This material is not intended to be, and should not be considered, a substitute for medical or other professional advice. Treatment for the conditions described in this material is highly dependent on the individual circumstances. And, while this material is designed to offer accurate information with respect to the subject matter covered and to be current as of the time it was written, research and knowledge about medical and health issues is constantly evolving and dose schedules for medications are being revised continually, with new side effects recognized and accounted for regularly. Readers must therefore always check the product information and clinical procedures with the most up-to-date published product information and data sheets provided by the manufacturers and the most recent codes of conduct and safety regulation. The publisher and the authors make no representations or warranties to readers, express or implied, as to the accuracy or completeness of this material. Without limiting the foregoing, the publisher and the authors make no representations or warranties as to the accuracy or efficacy of the drug dosages mentioned in the material. The authors and the publisher do not accept, and expressly disclaim, any responsibility for any liability, loss, or risk that may be claimed or incurred as a consequence of the use and/or application of any of the contents of this material.

Printed by Sheridan Books, Inc., United States of America

We dedicate this second edition to all palliative APRNs who step in every day to promote access to quality care for individuals with serious illnesses and support family caregivers. You provide excellence in palliative care and promote palliative care equity and inclusion to diverse populations with unique needs. As palliative© APRNs, you create new programs and initiatives across clinical, educational, research, policy, and payment settings, forge new roles, develop new programs, conduct palliative research and quality improvement initiatives, create new technologies, and steer social justice within palliative care. We know it takes courage, knowledge, skills, strength, energy, and support to do this work.

CONTENTS

<i>Preface</i>	<i>xi</i>
<i>Acknowledgments</i>	<i>xiii</i>
<i>Disclaimer</i>	<i>xv</i>
<i>Contributors</i>	<i>xvii</i>

SECTION I THE PALLIATIVE APRN

1. Palliative APRN Practice and Leadership: Past, Present, and Future <i>Constance Dahlin and Patrick J. Coyne</i>	<i>3</i>
2. Fundamental Skills and Education for the Generalist and Specialist Palliative APRN <i>Dorothy Wholihan, Charles Tilley, and Adrienne Rudden</i>	<i>19</i>
3. Credentialing, Certification, and Scope of Practice Issues for the Palliative APRN <i>Kerstin Lea Lappen, Matthew McGraw, and Kate Meyer</i>	<i>34</i>

SECTION II PALLIATIVE APRN ROLES

4. The Palliative APRN in Administration <i>Karen Mulvihill</i>	<i>47</i>
5. The Palliative APRN in Nursing Education <i>Carrie L. Cormack and Kathleen O. Lindell</i>	<i>62</i>
6. The Palliative APRN in Policy and Payment Models <i>Marian Grant</i>	<i>75</i>
7. The Palliative APRN in Research and Evidence-Based Practice <i>Janice Linton and Joan G. Carpenter</i>	<i>85</i>

SECTION III CLINICAL SETTINGS OF PALLIATIVE APRNS

8. The Palliative APRN in the Medical, Surgical, and Geriatrics Patient Care Unit <i>Phyllis B. Whitehead and Carolyn White</i>	<i>99</i>
9. The Palliative APRN in the Intensive Care Setting <i>Clareen Wiencek</i>	<i>109</i>
10. The Palliative APRN in the Emergency Department <i>Sarah Loschiavo and Angela Starkweather</i>	<i>120</i>
11. The Palliative APRN in the Palliative Care Clinic <i>Brooke Smith and Lisa A. Stephens</i>	<i>133</i>
12. The Palliative APRN in Primary Care <i>Rosemary Gorman, Dorothy Wholihan, and Sarah Bender</i>	<i>146</i>
13. The Palliative APRN in Specialty Cardiology <i>Beth Fahlberg, Ann Laramée, and Erin Donaho</i>	<i>156</i>
14. The Palliative APRN in the Community Setting <i>Nicole DePace</i>	<i>174</i>
15. The Palliative and Hospice APRN in Hospice and Home Health Programs <i>Rikki N. Hooper, Chari Price, and Jamie Lee Rouse</i>	<i>188</i>
16. The Palliative APRN in Rehabilitation <i>Lorie Resendes Trainor</i>	<i>199</i>
17. The Palliative APRN in Telehealth <i>Katherine Kyle and Constance Dahlin</i>	<i>208</i>
18. The Palliative APRN in the Rural Community <i>Traci Sickich</i>	<i>216</i>
19. The Palliative APRN in Residential Facilities <i>Melissa McClean and Victoria Nalls</i>	<i>227</i>

SECTION IV POPULATIONS AT RISK

20. Health Disparities in Palliative Care and Social Determinants of Health 239
Alma Y. Dixon and Cecilia R. Motschenbacher
21. Economically Disadvantaged Urban Dwellers 247
Natasha Curry
22. LGBTQ+ Inclusive Palliative Care 258
Jessica Nymeyer
23. Care of Veterans with Palliative Care Needs 270
Alice C. Foy, Robert David Rice, and Joseph Albert Melocoton
24. Recurrent Disease and Long-Term Survivorship 285
Denice Economou and Brittany Bradford

SECTION V PEDIATRIC PALLIATIVE CARE

25. The Pediatric Palliative APRN 297
Cheryl Ann Thaxton and Nicole Sartor
26. The Pediatric Palliative APRN in the Acute Care Setting 310
Faith Kinnear and Gina Santucci
27. The Pediatric Palliative APRN in Perinatal and Neonatal Palliative Care 328
Maggie C. Root and Mallory Fossa
28. The Pediatric Palliative APRN in the Clinic 343
Alice Bass and Vanessa Battista
29. The Pediatric Palliative APRN in Oncology 355
Amy Corey Haskamp and Joanne M. Greene
30. The Pediatric Palliative APRN in the Community 367
Joan "Jody" Chrastek and Jaime Hensel
31. Communication in Pediatric Palliative Care 379
Mallory Fossa, Julia McBee, and Rachel Rusch

SECTION VI COMMUNICATION IN PALLIATIVE CARE

32. Advance Care Planning: Advance Directives, Medical Order Sets, and Surrogate Decision-Making 395
Hannah N. Farfour
33. Family Meetings 404
Jennifer Gentry, Kerrith McDowell, and Paula McKinzie
34. Communication at the End of Life 417
Marlene E. McHugh, Penelope R. Buschman, and Susan M. Delisle

SECTION VII PSYCHOSOCIAL, CULTURAL, AND SPIRITUAL ASPECTS OF CARE

35. Culturally Respectful Palliative Care 433
Helen Foley and Polly Mazanec
36. Ensuring Quality Spiritual Care 447
Betty Ferrell
37. Life Review 456
Jamil Davis, Mimi Jenko, and James C. Pace
38. Grief and Bereavement 468
Katharine Adelstein and Elizabeth Archer-Nanda

SECTION VIII SYMPTOMS

39. Anorexia and Cachexia 481
Robert Smeltz and Renata Shabin
40. Bowel Symptoms 489
Kimberly Chow and Lauren Koranteng
41. Fatigue 501
Shila Pandey
42. Nausea and Vomiting 519
Katherine E. DeMarco
43. Pain 535
Judith A. Paice
44. Respiratory Symptoms 551
Ember S. Moore and Kathleen Broglio
45. Cognitive Impairment 575
Abraham A. Brody and Donna E. McCabe
46. Serious Mental Illness 590
Kristyn Pellecchia and Ryan Murphy
47. Patients with Substance Use Disorders and Dual Diagnoses 603
Jeannine M. Brant and Tonya Edwards
48. Anxiety 617
Kira Stalhandske
49. Delirium 629
Bonnie D. Evans and Erica J. Hickey
50. Depression and Suicide 650
John Chovan
51. Palliative Emergencies 666
Ann Quinn Syrett, Marcia J. Buckley, and Beth Carlson
52. Challenging Symptoms: Pruritus, Hiccups, Dry Mouth, Fevers, and Sleep Disorders 676
Barton T. Bobb and Devon S. Wojcikewych

SECTION IX ETHICAL CONSIDERATIONS

53. Navigating Ethical Dilemmas	691	57. Palliative Sedation	735
<i>Nessa Coyle and Timothy W. Kirk</i>		<i>David Collett and Kelly Baxter</i>	
54. Discontinuation of Cardiac Therapies	704	Appendix I Palliative APRN Billing and Coding	749
<i>Patricia Maani Fogelman and Janine A. Gerringer</i>		<i>Constance Dablin</i>	
55. Discontinuation of Respiratory Therapies	715	Appendix II Perinatal and Pediatric Pain and Symptom Tables	760
<i>Brenna Winn</i>		<i>Maggie C. Root, Mallory Fossa, Gina Santucci, Nicole Sartor, Faith Kinnear, Alice Bass, Jaime Hensel, Amy Corey Haskamp, Joanne M. Greene, Cheryl Ann Thaxton, Joan “Jody” Chrastek, Vanessa Battista, and Constance Dablin</i>	
56. Discontinuation of Other Life-Sustaining Therapies	723		
<i>Kathy Plakovic and Jennifer Donoghue</i>		Index	769

PREFACE

A palliative care textbook is always a labor of love. It symbolizes one's passion and commitment to the specialty. The ability to accomplish such a textbook is only through collaboration, patience, a sense of humor, and a north star of excellence and quality. The first edition of *Advanced Practice Palliative Nursing* was born out of the fact that there was no specific textbook for palliative APRNs. Prior to its publication, many seasoned APRNs learned content along the way and applied it to the APRN role. The goal of the first edition was to capture the uniqueness of the role, as well as validate and codify practice and ground the role the evidence, practice, and research. Each chapter was led by a practicing APRN to assure authenticity. Since that time, we have been thrilled from the outpouring of support for *Advanced Practice Palliative Nursing* as many APRNs said it met their need and their practice.

We recognize that we need to assure education and resources to the cadre of APRNs who will need to practice both primary and specialty palliative nursing. APRNs will need to develop new roles, lead new programs, and care for many populations across all health settings. The world and practice environment has changed considerably since the first edition. The APRN role continues to be the fastest growing segment of healthcare, and there will be a burgeoning of care for older adults. The current social construct puts more emphasis on the role of palliative care in crises including infectious disease such as the COVID-19 pandemic, humanitarian crises from conflicts, and natural disasters such as fires, floods, earthquakes, hurricanes, and the like. And the emphasis on health equity is urgent in palliative care, an issue brought to the forefront by the disparities illuminated by COVID-19 and structural racism.

Our plan had been to initiate the next edition in late 2022, as we were in the middle of other projects. However, the pandemic changed everyone's plans and it changed ours. We immediately thought to revise this edition, knowing that palliative APRNs were answering the call of the pandemic in many ways. They were particularly on the frontlines since palliative care expertise was needed to support patients in the crisis. We put out a call to authors and were pleasantly surprised when many said this would be a great diversion and provide some normalcy in a chaotic world. We were even more thrilled that 32 new chapter authors stepped in. To assure authenticity to each chapter, it was a requirement that the lead author of each chapter was an APRN currently in practice. Many of the authors APRNs are certified in advanced hospice and palliative nursing (ACHPN). It was a joy to coach and mentor them to succeed in the production of their chapters. We are grateful for all authors' contributions and appreciate the sharing of their expertise.

As a result, this textbook provides the essential knowledge and attitudes to improve skills and practice in palliative nursing to assure quality care. We hope it serves as a foundation for advanced practice palliative nursing practice. It is intended for the graduate nursing student as well as the novice, advanced beginner, and competent palliative APRN to support their specialty palliative care practice. It is also intended to support all APRNs in their provision of primary palliative care. We also hope it promotes role delineation and development within the spectrum of APRN practice. Finally, it is directed to nurse educators to help support their learners in primary and specialty palliative nursing and offer a curricular resource in preparing the next generation of palliative APRNs. We hope the reader will find the knowledge helpful to their practice and appreciate that it reflects current practice and research.

Constance Dahlin and Patrick J. Coyne

ACKNOWLEDGMENTS

We are grateful for the support and understanding of our families as we follow our passion to further the field. We thank Dr. Betty Ferrell for her previous editorship.

SECTION I

THE PALLIATIVE APRN

PALLIATIVE APRN PRACTICE AND LEADERSHIP

PAST, PRESENT, AND FUTURE

Constance Dahlin and Patrick J. Coyne

KEY POINTS

- The foundational principles of nursing and palliative care are synergistic. Modern nursing has always focused on alleviating suffering for individuals in health and illness. Palliative care focuses on quality of life.
- All advanced practice registered nurses (APRNs) practice primary palliative care within their practice. Specialty palliative APRNs focus on more complex care for individuals with serious illness.
- Palliative APRNs promote access to palliative care, facilitate evidence-based palliative practices, and deliver safe, quality palliative care across settings and populations.
- Palliative APRN leaders are essential to the evolution of palliative care.

HISTORY OF NURSING AND PALLIATIVE APRNs

As the largest segment of healthcare providers, nurses have a prominent role in the front line of care. Nurses spend the most time with patients and families. This proximity allows for comprehensive assessment of the person and family to facilitate personalized care, implementation and evaluation of the treatment plan, and care coordination. Nurses are uniquely positioned in healthcare to observe family interactions, support a patient's coping, and listen to a patient's inner most thoughts and concerns across many situations. Advanced practice registered nurses (APRNs) are one of the fastest growing segments of nursing and healthcare and will continue to have a growing influence on the accessibility and quality of healthcare.^{1,2}

Both nursing and palliative care have evolved to focus on health, wellness, and caring across a continuum.³ Nurses protect, promote, and optimize human function; prevent illness and injury; and alleviate suffering through their compassionate presence, including individuals coping with actual or potential serious illness.⁴ Florence Nightingale and Mary Seacole established nursing practice while caring for soldiers in the Crimean War, many of whom were critically wounded.⁵ Thus, the essence of nursing was grounded in caring for gravely ill individuals. When nursing moved to the United States,

Clara Barton of the American Red Cross advanced nursing through the Civil War. Again, nursing practice was based in the care of soldiers wounded in battle.⁶

Nursing has developed in its breadth and scope of practice to include registered nurses (RNs) and graduate-level (master's or doctoral)–prepared specialty nurses. In the mid-twentieth century, four advanced practice nursing roles developed: certified nurse midwife, nurse practitioner (NP), clinical nurse specialist (CNS), and certified nurse anesthetist. These roles play a significant part in hospice and palliative care in the United States today. This textbook highlights how APRNs are leaders in the assurance of high-quality palliative care for all, the delivery of palliative care, the development and administration of palliative programs, advocacy in policy related to palliative care, access to palliative care education, and the development and participation in necessary palliative care research, with an emphasis on nursing.

HISTORY OF HOSPICE AND PALLIATIVE CARE

The modern hospice movement was established in the 1960s in England by Dame Cicely Saunders, a physician who was first a nurse, then a social worker. At St. Joseph's Hospice, Dr. Saunders followed her calling to promote compassionate care to the dying, calling on her background in nursing and social work. She then founded St. Christopher's Hospice to further develop hospice care.⁶ These concepts traveled to the United States through the work of Dr. Florence Wald, then dean of the Yale School of Nursing. Dr. Wald developed an expansive nursing curriculum that emphasized the nursing skills necessary for caring for dying patients, specifically pain and symptom management and communication.⁷ Dr. Wald stated, "Hospice care is the epitome of good nursing care." She asserted, "It enables the patient to get through the end-of-life on their own terms. It is a holistic approach, looking at the patient as an individual, a human being. The spiritual role nurses play in the end-of-life process is essential to both patients and families."⁷ Dr. Wald then founded the Connecticut Hospice, the first hospice in the United States.

In 1982, the Medicare Hospice Benefit was enacted, offering benefits to patients with a terminal illness. Specific *Medicare Hospice Conditions of Participation* (CoPs) directed hospices to offer a certain set of services to patients and families.⁸ Within the benefit, nursing has a prominent

role as a core service. In programs across the United States, the majority of hospice care is provided by nurses visiting patients' homes. However, in its infancy, the Medicare Hospice Benefit recognized only RN practice. It was not until recently that the Medicare Hospice Benefit even acknowledged that APRNs lead hospice teams and oversee the care of hospice patients. The most recent version of the CoPs (2011) clarifies the role of the APRN.⁹

In addition, when the Medicare Hospice Benefit was started, care of dying patients was marked by a lack of consistency in care provision and little consensus on the defining characteristics of palliative care or quality indicators for adults and children. Even less was known about patients with serious illness. Research from the 1990s confirmed the worst fears about healthcare. *The Study to Understand Prognoses and Preferences for Outcomes and Risks of Treatment* (SUPPORT) demonstrated a failure to honor patients' preferences even when patients were clear about their wishes and preferences.¹⁰ The study found a continued lack of communication between patients and their healthcare providers about end-of-life care. Furthermore, patients who were seriously ill and dying reported high levels of pain and other symptoms, extensive financial stress, and, most importantly, a lack of concordance between care provided and their care preferences. Despite patient preferences to focus on quality of life, aggressive care was often continued despite reduced quality of life.¹⁰ In the intervention arm of the study, nurse-conducted patient interviews did not improve outcomes in aligning care with patient goals. However, there was variation in the SUPPORT study: both APRNs and RNs were used in the intervention which meant variability in communication skills and scope of practice. This may have caused an inconsistency in the interventions for patients and, ultimately, the affected consistency of outcomes.

As the findings from SUPPORT were being disseminated in the mid-1990s, hospice concepts moved into the academic hospital setting in the form of palliative care.¹¹ This care applied hospice concepts of symptom management, family support, goal-centered care, and quality of life earlier in the care of hospitalized patients. Care first focused on adults with serious and life-threatening illnesses whose care was complicated, as well as on terminally ill patients who were not ready for hospice.¹¹ Specialty pediatric palliative care then developed as well.

INCEPTION OF PALLIATIVE CARE AND PALLIATIVE NURSING

Pioneer palliative care programs were developed across the country. Many of these palliative care services had a large presence of APRNs.¹¹ With their enhanced graduate education and scope of practice, APRNs offered a wide range of clinical services to patients and families, such as taking histories, performing physical examinations, developing diagnoses, creating care plans, prescribing medications, and offering treatment options.^{11,12} Moreover, many APRNs had been selected as faculty scholars of the Open Society *Project on Death in America* to improve care at the end of life.¹³ APRNs

also had prominent roles in program development, research, and education of patients, families, professional colleagues, and health systems. The challenge was ensuring appropriate education and training so that APRNs could move into these roles. The development of the specialty of palliative APRN practice was just beginning. See Box 1.1 for a review of the specialty.

In the early years, most APRNs who moved into palliative care roles had to design their own education and support for clinical decision-making since there were no organized educational plans. Frequently, APRNs learned aspects of a palliative approach through clinical care over months to years. It was often the case of on-the-job skill building while developing individual models of care. Often education, practice expertise, and skills emanated from either oncology nursing or AIDS/HIV nursing, which involved a range of skills associated with symptom control, care at end of life, coping, and bereavement. Other nurses moved from hospice care into palliative care because of shared experience in pain and symptom management, counseling about life-limiting illness, and working with an interprofessional team.

ESSENTIAL REPORTS

The release of essential reports about dying in America influenced palliative advanced practice nursing. The 1997 Institute of Medicine (IOM) report *Approaching Death* described the state of end-of-life care in America.¹⁶ This report recommended the subspecialty of palliative care, reviewed the use of medications for pain and symptom management, supported financial investment in palliative care, and appealed for professional education that included palliative care content in various curricula, textbooks, and training programs.¹⁴

EVOLUTION OF PALLIATIVE CARE

The Precepts of Palliative Care were released by Last Acts (formerly a Robert Wood Johnson Foundation-funded organization, which was enveloped within the National Hospice and Palliative Care Organization).¹⁵ These precepts reaffirmed the comprehensive approach of palliative care as a specialized area of expertise. *The Precepts of Palliative Care* also stated that care should respect patient choices, affirmed that care utilizes the strengths of the interdisciplinary team, and encouraged the building of palliative care support through financing, outcomes, and research.¹⁵

In 2002, Last Acts published a seminal document, a state-by-state report card of end-of-life care in America, which captured a fairly bleak picture of palliative care in the United States.¹⁶ It promoted much discussion about a unified response from the palliative care community. This state reporting was subsequently monitored by the Center to Advance Palliative Care. Other significant reports included two IOM reports, *When Children Die* and *Crossing the Quality Chasm*, and a monograph by the National Hospice Work Group and the Hastings Center in association with the National Hospice and Palliative Care Organization (NHPCO) entitled *Access to Hospice Care: Expanding Boundaries, Overcoming Barriers*.¹⁷⁻¹⁹

1982	Enactment of the Medicare Hospice Benefit
1986	Establishment of the Hospice Nurses Association
1991	Release of American Nurses Association <i>Position Statement: Nursing and the Patient Self-Determination Act: Supporting Autonomy</i>
1993	Establishment of National Board for Certification of Hospice Nurses
1994	Establishment of the Open Society-Project on Death in America-to support the leadership development of interdisciplinary faculty, including APRNs, to address barriers to end-of-life care. Administration of first examination for hospice nursing offered by National Board for Certification of Hospice Nurses
1995	Release of the <i>Study to Understand Prognoses and Preferences for Outcomes and Risks of Treatments</i> (SUPPORT)
1997	Publication of Institute of Medicine Committee on Care at the End of Life <i>Approaching Death: Improving Care at the End of Life</i> Centers for Medicare and Medicaid Services first recognizes and allows the billable services of a nurse practitioner Development of first palliative nursing master's programs for NPs and CNSs
1998	Publication of American Association of Colleges of Nursing <i>Peaceful Death: Recommended Competencies and Curricular Guidelines for End-of-Life Nursing Care</i> Transition of the Hospice Nurses Association to the Hospice and Palliative Nurses Association (HPNA) Transition of National Board for Certification of Hospice Nurses to the National Board for Certification of Hospice and Palliative Nurses (NBCHPN)
1999	Publication of Last Acts <i>The Precepts of Palliative Care</i> Establishment of the Nursing Leadership Academy for End-of-Life Care to design an agenda for end-of-life care for the nursing profession
2000	Publication of the Institute of Medicine Committee on Palliative and End of Life Care <i>When Children Die: Improving Palliative and End-of-Life Care for Children and Their Families</i> and <i>Crossing the Quality Chasm: A New Health System for the 21st Century</i> City of Hope National Medical Center and American Academy of Colleges of Nursing collaborate to create the End-of-Life Nursing Education Consortium (ELNEC), which develops a nursing curriculum for care at end of life and partners. Publication of <i>HPNA Statement on the Scope and Standards of Hospice and Palliative Nursing Practice</i> (2nd ed.)
2001	Publication of <i>Advanced Practice Nurses Role in Palliative Care: A Position Statement from American Nursing Leaders</i> , supported by Promoting Excellence in End-of-Life Care Creation of <i>HPNA Professional Competencies for the Generalist Hospice and Palliative Nurse</i> Publication of <i>Oxford Textbook of Palliative Nursing</i> (1st ed.)
2002	Publication of HPNA and ANA <i>Scope and Standards of Hospice and Palliative Nursing Practice</i> (3rd ed.) Creation of <i>HPNA Competencies for the Advanced Practice Hospice and Palliative Care Nurse</i>
2003	Administration of first palliative and hospice examination for APRNs administered within a partnership of NBCHPN and American Nurses Credentialing Center
2004	Publication of National Consensus Project for Quality Palliative Care <i>Clinical Practice Guidelines</i> (1st ed.)
2005	Publication of <i>Oxford Textbook of Palliative Nursing</i> (2nd ed.)
2006	Recognition of NBCHPN by the Centers for Medicare and Medicaid Services as a national certifying body for APRNs allowing for practice solely as a palliative APRN, which allows palliative NPs to bill Release of <i>HPNA Position Statement: Value of the Advanced Practice Nurse in Palliative Care</i> (revised 2010, with name changed to <i>Value of the Advanced Practice Registered Nurse in Palliative Care</i>)
2007	Publication of HPNA and ANA <i>Hospice and Palliative Nursing: Scope and Standards of Practice</i> (4th ed.)

(continued)

2008	Enactment of National Council of State Boards of Nursing Licensure, Accreditation, Certification and Education (LACE) to standardize advance practice nursing across states, defining palliative nursing as an advanced practice nursing specialty, to be added to population-based licensure
2009	Publication of National Consensus Project for Quality Palliative Care <i>Clinical Practice Guidelines</i> (2nd ed.) Publication of <i>Core Curriculum for the Advanced Hospice and Palliative Registered Nurse</i> (1st ed.)
2010	Publication of <i>Oxford Textbook of Palliative Nursing</i> (3rd ed.)
2011	Publication of <i>HPNA Position Statement: The Nurse's Role in Advance Care Planning</i>
2013	Institute of Medicine forms the Transforming Care at the End-of-Life Committee to review and expand palliative care across healthcare settings. Publication of National Consensus Project for Quality Palliative Care <i>Clinical Practice Guidelines</i> (3rd ed.) Transition of National Board for Certification of Hospice and Palliative Nurses (NBCHPN) to the Hospice and Palliative Credentialing Center Publication of HPNA <i>Core Curriculum for the Advanced Practice Hospice and Palliative Registered Nurse</i> (2nd ed.)
2014	Publication of the Institute of Medicine <i>Dying in America—Improving Quality and Honoring Individual Preferences Near End of Life</i> Inauguration of Cambia Healthcare Foundation Sojourns Leadership Scholars Program funding leadership development for nurses and physicians Development of ELNEC for APRNs, which focuses on both clinical care and program development Publication of HPNA and ANA <i>Palliative Nursing: Scope and Standards—An Essential Resource for Nurses</i> (5th ed.) Publication of HPNA <i>Competencies for the Hospice and Palliative Advanced Practice Nurse</i>
2015	Release of ANA <i>Position Statement: Roles and Responsibilities in Providing Care and Support at the End of Life</i> Publication of HPNA <i>Standards for Clinical Education</i> to identify essential type of clinical experiences Publication of <i>Oxford Textbook of Palliative Nursing</i> (4th ed.)
2017	Release of ANA and HPNA <i>Call for Action: Nurses Lead and Transform Palliative Care</i>
2018	Publication of National Consensus Project for Quality Palliative Care <i>Clinical Practice Guidelines</i> (4th ed.) Centers for Medicare and Medicaid Services allows NPs and CNSs to certify home health care
2019	Publication of AACN primary palliative nursing competencies for graduate-prepared nurses, <i>Graduate Competencies and Recommendations for Educating Nursing Students (G-CARES)</i> . Publication of <i>Oxford Textbook of Palliative Nursing</i> (5th ed.)
2020	Release of ANA <i>Position Statement: Nursing Care and Do-Not-Resuscitate (DNR) Decisions</i> Publication of HPNA <i>Core Curriculum for the Advanced Practice Hospice and Palliative Registered Nurse</i> (3rd ed.)
2021	Publication of HPNA <i>Palliative Nursing: Scope and Standards of Practice</i> (6th ed.) Publication of HPNA <i>Competencies for the Palliative and Hospice Palliative APRN</i> (3rd ed.) Publication of AACN <i>The Essentials: Core Competencies for Professional Nursing Education</i> , which requires primary supportive/palliative/hospice nursing education

Adapted from American Nurses Association, Hospice and Palliative Nurses Association. *Palliative Nursing: Scope and Standards of Practice: An Essential Resource for Hospice and Palliative Nurses*. 5th ed.²⁰; Dahlin C, ed. *Palliative Nursing Scope and Standards of Practice*. 6th ed.²¹

These reports argued for significant changes in access to palliative care that would promote access for all ages, ensure care in all health settings, and provide services for all progressive chronic, serious, or life-threatening illness and injuries.^{17–19}

A significant development in the field was the 2004 release of the National Consensus Project for Quality

Palliative Care's (NCP) *Clinical Practice Guidelines*, created by the five major professional organizations dedicated to promoting hospice, palliative, and end-of-life care: the American Academy of Hospice and Palliative Medicine (AAHPM), the Center to Advance Palliative Care (CAPC), the Hospice and Palliative Nurses Association (HPNA),

Last Acts, and the National Hospice and Palliative Care Organization (NHPCO). These guidelines established principles to improve and ensure the quality of palliative care in the United States.²² They offer a framework for the future of palliative care and continue to serve as a blueprint to create new programs, guide developing programs, and set high expectations for excellence in existing programs. The guidelines set ideal practices and goals that palliative care services should strive to attain rather than setting minimally acceptable practices. The guidelines have three specific aims: (1) to promote quality and reduce variation in new and existing programs, (2) to develop and encourage continuity of care across settings, and (3) to facilitate collaborative partnerships among palliative care programs, community hospices, and a wide range of other healthcare delivery settings.^{22–24} Now in its fourth edition, the *NCP Clinical Practice Guidelines* are a collaboration of a wider group of professional organizations dedicated to care of individuals (both children and adults) with serious illness. Moreover, the guidelines stress specialty education, training, and certification; specific to APRNs is the promotion of obtaining advanced certification within hospice and palliative nursing.^{24,25}

Later in 2004, the first national meeting on palliative care research was convened in Bethesda, Maryland. The National Institutes of Health (NIH) held the first State of the Science Conference on Improving End-of-Life Care, which put forth statements to formulate future palliative research.²⁶ The co-chairs who convened the meeting concluded that (1) the definition of end-of-life care was vague and poorly understood and was experienced differently across subgroups of culture, healthcare settings, and disease populations; (2) the vague definition led to poor-quality, fragmented care, and lack of continuity; and (3) research measures and interventions in use were inconsistent and lacked validation.²⁶ In 2011, the National Institute for Nursing Research (NINR) convened a follow-up meeting that provided a summary of research initiatives and offered innovative methods to develop palliative metrics and measure quality.²⁷ It also emphasized the need for interdisciplinary research and training.²⁷ Palliative-focused research continues through the National Center for Palliative Care Research and the Palliative Care Research Cooperative Group.

In 2014, the IOM released its report *Dying in America: Improving Quality and Honoring Individual Preferences Near End of Life*.²⁸ The report focuses on five areas for quality palliative care: (1) delivery of person-centered and family-focused palliative care, (2) clinician–patient communication and advance care planning, (3) professional education in palliative care, (4) policies and payment for palliative care, and (5) public education and engagement in palliative care.²⁸ These areas would provide a focus for healthcare improvement and would move care upstream to patients with serious illness rather than focusing just on the end of life. In addition, the report calls for more coordinated and collaborative care that is based in the community. APRNs would have a major role in the implementation of these areas and, more broadly, in moving palliative care into the community.

In 2018, the Commonwealth Fund released the report *Health Care in America: The Experience of People with Serious Illness*. It outlines several important findings: (1) the distress of people with serious illness caused by physical and psychological symptoms and distress; (2) the challenges of care related to insurance coverage, procedures, and conflicting information; and (3) the financial devastation of serious illness. It offers three strategies: (1) assessment of social determinants of health and management of these needs, (2) coordination of care across teams, and (3) affordable care. These have become major themes as palliative care evolves into the future. The APRN has a role in addressing each of these strategies to improve the care of people with serious illness.²⁹

QUALITY

There have been several significant events related to the quality of palliative care. APRNs are obligated to ensure the quality of palliative nursing practice, which requires an awareness of these developments and standards and an appreciation of how they affect care delivery, the measurement of quality practice, and education. The National Quality Forum (NQF) is a nonprofit public–private partnership focused on quality care through the adoption of voluntary standards. Its goal is to develop meaningful information about care delivery, including timeliness, efficiency, safety, equality, and patient-centeredness.³⁰ In 2006, it published *A National Framework and Preferred Practices for Palliative and Hospice Care Quality: A Consensus Report*,³¹ which built on the NCP's eight domains of care and put forth 38 preferred practices for hospice and palliative care.

Related to the NQF was the formation of the National Priorities Partnership (NPP). In 2008, the NPP released the report *National Priorities & Goals: Aligning Our Efforts to Transform America's Healthcare*. It identified palliative and end-of-life care as one of the six National Priorities that, if addressed, would significantly improve the quality of care delivered to Americans.³² In 2010, the NPP convened a palliative and end-of-life care meeting. It developed several areas on which to focus strategies to promote palliative care, including quality improvement stakeholders, insurers, consumer groups, certification groups, professional groups, and educational institutions.³³ In 2012, the NQF developed 14 measures on palliative and end-of-life care.³⁴

Within the federal structures of healthcare reporting, work has been done as well. The Measure Applications Partnership (MAP) is a public–private partnership convened by the NQF. MAP was created to provide input to the Department of Health and Human Services on the selection of performance measures for public reporting and performance-based payment programs. Each year the MAP clinician workgroup reviews measures for the government to use in its reporting programs. It continues the work on the measures put forth by the NPP and the previous measures endorsed in 2012.

EVOLUTION OF PALLIATIVE NURSING EDUCATION

Other initiatives are exclusive to nursing. The multifaceted project *Strengthening Nursing Education to Improve End-of-Life Care* was funded by the Robert Wood Johnson Foundation and focused on improving nursing knowledge about end-of-life care.³⁵ The first component of the project reviewed nursing textbooks for end-of-life content, which was liberally defined as pain and symptom management, care of the dying patient, or spiritual care. This was completed in 1999, and it demonstrated that written content in end-of-life nursing care was nearly nonexistent.³⁵ One result was *The Oxford Textbook of Palliative Nursing*, originally co-edited by Betty Ferrell and Nessa Coyle. Now in its fifth edition, with Drs. Betty Ferrell and Judith Paice as editors, this nursing text serves as a reference for both the RN and APRN.

The second component of the project examined end-of-life care content in nursing licensing examinations. This resulted in the creation of baccalaureate education competencies in end-of-life care that were disseminated within the American Association of Colleges of Nursing (AACN) document, *Peaceful Death: Recommended Competencies and Curricular Guidelines for End-of-Life Nursing Care*.³⁶ Previous research had clearly demonstrated that both RNs and APRNs felt they had inadequate preparation in end-of-life care.^{37,38} These competencies have served as the basis for nursing education at both the graduate and undergraduate levels. Palliative and end-of-life content questions now appear on the National Council Licensure Examination (NCLEX) and on some national advanced practice certification examinations.

The third component was to support key organizations to improve end-of-life education for nursing. The result was the *Nursing Leadership Consortium on End-of-Life Care*, funded by the Project on Death in America. The goal was to design an agenda for the nursing profession in end-of-life care.³⁹ The agenda emphasized (1) educating nurse leaders in strategies of planning and managing change and advocacy related to palliative care and end-of-life care; (2) creating a system of support, networking, and mentorship for nurses engaged in leadership and advocacy in palliative and end-of-life care; and (3) developing and implementing innovative strategies to advance the priorities of the Nursing Leadership Consortium on End-of-Life Care.³⁹

An important collaboration between AACN and the City of Hope established the End-of-Life Nursing Education Consortium (ELNEC), which created a model of education for nurses.⁴⁰ The ELNEC curriculum, which initially focused the 1997 AACN's *Peaceful Death Competencies*, was created to educate nurses at all levels of practice and across all specialties. With a goal of developing a core of expert educators and teaching resources to enhance end-of-life care competency, many versions have been developed over the past 20 years, including core, graduate, oncology, critical care, geriatrics, pediatrics, and veterans.⁴⁰ More than 1 million nurses and health professionals have been trained. In 2013, the ELNEC Advanced Practice Registered Nurse Curriculum was developed, with the authors of this chapter serving as consultants for its development. The

goal is to offer education to new APRNs entering palliative care. There is a graduate version online as well as a curriculum for Doctor of Nursing Practice (DNP) faculty to teach them how to integrate palliative care into a DNP oncology curriculum. Recently, a curriculum specific to oncology APRNs has been created to help integrate primary palliative nursing skills into advanced oncology nursing practice. Current ELNEC versions include core, critical care, pediatric, geriatric, APRN, DNP palliative oncology, and oncology APRN.⁴⁰

In 2001, an important summit was held of national nursing leaders who represented clinical practice, academia, and research. The goal was to discuss advanced practice nursing in palliative care. The result was the document, *Advanced Practice Nurses Role in Palliative Care: A Position Statement from American Nursing Leaders*, which outlined the unique role of advanced practice nurses (APNs) in palliative care, and a companion monograph of pioneer APNs in the field.^{12,41} The position statement acknowledged the APN role in palliative care as a "valuable resource in national efforts to improve care and quality of life for Americans and their families living with advanced, life-limiting illness."⁴¹ These concepts were later woven into HPNA position statements.

Two graduate programs with a focus on specialist palliative nursing emerged early in palliative nursing development.⁶ In 1998, Ursuline College in Ohio offered preparation for the palliative CNS and New York University offered a program for the palliative NP. Both of the novel programs promoted specialist practice. The programs were successful for several years. However, in 2008, the National Council of State Boards of Nursing released the Licensure, Accreditation, Certification, and Education (LACE) model to increase the clarity and uniformity of APRN education and practice.⁴² The LACE model stated that APRNs must be educated in one of six population foci: (1) family/individual across the lifespan, (2) adult-gerontology, (3) pediatrics, (4) neonatal, (5) women's health/gender-related, or (6) psychiatric/mental health.⁴² Thus, APRN education was focused on population-based and primary practice rather than disease-focused specialties. The result was that palliative care was no longer recognized as a primary practice, but as a specialty practice. Thus, both programs needed to revise their curricula, moving away from a primary palliative care focus to meet the population/primary care focus of the LACE model. The LACE model remains controversial because palliative care cuts across all the foci and requires knowledge across the life trajectory of wellness and illness.

PALLIATIVE NURSING AS A SPECIALTY

In 1998, the Hospice Nurses Association embraced palliative care and changed its name to the Hospice and Palliative Nurses Association. In 2002, the *Scope and Standards of Hospice and Palliative Nursing Practice* was published in collaboration with the American Nurses Association.⁴³ These delineated the actions of RNs, APNs, and APRNs. Each subsequent standard represents the broader scope of palliative nursing for individuals with serious illness, beginning at diagnosis, through treatment and, if preferred by the patient

and family, continuing to hospice care, which focuses on the last 6 months of care. Moreover, they reflect the current social, cultural, and political milieu.^{20,21} Primary palliative nursing and specialty palliative nursing are described, and the different levels of advanced practice nursing within palliative care are delineated. One is a clinical role, where the APRN practices in the role of CNS, NP, certified nurse midwife, or certified nurse anesthetist. In a nonclinical role, the researcher, administrator, case manager, and educator are delineated as APNs.

To emphasize the practice of APRNs, *Competencies for the Advanced Practice Hospice and Palliative Care Nurse* were first developed in 2002 by the HPNA.⁴⁴ They are in their third edition and speak to care across the life continuum from perinatal to geriatric care. They focus on the fact that the principles of advanced practice and nursing process are consistent for all practice, although specific care delivery differs by age group.⁴⁵

In 2006, HPNA developed the *Standards for Clinical Practicum in Palliative Nursing for Practicing Professional Nurses*, which were updated in 2015.^{46,47} The goal of the standards is to ensure quality and consistency within palliative nursing education. Specific to advanced practice nursing is that a palliative program must have an Advanced Certified Hospice and Palliative Nurse (ACHPN) who leads the nursing education for graduate practicums and provides mentoring in the role development of an APRN. In addition, it sets the standard that palliative programs offering advanced nursing preceptorships or practicums must have been established for at least 2 years. It emphasizes the importance of using the NCP's *Clinical Practice Guidelines* as a framework for education. Finally, it requires palliative care programs offering APRN practicums or preceptorships to use the *Palliative Nursing: Scope and Standards of Practice* and the *Competencies for the Palliative and Hospice APRN*.

PALLIATIVE NURSING CERTIFICATION

Certification is a measure of specialty practice and serves as public recognition of an APRN's expertise. Within palliative care, nursing was first to develop a specialty hospice nursing certification in 1994, which in 2001 was expanded to include palliative nursing.^{6,21} (See Chapter 3, "Credentialing, Certification and Scope of Practice Issues for the Palliative APRN.") This was based on being recognized by ANA as a nursing specialty in 1987. Medicine offered certification in hospice and palliative medicine in 1996, and social work in 2000, followed later by chaplaincy organizations. In 2003, specialty certification at the APRN level was first offered.⁴⁸ As a note, palliative care was not recognized as a medical specialty by the American Board of Medical Specialties until 2007. As a collaborative effort between the American Nurses Credentialing Center and the National Board for the Certification of Hospice and Palliative Nursing, the examination necessitated evaluation of the CNS role and the NP role. The role delineation study found that the work in each role was almost identical and therefore only one examination was necessary; this study has been repeated several times with

similar results continuing with one examination. Starting in the early 2000s, many nurses used the ACHPN credential to establish palliative care as their primary practice.

An important milestone was achieved when the Center for Medicare and Medicaid Services recognized the National Board of Certification of Hospice and Palliative Nurses as one of seven recognized national certifications for reimbursement eligibility.^{49,50} However, this was short-lived, because implementation of the LACE model no longer allowed palliative care as a primary area of practice.⁴² Nevertheless, the role delineation study to determine the difference between CNS and NP practice was recently repeated, and the results again found that the activities were similar, necessitating one examination. To date, more than 2,200 APRNs have obtained the ACHPN credential.⁵¹

THE PALLIATIVE APRN TODAY

The palliative APRN role has evolved over the past 20 years, more rapidly in adult care than in pediatric care. APRNs are practicing primary palliative care and specialty palliative care across the lifespan, diseases, settings, and roles. Of note, pediatric APRN roles are still evolving because of how pediatric palliative care is billed and the prevalent consultant model of care. In addition, there is a difference in how pediatric care is delivered in designated children's hospitals that may have the luxury of more resources versus community or safety net hospitals that care for children.

There are two roles of advanced practice nursing in palliative care, set forth by the American Nurses Association and described in *Palliative Nursing: Scope and Standards of Practice*. One role is the graduate-level prepared specialty nurse who is educated at the master's or doctoral level but does not practice in the clinical arena.^{21, p. 23} The second role is the clinical role, or APRN, educated at a master's degree or higher, working across settings.^{21, p. 23} The phrase "advanced practice nurse" is an umbrella term which includes both types of graduate-prepared nurse. Therefore, all APRNs are APNs, but not all APNs are APRNs. Table 1.1 explains the two roles, and Table 1.2 gives information about the settings where APNs practice.

The current state of graduate palliative nursing education is inconsistent. Work has been done to create content guidelines for graduate programs for APRNs wanting to focus on palliative care as a minor or subspecialty. Table 1.3 and Table 1.4 offer resources and guidelines for palliative APRN practice. Several national organizations, such as ELNEC, CAPC, and HPNA, have recognized this gap in education and skill-building. HPNA offers palliative-focused continuing education for all levels of nursing practice. Since 2000, ELNEC has offered 2-day education programs focusing on eight modules. Recognizing the lack of APRN-specific education, in 2013, ELNEC launched a 2-day classroom APRN course focusing on six clinical modules (overview of palliative nursing, pain management, symptom management, communication, loss and grief, the final hours) and four program development models (finances, quality, education, and

Table 1.1 ADVANCED PRACTICE NURSING DESIGNATION, EDUCATION, AND ROLES

APN TYPE	EDUCATIONAL PREPARATION	ROLES
Graduate-level–prepared APN ^{4,20}	Master’s or doctoral degree	Administrator Researcher Case manager Academic educator Policy advocate Ethicist
Clinically educated APRN	Master’s, post-master’s, doctoral degree	Clinical nurse specialist (CNS) Nurse practitioner (NP) Certified nurse midwife (CNM) Certified registered nurse anesthetist (CRNA)

Table 1.2 ROLES AND SETTINGS FOR PALLIATIVE APRNS

Clinical nurse specialist or nurse practitioner	Hospice, home health agency, clinic, residential facility, skilled care facility, long-term care facility, hospital
Case manager	Insurance company, hospital (acute and rehabilitation), skilled care facility, hospice, home health agency, private practice
Educator	Academic setting, such as school of nursing and/or medicine, hospital, professional organization
Researcher	National research entity, such as National Institutes of Health or National Institute of Nursing Research, academic setting, such as school of nursing and/or medicine, academic medical setting, professional organization
Administrator	Hospice, home health agency, palliative care service
Policymaker	Professional organization, public organization, federal or state legislative body
Ethicist	Healthcare organizations, schools of nursing, professional organizations
Social justice advocate	Professional organizations, public organizations, federal or state legislative bodies, clinical settings (hospice, home health agency, clinics, residential facility, skilled care facility, long-term care facility, hospital, schools, prisons, group homes, rural clinics, etc.), payor settings (insurers and reimbursement entities), academic education settings, professional organization, public organization, federal or state legislative body
Technologist	Telehealth development within organizations, health apps, smart device integration, electronic information storage, health equipment

leadership), anticipating that APRNs would be leading more palliative care programs.

Outside of fellowships and observerships, there are few clinical experiences for APRNs. Of the few that exist, there are limitations in patient care exposure due to licensure, time, expense, and support for both CNSs and NPs.⁵⁷ There are few graduate programs that offer focused palliative care education, subspecialty, or certificate programs at either the master's or doctoral level.⁵⁸ Moreover, there are only a handful of APRN fellowships.⁵⁹ For pediatric care, there is only one graduate program devoted to pediatric palliative care and one fellowship focusing on developing pediatric expertise. Except for one community-based program, fellowships are offered at academic medical centers, with the majority targeted toward NPs.

The result is that the majority of fellowships are using this training to increase their workforce and retain APRNs rather than promote APRNs as leaders in the field.⁵⁷ Nonetheless, it is important to promote consistency in palliative APRN fellowships to assure that, even with the goal of interprofessional work, specific APRN role development and competencies are integrated into curricula. Graduate nursing program faculty with palliative care subspecialties developed consensus-based elements for palliative APRN education at the graduate level. This includes essential content, pedagogy, and competencies for the specialty palliative APRN to enter into practice content after graduation from these programs.⁵⁸ In addition, competencies and content have been built for postgraduate palliative APRN fellowships.⁵⁹

Graduate-level-prepared specialty nurses work in indirect roles, such as research, case management, administration, and education. Their settings of practice include academic research or education settings, schools of nursing, professional organizations, specialty clinics, and community settings. APRNs in these roles promote all aspects of palliative care and palliative nursing by developing diverse programs for the public, insurers, and international communities; creating

palliative care and nursing educational programs; and performing palliative care and palliative nursing research. Many documents frame such work, including the NQF's *A National Framework and Preferred Practices for Palliative and Hospice Care Quality: A Consensus Report*, the NPP's *Palliative and End-of-Life Convening Meeting Synthesis Report* strategies, and the NCP's *Clinical Practice Guidelines*.^{25,31,33} Although specialty palliative certification in these indirect roles does not exist, it is available in related areas, such as RN, administrator, pediatric nurse, or perinatal loss expert.

APRNs making a midcareer change into palliative care may find it a difficult transition. Educational opportunities are limited due to financial constraints, lack of education time, and shrinking education funds. There are also limits imposed by the variations of APRN practice—specifically, licensure variability from state to state makes it difficult for APRNs to cross into other states to obtain direct clinical experience. However, there are immersion programs that offer cost-effective exposure to APRN leaders in quality palliative care programs.⁶⁰ One such program, created by APRNs specifically for APRNs, is the Palliative APRN Externship. This is a 1-week program of both didactic and clinical exposure for a small cohort at three sites across the country; it has shown impressive outcomes.^{60,61}

APRN ROLES

Social Justice and Health Equity Advocate

The role of APRN as social justice and health equity advocate arises out of the new definition of nursing, one that places advocacy at the forefront for all patients and care. In the past few years, the role of the APRN as social justice and health equity advocate has become increasingly important through the exposure of systemic racial injustice in healthcare. APRNs use their education in community assessment to examine who is being cared for in the community and who is not, and they

collaborate with communities to help grow palliative care in underrepresented, underserved, and marginalized communities. APRNs can also foster the next generation of nurses by examining the palliative care workforce in their area and working to promote diversity. Finally, APRNs can work together in other roles to ensure equity and diversity in education, both in content and faculty, research in terms of populations, clinical practice in terms of assuring access for all, and policy to assure access for all.

Research

The role of research allows the APRN full participation to initiate, create, participate in, or lead research projects. This can include quantitative or qualitative research. There are the formal research roles of identifying clinical problems, developing and conducting research studies, and overseeing recruitment and data collection. Other important projects include quality improvement, translating research into practice, using research to create policies and procedures, educating others about the research process, and the use of evidence-based practice. In either type of role, the APRN draws on clinical experience from a patient or clinical perspective, enabling solutions to common palliative care concerns.

Education

The role of educator has both a formal and an informal dimension. Formal academic roles at schools of nursing include tenured faculty positions, such as adjunct professor, assistant professor, associate professor, and professor. Nontenured positions include instructors, lecturers, and adjunct clinical positions. Educator roles may also include educational positions within professional organizations, such as director or coordinator of education for a professional nursing organization or another discipline. Other education roles are present in palliative care and palliative care-related corporations, as with continuing education providers, pharmaceutical companies, or technical assistance companies, such as those providing learning management systems. Finally, there are educational initiatives that offer regional, national, and international opportunities in palliative care and palliative nursing education using the ELNEC curricula. APRN educators must ensure there is understanding of the various aspects of advanced nursing practice. Other aspects of education include palliative care development, APRN roles (role development and scope of practice), palliative care delivery (content, medications, communication, etc.), social context (ethical issues within palliative care), policy, reimbursement, technology, and health equity, to name a few.

Care Manager, Care Coordinator

The role of APRN care manager is found within healthcare organizations, insurers, and private companies. Care managers within hospitals are charged with increasingly difficult post-hospital care planning, with the emphasis on moving patients out of the hospital. In the community, there are more

APRN care managers who have the skills to create plans to keep complex patients in the community setting. These may include geriatric specialists, hospice specialists, or case managers within home health, hospice, or specialty programs, such as cardiac disease or pulmonary disease. With an increasingly complex health system and a growing geriatric population, care managers and care coordinators will be needed now more than ever before.

Administrator

The role of the APRN administrator is long established because many APRNs have started and led palliative care programs and palliative care initiatives. APRN administrators are charged with using their leadership skills inherent within the role and integrating skills from their graduate education. In addition, they may manage and coordinate programs depending on the progressiveness of the system in which they work. Similar to the collaborative work of interprofessional clinical care, the APRN administrator must collaborate with colleagues from business, finance, and informational technology to be effective in a leadership or managerial role. As palliative care develops, there are more aspects than just clinical care in which to lead.

Policy Expert

The APRN in policy and advocacy can be found in legislative entities or policy departments of professional organizations, associations, and insurers. Issues to work on include recognition of practice, ability to undertake full scope of practice, autonomy to support the Medicare Hospice Benefit, reimbursement, and prescriptive authority to name a few. Working in policy and advocacy, the APRN collaborates with others to determine strategic processes while also working to develop consistent messaging. The APRN grounds their work from their nursing practice and the public trust in nursing.

Clinical Practice

Within the clinical roles of CNS, NP, certified nurse midwife, and certified nurse anesthetist, many APRNs work in myriad health settings, including telehealth, home, hospice, ambulatory and outpatient clinics, long-term care, skilled nursing facilities, community and rural hospitals, and academic medical centers (see Table 1.2). They have met or been “grandmothered” into the requirements set by the National Council of State Boards of Nursing, or they may have completed a curriculum that combines population-specific issues with pain, palliative, or hospice concepts.

The APRN has two functions: a consultant or a primary care provider. In the consultant role, the APRN offers expertise in the care and management of patients with chronic progressive, serious advanced, or life-limiting illness. In this role, the APRN offers advice but does not write orders, request diagnostic tests, or write prescriptions. Part of the consulting process involves educating colleagues about the appropriateness of moving palliative care upstream to diagnosis. The other

part of consulting is performing expert care and offering expert opinion in the physical, psychological, spiritual, and emotional aspects of care. As a consultant, the APRN has limited control over the patient's care; rather, it is hoped that through the collaborative process, recommendations, suggestions, and advice will be followed. In a primary care role, the APRN takes on responsibility for the patient. In this role, he or she is responsible for all aspects of care, from diagnostics to prescriptions, from admission to discharge, and everything in between. As a primary provider, the APRN has more control but a larger burden of care. Patients may require more time and focus.

In addition, the APRN is part of an interdisciplinary team, as required by the definition of specialty palliative care stated in the NCP guidelines. The interdisciplinary team may include physicians, chaplains, nurses, nursing assistants, social workers, physical therapists, occupational therapists, speech and language pathologists, dietitians, pharmacists, volunteers, and bereavement specialists. The team must work collaboratively and capitalize on each member's strengths and expertise. Effective team communication is essential, because this is a clear indicator of quality care and patient and family satisfaction.

THE FUTURE OF PALLIATIVE APRNS INFLUENCING CARE DELIVERY

In the changing healthcare landscape, nurses, particularly APRNs, have been identified as an essential element to improving care and access, particularly as healthcare reform continues.^{1,41,57,62,63} The *Promoting Excellence: Advanced Practice Nurse Position Statement* acknowledged early on that APRNs offered promise for managing the changing needs of the aging population. Specifically, APRNs have the skills in clinical practice, education, and advocacy to develop palliative care in novel ways. The 2011 IOM report *The Future of Nursing: Leading Change, Advancing Health* acknowledged the essential contributions of nursing at the bedside and in healthcare redesign with four messages, on which work continues in the *Future of Nursing 2030*^{63,64}:

Nurses should practice to the full extent of their education and training.

Nurses should achieve higher levels of education and training through an improved education system that promotes seamless academic progression.

Nurses should be full partners with physicians and other healthcare professionals in redesigning healthcare in the United States.

Effective workforce planning and policymaking require better data collection and information restructure.

Each of these messages has important implications for hospice and palliative advanced practice nursing. APRNs should be practicing to the full extent of their education and training, but also to their scope of practice.

There is much work to be done to promote the APRN role within all types of programs. A more diverse population

of nurses should be encouraged to pursue graduate education and training to promote palliative care within primary care practices, specialty clinics, and specialty programs. This promotes health equity, quality care, and access to care. Of note, to ensure quality delivery, there must be more emphasis placed on promoting well-being and resiliency at the individual, team, and organizational levels.^{21,65,66,67,68} APRNs offer creative solutions in redesigning healthcare with population-focused initiatives and need to be involved in the development of technology for palliative care of the future. This allows them to create innovative models of care, develop software applications, and assess technological efficacy of care. APRNs may have a major role in workforce redesign and in restructuring care away from the hospital and back into the community where patients and family prefer care. Moreover, this promotes health equity because the *Future of Nursing 2030* promotes care that is patient-, family-, and community-centered. Positions are being created in the community that allow APRNs to use their full range of skills, outside the hierarchy inherent in hospital settings.

The National Academy of Medicine's *Future of Nursing for 2030: Charting a Path to Health Equity* recognizes the constant presence of nursing. The message is that nursing can create a culture of health, reduce health disparities, and improve the health and well-being of both the nurse and the US population in the twenty-first century.^{21,64,69} Palliative APRNs are part of the future, working to facilitate changes in clinical care, nurse education, nursing leadership, and nursing–community partnerships.⁶⁴

By the nature of their care, APRNs provide person-centered, family-focused care and engage in expert nurse–patient communication and advance care planning. APRNs are teaching and mentoring the next generation of clinicians, as well as their colleagues and the public, about palliative care. As a reimbursable provider and leaders of palliative care programs, APRNs have an integral role in payment and policies related to palliative care and need an understanding of reimbursement.⁷⁰ With the goal of palliative care being to keep patients at home and out of the hospital, APRNs are uniquely qualified and positioned to provide services, particularly in rural and community settings. They practice throughout the country in urban, suburban, community, and rural areas, with a focus on promoting wellness and alleviating suffering for patients and families living with illness. Within their scope of nursing practice, APRNs may diagnose, treat, prescribe for, and manage various health problems.

Within cancer care, there is a mandate for quality palliative care, and APRNs will be necessary to meet the growing demands of care. In 2012, the American Society of Clinical Oncology stated that palliative care should be offered to patients with advanced stages of lung cancer as well as for metastatic disease.⁶⁹ In the same year, the American College of Surgeons, in collaboration with the Commission on Cancer, issued a statement that palliative services should be offered to all cancer patients across the cancer trajectory.^{69,71} Finally, the 2013 IOM report *Delivering High-Quality Cancer Care: Charting a Course for a System in Crisis* suggests that scope of practice and reimbursement structures be created to promote comprehensive care.⁷² With the shortage of oncology

physicians, the interdisciplinary team will need to be maximally utilized based on their skills. APRNs will be needed to provide palliative care within oncology care.

In cardiovascular care, there is a new emphasis on palliative care. In 2014, the American Heart Association and the American Stroke Association issued joint guidelines for palliative care in caring for patients with heart disease and stroke.⁷³ The organizations recognized that palliative care should begin at the onset of such an event. In particular, this includes advance care planning, goal-setting, and family support, in particular for surrogate decision-makers. Given the call for palliative care for all stroke patients, APRNs will have a large role in promoting the use of palliative care and providing it across settings. This will have an impact on the large numbers of nurses in cardiovascular nursing. However, other chronic conditions, such as renal disease, neurodegenerative disease, and dementia have been integrating palliative care into their standards of treatment.

Despite this goal, clinical education and organized training in palliative care are seriously lacking. The NCP's *Clinical Practice Guidelines* offers a structure for future nursing education and research developed and initiated within the realm of advanced practice nursing in all aspects of palliative nursing. The provision of expert advanced palliative nursing requires clinical education and experience. The challenge for palliative APRNs will be developing the skills and knowledge necessary for their roles. For nurses entering a graduate program, there may be palliative care courses in pain and symptom management, advanced illness, and psychological coping. If an APRN is making a midcareer change into palliative care, there is a structure to allow development and mentorship within the palliative APRN role. While interprofessional education is appropriate for content and principles of palliative care, APRNs must receive coaching, mentoring, and education in specific palliative nursing principles and role-specific issues.

Furthermore, it is hoped that more innovative programs will be developed for midcareer transitions into palliative care. There are several examples of APRN-led palliative care programs: a NP-led primary care palliative care clinic,⁷⁴ a NP-led palliative care clinic imbedded in a health system,⁷⁵ and a CNS-led initiative in an oncology clinic.⁷⁶ There is the potential for more community-based models to emerge

in which palliative APRNs initiate or play a leading role in development and service delivery.

LEADERSHIP

As the numbers of APRNs grow, leadership will be essential. Leadership is necessary to improve the care of individuals with serious illness. Leadership gives APRNs the influence to guide social, practice, and environmental change. While there are many definitions of leadership, two are germane to palliative care. Kruse states that leadership is "a process of social influence that maximizes the efforts of others toward achieving a goal."^{77,78} This definition speaks to the aspects of leaders within a palliative care team focusing on quality care and access. Sullivan and Decker state that "Leadership involves influencing the attitudes, beliefs, behaviors and feelings of others."¹⁰ Leadership in palliative care is about influencing many constituencies. Patients, families, healthcare colleagues, healthcare systems, insurers, legislators, and communities need education on quality palliative care as part of quality healthcare (Box 1.2).

APRNs are increasingly being asked to lead initiatives such as palliative care programs, palliative care teams, policy initiatives, quality outcomes, and organizations.^{57,79} Leadership can occur within the areas of clinical practice, management and administration, research, education, policy, quality, health equity, well-being, and technology. Leadership encapsulates various characteristics and skills, including building connections, developing trust, engaging in critical thinking and critical listening, taking accountability and responsibility, communicating effectively, assessing oneself, giving constructive feedback, and negotiating conflict. The challenge is that there are limited leadership resources for APRNs, and most of these focus on management or administration and are expensive. Therefore, leadership is grounded within the NCP *Clinical Practice Guidelines*. APRN leadership includes expertise or continual growth in both evidence-based palliative care and advanced practice palliative nursing and understanding of palliative care models, healthcare principles, and Medicare guidelines. There are many good choices for obtaining leadership development through the programs and resources listed in Box 1.3.

Box 1.2 APRN LEADERSHIP EXAMPLES

- Designing new strategies to achieve health equity within palliative care by focusing on workforce diversity, culturally sensitive palliative care content, and initiatives to assure palliative care to unserved and underserved populations
- Developing, leading, managing, and administering hospice and palliative care teams across acute care, long-term care, ambulatory, residential, hospice, and home settings for populations across the life trajectory
- Role-modeling expert clinical care in acute care, long-term care, ambulatory, residential, hospice, and home settings
- Educating colleagues in palliative care principles (what it is; assessment of the physical, psychological, emotional, spiritual, and social domains; program development; quality; communication; and grief and loss) across acute care, long-term care, ambulatory, residential, hospice, and home settings
- Participating in and developing research of all aspects of palliative care and nursing and translating evidence into practice
- Consulting in patient care issues, program development, and quality issues
- Advocating for patients, caregivers, and healthcare professionals in terms of regulations, statutes, laws related to scope of practice, regulatory issues related to hospice and palliative care, advance care planning, pain management, access to care, and reimbursement

MENTORING

To ensure the maturity of the field, mentoring is essential. Mentoring is a professional relationship between an individual who is entering a profession, role, specialty, or organization and an individual with more experience who provides support, guidance, assistance, and education. APRNs, as experts and leaders, serve as important mentors to mentees (a novice or protégé) to help them invest in the specialty of palliative nursing, the nursing profession, the field of palliative care, or an organization. Palliative APRNs may be mentors in clinical settings, healthcare settings, professional organizations, healthcare systems, and policy organizations.

Mentoring can be formal, using an application process with established goals, objectives, and a contract, or it can be informal, building mutual respect in a more unstructured process. For the palliative APRN, the mentoring roles include structural, organizational, and career development domains. The domains are educational in terms of the role of the APRN, supportive in terms of a system or organization, or administrative in terms of a leadership role.⁵⁷ Again, there is a lack of formal mentoring programs. However, more APRNs are turning to mentor others in an informal structure.

SUMMARY

With their foundational nursing practice and primary palliative care skills, APRNs have more opportunities in emerging models of healthcare. Being the fastest growing sector of healthcare providers and with an emphasis on advocacy, well-being, and health equity, APRNs will be part of the solution to workforce shortages and an aging population. They will be situated in myriad settings in the community, and they must ensure quality access to all populations to reduce health disparities in marginalized or underserved populations, with a focus on patient-, family-, and community-centered care.⁶⁴ To promote better care for individuals with serious illness, the APRN's clinical settings include primary care clinics, in-home care for frail elders, and rural practices, as well as accountable care organizations and medical homes and hospitals.

Across these settings, APRNs will prevent unnecessary admissions and promote appropriate, safe, and timely discharges. In determining their roles and responsibilities, key areas for the APRN to survey will include knowledge, role clarification, palliative nursing competence, and a culture that embraces both advanced practice nursing and palliative nursing. Some of the issues APRNs will need to grapple with are (1) the clinical and didactic palliative care education required for clinical roles; (2) licensing, credentialing, and certification for both clinical and nonclinical roles; (3) qualifications to do either primary or specialty advanced palliative nursing; (4) the creation of supportive work environments; and (5) obtaining and ensuring appropriate financial support for their services.

Undoubtedly, the field of palliative care will continue to mature to meet the needs of individuals with serious

illness and an aging and sicker population. Specialty palliative APRNs will promote further maturity of the role and create new models of palliative care by building on their knowledge and expertise. Their future is bright as they shape care delivery under health reform.

2.

FUNDAMENTAL SKILLS AND EDUCATION FOR THE GENERALIST AND SPECIALIST PALLIATIVE APRN

Dorothy Wholihan, Charles Tilley, and Adrienne Rudden

KEY POINTS

- Advanced practice registered nurses (APRNs) provide primary palliative care through integration of basic palliative care interventions with their population-focused practice and through expert board-certified specialty palliative care.
- The Licensing, Accreditation, Certification, and Education (LACE) model of regulatory standards developed by the National Council of State Boards of Nursing defines specialist-level palliative care as an APRN specialty practice, which is defined by professional board certification.
- Current palliative care education for APRNs includes a variety of programs, including master's, post-master's, doctoral, and continuing professional education programs.

CASE STUDY: APRN EDUCATION

Carlos DeLeon has been an acute care registered nurse (RN) working in the medical intensive care unit of a hospital for 4 years. After a surge of COVID cases, he saw too many people die with uncontrolled symptoms and without any support for themselves or their families. He realized he needed a change in his practice and wanted to help people to stay out of the ICU at the end of their lives. During the pandemic, he was exposed to how the palliative care team worked closely with patients and families to manage symptoms and articulate their goals to attain the best outcomes possible. He attended a virtual End-of-Life Nursing Education Consortium (ELNEC) Critical Care conference, and this confirmed his calling to palliative care. He wants to return to school to obtain a master's degree to become an acute care APRN, with specialty training in palliative care. Alternatively, he is considering a bachelor of science in nursing (BSN) to doctor of nursing practice (DNP) program to develop the clinical leadership and quality improvement skills needed to influence his hospital system to improve end-of-life care for critically ill patients.

DEFINITION OF ADVANCED PRACTICE NURSING

Advanced practice registered nurses (APRNs) have played a pivotal role in palliative care over the past 20 years and will

continue to shape the future of hospice and palliative care. Broadly defined and practice-focused, APRNs treat and diagnose illnesses, advise the public on health issues, manage chronic disease, and engage in continuous education to remain current in their knowledge of developments in the field. APRNs hold at least a master's degree, in addition to the initial nursing education and licensing required for all registered nurses (RNs). Based on the definition originally developed by the American Association of Colleges of Nursing (AACN), the term "APRN" refers to master's-prepared nurses who provide direct clinical care.¹

ROADMAPS FOR EDUCATION

In the late 1990s, a national dialogue was ignited about the ability of the healthcare system to provide care to patients with life-threatening illness. In response to the dearth of end-of-life content in most nursing curricula at the time, combined with the realities of an aging population, the expense of unnecessarily prolonged dying driven by advanced technology, and public apprehension about suffering, the AACN, supported by the Robert Wood Johnson Foundation, assembled a panel of experts in 1997 to develop end-of-life competency statements.² This project, conducted in accordance with the mandate by the International Council of Nurses (ICN), detailed nurses' unique role in and responsibility for ensuring that individuals experience a peaceful death.³ A round table of expert nurses and other healthcare professionals, on the premise that the precepts underlying hospice care are essential principles for all end-of-life care, developed an interdisciplinary approach to the educational preparation of nursing students for end-of-life practice. The panel developed 16 end-of-life competency statements to be included in multiple content areas, including health assessment, pharmacology, psychiatric-mental health nursing, nursing management courses, ethical/legal courses, cultural issues content, nursing research, and professional issues/healthcare settings.²

The *Clinical Practice Guidelines for Quality Palliative Care* were originally published in 2004 by the National Consensus Project for Quality Palliative Care (NCP).⁴ The NCP started as a partnership of five national palliative care organizations: the American Academy of Hospice and Palliative Medicine (AAHPM), the Center to Advance Palliative Care (CAPC), the Hospice and Palliative Nurses Association

(HPNA), the Last Acts Partnership, and the National Hospice and Palliative Care Organization (NHPCO), later joined by the National Palliative Care Research Center and the National Association of Social Workers. The *Clinical Practice Guidelines* was the result of professional consensus in making recommendations about the development of palliative care programs by creating clinical practice guidelines that improve the quality of palliative care in the United States. The fourth edition of the *Clinical Practice Guidelines for Quality Palliative Care*, published in 2018, further delineates the original eight domains identified.⁴ Domain 1, Guideline 1.1 states that the interdisciplinary team includes palliative care professionals with the appropriate patient population-specific education, credentialing, and experience and the skills to meet the physical, functional, psychological, social, cultural, and spiritual needs of both patient and family. Of particular importance is assembling a team, which includes chaplains, nurses, advanced practice providers (physician assistants and APRNs), pharmacists, physicians, and social workers, appropriately trained and, ideally, certified in hospice and palliative care, when such certification is available.⁴

Building on the work of the NCP, the National Quality Forum (NQF), a nonprofit public-private partnership, focused on improving the quality of healthcare through setting voluntary consensus standards, in 2006 developed *A National Framework and Preferred Practices for Palliative and Hospice Care Quality* (NQF Preferred Practices).⁵ They incorporated the principles of the *Clinical Practice Guideline* domains into the framework, which were directly reflected in the preferred practices.

The NQF identified 38 preferred practices, including educational standards directly relatable to advanced practice education. NQF Preferred Practices 3, 4, and 5 directly addressed education.⁵

- *Preferred Practice 3.* Provide *continuing education* to all healthcare professionals on the domains of palliative care and hospice care.
- *Preferred Practice 4.* Provide *adequate training and clinical support* to assure that professional staff is confident in their ability to provide palliative care to patients.
- *Preferred Practice 5.* Hospice care and specialized palliative care professionals should be *appropriately trained, credentialed, and/or certified* in their area of expertise.

The NCP Clinical Guidelines recommend that Palliative care programs ensure appropriate levels of education for all palliative care professionals. “Advanced practice nurses, physicians, and rehabilitation therapists must have graduate degrees in their respective disciplines, with appropriate professional experience in hospice and palliative care.”^{24 p.6}

In 2010, the Institute of Medicine (IOM) published landmark recommendations on how to transform the nursing profession so that nurses can fully impact the nation’s health. This document, entitled, *The Future of Nursing: Leading Change, Advancing Health*, was congruent with many palliative position statements already mentioned in this chapter

as it attempted to address the needs of an aging population, the growing number of people with chronic diseases, and the need for care coordination.⁶ This report has influenced nursing education and practice for the past decade. Eight key recommendations were proposed, with two related to the promotion and elevation of nursing education⁶:

1. Nurses should practice to the full extent of their education and training.
2. Nurses should achieve higher levels of education and training through an improved education system that promotes seamless academic progression.

In response to the IOM report, the Robert Wood Johnson Foundation partnered with the American Association of Retired Persons (AARP) to launch a national campaign—the Future of Nursing: Campaign for Action—to advance the report’s recommendations through the establishment of state-based coalitions. Preliminary data at 10 years after the report reveals significant improvements, such as a doubling of the number of practicing nurses with doctoral degrees and a significant expansion of the number of nurses permitted to practice at the full extent of their education and training.⁷ The Campaign’s formal progress report was originally postponed due to the COVID pandemic but has now been posted to support the release of the new *Future of Nursing 2020–2030 Charting A Path to Achieve Health Equity*.⁸

In 2021, the AACN amended *The Essentials: Core Competencies for Professional Nursing Education*. For all levels of nursing education: baccalaureate, masters, and doctoral.⁹ The new essentials are competency-based and provide educational standards for nursing practice as defined within competencies for ten domains, competencies, and sub-competencies for advanced entry-level nursing practice.⁹ Hospice, palliative, and supportive care features dominantly, as one of the four defined spheres of care.

The competencies accompanying each domain are designed to be applicable across four spheres of care (disease prevention/promotion of health and well-being, chronic disease care, regenerative or restorative care, and hospice/palliative/supportive care), across the lifespan, and with diverse patient populations. While the domains and competencies are identical for both entry and advanced levels of education, the sub-competencies build from entry into professional nursing practice to advanced levels of knowledge and practice.^{9, p. 1}

PRIMARY PALLIATIVE CARE VERSUS SPECIALTY PALLIATIVE CARE

With the expansion of the field of palliative care, specialist workforce shortages have become apparent in all disciplines, including advanced practice nursing. There are not enough specialty-trained palliative care clinicians to meet the needs of all patients. As a solution, the concept of *primary palliative*

care has evolved. Primary palliative care should be provided by all healthcare professionals and includes the management of chronic illness, basic symptom management, communication, and the appropriate completion of advance directives. Specialty palliative care is provided by professionals with more extensive training and certification in palliative care and is focused on patients and families with more complex needs and serious, advanced illness. It is hypothesized that a combination of generalist and specialist palliative care can meet the palliative care needs of our population in a more sustainable and cost-effective manner.¹

All APRNs are educated to obtain the knowledge, skills, and competency to perform basic primary palliative nursing. However, additional graduate education and preparation is needed to promote practice at an advanced specialty level. More graduate programs are now including population-focused specialty palliative care education as either elective courses or as more extensive and formal specialty course programs.

PRIMARY PALLIATIVE REGISTERED NURSING PRACTICE

Since the essence of palliative care is embedded in all nursing practice, all nurses already practice primary palliative care. This is inherent in the definition of registered professional nursing as the alleviation of suffering through the diagnosis and treatment of human response to illness¹⁰ and advocacy in the care of individuals, families, communities, and populations. By the nature of their role, all nurses provide physical and psychosocial symptom management. They also have the skills to assess and assist care-planning discussions and to identify spiritual issues and cultural concerns.

Many undergraduate baccalaureate programs offer specific courses in palliative care or incorporate elements of palliative nursing into required classes. After graduating from an accredited nursing program, RNs at the generalist level are required to pass the National Council Licensure Examination (NCLEX-RN), which includes palliative care content.¹¹ Funded by the Cambia Foundation, the AACN, in conjunction with End of Life Nursing Education Consortium (ELNEC), released the *Competencies and Recommendations for Education Undergraduate Nursing Students (CARES)* document to define palliative care competencies and an online associated curriculum. This work was revised in 2020 to address the needs of new graduate nurses as well.^{12,13}

In 2017, the HPNA, in conjunction with the Hospice and Palliative Credentialing Center and the Hospice and Palliative Nurses Foundation, organized a Palliative Nursing Summit in Washington, DC, entitled *Palliative Care: Nurses Leading Change and Transforming Care*. The goal of this summit was to convene leaders from various nursing specialty organizations to develop a collaborative nursing agenda for primary palliative nursing. The work of the summit focused on three aspects of palliative nursing: communication/advance care planning, coordination/transitions of care, and pain and symptom management.¹⁴

ADVANCED PRACTICE PRIMARY PALLIATIVE NURSING

In 2018, the Cambia Foundation funded an initiative to develop competencies for primary palliative care for master's-prepared advanced practice nurses. ELNEC faculty developed and later revised a document entitled, "G-CARES: Primary Palliative Care Competencies for Masters and DNP Nursing Students".¹⁵ These competencies align with the AACN *Essentials* and the fourth edition of the *NCP Guidelines for Quality Palliative Care*. The twelve primary palliative care competencies are expected of all graduate nursing students, including APRN, Clinical Nurse Leaders (CNL), nurses in education, administration, informatics, and public health, and DNP students who will be directly or indirectly providing primary palliative care for seriously ill patients and their families, from infants and children through geriatric populations and across the illness trajectory. These primary palliative competencies can be applied to graduate students who will be providing direct primary palliative care across any clinical, community, or technology-mediated (telehealth) setting.¹⁵

Generalist palliative care competencies are included in the competency statements listed by several nursing organizations.^{16–18} The National Organization of Nurse Practitioner Faculty (NONPF) *Nurse Practitioner Core Competencies Content* identifies general core competencies in the realms of communication, cultural competence, ethics, and palliative and end-of-life care.¹⁶ It is important to note that the NONPF competencies are inclusive of all advanced practice nursing specialties and populations, including pediatrics, family, acute care, psychiatric-mental health, and primary care.¹⁹ Similarly, Midwifery Core Competencies include competencies in the realms of communication, collaboration, bioethics, psychosocial, and end-of-life care for the stillborn and family.¹⁷ Clinical nurse specialist (CNS) competencies include relationship-building communication to promote a peaceful end-of-life and engage in difficult conversations, as well as advocacy of ethical principles and ethical conflict resolution of nurses and staff.¹⁸ Table 2.1 outlines generalist-level advanced practice competencies that pertain to palliative care.

ADVANCED PRACTICE SPECIALTY PALLIATIVE NURSING

As described in *Palliative Nursing: Scope and Standards of Practice*,²⁰ there are two roles in advanced practice specialty palliative nursing practice. One advanced practice role is the graduate-level-prepared specialty nurse educated at the master's or doctoral level in nondirect care roles (e.g., education, research, administration). These nurses practice in a variety of settings such as academic medical centers, schools of nursing, specialty clinics, community settings, academic research or education settings, and various professional organizations. They promote educational programs in palliative care, palliative nursing research, and program development for diverse programs. Although advanced palliative nursing certification

Table 2.1 GENERALIST-LEVEL ADVANCED PRACTICE PALLIATIVE CARE COMPETENCIES

GENERALIST-LEVEL PALLIATIVE CARE COMPETENCIES	NURSE PRACTITIONER (NONPF) ADULT-GERIACUTE CARE NP ADULT-CARE PRIMARY CARE NP FAMILY NP PEDIATRIC NP NEONATAL NP PSYCHIATRIC MENTAL HEALTH NP			MIDWIFERY (ACNM)	CLINICAL NURSE SPECIALIST (NACNS)
Communication	Leadership competencies Communicates practice knowledge effectively, both orally and in writing		Hallmarks of midwifery - Skillful communication, guidance, and counseling - Collaboration with other members of the interprofessional healthcare team		Direct care - Uses relationship-building communication to promote health and wellness, healing, self-care, and peaceful end-of-life - Uses advanced communication skills in complex situations and difficult conversations
Ethics	Ethics competencies - Integrates ethical principles in decision-making. - Evaluates the ethical consequences of decisions - Applies ethically sound solutions to complex issues related to individuals, populations, and systems of care		Professional responsibilities Broad understanding of the bioethics related to the care of women, newborns, and families		Nurses and nursing practice - Leads efforts to resolve ethical conflict and moral distress experienced by nurses and nursing staff. Organizations/Systems - Advocates for ethical principles in protecting the dignity, uniqueness, and safety of all
Cultural competency	Health delivery system competencies - Facilitates the development of healthcare systems that address the needs of culturally diverse populations, providers, and other stakeholders Independent practice competencies - Incorporates the patient’s cultural and spiritual preferences, values, and beliefs into healthcare				
Symptom management and end-of-life care	Independent practice competencies Provides the full spectrum of healthcare services to include health promotion, disease prevention, health protection, anticipatory guidance, counseling, disease management, palliative, and end-of-life care		Components of midwifery care of women - Measures to support psychosocial needs during labor and birth Components of midwifery care of the newborn - End-of-life care for stillbirth and conditions incompatible with life		

From National Organization of Nurse Practitioner Faculties¹⁶; American College of Nurse-Midwives Board of Directors¹⁷; National Association of Clinical Nurse Specialists¹⁸; Population-Focused Competencies Task Force.¹⁹

is not available in these areas, generalist hospice and palliative certification is encouraged. Currently, appropriate examinations offered are for the RN, administrator, generalist pediatric nurse, and perinatal loss expert.²¹

The second, more common level of advanced palliative nursing practice is that of the APRN, a nurse educated at the master's level or above and practicing within one of the four roles defined by the 2008 *Consensus Model for APRN Regulation: Licensure, Accreditation, Certification, and Education (LACE)* document developed by the APRN Consensus Work Group & National Council of State Boards

of Nursing APRN Advisory Committee.²² According to this document, the APRN is a RN educated at the master's, post-master's, or doctoral level in one of four roles: a CNS, nurse practitioner (NP), certified nurse midwife (CNM), or certified RN anesthetist (CRNA). National certification is required to delineate basic advanced practice competency at the population level. Specialty practice (such as palliative care or oncology) allows depth in one's practice within the established population foci.²² CRNAs and CNMs working in palliative care may practice in areas like pain management or perinatal palliative care. Most hospice and palliative specialty

APRNs are CNSs and/or NPs. The national certification for palliative care advanced practice nursing is offered for specialty certification on top of basic population certification.²¹

SCOPE AND COMPETENCIES OF THE SPECIALIST PALLIATIVE APRN

The specialty palliative APRN role was first identified 20 years ago when nursing leaders from academia, clinical practice, and research held a national leadership meeting to discuss the vital role of APRN in palliative care (see Chapter 1). While palliative care is most often delivered by multidisciplinary teams, APRNs often lead these teams and are the glue that holds them together to provide optimal care.²³

The skills required for advanced practice in palliative nursing have been defined by the professional organization that represents this discipline. The American Nurses Association (ANA) and the HPNA have defined standards for practice in the document *Palliative Nursing: Scope and Standards of Practice*, which includes standards specific to advanced nursing practice.²⁰ In the 2021 sixth edition, the document

is accompanied by a more specific delineation of competencies in the HPNA publication entitled *Competencies for the Palliative and Hospice APRN*.²⁴ This document describes advanced core competencies that represent the knowledge, skills, and attitudes advanced practice hospice and palliative care nurses demonstrate when providing evidence-based care to patients and families experiencing life-limiting, progressive illness. This care encompasses the physical, psychosocial, emotional, and spiritual realms. Thus, graduate education must include these competency domains. Box 2.1 lists the basic areas of palliative APRN competency as defined by the HPNA.²⁴

DEFICITS IN NURSING EDUCATION

The topics of palliative and end-of-life care have been historically neglected within both medical and nursing education.²⁵ In a landmark study of nursing textbooks, Dr. Betty Ferrell and colleagues²⁶ first documented these deficits, finding that only 2% of nursing textbooks contained any reference to end-of-life care. Ten years later, deficits still remained. Shea

Box 2.1 PALLIATIVE NURSING: SCOPE AND STANDARDS OF PRACTICE DEFINED AREAS OF SPECIALTY PALLIATIVE APRN EXPERTISE

Clinical Judgment

Within palliative care, the palliative nurse demonstrates clinical judgment, clinical reasoning, critical thinking, and decision-making surrounding palliative nursing, integrating global knowledge of multidimensional needs of individuals with serious illness and their families using the nursing process.

Advocacy and Moral Agency

The palliative nurse integrates knowledge, attitudes, behaviors, and skills that are consistent with nursing professional standards, nursing codes of ethics, and scope of practice into their palliative nursing practice. This includes advocating for human rights of all individuals, with the goal of addressing and reducing health disparities, inequities, racism, and discrimination of people of color, LGBTQ+ individuals, and other marginalized groups.

Caring Practices

The palliative nurse integrates caring practices to create a compassionate, supportive, and therapeutic environment for individuals with serious illness, families, and staff, including vigilance, engagement, and responsiveness.

Collaboration

The palliative nurse collaboratively engages with individuals with serious illness, their families, and healthcare providers in a way that promotes each person's contributions toward achieving optimal yet realistic individual and family goals.

Systems Thinking

The palliative nurse identifies and utilizes the evidence and body of knowledge for palliative care delivery and clinical practice, as well as the tools to manage the environmental and system resources for the individual with serious illness, their family, and staff within a healthcare system and a community.

Response to Diversity

The palliative nurse has the cultural sensitivity to recognize, appreciate, and incorporate the cultural needs and preferences of individuals with serious illness into the provision of care. Assessment includes but is not limited to cultural identity, spiritual beliefs, sexual orientation, gender identity, gender expression, ethnic identity, socioeconomic status, age, educational level, and values.

Facilitation of Learning

The palliative nurse facilitates learning for individuals with serious illness, their families, nurse colleagues, other members of the healthcare team, and the community.

Clinical Inquiry

The palliative nurse utilizes the ongoing process of questioning and evaluating palliative practice and providing informed practice based on the established palliative care research evidence and related information.

From Dahlin.²⁴

and colleagues examined knowledge about end-of-life care of experienced nurses returning for graduate study and found that, for the most part, graduate students had no previous palliative care education (86.7%) and linked palliative care solely with end-of-life care.²⁷ To address this gap, the ELNEC-APRN curriculum was developed to promote optimal practice in 2013.²⁸ In 2018, the results of the first known national survey specific to APRNs practicing in hospice and palliative care was published, revealing that 60% still had no palliative care content in their graduate programs, and the majority of specialty APRNs received training through continued education.²⁹

CHANGES IN APRN EDUCATION: THE LACE MODEL

As described earlier, major changes in the education and licensing of advanced practice nurses came about with the proposal of the LACE model, a uniform model of regulation of APRNs across the states.²² The model established foundational requirements for educational tracks leading to APRN licensure. This model recategorizes APRNs, mandating that they have education and certification within a population focus. The consensus model specifies four advanced practice registered nursing roles which fall within at least one of six population-based foci: family/individual across the lifespan, adult-gerontology, pediatric, neonatal, women's health/gender related, or psychiatric/mental health). After extensive national dialogue, the decision was made to define the adult population as "adult-gerontology" in order to increase the number of APRNs prepared to care for the growing older population.²² This move has had a profound impact on the education of APRNs in that all adult programs now have a melded adult-gerontology focus. Increasing geriatric curriculum in all adult programs will, it is hoped, result in increased palliative care content as well.

CURRENT EDUCATIONAL MODELS: GRADUATE EDUCATION IN SPECIALTY PALLIATIVE CARE

As the specialty of palliative care has evolved over the past 20 years, so, too, have the educational models that form the basis of specialty advanced practice palliative nursing education. In 1998, the Breen School of Nursing at Ursuline College in Ohio offered the first master of science in nursing (MSN) program for the preparation of palliative CNSs. The same year, a program specifically designed to prepare palliative NPs was established at New York University. Both pioneering APRN programs included basic master's-level essential coursework, with clinical practice.²⁵

Since these original programs were offered, several different models have been developed to integrate specialist palliative nurse education and clinical practice into master's programs. Framed as minors, certifications, and subspecialties, university programs have delivered content in a variety

of formats ranging from single-course didactic elective classes to extensive clinical and classroom-based specialty tracks. Interprofessional master's programs with no clinical component have also been developed. Currently, there is a lack of consistency and standardization among programs, although some resources exist to assist with curriculum development. As the specialty palliative nursing organization, the HPNA developed both scope and standards and competencies for advanced practice. In addition, the HPNA established guidelines for clinical education entitled *Standards for Clinical Education*.³⁰ There has been recent work under way to develop consensus guidelines for graduate specialty palliative nursing education, and guidance is eagerly anticipated by many academic educators and administrators.³¹

With the expanding need for palliative APRNs, several universities have developed post-master's certificate programs. Designed for practicing APRNs who wish to develop a new area of expertise, these programs are increasingly popular among working advanced practice nurses wanting to move into palliative care. A variety of formats exist, from purely didactic online programs to 12-credit academic programs with up to 500 clinical practicum hours. Some programs are merged with DNP degree programs.

DOCTORAL EDUCATION IN PALLIATIVE CARE: PHD, DNS, DNSC, AND DNP

Doctoral education for the palliative care nurse provides the opportunity to contribute to the state of knowledge in the field. PhD, DNS, and DNSc programs in nursing provide the tools for nurses to design, conduct, analyze, and report theoretical and clinical research related to the care of those with advanced, progressive illness, while the DNP is a clinically based doctoral degree designed to translate evidence into practice and effect systems change.^{32,33} Table 2.2 outlines the fundamental characteristics of PhD, DNS, DNSc and DNP programs of study.^{32,33}

THE PALLIATIVE NURSE PREPARED AS PHD, DNS, OR DNSC

There is an urgent need for PhD-, DNS-, and DNSc-prepared nurses committed to increasing the body of knowledge within palliative nursing. *The Hospice and Palliative Nurses Associations (HPNA) 2019–2022 Research Agenda* highlights the need to integrate evidence into practice and guides nurse researchers in prioritizing research studies.³⁴ The *HPNA Research Agenda* emphasizes the need for well-designed studies to provide the necessary evidence-based foundation for optimal care of patients and their families along the full trajectory of serious illness. Within the framework of the eight NCP domains discussed earlier in this chapter, five priority gaps in palliative knowledge were identified by HPNA members emphasizing (1) Domain 1: Structure and Processes of Care, (2) Domain 2: Physical Aspects of Care, and (3) Domain 4: Social Aspects of Care.⁵ In spring of 2018, the HPNA Research Special Interest

Table 2.2 PhD, DNS, DNSc, AND DNP PROGRAMS

	PHD, DNS, DNSC	DNP
Focus	Nursing research	Nursing practice
Degree Objectives	To prepare nurse scientists to develop new knowledge for the science and practice of nursing. Graduates will lead interdisciplinary research teams, design and conduct research studies, and disseminate knowledge for nursing and related disciplines.	To create nursing leaders in interdisciplinary healthcare teams by providing students with the tools and skills necessary to translate evidence gained through nursing research into practice, improve systems of care, and measure outcomes of patient groups, populations and communities
Curriculum Focus	Emphasis on research methodology, theory and meta-theory. Cognates, courses in other disciplines that complement nursing science, are required. They provide knowledge of basic and social sciences that is relevant to the student's research focus.	Emphasis on translation of research to clinical practice. Specialized emphasis or tracks of practice: • Direct care of individual patients • Care of patient populations • Practice that supports patient care
Point of Entry	BSN or MSN (or related master's degree)	BSN or master's in advanced practice nursing
Dissertation	Dissertation, including a dissertation defense, is required.	Dissertation requirements differ and must be grounded in clinical practice. They vary greatly and may include: • No dissertation • Thesis • Capstone project
Clinical Requirements	Field research requirements vary.	Clinical practicum/residency requirements vary.
Employment Opportunities	Nurse scientist, nursing faculty	Healthcare administration, clinical nurse faculty

Adapted from Edwards N, Coddington J, Erler C, Kirkpatrick J. 2018³²; American Association of Colleges of Nursing. DNP Education. 2020.³³

Group (SIG) members met to generate a list of research area gaps.³⁴ Subsequently, the Research Advisory Council (RAC) members and other identified experts reached consensus on five research priorities: (1) pediatric hospice and palliative nursing research; (2) family caregiving; (3) interprofessional education and collaborative practice (IPECP); (4) Big Data science, precision health, and nursing informatics; and (5) implementation science.³⁴ In this document, the HPNA also strongly recommended an interdisciplinary research team approach, which PhD-prepared nurses are uniquely positioned to lead because they are among the frontrunners in developing interprofessional education models embodying the teamwork competency.

The HPNA is not alone in recognizing the dearth of research in end-of-life care and the need for evidence-based practice development. The AAHPM partnered with the HPNA Research Advisory Group on an initiative called *Measuring What Matters*.³⁵ The purpose of the initiative is to provide measures for palliative care programs to use in program improvement, which would be a companion to the NCP guidelines previously discussed.

The science of palliative care has been targeted as a priority area for the National Institute of Nursing Research (NINR). In 2011, the NINR, the lead National Institutes of Health (NIH) funder of palliative care, conducted a State-of-the-Science Conference on Improving End-of-Life Care and affirmed its commitment to funding and supporting research

in palliative care.³⁶ The 2016 NINR Strategic Plan identified two palliative care research foci, *Symptom Science: Promoting Personalized Health Strategies* and *End-of-Life and Palliative Care: The Science of Compassion* (NINR, 2016). The NINR Strategic Plan is due to be updated in 2021. At time of publication, several major funding opportunities for palliative nursing were open. Table 2.3 provides examples of funding opportunities for nurse researchers in palliative care.³⁷

THE DNP-PREPARED PALLIATIVE NURSE

The DNP is a terminal degree for nurses interested in a clinically focused, rather than research-based, doctorate. The development of this degree emerged from the need for highly educated, expert clinicians who could assume clinical leadership roles in shaping policy, developing clinical education and quality initiatives, and translating evidence at the point of patient contact.

There are currently two entry points for DNP education. The first is the post-bachelor's (BSN to DNP) program that integrates the preparation of APRNs within the roles and population foci described earlier. The other option is the post-master's DNP, for the master's-prepared APRN who is already practicing. Palliative education can be integrated into either option. Students in the BSN-to-DNP program can add the specialty to their population focus, and post-master's students can gain specialized knowledge while fulfilling the requirements for the doctoral degree.

Table 2.3 NATIONAL INSTITUTE OF NURSING RESEARCH (NINR) FUNDING OPPORTUNITIES FOR PALLIATIVE CARE RESEARCH

FUNDING OPPORTUNITY	TYPE OF GRANT*
End-of-life and palliative needs of adolescents and young adults with serious illnesses	R01, R21
End-of-life and palliative care health literacy: Improving outcomes in serious, advanced illness	R01
Advancing the science of geriatric palliative care	R01, R03, R21
End-of-life and palliative care approaches to advanced signs and symptoms	R01, R21

* Definition of grant types

R01: National Institute of Health (NIH)'s most commonly used grant program, used to support a discrete, specified, circumscribed research project. No specific dollar amount. Usually granted for 3–5 years.

R03: NIH Small grant program. Provides limited funding: Up to \$50,000 for up to 2 years. Provides limited funding for a variety of types of projects, including pilot or feasibility studies, collection of preliminary data, secondary analysis of existing data, small self-contained research projects, development of new technology.

R21: Encourages new, exploratory, and developmental research projects by providing support for the early stages of project development. Sometimes used for pilot and feasibility studies. Up to \$275,000 for up to 2 years. No preliminary data are generally required.

From National Institute for Nursing Research. Funding Opportunities. 2020.³⁷

The essential competencies of the DNP relate directly to the role of the palliative APRN, who often assumes systems-based responsibilities such as patient and professional education, quality improvement, and team leadership.³⁸ The DNP program requires a capstone project that demonstrates achievement of the DNP graduate's clinical competencies, emphasizes the translation of evidence into practice, and often provides the clinical scholarship leading to nursing policy change.³³

Integrating palliative care content into master's and doctoral programs has been a challenge due to the high credit requirements of many programs. Lack of faculty expertise in palliative care has also been a barrier. The HPNA has produced the third edition of *Core Curriculum for the Hospice and Palliative Advanced Practice Registered Nurse*.³⁹

The ELNEC developed several curricula in response to palliative care knowledge deficits among various levels of graduate faculty. For instance, funding from the National Cancer Institute promoted the development of an ELNEC Graduate Faculty Curriculum, which provided end-of-life train-the-trainer education to graduate nursing faculty. Over the 5 years of the ELNEC Graduate Curriculum project, 300 graduate nursing faculty members, representing 63% of the existing graduate schools of nursing, attended. Outcome data showed that thousands of graduate students have since been educated in this content.⁴⁰

With a grant from the National Cancer Institute, ELNEC also developed a program entitled *Integrating Palliative Oncology Care Into Doctor of Nursing Practice (DNP) Education and Clinical Practice*.⁴¹ The grant offered a national workshop to DNP nursing faculty and DNP clinical practitioners and covered information on establishing more formal palliative care coursework and integrating palliative care into core courses, clinical experiences, and DNP capstone projects.

There are a growing number of postgraduate clinical nursing fellowships available for APRNs. Most programs are sponsored by academic medical centers, and some use the

fellowships as workforce development within their institutions, rather than an as opportunity for APRNs to provide leadership in education and program development on a broader level. These programs are usually 1-year postgraduate clinical fellowships for NPs, often offered alongside medical fellowships in major institutions where palliative care is well developed. However, a few programs have been developed for midcareer APRNs. Barriers for APRN fellowship program development include the variation of state licensing requirements, low salaries, and inability to temporarily leave other positions. Currently, work is under way to define consistent standards for palliative APRN fellowships.⁴²

CONTINUING EDUCATION FOR THE APRN

Along with formal academic programs, professional continuing education in palliative nursing has flourished over recent years. The most significant and far-reaching continuing education initiative has been the national and international ELNEC program, previously mentioned. ELNEC began in 2000 and continues today to educate nursing faculty, clinical nurses, researchers, and administrators in palliative care, including specialty content for those teaching pediatrics, oncology, critical care, geriatrics, and veterans' care (visit <https://www.aacnnursing.org/ELNEC>). To date, more than 1 million nurses and other members of the interprofessional healthcare team have attended one of hundreds of national or international train-the-trainer courses held in every state across America and in more than 100 countries. The ELNEC curriculum also has been translated into 11 languages to further its international reach.⁴³

The ANA and HPNA *Call to Action—Nurses Lead and Transform Palliative Care* states that all nurses should receive ELNEC training as a minimum.⁴⁴ To target the education needs of the APRN, a 2-day ELNEC APRN curriculum is

offered. Recognizing both the clinical and program development needs of APRNs, the curriculum includes the following clinical and program development modules: Overview, Pain Management, Symptom Management, Communication, Final Hours, Business & Finance, Quality Measurement, Education, and Leadership. The program offers breakout sessions for communication and palliative care program development important for both the generalist and specialist palliative APRN. In addition, there are tracks for both adult and pediatric APRNs.⁴⁵ To address the interest in and need for detailed communication skills training, an ELNEC Communication course was also recently developed.⁴⁶ Participants are provided with diverse content that can be incorporated into various coursework within the specialist and graduate curriculum, so this course is attractive to nursing faculty as well.

For graduate-prepared APRNs who maintain a generalist practice outside of the clinical specialty realm, there is the ELNEC Core Curriculum. This content is divided into eight modules: Nursing Care at the End of Life; Pain Management; Symptom Management; Ethical/Legal Issues; Cultural Considerations in End-of-Life Care; Communication; Loss, Grief, Bereavement; and Preparation for and Care at the Time of Death. Table 2.4 details the curricular topics of the ELNEC Core, ELNEC APRN for adults and pediatrics, and ELNEC DNP courses.

A plethora of other continuing education programs are available for APRNs interested in developing or expanding their palliative care skill set. There are various conferences, such as the annual assembly co-organized by AAHPM and HPNA and the annual Clinical Practice Forum organized by HPNA. Nursing specialty organizations, such as the American Association of Critical Care Nurses (ACCN), the Oncology Nursing Society (ONS), and the Gerontological Advanced Practice Nursing Association (GAPNA) offer palliative care content at their annual conferences. Other interprofessional clinical conferences include those organized by the Center to Advance Palliative Care, the National Hospice and Palliative Care Organization, and the American Society of Clinical Oncology. Several academic and clinical settings offer brief specialized immersion courses, including the HPNA/Cambia week-long externships for experienced APRNs new to palliative care.⁴⁷ The Center to Advance Palliative Care, the City of Hope Pain and Palliative Care Resource Center, and the Palliative Care Network of Wisconsin are examples of extensive multifaceted repositories for practice and educational resources. Table 2.5 provides a sample of available palliative care educational resources for APRNs interested in continuing educational opportunities. A basic internet search will uncover a plethora of programs. It is especially important to note that, during the COVID pandemic, many opportunities were offered free of charge.

Table 2.4 END-OF-LIFE NURSING EDUCATION CONSORTIUM (ELNEC) CURRICULA

FUTURE DIRECTIONS IN APRN EDUCATION

As palliative care continues to rapidly expand, graduate, post-graduate, and continuing education programs will also grow, affording APRN educators the opportunity for innovation and creativity. Several trends in APRN education are emerging.

INTERPROFESSIONAL EDUCATION

Interprofessional education has become a mandate for the health sciences. Described as health professionals learning

with and about each other in the educational and practice settings, interprofessional education is interactive, cooperative, and experiential.⁴⁹ Four basic competencies, as developed by a collaborative expert panel, are (1) communication of roles and responsibilities, (2) demonstration of values and ethics in collaborative practice, (3) negotiation of roles, and (4) interprofessional teamwork.⁴⁹ Given the holistic preparation and focus of advanced practice nursing, APRNs often play leading roles on interprofessional teams. Advanced practice nurse educators must work with faculty colleagues across disciplines to ensure that advanced practice nursing is well represented in interprofessional

program planning, literature, and research for interprofessional practice.

MENTORSHIP

Mentorship is an important aspect of palliative nursing education. APRNs serve as mentors to nursing staff of all levels. APRNs frequently formally and informally mentor new practitioners in other fields, including medical students and residents, social workers, and other interdisciplinary team members. As palliative care programs continue to expand, experienced APRNs mentor both new graduates, experienced APRNs moving into palliative care, and nursing professionals at all levels. Nurses report that mentoring conversations improve their effectiveness in integral palliative skills, like communication.⁵⁰ Focused mentorship can help to develop critical thinking, expand evidence-based practice, and sustain resilience in APRNs.⁵¹

ONLINE AND LONG-DISTANCE EDUCATION

Online and long-distance educational programs have become the norm in many academic circles. Long-distance learning makes advanced education accessible to nurses in remote areas and provides a flexible platform for continuing education for nurses with varying responsibilities and work hours. However, this framework can create substantial challenges in teaching subjects that can be emotion-laden and necessitate interpersonal work.⁵² Advanced practice palliative nursing education requires significant direct role-playing for communication training. Use of online video streaming is one answer to this need for interactive work, and the required transition to virtual education during the COVID pandemic has led to improving educational technology that will undoubtedly influence the continuing development of online palliative care education.

SIMULATION

Simulation, particularly in relation to teaching communication skills, has increasingly become a mainstay of palliative care education at both the generalist and specialist levels. Simulation is now a common component of most advanced practice and palliative nursing educational programs.⁵³ Table 2.6 shows examples of program-specific palliative and end-of-life simulation scenarios utilized at a large urban university.

Although there remains a paucity of research regarding the translation of palliative care simulation pedagogies to clinical competence, these exercises are subjectively well-received by students who appreciate the opportunity for practice.⁵³ The first randomized controlled trial of patient- and family-reported outcomes revealed disappointing results, but a subsequent randomized trial of a simulation-based multi-session workshop to improve palliative care communication skills (Codetalk) resulted in an improvement in trainee's overall self-assessment of competence in communication skills ($P < .001$).⁵⁴ The intervention was also associated with an improvement in trainee self-assessments of three of the four skill-specific indicators: expressing empathy, discussing spiritual issues, and eliciting goals of care.⁵⁴ Another study employed an exploratory, pre- and post-test design with additional qualitative data to evaluate a pilot project, "TeamTalk," which adapted VitalTalk methodology for interprofessional learners to develop communication skills in palliative care.⁵⁴ Attitudes toward interprofessional collaboration improved from pre- to post-test, with no difference among the professional groups. Self-confidence for interprofessional communication improved in "eliciting the contributions of colleagues, including those from other disciplines" ($p < 0.001$) for all learners during Year 2; chaplains improved in the greatest number of areas (15/19), followed by nurses (7/19) and physicians (4/19).⁵⁴ Further rigorous outcome research is needed to ascertain the efficacy of this teaching strategy.

Table 2.6 EXAMPLES OF END-OF-LIFE SIMULATION SCENARIOS

Advanced practice population program	Simulation scenario
Family nurse practitioner Adult-gerontology primary care nurse practitioner	• Difficult communication: Advance directives, breaking bad news, requests for non-disclosure of patient information • Introducing palliative care • COVID-19: Stable and unstable adults (telehealth)
Adult-gerontology acute care nurse practitioner	• Leading family meetings • Withdrawal of life support • Advanced directives: End-stage renal disease
Pediatric nurse practitioner	Goals of care family meetings, breaking bad news, addressing opioid fears
Midwifery	Perinatal loss and bereavement: Stillborn
Psychiatric-mental health nurse practitioner	Grief and bereavement counseling

Developed by New York University Rory Meyers College of Nursing.

TELEHEALTH EDUCATION

The COVID-19 pandemic accelerated the use of telehealth technology in hospice and palliative settings, necessitating the rapid development of telehealth curricula in advanced practice nursing programs. (See Chapter 17, “The Palliative APRN in Telehealth”.) Guidelines compliant with the Health Insurance Portability and Accountability Act (HIPAA) were liberalized by the Department of Health and Human Services, allowing for a variety of nonpublic-facing video communication tools to be utilized as telehealth platforms.⁵⁵ Successful utilization of telehealth intervention to support end-of-life care and family meetings has been reported; however, these cases highlight the need to increase training for frontline care staff and those in palliative APRN programs to achieve telehealth competency.^{55,56}

In 2018, the NONPF published a position statement, *NONPF Supports Telehealth in Nurse Practitioner Education*, that suggests new strategies are needed to effectively address the national healthcare provider shortage, complexity of disease, aging of our population, and limited access to care. Included in the position paper were eight recommended NP competencies (see Box 2.2).⁵⁷ The shortage of palliative care specialist providers makes telehealth an attractive option for hospice and palliative care organizations, and the recent COVID pandemic made the intervention integral. Integration of telehealth curricula has been developing rapidly in both generalist and specialist palliative APRN education.

A CALL TO ACTION FOR PALLIATIVE CARE NURSE EDUCATORS

Since the mid-1990s, healthcare experts have called for improved palliative care for patients with serious illness, and major advances have been made in establishing palliative care as a recognized nursing and medical specialty. Yet much work remains to be done. There is growing evidence that palliative care in terminal illness can improve quality of life, reduce cost, and may prolong survival.^{58,59} In September 2014, the IOM released a report, *Dying in America: Improving Quality and Honoring Individual Preferences Near the End of Life*, with a chapter dedicated to education in palliative care.⁶⁰ Progress has been made since the early descriptive studies about the

deficits in care and the initial IOM report calling for sweeping changes in end-of-life care. But because advance care planning and patient-centered care have yet to be fully integrated into healthcare, many perceive that the recommendations of this report remain timely.

Healthcare reform has moved palliative care upstream and into the community, with a focus on establishing an operational definition of the seriously ill along with quality indicators for necessary changes needed within the health care system.⁶² In 2017, a new call to action was proposed by the ANA and the HPNA, which summed up the role of nursing in the future of palliative care: that all patients, families, and communities experiencing serious illness should receive quality palliative care by the delivery of primary palliative nursing by every nurse in all settings.⁴⁴ These national mandates lead us to continue to develop both primary and specialty palliative care education for advanced practice nursing.

Recent changes in the structure of advanced nursing education (adaptation of the LACE model and rapid development of DNP programs) complicate educational efforts for specialized palliative care. There are currently not enough APRN programs with a palliative care focus to meet current workforce needs. However, these changes also present opportunities for innovative programs that can be integrated into generalist APRN as well as specialist educational efforts. Work is in progress to delineate content for graduate nursing programs specialty palliative APRN entry into practice.³¹ Legislation introduced into Congress is evidence that policy-makers are starting to realize the importance of palliative care education. The *Palliative Care Training Act of 2004* addressed the critical health workforce need by calling for funding for education centers to expand interdisciplinary training in palliative and hospice care.⁶³ The Act also funds advanced education nursing grants, academic career awards, and career incentive awards to support nurses and other healthcare providers who provide palliative and hospice care training. It did not pass on first rounds, but the bill was reintroduced in 2017 as the *Palliative Care Health Education and Training Act (PCHETA)*. It passed in the House of Representative in 2019 and made it to the final docket in 2020, but with COVID-19, it was dropped from bills for review in the Senate⁶⁴ (see Chapter 10, “The Palliative APRN in the Emergency Department”).

Box 2.2 THE NATIONAL ORGANIZATION OF NURSE PRACTITIONER FACULTY (NONPF) SUGGESTED TELEHEALTH NURSE PRACTITIONER COMPETENCIES

1. Telehealth etiquette and professionalism while videoconferencing
2. Skills in using peripherals, such as otoscope, stethoscope and ophthalmoscope
3. An understanding of when telehealth should and should not be used
4. An understanding of privacy/protected health information (PHI) regulations
5. Proficiency in the use of synchronous and asynchronous telehealth technology
6. Knowledge of appropriate documentation and billing of telehealth technology
7. An ability to collaborate interprofessionally using telehealth technologies
8. Proficiency in taking a history, performing an appropriate physical exam, and generate differential diagnoses using telehealth

SUMMARY

The discipline of palliative care is expanding, and its professional knowledge base is growing. There is a growing awareness among the public, in the health professions, and among policymakers that palliative care education is integral to overall healthcare. The nursing profession has a mandate to educate its members through formal academic programs and continuing professional education to remain at the forefront of palliative care practice. The HPNA calls for nursing educators to take an active stance in promoting palliative care education for both specialist and generalist APRNs. Their position statement on the value of the APRN calls for nursing educators to become knowledgeable and expand the following areas:

- Continuing education to prepare and develop existing APRNs in palliative care competencies
- Integration of core palliative care competencies into programs for all APRN students, regardless of role or degree
- Provision of academic programs for specialized palliative care
- Provision of clinical mentoring in palliative care⁶⁵

The current healthcare environment provides an exciting time to practice palliative nursing, and many opportunities exist for nurses to take a leadership role in developing and leading palliative care programs in all settings. By providing advanced education for specialized clinical experts and expanding the primary palliative care knowledge base for generalist APRNs, palliative care educators can ensure that nursing remains at the forefront of this essential and rewarding work.

CREDENTIALING, CERTIFICATION, AND SCOPE OF PRACTICE ISSUES FOR THE PALLIATIVE APRN

Kerstin Lea Lappen, Matthew McGraw, and Kate Meyer

KEY POINTS

- The Consensus Model for APRN Regulation, Licensure, Accreditation, Certification, and Education (LACE), developed in 2008, provides guidance for states to adopt uniformity in the regulation of APRN roles and will have an ongoing impact on advanced palliative nursing practice, the curriculum for advanced practice nursing educational programs, and on the US healthcare system.
- Palliative advanced practice registered nurses (APRNs) must understand credentialing requirements to practice safely, legally, and to the fullest extent of their scope.
- Advanced specialty palliative nursing certification is a valuable endeavor to demonstrate the APRN's expertise and commitment to quality care and to the profession.

CASE STUDY: THE CLINICAL NURSE SPECIALIST

Denise earned her graduate degree in nursing in 2002, with a specialty focus as a medical-surgical clinical nurse specialist (CNS). However, her credential title changed in 2008 to CNS in adult health. Denise's work experience had always been in hospice and pain management. In addition to achieving her CNS certification for entry to practice, she became board certified as an advanced practice certified hospice and palliative nurse. She was hired to work as a consultant for a palliative care service in a large urban hospital. Denise is fortunate to live in a state that recognizes the CNS as an advanced practice registered nurse (APRN) who is able to bill for services and have prescriptive privileges. Her state's law allows APRNs to practice independently, without a collaborative practice or prescriptive agreement with a physician. Denise recently implemented a rural palliative telehealth service, and her employer is interested in expanding the program to neighboring states. Her CNS and nurse practitioner (NP) colleagues want to continue to practice to the full extent of their scope but worry about regulations in other states. As she begins researching how to roll out this initiative, her mentor commented that the project would be worthy for a Doctor of Nursing Practice project stating, "If you're going to do the work, you may as well take the credit."

INTRODUCTION

In 2002, Promoting Excellence in End-of-Life Care, a national program office of the Robert Wood Johnson Foundation, published *Advanced Practice Nurses Role in Palliative Care: A Position Statement from American Nurse Leaders*¹ to spark conversation among nursing leaders about how to improve the state of palliative advanced practice nursing, illustrate successful models of palliative advanced practice registered nursing practice, and promote the advanced practice nurse's role in providing palliative care. The final position statement called on leaders in the clinical professions, nursing educators, health service providers, healthcare payers, and public policy advocates to take the following actions:

- Continue to discuss the advanced practice registered nurse (APRN) role and opportunities and strategies to advance it in palliative care.
- Educate nursing faculty about palliative care to develop curriculum and competencies for both APRN students and existing APRNs with the goal being the integration of primary palliative care principles into nursing education and practice. Additionally, clinical tracks should be developed for APRN students who intend to specialize in palliative care.
- Work with payers of health services to recognize the specialty of palliative care and provide APRNs with adequate and consistent compensation that is commensurate with the APRN scope of practice, authority, and responsibility, regardless of practice setting or specialty.
- Call on the National Council of State Boards of Nursing (NCSBN) and individual state boards of nursing to work collaboratively to consistently recognize APRN scopes of practice and privileges regardless of specialty and subspecialty.
- Ask health systems and health service providers to develop or expand practice opportunities for APRNs in all settings that care for patients who may experience life-limiting illnesses.
- Hold APRNs practicing in the specialty of palliative care accountable for the documentation and dissemination of outcomes of practice experience and roles and for

engaging in interdisciplinary research with an emphasis on translating findings into practice.

- Clarify the challenges that APRNs face in training and licensure, along with regulatory and reimbursement barriers.

It was felt that, with the development of registered nurse and advanced practice registered nurse certification examinations and the creation of undergraduate and graduate advanced practice programs in palliative care, palliative nursing would be on the road to being recognized as a specialty in all states.¹

There has been substantial progress for the APRN in the two decades since the position statement was published in 2002. Four major initiatives have contributed to this growth in APRN practice. First, in 2008, the NCSBN and the Advanced Practice Nursing Consensus Work Group developed uniform APRN regulations that culminated in the publication of the *Consensus Model for APRN Regulation: Licensure, Accreditation, Certification & Education (The APRN Consensus Model)*.² NCSBN launched the Campaign for Consensus that continues to work toward states' adoption of the recommendations in the *APRN Consensus Model*. The goal was to have full implementation by 2015. As of early 2021, roughly half of the states and US territories have fully adopted and implemented legislation to support the *APRN Consensus Model* recommendations, with partial adoption by other states. Many palliative APRNs have been influenced by this work. The NCSBN website provides updated information about APRN practice in each state and territory.³

Second, in 2010, after a 2-year joint effort to assess the state of the nursing profession; the historical, cultural, regulatory, and policy barriers; and the future needs of the country, the Robert Wood Johnson Foundation and the Institute of Medicine (IOM) published the influential report *The Future of Nursing: Leading Change, Advancing Health*.⁴ In addition to addressing challenges in the nursing education system, the blueprint outlined recommendations to remove legal barriers to APRN practice. To achieve this recommendation, the IOM specified directives for Congress, state legislatures, the Centers for Medicare and Medicaid Services (CMS), the Office of Personnel Management for Federal Employees, the Federal Trade Commission (FTC), and the Antitrust Division of the Department of Justice. It is a clear indication that those who influence public policy and cultural change, such as the IOM, recognized the critical role APRNs play in the healthcare landscape of the country. The document specifically instructed Congress to expand the Medicare program to include coverage of APRN services that are within the scope of practice under applicable state law, just as physician services are now covered. CMS required that hospitals that participate in the Medicare program remove barriers that limit clinical privileges and membership on medical staffs for APRNs, thus promoting wider access to palliative care.

The work started by the IOM did not stop there as the recommendations of the report were monitored over the decade. A new report was planned for 2020 which was delayed enabling the inclusion of emergent health issues influenced

by the COVID-19 global pandemic and the exacerbation of social injustice and systemic racism. Through the convening of a diverse expert panel, The National Academies of Sciences, Engineering and Medicine examined how nursing profession would meet these demands. *The Future of Nursing 2020–2030 Charting a Path to Health Equity* was issued in May 2021 and it builds on the prior themes to have nurses be on the forefront of achieving health equity.⁵

Third, coming on the heels of the *Consensus Model* and the *Future of Nursing* report, the implementation of the 2010 Affordable Care Act brought about an overhaul in healthcare unprecedented since the creation of the Medicare and Medicaid programs in 1965. To meet the increased demand due to increased access to healthcare coverage, APRNs have filled the gap of healthcare providers. However, there is a palliative care workforce shortage, exacerbated by the COVID-19 pandemic. Palliative APRNs will need to practice to the full extent of their scope to support the needs of a cultural shift and a changing US demographic.

Finally, in late 2016, the Department of Veterans Affairs (VA) issued a final rule granting full practice authority to three of the four advanced-practice roles (NP, certified nurse midwife [CNM], and CNS).⁶ Largely driven by desire to improve access to care, the VA has stated that the omission of certified registered nurse anesthetists (CRNAs) in the rule was based not on their competence but rather on a lack of issues related to access problems to anesthesiology. The intent of the rule allowed APRNs to practice to the full extent of their license without clinical supervision, thereby addressing the provider shortage which has historically resulted in delayed care for veterans and ultimately poor health outcomes.⁷ Perhaps the most significant aspect of this rule is the declaration that removes the requirement for supervision or collaboration for those APRNs employed by the VA. This federal declaration supersedes state law, removing the barrier of variability by state. Palliative APRNs practice more consistently and to the full extent of their scope of practice. Moreover, more veterans have access to quality palliative care.

UNDERSTANDING THE APRN CONSENSUS MODEL: WHAT DOES IT MEAN AND WHY SHOULD ONE CARE?

The profession of advanced practice nursing has historically been a convoluted and complicated web of educational degrees, certifications, and regulations. Moreover, oversight occurs within multiple layers of hierarchies, including the CMS, state statutes and state boards of nursing, and individual institutional privileging and credentialing requirements. The number of APRNs continues to grow at a rapid rate, currently numbering 290,000 NPs⁸ and 70,000 specialists⁹ in the United States and its territories. Between 2010 and 2017, the number of NPs more than doubled. The forecasted annual growth of practitioners between 2016 and 2030 is greater among NPs (6.8%) than physicians (1.1%) and physician assistants (4.3%). The lack of uniformity and cohesion in the laws and regulations creates confusion for employers and consumers and barriers

and inconsistencies in how and where APRNs may practice. Knowing that APRNs will represent a larger proportion of healthcare, there is an opportunity to increase state and federal representation and align laws and regulations.^{7,10}

The *APRN Consensus Model* was created to guide all states and jurisdictions in implementing and overseeing the uniform licensure, accreditation, certification, education, and practice of APRNs.^{2,11–14} The *APRN Consensus Model* is composed of seven major elements (Box 3.1). APRNs should understand their own state regulations regarding title, recognition, education, credentialing, licensing, and independence to practice. If the APRN were to change jobs or location of employment, would their scope of practice be more or less restricted? Indeed, could they practice at all? The following elements are addressed in the *APRN Consensus Model*; APRNs should review these within their setting:

- **Title:** The purpose of a title is to differentiate professions, provide clarity to the consumer, and ensure consistent recognition regardless of location of practice.^{2,11} The *APRN Consensus Model* has designated “advanced practice registered nurse” as the agreed-upon title. One would think something as basic as a title would be straightforward, but, unfortunately, this is not the case. There is wide variability across the country in the use and legal recognition of “APRN.” Other titles used include advanced practice nurse (APN), nurse specialist, and advanced registered nurse practitioner (ARNP).
- **APRN Roles and Recognition:** There are four defined APRN roles with specific designated titles.
 - Certified nurse practitioner (CNP)
 - Clinical nurse specialist (CNS)
 - Certified registered nurse anesthetist (CRNA)
 - Certified nurse midwife (CNM)CNPs and CNSs are most common in the field of hospice and palliative care and are currently the only roles eligible for advanced practice specialty hospice palliative nursing certification.
- **Role Recognition Adoptions:** States vary in recognizing all four APRN roles, which certainly affects the ability of an APRN to move easily across state lines and continue

to practice. Several states do not recognize the CNS role and have placed the CNS in a “nurse practitioner” designation.

- **Licensure:** State boards of nursing vary regarding required certifications, registrations, and licenses for permission to practice. Many states allow the APRN to practice with only an RN license and additional APRN certifications. The *APRN Consensus Model* requires a separate APRN license in addition to the RN license. This additional licensure will ensure consistency in recognizing the APRN role from state to state and will give APRNs the flexibility to relocate for jobs and maintain their essential scope of practice.
- **Graduate or Postgraduate Education:** The *APRN Consensus Model* requires that the APRN be educated by a nationally accredited program of nursing, with a minimum of a master’s degree. The educational program must include the three core courses: advanced physiology or pathophysiology, advanced health assessment, and advanced pharmacology, with clinical and didactic experiences.^{2,11} The graduate nursing educational path changed with the adoption of the *APRN Consensus Model* in that all APRN students must be educated in one of six specific populations.²

The selection of population focus will dictate to what practice the APRN will be restricted. For example, a CNP whose education and clinical preparation was in women’s health would not be able to practice in adult/gerontology without additional education and certification. In the evolution of graduate-level nursing, the emphasis pivoted from role preparation (administration and education) to specialized clinical knowledge and practice (advanced practice nursing). Other health-related fields, including pharmacy, dental surgery, medicine, physical therapy, and psychology have clinical doctorate-level training. In 2004, the American Association of Colleges of Nursing (AACN) proposed moving APRN education from the master’s to the doctoral level, achieving parity with our colleagues in a terminal degree.¹⁵ There are currently two tracks for the doctoral-prepared nurse: the research-focused Doctor of Philosophy (PhD) or Doctor of Nursing Sciences (DNS, or DNSc) and the practice-focused Doctor of Nursing Practice (DNP) (Box 3.2).

**Box 3.1 SEVEN ELEMENTS OF THE
APRN CONSENSUS MODEL**

I. Title
II. APRN Roles and Recognition
III. Licensure
IV. Graduate or Postgraduate Education
V. Certification
VI. Independent Practice
VII. Full Prescriptive Authority

Box 3.2 TERMINAL DEGREES IN NURSING

Terminal degrees in nursing prepare nurses as experts in health administration, education, clinical research, and advanced clinical practice

Research-focused:

- Doctor of Philosophy (PhD)
- Doctor of Nursing Science (DNS or DNSc)
- Doctor of Education (EdD)

Practice-focused:

- Doctor of Nursing Practice (DNP)

The PhD, DNS, or DNSc in nursing has an accepted reputation for building the body of nursing knowledge through research. The DNP has come to address the need for enhanced nursing leadership, implementation of evidenced-based nursing practice, and broadening the educational experience of nursing faculty. It has been formalized that preparation at the practice doctorate (i.e., DNP with a clinical focus) includes advanced preparation in nursing practice based on nursing science and is at the highest level of nursing practice.¹⁶ Furthermore, the AACN (2018) in its white paper, describes how the DNP curriculum prepares nurses to generate new knowledge through innovation of practice change, the translation of evidence, and the implementation of quality improvement processes in specific practice settings, systems, or with specific populations to improve health or health outcomes.¹⁷

Postgraduate programs in palliative care are gaining traction and include observerships, practicums, preceptorships, internships, externships, residencies, and fellowships.¹⁸ Palliative APRN fellowships are typically 1-year programs offered in academic settings, often within a teaching hospital. A palliative care fellowship provides specialized clinical training and education in palliative care and may be in collaboration and conjunction with palliative medicine and social work fellowships. A palliative APRN fellowship program includes the orientation to and history of palliative nursing and nursing leadership, advanced education and lectures taught by inter-professional faculty, clinical experiences mentored by an APRN (who is ideally certified as an advanced certification hospice and palliative nurse [ACHPN]), and APRN role development supervised by an APRN. A fellowship program includes the completion of a palliative-focused project/case study, quality improvement project, or research study.¹⁸

- **Certification:** The *APRN Consensus Model* requires that all APRNs obtain certification to practice by passing a psychometrically sound and nationally accredited examination at the advanced practice nursing level that measures competency in the specific population of practice.^{2,11} The organization providing the certification program must be nationally accredited by the American Board of Nursing Specialties or the National Commission for Certifying Agencies.² The APRN must also demonstrate ongoing competence to maintain certification. Though advanced palliative and hospice care is not one of the population foci in the *APRN Consensus Model*, APRNs who practice in this specialty are encouraged to seek specialty certification to demonstrate their commitment to the field and to the patients they serve.
- **Independent Practice:** The *APRN Consensus Model* lobbies for the APRN to practice to full stated scope without physician supervision. In many states, there has been legislation to promote this practice; however, it has been met with fierce resistance from the medical establishment. APRNs should be very familiar with the

CMS requirement to work in collaboration with a physician with medical direction and appropriate supervision (though this supervision does not need to be direct) as required by the law of the state in which the services are furnished.¹⁹ As part of the credentialing and privileging process, many state legislatures and/or individual institutions require the APRN to have a collaborative practice and/or prescribing agreement with a supervising physician. The *APRN Consensus Model* accentuates a hallmark of APRN practice which is voluntary collaboration that emphasizes the interdependence and interreliance of healthcare professionals.^{2,11} In the adoption of this element of practice without physician oversight, some states have specified a period of physician or APRN supervision of newly graduated APRNs to ensure a smooth transition with close mentoring and guidance.

- **Full Prescriptive Authority:** The ability of the APRN to prescribe pharmacologic and nonpharmacologic therapies without physician oversight and/or a written collaborative agreement is the element of the *APRN Consensus Model* that has been met with the most opposition, primarily from organized medical groups. This is despite evidence that APRN outcome measures are equivalent to those of other medical providers.^{7,11,20} Full prescriptive authority is key to being able to provide care to populations with limited access to healthcare.

The NCSBN continues to track each state's progress toward adoption of the seven elements. APRNs can access the most accurate and up-to-date status of adoption of the Consensus Model by checking the website.³

- **Scope of Practice:** "The advanced practice hospice and palliative registered nurse responds to the individual, professional, and societal needs related to the experience of serious or life-threatening illness through the nursing process."²¹ Through graduate-level education at the master's or doctorate level, APRNs differ from generalists by being able to synthesize complex data, develop and implement advanced care plans, and provide leadership in hospice and palliative nursing. Besides the clinical focus of the CNS and CNP, there are graduate-level prepared nurses who are APNs. In hospice and palliative care, they may function as leaders/administrators, educators, researchers, consultants, case managers, program developers, and policymakers.
- **The Political Landscape of Advanced Practice Registered Nursing:** APRNs have struggled with practice barriers imposed by restrictive legislation, often supported by the political influence of medical associations. These restrictions lack any evidence or data showing inadequacies or concerns about the safety and outcomes of practice by APRNs—in fact, there is much evidence to the contrary. Multiple studies have found either no difference or actual improvement in comparable patient outcomes between APRNs and physicians. Also, APRNs show substantial cost savings and cost

avoidance in the provision of care.²² The consistent conclusion from these studies is that patient outcomes of care provided by APRNs are similar in terms of safety, effectiveness, quality, and patient satisfaction—in some aspects, they are better than care provided by physicians alone. APRNs are also recognized for their inherent focus on collaborative practice.^{7,20,22}

It is extremely significant that the FTC, which exists to monitor and prevent any unfair or deceptive acts or practices that would impair competition in the marketplace, including the healthcare industry, published a policy paper in March 2014 called *Policy Perspectives: Competition and the Regulation of Advanced Practice Nurses*.²³

The paper supports the ability of APRNs to practice to the full extent of their scope without unnecessary, unjustified, and restrictive supervisory requirements and collaborative practice agreements with physicians. The paper states that “APRN scope of practice limitations should be narrowly tailored to address well-founded health and safety concerns, and should not be more restrictive than patient protection requires.”²³ The FTC recognizes that the scope of practice of any healthcare provider should be consistent with each professional’s education and training, licensure and certification, and experience and capabilities. Current legislative or institutional requirements for physician supervision of the APRN to practice independently are identified by the FTC as a concern because they give one group of healthcare professionals control over another, resulting in restricted access to the market and potentially denying healthcare consumers the benefits of greater competition.²³

In the policy paper, the FTC identified several concerns about the present state of APRN scope of practice where unwieldy and unwarranted restrictions, under the guise of “consumer protection,” are actually contributing to less competition and, thus, less protection, including:

- Less access to safe and effective care, especially in underserved areas and for populations that are experiencing, in particular, primary care provider shortages.
- Impaired development of innovative models of healthcare delivery to meet the needs of the healthcare consumers.
- Increased costs and less oversight of cost containment.
- Less focus on the importance of measuring quality outcomes, with subsequent serious health and safety consequences.

This report, along with the *APRN Campaign for Consensus* and the IOM *Future of Nursing* recommendations discussed previously, have positioned APRN practice in its strongest standing to date. It remains to be seen how legislators, policymakers, and administrators will heed and implement these recommendations. Palliative APRNs can influence and support further changes and improvements in being able to practice to the fullest extent of their scope by getting involved with

their professional organizations, as well as staying informed about and engaged in practice issues critical to APRN professional health.

THE PROFESSIONAL LANDSCAPE OF ADVANCED PRACTICE REGISTERED NURSING

The scope and standards of APRN practice are defined by the national professional nursing organizations specific to the population focus for which they were educated. The APRN’s clinical scope includes the tasks of performing advanced assessments; interpreting diagnostic studies; forming a differential diagnosis; prescribing pharmacologic and nonpharmacologic treatments and equipment; ordering additional diagnostic tests, consultants, and support services; and evaluating the response to treatment.²⁴

APRNs are accountable to patients for the quality of the care they provide. They must be able to recognize the limits of their education, knowledge, and experience. They should know when to refer patients to other providers and practitioners for appropriate management when they are confronted by a situation that is outside their area of expertise. With this increased responsibility, no matter how long a nurse may have practiced as an RN, when they become an APRN, there is usually a period of transition and uncertainty. Many questions may arise about what is now within the scope of practice for the APRN, such as:

- Does the APRN role allow the APRN to prescribe, and, if so, are there any restrictions on what classes of medications may be prescribed?
- If the APRN was trained in the population of family practice, given that their education and training was not in the population focus of adult/gerontology, can they provide care to an older adult entering the end stage of a chronic illness?
- Is the APRN’s knowledge base adequate to diagnose and treat conditions for which they are seeing a patient?
- What are the limitations on the services that a CNS or CNP employed by a hospice program can provide in light of CMS rules that dictate which medical providers may complete face-to-face assessments and recertification of terminal illness?

These and other questions may cause the hospice and palliative APRN some level of anxiety because the responsibilities and liabilities change with the increased scope of practice. The American Nurses Association (ANA), along with Hospice and Palliative Nurse Association (HPNA), are the primary sources for guidelines about the scope and standards of APRN practice.²⁴ Above all, practice must be safe, quality-focused, and evidence-based. In response to the dilemma of what is considered appropriate practice within accepted scope, ANA advises the APRN to first consider the published

scope and standards of practice. Now in its fourth edition, *Nursing: Scope and Standards of Practice*, published in 2021, includes specific information about the scope of the APRN.

Second, the APRN should determine the current state laws and regulations that dictate his or her practice limitations. In addition to the NCSBN website, each state's board of nursing is the source of up-to-date and pertinent legislation that governs the practice of APRNs in the jurisdiction where they work.

Third, APRNs should review the institutional policies and procedures that apply to their practice. Although CMS and state regulations provide the "outer limits" of APRN scope of practice, APRNs may find their practice further limited by the interpretation and application of those regulations in individual institutions/facilities or health systems. For instance, CMS may allow a CNS to prescribe, but the hospital where a CNS is employed may have very stringent collaborative agreement requirements or restrictions that limit the CNS's ability to prescribe medications. Although the professional credentialing process at a facility or institution may choose to be more restrictive, a motivated and informed cohort of APRNs can change practice at the ground level so that local rules and regulations mirror the rules and regulations of the larger governing body.

Finally, the APRN should do an objective review of their skills and expertise in a process of self-determination, taking into account the skills and expertise of other members of the healthcare team and available consultants. The prudent APRN should also consider risk management and potential liability issues in particular situations and consider consulting with the institution's risk management or legal department or the malpractice insurer for support and clarification regarding a scope-of-practice question. There are many good resources available that offer guidance to the APRN wanting to gain a deeper understanding of legal issues, including *Law and Ethics in Advanced Practice Nursing*.²⁵

The APRN who practices in hospice and palliative care will find further information and guidance in the following resources specific to the specialty of palliative nursing:

- The Hospice and Palliative Nurses Association, *Palliative Nursing: Scope and Standards of Practice* (2021). A necessary resource for both APRNs and RNs, this edition discusses in detail what is expected of all hospice and palliative RNs and APNs. Practice accountabilities are divided into 16 standards with accompanying competencies, with additional competencies specified for APRNs. These standards provide the framework for guiding and evaluating the nurse's practice, along with behaviors and outcomes that would demonstrate whether he or she is meeting the minimal level of compliance with the standard.²¹
- Hospice and Palliative Nurses Association, *Competencies for the Palliative and Hospice Advanced Practice Registered Nurse* (3rd edition, 2021). This resource describes the explicit intellectual, interpersonal, technical, and moral competencies that are outcome-specific, measurable, and

considered necessary for quality palliative nursing.²⁶ It includes the following core characteristics applicable to the APRN, which are further delineated by advanced core behaviors based on the American Association of Critical Care Nurses *Synergy Model*²⁷:

- Clinical judgment
- Advocacy and moral agency
- Caring practices
- Collaboration
- Systems thinking
- Response to diversity
- Facilitation of learning
- Clinical inquiry
- Hospice and Palliative Nurses Association, *The Core Curriculum for the Hospice and Palliative Advanced Practice Registered Nurse* (2020). This book reflects the current evidence-based knowledge in advanced hospice and palliative nursing practice. The Core Curriculum provides a foundational work for the APRN and includes sections on role and practice concerns, management of common symptoms, psychosocial and spiritual aspects of care, and specific pathophysiology and disease-specific management. There is also information on vulnerable and special populations and an appendix with many references and tools for practice.²⁸
- The National Consensus Project for Quality Palliative Care (NCP), *Clinical Practice Guidelines* (4th edition, 2018). This collaborative effort of ten national palliative care organizations, including the HPNA, published a set of guidelines and recommendations for high-quality palliative care in eight domains of practice (Box 3.3).²⁹ Currently in its fourth edition, this updated publication builds on the work and developments that have occurred in hospice and palliative care since earlier guidelines were published in 2004, 2009, and 2013, with a focus on improving access to quality palliative care for all those with serious illness.

-

- American Association of Colleges of Nursing and City of Hope, *End-of-Life Nursing Education Consortium* (ELNEC). This educational initiative was founded in 2000, by Dr. Betty Ferrell and colleagues, to develop educational tools for undergraduate nursing faculty to ensure that topics in palliative care were taught as part of the nursing curriculum. Various versions of the curriculum have been developed for nurses in general practice and for special populations, such as veterans, pediatrics, geriatrics, and critical care units. ELNEC offers a course that addresses the unique needs of APRNs who are developing, leading, joining, or participating in a hospice and/or palliative care program or are incorporating palliative care into their current APRN role.³⁰

CREDENTIALING

The terms “credentialing,” “accreditation,” “licensure,” and “certification” are often misunderstood and thus are frequently used interchangeably and incorrectly. In a general sense, “credentialing” is an umbrella term that refers to several different processes overseen by a number of regulatory bodies (Box 3.4), such as licensure, certification, accreditation, recognition, and registration.³¹

Licensure involves a mandatory process by which a government agency grants time-limited legal status and permission for a person to engage in the practice of a profession in the public domain. Licensure signifies the provider has met minimal standards of competence, typically by passing a psychometrically sound examination. A license grants permission to use a particular title and provides protection of that title. It also defines a scope of practice for the profession. Licensure ultimately serves to protect the consumer and the public health, safety, and welfare. To this end, the individual state boards of nursing must have processes in place for anyone to file a complaint against a nurse whom they believe has acted in violation of nursing rules and the defined scope of practice. For instance, a consumer who has suffered harm from incompetent prescribing practices of an APRN could file a complaint with the board of nursing. The complaint would be investigated to determine if the APRN acted in an illegal or incompetent manner. If found to be at fault, discipline for

the APRN would likely include restrictions or even suspension of the professional license and thus the ability to practice.

Credentialing differs from licensure in that a credential it is a designation issued by a nongovernmental agency or association that the public can look to for assurance that an individual provider has achieved specific standards of competence that have been defined and promoted by the profession. APRNs may be familiar with the credentials granted by the American Nurses Credentialing Center or the American Academy of Nurse Practitioners after passing an accredited certification exam. There are different kinds of credentialing applicable to the APRN, and these are important to understand and differentiate.

“Entry to practice” credentialing is the “end product” of an educational program, achieved after graduation and the successful completion of a psychometrically sound examination from an accredited certification organization in the area of practice the provider was educated in. Successful completion of the exam provides the APRN with the required certification to obtain licensure to practice according to state statute and grants the legal right to use a specific title.

“Professional” credentialing is the process by which safe, high-quality, and competent care by APRNs (and other providers) is determined and verified by the facility or institution in which the APRN will be working. The Joint Commission requires that institutions have a systematic process to evaluate the provider who is applying for privileges.

The credentialing application is extensive and typically includes the elements listed here. APRNs should begin keeping a portfolio immediately after graduation that contains these documents for quick reference for any questions and future recredentialing processes³¹:

- Education, including proof of graduation and degree
- Previous work history
- Current licenses and certifications, National Provider Identifier (NPI) number, Drug Enforcement Administration (DEA) registration number, and a state registration for controlled substances
- Professional memberships
- Continuing education and competency assessments
- Collaborative practice and prescriptive agreements, if required
- Immunization status
- Any past or current disciplinary actions or suspensions from pertinent boards of practice
- Any past or current legal proceedings, both personal and professional
- Any physical, mental health, or chemical dependency issues that could affect one’s ability to practice safely and competently
- References from peers and a current resume.

Box 3.4 HEALTHCARE REGULATORY BODIES

- Federal and state law, including the Centers for Medicare and Medicaid Services (CMS) laws
- State boards of nursing
- Healthcare Quality Organizations—The Joint Commission (TJC), DNV-GL, Community Health Accreditation Partner (CHAP), Accreditation Commission for Health Care (ACHC)
- Hospital and facility provider bylaws and policies
- National certification associations and programs
- Professional organization statements

A credentialing committee at the institution reviews the application and, if approved, the APRN is granted privileges to practice. Clinical privileges are delineated to clarify specific sites where the APRN is able to practice and which practices and procedures the provider is allowed to provide, including prescriptive privileges. Clinical practice is often guided by, or in some cases is required to be based on, written guidelines and evidence-based protocols. There are many guidelines and evidence-based protocols in existence, so the APRN need not create something new. Rather, the APRN can adapt these to their setting. Depending on the specific practices and procedures the provider is requesting permission to perform, the committee may also require evidence of demonstrated competence.

Upon initial credentialing and privileging, APRNs can expect there to be a specified period of time in which their practice is closely monitored and evaluated by direct peer feedback and/or medical record review. Reappointments typically occur every 2 years, and the APRN must provide evidence of continued competency.

Payer credentialing involves the application for authorization to bill for reimbursement through Medicare, Medicaid, and other for-profit and nonprofit insurance carriers. The paperwork for credentialing varies widely by payer, but all processes begin by obtaining an NPI number, which recognizes the APRN as a unique healthcare provider under the Health Insurance Portability and Accountability Act (HIPAA) of 1996 guidelines and as one who maintains certifications and licensure.

THE VALUE AND PROCESS OF SPECIALTY CERTIFICATION

In most states, the CNP or CNS must obtain certification from a national, accredited certification organization after graduation from a master's or doctoral program in nursing in order to practice. Certification serves as a form of regulation by the state boards of nursing in recognizing a minimal level of competence. Certification is also now required for reimbursement for services through CMS, and as discussed previously, is required for practice, professional, and payer credentialing.

Specialty certification as an ACHPN is available through the Hospice and Palliative Credentialing Center (HPCC). It is voluntary for the individual APRN, but many employers require the additional specialty certification at the time of hire or require the nurse to obtain it within a specified time frame. The APRN is reminded, however, that the *APRN Consensus Model* now requires that the graduate student education program be focused on one of the six specific populations discussed earlier, with successful completion of the corresponding certification exam for entry to practice. In most states, hospice and palliative care is considered a "specialty" and the ACHPN examination is not accepted for entry to practice. The APRN should check with the individual state board of nursing and CMS to determine requirements for licensure and billing.

Some hospice and palliative APRNs wonder why they should work toward specialty certification in advanced hospice and palliative care when it might not be required. After all, it is an additional expense that may or may not be reimbursed by one's employer, and it is stressful and time-consuming to sit for an exam. But there are actually many benefits to obtaining certification in the specialty one practices in, and these perceived and actual values have been described in a study conducted by the American Board of Nursing Specialties.³² They include:

- An expanded and deeper knowledge base. The exercise of studying for the exam actually contributes to learning new information about the specialty.
- A commitment to professional growth, enhanced feelings of personal accomplishment, professional satisfaction, and increased empowerment and confidence in the role.
- Enhanced credibility and respect of coworkers; being seen as a staff resource.
- The standard of practice is raised throughout the profession, which in the long run serves to improve patient care outcomes and safety.
- Employers have found that specialty-certified nurses are desirable employees because certification reflects dedication to their profession and to providing the most relevant, evidence-based, and cutting-edge care to patients and their families.
- Financial benefits and professional growth. In addition to possible bonuses and salary increases, APRNs with specialty certification are often viewed as more competent and able to take on more responsibility, which can lead to career advancement and opportunities.
- Managers and employers have found that certified nurses help ensure a highly trained, progressive team, which elevates the perception of the medical facility or program. Hospitals applying for or renewing American Nurses Credentialing Center Magnet status or programs seeking The Joint Commission for specialty certification in palliative care must have a greater percentage of certified providers.³²

SPECIFICS AND PROCESS OF ATTAINING THE ACHPN

Initial certification as an ACHPN is attained by passing a psychometrically sound, computer-based examination. The content of the examination has been developed from a national job analysis survey that identified the activities performed by hospice and palliative APRNs. A task force of experienced hospice and palliative APRNs determined from the job analysis the activities and knowledge critical to the practice of the hospice and palliative APRN. These are specified in the Detailed Content Outline in the ACHPN Candidate

Handbook.³³ The content outline can be used to guide self-assessment and a study plan for the exam.

Although there is not a test question pertaining to each topic on the content outline, every question on the exam can be linked back to the outline. The questions are written by experienced APRNs in the field and are scrutinized by members of the HPCC APRN Exam Development Committee, with the guidance of a statistician from the professional testing agency that assists in the development, administration, scoring, and analysis of the certification examination.

RECERTIFICATION

HPCC certification must be renewed every 4 years through the Hospice and Palliative Accrual for Recertification process. It is the expectation that the APRN has continued to develop professionally with experience and exposure to new knowledge over that 4-year period. Continuing education and professional activities, along with a minimum number of practice hours, are the main requirements for certification renewal. Professional activities are converted to points, with a requirement to accrue an established minimum number of points in the 4-year period. Professional activities the APRN can complete for recertification include³³:

- Continuing nursing education
- Continuing medical education
- Academic education
- Professional publications
- Professional presentations
- Item writer workshop participation
- Self-assessment examination completion
- Professional volunteer activities related to hospice and palliative care
- Clinical mentoring/preceptorship of graduate nursing students

In support of the goal of encouraging continued competence in practice, a situational judgment exercise is also required for recertification. This is an open-book, online exercise that uses real-life, case-based scenarios to test the candidate's critical reasoning and clinical application beyond the level of the initial certification exam. As candidates are led through the scenario, they are asked to make decisions about what pertinent information to gather to guide decisions about the care and treatment of the patient and family. The cases involve more than just clinical decision-making; they also address professional judgment, patient education, communication, ethics, and collaborative practice issues. Points are accrued toward recertification based on the score achieved.

To accomplish recertification efficiently, the APRN should organize activities, dates, and documentation during

the 4-year accrual period. As most APRNs need to gather this information to recertify for their primary practice certification, relicensure, and credentialing, it should not require significant extra work. Although online documentation makes recordkeeping easier and more efficient, it is still important for the APRN to keep copies of continuing education certificates of attendance and documentation to support other professional development activities. It is much better to acquaint oneself with the recertification requirements soon after initial certification rather than waiting for the deadline to be looming and discover that meeting the recertification requirements will be more challenging than anticipated.

Certification and recertification in advanced hospice and palliative care demonstrate professional commitment and mastery of the field. While they are not necessarily required to practice in the field, they speak to the APRN's professional commitment and dedication to the specialty.

CASE STUDY: THE CLINICAL NURSE SPECIALIST (CONTINUED)

Denise educated herself about the variations in APRN scope of practice in the states she planned to deploy the CNS and NP team members to implement a rural palliative telehealth service. The project synced with graduate coursework in a DNP program, which led to national presentations and recognition for her innovation in palliative care. Denise was later invited to work on political advocacy projects exploring the variability of APRN practice across regions. What started as a program-level growth project morphed into a career-changing endeavor exploring the system-level variability in APRN practice.

SUMMARY

The landscape of our healthcare system is constantly changing, and APRNs will need to rise to the challenge to provide high-quality, efficient, cost-effective, and accessible care. The hospice and palliative APRN will increasingly be called upon to meet the needs of an aging population. To practice safely, legally, and to the fullest extent of their scope, APRNs must have a working knowledge of the sometimes confusing world of credentialing, privileging, certification, and licensure. APRNs must understand potential changes to their own practice regarding the implementation of the NCSBN *APRN Consensus Model* and the lifting of current restrictions to independent practice. APRNs practicing in the specialty of hospice and palliative care may best demonstrate their expertise and ongoing competence, in addition to professionalism, by achieving advanced certification in hospice and palliative care.

SECTION II

PALLIATIVE APRN ROLES

THE PALLIATIVE APRN IN ADMINISTRATION

Karen Mulvihill

KEY POINTS

- Graduate and doctoral programs do not provide the skills necessary to lead.
- The advanced practice registered nurse (APRN) interested in leadership roles need to seek out education in leadership and opportunities to lead.
- The APRN should seek out and utilize existing resources to develop their leadership skills.
- Conflict and change management are important skills in leading interdisciplinary teams.

CASE STUDY: LEADERSHIP

Cheryl is a new director for an inpatient palliative care team at a moderate-sized teaching hospital. One of her first tasks in the new role is to do the annual performance reviews for the 15 employees who report to her. She does not know where to begin and feels like an imposter in this role. Cheryl feels uncomfortable providing constructive feedback to her employees because she has never had to do that before. Although she is grateful for the chance to advance her career and experience, she wonders how she got into the role, given her lack of leadership experience.

INTRODUCTION

Florence Nightingale was the first nurse to recognize the need to formalize nursing as a practice, and she led the way for all nurses to ask, “How can I do more?” She was the first to identify the role of hygiene and sanitation in illness, thus becoming the first epidemiologist. She was the original nurse leader. Nursing roles have developed and expanded over time, placing more nurses in leadership positions. Advanced practice registered nurse (APRNs) are in a prime position to lead at local, regional, state, national, and global levels. Administration leadership roles may include myriad tasks such as developing programs, hiring and managing staff, creating strategic plans, education planning, quality improvement initiatives, and leading policy initiatives. The first step in being a leader is understanding leadership concepts and developing the necessary skills to be an effective leader.

Leadership is a core competency at all levels of nursing education and practice. The American Nurses Association

(ANA) *Nursing Scope and Standards of Practice* and the Hospice and Palliative Nurses Association (HPNA) *Palliative Nursing: Scope and Standards* identifies leadership as a standard of professional performance for both registered nurses (RN) and graduate-level prepared registered nurses (Boxes 4.1 and 4.2).^{1,2} The standard set the expectation for nurses to assume leadership roles at all levels. The *Nursing Scope and Standards of Practice* and the *Palliative Nursing: Scope and Standards* include ethical practice, accountability, communication, and moving the profession forward. The graduate-level competencies and advanced focus on decision-making, interprofessional teams, promoting policy, and role development through expert practice and mentoring.^{1,2}

The ANA sets practice for all nurses at both the RN and APRN levels of practice. The ANA *Nursing Scope and Standards of Practice* set the stage for guidelines for education, clinical practice, advocacy, administration, and research in nursing professions. The competencies focus on enhancing the effectiveness of the interdisciplinary team and outcomes through quality initiatives and research, promoting role development of advanced practice palliative nurses, modeling expertise, and mentoring (Box 4.2).¹

In 2010, the *Patient Protection and Affordable Care Act (ACA)* was passed and was important for healthcare reform. Subsequent to this legislation, the Institute of Medicine (IOM) and the Robert Wood Johnson Foundation (RWJF) collaborated on *The Future of Nursing: Leading, Change, Advancing Health*.³ The committee focused their charge on the role of nursing in the context of the entire workforce, expanding nursing faculty to meet the healthcare demand for an increased nursing workforce, developing innovative solutions for healthcare delivery and staffing, and retaining nurses in all settings. A key message in the report is grounded in nurses being full partners in redesigning the healthcare system. Specifically, the overall message of the report is that in order to transform our healthcare system, the nursing profession must develop competent leaders to collaborate with other healthcare professionals and use their knowledge to identify innovative models of quality care and healthcare delivery.³ Being a full partner involves “identifying problem areas of waste, devising and implementing a plan for improvement, tracking improvement over time, and making necessary adjustments to realize established goal.”³ (pp. 8)

In 2017, the ANA and HPNA collaborated to create the *Call for Action: Nurses Lead and Transform Palliative Care*.⁴ The document calls nurses to lead in practice, education, administration, policy, and research.⁴ As a leader, palliative APRNs

The registered nurse:

- Retains accountability for delegated nursing care.
- Promotes effective relationships (relational coordination) to achieve quality outcomes and a culture of safety.
- Engages in an interprofessional environment that promotes respect, trust, and integrity.
- Embraces practice innovations and role performance to achieve life-long personal and professional goals.
- Communicates to manage change and address conflict.
- Mentors colleagues and others to enhance their knowledge, skills, and abilities.
- Participates in professional activities and organizations for professional growth and influence.
- Advocates for all aspects of human and environmental health in practice and policy.

Additional Competencies for the Graduate-Level Prepared Registered Nurse, Including the APRN

In addition to the competencies of the registered nurse, the graduate-level prepared registered nurse including the APRN:

- Engages in decision-making bodies to implement an effective interprofessional environment that improves healthcare consumer outcomes and satisfaction.
- Interprets advanced practice nursing roles for policy makers and healthcare consumers.
- Models expert nursing practices to interprofessional team members and healthcare consumers.
- Mentors colleagues in their professional growth and participation in succession planning.

Adapted from American Nurses Association.¹

have a role in promoting specialty palliative nursing. They ensure staff having training in primary palliative care, facilitate specialty palliative care training, foster specialty palliative nursing certification, create and implement palliative care nurse residency and fellowship programs, and seek funding for programs. Palliative APRN administrators are positioned to facilitate workforce strategies to explore and implement innovative models of care to address cultural diversity and staffing challenges as well as initiatives for equitable access to quality palliative care.⁴

The American Association of Colleges of Nursing (AACN) has recently updated *The Essentials: Core Competencies for Professional Nursing Education*.⁵ The document provides core competencies across all levels of nursing education with specific subcompetencies for advanced nursing practice. The competencies are divided into domains and competencies which represent the four spheres of care: disease prevention, promotion of health and well-being, chronic disease care, regenerative or restorative care, and hospice, palliative, and supportive care.⁵ In addition to the updated *Essentials*, the AACN has provided specific guidance for masters' and doctoral programs, requiring leadership to be part of the APRN's education. AACN Essential II *Organizational and Systems Leadership*⁶ states "that organizational and systems leadership are critical to the promotion of high quality and safe patient care. Leadership skills are needed that emphasize ethical and critical decision-making, effective working relationships, and a systems-perspective."⁵ (pp. 4)

To be effective, palliative APRNs must rely on their graduate education. Whether master's-prepared or doctorally

prepared, leadership has been part of the APRN's education as outlined by the American Association of Colleges of Nursing (AACN). The AACN *Essentials of Master's Education* states that graduates must be prepared "to lead change to improve quality outcomes, advance the culture of excellence through lifelong learning, build and lead interprofessional teams, integrate care across the healthcare system, design innovative nursing practice and translate evidence into practice."⁶ (pp. 3–4)

The AACN *The Essentials of Doctoral Education for Advanced Practice Nursing* states that "enhanced leadership skills to strengthen practice and health care delivery" as a program benefit.⁷ (pp. 5) The essential for organization and systems leadership focuses on health disparities, policy development, quality improvement at both practice and policy levels, and "principles of economics and finance to redesign effective and realistic care delivery strategies."⁷ (pp. 10)

In a *US News & World Report* review of the top five graduate nurse practitioner and clinical nurse specialist programs, all of the top five programs had a basic leadership class as part of the standard curriculum across all advanced practice programs.^{8,9} Upon review of the graduate nursing curriculum at those top five schools, graduate programs only include one class focused on leadership competencies, with doctoral programs providing greater emphasis on leadership development.^{10–14} Further review revealed that the top five doctor of nursing practice programs had at least one leadership-focused class across their advanced practice programs.^{10–14} However, a single class on leadership is not enough to provide the graduate nurse with the leadership competencies needed to move into leadership roles.

The palliative registered nurse:

- Contributes to the establishment of an environment that supports and maintains respect, trust, and dignity.
- Encourages innovation in palliative nursing practice and role performance to attain personal and professional objectives, goals, and vision.
- Communicates to manage change and address conflict within palliative care delivery.
- Mentors colleagues for the advancement of palliative nursing practice and the nursing profession to enhance safe, quality, and equitable palliative care.
- Retains accountability for delegated care.
- Contributes to the evolution of the specialty of palliative nursing through participation in professional organizations.
- Influences local, regional, national, and international policies to promote health and access to quality palliative care.
- Influences decision-making bodies to improve the professional practice environment and outcomes for individuals with serious illness.
- Leads palliative care teams across settings to create new models of palliative care delivery.

Additional Competencies for the Graduate-Level Prepared Palliative Registered Nurse and the Palliative Advanced Practice Registered Nurse

The graduate-level prepared palliative registered nurse or the palliative APRN:

- Enhances the effectiveness of the palliative interdisciplinary team and outcomes through quality initiatives and research.
- Promotes advanced palliative practice nursing and role development by interpreting its role for the palliative interdisciplinary team, health colleagues, the public, and policymakers.
- Models expert advanced palliative nursing practice to the palliative interdisciplinary team, interprofessional colleagues, and other individuals.
- Mentors colleagues in the acquisition of clinical knowledge, skills, abilities, and management of individuals with serious illness.

Adapted from Dahlin.²

Although graduate nursing education contains leadership competencies, APRNs need further leadership skills. One option is to study leadership in an academic program with a focus on leadership. There are several master's programs focused on clinical leadership, nursing administration, and nurse executives. There are also clinical doctorate and research doctorate programs with a focus on leadership, including executive leadership, clinical leadership, and health system executive tracks. Other options include accelerated leadership programs specifically for nurses or business leadership programs for health professionals.

Huston identified essential competencies to prepare nurses for leadership (Box 4.4).¹⁵ The aim is for nursing programs and healthcare organizations to integrate these competencies into their programs for developing future leaders. The focus on a global vision of nursing and systems thinking.

LEADERSHIP COMPETENCIES

The first step in developing nurse leaders is to have a set of core competencies for nurse leaders. The ANA is the primary resource and voice for the millions of nurses across the

country. It provides guidance and education in all areas of nursing practice, certification, accreditation, research, and advocacy. The ANA Leadership identified 10 competencies for nurse leaders based on the ANA Competency Model, which pulls together the *Nursing Scope and Standards of Practice*, the *Code of Ethics for Nursing*, and *Nursing's Social Policy Statement* (Box 4.3).¹⁶ The model follows the ANA's *Model of Professional Practice*, which focuses on quality, safety, and evidence, with self-determination being the main focus of leadership. The ANA has developed a curriculum on leadership using evidence-based practice and a multidisciplinary approach to develop the nurse expert as they move into leadership roles.¹⁶ The important message is that the nursing leader leads themselves, leads others, and leads organizations.

Core competencies in leadership have also been established by advanced practice nursing professional organizations. The National Association of Clinical Nurse Specialist (NACNS) produced *Systems Leadership Competency*, which states that the clinical nurse specialist (CNS) should “manage change and empower others to influence clinical practice and political processes both within and across systems.”¹⁷ (pp. 20) Other leadership competencies for the CNS role include organization and systems leadership, healthcare business and finance, and professional development of healthcare team members, as well as continuing education, role-modeling, mentorship, coaching, and preceptorship.¹⁷ The National Organization of Nurse Practitioner Faculty (NONPF) established leadership as part of its core competencies as well. The core competencies include initiating and guiding change, fostering collaboration with stakeholders, using critical and reflective thinking, advocating for better access and quality of care, advancing practice, expert communication, and participation in professional organizations.¹⁸

PALLIATIVE NURSING LEADERSHIP

The HPNA focuses on leadership within the specialty of palliative nursing. Advancing Expert Care, comprised of HPNA, the Hospice and Palliative Credentialing Center (HPPCC), and the Hospice and Palliative Nurses Foundation (HPNF) published the *Palliative Nursing Leadership Position Statement*, which states that¹⁹:

- Palliative nursing leadership is transformative, leading to improved care of patients with advanced serious illnesses and influencing the values of care across all healthcare delivery settings.
- Palliative nursing leadership should be encouraged, developed, and recognized at all levels and in all aspects of palliative nursing, including clinical practice, management and administration, education, research, and policy.
- Palliative nursing leadership is advanced by palliative nurse involvement with national healthcare initiatives, collaboration with other nursing specialties, and engagement of other healthcare professionals to enhance quality palliative care.

The position statement supports transformational leadership within palliative nursing and has identified the skills of

self-assessment, listening, feedback, orchestration of inter-professional care, and negotiation as valuable in building integrity in palliative nursing.¹⁹ These skills are developed through education, collaborative practice, practice expertise, and self-awareness. The HPNA is training future nurse leaders within their Leadership Development program. The goal of the program “is to support nurses who wish to enhance their leadership skills, and to advance nurses into national leadership roles to serve as change agents to influence the future of palliative nursing practice and policies.”²⁰

The National Hospice and Palliative Care Organization (NHPCO) has a leadership and management conference to support leaders.²¹ The Center to Advance Palliative Care (CAPC) has Palliative Care Leadership Centers (PCLCs) where new program leaders can work in an organization similar to their own to learn from expert leaders.²² These PCLCs are a good resource for new programs and provide mentors to help nurses along the journey of program development.²² The American Academy of Hospice and Palliative Medicine has a leadership development page with resources for new and experienced leaders.²³ These serve as resources to advance leadership skills for the APRN.

In summary, leadership education within graduate programs is often not enough to prepare the APRN to take on leadership roles. Therefore, the palliative APRN must pursue other resources to attain the competencies listed in (Box 4.4). The ANA, HPNA, and other palliative care organizations are prioritizing future palliative care leaders and offering further skill development through education, training, and resources such as position statements, competencies, and leadership mentorships.

PALLIATIVE APRN LEADERSHIP: FROM BEDSIDE TO BOARDROOM

The move from clinical practice to leadership is often fraught with challenges. Leadership positions in healthcare are often patriarchal, with male physicians occupying leadership roles. APRNs may be emotionally attached to their role as a “nurse” and find it difficult to move from a subordinate role into one of leadership.²⁴ Palliative APRNs need to shift their thinking to overcome this expectation and see leadership as part of their role as well. Palliative APRN leaders must seek opportunities to be on committees and boards for their organizations and professional associations. Through these experiences, they gain leadership skills and experience and have a place to practice these skills. These will serve them in their administrative roles.

One leadership challenge is maintaining a clinical practice while developing leadership skills and competencies. The APRN may not be given the nonacademic time to serve in these roles and may need to pursue education and leadership activities on their own time. Leadership activities may include participating in local and national organizations and serving on boards that allow them ways to expand their roles outside of their clinical practice.

1. A global perspective or mindset regarding healthcare and professional nursing issues.
2. Technology skills that facilitate mobility and portability of relationships, interactions, and operational processes.
3. Expert decision-making skills rooted in empirical science.
4. The ability to create organization cultures that permeate quality healthcare and patient/worker safety.
5. Understanding and appropriately intervening in political processes.
6. Highly developed collaborative and team-building skills.
7. The ability to balance authenticity and performance expectations.
8. The ability to envision and proactively adapt to a healthcare system characterized by rapid change and chaos.

Adapted from Huston.¹⁵

Finding palliative APRN leader role models may be a challenge. Many healthcare organizations are physician-led. Therefore, it may be difficult to identify nurse role models and mentors to develop leadership competencies. It may be even more difficult to find mentors willing to support the APRN's move into an actual leadership position. Mentors may take many forms, from registered nurses to physician colleagues. According to Johnson, "Role models help create a positive work culture where all staff feel the impact of their efforts. They inspire trust, have a higher rate of job satisfaction, and help others to have the same."²⁵ (p. 289) Role models from within the healthcare system and organizations are necessary to move palliative APRNs into roles outside clinical practices.²⁶

Volunteering to serve on a board is a great place to start, but the first experience can be stressful. The ANA prioritized supporting nurses to sit on board by establishing the *Nurses on Boards Coalition*. This coalition offers both help in identifying boards that are looking for nurses and resources to encourage nurses to ensure their voices are heard.²⁷ Professional organizations, local chapters, organizational committees, and other committees provide opportunities for palliative APRNs to be part of a board.

A visible form of leadership occurs at organizational and department meetings. Meetings are essential vehicle to provide and glean information and keep a team together. Efficient and effective meetings are important for moral and action. Leading meetings is skill that many healthcare clinicians learn by example, rather than in any of their education and training. Being a committee or board member provides experience and promotes confidence and skill at leading meetings. Key strategies to successful meetings will help the APRN leader be more effective (Box 4.5).²⁸

LEADERSHIP IN CLINICAL SETTINGS

Since the 1990s, APRNs have been leaders in palliative care in both program development and clinical care. The leadership

role varies with location of practice. At a systems level, the palliative APRN leader develops a shared vision "to change the status quo of current care delivery to patients with advanced illnesses in the areas of effectiveness, efficiency, and timeliness, achieved through evidence-based palliative nursing practices."²⁹ (pp. 4) The palliative APRN needs to advocate for advancement into leadership positions. With all the resources available to lead, now is the time for APRNs to take this important step. Here are some questions to consider when seeking leadership roles.

Who are the advocates, partners, and cheerleaders of your program?

How can your program get the most visibility?

Is the palliative APRN embedded in oncology leading the palliative care initiative?

Have you been successful in palliative care screening and automatic referral within the hospitalist service?

All these potential questions can be answered through communication, education, and consistency, using what your team provides and in your working environment.

At the academic medical setting, APRNs may find themselves starting palliative care programs with a physician partner and then leading those programs as director. The APRN may develop and lead palliative care fellowship programs for both nursing and medicine. The palliative APRN is in a prime position to advocate for incorporating the appropriate palliative care curriculum into healthcare academic programs that have educational agreements with an academic center. They may develop and lead palliative care education initiatives for medical schools, schools of nursing, schools of social work, and spiritual care programs to name a few. This may include preceptorships, practicums, rotations, or orientation to the specialty.² The academic center also provides a robust opportunity to lead a truly interdisciplinary team and educate about palliative care.

- The agenda should be well-planned and published in advance.
- The committee should ideally create a charter for itself so that its intent and link to the larger organization are clear.
- Ground rules should be established early on.
- Meetings should start and end on time.
- Each meeting should have a stated purpose.
- Participants should come to the committee with their assignments complete and ready to participate fully in the work of the group.
- Opposing viewpoints should be welcomed and respected.
- The group should remain focused.
- Meaningful reports should be generated summarizing the committee's work.
- Time spent in committee meetings and in the accomplishment of committee tasks should further the goals of the organization.

Adapted from Rundio et al.²⁸

In community hospitals, the palliative APRN may be the only palliative care provider or may have a very small team. The palliative APRN leader will need to collaborate with all departments and work together to ensure quality care for patients and their families. Policy development and education will be a key role and a chance to foster collaboration. Additionally, the leadership role may expand beyond palliative care and include oversight of other smaller departments. Thus, there may be fewer people to do more work. Physician partners may only be part-time, resulting in the need to balance clinical work with a leadership role.

The community care setting is a growing area for palliative APRNs. Both clinical leadership and administrative leadership are essential for program development in office practices and clinics. This may include primary care practices and specialty clinics such as cancer care, heart failure clinics, and pulmonary clinics. The palliative APRN will need to use leadership skills to conduct a needs assessment and develop a strategic plan for program development and expansion. They will need clinical leadership to build relationships with providers and ensure expert communication with the care team, patient, and family.

In rural areas, the palliative APRN may have their own business because some states allow independent practice. The translates into the APRN being a clinical leader, an administrative leader of their practice, and a community leader in promoting an understanding of palliative care. The opportunity to be the “face of palliative care” necessitates APRN leadership skills of needs assessment, project management, and influence local and state policy.

With the aging of the population, long-term care is a growing place of leadership for palliative APRNs. Skilled facilities, such as chronic care/rehabilitation hospitals, skilled nursing facilities, long-term care, and assisted living facilities, provide opportunities to develop palliative care initiatives across the continuum of care. Several models highlight how APRNs

are leading the way in these settings. Insurers may offer the services of palliative APRNs to assess and manage patients with serious illness. A large inpatient service may expand its consultative services into long-term facilities. This may be a palliative APRN who rounds with facility staff, participates in care meetings, and establishes palliative care policies and standards for the facilities. Home health and hospice agencies may also employ APRNs to provide quality palliative care services within long-term care facilities.

LEADERSHIP THEORIES AND STYLE

Over the years, different leadership theories and styles have developed (Box 4.6). Having an understanding of one's style is critical to effective and compassionate leaderships. It is also important that a good leader adapt their style based on the climate of their team. During times of crisis, the leader may need to be authoritarian to get through disasters and emergencies. In a transition, the leader may need to be flexible. *Transactional leadership* is derived from the principles of social-exchange theory. Interactions between a leader and employee are meant to achieve balance.³⁰ *Transformational leadership* is a model that is often used by nurse leaders. The transformational leader inspires others to understand why change is necessary and to see the vision for the future.³⁰ Another type of leadership is *connective leadership*. Connective leadership depends on bringing employees together and uses collaboration, cooperation, collegiality, and coordination to lead. *Shared leadership* recognized the leaders in everyone, both formal and informal leaders. Shared governance and self-directed teams are examples of shared leadership.³¹ Finally, there is the *servant leader*. The servant leader puts the needs of others before their own and inspires others to do the same.³¹ *Adaptive leadership* has become important and was even more so during the COVID-19 pandemic, when teams had to be flexible to meet increasing challenges.

Box 4.6 LEADERSHIP STYLES

- Coaching: Focused on developing staff
- Visionary: Have a clear vision of where the program should be and how to get there
- Servant: Believe in people first
- Autocratic: The leader makes all the decisions on their own
- Laissez-faire: Hands-off leadership
- Bureaucratic: Based on rules
- Democratic: Decisions are shared
- Pacesetter: Very high standards and goals to get things done
- Transformational: Leaders inspire others to produce change
- Transactional: Punishments and incentives are used to motivate staff

Adapted from Campbell.²⁹

Transformational leadership is an appropriate model in palliative care.³⁰ Palliative APRNs are inherently transformational leaders by nature, being able to translate vision into reality, utilize effective communication skills, sustain a commitment to others, and always think bigger. Transformational leaders are continuous learners themselves while supporting the role development of their team members. They create safe and supportive environments and, through their own development, serve as role models. The transformational leader encourages the team through empowerment to identify issues, set goals, and resolve problems as they arise.³⁰ These characteristics are common of well-functioning teams, and a team is the heart of palliative care. There are four domains in transformational leadership: idealized leadership, inspired motivation, intellectual stimulation, and individualized consideration.³⁰

Communication is an essential aspect of leadership. There are three types of communication that leaders use in managing teams: upward, downward, and lateral or diagonal. *Upward communication* comes from your employees to the leader. *Downward communication* flows from the leader to the employees and is used to direct and inform them. Downward communication can appear authoritative and, depending on the content, may not be perceived as in the way that is meant. An example may be a staff meeting where the leader is giving organizational updates, or it could be having a difficult conversation with an employee. *Lateral or diagonal communication* may be used across groups and departments, often when there are projects or committees involving different departments. Lateral communication can also be a “give and take” conversation where the leader is at the same level as the employee. Being an expert communicator is a skill that all leaders must master, but it is especially true in palliative care.

Emotional intelligence also enhances leadership. There are four key competences to lead with good emotional

intelligence: self-awareness, self-management, social awareness, and relationship management.³¹ *Self-awareness* includes understanding your own emotions and understanding your strengths and weaknesses. *Self-management* is about keeping your emotions in check and being transparent and positive in all you do. Empathy and organizational awareness fall under *social awareness*. The most important competence is *relationship management*. Competence in emotional intelligence is reflected in being a visionary and being able to influence others.

Traits that are necessary to be an effective leader are the ability to build relationships and develop trust, think critically, utilize effective communication skills, be accountable for actions, provide constructive feedback, perform self-assessment, and be skilled at conflict negotiations.³² The true goal of the palliative APRN leader is to focus on ways to improve the quality of care for the seriously ill, which can be achieved by leading teams, motivating others, and changing behaviors to work collaboratively.³²

THE PROGRAM LEADER IN PALLIATIVE CARE

To lead a quality palliative care program, the program should be focused on the National Consensus Project for Quality Palliative Care *Clinical Practice Guidelines for Quality Palliative Care* (NCP). The NCP *Clinical Practice Guidelines* Domain 1: Structure and Process focuses on the organizational framework of your program, including interdisciplinary team (IDT) composition and the delivery of care and services in your program.³³ The frequency and function of the IDT and ensuring that the IDT is properly trained and continues to learn encourages certification and continued competence. The APRN leader needs to ensure appropriate policies and procedures are in place based on the healthcare setting.

The APRN leader promotes effective communication across the continuum of care to continually assess and reassess communications to ensure quality care. Leading staff may be the most difficult task the leader has to face. All team members are unique, with unique needs and styles. An effective leader must embrace each person’s unique abilities and what they contribute to the team.

TEAM HEALTH AND WELLNESS

Palliative care professionals meet patients and families with serious illness during difficult times. The work involves continual grief and loss and is difficult on the interdisciplinary team. The NCP *Clinical Practice Guidelines* Domains 1.7 and 1.8 are focused on caring for the IDT.³³ Well-being and health is a priority for all palliative care teams. Both the leader and the team are responsible for team wellness. Getting to know the team members will help one’s understanding of what matter most to them in developing a team and individual wellness plan. This should be a part of the team’s strategic plan, and

the palliative leader must recognize the emotional impact that palliative care has on the team.

The Institute of Health Improvement (IHI) published a white paper, *A Framework for Improving Joy in Work*, to address clinician burnout. The white paper describes burnout as an epidemic, and this is especially true in the field of palliative care.³⁴ The IHI identifies four steps to help employees restore and foster joy in their work, with each step serving as a foundation for the next. Step One is to ask staff “What matters to you?”,³⁴ a frequent question that palliative care clinicians ask their patients. Step Two is that the APRN leader must then seek out barriers to employees finding joy in their work. Step Three takes place is on a systems level, in which there needs to be a commitment to joy at work at all levels in the organization. Finally, Step Four is the quality improvement process of testing approaches and evaluating outcomes of the approach that is chosen for organizational implementation.

The National Academy of Sciences, Engineering, and Medicine published *Taking Action Against Clinician Burnout* to promote professional well-being by highlighting clinician burnout, improving understanding of challenges to clinician well-being, and advancing evidence-based solutions to take better care of the caregiver.³⁵ The Academy recommends the following step-wise approach to promote well-being:

- Goal 1: Create positive work environments.
- Goal 2: Create positive learning environments.
- Goal 3: Reduce administrative burdens.
- Goal 4: Enable technology.
- Goal 5: Provide support to clinicians and learners.
- Goal 6: Invest in research.

The CAPC published *Strategies for Maximizing the Health/Function of Palliative Care Teams* to guide development processes to promote team health.³⁶ Maintaining a health team takes time and deliberate attention and is the responsibility of all team members. The leader needs to pay close attention to team health and address issues early on. The CAPC monograph provides resources that range from assessing team health to implementing interventions to get the team back on track. It is important for teams to take time together to debrief difficult cases and grieve the losses they face on a regular basis. Staff should be aware of staff support groups and employee assistance programs to help cope with the stress and emotions of their daily work. Chaplain partners can provide regular debriefings during IDT meetings and other self-care activities. Other considerations include regular meetings focused on self-care activities such as meditation, coloring, or journaling. Yearly IDT retreats, which take place outside of the office, are a great way to build teams and to get to know each other better.

The APRN leader should structure such programs in a way that allows for some flexibility with schedules and values employees’ time off. Creating a wellness policy is a way

to show that self-care is a priority. Have each team member create an individualized self-care plan and include it as part of their yearly development goals. A team lunch is a great opportunity to educate about self-care and provide time to complete care plans. When mid-year and annual reviews occur, be sure to ask how team members have been managing their self-care and if they are meeting the goals they set for themselves. They do not need to share their care plan, but discussion at review demonstrates its importance. Finally, be sure to ask if there is anything that you, as their leader, can do to help them reach their goals and then actually work out a plan to achieve that.

During the crisis levels of COVID-19 pandemic, palliative care teams faced role changes and increased patient volume. Increased volumes put teams at higher risk of compassion fatigue and burnout. Also unique to the pandemic was the new anxiety and stress of providers getting sick themselves and bringing infection home to their families and others.³⁷ Palliative care teams had to use innovative ways to stay in touch with other team members, other teams, patients, and families.

In summary, team wellness is an essential aspect of leadership. Compassionate leadership and organizational support are needed to ensure healthy teams. The key to a successful team lies in empowering your team to make decisions, stick to agreed-on consultation requirements to ensure consistency in the referral process, and be very clear on the rules of engagement. Role-modeling and ensuring team wellness ensures program sustainability.

STAFF RECRUITMENT AND RETENTION

Hiring new employees can be challenging in palliative care. Not everyone has the ability to work in palliative care. New hires are costly to orient, onboard and train, so hiring the wrong candidate can be financially draining. The APRN leader is looking for a team member who has the required skill set for palliative care and who is a good fit with the team culture. Consider internal candidates for positions to help decrease onboarding and training costs.

Recruitment is usually done through human resources departments. Resources to make the recruiting process successful include: advertisement and social media networking, conferences and trade shows, employee personal networks, healthcare industry contacts and professional organization, organization websites, and being listed as an employer of choice.³⁸ However, now more than ever, it is important to consider workforce diversity. Does your team diversity match the diversity of the patients you serve? If not, why, and what is your plan for recruiting diverse team members?

To be successful and transparent, including your team in the interview process is a proven strategy. It also demonstrates that their opinions are valued. The first step in the hiring process is ensuring a clear and concise job description. Is the position appropriate for new graduate nurses or are you looking for experienced nurses?

When interviewing candidates, be sure to ask about their 1- and 5-year plans. Where do they see themselves in 1 year? In 5 years? Does their answer fit in with the goals of your program? Ask about how they resolve conflict and for examples of a time when they had to advocate for a patient. A strong candidate will be able to negotiate patient goals with care teams. Also, be sure to ask why they want to be part of the team, and, if new to palliative care, why they are interested in the field now. The decision to hire a new graduate or experienced candidate must take into consideration the team's bandwidth for orientation and training resources as well as the practice environment. A new graduate may have more support within an inpatient team rather than in a community program.

Employee retention is vital to a successful program. As the leader, it is your responsibility to support employees so they can develop meaningful careers that they are proud of. Onboarding a new employees should include the mission and vision of the program and the broader organization, if appropriate. Performance expectations and goals need to be clearly identified for each employee. It is important to include employee developmental goals as well as performance goals. How the employee's performance is measured should be clearly identified upon hiring. Employee satisfaction is key to retention and healthy teams. Employee satisfaction can be defined as "the terminology used to describe whether employees are happy and content and fulfilling their desires and needs at work. . . . [It] is a factor in employee motivation, employee goal achievement, and positive employee morale in the workplace."³⁸ Heathfield Important strategies for retaining employees are effective communication, workplace diversity, hiring of skilled employees, and having a training and development plan for employees.³⁸

Frequent turnover is a sign of issues within the team. Turnover can negatively affect team morale and patient satisfaction, not to mention quality of care. The APRN leader must conduct a deep dive with team to determine the reasons for turnover. Given the diversity of teams, this can be especially challenging for the APRN palliative leader.³⁶

GIVING FEEDBACK

Performance appraisals are a foundational aspect of leadership. The APRN leader should provide the employee with feedback on their performance and planning for future goals. Provide objective appraisals that focus on their positive performance for the year; this is not the time for addressing poor performance or behavior. There should be no surprises at an annual performance review, which means frequent updates and touchpoints with employees throughout the year.

While there are many models to assist with providing feedback, the Plus/Delta model is easy to remember and follow.³⁹ The Plus/Delta model is a well-known way of providing feedback in a constructive, positive way and is very useful in the palliative care setting. The Plus-Delta model is great for individual and team evaluations and feedback. The Plus looks at the positive aspects: what went well. The Delta identifies what could be done better, improved, or changed. It takes the

negative and turns it into an opportunity to learn about ways to improve.³⁹

CONFLICT MANAGEMENT

Conflict management is also an essential aspect of leadership when addressing employee behaviors. Moreover, it requires the leader to be objective and nonjudgmental. When addressing a behavior that is not aligned with expectations, it is important to address the behavior not the person⁴⁰ (Figure 4.1). First, assess the situation and identify the behavior. Was it a policy breach? Was the employee aware that a policy exists? Was it a misconception or a personality conflict? Address the behavior clearly and concisely without judgment. The next step is to be clear about your expectation and how the behavior goes against that expectation. Then stop and listen to the employee's response. Determine if there is "will" or "skill" involved. If it is skill, then the solution may be a policy review or retraining. If it is "will," it may be more challenging and implies a personality issue which may not be easily resolved. It is important to stop once consequences are given and move on. End the conversation when compliance is reached. Again, clear and concise is key. Do not prolong the conversation. If progress is not being made, consult with human resource partners for further guidance.⁴⁰

An example of inappropriate behavior occurs when the leader witnesses an employee using their cellphone on the floor when there is a clear policy prohibiting cellphone use. The leader approaches the employee and states "I saw you were on your cellphone on the nursing unit. We have a policy prohibiting cellphone use on the units. Were you aware of the policy?" If the employee states they were not aware of the policy, then you can direct them to the policy for clarification. If they are already aware of the policy but still used the cellphone, the response may be that if they continue to use the cellphone on the unit, they will be written up. Then the employee should respond with "OK" and "Thank you, I won't do it again," in which case you can move on. If they start with excuses and other comments, reiterate the consequences of cellphone use and end the conversation. If conflict continues, human resource involvement may be necessary.

There are many different types of conflict, and conflict is inevitable. The goal of conflict management is to maintain a sense of equilibrium. Not all conflict is bad, and it can be used to stimulate growth and coping behavior.⁴⁰ Conflict may be intrapersonal (within oneself), interpersonal (between the self and another person), intragroup (among members of a particular group), or intergroup (among members of two or more groups).⁴⁰ The goal of conflict resolution is to reach a "win-win" for both parties. Strategies for conflict resolution include focusing on goals, not personalities; meeting the needs of both parties equally, if at all possible; and building consensus. Common conflict resolution strategies include compromise, competing, cooperating, smoothing, avoiding, and collaborating.⁴⁰ *Compromising* is a positive solution while *avoiding* is a negative solution. Conflict will not be resolved if avoided. *Compromise*, *cooperating*, and *collaborating* will help resolve conflict and move forward.

Figure 4.1 Professional performance model.⁴⁰

In summary, it is important to face conflict head on and not avoid it. Practicing the conversation before addressing it will help the leader be more prepared. Be concise and to the point. There is no need to drag on or entertain ongoing arguing by the employee. Use your human resources if the situation does not go as planned.

STRATEGIC PLANNING AND PROGRAM DEVELOPMENT FOR PALLIATIVE CARE NURSE LEADERS

The NCP *Clinical Practice Guidelines* Domain 1: Structure and Process has specific preferred practices to help guide strategic planning and program development (Box 4.7).³³ It is important to do a thorough needs assessment for the project and identify champions to lead and encourage buy-in to the project.

NEEDS ASSESSMENT

The first step in creating a strategic plan for program development is to conduct a thorough needs assessment. The needs assessment will help to focus areas of development and set goals and priorities. Currently available resources will be identified, and, when conducted correctly, the assessment will identify champions from the organization that will help push the plan forward. By interviewing stakeholders for their input, champions can be identified and a leadership team for the project can be created who will drive the strategic plan and program development.⁴²

The CAPC has resources and tools to assist in completing a proper needs assessment.⁴² An example of a tool can be found for both inpatient programs and community programs at www.CAPC.org. The community needs assessment identifies four steps to a thorough needs assessment: self-assessment, stakeholder input, data analysis, and conclusions and next steps.⁴²

Box 4.7 NCP CLINICAL PRACTICE GUIDELINES

Domain 1-Structure and Processes 1.10

- 1.10.1 A community needs assessment is conducted to identify populations in need of palliative care, determine if demand and resources are sufficient to support a sustainable palliative care program model, design services specific to the target population(s), and identify partners.
- 1.10.2 Based on the needs assessment, a business plan with anticipated revenue and expenses is developed to ensure continuity of service to patients and families.
- 1.10.3 When launching a new program, key performance metrics are agreed on in advance to define when a program is meeting its goals.
- 1.10.4 The IDT develops strategic plans to prepare for changes in the target population and market forces, as well as other opportunities or threats that may affect the sustainability and growth of the program

Adapted from National Consensus Project for Quality Palliative Care.³³

Once the needs assessment is complete, the leader can use those results to create a strategic plan. *Strategic planning* may include program development, expanding your current program, or starting an inpatient palliative care unit. The plan allows for the setting of long-term objectives, creating a timeline for activities, and setting priorities for the program.

An important step in creating a strategic plan is assessment of your current status. Determining the strengths, weaknesses, opportunities, and threats using a SWOT analysis model will help the leader stay focused. The *SWOT analysis* will help the leader determine what they are doing well, what needs to improve, what the opportunities are, and what the barriers or threats to the project will be.

Goal setting is the next step. What are the goals for the project? What is the vision? It is important to align the values of the project with the values of the bigger organization to ensure buy-in from other leaders within the organization. Prioritizing goals and determining which steps need to happen first will allow for a greater chance at success. A clear plan for evaluation of the project is important to keep the project on track. What are the measures of success and the overall outcome being sought? Establishing how the project will be evaluated is important from day one of the project.⁴²

The next step is *program development*, and this is where the work really starts. The strategic plan is broken down even farther and specific tasks are assigned to the appropriate person in order to start moving the project forward. These tasks will include timelines, budgets, objectives, marketing, and data gathering. The CAPC has resources available to help the leader in palliative care be successful.⁴²

TEAM BUILDING

The interdisciplinary team is the heart of palliative care. In a sentinel article by Tuckman, in 1965, he identified the five states of team development as forming, norming, storming, performing, and adjourning.⁴³ *Forming* occurs as team members get to know each other and learn how best to communicate. Roles and responsibilities are established, as well as group rules of engagement. In *norming*, the team begins to function together, and they find their normal place in the group. In the *storming* state, conflict arises and needs to be dealt with to ensure the team's performance is meeting expectations. *Performing* occurs when the team develops a rhythm and process to working collaboratively and effectively. *Adjourning* does not happen with long-term teams, but can be modified to apply when a member leaves the team. When a member of the team resigns, the other team members should take the opportunity to get feedback from their co-worker on what they did well and what could have been done differently. This is a good opportunity to practice using a feedback model.

CHANGE MANAGEMENT

Change is an inevitable aspect of life. It may be difficult or easy. APRN leaders are at the forefront of change in palliative

care. Implementing palliative care services requires a culture shift from thinking of palliative care as hospice to its integration at the onset of a serious illness. Change for the palliative APRN leader can range from culture change, role change, and department change, to changes in team members and dynamics. The role of the palliative APRN leader in change can be difficult. The Kurt Lewin Change Model is well-known and laid the groundwork for other theories on change management.⁴⁴ Lewin's Change Model identifies three steps to change: unfreezing, movement, and refreezing.^{44,45} The transformational leader model type is more conducive to change in that it is a collaborative model that ensures employee involvement in decision-making during the process. Transparency in the unfreezing phase of change is crucial and will increase trust and decrease resistance to the change. Involving employees in the "movement" phase is key to employee satisfaction. Checking in with them frequently and adjusting the process in real time will help with achieving, implementing, and "refreezing" the new process.^{44,45}

QUALITY MANAGEMENT PLAN

As a leader in palliative care, it is important to develop a means of continually evaluating a program in meaningful ways and then analyzing that data to identify areas for improvement. The NCP *Clinical Practice Guidelines* Palliative Care Domain 1: Structure and Process identifies data analysis, and having a continuous quality improvement (CQI) initiative is essential in a quality palliative care program (Box 4.8).³³ It is the program leader's responsibility to pull this together and present the analyzed data in a constructive way. Utilize the IDT to determine where there is need for improvement and to establish the plan using CAPC data collection recommendations.⁴⁶

The Joint Commission (TJC) Standards for Palliative Care Programs⁴⁷ currently include a pain screen within 24 hours, a comprehensive pain assessment, dyspnea screen, documentation of goals of care conversation, and a plan of care that can travel with patients across settings. These are solid measures for new palliative care programs.

The Palliative Care Quality Collaboration (PCQC) is a national database which allows programs to benchmark against other programs and can help with goal setting in your palliative care program.⁴⁸ Examples of some national measures are days from hospital admission to consult, length of stay on the palliative care program, and number of consults per hospital admissions. Utilizing the plan-do-check-act (PDCA) cycle assists with successful improvement in your processes.

RISK MANAGEMENT

Risk management is inherent in palliative care. Palliative care programs should have a way to address complaints. Inpatient issues that may arise include clarification of advance directive documents, conservatorship, medication errors, and other legal issues. In outpatient programs, common risk issues arise around opioid contracts and prescribing and compliance.

Domain 1-Structure and Processes 1.9

- 1.9.1 The program measures and improves quality by systematically collecting and analyzing data on care processes and outcomes specific to the patient population and organization's capacity, setting improvement targets, and planning and implementing change. This cycle is repeated in an iterative and ongoing fashion until it achieves sustained improvement.
- 1.9.2 The interdisciplinary team (IDT) considers the six domains of healthcare quality as defined in 2001 by the Institute of Medicine (safe, effective, patient-centered, timely, efficient and equitable) in the design of its continuous quality improvement (CQI) program.
- 1.9.3 The IDT identifies care coordination measures and integrates these into CQI initiatives.
- 1.9.4 To the extent possible, the IDT uses assessment instruments, quality measures, and experience of care surveys that are validated, clinically relevant, and cross-cutting across settings or populations.
- 1.9.5 Patients, families, clinicians, and other partners participate in the evaluation of the IDT.
- 1.9.6 The IDT participates in quality reporting and accountability programs, as required or necessary to maintain licensure or accreditation

Adapted from National Consensus Project for Quality Palliative Care.³³

Inpatient programs may utilize their organizational risk management departments to help clarify legal issues that may arise. Community programs face some of the same issues as well as new ones, such as patient safety in the home setting, caregiver strain, and compliance with medication regimens. Opioid contracting is especially important due to increased risk of diversion in the community setting. Long-term care (LTC) facilities may have their own risk management programs. Some of the issues faced in LTC may include dietary requirements, difficulty negotiating appropriate patient-centered care plans, issues with reaching family members or conservators, and following through with end-of-life care plans. It is important to understand the risks and advocate for patients who otherwise may not have a voice.

The risk management department is very helpful in ensuring proper documentation when patients are not following the contract. These patients may need to discontinue opioids or even be discharged from the practice while maintaining the providers' obligation to the patient. Risk management can help with policy creation and keep you up to date on laws in your state. It is important to develop a relationship with your risk management department to maintain compliance and ensure that you and your team are practicing within the laws of your state. Ethics committees and consults can also be helpful in resolving conflicts that involve patient safety, autonomy, and social justice.

COMPLIANCE WITH CERTIFYING AGENCIES

There are a few different means to reaching the specialty palliative care program designation. All organizations offering this designation recognize excellence in palliative care services and validate compliance with NCP guidelines, CQI, and that the program provides family-centered care. TJC is a global leader for healthcare accreditation and

offers disease-specific certifications. Their designation offers Palliative Care Certification for hospital and community programs under home health and hospice.⁴⁷ The Community Health Accreditation Partners (CHAP) offers specially palliative care certification to community programs. Valid for 3 years, CHAP is progressive in offering the designation to palliative care programs at physician offices, assisted living facilities, skilled nursing facilities, and home health agencies as well as to independent providers of palliative care.⁴⁹ The Accreditation Commission for Health Care (ACHC) has a distinction for home health agencies and private duty agencies for palliative care that are focused on family-centered care and quality of life throughout the continuum of care and that address all realms of the patient and family based on the NCP guidelines.⁵⁰ They are developing a certification program as well. DNV is a certifying body for inpatient programs and recognizes excellence in palliative care treatment and delivery.⁵¹ Its requirements provide a "framework that assists organizations in the development and implementation of processes and systems which improve operational effectiveness and enhance positive health outcomes to improve the palliative care patient's quality of life."⁵¹

SUMMARY

With the changing landscape of healthcare, palliative APRNs are leading programs across settings and populations.⁵² The expertise and experience of palliative APRNs provides them with the foundation of a compassionate and effective leader to lead and develop interprofessional team members.^{52,33} There are resources to help palliative APRNs expand their knowledge and skills as leaders, allowing them to use knowledge and expertise to move the field of palliative care forward in new and innovative ways (Box 4.9). Palliative APRNs should embrace stepping outside their comfort zone of clinical work and bravely take on roles in leadership.

THE PALLIATIVE APRN IN NURSING EDUCATION

Carrie L. Cormack and Kathleen O. Lindell

KEY POINTS

- Palliative advanced practice registered nurses (APRNs) have the expertise and background to lead and implement palliative nursing education across all levels to meet the current needs of individuals with serious illness and facing end of life.
- Primary palliative care skills and knowledge are essential for all nurses at any level to help meet the needs of the increasing acuity and complexity of healthcare.
- The American Association of Colleges of Nursing (AACN) and End of Life Nursing Education Consortium (ELNEC) primary palliative care competencies provide a framework for undergraduate and graduate nursing programs to prepare students to care for individuals with serious illness and their families.
- Specialty graduate palliative care programs are necessary to help meet the urgent need for providers with advanced specialty skills in palliative care.
- Competencies for the hospice and palliative APRN guide the education of specialty advanced palliative nursing practice.

the critical knowledge required to provide primary palliative care in their chosen healthcare settings and positively impact the lives of patients and families facing serious illness and end of life.

In addition to preparing all students in primary palliative care, the palliative care faculty developed and launched a post-MSN-to-DNP in palliative care track specialty designed specifically for the working APRN interested in gaining deeper experience and focus on the needs of individuals with serious illness and their families. This was achieved with the assistance of an outside palliative APRN consultant to assist with the development and implementation of curriculum changes as well as the design of the new program. The current level of faculty expertise in palliative care was assessed by the consultant, and a faculty workshop for training in the new program was offered. Under the APRN leadership, all faculty at the college of nursing are now required to complete mandatory End of Life Nursing Education Consortium (ELNEC) training in addition to participation in palliative care workshops and conferences. Due to Caroline's initiative and the comprehensive approach to support specialty APRN faculty, the college has led the integration of palliative care across academic nursing programs, promoted specialty practice, and contributed to the needs of the workforce.

CASE STUDY: THE PALLIATIVE APRN EDUCATOR

Advanced practice registered nurses (APRNs) play an important role in the delivery of palliative care and palliative care education. Caroline is a Doctor of Nursing Practice (DNP) faculty member at a prominent college of nursing. She has worked with the dean and other members of the leadership team to ensure a commitment to prioritize palliative care across all educational programs, in practice, scholarship, and research, with the downstream effect being promoting and improving quality of life for individuals with serious illness and their families. The college supported both the education and training of specialty palliative APRN faculty as well as their sitting for the specialty palliative care certification examination. These specialty palliative APRNs have led significant curriculum changes, including the incorporation of primary palliative care across all programs (registered nurse-bachelor of science in nursing [RN-BSN], accelerated bachelor of science in nursing [ABSBN], master of science in nursing [MSN]/DNP, and doctoral degrees [doctor of philosophy PhD, doctor of nursing science [DNS]]). By doing this they ensure that all nursing students graduating from the nursing programs are equipped with

INTRODUCTION

The National Hospice and Palliative Care Organization (NHPCO) defines palliative care as “patient and family-centered care that optimizes quality of life by anticipating, preventing, and treating suffering. Palliative care throughout the continuum of illness involves addressing physical, intellectual, emotional, social, and spiritual needs and to facilitate patient autonomy, access to information, and choice.”¹

Palliative advanced practice registered nurses (APRNs) fill an important gap in access to evidence-based, high-quality care. With a background to provide holistic, person-centered care and advocate and seek patient goals of care,^{2,3} care provided by an APRN correlates perfectly with palliative care.⁴ APRNs have emerged as leaders in palliative care over the past several years. Leadership from APRNs in palliative care includes the domains of clinical care, advocacy and policy, research, administration and management, and education.⁵ The APRN as educator has a significant role in shaping the future generation of APRNs and specialty practice APRNs. These APRN educators must use their expertise to facilitate

education in primary and specialty palliative skills and clinical practice, and they must use leadership skills to shape change in nursing curriculum within schools of nursing. They may also shape change in nursing professional development with educational and clinical programs.

Nursing programs, especially those led by palliative APRNs as educators, must step up to the task of promoting palliative care education for both generalist and specialty nursing care. In order for nursing to remain at the forefront of this important work, palliative APRN educators must lead the way to properly prepare nurse graduates at all levels of education, within both academic and preparatory programs, to provide high-quality care to individuals with serious illness and their families.

Chapters 1 and 2 of this textbook discuss other aspects of the APRN role in education, including serving as mentors to other nurses and interprofessional colleagues and participating in palliative care research. This chapter focuses on the roles and opportunities for the palliative APRN in education, specifically for those teaching palliative care content and leading program development and implementation.

PALLIATIVE APRN EDUCATION

FACULTY

The Institute of Medicine's 2014 report, *Dying in America*, expressed the need for more professional palliative care education.⁶ This includes both primary palliative care and specialty palliative care. For nursing programs seeking to follow these recommendations, acquiring nursing faculty who are practicing at a high level of expertise in palliative care is essential.

APRNs with experience and expertise in palliative care are in a desirable position to serve as faculty and teach palliative care content across all levels of nursing students. This includes associate's, bachelor's, master's, and doctoral programs.

In addition to having palliative care experience and training, there are several considerations APRNs should make when seeking to transition from bedside patient care to academia. It is important for APRNs to thoroughly research the expectations of the academic institution, including education requirements and expectations,⁷ well in advance of this transition. Taking time to fully consider the role change and its impact may help ease any strain associated with this change. Seeking and establishing a formal mentor in the process can also be helpful. APRNs with specialty palliative certification or advanced certification in hospice and palliative nursing (ACHPNs) are especially fit for a faculty role because certification is evidence of expertise in the area of palliative and hospice care. Palliative nursing certification is achieved through the Hospice and Palliative Credentialing Center (HPCC)⁸ (see Chapter 3).

Palliative APRNs are well-situated to articulate the current needs of patients facing serious illness and end of life and to identify areas on which nursing education should focus.⁹ Palliative APRN nursing faculty are in a unique position to fill this gap and improve the quality of life for patients

and families by educating students in palliative care.¹⁰ Furthermore, palliative APRN faculty have the expertise and background to lead and implement curriculum and program changes while addressing potential barriers and overall impact.

PRIMARY PALLIATIVE NURSING EDUCATION

In 2017, the *Call to Action: Nurses Lead & Transform Palliative Care*, a collaboration between by the American Nurses Association (ANA) and the Hospice and Palliative Nurses Association (HPNA), was published.¹¹ This document includes recommendations for *all* nurses caring for patients with serious illness and their families to be prepared in primary palliative care. This foundational palliative care knowledge and skills are the care provided by non-palliative care specialty nurses to patients with serious or life-threatening illness.^{12,13}

Primary palliative nursing education involves teaching skills such as common pain and symptom assessment and management and role modeling communication techniques such as goals of care, advance directives, and providing information about resources available to patients and families in need.¹³ Because of the increasing acuity and complexity of patient care, providing this education is urgent and necessary across all levels of nursing programs. At time of graduation, new graduates should be expected to be competent in caring for patients who are seriously ill and their families, which further emphasizes the need for this content to be embedded into nursing programs.¹⁰

COMPETENCIES

To provide a framework for APRN nursing faculty to teach primary palliative care content, the AACN partnered with the ELNEC and released undergraduate and graduate primary palliative care competencies.^{14,15} By embedding these competencies into nursing programs, APRN faculty will ensure that students are prepared to provide high-quality care for individuals with serious illness and their families from time of diagnosis through the trajectory of a disease or illness. These competencies give faculty a road map and establish goals as they plan and develop the palliative care content.

For undergraduate programs, the document *CARES: Competencies and Recommendations for Educating Undergraduate Nursing Students: Preparing Nurses to Care for the Seriously Ill and Their Families*^{10,14} outlines the 17 competencies that all undergraduate nursing students should achieve by the time of graduation. The document reiterates the importance of each competency and provides recommendations for how to incorporate them into nursing courses and explanations of how they align with the AACN *Essentials of Baccalaureate Education*,¹⁶ which is essential for accreditation purposes.¹⁰

At the graduate level, palliative nursing faculty also have primary palliative care competencies to help guide this work. *Graduate Competencies and Recommendations for Educating Nursing Students (G-CARES)*¹⁵ was developed on

the foundation of the CARES¹⁴ document for master's and DNP nursing students. These competencies prepare graduates to "lead clinical practice, healthcare systems, quality improvement, and academic changes needed to advance the access of primary palliative care to all patients with serious illness."^{15(p. 4)} Graduate-level competencies are further broken down into two categories, one for all graduate nursing students and the other for those who will be providing direct primary palliative care to patients and families. Because the undergraduate competencies are aligned with the nursing essentials, the graduate competencies are also aligned with the *AACN Master's Essentials* and *DNP Essentials*.¹⁵ These competencies, at both the undergraduate and graduate levels, have marked a significant change in the way palliative care is taught in nursing programs.¹⁰

In addition to the previously mentioned *Essentials* aligned with baccalaureate, master's, and DNP education,^{15,16} in April 2021, the AACN released, *The Essentials: Core Competencies for Professional Education*, to provide a framework for nursing across the discipline.¹⁷ This document introduces 10 domains and competencies that highlight the uniqueness of the nursing profession. The AACN has recognized that one of the competencies across the 10 domains is the importance of hospice, palliative, and supportive care and has listed this as one of the areas of focus. This document will support APRN nursing faculty to teach palliative care content and expanding programs in this area and will assist faculty with "bridge(ing) the gap between education and practice."^{17(p. 1)} The concepts of compassionate care and ethics are woven throughout, highlighting the importance of these essential aspects of nursing practice.

INTEGRATING PRIMARY PALLIATIVE CARE INTO NURSING CURRICULUMS

APRN faculty should utilize available resources for embedding primary palliative care into existing programs. The CARES¹⁴ and G-CARES¹⁵ documents have appendices that specifically outline for faculty how the competencies are linked to palliative care content.^{10,15} Relying on these tools ensures that the approach is standardized for all students. Once the competencies are established, there are several options for offering palliative care content. Consideration must be given to the flexibility of the whole nursing curriculum and whether there is space for new content. The integration of content into the curricula may be achieved by two approaches. Specific courses in palliative care may be developed anew and implemented, or palliative care content may be embedded into existing courses.

Determining how palliative care content will be integrated into programs must be carefully considered by APRN faculty and nursing program leaders. One option is to offer a separate course or unit in palliative care, which may be offered to all students or as an elective. This is appealing for nursing students with a passion for palliative care or seeking to enhance their current knowledge of and preparedness for caring for patients with serious illness. The second option for programs is to take a more integrated approach to embed palliative care

content throughout the existing curriculum. Implementing this approach to learning has allowed for palliative care concepts to be introduced, reiterated, and reinforced continually until the desired competencies are attained.¹⁸ Either approach should include both didactic and clinical opportunities when possible.¹⁹

In an effort to support faculty to teach palliative care content, ELNEC²⁰ has developed online curriculums in primary palliative care specifically for nursing students. Utilizing these curriculums are one option for nursing faculty seeking to integrate this content. The content of these curricula is based on the ELNEC-Core curriculum, originally released in 2001, which was developed to guide palliative care education for nurses.²¹ These online curricula specifically meet the undergraduate and graduate competencies for primary palliative nursing and include recommendations for achieving these competencies.^{14,15} A benefit for faculty using this program is that there is no need to create similar type modules or courses for their students. Offered through Relias Learning Academy,²² access to the curricula may be purchased individually at a minimal fee per student or in a bundle by nursing programs. Each curriculum is comprised of six modules, each designed to take students approximately 1–1.5 hours to complete. Included within each module are learning activity sessions, case studies, video vignettes, and certification board–like type questions.^{10,15}

The format of incorporating these online ELNEC curricula into existing programs should be individualized based on nursing program structure. As noted earlier, this content may be embedded into existing courses within a program or offered as separate electives. Faculty options for offering the online ELNEC curriculum modules include

- *Option 1:* Offer the online modules as stand-alone, self-paced assignments, where students are given a final due date for completion. This format gives students the autonomy to work at their own pace and can be ideal, especially for the adult learner or within an online program. This is also a likely more practical method for the graduate student who may be more accustomed to self-study exercises as well as the sensitive content explored in the palliative care modules.
- Table 5.1 is an example of the ELNEC Graduate Modules offered in an accredited online DNP program. Within this example, the ELNEC Modules are offered during the last semesters of the DNP program (semesters 5/6) during the residency course. This placement was a deliberate faculty decision due to the higher level of thinking and decision-making required for some palliative care concepts. Students nearer to graduation have completed four semesters of clinical experience and are functioning at the level of a master's-prepared nurse. A lecture is given to all DNP students by a palliative APRN in the semester prior to opening the modules; this lecture reviews the foundations of palliative care as well as some advanced techniques in primary palliative care appropriate for APRN-level learning.

Table 5.1 EXAMPLE OF PRIMARY CARE PALLIATIVE EDUCATION EMBEDDED INTO A DOCTOR OF NURSING PRACTICE (DNP) PROGRAM

DNP COURSE	ELNEC GRADUATE MODULE	SUPPLEMENTAL ACTIVITIES
<i>Semester 4</i>		
Advanced Care Management 2 (clinical course #2)	—	Guest lecturer/content expert “Advanced Palliative Care Techniques” including Loss and Bereavement exercise, ²³ case studies, and video vignettes
<i>Semester 5</i>		
Residency I	Module 1: Introduction to Palliative Care Module 2: Communication in Palliative Care Module 3: Pain Management in Palliative Care	Ongoing consultation available by lead palliative care faculty Specialty clinical opportunities available
<i>Semester 6 (Final Semester in Program)</i>		
Residency II	Module 4: Symptom Management in Palliative Care Module 5: Final Hours of Life Module 6: APN Leadership in Serious Illness	Ongoing consultation available by lead palliative care faculty Specialty clinical opportunities available

- *Option 2:* The modules can be offered in more traditional face-to-face learning platforms, in-person or virtually, where an instructor uses PowerPoint presentations to teach each module to a group of students. While this may be more time-consuming, it allows students the opportunity to digest and reflect on the content, interact, ask questions, and collaborate with faculty and other experts in real time. Palliative care content can be emotionally challenging for some students. Having an opportunity to debrief with faculty and others may be beneficial.^{23,24,25}
- *Option 3:* Faculty may choose to offer these modules in a hybrid platform. This may include assigning a module to be completed independently and follow-up with interactive group discussion. The format of this session varies from Q&A opportunities, expert guest lectures, interactive group discussions, activities such as grief and bereavement exercises, and case studies.
See Table 5.2 for an example of this hybrid approach where the ELNEC Undergraduate Curriculum is embedded into an existing ABSN degree program along with supplemental activities following the completion of each module. Credit is given toward each semester grade for completion of each module.
- *Option 4:* The ELNEC modules may be offered as an in-person ELNEC course, held over 1–2 days, that student may take on their own timeline but that is required for graduation. This could include core, geriatric, pediatric APRN or critical care and may be offered independently within a school of nursing or in collaboration with a healthcare organization. The challenge is that many students may wait to do this at the end of their education and regret that they did not have the information earlier.

Having the options and flexibility of palliative care integration gives faculty autonomy with the program structure and

design and supports the unique needs of each individual nursing program. For both undergraduate and graduate students, a certificate of completion of ELNEC training is available at the end of the program for students’ curriculum vitae and portfolio to demonstrate this training to future employers.

Programs that choose not to utilize the online ELNEC Undergraduate and Graduate Curricula, should still access and use the faculty resources available through AACN ELNEC resources, including curriculum guidelines, modules, and a section designated for professional development (<https://www.aacnnursing.org/ELNEC/Resources>). APRN faculty who have undergone ELNEC training may elect to offer separate ELNEC modules such as communication or pain and symptom management, aligning them with existing coursework. These programs may rely more heavily on the expertise of the experienced APRN faculty teaching in the programs than when embedding palliative care content. Panel discussions with interdisciplinary team (IDT) members or content experts can be helpful for students as well as offering clinical opportunities with members of a palliative care team.

DEVELOPING SPECIALTY PALLIATIVE NURSING GRADUATE PROGRAMS

Specialty palliative nursing at the advanced practice level is distinguished from primary palliative nursing. At this level, APRNs have advanced skills, knowledge, communication techniques, and clinical judgment to care for individuals with serious illness and their families.^{11,26} The world, especially the United States, is facing an increased incidence of serious illness, aging demographics, and advancing healthcare technologies; the need for providers with advanced specialty skills in palliative care is urgent. Specialty palliative APRNs (postgraduate certificate or post-MSN-to-DNP degree) with expert palliative care knowledge and skills are essential to meet this demand.^{27,28}

Table 5.2 EXAMPLE OF PRIMARY CARE PALLIATIVE EDUCATION EMBEDDED INTO AN ACCELERATED BACHELOR OF SCIENCE IN NURSING (ABSN) PROGRAM

BSN COURSE	ELNEC UNDERGRADUATE MODULE	SUPPLEMENTAL ACTIVITY
<i>Semester 1</i>		
Foundations & Gerontologic Nursing	Module 1: Introduction to Palliative Nursing	Question/Answer session with guest lecturer/ content expert Simulation part 1
<i>Semester 2</i>		
Psychiatric and Mental Health Nursing	Module 2: Communication in Palliative Care	Question/Answer session with guest lecturer/ content expert; Simulation part 2
Medical Surgical Nursing I	Module 3: Pain Management in Palliative Care Module 4: Symptom Management in Palliative Care	Question/Answer session with guest lecturer/ content expert
<i>Semester 3</i>		
Population-Focused Nursing	Module 5: Loss, Grief, and Bereavement	Question/Answer session with guest lecturer/ content expert; Loss/grief/bereavement exercise ²³ ; Allow palliative care clinical group to share their clinical experiences with the class
Nursing Care with Children and Their Families	Module 6: Final Hours of Life	Question/Answer session with guest lecturer/ content expert. Have a hospice nurse come in and talk about applicable clinical experience

In addition to providing all nurses with a foundational knowledge of primary palliative care skills, nursing programs also have a responsibility to prepare more specialty palliative APRNs. Until recently, however, there has been a lack of consistency or models for graduate programs to follow when creating or providing this content. In 2015, a graduate faculty workgroup was formed with the goal of achieving consensus on the preparation of APRNs to practice specialized palliative care.²⁹ The faculty workgroup was comprised of graduate nursing faculty members from around the country involved with the education of nurses and led by Constance Dahlin, Clareen Wiencek, and Dorothy Wholihan, all of whom hold advanced degrees in nursing science. This section of the chapter will articulate the standards developed by the workgroup and later refined by additional APRN faculty experts for entry into specialty palliative APRN practice and serve as a guidebook for nursing programs seeking to prepare entry-level APRNs to practice specialized palliative care.

The standards for APRN entry into specialty palliative care practice include roles and expectations for both clinical nurse specialists (CNS) and nurse practitioners (NP). They were created with the acknowledgment that there are different models for specialty palliative care graduate nursing programs (i.e., postgraduate certificates, MSN/DNP programs, minor in palliative care). Program structure also varies from face-to-face, online, to hybrid. The goal when developing these standards was to set in place essential components applicable to any graduate nursing program regardless of format or structure.

EXISTING PROFESSIONAL AND REGULATORY STANDARDS

Nursing programs seeking to prepare APRNs to practice in specialty palliative care must be familiar with the recommendations and standards used to guide both palliative nursing and APRN practice. See Table 5.3 for a list of foundational documents used by the faculty workgroup and recommended for integration. The table also lists the relevance of each resource. As new curriculum is developed, APRN faculty should utilize these as well as accreditation documents to ensure that content maintains best practice and quality standards. When developing new programs in specialty palliative care, nursing faculty and leaders must follow all state and accrediting organization guidelines.

ORGANIZING FRAMEWORK: THE SYNERGY MODEL

The graduate faculty workgroup chose to use the AACN *Synergy Model*³⁰ as an organizing framework for the development of the standards. This model stems from the understanding that patient and family needs are similar across all health conditions and illness trajectories. These needs are what shape a nurse's practice and helps define nursing characteristics and competences. This model is the basis of *Palliative Nursing Scope and Standards*²⁶ and is comprised of eight domains including Clinical Judgement, Advocacy and Moral Agency, Caring Practices, Collaboration, Systems Thinking,

Table 5.3 RESOURCES FOR GRADUATE SPECIALTY PALLIATIVE CARE CONTENT INTEGRATION

RESOURCES FOR INTEGRATION	RELEVANCE
American Association of Colleges of Nursing (AACN) and City of Hope <i>End-of-Life Nursing Education Consortium (ELNEC) APRN Curriculum</i> ³¹	The ELNEC project is a national and international education initiative to improve palliative care. ELNEC is a partnership between the AACN, in Washington, DC, and the City of Hope, Duarte, CA. The project provides undergraduate and graduate nursing faculty, continuing education providers, staff development educators, specialty nurses in pediatrics, oncology, critical care, and geriatrics, and other nurses with palliative care training.
AACN <i>Graduate Competencies and Recommendations for Educating Nursing Students (G-CARES)</i> ¹⁵	The G-CARES document builds on the American Association of Colleges of Nursing (AACN) <i>Competencies and Recommendations for Educating Undergraduate Nursing Students (CARES)</i> document. CARES identifies the 17 essential competencies undergraduate nursing students need to have completed by the end of their pre-licensure education.
AACN <i>Competencies and Recommendations for Educating Undergraduate Nursing Students to Improve Palliative Care (CARES)</i> ¹⁴	This is a set of competencies and recommendations that will guide the education of future nurses on providing quality end-of-life care.
AACN <i>Doctoral Education for Advanced Nursing Practice</i> ³²	Outlines the necessary curriculum content and expected competencies of graduates from baccalaureate, master's, and Doctor of Nursing Practice programs, as well as the clinical support needed for the full spectrum of academic nursing.
AACN <i>Synergy Model</i> ³⁰	The AACN <i>Synergy Model</i> 2 nd ed. for Patient Care is a conceptual framework that aligns patient needs with nurse competencies. The central idea of the model is that a patient's needs drive the nurse competencies required for patient care. When nurse competencies stem from patient needs, and the characteristics of the nurse and patient match, synergy occurs. This synergy enables optimal outcomes. The model identifies eight patient characteristics and eight nurse competencies.
American Nurses Association (ANA) <i>Code of Ethics for Nurses with Interpretive Statements</i> ³³	This is a guide for all nurses regarding the professional responsibilities consistent with the quality in nursing care and the ethical obligations of the profession.
ANA/HPNA <i>Call to Action: Nurses Lead and Transform Palliative Care</i> ¹¹	The call for action, which has been approved by members of the ANA and HPNA Boards of Directors, outlines 12 key recommendations that indicate the steps necessary to achieve quality primary palliative nursing, regardless of setting.
ANA <i>Nursing: Scope and Standards</i> ³⁴	Provides detailed and practical discussion of the competent level of nursing practice and professional performance. Outlines key aspects of nursing's professional role and practice for any level, setting, population focus, or specialty.
Center to Advance Palliative Care (CAPC) ³⁵	This is a national organization dedicated to increasing the availability of quality palliative care services for people facing serious illness. As the leading resource for palliative care development and growth, CAPC provides healthcare professionals with the training, tools and technical assistance necessary to start and sustain successful palliative care programs in hospitals and other healthcare settings.
Hospice and Palliative Nurses Association (HPNA) <i>Competencies for the Palliative and Hospice APRN</i> ³⁶	Describes the explicit intellectual, interpersonal, technical, and moral competencies necessary for specialty quality advanced palliative nursing practice. Advanced practice is inclusive of APRNs and graduate-prepared nurses with doctoral education. Competencies are outcome-specific and measurable.
HPNA <i>Palliative Nursing: Scope and Standards of Practice</i> ²⁶	Provides information that encompasses hospice and palliative nursing. Provides essential guidance in the form of standards and competencies for all levels of practice for palliative nursing.
National Consensus Project for Quality Palliative Care <i>Clinical Practice Guidelines</i> , 4th ed. ¹²	This 4 th edition creates a blueprint for excellence by establishing a comprehensive foundation for gold-standard palliative care for all people living with serious illness, regardless of their diagnosis, prognosis, age, or setting.
National Council of State Boards of Nursing (NCSBN) ³⁷	The organization through which nursing regulatory bodies act and counsel on matters affecting public health, safety and welfare. This includes but is not limited to nursing licensure examinations.

Response to Diversity, Facilitation of Learning, and Clinical Inquiry.³⁰ In creating the standards for specialty palliative graduate nursing education, each of the eight content areas was explored and aligned with competencies from the *HPNA Competencies for the Palliative and Hospice APRN*.³⁶ In addition, essential content for program implementation was identified, including resources to guide curricula development and for faculty to gain expertise. Box 5.1 lists the *Palliative and Hospice APRN Competencies* aligned with each domain. The following section outlines the essential content necessary for graduate faculty to incorporate into a specialty care program as well as supporting resources.

Clinical Judgment

Faculty must ensure that students are prepared to practice diagnostic reasoning, clinical decision-making, and effective communication techniques with patients and families (Box 5.2). This competency encompasses a vast array of APRN

skills including clinical judgment, clinical reasoning, and decision-making at an advanced level of practice. In addition, they must be knowledgeable about illness trajectories across all setting and various specialties, including anticipatory guidance. Comprehensive palliative physical assessment skills and incorporation of these skills and tools per the *NCP Clinical Practice Guidelines*¹² are essential and should be assessed for competency throughout the program. This may be done through the use of standardized patients or in clinical settings with expert preceptors.

Specialty palliative APRNs nurses must fully manage and support patients and families nearing end of life. This may include coordination of care as well as palliative pharmacological and nonpharmacological options to address pain and symptoms associated with advanced illness. Competent history-taking and assessment skills, knowledge of common complications, considerations of opioid use and misuse, and socioeconomic factors are essential. APRNs should be comfortable documenting and revising the plan of care for

Box 5.1 PALLIATIVE APRN COMPETENCIES ALIGNED WITH SYNERGY MODEL DOMAINS

Clinical Judgment

The palliative APRN demonstrates advanced clinical judgment, clinical reasoning, and decision-making as appropriate to advanced practice nursing, based on expert knowledge and skill in the assessment (history, current concerns, and physical examination), diagnosis, planning, and management of complex human responses, and the integration of global knowledge of the multidimensional needs of individuals with serious illness and their families.

Advocacy and Moral Agency

The palliative APRN integrates knowledge, attitudes, behaviors, and skills that are consistent with and assumes responsibility for advanced practice nursing professional standards, nursing codes of ethics, and advanced practice scope of practice within their care delivery. The palliative APRN serves as a moral agent to identify and resolve moral and ethical concerns, including advocating for human rights of all individuals with the goal of addressing and reducing health disparities, inequities, racism, and discrimination.

Caring Practices

The palliative APRN integrates advanced caring practices to create a compassionate, supportive, and therapeutic environment for individuals with serious illness (perinates, neonates, children, adolescents, young adults, and older adults) and their families with the aim of promoting comfort, healing, and preventing unnecessary suffering. This is accomplished by, but is not limited to, vigilance, engagement, and responsiveness to themselves, individuals, families, and other healthcare providers.

Collaboration

The palliative APRN collaboratively engages with individuals with serious illness, their families, and healthcare providers in the provision of palliative care, with the focus on patient-centered and family-focused care in a way that promotes each person's contributions toward achieving optimal yet realistic individual and family goals.

Systems Thinking

The palliative APRN identifies and utilizes the evidence and body of knowledge for palliative care delivery and advanced clinical practice, as well as the tools to proactively manage the environmental and system resources for the individual with serious illness, their family, and staff within a health organization, a care system, and a community.

Response to Diversity

The palliative APRN has the cultural sensitivity to recognize, appreciate, and incorporate the differing cultural needs of individuals with serious illness into the provision of care, which may include but is not limited to cultural differences, spiritual beliefs, sexual orientation, gender identity, gender expression, race, ethnicity, lifestyle, socioeconomic status, age, and values.

Facilitation of Learning

The palliative APRN provides and facilitates learning for individuals with serious illness, their families, nurse colleagues, other members of the healthcare team, and the community in formats appropriate to the environment (i.e., virtual, in-person, or hybrid models).

Clinical Inquiry

The palliative APRN continually questions and evaluates advanced palliative nursing practice and palliative care and provides informed practice based on the established palliative care research evidence and related information. In addition, the palliative and hospice APRN uses research to promote improved outcomes for individuals with serious illness and the community.

**Box 5.2 RESOURCES FOR CURRICULAR
DEVELOPMENT: CLINICAL JUDGMENT**

Dahlin C, Moreines L, Root M (eds.). *The Hospice and Palliative Advanced Practice Registered Nurse Core Curriculum*. 3rd ed. Pittsburgh, PA: Hospice and Palliative Nurses Association; 2020.

individuals with serious illness and their families based on evolving needs and preferences and complex, competing, and shifting priorities in goals of care.

Advocacy and Moral Agency

Advocacy is intertwined with ethical principles and ethical theories and is an essential component in graduate nursing education and should include defining and identifying ethical conflicts and moral distress associated with families, patients, and staff and developing interventions to address these (Box 5.3). Goals of care conversations with families also fall under this umbrella including how to identify, document, and follow through on patients wishes and preferences for care including advance care planning. Faculty should model strategies to help patients and families weigh the pros and cons of aggressive life-prolonging or life-saving treatment and how these align with their goals of care. This may be best accomplished through the use of role-play and case studies. Faculty should ensure that students are practicing in accordance with the professional standards of the current versions of the *ANA Nursing: Scope and Standards of Practice* and *HPNA's Palliative Nursing: Scope and Standards of Practice* as well as the *ANA Code of Ethics for Nurses* and *HPNA's Code of Ethical Conduct*, which articulate the moral foundation of palliative and hospice advanced practice nursing. Students should also incorporate into their practice all appropriate federal laws, regulations, and standards from the Centers for Medicare and Medicaid Services (CMS) and state statutes, regulations, and laws as well as currently accepted professional standards of advanced practice nursing.

Caring Practices

Palliative APRN faculty must teach and role-model compassionate caring and patient- and family-centered care (Box 5.4). Theoretical models of caring are essential to nursing practice and even more significant when caring for individuals with serious illness and at end of life. The APRN in education must value the role of compassion and kindness and exhibit these traits in all aspects of their interactions, including with students, colleagues, and patients and families. Demonstration of compassion and respect for the inherent dignity, worth, and unique attributes of all people is essential. Self-care, caregiver burden, and compassion fatigue, as well as moral distress

and building resilience, are important content areas in this domain.

Collaboration

APRNs must be full partners with interprofessional team members,³⁸ especially when caring for individuals with serious illness (Box 5.5). To support an IDT team process, APRNs must be able to identify complementary areas of expertise as well as overlapping areas of expertise among disciplines and how this contributes to the care being provided to the patient and family. Demonstrating this teamwork will establish a climate of trust, respect, and partnership between individuals and families with serious illness and IDT members in the provision of specialty palliative care. Team communication skills and opportunities to work with or shadow palliative care IDT members in a clinical setting would be beneficial to the students. Program has implemented a wide range of projects to advance leadership in palliative care.³⁹

Systems Thinking

Systems thinking includes concepts such as system theories, healthcare finances, and policy work (Box 5.6). These topics are often covered in courses throughout an MSN/DNP program. Faculty must ensure that students focus on palliative care in relation to these consent areas. The students should examine the application of program cost-effectiveness measures, metrics, and marketing, as well as measures for quality improvement and accountability. Working with team members in various healthcare delivery settings, systems, and as part of interprofessional teams will allow students to get a behind the scenes experience of some of the access, barrier, cost, efficacy, and quality issues that present when making palliative care decisions with patients and families.

Response to Diversity

Nurse educators are responsible for instilling the importance of culturally respectful care from the start of a

student's educational journey. Students much learn to recognize and appreciate the cultural needs of individuals with serious illness and their families, which may include but are not limited to cultural differences, spiritual beliefs, sexual orientation, gender identity, gender expression, race, ethnicity, socioeconomic status, age, and values. Self-reflection on one's own values, beliefs, and perspectives and how this may impact the delivery of culturally sensitive care should be discussed and incorporated into all aspects of a program. Spiritual and religious influences on illness, grief, and bereavement should be explored and understood, including the cultural aspects of palliative care. An important aspect of this is introducing students to health disparities and social injustices within palliative care and how this may be approached and resolved. Chapter 35, "Culturally Respectful Palliative Care," further outlines the importance of care and may provide tools helpful for faculty embedding this content into their curriculums.

Facilitation of Learning

Knowledge about and involvement with existing professional associations and standards will be essential for graduate students to provide palliative care education to others in their role as palliative APRNs (Box 5.8). This includes not only patients and families, but other healthcare professionals and community members. As discussed earlier, ELNEC Modules and resources^{20,22} were specifically designed to advance palliative care education and should be introduced to students as a resource early in their program. Other associations such as the HPNA,⁴⁰ the Center to Advance Palliative Care (CAPC),³⁵ and the NHPCO¹ should be explored for their valuable patient, family, and provider resources, including educational materials and toolboxes.

Clinical Inquiry

Graduate nursing programs will prepare APRNs to evaluate evidence related to clinical practice in palliative care using standardized approaches related to the domains of the NCP *Clinical Practice Guidelines*¹² (including pain and symptom management, grief and bereavement, and spiritual care). Quality improvement principles and methods to promote change in nursing practice related to palliative care should be emphasized and modeled.

Evaluation of Content Areas

When integrating primary palliative care content into existing nursing curriculums or developing specialty palliative care programs, faculty should utilize a combination of innovative teaching modalities. These may include but are not limited to the following:

- Journaling
- Self-reflection
- Written assignment (e.g., resolution of ethical cases)
- Problem-based learning
- Simulation (high- and low-fidelity; using standardized patients)
- Case studies
- Content expert lectures
- Panel discussions (IDT)
- Group discussions
- Role-plays
- Interviews
- Book club review and/or movie reviews

- Graded case presentation or case studies
- Readings, podcasts, videos
- Clinical rotations
- Examinations (e.g., multiple-choice, short-answer, case-based questions)

In addition to the listed teaching modalities, faculty and program leaders must evaluate the outcomes of the palliative care programs and initiatives. This may be done through

- Course summaries
- Student academic outcomes (e.g., grade point averages, certification pass rate, oral or practical evaluation)
- Preceptor evaluations of student clinical work
- Student evaluations of program
- Student clinical outcomes
- Clinical preceptor and site evaluations
- Electronic student record of patient encounters for number and type of palliative care encounters and care provided
- Program outcome metrics
- Tracking admissions, attrition, certification pass rates, transcripts, etc.

Clinical Experiences

The HPNA *Standards for Clinical Education* (2nd ed.)¹⁹ should be used by faculty when incorporating clinical opportunities into nursing programs. These standards outline types of clinical experiences, including those for the RN and those for the APRN. The standards also review criteria for suitable preceptors, curriculum needs, and evaluation requirements.

Institute for Health Improvement. 2018. Boston, MA. <http://www.ihl.org>

Practicum specialty hours should be included, at the minimum with graduate specialty palliative care programs but may also be considered for undergraduate and graduate students as optional experiences for students seeking to gain additional expertise. Supervised practicum experiences are essential to the development of specialist graduate-level skills. Students should be exposed to both palliative and hospice care to assure competency in complex pain and symptom management, communication, and conflict resolution across the lifespan, and in various clinical settings.

Advanced certification in hospice and palliative nursing by the HPCC, requires didactic and clinical hours, including functioning as a CNS or NP with hospice and palliative advanced nursing practice of 500 hours in the most recent 12 months or 1,000 hours in the most recent 24 months prior to applying for the exam.⁸ Programs may consider meeting the requirements for sitting for certification by the end of their programs.

BARRIERS

Literature is abundant on the barriers that exist to integrating palliative care for individuals with serious illness and their families.⁴¹ Among these barriers, a recurrent theme is the lack of and need for more education and training, including preparing specialty trained providers in palliative care.^{6,11} Other barriers include time to attend such education, financial support, and space within nursing program curricula. This chapter has outlined solutions for APRN faculty to meet this need and incorporate elements of palliative care into existing and new nursing program curricula. Unfortunately, nursing programs and educators also face barriers when answering this call to action.

Despite having the support of the recommendations and guidelines published by organizations such as the National Academy of Medicine (formerly the Institute of Medicine),⁶ the ANA, and the HPNA¹¹ to advance palliative care education, faculty should anticipate challenges in developing and rolling out this content. The first step for faculty should be obtaining organizational buy-in. Palliative care education should be a prioritized part of the organizational strategic plan if programs are to be successful when changing curricula. Communication with senior leadership and focusing on the

known benefits of palliative care practice, including improving pain and symptoms, enhancing quality of life, reducing caregiver stress and burdens, and decreasing hospital costs and lengths of stay.

Expert APRN faculty should be prepared to provide education to those who may not be as familiar with the guidelines, recommendations, and benefits of increasing palliative care education. This includes not only senior leadership but also faculty who will be supporting students throughout their program. In the case study, an interactive faculty workshop was developed and implemented, faculty were mandated to complete the online ELNEC modules, and periodic “lunch and learn” mini conferences were offered on palliative care topics. When palliative care education is named a priority in strategic planning, it opens the door for advancement in this area.

Another barrier in implementing new content may exist because of already crowded curricula. A comprehensive review of courses should be completed to identify outdated content that may be removed from the curriculum to make necessary room for palliative care material. Additionally, curriculum change comes with a price tag. As with many new initiatives, finances are another barrier that faculty may face when incorporating palliative care into nursing programs. Financial impacts extenuate the importance of leadership and stakeholder buy-in. Expenses may include faculty time, marketing, access to the online ELNEC curriculum, expert consultative fees, professional development, and additional training necessary for faculty. APRN faculty should work with leadership to secure funding through grants, philanthropy, and allocations in the budget for palliative care initiatives.

Last, securing appropriate clinical sites with trained preceptors may be a barrier for programs wanting to offer students hands-on practical experience with patients and families in palliative care. Securing community partners will be essential early on in program development, and this will include specialty palliative care providers as well as IDT members. Offering students opportunities to engage with individuals with serious illness across the lifespan is optimal and may require travel, especially for those living in rural areas. Faculty should consider hospital-based care, community or outpatient care, residential facilities, and home-based palliative and hospice organizations.

SUMMARY

It is generally recognized that there is a need to increase palliative education across all levels of nursing programs in order to meet the demands associated with individuals with serious illness. Experienced APRNs in the field of palliative care should consider this an opportunity to take a leadership role in educating future nurses and advanced practice nurses in palliative care. Palliative care education is vital to answering the call to increase both primary and specialty palliative care access for individuals with serious illness and their families. Palliative APRN educators should use the resources available in addition to their experience and expertise to obtain leadership buy-in, develop and design curricula, implement curriculum changes, and support students and other faculty throughout the process. Based on their competence, expertise, and professionalism, palliative APRN educators are in a unique position to overcome existing barriers and truly make an impact on the lives of patients and families.

6.

THE PALLIATIVE APRN IN POLICY AND PAYMENT MODELS

Marian Grant

KEY POINTS

- Palliative care achieves all the key objectives of health reform and recent health policy revisions.
- Recent federal legislation and regulation is improving access to palliative care services.
- Healthcare payment is shifting toward paying for outcomes and value and palliative care can contribute to achieving those goals.
- New payment models could also increase access to palliative care services.
- Health policy and payment policy affect patient care and access to care, what palliative APRNs can do clinically, and what they can be reimbursed for.
- Advanced practice registered nurses (APRNs) can play a significant role in the development of policy and payment.

CASE STUDY 1: PALLIATIVE CARE REIMBURSEMENT

Shanice is a nurse practitioner (NP) who is a new member of an inner-city hospital's palliative care team. She really likes the people she works with, but she has been struck by the fact that the team seems more heavily staffed with physicians and NPs than with nurses, social workers, or even a chaplain. She knows from her previous hospice experience that the most holistic care is delivered by a fully interdisciplinary team. When she questioned the team about the interdisciplinary mix, her teammates answered that the hospital only wants billable providers on the team. This was a new concept to her because, when she worked in hospice, billing for her services did not come up. She also loved working in the home setting and was hoping that this might be an option on this new palliative care team, but now it seems that the hospital cannot afford to start a home-based palliative care program since there is not adequate payment for such a program.

Fortunately, one of the other palliative NPs on the team has become very involved in federal and state policy efforts and has been able to answer Shanice's questions and show her how policy shapes their team's makeup and responsibilities. This NP suggested that Shanice learn more about policy, and this chapter will cover some of the key things she has learned.

INTRODUCTION

Most palliative advanced practice registered nurses (APRNs) know it is important to be knowledgeable and current on palliative clinical practice. What some palliative APRNs do not realize, however, is the value of being aware of ongoing health policy and payment models. This knowledge is important because clinical practice in the United States is regulated. The care patients can receive, including access to palliative care, along with what APRNs can do and be reimbursed for, all depend on health policy and payment regulations (see Appendix I for information on reimbursement).

This chapter provides an overview on health policy and payment and how they relate to patient care, palliative care delivery, and APRN practice. To illustrate core concepts, two case studies are threaded throughout the chapter.

HEALTHCARE IN THE UNITED STATES

In 2018, US healthcare spending was \$3.6 trillion or \$11,172 per person. As a share of the nation's Gross Domestic Product (GDP), this health spending accounted for 17.7%.¹ That makes healthcare a major sector of the US economy and larger than manufacturing.

Healthcare has therefore become an important national issue given its size and role in the economy. However, although the United States leads the world in health technology and innovation, it lags on other important health aspects.

- The United States spends nearly twice as much other developed countries on healthcare, paradoxically having the lowest life expectancy and the highest suicide rates among the 11 other developed nations.
- The United States has the highest chronic disease burden, with an obesity rate that is two times higher than other developed countries.
- Compared to peer nations, the United States has among the highest number of hospitalizations from preventable causes and the highest rate of avoidable deaths.²

It is estimated that the care for only 5% of the US population represents close to 50% of total healthcare spending.³ Healthcare in the United States is not only expensive

for the government or insurance companies paying for it, but also for patients and their families. Specifically, as the costs of health insurance and medications have increased, so have deductibles, copays, and out-of-pocket expenses. It is estimated that these expenses cost the average American household \$5,000 per year, twice the amount from 1984.⁴ Approximately 60% of health insurance in this country is employment-based, and being unemployed unfortunately often goes hand in hand with being uninsured.⁵ These issues, along with problems of health coverage and access in the United States became magnified during the COVID-19 pandemic.⁶ The pandemic highlighted lack of access to care, higher morbidity and mortality among minority and vulnerable populations, and lack of systems to provide good care in the home, thereby revealing many of the underlying problems with the US healthcare system.⁶ The US health system is really not a system; rather it is inefficient, uncoordinated, and many Americans are under- or uninsured. Moreover, systemic racism and inequity continue to result in health disparities for minority communities that cause shorter life spans and higher morbidity.⁷

HEALTHCARE REFORM

It is therefore not surprising that the US healthcare system has been undergoing reform for some time. Much of that reform has been driven by what is called “the triple aim.” This is the goal of concurrently

- Improving the patient experience of care (including quality and satisfaction);
- Improving the health of populations; and
- Reducing the per capita cost of healthcare.⁸

These goals may sound familiar, but they are not obvious partners. Trying to improve something while at the same reducing costs can be challenging. Nonetheless, doing all three together has been the goal of many federal and state health policy changes. More recently, there has been talk of adding a fourth aim: “the quadruple aim.” Possible additions include improving clinician satisfaction, pursuing health equity, and other priorities.⁹ However, from a policy perspective, the original triple aim continues to be the most consistent goal even if it has yet to be fully realized.

Another factor in healthcare reform is the aging of the American population. The 73 million “baby boomers,” those born between 1946 and 1964, will all be older than 65 in 2030.¹⁰ At that point, they and others over age 65 will represent 20% of the population, or one in five Americans.¹⁰ Since the number of chronic conditions increases with age, almost half of all people aged 45–64 and 80% of those 65 and over have multiple chronic conditions.¹¹ This means that older people will represent increasingly more of the patients in the US health system. The aging of the population has been anticipated for a long time. However, recent developments, like

the COVID-19 pandemic and its higher mortality in nursing homes,¹² have demonstrated that our health system is not ready to provide safe and appropriate care for older patients¹³ and that further reform is still needed.

PALLIATIVE CARE AND HEALTHCARE REFORM

Fortunately, palliative care is a solution to many of healthcare’s current problems. First, it can deliver all three of the triple aims.¹⁴ It can improve the quality and satisfaction of an individual’s care by addressing their specific needs and providing support. Then, it can improve the health of the seriously ill population by, again, addressing physical symptoms, emotional and social issues, and providing support. Finally, it typically does this at equal or less cost than care without palliative care.¹⁵ This is achieved primarily due to the goals of care conversations palliative care teams have with patients. Those conversations focus on what matters most to the individual; then the treatment plan is developed to deliver on those personal goals. In many cases, once people are more aware of their health situation and prognosis and have been given the full range of treatment options, including less aggressive ones, they often choose a less aggressive approach, which saves money for them and those paying for their care.¹⁶ Even when people choose to continue pursuing all aggressive care, palliative care does not end up costing more because palliative care combined with aggressive care usually results in less hospitalizations or readmissions by better anticipating and managing health crises.¹⁶ It is because of this financial consideration that many hospitals have palliative care programs to both improve patient care and control healthcare costs. Shanice has heard her team talk about these benefits being why her team was able to add new staff recently.

Palliative care is appropriate for aging individuals, especially those with multiple chronic illnesses, as its focus on improving or maintaining quality of life. Shanice sees not only how her patients individually benefit from the palliative care services she and her team deliver, but she is also becoming aware of her team’s success, and her hospital’s interest, in reducing readmissions, intensive care unit (ICU) length of stay, and mortality—in the latter case by increasing hospice referrals—all of which palliative care has been shown to help achieve.¹⁷

HEALTH POLICY

According to the World Health Organization (WHO) health policy refers to

Decisions, plans, and actions that are undertaken to achieve specific healthcare goals within a society. An explicit health policy can achieve several things: it defines a vision for the future which in turn helps to establish targets and points of reference for the short

and medium term. It outlines priorities and the expected roles of different groups; and it builds consensus and informs people.¹⁸

Health policy can be formed at the institutional, local, state, or federal level and involves multiple stakeholders from citizens, patients, clinicians, healthcare providers and systems, government officials, policy experts, and professional and advocacy organizations, to name just a few. Their combined effort leads to health policy in the United States. The following content explains key federal policy components.

LEGISLATION

In the United States, governmental health policy is achieved via two mechanisms. The first is legislative action through new laws. The second is regulatory action through the interpretation and implementation of those laws. *The Affordable Care Act* (ACA), also known as Obamacare, was a law passed in 2009.¹⁹ Its provisions were then translated into regulations to provide the specifics on, for instance, how children receiving hospice could also receive concurrent curative care²⁰ (see Figure 6.1).

In terms of federal legislation, palliative care currently enjoys strong support in Congress in both the House and Senate and among both Republicans and Democrats. That is because members of Congress and their staff often have personal experience with serious illness that drives their interest in improving care. Some members of Congress are also nurses and physicians who likely better appreciate the benefits of palliative care.²¹ Nonetheless, it can take several sessions of Congress to get a bill passed. This has been the case with the *Palliative Care and Hospice Education and Training Act* (PCHETA), a bill to increase the funding for training physicians, nurses, and other team members, which has been introduced repeatedly since 2012²² and which has only ever passed in the House. See Box 6.1 for details on PCHETA.

Shanice has started advocating for PCHETA by responding to her nursing association's requests that she contact her elected federal officials to get them to support this and other important bills. She has also learned that members of Congress are interested in hearing both from their constituents and nurses, since nurses represent the largest healthcare workforce²³ and have been consistently rated the profession with the highest levels of honesty and ethics by the public since 2002.²⁴ Constituents who are also nurses are, therefore, likely to get a welcome response from their elected officials' offices.

Box 6.1 PALLIATIVE CARE AND HOSPICE EDUCATION AND TRAINING ACT (PCHETA) SUMMARY

- Establishes new palliative care and hospice education centers and fellowship programs within them for physicians and nurses
- Authorizes physician and nurse training programs
- Promotes career development via academic career awards and career incentive awards
- Establishes a national campaign to inform patients, families, and health professionals about the benefits of palliative care and the services that are available to support patients with serious or life-threatening illness
- Directs the National Institutes of Health to use existing authorities and funds to expand palliative care research to advance clinical practice and improve care delivery for patients with serious or life-threatening illness

See Congress.gov.⁶⁷

REGULATION

As noted, regulations are the other way health policy is implemented. While the wording for enacted laws is set in statute, the regulations for those laws must be interpreted from that wording and, in the case of some laws, periodically updated. The federal regulatory process includes a mandatory 60-day period for the public to comment on any proposed regulations, which is an opportunity to both educate and advocate for palliative care with the various regulatory agencies. Every year, the Centers for Medicare and Medicaid Services (CMS) update regulations for major aspects of healthcare such as hospital, hospice, nursing home, home health, and the Medicare drug (Part D) programs. These updated regulations dictate what and how healthcare providers like APRNs and physicians will be paid. Major palliative care organizations monitor federal regulations and advocate to include palliative care in programs for those with serious illness wherever possible.²⁵ They also monitor regulations to advocate that activities like advance care planning be included or required in as many federal programs as possible. For instance, after advocacy from the field, CMS introduced new billing codes for advance care planning in 2016, and nurse practitioners are among the healthcare providers who are eligible for reimbursement for having these conversations using these codes.²⁶

Figure 6.1 Government health policy.

MEDICARE ADVANTAGE SUPPLEMENTAL BENEFITS

Getting bills passed in Congress has become increasingly difficult due to increased partisanship, although regulatory opportunities in general, as well as for palliative care

Box 6.2 MEDICARE ADVANTAGE (MA) KEY DETAILS

- Available to Medicare beneficiaries as an alternate to traditional Medicare
- Provided via commercial health insurance plans
- Has become increasingly popular among those beneficiaries as it often provides additional benefits like dental, vision, and hearing services, things unfortunately not yet covered by traditional Medicare

Source: US Department of Centers for Medicare and Medicaid Services.⁶⁸

specifically, have increased over the past few years. This likely reflects the government's recognition of the needs of those living with serious illness²⁷ and the aging of the population. Some serious illness examples include allowing Medicare Advantage (MA) health insurance plans to offer additional services, such as home-based palliative care, to those with serious illness.²⁸ See Box 6.2 for more on MA.

Shanice read recently that the head of the big MA organization in her state is interested in offering home-based palliative care, and her team has discussed whether that might be an opportunity for them to pilot such a program with that MA plan.

TELEHEALTH

Another federal policy opportunity has been increasing flexibility for healthcare programs to be in touch with patients via telehealth. Historically, telehealth was limited to only patients in rural areas and required these patients to go to a designated healthcare facility to interact with providers elsewhere.²⁹ The COVID-19 pandemic resulted in some CMS waivers that allowed providers to contact patients at home in any geographic area, even using the telephone if the patient did not have a device that allowed video interaction. Shanice and her team were able to check on patients at home via telephone during the pandemic and found it surprisingly effective. Another hospital in her city has a palliative care discharge program where patients are given tablet devices to follow-up with the team virtually after discharge.³⁰ Many of these patients are elderly and have limited transportation options, and the team at the hospital has found telehealth with them surprisingly effective. Because of these types of experiences, the use of telehealth surged in 2020 during the pandemic and both providers and patients found it helpful. The federal government has subsequently started making some of these changes permanent, including home visits for the evaluation and management of a patient where the law allows telehealth services in the patient's home and certain types of visits for patients with cognitive impairments via new legislation and regulations.³¹ (See Box 6.3 and Chapter 17, "The Palliative APRN in Telehealth.")

Box 6.3 EXAMPLES OF CMS TELEHEALTH WAIVERS THAT BECAME PERMANENT

Contacting patient at home via telehealth in states where allowed
Contacting patient with cognitive impairment via telehealth

SOCIAL DETERMINANTS OF HEALTH

CMS is also interested in assessing and modifying payment in Medicare programs for those beneficiaries with social risk factors such as income, geographic location, education level, etc. It is estimated that these "social determinants of health" contribute up to 80% of health outcomes,³² and they are particularly important for those with serious illness as many with social risk factors have poorer outcomes and they and their families would benefit from additional services, including palliative care (see Chapter 20, "Health Disparities"). Shanice's care of people with lower-income, living near her city hospital, makes her very aware of social determinants of health and health disparities. A church in her neighborhood is developing a program to support family caregivers, for instance, and asked her to talk to their health committee about palliative care.

PAYMENT MODELS

Payment is a major focus area for health policy reform because it so strongly impacts care delivery. In many cases, you can change clinical practice by changing what is and is not paid for.

CASE STUDY 2: PRACTICE AUTHORITY

Derrick is a CNS who has now also joined the palliative care team Shanice works on. His previous experience was at the cancer center affiliated with their hospital, but he was interested in developing his palliative care skills and has been glad to join the palliative care team. In regard to policy, he has already been involved with some issues as state regulations limit his CNS scope of practice. This has been frustrating for him because he previously worked in a state where CNSs had full practice authority. His state CNS association has been lobbying for legislation to expand scope of practice, and he ended up on that association's policy committee and is knowledgeable about this issue and process.

FEE FOR SERVICE

Historically in the United States, healthcare providers have been paid on a fee-for-service (FFS) basis.³³ This means that each procedure or intervention has an agreed-upon fee attached to it. While this system sounds simple and made sense in the days when medical interventions were more limited, over time there has been the realization that it can

inadvertently encourage healthcare providers to do more interventions or tests than needed since that can help boost income. An additional problem with an FFS model was highlighted when patients stopped seeing their providers or coming into the hospital during the COVID-19 pandemic in 2020.³⁴ Since visits, procedures, and testing were all reduced by infection concerns from the pandemic, FFS revenue to clinical practices and hospitals was reduced as well. It was estimated that this could be a loss of revenue of \$15 billion to the primary care system alone.³⁵ Shifting to telehealth helped mitigate some of that patient contact and revenue loss, but healthcare organizations were significantly affected even though patients with serious illness were still ill and in need of care. Almost overnight, shifting from an FFS model became even more urgent.

Another consequence of an FFS model is that it focuses healthcare delivery on those interventions or providers that can be reimbursed. This has led palliative care programs to have proportionately more billable providers, such as physicians, APRNs, and physician assistants, versus nonbillable clinicians such as nurses, social workers, or chaplains. It also encourages those billable providers to focus on billable activities, such as medical interventions, rather than on nonbillable ones, such as providing spiritual or family support. This is why Shanice and Derrick's palliative care team is configured in the way that it is, with more physicians and APRNs and fewer of the other disciplines, which is unfortunate because it means the reality of payment often overrides the goal of interdisciplinary palliative care.

The FFS model has also made providing a home-based palliative care program too costly for a hospital since the reimbursement of only the billable providers for mostly medical services is not enough to cover the additional costs of nonbillable staff and their time and travel to peoples' homes. FFS is not just an issue for palliative care. The FFS payment structure encourages all healthcare providers to focus more on medical interventions than psychosocial ones that, while possibly needed, are not reimbursable. The result is a health system more focused on interventions than health. Of note, hospice care is not per FFS intervention or provider-based but is a daily amount per patient basis or per diem.³⁶ It is therefore required to have interdisciplinary teams because the payment for those services is bundled across the team.

VALUE-BASED PAYMENT

For these reasons, there is now a steady shift from paying providers on an FFS basis to paying them for *value* or *outcomes*.³⁷ The premise of this shift to value-based payment (VBP) is to promote and reward/pay for activities that increase quality or improve patient outcomes. At present, 30% of Medicare payments are value-based, and the federal government has the goal of eventually getting to 100% by 2025 (see Table 6.1).

MERIT-BASED INCENTIVE PAYMENT SYSTEM

A law in 2015, the *Medicare Access and CHIP Reauthorization Act* (MACRA),³⁸ established the Quality Payment Program, of which the most significant element is the Merit-Based Incentive Payment System or MIPS. MIPS is a VBP designed to tie payments to quality and cost-efficient care, drive improvement in care processes and health outcomes, increase the use of healthcare information, and reduce the cost of care. Most healthcare providers, including APRNs, likely participate in this program, which has four components.

- *Quality*: Practices pick six quality measures from a set list to report and have their performance measured on. In 2020, this category was weighted at 45%.
- *Promoting interoperability*: Practices have an incentive to share information with other clinicians or patients via information technology to improve and coordinate care. This used to be called "meaningful use." In 2020, this category was weighted at 25%.
- *Improvement activities*: This assesses how practices improve care processes, enhance patient engagement in care, and increase access to care. Practices can choose from a list of activities appropriate to them such as enhancing care coordination, patient and clinician shared decision-making, and expansion of practice access. In 2020, this category was weighted at 15%.
- *Cost*: The cost of the care provided is calculated by CMS based on the practice or provider's Medicare claims. MIPS uses cost measures to gauge the total cost of care during the year or during a hospital stay. In 2020, this category was weighted at 15%.³⁹

Table 6.1 PERCENTAGE OF US HEALTHCARE PAYMENTS TIED TO QUALITY AND VALUE

YEAR	MEDICAID	COMMERCIAL	MEDICARE ADVANTAGE	TRADITIONAL MEDICARE
2020	15%	15%	30%	30%
2022	25%	25%	50%	50%
2025	50%	50%	100%	100%

Source: Healthcare Payment Learning & Action Network.⁶⁹

The way MIPS works is that practices are scored each calendar year on their weighted performance across these four areas. Payment to the practice can be increased by up to 9% for exceptional performance across these areas. The weighting of the cost area has steadily increased since the program was launched in 2017 and is scheduled to go up to 30% in 2022, while the quality area will go down to 30% at that time.

Interestingly, palliative care can help practices improve their MIPS score and, therefore increase payment, by improving their patients' care, their care coordination, and reducing unwanted or unnecessary costs. This gives practices a financial incentive to include palliative care in addition to usual care. Derrick's contacts have resulted in an oncology practice in their area expressing interest in piloting palliative care to some of their clinic patients. While this is primarily because the evidence increasingly shows that patients with cancer tolerate their treatments better and have better outcomes by adding palliative care to usual oncology care,⁴⁰ it does not hurt that palliative care could also help this oncology practice have higher MIPS scores and, therefore, payment.

ACCOUNTABLE CARE ORGANIZATIONS

An additional VBP arrangement is accountable care organizations (ACOs). ACOs were established in the ACA⁴¹ and are an example of lesser known aspects of that law that sought to simultaneously improve quality and reduce health-care costs. ACOs are groups of doctors, hospitals, and other healthcare providers who come together voluntarily to give coordinated high-quality care to their Medicare patients.⁴¹ The goal of coordinated care is to ensure that patients get the right care at the right time while avoiding unnecessary duplication of services and preventing medical errors. When an ACO succeeds in both delivering high-quality care and spending healthcare dollars more wisely, the ACO will share in the savings it achieves for the Medicare program.⁴² The payment concept behind ACOs is that of encouraging savings versus usual care. ACOs can either get a share of those savings, which is called *one-sided risk* since there is only the chance for higher payment, or they can participate in *two-sided risk*, where their share of any savings can be higher, but they can also be penalized if there are no savings. The number of ACOs has been somewhat stable due to the challenges of delivering savings year after year.⁴³ Again, this arrangement is

also an opportunity to incorporate aspects of palliative care into the care that ACOs deliver,⁴⁴ since, as noted earlier this chapter, palliative care can improve quality while potentially reducing costs. The health system that Shanice and Derrick's hospital is a part of has an ACO for its outpatient clinics and that ACO has also been talking to their palliative care team about ways to work together.

ALTERNATE PAYMENT MODELS

A final VBP option is that of alternate payment models (APMs) or care model demonstrations. Here, the federal government develops and offers new clinical models that seek to change care delivery by changing how that care is paid for. The ACA established a new department in CMS, that of the Innovation Center (CMMI).⁴⁵ CMMI is tasked with testing new care models with the goal of delivering care at comparable or lower cost to traditional Medicare programs. Subsequently, MACRA established a new process that allowed providers to submit their own alternate payment models to a committee called the Physician-Focused Payment Model Technical Advisory Committee (PTAC).²⁷ (Many nurses are dissatisfied with the name of this committee.) Practices participating in a PTAC-supported advanced APM are released from having to participate in the more complicated MIPS program and also receive a 5% lump sum bonus each year.⁴⁶ Because serious illness affects both quality of life for patients and the cost of their care, there have been several APMs for this population since CMMI was created in 2009. Two that were approved by PTAC were models developed by the American Academy of Hospice and Palliative Medicine (AAHPM) and the Coalition to Transform Advanced Care (C-TAC).⁴⁷ However, while the committee approved these models, they were not subsequently picked up for testing by CMMI. See Table 6.2 for a review of value-based models. Other CMMI models for serious illness are described below.

Medicare Care Choices Model

The Medicare Care Choices Model (MCCM) was an attempt to revise the Medicare Hospice Benefit (MHB). As many people likely know, the MHB currently requires patients to forego curative treatment when they enroll in hospice.³⁶ This limitation made sense in the early 1980s, when the MHB was

Table 6.2 VALUE-BASED MODELS

NAME	MERIT-BASED INCENTIVE PAYMENT SYSTEM (MIPS)	ACCOUNTABLE CARE ORGANIZATIONS (ACOs)	ALTERNATE PAYMENT MODELS (APMs)
Goal	Payment for quality and cost efficient care	Coordinated high-quality care to their Medicare patients	New clinical models that change care delivery by changing how that care is paid for
Strategy	Achieved by driving improvement in care processes and health outcomes, increasing the use of healthcare information, and reducing the cost of care	Achieved by ensuring that patients get the right care at the right time, while avoiding unnecessary duplication of services and preventing medical errors	Physician-Focused Payment Model Technical Advisory Committee (PTAC) released from having to participate in the more complicated MIPS program and also receive a 5% lump sum bonus each year

established mainly for cancer patients for whom there were not many treatment options. However, it has become increasingly problematic since then as more curative and palliative treatments are available. Shanice is all too aware of the MHB's limitations from her work as a hospice NP, where many of her patients delayed selecting hospice until the last days of life as they sought curative treatment instead.⁴⁸ CMS is also aware of these issues but is restricted from changing the MHB without evidence that any such changes would be cost-neutral or cheaper.

The MCCM was a way to test concurrent hospice and curative care as a 5-year model that launched in 2016, with the goal of allowing patients who met specific criteria to receive some hospice services in addition to curative treatment.⁴⁹ Instead of being paid their usual daily rate, participating MCCM hospices were paid \$400 for per patient per month. For that fee, they were to provide symptom management and other support. The enrollment criteria limited eligible patients to having only four types of illnesses: advanced cancer, chronic obstructive pulmonary disease (COPD), congestive heart failure, or human immunodeficiency virus/acquired immunodeficiency syndrome (HIV/AIDS), and there were also limits on their Medicare insurance status.⁴⁹ The latter limits were loosened in 2017, when not enough patients were enrolled.⁵⁰ In 2020, CMS announced that they will extend the model by another year⁵⁰ and may further revise the elements of the model to make it available to more patients and to pay hospices more to participate. Shanice's former hospice was an MCCM participant, and she knew firsthand how challenging it was to provide appropriate care to those patients given the low monthly payments. Nonetheless, her hospice found that enough of their MCCM patients opted for full hospice sooner in their illness and therefore had longer lengths of stay with her hospice at the higher hospice daily rate. Derrick was also used to referring his former cancer patients to this MCCM program and is now grateful that this hospice offers MCCM as a way for their discharged palliative care patients not yet ready to choose full hospice to get some aspects of hospice care at home.

Primary Care First Model

A new CMMI model for serious illness will start in 2021. It is called the Primary Care First model and is intended to

improve care and care coordination for those patients lacking a primary care provider. Even though the focus is primary care, this model has an option for primary care practices to enroll patients with serious illness and work with palliative care programs and/or hospices to help provide more supportive care to these patients. Again, payment is limited, and participating programs will have to be efficient in their care delivery.⁵⁰ Another related model, Direct Contracting, will let ACOs taking care of large groups of patients (5,000 or more) allow those patients to have concurrent hospice and curative care as appropriate.⁵¹ Derrick and Shanice have heard the MCCM hospice in their area is interested in applying for the Serious Illness part of the new primary model since the hospice has learned how to optimize operations through its MCCM experience. And their health system's ACO is exploring the Direct Contracting option. The latter could be a way to fund the home-based palliative care program their team hopes for.

Medicare Advantage Value-Based Insurance Design Model

A final new model that has opportunities to improve access to care for serious illness is the Medicare Advantage Value-Based Insurance Design Model (MAV-BID).⁵² This is scheduled to start in 2021 and will allow MA plans to offer hospice. Currently, any patient in an MA plan who chooses hospice has to withdraw from that plan and their providers, go into traditional Medicare, and get hospice via the MHB there. This transition was not always smooth for patients, and some were reluctant to leave their previous MA network providers. Hospices, however, have been concerned that private insurance companies, who are the organizations that provide MA, may choose to do hospice on their own and not work with existing hospices in their areas. However, those MA plans that do work with existing hospices will be able to be flexible about when patients can enroll in hospice and can let them also have concurrent curative care. This could allow patients with serious illness enrolled in MA to get home-based palliative care as they transition into hospice care. Derrick and Shanice are guessing that the large MA plan in their state will likely want to participate in this VBID model and that this may give their patients who have MA an additional care option. See Table 6.3 for a comparison of CMMI models.

Table 6.3 CMS INNOVATION CENTER (CMMI) MODELS

MODEL	MEDICARE CARE CHOICES MODEL (MCCM)	PRIMARY CARE FIRST (PCF) MODEL	MEDICARE ADVANTAGE VALUE-BASED INSURANCE DESIGN MODEL (MAV-BID)
Year initiated and purpose	2016 launch for a 5-year test of concurrent hospice and curative care, now expanded through 2021	2021 launch to improve care and care coordination for those patients lacking a primary care provider.	2021 launch to allow MA plans to offer hospice
Goal	Allowing patients who met specific criteria to receive some hospice services in addition to curative treatment ⁴⁹	An option for primary care practices to enroll patients with serious illness and work with palliative care programs and/or hospices to help provide more supportive care to these patients	Goal of continuity of care, smoother transition of care

Health Insurance Company Models

In a good example of the benefits of a health system with public and private components, Aetna, a national health insurer, launched the Aetna Compassionate Care Program (ACCP) in 2004, targeting members diagnosed with an advanced illness with a view to increase access to palliative care and hospice services. This program continues to this day and has reported encouraging outcomes, such as 79% of members choosing hospice versus 59% of members not in the program and having improved quality of life while saving money in less aggressive treatment at the end of life.⁵³ More large health insurance plans have explored offering similar palliative care benefits or hiring community-based palliative care providers like Aspire,⁵⁴ Optum,⁵⁵ Resolution Care,⁵⁶ and Landmark⁵⁷ to provide these benefits to their members.

STATE POLICY

So far, this chapter has focused on federal policy and payment, but there are also encouraging developments for palliative care at the state level. Perhaps the most important is a 2018 California law that required all of the state's managed Medicaid programs to offer home-based palliative care to patients with advanced illness.⁵⁸ Because this was a statewide requirement, there was suddenly the need to set up home-based palliative care programs to provide these services in all 58 counties of California. Innovative programs sprang up, some using telehealth to reach patients in the most rural parts of the state.⁵⁶ These programs are young and working hard to overcome logistical barriers, such as identifying appropriate patients, seeing them quickly and regularly, and doing so on a cost-efficient basis. But the law and the home-based palliative care infrastructure it is building are of interest, and other states are now considering similar legislation as well.⁵⁹

Other states are also using legislation to set up palliative care councils to study opportunities for serious illness care and to begin to develop the infrastructure to deliver it.⁶⁰ New York passed laws requiring hospitals and other providers to tell patients of the existence of palliative care,⁶¹ but this law did not include money to pay for implementing that requirement. Maryland passed a law in 2013, requiring all hospitals with more than 50 beds to provide basic aspects of palliative care,⁶² although it is unclear if this has really improved access to palliative care there.⁶³ Other states have various additional bills which suggest a growing local interest in palliative care.⁵⁹ Derrick was part of an effort to lobby state legislators to consider a palliative care council bill in their state. He's also participated in his state's annual "Nurses Day," where nurses visit the state capitol to advocate for legislation they support. (He also met with state legislators to educate them about the benefits of expanding CNS scope of practice.)

Finally, local health insurance companies and other payers are setting up home- or community-based palliative care programs on their own as well. These are similar to the federal models but involve local health plans working with a palliative care program to identify patients who could benefit from

these services and then help them access this care.⁶⁴ Insurance companies have the incentive to both improve the quality of their care and to reduce costs, and, once again, palliative care can help do this for people with serious illness. Derrick learned of Blue Shield of California's home-based palliative care program at a national palliative care conference⁶⁵ and is hoping that their program could explore the same with the large insurance company in their area.

CASE STUDY: PRACTICE AUTHORITY (CONCLUSION)

After a smooth transition to the palliative care team, Derrick was able to help Shanice develop a better understanding of the importance of health policy to the care they deliver and that their patients and their families need. Both have seen how clinicians, APRNs in particular, need to be involved with policy developments since many of the care and payment models assume APRN participation. In the process, Derrick has started to become a policy expert in his own right and is becoming recognized for that expertise in nursing. Both he and Shanice have learned the truth to the policy saying: Be at the table or on the menu.⁶⁶ But, most important, they have learned how to use policy to improve the access and quality of the care that their patients and their families get—which has made them even more effective palliative APRNs.

SUMMARY

This chapter has discussed how health policy and payment policy affect the care of those with serious illness, particularly in regard to access to palliative care. It has used case studies of two APRNs, an NP and a CNS, to show the implications of policy on APRN practice. Palliative care has been shown to meet the triple aim of health reform by improving the quality of care and the health of the serious illness population and showing how unnecessary and unwanted treatments, and their resulting costs, can be reduced. Palliative care's contribution to value-based payment has also been shared. The chapter has reviewed some key legislative and regulatory developments that are encouraging for those living with serious illness and their access to palliative care services. Several encouraging alternate payment models and demonstrations will launch in the next few years that could further improve access and care for those with serious illness. Finally, the case study examples of the two APRNs show how palliative APRNs can become involved with policy and contribute to this important area.

THE PALLIATIVE APRN IN RESEARCH AND EVIDENCE-BASED PRACTICE

Janice Linton and Joan G. Carpenter

KEY POINTS

- Research is a systematic investigation that contributes to generalizable knowledge.
- Advanced practice registered nurses (APRNs) evaluate and apply research evidence in quality improvement projects and evidence-based practice.
- Evidence-based practice embodies the “quadruple aim” of improved patient outcomes, with high-quality care, at better cost, delivered by empowered clinicians.

CASE STUDY: FRAMING A RESEARCH QUESTION

A palliative advanced practice registered nurse (APRN) in the post-acute nursing home care setting noticed that many of his patients experience high levels of anxiety and insomnia after admission. Their medical diagnoses and comorbidities varied, but one commonality is that all had cognitive impairment and had been recently discharged from a hospital setting. He knew that changes in care setting can exacerbate confusion, but he also recognized that a change in care setting may disrupt the therapeutic interventions that were started and stabilized in the hospital. While he has managed their anxiety and insomnia with medications and improved their comfort, he began to consider how he might research this clinical problem and develop non-drug therapies to manage it.

INTRODUCTION

The advanced practice registered nurse (APRN) in research is uniquely situated to generate new evidence that is meaningful to advance hospice and palliative care science.¹ Through their holistic approach to patients with serious illness and care partners, palliative APRNs evaluate and apply research evidence in quality improvement (QI) projects and evidence-based practice (EBP).² However, some APRNs may be unsure how to integrate these activities into their busy clinical practice. Furthermore, APRNs may have had limited exposure to research and QI in their education and training. The purpose of this chapter is to

explore and expand the role of the APRN in research, QI, and EBP activities with a focus on hospice and palliative care.

DEFINING RESEARCH

“RESEARCH” AND “NOT RESEARCH”

According to the Code of Federal Regulations that govern the conduct of research, 45 CFR 46.102,³ research is “a systematic investigation including research development, testing and evaluation, designed to develop or contribute to generalizable knowledge.” Therefore, a project is research if it uses a commonly accepted scientific method and its results will be applied to the wider population that the study sample represents. In contrast, a project that includes an arbitrary collection of information without wide generalizability is not considered research.

The interpretation of the term “systematic investigation” depends on the scientific method—that is, the organized approach to gathering information. It is possible for research to be systematic without reflecting the process of the traditional scientific method (e.g., hypothesis testing using controlled experiments). For example, a palliative APRN may conduct interviews and observe the actions of nurses in an inpatient hospice unit caring for individuals with dyspnea. In this example, there may not be a hypothesis prior to data collection about how the nurses will respond to and treat dyspnea; however, data collection is purposeful in the selection of participants, decisions about actions to record, and interview questions to ask (e.g., data collection). To help clarify this, the Office of Human Research Protections (commonly referred to as OHRP) offers guidance of the systematic process of research as, “observations are obtained under clearly specified, and, where possible, controlled conditions that can be measured and evaluated.”⁴

SYSTEMATIC INQUIRY

Systematic investigation involves the collection and use of data. To conduct an investigation, the palliative APRN develops a study plan. This includes several steps that begin with a statement of the problem and its significance and

Figure 7.1 Framework for a Study Plan

end with a dissemination strategy. In between, the palliative APRN considers several key elements: a conceptual framework that organizes the research variables, the research question to be answered by the study, and, if needed, a list of hypotheses to be tested. An essential element is a depiction of the research approach—a description of the potential participants, the setting where the study will take place, and the process of data collection and analysis. It is important also to remember that beyond just reporting research results to the study team, the APRN should create a plan to widely disseminate systematic inquiry. This may involve presentations at peer-reviewed, professional conferences and local opportunities to present the research within the community or the organization where it was conducted, as well as articles in journals. Including the study site in the dissemination plan is recommended because study sites often state that they don't hear back from the team that conducted research in their settings. The framework in Box 7.1 presents a structured way of thinking through a study plan.

DATA AS EVIDENCE

Data are plain facts. When data are collected, processed, organized, structured, or presented in a given context to be useful, they are called *evidence*. Pieces of evidence can be used in an analysis of a problem, such as the diagnosis and treatment of a health condition. Research data can be quantitative or qualitative information that is collected, observed, or created for purposes of analysis to produce original research results. Table 7.1 provides common data definitions and related phrases.

It's important to remember that, more often than not, the plural form of data should be used. For example, "*these data* support previous findings" and "*the data* challenge current practice." Research data are generated for different purposes and through different processes and may be grouped into different categories. Each category of research may require a different type of data management plan. Two commonly accepted approaches to conducting research and collecting data are through qualitative and quantitative research methods.

QUALITATIVE RESEARCH

Qualitative data are narrative or subjective and often describe attitudes, beliefs, and feelings. They are not arrived at by statistical or other quantitative techniques. Rather, the goal is to understand behavior in a natural setting and the perspective of research participants within the context of their everyday life. Qualitative research is inductive, rather than deductive. Common methods palliative APRNs may use for qualitative inquiry include interviewing, ethnography, participant observation, and focus groups. APRNs may conduct primary data collection or analyze previously collected data (e.g., secondary data analysis).

An example of qualitative research is the study by Lim et al.⁵ They provide several examples of ways to apply qualitative inquiry in a previously conducted clinical trial testing a palliative care intervention. First, the team analyzed clinician documentation in medical records to describe the different components of a palliative care intervention. Second, they conducted focus groups and interviews to explore clinicians' perspectives on the results from the first study and validate their findings. Last, they performed an analysis of patient-clinician palliative care intervention audio recordings to endorse the findings from the first two studies. Applying qualitative inquiry in this way, the investigators were able to provide a deeper understanding of different components of the palliative care intervention.

Because of the subjective nature of qualitative research, it is important for investigators to maintain objectivity, avoid bias, and ensure trustworthiness when conducting qualitative inquiry. Credibility, dependability, and transferability are three concepts that strengthen trustworthiness. To achieve credibility, a researcher and their team members keep active documentation about the process. They write field notes describing events during data collection, keep a study diary that includes reflections during data collection and analysis, and conduct regular debriefing sessions. Debriefing and reflexive dialogue through discussion of beliefs, values, and assumptions help to prevent imposing preexisting views on data and diminish bias.⁶ An audit trail that contains detailed analytic memos made during data analysis contributes to dependability. In addition, when two or more data sources are employed, the investigator can use triangulation to develop a comprehensive understanding of the data and ensure dependability.⁷ Transferability, or how results from qualitative inquiry can be applied to other contexts, can be strengthened with the use of an audit trail, field notes, and memos. Researchers often refer to "thick description" as a way for others to determine to what extent the study findings transfer to other people and settings, or another context.⁸

QUANTITATIVE RESEARCH

The main purpose of quantitative research is to use numerical data to describe a situation or event, explain a relationship, or determine causality between independent (intervention) and dependent (outcome) variables.⁹ Quantitative data are

Table 7.1 DATA DEFINITIONS AND RELATED PHRASES

Categorical data	Categorical data are qualitative and suited to classification into categories. Further divisible into nominal (names), ordinal (levels of quality, development), and dichotomized (mutually exclusive).
Continuous data	Data that have an infinite number of possible values.
Database	An organized collection of data. A medical database is all the information that exists in the practice at any time.
Data adjustment	For useful results, data often need to be modified before analysis (e.g., for age, sex, or difficulty or number of attempts).
Data aggregation	A collection of protected health information used to conduct data analysis relating to the healthcare operations of the entity.
Data analysis	Submission of data to statistical analysis; includes sorting into categories and determining relationships between variables.
Data capture	A mechanism for collecting specified segments or categories of data from a stream of automatically recorded data, some of which may be irrelevant for the specific purpose.
Data processing	The collection of data, processing of the data to obtain usable information, and communication of this usable information.
Observational data	Data captured in real time, usually irreplaceable (e.g., sensor data, survey data, sample data, neurological images).
Ordinal data	A type of data containing limited categories with a ranking from the lowest to the highest (e.g., none, mild, moderate, severe). Subjects placed in order from high to low. For instance, an employer might rank applicants for a job on their professional experience, giving a rank of 1 to the subject who has the least experience, 2 to the next highest, and so on. This rank does not tell us by how much subjects differ.
Pre-existing data	Data that were in existence before the commencement of a study. Of limited value unless they are exactly the data required, they have been collected adequately, and a group of pre-existing controls with their corresponding data can be identified.
Prevalence data	Disease occurrences are recorded against the size of the population at risk at the time.
Ratio-level data	A higher level of data than the interval level because the ratio has an absolute zero point that we know how to measure. Thus, weight is an example of the ratio scale because it has an absolute zero that we can measure.
Raw data	Data as they are collected, before any calculation, ordering, etc., has been done.

Adapted from The Free Dictionary website (<http://medicaldictionary.thefreedictionary.com/data>).

measurable; data are collected, analyzed, and expressed in statistical form with numbers using descriptive and inferential statistics. Descriptive statistics can be used to answer questions that explore situations. For example, a palliative APRN may ask, “What is the length of stay in the hospital for patients after a palliative care consultation?” Inferential statistics elucidate the relationships among study variables and are often more complex than descriptive studies: “Are patients who receive a palliative care consultation more or less likely to be discharged home from the hospital on hospice care?” Studies that aim to predict and control or manipulate variables in experimental or quasi-experimental study designs rely on inferential statistics.

Well-conducted quantitative research studies depend on the extent to which an APRN enhances the quality of a study. Measurement of validity and reliability are important concepts to support rigor in quantitative studies.¹⁰ Internal validity means that a test or instrument used in a study is precise in measuring what it is supposed to. External validity is also

known as *generalizability*—the likelihood that findings will apply to a larger population than the study sample. Reliability implies consistency; that is, that the research methods produce the same results on the same object of measurement in the same setting over a number of repeated observations. To ensure validity and reliability, the palliative APRN should make sure that the research design is appropriate for the question to be answered and that the research is conducted carefully by a highly qualified team.

MIXED METHODS

Using both quantitative and qualitative data, mixed-method research integrates them and draws interpretations based on both sets of data to understand a research question. Combining the data, the researcher uses the strength of each approach in one method to better understand a phenomenon that quantitative or qualitative data may not explain individually. The key ingredient in this method is the *integration* of the two data

sources, not just the gathering of quantitative and qualitative data. According to Creswell,¹¹ three mixed-method designs include convergent, explanatory sequential, and exploratory sequential. *Convergent designs* collect both quantitative and qualitative data at the same time; researchers analyze the data together. In an *explanatory sequential design*, investigators use quantitative methods and then qualitative methods to explain the quantitative results. In an *exploratory sequential design*, qualitative methods are used to explore a problem. The results are then used to build a quantitative phase of the project.

what was previously known. In QI, APRNs may see observable results over time with direct benefit to those people directly involved. QI approaches may include qualitative, quantitative, or mixed methods. Furthermore, a project may be both QI and research. Palliative APRNs need to make sure they have the appropriate level of regulatory and organizational oversight for a project. Institutional Review Boards (IRBs) review and monitor human subject research and provide insight on whether a project qualifies as research or QI. Table 7.2 lists organizational research resources for palliative APRNs, and many of these resources also can be used to inform QI projects.

QUALITY IMPROVEMENT

QI is intended to improve a known gap in performance (e.g., standard) at a specific clinical site for an immediate effect to those involved. The purpose of QI is to apply what is already known (e.g., evidence) in local practice; its intent is to improve care in a specific setting. It is distinct from research: research methods are designed to add new, generalizable knowledge to

CASE STUDY: FRAMING A RESEARCH QUESTION (CONTINUED)

The palliative APRN met with one of his colleagues to discuss the anxiety and insomnia he has observed in his post-acute care patients. His colleague introduced him to a PhD-prepared nurse investigator with a funded research program studying persons

ORGANIZATION	DESCRIPTION	WEBSITE	UNIQUE ASPECTS
Hospice and Palliative Nurses Association (HPNA)	HPNA is the national professional organization that represents the specialty of palliative nursing. Research is one of five pillars of excellence.	https://advancingexpertcare.org/HPNA/Default.aspx	Opportunities for grant funding through the foundation and networking through the research special interest group Supports training and development for early-career APRN investigators through the research scholars program and the emerging research scholars special interest group Research agenda offers foci for increasing practice evidence Research advisory council
American Academy of Nurse Practitioners (AANP) Network for Research	The AANP Network for Research (AANPNR) is an online community for AANP members interested in research. It is a web-based platform to share resources and ideas with other NPs as well as a monthly newsletter with information on funding opportunities, upcoming conferences, research updates.	https://www.aanp.org/about/research-opportunities/aanp-network-for-research-aanpnr	Offers a variety of methods to collect high-quality data through surveys Researchers may also submit a set of tailored questions through AANP's annual surveys Unique access to the NP workforce
National Institute of Nursing Research (NINR) of the National Institutes of Health (NIH)	NINR supports and conducts clinical and basic research and research training on health and illness that develops the scientific basis for clinical practice.	https://www.ninr.nih.gov/ https://www.ninr.nih.gov/researchandfunding/desp/oepr	The lead NIH institute on end-of-life and palliative care research and training.
Palliative Care Research Cooperative	The PCRC is an interdisciplinary research community committed to advancing rigorous palliative care science and improving care for people with serious illness.	https://palliativecareresearch.org	Develops efficient palliative care research capacity nationally Infrastructure Supports the conduct, analysis, and dissemination of high-quality research in palliative care Trains and mentors new, existing, and future clinician-scientists committed to advancing palliative care research

living with mild cognitive impairment and dementia and their family care partners. They quickly reviewed and discussed the existing literature that describes this problem and realized there was very little evidence to guide practice. At that point, they wanted to design a project but could not decide if it should be research or QI.

- What do you think are the best next steps?
- What method do you think would help them come to a better understanding of his clinical phenomenon?
- What are the strengths and benefits of each of the approaches just described?
- What challenges might they face?

APPLYING RESEARCH EVIDENCE

Evidence comes from research, quality improvement projects, consensus statements, guidelines, expert opinions, practice and experience, and patient values. Delivering evidence-based care to improve patient outcomes and clinical practice is the role of palliative APRNs. APRNs may recall that, for decades, the protocol to maintain the patency of intravenous catheters was flushing every 8 hours with a heparin solution. Flushing intravenous catheters with heparin presented risks such as heparin-induced thrombocytopenia.¹² Research later supported that normal saline is effective in reducing catheter occlusion.¹³ Normal saline solution flush is now a part of the current practice to maintain the patency of intravenous access. Protocols and practice are no longer driven by “the way we have always done things” but by high-quality, EBP.

EVIDENCE-BASED PRACTICE

EBP is a structured problem-solving approach for health-related issues using the triad of best research (external evidence), clinical expertise (internal evidence), and patient preferences and values to support clinical decision-making for best outcomes (Figure 7.2).¹⁴ EBP embodies the Quadruple Aim¹⁵ of improved patient outcomes, with high-quality care, at better cost, delivered by empowered clinicians. Individuals are living longer, but many endure chronic and life-threatening illnesses. When hospitalized, these individuals facing life-threatening illnesses require interdisciplinary collaboration between intensivists, oncologists, and palliative care teams. Palliative APRNs engage in goals-of-care conversations with patients and families and use best evidence to support patient preferences and values. Palliative APRNs, empowered to engage in EBP, follow a seven-step systematic approach beginning with a deep sense of inquiry.

CASE STUDY: EVIDENCE-BASED PRACTICE

Mr. B, was a 75-year-old man who presented to the hospital for respiratory distress secondary to congestive heart failure exacerbation. He was in respiratory failure requiring ventilator support. His hospital course included recurrent pulmonary effusions,

Figure 7.2 Evidence-based practice elements.

despite ongoing diuretic therapy, and therapeutic thoracentesis. Lab results were significant for acute renal failure and hypoalbuminemia. Mr. B was extubated once during the hospitalization, but required reintubation in less than 24 hours. Documentation from specialists reflects Stage IV heart failure and cardio-renal syndrome requiring inotropic support. Mr. B was alert and engaged in his care, but when ventilator rates decreased, he became anxious and tachypneic.

A palliative APRN was consulted for a goals-of-care consultation. During the initial visit with Mr. and Mrs. B, the APRN discussed symptoms needs, illness understanding, treatment and treatment options. Mr. B's goals were control of his breathlessness and anxiety especially with ventilator changes. He knew his condition was serious but was hopeful to be breathing on his own in a couple of days. He was not interested in dialysis or ventricular assist devices. The APRN supported hope for this but expressed concern about his end-stage heart condition and failing kidneys. Mr. B agreed to a time-limited trial of low-dose extended-release morphine administered as disintegrating capsule pellets for shortness of breath and an anxiolytic timed prior to ventilator weaning. During the follow-up encounter, they discussed additional preferences for care and values. Due to increasing fatigue, the ICU team considered a tracheostomy and feeding tube.

A family meeting was held with Mr. B, Mrs. B, and the palliative care and ICU teams. The result was acknowledgment of the patient's terminal heart condition. Goals of care shifted to optimizing comfort and quality and a do-not-resuscitate code status. There was discussion of ventilator discontinuation because Mr. B stated that he did not want a prolonged withdrawal, in which the protocol was decreasing the delivered breaths from the ventilator by two every 15–30 minutes. However, the process was not evidence-based.

EVIDENCE-BASED PRACTICE

More than a decade ago, the National Academy of Medicine (NAM) set forth a goal that, by 2020, the best evidence will

drive and support 90% of clinical decision-making. According to the NAM's vision, patients will receive current, timely, accurate, and appropriate care with clinical decision-making grounded in EBP.¹⁶ Palliative APRNs must be knowledgeable about the seven steps¹⁴ of EBP and apply this stepwise approach to meet the goal of improved patient outcome, improved clinical practice, and improve organizational outcomes.

SEVEN STEPS OF EBP

1. Cultivate a spirit of inquiry with the EBP culture and environment.
2. Ask the burning clinical question in a population, intervention, comparison, outcome, time (PICOT) format.
3. Search for and collect the most relevant best evidence.
4. Critically appraise the evidence (i.e., rapid, critical appraisal, evaluation, synthesis, and recommendations).
5. Integrate the best evidence with one's clinical expertise and patient preferences and values in making a practice decision change.
6. Evaluate outcomes of the practice decision or change based on evidence.
7. Disseminate the outcomes of the EBP decision or change.¹⁴

As leaders, innovators, and healthcare systems thinkers, palliative APRNs must consistently question approaches to clinical practice and organizational norms. Organizational culture and environment must embrace a spirit of inquiry. The Hospice and Palliative Nurses Association (HPNA) *Position Statement on Evidence-Based Practice* recommends that healthcare employers of hospice and palliative nurses have the infrastructure to support EBP.¹⁷ Is the clinical practice of terminal weaning for a Stage IV heart failure patient, whose preference and values are to de-escalate nonbeneficial interventions such as mechanical support, current, timely, and appropriate?

Clinical questions rooted in the spirit of inquiry are formulated as a PICO (population, intervention, comparison, outcome) or PICOT (population, intervention, comparison, outcome, time) question. For the patient in the preceding case study, a well-formulated PICOT would be stated as follows:

In patients who are terminally ill and on a ventilator, whose preference is comfort-focused care (population), how does a compassionate extubation protocol (intervention) compared to terminal weaning protocol (comparison) impact the time of death during a 12-hour period (time)?

Not all clinical problems are intervention-focused, and the (I) can be driven by an issue of interest or a meaning type question. A meaning type clinical question would be stated

How do families (P) with terminally ill loved ones undergoing terminal weaning (I) perceive the suffering of the patient (O) during the 2-hour weaning process (T)?

Clinical questions in a PICOT format drive the literature search and allow the APRN to move through Step Two of collecting the most relevant and best evidence.¹⁴ The best evidence to drive intervention= or treatment-based decisions is systematic reviews or meta-analysis of randomized controlled trials (RCTs). Palliative APRNs have formalized education and experience with EBP and literature search methods.¹⁸ Finding information from reliable sources is pivotal to identifying the best evidence. Professional online databases or search engines such as the Cumulative Index to Nursing and Allied Health Literature (CINAHL), Cochrane Database of Systematic Reviews, MEDLINE, Ovid, and PubMed are appropriate sites that publish peer-reviewed articles. Clinical practice guidelines (CPGs) are robust, systematic evidence-based recommendations that help APRNs in clinical decision-making to optimize the care of a specific population.¹⁹ The Agency for Healthcare Research and Quality is a reliable repository for CPGs. Government sites such as the Center for Disease Control and Prevention and the US Department of Health and Human Services are other sources for peer-reviewed clinical information.

CRITICAL APPRAISAL OF THE EVIDENCE

Critical appraisal of the evidence allows the APRN to evaluate research studies collected from literature searches and examine key factors such as validity, reliability, and applicability.

- *Are the results of the study valid (Validity)?* Did the researcher use the best methods possible to measure key concepts in the study adequately? Is a questionnaire on nurses' perception of patient suffering during discontinuation of life-sustaining therapy truly measuring perception of patient suffering or measuring the nurse's discomfort with the end-of-life practices?
- *What are the results (Reliability)?* Did the researcher get a consistent answer when using the same instrument of measure more than once? When assessing symptom burden in a group of oncology patients receiving palliative care compared to patients receiving usual oncology care, does the Edmonton Symptom Assessment System (ESAS) tool measure patient-reported pain, fatigue, nausea, depression, anxiety, drowsiness, shortness of breath, appetite, well-being, and sleep when used?²⁰
- *Will the results help me deliver care to my patient (Applicability)?* Are the participants in the study similar to the patients seen in the APRN's practice? If the intervention in the study aligns with patient preferences, will the benefits outweigh the risks and be feasible to apply

in the practice setting? If a systemic review provided evidence to support compassionate extubation in ICU patients with brainstem infarctions, would a similar discontinuation of life support method apply to patients with similar neurologic events receiving palliative care services?

INTEGRATING THE EVIDENCE WITH CLINICAL EXPERTISE AND PATIENT PREFERENCES

Combining (a) critical appraisal and synthesis of the best evidence, (b) APRN clinical expertise, and (c) patient preferences is the next step in the EBP process. Clinical expertise is a culmination of the palliative APRN's education, training, clinical reasoning, clinical skills, and experience caring for a particular population. The centrality of patient preferences is pivotal to clinical decision-making. The assessment of a patient living with lung cancer revealed recurrent hospital admissions for anxiety and shortness of breath. During the patient encounter, the palliative APRN discussed multiple EBP, clinical experience, and benefits of extended-release morphine for dyspnea. Although compelling evidence supported morphine for symptom relief, the patient had reservations about the medication, and a shared decision was made to support the patient's preference and explore other treatment options.

EVALUATING THE OUTCOME OF PRACTICE CHANGE

Did the EBP change affect patient outcomes and yield similar results, as outlined in the literature? The palliative APRN must determine the clinical significance of the practice change on a micro and a macro level. Breathlessness, a common symptom in patients living with lung cancer, is challenging to manage in the outpatient setting. The usual care for breathlessness is pharmacologic administration of opioids and benzodiazepines. Evidence from a nurse-driven home-based program for managing breathlessness in cancer patients revealed that an educational program involving in-home pulmonary rehabilitation improved the level of breathlessness experience the participants.²¹ When evaluating outcomes of practice change, the palliative APRN implementing the in-home pulmonary rehabilitation for persons living with lung cancer anticipates the outcome of symptom control of dyspnea—the impact of EBP on a micro level. With effective practice change based on evidence, patients living with lung cancer can be managed through in-home pulmonary rehabilitation, ultimately reducing emergency department utilization and hospital readmissions—the impact of EBP on a macro level.

DISSEMINATING THE OUTCOMES OF THE EBP CHANGE

The *Essentials of a Master's Prepared Nurse* set forth by the American Association of Colleges of Nursing includes

Translating and Integrating Scholarship into Practice. This essential recognizes that the APRN functions as an agent of change and disseminates best practice results.²² The final step in the EBP process is disseminating the outcomes. Palliative APRNs are leaders who improve healthcare processes and outcomes. Too often, significant EBP change is not shared with other healthcare providers, thus limiting the benefits for other patients. Dissemination of the outcomes can be at the clinical practice site through collegial “lunch and learns.” Palliative APRNs must broaden their sphere beyond individual patient care and influence practice change by sharing clinical outcomes at local, state, and national conferences and through peer-reviewed publications. There is rigor to disseminating the outcomes, but there is a tremendous value for the patient, provider, and healthcare system. Palliative APRNs garner and disseminate best evidence through local and national palliative care organizations such as the HPNA, the Center to Advance Palliative Care (CAPC), and the End of Life Nursing Education Consortium (ELNEC) but also through other appropriate professional nursing organizations such as the American Association of Critical Care Nurses, the Oncology Nursing Society, and the like. EBP to support high-quality palliative care is also disseminated in palliative peer-reviewed journals such as the *Journal of Hospice and Palliative Nursing*, the *Journal of Pain and Symptom Management*, and the *Journal of Palliative Medicine*.

EVIDENCE-BASED COMPETENCIES FOR THE PALLIATIVE APRN

EBP is a widely used concept among healthcare providers, but APRNs report lacking the skills and competencies to effectively implement EBP.²³ The American Nurses Association (ANA) defines competency as “an expected level of performance that integrates knowledge, skills, abilities, and judgment, based on established scientific knowledge and expectations for nursing practice.”²⁴ Inadequate preparation at the academic level, the traditional pattern of healthcare delivery (e.g., “we have always done it this way”), and lack of organizational support impact APRNs' ability to consistently implement EBP.²³ Melnyk et al. developed an EBP competencies model with 24 elements for RNs and APRNs (Table 7.3).

While APRNs do not report high levels of competency in the any of the EBP competencies elements, they feel the most competent in questioning clinical practice to improve quality of care but least competent in leading transdisciplinary teams.²³ Studies support that structured education through academic–practice partnerships and principles of EBP readiness have been effective in enhancing knowledge and confidence in evidenced-based practice design and implementation.^{25,26} Advancing the NAM's vision of clinical decision-making grounded in EBP¹⁶ requires organizational culture and infrastructure for practice change sustainability of best processes. Organizations must foster and support APRNs in clinical inquiry, have clear EBP implementation processes, and develop competent EBP mentors to maintain the culture of best practice.

Table 7.3 EBP COMPETENCIES

Evidence-based practice competencies	
EBP competencies for registered nurses (RNs)	EBP competencies for APRNs All competencies for professional registered nurses with the following additional competencies
1. Questions clinical practices for the purpose of improving the quality of care	14. Systematically conducts an exhaustive search for external evidence ^a to answer clinical questions
2. Describes clinical problems using internal evidence	15. Critically appraises relevant pre-appraised evidence (i.e., clinical guidelines, summaries, synopses, syntheses of relevant external evidence) and primary studies, including evaluation and synthesis
3. Participates in the formulation of clinical questions using PICOT format.	16. Integrates a body of external evidence from nursing and related fields with internal evidence ^b in making decisions about patient care
4. Searches for external evidence to answer focused clinical questions	17. Leads transdisciplinary teams in applying synthesized evidence to initiate clinical decisions and practice changes to improve the health of individuals, groups, and populations
5. Participates in critical appraisal of preappraised evidence	18. Generates internal evidence through outcomes management and EBP implementation projects for the purpose of integrating best practices
6. Participates in the critical appraisal of published research studies to determine their strength and applicability to clinical practice	19. Measures processes and outcomes of evidence-based clinical decisions
7. Participates in the evaluation and synthesis of a body of evidence gathered to determine its strength and applicability to clinical practice	20. Formulates evidence-based policies and procedures
8. Collects practice data (e.g., individual patient data, quality improvement data) systematically as internal evidence for clinical decision-making in the care of individuals, groups, and populations.	21. Participates in the generation of external evidence with other healthcare professionals
9. Integrates evidence gathered from external and internal sources in order to plan evidence-based practice changes	22. Mentors others in evidence-based decision-making and the EBP process
10. Implements practice changes based on evidence and clinical expertise and patient preferences to improve care processes and patient outcomes	23. Implements strategies to sustain an EBP culture
11. Evaluates outcomes of evidence-based decisions and practice changes for individuals, groups, and populations to determine best practices	24. Communicates best evidence to individuals, groups, colleagues, and policymakers
12. Disseminates best practices supported by evidence to improve quality of care and patient outcomes	
13. Participates in strategies to sustain an evidence-based practice culture	

^a External evidence is evidence generated outside a clinical setting such as from systematic reviews, randomized controlled trials and practice guidelines.

^b Internal evidence is evidence generated internally within a clinical setting, such as patient assessment data, outcomes management, and quality improvement data.

From Melnyk et al.²³

IMPLEMENTING EBP

How we evolve from the “way we have always done things” to implementing EBP requires structural change. Leading organizations such as the National Academy of Medicine, the Agency for Healthcare Research and Quality, the American Association of Colleges of Nursing, and the US Preventative Services Task Force mandate EBP implementation, but

barriers prohibit adoption among all healthcare providers.²⁷ The path from clinical inquiry to practice change for best patient outcomes can be met with layers of administrative decisions, financial constraints, stakeholder influences, decision-making biases, time and training constraints, and attitude about EBP. Several models have been developed to implement EBP. There are differences in the application of

the models but the commonalities include practice problem, change agents, high-quality research, implementation and evaluation of practice change, and infrastructure to sustain practice change. The following is a list of models to guide EBP implementation:

- The Iowa Model of Evidence-based Practice to promote quality care²⁸
- John Hopkins Nursing Evidence-Based Practice Model²⁹
- Stetler Model of Evidence-Based Practice³⁰
- Model for Evidence-Based Practice Change³¹
- Advancing Research and Clinical Practice Through Close Collaboration (ARCC)³²
- Promoting Action on Research Implementation in Health Services (PARIHS) Framework³³
- The Clinical Scholar Model³⁴
- The Stevens Star Model of Knowledge Translation¹⁴

Palliative APRNs are experts in comprehensive management for patients living with serious illnesses. There is a deliberate focus on patient preferences during palliative encounters. The palliative APRN serves as an EBP mentor for critical care teams involved in goal-directed therapy for patients wanting to defer nonbeneficial intervention and optimize quality of life. EBP mentors are knowledgeable catalyst for EBP change.³⁵ As EBP mentors, palliative APRNs are aware that each EBP model has emphasis, strategies, and phases for implementation.

The Iowa Model of Evidence-Based Practice to promote quality care guides clinicians in decision-making about patient-related or organizational-focused issues.²⁸ The model outlines a multiphase strategic change process with feedback loops for ongoing improvement in quality of care. The initial phase or trigger begins with the clinicians' awareness of a problem-focused or knowledge-focused opportunity. Organizational problem-focused triggers include clinical issues, benchmark data comparison, and process improvement data. Knowledge-focused triggers include publication of research and change in protocols based on guidelines.²⁸ Utilizing the Iowa Model of Evidence-Based Practice to promote quality care as a framework (Figure 7.3) the palliative APRN can implement EBP to support the clinical inquiry "In terminally ill mechanically ventilated patients whose preference is comfort-focused care (population), how does a compassionate extubation protocol (intervention) compared to terminal wean protocol (comparison) impact the time of death during a 12-hour period (time)?" The stepwise approach described next provides an example of the Iowa EBP Model.²⁸

Step 1: Identifying triggering issues and opportunities. Terminal weaning versus compassionate extubation from nonbeneficial ventilator support is an element of care where palliative APRNs and the critical care teams collaborate. *Terminal weaning* is defined as the incremental decrease in ventilator assistance, such as oxygen supply, respiratory rate,

positive expiratory pressure support, or tidal volume, before removal of the endotracheal tube. *Compassionate extubation* is defined as removal of invasive mechanical ventilatory support, specifically the endotracheal tube, with no decrease in ventilator support. Palliative APRNs support patients, families, and bedside nurses through difficult medical decisions. Critical care nurses often express moral distress when caring for patients who endure a prolonged ventilator discontinuation weaning protocol but whose treatment preferences include comfort-focused care and removal from machines. These nurses see the duration for terminal weaning according to protocol as prolonging suffering for patients and families. Others express moral issues of hastening of the dying process during a compassionate extubation process. The example of the clinical question proposed presents a problem-focused trigger.

Step 2: Identifying the purpose of the clinical question and the priority for the organization. The palliative APRNs collaborates with the direct care nurses to determine if the current organization's withdrawal protocol aligns with current practice and patient preferences.²⁸ The organization values high-quality patient- and family-centered care. Honoring patient's treatment preferences is a key performance indicator and metric for the critical care physicians and team.

Step 3: Forming a team of stakeholders, conducting a literature search, and critically appraising the evidence for reliability, validity and application in current practice. The ARREVE observational study on terminal weaning or immediate extubation for withdrawal of support in critically ill patients reported no difference in ICU time of death after the initiation of terminal weaning and compassionate extubation.³⁶ Emerging themes from a qualitative study on the ICU team's perception of compassionate extubation and terminal weaning indicated that compassionate extubation eliminated medicalization of the dying process, reduced ambiguity of the dying process, and provided greater patient comfort. Themes for provider's preferences for terminal weaning included time for the patient to adapt to symptom management medications, better patient comfort, and optimizing any possibility of survival.³⁷ APRNs are scholarly experts in assessing the quality of both studies.

Leading the EBP initiative, the palliative APRN along with the palliative care team collaborates with the critical care physician champion, critical care medical residents, clinical nurse specialists, direct care registered nurses, nurse managers, pharmacists, respiratory therapists, and a patient-family champion. When the team has determined that there is supportive evidence for safe practice change, adequate resources are available, and administrative buy-in is established, they proceed to define, design, and pilot the practice change.

Step 4: Defining, designing, and piloting the practice change. The palliative APRN role is to increase the ICU team's awareness of terminal weaning and compassionate extubation processes. The APRN develops a compassionate extubation protocol with the ICU physician team to pilot in 10-bed unit. The team will standardize the implementation process, including material for the nurses and respiratory therapists. The team will determine and announce a pilot date

The Iowa Model Revised: Evidence-Based Practice to Promote Excellence in Health Care

Figure 7.3 The Iowa model revised: Evidence-based practice to promote excellence in health care.

and duration of the pilot. During the goals-of-care conversation with patients and families opting for comfort-focused care, the APRN will engage in a discussion of preferences for withdrawal of mechanical ventilator and, in conjunction with the critical care physician champion, identify candidates for terminal weaning and compassionate extubation. The APRN evaluates outcomes and modifies steps as needed. Post-pilot data are collected and reported to the team and practice change is adopted across all critical care units.

Step 5: Integrating and sustaining the practice change. After the reviewing the post-pilot data, the palliative APRN re-engages stakeholders along with the senior administrative team to hardwire system-level practice change. One of the EBP competencies of the APRN is implementing strategies to sustain an EBP culture.²³ A plan for sustainability of EBP

includes competency-based education, EBP mentors, steering committee researchers, and EBP champions.³⁸

Step 6: Disseminating the results. The palliative APRN disseminates the results to the critical care nursing team. The APRN will share patient, family, and staff satisfaction results with the senior leadership team at organizational reviews. On a larger scale, the APRN will present at local and nation conferences through podium or poster presentations. Finally, to expand the body of knowledge, the APRN will publish the results in palliative and critical care journals.

FUTURE WORK AND PRIORITIES

As healthcare clinicians, APRNs conduct projects that involve nursing issues and outcomes of care, including patient and family satisfaction with care. APRNs have the potential opportunity to serve as investigators of research projects and study team members, as well as translate their findings into practice. In public education and engagement, the ANA in collaboration with the HPNA published the 2017 *Call for Action: Nurses Lead and Transform Palliative Care*. The purpose of the document was to urge nurses to lead the growth of palliative care in several areas, including research. In this document, gaps in evidence and recommendations were identified. Box 7.1 lists additional organizational research, QI, and EBP priorities for palliative APRNs.

SUMMARY

Palliative APRNs in all settings are expected to be knowledgeable about research, QI, and EBP practices. Opportunities to generate knowledge and translate evidence into practice abound. Understanding the approach and type of data needed to inform these opportunities is an essential element of APRN practice. As healthcare leaders, APRNs directly impact patient outcomes. Best outcomes are driven by EBP. Palliative APRNs must be equipped with research knowledge and EBP implementation processes to guide future practitioners and advance both palliative nursing and palliative care. There are barriers to conducting research and translating the evidence from research to practice but the benefits of research and EBP have been supported for decades. A coalition of research and EBP mentors is necessary for sustainable best practice.

SECTION III

CLINICAL SETTINGS OF PALLIATIVE APRNS

THE PALLIATIVE APRN IN THE MEDICAL, SURGICAL, AND GERIATRICS PATIENT CARE UNIT

Phyllis B. Whitehead and Carolyn White

KEY POINTS

- More than 50% of all deaths occur in the acute care setting, where the focus is on active, curative treatment, not on managing symptoms and establishing realistic goals of care.
- Palliative advanced practice registered nurses (APRNs) are uniquely qualified to care for seriously ill patients by providing comprehensive, effective, compassionate, and cost-effective care that improves end-of-life care in acute care settings.
- Palliative APRNs orchestrate interdisciplinary care plans focused on alleviating suffering and promoting healing to enhance the quality of life for seriously ill patients and their loved ones.

CASE STUDY 1: EMERGENCY DEPARTMENT PALLIATIVE CARE

Paul was a 78-year-old Black American man who had been on hospice care at home for the preceding 3 weeks. His past medical history included dementia (diagnosed in 2015), hypertension, chronic kidney disease Stage 3 (glomerular filtration rate 30–59 mL/min), coronary artery disease, chronic diastolic heart failure, and squamous cell skin cancer of the right ear, right face, and right hand, untreated per his family's request. Paul's past medical history also included benign prostatic hypertrophy with urinary obstruction, chronic solar dermatitis, osteoarthritis, acute-on-chronic renal failure, and colon cancer (diagnosed in 2010). Paul's past surgical history included colectomy (2010) and exploratory abdominal laparotomy (2015). His medications included amlodipine, metoprolol, lisinopril, topical Metronidazole as needed for wound odor control, and oxycodone as needed for pain.

Paul presented to the emergency department with increased confusion and falls. His daughter, Nancy, reported Paul had been more confused and eating and drinking less for the past week. She also stated that his falls had increased. His review of systems revealed no fever, chest pain, or shortness of breath. According to Nancy, Paul had been having more difficulty swallowing his medications over the past few weeks. Nancy shared that Paul is a retired veteran.

Nancy also reported several episodes of bleeding from Paul's skin cancer lesions, which was a great concern to her. She also described how the hospice registered nurse came out to help with the wound care and medication management. She and the

hospice nurses performed local wound care several times a week, mainly to contain the drainage and bleeding. However, Nancy wished no further diagnostic studies regarding the skin cancer and stated, "I don't want to put him through any additional distress of unnecessary treatments and interventions." She wanted the admitting physician to investigate for any easily treatable causes of Paul's confusion and agitation.

Nancy had been caring for her father for the past 8 years, first at his home and then at her home. He had been living with her for the past 3 years. His wife and siblings were deceased. Nancy was married with two adult children and four adult grandchildren. She was solely responsible for Paul's care and shared that her husband had expressed frustration that she was spending all of her time with Paul. She was considering nursing home placement as she was not sure she could care for him any longer. Overall, Paul was declining, with a very poor appetite, weight loss (20 pounds over the past 8 weeks), weakness and fatigue, and increased confusion, agitation, and falls.

Based on the conversation with Nancy and the review of the diagnostics and laboratory values (creatinine 1.83 mg/dL and estimated glomerular filtration rate 29 mL/min/1.73 m²; see Table 8.2), a palliative care consult was ordered for Paul to discuss goals of care, as well as his pain and symptoms. A family meeting was scheduled, and the palliative APRN Stacey reviewed the role of palliative care in Paul's care. Stacey asked Nancy to share her understanding of Paul's condition. After listening to Nancy's understanding of Paul's condition, she explained that a stroke, cerebral bleed, and infection had all been ruled out as sources of his encephalopathy. Stacey clarified that the confusion, agitation, and decline were related to Paul's dementia and that his other underlying heart and kidney diseases were not reversible.

INTRODUCTION

Patients who are seriously ill and hospitalized represent a specialized patient population that greatly benefit from the expanded skills and knowledge of palliative APRNs.^{1,2} These patients and their loved ones have unique needs that are often unaddressed in a busy healthcare system.^{3,4} By the year 2030, almost one in five adults will be over the age of 65 years and have at least one chronic illness.^{5,6,7} The year 2030 marks an important demographic turning point in US history according to the US Census Bureau's 2017 National Population

Table 8.1 STAGES OF DEMENTIA

STAGE	IMPAIRMENT LEVEL
1	No impairment
2	Very mild decline: Unnoticeable memory lapses
3	Mild decline: Noticeable memory and concentration problems; losing items
4	Moderate decline: Forgetfulness of events; difficulty performing tasks
5	Moderate to severe decline: Gaps in memory, thinking; needs help with activities of daily living
6	Severe decline: Loss of awareness of recent experiences; remembers own name but has difficulty with others
7	Very severe decline: Total care; swallowing impaired; hospice eligible

Adapted from Ernecoff et al.⁵; Schoenherr et al.²; and Kyeremanteng et al.⁶

Projections. By 2030, all baby boomers will be older than age 65. This will expand the size of the older population so that 1 in every 5 residents will be of retirement age.¹

By 2060, the United States is projected to grow by 79 million (previously 78 million) people, from about 326 million today to 404 million. The population is projected to cross the 400-million threshold in 2058. In coming years, the rate at which the US population grows is expected to slow down. The population is projected to grow by an average of 2.3 million people per year until 2030. But that number is expected to decline to an average of 1.9 million (previously 1.8 million) per year between 2030 and 2040, and continue falling to 1.6 million (previously 1.5 million) per year from 2040 to 2060.¹

Often, patients with chronic illness have uncertain prognoses and poorly predictable disease trajectories resulting in numerous emergency department visits and hospital admissions. Hospitals have become places where patients go for “state-of-the-art” diagnostic and therapeutic interventions, procedures, complex surgeries, and powerful medications to support life at all costs. The modern acute care setting is overwhelmingly complicated and difficult to navigate for patients and their families, with countless specialists; it is often described as a “conveyor belt” approach to care.² Specialization of care may result in a sole focus on incremental improvement of a specific organ. This emphasis does not take into account “the big picture” of the patient’s overall clinical condition or the way that specific organ interactions affect the disease process.² The prevalence of hospital-based palliative care services has increased by 26% during the past decade; 67% of all hospitals and greater than 90% of hospitals with more than 300 beds currently offer palliative care services.² Additional barriers that interfere with providing effective end-of-life care in acute care settings include (1) poor communication among clinicians, patients, and caregivers; (2) a focus on life prolongation and technology; and (3) unrealistic expectations on the part of patients and their loved ones.³ To address these challenges,

inpatient specialty palliative care programs have grown dramatically over the past decade. APRNs have become an integral part of these growing programs and are well-prepared to care for complex acutely ill patients.^{2,3,4} APRNs may serve as the patient’s attending provider or as a pain or palliative consultant. Their numerous acute care roles include (1) direct clinical care, (2) expert coaching and guidance to colleagues, (3) ethical decision-making skills, (4) collaboration, (5) clinical and professional leadership, (6) research skills, (7) consultation, and (8) education.^{3,4,5}

Today, medical-surgical patients are sicker, with many comorbid conditions. One of the most challenging barriers in acute care settings is the lack of communication and coordination of patient care.³ APRNs are well-positioned to address this barrier. For example, while making rounds on their patients, APRNs can model effective communication with the patient and family, nursing staff, and medical teams. APRNs can address pain and symptom management of patients while coaching and mentoring their colleagues on the most current evidence-based standards of care. Furthermore, APRNs can identify seriously ill patients earlier in their disease trajectory who would benefit from aggressive pain and symptom management as well as goals-of-care discussions that otherwise may go unaddressed.^{2,4,6}

An illustration of this holistic approach to patient care is the unitary-caring praxis conceptual model for the palliative APRN embedded within the eight domains of the NCP Clinical Practice Guidelines (Figure 8.1).⁷ The use of a model guided by nursing theory can enhance the care of seriously ill patients while promoting spiritual and emotional healing when physical healing may not be possible. A theoretical framework resembling the unitary-caring praxis provides guidance for the APRN in caring for seriously ill patients by translating the national guidelines into a comprehensive but practical approach to palliative care.

CHRONIC KIDNEY DISEASE

END-STAGE RENAL DISEASE

With the growing elderly population, the number of patients with acute kidney injury, Stage 4 and 5 chronic kidney disease, or end-stage renal disease (ESRD) and other comorbidities is increasing.⁸ Mortality among ESRD patients is 10 to 100 times greater than in the general population when matched for age and gender. Many patients are older and have multiple comorbidities that add to their overall illness situation. The associated mortality is high even when the patients are on hemodialysis, about 20% annually. A review shows that for elderly patients starting dialysis (undifferentiated), 1-year survival is about 73% and 5-year survival is about 35%.^{9,10} The cost associated with ESRD is staggering, with hemodialysis costing \$89,000 per patient annually and amounting to \$42 billion in the United States.¹¹ Only 1% of the Medicare population has ESRD, but it accounts for up to 7% of the annual budget.¹¹

Figure 8.1 Palliative APRN unitary-caring praxis framework.

From Reed SM. A Unitary-Caring Conceptual Model for advanced practice nursing in palliative care. *Holist Nurs Pract*. 2010;24(1):23–34. Reprinted with permission from Wolters Kluwer Health, Inc.⁷

In 2000, the American Society of Nephrology and Renal Physicians Association published the first clinical practice guideline encouraging palliative care for ESRD patients. It was revised in 2010 to include information on an integrated prognostic model predicting the mortality of hemodialysis patients (available at <http://touchcalc.com/calculators/sq>).¹²

Patients with kidney disease face limited survival compared with the general population. Although mortality trends have improved, the median survival for those on maintenance dialysis is about 4–5 years. Despite this poor survival, hemodialysis continues to be offered in terms of longevity versus quality of life, especially at end of life. Patients on hemodialysis experience more hospital stays including more intensive care days, higher death risk while hospitalized, and less use of hospice as compared to those with advanced cancer or heart failure.⁸

It is clear that patients, loved ones, and hospitals need to be prepared to have end-of-life conversations, ideally before dialysis is initiated but most certainly when patients are functionally and physically declining despite dialysis. APRNs need to feel comfortable having the discussion with patients and their families regarding whether dialysis may offer a better quality and quantity of life compared to conservative management of symptoms.^{2,13–16} For example, patients older than 80 years who start dialysis experience a significant loss of functionality within the first 6 months of treatment, requiring caregiver support or placement in a nursing home.⁸ Unfortunately, randomized clinical trials evaluating the benefits of dialysis for older adults are lacking.^{8,15–17}

Paramount is the collaboration between the hospital's nephrologists and the dialysis nurses to implement the American Society of Nephrology and Renal Physicians Association's published clinical practice guidelines for palliative care counseling and symptom management. Early palliative care involvement and integration into routine ESRD management are preferred for creating trusting relationships with patients and their loved ones. Several instruments have been developed by Cohen and colleagues—the Dialysis Discontinuation Quality of Dying (DDQOD) and the Dialysis Quality of Dying Apgar (QODA)—which help distinguish between good and bad deaths for dialysis patients and may assist with end-of-life discussions.^{12,18} In 2018, the National Institute for Health and Care Excellence (NICE) published a guideline on conservative care of patients with chronic kidney disease.¹⁸ The guideline recommends starting counseling at least 1 year before any therapy may be needed. It further suggests that ESRD management be based on individual factors such as frailty, cognition, other comorbidities, and patient preference.²

Palliative care renal literature and guidelines suggest that the elements of good end-of-life care for ESRD patients include (1) advance care planning for agreed level of care and preferred place of care; (2) appropriate transition from life-sustaining to comfort care, including potential discontinuation of dialysis; (3) ongoing dialogues with patients and caregivers regarding prognosis and treatment options; and (4) aggressive symptom management throughout disease progression.^{19,20}

Physical assessment includes (1) skin turgor and color changes (i.e., gray-bronze color); (2) oliguria or anuria; (3) edema and/or ascites; (4) jugular vein distention; (5) fluid accumulation in the lungs; (6) blood pressure and orthostatic changes; (7) fluid retention resulting in weight gain; (8) hypocalcemia; (9) dry, flaky skin; (10) ammonia-smelling breath; (11) tremors/seizures; (12) easy bruising; and (13) signs of anemia.¹ Routine laboratory tests should be ordered, including blood urea nitrogen (BUN), creatinine, hemoglobin, hematocrit, calcium, phosphorus, sodium, and potassium. Other diagnostic testing may involve imaging (computed tomography [CT] or magnetic resonance imaging [MRI]), renal arteriograms, and kidney, ureters, and bladder (KUB) radiographs.^{2,11,19} The APRN should assess for common symptoms such as nausea and vomiting, anxiety, depression, constipation, diarrhea, pruritus, pain, fatigue, and anorexia. Morphine should be avoided; fentanyl, methadone, and oxycodone are preferred in the treatment of pain.^{11,19–21}

All reversible causes should be eliminated, especially in the treatment of acute renal failure. For ESRD, dialysis discussions should cover lifestyle changes, dietary restrictions, symptom management, potential complications, transplant option, and whether dialysis will continue until the patient dies or under what circumstances dialysis will be discontinued.^{19–21} Once a decision is made to stop dialysis, all nonessential medications must be stopped to avoid toxicities and to stop or at least minimize fluid volume. Patient and family education must be provided on what to expect, especially alleviating the fear of “drowning in fluids” that accompanies stopping dialysis. The patient’s diet should be liberalized so he or she can enjoy foods and beverages that have been restricted. The patient who has stopped dialysis has a prognosis usually measured in days to a few weeks. The APRN should review disposition planning options with the patient and family, including home with hospice, long-term care facility with hospice, or a residential hospice facility, and provide guidance in this decision.^{11,15,21–23}

Hole et al. suggests a model of supportive care for integrated kidney care where patients are guided from aggressive treatments to conservative and supportive interventions based upon their trajectory and prognosis.²² This model of supportive care examines how APRNs can make a distinct shift to a purely supportive approach including withdrawal of dialysis. Supportive care should be available to all patients with advanced chronic kidney disease.²²

DEMENTIA

Dementia is a common diagnosis on medical, surgical, and geriatric units. Frequently, families do not understand that dementia is a life-limiting condition.² APRNs are uniquely positioned to initiate conversations to help families understand the disease trajectory for dementia patients. The incidence of dementia is growing, and by 2050 the number is expected to rise to 135 million.²⁴ Worldwide, 50 million individuals are living with dementia, and this number is predicted to double

Table 8.2 STAGES OF CHRONIC KIDNEY DISEASE

STAGE	GLOMERULAR FILTRATION RATE (GFR)	STATUS
1	>90	Normal kidney function
2	60–89	Declining GFR with comorbidities
3	30–59	Decline, incidence of anemia, malnutrition, poor quality of life, consider palliative care consult
4	15–29	Pre-dialysis, preparation for dialysis
5	<15	Renal replacement therapy, kidney transplant, or hospice care

Adapted from Axelson et al.⁹ and Forzley et al.¹¹

over the next 20 years.²⁴ Dementia, specifically Alzheimer’s disease, is the fifth leading cause of death and accounts for 80% of the cases.²⁴ More than 5 million Americans live with dementia, with more than 1 million of those at late to end stage. This results in out of pocket expenses of \$66,000 in the last year of life and societal costs exceeding \$250 billion in 2018 and expected to double by 2030.^{3,5} Dementia is a progressive, incurable condition that causes limitations in life and should be recognized as a life-limiting condition.^{3,24,25}

Dementia can have many causes, such as Alzheimer’s disease, vascular dementia, advanced Parkinson’s or Huntington’s disease, Lewy body disease, and excessive or chronic alcohol use.^{3,24,25} Impairments in mental and physical functioning, such as memory loss, language impairment, personality changes, dysphagia, and inability to perform activities of daily living, characterize the condition.^{3,24,25} There are seven stages of dementia (Table 8.1). The APRN should be familiar with these stages in order to help clinicians and families understand the role of palliative and hospice care for patients and their loved ones.

One challenge for the acute care APRN is the difficulty of identifying dementia as a life-limiting illness and the importance of getting a palliative care consult for the patient. Evidence shows that patients with end-stage dementia are less likely to be referred to palliative care than other non-oncological end-stage disease patients (9% vs. 25%), and dementia patients are likely to be prescribed fewer palliative medications (28% vs. 51%).^{25,28} Only 27% of US nursing homes report any type of palliative or end-of-life care, despite 85% of large hospitals reporting specialty palliative care services.²⁵ Infections, hip fracture, and nutritional decline are common reasons for hospitalizations and signal worsened prognosis of a mortality risk of 20–50% within the next 6 months.^{3,25} Caregivers’ burden can be worsened when periods of stability are interrupted by acute exacerbations—in contrast to the more predictable decline

in patients with advanced cancer.³ Advance care planning and goal setting should be initiated early in the disease process, while the patient can provide guidance to loved ones. Due to the progression of dementia, it can be challenging for family and clinicians to know when to initiate palliation as a goal.^{3,28}

The use of functionality and cognition scales, such as the Minimum Data Set 2 (MDS-2) or the Functional Assessment Staging (FAST) instruments, can be helpful in quantifying the stage and identifying appropriate palliative and/or hospice patients.^{3,5} Both pain (39%) and dyspnea (46%) are common symptoms at end-of-life for many dementia patients.^{3,5,28} They should be aggressively treated on a first-line basis with an opioid, such as morphine. Patients with dementia receive less analgesia than patients who are cognitively intact. They often cannot express themselves verbally and hence receive suboptimal palliative care.²⁸ The APRN should integrate the use of behavioral pain assessment tools, such as the Pain Assessment in Advanced Dementia Scale (PAINAD).^{28,29} The American Society of Pain Management Nursing's *Position Statement on Pain Assessment in Patients Unable to Self-Report* recommends using patient self-report of pain if possible, review of known pain etiologies from the medical history, observation of pain-related behaviors, and family or proxy reports to assess for pain in the dementia patient.^{3,5,28,29} Agitation may affect up to half of end-stage dementia patients, necessitating a calm environment and the treatment of reversible causes, such as pain, dyspnea, and constipation.³ The APRN should assess for cognitive changes, including delirium. Tools such as the Mini-Mental State Examination (MMSE), the Short Portable Mental Status Questionnaire (SPMSQ), the Delirium Observation Screening Scale, and the Confusion Assessment Method (CAM) can be used to screen for cognitive changes and delirium to enhance symptom management.^{3,5}

Infections, such as pneumonia from aspiration, urinary tract infections, or pressure ulcers from lack of mobility are a natural part of the disease progression.^{3,25} The APRN must discuss with caregivers the role of antibiotics in the context of a life-prolonging intervention, especially in the late stages of the disease. Antibiotics are not benign and can cause complications, such as *Clostridium difficile* infection, so an early dialogue is warranted about the use of oral and/or intravenous antibiotics based on the patient's goals of care.^{3,25}

Due to the prevalence of dysphagia (93%),^{3,24,25,28} malnutrition and dehydration are common. Conversations on the use of medically administered hydration and nutrition should start early and continue as the disease progresses. There are many resources, such as the video from the University of North Carolina School of Medicine Palliative Care Resources on feeding options (<http://www.med.unc.edu/pcare/resources/feedingoptions>), to provide patients and their loved ones with accurate information on the benefits and risks of medically administered nutrition versus careful hand feeding so the patient and/or caregivers can make informed decisions. A speech-language pathologist referral should be considered to determine the safest oral intake/diet recommendations for the patient.

Frequently, loved ones ask how we can allow the patient to "starve to death."^{3,5,30} A candid discussion on the natural dying process for a dementia patient is imperative. Using a careful selection of words, such as "fasting," and explaining that this process is not uncomfortable can be helpful for caregivers. Comparing the fasting state to a time when the loved one has been ill and did not have a desire to eat may also be helpful.³⁰ It is important to emphasize that the patient will be offered comfort foods and/or sips of beverages, despite the risk of aspiration, along with frequent oral care.³⁰ Providing the information and allowing loved ones time to process it while providing empathy are essential APRN skills.

HIP FRACTURES

Elderly patients hospitalized for hip fractures are common on medical-surgical units. As the population ages, the number of hip fractures are estimated to rise by 11.9% by 2030.³¹⁻³⁴ More than 250,000 older adults sustain hip fractures annually in the United States, and, by 2030, this number is expected to rise to 260,000.³⁵ Most hip fractures are treated surgically with only about 10% treated nonoperatively.^{31,36} APRNs need to be familiar with the care of these patients, including pain and symptom management as well as the importance of initiating an early goals-of-care discussion with the patient (if possible) and family.^{32,37} Although one may not consider consulting palliative care for a hip fracture alone, it may be appropriate if the patient has multiple comorbidities (e.g., heart failure, dementia, chronic pulmonary and kidney disease) and is frail even at baseline. Patients with hip fractures have significant comorbidities and have a 1-year mortality rate of approximately 30%.^{32,34,36,38,39} Hip fractures in a patient older than 65 years old should trigger a palliative care consult.^{34-36,38,39}

Having a goals-of-care conversation with the patient and family can align the patient's priorities of care (cure vs. quality of life) while ensuring that both surgical and conservative intervention options are fully discussed, including the benefits and risks (mortality) of each.^{35-37,40} Many times the patient's main priority is to ambulate again, so surgery may be the better option if, realistically, rehabilitation is possible. It is important for patients and their loved ones to understand that pain and symptom management can be achieved via medical management.

In Case Study 1, although Paul did not sustain a fracture, he was at high risk because of his frequent falls. Hip fractures increase after the age of 60, and then exponentially after the age of 80.^{35-37,40} Approximately 30% of community-dwelling senior citizens age 65 and up fall annually, with higher numbers in institutions.^{38,39} Hip fractures are disabling and a major cause of morbidity and mortality in elderly individuals.³⁴⁻³⁶ Common risk factors for falls include (1) cognitive dysfunction; (2) bowel/bladder incontinence; (3) medications, such as opioids, sedatives, and diuretics; (4) impaired balance; (5) environmental hazards, such as throw rugs and slippery floors; (6) pets; and (7) weakness.^{32,34,36,38,39}

Nancy said she knew Paul's prognosis was limited since he had been enrolled in hospice for the past 3 weeks. She wanted to focus on comfort/quality of life and did not want to pursue life-sustaining interventions or procedures, including resuscitation, dialysis, and mechanical ventilation. However, when Paul fell, Nancy did not notify Paul's hospice before calling 911 for assistance and instead revoked Paul's hospice benefit and came to the hospital for evaluation.

Stacey recommended transferring Paul to the hospital's palliative care unit for symptom management while a disposition plan was established. Since the focus was on comfort and no surgical intervention, a wound care consult was placed. The purpose was to create a plan to manage odor and drainage of the large fungating and necrotic lesions on Paul's face and hand.

Nancy said she could not continue to care for Paul at her home. Stacey reviewed disposition options with her, including long-term care with hospice versus skilled nursing care. Unfortunately, there were no local residential hospice facilities in Nancy's community. Stacey consulted the palliative care social worker to assist Nancy in disposition planning. In the meantime, Paul was transferred to the palliative care unit (PCU).

The PCU APRN observed Paul cry out in pain upon positioning, and per the nursing staff, wound dressing changes were reported to be very painful for Paul. Stacey changed Paul's medications since he had dysphagia. She scheduled oral oxycodone (20:1 concentrate) 10 mg for pain every 4 hours and 30 minutes prior to dressing changes to address his pain.

Stacey and the nursing staff also identified a potential source of Paul's distress related to his past military service. Stacey explored with Nancy about Paul's service and if he had shared his experiences. Knowing that Paul's military service may be contributing to Paul's agitation, Stacey reached out to the PCU's chaplain and social worker to integrate strategies into Paul's care plan.

Over the next 72 hours, Paul continued to decline. He was unable to eat or drink. Stacey discussed medically administered hydration and nutrition with Nancy, who shared that Paul never wanted a feeding tube. Nancy stated that she knew Paul was dying and that even though he was 78 years old, it was hard to lose her father. Stacey encouraged Nancy to speak with the hospital chaplain or the palliative care bereavement counselor. Nancy expressed appreciation for the additional support and met with each of them.

The nursing staff and the PCU APRN closely assessed Paul for any signs of pain and agitation as well as the effectiveness of his medications. They documented that Paul's pain was better controlled with the scheduled oxycodone but required dose titration over the next day. Stacey and the palliative care team (physician, nurses, social worker, counselor, chaplain, and pharmacist) made rounds daily and collaborated to provide intensive psychosocial and spiritual care to Paul and Nancy. Paul died peacefully 4 days after he came to the PCU. Nancy expressed deep appreciation for the care Paul received.

The Institute of Medicine (IOM) and the American Society for Clinical Oncology (ASCO) continue to recommend early palliative care interventions in order to provide high-quality cancer care.^{1,25,41} ASCO has recommended full integration of palliative care as part of comprehensive cancer care in the United States by 2020.^{1,41-44} There is clear evidence that cancer patients experience better outcomes with palliative care including less pain, dyspnea, and depression; better quality of life; similar if not improved survival; and reduced costs.^{1,6,25,42,43,45} Unfortunately, fewer than 50% of patients with advanced cancer have palliative care consultation, and only one-third have goals-of-care discussions.^{6,25,42,43,45} To address the gap in care of the cancer patient, it is essential that palliative APRNs step up to ensure quality care of these patients' needs.²⁵ Palliative APRNs are uniquely positioned to manage challenging pain and symptoms while promoting goals-of-care dialogues.

Lung cancer has the highest morbidity and mortality, of which 80% are non-small cell lung cancers (NSCLC).⁴⁷ In recent years, a new cancer treatment called immunotherapy has emerged. Immunotherapy offers a novel way to target cancer cells by engaging the body's own immune system.^{46,47} Clinicians, patients, and their families are pursuing these treatments, even for those who may be at risk for low response rates and significant toxicities, such as those patients with low performance status and multiple comorbidities. Clinicians, both oncology and palliative, bear the challenge and responsibility of providing realistic and balanced information about the risks and benefits of these new immunotherapy agents.⁴⁸⁻⁵⁰

The APRN should understand that the typical side effects of chemotherapy, such as hair loss and blood cell abnormalities, are not prevalent with immunotherapy. These immunotherapy agents do, however, have side-effect profiles that include severe fatigue, diarrhea/colitis, pneumonitis, rash/pruritus, transaminitis, hypo- or hyper-thyroidism, diabetes, and adrenal insufficiency.^{41,50} More commonly, skin side effects are often noticed initially, followed by colitis/diarrhea. Skin manifestations can occur in up to 40% of melanoma patients receiving immunotherapy.⁵¹ These can include rash, pruritus, vitiligo, lichenoid dermatitis psoriasis, or oral mucosal inflammation.⁵⁰ Severe colitis occurs in fewer than 10% and can lead to increased risk of peritonitis and bowel perforation. Endocrine side effects also occur in approximately 10% of patients, and treatment should be targeted at replacing the affected hormone, treatment that is likely needed for life. Rarer side effects of immunotherapy can include episcleritis, uveitis, pancreatitis, neuropathies, nephritis, and cardiomyopathies.⁵⁰

Typically, most immunotherapy toxicities have a relatively predictable time course. Skin toxicities or reactions present the earliest, sometimes only 2-3 weeks after initiation. More severe organ toxicities, such as colitis, hepatitis, and pneumonitis, appear between 5 and 12 weeks after initiation. Endocrine toxicities that affect the thyroid and adrenals often present from 8 to 14 weeks after initiation. Knowing these timelines can help clinicians plan for and prepare patients

and involve the palliative care team when these side effects occur and even before they occur.^{48,50} Of note, glucocorticoids should be considered in the treatment of some side effects of immunotherapy agents. Because glucocorticoids counteract the same immune system activated by immunotherapies, some clinicians may incorrectly believe that these steroids are contraindicated, fearing they may reduce the efficacy of the immunotherapy. This has not been proved by research, and often the glucocorticoid is a necessary life-saving intervention. In fact, most clinical trials of immunotherapies allow for glucocorticoid use up to a dose of oral prednisone 10 mg daily or its equivalent.^{48,50} In some cases, low-dose glucocorticoids may be the only way a patient can continue with immunotherapy. Given their promise of potential durable remissions, the use of these immunotherapy agents will only grow. It is incumbent upon palliative APRNs to be aware of these new therapies, as well as their risks and benefits.

CASE STUDY 2: GOALS-OF-CARE DISCUSSIONS

Judy was a 26-year-old unmarried Latino woman who had been diagnosed with Stage IV non-small cell lung cancer (NSCLC) 6 months earlier. She was admitted over the weekend with intractable pain and dyspnea. The palliative APRN, Brook, met her on Monday morning rounds.

On reviewing her medical records, Brook observed that Judy presented with Stage IV disease with metastases to the brain and bones. She had undergone three cycles of cisplatin, vinblastine, and DTIC (CVD), but recent scans revealed widespread progressive disease. Judy rated her pain at 7/10 on patient-controlled analgesia (PCA) with morphine at a basal rate of 2 mg per hour, with a 2 mg bolus every 15 minutes as needed. Oxygen saturation was 94% on 2 liters of oxygen, but Judy complained of dyspnea.

Brook focused on establishing a bond with Judy and her parents, Ben and Jill, and worked to improve her symptoms. With Judy's permission, her parents stayed in the room during the initial assessment. She was "desperate" to be more comfortable but also wanted to be able to think and function coherently. Brook made it clear to Judy that she could be more comfortable, but it was going to take some adjustment in her current medications. The benefits of morphine were discussed—both for her pain and her breathing. Judy reported that she was tolerating the morphine fine, except for its constipating side effects. Judy was assured that the constipation could be countered with a good bowel regimen. Work began on improving her pain control. Brook reviewed the number of breakthrough doses Judy had attempted since her admission and adjusted her morphine dosage up to 3 mg/hr and gave her a 3 mg bolus every 20 minutes. Simultaneously, her bowel regimen was increased to include stool softeners and laxatives. An as-needed antiemetic was prescribed, as Judy had nausea with severe pain. Brook informed Judy that the first few days of titration might make her more sedated than she wanted, but she would adjust to the sedative effects to some degree over time and that Judy had been sleep-deprived due to her pain and dyspnea. Brook reinforced the principle of patient-controlled analgesia: that she was in control of how much she needed or wanted, and efforts to balance

her pain control with the level of sedation would be undertaken moving forward.

The next focus was her dyspnea. While the morphine would help with this, her chest x-ray from the preceding day revealed a large left pleural effusion and moderate right pleural effusion. Brook consulted with the oncologist to ask if he would consider tapping the effusions to improve her respiratory status. When he said yes, Brook made arrangements with the interventional radiology department to perform bilateral pleural taps later in the day or on Tuesday morning at the latest.

As the Brook left the room with them, Ben and Jill shared that Judy was the second of three daughters in their family. She was the first person in their family to go to college and then on to graduate school and had recently moved out of state to begin her career. Shortly after her move, Judy was diagnosed with NSCLC and elected to return to her parent's home to begin treatment. In her parent's words, she was the "golden child." Their home was a 1-hour drive away from the hospital. Their older daughter (28) lived out of state; their younger daughter (23) lived nearby but was finding being with her sister at this time very difficult. They shared that they were very aware of the gravity of their daughter's illness but were not prepared for what was ahead. Brook reassured them there were resources to help them feel better prepared. They agreed to meet with the social worker and confirmed that a chaplain would also be helpful for them. Brook discussed the plan and conversations with the nurse caring for Judy. The RN had already had a brief conversation with Judy's parents and agreed to reinforce the plan of care for the day and ensure that both the social worker and the chaplain visited.

On Tuesday, Judy's pain control was markedly improved, with a self-reported level of 2/10. Oxygen saturation was 99% after the pleural taps, and she did not feel she needed the oxygen all the time. A plan was made to meet to discuss next steps. With Judy's permission, Ben and Jill were included in the conversation. It was a difficult conversation. Judy and her parents were advised that the cancer had progressed in her bones and brain, which meant that the treatment she had received was not working. The oncologist reviewed other treatment options including immunotherapy, anticipated side effects, and the likelihood of the treatment extending her life. Judy shared that she wanted to try the immunotherapy, and her parents agreed that she would go home with the goal of starting the immunotherapy over the next week once the oncologist obtained approval for the medication. Brook converted her morphine from IV to oral in anticipation of discharge and made sure Judy had a good bowel regimen to prevent constipation. Brook reviewed the potential complications and provided follow-up instructions including a follow-up outpatient palliative care appointment.

Brook was on call for the palliative care service when she was consulted a few weeks later that Judy was admitted back to the oncology unit for renal failure related to her immunotherapy. Unfortunately, Judy had been unable to keep the palliative care outpatient appointment due to her fatigue. Brook was consulted now for symptom management and goals-of-care conversations. Understanding that Judy's renal function was poor, Brook transitioned Judy from oral morphine to a hydromorphone PCA. Brook met with Judy and her parents once Judy was more comfortable

and settled into her oncology room. Judy shared that she was so tired and now ready to focus on her comfort and being at home. She wanted to go home to be with her family and dog. In collaboration with the case manager, a plan was begun to discharge her home with hospice.

By Thursday, planning was complete. All the home hospice equipment had been delivered to Judy's house. Her hospital bed was in the family room that looked out over the ocean; there was an adjacent bathroom. Although Judy was not wearing the oxygen all the time, it had been delivered and set up, anticipating that she would need it in the future. The hospice agency had visited with Judy's parents and her sister. The hospice nurse and social worker on their team would meet with them frequently, initially, to help them better understand what to expect as Judy's disease progressed. Ben and Jill contacted their pastor and advised him they were coming home with Judy, and he told them he would visit them as often as they needed him. Judy was discharged to home hospice on Thursday afternoon. Two weeks later, Judy died comfortably in her home, surrounded by her family and with her dog by her side.

Bereavement follow-up revealed that Judy's family felt supported during the transitional care process. As difficult as it was for them to have her decide to stop treatment, they saw her make a decision that she felt was best for her. Although she stopped treatment, Judy was actively engaged in managing her symptoms so she could continue to enjoy her life until the very end.

SURROGATE OR PROXY DECISION-MAKING

Because seriously ill patients like Judy often lose their decision-making capacity, the APRN may have to rely on loved ones to advocate for the patient's wishes.^{11,25,40} State laws vary in the extent to which they authorize proxy decision-making; they also differ as to which family members have priority in the decision-making. Thus, the APRN should be familiar with the state's surrogate decision-making laws and regulations. The acute care APRN should initiate family meetings early during the hospital stay so that priorities of care can be established.

During the family meeting, the APRN needs to provide an accurate summary of the medical care to date, all of the medical treatment options being considered, and the potential outcomes, including prognosis. The APRN should summarize what the medical teams are recommending as the best care option(s) while focusing on the patient's preferences and values. For example, "In light of what we have talked about so far, what do you think Judy would want to do?"⁴⁰ The goals of the meeting are to minimize the surrogate decision-maker's burden of responsibility and remain focused on the patient's—not the decision-maker's—wishes.^{11,25,40}

Whether the APRN is serving as the patient's attending or as a consultant, there is an expanding palliative care role in the acute care setting.¹⁵ APRNs are defining hospitals' end-of-life policies and procedures as well as creating triggers for appropriate palliative care consults. APRNs provide optimal

symptom management, maximize patient and family function throughout treatment, and ensure seamless transitions to end-of-life care when cancer treatment is no longer possible or desirable.^{15,40,51} With the majority of deaths occurring in

acute care settings, where the focus of care is on active, curative treatment and not on managing symptoms or establishing realistic goals of care, palliative APRNs must be able to advocate for seriously ill patients and their loved ones.^{41,52} Patients need APRNs who are skilled in the science of palliative medicine as well as in the art of holistic healing. With the ever-changing healthcare environment, palliative APRNs are essential in providing specialized interventions to meet the diverse needs of acute care patients (Table 8.3).

SUMMARY

This chapter discusses the specialized role of the palliative APRN in the ever-changing acute care environment. More than 50% of all deaths occur in medical, surgical, and oncology units where the focus is on active, curative treatment, not on managing symptoms and establishing realistic goals of care. Palliative APRNs are uniquely qualified to care for seriously ill patients by providing comprehensive, effective, compassionate, and cost-effective care that improves end-of-life care in acute care settings. Care must be focused on patients with common conditions including end-stage renal disease, dementia, hip fractures, and oncological conditions and their associated sequelae.

THE PALLIATIVE APRN IN THE INTENSIVE CARE SETTING

Clareen Wiencek

KEY POINTS

- Palliative care is now an expected component of high-quality care in the intensive care unit (ICU).
- The palliative advanced practice registered nurse (APRN) has the ideal skill set to influence clinical outcomes in the ICU.
- The palliative APRN needs to acquire knowledge about pain and symptom management, resuscitation outcomes, withdrawal and withholding of life-sustaining treatments, and quality improvement activities in the ICU.

CASE STUDY: ESTABLISHING TRUST

The palliative advanced practice registered nurse (APRN) responded to a consult for an 87-year-old female patient, Mrs. S, who had suffered a massive intracerebral hemorrhage. She had multiple comorbidities and had been living at home with her grandson, John, prior to the acute event. Mrs. S was minimally responsive, intubated and mechanically ventilated, and on vasopressor support. She was a full code as a default due to the absence of an advance directive. The APRN was consulted to help with goals of care and was informed that the patient's grandson was unreasonable and abrasive. After an examination of the patient, the palliative APRN met with the intensivist and John. She started the meeting by asking John what he understood about his grandmother's condition and what the doctors had told him, and affirmed John's obvious love and devotion for his grandmother. In addition, the APRN asked what a typical "good day" looked like for his grandmother and what activities gave her joy. During that meeting, she began to establish trust with John and began to de-escalate some of the aggressive behavior. The palliative APRN assured him that the ICU team was doing everything they could to support his grandmother and did not press for a change in code status during the first encounter. Over several days, trust continued to increase but the patient's condition did not improve. The team and John agreed that more aggressive intervention would be more harmful than helpful to his grandmother and agreed to a do-not-resuscitate (DNR) order. The palliative APRN helped John to consider his grandmother's quality of life and dignity and to begin to think about possibly discontinuing the ventilator rather than performing a tracheostomy and continued support in light of grave neurological outcomes. The palliative APRN made recommendations on how to manage the patient's agitation and

sedation while on the ventilator. Over one weekend, John contacted the APRN and told her that he was ready to discontinue the ventilator. He shared that his grandmother had come to him in a dream and asked that he let her go. The palliative APRN worked with the intensivist and bedside nurse to allow John time with his grandmother and then premedicated the patient prior to extubation and removal of the ventilator. Spiritual care provided presence and support prior to the actual procedure. Mrs. S died peacefully 4 hours later with her grandson at her side in the ICU. John expressed gratitude to the palliative APRN and ICU team for the compassionate care of his beloved grandmother. His memory of a good death was preserved through the skilled delivery of palliative care.

INTRODUCTION

The early intensive care units (ICUs) of the 1950s were opened to care for the sickest patients and to concentrate the knowledge and skills of the nurses and physicians who worked there. The aim was rescue and survival of the most critical patients in a more efficient and effective physical space.¹ This mission has not changed over the past 60 years, but technological and medical advances have transformed those early units into modern, high-tech centers within acute care hospitals. At first glance, palliative care may seem an incongruous fit for the ICU due to the fundamental difference between the ICU goals of cure and rescue and the palliative goals of quality of life and symptom management. However, after a decade of explosive growth in acute care-based palliative care programs and considerable expansion of the evidence base, palliative care in the ICU setting is no longer a novelty but an essential component of high-quality care.^{2,3} Most critical care professional societies have issued position statements, protocols, or clinical practice guidelines that delineate the how and why of integrating palliative care in the care of the critically ill.⁴⁻⁷ The Center to Advance Palliative Care (CAPC) launched the Improve Palliative Care in the ICU (IPAL-ICU) initiative in 2010, and it is an excellent resource for quality improvement (QI).⁸ Given the ongoing shift in acceptance and viewpoints, the palliative advanced practice registered nurse (APRN) is ideally suited to deliver high-quality outcomes for critically ill patients and their families through the full integration of palliative care in the ICU setting, whether in the integrative or consultative role.⁸

All critically ill patients and their families have palliative care needs based on the definition found in the fourth edition of the National Consensus Project for Quality Palliative Care *Clinical Practice Guidelines* which states,

Beneficial at any stage of a serious illness, palliative care is an interdisciplinary care delivery system designed to anticipate, prevent, and manage physical, psychological, social, and spiritual suffering to optimize quality of life for patients, their families and caregivers. Palliative care can be delivered in any care setting through the collaboration of many types of care providers. Through early integration into the care plan of seriously ill people, palliative care improves quality of life for both the patient and the family.^{9(p. ii)}

This more expansive definition, broadening beyond just end-of-life care, has yet to be widely accepted in the ICU setting. However, all critically ill patients and their families have needs consistent with this definition: goal-oriented care that is aligned with their goals, preferences, and values; the management and relief of distressing symptoms related to the underlying critical illness and to the procedures and interventions inherent in that treatment; regular and effective communication between the critical care team and the patient and surrogate decision-makers, so common in the ICU setting; and deliberate planning for care transitions.²

The commonality of palliative needs in the critically ill and the palliative interventions to meet those needs can be driven by APRNs when they are allowed to practice to the full scope of their education, licensure, and certification. Full scope of practice was just one of the changes called for by the Institute of Medicine (IOM)'s 2010 report, *The Future of Nursing: Leading Change, Advancing Health*.¹⁰ The palliative APRN, when practicing to full scope, can improve care for those patients who will survive the life-threatening episode and for those who will die in the ICU. Although palliative care is broader than just terminal care, death is common in the ICU: one in five Americans die in the ICU or during an ICU-related admission.¹¹

The findings of the landmark Study to Understand Prognoses and Preferences for Outcomes and Risks of Treatments (SUPPORT)¹² and the 1997 IOM report *Approaching Death: Improving Care at the End of Life*¹³ revealed that Americans do not die well. The SUPPORT investigators found that 50% of the more than 9,000 seriously ill patients enrolled in the study died with unrelieved pain and experienced an undesirable ICU admission in the last week prior to death.¹³ Multiple studies since have reported limitations in the care of the critically ill. These discrepancies include unrelieved pain and other symptoms, inadequate communication and goal setting, divergence in goals of treatment, clinician burnout and moral distress, and inefficient resource utilization.^{5,14} Since death is common in the ICU and usually occurs after a course of aggressive, life-sustaining interventions, experts assert that an ICU admission is actually a therapeutic trial, and, only when it fails do providers, patients, and families entertain a change in goals from survival at all costs

to palliation.⁵ It is time to change that paradigm and fully integrate palliative care from time of admission. The palliative APRN can lead this transformation.

Although death remains common in the ICU setting, especially in medical units, the site of death is shifting. Teno and colleagues analyzed the care of Medicare beneficiaries in 2000, 2005, and 2009.¹⁵ Between 1989 and 2007, home deaths increased from 15% to 24%. However, the rate of ICU use in the last month of life increased from 24.3% to 29.2% in 2009. It is commonly agreed that hospitals are not the preferred place of death, as patients strongly prefer to return home but only after the full trial of advanced, aggressive medical technologies such as those found in the ICU. As noted by Rothman, "in the mid-20th century death and dying was removed and rendered invisible once through hospitalization and again through the intimidating locked doors of the ICU."^{1 (p. 2459)} The locked doors have opened for most ICUs, partially thanks to the efforts by the American Association of Critical Care Nurses (AACN) to promote open visitation,¹⁶ and it is now time for palliative care to be fully present.

Palliative APRNs must take up the challenge presented by the life-saving technology in today's ICUs and the expanding evidence base that the critically ill and their families not only could benefit from palliative care but should also expect it. Also, the greater awareness that palliative care does have a place in the ICU has led prominent stakeholders to call for more systematic integration. These stakeholders include the Joint Commission, the Institute for Healthcare Improvement, the Critical Care Societies Collaborative, and the IOM. Toward the goal of optimizing the palliative APRN's impact in the ICU, this chapter focuses on five dimensions: pain and symptom management, communication, discontinuation of life-sustaining treatments, and resuscitation outcomes, and QI activities. Additionally, the impact of the 2020 coronavirus pandemic on how palliative care and critical care were and can be integrated during this global crisis and the provision of primary and secondary palliative care in the emergency department setting, as an entry into the ICU, will be addressed.

PAIN AND SYMPTOM MANAGEMENT

PAIN: PREVALENCE AND CLINICAL PRACTICE GUIDELINES

Pain is a common symptom in the critically ill. Despite more than 20 years of research and quantification of the pain experience, the incidence of significant pain is still 50% or higher in both medical and surgical ICU patients.^{17–20} The seminal work by Puntillo¹⁷ in 1990 was one of the first studies to describe the pain experience of critically ill patients, and the multicenter Thunder Project II provided strong evidence of the high incidence, up to 80%, of procedural pain in this population and the inadequate management and relief.²¹ Such common procedures as turning, tracheal suctioning, line insertion, and dressing changes were found to be associated with significant levels of pain.²¹ The stress response evoked by

Table 9.1 THE PADIS GUIDELINES FOR ADULT ICU PATIENTS: PAIN MANAGEMENT

RECOMMENDATION	STRENGTH	QUALITY OF EVIDENCE
Use an assessment-driven, protocol-based, stepwise approach for pain and sedation management in critically ill adults.	Conditional	Moderate
Use acetaminophen as an adjunct to an opioid to decrease pain intensity and opioid consumption for pain management in critically ill adults.	Conditional	Very low
Use low-dose ketamine (1–2 µg/kg/hr) as an adjunct to opioid therapy when seeking to reduce opioid consumption in postsurgical adults.	Conditional	Low
Use an opioid, at lowest effective dose, for procedural pain management in critically ill adults.	Conditional	Moderate
Use a neuropathic pain medication with opioids for neuropathic pain management in critically ill adults.	Conditional	Low
Do not routinely use IV lidocaine as an adjunct for pain management in critically ill adults.	Conditional	Low
Do not routinely use a COX-1 selective NSAID as an adjunct to opioid therapy for pain management in critically ill adults.	Conditional	Low
Suggest using music therapy or massage for pain management in critically ill adults.	Conditional	Low
Suggest offering relaxation techniques for procedural pain management in critically ill adults.	Conditional	Very low
Do not use local analgesia or nitrous oxide for pain management during chest tube removal in critically ill adults.	Conditional	Low

Adapted from Devlin et al.²²

unrelieved pain in the critically ill can lead to impaired tissue perfusion, hyperglycemia, lipolysis, and impaired wound healing, thereby increasing not only patient discomfort but risk of prolonged morbidity.²⁰

The evidence that most critically ill patients experience pain and that pain continues to be undermanaged led to the development of the *Clinical Practice Guidelines for the Management of Pain, Agitation and Delirium (PAD) in Adult Patients in the Intensive Care Unit* by the American College of Critical Care Medicine, the consultative body of the Society of Critical Care Medicine.¹⁹ These 2013 guidelines were issued to define best practices for optimizing management of pain, agitation, and delirium in the critically ill; however, the authors report that only 60% of ICUs in the United States have implemented PAD guidelines, and compliance with such protocols remains low. These Guidelines were updated in 2018 to include immobility and sleep disruption, thus, they are now referred to as the *PADIS Guidelines*.²²

There are several reasons behind the continued prevalence of suboptimal pain management in the critically ill. One of the main reasons is the conflict in goals between rescue and comfort.¹⁸ Many ICU nurses and providers, especially those in training, may be concerned about and therefore reluctant to use medications such as opioids that could impact hemodynamic stability, threaten end-organ perfusion and function, or induce oversedation and respiratory depression.^{18,22} Second, critical care practitioners may not have the experience or knowledge about the use of opioids and adjuvant

medications, including routes other than the parenteral route widely used in the ICU setting.^{13,18} Third, there is a growing number of evidence-based management bundles and checklists used in the ICU setting that may complicate the delicate balance between treatment goals and quality of life for the patient.^{18–20} Finally, the preponderance of nonverbal patients in the ICU limits the gold standard of patient self-report, resulting in the use of surrogate reports or interpretations and therefore potentially leading to a reluctance to administer pain medications in doses adequate for relief.²³ The palliative APRN practicing in the ICU must be aware of and accommodate to these realities of pain management, especially when in the consultative role. Table 9.1 lists the major recommendations from the 2018 *PADIS Guidelines* for pain management. The full document includes 37 recommendations noting the strength and quality of evidence. Chapter 43 provides a full discussion of pain management principles.

PAIN AND SPECIAL PATIENT POPULATIONS: NONVERBAL PATIENTS

The prevalence of critically ill patients unable to self-report pain is high due to a multitude of factors that include severity of illness, neurological dysfunction or injury, intentional sedation, metabolic disturbances, and vital organ dysfunction. This prevalence poses a challenge to optimal pain management for the palliative APRN. Since these patients cannot self-report, the APRN must use standardized scales

and multiple measures on which to base assessment and management.²⁵ The palliative APRN should assess for behavioral signs of pain, such as grimacing, furrowed brow, restlessness, and delirium. Generally, vital signs as physiologic indicators are not sensitive for discriminating pain from other distressing triggers.²⁵ No single strategy will be sufficient, and the APRN must be aware that vital signs that are within normal ranges do not indicate an absence of pain.²⁵ In fact, the APRN should assume that pain is present for those on neuromuscular blockade and recommend appropriate analgesic therapy.²³

Clinical practice guidelines call for a hierarchy of pain assessment techniques in the adult, nonverbal patient: self-report, ruling out potential causes of pain, observing patient behaviors, using surrogate reporting, and attempting an analgesic trial.²⁵ A therapeutic trial is indicated if a pathologic or procedural reason exists for pain. For mild to moderate pain, a non-opioid analgesic should be given initially; if the patient's behaviors improve, continue the regimen. If the pain-related behaviors do not improve, the APRN should order a trial dose of a short-acting opioid and observe the effect. If there is no change in behavioral indicators of pain, the dose should be increased by 25–50% and the nurse should observe the effect.²⁵

The palliative APRN may use proxy reports of pain as a basis for management in the nonverbal patient. Proxy reports remain controversial; families often overestimate pain.²⁴ Even so, family members can provide valuable information, such as a history of chronic back pain, that can influence pain management outcomes.

Multiple scales are used to assess pain in the nonverbal adult population, but two scales are more commonly used and have sound psychometrics: the *Behavioral Pain Scale* (BPS) and the *Critical-Care Pain Observation Tool* (CPOT). These two scales are the most reliable and valid behavioral pain scales for assessing and monitoring pain in nonverbal medical, surgical, or trauma ICU patients and should be used at standardized intervals.^{22,24,25}

PAIN AND SPECIAL PATIENT POPULATIONS: RENAL AND HEPATIC FAILURE

It is estimated that up to 25% of all ICU patients present with or develop acute renal failure, depending on the setting and the definition.²⁶ In addition to patients with acute renal failure, chronic kidney disease is prevalent in the ICU setting.

If opioids are used by the palliative APRN to manage pain in this population, certain medications must be avoided or used with caution. However, there is a lack of hard pharmacokinetic data that support specific treatment guidelines.²⁷ Meperidine, codeine, dextropropoxyphene (propoxyphene), and morphine should be avoided due to toxicity and/or the accumulation of active, nondialyzable metabolites.²⁷ Oxycodone and hydromorphone should be used with caution. Oxycodone undergoes hepatic metabolism, but 19% is excreted unchanged in the urine. Hydromorphone should be used prudently in patients who are not on dialysis due to the rapid accumulation of its active metabolite.²⁷ Fentanyl and

Box 9.1 GUIDELINES TO OPTIMIZE PAIN MANAGEMENT IN PATIENTS WITH HEPATIC FAILURE

1. Reduce long-term acetaminophen dosing to 2–3 g/day.
2. A one-time acetaminophen dose of 3–4 g/day may be safe.
3. Use reduced doses of non-steroidal anti-inflammatory drugs (NSAIDs) and opioids in patients with cirrhosis.
4. Avoid using NSAIDs in patients with compensated or decompensated cirrhosis due to the risk of inducing acute renal failure from prostaglandin inhibition.
5. Avoid using opioids in patients with a history of encephalopathy.
6. Avoid using codeine and meperidine at all times.
7. Decrease hydromorphone dose by 50% of normal dose and administer it at prolonged dosing intervals.

methadone are considered to be the safest opioids for patients in renal failure.²⁷

The critically ill patient with hepatic failure also presents challenges in terms of optimal pain and symptom management. The greater the hepatic dysfunction, the greater the impairment in drug metabolism and removal.^{28,29} The efficiency of drug removal by the liver depends on blood flow, plasma protein binding, and hepatic enzymes. Advanced liver dysfunction alters the effects of many medications as a result of changes in pharmacokinetics, abnormal accumulation of the free drug in plasma, and end-organ response. The palliative APRN should be aware that the majority of pain medications are largely metabolized by the liver and that opioid clearance is reduced and drug bioavailability increased in hepatic failure. Fentanyl is the preferred opioid in this population.³⁰ Given the variability in response, the right dose and interval of any opioid are those tolerated by the patient. Dosing should be based on close and frequent assessment of the patient's response.³⁰ Box 9.1 provides guidelines on how to optimize pain management in patients with hepatic failure.^{28–30}

SYMPTOM MANAGEMENT: AGITATION AND DELIRIUM

Agitation is common in critically ill patients.²² The palliative APRN should assess for possible causes of agitation when developing the treatment plan, such as pain, delirium, hypoxemia, or withdrawal from alcohol or opioids. Strong evidence now exists that prolonged deep sedation is associated with adverse outcomes and that light sedation from which the patient can be aroused and can follow simple commands is preferred.²² Indeed, most ICUs have established treatment protocols with this goal. Due to the growing evidence that benzodiazepine use is strongly correlated with delirium in the acutely ill patient, patterns of use are changing. Currently, the dominant medications used for sedation of the critically ill

patient are midazolam and propofol (Diprivan), with decreasing use of lorazepam, rare use of diazepam and barbiturates, and growing use of dexmedetomidine (Precedex).²²

The palliative APRN caring for patients in the ICU should be familiar with the pharmacokinetics and side effects of propofol and dexmedetomidine due to their common use in this setting. Propofol is an intravenous sedative that binds to multiple central nervous system receptors to block neural impulses. It has sedative, hypnotic, anxiolytic, antiemetic, and anticonvulsant properties. Propofol does not possess any analgesic properties, so analgesics must be coadministered. This drug causes dose-dependent respiratory depression and hypotension but has rapid redistribution and a short duration, making it an ideal adjuvant for mechanical ventilator-related sedation that allows for daily sedation interruption protocols.^{22,23} Dexmedetomidine is a selective alpha-receptor agonist with sedative, analgesic or opioid-sparing, and sympatholytic properties that was approved in the United States more than 10 years ago for short-term sedation (<24 hours) at a maximum dose of 0.7 µg/kg/hour. Its pattern of sedation differs significantly from other sedatives as patients are more easily arousable, but its onset is also quick (in about 15 minutes). Dexmedetomidine produces minimal respiratory depression and therefore is the only sedative approved in the United States for administration in non-intubated patients. However, patients' ventilator and oxygenation status must still be closely monitored as the drug can cause loss of oropharyngeal muscle tone, putting the patient at risk of airway obstruction. The most common side effects of dexmedetomidine are hypotension and bradycardia. The opioid-sparing effects of this sedative may reduce opioid requirements in the critically ill patient.²²

Agitation can be distressing for the critically ill patient, family members, and the team. Preferred agents in the ICU

have changed over the past decade based on research, and strong evidence now supports the use of subjective sedation scales at regular intervals. The most valid and reliable sedation assessment tools for adult ICU patients are the *Richmond Agitation-Sedation Scale* (RASS) and the *Sedation-Agitation Scale* (SAS).²² These two scales demonstrated a high degree of interrater reliability and had robust methodology and sampling method. Table 9.2 provides recommendations from the 2018 PADIS guidelines on managing agitation and delirium in ICU patients.

Delirium is also highly prevalent in critically ill patients, affecting up to 80% of mechanically ventilated patients.²² Strong evidence now exists that even one episode of delirium is an independent predictor of adverse clinical outcomes, such as increased mortality, increased hospital length of stay, higher costs of care, and long-term cognitive impairment.^{31,32} Delirium is a syndrome associated with a change or fluctuation in mental status, inattention, and either disorganized thinking or an altered level of consciousness.²² Hypoactive delirium and hyperactive delirium exist, with hypoactive being more common, and ICU clinicians often underestimate its clinical presence.²² Formerly referred to as "ICU psychosis," it is no longer considered a benign condition in the ICU or acute care setting.

The ideal treatment for delirium is prevention and the use of standardized screening. The palliative APRN should be familiar with the *Confusion Assessment Method for the ICU* (CAM-ICU) and the *Intensive Care Delirium Screening Checklist* (ICDSC), which are the most valid and reliable instruments for the screening and monitoring of delirium in ICU patients.²² Moderate-quality evidence exists that routine monitoring for delirium is feasible and that monitoring compliance rates exceed 90%.²² There is mixed or a lack of evidence that haloperidol is effective as a preventive measure.

Table 9.2 PADIS GUIDELINES FOR ADULT ICU PATIENTS: AGITATION AND DELIRIUM

RECOMMENDATION	STRENGTH	QUALITY OF EVIDENCE
Use light sedation vs deep sedation in critically ill, mechanically ventilated adults.	Conditional	Low
Use propofol over a benzodiazepine for sedation in mechanically ventilated adults after cardiac surgery.	Conditional	Low
Critically ill adults should be regularly assessed for delirium with a valid tool.	N/A	N/A
Sedation strategies using non-benzodiazepines (propofol or dexmedetomidine) should be used over benzodiazepines for sedation in mechanically ventilated adult ICU patients.	Conditional	Low
Suggest not using haloperidol, dexmedetomidine, or ketamine to prevent delirium in all critically ill adults.	Conditional	Very low to low
Suggest not routinely using haloperidol to treat delirium.	Conditional	Low
Use a multicomponent, nonpharmacologic intervention that is focused on but not limited to reducing modifiable risk factors for delirium, improving cognition, and optimizing sleep, mobility, hearing, and vision in critically ill adults.	Conditional	Low

Adapted from Devlin et al.²²

SYMPTOM MANAGEMENT: DYSPNEA

Dyspnea is a prevalent symptom in the critically ill population.³³ Puntillo and other members of the IPAL-ICU Advisory Board conducted a comprehensive literature review related to palliation of pain, dyspnea, and thirst.³³ Optimal treatment for dyspnea was found to be identification and amelioration of the underlying condition, patient positioning, and, sometimes, supplemental oxygen. As for other symptoms, the use of a standardized symptom assessment scale is correlated with better outcomes. The *Respiratory Distress Observation Scale* is the only reported behavioral scale for assessment of dyspnea. A systematic review by Lorenz and colleagues focused on the management of dyspnea at end of life.³⁴ Strong evidence supported the use of beta-agonists and opioids in patients with chronic obstructive pulmonary disease, and weak evidence supported the use of opioids to relieve dyspnea in patients with cancer.

Several options are available for the treatment of dyspnea in patients at end of life. Systemic opioids, either oral or parenteral, are considered first-line medications. Opioid receptors are found in the respiratory centers of the brain and peripherally in the respiratory tract and lung tissue. Clinicians have suggested that nebulized opioids would result in less systemic absorption, leading to a safer clinical profile. However, robust trials and systematic reviews have found these to be no more effective than placebo.³⁵ Guidelines from the American College of Chest Physicians recommend the use of systemic opioids for relief of dyspnea.³⁶ A robust Cochrane Review concluded that evidence does not support the routine use of benzodiazepines in patients with dyspnea without coexisting anxiety.³⁷ However, the treatment of underlying conditions that exacerbate dyspnea, such as edema or inflammation, can provide benefit if glucocorticoids, bronchodilators, and diuretics are used.³⁵

SYMPTOM MANAGEMENT: OTHER CONSIDERATIONS

Although pain, dyspnea, and thirst are three of the most distressing and prevalent symptoms reported by critically ill patients,³³ other distressing symptoms can occur. These include anxiety, depression, nausea and vomiting, and sleep disturbances. The appropriate chapters in this text provide full discussions, as these are not unique to the ICU. What *is* unique is the impact that the delicate balance between the ICU goals of rescue and hemodynamic stability and the palliative goals of comfort and quality of life has on treatment plans. The palliative APRN needs to be aware of the medications and alternate routes that can be used in the ICU for patients across the continuum of survival to end of life because barriers exist to medication administration and choice of agents.³⁵ The choice of pharmacologic agents to treat symptoms must be considered after clear goals of care are established between the patient/family, ICU team, and palliative team.

Although symptom management requires a multimodal approach, pharmacologic agents are often used by the palliative APRN to relieve general symptoms. The route of

administration is predominantly intravenous, but if this route no longer exists, medications can be given by the buccal, sublingual, rectal, nebulized, or transdermal route. Liquid concentrates, sometimes referred to as *intensol* (i.e., lorazepam intensol), are up to 10 times more potent and can be given orally in very small volumes. These are considered high-alert medications by the Institute for Safe Medication Practices. Topical agents may be used with the intent of systemic absorption to control symptoms at end of life, but the APRN should be cautious about using compounded formulations because evidence is lacking to support efficacy. Frail or cachectic patients may have lower absorption and therefore inadequate symptom management due to low body fat stores. Transdermal fentanyl patches must be used with caution in this scenario or not at all. Rectal medications should be avoided in patients with thrombocytopenia, neutropenia, diarrhea, abdominal-perineal resection, and anorectal disease. Although many agents can be given by this route, patient comfort and choice must be considered. The subcutaneous route may be used as an alternate to the intravenous route but does result in slower drug absorption rates. These are limited to volumes of 1 mL or less, but continuous infusions can be administered if more than 1 mL is needed and have been shown to provide more stable symptom control. Limited evidence supports the use of nebulized morphine and fentanyl and these should not be used as a regular alternative to parenteral or oral formulations. Nebulized lidocaine has been shown to be effective for intractable cough at end of life.³⁵

THE PALLIATIVE APRN'S ROLE IN COMMUNICATION

Skilled communication is at the core of effective palliative care integration across all settings and is especially critical in the ICU. The transition from goals of rescue and cure to goals of comfort—or mixed goals combining elements of intensive care and palliative care—can be a turbulent time for patients, families, and the ICU team. The palliative APRN is ideally equipped with communication skills to help all stakeholders navigate this transition. As mentioned earlier in this chapter, the ICU setting is unique due to the delicate balance—and the potential divide—between ICU goals of rescue and the palliative goals of comfort and optimal quality of life. The ICU is the epitome of the technological imperative, so for a patient or family to request, or a consultant to suggest, the discontinuation or withholding of such technology can be a source of conflict unless grounded in expert listening and communication skills. Communication between ICU clinicians and families has been described as a delicate dance with many complex issues embedded in the relationship.³⁸ Skill is needed to deal with that complexity (see Chapter 32 “Advance Care Planning” and Chapter 33 “Family Meetings”).

Regular communication between critically ill patients and their families and the ICU team is now considered an essential component of high-quality care.^{2,5,39} Many studies have shown the value of proactive, structured clinician–family

communication in the ICU on the establishment of goals of care. These same studies have demonstrated a positive impact on family members' psychological well-being, consensus among surrogate decision-makers and the ICU team, and utilization of ICU resources.^{2,39-43} Yet regular meetings between families and ICU clinicians, as the standard of care, remain the exception and not the rule in many ICUs.²

The fact that practice is lagging behind evidence in this case may be due to the high incidence of surrogate decision-makers in the ICU. It is estimated that as many as 95% of critically ill patients lack decision-making capacity, requiring families to step forward to make often-difficult treatment decisions.⁵ Prognostic uncertainty also exists, although at least one study reported that 87% of surrogate decision-makers preferred that physicians discuss an uncertain prognosis, as they consider this uncertainty to be an unavoidable feature of critical illness.⁴⁴

The palliative APRN can use specific, evidence-based approaches to facilitate communication and goal setting in the ICU and remove the obstacles to family conferences. Competing time demands, lack of space, cultural differences, language barriers, and clinicians who are inadequately trained in communication skills are barriers to family conferences in the ICU setting.⁴⁵ Families are more satisfied with ICU communication when relational comments outweigh informational content (i.e., physiological data), when clinicians spend more time listening to and less time talking at the family members, when the family members feel their perspective is valued, and when their emotions are acknowledged and supported.⁵ The APRN can use the *Care and Communication Bundle*² developed by the IPAL-ICU project. This bundle is a systematized set of activities that culminate in a structured family meeting. It entails several crucial steps, including time frames that are evidence-based. Strategies for improving communication in the ICU are shown in Box 9.2.

Finally, authentic teamwork that involves communication among all team members, regardless of rank or position,

is essential to improve palliative care integration in the ICU. Experts assert that interdisciplinary collaboration based on open communication and mutual respect is the single most important element for success.² The palliative APRN should drive such team collaboration based on an understanding of the ICU culture and the evidence behind proactive, structured communication between patients, families, and the ICU team.

RESUSCITATION OUTCOMES AND THE WITHHOLDING AND DISCONTINUING LIFE- SUSTAINING TREATMENTS

A strong working knowledge of resuscitation outcomes and guidelines for discontinuation of life-sustaining treatments is a required element of the palliative APRN's practice in the ICU. This knowledge is essential for optimal outcomes in patient/family meetings, for prognostication, and to achieve congruence between the patient's preferences for treatment and the ICU treatment goals.

Since cardiopulmonary resuscitation (CPR) was first reported in a 1960 study,⁴⁶ overall survival to hospital discharge has remained essentially unchanged for decades.⁴⁷ The American Heart Association issued 2013 consensus recommendations to improve survival after in-hospital cardiac arrest.⁴⁷ The current prevalence of in-hospital cardiac arrests outside the ICU setting is 3.66 in 1,000 adult admissions and 1.14 in pediatric admissions, with 45% of adult and 65% of pediatric arrests occurring in ICUs. Adult survival to discharge after an in-hospital cardiac arrest is 18%, with a 1-year survival of 6.6%. This survival rate was similar to the survival rate of 17% that Weil and Freis reported in 2005 in their analysis of more than 14,000 in-hospital cardiac arrests⁴⁸ and in an earlier study by Peberdy and colleagues of 14,720 cardiac arrests.⁴⁹ More recent studies of out-of-hospital cardiac arrests show similar outcomes. A study conducted in Sweden analyzed more than 30,000 out-of-hospital cardiac arrests to determine whether bystander CPR performed before the arrival of Emergency Medical Services (EMS) correlated with survival and found that 30-day survival was 10.5% versus 4.0% when no CPR was performed.⁵⁰ Yan and colleagues conducted a systematic review and meta-analysis of 141 studies and 1.5 million incidents of out-of-hospital cardiac arrest completed between 1975 and 2019.⁵¹ They found that return of spontaneous circulation after CPR was 29.7%, survival to hospital admission 22%, survival to hospital discharge 8.8%, 1-month survival 10.7%, and 1-year survival 7.7%. Survival was more likely if the out-of-hospital cardiac arrest was witnessed, the victim received bystander CPR, and they were living in Europe or North America. The investigators concluded that global survival rates have increased over the past 40 years, but it should be noted that this survival-to-discharge rate of 8.8% in out-of-hospital cardiac arrests compares to the 17% survival rate of in-hospital cardiac arrest reported in earlier studies.

The American Heart Association has raised concerns that the current culture of hopelessness in outcomes after

Box 9.2 EVIDENCE-BASED COMMUNICATION STRATEGIES

1. Train clinicians in communication skills.
2. Conduct family meetings early in the ICU admission.
3. Increase proportion of time spent listening to family members.
4. Use VALUE mnemonic during family meetings:
 - a. *Value* statements by family members
 - b. *Acknowledge* emotions
 - c. *Listen* to family members
 - d. *Understand* who the patient is as a person
 - e. *Elicit questions* from the family members

Adapted from Troug et al.⁵

in-hospital cardiac arrests may lead to the early discontinuation of life-sustaining treatment and has noted that CPR outcomes should be interpreted with caution due to the lack of consistency in reporting these events.⁴⁷ Also, the rising use of therapeutic hypothermia is changing resuscitation outcomes. Three studies, conducted between 2002 and 2011 with a total of 1,391 participants, show better outcomes in the setting of the shockable rhythms of ventricular tachycardia and ventricular fibrillation; survival in this population ranged from 55% to 66%. For patients presenting with asystole or pulseless electrical activity, 8% had a favorable outcome from therapeutic hypothermia.^{52–54} Worse outcomes were associated with advanced age, low ejection fraction, seizures, and hemodynamic instability.^{52–54}

The palliative APRN should keep abreast of resuscitation outcomes in the ICU and the difference in outcomes between in- and out-of-hospital cardiac arrests or whether therapeutic hypothermia was performed. The APRN should use this prognostic data in combination with the patient's preferences and advance directives as the basis for discussions about whether to withhold or discontinue life-sustaining treatment. Such decisions are commonly made in the ICU setting, and the palliative APRN may be consulted to drive such decisions. There is no ethical distinction between withholding or discontinuing life-sustaining treatment, and experts consider that it is morally and legally permissible for a patient or his or her surrogate to make such life-limiting choices.^{55–57} Discontinuation of life-sustaining treatment has broad support in the United States and is based on three principles: discontinuing and withholding are equivalent, allowing death and killing are clearly distinct, and the doctrine of double effect.⁵

Even though there is no ethical distinction between withholding and discontinuing treatment, clinicians are generally more comfortable with the former. The decision to offer or discontinue an intervention should be based solely on a honest risk–benefit analysis in light of the patient's goals and preferences. High courts have upheld a person's right to refuse any unwanted medical treatment, even if life-sustaining.⁵ Thus, discontinuing such treatment, even if death follows, is considered to be allowing the person to die from the underlying condition and not to be killing. Finally, the principle of double effect applies to discontinuing or withholding life-sustaining treatment. The philosophical doctrine of double effect draws a moral distinction between giving medications with the intent to allow a natural death free from suffering and giving medications with the direct intent to kill the patient.^{5,56}

If the palliative APRN is coordinating discontinuation of life-sustaining treatment, several principles guide care. First, words matter. The APRN should be careful to use the words “discontinuation of technology,” avoiding the phrase “discontinuation of care.” Language is important, especially to family members who will live with the memory of their loved one's death. Second, there is no single, universally accepted protocol for discontinuation of treatment, so the APRN should be aware of unit or system policies and procedures. Acceptable strategies include nonescalation of current therapies and discontinuation of some or all current support.

The process of discontinuation may be gradual or immediate. Communication with the family and among the team should occur prior to removal of life-sustaining treatment. Third, the palliative APRN should anticipate symptom management needs, especially respiratory distress, if the patient is removed from mechanical ventilation and extubated. The possibility of stridor and airway compromise should be anticipated, and interventions, such as racemic epinephrine, should be readily available. Cook and Rucker³ found that no or only a low risk of physical distress is associated with discontinuation of renal replacement therapy and inotropes or vasopressors, but a risk of dyspnea is associated with removal of the endotracheal tube and mechanical ventilation. Again, the APRN should be prepared for distressing symptoms in order to act quickly.

Finally, multidisciplinary team members, such as the chaplain or social worker, should be recruited to offer additional support for the family and the ICU team.³ Cook and Rucker outline activities of dignity-conserving care in the setting of discontinuation of life-sustaining technology: awareness of one's attitudes and assumptions, dignity-enhancing behaviors such as sitting down and not rushing, using compassion to be sensitive to the suffering of others, and engaging in dialogue that acknowledges the personhood of the patient.³ The palliative APRN can serve as a role model for these dignity-enhancing behaviors to the ICU team when such treatments are discontinued.

THE PALLIATIVE APRN'S ROLE IN QUALITY IMPROVEMENT IN THE ICU

Due to several national initiatives, the palliative APRN has multiple resources for QI in the ICU. In 2002, the Robert Wood Johnson Foundation established the Promoting Palliative Care Excellence in Intensive Care project. The aim was to balance medically aggressive or even futile care with goal-directed palliative care. Seven domains were identified for QI: patient- and family-centered decision-making, communication, continuity of care, emotional and practical support, symptom management, spiritual support, and emotional and organizational support for ICU clinicians. The IPAL-ICU project at the Center to Advance Palliative Care⁵⁵ provides a wealth of resources for the palliative APRN to use in QI initiatives. In the Improvement Tools section, there are templates for family meetings, pocket cards to use for family conferences, professional education materials, and other resources. Also, the palliative APRN could use the PADIS guidelines to monitor the quality of outcomes related to the management of pain, agitation, or delirium in the ICU population.

National educational programs are also available that could form the basis for QI. The End-of-Life Nursing Education Consortium (ELNEC) was established more than 10 years ago with the goal to educate nurses, thereby improving the care of patients at end of life. An ELNEC curriculum specific to critical care was developed in 2006. In a statewide effort to educate critical care nurses, ELNEC was shown to be an effective strategy to improve end-of-life care in the ICU.⁵⁸

PALLIATIVE CARE AND CRITICAL CARE IN THE 2020 CORONAVIRUS PANDEMIC

The coronavirus global pandemic in 2020 presented unique challenges to the provision of palliative care in the ICU setting. In the early months, some ICUs and their teams, especially in the Northeast, were overwhelmed with critically ill patients suffering from COVID-19 infection. The consequences of this pandemic and the need to adjust care practices and family visitation policies had a direct effect on ICU and palliative care teams. These challenges included the evolving scientific understanding of the optimal way to treat patients with COVID-19, procedures to keep healthcare personnel safe with personal protective equipment (PPE), care practices that minimized exposure time, and mortality rates with the inherent proximity to the dying process that had a cumulative impact on the well-being of nurses and ICU teams.⁵⁹

The morbidity and mortality rates associated with COVID-19 highlighted the need to integrate palliative care and critical care. Rosa, Ferrell, and Wiencek reported on the resources available to palliative care and critical care teams to optimally support patients and their families and, as importantly, their teams.⁵⁹ Many professional associations offered high-quality COVID-19 resources free of charge on their websites.⁵⁹ The palliative APRN is directed to those sites as the pandemic continues to be a challenge to holistic care and clinician well-being.

PALLIATIVE CARE IN THE EMERGENCY DEPARTMENT

Many of the conditions and challenges that the palliative APRN must manage in the ICU setting also apply to the emergency department (ED) setting. The challenges of balancing the goals of cure and aggressive interventions against the reality of life-limiting disease or injuries and providing holistic care that encompasses the physical, psychological, social, and spiritual dimensions of quality of life in a typically frenetic environment are the same. As discussed in this chapter, the palliative APRN should use evidence-based pain and symptom management, use skilled communication with patients and families and the ED team, be familiar with resuscitation outcomes, and be sensitive to the workflow of the ED setting. The APRN is directed to Chapter 10, The Palliative APRN in the Emergency Department and the rich resources provided by the Center to Advance Palliative Care's initiative to integrate palliative care practices in the emergency department.⁵⁵

SUMMARY

Palliative care is now considered an essential component of high-quality critical care. ICU patients experience serious or life-threatening illnesses and the associated symptom burden. Distressing symptoms are common in the critically ill and are amenable to the intervention of palliative APRNs. Palliative APRNs, whether in a consultative or integrative role, can improve outcomes for the critically ill in the areas of pain and

symptom management, communication enhancement and family meeting structures, withholding and discontinuation of life-sustaining treatments, and the planning and implementation of QI activities. The palliative APRN has the skills to help patients and families and the ICU team navigate the often-tumultuous transition from the ICU goals of rescue to the more palliative goals of comfort and quality of life. The time is now for the full integration of these two disciplines.

THE PALLIATIVE APRN IN THE EMERGENCY DEPARTMENT

Sarah Loschiavo and Angela Starkweather

KEY POINTS

- The role of the palliative advanced practice registered nurse (APRN) in the emergency department (ED) incorporates expert provision of care that addresses the physical, psychological, emotional, and spiritual needs of patients with life-limiting illness and their family members.
- The ED often serves as a port of entry to palliative care services for patients with complex symptoms and/or care coordination, individuals with chronic or serious illness or injury, and individuals at the end of life.
- Models of palliative care in the ED may incorporate coordinated direct-admission services, palliative care team consultations, ED-based palliative APRN champions, and partnerships with external agencies that provide palliative care or hospice services.
- The palliative APRN can use systematic methods to identify patients with the greatest need for palliative care services or to initiate consultation/referral to palliative care in the ED setting.
- The palliative APRN has an important role in ED and telephonic communication because of the critical nature and timing of conversations that influence patient and family interactions with the healthcare team and ED palliative care outcomes.

CASE STUDY: EMERGENCY DEPARTMENT PALLIATIVE CARE

Mr. A was a 55-year-old man with a history of a glioblastoma multiforme who was found unconscious at home by his wife. En route to the hospital, the paramedics intubated him and provided basic life support. When he arrived in the ED, he immediately received a head computerized tomography (CT) scan and laboratory studies. The CT scan revealed a large tumor in the left temporal lobe, midline shift, and impending uncal herniation. Uncal herniation occurs secondary to large mass effect (glioblastoma) that will lead to increased intracranial pressure and herniation. Uncal herniation carries a lethal prognosis due to the direct compression of the vital midbrain centers. His wife was at the bedside, and, upon questioning, she stated that her husband complained of a headache over the past week but was otherwise

tolerating his cancer treatment. The attending neurosurgeon arrived at the bedside and recommended emergent neurosurgical decompression.

The palliative advanced practice registered nurse (APRN), Elizabeth, was called to provide support to Mr. A's wife and address the goals of care. On arrival at the bedside, Elizabeth realized she had cared for Mr. A during previous ED visits for complications related to his cancer and treatment. During his last ED visit, Elizabeth introduced palliative care and coordinated a referral to the outpatient palliative care clinic where he was being co-managed by medical oncology and palliative care in the setting of his aggressive cancer.

Without decision-making capacity, Mr. A's surrogate decision-maker was his wife. Elizabeth's initial priority was to ensure that Mrs. A understood her husband's condition, all treatment options available, and his prognosis. Elizabeth explained that while emergency medical treatments were keeping him alive, her husband was critically ill, and further interventions such as surgical decompression would only prolong his dying. Specifically, Elizabeth explained that there were three directions for his care: (1) surgical decompression for palliation (noncurative) with high risk of complications and immediate death, (2) sustaining life through artificial means as a short-term measure until brain death or cardiovascular arrest occurs, or (3) discontinuing life-prolonging therapies to allow a shift to comfort-focused care during the progression to natural death. Elizabeth asked Mrs. A the question "if your husband was here, what would he say?" Mrs. A responded "my husband's greatest fear was being in a coma and that he would not want to live in a way that he could not care for himself." His wife recalled a visit with his medical oncologist where they discussed cardiopulmonary resuscitation. When they arrived home that day, they had a discussion about what he would want done if there was clearly no chance of recovery from illness or injury. At the time, her husband stated that he hoped she would let him go, to allow natural death since he was certain he would be going to a better place rather than having to live out a life that was dependent on everyone else.

There were no advance directives present in the electronic medical record, and his wife stated they never completed the advance directive document. However, Mrs. A's statements regarding her husband's wishes and preferences provided adequate information to suggest that he would have made the decision to discontinue life-sustaining measures to allow natural death.

At this point, the wife asked if she should call their daughter to come to the hospital because she was a college freshman living

in a different part of the state. Recognizing that Mr. A would likely face impending death upon discontinuation of life-sustaining medical treatment, the APRN directed the focus of care to the family. While immediate discontinuation of mechanical ventilation would avoid any further suffering and use of resources that would not contribute to the recovery of the patient, this approach did not provide time for the family to say their last goodbyes, deal with the psychological and emotional aspects of the unexpected death of their family member, or perform necessary spiritual or religious rituals.

Elizabeth discussed the benefits and burdens of having the patient's 18-year-old daughter see her father in this condition. Mrs. A and Elizabeth decided that allowing her daughter to see that all possible measures had been taken would provide emotional comfort and closure for her. Elizabeth offered to call Mrs. A's daughter, but she insisted that she wanted to communicate with her directly and make sure she could travel safely to the hospital. Elizabeth then offered information on the next steps. This included the dying process, either in the ED or after transfer to the ICU. After the discussion, a plan was created with his wife to continue mechanical ventilation until after the daughter arrived and had time with her father; however, if cardiac arrest occurred before she arrived, compressions would not be initiated.

In addition, Mrs. A was informed that since her husband had a catastrophic brain injury and remained on mechanical ventilation, the local organ procurement organization was contacted as part of hospital procedure. The ED staff left the discussion of organ donation to a trained designated requestor or the organ procurement organization representative (a process that depends on state policy and procedures).

Mrs. A was very decisive about her husband wanting to donate his organs, and his wishes were further indicated on his driver's license. The patient's daughter arrived and was greeted by the social worker who provides emotional support for anticipatory grief. The daughter agreed that her father would want to proceed with organ donation, as he had mentioned this on several occasions. The family members expressed their comfort in knowing that their loved one's last act was one of giving, something he would have wanted. Elizabeth used molding clay to create a handprint as a remembrance. She then contacted the hospital chaplain for prayer and to perform a religious ritual as requested by the patient's wife. The family members said their last goodbyes to their husband and father before he was transferred to the ICU for organ procurement. Elizabeth provided bereavement information, and the social worker and chaplain stayed with the family to provide support until they were ready to leave the ED.

In the scenario of an imminent fatal outcome, the ethical values of beneficence and nonmaleficence extend to the patient's family as well as to the patient. Confronted with an unexpected fatal event, it is often unreasonable to expect a grieving family to make immediate decisions. However, Elizabeth established the patient's and family's goals of care and created a treatment plan to align with their goals, which incorporated their religious rituals and allowed the patient's family time to be present with him during the dying process. This case demonstrates the vital role of the advanced practice

registered nurse (APRN) in the ED to integrate palliative care for all patients who suffer from serious, chronic, and life-limiting illness. ED visits increase as serious illness progresses, regardless of the underlying disease, and as patients approach the end of life. The ED visit may present a unique opportunity for the APRN to connect patients in need with palliative care consultation and services. Early integration of palliative care concurrent with active treatment is optimal and recommended for all patients with advanced cancer.

This case also illustrates the decision-making process regarding palliative care and end-of-life care in a patient with an acute event. Advance directives were not available to help inform decisions, but the wife had previously discussed situations such as living in a coma and being incapacitated as well as whether her husband would want cardiopulmonary resuscitation when facing a terminal prognosis. The APRN utilized members of the interprofessional team to address the physical, emotional, psychological, and spiritual needs of the patient and family unit, thus providing holistic care.

Although not all scenarios are as clear-cut as this one, the APRN has a vital role in initiating such conversation in the ED, understanding disease trajectories of approaching death, establishing goals of care, and determining advance care planning. Often the patient's prognosis may not be clear until more invasive measures have taken place, which makes it challenging for the APRN to make the transition from the goals of cure to relieving suffering and providing comfort in death. In other situations, families may not agree with the goals of care, thus requiring lengthy discussions among the APRN, other consultants, and the family.

The scenario also demonstrates the process of shared decision-making between the provider and family. Once the prognosis is clear and the family understands the prognosis, this process can become much easier. However, establishing trust is imperative. Demonstrating that decisions will be made based on what the patient and family need, rather than the provider's goals, can take time. The APRN can serve as a consistent provider in these discussions (see Chapter 32, "Advance Care Planning" and Chapter 34, "Communication at End of Life" for further information).

INTRODUCTION

This chapter outlines the role of the palliative APRN in the emergency department (ED) and highlights strategies to identify patients at the greatest need for palliative care and the successful integration of palliative care in the ED setting, as well as common barriers to implementation. Various models that may be used are described, along with approaches to operationalize the provision of palliative care to patients in the ED. Methods to evaluate palliative care services in the emergency department are discussed, along with guidelines for delivering notification of death by telephone or use of other technologies.

Advances in disease-targeted therapies that have greatly enhanced survival and the world's aging demographics translate into a growing percentage of the overall population living

with serious illnesses such that one in every three adults suffers from multiple chronic conditions.¹ A growing number of patients with serious illness(es) and complex needs present to the ED, with one of the most frequent users of ED services being individuals over the age of 65 years; more than 50% of older adults visit the ED in the last month of life, and many are subsequently admitted and die in the hospital.²

Emergency medicine has traditionally focused on preserving life by providing rapid, aggressive resuscitation and stabilization of acutely presenting health conditions or injuries while palliative care needs have been delegated to other professionals and excluded from standard ED services. However, many patients present to the ED with complex physical symptoms or nonphysical aspects of suffering, life-limiting disease, and/or injuries that necessitate an alignment of the clinician's prognostic evaluation, the patient's values, and realistic goals of care. In these cases, the limited focus on acute stabilization and determination of an appropriate disposition can generate additional confusion and frustration for patients and families whose needs remain unmet or who are provided with care that is incongruent with their values, goals, or preferences.

The interactions that occur in the ED present key decision points that can influence the patient's treatment trajectory and set them on a pathway that is not congruent with their goals of care. A key to resolving this dilemma is through integrating palliative care in the ED because palliative services can be incorporated into patient care at any time along the trajectory of any type of serious illness, concurrent with curative, restorative, and any life-prolonging therapies.³ Because evidence has shown that early integration of palliative care into the care plan for seriously ill patients can improve quality of life and care coordination for the patient and family, there has been increased emphasis on identifying patients in the ED setting who would benefit from palliative care services.⁴ In addition, because palliative care principles and practices can be delivered by all clinicians who provide care to seriously ill patients in any setting, there is an enormous need to ensure that ED providers and personnel are equipped with the knowledge, skills, attitudes, and collaborative infrastructure to coordinate palliative care at any stage of illness or injury.

Recognition of missed opportunities for initiating palliative care early in the patient's course of illness and the challenges in identifying patients and families with difficulty in managing symptoms or other nonphysical aspects of illness have spurred the need to integrate palliative care into the ED setting.^{5,6} Management of physical suffering in the ED may entail symptomatic treatment of pain, dyspnea, loss of appetite, neurological deterioration, or general distress, which are typically part of a much longer trajectory of the patient's illness experience. In addition, assessment and management of nonphysical aspects of suffering are equally important and may involve cultural, psychological, social, spiritual, financial, ethical, and legal issues that influence the patient's care coordination.³

Palliative APRNs are leaders in clinical care, education, advocacy/policy, research, and administration/management, and this role can positively enhance holistic integration of palliative services in care provided within the ED.⁷ Specific to the

ED setting, the palliative APRN has an important clinical role in promoting care that is aligned with patient values and preferences. Major challenges to healthcare professionals in the ED include balancing the goal to cure against the context of life-limiting disease/injuries and incorporating physical, psychological, emotional, and spiritual needs in the provision of ED care. The palliative APRN can fill these gaps in care and address the multiple challenges to palliative care implementation that are frequently encountered in the ED setting as well as in other areas of healthcare.

Given the demands of making healthcare decisions in the ED, palliative APRNs can play an instrumental role in ensuring that patients and families are fully informed and understand the prognosis and its implications for management options; they can also foster a plan of care that is guided by the patient's values. With appropriate timing, education, palliative care models, and the increasing role of palliative APRNs in the ED, recent studies demonstrate the positive outcomes of palliative care initiation and coordination.⁸ These include improved patient outcomes, family and patient communication and satisfaction, reduction in hospital costs and patient's length of stay, and increased appropriate direct hospice consults.^{9–12}

PALLIATIVE CARE MANAGEMENT IN CRISES

In addition to serving the health needs of patients and families, the ED is a coordination hub for humanitarian crises and disaster management related to bioterrorism, geological and weather-related hazards (earthquakes, hurricanes, tornadoes, floods, and fires), mass casualty incidents, and public health emergencies such as COVID-19. Humanitarian crises that involve the sudden arrival of multiple critically ill patients require the implementation of multilevel triage, strategies to address surge capacity, and ability to manage resuscitation, stabilization, and palliation needs based on accessible resources, personnel, and infrastructure.¹³ During the COVID-19 pandemic, palliative APRNs have been leading such coordination efforts, particularly in the integration of palliative care in the ED for patients with COVID-19, and implementing new models of triage, identification, and patient and family communication.¹⁴

Integrated ED palliative care during crises serves a vital role in establishing the patient's wishes for life-sustaining treatment such as intubation and resource-intensive cardiopulmonary resuscitation and ensure they are aligned with a patient's goals and values.¹⁵ Having designated palliative care providers in the ED as well as providing palliative care education to all ED clinicians can help to avoid life-sustaining treatments in patients with a poor prognosis that are unlikely to be beneficial or that have a high risk of causing additional suffering.¹⁶ The high volume and acuity of patients during a crisis makes it extremely challenging for ED clinicians to take adequate time to clarify goals of care. Palliative care providers have a critical role during crises in identifying patients at the point of triage or initial assessment who may benefit from having crucial

conversations concerning goals of care, values, and preferences and in initiating communication with next of kin. Timely goals-of-care conversations by the palliative APRN can help avoid unwanted life-sustaining treatments for patients with a poor prognosis and provide comfort and support for families during their sudden and unanticipated loss.¹⁷

ADDRESSING RACISM AND HEALTH DISPARITIES IN THE ED

The ED serves as an entry point to the healthcare system, often due to lack of access to primary care, lack of insurance, and convenience of “on-demand” care.¹⁸ Despite advances and the growth of palliative care programs, low-income and minority populations remain significantly underserved.¹⁹ Research has documented racial differences in hospice use and end-of-life treatment intensity consistent with a broad range of disparities in healthcare use and health outcomes.²⁰ Reasons for these disparities include preferences for more aggressive care, mistrust of the healthcare system, lack of in-home resources, and miscommunication and misunderstanding of treatment options. There are several barriers to high-quality palliative and end-of-life care among racial/ethnic minority adults. Some of the barriers are due to institutional racism, including unfair profiling and denial of treatment or services, while other barriers are social or structural in nature, including economic insecurity, lack of adequate insurance, geographic location, cultural and spiritual values about health and medicine, underrepresentation of minorities in medicine, and the dismantling of affirmative action programs.²¹ Additionally, provider-level barriers, including communication and perceptions of discrimination, exist.²² Efforts to reduce disparities in the quality of palliative care must be prioritized. Targeted efforts to increase advance care planning, early palliative care integration, and hospice services among underrepresented populations should be expanded in order to improve health equity and ensure culturally sensitive care coordination.²³

For millions of Americans living in vulnerable rural and urban communities, the ED is an important—and often their only—source of healthcare.²⁴ Transformation among hospitals and healthcare systems is needed to address communities at risk of losing access to the healthcare services and resources they need to improve and maintain their health.²⁴ A recent study by Hanchate et al.²⁵ measured the differences in ED destination by the race/ethnicity of patients transported by emergency medical services (EMS) from the same geographic area. The study found race/ethnicity variation in ED destination for patients using EMS transport, with Black and Hispanic patients more likely to be transported to a safety-net hospital ED compared with white patients living in the same ZIP Code. A study by Hanna et al. showed disparities in the utilization of advanced imaging during emergency room visits.²⁶ Institutional racism in funding community resources such as EMS, housing, schools, and transportation, along with an ongoing lack of education and financial opportunities, perpetuate the need for ED services in low income neighborhoods and individuals in minimum-wage positions who

often must hold down multiple jobs to make ends meet. The role of emergency medicine healthcare professionals is significant as racial and ethnic communities seek healthcare in the ED. An increase in the size of vulnerable populations served by EDs is an important contributor to increases in ED visits.²⁷ Language barriers and lack of interpreter services impede healthcare delivery in the ED setting.

According to the Centers for Disease Control and Prevention, despite years of attention to disparities, the racial gap in Americans’ health continues to widen.²⁷ Evidence of disparities is most plentiful for African Americans. Of note, 80% of all heart failure hospitalizations originate in the ED. Racial disparities in hospitalization rates for ED patients with heart failure are well-documented.²⁸ African Americans are approximately 1.5 times more likely than white patients to be denied authorization for their ED visit.²⁷ Black individuals are significantly less likely to use hospice and more likely to have multiple ED visits and hospitalizations and undergo intensive treatment in the last 6 months of life compared with white individuals regardless of cause of death.²⁹ The top three causes of death in the United States are the same for Blacks and Whites, but the rates of death for Black people are strikingly higher: heart disease (30% higher), cancer (30% higher), and stroke (40% higher). African Americans prefer more “aggressive” care when seriously ill, which is influenced by cultural and religious values and perspectives.^{30,31} Palliative care teams have a significant role in helping patients reframe the meaning of their spiritual beliefs in the context of their medical circumstances in ways that do not exclude care in hospice and palliative care settings. In 2010, the American Academy of Pediatrics released a report reviewing the extant literature on racial/ethnic health and healthcare disparities among US children, concluding that care disparities were “extensive, pervasive, and persistent.” Black and Hispanic children faced disparities in emergency care across multiple dimensions when compared to non-Hispanic White children, while Asian children did not demonstrate such patterns.³²

The COVID-19 pandemic and recent social justice movements in the United States have led to an important moment for the palliative care community to step back and consider opportunities for expansion and growth.³³ The COVID-19 pandemic has shown that communities of color are disproportionately affected, with a higher burden of morbidity and mortality seen among African Americans.³⁴ Death rates from COVID-19 are three times higher nationally in Black counties compared with White counties, with 70% of deaths occurring among Blacks in certain states. Cultural humility enables healthcare practitioners to remain present to the individual patient’s reality and be able to assist them in making decisions that best align with their values regardless of prognosis or resource allocation limitations during a pandemic. In medical decision-making conversations, it is important to affirm a patient’s life first and subsequently what is important to them. This builds a foundation of trust that bridges difference in culture, ethnicity, and religion.³⁵

Due to long-standing systemic racism, the reasons for disparities in care and health outcomes are multifaceted, arising from individual and institutional sources that are conscious

and unconscious.³⁵ The moral duty of all healthcare providers is to ensure equity across all realms of decision-making and within the healthcare system and to consistently demonstrate authentic trustworthiness to all people.³⁵ Only when the importance of palliative care in the ED is recognized by both those that work there and those in palliative care, and the necessary skills are acquired, can systems begin to change to enable an environment better suited to its delivery.³⁶ Additionally, targeted efforts to increase advance care planning among Black and other racial minority populations should be expanded.²⁹

THE ROLE OF THE PALLIATIVE APRN IN THE ED

The role of the palliative APRN in the ED entails direct clinical care, education, and policy development and implementation, as well as research and administration.⁷ The palliative APRN plays a major role in identifying patients with palliative care needs.³⁷ Unlike other settings in which the diagnosis is known and the plan of care is clear, patients arriving to the ED are often confronted with options of undergoing a range of diagnostic tests and procedures before the net benefit can be considered regarding patient/family goals of care, life expectancy, or improvement in quality of life.

The palliative APRN can play an instrumental role in eliciting information from the patient and family that can inform decisions regarding the workup and plan of care in the ED.⁸ Palliative APRNs facilitate decisions that are aligned with the patient's values in the context of serious or life-limiting disease/injury as well as patient and family wishes and preferences when cure is no longer possible. The palliative APRN's assessment of the physical, psychological, emotional, and spiritual needs of the patient and family can have dramatic implications for the course of care provided. The role of the palliative APRN in the ED setting incorporates a process of negotiation among healthcare professionals, the patient, and family members to define realistic goals of care in the context of the patient's wishes and preferences.

A critically important role and prerequisite skill for aligning the goals of care with patient and family wishes and preferences is initiating difficult conversations. Palliative APRNs have exquisite skill in eliciting information from patients and family members as well as guiding crucial conversations that are culturally sensitivity and can inform the provision of patient-centered care in the ED.³⁷ The ED setting may be the first place in which the patient's prognosis is fully understood by the patient and family. Assisting the patient and family as they encounter limitations in life-preserving measures and the possibility or reality of death is a major role of the palliative APRN in the ED setting.

Coordination of care is another major role of the palliative APRN in the ED. This role incorporates navigating the healthcare system and accessing resources for the patient and family that support palliative care. Care transitions represent one of the most significant challenges to continuity of care and increase the risk of readmission.³⁸ Ensuring that all providers

involved in the care of the patient are informed of the palliative care plan and making certain that adequate resources are provided to address the trajectory of declining health status, distressing symptoms, and caregiver needs are important aspects in the palliative APRN's coordination of care.

The unique perspective of the palliative APRN also provides a foundation for advancing palliative care in the ED setting. Although there is a movement toward incorporating palliative care principles and practices utilizing the End-of-Life Nursing Education Consortium (ELNEC) Critical Care Curriculum across healthcare disciplines,^{39,40} the culture and infrastructure of the ED is currently based on rapid decision-making and determination of disposition to maximize revenue. The palliative APRN can be a resource and change agent by providing education to ED physicians, nurses, and staff regarding the identification of patients with palliative care needs, initiating conversations about palliative care with patients and families, and establishing palliative care services in the ED.

A change in the ED culture toward patient-centered care can result in an expansion of the palliative APRN's role in areas of policy development and implementation, research, and administration in order to integrate a care model that facilitates the goals of ED care while enhancing the ability to effectively provide palliative care services. Obtaining and analyzing data on patient palliative care needs in the ED as well as disposition and follow-up can initially inform the most relevant model of care to consider.³⁷ In addition, policies and procedures for identifying patients and families who would benefit from early palliative care services in the ED and quality improvement of the care coordination are other areas in which the palliative APRN can have great influence.

IDENTIFYING PATIENTS WHO NEED PALLIATIVE CARE IN THE ED

One of the major challenges to efficient implementation of palliative care services in the ED is identifying patients early in the patient encounter and trajectory of serious illness. Patients at high risk for needing palliative care can be identified through triggers or high-risk characteristics. Palliative APRNs may be responsible for selecting such triggers to embed in the electronic health record as well as educating triage nurses and EMS personnel on appropriate assignment to palliative care champions in the ED.

Triggers for palliative care consultation are listed in Table 10.1 and may include elderly patients with life-limiting conditions, such as advanced dementia, severe congestive heart failure, chronic obstructive pulmonary disease, advanced malignancy, and/or AIDS with at least moderate functional status limitations.¹ Additional criteria have been found to be applicable in identifying patients in need of palliative care, such as having recent losses in activities of daily living, high symptom distress, poor functional status, and high levels of caregiver burden.

Questions on these topics may be incorporated as part of the triage process to assist in identifying patients who need

Table 10.1 TRIGGERS TO IDENTIFY PATIENTS WHO NEED PALLIATIVE CARE

INDICATOR	CHARACTERISTICS
Serious illness, potentially life-limiting or life-threatening condition	Advanced cancer, dementia, severe congestive heart failure, chronic obstructive pulmonary disease, multi-organ disease, AIDS with at least moderate functional status limitations
Frequent admissions	More than one admission for same condition within several months or increasing frequency
Presentation due to difficult-to-manage physical or psychological symptoms	Moderate to severe symptom intensity/distress for more than 24–48 hours
Complex care requirements	Functional dependence, complex home support, high level of caregiver burden
Failure to thrive	Decline in function, feeding intolerance, or unintended decline in weight
Karnofsky Performance Scale	Performance status as predictor of survival
Palliative Performance Scale (PPS)	Predicts approximate 6-month survival
Palliative Prognostic Score (PaP)	Predicts 30-day mortality
Palliative Prognostic Index (PPI)	Predicts <3-week mortality

palliative care services and to inform assignment to the ED-based palliative APRN. Standardized screening tools have been shown to be feasible and increase the rates of palliative care referrals.⁴¹ The Palliative Care and Rapid Emergency Screening (P-CaRES) Table 10.2 can be used for rapid screening in triage.⁴¹ In addition, the 5-SPEED Box 10.1 screen was created for the purpose of identifying patients with the need for palliative care consultation.

However, because of the often urgent nature of care needs and brief encounter with triage nurses who have limited time to build rapport with patients and families, these questions are often difficult to administer. In addition, patients are often

too ill, too distressed, and unwilling to answer these screening questions in the ED setting.⁴⁰ Yet, when these factors are present on ED admission, a palliative care consultation may be beneficial. In addition, triggers may be embedded in the electronic health record to automatically ask the provider if a palliative care consultation is necessary.

One such approach is to use the surprise question as the threshold to initiate palliative care: “Would you be surprised if this patient died in the next 12 months?” When the provider answers “no” to this question (they would not be surprised), this can serve to alert the provider of the possible need for palliative care, and an automated notification to the palliative care team can be sent to initiate referral.⁴² Other triggers or prognostic indicators may include

- The Karnofsky Performance Scale
- Palliative Performance Scale (PPS)
- Palliative Prognostic Score (PaP)
- Palliative Prognostic Index (PPI)⁴³

These indicators can be used to consult palliative care services as well as initiate case management to assist in

Table 10.2 PALLIATIVE CARE AND RAPID EMERGENCY SCREENING (P-CARES) TOOL

STEP	QUESTION
Step 1	Does the patient have a life-limiting illness? <i>Select all that apply and proceed to Step 2 if one or more items are checked.</i> • Advanced dementia or central nervous system disease • Advanced cancer • Advanced heart failure • Advanced liver disease • Septic shock • Provider discretion: High chance of accelerated death
Step 2	Does the patient have two or more unmet palliative care needs? <i>Select all that apply. If two or more are checked, referral for palliative care is recommended.</i> • Frequent visits • Uncontrolled symptoms • Functional decline • Uncertainty about goals of care and/or caregiver distress Would you be surprised if the patient died in 12 months?⁴¹

Box 10.1 5-SPEED SCREEN

- Questions to assess for unmet palliative care needs
- How much are you suffering from pain?
 - How much difficulty do you have getting your care needs met at home?
 - How much are you having difficulties with your medications?
 - How much are you suffering with feeling overwhelmed?
 - How much difficulty are you have getting medical care that fits with your goals of care?

coordination of care. Coordinating the ED system with triggers or indicators of the need for palliative care can be a major role of the palliative APRN and can help drive the delivery of palliative care in the ED setting.

**DELIVERY OF PALLIATIVE CARE
IN THE ED**

Palliative APRNs play a vital role in the early recognition of critically ill patients requiring palliative care in the ED because the trajectory of resuscitation and stabilization using invasive diagnostic or treatment procedures as well as inpatient hospitalization is often set in the ED. Although 70% or more of older adults prefer quality of life over life extension, most individuals do not have advance directives on presentation to the ED.² Working from a framework of communication, the clinician in the ED can use a structured, stepwise approach to elicit information about patient and family goals of care by using open-ended questions such as, “Help me understand what you are hoping will happen?” Other tools, such as the REMAP framework (Reframe, Expect emotion, Map out the future, Align with values, Plan treatment that matches values),^{44,45} the Serious Illness Conversation Guide,⁴⁶ or the MVP (Medical situation, Values, Plan)⁴⁷ can also be useful for guiding conversations when there is limited time to build the patient–provider relationship and the plan of care needs to be quickly determined.⁴⁸

In a patient with advanced illness who is unlikely to benefit from invasive interventions, the palliative APRN should address the goals of care before initiating aggressive therapies. Immediately upon the patient’s presenting to the ED with a life-threatening emergency, full resuscitative efforts will occur unless the patient rejects treatment or an advance directive is in place. When resuscitative efforts cannot stabilize the patient’s condition and offer virtually no chance of clinical benefit, prolonged survival, or quality-of-life improvement, the palliative APRN and patient or family/surrogate decision-maker should decide whether to make the transition from resuscitation to comfort measures.

APRNs play a vital role in facilitating communication regarding the patient’s prognosis, patient and family wishes and preferences, and realistic goals of care in the ED. By following the steps in Box 10.2, they can promote communication and decision-making for patients with serious illness, acute devastating events, or individuals who are near the end of life. This process starts with determination of the patient’s decision-making capacity, identification of surrogates, and interpretation of advance directives.⁴⁹ In addition, communication to empower the patient, family, or surrogate decision-maker at the end of life should include the following⁵⁰:

- 1. Assess the patient’s or family or surrogate decision-maker’s understanding of what is happening.
- 2. Provide an honest view of the patient’s condition and prognosis.

**Box 10.2 STEPS OF PALLIATIVE
CARE COMMUNICATION**

Determine patient’s diagnosis and prognosis, decision-making capacity, surrogate, and advance directives.

- 1. Determine patient’s diagnosis and prognosis using assessment skills, documentation, or consultation with the patient’s other healthcare providers.
- 2. Determine patient’s decision-making capacity through documentation and/or verbal or written communication.
- 3. Identify the legal surrogate decision-maker.
- 4. Elicit patient values as expressed in completed advance directives or through verbal or written communication.

Discussion of integrating palliative care in the patient’s care plan.

- 1. Determine patient’s/surrogate’s understanding of prognosis, limitations of curative treatment, and expected goals of care.
- 2. Explain palliative care as a means to address quality of life and congruence between palliative care and patient’s goals of care.
- 3. Convey provider’s understanding of patient’s condition, prognosis, and treatment options with recommendation.
- 4. Share decisions regarding resuscitative efforts, invasive procedures designed to sustain life, and available resources to address patient/family physiological, psychological, social, and spiritual needs.
- 5. Consider options for organ donation.
- 6. Revise goals of treatment as necessary.

- 3. Elicit the patient’s values or the family/surrogate decision-maker’s best judgment of the patient’s values regarding end-of-life decisions.
- 4. Communicate medical information using understandable language.
- 5. Build trust and make decisions with the family that incorporate the patient’s values, beliefs, and preferences in determining the goals of care.

Continuity of care is cited as one of the most challenging aspects of palliative care from the perspective of patients and providers.^{49,50} Regardless of how aggressive the goals of care are for the patient, addressing symptom management is paramount. APRNs play a vital role in this process. First, they can ensure that symptom management strategies are used and anticipatory guidance is provided regarding expected symptoms, stages of illness, and dying. These educational topics are critical for helping the patient and family to understand the patient’s prognosis, how to obtain information and emotional support, and for reducing unnecessary ED visits. Education and planning should include the patient, family members,

and other caregivers as well as the primary care and specialty providers involved in the patient's care. Clear instructions should be provided about accessing care when necessary. Communication should also take place between the palliative care team and the primary care provider and on-call provider regarding palliative care or end-of-life management and goals of care in case a subsequent ED visit is inevitable.

MODELS OF PALLIATIVE CARE DELIVERY IN THE ED

In response to the growing number of patients with advanced illness cared for in the ED, several health systems have initiated programs to deliver ED-based palliative care, consultation, and/or coordination. There are typically three types: embedded palliative care in the ED with palliative APRNs and physicians on staff, ED-based consultation programs initiated by the inpatient (hospital-based) palliative care team, and ED partnerships with palliative care or hospice providers.

A greater number of palliative APRNs are being hired for full-time clinical practice and in leadership roles in the ED in response to the recognized need. There has been a positive response to using this model reported by other clinicians in the ED setting.⁵¹ An added benefit of having ED-based palliative APRNs is the ability to identify patients who may need palliative care as they arrive in the ED so that crucial conversations about the goals of care can take place early on. Education in palliative care practice is necessary so that uniform access to palliative care services can be provided in the ED. As more clinicians and healthcare systems are taking the opportunity to become adept at meeting the needs of palliative care patients in the ED, it is anticipated that there will be greater coordination of care. Palliative APRNs in the ED setting can play an instrumental role in advancing palliative care education and strengthening systems for the provision of palliative care in the ED, as well as in coordination of care and tracking palliative care outcomes.

Hospital-based palliative care teams routinely cover ED consultations, and the ED may provide a significant source of outpatient referrals or inpatient admissions to the palliative care team and/or unit. However, with increasing palliative care consultations throughout the hospital and time constraints in providing care on the inpatient side, ensuring timely consultation in the ED can be challenging. Regardless, patient management through palliative care services has been shown to decrease the number of ED visits. Billing and administrative data support the fact that ED-based palliative care consultation decreases hospital length of stay and costs for those who are admitted to and die in the hospital.^{10,11}

ED partnerships with hospice providers can also provide a system for increasing access to palliative care services. When patients are identified in the ED as requiring palliative or end-of-life care, the palliative APRN can facilitate transfer to the in-patient palliative care or hospice unit or initiate referral and transfer to a hospice facility or hospice services. For patients who can be managed at home, palliative care outpatient services or palliative or hospice home services may be

most useful. In addition, other services to enhance transitions in care, such as employing palliative APRNs and other providers after hours and on weekends, providing a palliative care hotline, or follow-up clinic/home services for patients recently seen in the ED, can be especially useful in improving care coordination.²⁸ Coordination of care can be easier to implement when partnerships are established between providers and institutions. An important competency of palliative APRNs is building systems and resources to ensure quality care during transitions and to support the patient and family while making these difficult decisions and through the process of bereavement.

EVALUATION OF PALLIATIVE CARE IN THE ED

The evaluation of palliative care services may involve operational, clinical, and patient/family satisfaction indicators (Table 10.3). *Operational indicators* are those that affect the operational aspects of providing palliative care in the ED.⁵² These include the number of palliative care consultations and referrals, the response time of the palliative care team, and the number of clinicians who are certified in the specialty of palliative care.⁵³

Clinical indicators represent actions carried out in the clinical setting that incorporate palliative measures. These include the number of patients screened for palliative care needs, documentation of advance directives, end-of-life decisions, and communication with patients and family concerning palliative and end-of-life care.

Patient and family satisfaction indicators are subjective assessments of how well the palliative care team addressed palliative care needs and the overall delivery of palliative care.⁵⁴ These indicators may include the level of care provided to address communication and decision-making, symptom management, and end-of-life support. Acquiring information from each of these realms is important to inform the quality of palliative care delivery from an organizational, a clinician, and an individual patient and family level.⁵⁵ The APRN may play a role in creating such assessments, initiating their use, following-up with patients and families, or evaluating and reporting the data.

NOTIFICATION OF DETERIORATION IN HEALTH STATUS OR DEATH

Communicating the deterioration and death of a family member is a difficult skill, particularly for providers with limited interactions with the patient or family. Although it is usually preferable to notify the family in person, APRNs must weigh the benefits of truthfulness against the risk of potential harm resulting from abrupt disclosure of the bad news. For instance, during the recent COVID-19 pandemic, these conversations were only allowed via phone using verbal or video communication due to restricted visitation.⁵³ Factors to consider in making this decision include whether the health

Table 10.3 METRICS INFORMING QUALITY OUTCOMES IN ED PALLIATIVE CARE

METRIC TYPE	PARAMETERS
Operational	Number of palliative care/hospice consultations/referrals
	Number of in-service education sessions provided, interprofessional participation, and ratings of the sessions, number of questions asked, and reports of application in practice
	Time from call for consultation to documented consultation
	Discharge status/disposition
	% palliative care patients returning to ED within 30 days
	% palliative care patients readmitted to hospital within 30 days
	Mean/median length of stay in ED
	% of patients admitted to palliative care services/unit
	Number of board-certified palliative care providers
	Hospital direct costs
Clinical	% of patients screened for need of palliative care services
	% of patients with advance directives in the EMR
	% of patients for whom the healthcare decision maker is documented in the EMR
	% of patients with documented pain assessment on presentation
	% of patients prescribed opioids with bowel regimen on discharge
	% of patient families with documented offer of spiritual support after ED death
	% of patient caregivers screened for caregiver strain
	% of patients with documented family meeting
	% of patients with documented family contact
Patient/family satisfaction	% of patients reporting excellent level of satisfaction with palliative care services/coordination
	% of patients reporting excellent pain/symptom management
	% of patients reporting excellent transition of care to palliative or hospice services
	% of patients discharged from ED who reported they were informed about their condition/prognosis/treatment options
	% of surrogates/families who reported excellent end-of-life care after ED death
	% of patient families who perceived that the management decisions were congruent with the patient's values

Adapted from Dundin A, Siegert C, Miller D, et al. A pivot to palliative: An interdisciplinary program development in preparation for a coronavirus patient surge in the emergency department. *Emerg Nurs*. 2020;doi:10.1016/p.jen.2020.08.003.

deterioration and death was expected or not, how well the provider knows the patient and the family, the relationship of the contact person to the patient, the anticipated emotional reaction of the contact person based on prior information, whether the contact person will be alone when receiving the information, the contact person's level of understanding, and the distance, availability of transport, time of day, and infection risk.⁵⁴ Communication between the palliative APRN and family takes place within the context of culture, language, and prior experiences and includes indirect cues (body language, facial expression, and gestures). When there is a

need to update family members regarding the health status of the patient, particularly regarding deterioration in health or to inform them of the patient's death by telephone or other technology, the call should be made as soon as possible when changes occur or following the death.⁵⁵

There are several key steps for the APRN to follow in notification of health deterioration or death. First, after positively identifying the patient, obtain relevant information about the patient (name, age, gender, patient identity numbers, and circumstances of deterioration in health or death).⁵⁶ Second, establish the relationship of the contact person to the patient;

Table 10.4 STEPS FOR TELEPHONIC COMMUNICATION WITH NEXT OF KIN WHEN PATIENT DETERIORATES OR DIES

Preparing for the call	Prepare for the call by gathering all information about the patient (name, gender, age, medical record number, circumstances of illness or death); verify information with colleagues who have cared for the individual to review events of the last few days. Review with a colleague what you will say, including the context of the call and history of care. Find a quiet place to call. Take a few minutes to prepare yourself using a mindfulness minute or deep breathing. Arrange for a medical interpreter, if needed. If using a personal phone, consider using technology to block the telephone number such as *67 or Doximity.
Determine next of kin as listed in the electronic health record or other source and ask an identifying question.	Identify yourself, your position, and ask to speak to the contact person indicated in the chart. If that person is not available, ask the identity of the person you are talking to, their relationship to the patient, and let them know you are urgently trying to reach the next of kin. Avoid responding to any direct questions until you have verified the identity of the person to whom you are speaking as the next of kin. Do not give health deterioration information or death notification to minor children. If you reach an answering machine or voice mail, only leave specific contact information for the family to call back (e.g., “This is Julie Smith, APRN at Shorline Hospital. Please call me back at the following number”). If you are unable to make contact within 1–2 hours, contact a hospital representative (e.g., social worker) to assist you in locating family or others.
Determine what the contact person knows about the patient’s illness/injury.	Speak clearly and slowly, allowing time for questions. If you do not have a prior relationship with the person you are speaking with, ask what he or she knows about the patient’s condition. “What has the healthcare team told you about [patient]’s condition?”
Provide a prelude to the conversation.	Provide a warning: “I’m afraid I have some bad news” or “I have some difficult news to share.” Find out if the person is in a safe place, is driving, or has anyone with them. Allow them time to pull over on the road, get to a room with another person, or call another person. Once they are ready, prepare to proceed.
Use clear and direct language, avoiding medical jargon.	“[_____]’s condition has deteriorated and we believe that [_____] will not live much longer. Do you want to arrange to come in or we can hold the phone next to [_____]’s ear so that you can say your good-bye’s?” If the family asks to see the patient via video, ensure that the platform is HIPAA compliant with the Health Insurance Portability and Accountability Act (HIPAA) and secure. “I’m sorry, [_____] has just died.” Use the word “died” or “dead.” Other terms, such as “expired,” “passed away,” or “didn’t make it,” can be misinterpreted.
Assess the person’s emotional response.	Allow time and silence for the next of kin to take in the information. Be prepared for the expression of emotions. Offer simple details about the sudden deterioration of the patient, events leading to or reasons for the deterioration, and comfort provided. Allow the family to ask additional questions and express feelings. Provide therapeutic listening and support
Ask the family if they would like to come to the hospital to view the body (if possible).	If the family chooses to come to see the body, arrange to meet with them personally when they arrive. If you are unable, make arrangements for a colleague such as a social worker or chaplain to meet them. Provide contact information for the clinical team member who can meet with them and answer questions about the patient’s death, funeral planning, and other administrative issues.
Closing the call.	Offer follow-up phone calls by the social worker or chaplaincy to help with support and funeral planning. Provide information about follow-up phone calls from the hospital, including the release of the body. Offer condolences and a statement for having to receive this information by phone. “Again, my condolences on the loss of your loved one. I wish I had been able to be with you in person during this time.”
Communicate to the team.	Document the call in the chart. Notify the clinical team and bereavement liaison that the call has been completed. Take a moment to reflect and provide a positive affirmation for providing a difficult call with empathy.⁵⁹

obtain the full name, address, and telephone numbers of the person(s) who need to be informed from the chart and/or nursing staff. Third, find a quiet or private area with a phone and thoroughly review the information to be conveyed. When making the phone call, follow the steps listed in Table 10.4 to ensure best practices are utilized.^{57–59} Telehealth technologies are being used more frequently to provide palliative care to patients and families, and, as they are being evaluated, it is anticipated that modifications to best practices will occur.⁶⁰

SUMMARY

The ED is an important setting for the initiation of palliative care. The quickly changing status of ED patients makes access to palliative services an important element of care. Moreover, communication is different from that in other departments, as often patients present without family members. The palliative APRN has a significant role in identifying patients who need palliative care; assessing the patient's physical, psychological, emotional, and spiritual needs; initiating difficult conversations; and coordinating care that is culturally sensitive and congruent with the patient's values and goals.

Palliative APRNs are experts in designing and implementing system-based standardized methods for advancing palliative care services in settings such as the ED. Working with the interprofessional team, the palliative APRN may be the leader in developing triggers for recognizing palliative care needs in ED patients. This process can make the system of triage and referral more efficient so that crucial conversations can take place early in the ED visit. The palliative APRN can initiate difficult conversations and negotiate realistic goals of care among the patient, family, and other providers involved in the patient's care, a process that often takes time to build trust and constant presence as the patient and family work through difficult decisions.

Using a holistic assessment of the patient and family, the palliative APRN offers a unique perspective in the ED that is focused on patient-centered care and congruence between the goals of care and the patient's wishes and preferences. Coordination of palliative care is also a major role of the palliative APRN in the ED, which is critical for ensuring quality and safety throughout care transitions. The palliative APRN also has expertise in designing outcomes for system improvement using quality indicators to evaluate how palliative care is being used and implemented in the ED. This is a critically important process to achieve the best use of palliative care services and improve the ways it is implemented in the ED setting.

THE PALLIATIVE APRN IN THE PALLIATIVE CARE CLINIC

Brooke Smith and Lisa A. Stephens

KEY POINTS

- The palliative advanced practice registered nurse (APRN) in a palliative care clinic provides continuity of care and symptom management concurrent with disease-modifying treatment that enhances patient satisfaction and reduces healthcare utilization.
- The palliative APRN offers collaborative decision support at key points along the disease trajectory to offer patient-centered, preference-sensitive treatment options.
- The palliative APRN's longitudinal relationship with the patient and family, as well as with other members of the patient's healthcare team, enhances their coping and fosters resilience.

CASE STUDY: THE PALLIATIVE CARE CLINIC APRN

Eileen was a 35-year-old woman with a history of asthma and obesity, status post gastric bypass surgery. She was admitted to the hospital with progressive, severe shortness of breath. She was diagnosed with pulmonary hypertension due to dermatomyositis-associated interstitial lung disease. Six years prior to her diagnosis, Eileen left her position as a bank manager and moved closer to her aged, ailing parents, with her fiancé and his two sons. She was estranged from her two sisters, who both struggled with alcoholism. Over the next 2 years, her mother and father died. One year prior to her admission, her fiancé died suddenly after a viral illness, leaving behind his 14- and 11-year-old sons. In the aftermath of that loss, their mother continued the previous custody arrangement, allowing the boys to stay with Eileen every other weekend.

In the first year after her diagnosis, despite treatment for her dermatomyositis, Eileen's pulmonary hypertension progressed significantly, resulting in cor pulmonale and New York Heart Association (NYHA) functional Class III–IV disease. In the setting of chronic steroid use, she gained more than 100 pounds, reaching a body mass index (BMI) of 38. She was admitted for initiation of vasodilator therapy, epoprostenol, which resulted in significant headache and muscle and joint pain. During this admission, she learned that she had been denied transplant listing by two different regional heart/lung transplant centers due to her weight. Faced with the progression of her disease and lack

of apparent options to treat it, she presented as hopeless and distressed. Her pulmonologist requested a consultation from the inpatient palliative care team to establish a longitudinal relationship for ongoing goals-of-care discussions, pain management, and psychosocial support. For continuity, she was seen by the outpatient palliative advanced practice registered nurse (APRN) during that admission and then followed closely in the outpatient clinic.

Over the second year, Eileen was seen monthly by the palliative APRN. Eileen's severe dyspnea made it difficult to navigate the healthcare campus, so the APRN saw her during monthly infusion therapy for dermatomyositis. It was hoped this would stabilize enough to again pursue heart/lung transplantation. A co-management model allowed the palliative APRN to assess and manage Eileen's pain and symptoms and provide appropriate prescriptions and nonpharmacologic interventions. Eileen suffered from headache, jaw pain, and shoulder aches secondary to epoprostenol but feared opioid addiction given her family history. The palliative APRN provided education regarding opioid misconceptions and counseling regarding coping strategies. Eileen was also followed closely by the outpatient palliative social worker. Knowledge of community resources on the part of the APRN and the social worker enhanced Eileen's access to services and allowed her to stay home longer. Emotionally, Eileen struggled to maintain hope without a certain plan for heart/lung transplant. She told the social worker, "I feel as if I have no past (referencing the death of her fiancé and parents), no future (referencing survival without a transplant), and the present sucks." Both the palliative APRN and social worker simultaneously enhanced Eileen's resilience in the face of physical debility and medical uncertainty and supported her coping with her changing physical abilities as a stepmother.

As she began the third year of her illness, now 37 years old, Eileen suffered increasingly with dyspnea and pain and worsening functional ability. Eileen's pulmonary, cardiology, and rheumatology teams shared with her that her disease was not responding as they had hoped. A transplant was no longer a possibility. She began to ask theoretical questions about stopping treatment of her pulmonary hypertension, stating, "I don't think I can do this anymore," but she was not ready to stop life-sustaining treatments out of concern that her stepsons would think she was a "quitter."

In response to Eileen's distress, the palliative APRN organized and led a multidisciplinary outpatient team meeting to discuss Eileen's goals of care. Eileen and her close friend, along

with her primary pulmonologist, cardiologist, and rheumatologist, were in attendance. Eileen described the misery of her home situation and made the request that someone “give me an achievable goal or let me go.” Her subspecialists responded that ongoing therapy of her pulmonary hypertension would only slow the rate of her inevitable decline and death. She asked what would happen if her epoprostenol was discontinued. The reply was she might die quickly and might suffer significantly worsened dyspnea or chest pain after withdrawal. She was offered the option of admission to the medical center’s cardiology floor for discontinuation of the drug in a monitored setting, with the expectation that she would die, which she accepted. She requested the admission be arranged after one last Christmas with her stepsons, at a time when all of her medical subspecialists, including the palliative APRN, could be present.

When Eileen was ultimately admitted, as requested, all her known providers were available including the palliative APRN and her primary cardiologist, pulmonologist, and rheumatologist. Before the epoprostenol was discontinued, she spent a wonderful day and a half with her close family and dear friend at her side. Each family member had an opportunity to say goodbye to her. The palliative social worker assessed the coping of each family member and ensured they had adequate supports going forward. The palliative APRN was the primary clinician responsible for Eileen’s comfort medications during the discontinuation process and provided intensive emotional support to the nursing staff. Eileen died peacefully several hours after her epoprostenol was discontinued, with her stepsons, aunt and uncle, and best friend at her side.

CONCURRENT CARE FROM DIAGNOSIS ONWARD

The prevalence of inpatient palliative care programs continues to rise in the United States. From 2000 to 2016, among hospitals with more than 50 beds, the number of palliative care teams increased by 178%.¹ While hospital-based palliative care has grown substantially over the years, continuity across all settings has been slower to grow. Outpatient palliative care often extends the impact of an inpatient program “upstream” by providing concurrent care from the time of diagnosis across the illness to end of life. The most common model of outpatient clinics has been the academic medical center model of outpatient palliative care clinics as a growth of inpatient palliative care services. Newer clinic models have emerged from a more community-based perspective. In these settings, palliative care clinics are developing from a breadth of community partnerships, such as hospice, home health agencies, independent practices, and community service agencies.

All along a patient’s disease trajectory, a palliative care clinic can enhance continuity of care, improve symptom management, increase patient satisfaction, and reduce healthcare utilization, particularly at the end of life.^{2–10} As the case study demonstrates, the initial palliative care consultation was requested during an inpatient admission,

but the referring team recognized that this patient needed longitudinal care. The patient, Eileen, had a high symptom burden and poor social support. Her goals were to continue pursuing disease-modifying treatment with the hope of prolonging her life. Her prognosis was poor, and she was overwhelmed. Outpatient palliative care clinics are often started as an extension of the inpatient palliative care team to enhance the quality and continuity of care throughout the disease trajectory.⁷

Palliative advanced practice registered nurse (APRN) play a pivotal role in the delivery of high-quality palliative care concurrent with disease-modifying treatments. A key component of quality is continuity of care, which is enhanced by a continuous patient–APRN relationship. This promotes the APRN’s ability to provide ongoing assessment and management of pain and symptoms, counseling regarding adjustment to illness, advance care planning (ACP), and education regarding the side effects of treatments and medications. Moreover, the palliative APRN is poised, through education and experience, to assess the patient’s emotional history and coping and to provide supportive counseling and screening for spiritual concerns.^{8,11–15} A pilot study, looking at the effects of integrating a palliative APRN into a community oncology center, found that, when compared to usual care, patients were six times less likely to be hospitalized and possibly even lived longer.⁸ In this study, the palliative APRN was integrated into the care of patients with advanced cancer at the time of diagnosis and followed the patient and family throughout the disease trajectory. This study, as well as other research, demonstrates the value of a continuous relationship with a palliative APRN who has specialized knowledge and experience.^{6,8,13}

The trust that is built by the palliative APRN over time also acts as a foundation for the difficult conversations that will come later in the disease trajectory. A preexisting relationship brings comfort to the patient, family, and caregivers when these conversations are revisited in times of crisis. Since most patients are ambulatory at the time of diagnosis and continue treatments on an outpatient basis, an outpatient palliative care clinic is the ideal place for the APRN to develop such relationships. In addition to improving patient satisfaction and quality of life and decreasing hospital admissions, concurrent palliative care has been proved, in a population of lung cancer patients, to increase survival.^{16–18} Box 11.1 lists the benefits of a clinic or outpatient palliative care services.

CORE SERVICES AND PRACTICE CONSIDERATIONS

The first step in building a palliative care clinic is to determine the primary population of patients to be served and the core services to be provided. This is best achieved by a needs assessment done with stakeholder. Most palliative care clinics serve patients with serious or life-limiting illness who have one or more of the following needs: complex pain and symptom management, complex medical decision support, assistance with goals of care clarification, assistance with ACP, and/or

- Allows for earlier involvement of palliative care at the time of diagnosis
- Builds relationship with patient and family before a crisis
- Improves symptom burden and quality of life for the patient
- Increases earlier advance care planning
- Allows for continuity of care over time
- Increases patient, family, and caregiver satisfaction and reduces caregiver burden
- Increases psychosocial support
- Often increases skills of other caregivers and providers
- Provides decision support at key points along the disease trajectory
- Improves transitions of care
- Often reduces unwanted healthcare utilization, such as hospital admissions and emergency room visits
- Reduces healthcare costs
- Increases hospice utilization and earlier hospice involvement

From Rabow et al.^{2,4,17}; Cunningham et al.^{3,19}; Kluger et al.⁵; Fulton et al.⁶; Smith et al.⁷; Prince-Paul et al.⁸; Hui and Bruera⁹; National Consensus Project¹⁵; Bakitas et al.¹⁶; and Temel et al.¹⁸

complex social and family dynamics, including substance use disorder and mental health needs (see Chapter 46, “Serious Mental Illness,” and Chapter 47, “Patients with Substance Use Disorder and Dual Diagnoses”). It is important to determine whether outpatient palliative care services will be provided to a certain disease-specific population based on a needs assessment that reveals challenges with patient populations or based on pain and symptoms.¹⁰

The most common reasons for referrals are management of pain and non-pain symptoms, prognosis and determining goals of care, end-of-life planning, and support for psychological issues.^{7,20} Often patients may be referred for one reason and additional needs may be discovered and addressed during the course of their visit.⁷ Defining the delivery model and core services is imperative to help guide referral sources and define the mission of the clinic. However, addressing unmet needs is often welcomed by the referring providers and patients and families. Prior to initiating an outpatient clinic, there must be well-defined descriptions of appropriate palliative patients, triggers that may warrant referral, and clear expectations of the services to be provided.

Palliative APRNs’ scope of practice may determine their role in a palliative care clinic. Specifically, individual state nurse practice acts and statutes, as well as institutional bylaws, need to be considered when designing the palliative care clinic. Furthermore, there may be differences between the role of a clinical nurse specialist (CNS) and a nurse practitioner (NP) in state nurse practice acts. Some states may allow autonomy through full independent practice without physician oversight; other states may have more restrictive practice acts requiring physician supervision. Another important

aspect of a palliative care clinic is prescription medications. There is state variation on prescriptive authority, with some states more progressive than others.²¹ The APRN in a more restrictive state will need to develop a plan for prescription writing. Due to COVID-19, some states have temporarily suspended or waived practice agreements and implemented temporary changes to prescriptive authority.²² It will be necessary to stay abreast of whether these changes become permanent.

Despite these state differences, the palliative APRN can function at the highest scope of practice and provide advanced knowledge of the physical, emotional, social, and spiritual needs of seriously ill patients. Moreover, palliative APRNs institute comprehensive care and provide communication to healthcare providers. In states where APRNs have full independent practice, collaborative practice with physician colleagues is still an important consideration for palliative care. Indeed, for optimizing the management of patients who need highly complex symptom management, a physician colleague can co-manage patients to assist with problem-solving and decision-making.

The ongoing shortage of board-certified hospice and palliative medicine physicians should not be a barrier to finding the right fit with a collaborating physician. If the palliative APRN is providing palliative care services to primarily heart failure or oncology patients, they may choose to collaborate with a cardiologist or an oncologist. A non-hospice and palliative medicine collaborating physician provides expertise in complex diagnostic and specific disease management issues that may arise, while the palliative APRN provides expertise on the assessment and treatment of symptoms and offers psychosocial and spiritual counseling as well as coordination of care.

MODELS OF OUTPATIENT PALLIATIVE CARE CLINICS

Across the United States, a wide variety of models are used to deliver outpatient palliative care services, ranging from outpatient clinics to home and nursing home visits. Once the scope of services is determined, the setting for the care can easily be identified. New models are emerging in the growth of community-based outpatient palliative care clinics. See Table 11.1 for a summary of three current palliative care clinic models: embedded, stand-alone, and co-located.

The *embedded model* is often used to start a palliative care clinic. Several successful and innovative embedded models have been described that use a palliative APRN as the core team member.^{8,11,13,24,25} Embedding a palliative APRN in an outpatient clinic has been associated with measurable benefits such as improved symptom management, decreased emergency department visits and hospital admissions, and possibly a decrease in mortality rate.^{8,11}

In the embedded model, palliative care is available as standard treatment for any clinic patient with a life-limiting illness. This patient-centered approach allows the palliative APRN to get a “foot in the door” with reluctant referrers and patients, decreasing the perception that palliative care is only for the imminently dying. Fairly quickly, referrers note the benefits of being supported in the arenas of complex symptom management, coordination of care, and complex goals-of-care discussions. Often, in the embedded clinic model, the palliative APRN becomes an informal teacher for other healthcare providers by modeling complex conversations or coaching other providers through these conversations, thus enhancing the care delivered. The embedded clinic model not only enhances the satisfaction of the referrers but may also provide support to the palliative APRN who, by practicing in collaboration with others, develops specialty-level knowledge of the disease state.

There are several disadvantages to an embedded clinic model and these are centered on lack of control for patient flow issues. The palliative APRN’s schedule depends on another clinician’s timeliness, and there is a higher likelihood

of unscheduled add-on appointments and a higher number of cancellations. Despite these inefficiencies, embedding an APRN in a clinic is often a cost-effective way to establish credibility and build relationships while slowly increasing referrals, possibly with a goal of developing a sustainable stand-alone clinic.

A recent review of the literature of models of outpatient palliative care in oncology concluded that the *stand-alone interdisciplinary palliative care clinic* has improved patient outcomes.^{26,27} Patients with cancer or non-cancer diagnoses can be easily cared for in a stand-alone clinic. In addition to the APRN, other team members, such as a chaplain or social worker, are highly valuable members of the palliative care team and should be available to see patients and family members on a part- or full-time basis. Palliative physicians may also see patients in tandem with the palliative APRN or may just consult on occasion.

Some strengths of the stand-alone model include its strong evidence of impact on patient outcomes; in addition, this model allows for more continuity and resource utilization, consistent referral criteria, and it is a visible space for the palliative care outpatient service. In a stand-alone clinic, the palliative APRN becomes an important consultant. Patients and families will see the added value of the palliative APRN separate from their other specialty or primary care providers.

Some palliative care clinics are *co-located* in a cancer clinic or an HIV or congestive heart failure clinic. The advantage to the host clinic is quick and easy access to the palliative APRN and other palliative care team members. This model may save costs for the palliative care service in terms of overhead and allow more incremental growth.²³

Outpatient palliative care services can also be provided as a combination of embedded and stand-alone clinics. In institutions where specialty outpatient clinics are in close proximity, palliative APRNs can float to multiple different clinics in the same day. An example might include seeing his or her own panel of patients in a stand-alone clinic, traveling to see others in the oncology infusion suite, and then joining a heart failure clinician for a joint visit. Advantages include in-time coordination and collaboration of care, allowing those

Table 11.1 MODELS OF PALLIATIVE CARE CLINICS

DESCRIPTION	FINANCING
<i>Independent clinic.</i> These are independently functioning, specialty clinics where patients receive specialty palliative care services. Referrals are received from physicians, APRNs, and PAs per CMS guidelines.	Palliative care clinic responsible for all costs.
<i>Co-located.</i> These palliative care clinics operate in a shared space with other medical services. Referrals to palliative care services may come from physicians, APRNs, and PAs within the specialty clinic in other specialties, or from other practices entirely.	Costs may be shared between the palliative care clinic and the host clinic.
<i>Embedded.</i> These palliative care services share similar characteristics with outpatient co-located clinics. Palliative care providers share space and work closely with other providers. There may be protocols that define how palliative care functions in tandem with other medical services.	The host clinic is typically responsible for all costs.

Adapted from: Cunningham et al.¹⁹ and Barbour et al.²³

patients who have long days with infusions or have a harder time getting from place to place to have palliative care services come to them.

This approach has the value of being extremely patient-centered by going to where the patient is, but it can be inefficient, as the palliative APRN loses valuable documentation time while in transit between clinics. The palliative APRN is again at the discretion of another clinic's schedule changes or appointment delays. For certain populations, however, having the palliative APRN travel to the patient is indispensable. Some instances include the reluctant or fearful patient who might not be willing to come to a stand-alone clinic visit or a patient with complex chronic illness who does not yet understand the role that palliative care can play in his or her care.

No matter what type of palliative care clinic, there may come a time when it is difficult for a patient to travel to a clinic. In these situations, the APRN must have knowledge about community resources to ease the transition of care to the home. Home palliative care services may include hospice when appropriate or desired, home health when the home-bound criteria are met and/or the patient declines hospice, and home palliative care from either hospice or independent providers (see Chapter 14, "The Palliative APRN in the Community Setting," and Chapter 15, "The Palliative and Hospice APRN in Hospice and Home Health Programs").

ROLE OF OTHER TEAM MEMBERS

Other team members may be embedded in the palliative care clinic or may require referral, notably social work and chaplaincy. However, dedicated team members such as a social worker or chaplain can enhance whole-person care, a tenet of providing palliative care.²⁸ In addition to providing in-depth counseling and support, social workers can help patients to complete advance directive forms and assist with finding resources for those with financial, insurance, or transportation needs. If a social worker and chaplain are not fully dedicated to a palliative care clinic, a plan must be in place for timely referrals. Early joint visits with the chaplain or social worker can facilitate rapport, allowing for subsequent visits to be completed separately from the palliative APRN.

Other team members who can be invaluable to the clinic include nurses and pharmacists. Pharmacists can provide valuable support with comprehensive assessments of medications, assistance with dose conversions, and assessment for any possible medication-related adverse events.^{29,30} Registered nurses can serve many roles in a palliative care clinic including education and support for staff, patients, families, and caregivers; help with ACP; and scheduling.³¹ Ideally, the palliative APRN will have institutional or local access to nutrition services; rehabilitative therapies, such as physical therapy, occupational therapy, and speech and language pathology; chronic pain management (if not covered by the palliative APRN); child life specialists; grief counseling for their patients; psychologists; psychiatrists; and addiction specialists.

FINANCES

A variety of funding sources are generally necessary to run a palliative care clinic. APRN billing and reimbursement will vary depending on whether a clinic is an independent practice, a hospital-owned clinic, or part of another entity. See the Appendix I for details on billing and coding issues. Typically, given low rates of reimbursement and relatively low clinic appointment volumes, billing revenues do not cover the full cost of an outpatient clinic practice and at least one other source of funding will be needed. In a survey of 20 outpatient palliative care practices, funding sources varied among the programs, but the most common was a combination of institutional support and billing revenues.⁷ Commonly, justification for a palliative APRN may include cost avoidance through decreased hospital admissions, decreased emergency department visits, decreased lengths of stay, and early admission to hospice. This cost avoidance may translate into financial support from the institution at large. Embedding an APRN in an oncology or primary care clinic has shown such cost avoidance through decreased healthcare utilization.^{8,11} Philanthropy, research, and private foundation support are also common funding sources. Funding will be required for staff (medical and nonmedical), overhead (space and supplies), billing, budgeting and information systems, and tracking of outcomes.¹⁹

LAUNCHING THE PALLIATIVE CARE CLINIC

ESTABLISHING VISIT TIMES

Once a model is chosen for the palliative care clinic, funding has been located, and a staffing plan has been identified, decisions should be made about clinic flow and practice, in particular establishing visit times. Visit times may need to be longer to accommodate travel time, lack of support staff, and documentation time. A survey of 20 outpatient palliative care programs showed that new consultation times were 40–120 minutes, with an average of 65 minutes, and follow-up visit times were 20–90 minutes, with an average of 37 minutes.¹¹ In another oncology-embedded APRN-run palliative care clinic visits were on average 56 minutes in length.¹³ In general, a good rule is to begin with 90 minutes for a new patient or new consultation and 45 minutes for a follow-up visit, unless more time is needed to travel from clinic to clinic. These appointment times provide a cushion for those days when a follow-up patient may have complex issues and extensive care coordination is needed. Clinic times may be adjusted on a case-by-case basis or shortened if needed to accommodate same-day appointments. Due to the COVID-19 pandemic, video visits have become frequently utilized as another way to offer palliative care to patients, families, and caregivers while maintaining social distance. These visits are often scheduled for the same time duration as usual in-person clinic visits (see Chapter 17, "The Palliative APRN in Telehealth").

REFERRALS AND SCHEDULING

Referrals can come from many sources, such as registered nurses, physician's assistants, physicians, social workers, rehabilitation therapists (physical therapy or occupational therapy), chaplains, other APRNs, or patient and family self-referral. Scheduling guidelines developed by the palliative care team members should be established prior to the startup of the palliative care clinic. Screening for inappropriate referrals should be outlined within these guidelines. In some practices, screening questions can be used by the scheduling secretary: the reason for the consult and the urgency.²³ These questions, as well as self-referrals, may trigger the palliative APRN to interview the patient or referring provider about the appropriateness of the consultation. Some self-referred patients may not have a serious, life-limiting illness but are looking for a new opioid prescriber or may be asking for patient care coordination that would be better provided by their primary care provider's team.

As a way of building clinic volumes or to reach a specific high-needs population, outpatient palliative care clinics can be part of disease-specific or algorithm-driven triggered consultations. Scheduling pathways can then be developed for automatic referrals in these groups. As an example, an automatic palliative care consultation could be scheduled for patients with newly diagnosed Stage IIIB or stage IV lung cancers, pancreatic cancer, New York Heart Association (NYHA) Stage III or IV heart failure, advanced chronic obstructive pulmonary disease, or amyotrophic lateral sclerosis. Automatic referrals require close collaboration with the specialty group. These automatic referrals not only make palliative care consultation part of the routine care provided by the specialty group but also decrease the perception that palliative care is only for patients at the very end of life. Hui et al.³² performed a Delphi study to develop international consensus on a list of referral criteria to outpatient palliative care for cancer patients. Box 11.2 lists these criteria that may assist in the development of automatic referral criteria.

PATIENT CARE RESPONSIBILITIES

The palliative APRN should explicitly communicate with referring clinicians about role expectations. The role may vary on a case-by-case basis, ranging from consultation only to co-management and even sometimes assuming primary responsibility for the patient.

Co-management is an ideal model for providing specialty palliative care for patients with serious illness. These patients have intense needs, and a co-management approach allows team members to lean on each other along the disease trajectory to off-load work and support each other emotionally, thus decreasing the risk of burnout. This collaboration also avoids a "handoff" when the patient's care needs tip toward a more palliative focus, away from disease-modifying therapies. This integrated, co-management model prevents the patient from feeling abandoned and enhances the concept that palliative care is an "extra layer of support" that is offered to many patients at the time of diagnosis.³³ Other providers

Box 11.2 REFERRAL CRITERIA FOR OUTPATIENT SPECIALTY PALLIATIVE CANCER CARE

- Severe physical symptoms (pain, nausea and vomiting, fatigue, dyspnea, etc)
- Severe emotional symptoms (depression, anxiety)
- Delirium
- Requests for assisted death
- Spiritual or existential crisis
- Assistance with decision-making or care planning
- Patient request for referral
- Oncology issues
 - Spinal cord compression
 - Brain or leptomeningeal disease
- Within 3 months of advanced diagnosis in patient with median survival of 1 year or less

From Hui et al.³²

may request consultation for a specific issue only (such as pain management) or for the palliative APRN to take over full care of the patient.

Consultation-only requests that require the referring provider to implement recommendations may not improve symptom control outcomes.¹⁷ The embedded model is the ideal setting for a consultation-only role as the APRN can work closely with the referring provider to guide the implementation of the recommendations. Assuming sole care for a patient can be time-intensive for the palliative APRN. However, it may be appropriate for a patient who has no primary care provider and is no longer receiving disease-modifying treatment or is referred to hospice care without a primary care provider.²³ Defining these roles up front, at the time of consultation, not only helps the patient clarify whom to call with specific issues but also improves collaboration between team members, ultimately benefiting the patient and increasing satisfaction among all team members.

THE INITIAL OUTPATIENT CONSULTATION

Prior to the visit, the palliative APRN should gain a comprehensive understanding of the patient's medical history, likely prognosis, and disease trajectory through chart review and discussion with primary specialists and/or the primary care provider. The underlying goal of the initial visit is to introduce the patient and family to the role of palliative care to establish rapport and to screen for and address the most pressing needs, whether those are physical symptoms, emotional distress, or

decision-making support. During the initial visit, the palliative APRN performs a comprehensive assessment of symptoms. Tools such as the Edmonton Symptom Assessment Scale,³⁴ the Memorial Symptom Assessment Scale,³⁵ and the Patient Health Questionnaire (PHQ-9)³⁶ can help identify patient-reported symptoms and assist with a comprehensive evaluation of physical and psychological symptoms.

The APRN should also assess, to the extent possible, the patient's and family's understanding of the illness and prognostic awareness, mentally bookmarking areas of significant disconnect between what the patient believes and what chart review has revealed. Communication about serious illness care goals should happen early in the course of a serious illness and be revisited at various times along the illness trajectory. The American College of Physicians High Value Task Force recommends having these conversations in the outpatient setting before a crisis and using a check list or conversation guide.³⁷ Ariadne Labs offers resources and tools to develop a Serious Illness Care Program and offers a tool, the *Serious Illness Conversation Guide*, that can be used to support best practices in having these conversations.³⁸ The guide helps to identify understanding of illness, information preferences, prognostic awareness, goals in the face of worsening health, fears and worries, critical functions, tradeoffs, and family awareness of priorities and wishes (see Chapter 32, "Advance Care Planning") and can assist the APRN in counseling regarding end-of-life preferences. The palliative APRN should perform a social assessment to determine the patient's and family's coping strengths and deficiencies.

After the initial consultation, the palliative APRN can identify longitudinal goals for addressing the identified areas of coping and symptom management needs and can suggest a frequency of follow-up visits. For example, if a patient is emotionally resilient, fully understands his or her disease trajectory and prognosis, and has no symptom issues, the palliative APRN might offer to see the patient every 1 to 2 months, in conjunction with surveillance, restaging diagnostics, or visits with the primary specialist. If, however, the palliative APRN identifies a number of coping needs, or there is a high likelihood that symptom burden may change rapidly due to beginning new disease-directed therapies (chemotherapy or radiation), the patient might need to be seen as soon as a few days or a week following the consult.

Above all, the palliative APRN should set realistic personal expectations himself in an initial consultation to avoid forcing an agenda on the patient and family members, potentially alienating them. The philosophy of promoting quality of life, maximizing functional status, optimizing psychosocial coping, and assisting with care management can guide care and help the patient and family understand the support of palliative care. If the patient/family is willing to return, the palliative APRN has succeeded and the work can continue. Box 11.3 lists unique components of the initial consultation note.

OPIOID AND CONTROLLED SUBSTANCES MANAGEMENT

It is imperative that the palliative APRN provide skillful pain and symptom management that mitigates risks when prescribing opioids or other controlled substances.³⁹ (See Chapter 43 on pain and Chapter 47 on substance use disorder for a more detailed approach to prescribing opioids and other controlled substances and mitigating risks.) The use of universal precautions is recommended for all patients, even in the palliative care clinic, and can mitigate risks and help develop an individualized ongoing assessment and monitoring plan.⁴⁰ Universal precautions include the use of an opioid risk screening tool, opioid agreement, calculating the morphine equivalent daily dose (MEDD), performing urine drug screening (UDS), and reviewing prescription drug monitoring programs (PDMP).⁴⁰ See Table 11.2 for an example of types of screening actions, risk stratification, and monitoring plans based on initial and ongoing assessments. In Table 11.2, the Opioid Risk Tool (ORT)^{39,41} is used.

SUBSEQUENT OUTPATIENT VISITS

Depending on the disease type and trajectory, the middle phase of outpatient palliative care work can last weeks, months, or even years. During this time, in addition to ongoing symptom management as indicated, the palliative APRN should work on fostering resilience and developing prognostic awareness in the patient and their caregivers.^{42,43} This work increases the patient's tolerance for difficult discussions and

Box 11.3 UNIQUE OUTPATIENT PALLIATIVE CARE DOCUMENTATION CHARACTERISTICS

Understanding of Illness or Illness Understanding

Goals of care: Hopes, worries, and priorities

Preferences: Communication, decision making, and advance directives

Social context: Social determinants of health, place of residence, important family members, occupation, and hobbies, employment status, insurance status

Emotional history: Existing coping strategies and their effectiveness; sources of strength, pride, meaning, and connection; fears; areas of significant personal distress (e.g., financial concerns, worries about family members' coping)

Spiritual history: Include a screening tool for spirituality

Cultural history: Meaning of current illness, cultural aspects of health, illness, and death within context of care

lays a foundation of trust in the relationship for the later, challenging work of end-of-life decision-making. The APRN should partner with the patient in celebrating the happy moments and solving problems through the tough times, effectively banking a store of goodwill in the relationship that increases the patient’s willingness to engage in less comfortable conversations when they are needed.

Once patients and families can rely on adequate coping skills and have appropriate prognostic awareness, they have the emotional energy to participate in legacy work: preparing for leave-taking. For those patients with adequate coping and strong familial and financial supports at diagnosis, this work may be engaged in much earlier, but for some particularly challenged patients or family members, the capacity may never evolve.⁴⁴

FOSTERING RESILIENCE

Addressing coping throughout the disease trajectory has been associated with improved patient-reported outcomes of improved quality of life and decreased depressive symptoms.⁴⁵ Early in the course of the relationship, the palliative APRN should inquire about, explicitly name, and validate the patient’s existing and past coping strategies and assess how well they worked in the past and are working now. If past strategies are no longer effective, offer alternatives and offer to brainstorm how new behaviors might work for the patient.⁴² Table 11.3 lists different coping strategies patients might employ. The palliative APRN relies on his or her ability to synthesize the coping history, prognosis, and emotional response to the illness in order to reflect core strengths

back to the patient. This approach will not only foster resiliency in the patient but also strengthen the patient–APRN relationship.

In addition to identifying existing coping styles and developing new ones, the palliative APRN should foster the experience of positive emotion. Facilitating discussions about things that bring joy and meaning to the patient provides important coping support.⁴² When patients report happy events, the APRN should celebrate those moments with them and, at other times, help them to recognize and enjoy those things they are grateful for.

Finally, the palliative APRN should strategically interpose challenging conversations or difficult encounters with more lighthearted interludes or matter-of-fact visits. This careful titration of discomfort is critical to avoid overwhelming the patient’s and family’s ability to cope, and it fosters the resilience needed to engage in the next difficult conversation to come.

IDENTIFICATION OF HIGH EMOTIONAL DISTRESS

One challenge is handling patients who struggle to adapt to these circumstances and who require more in-depth services. The palliative APRN should identify the patient with high emotional distress when they are first screened in palliative care and enlist the help of a skilled social worker or other counselor to engage more intensively in counseling around coping strategies. Box 11.4 lists a number of “red flag” characteristics that should prompt referral to a social worker or other

Table 11.3 SAMPLE COPING BEHAVIORS AND EXAMPLES⁴²

BEHAVIOR	DEFINITION	ACTIVITY
Distraction	Diverting attention from a stressor	Reading poetry, books or religious books. Listening to music, singing and poetry. Dancing and exercising.
Optimism	Focusing on the positive in life	Looking for the good or positive in situations, such as a serious illness, in terms of what it has meant or brought. Planning for the future and the good things it will bring.
Gratitude	Being thankful for the benefits in life	Communicating appreciation and thankfulness to loved ones, family circle of friends, and health care providers through expressions of verbal or written expressions of gratitude.
Joy	Enjoying the elements of life	Engaging in activities that bring happiness - time in nature, time with loved ones, time with art (painting, singing, dancing, building) or time with sports.
Meditation	Engaging the mind in a focused quietness	Reading, practicing yoga. Listening to guided meditation. Walking a labyrinth. Reading or attending religious rituals.
Humor	Finding amusement in a situation	Finding humor in current situation. Appreciating the absurd, irony, or silly side of life. Making jokes.
Problem-solving	Creating solutions to problems	Planning for the future with financial and legal planning. Embarking on closure.

clinician skilled in problem-solving therapies or cognitive-behavioral therapy.⁴⁶

COPING AND DENIAL

A common reason for referral is concern that the patient is in “denial.” In the face of life-threatening illness, patients cope by avoiding their painful new reality as a way of preserving psychological equanimity. Denial is adaptive until it is proved otherwise, and the palliative APRN should not seek to correct the denial by forcing the patient to discuss topics that are clearly causing discomfort. In patients with incurable lung cancer or non-colorectal cancer, Nipp et al. found that patient denial and self-blame correlated with worse quality of life and mood.⁴⁶ The palliative APRN in the clinic is afforded multiple visits over time to support a patient’s transition from denial to adaptive acceptance.

DEEPENING PROGNOSTIC AWARENESS

Most patients experience an acute stress response driven by a nervous system sympathetic discharge when they are first told they have a life-limiting illness. For many patients, this sympathetic response overloads their cognitive capacities and much of what they are subsequently told may be heard but not comprehended. Over time, the majority of patients pass

through this sympathetically charged, fear-driven stage and into a cognitively intact phase in which they have achieved an accurate understanding of their prognosis. Having this awareness facilitates goal-directed medical decision-making, as when discontinuing chemotherapy prior to enrolling in hospice or when electing not to pursue an implanted defibrillator in NYHA Class IV heart failure.⁴⁷

The minority of patients who struggle with this comprehension phase should be referred to a palliative care clinic to assist with improving prognostic awareness and establishing a relationship for future decision support. With the combination of education and experience in compassionate nursing care and expertise in symptom management, the APRN is well prepared to address “a patient’s capacity to understand his or her prognosis and the likely illness trajectory” (prognostic awareness).⁴³ When palliative care has been involved early in the course of the disease, or when the patient has a slowly progressive disease, the palliative APRN has time to work on fostering resilience, as described earlier. The APRN can intermittently test the patient’s tolerance for discussions of prognosis by asking him or her to imagine worse health states, making use of a “hope for the best, prepare for the worst” framework: “I’m really hopeful that this new chemotherapy regimen will do the trick, and I also wonder, though, if we should plan for what you might do if it doesn’t.”

When the patient’s disease progresses rapidly, or when he or she is referred late to palliative care, the patient may be faced with decisions that depend on adequate prognostic

Box 11.4 CORRELATES OF HIGH EMOTIONAL DISTRESS IN THE FACE OF SERIOUS ILLNESS

- Pessimism
- Regrets about past behaviors
- Denial
- Self-blame
- Relationship, partnership, or marital strain
- History of severe psychiatric illness or suicidal ideation/attempts
- Passive coping style or behavioral disengagement
- Expectation of few familial, friend, or community supports
- Feelings of isolation or hopelessness
- High level of disruption from normal life activities
- Tendency to blame others for personal misfortunes
- History of ineffective coping in response to past stressors
- Lack of trust in healthcare providers

Adapted from Weisman AD, Worden JW. The existential plight in cancer: Significance of the first 100 days. *Int J Psychiatry Med.* 1976–1977;7(1): 1–15; doi: 10.2190/uq2g-ugv1-3ppc-6387; and Nipp et al.⁴⁹

understanding even if he or she is not there yet. The palliative APRN should consider “naming the dilemma” as a way of aligning with the patient but ensuring the conversation is opened. “I can tell that talking about a time when your cancer is worse is really hard to do and I wish we didn’t have to, but I worry that if we don’t we won’t be able to make good decisions together. Can you help me think about a way to discuss this that would feel OK to you?”⁴³

SUPPORTING THE RESILIENCE OF REFERRING CLINICIANS

Palliative APRNs are well-positioned to support their referring colleagues and reduce the risk of compassion fatigue and burnout. The palliative APRN can lighten the referring APRN’s or physician’s workload and time pressures by handling intensive symptom management or by exploring goals and preferences. As a co-manager of complex cases, the palliative APRN serves as a mentor for difficult communication, and the palliative care team-at-large acts as a supportive community for other APRNs and physicians. The palliative APRN can also support the resiliency of other referring APRNs through relationship building that fosters informal discussions of complex cases, which may lead to requests for formal case reviews. Providing shadowing experiences for new APRNs during orientation can also bolster APRN colleagues’ confidence in discussing palliative care services with patients and their families.

COMPREHENSIVE, COORDINATED, CONTINUOUS CARE

An important aspect of quality palliative care is to provide a coordinated assessment and continuity of care along the disease trajectory. The National Consensus Project for Quality Palliative Care *Clinical Practice Guidelines* discuss domains of quality that form the basis of practice. Under Domain 1, Structure and Processes of Care, there is an emphasis on coordinated assessment and continuity of care across all health-care settings.¹⁵ Moreover, a recent review of the literature supporting the integration of palliative care into oncology care for patients with advanced cancer found that specialty palliative care that was team-based, initiated early in the disease trajectory, and targeted to those patients who may benefit (use of triggers for automatic referrals) improves patient outcomes.²⁶ Patients may have complex pain or symptoms requiring frequent medication adjustments and education; they may have multiple specialists involved in their care and experience increased vulnerability during transitions of care. The palliative APRN is well-suited to address this challenge and provide continuity of care.

A skilled coordinating RN is a critical support to the APRN. This RN is primarily responsible for phone triage in ensuring that patients’ symptoms are managed and psychosocial needs are met in a timely manner in between visits. The nurse also communicates with patients’ other providers and helps to coordinate hospital admissions. The RN acts to “extend” the reach of the APRN, handling basic symptom assessment and management (such as bowel medication titration), using appropriate guidelines to allow one to practice within one’s professional nursing scope of practice. When patients are undergoing dose titration of pain medications or require close monitoring for other reasons, the coordinating nurse can make routine phone calls to check in with the patient, ensuring that the correct protocol is followed and optimal results are achieved. Because this RN acts as the “right hand” of the APRN, they are best located in the clinic to ensure optimal communication and collaboration with the APRN and the team. Depending on workload, the nurse may also assist with checking patients in before visits, reconciling medications, assessing and evaluating the effectiveness of interventions, monitoring for adverse effects of medications, and screening for new symptoms or problems.

Another important aspect of providing coordinated care and continuity of care is through the interdisciplinary meeting. The expectation for an inpatient palliative care staff is similar to that for outpatient palliative care staff: the need to meet at least weekly to discuss patients and review new consults and particularly challenging situations. This ensures that the palliative care roles are defined, that handoffs through transition of care are thorough, and that care goals are in alignment. This meeting also provides support to clinicians in the ongoing clinical care.

When providing quality palliative care in the outpatient setting, access to a specialty palliative care provider should be available 24 hours a day, 7 days a week. This service is helpful

not only for patients who have active symptoms but also for referring providers who may need phone consultation about a complex symptom management situation. This is especially important when the palliative APRN dispenses prescriptions to enable follow-up care.

APPROACHING END OF LIFE: LATE WORK

As a patient's life approaches its close, the palliative APRN partners with other clinicians and discusses the perceived benefits and burdens of further disease-directed therapy. This discussion may trigger awareness that the patient's goals need further clarification. Chapter 33, "Family Meetings," offers a thorough review of conducting these discussions. In general, a goals-of-care discussion must be informed by the patient's values and goals and the medically available and/or appropriate treatment options that will meet those goals.

Most patients choose to continue disease-directed therapy as long as they perceive the treatment as beneficial (i.e., it is helping them to meet their goals) and not significantly limiting their quality of life. When a patient's scales tip such that the benefit is outweighed by the burdens, it is often the palliative APRN who learns, through the longitudinal relationship developed in the clinic, that a transition to purely palliative therapies is needed. Some patients may be perceived by their primary specialists as desiring inappropriately aggressive care. Palliative APRNs can elucidate the reasons for these choices: in one typical scenario, a patient is willing to temporarily accept an otherwise unacceptably low quality of life in order to meet certain goals, such as living long enough to be present for a major life event, like the birth of a grandchild. By sharing these motivations with the treatment team(s), the palliative APRN can ease some of the moral distress experienced by clinicians who worry the patient "just doesn't get it."

Increasingly, palliative APRNs are incorporated into the care team of patients with multiple chronic illnesses and multiple specialty providers. The palliative APRN is well-positioned to arrange and facilitate multidisciplinary meetings in the outpatient setting. The palliative APRN serves to translate medical information to the patient and family and helps to elicit the patient's goals, which are reflected back to the medical team. The benefits to patients are clear, given the often fragmented care and communication they experience because they have multiple specialists.

In addition to supporting patients through the transition to end-of-life care, the palliative APRN is in an optimal position to support the patient's primary provider, who may be struggling with anticipatory grief at the thought of losing a patient or guilt that he or she could not cure or forestall the disease's progression. The palliative APRN helps team members to cope through debriefing conversations that allow for expression of emotions and for thorough discussion of the patient's goals and preferences. Knowledge and acceptance of the patient's goals facilitate adaptive coping in the provider.

REFERRALS TO HOSPICE

The rapport and trust developed over time in the longitudinal relationship described in this chapter become the foundation for emotionally charged discussions closer to the end of life. Helping a patient and family make the transition to hospice is one of those complex conversations. In addition to skill in communicating empathically, the palliative APRN should have a thorough understanding of hospice eligibility criteria for the patient's diagnosis and the services provided in the patient's community. Assuming hospice eligibility criteria are met, a patient should be referred to hospice once they are no longer receiving disease-modifying therapy or when coming back and forth to the clinic has become burdensome. At the time of the hospice referral, the palliative APRN should review the patient's medication list to identify medications that might not be on the hospice formulary and suggest alternatives and should prepare for crisis events in the home by prescribing medications for crescendo pain, dyspnea, seizures, or agitation.

Prior to making a hospice referral, the palliative APRN should identify which provider will oversee the patient's care once on hospice. To promote quality care within the transition, the palliative APRN should be explicit that he or she remains available as a consultant to the hospice medical director and should state whether they will serve as the Provider Attending of Record for hospice care. This ongoing consultative relationship helps patients and families feel that they are not being abandoned once a referral to hospice is made and provides expert-level guidance to the clinician managing the patient's care going forward. It is important that the Attending of Record feels comfortable with the current plan of care and feels prepared to manage any foreseeable complex pain or symptom issues. Carefully communicated handoffs at the time of hospice referral are imperative to ensure a smooth transition.

SUMMARY

Embedded in the culture of nursing and APRN education are the skills of communication, assessment and management of symptoms, psychosocial and spiritual support, and coordination of care. The palliative APRN in the clinic draws on these skills, improving patient satisfaction and decreasing healthcare utilization. The longitudinal APRN-patient relationship enhances communication with patients and families, thereby improving the ability to offer patient-centered, preference-sensitive treatment options. Palliative APRNs deliver coordinated, comprehensive care that can lessen the burden of illness on patients and families and may improve the resilience of the clinicians who co-manage these patients with the palliative APRN.

THE PALLIATIVE APRN IN PRIMARY CARE

Rosemary Gorman, Dorothy Wholihan, and Sarah Bender

KEY POINTS

- The advanced practice registered nurse (APRN) in primary care requires a generalist (primary) palliative care skill set and an understanding of referral criteria to hospice and specialist palliative care.
- Primary palliative care skills include knowledge of disease trajectories and the management of multidimensional symptoms, as well as communication skills needed for determination of goals of care and advance care planning.
- Given their long-standing relationships with patients, primary care providers are well-suited to facilitate values-based conversations concerning goals of care.

care management (99496) with an additional 30 minutes spend discussing advance care planning (99498).

Mary's condition continued to decline at home in the next few weeks, and the APRN referred her to hospice after having a discussion with Mary and her family. Mary had her symptoms closely managed and spent her final months surrounded by her family and friends.

INTRODUCTION

The Healthy People 2020 Report, published by The Office of Disease Prevention and Health Promotion, uses the The National Academies of Sciences, Engineering, and Medicine (NASEM) (formerly known as the Institute of Medicine) definition of primary care which is “the provision of integrated, accessible healthcare services by clinicians who are accountable for addressing a large majority of personal healthcare needs, developing a sustained partnership with patients, and practicing in the context of family and community.”¹ Clinicians who provide such care are called primary care providers (PCPs). PCPs offer routine physicals, preventive care, chronic disease management, and referrals for specialty care. APRNs frequently serve as the PCP for patients throughout the life span, often being the first point of contact for a patient's medical care needs. The advanced practice registered nurse (APRN) PCP is therefore in a prime position to identify patients who could benefit from palliative care services. The APRN has the added benefit of working with patients and families over long periods of time with frequent interactions, therefore having well-established relationships.² This gives the APRN the opportunity to deliver primary palliative care by recognizing those patients who could benefit from symptom management of chronic diseases, prognostication, advance care planning (ACP), and timely hospice referrals.³

The implementation of the *Affordable Care Act (ACA)* in 2010 supported legislation to give nurse practitioners full practice authority in many states. The ACA highlighted the need for increased access to primary care as more people in the United States gained health insurance. At the same time, the United States is experiencing an increasing number of people over the age of 65 years who have increased health needs.⁴ Due to advances in medical therapies and technology, our population is living with chronic illnesses for longer. As of 2014,

CASE STUDY: TRANSITIONAL CARE MANAGEMENT

Mary was an 88-year-old woman with history of congestive heart failure (CHF), atrial fibrillation, hypertension, and chronic kidney disease (CKD) Stage 3, who was recently discharged from the hospital after a 7-day admission for lower extremity edema and acute kidney injury. Mary was taking double her Lasix dosing for her lower extremity edema and therefore became volume-depleted. She was treated with gentle oral and IV hydration until her creatinine was back to her baseline. Her furosemide and blood pressure medications were held at discharge. The primary care APRN was notified of her hospitalization and made an appointment within 7 days for high-complexity transitional care management (discussed in the billing and coding section).

During the transitional care management visit, Mary and the APRN discussed her hospitalization and treatment for her chronic conditions. Using palliative care communication skills, the advanced practice registered nurse (APRN) discussed prognostication with the patient, given her most recent symptoms. The APRN proposed a plan going forward for managing the patient's multiple comorbidities and addressed goals of care in this plan. Mary expressed that she values spending time with her family and being at home. She wished to be pain free and comfortable and not be readmitted to the hospital. A medical order for life-sustaining treatments (MOLST) form was filled out by the APRN, who spent an additional 30 minutes discussing advance care planning. The APRN bills for high-complexity transitional

60% of Americans has at least one chronic condition, and 42% had more than one chronic condition.⁵ This highlights the potential for primary palliative care to improve quality of life as the population ages.

According to *Palliative Nursing: Scope and Standards*,⁶ as nurses, all APRNs practice primary palliative care. Basic palliative care is inherent in the definition of nursing: alleviation of suffering through the diagnosis and treatment of human response and advocacy for patients and their families. Furthermore, all nurses provide psychosocial and spiritual support and assist with ACP within the context of a patient's cultural background.⁶ The National Consensus Project for Quality Palliative Care identifies four major domains for primary palliative care: assessment/treatment of physical symptoms; psychological, social, cultural, and spiritual aspects of care; serious illness communication issues; and care coordination.⁶ This includes basic management of physical symptoms, exploring religious beliefs and psychological suffering, ACP conversations, coordination with specialists, and appropriate and timely referrals. There has been a long-documented gap of palliative care demand compared to the availability of palliative care specialty providers.² APRN PCPs are uniquely suited to help fill the gap of palliative care needs within the primary care environment. This chapter discusses how to integrate palliative care skills into the primary care setting, including identifying patients who need palliative care, palliative care for common chronic illnesses, ACP in primary care, billing/coding, prognostication in primary care, and the emerging telehealth trend.

WHO NEEDS PALLIATIVE CARE?

The National Consensus Project for Quality Palliative Care *Clinical Practice Guidelines* defines palliative care as follows: “Beneficial at any stage of a serious illness, palliative care is an interdisciplinary care delivery system designed to anticipate, prevent, and manage physical, psychological, social, and spiritual suffering to optimize quality of life for patients, their families and caregivers.”^{7 (p. 8)} APRN PCPs must be cognizant that palliative care is not the same as hospice care. Moreover, in primary care, both are important and will support the care offered by the PCP.

Palliative care can be applicable early in the course of illness and is also appropriate in conjunction with treatment intended to prolong life. Palliative care focuses on the management of both physical and emotional symptoms experienced by those with serious illness. Palliative care helps to match treatment with a patient's self-identified goals. Since primary care is comprehensive care, basic palliative care must be incorporated as an integral part of primary care. When it is time for hospice, the APRN PCP will need to work with hospice nurses to develop a plan of care and will often continue to order medications and supervise the plan of care. There are numerous resources available to help PCPs determine when hospice referral is indicated.^{3,8}

Today's APRN PCPs must understand primary palliative care principles. Vigilant symptom management for patients

with multiple comorbid diseases can optimize quality of life and minimize unnecessary admissions. Communication skills essential to the determination of individual and family goals can ensure person-centered care. The awareness of and ability to connect with community resources assists patients to access appropriate services, which can help them remain at home. The primary care APRN PCP can provide background and guidance in the ongoing management of long-term patients referred to ambulatory or home-based palliative care or hospice.

The specialist palliative APRN has an important role in collaborating with PCPs in the community. When a patient is hospitalized, inpatient palliative care specialist consultants can assist with appropriate discharge and follow-up planning, providing essential but often-neglected care coordination by maintaining clear, open communication with community providers. Outpatient palliative care specialty clinics and office practices are expanding, and palliative APRNs in these settings need to increase awareness among PCPs about their contributions and how they can develop partnerships for patient care. Palliative care can be translated to the community settings through a variety of models. Outpatient palliative care improves access to early care by providing consultative services to primary care practices, home care agencies, and community residential agencies like assisted living. Early evidence reveals encouraging outcomes, such as increased caregiver support, decreased hospitalization rates, and improved symptom management and quality of life.⁹

Palliative APRNs also need to develop their teaching skills. Providing interprofessional educational opportunities for care partners can facilitate the development of working relationships, increase professional awareness of the benefits of palliative care, and improve the general levels of palliative care knowledge among PCPs. In addition, both primary care nurse practitioners and palliative APRN clinical nurse specialists are well-suited to provide public education in order to increase public awareness of the benefits and availability of palliative care in the community.

The aging of America's “baby boomers” will have a significant impact on healthcare. The number of Americans ages 65 and older is projected to nearly double from 52 million in 2018 to 95 million by 2060, and the 65-and-older age group's share of the total population will rise from 16% to 23%.¹⁰ Technological advances in both the pharmaceutical and medical device industries have improved medical care and resulted in the increased survival of individuals with chronic conditions. An estimated 50% of people older than 60 have more than one chronic condition.¹¹ Diseases previously considered terminal, such as HIV, end-stage renal disease, liver failure, heart failure, chronic obstructive pulmonary disease (COPD), and cancer, are now chronic long-term health problems, with basic healthcare managed by APRN PCPs in specialty consultation as needed.

Progressive chronic disease can have an uncertain illness trajectory, one characterized by intermittent disease exacerbations and progressive decline in functional status, together with an associated high symptom burden. This care requires palliative interventions to maintain quality of life. There is a

dearth of evidence for the management of patients with multiple coexisting chronic conditions, which adds to the complexity of treatment and difficulty with prognostication. The principles of palliative care can guide the APRN PCP in basic symptom management and the establishment of treatment plans based on realistic goals.

INTEGRATING PALLIATIVE CARE INTO THE PRIMARY CARE OF COMMON CHRONIC ILLNESS

HEART DISEASE IN PRIMARY CARE

The Centers for Disease Control and Prevention (CDC) identifies heart disease as the number one cause of death in the United States, with 6.2 million adults identified as having heart failure.¹² With evolving pharmacologic and technologic therapies, these patients are living longer. The symptom burden identified by those with heart failure has been reported to include general discomfort and fatigue, anorexia, dyspnea, depression, and anxiety. In addition, patients with advanced congestive heart failure routinely have multiple comorbidities and multiple symptoms. Primary palliative care can facilitate coping with complex symptoms, decrease frequency of exacerbation and hospitalization, and help with ongoing determination of care goals in the context of evolving specialized therapies¹³ (see Chapter 13, “The Palliative APRN in Specialty Cardiology” and Chapter 54, “Discontinuation of Cardiac Therapies” for more details on heart disease management).

CHRONIC OBSTRUCTIVE PULMONARY DISEASE IN PRIMARY CARE

COPD refers to a group of diseases that cause obstruction of the airways with resulting breathing problems; COPD includes emphysema and chronic bronchitis. The CDC cites COPD as the third leading cause of death in the United States, affecting more than 16 million Americans.¹⁴ COPD is a crippling disease and significantly affects quality of life. Breathlessness is the primary symptom of advanced COPD and can be accompanied by pain, fatigue, and insomnia. Anxiety, depression, and social isolation contribute to psychological suffering and the high symptom burden. Primary palliative care skills are integral to successful symptom management, but also help the PCP with the difficult issue of prognostication in this disease.¹⁵ Further discussion of palliative care issues in advanced respiratory disease can be found in Chapters 44 and 55.

CANCER AND SURVIVORSHIP IN PRIMARY CARE

The American Cancer Society reports that cancer survival rates have improved within almost all of the most common cancers. The 5-year relative survival rate for all cancers diagnosed from 2009 to 2015 was 67% overall, 68% in Whites, and 62% in Blacks.¹⁶ As these numbers grow, health professionals

are learning that there are a wide array of clinical issues which may arise, both physical and psychological. Some survivors will have little sequelae, while others may experience a higher probability of cancer recurrence, long-lasting emotional difficulties, or symptoms related to treatment side effects. These side effects may not occur until years after treatment is completed. Cardiac problems, neuropathy, osteoporosis, and liver or lung problems can arise, as well as an increased risk of other cancers. Anxiety and depression can also have a significant impact on quality of life. PCPs should determine who is at high risk for recurrence or late symptoms to provide appropriate surveillance and support.¹⁷ *Cancer survivorship care plans* are individualized treatment and follow-up plans which are now recommended by the major cancer care organizations and can be helpful for patients and PCPs who may not be familiar with chemotherapeutic agents and the possible long-term effects of cancer and cancer treatment.¹⁸

The American Society of Clinical Oncology (ASCO) and the National Comprehensive Cancer Network (NCCN) have issued evidence-based clinical practice guidelines for common symptom issues facing cancer survivors, including fatigue, anxiety, depression, chemotherapy-induced peripheral neuropathy, sexual dysfunction, and menopausal symptoms.¹⁷ In addition, the American Academy of Family Physicians has published a helpful series on the primary care of patients surviving specific types of cancer, detailing surveillance and symptom issues for those surviving cancers of the breast, prostate, and colorectal.^{19–22} While reimbursement is currently not available for the completion of the Survivorship Care Plan—composed of the treatment summary and long-term care plan—ASCO and others are actively working on legislation to enable providers to bill for this service, and the organization does provide some guidance on billing for survivor-related symptoms.²³ The APRN PCP should maintain awareness of ongoing survivorship issues and coordinate care with oncology services as needed (see Chapter 24 for more detail on specific care issues).

FRAILITY

The aging population and better long-term management of chronic conditions create a focus on frailty in the elderly. Although there is no consensus on definition, frailty is understood to be a state of increased vulnerability to adverse health outcomes in a defined age group.²⁴ Two primary tools used to evaluate for frailty are the Frailty Index, which is a ratio of deficits in a particular age group, and the Frailty Phenotype, which consists of three or more of the following traits: unintentional weight loss, fatigue, weakness, low walking speed, and low physical activity.²⁵ Similarities between frailty measurements and the Palliative Performance Scale (see section on Prognostication) shows the relevance of primary palliative care for frail patients.

Frail patients are at a higher risk of adverse health outcomes, including falls, hospitalizations, and even death.²⁵ Furthermore, frail patients have a higher symptom burden than their non-frail counterparts, which can decrease quality of life. Weight loss, weakness/slowness, fatigue, depression,

falls, and pain are the most common symptoms among frail patients.²⁵ Knowing that frailty contributes to worse health outcomes, it is less likely that aggressive medical interventions will be of value. Although frailty cannot be used as a primary hospice diagnosis, it often coincides with other chronic illnesses that can qualify a patient for hospice.

Recognition of frailty, optimization of community resources, and early ACP are essential. A scoping review of communication about frailty in the primary care setting found that older adults wish to discuss ways to prevent or improve their condition, potential complications, and prognosis.²⁶ APRN PCPs should recognize and address frailty as a syndrome and understand its effect on functionality and prognosis because it may have clear implications in terms of treatment decisions and goals of care. APRNs have the opportunity to improve the patient's quality of life by addressing symptoms of frailty and leading goals-of-care discussions accordingly in the primary care setting.

DEMENTIA

According to the Alzheimer's Association, Alzheimer's disease accounts for 60–80% of the cases of dementia and is now the sixth leading cause of death in the United States.²⁷ There are more than 5.8 million people age 65 or older living with Alzheimer's disease in 2020, with 13.8 million people expected to be living with the disease by 2050.²⁷ PCPs are on the frontlines of providing dementia care. Early recognition is key, and dementia should be addressed as a terminal disease. Patients with Alzheimer's disease and other dementias and their caregivers require complex symptom management and support.

Dementia is an incurable and life-limiting illness; it is characterized by a slow progressive decline of cognitive abilities and functional decline that ultimately limits participation in activities of daily living. This neurodegenerative disorder leads to severe cognitive deficits, gradual functional decline, and death. Currently, there is no cure or therapy to halt or reverse this devastating disease. Delirium and behavioral problems associated with dementia can be challenging to attribute to the disease itself versus other common etiologies, such as adverse drug effects, infection, dehydration, hyponatremia, and a wide variety of other chronic conditions.²⁸ Caregivers who report these symptoms often have their own degree of distress, reflecting the importance of managing the dyad of needs of both caregiver and patient.

Primary palliative care for people with advanced dementia can reduce symptom burden, prevent unnecessary interventions, improve caregiver burden, and increase quality of life.²⁹ Challenging prognostication issues and strict requirements for hospice admission leave dementia patients and their caregivers with few resources. The length of time from diagnosis to advance-staged illness means that APRN PCPs provide care for longer periods, with different types of interventions and support needed. The APRN PCP should guide care in line with palliative care principles that focus on proactive management of symptoms, caregiver support, and ACP.

Emphasis is placed on early recognition and management of behaviors and caregiver assistance in medical decision-making. Coordination of care among providers can also ensure that benefit versus burden is fully understood when treatment goals are determined (see Chapter 45, "Cognitive Impairment").

RENAL DISEASE

CKD affects approximately 15%—or 37 million—of US adults.^{30,31} Most patient with CKD will remain in Stages I–V, however some progress to end-stage renal disease (ESRD), as defined as a glomerular filtration rate (GFR) of less than 15 mL/min. ESRD is seen in approximately 650,000 patients per year in the United States, with the number increasing by 5% annually.³² Many of these patient are on hemodialysis for survival, which has a high symptom burden and is costly for the healthcare system. APRN PCPs have the obligation to discuss all treatment options for CKD and ESRD with their patients and develop a plan aligning with goals of care.

Shared decision-making is beneficial in the primary care setting when patients are healthy enough to participate and can discuss the benefits and burdens of treatment options.³³ APRN PCPs will often see renal disease patients throughout their illness trajectory and have the opportunity to have continuing goals-of-care discussions with their patients in which they outline symptoms burden and quality of life. These conversations often happen in collaboration with a nephrologist, family members, social workers, and anyone else familiar with the patient's CKD course. Information should include an estimated prognosis and a clear description of dialysis and conservative treatment options, including risks and benefits as well as side effects of all options.³⁴ Patients should be assured that ongoing symptom management and care will continue regardless of treatment course.

High symptoms burden in CKD appears to be as common in conservatively managed patients as in those managed with dialysis.³⁴ The myriad of symptoms may include pain, fatigue, pruritus, dyspnea, edema, dry mouth, muscle cramps, restless leg syndrome, sleep disturbance, and constipation.³¹ PCPs or a palliative care specialist, depending on the complexity, can manage these symptoms. Patients with ESRD are good candidates for palliative care referral given their large symptom burden, poor quality of life, and need for ACP. The trusted APRN PCP may be most suitable to suggest referral to palliative care specialists (see Chapter 8 to learn more about renal care).

PROGNOSTICATION

"How long do I have?" This is the question most frequently asked by patients facing a terminal illness or debilitating condition. *Prognosis* is a prediction of the outcome of a disease based on medical knowledge and experience.³⁵ Prognosis can affect treatment decisions as well as eligibility for hospice care. Diseases that result in chronic organ failure can have multiple exacerbations, any one of which could result in death, thus

making prognostication extremely difficult even for skilled palliative care specialists. The rate of decline in functional status can be a key indicator in determining prognosis. These tools can help palliative care specialists with prognostication:

- *The Palliative Performance Scale* (PPS) is a reliable and valid tool for the measurement of performance status in palliative care. It uses the patient's functional status to predict survival. The PPS evaluates ambulatory status, activity level, evidence of disease, level of consciousness, and the ability to perform self-care. Periodic measurements document the evolving physical deterioration of an individual. The rapidity of the functional decline likely corresponds with rapid deterioration and ultimately a shorter survival.³⁶
- *The “surprise question”*: “Would I be surprised if this patient died in the next year?” This simple question has been recognized as a tool to improve end-of-life care in both primary care and dialysis populations. A “no” answer to this question can serve to identify patients with a poor prognosis who would be appropriate for palliative care. Although research shows that the accuracy of the surprise question varies, it is a tool recommended and widely used.³⁵
- Mobile applications and online resources containing prognostic information and tools exist for a multitude of individual medical conditions. Box 12.1 lists useful resources to assist in prognostication in primary care.

A patient's relationship with a PCP develops over time. Due to advances in medical technology and pharmacotherapy, patients with chronic illness and multimorbidities can experience a long trajectory, with multiple exacerbations of each chronic disease. Given their long-standing relationships with patients, PCPs are well-suited to facilitate values-based communication concerning goals of care. ACP is a process that is ideally developed over multiple interactions, not during a period of crisis. Changes in a patient's condition warrant evolving discussions of treatment, including the specific impact of the treatment on the patient's quality of life and ongoing reassessment of ACP. An informed PCP can consider the synergistic symptom burden, along with the patient's specific goals and values, and counsel the patient accordingly. Racial and ethnic differences must also be considered; knowledge of a patient's cultural beliefs and practices may influence their care choices and define their decision-makers.^{37,38}

Patient-centered care requires that patients are well-informed about their condition. The success rate of proposed treatment, the overall prognosis with and without treatment, and the expected impact on quality of life are all important aspects for an individual to consider in making a decision regarding treatment and goals of care. Such information may help patients establish their priorities, make informed decisions regarding treatment, and ultimately formulate an advance directive. ACP is best done in the primary care setting because the established ongoing patient–practitioner relationship in the primary care setting gives the practitioner

- I. MPI (Multidimensional Prognostic Index), a prognostic tool based on a standard geriatric assessment, predicts short- and long-term mortality in the elderly.
- II. Qx Calculate, an app focused on highlighting tools used in clinical practice that affect diagnosis, treatment, and prognosis. It includes prognostic indicators for heart failure, lymphoma, myeloma, hemodialysis, COPD, transient ischemic attacks, pancreatitis, and many others.

insight into the patient's support system and values. This familiarity opens the door for an honest, nonintimidating discussion about values, ultimately leading to an advance care plan. Because goals and preference change over time, this is best done as an ongoing conversation between patients and providers.³⁹

The Conversation Project National Survey 2018 reports that 92% of Americans say that it is important to discuss wishes for end-of-life care, but only 32% have had this conversation. Ninety-five percent stated they would be willing to have this conversation, and 53% stated they would be relieved to discuss their end-of-life wishes.⁴⁰ ACP often involved completion of an advance directive (AD), which is a written document, varying by state, of a patient's assigned health care proxy (HCP) and their goals, values, and wishes for future healthcare, sometimes referred to as a Living Will.³⁹ Advance directives are typically followed if a patient loses decision-making capacity. Because goals and circumstances can change, it is important that the AD is an ongoing conversation with the patient. It is equally as important to assign an HCP who understands the patient's goals and values. The National Hospice and Palliative Care Organization website, CaringInfo,⁴¹ has a list of advance directives and instructions for each state. It is important that the PCP keeps an easily accessible and updated record of this document for all of their patients.

The ACA expanded access to high-quality end-of-life care for Americans with serious illness.⁴² Reimbursement for end-of-life discussions was one of the provisions of the ACA. Repeal or replacement of the ACA is a possibility, and this may shift the risk and responsibility for healthcare payments to individual states, healthcare organizations, commercial payers, and possibly even patients and families. State policy may be expected to play an increased role in determining who gets care and how it is paid for within the standards of quality and safety. Individually, some states have policies that require information on palliative care be made available to patients with serious illness, and other states are requiring hospitals, skilled nursing facilities, and long-term care facilities to identify those patients who could benefit from palliative care and distribute information regarding its availability. Many states are using their authority over professional licensure to increase access to palliative care by mandating that clinicians pursue continuing education in pain management, palliative care, and addiction.⁴³ Individual states vary in their acceptable ACP documents and the practitioners who can sign them to make them valid. Nurse practitioners can check the American Association of Nurse Practitioners website (www.aanp.org) to view the Nurse Practice Act for their individual state's restrictions.

The goal of ACP is to help ensure that people receive medical care that is consistent with their values, goals, and preferences during serious and chronic illness.⁴⁴ ACP has been proved to decrease healthcare costs, hospitalizations and prolonged intensive care unit admissions, do-not-resuscitate orders, and cardiopulmonary resuscitations, mechanical ventilation, and use of feeding tubes.⁴⁵ Families also report higher satisfaction when ACP has taken place. Given that PCPs can now bill for having these discussions, and ACP is considered a low-risk high-value intervention,⁴⁶ it is essential that the APRN PCP initiate these important conversations (for more information on the process, see Chapter 32).

ACP requires substantial communication skills and can be challenging. Healthcare professionals who have established long-term relationships with their patients may face the difficulty of “letting go.” Furthermore, end-of-life preferences can be complicated and influenced by religion, race, and culture, requiring providers to be culturally sensitive to the population they serve. When discussions about ACP become a routine part of a primary care visit, the interactions can be calm and nonthreatening.⁴⁷ APRNs can improve their comfort and competence in addressing goals of care through formal academic or continuing education programs that emphasize communication skills. The use of simulation has become increasingly popular in teaching communication strategies (see Chapter 2 for discussion of strategies to improve palliative APRN education). Strategies to improve completion rates of ACP in primary care include improved reimbursement, increased patient awareness, and educational efforts geared to improving communication skills among providers.⁴⁸ Chapter 33 discusses advance directives. Box 12.2 lists educational resources for professionals to facilitate ACP discussions in primary care settings. Box 12.3 presents resources for patients and families.

Box 12.2 EDUCATIONAL RESOURCES FOR ADVANCE CARE PLANNING DISCUSSIONS IN PRIMARY CARE

1. End-of-Life Nursing Education Consortium (ELNEC): ELNEC is a national education initiative to improve palliative care. ELNEC offers a 2-day course to prepare APRNs to deliver appropriate palliative and end-of-life care, including symptom management and communication. An additional intensive course on communication has also been developed. Free COVID-related materials available.⁴⁹

BILLING AND CODING FOR PALLIATIVE CARE WITHIN THE PRIMARY CARE VISIT

There are a number of opportunities for APRNs to bill for time spent performing palliative care skills during a visit, including ACP, transitional care management, and prolonged services. Providing palliative care in the primary care setting often requires an extended amount of time beyond the allotted visit time, and it is important for the APRN to learn how to be reimbursed for these services. To bill for these discussions, documentation must meet specific criteria under Medicare regulations. Private insurers may have specific codes, thus making these discussions reimbursable with specific criteria. Evaluation/management and diagnosis codes are based on location, complexity, and effort. When counseling/information-giving represents more than 50% of the patient visit, it may be most appropriate to bill by time, and the provider should select an evaluation and management code that corresponds to the total time of the face-to-face visit.⁵¹

BILLING FOR ADVANCE CARE PLANNING

ACP is defined as “the process that supports adults at any age or stage of health in understanding and sharing their personal

The *Five Wishes* tool is available in 28 languages and Braille; it is written in simple language and is legal in 42 states. Available through Aging with Dignity, which provides tools and guides for discussions with individuals, families, children, adolescents, and young adults (<http://agingwithdignity.org>).

PREPARE is a patient-friendly online resource to assist individuals in making complex medical decisions by using video. Videos are used to help identify values and how to communicate them with family and physician. The content is developed at a fifth-grade reading level and is easy to use (<http://prepareforyourcare.org>).

Mydirectives.com is a free online advance care planning service. My Directives is a global advance care planning digital platform and repository that allows patients and practices to develop their own documents or upload existing ones (<https://mydirectives.com/en/>).

Caring Conversations provides a workbook in Spanish and English to guide patients through the advance care planning process. Individual guidance is also available if needed (<https://practicalbioethics.org/programs/advance-care-planning.html>).

The Conversation Project is an initiative of the Institute of Healthcare Improvement (IHI), which emphasizes public engagement in values-based care planning and provides practical resources for public use, including a *What Matters to Me* workbook (<https://theconversationproject.org/>).

values, life goals, and preferences regarding future medical care. The goal of ACP is to help ensure that people receive medical care that is consistent with their values, goals and preferences during serious and chronic illness.⁵² There are two current procedural terminology (CPT) codes that can be used for ACP, either in addition to or independently from an E/M code. The code 99497 is “Advance care planning including the explanation and discussion of advance directives such as standard forms (with completion of such forms, when performed), by the physician or other qualified health care professional; first 30 minutes, face-to-face with the patient, family member(s), and/or surrogate.”⁵³ Code 99498 may be added to 99497 for each additional 30 minutes of time spent.

There is no limit to the number of times the code can be billed for a patient, as long as the documentation supports a change in health status or directives. ACP can include discussed goals/preferences of care, making complex decisions about life-limiting illness, and introducing and/or completing forms such as a health care proxy, durable power of attorney, living will, and medical orders for life sustaining treatment (MOLST).⁵¹ It is important for the APRN to document a brief summary of the conversation, who was present, total time in minutes (including start and end times), and if any forms were introduced or completed. More information about ACP can be found in Chapter 33 and billing and coding in Appendix I.

BILLING FOR TRANSITIONAL CARE MANAGEMENT

Transitional care management (TCM) was designed to allow health professions to provide postdischarge care for patients who were hospitalized for moderate to high-complexity medical conditions. Patient are especially vulnerable during the transition, especially elderly patients with chronic health conditions.⁵⁴ TCM was adopted by Medicare in 2013 to improve patient outcomes after being discharged to the community from a medical facility. This involves follow-up on patients discharged from an inpatient facility and their transition to home, as well as a face-to-face visit within a required timeframe. This face-to-face visit allows the practitioner to discuss the condition or exacerbation of the condition precipitating

the admission, the treatment that was rendered, and its impact on the patient’s quality of life and/or functional status. The potential for repeat exacerbations and the implications for further care can also be discussed. For example, an end-stage COPD patient who was recently hospitalized with an exacerbation requiring intubation may verbalize a request to never endure intubation again, leading to a pertinent goals’ discussion and the implementation of an AD document.

Clinicians can receive an enhanced reimbursement for office visits following an eligible discharge. There is a specific 30-day period for TCM which begins on the date the patient is discharged from a medical facility. Patients with high-complexity needs must be seen within 7 days of discharge and within 14 days for moderate-complexity needs.⁵⁵ Three components must be met: (1) interactive contact within 2 business days of discharge, (2) non-face-to-face services throughout the 30-day period, and (3) required face-to-face visit within 7 or 14 days of discharge. To complete non-face-to-face services throughout the 30-day period, the APRN may obtain and review discharge information, coordinate care with all clinicians treating the patient, educate patients and their families, establish referrals within the community, and assist with follow-up care.⁵⁶

There are two CPT codes that can be used for TCM: 99495 is used for services with moderate medical decision complexity within 14 days of discharge, and 99496 may be used for high medical decision complexity within 7 days of discharge. This visit may be done via telehealth, in accordance with existing Medicare regulations for telehealth services. Medicare beneficiaries who receive TCM services have been shown to have lower Medicare costs and decreased mortality in the subsequent month as compared to patients who do not receive these services.⁵⁴ APRNs can utilize TCM billing codes not only for higher reimbursement rates, but also to improve their patients’ coordination of care and outcomes.

BILLING FOR PROLONGED SERVICES

Providing palliative care services often requires APRNs to spend more face-to-face time than captured by E/M codes. *Prolonged services codes* are used to capture this time spent.

Examples of this include a family meeting to discuss treatment options or explaining complex treatments or additional factors (need for interpreters, visual aids, etc.). Prolonged service codes are *add-on* codes that can be used in conjunction with an E/M code. These codes are only billed when the time involved exceeds the typical time of E/M service by more than 30 minutes. The highest level of E/M code must be billed prior to billing for prolonged services.⁵⁷ For example, if the APRN saw a patient with moderate-complexity medical decision-making for approximately 25 minutes and 99214 was billed as the E/M code, the APRN would have to spend an additional 30 minutes (for a total 55 minutes) to bill for prolonged services. The CPT code used for prolonged services of 31- to 75-minute visits is 99354. Visits that last 76–105 minutes can use the codes 99354 and 99355. The APRN must be with the patient during all of the time being billed for prolonged services. The start and stop times must be documented, as well as the content of the prolonged services. The APRN who spends prolonged time providing palliative care skills to the patient should utilize these codes to get reimbursement for time spent.

Table 12.1 summarizes the CPT codes that can be used to bill for palliative care provided in the primary care setting. Further details of reimbursement for APRN palliative

care are detailed in Appendix 1, Palliative APRN Billing and Coding.

TELEHEALTH

Telehealth is a new and emerging trend in primary care, one accelerated during the COVID-19 pandemic. Telehealth, sometimes referred to as *telemedicine*, consists of using telecommunications and digital communication technologies to deliver and facilitate health and health-related services.⁵⁸ Video platforms, including Apple Face Time, Google Hangouts, Zoom, Skype, Doximity, and EMR platforms, are commonly used to provide telehealth services. The use of these different video platforms was liberalized during the COVID-19 pandemic by the US Department of Health and Human Services.⁵⁹ Furthermore, Medicare and Medicaid expanded insurance coverage to allow providers to bill for telehealth visits for the same reimbursement as face-to-face visits during the COVID-19 pandemic under the 1135 Waiver.⁵⁹ This transition toward telehealth in primary care is pivotal for providing access to care for vulnerable populations that often have difficulty accessing traditional medical services.⁶⁰

Table 12.1 COMMON CODES FOR PALLIATIVE CARE INTERVENTIONS

CPT CODE	DESCRIPTION	REQUIRED ELEMENTS	TIME-BASED CODING THRESHOLD	TIPS-NOTES
99497	Advance Care Planning (ACP) – first 30 minutes	Explanation and discussion of advance directives such as standard forms (including the completion of such forms) by the APRN; first 30 minutes, face-to-face with the patient, family members and/or surrogate.	First 30 minutes (16–45 min)	Forms do not have to be completed to bill this code.
99498	ACP – additional 30 minutes	ACP each additional 30 minutes	Each additional 30 minutes (>45 minutes)	Billed with 99497.
99495	Transitional Care Management Services – Moderate Level Decision Making	Three components – 1. Call required as initial interaction within 2 days of discharge; 2. F2F visit within 14 days; 3. Non F2F interaction throughout 30 days after discharge.	Face-to-face visit within 14 days of discharge	F2F must be completed within 14 days of discharge to bill for service.
99496	Transitional Care Management Services – High Level Decision Making	Three components – 1. Required initial interaction within 2 day - phone, telehealth, IT; 2. Non F2F interaction; 3. F2F visit within 7 days.	Face-to-face visit within 7 days of discharge	For more complex patients, who must be seen within 7 days of discharge.
99354	Office/Outpatient prolonged discussion with direct patient contact – first 30 minutes	Prolonged evaluation and management service before and/or after direct patient care; first 60 minutes	30 minutes beyond the usual service	Counseling, education or exploration of goals of care >50% of the encounter; the visit may be billed based on time.
99355	Office/Outpatient prolonged discussion with direct patient contact – additional 30 minutes	Prolonged evaluation and management service each additional 30 minutes	Each additional 30 minutes	Billed with 99354.

Adapted from CAPC^{51,55–57}

Telehealth visits provide a unique opportunity to have a face-to-face interaction with patients in their own environment, much like home-based care. Palliative care patients are often seriously ill and benefit from the ease and convenience of having a video visit in their home. The APRN has the chance to observe the patient's daily life, social supports, and functionality at home. For example, the APRN may observe the elderly patient ambulating down a hall or up the steps to assess their gait stability and use of assistive devices at home versus outside the home. The APRN might also ask to review the patient's medications by showing them how they store and take their medications for an accurate medication reconciliation. If family members can participate in the visit, the APRN might use the occasion to discuss ACP. These types of opportunities provide similar benefits to home care without the logistical challenges of a home visit. Furthermore, studies show that patients are highly satisfied with the quality of care they receive using telehealth platforms.⁵⁸ See Chapter 17 on the APRN in Telehealth for more information.

SUMMARY

Growing evidence demonstrates the benefits of early palliative care for patients with serious illness, and palliative care shares many common goals with primary care. Primary and palliative care address the patient with serious illness within the context of their diagnosis and their community, emphasizing symptom support and communication, with a focus on care over time^{7-8, 32}

APRN PCPs are well-suited to incorporate palliative care into their practices. Their unique blend of medical knowledge with an educational background based on a holistic nursing model makes the APRN a prime candidate to assume the role of PCP, able to deliver high-quality, patient-centered health-care. Practicing within a primary care framework allows the APRN to establish an ongoing relationship with the patient and family, which facilitates an honest, trusting bond and positions the APRN to monitor the patient's progress over time. This ongoing relationship can allow the primary care APRN to discuss goals of care with an educated patient/family in a nonemergent environment, revising the advance care plan as needed. APRNs who integrate palliative care into their primary care practices should understand the range of disease trajectories and multidimensional symptoms, as well as the communication skills needed for ACP and end-of-life decision making. Once adept at these skills of symptom management and care planning, primary care APRNs can play an integral role in incorporating primary palliative care into their practice and serving as a role model to others.

THE PALLIATIVE APRN IN SPECIALTY CARDIOLOGY

Beth Fahlberg, Ann Laramee, and Erin Donaho

KEY POINTS

- Patients with cardiac conditions have unique needs, experiences, pathophysiologies, and devices that necessitate a specialized approach to palliative care.
- The palliative advanced practice registered nurse (APRN) facilitates individualized discussions about goals of care and treatment considerations with patients and families.
- Effective teamwork is enhanced by the palliative APRN's understanding of common cardiac diagnoses, tests, treatments, and medications, as well as the patient with serious cardiac disease and the cardiology mindset.

CASE STUDY: IMPLANTABLE CARDIOVERTER DEFIBRILLATOR

RB was a 72-year-old retired bank executive with advanced heart failure whose history included myocardial infarction (MI) with cardiogenic shock and coronary artery bypass graft 15 years ago. He was admitted with a new MI, with an ejection fraction of 20% after experiencing several months of fatigue. He was not a candidate for bypass surgery or stent, so his medications were adjusted to make him more comfortable. Two months later, an implantable cardioverter defibrillator (ICD) was placed to prevent sudden death.

After ICD placement, RB was hospitalized for heart failure (HF) three times and his ICD shocked him on five separate occasions for ventricular fibrillation. To prevent additional shocks, his cardiologist prescribed the antiarrhythmic drug amiodarone. However, 1 month after starting this medication, RB developed worsening shortness of breath caused by amiodarone pulmonary toxicity. The amiodarone was discontinued, and his treatment was changed to oral prednisone and continuous home oxygen to treat his pulmonary symptoms. The prednisone caused fluid retention, exacerbating RB's HF. As the amiodarone wore off, RB's heart went into frequent arrhythmias.

One day, his ICD shocked him every 2 minutes five times in a row. He was alert through the incident, crying out in distress. When the paramedics arrived, they deactivated the ICD by placing a magnet on it and transported him to the hospital with continuous cardiac monitoring, advanced cardiac life support (ACLS) drugs, and external defibrillator ready for immediate use. Upon arrival to the emergency department an

electrophysiologist and device nurse interrogated his ICD. He had received two appropriate shocks for slow ventricular tachycardia while three were unexplained, likely due to a faulty lead. His daughter, who witnessed the episode at home, was traumatized, saying she would never forget that horrible experience.

RB's cardiologist placed a palliative care consult to clarify his goals of care and treatment options. Two treatment options were presented to RB and his family. The first was to replace his malfunctioning ICD with cardiac resynchronization therapy (CRT), with goal of improving his functional status and prolonging his life. The cardiologist explained that CRT had a 60% chance of improving his quality of life and functional status. However, the procedure imposed several important risks, including kidney injury and potential dialysis, infection, or HF exacerbation. It was also likely that RB would still receive shocks from a new ICD since he continued to have ventricular arrhythmias without the benefit of additional antiarrhythmic medications.

The second option would be to discontinue the ICD to prevent further shocks. This could result in sudden death at any time, but he would avoid further surgery, potential complications, and complex medical interventions as well as increased medical and insurance costs. The goal would be comfort with enrollment in hospice.

When the palliative advanced practice registered nurse (APRN) met RB, she assessed that he demonstrated signs of severe anxiety any time the ICD was mentioned. Knowing patients could develop posttraumatic stress disorder after repeated ICD shocks, she explored his feelings about the ICD. RB cried, "I just want this thing out of my body!" When asked about his goals of care, he exclaimed "I'm so tired of this! I just want to go home and be left in peace! My dad died in his sleep. That's the way to go. The life I've got now is hell on earth!"

Based on RB's goals, and with the agreement of the cardiac team, the palliative APRN facilitated a discharge plan with hospice focused on comfort. His ICD was deactivated. Five weeks later, RB died suddenly while watching a football game with his family.

INTRODUCTION

Heart disease is the leading cause of mortality in the United States for both men and women, accounting for approximately 655,000 deaths per year. As of 2016, approximately 6.2 million Americans had heart failure and sudden cardiac

death appears on 13.5% of death certificates.¹ Cardiovascular disease continues to grow in prevalence and cost. By 2035, it is estimated that 45% of the US population will have some form of cardiovascular disease, with total costs reaching \$1.1 trillion, rising from \$351.3 billion in 2015.¹ Even so, only 10–16% of inpatient patients with cardiac conditions receive a palliative care consult,² and patients with heart problems represent only 17.6% of Medicare patients who receive the support of hospice.³

The purpose of this chapter is to describe the role of the palliative advanced practice registered nurse (APRN) in an acute cardiac unit. The palliative APRN working with patients with cardiac disease must understand the cardiology mindset, the trajectory of cardiac disease, common symptoms, shared decision-making specific to cardiac tests and treatments, and the barriers to the use of palliative care.

The palliative APRN has a unique set of skills and perspectives that are beneficial within cardiology. Thus far, most efforts to integrate palliative care in cardiology have focused on patients with heart failure (HF) and advanced HF treatments. However, palliative care is also needed in acute care cardiac specialty units, as well as cardiology and cardiac surgery clinics. Many patients and their families are faced with decisions about potential interventions that pose significant risk, particularly in patients with significant comorbidities

or frailty or of advanced age. It is essential to have a foundational understanding of common cardiac medications, tests, and treatments, and the risks and benefits of each. The APRN should be familiar with tools for risk stratification and shared decision-making associated with common and challenging decisions about cardiac medications, procedures, and devices.

PALLIATIVE CARE FOR PATIENTS WITH ADVANCED CARDIAC DISEASE

Over the past 15 years, palliative care for patients with advanced cardiac disease has become widely accepted and increasingly evidence- and guideline-based due to the unflagging and coordinated efforts of both cardiology and palliative care clinicians, providers, and researchers.⁴ Despite these advancements, barriers exist to palliative care for patients with cardiac conditions. Due to the uncertainty of the cardiac illness trajectory, referrals to hospice care are often too late to benefit the patient and family.

Palliative care for advanced cardiac disease should be a seamless collaborative process with referrals to palliative specialists at key points in the disease trajectory, as illustrated by the stars in Figure 13.1. Early in the trajectory, the cardiac

Figure 13.1 Palliative care across the heart failure trajectory.

specialty team is responsible for providing primary palliative care, referring to palliative specialists as needed. When the cardiac disease progresses to advanced HF, which has a poor prognosis, the patient should be referred to palliative specialists because symptoms and shared decision-making become more complex.^{5,6}

Despite widespread recognition of palliative care as important, integration of palliative care in routine cardiology decision-making and practices can be challenging. Many barriers to specialist palliative care referral for patients with cardiac conditions have been described.^{7,8} These barriers include cardiology providers' lack of understanding of palliative care and its benefits, their discomfort communicating about palliative care issues, and reimbursement limitations. At any given time, the high volume of patients with cardiac issues in any healthcare organization may be an issue for a palliative care program. Smaller palliative care teams may become overwhelmed by referrals for patients with advanced heart disease and the complex situations they encounter. Evidence shows that HF outcomes can be improved using both primary and specialty palliative care.⁴ As a result, most palliative care within a cardiology population is often implemented using a primary or integrated palliative care model by cardiac nurses and primary care providers. Table 13.1 provides detailed information about cardiac medications.

The responsibility for the care of patients with HF falls within the circle of health providers that includes primary care, cardiology, and mental health as well as community supports. They will provide primary palliative care. This includes the assessment and treatment of physical, psychological, spiritual, emotional, and cultural aspects of care.⁴ This should begin at the diagnosis of the cardiac condition and be integrated throughout the continuum of cardiac disease and HF. The collaboration of a cardiology and HF team and palliative care facilitates better understanding of the illness and a more informed understanding of treatment options, with the goal of informed decision-making.⁹

Over the past several years, evidence has accumulated supporting the integration of palliative care into the management of patients with cardiac disease.⁴ Expert consensus guidelines in cardiology recommend the integration of palliative care throughout the patient's trajectory of illness, particularly when decisions are being made for advanced therapies such as mechanical circulatory devices or transplantation.⁹ However, the care of patients with advanced cardiac disease may be fraught with moral distress. While there have been improvements in care as a result of advancements and technology in cardiology, there is the potential for moral distress for clinicians surrounding care decisions. Therefore, it is important to learn from the experiences of patients and their families as well as clinicians to inform the translation of evidence into practice. Within palliative care, the goal is to optimize function and promote quality of life while the patient lives with advanced heart disease. At the end of life, the focus changes to dying well through the promotion of comfort and dignity at the end of life.

THE UNPREDICTABLE CARDIAC DISEASE TRAJECTORY

Heart disease may affect someone for 30 days or 30 years, and, in the midst of an acute cardiac event, it can be difficult to predict which outcome is more likely. This uncertainty can have a marked impact on patients and their families, who may not know what their future holds, how to plan, or which testing and treatment options will be best for them.⁷

A key barrier to the use of both palliative care and hospice for patients with HF is the unpredictability of the cardiac trajectory and experience (see Figure 13.1).^{10,11} The last several years of life for a person with HF have been described as "ambiguous dying."¹² Providers are often uncertain about whether the patient is dying and when death is likely to occur.¹² The patient with HF often has fluctuating symptoms and functional status and has experienced numerous life-threatening events, such as myocardial infarction, acute exacerbation, or sudden cardiac arrest. The decline of patients with heart disease is often subtle, occurring over years rather than months. Death may seem sudden, occurring within a few days of stability. This uncertainty extends to their providers, who may feel they have few objective predictors to determine prognosis other than the gradual development of frailty in their patients.¹³ One challenge is that most respected tools used to predict mortality in patients with cardiac disease are inaccurate.¹⁴

The second case study illustrates the fact that while patients are sick, their providers often overestimate survival. Therefore, they are unlikely to describe them as "dying" or to talk with them about planning for the possibility of a sudden death.¹⁵ This ambiguity about when or whether someone is dying also makes it difficult for providers to discuss prognosis or when to apply hospice admission criteria compared to diagnoses with more predictable trajectories leading to death. To complicate matters, patients also experience ambiguity and are overly optimistic about their life expectancy,¹⁶ and this can have serious consequences.

In addition, families live in confusion for years about their loved one's future and their own prospects and plans, not knowing how long their situation will last, what to expect, or how to prepare for what is to come. Even if the patient and family understand the future, their distress may be compounded when healthcare providers are not straightforward with them about the prognosis. This can be particularly distressing when the patient dies, yet the provider has communicated only messages of hope for a transplant, ventricular assist device (VAD), or other "fix" without providing anticipatory guidance about the very real and simultaneous risk of sudden death. Rather than relying on timing for palliative care involvement, one approach emphasized in the literature is using specific clinical markers such as hospitalization or not tolerating guideline-directed medical therapy (GDMT) and "need-based" referrals utilizing triggers such as refractory symptoms or family distress.¹⁷

Open, honest, and regular communication acknowledging the uncertainties,¹⁸ with a "hope for the best, plan for the worst" approach facilitates legacy-building and end-of-life

Table 13.1 GUIDELINE-BASED CARDIAC MEDICATIONS: PALLIATIVE CONSIDERATIONS

DIURETICS, LOOP: <i>FUROSEMIDE, TORSEMIDE, BUMETANIDE</i>					
DOSING	BENEFITS	DECISIONS	RISKS	MONITORING	SELF-CARE
Furosemide 20–40 mg 1–2 ×/day Up to 600 mg/day Torsemide 10–20 mg 1–2 ×/day Up to 200 mg/day Bumetanide 0.5–1 mg 1–2 ×/day Up to 10 mg/day Need both maintenance and PRN orders	Fluid status control: (maintenance dose) Diuresis: Increase dose or add metolazone Alternatives to furosemide can be more effective in diuretic resistance	↓ sx vs ↓ renal function and diuretic resistance Diuretic resistance: ↑ oral dose, change diuretic, add oral metolazone, IV bolus or IV infusion	↓ renal function ↓ BP, over-diuresis and falls in patients with poor intake, anorexia, nausea, or vomiting. May need to pause diuretics or dose diuretics only for ↑ wt until intake improves	Weights HF sx For ↑ wt/sx add prn dose until return to dry wt goal. ↑ or ↓ K Dosage of K replacement or aldosterone antagonist ↑ Creatinine	Daily wt ↓ Na diet Dose adjusted often: prescribed dose on container may not reflect the current dosing Diuretics may work best when supine: try dosing in early a.m. before getting up and early afternoon before nap to ↑ effect and ↓ nocturia
DIURETICS, THIAZIDE-LIKE: <i>METOLAZONE</i>					
DOSING	BENEFITS	DECISIONS	RISKS	MONITORING	SELF-CARE
Dosed PRN for fluid overload. Administer 30 minutes before furosemide. Start at 2.5 mg	Potent diuretic to treat fluid overload	Requires daily communication with patient, especially when initiating Tx	Marked diuresis, K loss, symptomatic hypotension	Relief of dyspnea and orthopnea Wt, K, signs of dehydration	Daily wt ↓ Na diet
ANGIOTENSIN CONVERTING ENZYME (ACEI): <i>ENALAPRIL, LISINAPRIL</i>					
DOSING	BENEFITS	DECISIONS	RISKS	MONITORING	SELF-CARE
For HFrEF: Titrate up to highest tolerable dose Enalapril 20 mg BID, start at 2.5 mg BID Lisinopril 40 mg daily, start at 2.5 mg daily	Prevent HF sx and ↑ survival in all patients with ↓ EF	Advanced HF: May need to stop ACE for symptomatic hypotension, yet ACEs are key for sx mgt	↓ renal function ↑ K with ↓ renal function or aldosterone antagonists Cough: 5–20% try ARB if bothersome	K, Cr. ↑ dose may ↑ creatinine: If Cr ↑ >30% consider d/c ACEI or ↓ dose	Stopping may cause rapid ↓ of heart function and sx
ANGIOTENSIN-RECEPTOR BLOCKERS (ARBs): <i>LOSARTAN, VALSARTAN, CANDESARTAN</i>					
DOSING	BENEFITS	DECISIONS	RISK	MONITORING	SELF-CARE
For HFrEF titrate up to highest tolerable target dose Losartan 50 mg daily Valsartan 160 mg BID Candesartan 32 mg daily	Prevent HF sx and ↑ survival in patient with ↓ EF ↓ cough than ACEI	Advanced HF: May need to d/c ARB for symptomatic ↓ BP, yet ARBs are key for sx mgt	↓ BP ↓ renal function Risk of ↑ K with ↓ renal function/K-sparing diuretics	K, Cr. ↑ dose may ↑ creatinine If Cr ↑ >30% consider d/c or reducing dose	Stopping may cause rapid ↓ of heart function, ↑ Sx
BETA-BLOCKERS: <i>METOPROLOL SUCCINATE, CARVEDILOL, BISOPROLOL</i>					
DOSING	BENEFITS	DECISIONS	RISKS	MONITORING	SELF-CARE
For HFrEF: titrate up to highest tolerated dose Metoprolol succinate 200 mg daily, start at 25 mg Carvedilol 25 mg BID, start at 3.125 mg BID Bisoprolol 10 mg daily, start at 1.25 mg	↓ EF in HFrEF: ↓ HF sx risk ↑ survival in CAD Controls ischemic sx by ↓ cardiac work. Arrhythmia Tx and HR control in AF, HTN	Consider ↓ dose or d/c if symptomatic ↓ HR (<55) ↓ BP (SBP <80) Should not d/c suddenly: reflex tachycardia	↓ HR, ↓ BP fatigue ↓ lung function in asthma/chronic obstructive pulmonary disease Blunted hypoglycemia sx in diabetes	Monitor HR, BP at each visit and sx of light-headedness, fatigue	Patient should know how to check pulse and check it periodically or if symptomatic

Table 13.1 CONTINUED

VASODILATORS/NITRATES: <i>ISOSORBIDE DINITRATE AND HYDRALAZINE</i>					
DOSING	BENEFITS	DECISIONS	RISKS	MONITORING	SELF-CARE
For HFrEF: Isosorbide dinitrate 20–40 mg TID Hydralazine 25–100 mg TID; dose based on BP tolerance	↑ survival ↑ QOL ↓ admissions	Use in HFrEF patients: -Who self-identify as Black -Who cannot take ACEI, ARB, or ARNI (i.e., angioedema) with NYHA class III or IV sx despite GDMTs	Common AEs: ↓ BP, headache and chest pain Hydralazine: drug-induced lupus Contraindicated with phosphodiesterase 5 inhibitors (i.e., sildenafil)	BP Antinuclear antibody before starting	Avoid dehydration TID dosing: Adherence is important but difficult
DIRECT ORAL ANTICOAGULANTS/FACTOR XA INHIBITORS: <i>APIXABAN, RIVAROXABAN</i>					
DOSING	BENEFITS	DECISIONS	RISKS	MONITORING	SELF-CARE
Based on age, weight, and renal function Apixaban 2.5–5 mg BID Rivaroxaban 20 mg once daily	Prevent and treat venous thrombotic emboli and stroke in atrial fibrillation	Severe renal dysfunction: renal dosing or consider warfarin Severe liver disease: contraindicated	↑ bleeding Antidote to reverse Factor Xa inhibitors is exanet alfa	No blood monitoring required so adherence is critical, renal function	Prevent falls and injuries
CARDIAC GLYCOSIDE: <i>DIGOXIN</i>					
DOSING	BENEFITS	DECISIONS	RISKS	MONITORING	SELF-CARE
Low dose recommended: high risk of toxicity (i.e., elderly, renal failure) May need to ↓ dose for progressive wt loss and cachexia at EOL	Atrial fibrillation: HR control adjunct to beta-blocker or calcium channel blocker. HFrEF: May ↑ functional status, ↑ quality of life and ↓ admissions in patient with HF sx with GDMTs	Risk vs. benefit: May help HF sx but toxicity risk, particularly with ↓ K, ↓ Mg, ↓ body mass, ↓ renal function, ↑ age	Many drug interactions Toxicity: Slow arrhythmias Heart block GI and neuro sx. Contraindicated in heart block without pacemaker.	HR should be ≥60 (lower may indicate toxicity) Digoxin levels Goal digoxin level: 0.5–0.9 ng/mL K, Mg, renal function	Accurate dosing essential to avoid toxicity
ANTICOAGULANTS: <i>WARFARIN (COUMADIN)</i>					
DOSING	BENEFITS	DECISIONS	RISKS	MONITORING	SELF-CARE
Complex dosing guided by algorithms and INR results, often managed by AC service Typical INR goals: Atrial fibrillation: INR 2–3 Thrombosis Tx and prevention: INR 2–3 Mechanical heart valve 2.5–3.5	↓ risk embolic stroke in atrial fibrillation and prosthetic valve Thrombus Tx	Individualized using shared decision-making High risk: previous CVA, TIA. Risk calculator for nonvalvular Afib: CHA ₂ DS ₂ -VASc Anticoagulation bleeding risk: HAS-BLED ATRIA	Many drug interactions ↓ INR: stroke ↑ INR: bleeding Heparin bridge for invasive tests and txs. Risk of bleeding/hemorrhagic stroke in patient at risk for falls. Aspirin/antiplatelet may be used when AC risk > benefit	INR fluctuates with changing health status, diet, medication changes. Many drug interactions.	INR blood test ≥1 ×/week when starting, monthly when stable. Vitamin K-balanced diet

Table 13.1 CONTINUED

SODIUM-GLUCOSE COTRANSPORTER 2 (SGLT2) INHIBITORS: <i>EMPAGLIFLOZIN, DAPAGLIFLOZIN</i>					
DOSING	BENEFITS	DECISIONS	RISKS	MONITORING	SELF-CARE
Empagliflozin 25 mg daily, starting dose 10 mg Dapagliflozin 10 mg daily, starting dose 5 mg	Diuresis and Tx of fluid overload ↓ mortality ↓ admissions ↓ serious renal issues and progression of renal disease in HFrEF patients with or without diabetes.	Evidence only for HFrEF but with or without diabetes; coordinate care with endocrine Avoid if GFR 30–44 Contraindicated if GFR < 30, dialysis or type 1 diabetes	Overdiuresis ↓ renal function UTI genital mycotic infections	Baseline renal function fluid status, watch for overdiuresis	Daily wt Watch for fluid overload/dehydration, Hold 3 days before surgery
ALDOSTERONE RECEPTOR ANTAGONIST: <i>SPIRONOLACTONE, EPLERENONE</i>					
DOSING	BENEFITS	DECISIONS	RISKS	MONITORING	SELF-CARE
For HFrEF: Titrate up to highest tolerated dose Spironolactone: 12.5 mg, 25 mg, 50 mg	↑ survival ↓ admissions in HFrEF ↓ BP ↓ K with loop diuretics	Spironolactone is less expensive	↑ K ↓ renal function For gynecomastia change to eplerenone	K BP renal function Fluid balance	Daily wt ↓ Na diet Avoid ↑ K rich foods
ANGIOTENSIN RECEPTOR BLOCKER-NEPRILYSIN INHIBITOR (ARNI): <i>SACUBITRIL/VALSARTAN</i>					
DOSING	BENEFITS	DECISIONS	RISKS	MONITORING	SELF-CARE
For HFrEF: Titrate up to highest tolerated dose Start at: 24 mg/26 mg, Target dose: 97 mg/103 mg	↑ survival with patients with HFrEF; ↓ admissions and sx	May start while in hospital; Assure ACEI or ARB are stopped at least 36 hours prior to starting. May cause hypotension	Same as ACEI. Angioedema possible at any time but especially with first dose 2% risk in black patients	Same as ACEI	Same as ACEI, orthostatic hypotension common
LIPID-LOWERING AGENTS: <i>ATORVASTATIN, LOVASTATIN, SIMVASTATIN, ETC.</i>					
DOSING	BENEFIT	DECISIONS	RISK	MONITORING	SELF-CARE
Titrate to lipid goals varying by patient's cardiac risk profile In CAD, LDL should be ↓ >50% with the highest tolerated dose of high-intensity statin	↓ CV events	cvriskcalculator.com Safe to d/c at EOL ⁶⁰	Myositis: muscle aches. Hold drug and check for ↑ creatinine kinase	Lipid levels	Diet Exercise Wt loss

↑: increase(d); ↓: decrease(d). ACEI, angiotensin-converting enzyme inhibitor; AC: anticoagulation; AE: adverse effects; BP, blood pressure; CAD: coronary artery disease; Cr: creatinine; CV, cardiovascular; EF, ejection fraction; EOL: end of life; GDMT, guideline-directed medical therapy; HF, heart failure; HFrEF: heart failure with reduced EF; HR, heart rate; ICD: Implantable cardioverter-defibrillator; INR, International Normalized Ratio; K: potassium; Mg: magnesium; Mgt: management; Na: sodium; Sx: symptoms; Tx: treatment; Wt: weight.

“closure” all along the trajectory. Discussing future “what-ifs” can start an ongoing dialogue to help assure that the patient’s business is complete and opportunities to say goodbye are not missed⁴ (see Chapter 32, “Advance Care Planning” and Chapter 33, “Family Meetings”).

REFERRING PATIENTS WITH ADVANCED CARDIAC DISEASE TO PALLIATIVE CARE

While palliative care is now recognized as a guideline-based intervention in advanced HF, the number of patients being

referred to specialist palliative care remains low. Moreover, the percentage of patients with HF referred to hospice remains low.³ Factors limiting cardiology referrals to specialty palliative care and the incorporation of palliative care interventions include:

1. Ongoing confusion between palliative care and hospice and when to refer patients for each⁷
2. The perception that cardiac symptom control requires specialty cardiac training and experience¹⁸

3. The sudden onset of new life-threatening cardiac and noncardiac events that require rapid decision-making based on guideline-focused algorithms¹⁸
 4. The misperception that specialty palliative providers mainly guide patients into hospice, leading to specialist palliative care referrals being delayed until the end of life¹⁸
 5. Lack of cardiology knowledge and experience for palliative care and hospice specialists, particularly for patients who require advanced therapies such as inotrope infusion or VAD.⁴
- Learning cardiac-specific, guideline-based policies and procedures and training for specialty palliative care and hospice providers
 - Assuring goal-concordant care, whether that is access to outpatient palliative care for patients who choose that their cardiac devices, such as implantable cardioverter defibrillator (ICD) or VAD, remain active or, if not, that they are referred to hospice.

THE PALLIATIVE APRN IN CARE OF PATIENTS WITH CARDIOLOGY AT END OF LIFE

The palliative APRN working in a cardiac specialty unit is in an ideal position to bridge the gap between cardiac and palliative care. Shared viewpoints, knowledge, and experiences between cardiac and palliative care providers will promote effective implementation of team-based palliative care in cardiac settings. The role of the palliative APRN within the cardiac care team is still developing, yet there is great opportunity for palliative APRNs to bridge the divide between cardiology and specialty palliative care to improve the experience of patients with cardiac disease and their families during this challenging and unpredictable journey.

Palliative APRNs can play a key role in promoting quality of life and facilitating “a good death” for patients with cardiac disease. They can encourage the development of positive memories and prevent traumatic end-of-life experiences and complicated grief for family members by:⁴

- Engaging in open, honest communication about what to expect using a “hope for the best, prepare for the worst” approach
- Assuring current, specific documentation of patient preferences for emergency care and resuscitation that can be easily retrieved by any provider in any setting, including the community
- Having early conversations about end-of-life choices, such as specialist palliative care referral, hospice, and resuscitation options, including specific preferences about devices
- Facilitating patient and family decision-making meetings when patients are faced with high-risk options or advanced treatments, such as VADs, transplant, and risky treatment choices
- Supporting family members and patients with complicated advanced heart problems (such as VAD) and/or while waiting transplant
- Facilitating hospice referral when the patient with advanced HF has chosen to forgo further procedural and device “fixes”

CASE STUDY 2: OVERESTIMATED PROGNOSIS

JD was a 34-year-old survivor of Hodgkin’s lymphoma. Ten years after his remission, he was diagnosed with doxorubicin-induced cardiomyopathy, with an ejection fraction of 15%. Once guideline-directed medical therapy was implemented, JD continued to have New York Heart Association (NYHA) Class III–IV symptoms, and he was placed on the cardiac transplant list with a plan for a ventricular assist device (VAD) as a bridge to transplant. JD was clinically stable and was scheduled for a biventricular pacer/implantable cardioverter defibrillator (ICD) placement in 2 weeks. However, because he was unable to work, his wife worked overtime hours at her job in addition to caring for their two young children and trying to do all the household chores that JD did in the past.

One night when cooking dinner with his family, JD collapsed on the kitchen floor. His wife called 911 and started cardiopulmonary resuscitation (CPR), yelling at him and crying the whole time, while his kids watched, not knowing what was going on. When the paramedics arrived, JD was in a fine ventricular fibrillation. Despite multiple shocks and advanced cardiac life support (ACLS) drugs, he could not be resuscitated.

After his death, JD’s wife tried to keep the family going, but she struggled with what she thought should be simple tasks, such as paying the bills and accessing their online bank accounts. JD had never compiled their account information in one place, and the passwords were all in his head. She was still trying to piece together their financial records and was frequently surprised by unpaid bills and calls from collection agencies. She was angry with JD for not planning ahead so they would stable financially without him. She also worried about her children. Her younger child had night terrors, reliving the memory of seeing her father die. Her older child had become detached and acted indifferently, indicating he had some deep emotional wounds.

The cardiac disease trajectory may be described as “stuttering,” with symptom exacerbations and remissions punctuated by significant events. These might include a new myocardial infarction (MI), an arrhythmia, or a serious infection, any of which could lead to death, particularly when the body’s taxed compensatory mechanisms fail. When the patient with advanced cardiac disease is stable, the body’s physiologic systems and compensatory mechanisms are in a delicately balanced homeostasis. A minor health issue, such as getting the flu, may trigger a rapid decline, leading to hospitalization, intensive care, or even death. In some cases, patients with advanced cardiac disease die within a few days of being stable.

Therefore, prior advance care planning and regular communication, including shared-decision-making, is essential to promote care that is realistic and based on the patient's current condition and consistent with their wishes. Hospitalizations and health status changes should be used to trigger discussions about goals of care where shared decision-making is applied and, in some instances, conversations about hospice referral.⁴

UNDERSTANDING THE CARDIOLOGY MINDSET

HEALTHCARE PROFESSIONALS IN CARDIOLOGY

Healthcare professionals working in cardiology respond rapidly to emergent changes in their patients' condition, employing algorithms, medications, devices, and procedures to save their patients' lives. A "good" outcome is life and a "bad" outcome is death. The word "death" or "dying" is not used; instead, the words used are "code," "cardiac arrest," "ventricular fibrillation," or "asystole." Those professionals working in cardiac specialty units are trained in cardiac monitoring, are certified in advanced cardiac life support (ACLS), and regularly demonstrate their competency in providing appropriate care in a cardiac emergency. Therefore, they are constantly on the alert and prepared to rapidly intervene when the patient is "crashing" so they won't die. Many healthcare professionals may have difficulty identifying the patient who is "actively dying" because the processes that cause this, usually arrhythmias and cardiogenic shock, happen quickly and prompt immediate action. Understandably, and similar to a health professional working in critical care, not intervening is difficult because it goes against the training and mindset of "doing something." As a result, it can be difficult for cardiac providers to accept, understand, or implement the idea of letting "nature take its course." When confronted with a patient who has an acute cardiac event but who has a do-not-resuscitate (DNR) order or a comfort-directed plan of care, it can be difficult to switch from a lifesaving to a palliative mindset.

PATIENTS AND THEIR FAMILIES

A challenge in providing palliative care for patients with cardiac disease is that advance care planning may not be straightforward. One example of this is the conversation regarding resuscitation. Resuscitation options in patients with cardiac conditions may be more complex than in other patient populations. The patient may have survived cardiac arrest because someone did CPR and shocked him with an automated external defibrillator (AED). After the initial hospitalization and recovery, the patient may report a happy, healthy life for years afterward, with an ICD providing a safety net in case cardiac arrest happens again. Patients often express their gratitude to the person who did CPR and state that the additional years were a gift they do not take for granted. With this experience in mind, the cardiac survivor with advanced HF may not be interested in a DNR order. He or she is likely to remember

the positive outcome and assume that the next time CPR is needed, the outcome will be the same, although not considering more recent changes in the patient's health.

PREVENTING RECURRENT ADMISSIONS

Preventing the readmission of HF patients is one of the top organizational priorities at hospitals across the United States. The *Affordable Care Act* (ACA) imposes Medicare reimbursement penalties for hospitals with HF 30-day readmission rates above the national benchmark.⁵ However, predicting the future can be a significant challenge because advanced HF is characterized by recurrent exacerbations despite meticulous HF care. In addition, social and behavioral factors are often predictive of recurrent HF hospitalization, yet these can be difficult or impossible to change. When a patient with advanced heart disease is hospitalized, a global comprehensive transition to plan of care at home offers opportunities to prevent future readmissions. One strategy is using "trajectory checks" at key periods to identify when palliative care should be consulted.^{4,5} Palliative specialty care and early hospice referral have been shown to reduce readmission rates over a period of 9 months.¹⁹

PALLIATIVE MANAGEMENT OF CARDIAC SYMPTOMS

As illustrated in the first case study, pain may not be the most common cause of physical distress among patients in the later stages of heart disease, in contrast to traditional palliative care priorities for other conditions. Fatigue, functional limitations, difficulty breathing, and ischemia-related chest discomfort are common and often distressing physical symptoms of advanced heart disease.⁴ These symptoms may have an insidious onset, slowly worsening over time. Patients may report "a lack of energy," "slowing down," "having to pace myself," or difficulty sleeping, and it can be difficult for both patients and providers to distinguish whether these symptoms are due to heart problems or another cause. Therefore, palliative APRNs must understand the common symptoms of HF and other cardiac conditions, as well as the medications and other interventions appropriate to the underlying cause of these symptoms. Box 13.1 provides a comprehensive list of symptoms to guide assessment.

DYSPNEA AND DIFFICULTY SLEEPING

Dyspnea is a common and distressing symptom in patients with cardiac disease and can be exacerbated by exertion or lying supine, or it may occur when sleeping. People with dyspnea on exertion often reduce their activity to avoid this symptom; therefore, an accurate assessment of the patient's actual recent physical activity is a key element of the history that can help identify problems and treat symptoms. *Orthopnea*, *paroxysmal nocturnal dyspnea*, and *bendopnea* (a novel symptom that occurs when patients bend forward) are hallmark signs of

Box 13.1 CLINICAL SIGNS OF HEART FAILURE

- Weight gain
- Elevated jugular vein pressure
- Hepatic congestion or enlargement
- Ascites with evidence of fluid wave
- Hepatojugular reflux
- Peripheral or dependent edema
- Crackles with lung auscultation
- Decreased breath sounds related to pleural effusions
- Signs of low cardiac output such as fatigue, dizziness, hypotension, tachycardia
- Elevated B-type natriuretic peptide (BNP)/N-terminal pro-hormone of brain natriuretic peptide (NT proBNP)

fluid overload in the patient with cardiac disease, warranting careful assessment and the possible need for diuresis (see Box 13.2 for further details). The absence of edema and crackles should not be used as sole indicators of fluid status as they may be absent in the patient with chronic HF who has fluid overload.

Fluid overload-related dyspnea requires diuresis for symptom management. This is usually accomplished with loop diuretics (see Table 13.1). Morphine and lorazepam can be used to alleviate feelings of air hunger and anxiety while diuresis is being accomplished. Yet, these drugs should not be used as the sole treatments for fluid-related dyspnea as they will only mask the cause of the symptoms rather than treating it, producing ongoing symptom distress.

Another source of dyspnea that should not be ignored is the possibility of a new cardiac event, such as a MI and/or acute pulmonary edema. The sudden onset of new symptoms should prompt rapid assessment and treatment as well as

Box 13.2 TYPES OF DYSPNEA CHARACTERISTIC OF HEART FAILURE

- *Dyspnea on exertion*: Feeling of shortness of breath while doing a mild or moderate activity
- *Orthopnea*: Shortness of breath that is exacerbated when lying flat; feeling of suffocation, or drowning prompts patients to sit up so they can breathe and prop themselves up in bed with pillows or sleep in a recliner
- *Paroxysmal nocturnal dyspnea (PND)*: Occurs while sleeping; the patient wakes up at night unable to breathe or feeling claustrophobic, alleviated by sitting upright or getting up
- *Bendopnea*: Sensation of feeling short of breath while leaning forward, associated with elevated ventricular filling pressures

communication with the family so that treatments are consistent with the patient's goals and plan of care.

An exception to the use of diuretics in treating fluid-related dyspnea may be the person who is actively dying as the result of a new cardiac event and whose expected prognosis is hours to a day. Diuretics are unlikely to provide symptomatic benefit if this person is in cardiogenic shock as the weakened heart will not adequately perfuse the body, severely limiting the absorption, distribution, and metabolism of drugs like diuretics and preventing excretion of excess fluid. In this end-of-life situation, the opioid-naïve patient with end-stage cardiac disease may benefit from small doses of opioids (and benzodiazepines if the opioids fail) to provide comfort while the patient and family say goodbye.

CARDIAC PAIN

In the patient with cardiac disease who reports pain, it is important to distinguish between “cardiac” and “noncardiac” pain, as the causes, treatments, and short-term implications are quite different. Assessment should not be limited to using the word “pain” as this may not prompt the patient to report his or her cardiac symptoms. Patients may perceive their cardiac ischemic symptoms in different ways and may describe their symptoms with terms like “discomfort,” “pressure,” or “heaviness.”

Cardiac “pain” or “discomfort,” also called *angina*, is a sign of poor perfusion to the heart muscle (ischemia or infarction). It is commonly aggravated by exertion and alleviated with rest (or stopping the activity), nitroglycerin, oxygen, and opioids. Cardiac symptoms may indicate serious problems, such as a new MI; therefore, in the absence of a treatment plan for symptomatic relief, the patient should be promptly evaluated for the cause and treated until the symptoms are completely relieved. Prompt treatment of cardiac symptoms with a goal of complete relief and ongoing prevention with medications that promote coronary perfusion will promote positive patient outcomes, including better quality of life and functional status.

Stable cardiac symptoms often present in the same way from one episode to the next; however, symptoms may differ markedly between patients. Higher risks for atypical symptoms or silent ischemia include being female, a diagnosis of diabetes, and being older than 65 years. In the absence of chest discomfort, patients with silent ischemia may have other symptoms, such as shortness of breath, lightheadedness, gastrointestinal upset, falls, or sudden decline in functional status. Dramatic changes in health status with these types of symptoms should raise a high index of suspicion for a new cardiac event, prompting rapid evaluation and treatment or implementation of the agreed-upon plan.

NONCARDIAC PAIN

Noncardiac pain is common in people with heart disease, usually associated with coexisting conditions such as arthritis, diabetic neuropathy, and back problems. However, nonsteroidal antiinflammatory drugs (NSAIDs) should be avoided in

heart disease patients if possible because they carry a higher risk of serious cardiovascular events, such as MI, stroke, and death.²⁰ NSAIDs block renal prostaglandin synthesis, which can compromise renal function and contribute to fluid retention in patients with HF and older adults. Many patients with cardiac disease take anticoagulants and antiplatelet medications, which are also contraindications to NSAIDs because of the additive risk of bleeding. Being aware of other medications to avoid in HF is also key to preventing exacerbation or causing new symptoms.²¹

SHARED DECISION-MAKING IN CARDIAC SPECIALTY CARE

When patients with cardiac disease and their families are faced with decisions related to cardiac medications, procedures, and devices, a shared decision-making approach should be used, one informed by a palliative perspective that prioritizes patient's goals, preferences, and resources with a realistic evaluation of potential benefits and risks.²² This is particularly important in patients with significant comorbid conditions, frailty, dementia, and advanced age.²³

Many life-saving treatments, and devices, such as cardiac interventions, surgery, VAD, and transplant, can alleviate symptoms and prolong life in even the sickest patients with cardiac disease, and these should be acknowledged as an important part of cardiac decision-making. With so many effective disease-directed therapies and devices available, providers must take care to avoid offering a laundry list of treatment options to patients and first determine a person's overall goals of care to assure that treatments are goal-concordant.

Common cardiac diagnoses for patients admitted to the hospital include MI, atrial fibrillation, and acute exacerbations of chronic HF. Many of these patients are elderly, with multiple comorbid conditions such as chronic kidney disease, dementia, and lung disease. Palliative consults often focus on shared decision-making around specific medications, diagnostic tests, procedures, or surgeries. Some tests and treatments have the potential to cause more burden than benefit. For example, with ischemic heart disease, a heart catheterization may be indicated, but for those with severe kidney disease contrast dye nephrotoxicity could lead to dialysis. Patients with atrial fibrillation may require anticoagulation or antiarrhythmic medications or a cardioversion, all with potential for serious adverse effects. Those who are frail and elderly could have significant consequences with certain medications, procedures, or advanced therapies, requiring thoughtful discussion of the options, risks, and benefits. Palliative specialists are also increasingly called upon to assist with shared decision-making around advanced therapies such as heart transplant, VADs, and heart valve procedures such as transaortic valve replacement (TAVR).

Evidence-based patient decision aids can assist patients and families faced with difficult decisions about medical treatments. Numerous decision aids are available for cardiac treatments, tests, and devices (e.g., medications for hypertension,

atrial fibrillation, high cholesterol, coronary angiogram, ablation, pacemaker, ICD, TAVR, and VAD) as well as for hospice.^{24,25}

EMERGENCY CARE AND DO-NOT- RESUSCITATE ORDERS

Advance care planning prior to hospitalization is critical because patients and their families are faced with complex decisions. Discussion with the patient and family before an emergent event and documentation of patient preferences can facilitate the decision-making process in a critical situation. Cardiac technologies and treatment developments have outpaced communication, documentation, and policies for patients with cardiac disease, particularly those with devices like ICDs and VADs. Therefore, the one-size-fits-most approach to advance care planning that is reflected in most legal documents does not apply to the patient with cardiac disease and their family. They may want more options, all while considering previous experiences, as well as the risks and benefits of each.⁴

Unfortunately, most advance care planning documents and DNR orders do not easily accommodate "special requests." Considering this, early advance care planning with patients with advanced cardiac conditions is important to address potential treatment decisions in the patient's future. Cardiac care options may include:

- CPR
- Emergency drugs
- ICD shock and pacing
- Defibrillation
- External pacing
- Mechanical ventilation
- Temporary suspension of DNR/do-not-intubate (DNI) for procedures or surgery
- Mechanical circulatory support
- Inotropes
- Coronary angioplasty and stent
- Dialysis
- Other invasive tests or treatments such as coronary angiogram, TAVR, or pacemaker
- Repeat hospitalizations
- Intensive care.

The palliative APRN working with patients with advanced cardiac conditions should be prepared to discuss the risks, burdens, and benefits of each option with the individual and legally document and effectively communicate the patient's specific goals of care and preferences.

CARDIAC HOSPITALIZATION

If a new cardiac hospitalization occurs, the patient's proxy, goals of care, and advance care plan documents should be immediately available to direct treatment decisions. Because patients can die within a short time of being stable, a rapid change in the patient's condition should prompt quick intervention, consistent with the patient's wishes. If the patient has chosen a comfort approach, the team's interventions should be directed toward promoting open, honest, empathetic communication and comfort for the patient and support for the family. Most important is realizing that the period when the patient is "actively dying" may be short and the end may come suddenly.

If an advance care plan has not been identified or if the patient has elected to have some or all resuscitative or life support measures employed, the palliative care team should facilitate ongoing communication about the patient's and family's decisions. Topics include the need for monitoring and intensive care, as well as anticipated tests and treatments. As the patient's condition declines, the palliative APRN can assist in clarifying the code status and begin preparing for resuscitation or activating a rapid response. The palliative APRN can ensure that the patient and family have adequate information, support, and resources to assist in shared decision-making and can promote their psychological, spiritual, and physical well-being throughout this challenging period.

CARDIAC PROCEDURES: ANGIOGRAM AND STENT

When a patient has a heart attack or worsening symptoms of coronary ischemia, testing often includes coronary angiogram, also called a "cardiac cath." Coronary angiogram involves inserting a catheter in a blood vessel in the groin, neck, or arm and threading it to the heart, where the coronary arteries are injected with dye to identify narrowed or blocked blood vessels. In many cases, another catheter with a balloon and metal coil called a "stent" can then be used to open the blocked artery, thus restoring blood flow to the affected area of the heart.^{26,27} This is the least invasive approach to treating coronary artery disease. Cardiac catheterization can also be used for other diagnostic tests and interventions including measuring pressures and oxygen levels inside the heart, determining pumping function (EF), cardiac tissue sampling (biopsy), and treating heart valve conditions.²⁶

CORONARY ARTERY BYPASS GRAFT SURGERY

Coronary artery bypass grafting (CABG), a surgical procedure to improve poor blood flow to the heart, is performed when the arteries supplying blood to heart tissue are narrowed or blocked, causing symptoms of cardiac ischemia or heart attack. CABG may prevent serious complications such as heart attack, stroke, and death in people with severe coronary artery disease. It may also be used emergently in a severe heart attack to save the person's life. The surgery involves using blood vessels from another part of the body, usually from the

arm or chest or veins from the legs, to connect blood vessels above and below the blocked artery, bypassing the blockage and restoring adequate blood flow to the heart. Bypass is usually performed when multiple blockages are present, making stent treatment less realistic. CABG is a treatment, but not a cure, for ischemic heart disease. Postoperative recommendations include taking prescribed cardiac medications, making heart-healthy lifestyle changes, and clinical follow-up to control symptoms, treat disease, and prevent complications.²⁸

HEART VALVE REPAIR AND REPLACEMENT

Heart valve repair or replacement is used to treat symptoms and preserve cardiac function in the person with symptomatic heart valve disease. There are two primary types of heart valve defects: stenosis and regurgitation. Stenosis is a narrowed valve, as seen in aortic stenosis, that prevents blood from being pushed out to the body. Regurgitation is a leaky valve (such as mitral regurgitation) that causes blood to back up in the heart and lungs. Both problems cause symptoms of HF such as fatigue, weakness, pulmonary congestion, and edema. Heart valve procedures are used to repair or replace the affected heart valves.

Surgical options to valve repair or replacement include open-heart surgery and minimally invasive heart surgery, as well as cardiac catheter-based procedures. Valve surgery may also be performed in conjunction with CABG in patients with both arterial and valvular disease. Palliative procedures such as TAVR or a "mitral clip" may be options if the patient is not a surgical candidate, with the goal of improving their functional status and quality of life. The palliative procedures can also carry significant risks for complications as patients often have a long history of symptomatic HF and multiple comorbidities. Procedural risks should be weighed against potential benefits using shared decision-making. This is when a palliative care consultation may be requested, weighing the procedure against a palliative medical/hospice care option.

The three common types of valve procedures are repair using annuloplasty or valvuloplasty and valve replacement. Annuloplasty is used to repair a regurgitant valve by reducing the diameter of the valve's fibrous ring. Valvuloplasty, the other repair option, is used to open a stiff, stenotic valve by using a heart catheter to place a balloon into the valve opening, where it is inflated to push open the stiff valve leaflets. Once the valve has been opened, the balloon is deflated and the catheter removed.²⁹

Valve replacement involves replacing the entire heart valve with either a mechanical or bioprosthetic valve. Decision-making about the type of valve usually focuses on two issues: anticoagulant requirements and the expected life of the implanted valve. While short-term anticoagulation with warfarin or a similar drug is needed with the bioprosthetic valve to prevent stroke or other embolic events, the mechanical valve requires long-term anticoagulation. If the patient with a bioprosthetic valve has or develops atrial fibrillation, a common postsurgical complication, anticoagulation will be needed while the arrhythmia persists. The expected life of

the two types of valves differs: while a mechanical valve may last for decades, a bioprosthetic valve usually has a shorter life expectancy. Therefore, mechanical valves are preferred for patients who are younger—with the tradeoff anticoagulant requirements—so they can avoid repeated valve replacement surgeries in the future, each with increasing risks of complications. Decision-making about valve repair or replacement should consider factors including the patient's age, life expectancy, comorbidities, indications, or contraindications for anticoagulant therapy and, perhaps most important, the patient's preference for the valve procedure.³⁰

Transcatheter Aortic Valve Replacement

Severe aortic stenosis typically occurs in older individuals. Once patients become symptomatic, those treated with medications alone have mortality rates of approximately 25% in 1 year and 50% in 2 years, with sudden death in 50%.³¹ While traditional surgical aortic replacement may be offered, the growing and evolving catheter-based TAVR procedure may be an option for many patients with severe aortic stenosis. However, patients with a life expectancy of 12 months or less or poor quality of life due to noncardiac comorbid conditions are unlikely to improve with a TAVR and may instead benefit more from a medical palliative approach.³² For patients who are high and intermediate surgical risk, TAVR may be the appropriate option if it is consistent with their goals of care. In patients with low surgical risk, the choice of surgical aortic replacement versus TAVR is not clear at this time as the evidence continues to evolve. Outcomes for patients who received a TAVR compared to medical management have demonstrated improved survival and increased functional status but with increased risk of stroke in the procedural phase. Compared to surgical aortic valve replacement, patients who have had a TAVR also had improved survival, especially women, and had decreased risk of kidney injury, new atrial fibrillation, or major bleeding. However, major vascular complications, need for a permanent pacemaker, and paravalvular regurgitation were less frequent with surgery.³² A critical part of the pre-TAVR checklist is assessment of the patients' preferences, values, goals, expectations, and advance care planning, ensuring that documents are in place before the procedure.³⁰

Mitral Clip

Patients with symptomatic mitral regurgitation typically have comorbidities that put them at high surgical risk, and they have typically been treated with medical therapy alone. However, the transcatheter mitral clip provides a palliative option to improve the patient's symptoms and quality of life while reducing the risk of hospitalization for patients who are poor surgical candidates.³³ As with TAVR, which is also used in a very sick patient population, the mitral clip has been associated with high rates of adverse events in the first 30 days after the procedure.³⁴ Surgical or transcatheter treatment for mitral regurgitation secondary to other heart problems is recommended only after other medical and device therapies have been instituted and optimized.³⁵

CARDIAC IMPLANTED ELECTRONIC DEVICES

Cardiac implantable electrical devices (CIEDs) include pacemakers, ICDs, and cardiac resynchronization therapy + defibrillator devices (CRTDs). These devices are widely used to treat cardiac electrical problems such as bradycardias, symptomatic and life-threatening arrhythmias, and cardiac dyssynchrony. All these devices can monitor, record, and treat the heart's electrical activity. When a patient has symptoms suggestive of device malfunction, the device can be interrogated by a specially trained cardiac professional or company representative, and the recorded heart activity and device interventions are reviewed to determine whether there are problems with the device or its programmed functions. Toward the end of life, patients with ICD often choose to have the shocking capabilities discontinued to prevent distressing shocks as they are dying. Palliative APRNs can play a key role in deactivation discussions.¹⁵

ICD shocks in a terminally ill patient are painful and distressing, serve no medical purpose, and should be avoided.⁴ Discussions regarding prognosis, end-of-life symptom management, and ICD deactivation may take place in the acute care setting, cardiology, or primary care office, and information about the option of deactivation should be included in pre-implantation teaching.¹⁵ In patients with a DNR order in place, deactivation of an ICD's shocking function should be discussed. Deactivating the pacemaker function of an ICD or a pacemaker itself should be avoided, as it can result in symptoms like dizziness and even syncope episodes (passing out) due to inadequate cardiac output.¹⁵

Deactivation or reprogramming of a CIED requires a medical order, and proper etiquette is to notify the cardiologist managing the device. Deactivation may be done by a cardiac device specialist or a representative from the company that made the device. In an emergent situation, such when an ICD is shocking a patient who is DNR and who is dying, ICD deactivation may be accomplished by taping a medical-grade magnet over the device, but this is not the case for all devices. Palliative APRNs should be aware of any CIEDs in their patients because patients with cardiac disease are at risk for rapid changes in their health, during which the CIED may need to be addressed.

IMPLANTABLE HEMODYNAMIC MONITOR

Implantable pulmonary artery (PA) pressure ambulatory monitoring devices can help healthcare providers proactively determine changes indicating worsening HF. The implantable hemodynamic monitor (IHM) device is used to remotely monitor PA pressures and is placed in the PA using a percutaneous procedure. Adjustments of guideline-based HF medications based on PA pressures can promote better quality of life and fewer hospitalizations for patients with HF compared to medication titration alone.³⁶ The ideal patient for PA pressure monitoring is someone who has ongoing symptoms of HF despite optimized GDMT.³⁷ Patients who may not be good candidates for PA pressure monitoring are those with end-stage HF or heading to advanced therapies or palliative

care, Stage IV–V chronic kidney disease who are not responding well to diuretics, a body mass index (BMI) greater than 35, and/or history of pulmonary emboli or deep vein thromboses (DVTs) making implantation difficult.³⁷

INOTROPE INFUSION

Inotropes are medications that help the heart beat more strongly by increasing contractility. They are used for temporary symptom palliation in select patients with advanced HF.^{23,38} Despite many attempts to develop oral inotropes that are safe and effective, inotropes are still only available as intravenous infusions. Inotropes are used in conjunction with guideline-based medications and cardiac device-based treatments in advanced HF to improve symptoms of poor cardiac output such as fatigue and breathlessness as well as the patient's functional status. Inotropes may be used in patients awaiting transplant or VAD implantation, giving them time to address key decisions while providing relief from distressing symptoms.³⁹ However, despite this symptom benefit, inotropes do not extend life,⁴⁰ and they may increase the risk of dangerous cardiac events such as arrhythmias, MI, and hypotension by forcing an already weakened heart to pump more vigorously.⁴¹

Advanced HF specialists may offer inotropes as a palliative treatment, explaining that their goal is to “improve symptoms but not survival.”⁴⁰ Palliative care issues to address with patients being considered for or receiving inotropes for symptom relief may include shared decision-making regarding ongoing use of these agents, the potential for inotrope discontinuation with disease progression, and the discussion of potential adverse events such as arrhythmias that may be life-threatening or that could cause ICD shocks. For patients who are not eligible for inotropes or do not wish to elect other advanced heart therapies, the involvement of palliative care is critically important to assist with decisions about home healthcare or hospice. All providers should emphasize at the beginning of inotrope therapy the different scenarios that may lead to the need to discontinue the medication. These include deteriorating health status as evidenced by decreased quality of life, functional status, increased symptoms, and arrhythmias.

An ongoing challenge with inotropes is access to hospice for these patients. Hospices that can provide inotropes for a period of time in addition to oral GDMT medications for symptom relief must have providers and nurses skilled in HF management. Hospice management of inotrope infusions requires coordination of care between the hospice and the infusion company, with periodic clinical reevaluation of the infusion's clinical efficacy. Weekly goals-of-care conversations are important, with assessment of the patient's functional and quality of life status. The clinical exam may consist of monitoring serial pulse pressures and proportional pulse pressure readings as a clinical parameter to determine the inotropes' ongoing efficacy.^{4,42}

VENTRICULAR ASSIST DEVICE

VADs are increasingly used in advanced HF to alleviate symptoms and improve functional status in patients with advanced

HF whose heart function continues to deteriorate on GDMT and other treatments. While VAD has the potential to significantly benefit patients, there are also many risks and obligations associated with VAD therapy. The risk of serious complications or death may be underrecognized by patients who may see this as a “miracle” being offered when they have become very symptomatic and disabled.

In 2013, the Centers for Medicare and Medicaid Services mandated palliative specialist involvement in the care of patients being considered for VADs used as a bridge to transplant and destination therapy, working with patients before and after placement of a VAD in collaboration with the multidisciplinary HF team.⁴³ Palliative care is key to improving preparation of the patient and their family/caregivers for this device and the outcomes they may experience.

Patients who are offered VAD often have multiple comorbidities with a significant symptom burden that needs to be addressed throughout the trajectory. Palliative interventions for VAD patients include treating physical and psychological symptoms, providing emotional and practical support for caregivers, and alleviating suffering.^{4,44} Palliative APRNs who work with a VAD program should learn about common VAD complications such as driveline infections, stroke, bleeding, and symptoms of persistent HF such as nausea and edema. APRNs should also gain experience in promoting support and alleviating distress during VAD deactivation, as well as managing advanced HF symptoms, especially treating dyspnea with diuretics and opiates.

Palliative APRNs are often consulted by potential VAD recipients to discuss quality of life, and this discussion does not routinely move to end-of-life discussions. Instead, palliative discussions center on “what matters most” to the patient regarding hopes for life and their goals of care with the device.⁴⁵ Palliative care discussions pre- and post-implant should be nuanced, evolving as the patient and family journey through the VAD process. The pre-implantation palliative care consult focuses on preparing patients to better understand VAD therapy and its tradeoffs. Issues that should be discussed may include expected outcomes and risks, advance care planning, postoperative symptom management, and caregiver support. An evidence-based VAD decision aid, available at patientdecisionaid.org/VAD,⁴⁵ is recommended by the Patient-Centered Outcomes Research Institute as an essential tool for palliative practice with this population. Research with this tool found that patients in the intervention group had better decision quality, with closer alignment of the VAD medical decision and the patients' care preferences. Interestingly fewer patients in the intervention arm went on to have VAD implantation (54% vs. 80%, $p < 0.01$). Post-implant palliative discussions may focus more on code status, VAD-specific symptoms, end-of-life symptom management, and comfort-focused care such as hospice.⁴⁶

A challenging part of VAD care is the issue of deactivation. Patients with VAD are dependent on the device for survival. Both intentional deactivation as well as accidental discontinuation of the VAD's external energy source can cause rapid decompensation and death. For this reason, a VAD device has a loud alarm that sounds if the energy supply is cut off;

patients and their caregivers must practice responding to the alarms troubleshooting issues, knowing that the patient's life is hanging in the balance. Deactivation of a VAD device may be either medically indicated, such as when a patient has a catastrophic event following implantation, or deactivation may be requested by the patient (e.g., if their quality of life is poor).⁴⁷ Ethically, it is important to recognize that the cause of death following VAD deactivation is the underlying advanced HF syndrome and not the act of deactivating the device⁴⁸ (see Chapter 53, "Navigating Ethical Dilemmas").

Palliative APRNs working with VAD patients should collaborate with HF clinicians to gain experience in deactivating commonly implanted VADs when the need arises. It is important to anticipate and treat the common symptoms that patients experience after VAD withdrawal.⁴ Deactivation decisions may be complicated when the VAD patient is not necessarily terminally ill, but they have chosen deactivation due to a poor quality of life, psychological distress, or existential suffering. It is important to work toward shared goals between the patient and family, ensuring adequate symptom management and support at the time of deactivation.^{4,45}

HEART TRANSPLANT

Heart transplant is a treatment of choice for some patients with advanced HF who remain symptomatic despite GDMT optimization. As of 2017, median survival after heart transplant was 11.8 years. In 2019, there were more than 55,000 heart transplants worldwide, but the number is limited by the availability of donor hearts. Absolute contraindications for heart transplant are systemic illness with life expectancy of less than 2 years, irreversible pulmonary hypertension, severe cerebrovascular disease, active substance abuse, and multisystem disease with severe organ dysfunction. Relative contraindications include advanced age (70 or older), BMI greater than 35, diabetes with poor control or end organ damage, neoplasm, infection, pulmonary embolism within 6–8 weeks, irreversible renal dysfunction, tobacco or substance abuse within 6 months, and inadequate support system to comply with treatment plan.⁴⁹ Palliative care consultation is recommended by clinical practice guidelines pre- and post-heart transplant, especially for progression of cardiac disease.⁵⁰

HOSPICE IN ADVANCED HEART DISEASE

One of the greatest challenges in working with patients with advanced cardiac disease can be determining when they are at the end of the testing and treatment process and ready to consider hospice. While a 6-month prognosis can be challenging to accurately determine, a pattern of worsening functional status with little improvement despite GDMT titration is a key indicator of limited life expectancy that has consistently emerged in the research. Other hospice eligibility criteria for the patient with advanced HF include:

- Symptoms of recurrent HF or angina at rest, discomfort with any activity despite optimal treatment with

guideline-directed medications such as diuretics, beta-blockers, and angiotensin-converting-enzyme inhibitors (ACEIs)

- Ejection of less than 20%
- Symptomatic arrhythmias
- History of cardiac arrest and CPR
- Unexplained syncope.

The use of hospice in patients with advanced HF, as well as in patients who are not interested in pursuing advanced treatment options, may prevent unwanted hospital admissions and nonbeneficial tests and treatments while reducing healthcare costs.¹⁸ A decision aid to assist patients and their family considering hospice care is available at patientdecisionaid.org/hospice.²⁴

Hospice can be a fearful prospect for the HF patient and family if the medications they are used to taking to manage their symptoms are stopped. Many cardiology providers incorrectly believe that GDMTs, including medications and some devices, must be stopped upon hospice admission, which may prevent them from entertaining the idea of hospice for their patients.⁴ The American College of Cardiology Foundation/American Heart Association and the Heart Failure Society of America (HFSA) have guidelines for end-of-life care in the HF patient.^{23,38} In addition, in 2014, the HFSA published *Consensus Statement: End-of-Life Care in Patients with Heart Failure*,⁵¹ while the American Heart Association issued a policy statement in 2016 providing guidance for the development and growth of palliative care in cardiovascular disease and stroke.⁴³ While guidelines specific to hospice and palliative care for patients with advanced heart disease have yet to be clearly articulated, these statements and guidelines are essential foundations for palliative care practice.

For the hospice-appropriate patient with advanced HF, the guidelines recommend care that includes^{23,38}

1. Clinical assessment of hemodynamic status, blood pressure, and weight with adjustment of GDMT
2. Continue guideline-based cardiac medications including ACEIs, angiotensin receptor blockers (ARBs), angiotensin receptor neprilysin inhibitors (ARNIs), beta-blockers, calcium channel blockers, nitrates, oral and intravenous diuretics, antiarrhythmics, and anticoagulants (see Table 13.1)
3. Intravenous inotrope infusion (milrinone, dobutamine, dopamine) for symptom palliation in select patients (see Table 13.1)
4. Intravenous administration of diuretics (furosemide or bumetanide) to relieve pulmonary congestion; thiazide/loop combination may also be helpful for symptom relief
5. Device deactivation including ICDs at the end of life
6. Ongoing advance care planning and discussions about goals of care

There are many challenges and opportunities as the HF and the hospice care communities interface to provide the best evidenced-based care throughout the entire trajectory of HF, from diagnosis to death. Intravenous inotropes, including dobutamine, milrinone, or, in rare cases, dopamine, are sometimes offered to patients with HF with reduce ejection fraction as an advanced palliative therapy. Palliative inotropes can be cost-prohibitive for some hospices, and many hospice agencies hesitate to accept patients on inotropes due to the capitated per diem model of hospice reimbursement.⁵²

It is important that HF teams develop partnerships with hospices that can provide palliative inotrope infusions for select patients while on hospice care. Patients likely to benefit from inotropes while in hospice are those who have demonstrated favorable hemodynamic or symptomatic benefit from inotropes, who have not tolerated an attempt at weaning, and whose goals are aligned with hospice care.⁵²

CARE OF THE PATIENT WHO IS IMMINENTLY DYING

The final phase of a person's life is an especially important time. Palliative APRNs have an opportunity and an obligation to help patients have a good death. There are three main commitments at the end of life

- expert symptom management
- supporting and preparing the patient and family
- intensive comfort-focused care

It is essential to recognize when someone is within hours to days of dying. The mode of death for cardiac disease can be very sudden with arrhythmias; however, patients are more likely to die from progressive symptoms related to cardiovascular or noncardiovascular causes, though these can cause death within a few days of being stable. A new cardiac event in the patient with comfort-focused care may cause a rapid change in the patient's condition. They may exhibit signs of progressive cardiogenic shock as the compensatory mechanisms fail, and death may happen within 24 hours of symptom onset. While the patient in this scenario is actively dying, ICD shock may occur if they have an active ICD. Deactivation of the ICD's shocking function should be a priority to prevent patient, family, and caregiver distress. However, if the patient has a pacemaker, this device will not prevent the person from dying a natural death and it will not cause distressing symptoms. In fact, deactivation of a pacemaker in someone pacemaker-dependent can *worsen* distressing symptoms, so pacemaker deactivation is not indicated. (Funeral homes should be notified about implanted pacemakers or ICDs because devices must be removed before cremation.)

Three symptoms that may abruptly worsen as the patient is dying are secretions, delirium, and shortness of breath. Symptom distress should be treated as an emergency, requiring

thoughtful escalation of medications and close bedside monitoring. At such a time in someone's life, it is more about them, less about the disease, and the priority is intensive, comfort-focused care.⁵³

Sensitive expert communication skills should be used to prepare and support the patient and their family. There are several principles in working with families.

1. Do not assume the family knows that the person is dying.
2. Assess what is important to the family, such as seeing a chaplain or wishes for family presence during resuscitation.
3. Explain what they can expect with the person's condition and management.
4. If the patient has transitioned to a comfort-directed plan of care, provide a specific description about what this means.
5. Using a shared decision-making approach, talk about the care that will and will not be provided.
6. Assess for factors that may contribute to complicated grief such as surrogate-made treatment decisions, discontinuation of life-sustaining treatments, or unresolved family issues.

THE PALLIATIVE APRN-AN INTEGRAL MEMBER OF THE CARDIAC TEAM

SUPPORT, COMMUNICATION, AND SYMPTOM MANAGEMENT

The palliative APRN in the cardiac setting should provide ongoing support for the patient and family while facilitating important discussions and advocating for the patient's goals and preferences in treatment decisions. At the same time, they may also be an important source of support for the members of the cardiac care team, especially those experiencing moral distress or grief resulting from complex and heartbreaking situations. The palliative APRN should also be a role model and teacher of palliative care communication, shared decision-making, and symptom management strategies, disseminating primary palliative care knowledge, skills, and attitudes throughout the cardiac care environment.

FAMILY LIAISON IN EMERGENT EVENTS

The palliative APRN with an understanding of ACLS and emergent cardiac care can play an important role in supporting the family and providing information during a code, rapid response, or other emergent event, while the cardiac team is busy caring for the patient. The family that is present should be offered the option of watching resuscitation efforts, though always accompanied by a clinician who can explain what is

happening. They can provide anticipatory guidance based on what is happening with the patient's response to medical efforts and facilitate decision-making, such as whether resuscitation efforts should be stopped when futile. The palliative APRN can also assist with contacting support systems and spiritual care.⁵⁴

Anticipatory guidance may be used early in the code to prepare the family for the possibility that the patient may die and about the option to stop resuscitation efforts at some point. As the code progresses, the palliative APRN can explain to the family what is happening and what they are seeing and hearing, according to their needs and answering their questions. The family may experience comfort in knowing that the team did all they could to save their loved one. This type of support during a family-witnessed resuscitation can prevent complicated grief and posttraumatic stress disorder in bereaved family members.⁵⁵ The palliative APRN can fill this important yet underimplemented role of family liaison for the code and rapid response teams.

EMERGING OPPORTUNITIES

In this chapter we envisioned the role of palliative APRNs on the cardiac specialty unit, yet this vision has been limited to patients with advanced HF. As this role becomes established, there is ample opportunity for expansion of the role to include decisional support and holistic symptom management care for many more types of cardiac issues.⁵⁶ The role of the palliative APRN in the care of patients being worked up for VAD is currently being identified. Another emerging APRN role in cardiac palliative care is decisional support for any high-risk patients who are considering their testing and treatment options. These roles will require greater understanding of cardiology as well as the risks, benefits, and nuances of different options. As evidence grows and more clinicians experience the complexities and rewards of this exciting area of clinical practice, the palliative APRN role on the cardiac specialty unit will continue to evolve.

SUMMARY

This chapter has delineated the many ways in which the patient with cardiac disease in the acute care setting can benefit from specialist palliative care. The palliative APRN plays an important role in the care of patients on the acute cardiac specialty unit by promoting a focus on comfort, quality of life, communication, shared decision-making, advance care planning, and family support. Patients with advanced cardiac disease and their families are challenged by needs, experiences, and pathophysiologic changes that are unique to this population, affecting their quality of life, decisions, and the advance care plans that are appropriate for them. An understanding of the cardiac provider's mindset and common cardiac diagnoses, tests, treatments, and decisions will enable the palliative APRN to become a trusted, effective member of the interdisciplinary cardiac team

so that, one day, specialty palliative care will be available to all patients with cardiac conditions, from diagnosis to death.

THE PALLIATIVE APRN IN THE COMMUNITY SETTING

Nicole DePace

KEY POINTS

- The palliative advanced practice registered nurse (APRN) possesses unique skills and abilities to meet the complex needs of seriously ill patients and their caregivers in the community setting.
- The palliative APRN practices in a variety of roles in the community setting and must advocate to practice at the highest level of their ability and scope of practice.
- Models of community-based palliative care are changing and evolving quickly, and APRNs continue to struggle with scalable and sustainable reimbursement structures.

CASE STUDY 1: MULTISITE PALLIATIVE CARE

Theo is a palliative advanced practice registered nurse (APRN) working for a multisite hospice organization providing palliative consultation services to patients with advanced serious illness living in senior housing communities, assisted living facilities, and private residences in a large suburban county. On Tuesday, Theo consulted on the following patients.

- An initial or new consultation at a residence for complex pain management in a 56-year-old man with esophageal cancer who was treated with chemotherapy and radiation. The man lived at home with his partner. Theo completed a comprehensive history and physical, a holistic and comprehensive pain assessment, an opioid risk assessment and initiated opioid therapy, and a bowel regimen. He communicated the plan to the primary oncology team, provided patient and caregiver education about safe medication administration and storage, counseled about potential side effects, coordinated the opioid prescription with the community pharmacy, and communicated a plan for follow-up with the patient and his caregiver.
- A subsequent or follow-up visit in senior housing where he addressed the needs for psychosocial support and clarified the wishes for a feeding tube in a 72-year-old veteran with amyotrophic lateral sclerosis (ALS) who lived alone. Theo spent an hour in ongoing discussion and counseling with this patient about his expected disease trajectory, the benefits and risks of a feeding tube, the caregiving considerations to manage a feeding tube at home as his illness progresses, and he provided psychosocial support. Theo contacted the ALS clinic and the VA social worker at the close of the visit to coordinate a home

health referral for an in-home speech and swallow evaluation, updated the team about this patient's decisions, and advocated for increased home-based services to support his independent living in his apartment.

- Two subsequent or follow-up visits within a memory care unit of an assisted living facility (ALF) to complete discussions regarding prognosis and hospice transition in a patient with end-stage vascular dementia, and he completed advance directives with the healthcare agent of a patient with advanced Parkinson's dementia. Theo conducted two family meetings, collaborated with the nursing staff in the wellness office at the ALF community, coordinated a hospice referral with the hospice organization, completed advance directives, updated each patient's primary care provider about the outcomes of each visit, and ensured that each patient's family understood who to call for further questions.

Theo typically spends 75–120 minutes with his new patients and 45–90 minutes in each follow-up visit. Most days he sees 3–4 patients, depending on their location and the balance of new consults to follow-up visits on his schedule. He typically sees his patients for 2–3 visits before (1) they are referred to hospice or home health services, (2) symptoms are stabilized and management is taken over by the primary care team, (3) adequate counseling and education is provided to the patient, family, and care team about expected disease trajectory and prognosis, and/or (4) an advance directive is completed. Theo manages all aspects of patient care at each visit including empathetic communication and comprehensive documentation within the electronic health record (EHR). He attempted to make phone calls for coordination of care during his patient encounters or immediately after. He communicated with his program manager on a regular basis to review his schedule to cluster patients geographically and minimize his daily drive time between visits to reduce the documentation burden at the end of each day.

INTRODUCTION

Community-based palliative care (CBPC) is the integration of palliative and serious illness care outside of the acute care setting which continues to develop in terms of program design, resources, reimbursement, and emerging models. Individuals living with serious illness require holistic support focused on meeting their complex needs where they

live. These patients and families need access to palliative care services that can follow them for longer periods of time and with flexible levels of intensity based on their often changing condition and needs. Failing to meet these long-term needs places patients and families at risk of unnecessary suffering, burdensome emergency room visits, and hospitalizations. Advanced practice registered nurses (APRNs) possess the necessary knowledge, skills, and abilities to provide palliative care in the community setting and are uniquely and rightly positioned to improve access to palliative care services for patients and families living with serious illness. This chapter focuses on CBPC provision in a home environment (e.g., residence, assisted living, nursing home, group home etc.) while recognizing that community-based care can and should entail any palliative care required outside of the hospital setting.

DEVELOPMENT OF PALLIATIVE CARE IN THE COMMUNITY

Every person living with serious illness deserves access to palliative care, regardless of the setting.¹ Because most patients want to receive care in their home and community, currently, CBPC serves to fill the gaps in care for seriously ill patients.² As CBPC matures, it may serve as the primary area of palliative care, although as CBPC programs evolve, they are designed to meet the unique characteristics of the communities they serve. Development is guided by a needs assessment of the specific community, as well as the organizational objectives and resources available to support the program's existence and growth. This flexibility has led to individual programs and services development unique to various markets. Moreover, there have been significant opportunities for the palliative APRN to serve as a direct care provider and clinical leader in this arena.

The lack of federal regulation or conditions of participation for palliative care in the community has the potential to contribute to market variability, if not confusion. Confusion may arise due to variability in program design and objectives. A majority of CBPC programs are administered by hospice and home health organizations. This can lead to misunderstanding or avoidance of using these services due to fears surrounding hospice and end-of-life care,³ worries about services meeting homebound criteria, or having limitations in the types of treatments that would remain available to patients. It is necessary for CBPC programs to fully differentiate themselves from hospice services and home health services and not base program eligibility on prognosis or homebound criteria.⁴ There is also a need to continue to educate the general public about palliative care because significant knowledge gaps exist about what palliative care is, how it is paid for, and how to access services.^{3,5} The patient, family, and community education is a role that the APRN must address both informally and formally. Once patients and caregivers are educated, they may be interested in palliative care with the reassurance that decisions will be based on their needs and not their prognosis.⁵

In 2018, the National Hospice and Palliative Care Organization (NHPCO) surveyed its members and found

that at least half of its organizations were providing CBPC services and another third were considering or in the process of developing services.⁶ The majority of accountable care organizations (ACOs) have implemented efforts to identify their seriously ill patient populations, but only 8% were offering CBPC.⁷ In 2019, the Center to Advance Palliative Care (CAPC) released *Mapping Community Palliative Care*, with 890 CBPC programs identifying themselves across the United States, and with 65% percent of these programs providing home visits.⁸ This proliferation still only leaves 39% of the counties in the United States with home-visiting palliative care services.²

The National Consensus Project for Quality Palliative Care (NCP) *Clinical Practice Guidelines* provide best practices for palliative program structure and processes.⁹ These guidelines, initially developed in 2004, are a consensus process that includes major hospice and palliative care organization, home health organizations, professional clinical organizations, and consumer organizations, and are endorsed by 100 organizations. These guidelines are widely recognized in inpatient settings, however, to date, these guidelines are less recognized in the CBPC setting. For both acute care and CBPC, there are barriers to adherence to the guidelines, especially those aimed at programs delivering fully staffed interdisciplinary teams and 24/7 availability.¹⁰ Yet, these are the distinct characteristics of effective specialty palliative care. This is due to market variability and the inability of the fee-for-service (FFS) model to cover the cost of interdisciplinary team members. However, in the community, the nonbillable team members—nursing aides, social workers, and counselors—may be most needed.² It is imperative that policymakers, payers, organizations, and clinicians work to reduce the burdens of people living with serious illness. APRNs must advocate for strategies and take actions that make it easier for patients, caregivers, and health-care providers to work together, address social service needs, and make care accessible and affordable.¹¹

DISPARITY IN PALLIATIVE CARE

Further gaps in CBPC exist in meeting the needs of diverse patient populations. In 2020, the COVID-19 pandemic and social justice movements highlighted the undeniable racial and socioeconomic inequality in healthcare. This is an important moment to consider the past, present, and future of palliative care, which focuses on equitable growth and development of our services.¹² There is evidence that demonstrates lower quality palliative care for minority populations in various domains, yet there is not robust research data to describe racial disparities in nonhospice palliative care.¹³ Two facts are known: (1) 82% of hospice patients identify as White¹⁴ and (2) there are numerous structural barriers that prevent end-of-life care from being accessible and acceptable to all patients, especially racial minority and vulnerable patient populations. Moreover, LGBTQ + individuals, persons who experience homelessness, persons who are incarcerated, and individuals with comorbid substance use disorders or serious psychiatric illness are at greater risk for lower quality palliative care (see

Chapter 20, “Health Disparities,” Chapter 22, “LGBTQ+ Inclusive Palliative Care,” Chapter 46, “Serious Mental Illness,” and Chapter 47, “Patients with Substance Use Disorder and Dual Diagnoses.”) These patient populations also lack access to providers who possess the skills and knowledge to adequately address their needs and provide care that is concordant with their wishes and respects their inherent dignity.

While the individual palliative APRN may not have the immediate ability to adequately address the disparity in care to minority and vulnerable populations, they can immediately begin to identify and partner with community providers and agencies who are doing the work of caring for diverse patient populations. Palliative APRNs can forge relationships and offer consultation and education to their clinician peers to improve the primary palliative care skills of their colleagues practicing in diverse clinical settings. Palliative APRNs must be willing to learn about the structural barriers that prevent adequate palliative care services from being provided to minority and vulnerable patient populations (Box 14.1). Once informed, the palliative APRN must commit to act to remove structural barriers to access to quality palliative care for all patients. Palliative APRNs and CBPC organizations should (1) participate in diverse community activities, (2) engage in dialogue with community organizations including faith leaders and clergy, and (3) demonstrate a culture of humility, caring, and service with diverse groups.¹⁵ Being a visible and supportive presence in the community is an essential component of CBPC and is necessary to become a trustworthy community resource for palliative care.

MODELS OF PALLIATIVE CARE IN THE COMMUNITY

CBPC fills the gap in care for patients living with serious illness and for those who have high disease burden, high health-care utilization, and who are neither hospice eligible, hospice accepting, nor require or desire hospitalization. CBPC may focus on meeting the needs of these patients over years or the last months of their lives, depending on program structure and objectives. The reality is that, too often, patients with serious illness are not extended palliative care support until they experience a crisis and are in the hospital. This inconsistency in palliative care access leaves patients and families with little or no support to remain in their community and home setting. There has been a proliferation of community programs to meet the needs of these patients and their families. Yet not all patients with serious illness have access to reliable CBPC.

The majority of CBPC is administered by hospice and home health organizations and provided to patients in their homes, which includes assisted living communities.^{6,8} Progress has been made in program development in recent years. Many CBPC teams are interdisciplinary, including some combination of APRNs, physicians, registered nurses (RNs), and social workers. Many programs report having three or more clinicians included in their CBPC teams.⁶ Palliative APRNs

are most often the dedicated full-time employees for these programs.^{8,16}

There are clearly identified needs for new payment models, beyond FFS payment. Most programs rely on FFS reimbursement as a single-payer source.⁶ An FFS payment structure alone does not cover program expenses or take into account reimbursement for interdisciplinary care or the time-intensive and repetitive nature of the discussions required by this patient population.² In the FFS model, there is no reimbursement structure for spiritual care, and reimbursement is limited for social work outside of the certified home health benefit.

An increasing numbers of programs have diversified their payment structures and are pursuing contracts with payers and other risk-sharing models, such as ACOs.¹⁷ Transitioning to other payment structures, such as case rate payment for service or per member per month models, has been suggested. Assistance with negotiation, strategic guidance, and national comparison of such payment structures and model design is necessary for programs to succeed.^{2,18,21} Despite these financial challenges, when executed well, CBPC improves symptom management, improves coordination of care, and reduces unnecessary ED visits and hospitalizations in the months before death.^{19,20,22} Sustainability of high-quality CBPC programs requires alignment of fiscal and quality incentives, and there is a continued need to see creative partnerships with health systems, service providers, and payers (Table 14.1).¹⁸

KEY ELEMENTS OF THE APRN ROLE IN THE COMMUNITY

Patients living with serious illness experience high disease-related burdens: complex and significant symptom burden, poor care coordination, poor understanding of their illness trajectory and options for care, and unmet psychosocial needs.^{21,22} Frequently, CBPC programs are asked to assist with goals-of-care discussions, patient and family education, symptom management, comprehensive assessments, advance care planning, and care coordination.⁶ Unfortunately, there is often poor awareness and understanding of CBPC services by non-palliative care clinicians and laypeople,^{22,23} which can delay access to care. The APRN responds to the needs of this patient population with expertise in comprehensive assessment, care management and coordination, clinical management, psychosocial support of patient and family, communication about goals of care, and advance care planning and education (Table 14.2).^{20,24–28}

MODELS OF COMMUNITY PALLIATIVE CARE USING APRNS

VNA CARE OF NEW ENGLAND

The VNA Care of New England (nonprofit home health and hospice agency) established a CBPC program in response to the needs of their health system. This Rhode Island health

What is known:

- There is mistrust of the healthcare system and medical providers by minority and vulnerable populations that is rooted in historical mistreatment of these populations by the healthcare system and providers.^{12,29,30}
- Differences in healthcare outcomes, quality of care, and access to care exist across racial and ethnic groups and other vulnerable populations.^{13,29,31}
- There is documentation of lower quality palliative care for minorities across the domains of satisfaction, communication, and pain management.^{13,31}
- Studies demonstrated lower rates of hospice utilization among non-White adults.^{13,15}
- Research and data are minimal on disparities in the use of non-hospice palliative care in minority populations^{13,31} and in other vulnerable populations.²⁹
- Minority patient populations do not have equal access to pain care in the United States.^{13,31}
- There are opportunities for community-based palliative care programs to improve access, reduce barriers, and reduce inequities in palliative care.¹²

What can be done to reduce and eliminate disparities in community based-palliative care:

- Provide resources and support to palliative care clinicians who care for minority and vulnerable patient populations in primary palliative care skills and on end-of-life care issues.²⁹
- Promote community-based partnerships with stakeholders and leaders in minority communities, including clergy, and with community agencies without expecting a payback.^{13,15,29}
- Address language barriers for specific groups of patients through the use of interpretive services in the community.^{13,15}
- Evaluate and measure the racial/ethnic composition of palliative care staff, goals, and culture pertinent to diversity and inclusion.^{13,15}
- Facilitate research and interventions that aim to understand and address health literacy, communication skills, and culturally specific models of care to meet the needs of diverse patient populations.¹³

What the community-based palliative APRN can do to reduce disparities:

- Provide affirmative nonjudgmental care, and approach cultural differences with humility and sensitivity.³⁰
- Create a trusting relationship and safe environment for all patients and families.
- Commit to learning the historical events and context that affect current interactions of minority and vulnerable populations with healthcare providers and systems.
- Learn principles of trauma-informed care as part of professional development.
- Provide peer support to clinician colleagues who are working with minority and vulnerable populations to increase their primary palliative care skills.^{16,31}
- Engage in community outreach and education to increase awareness and understanding of palliative care, advance care planning, and community bereavement resources.^{13,16,17}
- Address and reduce barriers to completion of advance directives in vulnerable populations.^{13,30,32}

Table 14.1 PAYMENT MODELS FOR COMMUNITY-BASED PALLIATIVE CARE (CBPC)

	KEY FEATURES	OPPORTUNITIES	RISKS
Fee for service (FFS)	Payment based on volume of services/number of visits. Paid for by Medicare Part B and other insurers.	Accounts for the majority of CBPC Medicare payments. Well-established and understood payment structure. Any provider eligible to bill Medicare Part B can provide palliative care services in this model.	Limits billing to services provided by physicians or advance practice providers. Variations by state regarding which clinicians can be reimbursed.
FFS linked to value-based payment supplements	A portion of payment is based on the quality or efficiency of service delivery.	Providers are rewarded or penalized based on performance. Providers can self-select the quality measures they choose to report on.	There are no palliative care specialty specific measures sets. Increases the complexity and expertise needed for billing and CMS data submission. Requires Medicare certified EHR.
Alternative payment models (APMs)	Payment is based on quality and cost, structure built on FFS model.	Shared risk and payment savings shared between Medicare and accountable care organizations. Organizations can include palliative care in bundled payment. Payment corresponds to a specific condition or episode of care. Allows for interdisciplinary structure.	Program assumes financial risk for the specific condition. Most bundled payments are in early phases and therefore not as well understood by CBPC programs.
Population-based payment	Payment is determined for an episode of care for each patient assigned to a care provider.	Supports service delivery for prolonged periods of time. Allows for interdisciplinary structure.	Payment is fixed. The service provider owns financial risk for providing all palliative services with allotted payment.

Adapted from CAPC.³³

system is comprised of hospitals, outpatient services, accountable care organization, and a community substance abuse treatment program. A catalyst for the development of the CBPC program was a taxed and overwhelmed inpatient palliative care consultation program.²⁴ The program relies on both the APRN and RN being allowed to operate to the full extent of their license and experience, with adequate support.

The CBPC program was designed and led by Therese Rochon, a palliative APRN responsible for program development, direct patient care, mentoring, and palliative care education for home healthcare nursing staff. The APRN used population health principles to identify patients at highest risk for hospitalization and poor prognosis. This was accomplished using data analytics software and Outcome and Assessment Information Set (OASIS) data.²⁴ The APRN led case conferences, provided real-time education to the nursing staff regarding disease trajectory, guided symptom management, and coached nurses about how to begin to address goals-of-care conversations with these medically frail patients. The APRN completed in-person home consultations with patients with the most complex needs and billed for services using the FFS model.

The palliative care referral stream, as built into this model, has a flow of patients across the system's continuum of care. Referrals to the palliative care program came from the inpatient team, RNs in the home health program, and primary and specialty medical providers, and from self-directed referrals from patients and families. Over the course of 5 years, the palliative care program has demonstrated a striking increase in the number of referrals to the hospice program and, more importantly, a meaningful increase in the average hospice length of stay.²⁴ VNA Care New England has been able to create a robust referral stream to CBPC from their community partners in care (home health nurses and physicians), meaning it is not solely dependent on the inpatient team to direct palliative care referrals.

One marker of program success is that completion of advance care planning conversations and documents increased from 8% to 78% over the course of 5 years.²⁴ This program has proved its ability to improve the quality of care of medically frail patients within the health system and grow the hospice program with appropriate and timely referrals. Engagement and collaboration with stakeholders across the health system have secured adequate infrastructure and support to sustain

Table 14.2 KEY ELEMENTS OF THE PALLIATIVE APRN ROLE IN THE COMMUNITY

Comprehensive assessment	Complete a comprehensive history and physical exam, a psychosocial assessment including risk for isolation, home safety evaluation, caregiver burden assessment, opioid risk assessment when appropriate.
Patient and family education	Conduct the necessary counseling to help patients and families understand the illness and its expected trajectory, prognosis, treatment options, community resources including hospice, home safety, and advance care planning. The palliative APRN has acquired advanced communication skills to ensure effective and empathetic communication with the seriously ill patient population.
Symptom management	Direct the plan of care to ensure adequate pharmacologic and nonpharmacologic management of distressing symptoms that is line with the patient's goals of care and treatment options. Ensure the patient has access to medications and treatments. Ensure an adequate plan for follow-up is established and communicated. Ensure the plan of care is patient-centered and family-focused.
Advance care planning	Conduct conversations with patients and families to determine wishes and preferences for future healthcare. Provide counseling about risks and benefits of life-prolonging medical treatment options. Document patient wishes in the medical record. Complete advance care planning documents including: a) surrogate decision maker forms- healthcare proxy forms, durable power of attorney forms, b) advance directives or living wills c) out of hospital orders for living sustaining treatments -POLST/MOLST forms, do-not-resuscitate orders. Repeat conversations and update documentations as frequently as necessary based on the patient's changing condition and priorities.
Care coordination	Facilitate communication between primary and specialty providers, direct referrals to home health and hospice, direct referrals to community service providers. Refer to and collaborate with interdisciplinary team (IDT) members, meet with IDT on a scheduled basis to review and update the plan of care to meet the patient's changing needs.
Community outreach	Informally or formally engage in community education about palliative care and advance care planning. Provide peer support to non-palliative care clinicians in primary palliative care skills. Form relationships with community service providers.

MOLST, medical orders for life-sustaining treatment; POLST, physician orders for life-sustaining treatment.

Adapted from Melhado³⁴; Rotundo³⁵; Frier³⁶; and Dahlin.³⁷

the program. The palliative APRN was successful in this program because institutional barriers to practice to the full extent of licensure and education (within the context of state and federal regulations) were removed.

PALLIATIVE CARE HOMEBOUND PROGRAM

The Mayo Clinic Palliative Care Homebound Program (PCHP) in Rochester, Minnesota, is an ACO-funded program focusing on the palliative care needs of a high-risk, frail, homebound population. Patients served in this program had higher rates of moderate to advanced dementia.³⁸ The interdisciplinary team consisted of nurse practitioners (NPs), RNs, and physicians. One RN was assigned to two NPs, and the team met with the physician weekly. The program also had access to the system's geriatricians, social services department, case managers, and pharmacists.

Each full-time NP was responsible for 20–35 high-acuity patients. This program aimed to provide early palliative care and has the capacity to care for this patient population in the months to years leading up to the terminal phase of their illness, when hospice would become appropriate. The NPs provided scheduled and acute in-home visits. Physicians were available for consultation and more limited home visitation. The program was committed to providing NP visits for acute symptom management needs within 24 hours. Additional

responsibilities included chronic disease management, home safety assessments, care coordination, goals of care, and advance care planning conversations.

PCHP reduced annual Medicare expenditures by \$18,251 per program participant compared with matched control patients.³⁹ Patients enrolled in this program had high rates of advance directive completion, documentation of frequent discussions regarding goals of care, decreased hospitalization rates, and fewer overall days spent in the hospital setting. Additionally, the team provided patient and family education and support.³⁸ This model demonstrated significant financial value, and the quality outcomes for patients were striking and contributed to more time at home with a higher quality of life. This model of a CBPC allowed NPs to function as primary palliative care providers in the home and delivered interdisciplinary high-value care to high-risk older adults (Table 14.3).

APRN ROLES IN COMMUNITY-BASED PALLIATIVE CARE

APRNs may practice in CBPC settings that do not support their practice within the full scope of their role as either an NP or a clinical nurse specialist (CNS) (see Chapters 2 and 3). They may function as a program coordinator, liaison between providers, educator, in telephonic management, and/or as support to patients and families. Successful CBPC programs rely

Table 14.3 COMPARING AND CONTRASTING TWO CBPC MODELS USING APRNS

	VNA CARE NEW ENGLAND	MAYO CLINIC HOMEBOUND PROGRAM
Organizational structure	Nonprofit home-health and hospice agency within a regional health system	Accountable care organization (ACO)
Role of APRN	Program design and leadership Leads case conference and interdisciplinary team (IDT) meetings Staff education and development Consultant for symptom management, advance care planning (ACP), and goals of care	Primary care provider for frail, homebound patients Chronic disease management Acute and chronic symptom management ACP, goals of care, care coordination
Payment/Funding source	Medicare Part B fee-for-service (FFS) billing Indirect revenue related to hospice transitions	ACO funding
Key outcomes	High completion rate of ACP conversations and documents Referrals from across the health system to the palliative care program Increase in referrals to hospice Increase of hospice length of stay	High completion rates of ACP conversation and documents Significant reduction in Medicare spending Frequent goals of care conversations Decreased hospitalizations and fewer days in hospital
Benefits	Access to IDT Sustainability through indirect financial benefit to hospice Leadership opportunity for APRN	Nurse practitioner (NP) and registered nurse (RN) partnership Access to physician, geriatrician pharmacist, social service consultants Early palliative care involvement allowed NP to care for patients for months to years
Challenges	Model is not sustainable without indirect hospice revenue Adequate support for Medicare Part B billing and support Differentiation of CBPC from hospice	Model is not sustainable without ACO funding Financial risk for program if outcomes are not favorable

Adapted from Rochon, Emard²⁴; Chen et al.^{38,39}

on the APRN's full scope of practice and expertise^{17,19,20,25,38} and benefit from the APRN's comprehensive clinical assessment and consideration of all aspects of the patient's illness, including psychosocial distress and functional capabilities.^{26,27} Patients with serious illness often experience fluctuating and protracted disease trajectories with needs that can change frequently over time. APRNs in CBPC provide insight into home environments, barriers to successful self-management, and caregiver function, and create patient and family-centered plans of care. These complex patients require a team of providers to address their diverse needs, and the APRN is central to care coordination, collaboration, and providing specialty-level palliative care in the home setting.

CARE MANAGEMENT AND COORDINATION

CASE STUDY 2: COMPREHENSIVE ASSESSMENT

Ben was an 84-year-old man with end-stage renal disease on hemodialysis, congestive heart failure (CHF), chronic obstructive pulmonary disease, diabetes, and transient ischemic attacks. Ben

initiated dialysis in the setting of increasingly difficult to manage fluid volume status and diuretic resistance. Initially, dialysis helped to reduce the number of hospitalizations for his CHF, and he felt dialysis was beneficial. He continued to make urine and his course was complicated by urinary retention and frequent complex urinary tract infections. His daughter, who was his primary healthcare agent, expressed distress around medical decision-making and balancing caring for her parents and her school-age children. Ben was hospitalized three times in 6 months for several healthcare issues and expressed increasing distress about being separated from his family. Following the third hospitalizations, Ben was referred by his primary care physician to the palliative APRN for consultation to assist with clarifying the goals of medical care and coordination of care. The APRN was able to provide a comprehensive assessment of Ben's physical, social, and psychological needs and explore the caregiver's source and level of distress. Through a series of conversations, the APRN was able to elicit Ben's goals to live for as long as he could if he was able to spend more days at home and if he could ensure adequate help at home without feeling that he was burdening his children. He was also able to identify that he would not want to live for as long as he could if he lost his ability to eat his favorite foods or walk to the bathroom. Through coordination of care with his multiple medical providers, home health clinicians, and his dialysis center,

the APRN was able to guide Ben's decision-making around outpatient tests and treatment that were tolerable and in line with his goals. A referral was placed to social work to assist with resource connection and additional family counseling and support.

Ben was able to remain at home for the next 18 months, with only one hospitalization and continuation of his dialysis treatment. His daughter expressed feeling relieved and better prepared to meet the needs of his changing functional status and increased personal caregiving needs. Unfortunately, Ben suffered from a stroke during dialysis treatment and was hospitalized. Once the effects of the stroke were understood by Ben's children, they were able to decide for Ben to return home with hospice services and focus his care on comfort. Ben died peacefully at home with his children and wife at his bedside.

A critical role of the palliative APRN is aligning the patient's treatment options with their goals of care and helping patients and families prepare for eventual decline or complications from their illness. The APRN must recognize that patients with organ failure experience disease-related burdens similar to patients with metastatic cancer yet often do not have access to early palliative care services.²⁸ These patients are less likely to have adequate information about their disease and do not always fully understand their prognosis and treatment options.^{21,28} This patient population is at greater risk for acute high-burden symptoms and caregiver burden.²¹ The CBPC palliative APRN can spend time with these patients and families and address goals of care and crisis planning, place timely referrals, and support proxy decision-makers.

COMMUNICATION AND EDUCATION

CASE STUDY 3: ADVANCE CARE PLANNING

Jennie was a 93-year-old woman with advanced vascular dementia who had been hospitalized four times in the past 5 months for complications related to her frail status and advancing dementia. The palliative APRN was asked to see Jennie by her home care RN to help Jennie's daughter with advance care planning and education regarding the dementia disease process. The home care RN expressed feeling frustrated that despite frequent education, she could not seem to get through to Jennie's daughter about the progression of Jennie's dementia.

The palliative APRN planned a co-visit with the home care RN. The APRN found that Jennie has been bed-bound for 2 years since a stroke left her unable to walk. She was incontinent, had chronic lower extremity contractures, and was lovingly hand-fed by her daughter for each meal. Through a process of obtaining a history from Jennie's daughter and discussion about what the daughter understands about Jennie's dementia, it became clear that Jennie's daughter did not understand her mother's illness. She revealed that Jennie's husband (her father) died of Lewy body dementia, and that was a very different experience. She also revealed that her dad died very quickly in the hospital of pneumonia after aspirating

at home, and she continues to worry that she missed something or waited too long to seek help for her dad.

Over a series of three home visits, the palliative APRN provided counseling and education to Jennie's daughter about vascular dementia, its expected trajectory and complications, options for managing complications in the home setting, expert consensus statements on the use of feeding tubes in a person with advanced dementia, and hospice services. The palliative APRN coached the home care RN about indicators for hospice eligibility and communication strategies to provide follow-up education and support to Jennie's daughter. The palliative APRN managed Jennie's symptoms, supported the home care RN, and completed advance directives. At the third and final visit with the APRN, the daughter expressed readiness for hospice transition and relief from her worry about not providing adequate care to her mom. Jennie remained at home, comfortable and lovingly cared for by her dedicated daughter for the remaining months of her life.

One of the most important functions of an APRN is the ability to understand complex pathophysiology, prognostic indicators, and treatment options and to integrate this information into the context of the unique patient and family system. The palliative APRN has a specialized ability to see the "big picture" and to communicate this information in a way that can be understood by the patient, family, and other clinicians. The palliative APRN can model empathetic and honest communication strategies and coach other clinicians in providing manageable "chunks" of information to assist patients and families in their understanding of and coping with the progression of a serious illness. The palliative APRN is versatile in their ability to respond to emotional cues and continue to engage in conversations that are difficult but necessary to provide patient-centered care and honor patient's wishes. In the third case study, Jennie exhibited signs of disease progression and complications associated with nearing the end of life. The palliative APRN provided a comprehensive assessment of the physical, social, and emotional needs of Jennie, her daughter, and the RN. This led to the development of a plan of care that was patient-centered, honored Jennie's wishes, addressed the caregiver's needs, and allowed Jennie to remain in her home through the end of her life.

Many community RNs express a lack of confidence or uncertainty in communicating with patients and families regarding disease trajectory or about initiating conversations about advance care planning.^{24,40} Having the ability to request the consultation of a palliative APRN to assist in the care of these patients at home is invaluable to patients and families and to the nursing staff who have the most frequent contact and are responsible for direct care provision.

Patients with dementia are less likely to receive specialist-level palliative care despite disease and symptom burdens that are similar to or greater than that of patients with cancer, especially as they near end of life.^{41,42} There is often a lack of understanding of the progressive and ultimately terminal nature of the disease and higher levels of functional impairment and caregiver distress, and end-of-life decision-making is likely to be made by a proxy decision-maker.²⁶ Emergency

department use at end of life is associated with poor quality of care and with reduced quality of life for people living with dementia.⁴¹ Acute care encounters are associated with negative consequences for the patient population in advanced disease. Unfortunately, as many as 70% of people with dementia will visit an ED in the last year of life, and the risk increases as they get closer to death.⁴³ Involvement of CBPC in the care of people with dementia allows for timely access to counseling and education about the disease process and expected complications of the illness, establishing and continuous evaluation of the goals of care, treatment of recurring symptoms in the home setting, and care coordination.⁴⁴ Providing access to CBPC in this patient population has been shown to prevent avoidable ED encounters and hospital admissions, especially as people living with dementia approach end of life,^{43,44} and better-coordinated care.⁴⁰

SYMPTOM MANAGEMENT AND ADVANCE CARE PLANNING

CASE STUDY 4: COMPLEX SYMPTOM MANAGEMENT

Michelle was a 50-year-old woman with metastatic breast cancer. She had been living with her cancer illness for 12 years and had undergone numerous treatment lines and clinical trials. She was married and had a 10-year-old daughter. Her Jewish faith was important to her, and she expressed her belief that all life is sacred. She wanted to pursue all treatment options available to preserve her life and to be present for her daughter for as long as possible. She had new brain metastases that caused her to experience seizures and headaches and new bony metastases in her right ribs and thoracic spine, necessitating a course of palliative radiation.

The palliative APRN was asked to see her by the primary oncology team to assist with complex symptom management and coordination of care. The APRN met Michelle at home, during the context of the COVID-19 pandemic. Michelle had not seen her primary oncologist in person for 2 months, and the majority of her care had been coordinated by telehealth encounters. In preparation for the initial home visit, the palliative APRN spoke with the oncologist who shared that there were no additional cancer-directed treatments available to Michelle and felt the best plan for Michelle would be a transition to hospice care at home. The oncologist had difficulty initiating this conversation with Michelle and her husband and worried about the effects of doing so during a telehealth consultation. The palliative APRN provided hands-on assessment of Michelle's symptoms and assessed the family dynamics and the ability to manage symptoms in the home setting. Michelle's husband was a paramedic and expressed comfort with performing personal care and medication management. His biggest worry was managing further seizure activity.

A trusting relationship was built with the APRN over a course of weeks, symptom management was optimized, and an emergency plan was developed for both a pain crisis and breakthrough seizure activity. Michelle and her husband agreed to let

the palliative APRN coordinate a co-visit with the oncologist via a telehealth consult. Michelle expressed that she would not want to die at home and wanted to focus on living for as long as possible, even if life-support were required. The palliative APRN and the oncologist were able to discuss options for hospital admission if there was uncontrollable seizure activity or symptoms become too much to manage at home. They discussed a plan to include the inpatient palliative care team if Michelle was admitted to the hospital. Michelle and her husband agreed with the APRN's recommendation to seek counsel from their Rabbi regarding Jewish teaching and end-of-life decision-making.

The goal of CBPC is to address the needs of patients and families living with serious illness and provide patient-driven family-centered care. The art of this practice is to meet patients where they are, to make good use of the resources at hand, and to build trust and help patients and families fully understand their options. Patients with advanced and terminal cancer may have significant fear and difficulty accepting their prognosis or approaching death.⁴⁵ APRNs can be effective in assessing and understanding the patient's complex psychological and spiritual experiences. Community clergy often minister to patients and families suffering during a terminal illness,⁴⁶ and the APRN must be aware of this. An opportunity exists for APRNs in CBPC to engage with community clergy to build informal networks and explore their educational needs around palliative and end-of-life care. An expressed desire by community clergy for end-of-life care provides palliative APRNs an opportunity to apply the NCP *Clinical Practice Guidelines* for interdisciplinary care and create informal networks of spiritual care services for their patients.^{9,46}

PRACTICING AT FULL SCOPE AND ABILITY

CASE STUDY 5: PROGRAM DEVELOPMENT

Lucia was an APRN employed by a system-based hospice and palliative care organization. Her organization had been awarded a 3-year grant to implement a population health model of CBPC care delivery. The focus of this project was to meet the palliative care needs of a high-morbidity patient population. Lucia took on the role of palliative care coordinator for a team of two RNs, one social worker, and a very part-time physician. She was responsible for care delivery and oversight of the team's ability to provide patient and caregiver outreach, consults for prognostication and hospice eligibility, complex symptom management, and running the weekly interdisciplinary team meeting. In her first year in the role, she was able to implement team-based training and establish program metrics. The program demonstrated a reduction in hospital admissions, but not ED encounters. The program also showed an increase in referrals to the hospice program. Lucia identified confusion among non-palliative care clinicians (physicians and nurses) regarding the differences between hospice and palliative care, which led to a reluctance to refer patients to the palliative care program. The benefits of the program to the system

Table 14.4 OPERATIONAL CONSIDERATIONS OF CBPC

	FOCUS	DESCRIBE	ROLE OF THE APRN
Clinical care model and patient population	Determine consultation only, co-management, primary care, or some combination of these models. Define referral criteria and patient population.	Define whether consultations will result in recommendations only, prescriptive authority, or taking on primary care responsibility for the patient. Medicare Part B billing criteria requires that a written request for consultation is provided by the referring provider. The program may receive referrals from a variety of sources including community primary care providers (PCPs), specialty providers, hospital discharge planning staff, complex care and transition management coordinators, and home care services, as well as patients and caregivers themselves.	Adheres to state practice requirements. Establishes collaborative relationships with referral sources and community organizations. Communicates with the PCP if the referral was not initiated by the PCP.
Patient eligibility	May differ between programs.	Criteria often include adults with serious illness and need for: Complex pain and symptom management Advance care planning Establishing or clarifying goals of care Risk for burnout of caregiver of frail elder.	Provides in-person evaluation of patient's clinical presentation, healthcare utilization, and psychosocial needs to best determine their level of acuity and complexity.
Patient encounters	Ensure continuity and individualized care.	Time and frequency will be determined by program design and patient needs.	Explains palliative care and the role of the APRN. Determines and communicates a plan for subsequent, follow-up care.
Catchment area	A determining factor in caseload and visits per day	Travel time may restrict productivity, should be regionalized whenever possible.	Communicates needs to program manager or coordinator to balance productivity, quality, and safety.
Visit preparation	Ensuring access to adequate clinical information.	Depending on practice structure, the APRN may review records from a variety of sources (e.g., electronic health record, fax or scanned documents, phone or email communication, etc.).	Ensures an adequate understanding of the patient's history, current situation and expectations of the referring provider to ensure safe and satisfying care.
Communication	Provide safe, comprehensive, and well-understood care.	Comprehensive assessments are documented in the electronic health record. Patients, families, and clinicians will have access to contact information for the CBPC program and know how and when to contact the APRN.	Provides verbal and written communication to referring provider/agency. Clinical notes are finished in a timely manner. Coordinates and communicates with IDT and community organizations. Documents advance directives in the patient record and shared with referring providers/agencies.

Adapted from Meier et al.³³; Melhado³⁴; Dahlin.³⁷

were demonstrable, and Lucia advocated for the addition of another APRN to the team. This allowed for more focus on complex pain and symptom management and more timely consultation for prognostication and hospice transition planning. With this additional resource, the program was better able to meet the needs of the patient population and plan for targeted education to clinicians in the system to help increase the understanding of the palliative care program and increase referrals. In preparation for the second year of the program, the APRN made plans to meet with the organization's data analytics, business development leaders, and clinical operations stakeholders to evaluate the program's current progress and reach consensus on additional

metrics that can be measured to demonstrate the sustainability of the program.

To ensure the future of APRNs' contributions to healthcare, the workforce must be able to protect and advance the APRN role. Palliative APRNs in all settings, including those outside of academic settings, must be allowed to overcome the threats to their scope of practice, reimbursement, and full practice authority.⁴⁷ The work of CBPC palliative APRNs needs to be visible, and their accomplishments need to be publicized (Table 14.4).⁴⁷

OPERATIONAL CONSIDERATIONS OF PALLIATIVE CARE IN THE COMMUNITY

INITIATING CARE

CBPC programs must be clear about the services they are offering to referring providers: consultation only, co-management, primary care, or some combination of these options. It is important to establish the prescribing capabilities and responsibilities of the program. Referrals to palliative care programs can be received from a variety of sources, including community primary care providers, specialty providers, hospital discharge planning staff, complex care and transition management coordinators, and home care services, as well as patients and caregivers themselves. Medicare Part B and most managed care payer source referrals require a form request/order from the requesting provider to receive payment for services rendered. Proper consultation etiquette suggests that the primary care provider be alerted if he or she has not initiated the referral. This establishes collaboration, which is an important aspect of any home palliative care program. Referrals should be managed by a clinically trained professional to assess eligibility and triage symptom management concerns and psychosocial needs.

The criteria for patient eligibility for palliative care differ between programs and are influenced by the needs of the local community. Criteria often include adults with serious illness including metastatic and progressing cancer, organ failure, and dementia. Eligibility for palliative care should take into consideration the patient's clinical presentation, healthcare utilization, and psychosocial needs to best determine his or her level of acuity and complexity.

PATIENT ENCOUNTERS

The patient's length of stay in a palliative care program depends on symptom burden, disease progression, and the psychosocial needs of the patient and family. Program design will also determine the length of stay on the CBPC program. Some initial consults may only require one visit due to an immediate transition to hospice. Visit frequency for each patient varies and should be determined at each appointment depending on the patient's current clinical and psychosocial needs as well as the staffing and resources of each practice. Visits can be scheduled between appointments with the patient's primary care provider or specialist to maintain continuity of care.

The amount of time spent completing initial palliative care consults and subsequent visits depends on the complexity and acuteness of the patient's needs. On meeting the patient and family for the first time, the palliative APRN explains the palliative care home-based service and clarifies the APRN's role. A working relationship with the patient and family is subsequently established, with the focus of care being patient-centered and patient-driven. With this approach, patients often prioritize their greatest health concerns early in the visit. Time is allowed for patients to describe their experience

of living with chronic illness, their coping mechanisms, and their life's journey.

EFFECTS OF CATCHMENT AREA

Geography is an important consideration for both the size of caseload and the number of visits per day. In addition to the length of time spent with each patient, the travel time between patients restricts the number of patient visits each day. Travel time is affected by whether the catchment area is urban, suburban, or rural. Practices with multiple providers should consider regionalizing providers to improve efficiency and in consideration of quality-of-life factors for staff.

PREPARATION AND COMMUNICATION

To make safe and beneficial clinical decisions, the palliative APRN practicing in the home setting must have access to adequate clinical information. Practicing in the home environment presents unique challenges in that it is not a controlled environment and can be unpredictable. Preparation is key for efficient and safe encounters. Preparation involves reviewing the patient's medical record and communicating with providers to clearly understand the patient's overall situation and the expectations of the consultation by the referring provider. The palliative APRN should have access to pertinent primary and medical specialty notes, recent hospital or ED discharge summaries, lab results and diagnostic reports, and medication lists before making in-home visits. A copy of the palliative APRN's consultation note should be sent to the referring provider after each encounter. This is a core component of consultation etiquette and is required to meet conditions for FFS billing.

Specialty-level palliative care consultation notes should be comprehensive and illustrate the holistic and comprehensive assessments and unique characteristics of palliative assessments. In the community setting, it is especially important to ensure that notes include detailed information about symptom status, cognitive status, functional and nutritional status, home safety and fall history, caregiver status and community supports, goals of care, and advance care planning discussions and documents.

Per the NCP *Clinical Practice Guidelines*, the palliative care team should meet regularly to discuss and collaborate on difficult cases.⁹ Team meetings provide an opportunity for interdisciplinary teams to discuss and address complex issues, identify referral resources for care coordination, and establish plans to address caregiver distress. Team meetings also offer opportunities to address conflicts in care and maintain team and professional caregiver wellness (Box 14.2).

SUMMARY

Palliative APRNs are instrumental in providing comprehensive care for patients with serious illness. Their advanced education and nursing experience allow them to bring a unique patient-centered approach to care into the home environment.

Patient Population

- Needs assessment of the community and organization/health system
- Community assessment of demographics and resources
- Analysis of potential patient populations (e.g., by risk, diagnosis, prognosis)
- Geographic catchment area

Palliative Care Service Delivery

- Model of clinical responsibility of the palliative care service: Consultative, co-management, primary provider, or mix of all three
- Coverage and Accessibility for After hours – evenings, weekends and holidays coverage of patients (by palliative care team or covering team)
- Scheduling: Frequency and duration of patient encounters
- Staffing of team members: Clinical staff, interdisciplinary team, and administrative support staff
- Design a comprehensive palliative care clinical note

Types of Services

- Management of physical needs - Pain and symptom management
- Management of psychological, spiritual, emotional needs of the patient and caregiver
- Skilled communication and support for complex medical decision making
- Advance care planning and goals of care conversations and advocacy for care delivery congruent with these conversations
- Conversations in context of culture, ethnicity and religion to reduce disparities of care
- Care coordination and management of quality transitions of care
- Medication management, reconciliation, and monitoring
- Planning for end-of-life care, with appropriate and timely referral to hospice when requested by the patient and family
- 24/7 accessibility to palliative care expertise and staff

Community Collaboration

- Establishment of relationships with primary care and specialty health providers
- Establishment of relationships with community services: Elder service programs, community alternative programs, community clergy, parish nurses, behavioral health service providers, legal services, interpreter services, transportation services, respite services, home health agencies, hospices
- Education to community partners: Address fears about hospice directly
- Education to lay community: Address fears related to prognosis and treatment directly

Administrative

- Electronic health record implementation and integration
- Reimbursement process
- Development of data and metrics by which to measure success and support financial viability
- Staff continuing education, certification, and retention

Adapted from Fitzgerald et al.⁴⁸

The palliative APRN provides individualized care through undivided attention and understanding of the complexity of serious illness, support systems, and home environment. Providing care to someone in their home is intimate, and the palliative APRN is successful in the environment by offering continuity of care, support, and trust. This unique relationship and setting allow for meaningful conversations regarding a patient's values and wishes. Palliative APRNs improve the quality of life of patients with serious illness by managing complex symptoms, addressing psychosocial needs, providing counseling and education, discussing goals care over time as needs change, and reducing the frequency of burdensome and unnecessary transitions. Functioning to the full extent of education, licensure, and skill is integral to the ability of the APRN in CBPC to expand the opportunities to meet the needs of patients and families living with serious illness at home.

THE PALLIATIVE AND HOSPICE APRN IN HOSPICE AND HOME HEALTH PROGRAMS

Rikki N. Hooper, Chari Price, and Jamie Lee Rouse

KEY POINTS

- Palliative advanced practice registered nurses (APRNs) in hospice and home health organizations are in an ideal position to extend palliative care in the community, achieving improved symptom management, effective communication, successful collaboration, decreased use of hospital services at the end of life, and earlier hospice transitions.
- An APRN is a leader and advocate for hospice care of patients with life-limiting illnesses, working within an interdisciplinary, holistic, and compassionate model of care focused on promoting quality of life. This model of care demands that APRNs function at the highest level of their education and training.
- Palliative and hospice APRN encounters are reimbursable services across settings and services through Medicare, private insurance, and Medicaid programs.

CASE STUDY 1: TRANSITION FROM PALLIATIVE CARE TO HOSPICE

Mr. A was a 46-year-old Native American man referred to palliative care services for symptom management and goals of care. Mr. A's medical history included end-stage renal disease (ESRD), new to hemodialysis, with congestive heart failure (CHF), hepatitis C, and a history of substance misuse. Mr. A had a history of multiple lengthy hospitalizations in the prior year and was recently discharged home from a skilled nursing facility after completing rehabilitation services. He had intermittently missed dialysis treatments because of nausea and anxiety.

He was not partnered and had three children. Mr. A lived with his aunt on disability insurance, retiring from the Forestry Service due to ESRD. His substance misuse consisted of cannabis and methamphetamine. Mr. A had completed advance care planning (ACP) and named his aunt as his surrogate decision-maker. His code status was do not intubate (DNI), and he wanted to continue dialysis in spite of his frequent missed appointments. His symptoms included bilateral pedal neuropathy and a triad of symptoms related to his dialysis, including nausea, fatigue, and anxiety. His Palliative Performance Scale was 60%. He received care at the Tribal Hospital.

Mr. A was followed by the palliative nurse practitioner (NP) over 5 months to control his nausea, anxiety, and fatigue with

medication adjustments. He subsequently moved in with his brother and began using cannabis because he felt it helped his symptoms. Over the next 3 months, Mr. A had several emergency department (ED) visits and hospitalizations secondary to cannabis hyperemesis syndrome. Mr. A continued to decline over the course of the following 2 months with significant worsening of his nausea, anxiety, and neuropathy resulting in missed dialysis treatments. Discussions regarding dialysis continuation versus discontinuation occurred at each palliative care visit during this time period because medication no longer managed his symptoms. Mr. A had weekly ED evaluations for significant symptom burden. Although dialysis discontinuation was strongly encouraged, he struggled with the decision until after the third visit.

Mr. A then shifted his focus to comfort measures only and was admitted to the Tribal Hospital for general inpatient hospice care. He chose the palliative NP to serve as his hospice attending of record as he appreciated her consistent support to him and his family. The palliative NP—in serving in the hospice role—provided recommendations to the hospitalists regarding symptom management medications. Several members of the hospital team struggled with Mr. A's decision to discontinue dialysis at his age. The staff was provided with hospice support and education by the NP and the hospice team to navigate their feelings about the death of this younger patient in his pursuit of comfort measures. Mr. A spent 18 days under hospice care, which managed his progressive pain, nausea, and agitation through medication adjustments until he died peacefully, surrounded by his family.

INTRODUCTION

Advanced practice registered nurses (APRNs) have a unique skill set ideally suited to working with people who are chronically seriously ill or at the end of life, being cared for either through a hospice or home health program, by providing a well-organized, consistent approach that is both comprehensive and proactive in providing symptom management. A position statement from nurse leaders described the APRN in both moving the field forward and preparing for the graying of America.¹ Usually the APRN, in either home health or hospice organizations, is a nurse practitioner (NP) or clinical nurse specialist (CNS). APRNs working within hospice or home health organizations have the opportunity to work to the full extent of their potential

while providing compassionate care to seriously chronically or terminally ill individuals and their families.

Using the nursing process, APRNs address the complex issues of seriously ill people by synthesizing complex data to develop and implement advanced person-centered care plans.^{2,3} APRNs combine palliative nursing's focus on the whole person⁴ and their advanced education to perform comprehensive physical evaluations and order and interpret diagnostic tests, in addition to prescribing medications (depending on state-specific APRN practice regulations).^{5,6} The palliative APRN acts as a case manager, involves other members of the interdisciplinary team when appropriate, and educates the patient and family, empowering them to fully participate in the plan of care and encouraging self-management whenever possible. Part of this assessment includes exploring the patient's value system and their culture, as well as leading discussions regarding goals of medical treatment and explaining different options for care or intervention which are set in context of the individual's advanced illness and preferences for care. These discussions often include choices regarding end-of-life care or resuscitation. By virtue of the nursing code of ethics and both scope and standards for nursing and palliative nursing, the APRN is accountable for advocating for the person's preferences.

HISTORY OF APRN ROLE IN SERIOUS ILLNESS CARE

This model of using advanced practice nurses in serious illness or end-of-life care is not new: the British Macmillan Nurse Model has existed for many years. In this model, advanced practice and specialty training offers registered general nurses (RGNs) an in-depth knowledge of advanced disease pathophysiology, as well as the psychological, social, and spiritual needs of patients with a life-threatening disease.⁷ Originally developed for nurses caring for cancer patients, the Macmillan Model has nurses follow people through their disease, from diagnosis onward, whether the treatment course is thought to be curative or palliative in nature. This model provides continuity for patients and families; it involves home visits and the nurse's presence at physician specialist appointments when an advocate might be beneficial. Macmillan nurses identified the following components as part of their role⁷: expert practitioner, consultant, educator, researcher, and leader. These components are also identified in the 2021 third edition of *Competencies for Palliative and Hospice APRN*, published by the Hospice and Palliative Nurses Association (HPNA), with the addition of case manager, advocate, program developer, and policymaker.^{8,9}

APRNs have consistently demonstrated commitment to providing excellent care to vulnerable populations in the United States: frail, poor, rural, and culturally diverse.⁷ They have performed this care with a high degree of autonomy, collaborating with physician colleagues when appropriate but exercising their excellent skills in critical thinking and implementing strategies to provide improved care.⁹ APRNs apply an evidence-based approach to care delivery, incorporating physical, emotional, psychosocial, spiritual, and existential

aspects.¹⁰ Using this multifaceted assessment, the APRN can apply a holistic approach to advance care planning with patients and families.

The role of palliative APRNs in these principally community-based organizations can be primarily clinical, but there are also roles in leadership such as clinical team leader, clinical director, chief clinical officer, and even chief executive officer. Clearly, palliative APRNs have roles not only in clinical work but also in leadership areas, and they have a role in influencing change in nursing practice and within organizations as a whole.³

THE HOSPICE MODEL OF CARE

Palliation of distressing symptoms at the end of life through hospice care has been available to people with terminal illnesses in the United States since the early 1970s, after interest was sparked during a 1963 visit by Dame Cicely Saunders from England. She has been referred to as the matriarch of the modern hospice model of care and Dr. Florence Wald is the mother of hospice in the United States. Hospice services were not reimbursable under the insurance system in the United States until 1982, so early hospice services were provided by volunteers, mostly nurses. The number of people accessing services has increased through the years, with most recent data reporting an increase in the number of Medicare beneficiaries receiving hospice care from 1.32 million to 1.55 million between 2014 and 2018.¹¹ This represented an average increase of 4% each year.¹¹ In 2011, the number of Medicare decedents enrolled in hospice care was 44.6%; by 2014, this was up to 47.8% and, in 2018, reached greater than half at 50.8%.¹¹ Additionally, people who enrolled in Medicare Advantage the same year they accessed hospice plans accounted for 36.9% of recipients, an increase of 6.5% between 2014 and 2018.¹¹ Although the total number of people receiving hospice services has increased, they are still only receiving services for around half of the benefit time, with average length of stay being 89.6 days in 2018, but median length of stay being 18 days, a decrease since 2011, when it was 18.7 days.¹¹

Hospice is a model of healthcare delivery that provides palliative care, defined by the National Consensus Project for Quality Palliative Care (NCP) as "patient and family-centered care that optimizes quality of life by anticipating, preventing, and treating suffering. Palliative care throughout the continuum of illness involves addressing the physical, intellectual, emotional, social and spiritual needs and to facilitate patient autonomy, access to information, and choice."¹² Since its inception, hospice care has matured into both an advanced model of care for terminally ill patients and a philosophy of care. The hospice model of care focuses on all dimensions of quality of life for both the patient and family; this model started in England in the 1960s, migrating to the United States in the 1970s. The first American hospice was opened in 1974, heavily influenced by the vision of an APRN, Dr. Florence Wald, Dean of the Yale School of Nursing. As a distinguished APRN, she collaborated with two pediatricians

and a chaplain to start the first home hospice program in New Haven, Connecticut.¹³

Today in the United States, hospice services are a guaranteed benefit for individuals over the age of 65, with a prognosis of 6 months or less to live if their terminal disease takes its natural course and they choose to focus on comfort only rather than curative interventions. The Centers for Medicare and Medicaid Services (CMS) oversees the provision of hospice services. Medicaid and many commercial and private insurance companies mirror the *Medicare Hospice Benefit* (MHB) for individuals younger than 65. In October 2020, changes to the hospice benefit began with the addition of the *Addendum to the Hospice Beneficiary Election Statement*, which allows for beneficiaries or their proxies to request an explanation of medications or services not covered by the hospice organization. This is described in the FY2020 Hospice Final Rule 84 FR 38508.^{14,15}

In 2021, changes to the Medicare Advantage (MA) coverage of hospice services occurred, using data from a demonstration project testing the inclusion of hospice benefits in the value-based insurance design model (VBID). This is often referred to as the *Medicare Advantage hospice carve-in* and is a 4-year project sponsored by the Center for Medicare and Medicaid Innovation (CMMI).^{16,17} The intent of this project is to increase access to hospice services and improve coordination between hospice providers and other clinicians caring for patients, with the goal of identifying and reducing gaps in hospice care. With more Americans choosing to enroll in MA plans rather than traditional Medicare, this proposal respects beneficiary choice and seeks to bridge needs and resources to ensure more seamless transitions of care and supportive services. The focus will continue to be on the provision of high-quality, person-centered care that has a higher level of integration. An underlying goal is to bring a broader range of palliative and supportive services upstream for individuals with serious life-limiting illness, with possible options for concurrent care.¹⁸

The demonstration project includes nine Medicare Advantage Organizations (MAOs) that applied to participate, covering care provided in 13 states and Puerto Rico during the first year with additional opportunities to apply for the 2022 enrollment.¹⁹ With the evolution of hospice care in the United States from a volunteer-based to small local organizations to even multistate organizations, payment structures have advanced as well and may be influenced by the outcomes of the VBID demonstration project. An overview of the different types of hospice providers can be seen in Table 15.1.

These agencies vary considerably in their organizational structure (not-for-profit vs. for profit), the communities they

Table 15.1 HOSPICE PROVIDERS BY TYPE

Provider by tax status type	% in 2012	% in 2018

Not-for-profit providers	31.9	26.94
Government providers	4.9	3.41

Adapted from NHPCO Facts and Figures 2020.¹¹

serve (rural vs. urban), size (from large to small), and setting (stand-alone and independent vs. beds within a nursing home).^{11,13} Hospice services are provided in any setting, anywhere along the age continuum, to individuals with a variety of diseases. In 2017, 94.9% of recipients were over the age of 65, demonstrating that most recipients are indeed eligible for Medicare benefits. However, as illustrated in Table 15.2, 81.2% of individuals received care at their place of residence, and approximately 82.3% had a non-cancer diagnosis spanning all organ systems.¹¹

Reimbursement for services varies across the country and whether it is provided in rural or urban settings. Routine-level care is reimbursed at much lower rates than inpatient-level care, reflecting the lower amount of resources needed for care provision. For example, in Western North Carolina, a predominantly rural area with a town, the routine level of care is reimbursed at \$178.20 per day (\$174.64 after sequestration) while inpatient-level care is reimbursed at \$941.50 (\$922.67 after sequestration). *Respite care*, which can be provided for 5 days per benefit period, is reimbursed at a rate of \$420.38 per day (\$411.97 after sequestration). It should be noted that the decreases for sequestration have been suspended during the 2020 COVID-19 pandemic.²⁰ Table 15.3 shows the difference in qualifications for each of these levels of care.

Hospice eligibility is based on benefit periods, with the first two periods of 90 days each, with subsequent periods of 60 days in length. Each of these subsequent benefit periods requires that a provider, either a physician or NP, has a face-to-face encounter with the patient to attest that there is continued eligibility for service. These requirements were initiated as part of the *Affordable Care Act* (ACA) in 2011.^{21,22} This documentation is key to continued payment for services provided and must paint the picture of continued eligibility in as objective a way possible. Descriptive expansion on elements such as appetite, functional status, and body habitus can be very helpful. For example, rather than describing the patient as “thin,” the NP could expand by describing the patient has having sunken orbits, temporal wasting, and generalized

Table 15.2 2018 SPENDING AND DAYS OF HOSPICE CARE PERCENTAGES BY PRINCIPAL DIAGNOSIS

DIAGNOSIS GROUP	% OF MEDICARE SPENDING BY PRINCIPAL DIAGNOSIS	DAYS OF HOSPICE CARE BY PRINCIPAL DIAGNOSIS
Dementia	25.3	105.2
Circulatory/Heart	20.2	80.2
Cancer	17.7	45.6
Other	13.3	64.3

Table 15.3 LEVELS OF HOSPICE CARE

LEVELS OF HOSPICE CARE	DESCRIPTION	SETTINGS
Routine	Visits by nursing, social work, and spiritual care as per care plan. Comprehensive nursing assessment visits at least every 15 days.	Home, ALF, SNF
Continuous care	Hospice provider crisis intervention, must include at least 8 hours continuous nursing care. May also receive hospice aide care as part of plan.	Home
Inpatient respite care	Short-term, up to 5 days in a contracted facility to give caregivers a break. Routine-level hospice care is provided during this time.	SNF, ALF, hospice in-patient unit
General inpatient care	Short-term care to manage uncontrolled symptoms that cannot be managed in another location. Generally requires frequent changes in symptom management plan of care. 24-hour nursing services are provided.	Hospice in-patient unit, hospital or SNF (if 24-hr registered nurse on site)

ALF, assisted living facility; SNF, skilled nursing facility.

Adapted from Medicare Regulations for Hospice Care.²³

muscle wasting and wearing ill-fitting clothes. Instead of saying that the patient is eating 25% of meals, a more accurate way of demonstrating this could be that the patient requires the assistance of a caregiver to eat, with multiple cues being given and much encouragement. Despite this and supplements being offered, the patient is still only ingesting 25% of recommended caloric intake.²²

Death is a natural part of life and can occur at any point in life, but in the United States it is predominantly associated with aging, and the aging population is growing. In 2014, 46 million adults in the United States were over age 65, but it is estimated that, by 2030, this will increase to 74 million individuals, almost 21% of the population.²⁴ In the United States, prior to death, most terminally ill individuals find themselves caught in a fragmented healthcare system, relying on complex medical interventions and burdened by rising costs. In contrast, when given a choice about end-of-life care, many Americans would prefer medical care that is coordinated and comprehensive; they want their care to reflect their wishes for comfort and quality of life, and they want information about what lies ahead for them and their family.²⁵ Hospice is the healthcare delivery model that provides this type of care. The demand for hospice services will likely increase, resulting in an increased demand for a skilled workforce. However, the shortage of hospice and palliative medicine physicians has led to an increased demand for palliative APRNs and will continue to do so.^{26,27}

THE USE OF APRNS IN HOSPICE CARE

The clinical APRN is an evolving role in hospice care, with most APRNs providing clinical care in hospices either as NPs or CNSs. APRNs are able to work in influential positions in hospice programs throughout the United States. In addition to clinical care, other roles includes chief clinical officer, chief executive officer, chief operating officer, clinical director, administrator, quality and performance improvement officer, and clinical manager, to name a few. APRNs in these

roles combine a tradition of advocacy and teaching, a broad clinical knowledge base, and their critical thinking skills to make complex decisions related to the structure and processes of patient care in the hospice setting.²⁸ This includes issues related to organizational and workforce excellence, as well as compliance with laws and regulations. Stewardship, accountability, and quality and performance improvement are all important elements of these roles.²⁹ As leaders at all organizational levels in hospice, APRNs understand the importance of patient-centered, whole-person, interdisciplinary care delivered within a framework of high-quality, evidence-based practice³⁰ along with expert communication skills that enable them to collaborate not only with clinical teams but also with administrative leaders of their own and other organizations. Specific tasks that rely on these skills are gathering and relaying information, negotiating, teaching, and resolving conflicts. APRNs in leadership roles must bring the unique care needs of hospice patients to the attention of the larger healthcare community through advocacy and education. Discussing end-of-life care even at an institutional level can be fraught with pitfalls, so the APRN must have expert guidance and coaching skills and a solid knowledge of the ethical issues associated with end-of-life care in the hospice setting.

In hospice, APRNs combine common theoretical concepts of both nursing practice and the hospice philosophy, including whole-person care and the impact of health on quality of life, with the skills needed to provide expert care at the end of life. The HPNA published the *Palliative Nursing: Scope and Standards of Practice*, which establish the competencies necessary to meet these standards. These standards are divided into Standards of Practice for Palliative Nursing, which incorporates the nursing process, and Standards of Professional Performance. The competencies are advanced clinical judgment, use of evidence and research, expert communication skills, collaboration, knowledge of ethical principles and professional standards, respect for cultural and spiritual diversity, advocacy, systems thinking, and an understanding of the importance of ongoing education in creating a professional practice that delivers expert end-of-life care.⁸ To

demonstrate their specialty practice, it is recommended that APRNs obtain certification as an advanced certified hospice and palliative nurse (ACHPN).

These standards and associated competencies are closely aligned with both the eight domains of quality palliative care as outlined in the NCP *Clinical Practice Guidelines for Quality Palliative Care*¹² and the National Hospice and Palliative Care Organization's (NHPCO) *Standards of Practice for Hospice Programs*, which stipulate that for hospice providers to provide high-quality patient- and family-centered palliative care, they must incorporate either the NCP *Clinical Practice Guidelines* or the NHPCO *Standards of Practice for Hospice Programs* into the delivery of hospice services.²⁹ This comparison can be seen in Table 15.4.

In addition, familiarity with the hospice local coverage determinations (LCDs), which are published by the local geographic area's Medicare administration contractor, and the hospice conditions of participation (COPs) criteria set forth by the CMS is essential. The LCDs are guidelines for determining eligibility and prognosis.²³ The COPs delineate the services that a certified hospice provider must provide to a patient as it relates to his or her terminal diagnosis and related conditions and set the standards for the delivery of hospice services, such as clinical record-keeping and staff credentials. To receive reimbursement from the CMS, a hospice provider

must comply with these standards and requirements.²³ Private insurers usually follow the CMS hospice guidelines for eligibility, the type of services provided, and reimbursement. The NHPCO works closely with these agencies to create these guidelines and requirements.

An extensive clinical knowledge base is essential for practice in a hospice setting. APRNs are expected to provide care for diverse patients of all ages in a variety of settings, with any and all terminal illnesses and within a finite reimbursement system. Such a broad sphere of practice demands creativity, flexibility, and a high level of critical thinking skills to produce good outcomes in such a multitude of situations. Some hospices provide services not required under the regulations set forth by CMS (e.g., specialized wound care or disease-specific care programs for individuals with cardiac or pulmonary conditions or dementia), which in turn requires a broader APRN expertise. Moreover, essential components of professional practice are the foundation of a comprehensive knowledge base for advanced practice nursing in hospice care. These guidelines, standards, and competencies guide the hospice APRN to care for the patient and family as the unit of care. Figure 15.1 illustrates these components, clearly showing the multifaceted dimensions of professional practice that contribute to the provision of expert end-of-life care by APRNs within the hospice model of care.

Figure 15.1 Overview of the requirements for expert professional practice for the hospice APRN.

Although hospice services are predominantly used by individuals over the age of 65, services are available to neonates, young children, adolescents, young adults, and middle-aged individuals.¹¹ Understanding each age group's developmental stage and cognitive capacity as well as physical and intellectual abilities is critical. Caring for individuals across the age continuum necessitates that palliative APRNs manage a multitude of disease states. This demands a comprehensive knowledge of many illnesses and conditions as well as their pathophysiology, manifestations, progression, and associated pharmacology.

The hospice APRN will also encounter a wide diversity of patients, such as military veterans; individuals with developmental or cognitive disabilities; individuals experiencing serious mental illness; individuals who are incarcerated; lesbian, gay, bisexual, transgender, and intersex individuals; individuals with substance use disorders; individuals experiencing homelessness; and individuals of low socioeconomic status. Cultural humility and sensitivity specific to these populations are essential. The COVID-19 pandemic has highlighted social injustices and systematic racism in healthcare as well as the clear differences in the way that individuals with different social and ethnic backgrounds have been affected by the Coronavirus³¹ (see Chapter 20, "Social Determinants of Health").

The setting in which hospice services are provided plays an important role in the delivery of hospice care. In 2018, 51.5% of people received care in their homes, whereas 12.3% were in an assisted living facility and 17.4% in a skilled facility.¹¹

These patients received care at the routine level, whereas the majority of the 12.8% of patients in a hospice inpatient facility or unit would have received the higher level of care provided under the general inpatient level, which is reimbursed at a much higher rate (almost five times that of routine-level care).

Caring for an individual in his or her home presents different challenges than in another type of conjugate care setting, such as an acute or skilled care facility. Stepping into a person's home is a privilege, as the APRN is a visitor. In the private home, family members are usually the primary caregivers. Their caregiver burden is significant due to little knowledge, training, or support to assess symptoms and then apply interventions. Paid caregivers, often with limited scope of practice and frequently minimal training, may also be providing the care in private homes. Hospice houses, or hospice inpatient units, depending on the population they serve, may have only paid unlicensed caregivers or highly skilled licensed and unlicensed personnel, or a mixture of both. All these scenarios present advantages and disadvantages in terms of symptom assessment and management, medication administration, and delivery of personal care. The hospice APRN must consider these when developing a plan of care unique to the patient and caregiver.

The hospice APRN must determine the knowledge and expertise of the caregivers in settings other than the private home. Moreover, each physical location outside of the home has regulatory oversight by state and federal licensing agencies based on their designation. The hospice APRN must understand how these regulations affect the treatment and

management of the patient’s symptoms. For example, nursing homes often have strict regulations regarding the use of certain antipsychotics, thus influencing the APRN’s choice of medications and how they might be prescribed in these facilities. In another example, many residential care facilities do not have the licensed staff to dispense medications like opiates. Therefore, these medications cannot be prescribed for use on an as-needed basis. In both cases, the hospice APRN must balance regulatory restrictions with recommended standards of care to develop an appropriate care plan.

In addition to physical location, the four CMS-mandated hospice levels of care that a hospice provider must offer strongly influence the delivery of hospice care. These four levels of care are routine home care; continuous home care for patients in crisis; inpatient respite care, usually provided in a contracted facility, for patients whose families need respite from caregiving; and general inpatient care for patients in crisis who cannot be managed at home.³²

In July 2015, Congress approved significant changes to hospice reimbursement, the first since the Medicare Hospice benefit went into effect in 1983. The changes went into effect January 1, 2016, and included a two-tiered routine home care rate and a service intensity add-on payment, as can be seen in Table 15.5. The two-tiered payment model for routine home care translates into a higher hospice reimbursement rate for the first 60 days of hospice care and a lower rate for any additional days of hospice care. Using the prior geographical example, the rates for the first 60 days are highlighted at \$178.20, but the rates decrease to \$140.83 on day 61 and thereafter for routine care.²⁰

The service intensity add-on payment reflects the higher acuity and needs of dying patients and their families in the last 7 days of life. It is calculated retrospectively based on nursing and social work visits and is equal to the continuous home care hourly rate up to 4 hours per day. For the region in the example, this is an hourly rate of \$53.27 prior to sequestration.²⁰ These reimbursement changes reflect the reality of short lengths of stay and a higher intensity of care in the

last week of life that many hospices encounter.³³ Clearly, the hospice APRN must be able to assess the patient’s and family’s needs and the skill of the caregivers, then incorporate this information into a care plan that meets regulatory oversight, all within finite monetary compensation to the hospice provider.

There is also the additional limitation of a capitated reimbursement for hospice services, which also affects the treatment plan. Appropriate resource utilization while achieving good outcomes is a standard of professional practice. The hospice organization is responsible for the cost of all the care of an individual as it relates to his or her terminal diagnosis. The latest rule from CMS reflects the right of an individual and their family to request a written rationale of non-coverage of medications, items, and services, otherwise known as the *addendum*, which became effective October 1, 2020. This additionally adds a time limit for when this care must be provided to patients: 5 days when requested upon admission or election of the benefit or 3 days when requested at a later time. This list of services or medications must be provided upon request to the patient or family and any other non-hospice medical providers if requested.¹⁴ Therefore, an extensive knowledge of pain and symptom management options is necessary to enable the creation of a care plan that provides comfort in any setting to any individual in a fiscally responsible manner. De-prescribing of medications is part of this plan, with the knowledge that individuals taking more than five medications are at higher risk for drug interactions.

Hospice APRNs must be aware of some of the barriers to accessing hospice services, including lack of healthcare provider and community knowledge, the predominant culture’s death-denying beliefs, the influence of an individual’s culture, and insurance issues, among others.⁷ The delivery of end-of-life care in a hospice setting is governed by financial restraints and regulatory issues, as discussed previously. Hospice APRNs must integrate these factors into their clinical decision-making when creating, maintaining, or changing hospice programs. Providing compassionate, evidence-based, patient- and family-centered care within these confines can be challenging.

The NHPCO has an extensive compilation of resources designed to help hospice providers and clinicians achieve good clinical outcomes within these regulatory and financial constraints; these can be accessed at NHPCO.org. Interpretation of the eligibility criteria has also been noted to be a barrier to service because many clinicians have trouble interpreting the LCDs or prognosticating accurately.³⁴ Tools often utilized by hospice providers to document this are not widely available to the general medical population; one such tool is the *International Classification of Functioning, Disability and Health* (ICF),³⁵ which goes beyond an individual’s terminal diagnosis and encompasses other determinants of health such as living situation and emotional well-being. This tool is used more widely in Europe than the United States but has some useful elements to examine when determining eligibility for hospice.³⁵

Table 15.5 HOSPICE LEVELS OF CARE AND REIMBURSEMENT

LEVEL OF CARE	REIMBURSEMENT RULES	REIMBURSEMENT AMOUNTS
Routine	Days 1-60	\$199.25
	Days 61+	\$157.49
	Last 7 days of life	Additional payment RN and SW
Continuous care	Full rate (24 hrs of care)	\$1,432.41
	Hourly rate	\$59.68
Respite	Per day	\$461.09
General inpatient	Per day	\$1,045.66

Adapted from CMS.gov.²³

CASE STUDY 2: HOME HEALTH

Mr. S was a 65-year-old man referred to palliative care/home health by his oncologist to assist with medical decision-making and symptom management in the setting of metastatic prostate cancer detected 3 years prior. Mr. S received 45 treatments of radiation therapy and achieved remission. Two years later, he developed left hip pain. Imaging revealed metastasis to the lung, hips, skull, and bladder. He was then hospitalized, during which an indwelling catheter was placed in the right lung to manage malignant effusions. Home health services were ordered for education and management of the catheter and pain control.

Mr. S was married to Amy, his second wife. He was retired, although his wife continued to work part-time. They both had children from previous marriages who lived out of state. He had completed paperwork designating his wife as his surrogate decision-maker. He wanted no extraordinary measures and an out of hospital DNR form was signed. The palliative APRN initiated discussion about a provider out-of-hospital order for life-sustaining treatment (POLST) form.

Mr. S's symptoms included pain, dyspnea, debility, insomnia, and anorexia. His Palliative Performance Scale (PPS) is 70%. His pain was in his right hip, and he was on morphine extended-release (ER) tablets 30 mg every 8 hours and oxycodone immediate-release (IR) tablets 10 mg every 4 hours with usual use 2–3 times daily. His oncologist asked for the palliative APRN to partner with him and take over prescribing Mr. S's pain medications. To assure safe prescribing, he was assessed for opioid narcotic abuse risk using an Opioid Risk Tool (ORT). He scored 0, indicating a low risk of abuse. He signed an agreement to have the palliative APRN as his sole prescriber of opioids. His dyspnea was related to his malignant pleural effusion, which was managed with use of the indwelling catheter that kept excess pleural fluid drained. Because he was weak, he received home health physical therapy. His insomnia was related to anxiety and dyspnea. Although he had zolpidem 5 mg prescribed by the oncologist, it had been unnecessary with the placement of the catheter. For his anorexia, he was prescribed prednisone 5 mg twice daily, which helped his appetite as well as his energy, his mood, and his pain.

Mr. S continued palliative chemotherapy with full understanding that his cancer was metastatic and had a poor prognosis. He had conveyed this to his family. He has begun financial planning for his wife and family. He had also informed his family that he wanted to focus on quality of life and remain at home, but wanted to continue life-sustaining therapies at the current time. The palliative APRN continued to check in and monitor his symptoms and support the family.

Over the following 18 months, Mr. S's functional status continued to decline as his PSA level increased despite treatment. Amy retired to be home with him full-time. She provided all the meals, housekeeping, and assisted with Mr. S's personal care. They had their bathroom adapted to allow Mr. S to use it more easily. The palliative APRN adjusted his pain medications to morphine sulfate ER 45 mg every 8 hours and morphine sulfate IR 15 mg 1–2 tabs every 4 hours as needed for pain.

One day, Mr. S had a fall and Amy could not get him up. She summoned the fire department and they came to the home and helped him up. Later, as he walked to the bathroom, he fell again, and emergency medical services (EMS) arrived and took him to the hospital. Work-up revealed a meningioma, and he underwent surgery for removal. After hospitalization, he was discharged to home with his wife to restart home health services to facilitate ambulation, strengthening, and balance.

Mr. S had mentioned wanting to stop cancer-directed treatments and “let nature take its course.” However, his oncologist urged him to continue treatments. The palliative APRN initiated conversations about goals and the transition to hospice. His wife left the decisions up to Mr. S, but tearfully stated she would support his decisions. He planned the transition from his current level of supportive service at that time. His goal was to make it to Thanksgiving, when he could see his children and grandchildren again.

The *Medicare Hospice Benefit* structure is limiting for patients desiring treatments or interventions deemed to be aggressive or “curative” in nature by a particular hospice, even when they are clearly used to palliate symptoms (e.g., palliative chemotherapy, inotropes for heart failure, or medications for amyotrophic lateral sclerosis are just a few examples). These limitations led to the development of the palliative care movement in the 1990s, when it became clear that technology had outgrown the underpinnings of the hospice benefit which was grounded in incurable cancers. Hospice principles moved into the acute care and community settings to become palliative care programs. In the community, palliative care is often provided within a home health organizational framework, where other therapies are also provided to support a patient's desire for independence at home. Home health services are provided by members of a multidisciplinary team in order to meet the patient's needs; however, unlike hospice, there is not the mandate for interdisciplinary care. Therefore, palliative APRNs may provide supportive care often without the benefit of a team designed around this purpose. In general, the goal of home healthcare is to provide treatment for an illness or injury. Where possible, home healthcare helps a person get better, regain their independence, and become as self-sufficient as possible. However, home healthcare may help a patient maintain a current condition or level of function or slow decline.

The *Home Health Care Benefit* is available to individuals with Medicare who meet certain criteria. This includes being under the care of a medical provider (until recently this had to be a physician) and have a need for some type of care, such as skilled nursing care, speech therapy, or physical or occupational therapy. These services must be deemed medically necessary as part of the plan of care, and the patient must be certified as being “homebound,” as defined in the Medicare Home Health information booklet.³⁶

- A person has difficulty leaving their home without help (like using a cane, wheelchair, walker, or crutches; special transportation; or help from another person) because

of an illness or injury, or leaving the home isn't recommended because of their condition.

- A person is normally unable to leave their home, but if they do it requires a major effort.
- A person may leave home for medical treatment or short, infrequent absences for no-medical reasons, like an occasional trip to the barber, a walk around the block or a drive, or attendance at a family reunion, funeral, graduation, or other infrequent or unique event. The person can still get home healthcare if they attend adult day care or religious services.

Services are often time-limited, lasting only a few weeks following an acute event or hospitalization. Additionally, home healthcare must be ordered by a physician who has had a face-to-face visit with the patient within the past 30 days.³⁷ Often when a patient is discharged following a hospitalization, home healthcare is ordered, but the physician ordering this is not usually the one who must complete the paperwork associated with the ongoing plan of care. This medically necessary visit was determined to be necessary as part of the ACA due to occurrences of fraudulent billing for services.³⁸ By virtue of being homebound, in that leaving requires considerable and taxing effort (see CMS definition), many individuals have difficulty accessing a physician at their office. Even though APRNs provide high-quality care to individuals in communities across the country, especially in rural or underserved areas, they have not in the past been permitted to sign certifications for home health services.³⁹

The COVID-19 pandemic in 2020 led to a relaxation of this rule, and NPs were granted the ability to order and certify home healthcare services through the passing of H.R.2150/S.296 *Home Health Care Planning Improvement Act*, as part of the *Coronavirus Aid, Relief, and Economic Security* (CARE) Act in May of 2020, though this is still state-dependent.⁴⁰ Though a relatively new development, it has become evident that billing for APRNs performing the care plan oversight has been successfully accomplished. Some home health organizations had difficulty grasping this concept, and some continue to refuse to accept orders and certifications from non-physician providers (NPPs), despite the provider being the individual who has provided all that patient's primary care services. Another area where APRNs have been able to successfully provide care for is in wound care, particularly in rural areas. These patients often have limited access to wound care experts and have difficulty getting to a wound center. APRNs can assist with this management and further utilize telehealth platforms to access consultations with wound specialists.⁴¹

It has become abundantly clear that, with advances in healthcare and technology, Americans are living longer. However, as the average life span has increased, so has the number of people living with chronic progressive disease. These individuals have multiple chronic medical conditions requiring longer and more sustained care and have psychosocial situations requiring additional support and assistance. Heart failure, for example, has become a leading factor in

chronic complex illness, with technological and pharmaceutical advances delaying the progression of the disease and leading to longer lives, but often with significant symptom burden and associated medical costs. The American Heart Association projects that direct costs for heart failure may be more than \$75 billion by 2030. Approximately 50% of people die within 5 years of being diagnosed with heart failure.⁴² Within a home health organization, the palliative APRN can facilitate services to maximize functional abilities and foster independence while addressing any palliative symptom needs. They can also provide case management services and coordinate the team. Within a home healthcare organization, the team should be most familiar with treatments for heart failure and the associated 30-day readmission rates.⁴² The palliative APRN is able to address not only the medical treatment needs of the individual and coordinate the interdisciplinary team but also address the goals of medical care and complete appropriate documentation as indicated in the individual state. The palliative APRN is uniquely qualified to provide education and support to individuals as they determine their goals of care and whether a transition to hospice care is appropriate. These decisions are often among the most difficult decisions they will make regarding their healthcare, and it is imperative that they are provided as much support as possible as they work through these decisions.⁴³

This role could be filled by either an NP or a CNS, although NPs could bill for some services, such as medical visits, advance care planning discussions, and, now, care plan oversight, a once-monthly service. This would elevate the quality of care for homebound patients, which is often uncoordinated, inaccessible, and ineffective.⁴¹ It has been shown that palliative care provided in the home setting is associated not only with a reduction in symptom burden, but also with increases patient and family satisfaction. Furthermore, studies in the United States and other countries have shown decreased utilization of healthcare resources and associated costs. Some organizations have developed disease-specific programs for individuals with heart failure, chronic obstructive pulmonary disease, and HIV/AIDS, as well as for those living with advanced cancer.⁴⁴ Individuals in these programs may not yet meet eligibility criteria for hospice care, want expensive life-sustaining therapies that may diminish quality of life, or want to pursue a curative plan of care. Thus, their palliative APRN facilitates the establishment of goals of care and advance care planning documents and completes orders for life-sustaining treatments as consistent and available within their state scope of practice.⁴⁵ These forms may be termed provider/physician orders for life-sustaining treatment (POLSTs), portable orders for life-sustaining treatment, medical orders for life-sustaining treatment (MOLSTs), or medical orders for scope of treatment (MOSTs) depending on the state. Many states have legislation allowing the completion of these documents by APRNs. Specific up-to-date information can be found at Post.org.

The inclusion of palliative APRNs as part of the team promotes nursing and guides the plan of care to truly enable the right care to be provided at the right time using a person-centered approach.⁴⁶ Goals-of-care discussions allow patients

and their families to make the decision about when to make a change to their plan of care. This may include a transition to hospice care services, and studies have shown that patients access these services for a longer period and have decreased hospitalizations during the last weeks and months of their life when a palliative care approach is incorporated into the home health model.⁴⁷ Individuals receiving palliative care as part of their home healthcare plan are also more likely to die at home.⁴⁴

SUMMARY

The demand for home health and hospice services will grow, and the roles available to APRNs in these organizations are rich and varied. These types of care are not limited by age, disease, or population, and hospice is not limited by setting. Even though the work is challenging, demanding that palliative APRNs work to their fullest professional capacity, caring for individuals living with and dying from serious illness and their families is a great privilege that offers many rewards. Palliative APRNs represent an invaluable resource for the healthcare field, particularly in these fields, and it is clear that it is time for core palliative care competencies to be incorporated into all APRN education programs.⁴⁸ Even though there has recently been an increased focus on education through fellowships with the passing of the *Palliative Care and Hospice Education Act* (PCHETA), it is unclear how much this would provide for APRN education in addition to that for physicians.⁴⁸ As far back as 2011, the Institute of Medicine highlighted the need for more APRNs and recommended maximizing their use to improve quality, cost-effective care through advanced care management programs.^{49,50} Both hospice and home health organizations provide opportunities for palliative APRNs to achieve these goals, and educational programs need to plan accordingly. Staffing will continue to be a major challenge for healthcare organizations, particularly following the pandemic in 2020, as will opportunities to leverage technology to expand options to increase patient access, not only in hospice care, but also in home healthcare. Utilizing telehealth platforms can be a more efficient way of reaching patients, especially in rural areas.⁵¹

THE PALLIATIVE APRN IN REHABILITATION

Lorie Resendes Trainor

KEY POINTS

- Rehabilitation and palliative care share similar values in providing patient-centered care with a focus on improving quality of life.
- Rehabilitation can be beneficial at all stages of palliative care involvement—including hospice.
- The palliative advanced practice registered nurse (APRN) is an important partner in the rehabilitation team, providing expert symptom management and education to staff and ensuring the patient's goals remain relevant throughout their rehabilitation journey.

CASE STUDY 1: HIP FRACTURE RECOVERY

Mark was an 80-year-old man with hypertension but otherwise healthy. He was hospitalized for a fall at home resulting in a hip fracture and was found to have newly diagnosed metastatic lung cancer. Mark lives with his elderly wife in a split-level home. They have limited support, and Mark is the primary caretaker in the home. Mark's recovery from his surgery was unremarkable, and he was sent to short-term rehabilitation due to his inability to navigate the stairs at his home.

The rehabilitation team and the palliative advanced practice registered nurse (APRN) met with Mark and his wife frequently throughout his rehabilitation stay. The team reviewed patient and family goals, which included safely returning home. The physical therapist provided a tailored exercise program for Mark and provided recommendations regarding assistive devices and fall prevention. Recommendations were made by the palliative APRN for a short-acting opioid to be given prior to therapy and as needed. The occupational therapist made recommendations to make bathing and dressing easier while expending less energy. The palliative APRN provided education regarding his new underlying disease and explored what matters most to him and his wife. Documents including a health care proxy and orders for life-sustaining treatment were completed. The palliative APRN placed these in the medical record and sent them home with Mark to ensure that his wishes were honored. The social worker facilitated discharge planning to a palliative care program within a VNA program and assisted with ensuring the proper equipment was at home, including bathroom handrails. The social worker also provided a referral to community-based

resources with the local Council on Aging to support both Mark and his wife, given their limited support.

Mark was able to increase his strength and was able to safely ambulate around his home. He and his wife felt adequately prepared at discharge to manage his care. Documentation of his rehabilitation stay and advance directives were sent to his new oncology team, thus ensuring continuity of care.

INTRODUCTION

Physical rehabilitation aims to maximize and restore function for those with disabilities.¹ It utilizes an interdisciplinary approach to optimize functional ability and improve quality of life.² There has been a steady increase in the utilization of rehabilitation services in the United States. In 2017, Medicare spent \$58.9 billion in payments to post-acute care facilities, including skilled nursing facilities (SNFs), home health agencies, inpatient rehabilitation facilities, and long-term care hospitals.³ Patients who utilize rehabilitation services represent a diverse group and include those with acute illness, traumatic injuries, and progressive chronic illnesses such as cardiopulmonary disease and cancer.¹ The Medicare rehabilitation benefit is widely used; almost 2.4 million beneficiaries accessed the benefit in 2017, representing 4.2% of all Medicare users.³ The majority of this rehabilitation will take place in an SNF.³ Beneficiaries increase rehabilitation utilization as they become more ill; one in three Medicare users access their SNF benefit in the last 6 months of life.⁴ Overall, patients entering these SNFs represent a more frail and medically complex population.^{5,6}

Palliative care and physical rehabilitation share similar goals (Table 16.1). Both are interdisciplinary and focused on improving a patient's quality of life.⁷ The palliative care population experiences a significant level of functional loss with disease progression, and this disability may lead to difficulty coping and increased healthcare utilization and caregiver stress.⁸ Similar to the palliative care population, rehabilitation patients also have diagnoses associated with high symptom burden.¹ Rehabilitation in the palliative care setting is focused on patients reaching their maximum physical and psychosocial potential within the constraints of their disease.⁸ Palliative care and rehabilitation also have a shared value of supporting caregivers through education;

Table 16.1 COMPARISON OF REHABILITATION AND PALLIATIVE CARE

REHABILITATION CARE	PALLIATIVE CARE
A set of interventions designed to optimize functioning and reduce disability in individuals with health conditions in interaction with their environment. ⁹	Palliative care is an approach that improves the quality of life of patients (adults and children) and their families who are facing problems associated with life-threatening illness. It prevents and relieves suffering through the early identification, correct assessment and treatment of pain and other problems, whether physical, psychosocial or spiritual. ¹⁰

professional rehabilitation staff are skilled in teaching caregivers proper body mechanics, use of adaptive equipment, and fall prevention.^{8–10}

Despite all their shared principles, palliative care is underutilized in rehabilitation. Conversely, rehabilitation care may be overlooked by palliative care providers as a tool which improves patient and family quality of life. Greater understanding of rehabilitation can broaden the palliative advanced practice registered nurse's (APRN) perspective of the many benefits that rehabilitation has to offer those with serious illness.

Even in the setting of advanced illness, patients have expressed a desire to remain physically active and wish to maintain independence for as long as possible.^{7,8} Rehabilitation provided to patients with advanced illness has demonstrated benefit. Studies have shown improved quality of life along with better control of pain, dyspnea, and mood.⁸ Rehabilitation and palliative goals of care can include both comfort and maximizing independence.¹ The collaboration between rehabilitation and palliative care offers patients a greater potential to reach their goals while also reducing caregiver burden.^{1,2}

FOCUS OF REHABILITATION

There are distinctions on the focus of rehabilitation based on a patient's clinical status and functional prognosis: preventative, restorative, supportive, and palliative (Table 16.2).^{8,11}

Providing education to the staff, patient, and family regarding the focus of rehabilitation will help to clarify expectations.

LOCATIONS FOR REHABILITATION

Patients can receive rehabilitation services in a variety of settings based on specific admission criteria according to their needs and goals. Long-term acute care hospitals (LTACHs) maintain a complex level of medical care while offering more therapy than the inpatient setting.¹ In 2018, the most common diagnoses for patients admitted to an LTACH were pulmonary edema and respiratory diagnoses requiring mechanical ventilation.³ LTACHs represent the smallest population of post-acute care facilities; they care for those who are critically ill, caring for 102,288 Medicare patients in 2018.³

Inpatient rehabilitation facilities (IRFs) require patients be able to participate in greater than 15 hours per week of physical and occupational therapy.¹ These patients are expected to make significant functional improvement.⁸ Because of this requirement, few Medicare beneficiaries are able to tolerate the intensity of an IRF.¹ The most common diagnoses for IRFs are stroke and other neurological disorders.³ Patients in IRFs are less medically complex and are able to participate more intensely with therapy than those in an LTACH. In 2018, more than 408,000 Medicare patients were cared for in an IRF.

The most utilized post-acute care location by far is the SNF.³ The SNF offers interdisciplinary collaboration for

Table 16.2 TYPES OF REHABILITATION AND THEIR FOCUS

TYPE	FOCUS	EXAMPLE
Preventative	To prevent or lessen the morbidity caused by treatment.	Patient with lung cancer attends rehabilitation prior to chemotherapy and surgery to optimize functional outcomes.
Restorative	To return a patient to their previous level of function when long-term impairment is not anticipated.	Patient with osteoarthritis undergoes hip replacement to improve their ability to walk without pain.
Supportive	To maximize function after permanent impairment.	Patient status post a stroke with hemiparesis adapting to new ways to ambulate and care for self.
Palliative	To reduce dependence in activity in self-care in setting of progressive disease.	Patient with metastatic cancer who wishes to be able to sit at dining room table with her family but is limited due to pain and low energy.

Table 16.3 LOCATIONS FOR REHABILITATION SERVICES

LOCATION	REQUIREMENTS	EXAMPLE
LTACH	Hospital level of care	Patient discharged from a prolonged hospitalization with a tracheostomy with goal of weaning from mechanical ventilation. He will participate with therapy as tolerated.
IRF	3 hours of PT/OT 5 days per week or 15 hours PT/OT per week	Patient with stroke resulting in severe functional deficits. She is physically able to participate in daily, intensive therapy to reach goal of returning home.
SNF	One hour of PT, OT +/- SLP per day	Elderly female with hip fracture. Goal is to return to her assisted living facility; she is not physically capable of intensive therapy.

SNF, Skilled Nursing Facility; IRF, inpatient rehabilitation facility; LTACH, long-term acute care hospital.

those with less intense rehabilitation needs, with requirements of 1 hour per day of therapy.⁸ In 2018, 4% of Medicare beneficiaries—more than 2.3 million patients—utilized their SNF benefit, with an average length of stay of 25 days (Table 16.3).³

THE APRN IN THE REHABILITATION SETTING

The role of the rehabilitation APRN in all post-acute care settings is supported by the Association of Rehabilitation Nurses.¹² The rehabilitation APRN serves to manage patients with complex rehabilitation needs, collaborate with the interdisciplinary team, and provide education for staff.^{13,14} The value of the APRN can be seen in improved cost-effectiveness of care, reduced frequency of complications for the rehabilitation patient, and increased quality of nursing care.¹³

The rehabilitation APRN also provides comprehensive medication management. This is of importance given the high risk of polypharmacy since patients are medically complex.¹ There is evidence of decreased antipsychotic use and indwelling catheter use in facilities with a dedicated APRN.¹⁵ The facility APRN is better able to understand the processes of the facility and develop closer working relationships with the staff to improve patient experiences and outcomes.¹⁵ When an APRN is embedded in a SNF, hospital transfers can be reduced because the clinician is more easily accessible and can provide complex care in the facility.^{13,14}

The palliative APRN has been shown to provide quality, comprehensive palliative care.¹⁶ While the rehabilitation APRN role encompasses many of the tenets of primary palliative care, such as basic symptom management and goals of care, the palliative specialist is more strongly associated with decreased symptom burden.¹⁷ The palliative APRN has the ability to help patients and families navigate goals of care in the setting of serious illness and coordinate care.⁷ Patients in the rehabilitation setting often experience significant symptom burden, which the palliative APRN is equipped to address.² Working together, the rehabilitation and palliative APRNs can optimize quality of care for patients.

THE REHABILITATION TEAM

THE PHYSIATRIST

Physical medicine and rehabilitation (PM&R) physicians are also known as *physiatrists*. This specialty aims to optimize, restore, and maintain functional ability for those with physical impairments and disabilities.¹ The skill set of the PM&R physician includes pain and symptom management along with helping patients to set functional goals. The goals are individualized and based on the patient's prognosis and ability to regain function.⁸ PM&R physicians are able to provide bedside pain management interventions and provide prognosis regarding functional outcomes.¹ The palliative APRN has an opportunity for collaboration with the PM&R physician in improving patient symptom control and setting realistic expectations, particularly for patients with complicated medical problems.¹

THE PHYSICAL THERAPIST

The intent of physical therapy is to optimize physical functioning.¹⁸ Physical therapists (PTs) are trained to improve functional quality of life through interventions that reduce discomfort, improve functional ability, and promote independence.¹⁹ They are trained to manage functional issues including muscle weakness, deconditioning, and motor deficits.⁸ Interventions include providing adaptive and assistive equipment and environmental modification.⁸ PTs also play a key role in providing symptom management in nonpharmacological ways (see Box 16.1). This is important because patients often report a preference for nonpharmacological management for certain symptoms such as fatigue.¹ Interventions includes education on energy conservation and exercise, which is utilized in the maintenance of muscle strength, range of motion, and balance.⁸

Another important role for the PT is assisting the patient and family with setting functional goals.¹⁹ The goals of the patient may shift in the setting of progressive debility; the PT is trained to modify their plan given the patient's limitations and focus on the priorities of the patient.¹⁹

**Box 16.1 PHYSICAL THERAPY INTERVENTIONS
FOR PAIN MANAGEMENT**

- Massage
- Heat
- Cold
- Ultrasound
- Transcutaneous electronic nerve stimulation
- Diathermy
- Splinting and braces
- Positioning and exercise

In palliative care, physical therapy is often underutilized.¹⁸ Even in the setting of progressive and serious illness, PTs can contribute to improving quality of life through significant reductions in pain, improved performance of activities of daily living (ADLs), and improvement in mood and fatigue.¹⁸ However, the payment structure for physical therapy requires sustainable improvements in function.¹⁸ This may not be feasible in the setting of serious illness and terminal disease. Patients with gradually declining diseases may benefit from intermittent physical therapy for reevaluation and intervention as their care needs evolve.¹⁸

The American Physical Therapy Association recognizes the importance of PTs partnering with palliative care,²⁰ and there is awareness of the need to expose physical therapy students to palliative care early in their training.²¹ However, there is currently limited education of palliative care among physical therapists.¹⁸ Given that there is not a palliative care specialization for rehabilitation, the palliative APRN is critical in providing ongoing staff education and collaboration to improve palliative care awareness and enhance quality of care. The palliative APRN can collaborate with the PT to ensure symptoms are managed using a multimodal approach, allowing the patient to comfortably participate in therapy.

THE OCCUPATIONAL THERAPIST

The occupational therapist (OT) provides assessment and management to improve fine motor skills performance with ADLs, work tasks, and recreation.⁸ Occupational therapy contributes to quality of life by enabling patients to lead fulfilling lives within the limitations of their disease.²² It decreases isolation, enabling patients to redefine their social roles and how they participate in activities.²³ This contributes to enhanced social relationships and personal dignity.²² OTs accomplish this through instructing patients on the use of aids and adaptive equipment in addition to developing strategies to accommodate their limitations and conserve energy.²³ Examples include built-up handles on toothbrushes and utensils, sock donners, grab bars, and raised toilet seats.¹ The OT works with patients and caregivers in setting activity-related

goals surrounding self-care, transfers, and home management.⁸ The OT works within the interdisciplinary team to inform others of the level of help the patient requires to make activity possible.²³

The role of the OT in enhancing quality of life is complementary to palliative care involvement. This is recognized by the American Occupational Therapy Association: "Occupational therapy services . . . integrate the physical, cognitive, emotional, and spiritual aspects of clients' experiences so they may participate in their life roles regardless of the stage of their disease process."²⁴ The palliative APRN works jointly with the OT to facilitate discussions of meaningful functional goals for the patient.

THE SPEECH LANGUAGE PATHOLOGIST

The speech language pathologist (SLP) provides rehabilitation services to patients with conditions impacting their communication, cognition, or swallowing.²⁵ While SLPs have not traditionally been associated with palliative care, they have an important role in maintaining quality of life for patients with serious illness and those who are terminally ill.²⁵ Patients may have impaired abilities to communicate as a result of their disease process. Impaired communication can affect the patient's ability to make their preferences known and influence their emotional status and even their symptom management.^{25,26} The SLP provides a comprehensive assessment and strategies to enhance communication.²⁵ Strategies include providing appropriate alternative communication tools (see Table 16.2).^{25,27} These interventions allow patients to continue to direct their own care and socially interact (Table 16.4).¹

Dysphagia management is another way that the SLP can facilitate quality of life in those with a serious illness. As patients enter the later stages of disease, decisions may need to be made regarding optimal routes of nutrition, which can lead to conflict within families and teams.²⁵ The SLP provides direction to the patient and team regarding modifying diets for safety and teaching safer and more comfortable swallowing techniques, allowing the patient to enjoy eating for as long as possible.²⁵ Decisions regarding risks and benefits of enteral nutrition and tracheostomy should be considered in conjunction with the entire interdisciplinary team, including the SLP, with respect to the patient's prognosis and goals of care²⁵ (see Chapter 56, "Discontinuation of Other Life-Sustaining Therapies"). As with other therapy disciplines, the palliative APRN plays a key role in educating the SLP regarding palliative care and participating in discussions regarding patient-centered goals of care.

Unaided systems	Aided systems
• Gestures • Body language • Facial expressions	• Pen and paper • Picture/alphabet boards • Computer generating speech devices

Adapted from American Speech-Language-Hearing Association.²⁷

THE DIETITIAN

Registered dietitians are specialized professionals trained to evaluate a patient's nutritional needs, prevent malnutrition, and improve nutritional status.²⁸ There can be confusion between the titles *dietitians* and *nutritionists*; registered dietitians must have at minimum a bachelor's degree and must pass a national certifying exam after completing specific academic and clinical requirements.²⁹ The more generic title "nutritionist" is not regulated in some states, and those with simply an interest in nutrition can use this label; in acute and long-term care settings, the dietitian is the designated professional to oversee food and nutrition services.²⁹

In rehabilitation care, the caloric needs of patients vary greatly, and malnutrition can lead to functional decline. For example, in patients with a hip fracture, malnutrition can lead to postoperative complications, poor functional improvement, and higher rates of rehospitalization.³⁰ For patients with dementia, nutritional issues will arise over the course of the disease including difficulty swallowing and taste changes.¹⁵ Given that one in four elderly patients admitted to rehabilitation with a hip fracture have insufficient caloric intake, problems with nutrition in this setting are significant.³⁰ Studies have shown increased dietary intake is associated with improved ADLs after hip fracture surgery.³⁰ The dietitian often works with the SLP to tailor a plan for the patient to optimize nutrition, including flexibility for patient preferences and caloric needs.³¹

THE SOCIAL WORKER

The needs of the rehabilitation patient are multidimensional and include psychosocial support.³² The role of the social worker (SW) in the rehabilitation setting is to empower residents and enhance their coping ability.³² Particularly in the SNF setting, the SW is a key part of the interdisciplinary team supporting the patient, family, and staff both formally and informally.³² SWs have comprehensive assessment skills and are able to engage the patient and family in eliciting what matters most to them.³³ These needs, including adequate treatment of depression and anxiety, can influence physical symptoms.³⁴ SWs support a patient's autonomy, emotional well-being, and quality of life.³¹ In palliative care, social workers are valued professionals who establish trust with patients and families to explore goals of care and validate concerns in the setting of serious illness.^{34,35} In the rehabilitation setting, SWs provide this support in addition to facilitating a safe discharge plan with the patient and family.³²

REHABILITATION DISEASE-SPECIFIC GROUPS

THE CANCER POPULATION

Patients with cancer may be admitted to rehabilitation facilities related to disability from the cancer itself, treatment-related debility, or complications such as pathologic fracture.³⁶

They may also be admitted to rehabilitation with the goal of "getting stronger" to pursue cancer-directed treatment.³⁷ Exercise during and after cancer treatment has been shown to be safe and is effective in decreasing fatigue, improving sleep quality, reducing long-term side effects, and even decreasing risk of recurrence.³⁸ The positive effects of rehabilitation can be seen across all stages of cancer, including survivorship.³⁹ Even in advanced cancer, rehabilitation techniques used for palliation can prevent decline and even improve ADLs.^{40,41} Such gains in function can be maintained several weeks after rehabilitation discharge.⁴¹ Maximizing independence, while important to patients, also plays a role in reducing caregiver burden.³⁶

In the setting of advanced cancer, the palliative APRN assists the rehabilitation team in setting realistic goals. For instance "getting stronger" for treatment may unfairly burden patients who are in the later stages of their disease and unable to stop their increasing frailty.³⁶ Among patients at one hospital who were discharged to rehabilitation with the goal of getting stronger for immunotherapy, only one-third received additional treatment.³⁷ Average survival of those who did not receive additional treatment was only 51 days, and 30-day readmission rates were high at 28%.³⁷ The palliative APRN can help the patient and rehabilitation team set expectations of possible improvement in symptoms such as fatigue while simultaneously having ongoing goals-of-care discussions.³⁶ The social worker also works with the patient in acknowledging the patient's desire to maintain a sense of self while coping with their changing body and roles.⁴² The palliative APRN can also optimize symptom management in this population, including management of fatigue, pain, and nausea that may interfere with a patient's ability to participate in rehabilitation. The palliative APRN also provides support with advance care planning and discussion of priorities in the setting of advanced disease.^{36,39} Coordination of symptom management should ideally occur among the oncology, rehabilitation, and palliative care teams.⁴⁰

THE PULMONARY POPULATION

Patients who have pulmonary disease may avoid activity due to dyspnea and can consequently become deconditioned.⁴³ Pulmonary rehabilitation serves to rebuild the functional capacity of patients who experience dyspnea and deconditioning.⁴³ Tools used to achieve this include addressing the underlying pulmonary disease and breathing retraining to improve gas exchange, along with airway clearance techniques.⁴³ Rather than being solely an exercise program, it is a comprehensive way of managing the disabling aspects of respiratory disease and has been shown to improve quality of life and symptom control.⁴³ Benefits include less dyspnea and fatigue, improved endurance, and better ability to perform ADLs. These benefits extend to those with limited life expectancy due to chronic obstructive pulmonary disease (COPD) and lung cancer.⁴³ The pulmonary patient receiving rehabilitation provides an opportunity to discuss advanced directives; this discussion can also alleviate anxiety regarding end of life and increase goals-of-care discussions.⁴⁴

THE CARDIAC POPULATION

Evidence shows that palliative care for patients with heart failure improves quality of life, patient satisfaction, and documentation of preferences and decreases rehospitalization.⁴⁵ The American College of Cardiology has recognized the importance of integrating palliative care throughout the course of management in patients with heart failure⁴⁶ and recommends considering referral to specialty palliative care when patients develop New York Heart Association (NYHA) Class III–IV symptoms.⁴⁵

Cardiac rehabilitation is a specialized program which combines exercise with addressing modifiable risk factors such as smoking, nutrition, and management of comorbid conditions such as hypertension and diabetes.⁴⁶ For patients with heart failure and NYHA Class II–III symptoms, exercise training improves exercise tolerance and health-related quality of life.⁴⁷ It has also been shown to decrease hospitalizations for those with reduced ejection fraction.⁴⁷ Cardiac rehabilitation is underutilized in the Medicare population, with only 1 in 4 eligible beneficiaries participating.⁴⁸

THE NEUROLOGY POPULATION

The course of neurological disease can be challenging for patients, families, and clinicians. The involvement of palliative care often depends on a patient's prognosis and the natural history of the illness.⁴⁹ Patients in the rehabilitation setting may have experienced a sudden event, such as a stroke, while others are grappling with the complications of their underlying progressive disease. In the setting of a sudden event such as stroke, prognosis can be uncertain and variable, leading to difficulty in decision-making among patients and families.⁵⁰ Patients can be faced with focusing on rehabilitation while preparing for a life that may include severe disability.⁵⁰ Surrogates may find themselves in a role of decision-making that they were not prepared for and may be hearing conflicting information regarding prognosis, thus contributing to their distress.^{50,51} A model of “preparing for survival, decline or death and hoping for the best” may be helpful, allowing patients and families to work through these life-altering events.⁵⁰

Patients with progressive neurological disorders such as Parkinson's disease can experience high symptom burden related to their motor dysfunction along with social and emotional distress.⁵² Neuropsychiatric symptoms such as dementia, depression, and apathy can also impair communication and social interactions.⁵² Proactive intervention is recommended to reduce symptom intensity, symptom frequency, and the need for crisis-level intervention.⁵² Therapies may be focused on treating underlying issues such as SLP for speech-amplifying devices in the setting of hypophonia, social worker support for anxiety, and PT and OT for activity modification. As with other diseases, physical activity remains important for those with neurological disorders—even if a person is wheelchair-bound.⁵² Rehabilitation interventions have been shown to maintain residual ability and prevent complications such as pressure ulcers, contractures, and pneumonia.⁵² Symptom management may include optimizing dopaminergic

medications in collaboration with the neurologist and monitoring for medication-induced side effects, such as sedation and orthostatic hypotension.⁵² Ensuring that inappropriate medications are not prescribed also supports quality symptom management. This includes avoiding certain neuroleptics and antiemetics that are dopamine receptor blocking agents that can worsen motor dysfunction.⁵²

THE DEMENTIA POPULATION

The treatment of patients with dementia requires comprehensive medical and social support.⁵³ Patients with dementia may be unable to express their preferences for care or verbalize their symptom needs.⁵⁴ Despite these limitations, patients with dementia can benefit from rehabilitation services.⁵⁵ The rehabilitation is focused on achieving goals important to the patient within the limitations of their disease.⁵⁵ All members of the rehabilitation team have the ability to improve the quality of life for the patient with dementia. Given that dysphagia develops in a majority of patients with dementia, the SLP is able to offer strategies to optimize swallowing and make it more comfortable.³¹ The dietician and SLP can work together to identify food and drink preferences to maximize nutrition while providing flexibility in the setting of decreased oral intake.³¹ The OT can provide equipment to make getting food to the mouth easier by offering modified cutlery and plates,³¹ in addition to strategies to minimize social isolation.²³ Hand feeding can be provided by staff and family once the SLP has identified the safest way for the patient to eat. The PT can provide an exercise program and interventions for fall reduction.² The focus of rehabilitation may be to maintain function and independence for as long as possible rather than making significant functional gains.¹⁹

SETTING GOALS OF CARE IN THE REHABILITATION SETTING

There can be misguided expectations from patients and family when a patient enters rehabilitation care. Patients may not have a clear understanding of the progressive nature of their illness because they are in rehabilitation care with the goal of improvement¹⁸ and may expect to leave rehabilitation “stronger and better.”⁷ Despite the many benefits of rehabilitation, many older patients who are discharged from the hospital to a facility have serious illnesses associated with poor prognoses.⁵⁶ The goal of regaining function and returning to independence may only be met in a minority of patients who have received palliative care in the hospital,⁵⁷ and overall survival is poor.⁵⁸ Transitions of care can be high in this population; studies show high rates of 30-day readmissions for patients who received a palliative care consultation in the hospital and are discharged to a SNF.⁵⁸ For Medicare patients in 2015, more than 43% had a nursing home stay in the last 90 days of life—almost 24 million people.⁵⁹ Such transitions can be burdensome to patients, leading to inadequate symptom management, pressure ulcers, and poorer end-of-life outcomes.^{56,57}

These transitions can also be difficult for family members and can exclude them from the end-of-life process.⁶⁰

Reasons for increased transitions for seriously ill patients in the SNF setting are varied. Patients with chronic diseases such as heart, lung, and kidney issues are at elevated risk for transitions due to poor coordination of care.⁶¹ Up to 49% of patients who receive a palliative care consultation in the hospital are discharged to an SNF⁵⁸; SNF staff may not have adequate symptom management training and often lack access to a palliative care clinician.⁵⁷ Lack of continuity of palliative care support can lead to poor communication and disruption of ongoing goals-of-care discussions.⁵⁷ Palliative care involvement in the SNF setting has been shown to lower rates of potentially burdensome care transitions.⁶²

Patients and families benefit from ongoing disease and prognostic information to make appropriate healthcare decisions.⁵⁶ The goal of the palliative APRN is to ensure patient-centered goals are consistently addressed and there is communication with the patient and family in setting realistic expectations.⁷ In the rehabilitation setting, this involves ensuring documentation of goals and values and ensuring these are conveyed across settings to avoid unwanted care.⁶³ Coordination with the rehabilitation staff to recognize decline and lack of progression is vital in these goals-of-care discussions.⁷ In situations of prognostic uncertainty, a *time-limited trial* may be helpful. A time-limited trial allows the patients, families, and staff to establish mutual expectations regarding how a patient is progressing based on an intervention and an established time frame for assessing outcomes.⁶⁴ Collaboration with rehabilitation staff and reassessment of goals is important throughout the patient's rehabilitation care.

CASE STUDY 2: DEMENTIA

Mary was a 90-year-old nursing home resident with advanced Alzheimer's dementia. She was sent to the hospital after falling while attempting to get up from her chair. She was noted to have a right hip fracture on imaging. Orthopedic surgery was consulted, and she underwent hip repair due to severe pain. She was sent back to her nursing home under the Medicare rehabilitation benefit.

At baseline, Mary is a one-person assist with transfers from bed to chair. She speaks a few words and eats a pureed diet with thickened liquids. She will occasionally have sundowning behaviors in which she becomes more confused and occasionally refuses care. Her healthcare proxy is her daughter Jennifer, and this proxy is activated.

The rehabilitation team and palliative APRN met with Jennifer to review the plan and elicit goals of care. Jennifer expressed her wish that her mother return to her baseline prior to the hip fracture, and she was worried that her mother had become increasingly anxious and uncomfortable since the hospital. PT began working toward Mary returning to her previous status of being able to transfer with assistance. Over time, it became clear that Mary was not making any progress, and goals were shifted to provide comfortable transfer with a mechanical lift. Her pain was managed by the palliative APRN with scheduled acetaminophen

and oxycodone as needed. Mary was experiencing delirium from the hospital, and the palliative APRN ensured her pain was managed and that she was not experiencing reversible sources of delirium such as opioid-induced constipation.

The palliative APRN communicated frequently with the rehabilitation staff as Mary continued to functionally decline. Since Mary's hospitalization, the dietician noted a 10% weight loss and continued poor oral intake despite supplementation. Mary also seemed to be sleeping more and was no longer speaking.

The team met with Jennifer to readdress goals of care. Jennifer did not want her mother to undergo any further hospitalizations and did not want any invasive measures such as a feeding tube. Goals were shifted solely to comfort care. The SLP worked with Mary to liberalize her food and drink consistency to allow comfort feeding. The staff nurses were educated on the importance of assessing and managing nonverbal signs of pain. The palliative APRN ensured wishes for no further hospitalizations were documented in the medical record, nonessential medications were stopped, and comfort medications were in place. Mary passed away comfortably while under her rehabilitation benefit with the support of the entire team.

END OF LIFE IN THE SKILLED NURSING FACILITY SETTING

The payment structure of rehabilitation favors functional progression rather than a focus on comfort.⁵⁷ Despite the functional improvement goal of rehabilitation, more than 9% of Medicare beneficiaries will die while utilizing their SNF rehabilitation benefit.⁵⁷ Financially, nursing homes are reimbursed at a higher rate for rehabilitation than for long-term care.⁵⁷ This may lead to interventions that support the goals of rehabilitation but not the patient's changing needs at end of life.⁴ For families, rehabilitation facilities may be the only financial option to cover the needed 24-hour care of their loved one after a hospitalization.⁴ Patients who are utilizing their rehabilitation benefit are not able to access their hospice benefit, leaving those who are at end of life without all the support hospice offers.⁵⁷ In the rehabilitation setting, APRNs are able to provide palliative care consultations through Medicare Part B billing⁶² without impacting the revenue of the rehabilitation facility, thus filling an important gap in end-of-life care in this setting.

The palliative APRN can address changes in a patient's condition that may not be recognized as end-of-life deterioration by rehabilitation staff.⁶⁵ This recognition is essential in providing the appropriate level of support for the patient and families⁴⁹ in addition to the symptom management that may be lacking from the rehabilitation staff.⁵⁸ The APRN can provide support to families who may be unprepared for their loved one's end of life due to the expectation of recovery with rehabilitation care. The APRN can also work with the rehabilitation staff to ensure that interventions are aligned with the patient's and family's goals of care at end of life and decrease the risk of hospitalization.⁶⁶

SUMMARY

Patients entering rehabilitation care often have complex medical and psychosocial needs. They may be facing debility due to a sudden event such as a stroke or experiencing ongoing debility from chronic illness. Rehabilitation care provides a comprehensive interdisciplinary team approach which includes physiatrists, PTs, OTs, SLPs, dietitians, and medical social workers. The benefits of rehabilitation can be seen at all stages of disease and has been shown to improve a patient's quality of life. The palliative APRN is a key member of the team and facilitates symptom management and ongoing goals-of-care discussions in collaboration with the rehabilitation staff. They are critical in eliciting patient-centered goals of care and helping patients and staff establish realistic expectations for rehabilitation. The palliative APRN assists the patient and family in navigating the complexities of both sudden and progressive diseases and provides ongoing support during uncertainty and shifting goals. They also provide expert end-of-life care for patients who die during rehabilitation and are unable to access their hospice benefit. Palliative care in the rehabilitation setting is underutilized and represents an opportunity to improve quality of life and coordination of care.

THE PALLIATIVE APRN IN TELEHEALTH

Katherine Kyle and Constance Dahlin

KEY POINTS

- Telehealth palliative care extends the boundaries of palliative care by promoting access to individuals previously limited by geography and providers while simultaneously complementing in-person provider visits.
- Telehealth has experienced recent rapid proliferation, offering opportunities of palliative care growth and expansion to marginalized populations.
- Palliative advanced practice registered nurses (APRNs) may provide telehealth delivery because it is within their scope of practice and reimbursement eligibility.
- Providing telehealth requires education, planning, and the use of skillful communication.

adjusted medications. In addition, the palliative APRN initiated advance care planning. Family members were able to attend the meeting. Mrs. K was able to share her goal of continuing treatments as long as they were helpful. When they were not longer helpful, she wanted to focus on staying at home and focusing on comfort.

The palliative APRN continued to monitor Mrs. K, who was still receiving chemotherapy infusions. She developed further nausea and vomiting and was admitted. Work-up revealed liver metastases. The palliative APRN followed her care in the hospital and provided inpatient telehealth visits so family members could be present in the care.

INTRODUCTION

DEFINITION OF TELEHEALTH

Telehealth is broadly defined as the delivery of health and health-related services using digital information and telecommunication technologies.¹⁻⁴ The Health Resource Services Administration (HRSA) defines *telehealth* as “the use of electronic information and telecommunications technologies to support and promote long-distance clinical healthcare, patient and professional health-related education, public health and health administration. Technologies include videoconferencing, the internet, store-and-forward imaging, streaming media, and terrestrial and wireless communications.”⁵

The terms *telehealth* and *telemedicine* are often used interchangeably but there are some key distinctions. Healthcare institutions and professional organizations also vary in their definitions but this adds emphasis to the fact that telehealth is a constant and rapidly evolving specialty that adapts to contemporary innovations in technology and to the healthcare needs of populations and societal conditions.^{6,7}

Telehealth is considered to be a more encompassing and holistic term, referring to a broad range of health services delivered remotely or from a distance through the use of electronic information and telecommunication technologies.^{1-4,7} *Telemedicine* means “healing at a distance” and refers to actual patient care through telehealth or the provision of clinical services using telecommunication technologies.⁶ The American Telemedicine Association (ATA) describes telemedicine as the exchange of medical information from one site to another or between providers using electronic communication with the intention of improving a patient’s clinical health status.⁸

CASE STUDY: TELEHEALTH CONSULTATION

Mrs. K was a 68-year-old woman with metastatic pancreatic cancer referred to palliative care for symptom management for cancer/treatment-related symptoms. At the time of visit, she was on her second-line chemotherapy with a high performance status. Her symptoms included abdominal pain, for which she was prescribed oxycodone 5 mg every 4 hours. She also had intermittent nausea and vomiting in the hours and days immediately following chemotherapy. For this, she was prescribed aprepitant on the day of infusions as well as Ondansetron ODT 8 mg as needed. The patient shared concern over her weight loss related to decreased appetite and intermittent bouts of nausea and vomiting in the days following chemotherapy infusions. Her decline and symptoms were causing her some symptoms of depression included sadness, anhedonia, and hopelessness, which was different for her.

The palliative advanced practice registered nurse (APRN) recommended adjusting her medications to long-acting oxycodone 30 mg scheduled twice daily with a breakthrough dose of oxycodone to 10 mg every 4 hours. The APRN prescribed mirazapine 7.5 mg at bedside for appetite stimulation as well as to assist with depression management. A referral was also made by the palliative APRN to an interventional pain clinic for celiac plexus nerve block. These interventions provided relief.

In-person follow-up was disrupted by the COVID-19 outbreak, so the palliative APRN conducted video visits. Since the nerve block, Mrs. K reported only needing breakthrough medication once a day. The palliative APRN monitored her symptoms and

There are six modalities of telecommunication technology used in telehealth as outlined here (Table 17.1).

Synchronous telecommunication refers to live or two-way interactions between a person (patient, caregiver, or provider) and a provider through audio-visual technologies that allows the exchange of health information in real time.^{1,7–10} Through the advancement of peripheral technology devices, such as electronic stethoscopes and otoscopes, these visits provide a comparable alternative to in-person visits. Synchronous telehealth can also include

educational programs between providers or from provider to patient.

Store-and-forward or *asynchronous telecommunication* involves the exchange of prerecorded health information or data through secure electronic communications between two or more individuals at different times.^{7,8}

A provider may use this technology for consultation. A patient's diagnostic imaging or case description may be sent through secure email to a specialist or expert to review and recommend treatment options.

Table 17.1 TELEHEALTH MODALITIES

MODALITY	DEFINITION	EXAMPLE
Synchronous	Live or two-way interactions between a person (patient, caregiver, or provider) and a provider through audio-visual technologies that allow the exchange of health information in real time	A referring provider places an order for a telepalliative care consult for patient hospitalized at satellite campus with COVID-19. Telepalliative care provider connects with patient using real-time videoconferencing to discuss goals of care.
Asynchronous	Exchange of prerecorded health information or data through secure electronic communications between two or more individuals at different times	A referring provider sends diagnostic imaging or case description of a patient through secure email to a specialist or expert who later reviews information and replies back with a probable diagnosis and options for treatment. ^{2,7–10} Another common use of asynchronous care involves virtual visits that use a standard set of clinically based questions to obtain specific information about present illness or health complaint in order to identify to probable diagnosis, provide recommendations for treatment, and, if appropriate, prescribe medications. ^{8,11}
Remote patient monitoring (RPM)	Technology to gather patient medical and other forms of data and electronically send that information to providers for assessment in order to create, track, and make changes to a patient's treatment and plan of care	A patient with congestive heart failure wears a remote monitor to track their activity level and changes in functional status, pulse oximetry, and dyspnea.
mHealth	Asynchronous and synchronous through mobile technology; mHealth is medical and public health practices supported by mobile devices or other wireless technologies including health apps for smartphones or tablets and devices used at home or wearable to monitor the patient	Mobile applications are used to assist with the assessment and monitoring of patient symptoms to improve management and communication between patient and provider. ¹²
eConsult	Secure electronic communication and consultations between providers and specialists	Providers connect with each other for asynchronous or store-and-forward consultations; this allows the primary team providers to connect with specialist to obtain expertise in managing complex patients. Primary care provider is electronically consulted by a palliative care specialist to discuss intractable abdominal pain in a patient with Stage IV pancreatic adenocarcinoma. The palliative care specialist reviews patient chart, medication history, imaging, and recommends provider and refers the patient to an interventional pain specialist for adjustment in opioids and celiac plexus nerve block.
Project ECHO (Extension for Community Health Outcomes)	Clinician links with expert issues in "virtual grand rounds"	A provider seeking continuing education uses the Project ECHO technology and platform to address global health disparities.

Remote patient monitoring (RPM) uses technology to gather patient medical information and other forms of data and electronically send that information to providers for assessment to create, track, and make changes to a patients' treatment and plan of care.^{7,8} Remote patient monitoring is commonly used to follow patients at home for chronic disease management and following hospitalizations to reduce escalation of care (hospital admissions and readmissions) with timely interventions in response to changes in patient information.^{7,8} There are a number of RPM monitoring devices and technologies that can be either synchronous or asynchronous. Targets of RPM include monitoring of a specific vital sign (blood pressure), pulse oximetry, electrocardiogram, and blood glucose levels.^{8,10} Very commonly, but not always, RPM is prescribed by a provider for both short- and long-term periods for data collection.⁸

mHealth, also referred to as *mobile health*, has become an increasingly utilized form of telehealth. This subset refers to both asynchronous and synchronous communication through mobile technology. mHealth comprises medical and public health practices supported by mobile devices or other wireless technologies including health apps for smartphones or tablets and monitoring devices used at home or worn by the patient.⁶⁻⁸ Applications can also be helpful in promote the adoption and maintenance of healthy lifestyle behaviors and safety with alerts, updates, and reminders.⁷

eConsult or electronic consults are secure electronic communication and consultations between providers and between providers and patients.⁸ Frequently, eConsults are used to connect primary care providers to specialists in order to receive expert assessment and recommendations for patients.^{7,13} eConsults can be cost-effective, eliminating unnecessary in-person subspecialty clinic visits that can be expensive for patients and health organizations.^{7,13} eConsults are delivered through synchronous communication technology with real-time video or through asynchronous communications through store-and-forward technology.⁷ Electronic consults in the outpatient setting are common practice, but inpatient e-consults are a relatively new practice. Academic medical centers have increased their use of e-consults where the availability of specialists cannot be maintained across growing health systems stretched across multiple sites.^{13,14} The options for specialist involvement in the inpatient setting traditionally have been a time-consuming in-person consult or the informal "curbside consult" that may have limited documentation in the patient's electronic health record.^{13,14}

Project ECHO (Extension for Community Health Outcomes) is a provider-focused education program that occurs within a free platform developed at the University of New Mexico. The focus is on shared knowledge to improve patient outcomes. It utilizes technology to share and promote health education, particularly in rural and underserved areas. It also allows for case-based learning and telementoring. It can be focused on a particular topic area, such as hospice and palliative medicine, or between organizations.

In 2016, telehealth visits accounted for 0.5% of Medicare billing. In 2017, the American Hospital Association (AHA)

reported that approximately 76% of hospitals had partially or fully instituted a telehealth program, a substantial increase from the reported 35% in 2010.¹⁵ However, telehealth only accounted for a small fraction of billable visits.^{16,17} Evidence demonstrates that telehealth increases access to care, improves patient satisfaction, increases the quality of care, and reduces overall healthcare costs.^{1,15,16}

TELEHEALTH IN THE UNITED STATES

Telehealth has a history dating back to the use of the telegraph during the Civil War.⁸ Throughout its evolution, the focus has been on connectivity between those in need of care and those who are able to attend to them,¹¹ as in an underserved community or rural area, or to reach individuals who have a hard time traveling to healthcare appointments. Over the past 50 years, telehealth has evolved from the transmission of health data between healthcare organizations to the creation of a network of health organizations in which telehealth interventions offer healthcare to individuals in the military, prison systems, and rural areas.^{1,8,18}

The federal government placed more emphasis on telehealth beginning with the *Balanced Budget Act of 1997*, which introduced Medicare reimbursement for telehealth and telehealth projects.⁸ However, reimbursement was limited to members who lived in medically underserved rural areas and to specific providers using billing codes established by the Centers for Medicare and Medicaid Services (CMS).⁸ This led to the establishment of the American Telemedicine Association (ATA), which assists with collaborations, development of standards, and working on legislation.⁸

When healthcare as an institution began to shift away from volume of care to value in terms of quality, efficiency, and cost, new modes of care delivery were required. With this change, telehealth has been embraced by the AHA. While there had been a slow increase in the development of telehealth within healthcare organizations, the COVID-19 pandemic accelerated telehealth with unprecedented expediency. Telehealth became essential to reduce rates of transmission, decrease contact in vulnerable patient populations, and preserve personal protective equipment.¹⁹

CURRENT STATE OF TELEHEALTH IN PALLIATIVE CARE

Regardless of setting, every individual with a serious illness has the right to palliative care.²⁰ The World Health Organization (WHO) estimates that, worldwide, only 14% of those individuals needing palliative care actually receive it.²¹ Despite the extensive need for palliative care, seriously ill patients continue experience difficulty with accessing hospice and palliative care services. The number of patients in need of palliative care services greatly exceeds the workforce of palliative care specialists.^{22,23} With a greater number of people living into advanced age and a palliative care workforce shortage, telehealth is one solution.

Telepalliative care refers to the use of telehealth to deliver palliative care services.²⁴⁻²⁶ This includes telephone-based

programs, video conferencing, and remote patient monitoring. The use of telemedicine in palliative care has been found to improve access to care and symptom management and increase patient and family satisfaction with care. However, the amount of evidence available is limited and fails to define how best to provide telepalliative services and other limitations.^{25,27}

Early applications of telehealth in the field of palliative care focused on using remote communication technology to provide hospice care and services to patients at a distance, also referred to as *telehospice*.²⁸ In the late 1990s, the University of Kansas Center for Telemedicine and Telehealth (KUCTT) established one of the first telehospice programs.²⁹

Palliative telehealth been used in the inpatient setting,^{24,26,30} and a home-based palliative care (HPBC) program implemented in a New York metropolitan area provides telehealth service that includes 24/7 access to providers by phone or videoconference.^{27,31} Compared to patients who received usual care, patients in the telepalliative program had a 34% lower rate of hospital admissions in last month of life, a 35% increase in hospice enrollments, and a significant increase in the median hospice length of stay.^{27,31}

Prior to the COVID-19 pandemic, telepalliative services were concentrated in the outpatient setting, often within specific patient populations including oncology, heart failure, and advanced lung disease, and for those in rural or geographically isolated environments. Palliative care in the outpatient setting is crucial in assessing and managing physical and psychosocial symptoms, establishing goals of care, assisting with medical decision-making regarding treatments, and coordinating care on the basis of the individual needs of the patient and their families.³² Telehealth be used to promote early transitions to hospice and to assist patients in completing advance care planning and clarifying preferences for hospitalization.²³

Telehealth has also been useful in providing online palliative care education through videoconferencing, training, and peer mentoring.^{33,34} Although there is lack of consensus on the ideal use and limitations of telepalliative care, evidence suggests that telepalliative care improves primary care access, reduces patient and family caregiver illness-related burden, offers remote monitoring and better management of symptoms, identifies anticipated or unexpected health decline, reduces escalations of care, and reduces unnecessary utilization of healthcare resource.^{27,30,31,33,35–38} In recent years, palliative telehealth has focused on rural areas.

IMPLEMENTATION OF PALLIATIVE TELEHEALTH

For any telehealth program, a well-planned implementation is essential. There must be collaboration from palliative care clinicians, administrative leadership, and informational technology experts. It will be important to validate professional licensing, prescribing limitations, healthcare malpractice, and privacy and security requirements.³⁹ Overall, planning must be done to consider reimbursement by patient insurers, the telehealth modality, and the roles and responsibilities of

participants. The program must be designed to provide a good clinical experience and proper documentation and coding, and be able to measure quality and satisfaction.

Scheduling of a telehealth visit can occur through several methods. These include creating 4-hour blocks of time similar to clinic schedules; devoting a full day to telehealth visits as needed, as for in-hospital visits based on the needs of patients, visitor restrictions, or distance of facility from patient family; on-call scheduling during evenings or weekends; or a mixed model of in-person and telehealth visits. Clinicians must remember to allow time to take breaks between virtual calls because the work is as demanding as in-person visits due to the co-management of technology, “reading” the patient, and leading the call.

It is important to assess the effectiveness of palliative telehealth visits. For a healthcare organization, this may include looking at overall telehealth metrics such as palliative care virtual visit volume and number of palliative providers trained and using virtual services. For population-specific metrics, it may include which types of patients do best in accessing palliative care (e.g., oncology, heart failure, pulmonary failure, neurocognitive disorders, etc.). Palliative care–specific metrics include reduction of no-show palliative care appointments, number of additional appointments available as a result of virtual visits, and number of advance care planning conversations as well as the documents completed. For patients and families, metrics also includes patient satisfaction in terms of access and wait time for a scheduled appointment.

OPPORTUNITIES AND CHALLENGES OF TELEHEALTH

There are a number of opportunities for palliative telehealth to enhance patient and clinician access; patient, family, and clinician travel times; and quality of care. With a focus on assuring palliative care across communities and rural areas, patients can experience an increased number of visits rather than clinic visits or home visits. Moreover, telehealth offers more care to individuals in long-term care settings, on reservations, or in prisons. It increases access for patients for whom travel is too expensive or difficult. Telehealth allows palliative care to decrease health inequities by offering care to marginalized patient populations as well.⁴⁰ Quality has been improved by more frequent follow-up and by using professionals to their full scope of practices. For instance, a registered nurse can do a telehealth visit for medication reconciliation and need for prescriptions. Advanced practice providers and physicians can do clinical visits.

Challenges exist as well. The move from in-person to virtual encounters with patients requires new skill development. The transition for palliative care providers who cherish in-person visits to establish an effective and therapeutic provider–patient relationship through “reading” nonverbal body language and real-time verbal expression has taken time. Inherent in web communications are connection delays and forced pauses. Moreover, the organization for a telehealth visit requires different planning. Specifically, there

are requirements for platforms and devices that are compliant with the *Health Insurance Portability and Accountability Act* (HIPAA). These requirements translate to start-up costs for implementing an organization-wide platform, buying smart devices, and educating providers on how to use them, as well as costs for robust internet and broadband connections to support the visits. For patients, education is required on how to use the technology and the visit platform, to obtain access to devices, and to access the internet and broadband networks. Older patients may have difficulty with technology and need coaching prior to visits (Table 17.2). Within the COVID-19 pandemic, some community palliative care agencies have redeployed staff to bring devices to patient’s homes and teach them how to use them. Other patients have been forced driven to known businesses (libraries or town offices) with guest access to internet.

TELEHEALTH ADVANCED PRACTICE NURSING

Telehealth provides opportunities to expand the reach of the omnipresent workforce of nurses. Project Enable (Educate, Nurture, Advise Before Life Ends) is one the earliest telehealth approaches in providing early palliative care intervention to rural patients with serious illness and their family caregivers.^{41–44} Palliative advanced practice registered nurses (APRNs) were central to the study, which focused on symptom management for patients in the community and laid groundwork for telehealth advanced practice nursing.

Telehealth provides APRNs with the opportunity to improve access to care for patients, but it also increases options for clinical practice.⁴⁵ The American Association

of Nurse Practitioners (AANP) position statement on telehealth acknowledges the support of providing healthcare services through telehealth but does not considers that services provided through telehealth are a separate specialty or are confined to the practice of one profession.⁴⁶ The shortage of palliative care specialist providers makes telehealth an attractive option for hospice and palliative care organizations, and the recent COVID-19 pandemic made the intervention integral. Integration of telehealth curricula has been developing rapidly in both generalist and specialist palliative APRN education.

Within a telehealth practice, palliative APRNs can provide the same services they would in-person: advance care planning, pain and symptom management, medication management, goals-of-care discussions, counseling, discharge planning, and planning for end of life.

PROVIDING A PALLIATIVE TELEHEALTH VISIT

The palliative APRN needs to plan for a telehealth visit.^{47–51} Ideally, this includes prior education about an organization’s capacities for telehealth, including the platform, device, and documentation.^{39,50} It may also include the downloading of any applications or creating an account for a platform.

STEPS TO A TELEHEALTH ENCOUNTER

Preparation

1. Prepare for the appointment ahead of time by connecting with the platform. The platform must be HIPAA compliant.
2. Choose the device you plan to use. It can be a computer, laptop, smartphone, or tablet. It is important to discern whether the device is Apple-, Google-, Windows-, or Android-based. Make sure it is compliant with the platform.
3. Use a high definition web camera and microphone.
4. Ensure a reliable internet connection.
5. Find a private area for the visit.
6. Consider your environment.
 - a. Consider lighting: Keep it neutral and well-lit.
 - b. Ensure a private space for the appointment to occur, to meet HIPAA regulations.
 - c. Make sure the space is quiet, and turn off cellphones and beepers.
7. Remember to dress appropriately for the clinical visit.
8. Set up the computer at eye level and check sound.
9. Review the patient’s chart ahead of time, including history, medications, and advance care plans.

Table 17.1 PALLIATIVE TELEHEALTH OPPORTUNITIES AND CHALLENGES

OPPORTUNITIES	CHALLENGES
Access	Provider education on conducting effective visit
Time: Decreased travel and transportation time for patients and families and provider	Legal variability by state
Quality: Patient satisfaction, increased interactions	Redesign of work flow; changing clinical encounter
More frequent interactions	Cost of equipment
Use of palliative care team members to the fullest scope of practice	Internet and broadband access for patients, providers, and, potentially, healthcare facilities
	Lack of equipment for patient, family, or providers (smart devices, computers)

Initiation of Visit

1. Remember to allow for transmission delay.
2. Provide introductions for everyone on the visit. Ask who else is in the room.
3. Confirm if translation services are needed.
4. Start the appointment with the patient. Ask the patient if they are new to virtual visits.
5. Ensure they have strong broadband and internet capacity. Speak loud and clear.
6. Ask them to gather anything they might need (e.g., their medication bottles and supplements).
7. Ask for permission to take notes or type while the patient is talking.
8. Let the patient know how long the visit will be. Establish the agenda (e.g., “We have 20 minutes for today’s visit”; “My schedule states this is an appointment for X”; “What brings you to today’s visit?”).
9. Ask the patient what topic is most important to discuss. Add what is important for you to discuss (e.g., “What are your most important concerns?”).
10. Perform the visit. This includes the palliative care questions about how they are doing, and their level of function. Make sure to review the plan at the end. Remember to pause due to internet connectivity lapses.
11. Perform an exam by helping them to move the device. Review vital signs.
12. Let the patient talk about their concerns.
13. Demonstrate empathy. Validate the patient’s concerns (“I wish I could be there in person”). Use the SAVE Model⁵⁰:
Support the patient: “I’m here for you.” “I’m here to help you or guide you.”
Acknowledge the situation: “This has been really hard.” “I wish there were better alternatives.” “I can hear your worry.”
Validate the emotions and experience: “Given your situation, I think many people would feel that way.”
Emotion: “I can imagine how difficult this has been.” “You sound frustrated/scared/anxious, etc.”
14. Tell the patient when you need to access computer files. Or share information on the screen as appropriate.
15. Review medications.
16. Give a warning shot when visit will close to ask if there are other issues to cover.
17. Make sure there is a follow-up plan.
18. Thank the patient and family for the encounter.

After the Visit

1. Provide a post visit summary and plan
2. Document the encounter.
3. Submit a charge for the encounter

DOCUMENTATION AND BILLING

The reimbursement for telehealth has been in flux over the years.^{50,51} CMS and private insurance organizations have covered telehealth in rural areas. During the COVID-19 pandemic, CMS offered waivers for telehealth and allowed for increased eligibility and scope beyond rural practice. Private payers also have adopted some coverage of telehealth services.^{14,50,51} It is unclear how telehealth reimbursement will level out. Even if they are not submitted, providing charges to your organization assists in the collection of information about the use of palliative telehealth.

In terms of actual charges, CMS allows APRNs to be reimbursed for telecommunication hospital, office, and home visits that generally occur in person. The APRN must use an interactive audio and video telecommunication platform. Telehealth cannot occur by email or telephone.

CMS allows billing for telehealth in a fee-for-service model. Commercial providers may allow telehealth under alternative payment models for enhanced case management and improved efficiency. Best practice suggests that palliative APRNs document and bill similarly to face-to-face visits (Box 17.1).

Box 17.1 DOCUMENTATION ELEMENTS OF PALLIATIVE TELEHEALTH PATIENT ENCOUNTERS

1. Patient consent: Need to document the patient’s consent of the visit (e.g., “Patient provided with patient risks and benefits of telehealth, verbal consent given for the telehealth visit”).
2. Participants in the visit: This should include who was present, what was discussed, and the start and stop times of the visit.
3. Essential components of a note: Document the history, physical examination, and medical decision-making.
Patient presents with *X* problem. Nurse reports physical findings (e.g., “Patient is calm, color is good, lips are pale. Breathing unlabored and even or using accessory muscles. Abdomen is distended when patient reveals stomach”).
4. Document counseling and topics: If more than 50% of time was spent on counseling and care coordination, this should be documented.
5. Include impression and recommendations or plan.
6. Document visit start times and stop times.

Table 17.3 PALLIATIVE TELEHEALTH CODING

Video visits	New patients 99201–99205
	New patients 99201–99205
Telephone visits	May be a temporary basis
	G20212
Online eVisit	99241–99423
Interprofessional eConsult	Palliative Consulting Provider codes 99446–99451
Telehealth evaluation and management codes	99441–99443

Adapted from American Academy of Family Physicians³⁹; and Lampert.⁵¹

There are consistent telehealth codes that the palliative APRN may use in the appropriate situations; see Table 17.3.

SUMMARY

Telehealth has been an emerging form of palliative care brought to the forefront by the COVID-19 pandemic. From a patient perspective, it offers an opportunity to facilitate early access to quality palliative care. Moreover, it allows delivery to individuals with serious illness for whom social determinants of care make in-person visits difficult. From a team perspective, telehealth allows the full participation of the palliative interdisciplinary team, which is the basis of holistic care. It also connects specialists, thus using people to maximum of their expertise and combining the expertise from different professions. From a policy perspective, telehealth is a cost-effective method of patient care delivery for appropriate patients.

Previously, there has been a lack of focus on telehealth in palliative care education. Palliative APRNs will need to ensure that their knowledge and skills are adequate to provide effective telehealthcare. They will need to monitor legislation about its application, guidelines, and reimbursement.

THE PALLIATIVE APRN IN THE RURAL COMMUNITY

Traci Sickich

KEY POINTS

- Individuals with serious illness who live in rural areas face unique challenges.
- The palliative advanced practice registered nurse (APRN) has the potential to improve the care of these individuals and become a vital resource for patients, families, and the medical community.
- Palliative care can be woven into the social fabric of the rural community and provide a bridge to rural hospice services.

CASE STUDY: RURAL PALLIATIVE CARE

Tom is a 60-year-old man who was evaluated by his primary care provider for persistent abdominal pain, weight loss over 3 months, and frequent episodes of diarrhea with incontinence. Tom lives in a remote town, with the nearest clinic 80 miles away, and he is only able to see a rotating primary care provider when they make scheduled monthly visits. Tom was given a referral for further evaluation at a large medical center 200 miles away, which required travel by air. There, he was found to have metastatic gastric cancer after imaging, labs, and biopsy were completed. Tom proceeded with cancer-directed treatment, including chemotherapy, radiation, and surgical resection of abdominal masses. These treatments required frequent travel out of his rural town to the larger medical community, and, after 2 years, Tom was referred to the palliative care team, who assisted with telehealth visits when Tom was home.

The palliative advanced practice registered nurse (APRN) assisted Tom with navigating local resources in his small community, as well as with coordinating clinic visits when Tom traveled to the city for oncology appointments. In addition, the APRN facilitated navigating goals-of-care discussions, provided support with completion of advance directives, and managed Tom's symptom burden. Balancing in-person clinic visits with rural telehealth visits provided a continuity of care for Tom, who was not only navigating advanced serious illness but also the challenges of rural living. After a number of months, Tom started reporting feeling burdened by having to travel such a long distance for care, stating he was not sure "how much more of this I can take."

Tom's cancer progressed while on chemotherapy, and he chose to pursue immunotherapy that was offered. Unfortunately, immunotherapy was poorly tolerated. At this point, Tom was cachectic, taking hours to eat small meals and balancing nausea

and pain with his oral intake. Tom stated he was spending all day trying to find the energy to eat. As the palliative APRN had a long-standing relationship with Tom, she provided guidance regarding his current functional status. Reminding him that in previous goals-of-care discussions Tom had stated that if he could no longer travel to the large city for care then he would want to spend his final days in his remote town. Tom chose to no longer pursue cancer treatment and decided to focus on comfort, spending all of his time with his family. Tom stated he felt validated and supported in his medical decisions, and he valued the medical input and recommendations shared by the palliative APRN. At his final clinic visit, Tom was suffering from large malignant pleural effusions. The palliative APRN was able to coordinate with the oncology team to have a Pleurx drain inserted for comfort before Tom traveled back home one last time.

Tom's remote town did not have a Medicare-certified hospice but did have a network of volunteers who helped those who wanted to stay in their rural town at end of life. The palliative APRN served a vital role in facilitating the delivery of necessary durable medical equipment and comfort medications and continued to provide virtual visits to Tom's family to assist with end-of-life symptom management. Because Tom was able to stay in his rural town for his final 3 months of life, he was able to participate in meaningful activities, such as being carried by his family to see his daughter graduate high school. He died peacefully 2 days later. The family shared with the palliative care team how important it was for Tom to be home and how thankful they were for the resources and support provided by the palliative care team despite their remote location.

INTRODUCTION

Rural communities across the United States face their own unique challenges that extend beyond the isolated setting. In the context of healthcare, rural populations experience a variety of factors affecting access to care, challenges with models of delivery, and resource limitations, which can lead to disproportionately high levels of healthcare burden and even mortality. There are approximately 60 million Americans who live in a rural setting.¹ Rural America is facing growing health disparities, with an increase in incidence of heart disease, cancer, respiratory disease, and stroke.² These poorer outcomes have been linked to numerous challenges facing

rural communities, including an aging population, increasing rates of poverty, and poor access to healthcare, including fewer available healthcare providers as well as closure of rural hospitals.² In addition to a lack of primary medical facilities, there is a shortage in specialty services, including palliative care. In fact, 90% of hospitals that offer palliative care services are located in urban areas.³

Palliative care is a basic human right, fundamental to health and human dignity for all individuals regardless of geographic location, socioeconomic status, or racial or cultural background.⁴ Access to healthcare, and specifically palliative and hospice care in rural communities, is challenged by geography, provider availability, and rural culture. The rural palliative APRN is identified as meeting a unique need for those facing serious illness compounded by the challenging factors of rural life.

In a healthcare context, populations at risk, such as those in rural areas, have an increased risk of or susceptibility to adverse health outcomes, as evidenced by higher morbidity, premature mortality, and diminished quality of life. Low socioeconomic level and lack of external and environmental resources may contribute to disease susceptibility and are therefore indicators of vulnerability.⁵ The purpose of this chapter is to describe barriers to access and delivery of palliative and hospice care in rural and remote areas, discuss the unique characteristics of rural culture, offer suggestions for developing a rural community palliative care program, provide an update on the current status of rural delivery of palliative and hospice care, and discuss future implications.

The National Consensus Project for Quality Palliative Care (NCP) *Clinical Practice Guidelines* establish a foundation on which quality palliative care is delivered. In relation to rural healthcare delivery, the social determinants of health can have an overwhelming influence on patients who are living with serious illness.⁶ The palliative APRN needs to be cognizant of the impacts of financial constraints, including lack of insurance, and skilled in identifying and addressing the social implications of a serious illness. This assessment is amplified in a rural setting, where it may require more time and increased communication to understand the community resources available or lack thereof. Additionally, the palliative advanced practice registered nurse (APRN) needs to be aware of the influence of culture on how patients and families navigate serious illness and medical decision-making, as evidenced by the NCP domain on culture.⁶ It is imperative for the palliative care team to understand the needs of the community and provide culturally appropriate care by performing a thorough needs assessment of patients who are part of an underserved population.

Significant barriers exist in the United States, as well as in other countries, that limit access to healthcare and palliative care for rural dwellers. For decades there has been a known shortage of healthcare providers in rural areas.⁷ In response, health centers were built, and rural healthcare became a specialty for physicians and APRNs. Federal legislation was created to address the issue of rural healthcare access, which led to the development of Area Health Education Centers (AHECs), National Health Service Corps (NHSC), and Federally Qualified Health Centers (FQHCs), as well as the

creation of critical access hospitals (CAHs).^{7,8} Despite all of these measures, there continues to be a physician shortage in rural settings, with an estimated 80% of rural counties reporting a lack of primary care doctors and concern that this number will rise given the number of those physicians who are age 60 or older.⁹

With the declining number of family practice physicians, changes in reimbursement, and a limited number of professionals who desire to work in rural areas, APRNs have assumed the role of primary care provider for many of these rural patients.¹⁰ According to the American Nurses Association, the *Affordable Care Act* (ACA) fosters the growth of independent practices for the APRN because their skills will be in demand to meet the healthcare needs of those in rural regions and other areas of health disparity.¹¹ Recent research has shown that APRNs working within a full-practice state have a greater impact on access to healthcare, especially in rural communities, which can decrease healthcare disparities in these settings.¹²

However, rural care delivery is different from urban care delivery. Barriers to healthcare access in the rural setting exist at the system, provider, and individual levels and are reflected in the lack of availability of palliative care in these areas.¹³ According to the Center to Advance Palliative Care (CAPC), linear growth is reported for the prevalence of palliative care across the country, now with 72% of US hospitals with more than 50 beds having a palliative care team—an increase from the 7% reported in 2001.³ Research from rural hospitals has shown clinical and financial findings that support the need for and potential benefit of rural palliative care programs.^{14,15} Unfortunately, complicating access to care even further is the recent development of a high concentration of rural hospital closures due to shrinking inpatient volume and more documented revenue occurring from outpatient care.¹⁶ Even though hospital-based palliative care programs are increasing, rural dwellers experience significant barriers to accessing palliative care and hospice services.¹³

Literature review of the role of palliative care in the rural community is limited, with most studies focusing on countries outside of the United States. Systematic reviews have identified barriers that include the geographical dispersion of residents, inadequate financial resources, limited support systems, and lack of qualified medical, psychosocial, and spiritual support to meet the needs of the patient, caregiver, and family.^{17,18} These research findings are consistent with the limited number of studies conducted in the United States and document the same barriers to access and delivery of palliative care.

THE RURAL COMMUNITY

There are three governing bodies that have established the definition of “rural.” The US Census Bureau uses “rural” to encompass all population, housing, and territory not included within an urbanized area (UA) of 50,000 or more people or an urban cluster (UC) of 2,500 to 50,000 people.¹⁹ The Office of Management and Budget uses metropolitan statistical areas (MSAs) to define urban and rural areas. An MSA is a

city with 50,000 or more residents and a surrounding metropolitan area of at least 100,000 people. All non-MSA areas are considered rural. The US Department of Agriculture Economic Research Service collaborated with the Federal Office of Rural Health Policy to develop the Rural Urban Commuting Area (RUCA) System.²⁰ This method utilizes the Census UAs and UCs together with information on commuting to further delineate metropolitan, micropolitan, small town, and rural areas.²⁰ According to the US Census Bureau, in the 2010 Census, 19.3% of the population was classified as rural (59,492,276), while greater than 95% of the land area was classified as rural; by contrast, 80.7% of the population was classified as urban (249,253,271), while 5% of the land was classified as urban.²⁰ In addition to a rural designation, areas may be known as *frontier*. According to the National Rural Health Association, “frontier” is defined as an area with fewer than six people per square mile.²⁰ No matter the definition one chooses, a rural area involves a small population spread over a large distance. The distance and the terrain present unique barriers to healthcare service delivery, including palliative care.

In addition to unique geographical considerations, rural life is a culture within itself, and this cultural lens has its own application to healthcare specifically. The culture of rural living is not bound to a specific geographic location or population but based on “social, structural, and behavioral norms that represent a continuum based on the degrees to which individuals internalize rural culture.”²¹ (p. 6) How a rural dweller defines health affects how they will seek out healthcare as well as influencing how they prefer to live.²² Rural life constructs are centered within rural nursing theory, first developed by Long and Weinert in 1989, who assert that rural-dwelling people define health “as the ability to be productive, to do, not necessarily as the absence of disease.”²³ (p. 120) There is a resiliency in rural people, a desire to be in control of their own decisions, to do and care for themselves.²⁴ Additional distinctive attributes found in studies of rural population include a strong sense of independence, a connection to the land, the influence of faith, and the use of informal networks.²¹

In rural communities, the healthcare provider may encounter clients with low health literacy, especially among individuals who have previously chosen to not seek out providers to address their healthcare needs. Health literacy plays a key role in a patient’s ability to discuss end-of-life care and must be considered and assessed by the palliative APRN. For example, in a family meeting with the goal to create a care plan, the patient or family members may have trouble understanding details the provider is sharing but may be too proud to ask for clarification. Members of the palliative care team can bridge the gap between the patient/caregiver and healthcare providers, eliminating confusion and frustration. They can provide essential support to patients who have never received healthcare but who have been diagnosed with a life-threatening illness and do not know what to do or how to cope with the diagnosis. In these situations, it often takes time to develop trust among the clinician, patient, and medical community, and the palliative care team may serve as a vital intermediary.²⁵ It is important to approach the rural patient

and family with a willingness to listen, rather than judge, in order to keep the path to trust open. Purposeful listening and being fully present are vital to the spiritual and emotional care of the rural palliative care patient.

ACCESS AND COORDINATION OF CARE

Chronic disease is among the most prevalent and costly health condition in the United States, killing an estimated 1.7 million Americans per year and accounting for nearly 75% of aggregate healthcare spending.²⁶ It is estimated that 81% of adults age 65 and older have two or more chronic disease conditions.²⁷ Based on the latest report of *The Older Population in Rural America: 2012–2016*, of the 46.2 million older adults in the United States, 10.6 million of them reside in rural areas, which is an increase from the last report in 2007.²⁸ In addition, the Medicare Payment Advisory Commission (MedPAC) report to Congress illustrates that 20% of Medicare beneficiaries live in a rural setting.²⁹ In a juxtaposition to who in the rural setting is receiving hospice care, the National Hospice and Palliative Care Organization illustrates how the percentage of Medicare beneficiaries enrolled varies from 60% in Utah to 22% in Alaska.³⁰

As the population ages, the number of adults who experience multiple chronic illnesses, cognitive impairment, and related disability and increasing dependency will increase. Many of these older adults in the rural community will be cared for in their home by family members with the support of both formal and informal care systems. There are both benefits and challenges to providing home palliative care in a rural setting. The rural APRN is in the unique position of having amplified social connections and may be called on to care for a close friend. These fluid professional and personal boundaries in the rural palliative care setting create a dual relationship in rural practice of provider and friend, which can create conflicting demands between work and personal requirements.³²

According to Hanson and colleagues, the benefits of palliative care in the rural setting include a familiarity between patient, primary family caregivers, and the formal care provider; flexibility in organizational support; and a vast informal support network of family, church members, neighbors, and friends.³² Challenges to end-of-life care relate to limited resources and caregiver stressors, including service boundaries leading to limited hours or availability of formal services and a lack of qualified caregivers, which increases primary family caregiver stress.³²

Accessing and coordinating palliative care services can be difficult in rural areas. Persistent barriers to accessing palliative care in the rural setting include fragmented services, unclear referral pathway, and lack of available providers.³³ The goal is for palliative care to be patient-centered and family-focused within the context of the patient’s home, thereby addressing the needs of the patient and caregivers. In the rural community, these needs are met through both formal and informal care providers.

Formal care refers to healthcare services commonly provided in the rural areas by a generalist practitioner, a nurse

practitioner (NP), clinical nurse specialist (CNS), or a physician assistant (PA). From 2008 to 2016, there has been an increase of 43% of rural nurse practitioners providing care.³⁴ All rural healthcare providers are engaged in “expert generalist” care with their patients, providing a range of healthcare in a limited resource setting.³¹ Rural patients are faced with limited access to formal care and sometimes need to make decisions on how far to travel to access care based on road or driving conditions.³⁵

Informal care refers to services that are provided by unpaid family members, friends, volunteers, or organizations. Informal care and networks may be a necessity rather than a choice. They reflect some of the strengths of rural relationships, such as social solidarity, close-knit relationships, and community commitments, and they may result in high-quality, integrated palliative and end-of-life services despite scarce resources (Table 18.1).³⁶

RURAL PALLIATIVE CARE PROGRAMS: CONSIDERATIONS

A rural palliative care program must be based on a thorough understanding of the rural community, including its beliefs and customs, prevalent medical diagnoses, and available community resources, including financial and human capital. Rural dwellers tend to have lower financial stability. They experience a consistently higher rate of poverty compared to urban counterparts, earning about 4% less than the median income for urban households.³⁷ Rural Americans are more likely to live below the poverty level and to rely heavily on the Federal Food Stamp Program at a rate of 16% per household compared to 13% in urban areas.³⁸ Disparity in incomes is even greater for minorities living in rural areas. Compared

to the urban population, rural dwellers are less likely to have employer-provided healthcare coverage or prescription drug coverage or to be covered by Medicare benefits, which in turn limits medical service availability.³⁹

There are 4,485 health professional shortage areas in rural and frontier areas, compared to 2,323 in urban areas.⁴⁰ Although nearly one-fourth of the population lives in these areas, only about 10% of physicians practice in rural America.⁴¹ A 2013 survey of family medicine physicians found that, of the 3,000 surveyed, only 33% stated they provided some palliative care. Additionally, the workforce distribution report of hospice and palliative boarded physicians found large disparities in the availability of those working in rural settings, noting a maldistribution problem because many tend to work near large university centers.³⁹ A perspective analysis of rural hospice medical directors illustrated common themes of heavy workloads, limited options for training, physical and emotional stress, and safety concerns related to travel when caring for rural patients at end of life.⁴² It can be extrapolated that APRNs who practice in rural areas mirror these statistics and share these concerns.

DESIGNING A RURAL PALLIATIVE CARE PROGRAM

An important first step in designing a successful palliative care program in a rural community is performing a needs assessment for the program within the community. This focuses on the current state of caring for patients with serious illness, local assets, resources, and stakeholders who recognize the need for palliative and hospice services. High-quality community-based palliative care requires clinical expertise in the field, knowledge around community care delivery, understanding of caregiver assessment, and support, as well as a thorough assessment of the home environment.⁴³ Community engagement is crucial to the success of a rural palliative care program, ensuring community buy-in of palliative care and an understanding of what these services can offer to the community.⁴⁴ Focusing on identifying community values using a respectful lens allows for a collaborative relationship between relevant stakeholders, community members, and palliative care providers.

Understanding the nature of family and community support is crucial to the success of the program. Studies have found that rural dwellers are accepting of barriers to healthcare due to their rurality and therefore are reticent about seeking care. Rural residents tend to *make do* with available resources, *solve their problems* independently, and be *self-reliant*. The sense of *community belonging* in rural culture means that “neighbors know and look out for each other,” and individuals in *close-knit communities* fear sharing their health-related issues and seek care due to privacy issues. These attributes are a source of strength and personal control for rural dwellers but may also be a barrier to seeking out palliative care at end of life.⁴⁵ However, acceptance and knowledge of the unique beliefs, customs, and rituals of rural culture will promote acceptance of the APRN and the palliative care program (Table 18.2).

Table 18.1 BARRIERS TO RURAL PALLIATIVE CARE

BARRIER	INDICATOR
Provider shortages	Difficulty with retention Low provider comfort with palliative care Limited APRN scope of practice
Education	Lack of formal palliative care education Lack of understanding referral criteria
Financial/Policy constraints	Reimbursement regulations Decrease reimbursement rate for rural setting Medicare constraints on definition of hospice care
Geography	Decreased socioeconomic status Lack of resources/accessibility Isolated providers
Patient	Misunderstanding of services Fear of unknown Rural culture

Data adapted from Tedder et al.¹⁷

Table 18.2 RURAL CULTURE INFLUENCE

POSITIVE INFLUENCE	NEGATIVE INFLUENCE
Resiliency	Increase in caregiver burden
Self-reliance	Lack of local support services
Community support networks Friends involved at end of life	Low expectations; “make do”
Attitude of acceptance of death with desire for less interventions	Reluctance to seek care

Data adapted from Kirby et al.⁴⁵

For a palliative care program to succeed in a rural community, healthcare providers must possess cultural competency and communication skills and be able to deliver effective care for patients with diverse values, beliefs, and behaviors. Mass media can be used as a health promotion tool to build community trust. The goal of public education and social marketing is to help people change their health behaviors by acquiring information and education they lack or through verbal and visual messaging that can shift the individual’s thinking, attitudes, and values. Effective use of the media requires positioning oneself as an expert in palliative care and being available *formally* and *informally* to explain, promote, and be a resource for information, referrals, and services.⁴⁶

Not all healthcare can be provided in the rural community itself, and travel may present unique barriers and challenges for the patient and family. As the expert in palliative care, the APRN must understand who to contact for services; how and where to obtain medications, equipment, and supplies; and ways to offer appropriate care that is within the financial means of the rural population. The APRN must also appreciate the benefits and burden of care, recognize when care needs exceed the rural area’s capacity, and when referral to a larger town or city is appropriate and necessary (Table 18.3).

Table 18.3 CORE COMPONENTS OF A RURAL PALLIATIVE CARE PROGRAM

COMPONENT	DESCRIPTION
Training and education	Offers local rural opportunities for providers and staff
Telehealth utilization	Increases patient access in rural setting
Clinical pathways	Creates accessible bridges between hospital, clinic, and home care
Concise payment/ Reimbursement structure	Leverages state and federal guidelines
Inclusion of community stakeholders	Creates a model based on each community, tailored to specific resources and needs

Data adapted from Hawkins-Taylor et al.⁴⁸; and Crooks et al.⁶⁸

TRAVEL FOR SPECIALTY
HEALTHCARE SERVICES

Distance, roadways, and weather conditions are significant factors when patients consider the commute for specialized healthcare services not available in the rural community. In a mountainous area, a 50-mile commute may take 3 hours. Early in the disease process, this may be acceptable to the patient, but as the disease progresses and treatments continue, the patient may decide the time burden is too much and may decide not to leave the community for care or may relocate to the urban area to be closer to specialized services. The costs for transportation, food, and lodging, as well as the time commitment are important considerations.¹⁷

Transportation is a common barrier for the rural dweller because public transportation may not exist or may exist for local areas only. Moreover, such transportation may be costly and time-consuming. The patient may already be experiencing financial hardships due to treatment and must then rely on family and friends for support and transportation. Family and friends must take time from work to drive the patient to the city and stay with the patient either for the day or several days, depending on the treatments required. Financial support is generally shared by family and friends. Many treatment facilities have agreements with agencies that provide lodging and meals for patients and caregivers at a reduced rate.

In addition to the considerations of time and cost, commuting may be anxiety-provoking for the patient who feels he or she is a burden to the family and community. Travel can also create significant anxiety for the caregiver. Strategies for coping with commuting include careful preparation for the trip, maximizing a routine, managing time, and maintaining significant relationships. Additionally, it may require care coordination to consolidate multiple provider appointments in the same day to ease the burden of travel. Anticipation of weather and traffic delays, planning for food and rest stops, scheduling pain medications and other pharmacologic agents to maintain analgesic coverage during the commute, and sharing quality time together may decrease the patient’s anxiety.⁴⁷ Worries about the feasibility of continuing the care plan once the patient returns home may also cause anxiety, and these concerns should be specifically addressed by the palliative APRN. The patient may not spontaneously provide information about relevant stressors, so the APRN will need to elicit this insight with sensitive and careful questioning.

Conversely, from the provider perspective, it is not the mileage alone but the road conditions (e.g., curves, elevation) and weather conditions (e.g., flooding, mud, snow and ice) that make it daunting for a provider to make a house call or for the patient to make a clinic visit. Considerations must be given to distance, travel time, and visit time. A community APRNs in rural areas may be only able to do 1-2 visits as day.

SITUATIONS OF LOST TO FOLLOW-UP
CARE AND ABANDONMENT

Being “lost to follow- up” in their own community is another concern for patients who choose to travel out of the rural area

for care. Such patients may lose contact with their local provider. The APRN can bridge this gap by assuming “ownership” of the patient’s case (acting as case manager) when the patient is referred, while the patient is under the care of providers in distant cities, and when the patient returns to the community. Frequently, the APRN serves as the communication link by providing continuity of care for the patient and family, including providing the referring provider with updates on the patient’s status and plan of care. Communication, either in person or by telephone, is paramount with this patient population to prevent the patient from being “lost to follow-up care.”⁴⁸

Another way in which patients may be “lost to follow-up care” may occur when there are limited or no palliative care providers in their rural area. If there are no defined palliative care services, their primary healthcare professional is expected to provide these services and coordinate their care. If their healthcare professional lacks primary palliative care education and training, the treatment plan that was established when the patient was discharged may not be continued. The patient may experience untreated, undertreated, or overtreated pain and symptoms, both physical and psychological.

The patient who does not have a primary care provider and who was not referred to a primary care provider by the discharging facility is at a great disadvantage. If the lack of a primary care provider is not recognized by the family and friends, the patient will truly be “lost to follow-up care.” To avoid these situations, a *rural–urban referral system* needs to be established. The APRN formulates and maintains a list of contacts in other facilities, communicates with the facility when a patient is referred, maintains verbal and written contact during the admission, monitors for the expected time of discharge, and anticipates the patient’s needs prior to their return to the rural community.

Second, the unfamiliar language of palliative care may be a barrier to rural patients, family members, and healthcare professionals who equate palliative care to hospice care. Hawkins-Taylor found that, in rural South Dakota, 73% of rural residents were unable to define the concept of palliative care.⁴⁸ Lack of understanding around the definition of palliative care can lead to rural patients experiencing disproportionate access to palliative care services. The existence of documented low health literacy among rural patients, combined with a rural culture of resiliency, individualism, and reticence in seeking care, may negatively affect the ways in which rural patients perceive specialized palliative care and discourage them from accessing these services.

Third, navigating the bureaucratic healthcare system may be a challenge for members of rural populations. It can be difficult to know what agencies to contact for help with securing medical services, obtaining financial resources to pay for medications and living expenses, and coordinating home health services and equipment. Challenges related to navigating the complex and often fractured healthcare system can cause emotional and psychological stress for the patient and family members who have always been self-sufficient and “do whatever it takes” to make things work. To address this concern, a community resource information flyer or magnet can

be developed, including the name of the facility or organization with relevant contact addresses and telephone numbers. If there are no hospice services in the patient’s rural area, the APRN should coordinate alternate providers for services, such as grief support to be provided by the funeral home or local clergy; pain and symptom management to be provided by emergency medical personnel or community members with appropriate medical skills; and support services, such as meals, respite care, transportation, and performing necessary errands to be coordinated through local churches and service organizations. Importantly, the ongoing development of coordinated palliative services and the provision of fundamental palliative education for healthcare professionals and the community will help to alleviate this stress and ultimately change the cultural attitude toward palliative care.

SITES OF CARE AND WORKFORCE

Many rural dwellers prefer to die at home, in their community or village, with family and friends present at the time of death because there is a strong connection between place and self in the rural setting.⁴⁹ The ethnography work of Rainsford found that rural patients equate a “good death” with that of a “safe death,” meaning that one’s identity was preserved, autonomy respected, and control maintained over decisions around end-of-life care.⁴⁹ The perception of a “safe death” is also rooted in creating a safe physical place, whether that be the rural homestead where one has a connection to self and memories or the rural hospital where a patient may still receive personal attention from well-known caregivers. The limited number of healthcare professionals trained in primary or specialty palliative care, homecare and volunteer services, nursing home beds, and/or alternate sites of care may create barriers to rural palliative care. If the family cannot care for the patient, it may be difficult to locate a skilled nursing facility close to the patient’s home. This scenario is common in rural areas in Alaskan villages as well as in Appalachia and other mountainous regions.

As noted earlier, the shortage of healthcare professionals and facilities in rural communities continues to be an issue for the APRN to address in order to provide continuity of care. MacDowell and colleagues conducted a nationwide survey of 1,031 rural hospital CEOs to determine if they perceived a shortage of healthcare professionals in their area.⁵⁰ Seventy-five percent of the responders reported shortages of all healthcare professionals (the survey did not address palliative care specialists.)⁵⁰ To address the shortage of rural physicians in the United States, the “Conrad State 30” program was developed to recruit foreign-trained physicians to work in rural areas in exchange for permanent residence. A similar program exists for APRNs and nursing faculty to serve in critical shortage facilities and accredited schools of nursing. The program pays 60% of their unpaid nursing student loans for 2 years of service and an additional 25% of the original balance for an optional third year.⁵¹ Continuing to pave the way for advancement

in education, work in Congress continues to push for the *Palliative Care and Hospice Education and Training Act* (PCHETA). This act, if passed, allows for an increase in the number of permanent faculty in palliative care at accredited programs, awards grants or contracts to academic programs (medical schools and nursing schools) and teaching hospitals, provides career incentive awards, and creates special preferences in existing nurse education to promote retention projects and workforce development.⁵²

Given the economic burden that serious illness places on rural dwellers, it is important to note the potential cost savings that a palliative care program can have at multiple system levels. Palliative care programs save hospitals money through cost avoidance (decreased daily costs, decreased length of stay, increased hospice referrals), as well as by supporting a home healthcare model to reduce emergency room visits and hospitalizations in general. One study found that a hospital with more than 50 beds that has a palliative care service can see a savings per patient per admission of \$2,659, which translates to an estimated \$1.2 billion in savings per year nationally.⁵³ In the rural setting, this economic savings would be seen at the hospital level due to decreased need to seek tertiary care if health needs are addressed in the community setting. Significant cost savings can occur for the patient as well, who will not have to travel as far for supportive health care.

FAMILY AND COMMUNITY SUPPORT

The challenge for the palliative APRN and the interdisciplinary team in the rural community is to coordinate formal and informal services to meet the needs of patients and caregivers. As noted earlier, rural dwellers tend to be reticent to seek care, possibly in part due to their inability to access and understand healthcare information (low health literacy), which impedes their acceptance of healthcare interventions.

Communication is a critical component of this coordination and is paramount to the peace of mind of the patient and caregiver. Additionally, communication around end-of-life concerns, critical medical decision-making, and the many stressors related to the experience of serious illness requires an additional skill set for the healthcare provider. Patient- and family-centered communication requires that the APRN is comfortable and competent in meeting the complex needs of patients with a life-limiting illness.⁵⁴

Frequently, the APRN is the leader of the palliative care team (officially or unofficially) and is responsible for care coordination from the patient and family perspective. By holding a family meeting to explore goals of care, the APRN can ensure that the patient's and family's perceived needs are met, including medical, financial, physical, and spiritual needs, as well as other requirements specific to the patient/family culture and belief systems. As part of the family meeting, the palliative APRN should discuss each member's perception of the shared information, should help determine what services are needed, should make necessary referrals, and, within 24 hours, should provide the patient and family with a written plan of care.

Providing information about the patient's illness, including how the condition will progress, the patient's life expectancy, and specific treatment options is an important aspect of care. As health literacy levels are reported to be low in many rural populations, patients and families may be confused about the disease process and treatment options, and their understanding and perceptions are often overshadowed by cultural beliefs and rituals. Assessing understanding and filling in knowledge gaps is a critical function of the APRN and is even more pronounced in the fractured rural healthcare system.

Teamwork is essential to the delivery of rural palliative care. The independence, cooperation, and collaboration evident in rural communities are the strengths that allow the APRN and healthcare professionals, family, and community to meet the needs of the patient, even though resources may be lacking.

COMPETENCIES FOR THE RURAL APRN

Whether palliative services are delivered using a specialist or generalist model, the APRN's educational needs are essentially the same. The American Nurses Association and the Hospice and Palliative Nurses Association jointly state that nursing education is rooted in primary palliative nursing skills, including advance care planning, basic pain and symptom management, and assessment of patient and family needs.⁵⁵ However, in the community, competence is necessary in pain and symptom management, addressing spiritual needs, assisting with the creation of advance directives, identifying psychosocial concerns, and providing family support. Barriers to professional development for rural practitioners include geographic and professional isolation, time constraints, workload, and lack of professional coverage during absences. Various modalities exist to acquire training and maintain skills; unfortunately, one-on-one and classroom presentations appear to be both the most rewarding for rural healthcare practitioners and the least accessible.

In the generalist model, there has been consistent evidence citing a lack of providers trained in primary palliative care. Core competencies of primary palliative care include physical, psychological, social, and spiritual assessment, as well as communication.⁵⁶ Even specialist palliative APRNs described a lack of palliative care education in their graduate curriculum.⁵⁷ Identified barriers for providers training in primary palliative care include lack of knowledge of the field of palliative care, absence of an interdisciplinary team, professional time constraints, lack of funding for educational opportunities, and lack of access to a palliative specialist.⁴⁴

The American Association of Colleges of Nursing has addressed this by developing competencies for all APRNs who pursue graduate education. These competencies include the assessments previously listed, as well as interprofessional collaboration to provide patient-centered and family-focused care, application of evidence-based care, legal and ethical issues in prescribing and de-prescribing medications,

communication expertise in primary palliative care skills, and complex symptom management related to serious illness.⁵⁸

The role of the palliative care specialist is further complicated by the tendency of some rural populations to have more trust in their “local expert” and therefore be less likely to seek care from specialists not known to their community.⁵⁹ Studies on APRN autonomy and satisfaction have found that while rural APRNs work more hours, this is balanced with greater practice autonomy, and APRNs report being highly satisfied with their work in rural communities, which improves retention.⁶⁰ The culture of a rural APRN has its own challenges and benefits, just as the rural culture does itself.

Given the importance of communication and collaboration in palliative care, as well as the geographic challenges just identified, generalist and specialist palliative APRNs should be able to incorporate telemedicine into their practice. *Telemedicine*, also known as *telehealth* or *health information technology*, is a rapidly developing application of clinical medicine using telephone, computers, the internet, and other networks to advance the delivery of rural and remote healthcare. Telehealth facilitates the exchange of information and knowledge regardless of geographic or environmental barriers while reducing access time and costs. Holland and colleagues demonstrated positive results using health information technology for rural palliative care and hospice patients and families, such as improved quality of life and satisfaction with care, reduced hospital readmissions, and reduced healthcare costs.⁶¹ The use of telehealth has increased despite ongoing rural barriers such as the availability of internet or broadband connectivity in remote locations and variable reimbursement from Centers for Medicare and Medicaid Services (CMS) for telemedicine services. CMS announced in 2020 an initiative to improve rural and telehealth access, the *Community Health Access and Rural Transformation (CHART)* model.⁶² This model aims to modify reimbursement to help ensure financial stability for rural providers and provide waivers that increase operational and regulatory flexibility, thereby enhancing beneficiaries’ access to services by increasing the ability for rural providers to stay in practice.⁶² Additionally, during the COVID-19 pandemic, CMS adapted telehealth policies to allow for increased reimbursement while limiting restrictions on telehealth related to its use by rural providers.⁶³ It is hoped that these regulations will continue after the pandemic (see Chapter 17 on the “Palliative APRN in Telehealth”).

RURAL HOSPICE

In the United States, the number of hospice agencies has decreased in the past 10 years. Currently, there are 878 rural hospices per the *2019 MedPAC Report to Congress*.⁶⁴ While there was a 2.6% decrease from 2016 to 2017 alone, there was a simultaneous increase in the percentage of rural Medicare beneficiaries who utilize hospice services.⁶⁴ Hospice care in the rural community has unique elements, including staffing by local citizens or volunteers, limited resources, and large geographic areas. Rural hospices are often a real part of the social fabric of their communities.

Changes from CMS as mentioned earlier have provided an updated wage index model and payment allocation for the different types of hospice care. Historically, hospices were reimbursed at a daily rate at \$17 less per day than their urban counterparts.⁴² The new proposed payment model is forecasted to provide a 3% increase in revenue for nonprofit and a 0.8% increase in for-profit hospice agencies.⁶⁵

Historically the role of the APRN has been limited in hospice as the eligibility form known as Certificate of Terminal Illness requires a physician signature. The rural community may benefit from a wider scope of practice for APRNs to provide continuity of care from the palliative care setting by creating a bridge to the hospice setting, particularly as an estimated 16% of Medicare beneficiaries report seeing an APRN or PA for their primary care services, which is a higher percentage than for urban beneficiaries.⁶⁶

Difficulties with maintaining financial stability may be accelerating the recent decline in the number of rural hospice agencies. Other healthcare delivery factors that affect rural hospice care include demographic changes in the rural community (i.e., availability of volunteers or an aging workforce), rural economics, and travel time for the hospice staff. Frequently, “windshield time” or lengthy drive times in rural locations can have a negative impact on care and present a reimbursement challenge. Time lost to driving may increase a nurse’s workload and result in lost productivity as well as in the ability of a provider to respond to a hospice emergency.⁴² With the aforementioned reimbursement changes, these historic difficulties may be changing the future landscape of rural hospice programs.

THE REALITY OF RURAL LIFE

Imagine a patient in a rural area with no access to healthcare. The patient receives a terminal diagnosis after visiting a city following a bad fall. The patient views the healthcare providers as haughty and only wanting money. A specialist offers aggressive treatment that may cure the patient’s disease. After several meetings and treatments, the patient gradually lets down his defenses and finds he not only trusts this clinician, but has also developed a sense of dependency on her because she offers a possible cure. However, the treatments stop working or do not achieve cure and actually make the patient sicker. At some point, the patient is told there is nothing more to be done, and he should go home and die. Imagine the level of distrust with the larger medical community that could result, as well as potential feelings of abandonment and thoughts around missed time with loved ones. Quality of life needs to be addressed early, especially in rural patients whose persistent barriers to healthcare can lead to poor outcomes.

The remedy is to begin palliative care early, soon after the diagnosis, and to collaborate with rural care providers. A shift toward seeing palliative care as part and parcel of care, rather than a last resort, is very welcome. In this way, palliative care becomes concurrent care, a bridge to support the patient and family throughout the journey of serious illness, whatever its length. Palliative care should be woven seamlessly

into treatment to reduce families' stress levels and improve patients' quality of life throughout their illness and in their final days.⁶⁷

SUMMARY

Palliative care is both a specialty and a philosophy of care that has evolved over many decades. Central to its practice is the development of an informed and compassionate approach to care for the chronically ill patient and family. Palliative care views the patient and family as a unit. Its goal is to improve the quality of life for both by treating pain and other symptoms; providing time-intensive communication; supporting complex medical decision-making; ensuring practical, spiritual, and psychological support; and coordinating care across all settings.

The palliative APRN serves a vital role in addressing whole-person care for those with serious illness, and this role is amplified in the rural community. The rural palliative APRN is woven into the social fabric of the rural community, addressing physical, spiritual, and at times complex social needs, thereby requiring an expert generalist model in order to provide competent care. In larger communities where resources are "just around the corner," this is more easily accomplished. However, in rural communities, where 80% of palliative care is provided by non-physician providers, the challenge for the APRN and members of the healthcare team is to design a community-based palliative care program that allows a seamless transition from curative care to comfort care while meeting the needs, wishes, and expectations of the patient and family.

THE PALLIATIVE APRN IN RESIDENTIAL FACILITIES

Melissa McClean and Victoria Nalls

KEY POINTS

- There is growing evidence that advanced practice registered nurses (APRNs) in residential facility settings such as assisted living facilities and nursing homes improve clinical outcomes for residents with advanced illness.
- APRNs with specialized training in palliative care are uniquely suited to elevate the quality of care for facility-dwelling individuals by assisting in the continuum of care: facilitating advance care planning, providing expert symptom management, and coordinating care during transitions.
- Implementing and sustaining APRN-led care models in these settings can be challenging due to regulatory restrictions on APRNs that impact scope of practice, variability in care delivery models, and a shortage of professionals educated and trained to support residents requiring palliative and end-of-life care.
- APRNs have the potential to lead facilities in education and training, process improvements, and culture change initiatives.

CASE STUDY: GOALS OF CARE

Ralph was an 87-year-old African American man who lived in a nursing home. Ralph's past medical history included hypertension, history of myocardial infarction, diabetes, peripheral vascular disease, chronic obstructive pulmonary disease (COPD), chronic kidney disease (CKD) Stage II, osteoarthritis, peripheral neuropathy, and mild dementia. Prior to residing in a nursing home, Ralph lived at home but had trouble managing his complicated medication regimen. Due to misunderstanding his medications, Ralph endured several hospitalizations. His daughter, Ralph's surrogate decision-maker, decided it was unsafe for him to live alone and moved him into the nursing home. Upon admission to the nursing home, the facility medical director completed Ralph's admission assessment. The facility-employed advanced practice registered nurse (APRN) continued to see Ralph for ongoing care. He initially received skilled therapy services for debility after the hospital. However, a short time later, he declined to participate because he resented being placed in a nursing home.

Three months into his stay, his nurse reported to the APRN that she has noticed Ralph huffing and puffing on occasion. Ralph reported he found it hard to breathe in the afternoon if he wheeled

himself around the facility "too much." He felt much better after pausing, taking some deep breaths, and resting. He denied any pain or difficulty getting air. Ralph still actively smoked and told the APRN, "Don't even tell me about stopping . . . going outside and smoking is the only thing that makes me happy in this awful place." His vital signs were stable at rest, but became elevated after activity. His mini-mental status examination (MMSE) was 24/30. His exam revealed displaced point of maximal impulse (PMI) with regular heart sounds, noted rales in the lung bases, normal bowel sounds, and +1 bilateral pedal edema.

To determine the plan of care, the APRN asked him what was most important to him, to which he replied, "I just want to go home." The APRN explored this sentiment a little further and learned that Ralph valued independence and disliked that staff dictated his day. Since he could not return home, he wanted to make sure that he could continue to go outside and smoke. When asked what he understood about his current medical situation, he stated, "I am old, and I haven't always taken good care of my body. If it's my time, then I want to go." The APRN attempted to explore this further, but Ralph was reluctant to talk about end-of-life wishes. When asked about his time in the hospital, Ralph shared that he disliked the hospital even more than the nursing home. The APRN shared with Ralph that she thought he may have heart failure, but they could manage his symptoms in the nursing home. Ralph was skeptical about the diagnosis of heart failure and asked for further evidence. The APRN provided two options that aligned with Ralph's preferences: facility work-up or cardiology consult. Ralph declined the cardiology consult, stating "I don't need any more doctors in my life." The APRN ordered an echocardiogram, chest x-ray, and lab work to be done in the facility. She also started Ralph on a diuretic.

The chest x-ray showed cardiomegaly with no active disease. Ralph's ejection fraction was 30%, and his blood work showed mild hyponatremia, CKD Stage III, and mild anemia. The APRN asked Ralph if she could include his daughter in a conversation for next steps. He confirmed his daughter as his medical power of attorney. A family meeting was held to plan the most appropriate treatment course.

At the end of a long conversation, the APRN summarized what she heard to be most important to Ralph. His daughter acknowledged his requests, and they completed an advance directive and a provider/physician order for life-sustaining treatment (POLST) form. The APRN also reviewed Ralph's medications and discontinued some medications that were no longer congruent with his goals of care. The most difficult topic was Ralph's smoking, which he was adamant he would not stop. The APRN helped the daughter understand that, although it

is not the healthiest choice, it made Ralph happy. The final plan included a do-not-resuscitate/do-not-intubate (DNR/DNI) order, transfer to a hospital for acute injury only, and managing Ralph's symptoms based on maintaining his ability to get outside and smoke. The APRN documented the conversation and billed for an advance care planning visit of longer than 30 minutes. She also communicated the changes to the physician, nurse, nursing assistant, and social worker of the facility.

A few months later, the APRN walked into the facility and found the nurses on Ralph's unit slightly panicked and reaching to call 911. Ralph had been found in his room lethargic, febrile, and with difficulty breathing. There was a concern he may have had COVID-19. The APRN reminded the staff of Ralph's preferred wishes and insisted on reviewing his POLST form and calling the daughter before calling emergency medical services (EMS). After a brief report from the APRN, the daughter agreed that Ralph would not be transferred to the hospital and comfort measures would be instituted in the nursing home. The APRN followed facility protocol regarding possible SARS-CoV-2 and adjusted Ralph's medications to include only those needed for symptom management. She donned her appropriate personal protective equipment (PPE) and assisted staff in making Ralph comfortable. She connected Ralph with his daughter through video chat. Ralph's daughter saw her father and asked if he was dying, to which the APRN replied, "Yes, I think he is dying." The daughter said good-bye to her father and thanked the APRN for engaging them in that important conversation months ago. Although Ralph's daughter was sad to lose her father, she stated that she felt some peace knowing she was able to follow her father's instructions. Ralph died within 2 days, in the comfort of familiar faces, voices, and surroundings.

year 2030.¹ Currently, 49 million Americans are 65 and older. These older adults are disproportionately affected by chronic disease that impacts their ability to remain independent.² The leading causes of death among older adults—cardiovascular disease, diabetes, lower respiratory diseases, and dementia—can limit older adults' ability to perform daily activities and result in the need for long-term services such as institutional or residential care.³ This chapter focuses on the care provided by advanced practice registered nurses (APRNs), specifically nurse practitioners (NPs) and clinical nurse specialists (CNSs), in two long-term care settings: assisted living facilities and nursing homes (see Table 19.1). NPs and CNSs have been practicing in various facility settings for more than three decades and demonstrate the ability to successfully manage the complex conditions of residents in long-term care settings.

DESCRIPTION OF FACILITY SETTINGS

ASSISTED LIVING

Assisted living (AL) facilities provide a variety of services for individuals who can no longer live independently but do not require continuous skilled nursing. AL facilities may be associated with skilled nursing homes or be a component of continuing care retirement communities and/or independent communities. Often the living arrangements resemble an apartment or private room, and typically AL facilities are private pay. Currently, there are approximately 28,900 AL communities with nearly 1 million licensed beds in the United States. The median stay of an individual in AL is about 22 months, and about 60% of AL residents will transition from an AL environment to a nursing home.⁴

INTRODUCTION

Currently, in the United States, people are living longer despite the occurrence and progression of chronic diseases. The fastest growing age group in the United States are those 65 and older, with one in five people expected to be 65 or older by the

NURSING HOMES

Like AL facilities, nursing homes (NH) provide a wide range of services, but additionally they offer continuous nursing care and rehabilitation services. NH residents typically have more complex health conditions and reside in a bedroom

Table 19.1 RESIDENTIAL FACILITY DEFINITIONS

Long-term care	A broad term that describes any facility where residents receive assistance with their medical needs and/or daily activities over a long period of time. Types of facilities include board and care homes, assisted living facilities, nursing homes, and continuing care retirement communities (CCRCs).
Assisted living	A facility that offers residents assistance with daily activities and some medical care but does not provide 24-hour nursing care. These facilities are usually regulated by the state and typically private pay, although some states may provide coverage via Medicaid waivers. Residents often live in apartments or private rooms with shared common areas.
Nursing home	A facility that offers residents assistance with daily activities, continuous nursing care, and supervision. These facilities are mostly both state and federally regulated and typically funded by Medicaid or private pay. Residents can live in private or shared rooms with shared common areas.
Skilled nursing facility	A nursing home that provides short-term post-acute skilled rehabilitation and/or daily skilled nursing service under the Medicare Part A benefit. Often the goal for residents on the skilled unit is to return home. Most nursing homes function and provide services as both nursing facility and skilled nursing facility.

within the facility rather than in an independent apartment. These residents require 24-hour skilled nursing care and supervision. NHs are mostly funded by Medicare and/or Medicaid programs depending on the services offered by the nursing facility. There are approximately 15,600 NHs with 1.7 million licensed beds in the United States. Approximately 1.4 million individuals live in NHs, with 84% of these residents over the age of 66, predominantly female, and non-Hispanic White.⁵

THE APRN IN FACILITY SETTINGS

APRNs including NPs and CNSs have been directing and delivering care in NHs since the 1970s. Those with enhanced training in the medical complexity of long-term care residents have positively impacted resident and facility outcomes.⁶ Prepared with a foundation in baccalaureate nursing, APRNs achieve an advanced level of knowledge through either graduate- or doctoral-level education. Upon successful completion of their program, APRNs also obtain national certification in advanced nursing practice and, often, specialty practice.

NURSE PRACTITIONERS

NPs participate in both direct and indirect care roles in facility settings. The number of these providers working in NHs has steadily increased over the past few decades.⁷ According to the American Academy of Nurse Practitioners (AANP), approximately 11.7% of the 290,000 NPs licensed in the United States hold privileges in long-term care.⁸ Of the NPs designated by certification, approximately 1.5% hold a specialty certification in hospice and palliative care. It should be noted that specialty certification is not mandatory, and therefore NPs who practice primary palliative care as part of general primary care or geriatrics are not recognized by this statistic. As direct care providers, NPs have expertise in assessing, diagnosing, and managing patients with complex health conditions, with a focus on interdisciplinary coordination of care.

CLINICAL NURSE SPECIALISTS

CNSs have expertise in affecting systems of care, including planning for, implementing, and evaluating improvements in quality and safety. Based on a recent systematic review, Salamanca-Balen et al. conclude that the role of the CNS in palliative care, and specifically in long-term care settings, is poorly recognized and not clearly defined.⁹ Furthermore, the National Association of Clinical Nurse Specialists (NACNS) does not differentiate the number of licensed CNS providers working in long-term care settings, nor does it differentiate the CNS providers holding certification in hospice and palliative care.¹⁰ Though these statistics are unclear, the education and certification required of a CNS complements the quality of care provided to residents in facility settings.

THE INFLUENCE OF STATE AND FEDERAL REGULATIONS

State and federal regulations significantly impact the management and day-to-day operations of long-term care facilities. It is important that an APRN practicing in either an AL or NH has a working knowledge of these regulations to ensure compliance and successful functioning within the facilities.

ASSISTED LIVING

The licensing and certification requirements for AL, along with the requirements for AL administrators, are dictated and enforced predominately at the state level. There are a few federal laws that apply to AL facilities, but mostly each state specifies which facilities qualify as AL communities. Between 2018 and 2019, many states updated plans to prevent or address potential abuse or neglect, requirements for staff training, emergency preparedness, and life safety plans.¹¹ APRNs practicing within an AL settings should become familiar with their state-specific regulations.

NURSING HOMES

NHs are governed by both state and federal regulations. The Foundation for Nursing Home Regulations was established in 1987 by the *Omnibus Budget Reconciliation Act*, also known as the Nursing Home Reform Act. For an NH to participate in Medicare and Medicaid, it must comply with requirements from the Centers for Medicare and Medicaid (CMS) for long-term care facilities. Some example requirements include having sufficient nursing staff, developing a comprehensive plan for each resident, maintaining the dignity and respect of each resident, providing activities of daily living assistance as appropriate, and promoting each resident's quality of life.¹²

REGULATIONS AND STANDARDS

As a federal entity, CMS is responsible for monitoring the quality of care and enforcing care standards at a national level. State surveyors employed by CMS conduct an on-site evaluation of the facility at least annually and investigate complaints from the public, residents, or facility employees should they occur. On-site evaluations are unannounced and involve a team of healthcare professionals. The focus of the evaluation includes assessment of patients' conditions, rights, and needs; assessment of facility's policies and procedures; assessment of medication management and skin care; and assessment of the facility environment, including food and service. Information is gathered from the medical record, interviews with patients (or patients' legal representative), and discussions with facility staff and medical providers caring for patients. If an evaluation reveals a failure to meet a standard(s), the facility may be issued a deficiency citation that requires action; this is called a *plan of correction* (POC). The POC must include corrective actions for (1) those patients affected by the deficiency, (2) identifying other patients who are also potentially affected by the deficiency, and (3) ensuring that the deficiency will not

recur. The POC must also include use of the facility’s quality assurance program to monitor the systems, policies, and procedures for ongoing compliance.

Deficiencies are classified on the seriousness of the offense, from being isolated and less serious to being widespread and very serious. Deficiencies are also judged according to severity, ranging from “no actual harm with potential for minimal harm” to the patient to “immediate jeopardy to resident health or safety.” Remedies are imposed based on the scope and severity of detected deficiencies and include required in-service training for the staff, fines to the facility or denial of payments for services provided, replacement of the facility administrator with temporary management, or installation of a state monitor in the facility. Ultimately, the failure of the facility to comply with standards can result in CMS revoking the facility’s certification.

CARE OF RESIDENTS

Long-term care facilities are compromised largely of frail older adults with several comorbid conditions. As such, these facilities are a challenging setting for clinical practice. CMS began the National Nursing Home Quality Initiative (NHQI) in 2002. From this initiative, NHs created Quality Measures based on the resident’s assessment data to include the resident’s physical and clinical conditions, their preferences, and life care wishes. In 2003, the Quality Measures were added to the Nursing Home Compare website, which is a site that allows the public to review and compare Medicare- and Medicaid-certified nursing homes’ inspection results across the country.¹³ In 2008, CMS implemented the Five Star Nursing Home Quality Rating System to facilitate easier interpretation of Quality Measures. The rating system is a 1- to 5-star scale, with NHs receiving 1 star considered to have below average quality care and NHs with 5 stars considered to have above average quality care. NHs receive a star rating for three types of performance measures domains, as well as an overall star rating. The three performance measures include Health Inspections, Staffing, and Quality Measures.¹⁴

Under regulation 483.25 *Quality of Care in the State Operations Manual*, CMS provides guidance on the assessment, management, and care planning for an NH resident approaching end of life.¹² Additionally, use of the ABCDE mnemonic is suggested as an approach to manage symptoms of residents with serious illness (see Table 19.2). The following must be accomplished and documented for NH residents approaching end of life: (1) identify the resident’s prognosis on the basis of a comprehensive assessment, (2) advise and educate the resident and family about palliative care and hospice, (3) discuss advance care planning (ACP) and document those parties involved (resident, family, interdisciplinary team), and (4) delineate the resident’s preferences regarding care. The developed plan of care must be reviewed and revised on a consistent basis to ensure services provided to the resident align with the wishes of the resident and family. Should an NH resident or designated healthcare surrogate elect hospice, documentation should reflect coordination of care between the facility and hospice.¹⁵

Table 19.2 ABCDE MNEMONIC

A	Ask the resident or legal representative about pain and other symptoms related to end of life on admission and periodically thereafter. Assess regularly and systematically for symptoms and their impact on the resident.
B	Believe the resident’s report of pain or other symptoms, then inquire what causes it and what makes it better or worse.
C	Choose symptom control options that are person-centered.
D	Deliver timely, coordinated interventions.
E	Empower the resident to participate in advance care planning to the extent possible. Evaluate the effectiveness of implemented interventions.

Adapted from CMS: State Operations Manual Appendix PP – Guidance to Surveyors for Long-Term Care Facilities.¹²

In 2016, CMS’s *Requirements for Participation for NHs* were revised to reflect the advances of medicine, service delivery, and safety. The changes included reducing the number of avoidable hospitalizations and healthcare-associated infections, enhancing person-centered care and behavioral/mental health management, providing culturally competent trauma-informed care, and utilizing technology and electronic health information exchange.¹⁶ Care provided by APRNs in long-term care has been shown to positively impact quality measures.¹⁷ For example, APRNs have successfully reduced avoidable hospitalizations.¹⁸ They have also led quality improvement projects addressing antibiotic stewardship and de-prescribing that positively impact the above-mentioned quality measures.¹⁷ Other possible roles for APRNs in long-term care include pressure ulcer prevention, overseeing wound rounds, providing staff education, and strategies to minimize psychotropics for behavioral and psychological symptoms of dementia.

REGULATORY RESTRICTIONS ON APRNS

Leveraging APRNs to care for residents in long-term care has been met with regulatory and cultural barriers. The scope of practice for APRNs varies by state, and some states limit the autonomy and prescribing practices of APRNs. Additionally, CMS has specific limitations for APRNs working in NHs. For example, APRNs are not allowed to conduct and bill for the initial skilled nursing facility admission visit nor write the admission orders. This limitation could impact the quality of care for the short-stay resident who is at risk of hospital readmission within the first 30 days of skilled nursing facility care. APRNs performing initial assessments could help mitigate this risk by identifying a resident’s decline sooner. APRNs also cannot sign a *Certification of Terminal Illness* required by the *Medicare Hospice Benefit* that allows a patient to transition to hospice care. These assessments are deemed complete only when performed by a physician. Other limitations to the APRN practice in NHs are outlined in Table 19.3.

Table 19.3 APRN APPROVED VISITS AND ACTIVITIES IN SKILLED NURSING FACILITIES

	INITIAL COMPREHENSIVE VISIT AND ADMISSION ORDERS	REQUIRED VISITS AS OUTLINED IN 483.30(C)(1)	MEDICALLY NECESSARY VISITS	CERTIFICATION AND RECERTIFICATION FOR MEDICARE A
Skilled nursing facility (Medicare A stay)				
APRN employed by the facility	May NOT perform or sign	May perform alternating visits	May perform and sign	May NOT sign
APRN NOT employed by facility	May NOT perform and sign	May perform alternating visits	May perform and sign	May sign subject to State regulation
Direct admission to nursing facility/LTC (NOT Medicare A stay)				
APRN employed by the facility	May NOT perform or sign	May NOT perform	May perform and sign	NA
APRN NOT employed by facility	May perform and sign if a physician approved in writing a recommendation for admission to the facility prior to admission	May perform	May perform and sign	NA

Adapted from CMS: State Operations Manual Appendix PP—Guidance to Surveyors for Long Term Care Facilities.¹²

Culturally, the acceptance of APRNs as providers within the long-term care settings is still evolving. Some residents, families, and staff struggle to understand the difference between a registered nurse (RN) and an APRN. There is also confusion given that the APRN can function similarly to the physician for medical management of the resident. The role and function of the APRN varies greatly among facilities and states. Some facilities utilize the APRN for more administrative roles, others for more clinical roles. Despite the ambiguity, more facilities are hiring APRNs in long-term care given their value in delivering quality resident- and family-centered care.

MODELS OF CARE DELIVERY IN FACILITY SETTINGS

As an interdisciplinary model of advanced illness care, palliative care entrusts various disciplines to holistically address the medical, psychosocial, and spiritual needs of individuals. With robust global efforts to incorporate aspects of palliative care into the standard of care in facility settings, a wide variety of practice models exist.^{19,20} These models can be aptly categorized by examining the discipline of the provider rendering care, the entity with fiscal responsibility of the provider, and determining whether palliative care is delivered to individuals with terminal illness through a federally regulated hospice program.

NON-APRN MODELS

A diverse array of healthcare professionals has demonstrated the capacity to lead palliative care efforts in facility settings,

including physicians, nurses, social workers, and chaplains. For example, Morris and Galicia-Castillo presented a consultant model of palliative care, also known as the CARES Program, intended to serve 170 nursing home residents in Virginia using two physicians and a chaplain.²¹ Additionally, Giuffrida presented an example of a palliative care program at a 364-bed skilled nursing and rehabilitation facility in New York where social workers were integral leaders in the program's success.²² As part of a federal effort to affect hospitalizations rates of facility residents, CMS supported two RN-led programs in their Initiative to Reduce Avoidable Hospitalizations among Nursing Facility Residents.²³ Since palliative care is inherently interdisciplinary, various healthcare professionals within the team are capable of operationalizing various modalities, and examples of these models exist in the literature.

MODEL OF EMBEDDED APRN

By virtue of their education and training, APRNs also lead and manage either primary or specialty-level palliative care delivery programs.²⁴ APRNs employed in facility settings take an active part in direct patient care including disease-specific treatment, medication reconciliation, wound management, and care coordination. Additionally, facility-employed APRNs can provide ongoing staff education and lead quality improvement efforts.²⁰ Perhaps most importantly, APRNs embedded in the facility can rapidly respond to acute changes in a patient's condition consistent with the resident and family's expressed preferences for care.¹⁹ APRNs working full-time in the facility build ongoing relationships with residents and their families, which improves communication, education,

and establishing goals of care.¹⁷ In these cases, the facility assumes full financial responsibility for the APRN employee but gains a valued and reliable team member.

MODEL OF CONTRACTED APRN

Facilities can also incorporate APRN-led care by contracting with physician groups, hospital systems, managed care organizations, or consultant services, often as part of a hospice organization. In 2016, the Center to Advance Palliative Care (CAPC) began conducting a 3-year project to assess community-based palliative care programs across the United States.²⁵ In the final report *Mapping Community Palliative Care*, Heitner et al. concluded that 28% of survey respondents serve long-term care settings. The following statement provides further detail:

Of the programs delivering palliative care in long-term care settings, 38% are operated by long-term care facilities, 32% are operated by hospices, 21% are operated by hospitals, 5% are operated by office practices or clinics, and 4% are operated by home health agencies.²⁵ (p. 4)

In these models, facilities assume minimal to no financial responsibility for the APRN employee. APRNs utilize fee-for-service billing reimbursable under Medicare Part B, Medicaid, and most commercial insurers. Consultant or contract models have been shown to influence facilities' processes in palliative care referral, document the presence of pain and other symptoms, and increase hospice utilization.²⁶ However, gaps in quality care coordination can exist when APRNs work in multiple settings or facilities to maintain or increase revenue. Furthermore, sustainability of these models depends on the facility's ability to embrace cultural shifts in care leaders and the funder's ability to ensure longevity of the program.^{20,27}

HOSPICE MODEL

Hospice is the most common model of palliative care delivery in facility settings.^{28,29} Hospice services are provided in 80.7% of NHs and 67.7% of residential care communities, including AL facilities.⁵ Despite the prevalence, not all residents have access to standardized end-of-life care. According to a report from the National Hospice and Palliative Care Organization (NHPCO), approximately 19.7% of recipients of hospice care resided in AL facilities and 17.3% resided in NHs, including skilled nursing facilities.³⁰ Lack of access to hospice services can impact symptom management and limit much-needed psychosocial support.²⁸

For NH residents who elect the hospice benefit, the facility and the hospice agency are jointly responsible for developing, implementing, and evaluating a coordinated plan of care. The facility maintains the responsibility for the overall care of the patient and must notify hospice if the patient experiences an acute change in condition. Value-added services demonstrated by hospice, beyond standard palliative care approaches

in the plan of care, include volunteer, pastoral care, bereavement services, and interdisciplinary staff who have specialized training and skills in providing end-of-life care. Research investigations have demonstrated fewer hospital admissions, fewer unmet needs, and improved pain and other symptom assessment and management when patients are admitted to hospice in the NH. As previously mentioned, APRNs cannot certify residents with a terminal illness to initiate hospice services. They also cannot provide reimbursable care to hospice-enrolled residents unless they are designated as the attending of record.

APRN CLINICAL PRACTICE IN FACILITY SETTINGS

Approximately 25% of US residents will die in a facility setting, despite residents' overwhelming preference to live their last moments at home.²⁸ A facility environment, either AL or NH, is perhaps a close second choice for residents who would prefer not to die in the hospital. Since the NH will inevitably be the final place of residence for many frail and elderly individuals with terminal illness who require continuous nursing care, integration of high-quality palliative care seems crucial. Many of CMS's regulations and standards of care for NHs align with the philosophy of palliative care and support that palliative care may be appropriate rather than seeking a cure for residents who have chronic, progressive illnesses.³¹ Additionally, high-quality palliative care initiatives can be developed by interpreting and adapting the National Consensus Project for Quality Palliative *Clinical Practice Guidelines*.³² The following sections highlight clinical practice considerations for the APRN delivering palliative care in ALs and NHs.

CONTINUUM OF ILLNESS

Given the stringent regulations around preventing decline, meticulous documentation by the APRN is crucial when providing palliative and end-of-life care to residents in the NH. Decline due to a natural disease trajectory must be reflected in the provider's note through the patient's history, the physical exam, and any pertinent diagnostic testing. For example, CMS revised its regulatory guidance around pressure injuries and acknowledged that pressure injuries may be unavoidable at end of life. However, a provider's documentation must still reflect standard of care for pressure injury prevention and interventions to prevent further decline. Additionally, the APRN must note that the patient has nonmodifiable physiology contributing to the formation of pressure injuries and note appropriate efforts to stabilize the resident's condition. Finally, the patient's plan of care must be resident-centered and aligned with the advance directives of the resident.¹² When defined and expected findings of disease progression are considered, the APRN should incorporate palliative management strategies into the plan of care.

ADVANCE CARE PLANNING

While true across all care settings, close attention to ACP is especially important in ALs and NHs. Patient preferences must be ascertained, documented, and followed by all care providers in a facility setting. It is important to initiate and continue discussions with facility-dwelling residents who, because of advanced frailty and multiple life-limiting illnesses, are expected to have a decreased life expectancy. With astute attention to disease trajectory and prognostication, APRNs can assist residents in identifying a power of attorney for healthcare or surrogate decision-maker before the resident becomes acutely ill or loses decision-making capacity. In this setting, preferences such as a do-not-resuscitate (DNR), do-not-intubate (DNI), or do-not-transfer (DNT) order are especially important to discuss and document according to the resident's stated goals of care. However, a DNR/DNI/DNT order does not preclude the need for discussions with the resident and family regarding other medical treatments. In these instances, it may be appropriate for the APRN to discuss whether the resident would elect other potentially life-saving medical treatments such as medically administered nutrition; intravenous antibiotics, fluids, or blood products; or dialysis. After the discussion, the APRN can note the resident's preferences into a portable medical order, national provider/physician order for life-sustaining treatment (POLST) form or similar form in the resident's state.³³

A recent systematic review conducted by Martin et al. explains that the type of ACP document utilized may vary from facility to facility but that the incidence of unwanted interventions reduces with use of the POLST form.³⁴ ACP also may lead to earlier and more frequent palliative care and hospice referrals.³⁴ The APRN can be instrumental in creating policies that make ACP part of the standard practice with every resident admitted to and residing in the facility. Such interventions work to identify and uphold residents' expressed wishes and can encourage more dignified end-of-life care with hospice.

SYMPTOM MANAGEMENT

Many residents experience undesirable symptoms as a result of chronic and advanced illnesses. In these instances, ongoing assessment of symptoms, management of symptoms according to evidence-based practices, and evaluation of selected interventions are necessary. APRNs working in ALs and NHs are in an ideal position to manage the complex symptoms associated with progressive illnesses because they are regularly on site and available for immediate attention, if necessary. Additionally, they can educate staff at the bedside, as well as have conversations with families regarding goals of care. The assessment and management of pain is of utmost importance when approximately 40–83% of residents' experience pain due to musculoskeletal conditions (e.g., osteoarthritis, post-stroke disabilities), cancer, and neuropathy.³⁵ Many barriers to pain assessment and management in the facility setting exist, especially in the care of residents with cognitive impairment whose self-reports of pain are more difficult to ascertain.³⁶

The current opioid epidemic also poses challenges to transparent reporting of pain.³⁷ APRNs possess the skills and knowledge to both adequately assess and treat pain symptoms. In an example of an APRN-led pain management intervention in a long-term care setting, Kassalainen et al. found that NPs are effective in reducing residents' pain and subsequently improving residents' function.³⁵ The study also reported that the facility relied on the NP's ability to educate staff on pain management assessment and intervention. Expert symptom management is one of the trademark skills of specialty palliative APRNs, and they can therefore target barriers to adequate pain management and advocate for the highest quality of care for residents.

TRANSITIONAL CARE AND CARE COORDINATION

APRNs have demonstrated the capacity to assist residents who transition from one care setting to another (e.g., from hospital to skilled nursing facility or from NH to the emergency room) in the event of a change in condition. APRNs, as care coordinators, influence greater communication between care providers and care settings to avoid unnecessary errors through medication reconciliation processes. Also, APRNs can provide the resident or family with anticipatory guidance to impact a resident's experience of care in a more favorable way. There are also times when transfer to an acute level of care is not congruent with the resident's expressed goals of care. In these instances, APRNs have been instrumental in reducing unavoidable hospitalizations by as much as 17%.¹⁸ These positive outcomes occur when the embedded APRN participates in daily rounding and can respond to acute changes in a timely manner or when an APRN consultant introduces specialty-level palliative care to address symptom management and initiates earlier conversations on the resident's goals of care.³⁸ By leveraging the APRN's role in care coordination and other palliative care interventions, the resident and family are likely to report more positive experiences with care and ultimately decrease healthcare spending.^{20,39}

CURRENT IMPLICATIONS AND FUTURE OPPORTUNITIES FOR APRNS

In 2017, the American Nurses Association (ANA) and the Hospice and Palliative Nurses Association (HPNA) partnered to issue a publication titled *Call for Action: Nurses Lead and Transform Palliative Care*. This document urges nurses, including all APRNs, to consider the role of palliative care in practice, education, administration, research, and policy in order to improve care to individuals with serious illness. APRNs are encouraged to assist in increasing access to specialist palliative care in all practice settings, including long-term care.⁴⁰ APRNs are also charged with elevating their practice in other areas, as described next. The following sections review two current implications in facility settings and explore ways in which APRNs can contribute to future efforts.

REFORMING CARE DELIVERY

Variability in care delivery models occurs when institutions are required to adapt to the characteristics of their setting. Aspects such as the geographic location of the facility, the health condition of residents, the vitality of the workforce, and the institutional culture created by administrators, medical directors, and payers all influence care in various ways, particularly in the operationalization of care models. For example, there existed a misalignment between the realities of institutionalized care and reimbursement for quality measures in the post-acute care setting. As such, legislation including the *Improving Medicare Post-Acute Transformation Act (IMPACT Act) of 2014* and *Protecting Access to Medicare Act (PAMA)* have influenced care standards, quality measures, and reimbursement for a wide array medical services including diagnostic imaging.^{41–43} Additionally, recent advances in technology have also contributed to a shift in care delivery. The wide acceptance of telehealth, as a response to the COVID-19 pandemic, prompted CMS to adopt temporary regulatory waivers and enact policy changes to increase access to and reimbursement for telehealth services. In rural setting, the use of telehealth allowed residents access to services not otherwise available.^{43–45} APRNs in facility settings will be challenged to adapt the ways in which they deliver care in these complex settings as policymakers cycle through the processes, innovation, legislation, and reformation efforts. As APRNs practice in concert with ongoing developments in healthcare, they can not only influence the quality of care delivered to residents, but they can also contribute to policy and research at local and national levels.

WORKFORCE CONSIDERATIONS

A stable and educated workforce is vital to caring for an aging population. However, building a strong force means overcoming existing obstacles such as staff turnover. Turnover in facility settings occurs widely, and the negative impact is multifaceted and well-documented.²⁹ Consistent turnover of nursing staff, administrators, and medical directors leads to knowledge deficits and increased training needs. For example, the indirect cost of training and education can negatively impact a palliative program's sustainability and cause financial hardship. Transitioning staff take with them institutional knowledge that would help inform coordinators or directors of effective strategies for sustainability and critical feedback to improve initiatives. Turnover also impacts efforts to understand the outcomes of palliative initiatives.⁴⁶ The validity and quality of clinical trials investigating the effects of symptom management, ACP, care coordination, and the resident's or family's experience can be weakened by staff turnover.^{29,46} Having knowledge of care that is safe, efficient, and quality-driven improves healthcare expenditures. A systematic review by Carpenter et al. found minimal high-quality evidence from 13 clinical trials investigating the effects of palliative care interventions in NHs, and staff turnover is cited as one of the many contributing factors.²⁶ In the end, the economic impact of this issue cannot be ignored. APRNs, as clinical leaders

in facility settings, can work to mitigate staff turnover by encouraging collaborative and interdisciplinary team-based interventions, educating staff on compassion fatigue and burnout, and promoting a culture of transparency and resilience. Future opportunities for practice and research include piloting and investigating APRNs as clinical leaders, such as medical directors in facility settings, to relieve today's facility administrators of the unrelenting challenges. There has never been a more appropriate time to reimagine the care delivered to a most precious generation.

SUMMARY

APRNs are ideally positioned to advance the delivery of evidence-based palliative care to residents in facility settings. Their education of advanced chronic disease management and their communication skills promote collaboration with resident's, families, and other members of the healthcare team. In their care of residents in facility settings, APRNs lead and participate in the continuum of care by facilitating ACP, providing expert symptom management, and coordinating care during transitions. While challenges to practicing in this setting exist, ample evidence confirms numerous positive outcomes when APRNs are involved in the care of facility-dwelling residents. There are tremendous opportunities for APRNs to affect the quality of living and dying for residents in these settings.

SECTION IV

POPULATIONS AT RISK

HEALTH DISPARITIES IN PALLIATIVE CARE AND SOCIAL DETERMINANTS OF HEALTH

Alma Y. Dixon and Cecilia R. Motschenbacher

KEY POINTS

- Awareness of structural vulnerability allows clinicians to view the social conditions that undermine the capacity of patients to access healthcare, adhere to treatment, and successfully modify lifestyles.
- In assessing the structurally vulnerable patient, clinicians need to be mindful and question if the patient elicits a potential stigma or stereotypical bias or if the patient's appearance, ethnicity, accent, addiction status, or behaviors cause the clinician to think this person does not deserve, want, nor be willing to participate in a treatment regime.
- The palliative advanced practice registered nurse (APRN) is a patient and family advocate who assesses the patient for structural vulnerability.
- The interdisciplinary team plays a key role in securing needed resources for the structurally vulnerable patient and for self-monitoring to determine if implicit biases exist.

CASE STUDY: SOCIAL DETERMINANTS OF HEALTH

Mr. J was a 62-year-old African American man recently diagnosed with recurrent metastatic head and neck cancer. He was referred to the supportive and palliative care (SPC) clinic by his oncologist for pain and symptom management. Upon initial assessment, it was noted that he was unable to read instructions provided to him and could not operate his smartphone, rendering him functionally illiterate. These challenges made it difficult for him to adhere to his complicated medication regimen. He had not completed high school, and his employment history included various jobs within the construction industry. He had married and had two estranged adult children. A brother lived nearby, but was not overly involved. Mr. J had a history of substance use disorder and had experienced homelessness. However, he had secured low-income housing. It was relatively close to his medical care, but he was without reliable transportation. As a result, he spent much of his time walking to the local food bank and to his necessary appointments.

Mr. J admitted that although his appetite was good, he could not afford enough food to keep him satiated. At times, he had to decide between paying for his prescribed medications or paying

for food. Mr. J endorsed right-sided cervical pain, which correlated with an enlarged malignant mass. The pain was relatively controlled with opioids and adjuvant therapy. He also had opioid-induced constipation. The palliative advanced practice registered nurse (APRN) referred Mr. J to the SPC social worker (LCSW), who performed a thorough psychosocial and needs assessment. She provided him with nutritional shakes from oncology and bus tokens for the local transportation system. She also requested support from the team registered nurse (RN) to reconcile his medication list, provide further education about medication administration, and create a system for him to label his bottles so he knew which medications were for which symptoms.

For many months, the palliative APRN ensured adequate symptom relief for Mr. J while the LCSW partnered with him for emotional, nutritional, and transportation support. Then suddenly, there was a 3-month gap of care during which Mr. J disappeared. He did not attend any of his medical appointments and his phone number was disconnected. Concerned, the APRN contacted Mr. J's brother to ensure his safety and encourage continued follow-up with his medical team. When Mr. J attended his next visit, the cervical mass had grown considerably and was now impeding his ability to swallow and receive adequate nutrition. Attempts to reconnect him to oncology services proved difficult because of he did not keep appointments with his specialists and primary care provider.

One afternoon, the SPC team was contacted regarding a patient whose family was at the front desk demanding he be seen urgently. Mr. J, cachectic and weak, had been transported to the clinic in a wheelchair by his brother who was afraid his brother was dying. He did not know what to do nor did he have the capacity to care for Mr. J. The palliative APRN arranged to have Mr. J admitted to the palliative care unit although this was complicated when a urine drug screen was positive for cocaine. The attending physician was conflicted about continued opioid utilization considering concurrent substance misuse and subsequently discontinued opioids during his inpatient stay. The APRN held a meeting between the inpatient and outpatient teams to advocate for the patient and determine a path forward. They determined that since he was dying and would be under the service of hospice, pain medications could be controlled. The pain regimen was reinitiated with opioid therapy, and Mr. J's pain was well-controlled. Coordination was made to transfer him to a skilled nursing facility with hospice services, and he was ultimately reconnected with his estranged daughter.

INTRODUCTION

This chapter discusses how social determinants of health undermine many patients' capacity to access healthcare, adhere to treatment, and modify lifestyles successfully. The foundation of understanding social determinants of health is that healthcare providers often have preconceived notions about a patient which limits their ability to develop an effective plan of care.¹ In the case study presented, Mr. J's homelessness, illiteracy, poverty, and social isolation need to be viewed as the social constructs that impeded his ability to actively engage in a plan of care. Because of these social determinants, he was placed at a lower rung of political and social hierarchies and, in fact, faced unique barriers in accessing and actively participating in his care. In addition, his race, social condition, and diagnosis may have resulted in negative preconceptions by healthcare providers. These preconceptions can result in clinicians prejudging patients like Mr. J's willingness to modify behavior. The collaboration of the palliative interdisciplinary team (IDT) is essential to ensure that patients like Mr. J are viewed as individuals with significant challenges rather than as individuals who are noncompliant and willfully choose not to adhere to their treatment regime.

DEFINITIONS

Structural vulnerability refers to an individual or group being at risk for adverse health outcomes due to their position within interconnecting socioeconomic, political, and cultural hierarchies that constrain the ability to pursue healthy lifestyles.¹ It occurs due to a combination of socioeconomic and demographic characteristics such as gender, gender expression, sexual orientation, socioeconomic status, race, ethnicity, sexuality, citizenship status, and physical location. Structural vulnerabilities vary depending on context but can include poverty, homelessness, social isolation, HIV status, ongoing trauma and violence, mental health and addictions, and experience with the criminal justice system.

Social determinants of health (SDOH) are conditions that determine individual and population health, as depicted in Figure 20.1. Individuals with structurally vulnerability may experience lack of income, inability to pay medical bills, substandard housing, homelessness, limited or no access to healthcare, lack of social support, illiteracy, and hunger.²

Health disparities represent the impact of race, socioeconomic status, gender, gender expression, sexual orientation, age, diagnosis, and mental ability on an individual's or group's ability to achieve positive health outcomes. They are

Figure 20.1 Social determinants of health.

Infographic adapted from Artiga S, Hinton E. Beyond health care: The role of social determinants in promoting health and health equity. May, 10, 2018. Kaiser Family Foundation.³

a direct result of political and economic structures that create inequality.¹

Implicit bias refers to the negative preconceptions that an individual has based on a patient's gender, ethnicity, sexual orientation, socioeconomic status, or diagnosis. Implicit negative biases are reflected in verbal judgments and nonverbal behavior. Patients who can be classified as structurally vulnerable often fall prey to healthcare providers' implicit bias. Implicit biases contribute to health disparities by adversely affecting patient assessment, treatment decisions, and healthcare follow-up.⁴

PALLIATIVE CARE AND THE TEAM

Individuals seeking palliative care tend to share similar socioeconomic and demographic profiles. For example, they reside in homes or assisted living facilities and have diagnoses with predictable outcomes, such as cancer, heart failure, or pulmonary disease. However, individuals who are structurally vulnerable do not fit this picture, especially people who are experiencing homelessness, poverty, serious mental illness, substance abuse, or stigmatized illnesses such as HIV and AIDS. These individuals tend to be unnoticed, and their needs go unmet.⁵

The palliative care team focuses on symptom management, care coordination, and advance care planning. This can be especially challenging when working with patients disproportionately affected by poverty, housing instability, food insecurity, behavioral health conditions, and substance use disorder. The team may adhere to the belief that, at the end of life, patients may wish to die at home, without pain, with family surrounding them. However, patients like Mr. J require that this mindset be examined. The notion of "at home" must be expanded to include homelessness, the idea of "without pain" needs to include pain management within a history of substance abuse, and "family" requires identification of supportive persons rather than biological ties.⁶ Patients like Mr. J rely on the collaboration of palliative team members to work as a cohesive whole to address their complex problems. Within the palliative care team, members can name and challenge implicit biases by asking tough questions.

- Does this patient elicit a sense of distrust because of behavior or lack of adherence to a plan of care?
- Does this patient's behavior indicate a lack of desire to participate in a plan of care?
- Does this patient's ethnicity, gender, gender expression, sexual orientation, or past behavior produce negative expectations of ability to engage in a plan of care?

By asking these questions, the team is empowered to acknowledge the impact of structural vulnerability on the outcomes of care.¹ Through the work of the IDT, the perception of Mr. J moved from an unreliable drug-seeking patient to a man with complex medical and social needs.

IMPLICATIONS FOR PALLIATIVE CARE

An exhaustive array of research has qualified the platitude that structurally vulnerable individuals receive a different standard of care and therefore achieve poorer health outcomes (see Chapter 18, "Palliative and Hospice Care in Rural Areas"; Chapter 47, "Patients with Substance Use Disorder and Dual Diagnoses"; Chapter 21, "Economically Disadvantaged Urban Dwellers"; and Chapter 23, "Care of Veterans with Palliative Care Needs").^{1,2,4-12} Awareness of such health disparities and inequities within the palliative care domain is essential to impart radical change that expands across care systems. A microcosm of the healthcare system at large reveals that hospice and palliative services are often not accessible to the most structurally vulnerable patients, specifically, those individuals who are lacking vital resources and supports as defined by their SDOH. The intersection between health outcomes and SDOH requires clinicians who are both adept at identifying a patient's and family's psychosocial needs and have a foundational understanding of the resources available to support their journey.⁷ The 2018 National Consensus Project for Quality Palliative Care (NCP), *Clinical Practice Guidelines*, Domain 4: Social Aspects acknowledges the importance of SDOH as an essential element to individualized care. It states that "social determinants of health, hereafter encompassed in the term 'social factors,' have a strong and sometimes overriding influence on patients with a serious illness. Palliative care addresses environmental and social factors that affect patient and family functioning and quality of life."¹⁰ (p. 26)

Patient advocacy is a core tenet of palliative advanced practice nursing. Palliative APRNs must be prepared to promote patient engagement, protect individual autonomy, and champion social justice.⁸ This can be performed at the individual, organizational, community, and national levels. Although the systematic challenges may seem insurmountable, the palliative APRN can impart practical interventions that can have a dramatic impact on patient access and well-being. It is vital to utilize and lean on the strengths of the IDT and local organizations to facilitate the identification of care gaps and the resources that may be utilized to address them.⁹ Within the public health arena, palliative APRNs have opportunities to participate within their organizations as well as within local and national legislative bodies to promote awareness and social equity.

ASSESSMENT

Traditional clinical assessments do not accurately identify patients with complex social and structural needs. As a palliative APRN, it is important to delve deeper into a patient's history to determine barriers and opportunities to improve healthcare access. This includes assessing environmental aspects of care, financial aspects of care, and community aspects of care (see Table 20.1). The National Hospice and

Table 20.1 SOCIAL DETERMINANT OF HEALTH ASSESSMENT

SOCIAL DETERMINANT DOMAIN	ASSESSMENT QUESTION
Economic stability	• How much of financial hardship is your illness for you or your family?^{2,13} • Are you able to pay for your medical care and medicine? • Are you receiving any government or financial assistance? • What is your current work situation? • Do you have money to pay your rent or get food? • Do you run out of money by the end of the month? • Have you or any of your family members been unable to get any of the following when it was needed in the past year? • Food • Clothing • Utilities • Childcare • Medications or any healthcare services • Phone
Education	• What is the best way to share health information with you? • How far did you go in school? Did you graduate? • Is English your first language? In what language would you prefer to receive your medical information?
Social and community context	• Do you have friends or family who can help you if you need it? • Do you have people with whom you can talk and feel supported? • Do you feel safe in your current living situation? • Have you ever felt discrimination has impacted your care? • Have you ever been arrested or incarcerated? • Are you exposed to illegal drug use or violence? • Are you a veteran?
Health and healthcare	• How much trouble do you have getting the medical care you need? • Where do you go for your medical care? • Do you have a primary care provider, and how often do you see them? • Do you have adequate medical insurance? • How do you get to your medical appointments? How reliable is your transportation? • Are there any situations that make it difficult to access healthcare?
Neighborhood and built environment	• Where do you live and with whom? • Is it a safe place to sleep and store your possessions? • Are you worried about losing your housing? • Do you have a safe place to spend your time? • Do you have access to transportation? • Do you have access to telephone services? • Do you have access to emergency services?
Food insecurity	• Do you have access to food storage? • Do you have access to cold food and safe food storage? • Do you have access to food banks? • Over the past 12 months, how often were you worried whether the food would run out before you had money to buy more? Or how often did the food not last and you didn't have money to get more?^{14–15}

From Centers for Disease Control and Prevention ²; Artiga S and Hinton E ³; and Grindrod. ⁵

Palliative Care Organization challenges clinicians to maintain awareness surrounding social constraints and the degree to which a patient's circumstances directly impact their health outcomes.¹⁰ Deficits in any of these areas may contribute to the concept of total pain and suffering, whereby lack of recognition about the significance of these attributes can directly impact the patient's well-being. If a patient cannot satisfy the prerequisites for care, medical access and adherence will decline accordingly.^{11–12}

Although there has been a considerable focus on SDOH at the national and global scales, there is limited research surrounding hospice and palliative care implications. There are several resources that define the importance of identifying patient SDOH and structural vulnerability to promote health outcomes, but valid and reliable clinical tools are lacking. Table 20.1 depicts a consolidation of assessment questions the APRN can utilize to facilitate identification of essential structural variables such as poverty, food insecurity, literacy,

safety, and legal status. Universal screening is not recommended because it may activate an inappropriate social prescribing pathway and negatively impact the patient–provider relationship. The general guidance is to seek clarity if a patient is exhibiting clinical concerns indicative of social constraint and inquire based on the individual context.¹³ Some questions may elicit responses from several of the overarching domains.

The palliative APRN needs to approach these sensitive topics in a caring, tactful, and culturally acceptable way to promote candid conversations and build rapport with the patient. The development of a trusting therapeutic alliance is essential to this practice because historically marginalized populations may be skeptical of the medical system at large. The APRN must also acknowledge, manage, and mitigate their inherent beliefs, which may contribute to the broader context of implicit bias and structural vulnerabilities. Once this information is obtained, it should be well-documented within the patient record to facilitate communication across care teams and facilitate comprehensive care planning in which social constructs are fully considered.¹⁶

PALLIATIVE CARE INTERVENTIONS

When a social need has been identified, connection to appropriate referral sources is paramount. If working within a robust organizational setting, leveraging the strengths and resources of the IDT is crucial. The NCP *Clinical Practice Guidelines* state that the palliative care IDT partners with the patient and family to identify and support their strengths and address areas of need (Box 20.1). Social workers are well-poised to assess complex psychosocial needs, provide emotional support, and connect patients to institutional and community resources. Institutions that recognize the importance of social equality have successfully implemented the role of community resource specialists who are knowledgeable about local and national assistance programs for financial, transportation, caregiver, food, housing, and legal needs. Community health workers function similarly, with the added benefit of case management to assist patients in navigating the health system.¹¹ Staff registered nurses (RNs) are invaluable for patient education, care coordination, and more frequent nurse–patient encounters to monitor the patient’s health status. Chaplains can assist the APRN in assessing the spiritual, cultural, and religious SDOH and in connecting patients and families with their faith community.

PALLIATIVE INTERVENTIONS

It can be challenging for clinicians to broach structural vulnerabilities and, this is understandable given the issue’s complexity and depth. The hospice and palliative APRN’s skill set, rooted in high-quality communication, allows for adaptability and interpretation of complex medical terminology in an understandable way. Patients with low health literacy or language barriers are well-served when information-sharing is adapted to suit their needs. Patient handouts should be simple, clear, concise, and in the patient’s preferred language.

Consideration should be given to using words or pictures depending on the patient’s literacy. Utilization of interpreter services ensures that medical terminology is conveyed and provides patients the opportunity to share their health concerns with the APRN. Visual aids, easy-to-understand instructions, and verbal teachback methods are helpful. They foster education and afford the clinician an opportunity to clarify information as necessary. Navigating patients through the healthcare system through simplification of treatment regimens and alignment of medical appointments across specialties are additional ways in which an APRN can bridge the gap of social inequity (see Box 20.2).

There are several considerations for patients with financial and transportation concerns. Cost of medications and medical supplies, copays, and transportation arrangements must be considered when developing a patient-centered plan of care. Coordination with the patient’s specialty and primary care provider to align visits can reduce the logistical burden and cost associated with frequent medical appointments. If appropriate and accessible by the patient, transition to intermittent telemedicine communication may also offset some stressors and allow for continued safety through remote monitoring. If financial concerns are a barrier to medication adherence, it is equally important to account for this when deciding on a treatment plan and avoid cost-prohibitive therapies.¹¹

PALLIATIVE CARE TEAM INTERVENTIONS

Palliative APRNs can work with their teams to promote more education on social determinants of care. This will necessitate some difficult conversations about health inequities. One important step is for the team to do some reflection on individual and team implicit biases and consider more culturally sensitive treatment planning. Then they can perform outreach within the community.¹⁷ This includes more education about the communities that the team is serving. The team also needs to be mindful of communities not being served (e.g., individuals with dual diagnoses such as serious illness and substance use disorders or serious mental illness). An assessment of these communities will need to consider the resources and collaborations necessary to include those populations.

SUMMARY

It is imperative that palliative APRNs understand the impact of structural vulnerabilities on their patients’ well-being and global health outcomes. Awareness of health inequities should allow the provider to identify social needs and connect patients to appropriate resources within the team, organization, and community. Although rectifying the social determinants for a patient may seem insurmountable, palliative APRNs are empowered to provide tailored interventions to mitigate healthcare barriers within their own practice. They can work with their teams to ensure access to quality palliative care and reduce health disparities caused by social determinants of care.

Domain 4: Social Aspects of Care

Social determinants of health, hereafter encompassed in the term “social factors,” have a strong and sometimes overriding influence on patients with a serious illness. Palliative care addresses environmental and social factors that affect patient and family functioning and quality of life. The palliative care interdisciplinary team (IDT) partners with the patient and family to identify and support their strengths and to address areas of need. The IDT includes a social worker to maximize patient functional capacity and achieve patient and family goals.

GUIDELINE 4.1 GLOBAL

The palliative care IDT has the skills and resources to identify and address, either directly or in collaboration with other service providers, the social factors that affect patient and family quality of life and well-being.

CRITERIA

4.1.1 The palliative care IDT includes a social worker with expertise and experience in:

- a. Assessing and supporting emotional aspects of care and improving quality of life (see Domain 3: Psychological and Psychiatric Aspects of Care)
- b. Identifying and addressing social consequences of a serious illness
- c. Collaborating with community-based services and supports and the organizations providing them
- d. Applying care management and care coordination techniques and evidence-based models of care transitions
- e. Working as part of an interdisciplinary team
- f. Utilizing patient- and family-centered and developmentally appropriate approaches to assessment, care planning, care management, and care delivery

4.1.2 All members of the IDT understand the impact of social factors on seriously ill patients and family members. The IDT:

- a. Is aware of the implications on care when patients are uninsured, under-insured, undocumented, homeless, or under the custody of the county or state
- b. Is cognizant of the financial impact of serious illness, including the cost of medications and other treatment, as well as the costs to the family
- c. Provides, directly or through referral, access to follow-up appointments, treatments, medications, nutrition, and other resources, as indicated in the plan of care

GUIDELINE 4.2 SCREENING AND ASSESSMENT

The IDT screens for and assesses patient and family social supports, social relationships, resources, and care environment based on the best available evidence to maximize coping and quality of life.

CRITERIA

4.2.1 Before involving family or caregivers, the patient or legal decision-maker identifies who can participate in the assessment and care planning process, as well as their level of involvement.

4.2.2 The IDT performs developmentally and culturally sensitive screening and assessment in the setting in which the patient receives care.

4.2.3 The social assessment includes:

- a. Family structure and function, including roles, quality of relationships, communication, and decision-making preferences and patterns, as well as an assessment of those involved if the patient is in the custody of the county or state
- b. Patient and family strengths, resiliency, social and cultural support, and spirituality

- c. The availability and ability of a support system to provide respite, assist with errands and chores, and guard against social vulnerability
- d. The effect of illness or injury on intimacy and sexual expression, prior experiences with illness, disability and loss, risk of abuse, neglect or exploitation, incarceration, or risk of social isolation
- e. Functional limitations that impact activities of daily living (ADLs), instrumental activities of daily living (IADLs), and cognition
- f. Changes in patient or family members' school enrollment, employment or vocational roles, recreational activities, and economic security
- g. Identification and documentation if the adult patient or a family member served in the military, and whether the patient or family member may be eligible for VA benefits
- h. Living arrangements and perceived impact of the living environment on patient and family quality of life, including safety issues
- i. Patient and family perceptions about caregiving needs, including caregiver availability and capacity
- j. The need for adaptive equipment, home modifications, or transportation.
- k. Financial vulnerability (e.g., ability to pay rent or mortgage and other bills).
- l. Ability to access prescription and over-the-counter medications for any reason, including functional or financial issues
- m. Nutritional needs and food insecurity
- n. Advance care planning and legal concerns (see Domain 8: Ethical and Legal Aspects of Care)
- o. Patient and caregiver ability to read and understand information from health and social service providers, insurance companies, and the IDT, as well as the ability of the patient and family to ask questions and advocate for their needs
- p. The ability of the patient and/or family to adhere to medication or treatment regimens
- q. Patient and family willingness and ability to engage or accept resources and referrals.

4.2.4 A separate assessment of the family's needs, resources, resiliency, and capacity to provide care is also conducted.

GUIDELINE 4.3 TREATMENT

In partnership with the patient, family, and other providers, the IDT develops a care plan for social services and supports in alignment with the patient's condition, goals, social environment, culture, and setting to maximize patient and family coping and quality of life across all care settings.

CRITERIA

4.3.1 The IDT engages the patient and family in developing a care plan that addresses the social needs and is in alignment with their goals. The care plan:

- a. Reflects patient and family culture, values, strengths, goals, and preferences, which may change over time
- b. Assesses factors that prevent the patient from remaining independent and connected with family and friends
- c. Specifies the role and contributions of family members and the types and sources of support that will be provided to the family
- d. Identifies community service providers and the type and amount of care they will provide
- e. Includes developmentally appropriate support for the patient and family, including children and adolescents
- f. Identifies outcomes specific to each goal

4.3.2 The IDT coordinates care with care manager(s) and care team(s) to address patient- and family-identified social needs, providing referrals to resources and services as needed.

ECONOMICALLY DISADVANTAGED URBAN DWELLERS

Natasha Curry

KEY POINTS

- Economically disadvantaged persons living with serious illness are ethnically, culturally, and linguistically diverse, with differing resources and unique challenges.
- By practicing cultural humility, the advanced practice registered nurse (APRN) is better able to understand the impact of serious illness on those who are economically disadvantaged and gain an appreciation of their worldviews.
- Collaboration with community health, social services, housing, substance use treatment services, mental health services, and, at times, the legal system, is vital if APRNs are to truly meet the palliative care needs of the economically disadvantaged population.

CASE STUDY: CARE FOR INDIVIDUALS
EXPERIENCING HOMELESSNESS

Danny was born in 1967 to an African American single mother in Oakland, California. His mother, Grace, had seven other children when Danny was born, all under the age of 10 with four different fathers, two of whom were incarcerated at the time and two of whom had “disappeared.” Grace received no form of child support for any of her children.

She loved her children, but caring for eight children in the increasingly expensive Bay Area was very difficult for Grace. She often turned to alcohol to help numb the pain and help her relax. Although they were all crammed into a two-bedroom apartment, Grace felt so fortunate that she had this stable, rent-controlled housing. Then, when Danny was 11 their elderly landlord died and his son decided to sell the property; the family became homeless. Danny and three of his siblings entered the foster care system, and Grace moved away. Danny never saw or heard from her again. Danny lived in more than seven different foster homes. Some families he liked, some he thought were only in it for the money and treated him like an annoyance.

As the years passed, Danny dropped out of school, left the foster care system to fend for himself, and fathered his first child when he was 17. He did not establish a relationship with the mother and would go on to have four other children with different women. Danny spent some years in and out of prison, held a number of minimum wage jobs in Oakland, and reunited with his father in his mid-30s. He would say, he was mostly “running the streets with the others.”

In his mid-40s Danny met Marcia, 15 years his junior, and for the first time he felt this was a woman he could trust. They had three children together, close in age. Danny took a job unloading fruits and vegetables for an organic delivery service while Marcia stayed in their small studio apartment in San Francisco’s Tenderloin district with the children. Danny said it felt as though his life was stabilizing. He was dreaming of returning to night school to get his GED; he wanted to teach, a dream he had held onto for many years. Save for an assault in 2017, which resulted in a fractured arm and leg, both of which required surgery, Danny had no health issues.

At the end of 2018, Danny found himself incarcerated again for a minor drug charge. Marcia and the three young boys lost their housing because there was no income coming in. They moved in with friends in the North Bay area, occasionally sleeping in their car or on friends’ couches. At the beginning of 2019, while still in prison, Danny noticed he was losing weight. He felt as though something was stuck in his throat, struggling to swallow, and he thought his voice was starting to sound odd, as if he “was a frog.” He went to the medical service, where he was given a rapid strep test and was told there was nothing wrong.

When he was released in March 2019, he started working under the table, the only job available to a felon, to send money to his kids. He moved in with his dad in San Francisco, sleeping on the couch. He still couldn’t swallow well and was mostly just drinking Mountain Dew to give him the energy to get through the day. Danny was losing weight rapidly. He knew it was time to see a medical provider again. His job obviously offered no benefits, so he had no commercial health insurance. However, he was able to make an appointment with a primary care nurse practitioner (NP) at an urban health clinic in San Francisco. It took 6 weeks until he could be seen, so he waited, increasingly unable to eat or drink much without pain or vomiting.

His primary care nurse practitioner (NP) was appropriately concerned and sent Danny to the otolaryngology team at the local safety net hospital for expedited evaluation and workup. The clinic squeezed him in in 10 weeks, the earliest available appointment. A computed tomography (CT) scan and fine needle aspiration (FNA) showed what his providers had feared: supraglottic squamous cell carcinoma, at least a Stage III. With only local advancement, oncology was going for a cure with total laryngectomy, likely to be followed by concurrent radiation and chemotherapy. To get him nutrition, an order was placed for a feeding tube, and Danny was scheduled for a full mouth dental extraction to get ready for radiation. Danny had gold grills—a type of

dental jewelry worn over the teeth—and he loved his grills. To Danny, his grills symbolized his enduring love for hip hop music, and, because they had cost him over a thousand dollars, they were also a symbol of the wealth he hoped to achieve for himself and his sons. He fought long and hard with his doctors to keep his teeth; he lost, and his teeth were removed.

Danny had been staying with his father to satisfy his parole expectations and taking public transport to spend time with his kids. There was no room for the entire family to stay with Danny's father. Marcia and the boys were now sleeping in the car every night. The kids were not enrolled in school because they kept getting moved on by the police, which meant Marcia had no way of knowing where they would spend the night.

Danny hated being in the hospital, not knowing where his kids were. He would spend hours on the hospital telephone trying to track his family down. He threatened on more than one occasion to go AMA because he couldn't locate them. At the end of May 2019, Danny had his surgery. He woke up in the ICU with a trach, no vocal cords, and a feeding tube. What's more, pathology showed positive margins; Danny was going to need radiation and chemotherapy.

With a long history of methamphetamine and alcohol use, most providers in the hospital were leery of giving him opioids. The palliative advanced practice registered nurse (APRN) was consulted, and the terror in Danny's eyes filled the room. This was someone who needed more opioids because of his substance use history, not fewer. At the APRN's suggestion, Danny was started on patient-controlled analgesia (PCA) and finally got some relief.

Two weeks later, Danny came to the palliative APRN's outpatient clinic. He still had the laryngeal tube and the percutaneous endoscopic gastrostomy (PEG), and in his hand he had a burger, fries, and milkshake. Danny pulled up the trash can, chewed then spat his burger and milkshake into it. Danny found himself back in the OR for an esophageal dilation. This was getting too much for him. Danny missed all of his follow-up appointments with oncology and was never started on treatment for the residual cancer. Calls to his phone either went straight to voice mail if he had been able to pay for his phone that month or went nowhere.

In February 2020, Danny passed out in the bathroom of a local grocery store. There was blood on the floor, and he showed signs of an infected groin abscess where he had been injecting methamphetamine. His PEG tube was also infected, and his trach ties were filthy. He was brought back into the hospital.

Danny's cancer had progressed and was now incurable. Radiation and chemotherapy could offer some relief and extra time, but he had missed the window for complete remission. The palliative APRN sat with Danny. His only way of communication was writing, and this took time. He became frustrated whenever anyone tried to hurry him along, and especially when people tried to finish his sentences for him. He told her how tired he was, how he just wanted to "end it all," but felt he needed to stay strong for his kids. He expressed his frustration at having lost his voice, and his sadness at being told he had less than a year to live. But he was going to make it to all his treatments this time; he had to, for his kids.

Then, in March 2020, everything was put on hold when the coronavirus hit his city. In-person clinic appointments were

cancelled—all visits were now to be either telephone or video visits, challenging for someone with no vocal cords. Danny's kids were to be schooled from home, Marcia lost her job, and the bus service was slashed, making it almost impossible for Danny to get to his daily radiation and weekly chemo treatments. Danny began missing treatments. The palliative APRN tried obtaining taxi vouchers, but these were now in short supply. One day in April, at 4 AM, Marcia left a message for the APRN: "I think Danny just died."

INTRODUCTION

In 2018, the official poverty rate in the United States stood at 11.8%, or 38.1 million people.¹ For a family of four in 2020, poverty is determined to be an income of less than \$26,200, and less than \$12,760 for an individual.² While these data showed the fourth consecutive annual decline, it was an unevenly shared experience. Some groups continue to face much higher levels of economic hardship, particularly Black and Hispanic populations, those with the lowest levels of education, and among individuals and families living in neighborhoods of concentrated poverty. The poverty rate for non-Hispanic Whites was 8.1% in 2018, with 15.7 million individuals in poverty; for Blacks in the same year, it was 20.8%, representing 8.9 million people; for the Latinx community it was 17.6%, representing 10.5 million. In addition, while the median income in 2018 for White households was at \$66,943, it was just \$43,161 for Black households.

Of the 31.1 million people living in poverty, more than 50%, or 15.3 million live in cities.³ There are many studies that show how poverty can lead to adverse health outcomes, both by increasing illness burden (morbidity) and leading to premature death.^{4,5} A seminal public health paper published in 2011 found that deaths attributable to social factors such as lack of education, racial segregation, limited social support, individual-level poverty, and area-level poverty were comparable to the number attributed to pathophysiological and behavioral causes.⁶ Basically, the economically disadvantaged are more likely to get sick, become seriously sick, and die younger. Clearly the urban poor are a population in need of the interdisciplinary approach offered by palliative care; however, low-income communities have traditionally underutilized palliative care services.⁷

Figure 21.1 shows just some of the factors associated with decreased survival in poor and medically underserved communities. Recent social and environmental factors that support health and longevity have been shown to have biological correlates that may ultimately provide a mechanistic understanding of the ways in which psychological stress associated with poverty, racial discrimination, and other social ills influence excessive mortality.

Barriers to palliative care for the urban poor are multifactorial: lack of health insurance, mistrust of the healthcare system, comorbid mental illness, drug and/or alcohol dependence, lack of transportation, competing demands of finding

Figure 21.1 Medical neglect syndrome.
Reprinted with permission from David Wendell Moller, *Dying at the Margins*. New York: Oxford University Press; 2018: 65.⁴

food and shelter, and insufficient social support.^{8,9} Other issues include availability, accessibility, and affordability.

1. **Availability:** One-third of US hospitals with 50 or more beds have no palliative care services, and, in the states reporting the greatest poverty (Alabama, Mississippi, New Mexico), fewer than 40% of the hospitals have palliative care teams. Nationwide, only 60% of public hospitals, often the only option for the urban poor, have palliative care programs, a number that has remained unchanged for the past 4 years.¹⁰
2. **Accessibility:** Most outpatient palliative care is provided at home, not in a clinic. Although many patients at comprehensive cancer centers have access to outpatient palliative care, access outside of these academic centers is very limited.¹¹ For the urban poor, “home” may be on the streets, may vary from week to week, or may be so run down and shabby that they do not want professionals visiting. And, if they are lucky enough to find a palliative care provider to order something to help with the metastatic cancer, it is a strong possibility that the pharmacy in the low-income neighborhood has chosen not to stock opioids out of concern that this will make them targets for theft.⁸
3. **Acceptability:** Is it any surprise that people who have endured deprivation all their lives would be suspicious of a medical team that does not revolve around life-saving and life-prolonging treatments?⁸ As stated by David Wendell Moller in *Dying at the Margins*, “Victimized by structural racism, poverty and discrimination, they are wary of mainstream institutions and how they represent the interests of a status quo that has been unhelpful to them throughout life.”⁸ (p. 39)
4. **Affordability:** The current fragmentation of health care can result in multiple outpatient visits, each of which often requires money for transportation. Just getting to the clinic or hospital for care is an especially difficult

challenge for the urban poor. For individuals with serious illness or who are dying, the obstacles are even more formidable.

As a result of these barriers, providing palliative care to the economically disenfranchised requires the palliative advanced practice registered nurse (APRN) to wear many hats: clinician, advocate, educator, therapist, care coordinator, social worker, and researcher.

The stereotype of the urban poor is a mentally ill, substance-using person, often male, who is living on the streets or in a single-room occupancy hotel. However, as with many stereotypes, this is not an accurate picture. They may have housing, although not in a place that many would think of as a “home.” Cowboy, the charming character featured Moller’s seminal work *Dancing with Broken Bones*, has lived under a bridge in a Midwestern city for decades and adamantly denies being homeless.¹² Some are working poor who may be undocumented or otherwise living on the margins of society. An increasing number of urban poor are single mothers.²

Danny’s story introduces several issues that are common in the care of urban poor: the role of safety net hospitals and community health systems in care delivery, the frequency with which patients are often “lost to follow-up,” the skills needed to manage pain in those with a substance use disorder, and the need to be an advocate for the patient living within the chaos, stress, and indignity of inner-city poverty.

A growing body of literature identifies the challenges of providing palliative care to the urban poor, such as illness-related issues, resource limitations, healthcare system interactions, and end-of-life preferences (see Table 21.1).

PRIMARY CARE FOR THE ECONOMICALLY DISADVANTAGED

Community health centers play a critical role in providing comprehensive primary healthcare services, chronic illness management, cancer screening, and other healthcare maintenance for underserved and vulnerable populations. But if the location of the clinic is inconvenient and its hours are not conducive to work schedules, the urban poor may have difficulty even getting there. Taking time off from work to obtain medical care is a problem for someone who does not have a car, does not have sick leave, is paid on an hourly basis, has more than one job, and does not have coworkers to cover their workload. It is especially difficult if the person’s income supports many other individuals. Lacking a medical home, many of the urban poor rely on the emergency department (ED), with its open-door access to medical care 24 hours a day, 365 days a year. A 2016 study of homeless patients who presented to the ED of a Bay Area hospital found that only 7.3% of visits resulted in hospitalization and that close to 50% of participants had made another ED visit in the past 6 months, significantly higher than the US age-matched population.¹³

Given these challenges, it is no surprise that Danny had no long-term relationship with a primary care provider. Sadly, with his initial presentation of oral symptoms while

Table 21.1 CHALLENGES OF PROVIDING PALLIATIVE CARE TO THE ECONOMICALLY DISADVANTAGED

Illness-related	Prevalence of concurrent mental illness and substance use disorder Lack of decision-making capacity Presentation with advanced disease Multiple comorbidities End-organ diseases altering pharmacodynamics
Resource challenges	Health literacy Language discordance with health care providers Family or friend caregiver availability Need for designated surrogate decision-maker in the event of loss of decision making Chaotic lives with little room for day-to-day illness demands Adverse childhood or adulthood events (trauma histories) Limited ongoing therapeutic relationships with health or social service providers Survival or addiction that overshadows illness management Competing role responsibilities Functional impairments, geographic distances, & transportation
Relationships with healthcare system or providers	Cultural history of racism, discrimination, or rejection in health care system As a result of disrespectful, rude, or dismissive interactions in past, patients may present as angry, avoidant, suspicious, or nonadherent with care recommendations Healthcare providers often have different cultural & ethnic backgrounds/worldviews
End-of-life preferences	Reluctance to relinquish aggressive medical management Different assumptions about optimal end-of-life care, particularly in communities of color Lack of advance care planning as life is survived moment to moment Tendency to equate goals of care modification with abandonment or continued poor care Spirituality may be a hidden resource for comfort and in guiding decision-making

Adapted from Dahlin et al.¹⁴

incarcerated, he was merely given a test for rapid strep then dismissed with no follow-up. More importantly, he had never participated in an advance care planning conversation with a trusted provider, nor had he been given the chance to nominate Marcia as his surrogate decision-maker.

Given that Danny presented with clinical “red flags” (weight loss and severe dysphagia), the clinic APRN in the neighborhood health center appropriately referred Danny to otolaryngology, where her suspicion of a malignancy was confirmed. Due to lack of resources in both community health and the safety net hospital, for an oncology treatment plan to be developed; a picture common across the United States. A 2018 report showed that the shortage of specialists working within the safety net can mean wait times of up to 8 months.¹⁵

By the time Danny met the palliative APRN, he had literally lost the ability to speak for himself. How does a palliative APRN meeting a patient for the first time provide information, support, and anticipatory guidance in this situation, particularly for a patient like Danny who lives on the margins of the dominant society? Very fortunately for Danny, this APRN was able to assess and understand his needs and advocate for him. She was able to get him pain medication when he needed it, after his surgical team had deemed him to be just another drug seeker. The APRN was able to get him the esophageal dilation when she discovered a postop stricture. The APRN was able to hold the space for him to explore, through writing, his fears, anxieties, and frustrations, and learn of his overarching love for his children above all. All this took time, and a clinician focused on hurrying through

the appointment to empty out the waiting room would have missed much of it.

The palliative APRN must complete a comprehensive social and cultural assessment while simultaneously being truly “present” for patients, listening to their story, attending to their immediate self-identified needs, and creating a therapeutic environment in which they feel valued, safe, and cared for as human beings. This is a population too often ignored by the biomedical healthcare model, a model that tends to miss the whole person while focusing on lab values and checklists.⁸

The National Consensus Project for Quality Palliative Care (NCP) *Clinical Practice Guidelines* outlines social and cultural assessment components relevant to the care of patients (Table 21.2).

ROLE OF SAFETY NET HOSPITALS AND PUBLIC HEALTH CARE SYSTEMS

In 2000, the Institute of Medicine defined *safety-net hospitals* (SNHs) as hospitals that, by mission or mandate, provide care to a substantial share of vulnerable patients regardless of their ability to pay.¹⁶ In short, these hospitals care for patients and communities who would otherwise “fall through the cracks.” Safety net providers serve vulnerable populations at risk for health disparities, such as communities of color, immigrants, and the uninsured or underinsured, and they play a critical role as training sites for physician trainees, undergraduate and graduate nursing students, and other allied health students. APRNs may be particularly drawn to practice in safety net

Table 21.2 SELECTED APRN ROLES AND BEHAVIORS IN CARING FOR THE URBAN POOR

ROLE	ADVANCED CORE BEHAVIORS
Advocacy and moral agency	Assesses the individual with serious illness with attention to populations at risk (e.g., older adults; children and youths; persons experiencing homelessness; persons of color; LGBTQ+ persons; persons experiencing substance abuse disorders; persons with serious mental illness; individuals without legal validation; individuals incarcerated in jails, prisons, and detention centers; persons with cognitive impairment, as well as developmental, intellectual, and physical disabilities) in an age-, cognitive-, and developmentally appropriate manner. Collaborates with the palliative interdisciplinary team, other health team professionals, and the public to protect human rights, promote health diplomacy, enhance cultural sensitivity and congruence, and reduce health disparities. Collaborates with other health professionals to ensure ethically sound organizational systems for access to and fair distribution of healthcare resources across all populations. Uses a systematic approach to ethical and legal review of clinical and palliative-related healthcare issues in collaboration with an ethics committee and legal counsel, particularly in the development of palliative-related policies and procedures, incorporating ethical principles (i.e., beneficence, autonomy, justice, nonmaleficence, veracity), and consulting ethics resources/services as appropriate.
Collaboration	Builds trusting and collaborative relationships with interdisciplinary team members, health colleagues of all disciplines, healthcare staff, and the community. Collaborates with community agencies to facilitate care in the setting preferred by the individual and family, when feasible, including both hospice and home care services provided in a variety of settings.
Systems thinking	Analyzes systems-level policies considering issues of access, quality and cost, and health disparities through the development and implementation of policies. Develops strategies of palliative care programs and systems to meet the needs of its communities, patient populations, and care locations, with particular attention to health, racial, and social disparities. Articulates the importance of population health principles and apply them to palliative care. Utilizes systematic methods to assess the palliative care needs of healthcare systems, healthcare organizations, individuals, and families.
Response to diversity	Practices with cultural awareness, sensitivity, and humility by performing self-examination of cultural beliefs and values and how they relate to healthcare and the environment in which one works. Identifies and responds to health disparities, social injustices and racism within palliative care and leads initiatives to mitigate them. Demonstrates ability to collect relevant cultural data related to the individual and family presenting health condition and unmet needs; accurately performs culturally specific assessment to deliver culturally competent interdisciplinary palliative care. Assesses, identifies, and addresses cultural, spiritual, and existential beliefs, behaviors, practices, needs, and concerns of individuals with serious illness and family members according to established protocols and documents in the interdisciplinary care plan. Accesses appropriate cultural, spiritual, and religious resources to deliver palliative care to individuals and families. Addresses conflicts that may arise between individuals, families, and healthcare providers resulting from differences in cultural and spiritual perspectives related to palliative care, and plans for effective strategies to allow for and accommodate those differences. Recognizes and educates others about diverse systems of belief and the role of diversity in the application of professional health provider obligations, including information on diagnosis; disclosure; decisional authority; care; and acceptance of decisions to continue, discontinue, or forgo treatments.

From Dahlin.^{14,17}

systems, given their social justice mission of improving the health and well-being of marginalized or underserved communities. In fact, a commitment to social justice is written into the American Nurses Association *Code of Ethics for Nurses*: “All nurses, through organizations and accrediting bodies involved in nurse formation, education, and development, must firmly anchor students in nursing’s professional responsibility to address unjust systems and structures, modeling the profession’s commitment to social justice and health through content, clinical and field experiences, and critical thought.”¹⁸ (p. 36)

In fiscal year 2018, safety net hospitals reported that more than half (54%) of their discharges were from racial/ethnic

minorities and three-quarters of patients were uninsured or covered by Medicaid or Medicare. Safety net hospitals provided nonemergent outpatient care to 80 million patients in 2018, and treated more than 14 million in EDs. Inpatient admissions averaged 18,000 per hospital, nearly three times more than the inpatient volume of other hospitals.¹⁹

The enactment of the *Affordable Care Act* (ACA) in 2010 and implemented in 2014 led to historic gains in health insurance coverage by extending Medicaid coverage to many low-income individuals. The number of uninsured nonelderly Americans decreased from more than 46.5 million in 2010 to just below 27 million in 2016, a historic low.²⁰ However, since 2016, the number of uninsured has increased by half a million

every year, and undocumented immigrants still remain ineligible for coverage. People of color are at higher risk of being uninsured than Whites; while they make up 43% of the non-elderly US population, they account for more than a half of uninsured population.²¹

While this expansion of newly covered Medicaid patients may appear on the surface to be a boon for safety net hospitals, early data have actually shown that non-safety net hospitals are now also attracting Medicaid patients. Although reimbursement rates are typically lower than treatment costs, because the majority of hospital costs are fixed and tend not to vary by patient volume, Medicaid admissions can contribute to overall hospital profitability.²⁰ The uninsured, however, will likely continue to receive the vast majority of their care from safety net hospitals.¹⁹

Safety net hospitals have generally been slower to initiate a palliative care service. The Center to Advance Palliative Care has found that far fewer public hospitals report palliative care services, compared to similarly sized not-for-profit hospitals.¹⁰ However, nurses in safety net hospitals are increasingly receiving training from the End-of-Life Nursing Education Consortium for Public Hospitals (ELNEC-PH), launched in 2012.²² Geography also plays a major role in the availability of palliative care for the poor. People living with a serious illness who reside in the northeastern United States have access to significantly more hospital palliative care programs than those living in other regions. However, these numbers continue to increase as safety net hospitals recognize the benefits of palliative care.

OVERCOMING LANGUAGE BARRIERS

The United States is linguistically and culturally diverse. The US Census Bureau's *American Community Survey of 2018* revealed that one in five of the population speaks a language other than English at home, and 8.3% of the US population speaks English "less than well," with numbers significantly higher in patients older than 65.²³ Certain states have disproportionately large numbers of persons with limited English proficiency, from 9% of total households in California to 0.9% in Maine.²³

These numbers are expected to increase in the 2020 US Census Bureau survey, suggesting that healthcare professionals will care for an increasing number of patients with limited English proficiency. The overlap between English proficiency and poverty is striking. Of the 38 million living below the poverty level in 2018, close to 30% speak a language other than English at home.²³

Discussing end-of-life wishes, goals of care, giving bad news, prognostication—these conversations, frequent in the palliative care setting, require clear, straight forward communication skills and can be challenging for all practitioners. Language barriers are known to contribute to worse healthcare quality and outcomes, with non-English speaking patients reporting lower satisfaction with care, often being vulnerable to inadequate pain assessment and management

and overall suffering from unnecessary physical emotional and spiritual suffering, particularly at the end of life.²⁴ The *1964 Civil Rights Act* required all hospitals to provide language services to patients with limited English proficiency.²⁵ This was reinforced in 2020, by Section 1557 of the ACA, which requires healthcare providers to provide patients with access to qualified interpreters. If a qualified interpreter is not provided, patients have the right to sue the provider for language access violations.²⁶ Given the complexity and emotional weight of the information being communicated in many palliative care encounters, modifications in meaning can still occur even when professional interpreters are used.

CASE STUDY: LANGUAGE BARRIERS

Mr. X and his family were meeting with his palliative APRN to review his latest imaging and lab results. He had been losing weight for some months, and he had some new back pain that just wouldn't go away, even if he took his pain medications. Recognizing that the patient and his family did not speak English well enough to properly understand his diagnosis, the APRN called the language line and put the Cantonese interpreter on speakerphone. She carefully explained that Mr. X has multiple myeloma and that he would be started on treatment by the oncology team. She waited while the interpreter explained, then sat silently to allow the family time to process what had just been said. The family looked confused. The teenage son spoke up, in English: "Does my dad have two cancers now? Did it spread to his skin?" After exploring with the son what had been said, it became evident that the interpreter had told the X family that he had a diagnosis of melanoma, not myeloma, two very different diagnoses and prognoses.

Indeed, the very term "palliative" does not translate smoothly into many other languages. Dr. Pan, writing on the Geriatrics and Palliative Care blog *Geripal* tells us that

The Google translation of Palliative Care is "姑息治疗." Back translated, the meaning is essentially "*Do Nothing Care*." Similarly, the Google translation of Hospice is "临终关怀," literally meaning "*Last Minute Care*." Is it any wonder that patients whose goals are comfort oriented end up declining hospice and palliative care once they hear the translated words?²⁷

Translations are not much better in Spanish. The Spanish-language page of the National Institute of Health translates hospice as *hospicio*, a term also used by many medical interpreters.²⁸ While the Spanish and English words have the same Latin root, *hospes*, in Spanish the word came to mean a place for the destitute.²⁹ As we discussed earlier, the Latinx community has lower use of hospice and palliative care services: Is it any a surprise, given the translation?¹⁰ The Spanish phrase "cuidados paliativos" has no negative connotations, but it remains an unfamiliar term for many. A 2019 survey by the Center to Advance Palliative Care (CAPC) found that almost half of all adults in America have never heard of palliative care.³⁰

Surveys of professional interpreters with extensive experience in end-of-life discussions have identified specific techniques to optimize providers' patient encounters.³¹ Guidelines for optimizing communication with healthcare interpreters are summarized in Box 21.1. The California Health Care Foundation also offers comprehensive recommendations for working with interpreters, specifically in a palliative care setting.³² These best practices emphasize direct communication with the interpreter and outline basic principles of interacting with interpreters, including structural and practical aspects of communication.

NEGOTIATING HOSPITALIZATION AND TREATMENT

Given the limited access to and availability of outpatient and community-based palliative care for the urban poor,¹⁰ it is most likely that patients will encounter palliative APRNs in the acute care setting. The patient in the case study, Danny, might receive education from an oncology APRN about his cancer diagnosis, treatment side effects, and recovery trajectory; a palliative APRN might assist with symptom management

Box 21.1 GENERAL GUIDELINES FOR WORKING WITH HEALTHCARE INTERPRETERS

- Use a professional interpreter (in person or via technology), unless an emergency or not available due to rare language dialect.
- Always brief the interpreter beforehand about the goal of the meeting and the issues to be discussed to make sure they are culturally appropriate.
- Introduce the interpreter to the family, set expectations, and address confidentiality concerns.
- Make eye contact at and speak directly to the patient, not the interpreter.
- Use short sentences or phrases and let the interpreter translate those into smaller sentences. Break up lengthy explanations or responses into multiple shorter responses.
- Avoid using euphemisms, proverbs, or cultural references, as they can lead to confusion or may not carry similar meaning when interpreted.
- Check for patient/family understanding frequently, either directly (e.g., teachback technique) or indirectly (checking with interpreter if he or she perceives that patient is or is not understanding).
- When trying to get the attention of the interpreter, start your comment with "Interpreter" to make it easier for the interpreter to distinguish the person you are addressing.

From Schenker et al.³³; and Association of American Medical Colleges.³⁴

and clarification of goals of care; a wound care APRN might be consulted regarding ostomy teaching or complex surgical wound management; and a psychiatric mental health APRN might help Danny identify coping resources for managing his new diagnosis and to acknowledge the impact of past traumas in his life. Regardless of the particular APRN role, an understanding of the hospitalization experience for Danny and others who are economically disadvantaged will be necessary to appreciate their understanding of the illness and its treatment demands.

Like many economically disadvantaged persons with serious illness, Danny had a difficult life story. Born in poverty, he was then passed from foster home to foster home, eventually ending up on the streets. He was incarcerated countless times, usually for minor drug charges. It's worth noting that while African Americans and Whites use drugs at similar rates, the imprisonment rate of African Americans for drug charges is almost six times that of Whites. For many, release from prison compounds preexisting disadvantage because people have difficulty finding stable accommodation and employment, accessing health services, and reconnecting with families, social groups, and communities.

Furthermore, the risk of premature mortality for adults released from incarceration is substantially higher than in the general population.³⁵ A 2017 study on the impact of socioeconomic status (SES) on esophageal cancer—Danny's diagnosis—found that the 5-year survival of patients with low SES is significantly lower than in patients with high SES.³⁶ The same pattern is seen in patients with other malignancies.^{37,38}

Moller describes how the illness narrative of so many urban poor is one of "disempowerment, neglect and fear."^{8(p. 61)} This mirrors Danny's situation:

- a) disempowered—Danny did not fully understand his prognosis or even treatment regimen; b) neglect—Danny had no transportation, his housing was unstable with his kids living in car; c) fear—fear of abandoning his kids, concerned that Marcia would leave him, fear of death.

Many patients cared for by safety net systems have been exposed to unimaginable life events prior to the diagnosis of a life-threatening illness, such as child abuse, intimate partner violence, homelessness, incarceration, sexual assault, wartime exposure, homicides and suicides of family and friends, and substance abuse. Epidemiological surveys show that more than 70% of men and 80% of women (aged 15–54 years) in the general population have experienced at least one psychological trauma in their lifetime.³⁹ While there are no official data specific to the urban poor, it is not difficult to imagine significantly higher numbers; their lives are often trauma-filled.⁴⁰ Add to this the inherent trauma to all palliative care patients—the threat to life itself—and it becomes clear that this is an area that needs to be addressed in all safety net palliative care patients.

There is a growing awareness of the physical, psychological, emotional, and existential toll trauma exposure has on individuals, communities, and even healthcare professionals

themselves. A healthcare setting poses unique risk for distress given the complex, invasive, and repetitive nature of traumatic exposure in this environment: persistent questioning by unfamiliar faces, unexpected tests in the dark hours of the night, the need to wear a dehumanizing hospital gown, endless blood draws—and during the COVID-19 pandemic, no visitors. What's more, patient care may be compromised because patients struggling with trauma histories are more likely to be anxious, depressed, distrustful, and angry, as well as avoidant of trauma reminders, which may include medical settings and medical personnel.⁴¹ What might this look like in clinical practice? For example, a patient with a history of rape may become combative and anxious, as well as depressed if they are not adequately prepared for a switch from oral medication to suppository-based medication.⁴¹

Recognizing this risk, mental health experts and organizations such as the Substance Abuse and Mental Health Services Association (SAMHSA) have developed a framework of *trauma-informed care* (TIC) to prevent and treat trauma responses. TIC recognizes and responds in meaningful ways to individuals who have experienced trauma and is based on the principles of safety, trustworthiness, collaboration, empowerment, and choice.⁴² While this remains a relatively new model of care, it undoubtedly will shape palliative care and other services for the economically disadvantaged and other vulnerable populations at high risk for posttraumatic stress disorder, as well as the healthcare and social service professionals working with them.

Perhaps because of their difficult biographies, many persons with limited resources have a remarkable resiliency.⁴³ When one lives at the financial edge, where daily life is shaped by constant struggle, a cancer diagnosis is often just one more bad thing to happen this week. According to Moller: “Poor patients can often show remarkable equanimity when told they are dying, in large part because their life-long experiences have taught them to expect bad news.”⁸ (p. 6)

Some of this resilience may be understood by spiritual and religious beliefs and practices that connect patients' experiences to something greater than their everyday existence. When looking at the populations most represented in the urban poor, 96% of African Americans say they believe in God and 75% say that God is “very important” in their life; in the Latinx community these numbers are 91% and 59%, respectively. Compare this with the White communities: 86% and 49%.⁴⁴

Let's review Danny and his family: as an African American, previously incarcerated male with little formal education, he was able to raise his children in one of the most expensive rental areas in the United States. His children were always well-dressed when they accompanied him to his appointments and polite to a T. Despite having no transportation, Danny made it on time to almost all of his appointments; he always had scraps of paper in his pocket to write on after his laryngectomy, and he joked with his palliative APRN that he would “buy us both steaks when I'm better.” The palliative APRN is pivotal in helping to draw on this resiliency within patients to help them face serious illness and navigate complex healthcare systems.

Beyond linguistic and cultural barriers, the urban poor face many difficulties in the healthcare system, including logistical and bureaucratic difficulties accessing care, insensitive or dismissive interactions with healthcare professionals and support staff, and delays in nursing and medical care that result in patients being made to feel less than human.⁴⁵ It is also well-documented that minority patients are more likely to receive inadequate pain treatment compared with White patients.⁴⁶ During the COVID-19 pandemic, many healthcare providers switched to telemedicine, a delivery method that has been gaining in popularity over the past decade. This in itself assumes technological literacy, equipment availability, income, a stable housing situation, and it means that many underserved populations are being excluded from this shift in healthcare delivery.⁴⁷

APRN COMPETENCIES IN CARING FOR ECONOMICALLY DISADVANTAGED PERSONS

For palliative APRNs caring for those who are economically disadvantaged, the knowledge and skills (competencies) are in many ways similar to the competencies required when caring for other palliative care populations, but there are some important differences to keep in mind. The Hospice and Palliative Nurses Association's *Competencies for the Palliative and Hospice APRN* with particular relevance to the urban poor are noted in Box 21.2.

ADVOCACY AND ETHICS

Moller states, “To be poor does not mean that one needs to die poorly.”⁸ One of the most important tenets of all health and social service professionals is advocacy for patients, families, and communities. This holds particular salience for palliative APRNs working with vulnerable or marginalized populations. Good palliative care embraces cultural, ethnic, and faith differences and preferences while interweaving the principles of ethics, humanities, and human values into every patient- and family-care experience.⁴⁸ This is reflective of the American Nursing Association *Standards of Professional Performance* that name advocacy as the “pillar of nursing” and requires *culturally congruent practice*: “The registered nurse practices in a manner that is congruent with cultural diversity and inclusion principles.”⁴⁹ (pp. 69–70)

In March 2017, the American Nurses Association and Hospice and Palliative Nurses Association (HPNA) published *A Call to Action: Nurses Lead and Transform Palliative Care*. This seminal document called for the funding, development, and evaluation of innovative palliative care models to address “the needs of communities of color, underserved populations, and other vulnerable groups, such as Native Americans, persons with intellectual and developmental disabilities, and others in rural and urban areas.”⁵⁰ (p. 4) The palliative APRN is encouraged to lead and transform palliative care in practice, education, research, administration, and policy.

Domain 4: Social Aspects of Care

GUIDELINE 4.2

Social determinants of health have a strong and sometimes overriding influence on patients with a serious illness. Palliative care addresses environmental and social factors that affect patient and family functioning and quality of life. The palliative care interdisciplinary team (IDT) partners with the patient and family to identify and support their strengths and to address areas of need.

CRITERIA [SELECTED]

- The interdisciplinary team (IDT) performs developmentally and culturally sensitive screening and assessment in the setting in which the patient receives care. This includes:
 - Family structure and function, including roles, quality of relationships, communication, and decision-making preferences and patterns, as well as an assessment of those involved if the patient is in the custody of the county or state
 - Patient and family strengths, resiliency, social and cultural support, and spirituality
 - The availability and ability of a support system to provide respite, assist with errands and chores, and guard against social vulnerability
 - The effect of illness or injury on intimacy and sexual expression, prior experiences with illness, disability and loss, risk of abuse, neglect or exploitation, incarceration, or risk of social isolation
 - Functional limitations that impact activities of daily living (ADLs), instrumental activities of daily living (IADLs), and cognition
 - Changes in patient or family members' school enrollment, employment or vocational roles, recreational activities, and economic security
 - Living arrangements and perceived impact of the living environment on patient and family quality of life, including safety issues
 - Patient and family perceptions about caregiving needs, including caregiver availability and capacity
 - Financial vulnerability (e.g., ability to pay rent or mortgage and other bills)
 - Ability to access prescription and over-the-counter medications for any reason, including functional or financial issues
 - Nutritional needs and food insecurity
 - Advance care planning and legal concerns
 - Patient and caregiver ability to read and understand information from health and social service providers, insurance companies, and the IDT, as well as the ability of the patient and family to ask questions and advocate for their needs
 - The ability of the patient and/or family to adhere to medication or treatment regimens
 - Patient and family willingness and ability to engage or accept resources and referrals

Domain 6: Cultural Aspects of Care

GUIDELINE 6.1

The palliative care program serves each patient, family and community in a culturally and linguistically appropriate manner.

CRITERIA [SELECTED]

- The IDT delivers care that respects patient and family cultural beliefs, values, traditional practices, language, and communication preferences and builds upon the unique strengths of the patient and family. Members of the IDT works to increase awareness of their own biases and seeks opportunities to learn about the provision of culturally sensitive care. The care team ensures that its environment, policies, procedures, and practices are culturally respectful.
- IDT members recognize that the provision of quality palliative care requires an understanding of the patient's and family's culture and how it relates to their decision-making process, and their approach to illness, pain, psychological, social, and spiritual factors, grief, dying, death, and bereavement.
- The IDT understands that each person's self-identified culture includes the intersections of race, ethnicity, gender identity and expression, sexual orientation, immigration and refugee status, social class, religion, spirituality, physical appearance, and abilities.
- The IDT recognizes that patients and families may have experienced barriers to receiving culturally respectful health care, and that these prior experiences may result in mistrust of the healthcare system.
- The IDT commits to continuously practice cultural humility and celebrate diversity.

And while one may be unable to fix the problems of poverty, it is incumbent on all palliative APRNs to improve the care of individual patients. Working with the urban poor requires creative, in-the-moment problem-solving to honor patients' preferences and goals. To effectively care for vulnerable populations, palliative APRNs must develop collaborative relationships with a wide range of social services and other safety net providers, and they need to have a good working knowledge of Medicaid, to avoid presenting plans that are not possible to achieve logistically.

Palliative APRNs must relearn how the art of caring can intersect with the science of treatment. One can see how poverty is a major risk for morbidity and mortality. However, the healthcare system too often looks past our more vulnerable patients, focusing on lab results and imaging rather than seeing them as a whole person. One needs to see beyond the biomedical model and take the time to really get to know our patients, listen to their stories, and provide culturally, socially, and linguistically appropriate treatment for the whole person.

SUMMARY

Caring for persons who are economically disadvantaged and in need of palliative care demands not only expert clinical acumen but also—and equally important—an appreciation of their community and their everyday lives. This chapter examines (1) palliative care across settings, (2) the role of safety net providers, (3) the challenges of communicating through an interpreter, and (4) the competencies needed by hospice and palliative APRNs who care for this special population.

LGBTQ+ INCLUSIVE PALLIATIVE CARE

Jessica Nymeyer

KEY POINTS

- The palliative advanced practice registered nurse (APRN) is conscious of the importance of tailoring the care plan for each patient based on the patient's and their family's goals and values.
- An individual's sexual and gender identity are essential components of their lived experience and should not be overlooked while they are receiving care for a serious illness.
- The palliative APRN must understand the context of the LGBTQ community and the challenges for an individual with serious illness.

It is important to establish an appropriate surrogate decision-maker for patients with serious medical conditions as soon as possible. Inclusive language may include:

1. If there comes a time when you are too sick to make your own decisions about your care, whom do you want to make decisions on your behalf? Have you already put that in writing? If not, can we do that today?
2. Do you have any concerns about a different person trying to step in to make decisions for you?
3. Have you spoken to them about your concerns? Does your chosen healthcare decision-maker know your concerns?
4. Privacy rules under the Health Insurance Portability and Accountability Act (HIPAA) guide that we can share information with your family and friends only with your permission. What information would you like us to share about your illness and medical condition and with whom?

CASE STUDY 1: INCLUSIVE CARE

Mr. G, a 68-year-old man, was admitted to the hospital with respiratory distress and is suspected of having COVID-19. He was a new patient to the health system so there was no information in the electronic medical record. For the safety of staff and other patients, he was placed in an isolation room with the door closed and not allowed to have any visitors. He reported his health history of type-2 diabetes, hypertension, and high cholesterol; however his ability to participate in prolonged discussion was limited by shortness of breath. The advanced practice registered nurse (APRN) overheard staff discussing that his SARS-CoV-2 PCR came back positive and that he was having progressive hypoxia requiring increasing oxygen. The primary medical team was overwhelmed and asked for assistance from the palliative APRN because they were worried Mr. G's condition could rapidly decline. How should the APRN approach him?

In any situation where there is a possibility for rapid decline, there is limited opportunity to develop a relationship and establish goals of care with a patient. Best practices guide clinicians to use LGBTQ-inclusive language for every patient encounter to avoid marginalizing a patient.¹

Recommended initial interview questions include:

1. What would you like me to call you?
2. What gender pronoun do you go by (he/him, she/her, them/their, etc.)?
3. Who do you consider to be your family?
4. Who is available to help you when you are sick?

INTRODUCTION

Delivering inclusive care to patients who identify as LGBTQ+ (lesbian, gay, bisexual, transgender, queer/questioning with+ representing other sexual or gender identities that are not named in the acronym) is not a political or religious statement; it has been clearly defined as a marker of best practices in delivering high-quality healthcare. The Joint Commission has issued guidance directing all healthcare facilities to consider the needs of the LGBTQ population in their policies and procedures with the goal to "advance effective communication, cultural competence, and patient-and family-centered care for all patients."²

As an advanced practice registered nurse (APRN), practice is guided by the American Nurses Association, which explicated the necessity for all nurses to provide inclusive care to sexual and gender minority (SGM) individuals in a 2018 position statement which states, "nurses must deliver culturally congruent care and advocate for lesbian, gay, bisexual, transgender, queer, or questioning (LGBTQ+) populations. . . . ANA is committed to the elimination of health disparities and discrimination based on sexual orientation, gender identity, and/or expression within health care."³

The goal of this chapter on LGBTQ+ inclusive palliative care is not to suggest a prescriptive approach to caring for any specific SGM but to ensure that all care delivered by the

palliative APRN is inclusive. Every clinician should presume that they care for patients who identify as LGBTQ+ and not assume that these individuals can be identified by external characteristics or life experiences, such as having children.⁴ This chapter describes physical and mental health issues that disproportionately impact the LGBTQ+ community, unique challenges SGM face while living with serious illness, raise the APRN's consciousness of the pervasive nature of heteronormative language and assumptions, and highlight techniques that individuals and institutions should use with all patients to provide inclusive care. Moreover, there may be some legal and financial issues for the palliative APRN to attend to when caring for patients that identify as SGM. Through the process of developing a knowledge base about the LGBTQ+ community and making an effort to thoughtfully reflect on their own behaviors and potential biases, the palliative APRN will be prepared to be a leader within their institutions in the care of SGM patients with serious illness.

DEFINITIONS AND LANGUAGE

Being familiar with the language associated with sexual and gender minorities has been shown to lead to more positive attitudes among healthcare providers when caring for LGBTQ+ individuals.⁵ However, an emphasis on learning facts about any population of people assumes that individuals within the population are homogenous and that language is static. It is understandable that the palliative APRN may not have a detailed understanding of all of the words individuals use to describe their sexuality and gender identity. The emphasis should not be on memorizing terms or assuming how a person would prefer to be described but instead on approaching each individual with an open heart and willingness to learn from them about their experiences.

The palliative APRN should strive for an attitude of *cultural humility* which directs focus on self-reflection and actively listening to individuals to more clearly understand their unique perspective.⁶ Key terms related to sexual and gender minorities, as defined by the Human Rights Campaign, are listed in Table 22.1. Terms, like the word “queer,” which many believe has been “reclaimed” from being a slur to becoming an inclusive term of SGM identity, have changed in meaning over time and are likely to continue to evolve.⁷ While some may perceive that patients would respond negatively, most patients are comfortable being asked questions about their sexual orientation and gender identity and understand what the questions mean.⁸ The palliative APRN should be empowered to recognize that emphasizing equality by ignoring sexual and gender identity represents a failure to provide person-centered care.⁹

The terms “men who have sex with men” (MSM) and “women who have sex with women” (WSW) have been used in public health literature; however, this only serves to describe a behavior and does not address sexual identity or gender. Up to 50% of individuals who have reported sexual encounters with someone of the same sex identify themselves as heterosexual.¹⁰

Younger people who identify as sexual or gender minorities may be more open than older individuals to disclose their identity given increased acceptance of LGBTQ+ in recent years. They may still likely face significant challenges in their families and communities due to ongoing stigma and have higher rates of homelessness, suicidal ideation, and sexual abuse than heterosexual peers.¹¹ A telephone survey of a nationally representative sample of US residents conducted in 2017 found that slurs, *microaggressions* (often unintentional actions or comments based on stereotypes), sexual harassment, and violence were experienced by more than 50% of LGBTQ survey participants.¹²

HISTORY OF CHALLENGES FOR LGBTQ INDIVIDUALS WITH SERIOUS ILLNESS

In 2011, the National Institutes of Health (NIH) published the Institute of Medicine (IOM – now known as the National Academy of Medicine) a report on the *Health of Lesbian, Gay, Bisexual and Transgender (LGBT) People*, which cited lack of social support and legal protections as barriers to access and quality of palliative care among sexual and gender minorities.¹³ The report recognized that improving the health of the LGBT community requires appreciation of their lived experience. While acknowledging the diversity of LGBT individuals, the report found that long-term discrimination, inadequate training of healthcare workers, and stigma associated with the HIV/AIDS epidemic have caused significant negative impact on the health of the population overall. The IOM described the ongoing HIV/AIDS epidemic as illustrative of the overall status of the LGBT population: unified and resilient in the face of stigma but with disparities exacerbated by race and ethnicity and limited understanding complicated by inadequate research funding.

Although legal protections have evolved since the IOM report, including the Supreme Court ruling in 2015 legalizing same-sex marriage¹⁴ and the June 2020 ruling that Title VII of the constitution includes protection for sexual and gender minorities against employment discrimination,¹⁵ the consequences of historical barriers remain, including state surrogacy laws that often prioritize biologic family over chosen family with lack of recognition of non-married partners. Box 22.1 describes some of the legal issues that disproportionately impact SGM that the palliative APRN should be aware of when providing care to LGBTQ+ individuals and their families. Lack of understanding of legal issues that disproportionately impact advance care planning for SGM can be a form of institutional discrimination inadvertently propagated by the palliative APRN.¹⁶

In addition to evidence of legal and social inequity, a record of discrimination against LGBTQ+ individuals exists within the healthcare system in the United States. Historically, identifying as a sexual or gender minority led to a psychiatric diagnosis. The American Psychiatric Association's *Diagnostic and Statistical Manual of Mental Disorders* (DSM) identified homosexuality as a “sociopathic personality disturbance” until 1973, and it wasn't until 1987 that diagnoses related to same-sex attraction were removed from the DSM.¹⁷

Table 22.1 GLOSSARY OF TERMS BASED ON HUMAN RIGHTS CAMPAIGN DEFINITIONS

TERM	DEFINITION
Androgynous	Identifying and/or presenting as neither distinguishably masculine nor feminine.
Asexual	The lack of a sexual attraction or desire for other people.
Bisexual	A person emotionally, romantically, or sexually attracted to more than one sex, gender, or gender identity though not necessarily simultaneously, in the same way or to the same degree.
Cis-gender	A term used to describe a person whose gender identity aligns with those typically associated with the sex assigned to them at birth.
Closeted	Describes an LGBTQ person who has not disclosed their sexual orientation or gender identity.
Coming out	The process in which a person first acknowledges, accepts, and appreciates his or her sexual orientation or gender identity and begins to share that with others.
Gay	A person who is emotionally, romantically, or sexually attracted to members of the same gender.
Gender dysphoria	Clinically significant distress caused when a person's assigned birth gender is not the same as the one with which they identify. According to the American Psychiatric Association's <i>Diagnostic and Statistical Manual of Mental Disorders</i> (DSM-5), the term—which replaces Gender Identity Disorder—“is intended to better characterize the experiences of affected children, adolescents, and adults.”
Gender expression	External appearance of one's gender identity, usually expressed through behavior, clothing, haircut, or voice, and which may or may not conform to socially defined behaviors and characteristics typically associated with being either masculine or feminine.
Gender-fluid	According to the <i>Oxford English Dictionary</i> , a person who does not identify with a single fixed gender; of or relating to a person having or expressing a fluid or unfixed gender identity.
Gender identity	One's innermost concept of self as male, female, a blend of both or neither—how individuals perceive themselves and what they call themselves. One's gender identity can be the same or different from their sex assigned at birth.
Gender non-conforming	A broad term referring to people who do not behave in a way that conforms to the traditional expectations of their gender or whose gender expression does not fit neatly into a category.
Homophobia	The fear and hatred of or discomfort with people who are attracted to members of the same sex.
Lesbian	A woman who is emotionally, romantically, or sexually attracted to other women.
LGBTQ	An acronym for “lesbian, gay, bisexual, transgender and queer.”
Living openly	A state in which LGBTQ people are comfortably out about their sexual orientation or gender identity—where and when it feels appropriate to them.
Outing	Exposing someone's lesbian, gay, bisexual, or transgender identity to others without their permission. Outing someone can have serious repercussions on employment, economic stability, personal safety, or religious or family situations.
Queer	A term people often use to express fluid identities and orientations. Often used interchangeably with “LGBTQ.”
Questioning	A term used to describe people who are in the process of exploring their sexual orientation or gender identity.
Sexual orientation	An inherent or immutable enduring emotional, romantic, or sexual attraction to other people.
Transgender	An umbrella term for people whose gender identity and/or expression is different from cultural expectations based on the sex they were assigned at birth. Being transgender does not imply any specific sexual orientation. Therefore, transgender people may identify as straight, gay, lesbian, bisexual, etc.
Transphobia	The fear and hatred of, or discomfort with, transgender people.

From Human Rights Campaign.⁵²

In 2014, the Department of Health and Human Services Departmental Appeals Board overruled a National Coverage Determination made in 1981 that designated “transsexual surgery” as “experimental,” allowing costs associated with transition to now be covered by the Centers for Medicare and Medicaid Services (CMS).¹⁸ In the most recent edition of the DSM (DSM-5; 2015), diagnoses associated with being transgender were specifically worded to ensure individuals

**Box 22.1 LEGAL CONSIDERATIONS FOR
THE APRN CARING FOR SERIOUSLY ILL
LGBTQ+ INDIVIDUALS**

- Marriage, civil unions, and domestic partnerships confer different benefits and rights in each state. Federal benefits of marriage, including Social Security, do not apply to unmarried domestic partners.
- Biologic, adopted, or co-parented children may require formal legal documentation to ensure that the appropriate guardian is recognized in the event of an emergency.
- Each state designates a surrogacy order for patients who have not named healthcare agents; this may or may not be consistent with an individual's preferences, and individuals are strongly encouraged to complete a healthcare proxy.
- The power of a healthcare agent commonly ends at death; specific documentation may be required to prevent automatic transition of rights to biologic next of kin.

From Lambda Legal.⁵³

could maintain access to care (which requires a medical diagnosis) while attempting to reduce the stigma associated with having a psychiatric diagnosis by creating a new term, *gender dysphoria*.¹⁷ This terminology clarifies that it is not a mental illness that causes the person to desire a different identity but nonpathologic distress in the context of the physical body not aligning with the individual's self-perception.⁵

Heteronormative views presume that heterosexual orientation is the normal or preferred sexual orientation. The nurse practitioners in one study emphasized sexual behaviors and risk of sexually transmitted infections as the primary healthcare issue differentiating care of sexual minorities from heterosexual patients and described their belief in the importance of treating all sexual minorities "the same" as heterosexual patients.¹⁹ This perspective demonstrates a knowledge gap of the unique psychosocial stressors and medical issues faced by SGM and highlights the prevalence of heteronormative assumptions. Box 22.2 highlights research findings about discrimination against SGM in the healthcare setting. An encouraging factor is that most healthcare staff want to provide high-quality care to all patients they work with and are open to receiving more information about issues impacting the LGBTQ community.²⁰ The opening case study reviews how the APRN may approach a patient with complex palliative care needs utilizing language that avoids heteronormative assumptions and moves to establish a trusting relationship in a short period of time.

**COMING OUT, DISCLOSURE, OR
FORTHCOMING LGBTQ+ IDENTITY**

Given the complex history of discrimination some SGM have encountered in the healthcare system, individuals may not

**Box 22.2 RESEARCH EVIDENCE OF UNEQUAL
TREATMENT OF SEXUAL AND GENDER
MINORITY IN HEALTHCARE SETTINGS**

- In a national survey conducted in 2017, 16% of SGM respondents described experiencing discrimination when receiving healthcare and about 20% reported that they avoided needed healthcare because of concerns about discrimination.¹²
- In communities in the United States where there is less acceptance of SGM, like the Southeast, up to 50% of LGBTQ+ individuals avoided healthcare due to concerns about discrimination.⁶⁰
- A 2020 study of hospice and palliative care clinicians including nurses, physicians, social workers, and chaplains found that more than 20% of respondents had observed discrimination against SGM patients and more than 50% felt that gay, lesbian, and bisexual patients were more likely to experience discrimination than heterosexual patients. Nearly 65% perceived that patients who identified as transgender were at increased risk of discrimination compared to cis-gendered individuals.⁶¹

reveal their LGBTQ+ identity even if they are "out" in other areas of their life. Some individuals will feel comfortable revealing their sexual and gender identity or naming their same-sex partner before being specifically asked by the palliative APRN; however, others may be hesitant to reveal due to concerns about stigma or episodes of past rejection related to their identity.²¹ An individual should not be forced to out themselves if they choose not to disclose their sexual or gender minority status.

Qualitative research has revealed a range of reasons a patient may choose not to be forthcoming to their medical team, many of which are described in Table 22.2.²² Disclosing sexual or gender identity may be perceived as unnecessary by some individuals who prefer to maintain privacy and instead focus on the pathology of their disease as the nature of the healthcare transaction. Others may disclose on their own terms for ease of interaction, including maintaining control of the timing of information sharing and allowing for discussion about other aspects of their life without feeling the stress of withholding sexual or gender identity or not being able to receive appropriate psychosocial support consistent with their lived experience. Partnered LGBTQ+ individuals may disclose to ensure their significant other is able to be involved as a support person; if the partner is not included by healthcare staff there may be significant distress. The presence of visible symbols of acceptance, including public display of nondiscrimination policies or rainbow pins or insignia, helps some individuals feel more comfortable forthcoming. Microaggressions including overheard comments or heteronormative assumptions made by staff or other patients may make the environment feel unsafe for disclosure.

Table 22.2 CONTRIBUTING FACTORS OF INDIVIDUALS WITH SERIOUS ILLNESS TO DISCLOSE SEXUAL AND GENDER MINORITY STATUS TO THE PALLIATIVE APRN

PROMOTING	DISCOURAGING
Welcoming physical space with markers of inclusion (i.e., rainbow flag, inclusive pictures and information in waiting and exam rooms)	Patient's previous experience of discrimination in healthcare environment
Intake process with inclusive documents	Lack of markers of inclusion for LGBTQ population
Inclusive language used by all staff	Gender-specific or noninclusive intake documents
APRN asks about sexual and gender identity	APRN doesn't ask about sexual or gender identity
APRN includes support person/partner during encounter, asking their role, and encourages participation in goals-of-care discussions as appropriate	APRN uses heteronormative language
Strong self-identity by patient and sense that disclosure is important or "easier"	Overheard homophobic comments
Patient perception that disclosure will result in better care	APRN assumes role of support person (i.e., a sibling or friend instead of partner)
	Hierarchical power differential between patient and clinician, especially when patient is seriously ill and vulnerable
	Patient perception that sexuality and gender identity are not relevant to treatment

From Fish et al.²²

HEALTH DISPARITIES

There is evidence that the LGBTQ+ population has higher rates of physical illnesses and mental health issues including anxiety, depression, and suicide attempts than do individuals who identify as heterosexual and *cis-gendered* (i.e., having a gender identity aligning with the one assigned at birth). In multiple studies researchers have identified that SGM have higher rates of cardiovascular disease, particularly among people of color.²³ The cause of these disparities is not completely understood, but it is recognized that they contribute to the complexity of serious illness among SGM individuals. One theoretical model to explain this phenomenon is *minority stress theory*, which describes an exacerbation of stress and mental health challenges among a minority population due to chronic discrimination, stigma, and prejudice. Conversely, for some individuals, identifying as a member of a minority group may build resilience and provide a positive protective factor.²⁴

Another theory, *intersectionality*, describes that each individual has multiple social identities including sexual and gender identity, age, race/ethnicity, education level, and physical ability, among others, that may be outwardly visible or hidden.²⁵ Intersectionality related to membership in multiple minority groups is one way to frame the additive challenges some SGM individuals may face and can help explain the health disparities that they experience.

Researchers have also found evidence that experiencing multiple psychological health risks can lead to additive negative health effects among LGBTQ+ individuals. In one study, participants who experienced three or more psychosocial risks including sexual assault, intimate partner violence, posttraumatic stress disorder (PTSD), substance use, or depression, all of which disproportionately impact the SGM community, had exponential risk of physical health conditions.²⁶

It is known that individuals in the United States who identify as SGM are more likely than cis-gendered heterosexual individuals to use tobacco, alcohol, and drugs, with some evidence that the highest risk is among those who identify as bisexual.²⁷ Using data from the 2015–2018 National Survey

on Drug Use and Health, researchers noted significant disparities in cigarette smoking, heavy episodic drinking (four or more drinks per day for women or five or more drinks per day for men), and marijuana use between lesbian and bisexual women when compared to heterosexual women.²⁸ These effects were significantly more pronounced between lesbian and bisexual women who identified as Black or Hispanic than those who identified as White. In contrast, both sexual minority status and identifying as a racial or ethnic minority had a smaller effect on the rates of smoking, drug, and alcohol use on male participants. Study authors highlight the importance of recognizing the heterogeneity of the LGBTQ+ population and suggest that intersectionality theory may serve as a partial explanation for these differences. Increased rates of substance use may contribute to stereotyping and discrimination of the LGBTQ+ community.

There are a variety of social factors that also contribute to health inequalities. In the past it was very difficult for LGBTQ+ individuals to obtain health insurance. Rates of health insurance coverage have significantly improved since the implementation of the *Affordable Care Act* (ACA) and the legalization of marriage for same-sex couples, which allows families to access insurance through an employer; however, LGBTQ families continue to have lower rates of insurance and report avoiding care due to cost.²⁹ Employment discrimination due to sexual and gender identity was ruled to be illegal by the Supreme Court in 2020, but a prolonged history of legal discrimination and stigma has resulted in unequal pay and increased rates of poverty among SGM. Older LGBTQ+ women have identified poverty and social isolation as some of their top concerns when living with serious illness.³⁰ These complex social factors and high rates of poverty have contributed to the fact that 20–40% of the homeless population identifies as LGBTQ+.³¹

Although it is now known that SGM face increased risk of many mental and physical health conditions, research about health issues facing LGBTQ+ individuals historically focused only on sexually transmitted infections, most notably

HIV/AIDS. Unfortunately, HIV continues to have a disproportionate impact on the health of SGM. MSM, including all sexual and gender identities, make up the highest number of new HIV diagnosis in the United States. The Centers for Disease Control and Prevention (CDC) reports that, in 2018, 69% of new HIV diagnoses were between MSM. Most new infections occurred in men aged 25–34 and disproportionately impacted Black and Hispanic/Latino individuals.³² Access to improved treatment regimens with antiviral medications has changed HIV from a near certain cause of death to a chronic condition that individuals may live with for decades; however, it continues to be an illness that carries significant stigma and can be a contributing factor to many health complications. In an analysis of insurance claims data from 2007 to 2016, researchers found significantly higher rates of diabetes, hypertension, stroke, cancer, and lung and cardiovascular diseases as well as cognitive impairment among individuals living with HIV when controlled for demographics, behavioral risk factors, and other comorbidities.³³

SPECIAL ISSUES IN CANCER CARE

There is clear evidence that sexual and gender minorities have higher rates of cancer than their heterosexual peers, although, due to a history of poor data collection, true rates of cancer incidence, survivorship, and mortality among SGM are not known. Stress-related factors, higher rates of chronic illness, and substance use likely contribute, but there appear to be additional, unexplained factors that contribute to cancer risk.³⁴

One factor is decreased cancer screening rates resulting in advanced stages of cancer at time of diagnosis. Major barriers to cancer screening by SGM include knowledge deficits of screening guidelines by both LGBTQ+ individuals and healthcare providers. Improved rates of cancer screening have been associated with well-informed clinicians who establish welcoming clinical environments and include the patient's preferred caregivers.³⁵

Another likely cause of higher rates of cancer for SGM is decreased access to quality healthcare due to stigma and barriers. While LGBTQ+ patients may have the opportunity and time to search for a primary care provider they feel will be accepting of their sexual and gender identity, referrals to specialty care for a serious medical condition, like cancer care or palliative care, may limit choice. This places the individual in a position of needing to balance the risks and benefits of disclosing their SGM status and risk of discrimination.²²

Heteronormative language and behaviors can be especially challenging in gender-specific cancers. For example, SGM with prostate cancer are less likely to self-disclose their sexual orientation and therefore may experience negative consequences ranging from embarrassment to inadequate side-effect management related to incontinence or erectile dysfunction, miss opportunities to receive meaningful psychosocial interventions from the care team, or have their preferred support person participate in difficult decision-making.³⁶ Research on oncology clinicians reveals a discomfort and lack of training about asking their seriously ill patients about sexual issues

related to their illness or treatment course, citing limited time during encounters, fear of offending their patient, and uncertainty about how to respond to disclosure of minority sexual or gender status as barriers.³⁷ This provides an opportunity for the palliative APRN to offer support and education to both patients and clinicians. Having an oncologist who lacks LGBT competence has been associated with unmet psychosocial needs and even posttraumatic stress among SGM cancer survivors.³⁸

CONSIDERATIONS IN THE CARE OF TRANSGENDERED INDIVIDUALS WITH SERIOUS ILLNESS

Gender identity exists on a continuum and choice of outward expression of gender identity may change over time for all individuals.^{5,39} It is important to note that having a gender identity that does not match the gender assigned at birth is a deeply held part of an individual's sense of self and is not the same as a "drag queen" or "drag king" who is a performer who entertains by presenting in exaggeratedly feminine or masculine ways.⁴⁰ An individual who does not identify as their assigned gender at birth may or may not be interested in hormone therapy or surgical intervention, also known as *gender affirmation therapies*, with the goal of aligning the physical body with the individual's self-identity.

In the event an individual does desire to pursue gender affirmation interventions, they are dependent on healthcare providers to deliver transition-related care, including prescription refills for hormone therapy, which creates a profound power imbalance with the medical system directly related to that person's sexual and gender identity. Long-term health implications of estrogen, antiandrogen, or testosterone therapy among transgender people who chose to use them are not clearly understood.

The ability to continue gender affirmation therapies while receiving care for a serious illness or at the end of life may be limited for a variety of reasons, including inability to tolerate medications, contraindication in the setting of hormone-sensitive cancers, or challenges associated with the cost or logistics of obtaining treatment while physically debilitated as a result of illness. An individual who is unable to complete or continue the process of gender affirmation therapy due to their illness may face significant grief due to an inability to maintain an outward appearance that is consistent with their self-identity. A transgendered individual may also choose to revert to their birth gender around biologic family members to maintain a challenged relationship.²¹ An individual nearing the end of life may also be concerned that their surrogate will honor their wish to be buried as their chosen gender.³⁰

As discussed in the opening case study, palliative APRN should ask each person in their care their preferred name, *preferred pronouns* (e.g., she/her, he/his, they/their, ze/zir, among others), and what language the individual prefers to use for their body anatomy if an exam of sexual organs is required. Care for diseases of sexual organs exacerbates the vulnerability of transgendered individuals and requires additional sensitivity. Inclusion of a support person may be very helpful

during exams. Language used to describe body organs should be as gender-neutral as possible. Comments about how masculine or feminine an individual or parts of their body appear are not helpful and contribute to objectifying their body. Screening exams should focus on the organ being evaluated and not the gender of the individual; a trans woman may benefit from both prostate cancer and breast cancer screening.

Transgender men have rates of cancer more closely related to cis-gender women, which is significantly higher than that of cis-gender men.⁴¹ Inadequate knowledge of screening recommendations for trans-masculine individuals who are at risk of HPV and cervical cancer may lead healthcare providers to wrongly assume that their risks are lower than cis-gendered women and not recommend regular screening. Personal and physical vulnerability may limit the trans individual's desire to seek screening tests like Pap smears.³⁹ An individual who feels confident or self-affirmed in their gender identity may be comfortable asking a healthcare provider to change their behavior or language; however, a patient who has experienced a history of trauma or oppression related to other aspects of their identity, such as race/ethnicity, poverty, or level of education, may further shift power balance to healthcare staff.

CASE STUDY 2: CARING FOR A TRANSGENDER PATIENT

A palliative care consult was placed for assistance with symptom management for a patient named Joanne, with newly diagnosed cervical cancer. The patient was admitted to the hospital from the chemotherapy suite with severe nausea, vomiting, and abdominal pain. The palliative APRN worked frequently with the GYN-oncology team and always enjoyed going to the newly remodeled Women's Health wing in the hospital to assist with the care of their patients. The APRN was surprised to see an ill-appearing man lying in the hospital bed when they passed the room and walked to the nurses station to double-check the room number for the consult. Staff confirmed the room number and explained that the patient is transmasculine. Joanne's assigned gender at birth was female; however, he identifies as a male and prefers to be called Joel with the pronouns "he" or "him."

Given that the patient is transmasculine, what can you safely assume about their identity?

- a. The gender of their sexual partners
- b. They have had surgical alteration of their sexual organs, called *gender correction* or *gender affirming surgery*
- c. They take hormone therapy with testosterone
- d. They are unlikely to be religious or spiritual
- e. You cannot assume anything and should address them as a unique individual

Making assumptions about any person limits the ability of the palliative APRN to provide person-centered care. The correct answer is "e." In order to learn more about Joel's sexual partners, surgical history, current medications and sources of support, including spiritual beliefs, a thoughtful interview is necessary.

When the palliative APRN entered his room they introduced themselves and asked if he is Joel Johnson—he indicated that he was and asked to be called Joel. Since the nurses confirmed that his preferred gender pronoun was he or him, the APRN did not need to ask him again but ensured they addressed him as he requests. Joel described his symptoms of chemotherapy associated nausea and abdominal pain. He described the experience of receiving chemotherapy as very upsetting and distressing. With further sensitive questioning, he explained that the chemotherapy suite in the women's cancer center was decorated with traditionally feminine designs, and he felt very uncomfortable as the only man in the room. He reported that he has noticed the staff and other patients staring at him and even the women's magazines and fliers in the lobby for wigs and special makeup events for cancer patients seemed to point out his gender. He felt like his cancer was a painful reminder of the emotional distress he suffered when he was living as a woman and he wondered if god is punishing him. When he thought about, it made his pain and nausea worsen. The palliative APRN recognized that Joel was suffering from emotional and spiritual distress as well as physical symptoms and would benefit from a team approach.

The interdisciplinary palliative care team worked closely with the GYN-onc team to support Joel during his hospitalization. The social worker and chaplain met with Joel regularly to provide emotional and spiritual support. He identified his partner and sister as his primary support people, and they were encouraged to visit regularly so that he would not feel so isolated. Fliers for the Women's Cancer Support Group were removed from the bulletin board in Joel's room and standard neutral-colored hospital gowns were obtained for him to wear instead of the mauve gowns designed especially for the women's health hospital wing. In coordination with the oncology department, plans were made for Joel to receive the remainder of his chemotherapy course in the general infusion center instead of the GYN-onc chemotherapy suite. Joel was referred to the palliative care outpatient clinic for ongoing symptom management and emotional support throughout his treatment course.

UNIQUE NEEDS OF OLDER LGBTQ+ INDIVIDUALS

Older SGM will experience similar challenges of aging as cis-gendered heterosexual adults, but they are less likely to be partnered or have children and are more likely to have *families of choice* as their primary supports, potentially raising the uncertainty of who may be available to act as a caregiver, if needed. Partners are the most common caregivers for older LGBTQ individuals, but about a quarter of caregivers for SGM are friends, a much higher rate than among heterosexual older adults.⁴² Friends who serve as caregivers are less likely to receive formal support or have legal rights to make decisions on behalf of the patient without proper documentation. Unfortunately, some LGBTQ individuals may be estranged from their families, and this may be a source of distress at the end of life.

In the United States, surrogacy laws vary from state to state, and unless an individual has clearly identified and documented a surrogate decision-maker, important advance care planning decisions may defer to biologic relatives and not the desired chosen family member. However, this should not lead the palliative APRN to assume that an older LGBTQ+ individual does not have a positive relationship with their biologic family or does not have children. SGM may be legally married or partnered with biologic or adopted children, and some may have previously been in heterosexual marriages and remain close to their biologic children and extended family.

Older LGBTQ+ individuals with serious illness who are facing transition into an assisted living or skilled nursing facility may have concerns about the safety of revealing their SGM identity. Many have spent much of their lives facing stigma and discrimination, criminalization, and pathologization of their sexual or gender identity and have reasonable concerns about trusting the healthcare system to provide compassionate end-of-life care when they are most vulnerable, especially in institutions with conservative or religious emphasis.⁹ This can be especially challenging for couples who would like to move to a facility together. This has been referred to as the “Gen Silent” phenomenon after a documentary film of the same name, released in 2010, highlighted the trend of elderly LGBTQ+ individuals hiding their identity to avoid discrimination when receiving long-term care.⁴³

Palliative APRNs should assess for elder abuse in all patients and recognize that seriously ill SGM may be at increased risk due to vulnerabilities throughout their life span.⁴⁴ Disconnection from biologic family resulting in reduced access to caregivers and housing, history of abuse, income discrimination, and lack of spousal benefits leading to limited financial resources and health insurance are all factors that contribute to risk. A history of discriminating heteronormative experiences with law enforcement or the healthcare system may lead the individual to feel unsafe reporting their experiences of abuse and result in a lack of traditional support services or assistance with establishing long-term care resources.

END OF LIFE AND BEREAVEMENT

Receiving care for a serious illness involves encounters with a range of healthcare staff in multiple settings and may require making difficult decisions about end-of-life care. For LGBTQ+ individuals, the challenge of considering the safety of expressing one’s sexual and gender minority status with each new clinical team can add distress during an already challenging time. When patients feel safe to reveal their identity, they report experiencing a higher quality of care.⁴⁵ Transitions in care location and goals require trusting relationships and clear communication between the healthcare team, the patient, and their identified supports; poorly coordinated transitions can be a point of great stress for SGM.⁴⁵

The process of eliciting the patient’s goals and values at the end of life is intensely personal. Honest and open communication is needed for the palliative APRN to successfully

elicit the seriously ill individual’s values and tailor a care plan to their needs. Identifying caregivers who are able to help a debilitated patient with activities of daily living may cause significant discomfort if, for example, a partner doesn’t feel safe to explain that they share a bed with the patient and are willing to help them with personal care. Some individuals may not feel comfortable having hospice staff come into the safety of their home if they perceive the visit would reveal more than they are comfortable sharing about their sexual or gender identity.⁴⁵

Spirituality is an important aspect of the human experience and may take increased prominence when individuals are facing the end of life. Conflict between religious beliefs and sexual or gender identity may result in psychological and spiritual distress. Some SGM have had negative experiences with organized religion and may be less engaged in religious communities than cis-gendered heterosexual individuals, but this is not a universal occurrence. A religious community that is affirming of LGBTQ+ members provides a positive source of support.⁴⁶

Partners of SGM individuals who die are faced with the same bereavement challenges as heterosexual partners as well as specific experiences related to their sexual and gender identity. Additional stressors include experience of homophobia, exclusion from important decision-making, limited acknowledgment of the value of the relationship, ability to be present at the end of life, and financial and legal pressures.⁴⁷ These factors raise the risk of *disenfranchised grief*, or the inability of the bereaved to openly express their grief due to social stigma.¹⁶ Transgender individuals who have their transition process interrupted or are not able to continue taking hormone therapy due to the severity of illness may experience their own forms of disenfranchised grief.

Many states stop recognizing a healthcare agent after death and custody of the body defaults to next of kin. The palliative APRN must be knowledgeable about the laws in the state where they practice and should ask all patients if they are comfortable with their next of kin having authority over their body after death. If a patient would prefer to name an alternative person, their wish must be documented appropriately to ensure it is honored after death.

IMPROVING CARE DELIVERY

Having an understanding of the origin of LGBTQ+ health disparities helps the palliative APRN appreciate the context within which the SGM individual with serious illness seeks care and highlights the value of creating safe spaces to provide inclusive, nonjudgmental care that affirms individuals as they define themselves.⁴⁸ In addition to being thoughtful and open about the needs of each patient in their care, a key component of cultural humility requires the palliative APRN to take time to reflect on their own response to caring for LGBTQ+ individuals and other minorities.

One tool for self-reflection during each clinical encounter is the mnemonic CAMPERS, outlined in Table 22.3.⁴⁹ The palliative APRN should enter the encounter with a

Table 22.3 CAMPERS TOOL FOR SELF-AWARENESS

STEP	DEFINITION
1. Know your <u>C</u> lear purpose	Understand the purpose of the interaction. Be conscious that this will likely evolve during the encounter based on patient needs
2. Know your <u>A</u> ttitudes and beliefs	Be aware of any assumptions you bring into the encounter; recognize that prejudgments are a natural human response but are often inaccurate. Be especially conscious if you feel more compassion for certain groups of people or specific illnesses
3. Know your <u>M</u> itigation plan	Identify the actions you will take to prevent the attitudes and beliefs you named from impacting your patient interaction, including a plan to minimize the power imbalance between you and the patient
4. Know the <u>P</u> atient	Learn about the patient as a person, including their gender and sexual identity—not only the patients you think are transgender
5. Know your <u>E</u> motions	Recognize your own feelings to prevent them from interfering with the quality of care you are providing
6. Know your <u>R</u> eactions	Be conscious of the way you express your emotions including body language, facial expressions, and tone
7. Know your <u>S</u> trategy	Pause to review each encounter and devise a plan for improving future interactions

From Acquaviva.⁴⁹

clear goal as well as the flexibility to understand that the goal will evolve based on the patient’s needs. Awareness of the assumptions that naturally develop about others based on biases, social norms, and in response to certain disease states is critically important. However, equally valuable is taking time to develop plans to mitigate those assumptions and acknowledge the power the clinician inherently holds in the clinical interaction to ensure the encounter remains focused on the patient’s needs and goals. The palliative APRN must make an effort to know each patient as an individual by asking questions, including clarifying the name they prefer, their sex assigned at birth and current gender identity with the pronouns they prefer, who they consider to be their family and supports, their current care needs, knowledge about their illness, and health-related goals. Being aware of the emotions that the encounter elicits as well as being conscious of the verbal and body language responses the emotion triggers are necessary to ensure the palliative APRN can remain focused on patient needs and does not allow personal responses to interfere with patient care. After each encounter, it is helpful to review the interaction to evaluate opportunities and challenges and consider what could be done differently to improve future encounters.

Table 22.4 describes ways the history of nurse’s attitudes toward caring for sexual and gender minorities have evolved

Table 22.4 EVOLUTION OF NURSING ATTITUDES TOWARD SEXUAL AND GENDER MINORITY WITH SERIOUS ILLNESS

DECADE	PERCEPTION
1980s	Fear associated with high rates of death from HIV exacerbated homophobia and heteronormative perceptions with strong desire by many nurses to avoid caring for gay men with serious illness
1990s/2000s	Evidence of increased intellectual belief in equal rights for homosexual individuals at all stages of life; however, continued negative emotional reactions toward caring for SGM patients is associated with decreased quality of care
2010s	Increasing emphasis on treating all patients equally by focusing on physiologic illness and “ignoring” sexuality results in unintentional reinforcement of heteronormative assumptions and failure to provide individualized care in advanced disease

From Dorsen, Devanter.¹⁹

alongside the social norms and policies in the United States.¹⁹ Research in the late 1980s found that significant negative attitudes toward LGBT persons were connected with the desire to avoid caring for patients with a diagnosis of AIDS. In the 1990s and 2000s, more nurse research participants identified the value of equal rights for all individuals but continued to report strongly negative emotional reactions to sexual minorities. More recent research has exposed a desire by nurses not to stereotype SGM; however, this has resulted in inadvertently furthering heteronormative assumptions.

The palliative APRN has an obligation to ensure that the entire care team is providing inclusive care to all patients, including SGM. In addition to clinical teams, patients and their support persons interact with multiple staff members during each clinical encounter, including security guards, front desk staff, billing professionals, housekeepers, and more. Both clinical and nonclinical staff require education and reinforcement of the necessity to create an environment that is safe and welcoming.⁵⁰ One study found that members of the interdisciplinary hospice team had largely positive perceptions of SGM patients and their caregivers, with most positive attitudes associated with higher education and longer work experience and more negative perceptions associated with reported strong religious affiliation.⁵¹ Encouraging individual and team reflection on biases and potential misunderstandings about caring for LGBTQ+ patients with serious illness and focusing on the importance of patient-centered care for all individuals are important steps in creating a welcoming space for SGM.

Including LGBTQ+ community members in the development of educational resources for healthcare staff and program development within the healthcare setting is an excellent way

**Box 22.3 ADVICE FROM LGBTQ PATIENTS FOR
THE PALLIATIVE APRN**

- Quality of care is affected by the palliative APRN's assumptions, knowledge, and skills about LGBTQ individuals.
- Disclosure of sexual and gender identity is decided based on the safety of the encounter.
- Each individual has a unique perspective based on intersecting identities and lived experiences.
- Care is more effective when the patient's support network is included.
- LGBTQ+ individuals are resilient, advocate for themselves, and can have transformative experiences while facing illness and marginalization.

From Kamen et al.⁶²

to improve care delivery and mitigate the risk of inadvertent exclusion of SGM.⁹ Box 22.3 includes important insights elicited through a qualitative study describing what seriously ill LGBTQ patients felt their caregivers should understand in order to meet their needs. Teams should consider how marketing materials portray the services that are provided and whom they are provided to; including patients of racial and ethnic minority groups and sexual and gender minorities will demonstrate a welcoming attitude to future patients (Box 22.3).⁴ For additional resources on caring for LGBTQ+ individuals with serious illness, see Table 22.5.

SUMMARY

Individuals who identify as sexual or gender minorities cannot be distinguished by exterior characteristics or health history. A history of discrimination in society and within the healthcare system may lead some SGM to avoid care or feel the need to withhold their identity from their clinicians. To provide holistic, inclusive, and supportive care to all patients they encounter, the palliative APRN must presume that each individual may be LGBTQ+ and approach with sensitivity and cultural humility. Recognizing that SGM are not a homogenous population is key to individualizing care; however, having an understanding of issues that disproportionately impact SGM with serious illnesses is necessary to provide quality care. Creating welcoming and inclusive settings for care delivery, avoiding heteronormative assumptions and language, and including the individual's partner or chosen family in their healthcare are important ways to establish a trusting relationship and develop a care plan that is consistent with the patient's goals and values. An understanding of legal issues, including the need for clearly documented healthcare agents if surrogates designated by state law are not consistent with the patient's preferences as well as documentation of wishes for care of their remains after death, allows the palliative APRN to fully support the patient's advance care planning needs. Keys to providing consistently high-quality care with all patients include acknowledging the emotions that arise when caring for SGM, being conscious of the verbal and body language reactions the APRN has during the encounter, and routinely reflecting on opportunities to improve care delivery.

Table 22.5 RESOURCES FOR THE PALLIATIVE APRN CARING FOR LGBTQ+ INDIVIDUALS

ORGANIZATION	RESOURCES	WEBSITE
Lambda Legal ⁵³	Nonprofit focusing on civil rights of LGBT individuals and those living with HIV through education and public policy	lambdalegal.org
LGBT HealthLink: Best and Most Promising Practices Throughout the Cancer Continuum ⁵⁴	Detailed and easy to use review of best practices throughout cancer care from surveillance to end of life care for sexual and gender minorities	Lgbthealthlink.org/ Cancer-Best-Practices
National LGBT Cancer Network ⁵⁵	Resources for LGBT individuals with cancer including provider referrals and resources for clinicians	cancer-network.org
National LGBTQIA+ Health Education Center ⁵⁶	Organization focused on advancing health equity for SGM thorough educational programs and resources for clinicians and health care organizations	lgbthealtheducation.org
Services and Advocacy for Gay, Lesbian, Bisexual & Transgender Elders (SAGE) ⁵⁷	National organization focused on supporting the needs of LGBT elders, including training on LGBT cultural competencies	sageusa.org
SAMHSA: Lesbian, Gay, Bisexual and Transgender ⁵⁸	Substance Abuse and Mental Health Services Administration (SAMHSA) resources focused on behavioral health equity	samhsa.gov/behavioral-health-equity/lgbt
UCSF Prevention Science: Center of Excellence For Transgender Health ⁵⁹	Excellent resource including training modules and detailed guidelines for clinicians caring for trans and gender non-binary individuals	prevention.ucsf.edu/transhealth

CARE OF VETERANS WITH PALLIATIVE CARE NEEDS

Alice C. Foy, Robert David Rice, and Joseph Albert Melocoton

KEY POINTS

- Veterans are a unique population. Knowledge and understanding of the veteran experience, whether during conflict or peacetime, is essential.
- Only a quarter of veterans receive care within veterans' programs. Numerous veterans receive care in communities across all geographies in the United States. Therefore, the palliative advanced practice registered nurse (APRN) must assess for military service and identify local and regional resources.
- Subpopulations of often marginalized veterans deserve special attention and include women veterans, LGBTQ+ veterans, veterans experiencing homelessness, veterans with mental health diagnoses, and veterans with substance use disorder, as well as veterans with both dual diagnoses of mental health and substance use disorders. These veterans may well have especially nuanced needs at end of life given the intersectionality these identities will impose on what may already be challenged coping and adapting skills.
- Within the Veterans Health Administration, there are exceptional resources to care for veterans in all phases of acute and chronic care, including end-of-life care, to guide the delivery of quality, veteran-focused palliative care.

CASE STUDY: PALLIATIVE CARE FOR A VETERAN

Eddie was a 71-year-old Vietnam War veteran with Stage IV pancreatic cancer. Because his cancer responded poorly to treatment and he was not a candidate for additional treatment, he was referred to an outpatient palliative care consultation service by his oncologist. His past medical history was complex including hepatitis C, type 2 diabetes, significant alcohol use history (4–5 beers per day), a brief history of intravenous drug 10 years prior, depression, and generalized anxiety disorder (GAD). The oncologist shared Eddie's history of homelessness; but Eddie had lived in low-income housing for 2 years. She noted that he was reluctant to trust providers, that his follow-up had been sporadic, with a history of leaving hospitalizations against medical advice. She mentioned his brief military service and its effect on his actions and behaviors. Eddie's prognosis was less than 6 months, and the oncologist worried about his poor social supports, his inability to care for himself, and her fear of him falling through the cracks.

At his appointment, the palliative advanced practice registered nurse (APRN), Kim, who was educated about trauma-informed

care, applied several principles during their encounter. Kim asked if he would like to meet with the door open or closed, explained in detail all aspects of her physical exam, and asked for permission before each step. Kim took extra time to listen and did not push him when he seemed hesitant. Initially he was withdrawn and stoic, but he slowly began to open up regarding his goals and concerns. He shared his knowledge of his advanced disease but wanted to live as long as possible because he felt guilty about his past life and had many relationships to mend. He shared that he pushed away most people in his life and now worried about dying alone and not having anyone to care for him when he became weaker. He expressed fear of what dying might feel like. He noted that he felt people doubted his pain and thought he was drug seeking due to his past history with drugs and alcohol. Although his pain had been controlled so far, he has been waking up more at night and “remembering bad things I saw during the Vietnam War.”

The palliative APRN reassured him that his pain management will be diligent, with sensitivity to his history. They discussed how hospice would manage his increasing pain needs and reviewed options for extreme or unmanaged pain at the end of life, such as palliative sedation. He agreed to a posttraumatic stress disorder (PTSD) screening, which was positive. He demonstrated signs of worsening chronic depression, and Kim suspected possible moral injury related to some of his shame-based statements about his war experience. Kim reached out to the Veteran's Administration (VA) PTSD consultation program and was able to speak with a specialist who recommended starting a selective serotonin reuptake inhibitor (SSRI). They also offered virtual counseling services for the veteran, and Eddie expressed interest in this program.

The palliative APRN requested the social worker to notify the local VA palliative care service to assist the veteran with accessing his VA-related hospice benefits. The social worker also initiated reassuring conversations with him about resources, including home assistance and placement options when his care needs began to escalate. The palliative APRN referred him to a local hospice that participates in the *We Honor Veterans* Program. These hospice professionals had extra training in caring for veterans as well as a volunteer program staffed with other veterans who might provide needed visitation and support. Kim informed Eddie that the hospice social worker would begin to guide him in locating the lost family he hoped to make amends with and could also assist him with legacy work. Kim knew the chaplain would provide needed support for his experience of moral injury.

The palliative APRN thanked Eddie for trusting her with the painful parts of his life and expressed gratitude for the service he gave to the country and the burdens he has carried afterward. In completing her consult, Kim assessed for depression and suicidal ideation, which was negative. Kim scheduled follow-up telephone appointments for a symptom check and medication management, as well as oncology, and ensured the coordination of hospice.

INTRODUCTION

Veterans represent a unique cultural group and a complex population. Title 38 of the *Code of Federal Regulations* defines a veteran as “a person who served in the active military, naval, or air service and who was discharged or released under conditions other than dishonorable.”¹ A *military veteran* is a person who has served in one or more branches of the military and is no longer in active service. Veterans who have served directly in combat are considered *war veterans*. *Active service* refers to full-time service as a member of the Army, Navy, Marine Corps, Air Force, Coast Guard, National Guard, or Reserves, or as a commissioned officer of the Public Health Service or the National Oceanic and Atmospheric Administration.²

There are approximately 20.3 million living military veterans in the United States and, approximately 15.7 million veterans served in wartime.³ Fifty-five percent of living veterans are 60 years of age or older. Twenty-four percent are between the ages of 65 and 74, and 23% are between the ages of 75 and 85 and over.³ Women only represent about 10% of veterans.³

While World War II and the Korean War veterans are the oldest of the veteran population, the demographics of the Vietnam War veterans present an aging population with physical and mental health comorbidities which put them at risk. There are an estimated 6.4 million Vietnam era veterans ranging in age from 60 to 102 years old (born between 1918 and 1960).⁴ Most notably now because of issues of aging, serious illness, and end-of-life care is the generation of veterans from the Vietnam War. Seventy-five percent of these veterans are older than 65.⁴

The 2.8 million all-voluntary post-9/11 veterans include those in US-led conflicts in Afghanistan and Iraq (Operation Enduring Freedom [OEF], Afghanistan; Operation Iraqi Freedom [OIF], Iraq; and Operation New Dawn [OND], Afghanistan). They are more often younger, male, and White.⁴ Service-related disabilities, at 35.9%, are nearly two times as high compared to veterans of previous wars. This is in part due to the survivability of modern-day warfare compared to past combat. Interestingly, a lower percentage of post-9/11 veterans are enrolled in Veteran's Health Administration health-care under Veterans Affairs (VA) than all other veterans, at only 20.7%.⁴

Nearly half, 9.8 of 20.3 million, of all US veterans used at least one VA service or benefit in fiscal year 2017.⁵ All enrolled veterans are eligible for hospice care if they meet the clinical criteria for hospice care.⁶ Care, including hospice care, may be delivered in VA medical centers. Of note, 4.7 million veterans live in rural areas: 2.7 million of these

veterans are enrolled in VA care and 55% of veterans in rural areas are 65 years and older.⁷ Much of the health and medical care services for veterans, including outpatient primary and specialty clinic services, home care, pharmacy, and palliative and hospice care, may be delivered by community providers. Given the unique needs of veterans at end of life, palliative APRNs play a critical role in delivering quality care that addresses the veteran's specific needs, values, and preferences.⁸ While many of those needs are similar to the general population, such as symptom management, grief counseling, psychological coping, and seeking closure, care of veterans will have nuances unique to the worldview and life experiences of the veteran.

While veterans, particularly those having served in combat, share unique experiences, it is disingenuous to assume that they all share common experiences. Wars and conflicts each have their place in history. The veteran's service experience will have a profound effect on how they face serious illness and death, including their age and own history. These experiences will be linked to the generation in which the veteran served and encountered them, as well as the life course framework in which the veteran finds himself at the time of the serious illness.⁹ The oldest veterans, those from World War II and the Korean War eras, will have a different life perspective than much younger men from the more recent conflicts in the Southwest Asia (the United States has between 60,000 and 70,000 troops stationed in numerous countries in the region).¹⁰

Men soldiers and women nurses from the earlier wars may have experienced severe, debilitating injuries, particularly if they were prisoners of war (POW). Frostbitten body parts may have portended long-standing cold sensitivity, neuropathic pain, and even the development of skin cancers.¹¹ Veterans who participated in what is known as “radiation-risk activities” may have developed, subsequent to ionizing radiation exposure, any number of solid tumor cancers and hematologic malignancies such as leukemia, aggressive non-Hodgkin lymphomas, and multiple myeloma.¹²

Hepatitis C (HCV) infection is a chronic health condition. It is particularly prevalent in the general population born between 1945 and 1965, as well as in the Vietnam veteran population which overlaps this era.¹³ Chronic and acute HCV infection can cause liver failure, liver cancer, and cirrhosis. With the advent of direct-acting antiviral (DAA) HCV therapy beginning in 2014, the VA has treated more than 92,000 HCV-infected veterans, with cure rates exceeding 90%.¹³ Given the preponderance of risk, the chronicity and latency of HCV infection, and therapies that can cure the disease, palliative APRNs should presumptively test for HCV infection in this population.

Vietnam War veterans who had potential exposure to Agent Orange, a tactical herbicide used by the US military to control vegetation, may experience a variety of health conditions such as soft tissue sarcomas, lymphomas, respiratory cancers, blood disorders, and acute peripheral neuropathy.¹⁴ Gulf War veterans had potential exposure to pesticides; oil well fires; heat injuries; chemical and biological weapon exposure; sand, dust, and particulate exposure; noise exposure;

infectious disease exposure; and more. A prominent, chronic, multisymptom illness is described by Gulf War veterans and is being followed closely in a multiyear health survey. These symptom clusters, which are largely otherwise medically unexplained, include dizziness, breathing disorders, insomnia, fatigue, headaches, myalgias, indigestion, and memory issues.¹⁵ Amyotrophic lateral sclerosis (ALS) has been found to disproportionately affect veterans regardless of military branch or service era. As a result, the VA has established service-connected benefits for this population. When a palliative care patient has a diagnosis of ALS and a history of military service, helping them connect to the VA can provide much-needed financial and medical support including home care services, adaptive devices and home modifications, and specialized ALS medical care provided at facilities throughout the country.^{16,17}

The phenomenon of PTSD is described in relation to all wars. In the US Civil War, it was called “soldier’s heart”; in World War I, “shell shock”; and in World War II, “combat fatigue.”¹⁸ PTSD became formalized as a psychiatric diagnostic criterion after extensive experience with Vietnam War veterans. The DSM-5 diagnostic criteria for PTSD can be found at this reference and there will be further discussion of the condition later in the chapter.¹⁹

To better serve veterans, the palliative APRN should be familiar with these generational and situational specificities of wartime veterans (and peacetime veterans). An excellent web-based resource, sponsored by the National Hospice and Palliative Care Organization (NHPCO), is called *We Honor Veterans* and can be found at <https://www.wehonorveterans.org/>.²⁰

MILITARY CULTURE

Hallmarks of military culture are commitment to the mission and a number of espoused values. These values include honor, duty, courage, commitment, respect, integrity, selfless service (service before self), and personal courage, to name a few (shared among branches) (Table 23.1).

The integration of a shared military ethos begins with basic training—or boot camp—where men and women of diverse backgrounds, geographies, socioeconomic status, religious and political backgrounds, ethnicities, and races undergo intensive training, field exercises, and classroom time. Spurred on by strong military purpose and survival instincts, the inductees gain skills and experiences intended to support responsibility, purpose, discipline, technical and

Table 23.1 SERVICE BRANCHES OF THE US MILITARY

MAIN MILITARY SERVICE BRANCHES	FUNCTION	MOTTO
Army	The Army defends the land mass of the United States, its territories, commonwealths, and possessions. It does so through providing forces and capabilities for sustained combat and stability operations on land. The Army also provides logistics and support to other branches. The Army is the largest and oldest branch of the military.	This We'll Defend ²¹
Marine Corps	The Marine Corps maintains ready expeditionary forces, sea-based and integrated air-ground units for contingency and combat operations, and the means to stabilize or contain international disturbance. The Marine Corps is an immediate response force that can be used to overwhelm the enemy. ²²	<i>Semper Fidelis</i> "Always Faithful" ²¹
Navy	The Navy maintains, trains, and equips combat-ready maritime forces capable of winning wars, deterring aggression, and maintaining freedom of the seas. The Navy is America's forward deployed force and is a major deterrent to aggression around the world. ²²	<i>Semper Fortis</i> "Always Courageous" ²¹
Air Force	The Air Force provides a rapid, flexible, and, when necessary, lethal air and space capability that can deliver forces anywhere in the world in less than 48 hours. It routinely participates in peacekeeping, humanitarian, and aeromedical evacuation missions. Air Force crews annually fly missions into all but five nations of the world. ²²	"Aim High . . . Fly-Fight-Win" ²¹
Space Force	The US Space Force (USSF) is the newest branch of the Armed Forces, established December 20, 2019. The USSF was established within the Department of the Air Force, meaning that the Secretary of the Air Force has overall responsibility for the USSF, under the guidance and direction of the Secretary of Defense. ²³	<i>Semper Supra</i> "Always Above" ²⁴
Coast Guard	The Coast Guard provides law and maritime safety enforcement, marine and environmental protection, and military naval support. Activities can include patrolling our shores, performing emergency rescue operations, containing and cleaning up oil spills, and keeping illegal drugs from entering American communities. ²²	<i>Semper Paratus</i> "Always Ready" ²¹

tactical proficiency (often leading to occupational specialty training), maturity, strength and resiliency, coping, and pride. The dedication to service over self leads to teamwork and cooperation, protecting the welfare of the team and creating deep friendships.²⁵

When service men and women return to civilian life, though, they may drift from the loss of the military community. In dealing with the rigors of military life and combat, veterans may have developed a self-defense mechanism of *stoicism*, which, in challenging times, can be quite helpful. However, in post-military life this may result in a steeling against physical, emotional, and psychological challenges. The idea of self-sufficiency takes precedence over the threat, be it external (such as an attack) or internal (such as cancer-related pain). The “can-do” mentality minimizes the effect of adverse events. The mind overconstructs and imposes this burden on the soldier, and, as a result, the soldier becomes traumatized and may not be able to resolve the bad event.²⁶

TRAUMA-INFORMED CARE

When working with veterans, it is essential to let their individual experience guide a thoughtful approach to care planning to promote a culture of empathy and support. *Trauma-informed care* focuses on treating the individual where they are. The palliative APRN must acknowledge that the veteran may have experienced a traumatic event (or multiple traumatic events) and understand the comprehensive picture of how past traumas and subsequent coping mechanisms influence health behaviors and the veteran’s response to illness and treatment. This approach to care recognizes the potential impact and consequences of military experience in one’s life and informs an evidence-based plan of care that focuses on both physical and psychological needs while ensuring emotional safety.²⁷ Understanding the effects of trauma can enable a more successful experience in managing and supporting symptoms and other needs, whether the goal is prolonging life or ensuring a peaceful death.

Supporting the complex needs and experience of veterans in the community can be daunting. When veterans are formally enrolled in the VA system, many programs exist to assist both veterans and the palliative APRNs in accessing the delivery of entitlements and resources, including mental health support and palliative care, which are available in person and through telemedicine. Reaching out and partnering with the palliative care providers at local VA centers can assist the community-based palliative APRN with managing the veteran with complex end-of-life issues. A comprehensive care planning guide and free training resources can be found at *We Honor Veterans—Trauma-Informed Care*.²⁸

Important initial steps in trauma-focused care are recognizing and screening for common issues such as PTSD, suicidal ideation, and moral injury. It is important to ask patients (or their caregiver) if they have ever served in the military and if they are willing to discuss their service, including possibly completing a military history checklist. Central to providing meaningful trauma-informed care is a thorough

understanding of military culture, the uniqueness of each era in which a veteran has served, and how it might have determined their individual experience. Specific groups, including those who have experienced interpersonal violence such as military sexual trauma (MST), will have additional considerations.²⁹ Women who experienced sexual trauma generally have sexual dysfunction and lower sexual satisfaction. They may have comorbid mental health issues with the sexual dysfunction.³⁰ One study found that while most women veterans felt welcome at the VA (85%), a significant percentage (26%) -had “stories about feeling uncomfortable or harassed in the VA.”³¹ The opportunities for further inquiry and research based on the experience of women veterans are numerous.

POSTTRAUMATIC STRESS DISORDER

PTSD is experienced by up to 7% of the US population at some point during their lifetime, with the highest incidence being in women. In recent studies, 10.6% of veterans being cared for at the VA had a diagnosis of PTSD, and, in the population that served in Iraq or Afghanistan, 27.6% have received the diagnosis.³² Individuals with PTSD can have an extra layer of complexity to their symptoms and end-of-life experience. PTSD may increase distress and amplify symptoms, particularly pain. Avoidance behaviors may undermine the ability to establish trust and interfere with continuity of medical care and following medical advice. Life-long behaviors related to trauma, including social isolation and avoidance, may result in diminished relationships, which are often a vital source of caregiving and support at end of life.³³

Assessing and diagnosing PTSD can be critical to providing good end-of-life care and can start with a military history checklist and further exploring any history of trauma.³⁴ Family, when available, can also be an important source of history. The VA has specific screening resources available on their website via the PTSD Consultation Program. The Primary Care PTSD Screen (available at www.ptsd.va.gov) is a five-item tool that identifies exposure to trauma and its effects on life and is developed for use in a primary care setting.³⁵

Treatment for PTSD includes both psychotherapy and pharmacotherapy. Examples of evidence-based therapies are detailed in the Table 23.2. Current guidelines favor trauma-focused psychotherapy as the first-line treatment for PTSD over pharmacotherapy. However, pharmacotherapy may be a preferred approach for some veterans, and medications may be essential in the instance of psychiatric comorbidity.⁴⁰ Current VA and Department of Defense (DoD) recommended pharmacotherapy approaches are detailed in Table 23.3.

In selecting the best approach to treatment, estimated prognosis as well as physical and emotional energy available to devote to interventions should be considered. A stepwise approach includes addressing immediate discomfort while ensuring social supports, enhancing coping skills, and later focusing on trauma-specific issues.⁴² Strategies for the palliative APRN to support the veteran with PTSD include therapeutic presence. This allows veterans to express emotion and

Table 23.2 THERAPIES FOR POSTTRAUMATIC STRESS DISORDER (PTSD)

PROCEDURE	COGNITIVE PROCESSING THERAPY (CPT) ³⁶	PROLONGED EXPOSURE THERAPY (PE) ³⁷	EYE MOVEMENT AND DESENSITIZATION AND REPROCESSING (EDMR) ³⁸	WRITTEN EXPOSURE THERAPY (WET) ³⁹
Evidence	Well-studied	Well-studied	Highly studied in civilian populations with strong recommendation as effective treatment.	Increasingly studied and found to be effective. Notable for low attrition rates.
Model and Process	Helps identify how trauma has altered both thoughts and feelings and reorganizes information to provide new interpretation of the experience.	Involves repeated exposure to fears, such as talking about the trauma, over and over, in a safe environment until the impact begins to diminish and emotions and fears are reduced in response to stimuli.	Goal is to change the reaction to memories of trauma by focusing on new learning being assimilated separately from existing memory pathways. Often involves focusing on external stimuli while recalling traumatic events (back-and-forth eye movements or sound).	Experiences of trauma, including thoughts and emotions, are explored through structured writing sessions which include ongoing support and feedback.
Application	Given in both individual and group settings. Helpful in patients with comorbid conditions (such as depression and personality disorders).	Useful in patients with comorbid psychological conditions.	Not studied in comorbid populations. Shorter treatment duration and easier training of providers may make this a useful intervention for hospice teams.	Can be given in both individual and group settings.

Table 23.3 COMMON MEDICATIONS USED FOR POSTTRAUMATIC STRESS DISORDER (PTSD)

THERAPEUTIC CATEGORY	INITIAL DOSE	DOSE RANGE	CLINICAL CONSIDERATIONS: COMORBIDITIES AND SAFETY
Antidepressants <i>Monotherapy</i>			
Fluoxetine ^a	10–20 mg daily	20–80 mg daily	Avoid abrupt discontinuation; withdrawal symptoms with sudden discontinuation of SSRIs and SNRIs, paroxetine and venlafaxine in particular Paroxetine and sertraline have FDA label indications for treating PTSD Common adverse effects of the SSRIs and SNRIs include nausea, headache, diarrhea, anxiety, nervousness, sexual dysfunction, agitation, dizziness, hyponatremia or SIADH, and serotonin syndrome Venlafaxine can elevate blood pressure; caution advised with patients with hypertension
Paroxetine ^a	10–20 mg daily	20–50 mg daily	
Sertraline ^a	25–60 mg daily	50–200 mg daily	
Venlafaxine ^a	IR: 25 mg 2 or 3 times a day XR: 375 mg once daily	75–375 mg in 2–3 divided doses of 75–225 mg once daily	
Nefazodone ^b	25–100 mg 2 times daily	150–600 mg in 2 divided doses	Nefazodone is associated with life-threatening hepatic failure; monitor for signs and symptoms including LFTs; avoid if active liver disease; do not re-challenge Nefazodone is subject to many drug interactions, particularly those involving CYP3A4 and glycoprotein
Imipramine ^b	25–75 mg daily	100–300 mg in 1 or 2 divided doses	Avoid TCAs within 3 months of an acute MI TCAs are relatively contraindicated in patients with coronary artery disease or prostatic enlargement TCAs side effects include dry mouth, dry eyes, constipation, orthostatic hypotension, tachycardia, ventricular arrhythmias, weight gain, and drowsiness Photosensitivity may occur
Phenelzine ^b	15 mg 3 times daily	15 mg daily; 90 mg in divided doses	Phenelzine considerations include drug-drug and drug-food interactions, risk of hypertensive crisis, hypotension, and anticholinergic effects

validate painful or traumatic events, and it helps them to feel in control and to focus on strengths and resilience and avoid triggers.⁴³

The VA recognizes the complexity and challenges of treating this condition, including the need to be able to access the latest assessment and diagnostic tools and receive guidance in evolving medication strategies. Individual guidance for the palliative APRN, as well as clinical management tools and resources that can be given to the veteran, are readily available through the free PTSD Consultation Program (www.ptsd.va.gov/consult or 866-948-7880). In addition to war- and military-related trauma, additional guidance and education is available around contemporary issues faced by many veterans, including PTSD and concomitant minority stress among LGBTQ+ individuals, racism-related stress and trauma, and experiences related to the COVID-19 pandemic.^{3,44}

MORAL INJURY

PTSD is not the singular form of emotional suffering that veterans face following military service. Often they carry deeper wounds, sometimes described as spiritual, existential, or “soul wounds” that do not respond to standard treatments. This is an increasingly common experience of shame- and guilt-based disturbances that some combat veterans experience after engaging in wartime acts of commission (such as killing), omission (such as failing to prevent atrocities), or simply acts felt to be transgressive and in violation of the goodness perceived in self or others. This experience in the “affliction of conscience” is felt to be the fallout of “morally injurious experiences: Perpetrating, failing to prevent, bearing witness to, or learning about acts that transgress deeply held moral beliefs and expectations.”⁴⁵ (p.700) These experiences cause *moral injury* which is known to intensify relational problems, social anxiety, isolation, depression, and suicide. The experience of shame “amplifies the impact of trauma across every category.”⁴⁶ (p. 56)

Veterans struggling with moral injury at the end of life may have particular sets of issues that can complicate illness and decline. The life review may reopen unresolved emotional and spiritual wounds. Seriously ill veterans may be unable to forgive themselves or be forgiven by others. They may not trust anyone enough to open up about their negative experiences. They may fear that they are not worthy of redemption and may experience enhanced despair due to loss of life meaning and purpose.⁴⁷ To support the veteran with suspected or known moral injury, a coordinated approach to care will include hospice chaplains, social workers, and mental health providers in addition to a compassionate and understanding nurse practitioner. A toolkit of techniques called Stress First Aid is available to support these caregivers.⁴⁸

LGBTQ+ VETERANS

Despite the fact that the Department of Veterans Affairs is presumed to be the largest provider of healthcare for

LGBTQ+ (lesbian, gay, bisexual, transgender, queer and questioning, and related identities) veterans, research on end-of-life needs for this population is scant. Many of these veterans have likely faced homophobia, stigma, harassment, and discrimination during their military service, often based on military policy. These acts may have significant long-term effects on their health and well-being. The LGBTQ+ population already has higher risks for depression and suicide, amplified by multiple chronic medical conditions and poor health outcomes.⁴⁹ A lifetime of coping with these issues impacts the dying process. Negative experiences may also erode trust and prevent a veteran or their family from seeking much-needed support or resources through the VA.⁵⁰ It is essential that the palliative APRN be skilled in communication with LGBTQ+ veterans. Having a relationship of trust and openness with their provider can be an important protective factor^{50,51} (see Chapter 22, “LGBTQ+ Inclusive Palliative Care”).

To address and support the unique needs of this vulnerable population, most VA facilities have LGBTQ+ websites. All facilities also have an LGBTQ+ Veteran Care Coordinator who can assist veterans with finding culturally competent caregivers comfortable with caring for them.⁵² Veteran-based programs and resources that are often essential during terminal illness require a connection through discharge status. For LGBTQ+ veterans, that status may have been undermined by previous policies that forced involuntary separation from the military due to sexual orientation, designating their discharge as “undesirable” or “dishonorable.” The *Bay Area Reporter* estimates that 114,000 veterans were “involuntarily separated from the military due to their sexual orientation between the end of World War II and the repeal in 2011 of the homophobic ‘Don’t Ask, Don’t Tell’ policy that barred LGBTQ+ individuals from serving openly in the military.”^{53,54} The acceptance of LGBTQ+ service members remains an active political issue. In 2011, the Obama administration reversed the “Don’t Ask Don’t Tell” policy and removed restrictions on transgender individuals serving in the military in 2016. This was reversed by Trump administration in 2017. In 2021, the Biden administrative again allowed transgendered service members to openly serve.

Even though veterans can upgrade or correct their discharges, many do not choose to do this because of the time and often substantial effort required to do so. The VA now lends assistance through its website to veterans who have a less than honorable discharge related to issues such as PTSD, sexual orientation (including Don’t Ask, Don’t Tell), MST, and traumatic brain injury (TBI). The VA provides guidance on discharge upgrades and valuable links to local Veteran Service Organizations, which have specialized claims agents and attorneys who can assist and advocate for veterans when navigating this process.⁵⁵ The website also provides guidance to pursue a discharge status upgrade, which may be useful for the veteran not only in terms of resources and benefits, but may also bring end-of-life closure to an experience of trauma, shame, or victimization experienced during their military service and ensure that they are recognized with the honor they are due.

SUBSTANCE USE DISORDERS AND PAIN MANAGEMENT

Management of pain is central to the care of veterans, especially at the end of life. The VA offers comprehensive pain management that is typically provided by an interdisciplinary collaborative team using multimodal approaches (pharmacological and nonpharmacological therapies). Veterans' experiences during their service, stoicism, psychological trauma, chronic disorders, and sociocultural factors (to name a few) can complicate and contribute to suboptimal pain management. Substance use disorder (SUD) remains a significant problem among veterans, and there is an increased risk of suicide associated with SUD for both male and female veterans.⁵⁶ (See Chapter 47, "Patients with Substance Use Disorder and Dual Diagnoses.")

Opioid prescription carries inherent risks and dangers for adverse outcomes such as overdose and death. The Comprehensive Addiction and Recovery Act of 2016 mandated the VA to designate a pain management team (PMT) to expand the Opioid Safety Initiative (OSI) and complementary and integrative medicine (CIM) and establish safe opioid prescribing practices such as the use of prescription drug monitoring programs (PDMPs) and the Opioid Overdose Education and Naloxone Distribution (OEND) Program.⁵⁷ Harm-reduction strategies, pain resources, and clinical automated decision support tools to assess for risk of adverse events are also available, such as the Stratification Tool for Opioid Risk Mitigation (STORM; a predictive model that estimates the likelihood of drug overdose or suicide-related events) along with the Opioid Therapy Risk Report (OTTR; a primary care panel report showing data or variables about risks, latest urine drug test results, etc.).

In a study by Davis et al. (2018), approximately 9% of veterans in the United States reported past-year cannabis use.⁵⁸ While cannabis is legal in many states for recreational and/or medical use, its use is illegal under federal law. A VA systematic review of the benefits and harm of cannabis for chronic pain and PTSD showed little benefit for either condition. While it may alleviate neuropathic pain, there was limited evidence in other pain or PTSD veteran populations and little generalizable evidence about the long-term effects of cannabis use.⁵⁹

COVID-19 AND VETERANS

The COVID-19 pandemic has affected in-person clinic visits and it is anticipated that the future of healthcare delivery will continue to evolve. To meet the demands in servicing geographically diverse and remotely located veterans, virtual technology consultations and the Specialty Care Access Network Extension for Community Healthcare Outcomes (SCAN-ECHO; a clinical videoconferencing from multiple specialty providers at the outpatient clinic nearest to the veteran's home) provide ways to maintain healthcare access. When transitioning to telehealth, palliative providers must deal with the complexities of intimate goals discussions and end-of-life

planning using technology versus usual care. When family members and loved ones cannot be present at the bedside of their dying loved ones due to restrictive visitation policies, palliative providers may use technology to allow those not present physically to participate virtually. COVID-19 has significantly impacted all health delivery, including home hospice, both in terms of demand for services, as well as in agency staff affected by COVID-19 infection. There is also the concern of patients and families, who fear that outsiders coming into the home may pose a risk of infection transmission.

Thus far during this pandemic, there was a 1,470% increase in virtual care telehealth visits (between March 1 and September 26, 2020) and 453,516 prescription refill requests (between September 27 and October 3, 2020) throughout the entire VA.⁶⁰ At the onset of the pandemic, geriatric healthcare providers at the VA also outlined proper education and containment strategies and recommended approaches to COVID-19 mitigation in long-term care facilities.⁶¹

HOMELESSNESS

Homelessness is a significant problem in the United States, with more than a half million people experiencing homelessness according to a 2017 point-in-time estimate.⁶² There are challenges to providing palliative and end-of-life care to homeless veterans from personal, clinical, and structural views. Unstable housing and the risks noted earlier can impact care access and follow-through, particularly for a veteran who has declining functional status and symptom burden, possibly in the context of substance use and behavioral mental health issues.⁶³ The palliative APRN has several roles: clinical responsibility for pain and symptom management, advocate and care coordinator for the veteran experiencing homelessness, and care manager collaborating with social work services and the hospice agencies to maintain seamless care.

At-risk veterans or veterans experiencing homelessness should be referred to their local VA medical center or call 1-877-424-3838 (1-877-4AID-VET) to access supportive services, which can include housing, aid to employment, medical care, and justice outreach (see Table 23.4). The US Department of Veterans Affairs,⁶⁴ Centers for Disease Control and Prevention,⁶⁵ the National Alliance to End Homelessness,⁶⁶ and other local and national organizations provide resources to support homeless people (see Chapter 21, "Economically Challenged Urban Dwellers").

AN EXEMPLAR PROGRAM

The VA Greater Los Angeles Healthcare System (VAGLAHS) has established support for homeless veterans under the Homeless Veteran Program: Community Engagement and Reintegration Services (CERS). This is the largest VA homeless program in the country, with more than 600 staff and resources to house 10,000 homeless veterans through emergency, transitional, and permanent housing. The CERS care

Table 23.4 HOME- AND COMMUNITY-BASED SERVICES AND SURVIVOR BENEFITS HOME- AND COMMUNITY-BASED SERVICES

Homemaker and Home Health Care Aide^{a,b} • Assistance with ADLs and personal care. • Provided through a VA-contracted agency to allow vets to remain at home.	Home-Based Primary Care^b • In-home longitudinal support for those with complex health care needs (e.g., severe illness, difficulty with clinic visits). • Provided by an interdisciplinary team led by the physician.	Respite Care Pays for short-term care to allow family/caregivers a break.^{a,b} • Home respite care pays for a person to come to the home. • Nursing home respite care: Short-term nursing home placement (maximum 30 days).
Skilled Home Health Care^b • Skilled transitional care (e.g., physical therapy, occupational therapy, speech therapy, wound care, etc.; short-term or ongoing).	Adult Day Health Care^b • Provides daytime social activities, peer support, companionship, and recreation through VA medical centers, State Veterans Homes, community organizations.	Remote Monitoring Care • Allows remote follow-up of health measurements with a care coordinator through a home monitoring equipment.
Veteran-Directed Care • Budget for private workers for personal care services and ADL assistance, managed by the veteran or their representative.	Caregiver Support Program (see updates from the VA Mission Act website) • Program of General Caregiver Support Services (PCGSS) • Provides education, resources, and support to caregivers of veterans (does not need to have a service-connected condition). • Program of Comprehensive Assistance for Family Caregivers (PCAFC) • For eligible veterans who have incurred or aggravated a serious injury in the line of duty on or after September 11, 2001. This program provides caregivers with resources, education, support, a financial stipend, health insurance, and beneficiary travel (if eligible).	Home Telehealth • Designed to give ready access to a care coordinator by using technology (e.g., telephone, computers) at home. • Enhances and extends care management to caregiver and may include education and training or online and telephone support groups).

Services vary by locations and the local VA Medical Centers will have more information on the programs available.

ADL, activities of daily living.

^aCan be combined with other home and community-based services.

SURVIVOR BENEFITS

Health Insurance

Civilian Health and Medical Program at VA (CHAMPVA)

Provides reimbursement for most medical expenses. The person cannot be eligible for TRICARE and must be one of the following:

- Spouse or child of a permanently rated and totally disabled veteran due to a service-connected (SC) disability.
- Surviving spouse or child of a vet who died from a VA-rated service-connected disability or who, at the time of death, was rated permanently and totally disabled.
- Surviving spouse or child of a veteran who died on active duty service and in the line of duty not due to misconduct (in most cases, these family members are eligible for Tricare).

Note: SC disability is an injury or illness that was incurred or aggravated during active military service; ranges from 0–100% and may qualify for disability compensation per regulation.

* CHAMPVA discontinues when a surviving spouse under 55 remarries.

* For those with Medicare entitlement, CHAMPVA becomes the secondary payer.

* Services can be provided under the CHAMP VA in-house Treatment Initiative Program (CITI).

* Coverage of services depends on the CHAMPVA benefit coverage.

TRICARE

Health program for Uniformed service members, National Guard/ Reserve members and their families, survivors, former spouses, medal of honor recipients, and others registered in the Defense Enrollment Eligibility Reporting System (DEERS).

<https://www.tricare.mil/Plans/Eligibility>

Dependency and Indemnity Compensation (DIC)

- Payment to spouse for a veteran's death from a disease or injury incurred or aggravated while on active duty, active duty training, inactive duty training, or a service-connected illness or injury.

* DIC may be paid to certain survivors of veterans who were totally disabled from service-connected conditions at the time of death, even if their service-connected disabilities did not cause their deaths (please visit the VA website for further details/eligibility/payment rates).

* Veteran's discharge must have been under conditions other than dishonorable.

www.va.gov/burials-memorials/dependency-indemnity-compensation

American Battle Monuments Commission

- No-fee passports may be available to family members who want to visit their loved one's grave at an American military cemetery on international soil.

www.abmc.gov

Table 23.4 CONTINUED

Bereavement Counseling

- Provided through VA Vet Centers for families of service members who die while on active duty (including federally activated members of the National Guard and reserve components).
- Available to all family members of veterans who die unexpectedly at a VA medical center or while under VA hospice or similar programs.

Education Benefits

- Dependents' Education Assistance
- Marine Gunnery Sergeant John David Fry Scholarship
- For children and spouses of members who died in the line of duty after 9/10/2001.
- *Education Benefits for Persons with Special Needs*

Montgomery GI Bill (MGIB) Death Benefit

- For educational assistance to designated survivors in the event of a service-connected death of members on active duty or within 1 year after discharge or release.

For more information, please visit www.gibill.va.gov

Burial and Memorial Benefits

- For veterans discharged from active duty under conditions other than dishonorable
- Burial in a VA cemetery (for eligible veterans, their spouses, and dependents): Includes gravesite, grave liner, opening and closing of the grave, headstones/markers, and perpetual care. Specifically, for veterans, it includes a burial flag, Presidential Memorial Certificate (PMC; if requested), military funeral honor, medallions in lieu of government headstone.
- VA operates 136 national cemeteries; for more information please visit www.cem.va.gov.

Death Pension

- For low-income surviving spouses and unmarried children of deceased veterans with wartime service.

Department of Defense Death Gratuity: One-time tax-free payment of \$100,000 to beneficiaries of service-members whose death is a result of hostile actions (through a designated combat operation/zone or while training for combat).

Life Insurance Through Veterans Group Life Insurance & Servicemembers Group Life Insurance (VGLI/SGLI)

- Voluntary life insurance products offered to veterans and active-duty personnel. Not all surviving family members may file a claim on this benefit.

VA Home Loan Guaranty

- For a spouse of a veteran or service member who died from a service-related disability.
- May be available to an unmarried spouse, surviving spouse who remarried at or after age 57, or a spouse of veteran or service member officially listed for more than 90 days as missing in action or currently a prisoner of war.

VA Burial Allowances

- Flat rate monetary benefits to cover burial and funeral costs.
- Service-connected death (on or after September 21, 2001): Maximum burial allowance is \$2,000 (\$1,500 for those who died before 9/21/2001).
- Non-service-connected death (payable if the veteran was VA-hospitalized at the time of death): \$300 burial allowance and \$780 for a plot (if death occurred on or after 10/1/2018).
- Cremation: VA does not pay for cremation directly, but families may be entitled to a burial allowance as above.

Tables compiled by Joseph Albert Melocoton, RN, MSN, NP-C, AOCNS, Palliative Care Advanced Practice Provider at VA Greater Los Angeles Healthcare System.

line includes seven distinct programs which provide services including walk-in centers, justice diversion and jail outreach, employment, short-term treatment programs, and primary and mental health care.

On any given night, there are an estimated 3,500 veterans experiencing homelessness in Greater Los Angeles's service area.⁶⁷ In fiscal year 2019, VAGLAHS provided services to almost 16,000 homeless veterans. During this time, GLA placed almost 1,830 veterans into their own apartments. Currently, the West Los Angeles campus has helped veterans with mental health issues and living in tents along the campus edge to move to platformed tents on the great lawn. These spaces provide up to 100 tents to house veterans with mental health issues. A building on campus has been repurposed to provide a recuperative and isolation ward for homeless veterans testing positive for COVID-19. A bridge home provides 100 emergency shelter beds in a large, prefabricated, structure. The master building plan for the organization includes the addition of up to 1,200 occupancy units in the next 2–3 years. These efforts have the

shared goal of keeping veterans safe and moving them to transitional and permanent housing and treatment programs.

The treatment programs include the Homeless Patient Aligned Care Team (medical home) which serves 3,000 veterans annually. This program provides high-intensity, interprofessional, team-based care to homeless veterans and prioritizes open-access, high-quality primary care, mental health care, and social work services. The Housing and Urban Development–VA Supported Housing (HUD-VASH) program is the largest in the country, with 7,440 vouchers assigned and case managing 5,100 formerly homeless veterans in their apartments. The Domiciliary Residential Rehabilitation Treatment Program is a 151-bed residential treatment facility where veterans participate in therapeutic programming each day, 7 days a week. The length of stay is typically between 60 and 90 days. These are just a few of the several integrated programs which make up the larger effort to support homeless veterans and help them transition to a more stable living environment, a healthy lifestyle, and better quality of life (unpublished VA report, on file).

SUICIDE

It is not unusual for individuals with serious illness to consider hastening death. A study that examined the experience of advanced cancer patients found depression and hopelessness to be strongest drivers of this desire.⁶⁸ Robinson et al. noted a relationship between poor quality of life and the desire to hasten death that is mediated by depression, loss of meaning and purpose, loss of control, and low self-worth.⁶⁹ Suicide is especially common in veteran populations, and certain variables are known to increase its probability including being male, depression, manic-depressive disorder, and alcohol abuse disorders. Because most veterans are seen outside of the VA in community settings, “providers should vigilantly assess suicide risk in their patients who are Veterans.”⁷⁰ (p. 711) The palliative APRN should be aware of issues that might contribute to suicidal thinking and initiate additional screening and precautions when indicated. Information should always be provided to the veteran for the Veterans Crisis Line (800-273-8255). Preventing suicide in this vulnerable population may require enhanced support at every level. Comprehensive screening, assessment, and treatment tools to assist the APRN in navigating the veteran’s needs can be readily accessed at <https://www.mentalhealth.va.gov/healthcare-providers/suicide-prevention.asp>.^{71,72}

PHYSICIAN-ASSISTED DEATH

Within the VA healthcare system, physician assisted death (PAD) is strictly prohibited. Legislation forbids the direct or indirect use of any funds in PAD-related practices. Although veterans have the right and may choose to seek help outside of the VA system for this purpose, APRNs and physicians within the VA may not assist with medical workups, prognostication, referrals, or collaboration with the intent to facilitate or support this practice. The VA is also prohibited from contracting with hospices or agencies that offer this service under 38 US Code § 1725 and 38 US Code § 1728 (Reimbursement for emergency treatment and Reimbursement of certain medical expenses).^{73,74}

CONCURRENT CARE

Palliative care is offered at the diagnosis of a serious illness. Hospice, however, is for patients with a prognosis of 6 months or less. Hospice services, when added as an adjunct program to standard care treatment models in end-stage disease, such as Stage IV lung cancer, often improve quality of life, both physically and psychologically. This approach to “concurrent care,” or the ability to simultaneously access these sometimes mutually exclusive approaches to disease management, has also been shown to be more cost effective, with patients choosing hospitalization and aggressive life support measures less frequently.⁷⁵

Unfortunately, under the current medical model, enrollment in hospice care focuses on comfort with the discontinuation

of many life-sustaining treatments, including palliative chemotherapy, immunotherapies, and radiation treatments, even though they may benefit the individual in terms of symptom management and quality of life. Continuing active treatment and concurrently providing hospice services will minimize the symptom burden on patient and families and provide emotional support as well as the important work of preparing for the end-of-life transition. The VA recognizes the value of both active treatment and hospice care and enables veterans to receive the full array of services through the VA under their funding model. This approach is receiving new appreciation in the private sector as well.⁷⁶

VA HOSPICE AND PALLIATIVE APRNS

The hospice and palliative APRN is an integral part of the VA workforce, serving veterans and their families. The APRN’s role has evolved throughout the system and plays a vital role in carrying out the mission of the VA to provide a continuum of care for veterans and their loved ones. The Veterans Health Administration (VHA) serves at least 9 million enrolled veterans yearly with 170 medical centers across the country and 1,074 outpatient clinics.⁷⁷ Only veterans with an honorable discharge status are eligible to receive VHA healthcare. However, veterans may challenge to upgrade their discharge status, as noted earlier.

To honor veterans’ preferences and promote veteran-centric, quality end-of-life care, the VA was one of the first healthcare institutions to mandate and embed hospice and palliative care services across its infrastructure (acute care consults, outpatient clinic, inpatient palliative/hospice units). The Comprehensive End-of-Life Care (CEC) initiative launched in 2009 paved the way for the concurrent care model, a unique policy which allowed veterans to enroll in hospice while undergoing cancer-directed or disease-modifying treatments. This commendable and concerted effort from the VA was associated with less aggressive medical treatment and significantly lower medical costs.⁷⁸ This initiative provides integrated care and bridges the separation between curative and palliative services, giving seriously ill patients a broader range of options for care instead of an either-or decision.

At the VA, palliative and hospice care are provided across care settings such as the home or the community, outpatient care, long-term care facilities, and inpatient units or through the inpatient consult service. Palliative APRNs serve essential roles in the healthcare system, from providing primary care to palliative and end-of-life care. The APRN is an integral part of the palliative care interdisciplinary team (along with physicians, pain pharmacists, chaplains, psychologists, and social workers) providing comprehensive symptom management to address the psychosocial needs of patients and families. The APRN plays a significant role in the day-to-day operations of the palliative care and hospice service to manage pain and other symptoms through interdisciplinary care, focusing on whole-person care, family support, and transitional care as indicated. Palliative care and hospice are part of every enrolled veterans’ benefit package. Dual-eligible veterans

(with both VA and Medicare benefits) may choose to have hospice services covered under the Medicare Hospice Benefit (thus retaining eligibility for VA care and benefits). If inpatient hospice service is needed, care can be provided through a VA facility (acute care or community living center [CLC]) or a VA-contracted community nursing home.

The military experience and culture create a unique set of care needs requiring distinct and specialized care approaches. Palliative care consultations allow for frank and realistic conversations about goals of care, encourage the initiation of timely discussions between patients and their loved ones/surrogates, and provide veterans with a better understanding of their medical conditions and prognosis. Too often, goals-of-care conversations occur late or happen during a crisis situation. This could be very challenging for such a highly vulnerable population. It may be even more challenging for veterans with few or no friends, family, or social support and those with no surrogate decision-makers. Palliative care consultations can assist in the process of advance care planning and in identifying surrogate decision-makers.

When consulted by a palliative care team, veterans and their families receive better emotional support and care planning.⁷⁹ Timely consults at the VA are associated with greater family satisfaction with care (outcomes from the Bereaved Family Survey [BFS]).⁷⁹ The impact of palliative care consultations on VA Standardized Mortality Ratio (SMR) and Strategic Analytics for Improvement and Learning (SAIL) indicators represent areas of future research.

A significant portion of veterans die outside the VA healthcare system, in places where their military experience or service-related conditions could be underappreciated or underevaluated.⁵ This poses a barrier to accessing veteran-specific care and resources and could severely impact veterans' overall quality of life, including their families and support systems.

EDUCATIONAL PREPARATION AND TRAINING FOR HOSPICE AND PALLIATIVE CARE AT THE VHA

Both general and specialized training and education in palliative/hospice care can be obtained from curricula such as the End-of-Life Nursing Education Consortium for Veterans (ELNEC—for Veterans) and ELNEC for APRNs.^{8,80} Free palliative care and hospice care educational services are also available through the VA Training Management System (TMS).

The VHA is one of only a handful of institutions that offer a Hospice and Palliative Care Nurse Practitioner fellowship program.⁸¹ By undergoing postgraduate palliative APRN training, the resident embarks on a year-long skills and development training to enhance competencies for entry-level specialty palliative/hospice care practice. Specifically, the curriculum provides training in pain and symptom management and communication skills along with interprofessional educational training and team-based care through a variety of formats such as supervised clinical experiences, face-to-face, and online, and in a variety of settings (either VHA-based, in

inpatient palliative care units, outpatient clinics, hospice care units at CLCs, pain clinics, hematology and oncology services, etc.; or non-VHA-based at community hospice agency networks). The APRN is a key factor in the selection, orientation, supervision, training, education, promotion of self-care, and role and professional development of the nurse practitioner fellows. APRNs also serve as faculty for VHA Palliative Care and Hospice Medicine fellowships and interdisciplinary hospice/palliative care fellowship programs such as social work, etc.

APRN FULL PRACTICE AUTHORITY

In 2017, the VA granted full practice authority to APRNs (for certified nurse practitioners, certified nurse-midwives, and clinical nurse specialists) to act within the full scope of their employment consistently throughout the VA system, regardless of the state in which they practiced.⁸² These APRNs are recognized as licensed independent practitioners (LIP). The VA defined the processes for credentialing, privileging, reappraisal, re-privileging, and adverse privileging actions. Most importantly, it removed APRN practice barriers, and this has been a monumental step in improving and maintaining veteran-centric quality care. This directive aimed to increase the pool of qualified healthcare providers, expand access to VHA healthcare (especially primary care in medically underserved areas), and reduce wait times for VHA medical appointments.

These APRNs have the practice authority to conduct goals-of-care conversations, write life-sustaining treatment plans and life-sustaining treatment orders (clear instructions regarding medical goals of care that do not expire unless goals change and that are portable across all VA settings), including do-not-attempt-resuscitation (DNAR)/do-not-resuscitate (DNR) and DNR-with-exception orders. APRNs are in the forefront of supporting and fostering patient-centered communication, engagement, and facilitation, and in documenting timely goals-of-care plan conversations and assisting in clarifying ambiguities to allow a common understanding of the veteran's goals, values, and wishes.

VARIOUS ROLES OF THE HOSPICE AND PALLIATIVE APRN AT THE VHA

The hospice and palliative APRN serves in a variety of roles as educator, advocate, direct clinical management, and healthcare system navigator, and assists with case management and team support. APRNs may be responsible for ensuring that policies and procedures are in place to facilitate the delivery of patient-centered care and for guiding and improving clinical and professional practice. They identify the educational needs and assist with role development of staff (also updating staff competencies) within the service and impacted service areas. They provide expert guidance, act as a consultant in an advisory capacity, and serve locally and nationally to support professional practice and development. They facilitate and are

actively involved in quality and performance improvement, evidence-based practice, and formal research to further health outcomes and improve practice. The APRN actively participates in implementing national initiatives and policies.

SYSTEM EDUCATION

In 2017, the VHA, led by the National Center for Ethics, launched a national quality improvement project, the Life-Sustaining Treatment Decisions Initiative (LSTDI). The aim was to promote a more proactive, personalized, patient-centered approach to eliciting, documenting, and honoring medical care preferences for veterans with serious illness.⁸³ LSTDI standardized practice and approaches to life-sustaining treatment decisions including staff education, training, and resources, as well as monitoring within VHA facilities. It established guidance on naturally administered nutrition and hydration, conflict resolution, and conscientious objection and also explained the prohibition on assisted suicide and euthanasia at the VHA.

VETERANS AFFAIRS MISSION ACT OF 2018

The passing of the *VA Maintaining Internal Systems and Strengthening Integrated Outside Networks (MISSION) Act* in 2018 paved the way for the consolidation and redesign of community care programs at the VHA, thus impacting the quality of healthcare delivery for veterans.⁸⁴ It created new community care eligibility criteria, provided a new urgent care benefit, modernized information technology, established a new Community Care Network (CCN), innovated service-delivery, expanded the Caregiver Support Program (CSP), and provided timely community provider payments.⁸⁵ It also allowed veterans to receive or have more access to care in the private sector for services that are not available within the VHA or when they meet certain eligibility criteria and in consideration of their circumstances (remote living with extended drive time or prolonged appointment wait time at their local VHA facility, etc.). Despite its implementation, challenges remain, particularly as it relates to the continuity, cost, and quality of healthcare that veterans will receive from the community. By opening access to the private sector and partnering care with the local community (e.g., specialty care access such as palliative care), Community Care aims to add more service choices, prevent appointment delays, and accommodate the needs of veterans, particularly those living in remote rural areas.

COMPLEMENTARY AND INTEGRATIVE HEALTH

Patients with life-limiting or serious illnesses may experience a variety of symptoms that affect biopsychosocial

well-being and overall quality of life. Relief may be derived not just from pharmacologic approaches, but from other therapeutic interventions aimed at reducing symptom burden while also reducing or avoiding medication side effects. As the nation's largest integrated healthcare system, the VHA has invested in research in, staff training in, and access to a variety of evidence-based integrative and complementary therapies to provide a whole-health system approach to care and also offer nonpharmacologic pain management strategies to combat the opioid crisis. These approaches (acupuncture, biofeedback, clinical hypnosis, guided imagery, massage therapy, meditation, tai chi, and yoga) could not be more relevant and impactful than in the hospice and palliative care population. Ongoing complementary and integrative health provider skills training is available through the VHA, and, thus far, the VHA has trained more than 4,600 providers in Battlefield Acupuncture (protocolized auricular acupuncture for pain), 88 in Battlefield Acupressure, 2,370 in health coaching, and 124 in mindfulness facilitation.⁸⁶

SUMMARY

Florence Nightingale once walked tirelessly through military hospital tents at night, guided by her lamp, giving comfort to wounded and dying soldiers. American Red Cross founder Clara Barton cared for sick and injured Civil War combatants who were starving, without supplies, and often lost and separated from loved ones. On the battlefield, these nurses found conditions unacceptable, and they became activists, scientists, and humanitarians who fundamentally changed entire healthcare systems and built the foundations of modern nursing.

More than a century later, wars are still here and soldiers still suffer. Consistent with the legacy of early nursing, contemporary APRNs now have the autonomy and resources to continue to revolutionize care and improve the lives and conditions of military men and women. Today's veterans are a large group with diverse experiences and complex health challenges and are at increased risk for a multitude of problems such as PTSD, moral injury, and suicide. The APRN ultimately recognizes that those who served often carry both physical and mental wounds for a lifetime and knows how to mobilize a vast array of services to ensure that veterans experience comfort and appreciation during the end of their lives for all they have sacrificed to defend our freedoms. Nightingale shone a light on the pain and suffering of dying soldiers, and her examples of bedside compassion, activism, and fierce advocacy continue to exemplify the greatest callings of the nursing profession.

RECURRENT DISEASE AND LONG-TERM SURVIVORSHIP

Denice Economou and Brittany Bradford

KEY POINTS

- Cancer survivors experience different trajectories from diagnosis to survivorship and potential recurrence.
- Integrating palliative care with survivorship care can provide more effective and efficient management of survivors' needs while conserving costs and sharing resources.
- Palliative advanced practice registered nurses (APRNs) provide essential care in care coordination and transitions of care.

(TUG) review of mobility, the Eastern Cooperative Oncology Group (ECOG) rating and assessment of instrumental activities of daily living and activities of daily living (IADL/ADL) is helpful to establish the baseline independence of this patient to anticipate risk of falls and potential supportive care needs.³ Mrs. P reported concerns about pain, diarrhea, gas, a history of neuropathy, and distress.

INTRODUCTION

Although survivorship care is defined as care beginning at diagnosis and continuing until death, most survivorship care services focus on the post-treatment care phase and extended survivorship. Long-term cancer survivors experience a variety of symptoms related to their disease type, treatment regimens, age, and comorbidities.⁴ When these patients have recurrent disease, as in the case study, multiple issues occur at the same time. Therefore, advanced practice registered nurses (APRNs) will provide important coordination of necessary care. The survivorship APRN must determine whether the patient is at risk for increased symptoms and additional cancers and develop a plan of care to manage these symptoms. Unless there are long-standing problems from their cancer treatment, most survivors ultimately return to their primary care physician for standard, annual recommended care, depending on their disease or treatment.

Recurrent disease in long-term survivors illustrates the partnership between the survivorship clinic and palliative care that may be necessary and how the APRN coordinates care between the two services as appropriate. Frequently, palliative APRNs manage patients in the oncology clinic through initial diagnosis—often at late stage—through treatment. These patients then stabilize, and the palliative APRN refers them to the survivorship program to meet their needs at that time. Survivors may deal with multiple long-term and late effects of their cancer and its treatment over time. Aging and other comorbidities may also complicate their management. APRNs with palliative care expertise are essential providers to meet the coordination and transitions of care needed in this population as they transition between survivor and recurrence.

The goal of survivorship care is to improve the quality of life for patients, their caregivers, and their families from the time their cancer is diagnosed through their life span. Integrating palliative care into survivorship care can improve

CASE STUDY 1: PALLIATIVE CARE FOR SURVIVORS

Mrs. P was a 76-year-old woman who presented with a second colon cancer as a new primary 6 years after her initial diagnosis. She had a rare hereditary syndrome, a subtype of hereditary nonpolyposis colorectal cancer (HNPCC) known as *Lynch syndrome*, which predisposed her to colon, gyno-urinary, and skin lesions. She had experienced multiple sebaceous tumors on her face and chest. Mrs. P's genetic findings (HNPCC/Lynch syndrome) put her at a very high risk for recurrence and second cancers. Her risk for developing additional cancers was high and caused her great distress.

Over the past 14 years, she has undergone multiple surgeries, starting with endometrial cancer, followed by her first colon cancer resection. She has had a recent laparoscopic colon resection with anastomosis. As a result, she experienced moderate bowel issues with diarrhea, gas, and minimal incontinence of stool. She lived with her 80-year-old husband of 55 years, who became her primary caregiver. Previously, Mrs. P had been physically challenged due to scoliosis and suffered from neuropathy in her feet. The lack of feeling in the soles of her feet necessitated the use of a walker at home.

Mrs. P was referred to survivorship to help with quality of life. Because Mrs. P was a geriatric oncology patient, maintaining functional mobility was essential for independence. The advanced practice registered nurse (APRN) planned a thorough assessment. In preparation for her planned initial survivorship telehealth encounter, the survivorship APRN asked Mrs. P to complete an Edmonton Symptom Assessment System and Patient Health Questionnaire 9 (PHQ-9). The APRN completed a Geriatric Assessment and the Blessed Memory Test.^{1,2} Although the virtual visit did not allow a timed up-and-go

the cancer survivor’s quality of life and relieve his or her suffering.^{4–6} Transitioning care between end of treatment and survivorship requires coordination of care across multiple cancer specialists and primary care providers.⁶ The estimated number of survivors who will be alive by January 2030 will be 22.1 million.⁷ People 65 years or older account for 64% of survivors. One in ten are 50 years or younger.⁷ Although survival rates are growing, cancer remains our country’s leading cause of death. Survivor-focused care includes prevention, detection, surveillance, coordination and communication of care, and interventions to relieve symptoms and suffering, with a focus on improving quality of life and health promotion. Overlapping survivorship care with the domains of palliative care provides a framework for the coordinated management strategies needed for this population. Figure 24.1 illustrates the overlap of survivorship care and palliative care.

In Figure 24.1, the four domains of the quality of life model provide the core framework, while the eight domains of the National Consensus Project for Quality Palliative Care (NCP) *Clinical Practice Guidelines* define the palliative care actions.^{5,8} Domain 1: Structure and Processes of Care, encompasses all of the domains and allows for the multidisciplinary assessment of patient and family. Domain 2: Physical Aspects of Care, covers the physical well-being of the quality of life model providing evidenced-based symptom management. Domain 3: Psychological and Psychiatric Aspects of Care, is included in the Psychological Well-Being of Survivorship quality of life model. This area includes anxiety, depression, distress, and fear of cancer recurrence. Domains 4, 6, and 8, the Social, Cultural, and Ethical/Legal Aspects of Care, fall under Social Well-Being in the quality of life domain. Domain 5: The Spiritual, Religious, and Existential Aspects

of Care, relates to the spiritual well-being of survivor’s quality of life model. Finally, Domain 7: Care of the Patient Nearing the End of Life, can be recognized from any domain in palliative care as caring for cancer survivors with recurrent disease; long-term survivors may transition to this level of care at any time. APRNs are essential in providing and overseeing this level of care due to their expertise and coordination skills. The key aspect of these models of care is that they both focus on care aimed at improving quality of life and minimizing or alleviating suffering.^{4,8}

As people with cancer complete primary treatment, challenges exist as they transition to long-term survivorship. In 2020, the National Coalition for Cancer Survivorship (NCCS) completed a State of Cancer Survivorship Survey, representing a broad range of cancer diagnoses and different stages of survivorship.⁹ A total of 1,319 survivors provided self-reported data between April 15 and May 1, 2020, with only 17% reported receiving a survivorship care plan post-treatment.⁹ They identified key side effects they were experiencing, which included fatigue (49%), depression and/or anxiety (30%), loss of appetite and/or taste (28%), muscle or joint pain (27%), and nausea/vomiting or diarrhea (27%). People who identified a greater number of post-treatment concerns were African Americans, Hispanics, women, and younger survivors and those who had received chemotherapy as part of their treatment regimens.⁹

Recognizing that symptoms vary depending on type of cancer, age and stage at diagnosis, types of treatments, and socioeconomic status, planning care to meet the needs of this population requires comprehensive and coordinated management. Improved survival has brought the benefits of living longer but also the challenges related to long-term and late

Figure 24.1 Quality of life model for survivors within eight NCP Domains of Care.
Adapted from Institute of Medicine. *From Cancer Patient to Cancer Survivor: Lost in Transition*. Washington DC: National Academies Press; 2006⁵; and National Consensus Project for Quality Palliative Care. *Clinical Practice Guidelines for Quality Palliative Care*. 4th ed. Richmond, VA: National Coalition for Hospice and Palliative Care; 2018.⁸

effects; many survivors are living with cancer as a chronic illness.^{10–14}

Cancer survivorship occurs over phases from diagnosis to treatment, the immediate post-treatment stage, long-term survivorship for 5 years or longer to end-of-life care.¹⁵ Cancer survivors may experience multiple symptoms and long-term effects during these phases of survivorship, which begin during treatment and continue into post-treatment, long-term survivorship, and possible recurrence.¹⁵ These late effects include fatigue, chemotherapy-induced peripheral neuropathy (CIPN), sleep dysfunction, and psychosocial problems, such as depression and anxiety.^{6,7,13} Late effects associated with cancer survivorship start after treatment completion and include cardiovascular disease related to anthracyclines, osteopenia, and hyperlipidemia. Additional effects include sexual dysfunction, infertility, lymphedema, urinary and bowel dysfunction, psychological symptoms, depression, and cognitive changes. Table 24.1 describes common late-stage recurrence symptoms associated with the top five cancers of both male and female survivors.

These patients may experience cycles of remission, recurrence, and remission; returning for palliative care support is likely, underscoring the importance of integrating survivorship care with palliative care. These effects vary depending on disease, type of treatments, stage of disease, age, culture-related disparities, and other comorbidities. Secondary symptoms may accompany primary symptoms, including weight gain, hyperlipidemia, and the development of hypertension.⁶ The potential for multiple symptoms shows how complicated the long-term management of cancer survivors can become.⁴ Extended cancer treatments, including endocrine therapy, targeted therapy, and hormone therapy, may cause problems in delineating cancer survivors but clearly influence their needs for combined survivorship and palliative care.¹⁶

RELATIONSHIP BETWEEN SURVIVORSHIP AND PALLIATIVE CARE

The goal of palliative care is to relieve suffering for the patient and family and improve quality of life.⁸ Cancer survivorship care is focused not only on treating symptoms associated with late and long-term effects of cancer and its treatment, but also on providing detection, prevention, and surveillance for recurrent or new disease.⁵ Communication and education are essential for both cancer survivorship and palliative models of care. Both palliative and survivorship care are focused on relieving suffering and improving quality of life, and the APRN plays an important role in providing both. Where the APRN roles overlap in these two models of care, integration and communication of the multidisciplinary team is essential. Integrated care allows for a shared-care model and the benefit of effective and efficient management of recurrent disease. In the integrated model of care, multidisciplinary experts can help manage the patient's

symptoms, coordinate surveillance needs, and plan the patient's goals of care.^{6,17,18}

THE ROLES OF THE APRN

APRNs are the essential providers in the interdisciplinary models of both palliative and survivorship care. The coordination and handling of a patient's needs may vary depending on the different disciplines that make up the palliative care team. Nonetheless, the responsibilities of the APRN within the multidisciplinary team remain the same: promoting ethical decisions, providing collaboration and consultation, and providing evidence-based interventions for direct patient care.

About one in six cancer survivors will experience recurrence and advanced disease,⁸ most commonly individuals with a history of prostate and breast cancer. Patients whose disease returns in an advanced stage may experience symptoms treated more effectively by the palliative care team. Oncology and palliative APRNs may have discharged these patients into long-term survivorship care and now will be faced with readmitting them to the palliative care service with new or recurrent symptoms related to advanced disease. The survivorship APRN performs a comprehensive assessment of the patient's needs and establishes or re-establishes a therapeutic relationship with the patient and family. Health outcomes depend on six core functions of the patient and provider: these include exchanging information, making decisions, fostering healing relationships, enabling patient self-management, managing uncertainty, and responding to emotions.¹⁹ The level of trust and communication that an APRN establishes serves as the foundation for meeting the comprehensive needs of the patient population experiencing recurrence of disease and approaching the end of life.^{20,21} The APRN provides survivorship care that meets the patient's needs, creates a therapeutic relationship, and employs research-based interventions to meet the challenges that these complicated patients present.

PALLIATIVE CARE IN PATIENTS WITH RECURRENT DISEASE

Similar to all health specialties, the COVID-19 pandemic has required survivorship clinics to provide care via telehealth. Although this has long been a model of rural healthcare, it is a new experience for many oncology and survivorship providers. There are many provider tools and applications that can facilitate a quality survivor clinic visit, although the completion of physical exams that include cardiac and pulmonary evaluations may require special telehealth equipment. When necessary, tools to aid physical assessment, such as stethoscopes and dermoscopes, can be used but require the patient to be present at a telehealth site. There, a registered nurse assists in those exams and conveys valuable information to the survivorship APRN. Survivorship APRNs can provide an algorithm for the staff registered nurse to follow that is within their scope of practice and supports a shared-care model.

Table 24.1 DISEASE SITE (% SURVIVORS) AND COMMON LATE-STAGE RECURRENCE SYMPTOMS

MALE		FEMALE	
CANCER	SYMPTOMS ASSOCIATED WITH LATE RECURRENCE	CANCER	SYMPTOMS ASSOCIATED WITH LATE RECURRENCE
Prostate (45%)	Pain Osteoporosis/fracture Urinary and bowel dysfunction Sexual dysfunction Increased cardiovascular disease risk Risk of diabetes Sleep dysfunction Depression	Breast (44%)	Pain Osteoporosis/fractures Cardiovascular disease Arthralgias/myalgias Risk of diabetes Peripheral neuropathy Lymphedema Sleep dysfunction Cognitive impairment Psychological late effects
Colorectal (10%)	Bowel dysfunction (diarrhea, constipation, obstruction) Bladder dysfunction Peripheral neuropathy Depression	Uterine corpus (9%)	Osteoporosis Lymphedema lower extremities Infertility Sleep dysfunction Sexual dysfunction
Melanoma (8%)	Pain Depends on where melanoma arises Cutaneous melanoma or mucosal melanoma: Fungating wounds Brain melanoma: Headache, fall risk, weakness, numbness, somnolence, behavioral changes Lung metastasis: Shortness of breath, cough Lymphedema Cord compression: Incontinence, paralysis Immunotherapy and targeted treatment side effects	Colorectal (9%)	Bowel dysfunction (diarrhea, constipation, obstruction) Bladder dysfunction Peripheral neuropathy Depression
Urinary bladder (8%)	Bladder dysfunction: reduced volume, unable to eliminate; failure of neo-bladder; frequency	Melanoma (8%)	Pain Depends on where melanoma arises Cutaneous melanoma or mucosal melanoma: Fungating wounds Brain melanoma: Headache, fall risk, weakness, numbness, somnolence, behavioral changes Lung metastases: shortness of breath, cough Lymphedema Cord compression: Incontinence, paralysis Immunotherapy and targeted treatment side effects
Non-Hodgkin's lymphoma (5%)	Radiation and monoclonal antibody effects Skin changes Stem cell transplant effects Recurrent infections; decreased blood counts	Thyroid (8%)	Thyroglobulin levels changing and difficult to maintain Potential for distant metastasis Symptoms depend on location and extent of tumor. Damage to nerves and voice changes Dry mouth and dental caries

From American Cancer Society.⁷

Other survivorship smart apps allow individualization of a care plan, care reminders, symptom review, and visual patient check-ins.²² These provide opportunities to enhance care to focus on patients' and families' individual needs in a cost-effective manner and limit exposure to infections. Although one size never fits all, with good risk stratification, telehealth visits can meet the palliative/survivor care needs of this special population of people with advanced cancer who are living with chronic disease or who face recurrence.^{22–24}

ASSESSMENT

Initially, the APRN evaluates the patient's areas of concern, focusing on the four domains of quality-of-life which overlap with the eight domains of palliative care, as illustrated in Figure 24.1.

Many long-term cancer survivors are older and the onset of common geriatric syndromes put them in need of complex interventions.¹⁷ In a 2020 national survey done by

Fitch et al. in Canada of 1,655 adults 75 years and older, 68.2% frequently described physical concerns as their number one challenge.¹⁸

PHYSICAL WELL-BEING-NCP DOMAIN 2: PHYSICAL ASPECTS OF CARE

CASE STUDY 1: PALLIATIVE CARE FOR SURVIVORS (CONTINUED)

The meeting took place at 10 AM because Mrs. P said she was not an early riser. She participated with her husband, who addressed questions about medications and his observations as a caregiver. She was dressed, her hair was combed, and she wore makeup. She claimed to have dressed herself, at which her husband smiled. Mrs. P complained primarily of pain in her back and neuropathy. Using a numeric rating scale, the patient stated her pain at 6–7, which for her was moderate pain. She was currently using a combination pill of oxycodone 5 mg/acetaminophen 325 mg for pain prescribed as 1–2 tablets twice every 6 hours. Her last dose was 4 hours prior, and she stated she would take another dose at 1 PM. Listening to her complaint of a deep pain at the base of her back, her husband explained it as being related to her scoliosis, where her “right hip meets her spine off center.” Additionally, when she was engaged in the conversation, Ms. P closed her eyes and admitted to being sleepy.

A primary symptom associated with advanced disease is pain.²⁵ The goal of the palliative APRN is the relief of the patient’s suffering, primarily by focusing on pain sources that are difficult to manage with standard approaches or that require difficult titrations or alternative routes (see Chapter 43 on pain management). In Mrs. P’s case, the palliative APRN must establish the patient’s pain management history and evaluate the current medication plan for effectiveness and complications. Pain assessment and listening to the patient’s self-report are most important.²⁶

It is known that in the United States more than 60% of cancer survivors are 65 years or older.²⁷ Assessing pain in the older adult has been validated using a Verbal Descriptor Scale, the Numeric Rating Scale, and the Faces Pain Scale.²⁸ Assessing how patients describe the pain is essential to understanding the source of pain. A “deep pain,” as Mrs. P describes, is often associated with bone pain. The neuropathy she describes in her feet may be related to spinal instability from scoliosis and possible stenosis related to aging.²⁹ Neuropathy is associated with motor, sensory, or autonomic dysfunction.²⁸ It would not be uncommon for long-term survivors who are older to experience non–cancer related pain such as arthritis or osteoporosis overlaying pain associated with their cancer or its treatment.²⁵ Because Mrs. P’s colon cancer was managed both times with a surgical resection and anastomosis, she did not undergo chemotherapy. The APRN differential diagnosis is that Mrs. P’s pain is related to both her cancer surgery and arthritic or spinal stenosis pain.

Pain with advanced or metastatic disease occurs in 64% of all cancer survivors.²⁵ Chronic pain syndromes related to surgery, chemotherapy, or radiation therapy may occur. Patients who have received certain chemotherapy drugs may experience peripheral neuropathy, as well as weakness and numbness. Situations where a tumor impinges on bone or nerves or causes a stretching of the viscera surrounding organs can cause the most pain for survivors.

Managing pain in geriatric survivor population requires coordination to manage symptoms and the secondary effects of pain medicines. Mrs. P’s sedation is possibly related to her pain medications. This is a safety issue because sedation can contribute to mobility issues or falls that could severely jeopardize her well-being. The combined product of hydrocodone and acetaminophen is not recommended for the older adult. Rather, the medications should be prescribed separately. It is recommended to use a short-acting opioid for moderate to severe pain and have separate acetaminophen dosing. In addition, nonpharmacologic interventions should be used when possible. Palliative care pain guidelines promote anticipating, preventing, and treating predictable side effects or the risk for adverse events.³⁰ A systematic review of the effectiveness and sustainability of nonpharmacological methods of managing pain in community-dwelling older adults found that nonpharmacologic methods such as acupressure, acupuncture, guided imagery, qigong, and periosteal stimulation reduced pain levels.³¹ Other interventions, such as cognitive behavioral interventions like relaxation and strategies to improve coping have been shown to be beneficial for cancer pain management.³² Using both pharmacologic and nonpharmacologic approaches in the management of pain in the older patient with cancer promotes better outcomes. Cognitive status may impact the use of behavioral interventions. A patient with minimal cognitive impairment may tolerate acupuncture, for instance, if the patient is prepared carefully for the procedure. Reimbursement remains a challenge for nonpharmacologic approaches. Many integrative therapies are not covered by many insurers or require larger co-payments. Medicare currently covers acupuncture for back pain and possibly soon for migraines, but coverage varies depending on the state where the patient receives care. Additional resources for pain management in the older adult can be found at the American Geriatrics Society website (www.AmericanGeriatric.org) and Geriatrics at Your Fingertips (GeriatricsCareOnline.org).^{29,33}

Assessing for the secondary effects of unrelieved pain is important as well. Older patients with unrelieved pain may be experiencing depression, fatigue, and sleep deprivation, which will increase sedation, cause lower energy, and further impact mobility for these patients.²⁸ Depression has been shown to be present in 25% of elderly cancer patients.³⁴ Antidepressants may be beneficial in helping with sleep and elevating mood.³⁰

Fatigue remains a concern in long-term cancer survivors.³⁵ Fatigue is associated with progressing disease, pro-inflammatory cytokines, and psychosocial issues like anxiety, depression, and unrelieved pain.³⁶ Unmanaged or prolonged stressors increase the risk to patients by reducing their immune system function and raising the potential for fatigue and depressive

symptoms.³⁷ Management strategies include understanding fatigue's potential sources, such as stress hormones, anxiety and distress over the risk of recurrence or new cancers, unrelieved pain, physical deconditioning, causing loss of mobility, and sleep dysfunction and attempting to minimize these through coordination with multidisciplinary teams that can assist in managing these multiple symptoms (e.g., occupational therapy, cancer physical therapy, and rehabilitation).

PSYCHOLOGICAL WELL-BEING-NCP DOMAIN 3: PSYCHOLOGICAL AND PSYCHIATRIC ASPECTS OF CARE

Psychological symptoms may fluctuate from diagnosis to long-term survival, and, with recurrence, such symptoms may fluctuate again. Depressive symptoms, anxiety, distress, and posttraumatic stress disorder (PTSD) are associated with recurrence in long-term cancer survivors.³⁸ Dealing with recurrence may result in PTSD, and the rate of PTSD may be as high as 32% in cancer survivors.³⁹ In addition, survivors may live with long-term treatment-induced residual cognitive disorders. Both of these conditions affect one's ability to cope with a new and unexpected diagnosis.

The burden that the diagnosis and treatment of cancer puts on a patient and family, the resources available to them, and additional indicators, such as culture, educational level, and economic status, all contribute to the psychological effects in a cancer patient throughout the course of disease.³⁸ The PHQ-9 Assessment Scale can help identify a major depressive disorder.³⁸

Mrs. P and her family required psychosocial support; this is an area that has been historically undermanaged in cancer survivors.⁴⁰ Assessment and coordination of support to manage these psychological symptoms can help reduce distress and promote quality of life.

Age and uncertainty related to the patient's increased risk for another cancer recurrence impacts the distress and anxiety they experience.⁴¹ The APRN must provide education where necessary to be sure the patient has accurate information and understands their prognosis. Assessing fears and maintaining communication is essential to help the patient cope with distress.^{19,42} Using telehealth visits to support self-management by providing education and goal development to guide the care specific to the patients' needs has been shown to be effective in managing pain, psychological distress, fatigue, and sleep disorders.²⁴

SOCIAL WELL-BEING-NCP DOMAINS 4, 6, AND 8

This domain of social well-being encompasses many issues that affect quality of life in cancer survivors after diagnosis. The quality-of-life model related to cancer survivors includes affection and sexual function, body image issues, family roles and relationships, social isolation, and ability to find joy.⁵ Social concerns in the cancer survivor include cultural

awareness, family concerns, work-related issues, and financial debt.⁴³ Recurrence brings many of these concerns back to the forefront in cancer survivors' lives. It is important to assess culture-related concerns by thoughtful discussions that can build trust and may be more helpful than standardized tools.⁴⁴

For a patient like Mrs. P, living with the fear of recurrent cancer saddened both her and her husband. The APRN's role of assessment, with a focus on the patient's social/emotional response to the change in health status, is essential. In addition, caregiver distress is important. The palliative APRN in the case study inquired about family distress to develop a plan of care. Posing the question itself can be therapeutic: it allows Mrs. P and her husband to discuss their concerns about their ability to continue to manage care at home "down the road" and their anxieties about healthcare costs and overall social worries of long-term survival in an environment of uncertainty. Voicing and discussing this areas reduces distress. Moreover, it assisted the palliative APRN in coordinating appropriate resources and making them available as part of the interdisciplinary palliative care service.

SPIRITUAL WELL-BEING-NCP DOMAIN 5: SPIRITUAL, RELIGIOUS, EXISTENTIAL ASPECTS OF CARE

Spirituality in cancer survivors may lead to hopefulness and better coping.⁴⁵ Studies demonstrate that cancer survivors experiencing psychological and social late effects describe multiple spiritual/religious or existential concerns.⁴⁶ Spiritual, religious, or existential concerns are an important part of whole-person care, and yet this is rarely part of a routine assessment.⁴⁷

Because there is a population of advanced disease survivors living with cancer, it is important to recognize that survivorship is relative to the understanding of their disease status. For those who have experienced recurrent disease, even though stable and being followed as survivors, it represents a loss of the future and an opportunity to question the meaning and purpose of life.^{47,48} Mrs. P discussed her spiritual beliefs with the palliative APRN. The APRN elicited spirituality concerns when discussing goals of care. As stated by Cormack et al., "spirituality is the essence of every human being."⁴⁴ (p. 475) Providing spiritual and/or religious support to the patient and caregiver as needed is a key component of good palliative and end-of-life care.⁴⁸ There will be moments of reappraisal of beliefs and transcendence or changes in what the patient believes that affects how they feel about themselves and what the meaning or purpose of their life has been.⁴⁸

The APRN's role in providing spiritual care begins with respecting the patient's beliefs and recognizing that the APRN is more of a guide, with the goal of relieving suffering as patients try to make sense of their recurrent diagnosis and the loss of the life they expected. The APRN's role is to collaborate with chaplaincy to assist patients through this moment and help them move forward in preparing for end of life. Asking Mrs. P and her husband about their beliefs, values, and desires is essential to help define the goals of care and

identify goals that provide them with peace. Compassionate listening displays the respect necessary to build the nurse–patient relationship and provides a supportive environment. Prayer, meditation, guided imagery, and breathing techniques may be meaningful interventions for patients. The role of the APRN in helping these challenging patients can be difficult and draining to one’s own spirituality and meaning. Being present necessitates strategies for clinician support.⁴⁹

Ms. P and her husband, although not religious, had spiritual discussions about what was important to them both. They valued time with their children and grandchildren and maintaining the highest quality of life for as long as possible. They accepted their stage of life and did not have expectations of living many years longer. They wanted to focus on pain relief, optimizing mobility, and enjoying what life was left, while being aware of possible new cancers so they could be identified early. For survivors, the provision of a tailored plan specific to the needs of patients living with chronic cancer or recurrence is helpful to coordinate providers to meet their needs and categorize their risks and goals.^{4,50,51} In the case study, the multidisciplinary team of palliative care working with the survivorship APRN provided the framework for meeting this complicated patient’s needs.

PALLIATIVE CARE IN LONG-TERM SURVIVORS

CASE STUDY 2: SECONDARY CANCER IN SURVIVORSHIP

Ms. D was a 70-year-old-Asian woman with a history of right-sided breast cancer; she was 19 years out from her original diagnosis. She had been followed in the breast cancer survivorship clinic for more than 5 years. Her original cancer was Stage IIIA, estrogen-receptor positive, progesterone-receptor positive, and Her-2/neu negative. She was treated with a right mastectomy and lymph node dissection; 12/15 positive lymph nodes were involved at that time. She underwent high-dose chemotherapy under a clinical trial and had a stem cell transplant, following which she received radiation and endocrine therapy.

Due to the lymph node dissection within her surgery, she has dealt with chronic lymphedema. The APRN assessed her right arm and referred her to occupational therapy for lymphedema manual massage and drainage. The therapists also fit her for a compression sleeve.

When Ms. D presented for her annual follow-up in the survivorship clinic, she had her usual mammogram and ultrasound, with both yielding normal results and no evidence of malignancy. She discussed with her APRN that she had been experiencing worsening fatigue, nausea, and just generally feeling unwell. Lab work revealed macrocytic anemia. Her hemoglobin was not substantially low, but low enough that the decision was made by the APRN to send her for a hematology evaluation.

Ms. D was seen by a hematologist; a bone marrow biopsy and aspiration was done. The hematologist had offered a potential diagnosis of myelodysplastic syndrome (MDS) as a result of

her breast cancer treatment. Ms. D was extremely anxious as she awaited the results of her biopsy. It has been 19 years since her breast cancer, and the thought of developing a secondary cancer as a side effect of her treatment had barely crossed her mind. Indeed, MDS was the diagnosis.

It was difficult for Ms. D to think about going through another cancer diagnosis and treatment alone. Ms. D’s husband had passed away from lung cancer 2 years prior. She had a church community that was a source of strength for her. Her survivorship APRN sent a referral to social work to help the patient with coping mechanisms and with logistics, such as determining which transportation services were available. The APRN spoke with the social worker and, based on the social workers assessment, Ms. D was referred to psychiatry.

PHYSICAL WELL-BEING

The APRN evaluated Ms. D using the four domains of quality care, recognizing that it is important to care for the whole person. Initially, the patient’s physical well-being was assessed. She felt generally unwell, nauseated, and was experiencing a flare-up in her lymphedema. The APRN used her knowledge of the patient’s disease to make educated steps toward getting to the cause of the patients’ symptoms.

The majority of hormone-negative breast cancer recurrences occur during the first 5 years after diagnosis, but for hormone-positive breast cancer, as in Ms. D, later recurrences are often seen.⁵² Knowing that this was a possibility for Ms. D, it was important to evaluate the patient’s mammogram and ultrasound, which was done and yielded benign findings.

The majority of breast cancer survivors have a good quality of life, but it is known that there are long-term effects from breast cancer–related therapy including fatigue, cognitive decline, lymphedema, pain, menopause symptoms, anxiety, and depression.⁵³ Ms. D expressed that she felt fatigue. This is known to be a long-term survivorship effect; however, she was experiencing worsening fatigue. Ms. D was a cancer survivor of 19 years, thus her description of worsening fatigue seemed to be a new symptom and not her baseline. The APRN evaluated this further by having a complete blood count (CBC) drawn, noticed that she had anemia, and ultimately consulted the hematology service for a bone marrow biopsy. The APRN also had the knowledge that, as a breast cancer survivor, Ms. D was at risk for a secondary cancer such as MDS; in those treated with chemotherapy, this risk is around 1%.⁵⁴ Other secondary cancers can be seen following radiation therapy or other chemotherapies.

Ms. D had also complained about lymphedema to the APRN. Breast cancer and its associated treatments are one of the leading causes of lymphedema. One study showed the occurrence of lymphedema in breast cancer survivors to be 17%.^{55,56} The main risk factors for breast cancer–related lymphedema include surgery with lymph node removal, invasive breast cancer, and radiation.^{55,56} It is important to rule out other causes of upper extremity swelling, in particular if the

onset is sudden, as is seen in the occurrence of a thrombosis. In this case, Ms. D had dealt with chronic lymphedema since her surgery, so referring her to occupational therapy for further management was the reasonable next step. Occupational therapists trained in lymphedema management can perform manual massage to drain the lymphatic fluid and ultimately improve the patient's symptom. Ms. D was also fitted for a sleeve and taught exercises that she could do at home to prevent her lymphedema from worsening.

PSYCHOLOGICAL WELL-BEING/SOCIAL WELL-BEING-NCP DOMAINS 3, 4, 6, AND 8

Many cancer patients affirm that once they have been through a cancer diagnosis, the thought of having a cancer recurrence is often in the back of one's mind. Fear of recurrence is a form of anxiety, and anxiety levels have been reported to be higher in patients with a history of cancer.⁵⁷ Risk factors for anxiety in cancer survivors include living alone, being a female survivor, and social isolation. The APRN recognized that Ms. D had many risk factors for anxiety and made a prompt referral to social work. Ms. D was in a difficult situation in that she was anxious regarding her own possibility of a second cancer, but was also still grieving the loss of her husband and the loss of her support system. The APRN referred her to social work and psychiatry because she recognized that the patient had unmet psychosocial needs. If she did have a secondary cancer, such as MDS, she would need to be aware of the resources available at the hospital to help her, since she was living alone. Social workers are wonderful resources, and in the case study, they connected Ms. D to transportation services, mentorship programs, and a support group that could help her navigate a new cancer diagnosis. The psychologist helped with cognitive behavioral interventions that have been shown to reduce anxiety over fear of progression.⁵⁸

SPIRITUAL WELL-BEING: DOMAIN 5: SPIRITUAL, RELIGIOUS, EXISTENTIAL

People often search for “meaning” or purpose from their catastrophic illnesses. A serious illness like cancer, or being the caregiver of someone with cancer, can often cause patients or caregivers to have doubts about their own spiritual beliefs. Some may feel they are being punished by God or may have a loss of faith after going through this experience. This is known as *spiritual distress* and is a normal response. Ms. D has been both caregiver and patient, so paying attention to her spiritual needs was an important aspect of her care. Ms. D did mention to the APRN that she attended church and that it was a source of strength and hope for her. Religion/spirituality has been shown to have a positive association with better health outcomes and quality of life.⁴⁶ The patient's church was also helpful in providing her support for feelings of loneliness

and lack of community.⁵⁹ Many religious organizations can provide practical support such as meals, rides to and from appointments, and a sense of community. The APRN discussed these concerns with Ms. D to learn more about what her beliefs were and how she could facilitate and encourage her in this area. Many hospital and cancer facilities have chaplains or spiritual counseling available, and many patients find this helpful.

SUMMARY

The role of the palliative APRN includes evaluating the educational needs of patients and families, promoting the palliative model of care, providing evidence-based practice, promoting organizational ethical values, organizing staffing, and providing economic oversight.⁶⁰ The APRN's overall advocacy for patients provides leadership to improve the quality of care. The APRN plays a significant role as a clinical consultant to ensure communication among physicians, the palliative care team, support staff, patients, and families.⁶¹ As the ultimate patient advocate and as part of providing whole-person care, the APRN coordinates the care of patients with recurrence of advanced disease and is committed to recognizing and dealing with the health disparities affecting palliative and end-of-life care. By providing care focused on meeting the quality-of-life needs of the cancer survivor with recurrence, integrating the principles of palliative care, and demonstrating expert symptom management, APRNs offer the comprehensive care necessary to manage this complicated patient population, despite the drop in numbers of the workforce of oncologists and primary care providers.^{12,61}

SECTION V

PEDIATRIC PALLIATIVE CARE

THE PEDIATRIC PALLIATIVE APRN

Cheryl Ann Thaxton and Nicole Sartor

KEY POINTS

- The pediatric palliative advanced practice registered nurse shares many of the same roles and competencies as the adult palliative APRN, with additional expertise in pediatrics.
- The pediatric palliative APRN combines in-depth knowledge of pharmacologic and nonpharmacologic therapies, communication techniques, familiarity with ethical and cultural issues, and ongoing access to grief and bereavement resources for children and their family members.
- Delivery of patient- and family-centered care involves collaboration across several disciplines; the APRN is often the interdisciplinary communication leader in pediatric palliative care (PPC).
- Advocacy for the PPC population may require the APRN to take on innovative roles, such as clinical expert, educator, entrepreneur, business marketing champion, and transformational leader.

CASE STUDY: PEDIATRIC PALLIATIVE CARE

King was a 5-year-old boy diagnosed with Beare-Stevenson cutis gyrata syndrome, epilepsy, hydrocephalus, cranial stenosis, ischemic encephalopathy, and chronic lung disease. King had a tracheostomy, gastrostomy tube, shunted hydrocephalus, history of cranial stenosis repair, history of repaired scoliosis, and was debilitated by spasticity, myoclonus, dystonia, and hypertonicity. The pediatric palliative advanced practice registered nurse provided care for King upon his transfer from a community hospital to the children's hospital with fever, increased secretions, and respiratory insufficiency. The pediatric intensive care unit (PICU) physician consulted the pediatric palliative care (PPC) team to help King and his family with goals of care, advance care planning, and family support. It was King's fifth admission within a 6-month period due to complications related to scoliosis repair and subsequent respiratory infections.

Upon initial examination, the pediatric palliative APRN found King in acute distress with apparent myoclonus in his right leg and dystonia. On examination, he had severe clonus in his upper and lower extremities, worsening dystonia, and agitation with noticeable tears. King was diaphoretic, flushed, and had vital sign variability. His gaze was fixed, and he was not interactive. He had copious clear secretions on his face and mouth, and

his tracheostomy required nearly constant suction as reported by the bedside nurses. Additionally, King had multiple areas of skin breakdown.

King's mother, Saisha, was not at the visit because she was unable to visit the hospital regularly due to limited childcare options for King's siblings and the cold and flu restrictions prohibiting visitors under the age of 13. After completing the assessment, the pediatric palliative APRN called Saisha to introduce the pediatric palliative team. Saisha later stated, "When I first heard about palliative care, I was not sure what it was. I was scared. I thought that it meant 'the end' for my child. The APRN educated me about palliative care and answered all of my questions. I knew that palliative care was the best option for my son. I understood that working with palliative care would give King the best chance to be at home, where he was most comfortable. King loves being around his family! I think that is what helps children thrive, being in their setting, and around their family."

The pediatric palliative APRN discussed King's physical examination with his mother and learned that his symptoms were not new; however, they were getting worse over time and with each episode of acute illness. The pediatric palliative APRN worked with King's mother to treat his pain and neurologic symptoms, thus preventing rapid response events and frequent transfers from the floor to the PICU. His mother further expressed that "King's symptom management has truly improved his quality of life. When King is in pain his heart rate will increase, his oxygen saturation will decrease, and he will cry. He cannot say where he is hurting because he is nonverbal. The symptom management plan that the PPC team put together has allowed us to relieve King's pain and uncontrollable neurologic symptoms. Sometimes King can work himself up, and it can be so hard to get him to calm down. I have found that having this symptom management plan in place allows us to anticipate distressing symptoms and control the symptoms before they get out of control and lead us back to the hospital." The pediatric palliative APRN arranged for community support and a discharge plan to monitor those symptoms.

PEDIATRIC PALLIATIVE NURSING

Many children have chronic, debilitating, and serious illness; although the numbers are lower than for adults. Pediatric palliative care (PPC) focuses on optimizing the quality of life of children; maximizing their function; exquisitely managing physical, psychological, social, or spiritual care needs;

and enhancing support at home. While the nursing process is the same no matter what the population, the care and management must be tailored to the unique needs of a population (see Chapter 26, “The Pediatric Palliative APRN in the Acute Care Setting”; Chapter 27, “The Pediatric Palliative APRN in Perinatal and Neonatal Care”; Chapter 28, “The Pediatric Palliative APRN in the Clinic”; Chapter 29, “The Pediatric Palliative APRN in Oncology”; and Chapter 30, “The Pediatric Palliative APRN in the Community”).

Pediatric palliative nursing is different from adult palliative care in that there are often lower caseloads, a wider scope of care members, more continuity across care continuums, and more access to resources, particularly philanthropy. The care provided to children must be age-, developmentally, and functionally appropriate. The necessity for the pediatric palliative advanced practice registered nurse (APRN) to be familiar with conditions and diseases specific to infants, children, and adolescents, as well as their trajectories, is essential. This includes pharmacological and nonpharmacological treatment options. In addition to impeccable assessment and treatment techniques, the pediatric palliative must have expertise in age- and developmentally appropriate communication skills for children and adolescents with serious illness and their families (see Chapter 31, “Communication in Pediatric Palliative Care”). Using skills in collaboration, the pediatric palliative APRN must identify and access community resources to support the infant, child, and adolescent and their family as well as the appropriate educational resources for the family. All aspects of PPC are aimed at keeping the child, parent, guardian, or family at the center of care for all decision-making, thus ensuring a patient- and family-centered approach.

HISTORY OF THE APRN ROLE IN PEDIATRIC PALLIATIVE NURSING

The role of the pediatric palliative APRN emerged based on the need to expand care across the life span, which initially correlated with the role of the palliative APRN (see Chapter 1, “Palliative APRN Practice and Leadership”). It is difficult to establish a definitive timeline for the development of PPC because the subspecialty has developed from multiple avenues: the establishment of the adult hospice and palliative care movement, the acknowledgment that children die, the emergence of family-centered care, the fact that children with chronic complex conditions are living longer,¹ and the grassroots movement of healthcare professionals and parents to promote better care for children. Early on, PPC struggled with care that can be described as being an “inch wide and a mile deep.” Programs and clinicians often fought for credibility and acceptance as well as access to patients.² The history of the pediatric palliative APRN role extends back to the 1970s and 1980s, with the initial focus of care related to hospice and to specific medical conditions, such as pediatric cancer (Box 25.1).

PPC has experienced rapid growth since 2000. A cross-sectional national survey revealed that many children’s

hospitals in the United States have PPC programs; however, a majority of these programs were understaffed.⁵ Of the 162 hospitals that responded to the survey, the mean full-time FTE for APRNs was 0.4, with a range of 0–3, and 54.5% of the programs employed no APRNs.⁶ According to the World Health Organization,⁷ people younger than 20 years comprise 25% of the global population and 40% of the global population of least-developed nations; there is an estimated 21 million neonates, infants, children, and adolescents who need PPC each year. Despite this apparent need, there is no clear data about the extent of PPC services internationally.

THE ROLE OF THE PEDIATRIC PALLIATIVE APRN

The expansion of PPC programs brought many significant advancements to the role of the pediatric palliative APRN. More attention is being focused on using PPC measures during the early stages of life-limiting illness for children receiving aggressive therapies for cancer, sickle cell disease, cystic fibrosis, and muscular dystrophy. Currently, around 69% of children’s hospitals offer PPC services, and 41% employ dedicated pediatric staff; only 10–20% of dying children receive hospice at the end of life.⁸ The trend in transitioning from pediatric to adult chronic illness calls for APRN skills that reflect the unique needs of children. Many communities do not have enough children with life-threatening medical conditions to support sufficient pediatric palliative APRN clinical expertise. Without enough exposure to care in the community, it is difficult to develop and maintain sufficient clinical acumen in assessment, evaluation, and management from diagnosis to end-of-life care. Thus, children with seriously illness and their families often travel far from home for treatment at academic medical centers.⁹

Palliative care coexists with treatment and is important from the time of diagnosis, throughout a child’s illness, and beyond. The pediatric palliative APRN is often a consistent team member for children and their families as they navigate inpatient to outpatient settings. APRNs are in ideal roles to provide PPC at the bedside because they spend the most time with children and their families.¹⁰ Pediatric palliative APRNs are often long-standing members of the team, individuals who have pioneered new programs.¹¹ These APRNs often serve as informal leaders without titles, garnering the respect of others through their longevity of team membership, an open mentoring process, or a nurturing style. The pediatric palliative APRN’s role in PPC is multifaceted and involves “wearing many hats.”

The pediatric palliative APRN contributes to the dynamic organizational infrastructure of PPC programs. The opening case study offered the story of a mother whose child had been through years of symptom distress related to a life-limiting illness. The pediatric palliative APRN assessed the level of suffering within the family, worked with the family to establish goals of care, and supported them through the illness trajectory. The overall growth rate of PPC programs across the

1955	Bozeman, Sutherland, and Orbach published one of the earliest psychological studies of dying children. ⁴
1972	Professor Ida Martinson, from the Department of Nursing at the University of Minnesota, recognized the need for pediatric homecare and received a 4-year grant from the National Cancer Institute for researching homecare of the dying child.
1978	Dr. W. Allan Hogge and Mrs. Hogge asked their Presbyterian Church for help in caring for their son with a serious, progressive neurological condition. They established Edmarc Children's Hospice in Suffolk, Virginia.
1978	Professor Myra Blubond-Langer, an anthropologist, published <i>The Private World of Dying Children</i> , a book based on her observations of hospitalized children with leukemia.
1979	Dr. L. Joseph Butterfield established a neonatal hospice program in Denver, Colorado.
1983	Ann Armstrong-Dailey established Children's Hospice International (CHI). Her advocacy work contributed to the Children's Program for All-inclusive Coordinated Care (ChiPACC) program in 1999.
1984	St. Mary's Hospital in New York established the first pediatric palliative care department in the United States.
1998	The World Health Organization published <i>Guidelines on Cancer Pain Relief and Palliative Care for Children</i> .
2000	Dr. Joanne Wolfe et al. published the seminal article "Symptoms and Suffering at the End of Life in Children with Cancer."
2000	American Academy of Pediatrics (AAP) published first policy statement on pediatric palliative care; it was updated in November 2013.
2004	End of Life Nursing Education Consortium (ELNEC), Pediatric Version, was developed as part of the comprehensive palliative nursing educational initiative with Dr. Betty Ferrell as principal investigator. As of 2022, more than 1 million nurses and other professionals have received ELNEC training in all the versions: Core, Geriatrics, Critical Care, Oncology, APRN, and Pediatrics. The Institute of Medicine (IOM) report, <i>When Children Die</i> , brought awareness to the need for clinical expertise, research, and program development.
2010	Education in Palliative and End-of-Life Care (EPEC) Pediatric is developed as part a comprehensive pediatric palliative care curriculum with Dr. Stefan Friedrichsdorf as primary investigator
2013	National Consensus Project for Quality Palliative Care <i>Clinical Practice Guidelines</i> (3rd ed.) includes broader pediatric palliative care content, which expanded in 2018 in the fourth edition.
2021	<i>Palliative Nursing: Scope and Standards of Practice</i> (6th ed.) was released by the Hospice and Palliative Nurses Association (HPNA); it includes pediatric content.

From Sisk et al.³

United States has led to the recognition of this subspecialty by several national organizations.

GENERAL PRINCIPLES OF PEDIATRIC PALLIATIVE CARE

Since its inception, the National Consensus Project Clinical for Quality Palliative Care (NCP) *Clinical Practice Guidelines* support the belief that palliative care is inclusive of all people with serious illness, regardless of setting, diagnosis, prognosis, or age.¹² The NCP *Clinical Practice Guidelines* delineate eight domains of palliative care: Structure and Processes of Care, Physical Aspects of Care, Psychological and Psychiatric Aspects of Care, Social Aspects of Care, Cultural Aspects of Care, Spiritual and Existential Aspects of Care, Care Nearing End of Life, and Ethical and Legal Aspects of Care. Timely integration of palliative care is the responsibility of all clinicians and disciplines caring for infants and children with serious illnesses including primary care practices, specialist care practices (e.g., oncology or neurology), hospitalists, nursing home staff, and palliative care specialist teams such as hospice, hospital, and community-based palliative care teams.^{13,14}

The fundamental principle of PPC is that the child and the family, as a unit of care, are the central focus. Moreover, the child's participation in the care—based on age, developmental,

cognitive, and functional abilities—should be encouraged. The reinforcement of quality initiatives supports best practices in palliative care and serves as the foundation for promoting evidence-based principles. The pediatric palliative APRN must keep abreast of these guidelines and ensure that the team is empowered to implement them throughout the evolution of the program. Practicing within the scope of care for the pediatric palliative APRN has historically involved the ability to incorporate a physical, biopsychosocial, and spiritual multimodal approach to caring for children and their families. As the role has evolved, the pediatric palliative APRN continues to be the role model for persistent child and family advocacy within institutions and community settings.

ROLE DESCRIPTION AND QUALIFICATIONS

Pediatric palliative APRNs come from a variety of educational and training backgrounds. APRNs employed as providers in PPC programs may be trained as family nurse practitioners, family or pediatric clinical nurse specialists, neonatal nurse practitioners, or pediatric nurse practitioners. A few programs across the United States offer palliative nursing fellowships; many of these offer adult palliative care clinical rotations and may not have extensive access to PPC patients

(see Chapter 2, “Fundamental Skills and Education for the Generalist and Specialist Palliative APRN”). Therefore, the pediatric palliative APRN is often the catalyst to establishing a structure for orientation and onboarding of roles in many health settings. The job description of the pediatric palliative APRN incorporates education, research utilization, consultation, and professional leadership and development (Box 25.2).

The role development for the pediatric palliative APRN should be clearly aligned with the job descriptions and incorporate key competencies. The Hospice and Palliative Nurses Association (HPNA)’s 2021 publication *Competencies for the Palliative and Hospice APRN*, delineates eight competencies of specialty palliative nursing practice; these include clinical judgment, advocacy and moral agency, caring practices, collaboration, systems thinking, response to diversity, facilitation

Box 25.2 SAMPLE PEDIATRIC PALLIATIVE APRN JOB DESCRIPTION

Position summary

The Pediatric Palliative APRN provides direct patient care services and performs medical care under in collaboration with physician (or supervision of physician as per state APRN statutes). Provides palliative care to perinatal, neonatal, pediatric, adolescent, and young adult patients requiring pain/symptom management, palliative care, and care at end of life. The APRN collects a health history; performs physical exams, collects, and documents data; conducts diagnostic and therapeutic procedures; orders and schedules laboratory studies and professional consultations; analyses and interprets data; prescribes appropriate pharmacotherapeutics and non-pharmacological strategies; conducts and participates in research; provides teaching, education, and provides leadership in the organization.

Position requirements

Education:

APRN: Work requires completion of accredited graduate nursing NP or CNS program.

Licensure:

APRN: Current licensure as a Registered Nurse (RN) and NP or CNS in the state of X.

Certification:

NP: National certification as an NP or CNS in Pediatrics (may consider Family Nurse Practitioner depending on level of experience).

Experience:

Master’s degree required with a preference for a minimum of ___ years’ experience in the clinical care of patients with complex medical problems facing end-of-life issues. Position requires demonstrated competency in pain, stress, and other symptom management. Strongly prefer candidate with at least one year of experience as an NP or CNS. Acute care experience preferred.

Life support:

- Basic Life Support (BLS)
- Pediatric Advanced Life Support (PALS)
- Advanced Cardiac Life Support (ACLS)
- Neonatal Resuscitation Program (NPR)

Job Responsibilities

Clinical Expert:

- In collaboration with the pediatric palliative care attending physicians and/or residents, round daily on patients to assess, diagnose, plan treatment, set priorities and realistic outcomes, and evaluate the effectiveness and cost efficiency of patient care.
- Provide and coordinate clinical care for service specific patients through established protocols and under the supervising physician or back up physician, who is either on site or virtually.
- Collaborate with the chief resident, residents, fellows, attendings, other APRNs, patient resource managers, chaplains, clinical social workers, and other healthcare providers to formulate treatment plans and monitor patient progress.
- Perform procedures specific to the work environment after demonstrated competency and within the guidelines of scope of practice of advanced practice nursing per the American Nurses Association, APRN credentialing protocols per the National Council of State Boards of Nursing; and palliative practice per the National Consensus Project for Quality Palliative Care, *Clinical Practice Guidelines for Quality Palliative Care*

- Assess patients for change in status and institute appropriate interventions.
- Develop patient care pathways, protocols, algorithms, and guidelines for the management of specific problems in conjunction with the palliative interdisciplinary team of medicine, nursing, social work, chaplaincy, pharmacy and other members of the health care team.
- Analyze and integrate best clinical practice so as to provide the best health care to increase effectiveness, efficiency, and best outcomes.
- Assesses cultural and spiritual aspects of health to ensure health care is respectful and culturally sensitive.
- Assesses social aspects of care including and social determinants of health to ensure health care meets the needs of the patient and their family.
- Communicate effectively on verbal, non-verbal and written forms pertinent to patient care and information.
- Documents effectively in the patients' health record all relevant data including but not limited to results of diagnostic tests; laboratory results; patients' condition and response to therapies/interventions; communications with supervising MD.
- Implements a specific plan of palliative care to alleviate suffering and promote the physical, emotional, psychological, and spiritual comfort of the patient and family.
- Utilizes prescriptive privileges for identified patient population, certification, and licensure.
- Utilizes prescriptive authority for prescribing, ordering, and or administering drugs according to the Drug Enforcement Administration (DEA) regulations within the state.
- Role models competence in all APRN advanced skills.
- Provides daily handoff to appropriate attending, APRN, resident and/or intern at the end of the shift.
- Assures effective transitions of care across settings.

Educator:

- Assesses educational needs of the patient-care staff and provides education in format conducive to learning including just in time learning or more formal education as needed.
- Assesses educational needs of the patients and families and provide culturally sensitive patient/family education interventions as indicated. Use non-technical language when educating patients and families. Document all education in patients' electronic medical record.
- Implements and evaluates appropriate educational programs for patient care staff and other healthcare providers as appropriate; utilize evidenced-based curriculums such as the End-of-Life Nursing Education Consortium (ELNEC) to provide ongoing education at least one or twice a year.
- Role models and precepts healthcare learners through contractual agreements.

Research Utilization:

- Utilizes current research and evidence-based decision-making in all clinical practice.
- Analyzes and integrates clinical research findings in the development and implementation of standards of care.
- Supports IRB approved clinical research/trials through a variety of activities including but not limited to obtaining consent; ordering diagnostic tests; recording laboratory & diagnostic results; administering therapeutic interventions; and reporting patient outcomes including toxicities or adverse events.
- Develops and participates in interdisciplinary quality improvement and/or research activities.
- Develops and participates in measuring and documenting outcomes.

Consultant:

- Provides expertise and resource information to other healthcare providers, patients and families, and the community at large related to palliative care measures and care of seriously ill individuals.
- Implements and evaluates appropriate educational programs for referring providers (physicians, physician assistants, nurse practitioners, clinical nurse specialists).
- Develops, implements, and evaluates standards of care/practice guidelines/policies and procedures/care maps/protocols within area of specialization.

Professional Leadership and Development:

- Role models advanced practice nursing professionalism through conduct, communication, dress, leadership, ethical decision-making, critical thinking, and problem-solving skills.
- Participates in organizational committees such as medical pharmacotherapeutics, quality improvement, measurement, governance.
- Participates in professional organization at the regional and national level.
- Advances the palliative care field through written publications, oral presentations, posters, continuing education, etc.
- Maintains all professional requirements for licensure and certification.

of learning, and clinical inquiry.¹⁵ Pediatric oncology APRNs often work with children facing chronic and life-threatening illnesses. Many of these APRNs pursue additional advanced palliative care training. Pediatric palliative APRNs have the unique opportunity to work with several clinical teams as part of their role in developing collaborations; these include but are not limited to oncology, cardiology, pulmonology, neurology, genetics, rheumatology, neonatology, and neuromuscular disorders. In addition, opportunities exist for APRNs to serve as pioneers for developing PPC programs within institutions that do not have formal PPC teams or sufficient team support. In terms of qualifications for the role, pediatric palliative APRNs may have a background in critical care nursing, oncology, hospice, or variations of chronic disease management (e.g., cardiac, pulmonary, neurology, etc.).

National nursing certification is the recognition of expertise in a specific area. Certification in palliative nursing palliative acknowledges the role of the pediatric APRN. The Hospice and Palliative Credentialing Center (HPCC) is the only organization that offers specialty certification to the hospice and palliative nursing team. More than 15,500 nurses at all levels of practice hold HPCC credentials that establish a professional commitment to safe, ethical, and evidence-based care.¹⁶ The pediatric palliative APRN can pursue palliative nursing certification by four means: (1) the advanced certified hospice and palliative nursing (ACHPN) examination (for the nurse practitioner or clinical nurse specialist), (2) the certified hospice and palliative pediatric nurse (CHPPN) examination, (3) the certified hospice and palliative nursing (CHPN) examination, and (4) the certified in perinatal loss care (CPLC) examination. Certification examination review courses are held across the United States and online.

THE PEDIATRIC PALLIATIVE APRN AS CLINICAL EXPERT

Pediatric palliative APRNs are clinical experts who collaborate with their interdisciplinary team to alleviate the suffering

of children with serious illness, their families, and colleagues in the health professions.¹⁷ The pediatric palliative APRN role has evolved over the past 10 years, moving outside of large academic medical centers and into clinics and communities where APRNs practice primary and specialty PPC.¹⁸ As stated by the American Nurses Association (ANA) and HPNA, all APRNs have primary palliative nursing skills and some specialize in palliative care, with a focus on pediatrics.¹⁹ Pediatric APRNs such as family nurse practitioners, clinical nurse specialists, and/or pediatric nurse practitioners must have the clinical expertise to care for PPC patients if they are to work in the role of the pediatric palliative APRN.

Primary PPC focuses on understanding serious illness in the pediatric population, common diseases, important indicators of decision-making for parents, the basics of pain and symptoms management with common medications such as morphine and oxycodone, advance care planning, and the difference between hospice and palliative care. Specialty palliative care is expertise in pediatric diagnoses and their trajectories, communication regarding goals of care and advanced illness, complex pain and symptom management, and a clear understanding of community resources and coverage of hospice, home health, and concurrent care. There can be various ranges of expertise in caring for neonatal, pediatric, adolescent, and young adult patients.

The pediatric palliative APRN cares for children with a wide range of conditions that include accidental and nonaccidental traumas, congenital malformations, chromosomal abnormalities, metabolic disorders, neuromuscular disorders, malignancies, and heart disease. In collaboration with the PPC attending physicians, fellows, residents, social workers, chaplains, child-life specialists, and other members of the team, the pediatric palliative APRN should regularly round on children to assess, diagnose, plan treatment, set priorities, and evaluate outcomes, in addition to assessing the effectiveness and cost-efficiency of patient care. As described in the *Palliative Nursing: Scope and Standards of Practice* and the *Competencies for the Palliative and Hospice APRN*, the pediatric palliative APRN collaborates to assess and identify

quality-of-life issues that may hinder clinical progression toward a meaningful recovery for pediatric patients, with a consistent focus on addressing the child's symptom burden. As a liaison for the child, family, and staff, the pediatric palliative APRN provides and coordinates clinical care for children through established protocols.²⁰

General pain management policies that are not specific to pediatrics can be reviewed by the pediatric palliative APRN and further developed to support the unique needs of children receiving care for serious illness. Children with chronic pain are best cared for with interdisciplinary assessment and management, and this requires a combination of medicine, psychology, and rehabilitation services for all pediatric patients referred for assessment and management of chronic pain.²¹ As a clinical expert in chronic pain, the pediatric palliative APRN collaborates to develop plans that promote pain relief for children with illnesses like juvenile rheumatoid arthritis, sickle cell disease, Crohn's disease, and many other chronic debilitating infirmities.

A major focus in PPC is pain at the end of a child's life. Pain management at end of life requires expert nursing process, including a history, an assessment, and the integration of appropriate therapies. A retrospective cross-sectional survey conducted at two US tertiary care pediatric institutions revealed that unrelieved pain was associated with parents' perspectives of hastening death in children with cancer. This study surveyed 141 parents of children who died of cancer (response rate 64%); only 19 reported that they would have considered hastening their child's death had the child been in uncontrollable pain.²² This research supports the essential clinical expertise necessary of the pediatric palliative APRNs role to managing pediatric pain, thus eliminating parents feeling that their child suffered.

As stated in the *Palliative Nursing: Scope and Standards of Practice* and the *NCP Clinical Practice Guidelines*, the pediatric palliative APRN should collaborate with palliative APRN and physician colleagues, nurses, case managers, chaplains, child life specialists, clinical social workers, and other healthcare providers to formulate treatment plans and monitor a child's progress. Additional plans for improving and promoting the quality-of-life goals for pediatric patients may involve organizing interdisciplinary team meetings that include respiratory therapists, physical and occupational therapists, pharmacists, nutritionists, home health providers, and hospice teams.

These team meetings help to outline clear pathways to formulate plans that are based on the child's and family's preferences. These gatherings can also help to decrease the chance of implementing treatments that are not aligned with these goals and preferences. The pediatric palliative APRN is often the lead facilitator of interdisciplinary communication. Care coordination by the APRN involves skills to promote safe, quality care (e.g., conduct family care conferences, manage pain and distressing symptoms, provide guidance with advance care planning) while demonstrating competency within state-specific scope of practice and credentialing protocols.

The pediatric palliative APRN should have a job description that sets the parameters of practice. To ensure success, regular performance reviews promote assessment of clinical practice patterns as well as efficient and quality palliative care. The use of prescriptive privileges within the identified pediatric population should reflect expertise and competence. Pediatric palliative APRN documentation in the medical record should incorporate all relevant data. This includes results of diagnostic tests, laboratory results, the child's condition, response to therapies and interventions, and any necessary communication with the supervising physician. Additionally, documentation should include specific recommendations for a child's palliative care plan with the aim of alleviating suffering and optimizing the physical, emotional, psychological, and spiritual comfort of the child and family.

The pediatric palliative APRN partners with other members of the team to address the pain plan and make referrals when necessary. A thorough knowledge of pediatric-specific pharmacological and nonpharmacological measures allows the APRN to provide guidance that helps with transition models for children with chronic illness. For example, the pediatric palliative APRN collaborates with the child life specialist to integrate expressive therapies, pet therapy, or other services available within the institution. Finally, the pediatric palliative APRN promotes continuity by providing daily "handoff" of patient care to appropriate physicians, other APRNs, residents, and/or interns at the end of the shift while ensuring that proper introductions to the child and family have taken place before departing.

THE PEDIATRIC PALLIATIVE APRN AS EDUCATOR

The pediatric palliative APRN assesses the educational needs of the patient care staff for formal and informal education. It is important to understand that education and teaching allow the APRN to role model professionalism. Inherent in each teaching and learning session is consideration of maintaining proper boundaries and being mindful of colleagues' reactions to challenging clinical situations. Pediatric palliative APRNs work to assess the educational needs of children and families as well, providing culturally sensitive educational interventions as indicated. It is essential to use nontechnical language when educating children and families. All education must be documented in the child's medical record. Although is continued growth of PPC programs, there is still limited access to preceptors in the clinical setting; thus, being a resource for new pediatric palliative APRNs is vital.

For APRNs seeking to expand their knowledge base in PPC, several evidence-based curriculums are available for understanding the palliative care needs of children. An End of Life Nursing Education Consortium (ELNEC) curriculum was developed to address the unique needs of APRNs who are starting a palliative care program, leading a hospice/palliative care team, joining and/or participating in a hospice/

palliative care team, or incorporating palliative care in their role as an APRN.²³ There are nine modules in which participants receive advanced nursing education encompassing an overview of palliative APRN practice, pain assessment and management, symptom assessment and management, communication, and final hours. To assist the APRN with program development, content also includes education about palliative care program development including finances, quality, education, and leadership. Participants can choose one of two tracks—adult- or pediatric-focused care.²⁴ Further resources are listed in Table 25.1.

Another curriculum, Education in Palliative and End of Life Care (EPEC) Pediatrics is a comprehensive adaptation of the EPEC curriculum designed to address the needs of children, their families, and pediatric oncology providers and other pediatric clinicians.²⁵ EPEC Pediatrics was developed by and continues to receive input from experts representing several pediatric disciplines as well as parent advocate advisors. It consists of 23 core and 2 elective topics in pain and symptom management in palliative care.²⁶ Keeping up with current research and trends in clinical practice can help the pediatric palliative APRN

in developing and implementing standards of care. This includes keeping abreast of the many PPC resources published by palliative care organizations, PPC special interest or focus groups within specialty nursing organizations (e.g., American Association of Critical Nurses, Association of Pediatric Hematology/Oncology Nurses National Association of Pediatric Nurse Practitioners), and palliative care blogs (e.g., BMJ Supportive and Palliative Care Blog, Pallimed). Other activities that promote keeping up to date in PPC development include participating in a palliative care journal club; state hospice and palliative care professional groups; or local, regional, or national HPNA committees, or taking advantage of the Center to Advance Palliative Care (CAPC) offerings and social networks (see Box 25.3).

Analysis of patient care through ongoing case reviews with the interdisciplinary team helps the pediatric palliative APRN to participate in measuring and documenting outcomes. This includes participation in interdisciplinary quality improvement activities, such as chart reviews. Tracking operational data about children seen by pediatric

palliative APRNs and a consultation service (i.e., diagnosis, referring service, reason for consultation, time from referral request to completion of consult, and disposition) is necessary to assess the effectiveness of program outreach, marketing, and education efforts in reaching children in need (not only children with serious illness, but also children who are part of underserved populations) and to plan for program staffing to accommodate a growth in demand for services. In the role of advocate, the pediatric palliative APRN should secure programmatic funding and resources to ensure the sustainability and growth of the PPC program.

As an educator, the pediatric palliative APRN serves as an expert and provides information to other healthcare providers, children, families, and the community at large on palliative care measures and end-of-life care. This effort should include developing, implementing, and evaluating standards of care for pediatric palliative pain and symptom management with the appropriate practice guidelines, policies, and procedures. If there are no clear guidelines for managing distressing symptoms such as dyspnea, insomnia, nausea, or pruritus for children at the end of life, the pediatric palliative APRN works to develop evidence-based plans of care or utilize established guidelines within the field to guide the bedside nurse.

THE PEDIATRIC PALLIATIVE APRN AS CLINICAL LEADER

As a leader, the pediatric palliative APRN serves as a role model of professionalism through conduct, communication, dress, leadership, ethical decision-making, critical thinking, compassion, and problem-solving skills. The pediatric palliative APRN is an advocate for PPC in all settings and ensures access to quality PPC. Advocacy involves speaking at conferences and participating in organization grand rounds or departmental meetings. It includes small-group lunches, learning sessions on a pediatric hospital unit, or an organization's orientation to educate new staff about the services provided by PPC teams. The pediatric palliative APRN also demonstrates responsibility for professional practice by actively participating in professional organizations. Specialty certification also demonstrates professionalism and leadership. The HPCC is the only nursing specialty organization to offer certification to all members of the nursing team (APRN, registered nurse [RN], pediatric RN, licensed practical/vocational nurse [LP/VN], nurse assistant [NA]) as well as hospice and palliative care program administrators and perinatal loss care professionals.²⁴ The examination measures skills in ethical decision-making, critical thinking, and problem-solving.

The pediatric palliative APRN maintains all professional requirements for licensure and certification (see Chapter 3, "Credentialing, Certification, and Scope of Practice Issues"). Participating in forums about legislative progress and policies surrounding pediatric healthcare initiatives enables the pediatric palliative APRN to talk with colleagues who share similar interests and empowers the APRN to promote

best practices. This is in alignment with advancing expert care. The Hospice and Palliative Nurses Association, the Hospice and Palliative Nurses Foundation, and the HPCC launched an initiative to (1) increase the number of certified hospice and palliative nurses, (2) advance research into best practices of hospice and palliative care, (3) elevate palliative nursing leadership at the local and national levels, and (4) enhance nursing competence through certification.²⁷ Other professional nursing organizations with palliative care initiatives include the Association of Pediatric Hematology/Oncology Nurses, National Hospice and Palliative Care Organization, National Association of Pediatric Nurse Practitioners, American Association of Colleges of Nursing, American Nurses Association, and National Association of Neonatal Nurses.

Building a PPC program requires qualities like self-motivation, creativity, resourcefulness, assertiveness, and perspicacity. Negotiation skills and flexibility help with navigating challenging cases and assisting in mediating conflict among staff during ethical quandaries. Pediatric palliative APRNs working with a newly developed PPC team may find it helpful to visit a nearby adult palliative APRN or neighboring program. Although many aspects of care are different between adults and children, the experience of rotating with an already established team can provide valuable insights for the APRN as the program moves forward.

THE PEDIATRIC PALLIATIVE APRN AS BUSINESS ADMINISTRATOR

The pediatric palliative APRN must have a business plan for program growth, expansion, and integration of PPC principles within an environment. Many of the palliative professional organizations, such as the Center to Advance Palliative Care, the National Hospice and Palliative Care Organization, and the California Healthcare Foundation, have resources to help develop a plan. In addition, there are several PPC state coalitions across the United States that offer vital resources for the pediatric palliative APRN and help strengthen program recognition through collaboration and partnerships. With the limited resources available in some organizations, pediatric palliative APRNs may need to be creative about marketing the awareness and benefits of PPC. Marketing via team brochures, newsletters, or flyers can help to educate the staff about the "who and what" of the PPC service in a meaningful way. Often parents of children with chronic illness meet several different teams, so a foldable brochure with the details of the services provided by the PPC team can be helpful. The APRN works with the clinical social work team to provide advance care planning services and ensures that bereavement resources and literature are accessible to the family.

Some healthcare providers misperceive that PPC is only appropriate at the end of life. The result is that the pediatric palliative APRN will spend considerable time dispelling myths about PPC. Promoting referrals early in the disease trajectory will enable the pediatric palliative APRN to meet the

child and family at a crucial point in the trajectory. APRNs must remain aware that the relationship between the primary team and the child and family is at the forefront of the connection and must not be disregarded. The APRN also partners with the chaplaincy team to support the spiritual needs of the child and family. All members of the team are vital, so the pediatric palliative APRN makes sure that the child and family understand the various roles of those involved in providing care, remaining available to answer questions when necessary.

Individual health teams across the care continuum may have questions about the types of services provided by PPC teams, how teams collaborate, who is responsible for what care issues, and financial aspects of care. To navigate these conversations, the APRN must acquire negotiation skills as well as diplomacy and humility. However, these questions provide the APRN with the opportunity to develop professional relationships and collaborative partnerships.

To increase awareness of PPC services, the pediatric palliative APRN educates teams about PPC by offering to meet with them. Establishing a relationship with the APRN of the referring team promotes partnerships and helps to maintain the relationship through honest feedback from an APRN colleague. The pediatric palliative APRN should solicit

feedback about the PPC service including referral process, care delivery, communication, and discharge. This facilitates quality improvement in PPC services. Developing consistent goals for follow-up can be vital to the growth of the program. For example, contacting the hospice agency of the child to discuss transition of care to hospice before and after death is important for the growth of the PPC service and, more importantly, can elicit feedback to review family satisfaction and patient outcomes.

TRANSFORMATIONAL LEADERSHIP

Transformation leadership is an approach that influences change in individuals and social systems. The pediatric palliative APRN must grow and mature as a transformational nurse leader in the midst of an ever-changing healthcare environment, often with limited resources. The APRN develops partnerships that lead to improved access to services for children. Some examples are listed here.

1. Contacting the local hospice agency to educate the nursing staff about managing dyspnea in infants, with

Table 25.2 ROLES OF THE PEDIATRIC PALLIATIVE APRN

ROLE	PROPOSED ACTIONS
Clinical expert	• Maintain advanced clinical skills in pain and symptom management • Acquire knowledge of novel pediatric pharmacological and nonpharmacological therapies • Develop protocols and procedures • Plan interdisciplinary team meetings • Facilitate communication • Provide compassionate care • Document appropriately • Demonstrate competency
Educator	• Provide information to other healthcare providers, children, families, and the community at large • Develop care maps and algorithms for managing distressing symptoms • Precept new pediatric palliative APRNs • Track clinical and/or operational metrics • Participate in quality improvement activities (e.g., chart reviews) • Participate in a journal club
Clinical Leader	• Join a national professional palliative care organization • Participate in hospital grand rounds • Role model professionalism through conduct, communication, dress, leadership, ethical decision making, critical thinking and problem-solving skills • Present during a lunch-and-learn session • Pioneer a new PPC program
Business Administrator	• Develop a business plan to expand services • Create a program brochure, newsletter, or flyer to promote awareness • Follow up regularly with referring teams • Elicit child/family satisfaction through surveys
Transformational Leader	• Contact local home hospice agencies to offer education for the nursing staff • Create a pain management task force • Start a PPC journal club • Promote the use of evidence-based guidelines and protocols for pain and symptom management in PPC • Develop partnerships within and outside of the institution

participation from the community pharmacy based on the evidence.

2. Creating a pain management task force in the pediatric intensive care unit to identify children at risk for having inadequately treated pain, with participation from the pharmacy department.
3. During the implementation of compassionate extubation, the pediatric palliative APRN starts a journal club to promote understanding and best practice organization-wide.

In all these examples, the pediatric palliative APRN seeks to build commitment to children with serious illnesses with the goal of transforming the healthcare environment into a place where all members of the institution are accountable for the care of the pediatric patient.

The pediatric palliative APRN works within the resources of the organization and community, using creativity and expertise to promote the growth and expansion of PPC initiatives. If there are questions about evidence-based guidelines for a procedure, a process of consensus building is initiated. Finally, as a transformational leader in PPC, the pediatric palliative APRN actively engages children, family, and staff throughout the patient care experience. To meet each child's needs, the APRN uses skills as clinical expert, educator, entrepreneur, and administrator, all while considering the available resources. (see Table 25.2).

SUMMARY

There are opportunities and challenges in PPC delivery. The pediatric palliative APRN will need to be adaptable and have a multifaceted skills to create programs that reflect the community, the organization, and available resources. These include clinical expertise, expert communication skills, program development knowledge, leadership skills, and professionalism. Ongoing self-awareness and self-care are vital for the pediatric palliative APRN. Personal goals for the APRN includes improving one's organizational and communication skills. Professional goals may include networking within the field of PPC and assuming a national leadership role in PPC. Finding a mentor within the field may also help tremendously. Ultimately, the goal of the pediatric palliative APRN is to improve the care of children with serious illness and their families by ensuring access to quality PPC.

THE PEDIATRIC PALLIATIVE APRN IN THE ACUTE CARE SETTING

Faith Kinnear and Gina Santucci

KEY POINTS

- Pediatric palliative care (PPC) is family-centered care that focuses on a child's and family's quality of life through the prevention and relief of suffering along a physical, psychological, emotional, spiritual, and social continuum.
- Many misconceptions and barriers still exist regarding PPC, including that it signifies death, giving up hope, no further provision of care, and abandonment.
- The number of children living with a variety of life-threatening illnesses is increasing, and families are frequently faced with difficult decisions about what interventions to choose. Pediatric palliative advanced practice registered nurses (PP APRNs) play a key role in guiding conversations about decision-making and goals of care.
- Principles for assessing and managing complex symptoms in children are unique but the PP APRN is well-equipped to take into account the child's developmental, cognitive, and biological factors. Case studies will illustrate a variety of these frequently encountered palliative care symptoms.
- PP APRNs are poised to be knowledgeable in pain and symptom management and advance care planning, to provide clear communication with patients and families, and to assist families with complex medical decision-making, including end-of-life care.
- Aside from patient responsibilities, the PP APRN may play an integral role in staff education, moral support, and well-being.

INTRODUCTION

Care for children living with chronic or life-threatening conditions historically has focused on treatment and cure. Yet, even with our best efforts and expanding scope of knowledge, children continue to experience prolonged courses and many still die from their disease process. Pediatric palliative care (PPC) aims to improve the quality of life for children and their families facing life-threatening illnesses through the prevention and relief of suffering by early identification and treatment of pain and other distressing symptoms, whether

physical, psychological, social, or spiritual. PPC is meant to be provided in primary care encounters, tertiary care facilities, community health centers, and children's homes.¹ This chapter focuses on the pediatric palliative advanced practice registered nurses (PP APRNs) in the acute care setting, which focuses on education, collaboration, and coordination.

The delivery of high-quality PPC was promulgated by the landmark 2002 Institute of Medicine (IOM) report *When Children Die*,² which challenged all healthcare providers to address the needs of children with complex chronic or life-threatening conditions and their families. Since that time, the field of PPC has continued to grow and healthcare providers now have an obligation to provide high-quality PPC for children with life-threatening conditions and their families, as evidenced by the most recently published IOM report, *Dying in America: Improving Quality and Honoring Individual Preferences Near the End of Life* (2014). More recently, the 2018 edition of National Consensus Project for Quality Palliative Care (NCP) *Clinical Practice Guidelines* emphasizes the needs of children and their families within patient- and family-centered care, such as illness understanding, parental preferences, and family engagement using a developmentally and age-appropriate framework across settings of care.³

Figure 26.1 illustrates the complexity of PPC while highlighting the primary goals of (1) prioritization, (2) understanding what is important for the patient and family, and (3) how the PPC team can meet the family's goals.⁴ PPC is available and delivered variety of settings. Care along the illness trajectory, from the time of diagnosis to completion of therapy or end of life, can vary greatly in length and is not always linear; goals may shift from care aimed at a cure to care focused on maximizing quality of life and back as patient needs change. This parallel planning or "hoping for the best, preparing for the worst," can be challenging for both providers and families. In pediatrics, prognostic uncertainty continues to be a formidable barrier to exploring the focus of care. Without prognostic certainty, it can be difficult to predict if and when a child's condition may improve or continue to decline or for how long the child will remain stable, which makes parallel planning a necessity.⁵ Discussing goals of care during an acute change or crisis may be stressful and emotionally charged for everyone involved, while advance parallel planning may help families express and balance their wants and wishes with their worries.

Figure 26.1 Facets of pediatric palliative care.

Reprinted with permission from Committee on Approaching Death: Addressing Key End of Life Issues; Institute of Medicine. *Dying in America: Improving Quality and Honoring Individual Preferences Near the End of Life*. Washington (DC): National Academies Press; 2015 Mar 19.⁴

Another barrier to initiating palliative care alongside cure- or recovery-directed care involves providers' uncertainty or inability to have these discussions, which can lead to their avoidance.⁶ Even in cases where providers were able to identify specific physiologic factors or conditions that signaled an appropriate time to involve palliative care, they found that the shift in goals of care was often initiated by parents. Ongoing education about palliative care is important if providers are to partner with families in allowing for ongoing goals-of-care discussions, expectation setting, and parallel planning.⁶

Currently, a great proportion of hospitalized children die in the pediatric intensive care unit (PICU) due to the withdrawal, withholding, or discontinuation of life-sustaining therapies.⁷ Research has shown that although pediatric providers in the ICU setting are skilled in providing high-level care, including many primary palliative care skills, most do not have formal training in providing specialized palliative care, and the patient and team may benefit from a specialty consult.⁸ The timing for initiating such a consult may be a barrier to connecting the family with palliative care. Inpatient PP APRNs are well-positioned to identify the unique needs of hospitalized children and families when their goals shift more toward palliation and to provide guidance and support to families and the rest of the interdisciplinary team.

ADDRESSING MISCONCEPTIONS AND BARRIERS

"Does palliative care mean that I'm giving up on my child?" is something that a parent shared at the mention of consulting palliative care. This comment illustrates one of many misconceptions and beliefs about PPC. Some believe that PPC signifies impending death, loss of hope, lack of care provision, and abandonment, all misconceptions that serve as barriers to PPC delivery. Other barriers include healthcare providers' lack of understanding and/or training in palliative care and

feelings of inadequacy in offering PPC to families, as well as not knowing when and if it is the right time to make a referral to the palliative care team.⁹ The challenge for the PP APRN then becomes not only providing high-quality PPC and staying current on evidenced-based practice but also addressing families' and colleagues' misconceptions about PPC.

One of the most effective methods to address common misconceptions and barriers is through increased PPC education. The pediatric APRN not specifically trained in PPC may wonder when to involve the PPC team: Is it at the time of diagnosis, or only when there are no further options for treatment? Can every child with a specific diagnosis benefit from PPC services? Will families be afraid if the PPC team is introduced too early, and would it signify giving up? Should there be specific time points in the illness trajectory, or should the presentation of specific symptoms warrant a referral to the PPC team, or should PPC be involved at all?¹⁰ The answers to these questions will look different for each patient.

The PP APRN provides PPC education and addresses common questions by "speaking to patients to find out their goals and preferences for treatment and end-of-life care."¹⁰ Currently, patient-centered care in the acute care setting is often perceived as "too little, too late."¹⁰ The pediatric APRN may be able to recommend a palliative care consult, if available, for patient goals that exceed the scope of primary palliative care. The pediatric APRN may also have developed rapport with the family, thus allowing for more open communication to introduce or address PPC benefits for the patient and family. Introducing PPC earlier in the disease trajectory can provide psychosocial support over time and not just at the end of life. The fear that patients and families "are not there yet" is often the worry when providers (and others) equate palliative care with end-of-life care. Educating families and providers about the longitudinal support, assistance with decision-making, and expertise in pain and symptom management of PPC may help alleviate these fears. The benefits of early involvement of PPC are summarized in Box 26.1.

**Box 26.1 BENEFITS OF EARLY PEDIATRIC
PALLIATIVE CARE CONSULTATION**

- Enhances relationship building and longitudinal support
- Helps clarify communication among team members, patient, and family
- Assists with complex decision-making
- Aligns intervention with patient and family goals of care
- Enhances care coordination, hospice, and concurrent care
- Provides team support; offers debriefings
- Follows patients across healthcare settings
- Provides assistance with complex pain and symptom management

Helping families clarify goals of care as the child's condition changes, assisting with complicated symptom management, and, when needed, providing excellent end-of-life care that honors the child's and family's wishes are pillars of PPC. Pediatric teams are often challenged to "do everything possible" to prolong life—but at what burden? PPC teams can facilitate communication, help with decisions regarding aggressive interventions, acknowledge uncertainty, and offer a space for meaningful conversations regarding prognosis. The American Academy of Pediatrics recommends palliative care consultation upon diagnosis of a serious and/or life-limiting illness.⁴ Given the diversity of pediatric diagnoses, the pediatric APRN should consider a palliative care consult, when available, if the trajectory of illness is unknown, when there is indecision regarding the right course of action, or when the child's overall quality of life has declined from their baseline, as summarized in Box 26.2.

**Box 26.2 WHEN SHOULD PARENTS CONSIDER
PALLIATIVE CARE CONSULTATION?**

- Treatments are no longer helpful or are becoming a source of pain and discomfort.
- Despite all interventions, patient continues to decline and prognosis is uncertain.
- Multiple subspecialties are involved, and there is a need to clarify communication and/or goals of care.
- Family needs help with complex medical decision-making.
- Patient has a serious, chronic, or complex medical diagnosis and could benefit from longitudinal support or support and relationship building over time in light of a potentially life-limiting condition.

**WHO RECEIVES INPATIENT PEDIATRIC
PALLIATIVE CARE?**

It is estimated that, in the US, approximately 50,000 children die every year, with some 80% of children dying in a hospital setting.¹¹ It is estimated that about 25% of these children may have benefited from PPC or hospice services.¹² What about the children who do not die? According to a 2015–2016 National Palliative Care Registry, 52 pediatric programs reported their data, and they represented 40% of the children's hospitals in 27 states and Washington, DC.¹² The age range and top five diagnoses from 75% of children discharged from the hospital are illustrated in Figure 26.2.¹³

**IMPACT OF LIFE-THREATENING
DISEASE ON PEDIATRIC
FAMILY UNITS**

Family-centered care can be broadly defined as "a partnership approach to health care decision-making between the family and health care provider."¹² Consensus has been reached about the principles that family-centered care encompasses: (1) information sharing that is "open, objective, and unbiased"; (2) creating relationships with respect for "diversity, culture, linguistic traditions, and care preferences"; (3) decision-making that encompasses the "needs, strengths, values, and abilities of all involved" and includes families "at the level they choose"; and (4) direct medical care and decision-making that reflects children "within the context of their family, home, school, daily activities, and quality of life within the community."¹² One of the most notable attributes of family-centered care is the concept of partnership and providing care that considers "the needs of all family members, not just the child."¹⁴

PPC is interdisciplinary by nature and includes providing psychological, social, spiritual, and emotional support.³ This is provided by a team of experts to meet the needs of children and adolescents as well as siblings and parents. This may be delivered by several members of the PPC team, including psychologists/psychiatrists, social workers, child life specialists, integrative therapists, and/or chaplains, in addition to clinicians, such as registered nurses, APRNs, and physicians.³ PPC involves facilitating "clear, compassionate, and forthright discussions about medical issues and the goals of care" and supporting "families, siblings, and health care staff"¹⁵ because care of a child with a serious illness affects the whole circle of care.

CHILD–FAMILY UNIT

A large component of providing PPC that is family-centered involves providing emotional support.¹⁶ This is especially important because a child living with a life-threatening illness can spend a lot of time in the hospital or at various medical appointments, and this affects the entire family unit. Parents, family members, siblings, and the child all suffer throughout the course of an illness, and although this may manifest differently, each person's suffering somehow affects the others.¹⁶

Figure 26.2 Age distribution and diagnoses of pediatric palliative care patients.

Adapted with data from Rogers M, Kirch R. Spotlight on pediatric palliative care: National landscape of hospital-based programs 2015–2016. CAPC blog. 2017. <https://www.capc.org>.¹³

Hospitalization is a traumatic and harrowing experience for children and even more so for those who spend time in the ICU.¹⁶ Schedules and daily family routines are interrupted, and parents or caregivers may struggle to find enough time and energy to spend with each other and the ill child's siblings, to transport them to their after-school activities or attend events at school. This burden may be exponentially increased in single-caregiver households. The PP APRN has a distinct role in supporting families by providing education and anticipatory guidance as well as emotional support through a family-centered model of care in the context of primary PPC.

SIBLINGS

Although there is little published evidence to support this hypothesis, it is well-recognized that siblings experience a significant amount of stress when their brothers or sisters face life-threatening illness. "Siblings' needs and suffering continue to be studied, but it has been recognized that they need special attention early on in the course of the disease of another child in the family."¹⁷ It can be difficult, however, for a parent(s) to provide enough support for both the child who is ill and any siblings, and they may unintentionally overlook the needs of their healthy children given that they are overwhelmed by the disease and the needs of the ill child. For this reason, other supports are crucial for siblings, such as school, community, and camp programs, as well as professional counseling and/or support group services that may be available either at the hospital or through an outpatient setting.¹⁷

Some hospitals offer specific support programs for siblings, such as Sibshops, a program that exists in 10 countries and focuses on meeting the needs of siblings of children living with illness through a mix of unique and developmentally and age-appropriate games, discussions, and friendship.¹⁸ Some

PPC programs may also offer home visits specifically for siblings by social workers, child life specialists, and/or art therapists from the team. Designating a "special person," such as a friend or relative who can take responsibility for each sibling specifically, may be helpful so that siblings get extra attention. The PP APRN can involve child life specialists or art or music therapists who may be beneficial for siblings, depending on the resources available.

EXTENDED FAMILY

Everyone considered part of a child's family, including grandparents, aunts and uncles, cousins, community, and friends, may be affected when a child has a life-threatening illness. The ramifications of life with an ill child can have lasting effects on marriages, partnerships, and relationships including stress, physical, and/or mental health problems. It may also affect finances as well as employment status, create social isolation or disengagement from peer-related activities, and foster a sense of loss, concern for the future, and grief.¹⁹ Grandparents are often very involved in a child's care and feel particularly helpless because of their inability to protect their grandchild from illness or protect their own child (the parent) from any pain and suffering. The PP APRN can assess the greater circle of extended family and their support needs.

Extended family members may wish to be supportive but are often unsure how to do so. It may feel overwhelming to parents to manage others' well-intentioned concerns, inquiries, and attempts to be helpful. The pediatric APRN may be able to anticipate the struggles that families will experience and provide them with anticipatory guidance, tips, and education about diagnoses and treatments. Evidence suggests that clinicians' attention to the needs of family members can enhance their resiliency, but they may need guidance in figuring out

new roles and ways in which they can support each other, since everyone copes in his or her own unique way.¹⁹

SUPPORT FOR FAMILY MEMBERS OUTSIDE THE HOSPITAL SETTING

Caring for the entire family is an essential, especially when care is being provided at home. Family members may have questions about preparation, what changes may occur in the child's physical and mental status, and whom they should call for additional support.²⁰ An important component of PPC is providing resources to support and involve siblings and other family members. As previously mentioned, some programs offer specific support for siblings, including home visits with child life specialists and art therapists who are trained to help siblings cope with illness and death.

The PP APRN and other members of the team must recognize that every family copes differently and will have an array of grief responses before and after a child dies. Being flexible and keeping communication open is key, as is providing families with ongoing bereavement support following the death. Primary teams should be familiar with local grief resources to which they can refer families. Some PPC teams send cards or make phone calls at regular time intervals and may have a formal bereavement program.

COMMUNITY AND SCHOOL

All families live within a community, and children are often at the epicenter of community-based activities. Within school, place of worship, neighborhood, sports team, or other recreational activities, families develop relationships; when a child becomes ill, the whole community may be affected. Community members can play a tremendous role in providing support to the child and family with hospital visits, support to siblings and family members at home, or helping with everyday tasks like grocery shopping, mowing the lawn, or preparing meals.

CHILD'S VIEW OF ILLNESS AND DEATH

Every child will have their own unique illness experience and may have difficulty expressing it. Children express themselves in different ways; some use words, some draw pictures, some engage in play, some use body language and behavior, and some don't speak at all. The NCP describes the expectation that pediatric teams "ascertain the developmental status and the children or teens' understanding of their disease as well as parental preferences for their child's care at the time of initial consultation,"²³ which should be revisited at each visit. In PPC, the team, including the PP APRN, interprets a child's modes of expression while helping children and families find an appropriate understanding about their illness.

Every child "should be considered as a product of chronological age, developmental stage, medical condition, size, handicap, and cognition."²¹ The team must develop a sense

of a child's developmental, emotional, and cognitive abilities. Understanding of development stage is essential because "different developmental tasks influence how children perceive and cope with illness and possible death."²¹ It is also important to recognize that "children, whose disease trajectory spans more than one developmental stage, require constant reevaluation and adaptation of the delivery of support and care,"²¹ because some children with advanced illness may progress or regress in developmental age.²¹ Table 26.1 summarizes children's developmental stages and perceptions of death in each stage.

CASE STUDY: A CHILD WITH A CARDIAC CONDITION

MJ was a 16-year-old adolescent with history of coarctation of the aorta repaired during infancy with subsequent biventricular failure requiring a heart transplant at 2 years of age. He was in good health until 3 years prior when he developed transplant-related coronary artery disease and renal insufficiency secondary to his transplant medications. MJ required multiple admissions for complications related to heart failure, including pleural effusions, ascites, fluid overload, and pain. He was evaluated several times for a heart re-transplant but he was deemed not a candidate due in part due to his inability to adhere to medical recommendations and the lack of parental oversight. MJ was known to palliative care from past consultations to assist with symptom management and to discuss his "goals" as they related to treatment options. During one admission to the cardiac care unit, MJ was in moderate respiratory distress due to overwhelming ascites and pleural effusions. A family meeting was planned to discuss potential medical options, acknowledging that MJ was not a re-transplant candidate. The following potential care plans were proposed: (1) frequent admission "tune-ups" to manage symptoms secondary to his heart failure, acknowledging he may have weeks to months to live; (2) placement of a ventricular assist device (VAD) to improve cardiac output, decrease symptom burden, and potentially provide more time with improved quality of life; or (3) minimize hospitalizations and focus on symptom management and maximizing quality of life with the help of hospice. The medical team strongly advocated for a VAD as "destination therapy" with the hopes this therapy would improve MJ's quality of life and potentially give him more time. The team also shared that if MJ demonstrated adherence to VAD therapy and medications he could potentially be re-evaluated for a second transplant.

DESTINATION THERAPY IN PEDIATRICS

Ventricular assist devices (VADs) may be offered in pediatric patients with end-stage heart failure either as (1) a bridge to transplant, (2) a bridge to recovery of myocardial function, (3) a bridge to decision when transplant candidacy has not been determined, or (4) as destination therapy when the child is not a heart transplant candidate.²² Regardless of the intention, the overriding goal is to reduce symptoms related to cardiac failure and improve the child's quality of life. The

Table 26.1 DEVELOPMENTAL STAGES AND PERCEPTIONS OF DEATH

AGE	BASIC CONFLICT	VIEW OF DEATH	SUGGESTIONS
Birth–18 months	Trust vs. mistrust	No sense of finality and is viewed as continuous with life Reactive to stress	Use simple physical communication and provide comforting and nurturing care.
Early childhood (2–3 years)	Autonomy vs. shame and doubt	Death is seen as reversible and not final May feel death is a punishment May feel responsible for death	Expect regression, clinging, or aggressive behavior. Encourage expression, as the child may be concerned about family function after he or she dies. Use honest and clear language to explain death and dying.
Preschool (3–5 years)	Initiative vs. guilt	Death continues to be understood as temporary May have a literal understanding of death and will respond with curiosity and questioning	Continue to use open communication with clear language. Encourage questions about death and dying.
School age (6–11 years)	Industry vs. inferiority	Death is understood as permanent and that the body ceases to function, with heart and respirations stopping May feel responsible and guilty for the illness May have spiritual ideas about afterlife May not want to discuss feelings	Reassure the child that death is not his or her fault. Strive to maintain as normal a structure as possible. Include the child in afterlife plans (funeral planning, last wishes).
Adolescence (12–18 years)	Identity vs. role confusion	Understands the finality of death and may develop a mature understanding of death May try to take responsibility for adult concerns within the family (such as finances and caretaking) Feelings of anger may be present	Allow time for reflection. Listen to concerns and questions. Support efforts for autonomy and control.

Mandac et al. Reprinted with permission from reference 19.

use of a VAD in children as destination therapy is evolving,²³ providing an important role for the APRN in the delineation of goals of care. These goals-of-care conversations should be initiated upon introduction of the intervention to ensure everyone is on the same page regarding the inherent risks and/or tradeoffs. Prior to the placement of a VAD (similar to other technologies such as pacemakers, implantable cardioverter defibrillator, extracorporeal membrane oxygenation [ECMO], tracheostomy, etc.), there should be an exploration of “what if scenarios” including discontinuation of the therapy if it is found to be no longer beneficial. Possible indications or scenarios for VAD deactivation take into account (1) when quality of life goals are no longer being met, (2) when a child has suffered a neurological insult (i.e., stroke), or (3) parental or patient request.²⁴ Using parallel planning—hoping for the best while planning for the worst—can be helpful when discussing goals. These conversations can be emotionally and morally charged and may benefit from the institutional support of ethics, leadership, and/or legal teams (see Chapter 53, “Navigating Ethical Conversations”). Advance care planning (ACP) tools can assist practitioners in guiding these discussions prior to an acute crisis. Borrowing language from *Voicing My Choices* or engaging in the card game *Go Wish* can be useful to facilitate conversations or help with prioritizing wishes in the older child or young adult (see Chapter 32, “Advance Care Planning”).

CASE STUDY: A CHILD WITH A CARDIAC CONDITION (CONTINUED)

After many discussions, MJ stated he did not want to proceed with a VAD. Although the team worried about decision-making capacity, his parents felt the decision was MJ’s to make since “he would have to live attached to a machine.” The team was also conflicted if MJ truly understood the ramifications of his decision—that his heart would continue to weaken and he could die within a few months from heart failure—which led to moral distress among the staff. Following consultation with the hospital ethics team, everyone was in agreement to support MJ’s decision. MJ was clear that he wanted to go home and live a normal life for as long as possible. Ultimately, a referral was made to hospice and an out-of-hospital do-not-resuscitate (DNR) order was completed. MJ continued to be admitted for “tune-ups” while on hospice but with lessening frequency.

Sometimes, children and families want all potential heart failure treatments even when the risks appear to outweigh the benefits. Healthcare providers should consider only offering interventions that may benefit the patient and are consistent with their goals of care. There are several uses of VAD or ECMO children in heart failure: as a bridge to heart transplantation, as short-term treatment for reversible conditions, or to provide more time to extend or improve the child’s

quality of life with the “destination therapy” or until death.²⁵ The term “destination therapy” may be distressing to families, which is why providers may choose to use the term “bridge to decision” instead.²⁵ Children discharged with a VAD should be followed longitudinally by palliative care providers to ensure goals of care have not changed and that this technology continues to meet their needs.

CASE STUDY: A CHILD WITH A CARDIAC CONDITION (CONTINUED)

MJ's heart failure symptoms were managed at home although he requested to return to the hospital when symptoms, primarily ascites refractory to oral diuretics, were uncomfortable. MJ's hospice nurse provided weekly updates to the PP APRN and cardiology.

Children with congenital heart disease (CHD) are at risk for developing heart failure. The Centers for Disease Control estimates that CHD occurs in 1% of births per year in the United States, which accounts for approximately 40,000 birth per year.²⁶ Approximately 2–3 million children and adults are living with CHD in the United States.²⁷ Although their mortality rate is decreasing, many are living with increased morbidity and risk of multiorgan complications,²⁸ often leading to frequent admissions and/or interventions for symptom management.²⁹ Early involvement of PPC for patient's like MJ can provide psychosocial support over time, which is invaluable when patients and their families may be tasked with complex medical decision-making at various timepoints. Longitudinal support can provide context when discussing changes during acute exacerbations, clarify communication between providers, and help align interventions with goals and wishes.^{30,31} The PP APRN plays a major role in collaborating with inpatient and outpatient providers, clarifying communication, assisting with symptom management, and, when appropriate, making a referral to hospice.

MANAGING SYMPTOMS IN HEART FAILURE

MJ's heart failure presented as fatigue, anorexia, dyspnea, abdominal pain, and nausea. In the later stages, patients can also develop hepatic and renal failure, malignant arrhythmias, stroke, or multiple-system organ failure.³² The hallmark of end-stage heart disease often manifests as low cardiac output, respiratory distress, cachexia, and/or anorexia.³³

Managing symptoms for heart failure, similar to other life-limiting conditions, should include a plan that offers a multidisciplinary approach including pharmacological, nonpharmacological, and, when appropriate, invasive treatments. Treatment options should ultimately decrease pain, relieve bothersome symptoms, improve functionality, and maximize quality of life. When prescribing medications for children, careful consideration of dosing is necessary due to differences in pharmacokinetics based on the child's age and weight and underlying disease pathophysiology.³⁴ Table 26.2 illustrates some common symptoms and therapeutic options.

Dosing recommendations for medications can be found in Appendix II.

Dyspnea, or the state of “breathlessness,” occurs when the body cannot keep up with oxygenation and ventilation demands. It is a common symptom seen with advanced illness and at the end of life. Dyspnea in children can be difficult to measure, and the use of assessment scales have not been shown to be reliable.³⁵ Management approaches for dyspnea include addressing and treating underlying reversible causes (anemia, fluid overload, effusion) and using a multimodal approach when possible. Opioids are the first line of treatment, especially at the end of life. In the opioid-naïve pediatric patient, it is recommended to start with 25–50% of the initial dose.³⁶ MJ's dyspnea was heart failure-related due to overwhelming ascites and pleural effusions. Intermittently, he required admission for intravenous diuretics and fluid drainage via a pleural catheter. Although many hospices have the ability to provide intravenous diuretics, his did not. After several admissions, his inpatient and hospice teams discussed discharging MJ with a pleural catheter for intermittent drainage because hospice had successfully cared for many patients with an implanted catheter at home. The risk-benefit of catheter-related infections and relief of symptoms was discussed with MJ and his family, and, ultimately, the decision was made to proceed with this intervention since infection, leakage at the site, and dislodgement were deemed low risk.³⁷

Many patients with advanced heart failure will experience pain secondary to worsening edema or ascites, palpitations, ischemia, or poor perfusion to vital organs. Skin integrity, gut dysmotility, and musculoskeletal pain from immobility are also common. Pain may manifest as visceral or neuropathic in nature.³⁸ Other symptoms include protein-losing enteropathy, fatigue, insomnia, muscle wasting, and cachexia.³⁹

INOTROPIC THERAPY FOR HEART FAILURE FOR INPATIENT OR HOME

Milrinone is a phosphodiesterase-3 inhibitor that has positive inotropic and vasodilator properties and can provide relief in patients with right ventricular heart failure.⁴² It requires a hospital admission for central line placement to monitor medication side effects including arrhythmias, thrombocytopenia, and hypotension. In addition, prior to discharge, it is essential for caregivers to receive education on medication safety and maintaining line integrity. Indications for continuous milrinone include short-term management of heart failure either as destination therapy while waiting for a transplant or as a palliative option to improve quality of life. Studies have shown that milrinone has improved cardiac function and quality of life in pediatric patients with heart failure.⁴³ Discharging a child home with milrinone, as with other treatments and technologies, involves working in partnership with the child's primary care provider, skilled home nursing agency, and, when appropriate, hospice to ensure everyone is up to date with the plan. The PP APRN can assist with care coordination and help bridge information and clarify goals from the inpatient to outpatient settings. The availability of concurrent care for children allows patients

Table 26.2 HEART FAILURE SYMPTOM MANAGEMENT

	POTENTIAL SOURCES	THERAPEUTIC OPTIONS		CONSIDERATIONS
		NONPHARMACOLOGICAL	PHARMACOLOGICAL	
Dyspnea	Anxiety Effusions Anemia Pulmonary embolism Electrolyte disturbances Pneumothorax Rib fracture	Position upright Fan Guided imagery, relaxation techniques Decrease fluids, consider decreasing or discontinuing parenteral fluids Therapeutic trial of supplemental oxygen delivered in least bothersome way Pleural catheter	Low-dose opioids (higher doses may be needed if patient is on chronic opioids) Anxiolytics (short-acting benzodiazepine) Diuretics	Align treatments with goals of care
Ascites, Effusions	Electrolyte disturbances Protein losing enteropathy Malnutrition	Fluid and sodium restriction Drain if aligns with goals of care	Diuretics +/- Albumin	
Pain	Palpitations Organomegaly Inflammation Deconditioning	Physical therapy Heat/cold application Transcutaneous electrical stimulation (TENS) unit Hypnosis	Analgesics Opioids Antispasmodics Tricyclic Antidepressants (TCA) Serotonin norepinephrine reuptake inhibitors (SNRI) Gabapentinoids N-methyl-D-aspartate receptor (NMDA)	Doses may need adjusting in hepatic or renal insufficiency TCA, 5-HT3, and NMDA medications can increase QTc.
Fatigue	Sedation medications Sleep disturbances Deconditioning Depression, anxiety Anemia/Hypoxemia Electrolyte abnormalities Uncontrolled pain Infection	Physical therapy, optimize function Encourage sleep/wake cycle Dietary changes Acupuncture Dietary supplements	Short trial steroids Antidepressants Psychostimulants	Steroids may interfere with sleep

Adapted from references^{39, 40, 41}

like MJ access to homecare nursing to monitor vital signs, dosing, and line integrity while continuing hospice support. After several deliberations, MJ decided against milrinone therapy for the same reasons of “not wanting to be hooked up to a machine.”

GOALS OF CARE, LIMITATIONS OF CARE, AND DECISION-MAKING

CODE STATUS DISCUSSIONS

Due to advances in medical technology, the number of children living with life-threatening illness continues to rise. Families frequently are faced with difficult decisions about whether to forgo life-sustaining medical treatment and resuscitation. The nomenclature summarized in Table 26.3 and interchangeability by providers can be confusing. “Allow natural death” may be more acceptable from a family standpoint as the result of natural disease progression⁴⁴; however, some cultures think that no death for a young person is natural.

Regardless of the terminology used, discussions regarding resuscitation status can be anxiety-provoking for both family members and providers. It is common for providers to feel pressure to “get the DNR” or to consult the PPC team to accomplish this. Often it becomes the role of the PPC team not only to have discussions with children and family members regarding goals of care as they relate to resuscitation status, but also to provide education and mentoring for other pediatric providers. Commonly, the PPC team’s role is to build trusting relationships with families over time and have

Table 26.3 ACRONYMS FOR CODE STATUS DESCRIPTIONS

Do-not-attempt resuscitation (DNAR)	No escalation of care (No ESC)
Do-not-resuscitate (DNR)	Allow natural death (AND)
Do-not-intubate (DNI)	

ongoing discussions about goals of care that are based on both a humanistic and an ethical framework.⁴⁵

Predicting outcomes for children living with life-threatening illness is a complex and difficult task. It is important to recognize that decisions about resuscitation status are usually the result of several conversations between providers and family members about their goals of care and if resuscitation achieves those goals. The role of the PP APRN is to collaborate with the teams involved in these discussions, facilitate family understanding of what interventions may or may not be beneficial to their children (e.g., chest compressions, intubation), and effectively communicate those wishes in the hospital and at home.

DECISION-MAKING AND HONORING WISHES

Decisions about healthcare treatments care are seldom “black and white.” Tools to guide decision-making and conversations about goals of care are essential. The NCP *Clinical Practice Guidelines* emphasize that children should be included in age- and developmentally appropriate conversations regarding their goals.³ Some children may explicitly express their wishes regarding their end-of-life and resuscitation status; other children may not want to address these topics. In some cases, children may feel more comfortable talking with the PPC team or other healthcare providers than talking with their family because they may fear disappointing their family if they choose not to pursue particular interventions. At other times, children and their family may disagree about what the goals of care should be as well as what particular interventions they should receive. Resources are available to help guide the decision-making process and to aid clinicians in navigating conversations with children of all ages and, in some instances, their designated decision-makers, regarding how they want to be treated throughout their illness and at the time of death from a medical, personal, emotional, and spiritual perspective.⁴⁶ Helpful documents are reviewed in detail in Chapter 32, “Advance Care Planning.”

OUT-OF-HOSPITAL ORDERS FOR LIFE-SUSTAINING TREATMENT

There are two documents that reflect out-of-hospital orders for life-sustaining treatment when children leave the hospital. These are the provider/physician orders for life-sustaining therapies (POLST)/medical orders for life-sustaining therapies (MOLST) and the out-of-hospital DNR (OOHDNR). These documents are state-specific and are a tool for helping to discuss goals of care. As official orders, they are signed by health professionals and the patient or surrogate decision-maker. It should be noted that some states do not allow children to have a DNR order until they enter hospice care.

The NCP *Clinical Practice Guidelines* state that a child's or adolescent's views and preferences for medical care and treatments, including assent for care (when developmentally appropriate) should be assessed, given weight in decision-making, and documented.³ Specifically, children and families

deserve to have their wishes honored whether they opt for full resuscitation or elect to forgo potentially life-sustaining treatments. Documentation of desired resuscitation and advance directives is important to limit undesired interventions, such as cardiopulmonary resuscitation (CPR), by first responders.⁴⁵ Families are best prepared for emergency situations with proactive discussions before the time of an emergency. Families should be informed that decisions can be changed should there be a change in the child's health status. However, if parents have a strong preference for noninclusion of or nondisclosure to the child in such decisions, the PPC assesses family motivations and values within this decision while simultaneously meeting the needs of the child within these expectations and boundaries.³

The PP APRN has a specific role in educating families that a POLST/MOLST is intended to articulate the parent's and child's care preferences and communicate them in a crisis when the parents may not be available. Additional forms that may be helpful to support advance directives in the pediatric population include guardianship documentation and medical power of attorney. The abbreviations, definitions, and intended use are summarized in Table 26.4 (see Chapter 32, “Advance Care Planning,” for more details on ACP).

CASE STUDY: PEDIATRIC PULMONARY DISEASE

JH was a 14-year-old girl with end-stage cystic fibrosis (CF), listed for lung transplantation. She was frequently hospitalized for infections, acute CF exacerbations, dyspnea, and worsening lung function. Palliative care was consulted during an admission as part of her lung transplant evaluation to assist with goals of care and medical decision-making. The palliative care team was able to help JH and her family discuss and honor her wishes to not pursue lung transplant due to the risks while providing support and symptom management throughout additional admissions and clinic visits.

Cystic fibrosis (CF) is an autosomal recessive genetic disorder caused by a mutation of the cystic fibrosis transmembrane conductance regulator (CFTR) gene. It is the second most common childhood genetic disorder, with approximately 30,000 people living with the disease in North America.⁴⁹ Chronic respiratory infections, inflammation, and pulmonary decline are the primary causes of morbidity and mortality. Other effects of the illness and decline are poor growth, malabsorption, pancreatic insufficiency, diabetes mellitus, hemolytic anemia, and hepatic biliary disease.

Currently, there is no cure for CF but with improvements in technology, aggressive medical management, and supportive care many children are living into adulthood, albeit with an increase in morbidity. Children with CF endure multiple daily therapies and may have frequent hospital stays to manage disease exacerbations. For certain children with advanced disease, lung transplantation may be an option to prolong and improve quality of life.⁵⁰ Post lung transplant survival rate is about 80% after 1 year and 50% after 5 years.⁵¹ The decision to proceed with lung transplantation can add new challenges for the patient and their family. Although the new lungs do not

Table 26.4 SUMMARY OF ADVANCE CARE PLANNING TERMS

DNAR, AND, No ESC, DNR	Inpatient code status	Should reflect the family's desires for attempts at resuscitation during the hospital stay
MOLST/POLST/OOHDNR	Outpatient resuscitation	Important to have to respect families desires for EMS or first responders to attempt CPR. Without form present they are required to provide CPR
Advance Directives	Resuscitation and care preferences	These may include inpatient and outpatient resuscitation choices, choice of surrogate decision-maker, end-of-life desires for treatment or interventions, and even funeral planning
Guardianship	Of the patient and/or their estate if the patient does not have mental capacity and is over the age of 18.	May be full, limited to healthcare/financial or other large decisions, or temporary in certain circumstances
Medical Power of Attorney (MPOA)	Person or persons chosen to act on an individual's behalf if incapacitated.	MPOA may be active upon signing or upon the patient's incapacitation. An expiration date can be set. The patient should communicate goals, advanced directives to MPOA(s)

DNAR, do-not-attempt-resuscitation; AND, allow natural death; No ESC, no escalation; DNR, do-not-resuscitate; MOLST, medical orders for life-sustaining treatment; POLST, physician orders for life-sustaining treatment; OOHDNR, out-of-hospital do-not-resuscitate.

Adapted with definitions from Texas Health and Human Services Website ⁴⁷ and Wikipedia. ⁴⁸

have the gene that causes CF, the disease is still present and the ability to fight infection is complicated by the need for continuous immune suppression.

The decision of when to integrate a palliative approach for patients' with chronic conditions like CF can be challenging, given the misconceptions about PPC. Early introduction of palliative care as an additional layer of support during acute CF exacerbations or when a patient is undergoing a transplant evaluation can (1) assist with difficult to manage pain or other bothersome symptoms; (2) help clarify communication among teams, patient, and family; and (3) help align goals of care with treatment options. The PPC team can also be helpful when trying to achieve a balance between aggressive interventions and quality of life (Box 26.3).

Managing progressive symptoms in CF, especially at the end of life, can be challenging. Overwhelmingly, evidence supports the benefits of using very low doses of opioids to treat dyspnea and benzodiazepines to treat associated anxiety.⁵² There are some fears and misconceptions that opioids may hasten a child's death, decrease respiratory drive, or that a child may develop an addiction to them. For children with CF, low-dose opioids and nonpharmacologic measures are mainstays to palliate progressive symptoms at the end of life. For example, the patient with worsening dyspnea may benefit from noninvasive positive pressure ventilation (NIPPV), supplemental oxygen, and use of a fan. PPC providers should collaborate with primary CF teams to provide the interdisciplinary support that is needed when caring for children with this progressive, chronic, and life-threatening condition.

CANCER

Curative or palliative treatment for oncological diagnoses may cause increased pain, additional symptom burden, or repeated hospitalizations. There is agreement among oncologists and

pediatric oncology nurses that early endorsement of PPC is beneficial to the child and family, improves their quality of life,⁵² helps with refractory pain and symptom management, and clarifies communication regarding prognosis.^{53–55} Parents have expressed that consultation with a palliative care team was a positive experience, although it was still equated with

Box 26.3 COLLABORATIVE BENEFIT OF PALLIATIVE CARE SERVICES IN CHILDREN WITH CYSTIC FIBROSIS WITH OR WITHOUT LUNG TRANSPLANTATION

- Collaborate with the team to develop strategies to reduce parental grief when given the news their child has a life-threatening disease.
- Support the team during admissions, provide strategies to decrease stress, and offer help with pain and symptom management as needed.
- As the disease progresses, collaborate with the team and family on treating bothersome pain and symptoms, answering difficult questions, addressing the “what ifs” and use of aggressive technologies, developing approaches to facilitate discussions related to transplantation, providing support to siblings, and suggesting care settings, including hospice.
- Support advance care planning discussions, including documenting patient preferences, medical power of attorney in accordance with state law, patient goals of care, and desired site of death.
- Develop a plan to address support for family and medical providers at the time of death, including community services to provide ongoing bereavement services.

end-of-life care⁵⁶ (see Chapter 29, “The Pediatric Palliative APRN in Oncology”).

MANAGING THE MEDICALLY
COMPLEX PEDIATRIC PATIENT

CASE STUDY: THE MEDICALLY
COMPLEX PATIENT

JJ was a 6-year-old 28-week premature baby with spastic quadriplegia, who was dependent on bilevel positive airway pressure (BiPAP), a gastrostomy tube (G-tube), and a jejunostomy tube (J-tube). JJ had several chronic medical conditions including obstructive sleep apnea (OSA), feeding intolerance of unclear etiology, and spasticity, and he was dependent on caregivers for all activities of daily living. JJ had been in and out of the hospital at least yearly. Over the past 2 years, his feeding intolerance has progressed so that only medications are administered through the G-tube and J-tube. He relies on total parenteral nutrition (TPN) through a central line for the remainder of his nutrition although there were two admission for central line bacteremia. JJ has been admitted to the ICU for 2 weeks with electrolyte abnormalities related to feeding intolerance. He was intubated, then extubated, and he tolerated his home BiPAP regimen. He was followed by multiple subspecialists. We will use JJ’s story to illustrate the palliative care topics covered in the next sections of this chapter.

GASTROINTESTINAL DYSMOTILITY/
FEEDING INTOLERANCE

Causes of feeding intolerance or gastrointestinal (GI) dysmotility vary in children. Some may have an extensive history of intestinal surgeries or colitis in infancy, while others may experience a progressive decline following an acute abdominal surgery for obstruction or volvulus.⁵⁷ The PP APRN needs to thoughtfully research what has already been tried, trial medications one at a time, and discontinue medications that are not helpful to avoid side effects and polypharmacy. It is also important to partner with the patient’s surgeon, dietician, gastroenterologist, and primary care provider to consider pharmacologic and nonpharmacologic management. Table 26.5 lists a table of recommendations from Hauer.⁵⁸

CASE STUDY: THE MEDICALLY COMPLEX
PATIENT (CONTINUED)

JJ was trialed on cyproheptadine twice daily, which decreased his retching and secretions significantly. Gabapentin was added for presumed visceral pain; this was rotated to intravenous methadone when JJ could no longer tolerate any oral medications. When he could no longer tolerate medications by G-tube, J-tube, buccal, or rectal routes, intravenous medications were administered.

Table 26.5 MANAGEMENT OF ABDOMINAL DISCOMFORT

CAUSE	MANAGEMENT OPTIONS	COMMENTS
Constipation	Polyethylene glycol Lactulose Milk of Magnesia Senna	Colonic distention from constipation can trigger pain symptoms due to visceral hyperalgesia and central neuropathic pain
GERD, motility disorders	H-2 blockers and PPIs Protective barrier: sucralfate Pro-motility drugs: erythromycin, metoclopramide Jejunostomy feeding tube	Motility disorders can be a result of impaired input from the CNS to the enteric nervous system Suggested by bloating, distension, retching, vomiting, discomfort Other problems can contribute, including constipation and pain
Vomiting reflex	Medications that block the 5HT-2, 5HT-3, H-1 Arch and D-2 receptors Cyproheptadine (5HT-2, H-1, Arch) Ondansetron (5HT-3)	Suggested by retching, forceful vomiting, and associated symptoms of sweating, pale skin, and appearing distressed
Visceral hyperalgesia, central neuropathic pain	Gabapentin Pregabalin Tricyclic antidepressants	Suggested by pain, retching, and emesis associated with feeding, intestinal gas, flatus, and bowel movements
Autonomic dysfunction	Gabapentin Pregabalin Clonidine	Suggested by pain and emesis associated with tachycardia, hyperthermia, diaphoresis, and skin flushing
Pseudo-obstruction	Conservative management Erythromycin Neostigmine or pyridostigmine	Suggested by recurrent episodes of abdominal distension, pain, emesis, and severe constipation, in the absence of mechanical obstruction

Ach: acetylcholine; CNS: central nervous system; D: dopamine; H: histamine; 5HT: serotonin; GERD: gastroesophageal reflux disease; PPI: proton pump inhibitor

PAIN MANAGEMENT CONSIDERATIONS IN SPECIAL POPULATIONS

Children with advanced disease deserve optimal pain control. The same guiding principles used for managing pain in adults can be applied to children, with additional considerations. The child's developmental age, cognitive ability, weight, the impact of pain on the child and family, and the maturity of the patient's renal and hepatic systems affect medication choices and dosing in pediatric pain management. (See Appendix II for pharmacological and nonpharmacological management). Palliative care teams, in consultation with the primary team caring for the child, should develop plans in conjunction with patients and families. A good pain management plan includes a thorough assessment using age- and behavior-appropriate tools, clarification of the goals of treatment, a description of expected side effects, a discussion of how increased pain will be addressed, and the incorporation of nonpharmacologic therapies (e.g., distraction, relaxation techniques, acupuncture, guided imagery, and play).⁵⁹

Special attention must be given to children who are nonverbal and have intellectual disabilities. This is a vulnerable group, and their inability to self-report pain can result in erroneous and inappropriate management.⁶⁰ It can be challenging to recognize pain in children, especially children who cannot express their pain, which is why so many with advanced illness do not have adequate pain control.⁶¹ Table 26.6 summarizes some pain behaviors by age groups.

The World Health Organization (WHO), the American Academy of Pediatrics (AAP), and the National Coalition for Hospice and Palliative Care (NCHPC) offer guidance on the initiation and titration of pain medications in children. The WHO step ladder is a universally accepted

first-line approach to pain management.⁶² The key concepts are listed here.

- Provide medications at scheduled times, rather than just as needed.
- Offer medications by the most appropriate route.
- Use oral dosing whenever possible.

The pathophysiology of pain is complex, and often a multimodal approach incorporating pharmacological and nonpharmacological methods work best. Pain medication should be given via the most effective and least traumatic route, at regularly scheduled intervals, with a plan for breakthrough pain. There is no standard dosing for opioids; rather "the right dose is the dose that works." However, there are considerations for opioid-naïve children versus those children who have had opioids in the past. For the opioid-naïve, start with the lowest dose based on weight and consideration of renal and hepatic effect. For children with prior opioid use, start with the medication and dose that was previously safe and effective. At the end of life, gut perfusion and/or absorption may be affected, requiring the APRN to investigate other routes (i.e., sublingual, subcutaneous, or intravenous routes).

Patient-controlled analgesia (PCA), an infusion pump that can be programmed to deliver intravenous medications at continuous prescribed doses, allows the patient (or parent) to deliver boluses of medication as needed. Children as young as 3 or 4 years can be taught how to "press the button" to deliver pain medications. PCA should be considered in the following situations: (1) pain is uncontrolled with increasing doses of oral or transdermal medication, (2) pain is uncontrolled on adequate doses of around-the-clock intravenous opioids, (3) pain is expected to escalate quickly, (4) routine care causes significant pain and may require additional dosing before activity, or (5) more control is desired over pain management by the child or the provider. The two main disadvantages of PCA are a child's unwillingness to use it and the need for intravenous or subcutaneous access. Morphine and hydromorphone are the common PCA opioids utilized, although circumstances may necessitate the use of fentanyl. Depending on the goals of care and resuscitation status, a bag-valve mask, supplemental oxygen, and continuous pulse oximetry may be needed for the first 24 hours on PCA and with subsequent dose increases to counterbalance respiratory depression.

SPASTICITY/DYSTONIA

Children with neurologic impairment can suffer from *dystonia*, abnormal involuntary movements that can lead to uncomfortable positions or postures like extreme back arching,⁶³ or *spasticity*, which is best characterized as increased tone in the affected body part.⁶³ While the conditions are different, the therapies may overlap and often require trial and error. It is also important to check for inciting factors

Table 26.6 PAIN BEHAVIORS IN CHILDREN

Infancy (1–12 months)	Inconsolability Feeding/sleeping difficulty Grimacing Change in activity level High-pitched cry Frequent yawning Tachycardia/tachypnea
Toddler (1–4 years)	Lost interest in play Moaning Irritability Loss of appetite Difficulty sleeping or excessive sleeping Overly clingy Guarding
School-age and adolescent (5–17 years)	Change in activity level Overly quiet or subdued Irritable or angry Mismatched cues Difficulty sleeping

Adapted from reference ⁶¹

Table 26.7 POTENTIAL SOURCES OF DISCOMFORT
IN CHILDREN WHO ARE NONVERBAL

INCITING FACTOR	WHAT TO LOOK FOR
Belly	Constipation, urinary retention, mechanical obstruction, pain
Brain	Change in level of alertness from baseline, sleep behaviors, seizure activity, changes in vital signs, developmental regression, stimulation
Breathing	Secretions; if on positive pressure or ventilator, does the child need more support or oxygen, has the look of the breathing changed?
Bugs	Fever, signs of infection
Bones	Grimacing or crying with diaper changes, episodes occur in certain position or while using certain equipment

that may exacerbate spasticity and dystonia; one approach is listed in Table 26.7. A list of interventions and the indications, as well as their potential drawbacks, is listed in Table 26.8. Patient JJ did well for a period of time with physical therapy, a clonidine patch, and gabapentin. As-needed diazepam for muscle spasms was added to his last hospital discharge.

NEUROIRRITABILITY

A child who has bouts of crying, flushed facies, tachycardia, teeth grinding, or self-injurious behaviors may suffer from neuroirritability. The exact cause is not well understood because these patients are often nonverbal, but the assessment is similar to that for dystonia or spasticity, as shown in Box 26.8. Interventions are directed at potential causes and may include changing positions, giving acetaminophen or ibuprofen to see if the irritability is pain related, venting gastric tubes, relieving a full bladder, decreasing stimulation, or trialing medications. Gabapentin is often first-line treatment if the preceding interventions are not successful because it is generally well-tolerated with minimal side effects.⁶⁴ Gabapentin may provide multiple benefits for neuroirritability, visceral or bone pain, and dystonia or spasticity in the neurologically impaired child.⁵⁸

DELIRIUM

When children like JJ are admitted to the hospital, they face a loss of daily routines and familiarity. During one admission, palliative care was informed that JJ was not focusing on his family, could not sleep for more than 20 minutes, and seemed disinterested in a favorite video show that made him smile. Bedside assessment determined that he was likely delirious, and risperidone was initiated.

Pediatric delirium, a disruption in brain function, has become more apparent as children with complex medical conditions are living longer. Those experiencing prolonged

Table 26.8 MANAGEMENT STRATEGIES FOR SPASTICITY AND/OR DYSTONIA

Intervention	Indication for dystonia (D), spasticity (S), or both (B)	Considerations
Nonpharmacologic therapies	B	
Positioning devices, braces, equipment	B	Equipment may need to be reordered as child grows
Targeted therapies		
Botox, ethanol, phenol injections	B	Will likely require repeat treatments
Oral medications		
Baclofen	B	Max doses
Benzodiazepines: Diazepam, clonazepam, lorazepam	B	Can be sedating
Clonidine	B	Hypotension, sedation; has patch form
Gabapentin	B	May exacerbate sedation
Tizanidine	S	Limited pediatric data
Levodopa	D	Limited pediatric data
Trihexyphenidyl	D	Drug interactions, anticholinergic effects
Tetrabenazine	D	Insomnia, mood changes, drug interactions
Surgical		
Intrathecal baclofen pump	B	Refills required, pump failure plan needed
Selective rhizotomy	S	
Orthopedic: Tendons, joint dislocations, scoliosis	B	
Deep brain stimulation	D	

Adapted from information in Graham et al.⁶³

hospitalizations have a higher risk of delirium in intensive care settings due to illness severity, medications, and underlying neurologic impairment.⁶⁵ The validated screening tools for pediatric delirium are the *Pediatric Confusion Assessment Method for the ICU* (pCAM-ICU), the *Preschool Confusion Assessment Method for the ICU* (psCAM-ICU), and the *Cornell Assessment of Pediatric Delirium* (CAPD).⁶⁵ Patients receiving medications that alter alertness or awareness, especially benzodiazepines, can have an increased risk for delirium.⁶⁵ Nonpharmacological interventions include clustering care, promoting sleep hygiene, avoiding sedatives when able, using newer agents like dexmedetomidine in place of benzodiazepines, adding melatonin to promote sleep/wake regulation, and using antipsychotic medication like quetiapine, risperidone, and olanzapine, if necessary. Risperidone comes in oral and oral dissolving tablet (ODT) formulations, and quetiapine has the lowest risk for undesirable hepatic effects.⁶⁶ See Appendix II for management of delirium.

ADVANCE CARE PLANNING FOR THE CHILD WITH NEUROLOGICAL IMPAIRMENT

As mentioned previously, ACP is a frequent reason for palliative care consultation. Many children are unable to use pediatric-appropriate ACP tools due to developmental abilities. Moreover, no tool specifically assists families of children with neurological impairment to express their desires for life-sustaining technology, extent of medical intervention, or desired location if death is inevitable, and to allow for funeral planning. An alternative option may be to utilize an ACP tool and reframe the questions to ascertain and record the family's wishes as well as the patient's code status. As always, such discussions should be documented and accessible to all health team members. A standardized template specific to an organization promotes consistency of practice.

TRACHEOSTOMY DECISION-MAKING

Patient JJ developed progressive weakness that led to increased respiratory effort and inability to clear his secretions. The option for tracheostomy was presented to the family and palliative care was asked to help with the medical decision regarding tracheostomy. Child tracheostomy decision guides are available on the internet, and some institutions may have their own pamphlets and processes. Regardless if there is a formal process, families should have a good understanding of why the tracheostomy is recommended; the requirements for taking their child home with a tracheostomy; the risks and benefits of the tracheostomy; expectations for speech, oral intake, and chance for decannulation; and what other options may be available.⁶⁷ This information is essential for families to make decisions best suited to meet their goals for their child.

END OF LIFE: DYING, PALLIATIVE SEDATION, AND WITHDRAWAL OF LIFE-SUSTAINING THERAPIES

Over 2 months JJ continued to worsen. His family made the decision not to pursue tracheostomy and to focus on his comfort. He was not a candidate for additional interventions as his renal failure progressed and his family made the decision to compassionately extubate him in a withdrawal of life sustaining therapies (WOLST). Given his underlying comorbidities, the team also made a plan for palliative sedation if needed. *Palliative sedation* is best defined as “the use of sedative medications to relieve intractable and refractory distress.”⁶⁸ Palliative sedation in pediatrics may raise ethical concerns and therefore it is best discussed ahead of time, ideally with experienced providers making the recommendations (see Chapter 57, “Palliative Sedation,” and Chapter for “Discontinuation of Other Life Sustaining Therapies” for further discussion).

The decision to discontinue life-sustaining therapies is made over time. It occurs after discussion of the family's goals of care, emphasizes the potential for a peaceful and dignified death, and promotes legacy building for the child and family.⁶⁹ A WOLST is a delicate and unique procedure for each child. It is essential that the family is provided a detailed explanation of the procedure, including anticipatory guidance about what to expect, especially in circumstances where the child may live for hours or days. This includes which team members will be involved, medications to be administered and who will administer them, and the timing for removal of equipment like a ventilator, the ECMO circuit, dialysis equipment, etc. The plan should be communicated to all parties involved in the child's care while being sensitive to the family's needs and grief. The same end-of-life care memory-making and legacy-building while providing a good death for any child in the hospital should also be included in the WOLST plan. Box 26.4 is an example of WOLST preparation documentation.

END-OF-LIFE CONSIDERATIONS

While some families may want to keep their child in the hospital for IV medications, the familiarity of providers, or because the child may be too sick to go home, an increasing number of families are choosing to keep their children at home for their death. This is a very personal choice for families and is based on a variety of factors such as honoring their child's wishes, cultural beliefs, availability of resources and support, who lives at home, and the family's past experiences with death. Families must be assured that there is no right or wrong choice about keeping their child in the hospital or taking them home. As with any comprehensive PPC plan, a home care plan should include careful assessment of the child's physical and emotional needs as well as their developmental level and ability to complete developmental tasks. Practical factors such as finances, living situation, social support, and religious or spiritual/existential beliefs and practices should also be considered.^{70,71}

Box 26.4 WITHDRAWAL OF LIFE-SUSTAINING THERAPIES PLAN

The medical team met to discuss the care of JJ. Considering that the patient's disease process is irreversible, it is appropriate to pursue withdrawal of life-sustaining therapies (WOLST) and focus on comfort measures at the end-of-life. This is consistent with the parent's wishes and is in the best interest of the child.

Adapted from Texas Children's Hospital Palliative Care Team guidelines.

Facilitating a smooth transition from inpatient care to home requires frequent communication between the inpatient teams and the outpatient and home care providers. The role of the PP APRN, along with the other members of the interdisciplinary PPC team, can ensure that families have their physical, emotional, and social needs met whether they choose to remain in the hospital or transition to home. Points to consider prior to a discharge to home are listed in Box 26.5.⁷²

HOSPICE CARE

One of the most beneficial resources for the home care of a child is the addition of hospice services. The terms "palliative" and "hospice care" are often used interchangeably due to their similar philosophical approaches to care. However, palliative care can be provided at any time during the disease, whereas

Box 26.5 POINTS TO CONSIDER PRIOR TO DISCHARGE

Clarifying expectations of team, family, and home care providers
Instructions for pain and symptom management. Ensure home care equipment and medications can be delivered prior to discharge.

Verify the contact number of medical provider and/or home care agency.

Discuss having an out-of-hospital do-not-resuscitate order if appropriate.

hospice care is traditionally introduced if the patient could die during the next 6 months.⁷² The PP APRN should be familiar with the distinct ways in which pediatric hospice care differs from adult hospice care, but especially the issues found in the *Concurrent Care for Children Requirement* section of the *Affordable Care Act*, which allows children to jointly receive curative treatments alongside hospice services. The pediatric APRN is well-suited to serve as the direct liaison with hospices teams prior to discharge. In some instances, the hospital PPC team will direct the care for a child at home with hospice by working directly with hospice providers to adjust medications and care plans to maintain the child's comfort and to support the family while at home. A few guidelines to consider when making a hospice referral are listed in Box 26.6.

Aside from resources like hospice and home care nursing, there are several practical aspects for the PP APRN to arrange for the child's care at home. Effective communication and an organized plan must be established to avoid errors while ensuring that pain and other symptoms are well managed.

Box 26.6 GUIDELINES FOR HOSPICE REFERRAL

Identify child who would benefit from hospice.

Communicate potential referral with primary team and care coordinators.

Determine eligibility of a prognosis of 6 months or less.

- Use the surprise question: "Would I be surprised if the child dies within the next 6 months?" If no, the child is likely eligible.
- Remember the child is not required to have a do-not-resuscitate (DNR) order to enroll in hospice.

Check insurance coverage of the child and discuss with parents.

- Most children with Medicaid may receive concurrent care.
- Many commercial payers may need to negotiate care.

Make referral to hospice program with required demographics and pertinent clinical information.

Contact hospice agency to arrange for meeting with liaison prior to discharge and provide any additional information.

Communicate discharge date and help with logistics of discharge as requested.

Adapted from Texas Children's Hospital Pediatric Advanced Care Team Guidelines.

SUMMARY

PPC is family-centered care by nature and focuses on addressing not only the needs of children living with life-threatening illness, but the needs of their family as well. It continues to evolve as an integral and multifactorial area of healthcare because more children are living with chronic and potentially life-threatening illnesses. As with all individuals with serious illness, children and their families deserve optimal quality of life tailored to pediatric principles of care. PPC is often initiated as the goals of care shift from a focus on cure to a focus on optimizing quality of life.

Access to a PPC interdisciplinary team of professionals promotes quality care; however, these teams are not always available outside of large academic settings. PP APRNs are vital in initiating and providing high-quality primary PPC by adequately addressing and anticipating children's and families' needs, allowing for ongoing discussions about goals of care, collaborating with other providers to provide comprehensive care, and thoroughly assessing and treating pain and other distressing symptoms.

THE PEDIATRIC PALLIATIVE APRN IN PERINATAL AND NEONATAL PALLIATIVE CARE

Maggie C. Root and Mallory Fossa

KEY POINTS

- The pediatric palliative advanced practice registered nurse (PP APRN) serves as a touchpoint for families along their journey, from diagnosis of a serious illness (prenatal or after birth) through transitions in care settings and goals of care, on to survivorship or bereavement.
- The PP APRN assesses, manages, and/or provides consultative service regarding pain and other physical symptoms that infant can experience.
- It is critical to attend to the emotional, psychological, practical, spiritual, educational, and developmental challenges that are faced by the parents, infants, and the extended family.
- The PP APRN is in an ideal position to assess the parents' understanding of the diagnosis, prognosis, and treatment options as well as the cultural and spiritual beliefs and views on what defines quality of life for their infant.
- Communication between family and healthcare providers can be coordinated by the PP APRN to reduce burden on the family and prevent clinician misunderstandings.

CASE STUDY 1: A BABY WITH MANY CONGENITAL ANOMALIES

Kristen (35 years old) and Antonio (32 years old) had been together for 8 years and were the parents of a 2-year-old daughter. Kristen was 32 weeks pregnant with a son with multiple congenital anomalies, including cystic kidney disease and cardiac defects, when she presented at a tertiary referral children's hospital. A perinatal palliative care consult was initiated by the maternal fetal medicine team supervising Kristen's care because their team thought Kristen and Antonio could benefit from added support during and after the pregnancy. In the initial perinatal palliative care consultation, Kristen and Antonio shared that it was important to them to continue to carry the pregnancy, even though their obstetrician had recommended termination. They expressed how it felt helpful to create a birth plan that acknowledged their values. Of primary importance was that they wanted to be present with their son as much as possible while also desiring support from life-prolonging medical technology. They hoped that the medical interventions would provide time to better understand the extent of their son's conditions and how

these may affect his future quality of life. The palliative care team discussed how the birth plan would be a modifiable communication tool and that, despite our best planning, changes were likely to occur over time.

The birth plan for the baby included a vaginal delivery with intubation at delivery if needed. However, the goal would be to protect him from the harm of cardiopulmonary resuscitation (CPR) if his heart were to stop. His parents remained hopeful that his condition would not be as severe as anticipated. They shared a desire for their daughter to meet their son in the hospital if possible. Kristen went into labor at 36 weeks and delivered vaginally. Antonio was present when their son Charlie was born. In the delivery room, the neonatal ICU (NICU) team noted Charlie was dusky with minimal respiratory drive. He was stabilized with noninvasive positive pressure ventilation (NIPPV) and Kirsten experienced skin-to-skin time with him before transfer to the NICU. Confirmatory diagnostic testing including echocardiogram, abdominal ultrasound, and head ultrasounds were performed. Charlie was found to have an atrial-septal defect that would likely require cardiac surgery in the first year of life. His single cystic kidney was confirmed. Charlie was also diagnosed with syndactyly, imperforate anus, and vertebral anomalies suggestive of a VACTERL-like syndrome with life-limiting prognosis.

During a family meeting, diagnostic information was shared and colostomy was recommended. Kristen and Antonio continued to share how it was important for them to follow Charlie's lead, especially since he was otherwise stable and had been weaned to 2L oxygen. Charlie underwent the recommended surgery without complication but developed kidney failure within a few days. A second family meeting where peritoneal dialysis was presented as a potential bridge to hemodialysis or renal transplant, with Charlie likely to require hospitalization until his transplant (which was expected to be more than a year away). Charlie's parents requested more time to consider the benefits and burdens of the procedure.

In follow-up visit with the palliative care team at Charlie's bedside, Kristen and Antonio described the importance of Charlie being able to run and play with his friends as he got older, hopes that they grieved as they saw a different reality. They worried about his quality of life, with frequent medical appointments, surgeries, procedures, and pain. The palliative team acknowledged Kristen and Antonio's love and support and courage in considering Charlie's experience. The palliative care team shared that some loving parents would decide not to pursue

dialysis and focus care on Charlie's comfort. The team shared that without dialysis, Charlie's prognosis was days to weeks. Kristen and Antonio shared that they had been wanting to avoid dialysis but were concerned that the medical teams would not approve. After the meeting, the pediatric palliative advanced practice registered nurse (PP APRN) discussed the conversation with the neonatology providers. A do-not-resuscitate (DNR) order was placed, and the palliative care team made recommendations on streamlining Charlie's care to focus on comfort. Education was provided to the bedside nurses regarding the plan of care and anticipated needs for Charlie and his family.

At this point, Kristen stopped visiting the hospital, which distressed the nursing staff. In discussion with Antonio, he revealed he was trying to shoulder the burden of grief and protect Kristen from the heartbreak of their child dying. The palliative care team addressed their fears of grief and normalized the worries regarding watching their child decline. Charlie was moved into a private room where Kristen and Antonio were able to spend time as a family. Both Charlie's sister and his grandparents were able to meet him. The PP APRN supported the family and educated them about signs and symptoms of dying and ensuring comfort. Charlie showed very little discomfort and was weaned to room air. Per Kristin and Antonio's wishes, a chaplain performed a blessing in the presence of extended family. The family engaged in memory- and legacy-making activities with a child life specialist. Ten days later, Charlie died in Kristen's arms with Antonio by their side.

settings of adoption]. This inclusive language is becoming more widely used in the obstetrics and midwifery communities.) If a fetus is prenatally diagnosed with a life-limiting condition, the birthing person will be faced with multiple decisions along the trajectory of care for themselves and the fetus.¹ Palliative care in the setting of a pregnancy and birth straddles two areas: perinatal and neonatal palliative care. Often these two subspecialties are practiced by different providers, but they are presented together in this chapter because some families may cross the perinatal to neonatal path and because neonatal palliative care providers must be mindful of the prenatal journey that families have faced. Figure 27.1 demonstrates how in a perinatal consult differs from a neonatal palliative care consultation.

This chapter illustrates how the pediatric palliative advanced practice registered nurse (PP APRN) uses evidence-based practice to better support parents and infants. Pregnancy and parenting are deeply personal, and each APRN should attempt to limit projections onto the birthing person and family as they navigate these decisions within the context of their own values. It is important to keep in mind that one should maintain a lens of self-reflection and consider how one's own values may impact clinical assumptions and judgments. Therefore, the PP APRN must critically analyze their own values and beliefs regarding quality of life, when life begins, suffering, treatment, and disability. Moreover, one must be mindful of implicit bias around cultural ethnicity, gender identity, and family structure. Awareness allows us to recognize when we feel pulled to make recommendations or judgments based on our own perspectives and values, when, instead, as palliative care providers our role is to support the family in making decisions based on their own values and cultural constructs.²

INTRODUCTION

When considering the care of a pregnant person, one must also consider the care for the unborn child. (Within the obstetrics and midwifery communities the inclusive terms "pregnant person" and "birthing person" are becoming more common. This acknowledges that not all people who give birth identify as women [i.e., men and nonbinary people] and not all people who give birth identify as parents [i.e.,

PERINATAL PALLIATIVE CARE

History of Perinatal Palliative Care

This early identification of high-risk pregnancies has allowed for the earlier integration of perinatal

Figure 27.1 Perinatal versus neonatal palliative care.

palliative care.³ Prior to the creation of hospital-based perinatal palliative care programs, services primarily involved community-based psychosocial supportive services for pregnant persons carrying a fetus with a fatal condition. Perinatal hospice services have grown over the past three decades to include a range of services.⁴ Greater uncertainty in prognostication, driven by technological advances, has led to the evolution of perinatal hospice into perinatal palliative care. Perinatal palliative care is a new area of specialization within palliative care and encompasses the journey of pregnancy regardless of the fetal outcomes or decisions around termination. Services may be provided in the home, clinic, or hospital setting and may extend through bereavement.⁵

CURRENT STATE OF PERINATAL
PALLIATIVE CARE

Across the country, although perinatal palliative care is growing, most perinatal palliative care programs are relatively young. Therefore, access to services has historically been limited and varied in scope.⁵ This puts PP APRNs in a unique position to improve the care of these vulnerable families and their infants. Many perinatal palliative care programs do not meet established guidelines for the provision of comprehensive palliative care, with most lacking formal training palliative care training for all team members.⁵ Hospital-based programs are becoming more common.⁵ Often, perinatal palliative care clinics and services

are provided in addition to subspecialist's primary clinics, and staffing may be difficult and varied based on institution.⁶ Frequently it is a nurse coordinator or APRN who will help to coordinate the care of the multiple specialists (including obstetrics, maternal-fetal medicine, neonatology, and pediatric subspecialists) in meeting the needs of the birthing person.¹

A prenatal palliative care consultation is performed by an interdisciplinary team² and may include unique participants, including maternal-fetal medicine specialists, obstetricians, fetal surgeons, and genetic counselors. Consultation emphasizes assistance with shared decision-making, birth planning, sibling support, and the provision of psychoemotional support throughout pregnancy, extending through birth and/or bereavement.^{2,6,7} Consistent with the National Consensus Project for Quality Palliative Care (NCP) *Clinical Practice Guidelines*, the provision of perinatal palliative care covers the domains of physical, psychological, social, spiritual, and cultural care of patients.² This section highlights the role of the PP APRN in supporting family decision-making, facilitating discussions of goals of care through understanding family values, and addressing the ways families make meaning, balance hopes and worries, and face uncertainty while carrying a fetus with a serious condition.⁸ Second, this section highlights the role of the PP APRN in developing a birth plan that covers each of the NCP *Clinical Practice Guidelines* domains. Finally, the role of the PP APRN in supporting other healthcare workers will be discussed (Table 27.1).

Table 27.1 CONDITIONS WHERE PERINATAL AND/OR NEONATAL PALLIATIVE CARE MAY BE APPROPRIATE

<i>Cardiac conditions</i> Acardia Complex congenital heart defects Pentalogy of Cantrell Patients requiring extracorporeal membrane oxygenation (ECMO) Support Heart transplant candidates	<i>Neurologic conditions</i> Anencephaly/acrania Intraventricular hemorrhage (Grade IV) Periventricular leukomalacia Holoprosencephaly Congenital severe hydrocephalus with absent or minimal brain growth Neurodegenerative diseases (spinal muscular atrophy) Spinal muscular atrophy Severe seizure disorders (i.e., Ohtahara Syndrome) Severe neurologic impairment
<i>Gastrointestinal conditions</i> Necrotizing enterocolitis requiring surgical resection Total parenteral nutrition (TPN) dependence Short gut Severe gastroschisis Liver failure Biliary atresia	<i>Pulmonary conditions</i> Severe congenital diaphragmatic hernia Cystic fibrosis Pulmonary hypertension Severe pulmonary hypoplasia Ventilator dependent respiratory failure Consideration of tracheostomy Consideration of lung transplant
<i>Genetic conditions</i> Trisomy 13, 15, or 18 Triploidy Thanatophoric dwarfism Lethal inborn errors of metabolism Osteogenesis imperfecta, Type II or III Epidermolysis bullosa Mitochondrial or metabolic disorders	<i>Renal conditions</i> Oligo/anhydramnios with pulmonary hypoplasia Potter syndrome Renal agenesis Bilateral multicystic/dysplastic kidneys Polycystic kidney disease

**Table 27.2 PERINATAL PALLIATIVE CARE
ASSESSMENT AREAS**

Physical	Consider how the physical experience of birth may guide the plan of care for the fetus or infant; symptom management for a live-born infant, regardless of goals of care.
Psychological	Address the emotional needs of the pregnant parent during the prenatal and post-partum periods.
Social	Consider normal developmental standards of the infant (i.e., first smile) and birth person (i.e., infant bonding, skin-to-skin contact) within a cultural context (i.e., importance of introducing the fetus or infant to family members).
Spiritual	Attend to the spiritual experience of the pregnant parent, their support persons, and family. Consider any the spiritual or religious values placed on birth (such as rituals, baptism, circumcision) may influence the plan of care.
Cultural	Ask the meaning of pregnancy in the pregnant person's culture. What are culturally normative childbirth experiences? What are the cultural reflections on fetal or infant loss (i.e., normal, shameful, meaningful)?
End-of-Life	Consider death of infant. Perinatal palliative care is for both live and non-live births when an infant's death is not imminently expected, as in the case where life-sustaining interventions are planned to address a serious condition.

From Carter.⁹

CASE STUDY 2: FACILITATING A BIRTH PLAN DISCUSSION

Meg, a PP APRN provided an initial perinatal consultation with June, a single woman who was 26 weeks pregnant. June's fetus was recently diagnosed with Trisomy 18. Meg dreaded the consult because she heard that June wanted to continue with her pregnancy. Before the consultation, Meg recognized that her feelings of despair emanated from her worry that June would be alone in caring for an infant with medical complexity. Meg's recognition of her own perceptions of parental burdens and quality of life allowed her to create space to better understand June's values in the consultation. This space allowed Meg to reflect on the families of children with Trisomy 18 who find tremendous joy in their children's continued life. Meg was reminded that this is not her pregnancy but June's and that June is making choices in the best interest of herself and her fetus.

SUPPORT SHARED DECISION-MAKING AND ESTABLISHING GOALS OF CARE

ADDRESSING PRIOR HEALTHCARE EXPERIENCES

The PP APRN holds a unique role in addressing the grief, conflict, and abandonment families may feel from prior

healthcare experiences related to a pregnancy (Table 27.2). The PP APRN must acknowledge a journey prior to this point. In receiving a life-limiting, life-threatening diagnosis⁹ for their child, parents have already experienced the loss of future-oriented hopes. It is common that, prior to a palliative care consultation, parents have been offered termination of the pregnancy (from an obstetric or specialist provider) if significant anomalies have been diagnosed.¹⁰

SUPPORTING UNDERSTANDING OF ILLNESS AND FAMILY VALUES

Parents should be given the opportunity to understand their child's diagnosis from the diagnosing specialists, preferably in the context of a family meeting. Unlike adult palliative care teams that frequently break bad news to patients, perinatal palliative care consultants are more frequently consulted after a family has already heard bad news. The palliative care team should arrange a meeting with the parents to further explore their understanding of this new diagnostic and prognostic information. Specifically, the palliative care team acknowledges parents' understanding of what has been told to them by other healthcare providers and asks them reflective questions such as "Based on this, what worries you the most?" and "What are you hoping for?"⁸

To provide perinatal palliative care, it is essential to understand the family system and values. It is well understood that even first-time parents have an internal sense of guiding principles to define a "good parent," which informs their decision-making and sense of parenthood.¹¹ These principles frame how parents perceive their unborn child's or infant's best interests. The PP APRN should ask open-ended questions such as "I have worked with many parents and have learned they often have a sense of what they need to do to be a good parent. What does being a good parent look like to you?"¹¹ Providing a silent presence can allow for parents to reflect and elaborate. These value-based questions can give the PP APRN a better understanding of what is important to parents. They should be used throughout the trajectory of care because goals and values are dynamic. Responses to these questions may change with parental experiences over time, redefining what it means to be a good parent and/or evolving in how they see their child.^{10,11}

ELICITING WHAT DEFINES QUALITY OF LIFE

Similarly to understanding a parents' definition of "good parent," understanding their definition of a "good life" or quality of life is a critical component of supporting medical decision-making. While parents may have an understanding of what their child's life could look like in the future, parents do not find this as helpful when making decisions about quality of life.¹² The PP APRN should guide the conversation from functional limitation and disease burden to a more holistic understanding of quality of life, as appropriate.¹² This is achieved through open-ended questions such as "What does a good life mean to you?" or "What's most important in thinking about

the future for your child?" In thinking about Charlie, initially Kristen and Antonio shared that it was important that Charlie have a more thorough postnatal evaluation to better understand his condition. As his parents learned more how his medical complexities would affect him over time, including the likely need for dialysis and multiple surgeries, they felt this was not consistent with their values of freedom from technology and thus not a good life for their child.

RESPECT FOR THE PARENT

Parents of a fetus or infant with a life-threatening condition face complex decisions throughout the pregnancy and after delivery. It is important to respect the birthing person, partner, and infant as each having value per the family system.¹³ Decision-making in the setting of a life-limiting fetal condition has been shown to be influenced by many factors, including religion,¹⁴ culture, severity of the fetal condition,¹⁵ perception of suffering,¹⁶ maternal age and education,¹⁷ if a birthing person has other children,¹⁸ and the level of prognostic certainty.¹⁴ The time course for decision-making may be longer in the setting of early prenatal diagnosis or abbreviated if the diagnosis is made close to birth. The PP APRN should provide anticipatory guidance regarding the birth process and potential interventions and procedures while relating these to alignment with the family's goals of care. It is the role of the PP APRN to encourage a parental sense of control while highlighting how the birth person and partner are good parents who make decisions in their child/fetus's best interest.

SHARED DECISION-MAKING

The transition from a paternalistic model of healthcare to one that emphasizes shared decision-making shifts the focus away from providing objective information and toward supporting the infant's parents in making decisions based on their family's values.¹⁹ The PP APRN supports the family in discerning treatment pathways. In addition to supporting the family, the PP APRN should help the primary care team to better understand how their own biases and values impact the guidance they give to families through modeling a reflective practice and facilitating proactive discussion among clinicians.

MEANING-MAKING

Parents of infants with life-limiting conditions have identified that they find value in continuing a pregnancy because it offers time to develop as a parent and bond with the fetus.^{20–22} The process of becoming and identifying as a parent includes multiple steps that should be supported by the PP APRN. Use of the language that identifies the fetus or the fetus's condition as incompatible with life is strongly discouraged³ as this invalidates the positive or growth-focused parental experiences of pregnancy and the lived experience of the family. Parents may derive meaning and add to their sense of being a parent through becoming informed about their child's condition, adjusting goals of the pregnancy, maximizing the quality

of the pregnancy experience, including the unborn child in legacy-making, planning for birth, and serving as the child's advocate before and after birth.²⁰ This process of becoming a parent to the individual child may reduce feelings of parental regret.²⁰

HOPES AND WORRIES

Parents can hold simultaneous hopes and worries that, on face value, may appear in conflict.²³ As with other populations, in perinatal palliative care it is important to assess the multiple hopes that birthing persons and families may hold.² As in Charlie's case, parents may have simultaneous worries about their child experiencing pain, being hospitalized, and having a complex medical condition while also hoping for time with the child and/or survival.²¹ Parents may hope to connect with families who have had a child with a similar condition. They may also hope that the child be born alive, may be able to go home from the hospital, and/or have what the family determines to be a good life.²¹

UNCERTAINTY

Given the uncertainty in perinatal diagnostics and medical prognostication, children with conditions previously considered fatal may survive beyond the neonatal period.²⁴ Families report these children as being happy with a good quality of life, despite clinician judgment that the child's disease would be fatal.²⁴ Uncertainty may underlie much of decision-making for both birthing persons and clinicians. Because of this significant uncertainty, it is critical that families be informed of the range of medically and ethically permissible treatment aims, from termination through life-prolonging or curative-intent therapies.³ Failing to disclose the range of possibilities fosters distrust between family and providers because parents inevitably will find this information elsewhere.²⁴ Parents report using community or online sources to find more information regarding others who have faced similar situations.^{3,24} Additionally, parents find value and meaning in having choice in the care of the infant, even when that means the choice of pursuing comfort-directed treatments.²⁵

Prenatally diagnosed conditions may have additional uncertainty because of limited diagnostic techniques in utero. Families may have received conflicting information from healthcare providers and are likely to have seen multiple specialists who provide organ-specific information. For example, the parent of a fetus with a prenatal diagnosis of anencephaly may have seen a primary obstetrician, who referred them to a maternal-fetal medicine specialist, pediatric geneticist, genetic counselor, pediatric neurologist, etc. It is the role of the PP APRN to synthesize information from these providers and elicit the family's understanding of the conditions. A birth plan may include postnatal diagnostic confirmation using imaging (such as echocardiogram or magnetic resonance imaging) or genetic testing (such as whole-genome sequencing or targeted genetic tests).¹² This information may further inform decision-making and treatment options. While waiting for confirmatory diagnostic results, a time-limited trial

of life-prolonging interventions may be appropriate based on family goals of care.

THE BIRTH PLAN

Birth plans are a communication tool for families and clinicians for all types of births, whether a live birth or non-live birth. While there is some overlap in content, a perinatal palliative care birth plan is distinct and more complex than popular birth plans for healthy infants. As such, they are evolving documents that may change as families gain new perspectives on the pregnancy, child, quality of life, and illness. The development of a birth plan is grounded in the individual family's values. Birth plans may reflect goals of care that are focused primarily on comfort, emphasize life-sustaining or disease-directed treatments, or anything in between.²¹ Birth plans are also appropriate when a non-live fetus is delivered, whether as a result of termination, miscarriage, or fetal demise. There is significant variation in birth plans among institutions, states, and regions reflecting local culture and legislation regarding the care of fetuses and infants. Birth plans should address five key content areas including identification, communication preferences, labor and delivery plan, postpartum care, and postmortem care. A nonexhaustive sample of birth plan elements is shown in Box 27.1.

DEVELOPMENT OF A BIRTH PLAN

Developing a birth plan incorporates family values, understanding of illness, and goals of care.¹⁰ Birth plans emphasize family-centered care and bring the family voice to the forefront.¹⁰ There is no one “right” plan; rather a plan must match the unique needs of the parents. Given the emotional nature of the content and the potential need for significant education, the process of birth planning can be lengthy and it may change as healthcare issues arise. General topics may include the birthing person's support companion, pain management during labor, comfort measures during labor, and important cultural rituals. When possible, avoid creating a birth plan in one sitting or treating the birth plan as a checklist. Forcing parents to make a decision on every topic or going down a list offering each intervention may be burdensome and run counter to the role of the PP APRN in aligning with the family and understanding the nuances of conversations. Instead, individualize the plan for each family. Not every topic may be appropriate for each family. Offering an “all or nothing” framework may place undue burden on the parents without providing the needed support found in shared decision-making. Many families choose a path that is not all one way or another, and they should be supported just the same by the PP APRN.

CHANGES IN BIRTH PLAN

In the setting of great prognostic and psychoemotional uncertainty, changes are inevitable. Changes to the birth plan may originate from the family, care team, or from the fetus's

Box 27.1 BIRTH PLAN COMPONENTS

- Identification
 - Chosen name of the fetus
 - Preferred terminology of the unborn (fetus, infant, child, baby)
 - Parental desire to know the sex of the fetus
- Communication preferences
 - Language
 - Written, verbal or auditory
 - Desire to know all details or limit content
 - Siblings: Who will communicate with them, and what has been communicated
- Labor & Delivery plan
 - Support person/attendant for the birthing person
 - Preference for vaginal or cesarian delivery
 - Use of cesarian for fetal distress?
 - Fetal monitoring
 - Pain management for birthing person
 - Physical environment (Music, lighting)
 - Does family wish to be informed if loss of heartbeat occurs during labor?
 - Who will cut the umbilical cord?
 - Resuscitative measures/warming plan
 - Parental bonding including skin to skin contact
 - Procedures
- Post-Partum
 - Location of infant care (Room-in, nursery, NICU)
 - Confirmatory diagnostic testing
 - Preferences for visitors/staff presence
 - Feeding and nutrition plan
 - Spiritual or religious preferences and rituals
 - Keepsakes
- Postmortem
 - Organ donation
 - Discussion of autopsy
 - Prior discussions of funeral arrangements (if appropriate)

From Perinatal Palliative Care: ACOG COMMITTEE OPINION, Number 786⁶; Cortez et al.¹⁰; Garten et al.³²

presentation. It is important to have ongoing discussions with the parents regarding the potential for changes in the plan of care, especially if the postnatal diagnosis is not equivalent to the prenatal predictions. The multiple hopes and worries that

families hold may shift over time²⁶ as parents may learn more about their child or the illness.

It is an important responsibility of the PP APRN to regularly reassess parental goals as these may change over the course of a pregnancy and/or after birth. The burden of reassessing goals should not lay solely with the parent. Families should be reassured that changes in hopes or goals are common and reflect the parental strength that comes with careful consideration of options.

COMPONENTS OF THE BIRTH PLAN

There are several components of birth plans including identification, communication preferences, labor and delivery plan, postpartum care, and postmortem care. Each birth plan should be customized to the family.

Identification

The PP APRN should elicit information on how the family would like the fetus to be addressed, such as by a specific name; as a child, son, or daughter; or as a fetus. Since birthing persons may or may not want to be identified as “mother” or “father,” the APRN should ask the family how they wish to be addressed by the healthcare team. In some pregnancies, the sex of the fetus may be a surprise. The APRN should assess if the family wishes to know the expected sex of the fetus and if the family wishes not to know, care should be taken to protect that knowledge.

Communication

The PP APRN should address the family’s preferred mode of communication (written, verbal, auditory) and language. Furthermore, the APRN should assess the extent to which the family would like information shared, whom information can be shared with, and if there are preferred members of the healthcare team whom the family sees as trusted. Siblings may have unique needs regarding communication of the pregnancy and birth (see further discussion later in the chapter).

Labor and Delivery Plan

Labor plans may include a discussion of medical interventions found in typical healthy birth plans, such as mode of delivery, location of labor (home, hospital room, operating room), fetal monitoring (intermittent, continuous, external, invasive), preferred method of pain management (including nonpharmacologic support), and an ideal physical birthing environment (lights dimmed, music choice, visitors in room). Unique components include whether the birthing person wishes to be informed of fetal demise if there is a loss of heartbeat during labor. As part of birth planning, the APRN should provide anticipatory guidance regarding what the infant may look like after birth, such as physical anomalies, color differences, or temperature changes. Care can be taken to cover areas of the child’s body with hats, clothing or blankets if the parent desires.

Postpartum Care

This birth plan area may include logistical needs, condition-specific procedures, a plan for breastmilk production and feeding, addressing spiritual needs, and legacy-making. Location of care options based on the medical plan of care should be reviewed (room-in, well-baby nursery, NICU). Routine post-birth care provided to healthy infants may or may not be appropriate for each birth plan. This includes length/weight measurements, vitamin K injection, erythromycin eye drops, and blood glucose testing. Families may choose to focus on the comfort of the infant and forgoing life-sustaining interventions. Therefore, maximizing family time with the child in the parents’ arms may dictate what “routine care” elements are continued. Respect for the infant and birthing person should be maintained regardless of whether the infant is born alive or deceased.

Condition-specific procedures may include confirmatory diagnostic or genetic testing,⁶ life-sustaining interventions (such as intubation in the setting of congenital diaphragmatic hernia with lung hypoplasia), or a trial of therapies to assess the infant’s response (bag-mask ventilation for an infant with Trisomy 13 and apnea at birth).

Lactation consultants are helpful to provide additional support to the birthing person. They may assist with milk production, suppression, pain from engorgement, and milk storage or donation.²⁷ The PP APRN should coordinate with lactation consultants regarding the evolving clinical scenario and importance of providing ongoing grief support because an inability to feed one’s child may be a source of distress for the birthing person.²⁷

Feeding one’s child may hold emotional, spiritual, or cultural meaning to parents of a seriously ill infant.²⁸ Feeding strategies need to be targeted to the infant depending on complexity of medical conditions and the family’s values and goals of care. There are a range of feeding options for seriously ill infants depending on the physiologic feeding ability, severity of the illness, goals of care, and local and state regulations regarding initiating, withholding, or discontinuing medically prescribed nutrition. In the immediate postpartum period, breast or chest feeding may be offered if congruent with the family goals of care. However, it may not be appropriate if medical resuscitation is anticipated at birth (i.e., if intubation is planned at delivery). Some infants (such as those with significant neurologic injury or craniofacial conditions) may not be able to latch and suck. Consultation with speech therapy may support the infant in engaging in feeding. Medically administered nutrition and hydration (MANH) may meet a variety of goals including providing comfort or life prolongation, and may be included as part of a birth plan. (See the later section on end-of-life care for additional information on feeding in actively dying children and withdrawal of MANH.)

Postmortem Care

Birth plans may address any discussions regarding autopsy (family education, family preferences, family concerns) and organ donation. As appropriate, the plans regarding funeral

or memorial services may also be included (such as preferred funeral home or religious needs regarding care of the body).

CASE STUDY 3: LISTENING TO THE INFANT'S BODY

Parents Lisa and Lindsay were counseled that their son, Brad, had a severe cardiac defect that was likely to lead to death shortly after birth. Given his cardiac physiology, the cardiac surgery team felt he was not a surgical candidate and would unlikely tolerate enteral feeds. His mothers felt it important to allow Brad to lead them in decision-making and also wanted to introduce him to his extended family if possible. They felt pursuing cardiac surgery was not in his best interest. The PP APRN prepared Lisa and Lindsay that Brad may not have the strength to breastfeed due to heart failure. Lisa gave birth to Brad at term, and an echocardiogram confirmed the prenatal cardiac diagnosis. Shortly after birth, Brad surprisingly showed interest in breastfeeding. With assistance from a lactation consultant, Brad latched and ate from the breast several times in his first 24 hours. He surprised the medical team and was discharged to home with hospice supports, continuing to breastfeed on demand.

Legacy-Making Activities

Legacy-making activities have been shown to provide benefit to families who experience fetal or infant loss.^{3,13} These may include keeping mementos such as lock of hair, identification band, crib card, and clothing and bedding. Parents may wish to take pictures of ultrasound findings, keep a monitoring strip from labor, or record the fetal or infant heartbeat. Some routine care elements may be adjusted to serve the palliative needs of the family. For example, taking length and head circumference measurements at the bedside may be a legacy-building activity with the measuring tape saved as a keepsake. Child life specialists may assist with mold-making of hands or feet, song-making, or recording memories of the pregnancy and infant in a journal.²⁹ Professional photography may also benefit parents as they grieve fetal or infant loss.³⁰ Organizations such as Now I Lay Me Down to Sleep (<https://www.nowilaymedowntosleep.org/>) offer these services through volunteer networks across the United States and internationally.³¹

Sibling Services

There are unique developmental considerations for siblings who are anticipating the birth of a brother or sister. The birth plan should include documentation of discussions regarding if siblings are expected to be present during or after a birth,³² what information the sibling has received,¹⁰ and context regarding their developmental and learning needs. The PP APRN should address logistical considerations, such as which adult will remain with the child and where they can safely eat and play during a hospitalization. Coordination with child life specialists, art therapists, or music therapists may be helpful in creating space for the sibling(s) to express

their feelings regarding the birth, regardless of the birth outcome and goals of care.²

COMMUNICATING THE BIRTH PLAN

The birth plan serves as a planning and communication tool. Each discussion regarding the birth plan may start with a brief synopsis of the family's understanding of illness/prognosis and their overarching values and goals of care. This helps to frame the decisions contained within the birth plan. It is important that the PP APRN ensure the birth plan has been shared with the involved delivery team and with supportive service providers (spiritual care providers, child life specialists, decedent affairs/patient relations) as appropriate. While birth plans for a planned healthy delivery are often written by parents, birth plans in the context of perinatal palliative care are most often written by healthcare providers to summarize discussions that occur with the family. Depending on the institution, this may be either documented in the medical record via a note or scanned in the electronic health record (EHR), where it can be referenced by all clinicians. Like any advance care plan, decision-makers can choose to deviate from this plan as the pregnancy and birth evolve.

SUPPORT OF HEALTHCARE PROVIDERS

A key role of the PP APRN is to provide both education and emotional support to other healthcare providers.^{2,33} Because of the evolving nature of perinatal palliative care and the variety of settings in which it is provided, many clinicians who encounter families may have unharnessed primary palliative care skills. The PP APRN should target education to obstetric, maternal fetal medicine, and neonatal clinicians including nurses, APRNs, and physicians. Providing educational offerings for other clinicians may also increase referrals to palliative care services and improve the care provided to families.³⁴

NEONATAL PALLIATIVE CARE

HISTORY

In 2003, the Institute of Medicine released the seminal report *When Children Die: Improving Palliative and End-of-Life Care for Children and Their Families*. This challenged healthcare providers to develop and implement practice guidelines for palliative, end-of-life, and bereavement care for infants, children, and their families.³⁵ From this report, the field of pediatric palliative care (including neonates) has dramatically evolved. Educational curriculum for APRNs has expanded to include pediatric APRN-specific End-of-Life Nursing Education Consortium (ELNEC) training³⁶ and specific certifications for perinatal/neonatal loss and pediatric palliative care.^{37,38} As the community of pediatric palliative care clinicians has grown, the needs of pediatric patients is more prominent in national discussions and policy documents regarding

palliative care. The NCP *Clinical Practice Guidelines* provide standards of care for all patients receiving palliative care including infants.²

CURRENT STATE

Despite advances in neonatal healthcare, about one-half of the deaths in children in the United States occur during the first year of life. In 2018, the infant mortality rate was 5.7 out of every 1,000 live births, resulting in more than 21,000 infant deaths.³⁹ The three leading causes of death in children under the age of 1 year include congenital malformations, low birth weight, and maternal complications.³⁹ Infants born prior to 32 weeks gestation have higher rates of morbidity and mortality, while those born very preterm (prior to 28 weeks gestation) have the highest rate of mortality, with a risk 186 times greater than an infant born full term.⁴⁰ Research demonstrates that palliative care consultation in the NICU increases psychosocial support for families and reduces the use of advanced life-prolonging technology at end of life.⁴¹ However, infants receive specialty palliative care consultation at very low rates despite comprising a large portion of deaths within children's hospitals.⁴²

CONSULT ETIQUETTE IN THE NICU

Despite improved outcomes for patients and acceptance by families, the role of palliative care in the NICU continues to be misunderstood in many institutions.⁴³ Some institutions have high rates of coordination, embedded NICU-specific palliative care teams, or clinicians dually trained in neonatology and palliative care. Other hospitals may have an adult palliative care service that occasionally consults in a community NICU. Because of the wide range of practices, the PP APRN needs to ensure humility as part of the consult process. Consult etiquette^{44,45} is of the utmost importance to growing the field of palliative care within the NICU setting. The scope of practice for palliative care in the NICU may be on a consultative basis, where recommendations are provided to the primary service. Unlike many adult ICU settings, even at end of life the primary NICU team may manage all medications and remain the conduit for information for the family. The PP APRN needs to carefully assess the institutional and unit-based norms regarding palliative care services and implement a “low and slow” approach to providing support in the NICU setting. The PP APRN should allow extra time to introduce themselves and the palliative care team to the primary NICU providers, including bedside nurses. This allows the APRN to establish rapport and trust with the NICU team and gather additional subjective information regarding the infant and family.

CARE OF THE INFANT

Much of symptom management for infants is similar in approach to children. Highlights of differences and areas of emerging emphasis in the neonatal population are noted. Please refer to Chapter 26, “The Pediatric Palliative APRN

in the Acute Care Setting,” for additional symptom management guidance.

Assessment

Careful assessment of infant experience is critical and should include pain,⁴⁶ dyspnea, delirium,⁴⁷ constipation, and vomiting.⁴⁸ The use of validated and reliable screening tools is strongly encouraged.² The infant's neurologic status, gestational age, and sedation status should be considered when selecting an appropriate measure because tools may be validated for different clinical scenarios. A list of symptom-specific tools is provided in the NCP *Clinical Practice Guidelines*, pediatric nursing textbooks, and herein.^{2,46,49}

Obtaining a history from the infant's caregivers, including parents, respiratory therapists, child life specialists, nurses, and physicians, is very important.² Consider the infant's patterns and rhythms during day and night when assessing symptoms. Knowledge of nap times, feeding times, and fussy times may provide insight into potential areas where quality of life may be improved. Infants may find comfort from familiar faces, voices, sounds, smells, and toys/stuffed animals. The PP APRN assesses which of these provides comfort to the infant and can implement comfort measures such as wrapping the infant in a blanket that has a parent's scent. Conversely, an overstimulating environment may cause infant distress. The PP APRN introduces neurologically appropriate environment (i.e., stimulation should match the infant's developmental needs) and provides education to the family and care team regarding the importance of sleep, rest, and routine. When assessing the infant for symptoms, observe the facial expressions, level of attention to faces, and responses to familiar sounds/voices as signs of behavior change.

Symptom Assessment and Management

Pain Assessment

The notion that infants do not feel pain has been proved incorrect.⁵⁰ Infants may experience pain throughout their lives, not just at end of life.^{51,52} Surviving infants who are repeatedly exposed to painful procedures in the NICU demonstrate hypersensitivity to pain in childhood. When caring and assessing for pain in the neonate, the APRN should be mindful of potential pain sources including procedures (e.g., needle sticks or endotracheal suctioning) and underlying conditions (e.g., central/neuropathic pain in severe neurologic impairment).^{53,54} The PP APRN should observe the infant's behaviors and assess the parental and bedside nursing's perceptions of pain.⁵³ Pain behaviors in infants include facial grimace, hiccups, yawning, furrowed brow, difficulty sucking or latching, inconsolability, irritability, alterations in level of activity, and crying.⁴⁶ Pain report by proxy, such as from a parent or nurse, can help in assessing the infant's comfort. Many parents become expert at interpreting their infant's cries and differentiating between cries of hunger versus discomfort.⁵⁵

An observational pain assessment tool that is validated in the specific neonatal or infant population should be utilized.

Many of these tools are multimodal assessments that take into account the infant's facial expressions, vital signs, and behavioral components.^{56–58} While hospitals and palliative care organizations may use specific tools in varying settings of care, it is important that the APRN not use a child or adult pain tool as these may under- or over-capture pain levels. In addition, some scales are validated in certain gestational ages (preterm vs. term infants) or based on pain types (acute pain vs. chronic pain vs. postoperative pain).⁵⁸ Examples of these tools include N-PASS,^{59,60} NIPS, COMFORT,⁵⁹ CRIES,⁶¹ FLACC,⁵³ and the Revised FLACC.^{46,55,62}

Pain Management

It is important to consider nonpharmacologic interventions with or without pharmacologic interventions.⁵⁶ Nonpharmacologic interventions should be continued even after pharmacologic interventions are initiated. Nonpharmacologic strategies can increase the parent–child bond and support normal infant development. Trial and error can be used to control the environment of care by reducing noxious stimuli (bright lights, noise, unnecessary touch).^{46,57} Audio recordings can be played of a parent's voice or favorite lullaby even when the family is not present at the infant's bedside. Swaddling, massage, breastfeeding, and non-nutritive sucking are interventions that may reduce the experience of pain in infants.⁶² Skin-to-skin care is now routinely offered in NICU settings as it has been shown to reduce pain in infants.⁶³ Parents also report that, at the end of life, holding their child skin-to-skin can be a positive experience for both infant and parent. The PP APRN should advocate for opportunities for parent–child bonding at end of life should the family desire.^{56,64} Of note, not all families desire to hold their child at end of life. The PP APRN should assess for educational needs (i.e., parental fear of hurting their child or hastening their child's death) and cultural considerations. Families should not be forced to hold their infants at end of life.

When considering pharmacological interventions for pain, dosing is important (see Appendix II for suggested medication dosing). Of note, opioids can be safely used in the neonatal population for the management of both pain and dyspnea. Due to their immature metabolism, neonates and infants are at higher risk for respiratory depression from opioids.⁶⁵ Therefore, opioids are dosed much lower in this population than for children. Starting morphine doses for pain are typically 25–35% of pediatric dosing, with longer dosing intervals due to delayed elimination and significantly prolonged half-life compared to children and adults.^{65,66} Depending on the severity of symptoms, either intermittent dosing or continuous infusions can be reasonable for administration.⁵⁶ Often morphine is the chosen opioid given its longer half-life than fentanyl.⁵⁶

Dyspnea

Prevalence and Assessment

Subjective assessment by proxy (parent or clinician report) can assist in the identification of dyspnea. Infants experiencing breathlessness may appear restless, have paradoxical breathing, grunting, bob their head, have asynchronous breaths over

a ventilator, nasal flaring, or exhibit facial expressions that imply distress.⁶⁷ Vital sign changes including tachycardia and tachypnea should also be considered. While there are currently no valid and reliable measures of dyspnea in the neonatal population, a modified version of the Respiratory Distress Observation Scale is under development for infants.⁶⁷

Management

The PP APRN should assess for dyspnea in all neonates given the high rates of pulmonary compromise in this population. Extra attention should be given to frequent assessment in the neonate at end of life.⁵⁶ Decreasing intravenous or enteral fluid supplementation may be considered as a way to reduce dyspnea caused by fluid overload at end of life. In the neonate, even seemingly miniscule fluid volumes can add to symptom burden. Depending on institutional pharmacy offerings, some intravenous medications can be prepared in more concentrated forms to allow for smaller volumes of fluid to be administered. Additional nonpharmacologic therapies include positioning for comfort (sidelying or elevated head of isolate) or having a fan or blow-by humidified air on the face. In addition to the management of pain, opioids can be used to treat dyspnea in the neonate at 25–50% of the dose used for pain.⁶⁵ While benzodiazepines can be used to mitigate agitation, it should be noted that they alone do not treat dyspnea.⁵⁶

Delirium

Delirium is the acute change in sensorium with changes to level of consciousness and ability to sustain attention. In the neonatal population this may manifest as psychomotor agitation or retardation.⁴⁷ In recent years the acknowledgment of delirium in infants has been more widely recognized. Among all hospitalized children, those under 2 years, critically ill, or requiring mechanical ventilation are at highest risk to develop delirium.^{47,68} Since many NICU patients meet all three of these high-risk criteria, the PP APRN should be alert to the possible emergence of delirium.

Assessment

For delirium in infants, it is important that the PP APRN interview both parents and caregivers (nursing, respiratory therapists, physicians, child life specialists, physical therapists) to identify patterns of behavior, preferred activities, and agitation triggers. The Cornell Assessment of Pediatric Delirium (CAPD) has been validated for infants and incorporates longitudinal measurements of behaviors and interactions over an 8- to 12-hour period.^{47,68} The Preschool Confusion Assessment Method for the ICU (psCAM-ICU) is also validated in this population.⁶⁹ In addition to the use of standardized tools, the APRN should personally assess the child, including watching for ventilatory synchrony, as delirium can be precipitated by dyspnea from uncomfortable vent settings.

Management

Nonpharmacologic management focuses on environmental changes and evaluation of precipitating factors. The PP

APRN should ensure that the infant has a warm, comfortable environment with reduction in overstimulating noise. Daily routines should be developed in consultation with the family, bedside nursing, and child life specialists. These routines may include feedings, nap time, play time, and bath time. Lighting should be used to help cue the infant to day–night differentiation. Clutter in the infant’s crib and room should be reduced, and blinking lights or monitor noises minimized as possible.⁵⁵ The PP APRN should educate the NICU team regarding the importance of routine and consider posting signs with the infant’s schedule at the bedside. Effective treatment of delirium also includes addressing the potential root causes, including uncontrolled pain or infection.⁶⁸ The mnemonic “I WATCH DEATH”^{70,71} can be used to recall the conditions that may precipitate delirium: infection, withdrawal from substances, acute metabolic conditions, trauma, central nervous system etiology, hypoxia, deficiencies of vitamins or hormones, endocrinopathies, acute vascular changes, toxicities, and heavy metals.^{70,71}

While concurrently addressing and assessing the cause, the PP APRN should consider pharmacological interventions for which the literature supports using antipsychotics as first-line pharmacological management. Second-generation antipsychotics can be used effectively in infants.⁴⁷ Refer to Appendix I “Pediatric Pain and Symptom Management” for dosing guidelines.

CARE OF THE FAMILY

In addition to the strategies described in Chapter 26, “The Pediatric Palliative APRN in the Acute Care Setting,” there are unique psychoemotional considerations for families with a baby in the NICU. Postpartum birthing persons may need additional support. The PP APRN must use language that supports the developing infant–parent relationship because many have difficulty bonding with their ill infant as a result of anxiety or depression.⁷² Coordination with social work, chaplaincy, obstetrics, psychology, and psychiatry is indicated as needed for assessment and treatment of postpartum mood disorders. Routine meetings between the family, palliative care team, and primary team are encouraged to establish and maintain collaborative communication.

LEGACY-MAKING IN THE NICU

Legacy-making may be an integrated component of family life for the infant with a prolonged NICU stay or those with life-threatening illness. Normal developmental milestones may be celebrated by the family and care team. Research shows that legacy projects, such as digital story-telling, hand/foot molds, and photography, are acceptable to many parents during the course of the NICU stay.⁷³ The PP APRN can encourage these activities regardless of goals of care. Allowing parents the opportunity to engage in memory-making, whether it is photography, dressing their infant in a special outfit, or making handprints/molds allows parents to feel more connected to their child while alive and after

death.⁷⁴ The PP APRN should work with other members of the healthcare team (social work, child life, nursing) to facilitate this legacy work. Coordinating the visits of extended family and siblings may be important. In the case study about Charlie, Kristen and Antonio initially did not wish for their daughter to meet Charlie. Once he was born, they later felt it was important and appreciated their time together as a family unit.

SIBLING SUPPORT

Siblings of NICU patients have unique needs related to developmental processing, grief, and bereavement. Visiting the baby in the NICU before death should be encouraged because this is associated with reduced anxiety and depression among surviving siblings.⁷⁵ Consultation with child life specialists and hospital-based school teachers, when available within the organization, are encouraged. See Chapter 38, “Grief and Bereavement,” for additional guidance on developmentally appropriate responses to grief in children.

COMMUNITY RESOURCES

In addition to sibling support and coordinating legacy work, the PP APRN should offer and coordinate referrals to community resources. Some organizations, such as Courageous Parents Network, may be appropriate for referral early in an illness or hospitalization. Courageous Parents Network was created by bereaved parents with the support of pediatric palliative care professionals to provide information on medical decision-making and life in the NICU.⁷⁶ Other resources may include a local March of Dimes chapter, disease-specific advocacy and support groups, or local parent networks.

CARE OF THE NICU TEAM

Because no infant remains in the NICU, transitions are a natural part of caring for critically ill neonates. Transitions include transfer to another unit (such as pediatric ICU or long-term ventilator unit), discharge to a skilled pediatric nursing facility, discharge to home (with or without home-based palliative supports), and death.

The PP APRN has a unique viewpoint on caring for children across care settings. It is important that future planning is integrated into the care plan by encouraging the primary healthcare team to anticipate future care needs, complications, or outcomes. The PP APRN can hold the “big picture,” allowing the primary care team to navigate the day-to-day illness management. Transitions may be challenging for NICU providers who may feel that transferring an infant equates to professional failure. Providers may also believe the infant or family needs to stay in the NICU because another care setting would not meet the same quality standards. Rarely are such decisions simple or clear-cut. The PP APRN should acknowledge and support the anticipatory grief and loss experienced by parents and the healthcare team prior to the actual transition of care.

MORAL INJURY AND BURNOUT

Moral distress and burnout are common among NICU nurses and physicians.⁷⁷ The PP APRN role includes identifying and addressing sources of distress for the care team. This distress may extend to custodial staff, unit clerks, and food service workers who have frequent interactions with the families of seriously ill infants. Skills used by the PP APRN with patients and families (such as active listening and attending to grief experiences) may also be employed to address staff distress and burnout.³³

Disagreements regarding goals of care and decisions along the treatment course may be a source of distress for parents and clinicians alike. When disagreement occurs, the PP APRN should facilitate a discussion of thoughts and feelings while holding space for grief among all stakeholders. Clinicians need to be aware of how their personal values and opinions can influence how they are providing care for others. The PP APRN should model critical self-reflection for other clinicians and help create a space where psychological safety is the norm. See Chapter 53, “Navigating Ethical Discussions” for additional content.

END-OF-LIFE CARE

FEEDING

Feeding by mouth at end of life may include breast feeding or feeding by bottle with formula or expressed milk. A dropper of expressed breast milk may also be used to moisten an infant’s mouth. For infants able to feed orally, feeding the infant may provide comfort to both child and family, especially when included in skin-to-skin care. The PP APRN should continue to assess for symptoms at end of life related to oral feeding such as gagging, dyspnea, vomiting, and constipation.

MEDICALLY ADMINISTERED NUTRITION AND HYDRATION

In rare situations, withdrawal of MANH may best align with goals of care and improve the infant’s comfort. The PP APRN should proactively facilitate consultation with pediatric bioethicists regarding the use of MANH at end of life, with the goal of supporting parental decision-making and educating the clinical team on ethically and legally permissible actions. Current ethical guidance from the American Academy of Pediatrics Committee on Bioethics indicates there are limited circumstances in which discontinuation of MANH may be ethically permissible in the care of infants.⁷⁸ It is important that the PP APRN be familiar with and adhere to local, state, and institutional laws and policies pertaining to the initiation, withholding, and discontinuing of MANH in infants and children.⁷⁹

Of note, parents of infants and children who died after withdrawal of MANH have reported satisfaction with their decision.⁸⁰ Furthermore, parents may feel that their children

received good quality end-of-life care, with time to hold their child and make memories together.⁴¹ Infants may live days to weeks after withdrawal of MANH, with one observational study finding an infant lived 37 days.⁸¹ Special attention should be provided to the infant’s skin during this time as pressure sores may occur over bony prominences due to limited subcutaneous fat. It is imperative that the PP APRN develop a plan to consistently support the family and health-care staff during the time after withdrawal of MANH, as this time period can be a source of moral distress for some.

ROLE OF THE PEDIATRIC PALLIATIVE APRN IN END-OF-LIFE CARE

Provide Assessment, Diagnosis, and Management of Symptoms

A primary role of the PP APRN when caring for an infant at end of life is to assess and diagnose symptoms. As discussed in the preceding section on “Consult Etiquette in the NICU,” the PP APRN may or may not directly manage medications depending on institutional policies and unit culture. The PP APRN may instead provide recommendations to the NICU service.

Family Counseling

When an infant is nearing end of life, the PP APRN should consider the educational and psychosocial needs of the family. Bereaved parents have shared that their child experiencing symptoms at the end-of-life was very distressing to them, especially after decisions around withdrawal of life-sustaining therapies were made.^{74,82} Parents have shared that their most distressing symptoms witnessed in their infant were respiratory distress, agitation, and pain.⁸² PP APRNs should provide education to the family on the anticipated course of the dying process and how the family can play an active role in providing care. For example, parents who elected to focus on their child’s comfort have shared their appreciation for the opportunity to provide skin-to-skin care and feedings.^{57,83,84}

The PP APRN supports parents by providing anticipatory guidance of the signs and symptoms of dying, how their child may appear, and the management of distressing symptoms. This helps to ensure parents that all measures are being taken to ensure the infant’s comfort.⁸² While counseling on symptom management and physiologic changes are important to discuss with parents, parents have also shared the importance of support for legacy work and bereavement during and after the infant has died.^{74,85} The PP APRN can provide guidance to the family regarding ways to create memories in the time left and how the family can anticipate being supported after the death. The PP APRN should work with the NICU team to address which team members will provide education to the family to avoid the family from being overwhelmed by repetitive information. In some cases, the NICU team may want to be present while the PP APRN provides end-of-life counseling to the family.

Coordinating with the Nursing Team

During the time that an infant may be dying, it is crucial to partner with the infant's bedside nursing team. The bedside nurse can help to facilitate nonpharmacologic measures as well as pharmacologic measures to ensure the child's comfort. The role of the PP APRN includes supporting the bedside nurses and nursing leadership. This may include creating a safe space for the nurses to ask questions regarding end-of-life care or addressing concerns around how the family has made decisions regarding goals of care. As part of capacity-building in the NICU, the PP APRN should identify NICU nurse "champions" who are interested and experienced in providing palliative care. These nurses can be advocates for palliative care in the unit⁹ and provide additional support to more novice nurses. The PP APRN should round frequently on the nursing staff to reinforce the plan of care and offer additional grief support as needed.³³

Coordinating Location of Death

In addition to symptom management, parents have shared that the environment in which they are in can be very important. Offering parents the ability to be in a private room may change their experience of their child's death. If parents would like to be at home, the palliative care team can coordinate with hospices to provide end-of-life care in the home when possible.⁷⁴ Before this is offered to the family, the PP APRN should consult with local hospices to assess their prior experiences in with caring for an infant at end of life as not all hospices accept infants into their care. Infants with complex symptom management needs (including intravenous medications) or receiving concurrent care may be challenging to place with a home hospice agency if there are no nurses with infant or pediatric experience available. The PP APRN should review all planned treatments, medications, and care instructions with the hospice prior to discharge to ensure that the hospice has a full picture of the family's needs.

Educating and Supporting NICU Team

A significant amount of time may be spent by the PP APRN providing education and support to the NICU team. NICU providers may have curiosity about the pathophysiology of the dying process, concerns regarding the range of parental decision-making, and questions about bereavement support for the family. The PP APRN should elicit and anticipate opportunities to provide just-in-time education to the NICU team. Other support of the NICU team should include assessing the grief and anticipatory bereavement needs of the staff. Clinicians may feel shame or guilt that their patient won't survive and may feel a sense of loss and grief while observing an infant at end of life. The PP APRN should normalize these feelings, create a safe space for clinicians to express vulnerability, and provide grief support to the NICU clinicians.

BEREAVEMENT

Bereavement care is a core component of palliative care, and is discussed in depth in Chapter 38, "Grief and Bereavement."² Parents have shared the importance of connecting with bereavement support both prior to the loss of their child and thereafter. This is accomplished by a follow-up phone call by any member of the team because it allows parents to feel connected to their team and may help to prevent any sense of abandonment that bereaved parents have experienced.⁸⁵ Sending a bereavement card, sharing memories of the child, and communicating to parents that their child was not forgotten is generally welcomed.^{64,74} The PP APRN should provide bereavement support to the family and refer them to hospital- or community-based bereavement services.² This may include grief and loss counselors, hospice-based bereavement programs, support groups for parents of children with special needs, and camps for parents or siblings who have had a loss.

SUMMARY

Families facing the birth, life, or death of their fetus or infant have unique needs and require expert support from the PP APRN. Care of the whole family, from diagnosis onward, may occur in multiple care settings and with a variety of healthcare providers. The PP APRN is in a unique position to support the family across this trajectory, holding the family narrative, values, and goals as the pregnancy and infant evolve. It is also imperative that the PP APRN provide support to other healthcare providers who may experience moral distress as a result of facing scenarios that may be emotionally triggering or challenge one's personal beliefs.

THE PEDIATRIC PALLIATIVE APRN IN THE CLINIC

Alice Bass and Vanessa Battista

KEY POINTS

- Pediatric palliative care (PPC) should exist in multiple care settings to provide continuity and support to children and adolescents and their families.
- Three main models exist for delivering PPC in the outpatient setting: consultative, co-management (embedded), and primary care (medical home).
- The pediatric palliative advanced practice registered nurse (PP APRN) plays a vital role in promoting, modeling, and providing PPC in the ambulatory setting in collaboration with other care teams.
- Specialty pediatric providers face unique challenges in the management of distressing symptoms for specific disease subsets as well as communication around goals of care and medical decision-making, particularly with advancing technology.
- Specialized PPC in outpatient clinic settings widens access to physical, psychosocial, and spiritual support for children suffering from serious illness and their families.
- Similar to inpatient programs, common barriers to ambulatory PPC include misperceptions about PPC only being appropriate at end of life, fears of “giving up” or abandonment, and discomfort around pediatric advance care planning or goals of care discussions.

follow-along for support, symptom management, and goals-of-care discussions. The pediatric palliative advanced practice registered nurse (PP APRN), Ted, discussed Meg who was concerned for overall very poor prognosis, specifically due to concern for evident neurological deterioration.

Ted met with Meg’s mother during a routine oncology clinic appointment. He introduced with the concept of palliative care as an additional support for Meg and the family. He discussed how PPC helped with pain and symptom management and care coordination. The PPC team could assist with defining goals of care to ensure they matched the family’s values and definition of a good quality of life. Meg’s mother was receptive and easy to engage, processing initial events leading up to Meg’s current clinical state. She described how the disease has impacted the family’s grief because Meg was a little girl who loved to play with her older sister and enjoyed family dinners and travel. The mother openly processed feelings around all of the barriers that Meg was up against and discussed feelings about suffering and how “perhaps Meg would suffer less if she would die suddenly,” rather than how they now found themselves in a situation where they must watch her slowly decline. Meg’s mother was able to recognize the value of having discussions around advance care planning, and a plan was made to continue to follow Meg at future clinic appointments.

CASE STUDY: PROGRESSIVE DECLINE IN A PEDIATRIC PATIENT

Meg was a 7-year-old girl who was diagnosed 18 months prior at an outside hospital with pre-B acute lymphoblastic leukemia. Six months following her initial diagnosis, Meg began to show signs of progressive encephalopathy and neurologic decline of unclear etiology. Her parents noticed behavioral changes that progressed to changes in speech and memory. Later, these progressed to difficulty swallowing and regression of fine motor skills. Repeat magnetic resonance imaging of the brain showed worsening global infarcts. Extensive infectious and diagnostic workup was negative or otherwise inconclusive.

In the following months, Meg continued to have worsening symptoms, and her family transitioned care to another institution in hopes of getting better answers about the cause of her symptoms. A referral was made by Meg’s new oncologist to the pediatric palliative care (PPC) team to introduce services and

INTRODUCTION

Pediatric palliative care (PPC) is a unique holistic approach to caring for children and adolescents living with life-threatening illnesses and their families. PPC is aimed at improving quality of life. Because the needs of children and adolescents differ in some ways from those of adults receiving palliative care, the definition of PPC reflects these principles. (*Note:* For simplicity, the term “child” will be used to include both children and adolescents.) The World Health Organization (WHO) defines PPC as “the active total care of the child’s body, mind, and spirit, and also involves giving support to the family.”¹ It ideally begins at the time of diagnosis yet is appropriate at any stage in a serious illness based on children’s needs and not their prognosis.^{1,2} PPC includes the evaluation and alleviation of physical, psychological, social, and spiritual distress whether or not a child receives disease-directed treatment.^{1,2} PPC requires an interdisciplinary approach, includes the use of community resources, and is designed to be provided in multiple settings including hospitals, tertiary care centers, community health centers, and children’s homes.²

The National Consensus Project for Quality Palliative Care (NCP) *Clinical Practice Guidelines* state that palliative care principles and practices can be integrated into any healthcare setting and delivered by all interdisciplinary clinicians and specialists with the appropriate professional qualifications, education, training, and support required to deliver optimal patient- and family-centered care.² For children, PPC should be tailored to their developmental status and disease understanding, as well as parental or familiar preferences for care, which should be assessed at the initial visit and revisited continually throughout the trajectory of care.² The NCP *Clinical Practice Guidelines* support the delivery of palliative care in multiple settings including acute and long-term care hospitals and facilities, rehabilitation centers (which includes settings for children as well), clinic settings, inpatient hospice settings, homes, correctional facilities, and homeless shelters.² The focus of this chapter is on the unique aspects of delivering high-quality PPC in ambulatory clinic settings.

THE ROLE OF THE PPC APRN

The pediatric palliative advanced practice registered nurse (PP APRN) plays a vital role in promoting, modeling, and providing PPC for children facing acute or chronic life-threatening illness in the outpatient or clinic setting, working closely with trusted members of the primary team caring for the child or adolescent. The PP APRN conducts visits independently or together with other specialty providers, recommends and/or prescribes medications to promote comfort and quality of life, and communicates compassionately with families regarding prognosis, treatment decisions, and advance care planning (ACP).³ These discussions are often difficult for not only families but also providers due to prognostic uncertainty, emotional or moral distress, lack of comfort, and lack of confidence or preparedness for having these discussions.⁴ PP APRNs are trained in effective verbal and nonverbal communication strategies and prepared to utilize best practice communication tools to promote open and empathic communication between other providers and families.⁵ Their understanding of children's views of illness and perceptions of death is a crucial concept for providing high-quality PPC. PP APRNs' knowledge not only directly impacts the children and families for whom they care, but also influences existing knowledge gaps or barriers through education about palliative care principles and skills for interdisciplinary colleagues. Involvement of specialized PPC providers has revealed improved communication and decision-making, which both enhances the care provided to families and reduces moral distress in healthcare providers.⁶

In addition to engaging in communication, the PP APRN actively manages distressing symptoms for children receiving PPC and supports families in navigating the complex path beginning at diagnosis, through treatment, amid shifts in goals of care, to end of life and beyond.³ Support has different meanings for children and families in various stages of care. Therefore, the PP APRN is skilled in supporting the unique needs of children and families, each in their individual journeys. They develop and advocate for patient-centered

Box 28.1 THE ROLE OF THE PEDIATRIC PALLIATIVE APRN IN THE CLINIC SETTING

- Provides, promotes, and models PPC independently and with the primary team
- Promotes strategies and resources to support optimal comfort and family-centered quality of life
- Communicates with families about prognosis, goals of care, and advance care planning
- Assesses, diagnoses, and manages physical and psychological symptoms
- Provides decision-making support
- Facilitates communication between families and interdisciplinary care teams
- Coordinates and prioritizes care
- Provides continuity of care between ambulatory and inpatient settings
- Provides education for interdisciplinary colleagues about PC principles and skills

and family-focused goals and promoting family-defined quality of life.² An essential skill is the assessment, diagnoses, and management of burdensome physical and psychological symptoms to promote optimal comfort. In collaboration with families and interdisciplinary colleagues, PP APRNs provide decision-making support when families are faced with challenging choices. They facilitate communication between families and care teams, eliciting treatment goals and coordinating care across the scale.³ Because children receiving PPC in the ambulatory setting may be hospitalized, the PP APRN serves as continuity for families and providers between ambulatory clinic and inpatient settings. Box 28.1 summarizes the role of the PP APRN in the ambulatory clinic setting.

THE NEED FOR PPC IN AMBULATORY SETTINGS

The American Academy of Pediatrics' Section on Hospice and Palliative Medicine advocates for PPC providers to work toward ensuring care that is high quality, readily accessible, and equitable across all settings.⁷ Most PPC services occur within the inpatient setting, with only about 60% of these programs offering services in some type of ambulatory setting.⁸ In concordance with the philosophy of palliative care, PPC delivery should traverse care settings to ensure support to families throughout the child's life span. This includes ambulatory clinics, in which children and families receive comprehensive care and longitudinal support through follow-up visits and crucial conversations. Outpatient teams specializing in pediatric oncology, cardiology, pulmonology, neonatology, genetics, neurology, and other specialties encounter children experiencing disease progression, with pain and

other distressing symptoms, who need of specialized management. Lack of education and training is a consistent barrier to provision of high-quality PPC for children and families.^{9,10} The PP APRN's presence in ambulatory clinics, in collaboration with primary teams, bridges these gaps to promote quality of life for children and their families. The ambulatory PP APRN in a clinical setting incorporates PPC principles to assess, diagnose, and manage symptoms; collaborate in defining children's and families' goals of care; and coordinate with interdisciplinary care teams and services to meet these unique needs holistically.

SPECIAL POPULATIONS

To determine which children may benefit most from PPC, *A Guide to the Development of Children's Palliative Care Services*, a 2009 sentinel report, is used to classify disease categories within broad definitions and classification.¹¹ The PP APRN is mindful of the unique characteristics of these disease classifications and specific clinic populations when approaching primary teams and families. The first category includes children or adolescents with a diagnosis or condition where cure is possible, but there is a risk for failure (e.g., cancer, congenital heart disease, or reversible organ failure).¹¹ The second category includes children with a near certain premature death, but for whom treatments exist to considerably prolong life and improve quality of life (e.g., cystic fibrosis or Duchenne muscular dystrophy).¹¹ It should be noted, however, that the landscape is changing dramatically for some of these diagnoses with the advent of technology and treatment since the report was published.¹¹ The third category is children with progressive disorders for which there is no cure or disease-directed therapy available.¹¹ Within this group, interventions are largely focused on management of sequelae rather than attempts to reverse or halt progression (e.g., Batten's disease or spinal muscular atrophy).¹¹ Diseases that once easily fell into this category are slowly shifting into the second category with new available therapies (including gene replacement therapy) aimed at slowing or halting disease

progression.¹² The fourth and final category involves children with neurological conditions whose underlying injuries are not expected to progress; however, their conditions result in significant medical complexities and leave them at very high risk for acute or unexpected life-threatening episodes (e.g., hypoxic ischemic encephalopathy or cerebral dysgenesis).^{11,12} See Table 28.1 for a summary of illness categories that may warrant the need for PPC. Clinical acumen is vital, as is a working knowledge of the special challenges that clinicians and families may face when discussing goals of care within each disease category. Table 28.2 summarizes some specialty areas where PPC referrals may be beneficial in the ambulatory setting, as well as some of the common symptoms to consider.

CARDIOLOGY

A variety of cardiac anomalies inherently warrant the philosophy of PPC as part of disease management, including routine PPC involvement in the ambulatory setting. Single ventricle congenital heart defects (SVCHD) occur when a lower cardiac chamber or valve of the heart is underdeveloped or missing.¹³ The highest risk of early mortality occurs within the first year of life, but risk remains present throughout the life span, with only 70% of children with SVCHD surviving to age 20 despite surgical palliation. It is recommended that PPC be introduced to these children and families early and routinely so that there is opportunity to establish a therapeutic relationship and provide continuity of support through the journey.¹³ For SVCHD, children are followed closely in cardiology clinic settings during interstage periods and beyond, and there are opportunities for the PP APRN to provide symptom management, anticipatory grief support, and discussions around ACP.

Another area where PPC may be helpful in the ambulatory setting is for children with progressive heart failure and those being evaluated for heart transplantation. Centers for Medicare and Medicaid Services (CMS) and the Joint Commission (TJC) require inclusion of palliative care for those patients pursuing ventricular assist device (VAD) as

Table 28.1 SUMMARY OF ILLNESS CATEGORIES THAT TRIGGER PEDIATRIC PALLIATIVE CARE INVOLVEMENT

CATEGORY	DESCRIPTION	EXAMPLE DIAGNOSES/DISEASE CATEGORIES
1	Cure is possible, but there is significant risk of failure	Cancer
2	Premature death is expected, but treatments exist to considerably prolong life and increase quality of life	Cystic fibrosis, Duchenne muscular dystrophy
3	Progressive disorders without available disease directed therapy or cure with interventions largely focused on management of sequelae	Infantile Tay Sach's disease, Aicardi syndrome
4	Neurological conditions whose underlying injuries are not necessarily progressive but remain static. However, their conditions result in significant medical complexities and leave them at very high risk for acute or unexpected life-threatening episodes	Hypoxic ischemic encephalopathy, cerebral dysgenesis

From Chambers et al.¹¹

Table 28.2 PEDIATRIC PALLIATIVE CARE SPECIALTY AREAS AND COMMON SYMPTOMS TO CONSIDER

POPULATION	SPECIAL CONSIDERATIONS IN ASSESSMENT
Cardiology	Symptom management Anorexia/Cachexia Cough Dyspnea Nausea/vomiting Feeding intolerance due to gut ischemia Fluid overload Pain management Chronic Procedural Decision-making support Bridge therapies Transplant Advance care planning
Complex care	Symptom management Agitation Dyspnea Feeding intolerance Musculoskeletal pain due to weakness and contractures Neuroirritability Pain management Neuropathic Procedural Visceral Advance care planning Anticipatory grief Decision-making support
Neurology	Symptom management Agitation Attention deficit/Hyperactivity Anxiety Constipation Dyspnea/Respiratory failure Musculoskeletal pain due to weakness and contractures Neuroirritability Weight gain or loss Pain management Neuropathic Procedural Visceral Advance care planning Anticipatory grief Decision-making support
Oncology	Symptom management Anorexia/Cachexia Anxiety Bone pain Chemotherapy toxicity Constipation Depression Dyspnea Graft versus host disease (GVHD) Pain management Neuropathic Procedural Visceral Advance care planning Decision-making support Disease-specific Treatment-/procedure-related

Table 28.2 CONTINUED

POPULATION	SPECIAL CONSIDERATIONS IN ASSESSMENT
Pulmonary	Symptom management Anorexia/Cachexia Cough Dyspnea Nausea/vomiting Fluid overload Morning headaches Respiratory failure Shortness of breath Pain management Chronic Procedural Advance care planning Decision-making support Noninvasive positive pressure ventilation (NIPPV) (e.g., BiPAP, CPAP) Tracheostomy and/or ventilation

destination therapy or bridge-to-transplant.¹⁴ Some PPC programs have incorporated automatic “trigger” PPC consultation into their standard of care for transplant workup,^{15,16} and, in many cases, evaluation occurs in the ambulatory setting. The PP APRN not only participates in meeting these children and families to assess their understanding of illness trajectory and elicit goals of care, but also provides continuity throughout their course regardless of outcome.

Management of children with cardiac conditions should always include assessment for ischemia and fluid overload issues, which are common and may negatively impact quality of life, as do anorexia, cachexia, cough, dyspnea, nausea, vomiting, and feeding intolerance (Table 28.2). Treatment plans should be approached in an interdisciplinary fashion, consistent with the family’s goals of care, focused on alleviation of symptoms or addressing the underlying disease. Pharmacological management of many of these symptoms can be found in the tables of Appendix II.

COMPLEX CARE

Children cared for in the complex care setting strongly benefit from a team of providers who are well-versed in complex, chronic conditions, and these children often require a high degree of care coordination to ensure that care fragmentation is minimized. Communication is a priority as multiple specialties are often involved to address a variety of issues and body systems. A primary care provider specializing in complex healthcare may serve as the child’s medical home and should include a multidisciplinary approach to care. The work of PPC is valuable in this arena and often overlaps with complex healthcare services as an adjunct to the coordinated family-centered care that already exists. The PPC assists with symptom management and ensures that families’ goals and values are at the forefront of decision-making conversations around treatment options and quality of life.

The population of children often seen in this setting are those who have a condition secondary to static encephalopathy such as hypoxic ischemic injury or congenital brain dysgenesis. While their underlying condition may not be expected to worsen, they are extremely medically fragile and vulnerable to severe complications.¹² The PP APRN provides expertise in pain and symptom management, which commonly focuses on musculoskeletal pain due to weakness and contractures. Procedural, visceral, and neuropathic pain are also common in this population.¹² Challenges to treating symptoms in this population may be related to chronic underlying issues that often require long-standing pain management; assessment of pain and response to interventions is also more challenging due to a large portion of this population being nonverbal or neurologically impaired.¹² Other concerning symptoms involve respiratory issues such as dyspnea or airway obstruction, secretion management, seizures, temperature instability, and/or feeding intolerance.¹²

ONCOLOGY

Given that PPC was initially rooted in oncology, palliative care may be considered more routine in oncologic disease management, especially with certain diagnoses such as bone marrow transplant, certain brain tumors, and rhabdomyosarcoma. The role of the PP APRN in the ambulatory oncology setting is paramount to managing symptoms and navigating goals-of-care conversations during visits as well as longitudinally between visits. The PP APRN frequently partners with the oncology APRN or oncologist to provide maximal support to children and families. For more detailed information on providing PPC in oncology settings, see Chapter 29, “The Pediatric Palliative APRN in Oncology.”

PERINATAL

Perinatal palliative care consultation occurs most often in the ambulatory setting, and special consideration should be paid to this population. The PP APRN helps expecting parents develop a palliative birth plan to convey their wishes for their child’s birth and the care they want their child to receive. It is important to ensure that appropriate supports are in place for the expectant family, birthing parent, and fetus. Early integration of palliative care in the antenatal period can contribute to parental understanding of the disease trajectory, expected outcomes, care options, and associated benefits versus burdens. This ensures that APRNs caring for the birthing parent and fetal dyad best understand the goals, hopes, worries, and definitions of unique acceptable outcomes for each family.¹⁷ Assessment of cultural and spiritual needs before birth may help clinicians and families better formulate a birth plan that meets families’ goals in a manner that extends beyond the physical care of the newborn.¹⁷ For more detailed information on providing PPC in perinatal populations, see Chapter 27, “The Pediatric Palliative APRN in Perinatal and Neonatal Care.”

Optimal PPC spans the continuum of care settings and should include primary care, hospitals, and the community.¹⁸ Pediatric primary care providers play an important role near end of life. More than 90% of children in the United States have a primary care provider, and thus they can be a key referral source in identifying PPC needs in children with serious illness.¹⁹ Many primary palliative care needs can be met by primary care providers who have the right tools and knowledge to provide this approach to care. As defined in the NCP guidelines, primary palliative care is “Palliative care that is delivered by health care professionals who are not palliative care specialists, such as primary care clinicians; physicians who are disease-oriented specialists (such as oncologists and cardiologists); and nurses, social workers, pharmacists, chaplains, and others who care for this population but are not certified in palliative care.”² The primary care provider often has built a foundation of trust, support, and guidance with a child and the family and thus often fosters an ideal space in which to incorporate PPC principles. Primary care providers are not only a source of continuity for a family, but also a space where bereft parents may return for the care of other children or for bereavement support.²⁰ With the growing demand for PPC and a shortage of specialty PPC providers, pediatric primary care providers can fill primary PPC needs that cannot always be met by specialty PPC providers.

The NCP *Clinical Practice Guidelines* describe how all providers should promote effective transitions of care between settings.² There is benefit to improving and maintaining lines of communication between PPC providers and pediatric primary care providers because children may rely on their primary care providers following a life-altering hospitalization or diagnosis; in practice, however, inpatient PPC communication with primary care providers is often lacking.²¹ Recommendations exist to improve communication between PPC teams and primary care providers with the transmission of written PPC plans to primary care providers following hospitalizations.²¹ When feasible, delivering PPC within the primary care setting can help to directly bridge communication gaps, identify outpatient needs, and provide greater continuity of PPC. Not only are follow-up primary care provider visits after inpatient PPC services appropriate, but primary care providers may place new referrals to PPC for children with more refractory symptoms or who require complex decision-making that calls upon the expertise of specialty providers such as the PP APRN.²⁰

Evidence also suggests that primary care providers might not be as likely to discuss the changing landscape of children’s medical needs with progression, have less experience in pediatric ACP (pACP) conversations, and may not be as knowledgeable about home-based palliative or hospice resources in the community compared to providers who deliver primary care across the life span.¹⁹ Integration of PPC can serve to enhance the family’s medical home as well as encourage and augment primary palliative care skills for the primary care provider.

REFERRALS

Referrals to ambulatory PPC involve several organizational considerations, including who can make referrals, clinic space, workflow, availability of PPC providers, and specialty care or institutional psychosocial supports. If the PPC clinic is part of a hospital system, the PPC team may be subdivided into two teams: one that responds to inpatient referrals and another that responds to outpatient, ambulatory, or clinic referrals. Creating a referral base for ambulatory clinics requires time and effort on the part of the PPC team. The PP APRN develops relationships with referring providers by offering to provide primary PPC education to clinic providers and staff as well as participate in interdisciplinary clinic rounds. There should be collaboration between PPC teams and referring clinic teams to help identify children and families that would be served best by a PPC presence in the ambulatory setting.²²

Referrals for ambulatory PPC may be requested for a number of reasons. Referring teams may seek PPC expertise related to decision-making, pain or symptom management, anticipatory grief support, and ACP, as well as information around community-based supports (i.e., home-based palliative programs or hospice). Thus, the first task is to determine the purpose or reason for the consult. It is imperative that communication occurs between the referring team and PPC team so that there is understanding of the focus of the visit based on the clinical situation and the options presented to the child/family,²² especially if there are constraints on the time or physical space in which the visit can occur.

Another consideration for ambulatory PPC is the desired timeliness of the referral to meet both the children's and families' needs as well as those of the referring team. Common issues for palliative care prioritization of visit timeliness exist for children and adults alike.²² For example, does the child need to be seen in clinic that very day, or is the preference to meet the family at their clinic visit next month? Does the child or family want a separate visit or one coordinated with a scheduled visit with the primary team? Would the PPC team need to arrange a time to meet the child and family independent of the referring team or set up a time to do telehealth? Last, it is important to ensure that the family is made aware by the primary referring team that a referral is being made to the PPC team and to understand how the referral is explained.

The introduction of palliative care services is often a delicate task because families may confuse the term with hospice or interpret involvement as abandonment on the part of the referring team.²² Ensuring that families are aware that a referral to PPC is being made as well as the purpose of the visit is essential. This can be challenging if left to an appointment scheduler or a member of the primary team who may not fully understand the role of the PPC team. Members of the primary team must be taught to understand the role of the PPC and use appropriate language to describe it such as, "PPC cares for children with serious illness alongside the primary team as an additional layer of support to promote enhanced communication, symptom management, and decision-making."

The PP APRN's physical assessment includes a thorough history and screening of symptoms using validated pediatric tools as well as assessing their impact on quality of life and function.² Symptoms commonly addressed in the PPC clinic visit include pain, nausea, vomiting, dyspnea, anxiety, mood, fatigue, delirium, agitation, anorexia, bowel issues, sleep, and feeding intolerance. Often, more than one issue may present itself, and the PP APRN addresses each issue using a combination of both pharmacological and nonpharmacological treatment options that best align with families' goals, values, and available resources.²³ Assessment should be performed in the child's and family's preferred language, using a qualified medical interpreter to promote effective communication.² While the parent's or caregiver's report of symptoms is extremely valuable, the child's report is the gold standard, when possible.²⁴ Using developmentally and age-appropriate language and techniques is important when assessing the child for symptoms of discomfort. To assess children with cognitive impairment, mental status changes, or developmental delay, the PP APRN should pay particular attention to physical signs and symptoms as well as caregiver reports.²⁴

Palliative care assessment of children involves a thorough physical exam, but also a good understanding of the child's culture, language, faith, and psychosocial stressors (finances, transportation, etc.) so that the PP APRN can adequately identify potential barriers to treatment, care, and follow-up. When available, the APRN should collaborate with other members of the child's interdisciplinary team to support families as well to provide developmental and culturally competent care.² In pediatrics, the child's role in the family must be considered to best understand what and how information is relayed to the child.^{2,23} Additionally, to adequately address goals of care of ACP, it is essential to elicit the child's understanding of their illness, their prognosis, and perception of death. The parents' decision-making framework and communication preferences are helpful to assess using value-based questions, such as asking parent "How do you define being a good parent?" or "How best do you receive information?" These types of questions provide insight into how best to support a family's goals of care and are generally welcomed by parents because they are role-affirming and can serve as a source of guidance.^{23,25} As expected, goals and values may change over time, and thus assessment should be continued across the child's illness trajectory and in all care settings.

PEDIATRIC ADVANCE CARE PLANNING

pACP involves furthering discussions around plans of care and clarifying children's and families' long- and short-term goals and treatment preferences. pACP is recommended internationally not only to better inform practitioners but also, more importantly, to support families' abilities to anticipate challenging decisions, seek support, reduce unnecessary suffering, and promote feelings of control and peace of mind in difficult situations.²⁶ Barriers to initiating and continuing

discussions include uncertain prognosis, provider difficulties in initiating discussions, lack of care coordination, concerns regarding parental burden, and challenges in identifying children's wishes.²⁷ As a result, many pACP conversations occur late, or even after an acute crisis. This is despite recommendations that effective pACP occurs in a timely and continuous manner, soon after diagnosis (based on family's readiness), after a change in care setting (e.g., discharge from hospital), or before acute admission to an ICU setting.²⁷

Clinic settings serve as an optimal place in which to initiate or continue pACP discussions. The PP APRN is poised to facilitate communication around pACP, navigating thoughtful conversations around goals of care in a family-centered manner that incorporates both the children's views of illness and death (when appropriate) as well as the parents' values, hopes, and worries around suffering and quality of life. Tools such as the Pediatric Conversation Starter Kit, *Voicing My Choices, My Wishes*, and *Five Wishes* may assist the PPC APRN in discussing pACP with families because they may provide more concrete examples and questions that families may wish to consider around care planning.^{28,29} Additionally, the PP APRN serves as an educator and collaborator, addressing barriers that exist in certain outpatient settings by promoting education in communication, palliative care skills, and knowledge of ACP²⁷ (see Chapter 32 for more information).

DEVELOPING A PLAN OF CARE

Effective palliative care requires careful thought about resources that are available to and needed by families. In addition to being part of the PP APRN's assessment, other social determinants of health (SDOH) such as health literacy, access to reliable transportation, insurance coverage, and availability of local resources and support help to determine the appropriate plan of care² (see Chapter 20, "Health Disparities in Palliative Care and Social Determinants of Health"). For example, if a pACP discussion is about preferred location of death, it would be important to know what home-based palliative care or hospices would be available to support the family at home because some programs may not be staffed to appropriately support pediatric patients. Similarly, some insurance plans do not cover home-based palliative care encounters nor provide concurrent care coverage (please see Chapters 26 and 30 for information on concurrent care) and so knowledge of community providers and insurance options must be obtained prior to the encounter if the plan involves discussion of home-based services.

Follow-up planning involves a good understanding of transportation barriers, and, when possible, visits should be coordinated with other appointments. This is particularly true if a child is medically complex and getting him or her out of the home requires overcoming multiple hurdles with regards to timing, symptoms, reliable means of transport, and caregiver assistance. There has been increasing use of virtual or telehealth services, and, when available and appropriate, these may be valuable in addressing disparities in access to services.³⁰ Thus, telehealth follow-up may be a wonderful option

in these cases as well to help both ease the burden on the child and family and allow for continuity of care.³⁰

For the older pediatric population, the concept of assent is worth mentioning. Most children under 18 years of age do not have legal decision-making rights but may have the capacity to agree or object to a plan of care put forth by the treatment team and parents.² Children with complex or chronic illness often have a greater understanding than what one may assume based on age alone.² As such, the PP APRN should, when developmentally and culturally appropriate, make efforts to include the child in decision-making, taking assent or dissent into consideration when practicing family-centered care.³¹

RESPONSIBLE PRESCRIBING

Expertise in symptom management is an important skill in providing high-quality PPC to children and their families. PPC delivery in the ambulatory setting involves participating in the prevention and management of distressing symptoms mentioned previously in this chapter. However with this type of support comes a duty and responsibility to provide safe prescribing of medications that can pose a risk for misuse. The adolescent and young adult (AYA) population has been shown to be susceptible to use of prescription medications for nonmedical use, with peak risk at age 16 years.³² The principles of safe prescribing and universal precautions in opioid prescribing apply to children (see Chapter 43, "Pain," for comprehensive management of pain syndromes, and Chapter 47, "Patients with Substance Use Disorder and Dual Diagnose," for further information).

OPIOID USE IN CHILDREN

The opioid crisis in the United States remains a significant problem, even in hospice and palliative care, and prescription drug abuse is a national issue worthy of careful thought and discussion for any healthcare provider.³³ While much of the controversy around opioids focuses on adults, the opioid epidemic facing children and adolescents should not go unnoticed. Opioid prescribing to children and adolescents has significantly increased in the past two decades, and, in 2016, 891,000 children in the United States between the ages of 12 and 17 reported nonmedical use of opioids. Adolescents who misuse opioids can be generally described as those who self-treat or use these medications for the sensation it provides.³⁴ Few pediatric studies exist that examine the risk of opioid abuse or diversion, and recommendations for management are lacking.³⁵ The PP APRN treating children in the ambulatory setting must maintain vigilance of potential risk factors for opioid misuse when determining an appropriate treatment course by implementing the guidelines from the US Centers for Disease Control and Prevention (CDC) on universal precautions for opioids and risk stratification for opioid prescribing. One PPC program documented the implementation of an "opioid bundle" to risk stratify all children for whom pain was managed in the ambulatory setting. This included a prescription drug monitoring report, urine drug screen (UDS), screening questionnaire for history of drug abuse or

mental health disorders, and pill count.³⁵ Other institutions are adopting similar measures to promote safer prescribing practices both to increase awareness and promote more rapid intervention for those believed to be victims of misuse or diversion, in turn minimizing serious risks to both the individual as well as the prescribing clinician.

Responsible prescribing on the part of the PP APRN also involves taking into consideration other factors that may impact adherence to and thus efficacy of a treatment plan. One significant factor is cost. For example, a decision to transition a child from scheduled oxycodone to long-acting oxycodone for ease of administration and to provide a reasonably long-acting alternative may be appropriate for a child able to swallow pills, but if not covered by the family’s insurance, the medication can be cost-prohibitive. This author experienced a parents’ struggle with being asked by a pharmacy to pay \$760 for a 30-day supply when ordered by their primary care provider. In this situation, this author advocated for transition to long-acting morphine for a fraction of the cost as covered by insurance.

CLINIC CARE MODELS

Providing ambulatory PPC often involves three clinical models: consultative, co-management (embedded), and primary care (a medical home in which PPC assumes the primary care role).²² Please see Table 28.3 for examples of each of the three clinical models. In a consultative model, the PP APRN may perform a visit within the “host clinic” or referring/primary team’s clinic, address the reason for consultation, and provide recommendations to the child and family or referring provider²² who can choose to accept, decline, or modify them; medication management typically falls to the referrer.

Under the consultative model, the PPC service may not provide ongoing care, although sometimes an initial consult may lead to the identification of further needs necessitating follow-up care. In the co-management or embedded model, the most common ambulatory model of PPC delivery, PPC teams work closely with referring providers in shared clinic settings, co-managing children’s care plans²²; recommendations are provided and care is coordinated over longer periods of time. This model allows referring providers to focus on other aspects of care related to the child’s underlying disease if goals remain curative or disease-directed, and families often appreciate the enhanced communication and collaboration that occurs between the PPC and primary team.³⁶

The primary care or medical home model is one in which the PPC team cares for children in a setting independent of a referring provider or “host clinic”²² operating under the medical home philosophy of care in which “a practice-based care team takes collective responsibility for the patient’s ongoing care.”³⁷ The PP APRN assumes a more direct role in the child’s care, and in some instances, the PP APRN may assume the role of primary care provider when other resources are less available or when the family’s goals shift toward less disease-modifying treatments and optimization of the child’s health. This model is more time- and resource-intensive because it involves primary medication management, including writing prescriptions and refills and managing medication adjustments and side effects as well as providing off-hours coverage.³⁸

OPPORTUNITIES AND CHALLENGES OF AMBULATORY PPC

The PP APRN faces a unique set of challenges when providing PPC in the ambulatory clinic setting. In addition to

Table 28.3 MODELS OF CLINIC-BASED PEDIATRIC PALLIATIVE CARE (PPC)

EXAMPLES OF PPC MODELS IN THE CLINIC SETTING	
Consultative (collaborative) model	The renal team consults the PPC team to consult on a 15-year-old adolescent with end-stage renal disease due to presence of potential delirium as he is picking repeatedly at his skin. The PP APRN evaluates the adolescent in the renal clinic and recommends haloperidol to the primary team. The PP APRN discusses the recommendation with the patient and family, at the primary team’s request, but the nephrologist will prescribe the haloperidol and contact the PPC team if further advice is needed.
Co-management (embedded) model	The oncology team consults PPC team on a 4 year-old girl with neuroblastoma who is having some pain. The PP APRN meets meet the girl and her family in the oncology clinic. The APRN evaluates the child, does a pain assessment, and begins discussions on goals of care with the family. The PP APRN creates a pain regimen, discusses the recommendations for pain management with the family and the primary oncologist, and then writes the prescriptions. The APRN plans to see the patient again at her next visit, along with the primary oncologist.
Medical home model (primary care)	The PP APRN schedules a meeting with a 3-month-old with complex congenital heart disease and her parents in the PPC clinic. During the visit with the family, the PP APRN performs a comprehensive history and assessment, including a psychosocial and spiritual assessment. The APRN makes a plan for pain management and discusses signs and symptoms of fluid overload with the parents. The APRN begins to address goals of care with the parents and suggests a possible future referral to hospice. The APRN also suggests meeting with the PPC chaplain and child life specialist for sibling support at the infant’s next visit. The PP APRN gives the parents the 24/7 on-call number for the PPC team and plans to follow-up with the family by phone in 2 days and to see them again in 2 weeks.

From Davies, Broglio.²²

the general barriers to PPC, such as buy-in and misconception from providers, misperceptions about the role of PPC for children and families, and fears around the notion of “giving up,”^{39,40} logistical challenges exist. Not all PPC programs have their own dedicated outpatient clinic space and often operate in embedded clinics, which involves coordination with a multitude of other specialty clinics in which to introduce services or deliver care.

While the advantage of embedding PPC within a “host clinic” is closer collaboration with the referring provider and more streamlined communication,⁴¹ the PP APRN is often at the mercy of clinic workflow in terms of timing and space. A busy clinic may lead to unpredictable wait times or interfere with the ability to have longer discussions if an exam room needs to be turned over shortly after the host clinician’s visit. Children and families may also be overwhelmed with seeing many providers in one day, and so it may be difficult to add on a visit with the PP APRN, thereby adding an additional 30 or 60 minutes to the total clinic time. In contrast, this may be an advantage for families if it prevents them from having to come to the hospital or clinic setting for an additional visit and spend more time at a health-care facility. In the current landscape, if physical access is an issue, telehealth visits may also be another viable option for the APRN and other members of the PPC team to meet with children and families while they remain in the comfort of their own home³⁰ (see Chapter 17, “The Palliative APRN in Telehealth”).

An additional “benefit versus burden” point regarding successful integration of ambulatory PPC is the issue of staffing. PPC programs are growing in both size and number in children’s hospitals,^{8,42} and PPC has become a new standard of practice in children’s hospitals. The presence of PPC programs within an institution is now a key criterion in how hospitals nationwide are evaluated.⁸ However, the need for PPC services appears to be growing incongruent to PPC teams’ abilities to adequately staff consultations or referrals to meet

this demand, depending on widely variable staffing models. This remains an issue within the inpatient consultation realm and raises similar concerns in the ambulatory setting as teams without adequate interdisciplinary PPC staffing to meet inpatient demands find similar challenges to providing care. This can be a significant challenge for PP APRNs when there are only one or two of them working on a very busy PPC team covering inpatient, ambulatory, and home care settings simultaneously. Most pediatric care occurs outside of the hospital, and this charges PPC programs with the task of developing “robust services across all settings, including home-based care and clinic services”⁸

It is important to consider variations in timing for when palliative care may be introduced along a child’s illness trajectory (Figure 28.1, Table 28.4). It is widely recommended that PPC ideally be introduced to families at the time of diagnosis, when cure may not be feasible.^{43–45} Additionally, parents have reported that the preferred time for PPC discussions is around the time of diagnosis or when their child is medically stable.⁴⁶ However, introduction of PPC services often occurs later in the family’s journey—during an acute life-threatening hospitalization or following news of disease progression or relapse. PPC involvement in the ambulatory setting may address this gap in preferred versus actual timing of PPC delivery, particularly for those children with disorders with slow or predictable progression who are not hospitalized frequently and have exacerbating symptoms that necessitate a series of outpatient visits with primary providers instead of acute presentations to an emergency department or inpatient admissions. Children with slowly progressive illnesses and their families may find themselves incrementally tackling non-urgent issue after non-urgent issue before realizing they are faced with a burden of care that seemed distant at the time of diagnosis. Additionally, children are often the most medically stable during routine ambulatory follow-up visits, which may also be the time when families are told about a new life-threatening

Figure 28.1 Potential healthcare events that may prompt introduction of pediatric palliative care (PPC) services (see Table 28.5 for the key to “The rollercoaster”). A general visualization of the extent of PPC involvement for a child diagnosed with a potentially life-limiting illness. PPC integration may occur at any time along a child’s illness trajectory, with multiple cases that can occur in the inpatient, clinic, or home setting. Table 28.2 lists examples of PPC introduced along many points in a child’s illness trajectory, from diagnosis to near end of life. Multiple opportunities exist along the continuum, in a variety of possible care settings, for the PP APRN to partner with primary providers in support of family goals and to enhance quality of life.

Table 28.4 KEY TO “THE ROLLERCOASTER”

EVENT KEY	SAMPLE DESCRIPTION OF EVENTS SURROUNDING INTRODUCTION OF PEDIATRIC PALLIATIVE CARE (PPC) SERVICES
A	At the time of diagnosis; the recommended ideal time to introduce PPC ^{43–45} even with curative options available and driving a family’s journey. The PPC can initially play a small role getting to know the family and their unique values and goals.
B	Following a particularly challenging or unexpected acute episode/hospitalization to establish rapport and provide support around grief themes, goals; the child may be medically stable, but family could benefit from initial conversations around pediatric advance care planning (pACP).
C	In the midst of a period where symptom management is a priority alongside curative or life-prolonging interventions, where PPC may assist not only with goal setting but also pain or other signs of physical distress.
D	PPC is sometimes introduced during a prolonged hospitalization where it may be important to address goals of care/pACP, assist with symptoms, facilitate communication, or coordinate care to ensure medical decisions remain in line with family goals.
E	As curative or life-prolonging treatment options begin to fail, or the child endures repeated life-threatening events, there is a clinic visit with news of relapse or progression, or there is concern that future options may negatively impact quality of life, PPC may be introduced to discuss advance care planning around the “what ifs,” including the family’s critical illness treatment preferences.
F	Parents and family elect to redirect goals toward aggressive comfort measures or child begins showing signs of active decline despite interventions and PPC is introduced to facilitate goals, discuss possible home-based resources (including hospice), and involvement is heavy from the start.

diagnosis or given knowledge of disease progression. Thus, the clinic setting may provide an ideal environment for these conversations to start or continue and the opportunity for the PP APRN to be present, support the child and family, and provide resources as needed.

CASE STUDY: PROGRESSIVE DECLINE IN A PEDIATRIC PATIENT (CONTINUED)

In the 6 months that followed, the PP APRN followed Meg and her family at least monthly in various clinic settings, coordinating closely with her oncologist, neurologist, psychiatrist, complex care, and physical medicine provider. Ted advocated for the involvement of the institution’s complex healthcare program and psychology to help optimize Meg’s care and provide her mother with resources to promote comfort at home. The PPC social worker worked together with Ted to identify and coordinate a referral to a hospice team local to the family’s home. The challenge was finding a program that honored Medicaid Concurrent Care benefits, in which Meg could receive comprehensive support at home and continue oral chemotherapy for her leukemia per the parents’ goals. Goals of care were discussed over continued visits and ultimately resulted in her parents’ agreement to complete an out-of-hospital do-not-resuscitate form in hopes of keeping comfort at the forefront of Meg’s care. Meg’s parents stated that if Meg declined to the point of imminent death, they wished her to be at home and surrounded by family.

As Meg’s function and interactivity continued to decline, her mother grew concerned about increasing spasticity making diaper changes more difficult. Pain had increased, as had constipation and feeding intolerance. With each visit, Ted performed a thorough assessment and collaborated with multiple members of Meg’s care team to implement the following symptom plan after various multiple medication trials and adjustments:

- Pain: Scheduled methadone and PRN oxycodone
- Spasticity: Clonazepam and Botox injections, scheduled Baclofen
- Constipation: Senna and polyethylene glycol
- Feeding intolerance: Intermittent venting, reduction of feeding rate
- Agitation: Quetiapine (scheduled and PRN), Clonidine (scheduled and PRN), clonazepam

While Meg’s hospice was providing support in home two or three times a week, they were primarily an adult provider open to accepting occasional pediatric patients. Thus, Ted and the PPC team provided consultation, guidance, and support to the home hospice team at the mother’s and hospice’s request. Upon further discussion regarding goals of care, her parents recognized continued decline and sought to minimize suffering. Meg ultimately could no longer tolerate enteral feeds and grew increasingly agitated with any movement. At that time, her parents elected to

forego further follow-up visits in clinic, discontinue feeds, and continue aggressive comfort measures. Meg ultimately died peacefully at home, in the arms of her mother with her father at her side. At the request of her parents, Ted coordinated with hospice and her institution's pathology department to help arrange the transport of Meg's body to the hospital's pathology department for autopsy and tissue donation. This honored Meg's legacy and their quest to continue to seek answers around the ultimate cause of her neurologically progressive disease.

SUMMARY

PPC in the ambulatory setting provides maximal support to children and adolescents and their families throughout the life span. The PP APRN is uniquely poised to offer pain and symptom management, decision-making support, ACP, and longitudinal support for children and their families, all principles that are the bedrock of high-quality PPC. Different models exist for the delivery of PPC in tertiary care settings, with the collaborative model being most common, where visits are conducted in shared clinic settings to promote close collaboration and communication between primary providers and the PP APRN. Successful presence of PPC in ambulatory settings requires a PP APRN who has expertise in outpatient care and the etiquette of consultation. Program development includes building referral sources, timing, staffing, and dosing of palliative care, all of which may differ from traditional inpatient models. Access to PPC within the pediatric clinic setting can extend longitudinal care and support for families navigating a complex health system, which not only reduces family stress but also improves family-centered care and quality of life for the child with life-limiting illness.²⁰

THE PEDIATRIC PALLIATIVE APRN IN ONCOLOGY

Amy Corey Haskamp and Joanne M. Greene

KEY POINTS

- Early integration of palliative care may mitigate suffering and fosters improved coping throughout the trajectory of the underlying disease.
- The pediatric palliative advanced practice registered nurse (PP APRN) must appreciate that children with a cancer or blood disease often suffer from a multitude of symptoms threatening the intactness and quality of life of the child and family.
- The pediatric palliative APRN can initiate therapies with curative intent concurrently with those that ease suffering and maximize quality of life.
- While the context of hope may change over time, it is an essential component of the well-being of the patient and family faced with a terminal illness.

CASE STUDY

A 13-year-old boy from Puerto Rico, Forest, was diagnosed with high-risk pre-B cell acute lymphocytic leukemia. With treatment, he achieved remission and finished therapy approximately 2 years later. Due to his treatment, he developed painful avascular necrosis (AVN) of the right knee.

Prior to his 18th birthday, Forest relapsed and underwent additional chemotherapy. During therapy, he developed a disseminated candida infection and sepsis, and chemotherapy was stopped. Unfortunately, Forest had no access to palliative care services. His mother felt his treatment-related side effects had been poorly managed, resulting in physical and emotional suffering, decreased quality of life, and increased stress and anxiety for their family.

With mounting fears related to suffering and potential relapse, Forest's mother transferred him to another treatment facility. There, Forest was enrolled on a clinical trial and introduced to the pediatric palliative care (PPC) team. Goals of care were discussed, and Forest and his mother desired aggressive treatment therapies working toward a goal of cure. The pediatric palliative advanced practice registered nurse (PP APRN) addressed physical symptoms of painful AVN of the knee, mucositis, nausea, abdominal pain with appetite disturbance, diarrhea, sleep disturbance, and fatigue. A PPC plan was developed which addressed his social and cultural isolation related to relocation to a new city for treatment, anxiety and mood disturbance, and spiritual

discord. Pharmacologic and nonpharmacologic interventions as well as integrative and complementary strategies were implemented. Although Forest was 18 years old, he felt ill-equipped to make his own treatment decisions, thus placing a heavy burden on his mother. His mother continued to direct all care decisions, with Forest agreeing or acquiescing to his mother's direction.

Forest received a chimeric antigen receptor T-cellular (CAR-T) infusion with several complications. Three months later, a bone marrow aspiration confirmed another relapse. The PP APRN facilitated many interdisciplinary team, staff, and family meetings to discuss Forest's care, including disease trajectory, goals of care, advance care planning (ACP), and ethical questions to ameliorate moral distress and compassion fatigue. Forest and his mother continued to request aggressive therapies which were non-beneficial nor effective. He suffered from neutropenic enterocolitis, respiratory failure requiring intubation, and sepsis. During this medically complex time, Forest and his mother maintained their desire to seek treatments with a curative intent despite a worsening prognosis. As a bridge to hemopoietic stem cell transplantation (HSCT), Forest received another CAR-T cell infusion. However, additional complications ensued including acute kidney injury (AKI) requiring continuous renal replacement therapy (CRRT), heart failure, and respiratory insufficiency which ultimately resolved. Forest then proceeded to HSCT, where he again required respiratory support. In the weeks leading up to his death, the PP APRN utilized tools such as *Voicing My Choices* to help with reframing goals of care and creating an end-of-life care plan to ensure a good death. Unfortunately, 2 months after his HSCT, Forest was compassionately extubated and died secondary to severe HSCT-related complications and multisystem organ failure with his family and staff at his bedside.

INTRODUCTION

The coordination of care between the primary pediatric oncology team and the pediatric palliative advanced practice registered nurse (PP APRN) is vital to the outcomes of patients and families. Pediatric oncology patients frequently report pain and other physical and psychological symptoms before, during, and after treatment for cancer. The PP APRN, with an interdisciplinary team, utilizes high-quality communication to assess and manage physical and psychological symptoms and facilitate discussions about goals of care and the end of life.

Cancer is much less common in children than in adults. Medical approaches to the management of pediatric cancer have made significant strides over the past decade. The overall incidence of pediatric cancer is 18.2 cases per 100,000 children in the United States and has increased by an average of 0.7% per year from 2000 to 2017.¹ While the 5-year survival rate for children and young adults 20 years old and younger with cancer improved from 58.8% in 1975 to 84.5% in 2012,² pediatric cancers remain the second leading cause of death in children aged 5–14 years.³ There are approximately 375,000 survivors of childhood and adolescent cancer living in the United States.⁴ In addition to those with a cancer diagnosis, the PP APRN can provide benefit to children with hematological disorders such as sickle cell disease, aplastic anemia, or hemophagocytic lymphohistiocytosis.

At diagnosis, patients frequently report cancer-related symptoms caused by the invasion or compression of vital structures of the body. Psychological or social distress may be caused by the uncertainty of the diagnosis, prognosis, or diagnostic testing. Cancer-directive therapies focused on a curative intent for highly aggressive cancers, hematopoietic stem cell transplantation, and chimeric antigen receptor T-cellular (CAR-T) therapy are often intensive in terms of time and high side-effect and symptom burden.

While many of the treatments for childhood cancers are administered with a curative intent, more than 12% of children with cancer will die from their illness.⁴ Approximately 60% of childhood cancer survivors will experience late effects from their cancer diagnosis and treatment, including infertility, muscular deficiencies, neurocognitive impairments, organ dysfunction, and secondary malignancies.⁵ A substantial effort is needed to minimize suffering experienced at the end of life. While survival rates have improved, each child and family faces prognostic uncertainty. The PP APRN can help children with cancer and their families cope with this uncertainty and the physical, psychological, social, and spiritual burdens of cancer and its treatment,⁶ thereby increasing quality of life throughout the trajectory of the cancer journey.

EARLY INTEGRATION OF PALLIATIVE CARE

As delineated for all persons with serious illness, palliative care for children with cancer is most beneficial when implemented soon after diagnosis. The physical, psychological, social, spiritual, and/or cultural suffering associated with pediatric cancer begins at diagnosis and continues throughout the child's and family's cancer journey. Unfortunately, children with cancer are often referred to pediatric palliative care (PPC) late in their treatment or close to the time of the child's death.⁷ Developing a relationship with the PP APRN at end of life, when physical and psychosocial suffering is acute, limits the benefits palliative care can provide children with cancer and their families.⁸

The American Society of Clinical Oncology (ASCO) recommends any patient with advanced cancer receive palliative care services at time of diagnosis along with active treatment.

Position statements from the American Academy of Pediatrics (AAP), the American Society of Pediatric Hematology/Oncology (ASPHO), and the International Society of Paediatric Oncology (ISPO) each advocate for early integration of pediatric palliative care services in the United States and internationally.^{9,10} PPC expands the center of supportive care to include the child's parents, grandparents, siblings, and others who have been integral in the growth and development of the child. Palliative care can enhance pain and symptom management thus enriching a child's quality of life, lead to fewer emergency room visits and shorter hospitalizations, and, in some cases, improve survival outcomes.¹¹

The benefits of PPC cannot be overemphasized because of the continual evolution of technology and medical advances to potentially prolong life in the pediatric population. Families without palliative care early in their treatment are less likely to have goals-of-care discussions, which may limit full participation in medical decision-making.¹² This results in a lack of opportunity to provide a detailed review of risks and benefits of proposed interventions which creates the foundation from which the patient/family can make informed shared decisions with the medical team. The PP APRN facilitates more opportunities for discussions related to the patient's and family's wishes surrounding end-of-life care, earlier documentation of advance directives, and fewer interventions at end of life as well as increased admissions to hospice.⁶

PP APRNs are in a unique position to coordinate care, help the child and family identify goals of care over time as the illness trajectory changes, facilitate difficult conversations, and support end-of-life care, death, and bereavement. Finally, there is a growing number of children who survive their cancer and require the expertise of a pediatric palliative team to manage late physical and psychosocial effects of cancer therapies.

INTRODUCING PALLIATIVE CARE INTO PEDIATRIC ONCOLOGY TREATMENT

Introducing palliative care as an integral part of the comprehensive management of children with cancer can be challenging. Families may have strong emotions related to palliative care based on past experiences with adult palliative care and hospice, including preconceived ideas about the implications of palliative care for their child. In addition, families may not fully understand the difference between palliative care and hospice and therefore focus on end-of-life care. It is important for the PP APRN to validate family concerns while articulating the mission of pediatric palliative and hospice care.

The importance of PPC services for children with life-threatening illnesses is supported by an abundance of research, but only 54% of pediatric oncology patients receive palliative care prior to their death.¹³ Although the policy statements published by the AAP demonstrate advocacy for referral to palliative care, pediatric oncology providers may be influenced by their own feelings and thoughts about introducing palliative care to patients and families.¹⁴ The rationale underlying

the lack of referrals from primary oncology teams to palliative care is most likely multifactorial but may result from the provider's belief that they are providing sufficient supportive care or that a referral will not provide any additional benefit to the current care.⁵ Reluctance on the part of the primary oncology provider to consult the palliative care team may also stem from a provider's concern that the family may feel that the oncology team is abandoning a curative approach to care or that the family may not be ready or open to including palliative care in their child's regime.^{5,15} Despite recommendations and evidence of improved quality of life and increasing availability of services, a gap continues between knowledge and provider's practice of referral to PPC.¹⁶

Late referral of children with cancer to palliative care can increase suffering. In a cohort review at a pediatric cancer center, more than one-third of children who died during a 4-year time frame were treated on an experimental protocol, with half of those treated on a Phase I clinical trial.¹⁷ In the same cohort, 51% of the children participating in clinical trials were admitted to the intensive care unit at least once during their treatment.¹⁷ The nature of Phase I and even Phase II clinical trials does not include a curative or therapeutic intent.

Only children who have not achieved success from conventional treatment options are eligible for participation in a Phase I trial. These children often may have a heavy symptom burden prior to participation and are very likely to not survive their cancer. A palliative care consultation prior to enrolling on a Phase I trial can allow families to hold onto the hope that a trial drug will provide a therapeutic benefit while balancing discussions centered around the child's goals and how one wishes to spend time on meaningful and important activities.¹⁸ Similarly, children undergoing hemopoietic stem cell transplantation (HSCT) often have exhausted all other treatment options. They may experience a variety of symptoms throughout their transplant and have a high rate of morbidity and mortality. The PP APRN can assist with treating the side effects of high-dose chemotherapy and/or radiation, symptoms caused by graft versus host disease, and psychosocial distress experienced by those receiving a HSCT.⁵ These novel therapies can result in complex and multisystem side effects and associated suffering, as highlighted in the case study.

PP APRNs should initiate conversations with primary oncology teams to identify barriers to referring patients to a PPC service. Providing education on palliative care to primary provider services has shown to improve the incidence of referrals to PPC.¹⁹ Identifying care objectives for management of treatment-related symptoms, the provision of quality care, excellent communication between families and providers, coordination of care between subspecialties, and family and provider shared decision-making will help to pave a pathway for increased referrals.

SETTINGS FOR PALLIATIVE CARE

Access to palliative care services should be available for children with cancer in all care settings. Identification of high-risk children and families without access to palliative care services

is important to allow for the physical and psychosocial support necessary to maximize quality of life. Rural areas are less likely to have specialty palliative care services for children than are urban areas, resulting in physical barriers to care.²⁰ Evolving telemedicine can help to bridge palliative care service gaps but insufficient family financial resources required for computers and smartphones may continue to create barriers. While the number of formal PPC programs has increased over the past decade, a deficit of available programs exists.²¹ There is an insufficient number of healthcare providers who have the formal training and knowledge or experience necessary to practice palliative care.²¹ Adult home health and hospice teams often provide services to pediatric and adolescent and young adult patients/families but may not have the education and training specific to addressing the needs of these unique populations. Family-specific elements, such as limited financial resources, educational level, race, or culture can influence the circumstances surrounding the family's ability to obtain PPC services.²⁰

PP APRNs can create opportunities for providing PPC in settings that best suits the family's individual needs. Generally, the preponderance of cancer care for children is managed in the outpatient setting.²² Outpatient palliative care increases opportunities to address distressing symptoms, implement psychosocial interventions, and initiate ACP discussions while the child is generally less acutely ill.²² Pediatric inpatient clinical areas continue to be the place in which most PPC programs reside. Children with cancer admitted to the hospital may have complex symptom burdens, higher acuity, and worsening prognosis or progress toward end of life or be experiencing intense family stress requiring multiple medical decisions.²³ The inpatient setting facilitates close collaboration with the primary oncology team and consulting services like child psychology, social work, child life, spiritual care, and integrative medicine. Inpatient PP APRNs can communicate with hospice to ease the transition to home hospice. Pediatric hospice provides all aspects of PPC in the home setting. Although there are limited data specific to where children and their families prefer to die, it appears that those with childhood cancer prefer to die at home, making hospice a vital setting for PPC.²⁴

SYMPTOM MANAGEMENT

Symptom management may be challenging in childhood cancer. A multitude of symptoms have been described in the literature by those undergoing treatment for cancer, childhood cancer survivors, and those at the end of life.^{25–28} Successful management of symptoms helps to build trust with the child and family and restores quality of life.²⁷

CONSTIPATION

Acute constipation has been identified in as many as 57% of children in active treatment for cancer.²⁸ Constipation in this population is defined as absence of a bowel movement in a 48-hour period.²⁸ Most common risk factors include inactivity,

dehydration, electrolyte imbalance (e.g., hypercalcemia, hypokalemia), bowel compression caused by an abdominal tumor, spinal cord compression, and medications (e.g., opioids, neurotoxic chemotherapy agents such as vincristine). Receiving vincristine and/or opioids has been shown to be a significant risk factor due to decreased intestinal motility.²⁸ Patients with a preexisting history of constipation are at increased risk for developing constipation during treatment. Constipation may impact quality of life due to its physical impact (pain, abdominal distension, nausea and vomiting, decreased appetite) as well as the psychological impact caused from the embarrassment or social avoidance²⁸ (for more detail, see Chapter 40, “Bowel Symptoms”).

Since older children and adolescents are often embarrassed when talking about bowel habits, these symptoms may be underreported. Therefore, the PP APRN must assess for risk factors critical to constipation. The APRN should speak honestly with the child about the distress caused by constipation and develop a treatment plan. Some adolescents understand the medical management and can be responsible for self-monitoring and treatment without the embarrassment of discussing these issues with their parents. The PP APRN should assess the character and frequency of stools; duration of symptoms; presence of blood or intermittent watery diarrhea; presence and character of bowel sounds; presence of abdominal, pelvic, or rectal pain; and presence of abdominal distention and palpable fecal masses.^{28,29} A rectal assessment for hemorrhoids, fissures, tears, or fistulas may be warranted, but a digital exam should be performed only when necessary and with caution. An abdominal x-ray may be warranted to assess the presence of stool in the bowel.

Prevention and prompt treatment are important to constipation management.²⁸ The PP APRN should provide education on prevention, including diet, hydration, and activity. Education to prevent constipation should include the importance of a high-fiber diet, which includes fruits, vegetables, grains, and non-dairy fluids. Ensuring privacy for bowel elimination and encouraging increased mobility are other nonpharmacologic strategies. If the child has difficulty with mobility, it may be important to obtain a bedside commode or bedpan. Passive range-of-motion exercises and frequent changing of body position to aid in gastric motility are important for the inactive child.

Prophylactic medications should be initiated when appropriate, with a goal of one soft stool every other day.²⁹ Unlike other side effects of opioids, opioid-induced constipation does not subside with ongoing use. Therefore, patients being prescribed opioids should be prescribed both a stool softener and stimulant to prevent constipation. Stool softeners alone have limited efficacy but have been shown to minimize pain associated with hard stools.²⁹ Initiating senna has been identified as an effective prophylactic agent in children with cancer.²⁹ Stool softeners such as polyethylene glycol can be very effective. Softeners are more effective when the child is well-hydrated, so increased fluid intake should be encouraged. If softeners and laxatives are ineffective at treating constipation, other agents, such as lactulose, glycerin suppositories, or enemas, may be required^{28,29} (see Appendix II, Table II.3). Consider

the risks before using suppositories or enemas in patients with pancytopenia. Methylnaltrexone, a selective inhibitor of mu receptors located in the gastrointestinal tract, has been used in the management of opioid-induced constipation.²⁸⁻³⁰

NAUSEA AND VOMITING

Nausea and vomiting are often among the most distressing symptoms described by children undergoing cancer therapy. They have been reported to occur in 35–80% of these patients.^{8,25,31} Nausea has been more commonly reported in those with multiday chemotherapy regimens and appears to be more prevalent in adolescents than in younger children.³² Chemotherapy-induced nausea and vomiting (CINV) may occur in two phases: the acute phase, which occurs within the first 24 hours after chemotherapy is administered, and the delayed phase, which may linger for up to a week or more after administration is complete. Improved control of acute CINV has been associated with control of delayed CINV.³² Prolonged nausea and vomiting may lead to the development of anticipatory nausea.

Nausea may occur with or without vomiting, but vomiting typically is associated with nausea. Many factors may contribute to the presence of nausea and vomiting: side effects of medications (e.g., antimicrobials, chemotherapy agents, and opioids), biliary or intestinal obstruction or tumor invasion, central nervous system tumors, decreased gastric motility, constipation, metabolic disturbances (e.g., hypercalcemia, hyponatremia, and adrenocortical insufficiency), primary renal or hepatic failure, abdominal irradiation, and increased intracranial pressure (for more detail, see Chapter 42, “Nausea and Vomiting”).

Nausea and vomiting may result in fatigue, dehydration, electrolyte imbalances, pain, anorexia, and decreased quality of life. Children find it difficult to attend school and perform schoolwork when nauseated. Nausea and vomiting have a negative impact on both the physical and psychological well-being of the child.²⁸

The PP APRN should assess for risk factors, triggers, frequency and duration, character of bowel sounds, palpable masses, hydration status, and associated neurological sequelae (e.g., headache, ataxia, or changes in consciousness). Electrolytes and kidney and liver function should be monitored, and abdominal radiography may be needed.³³ Treatment is aimed at removing triggers, if possible; alleviating symptoms; and relieving the psychological distress caused by nausea and vomiting. Management should include both a nonpharmacologic and pharmacologic approach. Parents should encourage small, frequent meals selected by the child, avoiding fatty or greasy foods. Oral care after meals and emesis is also recommended. It is important to eliminate strong smells or those that are unpleasant to the child to eliminate any environmental triggers. Anxiety can often provoke or potentiate nausea. Relaxation exercises, guided imagery, distraction, acupressure, and acupuncture are integrative approaches to reduce nausea and vomiting.^{28,34} In severe nausea and vomiting due to gastroparesis, the placement of a nasogastric tube can be helpful.

Choosing the appropriate pharmacologic prophylactic management for the management of CINV is critical. 5-HT₃-receptor antagonists (ondansetron and granisetron) have been shown to be appropriate for the treatment of CINV.^{28,32–34} Given concomitantly with an NK₁-receptor antagonist (aprepitant), they have been shown to be highly effective in managing acute CINV.^{32,34} If indicated, adding dexamethasone to this combination has shown greater efficacy than if these agents are used alone.^{28,32,34,35} Adding olanzapine to the standard antiemetic regimen of those patients who have experienced poor CINV control during previous cycles has been shown to help children achieve better nausea control.^{34,36} Scopolamine, an ACh_m-receptor antagonist, can be applied as a transdermal patch and is useful when children are too nauseated to take oral medications and obtaining line access is difficult. Benzodiazepines or alprazolam can be beneficial for those with anticipatory nausea.³⁴ If gastric irritation is suspected, an H₂ blocker or proton pump inhibitor would be warranted.³³ Cannabinoid receptor agonists (dronabinol) may be considered for refractory CINV.^{33,35,37} Families may also seek the use of medical cannabis for relief of CINV. While medical cannabis may be a potential treatment, it remains controversial due to its side effects and lack of evidence on a suggested route, schedule, or dose for maximal efficacy and safety.^{33,35} Access to medical cannabis depends on the location of the patient and legality within the patient's state of residence. (See Appendix II, Table II.5 for pharmacologic management of nausea and vomiting.)

ANOREXIA AND CACHEXIA

Anorexia is a decreased appetite and decreased consumption of food. *Cachexia* is the involuntary loss of more than 10% of a patient's weight, or muscle wasting, whereby the body breaks down skeletal and adipose tissue (see Chapter 39, "Anorexia and Cachexia").

These conditions generally lead to weakness and fatigue, decreased resistance to infections, shortened survival, body image changes in older children and adolescents, and psychological distress for patients and families, and they significantly impact a child's quality of life.^{28,38} Loss of appetite has been shown to occur in 50–75% of patients undergoing cancer treatment^{8,25,28} and nearly 100% of children dying of cancer.²⁸

Physical factors that contribute to anorexia are uncontrolled pain or other symptoms and feeding or swallowing problems like mucositis, nausea and vomiting, constipation, delayed gastric emptying, and changes in taste. Psychological factors include depression and anxiety.³⁹ Researchers believe that inflammation plays a role in cachexia. Inflammation is a result of the body's immune response to the tumor, resulting in cytokine production. Cytokines can aid in killing tumor cells, but they also increase the body's metabolism, resulting in a breakdown of muscle and fat.^{28,39}

The PP APRN should assess the pattern and timing of weight loss, daily caloric intake, changes in taste or smell, and presence of dysphagia, mucositis, nausea, constipation, or pain.³⁹ Laboratory tests to assess for nutritional depletion

may prove beneficial. Serum albumin decreases as nutritional status declines and has a half-life of 20 days, therefore is less affected by daily intake.³⁹ Assessing prognosis and goals of care is necessary to develop a care plan.

Treatment should be aimed at reversing contributing factors while focusing on the patient's comfort and minimizing distress caused by the anorexia and weight loss. Due to the multifactorial components that lead to anorexia and cachexia, its management may combine a variety of approaches, including treating secondary causes of anorexia, nutritional support, enteral or parenteral nutrition, pharmacological management, and psychosocial support.³⁹ Treating secondary causes of anorexia or weight loss include management of those potentially correctable contributing factors such as pain, nausea, fatigue, or depression. Nutritional support includes encouraging small, frequent meals of high-calorie foods and fluids, with as much choice as possible to maximize caloric intake and limit the focus on eating. The choice of when and what to eat allows the child some amount of control. Consulting a dietician may aid in providing education and recommendations for appropriate supplements. If required, enteral nutrition is favored over parenteral nutrition due to the side effects (e.g., infection, thrombosis, and electrolyte abnormalities) of parenteral nutrition, despite the need for placement of a nasogastric or gastrostomy tube. Enteral nutrition allows for continued stimulation of the intestine, making the transition to oral feedings much more tolerable. Many pediatric cancer patients have central venous access during the last phase of their life, and parents may wish to utilize this to provide their child with parenteral nutrition. However, given the associated risks, the APRN must provide education, and parenteral nutrition should be carefully considered in light of the patient and family's goals.^{28,39} Research findings on appetite stimulants is varied, showing some improvement in anorexia, but only minimal weight gain, no improvement in muscle mass or quality of life, and side effects.^{28,39,40}

Megestrol acetate improves appetite but appears to increase weight by increased adipose tissue rather than skeletal muscle.⁴⁰ Glucocorticoids also increase appetite but should be used judiciously due to side effects. Cannabinoids, such as dronabinol, are approved for appetite stimulation but lack consistent evidence on effectiveness in pediatric patients.²⁸ Dronabinol has shown an increase in appetite without weight gain.^{39,40} Medical cannabis or CBD oil is not recommended for cancer-related anorexia/cachexia given the lack of evidence supporting its use and potentially distressing side effects; in addition, it is not legally or financially available for all patients.^{28,40} See Appendix II, Table II.7 for pharmacological management of anorexia.

In terminal cancer, the metabolic demands of the tumor may exceed any nutritional supplements provided. As previously stated, these interventions have generally shown no improvement in weight gain, length of survival, or quality of life and may lead to increased suffering and decreased quality of life.^{28,39,40} Electing to forgo nutritional support is a difficult decision for many families because offering food is generally associated with comfort and plays a significant role in a

family's culture. Therefore, the choice to withhold nutrition creates many personal and ethical dilemmas for families.

FATIGUE

Cancer-related fatigue is a subjective, distressing side effect of cancer or its treatments. The physical, emotional, or cognitive tiredness or exhaustion is not proportional to the patient's activity level and interferes with daily function and quality of life.²⁸ Fatigue is one of the most commonly reported symptoms in children with cancer and is reported in 50% of those undergoing cancer treatments, at end-of-life, and in childhood cancer survivors.^{25,28,41}

There are multiple etiologies of cancer-related fatigue. It may be due to the cancer itself, treatments, or emotional factors. Cancer therapies have been identified as the primary cause, but other factors, such as pain, anemia, sleep/wake disturbances, metabolic abnormalities, nutritional deficiencies, emotional distress, reduced activity, deconditioning, and side effects of medications, may contribute (see Chapter 41, "Fatigue").

Physical and psychological factors may develop. The child may be too tired to eat, leading to anorexia. For adolescents, fatigue may lead to a lack of desire to attend school or interact socially with friends, leading to social isolation and depression. Adolescents may also find it difficult to perform age-appropriate tasks due to fatigue, leading to an increased dependence on others and further decreasing their quality of life.²⁸

Fatigue's multifactorial etiology necessitates a multidimensional approach to assessment. The PP APRN should ask if the child feels tired or lacks energy. Then the onset, duration, aggravating and alleviating factors, and its effect on the child's ability to go to school, play, or sleep should be assessed. Validated tools to evaluate fatigue are available, such as the Pediatric Quality of Life Inventory, the Childhood Fatigue Scale, and the Patient Fatigue Scale.⁴² Objective assessment includes evaluating vital signs, muscle strength, the presence of anxiety or depression, and hemoglobin levels to assess for anemia.

An interdisciplinary approach to the management of fatigue is most effective. Medical management may include blood transfusions for the treatment of anemia and/or medications, such as psychostimulants, antidepressants, sleep agents, or other agents, to combat the cause of the fatigue (e.g., nausea and vomiting, poor nutrition). While little evidence exists for the use of psychostimulants in fatigue management for children, based on the results of adult oncology studies and its frequent use in children for behavioral management, methylphenidate is commonly used for management of fatigue in children with cancer.⁴² Nursing interventions include minimizing sleep disturbances and developing a schedule and routine for each day. Child life specialists or psychotherapists can teach techniques for stress management, guided imagery, and other skills to promote relaxation or allow the child to discuss feelings associated with fatigue. Nutritionists can teach families proper nutrition to promote energy. Finally, physical and/or occupational therapy can implement a low-intensity exercise program and age-appropriate activities to minimize

boredom and social isolation. Increased physical activity may decrease the severity of cancer-related fatigue.⁴² Encouraging good sleep hygiene is also important in managing sleep/wake disturbances. Appendix II, Table II.6 highlights pharmacological management for fatigue.

PAIN

Pain has been reported in nearly half of all children with cancer,^{25,28,43} with nearly 75% of parents reporting pain in the first month of cancer therapy⁸ and as many as 62% at the end of life.^{25,28} Pain is one of the most frightening and anxiety-provoking components of cancer therapy. The presence of pain in children with cancer has been identified as a symptom associated with a decreased quality of life.^{38,43} In those with sickle cell disease, one-third reported experiencing pain by the age of 1 year, two-thirds by the age of 2 years, and more than 90% by the age of 6 years, with up to one-third of patients reporting pain daily.⁴⁴

Pain associated with cancer therapy (e.g., chemotherapy, radiation, medication, and/or surgery) was the most frequently reported source of pain for those undergoing cancer treatments.⁴³ Common causes of cancer therapy pain include surgical interventions and side effects of chemotherapy and radiation therapy (e.g., oral mucositis, peripheral neuropathy, skin burns, perirectal breakdown). Pain caused from medical procedures was the second most common source of pain (e.g., bone marrow aspiration/biopsy, lumbar punctures, venipuncture, dressing changes, injections). Vaso-occlusive crises are the most common cause of pain in children with sickle cell disease. Previous pain episodes as well as developmental, environmental, cultural, and psychosocial factors affect the pain experience (see Chapter 43, "Pain").

The child may report nociceptive and/or neuropathic pain and acute and/or chronic pain (Appendix II, Box II.2). Untreated pain can lead to a multitude of other complaints, such as depression, anxiety, sleep disturbance, fatigue, loss of appetite, increased pain sensitivity, limitation of social activities, and loss of trust in the healthcare team.^{28,43} Likewise, many of these symptoms can exacerbate pain, and generally all symptoms must be treated to achieve successful management.

To properly assess pain, the PP APRN must acknowledge that pain is a subjective experience, and the pain experience is unique to each patient. A history of the child's pain is essential, along with its potential causes or sources. Pain may go underreported in children with cancer if they fear it indicates progression or return of the disease. The PP APRN should learn the language the child uses to report pain. A self-report represents the gold standard, but behavioral observational scales may be required for a nonverbal patient.⁴⁵ It is important to use a developmentally appropriate and evidence-based pain assessment tool. Education of parents and children should include how to use the appropriate pain scale to ensure consistent measurement of pain. Parents should also be taught to maintain a daily log of the child's pain, what treatment or intervention was provided, and the effects of that intervention. Parents' confidence in their ability to manage their child's pain has been shown to be associated with how much

pain they perceived their child to have and whether they administered pain medications to their child.⁴³ Therefore, educating and empowering parents about their child's pain and available tools for pain management may improve a parent's confidence and thereby improve their child's overall pain and quality of life.⁴³

Assessment of pain includes pain score, location, characteristics, intensity, quality, pattern, alleviating/aggravating factors, duration, and the impact of pain. Behavioral indicators of pain should be observed (restlessness or agitation, grimacing, guarding, or moaning). Vital sign changes are generally not seen in those with chronic pain or in children who have learned to cope with pain in other ways.

The primary goal of pain management is to eliminate or reduce pain with the fewest side effects possible to restore quality of life. Acute pain should be treated based on the two-step analgesic ladder approach recommended by the World Health Organization (WHO). See Chapter 43, "Pain," for more information, and Appendix II, Table 11.1 for pediatric dosing recommendations. Pediatric dosing of sustained-release medications can be difficult, particularly if the child cannot swallow pills. Available dosage forms of many long-acting opioids may not be appropriate for smaller children. Methadone is available in a liquid form; it can be easily titrated for pediatric dosing and provides long-acting pain relief.

A multimodal approach to managing cancer pain, including a combination of pharmacological, physical, and psychosocial strategies, is recommended for best outcomes.^{43,46,47} Complementary nonpharmacologic methods can augment opioid administration (Appendix II, Box II.1). Psychotherapists can introduce cognitive-behavioral therapy to teach the child ways to relax and to learn to think about something other than pain. Physical therapy can be helpful to show the patient ways to move that are less painful or even stretching techniques that reduce pain.

PSYCHOSOCIAL DISTRESS

The diagnosis and treatment associated with pediatric cancer results in substantial psychosocial distress for the child and family and impacts the quality of life of the child.^{6,25,38,48–51} Psychological distress is defined by the National Comprehensive Cancer Network as a "multifactorial, unpleasant, emotional experience of a psychological (feelings, worries, thoughts, behavior), social and spiritual nature that may interfere with the ability to cope with cancer, its physical symptoms (and side effects) and treatment."⁴⁹ Although the majority of those psychologically affected during treatment will adjust over time, approximately 10–30% of cancer survivors or family members will have long-term severe psychological distress.^{6,48,49,51} Parents or caregivers of children with cancer are at higher risk for developing posttraumatic stress symptoms than are the patients themselves—as many as 50% of caregivers.^{6,51} Delayed introduction of routine psychosocial services has been linked to increased suffering.^{6,48,49,51,52} *The Psychosocial Standards of Care Project for Childhood Cancer* (PSCPCC), published in 2015, standardized the delivery of psychosocial care of children with cancer and their

family members.^{48,50} Early integration of routine psychosocial assessments by clinicians as well as an interdisciplinary palliative care team have been recommended to reduce immediate and long-term adverse psychosocial effects.^{6,48,49,51,52}

Psychosocial distress in children during therapy may manifest as image issues, difficulty concentrating, worrying, sadness, nervousness, sleep disturbance, and irritability. It has been reported in 15–40% of those undergoing cancer treatments, occurring at similar rates at end of life.²⁵ Psychological distress has been reported higher in girls than boys and for those children with brain tumors.²⁵

It is important for the PP APRN to ensure an early psychological screening and assessment using valid and reliable tools to identify and address individual and family strengths, resources, and challenges.^{26,49,53} Screening should then occur at regular intervals throughout the cancer trajectory, particularly during significant treatment milestones.⁴⁹

Implementing psychosocial interventions with those higher risk patients and families has shown to decrease depressive and anxiety symptoms in patients and have an impact on longer-term psychological outcomes.⁵ Encouraging psychosocial support of the child, siblings, and caregivers can serve as a protective factor against negative psychosocial outcomes; however, these interventions should be tailored to the individual patient and family.⁶ Hospital or online support groups or camps for children with cancer or their siblings may be beneficial to decrease the social isolation experienced by these patients.⁶ Expressive therapies, such as art, play, music, dance, and pet, may be helpful for expressing feelings and reducing distress during cancer treatments.⁴⁹ Referral to pediatric psychology for further assessment and integration of cognitive-behavioral therapy and counseling may be beneficial.^{6,49,51}

CARE OF ADOLESCENT AND YOUNG ADULTS

Adolescent and young adult (AYA) oncology as a subspecialty which developed from the Adolescent and Young Adult Oncology Progress Review Group held in 2006.⁵⁴ There are approximately 70,000 individuals between the ages of 15 and 39 years diagnosed with cancer each year.⁵⁵ Eighty percent of those AYAs will achieve 10-year survival.⁵⁶ Psychosocial maturation and movement toward adulthood for the AYA is the developmental priority, compared to the focus of physical growth in the earlier childhood years. Emotional and financial independence, maturing body image, social connections outside the family, and work identity and future roles become paramount.⁷ A cancer diagnosis can and often does negatively interfere with the AYA's maturation process and their ability to meet age-appropriate developmental milestones.⁵⁷ Coping with all the factors related to living with a life-threatening illness, AYAs with cancer are commonly affected by delayed or arrested emotional maturity, mood disorders, and priorities that conflict with oncology treatment plans.⁵⁸ AYAs commonly are not prepared for a life-changing diagnosis and may have inadequate or no health insurance. Individuals without adequate financial means to pay for healthcare are known to

have increased disease- and treatment-related complications, worse survival outcomes, and higher mortality rates than populations with adequate access to care and medical insurance.⁵⁹ Even when AYAs have access to healthcare, adherence to oncology management plans is a significant concern in this age group.⁶⁰

The AYA, family caregivers, and clinicians must be educated on the impact that cancer and associated therapies can have on the normal growth and development of AYAs. Early implementation of a comprehensive palliative care plan will help to mitigate challenges related to the AYA's age and developmental stage. Concerns commonly shared by this age group include worries about romantic relationships and social connections, symptom management, and late effects of treatment which may interfere with life goals after cure and well into survivorship.⁶¹ For the AYA population, APRNs must be prepared to assess and manage distress surrounding finances, post high school vocational training or education, employment, fertility and family planning, and family disagreements about goals of care. Coordination of care involving complex treatment plans and multiple psychosocial services is the foundation of the supportive care plan for the AYA.

By meeting AYAs where they are developmentally, APRNs help to facilitate and support their participation in their own medical decision-making. Engaging AYAs in conversations aimed at helping them shape a picture of quality of life is a vital palliative care intervention. Every AYA has their own level of cognitive understanding and emotional maturity, psychologic strengths and weakness, and thoughts about their own goals of care. Assessing and understanding those factors will allow the APRN to help AYAs communicate their wishes while advocating for themselves throughout the cancer journey.⁶² "Facilitating an AYA's concept of living well may be an empowering intervention, which initiates information sharing between AYAs and clinicians, thereby supporting their engagement in care across a disease trajectory."⁶³

GOALS OF CARE AND DECISION-MAKING

ACP is the process by which, through discussion, healthcare providers can begin to understand what an individual wants with respect to medical care in the future and at end of life (see Chapter 32, "Advance Care Planning"). As a part of ACP for children, shared decision-making and the development of goals of care build on some of the same principles used in adult practice although these are often viewed as much more difficult in pediatrics. Healthcare providers may be reluctant to initiate conversations with parents to discuss those medical interventions they may want for their child because the provider fears the conversation will be upsetting for the family and potentially undermine hope.⁶⁴ In a recent study, 56% of bereaved parents stated they wished they had developed an advance care plan prior to their child's death.⁶⁵

The process of shared decision-making between pediatric patients, their families, and healthcare teams must be approached as a fluid process. Healthcare decisions and goal

development in pediatric oncology are generally not concluded after one or two discussions. Instead these conversations happen along the care continuum. In addition, the roles that the child and families take in this process may change over time. A child's age, developmental level, acute or chronic issues, and understanding of their disease trajectory will impact how these conversations occur. Children at a variety of ages, including those possibly considered too young for decision-making, may be very involved in discussions about their care. Shared decision-making in pediatric oncology must be based on an assessment of each child's individual ability to understand and respond to information regardless of their chronologic age.⁶⁶

A parent's will to care for their child, protect them from unfavorable outcomes, guilt related to their child's illness, and their desire to ensure their child has the opportunity to grow and experience life may impact decision-making and goal-setting.⁶⁶ The PP APRN must recognize and address parental fears and concerns; they must be respectful of the child or parent whose goals of care may differ from those of the medical team and facilitate movement toward mutual understanding and agreement. Understanding what the child and family truly comprehend about the illness, treatment options, risks, and benefits related to interventions and potential short- and long-term outcomes will facilitate the family's ability to make informed decisions. Helping the child and family clarify supportive and palliative interventions, set goals for the present, and consider options should the child's disease progress or bring them closer to end of life is vital to medical decision-making in pediatrics and is known as *parallel planning*.⁶⁷ With each situation, making sure the desired care is congruent with parent and child values and preferences is the most important outcome.⁶⁸

REFRAMING GOALS OF CARE

Goals-of-care discussions are always a challenge when a child, adolescent, or young adult is the focus of the discussion. Goals of care may change many times during the cancer journey. At diagnosis, goals are often more cure-oriented, including the use of aggressive, life-sustaining therapies. At relapse, the focus may change to prolonging life and balancing the benefits of treatment against symptom distress. Goals for survivorship may include optimizing functionality, quality of life, and sense of well-being in all domains.

When it becomes evident that cure is no longer a possibility, helping the patient and family reframe their goals can be very difficult in that the family's mindset of ongoing treatment routines and potential cure is suddenly disrupted. Having a solid framework from which to initiate reframing a goals-of-care discussion helps to bring organization to a difficult conversation. REMAP (Reframe, Expect Emotion, Map out patient goals, Align with goals and Propose a plan) is a framework developed to help providers have conversations in which reframing of goals of care is necessary.⁶⁹ REMAP provides an organized process of sharing the changing or poor prognosis, responding to the emotions that the family

will express, discussing family values, and supporting shared decision-making when creating plans for medical care going forward, and this ultimately results in better care at end of life.⁶⁹ Reframing of patient and family goals at end of life should be used as a time for focusing on the child and family and what unmet needs they wish to address and less about making the right medical decisions. It is important to recognize that grief and bereavement start before the child's death, and reframing goals to support that process should be the focus. Finally, viewing the process as a healing one may dampen the moral distress often seen in those caring for a dying child.⁷⁰

ESSENTIAL ROLE OF HOPE

Hope is a very common emotion expressed by children and families in pediatric oncology. Hope is a valuable tool humans use as a protective factor directly impacting health and well-being.^{71,72} Hope serves as a mechanism by which people are able to express and attain their goals and achieve positive outcomes, particularly during times of uncertainty or stress.⁷¹ Hope can be an effective coping strategy and can provide the family a reason for placing one foot in front of the other and continuing with daily routines.

Hope has often been linked to an expectation of a favorable prognosis or cure.^{71,73–75} Given this belief that hope is connected to a positive outcome, clinicians often perceive giving bad or difficult news about a child's cancer diagnosis as being in opposition to a family's hope or taking away hope.^{73,74} The clinician may, therefore, find it difficult to give them full prognostic information. One example is relapsed or refractory cancer. Families may elect to take part in a Phase I study without understanding that these studies are designed to test the safety profile of a new agent with little known benefit. Clinicians may inadvertently intensify the family's hopes by overestimating the outcomes of the clinical trial. While the medical team is aware that the treatment may be of little benefit to the child, the family may elect to focus their discussions on the hope that the treatment will cure their child's cancer. Led by their own hopes for a cure, the survival of the child and a desire to support what they believe is the family's only hope, oncologists may sidestep disclosing the likely outcome of the trial to avoid further distress for the family. Yet parents are able to both hope for a cure and acknowledge realistic expectations for their child's future with an incurable cancer.^{73–75} Parents reported other hopes centered on their child's well-being, such as an improved quality of life, minimal suffering, for the child to feel loved, and for better treatments of future children with cancer.^{73,74} Open and honest dialogue regarding a child's prognosis has been shown to encourage patient and family autonomy and allow for personal choices for end-of-life care.⁷³

Two categories of hope have been identified in parents of children with cancer: future-oriented hope and present-oriented hope.⁷⁴ *Future-oriented hope* involves hope for a cure and treatment success, hope for the child's future, hope for a miracle, and hope for more quality time with the child.

Present-oriented hope involves hope for each day and each moment, hope for no pain and suffering, and hope for no complications.⁷⁴ Many parents recognize that their hope for a cure may differ from their expectations of what is likely to occur.⁷³ However, if clinicians assume a family's only hope is for a cure and do not assess or identify the patient or family's more achievable, present-oriented hopes (i.e., minimize suffering, being home, improving quality of life), these may never be achieved. It is important for the PP APRN to assess the patient's and family's future-oriented hopes, their expectations, and "what else are you hoping for" to identify those more achievable hopes in order to develop an effective plan of care for the child.^{73,74}

Hope expressed by families often vacillates over time depending on the presence of uncontrolled symptoms (i.e., pain, fatigue, dyspnea) and how the child is responding to therapy.^{71,75} The presence of anxiety or depression also appears to have an effect on hope.⁷² Children with clinical levels of anxiety and depressive symptoms have been shown to have significantly lower hope scores compared to those without clinical levels of anxiety and depressive symptoms.⁷² Likewise, improvements in quality of life are associated with improvements in one's hope.⁷¹ The PP APRN can enrich the family's hope by enhancing the child's quality of life by relieving suffering and optimizing function.

Patients and families will struggle if they have no hope or goals to work toward. Developing realistic goals can provide a sense of hope for something they can achieve. Families may need guidance with identifying realistic goals to provide for a new sense of hope when faced with a child with terminal cancer. Even though the plan of care may not involve a longer life, developing realistic goals can help children and families work on psychological healing and in achieving other milestones for closure. This produces more positive emotions in those with terminal illness and their families.

EMERGING THERAPIES

When a child has exhausted standard treatment options, the family may seek additional available therapies. In recent years, new and evolving biologic and immunotherapies have rapidly altered the landscape of cancer-directed therapy for children with advanced cancer.⁷⁶ Prior to these advances, when a child with cancer had not found success on an open Phase I clinical trial, few options for additional treatments were available.

However, currently, there are more potential therapies, generally without a curative intent. Occasionally these treatments may provide little symptom burden, can be done at home, and may meet the goals of the family to continue treatment for the child's cancer. Occasionally some of these therapies result in burdensome side effects, negatively impact the child's quality of life, and may require hospitalization or assessments away from their primary institution, their home state, and support systems.^{76,77} In addition, healthcare payment models may not allow for concurrent care (i.e., cancer-directed therapy received simultaneously with hospice).⁷⁶ Besides ensuring the child's symptoms are properly addressed,

delaying hospice enrollment may prevent the child from dying in their preferred location and also result in lack of preparation for the child's end of life.⁷⁸

The PP APRN must ensure open, honest communication with the patient and family to explore hopes, worries, goals, and perspectives to assist in guiding the family through informed decision-making. Through this process, the PP APRN serves as an advocate for the patient and family, collaborating with the oncologist, local healthcare systems, and the patient's payer source to ensure sound treatment options that meet the child's and family's goals.⁷⁶

SUMMARY

The diagnosis of cancer in a child is difficult for both families and medical teams. Recent advancements in pediatric cancer-directed therapies, particularly for advanced cancers, can pose additional interesting challenges for the APRN. Palliative care may relieve suffering and promote improved coping and a sense of hope for the family and healthcare teams. Assessment and management of symptoms and reevaluation of goals are paramount throughout the illness trajectory. Early integration of palliative care in this setting can allow relationships and trust to develop over time and can allow an improved understanding of the patient's and family's wishes. The PP APRN has an essential role in care of the child with cancer.

THE PEDIATRIC PALLIATIVE APRN IN THE COMMUNITY

Joan “Jody” Chrastek and Jaime Hensel

KEY POINTS

- The family is the unit of care. All interventions must be culturally sensitive, holistic, and evidence-based, addressing the physical, psychosocial, emotional, and spiritual needs of the child and family.
- As guide, ally, and advocate, the community-based pediatric palliative advanced practice registered nurse (CBPP APRN) collaborates with the child and their family in their own setting to ensure a culturally appropriate, equitable, practical, and realistic plan of care.
- No PP APRN works alone; team support and excellent professional boundaries are a must to provide best care and to protect the child and family and the professionals caring for them.
- There is a need for more widespread pediatric palliative care in the community; experienced providers of adult hospice and palliative care can help meet this need.
- Adult hospices unfamiliar with the care of children should access pediatric-specific resources to assure quality care.

CASE STUDY 1: INITIAL DIAGNOSIS OF A CHILD

Amir was 3 years old when his mother, Zara, noticed that his belly had enlarged over the span of a couple of weeks. During a diaper change, his mother found a firm abdominal mass. Amir was taken to his primary care pediatric nurse practitioner, who did a workup. Based on the concerning results, Amir was admitted to the hospital for an oncology workup which revealed a Wilms tumor of his right kidney.

Amir's initial hospital stay was difficult, for both Amir and Zara. Amir had difficult-to-control pain after his tumor resection. He developed nausea and constipation caused by the pain medications and itching secondary to an allergic reaction to the adhesive in one of his bandages. As a single working mother, Zara often felt guilty that she couldn't be at the hospital during the day. Amir's oncologist consulted inpatient pediatric palliative care for family support and symptom management.

Amir improved significantly with the implementation of the pediatric palliative care recommendations. Oncology made plans for Amir's outpatient chemotherapeutic regimen. As discharge planning started, Zara asked if there was any community-based palliative care available. A referral was placed to outpatient community-based pediatric palliative care.

INTRODUCTION

Community-based palliative care services have increased rapidly in the past couple of decades in the United States.¹ However pediatric services may be difficult to access because programs serving adults may not accept children.² Often, palliative care professionals who are competent to care for adults are unfamiliar with the care of children and may feel unprepared or even refuse to provide care for children.³ The adage “children are not little adults” may be used as a justification. Although this is both a truism and a guiding principle in pediatric care, professionals with palliative care skills should be reassured that they still have much to offer when caring for pediatric patients. Most adult palliative care interventions and techniques carry over to children, but some attributes make the provision of community pediatric palliative care (PPC) unique.²

The underlying principle of PPC is its fundamental grounding in a family-centered approach. The majority of children are neither their own decision-makers nor their own caretakers, although older adolescents may sometimes assume more of these responsibilities.⁴ Caregiving is, however, the natural role and privilege of parents or parental surrogates, whatever the health status of the child. The fact that family values, preferences, and goals serve as the basis for PPC cannot be overestimated.^{5–7} Most children eligible for palliative care, especially those who live past the neonatal stage, spend the majority of their lives at home. Research suggests that home is often the preferred location of death for children, according to both children and their families.^{3,8–10}

Sometimes the best comfort measure for a child is to facilitate a safe transition of care from the hospital to home. Managing a medically fragile child at home may be intimidating for families, particularly as the child nears end of life. Excellent education, support, and 24-hour availability of professionals allows families to remain at home through a child's disease process, their decline, and even death.³ Creative use of technology and collaborative alliances with existing providers often facilitate the provision of care, particularly for those patients who live in rural or underserved areas.^{11–13}

It is essential that palliative care is delivered with respect, compassion, and collaboration. A home is the family's space, and it is the team's privilege to be allowed to enter as a visitor. It is important to honor and respect the family's customs and rules. To be successful in providing excellent palliative care at home, the team must listen closely to the family and

seek to understand their point of view, values, and beliefs to engage them as partners. The intimate nature of home-based care requires cultural sensitivity for all healthcare professionals involved and a comprehensive view of the care of family which includes siblings, extended family, and the community.^{11,12}

To ensure holistic and collaborative care, the community-based pediatric palliative advanced practice registered nurse (CBPP APRN) often needs to engage diverse partners such as schools, community nursing agencies, summer camps, primary pediatricians, faith communities, and hospices. The CBPP APRN is a combination of clinician, supportive counselor, care coordinator, patient and family advocate, and educator. These roles may vary widely depending on the child's diagnosis, where the child lives, who comprises the interdisciplinary team, and the needs and preferences of the family, along with myriad other factors. The strength of palliative APRNs lies in their flexibility, adaptability, and the patient- and family-centered approach that is at the heart of palliative care.

ENTRY INTO PEDIATRIC COMMUNITY-BASED PALLIATIVE CARE

A thorough community assessment is critically important to providing comprehensive community palliative care, especially for APRNs new to community-based PPC or new to a healthcare community. Resources vary widely from one community to another; therefore, knowledge about social services and provider agencies may dramatically impact the way care is provided.^{11,14,15}

The initiation of community-based PPC varies widely. While children are most often referred from hospitals, they are also referred by primary care providers, parents, social services, home nursing agencies, or even other palliative or hospice organizations. Children with serious illness admitted to community-based palliative care may have an estimated prognosis of years or may be admitted to home hospice with an anticipated death within days or months.

Prior to admission to community palliative or hospice care, the primary care provider must have a goals-of-care conversation with the family (and the child if appropriate).¹⁶ PPC is a big tent that encompasses a wide breadth of care plans and treatment goals, from long-term symptom management to end-of-life care.¹⁷ It is important to listen to the family's understanding of their child's condition and what are their hopes and wishes.¹⁸

There may be times where a family's understanding is different from that of the medical team. In these situations, the team should gently attempt to align the family's understanding of their child's medical prognosis with the team's understanding. The team should also educate about the anticipated course of the illness and the likely symptoms the child may experience. Clinicians must be thoughtful about leaving room for differing cultural and religious beliefs, as well as leaving space for participation by the child if the child is able and the family permits this.^{18,19}

Once the family-clinician dyad forms a common understanding, then a shared plan of care can be developed. Faced with similar situations, each family chooses a different path. One family with a child diagnosed with widely metastatic cancer may prioritize time spent out of the hospital and desire a hospice plan of care. Another family, faced with a child with a similar diagnosis, may prioritize seeking additional treatment. The ability to have a kind, compassionate, culturally sensitive goals-of-care conversation is a necessary skill for all hospice and palliative APRNs.^{20,21} Box 30.1 offers selected resources about pediatric goals of care conversations.

Most states have forms that communicate preferences for life-sustaining treatments to community providers and

emergency medical personnel, generically known as out-of-hospital orders for life-sustaining treatment. Many states refer to this document as a *provider/physician orders for life sustaining treatment* (POLST). The completion of such documents requires a family meeting about what the form means and does not mean. Its completion offers families peace of mind and some reassurance that their wishes for their child will be followed in the community setting (see Chapter 32, “Advance Care Planning”).

The specific name and statutes for the completion of these documents may vary from state to state. In some states, APRNs may sign them; in other states it is the sole purview of physicians.²² In some locations families are required to co-sign the document on behalf of their child, while in other states this is not required. In some locations the document may be legally binding for adults but not for children. CBPP APRNs must understand the rules of POLST documents in the communities in which they practice, as well as the portability of POLST documents from one state to another. Of note, while a POLST is meant to simply express the wishes of the family, some hospices do require a POLST (with “do not resuscitate” selected) as a condition of admission. Even more confusing is that some states do not allow children to have a no-code status. A do-not-resuscitate (DNR) code status is not a requirement for hospice under the Centers for Medicare and Medicaid Services (CMS) Medicare Hospice Benefit Conditions of Participation (COPs). Thus, CBPP APRNs should understand the eligibility requirements of the hospices and states they work with.

Once goals are determined and documented, referral to a pediatric hospice is a formal process, requiring a physician to complete a form certifying terminal illness. Quality transitions of care include a handoff conversation between the referring provider and the receiving program to confirm the appropriateness of enrollment; provide additional information, such as a brief synopsis of relevant medical and social information; and to communicate the patient/family goals of care.²³ It should be noted that the primary or referring team often remains involved in the child’s care through the child’s end of life.

To enroll in hospice, the CMS Medicare Hospice Benefit COPs require certification of a terminal illness, specifically that an individual is in the last 6 months of life.²⁴ For adult patients, the decision to elect hospice is predicated on whether a patient is willing to forgo curative, disease-directed treatments to focus solely on comfort and quality of life.²⁵ While there are eligibility criteria for adults relating to common terminal conditions in adults, such as cancer, heart or liver failure, and dementia to name a few, there are no similarly standard criteria for pediatric patients.^{24,25} This is because children, in general, die of different diseases than adults. Genetics, for instance, plays a much larger role in pediatric end of life.²⁶ Children with conditions commonly found in the adult population, such as liver failure, often have a different underlying illness.²⁶ Moreover, children are more likely to have advanced medical support, such as total parental nutrition (TPN) dependence or gastrostomy (G-tube) feeding access, as part of their daily life.²⁶ Therefore, determination of hospice eligibility in children is based on clinician best judgment.

Although it is hard to talk about the financial cost of caring for seriously ill and dying children, it is a responsibility of the CBPP APRN to do so. Many children with life-limiting illnesses are covered under state Medicaid insurance or Children’s Health Insurance Program (CHIP),²⁷ while others are covered under their parents’ major commercial insurances. *Concurrent care* allows children to receive hospice care while remaining enrolled in other services, including disease-directed therapies and life-prolonging interventions.²⁸ Although a provision of the *Affordable Care Act*, passed in 2010, requires that Medicaid allow for a concurrent care model, this is not uniformly enacted in each state. While the *Concurrent Care for Children Requirement* (CCCR) is mandated on the federal level, the ways in which individual states have implemented and supplemented the CCCR differ because it is covered under Medicaid.²⁹ Many commercial insurance companies do honor concurrent care, but some do not, so clarity about insurance coverage is essential. These payer source differences have implications for financial aspects of care, and families must be informed about what a child’s insurance benefits will cover and what costs the families will incur when they consider individual treatment plans. The CBPP APRN needs to tailor plans to the finances and resources of the family. However, unlike adults, there is more often philanthropy available to support the care of children with financial hardship.

Community palliative care programs working with children must also work to be fiscally responsible. The Center to Advance Palliative Care collated data to demonstrate how palliative care can improve satisfaction and reduce costs.³⁰ The complexity of the healthcare reimbursement system in the United States has made demonstrating these metrics difficult because regulations can vary from state to state. But research has found that the provision of home-based palliative care across the country shows cost savings as well as improved quality of life for children with life-limiting illnesses.^{31–34} California (which has a state mandate for palliative care) and Washington have both implemented programs that have reduced costs and improved satisfaction,³⁵ and other states are following suit.³¹ As part of doing a community assessment, the CBPP APRN should gain a thorough understanding of the health landscape in their own region in order to best serve and guide children and their families. The National Hospice and Palliative Care Organization has a webpage that offers resources about pediatric care (<https://www.nhpco.org/pediatrics/>).

Prior to admission to the home-based organization, the CBPP APRN should perform a verbal home assessment, where the family is queried about the physical home itself. The APRN should ask questions about whether the house has running water, electricity, heat and cooling systems; the number of stairs into the home; whether the home has adequate outlets to plug in necessary equipment; and if there are adequate cooking facilities and food storage areas. Furthermore, the CBPP APRN should be proactive about care in potential emergencies: Is the house accessible by emergency services in the snow? Can the power company be notified that, if there is a power loss they should try to restore service to the patient’s house more quickly? What is the plan should there be a

natural disaster? The CBPP APRN should allow the parents to take the lead in addressing perceived barriers to care and be flexible in what solutions are considered acceptable while still formulating a safe and secure plan.

The home assessment continues throughout the time the child is under the home services. Once services have been initiated, the CBPP APRN or other members of the team can assess the child and family in their own environment. They may notice minor hazards such as loose carpet fringe, or major hazards such as hoarding, indoor smoking, or unsecured firearms. If a concern is noted, the CBPP APRN should find ways to sensitively and diplomatically express their concern and work with the family to find an acceptable remedy. The home care team should also be vigilant about the possibility of abuse. While most children are lovingly cared for, it is important to know that children with disabilities are considerably more likely than their peers without disability to experience physical, mental, and sexual abuse. As always, CBPP APRNs remain mandated reporters. See Box 30.2 for additional home assessment considerations.

Not all palliative care visits have to be conducted in person to be effective. Video visits have increased in healthcare and

can be of great benefit for some PPC patients, such as those who have difficulty leaving the house or those who live in remote areas.³⁷ With the appropriate introduction, technology allows the CBPP APRN to visualize where the child lives, interact with the child and their family, and partner in care provision. Once barriers to utilization, such as acquisition of appropriate hardware and adequate internet bandwidth, are overcome, virtual palliative care home visits and consultations have generally been shown to be beneficial and acceptable to many families.^{37,38} One drawback of telehealth visits is the limited physical exam. However, additional technology in the form of biometric trackers, smart devices, and apps may be a way to provide remotely some of the information usually gathered in a physical exam.³⁹

CARE PROVISION IN THE HOME

Continuity of care or “seamless care” is a common goal in today’s healthcare world for providers and patients alike. Continuity, guided by patients and families along with the healthcare team, is often highly complex.⁴⁰ Continuity of care

Box 30.2 SELECT HOME ASSESSMENT TOPICS

Caregiver considerations: Are there enough willing caregivers in the home? Are there back-up caregivers? Do the caregivers have the necessary training?

Abuse considerations: Is there concern for illicit substance use in the home? Does the child or any family member seem fearful, neglected, or show signs of physical abuse?

Safety considerations:

Neighborhood: Is the neighborhood safe? If not, what steps need to be taken to ensure visiting staff are safe?

Dwelling: Are there smoke detectors and carbon monoxide detectors? Is there a safe and useable emergency evacuation route available for the child? Are there pets in the home that might harm the child (or the nurse)? Are medications stored securely so that other children and pets don’t accidentally ingest them? Are there guns in the house, and, if so, are they safely stored? Are there fringed rugs? Is there a cigarette, cigar, or pipe smoker in the home?

Transportation: How far does the family and child live from regular medical care? Does the family and child have a reliable way to get to and from appointments? Can the family and afford the transportation?

Medical equipment considerations: Does the child need a specialized bed or mobility devices? Does the child need a lift? Is oxygen delivery available in the area? Where will other supplies, such as bed pads or syringes, come from? Will the child’s insurance cover all the costs and supplies? Is there a limit to how many disposable supplies the insurance will pay for?

Emergency medical services (EMS): Does the child live in an area covered by EMS? Is EMS aware of the child’s medical condition (if the family would like them to be)? How far is the nearest emergency room? What is the back-up plan for the child in the event of an emergency or loss of power?

Building considerations: Are there steps into the home? Does the home have adequate lighting? Are the doorways wide enough? Are the bathrooms equipped for the child’s use? Will deep pile rugs interfere with mobility devices? Is there an elevator?

Utility considerations: Does the house have an adequate and reliable power supply for the child to safely live at home? What is the plan if a power outage occurs? Will the new equipment increase utility bills, and, if so, can the family afford this increase?

Finance considerations: Is the family able to pay their bills? Does the family have enough food?

Community resources: Is the family connected to community resources? Is there access to grocery stores and pharmacies?

Cultural and language issues: Does the family have hold cultural beliefs that may influence how the care is provided and who the caregivers are? Is an interpreter needed for home visits? Is an interpreter available for on-call or urgent needs?

Housekeeping considerations: Is the house clean enough for care delivery? Is there is specialized medical waste (such as sharps)? What is the plan to dispose of medical waste safely?

is described as the continuous relationship between a provider or team of providers and a patient, as well as the coordination and sharing of information between providers' practices.^{41,42} This can be a particular challenge in PPC due to the large number of specialists involved in the care. It is here that the CBPP APRN is an important bridge between silos of care.⁴³ The need for collaboration extends even further beyond the hospital into all aspects of the child's life. For example, home-based services, nursing, physiotherapy, academic programs or other school-based therapies, outpatient clinics, and hospitals may all be part of a child's care team but may not share electronic medical records. With such a large and diverse team, communication often is incomplete, leaving providers and families frustrated and exhausted trying to fit the pieces together.⁴³

As discussed earlier, when a child comes home for hospice or palliative care, it is essential for the CBPP APRN to discuss the situation, including the social, emotional, physical, spiritual, and cultural aspects of care, with the referring team. Attention should be paid to reducing any health disparities. The child may live in a foster home, a group home, or move between the homes of divorced parents. The referring team can provide helpful context to the home-based team, including any concerns they may have regarding family coping, mental health issues, or substance abuse potential. In these situations, the CBPP APRN and team can develop a care plan in concert with the managing team to provide the best and safest care for the child and family and work to make the transition as smooth as possible.

Communication is essential for good palliative care. Once the child is at home, this means reaching out to many different parts of the child's life. See Box 30.3 for an example of the

larger community team that may interact with the child and family. It is important to ensure that communication aligns with the parents' wishes, especially with regards to confidentiality. As the CBPP APRN meets with the parents or caregivers in the home, the family is the center of all decisions: everything must be coordinated with them. Not all families are traditionally structured, nor do they make choices in the same way. The CBPP APRN can explore with the family who is involved in decision-making, how decisions are made, and what role culture and religion play in the care of the child.

Parents often have a close relationship with their child's primary medical provider or specialist, and that relationship continues to be very important even as care becomes more home-based. The CBPP APRN should collaborate with the family and involved teams to ensure clarity on who is managing which pieces of the child's care. The CBPP APRN may serve as the key point of communication among all of the teams.

When resources are scarce, the CBPP APRN collaborates with the family to access all available local resources. For instance, a palliative care team may not have a child life specialist, but they may be able to recruit the child's teacher to help guide the team in how best to work with the child and siblings on an appropriate developmental level. Telehealth can be a wonderful tool for collaboration and continuity, especially in areas where a specific specialist does not exist (see Chapter 17, "The Palliative APRN in Telehealth"). Parents have expressed decreased anxiety when a specialist is involved in their child's care,^{29,44} and video visits are one way to bring specialists to the child and family in underserved and rural areas. The CBPP APRN is often the coordinator of these types of collaborations, working to develop a comprehensive and cohesive team.

The CBPP APRN often takes the role of organizer and team lead on behalf of the child. They must use expert communication, provide attentive listening, build collaborative relationships, and share information. This can be quite stressful for the palliative APRN who lacks formal education in community-based pediatric palliative care.^{45,46} However, a CBPP APRN has a deep toolbox from which to draw in the roles of clinician, consultant, educator, leader, and researcher in service of their pediatric patients.

Families live in communities with friends and neighbors, many of whom may want information about the child or to offer assistance. At times this can be helpful, but at other times it may feel awkward and invasive. The home-based team can discuss child and family preferences and concerns in this area, specifically who they want as part of their inner circle of support and how much they want to share, if at all, outside that circle. Families often need assistance in creating pat answers for those times they do not wish to share. For example, a casual acquaintance may ask, "So how is the little darling?" and the parents can be coached to respond, "We are happy to have her home" and leave it at that. Each family will, of course, decide what phrases work best for them and their situation. However, it is helpful to have a plan in mind because often inquiries about the child's health come paired with unwanted advice and judgments.

Visitors to the home may also be helpful or burdensome. Some families may want private time at home without visitors

but feel rude turning well-meaning friends or caregivers away. In such cases, the CBPP APRN can offer to set up guidelines of the family's choosing that can then become the "provider rules." In this manner, the APRN helps the family set boundaries and relieves the family of the burden of saying no to visitors. For example, a family may let people know that "hospice has set visiting hours" for the child or limited the length of visits. Communicating closely with families can assure that the team is helping them make the most of their time at home with their child and keeping a keen focus on quality of life.

All children have wishes and desires: those children under palliative care or hospice are no different. The home-based palliative APRN can work with the team and family to investigate how to grant some of those wishes. For some children and their families, a last trip to a special place is extremely important. The palliative care team can help identify resources such as community or national organizations that may have funding to make these trips possible. The team can support these efforts by taking care of the medical logistics, which may include close collaboration with professionals at the trip destination. Some places, such as theme parks, are very familiar with hosting children with medical complexities, while other destinations are not. It is important to put together a travel packet that includes an official letter from the managing clinician with the child's diagnosis, history, code status, and medications, as well as contact information for the palliative team. Copies of other important documents related to the child's care should also be included. Pre-identifying hospitals on the way and at the destination can be helpful. Local hospices near the destination may be willing to contract to provide care if needed.

There are also camps for children with palliative care and hospice needs. The child may already be connected with one or may benefit from a referral. These camps tend to be well-organized and suited to provide both excellent medical care and a fun experience for the child. The forms and requirements are unique to each setting but are usually straightforward.

HOME DEATHS

CASE STUDY 2: INFANT DEATH AT HOME

Jenna was born with trisomy 13, with fatal renal and cardiac complications. Her parents, Ravi and Andrea, when informed about the diagnosis prenatally, requested comfort care only at birth. They asked for discharge home as soon as possible with hospice. They especially wanted their 4-year-old son David to have a chance to meet Jenna. Andrea had explained to David that Jenna would "just be a visitor and not stay very long," but reassured him that they themselves would not leave.

Jenna was born on a Monday evening and was stable. An early discharge was planned, and the hospice team visited the same day. The family was sent home from the hospital with emergency comfort medications (sublingual morphine for dyspnea, lorazepam for agitation, and atropine drops to reduce secretions) because they are not always easy to obtain quickly in the community.

The inpatient PP APRN also sent home a completed provider/physician orders for life-sustaining treatment (POLST).

Jenna and her parents arrived home to a family birthday party for Jenna arranged by her grandparents. The hospice APRN and the social worker arrived shortly after the family and were invited to enjoy a piece of cake. David was shy at first, but quickly warmed up to the hospice team, which had brought him some crayons and a coloring book to keep him occupied while they talked to his parents.

The hospice team listened to the parents' story and concerns and asked how much information on what to expect they would like. Andrea wanted to know everything but Ravi wanted just the minimum and said that Andrea could fill him in later. He wanted to just enjoy his new daughter.

As Andrea had never seen anyone die—or even been to a funeral—it was important to review the expected physiological changes, as well as medications and nonmedication interventions that could bring Jenna comfort. A step-by-step explanation was provided verbally and via a written symptom management guide. The team let Andrea know that Jenna would be registered as an expected death at home, so likely there would not be police involvement. Therefore, they emphasized, it was important at the time of death to call hospice and not 911.

Later that night, Jenna started to have apnea spells and some cyanosis. Andrea quickly called hospice and gave the morphine as instructed. It helped and Jenna fell asleep; her parents did not. The next morning, the hospice nurse found Jenna was declining quickly with 30- to 45-second apneic spells and cool, blue extremities. The nurse gently informed the parents death was close. Her grandparents were called and came to be there for David. Andrea and Ravi lay down in bed on either side of Jenna, while the hospice nurse gave them privacy and spent time playing with David. He said, "I found a dead bird in the garden—my mom said Jenna was going to die." This allowed the hospice nurse to engage in an age-appropriate conversation about death with him.

Twenty minutes later, the nurse heard Andrea calling for her. She told the nurse that Jenna had not breathed for 3 minutes, and she thought she had died. The nurse listened and found that her heart was still beating, just as Jenna took another breath. The nurse did a little bit of education about apnea at end of life, and let them know death was still close. Jenna died peacefully when both parents had dozed off, about an hour later. Initially Andrea and Ravi felt bad that they had missed the moment but were comforted by the nurse's reassurance that it was OK. The hospice nurse said, "Sometimes it seems that those who are loved as much as Jenna was can only die when their loved ones are asleep or not totally focusing on them. She knew she was surrounded by your love." The hospice nurse allowed them private time, called the medical examiner to report the expected death at home, then answered the family's questions about the experience.

CASE STUDY 3: DEATH OF CHRONICALLY ILL CHILD

Rosie, an only child, was diagnosed with a slow neurodegenerative condition when she was 5 years old, after an astute pediatrician noticed her increasing difficulty walking. Over the years as

her disease progressed, her parents became her nurses, case managers, advocates, and assumed many other roles on her behalf. Rosie's parents knew her condition was inevitably fatal, but their lives revolved around her. In addition to her parents, Rosie had a dedicated team of personal care attendants (PCA) who had cared for her for years. Rosie had been also referred to palliative care at the time of her diagnosis.

Rosie saw the palliative team infrequently for many years while her symptom needs were relatively low. With the slow progression of her condition, palliative care was there mainly to build rapport and to assist in decision-making. For instance, as a young child, Rosie loved to eat, but over time her swallowing became ineffective. The palliative care team helped facilitate a meeting with a gastroenterology consult to decide whether advanced nutrition support would be right for Rosie. Ultimately, a gastrostomy tube was placed and was used for many years.

Rosie's condition declined quickly when her respiratory system became more involved. When she started to have difficulty breathing, palliative care became more intensively involved in her care, and, not long after, hospice was initiated. Six months into her respiratory decline, Rosie was actively dying. Her parents were desperate to keep her at home but were also profoundly exhausted. They had good social support but found they needed help to organize all the willing volunteers. The palliative social worker was helpful in identifying community resources that allowed the family some relief.

Rosie began to show signs of feeding intolerance, vomiting, and cramping when she was given her medically administered nutrition. Hospice staff had discussed that this might occur, but the gastrostomy tube had become much so much a part of who Rosie was that it was very difficult for the family to even think about stopping. The team tried many different interventions to see if Rosie could tolerate the feeds, but eventually realized that her body could no longer process food and it was causing her pain. Her parents listened to the silent message Rosie was giving them and made the loving decision to stop the medically administered nutrition. It was clear her comfort improved even as she was dying. The hospice APRN met with the PCAs as they struggled to accept and support the family's decisions.

The hospice APRN and social worker met with the family regularly to talk about their wishes for Rosie, to keep her comfort at the center of her care, and even to help them plan the funeral. The parents had been thinking about Rosie's death for many years, but had done no concrete planning and appreciated the support to do so.

In the last month of Rosie's life, the hospice team reviewed with Rosie's parents and caregivers what Rosie's death might look like while cautioning them that every death is unique. Not long after the conversation, Rosie became very agitated, with frightening hallucinations and confusion. After multiple interventions failed, she needed significant sedation to be comfortable. Even the medical team was surprised at the amount of medication she needed, but they were able to titrate to an appropriate dose for comfort. The sedation decreased Rosie's agitation and induced relaxation, allowing her parents to concentrate on just spending time with her. It was a precious but difficult time, lasting 3 weeks. The long trajectory of her dying process was very difficult for the

family. They expressed feeling like they were hanging on a cliff with their fingernails. Although they did not want the death to happen, they found the stress of waiting for the inevitable was excruciating.

Rosie died peacefully one afternoon when everyone was in the kitchen making dinner. Her parents were sad, but also relieved that her suffering was over. They were confident that Rosie had known she was surrounded by love.

MEDICATIONS

When a family transitions home with a child who is expected to die in a short time, it is important to send them home with comfort medications, not just prescriptions. Some commonly used comfort medications may not be easily available in the community. Although many hospices have standing orders for their adult hospice patients, these standing orders may not be appropriate for children and young adults. Standing orders, if used at all, should be reviewed and individualized to the unique needs of that child. This process assures that the team has a customized comfort plan in place for each child.

It is expedient to give families a small supply of end-of-life comfort medications to have available if urgently needed prior to hospice's arrival and subsequent medication delivery. Usually this is a sublingual liquid opioid for pain and dyspnea, a benzodiazepine for anxiety, and an anticholinergic to help with secretions. (See Appendix II for pediatric pain and symptom management medications and dosages.) At times, intranasal medications such as midazolam or fentanyl may be the drug and route of choice due to their rapid action. Rectal and transdermal medications may also be utilized. Instructions on the use of all medications must be provided verbally and in writing, in a language the family understands and can read. If the family is not health or language literate, the CBPP APRN needs to help the family develop a way to ensure appropriate dosages and medications are given using pictures, color coding, or another similar tactic. A medical interpreter may also be needed.

INFORMATION

Families need to be provided information about what they might expect to see as the child moves toward death and the child's body shuts down in the dying process. It can be helpful to emphasize that every death is unique, just like every birth is unique. Death can come quickly, or it may take much longer than expected. The parents should be reassured that, whatever happens, the team has many strategies to keep the child comfortable.

Due to culture, ethnicity, or religion, some families are deeply uncomfortable or even refuse to talk about the upcoming death. This should be assessed by the CBPP APRN. However, it is very important that the main caregivers of a child at home know how to care for their dying child. In such situations, the use of hypothetical situations and stories can

be useful. For example the nurse may say, “Of course we never know exactly what will happen in the future, but I want to tell you a story about a similar child and how the parents took such good care of her.” This tactic provides an avenue to talk about how that (real or imagined) other family saw various changes that alerted them that their child was nearing death, gave the various prescribed medications, and what other helpful actions they took to ensure their child was comfortable and well cared for.^{47,48} There may be parents who refuse even oblique mentions of death and are offended that it is even mentioned. In these cases, in the home setting, the hospice team must continue to gently offer the family information but should not force conversations. It is the family’s prerogative whether to receive information or not.

It is essential that the hospice team be aware of any cultural traditions that the family observes around death and dying.^{47,48} For example, in some cultures, a dying child must be clothed in a specific garment, facing a certain direction, or have restrictions on who can touch the body after death. Impending death may also require rituals, such as baptism or other religious ceremonies, which require the presence of a clergy person. Families may rely on the APRN’s expertise in knowing when a child has transitioned to actively dying to ensure the rituals take place.

Funeral planning can be a terribly difficult thing for families to do, but when it is done prior to the death it can make it a little less awful since it can relieve the burden of decision-making in the immediate aftermath of a child’s death. The home hospice staff can help guide the family in the process if they are open to it. Often some funeral information is also provided in the standard written information from the home-based hospice team.

Some families may want to keep their child’s body at home for a prolonged period of time or even have a home funeral. In this case, pre-planning—either with the funeral home in mind or in collaboration with a home funeral group—is important to ensuring a smooth process. For instance, if the body is not kept properly cooled, rigor mortis sets in and the body starts to change colors. The length of time that it takes to set in depends on many factors, including the ambient temperature, but rigor mortis generally appears rapidly in children.⁴⁹ Advance planning makes a significant difference to the experience families have and ensures sure they have the right resources on hand to care for their child. Websites such as the Home Funeral Alliance can be helpful (<https://www.homefuneralalliance.org>).

SIBLINGS OR OTHER CHILDREN

It is helpful to talk to the parents about their plans for siblings when a child dies. Often siblings are left out as death nears, but children are perceptive and will feel the increased tension in the house as their sibling moves closer to dying. If the parents allow, it is important for the CBPP APRN or other members of the team to pay attention to the other children in a dying child’s life.⁵⁰ Families differ

in their comfort of allowing the sibling or other children to be present during the dying process. A family member or a close friend may be willing to be the buddy for the sibling if they are present. Regardless of where the siblings are at the time of death, parents should be strongly encouraged to provide age-appropriate truthful information to their other children. Otherwise, there is a real danger that siblings will use their vivid imaginations to construct their own narratives about what is happening, and these ideas may be much worse than reality.⁵¹

THE EXTENDED TEAM

PPC, especially end-of-life care for children, is commonly seen as a very stressful position for care providers,^{45,50} not only because of the child’s situation but also because of the close relationships that frequently develop between caregivers and the family in the community setting. Extended-hours (private duty) nurses or personal care attendants may themselves need the support of the hospice team. Some of these individuals may have cared for the child for many years and may have strong attachments to the child and family. This closeness, born of being at home with the family for long periods of time, can make it challenging for caregivers to maintain professional boundaries.³⁷ Even the family may begin to experience the visits as personal as well as professional.⁵¹ However, the relationship between the family and the nursing team is a professional one and differs from their personal friendships. It is not a relationship where both parties can share confidences equally. Rather, it is a relationship where families may share confidences in ways that a professional cannot. Healthy boundaries protect the patient, family, and the professional, and if boundaries are not maintained it can result in unfortunate consequences.^{45,50} Being aware of this possible facet of end-of-life care for children with an extended team is an important function of the CBPP APRN. Moreover, the pediatric palliative APRN may help facilitate anticipatory grief support for extended teams.

THE TIME OF DEATH

Most often, the CBPP APRN will not be present at the exact time of a child’s death. Therefore, the family will need clear instructions on who to call to report that the child has died. Most often this is the hospice provider, but the family may instinctively call one of their child’s physicians, who should then call hospice. A registered nurse will perform a home visit to verify the death and report it to the medical examiner. The medical examiner may ask a list of standard questions. See Box 30.4 for common medical examiner’s office questions. Depending on local laws and statutes, in some cases, a formal investigation may need to take place. Families should be prepared for this possibility and the prerogative of the medical examiner to initiate it at the time of death. However, families should be reassured that for most preregistered expected

The presence of any trauma
Funeral home name or plans for the body (e.g., home funeral)

deaths at home there is not a police investigation. A formal investigation is much more likely if the death is due to a previous nonaccidental injury, a vehicle accident, suspicious circumstances, or other unique situations.

A plan should be in place for care of the child's body after death. The home hospice agency may or may not have a set protocol regarding care of the child's body. If there is not a protocol, the CBPP APRN can gently ask the parents if they would like the nurse to wash the body, remove any tubes or medical paraphernalia, or dress the child in a special outfit. If the family has not planned on a home funeral, the funeral director will ultimately prepare the body and put on the final outfit, but some families prefer to wash or perform special rituals before the body is taken away.

After death, some families want their child's body removed quickly from the house, while others may want to keep the body at home for some time. If the family plans to keep the body at home for more than a few hours, the nurse should educate them about the changes they may see as rigor mortis sets in and about the skin color changes that may happen.

Families may also appreciate information about how the child's body will be picked up. Most commonly the funeral home will send two representatives to remove the body, but will come only after ensuring the family is ready. The vehicle used will depend on the funeral home. For infants and young children, they may simply come in a car. However, some funeral homes will always use a hearse. Once the vehicle arrives, some families prefer to carry the child's body out to the car if the child is small enough. For older children and young adults, the funeral home representatives will usually come with a stretcher, similar to an ambulance transfer. In some states, the family is allowed to transport the body themselves in a personal vehicle. It is important for the CBPP APRN to investigate local regulations before the child dies in order to provide families with accurate information.

MEDICATIONS AND SUPPLIES

The disposition of medications can be tricky. The issue of safe disposal should be discussed. With the enactment of the 2018 *Substance Use–Disorder Prevention that Promotes Opioid Recovery and Treatment (SUPPORT) for Patients and Communities Act*,⁵¹ medications ordered when a child is under hospice care can be disposed of by certain hospice personnel in states where laws allow it. A common disposal procedure is to empty all the medications into a sealable container with an inert substance such as flour, coffee grounds, or kitty litter; add water to make a slurry; and then place the whole container in the garbage.^{51,52} The home care and hospice nurse should use their agency's guidelines and have the signature of a witness. A nurse cannot take the medications out of the home to destroy them—this must occur on site.⁵²

The family may also ask what they should do with the child's durable medical equipment and remaining disposable supplies, such as wheelchairs, diapers, or cans of nutrition. While the family is obviously welcome to keep these supplies, many families wish to help others by donating them. The hospice or home health agency may have a list of local agencies that accept donations. Each agency will have its own guidelines regarding what it will accept.

AFTER THE CHILD'S DEATH

It can be very meaningful for many families when healthcare professionals attend a wake or a funeral for a child, especially if the relationship has been long or close. It is also usual for hospice clinicians to make a specific bereavement visit in the period after the child's death and funeral. On this visit, the hospice and palliative APRN should gently assess for any concerning signs of complicated grief that may lead to mental health issues (see Chapter 38, "Grief and Bereavement"). The bereavement care for the family may be taken over by the bereavement team, or the hospice team may provide that service for the next 13 months.

COMMUNITY PROVIDER SUPPORT

The CBPP APRN's role as educator and mentor cannot be overemphasized. While the APRN may provide formal and structured educational offerings, much of the time the APRN teaches by role-modeling excellent care and provides "just in time" education. This type of education is done at the point of care. With adult learners, this format is often more effective and lasting than a formal educational intervention. "Just in time" education is a common need for community-based service providers who have little or no prior experience in the provision of palliative or hospice care to children.

Excellent access and 24-hour availability of palliative care professionals can provide needed support to hospice staff who may not have pediatric experience and any private duty or extended-hours staff in the home and therefore help support

families in staying at home through a child's decline and death.¹ Many of the nurses in a child's care will have worked in the home for years and have a long-standing relationship with the child and family. Yet it is also common for nurses or other team members to have very little or no palliative care training or experience, resulting in fears and misunderstandings about palliative care.⁴⁵ In these situations, the CBPP APRN can provide technical clinical instruction, such how to flush a particular line or care for a wound. But the APRN also may give emotional and psychosocial support to help the home care nurse deal with personal fears concerning caring for a dying child or a child with a life-limiting condition. The intimate nature of home-based care may require particular cultural sensitivity on the part of providers and a comprehensive view of care that includes other clinicians and family members.^{11,12} Creative use of technology and collaborative alliances with existing providers may facilitate the provision of this support, particularly for those practicing in rural or underserved areas.^{54,55}

It is helpful for all team members to realize that palliative care is characterized by continuous learning for the whole team.¹¹ This education should include providing resources such as the national consensus guidelines. The National Consensus Project for Quality Palliative Care (NCP) *Clinical Practice Guidelines*⁵⁶ and the Center to Advance Palliative Care (CAPC) pediatric toolkit⁵⁷ are both valuable resources for those providing PPC.

WELL-BEING AND RESILIENCY FOR THE COMMUNITY-BASED PEDIATRIC PALLIATIVE APRN AND THE PEDIATRIC PALLIATIVE CARE TEAM

Caring for children who are dying or have life-limiting conditions can be emotionally taxing for the staff as well as for the family.^{5,58,59} Domain 1 of the NCP *Clinical Practice Guidelines* states that creating support for staff and including strategies for team well-being are part of quality care.⁵⁷ The concept of well-being has been a focus for all healthcare professionals in the past few years, as evidenced by initiatives from the National Academy of Medicine (Clinician Well-being), the Institute of Health Improvement (Joy at Work), and more recently the American Nurses Association (Well-being Initiative).^{60,61} To be sustainable, a PPC team must incorporate support mechanisms into regular practice and even have support as a focus of their strategic plan.⁶² Even while working as part of a community-based PPC team, clinicians and nurses often do their day-to-day rounds individually and thus lack the easy "curbside" check-ins available to hospital- or clinic-based practice. Therefore, it is essential for each community-based team member to develop a personalized plan to manage the inherent stress and emotional toll of PPC work. When this is ignored, it is to the detriment of not only the individual but also the functioning of the team and, ultimately, to the child and family.⁵⁹

Some programs require every team member to complete a personalized self-care plan and ask each person to choose other

team members as accountability partners to help maintain adherence. Individuals should select supportive and renewing activities that best suit their lifestyle and personality. The plan serves as a guide to remind individuals and the team of the importance of self-care so they can continue sustainably in this challenging but rewarding field of work. Supporting families through difficult times can be challenging but is a skill that all those who work in palliative care must build, particularly less-experienced nurses and clinicians. There are many different ways that well-being is accomplished: the important thing is that it *is* achieved.^{62,63}

One very important aspect of support that is often neglected is the skill of listening. Listening and caring for each team member is essential and is a shared responsibility between the team members and the organizations to which they belong. In the words of Julian of Norwich (1342–1416),

The sorrowing, the sick, the unwanted, the lonely, both young and old, rich and poor, all come to my window. No one listens, they tell me, and so I listen and tell them what they have just told me. And, I sit in silence, listening, letting them grieve. "Julian, you are wise," they say, "You have been gifted with understanding." All I did was listen. For I believe full surely that God's spirit is in us all, giving light, wisdom, understanding, speaking words in us when we cannot speak, showing us gently what we would not see; what we are afraid to see; so that we may show pity, mercy, forgiveness.

SUMMARY

This chapter has highlighted a few ways in which pediatric community palliative and hospice care differs from adult care or from PPC in other settings. However, the general shape of pediatric community palliative care should feel familiar. APRNs with primary palliative skills should find that their expertise forms a solid foundation from which to learn and adapt. Learning the local landscape of laws and resources, partnering with and educating diverse allies, and a strong emphasis on coordination will help ensure seamless care for children and their families.

While there are unique challenges, many CBPP APRNs find that providing community-based PPC is a privilege. Relationships formed with children and their families over the course of days, weeks, months, or years are especially intimate due to the location and style of care. Special consideration must be taken to partner with families and provide culturally sensitive and individually tailored support. In addition to the benefit to the family, the coordination of care can build stronger community ties among hospitals, schools, primary care practices, state agencies, hospice organizations, religious communities, and even utility companies. Community-based PPC is deeply necessary. There is currently considerable unmet need in many areas of the country. In addition to building community alliances in the service of patients, CBPP APRNs should be deliberate about finding support for

themselves and their own practice. Well-being is a necessity in building a sustainable career in PPC. A sustainable career in community PPC can be extraordinary: helping children and families to remain in their homes and facilitating lives outside of hospitals is immensely rewarding.
