison control operator can call back in case you are disconnected or summon help if needed.
- ❍ Give the name of the potential poison ingested and, if possible, the amount and time of ingestion. If the bottle or package is available, give the trade name and ingredients if they are listed.
- ❍ Be prepared to divulge the child's height, weight, age, and medical history.
- ❍ Describe the state of the poisoning victim. Is the victim conscious? Does he or she have any symptoms? What is the person's general appearance, skin color, respiration, breathing difficulties, mental status (alert, sleepy, unusual behavior)? Is the person vomiting? Having convulsions?

• Rapid initiation of proper treatment reduces mortality and morbidity rates. Consultation with a poison control center is necessary to assess and treat poisoned clients. **EB:** *Optimal management of the poisoned client depends on the poison, the severity of the symptoms, and time between exposure and presentation. Poison control centers can provide assistance (Rhyee, 2013).*

• Encourage the client and family to take first-aid and other types of safety-related programs. *These programs raise participants' level of emergency preparation.*

▲ Initiate referrals to peer group interventions, peer counseling, and other types of substance abuse prevention/rehabilitation programs when substance abuse is identified as a risk factor.

• Teach parents and other caregivers that cough and cold medications bought over the counter are not safe for children younger than 2 unless specifically ordered by a health care provider. **EB:** *Analysis of exposures to cough/cold preparations supports the concept that poisoning exposure occurs in children with substances that they can easily access (Spiller et al, 2013).*

• Teach parents about home prevention strategies to prevent accidental poisonings. **EB:** *Poisoning prevention programs (providing free or low cost cabinet locks and poison control stickers) have improved safe storage practices (Theurer & Bhavsar, 2013).*

• Teach parents that they can be a source of lead exposure for their children via contaminated work clothing from a lead-related occupation such as transportation workers or automobile repair or if they engage in certain hobbies such as stained glass

or ceramics (Schnur & John, 2014). Precautions should be taken to eliminate the risk of exposure.

Post-Trauma syndrome

Gail B. Ladwig MSN, RN, Julianne E. Doubet BSN, RN, EMT-B

NANDA-I

Definition

Sustained maladaptive response to a traumatic, overwhelming event.

Defining Characteristics

Aggression; alienation; alteration in concentration; alteration in mood; anger; anxiety (00146); avoidance behaviors; compulsive behavior; denial; depression; dissociative amnesia; enuresis; exaggerated startle response; fear (00148); flashbacks; gastrointestinal irritation; grieving (00136); guilt; headache; heart palpitations; history of detachment; hopelessness (00124); horror; hypervigilance; intrusive dreams; intrusive thoughts; irritability; neurosensory irritability; nightmares; panic attacks; rage; reports feeling numb; repression; shame; substance misuse

Related Factors

Diminished ego strength; environment not conducive to needs; exaggerated sense of responsibility; insufficient social support; perceives event as traumatic; self-injurious behavior; survivor role

At-Risk Population

Destruction of one's home; displacement from home; duration of traumatic event; event outside the range of usual human experience; exposure to disaster; exposure to epidemic; exposure to event involving multiple deaths; exposure to war; history of abuse; history of being a prisoner of war; history of criminal victimization; history of torture; human service occupations; serious accident; serious injury to loved one; serious threat to loved one; serious threat to self; witnessing mutilation; witnessing violent death

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Abuse Cessation; Abuse Protection; Abuse Recovery: Emotional, Aggression Self-Control, Anxiety Self-Control, Grief Resolution, Impulse Self-Control; Self-Mutilation Restraint; Sleep

Example NOC Outcome with Indicators

Abuse Recovery: Emotional as evidenced by the following indicators: Trauma-induced psychoneurotic behaviors, conduct disorders, and learning difficulties. (Rate outcome and indicators of **Abuse Recovery: Emotional:** 1 = extensive, 2 = substantial, 3 = moderate, 4 = limited, 5 = none [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Return to pretrauma level of functioning as quickly as possible
- Acknowledge traumatic event and begin to work with the trauma by talking about the experience and expressing feelings of fear, anger, anxiety, guilt, and helplessness
- Identify support systems and available resources and be able to connect with them
- Return to and strengthen coping mechanisms used in previous traumatic event
- Acknowledge event and perceive it without distortions
- Assimilate event and move forward to set and pursue life goals

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Counseling; Support System Enhancement

Example NIC Activities—Counseling

Encourage expression of feelings; Assist client to identify strengths and reinforce them

Nursing Interventions and *Rationales*

• Observe for a reaction to a traumatic event in all clients regardless of age or sex. **EBN:** *Treatment, after a traumatic incident, is usually concentrated on stabilizing the patient physically; what is not always addressed is the emotional and/or psychological damage that can follow a traumatizing event (Frank, Schroeter, & Shaw, 2017).*

• After a traumatic event, assess for intrusive memories, avoidance and numbing, and hyperarousal. **EB:** *The inability to complete goal-directed behavior by actively maintaining information while inhibiting irrelevant information is specific to symptoms of post-traumatic stress disorder (PTSD) (Bornyea, Amir, & Lang, 2013).*

• Remain with the client and provide support during periods of overwhelming emotions. **EB:** *Hansen et al (2014) studied the effects of an intervention for female victims of intimate partner violence (IPV) on perceived social support and found the overall aim of the stabilization part of this treatment was to provide the woman with a sense of control over her physical safety and her psychological and social situation.*

• Help the individual to comprehend the trauma if possible. **EBN:** *In their study of women exposed to IPV, Svavardottir, Orlygsdottir, and Gudmundsdottir (2015) found that appropriate first responses and immediate advocacy for the victims of IPV by the health care professional can be invaluable; these interventions support access to safer environments and the means to connect to continued assistance.*

• Use touch with the client's permission (e.g., a hand on the shoulder, holding a hand). **EBN:** *The application of appropriate touch has been used historically by nurses as a means of connecting with their patients and promoting restorative and therapeutic well-being (Coakley, Barron, & Annese, 2016).*

• Explore and enhance available support systems. **EBN:** *A nursing education piece published by the Australian Nursing and Midwifery Journal (Post-traumatic stress disorder, 2015) stated that PTSD is a mental illness and treatment must fit to the individual's needs; this may include referrals to mental health care providers.*

• Help the client regain previous sleeping and eating habits. **EB:** *In adult patients, interruptions in usual sleep patterns experienced soon after a traumatic event can be linked to an increased likelihood of developing PTSD (Pruitt, 2015).*

▲ Provide the client pain medication if he or she has physical pain. **EBN:** *Bridgeland et al (2014) affirmed other research describing high rates of chronic pain in returning veterans with polytrauma and PTSD; they concluded that a holistic approach is needed to treat these victims.*

▲ Assess the need for pharmacotherapy. **EB:** *Primary care physicians and/or psychiatrists may use medications for symptom relief in PTSD, including appropriate antidepressants and anxiolytics (Johnson, 2017).*

▲ Refer for appropriate psychotherapy: cognitive therapy, exposure therapy, eye movement desensitization and reprocessing (EMDR), and cognitive-behavioral therapy (CBT). **EB:** *These approaches can help the client gain control of the fear and distress that occur after a traumatic event (Mayo Clinic, 2014).* **EB:** *Chen et al (2014) confirmed that EMDR significantly reduces the symptoms of PTSD.*

• Help the client use positive cognitive restructuring to reestablish feelings of self-worth. **EB:** *Anke et al (2013) showed that cognitive therapy was well tolerated and led to a very large improvement in PTSD symptoms, depression, and anxiety; most clients showed reliable improvement that was clinically significant.*

• Provide the means for the client to express feelings through therapeutic drawing. **EB:** *Because traumatic events are many times too difficult to describe in words, art therapy gives victims another avenue by which they can project their emotions (Ramirez, 2016).*
• Encourage the client to return to his or her normal routine as quickly as possible. **EBN:** *For families following an intensive care unit admission, written information about possible psychological sequelae and psychological follow-up was found to be preferable, complemented by telephone support and guidance (Gledhill et al, 2014).*
• Talk to and assess the client's social support after a traumatic event. **EB:** *Given the high number of physical, mental, and social problems in trauma clients, identifying and strengthening support sources can be effective in the adaption of the effects of an amputation on an individual and improvement of the quality of their life (Valizadeh et al, 2014).*

Pediatric

• Refer to nursing care plan Risk for **Post-Trauma** syndrome.
▲ Carefully assess children exposed to disasters and trauma. Note behavior specific to developmental age. Refer for therapy as needed. **EBN:** *Zhang et al (2014) found continuous screening is recommended to identify adolescent earthquake survivors with PTSD symptoms, especially survivors who are prone to adapt passive coping strategies and who own external causal attribution.*

Geriatric

• Carefully screen older adults for signs of PTSD, especially after a disaster. **EB:** *Older persons who have undergone an earlier in life trauma may react in a different manner than younger persons to a disaster; age alone does not presage psychological outcomes (Cherry et al, 2015).*
• Consider using the Horwitz Impact of Event Scale, which is an appropriate instrument to measure the subjective response to stress in the older population. **CEB:** *The Impact of Event Scale–Revised is one of the most widely used self-report measures in the trauma literature (Beck et al, 2008).*
▲ Monitor the client for clinical signs of depression and anxiety; refer to a health care provider for medication if appropriate. **EB:** *Assessment and treatment of PTSD symptoms in older clients can be a challenging task because many older adults suffer cognitive and/or sensory deterioration and comorbid mental and physical disorders that, according to Dinnen, Simiola, and Cook (2015), may lead to incorrect diagnosis and ineffective treatments.*
• Instill hope. **EBN:** *Hope was intentionally used in this study as an intervention in a group setting in a nursing home; it was evident that hope is not static and can change over time (Moore, Hall, & Jackson, 2014).*

Multicultural

• Assess the influence of cultural beliefs, norms, and values on the client's ability to cope with a traumatic experience. **EB:** *When receiving treatment, African Americans may feel differently toward a European American clinician because of cultural mistrust. Furthermore, racism and discrimination experienced before or during the traumatic event may compound post-trauma reactions, affecting the severity of symptoms (Williams et al, 2014).*
• Acknowledge racial and ethnic differences at the onset of care. **EBN:** *Sabri et al (2014) showed that blacks and Asians were less likely than whites to be knowledgeable about workplace violence resources or use resources to address workplace violence.*
▲ Carefully assess refugees for PTSD and refer for treatment as appropriate;

encourage them to learn the language of their new residence. **EB:** *Two possible explanations were found for the persistently high prevalence of PTSD among refugees: one is the late onset of PTSD and the other is the low utilization of mental health care (Lamkaddem et al, 2014).*

• Use a family-centered approach when working with Latin, Asian, African American, and Native American clients. **EB:** *In their study of the mental well-being of Latina survivors of sexual abuse, Ulibarri, Ulloa, & Salazar (2015) found that health care professionals can benefit from increased knowledge of cultural norms and customs that play such large roles in Latino society.* **EB:** *Parent and self-reported mental health service use for social anxiety among high school students showed Asian American students endorsed a greater number of social anxiety symptoms than other ethnic groups. There were no differences in parent-reported impairment or service utilization (Brice et al, 2014).*

• When working with Asian American clients, provide opportunities by which the family can save face. **EB:** *Understanding Asian American beliefs concerning the basis of mental illnesses can assist health care professionals in recognizing the feelings of shame and stigma that prevent this group from seeking mental health treatment (Bignall, Jacquez, & Vaughn, 2015).*

• Incorporate cultural traditions as appropriate. **EB:** *Awareness of a patient's traditional beliefs in complementary and alternative medicine (CAM) allows the health care professional to provide insightful, culturally sensitive, and patient-centered care (Read et al, 2014).*

Home Care

▲ Assess family support and the response to the client's coping mechanisms. Refer the family for medical social services or other counseling as necessary. **EBN:** *The hospitalization of a loved one after a traumatic event, plus the emerging responsibilities of caregiving, can be acutely stressful, often triggering a family crisis and serving as the basis of psychological distress (Newcomb & Hymes, 2017).*

• Assess the effect of the trauma on family and significant others and provide empathy and caring to them. **EBN:** *Donaldson-Andersen (2017) affirmed that nurses must continuously assess and reevaluate the needs of patients, and the patient's loved ones, during a traumatic event and provide essential emotional and social support as needed.*

Client/Family Teaching and Discharge Planning

• Teach positive coping skills and avoidance of negative coping skills. **EB:** *CBT coupled with an exercise intervention was associated with positive results in an intervention for ovarian cancer clients (Moonsammy et al, 2013).*

• Teach stress reduction methods such as deep breathing, visualization, meditation, and physical exercise. Encourage their use especially when intrusive thoughts or flashbacks occur. **EB:** *Bormann et al (2013) explored the efficacy of private meditation-based mantra intervention for veterans to enhance spiritual well-being in outpatient veterans diagnosed with military-related PTSD.*

• Encourage other healthy living habits. **EB:** *Hall et al (2015) found in their study that PTSD is not only an extensive and expensive psychiatric condition, but is also linked to obesity and many cardiometabolic conditions.*

• Refer the client to peer support groups. **EB:** *Public stereotypes affect help seeking, at least early in the course of illness; peer-based outreach and therapy groups may help veterans engage in treatment and resist stigma (Mittal et al, 2013).*

• Consider the use of complementary and alternative therapies. **EB:** *Yoga has been*

found to help those with PTSD in adopting methods that encourage mindfulness and aid in managing emotions (Jindani & Khalsa, 2015).

Risk for Post-Trauma syndrome

Gail B. Ladwig MSN, RN, Julianne E. Doubet BSN, RN, EMT-B

NANDA-I

Definition

Susceptible to sustained maladaptive response to a traumatic, overwhelming event, which may compromise health.

Risk Factors

Related Factors

Diminished ego strength; environment not conducive to needs; exaggerated sense of responsibility; insufficient social support; perceives event as traumatic; self-injurious behavior; survivor role

At-Risk Population

Destruction of one's home; displacement from home; duration of traumatic event; event outside the range of usual human experience; exposure to disaster; exposure to epidemic; exposure to event involving multiple deaths; exposure to war; history of abuse; history of being a prisoner of war; history of criminal victimization; history of torture; human service occupations; serious accident; serious injury to loved one; serious threat to loved one; serious threat to self; witnessing mutilation; witnessing violent death

NOC (Nursing Outcomes Classification)

Refer to the care plan for **Post-Trauma** syndrome for suggested NOC outcomes

Example NOC Outcome with Indicators

Risk Detection as evidenced by the following indicators: Recognizes signs and symptoms that indicate risk/Uses health care services congruent with need. (Rate the outcome and indicators of **Risk Detection:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Identify symptoms associated with post-traumatic stress disorder (PTSD) and seek help
- Acknowledge event and perceive it without distortions
- Identify support systems and available resources and be able to connect with them
- State that he/she is not to blame for the event

NIC (Nursing Interventions Classification)

Refer to the care plan for **Post-Trauma** syndrome for suggested NIC interventions

Nursing Interventions and *Rationales*

- Assess for PTSD in a client who has chronic/critical illness, anxiety, or personality disorder; was a witness to severe injury or death; or experienced sexual molestation. **EBN:** *Current literature validates that early identification and intervention in the treatment of traumatic stress is essential to optimal recovery for trauma patients (Frank, Schroeter, & Shaw, 2017).*
- Consider the use of a self-reported screening questionnaire. **EB:** *PTSD self-screens are questionnaires that may help to identify those who could have PTSD; positive responses might signal that a referral to a mental health professional is be warranted (National Center for PTSD, 2017).*
- Assess for ongoing symptoms of post-traumatic stress such as dissociation, avoidance behavior, hypervigilance, and reexperiencing. **EB:** *The symptoms for individuals with PTSD can vary considerably, but they generally fall into these categories: reexperience, avoidance, negative changes in beliefs and/or feelings, and increased arousal (National Center for PTSD, 2017).*
- Assess for past experiences with traumatic events. **EBN:** *In their study of rural women with a history of trauma, Handley et al (2015) found that these clients may have other psychological and social repercussions, along with the development of PTSD.*
- Consider screening for PTSD in a client who is a high user of medical care. **EB:** *Dorrington et al (2014) showed that despite high rates of exposure to trauma, a middle-income population had lower rates of PTSD than high-income populations; there are high rates of non-PTSD diagnoses associated with trauma exposure that could be considered in interventions for trauma-exposed populations.*
- ▲ Provide deployed combat veterans with previous history of low mental or physical health status before deployment with appropriate referral after deployment. **EB:** *Yang and Burr (2016), in their study of the well-being of older veterans exposed to combat, cited a previous study done of identical and fraternal twin combat veterans. It was surmised in that study that both environmental and genetic components played a role in combat veterans' negative mental and physical health outcomes.*
- Provide peer support to contact coworkers experiencing trauma to remind them that others in the organization are concerned about their welfare. **EB:** *Motivating factors that urged transit workers to seek help with their emotional problems after a traumatic experience included family and peers (Bance et al, 2014).*
- Provide post-trauma debriefings. Effective post-trauma coping skills are taught, and each participant creates a plan for his or her recovery. **EB:** *Fakour et al (2014) showed the effectiveness of psychological debriefing in treatment of PTSD after an earthquake; the means of PTSD symptom frequency and severity of avoidance symptoms were reduced during the 3-month period of the study.*

• Provide post-trauma counseling. Counseling sessions are extensions of debriefings and include continued discussion of the traumatic event and post-trauma consequences and the further development of coping skills. **EB:** *Evidence suggested that the response to cognitive behavioral therapy may be enhanced in PTSD clients by preparing them with emotion regulation skills; however, a high attrition of participants during the study limits the conclusions (Bryant et al, 2013).*
• Consider exposure therapy for civilian trauma survivors after an assault or motor vehicle crash. **CEB:** *Prolonged exposure therapy is a beneficial first-line intervention for PTSD, no matter the manner of trauma (Rauch, Eftekhari, & Rozek, 2012).*

Things to Try: Critical Incident Stress Debriefing

• Instruct the client to use the following critical incident stress management techniques:
  ❍ Within the first 24 to 48 hours, engage in periods of appropriate physical exercise alternating with relaxation to alleviate some of the physical reactions; structure your time; keep busy; you are normal and are having normal reactions; do not label yourself as "crazy"; talk to people; talk is the most healing medicine; be aware of numbing the pain with overuse of drugs or alcohol; you do not need to complicate the stress with a substance abuse problem; reach out; people do care; maintain as normal a schedule as possible; spend time with others; help your coworkers as much as possible by sharing feelings and checking out how they are doing; give yourself permission to feel rotten and share your feelings with others; keep a journal; write your way through those sleepless hours; do things that feel good to you; realize that those around you are under stress; do not make any big life changes; do make as many daily decisions as possible to give yourself a feeling of control over your life (e.g., if someone asks you what you want to eat, answer the person even if you are not sure); get plenty of rest; recurring thoughts, dreams, or flashbacks are normal; do not try to fight them because they will decrease over time and become less painful; eat well-balanced and regular meals (even if you do not feel like it). **EB:** *Based on interview results with railroad employees exposed to trauma and in conjunction with management, Bardon and Mishara (2015) developed a thorough prevention, support, and care protocol to reduce the negative effect of critical incidents for employees: the protocol includes preventative actions, quick responses, prompt intervention, and long-term assistance as needed.*
▲ Assess for a history of life-threatening illness such as cancer and provide appropriate counseling. **EB:** *"The physical and psychological effect of having a life-threatening disease, undergoing cancer treatment, and living with recurring threats to physical integrity and autonomy constitute traumatic experiences for many cancer clients" (National Cancer Institute, 2013).* **EB:** *Problematic postbiopsy symptoms can lead to increased anxiety, distinct from distress related to a diagnosis of prostate cancer (Wade et al, 2013).*

Pediatric

• Children with cancer should continue to be assessed for PTSD into adulthood. **EB:** *The presence of health outcomes was ascertained using systematic exposure-based medical assessments among adult survivors of childhood cancer; using clinical criteria, the crude prevalence of adverse health outcomes for neurocognitive impairment was 48% (Hudson et al,*

2013).
• Provide protection for a child who has witnessed violence or who has had traumatic injuries. Help the child acknowledge the event and express grief over the event. **EB:** *Lafta, Aziz, and Al-Obaidi (2014) showed that more than half of the total sample in Baghdad had reported multiple experiences of trauma such as fear and/or terror and the painful recall of traumatic events, pointing to the need for medical educational opportunities.*
• Assess for a medical history of anxiety disorders. **EB:** *Findings from this study suggested that parents with social anxiety disorder may exhibit a unique pattern of behaviors when interacting with their children, including elevated levels of criticism and low levels of warmth; this parenting style has been linked to an increased risk for development of anxiety (Budinger, Drazdowski, & Ginsburg, 2013).*
▲ Assess children of deployed parents for PTSD and provide appropriate referrals. **EB:** *Lucier-Greer et al (2016) found in their research that multiple parental deployments are a powerful indicator of detrimental outcomes for adolescents in military families.*
• Consider implementation of a school-based program for children to decrease PTSD after catastrophic events. **EB:** *Tol et al (2014) used an evidence base from previous studies to draw conclusions about the benefits and risks of school-based intervention in reducing PTSD, anxiety, and depression.*

Geriatric and Multicultural

• Refer to the care plan for **Post-Trauma** syndrome.

Home Care

▲ Evaluate the client's response to a traumatic or critical event. If screening warrants, refer to a therapist for counseling/treatment. **EB:** *In the Osofsky et al (2017) study they found that addressing life stressors is an important function in integrated patient care.*
• Refer to the care plan for **Post-Trauma** syndrome.

Client/Family Teaching and Discharge Planning

• Instruct family and friends to use the following critical incident stress management techniques:
▲ Listen carefully; spend time with the traumatized person; offer your assistance and a listening ear, even if the person has not asked for help; help the person with everyday tasks such as cleaning, cooking, caring for the family, and minding children; and give the person some private time. Do not take the individual's anger or other feelings personally, and do not tell the person that he or she is "lucky it wasn't worse." Such statements do not console traumatized people. Instead, tell the person that you are sorry such an event has occurred and you want to understand and assist him or her (National Interagency Fire Center, CISM Information Sheets, 2014).
▲ After exposure to trauma, teach the client and family to recognize symptoms of PTSD and seek treatment for "recurrent and intrusive distressing recollections of the traumatic event," insomnia, irritability, difficulty concentrating, and hypervigilance. **EBN:** *Family and significant others will profit from assistance, education, and explanation concerning the likely effects relating to PTSD counseling (Australian Nursing & Midwifery Journal, 2015).*
• Provide education to explain that acute stress disorder symptoms may be common when preparing combatants for their role in deployment. Provide referrals if the symptoms persist. **EB:** *Because US military forces have been engaged in overseas conflicts*

since 2001, service men and women have faced stressors related to combat and long deployments. Most manage this stress successfully, but others struggle with mental health problems (Farmer et al, 2015).

Readiness for enhanced Power

Marina Martinez-Kratz MS, RN, CNE

NANDA-I

Definition

A pattern of participating knowingly in change for well-being, which can be strengthened.

Defining Characteristics

Expresses desire to enhance awareness of possible changes; expresses desire to enhance identification of choices that can be made for change; expresses desire to enhance independence with actions for change; expresses desire to enhance involvement in change; expresses desire to enhance knowledge for participation in change; expresses desire to enhance participation in choices for daily living; expresses desire to enhance participation in choices for health; expresses desire to enhance power

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Health Beliefs: Perceived Control; Participation in Health Care Decisions; Personal Autonomy

Example NOC Outcome with Indicators

Health Beliefs: Perceived Control as evidenced by the following indicators: Belief that own actions and decisions control health outcomes/Perceived responsibility for health decisions/Efforts at gathering information. (Rate the outcome and indicators of **Health Beliefs: Perceived Control** as 1 = very weak, 2 = weak, 3 = moderate, 4 = strong, 5 = very strong [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Describe power resources
- Identify realistic perceptions of control
- Develop a plan of action based on power resources
- Seek assistance as needed

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Mutual Goal Setting; Self-Esteem Enhancement; Self-Responsibility Facilitation

Example NIC Activities—Mutual Goal Setting

Encourage the identification of specific life values; Identify with client the goals of care; Assist client in examining available resources to meet goals

Nursing Interventions and *Rationales*

- Assess the meaning of the event to the person. **EBN:** *Assessing meaning gives a voice to clients and makes it more likely that solutions reached will have meaning and be useful to the individual (Bevan, 2013).*
- Collaborate with and encourage the person to identify resources to put a plan into action. **EBN:** *Collaborating with clients provides opportunities for learning and growth and is a client-empowering behavior that improves client health outcomes (Jerofke, Weiss, & Yakusheva, 2014).*
- Provide support for client families to identify the balance between client care responsibilities and self-care. **EBN:** *A recent study found that by supporting client families and considering them as resources, family feelings of powerlessness can be reduced (Lindgren, Söderberg, & Skär, 2016).*

• Initiate and facilitate family health conversations between the client and their family. **EBN:** *Research findings showed that participation in family health conversations mediated consolation, helped identify family members' problems and suffering, and assisted to identify their family's resources and strengths (Dorell & Sundin, 2016).*
• Identify the client's health literacy and provide access to information. **EBN:** *Providing clients with access to information is a client-empowering behavior that improves client health outcomes (Jerofke, Weiss, & Yakusheva, 2014).*
• Help client to mobilize social supports, which is a power resource. **EBN:** *Assisting clients with access to resources is a client-empowering behavior that improves client health outcomes (Jerofke, Weiss, & Yakusheva, 2014).*
• Refer client to an empowerment support group. **EBN:** *A randomized controlled trial found that clients who participated in an empowerment support group showed significant increases in levels of empowerment and self-care behaviors (Hsiao et al, 2016).*

Pediatric

• Provide empowerment-based education for parents that includes a focus on caregiving knowledge, caring behaviors, self-efficacy, and indicators of the child's recovery. **EBN:** *A study of an empowerment-based health education program for parents caring for children with a congenital heart defect (CHD) after corrective surgery showed parental improvement in caregiving knowledge, caring behaviors, and self-efficacy (Zhihong, Chao, & Xiaoling, 2016).*
• Initiate problem-solving opportunities, empowering discussions, and reflection to help families take action to manage their child's illness. **EBN:** *A randomized clinical trial found that implementation of an asthma family empowerment program decreased parental stress, improved family functioning, and increased children's pulmonary function (Yeh et al, 2016).*

Geriatric

• Provide health education for older individuals that is tailored, interactive, structured, continuous, and incorporates motivational and encouragement techniques. **EB:** *A systematic review of the literature showed that use of specific educational interventions for older nursing home residents were empowering strategies that increased self-efficacy and self-care (Shoberer et al, 2016).*

Multicultural

In addition to the preceding interventions as appropriate:

• Assess for the influence of communication patterns, cultural differences in medical consultations, and client perceptions of inequalities in care quality as contributors to client feelings of powerlessness. **EB:** *Understanding and addressing client perceptions of power disparities may decrease clients' feelings of powerlessness (Akhavan & Karlsen, 2013).*
• Provide support and educational interventions that are culturally tailored. **EB:** *A randomized control trial found that Latino families assigned to a culturally sensitive, cognitive-behavioral (CBT) group intervention reported lower neuropsychiatric symptoms in their relative, less caregiver distress, a greater sense of caregiver self-efficacy, and less depressive symptoms over time (Gonyea, Lopez, & Velasquez, 2016).*

Home Care

- The preceding interventions may be adapted for home care use.

Powerlessness

Marina Martinez-Kratz MS, RN, CNE

NANDA-I

Definition

The lived experience of lack of control over a situation, including a perception that one's actions do not significantly affect an outcome.

Defining Characteristics

Alienation; dependency; depression; doubt about role performance; frustration about inability to perform previous activities; inadequate participation in care; insufficient sense of control; shame

Related Factors

Anxiety; caregiver role; dysfunctional institutional environment; ineffective coping strategies; insufficient interpersonal interactions; insufficient knowledge to manage a situation; insufficient social support; low self-esteem; pain; social marginalization; stigmatization

At-Risk Population

Economically disadvantaged

Associated Condition

Complex treatment regimen; illness; progressive illness; unpredictability of illness trajectory

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Depression Self-Control; Health Beliefs; Health Beliefs: Perceived Ability to Perform, Perceived Control, Perceived Resources; Participation in Health Care Decisions

Example NOC Outcome with Indicators

Health Beliefs: Perceived Control as evidenced by the following indicators: Perceived responsibility for health decisions/Beliefs that own decisions and actions control health outcomes. (Rate the outcome and indicators of **Health Beliefs: Perceived Control:** 1 = very weak belief, 2 = weak belief, 3 = moderately strong belief, 4 = strong belief, 5 = very strong belief [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- State feelings of powerlessness and other feelings related to powerlessness (e.g., anger, sadness, hopelessness)
- Identify factors that are uncontrollable
- Participate in planning and implementing care; make decisions regarding care and treatment when possible
- Ask questions about care and treatment
- Verbalize hope for the future and sense of participation in planning and implementing care

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Cognitive Restructuring; Complex Relationship Building; Mutual Goal Setting; Self-Esteem Enhancement; Self-Responsibility Facilitation

Example NIC Activities—Self-Responsibility Facilitation

Encourage independence but assist client when unable to perform; Assist client to identify areas in which they could readily assume more responsibility

Nursing Interventions and *Rationales*

Note: Before implementation of interventions in the face of client powerlessness, nurses should examine their own philosophies of care to ensure that control issues or lack of faith in client capabilities will not bias the ability to intervene sincerely and effectively.

- Assess powerlessness with tools that are available for general and specific client groups:
    - Measure of Powerlessness for Adult Patients (De Almeida & Braga, 2006)
    - Personal Progress Scale–Revised, tested with women (Johnson, Worell, & Chandler, 2005)
    - Life Situation Questionnaire–Powerlessness subscale, tested with stroke caregivers (Larson et al, 2005)
    - Making Decisions Scale, tested in clients with mental illness (Hansson & Bjorkman, 2005)
    - Family Empowerment Scale, tested on parents of children with emotional disorders (Koren, DeChillo, & Friesen, 1992)
- Observe for factors contributing to powerlessness (e.g., immobility, hospitalization, unfavorable prognosis, lack of support system, misinformation about situation, inflexible routine, chronic illness, addiction, history of trauma, gender). Help clients channel their behaviors in an effective manner. **EB:** *Many studies identify factors*

contributing to feelings of powerlessness are related to losses of person, place, health, or social relationships; gender; or the effect of trauma (Salomé et al, 2013; Doyle, 2014).

• Engage with clients using respectful listening and questioning to develop an awareness of clients' most important concerns. **EB:** *Engaging clients will integrate clinician expertise with client needs and can diminish feelings of powerlessness (Sheridan et al, 2015).*

• Provide support for client families to identify the balance between client care responsibilities and self-care. **EBN:** *A recent study found that by supporting client families and considering them as resources, family feelings of powerlessness can be reduced (Lindgren, Söderberg, & Skär, 2016).*

• Use a rehabilitative behavioral learning model that assists clients to understand how the mechanisms of habit and ritual work to reinforce powerlessness in their lives. *For clients with addiction, understanding the learning processes and mechanisms of powerlessness is an important part of recovery (Butler et al, 2015).*

• Refer client to an empowerment support group. **EBN:** *A randomized controlled trial found that clients who participated in an empowerment support group showed significant increases in levels of empowerment and self-care behaviors (Hsiao et al, 2016).*

• Refer to the care plans for **Hopelessness** and **Spiritual** distress.

Pediatric

• Provided empowerment-based educational preparation for parents that includes a focus on caregiving knowledge, caring behaviors, self-efficacy, and indicators of the child's recovery. **EBN:** *A study of an empowerment-based health education program for parents caring for children with a congenital heart defect (CHD) after corrective surgery showed parental improvement in caregiving knowledge, caring behaviors, and self-efficacy (Zhihong, Chao, & Xiaoling, 2016).*

• Initiate problem-solving opportunities, empowering discussions, and reflection to help families take action to manage their child's illness. **EBN:** *A randomized clinical trial found that implementation of an asthma family empowerment program decreased parental stress, improved family functioning, and increased children's pulmonary function (Yeh et al, 2016).*

• Provide nursing care that shifts the focus from the illness to the child. **EBN:** *Research indicates that children with a new diagnosis of cancer feel powerless and can benefit from being viewed as a competent individual who requires information and is able to participate in their care (Darcy et al, 2014).*

Geriatric

• In addition to the preceding interventions as appropriate:

- ❍ Initiate and facilitate family health conversations between the older client and their family. **EBN:** *Research findings showed that participation in family health conversations mediated consolation, helped identify family members' problems and suffering, and assisted to identify their family's resources and strengths (Dorell & Sundin, 2016).*
- ❍ Provide health education for older individuals that is tailored, interactive, structured, continuous, and incorporates motivational and encouragement techniques. **EB:** *A systematic review of the literature showed that use of specific educational interventions for older nursing home residents was empowering strategies that increased self-efficacy and self-care (Shoberer et al, 2016).*

Multicultural

- In addition to the preceding interventions as appropriate:
  - Assess for the influence of communication patterns, cultural differences in medical consultations, and client perceptions of inequalities in care quality as contributors to client feelings of powerlessness. **EB:** *Understanding and addressing client perceptions of power disparities may decrease clients' feelings of powerlessness (Akhavan & Karlsen, 2013).*
  - Provide support and educational interventions that are culturally tailored. **EB:** *A randomized control trial found that Latino families assigned to a culturally sensitive, cognitive-behavioral (CBT) group intervention reported lower neuropsychiatric symptoms in their relative, less caregiver distress, a greater sense of caregiver self-efficacy, and less depressive symptoms over time (Gonyea, Lopez, & Velasquez, 2016).*

Home Care

- In addition to the preceding interventions as appropriate:
  - Assess for denial in clients with cancer and provide support for caregivers. **EB:** *Although denial may be a protective mechanism for the client with cancer, it can create additional burdens for caregivers who may experience powerlessness and an inability to meet their own needs (Kogan, Dumas, & Cohen, 2013).*

Client/Family Teaching and Discharge Planning

- The preceding interventions may be adapted for home care use.

Risk for Powerlessness

Gail B. Ladwig MSN, RN

NANDA-I

Definition

Susceptible to the lived experience of lack of control over a situation, including a perception that one's actions do not significantly affect the outcome, which may compromise health.

Risk Factors

Anxiety; caregiver role; dysfunctional institutional environment; ineffective coping strategies; insufficient interpersonal interactions; insufficient knowledge to manage a situation; insufficient social support; low self-esteem; pain; social marginalization; stigmatization

At-Risk Population

Economically disadvantaged

Associated Condition

Complex treatment regimen; illness; progressive illness; unpredictability of illness trajectory

NOC, NIC, Client Outcomes, Nursing Interventions and *Rationales*, Client/Family Teaching and Discharge Planning, and References

See the care plan for **Powerlessness**

Risk for Pressure Ulcer

Jo Ann Coar BSN, RN-BC, CWOCN, COS-C

Definition

Susceptible to localized injury to the skin and/or underlying tissue usually over a bony prominence as a result of pressure, or pressure in combination with shear (National Pressure Ulcer Advisory Panel [NPUAP], 2007).

Risk Factors

Decrease in mobility; dehydration; dry skin; extended period of immobility on hard surface; hyperthermia; inadequate nutrition; incontinence; insufficient caregiver knowledge of pressure ulcer prevention; insufficient knowledge of modifiable factors; pressure over bony prominence; scaly skin; self-care deficit; shearing forces;

skin moisture; smoking; surface friction; use of linen with insufficient moisture wicking property

At-Risk Population

ADULT: Braden Scale score <17; American Society of Anesthesiologists (ASA) Physical Status classification score ≥1; CHILD: Braden Q Scale ≤15; extremes of age; extremes of weight; female gender; history of cerebral vascular accident; history of pressure ulcer; history of trauma; low score on Risk Assessment Pressure Sore (RAPS) scale; New York Heart Association (NYHA) Functional Classification ≥1

Associated Condition

Alteration in cognitive functioning; alteration in sensation; anemia; cardiovascular disease; decrease in serum albumin level; decrease in tissue oxygenation; decrease in tissue perfusion; edema; elevated skin temperature by 1°C to 2°C; hip fracture; impaired circulation; lymphopenia; pharmaceutical agent; physical immobilization; reduced triceps skinfold thickness

NOC Outcomes (Nursing Outcomes Classification)

Suggested NOC Outcomes

Tissue Integrity: Skin and Mucous Membranes

Example NOC Outcome with Indicators

Intact Tissue Integrity: Skin and Mucous Membranes as evidenced by the following indicators: Skin intactness/Skin lesions absent/Tissue perfusion/Skin temperature. (Rate the outcome and indicators of **Tissue Integrity: Skin and Mucous Membranes:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Report any altered sensation or pain at site of tissue impairment
- Skin, without redness over bony prominences and capillary refill of less than 6 seconds over areas of redness
- Be repositioned off of bony prominences frequently if risk for pressure injuries is high (e.g., Braden scale score ≤18)
- Demonstrate understanding of plan to reduce pressure injury risk
- Describe measures to protect the skin

NIC Interventions (Nursing Interventions Classification)

Suggested NIC Interventions

Pain Management; Pressure Injury Care; Pressure Injury Prevention; Risk Identification; Skin Care: Topical Treatments; Skin Surveillance

Example NIC Activities—Pressure Injury Care

Monitor color of skin, temperature, edema, erythema, moisture, and appearance of surrounding skin; Note characteristics of skin over bony prominences or under/in contact with medical devices

Nursing Interventions and *Rationales*

▲ NPUAP redefined the definition of a pressure ulcer, which is now referred to as pressure injuries, during the NPUAP 2016 Staging Consensus Conference in 2016. The new definitions more accurately define alterations in tissue integrity from pressure. Classify pressure injuries (NPUAP & European Pressure Ulcer Advisory Panel [EPUAP], 2016) using national guidelines and definitions (see http://www.npuap.org/resources/educational-and-clinical-resources/npuap-

pressure-injury-stages/).

- **Pressure Injury:** A pressure injury is localized damage to the skin and underlying soft tissue usually over a bony prominence or related to a medical or other device. The injury can present as intact skin or an open ulcer and may be painful. The injury occurs as a result of intense and/or prolonged pressure or pressure in combination with shear. The tolerance of soft tissue for pressure and shear may also be affected by microclimate, nutrition, perfusion, comorbidities, and condition of the soft tissue (NPUAP & EPUAP, 2016).
- **Stage 1 Pressure Injury:** Nonblanchable erythema of intact skin
  Area of localized nonbleachable erythema that may appear differently in darkly pigmented skin, and changes in sensation, temperature, or firmness may precede visual changes. Color changes do not include purple or maroon discoloration which is more likely to indicate deep tissue pressure injury (NPUAP & EPUAP, 2016).
- **Stage 2 Pressure Injury:** Partial-thickness skin loss with exposed dermis
  Partial-thickness skin loss with exposed dermis in which the wound bed is pink/red and moist and adipose (fat) and deeper tissues are not visible. Granulation tissue, slough, and eschar are not present. A stage 2 pressure injury may also present as an intact or ruptured blister. These injuries commonly result from adverse microclimate and shear in the skin over the pelvis and shear in the heel. This stage should not be used to describe moisture-associated skin damage (MASD) including incontinence-associated dermatitis (IAD), intertriginous dermatitis (ITD), medical adhesive–related skin injury (MARSI), or traumatic wounds (skin tears, burns, and abrasions) (NPUAP & EPUAP, 2016).
- **Stage 3 Pressure Injury:** Full-thickness skin loss
  Full-thickness loss of skin, in which adipose is visible and granulation tissue and epibole (rolled wound edges) are often present and undermining/tunneling may occur. Slough and/or eschar may also be visible. Fascia, muscle, tendon, ligament, cartilage, and/or bone are not exposed. The depth of tissue damage varies by anatomical location, and areas of significant adiposity can develop deep wounds. If slough or eschar obscures the extent of tissue loss, then this is an unstageable pressure injury (NPUAP & EPUAP, 2016).
- **Stage 4 Pressure Injury:** Full-thickness skin and tissue loss
  Full-thickness skin and tissue loss with exposed or directly palpable fascia, muscle, tendon, ligament, cartilage, or bone, and slough and/or eschar may be visible. Epibole, undermining, and/or tunneling often occur and depth varies by anatomical location. If slough or eschar obscures the extent of tissue loss, then this is an unstageable pressure injury (NPUAP & EPUAP, 2016).

• **Deep Tissue Pressure Injury:** Persistent nonblanchable deep red, maroon, or purple discoloration
Intact or nonintact skin with localized area of persistent nonblanchable deep red, maroon, or purple discoloration or epidermal separation revealing a dark wound bed or blood-filled blister. Pain and temperature change often precedes skin color changes. Discoloration may appear differently in darkly pigmented skin. This injury results from intense and/or prolonged pressure and shear forces at the bone–muscle interface. The wound may evolve rapidly to reveal the actual extent of tissue injury,

or it may resolve without tissue loss. If necrotic tissue, subcutaneous tissue, granulation tissue, fascia, muscle, or other underlying structures are visible, then this indicates a full-thickness pressure injury (unstageable, stage 3, or stage 4). Do not use deep tissue pressure injury to describe vascular, traumatic, neuropathic, or dermatological conditions (NPUAP & EPUAP, 2016).

• **Unstageable Pressure Injury:** Obscured full-thickness skin and tissue loss Full-thickness skin and tissue loss in which the extent of tissue damage within the ulcer cannot be confirmed because it is obscured by slough or eschar. If slough or eschar is removed, a stage 3 or stage 4 pressure injury will be revealed. Stable eschar (i.e., dry, adherent, intact without erythema or fluctuance) on the heel or ischemic limb should not be softened or removed (NPUAP & EPUAP, 2016).

• Routinely assess clients for risk of pressure injuries using a valid and reliable risk assessment tool (NPUAP & EPUAP, 2014). A validated risk-assessment tool such as the Norton scale or Braden scale should be used to identify clients at risk for pressure-related skin breakdown (NPUAP & EPUAP, 2014). **EB:** *Targeting variables (e.g., Braden scale risk subscale categories, age, severity of illness) can focus assessment on particular risk factors (e.g., pressure, immobility, perfusion) and help guide the plan of prevention and care (NPUAP/EPUAP, 2014; Ratliff et al, 2017).*

• Pressure injury risk assessment should be completed on admission, daily, and after procedures or changes in the client's condition (NPUAP & EPUAP, 2014; Baranoski & Ayello, 2016).

• Inspect the skin daily, especially bony prominences and dependent areas for pallor, redness, and breakdown. In addition to assessing pressure injury risk, client-specific interventions should be implemented to prevent tissue injury. Implement the following interventions to prevent tissue breakdown:

- ❍ Turn and reposition all individuals at risk for pressure injury, unless contraindicated because of medical condition or medical treatments.
- ❍ Position client properly; use pressure-reducing or pressure-relieving devices (e.g., pillows, gel or foam cushions, alternating pressure mattress, air-fluidized bed, kinetic bed) if indicated. Continue to turn and reposition the individual regardless of the support surface in use. Establish turning frequency based on the characteristics of the support surface and the individual's response (NPUAP & EPUAP, 2014).
- ❍ Lift and move client carefully using a turn sheet and adequate assistance; keep bed linens dry and wrinkle-free.
- ❍ Perform actions to keep client from sliding down in bed (e.g., bend knees slightly when head of bed is elevated 30 degrees or higher) to reduce the risk of skin surface abrasion and shearing. Use the 30-degree tilted side-lying position (alternately, right side, back, left side) or the prone position if the individual can tolerate this and his or her medical condition allows (NPUAP & EPUAP, 2014).
- ❍ Select a seated posture that is acceptable for the individual and minimizes the pressures and shear exerted on the skin and soft tissues (NPUAP & EPUAP, 2014).
- ❍ Keep client's skin clean. Thoroughly dry skin after bathing and as often as needed, paying special attention to skinfolds and opposing skin surfaces (e.g., axillae, perineum, beneath breasts). Pat skin dry rather than rub, and use a mild soap for bathing. Apply moisturizing lotion at least once a day.
- ❍ Protect the skin from contact with urine and feces (e.g., keep perineal area clean and dry, apply a protective ointment or cream to perineal area).

- ❍ Provide and encourage adequate daily fluid intake for hydration for an individual assessed to be at risk of or with a pressure injury (NPUAP & EPUAP, 2016). This must be consistent with the individual's comorbid conditions and goals (NPUAP & EPUAP, 2014).
- ❍ If the individual cannot be moved or is positioned with the head of the bed elevated over 30 degrees, then place a polyurethane foam dressing on the sacrum (NPUAP & EPUAP, 2016). Use heel offloading device or polyurethane foam dressings on individuals at high risk for heel ulcers (NPUAP & EPUAP, 2016).
- ❍ Consult with nutrition/dietary specialist to evaluate client's nutritional status.
- ❍ Increase activity as allowed.

▲ **EB:** *Pressure injuries result in additional pain and treatment for the client and additional health care services and costs. A comprehensive assessment of the client's risk for pressure injuries and proactive interventions is necessary to reduce the risk for tissue injury (NPUAP & EPUAP, 2014; NPUAP & EPUAP, 2016).*

• Medical device–related pressure injuries (MDRPIs) result from the use of devices designed and applied for diagnostic or therapeutic purposes. The resultant pressure injury generally conforms to the pattern or shape of the device. The injury should be staged using the NPUAP pressure injury staging system and the etiology of the pressure injury noted to be caused by the device (NPUAP & EPUAP, 2016).

- ❍ The head/face/neck, heel/ankle/foot, coccyx/buttocks, abdomen, and extremities are common body regions for MDRPI.
- ❍ Common devices associated with pressure-related tissue injury include oxygen delivery and monitoring devices (e.g., face mask, nasal cannula, pulse oximetry, bilevel positive airway pressure [BiPAP] mask), feeding tubes (e.g., nasogastric, gastric, jejunal tubes), endotracheal devices (oral and/or nasal endotracheal tubes, tracheostomy tubes), urinary and bowel elimination equipment (indwelling urinary catheter, fecal containment catheter), and musculoskeletal appliances (cervical collar, splints, braces).
- ❍ Assess and evaluate the purpose and function of the medical device.
- ❍ Assess proper fit of the medical device and securement to prevent rubbing, torque, or pulling on the device and skin.
- ❍ Protect the skin below and around the device to reduce pressure.

▲ **EB:** *Incorporate daily and frequent skin inspection around and under the medical device. See the NPUAP Best Practice flyer to help provide education about medical device–related ulcers (see http://www.npuap.org/wp-content/uploads/2013/04/BestPractices-CriticalCare1.pdf).*

• Critically ill clients are at increased risk for pressure ulcers, often requiring frequent skin risk assessment and preventive interventions. **EB:** *Support surfaces are often needed to reduce pressure risk in the critically ill client (Behrendt et al, 2014). Reposition the client often more frequently than every 2 hours (Makic et al, 2014; NPUAP & EPUAP, 2014). Frequently assess skin for shear injury and pressure areas when the client is in prone positioning or lateral rotation therapy is used (NPUAP & EPUAP, 2014).*

• **EB:** *Efforts must be taken to disseminate evidence-based guidelines and ensure that health care providers, in all settings, are making every effort to identify individuals who are at risk for pressure injuries and implement preventative and treatment interventions (Ratliff et al, 2017). Consider optimizing work procedures at a professional level through the introduction of tailored staff education, role models or designated wound care "champions," nurse-led quality improvement programs, and cues to perform pressure ulcer prevention (NPUAP & EPUAP, 2014).*

• If tissue breakdown occurs, notify a health care provider or wound care specialist. See care plan for Impaired **Skin** integrity for additional interventions if a pressure ulcer occurs.

Pediatric

• Perform an age-appropriate pressure injury (NPUAP & EPUAP, 2016) risk assessment using a valid and reliable tool. **CEB/EB:** *The Braden Q and Glamorgan scales are valid and reliable scales to assess pediatric client risks for compromised skin integrity related to pressure (Anthony, Willock, & Bahrestani, 2010; Galvin & Curley, 2012; Tume et al, 2013). The Neonatal Skin Risk Assessment Scale was developed to assess unique skin breakdown risk in neonates (Dolack et al, 2013).*
• Implement a comprehensive plan to reduce the client's risk of skin breakdown from pressure. Assessment should include the following:
  - ❍ Client independent activity and mobility levels
  - ❍ Body mass index and/or birth weight; lower weight may increase client risk of pressure-associated skin breakdown
  - ❍ Skin maturity
  - ❍ Adequate nutritional and hydration status
  - ❍ Perfusion and oxygenation
  - ❍ Presence of external devices
  - ❍ Duration of hospital stay

▲ **EB:** *Pediatric clients with medical devices are at higher risk for pressure injuries (NPUAP & EPUAP, 2016). Inspect the skin under and around the device at least twice a day. Conduct more frequent (greater than twice daily) skin assessments at the skin–device interface in individuals vulnerable to fluid shifts and/or exhibiting signs of localized or generalized edema (NPUAP & EPUAP, 2014). Frequent (e.g., daily and after procedures) and ongoing assessment of the client's risk for pressure injury (NPUAP & EPUAP, 2016) is an important prevention intervention. Carefully assess the skin on the client's occiput as part of the assessment (NPUAP & EPUAP, 2014).*
• Select an age-appropriate support surface for premature neonates and pediatric clients at high risk for pressure ulcers. **CEBN:** *A longitudinal study found that the use of continuous and reactive low-pressure mattresses reduced the observed incidence of pressure ulcers (Garcia-Molina et al, 2012). Select a support surface to prevent occipital pressure ulcers for at-risk clients (NPUAP & EPUAP, 2014).*
• *Engage the client/family/legal guardian in the development of a client-specific plan of care to reduce pressure-related risk for skin breakdown (NPUAP & EPUAP, 2014).*
• Document risk assessment and interventions implemented to reduce the client's risk for pressure injury (NPUAP, 2016) development.

Geriatric

• Consider the older client's cognitive status when assessing the skin and in developing a comprehensive plan of care to prevent pressure injuries (NPUAP & EPUAP, 2014; NPUAP & EPUAP, 2016).
• Aging skin, medications (e.g., steroids), and moisture place the older client at increased risk for pressure-associated skin breakdown. **EB:** *Assess the client for pressure injury (NPUAP & EPUAP, 2016) risk, skin tear, and moisture-associated skin breakdown. It is important to differentiate the cause of the older client's skin breakdown to effectively implement prevention and treatment strategies. Frequently interventions complement each*

other in the overall goal to prevent a compromise in the client's skin integrity (Holmes et al, 2013; NPUAP & EPUAP, 2014).

- *Use atraumatic wound dressings to prevent and treat pressure injuries (NPUAP & EPUAP, 2016) to reduce further injury to frail older client's skin (NPUAP & EPUAP, 2014).*
- For older clients with continence concerns, develop and implement an individualized continence management program (NPUAP & EPUAP, 2014). **EB:** *Use skin barrier products and moisture wicking pads to reduce moisture-associated skin irritation that increases the risk for pressure injury (NPUAP & EPUAP, 2016) development; avoid the use of diapers except when the client is ambulating (NPUAP & EPUAP, 2014; Willson et al, 2014).*
- *Regularly reposition the older client who is unable to reposition independently. Consider pressure redistribution support surface for clients assessed to be at high risk for pressure injuries (NPUAP & EPUAP, 2014; Makic et al, 2014; NPUAP & EPUAP, 2016).*

Home Care

- The interventions described previously may be adapted for home care use.
- Instruct and assist the client and caregivers in how to assess the skin for excessive pressure. Provide written instructions for actions they can implement to reduce the risk of pressure injury (NPUAP, 2016) development.
- Educate client and caregivers on proper nutrition and when to call the agency and/or health care provider with concerns.

▲ It may be beneficial to initiate a consultation in a case assignment with a wound, ostomy, continence nurse (or wounds specialist) to establish a comprehensive plan for pressure ulcer risk reduction for clients at high risk for skin breakdown.

Ineffective Protection

Ruth M. Curchoe RN, BSN, MSN, CIC

NANDA-I

Definition

Decrease in the ability to guard self from internal or external threats such as illness or injury.

Defining Characteristics

Altered in clotting; alteration in perspiration; anorexia; chilling; coughing; deficient immunity; disorientation; dyspnea; fatigue; immobility; insomnia; itching, maladaptive stress response; neurosensory impairment; pressure ulcer; restlessness; weakness

Related Factors

Inadequate nutrition; substance abuse

At-Risk Population

Extremes of age

Associated Condition

Abnormal blood type; cancer; immune disorder; pharmaceutical agent; treatment regimen

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Health-Promoting Behavior; Blood Coagulation; Endurance; Immune Status

Example NOC Outcome with Indicators

Immune Status as evidenced by the following indicators: Recurrent infections/Tumors/Weight loss. (Rate the outcome and indicators of **Immune Status:** 1 = severe, 2 = substantial, 3 = moderate, 4 = mild, 5 = none [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Remain free of infection while in contact during contact with health care
- Remain free of any evidence of new bleeding as evident by stable vital signs
- Explain precautions to take to prevent infection including hand hygiene
- Explain precautions to take to prevent bleeding including fall prevention

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Bleeding Precautions; Infection Prevention; Infection Protection

Example NIC Activities—Infection Protection

Monitor for systemic and localized signs and symptoms of infection; Inspect skin and mucous membranes for redness, extreme warmth, or drainage

Nursing Interventions and *Rationales*

• Take temperature, pulse, and blood pressure (e.g., every 1–4 hours). **EBN:** *Changes in vital signs can indicate the onset of bleeding or infection. Rectal and oral temperature measurements are more accurate than other methods of temperature measurement such as temporal or axillary measurement (Perry & Potter, 2014).*

▲ Observe nutritional status (e.g., weight, serum protein and albumin levels, muscle mass, and usual food intake). Work with the dietitian to improve nutritional status if needed. **EB:** *Clients diagnosed with asthma or repeated respiratory infections should have a nutritional assessment.* **EB:** *Vitamin D influences the body's immune system by influencing the production of endogenous antimicrobial peptides and regulating the inflammatory cascade (Gunville, Mourani, & Ginde, 2013).*

• Observe the client's sleep pattern; if altered, see Nursing Interventions and *Rationales* for Disturbed **Sleep** pattern.

• Identify stressors in the client's life. If stress is uncontrollable, see Nursing Interventions and *Rationales* for Ineffective **Coping. EB:** *Nearly 30% of older clients experience delirium during hospitalization; the incidence is higher in intensive care units. Among older clients who have had surgery, the risk for delirium varies from 10% to more than 50% (Sternicuk, Rusak, & Rockwood, 2014).*

Prevention of Infection

▲ Monitor for and report any signs of infection (e.g., fever, chills, flushed skin, drainage, edema, redness, abnormal laboratory values, pain) and notify the health care provider promptly. **EBN:** *Although the white blood cell count may be in the normal range, an increased number of immature bands may be present (Perry & Potter, 2014).* **CEBN:** *A neutropenic client with fever represents an absolute medical emergency (Klastersky et al, 2016). If the client's immune system is depressed, notify the health care provider of elevated temperature, even in the absence of other symptoms of infection.* **EB:** *Clients with depressed immune function are unable to mount the usual immune responses to the onset of infection; fever may be the only sign of infection. A neutropenic client with fever represents an absolute medical emergency.* **CEBN:** *A neutropenic client with fever represents an absolute medical emergency (EB Medicine, 2013).*

• If white blood cell count is severely decreased (i.e., absolute neutrophil count of less than $1000/mm^3$), initiate the following precautions:

- ❍ Take vital signs every 2 to 4 hours
- ❍ Complete a head-to-toe assessment twice daily, including inspection of oral mucosa, invasive sites, wounds, urine, and stool; monitor for onset of new reports of pain

▲ Avoid any invasive procedures, including catheterization, injections, or rectal or vaginal procedures unless absolutely necessary. **EBN:** *Classic organisms such as influenza cause infections in the immunocompromised host; often their presentation is different and more serious (Flood, 2014).*

- ❍ Consider warming the client before elective surgery. Normothermia is associated with low postoperative infection rates (Moucha, 2016)

▲ Administer granulocyte growth factor as ordered. **EB:** *Clients most likely to benefit from therapy would be those with profound neutropenia or neutropenia with infections not responding to antimicrobial therapy (Flood, 2014).* **EB:** *Granulocyte macrophage colony-stimulating factor is mostly well tolerated, although some cancer and kidney disease clients have demonstrated significant complications such as leukopenia (McDowell, 2017).*

- ❍ Take meticulous care of all invasive sites; use chlorhexidine gluconate for cleansing. **EB:** *Use of chlorhexidine gluconate for vascular catheter site care reduces catheter-related bloodstream infections and catheter colonization (Centers for Disease Control and Prevention [CDC], 2011b).*
- ❍ Provide frequent oral care. **EBN:** *The effects of chemotherapy or radiation can cause changes in taste and smell resulting in pain and nutritional deficiencies (Poirier, 2013).*
- ❍ Follow Standard Precautions, especially performing hand hygiene to prevent health care–associated infections. **EBN:** *Hands of health care workers are the most common cause of health care–associated infections (CDC, 2011a; Haas, 2014).*

▲ Refer for appropriate prophylactic antifungal treatment and avoid pathogen exposure (through air filtration, regular hand hygiene, and avoidance of plants and flowers). *Practical measures can be taken to avoid exposing the client to fungi (Flood, 2014).* **EB:** *Highly active imidazoles have had a major effect on human fungal infections (Ferrara, MacDougall, & Gallagher, 2011).*

- ❍ Have the client wear a mask when leaving the room. **EB:** *To prevent health care–acquired pulmonary aspergillosis during hospital construction, neutropenic clients may be at lesser risk if masked when leaving their room (Thom, Kleinberg, & Roghmann, 2013). Limit and screen visitors to minimize exposure to contagion.*
- ❍ Help the client bathe daily.
- ❍ Practice food safety; a neutropenic diet may not be necessary. **EBN:** *No clear evidence exists that the neutropenic diet makes a difference in overall rates of infection (Thom, Kleinberg, & Roghmann, 2013).*
- ❍ Ensure that the client is well nourished. Provide food with protein, and consider vitamin supplements. If appetite is suppressed, institute a dietary referral. Keep track of serum albumin levels and transferrin and prealbumin levels. **CEB:** *Levels of the visceral proteins (albumin, transferrin, and prealbumin) are an indirect measure of nutritional status (Geismar, 2014).*
- ❍ Help the client cough and practice deep breathing regularly. Maintain an appropriate activity level.
- ❍ Obtain a private room for the client. Use high-energy particulate air filters if available and appropriate. Protective isolation is not recommended. Recognize that cotton cover gowns may not be effective in decreasing infection. **EBN:** *Complete an infection control risk assessment (ICRA) considering such issues as the type of transplant performed, the environment, and prior infection rates. Use the ICRA to decide the types of infections, processes, practices, and risk to be monitored (American Society for Healthcare Engineering [ASHE], 2014; Harris, 2014).*

▲ Watch for signs of sepsis, including change in mental status, fever, shaking, chills, and hypotension. If present, notify the health care provider promptly. *Change in mental status, fever, shaking, chills, and hypotension are indicators of sepsis (Curchoe, 2013).*

• Refer to care plan for Risk for **Infection.**

• Refer to care plan for Readiness for enhanced **Nutrition** for additional interventions.

Pediatric

• Suggest kangaroo care (KC), frequent and exclusive or nearly exclusive breastfeeding, and early discharge from hospital for low-birth-weight infants. **EBN:**

The practice of KC decreases the incidence of nosocomial infection. Early KC likely increases the chance of the infant being colonized with maternal flora rather than the flora in the nursery, which may include antibiotic-resistant organisms and coagulase-negative staphylococcus. Because KC is only undertaken between individual infant–mother dyads, it should not increase the spread of infection from one infant to another during infectious outbreaks (Jefferies, 2012).

• Assess postoperative fever in pediatric oncology clients promptly. **EB:** *Fever is a physiological mechanism that has beneficial effects in fighting infection. There is no evidence that fever itself worsens the course of an illness or that it causes long-term neurological complications (Sullivan & Farrer, 2011).*

• For hand hygiene with low-birth-weight infants, use alcohol hand rub and gloves. **EBN:** *Audit programs to track compliance with hand hygiene identified a drop in the incidence of health care–associated infections in very low-birth-weight infants in the neonatal intensive care unit (Helder et al, 2014).*

Geriatric

▲ If not contraindicated, promote exercise to promote improved quality of life in older adults. **EB:** *A study of 95 healthy adults 65 years and older suggested that the effects of resistance-type exercise training can counteract the loss of muscle mass and strength with aging (Buckines, 2017). Give older clients with imbalanced nutrition a vitamin D supplement to reduce risk of fracture.* **EB:** *Vitamin D deficiency has been correlated with increased risk and greater severity of infection, particularly of the respiratory tract. Vitamin D influences the body's immune system by influencing the production of endogenous antimicrobial peptides and regulating the inflammatory cascade (Dankers et al, 2016).*

• Refer to the care plan for Risk for **Infection** for more interventions related to the prevention of infection.

Prevention of Bleeding

▲ Monitor the client's risk for bleeding; evaluate results of clotting studies and platelet counts. *Laboratory studies give a good indication of the seriousness of the bleeding disorder.*

• Watch for hematuria, melena, hematemesis, hemoptysis, epistaxis, bleeding from mucosa, petechiae, and ecchymoses. **EBN:** *A study of 200 clients with idiopathic thrombocytopenic purpura revealed that 57% had ecchymoses, 42% had petechiae, 23% had bleeding from the gums, and 31.5% had epistaxis; 8% had two or more signs and symptoms and 73% were asymptomatic when the diagnosis was established (Garcia-Stivalet et al, 2014).*

▲ Give medications orally or intravenously only; avoid giving intramuscularly, subcutaneously, or rectally.

• Apply pressure for a longer time than usual to invasive sites, such as venipuncture or injection sites. *Additional pressure is needed to stop bleeding of invasive sites in clients with bleeding disorders.*

• Take vital signs often; watch for changes associated with fluid volume loss. Excessive bleeding causes decreased blood pressure and increased pulse and respiratory rates (Ackley & Ladwig, 2014).

• Monitor menstrual flow if relevant; have the client use pads instead of tampons. **EB:** *Menstruation can be excessive in clients with bleeding disorders. Adolescents presenting with heavy menstrual bleeding at or near menarche assessment should include bleeding disorders (Rydz & Jamieson, 2013; Singh et al, 2013).*

• Have the client use a moistened toothette or a very soft child's toothbrush instead of

an adult toothbrush. Follow the dentist's recommendation for flossing and appropriate rinses to use. Control gum bleeding by applying pressure to gums with gauze pad soaked in ice water. *These actions help prevent trauma to the oral mucosa, which could result in bleeding (National Institute of Dental and Craniofacial Research [NIDCR], 2015).*

• Ask the client either to not shave or to use only an electric razor. *This helps prevent any unnecessary trauma that could result in bleeding (Perry & Potter, 2014).*

▲ To decrease risk of bleeding, avoid administering salicylates or nonsteroidal antiinflammatory drugs (NSAIDs) if possible. **CEB:** *Gastrointestinal bleeding caused by NSAIDs, acetylsalicylic acid, or warfarin was the most common adverse drug reaction (ADR) that resulted in hospital admission and represented 40% of all ADRs (12 of 30), according to the World Health Organization (WHO) causality criteria (Tennant, 2015).*

Home Care

• Some of the interventions previously described may be adapted for home care use.

▲ Consider using a nurse-led patient-centered medical home (PCMH) for monitoring anticoagulant therapy. **EBN:** *Establishment of nurse-led medical homes to monitor anticoagulation therapy management clinics leads to improvements in quality of care in terms of improved control of international normalized ratio and reduced complications. Data support a conclusion that PCMHs do improve quality, access, and cost (Scudder, 2011).*

• For terminally ill clients, teach and institute all of the previously mentioned noninvasive precautions that maintain quality of life. Discuss with the client, family, and health care provider the consequences of contracting infection. Determine which precautions do not maintain quality of life and should not be used (e.g., physical assessment twice daily or multiple vital sign assessments). **CEB:** *Multiple assessments and other invasive procedures are recovery-based and cure-focused activities. The client and provider must agree on an approach to care for the clients during their remaining life (Periyakoil, Stevens, & Kraemer, 2013).*

Client/Family Teaching and Discharge Planning

Depressed Immune Function

• Teach the client and family how to take a temperature. Encourage the family to take the client's temperature between 3 and 7 p.m. at least once daily. **EBN:** *For most people, the difference between high and low values throughout the day is approximately 2°F (1.1°C) (97°F–99°F [36.1°C–37.2°C]), with the lowest value typically occurring in the early morning hours (2 a.m.–5 a.m.) and the highest values commonly occurring in the evening (Medline Plus, 2011; Fetzer, 2013).* Teach precautions to use to decrease the chance of infection (e.g., avoiding uncooked fruits and vegetables, using appropriate self-care including good hand hygiene ensuring a safe environment). Teach the client to avoid crowds and contact with persons who have infections. Teach the need for good nutrition, avoidance of stress, and adequate rest to maintain immune system function. **CEBN:** *Approaches to avoiding infection at home for the client with neutropenia include good hand hygiene and careful management of food, drink, and the client's environment (Yeung, 2014).*

Bleeding Disorder

• Teach the client to wear a medical alert bracelet and notify all health care personnel of his or her bleeding disorder. **CEB:** *Emergency identification schemes such as medical*

alert bracelets use emblems that alert health care professionals to potential problems and can ensure appropriate and prompt treatment (Medical and Scientific Advisory Council [MASAC], 2017). Teach the client and family the signs of bleeding, precautions to take to prevent bleeding, and action to take if bleeding begins. Caution the client to avoid taking over-the-counter medications without the permission of the health care provider. *Medications containing salicylates can increase bleeding.*

- Teach the client to wear loose-fitting clothes and avoid physical activity that might cause trauma.

Rape-Trauma syndrome

Julianne E. Doubet BSN, RN, EMT-B

NANDA-I

Definition

Sustained maladaptive response to a forced, violent, sexual penetration against the victim's will and consent.

Defining Characteristics

Aggression; agitation; alteration in sleep pattern; anger; anxiety; change in relationship(s); confusion; denial; dependency; depression; disorganization; dissociative identity disorder; embarrassment; fear (00148); guilt; helplessness; history of suicide attempt; humiliation; hyperalertness; impaired decision-making; low self-esteem; mood swings; muscle spasm; muscle tension; nightmares; paranoia; phobias; physical trauma; powerlessness (00125); self-blame; sexual dysfunction; shame; shock; substance misuse; thoughts of revenge

Related Factors

To be developed

At-Risk Population

Rape

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Abuse Cessation; Abuse Protection; Abuse Recovery: Emotional, Sexual, Coping; Impulse Self-Control; Self-Mutilation Restraint

Example NOC Outcome with Indicators

Abuse Recovery: Sexual as evidenced by the following indicators: Acknowledgment of right to disclose abusive situation/Expression of right to have been protected from abuse. (Rate the outcome and indicators of **Abuse Recovery: Sexual:** 1 = none, 2 = limited, 3 = moderate, 4 = substantial, 5 = extensive [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Share feelings, concerns, and fears
- Recognize that the rape or attempt was not client's own fault
- State that, no matter what the situation, no one has the right to assault another
- Describe medical/legal treatment procedures and reasons for treatment
- Report absence of physical complications or pain

• Identify support resources and attend psychotherapy/group assistance in coping with the trauma and effects of the traumatic experience
• Function at same level as before crisis, including sexual functioning
• Recognize that it is normal for full recovery to take a minimum of 1 year

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Abuse Protection Support; Counseling; Crisis Intervention; Sexual Counseling; Infection Protection; Rape-Trauma Treatment

Example NIC Activities—Rape-Trauma Treatment

Explain rape protocol and obtain consent to proceed through protocol; Implement crisis intervention counseling

Nursing Interventions and *Rationales*

• Escort the client to a treatment room immediately on arrival to the emergency department. Stay with (or have a trusted person stay with) the client. **EBN:** *Victims of sexual assault require special attention from caregivers so they do not feel victimized a second time in the medical facility (Durieux, 2014).*
• Assure the client of confidentiality. **EB:** *According to Ogunwale and Oshiname (2017), rape is a traumatic experience, which has known physical and psychosocial destructive effects, but survivors rarely seek support to escape being stigmatized.*
▲ Provide a sexual assault response team (SART), if available, that includes a sexual assault nurse examiner (SANE), rape counseling advocate, and representative of law enforcement for best possible outcomes. **EB:** *According to a study by Patterson and Tringali (2015), a team of forensic nurses and victim advocates partner together to provide treatment not only for the necessary physical and medical requirements of sexual assault survivors, but also for dealing with the complex legal and mental health needs that necessitate follow-up.*
• Observe for signs of physical injury. **CEB:** *Some locations to assess for obvious genital injuries would include tears or abrasions of the posterior labia, abrasion or bruising of the labia minora and fossa navicularis, and ecchymosis or tears of the hymen; document these injuries as evidence for any future legal proceedings (Linden, 2011).*
• Document the client's chief complaint and request an event history of the sexual assault in his or her own words. **EBN:** *Participants felt cared for and emotionally supported when they were probed about what had happened to them (Selenga & Jooste, 2015).*
• Encourage the client to verbalize his or her feelings. **EBN:** *Research by Thomas, Scott Tilley, and Esquibel (2015) indicated that survivors want nonjudgmental attitudes from health care providers, acknowledgment of the violence they have suffered, and that their stories are heard and believed.*
• Make sure that the victim understands everything you are doing. **EBN:** *The preservation of client dignity must be maintained, not only for the victim's protection, but also to show respect and caring; respecting dignity is one of the essential behaviors that nurtures caring (Gustafsson, Wingerblad, & Lindwall, 2013).*
• Explain to the client that all or some of the client's clothing may be kept for evidential purposes and photographs may be taken (with consent) to document the client's injuries. **CEB:** *Assessment and treatment of victims of sexual assault, as well as the precise collection and documentation of evidence, are critical for a solid case (Fitzpatrick et al,*

2012).

- ▲ If a law enforcement interview is permitted, provide support by staying with the client at his or her request. **EB:** *A study authorized by the Bureau of Justice (Kruttschnitt, Kalseek, & House, 2014) surmised that we must take into consideration the frequency and environment under which rape and sexual assault are committed because this is vital information in targeting resources for law enforcement and support for victims.*
- Use the sexual assault evidence collection kits that have been reviewed by the SART members and provided by your state to collect adequate and accurate evidence for analysis by a forensic laboratory. **EB:** *The health care provider who examines victims of sexual assault must be responsible to act in accordance with state and local statutory or policy requirements for the use of evidence-gathering kits (American College of Obstetrics and Gynecology [ACOG], 2014).*
- ▲ Discuss the possibility of pregnancy and sexually transmitted infections (STIs) and the treatments available. **EB:** *Victims of sexual assault should be advised that they are at risk for pregnancy, STIs, and posttraumatic stress disorder (PTSD); as a victim of sexual assault, he or she should be monitored and offered emergency contraception and STI prophylaxis (American College of Obstetrics and Gynecology, 2014).*
- ▲ Encourage the client to report the sexual assault to a law enforcement agency. **EB:** *Sexual assault survivors often feel apprehensive about involvement in the criminal justice system; therefore many do not report their sexual assault to law enforcement (Patterson & Tringali, 2015).*
- ▲ For those interested in a spiritual connection, make the appropriate recommendation. **EBN:** *According to Hellman (2014), research should be introduced to develop theory using religious and spiritual beliefs to aid in the recovery process of sexual assault victims.*
- ▲ Stress the necessity of follow-up care with a mental health professional to recognize and intervene with problems associated with the effects of rape-trauma/sexual assault. **EB:** *Price et al (2014) stated that although sexual assault increases the risk for psychiatric disorders and although there is treatment available, few victims choose mental health care after their attack.*
- Stress the importance of awareness throughout the community of the scope and severity of the effects of sexual abuse as a means of additional healing empowerment. **EB:** *Recovery from sexual assault/rape is frequently hindered by the public's failure to believe the victim and the need to obtain justice (Chapleau & Oswald, 2014).*

Geriatric

- Build a trusting relationship with the client. **EBN:** *A patient-centered communication style by the nurse can have positive outcomes in the patient–nurse relationship (Selenga & Jooste, 2015).*
- All examinations should be done on older adults as they would be done on any adult client after sexual assault, with modifications for comfort if necessary. **EB:** *In a study by Nobrega et al (2014) of the forensic assessment of older victims of sexual assault, the forensic evaluation was found to be essential in positive judicial outcomes and invaluable in identifying physical and biological confirmation of sexual assault.*
- Assess for mobility limitations and cognitive impairment. **EB:** *As the aging population swells, a rise in morbidity can be validated, and with it, not only an increase in chronic illnesses, but also the recognition of significant cognitive changes and physical disabilities (Kizie et al, 2014).*
- Explain and encourage the client to report sexual abuse. **EBN:** *It is of the utmost*

importance that the client's wishes, feelings, and beliefs are taken into consideration prior to any action being taken (Andrews, 2017).
• Observe for psychosocial distress. **EBN:** *The elderly are often isolated and mistreated, leaving them insecure and vulnerable and without support of family and/or friends (Sena Damasceno, de Sousa, & Moura, 2016).*
▲ Consider arrangements for safe housing victim of abuse. **EB:** *In Dakin's (2014) study involving a diverse group of older women who were given scenarios in which the scenario subjects, because of circumstances, had the option of choosing autonomy or protection, the majority picked protection over autonomy.*

Male Rape

▲ **EB:** *According to Javaid (2015), there appears to be three barriers to police acknowledgement of male rape: statistics, underreporting of male rape, and "the masculine police subculture."*
▲ Assess to determine whether physically abused women are also victims of sexual assault. **EBN:** *According to a study by Santos de Oliveira et al (2016), there is a need for primary care professionals to focus on women who are involved in relationships in which they experience sexual violence.*

Multicultural

▲ Assess for the influence of cultural beliefs, norms, and values on the client's ability to cope with the trauma of the rape experience. **EBN:** *Rejection by family and community after a rape remains an enormous concern among survivors of sexual violence (Kohli et al, 2013).*

Home Care

• Some of the interventions described previously may be adapted for home care use.
• Corroborate the client's feelings of self-worth. Posttraumatic disorders were the most common consequences in women victims of violence**. EB:** *Mason and Lodrick (2013) concluded in their study, that sexual violence can have long-lasting and destructive consequences including that of PTSD.*
• Assist the client with realistically assessing the home setting for safety and/or selecting a safe environment in which to live. **CEB:** *The protection or safeguarding of vulnerable adults must be an integral part of everyday nursing practice (Straughair, 2011).*
▲ Ensure that the client has systems in place for long-term support. **EBN:** *When treating a victim of sexual assault, the health care provider should not only treat the survivor's physical injuries, but understand and support the emotional needs of the survivor and follow-up with them during the period of recovery (Reis, Lopes, & Osis, 2017).*
▲ Design a practical discharge plan to include a safe shelter if needed, follow-up care for physical injury, and follow-up referral for psychological support. **EBN:** *It is vital to abused older adults to be sheltered in a safe, protected, violence-free, and medically suitable environment (Heck & Gillespie, 2013).*
▲ Assess for other client vulnerabilities, such as mental health issues or addiction, and refer the client to social agencies for implementation of a therapeutic regimen. **EB:** *Those who have the dual diagnosis of addiction and mental illness are highly prone to sexual victimization, and actions should be taken to reduce their vulnerability (de Waal, Decker, & Gouariaan, 2017).*

Client/Family Teaching and Discharge Planning

• Emphasize the client's needs for safety and to decrease the opportunities for repeat attacks. Recognize the vulnerability of the client. **EBN:** *In a qualitative study by Arend et al (2013) involving survivors of sexual assault in South Africa, it was found that nurses have numerous opportunities to improve the quality of post–sexual assault care, which in turn advances the clients' emotional and psychosocial outcomes.*
• Note: PTSD has a high probability of being a psychological sequela to rape. Research demonstrated two effective treatments for the improvement of PTSD in rape victims: prolonged exposure and stress inoculation training. Prolonged exposure involves reliving the rape experience by imagining it as vividly as possible, describing it aloud in the present tense, taping this description, and listening to the tape at least once daily. Stress inoculation training uses breathing exercises to diminish anxiety and instruction in coping skills, thought stopping, cognitive restructuring, self-dialog, and role playing. Research suggests that a combination of both treatments may provide the optimal effect. Furthermore, for those who reported the assault to police, lower levels of legal system success and satisfaction were linked to higher levels of perceived control over present recovery.

Ineffective Relationship

Gail B. Ladwig MSN, RN

NANDA-I

Definition

A pattern of mutual partnership that is insufficient to provide for each other's needs.

Defining Characteristics

Delay in meeting of developmental goals appropriate for family life cycle stage; dissatisfaction with complementary relationship between partners; dissatisfaction with emotional need fulfillment between partners; dissatisfaction with idea sharing between partners; dissatisfaction with information sharing between partners; dissatisfaction with physical need fulfillment between partners; inadequate understanding of partner's compromised functioning; insufficient balance in autonomy between partners; insufficient balance in collaboration between partners; insufficient mutual respect between partners; insufficient mutual support in daily activities between partners; partner not identified as support person; unsatisfying communication with partner

Related Factors

Ineffective communication skills; stressors; substance misuse; unrealistic expectations

At-Risk Population

Developmental crisis; history of domestic violence; incarceration of one partner

Associated Condition

Alteration in cognitive functioning in one partner

NOC, NIC, Client Outcomes, Nursing Interventions and *Rationales,* Client/Family Teaching and Discharge Planning, and References

Refer to care plan Readiness for enhanced **Relationship**

Readiness for enhanced Relationship

Marina Martinez-Kratz MS, RN, CNE

NANDA-I

Definition

A pattern of mutual partnership to provide for each other's needs, which can be strengthened.

Defining Characteristics

Expresses desire to enhance autonomy between partners; expresses desire to enhance collaboration between partners; expresses desire to enhance communication between partners; expresses desire to enhance emotional need fulfillment for each partner; expresses desire to enhance mutual respect between partners; expresses desire to enhance satisfaction with complementary relationship between partners; expresses desire to enhance satisfaction with emotional need fulfillment for each partner; expresses desire to enhance satisfaction with idea sharing between partners; expresses desire to enhance satisfaction with information sharing between partners; expresses desire to enhance satisfaction with physical need fulfillment for each partner; expresses desire to enhance understanding of partner's functional deficit

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Coping; Family Functioning/Integrity; Role Performance; Social Support

Example NOC Outcome with Indicators

Family Integrity as evidenced by the following indicators: Members share thoughts, feelings, interests, concerns/Members communicate openly and honestly with one another/Members encourage individual autonomy and independence/Members assist one another in performing roles and daily tasks. (Rate the outcome and indicators of **Family Integrity:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Family/Client Will (Specify Time Frame)

- Share thoughts and feelings with each other
- Communicate openly with each other
- Assist in performing family roles and tasks
- Provide support for each other
- Obtain appropriate assistance

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Coping Enhancement; Family Integrity Promotion; Role Enhancement

Example NIC Activities—Family Integrity Promotion

Facilitate a tone of togetherness within/among the family; Encourage family to maintain positive relationships; Facilitate open communication among family members

Nursing Interventions and *Rationales*

- Assess the ways in which the relationship has been altered (communication, sexuality, intimacy, etc.) from both partner's perspective. **EB:** *A recent review found that when involving both partners in marital interventions, it is necessary to assess both views of the relationship (Albuquerque, Pereira, & Narciso, 2016).*
- Assess relationship quality using the Relationship Flourishing Scale. **EB:** *The Relationship Flourishing Scale is a 12-item measure of eudaimonic relationship quality that assesses meaning, personal growth, relational giving, and goal sharing (Fowers et al, 2016).*

• Focus on helping couples maintain or develop marital closeness. **EB:** *A recent review found that marital closeness is a protective factor that may prevent relationship breakdown (Albuquerque, Pereira, & Narciso, 2016).*
• Assist couples to identify sources of their own perceived *dyadic* empathy in the relationship. **EB:** *Higher perceived empathy toward the relationship partner is associated with relationship satisfaction (Kimmes et al, 2014).*
• Assist families to identify sources of gratitude in their lives. **EB:** *Research showed that gratitude fostered all facets of posttraumatic growth, such as relationships, personal strengths, and awareness of meaningful possibilities (Ruini & Vescovelli, 2013).*
• Assist clients to identify sources of gratitude in their lives using a future-oriented focus. **EB:** *Research shows that clients with a regulatory focus of promotion were more likely to express gratitude, which inspired them to strengthen their relationships with helpful and responsive partners (Mathews & Shook, 2013).*
• Encourage couples to engage in reappraisal of conflict in their relationship. **EB:** *A study demonstrated that a reappraisal of conflict in their marriages protected participants against declines in marital quality over time (Finkel et al, 2017).*
• Encourage the use of positive relational humor and humor evaluation between partners. **EB:** *Relational humor, which is created and shared between partners, and humor evaluation, which is one partner's judgment of the other partner's sense of humor, were both strongly associated with relationship satisfaction in a meta-analysis (Hall, 2017).*
• Provide support resources to provide military members and their families with assistance in preparation for deployments and education about the importance of maintaining communication during deployment. **EBN:** *Veterans who have been deployed report that dedicated resources are needed to successfully reestablish their social connections with family and reclaim their place within the family (Messecar, 2017).*
• Encourage couples to participate together in leisure activities like dance. **EB:** *This study demonstrated that a light-intensity ballroom dancing intervention improved the life of cancer survivors and the relationship with loved ones (Pisu, Demark-Wahnefried, & Kenzik, 2017).*
• Refer to care plans Readiness for enhanced **Family** processes and Readiness for enhanced family **Coping.**

Pediatric

• Encourage guidance and information on communication for parents of seriously ill children. **EBN:** *The findings of this study suggested that parents are an important focus of care, and enhancing couples' communication is a way to address changes in marital relationships (Silva-Rodrigues et al, 2016).*

Geriatric

• Assess geriatric spousal caregivers for positive and negative consequences of providing medical care. **EB:** *A recent study found that more medical/nursing tasks were linked to greater caregiving gains. Spouses who assist with more medical/nursing tasks feel they are directly benefiting their partner, which further enhances perceptions of gains and promotes positive feelings among spousal caregivers (Polenick et al, 2017).*
• Assess sexuality needs and support consensual sexual expression. **EB:** *Older adult participants in an Australian study made suggestions related to the visibility and normalization of sex in later life, cultural representations of sex and older people, and the need to provide sex-positive aged care and retirement home facilities (Fileborn et al, 2017).*

• Facilitate and increase opportunities for social connectedness for older individuals through the use of technology training. **EBN:** *A recent study demonstrated that computer training at a senior citizens club helped participants build group cohesion and to form tiered connections with partners, family, and friends with whom they no longer live (Burmeister et al, 2016).*

Multicultural

• Provide a relationship-focused intervention to enhance communication for multicultural couples. **EB:** *A Korean study found that a relationship-focused communication intervention improved couples' abilities to communicate effectively and to resolve conflicts, and it enhanced intimacy (Kim et al, 2016).*
• Use culturally tailored cognitive behavioral techniques to promote communication, problem-solving, self-disclosure, empathic response skills, and sexual education and counseling. **EB:** A review of 39 studies found that interventions to promote communication, problem-solving, self-disclosure, empathic responses, and sexual education could enhance marital intimacy and strengthen family bonds and stability. Health care providers need to individualize interventions that are appropriate to the couple characteristics and their relationship (Kardan-Souraki et al, 2016).

Risk for ineffective Relationship

NANDA-I

Definition
Susceptible to developing a pattern that is insufficient for providing a mutual partnership to provide for each other's needs.

Risk Factors
Ineffective communications skills; stressors; substance misuse; unrealistic expectations

At-Risk Population
Developmental crisis; history of domestic violence; incarceration of one partner

Associated Condition
Alteration in cognitive functioning in one partner

NOC, NIC, Client Outcomes, Nursing Interventions and *Rationales*, and References
Refer to care plan for Ineffective **Relationship**

Impaired Religiosity

Barbara Baele Vincensi PhD, RN, FNP

NANDA-I

Definition
Impaired ability to exercise reliance on beliefs and/or participate in rituals of a particular faith tradition.

Defining Characteristics
Desire to reconnect with previous belief pattern; desire to reconnect with previous customs; difficulty adhering to prescribed religious beliefs; difficulty adhering to prescribed religious rituals; distress about separation from faith community; questioning of religious belief patterns; questioning of religious customs

Related Factors
Anxiety; cultural barrier to practicing religion; depression; environmental barrier to practicing religion; fear of death; ineffective caregiving; ineffective coping strategies; insecurity; insufficient social support; insufficient sociocultural interaction; insufficient transportation; pain; spiritual distress

At-Risk Population
Aging; end-stage life crisis; history of religious manipulation; hospitalization; life transition; personal crisis; spiritual crisis

Associated Condition
Illness

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes
Client Satisfaction: Cultural Needs Fulfillment

Example NOC Outcome with Indicators
Client Satisfaction: Cultural Needs Fulfillment as evidenced by the following indicators: Respect for religious beliefs/Respect for cultural health behaviors/Incorporation of cultural beliefs in health teaching/Respect for personal values. (Rate each indicator of **Client Satisfaction: Cultural Needs Fulfillment:** 1 = not at all satisfied, 2 = somewhat satisfied, 3 = moderately satisfied, 4 = very satisfied, 5 = completely satisfied [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Express satisfaction with the ability to express religious practices
- Express satisfaction with access to religious materials and rituals
- Demonstrate balance between religious practices and healthy lifestyles
- Avoid high-risk, controlling religious relationships that inflict physical, sexual, or emotional harm and/or exploitation

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Religious Ritual Enhancement; Culture Brokerage; Religious Addiction Prevention

Example NIC Activities–Religious Ritual Enhancement

Encourage the use of and participation in usual religious rituals that are not detrimental to health

Nursing Interventions and *Rationales*

- Recognize when clients integrate religious practices in their life. **EB:** *In a prospective study, of 110 patients pre-, during, and post chemotherapy, Kaliampos and Roussi (2017) found that use of religious coping significantly predicted a positive affect 7 months later.* **EB:** *In a mixed-methods study, those who were homeless (N = 500) and had difficulty with alcohol and substance abuse but participated in religious ceremonies or rituals were found to have better outcomes related to the quantity of abuse (Torchalla et al, 2014).*
- Encourage and/or coordinate the use of and participation in usual religious rituals or practices that support coping. **EBN:** *In a cross-sectional descriptive study (Akgül & Karadag, 2016) fecal ostomies were found to be a barrier to incorporating specific religious practices of salat, fasting, and pilgrimage in the lives of 150 Muslims postoperatively, providing an opportunity for nurses to assist patients in meeting their religious needs through adaptation or facilitation around this barrier.* **EB:** *In a secondary analysis, Ellison et al (2014) discovered that the introduction of prayer was helpful in shaping positive mental health in those who had a nonanxious and comfortable relationship with God; however, this did always have the same outcome for those who did not have a similar relationship with God or the Transcendent when using prayer in a similar manner.*
- Encourage the use of prayer or meditation as appropriate. **EB:** *In a cross-sectional cohort study of 132 participants, Watkins et al (2013) identified that encouraging religious practices, such as prayer and meditation, improved specific self-care activities in hard to control type II diabetics.* **EBN:** *In a qualitative study by Woods-Giscombé and Gaylord (2015) with 15 African American participants who had mindfulness meditation experience, the results indicated that mindfulness meditation was helpful in managing stress but it also had several concepts in common with African American religious concepts, suggesting this type of meditation could be used within a religious framework with this population.*
- Promote family coping using religious practices to help cope with loss, as appropriate. **EBN:** *In a longitudinal qualitative study by Nilmanat et al (2015) of 15 Thai patients dying of cancer, three themes emerged to help cope with the dying process: surrounded by love from family, moving beyond suffering, and reconnecting to religious faith to counter suffering.*
- ▲ Refer to a religious leader, professional counseling, or support group as needed. **EB:** *A cross-sectional survey by Ghesquiere et al (2015) of 591 hospices in the United States, found*

complicated grief or depression related to death can be assessed and managed by most hospices in varying degrees with the use of transdisciplinary teams, support groups, individual counseling, or group therapy. **EBN:** *In a descriptive study by Brelsford et al (2016) of 52 neonatal intensive care unit (NICU) parents, family cohesiveness decreased with the use of negative religious and spiritual coping, providing an indicator to nurses of a need for potential referral or support.*

Geriatric

- Promote established religious practices in older adults. **EB:** *In a systematic review by Agli, Bailly, and Ferrand (2015), the effects of encouraging spiritual and religious practices on older adults with dementia were increased positive coping strategies, increased cognitive function, and increased quality of life.* **EBN:** *Using a pre-post control group with 66 older patients admitted to an ICU, Elham et al (2015) found a significant inverse relationship between groups regarding spiritual well-being (SWB) and anxiety when patient concerns were met after an adequate assessment of spiritual/religious needs was completed and interventions implemented.*

Multicultural

- Promote religious practices that are culturally appropriate:
  - **African American. EB:** *Salas-Wright et al (2015) found an inverse relationship between religious involvement and violent and nonviolent antisocial behaviors in adolescent African American females residing in high-risk communities.* **EB:** *In a cross-sectional survey of 1013 African American women, Ludema et al (2015) found that those who highly identified with organized religion, nonorganized religion, and spirituality had less risky sexual behaviors for potential HIV exposure than those who had no affiliation.* **EBN:** *In a qualitative study by Woods-Giscombé and Gaylord (2015) with 15 African American participants who had mindfulness meditation experience, the results indicated that mindfulness meditation was helpful in managing stress. They also found several concepts that mindfulness meditation had in common with African American religious concepts, suggesting meditation could be used within a religious framework with this population for health concerns.*
  - **Korean. EB:** *A focused ethnographic research approach by Choi et al (2014) of middle and older aged Korean women identified that immigration experiences tended to be difficult; engaging in religion, prayer, and church community were found to be important supports for these women.*
  - **African. EBN:** *In a qualitative study of 10 participants addressing the challenges and resources of living with multiple sclerosis (MS) in the Western Cape area of Africa, Pretorius and Joubert (2014) found religion as one of the major themes for resources along with social support, mobility aids, and knowledge/education.*
  - **Jordanian. EBN:** *Using a cross-sectional and correlational design, Musa, Pevalin, and Shahin (2016) found that spiritual well-being and religiosity had a positive correlation with self-rated health in a convenience sample of 340 Jordanian Arab Christians who make up only 3% of the population of this country.*
  - **Hispanic. EB:** *With diabetes having a high prevalence in the Hispanic population, Riveria-Hernandez (2016) found a positive relationship between religiosity with diabetes care and blood sugar control in a sample of 2216 Hispanics 50 years and older living in Mexico.*

- **Sexual Minority Individuals (Lesbian, Gay, Bisexual, Transgender, Queer). EB:** *Brewster et al (2016) found religious coping strategies may or may not promote psychological well-being or relieve psychological symptoms of distress caused by internalization of specific thoughts and experiences in a sample of self-identified sexual minority participants (N = 143), in which sexual discrimination and harassment had occurred within and outside of the religious/church establishment. Therefore promotion of religious coping or practices for this minority should be approached carefully.*

Readiness for enhanced Religiosity

NANDA-I

Definition

A pattern of reliance on religious beliefs and/or participation in rituals of a particular faith tradition, which can be strengthened.

Defining Characteristics

Expresses desire to enhance belief patterns used in the past; expresses desire to enhance connection with a religious leader; expresses desire to enhance forgiveness; expresses desire to enhance participation in religious experiences; expresses desire to enhance participation in religious practices (e.g., ceremonies, regulations, clothing, prayer, services, holiday observances); expresses desire to enhance religious customs used in the past; expresses desire to enhance religious options; expresses desire to enhance use of religious material

NIC, NOC, Client Outcomes, Nursing Interventions and *Rationales*, Client/Family and Discharge Planning, and References

See care plan for Impaired **Religiosity**.

Pediatric

- Provide spiritual care for children based on developmental level. Theory: When nurses are comfortable providing spiritual care, they can implement numerous spiritual care activities and interventions to meet the spiritual needs of the child and family. After determining the child's spiritual beliefs and spiritual needs, a plan of care is developed based on the child's developmental age (Fowler, 1981, 1987; Elkins & Cavendish, 2004).
    - **Parents:** Incorporate religious traditions and faith practices for parents with hospitalized and chronically ill children. **EB:** *A qualitative study indicated that religion was a positive coping mechanism for parents with infants in the neonatal intensive care unit (NICU) (Huenink & Porterfield, 2017).* **EBN:** *In a quantitative descriptive study, parents of children with cancer demonstrated an increase in spiritual faith (Wiener et al, 2016).*
    - **School-age:** Encourage faith community involvement and religious attendance with parent(s). **EB:** *In a review of literature, studies consistently indicated that school-aged children who attend church with their parents demonstrated higher psychological well-being and greater spiritual closeness with parents in adolescence (Mahoney & Cano, 2014).*
    - **School Age:** Encourage children to participate in faith community health programs. **EBN:** *An ethnographic study indicated that faith communities provide a forum for healthy nutrition as part of the faith culture (Opalinski, Dyess, & Gropper, 2017).* **EB:** A *participatory action research study of African American churches in developing Focus on Youth programs indicated the importance of integrating faith and health to prevent disease and promote health (Lightfoot et al, 2014).*
    - **Adolescents:** Encourage religious coping in the adolescent population **EBN:** *Qualitative research indicates urban African American youth have multifaceted dimensions of their spirituality, including the role of prayer in their lives, an unwavering faith in a higher power, and the importance of giving back to their communities (Dill, 2017).* **EB:** *Access to religious resources may be a powerful factor that helps protect teens from turning to alcohol, marijuana, and cigarettes to cope with harsh parenting and poor self-control (Kim-Spoon et al,*

2014).

- **Adolescents:** Encourage prayer, particularly within the African American community. **EB:** *In a qualitative study, prayer was a positive coping mechanism and supported an intrinsic motivation for positive change (Breland-Noble et al, 2015).*
- **Adults:** Encourage centering prayer or other forms of mediation to promote mental and spiritual health. **EB:** *In a small sample, centering prayer demonstrated positive effects on emotional and spiritual health (Fox et al, 2016).*
- **Interprofessional:** Chaplain referral when individuals engage in religious coping mechanisms. **EB:** When individuals engage in religious coping, additional religious struggles follow, which may benefit from chaplain expertise to promote spiritual well-being (Fox et al, 2016). **EB:** *In a grounded theory study of hospitalized patients, patients look for a relationship with the chaplain, and the role of the chaplain in helping patients to discover and express meaning in their experiences to promote spiritual wellness (McCormick & Hildebrand, 2015).*
- **African American:** Collaborate with faith communities to promote wellness. **EB:** *In a qualitative participatory action study with church leaders, findings indicated medical distrust and self-management and suggested incorporating a religious orientation to rebuild trust within the African American community (Lew et al, 2015).* **EB:** *A program to decrease HIV stigma was developed with African American faith communities incorporating sermons and HIV testing (Derose et al, 2014).* **EB:** *A participatory action research study of African American churches in developing Focus on Youth programs indicated the importance of integrating faith and health to prevent disease and promote health (Lightfoot et al, 2014).*
- **African American:** Incorporate faith traditions in coping with chronic disease. **EBN:** *In an ethnographic study of African American parents of children with autism, faith in God was a positive theme and can support culturally congruent health care (Burkett et al, 2017).*
- **Latino:** Collaborate with faith communities to promote wellness. **EB:** *A program to decrease HIV stigma was developed with Latino faith communities incorporating sermons and HIV testing (Derose et al, 2014).*
- **Latino:** Incorporate faith traditions among patients and families in pediatric settings. **EBN:** *In an ethonursing study with Latino families and health care providers to develop a culturally competent model of care on a medical-surgical unit, findings indicated that five care factors as most valuable: family, faith, communication, care integration, and meeting basic needs (Mixer et al, 2015).*
- **Uninsured/low income:** Explore faith community nurses to provide wellness services and care monitoring. **EB:** *Faith Community Nursing is a nursing specialty focusing on integration of faith and health while providing wellness care within faith communities (Morris, 2015; Young et al, 2015).*
- **Geriatrics:** *Encourage listening to religious music.* **EB:** *In a national quantitative study, frequency of listening to religious music was associated with decreases in death anxiety and increases in life satisfaction, self-esteem, and sense of control (Bradshaw et al, 2015).*

Risk for impaired Religiosity

Gail B. Ladwig MSN, RN

NANDA-I

Definition

Susceptible to an impaired ability to exercise reliance on religious beliefs and/or participate in rituals of a particular faith tradition, which may compromise health.

Risk Factors

Insufficient transportation; pain; anxiety; depression; fear of death; ineffective caregiving; ineffective coping strategies; insecurity; insufficient social support; cultural barrier to practicing religion; environmental barrier to

practicing religion; insufficient sociocultural interaction; spiritual distress

At-Risk Population
Aging; end-stage life crisis; life transition; history of religious manipulation; hospitalization; personal crisis; spiritual crisis

Associated Condition
Illness

NOC, NIC, Client Outcomes, Nursing Interventions and *Rationales*, and References
Refer to care plan for Impaired **Religiosity**

Relocation stress syndrome

Mary Beth Flynn Makic PhD, RN, CCNS, FAAN, FNAP, Rebecca Johnson PhD, RN, FAAN, FNAP, Jessica Bibbo MA

NANDA-I

Definition
Physiological and/or psychosocial disturbance following transfer from one environment to another.

Defining Characteristics
Alienation; aloneness; alteration in sleep pattern; anger; anxiety (00146); concern about relocation; dependency; depression; fear (00148); frustration; increase in illness; increase in physical symptoms; increase in verbalization of needs; insecurity; loneliness; loss of identity; loss of self-worth; low self-esteem; pessimism; preoccupation; unwillingness to move; withdrawal

Related Factors
Ineffective coping strategies; insufficient predeparture counseling; insufficient support system; language barrier; move from one environment to another; powerlessness; significant environmental change; social isolation; unpredictability of experience

At-Risk Population
History of loss

Associated Condition
Compromised health status; deficient mental competence; impaired psychosocial functioning

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes
Relocation Adaptation; Anxiety Self-Control; Child Adaptation to Hospitalization; Coping; Depression Level; Depression Self-Control; Loneliness Severity; Psychosocial Adjustment: Life Change, Quality of Life; Stress Level

Example NOC Outcome with Indicators
Relocation Adaptation as evidenced by the following indicators: Recognizes reason for change in living environment/Participates in decision-making in new environment/Expresses satisfaction with daily routine/Expresses satisfaction with level of independence/Compares care needs with available resources/Expresses satisfaction with social relationships/Expresses satisfaction with variety of food/Expresses satisfaction with food preparation/Expresses satisfaction with retained personal belongings/Expresses satisfaction with living arrangements/Exhibits positive mood/Appears content/Respects others' rights/Maintains positive relationships with family/Maintains positive relationships with friends/Maintains positive relationships with others in new environment/Participates in social activities/Seeks information to reduce anxiety/Plans coping strategies for stressful situations/Uses effective coping strategies/Uses relaxation techniques to reduce anxiety/Maintains social relationships/Maintains adequate sleep/Controls anxiety response. (Rate the outcome and indicators of

Relocation Adaptation: 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Recognize and know the name of at least one staff member or new neighbor within 1 week of relocating
- Express concern about move when encouraged to do so during individual contacts within 24 hours of awareness of impending relocation
- Perform activities of daily living (ADLs) in usual manner
- Maintain previous mental and physical health status (e.g., nutrition, elimination, sleep, social interaction, physical activity) within 2 months of relocating

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Anxiety Reduction; Coping Enhancement; Discharge Planning; Hope Instillation; Self-Responsibility Facilitation; Animal-Assisted Therapy; Art Therapy; Music Therapy; Massage; Mood Management; Active Listening

Example NIC Activities—Anxiety Reduction

Stay with client to promote safety and reduce fear; Provide objects that symbolize safeness to the client

Nursing Interventions and *Rationales*

- Be aware that relocation to retirement communities may be a positive change. **EBN:** *A cross-sectional study of older individuals relocating to retirement communities found the older individual experienced less stress when they had more relocation controllability, positive cognitions, and adjustment resources (Bekhet & Zauszniewski, 2013).*
- Begin relocation planning as early in the decision process as possible. **EBN:** *Having a well-organized plan for the move with support and advocacy through the process may reduce anxiety (Sörensen, Mak, & Pinquart, 2011).*
- Obtain a history, including the reason for the move, the client's usual coping mechanisms, history of losses, and family support for the client. **EBN:** *A history helps the nurse determine the amount of support needed and appropriate interventions to decrease relocation stress (Brownie, Horstmanshof, & Garbutt, 2014).*
- Identify to what extent the client can participate in the relocation decisions and advocate for this participation. **EBN:** *Engaging older adults in the decision-making process is likely to increase the level of adjustment after the relocation (Bekhet & Zauszniewski, 2013) and promote psychological well-being (Street & Burge, 2012; Ewen & Chahal, 2013; Hertz et al, 2016).* **EB:** *A study of highly dependent older adults who were relocated were found to have a higher use of new antidepressant agents and new antibiotics orders, suggesting the need for vigilant planning to reduce the stress of the move (Mello & O'Connor, 2016).*
- Assess client's readiness to relocate and relocation self-efficacy. **EB:** *Relocation is a complex process that requires careful consideration and planning before the move (prelocation) and adjustment to the new home after the move (postrelocation) to promote the older client's adjustment (Hertz et al, 2016).*
- Consult an evidence-based practice guide for relocation. **EBN:** *Researchers compiled the latest findings to develop a protocol to assist in relocating older adults (Hertz et al, 2016).*
- Assess family members' perceptions of client's ability to participate in relocation

decisions. Particularly in cases of dementia, be alert to care workers' involvement in making the decision to relocate. They may need support and encouragement through the process. **CEB:** *Care workers were found to be highly stressed during the relocation decision-making process and "walking a tightrope" between the older adult's needs and those of the person's family members (Hortana, Fahlstrom, & Ahlstrom, 2010).*

• Consider the cultural and ethnic values of the client and family as much as possible when choosing roommates, foods, and other aspects of care. **EBN:** *Nurses need to be aware of the differences in values and practices of different cultures and ensure that they give culturally appropriate care that is respectful of older adults and family caregivers' beliefs about elder care (Bekhet & Zauszniewski, 2013).*

• Promote clear communication between all participants in the relocation process. **EB:** *A narrative study exploring older client's transitions found communication and exploring unspoken fears helped reduce concerns of loss of control and uncertainty (Lee, Simpson, & Froggatt, 2013).*

• Observe the following procedures if the client is being transferred to an extended care facility or assisted living facility:

- ❍ Facilitate the client's participation in decisions and choice of placement, and arrange a preadmission visit if possible.
- ❍ If the client cannot visit the new facility, arrange for a visit or telephone call by a member of the staff to welcome the client and show a videotape or at least provide pictures of the new care facility.
- ❍ Have a familiar person accompany the client to the new facility. This lessens client and family anxiety, confusion, and dissatisfaction.
- ❍ Recommend that the caregiver write a journal of thoughts and feelings regarding the relocation of his or her loved one.
- ❍ Continue to assess caregiver psychological distress during a 6-month period after relocation. Caregivers experience distress because of the responsibility of moving their loved one. **EB:** *Caregivers may begin to resolve conflicted feelings during this time and need support (Smit et al, 2011).*

• Identify previous routines for ADLs. Try to maintain as much continuity with the previous schedule as possible. **EB:** *Continuity of client's everyday personal care by care aides that is both empathetic and nurturing is perceived as supportive and compassionate and eases relocation stress (Andersen & Spiers, 2016).*

• Bring in familiar items from home (e.g., pictures, clocks, afghans). Familiarity eases transition and symbolizes safeness.

• Establish the way the client would like to be addressed (Mr., Mrs., Miss, first name, or nickname). *Calling clients by their desired name shows respect.*

• Thoroughly orient the client and the family to the new environment and routines; repeat directions as needed. **EB:** *Providing honest answers to client questions and supporting the individual adjustment to the new location will be necessary for at least 6 months until the client feels at home (Hertz et al, 2016).*

• Spend one-to-one time with the client. Allow the client to express feelings and convey acceptance of them; emphasize that the client's feelings are real and individual and that it is acceptable to be sad or angry about moving. **EB:** *Interventions should recognize personal values; allow adequate time to listen to and respect the views and needs of the older adult (Hertz et al, 2016).*

• Allocate a caring staff member to help the client adjust to the move. Assign the same staff members to the client for care if compatible with client; maintain consistency in the personnel with whom the client interacts.

• Ask the client to state one positive aspect of the new living situation each day.

Helping the client focus on the positive aspects of the move can help change attitude and reframe the situation in a positive fashion. **EBN:** *Assisting the client to focus on positive thinking has been found to promote their ability to manage daily activities and adapt to change. Clients with greater resourcefulness have been found to be able to adapt to challenging situations in a more constructive and successful manner (Bekhet & Zauszniewski, 2013).*

• Ask the client to state one positive aspect of the new living situation each day. *Helping the client focus on the positive aspects of the move can help change attitude and reframe the situation in a positive fashion (Bekhet & Zauszniewski, 2013; Hertz et al, 2016).*

• Monitor the client's health status and provide appropriate interventions for problems with social interaction, nutrition, sleep, new onset of infection, or elimination problems. **EB:** *Older clients and lower socioeconomic status are associated with greater risk of maladjustment after relocation (Hertz et al, 2016). A study found a significant increase in morbidity before and after transfer. Residents who transferred had increased rates of illness and greater antibiotic and antidepressant medication prescription rates in the months before and after relocation (Mello & O'Connor, 2016).*

• If the client is being transferred within a facility, have staff members from the new unit visit the client before transfer.

• Work with the caregivers and family members helping them deal with stages of "making the best of it," "making the move," and "making it better." **EBN:** *Provide opportunities for family to visit, encourage engagement in facility social events, and provide electronic access for the client to maintain ties with loved ones and friends (Hertz et al, 2016).*

• If a client is being transferred from the intensive care unit (ICU), have previous staff make occasional visits until the client is comfortable in the new surroundings. Ensure that the family is told relevant information. **EB:** *Providing an individualized transfer plan from the ICU to the medical-surgical unit that addresses patient and family questions prior to transfer reduces relocation stress (Lee et al, 2017).*

• Watch for coping problems (e.g., withdrawal, regression, angry behavior, impaired sleeping, refusal to eat, flat affect, anxiety) and intervene immediately. **EB:** *Loss of independence with transfer to a nursing home may manifest in anxiety, anger, and depression (Bekhet & Zauszniewski, 2013).*

• Encourage the client to express grief for the loss of the old situation; explain that it is normal to feel sadness over change and loss.

• Assess the client's psychological needs along with physiological needs. **EB:** *Although physical care may predicate the relocation, meeting psychosocial care needs must be individualized via careful assessment (Hertz et al, 2016).*

• Encourage the client to participate in care as much as possible and make his or her own decisions when possible (e.g., placement of the bed, choice of roommate, bathing routines). *Having choices helps prevent feelings of powerlessness that may lead to depression (Hertz et al, 2016).*

Pediatric

• Assess family history and contact information from children relocated to rescue shelters. **EB:** *Efforts have been made to develop systematic processes to reunite children that are separated from families during disasters. Current guidelines established by the Federal Emergency Management Agency (FEMA), the Red Cross, the Centers for Disease Control and Prevention (CDC), and the National Center for Missing and Exploited Children focus on providing effective, efficient action through*:

- ❍ *A shared understanding of local and national resources and capabilities,*

- ❍ *Collaboration, coordination, effective communication for children with disabilities and other access and functional needs, and needs assessments during disasters, and*
- ❍ *Shared operational procedures and technologies (FEMA, 2013).*

• Be aware that community relocation may be beneficial for children and assess community resources of new location.
• Provide support for a child and family who must relocate to be near a transplant center.
• In divorce situations, recommend alternative dispute resolution versus traditional litigated settlement. **EBN:** *This non-adversarial approach may mitigate some of the trauma of divorce experienced by children (Stein & Oler, 2010).*
• Assess presence of allergies before and after relocation.
• If the client is an adolescent, try to avoid a move in the middle of the school year, find a newcomers' club for the adolescent to join, and refer for counseling if needed. **EB:** *Most adolescents who relocate suffer a brief period of loss of companionship and intimacy with close friends (McBride, 2015).*
• Assess adolescents' perceptions of their acceptance by peers. **EB:** *Poor perceptions of peer acceptance have been related to less initiation of social interactions in new settings (McBride, 2015).*
• Help parents recognize that relocation stress syndrome may persist for prolonged periods (e.g., 2 years) in adolescents. **EB:** *Adolescents were found to commonly express their ideology of the relocation (Nuttman-Shwartz, Huss, & Altman, 2010).*
• Be aware that young people may cope with the transition by exerting control in particular domains. **EBN:** *Adolescents may be at risk of developing eating disorders after a major transition (Berge et al, 2012).*
• The effects of frequent relocation may not manifest immediately and may have long-term effects on physical and mental health. **EBN:** *Longitudinal analysis found that frequent relocation in adolescence was associated with higher rates of stress and physical exhaustion in adulthood (Lin,Twisk, & Huang, 2012).*

Geriatric

• Monitor the need for transfer and transfer only when necessary. **EB:** *Older adults often experience loss of function after relocation (Bekhet & Zauszniewski, 2013; Lee, Simpson, & Froggatt, 2013).*
• Implement discharge planning early and engage the older adult in decisions about relocation decisions. **EB:** *Engaging the older adult in decision-making is key to successful relocation (Hertz et al, 2016).*
• Use technologies, such as sensing devices, to measure average in-home gait speed (AIGS) as a predictor of fall risk. **EBN:** *AIGS was found to be a more reliable and valid predictor of fall risk than traditional physical performance assessments (Stone et al, 2015).*
• Implement a registered nurse (RN) care coordination model to restore older adults' health, maintain their independence, and reduce care costs. **EBN:** *RN care coordination was found to significantly and positively affect older adult outcome variables and to result in lesser costs of care (Rantz et al, 2014).*
• After the transfer, determine the client's mental status. Document and observe for any new onset of confusion. Confusion can follow relocation because of the overwhelming stress and sensory overload.
• Facilitate visits from companion animals. **EB:** *Pet therapy has been found to improve depressive symptoms and cognitive function in residents of long-term care facilities with mental illness (Moretti et al, 2011).*

Client/Family Teaching and Discharge Planning

- Teach family members and remind direct care staff about relocation stress syndrome. Encourage them to monitor for signs of the syndrome.
- Help significant others learn how to support the client in the move by setting up a schedule of visits, arranging for holidays, bringing familiar items from home, and establishing a system for contact when the client needs support. **EBN:** *Social support of family and friends was significantly related to relocation adjustment (Hertz et al, 2016).*
- Assist family members and the relocating older adult to use Internet/webcam technology for interaction to supplement in-person visits. **EB:** *When older adults in a care facility have less than one visitor per week, interaction can be supplemented with technological "visits" (Meyer, Marx, & Ball-Seiter, 2011; Hertz, 2016).*

Risk for Relocation stress syndrome

Marina Martinez-Kratz MS, RN, CNE

NANDA-I

Definition

Susceptible to physiological and/or psychosocial disturbance following transfer from one environment to another, which may compromise health.

Risk Factors

Ineffective coping strategies; insufficient predeparture counseling; insufficient support system; language barrier; move from one environment to another; powerlessness; significant environmental change; social isolation; unpredictability of experience

At-Risk Population

History of loss

Associated Condition

Compromised health status; deficient mental competence; impaired psychosocial functioning

NIC, NOC, Client Outcomes, Nursing Interventions and *Rationales*, Client/Family Teaching and Discharge Planning, and References

Refer to care plan for **Relocation** stress syndrome.

Impaired Resilience

Gail B. Ladwig MSN, RN, Julianne E. Doubet BSN, RN, EMT-B

NANDA-I

Definition

Decreased ability to recover from perceived adverse or changing situations, through a dynamic process of adaptation.

Defining Characteristics

Decreased interest in academic activities; decreased interest in vocational activities; depression; guilt; impaired health status; ineffective coping strategies; ineffective integration; ineffective sense control; low self-esteem; renewed elevation of distress; shame; social isolation

Related Factors

Community violence; disruption in family rituals; disruption in family roles; disturbance in family dynamics; dysfunctional family processes; inadequate resources; inconsistent parenting; ineffective family adaptation; insufficient impulse control; insufficient resources; insufficient social support; multiple coexisting adverse situations; perceived vulnerability; substance misuse

At-Risk Population

Chronicity of existing crisis; demographics that increase chance of maladjustment; economically disadvantaged; ethnic minority status; exposure to violence; female gender; large family size; low intellectual ability; low maternal educational level; new crisis; parental mental illness

Associated Condition
Psychological disorder

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes
Personal Resiliency; Coping; Decision-Making; Self-Esteem

Example NOC Outcome with Indicators
Personal Resiliency as evidenced by the following indicators: Adapts to adversities as challenges. (Rate the outcome and indicators of **Personal Resiliency:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Demonstrate reduced or cessation of drug and alcohol usage
- State effective life events on feelings about self
- Seek help when necessary
- Verbalize or demonstrate cessation of abuse
- Adapt to unexpected crises or challenges
- Verbalize positive outlook on illness, family, situation, and life
- Use available resources to meet coping needs
- Identify role models
- Identify available assets and resources
- Be able to verbalize meaning of one's life

NIC (Nursing Interventions Classification)

Suggested NIC Interventions
Resiliency Promotion; Coping Enhancement; Counseling; Emotional Support; Self-Esteem Enhancement; Support Group; Support System Enhancement

Example NIC Activities—Resiliency Promotion
Encourage positive health-seeking behaviors; Facilitate family communication

Nursing Interventions and *Rationales*

- Encourage positive, health-seeking behaviors. **EB:** *Johansson et al (2016) concluded in their study of diabetic health, that caregivers should establish an atmosphere of open learning that generates interactions, in a climate that establishes and encourages contemplation to promote health and well-being.*
- Ensure access to biological, psychological, and spiritual resources. **EBN:** *Identifying and linking persons to available resources will foster engagement in resources that enhance protective factors and resilience (Tuck & Anderson, 2014).*
- Foster communication skills through basic communication skill training. **CEB:** *Individuals who are skilled communicators have fewer problems with family relationships and can articulate their own viewpoint (Szanton & Gill, 2010).*
- Foster cognitive skills in decision-making. **EB:** *Patient's comprehension of pertinent information is an essential part of the standard that allows for informed decisions (Gerstenecker et al, 2015).*

• Assist client in cognitive restructuring of negative thought processes. **EBN:** *Positive thinking has been associated with increased feelings of coherence and resourcefulness when dealing with adversity (Everly et al, 2014).*
• Facilitate supportive family environments and communication. **EBN:** *Individuals found to be resilient if raised in families with greater levels of parental supervision and consistent expectations, rules, and consequences for problem behaviors, and effective systems for monitoring children and adolescents (Schofield, Conger, & Neppl, 2014).*
• Promote engagement in positive social activities. **EB:** *In their study of persons with learning disabilities, Howarth et al (2016) ascertained that taking part in various social activities provided a key opportunity for individuals to expand their social connections.*
• Assist client to identify strengths, and reinforce these. **EB:** *According to McMahon, Kenyon, and Carter (2013), in their study of American Indian youth, interventions that promoted their strengths, as opposed to their problems, showed increased promise in combating stress.*
• Help the client identify positive emotions during adverse situations. **EB:** *Even though positive emotions may be the transitory, their benefits stockpile and intensify to forecast resilience and anticipate thriving mental well-being (Ruthig, Trisko, & Chipperfield, 2013).*
• Build on supportive counseling and therapy. **EBN:** *Education and counseling are important interventions in patient care, but patients can also gain a feeling of well-being and control using their own inner strengths and methods of coping (Sandruddin et al, 2017).*
• Identify protective factors such as assets and resources to enhance coping. **CEB:** *According to the protective factor model of resilience, a protective factor that interacts with a stressor reduces the likelihood of negative outcomes (Vahia et al, 2011).*
• Provide positive reinforcement and emotional support during the learning process. **EB:** *Clients with positive, supportive educational environments show self-efficacy in attaining goals during adverse situations (Masten, 2014).*
• Encourage mindfulness, a conscious attention, and awareness of self. **EBN:** *Key elements that promote the alleviation of stress and encourage resilience are mindfulness and meditation (Savel & Munro, 2017).*
• Educate and encourage the use of stress-reduction techniques, such as guided imagery, in which the client focuses on positive images and emotions. **EB:** *Negative thoughts influence both emotions and behaviors. Positive imagery has been shown to reduce subjective feelings of stress (Park et al, 2013).*
• Enhance knowledge and use of self-care strategies. **EB:** *Promoting stress reduction and enhancing self-care has been shown to positively affect quality of life (Bryant & Nickerson, 2014).*
• Assist the client to have an optimistic world view. **EBN:** *Stagman-Tyrer (2014), in her study of the importance of optimism in nurse leaders, found that optimism can be initiated, cultivated, and achieved with enterprise and determination.*

Pediatric

• The preceding interventions may be adapted for the pediatric client.
• Promote nurturing, supportive relationships with family. **EB:** *According to the National Scientific Council on the Developing Child (2015), "Supportive relationships with adults help children develop resilience, or the set of skills needed to respond to adversity and thrive."*
• Support the seeking of opportunities to improve cognitive abilities, such as tutoring and other resources; the development of positive and supportive relations, such as

family, community members, or mentors; and the improvement of general health. **CEB:** *These activities help encourage the promotion of protective factors of adolescent resilience such as positive coping and positive self-esteem (Lau & van Niekerk, 2011).*

• Promote the development of positive mentor relationships. **EB:** *DeWit et al (2016) found in their study of supported mentoring that girls and boys involved in long-term, supported mentoring connections, experienced beneficial outcomes.*

▲ Consider referral to appropriate community resources, such as faith-based communities for children who have had adverse childhood experiences. *There is a critical need to identify cost-effective community resources that optimize stress resilience. Faith-based communities may promote forgiveness rather than retaliation, opportunities for cathartic emotional release, and social support, all of which have been related to neurobiology, behavior, and health outcomes. Although spirituality and religion can be related to guilt, neurotic, and psychotic disorders, they also can be powerful sources of hope, meaning, peace, comfort, and forgiveness for the self and others (Brewer-Smyth & Koenig, 2014).*

Readiness for enhanced Resilience

Gail B. Ladwig MSN, RN, Julianne E. Doubet BSN, RN, EMT-B

NANDA-I

Definition

A pattern of ability to recover from perceived adverse or changing situations, through a dynamic process of adaption, which can be strengthened.

Defining Characteristics

Expresses desire to enhance available resources; expresses desire to enhance communication skills; expresses desire to enhance environmental safety; expresses desire to enhance goal-setting; expresses desire to enhance involvement in activities; expresses desire to enhance own responsibility for action; expresses desire to enhance positive outlook; expresses desire to enhance progress toward goal; expresses desire to enhance relationships with others; expresses desire to enhance resilience; expresses desire to enhance self-esteem; expresses desire to enhance sense of control; expresses desire to enhance support system; expresses desire to enhance use of conflict management strategies; expresses desire to enhance use of coping skills; expresses desire to enhance use of resource

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Personal Resiliency; Family Resiliency; Quality of Life

Example NOC Outcome with Indicators

Personal Resiliency as evidenced by the following indicator: Adapts to adversities and challenges. (Rate the outcome and indicators of **Personal Resiliency:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Adapt to adversities and challenges
- Communicate clearly and appropriately for age
- Take responsibility for own actions
- Make progress towards goals
- Use effective coping strategies
- Express emotions

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Resiliency Promotion; Self-Efficacy Enhancement; Counseling; Emotional Support

Example NIC Activities—Self-Efficacy Enhancement

Explore individual's perception of his or her capability to perform the desired behavior

Nursing Interventions and *Rationales*

- Listen to and encourage expressions of feelings and beliefs. **EBN:** *Communication assists individuals and families resolve conflicts and facilitate potential for growth, identify inherent strengths, and problem-solve effectively (Doherty & Thompson, 2014).*
- Establish a therapeutic relationship based on trust and respect. **EBN:** *Schwind et al (2014), in their study of how best to advance nursing students toward person-centered care (PCC), found that PCC is based on the principles of respect, autonomy, and empowerment and necessitates the establishment of interpersonal relationships.*
- Assist client in rating current level of resilience. **EBN:** *Although there are many excellent theories that can be used to measure resilience, it remains a complex task that involves "person-level perspectives, individual resources, processes of adaptation, and emotional well-being" (Rosenberg, Starks, & Jones, 2014).*
- Facilitate supportive family environments and communication. **EBN:** *Individuals were found to be resilient if raised in families with greater levels of parental supervision and consistent expectations, rules, and consequences for problem behaviors, and effective systems for monitoring children and adolescents (Schofield, Conger, & Neppl, 2014).*
- Assist client to identify and reinforce strengths. **EB:** *Fostering the use of protective factors promotes the ability of an individual to overcome adverse situations (Poteat, Scheer, & Mereish, 2014).*
- Enhance skills associated with social and executive functioning. **EB:** *Research has shown that social and self-regulation skills enhance one's ability to respond sensitively and are associated with better school adjustment, increased competence, and life success (Masten, 2014).*
- Provide positive reinforcement and emotional support during implementation of care. **EB:** *Providing positive reinforcement and emotional support will enhance a client's self-esteem, which is a key component of physical and mental health; individuals with higher self-esteem are more likely to be resilient than peers with less self-esteem (Masten, 2014).*
- ▲ Facilitate the development of mentorship and volunteer opportunities. **EB:** *Mentoring programs have been shown to prevent negative outcomes and foster a sense of social and community engagement for clients across the life span (Klinedinst & Resnick, 2014).*
- Determine how family behavior affects the client. **EB:** *Resilience models are based on the presupposition that individuals and families are connected to each other and their community and have collective strengths, which help them compensate for their adversity (Masten, 2014).*
- Promote use of mindfulness and other stress-reduction techniques. **EB:** *In their study of the use of mindfulness-based stress reduction (MBSR) in Parkinson's disease, McClean et al (2017) noted that the use of MBSR as an intervention has increased and improved outcomes in a mix of long-term conditions, including stress and depression.*
- Establish individual/family/community goals. **EBN:** *Individuals, families, and communities that set goals will focus on attaining or achieving positive outcomes despite adversity (Masten, 2014).*

Pediatric

- The preceding interventions may be adapted for the pediatric client.
- Encourage the promotion of protective factors by fostering the seeking of

opportunities to improve cognitive abilities, such as tutoring and other resources; the development of positive and supportive relations such as family, community members, or mentors; and the improvement of general health. **EB:** *According to Lehrer et al (2017), adolescents who experience positive emotions and receive social support will develop an increased sense of well-being.*

Multicultural

- Use teaching strategies that are culturally and age appropriate. **EBN:** *In their study of nurses' cultural competency, Norton and Marks-Maran (2014) found that the nurses must frame education and skills training into a culturally appropriate design, if they are to be of any value to the recipients.*

Risk for impaired Resilience

Gail B. Ladwig MSN, RN, Julianne E. Doubet BSN, RN, EMT-B

NANDA-I

Definition

Susceptible to decreased ability to recover from perceived adverse or changing situations, through a dynamic process of adaptation, which may compromise health.

Risk Factors

Community violence; disruption in family rituals; disruption in family roles; disturbance in family dynamics; dysfunctional family processes; inadequate resources; inconsistent parenting; ineffective family adaptation; insufficient impulse control; insufficient resources; insufficient social support; multiple coexisting adverse situations; perceived vulnerability; substance misuse

At-Risk Population

Chronicity of existing crisis; demographics that increase chance of maladjustment; economically disadvantaged;

ethnic minority status; exposure to violence; female gender; large family size; low intellectual ability; low maternal educational level; new crisis; parental mental illness

Associated Condition

Psychological disorder

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Personal Resiliency; Family Resiliency; Knowledge: Health Resources

Example NOC Outcome with Indicators

Personal Resiliency as evidenced by the following indicator: Takes responsibility for own actions. (Rate the outcome and indicators of **Personal Resiliency:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Identify available community resources
- Propose practical, constructive solutions for disputes
- Identify and access community resources for assistance
- Accept assistance with activities of daily living from family and friends
- Verbalize an enhanced sense of control
- Verbalize meaningfulness of one's life

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Resiliency Promotion; Assertiveness Training; Values Clarification; Parenting Promotion

Example NIC Activities—Resiliency Promotion

Encourage family involvement with child's schoolwork and activities; Assist family in providing atmosphere conducive to learning

Nursing Interventions and *Rationales*

- Determine how family behavior affects client. **EBN:** *The model of resilience is based on the presupposition that individuals and families are connected to each other and their community and have collective strengths, which will help them compensate for their adversity (Deist & Greeff, 2015).*
- Help identify personal rights, responsibilities, and conflicting norms. **EBN:** *All nurses have a responsibility to actively promote both mental and physical health and well-being for their clients, so stated Patrick and Robertson (2016) in their study of men's health.*
- Encourage consideration of values underlying choices and consequences of the choice. **EBN:** *It was found in a study by Finderup et al (2016) that acceptance of responsibility must take place before one can make lifestyle choices and/or feel satisfaction for these choices.*
- Help client practice conversational and social skills. **EBN:** *Children who are found to have poor speech, language, and communications skills require prompt intervention and support because these skills are crucial to other areas of childhood development (Crichton, 2013).*

• Assist client to prioritize values. **EBN:** *Evidence-based practice merges cutting-edge research with clinical proficiency and patient values to implement objective interventions for favorable patient outcomes and improvement in quality of life (Butcher, 2016).*
• Help to create an accepting, nonjudgmental atmosphere. **EB:** *The results of a study by Usaite and Cameron (2015) found that active participation in pleasurable, but structured pastimes, can enrich the lives of children and their families by promoting "a positive sense of self, constructive relationships, roles, routines and responsibilities."*
• Help identify self-defeating thoughts. **EBN:** *Cognitive reframing is a tool that assists individuals in reflecting and shifting negative thinking toward positive perspectives (Resnick, 2014).*
▲ Refer to community resources/social services as appropriate. **EB:** *Social support is assistance provided by others in the community that promotes and maintains a client's well-being and resilience (Fuentes-Pelaez et al, 2016).*
▲ Help clarify problem areas in interpersonal relationships. **EBN:** *Individuals who were socially connected to their environment, family, and sense of self can maintain a supportive mindset and experience a decent quality of life despite compromising health conditions, serious diagnosis, and poor prognosis (Stuckey et al, 2014).*
▲ Promote a sense of an individual's autonomy and control over choices to be made in one's environment. **EBN:** *Autonomy promotes a sense of self-efficacy and has been linked to increased quality of life and positive health outcomes for clients (Resnick, 2014).*
▲ Identify and enroll high-risk families in follow-up programs. **EBN:** *Families with adequate resources and positive relationships have a better chance of managing stress and restoring balance in the presence of adversity and limited resources (Lester et al, 2013).*

Parental Role conflict

Kimberly Silvey MSN, RN

NANDA-I

Definition
Parental experience of role confusion and conflict in response to crisis.

Defining Characteristics
Anxiety; concern about change in parental role; concern about family; disruption in caregiver routines; fear; frustration; guilt; perceived inadequacy to provide for child's needs; perceived loss of control over decisions relating to child; reluctance to participate in usual caregiver activities

Related Factors
Interruptions in family life due to home care regimen; intimidated by invasive modalities; intimidation by restrictive modalities; parent–child separation

At-Risk Population
Change in marital status; home care of a child with special needs; living in nontraditional setting

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes
Caregiver Emotional Health; Caregiver Well-Being; Caregiver Lifestyle Disruption; Coping; Parenting Performance; Role Performance; Family Coping

Example NOC Outcome with Indicators
Family Coping as evidenced by the following indicators: Establishes role flexibility/Manages family problems/Uses family-centered stress reduction activities. (Rate the outcome and indicators of **Family Coping:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Express feelings and perceptions regarding effects of illness, disability, and/or hospitalization on parental role
- Participate in hospital and home care as much as able given the availability of resources and support systems
- Exhibit assertiveness and responsibility in active family decision-making regarding care of the child
- Describe and select available resources to support parental management of the needs of the child and family

NIC (Nursing Interventions Classification)

Suggested NIC Interventions
Caregiver Support; Counseling; Decision-Making Support; Family Process Maintenance; Family Therapy; Parenting Promotion; Role Enhancement

Example NIC Activities—Role Enhancement
Teach new behaviors needed by client/parent to fulfill a role; Serve as role model for learning new behaviors as appropriate

Nursing Interventions and *Rationales*

- Assess and support parent's previous coping behaviors. **EBN:** *Understanding what*

experience a parent has with coping will enable the nurse to support the parents in the current situation (Senger, 2016).

• Determine parent/family sources of stress, usual methods of coping, and perceptions of illness/condition. Maximize the identified strengths. **EB:** *Helping to identify stressors in a family's life can help parents better cope with theirs child's illness (Pritchard & Montgomery-Hönger, 2014).*

• Evaluate the family's perceived strength of its social support system, including religious beliefs. Encourage the family to use social support. **EB:** *Parents use their support from their family to help reduce anxiety (Nabors et al, 2013).*

• Determine the older childbearing woman's support systems and expectations for motherhood. **EBN:** *Supporting mothers during their transition into parenthood can assist with the bonding of the mother and the infant (Gilmer, 2016).*

• Consider the use of family-centered theory as the conceptual foundation to help guide interventions. **EB:** *When planning care for a child, family is always the constant in their lives and should be included in all decision-making (King & Chiarello, 2014).*

• Be available to accept and support parents by listening and discussing concerns. **EBN:** *The nurse's ability to observe and listen to parents helps parents gain confidence in caring for their child (Panicker, 2013).*

▲ Maintain parental involvement in shared decision-making regarding care by using the following steps: incorporate parents' information concerning the child's typical routines, behaviors, fears, likes, and dislikes; provide clear and direct firsthand information concerning the child's condition and progress; normalize the home/hospital environment as much as possible; collaborate in care by providing choices when possible. **EB:** *Understanding the ways decisions are made by the parents will help the nurse better care for the child (Schmidt, 2014).*

• Seek and support parental participation in care. **EBN:** *Nurses should support the parents in whatever way they choose to participate in care and involve them in as much as the parents feel comfortable (Romaniuk et al, 2014).*

• Provide support for each parent's primary coping strategies and needs. **EBN:** *Parent support at home can enhance parents' confidence in caring for their child (Callery et al, 2013).*

▲ Inform parents of financial resources, respite care, and home support to assist them in maintaining sufficient energy and personal resources to continue caregiving responsibilities. **EB:** *There can be a financial burden on parents of children with chronic illness and a need to help the family identify their resources (Stewart et al, 2016).*

• Encourage the parent to meet his or her own needs for rest, nutrition, and hygiene. Provide bed space so that the parent may stay with the sick child. **EB:** *Children with an illness can have an effect on parent sleep, which in turn can cause parental fatigue and lead to other health problems (Mörelius & Hemmingsson, 2014).*

• Provide family-centered care: allow parents to touch and talk to the child, and assist in the handling of medical equipment; offer a comfortable chair, preferably a rocking chair. Provide opportunities and offer praise for successful caregiving. **EBN:** *Allowing the parents to participate in care as they feel comfortable enhances family-centered care (Romaniuk et al, 2014).*

• Refer parents to available telephone and/or Internet support groups. **EB:** *Many parents find that Internet support groups help in coping with their child's illness (Clifford & Minnes, 2013).*

• Involve new mother's partner or parents in clinical encounters and invite family members to discuss their expectations and parenting experiences. **EBN:** *Health care providers realize the importance of family-centered care of the infant to help the mother and her partner care for the infant (Dzubaty, 2016).*

Multicultural

- Acknowledge racial/ethnic differences at the onset of care. **EBN:** *Providing culturally competent care is important to health care equality and is important for nurses to understand the importance of identifying the cultural differences that their patients will require (Dzubaty, 2016).*
- Assess for the influence of cultural beliefs, norms, and values on the client's perceptions of the parental role. **EBN:** *Understanding the cultures and beliefs of parents can enhance the interactions between nurse and family and assist the nurse to better care for the child and their family (Xiong et al, 2016).*
- Acknowledge that value conflicts arising from acculturation stresses may contribute to increased anxiety and significant conflict with the parental role. **EBN:** *Nurses should assess for any care that may interfere with a family's cultural beliefs and practices (Majdalani et al, 2014).*
- Promote the female parenting role by providing a treatment environment that is culturally based and woman centered. **EBN:** *Mothers should be the main focus for shorter hospital stays and better infant bonding (Miah, 2013).*
- Support the client's parenting role in her usual setting via social exchange, including online support. **EBN:** *Online messaging boards can be very helpful and support the client's parenting role (Porter & Ispa, 2013).*

Home Care

- The interventions described previously may be adapted for home care use.
- Assess family adjustment prenatally and postpartum; assist new parents to renegotiate parenting roles and responsibilities with coparenting. Encourage the father to take an active role in infant care with the mother's support. **EBN:** *Home visits can have a positive effect on both the mother and father (Ferguson & Vanderpool, 2013).*

Client/Family Teaching and Discharge Planning

- Offer family-led education interventions to improve participants' knowledge about their condition and its treatment and decreasing their information needs. **EBN:** *Education of client and family on the condition can improve self-care at home (Swerczek et al, 2013).*
- For children and their parents involved in bereavement support groups, identify the family's positive way of coping. **EB:** *Support groups and bereaving programs can help parents better cope with the death of a child (Ayers et al, 2013).*
- ▲ Refer parents of children with behavioral problems to parenting programs. **EB:** *Parenting programs can help parents identify and reduce problem behaviors in children (Salari et al, 2013).*
- Involve parents in formal and/or informal social support situations, such as Internet support groups. **EBN:** *Online support groups can allow families to receive support from their peers from around the world and share the knowledge and problems of their child (Mo & Coulson, 2014).*
- Teach the client about available community resources (e.g., therapists, ministers, counselors, self-help groups). **EBN:** *Community-based resources can support caregivers and ensure that they can identify needed services (Tallon et al, 2017).*
- Encourage parents with chronic illnesses to identify areas of family conflicts and assist to integrate interventions into the family. **EBN:** *Supporting chronically ill parents*

to identify conflicts will help the parents to better care for the child (Popp et al, 2014).

Ineffective Role performance

NANDA-I

Definition

A pattern of behavior and self-expression that does not match the environmental context, norms, and expectations.

Defining Characteristics

Alteration in role perceptions; anxiety; change in capacity to resume role; change in other's perception of role; change in self-perception of role; change in usual patterns of responsibility; depression; discrimination; domestic violence; harassment; inappropriate developmental expectations; ineffective adaptation to change; ineffective coping strategies; ineffective role performance; insufficient confidence; insufficient external support for role enactment; insufficient knowledge of role requirements; insufficient motivation; insufficient opportunity for role enactment; insufficient self-management; insufficient skills; pessimism; powerlessness; role ambivalence; role conflict; role confusion; role denial; role dissatisfaction; role strain; system conflict; uncertainty

Related Factors

Alteration in body image; conflict; depression; domestic violence; fatigue; inadequate role model; inappropriate linkage with the health care system; insufficient resources; insufficient rewards; insufficient role preparation; insufficient role socialization; insufficient support system; low self-esteem; pain; stressors; substance misuse; unrealistic role expectations

At-Risk Population

Developmental level inappropriate for role expectation; economically disadvantaged; high demands of job schedule; low educational level; young age

Associated Condition

Neurological defect; personality disorder; physical illness; psychosis

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Coping; Psychosocial Adjustment: Life Change; Role Performance

Example NOC Outcome with Indicators

Role Performance as evidenced by the following indicators: Knowledge of role transition periods/Reported comfort with role changes. (Rate the outcome and indicators of **Role Performance:** 1 = not adequate, 2 = slightly adequate, 3 = moderately adequate, 4 = substantially adequate, 5 = totally adequate [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Identify realistic perception of role
- State personal strengths
- Acknowledge problems contributing to inability to perform usual role
- Accept physical limitations regarding role responsibility and consider ways to change lifestyle to accomplish goals associated with role performance
- Demonstrate knowledge of appropriate behaviors associated with new or changed role
- State knowledge of change in responsibility and new behaviors associated with new responsibility
- Verbalize acceptance of new responsibility

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Role Enhancement

Example NIC Activities—Role Enhancement

Assist client to identify behaviors needed for role development; Assist client to identify positive strategies for managing role changes

Nursing Interventions and *Rationales*

- Assess the client's level of resilience and implement nursing actions that increase client resilience and sense of coherence. **EBN:** *A study of individuals with chronic obstructive pulmonary disease indicated that high levels of a sense of coherence and resilience were negatively associated with symptoms of anxiety and depression and perceived illness-specific disability (Keil et al, 2016).*
- Assess the effect of uncertainty on the client's role and provide support and education. **EBN:** *A study of caregivers with hospitalized children showed that levels of uncertainty and stress decreased, and role performance improved after an educational intervention (Jeon & Kwon, 2016).*
- Assess the client's social support system. **EB:** *A recent study showed that clients with good social support are more likely to change their lifestyle and make more changes (Clementi et al, 2016).*
- Assess for the presence of shame related to current health situation. **EBN:** *A Greek study of intensive care unit (ICU) families found family members who live with the client and have low educational levels are prone to feel shame, which could interfere with coping and caregiving (Koulouras, 2017).*
- Assess for the characteristics of role stress. **EB:** *A recent study showed that a lack of role clarity was significantly linked to emotional exhaustion (Portoghese, 2017).*
- Assess male military members for gender role stressors with the Male Gender Role Stressor Inventory (MGRSI). **EB:** *Research piloting the MGRSI found that honor, strength, and achievement were the most commonly reported sources of male gender role stress and may be associated with suicidal behaviors (Sterling et al, 2016).*
- Ask the client what they need to feel prepared for the tasks and demands of their role. **EB:** *A study of caregivers found that preparedness was significantly associated with higher levels of hope and reward and with a lower level of anxiety (Henriksson & Arestad, 2013).*
- ▲ Refer the client to Acceptance and Commitment Therapy (ACT). **CEB:** *ACT is a therapy that focuses on the development of psychological flexibility through acceptance of what is out of personal control and a commitment to action that improves and enriches one's life (Hayes, Strosahl, & Wilson, 2011).*
- Support the client's spirituality practices. **EB:** *Spiritual care was found to reduce care strain in caregivers of elderly patients with Alzheimer's disease (Mahdavi et al, 2017).*
- Refer to the care plans for Readiness for enhanced family **Coping,** Readiness for enhanced **Decision-Making,** Impaired **Home** maintenance, Impaired **Parenting,** Risk for **Loneliness,** Readiness for enhanced community **Coping,** Readiness for enhanced **Self-Care,** and Ineffective **Sexuality** pattern.

Pediatric

- ▲ Provide parents of disabled children with information about and referrals to

educational and social resources available to assist their child. **EB:** *A longitudinal study found that parents' educational expectations shape academic development and changes in self-concept among young people with different types of disabilities (McCoy et al, 2016).*
• Assist new parents to adjust to changes in workload associated with childbirth. Mothers may need additional support. **EBN:** *A Brazilian study found that women in the postpartum period experience multiple stressors that affect their role performance (Cavalcanti et al, 2014).*
• Assess mothers who present with depressive symptoms in the postpartum period for evidence of role performance distress. **EBN:** *Nursing research indicates that role performance disturbances are correlated with depressive symptoms in the postpartum period (Cavalcanti et al, 2014).*
• Provide parents with information about mindfulness-based interventions (MBIs) to enhance coping when the role change is associated with a critically and chronically ill child. **EB:** *Research found that MBI is a culturally adaptable, acceptable, and effective method to improve quality of life and positive stress reappraisal coping in parents of children with autism spectral disorder (Rayun & Ahmad, 2016).*
• Provide parents with information to increase their awareness of their child's psychological and social needs after a critical illness. **EBN:** *Childhood survivors of critical illness face a complex trajectory of recovery with enduring psychosocial adversity. Parents and families are fundamental in shaping psychological and social well-being of survivors (Manning et al, 2014).*

Geriatric

• Assess older adults' choices regarding their care and enable them to live as they wish and receive the help they want by carefully listening to their stories. **EB:** *A recent study found that complementing standardized assessment data with informal interviews provided information that older adults and their families believed was important to their care (Lafortune et al, 2017).*
• Assess older adults for a sense of competence in their daily life. **EB:** *A French study showed that increased competence was associated with a decrease of depressive symptoms and apathy (Souesme et al, 2016).*
• Provide support and practice for older adults to use technology. **EB:** *A recent study found that participants used information and communication technology (ICT) to connect with friends and family. ICT use predicted higher well-being across outcomes (Sims et al, 2017).*
• Support the client's spiritual beliefs and activities and provide appropriate spiritual support persons. **EB:** *Spiritual care was found to reduce care strain in caregivers of elderly patients with Alzheimer's disease (Mahdavi et al, 2017).*
• Explore community needs after assessing the client's strengths. Encourage older adults to participate in volunteer programs. **EB:** *Research indicated an association between volunteering and reductions in symptoms of depression, better overall health, fewer functional limitations, feeling appreciated and needed, and greater longevity with vulnerable seniors benefiting the most (Anderson et al, 2014).*

Multicultural

• Assess for the influence of cultural beliefs, norms, values, and expectations on the individual's role. **CEB:** *The individual's role may be based on cultural perceptions (Leininger & McFarland, 2002).*

• Assess for conflicts between the caregiver's cultural role, obligations, and competing factors, such as employment or school. **EB:** *A study found that it is important to identify and understand culturally and geographically influenced barriers to cancer treatment and symptom management (Itty, Hodge, & Martinez, 2014).*
• Negotiate with the client regarding the aspects of their role that can be modified and still honor cultural beliefs. **CEB:** *Give-and-take with the client will lead to culturally congruent care (Leininger & McFarland, 2002).*
• Identify perceived barriers to family to use support groups or other service programs to assist with role changes. **EB:** *A systematic review identified that assessment for support resources, home care, or community assistance was needed prior to discharge and at routine intervals throughout the care situation (Greenwood et al, 2015).*
• The preceding interventions may be adapted for home care use.

Client/Family Teaching and Discharge Planning

▲ Refer client to comprehensive services to assist with transition needs at discharge. **EB:** *A study found no 30-day rehospitalizations for participants in the Kentucky Care Coordination for Community Transitions ([KCT]-T-3) program, which provided access to medical, social, and environmental services to support community transitions (Kitzman et al, 2017).*
• Provide educational materials to family members on client behavior management plus caregiver stress-coping management. **EB:** *Research has identified multiple components to provide education, support, counseling, care continuity, and linkage to community resources to ease transitions can improve caregiver health and coping (Naylor et al, 2017).*
• Help the client identify resources for assistance in caring for a disabled or aging parent (e.g., adult day care, nursing home placement). **EB:** *A systematic review identified assessment for support resources, home care, or community assistance was needed prior to discharge and at routine intervals throughout the care situation (Greenwood et al, 2015).*

Sedentary lifestyle

Marina Martinez-Kratz MS, RN, CNE

NANDA-I

Definition

A habit of life that is characterized by a low physical activity level.

Defining Characteristics

Average daily physical activity is less than recommended for gender and age; physical deconditioning; preference for activity low in physical activity

Related Factors

Insufficient interest in physical activity; insufficient knowledge of health benefits associated with physical exercise; insufficient motivation for physical activity; insufficient resources for physical activity; insufficient training for physical exercise

NOC(Nursing Outcomes Classification)

Suggested NOC Outcomes

Ambulation; Activity Tolerance; Endurance; Exercise Participation; Health Promoting Behavior; Lifestyle Balance; Personal Health Status; Physical Fitness; Exercise Promotion

Example NOC Outcome with Indicators

Ambulation as evidenced by the following indicators: Walks with effective gait/Walks at moderate pace/Walks up and down steps/Walks moderate distance. (Rate the outcome and indicators of **Ambulation:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Engage in purposeful moderate-intensity cardiorespiratory (aerobic) exercise for 30 to 60 minutes/day on 5 or more days per week for a total of 2 hours and 30 minutes (150 minutes) per week
- Increase exercise to 20 minutes/day (<150 minutes/week); light to moderate intensity exercise may be beneficial in deconditioned persons
- Increase pedometer step counts by 1000 steps per day every 2 weeks to reach a daily step count of at least 7000 steps per day, with a daily goal for most healthy adults of 10,000 steps per day

• Perform resistance exercises that involve all major muscle groups (legs, hips, back, chest, abdomen, shoulders, and arms) performed 2 to 3 days/week
• Perform flexibility exercise (stretching) for each of the major muscle-tendon groups 2 days/week for 10 to 60 seconds to improve joint range of motion; greatest gains occur with daily exercise
• Engage in neuromotor exercise 20 to 30 minutes/day including motor skills (e.g., balance, agility, coordination, and gait), proprioceptive exercise training, and multifaceted activities (e.g., Tai chi and yoga) to improve and maintain physical function and reduce falls in those at risk for falling (older persons)

NIC(Nursing Interventions Classification)

Suggested NIC Interventions

Exercise Therapy: Ambulation; Joint Mobility; Positioning; Exercise Promotion; Activity Therapy; Energy Management

Example NIC Activities—Exercise Therapy: Ambulation

Assist the client to use footwear that facilitates walking and prevents injury; Instruct in availability of assistive devices, if appropriate

Nursing Interventions and *Rationales*

• Observe the client for sedentary behaviors such as prolonged sitting, physical inactivity, and prolonged sleep. **EB:** *Prolonged sitting, physical inactivity, and prolonged sleep were identified as lifestyle health risk behaviors in an Australian study (Ding et al, 2015).* See care plans for Ineffective **Coping** or **Hopelessness.**
• Use the Self-Efficacy for Exercise Scale (Resnick & Jenkins, 2000) and the Outcome Expectation for Exercise Scale (Resnick et al, 2001) to determine client's self-efficacy and outcome expectations toward exercise (Resnick & D'Adamo, 2011). **CEB:** *Interventions most effective in promoting physical activity were those that focused only on the targeted behavior of physical activity and those that used behavioral strategies (e.g., rewards, contracts, goal setting, feedback and cueing) and self-monitoring (e.g., tracking physical activity using logs or websites). Supervised exercise, tailoring, contracting, exercise prescription, intensity recommendations, behavioral cueing, and fitness testing were also effective, although only modestly supported (Ruppar & Conn, 2010).*
• Assess client with exercise preparticipation health screening prior to implementing physical activity interventions. **EB:** *The American College of Sports Medicine (ACSM) has made recommendations to identify individuals (1) who should receive medical clearance before initiating an exercise program or increasing the frequency, intensity, and/or volume of their current program; (2) with clinically significant disease(s) who may benefit from participating in a medically supervised exercise program; and (3) with medical conditions that may require exclusion from exercise programs. The specific ACSM guidelines can be accessed at: http://certification.acsm.org/docs/default-source/files-for-resource-library/acsm-101-prescreeninginfographiccolorlegal-2015-12-15-v02.pdf?sfvrsn=cd75273d_4 (Riebe et al, 2015).*
• Recommend the client enter an exercise program with an active person who supports exercise behavior (e.g., friend or exercise buddy). **EB:** *A 12-week pilot controlled trial of a physical activity buddy program found that the active buddy group (P = 0.005) showed significantly higher step changes than the inactive buddy group (Choi, 2017).*
• Recommend the client use a mobile fitness application for customizing, cueing,

tracking, and analyzing an exercise program. **EB:** *A study showed exercise app users were more likely to exercise during their leisure time, and the data suggest exercise apps may increase exercise levels and health outcomes, such as body mass index (BMI), by making it easier for users to overcome barriers to exercise, leading to increased self-efficacy (Litman et al, 2015).*

• Recommend participation in group physical activity programs. **EBN:** *A nurse-monitored 7-week group exercise training program (ETP) with obese women improved adherence to some type of physical activity program 1 year after the intervention period, and the likelihood of adherence increased with the number of ETP sessions attended (del Rey-Moya et al, 2013).*

• Recommend client begin performing resistance exercises for additional health benefits. **EB:** *A research review found that resistance training is effective in controlling and improving cholesterol levels (Mann, 2014).*

• Encourage prescriptive resistance exercise of each major muscle group (hips, thighs, legs, back, chest, shoulders, and abdomen) using a variety of exercise equipment. **EB:** *Equipment such as free weights, bands, stair climbing, or machines should be used 2 to 3 days/week. Involve the major muscle groups for 8 to 12 repetitions to improve strength and power in most adults, 10 to 15 repetitions to improve strength in middle-aged and older persons starting exercise, and 15 to 20 repetitions to improve muscular endurance. Intensity should be between moderate (5 to 6) and hard (7 to 8) on a scale of 0 to 10 (ACSM, 2014).*

• Encourage gradual progression of greater resistance, more repetitions per set, and/or increasing frequency. **EB:** *A study found that a global progressive resistance strength training program was effective for improving the functional capacity of patients with rheumatoid arthritis (Lourenzi et al, 2015).*

Multicultural

• Assess for reasons why the client would be unable to participate in regular physical activity; address reasons and refer to resources as needed. **EB:** *A systematic integrative literature review to identify barriers to physical activity among African American women found intrapersonal barriers (lack of time, knowledge, and motivation; physical appearance concerns; health concerns; monetary cost of exercise facilities; and tiredness/fatigue), interpersonal barriers (family/caregiving responsibilities; lack of social support; and lack of a physical activity partner), and environmental barriers (safety concerns; lack of facilities; weather concerns; lack of sidewalks, and lack of physically active African American role models) (Jackson et al, 2015).*

• Assess for their perceptions of the neighborhood they reside in. **EB:** *A study found that negative neighborhood environment perceptions were associated with greater sedentary time for individuals living in lower socioeconomic areas (Ahuja et al, 2017).*

Pediatric

• Assess the child's current activity status using the Pediatric Inactivity Triad (Faigenbaum et al, 2018). **EB:** *Components of the Pediatric Inactivity Triad include (1) exercise deficit disorder (less than 60 minutes of recommended physical activity daily), (2) pediatric dynapenia (decreased muscle strength and power), and (3) physical illiteracy (low competence and confidence). Addressing these components collectively will enhance effective change (Faigenbaum et al, 2018).*

• Children and adolescents should participate in 60 minutes (1 hour) or more of physical activity daily.

- ❍ Aerobic: Sixty or more minutes a day should be either moderate-intensity or vigorous-intensity aerobic physical activity, and should include vigorous-intensity physical activity at least 3 days a week.
- ❍ Muscle-strengthening: As part of daily physical activity, children and adolescents should include muscle-strengthening physical activity on at least 3 days of the week.
- ❍ Bone-strengthening: As part of daily physical activity, children and adolescents should include bone-strengthening physical activity on at least 3 days of the week.
- ❍ Providing activities that are age appropriate, enjoyable, and offer a variety will encourage young people to participate in physical activities (US Department of Health and Human Services, 2018).

• Assist families to develop family-based interventions to increase child physical activity. **EB:** *A meta-analysis of family-based interventions found a small effect on physical activity when interventions were tailored to the ethnicity, motivation, and time constraints of the family; combined goal-setting and reinforcement techniques were used; educational strategies were used to increase knowledge as needed; and consideration of the family psychosocial environment (Brown et al, 2016).*

• Encourage parents and caregivers to adhere to the following American Academy of Pediatrics guidelines for children's media use (Chassiakos et al, 2016):

- ❍ For children younger than 18 months, avoid use of screen media other than video-chatting.
- ❍ Parents of children 18 to 24 months of age who want to introduce digital media should choose high-quality programming and watch it with their children to help them understand what they are seeing.
- ❍ For children ages 2 to 5 years, limit screen use to 1 hour/day of high-quality programs. Parents should co-view media with children to help them understand what they are seeing and apply it to the world around them.
- ❍ For children ages 6 and older, place consistent limits on the time spent using media, and the types of media, and make sure media does not take the place of adequate sleep, physical activity, and other behaviors essential to health.
- ❍ Designate media-free times together, such as dinner or driving, and media-free locations at home, such as bedrooms.
- ❍ Have ongoing communication about online citizenship and safety, including treating others with respect online and off-line.
- ❍ Encourage parents and caregivers to create their personalized family media plan (see https://www.healthychildren.org/English/media/Pages/default.aspx).

Geriatric

• Use valid and reliable criterion-referenced standards for fitness testing (e.g., Senior Fitness Test) designed for older adults that can predict the level of capacity associated with maintaining physical independence into later years of life (e.g., get up and go test). *Interventions can subsequently be designed to target weak areas and therefore help reduce the risk of immobility and dependence (Bhattacharya, Deka, & Roy, 2016).*

• Recommend the client begin a regular exercise program, even if generally active. **EB:** *A meta-analysis of the association between time in sedentary behavior and hospitalizations, mortality, cardiovascular disease, cancer, and diabetes found prolonged*

sedentary time associated as an independent risk factor for poor health outcomes despite engagement in physical activity (Biswas et al, 2015).

▲ Refer the client to physical therapy for resistance exercise training, as able, involving all major muscle groups. **CEB:** *A Cochrane review found that progressive resistance-strength training for physical disability in older clients resulted in increased strength and positive improvements in some limitations (Liu & Latham, 2009).*

• Implement progressive resistance training plus balance exercise for older adults as indicated. **EB:** *A cluster randomized controlled trial showed that the Sunbeam Program of progressive resistance training in conjunction with balance exercise significantly reduced the rate of falls and improved physical performance in clients of residential care (Hewitt et al, 2018).*

• Use the Function-Focused Care (FFC) rehabilitative philosophy of care with older adults in residential nursing facilities to prevent avoidable functional decline. **EBN:** *The primary goals of FFC are to alter how direct care workers provide care to residents to maintain and improve time spent in physical activity and improve or maintain function. Residents receiving FFC had less functional decline, and a greater percentage who were not ambulating returned to ambulatory status for short functional distances. Residents with dementia also had a significant decrease in falls (28% versus 50% in the control group) (Galik et al, 2013).*

• Recommend the older client practice Tai chi. **EBN:** *A study of older community dwelling stroke survivors found that Tai chi led to improved aerobic endurance and was more effective in reducing fall rates than other interventions (Taylor-Pilae et al, 2014).*

• Prior to surgery, refer clients to a personalized prehabilitation program that includes a warm-up followed by aerobic, strength, flexibility, neuromotor, and functional task work. **EB:** *A study of major surgery clients assigned to personalized prehabilitation programs showed enhanced aerobic capacity and reduction in postoperative complications by 51% (Barbaren-Garcia et al, 2018).*

Home Care

• The preceding interventions may be adapted for home care use.

▲ Assess home environment for factors that create barriers to mobility. Refer to physical and occupational therapy services if needed to assist the client in restructuring home environment and daily living patterns.

Client/Family Teaching and Discharge Planning

• Work with the client using theory-based interventions (e.g., social, cognitive, theoretical components such as self-efficacy; transtheoretical model). **EBN:** *Residents living in senior housing who attended a 12-week intervention including education, motivational modalities, and exercise classes reported stronger outcome expectations for exercise, less pain, and decreased intake of fat and salt (Resnick et al, 2014).*

• Consider using motivational interviewing techniques when working with both children and adult clients to increase their activity. **EB:** *A study to increase physical activity among patients with rheumatoid arthritis found that at posttreatment and 6-months follow-up, significantly more clients met current physical activity recommendations (Knittle et al, 2015).*

Readiness for enhanced Self-Care

Ruth A. Wittmann-Price PhD, RN, CNS, CNE, CHSE, ANEF, FAAN

NANDA-I

Definition

A pattern of performing activities for oneself to meet health-related goals, which can be strengthened.

Defining Characteristics

Expresses desire to enhance independence with health; expresses desire to enhance independence with life; expresses desire to enhance independence with personal development; expresses desire to enhance independence with well-being; expresses desire to enhance knowledge of self-care strategies; expresses desire to enhance self-care

NOC(Nursing Outcomes Classification)

Suggested NOC Outcomes

Adherence Behavior; Health-Seeking Behavior; Self-Care Status

Example NOC Outcome with Indicators

Health-Seeking Behavior as evidenced by the following indicators: Completes health-related tasks/Performs self-screening/Obtains assistance from health professionals. (Rate the outcome and indicators of **Health-Seeking Behavior:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Evaluate current levels of self-care as optimum for abilities
- Express the need or desire to continue to enhance levels of self-care
- Seek health-related information as needed
- Identify strategies to enhance self-care
- Perform appropriate interventions as needed
- Monitor level of self-care
- Evaluate the effectiveness of self-care interventions at regular intervals

NIC(Nursing Interventions Classification)

Suggested NIC Interventions

Coping Enhancement; Energy Management; Learning Facilitation; Multidisciplinary Care Conference; Mutual Goal Setting; Self-Care Assistance

Example NIC Activity—Self-Care Assistance

Encourage person to perform normal activities of daily living to level of ability

Nursing Interventions and *Rationales*

• For assessment of self-care, use a valid and reliable screening tool if available for specific characteristics of the person, such as arthritis, diabetes, stroke, heart failure (HF), or dementia. **EBN:** *Bryant (2017) developed a Self-Care to Success toolkit that supports nurse practitioners to empower patients with HF and promote self-care behaviors (SCBs) successfully.* **EBN:** *Researchers completed a systematic review of self-care instruments (N = 26) and found seven instruments based on Orem's Self-Care Theory, but none of the instruments reviewed were fully recommended because of deficits in methodological quality and measurement properties (Matarese, Lommi, & DeMarinis, 2017). Conduct mutual goal setting with the person.* **EBN:** *Todhunter (2017) explored self-administered compression therapy for patients with chronic edema from venous and lymphatic impairment and found that by including patients in their treatment decisions they were empowered and more likely to be accountable.* **EBN:** *Researchers explored outcomes for patients with diabetic foot ulcers and found that the majority of focus was on patient compliance (adherence) rather than on self-care management. Researchers suggested that shifting focus to self-care will improve outcomes (Costa, del Pilar Camargo Plazas, & Tregunno, 2017).*
• Support the person's awareness that enhanced self-care is an achievable, desirable, and positive life goal. **EBN:** *Crown and Vogel (2017) completed a mixed-method pilot study of patients receiving hemodialysis in relation to self-care about dietary fluid restrictions. Researchers used motivational interviewing to promote self-care fluid management, and participants deemed it as helpful.* **EBN:** *Kauric-Klein, Peters, and Yarandi (2017) examined how educational sessions and individual counseling effected blood pressure self-efficacy and self-care outcomes in adults (N = 118) receiving hemodialysis, and results demonstrated that self-efficacy was related to SCBs such as decreased salt intake, lower weight gain, increased adherence to medications, and fewer missed appointments.*
• Show respect for the person, regardless of characteristics and/or background. **EBN:** *Marzband and Zakayi (2017) explored the concept of self-care from Islamic texts and found that self-care is participating in responsible activities to God for health promotion, preventive disease, and treatment. Self-care included physical, mental, spiritual, and social dimensions.* **EBN:** *Gowani, Gul, and Dhakam (2017) explored, using a cross-sectional survey, SCB among patients with HF in Karachi, Pakistan. The survey was the European Heart Failure Self-Care Behavior Scale, and of six variables, only three factored into self-care for this population, including education, income, and chronicity of the HF, suggesting that different populations define self-care differently.*
• Promote trust and enhanced communication between the person and health care providers. **EBN:** *Reb et al (2017) studied a Self-Management Survivorship Care Planning intervention in colorectal and lung cancer survivors (N = 30) with pretest and posttest and results revealing significant differences in depression, anxiety, self-efficacy, physical functioning, role limitations (physical, pain, general health, health transition, physical health summary), and total quality of life. Participants also expressed that they felt empowered from the nurse-driven intervention.* **EBN:** *Researchers studied the patient–provider relationships (communication, integration, collaboration, and empowerment) in pregnant patients (N = 139) in relation to better patient self-care and women's perceptions of better communication, collaboration, and empowerment from their midwives, which were associated with more frequent SCBs (Nicoloro-SantaBarbara et al, 2017).*
• Promote opportunities for spiritual care and growth. **EBN:** *Salamizadeh, Mirzaei, and Ravari (2017) studied the effects of a spiritual care educational intervention with caretakers (N = 60) of Alzheimer's patients using a random group pretest–posttest method and concluded that spiritual care enhanced the self-efficacy of the caregivers.*
• Promote social support through facilitation of family involvement. **EB:** *Morgan et al (2017) performed a literature review regarding social support for self-management for patients*

to manage their chronic condition(s) in terms of disease control and found the two elements that were most important for self-care were commitment and empowerment. **EB:** *Campbell et al (2017) examined the social adaptability index (SAI) with patients (N = 615) and its applicability to self-care and diabetes outcomes and revealed that the SAI was correlated with quality of life but not SCBs, suggesting that five items alone are not enough to explain self-care in relation to social adaptability for patients with type 2 diabetes.*

• Provide opportunities for ongoing group support through establishment of self-help groups on the Internet. **EB:** *Nickel, Trojan, and Kofahl (2017) studied the outcomes of a health care initiative "Self-Help Friendliness (SHF) and Patient-Centeredness in Health Care" to describe (1) how patients were involved in the development of SHF and (2) to test the survey. The study results identified the following important aspects of SHF: cooperation and involvement in establishing the quality criteria and it appears to be a good fit to study self-care groups.* **EB:** *Researchers completed a meta-analysis (N = 47) review to determine the effectiveness of group-based interventions compared with individual interventions for improving clinical, lifestyle, and psychosocial outcomes in people with type 2 diabetes. They found that group-based interventions are more effective than individual education at improving clinical, lifestyle, and psychosocial outcomes in people with type 2 diabetes (Odgers-Jewell et al, 2017).*

• Help the person identify and reduce the barriers to self-care. **EBN:** *Woith et al (2017) qualitatively explored homeless people's (N = 15) perceptions of their interactions with nurses and identified three major themes: (1) nurses should be civil, (2) SCBs, and (3) barriers to care indicating that homeless people find nurses uncivil toward them and this becomes a self-care barrier.* **EBN:** *Restorick Roberts, Betts Adams, and Beckette Warner (2017) used a mixed-methods study to look at the experience of living with chronic illness and identified barriers to self-care in older women (N = 130) and found that barriers to self-care included pain, lack of financial resources, and worry.*

• Provide literacy-appropriate education for self-care activities. **EBN:** *Lelorain et al (2017) studied health care professionals' perception of therapeutic patient education for promoting self-care and found that nurses often lack skills and knowledge, and are disillusioned about the effectiveness of therapeutic patient education and that* patient-centered *care* is needed *in many places to promote education that can increase self-care.* **EB:** *Hayward et al (2017) completed a pilot study in people with liver cirrhosis (N = 50) and found that only 54% of patients could recall being given written information and 64% had self-sought Internet information. In addition patients reported difficulties understanding the written material.*

• Facilitate self-efficacy by ensuring the adequacy of self-care education. **EBN:** *Grafton and Bassett (2017) studied HF patients' (N = 40) confidence in relation to self-care and found that confidence is an important element in successful self-care activities.* **EBN:** *Researchers used a correlation (a descriptive design to examine the relationship between glycemic control and SCBs in patients with type 2 diabetes) and found that patients with poor glycemic control had poorer self-efficacy and SCBs (D'Souza et al, 2017).*

• Provide alternative mind–body therapies such as reiki, guided imagery, yoga, and self-hypnosis. **EBN:** *Orellana-Rios et al (2017) piloted an "on the job" mindfulness and compassion-oriented meditation training for interdisciplinary team members (N = 27) designed to reduce distress, foster resilience, and strengthen a prosocial motivation in the clinical encounter. Improvements were realized in two burnout components (emotional exhaustion and personal accomplishment), and overall improvement of self-care.* **EB:** *Rothberg and Friedman (2017) completed a literature review about low back pain (LBP) and complementary therapies (spinal manipulation, massage, exercise, or yoga), and found that for patients with LBP evidence does not support the use of spinal manipulation or exercise*

therapy.

• Promote the person's hope to maintain self-care. **EB:** *Anderson, Turner, and Clyne (2017) developed a self-management intervention called the Help to Overcome Problems Effectively (HOPE: MS) to improve the physical and psychological well-being of people living with multiple sclerosis (MS) and found that the HOPE: MS was helpful and useful to patients living with MS and covered the parameters needed to identify self-care needs.* **EB:** *Ritholz, MacNeil, and Weinger (2017) investigated how adults (N = 148) with diabetes were educated about microvascular complications and found the first discussions focused on prevention, but when complications occurred, 78% of participants perceived the provider-provided comprehensive interactive education; specific self-care guidance; reassuring messages; and referrals, follow-ups, and results indicated that training is needed to help providers discuss complications with honest but positive messages so diabetic patients can remained informed and maintain hope.*

Pediatric

• Assess and evaluate a child's level of self-care and adjust strategies as needed. **EBN:** *Sawin et al (2017) developed a theory-based conversation guide to assist parents of hospitalized chronically ill children better prepare for self-management of home care for the child and found the theory-based intervention operationalized self-management was well-received.* **EB:** *Burns-Nader, Joe, and Pinion (2017) studied using computer tablets with children who were burned during treatments, and nurses reported significantly less pain and anxiety for the tablet distraction group compared with the control group.*

• Assist families to engage in and maintain social support networks. **EB:** *Pumar-Mendez et al (2017) interviewed stakeholders (N = 90) in six countries about the support for self-care for patients with chronic illness (SSSC) and investigated the stakeholders' roles. The stakeholders described the ideal SSSC as inclusive, interdependent, and patient-centered and needed support was from patients, governments, health care professionals, associations, private companies, and the media. The recommendations were to continue to promote SSSC with stakeholders and health professionals to improve care.* **EB:** *Researchers qualitatively studied a parenting intervention, Circle of Security, for mothers with mood and anxiety disorders at a pediatric clinic and through surveys and medical records found that the intervention is feasible and will assist with pediatric care (Kimmel et al, 2017).*

• Encourage activities that support or enhance spiritual care. **EBN:** *O'Shea et al (2017) completed a qualitative descriptive study about meeting the physical, emotional, and spiritual needs of parents with seriously ill children and found there was a need among providers to enhance both basic education and advanced skills in pediatric palliative and end-of-life care education statewide.* **EB:** *Campos, Soria, and Liz (2016) studied pediatric complex chronic conditions (CCC) by developing a multidisciplinary team (called the PRINCEP program) that included a pediatrician, nurse, social worker, and psychospiritual specialist to offer patient-centered care. The program assisted with family's needs being met and better satisfaction.*

Multicultural

• Identify cultural beliefs, values, lifestyle practices, and problem-solving strategies when assessing the client's level of self-care. **EB:** *Oh, Ell, and Palinkas (2017) studied SCBs (healthy diet, exercise, self-blood glucose monitoring, and foot care) to see if changes in them predicted depression in low-income Hispanic patients with diabetes. Results supported that poor diet and lack of exercise are indicators of depression.* **EB:** *Researchers evaluated the validity and reliability of the Danish version of the European Heart Failure Self-Care Behavior*

Scale (EHFScBS-9) on a Danish population of patients (N = 147) and found it a valid and reliable instrument to assess HF self-care behaviors in a Danish population (Ostergaard et al, 2017). Enhance cultural knowledge by seeking out information regarding different cultural or ethnic groups. **EBN:** *Researchers studied the COM-B model (consisting of capability, opportunity, and motivation) to explore SCBs and examine the self-care confidence on Chinese patients (N = 321) with chronic HF and found that Chinese patients have poor SCBs caused by lack of confidence, functional capacity, knowledge, and health literacy (Zou et al, 2017).*

• Recognize the effect of culture on SCBs. **EB:** *Researchers studied the elements that effect self-care in HF patients (N = 226) in Jordan by looking at knowledge, sociodemographics, and SCBs. Results revealed that knowledge, income, and educational levels; shorter duration of disease; fewer people living at home; older age; and being unemployed were significant predictors of low self-care scores (Tawalbeh et al, 2017).*

• Provide culturally competent care. **EBN:** *Labore et al (2017) culturally explored the meaning of transition to self-care in sickle cell disease patients using an existential framework, and meaning was found in lived time, space, body, and human relationship.* **EB:** *DiZazzo-Miller et al (2017) completed a qualitative study to examine providers' perspectives on cultural barriers and facilitators to diabetes self-management in Arab Americans, and results identified that the main barriers are the disease itself and patients' denial or refusal to recognize the diabetes. These findings reflect the cultural stigma associated with diabetes by many Arab Americans.*

• Support independent self-care activities. **EBN:** *Teppala et al (2017) studied post-acute rehabilitation for patients with hip fracture by examining the variation in mobility and self-care using a retrospective cohort study and found variation in discharge mobility and self-care related to health care organization differences.* **EB:** *Researchers investigated self-care deficits, health behaviors, and management of patients (N = 12) with chronic systemic sclerosis because it affects a person's physical, emotional, psychosocial, and spiritual dimensions. They found Thai patients developed specific self-care agencies to improve their health and well-being. The study assists in the understanding of how patients live and cope with systemic sclerosis (Hornboonherm et al, 2017).*

Home Care

• The nursing interventions described previously may also be used in home care settings. **EBN:** *Revell (2017) studied nausea and vomiting in pregnancy and patients' coping mechanisms and found that many women self-manage and the condition affects both psychological and physiological well-being. Nausea and vomiting interrupt activities of daily living and self-care should be augmented by provider-implemented management.* **EBN:** *Lee et al (2017) studied rural residents (N = 580) with HF to explore the variables (health literacy, psychosocial status, current symptom status, and aging status) related to self-care and found that depressive symptoms, lower perceived control, better symptom status, and annual income of <$20,000 were negatively associated with self-care. Support the new sense of self that may occur with complex health problems.* **EBN:** *Kao, Chuang, and Chen (2017) studied chronic disease self-management using smartphone applications that support patient self-management of chronic disease, facilitating health management, and health promotion, which have been shown to assist health care professionals and patients manage their diseases.* **EB:** *Chang et al (2017) explored depression's effect on self-care, self-care confidence, and resilience in stable outpatients (N = 201) with HF and found depression reduced self-care by decreasing self-care confidence for patients with moderate and high levels of resilience.*

• Assist individuals and families to prevent exacerbations of chronic illness symptoms so rehospitalization is not necessary. **EB:** *Blashill et al (2017) studied the*

relationship of body image, self-care, and depression in HIV-positive minority men (N = 44) comparing cognitive behavioral therapy as a mediator and found that it assisted in improving body image and HIV SCBs. **EB:** *Patel et al (2017) studied African American women (N = 422), asthmatics, and a telephone-based self-regulation intervention and compared the results with a control group. Findings demonstrated that patients who completed a culturally responsive self-care program had improvements in asthma outcomes when compared with the control group, even when comorbidities were present. In complex chronic illnesses such as HF, individuals and families should be helped to accept continued functional disabilities and work toward maintenance of optimum functional status, considering the reality of illness status.* **EB:** *Reid et al (2017) studied cognitive-behavioral pain self-management by older adults (N = 588) with activity-limiting pain living at home in a randomized control trial and found no significant result differences in the treatment and control groups, indicating other variables should be explored.* **EBN:** *Lai, Ching, and Wong (2017) studied experiences of patients (N = 10) with breast cancer using a mixed-methods approach and found that chemotherapy affected the patients in different ways. Most women adopted behavioral, social, cognitive, and emotional strategies to cope, and researchers found that chemotherapy can be equated to going on a hike.*

- Use educational guidelines for stroke survivors. **EB:** *Murdolo et al (2017) studied the Graded Repetitive Arm Supplementary Program (GRASP) with patients who experienced a stroke. Patients perceived the program as helpful in activities of daily living during the acute stroke phase.* **EB:** *Atler et al (2017) completed a study about yoga as an intervention in poststroke patients (N = 13), and five themes were identified from qualitative analysis: (1) improved abilities, (2) gained new knowledge, (3) enhanced engagement in activities, (4) improved relaxation, and (5) increased confidence.*
- Ensure appropriate *interdisciplinary communication to support client safety.* **EB:** *Johnson et al (2017) explored the consensus of an expert panel related to over-the-counter (OTC)* proton pump *inhibitors (PPIs) for gastroesophageal reflux disease and found that although OTC PPI would probably not mask gastric cancer, effect bone density,* Clostridium difficile *infection, or cardiovascular adverse events, they may be associated with slightly increased risks for infectious diarrhea, certain idiosyncratic reactions, and cirrhosis-related spontaneous bacterial peritonitis.*
- For public safety health *care professionals and consumers should participate in decision-making when managing reflux-related symptoms in the self-care setting.* **EBN:** *Mackintosh et al (2017) explored the experiences of women (N = 22) with pregnancy complications and found that women and relatives used self-diagnosis, self-care, and seeking triage, but they also found that health care providers did not pay attention to their needs as they saw appropriate and therefore did not encompass "safety partnerships."*
- Enhance individual and family coping with chronic illnesses. **EBN:** *Kim and Kim (2017) studied elements that effected health-related quality of life (HRQOL) in elderly patients (N = 365) with diabetes and found that gender (male) and depression were negatively correlated with diabetic self-care.* **EB:** *Kessing et al (2017) investigated quality of life in patients (N = 459) with HF in relation to self-care and found that quality of life and degree of self-care was affected by depression and could be affected poorly by increased anxiety.*
- Implement a community care management program. **EBN:** *Merius and Rohan (2017) completed a literature review (N = 14) related to adult attrition from community programs on diabetes self-care and found barriers for retention included transportation, family obligations, and scheduling conflicts.*

- Teach clients how to regularly assess their level of self-care.
- Instruct clients that a variety of interventions may be needed to enhance self-care.
- Help clients to understand that enhanced self-care is an achievable goal.
- Empower clients.
- Teach clients about the decision-making process and self-care activities needed to manage their illness state and promote well-being.
- Continuously stress that all self-care activities must be regularly evaluated to ensure that enhanced levels of self-care can be maintained.

Bathing Self-Care deficit

NANDA-I

Definition
Inability to independently complete cleansing activities.

Defining Characteristics
Impaired ability to access bathroom; impaired ability to access water; impaired ability to dry body; impaired ability to gather bathing supplies; impaired ability to regulate bath water; impaired ability to wash body

Related Factors
Anxiety; decrease in motivation; environmental barrier; pain; weakness

Associated Condition
Alteration in cognitive functioning; impaired ability to perceive body part; impaired ability to perceive spatial relationships; musculoskeletal impairment; neuromuscular impairment; perceptual disorders

NOC(Nursing Outcomes Classification)

Suggested NOC Outcomes
Self-Care: Activities of Daily Living (ADLs); Self-Care: Bathing; Self-Care: Hygiene

Example NOC Outcome with Indicators
Self-Care: ADLs as evidenced by the following indicators: Bathing/Hygiene. (Rate outcome and indicators of **Self-Care: ADLs:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Remain free of body odor and maintain intact skin
- State satisfaction with ability to use adaptive devices to bathe
- Use methods to bathe safely and effectively with minimal difficulty
- Bathe with assistance of caregiver as needed and report satisfaction and dignity maintained during bathing experience
- Bathe with assistance of caregiver as needed without exhibiting defensive (aggressive) behaviors

NIC(Nursing Interventions Classification)

Suggested NIC Intervention
Self-Care Assistance: Bathing/Hygiene

Example NIC Activities—Self-Care Assistance: Bathing/Hygiene
Determine amount and type of assistance needed; Consider the culture of the client when promoting self-care activities; Provide assistance until client is fully able to assume self-care

Nursing Interventions and *Rationales*

- **QSEN** (Patient-Centered): Ask patients about their bathing preferences, which can increase patient privacy and satisfaction. **EBN:** *Perceptions of patients (N = 71) after an*

acute myocardial infarction who received bed baths were not as positive as those of patients who took showers (Lopes, Nogueira-Martins, & Barros, 2013).

• **QSEN** (Safety): Warm bathing area above 25.1°C (77.18°F) while bathing, especially on cold days. **EB:** *Bathing and ambient temperature decreasing from 25.1°C can be a trigger for increasing occurrence of out-of-hospital cardiac arrest (Nishiyama et al, 2011).*

• **QSEN** (Safety): Use chlorhexidine-impregnated cloths rather than soap and water for daily patient bathing. **EB:** *Chlorhexidine reduces hospital-acquired infection risk from the potentially harmful pathogens methicillin-resistant* Staphylococcus aureus *(MRSA) and vancomycin-resistant enterococcus (VRE) (Kassakian et al, 2011).*

• **QSEN** (Safety): Consider using a prepackaged bath, especially for patients at high risk for infection (older adult, immunocompromised, invasive procedures, wounds, catheters, drains), to avoid patient exposure to multidrug-resistant pathogens from contaminated bath basins. **EB:** *In a 44-month study by Marchaim et al (2012), hospital bath basins (N = 1103) were found 62.2% of the time to be contaminated with hospital-acquired pathogens.*

• **QSEN** (Safety): Use chlorhexidine gluconate for bath basin bathing. **EBN:** *Powers et al (2012) found in a study (N = 90) that when patients are bathed with chlorhexidine gluconate the bacterial growth in the bath basin is significantly reduced.*

• **QSEN** (Patient-Centered): Use patient-centered bathing interventions: plan for patient's comfort and bathing preferences, show respect in communications, critically think to solve issues that arise, and use a gentle approach. **CEB:** *Focusing on the patient rather than the task of bathing results in greater comfort and fewer aggressive behaviors, which are likely defensive behaviors that result from feeling threatened or anxious, and increase with shower (especially) and tub bathing (Hoeffer et al, 2006).*

▲ Provide pain relief measures, such as ice packs, heat, and analgesics for sore joints 45 minutes before bathing; move extremities slowly and carefully; and inform the client before movements associated with pain occur (walking; transferring to a new location; moving joints; and washing genitals, face, and between toes and under arms). Have the client wash painful areas; recognize indicators of pain and apologize for any pain caused. **CEB:** *Pain relief and client participation reduce discomfort, preserve dignity, and give a sense of control (Rader et al, 2006).*

• Use a comfortable padded shower chair with foot support, or adapt a chair: pad it with towels/washcloths, cover the cold back with dry towels, and cover the arms with foam pipe insulation. **CEB:** *Unpadded shower chairs with large openings and no foot support contribute to pain by allowing clients to sink into the opening with their feet unsupported (Rader et al, 2006).*

• Ensure that bathing assistance preserves client dignity through use of privacy with a traffic-free bathing area and posted privacy signs, timeliness of personal care, and conveyance of honor and recognition of the deservedness of respect and esteem of all persons. **CEBN:** *Older adults report that dignity is promoted via respect, independence, exerting control, timeliness, privacy for the body, cleanliness, independence and sufficient time from staff, attitudes toward older people, and communication (Webster & Bryan, 2009).*

• For cognitively impaired clients, avoid upsetting factors associated with bathing: instead of using the terms *bath, shower,* or *wash,* use comforting words, such as *warm, relaxing,* or *massage.* Start at the client's feet and bathe upward; bathe the face last after washing hands and using a clean cloth. Use a beautician/barber or wash hair at another time to avoid water dripping in the face. **CEB:** *Some words are associated with unpleasant bathing experiences, whereas others convey a pleasant bathing experience. Starting with the face or hair is distressing, because water drips on the face and the head becomes cold and wet (Rader et al, 2006).*

• Use towel bathing to bathe client in bed, a bath blanket, and warm towels to keep the client covered the entire time. Warm and moisten towels/washcloths and place in plastic bags to keep them warm. Use the towels to massage large areas (front, back) and one washcloth for facial areas and another one for genital areas. No rinsing or drying is needed as is commonly thought for bathing. **CEB:** *Towel bathing is a gentle experience with less discomfort that significantly reduces aggression as well as bathing time and soap residue after showering without accumulation of pathogenic bacteria (Hoeffer et al, 2006).*
• **QSEN** (Patient-Centered): For shower bathing use patient-centered techniques, keep patient covered with towels and cleanse under the towels, use no-rinse products, use favorite bathing items, and use a handheld shower with adjustable spray. **CEB:** *Covering the patient is an easy means to maintain dignity, reduce embarrassment, and keep the patient warm and unexposed without increasing bathing time (Rader et al, 2006).*
▲ **QSEN** (Teamwork and Collaboration): Request referral of patient who has had a stroke to rehabilitation services. **EB:** *In a systematic review of 19 studies, Mehrholz et al (2012) found that electromechanical and robot-assisted arm training devices used in rehabilitation may assist in improving arm function after stroke, which is important for ADLs such as bathing.*
▲ **QSEN** (Patient-Centered): Use a wrapped warm footbath for relaxation in patients with cancer. **EBN:** *Yamamoto and Nagata (2011) found in a randomized controlled trial that the wrapped warm footbath in patients with cancer can increase relaxation and provide pain relief.*

Geriatric

• **QSEN** (Patient-Centered, Safety): Advocate for the use of the Bathing Without a Battle educational program for patients with dementia. **EB:** *In a randomized crossover diffusion study, the Bathing Without a Battle educational program that trains caregivers in methods for improving the bathing experience of patients with dementia in nursing homes was found to be effective in reducing the rate of aggressive and agitated behaviors (Gozalo et al, 2014).*
• **QSEN** (Patient-Centered): Provide nighttime bathing options for nursing home residents. **EBN:** *Hashimoto (2014), in an interview survey of administrators of nursing homes (N = 3), found that nighttime bathing options provided more flexibility for bathing needs, improved sleep, and quality of life for the residents, and for caregivers it provided improved care quality and ability to provide patient-centered care.*
• Design the bathing environment for comfort: **Visual.** Reduce clutter and use partitions to hide equipment storage. Laminate and put artwork or decorative objects in bather's view, or place cue cards to bathing process (wall, ceiling, shower). Stand or sit in bather's position to experience what he or she sees. Decrease glare from tiles, white walls, and artificial lights. Use contrasting colors and soft but adequate lighting on a dimming switch for adjustment. *Bathing rooms are sterile, institutional, and frightening spaces filled with unfamiliar equipment—tubs with sides that open up and look like they might swallow you, or gurneys with arms that look like construction cranes. Overhead lights can be bright and shine into the bather's eyes. Glare can cause visual discomfort, especially in clients with visual changes or cataracts (Calkins, 2005).*
• Arrange the bathing environment to promote sensory comfort: **Auditory.** Reduce noise of voices and water. Do not allow traffic into bathing room. Add fabric to absorb sound (three to four times the width of the opening for sound-absorbing folds). Play soft music. **CEB:** *Noise discomfort can result from high-echo tiled walls, loud*

voices, and running water. Traffic can compromise privacy. Absorb negative sounds, and add positive sounds through music (Calkins, 2005). **EBN:** *In an observational study (N = 53) by Joosse (2012), sound was a predictor of agitation for those with dementia.*

• Design the bathing environment for comfort: **Tactile.** Use heat lamps or radiant heat panels to keep the room warm. Use powder-coated grab bars in decorative colors with nonslip grip. Provide a soft rug to stand on. Ensure that flooring is not slippery (a high coefficient of friction, ideally above 80, is desired and obtained through flooring coatings). **CEB:** *If the caregiver is warm to the point of sweating, room temperature is about right for an older person being bathed. Appealing, stable grab bars are needed for balance. Preventing the floor from becoming slippery from water is essential (Calkins, 2005).*

• Use music during shower for clients with dementia. *Music may reduce agitation and improve moods to increase job satisfaction (Ray & Fitzsimmons, 2014).*

• Train caregivers bathing clients with dementia to avoid behaviors that can trigger assault: confrontational communication, invalidation of the resident's feelings, failure to prepare a resident for a task, initiating shower spray or touch during bathing without verbal prompts beforehand, washing the hair and face, speaking disrespectfully to the client, and hurrying the pace of the bath. **CEB:** *During bathing, assaults (defensive behavior) by nursing home residents with dementia are frequently triggered by caregiver actions that startle, frighten, hurt, or upset the resident. This might happen when caregivers spray water on a resident without warning or when they touch a resident's feet, axilla, or perineum, which is possibly caused by the startle reflex (Somboontanont et al, 2004).*

• Develop awareness of the ethics of presence during bathing to better meet clients' needs. Raholm (2012) found in a phenomenological study of nurses in elder care (*N* = 7) who discussed bathing that one must go beyond being physically present and enter into a caring relationship in which there is no indifference to the client's unique needs.

• Focus on the abilities of the client with dementia to obtain client's participation in bathing. **EBN:** *The use of an abilities-focused approach increases the ability of people with dementia to participate in their care (Sidani, Streiner, & LeClerc, 2012).*

• **QSEN** (Patient-Centered): Use a Chinese herb formula in bath water to reduce paraplegia spasm. **EB:** *In a randomized controlled trial by Liu et al (2014), Chinese herbs placed in bath water (N = 160) reduced paraplegia spasticity.*

Multicultural

• **QSEN** (Patient-Centered): Ask the patient for input on bathing habits and cultural bathing preferences. **CEB:** *Bathing is a personal experience with variability in attitudes, preferences, and adaptations to disability to be considered when developing interventions for bathing (Ahluwalia et al, 2010).*

Home Care

• If in a typical bathing setting for the client, assess the client's ability to bathe self via direct observation using physical performance tests for ADLs. *Observation of bathing performed in an atypical bathing setting may result in false data.*

• **QSEN** (Safety): Turn down temperature of water heater and recommend use of a water temperature-sensing shower valve to prevent scalding. *Older or disabled people have slower reflexes to respond to hot water and may be unable to regulate water temperature, yet they may be left unattended. Water at 130°F produces a first-degree burn in 20 seconds; at 135°F to 140°F, exposure for 5 to 6 seconds causes third-degree burns (Fathers, 2004).*

Client/Family Teaching and Discharge Planning

• Inform clients with extremity casts or bandages of inexpensive options to protect these devices during showering such as with plastic newspaper bags or bread bags. In a case study, Naram, Makhijani, and Chao (2011) reported on the use of inexpensive or free cast and bandage protector bags.

Dressing Self-Care deficit

Linda S. Williams RN, MSN

NANDA-I

Definition
Impaired ability to perform or complete dressing activities for self.

Defining Characteristics
Impaired ability to choose clothing; impaired ability to fasten clothing; impaired ability to gather clothing; impaired ability to maintain appearance; impaired ability to pick up clothing; impaired ability to put clothing on lower body; impaired ability to put clothing on upper body; impaired ability to put on various items of clothing; impaired ability to remove clothing item; impaired ability to use assistive device; impaired ability to use zipper

Related Factors
Anxiety; decrease in motivation; discomfort; environmental barrier; fatigue; pain; weakness

NOC(Nursing Outcomes Classification)

Suggested NOC Outcomes
Self-Care: Activities of Daily Living (ADLs), Dressing, Hygiene

Example NOC Outcome with Indicators
Self-Care: Dressing as evidenced by the following indicators: Gets clothing from drawer and closet/Puts clothing on upper body and lower body. (Rate outcome and indicators of **Self-Care: Dressing:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Dress and groom self to optimal potential
- Use assistive technology to dress and groom
- Explain and use methods to enhance strengths during dressing and grooming
- Dress and groom with assistance of caregiver as needed

NIC(Nursing Interventions Classification)

Suggested NIC Intervention
Self-Care Assistance: Dressing/Grooming

Example NIC Activities—Self-Care Assistance: Dressing/Grooming
Be available for assistance in dressing, as necessary; Reinforce efforts to dress self; Maintain privacy while the client is dressing

Nursing Interventions and *Rationales*

- **QSEN** (Patient-Centered): Assess independence in dressing and bathing skills after rehabilitation to determine the need for follow-up care. **EB:** *It was found that dressing and bathing independence at rehabilitation discharge were predictors of independence at 5 years after stroke (De Wit et al, 2014).*
- **QSEN** (Teamwork and Collaboration): Assess functional impairment and report functional changes to health care provider to aid in earlier cancer diagnosis. **EB:** *Functional impairments were found to be symptoms during the diagnostic phase that occurred in clusters based on cancer site: head/neck—impairments in dressing, eating/feeding, bathing, toileting, and walking (Fodeh et al, 2013).*
- **QSEN** (Teamwork and Collaboration): Refer patients after stroke to occupational therapy for ADL rehabilitation. **EB:** *A systematic review of nine studies (N = 994) found*

low-quality evidence that occupational therapy improves ADL performance after stroke and reduces risk of ADL deterioration (Legg et al, 2017).

• **QSEN** (Patient-Centered): For clients with spinal cord injury, encourage their self-efficacy and involve them in decision-making. **EBN:** *A systematic review of 6 studies (N = 84) showed that rehabilitation is influenced by resilience, which can be enhanced with encouragement by nurses (Kornhaber et al, 2018).*

• **QSEN** (Patient-Centered): Use adaptive dressing and grooming equipment as needed (e.g., button hooks, dressing stick, elastic shoelaces, long-handled shoehorn, reacher, sock application devices, Velcro clothing and shoes, zipper pull, long-handled brushes, soap-on-a-rope, suction holders). *Use of adaptive clothing and devices for dressing and grooming can improve self-care ability and promote independence.*

• QSEN (Patient-Centered): Provide client analgesics prior to dressing as needed, sufficient time for dressing, and assist as needed. *Analgesics, adequate time, and assistance if tiring can promote independence in dressing.*

Geriatric

▲ **QSEN** (Teamwork and Collaboration): Refer older cognitively impaired patients to physical and/or occupational therapy for functional rehabilitation with ADLs. **EB:** *An observational study using the Barthel ADL tool found that even those with moderate cognitive ability improved ADL function with rehabilitation (Poynter, Kwan, & Vassallo, 2013).*

• **QSEN** (Patient-Centered): Offer residents choices in what to wear and ensure staff is trained to do so. **EBN:** *A controlled study by Schnelle et al (2013) provided training of nursing aides on how to offer long-term care residents (N = 169) morning care choices that resulted in increased frequency of choice being offered in timing for getting out of bed, clothing selection, and incontinence care.*

• **QSEN** (Patient-Centered): Allow post stroke patients who are cognitively impaired, especially if unimanual, to practice dressing. **CEB:** *Fletcher-Smith, Walker, and Drummon (2012) found that bimanual cognitively impaired stroke survivors did better with dressing skills than those who are unimanual, although with practice those with arm paresis improved significantly.*

• **QSEN** (Patient-Centered): Inform patient that a winter coat with a funnel sleeve design can be easier to put on. **CEB:** *Green et al (2011) found that older adults (N = 8) required less shoulder range of motion in putting on a winter coat with a funnel sleeve design, which could reduce social isolation in winter.*

Multicultural

• Consider use of assistive technology versus personal care assistance for Native Americans. **CEB:** *Older American Indians use more assistive technology for assistance with ADLs than the general same-age population (Goins et al, 2010).*

Home Care

• **QSEN** (Patient-Centered): Teach assisted living staff the philosophy and methods to increase resident participation in dressing. **EBN:** *Staff awareness and knowledge increased significantly after a training program to encourage residents to participate more in dressing themselves (Walker, Harrington, & Cole, 2013).*

Client/Family Teaching and Discharge Planning

• **QSEN** (Teamwork and Collaboration): Include caregiver's perceptions of client rehabilitation needs after stroke. **EB:** *A meta-analysis of 66 studies of stroke survivors needs as perceived by their caregivers found three areas of need themes whose outcomes may be improved by including caregivers in rehabilitation planning (Krishnan et al, 2017).*

Feeding Self-Care deficit

Linda S. Williams RN, MSN

NANDA-I

Definition

Inability to eat independently.

Defining Characteristics

Impaired ability to bring food to the mouth; impaired ability to chew food; impaired ability to get food onto utensils; impaired ability to handle utensils; impaired ability to manipulate food in mouth; impaired ability to open containers; impaired ability to pick up cup; impaired ability to prepare food; impaired ability to self-feed a complete meal; impaired ability to self-feed in an acceptable manner; impaired ability to swallow food; impaired ability to swallow sufficient amount of food; impaired ability to use assistive device

Related Factors

Anxiety; decrease in motivation; discomfort; environmental barrier; fatigue; pain; weakness

Associated Condition

Alteration in cognitive functioning; musculoskeletal impairment; neuromuscular impairment; perceptual disorders

NOC(Nursing Outcomes Classification)

Suggested NOC Outcomes

Self-Care: Activities of Daily Living (ADLs), Eating

Example NOC Outcome with Indicators

Self-Care: Eating as evidenced by the following indicators: Opens containers/Uses utensils/Completes a meal. (Rate the outcome and indicators of **Self-Care: Eating:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Feed self safely and effectively
- State satisfaction with ability to use adaptive devices for feeding
- Use assistance with feeding when necessary (caregiver)

NIC(Nursing Interventions Classification)

Suggested NIC Intervention

Self-Care Assistance: Feeding

Example NIC Activities—Self-Care Assistance: Feeding

Provide adaptive devices to facilitate client's feeding self (e.g., long handles, handle with large circumference, or small strap-on utensils), as needed; Provide frequent cueing and close supervision as appropriate

Nursing Interventions and *Rationales*

- **QSEN** (Safety): Consider assessment of patients in the intensive care unit (ICU) and stepdown patients or of patients with acute stroke for readiness of an oral diet with a 3-ounce water swallow challenge by a trained provider. **EB:** *If a 3-ounce water swallow challenge, administered by a trained provider to a patient in ICU or to a stepdown patient, is passed, then an individualized diet plan can be made safely (Leder et al, 2011).* **EB:** *Leder et al (2012) studied (N = 75) patients with acute stroke who were given a 90-mL water swallow challenge and found that specific oral diets could be successfully recommended after passing the 90-mL water swallow challenge.*
- **QSEN** (Patient-Centered): Conduct repeat structured observations of patients at mealtime after a stroke to detect patients with eating difficulties to prevent possible social and functional consequences. **EBN:** *In a longitudinal and comparative study (N = 36), Medin et al (2012) found eating difficulties continued among clients 3 months after stroke despite improvement in other physical functions, indicating that factors such as psychological well-being should be assessed.*
- **QSEN** (Patient-Centered): Develop an overriding guideline for assisted feeding so it is less dependent on a caregiver's own beliefs, time pressures, and organizational characteristics. **EBN:** *Martinsen and Norlyk (2012a) conducted a qualitative study interviewing caregivers (N = 12) on their experience with assisted feeding and found a focus on nutrition blended with their own beliefs and societal norms about eating.*
- **QSEN** (Patient-Centered): Prioritize assisted feeding as important in a caregiver's assignment to allow adequate dedicated time to the activity. **EBN:** *The experience of assisted feeding for clients with language impairment (N = 42) depends on the caregiver's availability and goal for efficiency rather than the relational and affective aspects of meals,*

which institutions could address with flexible feeding assistance times that are free from other responsibilities (Martinsen & Norlyk, 2012b).

▲ **QSEN** (Teamwork and Collaboration): Give priority to continuity in the cooperation between the parties involved in assisted feeding for those who are completely dependent. **CEBN:** *The continuity in the cooperation between the parties involved in assisted feeding is significant in creating a new eating pattern (Martinsen, Harder, & Biering-Sorensen, 2008).*

• **QSEN** (Patient-Centered): Consult patient on the benefit or desire to use assistive devices for feeding. **CEBN:** *The value of a particular assistive device can only be determined by the patient who may feel that it is insulting (Martinsen, Harder, & Biering-Sorensen, 2008).*

• **QSEN** (Safety): Presentation of feeding: provide 1 teaspoon of solid food or 10 to 15 mL of liquid at a time; wait until patient has swallowed the prior food/liquid. **CEB:** *Feeding large volumes and feeding quickly occurred commonly because caregivers lacked knowledge that this could exacerbate dysphagia and increase the risk of health problems (Pelletier, 2004).* **EBN:** *For a water swallow to accurately identify dysphagia, it is critical to administer 10 teaspoons (Martino, Maki, & Diamant, 2014).*

• **QSEN** (Safety): Ensure oral care is provided to all patients regardless of type of feeding. **EBN:** *Patients receiving tube feedings had inferior oral hygiene compared with those receiving oral feeding, creating a higher risk for aspiration pneumonia for patients receiving tube feedings (Maeda et al, 2011).*

Geriatric

• **QSEN** (Safety): Assess for tooth loss in older patients prior to feeding. **EB:** *Tooth loss contributes to swallowing difficulties that can increase risk of aspiration in the older patient (Okamoto et al, 2012).*

• **QSEN** (Patient-Centered): Assess the ability of patients with dementia to self-feed, and supervise the feeding of those with moderate dependency by providing verbal or physical assistance. **CEBN:** *Although low-dependency patients can self-feed, and those with severe dependency are fed, food intake among residents with moderate dependence is often ignored (Lin, Watson, & Wu, 2010).*

• **QSEN** (Patient-Centered): Implement Montessori interventions for patients with dementia who have eating problems, such as playing music to signal learning session start for hand-eye coordination, scooping, pouring, and squeezing activities. **EBN:** *In an experimental crossover design, Lin et al (2011) confirmed that use of a Montessori intervention method for those with dementia helps maintain self-feeding ability and can reduce caregiver feeding frequency.*

▲ **QSEN** (Patient-Centered): Reduce interruptions during mealtimes and provide additional feeding assistance for older patients, especially those with cognitive impairment. **EB:** *Additional assistance with feeding and protected mealtimes while hospitalized can improve nutritional intake in older clients (Young et al, 2013).*

• **QSEN** (Patient-Centered): Use high-calorie oral supplements for patients with advanced dementia. **EB:** *Desirable weight gain has been shown with the use of high-calorie oral supplements in patients with dementia who have feeding problems (Hanson et al, 2011).*

• **QSEN** (Patient-Centered): Provide nutritional supplement drinks in a glass to older adults with cognitive impairment. **EBN:** *Allen, Methven, and Gosney (2014) conducted a nonblind randomized control trial that identified that the best method to provide nutritional supplement drinks to older adults with cognitive impairment is in a glass/beaker rather than using a straw in the container.*

• **QSEN** (Patient-Centered): Allow a resident an average of 42 minutes of staff time per meal and 13 minutes per between-meal snack to improve oral intake. **CEB:** *When these time frames are provided for staff to assist with meals and snacks, improved oral intake and weight gain in residents at risk for weight loss results (Simmons et al, 2008).*
• **QSEN** (Patient-Centered): Discuss meaningful life topics, as identified by family members, with residents with dementia during mealtimes. **EB:** *Cleary et al (2012) found that conversations during meals that generated reminiscence may improve food intake during the reminiscence state for residents with dementia.*
• **QSEN** (Patient-Centered): Encourage family visits at mealtimes for patients with dementia. **EB:** *Family participation at mealtimes increased feeding assistance and helped promote satisfactory adaptation to the nursing home environment, which was found by Durkin, Shotwell, and Simmons (2014) in a study of 74 residents and their visitors during mealtimes.*
• **QSEN** (Patient-Centered): Play familiar music during meals for clients with dementia. **EB:** *Agitation often increases at mealtimes in patients with dementia, which seems to be reduced by music (Whear et al, 2014).*
• Use aromatherapy with the smell of baking bread for those with dementia. **CEB:** *The smell of baking bread increased intake of food and self-feeding in those with dementia (Cleary et al, 2008).*
▲ **QSEN** (Teamwork and Collaboration): Provide feeding training and education programs for nursing home staff. **EBN:** *Liu, Cheon, and Thomas (2014) did a systematic review of the literature about interventions for mealtime difficulties in older adults with dementia and found that training and education programs for professionals demonstrated moderate evidence to increase eating time and decrease feeding difficulty.*

Multicultural

• **QSEN** (Patient-Centered): For those with impaired hand function who use chopsticks, suggest adapted chopsticks. **CEB:** *In a pilot equipment study, adapted chopsticks, which can be inexpensive and easily constructed, for those with lower cervical spinal cord injury and residual gross grasp were found to convert gross grasp into 2-point pinch (Chang et al, 2006).*
• **QSEN** (Patient-Centered): Use the simplified Chinese Edinburgh Feeding Evaluation in Dementia scale to measure feeding problems in people with dementia from Mainland China and other Chinese cultural groups. **EBN:** *Identifying patient behaviors during feeding allows development of effective interventions for feeding (Liu, Watson, & Lou, 2014).*

Home Care

• **QSEN** (Teamwork and Collaboration): Request referral for physical therapy and occupational therapy to assess client's ability to position and self-feed and provide client and caregiver support with feeding. **EB:** *Ingestive skill difficulties are frequent among acutely hospitalized frail elderly patients (Hansen, Lambert, & Farber, 2012).*

Client/Family Teaching and Discharge Planning

• **QSEN** (Teamwork and Collaboration): Discuss with family caregivers, who are involved in the feeding of a family member with advanced dementia, the feeding experience to provide support to ensure that the mealtime purpose is preserved. **EBN:** *Lopez and Amella (2011) in a phenomenological study interviewed family caregivers (N = 16)*

of those with advanced dementia who indicated that the feeding assistance experience was like living in a time warp with an uncertain future.

▲ **QSEN** (Patient-Centered): Educate family members that neither insertion of a feeding tube nor timing of its insertion affects client survival for those with advanced dementia who have eating problems. **EB:** *Teno et al (2012) studied all nursing home residents with advanced dementia who had eating problems from 1999 to 2007 (N = 36,492) and found that survival was not affected by insertion of or timing of insertion of a percutaneous endoscopic gastrostomy feeding tube.*

Toileting Self-Care deficit

Linda S. Williams RN, MSN

NANDA-I

Definition

Impaired ability to perform or complete self-toileting activities.

Defining Characteristics

Impaired ability to complete toilet hygiene; impaired ability to flush toilet; impaired ability to manipulate clothing for toileting; impaired ability to reach toilet; impaired ability to rise from toilet; impaired ability to sit on toilet

Related Factors

Alteration in cognitive functioning; anxiety; decrease in motivation; environmental barrier; fatigue; impaired ability to transfer; impaired mobility; musculoskeletal impairment; neuromuscular impairment; pain; perceptual impairment; weakness

NOC(Nursing Outcomes Classification)

Suggested NOC Outcomes

Self-Care: Activities of Daily Living (ADLs), Toileting

Example NOC Outcome with Indicators

Self-Care: Toileting as evidenced by the following indicators: Responds to full bladder and urge to have a bowel movement in a timely manner/Gets to toilet between urge and passage of urine/Between urge and evacuation of stool. (Rate the outcome and indicators of **Self-Care: Toileting:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Remain free of incontinence and impaction with no urine or stool on skin
- State satisfaction with ability to use adaptive devices for toileting
- Explain and demonstrate use of methods to be safe and independent in toileting

NIC(Nursing Interventions Classification)

Suggested NIC Interventions

Environmental Management; Self-Care Assistance: Toileting

Example NIC Activities—Self-Care Assistance: Toileting

Assist client to toilet/commode/bedpan/fracture pan/urinal at specified intervals; Institute a toileting schedule, as appropriate

Nursing Interventions and *Rationales*

- **QSEN** (Safety): Assess patients for fall risk using established and valid fall risk assessment tools (Morse and Heindrich) and implement fall prevention interventions for those at risk for falling or in physical restraints. **EBN:** *In a retrospective study of 3 years of acute care fall incident reports (N = 547), Huey-Ming and Chang-Yi (2012) found 45.2% of falls were related to toileting, and that predictors of toileting-related falls were having a previous fall, being physically restrained, and being a fall risk.*
- **QSEN** (Patient-Centered): Assess patient's prior use of incontinence briefs and avoid use for hospitalized continent but limited mobility patient. **EBN:** *Use of adult incontinence briefs for low-mobility continent clients versus self-toileting occurs more frequently for females and can be associated with adverse outcomes (Zisberg, 2011).*
- **QSEN** (Patient-Centered): Assess patients who have had sphincter-saving surgery for self-care strategies to manage bowel symptoms to help support these strategies. **EBN:** *In a quantitative descriptive study of self-care strategies used by patients who had sphincter-saving surgery and bowel symptoms (N = 143), the strategy of proximity and knowing the location of a toilet at all times was used most by those with more bowel symptoms (Landers et al, 2014).*
- **QSEN** (Safety): Make assistance call button readily available to the client and answer call light promptly. **CEBN:** *Falls often occur related to toileting, and individualized planning for safe transfer to toilet is essential to safety (Tzeng, 2010).*
- **QSEN** (Safety): Provide folding commode chairs in client bathrooms/at bedside. **EBN:** *Availability of a folding commode chair as part of a fall prevention program can increase accessibility and efficiency in patient care (Tzeng, 2011).*
- **QSEN** (Patient-Centered): Before use of a bedpan, discuss its use with clients. **CEBN:** *When nurses facilitate discussion about bedpan use with orthopedic patients, they may be less anxious about its use (Cohen, 2009).*
- **QSEN** (Patient-Centered): Use necessary assistive toileting equipment. **EB:** *Amyotrophic lateral sclerosis clients reported satisfaction and usefulness of all bathroom assistive technology such as elevated toilet seat and arm rails by the toilet (Gruis, Wren, & Huggins, 2011).*
- **QSEN** (Safety): Close toilet lid before flushing toilet and teach patient to do so. **EB:** *A literature review of studies of toilet plume aerosols found that potential infectious aerosols during toilet flushing are produced, which can continue to expose toilet users later when some of the aerosols become droplet nuclei in air currents (Johnson et al, 2013).* **EB:** *A study revealed viral contamination of aerosol and surfaces through toilet use (Verani, Bigazzi, & Carducci, 2014).*

Geriatric

- Assess residents without dementia for risk factors associated with toileting disability (such as rating health as fair or poor; living in a residence with four or less residents or that is for-profit, incontinence; physical, visual, or hearing impairment; and need for ADL or transferring assistance) to guide prevention interventions. **EBN:** *In a cross-sectional analysis of adults 65 years or older without dementia in residential care facilities (N = 2395), 15% were found to have toileting disability that was associated with*

rating health as fair or poor; living in a residence with four or fewer residents or that is for-profit; incontinence; physical, visual, or hearing impairment; and need for ADL or transferring assistance (Talley et al, 2014).

• **QSEN** (Patient-Centered): Consider use of urine alarm systems for patients with dementia. **EB:** *Caregivers preferred use of urine alarms over time toileting to reduce urinary accidents (Lancioni et al, 2011).*

• **QSEN** (Patient-Centered): Assess the patient's functional ability to manipulate clothing for toileting, and if necessary modify clothing with Velcro fasteners, elastic waists, drop-front underwear, or slacks. *For clients with impaired dexterity or weakness, wearing dresses, athletic bottoms, or skirts with a stretch waistband makes it easier to use the toilet than wearing clothing with buttons and zippers (Cohen, 2008).*

• **QSEN** (Patient-Centered): Provide patients with dementia access to regular exercise. **EBN:** *ADL performance improved with a regular exercise program of stretching, walking, and leg weight bearing (Chang et al, 2011).*

Multicultural

• **QSEN** (Patient-Centered): Remove barriers to toileting, support patient's cultural beliefs, and preserve dignity. **CEB:** The physical and sociocultural environments in long-term care require older patients to overcome greater physical and cognitive challenges to maintain their participation, autonomy, and dignity in toileting than if they were at home (Sacco-Peterson & Borell, 2004).

Home Care

• **QSEN** (Patient-Centered): To design a bathroom for an older adult, consider adaptable bath fixtures/furniture and safety needs. **EB:** *Poor bathroom design requires use of assistive adaptive devices, reduces quality of life, and contributes to safety concerns such as falls (Burton, Reed, & Chamberlain, 2011).*

Client/Family Teaching and Discharge Planning

• Teach men who perform routine clean intermittent catheterization that a 40-cm intermittent catheter was found to provide ease of use, instill confidence in bladder emptying, and draining of urine into a receptacle. **EB:** *Costa et al (2013) found in a randomized controlled study of self-catheterizing wheelchair-using men (N = 81) that a 40-cm intermittent catheter was preferred over one that was 30 cm.*

• Have the family install a toilet seat of a contrasting color. **CEB:** *Visualization of the toilet is aided by installing a toilet seat of a contrasting color (Gerdner, Buckwalter, & Reed, 2002).*

• Explain to family and caregivers of clients with dementia that toilet self-care activities decrease when self-awareness is lost. *An observational study of toileting self-care in older adults with dementia revealed that toilet activities are affected and decline when self-awareness is lost (composed of theory of mind, self-evaluation, and self-consciousness) (Uchimoto et al, 2013).*

Readiness for enhanced Self-Concept

Marina Martinez-Kratz RN, MS, CNE

NANDA-I

Definition

A pattern of perceptions or ideas about the self, which can be strengthened.

Defining Characteristics

Acceptance of limitations; acceptance of strengths; actions are congruent with verbal expression; confidence in abilities; expresses desire to enhance role performance; expresses desire to enhance self-concept; expresses satisfaction with body image; expresses satisfaction with personal identity; expresses satisfaction with sense of worth; expresses satisfaction with thoughts about self

NOC(Nursing Outcomes Classification)

Suggested NOC Outcomes

Self-Esteem; Personal Well-Being; Psychosocial Adjustment Life Change

Example NOC Outcome with Indicators

Self-Esteem as evidenced by the following indicators: Verbalizations of self-acceptance/Open

communication/Confidence level/Description of pride in self. (Rate the outcome and indicators of **Self-Esteem:** 1 = never positive, 2 = rarely positive, 3 = sometimes positive, 4 = often positive, 5 = consistently positive [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- State willingness to enhance self-concept
- State satisfaction with thoughts about self, sense of worthiness, role performance, body image, and personal identity
- Demonstrate actions that are congruent with expressed feelings and thoughts
- State confidence in abilities
- Accept strengths and limitations

NIC(Nursing Interventions Classification)

Suggested NIC Intervention

Self-Esteem Enhancement

Example NIC Activities—Self-Esteem Enhancement

Encourage client to identify strengths; Assist client in setting realistic goals to achieve higher self-esteem

Nursing Interventions and *Rationales*

- Encourage client to express feelings through songwriting. **EB:** *Study findings suggested that people who find songwriting has strong meaning for them might be more likely to start accepting their emotions and as a result experience decreases in anxiety and depression (Baker, 2016).*
- Refer to nutritional and exercise programs to support weight loss. **EB:** *Study findings suggested that weight-loss treatments emphasize changes in self-perception (Annesi & Porter, 2015).*
- Offer client complementary and alternative medicine (CAM) interventions like acupressure, aromatherapy, compress, and massage. **EBN:** *A recent study reviewed the development of a complex nursing intervention including CAM for breast and gynecological cancer patients during chemotherapy to improve quality of life (Klafke et al, 2016).*
- Support homeless individuals to identify and endorse a positive self-concept. **EB:** *A study found that assumption of positive identity meanings, even a stigmatized identity such as being a homeless person, may provide support for a more general sense of self-esteem (Parker et al, 2016).*
- Support unemployed individuals to cope with identity threats and support individual identity growth. **EB:** *Research shows that to cope with self-definition threats, mature-aged workers protect and restructure their self-definitions with alternative goals of either remaining in paid employment or opting out from it (Kira & Klehe, 2016).*
- Support establishing community-based partnerships to address health needs. **EBN:** *To prevent suicide and substance abuse, a community-based participatory research approach was used to obtain community input, which led to the development of a strengths-based intervention incorporating the Gathering of Native Americans' curriculum (Holliday et al, 2016).*
- For clients with a history of trauma, offer a mindfulness-based intervention of hatha yoga. **EB:** *A qualitative study explored the experiences of women with posttraumatic stress*

disorder (PTSD) who participated in a 10-week Trauma Sensitive Yoga (TSY) class. It was found that they specifically perceived changes in symptoms and feelings of gratitude and compassion, relatedness, acceptance, centeredness, and empowerment (West et al, 2017).

Pediatric

- Consider the development of a Healthy Kids Mentoring Program that has four components: (1) relationship building, (2) self-esteem enhancement, (3) goal setting, and (4) academic assistance (tutoring). Mentors met with students twice each week for 1 hour each session on school grounds. During each meeting, mentors devoted time to each program component. **CEB:** *The Healthy Kids Mentoring Program results indicated that students' overall self-esteem, school connectedness, peer connectedness, and family connectedness were significantly higher at posttest than at pretest (Kelly et al, 2011).*
- Facilitate healthy relationships with teachers, coaches, and other supportive adults in the adolescents' lives. **EB:** *Research found that the presence of supportive teachers and coaches in an adolescents' social network is associated with healthier self-concept and decreased substance use (Dudovitz et al, 2017).*
- Provide parents with information designed to promote body satisfaction, healthy eating, and weight management in early childhood. **EB:** *Research evaluated Confident Body, Confident Child (CBCC), which is an intervention for parents of 2- to 6-year-old children and found significant increases in parents' intentions to use positive behaviors and knowledge of child body image and healthy eating patterns (Hart et al, 2016).*
- Promote the adoption of a recovery identity through online interactions and support groups for individuals with eating disorders. **EB:** *A study found that an eating disorder identity is seen as problematic and most interventions are targeted at changing an individual's self-concept. The study suggested that interventions could instead focus on identity resources to support a transition to a recovery identity (McNamara & Parsons, 2016).*
- Provide activities to bolster physical self-concept. **EB:** *A meta-analytic review found that physical activity interventions increased positive self-concept in adolescents (Spruit et al, 2016).*
- ▲ Consider wheelchair dancing for disabled adolescents. **EB:** *A wheelchair dancing intervention was associated with an improvement in self-esteem among disabled adolescents (de Villiers et al, 2013).*
- ▲ Provide overweight adolescents access to group-based weight control interventions. **EB:** *A 12-week group-based exergaming intervention was associated with positive effects on overweight and obese adolescent girls' television viewing, self-efficacy, and intrinsic motivation (Staiano et al, 2016).*
- Provide an alternative school-based program for pregnant and parenting adolescents. **EB:** *Despite Title IX legislation mandating equal educational opportunities for pregnant and parenting teens, only 50% of adolescent parents graduate high school. A study found themes of struggle, support, hope, perseverance, and transformation in a cohort of young mothers' descriptions of finishing high school (Watson et al, 2016).*

Geriatric

- Assess for depression as needed. **EB:** *A study found that self-concept, particularly physical self-concept, was an important predictor of psychosocial well-being in elderly residents (Grace & Toukhsati, 2014).*
- Encourage clients to consider a web-based support program when they are in a caregiving situation. **EBN:** *Research found participation in a web-based family support*

network provided a venue to share experiences, to be informed, and to gain insights into care issues. Participation reinforced the caregiver's sense of competence, helped them meet caregiving demands, and allowed them to identify the positive aspects of their situation (Andersson et al, 2016).

• Encourage activity and a strength, mobility, balance, and endurance training program. **EB:** *Older participants in a fitness training trial demonstrated beneficial effects on muscular strength, functionality, and confidence (Schreier et al, 2016).*

• Support meaning and purpose in the lives of older adults through a focus on everyday well-being and facilitation of personally treasured activities. **EBN:** *An exploratory study found four key experiences that promote meaning and purpose in life: (1) physical and mental well-being, (2) belonging and recognition, (3) personally treasured activities, and (4) spiritual closeness and connectedness (Drageset et al, 2017).*

• Use an approach that reduces the emphasis put on ageist self-concept attributions when working with older clients. **EB:** *Ageism includes cognitive, behavioral, and emotional manifestations. Ageism tends to reinforce social inequalities because it is more pronounced toward older women, poor people, or those with dementia (Ayalon et al, 2017).*

Multicultural

• Carefully assess each client and allow families to participate in providing care that is acceptable based on the client's cultural beliefs. **EBN:** *What the client considers normal and abnormal health behavior may be based on cultural perceptions (Itty, Hodge, & Martinez, 2014).*

• Refer to the care plans Disturbed **Body Image,** Readiness for enhanced **Coping,** Chronic low **Self-Esteem,** and Readiness for enhanced **Spiritual** well-being.

Home Care

• Previously discussed interventions may be used in the home care setting.

Chronic low Self-Esteem

Marina Martinez-Kratz MS, RN, CNE

NANDA-I

Definition

Negative evaluation and/or feelings about one's own capabilities, lasting at least three months.

Defining Characteristics

Dependent on others' opinions; exaggerates negative feedback about self; excessive seeking of reassurance; guilt; hesitant to try new experiences; indecisive behavior; nonassertive behavior; overly conforming; passivity; poor eye contact; rejection of positive feedback; repeatedly unsuccessful in life events; shame; underestimates ability to deal with situation

Related Factors

Cultural incongruence; inadequate affection received; inadequate belonging; inadequate group membership; inadequate respect from others; ineffective coping with loss; receiving insufficient approval from others; spiritual incongruence

At-Risk Population

Exposure to traumatic situation; pattern of failure; repeated negative reinforcement

Associated Condition

Psychiatric disorder

NOC(Nursing Outcomes Classification)

Suggested NOC Outcome

Self-Esteem

Example NOC Outcome with Indicators

Demonstrates improved **Self-Esteem** as evidenced by the following indicators: Verbalizations of acceptance of self and limitations/Open communication. (Rate the outcome and indicators of **Self-Esteem:** 1 = never positive, 2 = rarely positive, 3 = sometimes positive, 4 = often positive, 5 = consistently positive [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Demonstrate improved ability to interact with others (e.g., maintains eye contact, engages in conversation, expresses thoughts/feelings)
- Verbalize increased self-acceptance through positive self-statements about self
- Identify personal strengths, accomplishments, and values
- Identify and work on small, achievable goals
- Improve independent decision-making and problem-solving skills

NIC(Nursing Interventions Classification)

Suggested NIC Intervention

Self-Esteem Enhancement

Example NIC Activities—Self-Esteem Enhancement

Encourage patient to identify strengths; Assist in setting realistic goals to achieve higher self-esteem

Nursing Interventions and *Rationales*

- Actively listen to and respect the client. **EB:** *This study described active listening as essential in uncovering patients' emotions (Del Piccolo et al, 2014).*
- Assess the client's environmental and everyday stressors, including physical health concerns and the potential for abusive relationships. **EB:** *Findings in this study suggested that early adverse conditions have lasting implications for physical health and that continued exposure to increased levels of both social and nonsocial stress in adolescence, as well as the presence of depression, might be important mechanisms by which early adversity affects later physical health (Raposa et al, 2014).*
- Assess existing strengths and coping abilities, and provide opportunities for their expression and recognition. **CEB:** *Persons with psychiatric illness need help to stop their "negative self-image" and become more conscious of affirmative self-evaluation (Kunikata, 2010).*
- Assess the client's self-esteem using valid and established tools like the Rosenberg Self-Esteem Scale. **EBN:** *The use of valid and established measures of self-esteem will facilitate the identification of appropriate nursing interventions that strengthen self-esteem (McMullen & Resnick, 2013).*
- Assess the client for addictive use of social media. **EB:** *Results from a recent study demonstrated that lower age, being a woman, not being in a relationship, being a student, lower education, lower income, lower self-esteem, and narcissism were associated with higher scores on the Bergen Social Media Addiction Scale (BSMAS) (Andreasson et al, 2017).*

• Reinforce the personal strengths and positive self-perceptions that a client identifies. **EB:** *A recent study found that self-esteem mediates the relationship between hope and life satisfaction (Du et al, 2015).*
• Encourage self-affirmations by reflecting on values and strengths, in response to daily threats. **EB:** *A study found that engaging in spontaneous self-affirmation was related to greater happiness, hopefulness, optimism, subjective health, personal health efficacy, and less anger and sadness (Emanuel et al, 2016).*
• Identify client's negative self-assessments. **EB:** *Body image was found to have significant effects on both self-esteem and depression (You et al, 2017).*
• Assess individuals with low self-esteem for nonsuicidal self-injury (NSSI). **EB:** *A systemic review indicated a significant negative relationship between self-esteem and NSSI (Forrester et al, 2017).*
• Assess individuals with low self-esteem for symptoms of depression. **EB:** *Self-esteem is related to depressive symptoms and interpersonal problems. Improvement of self-esteem during psychotherapy correlates with improvements of symptoms and interpersonal problems (Dinger et al, 2017).*
• Encourage realistic and achievable goal setting and resources and identify impediments to achievement. **EB:** *A combined decision support and goal-setting intervention improved diet quality, diabetes-related self-efficacy, and empowerment, and reduced diabetes-related distress and depressive symptoms (Swoboda et al, 2017).*
• Assist client to challenge negative perceptions of self and performance. **EB:** *A study found that more often than not, self-critical thoughts were viewed as facts and would rarely be seen as distorted or biased (Kolubinski et al, 2016).*
• Encourage the client's usual religious or spiritual practices. **EB:** *Research supports a positive association between religious involvement and self-esteem (Schieman et al, 2017).*
• Promote maintaining a level of functioning in the community and a sense of community feeling. **EB:** *Research found that the community feeling is positively connected with self-esteem and psychological well-being (Kałużna-Wielobób, 2017).*

Pediatric

• Assess children/adolescents with chronic illness for evidence of reduced self-esteem and make needed referrals. **EB:** *Children and adolescents with chronic illness have lower levels of self-esteem compared with their healthy peers; experiences of success and positive peer relations are important sources of self-esteem (Pinquart, 2013).*
• Encourage mothers of premature infants to use kangaroo care for at least 30 minutes/day. **EBN:** *A recent study found kangaroo care showed significantly positive effects on stabilizing infant physiological functions such as respiration rate, increasing maternal–infant attachment, and reducing maternal stress (Cho et al, 2016).*
• Implement interventions that promote and maintain positive peer relations for adolescent patients. **EB:** *Peer relationships had the greatest effect on self-esteem for adolescent patients (Farineau et al, 2013).*
• Encourage attendance at social support groups. **EB:** *A study found that lesbian, gay, bisexual, transgender, and queer (LGBTQ) youth who attended a Hatch group-level intervention that consisted of unstructured social time, consciousness-raising (education), and a youth-led peer support group had higher levels of self-esteem (Wilkerson et al, 2016).*
• Encourage parents to praise children in ways that are not overly positive or inflated. **EB:** *A study found that parents' inflated praise predicted lower self-esteem in children (Brummelman et al, 2017).*
• Provide parents with information designed to promote body satisfaction, healthy

eating, and weight management in early childhood. **EB:** *Research evaluated Confident Body, Confident Child (CBCC), which is an intervention for parents of 2- to 6-year-old children, and found significant increases in parents' intentions to use positive behaviors and knowledge of child body image and healthy eating patterns (Hart et al, 2016).*

• Assess children/adolescents that express a body image of self-perceived underweight, self-perceived overweight (OW), and/or frustration with appearance for evidence of bullying. **EB:** *Research indicated that self-perceived underweight, self-perceived OW, and frustration with appearance were positively associated with being bullied (Lin et al, 2017).*

▲ Provide bully prevention programs and include information on cyberbullying. **EB:** *A moderate and statistically significant relationship exists between low self-esteem and experiences with cyberbullying (Lin et al, 2017).*

Geriatric

• Support client in identifying and adapting to functional changes. **EBN:** *A study outlined the importance of enquiring about feelings of uselessness, which is linked to both psychological and physical health status, especially in older people who need help in daily activities (Curzio et al, 2017).*

• Use reminiscence therapy and productive activities. **EB:** *This study suggested that productive activities with reminiscence therapy may alleviate depressive symptoms and improve task performance of older people with dementia (Nakamae et al, 2014).*

• Encourage older adult clients to participate in flexibility, toning, and balance exercise. **EB:** *Older participants in a fitness training trial demonstrated beneficial effects on muscular strength, functionality, and confidence (Schreier et al, 2016).*

• Encourage regular physical activity with prerecorded workouts. **EB:** *Research found that a DVD-delivered exercise intervention for older adults was associated with improved and maintained levels of self-esteem (Awick et al, 2017).*

• Encourage participation in intergenerational social activities. **EB:** *Older adults reported that their participation in the "Time after Time" intergenerational program enhanced their confidence, self-esteem, and social skills; contributed to their emotional and overall health and well-being; and enabled them to learn about others and feel connected to their community (Teater, 2016).*

• Encourage activities in which a client can support/help others. **EB:** *Research indicated an association between volunteering and reductions in symptoms of depression, better overall health, fewer functional limitations, feeling appreciated and needed, and greater longevity with vulnerable seniors benefitting the most (Anderson et al, 2014).*

Multicultural

• Assess for the influence of cultural beliefs, norms, and values on the client's sense of self-esteem. **EB:** *A study of Latino youth suggested that specific cultural orientations were associated with increased global self-worth, and increased levels of acculturation risk factors were associated with decreased global self-worth (Kapke, 2017).*

• Assess individuals with low self-esteem for symptoms of depression. **EB:** *Research found that low self-esteem and high depressive symptoms are more closely associated among blacks than whites (Assari, 2017).*

• Validate the client's feelings regarding ethnic or racial identity. **EB:** *A study found high ethnic identity was found to be protective against perceived stress (Espinosa et al, 2017).*

Home Care

• Assess a client's immediate support system/family for relationship patterns and content of communication. **EB:** *A recent study supported the beneficial effects of perceived family support on mental and physical health after surgery (Cardoso-Moreno & Tomás-Aragones, 2017).*

▲ Refer to continuous support and help from medical social services to assist the family in care of the client and support the caregiver's well-being. **EB:** *A recent study found that caregiving stress showed a significant positive correlation with depression and with economic and psychological stress, and it showed a significant negative correlation with self-esteem (Kim, 2017).*

▲ If a client is involved in counseling or self-help groups, monitor and encourage attendance. Help the client identify the value of group participation after each group encounter. *Discussion about group participation clarifies and reinforces group feedback and support.*

Client/Family Teaching and Discharge Planning

▲ Refer to community agencies for psychotherapeutic counseling. **EB:** *Self-esteem is related to depressive symptoms and interpersonal problems. Improvement of self-esteem during psychotherapy correlates with improvements of symptoms and interpersonal problems (Dinger et al, 2017).*

▲ Refer to psychoeducational groups on stress reduction and coping skills. **EB:** *Research findings indicated that participants reported improved self-esteem and knowledge of healthy relationship dynamics after enrollment in psychoeducation groups (Marrs Fuchsel, 2014).*

▲ Refer to self-help support groups specific to needs. **EB:** *Research shows that client participation in support groups increases self-esteem (Seebohm et al, 2013).*

Situational low Self-Esteem

Marina Martinez-Kratz MS, RN, CNE

NANDA-I

Definition
Development of a negative perception of self-worth in response to a current situation.

Defining Characteristics
Helplessness; indecisive behavior; nonassertive behavior; purposelessness; self-negating verbalizations; situational challenge to self-worth; underestimates ability to deal with situation

Related Factors
Alteration in body image; alteration in social role; behavior inconsistent with values; decrease in control over environment; inadequate recognition; pattern of helplessness; unrealistic expectations

At-Risk Population
Developmental transition; history of abandonment; history of abuse; history of loss; history of neglect; history of rejection; pattern of failure

Associated Condition
Functional impairment; physical illness

NOC(Nursing Outcomes Classification)
Refer to Chronic low **Self-Esteem** for suggested NOC outcomes

Client Outcomes

Client Will (Specify Time Frame)

- State effect of life events on feelings about self
- State personal strengths
- Acknowledge presence of guilt and not blame self if an action was related to another person's appraisal
- Seek help when necessary
- Demonstrate self-perceptions are accurate given physical capabilities
- Demonstrate separation of self-perceptions from societal stigmas

NIC(Nursing Interventions Classification)
Refer to Chronic low **Self-Esteem** for suggested NIC interventions

Nursing Interventions and *Rationales*

- Assess the client for signs and symptoms of depression and potential for suicide and/or violence. If present, immediately notify the appropriate personnel of symptoms. **EB:** *Recent research supported the vulnerability model of low self-esteem and depression with findings that indicated that individuals with high self-esteem have a lower risk for developing depression (Orth et al, 2016).* See care plans for Risk for other-directed **Violence** and Risk for **Suicide**.
- Assess the client's environmental and everyday stressors, including evidence of abusive relationships. **EB:** *Research showed dysfunctional forms of self-esteem were significantly associated with the number of negative events reported and an increased risk of developing stress-related symptoms (Alessandri et al, 2016).*

▲ Assess the client's self-esteem using valid and established tools like the Rosenberg Self-Esteem Scale. **EBN:** *The use of valid and established measures of self-esteem will facilitate the identification of appropriate nursing interventions that strengthen self-esteem (McMullen & Resnick, 2013).*
• Assess for unhealthy coping mechanisms, such as substance abuse, and make appropriate referrals. **EB:** *Numerous factors influence the onset and continuation of alcohol use, including the complex ways that genes interact with one another and with the environment (Faye et al, 2015).*
• Encourage expressions of gratitude through a gratitude journal or kind acts. **EB:** *Research shows that gratitude is significantly and positively associated with several domains of life satisfaction and overall life satisfaction in both the United States and Japan (Robustelli & Whisman, 2018).*
• Use a cognitive approach like problem-solving education (PSE) to assist in the identification of problems and situational factors that contribute to problems and offer options for resolution. **EB:** *A recent study found that supplementing drug abuse treatment with PSE reduced relapse rates and enhanced self-efficacy and self-esteem among patients (Habibi et al, 2016).*
• Mutually identify strengths, resources, and previously effective coping strategies. **EB:** *A recent study showed that a behavioral intervention focusing on the individual's strengths showed a reduction of psychological distress and improvement of self-esteem, optimism, and quality of life compared with the control group (Victor, Teismann, & Willutzki, 2017).*
• Encourage self-affirmations by reflecting on values and strengths, in response to daily threats. **EB:** *A study found that engaging in spontaneous self-affirmation was related to greater happiness, hopefulness, optimism, subjective health, personal health efficacy, and less anger and sadness (Emanuel et al, 2016).*
• Accept client's own pace in working through grief or crisis situations. **EB:** *Rigid adherence to stage or time line models of grief models is too simplistic and limited; they fail to represent the complex emotions and processes of grief and grieving (Stroebe et al, 2017).*
• Encourage the client to accept their own defenses, feelings, and urges in dealing with the crisis. **EB:** *Acceptance and commitment therapy (ACT) is an intervention that enhances well-being and reduces distress (Wersebe et al, 2018).*
• Provide information about support groups of people who have common experiences or interests. **EBN:** *Research shows that client participation in support groups increases self-esteem (Seebohm et al, 2013).*
• Teach the client mindfulness techniques to cope more effectively with strong emotional responses. **EB:** *Mindfulness training has direct positive effects on self-esteem (Pepping et al, 2013).*
• Encourage objective appraisal of self and life events and challenge negative or perfectionist expectations of self. **EB:** *Self-critical perfectionism has been reliably associated with poor goal progress (Moore et al, 2018).*
• Provide psychoeducation to client and family. **EB:** *Research findings indicated that participants reported improved self-esteem and knowledge of healthy relationship dynamics after enrollment in psychoeducation groups (Marrs Fuchsel, 2014).*
• Acknowledge the presence of societal stigma. Teach management tools. **EBN:** *Stigma toward mental illness affects both self-esteem and recovery and treatment adherence (Vass et al, 2017).*
• Validate the effect of negative past experiences on self-esteem and work on corrective measures. **EB:** *Negative life events influence current self-esteem (Tetzner et al, 2016).*

Geriatric and Multicultural

- See care plan for Chronic low **Self-Esteem.**

Home Care

- Establish an emergency plan and contract with the client for its use. Having an emergency plan is reassuring to the client. Establishing a contract validates the worth of the client and provides a caring link between the client and society.
- Access supplies that support a client's success at independent living.
- See care plan for Chronic low **Self-Esteem.**

Client/Family Teaching and Discharge Planning

- Assess the person's support system (family, friends, and community) and involve them if desired. **CEB:** Teach client and family that the crisis is temporary. Knowing that the crisis is temporary provides a sense of hope for the future.
- ▲ Refer to self-help support groups specific to needs. **EB:** *Research showed that client participation in support groups increases self-esteem (Seebohm et al, 2013).*
- ▲ Refer to appropriate community resources or crisis intervention centers.
- ▲ Refer to resources for handicap and/or disability services.
- See care plan for Chronic low **Self-Esteem.**

Risk for chronic low Self-Esteem

Gail B. Ladwig MSN, RN

NANDA-I

Definition
Susceptible to longstanding negative self-evaluating/feelings about self or self-capabilities, which may compromise health.

Risk Factors
Cultural incongruence; inadequate affection received; inadequate belonging; inadequate group membership; inadequate respect from others; ineffective coping with loss; receiving insufficient approval from others; spiritual incongruence

At-Risk Population
Exposure to traumatic situation; pattern of failure; repeated negative reinforcement

Associated Condition
Psychiatric disorder

NOC, NIC, Client Outcomes, Nursing Interventions and *Rationales*, and References
Refer to care plan for Chronic low **Self-Esteem**

Risk for situational low Self-Esteem

Marina Martinez-Kratz MS, RN, CNE

NANDA-I

Definition
Susceptible to developing a negative perception of self-worth in response to a current situation, which may compromise health.

Risk Factors
Alteration in body image; alteration in social role; behavior inconsistent with values; decrease in control over environment; inadequate recognition; pattern of helplessness; unrealistic self-expectations

At-Risk Population
Developmental transition; history of abandonment; history of abuse; history of loss; history of neglect; history of rejection; pattern of failure

Associated Condition
Functional impairment; physical illness

NOC(Nursing Outcomes Classification)
See Chronic low **Self-Esteem** for suggested NOC outcomes

Client Outcomes

Client Will (Specify Time Frame)

- State accurate self-appraisal
- Demonstrate the ability to self-validate
- Demonstrate the ability to make decisions independent of primary peer group
- Express effects of media on self-appraisal
- Express influence of substances on self-esteem
- Identify strengths and healthy coping skills
- State life events and change as influencing self-esteem

NIC(Nursing Interventions Classification)

See Chronic low **Self-Esteem** for suggested NIC interventions

Nursing Interventions and *Rationales*

- Assist client to challenge negative perceptions of self and performance. **EB:** *A study found that more often than not, self-critical thoughts were viewed as facts and would rarely be seen as distorted or biased (Kolubinski et al, 2016).*
- Assess the client's self-esteem using valid and established tools like the Rosenberg Self-Esteem Scale. **EBN:** *The use of valid and established measures of self-esteem will facilitate the identification of appropriate nursing interventions that strengthen self-esteem (McMullen & Resnick, 2013).*
- Encourage client to maintain highest level of community functioning. **EB:** *Research found that the community feeling is positively connected with self-esteem and psychological well-being (Kałużna-Wielobób, 2017).*
- Encourage self-affirmations by reflecting on values and strengths, in response to daily threats. **EB:** *A study found that engaging in spontaneous self-affirmation was related to greater happiness, hopefulness, optimism, subjective health, personal health efficacy, and less anger and sadness (Emanuel et al, 2016).*
- Encourage realistic and achievable goal setting and resources and identify impediments to achievement. **EB:** *A combined decision support and goal-setting intervention improved diet quality, diabetes-related self-efficacy, and empowerment, and reduced diabetes-related distress and depressive symptoms (Swoboda et al, 2017).*
- ▲ Assess the client for symptoms of depression and anxiety. Refer to specialist as needed. Prompt and effective treatment can prevent exacerbation of symptoms or safety risks. **EB:** *Recent research supported the vulnerability model of low self-esteem and depression with findings that indicated that individuals with high self-esteem have a lower risk for developing depression (Orth et al, 2016).*
- See care plans for Disturbed personal **Identity,** Situational low **Self-Esteem,** and Chronic low **Self-Esteem.**

Pediatric

- Assess children/adolescents with chronic illness for evidence of reduced self-esteem and make needed referrals. **EB:** *Children and adolescents with chronic illness have lower levels of self-esteem compared with their healthy peers; experiences of success and positive peer relations are important sources of self-esteem (Pinquart, 2013).*
- Identify environmental and/or developmental factors that increase risk for low self-esteem, especially in children/adolescents, to make needed referrals. **EB:** *A study found that relative to other students, risk for internalizing problems and low self-esteem was elevated for aggressive adolescents, students who were hassled or bullied at school, and those who were rejected by peers or in conflict with their parents (Cicchetti et al, 2014).*

• Encourage attendance at social support groups. **EB:** *A study found that lesbian, gay, bisexual, transgender, and queer (LGBTQ) youth who attended a Hatch group-level intervention that consisted of unstructured social time, consciousness-raising (education), and a youth-led peer support group had higher levels of self-esteem (Wilkerson et al, 2016).*
• Assess children/adolescents who are either a victim or an offender of cyberbullying for low self-esteem. **EB:** *A moderate and statistically significant relationship exists between low self-esteem and experiences with cyberbullying (Lin et al, 2017).*
▲ Encourage a combination of extracurricular activity for adolescents in a safe, supportive, and empowering environment. **EB:** *Research suggested that enabling relations within the family, school, peer, and community are factors related to youth self-satisfaction (Simon, 2018).*

Geriatric

• Support humor as a coping mechanism. **EB:** *This paper identified that humor has a positive effect on all of these issues with an increasing sense of well-being and life satisfaction for the elder (Lurie & Monahan, 2015).*
• Support client in identifying and adapting to functional changes. **EBN:** *A study outlined the importance of enquiring about feelings of uselessness, which is linked to both psychological and physical health status, especially in older people who need help in daily activities (Curzio et al, 2017).*
• Encourage participation in intergenerational social activities. **EB:** *Older adults reported that their participation in the "Time after Time" intergenerational program enhanced their confidence, self-esteem, and social skills; contributed to their emotional and overall health and well-being; and enabled them to learn about others and feel connected to their community (Teater, 2016).*
• Assist the client in life review and identifying positive accomplishments. *Life review is a developmental task that increases a person's sense of peace and serenity.*
• Help client establish a peer group and structured daily activities. *Social isolation and lack of structure increase a client's sense of feeling lost and worthless.*
• See care plans for Situational low **Self-Esteem** and Chronic low **Self-Esteem.**

Home Care

• Assess current environmental stresses and identify community resources. *Accessing resources to help decrease environmental stress will increase the client's ability to cope.*
• Encourage family members to acknowledge and validate the client's strengths. *Validation allows the client to increase self-reliance and to trust personal decisions.*
• Assess the need for establishing an emergency plan. *Openly assessing safety risks increases the client's sense of limits, boundaries, and safety.*
• See care plans for Situational low **Self-Esteem** and Chronic low **Self-Esteem.**

Client/Family Teaching and Discharge Planning

▲ Refer the client/family to community-based self-help and support groups. **EB:** *Research showed that clients who participate in support groups show increased self-esteem (Seebohm et al, 2013).*
▲ Refer to psychoeducational groups on stress reduction and coping skills. **EB:** *Research findings indicated that participants reported improved self-esteem and knowledge of healthy relationship dynamics after enrollment in psychoeducation groups (Marrs Fuchsel, 2014).*

▲ Refer the client to community agencies that offer support and environmental resources. Make referrals as needed.
• See care plans for Situational low **Self-Esteem** and Chronic low **Self-Esteem.**

Risk for Self-Mutilation

Kathleen L. Patusky MA, PhD, RN, CNS

NANDA-I

Definition

Susceptible to deliberate self-injurious behavior causing tissue damage with the intent of causing nonfatal injury to attain relief of tension.

Risk Factors

Absence of family confidant; alteration in body image; dissociation; disturbance in interpersonal relationships; eating disorder; emotional disturbance; feeling threatened with loss of significant relationship; impaired self-esteem; impulsiveness; inability to express tension verbally; ineffective communication between parent and adolescent; ineffective coping strategies; irresistible urge for self-directed violence; irresistible urge to cut self; isolation from peers; labile behavior; loss of control over problem-solving situation; low self-esteem; mounting tension that is intolerable; negative feeling; pattern of inability to plan solutions; pattern of inability to see long-term consequences; perfectionism; requires rapid stress reduction; substance misuse; use of manipulation to obtain nurturing relationship with others

At-Risk Population

Adolescence; battered child; childhood illness; childhood surgery; developmental delay; family divorce; family history of self-destructive behavior; family substance misuse; history of childhood abuse; incarceration; living in nontraditional setting; loss of significant relationship; peers who self-mutilate; sexual identity crisis; violence between parental figures

Associated Condition

Autism; borderline personality disorder; character disorder; depersonalization; psychotic disorder

NOC(Nursing Outcomes Classification)

See care plan for **Self-Mutilation** for suggested NOC outcomes

Client Outcomes

Client Will (Specify Time Frame)

- Refrain from self-injury
- Identify triggers to self-mutilation
- State appropriate ways to cope with increased psychological or physiological tension
- Express feelings
- Seek help when having urges to self-mutilate
- Maintain self-control without supervision
- Use appropriate community agencies when caregivers are unable to attend to emotional needs

NIC(Nursing Interventions Classification)

See care plan for **Self-Mutilation** for suggested NIC interventions

Nursing Interventions and *Rationales*

Note: Before implementing interventions in the face of self-injury, nurses should examine their own knowledge base and emotional responses to incidents of self-injury to ensure that interventions will not be based on countertransference reactions. **EBN:** *Lack of educational background on self-harm can influence response to self-harm clients. Nurses' tendency to focus on physical care, especially when working under stressful conditions, can hinder awareness of and response to psychosocial issues (Cleaver, 2014).*

- A nonjudgmental approach to clients is critical. **EBN:** *A qualitative study of nurses' experiences caring for patients who self-harmed indicated the need for acceptance of the client (Moola, 2017).*
- Assess for history of self-harm behavior. **EB:** *A meta-analysis of self-harm risk factors revealed prior history as a strong predictor of current self-harm behavior (Fox et al, 2015).*
- Assess client's ability to regulate his or her own emotional states. These states may be influenced by the client's perception of his or her body or by the presence of a psychiatric disorder. **EB:** *Clients who self-injure are more likely to be lower in emotional*

self-regulation and regulation of affect than persons who do not self-injure, especially in adolescents and young adults. They may use self-harm to increase or decrease feelings. Self-injury has been associated with low body regard (Muehlenkamp et al, 2013; Sadeh et al, 2014).

• Assess client's perception of powerlessness. Refer to the care plan for **Powerlessness**. **EBN:** *Involve clients in clinical decision-making (Moola, 2017).*

• Assessment data from the client and family members may have to be gathered at different times; allowing a family member or trusted friend with whom the client is comfortable to be present during the assessment may be helpful. **CEBN:** *Self-mutilation sometimes occurs if clients have been victims of abuse or other types of adverse family experiences (Catledge, Scharer, & Fuller, 2012). Clients or family members may be more willing to disclose the presence of abuse if greater privacy is afforded them, or if presence of a trusted family member or friend helps clients to respond more comfortably to the interview situation.*

• Perform a thorough skin assessment at least annually and check for behavioral cues of self-harm. **CEBN:** *Skin assessment must cover body areas normally clothed. Signs of self-harm include scratches, burns, lacerations, objects embedded under the skin (e.g., razor blades), multiple scars, or carved words. Scars may vary in age and depth. Behavioral cues include wearing long sleeves and pants, wristbands or bulky bracelets, and avoiding situations that would result in exposed skin (e.g., physical education class) (Catledge, Scharer, & Fuller, 2012).*

• Assess for co-occurring disorders that require response, especially childhood abuse, substance abuse, and suicide attempts. Implement reporting or referral as indicated. **EB:** *Self-mutilation has been associated with multiple psychiatric disorders (Moller, Tait, & Byrne, 2013; Sadeh et al, 2014).*

• Assess family dynamics and the need for family therapy and community support. **EBN:** *A comprehensive assessment of needs should address social, psychological, and motivational elements of the client and family members (Moola, 2017).*

• Assess for the presence of medical disorders, mental retardation, medication effects, or disorders such as autism that may include self-mutilation. Initiate referral for evaluation and treatment as appropriate. *Self-mutilation has been reported as a presenting or ongoing symptom with medical disorders.*

• Be alert to other risk factors of self-mutilation in clients with psychosis, including acute intoxication, dramatic changes in body appearance, preoccupation with religion and sexuality, and anticipated or perceived object loss. *Many psychiatric disorders have shown a connection with self-mutilation. Command hallucinations occurring in schizophrenia or brief psychotic episodes may direct the client to hurt himself or herself or others.*

• Monitor the client's behavior closely by using engagement and support as elements of safety checks while avoiding intrusive overstimulation. Offer activities that will serve as a distraction. *When lack of control exists, client safety is an important issue and close observation is essential.* **EBN:** *Clients may feel overstimulated by intrusive close observation, resulting in agitation (Moola, 2017).*

• Focus on understanding the function that self-harm serves for the client and on managing the client's distress. **EB:** *Self-harm is a form of distress management. A qualitative study of mental health staff interventions and efficacy suggested individualized care highlighting management of distress and identification of obstacles to interventions are more effective. If clients are unable to self-harm, prevention can lead to power struggles and the use of more harmful methods (Thomas & Haslam, 2017).*

• Establish trust, show a caring attitude and hope for recovery, listen to client, convey safety, promote client's verbal expression, and assist in developing positive goals for the future. Assist client to identify triggers and identify prevention activities. **EBN:** *A*

qualitative study of nursing interventions focused on identifying and dealing with triggers, and promoting person-centered nursing (Tofthagen, Talseth, & Fagerstrom, 2014).

• Refer to mental health counseling. Multiple therapeutic modalities are available for treatment.

▲ Case finding and referral by school nurses for psychological or psychiatric treatment is critical. Treatment includes starting therapy and medications, increasing coping skills, facilitating decision-making, encouraging positive relationships, and fostering self-esteem. **EB:** *Although the repeat rate of self-harm is around 21%, clients may have a very low treatment follow-up rate. Access to care must be a consideration (Hunter et al, 2018).*

• Inform the client of expectations for appropriate behavior and consequences within the unit. Emphasize that the client must comply with the rules. Give positive reinforcement for compliance and minimize attention paid to disruptive behavior while setting limits. *Clients benefit from clear guidance regarding behavioral expectations and consequences, providing much needed structure. It is important to reinforce appropriate behavior to encourage repetition.* **EB:** *Treatment should involve assisting the client to learn healthier affective regulation skills (Sadeh et al, 2014).*

• Clients need to learn to recognize distress as it occurs and express it verbally rather than as a physical action against the self. **CEB:** *Treatment should involve assisting the client to learn healthier affective regulation skills (Sadeh et al, 2014).*

• Assist the client to identify the motives/reasons for self-mutilation that have been perceived as positive. Self-harm serves as a defense mechanism. **CEB:** *Persecutory self-criticism and limited coping skills are linked with self-harm.*

• Assist clients to identify ways to soothe themselves and generate hopefulness when faced with painful emotions. *Generating hopefulness is an important self-comforting intervention.*

• Reinforce alternative ways of dealing with depression and anxiety, such as exercise, engaging in unit activities, or talking about feelings. *Goal direction enhances self-efficacy, which is an important antecedent of empowerment.*

• Keep the environment safe; remove all harmful objects from the area. Use of unbreakable glass is recommended for the client at risk for self-injury. *Client safety is a nursing priority. Unbreakable glass would eliminate this type of injury.*

• Anticipate trigger situations and intervene to assist the client in applying alternatives to self-mutilation. *When triggers occur, client stress level may obstruct the ability to apply recent learning. Cognitive strategies can be useful to correct irrational beliefs that are part of the trigger.*

• If self-mutilation does occur, use a calm, nonpunitive approach. Whenever possible, assist the client to assume responsibility for consequences (e.g., dress self-inflicted wound). Refer to the care plan for **Self-Mutilation.** *This approach does not promote inappropriate attention-getting behavior, may decrease repetition of behavior, and reinforces self-responsibility and self-care management.*

• If the client is unable to control self-mutilation behavior, provide interactive supervision, not isolation. *Isolation and deprivation take away the individual's coping abilities and place him or her at risk for self-harm. Implementing seclusion for clients who have injured themselves in the past may actually facilitate self-injury. Clients are extraordinarily resourceful at identifying environmental objects with which to self-mutilate.*

▲ Refer to protective services if evidence of abuse exists. *It is the nurse's legal responsibility to report abuse.*

• Refer to the care plan for **Self-Mutilation.**

Pediatric

• The same dynamics described previously applies to adolescents. **CEBN:** *Self-harm is a major public health issue arising in persons aged 12 to 24 years, and most often in females (Catledge, Scharer, & Fuller, 2012).*
• Maintaining a therapeutic relationship with teens requires explicit assurances of confidentiality, consistency of clinical routines, and a nonjudgmental communication style. **CEB:** *Even adolescents younger than age 18 years need assurances that confidentiality will be maintained unless there is a serious risk of harm to themselves or others. However, teens of all ages should be advised that parental notification will be made to ensure the teen's safety and to implement a treatment plan (Derouin & Bravender, 2004).*
• Encourage expression of painful experiences and provide supportive counseling. **CEBN:** *Among female adolescents, themes from a qualitative study included living with childhood trauma, feeling abandoned, being an outsider, loathing self, silently screaming, releasing the pressure, feeling alive, being ashamed, and being hopeful (Lesniak 2010; Rissanen, Kylma, & Laukkanen, 2011).*
• Assess for the presence of an eating disorder, history of sexual abuse and/or substance abuse, or nascent psychiatric disorders. Attend to the themes that preoccupy teens with eating disorders who self-mutilate. **EB:** *Self-harmers with a history of childhood sexual abuse reported more eating disorders (Sadeh et al, 2014).*
• Be mindful of possible social influences on self-harm behaviors. **EB:** *A systematic review of 86 studies considering positive associations between self-harm and suicidal behaviors among peer group members supported the finding that young people were more likely to engage in such behaviors when peers had also done so (Quigley, Rasmussen, & McAlaney, 2017).*
• Evaluate for suicidal ideation/suicide risk. Refer to the care plan for **Suicide** for additional information. **CEB:** *Adolescents who attempted suicide by overdose admitted to some method of self-mutilation. The self-mutilators were significantly more likely than non–self-mutilators to be diagnosed with oppositional defiant disorder, major depression, and dysthymia and had higher scores on measures of hopelessness, loneliness, anger, risk-taking, and alcohol use (Guertin et al, 2001).*
• Be aware that there is no complete overlap between self-mutilation and suicidal behavior. The motivation may be different (coping with difficult feelings rather than ending life), and the method is usually different.
• Use treatment approaches detailed in nursing interventions, with modifications as appropriate for this age group.

Geriatric

• Provide hand or back rubs and calming music when older clients experience anxiety. *Calming music or hand massage can soothe agitation for up to 1 hour. No additional benefit was found from combining the two interventions.*
• Provide soft objects for older clients to hold and manipulate when self-mutilation occurs as a function of delirium or dementia. Apply mitts, splints, helmets, or restraints as appropriate. *Delirious or demented clients may scratch or pick at themselves. Soft objects may provide a substitute object to pick at; mitts or restraints may be necessary if the client is unable to exercise self-restraint. They should only be used for a limited amount of time because they may contribute to delirium.*
• Be aware that older adults may demonstrate self-neglect. Older adults who show self-destructive behaviors should be evaluated for dementia. **EB:** *In a qualitative study*

of unsupervised assisted living residents, more than half of the participants showed self-neglect behaviors (Caspi, 2014).

Home Care

• Communicate degree of risk to family/caregivers; assess the family and caregiving situation for ability to protect the client and to understand the client's self-mutilative behavior. Provide family and caregivers with guidelines on how to manage self-harm behaviors in the home environment. *Client safety between home visits is a nursing priority. Appropriate family/caregiver support is important to the client. Appropriate support will only be forthcoming if all parties understand the basis of the behavior and how to respond to it.*
• Establish an emergency plan, including when to use hotlines and 911. Develop a contract with the client and family for use of the emergency plan. Role-play access to the emergency resources with the client and caregivers. *Having an emergency plan reassures the client and caregivers and promotes client safety. Contracting gives guided control to the client and enhances self-esteem.*
• Assess the home environment for harmful objects. Have family remove or lock objects as able. *Client safety is a nursing priority.*
▲ If client behaviors intensify, institute an emergency plan for mental health intervention. The degree of disturbance and the ability to manage care safely at home determine the level of services needed to protect the client.
▲ Refer for homemaker or psychiatric home health care services for respite, client reassurance, and implementation of therapeutic regimen. *Responsibility for a person at high risk for self-mutilation provides high caregiver stress. Respite decreases caregiver stress. The presence of caring individuals is reassuring to both the client and caregivers, especially during periods of client anxiety. A client with self-mutilative behavior, especially if accompanied by depression, can benefit from the interventions described previously that are modified for the home setting.*
▲ If the client is on psychotropic medications, assess client and family knowledge of medication administration and side effects. *Teach as necessary. Knowledge of the medical regimen promotes compliance and promotes safe use of medications.*
▲ Evaluate the effectiveness and side effects of medications. Accurate clinical feedback improves health care provider's ability to prescribe an effective medical regimen specific to client needs.

Client/Family Teaching and Discharge Planning

• Explain all relevant symptoms, procedures, treatments, and expected outcomes for self-mutilation that are illness based (e.g., borderline personality disorder, autism). *Participation in treatment enhances a sense of control.*
• Assist family members to understand the complex issues of self-mutilation. Provide instruction on relevant developmental issues and on actions that parents can take to avoid media that glorify self-harm behaviors. *Family members need to understand the behaviors they are dealing with, receive positive reinforcement that will promote their patience and perseverance, and know that they can take positive action to remove media triggers for self-mutilation.*
• Provide written instructions for treatments and procedures for which the client will be responsible. *A written record provides a concrete reference so that the client and family can clarify any verbal information that was given.*

• Instruct the client in coping strategies (assertiveness training, impulse control training, deep breathing, and progressive muscle relaxation). *Clients who self-mutilate have difficulty dealing with stress and painful emotions, which serve as triggers to self-harm. Once clients are able to identify these triggers, they need to learn how to respond to them more effectively through assertiveness, impulse control, or relaxation, as appropriate.*
• Role-play responses to stressful situations (e.g., say, "Tell me how you will respond if someone ignores you"). *Role-playing is the most commonly used technique in assertiveness training. It deconditions the anxiety that arises from interpersonal encounters by allowing the client to practice how he or she might respond in a given situation. Anxiety levels tend to be higher in situations that are unfamiliar.*
• Teach cognitive-behavioral activities, such as active problem-solving, reframing (reappraising the situation from a different perspective), or thought-stopping (in response to a negative thought, picture a large stop sign and replace the image with a prearranged positive alternative). Teach the client to confront his or her own negative thought patterns (or cognitive distortions), such as catastrophizing (expecting the very worst), dichotomous thinking (perceiving events in only one of two opposite categories), or magnification (placing distorted emphasis on a single event). *Cognitive-behavioral activities address clients' assumptions, beliefs, and attitudes about their situations, fostering modification of these elements to be as realistic and optimistic as possible. Through cognitive-behavioral interventions, clients become more aware of their cognitive choices in adopting and maintaining their belief systems, exercising greater control over their own reactions.*
▲ Provide the client and family with phone numbers of appropriate community agencies for therapy and counseling. Continuous follow-up care should be implemented; therefore the method to access this care must be given to the client.
▲ Give the client positive things on which to focus by referring to appropriate agencies for job-training skills or education. *Clients benefit from the desire for goals they could aim for as a means of regaining a positive view of the future.*

Self-Mutilation

Kathleen L. Patusky MA, PhD, RN, CNS

NANDA-I

Definition

Deliberate self-injurious behavior causing tissue damage with the intent of causing nonfatal injury to attain relief of tension.

Defining Characteristics

Abrading; biting; constricting a body part; cuts on body; hitting; ingestion of harmful substances; inhalation of harmful substances; insertion of object into body orifice; picking at wounds; scratches on body; self-inflicted burn; severing of a body part

Related Factors

Absence of family confidant; alteration in body image; dissociation; disturbance in interpersonal relationships; eating disorder; emotional disorder; feeling threatened with loss of significant relationship; impaired self-esteem; impulsiveness; inability to express tension verbally; ineffective communication between parent and adolescent; ineffective coping strategies; irresistible urge for self-directed violence; irresistible urge to cut self; isolation from peers; labile behavior; loss of control over problem solving; low self-esteem; mounting tension that is intolerable; negative feeling; pattern of inability to plan solutions; pattern of inability to see long-term consequences; perfectionism; requires rapid stress reduction; substance misuse; use of manipulation to obtain nurturing relationship with others

At-Risk Population

Adolescence; battered child; childhood illness; childhood surgery; developmental delay; family divorce; family history of self-destructive behavior; family substance misuse; history of childhood abuse; history of self-directed violence; incarceration; living in nontraditional setting; peers who self-mutilate; sexual identity crisis; violence between parental figures

Associated Condition

Autism; borderline personality disorder; character disorder; depersonalization; psychotic disorder

NOC(Nursing Outcomes Classification)

Suggested NOC Outcomes

Self-Control; Distorted Thought Self-Control; Impulse Self-Control; Mood Equilibrium; Risk Detection; Self-Mutilation Restraint

Example NOC Outcome with Indicators

Self-Mutilation Restraint as evidenced by the following indicators: Refrains from gathering means for self-injury/Obtains assistance as needed/Upholds contract not to harm self/Maintains self-control without supervision/Refrains from injuring self. (Rate the outcome and indicators of **Self-Mutilation Restraint:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Have injuries treated
- Refrain from further self-injury
- State appropriate ways to cope with increased psychological or physiological tension
- Express feelings
- Seek help when having urges to self-mutilate
- Maintain self-control without supervision
- Use appropriate community agencies when caregivers are unable to attend to emotional needs

NIC(Nursing Interventions Classification)

Suggested NIC Interventions

Active Listening; Anger Control Assistance; Behavior Management: Self-Harm; Calming Technique; Environmental Management: Safety; Limit Setting; Mood Management; Mutual Goal Setting; Risk Identification; Self-Responsibility Facilitation

Example NIC Activities—Behavior Management: Self-Harm

Anticipate trigger situations that may prompt self-harm and intervene to prevent it; Teach client and reinforce effective coping behaviors and appropriate expression of feelings

Nursing Interventions and *Rationales*

Note: Before implementing interventions in the face of self-mutilation, nurses should examine their own knowledge base and emotional responses to incidents of self-harm to ensure that interventions will not be based on countertransference reactions. **EBN/EB:** *Lack of educational background on self-harm can influence response to self-harm clients. Nurses' tendency to focus on physical care, especially when working under stressful conditions, can hinder awareness of and response to psychosocial issues (Cleaver, 2014).*

- A nonjudgmental approach to clients is critical. **EBN:** *A qualitative study of nurses' experiences caring for patients who self-harmed indicated the need for acceptance of the client (Moola, 2017).*
- Consider using a measure of self-harm risk that is available for clients: **EB:** *The Ottawa Self-Injury Inventory addresses both functions and potential addictive elements of self-harm (Martin et al, 2013).* **EBN:** *A systematic review of multiple instruments rated most of their support as Grade B. The Suicide Attempt Self-Injury Interview (SASII) was reviewed as Level 3, although its length was noted as an issue (Borschmann et al, 2012; Li, 2017).*
- ▲ Provide medical treatment for injuries. Use aseptic technique when caring for wounds. Care for the wounds in a matter-of-fact manner. **CEBN:** *A significant impediment to wound healing is infection. A matter-of-fact approach avoids positive reinforcement and may decrease repetition of behavior. Recognize that the distress behind self-harm can motivate a response to psychological intervention (Catledge, Scharer, & Fuller, 2012).*
- Assess for risk of suicide or other self-damaging behaviors. **EBN:** *Although self-mutilation should not be viewed simply as failed suicide, it is a significant indicator of suicide risk. Clients may also engage in other self-damaging behaviors, including substance abuse or eating disorders (Moller, Tait, & Byrne, 2013; Cleaver, 2014). Refer to the care plan for Risk for* ***Suicide.***
- Assess for signs of psychiatric disorders, including depression, anxiety, borderline

personality disorder, dissociative disorders, eating disorders, and impulsivity. **EB:** *Self-mutilation has been associated with multiple psychiatric disorders (Moller, Tait, & Byrne, 2013).*

• Assess for the presence of hallucinations. Ask specific questions: "Do you hear voices that other people do not hear?" "Are they telling you to hurt yourself?" *Command hallucinations occurring with schizophrenia or brief psychotic episodes may direct the client to hurt himself or herself or others.*

▲ Assure the client that he or she will be safe during hallucinations, and engage supportively. Provide referrals for medication. *Hallucinations can be very frightening; therefore clients need reassurance that they will be kept safe while avoiding a sense of intrusion that overstimulates clients.*

▲ Assess for the presence of medical disorders, mental retardation, medication effects, or disorders such as autism that may include self-mutilation. Initiate referral for evaluation and treatment as appropriate. *Self-mutilation has been reported as a presenting or ongoing symptom with medical disorders.*

▲ Case finding and referral by school nurses for psychological or psychiatric treatment is critical. *Treatment includes starting therapy and medications, increasing coping skills, facilitating decision-making, encouraging positive relationships, and fostering self-esteem.* **EB:** *Although the repeat rate of self-harm is around 21%, clients may have a very low treatment follow-up rate. Access to care must be a consideration (Hunter et al, 2018).*

• Monitor the client's behavior closely, using engagement and support as elements of safety checks while avoiding intrusive overstimulation. *When lack of control exists, client safety is an important issue, and close observation is essential.* **EBN:** *Clients may feel overstimulated by intrusive close observation, resulting in agitation (Moola, 2017).*

• Focus on understanding the function that self-harm serves for the client and on managing the client's distress. **EB:** *Self-harm is a form of distress management. A qualitative study of mental health staff interventions and efficacy suggested individualized care highlighting management of distress and identification of obstacles to interventions are more effective. If clients are unable to self-harm, prevention can lead to power struggles and the use of more harmful methods by the client (Thomas & Haslam, 2017).*

• Establish trust, listen to client, convey safety, and assist in developing positive goals for the future. **EBN:** *A qualitative study of nursing interventions focused on identifying and dealing with triggers, and promoting person-centered nursing (Tofthagen, Talseth, & Fagerstrom, 2014).*

• Problem-solving therapy, access to emergency contacts, and long-term psychological therapy may be helpful. Although some studies suggest interventions that may be helpful, findings should be used with caution. **EB:** *A Cochrane Review found some usefulness of problem-solving therapy, access to emergency contacts, and long-term psychological therapy with female patients with borderline personality disorder (Hawton et al, 2015a).*

▲ Use a collaborative approach for care. A collaborative approach to care is more helpful to the client.

• Refer to the care plan for Risk for **Self-Mutilation** for additional information.

Pediatric

• Self harm is a major concern in children and adolescents, although few interventions have been adequately tested. **EB:** *An updated Cochrane Review concluded that studies have not supported group therapy as an effective treatment for children and adolescents; mentalization and dialectical behavior therapy (DBT) show some promise*

(Hawton et al, 2015b).

Self-Neglect

Susanne W. Gibbons PhD, C-ANP/GNP, Mary Rose Day DN, MA, PGDip PHN, BSc, Dip Management (RCSI), RPHN, RM, RGN

NANDA-I

Definition

A constellation of culturally framed behaviors involving one or more self-care activities in which there is a failure to maintain a socially accepted standard of health and well-being (Gibbons, Lauder, & Ludwick, 2006).

Defining Characteristics

Insufficient environmental hygiene; insufficient personal hygiene; nonadherence to health activity

Related Factors

Deficient executive function; fear of institutionalization; inability to maintain control; lifestyle choice; stressors; substance misuse

Associated Condition

Alteration in cognitive functioning; Capgras syndrome; frontal lobe dysfunction; functional impairment; learning disability; malingering; psychiatric disorder; psychotic disorder

NOC(Nursing Outcomes Classification)

Suggested NOC Outcomes

Cognitive Function; Executive Function; Depression; Alcohol and Other Substance Use; Activities of Daily Living (ADLs), Instrumental Activities of Daily Living (IADLs); Safety; Nutritional Status; Social Support, Medication Safety Assessment

Examples of NOC Outcome with Indicators

Self-Neglect Status as evidenced by the following indicators: Maintains personal cleanliness and health/Recognizes safety needs in the home. (Rate outcome and indicators of **Self-Neglect Status:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Reveal improvement in cognition (e.g., if reversible and treatable)
- Show improvement in mental health problems
- Show improvement in chronic medical problems
- Demonstrate improvement in functional status (e.g., basic and IADLs)
- Demonstrate adherence to health activities (e.g., medications and medical appointments)
- Exhibit improved personal hygiene
- Exhibit improved environmental hygiene
- Have fewer hospitalizations and emergency room visits
- Increase safety of client
- Increase safety of community in which client lives
- Agree to necessary personal and environmental changes that eliminate risk/endangerment to self or others (e.g., neighbors)
- Improve social networks
- Identify eligibility for public services and other benefits

Note: Because self-neglect is present along a continuum of severity and includes an array of behavioral and environmental issues, a change in a client's status must occur in such a way that it balances obligation for protection and respects individual rights (e.g., autonomy and self-determination) while ensuring individual health and well-being. This is accomplished through a client–provider partnership that keeps the door open even though the client may initially decline help. Building a relationship with the client will improve trust and assist in developing an individually tailored care plan to address problems contributing to self-neglect. Interdisciplinary collaboration and teamwork, and in some instances assistance of next of kin and/or adult protective services (APS), may be needed (e.g., a state agency or local social services program).

NIC(Nursing Interventions Classification)

Suggested NIC Interventions

Self-Neglect; Self-Care Assistance: Activities of Daily Living; Support System Enhancement

Example NIC Activities—Self-Care Assistance: Instrumental Activities of Daily Living

Determine individual's need for assistance with IADLs (e.g., shopping, cooking, housekeeping, laundry, use of transportation, managing money, managing medications, use of communication, and use of time)

Nursing Interventions and *Rationales*

• Monitor individuals with acute or chronic mental and physical illness for defining characteristics for self-neglect. **EBN/CEB:** *Holistic assessment includes medical and social history, cognitive status, state of mental health, well-being, physical function, social networks, medication, alcohol use, and data on factors that limit individual coping and self-care ability (Pavlou & Lachs, 2008; Mulcahy, Leahy-Warren, & Day, 2018).*
• Assist individuals with complex mental and physical health issues to adopt positive health behaviors so that they may maintain their health status in the community. **EB:** *Greater severity self-neglect was associated with an increased 30-day hospital readmission rate (Dong & Simon, 2014).*
• Assist individuals with reconnecting with family, friends, and other social networks available to them. **EBN:** *Social isolation is a risk for self-neglect (Mulcahy, Leahy-Warren, & Day, 2018).*
• Assist individuals whose self-care is failing with managing their medications regimen. **EB:** *Individuals who exhibit self-neglect may have difficulty managing medications because of complex medication regimens, and low adherence is significant among older adults who self-neglect (Alpert, 2014).*
• Assist persons with self-care deficits caused by ADL or IADL impairments. **CEB:** *Individuals with self-care deficits may have difficulty with ADLs and IADLs because greater self-neglect severity has been associated with lower levels of physical function among older adults (Lachs et al, 2002; Hildebrand, Taylor, & Bradway, 2014).*
• Assess persons with failing self-care for changes in cognitive function (e.g., dementia or delirium). **EB:** *Individuals with failing self-care may have changes in cognition. Decline in executive function has been associated with risk of reported and confirmed elder self-neglect, and decline in global cognitive function has been associated with risk of greater self-neglect severity (Mackay, 2017; Mills & Naik, 2018).*
• Refer persons with failing self-care to appropriate specialists (e.g., psychologist, psychiatrist, social worker) and therapists (e.g., physical therapy, occupational therapy). **EBN/EB:** *Individuals with self-care deficits may need assistance from other health professionals using an interprofessional team approach, open communication, and collaboration (Burnett et al, 2014; Braye, Orr, & Preston-Shoot, 2014).*
• Use behavioral modification as appropriate to bring about client changes that lead to improvement in personal hygiene, environmental hygiene, and adherence to medical regimen. **CEB:** *Behavioral modification approaches have been effective in reversing self-neglect in older adults who had triggers or events that brought about the behavior (Thibault, 2008).*
• Monitor persons with substance abuse problems (i.e., drugs, alcohol, smoking) for adequate safety. **EBN/EB:** *Because mental health and substance use disorders can go unrecognized and untreated in this population, identified self-neglecting clients should be screened as appropriate (Hansen et al, 2016; Alpert et al, 2014).*
▲ Refer persons with failing self-care who are significantly impaired cognitively (e.g., executive function, dementia) or functionally and/or who are suspected victims of abuse to APS. **EB/CEB:** *Self-neglect has been associated with mistreatment in older adults, especially those who live alone (Dyer et al, 2007; Pavlou & Lachs, 2008).*

Geriatric

▲ Assess client's socioeconomic status and refer for appropriate support. **EBN/EB:** *Providers are advised to assess available financial and other resources to help older adults and their families obtain essential goods and services (Zhao et al, 2017; Mulcahy, Leahy-Warren, & Day, 2018).*

▲ Refer persons demonstrating a significant decline in self-care abilities (e.g., posing a threat to themselves or to their community) for formal evaluation of capacity and executive function. **CEB:** *Current evidence indicates that executive dyscontrol contributes to self-neglect in the older adult population, in which it is considered a geriatric syndrome (Dyer et al, 2007; Pavlou & Lachs, 2006).*

Multicultural

• Deliver health care that is sensitive to the culture and philosophy of individuals whose self-care appears inadequate. **EBN:** *Providers must be careful not to prematurely judge clients' health choices or living arrangements because personal values and beliefs that might appear as self-neglect do not necessarily indicate self-neglect. However, when client behavior poses a risk to self and/or others, providers have an ethical obligation to intervene (Gibbons, Lauder, & Ludwick, 2006; Braye, Orr, & Preston-Shoot, 2018).*

Sexual dysfunction

Elaine E. Steinke PhD, APRN, CNS-BC, FAHA, FAAN

NANDA-I

Definition

A state in which an individual experiences a change in sexual function during the sexual response phases of desire, arousal, and/or orgasm, which is viewed as unsatisfying, unrewarding, or inadequate.

Defining Characteristics

Alteration in sexual activity; alteration in sexual excitation; alteration in sexual satisfaction; change in interest toward others; change in self-interest; change in sexual role; decrease in sexual desire; perceived sexual limitation; seeking confirmation of desirability; undesired change in sexual function

Related Factors

Absence of privacy; inadequate role model; insufficient knowledge about sexual function; misinformation about sexual function; presence of abuse; psychosocial abuse; value conflict; vulnerability

At-Risk Population

Absence of significant other

Associated Condition

Alteration in body function; alteration in body structure

NOC(Nursing Outcomes Classification)

Suggested NOC Outcomes

Abuse Recovery: Sexual; Knowledge: Sexual Functioning, Physical Aging; Psychosocial Adjustment: Life Change; Risk Control: Sexually Transmitted Diseases (STDs); Sexual Functioning; Sexual Identity

Example NOC Outcome with Indicators

Sexual Functioning as evidenced by the following indicators: Expresses comfort with sexual expression/Expresses comfort with body/Expresses sexual interest. (Rate the outcome and indicators of **Sexual Functioning:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Identify individual cause of sexual dysfunction
- Identify stressors that contribute to dysfunction
- Discuss alternative, satisfying, and acceptable sexual practices for self and partner
- Identify the degree of sexual interest by the client and partner
- Adapt sexual technique as needed to cope with sexual problems
- Discuss with partner concerns about body image and sex role

NIC(Nursing Interventions Classification)

Suggested NIC Interventions

Sexual Counseling; Teaching: Sexuality

Example NIC Activities—Sexual Counseling

Provide privacy and ensure confidentiality; Discuss necessary modifications in sexual activity, as appropriate; Provide referral/consultation with other members of the health care team, as appropriate

Nursing Interventions and *Rationales*

• Gather the client's sexual history, noting normal patterns of functioning and the client's vocabulary, and encouraging clients to ask questions or discuss sexual problems experienced. **EB:** *In a nationally representative sample of women in the United States, those who were sexually active had greater relationship satisfaction, better communication, and higher ratings of the importance of sexual activity, illustrating the importance of assessing sexual activity and encouraging discussion of any sexual concerns or problems (Thomas, Hess, & Thurston, 2015).* **EB:** *In a large cross-sectional study of men, the prevalence of erectile dysfunction (ED) increased for those with comorbidities such as hypertension, diabetes mellitus, depression, or benign prostatic hypertrophy (BPH) (Mulhall et al, 2016).*

▲ Assess duration and risk factors for sexual dysfunction and explore potential causes such as medications, medical problems, aging process, or psychosocial issues. **EBN:** *In a population-based sample comparing those with a cardiac condition to those without a cardiac condition, those with coronary artery disease, angina, and myocardial infarction reported significantly less sexual activity, as did those who smoked, had a weight problem, had lung problems, had depression, had shortness of breath or chest pain with exertion, or took certain medications. This illustrated that multiple factors affect sexual activity and may contribute to sexual dysfunction (Steinke, Mosack, & Hill, 2017).*

▲ Assess for history of sexual abuse. **EB:** *Men who were forced to have sex by a woman had greater risks such as higher number of lifetime partners and greater alcohol and drug use, compared with nonvictimized men, putting them at increased risk of sexually transmitted infections (Cook et al, 2016).*

▲ Assess and provide treatment for sexual dysfunction, involving the person's partner in the process, and evaluating pharmacological and nonpharmacological interventions. **EB:** *Results of a systematic review of men and women found that dehydroepiandrosterone (DHEA) improved sexual interest, pain, arousal, lubrication, orgasm, and frequency of sexual activity, particularly for women and those with sexual dysfunction, whereas some men had improved erectile function, but others did not (Peixoto et al, 2017).* **EB:** *Phosphodiesterase type 5 (PDE5) inhibitors are first-line therapies for ED in men with several drugs available. Tadalafil as a once daily treatment was found to be well tolerated and provides an alternative to as needed dosing of PDE5 inhibitors (Kim et al, 2015).*

• Assess risk factors for sexual dysfunction, especially with varying sexual partners. **EB:** *In substance-dependent men who were polydrug users, having occasional sexual partners resulted in 14 times the risk of ED compared with married men, illustrating the importance of a complete sexual history and evaluation of risks for sexual dysfunction (Clemente et al, 2017).*

• Observe for stress and anxiety as possible causes of dysfunction. **EBN:** *In men with diabetes mellitus type 2, 82% experienced ED and overall mild anxiety; thus both physical and psychological causes of sexual dysfunction should be routinely evaluated (Erden & Kaya, 2015).* **EB:** *In women, fibromyalgia significantly affected sexual function, and the severity and duration of fibromyalgia, the duration of the sexual partnership, and severity of anxiety significantly increased the degree of sexual dysfunction (Hayta & Mert, 2017).*

▲ Assess for depression as a possible cause of sexual dysfunction, and institute appropriate treatment. **EBN:** *In women who had given birth in the prior 12 months, 24% reported postnatal depression, which was significantly associated with sexual dysfunction, not initiating partnered sexual activity, and relationship dissatisfaction, illustrating the importance of assessment and early intervention for both depression and sexual dysfunction (Khajehei & Doherty, 2017).*

• Observe for grief-related loss (e.g., amputation, mastectomy, ostomy) because a change in body image often precedes sexual dysfunction. See care plan for Disturbed **Body Image.** **EBN:** *In men after lower anterior resection for rectal cancer, ED occurred in*

97% compared with 76% in those undergoing colectomy, and worse overall sexual function for those with lower anterior resection, particularly for those with a stoma. This illustrates the importance of discussing sexual function and loss in those diagnosed with rectal cancer (Shieh et al, 2016).

▲ Explore physical causes of sexual dysfunction such as diabetes, cardiovascular disease, arthritis, or BPH. **EB:** *In men and women with heart failure, approximately 60% experienced sexual problems related to performance, overall sexual function, and decreased sexual pleasure and satisfaction; contributing factors included lack of energy, decreased exercise capacity, and depressed mood (Jaarsma, Fridlund, & Mårtensson, 2014).*

▲ Consider that ED may indicate the presence of cardiovascular disease, and screening and referral of men is recommended. **EB:** *Vasculogenic ED may be a sign of silent or future cardiovascular disease; thus cardiovascular risk stratification using the Framingham Risk Score is indicated. Management of those men with ED of low cardiovascular risk focuses on risk factor control, whereas men at high risk should be referred to a cardiologist (Miner et al, 2014).*

• Certain chronic diseases such as cancer often have significant effects on sexual function, and both the disease process and treatment can contribute to sexual dysfunction. **EBN:** *Although women after gynecological cancer were sexually active, 54% had impaired sexual satisfaction and experienced problems such as vaginal dryness and discomfort with vaginal penetration during sexual activity (Sekse, Hufthammer, & Vika, 2016).*

• Consider that neurological diseases can affect sexual function directly, with secondary effects caused by disability related to the illness and social and emotional effects. **EB:** *In men and women with a diagnosis of muscular dystrophy, spinal cord injury, or postpolio syndrome, only 37.8% reported engaging in sexual activity in the past 30 days, and sexual dysfunction was a significant predictor of sexual satisfaction regardless of type of disability, and depression was also a significant predictor in women (Smith et al, 2015).*

• Explore behavioral or other causes of sexual dysfunction, such as smoking, dietary factors, or obesity. **EB:** *Although smoking and ED have been linked in men, a study of women supported prior findings that women smokers were not at increased risk for sexual dysfunction, although nicotine dependence might negatively affect libido (Costa & Peres, 2015).*

▲ Consider medications as a cause of sexual dysfunction. **EB:** *Cardiovascular drug effects on sexual function include overall negative effects of beta blockers (with the exception of nebivolol), cardiac glycosides, antiarrhythmics, and diuretics; neutral effects with alpha blockers, angiotensin-converting enzyme inhibitors, vasodilators, and calcium channel blockers; and positive effects from angiotensin receptor blockers, although there are mixed results for some of these drug classes (La Torre et al, 2015).* **EB:** *A meta-analysis from 63 studies of second-generation antidepressants in clients with major depressive disorder showed that bupropion conferred a significantly lower risk of sexual dysfunction, and citalopram and paroxetine were significantly associated with higher risk of sexual dysfunction compared with other second-generation drugs (Reichenpfader et al, 2014).*

▲ Refer to appropriate medical providers for consideration of medication for premature ejaculation, ED, or orgasmic problems. **EB:** *A combination treatment with a selective serotonin reuptake inhibitor and a PDE5 inhibitor was superior in treating men with premature ejaculation (Bai et al, 2015).* **EB:** *Treatment response for the ED drug sildenafil was better than placebo in men with no comorbidity and for those with cardiovascular disease/hypertension only, diabetes only, or depression only, regardless of age (Goldstein, Stecher, & Carlsson, 2017).*

• Refer to the care plan Ineffective **Sexuality** pattern for additional interventions.

Geriatric

▲ Carefully assess the sexuality needs and sexual dysfunction of older adults and refer for counseling if needed. **EBN:** *Treatment approaches for ED in older adults include behavioral and lifestyle changes (e.g., smoking cessation, healthy diet, physical activity, limiting alcohol intake), pelvic floor muscle exercises, PDE5 inhibitors, psychotherapy, and assistive devices (Marchese, 2017).*

• Teach about normal changes that occur with aging that may be perceived as sexual dysfunction, such as reduction in vaginal lubrication and reduction in duration and resolution of orgasm for women; for men these changes include increased time required for erection and for subsequent erections, erection without ejaculation, less firm erection, and decreased volume of seminal fluid. **EBN:** *Results of a phenomenological study revealed that older men showed sexual interest regardless of age, health, or sexual function, although anxiety was increased when biomedical interventions for ED were unsuccessful; nurses and health care professionals must proactively assess and discuss sexual function with older adults (Gledhill & Schweitzer, 2014).*

• If prescribed, instruct clients with chronic pain to take pain medication before sexual activity. **EB:** *In a randomized controlled trial of estrogen-deficient breast cancer survivors who had severe dyspareunia with vaginal penetration, compared with saline, the use of 4% aqueous lidocaine to the vulvar vestibule for three minutes prior to vaginal penetration resulted in less pain during intercourse, decreased sexual distress, and improved sexual function (Goetsch, Lim, & Caughey, 2015).*

• See care plan for Ineffective **Sexuality** pattern.

Multicultural

• Evaluate culturally influenced risk factors for sexual function and dysfunction. **EBN:** *Bisexual women had greater sexual coercion, more lifetime partners, physical and sexual violence, traded sex for resources, and had posttraumatic stress disorder symptoms, illustrating the importance of history-taking, screening protocols, and counseling, taking into account race, ethnicity, gender, class, and sexual identity (Alexander et al, 2016).*

• Validate client feelings and emotions regarding the changes in sexual behavior by letting the client know that the nurse heard and understands what was said, promoting the nurse–client relationship. **EB:** *Culturally sensitive approaches with older adults includes discussing sexual function and dysfunction regardless of culture, sexual orientation, age, gender, or marital status, and inquiring about culture in a nonjudgmental way (Atallah, 2016).*

Home Care

• Previously discussed interventions may be adapted for home care use.

▲ Identify specific sources of concern about sexual dysfunction and provide reassurance and instruction on appropriate expectations as indicated. **EB:** *Clients with schizophrenia and sexual dysfunction had significantly worse subjective quality of life, and aspects of physical arousal such as vaginal lubrication and penile erection were commonly affected; it is important to address causes of sexual dysfunction and implement management strategies tailored to the client (Bushong, Nakonezny, & Byerly, 2013).*

▲ Confirm that physical reasons for dysfunction have been addressed, and refer for therapy and/or support groups if appropriate. **EB:** *Most individuals with sexual problems would benefit from both pharmacologic and psychological treatment, including*

sexual counseling and therapy (Almås, 2016).

• See care plan for Ineffective **Sexuality** pattern.

Client/Family Teaching and Discharge Planning

• Provide accurate information for clients regarding interventions for sexual dysfunction. **EB:** *To address sexual problems in those with cancer, psychosexual counseling should be offered to both men and women. Women may benefit from pelvic floor physiotherapy, hormonal therapy for vasomotor symptoms (if safe), and vaginal lubricants, whereas men might be offered PDE5 inhibitors, vacuum erectile devices, and intracavernosal injection (Barbera et al, 2017).*

• *Include the partner/family in discharge instructions because partner concerns are often overlooked regarding sexual issues.* **EB:** *Women as cervical cancer survivors wanted both information and practical advice in dealing with sexual dysfunction; physical functioning, sexual distress, relationship satisfaction, and partner perspectives should be assessed, with interventions tailored to the particular needs of the couple (Vermeer et al, 2016).*

• Teach the client and partner about condom use, for those at risk. **EB:** *In couples, feelings of commitment to the sexual partner resulted in reduced perceived sexual risk, illustrating that interventions for couples should include discussion of sexual risk, prevention of HIV risk, including condom use, and monogamy agreements before condoms are discontinued (Agnew et al, 2017).*

▲ Refer to appropriate community resources, such as a clinical specialist, family counselor, or cardiac rehabilitation, including the partner if appropriate; for complex issues, a referral to a sex counselor, urologist, gynecologist, or other specialist may be needed. **EB:** *College students stated a preference for help-seeking related to sexual problems from gynecologists, urologists, and family physicians, with the next preference being sex therapists, psychologists, and counselors (Bergvall & Himelein, 2014).* **EB:** *Men and their partners need comprehensive information before and after treatment for prostate cancer, including support groups to help patients and partners gain education and support (Albaugh et al, 2017).*

▲ Refer for medical advice when ED lasts longer than 2 months or is recurring. **EB:** *ED can be treated, and underlying causes need to be investigated through a thorough medical and sexual history (Glina, Cohen, & Vieira, 2014).*

• Teach the following interventions to decrease the likelihood of ED: limit or avoid the use of alcohol, stop smoking, exercise regularly, reduce stress, get enough sleep, deal with anxiety or depression, and see a health care provider for regular checkups and medical screening tests. **EB:** *In a study of nondiabetic men with cardiovascular risk factors, those with ED were more likely to be smokers, sedentary, and consumed more alcohol, whereas those consuming more nuts and vegetables had less ED, illustrating the importance of counseling regarding lifestyle and its effect on ED (Ramírez et al, 2016).*

• See care plan for Ineffective **Sexuality** pattern.

Ineffective Sexuality pattern

Elaine E. Steinke PhD, APRN, CNS-BC, FAHA, FAAN

NANDA-I

Definition

Expressions of concern regarding own sexuality.

Defining Characteristics

Alterations in relationship with significant other; alteration in sexual activity; alteration in sexual behavior; change in sexual role; difficulty with sexual activity; difficulty with sexual behavior; value conflict

Related Factors

Conflict about sexual orientation; conflict about variant preference; fear of pregnancy; fear of sexually transmitted infection; impaired relationship with a significant other; inadequate role model; insufficient knowledge about alternatives related to sexuality; skill deficit about alternatives related to sexuality; absence of privacy

At-Risk Population

Absence of significant other

NOC(Nursing Outcomes Classification)

Suggested NOC Outcomes

Abuse Recovery: Sexual; Body Image; Child Development: Middle Childhood/Adolescence; Client Satisfaction: Teaching; Knowledge: Pregnancy and Postpartum Sexual Functioning; Knowledge: Sexual Functioning; Psychosocial Adjustment: Life Change; Risk Control: Sexually Transmitted Diseases (STDs); Risk Control: Unintended Pregnancy; Role Performance; Self-Esteem; Sexual Functioning; Sexual Identity

Example NOC Outcome with Indicators

Risk Control: Sexually Transmitted Diseases (STDs) as evidenced by the following indicators: Acknowledges personal risk factors for STD/Uses strategies to prevent STD transmission. (Rate the outcome and indicators of **Risk Control: Sexually Transmitted Diseases (STDs):** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- State knowledge of difficulties, limitations, or changes in sexual behaviors or activities
- State knowledge of sexual anatomy and functioning
- State acceptance of altered body structure or functioning
- Describe acceptable alternative sexual practices
- Identify importance of discussing sexual issues with significant other
- Describe practice of safe sex with regard to pregnancy and avoidance of sexually transmitted infections (STIs)

NIC(Nursing Interventions Classification)

Suggested NIC Interventions

Abuse Protection Support: Child; Abuse Protection Support: Domestic Partner; Abuse Protection Support: Elder; Abuse Protection Support: Religious; Behavior Management: Sexual; Sexual Counseling; Teaching: Safe Sex; Teaching: Sexuality

Example NIC Activities—Sexual Counseling

Provide privacy and ensure confidentiality; Provide information about sexual functioning, as appropriate

Nursing Interventions and *Rationales*

- After establishing rapport or therapeutic relationship, give the client permission to discuss issues dealing with sexuality, for example, "Have you been or are you concerned about functioning sexually because of your health status?" **EB:** *Use the PLISSIT model (permission, limited information, specific suggestions, referral to intensive therapy) to uncover additional concerns and begin with more general questions and then those more personal, such as discussing exercise recommendations and then sexual activity as another form of exercise (Steinke et al, 2013); use of the model has been shown to improve sexual function in women with multiple sclerosis (MS) (Khakbazan et al, 2016).*
- Use assessment questions and standardized instruments to assess sexual problems, where possible. **EBN:** *Use specific assessment questions to obtain information on current level of sexual activity, changes in sexual satisfaction, the nature of any problems experienced, underlying causes, medication review, and beliefs and misconceptions (Steinke, Mosack, & Hill, 2015).*
- ▲ Assess any risks associated with sexual activity, particularly coronary risks. **EB:** *Cardiac patients without angina or with mild angina who can exercise at a rate of at least 3 to 5 METs (amount of energy expenditure), and without experiencing angina, ischemic ST segment changes, or excess dyspnea are generally at low risk for cardiac events with sexual activity. For those at high risk or if a risk classification has not been determined, exercise stress testing is recommended (Lange & Levine, 2014).* **EB:** *If a cardiac patient is able to engage in physical activity at the rate of 3 to 5 METs or 3 to 4 miles per hour on a treadmill, or climb two flights of stairs briskly, sexual activity can generally be resumed (Steinke & Jaarsma, 2015).*
- Assess knowledge about sexual functioning and return to sexual activity after experiencing a health problem with both patients and partners. **EBN:** *Information provided to partners is often inadequate, and discussing sexual issues increases partner understanding and may minimize overprotectiveness by the partner; in post myocardial infarction (MI) patients and partners, patient knowledge about sex after MI improved at 1 year, whereas partners' knowledge did not change (Brännström et al, 2014).*
- Encourage the client to discuss concerns with his or her partner. **EB:** *Not communicating sexual concerns as a couple can lead to stress and deterioration in the relationship, whereas open and honest discussions with one's partner can promote sexual intimacy; an ideal time for such discussions might be during a daily walk together (Steinke et al, 2013).*
- Explore attitudes about sexual intimacy and changes in sexuality patterns. **EBN:** *Women with hematopoietic cell transplantation reported absent to low sexual desire, inadequate lubrication, problems with orgasm, pain with vaginal penetration, and overall sexual dissatisfaction, although quality of life scores improved in the first year, particularly for those with decreased psychosocial and physical symptoms, and there was improved sexual satisfaction (Tierney, Palesh, & Johnston, 2015).* **EBN:** *After breast cancer, women had reduced sexual desire, frequency, and satisfaction, with no association between sexual performance and body image (de Morais et al, 2016).*

• Assess psychosocial function such as anxiety, fear, depression, and low self-esteem. **EBN:** *Coronary heart disease patients who screened positive for moderate to high risk of depression while in acute care later had greater depression and anxiety, and less well-being and social support, emphasizing the importance of screening for psychological sequelae (Ski et al, 2015).* **EBN:** *In a population-based study, men who had sex with men had greater depressive symptoms compared with those with partners of the opposite sex (Scott, Lasiuk, & Norris, 2016).*
• Discuss alternative sexual expressions for altered body functioning or structure, including closeness and sexual and nonsexual touching as other forms of expression. **EBN:** *Women with fibromyalgia experienced pain with sexual activity, postcoital stiffness, anxiety about sex, and altered body image, although maintaining an active sex life was important; therefore discussion of sexual concerns, individual symptoms, and psychoemotional needs can assist in developing approaches for sexual activity, such as changes in position or alternatives to sexual intercourse when symptom burden is high (Jiménez et al, 2017).* **EB:** *For some clients with severe heart failure, activities such as mutual masturbation, oral sex, or sexual intercourse may not be possible if exercise capacity is compromised, making other expressions of intimacy of greater importance (Steinke, 2013a).*
• Assess the client's sexual orientation and usual pattern of sexual activities, and discuss prevention of illnesses for which the client may be at increased risk (e.g., anorectal cancer), asking specific questions about sexual orientation, for example, "Do you have sexual relationships with men, women, or both?" Assess use of safer sex practices (e.g., condom use); the frequency of anal intercourse; number of sexual partners in the last year; last HIV screening/results; and use of medications, alcohol, and illicit drugs. **EBN:** *Transgender women had low levels of HIV risk perception and knowledge about HIV risk and transmission, illustrating the importance of assessing transgender women's sexual health care needs and educating regarding risks (De Santis et al, 2017).*
• Specific guidelines for sexual activity for clients who have had total hip arthroplasty (THA) include the following: sexual activity can be generally resumed 1 to 2 months after surgery, and positioning to avoid hip dislocation, e.g., a supine position ("missionary") at maximum abduction in extension, or the man and woman standing, with the woman's legs slightly bent and the man approaching the woman from behind (McFadden, 2013). **EB:** *In a systematic review of THA and sexual activity, 76% of individuals identified hip arthritis as contributing to sexual problems, whereas post-THA, 44% reported improvement in sexual satisfaction, 27% reported increased intercourse frequency, and most returned to sexual activity at 4 months post-THA. Health care professionals and surgeons should discuss return to sexual activity after THA, including the best positions postsurgery (Harmsen et al, 2017; Issa et al, 2017).*
• Specific guidelines for those who have had an MI include the following: sexual activity can generally be resumed 1 week after MI unless complications are experienced, such as arrhythmias or cardiac arrest, if the client does not have cardiac symptoms during mild to moderate physical activity; begin with activities that require less exertion, such as fondling or kissing, building confidence in tolerance for sexual activity prior to sexual intercourse; engage in sexual activity in familiar surroundings with the usual partner; have a comfortable room temperature, and be well rested to minimize cardiac stress; avoid heavy meals or alcohol for 2 to 3 hours before sexual activity; and choose a position of comfort to minimize stress of the cardiac client (Steinke et al, 2013). **EB:** *Among younger individuals experiencing MI in the United States and Spain, 72% of women and 86% of men reported return to sexual activity at 1 month post MI, and the majority rated sexual activity as important, illustrating the*

importance of providing sexual education while hospitalized and during the early recovery period (Lindau et al, 2014).

• Specific guidelines include that those who have had complete coronary revascularization, in addition to those mentioned with MI, including those with successful percutaneous cardiovascular revascularization without complication, can resume sex within a few days, and those who have had standard coronary artery bypass grafting (CABG) or noncoronary open heart surgery may resume sex in 6 to 8 weeks. Incisional pain with sexual activity can be managed by premedicating with a mild pain reliever, and reassurance should be provided to the partner that sexual activity will not harm the sternum as long as direct pressure is avoided (Steinke et al, 2013). **EB:** *Women, particularly those with large breasts, may report more issues related to pain in the breast, chest numbness, and difficulty healing; therefore encourage these women to choose a position of comfort, support with pillows, and take a pain reliever such as acetaminophen before sexual activity (Steinke & Jaarsma, 2015).*

• Specific guidelines for those with an implantable cardioverter defibrillator (ICD) include returning to sexual activity is generally safe after ICD implantation if moderate physical activity does not precipitate arrhythmias; avoid strain on the incision at the implant site; assure the client and partner that fears about being shocked during sexual activity are normal; if the ICD discharges with sexual activity, the client should stop, rest, and later notify the health care provider that the device fired so that a determination can be made if this was an appropriate shock or not; and report any dyspnea, chest pain, or dizziness with sexual activity (Steinke et al, 2013). **EB:** *Although most clients with ICD reported the ability to engage in sexual activity (64.6%), 51% chose to avoid sexual activity, citing reasons such as fear of shock, fear of increased heart rate, and no desire, illustrating the importance of evaluating and discussing both psychological and physical aspects of return to sexual activity (Cutitta et al, 2014).*

• Specific guidelines for those with chronic lung disease include planning for sexual activity when energy level is highest; use of controlled breathing techniques; avoiding physical exertion prior to sexual activity; using positions that minimize shortness of breath, such as a semireclining position; engaging in sexual activity when medications are at peak effectiveness; use of an oxygen cannula, if prescribed, to provide oxygen before, during, or after sex; and use of continuous positive airway pressure (CPAP) therapy, if prescribed (Steinke, 2013b). **EB:** *For patients and families participating in exercise training and psychoeducational support, family members reported significantly greater improvement in sexual relationships and psychological distress compared with the control group, demonstrating the importance of psychoeducational sexual interventions (Marques et al, 2015).* **EB:** *In a systematic review of sexual dysfunction and obstructive sleep apnea in men, CPAP improved daytime sleepiness and erectile and orgasmic dysfunction, although sildenafil was superior to CPAP in improving erectile dysfunction; intervention studies for women were not available (Steinke et al, 2016).*

• Specific guidelines for those with MS include treatment of symptoms with prescribed medications, assessing changes in body image, and supportive therapies to assist with a more satisfying sexual experience, including treatment of neuropathic pain, sexual positions that are most supportive, discussing changes in sensation and stimulation with the partner, use of stretching exercise for tight muscles prior to sexual activity, and avoiding a distended bowel or bladder that may cause discomfort. **EB:** *Women with MS attending a 12-week sexual therapy program significantly improved sexual desire, arousal, lubrication, orgasm, satisfaction, overall quality of life, energy, cognitive function, and social function; designing targeted educational and sexual interventions are important to improve sexual and overall quality of life (Zamani et al, 2017).*

• Refer to the care plan **Sexual** dysfunction for additional interventions.

Pediatric

• Initiate discussions regarding sexual health, attitudes, and knowledge about sexual behavior, and sexual abstinence, providing information that is age-appropriate and accurate regarding sexual activity and risky sexual behaviors. **EBN:** *In a small intervention study of African American girls between the ages of 12 and 14 years, mother and daughter dyads that completed the sexual communication intervention had improved sexual knowledge, confidence to discuss sexual issues, and openness to communication, illustrating the importance of initiating these conversations with adolescents and their families (Aronowitz et al, 2015).* **EB:** *Focus groups conducted in black churches with senior pastors, youth ministers, parents of youth, and youth ages 13 to 19 years, on the topic of youth sexual and reproductive health, resulted in the themes of engaging stakeholders, the authenticity of the curriculum, making the curriculum relevant to youth, discussion of relationships, and adaptation, providing an example that implementing sexual health programs in new settings can be successful in reaching youth and the community (Weeks et al, 2016).*
• Provide age-appropriate information for adolescents regarding HIV / AIDS and sexual behavior, and discuss STIs, particularly human papillomavirus, including the risks of perinatal transmission and methods to reduce risks among HIV-infected adolescents. **EB:** *African American female adolescents who participated in an HIV prevention intervention with specific sexual health telephone counseling contacts had greater improvement in depressive symptoms than the comparison group. More than 40% had moderate to severe depression at baseline, illustrating the importance of addressing depression in intervention programs (Brown et al, 2014).*
• Provide age-appropriate information regarding potential for sexual abuse. **EBN:** *A structured teaching program on prevention of sexual abuse with high school students resulted in improved knowledge of prevention strategies, illustrating the importance of education and directly addressing this sensitive issue (Fulgen, 2017).*

Geriatric

• Carefully assess the sexuality needs of the older client and refer for counseling if needed; the ability to form satisfying social relationships and to be intimate with others, including building strong emotional intimate connections, contributes to adaptation and successful aging (Steinke, 2013b). **EB:** *Positive affect and life satisfaction was associated with increased sexual behavior in community-dwelling older men and women, regardless of depressive symptoms, physical health, and chronic diseases, whereas unpartnered adults' life satisfaction was linked with more physical tenderness and less sexual behavior, demonstrating the importance of sexual assessment of all older adults and in promoting psychological and sexual well-being (Freak-Poli et al, 2017a).*
▲ Explore possible changes in sexuality related to health status, menopause, medications, and sexual risk, and make appropriate referrals. **EB:** *Although two-thirds of older adults had experienced some sexual problems, most were not distressed by it, reporting positive sexual well-being, with positive sexual self-esteem and attitudes toward sex, high sexual satisfaction and interest, and frequently engaging in sexual activity, illustrating that although some older adults may experience challenges regarding sexual activity, many report positive sexual health (Santos-Iglesias, Byers, & Moglia, 2016).* **EB:** *Sexual risk-taking was prevalent among older adults, with 49% reporting engaging in vaginal sex and 43% engaging in oral sex without a condom in the prior 6 months, although 65.5% of the sample believed*

they were not susceptible to STIs, revealing the need for assessment, education, and intervention related to sexual risk (Syme, Cohn, & Barnack-Tavlaris, 2017).

• Allow the client to verbalize feelings regarding loss of sexual partner, and acknowledge problems such as disapproving children, lack of available partner for women, and environmental variables that make forming new relationships difficult. **EB:** *Health status, frequency of sexual activity, and importance of sexual behavior were important predictors of quality of life, and these findings were independent of the presence of a spouse/partner, illustrating the importance of health care providers evaluating sexual activity as a component of quality of life with all clients (Flynn & Gow, 2015).*

▲ Provide a milieu that allows for discussion of sexual issues and a higher level of sexual satisfaction, including allowing couples to room together and the provision of privacy. **EBN:** *Sexual expression and consent should be openly addressed in long-term care settings, and results from a qualitative study of directors of long-term care facilities revealed the common themes of addressing the issue, making environmental changes, identifying staff expertise, providing education and training, assessing sexuality initially and recurrently, establishing policies and procedures for sexual expression management, developing assessment tools, and clarifying legal issues. These are all important areas that staff in long-term care facilities can use to improve the sexual health of their residents (Syme, Lichtenberg, & Moye, 2016).*

• See care plan for **Sexual** dysfunction.

Multicultural

• Assess for the influence of cultural beliefs, norms, and values on client's perceptions of sexual behavior. **EBN:** *Among Hispanic men who had sex with men, parental knowledge and rejection of their sexual orientation contributed to greater depressive symptoms and no effect on safer sex behaviors, although acculturation (Americanism) may have had a protective role. These findings emphasized the importance of educating and supporting both the individual and family, including assessing mental health (Mitrani et al, 2017).*

Home Care

• Previously discussed interventions may be adapted for home care use. Also see care plan for **Sexual** dysfunction.

• Help the client and significant other identify a place and time in the home and daily living for privacy in sharing sexual or relationship activity, and, if necessary, help the client communicate the need for privacy to family members. **EB:** *In community-dwelling older adults, most reported experiencing physical tenderness and about half engaged in sexual activity, with sexual activity more likely in those of younger age, those with greater social support, those with healthier behaviors, and those with better psychological and physical health, illustrating the importance of maintaining sexual quality of life regardless of setting, not assuming that the older person is not interested in sexual pleasure, and having health care professionals proactively address sexuality and sexual health (Freak-Poli et al, 2017b).*

• Confirm that physical reasons for dysfunction have been addressed, and provide support for coping behaviors, including participation in support groups or therapy if appropriate. **EB:** *A pilot study using a psychoeducational group intervention in women with MS and spinal cord injury resulted in improved sexual functioning, particularly for sexual desire and arousal, demonstrating the importance of supportive interventions to improve sexual functioning (Hocaloski et al, 2016).*

Client/Family Teaching and Discharge Planning

- Refer to appropriate community agencies (e.g., certified sex counselor, Reach to Recovery, Ostomy Association, American Association of Sex Educators, Counselors, and Therapists). **EBN:** *Sexuality concerns should be addressed with all clients for whom sexual function might be affected because of an acute or chronic condition (Steinke, 2013a).*
- Sexuality education is important to all populations, whether hearing or deaf, sighted or blind, disabled or not disabled; discuss contraceptive choices as appropriate, safer sexual practices, and refer to a health professional (e.g., gynecologist, urologist, nurse practitioner). **EB:** *Sexuality education of older adults is often overlooked, and they may have inaccurate perceptions regarding sexual risk behaviors and STIs (Syme, Cohn, & Barnack-Tavlaris, 2017).*

Risk for Shock

Tara Cuccinelli RN, MS, AGCNS-BC

NANDA-I

Definition

Susceptible to an inadequate blood flow to the body's tissues that may lead to life-threatening cellular dysfunction, which may compromise health.

Risk Factors

To be developed

Associated Condition

Hypotension; hypovolemia; hypoxemia; hypoxia; infection; sepsis; systemic inflammatory response syndrome (SIRS)

NOC(Nursing Outcomes Classification)

Suggested NOC Outcomes

Cardiac Pump Effectiveness; Fluid Balance; Infection Severity; Respiratory Status: Gas Exchange; Neurological Status: Autonomic; Tissue Perfusion: Cellular

Example NOC Outcome with Indicators

Neurological Status: Autonomic as evidenced by the following indicators: Apical heart rate/Systolic blood pressure/Urinary elimination pattern/Thermoregulation. (Rate the outcome and indicators of **Neurological Status: Autonomic:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Discuss precautions to prevent complications of disease
- Maintain adherence to agreed-on medication regimens
- Maintain adequate hydration
- Monitor for infection signs and symptoms
- Maintain a mean arterial pressure (MAP) above 65 mm Hg
- Maintain a heart rate between 60 and 100 with a normal rhythm
- Maintain urine output greater than 0.5 mL/kg/hr
- Maintain warm, dry skin

NIC(Nursing Intervention Classification)

Suggested NIC Interventions

Admission Care; Allergy Management; Cardiac Care; Cerebral Perfusion Promotion; Electrolyte Monitoring; Fever Treatment; Fluid Management; Hemodynamic Regulation; Infection Precaution; Medication Management; Oxygen Therapy; Postanesthesia Care; Risk Identification; Shock Prevention; Teaching: Disease Process; Temperature Regulation; Vital Signs Monitoring

Example NIC Activities—Shock Prevention

Monitor circulatory status; Monitor for signs of inadequate tissue oxygenation; Administer oxygen and/or mechanical ventilation, as appropriate; Instruct client and/or family on precipitating factors of shock

Nursing Interventions and *Rationales*

- Review data pertaining to client risk status including age, primary diseases, immunosuppression, antibiotic use, and presence of hemodynamic alterations such as tachycardia, tachypnea, and decrease in blood pressure (BP). **EB:** *Many clients who develop shock have underlying circumstances that predispose them to shock states as evidenced by hypotension and inadequate organ perfusion (Kalil, 2014; Kleinpell, Schorr, & Balk, 2016).*
- Review client's medical and surgical history, noting conditions that place the client at higher risk for shock, including trauma, myocardial infarction, pulmonary embolism, head injury, dehydration, infection, endocrine problems, certain medications, and pregnancy. **EB:** *Certain clinical conditions place clients at higher risk for shock, which requires prompt identification and treatment to improve morbidity and mortality outcomes (Delgado et al, 2013; American Heart Association [AHA], 2016).*
- Complete a full nursing physical examination. *A full nursing physical examination is crucial in identifying all factors that might place that client at risk for the development of shock, such as hypoperfusion of internal organs (manifesting as decreased urinary output and*

shortness of breath) and tissue hypoperfusion (manifesting as cool, clammy, mottled skin and diminished pulses). **EB:** *The use of extremity skin temperatures alone, as a predictor of decreased cardiac output (CO), cannot be validated or supported because of a lack of consensus in the literature (Hiemstra et al, 2017).* However, the presence of skin mottling, especially over the knees, ears, and fingers, suggests tissue hypoperfusion states often seen in shock (Contou & de Prost, 2016).

• Monitor circulatory status (e.g., BP, MAP, skin color, skin temperature, heart sounds, heart rate and rhythm, presence and quality of peripheral pulses, pulse oximetry, and end-tidal carbon dioxide monitoring [$EtCO_2$]). **EB:** *The initial phase of shock is characterized by decreased CO and tissue perfusion, which results in immediate compensatory changes evidenced by a drop in BP, increased heart rate, and shunting of blood away from the periphery, resulting in pale, cooler, damp skin, and mottling with reduced peripheral pulses (Kalil, 2014; Contou & de Prost, 2016; Kleinpell, Schorr, & Balk, 2016).*

• Maintain intravenous (IV) access and provide isotonic IV fluids such as 0.9% normal saline or Ringer's lactate as ordered; these fluids are commonly used in the prevention and treatment of shock. **EB:** *Restrictive fluid resuscitation and permissive hypotension (achievement of systolic pressure around 90 mm Hg) may have an advantage over standard higher volume fluid resuscitation regarding overall and early intraoperative survival benefit in trauma patients experiencing shock (Sweeney, 2013; Carrick et al, 2016).* **EB:** *Septic shock hypoperfusion should be initially managed with a 30 mL/kg bolus of crystalloid fluid for patients who have no underlying comorbidities (e.g., congestive heart failure or chronic renal conditions) (Rhodes et al, 2017).*

• Monitor for inadequate tissue oxygenation (e.g., apprehension, increased anxiety, altered mental status, agitation, oliguria, cool/mottled periphery) and determinants of tissue oxygen delivery (e.g., PaO_2, SpO_2, $ScvO_2/SvO_2$, MAP, hemoglobin levels, lactate levels, CO). *Assessment of tissue oxygen delivery and oxygenation patterns provides data to assess trends in client's status and evaluates treatment responses (Kalil, 2014). Changes in client mental status are highly sensitive to changes in perfusion and oxygenation (Singer, 2016).* **EB:** *Invasive monitoring has not been shown to improve overall mortality. Many clinicians are using noninvasive monitoring even for hemodynamically unstable patients including the use of bedside ultrasonography and infrared spectroscopy (Seymour & Rosengart, 2015; Rhodes et al, 2017).* **EB:** *Reduction in mortality was observed with interventions aimed at lactate-guided resuscitation (Rhodes et al, 2017).*

▲ Maintain vital signs (BP, pulse, respirations, and temperature) and pulse oximetry within normal parameters. **EB:** *Trending of vital signs using an early warning score (EWS) is a quick cost-effective way to identify early patients at risk of deterioration and intervene in a timely manner (Albur, Hamilton, & MacGowan, 2016).* **EB:** *Increased heart rate (above 90 beats per minutes), hypotension (BP below 90 mm Hg systolic), tachypnea (greater than 20 breaths per minute), hypoxia (SpO_2 below 90%), lactate levels (above 2 mmol/L), and change in mentation are indicators of shock (Dellinger et al, 2013, Kalil, 2014; Singer, 2016; Rhodes et al, 2017). Temperature greater than 38°C or less than 36°C with white blood cell count greater than 12,000/mm^3 or less than 4000/mm^3 plus symptoms listed earlier are indicators of SIRS (Dellinger et al, 2013; Rhodes et al, 2017).* **EB:** *Quick Sequential Organ Failure Assessment (qSOFA), which looks at altered mentation, systolic BP of 100 mm Hg or less, and respiratory rate greater than 22 breaths per minute has shown to identify patients who are likely to have poor outcomes (Singer, 2016).*

▲ Administer oxygen immediately to maintain SpO_2 greater than 90%, and antibiotics and other medications as prescribed to any client presenting with symptoms of early shock. **EBN:** *The experienced nurse has an important role in the implementation of the*

Surviving Sepsis Campaign (SSC), which includes specific early goal-directed therapies that enhance client survival (Kleinpell, Aitken, & Schorr, 2013; Turi & Von Ah, 2013; Kleinpell, Schorr, & Balk, 2016). **EB:** *Early goal-directed therapy protocols focusing on administration of oxygen, fluid resuscitation, antibiotics administered within an hour, and vasoactive medications provide early correction of risks for shock and improve survival of shock. Antibiotics as prescribed administered within 1 hour of diagnosis of a sepsis state facilitates a better rate of survival. For each hour in delayed antibiotic administration, survival decreases by 7.6% (Seymour & Rosengart, 2015; Rhodes et al, 2017).*

▲ Monitor trends in noninvasive hemodynamic parameters (e.g., MAP) as appropriate. **EB:** *A MAP less than 60 to 65 mm Hg for any extended time period is associated with poor outcomes (Leone et al, 2015)* **EB:** *Restoring MAP to desired levels (above 65 mm Hg) facilitates adequate perfusion to organs; (Dellinger et al, 2013; Rhodes et al, 2017; Singer, 2016).* **EB:** *An overarching goal of cardiovascular support is optimization of blood flow to tissues; however, there is no single optimum MAP that can be applied to all. In patients with chronic arterial hypertension, a higher MAP (75–85 mm Hg) may be preferable (Leone et al, 2015; Rhodes et al, 2017). Monitor hydration status including daily weights, postural BP changes, serum electrolytes (sodium, potassium, chloride, bilirubin, creatinine, and blood urea nitrogen), intake and output, and skin turgor. Consider insertion of an indwelling urinary catheter as ordered to measure hourly output for a goal of 0.5 mL/kg/hr (Kleinpell, Schorr, & Balk, 2016).*

▲ Monitor serum lactate levels and interpret them within the context of each client. **EB:** *Elevations in serum lactate (above 2 mmol/L) may indicate circulatory failure and resultant tissue hypoxia from anaerobic metabolism that results in toxin accumulation, cellular inflammation, and cellular death with higher lactate levels predictive of higher mortality (Casserly et al, 2015).* **EB:** *Progression to septic shock may result as characterized by the onset of SIRS (Rhodes et al, 2017). Two or more of the following indicators suggest SIRS: altered temperatures; heart rates above 90 beats per minute; tachypnea or hypocarbia; and/or leukocytosis/leukopenia, which may or may not be related to infection as other causative factors exist (Kaplan & Pinsky, 2014; Rhodes et al, 2017). The degree of serum lactate elevation correlates with morbidity and mortality in sepsis; early detection facilitates early treatment and is a more accurate triage tool than vital signs (Casserly et al, 2015). Monitor blood glucose levels frequently and administer insulin as prescribed to targeted blood glucose levels of <180 mg/dL (Rhodes et al, 2017).*

▲ Prepare the client for the placement of an additional IV line, central line, and/or a pulmonary artery catheter as prescribed. *Adequate IV and central line access may be required for fluid resuscitation and medication delivery. Maintaining more than one IV access ensures rapid IV medication and fluid delivery in a crisis situation. Large amounts of fluid can be delivered more efficiently through centrally placed vascular access sites. Most vasoactive agents, especially vasopressors, should be delivered only through central lines because of risk of tissue sloughing.* **EB:** *A Cochrane systematic review of 13 studies on 5686 clients found no difference in mortality rates or days spent in an intensive care unit (ICU) between those clients with a pulmonary artery catheter and those without (Rajaram et al, 2013).*

▲ Monitor trends in hemodynamic parameters (e.g., central venous pressure [CVP], CO, cardiac index [CI], systemic vascular resistance [SVR], pulmonary artery pressure [PAP], MAP) as appropriate. *Hemodynamic indices will be altered depending on the underlying form of shock (hypovolemic, distributive, or cardiogenic). Dehydration will result in reduced CVP, CO, PAP, and ultimately MAP because of hypovolemia. Vasodilation as seen*

in distributive shock patterns (forms of third spacing as in neurogenic, anaphylactic, and septic shock states) will decrease BP and CVP (a surrogate for intravascular volume) and other hemodynamic indices. Cardiogenic shock will result in low CO and MAP with higher PAP and CVP indices caused by heart failure and subsequent congestion of the cardiopulmonary systems. Compensatory mechanisms to address reductions in CO and MAP include tachycardia and reduced urinary output (less than 0.5 mL/kg/hr). Both CO and SVR may temporarily increase with the onset of shock because of compensatory mechanisms; however, as shock progresses, both CO and SVR decline (Dellinger et al, 2013; Kalil, 2014).

▲ Monitor electrocardiography. Tachycardia may be present as a result of decreased fluid volume, which will be seen before a decrease in BP as a compensatory mechanism. **EB:** *As oxygen demands increase, tachycardia and cardiac dysrhythmias may be evident, such as premature ventricular contractions (Dellinger et al, 2013).*

▲ Monitor arterial blood gases, coagulation, blood chemistries, blood glucose, cardiac enzymes, blood cultures, and hematology labs. **EB:** *Abnormalities can identify the cause of the perfusion deficits and identify complications related to the decreased perfusion or shock state. Cardiogenic shock may be identified by elevations in cardiac enzymes as a result of myocardial infarction in association with low MAP. Elevation/reductions in white blood cell counts may be indicative of septic shock when associated with alterations in MAP (Kalil, 2014; Rhodes et al, 2017).*

▲ Administer vasopressor agents as prescribed. **EB:** *Norepinephrine is the vasopressor of choice for septic shock (Avni et al, 2015; Rhodes et al, 2017). Norepinephrine should be administered through a central line.* **EB:** *Low-dose dopamine should not be started for renal protection (Rhodes et al, 2017).*

• If the client is in shock, refer to the following care plans: Risk for ineffective **Renal** perfusion, Risk for ineffective **Gastrointestinal** perfusion, Impaired **Gas** exchange, and Decreased **Cardiac** output.

Client/Family Teaching and Discharge Planning

▲ *Teach client and family or significant others about any medications prescribed. Instruct the client to report any adverse side effects to his or her health care provider. Medication teaching includes the drug name, purpose, administration instructions (e.g., with or without food), and any side effects. Provision of such information using clear communication principles and with an understanding of what the health literacy level of the client/family/significant others may be can facilitate appropriate adherence to the therapeutic regimen (Balentine, 2014; National Institutes of Health [NIH], 2016).*

• Instruct the client and family on disease process and rationale for care. **EB:** *Tailored interventions targeted to the level of the learner enhance client activation (Hibbard & Greene, 2013). Knowledge empowers clients and family members, allowing them to be active participants in their care (Finchman, 2013).* **EB:** *When clients and their family members have sufficient understanding of their disease process, they can participate more fully in care and healthy behaviors (Finchman, 2013).*

• Instruct clients and their family members on the signs and symptoms of low BP to report to their health care provider (dizziness, lightheadedness, fainting, dehydration and unusual thirst, lack of concentration, blurred vision, nausea, cold, clammy, pale skin, rapid and shallow breathing, fatigue, and depression). **EBN:** *Teach-back methods were found to be significantly associated with self-care activities and fewer hospitalizations in a sample of 276 clients with heart failure (White et al, 2013).* **EB:** *Use of the teach-back method enhances an individual's knowledge and adherence behaviors (Negarandeh et al, 2013). Early recognition and treatment of these symptoms may avoid more serious sequelae (AHA, 2016).*

- Promote a culture of client safety and individual accountability. **EB:** *Organizations that promote a just culture of safety help to reduce or prevent errors and improve overall health care quality (Agency for Healthcare Research and Quality [AHRQ], 2017). Include health literacy strategies into all aspects of client-centered care and weave into organizational values (Koh et al, 2013).*

Impaired Sitting

Ruth A. Wittmann-Price PhD, RN, CNS, CNE, CHSE, ANEF, FAAN

NANDA-I

Definition

Limitation of ability to independently and purposefully attain and/or maintain a rest position that is supported by the buttocks and thighs, in which the torso is upright.

Defining Characteristics

Impaired ability to adjust position of one or both lower limbs on uneven surface; impaired ability to attain a balanced position of the torso; impaired ability to flex or move both hips; impaired ability to flex or move both knees; impaired ability to maintain the torso in balanced position; impaired ability to stress torso with body weight

Related Factors

Insufficient endurance; insufficient energy; insufficient muscle strength; malnutrition; pain; self-imposed relief posture

Associated Condition

Alteration in cognitive functioning; impaired metabolic functioning; neurological disorder; orthopedic surgery; prescribed posture; psychological disorder; sarcopenia

NOCOutcomes (Nursing Outcomes Classification)

Suggested NOC Outcomes

Activity Tolerance; Balance; Body Mechanics Performance; Body Positioning: Self-Initiated; Endurance; Tissue Perfusion: Peripheral; Self Care Status; Skeletal Function

Example NOC Outcome with Indicators

Body Mechanics Performance: as evidenced by the following indicators: Uses correct sitting posture; Uses supportive devices correctly. (Rate outcome and indicators of **Body Mechanics Performance:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated].)

Client Outcomes

Client Will (Specify Time Frame)

- Verbalize importance of being able to sit as a method to engage in activities of daily living
- Understand somatic physiology of posture control
- Choose health care options that enhance ability to sit
- Engage in physical conditioning exercises to enhance sitting ability
- Understand relationship of posture and emotions
- Control pain to increase ability to sit

NICInterventions (Nursing Interventions Classification)

Suggested NIC Interventions

Activity Therapy; Body Mechanics Promotion; Fall Prevention; Energy Management; Exercise Promotion: Strength Training; Exercise Therapy: Balance, Joint Mobility, Muscle Control; Functional Ability Enhancement; Positioning; Pressure Ulcer Prevention

Example NIC Activities—Exercise Therapy: Sitting

Assist client to use chair that facilitates sitting and prevents injury; Transfer safely from bed to chair; Encourage to sit in chair, as tolerated; Provide activities that can be completed while sitting

Nursing Interventions and *Rationales*

- Acknowledge the importance of being able to sit as a method to engage in activities of daily living. **EB:** *Junhyuck, Jihwan, and Jongeun (2017) investigated upper limb function, balance, gait, and quality of life in two groups of stroke patients (N = 26) before and after a sitting boxing program and found that the Stroke-Specific Quality of Life questionnaire (SS-QOL) scores were significantly improved in the boxing group concluding that the sitting boxing program group had positive effects on upper extremity function, balance, gait, and quality of life.* **EB:** *Swinton, Cooper, and Hancock (2017) performed a literature review (N = 12) about how workplace interventions improved workers' sitting posture and found limited evidence to indicate that ergonomic workplace interventions improved gross sitting posture. Additional research is needed about proper sitting conditions in workplaces so patients can better participate in activities of daily living.*
- Understand the somatic physiology of posture control. **EB:** *DongGeon et al (2017) studied trunk muscle activities in four types of seated postures, including cross-legged, long, side, and W-shaped in adults (N = 8), and found that trunk muscle activity did not significantly differ between the four types of sitting postures.* **EB:** *Researchers studied the effect of different sitting positions on hip joint loading by examining three different sitting positions, such as a simple chair, a car seat, and a kneeling chair, and found that the kneeling chair was the best ergonomic sitting position for hip joints (Van Houcke et al, 2017).*
- Choose the musculoskeletal options that enhance ability to sit properly. **EB:** *Milosevic et al (2017) studied patients (N = 25) with thoracic spinal cord injury (SCI) in relation to unsupported sitting and found that patients with high- and low-thoracic SCI swayed more with unsupported sitting. Recommendations include providing patients with different postural regulation strategies to enhance proper sitting.* **EB:** *Lee, Lee, and Shin (2017) studied forward head posture in seven different posture conditions in patients (N = 20) including sitting comfortably and sitting with the back straight and found that head posture evaluation is a reliable assessment for evaluating proper sitting conditions.*
- Engage in physical conditioning exercises to enhance proper sitting ability. **EB:** *Molik et al (2017) investigated disabled patients playing volleyball in a sitting position and found that the vertical sitting position and degree of disability directly related to performance, but the exercise was beneficial.* **EB:** *Sanchez et al (2017) studied full trunk control (head-trunk alignment) in sitting with patients (N = 10) with neuromotor disability using the Segmental Assessment of Trunk Control (SATCo) and used video for clinical evaluation to determine whether the upper limbs were free. This study shows promise in developing the first stages of a clinically friendly, fully automated method to assess proper sitting and understand the relationship of posture and somatic functioning.* **EB:** *Alghdir, Zafar, and Iqbal (2017) studied the effects of upright and slouch sitting postures and voluntary teeth clenching on hand grip strength (HGS) in patients (N = 100) and found that HGS was actually stronger during slouching than sitting upright and HGS had no effect on teeth clenching, indicating that*

sitting posture may matter when testing HGS in a physical assessment evaluation. **EB:** *Nutritional researchers studied protein digestion in patients sitting in an upright position compared with a recumbent position and found increased gastric emptying and increased postprandial elevation in plasma amino acid availability when patients are sitting (Holwerda et al, 2017).*

• Understand the relationship of posture and emotions. **EB:** *Shinpei et al (2017) investigated physical and psychological effects of the Shiatsu Stimulation (SS) (finger pressure) in a sitting position on patients (N = 20). The SS demonstrated significant change in all six mood states (tension-anxiety, depression-dejection, fatigue, and confusion decreased while vigor elevated).* **EB:** *Researchers examined sitting and the use of social media in patients (N = 1120) with physiological and psychological conditions (cardiovascular disease, type 2 diabetes, obesity, and poorer mental health status) and found that patients with high social media use had significantly greater sitting times especially on nonworkdays for leisure, but the negative affect on health was not correlated and the study indicated that a longitudinal study is needed (Alley et al, 2017).*

• Maintain pain levels below 3 to 4 on a 0 to 10 scale to increase ability to sit. **EB:** *Joshi et al (2017) studied neuropathy of the posterior femoral cutaneous nerve, which can cause pain while sitting, and performed magnetic resonance (MR)-guided cryoablation to successfully treat sitting pain caused by neuropathy.* **EB:** *Researchers studied the relationship between office workers (N = 35) and musculoskeletal pain by comparing the ergonomic, physical, and psychosocial factors and found that computer office workers who reported pain had worse ergonomics for their chair workstation, but psychosocial factors did not demonstrate a difference (Santana et al, 2017).*

Pediatric

• Increase cognitive and physical functioning by promoting proper sitting ability. **EB:** *Researchers studied the change of sagittal spinal curvatures in children (N = 56) with generalized joint hypermobility (GJH) who were instructed with the "straighten your back" (SYB) command and found that it did not improve standing and sitting positioning; this command is recommended but not to be used (Czaprowski et al, 2017).* **EBN:** *Hitchcock (2017) reviewed the research regarding safe infant sleeping and addressed the fact that sitting devices are not recommended. Nurses should model recommended behaviors for safe infant sleep and teach parents about safe infant sleep throughout the hospital stay.*

Geriatric

• Increase cognitive and physical functioning by promoting prober sitting ability. **EB:** *Researchers studied the effects of aging on patients' (N = 39) muscle control during transition from lying to sitting positions using myotonometry measurements of tone, stiffness, and elasticity; results suggested that increased age increases stiffness and tone and decreases the elasticity of muscles (Kocur et al, 2017).* **EB:** *Bell et al (2017) studied elderly patients (age 65 and older) in the hospital and community in relation to their ability to open food packages in a sitting and laying down position and found that while laying down greater strength was required to open packages and that sitting improved eating overall.*

Multicultural

• Understand the importance of unimpaired sitting to different populations. **EB:** *A case study analyzed in Japan discussed the researchers' novel "hip prosthesis in the sitting posture" on a patient who was an amputee and found that implanting a hip prosthesis in a*

sitting position enabled the patient to better stand, walk, and begin balance training (Yukiyo et al, 2017). **EB:** *Lazennec et al (2017) completed a study in France that investigated the effect of spinal fusion effects on sitting in patients (N = 93) and found that the fusion assisted in patients' ability to position themselves from standing to sitting.*

Home Care

- Encourage proper sitting posture in the home environment to promote health. **EB:** *Chun-Ting et al (2017) studied patients (N = 16) in four modes of reclining wheelchairs with and without different sitting devices and found the lumbar support with femur upward with back reclined mode provided the most significant reduction in stress load on the ischial area.* **EB:** *Eriksson et al (2017) explored activation of a range of trunk muscles using intramuscular electromyography in patients (N = 13) and results revealed muscles demonstrated a directional preference and the least muscular energy was spent in an upright sitting position.*

Impaired Skin integrity

Jo Ann Coar BSN, RN-BC, CWOCN, COS-C

NANDA-I

Definition

Altered epidermis and/or dermis.

Defining Characteristics

Acute pain; alteration in skin integrity; bleeding; foreign matter piercing skin; hematoma; localized area hot to touch; redness

Related Factors

External

Chemical injury agent; excretions; humidity; hyperthermia; hypothermia; moisture; pressure over bony prominence; secretions

Internal

Alteration in fluid volume; inadequate nutrition; psychogenic factor

At-Risk Population

Extremes of age

Associated Condition

Alteration in metabolism; alteration in pigmentation; alteration in sensation; alteration in skin turgor; arterial puncture; hormonal change; immunodeficiency; impaired circulation; pharmaceutical agent; radiation therapy; vascular trauma

NOC(Nursing Outcomes Classification)

Suggested NOC Outcomes

Tissue Integrity: Skin and Mucous Membranes; Wound Healing: Primary Intention, Secondary Intention

Example NOC Outcome with Indicators

Tissue Integrity: Skin and Mucous Membranes will be intact as evidenced by the following indicators: Skin integrity/Skin lesions not present/Tissue perfusion/Skin temperature/Skin thickness. (Rate the outcome and indicators of **Tissue Integrity: Skin and Mucous Membranes:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Regain integrity of skin surface
- Report any altered sensation or pain at site of skin impairment
- Demonstrate understanding of plan to heal skin and prevent reinjury or complications
- Describe measures to protect and heal the skin and to care for any skin lesion

NIC(Nursing Interventions Classification)

Suggested NIC Interventions

Incision Site Care; Pain Management; Pressure Ulcer Care (currently referred to as Pressure Injury Care [National Pressure Ulcer Advisory Panel (NPUAP), 2016]); Pressure Ulcer Prevention (Pressure Injury Prevention [NPUAP, 2016]); Risk Identification; Skin Care: Topical Treatments; Skin Surveillance; Wound Care; Wound Irrigation

Example NIC Activities—Pressure Ulcer Care (Pressure Injury Care [NPUAP, 2016])

Monitor color of wound bed, temperature, edema, erythema, moisture, and appearance of surrounding skin; Note characteristics of any drainage

Nursing Interventions and *Rationales*

- NPUAP redefined the definition of a pressure ulcer, now referred to as pressure injuries, during the NPUAP 2016 Staging Consensus Conference. The new definitions more accurately define alterations in tissue integrity from pressure as the following: *A pressure injury is localized damage to the skin and underlying soft tissue usually over a bony prominence or related to a medical or other device. The injury can present as intact skin or an open ulcer and may be painful. The injury occurs as a result of intense and/or prolonged pressure or pressure in combination with shear. The tolerance of soft tissue for pressure and shear may also be affected by microclimate, nutrition, perfusion, comorbidities, and condition of the soft tissue (NPUAP, 2016).*
- Pressure ulcer is no longer a current clinical term; rather, pressure injury is used to describe an alteration in tissue integrity from pressure (NPUAP, 2016). Similarly, hospital-acquired pressure ulcers (HAPUs) are currently referred to as hospital-acquired pressure injury (HAPIs).
- Assess site of skin impairment and determine cause or type of wound (e.g., acute or chronic wound, burn, dermatological lesion, pressure injury, skin tear). **EB:** *Identification of etiological factors, or what is causing the impairment, is the first step, and requires a thorough assessment of the individual, not only the impairment. The assessment should include the medical history, current medical status, medications, and family history (Baranoski & Ayello, 2016; Murphree, 2017). Skin and tissue assessment is important in*

pressure injury prevention, classification, diagnosis, and treatment (NPUAP, European Pressure Ulcer Advisory Panel [EPUAP], 2014; NPUAP, 2016).

• Use a risk assessment tool to systematically assess client risk factors for skin breakdown caused by pressure. **EB:** *A validated risk assessment tool such as the Norton scale or Braden scale should be used to identify clients at risk for immobility-related skin breakdown (NPUAP/EPUAP, 2014). An individual identified at risk for pressure injury development or who has healed pressure injuries will need to be evaluated for pressure redistributing surfaces (Murphree, 2017). Targeting variables (e.g., age and Braden Scale Risk Category) can focus assessment on particular risk factors (e.g., pressure) and help guide the plan of prevention and care (NPUAP/EPUAP, 2014).*

• Determine the extent of the skin impairment caused by pressure using the revised classification system and definition for pressure injuries (NPUAP, 2016).

- ❍ **Stage 1 Pressure Injury:** Nonblanchable erythema of intact skin
  Area of localized nonblanchable erythema that may appear differently in darkly pigmented skin, and changes in sensation, temperature, or firmness may precede visual changes. Color changes do not include purple or maroon discoloration, which is more likely to indicate deep tissue pressure injury (NPUAP, 2016).
- ❍ **Stage 2 Pressure Injury:** Partial-thickness skin loss with exposed dermis
  Partial-thickness skin loss with exposed dermis in which the wound bed is pink/red and moist and adipose (fat) and deeper tissues are not visible. Granulation tissue, slough, and eschar are not present. A stage 2 pressure injury may also present as an intact or ruptured blister. These injuries commonly result from adverse microclimate and shear in the skin over the pelvis and shear in the heel. This stage should not be used to describe moisture-associated skin damage (MASD) including incontinence-associated dermatitis (IAD), intertriginous dermatitis (ITD), medical adhesive–related skin injury (MARSI), or traumatic wounds (skin tears, burns, and abrasions) (NPUAP, 2016).
- ❍ **Stage 3 Pressure Injury**: Full-thickness skin loss
  Full-thickness loss of skin, in which adipose is visible and granulation tissue and epibole (rolled wound edges) are often present and undermining/tunneling may occur. Slough and/or eschar may also be visible. Fascia, muscle, tendon, ligament, cartilage, and/or bone are not exposed. The depth of tissue damage varies by anatomical location, and areas of significant adiposity can develop deep wounds. If slough or eschar obscures the extent of tissue loss this is an unstageable pressure injury (NPUAP, 2016).
- ❍ **Stage 4 Pressure Injury**: Full-thickness skin and tissue loss
  Full-thickness skin and tissue loss with exposed or directly palpable fascia, muscle, tendon, ligament, cartilage or bone, and slough and/or eschar may be visible. Epibole, undermining, and/or tunneling often occur, and depth varies by anatomical location. If slough or eschar obscures the extent of tissue loss, this is an unstageable pressure injury (NPUAP, 2016).
- ❍ **Deep Tissue Pressure Injury:** Persistent nonblanchable deep red, maroon, or purple discoloration
  Intact or nonintact skin with localized area of persistent nonblanchable deep red, maroon, or purple discoloration or epidermal separation revealing a dark wound bed or blood-filled blister. Pain and temperature change often precede skin color changes. Discoloration may appear

differently in darkly pigmented skin. This injury results from intense and/or prolonged pressure and shear forces at the bone–muscle interface. The wound may evolve rapidly to reveal the actual extent of tissue injury, or it may resolve without tissue loss. If necrotic tissue, subcutaneous tissue, granulation tissue, fascia, muscle, or other underlying structures are visible, this indicates a full-thickness pressure injury (unstageable, stage 3, or stage 4). Do not use the term deep tissue pressure injury to describe vascular, traumatic, neuropathic, or dermatological conditions (NPUAP, 2016).

- ❍ **Unstageable Pressure Injury**: Obscured full-thickness skin and tissue loss Full-thickness skin and tissue loss in which the extent of tissue damage within the ulcer cannot be confirmed because it is obscured by slough or eschar. If slough or eschar is removed, a stage 3 or stage 4 pressure injury will be revealed. Stable eschar (i.e., dry, adherent, intact without erythema or fluctuance) on the heel or ischemic limb should not be softened or removed (NPUAP, 2016).
- ❍ **Mechanical device–related pressure injury** is used to describe alterations in tissue integrity caused by pressure from mechanical devices used in the care of clients (e.g., indwelling urinary catheters, endotracheal tubes, nasogastric tubes, drains). The pressure injury typically conforms to the shape of the device (NPUAP, 2016).
- ❍ **Mucosal Membrane Pressure Injury:** Mucosal membrane pressure injury is found on mucous membranes with a history of a medical device in use at the location of the injury. Because of the anatomy of the tissue, these ulcers cannot be staged (NPUAP, 2016).

• Inspect and monitor site of skin impairment at least once a day for color changes, redness, swelling, warmth, pain, or other signs of infection. Determine whether the client is experiencing changes in sensation or pain. Closely assess high-risk areas such as bony prominences, skinfolds, the sacrum, and heels. *Systematic inspection can identify impending problems early (NPUAP/EPUAP, 2014; Baranoski & Ayello, 2016). When conducting a skin assessment in an individual with darkly pigmented skin prioritize assessment of skin temperature, presence of edema, and change in tissue consistency in relation to surrounding tissue (NPUAP/EPUAP, 2014).*

• Monitor the client's skin care practices, noting type of soap or other cleansing agents used, temperature of water, and frequency of skin cleansing. *Cleansing should not compromise the skin (Baranoski & Ayello, 2016).* **EB:** *Keep the skin clean and dry. Use a pH balanced skin cleanser. Consider using a skin moisturizer to hydrate dry skin to reduce risk of skin damage. Protect the skin from exposure to excessive moisture with a barrier product to reduce the risk of pressure damage (NPUAP/EPUAP, 2014). Products to promote healthy skin in the elderly include cleansers that are pH balanced, preferably no-rinse in soft disposable cloths and superfatted nonalkaline soaps (Murphree, 2017).*

• Consider using normal saline to clean the pressure injury or as ordered by the health care provider, but if necessary tap water suitable for drinking may be used to clean the wound. **EB:** *A Cochrane review found no evidence that using tap water to cleanse acute wounds in adults or children increases or reduces infection (Fernandez & Griffiths, 2012). Cleanse most pressure injuries with potable water (i.e., water suitable for drinking) or normal saline (NPUAP/EPUAP, 2014; NPUAP, 2016).*

• Maintain good skin hygiene, using mild nondetergent soap, drying gently, and lubricating with lotion or emollient to reduce the risk of dermal trauma; improve circulation; and promote comfort. Provide client education on good skin hygiene practices (Doenges, Moorhouse, & Murr, 2016).

• Urinary and fecal incontinence can cause skin breakdown. **EB:** *Develop and implement an individualized continence management plan. Cleanse the skin promptly after episodes of incontinence. Protect the skin from exposure to excessive moisture with a barrier product to reduce the risk of pressure damage (NPUAP/EPUAP, 2014).* **EB:** *Implementing an incontinence prevention plan with the use of a skin protectant or a cleanser protectant can significantly decrease skin breakdown and pressure injury formation (Scemons, 2013).*
• For clients with limited mobility and activity, use a risk assessment tool to systematically assess immobility and activity-related risk factors. **EB:** *A validated risk assessment tool such as the Norton scale or Braden scale should be used to identify clients at risk for immobility-related skin breakdown (NPUAP/EPUAP, 2014).* **EBN:** *A study found that the most commonly reported interventions to reduce skin breakdown in acutely ill patients were protocol development, staff education, new use of a risk assessment tool, performance monitoring, development of a team approach, use of new beds/support surfaces, implementation of guidelines, providing feedback to staff, and linking staff with resources (Stotts et al, 2013).*
• Do not position the client on site of skin impairment. If consistent with overall client management goals, reposition the client as determined by individualized tissue tolerance and overall condition. Reposition and transfer the client with care to protect against the adverse effects of external mechanical forces such as pressure, friction, and shear. **EB:** *Do not position an individual directly on a pressure injury. Continue to turn/reposition the individual regardless of the support surface in use. Establish turning frequency based on the characteristics of the support surface and the individual's response (NPUAP & EPUAP, 2014). If the goal of care is to keep the client (e.g., a terminally ill client) comfortable, turning and repositioning may not be appropriate (NPUAP & EPUAP, 2014).*
• Evaluate for use of support surfaces (specialty mattresses, beds), chair cushions, or devices as appropriate. Maintain the head of the bed at the lowest possible degree of elevation to reduce shear and friction, and use lift devices, pillows, foam wedges, and pressure-reducing devices in the bed (Brienza et al, 2016; NPUAP & EPUAP, 2014).
• Implement a written treatment plan for topical treatment of the site of skin impairment. *A written plan ensures consistency in care and documentation (Baranoski & Ayello, 2016).*
• Select a topical treatment that will maintain a moist wound-healing environment (stage 2) that is balanced with the need to absorb exudate. Stage 1 pressure injuries may be managed by keeping the client off of the area and using a protective dressing (Baranoski & Ayello, 2016). **EBN:** *Choose dressings that provide a moist environment, keep periwound skin dry, and control exudate and eliminate dead space (NPUAP & EPUAP, 2014). Select a wound dressing based on the ability to keep the wound bed moist; need to address bacterial bioburden; nature and volume of wound exudate; condition of the tissue in the ulcer bed; condition of periulcer skin; ulcer size, depth, and location; presence of tunneling and/or undermining; and goals of the individual with the ulcer (NPUAP & EPUAP, 2014).*
• Avoid massaging around the site of skin impairment and over bony prominences. **EB:** *Research suggested that massage may lead to deep tissue trauma (NPUAP & EPUAP, 2014).*
• Assess the client's nutritional status. Refer for a nutritional consult and/or institute dietary supplements as necessary. **EB:** *Optimizing nutritional intake, including calories, fatty acids, protein, and vitamins, is needed to promote wound healing. Both the EPUAP and NPUAP (NPUAP & EPUAP, 2014) endorse the application of reasonable nutritional assessment and treatment for clients at risk for and with pressure ulcers.*
• Identify the client's phase of wound healing (inflammation, proliferation, or maturation) and stage of injury. **EBN:** *The selection of the dressing is based on the tissue in*

the ulcer bed (wound bed), the condition of the skin around the ulcer bed, and the goals of the person with the ulcer. Generally, maintaining a moist ulcer bed is the ideal when the ulcer bed is clean and granulating to promote healing and closure (NPUAP & EPUAP, 2014). No single wound dressing is appropriate for all phases of wound healing.

Home Care

- The interventions described previously may be adapted for home care use.
- Instruct and assist the client and caregivers in how to change dressings and maintain a clean environment. Provide written instructions and observe the client completing the dressing change before hospital discharge and in the home setting.
- Educate client and caregivers on proper nutrition, signs and symptoms of infection, and when to call the agency and/or health care provider with concerns.
- It may be beneficial to initiate a consultation in a case assignment with a wound, ostomy, continence nurse (or wounds specialist) to establish a comprehensive plan for complex wounds (Vrtis, 2013).

Client/Family Teaching and Discharge Planning

- Teach skin and wound assessment and ways to monitor for signs and symptoms of infection, complications, and healing. Early assessment and intervention help prevent serious problems from developing. **EB:** *A home visit by a wound care specialist can provide essential in-home education, client specific plan of care, and reduce health care costs (Vrtis, 2013).*
- Teach the client why a topical treatment has been selected. **EBN:** *The type of dressing needed may change over time as the wound heals and/or deteriorates (NPUAP & EPUAP, 2014).*
- If consistent with overall client management goals, teach how to reposition as client condition warrants. **EB:** *If the goal of care is to keep a client (e.g., terminally ill client) comfortable, turning and repositioning may not be appropriate (NPUAP & EPUAP, 2014).*
- Teach the client to use pillows, foam wedges, chair cushions, and pressure-redistribution devices to prevent pressure injury (Brienza et al, 2016). *Individualize the selection and periodic reevaluation of a seating support surface and associated equipment for posture and pressure redistribution with consideration of body size and configuration, the effects of posture and deformity on pressure distribution, and mobility and lifestyle needs (NPUAP & EPUAP, 2014).*

Risk for impaired Skin integrity

Jo Ann Coar BSN, RN-BC, CWOCN, COS-C

NANDA-I

Definition

Susceptible to alteration in epidermis and/or dermis, which may compromise health.

Risk Factors

External

Chemical injury agent; excretions; humidity; hyperthermia; hypothermia; moisture; secretions

Internal

Alteration in fluid volume; inadequate nutrition; pressure over bony prominence; psychogenetic factor

At-Risk Population

Extremes of age

Associated Condition

Alteration in metabolism; alteration in pigmentation; alteration in sensation; alteration in skin turgor; arterial puncture; hormonal change; immunodeficiency; impaired circulation; pharmaceutical agent; radiation therapy; vascular trauma

NOC(Nursing Outcomes Classification)

Suggested NOC Outcomes

Immobility Consequences: Physiological; Tissue Integrity: Skin and Mucous Membranes

Example NOC Outcome with Indicators

Tissue Integrity: Skin and Mucous Membranes will be intact as evidenced by the following indicators: Skin intactness/Skin lesions not present/Tissue perfusion/Skin temperature. (Rate the outcome and indicators of **Tissue Integrity: Skin and Mucous Membranes:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Report altered sensation or pain at risk areas as soon as noted
- Demonstrate understanding of personal risk factors for impaired skin integrity
- Verbalize a personal plan for preventing impaired skin integrity

NIC(Nursing Interventions Classification)

Suggested NIC Interventions

Positioning: Pressure Management; Pressure Ulcer Care (currently referred to as Pressure Injury Care [National

Pressure Ulcer Advisory Panel (NPUAP), 2016]); Pressure Ulcer Prevention (Pressure Injury Prevention [NPUAP, 2016]; Skin Surveillance

Example NIC Activities—Pressure Ulcer Care

Monitor color of wound bed, temperature, edema, erythema, moisture, and appearance of surrounding skin; Note characteristics of any drainage

Nursing Interventions and *Rationales*

• The NPUAP redefined the definition of a pressure ulcer, which is now referred to as a pressure injury, during the NPUAP 2016 Staging Consensus Conference in 2016. The new definition more accurately defines alterations in tissue integrity from pressure as the following: A pressure injury is localized damage to the skin and underlying soft tissue usually over a bony prominence or related to a medical or other device. The injury can present as intact skin or an open ulcer and may be painful. The injury occurs as a result of intense and/or prolonged pressure or pressure in combinations with shear. The tolerance of soft tissue for pressure and shear may also be affected by microclimate, nutrition, perfusion, comorbidities, and conditions of the soft tissue (NPUAP, 2016).
• Identify clients at risk for impaired skin integrity as a result of immobility, chronological age, malnutrition, incontinence, compromised perfusion, immunocompromised status, or chronic medical condition, such as diabetes mellitus, spinal cord injury, or renal failure. **EB:** *These client populations are known to be at high risk for impaired skin integrity (Baranoski & Ayello, 2016). Targeting variables (e.g., age and Braden Scale Risk Category) can focus assessment on particular risk factors (e.g., pressure) and help guide the plan of prevention and care (NPUAP & European Pressure Ulcer Advisory Panel [EPUAP], 2014).*
• Inspect and monitor skin condition at least once a day for color or texture changes, redness, localized heat, edema or induration, pressure damage, dermatological conditions, or lesions and any incontinence-associated dermatitis. Determine whether the client is experiencing loss of sensation or pain. *Systematic inspection can identify impending problems early (NPUAP & EPUAP, 2014; Baranoski & Ayello, 2016). When conducting a skin assessment in an individual with darkly pigmented skin prioritize assessment of skin temperature, presence of edema, and change in tissue consistency in relation to surrounding tissue (NPUAP & EPUAP, 2014).*
• Monitor the client's skin care practices, noting type of soap or other cleansing agents used, temperature of water, and frequency of skin cleansing. *Individualize plan according to the client's skin condition, needs, and preferences (Baranoski & Ayello, 2016).*
• Keep skin clean and dry. Cleanse the skin gently with pH-balanced cleansers. Consider use of skin moisturizers to hydrate skin to reduce risk of skin damage. Protect skin from exposure to excessive moisture with a barrier product to reduce the risk of pressure-related damage (NPUAP & EPUAP, 2014).
▲ Develop and implement an individualized continence management plan. Cleanse the skin promptly after episodes of incontinence. Use incontinence skin barriers including creams, ointments, pastes, or film-forming skin protectants as needed to protect skin and maintain intact skin (Ratliff et al, 2017). **EB:** *Implementing an incontinence prevention plan with the use of a skin protectant or a cleanser protectant can significantly decrease skin breakdown and pressure ulcer formation (NPAUP & EPUAP 2014; Baranoski & Ayello, 2016).*
• For clients with limited mobility, inspect and monitor condition of skin covering

bony prominences. *Pressure injuries usually occur over bony prominences, such as the sacrum, coccyx, trochanter, and heels, as a result of unrelieved pressure between the prominence and support surface, or with shearing and friction (Wound, Ostomy, and Continence Nurses Society [WOCN], 2010; NPUAP & EPUAP, 2014; Baranoski & Ayello, 2016). Position individuals in the sitting position with special attention to anatomy, weight distribution, postural alignment, and support of feet (Ratliff et al, 2017).*

• Implement and communicate a client-specific prevention plan. **EB:** *A plan of care clearly documented in the client's electronic health record will assist in ensuring consistency in care and documentation (Baranoski & Ayello, 2016).*

• At-risk clients should be frequently repositioned. Frequency of repositioning will be influenced by variables concerning the individual's independent mobility and the support surface in use. Frequency of repositioning should be determined by the individual's tissue tolerance and medical condition (NPUAP & EPUAP, 2014). Use of heel suspension devices can remove pressure from the heels and support the lower extremity of individuals who are unable to keep pressure off the heels, without placing pressure on the Achilles tendon (Ratliff et al, 2017).

• Evaluate for use of specialty mattresses, beds, or devices as appropriate (Lippoldt et al, 2014; Brienza et al, 2016). *Maintain the head of the bed at the lowest possible degree of elevation to reduce shear and use lift devices, pillows, foam wedges, and pressure-reducing devices in the bed (Lippoldt et al, 2014). If the goal of care is to keep the client (e.g., a terminally ill client) comfortable, turning and repositioning may not be appropriate; reposition the client for position of comfort and provide pain relief measures (Horn & Irion, 2014). Pressure redistributing devices are adjuncts and not replacements for regular repositioning (Ratliff et al, 2017).*

• Avoid massaging or vigorously rubbing over bony prominences. *Massage may lead to deep tissue trauma (NPUAP & EPUAP, 2014).*

▲ Assess the client's nutritional status; refer for a nutritional consult, and/or institute dietary supplements. **EB:** *Meeting nutritional needs of the client is important to prevention of skin breakdown and preventing complications of illness. Adequate nutrition is important for maintaining overall homeostasis and health (O'Hanlon, Dowsett, & Smyth, 2015).*

Geriatric

• Limit the number of complete baths to two or three per week, and alternate them with partial baths. Use a tepid water temperature (between 90° F and 105° F) for bathing or use a no-rinse alternative product. **EB:** *Excessive bathing, especially in hot water, depletes aging skin of moisture and increases dryness. The ability to retain moisture is decreased in aging skin because of diminished amounts of dermal proteins. One of the most common age-related changes to the skin is damage to the stratum corneum (Baranoski & Ayello, 2016).*

• Use lotions and moisturizers to prevent skin from drying out, especially in the winter. **EB:** *Avoid skin care products that contain allergens such as lanolin, latex, and dyes (Baranoski & Ayello, 2016). Use barrier products to protect aged skin from exposure to excessive moisture to reduce the risk of pressure damage (NPUAP & EPUAP, 2014).*

• Increase fluid intake within cardiac and renal limits to a minimum of 1500 mL/day. *Dry skin is caused by loss of fluid; increasing fluid intake hydrates the skin (Baranoski & Ayello, 2016). Recommend individuals with nutritional and pressure injury risks a minimum of 30 to 35 kcal/kg body weight per day, 1.25 to 1.5 g of protein/kg body weight per day, and 1 mL of fluid intake per kilocalorie per day, if there are no contraindications (Ratliff et al, 2017).*

• Increase humidity in the environment, especially during the winter, by using a humidifier or placing a container of water on a warm object. *Increasing the moisture in the air helps keep moisture in the skin.*

Home Care

• Assess client and caregiver ability to recognize potential risk for skin breakdown. Provide resources for client/caregiver to contact health care provider with questions/concerns related to skin and incontinence care as needed (Vrtis, 2013). Engage family, caregivers, or legal guardian when establishing goals of care and validate their understanding of these goals. Educate the individual and his or her caregiver regarding skin changes in aging and at end of life (NPUAP & EPUAP, 2014).
▲ Initiate a consultation in a case assignment with a wound care specialist or wound, ostomy, and continence nurse to establish a comprehensive plan as soon as possible (Vrtis, 2013).
• See the care plan for Impaired **Skin** integrity.

Client/Family Teaching and Discharge Planning

• Teach the client skin assessment and ways to monitor for impending skin breakdown. Early assessment and intervention help prevent the development of serious problems. **EB:** *Basic elements of a skin assessment are assessment of temperature, color, moisture, turgor, and intact skin (Baranoski & Ayello, 2016). Seek information from the health care team to address individual pressure injury prevention and treatment needs (NPUAP & EPUAP, 2014).*
• If consistent with overall client management goals, teach how to turn and reposition the client. **EB:** *Do not position an individual directly on a pressure ulcer. Continue to turn/reposition the individual even if a low-airloss support surface is in use. Establish turning frequency based on the characteristics of the support surface and the individual's response (NPUAP & EPUAP, 2014). If the goal of care is to keep the client (e.g., a terminally ill client) comfortable, turning and repositioning may not be appropriate (Horn & Irion, 2014; NPUAP & EPUAP, 2014).*
• Teach the client and/or caregivers to use pillows, foam wedges, and pressure-reducing devices to prevent pressure injury (NPUAP & EPUAP, 2014). **CEB:** *The use of effective pressure-reducing seat cushions for older wheelchair users may significantly prevent sitting-acquired pressure injuries (Brienza et al, 2016). Pressure redistribution devices serve as adjuncts to prevention and do not replace repositioning (Ratliff et al, 2017).*

Sleep deprivation

Judith Ann Floyd PhD, RN, FNAP, FAAN

NANDA-I

Definition

Prolonged periods of time without sustained natural, periodic suspension of relative consciousness that provides rest.

Defining Characteristics

Agitation, alteration in concentration, anxiety, apathy, combativeness, confusion, decrease in functional ability, decrease in reaction time, drowsiness, fatigue, fleeting nystagmus, hallucinations, hand tremors, heightened sensitivity to pain, irritability, lethargy, malaise, perceptual disorders, restlessness, transient paranoia

Related Factors

Age-related sleep stage shifts; average daily physical activity less than recommended for gender and age; environmental barrier; late day confusion; nonrestorative sleep pattern; overstimulating environment; prolonged discomfort; sleep terror; sleep walking; sustained circadian asynchrony; sustained inadequate sleep hygiene

At-Risk Population

Familial sleep paralysis

Associated Condition

Conditions with periodic limb movement; dementia; idiopathic central nervous system hypersomnolence; narcolepsy; nightmares; sleep apnea; sleep-related enuresis; sleep-related painful erections; treatment regimen

NOC(Nursing Outcomes Classification)

Suggested NOC Outcomes

Rest; Sleep; Symptom Severity

Example NOC Outcome with Indicators

Sleep as evidenced by the following indicators: Hours of sleep/Sleep pattern/Sleep quality/Sleep efficiency/Feels rejuvenated after sleep/Sleeps through the night consistently. (Rate the outcome and indicators of **Sleep:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Verbalize plan that provides adequate time for sleep
- Identify actions that can be taken to ensure adequate sleep time
- Awaken refreshed once adequate time is spent sleeping
- Be less sleepy during the day once adequate time is spent sleeping

NIC(Nursing Interventions Classification)

Suggested NIC Intervention

Sleep Enhancement

Example NIC Activities—Sleep Enhancement

Monitor/record client's sleep pattern and number of sleep hours; Encourage client to establish a schedule that allows age-appropriate hours of sleep with minimal environmental and personal disruptions

Nursing Interventions and *Rationales*

- Assess the amount of sleep obtained each night compared with the amount of sleep needed. **EB:** *A national survey of 444,306 American adults found that more than one-third (34.8%) slept less than 7 hours per night, an amount at which physiological and neurobehavioral deficits manifest and become progressively worse under chronic conditions (Liu et al, 2016).*
- Assess the extent to which patients can be provided three to four consecutive hours of sleep time that is free from disturbance. **CEB:** *A meta-analysis using data from 159 studies found the deepest stages of sleep occurred during the first 3 to 4 hours of the sleep period followed by several 90- to 110-minute sleep cycles that consisted of increasingly lower percentages of deep sleep (Floyd, 2002).* **EB:** *Sleep hygiene education focuses on teaching healthy sleep habits such as avoiding caffeine, exercising regularly, eliminating noise from the sleeping environment, and maintaining a regular sleep schedule. However, research exploring direct links to these actions and subsequent sleep as a treatment for insomnia has been limited and inconclusive (Irish et al, 2015).*
    - ❍ Minimize environmental factors that deprive clients of sleep. See Nursing Interventions and *Rationales* for Disturbed **Sleep** pattern.
    - ❍ Minimize personal factors that deprive clients of sleep. See Nursing Interventions and *Rationales* for **Insomnia.**
- When required nighttime care leaves patients sleep deprived, schedule a specific time for rest and sleep during the day. **EBN:** *An action research study based on an evidence review, plus experiences of 22 intensive care unit (ICU) patients, and suggestions from approximately 250 health-setting personnel led to the development of an ICU clinical practice guideline that included planned daytime rest/sleep periods (Elliot & McKinley, 2014).*
- Assess for hypersensitivity to pain. **EB:** *In a laboratory experiment using 14 healthy adults, sleep restriction protocols altered processes of pain habituation and sensitization, which may help explain why chronic pain conditions often accompany insufficient sleep (Simpson et al, 2017).* **EB:** *In an observational study of postoperative orthopedic surgery patients (N = 50), a significant correlation was found between increased self-reported pain scores and decreased total sleep time (Miller et al, 2015).*
- When daytime drowsiness occurs despite adequate periods of undisturbed nighttime sleep, consider sleep apnea as a possible cause. **EB:** *In a household survey of more than 7000 adults, unexplained excessive daytime sleepiness was identified as a predictor of undiagnosed sleep apnea (Dosman et al, 2014).*
- Monitor caffeine intake (amounts and time of day) in sleep-deprived clients who may overuse caffeinated drinks to ward off daytime drowsiness. **EB:** *An experimental study of 12 participants found that caffeine (400 mg), even when consumed 6 hours before bedtime, had a disruptive effect on both objective and subjective sleep measures (Drake et al, 2013).*
- If evidence-based interventions are inadequate, consider and carefully evaluate unstudied but commonly used countermeasures for fighting drowsiness. **CEB:** *A descriptive study of 77 middle-aged adults identified the following unstudied strategies as possibly effective interrupters of drowsiness: (1) change physical position, (2) improve ventilation (e.g., get fresh air, turn on fan, open window), (3) reduce air temperature (e.g., turn on air conditioning, turn on fan), (4) increase auditory stimulation (e.g., play music, sing, engage in conversation, listen to debate), and (5) engage in interesting visual activity*

(e.g., board games, watching TV sports events, watching serial TV dramas) (Davidsson, 2012).

Pediatric

• Assess the amount of sleep obtained each night compared with the amount of sleep needed to avoid daytime drowsiness. **EB:** *Using data from a nationally representative survey (N = 2832), normal sleep times were found to vary by several hours at each age from birth to 18 years (Williams, Zimmerman, & Bell, 2013).*
• Encourage daily schedules that allow for late awakening times for adolescents. **EB:** *A review of evidence from 38 reports showed that delaying school start time increased sleep duration among adolescents, primarily by delaying rise times (Wheaton, Chapman, & Croft, 2016).*
• See the Pediatric section of Nursing Interventions and *Rationales* for Disturbed **Sleep** pattern**.**

Geriatric

▲ If an older client has daytime symptoms of sleep deprivation despite long nighttime sleep, refer to a sleep laboratory to evaluate the client for sleep apnea. *Older adults with heart failure, pulmonary disease, and dementia have a higher risk of sleep apnea, which may be undiagnosed (Gooneratne & Vitiello, 2014).*
• Assess the amount of sleep obtained each night compared with the amount of sleep needed to function well during the day. **EB:** *An integrative review of research published since 2000 suggested that sleep need in adults does not change across the life span, but obtaining adequate sleep becomes more difficult for older adults because of gradual changes in circadian functioning and sleep structure (Rybarczyk et al, 2013).*
• Assess how much time the client spends in bed unable to sleep and client's comfort with low sleep efficiency. **EBN:** *A meta-analysis of results from samples representing 5061 general-population adults showed a steady increase after age 50 in the amount of time set aside for nighttime sleep, which contributed to a steady decline in sleep efficiency over the life span (Floyd, 2017).*
• If a client is obtaining less sleep than required for optimal daytime function, explore if daytime napping will supplement, rather than replace, nighttime sleep. **CEB:** *In a pretest/posttest study of 22 older adults, a consistent regimen of daily napping for 45 minutes enhanced waking function without negatively affecting nighttime sleep (Campbell et al, 2011).*
• See the Geriatric section of Nursing Interventions and *Rationales* for disturbed **Sleep** pattern and **Insomnia.**

Multicultural

• Be aware of racial and ethnic disparities in sleep deprivation. **EB:** *A national survey of 444,306 American adults found that non-Hispanic black, American Indian/Alaska Native, Native Hawaiian/Pacific Islander, and multiracial populations reported a higher prevalence of sleeping less than 7 hours sleep compared with the rest of the US adult population (Liu et al, 2016).*

Home Care

• Teach family members about the short-term and long-term consequences of inadequate amounts of sleep for both clients and family caregivers. **CEB:** *In an*

integrative review of 10 studies, insufficient sleep was associated with poor attention, decreased performance, increased mortality and morbidity, and cardiovascular risk factors, including hypertension, insulin resistance, hormonal deregulation, and inflammation (Mullington et al, 2009).

- Teach client/family caregivers about the need for those with medical conditions to avoid schedules and commitments that interfere with obtaining adequate amounts of sleep. **EB:** *Critical appraisal of 22 studies provided evidence that sleep disturbance was common in critically ill patients up to 12 months after hospital discharge (Altman, Knauert, & Pisani, 2017).* **CEB:** *In a study of 21 subjects with left ventricular assist devices, nurse researchers found they obtained inadequate sleep persisting up to 6 months after surgery (Casida et al, 2011).*
- Promote adoption of behaviors that ensure adequate amounts of sleep for all family members. See Nursing Interventions and *Rationales* for Readiness for enhanced **Sleep.**
- Teach family members ways to avoid chronic sleep loss. See Nursing Interventions and *Rationales* for Disturbed **Sleep** pattern.
- Advise against chronic use of caffeinated drinks to overcome daytime fatigue and drowsiness while focusing on elimination of factors that lead to chronic sleep loss. **CEB:** *In an integrative review of 26 controlled laboratory studies of adult subjects, caffeine was found helpful in the temporary management of sleepiness, but overuse and late-day use contributed to subsequent sleep disruption and caffeine habituation (Roehrs & Roth, 2008).*

Readiness for enhanced sleep

Judith Ann Floyd PhD, RN, FNAP, FAAN

NANDA-I

Definition

A pattern of natural, periodic suspension of relative consciousness to provide rest and sustain a desired lifestyle, which can be strengthened.

Defining Characteristics

Expresses desire to enhance sleep

NOC(Nursing Outcomes Classification)

Suggested NOC Outcomes

Personal Well-Being; Rest; Sleep

Example NOC Outcome with Indicators

Sleep as evidenced by the following indicators: Hours of sleep/Sleep pattern/Sleep quality/Sleep efficiency/Feels rejuvenated after sleep/Napping appropriate for age. (Rate each indicator of **Sleep:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Verbalize a current interest in what constitutes normal sleep
- Reflect on own experiences and beliefs about sleep
- Verbalize an interest in nonpharmacological approaches to sleep promotion
- Take concrete steps to establish an environment conducive to sleep initiation and maintenance

NIC(Nursing Interventions Classification)

Suggested NIC Intervention

Sleep Enhancement

Example NIC Activities—Sleep Enhancement

Assess client's sleep/activity pattern; Assist/encourage client to create an environment that facilitates sleep; Assist/encourage client to adopt personal practices that enhance sleep

Nursing Interventions and *Rationales*

• Assess client's current knowledge and beliefs about sleep need and factors affecting sleep quantity. **EB:** *In a descriptive study of 1707 subjects from nine primary care practices, assessment of knowledge and beliefs about sleep were identified as an essential first step in patient education programs (Phillips et al, 2014).* **EB:** *In an observational study of 229 subjects, false beliefs about sleep requirements were associated with sleep disorders (Cronlein et al, 2014).*
• Whenever there is a lack of knowledge or false beliefs about sleep requirements, provide information regarding sleep need and encourage clients to identify their personal sleep requirements. **CEB:** *In a meta-analysis (N = 180 studies), a nurse researcher found that normal-population adults averaged 7.5 to 9.0 hours of sleep per night (range of 6.5–10.0 hours) and fell asleep within 20 minutes initially and more quickly if awakened during the night; daytime was characterized by no naps or regularly scheduled brief naps, and little fatigue or sleepiness (Floyd, 2002).* **EB:** *In a review of research by a panel of 15 sleep experts, sleep need was found to be highly variable among adults, but 7 or more hours of sleep on a regular basis was found to promote optimal health and reduce risk of adverse health outcomes; it was unclear if averaging more than 9 hours was associated with health risk (Watson et al, 2015).*
• Based on assessment, focus on one or more of the following sleep hygiene strategies, choosing the most relevant. **EBN:** *An experimental study involving 40 community-based adults living with HIV/AIDS found that a sleep hygiene educational program focused on changing the interpersonal system was effective for changing beliefs and behavior and for improving sleep patterns (Webel et al, 2013).* **EBN:** *An experimental study of 79 college students with complaints of insomnia found that sleep hygiene strategies improved sleep (Lillehei et al, 2015). Sleep hygiene strategies include:*
    - ❍ Regular scheduling of the nighttime sleep period, daytime exposure to light, exercise, napping, and mealtimes characterized by (1) vigorous exercise during the day, (2) avoidance of long periods of daytime sleep (unless a night-shift worker), (3) avoidance of large meals before bed, and (4) arising at the same time each day even if sleep was poor during the previous night. *Experts have concluded that regular schedules of rest/activity and light/dark promote sleep initiation and sleep maintenance by maintaining a circadian rhythm of alertness/drowsiness (Gooneratne & Vitiello, 2014; Meltzer, Moreno, & Johnson, 2014).* **EB:** *An experimental study of 173 young adults suggested interactions among rest/activity, light/dark, sleep, and other physiological parameters (body temperature, blood pressure, and heart rate) are complex and require more study, but factors that suppress or stimulate melatonin secretion likely play a key role in circadian rhythm interactions (Gubin et al, 2017).*
    - ❍ Relaxing bedtime routine that includes (1) activities that calm the mind (e.g., mindfulness or other types of meditation, listening to music, prayer) and (2) activities that relax the body (e.g., warm baths, massage, progressive muscle relaxation). *Both mental and physical relaxation practices are believed to facilitate sleep initiation (Gooneratne & Vitiello, 2014; Meltzer, Moreno, & Johnson, 2014).* **EBN:** *A review of evidence from nine intervention studies suggested relaxation, meditation, guided imagery, or a combinations of these strategies resulted in better sleep and less fatigue in heart-failure patients (Kwekkeboom & Bratzke, 2016).*
    - ❍ *Oil of lavender.* **EBN:** *An experimental study of 79 college students with complaints of insomnia found that adding the scent of lavender to the sleep environment as part of a sleep hygiene program improved sleep duration beyond the improvements achieved by other hygiene practices (Lillehei et al, 2015).*

- ❍ Creation of an environment conducive to sleep including (1) comfortable sleepwear, sleep surface, and room temperature; (2) low or masked levels of light and noise; and (3) a sleep space as free as possible from interruptions from others including pets. *A quiet, dark, physically comfortable sleep setting free from interruptions is believed best for promoting sleep (Gooneratne & Vitiello, 2014; Meltzer, Moreno, & Johnson, 2014).* **CEB:** *In an experimental study of 122 sociodisadvantaged new mothers, nurse researchers found that sleep hygiene measures, including infant proximity, noise masking, and dim lighting, improved sleep quality during the postpartum period (Lee and Gay, 2011).*
- ❍ Management of any sources of pain as needed prior to sleep. **EB:** *In a national survey of 1029 noninstitutionalized adults aged 18 years or older, pain was associated with lower sleep quality, more sleep disruption, and greater sleep deprivation (National Sleep Foundation, 2015). (See further Nursing Interventions and* Rationales *for Acute* ***Pain*** *and Chronic* ***Pain.****)*
- ❍ Avoidance of late-day electronic device-use. **EB:** *A descriptive study of 1674 adults found participants with more screen time from TV watching and use of computers and other electronic devises reported more difficulty falling asleep and staying asleep (Vallance et al, 2015).* **EB:** *A representative survey of 1508 adults found that 90% of Americans used some type of electronics at least a few nights per week before bedtime and also found that adults who reported use of e-readers had reduced evening sleepiness, took longer to fall asleep, and reported reduced next-morning alertness compared with adults who read printed books at bedtime (Chang et al, 2015).*
- ❍ Monitoring of late-day intake of caffeine from all sources including energy drinks, coffee, colas, teas, and chocolate. *Many common beverages and foodstuffs contain large enough doses of caffeine to affect nighttime sleep (Gooneratne & Vitiello, 2014; Meltzer, Moreno, & Johnson, 2014).* **EB:** *In an experimental study (N = 12) researchers found that caffeine consumption (400 mg) up to 6 hours before bedtime had a disruptive effect on objectively measured and self-reported symptoms of insomnia (Drake et al, 2013).*
- ❍ Avoidance of alcoholic beverages to induce sleep. *Experts have concluded that alcoholic drinks before bed interfere with overall sleep quality (Gooneratne & Vitiello, 2014; Lenz, 2014).* **CEB:** *In a descriptive study of 50 oncology outpatients, nurse researchers found that limited alcohol use (one to two drinks) was related to shortened time to falling asleep and increased depth of sleep the first 2 hours, as well as suppressed rapid eye movement (REM) sleep, which sometimes led to REM rebound (i.e., lighter, more fragmented sleep later in the night) (Dean et al, 2010).*
- ❍ Avoidance of nicotine. *Experts have concluded that nicotine use interferes with overall sleep quality (Gooneratne & Vitiello, 2014; Lenz, 2014).* **CEB:** *In a national survey of 6400 participants, cigarette smokers took longer to fall asleep and had shorter and lighter nighttime sleep than nonsmokers; however, acute nicotine withdrawal caused even more sleep disruption (Zhang et al, 2006).*
- ❍ Avoidance of a sedentary lifestyle. **EB:** *In a national survey of 1000 representative adults aged 23 to 60, excessive sitting during waking hours was associated with poor sleep quality (Buman et al, 2015).*

Geriatric

- Interventions discussed previously can all be adapted for use with geriatric clients.
- Counsel the older client regarding normal age-related sleep changes. *Older adults*

may be unaware of which age-related sleep changes are typical versus symptoms of a sleep disorder (Gooneratne & Vitiello, 2014). **CEB:** *In a meta-analysis (N = 180 studies), a nurse researcher discovered that as adults aged, they increased time needed to fall asleep, increased the frequency and duration of waking after sleep onset, and decreased nighttime sleep amount (Floyd, 2002).*

- Elicit the older client's beliefs about sleep and correct any misconceptions, which may manifest as undue concern for some, but too little concern for others. *Experts have concluded that the older adult may be unduly concerned about normal age-related changes in sleep patterns (Gooneratne & Vitiello, 2014).* **EB:** *In a descriptive study comparing sleep beliefs and behaviors of 41 black and 24 white older women, the majority of women, regardless of race/ethnicity, incorrectly stated that poor sleep did not have negative effects on other health conditions (Grandner et al, 2013).*
- Review older client's prescription medications; use of over-the-counter (OTC) medications; and use of caffeine, tobacco, and alcohol. *Older adults may be unaware of how their medications and commonly used psychoactive substances affect sleep (Allen et al, 2013).* **EB:** *A double-blind cross-over study (N = 46) of adults in their fifties compared with young adults found caffeine interfered with initiation of deep sleep in all and that the older adults experienced even more sensitivity to caffeine intake than the younger adults (Robillard et al, 2015).*
- Assess and refer as appropriate if coexisting conditions may be affecting older client's sleep. *Depression, sleep apnea, and restless leg syndrome are commonly missed coexisting conditions in older adults (Allen et al, 2013; Gooneratne & Vitiello, 2014).*
- Expand older client's awareness of sleep hygiene behaviors for improving sleep. **EB:** *In a descriptive study of 195 older adults, only three strategies were heavily used by elders to address sleep concerns: ignoring the symptoms, staying in bed or resting, and praying (Sandberg et al, 2014).* **EBN:** *A meta-analysis of results from samples representing 5061 general-population adults showed a steady increase after age fifty in the amount of time spent in bed with the intent to sleep, which contributed to a steady decline in sleep efficiency with aging (Floyd, 2017).*
- Encourage the older client to walk and engage in other exercise outside unless contraindicated. *Experts have concluded that exercise and exposure to natural light reinforce circadian rhythms that control sleep (Gooneratne & Vitiello, 2014; Meltzer, Moreno, & Johnson, 2014).* **EB:** *In an evidence review of 34 research reports, exercise increased sleep efficiency and duration in healthy older adults regardless of the mode and intensity of activity, and even more so in the elderly with chronic conditions such as hypertension, obesity, diabetes, rheumatoid arthritis, or sleep disorders (Dolezal et al, 2017).*

Home Care

- All interventions discussed previously can be adapted for home care use.
- Assess family caregivers' readiness for enhancing sleep. **EB:** *A qualitative study of 12 people with dementia and their family caregivers found that family members need guidance with balancing their own sleep requirements with those of homecare recipients (Gibson, Gander, & Jones, 2014).* **EB:** *A secondary analysis of quantitative data from 395 family caregivers of hospice patients found nearly one-third experienced clinically noteworthy levels of sleep problems and/or anxiety that can interfere with sleep initiation (Washington et al, 2018).*
- Assess the conduciveness of the home environment for promoting both caregiver and client sleep and the resources needed to improve the sleep environment. **EB:** *A qualitative study of 12 people with dementia and their family caregivers found many factors in*

the home can promote or interfere with creating an environment conducive to sleep (Gibson et al, 2014). **CEB:** *In an experimental study of 122 sociodisadvantaged new mothers, nurse researchers found approximately two-thirds of homes incorporated sleep hygiene recommendations consistently over three months (Lee & Gay, 2011).*

Disturbed Sleep pattern

Judith Ann Floyd PhD, RN, FNAP, FAAN

NANDA-I

Definition

Time-limited awakenings due to external factors.

Defining Characteristics

Difficulty in daily functioning; difficulty initiating sleep; difficulty maintaining sleep state; dissatisfaction with sleep; feeling unrested; unintentional awakening

Related Factors

Disruption caused by sleep partner; environmental barrier; immobilization; insufficient privacy; nonrestorative sleep pattern

NOC(Nursing Outcomes Classification)

Suggested NOC Outcomes

Personal Well-Being; Rest; Sleep

Example NOC Outcome with Indicators

Sleep as evidenced by the following indicators: Hours of sleep/Sleep pattern/Sleep quality/Sleep efficiency/Feels rejuvenated after sleep. (Rate the outcome and indicators of **Sleep:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Verbalize plan to implement sleep promotion routines
- Maintain a regular schedule of sleep and waking
- Fall asleep without difficulty
- Remain asleep throughout the night
- Awaken naturally, feeling refreshed and is not fatigued during day

NIC(Nursing Interventions Classification)

Suggested NIC Intervention

Sleep Enhancement

Example NIC Activities—Sleep Enhancement

Determine external factors leading to sleep fragmentation; Reduce environmental disrupters of sleep

Nursing Interventions and *Rationales*

- Obtain a sleep history to identify (1) noise, temperature, and light levels in the sleep environment; (2) activities occurring in the sleep environment during hours of sleep including use of handheld technology; (3) number of times awakened during the sleep period; and (4) when during the sleep period, time is available for undisturbed sleep. **EBN:** *A qualitative study of hospital staff and patients (N = 24) showed environmental disturbances during hospitalization were caused by noise, light, and provision of care (Ding et al, 2017).* **EB:** *A descriptive study of environmental characteristics in a 12-bed rehabilitation unit found that average temperatures and noise levels were above the recommended levels, and abrupt increases of light and noise levels were high enough to cause sleep fragmentation (Yelden et al, 2015).*
- Negotiate use of handheld technology whenever clients have access to electronic devises in the care setting. **EB:** *A representative survey of 1508 adults found that that 90% of Americans used some type of electronics at least a few nights per week before bedtime and also found that adults who reported use of e-readers had reduced evening sleepiness, took longer to fall asleep, and reported reduced next-morning alertness compared with adults who read printed books at bedtime (Chang et al, 2015).*
- Keep environment quiet during sleep periods. **EB:** *Recorded intensive care unit (ICU) noise led to more fragmented sleep, less slow-wave (deep) sleep, more arousals, and more time awake when played during sleep (N = 17) (Perrson-Waye et al, 2013).* **EBN:** *An evidence review of 51 papers showed that noise remains a persistent disruption to sleep at night in hospitals and continues to register as a concern on patient satisfaction surveys (Fillary et al, 2015).*
- Consider masking hospital noise that cannot be eliminated. **CEB:** *In a systematic review of nine experimental studies, nurse researchers found that recorded natural sounds, music, and music videos were effective for masking noise in health care settings (Hellstrom, Fagerstrom, & Willman, 2011).*
- Offer earplugs when feasible. **EB:** *The English-language abstract of a foreign-language research paper reported better sleep when earplugs were used alone or with other sleep promoting interventions (N = 80) (Eliyasianfar et al, 2016).* **EBN:** *Results from an experimental study of patients in intensive care (N = 50) showed that perceptions of nighttime noise decreased significantly in patients who used earplugs (Hu et al, 2015).*
- Dim the lights during sleep periods. **EB:** *A sequential prestudy/poststudy (N = 171) found the number of awakenings decreased when monitored lighting levels were part of a multicomponent program to decrease sleep disruption in intensive care (Patel et al, 2014).*
- Offer eye covers when lighting cannot be dimmed. **EB:** *The English-language abstract of a foreign-language research paper reported that hospitalized cardiac care patients (N = 80) had better sleep when eye covers were used alone or with other sleep-promoting interventions (Eliyasianfar et al, 2016).* **EBN:** *A combination of nonpharmacological interventions that included eye covers was useful for promoting sleep in ICU adult patients (Hu et al, 2015).*
- Be aware that use of eye covers in intubated clients may lead to sensory deprivation and anxiety. **CEB:** *An experimental study of eye cover use in ICU patients (N = 18) reported less sleep fragmentation, but 72% of intubated patients refused eye covers or removed them prematurely because of restlessness (30%), discomfort (20%), or anxiety (11%) (Simons, van den Boogaard, & de Jager, 2012).*
- Consolidate essential care to provide the opportunity for uninterrupted sleep the first 3 to 4 hours of the sleep period. Follow with periods of 90 to 110 minutes

between interruptions. **CEB:** *In a meta-analysis using data from 159 studies a nurse researcher found that the deepest stages of sleep occurred during the first 3 to 4 hours of the sleep period followed by several 90- to 110-minute sleep cycles that consisted of increasingly lower percentages of deep sleep (Floyd, 2002).*

• If the client must be disturbed the first 3 to 4 hours of the sleep period, attempt to protect 90- to 110-minute blocks of time between awakenings. **CEB:** *In three studies of hospitalized patients, nurse researchers found that the high frequency of nocturnal care interactions left patients with no 90-minute blocks of uninterrupted time for sleep (Missildine, 2008; Missildine et al, 2010a,b).* **EB:** *In an experimental study that included protocols for consolidating care, the number of patient nights that contained a 3-hour window of uninterrupted sleep was increased (Patel et al, 2014).*

• Assess for medications and other stimulants that fragment sleep. Use caution when administering sleep medications. See Nursing Interventions and *Rationales* for **Insomnia.**

• Schedule newly ordered medications to avoid the need to wake the client the first few hours of the night. **CEB:** *A survey of sleep promotion protocols (N = 68) conducted by nurse researchers identified the need for nurses to plan ahead when initiating new medication regimens to help ensure uninterrupted sleep periods (Hofhuis et al, 2012).*

• Combine the previously mentioned interventions as feasible to create a sleep-promotion care bundle. **EBN:** *A combination of nonpharmacological interventions that included earplugs, eye covers, and relaxing music was useful for promoting sleep in ICU adult patients (Hu et al, 2015).* **EBN:** *A qualitative study of how experienced nurses promote sleep in hospitals (N = 8) identified use of a comprehensive set of cost-effective sleep-promoting measures that adapted the hospital environment for sleep and also reduced the use of sedative drugs (Salzmann-Erikson, Lagerqvist, & Pousette, 2016).*

Pediatric

• Assess use of nighttime texting and consider limiting as needed to protect sleep. **EBN:** *A study of 278 community-based teens found that sending and/or receiving text messages at night was significantly associated with later bedtimes, shorter time in bed, daytime tiredness, and irregular sleep habits (Garmy & Ward, 2017).*

• Adapt interventions for pediatric clients with caution because of limited empirical evidence regarding the effects of their use. **EB:** *A survey of 341 pediatric critical care providers worldwide found that use of earplugs, eye masks, noise reduction, and lighting optimization for sleep promotion was uncommon (Kudchadkar, Yaster, & Punjabi, 2014).* **EBN:** *During a focus-group study, nurses (N = 30) working on general and critical-care pediatric units identified several interrelated factors that create challenges to promoting children's sleep in hospitals and highlighted the need for formal policy and mentoring related to provision of nursing care at night in pediatric settings (Stremler, Adams, & Dryder-Palmer, 2015).*

Geriatric

• Most interventions discussed previously can all be adapted for use with geriatric clients.

• Use of earplugs and eye covers with ataxic clients and clients with dementia may contribute to disorientation. **CEB:** *A case report and integrative review of the literature suggested sensory deficits in patients with dementia, which can be augmented by use of earplugs and eye covers, decrease their quality of life, increase their risk for delirium and falls,*

and pose a higher risk for poor outcomes (Haque, Abdelrehman, & Alavi, 2012).

Multicultural

- Be aware that cultural sleep practices may alter the kinds of environmental sleep disruptors that require management. **CEB:** *As the result of an integrative review of the literature on family sleep practices, nurses found that bed sharing and other aspects of the sleep environment were influenced most by ethnic factors (Jain, Romack, & Jain, 2011).*

Home Care

- Consider the unique characteristics of each home sleep environment when addressing sleep disruption. **EBN:** *A longitudinal study of postpartum women (N = 142) showed that new mothers' sleep was disturbed 56% of the time by their infant's cries, but other environmental disrupters included (1) family, friends, and pets in the home; (2) sleeping with the television on; (3) traffic sounds; and (4) other outside noise from neighbors (Doering, 2013).*
- In addition, see the Home Care section of Nursing Interventions and *Rationales* for Readiness for enhanced **Sleep**.

Impaired Social interaction

Marina Martinez-Kratz MS, RN, CNE

NANDA-I

Definition

Insufficient or excessive quantity or ineffective quality of social exchange.

Defining Characteristics

Discomfort in social situations; dissatisfaction with social engagement; dysfunctional interaction with others; family reports change in interaction; impaired social functioning

Related Factors

Communication barrier; disturbance in self-concept; disturbance in thought process; environmental barrier; impaired mobility; insufficient knowledge about how to enhance mutuality; insufficient skills to enhance mutuality; sociocultural dissonance

At-Risk Population

Absence of significant other

Associated Condition

Therapeutic isolation

NOC(Nursing Outcomes Classification)

Suggested NOC Outcomes

Child Development: Middle Childhood, Adolescence; Play Participation; Role Performance; Social Interaction Skills; Social Involvement

Example NOC Outcome with Indicators

Social Involvement as evidenced by the following indicator: Interacts with close friends, neighbors, family members, and members of work groups. (Rate the outcome and indicators of **Social Involvement:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Identify barriers that cause impaired social interactions
- Discuss feelings that accompany impaired and successful social interactions
- Use available opportunities to practice interactions
- Use successful social interaction behaviors
- Report increased comfort in social situations
- Communicate, state feelings of belonging, demonstrate caring and interest in others
- Report effective interactions with others

NIC(Nursing Interventions Classification)

Suggested NIC Intervention

Socialization Enhancement

Example NIC Activities—Socialization Enhancement

Encourage patience in developing relationships; Help client increase awareness of strengths and limitations in communicating with others

Nursing Interventions and *Rationales*

- Monitor the client's use of defense mechanisms and support healthy defenses (e.g., the client focuses on the present and avoids placing blame on others for personal behavior). **CEBN:** *Solution-focused techniques have been demonstrated to be beneficial. Therapy focuses on the client's present and future, capitalizing on the strengths and resources of the client and significant others around them (Wand, 2010).*
- Encourage the client to keep a gratitude journal. **EB:** *A recent study demonstrated that study participants who participated in a gratitude journal intervention experienced more positive emotions during the social interactions (Drążkowski, Kaczmarek, & Kashdan, 2017).*
- Encourage dancing with Parkinson's programs for individuals with Parkinson's disease. **EB:** *Research demonstrated that dance programs provide opportunities for social interaction and nonverbal communication (Bognar et al., 2017).*
- Model appropriate social interactions and use focused imitation interventions. Give positive verbal and nonverbal feedback for appropriate behavior (e.g., make statements such as, "I'm proud that you made it to work on time and did all the tasks assigned to you"; make eye contact). If not contraindicated, touch the client's arm or hand when speaking. **CEBN:** *Use of focused imitation interventions improved social functioning in children with autism spectrum disorders (ASDs) (Ingersoll, 2012).*
- Consider use of social cognition and interaction training (SCIT) combined with social mentoring to improve social functioning. **EB:** *A randomized controlled trial using SCIT and social mentoring demonstrated improved social cognition and social functioning in individuals with severe mental illness living in the community (Hasson-Ohayon et al, 2014).*
- Consider use of animal-assisted therapy (AAT). **EB:** *An AAT-treatment group showed improvement in negative symptoms of schizophrenia such as apathy, asociality, anhedonia, and alogia (Calvo et al., 2016).*
- Refer client for social cognition training to increase social skills. **EB:** *Social cognition training using targeted programs are most effective at improving social functioning in clients with a diagnosis of psychosis or schizophrenia (Henderson, 2013).*
- Refer rehabilitation clients for assistive technologies to increase therapeutic

engagement and promote social engagement. **EB:** *Rehabilitation clients' desire to use mainstream technologies (cell phones, tablets, and computers) underscores the need for accessible options that will provide opportunities to engage in therapeutically meaningful activities and promote social interaction (Fager & Burnfield, 2014).*
• Refer to care plans for Risk for **Loneliness** and **Social** isolation for additional interventions.

Pediatric

• Provide supervised interaction opportunities for children of chronically ill parents. **EBN:** *Research has identified that social isolation is a challenge for children with parents who experience chronic disabling pain (Umberger, Risko, & Covington, 2015).*
• Encourage family style dining (FSD) for preschool children to promote social interactions during mealtimes. **EB:** *The current study showed that rates of interactions were increased during FSD (Lochetta, Barton, & Kaiser, 2017).*
• Use peer-mediated interaction (PMI) to increase social interactions of children on the autistic spectrum. **EB:** *A review of studies showed that PMI was an effective intervention to increase social interaction intervention for promoting social interaction between students with ASD and their peers (Watkins et al., 2015).*
• Provide computers and Internet access to children with chronic disabilities that limit socialization. **EB:** *Children with autism showed more active other-awareness using technology with a supportive interface and when collaborating with a peer (Holt & Yuill, 2014).*
▲ Refer children with autism for family-centered music therapy (FCMT). **EB:** *Research demonstrated that family participation in FCMT improved social interactions in the home and community and the parent–child relationship (Thompson, McFerran, & Gold, 2014).*
• Consider the use of animal-assisted activities for children on the autistic spectrum. **EB:** *Research demonstrated significant improvements in social functioning and decreases in social withdrawal behaviors after 8 weeks of animal exposure in a school classroom in addition to 16 20-minute animal-interaction sessions (O'Haire et al, 2014).*

Geriatric

• Assess for depression in clients with impaired social functioning. **EB:** *Research shows higher depressive symptoms were associated with smaller numbers of close, inner circle relationships (Shouse, Rowe, & Mast, 2013).*
• Assess older clients for hearing loss and refer for hearing aids as needed. **EB:** *A recent study demonstrated that hearing aid fitting was associated with a subsequent improvement in older person-specific quality of life (Yamada, Švejdíková, & Kisvetrová, 2017).*
• Assess the communication patterns of clients with verbal domain problems for enactment strategies, paralinguistic features, and nonvocal communication. **EBN:** *Research has demonstrated that clients with semantic dementia spontaneously use enactment (acting out scenes), paralinguistic features (pitch and volume of tone), and nonvocal communication (e.g., body posture, pointing, facial expression) to compensate for loss of verbal abilities (Kindell et al, 2013).*
• Encourage socialization through physical activity and meaningful activities incorporated into normal daily care practices. **EB:** *The current study shows that when activities are performed, residents of a green care farm were more engaged and had more social interaction (de Boer et al., 2017).*
• Provide live concert music for clients with dementia. **EB:** *A recent study showed that*

clients with mild to midstage dementia had increased levels of cooperation, interaction, and conversation after a live music concert (Shibazaki & Marshall, 2015).

▲ Refer depressed clients to services for cognitive-behavioral therapy (CBT). **EB:** *A systematic review indicated that CBT was likely to be efficacious for depression and accompanying symptoms such as impaired social functioning in older people (Jayasekara et al, 2015).*

• Refer to care plans for **Frail Elderly** syndrome, Risk for **Loneliness,** and **Social** isolation for additional interventions.

Multicultural

• Approach individuals of color with respect, warmth, and professional courtesy. **EBN:** *To provide client- and family-centered care, nurses must acknowledge their cultural differences, be willing to incorporate their beliefs within the health care treatment plan, and respect their values and lifeways of differing cultures (Hart & Mareno, 2015).*

• Use interpreters as needed. **EB:** *Primary care nurses act as gatekeepers to interpreting services (McCarthy et al, 2013).*

• Refer to care plan for **Social** isolation for additional interventions.

Home Care

• Previously discussed interventions may be adapted for home care use.

Client/Family Teaching and Discharge Planning

• Previously discussed interventions may be adapted for client/family teaching and discharge planning.

Social isolation

Julianne E. Doubet BSN, RN, EMT-B

NANDA-I

Definition

Aloneness experienced by the individual and perceived as imposed by others and as a negative or threatening state.

Defining Characteristics

Absence of support system; aloneness imposed by others; cultural incongruence; desire to be alone; development delay; disabling condition; feeling different from others; flat affect; history of rejection; hostility; illness; inability to meet expectations of others; insecurity in public; meaningless actions; member of a subculture; poor eye contact; preoccupation with own thoughts; purposelessness; repetitive actions; sad affect; values incongruent with cultural norms; withdrawn

Related Factors

Developmentally inappropriate interests; difficulty establishing relationships; inability to engage in satisfying personal relationships; insufficient personal resources; social behavior incongruent with norms; values incongruent with cultural norms

Associated Condition

Alteration in mental status; alteration in physical appearance; alteration in wellness

NOC(Nursing Outcomes Classification)

Suggested NOC Outcomes

Loneliness Severity; Mood Equilibrium; Personal Well-Being; Play Participation; Social Anxiety Level; Social Interaction Skills; Social Involvement; Social Support

Example NOC Outcome with Indicators

Social Involvement as evidenced by the following indicator: Interacts with close friends, neighbors, family members, and members of work groups. (Rate the outcome and indicators of **Social Involvement:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Identify feelings of isolation
- Practice social and communication skills needed to interact with others
- Initiate interactions with others; set and meet goals
- Participate in activities and programs at level of ability and desire
- Describe feelings of self-worth

NIC(Nursing Interventions Classification)

Suggested NIC Intervention

Socialization Enhancement

Example NIC Activities—Socialization Enhancement

Encourage patience in developing relationships; Help patient increase awareness of strengths and limitations in communicating with others

Nursing Interventions and *Rationales*

- Establish a therapeutic relationship with the client. **EBN:** *In her study, Skingley (2013) suggested that many of the circumstances that contribute to social isolation are amendable and that the community nurse is in the position to affect changes.*
- Observe for barriers to social interaction. **EBN:** *A study by Drury (2014) stated that social isolation can be measured by objective indicators, such as the client's social network, his or her participation in community activities, and by subjective indicators, including a client's self-rating of loneliness and perception of support.*
- Discuss/assess causes of perceived or actual isolation. **EBN:** *Some variables that were recognized by Nicholson, Dixon, and McCorkle (2014) as precursors to diminished social interaction included severe health problems, symptoms of depression, smoking, and decreased religious participation.*
- Allow the client opportunities to describe his or her daily life and to introduce any issues that may be of concern. **EBN:** *McDonald (2014) surmised that the biggest problem in health care today is lack of communication skills, which can then be related to poor client outcome, and maintained that the nurse of today must be proficient in effective communication.*
- Promote social interactions. **EB:** *Positive social interactions may act as a basis for the client to establish new social group relationships (Cruwys et al, 2014).*
- Assist the client in identifying specific health and social problems and involve him

or her in their resolution. **EBN:** *Pearce (2013) maintained that interventions customized to fit a client's disorganized lifestyle reduced his or her social isolation.*

• Assist the client in identifying activities that encourage socialization. **EB:** *According to this study, the sooner the older client is supported in mobility and social participation, the sooner he or she will be able to experience a sense of well-being and lessening of the feelings of social isolation (Elbasan et al, 2013).*

• Identify available support systems and involve those individuals in the client's care. **EBN:** *According to Mattila et al (2014), nurse support of clients and their families is effective in establishing a positive outlook, mental well-being, and thoughts of getting well.* **EB:** *"Clinicians should be aware of social isolation and loneliness in late life and discuss nonpharmacological treatment options with their aging patients" (Canham, 2014).*

▲ Refer clients and caregivers to support groups as necessary. **EB:** *Caring for a family member who is physically and/or mentally challenged can be a drain on caregivers, causing a negative effect both on the client and the caregiver: effective outside assistance might be a factor in modifying the challenges confronted by these families (Thompson et al, 2014).*

• Encourage interactions with others with similar interests. **EBN:** *According to this research study, a community integrative therapy program will allow those involved to form new relationships, gather emotional support, reinforce ties, and reduce social isolation (da Roche et al, 2013).*

• See the care plan for Risk for **Loneliness.**

Pediatric

▲ Refer obese adolescents for diet, exercise, and psychosocial support. **EB:** *Nesbit et al (2014) suggested that to combat adolescent obesity interventions should target sedentary behavior and promote the increase of physical activity. Interventions should also address parental concerns about neighborhood safety and access to safe areas for physical activity development.* **EBN:** *This study found that family meals two to three times per week during adolescence are an important factor in preventing obesity in young adulthood (Berge et al, 2015).*

▲ Assess socially isolated adolescents. Refer to appropriate rehabilitation programs as needed. **EB:** *A study by Plaiser and Konijn (2013) implied that both peers and media have a firm influence on adolescents and that peer rejection may be why adolescents turn to antisocial media content.*

Geriatric

▲ Assess physical and mental status to establish an early baseline for referring at-risk individuals to community resources. **CBE:** *In this study, Nicholson (2012) stated that health professionals can take measures that will allow early detection of social isolation in at-risk, older clients and match them to suitable community resources; this may serve to prevent negative health outcomes.* **EB:** *Older individuals should be routinely screened for depression because it may be a crucial factor in giving rise to later social isolation (Pritchard et al, 2014).*

• Assess for hearing. **EB:** *It is well documented that hearing loss is common in older adults; it is also considered a known factor in the cause of social isolation, depression, and dementia (Genther et al, 2014).*

• Involve client in planning activities. **EBN:** *According to Drury (2014), programs for the socially isolated should be planned and coordinated with contributions from various community groups and those of the recipients.*

• Involve nonprofessionals in activities and projects with the client. **EB:** *Pettigrew et al*

(2014) wrote that both group activities and a focused approach to those clients who are at risk for social isolation may be the way to manage the problem.

• Suggest varied social activities that would decrease isolation and encourage participation. **EB:** *Leisure activities can play a significant part in an older person's social life and improve their quality of life; these could include volunteer work, cultural activities, sports, reading books, hobbies, and shopping (Toepoel, 2013).*

▲ Consider the use of simulated presence therapy (see the care plan for **Hopelessness**). **EB:** *Obdrzalek et al (2013) promoted an automated exercise coaching system for older adults living in assisted homes: this technique is designed to allow remote interaction with a coach and to strengthen the social aspects of exercise.*

• Consider using computers and the Internet to alleviate or reduce loneliness and social isolation. **EB:** *The use of technology that is tailored to older people may aid in better self-management of health conditions; thus it may produce an increased improvement in social connectedness (Morris et al, 2014).*

Multicultural

• Acknowledge racial/ethnic differences at the onset of care. **EB:** *Every client has a unique culture that has many aspects, is vibrant, and cannot be labeled by race or language group (Hawes & Viera, 2014).*

• Assess for the influence of cultural beliefs, norms, values, and the client's personal cultural needs. **EBN:** *Culturally responsive caregiver involvement is necessary to make certain that people of culturally and linguistically dissimilar backgrounds have the proper skills to self-manage their multifaceted medical conditions (Williams et al, 2014).*

• Use a culturally competent, professional approach when working with clients of various ethnic groups. **EBN:** *Today's professional nurse must be aware of the role of cultural competency and cultural safety in his or her practice (Rowan et al, 2013).*

• Promote a sense of ethnic attachment. **EB:** *According to Enguidanos et al (2014), there is a need for client-centered intervention and prevention standards that incorporate the client's cultural background, health care requirements, and individual preferences.*

• Assess the client's feelings regarding social isolation. **EBN:** *Feelings that contribute to the client's perception of social isolation may include loneliness, anger, fear, despair, and sadness (Hadi & Hadi, 2017).*

• Assist those ethnic minorities who are underserved to access essential health care. **EBN:** *Jeffreys and Dogan (2013) maintained that a comprehensive nursing assessment is the first step necessary in providing culturally specialized care, recognition of high-risk groups, and reduction of health care inequality.* **EBN:** *According to Waite, Nardi, and Killian (2014), it is vital that clinicians recognize the necessity of cultural competence in their practice to both improve and maintain health care for their clients.*

Home Care

• The interventions described previously may be adapted for home care use.

• Confirm that the home setting has health-safety systems in place. **EB:** *The medical and safety goals for older adults should be taken into account when redesigning an approach for home care delivery (Depuccio & Hoff, 2014).*

• Consider the use of the computer and Internet to decrease isolation social interaction. **EBN:** *A study by Culley et al (2013) illustrated the ability of technology to develop connectedness and diminish the feeling of isolation in community-dwelling older adults.*

• Assess options for living that allow the client privacy but not isolation. **EBN:** *Rulliere (2014) explained that a person's dignity and privacy must be preserved, regardless of his or her cognitive ability, not only when receiving nursing care but also in all phases of life.*
• Assist clients to interact with neighbors in the community when they move to supported housing. **EB:** *Those clients transferring to supported housing will be placed in an unfamiliar environment that necessitates the need to develop skills to successfully adapt to their new surroundings (Kirchen & Hersch, 2015).*

Client/Family Teaching and Discharge Planning

• Assist the client in initiating contacts with self-help groups, counselors, and therapists. **EBN:** *Seebohm et al (2013) advised, as a result of their study, that policy-makers might partner with the local population to provide support for diverse types of residents to facilitate their own self-help/mutual aid groups.*
• Provide information to the client about senior citizen services and community resources. **EB:** *Senior centers are excellent locations to deliver evidence-based health support programs that will bolster this rapidly growing age group in remaining healthy and independent (Felix et al, 2014).*
• Refer socially isolated caregivers to appropriate support groups. **EBN:** *Eriksson, Sandberg, and Hellstrom (2013) maintained that woman who are 24/7 caregivers need choices that can be recommended by health care professionals who will not disregard their ethical concerns.*
• See the care plan for **Caregiver Role Strain**.

Chronic Sorrow

Tracy P. George DNP, APRN-BC, CNE

NANDA-I

Definition

Cyclical, recurring, and potentially progressive pattern of pervasive sadness experienced (by parent, caregiver, individual with chronic illness or disability) in response to continual loss throughout the trajectory of an illness or disability.

Defining Characteristics

Feeling that interferes with well-being; overwhelming negative feelings; sadness

Related Factors
Crisis in disability management; crisis in illness management; missed milestones; missed opportunities

At-Risk Population
Death of significant other; developmental crisis; length of time as a caregiver

Associated Condition
Chronic disability; chronic illness

NOC(Nursing Outcomes Classification)

Suggested NOC Outcomes
Acceptance: Health Status; Depression Level; Depression Self-Control; Grief Resolution; Hope; Mood Equilibrium

Example NOC Outcome with Indicators
Grief Resolution with plans for a positive future as evidenced by the following indicators: Describes meaning of loss or death/Reports decreased preoccupation with loss/Reports adequate nutritional intake/Reports adequate sleep/Expresses positive expectations about the future. (Rate the outcome and indicators of **Grief Resolution:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Express appropriate feelings of guilt, fear, anger, or sadness
- Identify problems associated with sorrow (e.g., changes in appetite, insomnia, nightmares, loss of libido, decreased energy, alteration in activity levels)
- Seek help in dealing with grief-associated problems
- Plan for the future one day at a time
- Function at normal developmental level

NIC(Nursing Interventions Classification)

Suggested NIC Interventions
Grief Work Facilitation; Grief Work Facilitation: Perinatal Death

Example NIC Activities—Grief Work Facilitation
Encourage client to verbalize memories of loss, both past and current; Assist client in identifying personal coping strategies

Nursing Interventions and *Rationales*

- Determine the client's degree of sorrow. **EBN:** *Use the Adapted Burke Questionnaire for the individual or caregiver, which assesses eight mood states including grief, shock, anger, disbelief, sadness, hopelessness, fear, and guilt on a four-point scale (Whittingham et al, 2013).*
- Assess for the four discrete stages of grieving in chronic obstructive pulmonary disease (COPD) clients. **EB:** *The four stages of grief for clients with COPD can be assessed by the Acceptance of Disease and Impairments Questionnaire (Boer et al, 2014).*
- Provide coping strategies for caregivers who may experience chronic sorrow. **EBN:** *Coping strategies for the caregivers of clients with schizophrenia may include discussing their feelings about the situation with others, reading, praying, being physically active; emotional*

*strategies such as crying; and cognitive strategies such as thinking positively about the situation (Olwit et al, 2015). See care plan for **Caregiver Role Strain**.*

• Assess clients for chronic sorrow and provide them with coping strategies. **CEB:** *Clients who come to the emergency department frequently may be at an increased risk for chronic sorrow (Joseph, 2012).*

• Develop a trusting relationship to care for clients with chronic sorrow. **EBN:** *Creating rapport and a close connection is helpful when caring for clients experiencing chronic sorrow (Johnson, 2015).* **EBN:** *Nurses should offer compassion, empathy, consideration, and knowledge to those experiencing chronic sorrow (Glenn, 2015).*

• Help the client understand that sorrow may be ongoing. **CEB:** *Studies have demonstrated that feelings of sadness, guilt, anger, frustration, and fear occur periodically throughout the lives of people experiencing chronic loss, resulting in chronic sorrow (Isaksson & Ahlström, 2008).*

• Urge the client to use positive coping techniques:

- ❍ **EBN:** *Encourage the client to participate in a support group, talk with others, or communicate via an online support group (Vitale & Falco, 2014).* **EBN:** *Support groups, counseling, and participating in activities are strategies that can be used with clients who are experiencing chronic sorrow (Marcella-Brienza, 2015).*
- ❍ **EBN:** *Encourage the client to engage in a hobby or physical activity (Vitale & Falco, 2014).*
- ❍ **EBN:** *Encourage the client to think positively about the situation (Vitale & Falco, 2014).*
- ❍ **EBN:** *Encourage the client to discuss his or her situation with a provider, such as a nurse, physician, or social worker (Vitale & Falco, 2014).*
- ❍ **EBN:** *Discuss the need for the client to anticipate triggers that may increase chronic sorrow (Vitale & Falco, 2014).* **EB:** *Triggers for parents of children with cerebral palsy may include times in which there is awareness of the actual versus expected achievements of the child or during times of medical intervention (Whittingham et al, 2013).*
- ❍ **EB:** *Refer for professional counseling if needed (Hottensen, 2013).*

▲ Refer the client for mental health services if needed. **EB:** *There may be an increase in depression among patients with chronic sorrow, so the nurse may need to refer the patient for mental health care (Ghesquiere et al, 2016).*

- ❍ Refer clients for financial assistance if needed. **EB:** *Bereavement may be associated with financial burdens caused by the loss of income (Ghesquiere et al, 2016).*

Pediatric

• Encourage the parents of children with uncommon diseases to use online resources to manage their chronic sorrow. **EBN:** *In a study of 16 mothers of children with a rare disease, online communication was used effectively to manage chronic sorrow (Glenn, 2015).*

• Educate parents that an increase in chronic sorrow can occur after stressful events. **EB:** *An increase in chronic sorrow was noted in parents with children who have cerebral palsy after triggering events, indicating that recurring grieving can occur after the diagnosis is made. Triggers can include when the child would have met a developmental milestone or started school (Whittingham et al, 2013).*

• Nurses should assess for chronic sorrow and discuss coping strategies for parents of children who have been in the neonatal intensive care unit (NICU). **EBN:** *Chronic sorrow is a useful framework for families affected by a NICU stay (Vitale & Falco, 2014).*

• Allow children the opportunity to talk about the impending death of a parent or loved one. **CEB:** *In a qualitative study of seven children whose parent was dying, children often were not encouraged to discuss their feelings, and they developed anxiety and ways to deal with the stress (Buchwald, Delmar, & Schantz-Laursen, 2012).*
• Encourage parents to listen to their child's expression of grief. **EB:** *It is important for parents whose child is grieving to listen to their child's concerns and create a balance between making new memories while holding onto the old memories (Bugge et al, 2014).*
• Educate parents that children may grieve differently than adults. **EB:** *Children may grieve intermittently for short periods of time in "grief puddles," certain children may grieve at each developmental stage, and some children may try to console their parents instead of going through the grieving process themselves (Gao & Slaven, 2017).*
▲ Refer grieving children to peer support groups. **EB:** *Peer support groups with other children who are grieving are important for children with chronic sorrow (Gao & Slaven, 2017).*
• Encourage children experiencing grief to participate in bereavement activities and camps. **EB:** *In children who participated in a ropes course as activities-based counseling during bereavement camp, five themes were noted: grief as a process, expression of feelings, support, coping, and empowerment and hope (Swank, 2013).*
• Encourage children who are grieving to participate in other forms of therapy, in addition to individual counseling and psychotherapy. **EB:** *Art therapy, play therapy, music therapy, and bibliotherapy are useful for children with chronic sorrow (Gao & Slaven, 2017).*
• Help the adolescent with chronic sorrow determine sources of support and refer for counseling if needed**. EB:** *Cognitive-behavioral therapy along with parental counseling has been useful in adolescents who experience prolonged grief (Spuij, Dekovic, & Boelen, 2015).*
• Provide family-centered care to parents of children with disabilities, and encourage parents to attend support groups. **EB:** *Caring for a child with cerebral palsy affects the quality of life for families and is related to anticipatory grieving among parents (Al-Gamal, 2013).*
• Encourage parents with chronic sorrow to participate in an online support group and learn coping strategies. **EB:** *Online bereavement support groups for parents who have lost children can be a convenient and anonymous way to obtain coping support (Elder & Burke, 2015).*
• Recognize that mothers who have a miscarriage or lose an infant often grieve and experience sorrow. **EB:** *Telephone hotlines staffed 24-hours a day by peer volunteers can be an effective way to provide support for women who have experienced the loss of a pregnancy (Boyle et al, 2015).* **EBN:** *It is important for providers to offer compassionate care to women after the loss of an infant (McGuinness, Coughlan, & Power, 2014).*

Geriatric

• Identify previous losses and assess the client for depression. **EB:** *Bereavement may result in major depression in some older adults, and participation support groups can be helpful in depression management (Ghesquiere, Shear, & Duan, 2013).*
• Evaluate the social support system of the older client and refer for bereavement counseling if needed. **EB:** *In a study of 28 geriatric clients who had recently experienced a death, older adults often used family and friends as a support network after death, but community-based organizations also play an important role in bereavement support (Bellamy et al, 2014).*

Home Care

- In-home bereavement follow-up by nurses should be considered if available. **EBN:** *In Australia, home health nurses provide bereavement visits in which they provide comfort, counseling, client education, and encouragement and also evaluate the client who has recently experienced a loss (Brownhill et al, 2013).*
- Assess the client for depression and refer for mental health services if appropriate. **EB:** *Clients experiencing bereavement are at risk for depression, so assessing for depression is necessary (Ghesquiere, Shear, & Duan, 2013).*
- Encourage the client to participate in activities that are diversionary and uplifting as tolerated (e.g., outdoor activities, hobby groups, church-related activities, pet care). **EBN:** *Diversionary activities decrease the time spent in sorrow, can give meaning to life, and provide a sense of well-being (Vitale & Falso, 2014).*
- Encourage the client to participate in support groups appropriate to the area of loss or illness. **EBN:** *Support groups can increase an individual's sense of belonging (Vitale & Falco, 2014).*
- Provide empathetic communication for family/caregivers. **EB:** *Nurses should offer compassion and empathy to those experiencing chronic sorrow (Glenn, 2015).*
- The interventions described previously may be adapted for home care use.
- See the care plans for Chronic low **Self-Esteem**, Risk for **Loneliness,** and **Hopelessness.**

Spiritual distress

Barbara Baele Vincensi PhD, RN, FNP, Elizabeth Burkhart PhD, RN, ANEF

NANDA-I

Definition

A state of suffering related to the impaired ability to experience meaning in life through connections with self, others, the world, or a superior being.

Defining Characteristics

Connections to Self

Anger; decrease in serenity; feeling unloved; guilt; inadequate acceptance; ineffective coping strategies; insufficient courage; perceived insufficient meaning in life

Connections with Others

Alienation; refuses to interact with spiritual leader; refuses to interact with significant other; separation from support system

Connections with Art, Music, Literature, Nature

Decrease in expression of previous pattern of creativity; disinterest in nature; disinterest in reading spiritual literature

Connections with Power Greater Than Oneself

Anger toward power greater than self; feeling abandoned; hopelessness; inability for introspection; inability to experience the transcendent; inability to participate in religious activities; inability to pray; perceived suffering; request for a spiritual leader; sudden change in spiritual practice

Related Factors

Anxiety; barrier to experiencing love; change in religious ritual; change in spiritual practice; cultural conflict; depression; environmental change; inability to forgive; increasing dependence on another; ineffective relationships; loneliness; low self-esteem; pain; perception of having unfinished business; self-alienation; separation from support system; social alienation; sociocultural deprivation; stressors; substance misuse

At-Risk Population

Aging; birth of a child; death of significant other; exposure to death; exposure to natural disaster; life transition; loss; racial conflict; receiving bad news; unexpected life event

Associated Condition

Actively dying; chronic illness; illness; imminent death; loss of body part; loss of function of a body part;

physical illness; treatment regimen

NOC(Nursing Outcomes Classification)

Suggested NOC Outcomes

Coping; Dignified Life Closure; Grief Resolution; Hope; Spiritual Health; Stress Level

Example NOC Outcome with Indicators

Spiritual Health as evidenced by the following indicators: Quality of faith, hope, meaning, and purpose in life/Connectedness with inner-self and with others to share thoughts, feelings, and beliefs. (Rate each indicator of **Spiritual Health:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Express meaning and purpose in life
- Express sense of hope in the future
- Express sense of connectedness with self
- Express sense of connectedness with family/friends
- Express ability to forgive
- Express acceptance of health status
- Find meaning in relationships with others
- Find meaning in relationship with Higher Power
- Find meaning in personal and health care treatment choices

NIC(Nursing Interventions Classification)

Suggested NIC Interventions

Active Listening, Forgiveness Facilitation, Grief Work Facilitation, Hope Inspiration, Humor, Music Therapy, Presence, Referral, Reminiscence Therapy, Self-Awareness Enhancement, Simple Guided Imagery, Simple Massage, Simple Relaxation Therapy, Spiritual Support, Therapeutic Touch, Touch

Example NIC Activities—Spiritual Support

Encourage use of spiritual resources if desired; Be available to listen to client's feelings

Nursing Interventions and *Rationales*

- Observe clients for cues indicating difficulties in finding meaning, purpose, or hope in life. **EB:** *In a correlational study of 132 participants with American Heart Association (AHA)/American College of Cardiology (ACC) classification of stage B heart failure, Mills et al (2015) found that spiritual well-being was associated with fewer depressive episodes, especially when focusing on increasing meaning and peace in patient's lives.* **EB:** *In a state of the science consensus report, spirituality included meaning and peace, hope, forgiveness, and gratitude (Steinhauser et al, 2017).*
- Observe clients with chronic illness, poor prognosis, or life-changing conditions for loss of meaning, purpose, and hope in life. **EBN:** *In a clinical validation study using logistic regression, Caldeira, Carvalho, and Vieira (2014) were able to identify significant correlations between patient variables of lower education levels and previous treatment with antidepressants, to the presence of spiritual distress in the 45 study participants of elderly cancer patients.*

• Promote a sense of love, caring, and compassion in nursing encounters. **EBN:** *In a cross-sectional, descriptive study of 202 cognitively intact nursing home residents, the nurse–patient interaction had a significant effect on the development of meaning in life, hope, and self-transcendence, potentially promoting health and well-being in this population (Haugan et al, 2014).*
• Be physically present and actively listen to the client. **EBN:** *In a cross-sectional correlational study by Haugan et al (2014), nurses were found to facilitate both interpersonal and intrapersonal transcendence for long-term nursing home residents by their presence and by encouraging connections with oneself and others in meaningful ways.*
• Help the client find a reason for living, be available for support, and promote hope. **EBN:** *A cross-sectional descriptive study in 44 different nursing homes found nurse–resident interaction was a resource for hope, meaning in life, and self-transcendence for residents (Haugan et al, 2014). Listen to the client's feelings about suffering and/or death. Be nonjudgmental and allow time for grieving.* **EB:** *Swinton et al (2017) conducted 208 semistructured interviews with 70 dying patients, 76 family members, and 150 health care providers in an intensive care unit (ICU) to describe how spirituality was expressed during the dying process. The outcome was the development of a program to support the expressions of spirituality during the dying process (i.e., peace, connections, spiritually enhanced environments, and specific expressions of spirituality).*
• Respect the client's beliefs; avoid imposing your own spiritual beliefs on the client. Be aware of your own belief systems and accept the client's spirituality. **EB:** *In a state of the science consensus report, spirituality is not a monoism phenomenon but is holistic and infuses all aspects of being human and requires honoring individuality, promoting conversations, and capturing the breadth of experience (Steinhauser et al, 2017).*
• Monitor and promote supportive social contacts. **EB:** *In a meta-analytic review, Sherman et al (2015) found that those with greater spiritual and religious involvement have a greater ability to maintain satisfying social roles and relationships in individuals with cancer.*
• Integrate and assist family in searching for meaning in the client's health care situation. **EB:** *A scoping review indicated spirituality and spiritual practices can support resilience and coping with life-altering conditions, including spinal cord injury (Jones et al, 2015) and palliative care (Balboni et al, 2017).*
• Offer spiritual support to family and caregivers. **EB:** *In a state of the science report, patients and families who experience serious illness have spiritual needs (Balboni et al, 2017).*
• *Screen for spiritual needs and if a need arises, offer chaplain referral.* **EB:** *In a state of the science report, spiritual screening is an initial assessment for spiritual need, whereas chaplains provide a more in-depth assessment (Balboni et al, 2017).*
• Support mind–body interventions (e.g., meditation, guided imagery, relaxation, massage). Support outdoor activities. **EB:** *In a state of the science report, mind–body interventions are encouraged to promote spiritual healing (Balboni et al, 2017).*
• Encourage journaling. **EB:** *In a scoping review, Jones et al (2015) found use of narratives helpful in coping with spinal cord injury.* **EB:** *In a state of the science report, journaling was a spiritual care intervention (Balboni et al, 2017).*
• Provide privacy or a "sacred space." **EB:** *In a state of the science report, meditation and life review were spiritual care interventions that may require privacy (Balboni et al, 2017).*
• Integrate spiritual care in interprofessional palliative care teams. **EB:** *A state of the science report indicated that multidisciplinary palliative care teams incorporate a spiritual care component (Balboni et al, 2017).*
• Encourage life review at end of life, including recalling, evaluating, and integrating life experiences. **EB:** *A state of the science report indicated that life review enhanced a personal sense of legacy and promoted dignity when facing terminal illness (Balboni et al,*

2017).

Geriatric

- Identify client's past spiritual practices that have been helpful. Help the client explore his or her life and identify those experiences that are noteworthy. **EBN:** *A cross-sectional study of 202 cognitively intact nursing home residents revealed a significant relationship between promotion of intrapersonal and interpersonal self-transcendence and meaning in life for the resident and the type of nurse–resident interaction (Haugan et al, 2014).*
- Offer opportunities to practice one's religion. **EBN:** *In a descriptive cross-sectional study of older adult patients admitted to a coronary care unit, Elham et al (2015) found a significant difference in the means between those who received spiritual care interventions by nurses regarding state-trait anxiety levels, but not in the control group.*

Pediatric

- Offer adolescents opportunities for reflection and storytelling to express their spirituality. **EB:** *In a longitudinal study of 46 adolescents with cystic fibrosis, Reynolds et al (2014) found those who used positive spiritual coping strategies, such as reframing/rethinking difficult situations from a spiritual perspective, had slowing of disease progression over a 5-year period.*
- Foster spiritual activities among adolescents. **EB:** *Mirghafourvand et al (2016) found that in a sample of 520 Iranian adolescent girls, spiritual well-being was highly correlated with health-related quality of life ($r = .60$, $p < .001$).*

Multicultural

- Recognize the importance of spirituality and provide culturally competent spiritual care to specific populations:
  - Muslims. **EBN:** *In a cross-sectional descriptive study (Akgül & Karadag, 2016) fecal ostomies were found to be a barrier to incorporating specific religious practices of salat, fasting, and pilgrimage in the lives of 150 Muslims postoperatively, providing an opportunity for nurses to assist patients in meeting their religious needs through adaptation or facilitation around this barrier.*
  - Hispanic. **EB:** *With diabetes having a high prevalence in the Hispanic population, Rivera-Hernandez (2016) found a positive relationship between religiosity/spirituality with diabetes care and blood sugar control in a sample of 2216 Hispanics 50 years and older living in Mexico.*
  - African Americans (AAs). **EBN:** *One of four themes identified in analyzing secondary data with content analysis indicated spirituality for AA women was a source of inner peace, joy, strength, hope, comfort, calm, coping, and other positive aspects contributing to well-being and potentially supportive of health-promoting behaviors (Conway-Phillips & Janusek, 2016).*
  - Veterans of Armed Services. Recognize the unique spiritual needs of veterans and provide spiritual support or appropriate referrals. **EB:** *An exploratory study by Ganocy et al (2016), found an inverse relationship to suicidal ideation, posttraumatic stress disorder (PTSD), and alcohol use with existential and spiritual well-being for National Guard who had ever been deployed overseas at least once.*

Home Care

- All of the nursing interventions described previously apply in the home setting.

Risk for Spiritual distress

Gail B. Ladwig MSN, RN

NANDA-I

Definition

Susceptible to an impaired ability to experience and integrate meaning and purpose in life through connectedness within self, literature, nature, and/or a power greater than oneself, which may compromise health.

Risk Factors

Anxiety; barrier to experiencing love; change in religious ritual; change in spiritual practice; cultural conflict; depression; environmental change; inability to forgive; increasing dependence on another; ineffective relationships; loneliness; low self-esteem; pain; perception of having unfinished business; self-alienation; separation from support system; social alienation; sociocultural deprivation; stressors; substance misuse

At-Risk Population

Aging; birth of a child; death of significant other; exposure to death; life transition; loss; exposure to natural disaster; racial conflict; receiving bad news; unexpected life event

Associated Condition

Actively dying; chronic illness; illness; imminent death; loss of a body part; loss of function of a body part; physical illness; treatment regimen

NIC, NOC, Client Outcomes, Nursing Interventions and *Rationales*, and References

Refer to care plan for **Spiritual Distress**

Readiness for enhanced Spiritual well-being

Elizabeth Burkhart PhD, RN, ANEF, Barbara Baele Vincensi PhD, RN, FNP

NANDA-I

Definition

A pattern of experiencing and integrating meaning and purpose in life through connectedness with self, others, art, music, literature, nature, and/or a power greater than oneself that is sufficient for well-being and can be strengthened.

Defining Characteristics

Connections to Self

Expresses desire for enhanced acceptance; expresses desire for enhanced coping; expresses desire for enhanced courage; expresses desire for enhanced hope; expresses desire for enhanced joy; expresses desire for enhanced love; expresses desire for enhanced meaning in life; expresses desire for enhanced purpose in life; expresses desire for enhanced satisfying philosophy of life; expresses desire for enhanced self-forgiveness; expresses desire for enhanced serenity (e.g., peace); expresses desire for enhanced surrender; meditation

Connections with Others

Provides service to others; requests forgiveness of others; requests interactions with significant others; requests interaction with spiritual leaders

Connections with Art, Music, Literature, Nature

Displays creative energy (e.g., writing, poetry, singing); listens to music; reads spiritual literature; spends time outdoors

Connection with Power Greater Than Self

Expresses awe; expresses reverence; participates in religious activities; prays; reports mystical experiences

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Personal Health Status; Coping; Dignified Life Closure; Grief Resolution; Hope; Personal Health Status; Psychosocial Adjustment: Life Change; Quality of Life; Social Involvement; Spiritual Health

Example NOC Outcome with Indicators

Hope as evidenced by the following indicators: Expresses expectation of a positive future/Faith/Optimism/Belief in self/Sense of meaning in life/Belief in others/Inner peace. (Rate each indicator of **Hope:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = constantly demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Express hope
- Express sense of meaning and purpose in life
- Express peace and serenity
- Express love
- Express acceptance
- Express surrender
- Express forgiveness of self and others
- Express satisfaction with philosophy of life
- Express joy
- Express courage
- Describe being able to cope
- Describe use of spiritual practices
- Describe providing service to others
- Describe interaction with spiritual leaders, friends, and family
- Describe appreciation for art, music, literature, and nature

NIC(Nursing Interventions Classification)

Suggested NIC Interventions

Active Listening, Coping Enhancement, Counseling, Crisis Intervention, Decision-Making Support, Grief Work Facilitation, Hope Instillation, Meditation Facilitation, Mutual Goal Setting, Presence, Religious Ritual Enhancement, Imagery, Simple Relaxation Therapy, Socialization Enhancement, Spiritual Growth Facilitation, Spiritual Support, Support System Enhancement, Touch, Values Clarification

Example NIC Activities—Spiritual Support

Encourage use of spiritual resources if desired; Be available to listen to client's expression of feelings

Nursing Interventions and *Rationales*

- Perform a spiritual assessment that includes the client's relationship with God, meaning and purpose in life, religious affiliation, and any other significant beliefs. **EBN:** *In a pre/post non-randomized interventional study, researchers Vlasblom et al (2015) found referrals to spiritual caregivers (chaplains) increased after implementing a spiritual assessment instrument by nurses at patient admission, in spite of nurse hesitancy in using the tool.*
- Be present and actively listen to the client. **EB:** *In a state of the science report, spirituality requires observations and understanding of human experience (Steinhauser et al, 2017).*
- Encourage the client to engage in other spiritual meditative or mind–body practices. **EBN:** *In a quasi-experimental interprofessional study with nursing, Sun et al (2015) discovered that religious affiliation and practices improved coping, comfort, and faith in palliative care patients.* **EB:** *In a state of the science report, mind–body interventions are encouraged to promote spiritual healing (Balboni et al, 2017).*
- Coordinate or encourage nurses to attend spiritual retreats or courses. **EBN:** *Attard, Baldacchino, and Camilleri (2014), using a pre/post methodology, found that nurses who received specific education on spiritual care in Malta had higher overall competency scores on spiritual caregiving. This supported the intentionality of spiritual care, which the authors stated was something that needs to be "taught" and not "caught" in practice.*
- Promote hope. **EBN:** *Using a cross-sectional descriptive design, Haugan (2014) found important factors for health in cognitively intact nursing home patients were nurse–patient interactions, which promoted hope and self-transcendence.*

• Encourage clients to reflect on what is meaningful to them in life. **EBN:** *In a descriptive, cross-sectional design of 202 cognitively intact nursing home patients, the ability to use reflection to discover meaning in life was enhanced by the patient's interactions with the nurse (Haugan, 2014).*
• Offer spiritual support to family and caregivers. **EB:** *In a state of the science report, patients and families who experience serious illness have spiritual needs (Balboni et al, 2017).*
• Assist the client in identifying religious or spiritual beliefs that encourage integration of meaning and purpose in the client's life. **EBN:** *Haugan (2014) discovered in a cross-sectional descriptive study that nurse's interactions with the patient positively affected hope, meaning in life, and intrapersonal self-transcendence of the patient.*
• Support spiritual practices, including meditation, guided imagery, journaling, relaxation, and involvement in art, music, or poetry. **EB:** *In a meta-analysis, Oh and Kim (2014) found spiritual interventions that focused on meaning-centered meditation, psychotherapy, or counseling had a significant but moderate effect on spiritual well-being, meaning of life, and depression.* **EB:** *In a state of the science report, mind–body interventions are encouraged to promote spiritual healing (Balboni et al, 2017).*
• Encourage expressions of spirituality. **EB:** *Swinton et al (2017) conducted 208 semistructured interviews with 70 dying patients, 76 family members, and 150 health care providers in an intensive care unit (ICU) to describe how spirituality was expressed during the dying process. The outcome of these interviews was the development of the 3 Wishes Program to support the expressions of spirituality during the dying process (i.e., peace, connections, spiritually enhanced environments, and specific expressions of spirituality).*
• Encourage integration of spirituality in healthy lifestyle choices. **EBN:** *In a phenomenological study of African-Caribbean women poststroke, Moorley, Cahill, and Corcoran (2016) identified one of three themes, which included the use of faith, spirituality, and church, to promote choices for healthy behaviors.*
• Encourage forgiveness. **EB:** *Park et al (2014) found that, in a sample of 111 patients with chronic heart failure, forgiveness was related to less subsequent depression.*

Geriatric

• Offer opportunities to practice one's religion. **EB:** *Freeze & DiTommaso (2014) identified in their descriptive study and development of a structural equation model (SEM) that a secure connection to God through religious behaviors and prayers lessened emotional distress and increased a sense of purpose in life.* **EB:** *Soriano et al (2016) found in a sample of 200 Filipino older adults living in a community and institutional setting that regular visits with chaplains and religious practices enhanced older adult's spiritual contentment and religion and culture quality of life. Encourage social relationships and connections with family for institutionalized older adults.* **EB:** *Soriano et al (2016) found that the loss of familial and peer relationships on admission to a nursing home was associated with lower religion and culture quality of life and quality of life overall.*
• For those with chronic disease, encourage individual spiritual practices that promote meaning and peace. **EB:** *Mills et al (2015), in a sample of 132 men and women with asymptomatic stage B heart failure, found that spiritual well-being, particularly meaning and peace, was associated with less depression.* **EB:** *Park et al (2014) found that, in a sample of 111 patients with advanced chronic heart failure, daily spiritual experiences were linked with higher existential well-being and predicted less subsequent spiritual strain.*
• For those with chronic illness, encourage patients to attend meaning-centered meditation programs, therapy, or counseling. **EB:** *In a meta-analysis, Oh and Kim (2014) found spiritual interventions that focused on meaning-centered meditation, psychotherapy, or*

counseling had a significant but moderate effect on spiritual well-being, meaning of life, and depression.

• Promote spiritual activities for those receiving palliative care. **EB:** *Chaiviboontham (2014) found that, in a sample of 240 patient with advanced cancer, patients with higher spiritual well-being significantly responded better to palliative care strategies.*

• During bereavement, encourage bereavement life review to promote spiritual well-being and alleviate depression. **EB:** *In a sample of 20 bereaved Hawaiian Americans, Ando et al (2015) found that participating in bereavement life review statistically significantly increased spiritual well-being and decreased depression.*

Pediatric

❍ Offer adolescents opportunities for reflection and storytelling to express their spirituality. **EB:** *In a longitudinal study of 46 adolescents with cystic fibrosis Reynolds et al (2014) found those who used positive spiritual coping strategies, such as reframing/rethinking difficult situations from a spiritual perspective, had slowing of disease progression over a 5-year period.*

❍ Foster spiritual activities among adolescents. **EB:** *Mirghafourvand et al (2016) found that, in a sample of 520 Iranian adolescent girls, spiritual well-being was highly correlated with health-related quality of life ($r = .60$, $p < .001$).*

Multicultural

• Recognize the importance of spirituality and provide culturally competent spiritual care to specific populations:

❍ Muslims. **EB:** *In a cross-sectional study with 223 Iranian patients with type 2 diabetes, Jafari et al (2014) found those with a higher spiritual well-being had significantly better diabetes control, improved quality of life, and less depression related to their disease.*

❍ Thai. **EB:** *In a 4-year longitudinal study of Thai elders ($N = 3537$), Hsu (2014) used hierarchical linear modeling for analysis and found that certain religious activities helped to reduce depressive symptoms and increase coping over time.*

❍ Latinos. **EBN:** *In a cross-sectional secondary analysis of a longitudinal study, Prince et al (2015) found that Hispanic stem cell transplant survivors ($N = 171$) had greater spiritual well-being and quality of life than non-Hispanic survivors, even at ≥3 years posttransplant.*

❍ African Americans (AAs). **EBN:** *One of four themes identified in analyzing secondary data with content analysis indicated spirituality for AA women was a source of inner peace, joy, strength, hope, comfort, calm, coping, and other positive aspects contributing to well-being and potentially supportive of health-promoting behaviors (Conway-Phillips & Janusek, 2016).* **EB:** *In a cross-sectional survey of 1013 AA women, Ludema et al (2015) found that those who identified with high organizational religion, high nonorganizational religion, and high spirituality had less risky sexual behaviors for potential HIV exposure.*

❍ Sheltered Homeless. **EBN:** *In a cross-sectional correlational study examining the relationship between spiritual resources and life attitudes in 160 sheltered homeless AA women, a significant relationship was found between a potential for moving out of homelessness and higher levels of faith, instrumental religion and spiritual resources, and increased coping skills (Gash et al, 2014).*

❍ Chinese. **EB:** *Leung et al (2015) used a pretest/posttest methodology with 160 Chinese patients diagnosed with chronic disease to study the effects of a psychoeducational death preparation intervention. The findings indicated that there was significant improvement in psychological, behavioral, and spiritual dimensions*

over time related to fear of death and preparation for death.

- Armed Forces. **EB:** *An exploratory study by Ganocy et al (2016) found an inverse relationship to suicidal ideation, posttraumatic stress disorder (PTSD), and alcohol use with existential and spiritual well-being for National Guard who had ever been deployed overseas at least once.*

• Integrate spiritual practices in health-promoting programs, particularly within the AA community. **EB:** *In a cross-sectional study (N = 144) using regression analysis, spirituality was found to be a protective factor within a culturally informed risk-protective framework for AA women of lower socioeconomic status living in disordered neighborhoods with parenting stress (Lamis et al, 2014).*

Home Care

• All of the nursing interventions described previously apply in the home setting.

Impaired Standing

Tracy P. George DNP, APRN-BC, CNE

NANDA-I

Definition

Limitation of ability to independently and purposefully attain and/or maintain the body in an upright position from feet to head.

Defining Characteristics

Impaired ability to adjust position of one or both lower limbs on uneven surface; impaired ability to attain a balanced position of the torso; impaired ability to extend one or both hips; impaired ability to extend one or both knees; impaired ability to flex one or both hips; impaired ability to flex one or both knees; impaired ability to maintain the torso in balanced position; impaired ability to stress torso with body weight

Related Factors

Emotional disturbance; insufficient endurance; insufficient energy; insufficient muscle strength; malnutrition; obesity; pain; self-imposed relief posture

Associated Condition

Circulatory perfusion disorder; impaired metabolic functioning; injury to lower extremity; neurological disorder; prescribed posture; sarcopenia; surgical procedure

NOCOutcomes (Nursing Outcomes Classification)

Suggested NOC Outcomes

Activity Tolerance; Balance; Body Mechanics Performance; Body Positioning: Self-Initiated; Comfort Status: Physical; Endurance; Mobility; Risk Control: Hypotension; Skeletal Function

Example NOC Outcome with Indicators

Mobility as evidenced by the following indicators: Balance/Coordination/Body positioning performance. (Rate outcome and indicators of **Mobility:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Demonstrate optimal independence and safety when standing
- Demonstrate the proper use of assistive devices
- State benefits of standing

NICInterventions (Nursing Interventions Classification)

Suggested NIC Interventions

Body Mechanics Promotion

Example NIC Activities

Instruct client on structure and functional spine and optimal posture for moving and using the body

Nursing Interventions and *Rationales*

- Encourage clients to stand at intervals throughout the day. **EB:** *In a randomized control trial of overweight or obese Australian office workers, participants who completed work while alternating between sitting and standing at 30-minute intervals throughout the day demonstrated a 11.1% decrease in glucose levels after meals (Thorp et al, 2014).* **EB:** *Patients who engaged in standing, walking, or cycling during an 8-hour work period had lower 24-hour and postprandial blood sugars than those who sat (Crespo et al, 2016). Advise patients of the physical and psychological benefits of being upright and active.* **EB:** *In patients 1 to 3 years after suffering a stroke, depression, left hemisphere infarction, visual neglect, and difficulty with mobility and balance were associated with being less active (Kunkel et al, 2015).*
- Educate patients about the health risks of sitting. **EB:** *In a study of 221,240 adults ages 45 and older in Australia, standing less than 2 hours/day was associated with a greater mortality rate from all causes compared with standing from 2 to 5 hours, 5 to 8 hours, or greater than 8 hours/day (van der Ploeg et al, 2014).*

Geriatric

- Advise older clients who have difficulty standing to use assistive devices. **EB:** *In a Swedish study using the Psychosocial Impact of Assistive Devices Scale, Nordström et al (2014) found that the frequent use of standing assistive devices was associated with higher psychosocial scores in older adults.*
- Encourage trunk exercises after clients have had strokes. **EB:** *In a meta-analysis of six randomized controlled studies, trunk exercises were associated with improvements in standing and walking for clients after strokes (Sorinola, Powis, & White, 2014).*
- Encourage clients who are unable to stand to consider chair exercises. **EB:** *In a study of 100 older adults with lower extremity osteoarthritis, the 40 adults who participated in chair yoga twice a week for 8 weeks reported less pain than the 60 participants who participated in a health education program two times per week for 8 weeks (Park et al, 2016).*
- Encourage clients poststroke to participate in rehabilitation interventions that

promote standing. **EB:** *In a meta-analysis using 11 studies, interventions used after strokes to improve standing were associated with faster sitting-to-standing position times and improved lateral symmetry during sitting-to-standing position changes (Pollock et al, 2014).* **EB:** *A study of seven participants found that a home-based intervention, Rehab@home, can be used effectively to improve the rehabilitation of balance and the movement from the sitting to standing position in patients with neurological deficits, without the presence of a physical therapist (Faria, Silva, & Campilho, 2015).*

- Raise the height of the bed and encourage the use of the client's hands when an older adult is rising from a sitting to standing position. **EB:** *In a study of 24 older clients, Lindemann et al (2014) found that raising the bed height and using the hands while transferring from a sitting to standing position resulted in less effort.*
- Educate older adults who have fallen about the need for balance and muscle training of the ankle joint. **EB:** *In a randomized controlled trial of 26 older clients who were at risk of falling and had fallen previously, Jung-Hyun and Nyeon-Jun (2015) found that balance and ankle muscle training resulted in improvements in the gait of older adults.*
- Educate adults older than age 80 years on the need for vitamin D. **EB:** *Low serum 25-hydroxyvitamin D (25OHD) levels were associated with orthostatic hypotension in a study involving community-dwelling clients 80 years of age and older (N = 329) (Annweiler et al, 2014).*
- Advise older clients who are at risk for falls to avoid doing multiple tasks at one time while standing. **EB:** *In a study of 243 adults ages 65 years and older, older participants' standing balance was worse than that seen in younger participants; the standing balance was worse when clients were performing a second task, which is important when considering the risk of falls (Coelho et al, 2016).*

Client/Family Teaching and Discharge Planning

- Educate clients that standing can be beneficial for their health. **EB:** *In a Canadian prospective cohort study in which participants were followed for a mean duration of 12 years, Katzmarzyk (2014) found that increased daily standing times were associated with decreased cardiovascular and all-cause mortality rates.* **EB:** *In a study of participants with chronic pain (N = 18) and participants without chronic pain (N = 19), Raijmakers et al (2015) found that patients with chronic pain spent more time lying and less time sitting and standing over a 1-week period.*
- Teach clients about the need to take frequent breaks when standing for long periods. **EB:** *With 45 minutes of standing to 15 minutes of sitting (3:1 ratio), 55% of participants experienced low back pain while standing, so this ratio may be not be adequate, and alternate rest activities may be needed (Gallagher, Campbell, & Callaghan, 2014).*
- Instruct clients about the use of yoga for individuals who have difficulty with standing balance. **EB:** *In a randomized control of obese adults with poor standing balance, participation in yoga classes three times per week was associated with improved static and dynamic standing balance (Chaiyong et al, 2015).*

Stress overload

Gail B. Ladwig MSN, RN

NANDA-I

Definition

Excessive amounts and types of demands that require action.

Defining Characteristics

Excessive stress; feeling of pressure; impaired decision-making; impaired functioning; increase in anger; increase in anger behavior; increase in impatience; negative impact from stress; tension

Related Factors

Insufficient resources; repeated stressors; stressors

NOC(Nursing Outcomes Classification)

Suggested NOC Outcomes

Anxiety Level; Caregiver Stressors; Stress Level; Health-Promoting Behavior; Knowledge: Stress Management

Example NOC Outcome with Indicators

Stress Level as evidenced by the following indicators: Increased blood pressure, restlessness, emotional outbursts, anxiety, diminished attention to detail. (Rate the outcome and indicators of **Stress Level:** 1 = severe, 2 = substantial, 3 = moderate, 4 = mild, 5 = none [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Review the amounts and types of stressors in daily living
- Identify stressors that can be modified or eliminated
- Mobilize social supports to facilitate lower stress levels
- Reduce stress levels through use of health promoting behaviors and other strategies

NIC(Nursing Interventions Classification)

Suggested NIC Interventions

Active Listening; Anger Control Assistance; Anxiety Reduction; Aroma Therapy; Counseling; Crisis Intervention; Emotional Support; Family Integrity Promotion; Presence; Support System Enhancement

Example NIC Activities—Support System Enhancement

Identify psychological response to situation and availability of support system; Determine adequacy of social networks; Explain to concerned others how they can help; Refer to a self-help group or Internet-based resource as appropriate; Provide services in a caring and supportive manner

Nursing Interventions and *Rationales*

- Assist client in identification of stress overload during vulnerable life events. **EBN:** *Research suggested that role overload, associated with high stress levels, among nurses and volunteer caregivers may negatively affect health, well-being, and job performance (Akintola,*

Hlengwa, & Dageid, 2013; *Kath et al, 2013*). **EB:** *In a systematic review of 40 studies it was found that at least 33% of surrogates experience stressful emotional burden on making treatment decisions for others (Wendler & Rid, 2011).* **CEB:** *Women with breast cancer who were involved in group therapy focusing on stress reduction and muscle relaxation were 56% less likely to succumb to the disease and 45% less likely to experience a recurrence (Andersen et al, 2008). Men with high stress have higher all-cause mortality, and the effects are more pronounced among middle-aged men (Nielsen et al, 2008).*

• Listen actively to descriptions of stressors and the stress response. **EBN:** *In a recent longitudinal study of clients with heart failure, researchers found that clients with high anxiety experienced shorter periods of event-free (hospitalization, mortality) survival than those with lower anxiety (P = .03) (Dejong et al, 2011).* **EB:** *Adolescents exposed to daily stress demonstrate increased risky decision-making compared with those with low stress (Galván & McGlennen, 2012).*

• In younger adult women, assess interpersonal stressors. **EB:** *In a sample of 127 spouse caregivers of clients with Alzheimer's disease who were predominantly female (71%), greater stress was associated with more depressive symptoms, and these symptoms were significantly associated with decreased personal mastery (P = .006), self-efficacy (P < .001), increased avoidance coping (P < .001), and activity restriction (P = .040) (Mausbach et al, 2012).* **CEB:** *A systematic review and meta-analysis of 30 studies found that maternal exposure to the stress of domestic violence results in significantly increased risk of low birth weight and preterm birth (Shah & Shah, 2010).*

• Categorize stressors as modifiable or nonmodifiable. **EB:** *Strategizing on nonavoidance coping and increased socialization along with enhanced personal mastery and self-efficacy in use of problem-solving coping may minimize depression symptoms in Alzheimer's disease caregivers (Mausbach et al, 2012).* **CEBN:** *Removing or minimizing some stressors, changing responses to stressors, and modifying the long-term effects of stress are all actions that can assist those with chronic illnesses and stress (Upton & Solowiej, 2010).*

• Help clients modify or mitigate stressors identified as modifiable. **EBN:** *In a sample of 480 nurse managers from 36 hospitals in the southwestern United States, role overload was found to be the most significant predictor of work-related stress followed by organizational constraints and role conflict (all P < .01 [two-tailed]); all three are areas that organizational leaders need to be aware of to mitigate stress overload in managerial staff (Kath et al, 2013).* **CEB:** *There are numerous possible strategies to modify stressors, including time management, improved organizational skills, problem-solving, changing perceptions of stress, breathing, relaxation techniques, visual imagery, and soothing rituals (Lloyd, Smith, & Weinger, 2005).*

• Help clients distinguish among short-term, chronic, and secondary stressors. **EB:** *Cellular aging, identified by leukocyte telomere length (TL), was found to be different in a sample of 36 ethnically diverse, older adults between four pain/stress groups (P = .01) in which those with chronic pain/higher stress had the shortest TL indicative of cellular aging (Sibille et al, 2012).* **CEBN:** *Social support is a critical dimension of health and health promotion and serves as a buffer in the stress response (Pender, Murtaugh, & Parsons, 2010).*

• Provide information as needed to reduce stress responses to acute and chronic illnesses. **EBN:** *Nursing interventions including strategies to deal with child behavior, a focus on physical health, and planning to meet resource needs may enhance the well-being of African American grandmothers raising grandchildren (Kelley, Whitley, & Campos, 2013). Proactive nursing interventions including assessment of caregiver needs for support and preparedness including early psychoeducational interventions can enhance caregiver ability to navigate the challenges associated with caring for a relative with Alzheimer's disease (Ducharme et al, 2011).*

▲ Explore possible therapeutic approaches such as cognitive-behavioral therapy,

biofeedback, neurofeedback, acupuncture, pharmacological agents, and complementary and alternative therapies. **EBN:** *Nonpharmacological nursing interventions through the use of nature-based sounds played through headsets was found to effectively decrease the stress response in mechanically ventilated clients in a sample of 60 Iranian clients aged 18 to 65 (Saadatmand et al, 2013).* **EB:** *In a sample of 111 healthy adults, those who exercised regularly were more resistant to acute stress (Childs & de Wit, 2014). Mindfulness techniques have been suggested as an effective means of reducing stress in adolescents (Broderick & Jennings, 2012), nursing personnel (Zeller & Levin, 2013), and older adults (Gallegos et al, 2013).*

• Help the client to reframe his or her perceptions of some of the stressors. **EBN:** *A study on 335 Thai nursing students found that coping mediated the effects of stress on physical and psychological health (Klainin-Yobas et al, 2014). Researchers found that nursing students with higher anxiety states were 62% less optimistic, with findings supporting that individuals with pessimistic outlooks perceive situations as more threatening (Warning, 2011).*

• Assist the client to mobilize social supports for dealing with recent stressors. **CEBN:** *Emotional support in Taiwanese caregivers is suggested as a moderator of stressors experienced by caregivers of clients with Alzheimer's disease or stroke, particularly in caregivers with lower household incomes (Huang et al, 2009).* **EB:** *In a sample of 79 German adults a predicted association between needed and received emotional support and well-being was found in younger adults (aged 23–34) (Wolff et al, 2013).*

Pediatric

• With children, nurses should work with parents to help them to reduce children's stressors. **EB:** *A longitudinal study on 115 children aged 7 to 12 suggested that early life stress and trauma may result in increased limbic activity, which is a biomarker that may have implications as a risk for later psychiatric diagnoses (Suzuki et al, 2014). A study on 181 18 to 20 year olds suggested that more positive parenting behaviors are statistically significantly ($P < .01$) associated with more adaptive cognitions in the emerging adult, which may affect stress/health outcomes (Donnelly, Renk, & McKinney, 2013).*

• Help children to manage their feelings related to self-concept. **CEB:** *Perceived isolation as experienced in high school associated with victimization results in higher stress and longer lasting negative psychological outcomes (Newman, Holden, & Delville, 2005).*

• Help children to deal with bullies and other sources of violence in schools and neighborhoods. **EB:** *In a sample of 1420 children and adolescents the number of times that the individual was bullied predicted higher levels of C-reactive protein (CRP) (a risk factor for negative health consequences later in life) in which those who bullied had lower levels of CRP (Copeland et al, 2014). Violence in schools and neighborhoods has significant effects on children's stress. In a recent study of college-aged respondents ($N = 1339$), researchers found that a history of being bullied (victimized) was associated with both increased stress and use of avoidant behaviors (Newman, Holden, & Delville, 2011).*

• Help children to manage the complexities of chronic illnesses. **EB:** *Individuals who grow up with a chronic illness have lower odds of graduating college, being employed, having a good income, and have a higher need for public assistance, although they do succeed socially, which is evident by similar odds of marriage, having children, and living with their parents compared with those without chronic illness (Maslow et al, 2011).* **CEB:** *Teenagers who had recently been diagnosed with diabetes described high levels of stress that often related to the complexities of managing the illness (Davidson et al, 2004).*

Geriatric

- Assess for chronic stress with older adults and provide a variety of stress relief techniques. **EB:** *In a sample of over 9000 American adults over the age of 60, lifetime posttraumatic stress disorder (PTSD) was found to be associated with greater odds of being diagnosed with hypertension, angina pectoris, tachycardia, other heart disease, stomach ulcer, gastritis, and arthritis (Pietrzak et al, 2012).*
- Encourage older adults to seek appropriate counseling. **EB:** *Treatment modalities for PTSD in older adults may vary depending on whether the PTSD was experienced early or late in life; however, trauma confrontation and cognitive restructuring combined with age-specific life review in cognitive-behavioral therapy may hold the most promise (Böttche, Kuwert, & Knaevelsrud, 2012).* **CEB:** *Bereavement-related major depression differs from major depression seen in other stressful life events only in relation to older age at onset. Individuals are more likely to be female; have lower levels of treatment-seeking; and have higher levels of guilt, fatigue, and loss of interest; therefore they should not be excluded from a diagnosis of major depression (Kendler, Myers, & Zisook, 2008).*

Multicultural

- Review cultural beliefs and acculturation level in relation to perceived stressors. **EBN:** *A study done to assess how the type of premigration trauma, postmigration stressors, and resources predicted PTSD and major depressive disorder (MDD) symptoms found that postmigration-related stressors greatly increased the odds (nearly 16-fold) of being in a comorbid group (PTSD or MDD) (Norris, Aroian, & Nickerson, 2011).* **EB:** *A review of qualitative studies found that organizational constraints, work overload, and interpersonal conflict were universally experienced stressors in studies that assessed occupational stress on an international perspective (Mazzola, Schonfeld, & Spector, 2011). Assess families for whether they experience high stress or low stress.* **EB:** *In a sample of 97 native Norwegian adolescents and 59 immigrant adolescents from an urban Norwegian secondary school, global victimization was found to be higher in the immigrant group compared with the native group, although there was no difference in the report of depressive symptoms (Fandrem, Strohmeier, & Jonsdottir, 2012).* **CEB:** *Stress related to racial microaggressions experienced by African Americans may have a negative cumulative effect on health outcomes (Sue et al, 2007).*

Home Care

- The preceding interventions may be adapted for home care use.
- Develop community-based programs for stress management as needed for groups with increased risk of stress overload (e.g., firefighters, policemen, military personnel, nurses). **CEB:** *Some situations have higher risks of stress overload. Stress management interventions may prevent or modify the experience of stress overload (McNulty, 2005).*
- Support and encourage neighborhood stability. **CEB:** *A "significant proportion of health differentials across neighborhoods is due to disparate stress levels across [Detroit] neighborhoods," and neighborhood stability was a buffer to reduce the negative effects of high stress (Boardman, 2004).*

Client/Family Teaching and Discharge Planning

- Diagnose the possibility of stress overload before teaching.
- Establish readiness for learning.
- Provide manageable amounts of information at the appropriate educational level.

- Evaluate the need for additional teaching and learning experiences.

Acute Substance Withdrawal syndrome

Marina Martinez-Kratz MS, RN, CNE

NANDA-I

Definition

Serious, multifactorial sequelae following abrupt cessation of an addictive compound.

Defining Characteristics

Acute confusion (00128); anxiety (00146); disturbed sleep pattern (00198); nausea (00134); risk for electrolyte imbalance (00195); risk for injury (00035)

Related Factors

Developed dependence to alcohol or other addictive substance; heavy use of an addictive substance over time; malnutrition; sudden cessation of an addictive substance

At-Risk Population

History of previous withdrawal symptoms; older adults

Associated Condition

Comorbid mental disorder; comorbid serious physical illness

NOC(Nursing Outcomes Classification)

Suggested NOC Outcomes

Anxiety Level; Comfort Status; Drug Abuse Cessation Behavior; Electrolyte Balance; Seizure Severity; Substance Addiction Consequences; Substance Withdrawal Severity; Symptom Severity; Vital Signs

Example NOC Outcome with Indicators

Substance Withdrawal Severity as evidenced by the following indicators: Substance cravings/Change in vital signs/Irritability/Nausea. (Rate the outcome and indicators of **Substance Withdrawal Severity:** 1 = severe deviation from normal range, 2 = substantial deviation from normal range, 3 = moderate deviation from normal range, 4 = mild deviation from normal range, 5 = no deviation from normal range [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Will stabilize and remain free from physical injury
- Verbalizes effects of substances on body
- Maintain vital signs and lab values within normal range
- Verbalizes importance of adequate nutrition

NIC(Nursing Interventions Classification)

Suggested NIC Interventions

Behavior Management; Drug Withdrawal; Electrolyte Monitoring; Emotional Support; Nausea Management; Seizure Precautions; Smoking Cessation Assistance; Substance Use Treatment: Alcohol Withdrawal; Substance Use Treatment: Anxiety Reduction

Example NIC Activities—Substance Use Treatment: Alcohol Withdrawal

Monitor vital signs during withdrawal, Monitor for delirium tremens, Administer medications, Provide symptom management, Implement seizure precautions

Nursing Interventions and *Rationales*

Alcohol-Induced Withdrawal Syndrome

- Assess for client's pattern of alcohol use, last drink, and current blood alcohol levels. **EB:** *Because of ethanol's short action, withdrawal symptoms begin within 6 to 8 hours after blood alcohol levels decrease, peak at 72 hours, and are markedly reduced by days 5 through 7 (Schuckit, 2014; Long, Long, & Koyfman, 2017).*
- Implement seizure precautions. **EB:** *Clients in alcohol withdrawal are at risk for developing withdrawal seizures related to central nervous system (CNS) hyperstimulation caused by loss of gamma-aminobutyric acid (GABA) inhibitory effect (Long, Long, & Koyfman, 2017). The development of acute symptomatic seizures during an alcohol withdrawal episode is associated with a fourfold increase in the mortality rate that is caused by complications of severe alcohol use disorder (Jesse et al, 2017).*
- Rule out other causes of symptoms. **EB:** *The presence of other disease processes requires immediate treatment and stabilization (Long, Long, & Koyfman, 2017). Other assessments should include a check of blood gases, a review of glucose and electrolyte laboratory panels, a review of potential medication reactions, presence for infection, and other conditions.*
- Monitor vital signs. **EB:** *Tachycardia and hypertension are among the broad symptoms of alcohol withdrawal (Long, Long, & Koyfman, 2017).*
- Assess for progression of withdrawal symptoms such as insomnia, anxiety, nausea/vomiting, tremulousness, headache, diaphoresis, palpitations, increased body

temperature, tachycardia, and hypertension. **EBN:** *These are the broad symptoms of alcohol withdrawal that can progress in intensity without treatment (Makic, 2017).*

- Monitor severity of withdrawal symptoms with the Clinical Institute Withdrawal Assessment (CIWA-Ar). **CEB:** *The CIWA-Ar is a 10-item scale for clinical quantification of the severity of the alcohol withdrawal syndrome (Sullivan et al, 1989; Kattimani & Bharadwaj, 2013). The CIWA-Ar scale is available at http://www.cbhallc.com/documents/4a-detox%20guidelines.pdf.*
- Evaluate the client for progression to the delirium tremens (DTs). **EB:** *The DTs are severe and life-threatening withdrawal symptoms that occur in 3% to 5% of patients on about the third day of withdrawal. DT symptoms have a rapid onset and include the broad alcohol withdrawal symptoms, fluctuating levels of cognition and attention, and autonomic instability. Associated risk factors are previous DTs, untreated seizures, CIWA-Ar score > 15, heart rate > 100, history of sustained drinking, systolic blood pressure > 150 mm Hg, alcohol intake > 2 days, age > 30 years, recent misuse of benzodiazepines, and concurrent medical illness (Long, Long, & Koyfman, 2017).*
- Assess nutritional status for risk of malnutrition. Assess for thiamine (B_1) deficiency, which is associated with chronic alcohol abuse, folate deficiency, and vitamin D deficiency associated with a history of inadequate exposure to sunlight. Consult with health care provider as needed for supplement order. **EB:** *Alcoholism is a major cause of malnutrition in the United States. Thiamine deficiencies contribute to the development of Korsakoff's syndrome and Wernicke's encephalopathy, which are neurological complications of alcohol abuse (Manzo et al, 2014; Dugum & McCullough, 2015). Vitamin D insufficiency is associated with cognitive impairment (Goodwill & Szoeke, 2017).*
- Address hydration needs. **EB:** *Clients in alcohol withdrawal require administration of fluids to correct dehydration (Mirijello et al, 2015; Long, Long, & Koyfman, 2017).*
- Determine hepatic and renal functioning prior to administration of medications. **EB:** *Hepatic or renal disease can slow the clearance of medications and lead to complications or toxicities (Long, Long, & Koyfman, 2017).*

Opioid-Induced Withdrawal Syndrome

- Assess for client's opioid of choice, last use, and current withdrawal symptoms. **EB:** *The onset of withdrawal symptoms depends on the half-life of the opioid used. Heroin withdrawal occurs 6 to 8 hours after the last use, and methadone and fentanyl withdrawal occurs 1 to 3 days after the last dose (Donroe et al, 2017).*
- Monitor severity of withdrawal symptoms with the Clinical Opiate Withdrawal Scale (COWS). **EB:** *A standardized assessment tool is necessary for evaluating and treating opioid withdrawal. The COWS is scored numerically based on severity, with values summed to give a cumulative score. A threshold score indicates when treatment should be initiated (Wesson & Ling, 2003).*
- Nurses should wait to administer the first dose of buprenorphine to opioid-dependent patients until clients are experiencing mild to moderate opioid withdrawal symptoms. **EB:** *The American Society of Addiction Medicine (ASAM) National Practice Guidelines recommended waiting to administer the first dose of buprenorphine until clients are experiencing mild to moderate opioid withdrawal symptoms to reduce the risk of precipitated withdrawal (Kampman & Jarvis, 2015).*
- Assess and manage early opioid withdrawal symptoms (agitation, anxiety, insomnia, muscle aches, increased lacrimation, rhinorrhea, sweating, and yawning) and late opioid withdrawal symptoms (abdominal cramping, diarrhea, pupillary dilation, nausea, vomiting, and piloerection) of opioid withdrawal. **EBN:** *Severe*

withdrawal can lead to fluid and electrolyte imbalances, cardiac dysrhythmias, acute kidney injury, or rhabdomyolysis. A failure to treat could result in client injury or in clients leaving the clinical setting against medical advice (Turner et al, 2018).

• Monitor vital signs. **EBN:** *Parameters for blood pressure should be followed especially for patients treated with clonidine or other alpha-2 agonists, which can cause hypotension (Turner et al, 2018).*

• Teach the client about the anticipated withdrawal symptoms and opioid cravings while offering support and encouragement. **EBN:** *A lack of knowledge in conjunction with decreased nurse empathy and engagement are barriers to treatment (Worley, 2017).*

▲ Monitor laboratory reports and report to health care provider. **EBN:** *Serum electrolytes are closely evaluated for abnormalities and replaced as indicated (Turner et al, 2018).*

▲ Refer patient for buprenorphine, methadone, or naltrexone treatment. **EB:** *Using medications for opioid withdrawal management is recommended over abrupt cessation of opioids. Abrupt cessation of opioids may lead to strong cravings, which can lead to continued use (Kampman & Jarvis, 2015). A recent study showed that emergency department–initiated buprenorphine was associated with increased engagement in addiction treatment and reduced illicit opioid use during the 2-month interval when buprenorphine was continued in primary care (D'Onofrio et al, 2017).*

Benzodiazepine-Induced Withdrawal Syndrome

• Assess for client's last benzodiazepine use, and current withdrawal symptoms. **EB:** *The onset of withdrawal symptoms occurs within 1 to 3 days of drug cessation. Common withdrawal symptoms include any of the following: autonomic instability (tachycardia, elevated blood pressure), tremulousness, diaphoresis, insomnia, anxiety, depression, psychosis (hallucinations, delusions), sensory hypersensitivity (photophobia, hyperacusis), perceptual distortions, depersonalization, agoraphobia, flulike symptoms, paresthesias, muscle stiffness, ataxia, visual disturbances, DTs, and seizures (Puening et al, 2016).*

• Implement seizure precautions. **EB:** *Clients withdrawing from benzodiazepines may also experience seizures on withdrawal (Puening et al, 2016).*

• Rule out delirium from other causes or other withdrawal syndromes. **EB:** *The symptoms of benzodiazepine withdrawal appear similar to delirium, as well as barbiturate or alcohol withdrawal (Puening et al, 2016).*

▲ Anticipate use of the same treatment protocols as for alcohol withdrawal and use of a long-acting benzodiazepine in tapering doses over time. **EB:** *A tapering schedule will assist with prevention of relapse (Donroe et al, 2017).*

Cocaine/Methamphetamine-Induced Withdrawal Syndrome

• Assess for client's last stimulant use, and current withdrawal symptoms. **EB:** *The onset of withdrawal symptoms occurs within 24 hours after abrupt discontinuation of using high amounts of amphetamine-type substances over a prolonged period of time. Common stimulant withdrawal symptoms include depressed mood with any of the following: fatigue, vivid dreams, insomnia, increased appetite, psychomotor retardation, and agitation. Cocaine withdrawal is mild and treated supportively. Methamphetamine use can result in significant psychiatric withdrawal symptoms and intense craving after abrupt cessation (Donroe et al, 2017).*

Cannabis-Induced Withdrawal Syndrome

• Assess for client's last cannabis use, and current withdrawal symptoms. **EB:** *The onset of withdrawal symptoms occurs within a week of cannabis cessation. Common cannabis withdrawal symptoms include any of the following: anxiety, irritability, malaise, dysphoria, decreased appetite, restlessness, and sleep disturbances (Zehra et al, 2018).*
• Direct nursing actions to address anxiety, irritability, sleep disturbances, and decreased appetite. **EB:** *Nursing care should target the specific symptoms of cannabis withdrawal as part of a treatment that targets cannabis use reduction and prevention of relapse (Zehra et al, 2018).*

Nicotine-Induced Withdrawal Syndrome

• Assess for client's last nicotine use, and current withdrawal symptoms. **EB:** *The onset of withdrawal symptoms occurs within hours of last use. Common nicotine withdrawal symptoms include craving for nicotine, irritability, anger, frustration, anxiety, difficulty concentrating, restlessness, decreased heart rate, increased appetite, weight gain, tremor, headaches, craving, delirium, and sleep disturbance (Ginige, 2016).*
• Rule out nicotine withdrawal as the cause of delirium in critically ill clients. **EB:** *Chronic consumption of nicotine can cause desensitization and upregulation of acetylcholine receptors. In an acute nicotine withdrawal state, the lack of sufficient nicotinic stimulation leads to acetylcholine deficiency, which is associated with delirium (Ginige, 2016).*

All Withdrawal Syndromes

• Obtain a drug and/or alcohol history using a tool such as the AUDIT-C or the DAST-10. **EB:** *The Audit-C is a simple 3-question screen for hazardous or harmful drinking that can stand alone or be incorporated into general health history questionnaires. The DAST-10 is a 10-item, yes/no self-report instrument that takes less than 8 minutes to complete (Mulvaney-Day et al, 2018).*
• Implement and follow institutional withdrawal protocols. **EB:** *A recent study suggested that using a protocol for treatment of critical care patients with alcohol withdrawal leads to decreased intensive care unit (ICU) length of stay and reduced ICU cost (Tavani et al, 2017).*
• Assess for signs of recent trauma or head injury. **EB:** *A study found that trauma patients that present to the hospital in a delayed fashion have unique characteristics and are more likely to suffer negative outcomes including substance withdrawal (Kao et al, 2017).*
• Assess client's level of consciousness, monitor for changes in behavior, and orient to reality as needed. **EB:** *Reality orientation will support the client with changes in level of consciousness or behavior and may indicate progression of withdrawal (Mirijello et al, 2015).*
• Assess vital signs and monitor for existing medical conditions and current medications. **EB:** *Withdrawal symptoms can be exacerbated or masked by existing medical conditions, medications, or treatments (Long, Long, & Koyfman, 2017).*
• Assess and monitor for expression of psychological distress. **EB:** *Withdrawal can cause or exacerbate current emotional, psychological, or mental problems (Harford et al, 2018).*
• Collect urine/serum samples for laboratory tests. **EB:** *Routine treatment for substance withdrawal should include serum (or breath) alcohol concentrations, complete blood count, renal function tests, electrolytes, glucose, liver enzymes, urinalysis, and urine toxicology screening (Mirijello et al, 2015).*
• Address craving for substances with mindfulness-based techniques. **EB:** *Compared with those receiving usual care, a study found mindfulness-based addiction treatment participants reported lower anxiety, concentration difficulties, craving, and dependence, as*

well as higher self-efficacy for managing negative affect without smoking (Spears et al, 2017).

• Respond to agitated behavior with deescalation techniques. **EBN:** *Research shows staff intervention can modify processes and reduce further conflict (Berring, Pedersen, & Buus, 2016).*

• Administer as needed (PRN) medications for agitation and symptom control as ordered. **EB:** *A study found symptom-triggered treatment for alcohol withdrawal syndrome individualizes treatment, is safe, decreases treatment duration and the use of benzodiazepines, and consequently reduces health care costs (Soravia et al, 2018).*

• Provide a quiet room without dark shadows, noises, or other excessive stimuli. **EB:** *Supportive care includes controlling environmental stimuli that may increase client agitation or irritability (Mirijello et al, 2015).*

• Provide suicide precautions and 1:1 staffing for clients that are delirious or who may present a danger to themselves or others. **EB:** *A recent study showed that substance use disorders are associated with self- and other-directed violence (Harford et al, 2018).*

Client/Family Teaching and Discharge Planning

▲ After withdrawal symptoms have subsided, refer client to substance use treatment. **EB:** *Collaborative discharge planning can increase the likelihood of the patient's success with substance abstinence. Referral to appropriate services can reduce discharges against medical advice and increase follow-up in postdischarge addiction treatment centers (Donroe et al, 2017).*

▲ Refer for smoking cessation services that target nicotine craving. **EB:** *A recent study found that nicotine craving may be a useful therapeutic target for increasing the effectiveness of smoking-cessation treatment (Magee, Lewis, & Winhusen, 2016).*

Risk for acute Substance Withdrawal syndrome

Marina Martinez-Kratz MS, RN, CNE

NANDA-I

Definition

Susceptible to serious, multifactorial sequelae following abrupt cessation of an addictive compound, which may compromise health.

Risk Factors

Developed dependence to alcohol or other addictive substance, heavy use of an addictive substance over time, malnutrition, sudden cessation of an addictive substance

At-Risk Population

History of previous withdrawal symptoms; older adults

Associated Condition

Comorbid mental disorder; comorbid serious physical illness

NOC(Nursing Outcomes Classification)

Suggested NOC Outcomes

Anxiety Level; Comfort Status; Drug Abuse Cessation Behavior; Electrolyte Balance; Seizure Severity; Substance Addiction Consequences; Substance Withdrawal Severity; Symptom Severity; Vital Signs

Example NOC Outcome with Indicators

Substance Withdrawal Severity as evidenced by the following indicators: Substance cravings/Change in vital signs/Irritability/Nausea. (Rate the outcome and indicators of **Substance Withdrawal Severity:** 1 = severe deviation from normal range, 2 = substantial deviation from normal range, 3 = moderate deviation from normal range, 4 = mild deviation from normal range, 5 = no deviation from normal range [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Will stabilize and remain free from physical injury
- Verbalizes effects of substances on body
- Maintain vital signs and lab values within normal range
- Verbalizes importance of adequate nutrition

NIC(Nursing Interventions Classification)

Suggested NIC Interventions

Anxiety Reduction; Behavior Management; Electrolyte Monitoring; Emotional Support; Nausea Management; Seizure Precautions; Smoking Cessation Assistance; Substance Use Treatment: Alcohol Withdrawal; Substance Use Treatment: Drug Withdrawal

Example NIC Activities—Substance Use Treatment: Alcohol Withdrawal

Monitor vital signs during withdrawal, Monitor for delirium tremens, Administer medications, Provide symptom management, Implement seizure precautions

Nursing Interventions and *Rationales*

Risk for Alcohol-Induced Withdrawal Syndrome

- Assess for client's pattern of alcohol use, last drink, and current blood alcohol levels. **EB:** *Because of ethanol's short action, withdrawal symptoms begin within 6 to 8 hours after blood alcohol levels decrease, peak at 72 hours, and are markedly reduced by days 5 through 7 (Schuckit, 2014; Long, Long, & Koyfman, 2017).*
- Implement seizure precautions. **EB:** *Clients in alcohol withdrawal are at risk for developing withdrawal seizures related to central nervous system (CNS) hyperstimulation caused by loss of gamma-aminobutyric acid (GABA) inhibitory effect (Long, Long, & Koyfman, 2017). The development of acute symptomatic seizures during an alcohol withdrawal episode is associated with a fourfold increase in the mortality rate caused by complications of severe alcohol use disorder (Jesse et al, 2017).*
- Rule out other causes of symptoms. **EB:** *The presence of other disease processes requires immediate treatment and stabilization (Long, Long, & Koyfman, 2017). Other assessments should include a check of blood gases, a review of glucose and electrolyte laboratory panels, a review of potential medication reactions, presence for infection, and other conditions.*
- Monitor vital signs. **EB:** *Tachycardia and hypertension are among the broad symptoms of*

alcohol withdrawal (Long, Long, & Koyfman, 2017).

- Assess for progression of withdrawal symptoms such as insomnia, anxiety, nausea/vomiting, tremulousness, headache, diaphoresis, palpitations, increased body temperature, tachycardia, and hypertension. **EBN:** *These are the broad symptoms of alcohol withdrawal that can progress in intensity without treatment (Makic, 2017).*
- Monitor severity of withdrawal symptoms with the Clinical Institute Withdrawal Assessment (CIWA-Ar). **CEB:** *The CIWA-Ar is a 10-item scale for clinical quantification of the severity of the alcohol withdrawal syndrome (Sullivan et al, 1989; Kattimani & Bharadwaj, 2013). The CIWA-Ar scale is available at http://www.cbhallc.com/documents/4a-detox%20guidelines.pdf.*
- Evaluate the client for progression to the delirium tremens (DTs). **EB:** *The DTs are severe and life-threatening withdrawal symptoms that occur in 3% to 5% of patients on about the third day of withdrawal. DT symptoms have a rapid onset and include the broad alcohol withdrawal symptoms, fluctuating levels of cognition and attention, and autonomic instability. Associated risk factors are previous DTs, untreated seizures, CIWA-Ar score > 15, heart rate > 100, history of sustained drinking, systolic blood pressure > 150 mm Hg, alcohol intake > 2 days, age > 30 years, recent misuse of benzodiazepines, and concurrent medical illness (Long, Long, & Koyfman, 2017).*
- Assess nutritional status for risk of malnutrition, thiamine (B_1) deficiency associated with chronic alcohol abuse, folate deficiency, and vitamin D deficiency–associated history of inadequate exposure to sunlight. Consult with health care provider as needed for supplement order. **EB:** *Alcoholism is a major cause of malnutrition in the United States. Thiamine deficiencies contribute to the development of Korsakoff's syndrome and Wernicke's encephalopathy, which are neurological complications of alcohol abuse (Manzo et al, 2014; Dugum & McCullough, 2015). Vitamin D insufficiency is associated with cognitive impairment (Goodwill & Szoeke, 2017).*
- Address hydration needs. **EB:** *Clients in alcohol withdrawal require administration of fluids to correct dehydration (Mirijello et al, 2015; Long, Long, & Koyfman, 2017).*
- Determine hepatic and renal functioning prior to administration of medications. **EB:** *Hepatic or renal disease can slow the clearance of medications and lead to complications or toxicities (Long, Long, & Koyfman, 2017).*

Risk for Opioid-Induced Withdrawal Syndrome

- Assess for client's opioid of choice, last use, and current withdrawal symptoms. **EB:** *The onset of withdrawal symptoms depends on the half-life of the opioid used. Heroin withdrawal occurs 6 to 8 hours after the last use, and methadone and fentanyl withdrawal occurs 1 to 3 days after the last dose (Donroe et al, 2017).*
- Monitor severity of withdrawal symptoms with the Clinical Opiate Withdrawal Scale (COWS). **EB:** *A standardized assessment tool is necessary for evaluating and treating opioid withdrawal. The COWS is scored numerically based on severity, with values summed to give a cumulative score. A threshold score indicates when treatment should be initiated (Wesson & Ling, 2003).*
- Assess and manage early opioid withdrawal symptoms (agitation, anxiety, insomnia, muscle aches, increased lacrimation, rhinorrhea, sweating, and yawning) and late opioid withdrawal symptoms (abdominal cramping, diarrhea, pupillary dilation, nausea, vomiting, and piloerection) of opioid withdrawal. **EBN:** *Severe withdrawal can lead to fluid and electrolyte imbalances, cardiac dysrhythmias, acute kidney injury, or rhabdomyolysis. A failure to treat could result in client injury or in clients leaving the clinical setting against medical advice (Turner et al, 2018).*

• Monitor vital signs. **EBN:** *Parameters for blood pressure should be followed especially for patients treated with clonidine or other alpha-2 agonists, which can cause hypotension (Turner et al, 2018).*
• Clients should be taught about risk of relapse and other safety concerns from using opioid withdrawal management as stand-alone treatment for opioid use disorder. **EB:** *Opioid withdrawal management on its own is not a treatment method (Kampman & Jarvis, 2015).*
• Teach the client about the anticipated withdrawal symptoms and opioid cravings, while offering support and encouragement. **EBN:** *A lack of knowledge in conjunction with decreased nurse empathy and engagement are barriers to treatment (Worley, 2017).*
▲ Monitor laboratory reports and report to health care provider. **EBN:** *Serum electrolytes are closely evaluated for abnormalities and replaced as indicated (Turner et al, 2018).*
▲ Refer patient for buprenorphine or methadone treatment. **EB:** *Using medications for opioid withdrawal management is recommended over abrupt cessation of opioids. Abrupt cessation of opioids may lead to strong cravings, which can lead to continued use (Kampman & Jarvis, 2015). A recent study showed that emergency department–initiated buprenorphine was associated with increased engagement in addiction treatment and reduced illicit opioid use during the 2-month interval when buprenorphine was continued in primary care (D'Onofrio et al, 2017).*

Risk for Benzodiazepine-Induced Withdrawal Syndrome

• Assess for client's last benzodiazepine use, and current withdrawal symptoms. **EB:** *The onset of withdrawal symptoms occurs within 1 to 3 days of drug cessation. Common withdrawal symptoms include any of the following: autonomic instability (tachycardia, elevated blood pressure), tremulousness, diaphoresis, insomnia, anxiety, depression, psychosis (hallucinations, delusions), sensory hypersensitivity (photophobia, hyperacusis), perceptual distortions, depersonalization, agoraphobia, flulike symptoms, paresthesia, muscle stiffness, ataxia, visual disturbances, DTs, and seizures (Puening et al, 2016).*
• Implement seizure precautions. **EB:** *Clients withdrawing from benzodiazepines may also experience seizures on withdrawal (Puening et al, 2016).*
• Rule out delirium from other causes or other withdrawal syndromes. **EB:** *The symptoms of benzodiazepine withdrawal appear similar to delirium, as well as barbiturate or alcohol withdrawal (Puening et al, 2016).*
▲ Anticipate use of the same treatment protocols as for alcohol withdrawal and use of a long-acting benzodiazepine in tapering doses over time. **EB:** *A tapering schedule will assist with prevention of relapse (Donroe et al, 2017).*

Risk for Cocaine/Methamphetamine-Induced Withdrawal Syndrome

• Assess for client's last stimulant use, and current withdrawal symptoms. **EB:** *The onset of withdrawal symptoms occurs within 24 hours after abrupt discontinuation of using high amounts of amphetamine-type substances over a prolonged period of time. Common stimulant withdrawal symptoms include depressed mood with any of the following: fatigue, vivid dreams, insomnia, increased appetite, psychomotor retardation, and agitation. Cocaine withdrawal is mild and treated supportively. Methamphetamine use can result in significant psychiatric withdrawal symptoms and intense craving after abrupt cessation (Donroe et al, 2017).*

Risk for Cannabis-Induced Withdrawal Syndrome

• Assess for client's last cannabis use, and current withdrawal symptoms. **EB:** *The onset of withdrawal symptoms occurs within a week of cannabis cessation. Common cannabis withdrawal symptoms include any of the following: anxiety, irritability, malaise, dysphoria, decreased appetite, restlessness, and sleep disturbances (Zehra et al, 2018).*
• Direct nursing actions to address anxiety, irritability, sleep disturbances, and decreased appetite. **EB:** *Nursing care should target the specific symptoms of cannabis withdrawal as part of a treatment that targets cannabis use reduction and prevention of relapse (Zehra et al, 2018).*

Risk for Nicotine-Induced Withdrawal Syndrome

• Assess for client's last nicotine use, and current withdrawal symptoms. **EB:** *The onset of withdrawal symptoms occurs within hours of last use. Common nicotine withdrawal symptoms include craving for nicotine, irritability, anger, frustration, anxiety, difficulty concentrating, restlessness, decreased heart rate, increased appetite, weight gain, tremor, headaches, craving, delirium, and sleep disturbance (Ginige, 2016).*
• Rule out nicotine withdrawal as the cause of delirium in critically ill clients. **EB:** *Chronic consumption of nicotine can cause desensitization and upregulation of acetylcholine receptors. In an acute nicotine withdrawal state, the lack of sufficient nicotinic stimulation leads to acetylcholine deficiency, which is associated with delirium (Ginige, 2016).*

All Withdrawal Syndromes

• Obtain a drug and/or alcohol history using a tool such as the AUDIT-C or the DAST-10. **EB:** *The Audit-C is a simple 3-question screen for hazardous or harmful drinking that can stand alone or be incorporated into general health history questionnaires. The DAST-10 is a 10-item, yes/no self-report instrument that takes less than 8 minutes to complete (Mulvaney-Day et al, 2018).*
• Implement and follow institutional withdrawal protocols. **EB:** *A recent study suggested that using a protocol for treatment of critical care patients with alcohol withdrawal leads to decreased intensive care unit (ICU) length of stay and reduced ICU cost (Tavani et al, 2017).*
• Assess for signs of recent trauma or head injury. **EB:** *A study found that trauma patients that present to the hospital in a delayed fashion have unique characteristics and are more likely to suffer negative outcomes including substance withdrawal (Kao et al, 2017).*
• Assess client's level of consciousness, monitor for changes in behavior, and orient to reality as needed. **EB:** *Reality orientation will support the client with changes in level of consciousness or behavior and may indicate progression of withdrawal (Mirijello et al, 2015).*
• Assess vital signs and monitor for existing medical conditions and current medications. **EB:** *Withdrawal symptoms can be exacerbated or masked by existing medical conditions, medications, or treatments (Long, Long, & Koyfman, 2017).*
• Assess and monitor for expression of psychological distress. **EB:** *Withdrawal can cause or exacerbate current emotional, psychological, or mental problems (*Harford et al, 2018*).*
• Collect urine/serum samples for laboratory tests. **EB:** *Routine treatment for substance withdrawal should include serum (or breath) alcohol concentrations, complete blood count, renal function tests, electrolytes, glucose, liver enzymes, urinalysis, and urine toxicology screening (Mirijello et al, 2015).*
• Address craving for substances with mindfulness-based techniques. **EB:** *Compared with those receiving usual care, a study found mindfulness-based addiction treatment*

participants reported lower anxiety, concentration difficulties, craving, and dependence, as well as higher self-efficacy for managing negative affect without smoking (Spears et al, 2017).

• Respond to agitated behavior with deescalation techniques. **EBN:** *Research shows staff intervention can modify processes and reduce further conflict (Berring, Pedersen, & Buus, 2016).*

• Administer as needed (PRN) medications for agitation and symptom control as ordered. **EB:** *A study found symptom-triggered treatment for alcohol withdrawal syndrome individualizes treatment, is safe, decreases treatment duration and the use of benzodiazepines, and consequently reduces health care costs (Soravia et al, 2018).*

• Provide a quiet room without dark shadows, noises, or other excessive stimuli. **EB:** *Supportive care includes controlling environmental stimuli that may increase client agitation or irritability (Mirijello et al, 2015).*

• Provide suicide precautions and 1:1 staffing for clients that are delirious or who may present a danger to themselves or others. **EB:** *A recent study showed that substance use disorders are associated with self- and other-directed violence (Harford et al, 2018).*

Client/Family Teaching and Discharge Planning

▲ After withdrawal symptoms have subsided, refer client to substance use treatment. **EB:** *Collaborative discharge planning can increase the likelihood of the patient's success of substance abstinence. Referral to appropriate services can reduce discharges against medical advice and increase follow-up in postdischarge addiction treatment centers (Donroe et al, 2017).*

▲ Refer for smoking cessation services that target nicotine craving. **EB:** *A recent study found that nicotine craving may be a useful therapeutic target for increasing the effectiveness of smoking-cessation treatment (Magee, Lewis, & Winhusen, 2016).*

Risk for Sudden Infant Death

Marina Martinez-Kratz MS, RN, CNE

NANDA-I

Definition

Susceptible to unpredicted death of an infant.

Risk Factors

Delay in prenatal care; exposure to secondhand smoke; infant overheating; infant overwrapping; infant placed in prone position to sleep; infant placed in side-lying position to sleep; insufficient prenatal care; soft sleep surface; soft, loose objects placed near infant; infant less than 4 months, placed in sitting devices for routine sleep

At-Risk Population

African American ethnicity; age 2 to 4 months; infant not breastfed exclusively or fed with expressed breast milk; low birth weight; male gender; maternal smoking during pregnancy; Native American ethnicity; postnatal exposure to alcohol; postnatal exposure to elicit drug; prematurity; prenatal exposure to alcohol; prenatal exposure to elicit drug; young parental age

Associated Condition
Cold weather

NOC(Nursing Outcomes Classification)

Suggested NOC Outcomes
Knowledge: Infant Care; Parenting Performance; Safe Home Environment; Safe Sleep Environment

Example NOC Outcome with Indicators
Knowledge: Infant Care as evidenced by the following indicators: Proper infant positioning/Age-appropriate cardiopulmonary resuscitation techniques. (Rate the outcome and indicators of **Knowledge: Infant Care:** 1 = no knowledge, 2 = limited knowledge 3 = moderate knowledge, 4 = substantial knowledge, 5 = extensive knowledge [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Explain appropriate measures to prevent sudden infant death syndrome (SIDS)
- Demonstrate correct techniques for positioning and blanketing the infant, protecting the infant from harm

NIC(Nursing Interventions Classification)

Suggested NIC Interventions
Infant Care; Teaching: Infant Safety 0 to 3 Months

Example NIC Activities—Teaching: Infant Safety
Instruct parent/caregiver to place infant on back to sleep and keep loose bedding, pillows, and toys out of crib; Instruct parent/caregiver to avoid holding infant while smoking or holding hot liquids

Nursing Interventions and *Rationales*

- Position the infant supine to sleep during naps and night; do not position in the prone position or side-lying position (American Academy of Pediatrics [AAP], 2014a). **EB:** *In a research review, evidence shows sleeping prone or in a side-lying position is associated with an increased risk of SIDS (Carlin & Moon, 2017).*
- Avoid use of bedding, such as blankets and loose sheets, for sleeping. Also keep quilts, pillows, bumpers, sheepskins, and soft toys out of the infant's bed. Dress the child in one-piece sleepers or wearable blankets (AAP, 2014b). *Infants can suffocate from close proximity to these soft items.*
- Avoid over bundling, overheating, and swaddling the infant. The infant should not feel hot to touch. **EB:** *Swaddling increases the risk of SIDS twofold in infants 6 months or younger (Pease et al, 2016). Swaddling has been associated with infant death, especially when the infant has shown the ability to roll over (Carlin & Moon, 2017).*
- Provide the infant a certain amount of time in the prone position while the infant is awake and observed. Change the direction that the baby lies in the crib from one week to the next; avoid too much time in car seats and carriers. *Prolonged time in the supine position can result in a flat head shape and decreased strength of the neck and shoulder muscles (AAP, 2014a).*

Home Care

• Most of the interventions and client teaching information are relevant to home care.
• Evaluate home for potential safety hazards, such as inappropriate cribs, cradles, or strollers.
• Determine where and how the child sleeps, and provide instructions on safe sleeping positions and environments as needed.

Multicultural

• Encourage pregnant American Indian mothers and native Alaskan Indian mothers to avoid drinking alcohol and to avoid wrapping infants in excessive blankets or clothing. **EB:** *A study of the death rate of infants of Indian mothers found an increased rate of SIDS compared with the white population, which was thought to be associated with alcohol ingestion and excessive clothing and blankets used by the mothers (Wong et al, 2014).*
• Encourage Hispanic and black mothers to find alternatives to bed sharing or placing infants for sleep on adult beds, sofas, or cots, and to avoid placing pillows, soft toys, and soft bedding in the sleep environment. **EB:** *A study found that both Hispanic and black mothers were more likely to share a bed with an infant, and as a result there is an increasing rate of SIDS in their infants (Colson et al, 2013).*

Client/Family Teaching and Discharge Planning

• Teach the safety guidelines for infant care in the previous interventions.
• Provide parents of both term and preterm infants with verbal and written education about SIDS and ways to reduce the risk of SIDS before discharge to home. **EBN:** *Study results demonstrated that providing current written material along with modeling safe sleep practices in the hospital prior to discharge to home can help further reduce the incidence of SIDS (Dufer & Godfrey, 2017).*
• Recommend breastfeeding. **EB:** *A review identified breast feeding as a protective factor (Carlin & Moon, 2017).*
• Teach parents the need to obtain a crib that conforms to the safety standards of the Consumer Product Safety Commission (CPSC). *Drop-side rail cribs are now prohibited; cribs need stronger slats and mattress supports and better quality hardware (CPSC, 2013).*
• Teach the need to stop smoking during pregnancy and to not smoke around the infant. Do not allow the infant to be exposed to any secondhand smoke. **EB:** *Maternal smoking remains the strongest prenatal modifiable risk factor for SIDS (Friedmann et al, 2017).*
• Teach parents, especially mothers, not to use alcohol, medications, or illicit drugs while caring for or bed sharing with an infant. **EB:** *Research has shown that mothers who were previously diagnosed with alcoholism had infants with a significant risk for SIDS (O'Leary et al, 2013).*
• Teach parents not to sleep in the same bed with the infant, regardless of alcohol, medications, smoking, or illicit drug use. **EB:** *A study of more than 1000 SIDS cases found that bed sharing with an infant resulted in an increased incidence of SIDS even without illicit drugs, alcohol, or smoking (Carpenter et al, 2013).*
• Teach parents not to place the infant on a cushion to sleep, or a sofa chair or other soft surface. Infants should sleep in a crib *(AAP, 2014a).*
• Recommend an alternative to sleeping with an infant of placing the infant's crib near their bed to allow for more convenient breastfeeding and parent contact. *Parents should be advised to place the baby in his or her own crib next to the parent's bed (AAP, 2014a).*

- Recommend that parents with infants in child care make it very clear to the employees that the infant must always be placed in the supine position to sleep, not prone or in a side-lying position (AAP, 2014a).

Risk for Suffocation

Melodie Cannon DNP, MSc/FNP, BHScN, RN(EC), NP-PHC, CEN, GNC(C)

NANDA-I

Definition

Vulnerable to inadequate air availability for inhalation, which may compromise health.

Risk Factor

Access to empty refrigerator/freezer; eating large mouthfuls of food; emotional disturbance; gas leak; insufficient knowledge of safety precautions; low-strung clothesline; pacifier around infant's neck; playing with plastic bag; propped bottle placed in infant's crib; small object in airway; smoking in bed; soft underlayment; unattended in water; unvented fuel-burning heater; vehicle running in closed garage

Associated Condition

Alteration in cognitive functioning; alteration in olfactory function: face/neck disease; face/neck injury; impaired motor functioning

NOC(Nursing Outcomes Classification)

Suggested NOC Outcomes

Knowledge: Infant Care; Parenting: Adolescent Physical Safety, Early/Middle Childhood Physical Safety, Infant/Toddler Physical Safety; Personal Safety; Risk Control; Risk Detection; Safe Home Environment; Substance Addiction Consequences

Example NOC Outcome with Indicators

Knowledge: Infant Care as evidenced by the following indicators: Strategies to prevent choking/Appropriate activities for child's developmental level/First aid techniques. (Rate the outcome and indicators of **Knowledge: Infant Care:** 1 = no knowledge, 2 = limited knowledge, 3 = moderate knowledge, 4 = substantial knowledge, 5 = extensive knowledge [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Undertake appropriate measures to prevent suffocation
- Demonstrate correct techniques for emergency rescue maneuvers (e.g., Heimlich maneuver, rescue breathing, cardiopulmonary resuscitation [CPR]) and describe situations that require them

NIC(Nursing Interventions Classification)

Suggested NIC Interventions

Aspiration Precautions; Environmental Management: Safety; Infant Care; Positioning; Security Enhancement; Surveillance; Surveillance: Safety; Teaching: Infant Safety

Example NIC Activities—Environmental Management: Safety

Identify safety hazards in the environment (i.e., physical, biological, and chemical); Remove hazards from the environment, when possible

Nursing Interventions and *Rationales*

• Identify hospitalized clients at particular risk for suffocation, including the following:
    - ❍ Clients with altered levels of consciousness
    - ❍ Infants or young children
    - ❍ Clients with developmental delays
    - ❍ Clients with mental illness, especially schizophrenia
    - ❍ Clients who have been physically or chemically restrained

Restraint use has been associated with mortality.
EB: *A review of restraint use in nursing home patients found evidence of physical restraint associated deaths. Neck compression was found to be the most common mechanism that resulted in asphyxia (Bellenger et al, 2017).*
Institute safety measures such as proper positioning and feeding precautions. See the care plans for Risk for **Aspiration** and Impaired **Swallowing** for additional interventions. Vigilance and special protective measures are necessary for clients at greater risk for suffocation. **EB:** *Swallowing disorders are common in schizophrenia with associated morbidity and mortality from either acute asphyxia from airway obstruction or from aspiration and pneumonia. The death rate from acute asphyxia is significantly higher in these patients (up to 100 times greater than the general population) (Kulkarni, Kamath, & Stewart, 2017).*

Pediatric

• Counsel families on the following for care of an infant:
    - ❍ Position infants on their back to sleep; do not position them on their side or prone *(Registered Nurses' Association of Ontario, 2014).*
    - ❍ Position infants on their back to sleep; do not position them on their side or prone. Obtain a new crib that conforms to the safety standards of the Federal Safety Commission. *Ensure cribs/playpens are properly assembled to prevent collapse. Only the original size mattress should be used to prevent gaps in which the child could potentially become wedged. Cribs/playpens that do not conform to current safety standards should not be used (Theurer & Bhavsar, 2013).* Place the infant in the crib with a properly fitted mattress, only to sleep, not on an adult bed, sofa, chair, baby seats, swings, slings, or playpen. *The safest infant sleep surface is a firm, tight-fitting mattress. Cribs, bassinets, and playpens that meet these criteria may be acceptable. Soft bedding, bumper pads, pillows, blankets, positioning devices, and sheepskins are associated with an increase in sudden infant death syndrome. Soft bedding also increases the risk of unintentional suffocation and asphyxia (Carlin & Moon, 2017).* **EB:** *A study demonstrated that the sofa as a sleep surface is extremely hazardous and increases the risk of sudden and unexplained infant deaths. Sofa deaths were associated with surface sharing, being found in the side position, a change in sleep location, and prenatal tobacco exposure (Rechtman et al, 2014).*
    - ❍ Avoid use of loose bedding, such as blankets and sheets, for sleeping. If blankets are used, they should be tucked in around the crib mattress so the infant's face is less likely to become covered by bedding. The blanket should end at the level of the infant's chest. **EB:** *A study of sleep-related infant deaths found that infants from 0 to 3 months were more likely to die while sharing a bed surface, whereas infants 4 months up to 364 days were more likely to die having been found in the prone position with blankets and stuffed animals in the area (Colvin et al, 2014). See care plan Risk for* ***Sudden Infant Death*** *for further interventions.*
• Assess for signs and symptoms of abuse such as Munchausen syndrome by proxy (MSBP). **CEB:** *Suffocation in MSBP is one important differential diagnosis in suspected cases of SIDS (Vennemann et al, 2005).*

• Conduct risk factor identification, noting special circumstances in which preventive or protective measures are indicated. Note the presence of environmental hazards, including plastic bags; cribs with slats wider than 2 inches; ill-fitting crib mattresses that can allow the infant to become wedged between the mattress and crib; pillows/loose bedding in cribs; placement of crib near windows with blinds or cords; co-sleeping; abandoned large appliances such as refrigerators, dishwashers, or freezers; clothing with cords or hoods that can become entangled; bibs; pacifiers on a string; necklaces in infants and children; drapery cords; and pull-toy strings. *Suffocation by airway obstruction is a leading cause of death in children younger than 6 years of age. Families need to be taught child protection. Cribs should not be near walls, furniture, or any object that could result in entrapment should the child get out of the crib. Items with cords and strings should also be removed (Theurer & Bhavsar, 2013).* **EB:** *Bed sharing is associated with accidental suffocation and strangulation and sudden infant death. The risk of infant bed sharing is increased in infants who have no identified place to sleep, have health or care issues, and are breast fed. Education should support breastfeeding without bed sharing, highlight the need for safe sleep places, and address the risk factors for sleep-related deaths (Heere et al, 2017).*
• Counsel families to evaluate household furniture for safety, including large dressers, televisions, book shelves, and appliances, which may need to be anchored to the wall to prevent the child from climbing on the furniture and it falling forward and suffocating the child.
• *Strategies to prevent suffocation should essentially include removing any item from the child's sleep or play area that could potentially cause harm or even death caused by entrapment or entanglement (Theurer & Bhavsar, 2013).* **EB:** *Injuries to children by falling televisions have become more frequent. Dressers and other furniture not designed for holding televisions were commonly involved. Toddlers ages 1 to 3 most frequently suffer head and neck injuries. Small children may suffer secondary brain injuries or death by mechanical asphyxia because of their small size compared with the size of the television (Cusimano & Parker, 2016).*
• Counsel families not to serve these foods to the child younger than 5 years of age: nuts, seeds, hot dogs, popcorn, pretzels, chips, chunks of meat, hard pieces of fruit or vegetables, raisins, whole grapes, hard candies, gum, chewable vitamins, fish with bones, snacks on toothpicks, and marshmallows. **EB:** *A review of the literature demonstrated that seeds, nuts, and legumes were the most commonly aspirated food items. There is legislation by the Consumer Product Safety Commission regarding labeling of toy parts, but there are no similar guidelines for food products (Sidell et al, 2013).*
• Counsel families to keep the following items away from the sight and reach of infants and toddlers: buttons, beads, jewelry, pins, nails, marbles, coins, stones, magnets, and balloons. Choose age appropriate toys and games for children and check for any small parts that may be a choking hazard because children have the need to put everyday objects in their mouths (Safekids.org, 2015). *Reviews of foreign body injuries found that pearls, balls, coins, nuts, seeds, and toy parts were common objects ingested by children and resulted in increased morbidity and mortality (choking) (Passali et al, 2015).*
• Stress water and pool safety precautions, including vigilant, uninterrupted parental supervision. *Children can drown quickly in various water sources including tubs, buckets, pools, ponds, and lakes. Open water drowning is prevalent in older teens and young adults and prevention strategies should include the need for personal flotation devices and education regarding impaired judgment with alcohol use (Johnston & Ebel, 2013).* **EB:** *The majority of pediatric immersion-related deaths could be prevented with supervision (Bamber et al, 2014). Pools should be surrounded completely by fencing that is difficult to climb, is regularly*

assessed for structural defects, and has self-closing latches. Four-sided isolation fencing has been found to significantly reduce the risk of drowning (Johnston & Ebel, 2013).
• Underscore the necessity of not allowing children to play with or near electric garage doors and of keeping garage door openers out of the reach of young children. *Children close to the ground may not be large enough to trigger reversal mechanisms on the door and may become trapped.*
• For adolescents, watch for signs of depression that could result in suicide by suffocation. **EB:** *Suicide in adolescents and young adults is increasing. According to 2014 data, for males and females in all age groups (including adults), the rate of suicide by suffocation has increased over the years (Curtin, Warner, & Hedegaard, 2016).* **EB:** *A surveillance data review of suicide in children and early adolescents found that compared with adolescents who commit suicide, in death by suicide in children, the victims were commonly male, black, and died by hanging, strangulation, or suffocation. Children who died by suicide often experienced relationship problems with family, girlfriends, or boyfriends (Sheftall et al, 2016).*

Geriatric

• Assess the status of the swallow reflex. Offer appropriate foods and beverages accordingly. Older adults, especially those receiving antipsychotic medications, have an increased incidence of choking. Refer to Impaired **Swallowing.** **EB:** *Dysphagia is a common problem in adults with mental health illness and has a significant mortality risk because of choking asphyxiation (Aldridge & Taylor, 2012).*
• A swallowing assessment by a speech-language pathologist is recommended in patients with suspected or confirmed dysphagia to ensure the appropriate type and consistency of diet to mitigate choking and aspiration risk. **EBN:** *Safe nursing care includes a consultation with a speech-language pathologist whenever doubts arise regarding a client's ability to tolerate oral-supported nutrition in any form (Teasell et al, 2015).*
• Ensure proper positioning during and after feeding to decrease the risk of aspiration. *Dysphagia in the elderly results in increased morbidity and mortality. It is important to recognize the relationship between dysphagia and aspiration pneumonia in the elderly because of the high mortality rate associated with this (Smukalla et al, 2017).*
• Use care in pillow placement when positioning frail older clients who are on bed rest. *Frail older clients are at risk for suffocation if the head becomes lodged against pillows and the client cannot reposition himself or herself because of weakness. Older adults who are cognitively impaired require assessment of the safety of their sleep environment for potential hazards similar to sleeping risks for the very young (Byard & Gilbert, 2011).*
• Recognize that older adults in depression may use hanging, strangulation, and suffocation as a means of suicide. **EB:** *Suicide attempts in seniors often result in death. Social isolation, poor health, frailty, loneliness, and depression are thought to be possible contributing factors. Regardless of age, suffocation, which includes hanging and strangulation, accounted for almost half of the suicides in Canada in 2012 (Skinner et al, 2016).*

Home Care

• Assess the home for potential safety hazards in systems that are not likely to be fixed (e.g., faulty pilot lights or gas leaks in gas stoves, carbon monoxide release from heating systems, kerosene fumes from portable heaters).
• Assist the family in having these areas assessed and making appropriate safety

arrangements (e.g., installing detectors, making repairs, home safety inspections). *Assessment and correction of system problems prevent accidental suffocation.*
• Advise the family to have a safety plan for potential escape routes from the home in the event of detectors going off, fire, or other emergencies.

Client/Family Teaching and Discharge Planning

• Recommend that families who are seeking day care or in-home care for children, geriatric family members, or at-risk family members with developmental or functional disabilities inspect the environment for hazards and examine the first aid preparation and vigilance of providers. *Many working families must trust others to care for family members.*
• Recommend to families that they advise any caregivers of specific food consistency, types, and any feeding precautions and strategies required to decrease risk of choking and aspiration in high-risk children or adults.
• Ensure family members learn and practice rescue techniques, including treatment of choking and lack of breathing, as well as CPR. *Family members need preparation to deal with emergency situations and should take part in the American Heart Association Basic Lifesaving Course or the American Red Cross Infant/Child CPR Course.*
• *Use client/family encounters to provide age appropriate anticipatory guidance for safety precautions for infants and children and education regarding risk reduction for suffocation for vulnerable older adults or clients with physical or mental disabilities.*

Risk for Suicide

Kathleen L. Patusky MA, PhD, RN, CNS

NANDA-I

Definition

Susceptible to self-inflicted, life threatening injury.

Related Factors

Behavioral

Changing a will; giving away possessions; impulsiveness; making a will; marked change in attitude; marked change in behavior; marked change in school performance; purchase of a gun; stockpiling medication; sudden euphoric recovery from major depression

Psychological

Guilt (substance misuse)

Situational

Access to weapon; loss of autonomy; loss of independence

Social

Cluster suicides; disciplinary problems; disrupted family life; grieving; helplessness; hopelessness; insufficient social support; legal difficulty; loneliness; loss of significant relationship; social isolation

Verbal

Reports desire to die; threats of killing self

Other

Chronic pain

At-Risk Population

Adolescence; adolescents living in nontraditional settings; Caucasian ethnicity; divorced status; economically disadvantaged; older adults; family history of suicide; history of childhood abuse history of suicide attempt; homosexual youth; institutionalization; living alone; male gender; Native American ethnicity; relocation; retired; widowed; young adult males

Associated Condition

Physical illness; psychiatric disorder; terminal illness

NOC(Nursing Outcomes Classification)

Suggested NOC Outcomes

Depression Level; Impulse Self-Control; Loneliness Severity; Mood Equilibrium; Risk Detection; Suicide Self-Restraint

Example NOC Outcome with Indicators

Suicide Self-Restraint as evidenced by the following indicators: Expresses feelings/Refrains from attempting suicide/Verbalizes suicidal ideas/Controls impulses. (Rate the outcome and indicators of **Suicide Self-Restraint:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Consider using one of the measures of suicide risk that are available for clients: Nurses' Global Assessment of Suicide Risk (Cutcliffe & Barker, 2004); Center for Epidemiological Studies Depression Scale measures depressed mood level (Chiu et al, 2010); Beck Suicide Intent Scale identifies a strong intent to die (Astruc et al, 2004); Suicide Assessment Checklist (Rogers, Lewis, & Subich, 2002)

Client Outcomes

Client Will (Specify Time Frame)

- Not harm self
- Maintain connectedness in relationships
- Disclose and discuss suicidal ideas if present; seek help
- Express decreased anxiety and control of impulses
- Talk about feelings; express anger appropriately
- Refrain from using mood-altering substances
- Obtain no access to harmful objects
- Yield access to harmful objects
- Maintain self-control without supervision

NIC(Nursing Interventions Classification)

Suggested NIC Interventions

Anxiety Reduction; Coping Enhancement; Crisis Intervention; Delusion Management; Mood Management; Substance Use Prevention; Suicide Prevention; Support System Enhancement; Surveillance

Example NIC Activities—Suicide Prevention

Determine presence and degree of suicidal risk; Encourage patient to seek out care providers to talk as urge to harm self occurs

Nursing Interventions and *Rationales*

The American Psychiatric Nurses Association (APNA, 2015) has adapted a set of essential competencies for psychiatric nurses, all of which can be useful for generalist nurses. These competencies have been incorporated in the following sections.

- Before implementing interventions in the face of suicidal behavior, nurses should examine their own emotional responses to incidents of suicide to ensure that interventions will not be based on countertransference reactions. **EBN:** *Understanding of nurses' responses to suicidal clients can facilitate suicide prevention and recovery (Talseth & Gilje, 2011; APNA, 2015).*
- Pursue an understanding of suicide as a phenomenon at all levels of nursing practice. Elements to be considered include the terminology used with suicidality and self-harm phenomena, the epidemiology of suicide, the risk and protective influences on suicide, and the evidence-based best practices in preventing and responding to

suicidality (APNA, 2015).

• Assess for suicidal ideation when the history reveals the following: depression, substance abuse; bipolar disorder, schizophrenia, anxiety disorders, posttraumatic stress disorder, dissociative disorder, eating disorders, substance use disorders, antisocial or other personality disorders; attempted suicide, current or past; recent stressful life events (divorce and/or separation, relocation, problems with children); recent unemployment; recent bereavement; adult or childhood physical or sexual abuse; gay, lesbian, or bisexual gender orientation; family history of suicide; and history of chronic trauma. *Clinicians should be alert for suicide when the previously mentioned factors are present in asymptomatic persons (Li et al, 2011; American Psychiatric Association [APA], 2015).* **EB:** *In a 10-year longitudinal study, 83% of persons who committed suicide received health care within the previous year; only 24% had been diagnosed with a mental disorder in the 4 weeks prior to death. Medical specialty and primary care accounted for the most common visits (Ahmedani et al, 2014).* Assess all medical clients and clients with chronic illnesses, traumatic injuries, or pain for their perception of health status and suicidal ideation. *Medical clients who perceived their health to be poor or who were in chronic pain were significantly more likely to report current suicidal ideation.* **EB:** *Research, including systematic review, supported the association of both type 1 and type 2 diabetes with an increase in suicidal ideation (Ceretta et al, 2012; Pompili et al, 2014). Myocardial infarction has been connected with higher suicide rates, especially during the first month after discharge, and with impaired prognosis (Larsen, 2013). Persons living with HIV/AIDS who had depressive symptoms and low life satisfaction were at significantly higher risk of suicide (Davis et al, 2011).*

• Assess the client's ability to enter into a no-suicide contract. Contract (verbally or in writing) with the client for no self-harm if the client is appropriate for a contract; recontract at appropriate intervals. *Discussing feelings of self-harm with a trusted person provides relief for the client. A contract gets the subject out in the open and places some of the responsibility for safety with the client.* **CEB:** *Some clients are not appropriate for a contract, such as those under the influence of drugs or alcohol or unwilling to abstain from substance use, and those who are isolated or alone without assistance to keep the environment safe (Hauenstein, 2002). If the client will not contract, the risk of suicide should be considered higher.* **CEBN:** *Note: Although contracting is a common practice in psychiatric care settings, research has suggested that self-harm is not prevented by contracts. Thorough, ongoing assessment of suicide risk is necessary, whether or not the client has entered into a no-self-harm contract. Contracts may not be appropriate in a community setting (McMyler & Pryjmachuk, 2008).*

• Be alert for the following warning signs of suicide: making statements such as, "I can't go on," "Nothing matters anymore," "I wish I were dead"; becoming depressed or withdrawn; behaving recklessly; getting affairs in order and giving away valued possessions; showing a marked change in behavior, attitudes, or appearance; abusing drugs or alcohol; and suffering a major loss or life change. *Suicide is rarely a spontaneous decision. In the days and hours before people kill themselves, clues and warning signs usually appear.*

• Take suicide notes seriously and ask if a note was left in any previous suicide attempts. Consider themes of notes in determining appropriate interventions. *Clients who leave a suicide note may be at higher risk of completed suicide in the future. A note should be viewed as an indication of a failed but serious attempt.*

• Question family members regarding the preparatory actions mentioned. *Clinicians should be alert for suicide when these factors are present in asymptomatic persons (APA, 2015).*

• Determine the presence and degree of suicidal risk. A number of questions will elicit the necessary information: Have you been thinking about hurting or killing yourself? How often do you have these thoughts and how long do they last? Do you have a plan? What is it? Do you have access to the means to carry out that plan? How likely is it that you could carry out the plan? Are there people or things that could prevent you from hurting yourself? What do you see in your future a year from now? Five years from now? What do you expect would happen if you died? What has kept you alive up to now? **CEB:** *Using the acronym SAL, the nurse can evaluate the client's suicide plan for its specificity (how detailed and clear is the plan), availability (does the client have immediate access to the planned means), and lethality (could the plan be fatal, or does the client believe it would be fatal). Assessment of reasons for living is another important part of evaluating suicidal clients (Malone et al, 2000).*
• Observe, record, and report any changes in mood or behavior that may signify increasing suicide risk and document results of regular surveillance checks. **EB:** *Suicidal ideation often is not continuous; it may decrease and then increase in response to negative thinking or exposure to stressors (e.g., family visits). Documentation of surveillance will alert all members of the health care team to changes in the clients' potential risk for suicide so they may be prepared to respond in the event of suicidal behavior (APNA, 2015).*
• Develop a positive therapeutic relationship with the client; do not make promises that may not be kept. *Be aware that some clients may offer to self-disclose if the nurse will promise not to tell anyone what they have said. Clarify with the clients that anything they share will be communicated only to other staff but that secrets cannot be kept.* **EBN:** *Nurses reconnect suicidal clients with humanity by guiding the client, helping them learn how to live, and helping them connect appropriately with others. Positive support can buffer against suicide, whereas conflictual interactions can increase suicide risk (Hirsch & Barton, 2011; APNA, 2015).*
• Express desire to help client. Provide education about suicide and the effectiveness of intervention. Validate the client's experience of psychological pain while maintaining a safe environment for the client. *The nurse must reconcile their goal of preventing suicide with recognition of the client's goal to alleviate their psychological pain (APNA, 2015).*
▲ Refer for mental health counseling and possible hospitalization if evidence of suicidal intent exists, which may include evidence of preparatory actions (e.g., obtaining a weapon, making a plan, putting affairs in order, giving away prized possessions, preparing a suicide note). **EB:** *Clients vary in the preparation for suicide attempts, and professional assessment is required to determine the need for hospitalization (APA, 2015). The following interventions may be instituted.*
• Perform risk assessment for possible suicidality on admission to the hospital and thereafter during hospitalization. Alert treatment team to level of risk. *Risk assessment includes evaluating each client's risk factors, ameliorating factors, stated suicidal intent, mental status, history of physical or psychological trauma, triggers that prompt distress, tendency to minimize or exaggerate symptoms, sources of assistance, warning signs of acute risk, and history of previous suicidal or self-harm behavior (APNA, 2015).*
• Determine client's need for supervision and assign a hospitalized client to a room located near the nursing station. *Close assignment increases ease of observation and availability for a rapid response in the event of a suicide attempt (APNA, 2015).*
• Search the newly hospitalized client and the client's personal belongings for weapons or potential weapons and hoarded medications during the inpatient admission procedure, as appropriate. Remove dangerous items. *Clients who are intent on suicide may bring the means with them. Action is necessary to maintain a hazard-free*

environment and client safety (APNA, 2015).
• Limit access to windows and exits unless locked and shatterproof, as appropriate. *Suicidal behavior may include attempts to jump out of windows or to escape the unit to find other means of suicide (e.g., gaining roof access for a jump). Hospitals should ensure that exits are secure.*
• Monitor the client during the use of potential weapons (e.g., razor, scissors). *Clients with suicidal intent may take advantage of any opportunity to harm themselves (APNA, 2015).*
• Increase surveillance of a hospitalized client at times when staffing is predictably low (e.g., staff meetings, change of shift report, periods of unit disruption). *Clients who remain intent on suicide will be watchful of periods when staff surveillance lessens to permit completion of a suicide plan.*
• Ensure that all oncoming staff members have adequate information to assist the client, using the acronym SBARR: situation (current status, observations), background (relevant client history), assessment (including nurse's current risk assessment and relevant lab findings), recommendations (what the nurse believes is necessary going forward), and response feedback (verification of oncoming staff members' understanding) (APNA, 2015).
▲ If imminent suicide is suspected or an attempt has occurred, call for assistance and do not leave the client alone. Client and staff safety will be served by assistance in the response. The client may attempt additional self-harm if left alone.
• Place the client in the least restrictive, safe, and monitored environment that allows for the necessary level of observation. Assess suicidal risk at least daily and more frequently as warranted. *Close observation of the client is necessary for safety as long as intent remains high. Suicide risk should be assessed at frequent intervals to adjust suicide precautions and limitations on the client's freedom of movement and to ensure that restrictions continue to be appropriate.* **EB:** *Inpatient root cause analyses of suicide attempts and environmental safety checklists for units can be helpful in maintaining safety (Mills et al, 2008; APNA, 2015).*
• Consider strategies to decrease isolation and opportunity to act on harmful thoughts (e.g., use of a sitter). **CEB:** *Clients have reported feeling safe and having their hope restored in response to close observation (Bowers & Park, 2001).*
• Explain suicide precautions and relevant safety issues to the client and family (e.g., purpose, duration, behavioral expectations, and behavioral consequences). **CEB:** *Suicide precautions may be viewed as restrictive. Clients have reported the loss of privacy as distressing (Bowers & Park, 2001).*
▲ Refer for treatment and participate in the management of any psychiatric illness or symptoms that may be contributing to the client's suicidal ideation or behavior. *Psychiatric disorders have been associated with suicidal behavior. Symptoms of the disorder may require treatment with antidepressant, antipsychotic, or antianxiety medications.* **EB:** *A systematic review has shown a highly significant effect for cognitive behavior therapy in reducing suicidal behavior (Tarrier, Taylor, & Gooding, 2008).*
▲ Verify that the client has taken medications as ordered (e.g., conduct mouth checks after medication administration). *The client may attempt to hoard medications for a later suicide attempt.*
▲ Maintain increased surveillance of the client whenever use of an antidepressant has been initiated or the dose increased. Antidepressant medications take anywhere from 2 to 6 weeks to achieve full efficacy. *During that period the client's energy level may increase, although the depression has not yet lifted, which increases the potential for suicide.*
• Involve the client in treatment planning and self-care management of psychiatric

disorders. *Self-care management promotes feelings of self-efficacy, particularly for clients with depression. Suicidal ideation may occur in response to a sense of hopelessness, or a sense that the client has no control over life circumstances. The more clients participate in their own care, the less powerless and hopeless they feel. Refer to the care plan for* ***Powerlessness.***
• Explore with the client all circumstances and motivations related to the suicidality. Listen to the client's own views on his or her problems. **EB:** *Primary reasons for suicide attempts were found to be feelings of loneliness or hopelessness and mental illness/psychological problems (APA, 2015).*
• Explore with the client all perceived consequences that could act as a barrier to suicide (e.g., effect on family, religious beliefs). **CEB:** *The most common barrier to suicide is consequences to family members (Bell, 2000).*
• Keep discussion oriented to the present and future. *Clients under stress have difficulty focusing their thoughts, which leads to a sense of being overwhelmed by problems. Focusing on the present and future helps the client to address problem-solving regarding current stressors.*
• Discuss plans for dealing with suicidal ideation in the future (e.g., how to identify precipitating factors, who to contact, where to go for help, and how to respond to desire for self-harm). *Clients are supported in self-care management when they are helped to identify actions they can take if suicidal ideation recurs.*
• Assist the client in identifying a network of supportive persons and resources (e.g., clergy, family, care providers). **EB:** *Social support and positive events were found to have a protective support against suicidal ideation (Kleiman, Riskind, & Schaefer, 2014).*
▲ Refer family members and friends to local mental health agencies and crisis intervention centers if the client has suicidal ideation or a suspicion of suicidal thoughts exists. *Clients at risk should receive evaluation and help (APA, 2015).*
▲ Document client behavior in detail to support outpatient commitment or an overnight psychiatric observation program for an actively suicidal client. *Involuntary outpatient commitment can improve treatment, reduce the likelihood of hospital readmission, and reduce episodes of violent behavior in persons with severe psychiatric illnesses. Overnight psychiatric observation followed by outpatient referral also can be an effective alternative to traditional hospitalization without leading to an increase in suicide gestures or attempts.*
• Use cognitive-behavioral techniques that help the client to modify thinking styles that promote depression, hopelessness, and a belief that suicide is a valid means of escaping the current situation. *Suicide has been shown to be associated with constriction in cognitive style, leading to decreased problem-solving and information processing.* **EB:** *Cognitive-behavioral therapy has been shown to be effective in decreasing suicide attempts with improvement in problem-solving skills (Ghahramanlou-Holloway et al, 2012).*
• Engage the client in group interventions that can be useful to address recurrent suicide attempts. *Group therapy was shown to decrease suicidality.*
• With the client's consent, facilitate family-oriented crisis intervention. Family-oriented crisis intervention can clarify stresses and allow assessment of family dynamics. **EBN:** *An educational intervention addressing ability to care, stress levels, and attitudes toward the suicidal family member was effective in promoting attitudes toward and ability to care for a suicidal family member (Sun et al, 2014).*
• Involve the family in discharge planning (e.g., illness/medication teaching, recognition of increasing suicidal risk, client's plan for dealing with recurring suicidal thoughts, community resources). *Suicidal clients often are ambivalent about hurting themselves; they may not want to die so much as to escape an intolerable situation. Consequently, they often leave clues about their state of mind.* **EBN:** *Family members must learn before clients leave the hospital how to respond to clues early, support the treatment regimen, and encourage the client to initiate the emergency plan. Nurses help in guiding*

families through the process (Sun et al, 2014).

▲ Before discharge from the hospital, ensure that the client has a supply of ordered medications, has a plan for outpatient follow-up, understands the plan or has a caregiver able and willing to follow the plan, and has the ability to access outpatient treatment. *Clients may be discharged before they have recovered substantial functional ability and may have difficulty concentrating on the plan for follow-up. They may need the assistance of others to ensure that prescriptions are filled, that they attend appointments, or that they have transportation to the outpatient care setting.*

▲ In the event of successful suicide, refer the family to a therapy group for survivors of suicide. Recommended clinical interventions include addressing psychological distress, normalizing denial as an effective coping strategy, working with concerns about family disintegration, and helping families deal with stigmatization. **EB:** *Psychoeducational support group participants found relief in sharing a personal narrative of their suicide bereavement with others (Feigelman & Feigelman, 2011a,b).*

• See the care plans for Risk for self-directed **Violence, Hopelessness,** and Risk for **Self-Mutilation.** *Clients with suicidal ideation often are reacting to a feeling of hopelessness.*

Pediatric

• The previously mentioned interventions may be appropriate for pediatric clients.

• Use brief self-report measures to improve clinical management of at-risk cases. **CEBN:** *The Home, Education, Activities, Drug use and abuse, Sexual behavior, and Suicidality and depression (HEADSS) instrument has been found useful in suicide risk assessment of adolescents (Biddle et al, 2010).*

• Recognize that the developmental issues of childhood and adolescence may heighten suicide risks and involve different issues from those with adults. Assess specific stressors for the pediatric client, including bullying. **EBN:** *The experience of being bullied can contribute to suicidality (Cooper, Clements, & Holt, 2012).* **CEBN:** *A model accounting for 41.9% of adolescents' suicide risk showed that negative life events and rumination contributed to suicidal risk behaviors, whereas resilience and social support could decrease the risk (Thanoi et al, 2010).*

• Assess for exposure to suicide of a significant other. **CEB:** *Among risk factors of previous psychiatric history, poor psychosocial function, dysphoric mood, and psychomotor restlessness, suicide of a significant other was shown to create risk for adolescents diagnosed with adjustment disorder (Pelkonen et al, 2005).*

• Be alert to the presence of school victimization around lesbian, gay, bisexual, and transgender (LGBT) issues and be prepared to advocate for the client. **EBN/EB:** *Male adolescents experience greater levels of depression and suicidal ideation in response to high rates of LGBT school victimization (Hatzenbuehler, 2011; Russell et al, 2011; Lea, deWit, & Reynolds, 2014).*

• Evaluate for the presence of self-mutilation and related risk factors. Refer to care plan for Risk for **Self-Mutilation** for additional information. *Self-mutilation and suicidality may co-occur.*

• Be aware that complete overlap does not exist between suicidal behavior and self-mutilation. The motivation may be different (ending life rather than coping with difficult feelings), and the method is usually different. **CEB:** *In one study, about half of the participants reported both attempted suicide and self-mutilation; in the other half there was no overlap in types of acts (Bolognini et al, 2003).*

• Involve the adolescent in multimodal treatment programs. **CEBN:** *A systematic review identified that individual, family, group, and psychopharmacological therapies are used*

for treatment; however, limited research exists to determine which therapy is most effective (Pryjmachuk & Trainor, 2010). Cognitive behavior therapy was cited as showing promise in one study included in a systematic review, but further study was recommended (Robinson, Hetrick, & Martin, 2011).

• Before discharge from the hospital, ensure that the client's parent has a supply of ordered medications, has a plan for outpatient follow-up, has a caregiver who understands the plan or is able and willing to follow the plan, and has the ability to access outpatient treatment. **CEB:** *A compliance enhancement intervention (including contracting interviews with parent and adolescent and telephone contacts) improved attendance at follow-up appointments only when barriers to service were controlled (e.g., delays in getting appointments, placement on a waiting list, inability to switch therapists, problems with insurance coverage) (Spirito et al, 2002).*

• Parental education groups can influence suicide risk factors. **CEB:** *A program of parent education groups focused on improved communication skills and relationships with adolescents. Students in the intervention group reported increased maternal care, decreased conflict with parents, decreased substance abuse, and decreased delinquency (Toumbourou & Gregg, 2002).*

• Support the implementation of school-based suicide prevention programs. *School nurses can be key to early intervention.* **EB:** *School-based suicide prevention programs have been shown in systematic review to improve knowledge, attitude, and help-seeking behavior, with some reports of decreased suicidal ideation (Cusimano & Sameem, 2011). A randomized controlled trial including more than 11,000 students in the European Union were divided into the following three groups: a question and refer group, a mental health awareness group, and a professional screening group. No differences between the groups showed up at 3 months. At 12 months the mental health awareness group showed significant reduction in suicide attempts and severe suicidal ideation (Wasserman et al, 2015).*

Geriatric

• Evaluate the older client's mental and physical health status and financial stressors. **EB:** *Depression in particular is more prevalent in persons with chronic medical conditions, including cardiac disease, diabetes mellitus, cancer, and so forth. Psychological distress, daily hassles, and marital status, along with chronic illnesses and substance abuse, have been associated with suicidal ideation (Bosse et al, 2011; Shelef et al, 2014).*

• Explore with the client any concerns or pressures (physical and financial) regarding the ability to secure support of medical care, especially perceived pressures about being a burden on family. **EB:** *"Perceived burdensomeness" has been found to be a risk factor of older adults' suicidality, whether clinical depression is present or not, accounting for 68.3% variance of suicidal ideation (Jahn et al, 2011). The presence of stressful life events in the previous year and the presence of untreated major depression were also found to increase suicidal behavior (Pompili et al, 2014).*

• Conduct a thorough assessment of clients' medications. **EB:** *The use of psychotropic medications, especially long-term use and high doses of benzodiazepines, has been significantly associated with suicidal ideation or death thoughts (Bosse et al, 2011).*

• When assessing suicide risk factors, incorporate a higher degree of risk for older men and for some older adults who have lost a loved one in the previous year. **CEB:** *Although mortality for oldest old adults (80+) has increased, the suicide mortality has not decreased. In one study, oldest old men had the highest increase in suicide risk after death of a partner (more so than oldest old women) and took a longer time to recover from the death of a spouse (Erlangsen et al, 2004). Suicide rate may be rising among men older than age 65, and*

marriage may no longer be the protective factor it was once considered to be (Lamprecht et al, 2005).

• Explore triggers of and barriers to suicidal behavior, with particular attention to real and perceived losses (e.g., professional role, health). **EB:** *A qualitative study found that older adults' reflections preceding their suicide attempt included loss of a significant other, loneliness, loss of control, and unwillingness to live under these conditions (Bonnewyn et al, 2014). "Perceived burdensomeness" has been found to be a risk factor of older adults' suicidality, whether clinical depression is present or not, accounting for 68.3% variance of suicidal ideation (Jahn et al, 2011).*

• An older adult who shows self-destructive behaviors should be evaluated for dementia. **EB:** *Reviews of older adult psychiatric care for both the medical and psychiatric communities emphasize the possible overlap of depression, dementia, and suicidality (DeMers, Dinsio, & Carlson, 2014).*

▲ Advocate for the older client with other professionals in securing treatment for suicidal states. Primary care providers have been noted to under recognize and undertreat older adult clients with depression. **EB:** *In a 10-year longitudinal study, 83% of persons who committed suicide received health care within the previous year; only 24% had been diagnosed with a mental disorder in the 4 weeks prior to death. Medical specialty and primary care accounted for the most common visits (Ahmedani et al, 2014).*

• Encourage physical activity in older adults. **EB:** *Suicide and sleep disturbances have been linked. Exercise has been associated with improved sleep and lower suicide risk (Davidson et al, 2013).*

▲ Refer older adults in primary care settings for care management. **EBN:** *The Depression Care for Patients at Home (Depression CAREPATH) program provided assistance for medical and surgical homebound clients as a routine part of clinical practice (Bruce et al, 2011).*

• Consider telephone contacts as an effective intervention for suicidal older adults. **EB:** *One study predicted that, over a 10-year period, telephone and chat services could help to avoid about 36% of suicides and attempts in a high-risk population with a modest effect on quality-adjusted-life-years (Pil et al, 2013).*

Multicultural

• Assess for the influence of cultural beliefs, norms, and values on the client's perceptions of suicide and on the nurse's perception and approach to suicide. **EBN:** *A qualitative study of suicidal ideation in Korean college students found that the facilitators of suicidal ideation included physical, psychological, and societal factors. Inhibitors were religious and cultural factors. Buddhism and Confucianism influenced reasons not to attempt suicide (Jo, An, & Sohn, 2011).* **EB:** *A systematic review of psychological autopsies across multiple countries concluded that cultural influences in the diagnosis of a mental disorder might account for the variance in cases without a psychiatric diagnosis (Milner, Sveticic, & DeLeo et al, 2013).*

• Identify and acknowledge the stresses unique to culturally diverse individuals. *Financial difficulties and maintaining cultural values are two of the most common family stressors in women of color.* **EB:** *Acculturative stress and perceived discrimination, moderated by hopelessness, can increase vulnerability to suicide. A strong ethnic identity can serve as a buffer (Polanco-Roman & Miranda, 2013).*

• Identify and acknowledge unique cultural responses to stressors in determining sensitive interventions to prevent suicide. **CEB:** *In a randomized controlled trial, the Mexican American Problem Solving (MAPS) program addressed depression symptoms of*

immigrant Mexican women and their fourth- and fifth-grade children using home visits and afterschool programs. Family problem-solving communication improved, and children's depression symptoms decreased (Cowell et al, 2009). Encourage family members to demonstrate and offer caring and support to each other. **EB:** *Connectedness had been identified as a culture-based protective factor against suicide among young Alaska natives (Mohatt et al, 2011).*

• Validate the individual's feelings regarding concerns about the current crisis and family functioning. *Validation lets the client know that the nurse has heard and understood what was said, and it promotes the nurse–client relationship (APNA, 2015).*

Home Care

• Communicate the degree of risk to family and caregivers; assess the family and caregiving situation for the ability to protect the client and to understand the client's suicidal behavior. Provide the family and caregivers with guidelines on how to manage self-harm behaviors in the home environment. *Client safety between home visits is a nursing priority. Family and caregivers may become frightened by the client's suicidal ideation, may be angry at the client's perceived lack of self-control, or may feel as if they are walking on eggshells awaiting another suicide attempt.*

• Assess risk factors in the home. *The presence of a gun must be determined. Safe gun ownership should address the five Ls: locked, loaded, little children, feeling low, and learned owner (Pinholt et al, 2014).*

• If the client's suicidal ideation intensifies, or if a suicide plan with access to means becomes evident, institute an emergency plan for mental health intervention. **CEB:** *More than a quarter (29%) of clients who had previously self-harmed died within 3 months of discharge from psychiatric care and 36% had missed their last service appointment. Measures that may prevent suicide pacts in the mentally ill include the effective treatment of depression and closer supervision in both inpatient and community settings (Hunt et al, 2009).*

• Identify the client's concerns and implement interventions to address the consequences of disability in a client with medical illness. **EB:** *Depression, perceived social support, and disability have been found to be predictors of suicidal ideation. Lower levels of family support have been implicated in higher levels of suicidal ideation (Park et al, 2014).* Refer to the care plans for **Hopelessness** and **Powerlessness.**

▲ Refer for homemaker or psychiatric home health care services for respite, client reassurance, and implementation of a therapeutic regimen. *Respite decreases the high degree of caregiver stress that goes with the responsibility of caring for a person at risk for suicide.* **EBN:** *The Depression CAREPATH program provided assistance for medical and surgical homebound clients as a routine part of clinical practice (Bruce et al, 2011).*

▲ If the client is on psychotropic medications, assess the client's and family's knowledge of medication administration and side effects. Teach as necessary. *Knowledge of the medical regimen promotes compliance and promotes safe use of medications.*

▲ Evaluate the effectiveness and side effects of medications and adherence to the medication regimen. Review with the client and family all medications kept in the home; encourage discarding of old prescriptions. Monitor the amount of medications ordered/provided by the health care provider; limiting the amount of medications to which the client has access may be necessary. *Accurate clinical feedback improves the health care provider's ability to prescribe an effective medical regimen specific to the client's needs. At home, clients may have greater access to medications, including old prescriptions that may be used to overdose.*

Client/Family Teaching and Discharge Planning

- Establish a supportive relationship with family members. **EBN:** *Family members experience a great deal of stress around suicidal ideation and benefit from nurses' support (Sun et al, 2014).*
- Explain all relevant symptoms, procedures, treatments, and expected outcomes for suicidal ideation that is illness based (e.g., depression, bipolar disorder). **CEBN:** *The Health Belief Model identifies perceived barriers and perceived susceptibility to disease as powerful predictors of clients' motivation in taking action to prevent disease and participate in self-care management (Pender, Murdaugh, & Parsons, 2010).*
- Teach the family how to recognize that the client is at increased risk for suicide (changes in behavior and verbal and nonverbal communication, withdrawal, depression, or sudden lifting of depression). **EBN:** *A client may be at peace because a suicide plan has been made and the client has the energy to carry it out. Therefore when depression lifts, increased vigilance is necessary (Sun et al, 2014).*
- Provide written instructions for treatments and procedures for which the client will be responsible. **EBN:** *A written record provides a concrete reference so that the client and family can clarify any verbal information that was given (Sun et al, 2014).*
- Instruct the client in coping strategies (assertiveness training, impulse control training, deep breathing, progressive muscle relaxation). **CEBN:** *Suicidal ideation may be triggered by stress and painful emotions. Once clients are able to identify these triggers, they need to learn how to respond to them more effectively through assertiveness, impulse control, or relaxation techniques, as appropriate (Lakeman & FitzGerald, 2008).*
- Teach cognitive-behavioral activities, such as active problem-solving, reframing (reappraising the situation from a different perspective), or thought stopping (in response to a negative thought, picturing a large stop sign and replacing the image with a prearranged positive alternative). Teach the client to confront his or her own negative thought patterns (or cognitive distortions), such as catastrophizing (expecting the very worst), dichotomous thinking (perceiving events in only one of two opposite categories), or magnification (placing distorted emphasis on a single event). *Cognitive-behavioral activities address clients' assumptions, beliefs, and attitudes about their situations and foster modification of these elements to be as realistic and optimistic as possible. Through cognitive-behavioral interventions, clients become more aware of their cognitive choices in adopting and maintaining their belief systems, exercising greater control over their own reactions (Hagerty & Patusky, 2011).*
- Provide the client and family with phone numbers of appropriate community agencies for therapy and counseling. The National Alliance on Mental Illness (NAMI) is an excellent resource for client and family support. *Continuous follow-up care should be implemented; therefore the method to access this care must be given to the client (NAMI, 2012).*

Delayed Surgical Recovery

Mary Beth Flynn Makic PhD, CNS, CCNS, FAAN, FNAP

NANDA-I

Definition

Extension of the number of postoperative days required to initiate and perform activities that maintain life, health, and well-being.

Defining Characteristics

Discomfort; evidence of interrupted healing of surgical area; excessive time required for recuperation; impaired mobility; inability to resume employment; loss of appetite; postpones resumption of work; requires assistance for self-care

Related Factors

Malnutrition; obesity; pain; postoperative emotional response

At-Risk Population

Extremes of age; history of delayed wound healing

Associated Condition

American Society of Anesthesiologists (ASA) Physical Status classification score ≥2; diabetes mellitus; edema at surgical site; extensive surgical procedure; impaired mobility; perioperative surgical site infection; persistent nausea; persistent vomiting; pharmaceutical agent; prolonged surgical procedure; psychological disorder in postoperative period; surgical site contamination; trauma at surgical site

NOC(Nursing Outcomes Classification)

Suggested NOC Outcomes

Endurance; Infection Severity; Mobility; Pain Control; Self-Care: Activities of Daily Living (ADLs); Surgical Recovery: Convalescence/Immediate Postoperative; Wound Healing: Primary Intention

Example NOC Outcome with Indicators

Surgical Recovery: Convalescence as evidenced by the following indicators: Extent of physiological, psychological, and role function after discharge from postanesthesia care to the final postoperative clinic visit/Vital signs/Performance of normal activities, self-care activities. (Rate the outcome and indicators of **Surgical Recovery: Convalescence** 1 = severe deviation from normal range, 2 = substantial deviation from normal range, 3 = moderate deviation from normal range, 4 = mild deviation from normal range, 5 = no deviation from normal range [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Have surgical area that shows evidence of healing: no redness, induration, draining, or immobility
- State that appetite is regained
- State that no nausea is present
- Demonstrate ability to move about
- Demonstrate ability to complete self-care activities
- State that no fatigue is present
- State that pain is controlled or relieved after nursing interventions
- Resume employment activities/ADLs
- State no depression or anxiety related to surgical procedure

NIC(Nursing Interventions Classification)

Suggested NIC Interventions

Incision Site Care; Nutrition Management; Pain Management; Self-Care Assistance; Surgical Assistance

Example NIC Activities—Incision Site Care

Teach the client and/or the family how to care for the incision, including signs and symptoms of infection; Inspect the incision site for redness, swelling, or signs of dehiscence or evisceration

Nursing Interventions and *Rationales*

• Encourage smoking cessation prior to surgery. **EB:** *Smoking cessation improves tissue oxygenation and improves pulmonary function. Clients who smoke are at higher risk of developing blood clots (venous thromboembolism) postoperatively and may experience delayed surgical wound healing (Wechter, 2016).*

• Preoperatively, perform a thorough assessment of the client, including risk factors. Allow time to be with the client, and actively listen to client's concerns and questions about care, functional status, and recovery. **EB:** *Assessment of clients preoperatively is an important part of the surgical intervention, and ensuring health care literacy is addressed during this assessment is important for postoperative education and surgical recovery (Ross, 2013).* **EB:** *Clients with higher presurgery levels of emotional distress appear to be at greater risk for experiencing higher levels of postsurgery side effects (Sadati et al, 2013).*

• Assess for the presence of medical conditions and treat appropriately before surgery. If the client is diabetic, maintain normal blood glucose levels before surgery. **EB:** *High blood glucose levels slow healing and increase risk of infection. The American Diabetes Association (ADA) recommended that blood glucose should be less than 180 mg/dL for people in the hospital or having surgery. For some, the goal is less than 140 mg/dL (ADA, 2014; Sudhakaran & Surani, 2015).*

• Carefully assess client's use of dietary supplements such as feverfew, fish oil, ginkgo biloba, garlic, ginseng, ginger, valerian, kava, St. John's wort, ephedra (Ma huang or metabolite), and *Echinacea*. It is recommended that all clients be advised to stop all dietary supplements at least 1 week before major surgical or diagnostic procedures. **EB:** *Because of the increasingly complicated medication regimens and polypharmacy, it is important to assess client's use of herbal and dietary supplements because they can cause medication reactions or have unintended medical side effects (Nieva et al, 2012).* **EB:** *Herbal remedies are common in clients presenting for anesthesia. Because of the potential interactions between anesthetic drugs or techniques and such medication, it is important for anesthetists to be aware of their use (Bajwa & Panda, 2012; Kaye, 2014).*

• Assess and treat for depression and anxiety in a client before surgery and postoperatively. **CEB/EB:** *Clients with higher levels of preoperative anxiety and depression report increased postoperative pain, nausea, fatigue, and morbidity (Ghoneim & O'Hara, 2016; Manworren, Gordon, & Montgomery, 2018).* **EB:** *Early identification of clients with preoperative depression and anxiety allows the nurse to prepare postoperative interventions and support systems that may facilitate postoperative recovery (Ghoneim & O'Hara, 2016).*

• Play music of the client's choice preoperatively, intraoperatively, and postoperatively. **EBN:** *Listening to self-selected music during the preoperative period can effectively reduce anxiety levels and should be a useful tool for preoperative nursing (Ni et al, 2012; McClurkin & Smith, 2016).* **CEBN:** *Results of this research provided evidence to support the use of music and/or a quiet rest period to decrease pain and anxiety. The interventions pose no risks and have the benefits of improved pain reports and decreased*

anxiety (Pittman & Kridli, 2011).

• Consider using healing touch and other mind-body-spirit interventions such as stress control, therapeutic massage, and imagery in the perianesthesia setting. **EBN:** *Research shows that use of holistic therapies in the perioperative setting can decrease pain, surgical trauma, and anesthesia complications, leading to increased client satisfaction with health care (Selimen & Andsoy, 2011).* **EB:** *Therapeutic touch may help restore client's integrity by providing consolation and a sense of safety (Airosa et al, 2013).*

• Use reflective blankets to reduce heat loss during surgery. **EBN:** *A randomized control trial found that reflective blankets were a more effective method of passive warming than warm blankets (Koenen, Passey, & Rolf, 2017).*

• Postoperatively, discuss with the surgeon vital sign parameters, signs, and symptoms that could indicate early postoperative infection. **EB:** *Surgical site infections are a leading cause of prolonged hospitalization, which increase cost of care and are associated with poorer outcomes (Tanner et al, 2013).*

• Use careful aseptic technique when caring for wounds. **EBN:** *Handwashing continues to be the most important factor in reducing health care–associated infection, but the use of an aseptic technique will further cut the risk of infection (Harrington, 2014).* **EBN:** *Dressings should be changed by nurses who are trained in antiseptic, nontouch technique.*

• Clients should be allowed to shower after surgery to maintain cleanliness if not contraindicated because of the presence of pacemaker wires. **EB:** *In an analysis of existing studies, it was determined that there was no statistically significant increase in wound infection related to early bathing. Avoiding washing may have an adverse effect on the wound because of accumulation of sweat or dirt at the site. The decision to bathe the client immediately postoperatively should be specific to surgical type and site (Toon et al, 2013).*

• Promote early ambulation and deep breathing. **EBN:** *A quality improvement study found that early ambulation improved client and nurse satisfaction, decreased postoperative ileus events, and there was noted improvement in postoperative client progress and discharge readiness (Kilber et al, 2012)*

• The client should be provided with a complete, balanced therapeutic diet after the immediately postoperative period (24–48 hours). **EBN:** *Optimal wound healing requires adequate nutrition. Nutrition deficiencies impede the normal processes that allow progression through stages of wound healing. Malnutrition has also been related to decreased wound tensile strength and increased infection rates (Collins & Sloan, 2013).*

• Encourage the client to use prayer as a form of spiritual coping if this is comfortable for the client. **EB:** *Prayer has been shown to reduce pain intensity and provide a stabilizing effect on cardiovascular measurements (Jegindø et al, 2013).*

• Carefully assess functional status of client postoperatively using a fall-risk stratification tool, such as the Morse Fall Scale, to identify clients at high risk for fall. **EBN:** *The Morse Fall Scale has been validated in numerous studies, and it helps identify clients at high risk for falls. All clients identified as high risk should have increased monitoring and nursing and be placed under increased safety precautions until discharge, regardless of functional improvement (Baek et al, 2014).*

• See the care plans for **Anxiety,** Acute **Pain, Fatigue,** Risk for deficient **Fluid** volume, Risk for **Perioperative Positioning** injury, Impaired physical **Mobility,** and **Nausea.**

Pediatric

• Encourage children to ask questions about their procedures and postoperative expectations regarding pain, function, and long-term social and emotional care needs. **EBN:** *Children often report having little input or understanding of their medical conditions*

and requirements for surgical and functional interventions. Parents and children report higher levels of satisfaction, decreased preoperative anxiety, and better experiences if they are given the opportunity preoperatively to discuss all aspects of the surgery, including realistic postoperative expectations (Bray, Callery, & Kirk, 2012; Alanazi, 2014).
• Teach imagery and encourage distraction for children for postsurgical pain relief. **EBN:** *Distraction decreases pain in children undergoing painful procedures (Helgadottir & Wilson, 2014; Ha & Kim, 2013).*

Geriatric

• Perform a thorough preoperative assessment, including a cardiac, social support, and skin assessment. **EB:** *The condition of the client' skin should be noted before and after the procedure and should be fully documented using an objective evaluation tool, such as the Braden scale, to allow early identification of older clients at higher risk for developing surgical site infections or other types of skin breakdown (Cohen et al, 2012).*
• Older clients are at increased risk of delayed surgical recovery associated with physical and psychological postsurgical stress, nutritional deficits, aging immune system, and comorbid disease states. **EB:** *Older clients requiring surgical procedures need individualized assessments that explore nutrition, frailty and functional status, and cognitive assessment in addition to preexisting comorbid diseases (Kim, Brooks, & Groban, 2014).*
• Routinely assess pain in postoperative clients using a pain scale that is appropriate for clients with impaired cognition or inability to verbalize. **CEB:** *The Pain Assessment in Advanced Dementia (PAINAD) and Pain Assessment Checklist for Seniors with Limited Ability to Communicate (PACSLAC) have been validated for reliability (Herr, 2011).*
• Serially evaluate the client's vital signs, including temperature. Know what is normal and abnormal for each client. Check baseline vital signs and monitor trends. **EB:** *Physiological changes of aging often result in lower baseline body temperatures and decreased heart rates, and prevent the older client from developing fever. Medications, such as blood pressure agents, may prevent client from having an increased heart rate (Chester & Rudolph, 2011).*
• Ongoing evaluation of the older client for signs and symptoms of delirium should be incorporated into each assessment. Provide tools such as clocks, calendars, and other orientation tools to help reduce the risk of delirium in the postoperative area. Ensure that hearing aids and glasses are also available as needed. **EBN:** *A quality improvement project that continuously reviewed the older clients' physiological recovery and implemented frequent assessment for delirium and reorientation strategies reduced delirium events (Brooks et al, 2014).*
• Offer spiritual support. **EB:** *Religiousness is related to significantly fewer depressive symptoms, better quality of life, less cognitive impairment, and less perceived pain. Clinicians should consider taking a spiritual history and ensuring that spiritual needs are addressed among older clients in rehabilitation settings (Lucchetti et al, 2011).*

Home Care

• The preceding interventions may be adapted for the home setting.
• Provide supportive telephone calls from nurse to client as a means of decreasing anxiety and providing the psychosocial support necessary for recovery from surgery. **EBN:** *A systematic review of qualitative studies found that clients report being motivated to participate in recovery but face challenges with symptoms (e.g., pain, nausea, weakness). Postoperative follow-up and phone calls provide much needed encouragement and additional*

assistance to facilitate recovery (Sibbern et al, 2017).

Client/Family Teaching and Discharge Planning

- Provide discharge planning and teaching in a language that is appropriate to the client and caregiver's education and literacy level. **EBN:** *Do not use technical or medical jargon, and be aware that clients and caregivers may to be reluctant to ask for explanation or clarification because of embarrassment and may verbalize dishonestly understanding. Allow the client to repeat their understanding of the discharge plan (Ross, 2013).*
- Meet with client and caregivers to create a discharge plan that includes measurable goals for functional ADLs and pain levels, discuss expectations for recovery, and address signs and symptoms of postoperative complications. **EBN:** *In a study on successful discharge planning, it was found that plans that were detailed and precise, and addressed client and caregiver feedback, situations, preferences, and agreement with the care plan had greater satisfaction and plan adherence (Tomura et al, 2011).*
- Provide individualized teaching plans for the client with an ostomy. Assess client's ability to manage basic needs such as (1) maintenance of a pouching seal for a consistent, predictable wear time; (2) maintenance of peristomal skin integrity; and (3) social and professional support. Referrals for home wound care or nursing visits may be necessary to help client maintain hygiene and prevent readmission for complications. **EBN:** *Careful assessment of client's ability to manage colostomy will help the nurse anticipate possible problems with routine care requiring close follow-up and referrals for skilled care after discharge (Walker & Lachman, 2013).*

Risk for delayed Surgical recovery

Gail B. Ladwig MSN, RN, Mary Beth Flynn Makic PhD, CNS, CCNS, FAAN, FNAP

NANDA-I

Definition

Susceptible to an extension of the number of postoperative days required to initiate and perform activities that maintain life, health, and well-being, which may compromise health.

Risk Factors
Malnutrition, obesity, pain, postoperative emotional response

At-Risk Population
Extremes of age, history of delayed wound healing

Associated Conditions
American Society of Anesthesiologists (ASA) >2, diabetes mellitus, edema at surgical site, extensive surgical procedure, impaired mobility, perioperative surgical site infection, persistent nausea, persistent vomiting, pharmaceutical agent, prolonged surgical procedures, psychological disorder in postoperative period, surgical site contamination, trauma at surgical site

NIC, NOC, Client Outcomes, Nursing Interventions and *Rationales*, Client/Family Teaching and Discharge Planning and References
See the care plan for Delayed **Surgical** recovery.

Impaired Swallowing

Mary E. Oesterle MA, CCC-SLP, Marina Martinez-Kratz MS, RN, CNE

NANDA-I

Definition
Abnormal functioning of the swallowing mechanism associated with deficits in oral, pharyngeal, or esophageal structure or function.

Defining Characteristics

First Stage: Oral
Abnormal oral phase of swallow study; choking prior to swallowing; coughing prior to swallowing; drooling; food falls from mouth; food pushed out of mouth; gagging prior to swallowing; inability to clear oral cavity; incomplete lip closure; inefficient nippling; inefficient suck; insufficient chewing; nasal reflux; piecemeal deglutition; pooling of bolus in lateral sulci; premature entry of bolus; prolonged bolus formation; prolonged mealtime with inefficient consumption; tongue action ineffective in forming bolus

Second Stage: Pharyngeal
Abnormal pharyngeal phase of swallow study; alteration in head position; choking; coughing; delayed swallowing; fevers of unknown etiology; food refusal; gagging sensation; gurgling voice quality; inadequate laryngeal elevation; nasal reflux; recurrent pulmonary infection; repetitive swallowing

Third Stage: Esophageal
Abnormal esophageal phase of swallow study; acidic-smelling breath; bruxism; difficulty swallowing; epigastric pain; food refusal; heartburn; hematemesis; hyperextension of head; nighttime awakening; nighttime coughing; odynophagia; regurgitation; repetitive swallowing; reports "something stuck"; unexplained irritability surrounding mealtimes; volume limiting; vomiting; vomitus on pillow

Related Factors
Behavioral feeding problem; self-injurious behavior

At-Risk Population
Behavioral feeding problem; failure to thrive; history of enteral feeding; self-injurious behavior; developmental delay and prematurity

Associated Condition

Abnormality; achalasia; acquired autonomic defects; brain injury; cerebral palsy; conditions with significant hypotonia; congenital heart disease; cranial nerve involvement; esophageal reflux disease; laryngeal abnormality; laryngeal defect; mechanical obstruction; nasal defect; nasopharyngeal cavity defect; neurological problems; neuromuscular impairment; protein-energy malnutrition; respiratory condition; tracheal defect; trauma; upper airway anomaly

NOC(Nursing Outcomes Classification)

Suggested NOC Outcomes

Swallowing Status: Esophageal Phase, Oral Phase, Pharyngeal Phase

Example NOC Outcome with Indicators

Swallowing Status as evidenced by the following indicators: Delivery of bolus to hypopharynx is timed with swallow reflex/Ability to clear oral cavity/Number of swallows appropriate for bolus size and texture/Voice quality/Choking, coughing, gagging/Normal swallow effort. (Rate the outcome and indicators of **Swallowing Status:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Demonstrate effective swallowing without signs of aspiration (see the section Defining Characteristics)
- Remain free from aspiration (e.g., lungs clear, temperature within normal range)

NIC(Nursing Interventions Classification)

Suggested NIC Interventions

Aspiration Precautions; Swallowing Therapy

Example NIC Activities—Swallowing Therapy

Assist client to sit in erect position (as close to 90 degrees as possible) for feeding/exercise; Instruct client not to talk during eating, if appropriate

Nursing Interventions and *Rationales*

- Complete swallow screen per facility protocol. **EBN:** *Nurse-initiated dysphagia screening with formal guidelines for the identification and management of dysphagia may have a significant effect on serious adverse outcomes such as chest infections and death (Hines, Kynoch, & Munday, 2016).*
- ▲ Do not feed clients with impaired swallowing orally until an appropriate diagnostic workup is completed. **EBN:** *Impaired swallow function or dysphagia places a patient at greater risk for dehydration and malnutrition Dehydration thickens secretions, increasing the risk for certain respiratory problems, and aspiration may lead to pneumonia and death (Mauk, 2017, p 578).*
- ▲ Ensure proper nutrition by consulting with a health care provider regarding alternative nutrition and hydration when oral nutrition is not safe/adequate. **EBN:** *The decision to proceed with tube feeding should be made as early as possible after admission, usually within the first 3 days of admission in collaboration with the patient, family (or substitute decision maker), and interprofessional team. Enteral nutrition via intravenous, nasogastric, or percutaneous endoscopic gastrostomy (PEG) tube could substantially reduce risks of aspiration and choking while providing patients with needed hydration and nutrients.*

▲ Refer to a speech-language pathologist for evaluation and diagnostic evaluation of swallowing to determine swallowing problems and solutions as soon as oral and/or pharyngeal dysphagia is suspected. **EBN:** *Safe nursing care includes a consultation with a speech-language pathologist whenever doubts arise regarding a client's ability to tolerate oral-supported nutrition in any form (Teasell et al, 2016). Video fluoroscopic swallow study (VSS, VFSS, or MBS), or fiberoptic endoscopic examination of swallowing (FEES), should be performed on all patients considered at risk for pharyngeal dysphagia or poor airway protection based on results from the bedside swallowing assessment (Gomes et al, 2013).*

▲ To manage impaired swallowing, use a multidisciplinary dysphagia team composed of a speech pathologist, dietitian, nursing, health care provider, and medical staff. A comprehensive assessment from a multidisciplinary dysphagia team can lead to personalized therapeutic interventions that can help the client learn to swallow safely and maintain a good nutritional status. **EBN:** *Elderly patients with dysphagia require a multidisciplinary team working closely together to perform feeding management. Nurses have more opportunities to contact patients in clinical work, so they must learn the correct guidance of safe eating and feeding for elderly patients with dysphagia (Li et al, 2015).*

▲ Observe the following feeding guidelines:

- ❍ Before giving oral feedings, determine the client's readiness to eat (e.g., alert, able to hold head erect, follow instructions, move tongue in mouth, and manage oral secretions). *If one of these elements is missing, it may be advisable to withhold oral feeding and use enteral feeding for nourishment.*
- ❍ Monitor client during oral feedings and provide cueing as needed to ensure client follows swallowing guidelines/aspiration precautions recommended by speech-language pathologist or dysphagia specialist. Note: General aspiration precautions include the following: sit at 90 degrees for all oral feedings, take small bites/sips, eat at a slow rate, and no straws. However, client-specific strategies will be determined via bedside and/or instrumental swallowing evaluation performed by dysphagia specialist. *Postural changes, sensory enhancements, swallow maneuvers, or voluntary controls exerted over the swallow can improve swallow, but the use and effectiveness of these treatments will vary systematically with the client's medical diagnosis (Logemann & Larsen, 2012).*
- ❍ Keep bolus size to 5 mL or smaller. **EB:** *Evidence gathered from the appraised studies generally supports the clinical hypothesis that a small bolus size (5 mL or smaller) decreases the risk of penetration or aspiration of liquids during swallowing events (Rizzo et al, 2016).*
- ❍ *If the client is older or has gastroesophageal reflux disease, ensure the client is kept in an upright posture for an hour after eating.* **CEB:** *An upright posture after eating has been associated with a decreased incidence of pneumonia in older adults (Coleman, 2004). Because the trachea is in front of the esophagus while sitting up straight and the trachea is above the esophagus while leaning back or lying down, aspiration into the trachea can be reduced because of gravity (Logemann & Larsen, 2012).*

• During meals and all oral intake, observe for signs associated with swallowing problems such as coughing, choking, spitting of food, drooling, difficulty handling oral secretions, double swallowing or delay in swallowing, watering eyes, nasal discharge, wet or gurgling voice, decreased ability to move the tongue and lips, decreased mastication of food, decreased ability to move food to the back of the pharynx, and slow or scanning speech. **CEB:** *Perceptual judgments of a clear postswallow*

voice quality provided reasonable evidence that aspiration and dysphagia were absent as measured by video fluoroscopy (Waito et al, 2011).

- Watch for uncoordinated chewing or swallowing; coughing immediately after eating or delayed coughing; pocketing of food; wet-sounding voice; sneezing when eating; delay of more than 1 second in swallowing; or a change in respiratory patterns. If any of these signs of dysphagia and/or aspiration is present, remove all food from the oral cavity, stop feedings, and consult with speech-language pathologist and dysphagia team. *Placing a client with suspected dysphagia on nothing by mouth (NPO) status is the strongest measure that can be taken to prevent choking and aspiration (Tanner & Culbertson, 2014).*
- If signs of aspiration or pneumonia are present, auscultate lung sounds after feeding. Note new onset of crackles or wheezing, or elevated temperature. **CEB:** *Bronchial auscultation of lung sounds was shown to be specific in identifying clients at risk for aspiration (Shaw et al, 2004).*
- Assess for signs of malnutrition and dehydration and keep a record of food intake. **EB:** *A recent study showed that patients with diagnosed high-risk dysphagia had significantly lower scores on the geriatric nutritional risk index (Saito et al, 2017).*
- Evaluate nutritional status daily. Weigh the client weekly to help evaluate nutritional status. If the client is not adequately nourished, work with the dysphagia team to determine whether the client needs therapeutic feeding only or needs enteral feedings until the client can swallow adequately. **CEB:** *PEG feedings are preferable to nasogastric tube (NGT) feedings when longer term feeding is required (Geeganage et al, 2012).*
- *Assist client in following dysphagia specialist's recommendations and provide open, accurate, and effective communication with dysphagia team regarding client's diet tolerance. Understanding and following dysphagia specialist's recommendations is a pivotal role that nurses play in helping ensure positive dysphagia management outcomes (Tanner & Culbertson, 2014).*
- Document and notify the health care provider and dysphagia team of changes in medical, nutritional, or swallowing status. *Many negative dysphagia management outcomes can be avoided by ensuring dysphagia communication is accurate, complete, and disseminated among and between health care professionals; nurses are pivotal in this process (Tanner & Culbertson, 2014).*
- Work with the client on swallowing exercises prescribed by the dysphagia team. **EB:** *Exercise programs can improve airway closure, the range of oral or pharyngeal structure movement during swallow, cricopharyngeal opening, and tongue strength (Logemann & Larsen, 2012).*
- If needed, provide meals in a quiet environment away from excessive stimuli, such as a community dining room, for some clients who are easily distracted. *A noisy environment can be an aversive stimulus and can decrease effective chewing and swallowing.*
- For many adult clients, avoid the use of straws if recommended by the speech pathologist. *Use of straws can increase the risk of aspiration, because straws can result in spilling of a bolus of fluid rapidly in the posterior pharynx.*
- Recognize that the client can aspirate oral feedings, even if there are no symptoms of coughing or distress. This phenomenon is called silent aspiration and is common. **EB:** *In a study of elderly long-term residents, dementia was the best predictor of silent aspiration (Sakai et al, 2016).*
- Ensure oral hygiene is maintained. **EB:** *Oral health care including toothbrushing after each meal, cleaning dentures once a day, and consistent professional oral health care reduces the incidence of aspiration pneumonia (van der Maarel-Wierink et al, 2013).*
- Check the oral cavity for proper emptying after the client swallows and after the

client finishes the meal. Provide oral care at the end of the meal. It may be necessary to manually remove food from the client's mouth. If this is the case, use gloves and keep the client's teeth apart with a padded tongue blade. *Food may become pocketed on the affected side and cause stomatitis, tooth decay, and possible later aspiration.*

▲ Praise the client for successfully following directions and swallowing appropriately. *Praise reinforces behavior and sets up a positive atmosphere in which learning takes place.*

▲ Keep the client in an upright position for 45 minutes to an hour after a meal. **CEB:** *Matsui et al (2002) found the number of older clients who developed a fever was significantly reduced when clients were kept sitting upright after eating.*

▲ Recognize that impaired swallowing may be caused by the medications the client is taking. Side effects of medications include xerostomia (antidepressants, anticholinergics, antihistamines, bronchodilators, antineoplastic, and anti-Parkinson), central nervous system depression (anticonvulsants, benzodiazepines, antispasmodics, antidepressants, and antipsychotics), myopathy (corticosteroids, lipid-lowering agents, and colchicines), and decreased esophageal sphincter tone (antihistamines, diuretics, opiates, antipsychotics, antihypertensives, and anticholinergics). *Medications can cause impaired swallowing in multiple ways.*

▲ For clients receiving mechanical ventilation with a tracheostomy tube or after postextubation, request a referral to a speech-language pathologist or dysphagia specialist for an instrumental swallowing evaluation before beginning oral diet. **EB:** *Objective swallowing studies and early intervention are the best ways to determine the safest oral intake and rule out silent aspiration in these clients (Rodrigues et al, 2015).*

Pediatric

▲ Refer a child who has difficulty swallowing and symptoms such as difficulty manipulating food, delayed swallow response, and pocketing of a bolus of food to a speech-language pathologist (or dysphagia specialist) and a dietitian. *Adequate nutrition is extremely important for children to ensure sufficient growth and development of all body systems.*

▲ Consult with a speech-language pathologist or dysphagia specialist regarding modifications to nipple, appropriate positioning and feeding strategies, and other therapeutic activities deemed most appropriate based on bedside and instrumental swallowing evaluation. *Speech-language pathologists are trained to evaluate and treat pediatric dysphagia. Consultation with a speech-language pathologist or feeding therapist with pediatric expertise improves the diagnostic utility of a feeding assessment and can result in better outcomes.*

▲ The following are general feeding guidelines. Specific strategies to eliminate aspiration and maximize intake should be individualized and determined by a swallowing specialist through bedside and instrumental swallowing evaluation.

• Attempt feedings when infant is in an optimal behavioral feeding state (e.g., awake, alert, not agitated) and halt feedings if infant is not able to maintain or regain a proper feeding state. *Infants' feeding state can fluctuate rapidly and caregiver's attention to this state can influence feedings (Lau, 2014).*

• In a preterm infant, provide opportunities for patterned nonnutritive sucking (NNS). **EB:** *Although adequate NNS is not sufficient to predict adequacy of oral feeding (Lau, 2014), providing skilled training in patterned NNS has been demonstrated to accelerate the transition from NNS to oral feeding (Lau et al, 2012).*

• In a preterm infant, alter nipple flow rate to one that is easily managed by infant to facilitate intake while achieving physiological stability. **CEB:** *Increased flow rate should*

only be considered when doing so assists the infant in obtaining adequate intake while maintaining physiological stability. Aspiration risk is increased with faster flow rates.
• Watch for indicators of aspiration and physiological instability during feeding: coughing, a change in vocal quality or wet vocal quality, perspiration and color changes, sneezing, apnea, and/or increased heart rate and breathing. Infants and children with silent aspiration may only have indicators of increased respiratory mucous, congestion and chronic wheeze or rhonchi, recurrent bronchitis, or recurrent pneumonia (Tutor & Gosa, 2012).
• Watch for warning signs of reflux such as sour-smelling breath after eating, sneezing, lack of interest in feeding, crying and fussing extraordinarily when feeding, pained expressions when feeding, and excessive chewing and swallowing after eating. *Many premature and medically fragile children experience growth deficits and respiratory problems from an underlying dysphagia. Some infants may need to work harder to breathe than others and as a result develop a decreased tolerance for food intake. They also demonstrate inconsistent arousal and poor/uncoordinated suck-swallow-breath synchrony. Many of these infants require supplemental tube feedings and the use of special nipples or bottles to boost oral intake.*
• Observe infant's behavior and cues and adjust feeding to promote a safe pleasurable feeding experience while eliminating aspiration and maximizing intake. *Individualize interventions based on infant's cues related to swallowing, breathing, physiological stability, postural control, and state regulation to help infant maintain or regain stability. Some approaches include reducing noise/light levels, adjusting feeding position, letting infant regulate milk flow, and varying number and/or duration of feedings to reduce adverse events (Lau, 2014).*

Geriatric

▲ Recognize that age-related changes can affect swallowing and these changes have a more pronounced effect when superimposed on disease such as neurological and other chronic medical problems. *Subtle motor changes and age-related decrements in oral moisture, taste, and smell can contribute to less efficient and effective swallowing in older adults (Sura et al, 2012).*
▲ Evaluate medications the client is presently taking and consult with the pharmacist for assistance in monitoring for incorrect doses and drug interactions that could result in dysphagia. *Most older clients take numerous medications, which when taken individually can slow motor function, cause anxiety and depression, and reduce salivary flow. When taken together, these medications can interact, resulting in impaired swallowing function.*
▲ Ensure all nursing home residents are screened for swallowing problems. *It is estimated that up to 40% to 60% of nursing home residents have swallowing problems (Tanner, 2013).*
▲ Encourage and provide good oral hygiene when indicated. **EB:** *Good oral health care reduces the incidence of aspiration pneumonia (van der Maarel-Wierink et al, 2013).*
▲ Consult with occupational therapist for adaptive equipment when appropriate. *The use of adaptive equipment such as cups without rims and angled utensils can improve outcomes for older clients with dysphagia (Sura et al, 2012).*
▲ Recognize that the older client with dementia may need a longer time to eat and is often easily distracted. Help optimize hydration and nutrition using the following techniques:
- ❍ Encourage six small meals and hydration breaks per day.
- ❍ Offer foods that are sweet, spicy, or sour to increase sensory input.

- ❍ Allow clients to touch food and self-feed, if necessary (Tanner, 2013).
- ❍ Eliminate from the tray or table nonfoods such as salt and pepper, or anything that can be distracting. *Dementia clients are often impulsive and easily distracted.*
- ❍ Keep desserts out of sight until the end of the meal.
- ❍ Offer finger foods to the client who has trouble holding still to eat.
- ❍ Allow clients to eat immediately when they come for the meal.
- ❍ Recognize that the client with advanced dementia, who is unable to swallow, may or may not benefit from enteral tube feedings. *Some dementia clients enter into a catabolic state with negative protein balance, and it may be irreversible. In addition, there is often an increased risk for aspiration pneumonia in the tube-fed client.*

Home Care

▲ Refer to speech therapy. Speech-language pathologists can work with clients to enhance swallowing ability and teach compensatory strategies.

Client/Family Teaching and Discharge Planning

▲ Teach the client and family exercises prescribed by the dysphagia team.
▲ Teach the client a systematic method of swallowing effectively as prescribed by the dysphagia team.
• Educate the client, family, and all caregivers about rationales for food consistency and choices. *It is common for family members to disregard necessary dietary restrictions and give the client inappropriate foods that predispose to aspiration.*
• Teach the family how to monitor the client to prevent and detect aspiration during eating.

Risk for Thermal injury

Wendie A. Howland MN, RN-BC, CRRN, CCM, CNLCP, LNCC

NANDA-I

Definition

Susceptible to extreme temperature damage to skin and mucous membranes, which may compromise health.

Risk Factors

Fatigue; inadequate protective clothing; inadequate supervision; inattentiveness; insufficient caregiver knowledge of safety precautions; insufficient knowledge of safety precautions; smoking; unsafe environment

At-Risk Population

Extremes of age; extremes of environmental temperature

Associated Condition

Alcohol intoxication; drug intoxication; alteration in cognitive functioning; neuromuscular impairment; neuropathy; treatment regimen

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Safe Home Environment; Parenting: Early/Middle/Adolescent; Physical Safety

Client Outcomes

Client Will (Specify Time Frame)

- Be free of thermal injury to skin or tissue
- Explain actions can take to protect self and others from thermal injury
- Explain actions can take to protect self and others in the work environment

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Environmental Management: Safety

Example NIC Activities—Environmental Management: Safety

Identify safety hazards in the environment; Modify the environment to minimize hazards and risk

Nursing Interventions and *Rationales*

• Teach the following interventions to prevent fires in the home, to handle any possible fire, and to have a readily available exit from the home:
    - ❍ Avoid plugging several appliance cords into the same electrical socket.
    - ❍ Do not use open candles or allow smoking in the home.
    - ❍ Keep a fire extinguisher within reach in case a fire should occur.
    - ❍ Install smoke alarms on every level of the home and in every sleeping area.
    - ❍ Keep furniture and other heavy objects out of the way of doors and windows.
    - ❍ Develop a fire escape plan that includes two ways out of every room and an outside meeting place. Practice the escape plan at least twice a year.
• Teach clients about home grill safety to prevent thermal injury (propane and charcoal grills). **EB:** *The National Fire Protection Association (NFPA) suggested that grills should be inspected annually, especially when not used frequently; complete the "soapy bubble" test with propane grills to look for leaks that may result in fires; keep children and pets at a safe distance from the grill; and only grill outdoors (NFPA, 2016).*
• Apply sunscreen as directed on the container when out in the sun. Also use sun-blocking clothing, and stay in the shade if possible. **EB:** *Sunburn is a clear indicator of overexposure to ultraviolet (UV) radiation and increases the risk of skin cancer. The estimated prevalence of sunburn in the United States is high; 37.1% of adults and 55.8% of youth reported one or more sunburns in the past 12 months. Emergency room costs for sunburn nationally are considerable (Guy, Berkowitz, & Watson, 2017).*
• Teach clients safety measures to prevent fires in the home in which medical oxygen is in use:
    - ❍ **Never smoke** in a home in which medical oxygen is in use. "No smoking" signs should be posted inside and outside the home. **EB:** *There is considerable morbidity and mortality from burns secondary to smoking while using home oxygen. Ongoing education and careful consideration of prescribing home oxygen therapy for known smokers is highly encouraged (Carlos et al, 2016).*
    - ❍ Do not wear oxygen near an ignition source (e.g., open flame, gas stove, fireplace, candles, cigarettes, matches, lighters). Note that petroleum jelly, lip balm, skin lotion, or the like will not spontaneously combust in the presence of supplemental oxygen without an ignition source (e.g., flame or spark) and are safe to use on the face and in bed in the presence of oxygen (Winslow & Jacobsen, 1998; Hadjiliadis, 2016).
    - ❍ Homes with medical oxygen must have working smoke alarms that are tested monthly.
    - ❍ Test fire extinguishers every 3 to 6 months. Keep a fire extinguisher within reach. If a fire occurs, turn off the oxygen, leave the home, and summon the fire department.
    - ❍ Develop a fire escape plan that includes two ways out of every room and an outside meeting place. Practice the escape plan at least twice a year.
• Be aware that thermal injury also includes injury from cold materials and environmental conditions, including freezing injury, nonfreezing injury, and hypothermia. *Frostbite is classified in the same way as burns and can inflict similar damage on tissue (Handford, Thomas, & Imray, 2016; Fabian, Taljaard, & Perry, 2017).*
• Provide adequate environmental temperatures. Older clients and others at risk for temperature dysregulation can easily become hypothermic in air-conditioned environments (e.g., a surgical suite), with inadequate clothing, inhaling cold gases, or when exposed to room temperature or chilled fluids (e.g., intravenous, gastric lavage, bowel prep, continuous renal replacement therapy (CRRT), dialysis). *Inadvertent*

hypothermia is common in surgical procedures, affecting 70% of surgical patients, and can predispose to infection, blood loss, pressure injury, cardiac events, and shivering that increases metabolic demands (Giuliano & Hendricks, 2017).

• Monitor temperature in vulnerable clients. Core temperature is the best measure to assess for hypothermia. If a pulmonary artery catheter is not available, use a thermometer calibrated for lower body temperature such as a distal esophageal probe or rectal or bladder temperature probe (Leon & Bouchama, 2015).

• Use active warming measures to help clients maintain body temperature (e.g., warming blankets, warmed fluids, forced warm air warming devices, foil wraps, radiant warmers) as indicated. Be aware that passive devices (e.g., socks or blankets) do not add heat to body tissues.

• Ensure that exposed skin is protected from cold with adequate clothing.

• Monitor for developing cold thermal injury by checking peripheral circulation, temperature, and sensation. Be aware that fine motor coordination decreases as a very early sign of hypothermia. *Preventing progression of thermal injury is critical to client outcomes. Shivering is the body's attempt to generate heat through muscle activity; it consumes considerable metabolic energy, and is a late sign of hypothermia.*

• Check the temperature of all equipment and other materials before allowing them to contact client skin, especially if client has increased risk factors for thermal injury.

Pediatric

- Teach the following activities to homes with small children:
  - ❍ Lock up matches and lighters out of sight and reach.
  - ❍ Never leave a hot stove unattended.
  - ❍ Do not allow small children to use the microwave until they are at least 7 or 8 years of age.
  - ❍ Keep all portable heaters out of children's reach and at least 3 feet away from anything that can burn.
  - ❍ Teach fire prevention and safety to older children.
- Install thermostatic mixer valves in a hot water system to prevent extreme hot water causing scalding burns. **EB:** *Scald injuries in children can be decreased by parental education on risk factors (Stewart et al, 2016). Risk factors for residential fire death are common in urban pediatric emergency department patients (Wood et al, 2016). The majority of pediatric burn injuries are scald burns that occur at home and primarily affect the lower extremities in Caucasian and African American males. Among Caucasian teenagers flame burns predominate. The results of this study highlight the need for primary prevention programs focusing on avoiding home scald injuries in the very young and fire safety training for teenagers (Lee et al, 2016).*

Ineffective Thermoregulation

Rosemary Timmerman DNP, APRN, CCNS, CCRN-CSC-CMC

NANDA-I

Definition

Temperature fluctuation between hypothermia and hyperthermia.

Defining Characteristics

Cyanotic nail beds; flushed skin; hypertension; increase in body temperature above normal range; increase in respiratory rate; mild shivering; moderate pallor; piloerection; reduction in body temperature below normal range; seizure; skin cool to touch; skin warm to touch; slow capillary refill; tachycardia

Related Factors

Dehydration; fluctuating environmental temperature; inactivity; inappropriate clothing for environmental temperature; increase in oxygen demand; vigorous activity

At-Risk Population

Extremes of age; extremes of weight; extremes of environmental temperature; increased body surface area to weight ration; insufficient supply of subcutaneous fat

Associated Condition

Alteration in metabolic rate; brain injury; condition affecting temperature regulation; decrease in sweat response; illness; inefficient nonshivering thermogenesis; pharmaceutical agent; sedation; sepsis; trauma

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Thermoregulation; Thermoregulation: Newborn

Example NOC Outcome with Indicators

Thermoregulation as evidenced by the following indicators: Body temperature/Skin temperature/Skin color changes/Hydration/Reported thermal comfort. (Rate the outcome and indicators of **Thermoregulation:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Maintain temperature within normal range
- Explain measures needed to maintain normal temperature

- Describe two to four symptoms of hypothermia or hyperthermia
- List two or three self-care measures to treat hypothermia or hyperthermia

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Temperature Regulation; Temperature Regulation: Inoperative

Example NIC Activities—Temperature Regulation

Institute use of a continuous core temperature-monitoring device, as appropriate; Promote adequate fluid and nutritional intake

Nursing Interventions and *Rationales*

Temperature Measurement

- Measure and record the client's temperature using a consistent method of temperature measurement every 1 to 4 hours depending on the severity of the situation or whenever a change in condition occurs (e.g., chills, change in mental status). **CEB:** *Errors in accurate temperature measurement are most often associated with instrument-related errors, choice of temperature site chosen for monitoring, and operator error (Makic et al, 2011).* **CEB/EBN:** *A consistent mode of temperature measurement for accurate trending of body temperature is important for accurate treatment decisions; if different devices are used to obtain temperature measurements, the results should not vary more than 0.3°C to 0.5°C (Makic et al, 2011; Munro, 2014).*
- Select core, near core, or peripheral temperature monitoring mode based on ability to obtain an accurate temperature from that site and clinical situation dictating the need for mode of temperature monitoring required for clinical treatment decisions. **CEB/EB:** *Core temperature is obtained by pulmonary artery catheter and distal esophagus; near core temperature measurements include oral, bladder, rectal, tympanic membrane, and temporal artery; and peripheral measurements are obtained by skin surface measurements such as measurement in the axilla (Munro, 2014; Niven et al, 2015).*
- Caution should be taken in interpreting extreme values of temperature (less than 35°C or greater than 39°C) from a near core temperature site device. **CEB/EBN:** *Accurate oral temperature measurement requires the probe to be placed in the posterior sublingual pocket to provide a reliable near core temperature measurement (Makic et al, 2011; El-Radhi, 2013).* **EBP:** *Research has demonstrated that the accuracy of temperature measurement from most accurate to least accurate are intravascular (pulmonary artery), distal esophageal, bladder thermistor, rectal, and oral (Niven & Laupland, 2016); axillary temperature is accurate in neonates but is not well supported in adults (Smith, Alcock, & Usher, 2013).* **EB/EBN:** *Tympanic membrane and temporal artery measurements and chemical dot thermometers are least accurate and should be avoided in caring for the acutely ill adult client. Evidence is limited in testing the accuracy of temperature measurement devices outside of normal temperature ranges (Bijur, Shah, & Esses, 2016; Kiekkas et al, 2016).*
- Evaluate the significance of a decreased or increased temperature. *Normal adult temperature is usually identified as 98.6°F (37°C), but in actuality the normal temperature fluctuates throughout the day; in the early morning it may be as low as 96.4°F (35.8°C) and in the late afternoon or evening as high as 99.1°F (37.3°C); disease, injury, or pharmacological agents may cause an adaptive increase in the hypothalamic set point resulting in fever (Hooper et al, 2010; Niven & Laupland, 2016).*
- ▲ Notify the health care provider of temperature according to institutional standards

or written orders, or when temperature reaches 100.5°F (38.3°C) and above; use a lower threshold for immunocompromised clients who will be less likely to exhibit a fever when seriously ill (Niven & Laupland, 2016). Also notify the health care provider of the presence of a change in mental status and temperature greater than 100.5°F (38.3°C) or less than 96.8°F (36°C). *A change in mental status may indicate the onset of septic shock (Rhodes et al, 2017).*

Fever (Pyrexia)

- Recognize that fever is characterized as a temporary elevation in internal body temperature 1°C to 2°C higher than the client's normal body temperature. *A rise in body temperature is an innate immune response to a perceived threat and is regulated by the hypothalamus. Hyperthermia may occur when a client gains heat through either an increase in the body's heat production or is unable to effectively dissipate heat, and hypothermia occurs when a client loses heat or cannot generate heat (Rehman & deBoisblanc, 2014; Leon & Bouchama, 2015).*
- Recognize that fever is a normal physiological response to a perceived threat by the body, frequently in response to an infection. **EB:** *Fever is a deliberate, active thermoregulatory defense action by the body; metabolic heat accelerates the body's antibody production to defend the body and assists the body's cellular repair processes (nursing care should focus on supporting the body's normal physiological response [fever], locating the cause for the fever, and providing comfort) (Munro, 2014; Rehman & deBoisblanc, 2014).*
  - ▲ Review client history to include current medical diagnosis, medications, recent procedures/interventions, recent travel, environmental exposure to infectious agents, recent blood product administration, and review of laboratory analysis for cause of ineffective thermoregulation. **EB:** *Changes in body temperature (fever) should be explored for possible problems associated with a client's health status (Munro, 2014; Rehman & deBoisblanc, 2014).*
- Recognize that fever may be low grade (96.8°F–100.4°F [36°C–38°C]) in response to an inflammatory process such as infection, allergy, trauma, illness, or surgery; moderate to high-grade fever (100.4°F–104°F [38°C–40°C]) indicates a more concerted inflammatory response from a systemic infection; hyperpyrexia (40°C and higher) occurs as a result of damage of the hypothalamus, bacteremia, or an extremely overheated room (Munro, 2014; Niven & Laupland, 2016). **EB:** *Interventions to treat fever focus on client comfort, allowing the body to progress through the natural course of fever; exceptions may exist for the client with hyperpyrexia or when oxygen consumption threatens to exhaust metabolic reserves (Munro, 2014; Rehman & deBoisblanc, 2014).*
- Recognize that fever has a predictable physiological pattern; *the initial phase (cold or chill stage) presents with an increased heart rate, respiratory rate, shivering, pale, cold skin, absence of sweat, and piloerection. As the hypothalamus adjusts, the body temperature shivering ceases, skin becomes warm, and heart rate and respiratory rate remain elevated. The client may complain of thirst, poor appetite, painful muscles, exhaustion, and lethargy. The resolution phase presents with warm, flushed, sweaty skin, reduced shivering, and possible signs of dehydration (Adam, 2013; Rehman & deBoisblanc, 2014).*
- Monitor and intervene to provide comfort during a fever by:
  - ❍ Obtaining vital signs and accurate intake and output
  - ❍ Checking laboratory analysis trends of white blood cell counts and other markers of infection
  - ❍ Providing blankets when the client complains of being cold, but removing surplus of blankets when the client is too warm

- ❍ Encouraging fluid and nutrition
- ❍ Limiting activity to conserve energy
- ❍ Providing frequent oral care
- ❍ Adjust room temperature for client comfort

▲ **EBN/EB:** *Current evidence that examined the evidence of antipyretic therapies used to treat fever, such as administration of antipyretic medications, cooling blankets, and sponge baths, found these therapies did not reduce the duration of illness and may even prolong it (Munro, 2014; Niven et al, 2013).*

Hypothermia

• Take vital signs frequently, noting changes associated with hypothermia, such as increased blood pressure, pulse, and respirations, that then advance to decreased values as hypothermia progresses. *Mild hypothermia activates the sympathetic nervous system, which can increase the levels of vital signs; as hypothermia progresses, the heart becomes suppressed, with decreased cardiac output, heart rate, blood pressure, and respiratory rate (Paal et al, 2016; Zafren, 2017).*
• Monitor the client for signs of hypothermia (e.g., shivering, cool skin, piloerection, pallor, slow capillary refill, cyanotic nailbeds, decreased mentation, dysrhythmias) (Paal et al, 2016; Zafren, 2017).
• See the care plan for **Hypothermia** as appropriate.

Hyperthermia

• Recognize that hyperthermia is a different etiology than fever so the cause of the elevated body temperature should be explored for definitive treatment. *Hyperthermia is a condition in which an environmental (e.g., heat stroke), pharmacological (malignant hyperthermia), or endocrine (e.g., thyrotoxicosis) stimulus results in an increase in body temperature without a corresponding increase in the hypothalamic set point (Leon & Bouchama, 2015; Niven & Laupland, 2016).*
• Note changes in vital signs associated with hyperthermia, such as rapid, bounding pulse; increased respiratory rate; and decreased blood pressure, accompanied by orthostatic hypotension; and signs and symptoms of dehydration (Gaudio & Grissom, 2016; Niven & Laupland, 2016). *Consistent monitoring promotes prevention and early intervention in clients with altered cardiopulmonary status associated with hyperthermia (Gaudio & Grissom, 2016; Rehman & deBoisblanc, 2014).*
• Monitor the client for signs of hyperthermia (e.g., headache, nausea and vomiting, weakness, extreme fatigue, delirium, coma). *Monitoring for the defining characteristics of hyperthermia allows for early intervention.*
• Adjust clothing to facilitate passive warming or cooling as appropriate.
• See the care plan for **Hyperthermia** as appropriate.

Pediatric

• For routine measurement of temperature, use an electronic thermometer in the axilla in infants younger than 4 weeks; for a child up to 5 years of age, use an electronic thermometer in the axilla or an infrared temporal artery thermometer. **EB:** *Oral and rectal routes should not be used routinely to measure the temperature of infants to children of 5 years of age (National Institute for Health and Clinical Excellence [NICE], 2017). Tympanic thermometers often provide inaccurate temperature from incorrect placement in the ear canal and presence of cerumen adversely affecting temperature reading; fever strips*

and pacifier thermometers often provide inaccurate readings (Adam, 2013; Zhen et al, 2014).

• Recognize that pediatric clients have a decreased ability to adapt to temperature extremes. Take the following actions to maintain body temperature in the infant/child:

- ❍ Keep the head covered.
- ❍ Use blankets to keep the client warm.
- ❍ Keep the client covered during procedures, transport, and diagnostic testing.
- ❍ Keep the room temperature at 72°F (22.2°C).

The combination of a relatively smaller body surface area, smaller body fluid volume, less well-developed temperature control mechanisms, and smaller amount of protective body fat limits the ability of the infant and child to maintain normal temperatures (NICE, 2017).

• Recognize that the infant and small child are both vulnerable to develop heat stroke in hot weather; ensure that they receive sufficient fluids and are protected from hot environments. *Infants and young children are at risk for heat stroke for many reasons, including a decreased thermoregulatory ability in the young body and the inability to obtain their own fluids (Leon & Bouchama, 2015).*

• Antipyretic treatments typically are not indicated unless the child's temperature is higher than 38.3°C and may be given to provide comfort. **EB:** *The use of antipyretics in febrile children should be examined in light of the therapeutic goal for treatment, which may be primarily to improve the child's discomfort; acetaminophen and ibuprofen are the only antipyretic medications recommended for pediatric clients; both agents should not be administered simultaneously because of concern for inaccurate dosing; alternating doses may be considered only if client distress is not relieved before the next dose is due (Chiappini et al, 2017; NICE, 2017).*

Geriatric

• Do not allow an older client to become chilled; keep the client covered when giving a bath and offer socks to wear in bed; be aware of factors such as room temperature (heating/air conditioning), clothing (layered/loose), and fluid intake. *Older adults have a decreased ability to adapt to temperature extremes and need protection from extreme environmental temperatures; the response to cold environment is also compromised with the cutaneous vasoconstrictor response, the shivering process being less effective, decreased ability to feel cold, and medications commonly used to treat chronic age-associated diseases (Leon & Bouchama, 2015).*

• Recognize that the older client may have an infection without a significant rise in body temperature. **EB:** *Febrile response to infection was found to be reduced with increasing age, and baseline temperatures were generally lower in older clients; therefore this blunted febrile response may lead to delayed diagnosis and treatment necessitating review of all data to include a change in temperature, rather than fever (Munro, 2014; Rehman & deBoisblanc, 2014).*

• Fever does not put the older adult at risk for long-term complications; thus fever should not be treated with antipyretic agents or other external methods of cooling, unless there is serious heart disease present. **CEB:** *Exceptions in treating fever should be considered in some older clients with significant cardiovascular disease, because fever may increase metabolic rate by 10% and shivering may double the metabolic rate, greatly increasing the oxygen consumption requirements of the body and creating significant stress on the cardiovascular system (Outzen, 2009).*

• Ensure that older clients receive sufficient fluids during hot days and stay out of the sun. *Older adults may have trouble walking independently to obtain fluids, have decreased thirst sensation, and have chronic illnesses that predispose them to heat stroke, which is a hyperthermic condition (Leon & Bouchama, 2015).*
• Assess the medication profile for the potential risk of drug-related altered body temperature. *Anesthetics, barbiturates, salicylates, nonsteroidal antiinflammatory drugs, diuretics, antihistamines, anticholinergics, beta-blockers, and thyroid hormones have been linked to decreased body temperature (American Geriatrics Society, 2015; Beers Criteria Update Expert Panel, 2015).*

Home Care

Treating Fever

• Instruct client/parents on the physiological benefits of fever and provide interventions to treat fever symptoms, avoiding antipyretic agents and external cooling interventions.
• Ensure that client/parents know when to contact a health care provider for fever-related concerns.

Prevention of Hypothermia in Cold Weather

See the care plan **Hypothermia.**

Prevention of Hyperthermia in Hot Weather

See the care plan **Hyperthermia.**

Client/Family Teaching and Discharge Planning

• Teach the client and family the signs of fever, hypothermia, and hyperthermia and appropriate actions to take if either condition develops.
• Teach the client and family an age-appropriate method for taking the temperature.
• Teach the client to avoid alcohol and medications that depress cerebral function. *When the client is sedated or under the influence of alcohol, mentation is depressed, which results in decreased activities to maintain an adequate body temperature.*

Risk for ineffective Thermoregulation

Mary Beth Flynn Makic PhD, RN, CCNS, FAAN, FNAP

NANDA-I

Definition

Susceptible to temperature fluctuation between hypothermia and hyperthermia, which may compromise health.

Risk Factors

Dehydration; fluctuating environmental temperature; inactivity; inappropriate clothing for environmental temperature; increase in oxygen demand; vigorous activity

At-Risk Population

Extremes of age; extremes of weight; extremes of environmental temperature; increase body surface area to weight ration; insufficient supply of subcutaneous fat

Associated Condition

Alteration in metabolic rate; brain injury; condition affecting temperature regulation; decrease in sweat response; illness; inefficient nonshivering thermogenesis; pharmaceutical agent; sedation; sepsis; trauma

NOC, NIC, Client Outcomes, Nursing Interventions and *Rationales,* Client/Family Teaching and Discharge Planning, and References

Refer to care plans for Ineffective **Thermoregulation** (fever), **Hyperthermia,** or **Hypothermia.**

Impaired Tissue integrity

Jo Ann Coar BSN, RN-BC, CWOCN, COS-C

NANDA-I

Definition
Damage to the mucous membrane, cornea, integumentary system, muscular fascia, muscle, tendon, bone, cartilage, joint capsule, and/or ligament.

Defining Characteristics
Acute pain, bleeding, destroyed tissue, hematoma, localized area hot to touch, redness, tissue damage

Related Factors
Chemical injury agent, excessive fluid volume, humidity, imbalanced nutritional state, insufficient fluid volume, insufficient knowledge about maintaining tissue integrity, insufficient knowledge about protecting tissue integrity

At-Risk Population
Extremes of age, extremes of environmental temperature, exposure to high-voltage power supply

Associated Condition
Alteration in metabolism; alteration in sensation; arterial puncture; impaired circulation; impaired mobility; peripheral neuropathy; pharmaceutical agent; radiation therapy; surgical procedure; vascular trauma

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes
Tissue Integrity: Skin and Mucous Membranes; Wound Healing: Primary Intention, Secondary Intention

Example NOC Outcome with Indicators
Intact **Tissue Integrity: Skin and Mucous Membranes** as evidenced by the following indicators: Skin intactness/Skin lesions absent/Tissue perfusion/Skin temperature. (Rate the outcome and indicators of **Tissue Integrity: Skin and Mucous Membranes:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Report any altered sensation or pain at site of tissue impairment
- Demonstrate understanding of plan to heal tissue and prevent reinjury
- Describe measures to protect and heal the tissue, including wound care
- Experience a wound that decreases in size and has increased granulation tissue

NIC (Nursing Interventions Classification)

Suggested NIC Interventions
Incision Site Care; Pain Management; Pressure Ulcer Care; Risk Identification; Skin Care: Topical Treatments; Skin Surveillance; Wound Care; Wound Irrigation

Example NIC Activities—Pressure Ulcer Care
Monitor color of wound bed, temperature, edema, erythema, moisture, and appearance of surrounding skin; Note characteristics of any drainage

Nursing Interventions and *Rationales*

- The National Pressure Ulcer Advisory Panel (NPUAP) redefined the definition of a pressure ulcer, which is now referred to as a pressure injury, during the NPUAP 2016

Staging Consensus Conference. The new definitions more accurately define alterations in tissue integrity from pressure as follows: A pressure injury is localized damage to the skin and underlying soft tissue usually over a bony prominence or related to a medical device or other device. The injury can present as intact skin or an open ulcer and may be painful. The injury occurs as a result of intense and/or prolonged pressure or pressure in combination with shear. The tolerance of soft tissue for pressure and shear may also be affected by microclimate, nutrition, perfusion, comorbidities, and condition of the soft tissue (NPUAP/European Pressure Ulcer Advisory Panel [EPUAP], 2016).

- The first step is to identify etiological factors or what is causing the impairment. A thorough assessment of the individual, not only the impairment, is crucial. This includes a comprehensive medical history, current medical status, medications, and family history (Murphree, 2017). Differentiate pressure injuries form other types of wounds such as moisture-associated skin damage (MASD) (Ratliff et al, 2017). A comprehensive assessment helps identify specific risk factors and systemic factors, which aids the clinician in a more successful wound management approach (Murphree, 2017).
- Determine the size (length, width) and depth of the wound. Select a uniform, consistent method for measuring wound length, width or wound area, and depth to facilitate meaningful comparisons of wound measurements over time. A careful assessment should be performed to avoid causing injury when probing the depth of a wound bed or determining the extent of undermining or tunneling (NPUAP/EPUAP, 2014).

▲ Classify pressure injuries (NPUAP, 2016) using national guidelines and definitions (see http://www.npuap.org/resources/educational-and-clinical-resources/npuap-pressure-injury-stages/).

- ❍ **Pressure Injury:**
  A pressure injury is localized damage to the skin and underlying soft tissue usually over a bony prominence or related to a medical or other device. The injury can present as intact skin or an open ulcer and may be painful. The injury occurs as a result of intense and/or prolonged pressure or pressure in combination with shear. The tolerance of soft tissue for pressure and shear may also be affected by microclimate, nutrition, perfusion, comorbidities, and condition of the soft tissue (NPUAP, 2016).
- ❍ **Stage 1 Pressure Injury:** Nonblanchable erythema of intact skin
  Area of localized nonblanchable erythema that may appear differently in darkly pigmented skin, and changes in sensation, temperature, or firmness may precede visual changes. Color changes do not include purple or maroon discoloration, which is more likely to indicate deep tissue pressure injury (NPUAP, 2016).
- ❍ **Stage 2 Pressure Injury:** Partial-thickness skin loss with exposed dermis
  Partial-thickness skin loss with exposed dermis in which the wound bed is pink/red and moist and adipose (fat) and deeper tissues are not visible. Granulation tissue, slough, and eschar are not present. A stage 2 pressure injury may also present as an intact or ruptured blister. These injuries commonly result from adverse microclimate and shear in the skin over the pelvis and shear in the heel. This stage should not be used to describe MASD including incontinence-associated dermatitis (IAD), intertriginous dermatitis (ITD), medical adhesive–related skin injury (MARSI), or traumatic wounds (skin tears, burns, and abrasions) (NPUAP, 2016).

- ❍ **Stage 3 Pressure Injury:** Full-thickness skin loss
  Full-thickness loss of skin, in which adipose is visible and granulation tissue and epibole (rolled wound edges) are often present, and undermining/tunneling may occur. Slough and/or eschar may also be visible. Fascia, muscle, tendon, ligament, cartilage, and/or bone are not exposed. The depth of tissue damage varies by anatomical location, and areas of significant adiposity can develop deep wounds. If slough or eschar obscures the extent of tissue loss this is an unstageable pressure injury (NPUAP. 2016).
- ❍ **Stage 4 Pressure Injury:** Full-thickness skin and tissue loss
  Full-thickness skin and tissue loss with exposed or directly palpable fascia, muscle, tendon, ligament, cartilage, or bone and slough and/or eschar may be visible. Epibole, undermining, and/or tunneling often occur and depth varies by anatomical location. If slough or eschar obscures the extent of tissue loss, this is an unstageable pressure injury (NPUAP, 2016).
- ❍ **Deep Tissue Pressure Injury:** Persistent nonblanchable deep red, maroon, or purple discoloration
  Intact or nonintact skin with localized area of persistent nonblanchable deep red, maroon, or purple discoloration or epidermal separation revealing a dark wound bed or blood-filled blister. Pain and temperature change often precede skin color changes. Discoloration may appear differently in darkly pigmented skin. This injury results from intense and/or prolonged pressure and shear forces at the bone–muscle interface. The wound may evolve rapidly to reveal the actual extent of tissue injury, or it may resolve without tissue loss. If necrotic tissue, subcutaneous tissue, granulation tissue, fascia, muscle, or other underlying structures are visible, this indicates a full-thickness pressure injury (unstageable, stage 3, or stage 4). Do not use deep tissue pressure injury to describe vascular, traumatic, neuropathic, or dermatological conditions (NPUAP, 2016).
- ❍ **Unstageable Pressure Injury:** Obscured full-thickness skin and tissue loss
  Full-thickness skin and tissue loss in which the extent of tissue damage within the ulcer cannot be confirmed because it is obscured by slough or eschar. If slough or eschar is removed, a stage 3 or stage 4 pressure injury will be revealed. Stable eschar (i.e., dry, adherent, intact without erythema or fluctuance) on the heel or ischemic limb should not be softened or removed (NPUAP, 2016).

• Inspect and monitor the site of impaired tissue integrity at least once daily for color changes, redness, swelling, warmth, pain, or other signs of infection or per facility/agency policy. Monitor the status of the skin around the wound. Pay special attention to all high-risk areas such as bony prominences, skinfolds, sacrum, and heels. There is evidence that stage 1 pressure injuries are under detected in individuals with darkly pigmented skin because areas of redness are not easily identified. *Systematic inspection can identify impending problems early (NPUAP/EPUAP, 2014).* **EB:** Determine whether the client is experiencing changes in sensation or pain. *An initial pain assessment, using a validated tool, should include the following four elements: a detailed pain history including the character, intensity, and duration of pressure ulcer pain; a physical examination that includes a neurological component; a psychosocial assessment; and an appropriate diagnostic workup to determine the type and cause of the pain. Select a wound dressing that requires less frequent changing, is nonadherent, and maintains a moist wound environment (NPUAP/EPUAP, 2014).*

• *Individualizing plans for bathing frequency, pH-balanced soaps, and applying moisturizing products while skin is still damp can help improve skin integrity (Murphree, 2017).*
• Assess for incontinence and implement an individualized plan for management. Differentiate wounds caused by incontinence from other types of wounds. Cleanse the skin promptly after episodes of incontinence and use pH-balanced cleansers (NPUAP/EPUAP, 2014). Use incontinence skin barriers including creams, ointments, pastes, or film-forming skin protectants as needed to protect and maintain skin integrity with incontinent individuals (Ratliff et al, 2017).
• Monitor for correct placement of tubes, catheters, and other devices. Assess the skin and tissue affected by the pressure of the devices and tape used to secure these devices. **EB:** *Reposition the individual and/or the medical device to redistribute pressure and decrease shear forces. Keep skin clean and dry under medical devices. Moisture underneath a medical device can create an environment in which the skin is more vulnerable to alterations in skin integrity, including irritant dermatitis and ulceration (NPUAP/EPUAP, 2014).*
• Medical device–related pressure injury describes an etiology. Medical device–related pressure injuries result from the use of devices designed and applied for diagnostic or therapeutic purposes. The resultant pressure injury generally conforms to the pattern or shape of the device. The injury should be staged using the previously discussed staging system (NPUAP, 2016).
• Assess frequently for correct placement of foot boards, restraints, traction, casts, or other devices, and assess skin and tissue integrity. Frequently assess for signs and symptoms of compartment syndrome (refer to the care plan for Risk for **Peripheral Neurovascular** dysfunction). Reposition the individual and/or the medical device to redistribute pressure and decrease shear force (NPUAP/EPUAP, 2014).
• Implement and communicate a comprehensive treatment plan for the topical treatment of the skin impairment site. *To improve care and outcomes for individuals with or at risk for skin impairments, evidence-based guidelines must be disseminated to ensure that health care providers are making every effort to identify individuals with or at risk for skin alterations and implement appropriate preventative and treatment interventions (Ratliff et al, 2017).*
▲ Identify a plan for debridement if necrotic tissue (eschar or slough) is present and if consistent with overall client management goals (i.e., curative versus palliative care). **EB:** *Debride devitalized tissue within the wound bed or edge of pressure injuries (NPUAP, 2016) when appropriate to individual's condition and consistent with overall goals of care. Do not debride stable, hard, dry eschar in ischemic limbs or heels (NPUAP/EPUAP, 2014).*
• Select a topical treatment that maintains a moist, wound-healing environment and also allows absorption of exudate and filling of dead space. *No single wound care product provides the optimal environment for healing all wounds.* **EB:** *Choose dressings that provide a moist healing environment, keep periwound skin dry, and control exudate and eliminate dead space NPUAP/EPUAP, 2014*).
• Avoid positioning the client on the site of impaired tissue integrity. **EB:** *If it is consistent with overall client management goals, reposition the client based on level of tissue tolerance and overall condition, and transfer or reposition the client carefully to avoid adverse effects of external mechanical forces (pressure, friction, and shear) (NPUAP/EPUAP, 2014).*
• Evaluate for the use of support surfaces (specialty mattresses, beds) chair cushion, or devices as appropriate (Lippoldt, Pernicka, & Staudinger, 2014). Before replacing the existing mattress evaluate the effectiveness of previous and current prevention and treatment plans and set treatment goals consistent with the individual's goals and lifestyle (NPUAP/EPUAP, 2014). Continued repositioning of individuals placed on a pressure redistribution support surface is paramount (NPUAP/EPUAP, 2014).

• If the goal of care is to keep the client comfortable (e.g., for a terminally ill client), repositioning may not be appropriate. *Position the client in position of optimal comfort (Horn & Irion, 2014). Reposition and turn the individual, periodically, in accordance with the individual's wishes, comfort, and tolerance (NPUAP/EPUAP, 2014). Maintain the head of the bed at the lowest degree of elevation possible to reduce shear and friction and use lift devices, pillows, foam wedges, and pressure-reducing devices in the bed (NPUAP/EPUAP, 2014; Baranoski & Ayello, 2016).*
▲ Assess the client's nutritional status. Refer for a nutritional consult and/or institute dietary supplements as necessary. *Optimizing nutritional intake, including calories, fatty acids, protein, and vitamins, is needed to promote wound healing (NPUAP/EPUAP, 2014; O'Hanlon, Dowsett, & Smyth, 2015).* Review client nutrition plan evaluating for the intake of 1.25 to 1.5 g of protein per kilogram body weight daily, unless medically contraindicated, for adults at risk of a pressure injury or with existing pressure injuries. Offer 1 mL of fluid intake per kilocalorie per day, unless medically contraindicated (Ratliff et al, 2017). Reassess as condition changes (NPUAP/EPUAP, 2014).
▲ Develop a comprehensive plan of care that includes a thorough wound assessment, treatment interventions, support surfaces, nutritional products, adjunctive therapies, and evaluation of the outcome of care. *Documentation of these essential elements is paramount to establishing a framework for quality care.*

Home Care

• Some of the interventions previously described may be adapted for home care use.
▲ Assess the client's current phase of wound healing (inflammation, proliferation, or maturation) and stage of injury; initiate appropriate wound management. **EB:** *A holistic assessment is required to guide correct dressing selection. Underlying pathophysiological factors need to be addressed to improve outcomes.*
• Instruct and assist the client and caregivers in understanding how to change dressings and in the importance of maintaining a clean environment. Provide written instructions and observe them completing the dressing change.
▲ Initiate a consultation in a case assignment with a wound specialist or wound, ostomy, and continence nurse to establish a comprehensive plan as soon as possible. Plan case conferencing to promote optimal wound care. *Case conferencing ensures that cases are regularly reviewed to discuss and implement the most effective wound care management to meet client needs.*
▲ Consult with other health care disciplines to provide a thorough, comprehensive assessment. *Consider referring to a dietitian, physical therapist, occupational therapist, and social worker/case manager as needed. Early engagement of wound care specialists can enhance overall care and reduce health care costs (Vrtis, 2013).*

Client/Family Teaching and Discharge Planning

• Teach skin and wound assessment and ways to monitor for signs and symptoms of infection, complications, and healing. *Early assessment and intervention help prevent serious problems from developing.*
• Teach the client why a topical treatment has been selected. Explain wound bed changes that the caregiver can expect to see. Instruct on when the dressing needs to be changed. Assess pressure injuries with each wound dressing change and confirm the appropriateness of the current dressing regimen (NPUAP/EPUAP, 2014). **EB:** *The type*

of wound dressing needed may change over time as the wound heals and/or deteriorates (NPUAP/EPUAP, 2014; Baranoski & Ayello, 2016).

▲ Teach the use of pillows, foam wedges, and pressure-reducing devices, on beds and chairs to prevent pressure injury. Pressure redistributing surfaces serve as adjuncts and not replacements to regular repositioning (Ratliff et al, 2017).

Risk for impaired Tissue integrity

Mary Beth Flynn Makic PhD, RN, CCNS, FAAN, FNAP

NANDA-I

Definition

Susceptible to damage to the mucous membrane, cornea, integumentary system, muscular fascia, muscle, tendon, bone, cartilage, joint capsule, and/or ligament, which may compromise health.

Risk Factors

Chemical injury agent; excessive fluid volume; humidity; imbalanced nutritional state; insufficient fluid volume; insufficient knowledge about maintaining tissue integrity; insufficient knowledge about protecting tissue integrity

At-Risk Population

Extremes of age; extremes of environmental temperature; exposure to high-voltage power supply

Associated Condition

Alteration in metabolism; alteration in sensation; arterial puncture; impaired circulation; impaired mobility; peripheral neuropathy; pharmaceutical agent; radiation therapy; surgical procedure; vascular trauma

NOC, NIC, Client Outcomes, Nursing Interventions and *Rationales*, Client/Family Teaching and Discharge Planning, and References

Refer to care plan for Impaired **Tissue** integrity

Ineffective peripheral Tissue Perfusion

NANDA-I

Definition
Decrease in blood circulation to the periphery, which may compromise health.

Defining Characteristics
Absence of peripheral pulses; alteration in motor function; altered skin characteristics; ankle-brachial index <0.90; capillary refill time >3 seconds; color does not return to lowered limb after 1 minute of leg elevation; decrease in blood pressure in extremities; decrease in pain-free distances during a 6-minute walk test; decrease in peripheral pulses; delay in peripheral wound healing; distance in the 6-minute walk test below normal range; edema; extremity pain; femoral bruit; intermittent claudication; paresthesia; skin color pales with limb elevation

Related Factors
Excessive sodium intake; insufficient knowledge of disease process; insufficient knowledge of modifiable factors; sedentary lifestyle; smoking

Associated Condition
Diabetes mellitus; endovascular procedure; hypertension; trauma

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes
Circulation Status; Fluid Balance; Hydration; Tissue Perfusion: Peripheral

Example NOC Outcome with Indicators
Demonstrates adequate **Circulation Status** as evidenced by the following indicators: Peripheral pulses strong/Peripheral pulses symmetrical/Skin color and temperature/Peripheral edema not present. (Rate the outcome and indicators of **Circulation Status:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Demonstrate adequate tissue perfusion as evidenced by palpable peripheral pulses, warm and dry skin, adequate urine output, and absence of respiratory distress
- Verbalize knowledge of treatment regimen, including appropriate exercise and medications and their actions and possible side effects
- Identify changes in lifestyle needed to increase tissue perfusion

NIC (Nursing Interventions Classification)

Suggested NIC Intervention
Circulatory Care: Arterial Insufficiency

Example NIC Activities—Circulatory Care: Areterial Insufficiency
Evaluate peripheral edema and pulses; Inspect skin for arterial ulcers and tissue breakdown

Nursing Interventions and *Rationales*

▲ Check the brachial, radial, dorsalis pedis, posterior tibial, and popliteal pulses bilaterally. If unable to find them, use a Doppler stethoscope and notify the health

care provider immediately if new onset of absence of pulses along with a cold extremity. **EB/QSEN:** *Audible handheld Doppler ultrasound proved to be a reliable, simple, rapid, and inexpensive bedside test of peripheral arterial disease in diabetic and nondiabetic patients (Alavi et al, 2015).*

• Note skin color and feel the temperature of the skin. Check capillary refill.

• Assess for pain in the extremities, noting severity, quality, timing, and exacerbating and alleviating factors. Differentiate venous from arterial disease. **EB:** *When peripheral artery disease (PAD) involves the lower extremities it produces signs and symptoms like claudication, ischemic rest pain, or skin ulceration (Wei et al, 2017).*

• Note skin texture and the presence of hair, ulcers, or gangrenous areas on the legs or feet. **EB:** *A chronic wound is defined as an area in which the skin is not intact that fails to heal within 8 weeks. Chronic wounds often develop on the lower limbs as a complication of diabetes, venous insufficiency, or inadequate arterial perfusion (Ruttermann et al, 2013; Bosanquet & Harding, 2014).*

• Note the presence of edema in the extremities and rate severity on a four-point scale. Measure the circumference of the ankle and calf at the same time each day in the early morning (Busti, 2016).

▲ Prepare for vascular lab. **EB:** *Evaluation for PAD if signs and symptoms are present frequently involves a non-invasive vascular lab assessment as a next step in diagnosis (Wei et al, 2017).*

Arterial Insufficiency

▲ Monitor peripheral pulses. If there is new onset of loss of pulses with bluish, purple, or black areas and extreme pain, notify the health care provider immediately. *These are symptoms of arterial obstruction that can result in loss of a limb if not immediately reversed.* **EB:** *Risks of peripheral disease increased proportionally with the number of absent peripheral pulses, with the highest risks observed in patients with three or four absent pulses. Every additional absent pulse increases the risk of all outcome (Mohammedi et al, 2016).*

▲ Measure ankle-brachial index (ABI) via Doppler imaging. **EB:** *Measurement of the ABI via a palpatory method offers an inexpensive, readily available alternative approach for early disease detection of PAD. Normal ABI is >0.9 (Orellana-Barrios et al, 2014).*

• Avoid elevating the legs above the level of the heart. With arterial insufficiency, leg elevation decreases arterial blood supply to the legs.

▲ For early arterial insufficiency, encourage exercise such as walking or riding an exercise bicycle from 30 to 60 minutes per day as ordered by the health care provider. **EB:** *Regardless of exercise length and modality, regularly intensive walking exercise improves walking ability in PAD patients more than usual care (Lyu et al, 2016).*

• Keep the client warm and have the client wear socks and shoes or sheepskin-lined slippers when mobile. Do not apply heat. Clients with arterial insufficiency report being constantly cold; keep extremities warm to maintain vasodilation and blood supply. Heat application can easily damage ischemic tissues.

▲ Pay meticulous attention to foot care. Refer to a podiatrist if the client has a foot or nail abnormality. Ischemic feet are vulnerable to injury; meticulous foot care can prevent further injury. **EB:** *Symptoms or signs of PAD can be observed in up to 50% of the patients with a diabetic foot ulcer and is a risk factor for poor healing and amputation (Hinchliffe et al, 2016).*

• If the client has ischemic arterial ulcers, refer to the care plan for Impaired **Tissue** integrity.

▲ If the client smokes, aggressively counsel the client to stop smoking and refer to the

health care provider for medications to support nicotine withdrawal and a smoking withdrawal program. **EB:** *Smoking is a particularly strong risk factor for PAD, and several newer risk markers have shown independent associations with PAD (Criqui & Aboyans, 2015).*

▲ Educate on use and safety of antiplatelet medications. **EB:** *Dual antiplatelet therapy is associated with reduced rates of major adverse cardiovascular events and mortality among patients with severe symptomatic PAD (Armstrong et al, 2015).*

Venous Insufficiency

▲ Elevate edematous legs as ordered and ensure no pressure under the knee and heels to prevent pressure ulcers. **EB:** *Patients who are inactive (sedentary) for long periods may have leg edema because the calf muscle pump is underused or ineffective. Elevating the ankles above the level of the heart can help relieve this type of swelling (Evans & Ratchford, 2016).*

▲ Apply graduated compression stockings as ordered. Ensure proper fit by measuring accurately. Remove the stockings at least twice a day, in the morning with the bath and in the evening, to assess the condition of the extremity, then reapply. Knee length is preferred rather than thigh length. **EB:** *Hosiery is a dominant treatment; that is, on average it results in higher quality-adjusted life years and lower costs than bandages (Rebecca, 2014).*

• Encourage the client to walk with compression stockings on and perform toe-up and point-flex exercises. *Exercise helps increase venous return, builds up collateral circulation, and strengthens the calf muscles.* **EBN:** *Physical therapy modalities improve ABI, Doppler flow velocity, and blood parameters in clients with type 2 diabetes (Castro-Sanchez, 2013).*

• If the client is overweight, encourage weight loss to decrease venous disease.

• If the client has venous leg ulcers, encourage the client to avoid prolonged sitting, standing, and elevation of the involved leg. Encourage proper use of compression stockings. Pain may prevent compliance. **EBN:** *A study shows a high incidence of ulcer pain, confirming that pain has a great effect on clients with venous leg ulcers (Akessonrut et al, 2014).*

▲ If the client is mostly immobile, consult with the health care provider regarding use of a calf-high pneumatic compression device for prevention of deep venous thrombosis (DVT). **EB:** *Below-the-knee devices have demonstrated the most efficacy with multiple guidelines recommending usage (Pierce et al, 2015; Kearon et al, 2016).*

• Observe for signs of DVT, including pain, tenderness, swelling in the calf and thigh, and redness in the involved extremity. Take serial leg measurements of the thigh and calf circumferences. In some clients a tender venous cord can be felt in the popliteal fossa. Do not rely on Homan's sign. **EBN:** *Screening and detection of DVT must be as accurate as possible. Failing to diagnose a DVT can contribute to a fatal pulmonary embolism (PE), whereas false-positive screening can result in costly diagnostics or the patient's unnecessary anticoagulation (Anthony, 2013).*

▲ Note the results of a D-dimer test and ultrasounds. **EB:** *A study suggested that the D-dimer test be used during the initial workup for all patients who present to the emergency department (ED) for suspected DVT (Mousa et al, 2017).*

• If DVT is present, observe for symptoms of a PE. **EB:** *PE is a significant risk of a DVT. Signs and symptoms range from sudden onset, acute chest pain of a sharp stabbing nature, anxiety, and cough (Kearon et al, 2016).*

▲ Educate on use and safety of anticoagulant medications. **EB:** *DVT and PE are two manifestations of venous thromboembolism (VTE). The mainstay of therapy for DVT is*

anticoagulation, provided there is no contraindication (Lip & Hull, 2017). Clients need to be aware of adverse effects of anticoagulant medications, wear a medical alert bracelet, and be aware of food–drug interactions (Kearon et al, 2016).

Geriatric

• Complete a thorough lower extremity assessment, documenting the smallest change from previous assessment, and implement a plan immediately. **EB:** *Complete and accurate assessment is essential to guide health care providers in formulating efficacious plans of care. The prevalence of peripheral arterial disease increases with age. The elevated risk of ulcerations leading to amputation among older adults reflects not only increased rates of PAD and diabetic pathologies but also age-related changes of the integument (Hakim & Heitzman, 2013).*
• Recognize that older adults have an increased risk for development of PE. **EB:** *PE is associated with high short-term mortality in elderly patients, even when hemodynamically stable (Castelli et al, 2014).*

Home Care

• The interventions previously described may be adapted for home care use.
• If arterial disease is present and the client smokes, aggressively encourage smoking cessation.
• Examine the feet carefully at frequent intervals for changes and new ulcerations. Encourage the client to perform regular assessment of the feet.
▲ Assess the client's nutritional status, paying special attention to obesity, hyperlipidemia, and malnutrition. Refer to a dietitian if appropriate.
• Monitor for development of gangrene, venous ulceration, and symptoms of cellulitis (redness, pain, and increased swelling in an extremity).

Client/Family Teaching and Discharge Planning

• Explain the importance of good foot care. Teach the client and family to wash and inspect the feet daily. Recommend that the diabetic client wear comfortable shoes and break them in slowly, watching for blisters (Oliveira et al, 2014).
▲ Teach the diabetic client that he or she should have a comprehensive foot examination at least annually (which includes an analysis for predicting foot ulceration risk), which includes assessment of sensation using the Semmes–Weinstein monofilaments. If good sensation is not present, refer to a footwear professional for fitting of therapeutic shoes and inserts, the cost of which is covered by Medicare.
• For arterial disease, stress the importance of not smoking, following a weight loss program (if the client is obese), carefully controlling a diabetic condition, controlling hyperlipidemia and hypertension, maintaining intake of antiplatelet therapy, and reducing stress.
• Teach the client to avoid exposure to cold; limit exposure to brief periods if going out in cold weather and wear warm clothing.
• For venous disease, teach the importance of wearing compression stockings as ordered, elevating the legs at intervals, and watching for skin breakdown on the legs.
• Teach the client to recognize the signs and symptoms that should be reported to a health care provider (e.g., change in skin temperature, color or sensation, or the presence of a new lesion on the foot).
• Provide clear, simple instructions about plan of care.

• Instruct and provide emotional support for client undergoing hyperoxygenation treatment. **EB:** *Hyperbaric oxygen may be associated with ulcer healing in selected diabetic foot ulcers (Oliveira et al, 2014).*

Risk for ineffective peripheral Tissue Perfusion

Mary Beth Flynn Makic PhD, RN, CCNS, FAAN, FNAP

NANDA-I

Definition
Susceptible to a decrease in blood circulation to the periphery, which may compromise health.

Risk Factors
Excessive sodium intake; insufficient knowledge of disease process; insufficient knowledge of modifiable Factors; sedentary lifestyle; smoking

Associated Condition
Diabetes mellitus; endovascular procedure; hypertension; trauma

NOC, NIC, Client Outcomes, Nursing Interventions and *Rationales*, Client/Family Teaching and Discharge Planning, and References
Refer to care plan for Ineffective peripheral **Tissue Perfusion**

Impaired Transfer ability

Kerri J Reid RN, MS, CNS, CCRN-K

NANDA-I

Definition
Limitation of independent movement between two nearby surfaces.

Defining Characteristics
Impaired ability to transfer between bed and chair; impaired ability to transfer between bed and standing position; impaired ability to transfer between car and chair; impaired ability to transfer between chair and floor; impaired ability to transfer between chair and standing position; impaired ability to transfer between floor and standing position; impaired ability to transfer between uneven levels; impaired ability to transfer in or out of bath tub; impaired ability to transfer in or out of shower; impaired ability to transfer on or off a commode; impaired ability to transfer on or off a toilet

Related Factors
Environmental barrier; impaired balance; insufficient knowledge of transfer techniques; insufficient muscle strength; obesity; physical deconditioning; pain

Associated Condition
Alteration in cognitive functioning; impaired vision; musculoskeletal impairment; neuromuscular impairment

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes
Balance; Body Positioning: Self-Initiated; Transfer Performance

Example NOC Outcome with Indicators
Transfer Performance as evidenced by the following indicators: Transfers from bed to chair and back/Transfers from wheelchair to toilet and back/Transfers from wheelchair to vehicle and back. (Rate the outcome and indicators of **Transfer Performance:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Transfer from bed to chair and back successfully
- Transfer from chair to chair successfully
- Transfer from wheelchair to toilet and back successfully
- Transfer from wheelchair to car and back successfully

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Exercise Promotion: Strength Training; Exercise Therapy: Muscle Control

Example NIC Activities—Exercise Promotion: Strength Training

Obtain medical clearance for initiating a strength-training program, as appropriate; Assist to set realistic short- and long-term goals and to take ownership of the exercise plan

Nursing Interventions and *Rationales*

- Specify level of independence using a standardized functional scale. **EB:** *Use a nurse-driven bedside assessment tool to evaluate the patient's mobility status. Continuous surveillance of patients by nurses and using a mobility evaluation tool allows more awareness of the knowledge and skill needed for safe patient handling and mobility, reducing the risk for fall and potential injury to the nursing staff (Boynton et al, 2014).*
- Assess level of patient ability to perform specific tasks prior to transfer of patient. **EB:** *Valid and reliable assessment tools such as The Bedside Mobility Assessment Tool provides assessment of a patient using "levels of activity" to indicate safe patient handling and mobility (Boynton et al, 2014; Boynton, Kelly, & Perez, 2014; Hillrom, 2018).*
- ▲ Complications associated with immobility and resultant muscle loss begins within 48 hours of onset or injury and is greatest during the first 2 to 3 weeks (Cameron et al, 2015). Request consult for a physical and/or occupational therapist (PT and OT) to develop plan of care for safe patient handling and mobility. **EB:** *Progressive mobility, or mobility that starts earlier and more aggressively during a patient's hospital stay, even as early as in the intensive care unit (ICU), decreases mechanical ventilation days and decreases complications such as weakness from disuse and contractures (Kalisch, Dabney, & Lee, 2013). Early exercise in the ICU improved patients' abilities to complete activities of daily living (bathing, dressing, eating, grooming, transferring from bed to chair, and using the toilet) and increased the distances they were able to walk (Schubert 2011; Stiller 2013).*
- Assess client's dependence, weight, strength, balance, tolerance to position change, cooperation, fatigue level, and cognition plus available equipment and staff ratio/experience to decide whether to do a manual or device-assisted transfer (Cohen et al, 2010; American Nurses Association [ANA] 2013).
- ▲ Obtain a consult for a PT, OT, or orthotist to evaluate and fit clients with proper orthoses, braces, collars, and walking aids before helping them stand. **CEB:** *Equipment helps clients move and function safely, comfortably, and independently (Hoeman, Liszner, & Alverzo, 2008).*
- ▲ Help client put on/take off collars, braces, prostheses in bed, and put on/take off antiembolism stockings and abdominal binders. If applying antiembolism stockings is prescribed to reduce the risk of DVT, apply while the client is in bed for ease of application. **EB:** *In patients with diagnosed acute DVT of the leg, compression stockings may not be routinely used to prevent postthrombotic syndrome (PST). PST is a complication that may occur after a DVT develops from venous insufficiency producing symptoms of pain, edema, and venous ulcers. Current guidelines recommend not routinely using compression*

stockings with patients who have a DVT (Kearon et al, 2017).

▲ Collaborate with PT and OT to use algorithms to identify technological aids to handle and transfer dependent and obese clients. Use assistive mobility devices such as gait belts, lifts, and transport devices to move obese clients to avoid harm to both client and health care professional (Choi & Brings, 2015). *Assess the client for appropriate use of assistive devices to include powered stand-assist devices, mechanical lifts, stretchers to chairs, and friction-reducing devices to prevent musculoskeletal injuries of staff and allow safe client handling (ANA, 2013; Centers for Disease Control and Prevention, 2015; Choi & Brings, 2015).*

• Implement and document type of transfer (e.g., slide board, pivot), weight-bearing status (non–weight-bearing, partial), equipment (walker, sling lift), and level of assistance (standby, moderate) on care plan, white board in room, and/or electronic medical record.

• Apply a gait belt with handles before transferring clients with partial weight-bearing abilities; keep the belt and client close to provider during the transfer. *If used incorrectly, such as at arm's length, it prevents support of client and places staff at risk for back and arm injuries (Kalisch, Dabney, & Lee, 2013; Choi & Brings, 2015; Hallmark, Meachan, & Shores, 2015).*

• Help clients when wearing shoes with nonskid soles and socks/hose. *Proper shoes help prevent slips/pain/pressure and improve balance.* **CEB:** *Suggest trying a running shoe that is comfortable and lightweight. A recent study found that participants, who were unable to see the type of shoe (control shoe, running shoe, or orthopedic shoe), chose the running shoe based on comfort and weight (Riskowski, Dufour, & Hannan, 2011).*

• Remove or swivel wheelchair armrests, leg rests, and footplates to the side, especially with squat or slide board transfers. *This gives clients and nurses feet space in which to maneuver and provides fewer obstacles to trip over.*

• Adjust transfer surfaces so they are similar in height. For example, lower a hospital bed to about an inch higher than commode height. **EB:** *Similar heights between seat surfaces require less upper extremity muscular effort during transfers (Darragh et al, 2015).*

• Place wheelchair and commode at a slight angle toward the surface onto which the client will transfer. *The two surfaces are close together yet allow room for the caregiver to adjust the client's movements during the transfer (Darragh et al, 2015).*

• Teach client to consistently lock brakes on wheelchair/commode/shower chair before transferring. *Wheels will roll if not locked, creating risk for falls. Pneumatic wheelchair tires must be adequately inflated for brakes to lock effectively (Choi & Brings, 2015; Darragh et al, 2015).*

• Give clear, simple instructions, allow client time to process information, and let him or her do as much of the transfer as possible. *Over-assistance by staff and family may decrease client learning, independence, self-care, and self-esteem.*

▲ Remind clients to comply with weight-bearing restrictions ordered by their health care provider. *Weight-bearing may retard healing in fractured bones.*

• Place client in set position before standing him or her, for example, sitting on edge of surface with bilateral weight-bearing on buttocks and hips, with knees flexed, balls of feet aligned under knees, and head in midline. *This position prepares individuals for bearing weight and permits shifting of weight from pelvis to feet as the center of gravity changes while rising.*

• Support and stabilize client's weak knees by placing one or both of your knees next to or encircling client's knees, rather than blocking them. *This allows client to flex his or her knees and lean forward to stand and transfer.*

❍ Squat transfer: client leans well forward, slightly raises flexed hips off the

surface, pivots, and sits down on new surface. *This is beneficial for clients with slight weight-bearing ability.*

- ❍ Standing pivot transfer: client leans forward with hips flexed and pushes up with hands from seat surface (or arms of chair), then stands erect, pivots, and sits down on new surface. *This is beneficial for clients who have fair weight-bearing ability.*
- ❍ Slide board transfer: client should have on pants or have a pillowcase over the board. Remove arm and leg rest from wheelchair on one side, then slightly angle chair toward new surface. Help client lean sideways, shifting his or her weight so the transfer board can be placed well under the upper thigh of the leg next to new surface. Make sure the board is safely angled across both surfaces. Help client to sit upright and place one hand on the board and the other hand on the surface. Remind and help client perform a series of pushups with arms while leaning slightly forward and lifting (not sliding) hips in small increments across the board with each pushup. *This benefits clients with little to no weight-bearing ability (Hoeman, Lizner, & Alverzo, 2008; Cameron et al, 2012; Hallmark, Mechan, & Shores, 2015; Darragh et al, 2015).*

• Position walking aids appropriately so a standing client can grasp and use them once he or she is upright. These aids help provide support, balance, and stability to help client stand and step safely (Kalisch, Dabney, & Lee, 2013; Mayeda-Letourneau, 2014).

• Reinforce to clients who use walkers to place one hand on walker and push with opposite hand against chair arm or surface from which they are arising to stand up. *Placing both hands on the walker may cause it to tip and the client to lose balance and fall.*

• Use ceiling-mounted or bedside mechanical bariatric lifts to transfer dependent bariatric (extremely obese) clients. *Equipment prevents client/staff injury and is essential for clients who require a moderate/maximum assist transfer (Cohen et al, 2010; ANA 2013; Choi & Brings, 2015).*

• Use bariatric devices and use available safe client handling equipment for lifting, transferring, positioning, and sliding client (Cohen et al, 2010; ANA 2013; Choi & Brings, 2015).

• Place a mechanical lift sling in the wheelchair preventively. Place two transfer sheets or a slide board under the bariatric client. *Reinforce that head should be leaning forward and that knees should be level with hips; help hold wheelchair in place as therapist directs/helps client with a scoot transfer. Client may be too fatigued to do a manual transfer back to bed after sitting, so sling/lift can be used.*

• Perform initial and subsequent fall risk assessment. *Use standardized tools for fall risk assessment and interdisciplinary multifactorial interventions to reduce falls and risk of falling in hospitals.* **EB:** *Best practice in falls reduction occurs when fall risk assessment; visual identification of individuals at high risk for falls; falls risk factor directed interventions; and standardized multifactorial education, including visual tools for staff, families, and, patients are implemented (Degelau et al, 2012; Low et al, 2015).*

▲ Collaborate with PT, OT, and pharmacist for individualized preventive/postfall plans; for example, scheduled toileting, balance and strength training, removal of hazards, chair alarms, call system/phone in reach, and review of medications. **EB:** *A systematic review of the evidence found low-intensity exercise and incontinence care in residents in nursing homes reduced falls (Low et al, 2015; Hopkins, Mitchell, Thomsen, et al. (2016).*

• Coordinate a follow-up encounter within 30 days of discharge from any inpatient

facility with a licensed provider to perform a medication reconciliation to include all medications the client has been taking or receiving prior to the outpatient visit to provide quality care and improve quality of communication related to medications (Agency for Healthcare Research and Quality [AHRQ], 2015). **EB:** *Review of medications, especially new medications added to a client plan of care, can place the individual at risk for falls, changes in mentation, or mobility limitations (AHRQ, 2015).*

• Encourage an exercise component such as Tai chi, physical therapy, or other exercise for balance, gait, and strength training in group programs or at home.

• Integrate structured and progressive exercise protocols into a client's plan of care and innovative partnerships with other providers to create longer duration interventions for clients at risk of falling. *This promotes strength and aids in increasing confidence and will then reduce the risk for falling (Schubert, 2011; Low et al, 2015).*

• Modify the environment for safety; recommend vision assessment and consideration for cataract removal.

• To reduce the risk of falling, assess the physical environment (e.g., poor lighting, high bed position, improper equipment). *Continuous and intentional observational assessment of the environment promotes safety by reducing potential fall hazards (Low et al, 2015).*

• Recommend polypharmacy assessment with special consideration to sedatives, antidepressants, and drugs affecting the central nervous system; recommend evaluation for orthostatic hypotension and irregular heartbeats; and recommend vitamin D supplementation 800 IU/day (AHRQ, 2015).

Home Care

▲ Obtain referral for OT and PT to teach home exercises and balance and fall prevention and recovery. They also evaluate for potential modifications such as an entry ramp, elevated toilet seat/toilevator (raised base under toilet), tub seat or shower chair, need for shower stall with built-in seat or wheel-in shower stall without a curb/threshold, handheld flexible shower head, lever-type facets, pull-out drawers with loop handles versus cupboards, standing lift, and so on. **EB:** *A study found that evaluating the home environment that facilitated assistive devices was necessary for safe and successful mobility of clients within the dwelling and outdoors (Clark, 2014).*

• Develop a multifactorial/multicomponent interventions risk strategy to reduce the risk for falls that include adaptation or modification of the home environment; withdrawal or minimization of psychoactive medications; withdrawal of minimization of other medications; management of postural hypotension; management of foot problems and footwear; and exercise, particularly balance, strength, and gait training (AHRQ, 2013; Skelton et al, 2013).

• Assess for adequate lighting and hazards such as throw/area rugs, clutter, cords, and unfitted bedspreads. Suggest safe floor surfaces, such as use of adhesive nonslip strips in tubs/thresholds/areas in which floor height changes; removal of wax from slippery floors; and installing low-pile carpet/nonglazed or nonglossy tiles/wood/linoleum coverings. Stress relocating commonly used items to shelves/drawers in reach; applying remote controls to appliances; and optimizing furniture placement for function, maneuverability, and stability. *Barrier removal promotes safety and accessibility; steady furniture can be used to steady or pull oneself up if a fall occurs (Chase et al, 2012; Skelton et al, 2013).*

• Assess clients for impairment of vision because this can result in a loss of function in activities of daily living and, consequently, result in impaired functional capacity

and is an important risk factor for falls. **EB:** *Possible mechanisms to reduce activity restriction and improve mobility include environmental and behavioral interventions delivered by multiple types of health professionals, including OTs (Skelton et al, 2013).*

• Nurses can provide further safety assessments by suggesting installing hand rails in bathrooms and by stairs, ensuring client's slippers and clothes fit properly, and recommending repairing or discarding broken equipment in the home (Taylor et al, 2011).

▲ Involve social worker or case manager to educate clients about potential assistive technology, financial cost and benefits, regulations of payers, and local resources. *Information helps clients understand options and cost of services and aids to make informed decisions.*

▲ Implement approaches for home care staff and family to safely handle and transfer clients. *Risk of injury is high because people often work alone, without mechanical aids or adjustable beds and in crowded spaces, while giving care (Mayeda-Letourneau, 2014).*

• For further information, refer to care plans for Impaired physical **Mobility** and Impaired **Walking.**

Client/Family Teaching and Discharge Planning

• Assess for readiness to learn and use teaching modalities conducive to personal learning styles, including written instructions for home use.

• Supervise practice sessions in which client and family apply items such as gait belts, braces, and orthoses. Check skin once aids are removed. *Repetition reinforces motor learning for safety and sound skin integrity.*

• Teach and monitor client/family for consistent use of safety precautions for transfers (e.g., nonskid shoes, correctly placed equipment/chairs, locked brakes, leg rests swiveled away) and for correct performance of transfer or use of lifts/slings. *Promotes safety.*

• Teach client/family how to check brakes on chairs to ensure they engage and how to check tires for adequate air pressure; advise routine inspection and annual tune-up of devices. *Long-term use may loosen brakes or cause them to slip; brakes work only if they make sound contact with tire or wheel. Pneumatic tires must be adequately inflated.*

• Offer information on safe use of shower and commode chairs to prevent discomfort, pressure, and falls during transfer, transport, care, and hygiene.

• For further information, refer to the care plans for Impaired physical **Mobility,** Impaired **Walking,** and Impaired wheelchair **Mobility.**

Risk for physical Trauma

Julianne E. Doubet BSN, RN, EMT-B

NANDA-I

Definition

Vulnerable to accidental tissue injury (e.g., wound, burn, fracture), which may compromise health.

Risk Factors

External

Absence of call for aid device; absence of stairway gate; absence of window guard; access to weapon; bathing in very hot water; bed in high position; children riding in front seat of car; defective appliance; delay in ignition of gas appliance; dysfunctional call for aid device; electrical hazard (e.g., faulty plug, frayed wire, overloaded outlet/fuse box); exposure to corrosive product; exposure to dangerous machinery; exposure to radiation; exposure to toxic chemical; extremes of environmental temperature; flammable object (e.g., clothing, toys); gas leak; grease on stove; high-crime neighborhood; icicles hanging from roof; inadequate stair rails; inadequately stored combustible (e.g., matches, oily rags); inadequately stored corrosive (e.g., lye); insufficient lighting; insufficient protection from heat source; misuse of headgear (e.g., hard hat, motorcycle helmet); misuse of seat restraint; insufficient antislip material in bathroom; nonuse of seat restraints; obstructed passageway; playing with dangerous object; playing with explosive; pot handle facing front of stove; proximity to vehicle pathway (e.g., driveway, railroad track); slippery floor; smoking in bed; smoking near oxygen; struggling with restraints; unanchored electric wires; unsafe operation of heavy equipment (e.g., excessive speed while intoxicated with required eyewear); unsafe road; unsafe walkway; use of cracked dishware; use of throw rugs; use of unstable chair; use of unstable ladder; wearing loose clothing around open flame

Internal

Alteration in cognitive functioning; alteration in sensation (e.g., resulting from spinal cord injury, diabetes mellitus); decrease in eye–hand coordination; decrease in muscle coordination; economically disadvantaged; emotional disturbance; history of trauma (e.g., physical, psychological, sexual); impaired balance; insufficient knowledge of safety precautions; insufficient vision; weakness

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Risk Control; Fall Prevention Behavior

Example NOC Outcome with Indicators

Accomplishes **Risk Control** as evidenced by the following indicators: Acknowledges risk/Develops effective risk-control strategies/Follows selected risk control strategies. (Rate the outcome and indicators of **Risk Control:** 1 = never demonstrated; 2 = rarely demonstrated; 3 = sometimes demonstrated; 4 = often demonstrated; 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Remain free from trauma
- Explain actions that can be taken to prevent trauma

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Environmental Management: Safety; Skin Surveillance

Example NIC Activities—Environmental Management

Provide family/significant other with information about making home environment safe for client; Remove harmful objects from the environment

Nursing Interventions and *Rationales*

- Provide vision aids for visually impaired clients. **EB:** *Low-vision rehabilitation enables people to restart and/or maintain the capability of performing the tasks of daily living (Virgili et al, 2013).*
- Assist the client with ambulation. Encourage the client to use assistive devices in

activities of daily living (ADLs) as needed. **EB:** *Studies reviewed by Edelstein (2013) have shown the advantages, if used correctly, of using time-honored assistive devices (e.g., crutches, walker).*

• Evaluate client's risk for burn injury. **EBN:** *Grant (2013) stated that the very young and the elderly are at an increased risk for burn injuries compared with any other age group.* **EBN:** *It is apparent to Goodarzi et al (2014) in their research that there is a continuing need for further safety education and the utilization of environmental safety measures to reduce burn trauma.*

• Assess the client for causes of impaired cognition. **EB:** *Adults with intellectual disabilities are likely to have an elevated risk for traumatic injury compared with the general populace (Finlayson et al, 2014).*

• Provide assistive devices in the home. **EBN:** *According to Johnston et al (2014), shared conclusions between the health care giver and the client with disabilities allows the client to choose the best assistive devices and services that are vital to achieving their goals of education, community living, and employment.*

▲ Question the client concerning his or her sense of safety. **EBN:** *In their study, Edwards et al (2014) stated that clients who wish to remain at home at the end of life are at increased risk for trauma caused by declining cognitive and/or physical capabilities, environmental dangers, and concerns with caregivers.*

▲ Assess for a substance abuse problem and refer to appropriate resources for drug and alcohol education. **EB:** *According to Choi, DiNitto, and Marti (2014), older adults who abuse alcohol and/or illicit drugs should be sent to the most appropriate service that meets his or her needs, both for rehabilitation and any mental health challenges that may be involved.* **EB:** *Although drinking and driving among student drivers has declined in recent years, driving after the use of marijuana has increased; therefore O'Malley and Johnston (2013) believed that more attention should be focused on preventing those under the influence of illicit drugs from driving.*

• Review drug profile for potential side effects that may inhibit performance of ADLs. *In their study of pain management in the elderly, Veal and Peterson (2015) found that older adults are at increased risk for detrimental medication side effects caused by changes in drug metabolism and to polypharmacy that may put them at risk for drug interactions.*

• See care plans for Risk for **Aspiration,** Risk for **Falls,** Impaired **Home** maintenance, Risk for **Injury,** Risk for **Poisoning,** and Risk for **Suffocation.**

Pediatric

• Assess the client's socioeconomic status. **EB:** *The presently used evaluations that measure evidence of adverse childhood experiences (ACEs) may be insufficient to recognize the extent of adversity to which low-income urban children are exposed (Wade et al, 2014).*

• Never leave young children unsupervised. **EB:** *According to van Beelen et al (2014), the death, disability, and loss of quality of life among young children is directly related to injuries that occur in the home.*

• Keep flammable and potentially flammable articles out of reach of young children. **EB:** *Infants and toddlers who scald themselves by spilling hot liquids on themselves or touching irons and hair straighteners are a main cause for concern for targeted prevention (Kemp et al, 2014).* **EBN:** *Hollywood and O'Neill (2014) maintained that nurses working with children in hospitals, schools, and the community can connect with parents, families, school staff, and children to offer professional advice and health and safety guidance for burn prevention.*

• Lock up harmful objects such as guns. **EB:** *Easy access to firearms in the home is*

responsible for injury to thousands of children in the United States (Barton & Kologi, 2014). **EB:** *There is an increased risk for childhood injury when firearms are left loaded and unlocked (Schwebel et al, 2014).*

Geriatric

- Assess the geriatric client's cognitive level of functioning. **EB:** *Patel et al (2014) agreed that the occurrence of neurocognitive disorders can be an obstacle to the capability of older adults to perform ADLs and this deficit will continue to escalate with age.*
- Assess for routine eye examinations. **EBN:** *The older client may find it difficult to adjust to vision loss and aging because of the psychological, functional, social, and health implications that play a significant role in the process (Mac Cobb, 2013).*
- Perform a home safety assessment and recommend the following preventive measures: keep electrical cords out of the flow of traffic; remove small rugs or make sure they are slip resistant; increase lighting in hallways and other dark areas; place a light in the bathroom; keep towels, curtains, and other items that might catch fire away from the stove; store harmful products away from food products; provide at least one grab bar in tubs and showers; check prescribed medications for appropriate labels; store medications in original containers or in a dispenser of some type (e.g., egg carton, 7-day plastic dispenser). If the client cannot administer medications according to directions, secure someone to administer medications. Mark stove knobs with bright colors (yellow or red) and outline the borders of steps. **EBN:** *As part of a person-centered, evidenced-based approach, a professional case manager/care coordinator can perform a thorough assessment of the client's needs and will design and put into operation an all-inclusive care plan to meet the clinical, psychosocial, and environmental requirements of the client (Johansson & Harkey, 2014).*
- Discourage driving at night. **EB:** *Gruber et al (2013) suggested that there is an increasing number of older adults who continue to drive, and the population of drivers who are affected by deteriorating night vision is increasing.*
- Encourage the client to participate in resistance and impact exercise programs as tolerated. **EB:** *In their review of current evidence, Carvalho et al (2014) suggested that physical activity may not only aid in improving cognitive function in older adults, but it could also play a part in delaying the development of cognitive impairment in the older adult.*

Client/Family Teaching and Discharge Planning

- Educate the family regarding age-appropriate child safety precautions, environmental safety precautions, and intervention in an emergency. **EB:** *Safety education for parents of young children is essential in the prevention of accidental injuries in and/or around the home (van Beelen et al, 2013).* **EB:** *In their study, Morrongiello, McArthur, and Bell (2014) found that to decrease a child's risk of harm, the child must first understand the safety issue.*
- Teach the family to assess the child care provider's knowledge regarding child safety. **EB:** *Home safety interventions not only aid in reducing children's injuries, but they also enhance the general safety of the home (Kendrick et al, 2013).*
- Educate the client and family regarding helmet use during recreation and sports activities. **EB:** *It has been proven time and time again that wearing a bicycle helmet has averted or reduced the risk of serious head injuries (Basch et al, 2014).*
- Encourage the proper use of car seats and safety belts. **EB:** *Himle and Wright (2014) stated that child passenger safety restraint, when used correctly, can diminish the risk of severe*

injury and/or death in motor vehicle crashes.

- Teach parents to restrict driving for teens. **EB:** *According to Taubman et al (2014), research studies have shown that parents are the most important influence on young people's driving conduct.*
- Teach parents the importance of monitoring children after school. **EB:** *In a study by Freisthler et al (2014), children who are not supervised appropriately, either by inattentive parents and/or caregivers, could be considered neglected.*
- Teach firearm safety. **EB:** *According to Schwebel et al (2014), firearms in the home that are loaded and unlocked are sources of increased risks for trauma.* **EB:** *Health care professionals must have knowledge and skills to address safe gun ownership in older adults (Pinholt et al, 2014).*
- For further information, refer to care plans for Risk for **Aspiration,** Risk for **Falls,** Impaired **Home** maintenance, Risk for **Injury,** Risk for **Poisoning,** and Risk for **Suffocation.**

● = Independent; ▲ = Collaborative; **EBN** = Evidence-Based Nursing; **EB** = Evidence-Based

Unilateral Neglect

Lori M. Rhudy PhD, RN, CNRN, ACNS-BC

NANDA-I

Definition

Impairment in sensory and motor response, mental representation, and spatial attention of the body, and the corresponding environment, characterized by inattention to one side and overattention to the opposite side. Left-side neglect is more severe and persistent than right-side neglect.

Defining Characteristics

Alteration in safety behavior on neglected side; disturbance of sound lateralization; failure to dress neglected side; failure to eat food from portion of plate on neglected side; failure to groom neglected side; failure to move eyes in the neglected hemisphere; failure to move head in the neglected hemisphere; failure to move limbs in the neglected hemisphere; failure to move trunk in the neglected hemisphere; failure to notice people approaching from the neglected side; hemianopsia; impaired performance on line cancellation, line bisection, and target cancellation tests; left hemiplegia from cerebrovascular accident; marked deviation of the eyes to stimuli on the non-neglected side; marked deviation of the trunk to stimuli on the non-neglected side; omission of drawing on the neglected side; perseveration; representational neglect; substitution of letters to form alternative words when reading; transfer of pain sensation to the non-neglected side; unaware of positioning of neglected limb; unilateral visuospatial neglect; use of vertical half of page only when writing

Related Factors

To be developed

Associated Condition

Brain injury

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Body Image; Body Positioning: Self-Initiated; Mobility; Self-Care: Activities of Daily Living (ADLs)

Example NOC Outcome with Indicators

Mobility as evidenced by the following indicators: Balance/Coordination/Gait/Muscle movement. (Rate the outcome and indicators of **Mobility:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5= not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Use techniques that can be used to minimize unilateral neglect (UN)
- Care for both sides of the body appropriately and keep affected side free from harm
- Return to the highest functioning level possible based on personal goals and abilities
- Remain free from injury

NIC (Nursing Interventions Classification)

Suggested NIC Intervention
Unilateral Neglect Management

Example NIC Activities—Unilateral Neglect Management
Ensure that affected extremities are properly and safely and positioned; Rearrange the environment to use the right or left visual field

Nursing Interventions and *Rationales*

- ▲ Assess the client for signs of UN (e.g., not washing, shaving, or dressing one side of the body; sitting or lying inappropriately on affected arm or leg; failing to respond to environmental stimuli contralateral to the side of lesion; eating food on only one side of plate; or failing to look to one side of the body). **EB:** *Many tests for UN exist, but there is no consensus about which is the most valid. Joint assessments of that include both clinical observation and precise testing perform better than either used alone (Grattan & Woodbury, 2017).* **EB:** *In one study, 67.8% of patients had UN on admission to inpatient rehabilitation (Chen et al, 2015).*
- ▲ Collaborate with health care provider for referral to a rehabilitation team (including, but not limited to, rehabilitation clinical nurse specialist, physical medicine and rehabilitation health care provider, neuropsychologist, occupational therapist, physical therapist, and speech and language pathologist) for continued help in dealing with UN. **EB:** *There is some evidence that rehabilitation for unilateral spatial neglect using tools such as visual scanning and prism adaptation improves function, but their effect on disability is not clear. Further studies are needed (Gillen et al, 2015).*
- Use the principles of rehabilitation to progressively increase the client's ability to compensate for UN by using assistive devices, feedback, and support. **EB:** *Studies demonstrated that recovery from UN generally resolves within 1 month of stroke, but it can still be detectable after 3 months and/or at discharge from inpatient rehabilitation (Chan & Man, 2013; Chen et al, 2015).*
- Teach the client to be aware of the problem and modify behavior and environment. **EB:** *Awareness of the environment decreases risk of injury. There is some evidence that use of scanning techniques may decrease visual neglect (Chan & Man, 2013).*
- Set up the environment so that essential activity is on the unaffected side:
    - ❍ Place the client's personal items within view and on the unaffected side.
    - ❍ Position the bed so that client is approached from the unaffected side.
    - ❍ Monitor and assist the client to achieve adequate food and fluid intake.

Helps in focusing attention and aids in maintenance of safety.

- Implement fall prevention interventions. *Clients with right hemisphere brain damage are twice as likely to fall as those with left hemisphere damage.* **EB:** *Patients with poor timed up and go (TUG) performance, longer times since stroke onset, and right-hemisphere injury have particularly high fall rates (Pinto et al, 2014).* **EB:** *UN is significantly related to falls in*

patients with a neurological diagnosis (Bergman & Papendick, 2014).
• Position affected extremity in a safe and functional manner. **EB:** *A study found that musculoskeletal pain, shoulder subluxation, spasticity, and joint contracture were among the most common complications during the first year after stroke (Kuptniratsaikul et al, 2013).* **EB:** *Clients with neglect had significantly lower functional independence measure (FIM) scores (Chen et al, 2015).*
▲ Collaborate closely with rehabilitation professionals to identify and reinforce therapies aimed at reducing neglect symptoms. *Techniques such as scanning, visual cuing approaches, limb activation strategies, prisms, mirror therapy, and music listening are being used to treat UN (Pernet, Jughters, & Kerckhofs, 2013; Tsai et al, 2013; Pandian et al, 2014), but the evidence is limited and inconclusive on the most effective approach (Azouvi, Jacquin-Courtois, & Luaute, 2017), and the type of neglect may affect outcomes associated with each technique.*

Home Care

• Many of the previously listed interventions may be adapted for use in the home care setting.
• Position bed at home so that client gets out of bed on unaffected side. *Positioning the bed so that the client gets out on the unaffected side can increase safety.*

Client/Family Teaching and Discharge Planning

• Engage discharge planning specialists for comprehensive assessment and planning early in the client's stay. **EB:** *Clients with UN have longer lengths of stay and more difficulty resuming ADLs (Chan & Man, 2013).* **EB:** *In one study 67.8% of patients on admission and 47.2% on discharge had symptoms of spatial neglect (Chen et al, 2015).* **EB:** *Neglect scores at admission negatively predicted FIM scores at discharge (Chen et al, 2015).*
• Encourage family participation in care. **EB:** *Severity of stroke and presence of UN were significant prognostic indicators for inability to gain independence in ADLs (Morone, Paolucci, & Iosa, 2015; Semrau et al, 2015).*
• Explain pathology and symptoms of UN to both the client and family. *Family members may not understand that inattention is a complication of the neurological injury.*
• Teach the client how to scan regularly to check the position of body parts and to regularly turn head from side to side for safety when ambulating, using a wheelchair, or doing self-care tasks. **EB:** *In one study, incorporating task-specific treatments, such as eating food from a plate and grooming, improved functional outcome and reduced neglect symptoms (Patole et al, 2015).* **EB:** *One study found that effectiveness of cues depended on severity of neglect (Wansard et al, 2014).*
• Teach caregivers to cue the client to the environment.

Impaired Urinary elimination

Michelle Acorn DNP, NP PHC/Adult, BA, BScN/PHCNP, MN/ACNP, GNC(C), CGP

NANDA-I

Definition
Dysfunction in urine elimination.

Defining Characteristics
Dysuria; frequent voiding; hesitancy; nocturia; urinary incontinence; urinary retention; urinary urgency

Related Factors
Multiple causality

Associated Condition
Anatomic obstruction; sensory motor impairment; urinary tract infection

NOC (Nursing Outcomes Classification)

Suggested NOC Outcome
Urinary Elimination

Example NOC Outcome with Indicators
Urinary Elimination as evidenced by the following indicators: Urine clarity/urine odor, fluid intake, pain with urination. (Rate the outcome and indicators of **Urinary Elimination:** 1 = severely compromised 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- State absence of pain or excessive urgency during urination
- Demonstrate voiding frequency no more than every 2 hours

NIC (Nursing Interventions Classification)

Suggested NIC Intervention

Urinary Elimination Management

Example NIC Activities—Urinary Elimination Management

Monitor urinary elimination, including frequency, consistency, odor, volume, and color, as appropriate; Teach client signs and symptoms of urinary tract infection (UTI)

Nursing Interventions and *Rationales*

- Ask the client about urinary elimination patterns and concerns. Urinary elimination problems have many presenting signs and symptoms. Asking the client questions may help understand the subtle signs and symptoms associated with urinary elimination (Mayo Clinic, 2017).
- Question the client regarding the following:
    - ❍ Presence of symptoms such as incontinence, dribbling, frequency, urgency, dysuria, and nocturia
    - ❍ Presence of pain in the area of the bladder
    - ❍ Pattern of urination and approximate amount
    - ❍ Possible aggravating and alleviating factors for urinary problems
- Ask the client to keep a bladder diary/bladder log. **EB:** *Use of a bladder diary may reduce client discrepancies in recall and is a valuable tool for assessment; short (24-hour) duration of the bladder diary may yield inadequate data, and excessive diary duration reduces compliance (Bright, Drake, & Abrams, 2011).*
- For interventions on urinary incontinence, refer to the following nursing diagnosis care plans as appropriate: Stress urinary **Incontinence,** Urge urinary **Incontinence,** Reflex urinary **Incontinence,** Overflow urinary **Incontinence,** or Functional urinary **Incontinence.**
- ▲ Perform a focused physical assessment including inspecting the perineal skin integrity, percussion, and palpation of the lower abdomen looking for obvious bladder distention or an enlarged kidney. *A palpable kidney or bladder provides direct evidence of a dilated urinary collection system (Policastro, Sinert, & Guerrero, 2014).* If signs of urinary obstruction are present, refer client to a urologist. *Unrelieved obstruction of urine can result in renal damage, and if severe, renal failure (Policastro, Sinert, & Guerrero, 2014). Refer to the nursing care plan for* ***Urinary Retention*** *if retention is present.*
- ▲ Check for costovertebral tenderness. *Costovertebral tenderness is seen with pyelonephritis and kidney stones (Gupta & Trautner, 2015; Pietrucha-Dilanchian & Hooton, 2016).*
- ▲ Review results of urinalysis for the presence of urinary infection such as white blood cells, red blood cells, bacteria, and positive nitrites. If urinalysis results are not available, request a midstream specimen of urine (urine obtained during voiding, discarding the first and last portions) for a urinalysis (Pietrucha-Dilanchian & Hooton, 2016).

▲ If blood or protein is present in the urine, recognize that both hematuria and proteinuria are serious symptoms, and the client should be referred to a urologist to receive a workup to rule out pathology.
• Inquire about the client's history of smoking. **EB:** *Smoking and bladder symptoms in women found that urgency and frequency are three times more common among current than never smokers. Parallel associations suggest dose-related response associations. Nocturia and stress urinary incontinence (SUI) are not associated with smoking. Smoking cessation is recommended (Tahtinen et al, 2011).*

Urinary Tract Infection

▲ Consult the provider for culture and sensitivity testing and antibiotic treatment in the individual with evidence of a symptomatic UTI. *UTI is a transient, reversible condition that is usually associated with urgency or urge urinary incontinence (Nicolle & Norrby, 2016). Eradication of UTI will alleviate or reverse symptoms of suprapubic pressure and discomfort, urgency, daytime voiding frequency, and dysuria (Nicolle & Norrby, 2016).*
▲ Teach the client to recognize symptoms of UTI, such as dysuria that crescendos as the bladder nears complete evacuation; urgency to urinate followed by micturition of only a few drops; suprapubic aching discomfort; malaise; and voiding frequency; sudden exacerbation of urinary incontinence with or without fever, chills, and flank pain. Recognize that a cloudy or malodorous urine, in the absence of other lower urinary tract symptoms, may not indicate the presence of a UTI and that asymptomatic bacteriuria in the older adult does not justify a course of antibiotics. *Asymptomatic bacteriuria may be associated with cloudy or malodorous urine, but these signs alone do not justify antimicrobial therapy when balanced against the potential adverse effects of treatment, including adverse side effects of the various antibiotics and encouragement of colonization of the urine with antibiotic-resistant bacterial strains (Ariathianto, 2011; Nicolle & Norrby, 2016).*
▲ Refer the individual with chronic lower urinary tract pain to a urologist or specialist in the management of pelvic pain. *Bladder pain and storage symptoms, in the absence of an acute urinary infection, may indicate the presence of interstitial cystitis, which is a chronic condition requiring ongoing treatment (Interstitial Cystitis Association, 2017).*

Geriatric

• Evidence for behavioral interventions include the following: (1) prompted voiding is effective in the treatment of daytime symptoms when patients and caregivers comply; (2) prompted voiding is ineffective and should not be used for people who need the assistance of more than one person to transfer, instead manage with "check and change"; (3) promoted voiding should not be continued in people who have less than 20% reduction in wet checks or toilet successfully less than two-thirds of the time after a 3-day trial; and (4) interventions combining toileting, exercise, food, and fluids are effective (Wagg et al, 2014).
• Encourage older women to consume one to two servings of fresh blueberries and consider drinking at least 10 ounces of cranberry juice daily or supplement the diet with cranberry concentrate capsules as ordered. **EB:** *Although the evidence supporting the consumption of cranberry juice or tablets to reduce UTIs is inconclusive (Jepson, Williams, & Craig, 2012; Foxman et al, 2015), some evidence does suggest that the consumption of 8 to 10 ounces of cranberry juice, ascorbic acid (vitamin C) supplement, or an equivalent portion of foods containing whole cranberries or blueberries exerts a bacteriostatic effect on* Escherichia

coli, *which is the most common pathogen associated with urinary infection among community-dwelling adult women (Aydin et al, 2014).*

▲ Refer the older woman with recurrent UTIs to her health care provider for possible use of topical estrogen creams for treatment of atrophic vaginal mucosa from decreased hormonal stimulation, which can predispose to UTIs (Aydin et al, 2014; Nicolle & Norrby, 2016).

• Postresidual volumes (PRVs) should be assessed in older women with overactive bladder (OAB). A volume of greater than 200 mL is significant. A history of back or pelvic injury or surgery increases the risk of greater PRV (Park and Palmer, 2015).

▲ Recognize that UTIs in older men are typically associated with prostatic hyperplasia or strictures of the urethra. Refer the client to a urologist (Nicolle & Norrby, 2016).

• Analysis of urinary elimination patterns of clients could help in clinical follow-up of elderly postoperative patients and in the selection of best nursing interventions. **EB:** *A study exploring NOC indictor interrater reliability showed classifications can be useful for monitoring clinical changes related to urinary elimination. High agreements for the indicators of urine odor, leukocytes, nitrates, blood, painful urination, and urinary continence were found (Bitencourt et al, 2016).*

• Practice recommendations when caring for older clients include (1) frailty, not age should guide urinary elimination treatment decisions; (2) caring for individuals with urinary incontinence and cognitive impairment needs to be tailored to the individuals abilities; and (3) be cautious of anticholinergic medications and weigh the risk and benefits for antimuscarinics (Wagg et al, 2014).

Client/Family Teaching and Discharge Planning

• Teach the client/family methods to keep the urinary tract healthy. Refer to Client/Family Teaching in the care plan for Readiness for enhanced **Urinary** elimination.

• Teach the following measures to women to decrease the incidence of UTIs:

- ❍ Urinate at appropriate intervals. Do not ignore need to void, which can result in stasis of urine.
- ❍ Drink plenty of liquids, especially water. *Drinking water helps dilute the urine, allowing bacteria to be flushed from the urinary tract before an infection can begin (Nicolle & Norrby, 2016).*
- ❍ Wipe from front to back. *This helps prevent bacteria in the anal region from spreading to the vagina and urethra.*
- ❍ Wear underpants that have a cotton crotch. *This allows air to circulate in the area and decreases moisture in the area, which predisposes to infection.*
- ❍ Avoid potentially irritating feminine products. *Using deodorant sprays, bubble baths, or other feminine products, such as douches and powders, in the genital area can irritate the urethra. There are multiple common sense measures that can be used to decrease the incidence of UTIs (Gupta & Trautner, 2015; Mayo Clinic, 2017).*

• Teach the sexually active woman with recurrent UTIs prevention measures including:

- ❍ Void after intercourse to flush bacteria out of the urethra and bladder.
- ❍ Use a lubricating agent as needed during intercourse to protect the vagina from trauma and decrease the incidence of vaginitis.
- ❍ Watch for signs of vaginitis and seek treatment as needed.
- ❍ Avoid use of diaphragms with spermicide.

Sexually active women have the highest incidence of UTIs (Nicolle & Norrby, 2016). The vagina and periurethral area can become colonized with organisms from the intestinal flora, such as E. coli, *and increase the risk for UTIs (Gupta & Trautner, 2015; Pietrucha-Dilanchian and Hontoon, 2016).*

- Teach clients with spinal cord injury and neurogenic bladder dysfunction to consider adding cranberry extract tablets or cranberry juice, or fruits containing D-mannose (e.g., apples, oranges, peaches, blueberries) on a daily basis, monitor fluid intake. The client is encouraged to discuss the use of probiotics and antibiotic therapy with the provider for frequent recurrent symptomatic UTIs. **EB:** *Limited evidence suggested that clients who regularly consume cranberry extract tablets experience fewer UTIs than clients who do not routinely consume cranberry extract tablets (Jepson et al, 2012; Keifer, 2013; Foxman et al, 2015). Additionally, clients with spinal cord injury and neurogenic bladder dysfunction are at higher risk for UTI, and more frequent monitoring of symptomatic infection is necessary (Goetz & Klausner, 2014).*
- Teach all persons to recognize hematuria and to promptly seek care if this symptom occurs.

Urinary Retention

NANDA-I

Definition
Inability to empty bladder completely.

Defining Characteristics
Absent of urinary output; bladder distention; dribbling of urine; dysuria; frequent voiding; overflow incontinence; residual urine; sensation of bladder fullness; small voiding

Related Factors
To be developed

Associated Condition
Blockage in urinary tract; high urethral pressure; reflex arc inhibition; strong sphincter

NOC (Nursing Outcomes Classification)

Suggested NOC Outcome
Urinary Elimination

Example NOC Outcome with Indicators
Urinary Elimination as evidenced by the following indicators: Empties bladder completely/Absence of urinary leakage/Urine clarity. (Rate the outcome and indicators of **Urinary Elimination:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Demonstrate consistent ability to urinate when desire to void is perceived
- Have measured urinary residual volume of less than 300 mL
- Experience correction or relief from dysuria, nocturia, postvoid dribbling, and voiding frequently
- Be free of a urinary tract infection

NIC (Nursing Interventions Classification)

Suggested NIC Interventions
Urinary Catheterization; Urinary Retention Care

Example NIC Activities—Urinary Retention Care
Perform a comprehensive urinary assessment focusing on incontinence (e.g., urinary output, urinary voiding pattern, cognitive function, and preexistent urinary problems); Use the power of suggestion by running water or flushing toilet

Nursing Interventions and *Rationales*

- Obtain a focused urinary history including questioning the client about episodes of acute urinary retention (UR; complete inability to void) or chronic retention (documented elevated postvoid residual volumes), as well as symptoms such as

dysuria, nocturia, postvoid dribbling, and voiding frequently. *A history of difficulty voiding, pain, infection, or decreased urine volume is common in clients with urinary obstruction (Seifter, 2012).*

- Question the client concerning specific risk factors for UR including:
  - ❍ Spinal cord injuries
  - ❍ Ischemic stroke
  - ❍ Metabolic disorders such as diabetes mellitus, chronic alcoholism, and related conditions associated with polyuria and peripheral polyneuropathies
  - ❍ Herpetic infection
  - ❍ Heavy-metal poisoning (lead, mercury) causing peripheral polyneuropathies
  - ❍ Advanced stage HIV infection
  - ❍ Medications including antispasmodics/parasympatholytics, alpha-adrenergic agonists, antidepressants, sedatives, narcotics, psychotropic medications, illicit drugs
  - ❍ Recent surgery requiring general or spinal anesthesia
  - ❍ Vaginal delivery within the past 48 hours
  - ❍ Bowel elimination patterns, history of fecal impaction, encopresis
  - ❍ Recent surgical procedures
  - ❍ Recent prostatic biopsy

UR is related to multiple factors affecting either detrusor contraction strength or urethral resistance to urinary outflow (Policastro et al, 2016).

- Complete a pain assessment including pain intensity using a self-report pain tool, such as the 0 to 10 numerical pain rating scale. Also determine location, quality, onset/duration, intensity, aggravating/alleviating factors, and effects of pain on function and quality of life. **EB:** *Acute onset of obstruction with inability to void is associated with significant pain; partial obstruction causes minimal pain, which may delay diagnosis (Policastro et al, 2016). Bladder distention is associated with pain overlying the bladder (Seifter, 2012).*
- Perform a focused physical assessment including perineal skin integrity and inspection, percussion, and palpation of the lower abdomen, looking for obvious bladder distention or an enlarged kidney. *A palpable kidney or bladder provides direct evidence of a dilated urinary collection system (Policastro et al, 2016).*
- Recognize that unrelieved obstruction of urine can result in kidney damage and, if severe, kidney failure. UR can be a medical emergency and should be reported to the primary provider as soon as possible. **EB:** *As urine backs up in the urinary tract, the pressure increases inside the ureters, which results in pressure on the nephrons, damaging the nephrons and decreasing glomerular blood flow (Policastro et al, 2016).*
- Review laboratory test results including serum electrolytes, blood urea nitrogen (BUN) and creatinine, along with calcium, phosphate, magnesium, uric acid, and albumin. *Serum electrolytes (sodium, potassium, chloride, bicarbonate, BUN, and creatinine) and calcium, phosphate, magnesium, uric acid, and albumin should be measured. Elevations of BUN and creatinine and changes in electrolytes may be caused by kidney failure secondary to obstruction (Policastro et al, 2016).*
- Monitor for signs of dehydration, peripheral edema, elevating blood pressure, and heart failure. *The kidney can develop concentrating defects associated with partial obstruction of urine flow, resulting in symptoms that indicate kidney insufficiency (Policastro et al, 2016).*

Ask the client to complete a bladder diary including patterns of urine elimination, urine loss (if present), nocturia, and volume and type of fluids consumed for a period of 3 to 7 days.

- Consult with the provider concerning eliminating or altering medications suspected of producing or exacerbating UR.
- **EB:** *Assess for postresidual voids (PVR) greater than 300 mL because it is the minimal volume at which a bladder becomes palpable (American Urological Association, 2016).*
- Both men and women may develop UR from obstruction of the bladder outlet and abnormalities in detrusor contractility. **EB:** *A common cause of bladder outlet obstruction (BOO) is caused by prostate/bladder neck enlargement, urethral stricture, vaginal vault prolapse, obstructing urethral sling, or impacted stool. Long-term use of medications such as alpha-agonists and tricyclic antidepressants contribute* to the problem *(American Urological Association, 2016).*
- In clients treated with an indwelling urethral catheter (IUC), complications such as catheter-associated urinary tract infections are common, whereas underuse of IUC may cause harmful UR. **EB:** *A quality improvement (QI) program aimed at staff ability to identify and manage patient risk, prevention, and treatment of UR optimizes appropriate IUC use (Anderson et al, 2017).*
- Advise the male client with UR related to benign prostatic hyperplasia (BPH) to avoid risk factors associated with acute UR:
    - ❍ Avoid over-the-counter (OTC) cold remedies containing a decongestant (alpha-adrenergic agonist) or antihistamine, such as diphenhydramine, which has anticholinergic effects.
    - ❍ Avoid taking OTC dietary medications (frequently contain alpha-adrenergic agonists).
    - ❍ Discuss voiding problems with a health care provider before beginning new prescription medications.
    - ❍ After prolonged exposure to cool weather, and warm the body before attempting to urinate.
    - ❍ Avoid overfilling the bladder by regular urination patterns and refrain from excessive intake of alcohol.

EB: *Botulinum toxin injection into the bladder neck is a promising minimally invasive, tolerated, and cost-effective approach for the treatment of UR in patients with benign prostatic obstruction who are not candidates for surgery and for whom medical treatments have failed (Alam et al, 2016).*

These modifiable factors predispose the client to acute UR by over distending the bladder and decreasing muscle contraction (Mayo Clinic, 2017).

- Advise the client who is unable to void of specific strategies to manage this potential medical emergency as follows:
    - ❍ Attempt urination in complete privacy.
    - ❍ Place the feet solidly on the floor.
    - ❍ If unable to void using these strategies, take a warm sitz bath or shower and void (if possible) while still in the tub or shower.
    - ❍ Drink a warm cup of caffeinated coffee or tea to stimulate the bladder, which may promote voiding.
- If unable to void within 6 hours or if bladder distention is producing significant pain, seek urgent or emergency care. *Attempting urination in complete privacy and placing the feet solidly on the floor help relax the pelvic muscles and may encourage voiding. Warm water also stimulates the bladder and may produce voiding; the cooling experienced by leaving the tub or shower may again inhibit the bladder (Joanna Briggs Institute, 2013).*

• Perform sterile (in acute care) or clean intermittent catheterization at home as ordered for clients with UR. Refer to care plan for Reflex urinary **Incontinence** for more information about intermittent catheterization.
▲ Insert an indwelling catheter only as ordered by a health care provider. Understand the indication for the urinary catheter to be placed as part of client management. Catheter-associated urinary tract infections (CAUTIs) are among the most common health care–associated infections. Each CAUTI episode is estimated to cost $600, rising to $2800 per episode when a CAUTI leads to a bloodstream infection. Although certain conditions among hospitalized clients may require the use of a urinary catheter, limiting their use and decreasing the length of use are the most effective methods of reducing clients' exposure to CAUTIs (Choosing Wisely and the American Academy of Nursing, 2014).
• Nurse-led and computer-based reminders are both successful in reducing how long urinary catheters remain in place (Bernard, Hunter, & Moore, 2012).
• Nurse-driven practice recommendations to reduce CAUTI risk include securing catheters; maintaining drainage bags lower than level of bladder; emptying drainage bags every 8 hours, when two-thirds full, and before any transfer; daily evaluation of catheter indication/need to promote removal; and use of bladder scanner to prevent reinsertion. **EB:** *Incorporating practice policies that use nurse-driven catheter practices was found to reduce catheter days, decrease length of hospital stay, and decrease reinsertions (Alexaitis & Broome, 2014).*
• Current practice recommendations support aseptic catheter insertions, whereas the use of hydrophilic-coated catheters for clean intermittent catheters can reduce the rate of CAUTIs. Suprapubic catheterization is not more effective than urethral catheterization in reducing the incidence of catheter-related bacteremia. **EB:** *Evidence does not support routine use of antimicrobial-impregnated catheters to prevent CAUTIs (Tenke, Koves, & Johansen, 2014).*
• For the individual with UR who is not a suitable candidate for intermittent catheterization, recognize that the catheter can be a significant cause of harm to the client through development of a CAUTI or through genitourinary trauma when the catheter is pulled. *An indwelling catheter provides continuous drainage of urine; however, the risks for serious urinary complications, such as chronic CAUTIs, with prolonged use are significant.* **EB:** *One study found that the risk for genitourinary trauma was as common as symptomatic urinary tract infection when clients were repeatedly catheterized (Leuck et al, 2012).* **EBN:** *Indwelling urinary catheters are associated with up to 80% of hospital-acquired CAUTIs. Appropriate use of bladder ultrasonography can reduce the rate of bladder damage and the need to use catheters. Incorporating bladder ultrasonography into the client's assessment can lead to decreased use of urinary catheter and rate of CAUTIs, lower risk for spread of multiresistant gram-negative bacteria, and lower hospital costs (Johansson et al, 2013).*
• Advise clients with indwelling catheters that bacteria in the urine is an almost universal finding after the catheter has remained in place for more than 1 week and that only symptomatic infections warrant treatment. *The long-term indwelling catheter is inevitably associated with bacterial colonization, with formation of biofilm on the catheter surfaces (Nicolle & Norrby, 2016).*
• Use the following strategies to reduce the risk for CAUTI whenever feasible:
    ❍ Insert the indwelling catheter with sterile technique, only when insertion is indicated.
    ❍ Remove the indwelling catheter as soon as possible; acute care facilities should institute a policy for regular review of the necessity of an indwelling

catheter.
- ❍ Maintain a closed drainage system whenever feasible.
- ❍ Maintain unobstructed urine flow, avoiding kinks in the tubing and keeping the collecting bag below the level of the bladder at all times.
- ❍ Regularly cleanse the urethral meatus with a gentle cleanser to remove apparent soiling.
- ❍ Change the long-term catheter every 4 weeks; more frequent catheter changes should be reserved for clients who experience catheter encrustation and blockage.

• Educate staff about the risks for CAUTI development and specific strategies to reduce these risks. **EB:** *These strategies are supported by sufficient evidence to recommend routine use (Felix et al, 2014). Numerous nursing studies have demonstrated that nurse-controlled methods to decrease the length of catheterization such as chart reminders and computerized interventions lead to decreased incidences of CAUTI (Andreessen, Wilde, & Herendeen, 2012).*

Postoperative Urinary Retention

• UR is a common complication of surgery, anesthesia, and advancing age. If conservative measures do not help the client pass urine, then the bladder needs to be drained using either an intermittent catheter or IUC, which places the client at risk for development of CAUTI (Steggall, Treacy, & Jones, 2013). **EBN:** *A study demonstrated increased UR after transurethral resection of the prostate in clients with preoperative increased prostate size, urinary tract infection, and clot retention (McKinnon et al, 2011).*
• Remove the IUC at midnight in the hospitalized postoperative client to reduce the risk for acute UR.
• Perform a bladder scan before considering inserting a catheter to determine PVR volume after surgery. **EBN:** *A study in postoperative patients demonstrated a significant decrease in the number of catheterizations when ultrasonic bladder scanning was done to monitor postoperative UR (Daurat et al, 2015).* **CEB:** *Another study found that in hip fracture clients, use of bladder scanning and intermittent catheterization resulted in less retention after surgery than in clients in whom a retention catheter was inserted (Johansson & Christensson, 2010).* **CEB:** *A meta-analysis found that performing bladder scanning was effective in decreasing urinary catheterization and development of urinary tract infection (Palese et al, 2010).*
• The overall incidence of postoperative urinary catheterization is 40% for total hip and knee arthroplasties. **EB:** *Spinal anesthesia is a risk factor (Bjerregaard et al, 2015).*

Geriatric

• Aggressively assess older clients, particularly those with dribbling urinary incontinence, urinary tract infection, and related conditions for UR. **CEB:** *Older women and men may experience UR with few or no apparent symptoms; a urinary residual volume and related assessments are necessary to determine the presence of retention in this population (Johansson & Christensson, 2010).*
• Assess older clients for impaction when UR is documented or suspected**:** Monitor older male clients for retention related to BPH or prostate cancer. *Prostate enlargement in older men increases the risk for acute and chronic UR.*

Home Care

• Encourage the client to report any inability to void.
• Maintain an up-to-date medication list; evaluate side effect profiles for risk of UR. *New medications or changes in dose may cause UR.*
• Refer the client for health care provider evaluation if UR occurs. *Identification of cause is important. Left untreated, UR may lead to urinary tract infection or kidney failure.*

Client/Family Teaching and Discharge Planning

• Teach the client with mild to moderate obstructive symptoms to double void by urinating, resting in the bathroom for 3 to 5 minutes, and then trying again to urinate. *Double voiding promotes more efficient bladder evacuation by allowing the detrusor to contract initially and then rest and contract again (Mayo Clinic, 2017).*
• Teach the client with UR and infrequent voiding to urinate by the clock. *Timed or scheduled voiding may reduce UR by preventing bladder over distention (Mayo Clinic, 2017).*
• Teach the client with an indwelling catheter to assess the tube for patency, maintain the drainage system below the level of the symphysis pubis, and routinely cleanse the bedside bag as directed.
• Teach the client with an indwelling catheter or undergoing intermittent catheterization the symptoms of a significant urinary infection, including hematuria, acute-onset incontinence, dysuria, flank pain, fever, or acute confusion.

List of Planning Care by Letter: V

Risk for Vascular Trauma	Risk for Venous Thromboembolism	Impaired spontaneous Ventilation
Dysfunctional Ventilatory weaning response	Risk for other-directed Violence	Risk for self-directed Violence

V

● = Independent; ▲ = Collaborative; **EBN** = Evidence-Based Nursing; **EB** = Evidence-Based

Risk for Vascular Trauma

Elyse Bueno MS, ACCNS-AG, CCRN

NANDA-I

Definition

Susceptible to damage to vein and its surrounding tissues related to the presence of a catheter and/or infusion solutions, which may compromise health.

Risk Factors

Inadequate available insertion site; prolonged period of time catheter is in place

Associated Condition

Irritating solution; rapid infusion rate

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Risk Control; Tissue Integrity: Skin and Mucous Membranes

Example NOC Outcome with Indicators

Accomplishes **Risk Control** as evidenced by the following indicators: Monitors environmental risk factors/Develops effective risk control strategies/Modifies lifestyle to reduce risk. (Rate the outcome and indicators of **Risk Control:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Remain free from vascular trauma
- Remain free from signs and symptoms that indicate vascular trauma
- Remain free of signs and symptoms of vascular inflammation or infection
- Remain free from impaired tissue and/or skin
- Maintain skin integrity, tissue perfusion, usual tissue temperature, color, and pigment
- Report any altered sensation or pain
- State site is comfortable

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Intravenous Therapy; Medication Administration: Intravenous

Example NIC Activities—Intravenous Therapy

Monitor intravenous (IV) flow rate and IV site during infusion; Perform IV site care according to agency protocol

Nursing Interventions and *Rationales*

Client Preparation

▲ Verify objective and estimate duration of treatment. Check health care provider's order. *Verify if client will remain hospitalized during the entire treatment or will go home with the device (Phillips, 2014).*

• Assess client's clinical situation when venous infusion is indicated. *Consider possible clinical conditions that cause changes in temperature, color, and sensitivity of the possible venous access site. Verify situations that alter venous return (e.g., mastectomy, stroke) (Phillips, 2014). The site of catheter insertion influences the risk of infection and phlebitis, such as preexisting catheters, anatomic deformity, and bleeding diathesis (Xue, 2014).*

• Assess if client is prepared for an intravenous (IV) procedure. Explain the procedure if necessary to decrease stress. *Stress may cause vasoconstriction that can interfere in the visualization of the vein and flow of the infused solution (Xue, 2014).*

• Provide privacy and make the client comfortable during the IV insertion. *Privacy and comfort help decrease stress (Phillips, 2014).*

• Teach the client what symptoms of possible vascular trauma he or she should be alert to and to immediately inform staff if any of these symptoms are noticed. *Prompt attention to adverse changes decreases the chance of adverse effects from complications.*

Insertion

• Wash hands before and after touching the client, as well as when inserting, replacing, accessing, repairing, or dressing an intravascular catheter (Infusion Nurses Society [INS], 2016).

• Maintain aseptic technique for the insertion and care of intravascular catheters. *Using an approved antiseptic solution, wearing gloves during insertion of an IV catheter, and immediately covering the insertion site with a transparent sterile semipermeable dressing are important interventions to reduce the risk of infection (McGowan, 2014; Xue, 2014).*

• In preparation, assess the patient's medical history for disease processes such as diabetes and hypertension, frequent venipuncture, variations in skin color, skin alteration, age, obesity, fluid volume deficit, and IV drug use; these factors may lead to difficult vascular visualization (INS, 2016).

• When vascular visualization is difficult, consider the use of visible light devices that provide transillumination of the peripheral veins or ultrasonography (INS, 2016). *Ultrasonography reduces the number of venipuncture attempts and procedure time.*

• Avoid areas of joint flexion or bony prominences. *Movement in these sites can cause mechanical trauma in veins (McGowan, 2014).*

• Avoid the use of the antecubital area, which has high failure rates, and do not use lower extremities unless necessary because of the risk of tissue damage, thrombophlebitis, and ulceration (INS, 2016).

▲ Avoid the dorsal hand, radial wrist, and the volar (inner) wrist, if possible. *These are high-risk areas for venipuncture-related nerve injury (INS, 2016).*
▲ Consider topical anesthetic prior to IV cannula insertion to reduce pain (Porritt, 2015a).
• Choose an appropriate vascular access device (VAD) based on the types and characteristics of the devices and insertion site. Consider the following:
    - ❍ Peripheral cannulae: these are short devices that are placed into a peripheral vein. They can be straight, winged, or ported and winged.
    - ❍ Midline catheters or peripherally inserted central catheters (PICCs) that range from 7.5 to 20 cm.
    - ❍ Central venous access devices (CVADs) are terminated in the central venous circulation and are available in a range of gauge sizes; they can be nontunneled catheters, skin-tunneled catheters, implantable injection ports, or PICCs.
    - ❍ Polyurethane venous devices and silicone rubber may cause less friction and, consequently, may reduce the risk of mechanical phlebitis (Phillips, 2014).

▲ Choose a device with consideration of the nature, volume, and flow of prescribed solution. **EBN:** *Choosing the right gauge size reduces the risk of vascular trauma (McGowan, 2014). Verify that the osmolarity of the solution to be infused is compatible with the available access site and device (Phillips, 2014; Loubani & Green, 2015).*
• If possible, choose the venous access site considering the client's preference. *Engaging the client in choosing the venous access site, when possible, may facilitate line patency.*
• Select the gauge of the venous device according to the duration of treatment, purpose of the procedure, and size of the vein. **EB:** *Emergency situations require short, large-bore cannulae. Hydration fluids and antibiotics can be delivered through much smaller cannulae (Loubani & Green, 2015). Select the smallest gauge necessary to achieve the prescribed flow rate (INS, 2013; Vizcarra et al, 2014). The time of infusion of the drug, especially chemotherapy and vasoactive agents, can contribute to the occurrence of phlebitis (Loubani & Green, 2015).*
• Verify whether the client is allergic to fixation or device material.
• Disinfect the venipuncture site. Assess that skin is dry before puncturing to *achieve maximal benefit of the disinfection agent.*
• Provide a comfortable, safe, hypoallergenic, easily removable stabilization dressing, allowing for visualization of the access site. *Catheter stabilization should be used to preserve the integrity of the access device, to minimize catheter movement at the hub, and to prevent catheter migration and loss of access (INS, 2013; Vizcarra et al, 2014). Some peripheral cannulae have stabilization wings (which increase the external surface area) and/or ports (which are used to administer bolus medication) incorporated into their design.*
• Use sterile, transparent, semipermeable dressing to cover catheter site. *Replace dressing with catheter change, or at a minimum every 7 days for transparent dressings (INS, 2013; Vizcarra et al, 2014). The use of a transparent occlusive dressing can facilitate regular monitoring by visually inspecting the VAD (McGowan, 2014; Xue, 2014). Use of gauze may be necessary if the client is diaphoretic, if the site is oozing or bleeding, or if it becomes damp; if gauze is used, it should be changed every 2 days (INS, 2013; Vizcarra et al, 2014).*
• Document insertion date, site, type of VAD, number of punctures performed, other occurrences, and measures/arrangements.
• Always decontaminate the device before infusing medication or manipulating IV equipment (Xue, 2014; Helm et al, 2015).

▲ Verify the sequence of drugs to be administrated. Vesicants should always be administered first in a sequence of drugs (Loubani & Green, 2015).

Monitoring Infusion

• Monitor permeability and flow rate at regular intervals.
• Monitor catheter–skin junction and surrounding tissues at regular intervals, observing possible appearance of burning, pain, erythema, altered local temperature, infiltration, extravasation, edema, secretion, tenderness, or induration. Remove promptly. *The infusion should be discontinued at the first sign of infiltration or extravasation, the administration set disconnected, and all fluid aspirated from the catheter with a small syringe (INS, 2013; Vizcarra et al, 2014).*
▲ Replace device according to institution protocol. **EBN:** *Remove peripheral IV cannula if there are signs of phlebitis, infection, or if the cannula is no longer functioning. There is no need to routinely change the catheter every 72 to 96 hours (Porritt, 2015b).*
▲ Flush vascular access according to organizational policies and procedures, and as recommended by the manufacturer. *A pulsating flushing technique should be used (Porritt, 2016). VADs should be flushed after each infusion to clear the infused medication from the catheter lumen, preventing contact between incompatible medications (INS, 2013; Vizcarra et al, 2014). Sodium chloride 0.9% or heparinized sodium chloride has been studied to determine optimal solution for catheter patency. A recent Cochrane review found little difference in catheter patency between either solution; thus given the cost and possible client risks to heparin exposure, sodium chloride flush solution is recommended (López-Briz et al, 2014).* When locking a catheter, use enough fluid to fill the entire catheter and use a positive pressure technique when disconnecting the syringe (Porritt, 2016).
• Remove catheter on suspected contamination, if the client develops signs of phlebitis or infection, the catheter is malfunctioning, or when the catheter no longer required. *VADs should be removed on unresolved complication, therapy discontinuation, or if deemed unnecessary (INS, 2013; Vizcarra et al, 2014). Replace any catheter inserted under emergency conditions within 24 hours because the sterility of the procedure may have been compromised.*
• Encourage clients to report any discomfort such as pain, burning, swelling, or bleeding (Xue, 2014).

Pediatric

• The preceding interventions may be adapted for the pediatric client. *Consider age, culture, development level, health literacy, and language preferences (INS, 2013; Vizcarra et al, 2014; American Nurses Association [ANA], 2015).*
• Inform the client and family about the IV procedure; obtain permissions, maintain client's comfort, and perform appropriate assessment prior to venipuncture. Assess the client for any allergies or sensitivities to tape, antiseptics, or latex. *Choose a healthy vein and appropriate site for insertion of selected device (Abolfotouh et al, 2014).*
• Consider using a two-dimensional ultrasound for venous cannulation. **EBN:** *Ultrasound has been shown more effective than traditional techniques and should be considered for pediatric patients (Jayasekara, 2017).* **EBN:** *The cephalic vein in the proximal forearm is the best initial site for ultrasound-guided catheterization when veins are not visible or palpable (Jayasekara, 2017).*
• The use of an appropriate device to obtain blood samples reduces discomfort in the pediatric client. *Accessing a pediatric client's vein successfully can be difficult, and measures*

to optimize the health care provider's skill are important to ensure successful venous cannulation (Goff et al, 2013).

• Avoid areas of joint flexion or bony prominences. *Cannulae inserted away from joints remain patent for longer periods of time (McGowan, 2014).*

▲ Consider whether sedation or the use of local anesthetic is suitable for insertion of a catheter, taking into consideration the age of the pediatric client. *The use of effective local anesthetic methods and agents before each painful dermal procedure should be discussed with the health care provider (INS, 2013; Vizcarra et al, 2014).*

▲ Use diversion while performing the procedure. *Diversion reduces anxiety (Goff et al, 2013).*

Geriatric

• The preceding interventions may be adapted for the geriatric client.

• Consider the physical, emotional, and cognitive changes related to older adults.

• Use strict aseptic technique for venipuncture of older clients. **EB:** *Older adults are at an increased risk of infection because of decreased immunological function (Azar & Ballas, 2017).*

Home Care

• Some devices may remain after discharge. Provide device-specific education to the client and family members about care of the selected device.

• Help in the choice of actions that support self-care. The nurse can provide valuable information that can be used to guide decision-making to maximize the self-care abilities of clients receiving home infusion therapy.

• Select, with the client, the insertion site most compatible with the development of activities of daily living (ADLs) (McGowan, 2014; Xue, 2014).

• Minimize the use of continuous IV therapy whenever possible. **CEBN:** *Clients who received intermittent IV therapy via a saline lock were more independent regarding ability to perform self-care ADLs than those who received continuous IV therapy. The need for assistive mobility devices was also an independent predictor of ability to perform self-care ADLs (O'Halloran, El-Masri, & Fox-Wasylyshyn et al, 2008).*

Risk for Venous Thromboembolism

Dina M. Hewett PhD, RN, NEA-BC, CCRN-A

NANDA-I

Definition

Susceptible to the development of a blood clot in a deep vein, commonly in the thigh, calf or upper extremity, which can break off and lodge in another vessel, which may compromise health.

Risk Factors

Dehydration; impaired mobility; obesity

At-Risk Population

Age > 60; critical care admission; current smoker; first degree relative with history of venous thromboembolism; history of cerebral vascular accident; history of previous venous thromboembolism; less than 6 weeks postpartum

Associated Condition

Cerebral vascular accident; current cancer diagnosis; trauma below the waist; significant medical comorbidity; postoperative for major surgery; postoperative for orthopedic surgery; surgery and total anesthesia time > 90 minutes; thrombophilia; trauma of upper extremity; use of estrogen-containing contraceptives; use of hormone replacement therapy; varicose veins

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Tissue Perfusion: Peripheral; Tissue Perfusion: Pulmonary Risk Control: Dehydration; Hydration; Knowledge Thrombus Threat Reduction; Risk Control: Thrombus

Example NOC Outcome with Indicators

Risk Control: Thrombus as evidenced by the following indicators: Seeks current information about embolus prevention/Identifies risk factors for thrombus formation/Monitors for warning signs and symptoms of thrombus formation or embolus. (Rate outcome and indicators of **Risk Control: Thrombus:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Not develop a venous thromboembolism (VTE) during hospitalization
- State the relevant risk factors associated with the development of a VTE
- Engage in behaviors or lifestyle changes to reduce risk of developing a VTE

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Embolus Precautions; Embolus Care: Peripheral; Embolus Care: Pulmonary; Lower Extremity Monitoring

Example NIC Activities

Obtain a history of the client's present illness and medical history to evaluate the risk of VTE and implement preventative interventions

Nursing Interventions and *Rationales*

- It is estimated that 40% of patients with a deep vein thrombosis (DVT) will progress to postthrombotic syndrome (PTS); therefore prevention of DVT is a key component. *PTS is a chronic disorder characterized by pain, swelling, redness (erythema), and ulcerations. The degree will vary from client to client. Individuals with recurrent ipsilateral DVT are considered the highest risk for PTS (Kvamme & Costanzo, 2015; Lenchus et al, 2017).*
- Assess client's risk factors to develop VTE. **EB:** *There are several factors that may predispose a client to DVT. According to Bruni-Fitzgerald (2015), the strongest risk factors include:*
  - ❍ Venous stasis as a result of dehydration, immobility, heart failure, or venous compressions from a tumor
  - ❍ Hypercoagulable states from disease, obesity, and trauma
  - ❍ Immobilization from prolonged bed rest or limb casting
  - ❍ Surgery and trauma, especially hip, pelvic, and spinal surgery, and leg amputation; several burns also predispose clients to DVT
  - ❍ Pregnancy results in a hypercoagulable state placing these clients at risk; although fatal events are rare
  - ❍ Oral contraceptives and estrogen replacement may place clients at risk, which is proportional to the estrogen content; postmenopausal women on hormone replacement therapy are considered at risk
  - ❍ In malignancy cases 17% of patients with VTE have a neoplasm with the most frequent occurrence in patients with pancreatic cancer
- *Use a VTE risk assessment tool to determine individual susceptibility to VTE.* **EB:** *Determining a patient's risk may be guided through the use of an assessment tool such as the Wells Criteria or the Caprini Risk Assessment Model. Assessment tools in the acute care setting are developed based on evidence-based research (Modi et al, 2016).*

▲ Implement evidence-based prevention methods, both chemical (pharmacological) and/or mechanical. **EB:** *The nurse must be proactive in the assessment of the client for risks for VTE and implementing prophylactic measures as prescribed (Adams, 2015).*

▲ Chemical thromboprophylaxis should be anticipated in the postoperative care of critically ill clients. **CEB/EB:** *Research has shown that chemical thromboprophylaxis, when initiated in critically ill and postoperative clients, such as anticoagulants, are not associated with clinically significant bleeding (Makic, 2014). Evidence-based practice guidelines support the use of chemical and mechanical prophylaxis interventions for clients undergoing orthopedic surgery for a minimum of 14 to 35 days to reduce VTE risk (Falck-Ytter et al,*

2012).

• Implement mechanical prophylaxis through use of intermittent pneumatic compression (IPC) devices (Ho & Harahsheh, 2016). **EB:** *IPC is demonstrated to be more effective than no IPC at reducing DVT and is essential when pharmacological therapy is contraindicated because of an increased risk of bleeding (Dunn & Ramos, 2017). IPC devices reduce the risk of venous stasis by increasing the velocity of venous outflow and promoting the emptying of valvular cusps (Muñoz-Figueroa & Ojo, 2015).*

• Ensure proper fit and application of the device. **EB:** *Moore (2012) recommended using a measuring tape to obtain accurate measurements and follow the manufacturer's recommendations for correct sizing. Two fingers should be easily placed between the patient's leg and the sleeve. Monitor for edema and resize as needed.*

• Implement progressive mobility and early ambulation as the client tolerates to reduce risk of VTE. **EB:** *Studies indicate early mobility may reduce patient deconditioning and VTE complications (Booth et al, 2016). One study conducted in a trauma critical care unit revealed a statistically significant (P = .0004) reduced rate of DVT in patients in which early mobility and ambulation were implemented (Booth et al, 2016).*

• Provide education to the client and family about the importance of continued use of IPC after the client is ambulatory. Ensure that IPC is reapplied after ambulation (Corbett & Hannison, 2016; Dunn & Ramos, 2017). **EB:** *IPC should be reapplied after the client ambulates and returns to bed to maintain prevention interventions for VTE (Makic, 2014; Dunn & Ramos, 2017).*

• Perform a skin inspection during the bathing. *It is important to assess the skin with each application of the IPC and during the bath for signs of skin irritation or breakdown from the device.*

• IPC should be applied even when the client is sitting in a chair (Dunn & Ramos, 2017).

• Provide appropriate education or referral to a smoking cessation program. Smoking is a well-established risk factor for atherosclerotic disease that increases the client's risk for VTE. **EB:** *A systematic review and meta-analysis found that smoking increased the risk of VTE and the risk increased by 10.2% for every additional 10 cigarettes smoked per day or by 6.1% for every additional 10 pack-years of smoking. The study also found smokers who were overweight had a higher risk of VTE (Cheng et al, 2013).*

• Obesity is an independent risk for VTE. **EB:** *A study of 27,818 clients who underwent bariatric surgery found significant risk factors to include male gender, operative time greater than 3 hours, type of procedure risk increased as body mass index (BMI) increased, and age (Finks et al, 2012). A systematic review of bariatric surgery clients found that male gender, increased BMI, smoking history, and operative procedure and time were risk factors for VTE (Bartlett, Mauck, & Daniels, 2015). Chemical and mechanical preventative interventions should be implemented to reduce the risk of VTE in the bariatric client population (Bartlett, Mauck, & Daniels, 2015).*

• Patients with cancer are at an increased risk of developing a DVT mainly because of the release of certain chemicals from the tumor and spread of the tumor into blood vessels. Generally, bloodstream cancers such as leukemia carry the highest risk for development of DVT followed by solid tumors of the pancreas, stomach, lungs, ovaries, uterus, bladder, and brain (Udoh, 2016).

Pediatric

• The nurse should be alert to certain diagnoses that increase the pediatric client's risk for VTE. *Diagnoses associated with increased risk of VTE include sepsis, acute infection,*

oncological malignant growth, surgery/trauma, congenital heart disease, systemic lupus, obesity, and immobility (Prentiss, 2012).

• Incidence of VTE in children is low; however, the rate of VTE in hospitalized children is much higher (Austin, Jenkins, & Hines, 2017).

• Risk factors for pediatric development of VTE include use of central venous access devices (Prentiss, 2012). **EB:** *A study by Austin, Jenkins, and Hines (2017) found that pediatric patients are at risk of a catheter-associated DVT because of the size of the device and resulting damage to the fragile intima, leading to clot formation and dislodgement of the clot.*

• Neonatal and adolescent age groups are at higher risk for VTE compared with other pediatric age groups (Prentiss, 2012). Additional studies are needed to further understand the risks and interventions for this population.

Geriatric

• The risk of VTE increases with age, increasing 90% between the ages of 15 and 80. *Many of the risk factors for VTE are commonly seen in the older patient with heart failure, chronic obstructive pulmonary disease, and malignancy. VTE is also seen in patients on bed rest and those with implantable devices such as pacemakers and hip/knee replacements (Bruni-Fitzgerald, 2015).*

• It is well established that older patients are at a greater risk to develop atrial fibrillation (Heeringa et al, 2006). The Framingham study indicated increasing risk of developing atrial fibrillation with increasing age (Wolf, Abbott, & Kannel, 1991). *Treatment for chronic atrial fibrillation requires the use of anticoagulants to reduce the risk of an embolic event.*

Home Care

• Provide client education on the importance of continued use of compression stockings as directed. *Ensuring the client is aware of the benefit of compression stockings reduces the risk of VTE and may facilitate compliance in wearing the compression stocking. The client may only be required to wear stockings during the day and be allowed to remove them at night (Bonner & Johnson, 2014; Kaur et al, 2016; Pai & Douketis, 2017).*

• Provide education to the client and/or family caregiver about the continued use of anticoagulant pharmacological therapy as directed. *The client and/or family caregiver may need instruction on proper injection technique if the client is not discharged on an oral anticoagulant.* **EB:** *If the client is discharged home on subcutaneous low-molecular-weight heparin or fondaparinux, the nurse needs to teach the client and or family caregiver how to properly administer the medication by injection (Bonner & Johnson, 2014; Pai & Douketis, 2017).*

• Patients who take the anticoagulant warfarin should have dietary education. Warfarin's effects may be decreased with a diet rich in vitamin K. *Food containing vitamin K includes dark green leafy vegetables such as kale, Brussels sprouts, collard greens, and spinach. Avoid eating large quantities of these vegetables. Cranberry juice and alcohol should be avoided because it enhances the effects of warfarin and may lead to bleeding.*

• The newer anticoagulants, such as rivaroxaban, apixaban, and edoxaban, do not have the same medication–food interactions as warfarin.

Impaired spontaneous Ventilation

Debra Siela PhD, RN, CCNS, ACNS-BC, CCRN-K, CNE, RRT

NANDA-I

Definition
Inability to initiate and/or maintain independent breathing that is adequate to support life.

Defining Characteristics
Apprehensiveness; decrease in arterial oxygen saturation (SaO_2); decrease in cooperation; decrease in partial pressure of oxygen (PO_2); decrease in tidal volume; dyspnea; increase in accessory muscle use; increase in heart rate; increase in metabolic rate; increase in partial pressure of carbon dioxide (PCO_2); restlessness

Related Factors
Respiratory muscle fatigue

Associated Condition
Alteration in metabolism

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes
Neurological Status: Central Motor Control; Respiratory Status: Gas Exchange, Ventilation

Example NOC Outcome with Indicators
Achieves appropriate **Respiratory Status: Ventilation** as evidenced by the following indicators: Respiratory rate/Respiratory rhythm/Depth of inspiration/Symmetrical chest expansion/Ease of breathing/Moves sputum out of airway/Accessory muscle use not present/Adventitious breath sounds not present/Chest retraction not present/Tidal volume/Vital capacity. (Rate the outcome and indicators of **Respiratory Status: Ventilation:** 1 = severe deviation from normal range, 2 = substantial deviation from normal range, 3 = moderate deviation from normal range, 4 = mild deviation from normal range, 5 = no deviation from normal range [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Maintain arterial blood gases within safe parameters
- Remain free of dyspnea or restlessness
- Effectively maintain airway
- Effectively mobilize secretions

NIC (Nursing Interventions Classification)

Suggested NIC Interventions
Artificial Airway Management; Mechanical Ventilation: Invasive; Respiratory Monitoring; Resuscitation: Neonate; Ventilation Assistance; Mechanical Ventilation Management: Noninvasive

Example NIC Activities—Mechanical Ventilation Management
Monitor for conditions indicating a need for ventilation support (e.g., respiratory muscle fatigue, neurological dysfunction second to trauma, anesthesia, drug overdose, refractory respiratory acidosis); Consult with other health care personnel in selection of a ventilator mode

Nursing Interventions and *Rationales*

▲ Collaborate with the client, family, and health care provider regarding possible intubation and ventilation. Ask whether the client has advanced directives and, if so, integrate them into the plan of care with clinical data regarding overall health and

reversibility of the medical condition. **EB:** *Client preferences and goals of care need to be acknowledged and discussed when planning care. Advanced directives protect client autonomy and help ensure that the client's wishes are respected (You et al, 2014).*

• Assess and respond to changes in the client's respiratory status. Monitor the client for dyspnea, increase in respiratory rate, use of accessory muscles, retraction of intercostal muscles, flaring of nostrils, decrease in O_2 saturation, cyanosis, and subjective complaints (Kjellström & van der Wal, 2013; Gallagher, 2017).

• Have the client use a numerical scale (0–10) or visual analog scale to self-report dyspnea before and after interventions. *The numerical rating scale is a valid measure of dyspnea and has been found to be easiest for clients to use. Incorporating client self-report of dyspnea assists with assessment of symptom intensity, distress, progression, affect, and resolution of dyspnea (Mahler & O'Donnell, 2015). Determine intensity, unpleasantness, or distress of dyspnea using a rating scale such as an intensity-focused modified Borg scale or visual analog scale (Kjellström & van der Wal, 2013).*

• Assess for history of chronic respiratory disorders when administering oxygen. *When managing acute respiratory failure (ARF) in clients with chronic obstructive pulmonary disease (COPD), continually assess the client's oxygenation needs. Long-term administration of oxygen (>15 hours per day) has been shown to increase survival in clients with severe, resting hypoxemia (GOLD, 2017).*

▲ Collaborate with the health care provider and respiratory therapists in determining the appropriateness of noninvasive positive pressure ventilation (NPPV) and noninvasive ventilation (NIV) for the decompensated client with COPD. Ventilatory support in a COPD exacerbation can be provided by either noninvasive or invasive ventilation (GOLD, 2017). NIV improves respiratory acidosis and decreases respiratory rate, severity of breathlessness, incidence of ventilator-associated pneumonia (VAP), and hospital length of stay (Mas & Masip, 2014; American Association of Critical Care Nurses [AACN], 2017a; GOLD, 2017).

▲ Assist with implementation, client support, and monitoring if NPPV/NIV is used. **EB/CEB:** *In a client with exacerbation of COPD, NPPV/NIV can be as effective as intubation with use of a ventilator (Ramsey & Hart, 2013; Lindenauer et al, 2014). NPPV/NIV also has been found to improve outcomes in clients with acute cardiogenic pulmonary edema (Bakke et al, 2014; Mas & Masip, 2014). It also can be used in ARF causes such as asthma, pneumonia, postextubation failure, thoracic trauma, and palliative care (Masclans et al, 2013; Nava et al, 2013; Gifford, 2014; Johnson et al, 2014; Lin et al, 2014; Pallin & Naughton, 2014; Murad et al, 2015). The use of continuous positive airway pressure and bilevel positive airway pressure has been shown to improve oxygenation and decrease the rate of endotracheal intubation in clients with acute pulmonary edema (Frazier, 2017; GOLD, 2017).*

• If the client has apnea, respiratory muscle fatigue, somnolence, hypoxemia, and/or acute respiratory acidosis, then prepare the client for possible intubation and mechanical ventilation. **EB:** *These indicators may predict the need for invasive mechanical ventilation to support the client's respiratory efforts (Gallagher, 2017; Stacy, 2018). The indications for initiating invasive mechanical ventilation during a COPD exacerbation include a failure of an initial trial of NIV (Gallagher, 2017; GOLD, 2017).*

• *If a client with ARF has a rapid shallow breathing index (RSBI) >105, endotracheal intubation is likely needed with invasive mechanical ventilation. A client with ARF with an RSBI of <105 may require only noninvasive ventilation (Karthika et al, 2016).*

Ventilator Support

▲ Explain the endotracheal intubation and mechanical ventilation process to the

client and family as appropriate, and during intubation administer sedation for client comfort according to the health care provider's orders. **EBN:** *Explanation of the procedure decreases anxiety and reinforces information; premedication allows for a more controlled intubation with decreased incidence of insertion problems (Joanna Briggs Institute, 2013; Gallagher, 2017).*

• Secure the endotracheal tube in place using either tape or a commercial available device, auscultate bilateral breath sounds, use a CO_2 detector, and obtain a chest radiograph to confirm endotracheal tube placement. **EBN:** *Security of the tube is needed to prevent inadvertent extubation. Nursing studies have shown conflicting results regarding the preferable way to secure the endotracheal tube (Goodrich, 2017a).* **EB:** *Auscultation alone is an unreliable method for checking endotracheal tube placement. A CO_2 detector can be used to confirm tube placement in the trachea (Goodrich, 2017b; Stacy, 2018); however, correct position of the endotracheal tube in the trachea (3–5 cm above the carina) must be confirmed by chest radiograph (Goodrich, 2017a,b; Stacy, 2018). Calorimetric CO_2 detectors have also been used successfully to detect inadvertent airway intubation during gastric tube placement (Goodrich, 2017a,b).*

• Review ventilator settings with the health care provider and respiratory therapy to ensure support is appropriate to meet the client's minute ventilation requirements (Chacko et al, 2015; Stacy, 2018). *Ventilator settings should be adjusted to prevent hyperventilation or hypoventilation. A variety of new modes of ventilation are currently available that are responsive to client effort (pressure support)(Gallagher, 2017).*

▲ Suction as needed and hyperoxygenate according to facility policy. Refer to the care plan for Ineffective **Airway** clearance for further information on suctioning.

• Check that monitor alarms are set appropriately at the start of each shift. *This action helps ensure client safety (Gallagher, 2017).*

• Respond to ventilator alarms promptly. If unable to immediately locate the source/cause of an alarm, use a manual self-inflating resuscitation bag to ventilate the client while waiting for assistance. *Common causes of a high-pressure alarm include secretions, condensation in the tubing, biting of the endotracheal tube, decreased compliance of the lungs, and compression of the tubing. Common causes of a low-pressure alarm are ventilator disconnection, leaks in the circuit, and changing compliance. Using a manual self-inflating resuscitation bag with supplemental oxygen, the nurse can provide immediate ventilation and oxygenation as needed (Gallagher, 2017).*

• Prevent unplanned extubation by maintaining stability of the endotracheal tube (Goodrich, 2017b). **EB:** *Prevent unplanned extubation with use of weaning protocol (Karthika et al, 2016).*

• Drain collected fluid from condensation out of ventilator tubing as needed. *This action reduces the risk for infection by decreasing inhalation of contaminated water droplets (Gallagher, 2017).*

• Note ventilator settings of flow of inspired oxygen, peak inspiratory pressure, tidal volume, and alarm activation at intervals and when removing the client from the ventilator for any reason (Gallagher, 2017). *Checking the settings ensures that safety measures are taken and that the client is not left on 100% oxygen after suctioning (Gallagher, 2017).*

▲ Administer analgesics and sedatives as needed to facilitate client comfort and rest. Use behavioral and sedation scales for nonverbal clients to provide a consistent way of monitoring pain and sedation levels and ensuring that therapeutic outcomes are being met (Barr et al, 2013; Dale et al, 2014; Reade & Finfer, 2014). Clients receiving mechanical ventilation frequently require sedation to help attenuate the anxiety, pain,

and agitation associated with this intervention (Barr et al, 2013). The overall goal of sedation during mechanical ventilation is to provide physiological stability, ventilator synchrony, and comfort for clients (Makic et al, 2015).

• Tools such as the Riker Sedation-Agitation Scale, the Motor Activity Assessment Scale, the Ramsey Scale, or the Richmond Agitation-Sedation Scale may be useful in monitoring levels of sedation. *Each of these instruments has established reliability and validity and can be used to monitor the effect of sedative therapy (Barr et al, 2013; Dale, 2014).*

• Alternatives to medications for decreasing anxiety should be attempted, such as music therapy with selections of the client's choice played on headphones at intervals. **CEB/EBN:** *Music therapy has been reported to decrease anxiety and reduce heart and respiratory rate in critically ill and intubated clients (Hunter et al, 2010; Tracy & Chlan, 2011; Gelinas et al, 2013; Hetland, Lindquist, & Chlan, 2015).*

• Analyze and respond to arterial blood gas results, end-tidal CO_2 levels, and pulse oximetry values. *Ventilatory support must be closely monitored to ensure adequate oxygenation and acid-base balance.* **EBN:** *End-tidal CO_2 monitoring is best used as an adjunct to direct client observation and is used to monitor a client's ventilatory status and pulmonary blood flow (Gallagher, 2017).*

• Use an effective means of verbal and nonverbal communication with the client. Barriers to communication include endotracheal tubes, sedation, and general weakness associated with a critical illness. Basic technologies should be readily available to the client, including eyeglasses and hearing aids. A variety of communication devices are available, including electronic voice output communication aids, alphabet boards, picture boards, computers, and writing slate. Ask the client for input into their care as appropriate (ten Hoorn et al, 2016).

• Move the endotracheal tube from side to side at least every 24 hours, and tape it or secure it with a commercially available device. Assess and document client's skin condition, and ensure correct tube placement at the lip line (National Pressure Ulcer Advisory Panel, 2013; Vollman, Sole, & Quinn, 2017).

• Implement steps to prevent ventilator-associated events (VAE), such as VAP, including continuous removal of subglottic secretions, elevation of the head of bed to 30 to 45 degrees (Patient Safety Movement Foundation, 2017; AACN, 2017a) unless medically contraindicated, change of the ventilator circuit no more than every 48 hours, and handwashing before and after contact with each client.

• *The accumulation of contaminated oropharyngeal secretions above the endotracheal tube may contribute to the risk of aspiration.* Use endotracheal tubes that allow for the continuous aspiration of subglottic secretions (Frost et al, 2013; Vollman, Sole, & Quinn, 2017). **EB:** *Subglottic secretion drainage during mechanical ventilation results in a significant reduction in VAE, including late-onset VAP (Frost et al, 2013; Vollman, Sole, & Quinn, 2017). Use of continuous subglottic suctioning endotracheal tubes for intubation in clients who are predicted to require more than 48 hours of intubation likely results in decreased incidence of VAP (AACN, 2017b).*

• Position the client in a semirecumbent position with the head of the bed at a 30 to 45 degree angle to decrease the aspiration of gastric, oral, and nasal secretions (Patient Safety Movement Foundation, 2017; AACN, 2017b; Vollman, Sole, & Quinn, 2017). Consider use of kinetic therapy, using a kinetic bed that slowly moves the client with 40 degree turns. *Rotational therapy may decrease the incidence of pulmonary complications in high-risk clients with increasing ventilator support requirements, at risk for VAP, and with clinical indications for acute lung injury or acute respiratory distress syndrome with worsening PaO_2:FiO_2 ratio, presence of fluffy infiltrates via chest radiograph concomitant with*

pulmonary edema, and refractory hypoxemia (Joanna Briggs Institute, 2014; Klompas, 2014; Makic et al, 2015; Hanneman, 2015; St. Clair et al, 2017).

• Perform handwashing using both soap and water and alcohol-based solution before and after all mechanically ventilated client contact to prevent spread of infections (Makic et al, 2013; Centers for Disease Control and Prevention, 2014).

• Provide routine oral care using toothbrushing and oral rinsing with an antimicrobial agent if needed (Joanna Briggs Institute, 2014; AACN, 2017a,b; Vollman, Sole, & Quinn et al, 2017). **EB:** *Reducing bacterial colonization of the oral cavity includes interventions of daily oral assessment, deep suctioning every 4 hours, toothbrushing twice per day with a plaque reducer, and oral tissue cleaning with peroxide every 4 hours. A Cochrane review found that routine oral care that included chlorhexidine mouthwash or gel resulted in a 40% reduction in development of VAP (Shi et al, 2013).*

• Maintain proper cuff inflation for both endotracheal tubes and cuffed tracheostomy tubes with minimal leak volume or minimal occlusion volume to decrease risk of aspiration and reduce incidence of VAP (AACN, 2016; Johnson, 2017; Stacy, 2018).

• Reposition the client as needed. Use rotational bed or kinetic bed therapy in clients for whom side-to-side turning is contraindicated or difficult. **EBN:** *Changing position frequently decreases the incidence of atelectasis, pooling of secretions, and resultant VAP (Johnson, 2017; St. Clair et al, 2017).* **EB/EBN:** *Continuous, lateral rotational therapy has been shown to improve oxygenation and decrease the incidence of VAP (Joanna Briggs Institute, 2014; St. Clair et al, 2017).*

▲ Patients mechanically ventilated for more than 24 hours can benefit from protocolized rehabilitation directed toward early mobilization (Schmidt et al, 2017).

• Assess bilateral anterior and posterior breath sounds every 2 to 4 hours and as needed; respond to any relevant changes (Gallagher, 2017).

• Assess responsiveness to ventilator support; monitor for subjective complaints and sensation of dyspnea (Gallagher, 2017).

▲ Collaborate with the interdisciplinary team in treating clients with ARF to meet the client's ventilator care needs and avoid complications (Karthika et al, 2016). **EB:** *A collaborative approach to caring for mechanically ventilated clients has been demonstrated to reduce length of time on the ventilator and length of stay in the intensive care unit (Rose et al, 2014).*

• *Document assessments and interventions according to policy.*

Geriatric

• Recognize that critically ill older adults have a high rate of morbidity when mechanically ventilated.

▲ NPPV may be used during acute treatment of older clients with impaired ventilation. **EB:** *A recent study found that older immunocompromised clients admitted with pneumonia had decreased morbidity and mortality when NPPV compared with mechanical ventilation was used to support impaired ventilation (Johnson et al, 2014).*

Home Care

▲ Some of the interventions listed previously may be adapted for home care use. Begin discharge planning as soon as possible with the case manager or social worker to assess the need for home support systems, assistive devices, and community or home health services.

▲ With help from a medical social worker, assist the client and family to determine

the fiscal effect of care in the home versus an extended care facility.
• Assess the home setting during the discharge process to ensure the home can safely accommodate ventilator support (e.g., adequate space and electricity).
• Have the family contact the electric company and place the client residence on a high-risk list in case of a power outage. *Some home-based care requires special conditions for safe home administration.*
• Assess the caregivers for commitment to supporting a ventilator-dependent client in the home.
• Be sure that the client and family or caregivers are familiar with operation of all ventilation devices, know how to suction secretions if needed, are competent in doing tracheostomy care, and know schedules for cleaning equipment. Have the designated caregiver or caregivers demonstrate care before discharge. *Some home-based care involves specialized technology and requires specific skills for safe and appropriate care.*
• Assess client and caregiver knowledge of the disease, client needs, and medications to be administered via ventilation-assistive devices. Avoid analgesics. Assess knowledge of how to use equipment. Teach as necessary. *A client receiving ventilation support may not be able to articulate needs. Respiratory medications can have side effects that change the client's respiration or level of consciousness.*
• Establish an emergency plan and criteria for use. Identify emergency procedures to be used until medical assistance arrives. Teach and role-play emergency care. *A prepared emergency plan reassures the client and family and ensures client safety.*

Client/Family Teaching and Discharge Planning

• Explain to the client the potential sensations that will be experienced, including relief of dyspnea, the feeling of lung inflations, the noise of the ventilator, and the reality of alarms. **EBN:** *Knowledge of potential sensations and experiences before they are encountered can decrease anxiety. Administration of sedatives and/or narcotics may be needed to provide adequate oxygenation and ventilation in some clients (Barr et al, 2013; Gallagher, 2017).*
• Explain to the client and family about being unable to speak, and work out an alternative system of communication. See previously mentioned interventions (Gallagher, 2017).
• Demonstrate to the family how to perform simple procedures, such as suctioning secretions in the mouth with a tonsil-tip catheter, providing range-of-motion exercises, and reconnecting the ventilator immediately if it becomes disconnected. *Families are a critical part of the client's care, may be present at the bedside for prolonged periods of time, and need information about the plan of care (Gallagher, 2017).*
• Offer both the client and family explanations about how the ventilator works and answer any questions. *Having questions answered is often cited as an important need of clients and families when a client is on a ventilator (Gallagher, 2017).*

Dysfunctional Ventilatory weaning response

Debra Siela PhD, RN, CCNS, ACNS-BC, CCRN-K, CNE, RRT

NANDA-I

Definition

Inability to adjust to lowered levels of mechanical ventilator support that interrupts and prolongs the weaning process.

Defining Characteristics

Mild

Breathing discomfort; fatigue; fear of machine malfunction; feeling warm; increase in focus on breathing; mild increase in respiratory rate over baseline; perceived need for increased in oxygen; restlessness

Moderate

Abnormal skin color; apprehensiveness; decrease in air entry on auscultation; diaphoresis; facial expression of fear; hyperfocused on activities; impaired ability to cooperate; impaired ability to respond to coaching; increase

in blood pressure from baseline (<20 mm Hg); increase in heart rate from baseline (<20 beats/minute); minimal use of respiratory accessory muscles; moderate increase in respiratory rate over baseline

Severe

Abnormal skin color; adventitious breath sounds; agitation; asynchronized breathing with the ventilator; decrease in level of consciousness; deterioration in arterial blood gases from baseline; gasping breaths; increase in blood pressure from baseline (≥20 mm Hg); increase in heart rate from baseline (≥20 beats/minute); paradoxical abdominal breathing; profuse diaphoresis; shallow breathing; significant increase in respiratory rate above baseline; use of significant respiratory accessory muscles

Related Factors

Physiological

Alteration in sleep pattern; inadequate nutrition; ineffective airway clearance; pain

Psychological

Anxiety; decrease in motivation; fear; hopelessness; insufficient knowledge of weaning process; insufficient trust in health care professional; low self-esteem; powerlessness; uncertainty about ability to wean

Situational

Environmental barrier; inappropriate pace of weaning process; insufficient social support; uncontrolled episodic energy demands

Associated Condition

History of unsuccessful weaning attempt; history of ventilator dependence >4 days

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Respiratory Status: Gas Exchange; Ventilation

Example NOC Outcome with Indicators

Achieves appropriate **Respiratory Status: Ventilation** as evidenced by the following indicators: Respiratory rate/Respiratory rhythm/Depth of inspiration/Symmetrical chest expansion/Ease of breathing/Moves sputum out of airway/Accessory muscle use not present/Adventitious breath sounds not present/Chest retraction not present/Tidal volume/Vital capacity. (Rate the outcome and indicators of **Respiratory Status: Ventilation:** 1 = severe deviation from normal range, 2 = substantial deviation from normal range, 3 = moderate deviation from normal range, 4 = mild deviation from normal range, 5 = no deviation from normal range [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Wean from ventilator with adequate arterial blood gases
- Remain free of unresolved dyspnea or restlessness
- Effectively clear secretions

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Mechanical Ventilation Management: Invasive; Mechanical Ventilatory Weaning

Example NIC Activities—Mechanical Ventilatory Weaning

Monitor for optimal fluid and electrolyte status; Monitor to ensure client is free of significant infection before weaning

Nursing Interventions and *Rationales*

- Assess client's readiness for weaning as evidenced by the following:
  - ❍ Physiological and psychological readiness; there has been little research devoted to the study of psychological readiness to wean. **EBN:** *Assess fears and anxieties that can contribute to prolonged and repeated failure of ventilator weaning (Ward & Fulbrook, 2016).*
  - ❍ Resolution of initial medical problem that led to ventilator dependence.
  - ❍ Hemodynamic stability.
  - ❍ Normal hemoglobin levels.
  - ❍ Absence of fever.
  - ❍ Normal state of consciousness.
  - ❍ Metabolic, fluid, and electrolyte balance.
  - ❍ Adequate nutritional status with serum albumin levels >2.5 g/dL.
  - ❍ Adequate sleep.
  - ❍ Adequate pain management and minimal sedation.

EB: *A rapid shallow breathing index (RSBI) may predict weaning success (Penuelas, Thille, & Esteban, 2015; Karthika et al, 2016). A spontaneous breathing trial (SBT) is often preceded by evaluation of the patient's level of consciousness, physiological and hemodynamic stability, adequacy of oxygenation and ventilation, spontaneous breathing capability, and respiratory rate (RR) and pattern. Routine weaning predictor parameters include negative inspiratory force (NIF), vital capacity (VC), tidal volume (VT), RR, minute volume (VE), and RSBI (Kacmarek, 2013), although, applying these weaning predictors should not delay extubation decisions (Penuelas, Thille, & Esteban, 2015). Decreased heart rate variability and RR variability are associated with weaning/extubation failure and should be assessed to help predict weaning outcomes (Huang et al, 2014; Seely et al, 2014). Assessment of the percentage of change in diaphragm thickness (Δtdi%) between end-expiration and end-inspiration can reflect diaphragm strength. This measurement is analogous to the ejection fraction of the heart (Matamis et al, 2013; DiNino et al, 2014; Penuelas, Thille, & Esteban, 2015). Predictors of extubation failure include disease severity, secretion burden, higher minute ventilation, and lower oxygenation (Miu et al, 2014).*

▲ Noninvasive weaning may be used in place of invasive mechanical support in adults with respiratory failure. **EB:** *Noninvasive weaning reduces rates of death and pneumonia without increasing the risk of weaning failure or reintubation. In subgroup analyses, mortality benefits were significantly greater in patients with chronic obstructive pulmonary disease (COPD) (Burns et al, 2013; Penuelas, Thille, & Esteban, 2015). After an SBT to extubation high-risk patients receiving mechanical ventilation for more than 24 hours should be placed on noninvasive ventilation (NIV; Schmidt et al, 2017). Early use of NIV as a prophylactic intervention can be used to prevent reintubation for patients considered at high risk (Bajaj et al, 2015).*

- *Patients managed with ventilator liberation protocols spend fewer hours on mechanical ventilation and earlier intensive care unit (ICU) discharge than did patients managed without a protocol. However, ventilator liberation protocols have no significant effect on mortality or reintubation rates (Schmidt et al, 2017).*

▲ A spontaneous awakening trial (SAT) in conjunction with a daily weaning assessment has a great effect on ventilator liberation outcomes (Haas & Loik, 2012; Jones et al, 2014, Klompas et al, 2015; Penuelas, Thille, & Esteban, 2015). **EB:** *Using computerized automated weaning systems based on weaning protocols decreases weaning time, time to successful extubation, ICU length of stay (LOS), and number of patients requiring prolonged mechanical ventilation (Blackwood et al, 2014; Burns et al, 2014; Dale et al, 2014; Rose et al, 2014).* **EB:** *Goal-directed weaning decreased ventilator days and ICU and hospital LOS (Zhu et al, 2015). Pairing of an SBT and SAT or sedation interruption reduced ICU and hospital LOS, duration of mechanical ventilation, and ventilator-associated events (Klompas et al, 2015; Rose, 2015).*

▲ *The use of lighter sedation resulted in less duration of mechanical ventilation, more ventilator-free days and ICU-free days, and reduced mortality (Dale et al, 2014; Reade & Finfer, 2014; Schmidt et al, 2017).*

• *An early mobility and walking program can promote weaning from ventilator support as a client's overall strength and endurance improve (Balas et al, 2014; Penuelas, Thille, & Esteban, 2015). Acutely hospitalized patients who are mechanically ventilated for greater than 24 hours require early mobilization (Schmidt et al, 2017). When assessing clinical outcomes of survivors of critical illness requiring prolonged mechanical ventilation, the combination of high protein and a mobility-based rehabilitation program leads to increased rates of discharge home and ventilator weaning success (Wappel et al, 2017).*

• *Early mobility and physical rehabilitation can reduce muscle weakness, mechanical ventilation duration, and ICU and hospital stays (Penuelas, Thille, & Esteban, 2015; Spruit et al, 2013). Patients mechanically ventilated for more than 24 hours can benefit from protocolized rehabilitation directed toward early mobilization (Schmidt et al, 2017).* **CEB/EB:** *The Awakening and Breathing Coordination, Delirium Monitoring and Management, and Early Mobility (ABCDE) bundle has criteria to determine when clients are candidates for early mobility (Balas et al, 2012; Costa et al., 2017).*

• Provide adequate nutrition to ventilated clients, using enteral feeding when possible. *When assessing clinical outcomes of survivors of critical illness requiring PMV, the combination of high protein and a mobility-based rehabilitation program leads to increased rates of discharge home and ventilator weaning success (Wappel et al, 2017).*

• Use evidence-based weaning and extubation protocols as appropriate. **EBN/EB:** *The American Thoracic Society recommended use of ventilator liberation protocols to manage patients who have been mechanically ventilated for over 24 hours (Schmidt et al, 2017). The duration of treatment with mechanical ventilation and ventilation utilization ratio (VUR) were reduced in clients who received a SBT protocol (Jones et al, 2014). Protocol-directed weaning has been demonstrated to be safe and effective but not superior to other weaning methods that used structured rounds and other processes that allow for timely and ongoing clinical decision-making by expert nurses and health care providers (Balas et al, 2012; Costa et al, 2017).*

• Identify reasons for previous unsuccessful weaning attempts, and include that information in the development of the weaning plan. **EBN:** *Compared with the Venturi mask, high-flow nasal cannula oxygen use results in better oxygenation for the same set FiO_2 after extubation. Use of high-flow nasal cannula is associated with better comfort, fewer desaturations and interface displacements, and a lower reintubation rate (Maggiore et al, 2014; Penuelas, Thille, & Esteban, 2015). Pressure support reduces respiratory effort compared with T-piece. Continuous positive airway pressure of 0 cm H2O and T-piece more accurately reflect the physiological conditions after extubation (Penuelas, Thille, & Esteban, 2015; Sklar et al, 2017).*

• Reducing the size of artificial airways can increase airway resistance and overly increase energy expenditures of the diaphragm (Penuelas, Thille, & Esteban, 2015). **EB:** *Deflating the tracheal cuff in tracheostomized patients shortens weaning, reduces respiratory infections, and probably improves swallowing (Hernandez et al, 2013; Penuelas, Thille, & Esteban, 2015). A cuff leak test (CLT) should be performed in patients who meet extubation criteria and are at high risk for postextubation stridor (PES). PES may result in reintubation. Systemic steroids may be necessary 4 hours before extubation for patients who failed their CLT (Schmidt et al, 2017).*

▲ *Extubation failure may be avoided in patients with neurological disease by using protective ventilation, early enteral nutrition, antibiotic therapy standardization, and systematic testing*

extubation compared with a conventional strategy (Penuelas, Thille, & Esteban, 2015).
▲ Collaborate with an interdisciplinary team (health care provider, nurse, respiratory therapist, physical therapist, and dietitian) to develop a weaning plan with a time line and goals; revise this plan throughout the weaning period. **CEB/EB:** *Decisions related to weaning trials should be made in conjunction with members of the interdisciplinary team (Balas et al, 2012; Haas & Loik, 2012; Rose et al, 2014; Costa et al, 2017).*
• In clients with COPD who fail extubation, NIV facilitates weaning, prevents reintubation, and reduces mortality. Early NIV after extubation reduces the risk for respiratory failure and lowers 90-day mortality in clients with hypercapnia during an SBT (Burns et al, 2013; Mas & Masip, 2014; Ward & Fulbrook, 2016).
• Assist client to identify personal strategies that result in relaxation and comfort (e.g., music, visualization, relaxation techniques, reading, television, family visits). Support implementation of these strategies. Music intervention can be used to allay anxiety and can be a powerful distractor from distressful sounds and thoughts in the ICU (Tracy & Chlan, 2011; Bradt & Dileo, 2014). **EBN:** *Evidence supports music as an effective intervention that can lessen symptoms related to mechanical ventilation and promote effective weaning (Hetland, Lindquist, & Chlan, 2015). Music therapy increases weaning duration on daily weaning and also decreases RR and dyspnea (Liang et al, 2016). Patients who received a guided imagery intervention had reduced length of hospital stay (1.4 less days) and 4.88 less mechanical ventilation days compared with the comparison group (Spiva et al, 2015).*
• Provide a safe and comfortable environment.
• If unable to stay, make the call light button readily available and assure the client that needs will be met responsively. **EBN:** *Presence entails a focus by the nurse to engage attentively with the client (Tracy & Chlan, 2011).* **EBN:** *Knowing the client in association with objective clinical data helps individualize the weaning process (Rose et al, 2014).*
▲ Coordinate pain and sedation medications to minimize sedative effects. Appropriate levels of sedation may be key to successful weaning (Reade & Finfer, 2014). **EBN:** *Nursing-implemented sedation protocols have been used effectively to improve the probability of successful extubation (Balas et al, 2012; Costa et al, 2017). Wake up and breathe protocols that pair daily SATs with daily SBTs result in better outcomes for mechanically ventilated clients in intensive care (Balas et al, 2012, 2014; Haas & Loik, 2012; Khan et al, 2014; Klompas et al, 2015; Costa et al, 2017). Daily interruption of sedation (DIS) is safe in mechanically ventilated medical ICU clients. Further information is needed to determine benefits in other client populations. Current practice evidence suggested that sedation should be client specific to avoid overuse of sedating agents. DIS may not reduce the duration of mechanical ventilation (Makic et al, 2015).*
• Administer analgesics and sedatives as needed to facilitate client comfort and rest. Use behavioral and sedation scales for nonverbal clients to provide a consistent way of monitoring pain and sedation levels and ensuring that therapeutic outcomes are being met (Barr et al, 2013; Dale et al, 2014; Reade & Finfer, 2014). **EB:** *Clients receiving mechanical ventilation frequently require sedation to help attenuate the anxiety, pain, and agitation associated with this intervention (Balas et al, 2012; Barr et al, 2013; Reade & Finfer, 2014). The overall goal of sedation during mechanical ventilation is to provide physiological stability, ventilator synchrony, and comfort for clients (Balas et al, 2012; Makic et al, 2015).*
• Tools such as the Riker Sedation-Agitation Scale, the Motor Activity Assessment Scale, the Ramsey Scale, or the Richmond Agitation-Sedation Scale may be useful in monitoring levels of sedation (Balas et al, 2012; Barr et al, 2013; Dale et al, 2014).
• Schedule weaning periods for the time of day when the client is most rested. Cluster care activities to promote successful weaning. Avoid other procedures during weaning: keep the environment quiet and promote restful activities between weaning

periods.
• Promote a normal sleep-wake cycle, allowing uninterrupted periods of nighttime sleep. *Limit visitors during weaning to close and supportive persons; ask visitors to leave if they are negatively affecting the weaning process.* **EB:** *Communication with a client and/or the client's family is important to assess the client's typical pattern of sleep (Tracy & Chlan, 2011; Ward & Fulbrook, 2016).*
• During weaning, monitor the client's physiological and psychological responses; acknowledge and respond to fears and subjective complaints. Validate the client's efforts during the weaning process.
• Involve the client and family in the weaning plan. Inform them of the weaning plan and possible client responses to the weaning process (e.g., potential feelings of dyspnea). Foster a partnership between clients and nurses in care planning for weaning. **EBN:** *Consider the experience of the client and the client's family members to develop interventions for weaning success (Rose et al, 2014).*
• Coach the client through episodes of increased anxiety. Remain with the client or place a supportive and calm significant other in this role. Give positive reinforcement and, with permission, use touch to communicate support and concern. *It is not unusual for a client with lung disease to experience self-limiting episodes of increased shortness of breath. Supporting and coaching a client through such episodes allows weaning to continue (Tracy & Chlan, 2011; Ward & Fulbrook, 2016).*
• Terminate weaning when the client demonstrates predetermined criteria or when the following signs of weaning intolerance occur:
    - ❍ Tachypnea, dyspnea, or chest and abdominal asynchrony
    - ❍ Agitation or mental status changes
    - ❍ Decreased oxygen saturation: $SaO_2 < 90\%$
    - ❍ Increased $PaCO_2$ or $EtCO_2$
    - ❍ Change in pulse rate or blood pressure or onset of new dysrhythmias

▲ If the dysfunctional weaning response is severe, consider slowing weaning to brief periods (e.g., 5 minutes). Continue to collaborate with the team to determine whether an untreated physiological cause for the dysfunctional weaning pattern remains. Consult with health care provider regarding use of NIV immediately after discontinuing ventilation. Consider an alternative care setting (subacute, rehabilitation facility, or home) for clients with prolonged ventilator dependence as a strategy that can positively affect outcomes.

Geriatric

• Recognize that older clients may require longer periods to wean. **EBN:** *An integrative review found that nursing interventions that incorporated early mobility, close monitoring of fluid and electrolyte balance, effective pain management minimizing sedation, and early and frequent assessment of readiness to wean can reduce ventilator days. The study also found the assessment of frailty is important in discussing weaning options (Stieff, Lim, & Chen, 2017).*
• Frequently assess the older client for hypodelirium and hyperdelirium states. **EB:** *Delirium in the older client may prolong mechanical ventilation and worsen overall morbidity and mortality risk (Stieff, Lim, & Chen, 2017).*

Home Care

• Weaning from a ventilator at home should be based on client stability and comfort

of the client and caregivers under an intermittent care plan. *Generally the client will be safer weaning in a hospital environment.*

Risk for other-directed Violence

Kathleen L. Patusky MA, PhD, RN, CNS

NANDA-I

Definition

Susceptible to behaviors in which an individual demonstrates that he or she can be physically, emotionally, and/or sexually harmful to others.

Risk Factors

Access to weapon; impulsiveness; negative body; pattern of indirect violence; pattern of other directed violence pattern of threatening violence); pattern of violent antisocial behavior; suicidal behavior

At-Risk Population

History of childhood abuse; history of cruelty to animals; history of fire-setting; history of motor vehicle offense; history of substance misuse; history of witnessing family violence

Associated Condition

Alteration in cognitive functioning; neurological impairment; pathological intoxication; perinatal complications; prenatal complications; psychotic disorder

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Abuse Cessation; Abusive Behavior Self-Restraint; Aggression Self-Restraint; Distorted Thought Self-Control; Impulse Self-Control; Risk Detection

Example NOC Outcome with Indicators

Aggression Self-Restraint as evidenced by the following indicators: Refrains from harming others/Expresses/Vents needs and negative feelings in a nondestructive manner/Identifies when angry. (Rate the outcome and indicators of **Aggression Self-Restraint:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Stop all forms of abuse (physical, emotional, sexual; neglect; financial exploitation)
- Have cessation of abuse reported by victim
- Display no aggressive activity
- Refrain from verbal outbursts
- Refrain from violating others' personal space
- Refrain from antisocial behaviors
- Maintain relaxed body language and decreased motor activity
- Identify factors contributing to abusive/aggressive behavior
- Demonstrate impulse control or state feelings of control
- Identify impulsive behaviors
- Identify feelings/behaviors that lead to impulsive actions
- Identify consequences of impulsive actions to self or others
- Avoid high-risk environments and situations
- Identify and talk about feelings; express anger appropriately
- Express decreased anxiety and control of hallucinations as applicable
- Displace anger to meaningful activities
- Communicate needs appropriately
- Identify responsibility to maintain control
- Express empathy for victim
- Obtain no access or yield access to harmful objects
- Use alternative coping mechanisms for stress
- Obtain and follow through with counseling
- Demonstrate knowledge of correct role behaviors

Victim (and Children if Applicable) Will (Specify Time Frame)

- Have safe plan for leaving situation or avoiding abuse
- Resolve depression or traumatic response

Parent Will (Specify Time Frame)

- Monitor social/play contacts
- Provide supervision and nurturing environment
- Intervene to prevent high-risk social behaviors

NIC (Nursing Interventions Classification)

Suggested NIC Interventions

Abuse Protection Support; Anger Control Assistance; Behavior Management; Calming Technique; Coping Enhancement; Crisis Intervention; Delusion Management; Dementia Management; Distraction; Environmental Management: Violence Prevention; Mood Management; Physical Restraint; Seclusion; Substance Use Prevention

Example NIC Intervention—Environmental Management: Violence Prevention

Remove other individuals from the vicinity of a violent or potentially violent client; Provide ongoing surveillance of all client access areas to maintain client safety and therapeutically intervene as needed

Nursing Interventions and *Rationales*

Client Violence

- Aggressive/violent behavior may be impulsive, but more commonly it evolves in reaction to the environment (internal or external). In either case, nursing staff must go through specialized training to be prepared for a quick response. **EBN:** *Aggression management may include the use of physical or chemical restraints (medications), but the former should be used for brief periods only, and the latter should include monitoring for side effects. Music therapy may positively influence the environment (Fong, 2016).*
- Monitor the environment, evaluate situations that could become violent, and intervene early to deescalate the situation. Know and follow institutional policies and procedures concerning violence. Consider that family members or other staff may initiate violence in all settings. Enlist support from other staff rather than attempting to handle situations alone. **EBN:** *American Psychiatric Nurses Association (APNA) guidelines (2016) warn that workplace violence can occur in all settings and from a variety of sources. Nurses need to be aware and informed of department policies and procedures. Policies should be developed and training programs should be provided in proper use and application of restraints. All nursing units should develop a proactive plan for dealing with violent situations.*
- Assess causes of aggression, such as social versus biological. *Knowing the client, having experience with similar clients, paying attention, and planning interventions are expert practices used by clinicians to predict and respond to aggressive behavior effectively. A nonconfrontational approach is the most effective.*
- Assess the client for risk factors of violence, including those in the following categories: personal history (e.g., past violent behavior, especially violent behavior in the community within 2 weeks of admission); psychiatric disorders (particularly psychoses, paranoid or bipolar disorders, substance abuse, posttraumatic stress disorder [PTSD], antisocial personality, borderline personality disorder); neurological disorders (e.g., head injury, temporal lobe epilepsy, cardiovascular accident, dementia or senility), medical disorders (e.g., hypoxia, hypoglycemia, hyperglycemia), psychological precursors (e.g., low tolerance for stress, impulsivity, hostility), coping difficulties (e.g., inability to plan solutions or see long-term consequences of behavior), younger age, risk of suicide, and childhood or adolescent disorders (e.g., conduct disorders, hyperactivity, autism, learning disability). **EBN/EB:** *All of these risk factors have been implicated in aggressive, agitated, or violent behavior, with prior history as a key indicator (APNA, 2014a,b; Battaglini, 2014a).*
- Measures of violence may be useful in predicting or tracking behavior, and serving as outcome measures. **EBN:** *The Broset Violence Checklist (BVC) and the Kennedy Axis V*

have been shown to help identify clients at risk for seclusion (Sande et al, 2013). **CEB:** *The Alert System identifies potential violent incidents (odds ratio = 7.74, 95% confidence interval [CI] = 4.81–12.47), but they should be combined with resources and procedures to prevent escalation of behavior (Kling et al, 2011).*

• Assess the client with a history of previous assaults, especially violent behavior in the community, within 2 weeks of admission. Listen to and acknowledge feelings of anger, observe for increased motor activity, and prepare to intervene if the client becomes aggressive. **EBN/EB:** *The most significant risk factor for physical violence is a past history of physically aggressive behavior (Battaglini, 2014a).*

• Assess the client for physiological signs and external signs of anger. Internal signs of anger include increased pulse rate, respiration rate, and blood pressure; chills; prickly sensations; numbness; choking sensation; nausea; and vertigo. External signs include increased muscle tone, changes in body posture (clenched fists, set jaw), eye changes (eyebrows lower and drawn together, eyelids tense, eyes assuming a "hard" appearance), lips pressed together, flushing or pallor, goose bumps, twitching, and sweating. *Anger is an early warning sign of possible violence.*

• Assess for the presence of hallucinations. *Command hallucinations may direct the client to behave violently.*

• Apply STAMPEDAR as an acronym for assessing the immediate potential for violence. **CEBN:** *A study of nurses experienced in workplace violence identified the following as factors and behaviors indicating the likelihood of a violent episode: staring, tone of voice, anxiety, mumbling, pacing, emotions, disease process, assertive/nonassertive behavior, and access to resources that might be used for violent behavior (STAMPEDAR) (Chapman et al, 2009).*

• Determine the presence and degree of homicidal or suicidal risk. A number of questions will elicit the necessary information: Have you been thinking about harming someone? If yes, who? How often do you have these thoughts, and how long do they last? Do you have a plan? What is it? Do you have access to the means to carry out that plan? What has kept you from hurting the person until now? Refer to the care plan for Risk for **Suicide.** Mental health providers are required to report harm or threats of harm to another person, referred to as the "duty to warn." State laws and mental health codes should be checked to determine local mandates for threat reporting by specific health care professionals.

• Take action to minimize personal risk; use nonthreatening body language. Respect personal space and boundaries. Maintain at least an arm's length distance from the client; do not touch the client without permission (unless physical restraint is the goal). Do not allow the client to block access to an exit. If speaking with the client alone, keep the door to the room open. Be aware of where other staff is at all times. Notify other staff of where you are at all times. Take verbal threats seriously and notify other staff. Wear clothing and accessories that are not restricting and that will not be dangerous (e.g., sandals or shoes with heels can lead to twisted ankles; necklaces or dangling earrings could be grabbed). Ensure staff training to deal with violence. **EBN/EB:** *Aggression management training has been identified as a critical need (Battaglini, 2014a; Chu, 2014a). Programs for violence prevention have been implemented that reduce workplace violence. For Occupational Safety and Health Association (OSHA) guidelines, see https://www.osha.gov/SLTC/workplaceviolence/index.html.*

• Remove potential weapons from the environment. Be prepared to remove obstructions to staff response from the environment. Search the client and his or her belongings for weapons or potential weapons on admission to the hospital as appropriate. **EBN:** *Preventive strategies are important (Chu, 2014a; Zhili, 2013). Clients*

prone to violence may use available weapons opportunistically. If client restraint becomes necessary, environmental hazards (e.g., chairs, wastebaskets) should be moved out of the way to prevent injuries.

• Inform the client of unit expectations for appropriate behavior and the consequences of not meeting these expectations. Emphasize that the client must comply with the rules of the unit. Give positive reinforcement for compliance. Increase surveillance of the hospitalized client at smoking, meal, and medication times. **CEB/EBN:** *Clients benefit from clear guidance and positive reinforcement regarding behavioral expectations and consequences, providing much needed structure and emphasizing client responsibility for his or her own behavior (APNA, 2014a,b). The unit serves as a microcosm of the client's outside world, so adherence to social norms while on the unit models adherence on discharge and provides the client with staff support to learn appropriate coping skills and alternative behaviors.*

• Assign a single room to the client with a potential for violence toward others. The client will be able to take time away from unit stimulation to calm self as needed. Another client will not be placed at risk as a roommate.

• Maintain a calm attitude in response to the client. Provide a low level of stimulation in the client's environment; place the client in a safe, quiet place, and speak slowly and quietly. Anxiety is contagious. **EBN/EB:** *Maintenance of a calm environment contributes to the prevention of aggression (APNA, 2014a,b). Harmony among staff can help prevent violence, in that disharmony transmits itself to clients' emotional state (Battaglini, 2014a). Music therapy may help (Chu, 2014b).*

• Redirect possible violent behaviors into physical activities (e.g., walking, jogging) if the client is physically able. Using a punching bag or hitting a pillow is not indicated because these are not calming activities and they continue patterning violent behavior. However, activities that distract while draining excess energy help build a repertoire of alternative behaviors for stress reduction.

• Provide sufficient staff if a show of force is necessary to demonstrate control to the client. *When staff respond to an escalating or violent situation, it can reassure clients that they will not be allowed to lose control. On the other hand, leave immediately if the client becomes violent and you are not trained to handle it.*

• Deescalation is the first and most important action in response to anger and hostility. Constant special observation may be implemented. **EBN:** *Response to hostility should be appropriate, measured, and reasonable. Constant special observation should be used to prevent acutely disturbed clients from harming self or others (Battaglini, 2014a).*

• Protect other clients in the environment from harm. Remove other individuals from the vicinity of a violent or potentially violent client. Follow safety protocols of the department. The risk of a violent client to others in the area (other clients, visitors) should be anticipated, even as efforts proceed to deescalate the situation with the client. **EBN:** *Clients exposed to violence need timely support and assistance (Chu, 2014a).*

• Maintain a secluded area for the client to be placed when violent. Ensure that staff is continuously present and available to client during seclusion. **EBN:** *Staff presence is necessary to prevent the harmful effects of social isolation and to honor clients' motivation to connect with staff (APNA, 2014b). Seclusion should be short and should be reviewed at least every 2 hours (Zhili, 2013).*

▲ Recognize legal requirements that the least restrictive alternative of treatment should be used with aggressive clients. The hierarchy of intervention is as follows: promote a milieu that provides structure and calmness, with negotiation and collaboration taking precedence over control; maintain vigilance of the unit and respond to behavioral changes early; talk with client to calm and promote

understanding of emotional state; use chemical restraints as ordered; increase to manual restraint if needed; increase to mechanical restraint and seclusion as a last resort. **EBN:** *APNA guidelines (2014a,b) support early assessment and intervention to prevent aggression, with nursing actions to reduce stimulation, divert client from aggressive thought patterns, set appropriate limits on behavior, and provide medications as needed. Chemical restraints are useful, but clients* must *be monitored for response and side effects (Chu, 2014b). Physical restraints should be avoided and used for short periods when necessary (Battaglini, 2014a; Chu, 2014b).*

▲ Use mechanical restraints if ordered and as necessary. Physical restraint can be therapeutic to keep the client and others safe. **EBN:** *Physical restraints should be avoided and used for short periods when necessary (Battaglini, 2014a; Chu, 2014b). Restraint skill training, audits of adverse events, and examination of the safe use of restraints and medications are important to safe restraint practices (APNA, 2014a,b).*

▲ Follow the institutional protocol for releasing restraints. Observe the client closely, remain calm, and provide positive feedback as the client's behavior becomes controlled. **EBN:** *The period during which restraints are removed can be dangerous for staff if they do not recognize that the client may choose to reinitiate violence. Protocols will specify safe procedures for removing restraints (APNA, 2014a,b).*

▲ After a violent event on a unit, debriefing and support of both staff and clients should be made available. *Allowing discussion of a violent episode, either individually or in a group, among other clients present reveals clients' responses to the event and provides the opportunity for staff to offer reassurance and support. Clients may have concerns that staff will attempt to restrain them without reason or may feel uncertain whether staff can keep them safe.* **EBN:** *A study of the effect of serious events on psychiatric units found that staff reported a variety of negative emotional responses, levels of containment increased, the provision of care could be affected, and client reactions were largely ignored (APNA, 2014a,b). Injury after violence has a strong negative influence on staff and calls for treatment (Chu, 2014a).*

• Form a therapeutic alliance with the client, remaining calm, identifying the source of anger as external to both nurse and client, and using the therapeutic relationship to prevent the need for seclusion or restraint. The development of a therapeutic relationship before aggressive behavior occurs provides an alternative for working through anger and frustration. Assisting the client to identify a source of anger or frustration that is external to both the nurse and client prevents the need for defensiveness by both and directs energy at solving an external problem. **EBN:** *A therapeutic environment has a mitigating effect against violence (Zhili, 2013).*

• Allow, encourage, and assist the client to verbalize feelings appropriately either one-on-one or in a group setting. Actively listen to the client; explore the source of the client's anger, and negotiate resolution when possible. Teach healthy ways to express feelings/anger, appropriate gender roles, and how to communicate needs appropriately.

• Identify with client the stimuli that initiate violence and the means of dealing with the stimuli. Have the client keep an anger diary and discuss alternative responses together. Teach cognitive-behavioral techniques. Assisting the client to identify situations and people that upset him or her provides information needed for problem solving. The client may then identify alternative responses (e.g., leaving the stimulus; using relaxation techniques, such as deep breathing; initiating thought stopping; initiating a distracting activity; responding assertively rather than aggressively).

▲ Initiate and promote staff attendance at aggression management training programs. **EBN:** *Aggression management training programs have a positive influence on the ability and confidence of nurses in responding to aggressive or violent behavior (APNA,*

2011).

Intimate Partner Violence/Domestic Violence

Note: Before implementation of interventions in the face of domestic violence, nurses should examine their own emotional responses to abuse, their knowledge base about abuse, and systemic elements within the emergency department (ED) to ensure that interventions will be compassionate and appropriate. **EBN:** *A meta-synthesis of health care provider studies identified a strong therapeutic relationship and the ability to hear what the client is not saying as facilitators of intimate partner violence (IPV) screening (LoGiudice, 2015).*

• Screen for possible abuse in women or children with a pattern of multiple injuries, particularly if any suspicion exists that the physical findings are inconsistent with the explanation of how the injuries were incurred. *IPV/domestic violence is recognized as a nationwide public health issue.*

▲ Report suspected child abuse to Child Protective Services. Refer women suspected of being in a spousal abuse situation to an area crisis center and provide phone number of area crisis hotline. *Rapid screening tools are helpful to identify IPV. All nurses are required by law to report suspected child abuse.* **EBN:** *Systematic reviews resulted in best practice recommendations: Positive Parenting Program as a hospital-based educational program, parent–child interaction therapy, cognitive-behavioral therapy, school-based instruction for children and adolescents about protective behaviors in the face of sexual abuse, and community-based group therapy for women in IPV relationships (Le, 2016).*

• Assess for physical and mental concerns of women, including risk of HIV. *Major health needs of women with a history of IPV include chronic pain, chronic diseases, and mental illness, as well as concerns regarding risk of HIV. Barriers to health care created by the IPV may prevent these concerns from being addressed.*

• Assist the client in negotiating the health care system and overcoming barriers. *Victims of IPV experience barriers, including inappropriate responses from providers, when attempting to access health care services.*

• With women who repeatedly experience injuries from domestic violence, maintain a nonjudgmental approach and continue to offer resources/referrals. If the woman voices a willingness to leave her situation, assist with developing an emergency plan that will consider all contingencies possible (e.g., safe location, financial resources, care of children, when to leave safely). A woman in a domestic violence situation may change her mind several times before actually leaving. Proactive organization of an emergency plan helps increase the possibility that women will be able to leave safely. The most dangerous time of a domestic violence situation is when the spouse tries to leave.

• Maintain a nonjudgmental response when clients return to husbands or refuse to leave them. Women have many reasons for remaining in an abusive relationship, including economic concerns (especially with children), socialization about the woman's role, political or legal obstacles, powerlessness, and a realistic fear of retaliation or death. Refer to the care plan for **Powerlessness.** Experienced nurses working with abused women define success as client personal growth over time, rather than the woman leaving the relationship.

• Focus on providing support, ensuring safety, and promoting self-efficacy while encouraging disclosure about IPV events. *Nursing care should focus on providing physical, psychological, and emotional support; ensuring safety of the client and family; and promoting the self-efficacy of the woman.*

• Pregnancy is a particular risk period for interpersonal violence. Screen pregnant women for the potential for domestic violence during pregnancy, especially in teenage pregnancies. **EBN:** *In a comprehensive review of effective interventions, group*

interventions with pregnant women have included establishing a social support network, emphasizing a positive perspective and self-care knowledge, teaching goal setting and communication skills, and developing skills in assessing risks in the relationship. Individual interventions have included weekly telephone support sessions, self-help workbooks, empowerment training, and music therapy. In some of the individual approaches, depression improved but the rate of IPV did not. Women preferred to focus on the pregnancy or basic needs, feeling judged when the IPV was a focus (Morales & Records, 2013). **CEB:** *Less educated women, women who reported substance abuse by spouse, and women who reported unwanted pregnancies were at risk for IPV both during and after pregnancy. Violence during pregnancy predicted postpartum violence. American women employed during pregnancy were most likely to leave an abusive partner at 1 year postpartum (Charles & Perreira, 2007).*

• Women with physical or mental disabilities require extended assessment, including a comprehensive functional assessment, with attention to cultural issues, the nature of the disability, and needed resources. Women with disabilities may experience abuse from multiple sources, and particular attention should be paid to the additional emotional stressors present. Difficulties leaving home, physical needs that a shelter may not be able to accommodate, and the undesirability of nursing home placement are just a few stressors. Personal assistance providers may be abusive or take advantage financially.

▲ Referral for spiritual counseling may be considered, but be aware that clergy vary in their helpfulness. *Survivors of sexual violence may be able to cope with their situation through spiritual connection, spiritual journey, and spiritual transformation.*

• Evaluate medical and mental illness as precursors to elder abuse. **EBN:** *Systematic reviews identify the need to address medical and mental illnesses in providing care (Lizarondo, 2016b).*

• Consider risk versus benefit when deciding if, when, and in how great a depth to explore client responses to abuse or violence. **EB:** *A systematic review of research on violence and abuse concluded that risks and benefits may derive from clients talking about such experiences (McClinton Appollis et al, 2015). Clinical judgment must be exercised in the decision to introduce the topic of abuse. Is the client ready? Will raising the issue now prevent further disclosure? Do the current circumstances allow for sufficient resolution of affect?*

▲ When spouse or child abuse accompanies substance abuse, refer the abusive client to a substance abuse treatment program. Refer the spouse receiving abuse to Al-Anon and the children to Alateen. *Use of drugs or alcohol may decrease impulse control and aggravate abusive behavior, depending on the specific drug used and culture.*

▲ When an adult reveals a history of unresolved/untreated sexual abuse as a child, referral to a local Adults Molested as Children (AMAC) group may be helpful. *Childhood sexual abuse has been associated with adult depression, attempted suicide, self-harm, and higher risk for later interpersonal violence. Interventions tailored to the AMAC experience may be helpful (AMAC, 2017).* Refer to the care plans for Risk for **Suicide, Self-Mutilation,** and Risk for **Self-Mutilation.**

▲ Referral of women for psychiatric/psychological treatment or parenting classes should be considered as an appropriate intervention. *Overcoming shame, building a stable sense of identity, and becoming less dependent on others' approval should be addressed, along with physical health and PTSD symptoms.*

▲ Referral of children for psychiatric/psychological treatment should be considered as an appropriate intervention. **CEB:** *Children living with domestic violence were found to express fear and anxiety, self-esteem issues, ambivalent relationships with the abuser, and a sense of a lost childhood (Buckley et al, 2007).*

▲ Refer to batterer intervention programs that are often available and may be court

mandated. *Batterers may believe behaviors toward them are not justified, and their behaviors toward others are justified and minimized. Treatment should include emotional skills training that addresses these areas.*

Social Violence

• Assess for acute stress disorder (ASD) and PTSD among victims of violence. **CEB:** *In the acute phase after an assault, women reported high rates of ASD symptoms. Four months after an attack, dissatisfaction with previous life, prior mental health problems, recent life events, and earlier abuse were risk factors for PTSD (Renck, 2006).*
▲ Assess the support network of women who become victims of violent crime and refer for appropriate levels of assistance. Of particular concern would be women who do not have family or friends to provide support or who have difficulty accessing other types of assistance.
• Be aware that hate crime is increasing, particularly toward gay and transgendered individuals, and it requires support and advocacy for victims. **CEB:** *Gay men who experienced antigay abuse reported that the events affected their self-image. In addition to verbal and physical abuse, spiritual abuse emerged as the men internalized schemas of outcast and sinner (Lucies & Yick, 2007).*
▲ Victims of violence seen in the ED should receive an assessment for needed services and assignment to case management. *Establishment of linkages with social service agencies can provide important services for referral.*

Rape-Trauma Syndrome

• Brief relationship abuse instruction with counseling in a student health center can be effective in preventing and responding to episodes of sexual coercion. **EB:** *In a randomized control trial (RCT), a student health service provided effective interventions in addressing abusive relationship with adolescents (Miller et al, 2015).*
• Assist client to cope with potential stalking activity. **EBN:** *The usual coping of college students in response to stalking was found to include ignoring or minimizing the problem; distancing or depersonalizing, using verbal escape strategies; attempting to end the relationship; and restricting availability (Amar & Alexy, 2010). Emphasizing the need to take stalking behavior seriously and problem-solving interventions may prevent a rape situation.*
• Approach client with sensitivity. **CEBN:** *Using Peplau's theory of nursing roles, researchers found that the roles of counselor and technical expert were most helpful, with interpersonal sensitivity important to clients (Courey et al, 2008).*
▲ Monitor for paradoxical drug reactions, and report any to the health care provider. Violent behavior can be stimulated by a medication intended to calm the client.
• Assess for brain insults, such as recent falls or injuries, strokes, or transient ischemic attacks. Clients with brain injuries may respond to stimulus control, problem-solving, social skills training, relaxation training, and anger management to reduce aggressive behaviors. Brain injuries, lowered impulse control, and reduced coping can cause violent reactions to self or others. Brain injury symptoms may be mistaken for mental illness.
• Decrease environmental stimuli if violence is directed at others. Removal of the client to a quiet area can reduce violent impulses. Use a calm voice to "talk down" the client.
• Assess holistic needs of the client. *Negative mental health outcomes after sexual violence may be low income, low education level, lack of social support, and poor health promotion.*

• Discuss with client her wishes regarding use of an emergency contraceptive.
▲ If abuse or neglect of an older client is suspected, report the suspicion to an adult protective services agency with jurisdiction over the geographical area in which the client lives.

Pediatric

• Assess for predictors of anger that can lead to violent behavior. **EBN:** *A correlational study of adolescent anger predictors identified trait anger, anxiety, depression, stress, exposure to violence, and parental drinking behaviors as predictors of anger. Frequency of religious participation was associated with decreased anger (Pullen et al, 2015).*
• Be alert for both shaken baby syndrome and exposure of children to violence. *In homes in which domestic violence exists, children are involved as either witnesses or victims. Such children tend not to seek help and need care providers to elicit actively the need for assistance.*
• Pregnant teens should be assessed for abuse, particularly if they are with an older partner.
▲ In the case of child abuse or neglect, refer for early childhood home visitation. **CEB:** *Home visits during a child's first 2 years of life may be effective in preventing child abuse and neglect.*

Geriatric

• Be alert to the potential for elder abuse in clients, including the possibility of psychological abuse. **EBN:** *Abuse may be physical, sexual, psychological, financial, or may appear as neglect. Look for signs of bruising, malnutrition, and fearful responses to or around caregivers (Battaglini, 2014b). Cognitive impairment, behavioral problems, and psychiatric illness in the client are risk factors for becoming recipients of abuse (Battaglini, 2014c). Assess for changes in physiological functions (e.g., constipation, dehydration) or impairment of the ability to meet basic needs (e.g., inadequate toileting, decreased mobility). Observe for signs of fear, anxiety, anger, and agitation, and intervene immediately. In older adults, subtle physiological changes, interruptions of or changes in routine, or fears about medical disorders or potential loss of independence can be transformed into anger, irritability, or agitation. A comprehensive physical exam should include a neurological exam and x-rays as needed (Battaglini, 2014b).*
• Assess for presence or client history of mental illness or treatment. **EBN:** *There is a high likelihood of elder abuse in the presence of mental illness, even if receiving psychiatric treatment (Battaglini, 2014c).*
• Assess and observe for aggressive behavior in older clients at long-term care facilities. **EBN:** *Between 25% and 50% of clients with dementia have demonstrated aggressive behavior. Knowledge of the client's history and risk factors is important. Treatment with antipsychotics should be individualized and carefully monitored. Use of restraints should be avoided, used for a short time, and removed at the earliest possible time. Staff should receive training in aggression management (Battaglini, 2014d). Insufficient evidence supports the efficacy of agitation reduction protocols or emotion-oriented care (Lizarondo, 2016a).*
• Observe clients for dementia and delirium. **EBN:** *Between 25% and 50% of clients with dementia have demonstrated aggressive behavior. Clients with dementia or delirium may strike out if they are frustrated or if they have the sense that their personal space is being violated. The competency of the client should be assessed to determine whether he or she possesses a cognitive capacity that permits discussion of the behavior (Battaglini, 2014c,d).*

• For clients with dementia, provide music therapy. **EB:** *A systematic review of interventions with aggression in adults with dementia demonstrated significant improvement with music therapy. Patient-centered care, communication skills training, and dementia care matching showed reductions in aggression for up to 6 months (Lizarondo, 2016a).*
• Be aware of laws and regulations in the appropriate jurisdiction in which the client is located. **EBN:** *Confidentiality, consent, and information sharing are sensitive issues that are determined by federal and local regulation (Battaglini, 2014b; Goh, 2014a).*
• Document and record suspected elder abuse according to mandatory regulations. **EBN:** *Incidents of abuse should be recorded with date, time, chronology of abuse, family history, potential indicators of abuse, details regarding care planning and decision-making process, and actual care provided. Photographic evidence of abuse should be obtained. The police may be requested to take forensic pictures (Goh, 2014b).*
• Apart from mandated requirements, abide by the older client's wishes regarding action to be taken in response to abuse. Avoid interventions that increase the risk of abuse. **EBN:** *Discuss with client his or her reasons for refusing to disclose abuse. There may be a fear that the only available caregiver will withdraw, leaving the client helpless. Allow adequate time for the discussion; respect the client's pace and need for a sense of control. Corroborate events as possible (Battaglini, 2014b). Avoid the use of antidepressants or sedatives without a thorough abuse assessment, the recommendation of family counseling without intervention for the abuser, blaming the victim, colluding with the abuser, or minimizing the possible danger (Goh, 2014c).*
• Develop a safety plan and provide referrals to all relevant agencies or services. **EBN:** *Discuss safety options for both client and provider. Contact police if there is a concern regarding the availability of a gun. The registered nurse should debrief with manager as necessary (Battaglini, 2014c). Multidisciplinary and interagency collaboration is important to meet client needs (Goh, 2014c).*

Multicultural

• Exercise cultural competence when dealing with domestic violence. **CEBN:** *Battered Latina women reported protecting their partner, preventing their mother from worrying, and fear of losing their children as barriers to disclosing IPV (Montalvo-Liendo et al, 2009).*
• Identify and respond to unique needs of immigrant women who experience IPV. C**EBN:** *A study of Sri Lankan immigrants to Canada revealed that violence prior to the immigration, gender inequity in the marriage, changes in social networks and supports, and changes in socioeconomic status were identified by the women as factors involved in IPV (Guruge et al, 2010). Filipina women focused on keeping their family together and did not realize that IPV had a negative influence on the mental health of the women and their children (Shoultz et al, 2010).*
• Assist with acculturation and activating social support. **CEB:** *Type of support and acculturation helped promote resiliency and improved mood among Hispanic women in IPV situations (Shoultz & Magnussen, 2009).*

Home Care

• Be alert to the potential for violent behavior in the home setting. Respond to verbal aggression with interventions to deescalate negative emotional states. Violence is a process that can be recognized early. Deescalation involves reducing client stressors, responding to the client with respect, acknowledging the client's feeling state, and assisting the client to regain control. If deescalation does not work, the nurse should

leave the home.
• Assess family members or caregivers for their ability to protect the client and themselves. The safety of the client between home visits is a nursing priority. Caregivers often need assistance with recognizing or admitting fear of or danger from a loved one. **EBN:** *A qualitative study with home care staff and caregivers of clients with dementia advised that staff use a calm, compassionate approach and minimize controlling strategies such as medications or restraints in dealing with aggressive behavior. A patient-centered approach was recommended (Lizarondo, 2016a).*
• Include an initial and ongoing assessment and evaluation of potential abuse and neglect. Photograph evidence of abuse or neglect when possible. *Victims of abuse perceive themselves to be powerless to change the situation. Indeed, the abuser fosters this perception and may threaten violence or death if the victim attempts to leave. Chronic abuse and neglect by a spouse or other family among older adults is often hidden until home care is actively involved.* Refer to the care plan for **Powerlessness.**
▲ If neglect or abuse is suspected, identify an emergency plan that addresses the problem immediately, ensures client safety, and includes a report to the appropriate authorities. Discuss when to use hotlines and 911. Role-play access to emergency resources with the client and caregivers. *Client safety is a nursing priority. An emergency plan should address either immediate removal to a safe environment or identification of appropriate steps to take in the event of abuse and the securing of resources for the anticipated action (e.g., available phone, packed bag, alternative living arrangements). Reporting is a legal requirement for health care workers.*
• Encourage appropriate safety behaviors in abused women; call the client at intervals during a 6-month period to determine whether safety behaviors are being performed. **CEB:** *A study of telephone contacts to women who sought help through the district attorney's office demonstrated that safety behaviors increased dramatically. Safety behaviors included hiding money; hiding an extra set of house and car keys; establishing a code for abuse occurrence with family or friends; asking neighbors to call police if violence occurs; removing weapons; keeping available family social security numbers, rent and utility receipts, family birth certificates, identification or driver licenses, bank account numbers, insurance policies and numbers, marriage license, valuable jewelry, important phone numbers, and a hidden bag with extra clothing (McFarlane et al, 2002).*
• Assess the home environment for harmful objects. Have the family remove or lock objects as able. *The safety of the client and caregivers is a nursing priority.*
▲ Refer for homemaker or psychiatric home health care services for respite, client reassurance, and implementation of a therapeutic regimen. Responsibility for a person who may become violent provides high caregiver stress. Respite decreases caregiver stress. The presence of caring individuals is reassuring to both the client and caregivers, especially during periods of client anxiety. Individuals exhibiting violent behaviors can respond to the interventions described previously, modified for the home setting.
▲ If the client is taking psychotropic medications, assess client and family knowledge of medication and its administration and side effects. Teach as necessary. Knowledge of the medical regimen supports compliance.
▲ Evaluate effectiveness and side effects of medications. Accurate clinical feedback improves the health care provider's ability to prescribe an effective medical regimen specific to a client's needs.
• If client displays mildly intensifying aggressive behavior, attempt to diffuse anger or violence (e.g., ask for a glass of water to distract client). Later in the visit, explain that aggressive behavior is not acceptable and present consequences of continued

aggressive behavior (i.e., right of agency to discontinue services). *Mild aggression can be defused safely. Confronting the client before severe aggression is evident places responsibility on the client and family for respectful partnership in care.*
• Document all acts or verbalizations of aggression. Safety of the staff is a primary responsibility of home health agencies. Law enforcement intervention may be necessary.
▲ If client verbalizes or displays threatening behavior, notify your supervisor and plan to make joint visits with another staff person or a security escort. *Having a second person at the visit is a show of power and control used to subdue aggressive behavior.*
• If the client's behavior is not overtly threatening but makes the nurse uncomfortable, a meeting may be held outside the home in sight of others (e.g., front porch). *The nurse should trust a "gut" reaction that prompts concern regarding the client's potential for aggressive or violent behavior. Such intuitive reactions are often the result of subliminal cues that are not readily voiced.*
• Never enter a home or remain in a home if aggression threatens your well-being.
▲ Never challenge a show of force, such as a gun threat. Leave and notify your supervisor and the appropriate authorities. Document the incident. *Safety of the staff is a primary responsibility of home health agencies. Law enforcement intervention may be necessary.*
▲ If client behaviors intensify, refer for immediate mental health intervention. The degree of disturbance and ability to manage care safely at home determines the level of services needed to protect the client.

Client/Family Teaching and Discharge Planning

• Instruct victims of IPV in the dynamics and prognosis of domestic violence behavior, as well as the effect on children who witness or are victims of domestic violence. *Victims of IPV feel alone and isolated. They can begin to take back control of their circumstances once they better understand what is happening within the interpersonal relationship, what their options are, and what the consequences of inaction may be. Do not expect an immediate change in the victim's behavior.*
• Teach relaxation and exercise as ways to release anger and deal with stress.
• Teach cognitive-behavioral activities, such as active problem-solving, reframing (reappraising the situation from a different perspective), or thought stopping (in response to a negative thought, picture a large stop sign and replace the image with a prearranged positive alternative). Teach the client to confront his or her own negative thought patterns (or cognitive distortions), such as catastrophizing (expecting the very worst), dichotomous thinking (perceiving events in only one of two opposite categories), magnification (placing distorted emphasis on a single event), or unrealistic expectations (e.g., "should get what I want when I want it"). *Cognitive-behavioral activities address clients' assumptions, beliefs, and attitudes about their situations, fostering modification of these elements to be as realistic as possible. Through cognitive-behavioral interventions, clients become more aware of their cognitive choices in adopting and maintaining their belief systems, exercising greater control over their own reactions.*
▲ Refer to individual or group therapy.
• Teach the adolescent client violence prevention, and encourage him or her to become involved in community service activities. School programs that couple community service with classroom health instruction can have a measurable effect on violent behaviors of young adolescents at high risk for being both the perpetrators and victims of peer violence. Community service programs may be a valuable part of

multicomponent violence prevention programs.
• Teach the use of appropriate community resources in emergency situations (e.g., hotline, community mental health agency, ED, 911 in most places in the US, the toll-free National Domestic Violence Hotline [1-800-799-SAFE]). Internet resources are increasing and should be made available to clients. It is necessary to get immediate help when violence occurs.
• Encourage the use of self-help groups in nonemergency situations.
• Inform the client and family about any applicable medication actions, side effects, target symptoms, and toxic reactions.

Risk for self-directed Violence

Kathleen L. Patusky MA, PhD, RN, CNS

NANDA-I

Definition

Susceptible to behaviors in which an individual demonstrates that he or she can be physically, emotionally, and/or sexually harmful to self.

Risk Factors

Behavioral cures of suicidal intent; conflict about sexual orientation; conflict in interpersonal relationship(s); employment concern; engagement in autoerotic sexual acts; history of multiple suicide attempts; insufficient personal resources; social isolation; suicidal ideation; suicidal plan; verbal cues of suicidal intent

At-Risk Population

Age ≥45 years; age 15 to 19 years, history of multiple suicide attempts; marital status; occupation; pattern of difficulties in family background

Associated Condition

Mental health issue; physical health issue; psychological disorder

NOC, NIC, Client Outcomes, Nursing Interventions and *Rationales,* Client/Family Teaching and Discharge Planning, and

References

Refer to care plans for Risk for **Suicide, Self-Mutilation,** and Risk for **Self-Mutilation**

Impaired Walking	Wandering	

W

• = Independent; ▲ = Collaborative; **EBN** = Evidence-Based Nursing **EB** = Evidence-Based

Impaired Walking

Wendie A. Howland MN, RN-BC, CRRN, CCM, CNLCP, LNCC

NANDA-I

Definition

Limitation of independent movement within the environment on foot.

Defining Characteristics

Impaired ability to climb stairs; impaired ability to navigate curbs; impaired ability to walk on decline; impaired ability to walk on incline; impaired ability to walk on uneven surface; impaired ability to walk required distance

Related Factors

Alteration in mood; decrease in endurance; environmental barrier; fear of falling; insufficient knowledge of mobility strategies; insufficient muscle strength; obesity; pain; physical deconditioning

Associated Condition

Alteration in cognitive functioning; impaired balance; impaired vision; musculoskeletal impairment; neuromuscular impairment

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes

Ambulation, Mobility

Example NOC Outcome with Indicators

Ambulation as evidenced by the following indicators: Walks with effective gait/Walks at moderate pace/Walks up and down steps/Walks moderate distance. (Rate the outcome and indicators of **Ambulation:** 1 = severely compromised, 2 = substantially compromised, 3 = moderately compromised, 4 = mildly compromised, 5 = not compromised [see Section I].)

Client Outcomes/Goals

Client Will (Specify Time Frame)

- Demonstrate optimal independence and safety in walking
- Demonstrate the ability to direct others on how to assist with walking
- Demonstrate the ability to use and care for assistive walking devices properly and safely

NIC (Nursing Interventions Classification)

Suggested NIC Intervention
Exercise Therapy: Ambulation

Example NIC Activities—Exercise Therapy: Ambulation

Assist client to use footwear that facilitates walking and prevents injury; Encourage to sit in bed, on side of bed ("dangle"), or in chair, as tolerated

Nursing Interventions and *Rationales*

• Progressive mobilization as tolerated (gradually raising head of bed [HOB], sitting in reclined chair, standing, with assistance). Progressing mobility gradually from bed rest to increased sit to stand times to short distance walking and timed testing can provide goals for the client and staged mobility successes (Ellison et al, 2016). See also the care plan for Impaired physical **Mobility.**
• Consider and monitor for side effects of prescribed hydration and medications; physical condition; length of immobility contributing to orthostatic hypotension; and/or if lightheadedness, dizziness, syncope, or unexplained falls occur. **EB:** *Understanding the mechanisms of blood pressure regulation is critical for assessment (Lowry, Windsor, & Ashelford, 2016). Orthostatic hypotension is highly prevalent in patients with unexplained syncope and is associated with the use of antihypertensive drugs (Van Twist et al, 2017).*
▲ Assess for orthostatic hypotension if systolic pressure falls 15 mm Hg or diastolic pressure falls 7 mm Hg from sitting to standing within 3 minutes. If this occurs, then replace client in bed and notify prescriber (Arnold & Raj, 2017). *Orthostatic hypotension increases fall risk (Windsor, 2016).*
• Apply thromboembolic deterrent (TED) stockings and/or elastic leg wraps and abdominal binders as prescribed; raise HOB slowly in small increments to sitting, have client move feet/legs up and down, and then stand slowly; avoid prolonged standing. *Movement enhances venous return, improving cardiac output and decreasing syncope.*
• Assess for cognitive, neuromuscular, and sensory deficits that will affect safety when walking (e.g., stroke, diabetic neuropathy, history of falls).
▲ Take pulse rate/rhythm, respiratory rate, and pulse oximetry before walking clients, and reassess within 5 minutes of walking, then ongoing as needed. If abnormal, have the client sit 5 minutes, then remeasure. If still abnormal, walk clients more slowly and with more help or for a shorter time, or notify physician. If uncontrolled diabetes/angina/arrhythmias/tachycardia (100 beats per minute or more) or resting systolic blood pressure (SBP) at or above 200 mm Hg or diastolic blood pressure (DBP) at or above 110 mm Hg occurs, do not initiate walking exercise. Refer to the care plan **Activity** intolerance.
• Assist clients to apply orthosis, immobilizers, splints, braces, and compression stockings as prescribed before walking.
• Eat frequent small, low-carbohydrate meals. *Low-carbohydrate meals help prevent postprandial hypotension.*
• Reinforce correct use of prescribed mobility devices, and remind clients of weight-bearing restrictions.
• Emphasize the importance of wearing properly fitting, low-heeled shoes with nonskid soles and socks/hose, and of seeking medical care for foot pain or problems

with abnormal toenails, corns, calluses, or diabetes. Refer to podiatric consult if indicated.
▲ Use a snug gait belt with handles and assistive devices while walking clients, as recommended by the physical therapist (PT). **EB:** *A gait belt should be applied before and during all ambulation and functional gait activities; it should be applied securely around the waist and held firmly. Do not rely on clothing for a safe grip (Collins, 2016).*
• Walk clients frequently with an appropriate number of people; have one team member state short, simple motor instructions. *Standing/weight-bearing benefits gut motility, spasticity, and respiratory/bowel/bladder function, and promotes muscle stretching (Collins, 2016).*
• Cue and manually guide clients with neglect as they walk. *Prevents clients bumping into objects/people.*
• Document the number of helpers, level of assistance (maximum, standby, etc.), type of assistance, and devices needed in communication tools (e.g., plan of care, client room signage, verbal report).

Special Considerations: Lower Extremity Amputation

• Teach clients to don stump socks, liner, immediate postoperative prostheses (IPOP), or traditional prosthesis correctly before standing/walking. **EB:** *IPOPs often reduce pain, healing time, and knee flexion contractures and promote early ambulation (Samuelsen et al, 2017). A thin nylon sheath prevents the limb from turning in the socket of the prosthesis. A stump sock establishes proper fit between limb and socket. The liner helps prevent pressure ulcers.*
• Teach clients the importance of avoiding prolonged hip and knee flexion. If contractures occur, they will affect prosthesis fit and function. **EB:** *Limit amount of time the client is permitted to sit to no more than 40 minutes of each hour. Ensure that when client sits, stands, or is recumbent, the hip and knee are in extension and periodic prone lying is recommended (Fairchild, 2013).*

Geriatric

▲ Assess for swaying, poor balance, weakness, and fear of falling while elders stand/walk. If present, implement fall protection precautions and refer for PT evaluation and recommendations.
▲ Review medications for polypharmacy (more than five drugs) and medications that increase the risk of falls, including sedatives, antidepressants, and drugs affecting the central nervous system (CNS). *Consult with pharmacist as part of polypharmacy assessment (Fritsch & Shelton, 2017).*
• Encourage Tai chi, PT, or other exercise for balance, gait, and strength training in group programs or at home.
• Recommend vision assessment and consideration for cataract removal if needed.

Home Care

• Establish a support system for emergency and contingency care (e.g., wearable medical alert alarm; notify local emergency medicine services [EMS] of potential need). *Impaired walking may be life-threatening during a crisis (e.g., fall, fire, orthostatic episode).*
• Assess for and modify any barriers to walking in the home environment.
▲ Refer to occupational therapist (OT)/PT for home assessment and evaluation for

home assessment for barriers, individualized strength, balance retraining, an exercise plan, and environmental modifications for safety (Peterson et al, 2016).
▲ Make referrals for home health services for support and assistance with activities of daily living (ADLs). An activity program pairing trained health care assistants with frail elders resulted in significant improvements in health outcomes and functional activity (Muramatsu et al, 2017).

Client/Family Teaching and Discharge Planning

• Teach clients to check ambulation devices weekly for cracks, loose nuts, or worn tips and to clean dust and dirt on tips.
• Teach diabetics that they are at risk for foot ulcers and teach them preventive interventions. See care plan Risk for ineffective peripheral **Tissue Perfusion.**
▲ Instruct clients at risk for osteoporosis or hip fracture to bear weight, walk, engage in resistance exercise (with appropriate adjustments for conditions), ensure good nutrition (especially adequate intake of calcium and vitamin D), drink milk, stop smoking, monitor alcohol intake, and consult a physician for appropriate medications. **EB:** *Supplementation with vitamin D_3 and calcium reduced the risk of hip fracture by 43%. The National Osteoporosis Foundation recommends daily calcium intake of at least 1200 mg with diet plus supplements, if needed, for postmenopausal women and men age 50 years and older and vitamin D_3 800 to 1000 IU per day (Cosman et al, 2014).*

Wandering

Olga F. Jarrín PhD, RN

NANDA-I

Definition
Meandering; aimless or repetitive locomotion that exposes the individual to harm; frequently incongruent with boundaries, limits, or obstacles.

Defining Characteristics
Continuous movement from place to place; eloping behavior; frequent movement from place to place; fretful locomotion; haphazard locomotion; hyperactivity; impaired ability to locate landmarks in a familiar setting; locomotion into unauthorized spaces; locomotion resulting in getting lost; locomotion that cannot be easily dissuaded; long periods of locomotion without an apparent destination; pacing; periods of locomotion interspersed with periods of nonlocomotion; persistent locomotion in search of something; scanning behavior; searching behavior; shadowing a caregiver's locomotion; trespassing

Related Factors
Alteration in sleep-wake cycle; desire to go home; overstimulating environment; physiological stage; separation from familiar environment

At-Risk Population
Premorbid behavior

Associated Condition
Alteration in cognitive functioning; cortical atrophy; psychological disorder; sedation

NOC (Nursing Outcomes Classification)

Suggested NOC Outcomes
Safe Wandering; Safe Home Environment; Safe Health Care Environment; Caregiver Emotional Health; Caregiver-Patient Relationship; Family Normalization: Autism Spectrum Disorder; Family Normalization: Dementia; Community Competence

Example NOC Outcome with Indicators
Safe Wandering as evidenced by the following indicators: Moves about without harming self or others/Sits for more than 5 minutes at a time/Paces a given route/Appears content in environment/Distracts easily/Can be redirected from unsafe activities. (Rate the outcome and indicators of **Safe Wandering:** 1 = never demonstrated, 2 = rarely demonstrated, 3 = sometimes demonstrated, 4 = often demonstrated, 5 = consistently demonstrated [see Section I].)

Client Outcomes

Client Will (Specify Time Frame)

- Maintain psychological well-being and reduce need to wander
- Reduce episodes of wandering in restricted areas/getting lost/elopement
- Maintain appropriate body weight
- Remain safe and free from falls
- Maintain physical activity and remain comfortable and free of pain

Caregiver Will (Specify Time Frame)

- Be able to explain interventions he or she can use to provide a safe environment for a care receiver who displays wandering behavior
- Develop strategies to reduce caregiver stress levels

NIC (Nursing Interventions Classification)

Suggested NIC Interventions
Dementia Management: Wandering; Anxiety Reduction; Area Restriction; Exercise Promotion; Environmental

Management; Family Mobilization; Family Support; Normalization Promotion

Example NIC Activities—Dementia Management: Wandering

Include family members in planning, providing, and evaluating care to the extent desired; Identify usual patterns of wandering behavior; Alert neighbors and police about the patient's wandering behavior; Provide a secure and safe place for wandering; Encourage physical activity during the daytime; Consider use of electronic devices to locate patient and monitor wandering.

Nursing Interventions and *Rationales*

- Assess for physical distress or unmet needs (e.g., hunger, thirst, pain/discomfort, elimination needs). **EBN:** *Behavioral signs of unmet need for bowel movement or urination include anxiety, taking off/putting on clothes, restlessness, attempting to go elsewhere, scratching skin, repeated behavior, and making strange sounds (Shih et al, 2015).*
- Assess for emotional or psychological distress, such as anxiety, fear, or feeling lost; considering the situated experience of the client. **EB:** *Restlessness and wandering may be understood as expressions of existential needs and feelings of anxiety, loneliness, and separation (Solomon & Lawlor, 2018).* **CEB:** *Triggers for wanderers include being placed in an unfamiliar environment, seeing a coat and hat, experiencing an argumentative or confrontational situation, a change in schedule or routine, and recent relocation to a care facility (Algase et al, 2009).*
- Assess and document the pattern, rhythm, and frequency of wandering over time. **EBN:** *Wandering should be assessed with one or more of the following scales: Cohen-Mansfield Agitation Inventory (CMAI), the Rating Scale for Aggressive Behavior in the Elderly (RAGE), the Neuropsychiatric Inventory (NPI), the Revised Algase Wandering Scale (RAWS), or its version for community (RAWS-CV) and long-term care settings (RAWS-LTC) (White & Montgomery, 2013; Graham, 2017).*
- Obtain a psychosocial history, including stress-coping behaviors. **CEB:** *Premorbid personality traits (e.g., history of a physically active job or leisure activities) and behavioral responses to stress (e.g., history of responding to stress with psychomotor activity) may reveal circumstances under which wandering will occur and can aid in interpreting both positive and negative meanings of wandering behavior (Nelson & Algase, 2007).*
- Observe the location and environmental conditions in which wandering is occurring and modify those that appear to induce wandering. **EBN:** *In a recent observational study, wanderers were less likely to wander from where the likelihood of social interaction was greater (i.e., activities room, dayroom, staff area); where the environment was more soothing (i.e., their own room); or where rooms had a designated purpose (e.g., dayrooms, the wanderer's own room, activities and staff areas), and wandering was less likely when lighting was low and variation in sound levels was small (Algase et al, 2010).*
- Assess the client's environment and advocate for appropriate modifications using a survey such as the Wayfinding Evidence-Based Checklist and Rating (WEBCAR) instrument (Benbow, 2013). **EBN:** *Residents with dementia depend on meaningful cues at decision points, such as distinctive and colorful architectural features, landmarks, and signs (Davis & Weisbeck, 2016).*
- Use a full-length mirror in front of exit doors to deter elopement. **EBN:** *Looking in the mirror raises patients' awareness regarding self-care and is effective in decreasing exiting by residents with severe cognitive impairment (Gu, 2015).*
- Use camouflage (a cloth panel or wall hanging) to cover door knobs or locks to prevent elopement (check fire safety code/policy first). **EBN:** *Covering door knobs and locks is an effective strategy to prevent elopement of residents with advanced dementia (Gu, 2015).*

• Change the floor pattern to create a subjective barrier (illusion of a step, hole, or pit) at exit door. **EBN:** *Impaired depth perception can cause a sharp contrast in the pattern of the floor (such as black stripes of tape or black floor tiles in front of door area) to create the illusion of steps, a hole, or pit, reducing elopement for some clients (Gu, 2015; Nelson & Algase, 2007).*
• Increase social interaction and offer structured activity and stress-reducing approaches, such as walking and exercise, music, massage, or a rocking chair. **EB:** *Wandering in restricted areas was reduced 50% to 80% by the use of nonpharmacological multimodal behavioral approaches and cognitive techniques such as problem-solving, behavioral rehearsal, and relaxation training (Nascimento Dourado & Laks, 2016).* **CEB:** *Montessori methods and activities using household materials and games can provide a rich social and caring environment to encourage socialization, meaningful activity, and diversion (Padilla, 2011).*
• Create a familiar, low-stress or home-like environment with familiar belongings and regular daily activities. **EB:** Environments with low stress or stimuli, home-like, or multi-sensory/transformed environments decrease wandering *(Gu, 2015; Lee et al, 2017).*
• Provide safe and secure surroundings that deter and detect accidental elopements, using perimeter control devices or electronic tracking systems (including radiofrequency identification [RFID] tags, *global positioning system* [GPS] locator, smart watch, or cell phone application). **CEB:** *A review of technology identified boundary alarms activated by wrist bands, alarms alerting caregivers of wandering behavior, and electronic monitoring and tracking systems, such as GPS, as effective in improving client safety (Gu, 2015).*
• When using electronic tracking technologies, an approach emphasizing relationships, respect, and the individual needs of patients and caretakers is best suited to finding solutions that both protect and empower. **EB:** *Balancing the ethical principles of beneficence and respect in treating cognitively impaired persons goes beyond the necessary step of evaluating decision-making capacity to include partnering with families, caretakers, and cognitively impaired individuals who wander in a collaborative coalition of care (Yang & Kels, 2017). Resistance to surveillance technology is associated with clients feeling stigmatized, missing the company of human supervision, and disliking being "watched" (Niemeijer et al, 2015).*
• Develop and update unit and facility procedures and staff education related to wandering. **EBN:** *A facility-based risk management approach should include identification of the wanderer, a wandering prevention program, an elopement response plan when patients are missing, and staff mobilization around the problem (Futrell, Devereaux Melillo, & Remington, 2016).*
• Role model person-centered care and provide appropriate supervision, support, and education of direct-care staff. **EBN:** *Positive work environments for staff are associated with lower prevalence of client escape, restlessness, and wandering behaviors compared with less positive work environments (Gu, 2015).*
    - ❍ Establish a caring, calm, friendly, and inviting climate in which relationships are valued.
    - ❍ Develop a culture of team spirit in which staff feel valued.
    - ❍ Support the development and maintenance of staff competencies in dementia care.
    - ❍ Encourage discussion of ethical issues and conflicts that arise during care.
• Help residents find their rooms by placing signs with their names and portraits of themselves at a younger age next to the doorways. **EB:** *External memory aids in the form of signs with the person's name and portrait photograph can help people with dementia*

navigate their environment (Jensen & Padilla, 2017).
• Provide a regularly scheduled and supervised exercise or walking program, particularly if wandering occurs excessively during the night or at times that are inconvenient in the setting *(Jensen & Padilla, 2017).*
• Keep a current client photograph on file to help with identification (see Client/Family Teaching and Discharge Planning section regarding community safe return programs, including AMBER and Silver alerts).
• Refer to the care plan for **Caregiver Role Strain**.
• For clients with dementia, also see care plan for Chronic **Confusion**.

Multicultural

• Assess for the effect of cultural assets, beliefs, life experiences, and values on the family's understanding of wandering behavior and caregiving. **CEB:** *Wandering behavior is prevalent among people with dementia, regardless of culture, but may be viewed as part of the normal process in some cultures and as abnormal behavior in others; cultural differences may buffer stress and caregiver burden (Nelson & Algase, 2007).*
• Assess client preferences for use of social services and family caregivers' availability and willingness to provide care. **EB:** *A qualitative study in North Carolina found that service providers assumed that Latino families did not want to use government services and that they preferred to care for their elders; however, Latino participants expressed the need to work and not depend on family members for caregiving and financial support (Larson et al, 2017).*

Client/Family Teaching and Discharge Planning

• Use a broad range of descriptions for the term "wandering" to enhance caregivers' understanding. **EB:** *In structured interviews, it was found that informal caregivers rarely used the term "wandering," which could lead to miscommunication with health care providers (Nelson & Algase, 2007).*
• Teach caregivers about AMBER and Silver Alert, Safe Return/Safely Home, and/or Project Lifesaver programs. **CEB:** *The Alzheimer's Association's Medic Alert + Safe Return program (called "Safely Home" in Canada), and Project Lifesaver International (PLI) have assisted in locating numerous persons who have eloped from their homes or other residential care settings (Petonito et al, 2013).* **EB:** *Similar to the AMBER alert emergency response system for missing children, the Silver alert system has been enacted in some but not all states (Gergerich & Davis, 2017).*
• Refer to supportive community and social services, such as a psychiatric home health nurse and companion or respite care, to assist with the impact of caregiving for the wandering client. **CEB:** *Caring for a person at high risk for wandering is associated with high caregiver stress (Nelson & Algase, 2007).*

Home Care

• The previously mentioned interventions may be adapted for home care use.
• Help the caregiver set up a plan to reduce and manage wandering behavior, including a plan of action to use if the client elopes:
    ❍ Assess the home environment for modifications that will protect the client and prevent elopement. **EB:** *Security devices are available to notify the caregiver of the client's movements, such as alarms at doors, bed alarms, and ongoing surveillance (Gu, 2015).*

- ❍ Assist the family to set up a plan of exercise for the client, including safe walking. **EB:** *Welfare concerns arise when freedom to walk outdoors is restricted; however, the risk of getting lost or injured must be minimized (Bantry White & Montgomery, 2016).*

• Provide information about therapy dog/assistance dog resources. **EB:** *Therapy dogs provide a calming presence and are trained to keep children with autism from straying by circling them and barking to alert family members (Burgoyne et al, 2014).*

Entries followed by *b*, *t*, or *f* indicate boxes, tables, or figures, respectively. **Boldface** entries indicate care plan titles. Page numbers in *italics* indicate care plan locations.

A

Abdominal distention, 18

Abdominal hysterectomy, 18, Hysterectomy

Abdominal pain, 18
- acute, 20

Abdominal surgery, 18, Small bowel resection
- aneurysm and, 25

Abdominal trauma, 18

Ablation, radiofrequency catheter, 18

Abortion
- induced, 18
- spontaneous, 18

Abruptio placentae, 18–19

Abscess
- anorectal, 26
- formation of, 19

Abuse
- child, 37–38
- drug, Substance abuse
- laxative, 72
- spouse, parent, or significant other, 19
- substance, 111

Accident prone, 19

Accidental hypothermia, 493–495

Achalasia, 19

Acid-base imbalances, 19

Acidosis
- lactic, 71
- metabolic, 19
- respiratory, 19

Acne, 19

Acquired immunodeficiency syndrome, 22

Acromegaly, 19

ACS, Acute coronary syndrome

Activity intolerance, 122*b*, *122–127*
- **risk for**, *127*

Activity planning, ineffective, *127–130*, 128*b*
risk for, *130–131*
Acute abdominal pain, 20
Acute alcohol intoxication, 20
Acute back pain, 20
Acute Confusion, 41, 241*b*–242*b*, *241–249*
risk for, *254*
Acute coronary syndrome (ACS), 20
Acute lymphocytic leukemia (ALL), 20
Acute pain, 676*b*–677*b*, *676–683*
Acute respiratory distress syndrome (ARDS), 27
Acute Substance Withdrawal syndrome, 20, 111, 880*b*–881*b*, *880–884*
risk for, 885–889, 885*b*
Acute tubular necrosis, Renal failure
Adams-Stokes syndrome, Dysrhythmia
Adaptive capacity, Intracranial, decreased, 581*b*–582*b*, *581–583*
Addiction, Alcoholism, Substance abuse
nicotine, 85
Addison's disease, 20
Adenoidectomy, 20
Adhesions, lysis of, Abdominal surgery
Adjustment
disorder, 21
impairment, 21, Health behavior, risk-prone
Adolescent
maturational issues in, 77
pregnancy, 21
sexuality of, 107
substance abuse, 111
terminally ill, 114
Adolescent Eating dynamics, ineffective, *351–353*, 352*b*
Adoption, 21
ADPIE acronym, 2, 3*f*
assessment in, 3
diagnosis in, 3–7
evaluation in, 10
implementation in, 10
planning in, 7–10, 9*t*
Adrenocortical insufficiency, 21
Adults
inflammatory bowel disease, 67
seizure disorders, 105
terminally ill, 114
Advance directives, 21
Adverse reaction to Iodinated Contrast Media, risk for, 275*b*–276*b*, *275–278*
Affective disorders, Bipolar disorder I; Depression; Dysthymic disorder; Major depressive disorder; Manic disorder; Seasonal affective disorder
Age-related macular degeneration, Macular degeneration

Aggressive behavior, 21
Aging, 21–22
Agitation, 22
Agoraphobia, 22
Agranulocytosis, 22
AIDS, 22
  dementia, 22, Dementia
Airborne precautions, 548
Airway clearance, ineffective, 131*b*–132*b*, *131–136*
Airway obstruction/secretions, 22, Airway clearance, ineffective
Alcohol withdrawal, 23
Alcoholism, 23
ALL, Acute lymphocytic leukemia
Allergies, 23
  contrast media, 276–277
  food, 54
  gluten, Celiac disease
  severe, 138
Allergy reaction, **Latex**, 72, 590*b*–591*b*, *590–593*
  risk for, *593–595*, 594*b*
Allergy reaction, risk for, *136–139*, 137*b*
Alopecia, 23
ALS, Amyotrophic lateral sclerosis
Alzheimer's disease, 23–24
AMD, Macular degeneration
Amenorrhea, 24
AMI, Myocardial infarction
Amnesia, 24
Amniocentesis, 24
Amnionitis, Chorioamnionitis
Amniotic membrane rupture, Premature rupture of membranes
Amputation, 24
Amyotrophic lateral sclerosis (ALS), 24
Anal fistula, Hemorrhoidectomy
Analgesia, patient-controlled, 90–91
Anaphylactic shock, 24
Anaphylaxis, 138
  prevention, 24, **Allergy reaction, risk for**
Anasarca, 24
Anemia, 24–25
  aplastic, 27
  pernicious, 92
  in pregnancy, 25
  sickle cell, 25, 107
Anencephaly, 84
Aneurysm

abdominal surgery, 25
cerebral, 37
dissecting, 48
Anger, 25
Angina, 25
Angiocardiography, Cardiac catheterization
Angioplasty, coronary, 25
Anomaly, fetal/newborn, 25–26
Anorectal abscess, 26
Anorexia, 26
Anorexia nervosa, 26
Anosmia, 26
Antepartum period, Pregnancy, normal; Prenatal care, normal
Anterior colporrhaphy, 26, Vaginal hysterectomy
Anterior repair, 26
Anticipatory grieving interventions, 435–436
Anticoagulant therapy, 26
safety guidelines for, 165–166
Antisocial personality disorder, 26, 109
Anuria, Renal failure
Anus, imperforate, 65
Anxiety, 140*b*–141*b*, *140–144*
Anxiety, death, 144*b*–145*b*, *144–147*
Anxiety disorder, 26–27
Aortic aneurysm repair, Abdominal surgery
Aortic valvular stenosis, Cardiac anomalies; Congenital heart disease
Aphasia, 27
Aplastic anemia, 27
Apnea
in infancy, 27
sleep, 108
obstructive, 86
Apneustic respirations, 27
Appendectomy, 27
Appendicitis, 27
Apprehension, 27
ARDS, Acute respiratory distress syndrome
Arrhythmia, Dysrhythmia
Arterial insufficiency, 27, 930
Arteriolar nephrosclerosis, 75
Arthritis, 27
rheumatoid, 107
juvenile, 70
Arthrocentesis, 27
Arthroplasty, 27

Arthroscopy, 27
Ascites, 27–28
Asperger's syndrome, 28
Asphyxia, birth, 28
Aspiration, risk for, 147*b*, *147–152*
Assault victim, 28
Assaultive client, 28
Assessment, in nursing process, 3
Asthma, 28
Ataxia, 28
Atelectasis, 28
Atherosclerosis, Cerebrovascular accident; Myocardial infarction; Peripheral vascular disease
Athlete's foot, 28, 115
Atresia
  biliary, 30
Atrial fibrillation, Dysrhythmia
Atrial septal defect, Cardiac anomalies; Congenital heart disease
Atrophy, muscular, 81
Attachment, impaired, risk for, 153*b*, *153–159*
Attention deficit disorder, 28–29
Autonomic Dysreflexia, *159–162*, 160*b*
  risk for, *163*
Autonomic hyperreflexia, Autonomic dysreflexia

B
Baby care, 29
Back pain
  acute, 20
  low, 74
Bacteremia, 29
Balanced energy field, **Imbalanced Energy field**
Barrel chest, 29
Bathing problems, 29
Bathing Self-Care deficit, 106, 781*b*–782*b*, *781–785*
Battered child syndrome, 29
Battered person, Abuse, spouse, parent, or significant other
Bed Mobility, impaired, 79, 615*b*–616*b*, *615–620*
Bed positioning, 618
Bed rest, prolonged, 29–30
Bedbugs, infestation, 29
Bedsores, 30
Bedwetting, 30
Behavior
  aggressive, 21
  defensive, 45

destructive, toward others, 46
hitting, 61
hostile, 61
infant, 66
manipulative, 76
self-destructive, 106
smoking, 108
violent, 120
wellness-seeking, 119

Behavior, Health, risk-prone, *447–451*, 448*b*

Behavior, Infant, disorganized, *540–545*, 541*b*–542*b*

risk for, *546*

Behavior, Infant, organized, readiness for enhanced, *545–546*

Bell's palsy, 30

Benign prostatic hypertrophy, 32

Bereavement, 30

Biliary atresia, 30

Biliary calculus, Cholelithiasis

Biliary obstruction, Jaundice

Bilirubin elevation, in neonate, **Hyperbilirubinemia, neonatal**

Biologicals, contamination with, 270

Biopsy, 30

bone marrow, 31
breast, 32
liver, 73

Bioterrorism, 30

Bipolar disorder I, 30

Birth

asphyxia, 28
breech, 33

Birth control, Contraceptive method

Bladder

cancer, 30
distention, 30
neurogenic, 84
training, 30–31, Toilet training
program, 532

Bleeding

disorder, 736–737
gastrointestinal, 57
prevention of, geriatric, 735–736
rectal, 101
tendency, 31
uterine, 119

Bleeding, risk for, *163–167*, 164*b*

Blepharoplasty, 31

Blindness, 31

Blood

disorder, 31
transfusion, 31

Blood glucose, low, Hypoglycemia
Blood Glucose level, risk for unstable, 430*b*–431*b*, *430–434*
Blood pressure, alteration of, Hypertension; Hypotension
Blood Pressure, Unstable, risk for, 110, 168*b*, *168–171*
Body
dysmorphic disorder, 31
image change, 31
temperature, altered, 31
Body Image, disturbed, *171–174*, 172*b*
Bone marrow biopsy, 31
Borderline personality disorder, 31
Boredom, 31
Botulism, 31
Bowel
movements, 74
obstruction, 31–32
resection, Abdominal surgery
sounds
absent or diminished, 32
hyperactive, 32
training, Toilet training
Bowel Incontinence, 31, 535*b*, *535–540*
BPH, Benign prostatic hypertrophy
Bradycardia, 32
Bradypnea, 32
Brain
injury, 32, Intracranial pressure, increased
traumatic, 113–114
surgery, Craniectomy; Craniotomy
tumor, 32
Braxton Hicks contractions, 32
Breast
biopsy, 32
cancer, 32
lumps, 33
mastectomy, 76
modified radical, 79
mastitis, 77
painful
engorgement, 88–89
sore nipples, 89
pumping, 33
self-examination, Self-breast examination
Breast Milk, insufficient, 33, *174–176*, 175*b*
Breastfeeding
effective, 33
sore nipples from, 109
Breastfeeding, ineffective, 33, *176–179*
Breastfeeding, interrupted, 33, *179–182*, 180*b*

Breastfeeding, readiness for enhanced, *182–185*, 183*b*
Breath sounds, decreased or absent, Atelectasis; Pneumothorax
Breathing pattern, alteration, 33
Breathing pattern, ineffective, 185*b*, *185–190*
Breech birth, 33
Bronchitis, 33
Bronchopulmonary dysplasia, 33
Bronchoscopy, 33
Bruits, carotid, 33
Bryant's traction, Casts; Traction
Buck's traction, Casts; Traction
Buerger's disease, Peripheral vascular disease
Bulimia, 33
Bullying, 33–34
Bunion, 41
Bunionectomy, 41
Burns, 41
  risk for, 41, **Thermal injury, risk for**
Bursitis, 41
Bypass graft, Coronary artery bypass grafting

C
CABG, Coronary artery bypass grafting
Cachexia, 34
Calcium alteration, Hypercalcemia; Hypocalcemia
Cancer, 34–35
  bladder, 30
  breast, 32
  liver, 73
  lung, 74
  pancreatic, 89
  skin, 108
Candidiasis, oral, 35
Capillary refill time, prolonged, 35, Shock, hypovolemic
Carbon monoxide poisoning, Smoke inhalation
Cardiac anomalies, 41, 115
Cardiac arrest, 35, Dysrhythmia, Myocardial infarction
Cardiac catheterization, 35
Cardiac disorders, in pregnancy, 35
Cardiac dysrhythmia, Dysrhythmia
Cardiac output, decreased, 35, *190–197*, 191*b*
  risk for, *198*
Cardiac tamponade, 36
Cardiac tissue perfusion, risk for decreased, 198*b*–199*b*, *198–203*
Cardiogenic shock, 107

Cardiovascular disease, activity intolerance due to, 124–125
Care plan, recording of, 8–10
Caregiver Role Strain, 36, *203–210*, 205*b*
  risk for, *210–211*
Carious teeth, Cavities, in teeth
Carotid endarterectomy, 36
Carpal tunnel syndrome, 36
Carpopedal spasm, Hypocalcemia
Casts, 36, 116
Cataract extraction, 36
Catatonic schizophrenia, 36
Catheter
  condom, 523
  urinary, 118
Catheterization
  cardiac, 35
  intermittent self-, 522
  urinary, 36
Cavities, in teeth, 36
Celiac disease, 36
Cellulitis, 36
  periorbital, 36
Central line insertion, 36–37
Cerebral aneurysm, 37, Craniectomy, Craniotomy, Intracranial pressure, increased, Subarachnoid hemorrhage
Cerebral palsy, 37
Cerebral perfusion, 37
Cerebral tissue perfusion, ineffective, risk for, *211–214*, 212*b*
Cerebrovascular accident (CVA), 44, 111
Cervicitis, 37
Cesarean delivery, 37
Chemical contamination, 270
Chemical dependence, Alcoholism; Substance abuse
Chemotherapy, 37
  nausea after, 642–643
  oral mucous membrane and, 660
Chest pain, 37
Chest tubes, 37
Cheyne-Stokes respiration, 37
Chicken pox, 41
Child Eating dynamics, Ineffective, 354*b*–355*b*, *354–357*
Childbearing problems, 38
Childbearing process, ineffective, *214–218*, 215*b*
  risk for, *224*
Childbearing process, readiness for enhanced, *218–224*, 219*b*
Childbirth, 38, Labor, normal
Children

abuse of, 37–38
for adoption, 21
with AIDS, 22
bladder training, Toilet training
bowel training, Toilet training
with chronic condition, 38
communicable disease in, 41
death of, 114
disturbed sleep pattern in, 108
eating dynamics, 50
failure to thrive, 53
gastroenteritis in, 56
gastroesophageal reflux in, 56
hospitalized, 61
inflammatory bowel disease in, 67
obesity in, 38
oral hygiene in, 330
premature, 97
renal failure in, acute/chronic, 102
safety of, 104
seizure disorders in, 105
sepsis in, 106
suspected child abuse and neglect (SCAN), 112
terminally ill, 114
Chills, 38
Chlamydia infection, Sexually transmitted disease
Chloasma, 39
Choking with eating, 39, **Aspiration, risk for**
Cholecystectomy, 39
Cholelithiasis, 39
Chorioamnionitis, 39
Chronic Confusion, 41, 249*b*–250*b*, *249–253*
Chronic functional Constipation, 39, *265–269*, 266*b*
risk for, *269*
Chronic low Self-Esteem, 106, 797*b*, *797–801*
risk for, *803–804*
Chronic lymphocytic leukemia, Leukemia
Chronic obstructive pulmonary disease (COPD), 42
Chronic pain, *683–691*, 684*b*
Chronic pain syndrome, *691–692*
Chronic renal failure, Renal failure
Chronic sorrow, *861–864*, 862*b*
Chvostek's sign, 39
Circumcision, 39
Cirrhosis, 39
Cleft lip, 39–40
Cleft palate, 39–40
Client, term, 2
Client violence, 973–976

Clinical reasoning, 3
Clotting disorder, 40
Cocaine baby, Neonatal abstinence syndrome
Codependency, 40
Cold, viral, 40
Colectomy, 40
Colitis, 40
Collaboration, 12
Collagen disease, 40
Colon, spastic, Irritable bowel syndrome
Colostomy, 40, 110
Colporrhaphy, anterior, 26, Vaginal hysterectomy
Coma, 40
  diabetic, 47
Comfort, impaired, 225*b*, *225–228*
Comfort, loss of, 40
Comfort, readiness for enhanced, 228*b*–229*b*, *228–233*
Communicable diseases, childhood, 41, Scabies
Communication, 41
  problems with, 41
Communication, readiness for enhanced, 233*b*–234*b*, *233–235*
Communication, verbal, impaired, 236*b*–237*b*, *236–241*
Community coping, 41
Community Coping, ineffective, *295–298*, 296*b*
Community Coping, readiness for enhanced, 278*b*, *278–281*
Community Health, deficient, 445*b*, *445–447*
Community health problems, 41
Companion animal, 41
Compartment syndrome, 41
Complicated Grieving, 441*b*, *441–444*
  risk for, *444*
Complicated Immigration Transition, risk for, 65, *510–513*, 511*b*
Compromised family Coping, *298–304*, 299*b*
Compromised host defenses, 553–554
Compromised Human Dignity, risk for, 478*b*, *478–480*
Compulsion, Obsessive-compulsive disorder
Computer literacy, 14
Conceptual mapping, 11, 11*f*–12*f*
Condom catheter, 523
Conduction disorders, cardiac, Dysrhythmia
Conflict, Decisional, *311–314*, 312*b*
Confusion, acute, 41, 241*b*–242*b*, *241–249*
  risk for, *254*
Confusion, chronic, 41, 249*b*–250*b*, *249–253*

Congenital heart disease, 41, 115
Conjunctivitis, 41
Consciousness, level of
altered, 41–42
decreased, **Confusion, acute; Confusion, chronic**
Constipation, 42, *254–260*, 255*b*
risk for, 42, 261
Constipation, chronic functional, 39, 42, *265–269*, 266*b*
risk for, *269*
Constipation, perceived, 42, 261*b*–262*b*, *261–265*
Contact precautions, 548–549
Contamination, 42, *270–274*, 271*b*
risk for, *274–275*
Continent ileostomy, 42
Contraceptive method, 42
Contrast Media, Iodinated, adverse reaction to, risk for, 275*b*–276*b*, *275–278*
Contrast-induced nephropathy (CIN), 276
Convulsions, 42
COPD, Chronic obstructive pulmonary disease
Coping, 42
problems with, 42
Coping, community, ineffective, *295–298*, 296*b*
Coping, community, readiness for enhanced, 278*b*, *278–281*
Coping, defensive, 281*b*–282*b*, *281–284*
Coping, family, compromised, *298–304*, 299*b*
Coping, family, disabled, 304*b*–305*b*, *304–306*
Coping, family, readiness for enhanced, *306–309*, 307*b*
Coping, ineffective, *284–291*, 285*b*
Coping, readiness for enhanced, 291*b*–292*b*, *291–295*, 307*b*
Corneal injury, 42
Corneal Injury, risk for, *562–565*, 563*b*
Corneal reflex, absent, 43
Corneal transplant, 43
Coronary artery bypass grafting (CABG), 43
Costovertebral angle tenderness, Kidney, stone; Pyelonephritis
Cough
ineffective, 43
whooping, 92
Coughing with eating, 39
Crackles in lungs
coarse, 43
fine, 43
Craniectomy, 43
Craniotomy, 43
Crepitation, subcutaneous, Pneumothorax
Crisis, 43

situational, 108
Critical incident stress debriefing, 720–721
Crohn's disease, 43
Croup, 43, 102
Cryosurgery for retinal detachment, Retinal detachment
Cultural awareness, 12
Cushing's syndrome, 43
Cuts (wounds), Lacerations
CVA, Cerebrovascular accident
Cyanosis
central, 44
peripheral, 44
Cystic fibrosis, 44
Cystitis, 44
interstitial, 68
Cystocele, 44
Cystoscopy, 44

D

D&C, Dilation and curettage
Deafness, 45
Death, 45
of child, 114
of loved one, grieving interventions in, 436–437
oncoming, 45
Death Anxiety, 144*b*–145*b*, *144–147*
Death syndrome, Infant, Sudden, 107–108, 111
risk for, *889–891*, 890*b*
Debriefing, critical incident stress, 720–721
Decisional Conflict, *311–314*, 312*b*
Decision-Making, impaired emancipated, *314–318*, 315*b*
risk for, 321*b*–322*b*, *321–324*
Decision-Making, readiness for enhanced, 309*b*, *309–311*
Decision-Making, readiness for enhanced emancipated, 315*b*, *318–321*, 319*b*
Decisions, difficulty making, 45
Decreased Cardiac output, 35, *190–197*, 191*b*
risk for, *198*
Decreased Cardiac tissue perfusion, risk for, 198*b*–199*b*, *198–203*
Decreased Diversional activity engagement, *346–351*, 347*b*
Decreased Intracranial adaptive capacity, 581*b*–582*b*, *581–583*
Decubitus ulcer, Pressure ulcer
Deep vein thrombosis (DVT), 49, 115
prevention of, 708
Defensive behavior, 45
Defensive Coping, 281*b*–282*b*, *281–284*
Deficient community Health, 445*b*, *445–447*

Deficient Fluid volume, 54, 406*b*–407*b*, *406–412*
risk for, *417*
Deficient Knowledge, 72, 584*b*, *584–587*
Defining characteristics phrase, 4, 6
Dehiscence
abdominal, 45
wound, 120
Dehydration, 45
Delayed Development, risk for, 334*b*, *334–336*
Delayed Surgical recovery, 906*b*–907*b*, *906–910*
risk for, *910–911*
Delirium, 45
Delirium tremens, Alcohol withdrawal
Delivery, cesarean, 37, Labor, normal
Delusions, 45
Dementia, 45–46
Denial, ineffective, *324–327*, 325*b*
Denial of health status, 46
Dental caries, 46
Dentition, impaired, *327–333*, 328*b*
Depressed immune function, 736
Depression, 46
Deprivation, sleep, 108, *843–846*, 844*b*
Dermatitis, 46
Despondency, 46
Destructive behavior, toward others, 46
Development, delayed, risk for, 334*b*, *334–336*
Developmental concerns, 46
Diabetes insipidus, 46
Diabetes mellitus, 46–47
juvenile, 47
Diabetic coma, 47
Diabetic ketoacidosis, 70
Diabetic neuropathy, Neuropathy, peripheral
Diabetic retinopathy, 47
Diagnosis, nursing, 3–7
application and examples of, 5
case study on, 5–6
formulation, with related factors and defining characteristics, 4
types of, 4–5
Diagnostic categories, wellness-oriented, D-1–D-3
Dialysis, Hemodialysis; Peritoneal dialysis
Diaphragmatic hernia, 102, Hiatal hernia
Diarrhea, 47, 336*b*–337*b*, *336–341*
Diarrhea, traveler's, 114

DIC, Disseminated intravascular coagulation
Digitalis toxicity, 47
Dignity, Human, risk for compromised, 478*b*, *478–480*
Dignity, loss of, 47
Dilation and curettage (D&C), 47
Dirty body, for prolonged period, 47
Disabled family Coping, 304*b*–305*b*, *304–306*
Discharge planning, 47–48
Discomforts, of pregnancy, 48
Disk
  excision, Laminectomy
  herniated, Low back pain
  ruptured, Low back pain
Dislocation, of joint, 48
Disorganized Infant behavior, *540–545*, 541*b*–542*b*
  risk for, *546*
Dissecting aneurysm, 48
Disseminated intravascular coagulation (DIC), 47
Dissociative identity disorder, 48, 81
Distress, 48
  fetal, 54
Distress, Moral, *630–634*, 631*b*
Distress, spiritual, 109, 865*b*–866*b*, *865–868*
  risk for, *868–869*
Disturbed Body Image, *171–174*, 172*b*
Disturbed Maternal-Fetal dyad, risk for, 605*b*–606*b*, *605–608*
Disturbed personal Identity, 503*b*–504*b*, *503–510*
  risk for, *510*
Disturbed Sleep pattern, 108, *850–854*, 851*b*
Disuse syndrome, potential to develop, 48
Disuse syndrome, risk for, 342*b*, *342–346*
Diversional activity engagement, decreased, *346–351*, 347*b*
Diversional activity engagement, lack of, 48
Diverticulitis, 48
Dizziness, 48
Documentation, of care plan, 8–10
Domestic violence, 48, 976–978
Donor, kidney transplantation, 70
Down syndrome, Children, with chronic condition; Intellectual disability
Dress self, inability to, 48
Dressing Self-Care deficit, 106, 785*b*–786*b*, *785–787*
Dribbling, of urine, 48–49
Drooling, 49
Droplet precautions, 548
Dropout, from school, 49

Drug abuse, Substance abuse
Drug withdrawal, Acute substance withdrawal syndrome
Dry eye, 49
Dry Eye, risk for, *365–368*, 366*b*
Dry eye syndrome, 70
Dry mouth, 49
Dry Mouth, risk for, 634*b*, *634–639*
Dry stool, 110
Duodenal ulcer, 117
DVT, Deep vein thrombosis
Dying client, Terminally ill adolescent; Terminally ill adult; Terminally ill child
Dysfunctional eating pattern, 49
Dysfunctional Family processes, 23, *377–381*, 378*b*
Dysfunctional family unit, Family, problems
Dysfunctional Gastrointestinal motility, *426–429*, 427*b*
  risk for, *426*
Dysfunctional Ventilatory weaning response, 49, *966–972*, 967*b*
Dysmenorrhea, 49
Dyspareunia, 49
Dyspepsia, 49
Dysphagia, 49, **Impaired Swallowing**
Dysphasia, 49
Dysplasia, bronchopulmonary, 33
Dyspnea, 49
  paroxysmal nocturnal, 94
  physiological, 186–189
  psychological, 186
Dysreflexia, Autonomic, *159–162*, 160*b*
Dysrhythmia, 49–50, 113
Dystocia, 119

E

Ear surgery, 50
Earache, 50
Eating dynamics
  adolescents, 50
  child, 50
  infant, Feeding dynamics, infant
Eating dynamics, adolescent, ineffective, *351–353*, 352*b*
Eating dynamics, child, ineffective, 354*b*–355*b*, *354–357*
Eclampsia, 50
ECMO, Extracorporeal membrane oxygenator
ECT, Electroconvulsive therapy
Ectopic pregnancy, 50–51
Eczema, 51

ED, Erectile dysfunction
Edema, 51
Elder abuse, Abuse, spouse, parent, or significant other
Elderly, Aging; Frail elderly syndrome
Electroconvulsive therapy (ECT), 50
Electrolyte imbalance, 51
Electrolyte imbalance, risk for, 360*b*, *360–363*
Elimination, Urinary, impaired, 118, *944–948*, 945*b*
Emaciated person, 51
Emancipated decision-making, impaired, 51
Embolectomy, 51
Embolism
in leg or arm, 51
pulmonary, 99
prevention of, 708
Emesis, 51, Nausea, Vomiting
Emotional Control, labile, 368*b*–369*b*, *368–371*
Emotional problems, Coping, problems with
Empathy, 51
Emphysema, Chronic obstructive pulmonary disease
Emptiness, 51
Encephalitis, 77–78
Endocardial cushion defect, 51
Endocarditis, 51–52
Endometriosis, 52
Endometritis, 52
Energy field, imbalanced, 363*b*, *363–365*
Enhanced health Literacy, **readiness**, *595–598*, 596*b*
Enhanced relationship, **readiness for**, *742–745*, 743*b*
Enhanced Religiosity, **readiness for**, *748–750*
Enhanced Resilience, **readiness for**, 759*b*, *759–761*
Enteral feedings, 148–150
Enuresis, 52
Environmental interpretation problems, Confusion, chronic
Epididymitis, 52
Epiglottitis, 52, 102
Epilepsy, 52, 105
Episiotomy, 52
Epistaxis, 52
Epstein-Barr virus, Mononucleosis
Erectile dysfunction (ED), 51–52
Erythema multiforme, 116
Escherichia coli infection, 52
Esophageal varices, 52

Esophagitis, 52
Ethical dilemmas, 80
Etiology, in nursing diagnosis, 4
Evaluation, in nursing process, 10
Evidence-based nursing, 13
Evidence-based practice (EBP), 13
Evisceration, 120, Dehiscence, abdominal
Excess Fluid volume, 54, *412–416*, 413*b*
Exercise, bed mobility and, 618
Exhaustion, 52
Exposure to hot or cold environment, 52–53
External fixation, 53
Extracorporeal membrane oxygenator (ECMO), 50
Extremities
    pallor of, 89
    rubor of, 108
Eye, dry, 49, 70
Eye, dry, risk for, *365–368*, 366*b*
Eye discomfort, 53
Eye surgery, 53
    laser-assisted in situ keratomileusis, 72

F
Failure to thrive, child, 53
Falls, risk for, 53, 371*b*–372*b*, *371–376*
Family
    problems, 53
    process, 53
Family Coping, compromised, *298–304*, 299*b*
Family Coping, disabled, 304*b*–305*b*, *304–306*
Family Coping, readiness for enhanced, *306–309*, 307*b*
Family Health management, ineffective, 461*b*–462*b*, *461–464*
Family processes, dysfunctional, 23, *377–381*, 378*b*
Family processes, enhanced, readiness for, 384*b*–385*b*, *384–387*
Family processes, interrupted, *381–384*, 382*b*
Fatigue, 53, 387*b*–388*b*, *387–392*
Fear, 53, *392–396*, 393*b*
Febrile seizures, 105, Seizure disorders, childhood
Fecal impaction, Impaction of stool
Fecal incontinence, 53
Feeding dynamics, infant, 53
Feeding dynamics, infant, ineffective, *357–359*, 358*b*
Feeding pattern, infant, ineffective, 66, 396*b*–397*b*, *396–399*
Feeding problems, newborn, 54
Feeding Self-Care deficit, 106, *787–791*, 788*b*

Female genital mutilation, 54
Female genital mutilation, risk for, 399*b*–400*b*, *399–402*
Femoral popliteal bypass, 54
Femur, fracture of, 87
Fetal alcohol syndrome, Neonatal abstinence syndrome
Fetal distress/nonreassuring fetal heart rate pattern, 54
Fetal dyad, disturbed Maternal, risk for, 605*b*–606*b*, *605–608*
Fever, 54, 920–921, **Hyperthermia;**, **Ineffective Thermoregulation**
  treating, 922
Fibrocytic breast disease, Breast, lumps
Filthy home environment, 54
Financial crisis, in home environment, 54
First aid, for allergic reaction, 137–138
Fistula
  anal, Hemorrhoidectomy
  tracheoesophageal, 116
Fistulectomy, Hemorrhoidectomy
Fixation, internal, open reduction of fracture with, 87
Flail chest, 54
Flashbacks, 54
Flat affect, 54
Fluid volume, deficient, 54, 406*b*–407*b*, *406–412*
Fluid volume, excess, 54, *412–416*, 413*b*
Fluid volume, imbalanced, risk for, 54, 402*b*–403*b*, *402–406*
Food allergies, 54
Food intolerance, 57
Food safety, 471
Foodborne illness, 57
Foreign body aspiration, 57
Formula feeding, of infant, 57
Fracture, 57
  femur, 87
  hip, 60–61
  open reduction of, with internal fixation, 87
  rib, 107
Frail Elderly syndrome, 57, *417–420*, 418*b*
  risk for, *420*
Frequency of urination, 58
Friction rub
  pericardial, 91
  pleural, 94
Friendship, 58
Frostbite, 58
Frothy sputum, Seizure disorders
Functional urinary Incontinence, 516*b*–517*b*, *516–519*
Fusion, lumbar, 58

G

Gag reflex, depressed or absent, 55

Gallop rhythm, 55

Gallstones, Cholelithiasis

Gang member, 56

Gangrene, 56

Gas exchange, **impaired**, 56, *420–425*, 421*b*

Gastric motility, slowed, 427–428

Gastric ulcer, 117

Gastritis, 56

Gastroenteritis, 56

  child, 56

Gastroesophageal reflux (GERD), 56

  child, 56

Gastrointestinal bleeding (GI bleed), 57

Gastrointestinal motility, **dysfunctional**, *426–429*, 427*b*

  risk for, *426*

Gastrointestinal motility, increased, 428–429

Gastrointestinal surgery, 56

Gastroschisis, 56

Gastrostomy, 56

Gender dysphoria, 56–57

Genital herpes, Herpes simplex II

Genital warts, Sexually transmitted disease

GERD, Gastroesophageal reflux

Gestational diabetes, 57

Gingivitis, 57

Glaucoma, 57

Glomerulonephritis, 57

Glucose level, blood, risk for unstable, 430*b*–431*b*, *430–434*

Gluten allergy, Celiac disease

Gonorrhea, 57

Gout, 57

Grand mal seizure, 57

Grandchildren, grandparents raising, 57

Grandiosity, 57

Grandparents, raising grandchildren, 57

Graves' disease, Hyperthyroidism

Grieving, 57, *434–440*, 435*b*

Grieving, complicated, 60, 441*b*, *441–444*

  risk for, *444*

Groom, self, inability to, 60

Growth and development lag, Failure to thrive, child

Guillain-Barré syndrome, 60–61

Guilt, 61

H

Hair loss, 58
Halitosis, 58
Hallucinations, 58
Hard stool, 110
Head injury, 58
Headache, 58
Health, community, deficient, 445*b*, *445–447*
Health behavior, risk-prone, 58, *447–451*, 448*b*
Health maintenance, ineffective, 464*b*–465*b*, *464–468*
Health maintenance problems, 58
Health management, Enhanced, readiness for, 457*b*, *457–461*
Health management, Family, ineffective, 461*b*–462*b*, *461–464*
Health management, ineffective, 452*b*, *452–457*
Health promotion nursing diagnosis, 4–5
Health-seeking person, 58
Hearing impairment, 58
Heart
  congenital disease, 41, 115
  surgery, Coronary artery bypass grafting; Open heart surgery
Heart attack, Myocardial infarction
Heart failure, 59, **Decreased Cardiac output**
Heart rate pattern, fetal, nonreassuring, 54
Heartburn, 58–59
Heat stroke, 59, 488–489
Hematemesis, Gastrointestinal bleeding
Hematuria, Kidney, stone; Urinary tract infection
Hemianopia, 59
Hemiplegia, 59
Hemodialysis, 59
Hemodynamic monitoring, 59
Hemolytic uremic syndrome, 59
Hemophilia, 59–60
Hemoptysis, 60
Hemorrhage, 60, Bleeding
  gastrointestinal, Gastrointestinal bleeding
  postpartum, 95, 119
  subarachnoid, 111
Hemorrhoidectomy, 60
Hemorrhoids, 60
Hemothorax, 60
Hepatitis, 60
Hernia

diaphragmatic, 102
hiatal, 60
repair, Inguinal hernia repair
Herniated disk, Low back pain
Herniorrhaphy, Inguinal hernia repair
Herpes
genital, Herpes simplex II
in pregnancy, 60
Herpes simplex I, 60
Herpes simplex II, 60
Herpes zoster, Shingles
HHNS, Hyperosmolar hyperglycemic nonketotic syndrome
Hiatal hernia, 60
Hip
fracture, 60–61
total replacement, 27
Hirschsprung's disease, 61
Hirsutism, 61
Hitting behavior, 61

Hypocalcemia, 63
Hypoglycemia, 63
Hypokalemia, 63
Hypomagnesemia, 63
Hypomania, 63
Hyponatremia, 63, 109
Hypoplastic left lung, Congenital heart disease
Hypotension, 63–64
  orthostatic, Dizziness
Hypothermia, 64, 921
  prevention of, 921
Hypothermia, 492*b*–493*b*, *492–498*
  risk for, *498–499*
Hypothermia, Perioperative, risk for, 499*b*–500*b*, *499–503*
Hypothyroidism, 64
Hypovolemic shock, 107
Hypoxia, 64
Hysterectomy, 64
  vaginal, 118

I

IBS, Irritable bowel syndrome
ICD, Implantable cardioverter/defibrillator
Identity, personal, disturbed, 503*b*–504*b*, *503–510*
  risk for, *510*
Identity disturbance/problems, 64
Idiopathic thrombocytopenic purpura (ITP), 64, 68, 115
Ileal conduit, 64, 118
Ileostomy, 64, 110
Ileus, 65
  paralytic, 90

postoperative, 428
Imbalanced Energy field, 363*b*, *363–365*
Imbalanced Fluid volume, risk for, 54, 402*b*–403*b*, *402–406*
Imbalanced Nutrition: less than body requirements, *651–657*, 652*b*
Immigration Transition, Complicated, risk for, 65, *510–513*, 511*b*
Immobility, 65
Immunization, 65
Immunosuppression, 65
Impaction of stool, 65
Impaired Attachment, risk for, 153*b*, *153–159*
Impaired bed Mobility, 79, 615*b*–616*b*, *615–620*
Impaired Comfort, 225*b*, *225–228*
Impaired Dentition, *327–333*, 328*b*
Impaired emancipated Decision-Making, *314–318*, 315*b*
risk for, 321*b*–322*b*, *321–324*
Impaired gas exchange, 56, *420–425*, 421*b*
Impaired Home maintenance, *468–471*, 469*b*
Impaired Liver function, risk for, 598*b*, *598–601*
Impaired Memory, 608*b*–609*b*, *608–611*
Impaired Mood regulation, 628*b*, *628–630*
Impaired Oral Mucous Membrane integrity, *657–662*, 658*b*
risk for, *663*
Impaired Parenting, 90, *695–699*, 696*b*–697*b*
risk for, 90, *702*
Impaired physical Mobility, 79, 620*b*–621*b*, *620–624*
Impaired Religiosity, *745–748*, 746*b*
risk for, *750*
Impaired Resilience, 756*b*–757*b*, *756–759*
risk for, 761*b*–762*b*, *761–763*
Impaired Sitting, 65, 108, *832–835*, 833*b*
Impaired Skin integrity, 836*b*–837*b*, *836–840*
risk for, 840*b*–841*b*, *840–843*
Impaired Social interaction, 108, 854*b*–855*b*, *854–857*
Impaired spontaneous Ventilation, *960–966*, 961*b*
Impaired Standing, 65, 873*b*–874*b*, *873–875*
Impaired Swallowing, *911–916*, 912*b*
Impaired Tissue integrity, 924*b*–925*b*, *924–928*
risk for, *928–929*
Impaired Transfer ability, 933*b*–934*b*, *933–938*
Impaired Urinary elimination, 118, *944–948*, 945*b*
Impaired verbal Communication, 236*b*–237*b*, *236–241*
Impaired Walking, 119, 983*b*–984*b*, *983–986*
Impaired wheelchair Mobility, 79, *624–628*, 625*b*
Imperforate anus, 65
Impetigo, 41, 65

Implantable cardioverter/defibrillator (ICD), 64

recipient, 70
tumor, Wilms' tumor
Kissing disease, Mononucleosis
Knee replacement, Total joint replacement
Knowledge, 72
Knowledge, deficient, 72, 584*b*, *584–587*
Knowledge, enhanced, readiness for, 587*b*–588*b*, *587–589*
Kock pouch, 42
Korsakoff's syndrome, 72

L
Label, nursing diagnosis, 4
Labile Emotional Control, 368*b*–369*b*, *368–371*
Labor, **Ineffective Childbearing process**
induction of, 66
normal, 71
preterm, 98, 112
suppression of, Preterm labor
uterine atony in, Dystocia
Labor pain, 71, 692*b*–693*b*, *692–695*
Labyrinthitis, 71
Lacerations, 71
Lactation, Breastfeeding
Lactic acidosis, 71
Lactose intolerance, 71
Laminectomy, 71–72
Language impairment, Speech, disorders
Laparoscopy, 72
Laparotomy, Abdominal surgery
Large bowel resection, Abdominal surgery
Laryngectomy, 72
Laser surgery, 72
Laser-assisted in situ keratomileusis, 72
LASIK eye surgery, 72
Latex Allergy reaction, 72, 590*b*–591*b*, *590–593*
risk for, *593–595*, 594*b*
Laxative abuse, 72
Lead poisoning, 72
Left heart catheterization, Cardiac catheterization
Legionnaires' disease, 72
Lens implant, Cataract extraction
Lethargy, 72–73
Leukemia, 73
Leukopenia, 73

Lice, 41, 73
Lifestyle, sedentary, 73, *770b–771b*, *770–774*
Lightheadedness, Dizziness; Syncope
Limb reattachment procedures, 73
Lip, cleft, 39–40
Liposuction, 73
Listlessness, 72–73
Lithotripsy, 73
Liver
biopsy of, 73
cancer of, 73
function of, 73
transplant of, 73–74
Liver function, impaired, risk for, 598*b*, *598–601*
Living will, 74
Lobectomy, Thoracotomy
Loneliness, 74
Loneliness, risk for, *601–605*, 602*b*
Loose stools, 74
Loss of bladder control, Incontinence, urinary
Loss of bowel control, Incontinence, stool
Lou Gehrig's disease, Amyotrophic lateral sclerosis
Low back pain, 74
Low blood glucose, Hypoglycemia
Low blood pressure, Hypotension
Low Self-Esteem, chronic, 106, 797*b*, *797–801*
risk for, *803–804*
Low Self-Esteem, situational, 106, *801–803*
Lower GI bleeding, Gastrointestinal bleeding
Lumbar puncture, 74
Lumpectomy, 74
Lungs
cancer of, 74
crackles in
coarse, 43
fine, 43
hypoplastic left, Congenital heart disease
surgery, Thoracotomy
Lupus erythematosus, 74
Lyme disease, 74–75
Lymphedema, 80
Lymphocytic leukemia
acute, 20
chronic, Leukemia
Lymphoma, Cancer

M

Macular degeneration, 75
Magnetic resonance imaging (MRI), 80
Major depressive disorder, 46, Sadness
Malabsorption syndrome, 75
Maladaptive behavior, Crisis; Post-trauma syndrome; Suicide attempt
Malaise, Fatigue
Malaria, 75
Male infertility, Erectile dysfunction
Male rape, 740
Malignancy, Cancer
Malignant hypertension, 75
Malignant hyperthermia, 75–76
Malnutrition, 76
Mammography, 76
Manic disorder, bipolar I, 76
Manipulative behavior, 76
Marfan syndrome, 76
Mastectomy, 76
  modified radical, 79
Mastitis, 77
Maternal infection, 77
Maternal-Fetal dyad, disturbed, risk for, 605*b*–606*b*, *605–608*
Maturational issues, adolescent, 77
Maze III procedure, Dysrhythmia; Open heart surgery
Measles, 41
Meconium
  aspiration, 102
  delayed, 77
Medical marijuana, 77
Medication safety, 713–714
Melanoma, 77
Melena, 77
Memory, impaired, 608*b*–609*b*, *608–611*
Memory deficit, 77
Ménière's disease, 77
Meningitis, 77–78
Meningocele, 84, Spina bifida
Menopause, 78
Menorrhagia, 78
Mental illness, 78
Mental status, altered, Confusion; Memory deficit
Metabolic acidosis, 19
Metabolic alkalosis, 78

Metabolic imbalance syndrome, 78
Metabolic Imbalance syndrome, risk for, *611–615*, 612*b*
Metastasis, Cancer
Methicillin-resistant *Staphylococcus aureus* (MRSA), 80
MIDCAB, Minimally invasive direct coronary artery bypass
Midlife crisis, 79
Migraine headache, 79
Military families, personnel, 79
Milk intolerance, Lactose intolerance
Minimally invasive direct coronary artery bypass (MIDCAB), 79
Miscarriage, Pregnancy, loss
Mitral stenosis, 79
Mitral valve prolapse, 79
Mobility, bed, impaired, 79, 615*b*–616*b*, *615–620*
Mobility, physical, impaired, 79, 620*b*–621*b*, *620–624*
Mobility, wheelchair, impaired, 79, *624–628*, 625*b*
Modified radical mastectomy, 79
Mononucleosis, 79–80
Mood disorders, 80
Mood regulation, impaired, 628*b*, *628–630*
Moon face, 80
Moral dilemmas, 80
Moral Distress, *630–634*, 631*b*
Morning sickness, Hyperemesis gravidarum; Pregnancy, normal
Motility, Gastrointestinal, dysfunctional, *426–429*, 427*b*
  risk for, *426*
Motility, Gastrointestinal, increased, 428–429
Motion sickness, Labyrinthitis
Motivational interviewing, 12
Motor vehicle crash, Fracture; Head injury; Injury; Pneumothorax
Mottling, of peripheral skin, 80
Mourning, Grieving
Mouth, dry, risk for, 634*b*, *634–639*
Mouth lesions, **Mucous Membrane integrity, Oral, impaired**
MRSA, Methicillin-resistant *Staphylococcus aureus*
Mucocutaneous lymph node syndrome, Kawasaki disease
Mucous Membrane integrity, Oral, impaired, *657–662*, 658*b*
  risk for, *663*
Multi-infarct dementia, Dementia
Multiple gestations, 80–81
Multiple personality disorder, 81
Multiple sclerosis, 81
Mumps, 41
Murmurs, 81

Muscular atrophy/weakness, 81
Muscular dystrophy, 81
Mycoplasma pneumonia, Pneumonia
Myelomeningocele, 84, Spina bifida
Myocardial infarction, 78–79, 110
Myxedema, Hypothyroidism

N

Nail beds, cyanosis of, 44
Narcissistic personality disorder, 82
Narcolepsy, 82
Narcotic use, Opioid use
Nasogastric suction, 82
Nausea, 82, *639–644*, 640*b*
Near-drowning, 82–83
Nearsightedness, 83
  corneal surgery, LASIK eye surgery
Neck vein distention, 83
Necrosis
  acute tubular, Renal failure
  kidney failure, Renal failure
Necrotizing enterocolitis, 83
Negative feelings about self, 83
Neglect, child, Children, abuse of; Failure to thrive
Neglect, Self, *814–817*, 815*b*
Neglect, unilateral, 942*b*–943*b*, *942–944*
Neglectful care, of family member, 83
Neonatal abstinence syndrome, 83, *644–647*, 645*b*
Neonatal hyperbilirubinemia, 84, *480–485*, 481*b*–482*b*
  risk for, *485–486*
Neonate, 84
  bilirubin elevation in, **Hyperbilirubinemia, neonatal**
  jaundice, 69
  respiratory conditions of, 102
Neoplasm, 84
Nephrectomy, 84
Nephropathy, contrast-induced, 276
Nephrostomy, percutaneous, 84
Nephrotic syndrome, 84
Neural tube defects, 84, Spina bifida
Neuralgia, *See* Trigeminal neuralgia
Neuritis, 84
Neurogenic bladder, 84
Neuroleptic malignant syndrome, 489–490
Neurologic disorders, 84–85

Neuropathy, peripheral, 84–85, Sciatica
Neurosugery, Craniectomy; Craniotomy
Neurovascular dysfunction, peripheral, risk for, 707*b*, *707–708*
Newborn
  normal, 85
  postmature, 85
  small for gestational age, 85
Nicotine addiction, 85
NIDDM, Non-insulin-dependent diabetes mellitus
Nightmares, 85
Nipple soreness, 85
Nocturia, 85–86
Nocturnal myoclonus, Restless leg syndrome; Stress
Nocturnal paroxysmal dyspnea, Paroxysmal nocturnal dyspnea
Non-insulin-dependent diabetes mellitus, 85
Non-ST-elevation myocardial infarction, Myocardial infarction
NPH, Normal pressure hydrocephalus
Nursing, Breastfeeding, effective; Breastfeeding, ineffective; Breastfeeding, interrupted
Nursing, evidence-based, 13
Nursing diagnosis, 3–7
  application and examples of, 5
  case study on, 5–6
  formulation, with related factors and defining characteristics, 4
  types of, 4–5
Nursing diagnosis label, 4
Nursing Interventions Classification (NIC), 8
Nursing Outcomes Classification (NOC), 8, 9*t*
Nursing process, 2, 3*f*
  advanced concepts of, 11–15
  assessment in, 3
  conceptual mapping and, 11, 11*f*–12*f*
  diagnosis in, 3–7
  evaluation in, 10
  implementation in, 10
  planning in, 7–10, 9*t*
Nutrition, Malnutrition
  total parenteral, 116
Nutrition, imbalanced: less than body requirements, *651–657*, 652*b*
Nutrition, readiness for enhanced, 648*b*, *648–651*

O

Obesity, 86, *663–667*, 664*b*
Objective information, in assessment, 3
Obsessive-compulsive disorder, 86
Obstruction
  airway, 22
  biliary, Jaundice

bowel, 31–32
Obstructive sleep apnea, 86
Occupational injury, 86
Occupational Injury, risk for, 565*b*–566*b*, *565–574*
OCD, Obsessive-compulsive disorder
ODD, Oppositional defiant disorder
Off-pump coronary artery bypass (OPCAB), Angioplasty, coronary; Coronary artery bypass grafting
Older adult, Aging
Oliguria, 87
Omphalocele, 56
Onychomycosis, 115
Oophorectomy, 87
Open heart surgery, 87
Open reduction of fracture, with internal fixation, 87
Opioid use, 87
Opportunistic infection, 87
Oppositional defiant disorder, 86–87
Oral hygiene, 330
Oral Mucous Membrane integrity, impaired, 87, *657–662*, 658*b*
risk for, *663*
Oral mucous membranes, cyanosis of, 44
Oral thrush, Candidiasis, oral
Orchitis, 87
Organic brain syndrome, Dementia; Organic mental disorders
Organic mental disorders, 87
Organized Infant behavior, readiness for enhanced, *545–546*
Orthopedic traction, 87
Orthopnea, 87
Orthostatic hypotension, Dizziness
Osteoarthritis, 90
Osteomyelitis, 90
Osteoporosis, 90–91
Ostomy, 91
Other-directed Violence, risk for, 972*b*–973*b*, *972–982*
Otitis media, 91
Outcomes, in nursing diagnosis, 8
SMART, 7–8
Ovarian carcinoma, 91
Overflow urinary Incontinence, *520*
Overweight, *667–671*, 668*b*
risk for, *671–675*, 672*b*

P

Risk for Bleeding, *163–167*, 164*b*
Risk for Caregiver Role Strain, *210–211*
Risk for chronic functional Constipation, *269*
Risk for chronic low Self-Esteem, *803–804*
Risk for complicated Grieving, *444*
Risk for Complicated Immigration Transition, 65, *510–513*, 511*b*
Risk for compromised Human Dignity, 478*b*, *478–480*
Risk for Constipation, *261*
Risk for Contamination, *274–275*
Risk for corneal Injury, *562–565*, 563*b*
Risk for decreased Cardiac output, *198*
Risk for decreased Cardiac tissue perfusion, 198*b*–199*b*, *198–203*
Risk for Deficient Fluid volume, *417*
Risk for delayed Development, 334*b*, *334–336*
Risk for delayed Surgical recovery, *910–911*
Risk for disorganized Infant behavior, *546*
Risk for disturbed Maternal-Fetal dyad, 605*b*–606*b*, *605–608*
Risk for disturbed personal Identity, *510*
Risk for Disuse syndrome, 342*b*, *342–346*
Risk for dry Eye, *365–368*, 366*b*
Risk for dry Mouth, 634*b*, *634–639*
Risk for dysfunctional Gastrointestinal motility, *426*
Risk for Electrolyte imbalance, 360*b*, *360–363*
Risk for Falls, 53, 371*b*–372*b*, *371–376*
Risk for Female genital mutilation, 399*b*–400*b*, *399–402*
Risk for Frail Elderly syndrome, *420*
Risk for Hypothermia, *498–499*
Risk for imbalanced Fluid volume, 54, 402*b*–403*b*, *402–406*
Risk for impaired Attachment, 153*b*, *153–159*
Risk for impaired emancipated Decision-Making, 321*b*–322*b*, *321–324*
Risk for impaired Liver function, 598*b*, *598–601*
Risk for impaired Oral Mucous Membrane integrity, *663*
Risk for impaired Religiosity, *750*
Risk for impaired Resilience, 761*b*–762*b*, *761–763*
Risk for impaired Skin integrity, 840*b*–841*b*, *840–843*
Risk for impaired Tissue integrity, *928–929*
Risk for Ineffective Activity planning, *130–131*
Risk for ineffective Cerebral tissue perfusion, *211–214*, 212*b*
Risk for ineffective Childbearing process, *224*
Risk for ineffective peripheral Tissue Perfusion, *933*
Risk for ineffective Relationship, *745*
Risk for ineffective Thermoregulation, *923–924*
Risk for Infection, *546–552*, 547*b*
Risk for Injury, *558–562*, 559*b*
Risk for Latex Allergy response, *593–595*, 594*b*
Risk for Loneliness, *601–605*, 602*b*
Risk for Metabolic Imbalance syndrome, *611–615*, 612*b*
Risk for Neonatal Hyperbilirubinemia, *498–499*
Risk for occupational Injury, 565*b*–566*b*, *565–574*
Risk for other-directed Violence, 972*b*–973*b*, *972–982*
Risk for Overweight, *671–675*, 672*b*
Risk for Perioperative Hypothermia, 499*b*–500*b*, *499–503*
Risk for perioperative positioning, 703*b*, *703–706*
Risk for peripheral neurovascular dysfunction, 707*b*, *707–708*

Risk for poisoning, 95, 709*b*, *709–714*
Risk for Post-Trauma syndrome, 95, 719*b*, *719–722*
Risk for Powerlessness, *727–728*
Risk for pressure ulcer, 728*b*–729*b*, *728–733*
Risk for self-directed Violence, *982–983*
Risk for Self-Mutilation, *806–811*
Risk for Shock, 828*b*–829*b*, *828–832*
Risk for situational low Self-Esteem, *804–806*
Risk for Spiritual Distress, *868–869*
Risk for Sudden Infant Death, *889–891*, 890*b*
Risk for Suffocation, 892*b*, *892–896*
Risk for Suicide, *896–905*, 897*b*
Risk for surgical site Infection, 552*b*–553*b*, *552–558*
Risk for thermal injury, *916–918*, 917*b*
Risk for physical trauma, *938–942*, 939*b*
Risk for unstable blood Glucose level, 430*b*–431*b*, *430–434*
Risk for Unstable Blood Pressure, 110, 168*b*, *168–171*
Risk for Urge urinary Incontinence, *534*
Risk for urinary tract Injury, 574*b*–575*b*, *574–577*
Risk for Vascular Trauma, 953*b*, *953–957*
Risk for Venous Thromboembolism, 957*b*, *957–960*
Risk-prone Health behavior, 58, *447–451*, 448*b*
Roaches, invasion of home with, 107–108
Rodents, in home, 100
Role performance, altered, 108
Role performance, ineffective, *766–770*, 767*b*
Role Strain, Caregiver, 36, *203–210*, 205*b*
risk for, *210–211*
ROP, Retinopathy of prematurity
RSV, Respiratory syncytial virus
Rubella, 41
Rubor, of extremities, 108
Ruptured disk, Low back pain

S

SAD, Seasonal affective disorder
Sadness, 104
Safe sex, 104
Safety
childhood, 104
food, 471
home, 471
medication, 713–714
QSEN and, 13
Salmonella, 104
Salpingectomy, 104
Sarcoidosis, 104
SARS, Severe acute respiratory syndrome
SBE, Self-breast examination

Scabies, 41, 104
Scared, 104
Schizophrenia, 104–105, 115
Sciatica, 105
Scoliosis, 105
Seasonal affective disorder (SAD), 103
Sedentary lifestyle, 105, *770b–771b*, *770–774*
Seizure disorders
  adult, 105
  childhood, 105
Seizures
  febrile, 105
  petit mal, 92
Self-breast examination (SBE), 104–105
Self-care, 105
Self-Care, readiness for enhanced, *774b–775b*, *774–781*
Self-Care deficit, bathing, 106, *781b–782b*, *781–785*
Self-Care deficit, dressing, 106, *785b–786b*, *785–787*
Self-Care deficit, feeding, 106, *787–791*, *788b*
Self-Care deficit, toileting, 106, *791b*, *791–793*
Self-catheterization, intermittent, 522
Self-concept, 106
Self-Concept, readiness for enhanced, *793–796*, *794b*
Self-destructive behavior, 106
Self-directed Violence, risk for, *982–983*
Self-Esteem, low, chronic, 106, *797b*, *797–801*
  risk for, *803–804*
Self-Esteem, low, situational, 106, *801–803*
Self-examination
  breast, 104–105
Self-Mutilation, 106, *811–814*, *812b*
  risk for, *806–811*
Self-Neglect, *814–817*, *815b*
Senile dementia, 106
Separation anxiety, 106
Sepsis, in child, 106
Septic shock, 107
Septicemia, 106
Service, animal, 106
Severe acute respiratory syndrome (SARS), 106
Sexual dysfunction, 106, *817b–818b*, *817–822*
Sexual harassment victim, 106–107
Sexuality, adolescent, 107
Sexuality pattern, ineffective, 107, *822b–823b*, *822–828*
Sexually transmitted disease (STD), 107, 110

Shaken baby syndrome, 107
Shakiness, 107
Shame, 107
Sheath system, 523
Shingles, 107
Shivering, 107
Shock
  anaphylactic, 24
  cardiogenic, 107
  hypovolemic, 107
  insulin, Hypoglycemia
  septic, 107
Shock, risk for, 828*b*–829*b*, *828–832*
Shoulder, repair of, 107
Sickle cell anemia/crisis, 25, 107
SIDS, Sudden infant death
Sitting, impaired, 65, 108, *832–835*, 833*b*
Situational crisis, 108
Situational low Self-Esteem, 106, *801–803*
SJS, Stevens-Johnson syndrome
Skin
  cancer, 108
  disorders, 108
  turgor, change in elasticity, 108
Skin integrity, impaired, 836*b*–837*b*, *836–840*
  risk for, 840*b*–841*b*, *840–843*
Sleep, 108
  problems, 108
Sleep, readiness for enhanced, 847*b*, *847–850*
Sleep apnea, 108
  obstructive, 86
Sleep deprivation, 108, *843–846*, 844*b*
Sleep pattern, disturbed, 108, *850–854*, 851*b*
Slurring, of speech, 108
Small bowel resection, 108
SMART outcomes, 7–8
Smell, loss of ability to, 26, 108
Smoke inhalation, 108
Smoking behavior, 108
Social interaction, impaired, 108, 854*b*–855*b*, *854–857*
Social isolation, 109, *857–861*, 858*b*
Social violence, 978
Sociopathic personality, Antisocial personality disorder
Sodium, decrease/increase, Hypernatremia; Hyponatremia
Somatization disorder, 109
Sore nipples, 109

Sore throat, 109
Sorrow, 109
Sorrow, chronic, *861–864*, 862*b*
Spastic colon, Irritable bowel syndrome
Speech
  disorders of, 109
  slurring of, 108
Spina bifida, 84, 109
  anencephaly, Spina bifida
Spinal cord injury, 109
Spinal fusion, 109
Spiritual distress, 109, 865*b*–866*b*, *865–868*
  risk for, *868–869*
Spiritual well-being, 109
Spiritual well-being, readiness for enhanced, 869*b*–870*b*, *869–873*
Splenectomy, 109
Spontaneous abortion, 18
Spontaneous Ventilation, impaired, *960–966*, 961*b*
Sprains, 110
Standard precautions, 548
Standing, impaired, 65, 873*b*–874*b*, *873–875*
Standing problems, 110
Stapedectomy, 110
Staphylococcus aureus, methicillin-resistant, 80
Stasis ulcer, 110
STD, Sexually transmitted disease
ST-elevation myocardial infarction (STEMI), Myocardial infarction
Stenosis
  aortic valvular, Cardiac anomalies; Congenital heart disease
  mitral, 79
  pulmonary, Congenital heart disease
  pyloric, 99–100
Stent, coronary artery, 110
Sterilization surgery, 110
Stertorous respirations, 110
Stevens-Johnson syndrome (SJS), 108, 110
Stillbirth, 110
Stoma, Colostomy; Ileostomy
Stomatitis, 110
Stool
  hard/dry, 110
  impaction of, 65
  incontinence of, 66
  loose, 74
Straining, with defecation, 110
Strep throat, 110

Stress, 110–111
Stress debriefing, critical incident, 720–721
Stress overload, *875–880*, 876*b*
Stress urinary Incontinence, 111, 524*b*–525*b*, *524–529*
Stridor, 111
Stroke, Cerebrovascular accident
Stuttering, 111
Subarachnoid hemorrhage, 111
Subjective information, in assessment, 3
Substance abuse, 111
  adolescent, 111
Substance withdrawal, Acute substance withdrawal syndrome
Sucking reflex, 111
Sudden infant death, 107–108, 111
  risk for, *889–891*, 890*b*
Suffocation, risk for, 111, 892*b*, *892–896*
Suicide, risk for, *896–905*, 897*b*
Suicide attempt, 112
Support system, inadequate, 112
Suppression of labor, Preterm labor
Surgery
  abdominal, 18
  brain, Craniectomy; Craniotomy
  ear, 50
  eye, 53
    laser-assisted in situ keratomileusis, 72
  gastrointestinal, 56
  heart, Coronary artery bypass grafting; Open heart surgery
  ileus following, 428
  jaw, 70
  lungs, Thoracotomy
  nausea following, 642
  perioperative care, 112
  postoperative care, 112
  preoperative care, 112
  rectal, Hemorrhoidectomy
  sterilization, 110
Surgical recovery, delayed, 112, 906*b*–907*b*, *906–910*
  risk for, *910–911*
Surgical site infection, 112
Surgical site Infection, risk for, 552*b*–553*b*, *552–558*
Suspected child abuse and neglect (SCAN)
  child, 112
  parent, 112–113
Swallowing, impaired, *911–916*, 912*b*
Symptoms
  management, 10
  in nursing diagnosis, 4
  pattern recognition, and/or triggers, 7

Syndrome Nursing Diagnoses
Post-Trauma syndrome, 95, 715*b*, *715–719*
Rape-Trauma syndrome, 100, 738*b*, *738–741*, 978
Risk for Disuse syndrome, 342*b*, *342–346*
Risk for Post-Trauma syndrome, 95, 719–722, 719*b*
Syphilis, Sexually transmitted disease
Systemic lupus erythematosus, Lupus erythematosus

T

T&A, Tonsillectomy and adenoidectomy
Tachycardia, Dysrhythmia
Tachypnea, 113
Tardive dyskinesia, 113
Targeted temperature hypothermia, 495–496
Taste abnormality, 113
TBI, Traumatic brain injury
TD, Traveler's diarrhea
Teaching, preoperative, Surgery, preoperative care
Teamwork, collaboration and, 12
Technology addiction, 114
Temperature
decreased, 114
high, 114
measurement
in hyperthermia, 487–488
in hypothermia, 493
in perioperative hypothermia, 500
regulation impairment, 114, **Ineffective Thermoregulation**
TEN, Toxic epidermal necrolysis
TENS unit (transcutaneous electrical nerve stimulation), 114
Tension, 114
Terminally ill adolescent, 114
Terminally ill adult, 114
Terminally ill child, 114
Terminally ill infant, 114
Terminally ill preadolescent, 114
Terminally ill preschool child, 114
Terminally ill school-age child, 114
Terminally ill toddler, 114
Tetralogy of Fallot, Cardiac anomalies; Congenital heart disease
Tetraplegia, 115
Thermal injury, risk for, *916–918*, 917*b*
Thermoregulation, ineffective, 115, 919*b*, *919–923*
risk for, *923–924*
Thoracentesis, Pleural effusion
Thoracotomy, 115

Thought disorders, Schizophrenia
Throat
sore, 109
strep, 110
Thrombocytopenic purpura, Idiopathic thrombocytopenic purpura
Thrombophlebitis, Deep vein thrombosis
Thrombosis, deep vein, prevention of, 708
Thyroidectomy, 115
TIA, Transient ischemic attack
Tic disorder, Tourette's syndrome
Tinea capitis, 115
Tinea corporis, Ringworm, of body
Tinea cruris, Jock Itch
Tinea pedis, Athlete's foot
Tinea unguium, 115
Tinnitus, 115
Tissue damage, integumentary, 115
Tissue integrity, impaired, 924*b*–925*b*, *924–928*
risk for, *928–929*
Tissue perfusion, Cardiac, risk for decreased, 198*b*–199*b*, *198–203*
Tissue perfusion, Cerebral, risk for ineffective, *211–214*, 212*b*
Tissue perfusion, peripheral, 115
Tissue Perfusion, peripheral, ineffective, 929*b*–930*b*, *929–932*
risk for, *933*
Toilet training, 116
Toileting problems, 115
Toileting Self-Care deficit, 106, 791*b*, *791–793*
Tonsillectomy and adenoidectomy (T&A), 113, 116
Toothache, 116
Total anomalous pulmonary venous return, Cardiac anomalies; Congenital heart disease
Total hip replacement, 27, 116
Total joint replacement, 116
Total knee replacement, 116
Total parenteral nutrition (TPN), 116
Total shoulder replacement, 116
Tourette's syndrome (TS), 115–116
Toxemia, Pregnancy-induced hypertension
Toxic epidermal necrolysis (TEN), 114, 116
TPN, Total parenteral nutrition
Tracheoesophageal fistula, 116
Tracheostomy, 116
Traction, 116
Transfer ability, 116
Transfer ability, impaired, 933*b*–934*b*, *933–938*

Transient ischemic attack (TIA), 115–116
Transplant
corneal, 43
kidney, 70
donor, 70
recipient, 70
liver, 73–74
Transposition of great vessels, Cardiac anomalies; Congenital heart disease
Trauma
abdominal, 18
Trauma, physical, risk for, *938–942*, 939*b*
Trauma, Vascular, risk for, 953*b*, *953–957*
Trauma syndrome, Post, 95, 715*b*, *715–719*
risk for, 95, 719*b*, *719–722*
Trauma syndrome, Rape, 100, 738*b*, *738–741*, 978
Traumatic brain injury (TBI), 113–114
Traveler's diarrhea (TD), 114
TS, Tourette's syndrome
TSE, *See* Testicular self-examination
Tuberculosis (TB)
pulmonary, 113
Tumor
brain, 32
kidney, Wilms' tumor
Wilms', 120
TURP, *See* Transurethral resection of the prostate

U
Ulcer
duodenal, 117
gastric, 117
peptic, 117
pressure, 97–98
stasis, 117
Ulcer, pressure, risk for, 728*b*–729*b*, *728–733*
Ulcerative colitis, Inflammatory bowel disease
Unilateral neglect, 942*b*–943*b*, *942–944*
Unilateral neglect, of one side of body, 117
Unintentional perioperative hypothermia, 500–501
Unsanitary living conditions, 118
Unstable blood Glucose level, risk for, 430*b*–431*b*, *430–434*
Unstable Blood Pressure, risk for, 110, 168*b*, *168–171*
Upper respiratory infection, Cold, viral
Urge suppression, 532–533
Urge urinary Incontinence, 529*b*–530*b*, *529–534*
risk for, *534*
Urgency to urinate, 118

Urinary catheter, 118
Urinary catheterization, 36
Urinary diversion, Ileal conduit
Urinary elimination, impaired, 118, *944–948*, 945*b*
Urinary incontinence, 66, 118
Functional urinary Incontinence, 516*b*–517*b*, *516–519*
Overflow urinary Incontinence, *520*
Reflex urinary Incontinence, *520–524*, 521*b*
Stress urinary Incontinence, 524*b*–525*b*, *524–529*
Urge urinary Incontinence, 529*b*–530*b*, *529–534*
risk for, *534*
Urinary Retention, 119, 948*b*–949*b*, *948–953*
Urinary tract infection (UTI), 119, 946
Urinary tract Injury, risk for, 574*b*–575*b*, *574–577*
Urolithiasis, Kidney, stone
Uterine atony
in labor, Dystocia
in postpartum, Postpartum hemorrhage
Uterine bleeding, 119
UTI, Urinary tract infection
